$$K_j|_{u=0}=0 \quad (j=0,1,...,l). \tag{3.17}$$

Similarly, (3.12) associated with the assumption $\sigma_0|_{u=0}=0$ yields also

$$\sigma_j|_{u=0}=0 \quad (j=1,2,...,k). \tag{3.18}$$

The above results can be generalized to the following theorem:

Theorem 1: Suppose that for any given vector field $Y=Y(t,x,u)\in V^{(s)}(Y|_{u=0}=0)$ the function matrix equation (3.6) possesses unique solutions vector field $X=X(t,x,u)\in V^{(s)}$ and function matrix $N=N(t,x,\eta,u)\in\mathscr{L}(Q_0^{(m)})$ which satisfy the condition (3.7). Then the vector field $K_l\in V^{(s)}$ constructed in turn by (3.8) meets the condition (3.17) and has a unique implicit representation (3.4), in which the function matrix $N_l=N_l(t,x,\eta,u)\in\mathscr{L}(Q_0^{(m)})$ is described by (3.10). While if there exist solutions $\sigma_0\in V^{(s)}$ $(\sigma_0|_{u=0}=0)$ and $W_0\in\mathscr{L}(Q_0^{(m)})$ satisfying (3.11), then the vector field $\sigma_k\in V^{(s)}$ constructed in turn by (3.11) and (3.12) satisfies Condition (3.18) and has also a unique implicit representation (3.5) where $P_k=P_k(t,x,\eta,u)\in\mathscr{L}(Q_0^{(m)})$ is expressed by (3.14) and p_0 and A_0 in (3.14) satisfy

$$[A_0,\ M|_{u=0}]=-p_0M|_{u=0}+M_{\eta}|_{u=0}\eta. \tag{3.19}$$

Here it suffices to deduce (3.19). In fact, substituting the condition (3.14) into Eq. (3.5) and noticing $M'[\sigma_k]|_{u=0}=0$ yield (3.19) easily.

IV. PRODUCT FUNCTION MATRICES AND RELATED ALGEBRAIC STRUCTURES

In this section, we first introduce the notion of product function matrices.

Definition 4: Suppose, respectively K_l and $\sigma_k\in V^{(s)}$ are the isospectral and nonisospectral flows of the Lax integrable system associated with the linear problem (1.1) and have the unique implicit representations (3.4) and (3.5). Then

$$\langle N_l,\ N_k\rangle=N_l'[K_k]-N_k'[K_l]+[N_l,\ N_k], \tag{4.1a}$$

$$\langle N_l,P_k\rangle=N_l'[\sigma_k]-P_k'[K_l]+[N_l,P_k]+N_{l,\eta}\eta^{\alpha k+\beta}, \tag{4.1b}$$

$$\langle P_l,P_k\rangle=P_l'[\sigma_k]-P_k'[\sigma_l]+[P_l,\ P_k]+P_{l,\eta}\eta^{\alpha k+\beta}-P_{k,\eta}\eta^{\alpha l+\beta} \tag{4.1c}$$

are named three kinds of product function matrices.

Concerning the product function matrices, we give the following theorems:

Theorem 2: Suppose that $\langle N_l,\ N_k\rangle$, $\langle N_l,\ P_k\rangle$, and $\langle P_l,\ P_k\rangle$ are defined by (4.1) and $\beta-1=\alpha i_0$ (i_0 integer). Then we have

$$M'[[K_l,\ K_k]]=\langle N_l,\ N_k\rangle_x+[\langle N_l,\ N_k\rangle,\ M], \tag{4.2a}$$

$$M'[[K_l,\ \sigma_k]]=\langle N_l,\ P_k\rangle_x+[\langle N_l,\ P_k\rangle,\ M], \tag{4.2b}$$

$$M'[[\sigma_l,\ \sigma_k]]=\langle P_l,\ P_k\rangle_x+[\langle P_l,\ P_k\rangle,\ M]-\alpha(l-k)M_\eta\eta^{\alpha(l+k+i_0)+\beta}. \tag{4.2c}$$

Proof: We only prove the equality (4.2b); the other equalities (4.2a) and (4.2c) can be obtained similarly. Respectively, from the representations (3.4) and (3.5), we have

$$(M'[K_l])'[\sigma_k]=N'_{l,x}[\sigma_k]+[N'_l[\sigma_k],\ M]+[N_l,\ P_{k,x}]+[N_l,\ [P_k,\ M]]-[N_l,\ M_\eta]\eta^{\alpha k+\beta} \tag{4.3a}$$

and

$$\begin{aligned}(M'[\sigma_k])'[K_l]=&P'_{k,x}[K_l]+[P'_k[K_l],\ M]+[P_k,\ N_{l,x}]\\&+[P_k,\ [N_l,\ M]]-N_{l,x\eta}\eta^{\alpha k+\beta}-[N_l,\ M]_\eta\eta^{\alpha k+\beta}.\end{aligned} \tag{4.3b}$$

Because of

$$[N_l,\ [P_k,\ M]]-[P_k,\ [N_l,\ M]]=[[N_l,\ P_k],\ M],$$

(4.3) suggests

$$\begin{aligned}(M'[K_l])'[\sigma_k]-(M'[\sigma_k])'[K_l]=&(N'_l[\sigma_k]-P'_k[K_l]+[N_l,\ P_k]+N_{l,\eta}\eta^{\alpha k+\beta})_x\\&+[N'_l[\sigma_k]-P'_k[K_l]+[N_l,\ P_k]+N_{l,\eta}\eta^{\alpha k+\beta},\ M].\end{aligned} \tag{4.4}$$

From (4.4) and using Lemma 4 and Definition 4, we obtain (4.2b) immediately.

Theorem 3: Suppose that the matrices N_l and P_k are respectively described by (3.10) and (3.14). Then

$$\langle N_l,\ N_k\rangle|_{u=0}=0, \tag{4.5a}$$

$$\langle N_l,\ P_k\rangle|_{u=0}=(\alpha l+\mu+p_0)N_{l+k+i_0}|_{u=0}, \tag{4.5b}$$

$$\langle P_l,\ P_k\rangle|_{u=0}=\alpha(l-k)P_{l+k+i_0}|_{u=0}. \tag{4.5c}$$

Proof: By Theorem 1, we know $K_i|_{u=0}=0$ and $\sigma_j|_{u=0}=0$. Thus

$$N'_l[K_k]|_{u=0}=N'_k[K_l]|_{u=0}=N'_l[\sigma_k]|_{u=0}=0, \tag{4.6a}$$

$$P'_l[\sigma_k]|_{u=0}=P'_k[\sigma_l]|_{u=0}=P'_k[K_l]|_{u=0}=0. \tag{4.6b}$$

Recalling the condition (3.10) we obtain

$$\langle N_l,\ N_k\rangle|_{u=0}=[N_l,\ N_k]|_{u=0}=[M|_{u=0},\ M|_{u=0}]\eta^{\alpha(l+k)+2\mu}=0. \tag{4.7}$$

Next, using (3.14), we have

$$\begin{aligned}\langle N_l,\ P_k\rangle|_{u=0}=&[N_l,\ P_k]|_{u=0}+N_{l,\eta}\eta^{\alpha k+\beta}|_{u=0}\\=&[M,\ A_0]|_{u=0}\eta^{\alpha(l+k+i_0)+\mu}+M_\eta|_{u=0}\eta^{\alpha(l+k+i_0)+\mu+1}\\&+(\alpha l+\mu)M|_{u=0}\eta^{\alpha(l+k+i_0)+\mu}.\end{aligned} \tag{4.8}$$

Substitution of (3.19) into (4.8) yields (4.5b). At last, it follows from a similar argument that

$$\begin{aligned}\langle P_l,\ P_k\rangle|_{u=0}&=[P_l,\ P_k]|_{u=0}+P_{l,\eta}\eta^{\alpha k+\beta}|_{u=0}-P_{k,\eta}\eta^{\alpha l+\beta}|_{u=0}\\&=\alpha(l-k)(p_0xM|_{u=0}+A_0)\,\eta^{\alpha(l+k+i_0)+\beta-1}\\&=\alpha(l-k)P_{l+k+i_0}|_{u=0}.\end{aligned}\tag{4.9}$$

V. LIE ALGEBRAIC STRUCTURE OF THE FLOWS K_l AND σ_k

In this section, we use the equalities (4.2) and (4.5) which the product function matrices satisfy to derive the Lie algebraic structure of the flows K_l and σ_k.

Theorem 4: Suppose respectively that the isospectral flows K_l and nonisospectral flows σ_k have the unique implicit representations (3.4) and (3.5), and that N_l and P_k are described by (3.10) and (3.14). Then

$$[\![K_l,\ K_k]\!]=0,\tag{5.1a}$$

$$[\![K_l,\ \sigma_k]\!]=(\alpha l+\mu+p_0)K_{l+k+i_0},\tag{5.1b}$$

$$[\![\sigma_l,\ \sigma_k]\!]=\alpha(l-k)\sigma_{l+k+i_0}.\tag{5.1c}$$

Proof: Since the implicit representation of K_0 is unique, i.e., (3.8a) has solitary solutions, it follows that (3.15) only admits zero solutions and so does Eq. (4.2a) [under the condition (4.5a)]. That is to say, (5.1a) is valid. Next, set

$$\theta=[\![K_l,\ \sigma_k]\!]-(\alpha l+\mu+p_0)K_{l+k+i_0},\tag{5.2a}$$

$$\widetilde{N}=\langle N_l,\ P_k\rangle-(\alpha l+\mu+p_0)N_{l+k+i_0}.\tag{5.2b}$$

Obviously, $\theta\in V^{(s)}$ and $\widetilde{N}\in\mathscr{L}(Q_0^{(m)})$. By Theorem 1 we have

$$M'[K_{l+k+i_0}]=N_{l+k+i_0,x}+[N_{l+k+i_0},\ M].\tag{5.3}$$

Then it follows from (4.2b), (5.3), and (4.5b) that

$$M'[\theta]=\widetilde{N}_x+[\widetilde{N},\ M],\quad \widetilde{N}|_{u=0}=0,\tag{5.4}$$

has only zero solutions $\theta=0$ and $\widetilde{N}=0$; that means (5.1b) is true. At last, set

$$\omega=[\![\sigma_l,\ \sigma_k]\!]-\alpha(l-k)\sigma_{l+k+i_0},\tag{5.5a}$$

$$\widetilde{P}=\langle P_l,\ P_k\rangle-\alpha(l-k)P_{l+k+i_0};\tag{5.5b}$$

clearly, $\omega\in V^{(s)}$ and $\widetilde{P}\in\mathscr{L}(Q_0^{(m)})$. By Theorem 1 we also know

$$M'[\sigma_{l+k+i_0}]=P_{l+k+i_0,x}+[P_{l+k+i_0},\ M]-M_\eta\eta^{\alpha(l+k+i_0)+\beta}.\tag{5.6}$$

Similarly, (5.6) together with (4.2c) and (4.5c) yields

$$M'[\omega]=\widetilde{P}_x+[\widetilde{P},\ M],\quad \widetilde{P}|_{u=0}=0.\tag{5.7}$$

Hence we have $\omega=0$ and $\widetilde{P}=0$, which means (5.1c) is also right.

If by $\mathscr{A}$ we denote an infinite-dimensional linear space which is generated by all the isospectral flows K_l and nonisospectral flows σ_k, and by $\mathscr{A}_1$ and $\mathscr{A}_2$ denote two subspaces of $\mathscr{A}$ which

are generated respectively by all the isospectral flows K_l and nonisospectral flows σ_k, then Theorem 4 shows that $\mathscr{A}$ constitutes an infinite-dimensional Lie algebra with respect to the binary operation (2.4), and $\mathscr{A}_1$ and $\mathscr{A}_2$ are, respectively, a commutative subalgebra and a Virasoro subalgebra of $\mathscr{A}$.

Furthermore, in the above proof, we have already obtained $\langle N_l, N_k\rangle=0$, $\widetilde{N}=0$, and $\widetilde{P}=0$. Therefore, the following result holds.

Corollary 1: The function matrices N_l and P_k in the implicit representations of K_l and σ_k satisfy the following algebraic relations:

$$\langle N_l, N_k\rangle=0, \tag{5.8a}$$

$$\langle N_l, P_k\rangle=(\alpha l+\mu+p_0)N_{l+k+i_0}, \tag{5.8b}$$

$$\langle P_l, P_k\rangle=\alpha(l-k)P_{l+k+i_0}, \tag{5.8c}$$

which are similar to those of K_l and σ_k for $[\![\cdot,\cdot]\!]$.

From Theorem 4, we can still deduce K symmetry, τ symmetry, and their infinite-dimensional Lie algebra structure of a general isospectral evolution equation.

Corollary 2: The two sets of symmetries of Eq. (3.2) are K_j and $\tau_k^l=(\alpha l+\mu+p_0)tK_{l+k+i_0}+\sigma_k$, and satisfy the following Lie algebraic relations:

$$[\![K_j, K_k]\!]=0, \tag{5.9a}$$

$$[\![K_j, \tau_k^l]\!]=(\alpha j+\mu+p_0)K_{j+k+i_0}, \tag{5.9b}$$

$$[\![\tau_j^l, \tau_k^l]\!]=\alpha(j-k)\tau_{j+k+i_0}^l. \tag{5.9c}$$

VI. APPLICATION

1. To AKNS system

It is well-known that the hierarchies of isospectral and nonisospectral evolution equations of the AKNS system are

$$u_t=K_l, \quad K_l=L^l(2\gamma u) \quad (l=0,1,2,\ldots) \tag{6.1.1a}$$

and

$$u_t=\sigma_k, \quad \sigma_k=L^k(x\gamma u) \quad (k=0,1,2,\ldots), \tag{6.1.1b}$$

where K_l, and $\sigma_k\in V^{(2)}$ and L is a recursion operator given by

$$L=\tfrac{1}{2}(\gamma \mathrm{D}-2\gamma u \mathrm{I} u^T\delta), \tag{6.1.2a}$$

$$\gamma=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix}, \quad \delta=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \quad u=\begin{pmatrix}q\\ r\end{pmatrix}, \tag{6.1.2b}$$

$$\mathrm{D}=\frac{\partial}{\partial x}, \quad \mathrm{I}=\int_{-\infty}^{x}\cdot\, dx, \quad \mathrm{DI}=\mathrm{ID}=1. \tag{6.1.2c}$$

Set

$$M=\begin{pmatrix} -\eta & q \\ r & \eta \end{pmatrix}. \tag{6.1.3}$$

Then the hierarchies (6.1.1) are associated with the linear problem (1.1).

Now, we explain that the flows K_l and σ_k have respectively the unique implicit representations (3.4) and (3.5) with $\alpha=1$, $\mu=-1$, $\beta=0$, $p_0=1$, and $A_0=0$.

By Theorem 1, first, we have to prove that for any given vector field $Y=(Y_1,Y_2)^T\in V^{(2)}(Y|_{u=0}=0)$, Eq. (3.6) has only a couple of solutions $X=(X_1,X_2)^T\in V^{(2)}$ and $N\in Q_0^{(2)}$ satisfying Condition (3.7). Here, $\alpha=1$ and $\mu=-1$. For this sake, write (3.6) in the following form:

$$\begin{pmatrix} 0 & X_1-\eta Y_1 \\ X_2-\eta Y_2 & 0 \end{pmatrix}=N_x+[N,\ M]. \tag{6.1.4}$$

Setting

$$N=N(t,x,u)=\begin{pmatrix} A & B \\ C & -A \end{pmatrix}, \tag{6.1.5}$$

we have

$$A_x=qC-rB, \tag{6.1.6a}$$

$$X_1-\eta Y_1=B_x+2\eta B+2qA, \tag{6.1.6b}$$

$$X_2-\eta Y_2=C_x-2\eta C-2rA. \tag{6.1.6c}$$

Comparing the coefficients of the same powers of η and noticing N independent of η yield

$$A=\mathrm{I}u^T\delta\gamma F-\delta_0,\quad Y=2\gamma F, \tag{6.1.7a}$$

$$X=2L\gamma F+2\delta_0\gamma u, \tag{6.1.7b}$$

where $F=(B,C)^T$, and δ_0 is given by (3.7b). Further, we have

$$A=\tfrac{1}{2}\,\mathrm{I}u^T\delta Y-\delta_0,\quad F=\tfrac{1}{2}\,\gamma Y, \tag{6.1.8a}$$

$$X=LY+2\delta_0\gamma u. \tag{6.1.8b}$$

It is obvious that for any given $Y\in V^{(2)}(Y|_{u=0}=0)$, the unique vector field X and unique function matrix N respectively defined by (6.1.8b) and (6.1.8a) satisfy (3.6) and (3.7). Especially, when $Y=0$ (6.1.8) gives

$$X=K_0=2\gamma u,\quad N=U_0=\gamma. \tag{6.1.9}$$

Second, by a similar discussion, it is easy to get the solutions of (3.11) with $\beta=0$, $p_0=1$, and $A_0=0$:

$$\sigma_0=x\gamma u\quad(\sigma_0|_{u=0}=0),\quad W_0=x\gamma. \tag{6.1.10}$$

From the above statements, it is shown that if we choose $\alpha=1$, $\beta=0$, $\mu=-1$, $p_0=1$, and $A_0=0$, then Theorem 4 holds for the AKNS system. That means the following:

Theorem 5: The isospectral flows K_l and nonisospectral flows σ_k of the AKNS system constitute an infinite-dimensional Lie algebra, and possess the following commutator relations (also see Ref. 4):

$$[\![K_l,\ K_k]\!]=0, \tag{6.1.11a}$$

$$[\![K_l,\ \sigma_k]\!]=lK_{l+k-1}, \tag{6.1.11b}$$

$$[\![\sigma_l,\ \sigma_k]\!]=(l-k)\sigma_{l+k-1}. \tag{6.1.11c}$$

Recalling Corollary 2 (or directly using Theorem 5) we have the following.

Corollary 3: The two sets of symmetries of the Eq. (6.1.1a) are K_j and $\tau_k^{\,l}=ltK_{l+k-1}+\sigma_k$ which constitute a Lie algebra with the following commutator relations:

$$[\![K_j,\ K_k]\!]=0, \tag{6.1.12a}$$

$$[\![K_j,\ \tau_k^{\,l}]\!]=jK_{j+k-1}, \tag{6.1.12b}$$

$$[\![\tau_j^{\,l},\ \tau_k^{\,l}]\!]=(j-k)\tau_{j+k-1}^{\,l}. \tag{6.1.12c}$$

2. To generalized HD system

In this subsection, we will consider the second-order linear spectral problem:

$$\psi_{xx}+\left(\sum_{i=0}^{h} u_i\eta^i\right)\psi=0, \quad u_h=-1. \tag{6.2.1}$$

If we set $\phi_1=\psi$, $\phi_2=\psi_x$, and $\phi=(\phi_1,\phi_2)^T$, (6.2.1) can be written in the form of (1.1a) where

$$M=\sum_{i=0}^{h} M_i\eta^i=\begin{pmatrix} 0 & 1 \\ -\sum_{i=0}^{h} u_i\eta^i & 0 \end{pmatrix}, \tag{6.2.2a}$$

$$M_i=\begin{pmatrix} 0 & \delta_{0,i} \\ -u_i & 0 \end{pmatrix} \quad (i=0,1,...,h). \tag{6.2.2b}$$

From Eq. (3.1), one can obtain the hierarchies of isospectral and nonisospectral evolution equations,[6,8,9] i.e.,

$$u_t=K_l, \quad K_l=\mathrm{D}L^l u \quad (l=0,1,2,\ldots) \tag{6.2.3a}$$

and

$$u_t=\sigma_k, \quad \sigma_k=\tfrac{1}{2}\mathrm{D}L^k(hxu+\theta \mathrm{I}u) \quad (k=0,1,2,\ldots), \tag{6.2.3b}$$

where

$$u=u(t,x)=(u_0,u_1,u_2,\ldots,u_{h-1})^T, \tag{6.2.4a}$$

$$L=\sum_{i=0}^{h-2} E_{i+1,i}+\sum_{i=0}^{h-1} J_i E_{i,h-1}, \tag{6.2.4b}$$

$$\theta=\sum_{i=0}^{h-1}(h-2i)E_{ii}, \tag{6.2.4c}$$

D and I are described by (6.1.2c). The operators J_i and the $h\times h$ matrices E_{ij} are respectively given by

$$J_i=\tfrac{1}{4}\delta_{0i}\mathrm{D}^2+u_i-\tfrac{1}{2}\mathrm{I}u_{i,x}\quad(i=0,1,...,h-1) \tag{6.2.4d}$$

and

$$(E_{ij})_{kl}=\delta_{ik}\delta_{jl}. \tag{6.2.4e}$$

For convenience, we appoint that if a vector field $Z\in V^{(h)}$, then Z has the following form:

$$Z=(Z_0,Z_1,Z_2,..,Z_{h-1})^T. \tag{6.2.5}$$

In Eq. (3.6) and Condition (3.7), we take $\alpha=1$, $\mu=0$, X and $Y\in V^{(h)}$, $N\in\mathscr{L}(Q_0^{(2)})$, and

$$N=\overline{N}+q(M-M_0),\quad \overline{N}=\begin{pmatrix}\overline{A} & \overline{B}\\ \overline{C} & -\overline{A}\end{pmatrix}, \tag{6.2.6}$$

where $\overline{A}$, $\overline{B}$, $\overline{C}$, and q are all undetermined functions independent of η. It follows that (3.6) can be written as

$$M'[X-\eta Y]=(\overline{N}+q(M-M_0))_x+[\overline{N},\,M]-q[M_0,\,M]. \tag{6.2.7}$$

Substituting (6.2.2a) into (6.2.7) and comparing the coefficients of the same powers of η yield

$$M_0'[X]=\overline{N}_x+[\overline{N},\,M_0], \tag{6.2.8a}$$

$$M_i'[X]-M_{i-1}'[Y]=(qM_i)_x+[\overline{N},\,M_i]-q[M_0,\,M_i]\quad(i=1,2,...,h-1), \tag{6.2.8b}$$

$$-M_{h-1}'[Y]=(qM_h)_x+[\overline{N},\,M_h]-q[M_0,\,M_h]. \tag{6.2.8c}$$

From (6.2.8a), (6.2.8b), and (6.2.8c), respectively, we have

$$\overline{A}_x=u_0\overline{B}+\overline{C},\quad \overline{B}_x+2\overline{A}=0,\quad X_0=-\overline{C}_x-2u_0\overline{A}, \tag{6.2.9a}$$

$$q=\overline{B},\quad X_i=2\mathrm{D}J_i\overline{B}+Y_{i-1} \tag{6.2.9b}$$

and

$$\overline{B}=\tfrac{1}{2}\mathrm{I}Y_{h-1}+\delta_0, \tag{6.2.9c}$$

where (6.2.9a) implies

$$X_0=2\mathrm{D}J_0\overline{B}. \tag{6.2.10}$$

Substituting (6.2.9c) into (6.2.9a), (6.2.9b), and (6.2.10), we obtain easily

$$\overline{A}=-\tfrac{1}{4}Y_{h-1}, \tag{6.2.11a}$$

$$q=\overline{B}=\tfrac{1}{2}\mathrm{I}Y_{h-1}+\delta_0, \tag{6.2.11b}$$

$$\overline{C}=-\tfrac{1}{4}\big(D+2u_0\mathrm{I}\big)Y_{h-1}-\delta_0 u_0, \tag{6.2.11c}$$

and

$$X=\mathrm{D}LIY+\delta_0 u_x, \tag{6.2.11d}$$

where δ_0 is given by (3.7b). By now, we have proved that for any given $Y\in V^{(h)}(Y|_{u=0}=0)$, the unique vector field $X\in V^{(h)}$ and unique function matrix $N\in\mathscr{G}(Q_0^{(2)})$ respectively defined by (6.2.11d) and (6.2.11a)–(6.2.11c) satisfy (3.6) and (3.7). In particular, when $Y=0$, we obtain

$$X=K_0=u_x, \quad N=U_0=M. \tag{6.2.12}$$

Next, in order to find the solutions of (3.11), we take

$$W_0=\widetilde{W}_0+\widetilde{q}(M-M_0), \quad \widetilde{W}_0=\begin{pmatrix}\widetilde{A}_0 & \widetilde{B}_0\\ \widetilde{C}_0 & -\widetilde{A}_0\end{pmatrix} \tag{6.2.13}$$

and $\widetilde{W}_0$ is independent of η. Substituting (6.2.13) into (3.11a) (with $\beta=1$) and comparing the coefficients of the same powers of η lead to

$$M_0'[\sigma_0]=\widetilde{W}_{0,x}+[\widetilde{W}_0,\ M_0], \tag{6.2.14a}$$

$$M_i'[\sigma_0]=(\widetilde{q}M_i)_x+[\widetilde{W}_0,\ M_i]-\widetilde{q}[M_0,\ M_i]-iM_i \quad (i=1,2,...,h-1), \tag{6.2.14b}$$

$$0=(\widetilde{q}M_h)_x+[\widetilde{W}_0,\ M_h]-\widetilde{q}[M_0,\ M_h]-hM_h. \tag{6.2.14c}$$

From these equalities, an argument similar to above yields

$$\sigma_0=\tfrac{1}{2}\mathrm{D}(hxu+\theta\mathrm{I}u) \quad (\sigma_0|_{u=0}=0), \quad W_0=\frac{h}{4}(\gamma+2xM), \tag{6.2.15}$$

which meet (3.11) with $p_0=h/2$ and $A_0=h\gamma/4$, where θ and γ are given by (6.2.4c) and (6.1.2b), respectively.

So it follows from Theorem 1 that the flows K_l and σ_k possess respectively the unique implicit representations (3.4) and (3.5).

In light of the results described in Sec. V, we obtain immediately the following.

Theorem 6: The isospectral flows K_l and nonisospectral flows σ_k of the generalized HD system associated with the linear problem (1.1) [in which M is given by (6.2.2)] constitute an infinite-dimensional Lie algebra, and possess the following commutator relations (also see Ref. 6):

$$[\![K_l,\ K_k]\!]=0, \tag{6.2.16a}$$

$$[\![K_l,\ \sigma_k]\!]=\Big(l+\frac{h}{2}\Big)K_{l+k}, \tag{6.2.16b}$$

$$[\![\sigma_l,\ \sigma_k]\!]=(l-k)\sigma_{l+k}. \tag{6.2.16c}$$

Corollary 4: The two sets of symmetries of Eq. (6.2.3a) are K_j and $\tau_k^{\,l}=(l+h/2)tK_{l+k}+\sigma_k$ which constitute a Lie algebra with the following relations:

$$[\![K_j,\ K_k]\!]=0, \tag{6.2.17a}$$

$$[\![K_j,\ \tau^{\ l}_k]\!]=\left(j+\frac{h}{2}\right)K_{j+k}, \tag{6.2.17b}$$

$$[\![\tau^{\ l}_j,\ \tau^{\ l}_k]\!]=(j-k)\tau^{\ l}_{j+k}. \tag{6.2.17c}$$

3. To *n*-wave interaction system

In the linear problem (1.1), set

$$M=\eta H+S \tag{6.3.1}$$

and $H,\ S\ \in Q_0^{(n)}$ and $N\in\mathscr{S}(Q_0^{(n)})$ where H is a constant diagonal matrix:

$$H=\mathrm{diag}(h_1,h_2,h_3,\ldots,h_n)\quad (h_i\neq h_j, i\neq j), \tag{6.3.2a}$$

$$S=S(t,x,u)=\sum_{i,j=1\ i\neq j}^{n} u_{ij}E_{ij}, \tag{6.3.2b}$$

in which the vector field $u\ \in\ V^{(n(n-1))}$ is described by

$$u=(u_{12},u_{13},\ldots,u_{1n},u_{21},u_{23},\ldots,u_{ij},\ldots,u_{n,n-1})^T\quad (i\neq j). \tag{6.3.2c}$$

The $n(n-1)$ u_{ij}'s are nonzero functionally independent potentials and the $n\times n$ matrices E_{ij}'s are given by (6.2.4e).

Then, from the compatible condition (3.1) of (1.1), we can obtain isospectral and nonisospectral flows K_l and σ_k of the n-wave interaction system. In a general way, it is very difficult to write these flows in the form $K_l=\Phi^l K_0$ and $\sigma_k=\Phi^k\sigma_0$, where $\Phi\ \in\ Q^{(n(n-1))}$ is some operator. Therefore, Ma's method (see Ref. 3) cannot be applied to construct the flows' Lie algebra for this kind of Lax integrable system. However, our method has such advantage indeed, because we derive the isospectral and nonisospectral flows and their Lie algebraic properties without using the recursion operator Φ of the integrable system.

In fact, by Theorem 4, we only need to prove that there exist respectively the unique implicit representations (3.4) and (3.5) for flows K_l and σ_k of the n-wave interaction system.

For simplicity, in what follows, we make the appointment that

$$Z=(Z_{12},Z_{13},\ldots,Z_{1n},Z_{21},Z_{23},\ldots,Z_{ij},\ldots,Z_{n,n-1})^T\quad (i\neq j), \tag{6.3.3}$$

if vector field $Z\ \in\ V^{(n(n-1))}$.

Now, in Eq. (3.6) and the condition (3.7), for any given $Y\ =\ Y(t,x,u)\ \in\ V^{(n(n-1))}(Y|_{u=0}\ =\ 0)$, we take $X\ =\ X(t,x,u)\ \in\ V^{(n(n-1))}$ $N=N(t,x,u)\in Q_0^{(n)}$ and $\alpha=1$, $\mu=-1$. Then (3.6) can be written in the form

$$S'[X]-\eta S'[Y]=N_x+\eta[N,\ H]+[N,\ S]. \tag{6.3.4}$$

Comparison of the coefficients of the same powers of η in the above equality yields

$$\sum_{i,j=1 i\neq j}^{n} X_{ij}E_{ij}=N_x+[N,\ S],\qquad \sum_{i,j=1 i\neq j}^{n} Y_{ij}E_{ij}=[H,\ N]. \tag{6.3.5}$$

Further, let I and δ_0 be described respectively by (6.1.2c) and (3.7b). We have

$$N_{ij}=\frac{Y_{ij}}{h_i-h_j}\quad (i\neq j), \tag{6.3.6a}$$

$$N_{ii}=\mathrm{I}\sum_{k=1,k\neq i}^{n}\frac{u_{ki}Y_{ik}+u_{ik}Y_{ki}}{h_k-h_i}+\delta_0 h_i, \tag{6.3.6b}$$

and

$$\begin{aligned}X_{ij}=&\frac{Y_{ij,x}}{h_i-h_j}+\sum_{k=1,k\neq i,j}^{n}\left(\frac{u_{kj}Y_{ik}}{h_i-h_k}-\frac{u_{ik}Y_{kj}}{h_k-h_j}\right)\\&+u_{ij}\mathrm{I}\left(\sum_{k=1,k\neq i}^{n}\frac{u_{ki}Y_{ik}+u_{ik}Y_{ki}}{h_k-h_i}-\sum_{k=1,k\neq j}^{n}\frac{u_{kj}Y_{jk}+u_{jk}Y_{kj}}{h_k-h_j}\right)\\&+u_{ij}\delta_0(h_i-h_j)\quad(i\neq j),\end{aligned} \tag{6.3.6c}$$

which immediately shows that for any given vector field $Y\in V^{(n(n-1))}(Y|_{u=0}=0)$. Equation (3.6) has unique solutions X and N satisfying the condition (3.7), and in particular, if $Y=0$, the solutions X and N are given respectively by

$$X=K_0,\quad K_{0ij}=(h_i-h_j)u_{ij}\quad(i\neq j), \tag{6.3.7a}$$

and

$$N=U_0=H. \tag{6.3.7b}$$

Second, taking $\beta=0$, $p_0=1$, and $A_0=0$ in (3.11), we have

$$S'[\sigma_0]=W_{0,x}+\eta[W_0,\,H]+[W_0,\,S]-H. \tag{6.3.8}$$

Here, $\sigma_0\in V^{(n(n-1))}$ and $W_0\in Q_0^{(n)}$ are all independent of η. Equation (6.3.8) implies

$$\sum_{i,j=1i\neq j}^{n}\sigma_{0ij}E_{ij}=W_{0,x}+[W_0,\,S]-H,\quad[W_0,\,H]=0, \tag{6.3.9}$$

which suggests a couple of solutions σ_0 and W_0 described respectively by

$$\sigma_{0ij}=(h_i-h_j)xu_{ij}\quad(i\neq j,\sigma_0|_{u=0}=0) \tag{6.3.10a}$$

and

$$W_0=xH. \tag{6.3.10b}$$

So we have shown that the conditions of Theorem 1 are satisfied for the n-wave interaction system. That is to say, the flows K_l and σ_k of this system can be generated by (3.8), and (3.11), and (3.12), respectively and have their unique implicit representations.

Further, according to the results of Sec. V, we have the following.

Theorem 7: The isospectral flows $K_l\in V^{(n(n-1))}$ and nonisospectral flows $\sigma_k\in V^{(n(n-1))}$ of the n-wave interaction system associated with the linear problem (1.1) [in which M is described by (6.3.1)] constitute an infinite-dimensional Lie algebra, and possess the following commutator relations:

$$[K_l,\,K_k]=0, \tag{6.3.11a}$$

$$[K_l,\,\sigma_k]=lK_{l+k-1}, \tag{6.3.11b}$$

$$[\sigma_l,\ \sigma_k]=(l-k)\sigma_{l+k-1}. \tag{6.3.11c}$$

Theorem 7 shows that the flows' commutator relations of the n-wave interaction system are independent of wave number n. Therefore, if set $n=2$ and $h_1=-h_2=1$, then (6.3.11a)–(6.3.11c) becomes (6.1.11a)–(6.1.11c). That is to say, isospectral flows K_l and nonisospectral flows σ_k of the n-wave interaction system constitute the same infinite-dimensional Lie algebraic structure as the AKNS system. The similar conclusion for symmetries of the two systems is also valid. So we have the following.

Corollary 5: The two sets of symmetries of the isospectral equation $u_t=K_l$ are K_j and $\tau_k^{\,l}=ltK_{l+k-1}+\sigma_k$, which constitute a Lie algebra with the following relations:

$$[K_j,\ K_k]=0, \tag{6.3.12a}$$

$$[K_j,\ \tau_k^{\,l}]=jK_{j+k-1}, \tag{6.3.12b}$$

$$[\tau_j^{\,l},\ \tau_k^{\,l}]=(j-k)\tau_{j+k-1}^{\,l}. \tag{6.3.12c}$$

As mentioned earlier, it is not easy to derive the general explicit expressions of the flows K_l and σ_k of the n-wave interaction system, which leads to the algebraic properties of these flows and related symmetries have not been reported in any literature up to now. So we have enough reason to believe that Theorem 7 and *Corollary 5* obtained by means of the so-called ''implicit representations'' are new results.

I. INTRODUCTION

The (a,b,c) or 3D Lotka–Volterra dynamical system[1,2]

$$\dot{x}=x(cy+z), \quad \dot{y}=y(az+x), \quad \dot{z}=z(bx+y), \tag{1}$$

where (a,b,c) are three real (or complex) parameters, appears in various areas of science such as ecology (in which it models a three-species competition), plasma physics (in which it approximates the Vlasov–Poisson equation), and so on.

It can be generalized by adding an isotropic linear damping term. Indeed, the dynamical system

$$\dot{x}=x(\lambda+cy+z), \quad \dot{y}=y(\mu+az+x), \quad \dot{z}=z(\nu+bx+y), \tag{2}$$

reduces to Eq. (1), if $\lambda=\mu=\nu$, by setting

$$x'=xe^{-\lambda t}, \quad y'=ye^{-\lambda t}, \quad z'=ze^{-\lambda t}, \quad t'=e^{\lambda t},$$

and then dropping the primes. It may be worth noticing that the linear term isotropy is a necessary condition for Eq. (2) to have the Painlevé property.[3]

Up to now, using various techniques (extension of the Lie symmetry method,[4] Painlevé analysis[3]), the following cases of polynomial integrability of the system (1) have been found (see Refs. 4 and 5 for further matter):

1. $abc=-1\Rightarrow I=x-cy-b^{-1}z$;

2. $abc=-1\Rightarrow I=x^{ab}y^{-b}z$; one sees that this integral can be made a polynomial iff $(a,b,c)\in(\mathbf{Q}^{-})^3$;

3. $abc=1$ and $a=-(c+1)^{-1}$ and $b=-(c+1)/c\Rightarrow I=x^2+c^2y^2+c^2(c+1)^{-2}z^2-2cxy+2c^2(c+1)^{-1}xz+2c(c+1)^{-1}yz$.

The aim of this paper is to show that there are no other cases of polynomial integrability and no other polynomial first integrals than these ones and their combinations when the parameters are real, which is the case in the biological and physical applications. We will prove this result in the following way. In Sec. II, we recall the definition and the general properties of the Darboux polynomials of a polynomial dynamical system. Then we establish some useful features of the Darboux polynomials of the Lotka–Volterra system. Section III is devoted to the proof of the result itself; and Sec. IV summarizes our results.

II. ON THE DARBOUX POLYNOMIALS OF THE LOTKA–VOLTERRA SYSTEM

Consider an autonomous polynomial dynamical system

$$\dot{x}_i = V_i(x_1,\ldots,x_n), \quad i = 1\cdots n. \tag{3}$$

It induces a derivation D—i.e., a linear endomorphism such that $D(fg)=D(f)g+fD(g)$—on the space of real (or complex) polynomials in n variables, called *derivation associated to (or with respect to) the system* (3), which reads

$$Df = \sum_{i=1}^{n} f_{x_i} V_i .$$

Then a Darboux polynomial[6] of Eq. (3) is a polynomial $f(x_1,\ldots,x_n)$ such that there is another polynomial $p(x_1,\ldots,x_n)$ satisfying $Df=pf$. The couple (p,f) may also be called a *Darboux element*. The following properties of Darboux elements can be shown easily:

(1) If m is the greatest of deg V_i, $i=1\cdots n$, then deg $p \leqslant m-1$.
(2) The product of two Darboux polynomials is still Darboux, namely ($Df_1=p_1f_1$ and $Df_2=p_2f_2$)$\Rightarrow D(f_1f_2)=(p_1+p_2)(f_1f_2)$. This can be generalized to any number of factors.
(3) All the irreducible factors of a Darboux polynomial are Darboux. Thus the search for Darboux polynomials can be restricted to irreducible f.
(4) If the dynamical system (3) is homogeneous of degree m, i.e., all V_i are homogeneous of degree m, then p is homogeneous of degree m—1 and all homogeneous components of f are Darboux. Thus the search can be restricted to homogeneous f.

Darboux polynomials give rise to numerous (polynomial or not) first integral search techniques for polynomial dynamical systems, such as the Prelle–Singer procedure.[7] Indeed a polynomial first integral f is a Darboux polynomial with $p=0$. Up to now, only semidecisive procedures are known; however it is possible to find a reciprocal for some dynamical systems. This shall we undertake with the (a,b,c) system, using its homogeneity and symmetry properties.

These properties yield first that for any Darboux element (p,f), p is homogeneous of first degree and f can be taken homogeneous; so the definition equation for the Darboux polynomials of (1) is

$$x(cy+z)f_x + y(az+x)f_y + z(bx+y)f_z = (\alpha x+\beta y+\gamma z)f, \tag{4}$$

where α, β, γ as well as the coefficients of f are *a priori* complex. For a Darboux polynomial f, the coefficients α, β, γ in Eq. (4) may be denoted $\alpha(f),\beta(f),\gamma(f)$.

The following statements are evident:

• The Lotka–Volterra system (1) is invariant by simultaneous cyclical permutations of (x,y,z) and (a,b,c); and identically Eq. (4) is invariant by simultaneous cyclical permutations of (x,y,z), (a,b,c), and (α,β,γ).

• x, y, and z—and thus all monomials—are Darboux polynomials of the system (1).

The following notations will be of constant use. For any polynomial $g(x,y,z)$ we shall write $\hat{g}(y,z)=g(0,y,z)$, $\widetilde{g}(x,z)=g(x,0,z)$, $\overline{g}(x,y)=g(x,y,0)$. These restriction operators commute with derivation with respect to the *other* variables.

Proposition 2.1: Let f be a (homogeneous) solution of degree m to Eq. (4). Then if $\gamma\neq 0$, f has no z^m term and thus reads $f(x,y,z)=x\varphi(x,y,z)+y\psi(x,y,z)$.

Since the polynomial f is homogeneous, we use Euler's theorem:

$$xf_x + yf_y + zf_z = mf.$$

Eliminating, e.g., f_x between this equality and Eq. (4), we find that

$$yf_y(az+x-cy-z)+zf_z(bx+y-cy-z)=[\alpha x+(\beta-mc)y+(\gamma-m)z]f.$$

Setting $x=0$ and $y=0$ [and $F(z)=f(0,0,z)$] yields

$$-z^2F'(z)=(\gamma-m)zF(z),$$

thus $F=\lambda z^{m-\gamma}$. But, as f is homogeneous of degree m, the only term containing only z is necessarily z^m. Hence, if $\gamma\neq 0$, we have $F=0$, which means that $f(x,y,z)$ is in the ideal generated by x and y.

Proposition 2.2: Let f be a solution of Eq. (4). Then $(\gamma\notin\mathbf{N}\Rightarrow y|f)$ *and* $(\gamma\notin a\mathbf{N}\Rightarrow x|f)$, *and, cyclically*:

- $(\beta\notin\mathbf{N}\Rightarrow x|f)$ and $(\beta\notin c\mathbf{N}\Rightarrow z|f)$;
- $(\alpha\notin\mathbf{N}\Rightarrow z|f)$ and $(\alpha\notin b\mathbf{N}\Rightarrow y|f)$.

If $\gamma\notin\mathbf{N}$ or $\gamma\notin a\mathbf{N}$, then $\gamma\neq 0$, and thus $f(x,y,z)=x\varphi(x,y,z)+y\psi(x,y,z)$. Setting this in Eq. (4) yields

$$xD\varphi+yD\psi=(\alpha x+\beta y+\gamma z-cy-z)x\varphi+(\alpha x+\beta y+\gamma z-az-x)y\psi. \tag{5}$$

Suppose $\gamma\notin\mathbf{N}$. Set $y=0$ in Eq. (5):

$$x\widetilde{D\varphi}=(\alpha x+(\gamma-1)z)x\widetilde{\varphi}.$$

The operator $\varphi\mapsto\widetilde{\varphi}$ commutes with the derivations with respect to x and z, hence

$$xz\left(\frac{\partial\widetilde{\varphi}}{\partial x}+b\,\frac{\partial\widetilde{\varphi}}{\partial z}\right)=(\alpha x+(\gamma-1)z)\widetilde{\varphi}. \tag{6}$$

So x divides the right-hand side; since $\gamma\notin\mathbf{N}$, $\gamma-1\neq 0$, and x does not divide $[ax+(\gamma-1)z]$. Thus $x|\widetilde{\varphi}$.

Setting $\widetilde{\varphi}=x\varphi_1$ we get

$$\frac{\partial\widetilde{\varphi}}{\partial x}=x\,\frac{\partial\varphi_1}{\partial x}+\varphi_1,\quad \frac{\partial\widetilde{\varphi}}{\partial z}=x\,\frac{\partial\varphi_1}{\partial z},$$

and Eq. (6), after some calculations, may be rewritten as

$$xz\left(\frac{\partial\varphi_1}{\partial x}+b\,\frac{\partial\varphi_1}{\partial z}\right)=[\alpha x+(\gamma-2)z]\varphi_1.$$

Since $\gamma\neq 2$, one has $x|\varphi_1$, so $x^2|\widetilde{\varphi}$; and if $\gamma\notin\mathbf{N}$ the same argument can be repeated indefinitely. The polynomial $\widetilde{\varphi}$ is divisible by any power of x, hence is zero. As $\widetilde{\varphi}(x,z)=\varphi(x,0,z)$, this means that φ is divisible by y; hence $f=x\varphi+y\psi$ is divisible by y. QED.

If we now assume $\gamma\notin a\mathbf{N}$, setting $x=0$ in Eq. (5) yields

$$yz\left(a\,\frac{\partial\hat{\psi}}{\partial y}+\frac{\partial\hat{\psi}}{\partial z}\right)=[\beta y+(\gamma-a)z]\widetilde{\varphi}.$$

By recurrence it can be shown as above that $\hat{\psi}$ is divisible by any power of y, hence is zero, hence that $x|\psi$ and f is divisible by x.

This leads to the following statement, a characterization of the ''eigenvalues'' of the Darboux polynomials of the system (1), which will be a fundamental tool for proving our main result.

Proposition 2.3: Let f be a nonzero Darboux polynomial. Then there exist two positive integers γ_1 and γ_2 such that $\gamma=\gamma_1+\gamma_2 a$.

Suppose $\gamma \notin \mathbf{N}+\mathbf{N}a$. So $\gamma \notin \mathbf{N}$ and $\gamma \notin Na$. Hence by Proposition 2.2 f is divisible by x:

$$f = xf_1 \quad \text{and} \quad Df_1 = [\alpha x + \beta y + (\gamma - 1)z]f_1.$$

But $\gamma - 1$ cannot be in $\mathbf{N}+\mathbf{N}a$ unless γ be in it. As this procedure can be repeated indefinitely, f may be divided by an infinity of powers of x, hence is zero. Contradiction.

This result allows to classify all the Darboux polynomials of Eq. (1) when $(a,b,c) \in (\mathbf{R}\backslash\mathbf{Q}^+)^3$, as is shown in the two following propositions.

Proposition 2.4: Let f be a solution of Eq. (4). If a is neither zero nor a positive rational number, then f reads

$$f = x^{\gamma_1} y^{\gamma_2} f_1, \tag{7}$$

where the positive integers γ_1 and γ_2 satisfy $\gamma(f) = \gamma_1 + a\gamma_2$ and f_1 is a solution to Eq. (4) such that $\gamma(f_1) = 0$.

If $a \notin \mathbf{Q}^+$, $\mathbf{N} \cap \mathbf{N}a = \{0\}$. If γ is zero, setting $\gamma_1 = \gamma_2 = 0$ yields the result. If not, then either $\gamma \notin \mathbf{N}$ or $\gamma \notin \mathbf{N}a$. Assume $\gamma \notin \mathbf{N}$; f can be divided by y. Let this procedure be repeated as many times as it can, and let γ_2 be the number of times it can. We have $f = y^{\gamma_2} f_0$, and f_0 is solution to Eq. (4) with $\gamma(f_0) = \gamma(f) - a\gamma_2$. This $\gamma_1 = \gamma(f_0)$ must be integer since we had to stop the division procedure of f by y.

Thus either $\gamma_1 = 0$ or $\gamma_1 \notin \mathbf{N}a$. In the first case, Eq. (7) is satisfied with $f_1 = f_0$. In the second case, f_0 can be divided γ_1 times by x, and Eq. (7) is satisfied with $f_1 = f_0 / x^{\gamma_1}$.

Assume now $\gamma \in \mathbf{N}^*$; applying only the second step of the above procedure yields the same conclusion. In both cases, it follows from the basic properties of Darboux polynomials that f_0 is solution to Eq. (4) with $\gamma(f_0) = 0$ and that $\gamma(f) = \gamma_1 + a\gamma_2$.

Theorem 2.5: *Let f be a solution of Eq. (4). If none of the three system parameters is zero or a positive rational number, then there exist three positive integers p,q,r and a polynomial first integral I of Eq. (1)—which may be trivial—such that*

$$f = x^p y^q z^r I \tag{8}$$

and

$$\alpha = q + br, \quad \beta = r + cp, \quad \gamma = p + aq. \tag{9}$$

By cyclical permutations Proposition 2.4 can be rewritten as statements on α and β. These three results will be successively used in the following algorithm:

(1) Set $n = 0$ and $f_n = f$.
(2) Applying Proposition 2.4 for α yields
$$f_n = y^{\alpha_1} z^{\alpha_2} f_{n+1}, \quad \alpha(f_{n+1}) = 0.$$
(3) If f_{n+1} is a first integral, go to the final step, else increment n by one.
(4) Applying Proposition 2.4 for β yields
$$f_n = z^{\beta_1} x^{\beta_2} f_{n+1}, \quad \beta(f_{n+1}) = 0.$$
(5) If f_{n+1} is a first integral, go to the final step, else increment n by one.
(6) Applying Proposition 2.4 for γ yields
$$f_n = x^{\gamma_1} y^{\gamma_2} f_{n+1}, \quad \gamma(f_{n+1}) = 0.$$
(7) If f_{n+1} is a first integral, go to the final step, else increment n by one and return to step 2.
(8) (Final step) Set $I = f_{n+1}$ and, using the sequence of equations linking f_i to f_{i+1}, $i = 1 \cdots n$ given by the algorithm, determine the exponents (p,q,r) in Eq. (8).

At every step, one has $\deg f_{i+1} \leqslant \deg f_i$; and when three consecutive terms of the sequence are of same degree, they are equal and $\alpha(f_i)=\beta(f_i)=\gamma(f_i)=0$, so f_i is a first integral. Thus the algorithm converges in a finite number of steps. Once the existence of (p,q,r) is proven, Eq. (9) follow by the basic properties of Darboux polynomials.

III. POLYNOMIAL FIRST INTEGRALS

Proposition 3.1 Let f be a polynomial first integral of degree m with a nonzero z^m term. Then a must be nonzero and there exists a polynomial $k(x,y,z)$ such that

$$f=\lambda\left[(z-bx)^m+\left(z-\frac{y}{a}\right)^m-z^m\right]+xyk(x,y,z).$$

The homogeneity of f yields $f(x,y,z)=x\varphi(x,y,z)+y\psi(x,y,z)+\lambda z^m$. Thus, $Df=0$ reads

$$xD\varphi+yD\psi=-(cy+z)x\varphi-(az+x)y\psi-\lambda(mbx+my)z^m. \tag{10}$$

Set $y=0$ in Eq. (10)

$$\widetilde{xD\varphi}=-zx\widetilde{\varphi}-\lambda mbxz^m.$$

Simplifying by x we get after some calculations:

$$xz\left(\frac{\partial\widetilde{\varphi}}{\partial x}+b\,\frac{\partial\widetilde{\varphi}}{\partial z}\right)=-z\widetilde{\varphi}-\lambda mbz^m. \tag{11}$$

This shows that

$$x\,|-\widetilde{\varphi}-\lambda mbz^{m-1}.$$

Hence we set

$$\varphi_0=\widetilde{\varphi}=x\varphi_1-\lambda mbz^{m-1},$$

then the derivatives of $\widetilde{\varphi}$ are

$$\frac{\partial\widetilde{\varphi}}{\partial x}=x\,\frac{\partial\varphi_1}{\partial x}+\varphi_1,\quad \frac{\partial\widetilde{\varphi}}{\partial z}=x\,\frac{\partial\varphi_1}{\partial z}-\lambda(m-1)mbz^{m-2}.$$

Putting these expressions in Eq. (11) gives

$$xz\left(x\,\frac{\partial\varphi_1}{\partial x}+\varphi_1+b\,\frac{\partial\varphi_1}{\partial z}\right)=-zx\varphi_1-z\lambda(-mb)z^{m-1}-\lambda mbz^m.$$

The last two terms compensate; in all other terms x is in factor and we simplify:

$$xz\left(\frac{\partial\varphi_1}{\partial x}+b\,\frac{\partial\varphi_1}{\partial z}\right)=-2z\varphi_1+\lambda mb(m-1)bz^{m-1}.$$

By recurrence, we get a sequence of PDE,

$$xz\left(\frac{\partial\varphi_k}{\partial x}+b\,\frac{\partial\varphi_k}{\partial z}\right)=-(k+1)z\varphi_k+\lambda(k+1)(-b)^{k+1}C_m^{k+1}z^{m-k}, \tag{12}$$

linked by the recurrence formula

$$\varphi_{k-1}=x\varphi_k+\lambda(-b)^k C_m^k z^{m-k}. \tag{13}$$

As $\deg\varphi_0=\deg\varphi=m-1$, this formula shows that $\deg\varphi_k=m-1-k$; thus $\deg\varphi_{m-1}=0$ and $\varphi_{m-1}=C=\text{cst}$. Then Eq. (12) reads

$$xz0=-mzC+\lambda m(-b)^m z^1$$

or $C=\lambda(-b)^m$. Hence the sequence of Eq. (13) yields finally

$$\tilde{\varphi}=\lambda\sum_{k=0}^{m-1} x^k(-b)^{k+1}C_m^{k+1}z^{m-1-k}$$

or, since $\tilde{\varphi}=\varphi(.,0,.)$:

$$\varphi=\frac{\lambda}{x}\left[(z-bx)^m-z^m\right]+yK_1(x,y,z). \tag{14}$$

We now determine ψ similarly. Setting $x=0$ in Eq. (10) yields

$$yz\left(a\,\frac{\partial\hat{\psi}}{\partial y}+\frac{\partial\hat{\psi}}{\partial z}\right)=-az\hat{\psi}+\lambda(-m)z^m. \tag{15}$$

Thus,

$$y|-a\hat{\psi}+\lambda(-m)z^{m-1}.$$

This shows $a\neq 0$, otherwise we get the contradiction $y|\lambda z^{m-1}$ with $\lambda\neq 0$. Now, Eq. (15) is integrated by a method similar to that used for Eq. (11). So we find that

$$\psi=\frac{\lambda}{y}\left[\left(z-\frac{y}{a}\right)^m-z^m\right]+xK_2(x,y,z).$$

Since $f=x\varphi+y\psi+\lambda z^m$ we have

$$f=\lambda_1[(z-bx)^m+(z-y/a)^m-z^m]+xyk_1(x,y,z), \tag{16}$$

which we had to prove.

Using the variable and coefficient symmetry, we get the following results:

• if f is a polynomial first integral with nonzero y^m term then $c\neq 0$ and

$$f=\lambda_2[(y-az)^m+(y-x/c)^m-y^m]+xzk_2(x,y,z), \tag{17}$$

• if f is a polynomial first integral with nonzero x^m term then $b\neq 0$ and

$$f=\lambda_3[(x-cy)^m+(x-z/b)^m-x^m]+zyk_3(x,y,z). \tag{18}$$

These facts yield a first distinction between polynomial first integrals.

Proposition 3.2: Let f be a polynomial first integral of degree m of (1). Then the coefficients of x^m, y^m, z^m—which we will call the extremal terms*—are either all zero or all nonzero.*

Assume that the z^m term is zero, i.e., $f=x\varphi+y\psi$. The equivalent of Eq. (11) in that case is

$$xz\left(\frac{\partial\tilde{\varphi}}{\partial x}+b\,\frac{\partial\tilde{\varphi}}{\partial z}\right)=-z\tilde{\varphi}.$$

Thus, $x|\widetilde{\varphi}$, then repeating the proof of Proposition 2.2 yields $\widetilde{\varphi}=0$; or $y|\varphi$ and thus $y|f$. In particular the x^m term in f is zero.

Suppose the coefficient of y^m is nonzero. Then $c\neq 0$ and Eq. (17) shows that the coefficient of x^m is nonzero. Contradiction.

The variable symmetry allows to complete the proof: if any of the extremal terms is zero, so are the other two. QED.

The first integrals with no extremal terms are characterized by the following statement.

Proposition 3.3: Let f be a polynomial first integral of degree m, with no x^m, y^m, z^m terms. Then:

• *the system parameters (a,b,c) are negative rational numbers whose product is -1;*

• *we have $f=x^p y^q z^r I$, where I is another polynomial first integral—which may be trivial—and (p,q,r) satisfy Eq. (9) with $\alpha=\beta=\gamma=0$, i.e.,*

$$q+br=0, \quad r+cp=0, \quad p+aq=0. \tag{19}$$

If f has no extremal terms, it reads

$$f(x,y,z)=xy\varphi(x,y,z)+xz\chi(x,z)+yz\psi(y,z),$$

i.e., all terms divisible by xyz have been put in φ. Then $Df=0$ yields

$$\begin{aligned}&(bx+y)z(x\chi+y\psi+xz\chi_z+yz\psi_z+xy\varphi_z)+y(x+az)(x\varphi+z\psi+yz\psi_y+xy\varphi_y)\\&+x(cy+z)(z\chi+y\varphi+xz\chi_x+xy\varphi_x)=0,\end{aligned} \tag{20}$$

thus, setting $x=0$,

$$(y+az)\psi+yz(a\psi_y+\psi_z)=0.$$

Hence we have $z|\psi$; by recurrence we can show that ψ is divisible by any power of z. Thus $\psi=0$.

If similarly we set $y=0$ in Eq. (20), we get

$$(bx+z)\chi+xz(\chi_x+g\chi_z)=0.$$

Hence $x|\chi$; by recurrence we show that χ is divisible by any power of x. Thus $\chi=0$.

Finally, replacing z with 0 in Eq. (20) yields

$$(x+cy)\overline{\varphi}+xy(c\overline{\varphi_x}+\overline{\varphi_y})=0.$$

Hence $\overline{\varphi}=0$, which means $\varphi=zQ$. Thus we have $f=xyzQ$. Then $Df=0$ reads

$$xyzDQ+[(1+b)x+(1+c)y+(1+a)z]xyzQ=0.$$

By definition, Q is thus a Darboux polynomial with $\alpha(Q)=-(1+b)$, $\beta(Q)=-(1+c)$, $\gamma(Q)=-(1+a)$. Proposition 2.3 shows that the parameters (a,b,c) are strictly negative. Indeed, if, e.g., $a\geqslant 0$, it yields $\gamma\geqslant 0$, but $\gamma=-1-a<0$. Hence Theorem 2.5 holds for Q and $Q=x^{p_1}y^{q_1}z^{r_1}I$. Hence $f=x^p y^q z^r I$ with $p=p_1+1$, etc.

We check that (a,b,c) satisfy Eq. (19). Those imply $a,b,c\in\mathbf{Q}^-$, since p,q,r are positive integer numbers. Moreover, in order for this linear system to admit a nonzero solution (p,q,r), it is necessary that its determinant be zero; but this determinant is precisely $abc+1$. QED.

As for the first integrals with extremal terms, we shall prove that when (a,b,c) are real the condition $abc=\pm 1$ is a necessary one for their existence.

Proposition 3.4: Let f be a polynomial first integral of degree m with extremal terms. Then the system parameters satisfy $(-abc)^m=1$. Thus, if they are real the condition $abc=\pm 1$ holds, the plus sign being excluded if m is odd. Moreover, f satisfies in all cases:

$$f=\lambda((-a)^m((z-bx)^m-z^m-(-bx)^m)+(y-az)^m+(y-x/c)^m-y^m)+xyzQ(x,y,z). \tag{21}$$

First, the presence of all extremal terms implies that the three system parameters are nonzero. Hence the three expressions (16), (17), and (18) for f hold. We can identify the terms without the variable x in Eqs. (16) and (17):

$$\lambda_2(y-az)^m=\lambda_1(z-y/a)^m.$$

Hence $\lambda_1=\lambda_2(-a)^m$. Then we identify the terms containing x in factor:

$$\lambda_2[(y-x/c)^m-y^m]+xzk_2=\lambda_2(-a)^m[(z-bx)^m-z^m]+xyk_1. \tag{22}$$

The identification of the coefficients of x^m yields $(-1/c)^m=(ab)^m$; in other words, $-abc$ must be an mth root of unity. Since the parameters are real, we must have $abc=-1$ if m is odd and $abc=\pm 1$ if m is even.

Setting $y=0$ in Eq. (22) and recalling the compensation of the x^m terms, we get

$$xz\tilde{k}_2=\lambda_2(-a)^m[(z-bx)^m-z^m-(-bx)^m],$$

hence the equality

$$xzk_2=\lambda_2(-a)^m[(z-bx)^m-z^m-(-bx)^m]+xyzQ,$$

which combined to Eq. (17) yields Eq. (21).

Up to now, all computations could have been carried with real or complex parameters and/or Darboux elements. However, the assumption of reality for (a,b,c) will play a crucial role for completing the proof of the result announced in the Introduction.

Indeed, there are only two real roots of unity: 1 (''first'' root) and -1 (square or ''second'' root). The above Proposition suggests that when $abc=\pm 1$ a polynomial first integral of first or second degree *may* exist; but we know it *does*. Then the most natural idea is to compare these known first integrals to Eq. (21). But the latter contains a polynomial Q which seems hard to determine: we have exhausted all the arithmetic arguments. Now we have got it: if $\deg f=1$ or 2, then the $xyzQ$ term in Eq. (21) must be zero. *This allows us to guess what the least-degree first integral should be and at what condition it is a first integral*. We are now able to prove that in both cases the polynomial first integrals reduce to the known ones.

Now, in the case where the parameters can be complex, Proposition 3.4 suggests that other cases can exist, and indeed they do.[5] But they cannot be found out by the above theory. When $-abc$ is a *primitive* mth root of unity, a polynomial first integral needs to be of degree at least m. Thus, it cannot be derived from Eq. (21) because of the $xyzQ$ term. In other words, we can check that this formula holds in the integrability cases with complex parameters, *but it does not allow to guess new cases nor to discard their existence*. We intend to reserve the problem of integrability with complex parameters for a future publication.

Theorem 3.5: *If $abc=-1$, the generators of the algebra of polynomial first integrals are*:

• *in all cases, the first integral $f_1=abx+y-az$*;

• *when, moreover, $(a,b,c)\in(\mathbf{Q}^-)^3$, $x^py^qz^r$, where (p,q,r) is the least positive integer solution to the system (19).*

We shall use the following algorithm:

1. If f has no extremal terms, apply Proposition 3.3 as many times as f can be factored by $x^p y^q z^r$. Finally, we get either a constant, or a first integral of strictly lower degree, with extremal terms. In the first case we have $f=\lambda(x^p y^q z^r)^i$ for some i, which is in the algebra defined by our statement. In the second case, go to the following step.

2. If f possesses extremal terms, it satisfies Eq. (21). Indeed, setting $c=-1/ab$ and $m=1$, this formula does read $f=\lambda f_1=\lambda(abx+y-az)$, and for $m=2$, $f=\lambda(f_1)^2$—we recall that if deg $f<3$, the term $xyzQ$ must be zero. Suppose $m=\deg f\geqslant 3$. The terms in the expansion of $(f_1)^m$ which do not contain xyz in factor are the ones in factor of λ in Eq. (21). Consequently

$$f=\lambda(f_1)^m+xyzQ_1.$$

On the other hand, we check that $Df_1=(1+abc)xy=0$, hence $xyzQ_1$ is a polynomial first integral with no extremal terms. If it is zero, then $f=(f_1)^m$, else return to the first step.
As the first step produces an integral of strictly lower degree, this algorithm must terminate in a finite number of steps. So we shall obtain an expression of f in function of f_1 and $x^p y^q z^r$.

Theorem 3.6: *If* $abc=1$, *polynomial first integrals exist on the extra condition that* $1+b+ab=0$, *and in this case the algebra they span is generated by* $f_2=a^2b^2x^2-2abxy+y^2-2ayz-2a^2bxz+a^2z^2$.
We know that for $abc=1$ the degree of the integral is necessarily even: $m=2k$. When $k=1$ and $c=1/ab$, Eq. (21) reads $f=\lambda f_2$—since the term $xyzQ$ must then be zero. If we calculate the derivative of this function with respect to the system (1), we find

$$Df_2=-4axyz(1+b+ab),$$

thus, as $a\neq 0$, f_2 cannot be a first integral unless $1+b+ab=0$.

For $k>1$, Eq. (21) shows $f-(f_2)^k=xyzQ_1$, or, since f is assumed to be a first integral,

$$D[f-(f_2)^k]=0-D[(f_2)^k]=D(xyzQ_1),$$

which yields

$$4akxyz(1+b+ab)(f_2)^{k-1}=xyz\{DQ_1+[(1+b)x+(1+c)y+(1+a)z]Q_1\}.$$

The linear differential operator in Q_1 which appears in the right-hand side has been studied in the proof of Proposition 3.3. In particular, a necessary condition for its kernel to be nontrivial is $abc=-1$, which is clearly not true. Hence, this operator is injective, and, if $1+b+ab=0$, we have $Q_1=0$ and $f=\lambda(f_2)^k$.

The rest of the proof will be devoted to show that the case $1+b+ab\neq 0$ is in fact impossible. Suppose *ab absurdo* that $1+b+ab\neq 0$; then the previous equation reads

$$\mu(f_2)^{k-1}=\{DQ_1+[(1+b)x+(1+c)y+(1+a)z]Q_1\}, \tag{23}$$

with $\mu\neq 0$. Setting then $z=0$ in this equality yields

$$xy\left(c\,\frac{\partial\overline{Q_1}}{\partial x}+\frac{\partial\overline{Q_1}}{\partial y}\right)+[(1+b)x+(1+c)y]\overline{Q_1}=\mu(abx-y)^{2k-2}. \tag{24}$$

Clearly if Eq. (23) admits a polynomial solution—which must be of degree $2k-3$—then Eq. (24) does. We shall integrate this equation by the method of characteristics.

Equation (24) is equivalent to the following system:

$$\dot{x}=cxy,\quad \dot{y}=xy,$$

$$\dot{u}=-[(1+b)x+(1+c)y]u+\mu(abx-y)^{2k-2}, \tag{25}$$

by the correspondence $u(t)=\overline{Q_1}[x(t),y(t)]$.

The first two equations can be uncoupled from the third one. Their quotient yields $\dot{x}/\dot{y}=c$, thus, $\dot{x}=c\dot{y}$ or $x=c(y-y_0)$, where y_0 is an integration constant. Then the second becomes $\dot{y}=cy(y-y_0)$, a separable variable equation which easily integrates as

$$y=\frac{y_0}{1-e^{cy_0t}},$$

and, since $x=c(y-y_0)$,

$$x=\frac{cy_0e^{cy_0t}}{1-e^{cy_0t}}.$$

Setting $X=e^{cy_0t}$ and $Y=y_0$, we get

$$x=\frac{cXY}{1-X},\quad y=\frac{Y}{1-X}.$$

Before we integrate the third equation in Eq. (25), we remark that $\overline{Q_1}$ is a homogeneous polynomial of degree $2k-3$ in (x,y) iff $u(t)$ can be written as $u=Y^{2k-3}A(X)/(1-X)^{2k-3}$ where $A(X)$ is a polynomial of degree $2k-3$. Then we get

$$\dot{u}=\frac{\partial}{\partial X}\left(\frac{Y^{2k-3}A(X)}{(1-X)^{2k-3}}\right)\frac{dX}{dt},$$

with $dX/dt=cy_0e^{cy_0t}=cXY$ and $dY/dt=0$.

Then the third equation in Eq. (25) reads

$$cXY\left[\frac{A'(X)(1-X)^{2k-3}+(2k-3)(1-X)^{2k-4}A(X)}{(1-X)^{4k-6}}\right]Y^{2k-3}$$
$$=\frac{Y^{2k-3}A(X)}{(1-X)^{2k-3}}\left(\frac{-c(1+b)XY-(1+c)Y}{1-X}\right)+\mu\left(\frac{abcXY-Y}{1-X}\right)^{2k-2}.$$

Since $abc=1$, the last term simplifies as Y^{2k-2}. Multiplying then this equation by $(1-X)^{2k-2}$ and dividing it by Y^{2k-2} yields

$$cX[A'(X)(1-X)+(b+2k-2)A(X)]+(1+c)A(X)=\mu(1-X)^{2k-2}. \tag{26}$$

The latter is a linear differential equation. Notice, that $c\neq-1$ for otherwise we would have $X|\mu(1-X)^{2k-2}$ which is impossible since $\mu\neq0$. The general solution to the homogeneous equation is

$$A(X)=K(1-X)^{b+2k-1+1/c}X^{-(1+1/c)}. \tag{27}$$

Let the constant vary: $K=K(X)$. Then Eq. (26) becomes

$$K'(X)=\frac{\mu}{c}X^{1/c}(1-X)^{-(2+b+1/c)}.$$

For any $\alpha\in\mathbf{R}$, we denote $(\alpha)_n=\alpha(\alpha+1)\cdots(\alpha+n-1)$; i.e., the generating function of the $(\alpha)_n$ being $(1-X)^{-\alpha}$, we have

$$K'(X)=\frac{\mu}{c}\sum_{n=0}^{\infty}(2+b+1/c)_n\frac{X^{n+1/c}}{n!}.$$

We see that if there exists $n\in\mathbf{N}$ such that $n+1/c=-1$, the function K has a logarithmic singularity at 0; and so does A.

Hence, if A is a polynomial, then necessarily $c\notin-\mathbf{N}^*$ and the indefinite integral is calculated as

$$K(X)=\frac{\mu}{c}\sum_{n=0}^{\infty}(2+b+1/c)_n\frac{X^{n+1+1/c}}{(n+1+1/c)n!}+k$$

($k=$cst), and so

$$A(X)=(1-X)^{b+2k-1+1/c}\left(\frac{\mu}{c}\sum_{n=0}^{\infty}(2+b+1/c)_n\frac{X^n}{(n+1+1/c)n!}+kX^{-(1+1/c)}\right).$$

Clearly, the integral series in this formula is not equal to a power of $1-X$. Thus A being a polynomial implies that $(2+b+1/c)_n$ is zero for n sufficiently large, i.e., $2+b+1/c=-n_1\in-\mathbf{N}$ and that $b+2k-1+1/c\in\mathbf{N}$; since the value of this integer must be at most $\deg A=2k-3$, we get once more the condition $2+b+1/c\in-\mathbf{N}$.

This is the only possibility of existence of a polynomial solution to Eq. (26)—hence to Eq. (24). If it holds, we check that $\deg A=2k-3$. But the analysis carried out by suppressing the variable z can be achieved by setting $x=0$ or $y=0$ and hence we get the three equalities

$$2+b+1/c=-n_1,\quad 2+a+1/b=-n_2,\quad 2+c+1/a=-n_3, \tag{28}$$

where n_1, n_2, $n_3\in\mathbf{N}$. Since $abc=1$, there are two possibilities: either the three parameters are positive, or one is positive, e.g., a and the other two are negative. The first possibility is excluded by Eq. (28).

Thus, if $a>0$ and $b,c<0$, the second equation yields $0<a=-n_2-2-1/b$ or $-1/b>n_2+2\geqslant 2$ and hence $|b|<1/2$. In the same way we get $|1/c|<1/2$. Then the first equation in Eq. (28) yields $-n_1=2+b+1/c>2-1/2-1/2=1$, a contradiction.

Consequently, it is absurd to assume the existence of a polynomial solution to Eq. (23). Hence, in the case $abc=1, 1+b+ab\neq 0$, there cannot be a polynomial first integral to the dynamical system (1).

IV. CONCLUSION

We have proved the following characterization of all existence cases and values of polynomial first integrals for the Lotka–Volterra dynamical system with real parameters.

(1) The (a,b,c) Lotka–Volterra system cannot have a nontrivial polynomial first integral unless $abc=\pm 1$.
(2) If $abc=1$, the algebra of polynomial first integrals is generated by the integral $I_2=a^2b^2x^2-2abxy+y^2-2ayz-2a^2bxz+a^2z^2$ if $1+b+ab=0$, and trivial if not.
(3) If $abc=-1$ and $(a,b,c)\notin(\mathbf{Q}^-)^3$, this algebra is generated by $I_1=abx+y-az$.
(4) If $abc=-1$ and $(a,b,c)\in(\mathbf{Q}^-)^3$, the generators are $I_1=abx+y-az$ and $x^py^qz^r$, where (p,q,r) is the least strictly positive solution to the linear system (19).

Our method yields no characterization of the integrability cases for complex parameters. It gives however a necessary, but clearly not sufficient, condition for their existence, which is effectively satisfied by all known cases.[5]

Differential–difference equations of the form $\ddot{u}_n = F_n(t, u_{n-1}, u_n, u_{n+1})$ are classified according to their continuous Lie point symmetry groups. It is shown that for nonlinear equations, the symmetry group can be at most seven-dimensional. The integrable Toda lattice is a member of this class and has a four-dimensional symmetry group. © *1996 American Institute of Physics.* [S0022-2488(96)03906-0]

I. INTRODUCTION

The purpose of this article is to classify differential–difference equations ($D\Delta E$) of the form

$$\Delta_n \equiv \ddot{u}_n(t) - F_n(t, u_{n-1}(t), u_n(t), u_{n+1}(t)) = 0, \tag{1.1}$$

into conjugacy classes and to determine the Lie point symmetries for each conjugacy class. Conjugacy is considered under a group of ''allowed transformations,'' preserving the form of Eq. (1.1), while possibly changing the function F_n. We restrict the allowed transformations to be fiber preserving, i.e., to have the form

$$u_n(t) = \Omega_n(\tilde{u}_n(\tilde{t}), t, g), \quad \tilde{t} = \tilde{t}(t, g), \quad \tilde{n} = n, \tag{1.2}$$

where Ω_n and $\tilde{t}$ are some locally smooth and monotonous (invertible) functions, and g represents the group parameters. These functions are such that $\tilde{u}_n(\tilde{t})$ satisfies an equation of the form (1.1) with F_n replaced by some function $\tilde{F}_n(\tilde{t}, \tilde{u}_k(\tilde{t}))$ $k = n-1, n, n+1$.

With this formulation, Lie symmetries of Eq. (1.1) are special cases of allowed transformations, namely, those for which we have

$$\tilde{F}_n(\tilde{t}, \tilde{u}_k(\tilde{t})) = F_n(\tilde{t}, \tilde{u}_k(\tilde{t})). \tag{1.3}$$

In this article we restrict to Lie point symmetries only. The algorithm for calculating them for a given equation was presented in our earlier articles[1,2] and was called ''the intrinsic method'' in Ref. 2. Thus we assume that the Lie algebra of the symmetry group is realized by vector fields of the form

$$\hat{X} = \tau(t, u_n)\partial_t + \phi_n(t, u_n)\partial_{u_n}, \tag{1.4}$$

and request that the prolongation $\mathrm{pr}\,\hat{X}$ of $\hat{X}$ should annihilate the equation on its solution set

$$\mathrm{pr}\,\hat{X}\Delta_n|_{\Delta_n = 0} = 0. \tag{1.5}$$

The prolongation formula for $D\Delta E$ was given earlier.[1] This definition of Lie point symmetries [as in Eqs. (1.2),...,(1.5)] is closely related to that of Maeda[3] for difference equations, and also to that of Quispel *et al.*[4] We note that the restriction $\tilde{n} = n$ is an important one and significantly cuts down

[a]Permanent and present address: Dipartimento di Fisica, Università di Roma III, and INFN-Sezione di Roma, P. le A. Moro 2, 00185 Roma, Italy.

on the number of symmetries of a difference equation, as opposed to a differential one. Symmetries transforming the discrete variables, can also be incorporated systematically, but that is a topic for a different article.[5]

Our motivation is the same as for classifying differential equations according to their symmetries. Dynamical systems of the form (1.1) occur in many applications, ranging from classical mechanics to molecular physics, or mathematical biology.[6–8] If the function $F_n(t,u_k)$ is such that Eq. (1.1) allows a nontrivial symmetry group, then it is usually possible to obtain exact analytical solutions satisfying certain symmetry requirements.

A different aspect is the possible connection between symmetries and integrability. Indeed, integrable equations, be they differential, or differential–difference ones, tend to have large Lie point symmetry groups. For instance, the Korteweg–de Vries equation with variable coefficients was shown to have at most a four-dimensional Lie point symmetry group.[9] More important, it has a four-dimensional symmetry algebra precisely if it is equivalent, under point transformations, to the KdV equation itself.

In the same context, we mention that integrable equations involving three independent variables (like the Kadomtsev–Petviashvili, Davey–Stewartson, 3-wave equations, and others) have infinite dimensional Lie point symmetry algebras with a specific Kac–Moody–Virasoro structure.[10–13] Interestingly enough, this is also true when one of the three variables is discrete, as in the two-dimensional Toda lattice.[1,2]

In short, nonlinear differential and differential–difference equations with large Lie point symmetry groups are prime candidates for being integrable, or having some of the attributes of integrability.[14]

Throughout this article we impose some restrictions.

(1) Only point symmetries are considered, i.e., all elements of the symmetry algebra have the form (1.4).

(2) The interaction F_n and the vector field $\hat{X}$ depend continuously on n. This rules out terms of the type $[A\pm(-1)^nB]$ in F_n, or ϕ_n. Such terms will be considered elsewhere, once we treat systems of $D\Delta E$. Indeed, they correspond to treating even and odd values of n separately.

(3) In the bulk of the article the interaction F_n is assumed to be nonlinear and coupled, i.e.,

$$\frac{\partial^2 F_n}{\partial u_i \partial u_k} \neq 0, \quad \left(\frac{\partial F_n}{\partial u_{n-1}}, \frac{\partial F_n}{\partial u_{n+1}}\right) \neq (0,0) \tag{1.6}$$

(on some open set of values of the variables). The linear case is considered in Sec. VIII.

(4) The interaction F_n involves only nearest neighbors on the lattice, i.e., depends on u_n, u_{n+1}, u_{n-1}, but not say on u_{n+2}.

(5) We only list the ''maximal'' symmetry algebras for a given interaction F_n. Thus if F_n allows say a five-dimensional symmetry algebra, we will not include it among those with symmetry algebras of dimension $\dim L \leqslant 4$.

In Sec. II we present the determining equations for the symmetries and introduce the classification group, i.e., the allowed transformations. We also find all interactions F_n with one-dimensional symmetry algebras. Section III is devoted to interactions with abelian symmetry algebras. We denote them $\mathrm{A}_{i,k}$, where the first index shows the dimension of the algebra. This turns out to satisfy $1 \leqslant \dim L \leqslant 4$. All nilpotent nonabelian symmetry algebras are found in Sec. IV. We call them $\mathrm{N}_{i,k}$ with i indicating the dimension. In this case we have $3 \leqslant \dim L \leqslant 5$. Solvable symmetry algebras $\mathrm{SN}_{i,k}$ with nonabelian nilradicals are treated in Sec. V. There exist eight classes of such algebras. Their dimensions are four, or six. Section VI is devoted to solvable symmetry algebras with abelian nilradicals $\mathrm{SA}_{i,k}$. Their dimensions satisfy $3 \leqslant \dim L \leqslant 5$ and there are altogether 30 inequivalent symmetry algebras of this type. In Sec. VII we treat nonsolvable symmetry algebras. They all contain $\mathrm{sl}(2,\mathbb{R})$ as a subalgebra. Their dimensions are $\dim L = 3$, 4, 5, and 7 and there exist five inequivalent ones. Linear equations were so far excluded from consid-

eration and are investigated in Sec. VIII. Their symmetry algebras are infinite-dimensional, but this just reflects the linear superposition principle. A summary of results and some conclusions are presented in the final Sec. IX.

II. FORMULATION OF THE PROBLEM AND EQUATIONS WITH ONE-DIMENSIONAL SYMMETRY ALGEBRAS

In order to implement the symmetry algorithm (1.5) for Eq. (1.1), we need the second prolongation of the vector field (1.4). We use the general formulas presented earlier,[1,2] i.e., in our case

$$\mathrm{pr}^{(2)}\, X=\tau(t,u_n)\partial_t+\sum_{k=n-1}^{n+1}\phi_k(t,u_k)\partial_{u_k}+\phi_n^{tt}\partial_{\ddot{u}_n}, \tag{2.1}$$

$$\phi_n^{tt}=D_t^2\phi_n-(D_t^2\tau)_{\dot{u}_n}-2(D_t\tau)_{\ddot{u}_n}, \tag{2.2}$$

where D_t is the total derivative.

We apply $\mathrm{pr}^{(2)}\, X$ to Eq. (1.1), eliminate the $\ddot{u}_n$ terms using Eq. (1.1) and then request that the coefficients of $(\dot{u}_n)^k$, $k=0,1,2,3$ should vanish. We find that, for any F_n that depends nontrivially on at least one u_k, $k\neq n$, the coefficients in the vector field (1.4) satisfy

$$\phi_n(t,u_n)=(\tfrac{1}{2}\dot{\tau}(t)+a_n)u_n+\beta_n(t),\quad \tau(t,u_n)=\tau(t),\quad \dot{a}_n=0. \tag{2.3}$$

Moreover, the constants a_n and functions $\tau(t)$, $\beta_n(t)$ satisfy the remaining determining equation (the coefficient of the term independent of $\dot{u}_n$)

$$\tfrac{1}{2}\dddot{\tau}u_n+\ddot{\beta}_n+(a_n-\tfrac{3}{2}\dot{\tau})F_n-\tau F_{n,t}-\sum_{\alpha=n-1}^{n+1}[(\tfrac{1}{2}\dot{\tau}+a_\alpha)u_\alpha+\beta_\alpha]F_{n,u_\alpha}=0. \tag{2.4}$$

Let us now determine the allowed transformation (1.2). Substituting Eq. (1.2) into Eq. (1.1) and requiring that the terms $(\dot{\tilde{u}}_n)^2$ and $\ddot{\tilde{u}}_n$ be absent, we find that the allowed transformation (1.2) must be linear and satisfy

$$u_n(t)=\frac{A_n}{\sqrt{\dot{\tilde{t}}_t}}\,\tilde{u}_n(\tilde{t})+B_n(t),\quad \tilde{t}=\tilde{t}(t),\quad A_{n,t}=0,\quad \dot{\tilde{t}}\neq 0,\quad A_n\neq 0,\quad \tilde{n}=n. \tag{2.5}$$

Equation (1.1) is transformed into

$$\ddot{\tilde{u}}_n=\frac{1}{A_n}\,(\dot{\tilde{t}})^{-3/2}\left\{F_n(t,u_k)+\left[-\tfrac{3}{4}A_n(\dot{\tilde{t}})^{-5/2}(\ddot{\tilde{t}})^2+\frac{A_n}{2}\,(\dot{\tilde{t}})^{-3/2}\dddot{\tilde{t}}\right]\tilde{u}_n(\tilde{t})-\ddot{B}_n\right\}, \tag{2.6}$$

where t, u_{n-1}, u_n, and u_{n+1} must be expressed in terms of $\tilde{t}$, $\tilde{u}_k$, using Eq. (1.2).

The vector field

$$\hat{X}=\tau(t)\partial_t+[(\tfrac{1}{2}\dot{\tau}(t)+a_n)u_n+\beta_n(t)]\partial_{u_n}, \tag{2.7}$$

is transformed into

$$\hat{X}=\tau(t)\dot{\tilde{t}}\partial_{\tilde{t}}+\left\{\left[\frac{\tau}{2}\,\ddot{\tilde{t}}(\dot{\tilde{t}})^{-1}+\frac{1}{2}\,\dot{\tau}+a_n\right]\tilde{u}_n+(\dot{\tilde{t}})^{1/2}A_n^{-1}\left[\left(\frac{1}{2}\,\dot{\tau}+a_n\right)B_n+\beta_n-\tau\dot{B}_n\right]\right\}\partial_{\tilde{u}_n}. \tag{2.8}$$

Let us now assume that the interaction F_n is given and that it is invariant under a one parameter symmetry group, generated by the vector field (2.7), with coefficients satisfying Eq. (2.4). Let us now use the allowed transformation (2.6) to simplify the vector field $\hat{X}$, i.e., transform it into a convenient ''canonical'' form. Once this is done, we insert the coefficients of the canonical vector field into the determining equation (2.4) and solve this equation for $F_n(t,u_k)$. This is easy to do, since we have a first order linear partial differential equation and we simply apply the method of characteristics.

We see from Eq. (2.8) that three different possibilities occur.

A. $\tau(t)\neq 0$

If we have $\tau(t)\neq 0$ (in some open neighborhood), we choose $\tilde{t}(t)$ and $B_n(t)$ to satisfy

$$\frac{d\tilde{t}}{dt}=[\tau(t)]^{-1}, \quad \tau\frac{dB_n}{dt}-\left(\frac{1}{2}\dot{\tau}+a_n\right)B_n-\beta_n=0.$$

We obtain

$$A_{1,1}: \quad \hat{X}=\partial_t+a_n u_n\partial_{u_n}, \tag{2.9}$$

and using Eq. (2.4) with $\tau=1$, $\beta_n=0$ we find

$$F_n(t,u_k)=f_n(\xi_k)e^{a_n t}, \quad \xi_k=u_k e^{-a_k t}, \quad k=n-1,n,n+1. \tag{2.10}$$

In particular, for $a_n=0$ we have invariance with respect to time translations: F_n does not depend on t.

B. $\tau(t)=0$, $a_n\neq 0$

We choose $B_n=-\beta_n(t)/a_n$ and obtain

$$A_{1,2}: \quad \hat{X}=a_n u_n\partial_n, \tag{2.11}$$

$$F_n(t,u_k)=u_n f_n(t,\xi_k), \quad \xi_k=u_k^{a_n}u_n^{-a_k}, \quad k=n\pm 1. \tag{2.12}$$

The vector field (2.11) can be interpreted as generating site dependent (n dependent) dilations of the function u_n.

C. $\tau(t)=0$, $a_n=0$, $\beta_n(t)\neq 0$

In this case we already have

$$A_{1,3}: \quad \hat{X}=\beta_n(t)\partial_{u_n}, \tag{2.13}$$

and obtain

$$F_n(t,u_k)=\frac{\ddot{\beta}_n}{\beta_n}u_n+f_n(t,\xi_k), \quad \xi_k=\beta_n(t)u_k-\beta_k(t)u_n, \quad k=n\pm 1. \tag{2.14}$$

In this case allowed transformations provide the equivalence

$$\beta_n(t)\sim\beta_n(t)(\tilde{t}_t)^{-1/2}A_n^{-1}. \tag{2.15}$$

In particular, if $\beta_n(t)$ factorizes as a function of n and t, i.e., $\beta_n(t)=\mu_n h(t)$, $\dot{\mu}_n=0$, we can transform $\beta_n(t)$ into $\beta_n(t)=1$. In this case the vector field (2.13) corresponds to a translation of the dependent variable: $u_n \to u_n + c$.

We see that the existence of a one-dimensional symmetry algebra imposes a certain restriction on the form of F_n. Instead of being an arbitrary function of four variables, it will involve a function of only three ''symmetry'' variables. By allowed transformations it can be taken into one of three ''standard'' form Eq. (2.10), (2.12), or (2.14).

Below we shall always assume that F_n and one of the symmetry generators is already in standard form and will show how F_n is further restricted by the existence of a higher dimensional symmetry algebra.

The strategy that we shall follow is to proceed ''structurally.'' Thus we shall first find all interactions that allow abelian symmetry algebras (of any dimension N, but it turns out that in this case we have $N \leqslant 4$). We then proceed to classify nilpotent (nonabelian) symmetry algebras. For these we find that their dimensions satisfy $3 \leqslant N \leqslant 5$. The classification of abelian and nilpotent symmetry algebras is then used to find all solvable (nonabelian) Lie algebras. To do this we use a known result, namely, that a solvable Lie algebra L of dimension $\dim L = d$, has a (unique) nilradical $\mathrm{NR}(L)$ of dimension $\dim \mathrm{NR}(L) \geqslant d/2$. The nilradical is defined as the maximal nilpotent ideal of a Lie algebra.[15] Finally, we shall construct all nonsolvable Lie algebras. These are either simple, or they have a nontrivial Levi decomposition[15,16] into a semidirect sum of a simple Lie algebra and a solvable one (the radical, i.e., the maximal solvable ideal, unique up to equivalence).

III. ABELIAN SYMMETRY ALGEBRAS

The procedure that we adopt for finding all interactions F_n allowing abelian symmetry algebras is an inductive one. We start from each of the $\dim L = 1$ cases found in Sec. II, and then add further generators X_i of the form (2.7), commuting with those that have already been standardized. Thus X_1 is chosen in the form (2.9), (2.11), or (2.13), respectively. We then add X_2, satisfying $[X_1, X_2]=0$ and take F_n in the form (2.10), (2.12), or (2.14), as the case may be. The generator X_2 is first simplified, using allowed transformations that leave the space $\{X_1\}$ invariant. The standardized X_2 and F_n are then inserted into the determining equation (2.4) and this is solved for the arbitrary function f_n in Eq. (2.10), (2.12), or (2.14), respectively. Thus we obtain two-dimensional abelian symmetry algebras and the corresponding interactions, again in ''canonical forms.'' To obtain higher dimensional symmetry algebras, we successively add further linearly independent vector fields to the already established ''canonical'' algebras and impose further restrictions on F_n. The results for $\dim L = 2$ can be summed up in theorem that we state without proof. The interaction F_n throughout satisfies condition (1.6).

Theorem 1: *There exist precisely 5 classes of interactions F_n for which Eq. (1.1) allows a two-dimensional abelian symmetry algebra. The algebras and interaction functions can be represented as follows:*

$$A_{2,1}: \quad X_1 = \partial_t + a_{1n} u_n \partial_{u_n}, \quad X_2 = a_{2n} u_n \partial_{u_n}, \tag{3.1}$$

$$F_n = u_n f_n(\xi_k), \quad \xi_k = u_k^{a_{2n}} u_n^{-a_{2k}} e^{(a_{1n}a_{2k} - a_{1k}a_{2n})t}, \quad a_{2n} \not\equiv 0, \quad k = n-1, n+1. \tag{3.2}$$

$$A_{2,2}: \quad X_1 = \partial_t + a_n u_n \partial_{u_n}, \quad X_2 = e^{a_n t} \partial_{u_n}, \tag{3.3}$$

$$F_n = a_n^2 u_n + e^{a_n t} f_n(\xi_k), \quad \xi_k = u_k e^{-a_k t} - u_n e^{-a_n t}, \quad k = n-1, n+1. \tag{3.4}$$

$$A_{2,3}: \quad X_1 = a_{1n} u_n \partial_{u_n}, \quad X_2 = a_{2n} u_n \partial_{u_n}, \tag{3.5}$$

$$F_n = u_n f_n(t,\xi), \quad \xi = u_{n-1}^{\alpha_{n+1n}} u_n^{\alpha_{n-1n+1}} u_{n+1}^{\alpha_{nn-1}}, \quad \alpha_{kl} = a_{1k}a_{2l} - a_{1l}a_{2k} \neq 0. \tag{3.6}$$

$$A_{2,4}: \quad X_1 = \beta_{1n}(t)\partial_{u_n}, \quad X_2 = \beta_{2n}(t)\partial_{u_n}, \quad \begin{vmatrix} \beta_{1n} & \beta_{2n} \\ \beta_{1n+1} & \beta_{2n+1} \end{vmatrix} \neq 0, \tag{3.7}$$

$$F_n = \frac{(\beta_{1n}\ddot{\beta}_{2n} - \ddot{\beta}_{1n}\beta_{2n})u_{n+1} - (\beta_{1n+1}\ddot{\beta}_{2n} - \ddot{\beta}_{1n}\beta_{2n+1})u_n}{\beta_{1n}\beta_{2n+1} - \beta_{1n+1}\beta_{2n}} + f_n(t,\xi), \tag{3.8}$$

$$\xi = (\beta_{1n}\beta_{2n+1} - \beta_{1n+1}\beta_{2n})u_{n-1} + (\beta_{1n+1}\beta_{2n-1} - \beta_{1n-1}\beta_{2n+1})u_n + (\beta_{1n-1}\beta_{2n} - \beta_{1n}\beta_{2n-1})u_{n+1}.$$

$$A_{2,5}: \quad X_1 = \partial_{u_n}, \quad X_2 = t\partial_{u_n}, \tag{3.9}$$

$$F_n = f_n(t,\xi_k), \quad \xi_k = u_k - u_n, \quad k = n-1, n+1. \tag{3.10}$$

Comments: (1) Notice that for $A_{2,1},\ldots,A_{2,4}$ the interaction involves an arbitrary function f_n of two variables. For $A_{2,5}$ f_n depends on three variables. In all cases we require $f_n \neq 0$. (2) It is easy to verify that no algebra in the representative list is conjugate to any other one in the list (under allowed transformations) and that any two-dimensional abelian symmetry algebra is conjugate to precisely one in the list.

For $\dim L = 3$ we proceed in the same manner. We start from the algebras $A_{2,1},\ldots A_{2,5}$ and add a further linearly independent element X_3, commuting with X_1 and X_2. Again, without proof, we present the following result.

Theorem 2: *Precisely four classes of three-dimensional abelian symmetry algebras exist. They are represented by the following ones.*

$$A_{3,1}: \quad X_1 = \partial_t + a_n u_n \partial_{u_n}, \quad X_2 = b_n u_n \partial_{u_n}, \quad X_3 = c_n u_n \partial_{u_n}. \tag{3.11}$$

$$F_n = u_n f_n(\xi),$$

$$\xi = u_{n-1}^{\alpha_{n+1n}} u_n^{\alpha_{n-1n+1}} u_{n+1}^{\alpha_{nn-1}} \exp(a_{n-1}\alpha_{nn+1} + a_{n+1}\alpha_{n-1n} + a_n\alpha_{n+1n-1})t, \tag{3.12}$$

$$\alpha_{km} = b_k c_m - b_m c_k.$$

$$A_{3,2}: \quad X_1 = \partial_t + a_n u_n \partial_{u_n}, \quad X_2 = e^{a_n t}\partial_{u_n}, \quad X_3 = \gamma_n e^{a_n t}\partial_{u_n}, \quad \gamma_{n+1} \neq \gamma_n, \quad \dot{\gamma}_n = 0. \tag{3.13}$$

$$F_n = a_n^2 u_n + e^{a_n t} f_n(\xi),$$

$$\xi = (\gamma_n - \gamma_{n+1})u_{n-1}e^{-a_{n-1}t} + (\gamma_{n+1} - \gamma_{n-1})u_n e^{-a_n t} + (\gamma_{n-1} - \gamma_n)u_{n+1}e^{-a_n t}, \tag{3.14}$$

$$A_{3,3}: \quad X_1 = \beta_{1n}(t)\partial_{u_n}, \quad X_2 = \beta_{2n}(t)\partial_{u_n}, \quad X_3 = [\lambda_1(t)\beta_{1n}(t) + \lambda_2(t)\beta_{2n}(t)]\partial_{u_n}, \tag{3.15}$$

$$\ddot{\lambda}_1\beta_{1n} + 2\dot{\lambda}_1\dot{\beta}_{1n} + \ddot{\lambda}_2\beta_{2n} + 2\dot{\lambda}_2\dot{\beta}_{2n} = 0, \quad \begin{vmatrix} \beta_{1n} & \beta_{1n+1} \\ \beta_{2n} & \beta_{2n+1} \end{vmatrix} \neq 0, \quad \dot{\lambda}_1\dot{\lambda}_2 \neq 0. \tag{3.16}$$

F_n as in Eq. (3.8)

$$A_{3,4}: \quad X_1 = \partial_{u_n}, \quad X_2 = t\partial_{u_n}, \quad X_3 = \beta_n(t)\partial_{u_n}, \quad \beta_{n+1} \neq \beta_n, \quad \ddot{\beta}_n \neq 0. \tag{3.17}$$

$$F_n=\frac{\ddot{\beta}_n}{\beta_{n+1}-\beta_n}\,(u_{n+1}-u_n)+f_n(t,\xi),$$

$$\xi=(\beta_n-\beta_{n+1})u_{n-1}+(\beta_{n+1}-\beta_{n-1})u_n+(\beta_{n-1}-\beta_n)u_{n+1}. \tag{3.18}$$

Comments: (1) Equation (3.16) can be solved in all generality to yield

$$\beta_{1n}=\frac{1}{\sqrt{\dot{\lambda}_1}}\,\phi(t),\quad \beta_{2n}=\frac{1}{\sqrt{\dot{\lambda}_2}}\left[\gamma_n-\int_0^t\sqrt{\frac{\dot{\lambda}_1(s)}{\dot{\lambda}_2(s)}}\,\dot{\phi}_n(s)ds\right],\quad \dot{\gamma}_n=0. \tag{3.19}$$

We see that interaction (3.8) always allows the two-dimensional symmetry algebra $A_{2,4}$. If the functions β_{1n} and β_{2n} satisfy Eq. (3.16), i.e., can be expressed in terms of one function $\phi_n(t)$ of n and t, two functions $\lambda_1(t)$ and $\lambda_2(t)$ of t alone, and one function γ_n of n, then the symmetry algebra is three-dimensional.

(2) For $\ddot{\beta}_n=0$ in Eq. (3.17) the interaction $F_n=f_n(t,\xi)$ allows a four-dimensional symmetry algebra, a special case of Eq. (3.34) below.

(3) The algebra $\{X_i=\beta_{in}(t)\partial_{u_n},\ i=1,2,3\}$ with β_{in} satisfying

$$\begin{vmatrix}\beta_{1n-1} & \beta_{2n-1} & \beta_{3n-1}\\ \beta_{1n} & \beta_{2n} & \beta_{3n}\\ \beta_{1n+1} & \beta_{2n+1} & \beta_{3n+1}\end{vmatrix}\neq 0, \tag{3.20}$$

is not listed above. The reason is that the corresponding invariant equation has the form

$$\ddot{u}_n=A_n(t)u_n+B_n(t)u_{n-1}+C_n(t)u_{n+1}+D_n(t).$$

Thus the equation is linear (inhomogeneous) and the invariance algebra is a reflection of the linear superposition principle (see Sec. VIII below).

(4)The algebra $\{X_i=a_{in}u_n\partial_{u_n},\ i=1,2,3\}$ also corresponds only to a system of decoupled linear equations.

The algebras $A_{3,1}$ and $A_{3,2}$ cannot be extended to four-dimensional ones, or rather, the corresponding invariant equations would be linear. Hence, for $\dim L\geqslant 4$ the symmetry algebra must have the form $X_i=\beta_{in}(t)\partial_{u_n}$, $i=1,2,\cdots$. At most two of the functions $\beta_{in}(t)$ can be linearly independent as functions of n, otherwise the equation would be linear. If all β_{in} are proportional to $\beta_{1n}(t)$, then L is at most two-dimensional. Hence, we need only consider

$$X_1=\beta_{1n}(t)\partial_{u_n},\quad X_2=\beta_{2n}(t)\partial_{u_n},\quad \beta_{1n}\beta_{2n+1}-\beta_{1n+1}\beta_{2n}\neq 0,$$

$$X_3=[\lambda_1(t)\beta_{1n}(t)+\lambda_2(t)\beta_{2n}(t)]\partial_{u_n},\quad X_4=[\mu_1(t)\beta_{1n}(t)+\mu_2(t)\beta_{2n}(t)]\partial_{u_n}. \tag{3.21}$$

We consider separately the cases $\lambda_1\lambda_2=0$ (or $\mu_1\mu_2=0$) and $\lambda_1\lambda_2\mu_1\mu_2\neq 0$.

In both cases we find that the existence of an abelian symmetry algebra of the type (3.21) ($\dim L=4$) implies that the interaction has the form

$$F_n=P_n(t)u_{n+1}+Q_n(t)u_n+f_n(t,\xi), \tag{3.22}$$

$$\xi=(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1}, \tag{3.23}$$

$$\gamma_{n+1}\neq\gamma_n,\quad \dot{\gamma}_n=0,\quad f_{n,\xi\xi}\neq 0.$$

Let us now find the abelian symmetries for interaction (3.22). We already know that they have the form $X_i = \beta_{in}(t)\partial_{u_n}$. Substituting Eq. (3.22) into Eq. (2.4) and solving the corresponding determining equations, we find

$$\beta_{in}(t)=\phi_i(t)+\gamma_n\psi_i(t), \quad i=1,2, \tag{3.24}$$

where the functions $\phi_i(t)$ and $\psi_i(t)$ satisfy

$$\ddot{\phi}_i+\ddot{\psi}_i\gamma_n-(\phi_i+\psi_i\gamma_{n+1})P_n-(\phi_i+\psi_i\gamma_n)Q_n=0, \quad i=1,2. \tag{3.25}$$

The two equations (3.25) determine the dependence of P_n and Q_n on n. The condition $\beta_{2n}(t)\neq\lambda(t)\beta_{1n}(t)$ implies $\phi_1\psi_2-\phi_2\psi_1\neq 0$, and we obtain

$$\begin{aligned} P_n&=-\frac{1}{\gamma_n-\gamma_{n+1}}[A+(B+C)\gamma_n+D\gamma_n^2], \\ Q_n&=\frac{1}{\gamma_n-\gamma_{n-1}}[A+B\gamma_n+C\gamma_{n+1}+D\gamma_n\gamma_{n+1}], \end{aligned} \tag{3.26}$$

where A, B, C, and D are arbitrary functions of time t. The determining equations for the symmetries X_i with β_{in} as in Eq. (3.24) reduce to

$$\ddot{\psi}-B\psi+D\phi=0, \quad \ddot{\phi}+C\phi-A\psi=0. \tag{3.27}$$

The general solution of Eq. (3.27) involves four arbitrary constants, hence the abelian symmetry algebra L will be precisely four-dimensional and never larger.

Allowed transformations make it possible to exchange the roles of ϕ_i and ψ_i, hence of (B,D) and (C,A). Two cases can be distinguished.

(1) $A\neq 0$ (or equivalently, $D\neq 0$). We reduce Eq. (3.27) to

$$\psi=\frac{1}{A}(\ddot{\phi}+C(t)\phi), \tag{3.28}$$

$$\dddot{\phi}^{\cdot}+2A\left(\frac{1}{A}\right)^{\cdot}\dddot{\phi}+A\left[\left(\frac{1}{A}\right)^{\cdot\cdot}+\frac{C-B}{A}\right]\ddot{\phi}+2A\left(\frac{C}{A}\right)^{\cdot}\dot{\phi}+A\left[\left(\frac{C}{A}\right)^{\cdot\cdot}+\frac{DA-BC}{A}\right]\phi=0. \tag{3.29}$$

A basis for the symmetry algebra is obtained in the form

$$X_i=\left[\phi_i+\frac{1}{A}(\ddot{\phi}_i+C\phi_i)\gamma_n\right]\partial_{u_n}, \quad i=1,\ldots,4, \tag{3.30}$$

where $\phi_1,\ldots\phi_4$ are four linearly independent solutions of Eq. (3.29). Using allowed transformations we can set $\phi_1=1$ and hence

$$\left(\frac{C}{A}\right)^{\cdot\cdot}+\frac{DA-BC}{A}=0. \tag{3.31}$$

(2) $A=D=0$. Using allowed transformations we set $\phi_1=1$ and thus $C=0$, and $\phi_2=t$.

Then ψ_1 and ψ_2 are two linearly independent solutions of the equation

$$\ddot{\psi}-B(t)\psi=0. \tag{3.32}$$

We arrive at the following result.

Theorem 3: *An abelian symmetry algebra of Eq. (1.1) satisfying conditions (1.6) can be at most four-dimensional. A four-dimensional symmetry algebra occurs in the following two cases.*

$$A_{4,1}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad X_3=\psi_1(t)\gamma_n\partial_{u_n}, \quad X_4=\psi_2(t)\gamma_n\partial_{u_n}, \tag{3.33}$$

$$\gamma_{n+1}\neq\gamma_n, \quad \dot{\gamma}_n=0.$$

$$F_n=\frac{B_n(t)\gamma_n}{\gamma_n-\gamma_{n+1}}(u_n-u_{n+1})+f_n(t,\xi), \quad f_{n,\xi\xi}\neq 0, \tag{3.34}$$

with ξ as in Eq. (3.23) and ψ_1, ψ_2 satisfying Eq. (3.32) and hence also

$$\psi_1\dot{\psi}_2-\dot{\psi}_1\psi_2=\text{const.} \tag{3.35}$$

$$A_{4,2}: \quad X_i=[\phi_i(t)+\psi_i(t)\gamma_n]\partial_{u_n}, \quad i=1,\ldots,4, \tag{3.36}$$

$$F_n=\frac{1}{\gamma_n-\gamma_{n+1}}[A(t)+(B(t)+C(t))\gamma_n+D(t)\gamma_n\gamma_{n+1}]u_{n+1}$$
$$+\frac{1}{\gamma_n-\gamma_{n+1}}[A(t)+B(t)\gamma_n+C(t)\gamma_{n+1}+D(t)\gamma_n\gamma_{n+1}]u_n+f_n(t,\xi), \tag{3.37}$$

where $(A,D)\neq(0,0)$, ϕ_i and ψ_i are solutions of Eq. (3.27), ξ is as in Eq. (3.23), and $f_{n,\xi\xi}\neq 0$.

IV. NILPOTENT NONABELIAN SYMMETRY ALGEBRAS

Nilpotent nonabelian Lie algebras L exist for dim $L\geqslant 3$. For dim $L=3$ the only such algebra is the Heisenberg algebra with commutation relations

$$[X_2,X_3]=X_1, \quad [X_1,X_2]=[X_1,X_3]=0. \tag{4.1}$$

To construct all such algebras, we let X_1 run through the three possible standard forms (2.9), (2.11), and (2.13). The generators X_2 and X_3 are taken in generic form, and further simplified by allowed transformations, after the commutation relations (4.1) are imposed. We thus obtain two mutually nonconjugate representative Heisenberg algebras, namely,

$$N_{3,1}: \quad X_1=\partial_{u_n}, \quad X_2=\partial_t, \quad X_3=t\partial_{u_n}, \tag{4.2}$$

$$F_n=f_n(\xi_k), \quad \xi_k=u_k-u_n, \quad k=n+1,n-1. \tag{4.3}$$

$$N_{3,2}: \quad X_2=\partial_t+a_nu_n\partial_{u_n}, \quad X_3=(t+\gamma_n)e^{a_nt}\partial_{u_n}, \quad X_1=e^{a_nt}\partial_{u_n}, \tag{4.4}$$

$$\dot{a}_n=0, \quad \dot{\gamma}_n=0, \quad \gamma_n\neq\gamma_{n+1},$$

$$F_n=\frac{a_n^2(\gamma_{n+1}-\gamma_n)-2a_n}{\gamma_{n+1}-\gamma_n}u_n+\frac{2a_n}{\gamma_{n+1}-\gamma_n}u_{n+1}e^{(a_n-a_{n+1})t}+e^{a_nt}f_n(\xi),$$

$$\xi=(\gamma_n-\gamma_{n+1})u_{n-1}e^{-a_{n-1}t}+(\gamma_{n+1}-\gamma_{n-1})u_ne^{-a_nt}+(\gamma_{n-1}-\gamma_n)u_{n+1}+e^{-a_{n+1}t}. \tag{4.5}$$

Notice that the algebra (4.2) is obtained from Eq. (4.4) by setting $a_n=0$, $\gamma_n=0$, however, interaction (4.3) is more general than the one obtained from Eq. (4.5) by setting $a_n=\gamma_a=0$. Hence $N_{3,1}$ is *not* a special case of $N_{3,2}$.

Every nonabelian nilpotent Lie algebra contains a Heisenberg subalgebra, so we can proceed to higher dimensions, by adding further operators to $N_{3,1}$, or $N_{3,2}$.

The algebra $N_{3,1}$ thus yields a five-dimensional Lie algebra, namely,

$$N_{5,1}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad X_3=\left(\frac{kt^2}{2}+\gamma_n\right)\partial_{u_n}, \quad X_4=\left(\frac{kt^3}{6}+\gamma_n t\right)\partial_{u_n}, \tag{4.6}$$

$$X_5=\partial_t, \quad k=0,1,$$

$$F_n=\frac{2k}{\gamma_{n+1}-\gamma_n}(u_{n+1}-u_n)+f_n(\xi), \tag{4.7}$$

ξ as in Eq. (3.23). The commutation relations are

$$\begin{pmatrix}[X_5,X_1]\\ [X_5,X_2]\\ [X_5,X_3]\\ [X_5,X_4]\end{pmatrix}=\begin{pmatrix}0 & & & \\ 1 & 0 & & \\ & k & 0 & \\ & & 1 & 0\end{pmatrix}\begin{pmatrix}X_1\\ X_2\\ X_3\\ X_4\end{pmatrix}, \quad [X_i,X_k]=0, \quad i,k=1,2,3,4. \tag{4.8}$$

If we leave out the generator X_4, we obtain a four-dimensional nilpotent subalgebra. However, the corresponding invariant interaction is again Eq. (4.7), so this subalgebra need not be listed separately. We mention that $\{X_1,\ldots,X_4\}$ is an abelian subalgebra of $N_{5,1}$. It corresponds to $A_{4,2}$ of Sec. III, with $A=2k$, $B=C=D=0$.

Finally, the Lie algebra $N_{3,2}$ can be extended to a four-dimensional nilpotent symmetry algebra of a nonlinear interaction precisely if we have

$$a_n\neq a_{n+1}, \quad \gamma_n=-\frac{1}{2a_n}. \tag{4.9}$$

The result is

$$N_{4,1}: \quad X_1=a_n e^{a_n t}\partial_{u_n}, \quad X_2=(-a_n t+\tfrac{1}{2})e^{a_n t}\partial_{u_n},$$

$$X_3=(\tfrac{1}{2}a_n t^2-\tfrac{t}{2})e^{a_n t}\partial_{u_n}, \quad X_4=\partial_t+a_n u_n\partial_{u_n}, \tag{4.10}$$

$$F_n=\frac{(a_n)^2}{a_{n+1}-a_n}[4a_n e^{(a_n-a_{n+1})t}u_{n+1}-(3a_{n+1}+a_n)u_n]+e^{a_n t}f_n(\xi),$$

$$\xi=(a_n-a_{n+1})u_{n-1}e^{-a_{n-1}t}+(a_{n+1}-a_{n-1})u_n e^{-a_n t}+(a_{n-1}-a_n)u_{n+1}e^{-a_{n+1}t}. \tag{4.11}$$

The commutation relations are

$$\begin{pmatrix}[X_4,X_1]\\ [X_4,X_2]\\ [X_4,X_3]\end{pmatrix}=\begin{pmatrix}0 & 0 & 0\\ 1 & 0 & 0\\ 0 & 1 & 0\end{pmatrix}\begin{pmatrix}X_1\\ X_2\\ X_3\end{pmatrix}, \quad [X_i,X_k]=0, \quad i,k=1,2,3. \tag{4.12}$$

We can sum up the results as follows:

Theorem 4: *Four classes of nonlinear interactions with nilpotent symmetry algebras exist. They are represented by $N_{3,1}$, $N_{3,2}$, $N_{4,1}$, and $N_{5,1}$, respectively.*

V. SOLVABLE SYMMETRY ALGEBRAS WITH NONABELIAN NILRADICALS

All nilpotent symmetry algebras were classified in Sec. IV. Let us now embed them into solvable Lie algebras as nilradicals and find the corresponding invariant interactions. In all cases it is possible to add at most one element Y outside the nilradical. The commutation relations are hence those of the nilradical plus the relation

$$[X_i, Y] = A_{ik} X_k, \tag{5.1}$$

where A is some fixed matrix.

A. Nilradical $N_{3,1}$

To the basis elements $\{X_1, X_2, X_3\}$ of Eq. (4.2) we add a general element Y of the form (2.7). Imposing the commutation relations (5.1) we find that $\tau(t)$ in Y must satisfy either $\tau = t$ or $\tau = 0$. We consider the two cases separately. Simplifying by allowed transformations and solving the determining equations, we find that the symmetry algebras can be at most four-dimensional. We obtain four classes of such symmetry algebras and they can be represented as follows. The nilradical is as in Eq. (4.2) with commutation relations (4.1).

Below we list Y, the matrix A, the elements of which figure in Eq. (5.1), and the invariant interactions.

$$\mathrm{SN}_{4,1}: \quad Y = t\partial_t + (\tfrac{1}{2} + a) u_n \partial_{u_n}$$

$$A = \begin{pmatrix} \frac{1}{2}+a & & \\ & 1 & \\ & & -\frac{1}{2}+a \end{pmatrix}, \quad a \neq -\frac{1}{2}, \tag{5.2}$$

$$F_n = (u_{n+1} - u_n)^{(a-3/2)/(a+1/2)} f_n(\xi), \quad \xi = \frac{u_{n-1} - u_n}{u_{n+1} - u_n}.$$

$$\mathrm{SN}_{4,2}: \quad Y = t\partial_t + (2u_n + t^2)\partial_{u_n}$$

$$A = \begin{pmatrix} 2 & & \\ & 1 & 2 \\ & 0 & 1 \end{pmatrix}, \tag{5.3}$$

$$F_n = \ln(u_{n+1} - u_n) + f_n(\xi), \quad \xi = \frac{u_{n-1} - u_n}{u_{n+1} - u_n},$$

$$\mathrm{SN}_{4,3}: \quad Y = t\partial_t + \gamma_n \partial_{u_n}, \quad \gamma_{n-1} \neq \gamma_n,$$

$$A = \begin{pmatrix} 0 & & \\ & 1 & \\ & & -1 \end{pmatrix}, \tag{5.4}$$

$$F_n = \exp\left(-2 \frac{u_{n+1} - u_n}{\gamma_{n+1} - \gamma_n} \right) f_n(\xi),$$

with ξ as in Eq. (3.23)

$$\mathrm{SN}_{4,4}: \quad Y=u_n\partial_{u_n},$$

$$A=\begin{pmatrix} 1 & & \\ & 0 & \\ & & 1 \end{pmatrix}, \tag{5.5}$$

$$F_n=(u_{n+1}-u_n)f_n(\xi), \quad \xi=\frac{u_{n-1}-u_n}{u_{n+1}-u_n}.$$

B. Nilradical $N_{3,2}$ and $N_{4,1}$

Proceeding as for $N_{3,1}$, we find that no solvable symmetry algebras with nilradicals $N_{3,2}$ or $N_{4,1}$ exist for nonlinear equations.

C. Nilradical $N_{5,1}$

We start from the algebra $N_{5,1}$ with basis as in Eq. (4.6) and commutation relations as in Eq. (4.8). We add a further operator Y and find that this is possible only for $k=0$ in Eq. (4.6). For γ_n generic we find that the corresponding solvable algebras are six-dimensional. The case $\gamma_n=A+(-1)^nB$ would lead to a seven-dimensional Lie algebra, but by caveat we do not consider such algebras in this article.

For generic γ_n with $\gamma_{n+1}\neq\gamma_n$ we have the nilradical (4.6) and commutation relations (4.8) with $k=0$. The interaction will in all cases be

$$F_n=f_n(\xi), \tag{5.6}$$

with ξ as in Eq. (3.23). Four nonequivalent cases occur:

$$\mathrm{SN}_{6,1}: \quad Y=t\partial_t+(\tfrac{1}{2}+a)u_n\partial_{u_n},$$

$$F_n=c_n\xi^{(a-3/2)/(a+1/2)}, \quad a\neq-\tfrac{1}{2}, a\neq\tfrac{3}{2},$$

$$A=\mathrm{diag}\{\tfrac{1}{2}+a,-\tfrac{1}{2}+a,\tfrac{1}{2}+a,-\tfrac{1}{2}+a,1\} \tag{5.7}$$

$$\mathrm{SN}_{6,2}: \quad Y=t\partial_t+[2u_n+(a+b\gamma_n)t^2]\partial_{u_n}, \quad (a,b)\neq(0,0)$$

$$F_n=c_n+(a+b\gamma_n)\ln\xi,$$

$$A=\begin{pmatrix} 2 & & & & \\ & 1 & & & \\ & 0 & 2 & & \\ & 0 & 0 & 1 & \\ & 2a & 0 & 2b & 1 \end{pmatrix} \tag{5.8}$$

$$\mathrm{SN}_{6,3}: \quad Y=t\partial_t+\rho_n\partial_{u_n}, \quad \rho_n\neq A+B\gamma_n, \quad \dot{\rho}_n=0, \tag{5.9}$$

$$F_n=c_n\exp\left(-\frac{2\xi}{(\gamma_n-\gamma_{n+1})\rho_{n-1}+(\gamma_{n+1}-\gamma_{n-1})\rho_n+(\gamma_{n-1}-\gamma_n)\rho_{n+1}}\right), \tag{5.10}$$

$$A=\mathrm{diag}\{0,-1,0,-1,1\}.$$

Theorem 5: *Seven classes of solvable symmetry algebras with nonabelian nilradicals exist for equations of type (1.1). Their dimension can be 4, or 6 and the algebras and invariant interactions are represented above as* $SN_{4,1},\ldots,SN_{4,4}$, *with nilradical* $N_{3,1}$ *and* $SN_{6,1},\ldots,SN_{6,3}$ *with nilradical* $N_{5,1}$.

VI. SOLVABLE LIE ALGEBRAS WITH ABELIAN NILRADICALS

A. General strategy

We shall run through all abelian Lie algebras of Sec. IV and denote their basis elements X_i. We extend them by a nonnilpotent element Y in the general form (2.7). We then find the invariant interaction $F_n(t,u_{n-1},u_n,u_{n+1})$, keeping it only if F_n is nonlinear and coupled. We then check whether the considered algebra is maximal among those that leave the obtained equation (1.1) invariant. We shall only list maximal symmetry algebras. Once a maximal symmetry algebra is found, we check whether we can add further non-nilpotent elements Y_i, to the Lie algebra. If that is the case, we then obtain the further restricted interaction F_n.

We use several results on the structure of solvable Lie algebras.[15–22]

(1) The nilradical $\mathrm{NR}(L)$ of a solvable Lie algebra is uniquely defined (up to conjugacy) and its dimension satisfies

$$\dim \mathrm{NR}(L) \geqslant \tfrac{1}{2}\dim L. \tag{6.1}$$

(2) The derived algebra is contained in the nilradical $D(L)\subseteq NR(L)$.

(3) If the nilradical $\{X_1,\ldots,X_n\}$ is abelian, then the commutation relations for the solvable Lie algebra L can be written as

$$[X_i,Y_k]=(A_k)_{ij}X_j, \quad [A_k,A_l]=0, \quad [Y_i,Y_k]=c_{ik}^l,X_l, \quad [X_i,X_k]=0. \tag{6.2}$$

The matrices A_k commute and are linearly nilindependent (i.e., no nontrivial linear combination of them is a nilpotent matrix).

If only one element Y outside the nilradical exists, we have

$$[X_i,Y]=A_{ik}X_k, \tag{6.3}$$

and the non-nilpotent matrix A can be taken in Jordan canonical form.

(4) A partial classification of solvable Lie algebras exists.[17–22]

B. dim NR(L)=1

The commutation relation is Eq. (6.3) with $A=1$; X_1 runs through the standard forms (2.9), (2.11), and (2.13). The algebra (2.11) cannot be extended, nor can Eq. (2.9) for $a_n\neq 0$. The remaining cases provide four solvable Lie algebras and the corresponding interactions. They are

$$\mathrm{SA}_{2,1}: \quad X=\partial_t, \quad Y=t\partial_t+(\tfrac{1}{2}+a_n)u_n\partial_{u_n}, \quad a_n\neq -\tfrac{1}{2}, \tag{6.4}$$

$$F_n=u_n^{\alpha_n}f_n(\xi_{n-1},\xi_{n+1}),$$

$$\xi_k=u_k^{a_n+1/2}u_n^{-a_k-1/2}, \quad k=n-1,n+1, \quad \alpha_n=\frac{a_n-3/2}{a_n+1/2}, \tag{6.5}$$

$$\mathrm{SA}_{2,2}: \quad X=\partial_t, \quad Y=t\partial_t+\partial_{u_n} \tag{6.6}$$

$$F_n=e^{-2u_n}f_n(\xi_{n-1},\xi_{n+1}),$$

$$\xi_k = u_k - u_n, \quad k = n-1, n+1,$$

$$\mathrm{SA}_{2,3}: \quad X = e^{(a_n-1)t}\partial_{u_n}, \quad Y = \partial_t + a_n u_n \partial_{u_n}, \tag{6.7}$$

$$F_n = (a_n-1)^2 u_n + e^{a_n t} f_n(\xi_{n-1}, \xi_{n+1}),$$

$$\xi_k = u_k e^{-a_k t} - u_n e^{-a_n t}, \quad k = n-1, n+1,$$

$$\mathrm{SA}_{2,4}: \quad X = \beta_n(t)\partial_{u_n}, \quad Y = u_n \partial_{u_n},$$

$$F_n = \frac{\ddot{\beta}_n}{\beta_n} u_n + (\beta_n u_{n+1} - \beta_{n+1} u_n) f_n(t, \xi), \quad \xi = \frac{\beta_n u_{n-1} - \beta_{n-1} u_n}{\beta_n u_{n+1} - \beta_{n+1} u_n}. \tag{6.8}$$

We see that in all cases the interaction involves an arbitrary function f_n of two variables. For algebra $\mathrm{SA}_{2,1}$, $\mathrm{SA}_{2,2}$, and $\mathrm{SA}_{2,3}$ the transformations act nontrivially on time and induce a gauge transformation of u_n. For $\mathrm{SA}_{2,4}$ we have pure gauge transformations.

C. dim NR(L)=2

Five classes of two-dimensional abelian symmetry algebras exist, namely, $A_{2,1},\ldots,A_{2,5}$ of Sec. III. We have dim $L=3$, or 4. The algebra $A_{2,3}$ does not allow any solvable extensions; the others do, at least in special cases. We shall present the Lie algebras, interactions F_n and matrices A of Eq. (6.3).

1. NR(L)=$A_{2,1}$

We must take $a_n=0$ and we obtain a decomposable Lie algebra, namely,

$$\mathrm{SA}_{3,1}: \quad X_1 = \partial_t, \quad X_2 = b_n u_n \partial_{u_n}, \quad Y = t\partial_t + (\tfrac{1}{2} + c_n) u_n \partial_{u_n}, \quad c_n \neq -\tfrac{1}{2}.$$

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}. \tag{6.9}$$

The invariant interaction is

$$F_n = u_n [u_{n+1}^{b_n} u_n^{-b_{n+1}}]^{4/(\alpha_{nn+1})} f_n(\xi), \quad \xi = u_{n-1}^{\alpha_{nn+1}} u_n^{\alpha_{n+1n-1}} u_{n+1}^{\alpha_{n-1n}},$$

$$\alpha_{km} = b_m - b_k - 2(b_k c_m - b_m c_k). \tag{6.10}$$

2. NR(L)=$A_{2,2}$

For $a_n \neq 0$ we get just one extension, namely,

$$\mathrm{SA}_{3,2}: \quad X_1 = e^{a_n t}\partial_{u_n}, \quad X_2 = \partial_t + a_n u_n \partial_{u_n}, \quad Y = u_n \partial_{u_n},$$

$$F_n = a_n^2 u_n + (u_{n+1} e^{(a_n - a_{n+1})t} - u_n) f_n(\xi), \tag{6.11}$$

$$\xi = \frac{u_{n-1} e^{-a_{n-1}t} - u_n e^{-a_n t}}{u_{n+1} e^{-a_{n+1}t} - u_n e^{-a_n t}}.$$

The commutation relations are as in the case (6.9).

For $a_n=0$, further possibilities arise, namely,

$$\mathrm{SA}_{3,3}: \quad X_1=\partial_t, \quad X_2=\partial_{u_n}, \quad Y=t\partial_t+\gamma_n\partial_{u_n},$$

$$F_n=\exp\left(-2\frac{u_n-u_{n+1}}{\gamma_n-\gamma_{n+1}}\right)f_n(\xi), \quad \gamma_n\neq\gamma_{n+1}, \tag{6.12}$$

$$\xi=(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1}.$$

The commutation relations are as in the case (6.9).

$$\mathrm{SA}_{3,4}: \quad X_1=\partial_t, \quad X_2=\partial_{u_n}, \quad Y=t\partial_t+(\tfrac{1}{2}+a)u_n\partial_{u_n}, \quad a\neq-\tfrac{1}{2}$$

$$F_n=(u_{n+1}-u_n)^{(a-3/2)/(a+1/2)}f_n(\xi), \quad \xi=\frac{u_{n-1}-u_n}{u_{n+1}-u_n}. \tag{6.13}$$

$$A=\begin{pmatrix}1 & 0\\ 0 & a+\frac{1}{2}\end{pmatrix}, \tag{6.14}$$

$$\mathrm{SA}_{3,5}: \quad X_1=\partial_{u_n}, \quad X_2=\partial_t, \quad Y=t\partial_t+(u_n+t)\partial_{u_n}, \quad F_n=(u_{n+1}-u_n)^{-1}f_n(\xi),$$

$$\xi=\frac{u_{n-1}-u_n}{u_{n+1}-u_n}, \quad A=\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}. \tag{6.15}$$

3. $NR(L)=A_{2,4}$

When the nilradical is $A_{2,4}$ the additional operator Y can be further simplified so as to have $\tau=1$, or $\tau=0$, $a_n\neq0$. Moreover, the case with $\tau=0$ leads to F_n linear. We obtain the following three-dimensional Lie algebras

$$\mathrm{SA}_{3,6}: \quad X_1=e^{(a_n-1)t}\partial_{u_n}, \quad X_2=\gamma_n e^{(a_n-p)t}\partial_{u_n}, \quad Y=\partial_t+a_nu_n\partial_{u_n},$$

$$F_n=(a_n-1)^2u_n-\frac{\gamma_n}{\gamma_n-\gamma_{n+1}}(p-1)(2a_n-p-1)[u_n-u_{n+1}e^{(a_n-a_{n+1})t}]+e^{a_nt}f_n(\xi),$$

$$\xi=(\gamma_n-\gamma_{n+1})u_{n-1}e^{-a_{n-1}t}+(\gamma_{n+1}-\gamma_{n-1})u_ne^{-a_nt}+(\gamma_{n-1}-\gamma_n)u_{n+1}e^{-a_{n+1}t}, \quad \gamma_{n+1}\neq\gamma_n, \tag{6.16}$$

with

$$A=\begin{pmatrix}1 & 0\\ 0 & p\end{pmatrix} \tag{6.17}$$

$$\mathrm{SA}_{3,7}: \quad X_1=e^{(a_n-p)t}\cos(t-\alpha_n)\partial_{u_n}, \quad X_2=e^{(a_n-p)t}\sin(t-\alpha_n)\partial_{u_n}, \quad Y=\partial_t+a_nu_n\partial_{u_n},$$

$$F_n=[(a_n-p)^2-1-2(a_n-p)\cot(\alpha_n-\alpha_{n+1})]u_n+\frac{2(a_n-p)}{\sin(\alpha_n-\alpha_{n+1})}u_{n+1}e^{(a_n-a_{n+1})t}+e^{a_nt}f_n(\xi),$$

$$\xi=u_{n-1}e^{-a_{n-1}t}\sin(\alpha_n-\alpha_{n+1})+u_ne^{-a_nt}\sin(\alpha_{n+1}-\alpha_{n-1})$$
$$+u_{n+1}e^{-a_{n+1}t}\sin(\alpha_{n-1}-\alpha_n), \quad \alpha_n\neq\alpha_{n+1}, \tag{6.18}$$

with

$$A=\begin{pmatrix} p & 1 \\ -1 & p \end{pmatrix}, \tag{6.19}$$

$$\begin{gathered} \mathrm{SA}_{3,8}: \quad X_1=e^{(a_n-1)t}\partial_{u_n}, \quad X_2=(-t+\gamma_n)e^{(a_n-1)t}\partial_{u_n}, \quad Y=\partial_t+a_n u_n\partial_{u_n}, \\ F_n=(a_n-1)^2u_n-\frac{2(a_n-1)}{\gamma_n-\gamma_{n+1}}(u_n-u_{n+1})e^{(a_n-a_{n+1})t}+e^{a_n t}f_n(\xi), \end{gathered} \tag{6.20}$$

with ξ as in Eq. (6.16) and

$$A=\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}. \tag{6.21}$$

4. $NR(L)=A_{2,5}$

We add Y in the general form (2.7) to X_1 and X_2. The commutation relations imply $\tau=\tau_0+\tau_1 t+\tau_2 t^2$, $a_n=a$. Using allowed transformations we set $\beta_n(t)=0$. Four inequivalent three-dimensional symmetry algebras are obtained.

$$\begin{gathered} \mathrm{SA}_{3,9}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad Y=u_n\partial_{u_n}, \\ F_n=(u_{n+1}-u_n)f_n(t,\xi), \quad \xi=\frac{u_{n-1}-u_n}{u_{n+1}-u_n}, \end{gathered} \tag{6.22}$$

with

$$A=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{6.23}$$

$$\mathrm{SA}_{3,10}: \quad X_1=\partial_{u_n}, \quad X_2=-t\partial_{u_n}, \quad Y=\partial_t+u_n\partial_{u_n}, \tag{6.24}$$

$$F_n=(u_{n+1}-u_n)f_n(\xi_{n-1},\xi_{n+1}), \quad \xi_k=e^{-t}(u_k-u_n), \quad k=n\pm 1,$$

with

$$A=\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \tag{6.25}$$

$$\begin{gathered} \mathrm{SA}_{3,11}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad Y=t\partial_t+(\tfrac{1}{2}+a)u_n\partial_{u_n}, \\ F_n=(u_{n+1}-u_n)^{(a-3/2)/(a+1/2)}f_n(\xi_{n-1},\xi_{n+1}), \\ \xi_k=(u_k-u_n)t^{-a-1/2}, \quad a\neq-\tfrac{1}{2}, k=n\pm 1, \end{gathered} \tag{6.26}$$

with

$$A=\begin{pmatrix} a+\frac{1}{2} & 0 \\ 0 & a-\frac{1}{2} \end{pmatrix}, \tag{6.27}$$

$$\mathrm{SA}_{3,12}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad Y=(t^2+1)\partial_t+(t+a)u_n\partial_{u_n},$$

$$F_n=(u_{n+1}-u_n)(t^2+1)^{-2}f_n(\xi_{n-1},\xi_{n+1}), \tag{6.28}$$

$$\xi_k=(t^2+1)^{-1/2}(u_k-u_n)e^{-a\ \arctan t}, \quad k=n\pm 1,$$

with

$$A=\begin{pmatrix} a & 1 \\ -1 & a \end{pmatrix}. \tag{6.29}$$

We see that for algebras $\mathrm{SA}_{3,1},\ldots,\mathrm{SA}_{3,8}$ the interaction F_n involves an arbitrary function f_n of one variable ξ. None of these algebras can be further extended by another symmetry operator $\widetilde{Y}$, outside the nilradical. Indeed, the existence of such an operator would force the interaction to be linear.

The situation is different for algebras $\mathrm{SA}_{3,9},\ldots,\mathrm{SA}_{3,12}$, where F_n involves an arbitrary function of two variables. Extensions of these algebras lead to two inequivalent four-dimensional solvable Lie algebras with two-dimensional nilradicals, namely, the following:

$$\mathrm{SA}_{4,1}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad Y_1=u_n\partial_{u_n}, \quad Y_2=(t^2+1)\partial_t+tu_n\partial_{u_n},$$

$$F_n=(u_{n+1}-u_n)(t^2+1)^{-2}f_n(\xi), \quad \xi=\frac{u_{n-1}-u_n}{u_{n+1}-u_n}. \tag{6.30}$$

$$\mathrm{SA}_{4,2}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad Y_1=u_n\partial_{u_n}, \quad Y_2=t\partial_t+\tfrac{1}{2}u_n\partial_{u_n},$$

$$F_n=(u_{n+1}-u_n)t^{-2}f_n(\xi), \quad \xi=\frac{u_{n+1}-u_n}{u_{n-1}-u_n}. \tag{6.31}$$

D. dim NR(L)=3

1. $NR(L)=A_{3,1}$

This algebra can figure as a nilradical only for $a_n=0$. We then obtain

$$\mathrm{SA}_{4,3}: \quad X_1=\partial_t, \quad X_2=b_nu_n\partial_{u_n}, \quad X_3=c_nu_n\partial_{u_n}, \quad Y=t\partial_t+(\tfrac{1}{2}+a_n)u_n\partial_{u_n},$$

$$F_n=p_nu_n\xi^{-2/\alpha}, \quad \begin{vmatrix} b_n & b_{n+1} \\ c_n & c_{n+1} \end{vmatrix}\neq 0,$$

$$\xi=u_{n-1}^{\alpha_{nn+1}}u_n^{\alpha_{n+1n-1}}u_{n+1}^{\alpha_{n-1n}}, \quad \alpha_{km}=b_mc_k-b_kc_m, \tag{6.32}$$

$$\alpha=(\tfrac{1}{2}+a_{n-1})\alpha_{n,n+1}+(\tfrac{1}{2}+a_n)\alpha_{n+1,n-1}+(\tfrac{1}{2}+a_{n+1})\alpha_{n-1n},$$

$$A=\begin{pmatrix} 1 & & \\ & 0 & \\ & & 0 \end{pmatrix}. \tag{6.33}$$

2. $NR(L)=A_{3,2}$

The algebra $A_{3,2}$ can serve as a nilradical only for $a_n=0$. We add Y as usual and it turns out that we must have τ of the form $\tau=\tau_1 t+\tau_0$. However, the invariant interactions obtained are either linear, or such that they allow a symmetry algebra with a larger (four-dimensional) nilradical. Hence, no algebras L with $\mathrm{NR}(L)=A_{3,2}$ are obtained.

3. $NR(L)=A_{3,3}$

Using allowed transformations we can simplify $\tau(t)$ in the additional operator Y to be $\tau=1$, or $\tau=0$. We can always set $\beta_n(t)\to 0$ in Y. For a four-dimensional symmetry algebra the nonzero commutation relations will be as in Eq. (6.3) (with $1\leqslant i,\ k\leqslant 3$). We list the matrices A below. Inequivalent symmetry algebras are distinguished by the Jordan canonical forms of A.

The algebras we obtain are

$$\mathrm{SA}_{4,4}:\quad X_1=(2a_n-p_2-p_3)e^{(a_n-p_1)t}\partial_{u_n},$$

$$X_2=(2a_n-p_1-p_3)e^{(a_n-p_2)t}\partial_{u_n},$$

$$X_3=(2a_n-p_1-p_2)e^{(a_n-p_3)t}\partial_{u_n},\quad p_1<p_2<p_3, \tag{6.34}$$

$$Y=\partial_t+a_n u_n\partial_{u_n},\quad a_{n+1}\neq a_n,$$

$$F_n=A_n u_n+B_n e^{(a_n-a_{n+1})t}u_{n+1}+e^{a_n t}f_n(\xi),$$

$$\xi=(a_n-a_{n+1})u_{n-1}e^{-a_{n-1}t}+(a_{n+1}-a_{n-1})u_n e^{-a_n t}+(a_{n-1}-a_n)u_{n+1}e^{-a_{n+1}t},$$

$$A_n=\frac{1}{2(a_{n+1}-a_n)}\{2a_{n+1}[-3a_n^2+2a_n(p_1+p_2+p_3)-p_1p_2-p_2p_3-p_3p_1]$$
$$-2a_n(a_n-p_1-p_2-p_3)^2+(p_1+p_2)(p_2+p_3)(p_3+p_1)\},$$

$$B_n=\frac{1}{2(a_{n+1}-a_n)}(2a_n-p_1-p_2)(2a_n-p_2-p_3)(2a_n-p_3-p_1),$$

$$A=\mathrm{diag}(p_1,p_2,p_3). \tag{6.35}$$

$$\mathrm{SA}_{4,5}:\quad X_1=e^{(a_n-p)t}\cos(t-\gamma_n)\partial_{u_n},$$

$$X_2=e^{(a_n-p)t}\sin(t-\gamma_n)\partial_{u_n},\quad X_3=e^{(a_n-q)t}\cos\gamma_n\partial_{u_n},\quad Y=\partial_t+a_n u_n\partial_{u_n}, \tag{6.36}$$

$$\tan\gamma_n=\frac{(2a_n-p-q)(p-q)+1}{2(a_n-p)},\quad a_{n+1}\neq a_n,$$

$$F_n=[(a_n-p)^2-1-2(a_n-p)\cot(\gamma_n-\gamma_{n+1})]u_n+2\frac{a_n-p}{\sin(\gamma_n-\gamma_{n+1})}u_{n+1}e^{(a_n-a_{n+1})t}+e^{a_n t}f_n(\xi),$$

$$\xi=u_{n-1}e^{-a_{n-1}t}\sin(\gamma_n-\gamma_{n+1})+u_n e^{-a_n t}\sin(\gamma_{n+1}-\gamma_{n-1})+u_{n+1}e^{-a_{n+1}t}\sin(\gamma_{n-1}-\gamma_n)$$

$$A=\mathrm{diag}\left[\begin{pmatrix} p & 1\\ -1 & p\end{pmatrix},q\right]. \tag{6.37}$$

$$\mathrm{SA}_{4,6}: \quad X_1=\tfrac{1}{2}[(a_n-1)^2-(a_n-p)^2]e^{(a_n-1)t}\partial_{u_n},$$

$$X_2=\{-\tfrac{1}{2}[(a_n-1)^2-(a_n-p)^2]t+(a_n-1)\}e^{(a_n-1)t}\partial_{u_n},$$

$$X_3=(a_n-1)e^{(a_n-p)t}\partial_{u_n}, \quad p\neq 1,$$

$$Y=\partial_t+a_nu_n\partial_{u_n}, \quad a_{n+1}\neq a_n, \tag{6.38}$$

$$F_n=\frac{a_n-1}{a_{n+1}-a_n}[(a_{n+1}-1)(2p-3a_n+1)-(a_n-p)^2]u_n$$
$$+\frac{(a_n-1)(2a_n-1-p)^2}{a_{n+1}-a_n}u_{n+1}e^{(a_n-a_{n+1})t}+e^{a_nt}f_n(\xi),$$

with ξ as for algebra $\mathrm{SA}_{4,4}$.

$$A=\mathrm{diag}\left[\begin{pmatrix}1&0\\1&1\end{pmatrix},p\right]. \tag{6.39}$$

$$\mathrm{SA}_{4,7}: \quad X_1=(2a_n-1)e^{a_nt}\partial_{u_n}, \quad X_2=[(2a_n-1)t+1]e^{a_nt}\partial_{u_n},$$

$$X_3=2a_ne^{(a_n-1)t}\partial_{u_n}, \quad Y=\partial_t+a_nu_n\partial_{u_n}, \tag{6.40}$$

$$F_n=\frac{[a_n(a_n-a_{n+1})-(2a_{n+1}-1)(2a_n-1)]a_n}{a_n-a_{n+1}}u_n+\frac{(2a_n-1)^2a_n}{a_n-a_{n+1}}u_{n+1}e^{(a_n-a_{n+1})t}+e^{a_nt}f_n(\xi),$$

with ξ as for algebra $\mathrm{SA}_{4,4}$.

$$A=\mathrm{diag}\left[\begin{pmatrix}0&0\\1&0\end{pmatrix},1\right]. \tag{6.41}$$

$$\mathrm{SA}_{4,8}: \quad X_1=(a_n-1)e^{(a_n-1)t}\partial_{u_n}, \quad X_2=(-(a_n-1)t+\tfrac{1}{2})e^{(a_n-1)t}\partial_{u_n},$$

$$X_3=\tfrac{1}{2}[(a_n-1)t^2-t]e^{(a_n-1)t}\partial_{u_n}, \quad Y=\partial_t+a_nu_n\partial_{u_n},$$

$$F_n=\frac{(a_n-1)^2}{a_{n+1}-a_n}\{[(a_{n+1}-a_n)-4(a_{n+1}-1)]u_n+4(a_n-1)u_{n+1}e^{(a_n-a_{n+1})t}\}+e^{a_nt}f_n(\xi), \tag{6.42}$$

with ξ as for algebra $\mathrm{SA}_{4,4}$.

$$A=\begin{pmatrix}1&0&0\\1&1&0\\0&1&1\end{pmatrix}. \tag{6.43}$$

We see that the matrix A in Eq. (6.43) is indecomposable. The case (6.35) corresponds to the decomposition $1+1+1$, while Eqs. (6.37), (6.39), and (6.41) correspond to the decomposition $2+1$, with different structures of the 2×2 block.

4. NR(L)=$A_{3,4}$

We take $\{X_1, X_2, X_3\}$ as in Eq. (3.17) and add Y in the form (2.7). The commutation relations (6.3) imply that the coefficients in Y must satisfy $a_{n+1}=a_n$ and $\tau=\tau_0+\tau_1 t+\tau_2 t^2$. By allowed transformations we take τ into one of the following: $\tau=0,1,t,1+t^2$. Moreover, $\beta_n(t)$ of Y can be set equal to zero. We find that $\tau=0$ leads to a linear equation. The values $\tau=1$, t and t^2+1 lead to five different four-dimensional symmetry algebras. However, none of them is maximal among those existing for the given interaction F_n. In each case the abelian nilradical can be extended to a four-dimensional one and the corresponding maximal symmetry algebras will appear below.

E. dim NR(L)=4

1. NR(L)=$A_{4,1}$

We take $X_1,\ldots X_4$ as in Eq. (3.33). The additional element Y must again satisfy $a_{n+1}=a_n$, $\tau=1$, t or t^2+1, $\beta_n(t)=0$.

Up to allowed transformations the following five-dimensional symmetry algebras represent all possibilities. In each case we list the algebra, the interaction and the matrix A of Eq. (6.3).

$$\mathrm{SA}_{5,1}: \quad X_1=-\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad X_3=e^t\gamma_n\partial_{u_n},$$

$$X_4=e^{-t}\gamma_n\partial_{u_n}, \quad Y=\partial_t+au_n\partial_{u_n}, \quad a\neq 0$$

$$F_n=\frac{\gamma_n(u_{n+1}-u_n)}{\gamma_{n+1}-\gamma_n}+e^{at}f_n(\xi), \tag{6.44}$$

$$\xi=[(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1}]e^{-at},$$

$$A=\mathrm{diag}\left\{\begin{pmatrix} a & 0\\ 1 & a\end{pmatrix}, a-1, a+1\right\}.$$

$$\mathrm{SA}_{5,2}: \quad X_1=-\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad X_3=-\gamma_n\partial_{u_n},$$

$$X_4=t\gamma_n\partial_{u_n}, \quad Y=\partial_t+u_n\partial_{u_n}, \quad F_n=e^t f_n(\xi), \tag{6.45}$$

$$A=\mathrm{diag}\left\{\begin{pmatrix} 1 & 0\\ 1 & 1\end{pmatrix}, \begin{pmatrix} 1 & 0\\ 1 & 1\end{pmatrix}\right\}.$$

Here, ξ is as in case $\mathrm{SA}_{5,1}$ with $a=1$

$$\mathrm{SA}_{5,3}: \quad X_1=-\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad X_3=\gamma_n \sin t\partial_{u_n},$$

$$X_4=\gamma_n \cos t\partial_{u_n}, \quad Y=\partial_t+au_n\partial_{u_n}, \tag{6.46}$$

$$F_n=-\frac{\gamma_n(u_{n+1}-u_n)}{\gamma_{n+1}-\gamma_n}+e^{at}f_n(\xi), \quad A=\mathrm{diag}\left\{\begin{pmatrix} a & 0\\ 1 & a\end{pmatrix}, \begin{pmatrix} a & -1\\ 1 & a\end{pmatrix}\right\}.$$

Again, ξ as in case $\mathrm{SA}_{5,1}$.

$$\mathrm{SA}_{5,4}: \quad X_1=\partial_{u_n}, \quad X_2=t\partial_{u_n}, \quad X_3=t^{1/2+a-p}\gamma_n\partial_{u_n},$$

$$X_4=t^{1/2-a+p}\gamma_n\partial_{u_n}, \quad Y=t\partial_t+(\tfrac{1}{2}+a)u_n\partial_{u_n},$$

$$F_n=\frac{[(a-p)^2-\frac{1}{4}]\gamma_n(u_{n+1}-u_n)}{(\gamma_{n+1}-\gamma_n)t^2}+t^{a-3/2}f_n(\xi), \tag{6.47}$$

$$\xi=[(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1}]t^{-a-1/2},$$

$$A=\mathrm{diag}(\tfrac{1}{2}+a,-\tfrac{1}{2}+a,p,a-p),\quad p\neq a.$$

$$\mathrm{SA}_{5,5}:\quad X_1=\partial_{u_n},\quad X_2=t\partial_{u_n},\quad X_3=\gamma_n\sqrt{t}\,\cos(\ln t)\partial_{u_n},$$

$$X_4=\gamma_n\sqrt{t}\,\sin(\ln t)\partial_{u_n},\quad Y=t\partial_t+(\tfrac{1}{2}+a)u_n\partial_{u_n},$$

$$F_n=-\frac{5}{4}\frac{\gamma_n(u_{n+1}-u_n)}{(\gamma_{n+1}-\gamma_n)t^2}+e^{at}f_n(\xi),\quad A=\mathrm{diag}\left\{a+\frac{1}{2},a-\frac{1}{2},\begin{pmatrix}a & 1\\ -1 & a\end{pmatrix}\right\}, \tag{6.48}$$

with ξ as in case $\mathrm{SA}_{5,1}$

$$\mathrm{SA}_{5,6}:\quad X_1=\partial_{u_n},\quad X_2=t\partial_{u_n},\quad X_3=\gamma_n\sqrt{t^2+1}\,\cos(q\ \arctan\ t)\partial_{u_n},$$

$$X_4=\gamma_n\sqrt{t^2+1}\,\sin(q\ \arctan\ t)\partial_{u_n},\quad Y=(t^2+1)\partial_t+(t+a)u_n\partial_{u_n},$$

$$F_n=\frac{(1-q^2)\gamma_n(u_{n+1}-u_n)}{(\gamma_{n+1}-\gamma_n)(t^2+1)^2}+\frac{e^{a\ \arctan\ t}}{(t^2+1)^{3/2}}f_n(\xi),$$

$$\xi=\{(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1}\}\frac{e^{-a\ \arctan\ t}}{(t^2+1)^{1/2}},$$

$$A=\mathrm{diag}\left\{\begin{pmatrix}a & 1\\ -1 & a\end{pmatrix},\begin{pmatrix}a & q\\ -q & a\end{pmatrix}\right\},\quad q>0. \tag{6.49}$$

$$\mathrm{SA}_{5,7}:\quad X_1=\partial_{u_n},\quad X_2=-t\partial_{u_n},\quad X_3=(-\ln t+\gamma_n)\partial_{u_n},$$

$$X_4=(t\ \ln\ t+\gamma_n t)\partial_{u_n},\quad Y=t\partial_t+(\tfrac{1}{2}+a)u_n\partial_{u_n}, \tag{6.50}$$

$$F_n=\frac{u_{n+1}-u_n}{t^2(\gamma_{n+1}-\gamma_n)}+t^{a-3/2}f_n(\xi),$$

$$A=\begin{pmatrix}\frac{1}{2}+a & & & \\ 0 & -\frac{1}{2}+a & & \\ 1 & 0 & \frac{1}{2}+a & \\ 0 & 1 & 0 & -\frac{1}{2}+a\end{pmatrix} \tag{6.51}$$

with ξ as in the case $\mathrm{SA}_{5,4}$.

None of the algebras $\mathrm{SA}_{4,3},\ldots,\mathrm{SA}_{4,8}$ nor $\mathrm{SA}_{5,1},\ldots,\mathrm{SA}_{5,7}$ can be extended by a further element Y_2, outside the nilradical.

Let us sum things up as theorem.

Theorem 6: *Altogether 31 classes of solvable symmetry algebras with abelian nilradicals exist for Eq. (1.1). Their dimensions are 2, 3, 4, and 5. Each class is represented by one algebra in this Section, namely, $SA_{2,1},\ldots,SA_{2,4}$; $SA_{3,1},\ldots,SA_{3,12}$; $SA_{4,1},\ldots,SA_{4,8}$, and $SA_{5,1},\ldots,SA_{5,7}$.*

VII. NONSOLVABLE SYMMETRY ALGEBRAS

A nonsolvable Lie algebra must contain a simple subalgebra. The only simple Lie algebra that can be realized in terms of vector fields of the form (2.7) is $\mathrm{sl}(2,\mathbb{R})$. Upto allowed transformations it can only be realized, together with the corresponding invariant interaction, as

$$\mathrm{NS}_{3,1}: \quad X_1=\partial_t, \quad X_2=t\partial_t+\tfrac{1}{2}u_n\partial_{u_n}, \quad X_3=t^2\partial_t+tu_n\partial_{u_n}, \tag{7.1}$$

$$F_n=\frac{1}{u_n^3}\,f_n(\xi_{n-1},\xi_{n+1}), \quad \xi_k=\frac{u_k}{u_n}. \tag{7.2}$$

We now write the determining equation (2.4) for F_n in the form (7.2) and look for additional symmetries. As a result we obtain algebras containing (7.1), plus further vector fields, forming the radical of the final symmetry algebra. They are

$$\mathrm{NS}_{4,1}: \quad X_4=a_nu_n\partial_{u_n}, \quad a_{n+1}\neq a_n,$$

$$F_n=u_n^{-3}\left(\frac{u_{n+1}}{u_n}\right)^{(4a_n)/(a_{n+1}-a_n)} f_n(\xi), \tag{7.3}$$

$$\xi=u_{n+1}^{a_{n-1}-a_n}u_n^{a_{n+1}-a_{n-1}}u_{n-1}^{a_n-a_{n+1}}.$$

$$\mathrm{NS}_{5,1}: \quad X_4=a_nu_n\partial_{u_n}, \quad X_5=b_nu_n\partial_{u_n},$$

$$a_{n+1}\neq a_n, \quad b_{n+1}\neq b_n, \quad b_n\neq\lambda a_n,$$

$$F_n=c_nu_n[u_{n-1}^{(b_{n+1}a_n-b_na_{n+1})}u_n^{(b_{n-1}a_{n+1}-b_{n+1}a_{n+1})}u_{n+1}^{(b_na_{n-1}-b_{n-1}a_n)}]^{4/\alpha_n}, \tag{7.4}$$

$$\alpha_n=b_{n-1}(a_n-a_{n+1})+b_n(a_{n+1}-a_{n-1})+b_{n+1}(a_{n-1}-a_n).$$

$$\mathrm{NS}_{5,2}: \quad X_4=\partial_{u_n}, \quad X_5=t\partial_{u_n}, \tag{7.5}$$

$$F_n=(u_{n+1}-u_n)^{-3}f_n(\xi), \quad \xi=\frac{u_{n+1}-u_n}{u_{n-1}-u_n}.$$

$$\mathrm{NS}_{7,1}: \quad X_4=\partial_{u_n}, \quad X_5=t\partial_{u_n}, \quad X_6=\gamma_n\partial_{u_n}, \quad X_7=t\gamma_n\partial_{u_n}, \tag{7.6}$$

$$F_n=[(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1}]^{-3}.$$

To sum up:

Theorem 7: *Nonsolvable symmetry algebras of Eq. (1.1) can have dimensions 3, 4, 5, or 7. There are 5 classes of them, $NS_{3,1}$, $NS_{4,1}$, $NS_{5,1}$, $NS_{5,2}$, and $NS_{7,1}$.*

VIII. SYMMETRIES OF LINEAR DIFFERENTIAL–DIFFERENCE EQUATIONS

Let us now consider the case excluded in the rest of this article, namely when Eq. (1.1) has the form

$$\ddot{u}_n = A_n(t)u_{n-1} + B_n(t)u_n + C_n(t)u_{n+1} + D_n(t), \tag{8.1}$$

i.e., is a linear inhomogeneous $D\Delta E$. Substituting into the determining equation (2.4) and reading off the coefficients of u_{n-1}, u_{n+1}, u_n, and 1 we obtain four equations.

$$[(a_n - a_{n-1}) - 2\dot{\tau}]A_n - \tau\dot{A}_n = 0, \tag{8.2}$$

$$[(a_n - a_{n+1}) - 2\dot{\tau}]C_n - \tau\dot{C}_n = 0, \tag{8.3}$$

$$\tfrac{1}{2}\dddot{\tau} - 2\dot{\tau}B_n - \tau\dot{B}_n = 0, \tag{8.4}$$

$$\ddot{\beta}_n + (a_n - \tfrac{3}{2}\dot{\tau})D_n - \tau\dot{D}_n - \beta_{n-1}A_n - \beta_n B_n - \beta_{n+1}C_n = 0. \tag{8.5}$$

For A_n and C_n generic, Eqs. (8.2) and (8.3) imply

$$\tau = 0, \quad a_{n+1} = a_n \equiv a. \tag{8.6}$$

Equation (8.4) is satisfied identically and Eq. (8.5) has the following solutions:

(1) For $a = 0$ we have

$$X(\beta) = \beta_n(t)\partial_{u_n}, \tag{8.7}$$

where $\beta_n(t)$ is a solution of the homogeneous equation, i.e., Eq. (8.1) with $D_n(t) = 0$.

(2) For $a \neq 0$ choose $a = -1$. We then have

$$X_I = [u_n - \beta^{(t)}_{n,I}]\partial_{u_n}, \tag{8.8}$$

where $\beta_{n,I}$ is any solution of the inhomogeneous equation (8.1).

Thus the symmetry algebra is infinite dimensional, but this simply reflects the linear superposition principle. This is still a useful property. Indeed the existence of an infinite-dimensional symmetry algebra can serve as a criterion of linearizability by point transformations for equations of the form (1.1), just as in the case of partial differential equations.[23] The linearizing transformations would of course not be amongst the allowed transformations (2.5).

Now let us find additional symmetries existing for special forms of Eq. (8.1). Allowed transformation preserve linearity, so we can use them to simplify the vector field X.

Let one additional symmetry generator exist.

A. $\tau = 0$

For $A_n \neq 0$, or $C_n \neq 0$ we find $a_{n+1} = a_n$ and we reobtain the generator (8.8) and hence nothing new.

For $A_n = C_n = 0$ Eq. (8.1) decouples into

$$\ddot{u}_n = B_n(t)u_n + D_n(t). \tag{8.9}$$

For each n separately we obtain an $sl(3,\mathbb{R})$ symmetry algebra, as in the case for any linear, or linearizable ODE.[24]

B. $\tau \neq 0$

We transform τ into $\tau = 1$ and consider X in the form (2.9). Solving the determining equations (8.2),...,(8.4) for the coefficients A_n, B_n, C_n, D_n, we find that such an additional symmetry exists only for

TABLE I. The results of the symmetry classification of the nonlinear $D\Delta E$ (1.1).

dim L	A	N	SN	SA	NS	T
7	0	0	0	0	1	1
6	0	0	3	0	0	3
5	0	1	0	7	2	10
4	2	1	4	8	1	16
3	4	2	0	12	1	19
2	5	0	0	4	0	9
1	3	0	0	0	0	3

$$\ddot{u}_n = R_n e^{(a_n - a_{n-1})t} u_{n-1} + B_n u_n + S_n e^{(a_n - a_{n+1})t} u_n + W_n e^{a_n t},$$
$$\dot{R}_n = \dot{B}_n = \dot{W}_n = \dot{S}_n = 0, \quad X = \partial_t + a_n u_n \partial_{u_n}. \tag{8.10}$$

A two-dimensional additional symmetry algebra for coupled equations (R_n and S_n not both vanishing) can exist only if we have $A_n = 0$, or $C_n = 0$ and also $a_n = 0$ in Eq. (8.10). For instance, for $C_n = 0$, $A_n \neq 0$, we have

$$F_n = A_n u_{n-1} + D_n, \quad X_1 = \partial_t, \quad X_2 = t\partial_t + [(\tfrac{1}{2} + 2n + \rho)u_n + \beta_n]\partial_{u_n}, \tag{8.11}$$

where ρ and β_n satisfy

$$\ddot{\beta}_n + (2n + \rho - \tfrac{3}{2})D_n - \beta_{n-1} A_n = 0.$$

If, in particular, we also have $D_n = 0$, then the entire symmetry algebra is as follows:

$$\ddot{u}_n = A_n u_{n-1}, \tag{8.12}$$

$$X_1 = \partial_t, \quad X_2 = t\partial_t + (\tfrac{1}{2} + 2n) u_n \partial_{u_n},$$

$$X_3 = \partial_{u_n}, \quad X(\beta) = \beta_n(t) \partial_{u_n},$$

where $\beta_n(t)$ is a solution of Eq. (8.12).

IX. CONCLUSIONS

(1) The results of the symmetry classification of the nonlinear $D\Delta E$ (1.1) are summed up in Table I.

In the first row A, N, SN, SA, NS, and T mean abelian, nilpotent, solvable with nonabelian nilradical, solvable with abelian nilradical, nonsolvable, and total, respectively. In the second to fifth column we give the number of each type of symmetry algebra for each dimension dim L. The total number for each dimension is given in the last column.

The A, N, SN, SA, and NS type symmetry algebras are reviewed in Secs. III–VII, respectively.

We see that we have dim $L \leqslant 7$. For dim $L = 6$, or 7 the interactions F_n are completely specified (up to 1 or more functions of n). Several types of ''symmetry variables'' occur for the higher dimensional symmetry algebras. Let us denote them as follows:

$$\xi=(\gamma_n-\gamma_{n+1})u_{n-1}+(\gamma_{n+1}-\gamma_{n-1})u_n+(\gamma_{n-1}-\gamma_n)u_{n+1},$$
$$\eta=\xi h(t),\quad \zeta=p_{n-1}(t)u_{n-1}+p_n(t)u_n+p_{n+1}u_{n+1},$$
$$\rho=\frac{u_{n+1}-u_n}{u_{n-1}-u_n},\quad \sigma=u_{n-1}^{a_{n-1}}u_n^{a_n}u_{n+1}^{a_{n+1}}, \tag{9.1}$$

where γ_n and q_n depend only on n, $h(t)$ is some (specific in each case) function of t and $p_n(t)$ is a (specific) function of n and t.

We can write the interactions having symmetry algebras of dimension $5\leqslant\dim L\leqslant 7$ as follows:

$$\mathrm{NS}_{7,1}:\quad F_n=c_n\xi^{-3}, \tag{9.2}$$

$$\mathrm{SN}_{6,1}:\quad F_n=c_n\xi^{p}, \tag{9.3a}$$

$$\mathrm{SN}_{6,2}:\quad F_n=c_n+(a+b\gamma_n)\ln\,\xi, \tag{9.3b}$$

$$\mathrm{SN}_{6,3}:\quad F_n=c_n+e^{b_n\xi}, \tag{9.4a}$$

$$\mathrm{SN}_{6,4}:\quad F_n=c_n\xi^{-1}, \tag{9.4b}$$

$$\mathrm{SN}_{6,5}:\quad F_n=\frac{2k}{\gamma_{n+1}-\gamma_n}+f_n(\xi), \tag{9.4c}$$

$$\mathrm{SA}_{5,1},\ldots,\mathrm{SA}_{5,7}:\quad F_n=\frac{\alpha(t)+\beta(t)\gamma_n}{\gamma_{n+1}-\gamma_n}(u_{n+1}-u_n)+g(t)f_n(\eta), \tag{9.5a}$$

where the functions of α, β, g, and h are different in each case

$$\mathrm{NS}_{5,1}:\quad F_n=c_n\sigma, \tag{9.5b}$$

$$\mathrm{SN}_{5,2}:\quad F_n=(u_{n+1}-u_n)^{-3}f_n(\rho). \tag{9.5c}$$

For $1\leqslant\dim L\leqslant 4$, see Secs. II, III, and VI.

(2) Among the interactions with four-dimensional symmetry algebras a case of particular interest is $\mathrm{SN}_{4,3}$ of Eq. (5.4). This case contains the well-known and integrable Toda lattice.[25] Indeed, if we choose

$$\gamma_n=2n,\quad f_n(\xi)=-1+e^{1/2\xi}, \tag{9.6}$$

we obtain the equation

$$u_{n,tt}=e^{u_{n-1}-u_n}-e^{u_n-u_{n+1}}. \tag{9.7}$$

Thus the Toda lattice is not singled out by its Lie point symmetry group, at least not by symmetries generated by vector fields of the type (1.4). Instead, it comes in a family involving two arbitrary functions, γ_n and $f_n(\xi)$. Nor is the Toda lattice the one with the largest symmetry group of the considered type. This distinction goes to the interaction (9.2).

(3) The connection between Lie point symmetries of $D\Delta E$ and their integrability remains open. We plan to investigate other types of symmetries of Eq. (1.1), or at least special cases thereof in the near future.

The behavior of nearby trajectories in magnetic billiards

Tamás Tasnádi[a)]
Institute for Solid State Physics, Eötvös University, 6-8., Múzeum krt., Budapest, 1088 Hungary

(Received 12 February 1996; accepted for publication 3 May 1996)

In chaos theory the separation of infinitesimally close trajectories has great importance. In present paper this behavior is investigated for classical magnetic billiard systems on Riemannian manifolds. The separation of the trajectories during the bounceless segments as well as at the reflections is studied generally, with a method similar to that of Jacobi fields for geodesic flows. For two-dimensional manifolds the results are also given in a natural coordinate frame, and they are illustrated in special (homogeneous) cases. We relate our issues to the known properties of the curvature of the horocycles, too. © *1996 American Institute of Physics.* [S0022-2488(96)00609-3]

I. INTRODUCTION

The geodesic motion on Riemannian manifolds became a very important model in ergodic theory, since due to the theorem of Lobatchewski and Hadamard[1] the geodesic flow on the unitary tangent bundle of any compact Riemannian manifold with negative curvature shows strongly stochastic properties, it is a *C*-system, ergodic, mixing and has positive entropy.[2,3] With the method of Jacobi fields[4] it has been shown that on Riemannian manifolds with negative curvature the separation of nearby geodesic trajectories is exponential and the long-time evolution depends very sensitively on the initial conditions, i.e., the system is chaotic.

Slightly more difficult systems are the billiards, which were also traditionally investigated in chaos theory[5–9] and later from the point of view of quantum chaos, too.[10–12] In these systems a particle moves freely (along geodesic segments) in a bounded region of a Riemannian manifold, and changes its velocity according to the law of elastic reflection at the boundaries of the billiard. The long-time behavior of nearby trajectories is controlled by two effects; by the separation of the geodesic segments between subsequent bounces, and by the reflections themselves, which can focus or defocus the bunch of trajectories. The first effect is essentially equivalent with that mentioned in the previous paragraph, and depends on the curvature of the Riemannian manifold, while the second one is an instantaneous, local effect, which does not depend on the properties of the manifold, but only on the curvature of the billiard boundary at the reflection point and on the angle of reflection. A conventional way, motivated by geometric optical analogies, for keeping track of these separating effects is to follow the evolution of the curvature of the horocycle (wavefront in geometric optics) along the investigated bunch of trajectories.[5,6,8,11,13,14] The curvature κ of the horocycle satisfies a first-order ordinary differential equation along the geodesic segments, and it has jumps depending on the angle of reflection and on the curvature of the wall at the bounces. Having known the time (or parameter) dependence of κ, one can get the transverse separation of nearby trajectories by integration.

A bit more complicated family of systems are billiards with force field, which results in that the particle no longer follows geodesic segments between the subsequent bounces. Special types of these systems are the magnetic billiards, in which a charged particle moves in the billiard under the action of magnetic Lorentz force, that changes only the direction of its velocity, but does not change its kinetic energy. These systems also have a great importance in chaos theory because of their (relative) simplicity and richness.[14–17] The presence of the magnetic field breaks the time-

a)Electronic mail address: tasnadi@galahad.elte.hu

reversal symmetry of the system, and strongly influences the behavior of nearby trajectories during the bounceless segments as well as at the reflections. Changing the value of the magnetic field one can study the transition from completely integrable systems to soft or hard chaos.[14,17] Since the Schrödinger equation can be relatively easily treated in magnetic billiards with numerical methods, these systems also provide a good framework for studying the quantum mechanical aspects of classical chaos.[18]

In this paper we study magnetic billiard systems from a classical point of view, and derive some formulas describing the separation of nearby trajectories during the bounceless periods and at the reflections. With the help of these formulas one can calculate the Lyapunov exponent for special trajectories. We summarize the main results of the paper along with its organization.

In Sec. II the bounceless motion of a charged particle is studied on a Riemannian manifold with magnetic field, and, using a method similar to that of Jacobi fields for geodesics,[4] a generalization of the Jacobi equation[4] is also derived for this case. This latter equation describes the infinitesimal separation of nearby trajectories in magnetic systems. In Appendix A a mathematical addendum is given about the properties of vector fields along mappings needed in Sec. II.

From Sec. III our attention is restricted to two-dimensional systems. In the third section we rewrite the Jacobi equation obtained in Sec. II in a more expressing form using a naturally chosen coordinate frame along the investigated trajectory, and discuss the behavior of its solutions. It is shown that the positive (Gaussian) curvature and the presence of the magnetic field locally stabilize the given bunch of trajectories, the behavior of which is also influenced by the transverse inhomogeneity of the magnetic field. The results are illustrated in simple, homogeneous cases, with special emphasis on the Bolyai–Lobatchewski plane with constant magnetic field.[18] Appendix B contains a brief survey of the cycles and isometries of the hyperbolic plane using its pseudosphere model.[10]

In Sec. IV the bouncing effects are investigated, and a formula is derived, which gives the jump of the Jacobi field at the reflections. In contrast with geodesic billiards, at the presence of magnetic field this jump depends on the value of the field, too; moreover, the field can also change the focusing or defocusing character of the bounce. We illustrate this in a simple case using purely classical geometrical tools in Appendix C.

In Sec. V we relate our method, using generalized Jacobi fields along the trajectories for calculating the behavior of nearby trajectories, to the method which uses the curvature κ of horocycles. We express κ with the help of the Jacobi field, rewrite our results as equations for κ, and show that they agree with the known results when the magnetic field is zero,[5,6,8,11,13] or when the magnetic field is homogeneous and the curvature of the billiard plane is zero.[14]

Our main results are summarized again in Sec. VI.

II. INFINITESIMAL VARIATIONS AND GENERALIZED JACOBI EQUATION

From this section, in differential geometrical calculations we generally adopt the notations of Ref. 4. For a smooth manifold $M, T_x(M)$ denotes its tangent space at the point $x \in M$, $T(M)$ and $\pi_M: T(M) \to M$ denotes the tangent bundle and its canonical projection to M. $\mathscr{F}(M)$ is the algebra of smooth functions on M and $\mathscr{V}(M)$ is the Lie algebra of smooth vector fields on M. For a differentiable mapping $f: N \to M$ we denote its differential (resp. its differential at a point $p \in N$) with f_* [resp. with $(f_*)_p$]. The tensor field $f^*\Omega$ is the pull back of the covariant tensor field Ω given on M to the manifold N. The set of smooth vector fields along f is denoted by $\mathscr{V}_f$. If $\mathbf{\nabla}: \mathscr{V}(M) \times \mathscr{V}(M) \to \mathscr{V}(M)$ is a connection of M, then the induced connection $\tilde{\mathbf{\nabla}}: \mathscr{V}(N) \times \mathscr{V}_f \to \mathscr{V}_f$ is distinguished by a tilde. Since our derivations are strongly based on the concept of vector fields along mappings,[19] we give the definition and summarize the basic properties of this notion in Appendix A.

Let $(M, \langle \cdot, \cdot \rangle)$ be an m-dimensional Riemannian manifold with scalar product $\langle \cdot, \cdot \rangle$, and let us denote its Levi-Civita connection, torsion, and curvature tensor with $\mathbf{\nabla}$, $T(=0)$ and R, respectively.

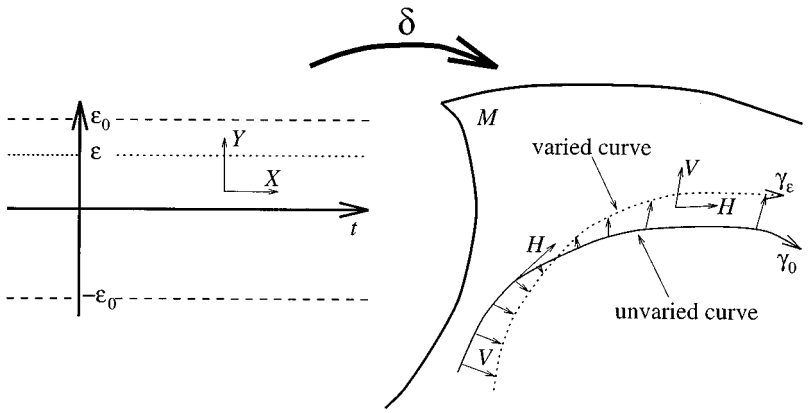

FIG. 1. The variation of a trajectory.

Let B be a given antisymmetric tensor field of type (1,1) [i.e., $\langle X,B(X)\rangle=0$ for all $X\in\mathscr{V}(M)$]. This plays the role of the magnetic field in our system. The equation of motion of a particle of unit charge and mass is

$$\nabla_{\dot\gamma}\dot\gamma=B(\dot\gamma), \tag{1}$$

where $\gamma:\mathfrak{R}\to M$ gives the trajectory of the particle parametrized with time. For physical reasons we assume furthermore that in the investigated system every solution of Eq. (1) is complete, so the motion of the particle can always be followed infinitely both backwards and forwards in time. Multiplying the equation with $\dot\gamma$ we get that $(d/dt)\langle\dot\gamma,\dot\gamma\rangle = 2\langle\dot\gamma,\nabla_{\dot\gamma}\dot\gamma\rangle = 2\langle\dot\gamma,B(\dot\gamma)\rangle = 0$, so the speed (kinetic energy) of the particle is constant. We can assume, without loss of generality, that

$$|\dot\gamma|^2=1. \tag{2}$$

(Otherwise one should change the scale of time and magnetic field by $|\dot\gamma|$.)

The following two concepts help us to handle the behavior of nearby trajectories (Fig. 1).

Definition 1: Let $\gamma_0:\mathfrak{R}\to M$ be a solution of the equation of motion (1). A differentiable mapping $\delta:\mathfrak{R}\times(-\varepsilon_0,\varepsilon_0)\to M$ $(\varepsilon_0>0)$ is said to be a *variation of the curve* γ_0, if $\delta(t,0)=\gamma_0(t)$ $(t\in\mathfrak{R})$, and the curves $\gamma_\varepsilon:\mathfrak{R}\to M$ defined by $\gamma_\varepsilon(t):=\delta(t,\varepsilon)$ also satisfy Eq. (1). The curves γ_ε are the *varied curves*. If the varied curves satisfy also the additional condition (2), δ is called a *special variation.*

Definition 2: Let γ_0 be a solution of Eq. (1), and let δ be a variation of it. The *infinitesimal variation* of γ_0 corresponding to the variation δ is a smooth vector field $V_0\in\mathscr{V}_{\gamma_0}$ along γ_0, for which $V_0(t)=(\partial/\partial\varepsilon)|_{(t,0)}\delta(t,\varepsilon)$. In accordance with the previous definition, V_0 is called a *special infinitesimal variation* if it is induced by a special variation. We denote the set of infinitesimal variations (resp. special infinitesimal variations) along γ_0 with $\mathscr{J}_{\gamma_0}$ (resp. with $\mathscr{SJ}_{\gamma_0}$).

It is intuitively clear that a (special) infinitesimal variation of a trajectory describes the relative motion of another particle moving (at the same speed) along an infinitesimally close path. Since the possible initial conditions of a trajectory constitute a finite-dimensional manifold, it is also expectable that the set $\mathscr{J}_\gamma$ (or $\mathscr{SJ}_\gamma$) of (special) infinitesimal variations along γ form a finite-dimensional subspace of the infinite-dimensional vector space $\mathscr{V}_\gamma$. In the following we define a finite-dimensional subspace of $\mathscr{V}_\gamma$, whose elements are called (special) generalized Jacobi fields, and show that these vector fields are exactly the (special) infinitesimal variations of γ.

Definition 3: Let $\gamma:\mathfrak{R}\to M$ be a solution of the equation of motion (1). A vector field $V\in\mathscr{V}_\gamma$ along γ is a *generalized Jacobi field along* γ, if it satisfies the following second-order ordinary differential equation called *generalized Jacobi equation*:

$$V''=(\nabla_V B)(\dot\gamma)+B(V')-R(V,\dot\gamma)\dot\gamma, \tag{3}$$

where R is the curvature tensor of M, and $V'\in\mathscr{V}_\gamma$ is the derivative $\tilde\nabla_{\partial/\partial t}V$ of $V\in\mathscr{V}_\gamma$ with respect to the parameter $t\in\mathfrak{R}$ of γ. If V beside the equation (3) also satisfies the condition

$$\langle V',\dot\gamma\rangle=0, \tag{4}$$

then V is said to be a *special* (generalized) *Jacobi field*. The set of (generalized) Jacobi fields and special (generalized) Jacobi fields along γ are denoted by $\mathscr{J}_\gamma$ and $\mathscr{SJ}_\gamma$, respectively.

We note that, if the magnetic field is zero, the first two terms on the right side of Eq. (3) vanish, and the generalized Jacobi equation simplifies to the usual Jacobi equation for geodesic variations.[4] In this paper variations of geodesics are not treated, so for the sake of brevity the attribute (generalized) of Jacobi fields and Jacobi equation is omitted.

Since Eq. (3) and condition (4) are linear in V, $\mathscr{J}_\gamma$ and $\mathscr{SJ}_\gamma$ are vector spaces over $\mathfrak{R}$. To give a particular solution $V\in\mathscr{J}_\gamma$ of (3), $V(t_0)$, $V'(t_0)\in T_{\gamma(t_0)}(M)$ must be prescribed (arbitrarily) at a given instant of time t_0. This means, that $\dim\mathscr{J}_\gamma=2m$ $[m=\dim(M)]$.

A straightforward calculation shows that for a Jacobi field $V\in\mathscr{J}_\gamma$ the scalar product $p:=\langle V',\dot\gamma\rangle$ is independent of time. Indeed, $dp/dt = d/dt\langle V',\dot\gamma\rangle = \langle V'',\dot\gamma\rangle + \langle V',\nabla_{\dot\gamma}\dot\gamma\rangle$, and inserting V'' from (3) and $\nabla_{\dot\gamma}\dot\gamma$ from (1) we obtain

$$\frac{dp}{dt}=\frac{d}{dt}\langle V',\dot\gamma\rangle=-\langle R(V,\dot\gamma)\dot\gamma,\dot\gamma\rangle+\langle(\nabla_V B)(\dot\gamma),\dot\gamma\rangle+\langle B(V'),\dot\gamma\rangle+\langle B(\dot\gamma),V'\rangle=0, \tag{5}$$

which is zero due to the properties of the curvature tensor and the antisymmetry of B. So if the condition (4) is satisfied at an arbitrary instant of time, then it holds for all parameter values $t\in\mathfrak{R}$. It means that $\mathscr{SJ}_\gamma$ is a hyperplane ($2m-1$-dimensional subspace) of $\mathscr{J}_\gamma$. It is also easy to show that for every $a\in\mathfrak{R}$, $a\dot\gamma\in\mathscr{V}_\gamma$ is a special Jacobi field.

The following theorem gives the connection between the (special) Jacobi fields and the (special) infinitesimal variations along a trajectory γ.

Theorem 4: For every solution $\gamma_0:\mathfrak{R}\to M$ of the equation of motion (1), the set $\mathscr{T}_{\gamma_0}$ of infinitesimal variations of γ_0 is identical with the set $\mathscr{J}_{\gamma_0}$ of Jacobi fields along γ_0. Moreover, for a solution η_0 of the equation (1), which also satisfies the condition (2), the set $\mathscr{ST}_{\eta_0}$ of special infinitesimal variations of η_0 is identical with the set $\mathscr{SJ}_{\eta_0}$ of special Jacobi fields along η_0.

Proof: First we prove that every infinitesimal variation of γ_0 satisfies the Jacobi equation. Let $\delta:\mathfrak{R}\times(-\varepsilon_0,\varepsilon_0)\to M(\varepsilon_0>0)$ be a variation of γ_0, and let us denote the canonical base vector fields on the parameter plane $\mathfrak{R}\times(-\varepsilon_0,\varepsilon_0)$ with $X:=\partial/\partial t$ and $Y:=\partial/\partial\varepsilon$, where t is the first and ε is the second coordinate of the parameter plane (Fig. 1). The *longitudinal vector field* $H\in\mathscr{V}_\delta$ and the *transverse vector field* $V\in\mathscr{V}_\delta$ are constructed from these base fields with the help of δ_*:

$$H:=\delta_* X,\quad V:=\delta_* Y. \tag{6}$$

[If the mapping δ were injective, the vector fields X and Y could be simply pushed forward to the manifold M. But generally δ is not injective; moreover, it usually has critical points along γ_0 (conjugate points). This is the reason why H and V have to be defined as vector fields along δ.]

It is clear that $V(t,0)$ is just the infinitesimal variation corresponding to δ at the point $\gamma_0(t)$, and that the longitudinal vector field H consists of the tangent vectors of the varied curves, i.e., $H(t,\varepsilon)=\dot\gamma_\varepsilon(t)$. Since the varied curves also obey Eq. (1), we have

$$\tilde{\nabla}_X H = B(H) \tag{7}$$

for H ($\tilde{\nabla}$ denotes the covariant derivation on $\mathscr{T}_\delta$ induced by ∇). Differentiating Eq. (7) with respect to Y, we obtain

$$\tilde{\nabla}_Y \tilde{\nabla}_X H = \tilde{\nabla}_Y (B(H)). \tag{8}$$

Now we transform this equation into a form which does not contain derivations of H or V with respect to Y, so in which it is enough to know H and V along γ_0. Using (A2) and the facts that $T=0$ and $[X,Y]=0$, we have

$$\tilde{\nabla}_X V = \tilde{\nabla}_Y H. \tag{9}$$

Using (A3) and (9), the left side of Eq. (8) can be rewritten in the following form:

$$\tilde{\nabla}_Y \tilde{\nabla}_X H = R(V,H)H + \tilde{\nabla}_X \tilde{\nabla}_Y H + \tilde{\nabla}_{[Y,X]} H = R(V,H)H + \tilde{\nabla}_X \tilde{\nabla}_X V. \tag{10}$$

The right side of (8) can be written as follows:

$$\tilde{\nabla}_Y (B(H)) = (\tilde{\nabla}_Y B)(H) + B(\tilde{\nabla}_Y H) = (\tilde{\nabla}_Y B)(H) + B(\tilde{\nabla}_X V). \tag{11}$$

Putting together the two sides (10) and (11), considering the equation obtained at $\varepsilon=0$, and writing $\dot{\gamma}_0(t)$ in place of $H(t,0)$, we obtain

$$R(V,\dot{\gamma}_0)\dot{\gamma}_0 + V'' = (\nabla_V B)(\dot{\gamma}_0) + B(V'), \tag{12}$$

which agrees with the Jacobi equation (3).

For a special variation δ of the curve η_0, the property (4) of the corresponding infinitesimal variation V can be proved using a similar trick. Let X, Y, H, and V be the same vector fields as before. Since δ is a special variation, we have

$$\langle H,H\rangle = 1 \tag{13}$$

for H. Differentiating it with respect to Y and using (9), we find that

$$\tilde{\nabla}_Y \langle H,H\rangle = 2\langle \tilde{\nabla}_Y H, H\rangle = 2\langle \tilde{\nabla}_X V, H\rangle = 0. \tag{14}$$

Considering it at $\varepsilon=0$, we find that $\langle V', \dot{\eta}_0\rangle = 0$, so V is indeed a special Jacobi field.

Now we sketch the proof of the theorem in the opposite direction. Let $\tilde{V}$ be a given Jacobi field along the trajectory γ_0. From $\tilde{V}$ we construct a variation δ, for which the transverse vector field $V \in \mathscr{T}_\delta$ is identical with $\tilde{V}$ along γ_0. Since both $\tilde{V}$ and $V|_{\varepsilon=0}$ are Jacobi fields, to prove their equality it is enough to show that they and their first derivatives with respect to $\dot{\gamma}_0$ agree at a single point of γ_0. However, using (9) the derivations with respect to tangent vectors of γ_0 can be rewritten as derivations with respect to transverse vectors. The construction of δ can be followed in Fig. 2.

Let $\nu:(-\varepsilon_0,\varepsilon_0)\to M(\varepsilon_0>0)$ be a smooth injective curve, for which $\nu(0)=\gamma_0(0)$ and $\dot{\nu}(0) = \tilde{V}(0)$. Let G and $K \in \mathscr{T}_\nu$ be the vector fields along ν, obtained by autoparallel translation of $\dot{\gamma}_0(0)$ and $\tilde{V}'(0)$ along ν, respectively. Let us define the ''longitudinal'' vector field $\tilde{H}$ along ν by

$$\tilde{H}(\varepsilon) := G(\varepsilon) + \varepsilon K(\varepsilon) \tag{15}$$

[$\varepsilon \in (-\varepsilon_0,\varepsilon_0)$]. It comes immediately from this construction that

$$\nabla_{\tilde{V}(0)} \tilde{H} = K(0) = \tilde{V}'(0). \tag{16}$$

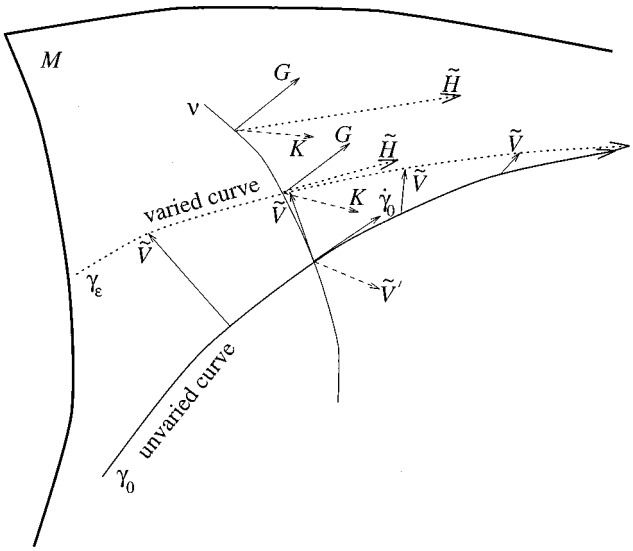

FIG. 2. The construction of the variation from the Jacobi field.

Now let us define the varied curves γ_ε $[\varepsilon\in(-\varepsilon_0,\varepsilon_0)]$ as the solutions of Eq. (1) with initial conditions $\gamma_\varepsilon(0)=\nu(\varepsilon)$ and $\dot{\gamma}_\varepsilon(0)=\widetilde{H}(\varepsilon)$, and define the variation with $\delta(t,\varepsilon):=\gamma_\varepsilon(t)$. (It is a simple consequence of the construction that δ is indeed a smooth variation of γ_0.)

Let X, Y and H, $V\in\mathscr{V}_\delta$ denote the canonical vector fields on the parameter plane and the longitudinal, transverse vector field along δ, respectively, as before. Due to the construction of δ, H coincides with $\widetilde{H}$ and V coincides with $\dot{v}$ along ν, so especially V agrees with $\widetilde{V}$ and $\dot{\nu}$ at $\gamma_0(0)$ and $\nabla_{V(0,0)}H=\nabla_{\widetilde{V}(0)}\widetilde{H}$. Using (16) and (9), this means, that V' agrees with $\widetilde{V}'$ at $\gamma_0(0)$. Since the values and the first derivatives of the Jacobi fields V and $\widetilde{V}\in\mathscr{J}_{\gamma_0}$ coincide at $\gamma_0(0)$, V agrees with $\widetilde{V}$ along the whole trajectory.

If η_0 is a trajectory satisfying condition (2) and $\widetilde{V}$ is a special Jacobi field, we must construct a special variation inducing $\widetilde{V}$. For this reason the equation (15) defining $\widetilde{H}$ has to be slightly changed:

$$\widetilde{H}(\varepsilon):=\frac{G(\varepsilon)+\varepsilon K(\varepsilon)}{|G(\varepsilon)+\varepsilon K(\varepsilon)|}. \tag{17}$$

Since in this case $|\dot{\eta}_0|=1$ and $\langle V',\dot{\eta}_0\rangle=0$, the denominator in (17) is of order $1+\varepsilon^2$, and (16) remains valid. With this modification $|\widetilde{H}|=1$, so the corresponding δ is a special variation. The proof can be finished in the same way as in the previous case.

This completes the proof of Theorem 4.

Q.E.D.

We note, that the Jacobi field $V(t)=a\dot{\gamma}(t)$ $(a\in\mathfrak{R})$ along γ corresponds to the variation $\delta(t,\varepsilon)=\gamma(t+a\varepsilon)$, which is a translation of γ in its parameter line $\mathfrak{R}$.

For a Jacobi field $V\in\mathscr{J}_\gamma$ let $p:=\langle V',\dot{\gamma}\rangle\in\mathfrak{R}$. [As we have seen in (5), p is independent of time.] A simple calculation shows that p is the rate of change of the speed of the varied trajectories γ_ε as a function of ε:

$$\left.\frac{\partial}{\partial\varepsilon}\right|_{(t,0)}|\dot{\gamma}_\varepsilon(t)|=\left.\frac{\partial}{\partial\varepsilon}\right|_{(t,0)}|H(t,\varepsilon)|=\frac{\langle\widetilde{\nabla}_Y H(t,0),H(t,0)\rangle}{|H(t,0)|}=\frac{\langle V',\dot{\gamma}_0\rangle}{|\dot{\gamma}_0|}=p. \tag{18}$$

[Here the notations were introduced before, and Eqs. (2) and (9) were used.] It is also clear that for a special infinitesimal variation p is zero; namely, this is the condition (4) in Definition 3 of special Jacobi fields.

III. SPECIAL FORMULAS FOR TWO-DIMENSIONAL MANIFOLDS

From here our study is restricted to two-dimensional manifolds. The low dimensionality enables us to introduce a natural coordinate system along the trajectories, in which the Jacobi equation (3) and condition (4) can be written in a more adequate form.

Let $(M,\langle\cdot,\cdot\rangle)$ be a two-dimensional Riemannian manifold with magnetic field B, and let Ω denote the antisymmetric tensor field of type (1,1) corresponding to the volume form ω [i.e., $\langle\Omega(Y),X\rangle=\omega(X,Y)$ for all $X,Y\in\mathscr{X}(M)$]. Due to the properties of the metric tensor and the volume form, Ω satisfies the following two conditions:

$$\Omega^2=-1, \quad \nabla\Omega=0. \tag{19}$$

(The effect of Ω on a tangent vector is just a rotation of 90° in the tangent plane.)

Since $\dim(M)=2$, the magnetic field B can be uniquely written in the form

$$B=\beta\Omega, \tag{20}$$

where $\beta\in\mathscr{F}(M)$ is a smooth function.

Let $V\in\mathscr{J}_\gamma$ be a Jacobi field along the trajectory γ of unit speed ($|\dot\gamma|=1$), and let us denote the (strength of the) magnetic field along γ by $\beta_\gamma:=\beta\circ\gamma:\mathfrak{R}\to\mathfrak{R}$. Inserting (20) into the Jacobi equation (3), we obtain

$$V''=V(\beta)\dot\gamma^\perp+\beta_\gamma\Omega(V')-R(V,\dot\gamma)\dot\gamma, \tag{21}$$

where $V(\beta)$ is the derivative of β in the direction of V, and $\dot\gamma^\perp:=\Omega(\dot\gamma)$ denotes the vector field of unit vectors perpendicular to $\dot\gamma$ along the trajectory.

Since $\dim(M)=2$, $V\in\mathscr{J}_\gamma$ can be uniquely written in the form

$$V=a\dot\gamma+b\dot\gamma^\perp, \tag{22}$$

where a and b are functions on $\mathfrak{R}$. The coordinate function a describes the *longitudinal* separation of nearby trajectories, while function b shows the relative motion of two infinitesimally closed trajectories in the *transverse* direction.

In the following theorem the Jacobi equation (21) is expressed with the help of these coordinate functions.

Theorem 5: A vector field $V=a\dot\gamma+b\dot\gamma^\perp\in\mathscr{X}_\gamma$ along the trajectory γ of unit speed on a two-dimensional manifold M is a Jacobi field if and only if the coordinate functions a and b of V satisfy for some $p\in\mathfrak{R}$ the following system of differential equations:

$$a'=p+\beta_\gamma b, \quad b''=-b(r+\beta_\gamma^2-\beta_\gamma^\perp)-\beta_\gamma p, \tag{23}$$

where $\beta_\gamma^\perp:=\dot\gamma^\perp(\beta)$ denotes the derivative of β with respect to $\dot\gamma^\perp$, $\beta_\gamma=\beta\circ\gamma$, and $r:=\langle R(\dot\gamma^\perp,\dot\gamma)\dot\gamma,\dot\gamma^\perp\rangle:\mathfrak{R}\to\mathfrak{R}$ is the sectional (Gaussian) curvature of M along γ. Here V is a special Jacobi field, if $p=0$.

If $V\in\mathscr{J}_\gamma$ is a Jacobi field, then the constant p is

$$p=\langle V',\dot\gamma\rangle=a'-\beta b\in\mathfrak{R}. \tag{24}$$

(It is in accordance with our previous notation.)

It is worth mentioning that (23) is not a real coupled system of differential equations; the second equation of (23) is an ordinary differential equation only for b. Having known the initial conditions $a(t_0),b(t_0),a'(t_0),b'(t_0)\in\Re$, expression (24) gives the value of p, the time dependence of b can be obtained by solving the second equation of (23), and inserting it into the first equation of (23), an integration gives the function $a(t)$.

Proof: First we prove the ''only if'' part of the theorem. Let $V=a\dot{\gamma}+b\dot{\gamma}^{\perp}\in\mathcal{J}_{\gamma}$ be a Jacobi field. Using the expressions (19) and (20) and the equation of motion (1), the derivatives of V can be written as follows:

$$V'=(a'-\beta_{\gamma}b)\dot{\gamma}+(b'+\beta_{\gamma}a)\dot{\gamma}^{\perp}, \tag{25}$$

$$V''=(a''-\beta_{\gamma}'\,b-2\beta_{\gamma}\,b'-b^2a)\dot{\gamma}+(b''+\beta_{\gamma}'a+2\beta_{\gamma}\,a'-\beta_{\gamma}^2\,b)\gamma^{\perp}. \tag{26}$$

Substituting these equations as well as expression (22) into the Jacobi equation (21), using again the properties (19) of Ω and the symmetry properties of R, we obtain the following system of ordinary differential equations for the coordinate functions a and b:

$$a''=\beta_{\gamma}'b+\beta_{\gamma}b'=(\beta_{\gamma}\,b)', \quad b''=-b(r-\beta_{\gamma}^{\perp})-\beta_{\gamma}a'. \tag{27}$$

With the help of the expression (24) for p, it is easy to transform this system of equations into the desired form (23), and it is also obvious that, if V is a special Jacobi field, then $p=0$. This proves the ''only if'' part of the theorem, and following the calculations backwards, one can easily check, that the ''if'' part is also true.

Q.E.D.

If the factor $r+\beta_{\gamma}^2-\beta_{\gamma}^{\perp}$ were constant on the right side of the second equation of (23) then the solution $b(t)$ would be an exponential or a harmonic (sine or cosine) function depending on the sign of $r+\beta_{\gamma}^2-\beta_{\gamma}^{\perp}$. According to this fact, a trajectory γ is said to be *locally stable* at a point $\gamma(t_0)$, if $r+\beta_{\gamma}^2-\beta_{\gamma}^{\perp}>0$ at that point, and *locally instable*, if $r+\beta_{\gamma}^2-\beta_{\gamma}^{\perp}<0$. The negative curvature causes instability, the presence of the magnetic field works against it, and the inhomogeneity of the magnetic field also influences the stability of the trajectories. (The fact that the magnetic field suppresses chaos has been also observed in Ref. 17.)

In the remaining part of this section the results obtained are illustrated by presenting particular cases, where the Gaussian curvature r and the magnetic field β is constant. In this case $\beta^{\perp}=0$, so the stability of the trajectories depends (globally) on the sign of $r+\beta^2$. If the scalar curvature is positive, the trajectories are stable for every value β of the magnetic field. It is more interesting that in the case of negative curvature the trajectories can be either stable or instable, depending on the strength of the magnetic field.

First we study in detail the motion of a charged particle on the hyperbolic (Bolyai–Lobatchewski) plane, denoted by S, for which $r=-1$. This means, that for magnetic fields $|\beta|<1$ the trajectories are instable, and for fields $|\beta|>1$ the trajectories are stable.[18] In Appendix B we summarize some basic facts connected with the cycles and isometries of the hyperbolic plane using the pseudosphere model.[10]

For a trajectory $\gamma:\Re\to S$ let the image of the mapping γ (as a subset of S) be called the *path* of the particle (or the *path* belonging to the trajectory γ). The following theorem relates the cycles of the hyperbolic plane to the paths of charged particles.

Theorem 6: The possible paths of charged particles moving on the hyperbolic plane in constant nonzero magnetic field are the cycles. If the charge, mass, and speed of the particle is unit, then for magnetic fields $|\beta|<1$ the paths are hypercycles, for $|\beta|>1$ the paths are circles, and at the magnetic fields $|\beta|=1$ the particles move along paracycles.

The possible directed paths (i.e., the directed cycles) constitute in a natural way a three-dimensional differentiable manifold P. The points of P can be identified with the paths belonging

to trajectories of unit speed, and the tangent plane $T_\gamma(P)$ at the point $\gamma \in P$ can be brought into one-to-one correspondence with the factor space $\mathscr{J}_\gamma/\Re\dot{\gamma}$, where $\Re\dot{\gamma} \subset \mathscr{S}\mathscr{J}_\gamma$ is a one-dimensional subspace of the (special) Jacobi fields.

Proof: It is a direct consequence of the rich symmetry (homogeneity and isotropy) of the hyperbolic plane S, and the autonomity of the equation of motion (1), that the trajectories can be translated along themselves. Indeed, for every two tangent vectors $\dot{\gamma}(t_0)$ and $\dot{\gamma}(t_1)$ $(t_0, t_1 \in \Re)$ of a solution γ of (1), there is an isometry of S, which transforms the first vector into the second one. (See Lemma 14.) Since the equation of the motion is independent of time, this isometry transforms the path of the trajectory γ onto itself.

It is also obvious that the trajectories are curves of constant curvature. The equation of motion (1) just tells us that the curvature of a solution γ of speed $v = |\dot{\gamma}|$ in magnetic field β is $|\nabla_{\dot{\gamma}/|\dot{\gamma}|}\dot{\gamma}/|\dot{\gamma}|| = (\beta/v^2)|\dot{\gamma}^\perp| = \beta/v$. So, using Lemma 17, the trajectories of unit speed are hypercycles of altitude $\operatorname{artanh}|\beta|$, if $|\beta|<1$; paracycles, if $|\beta|=1$, and circles of radius $\operatorname{arcoth}|\beta|$, if $|\beta|>1$. This proves the first part of the theorem.

For defining a differentiable structure on the set of directed cycles we use the pseudosphere model of the hyperbolic plane. Let $(\mathbf{V}, \langle\cdot,\cdot\rangle)$ be the three-dimensional Minkowskian vector space into which the pseudosphere S is embedded. (See Lemma 12 and Definition 13 in Appendix B.) First we prove that the set of all oriented affine hyperplanes (i.e., two-dimensional affine subspaces) of $\mathbf{V}$ possesses a natural differentiable structure. For this reason, let us introduce (beside the Minkowskian structure $\langle\cdot,\cdot\rangle$) a Riemannian (positive definite) scalar product $g: \mathbf{V}\times\mathbf{V} \to \Re$ on $\mathbf{V}$. With the help of this multiplication every directed hyperplane of $\mathbf{V}$ can be unambiguously characterized by its (g-orthogonal) normal (unit) vector and its distance from the origin of $\mathbf{V}$ measured in the direction of the normal vector. (The normal vector gives also the orientation of the hyperplane.) So the hyperplanes are in one-to-one correspondence with the points of the product manifold $N\times\Re$, where N is the g-unit sphere of $\mathbf{V}$, and the differentiable structure of $N\times\Re$ can be carried over to the set of affine hyperplanes of $\mathbf{V}$. It is also easy to show that this is a canonical differentiable structure, i.e., independent of the special choice of the scalar product g.

According to Lemma 17, the cycles are the plane sections of the pseudosphere S in $\mathbf{V}$. Since the affine hyperplanes intersecting the pseudosphere in more than one point correspond to the elements of an open subset of $N\times\Re$, the cycles indeed form in a natural way a differentiable submanifold P of the manifold of all affine hyperplanes of $\mathbf{V}$.

As we have seen, the curvature of a trajectory of speed v in magnetic field β is β/v. This means that at an appropriate value of the magnetic field β every cycle (of arbitrary curvature) can be realized as the path belonging to a trajectory of unit speed, so the points of P can be regarded as the paths belonging to the trajectories of unit speed.

To establish the correspondence between the tangent plane $T_\gamma(P)$ and the factor space $\mathscr{J}_\gamma/\Re\dot{\gamma}$ is also easy, but a bit more cumbersome. In Definition 1 the magnetic field is fixed during the variation of a trajectory, and the speed of the varied trajectories can be changed, while the points of P are regarded as paths of trajectories of unit speed, corresponding to different values of the magnetic field. So, first the varied trajectories have to be brought into correspondence with the trajectories of unit speed. This can be easily done by relating a trajectory of speed v at magnetic field β to the trajectory of unit speed belonging to the same path at magnetic field β/v. Using this connection, the variation of a trajectory $\gamma \in P$ is just a curve in the manifold P, and an infinitesimal variation, or Jacobi field along γ corresponds to a tangent vector in $T_\gamma(P)$. It is also evident that $\mathscr{J}_\gamma$ has to be factorized with $\Re\dot{\gamma}$, since the infinitesimal variations $\Re\dot{\gamma}$ move γ along itself, so they present the null vector in $T_\gamma(P)$.

This completes the proof of Theorem 6.

Q.E.D.

Figure 3 shows the variation of a hypercycle and a circle on the pseudosphere model. The behavior of the transverse coordinates b can be clearly seen in both cases. This figure also illustrates that in the manifold of the cycles P there is a preferred path between every pair of different points $\Sigma, \Pi \in P$ consisting of the plane sections of S with planes having a common line

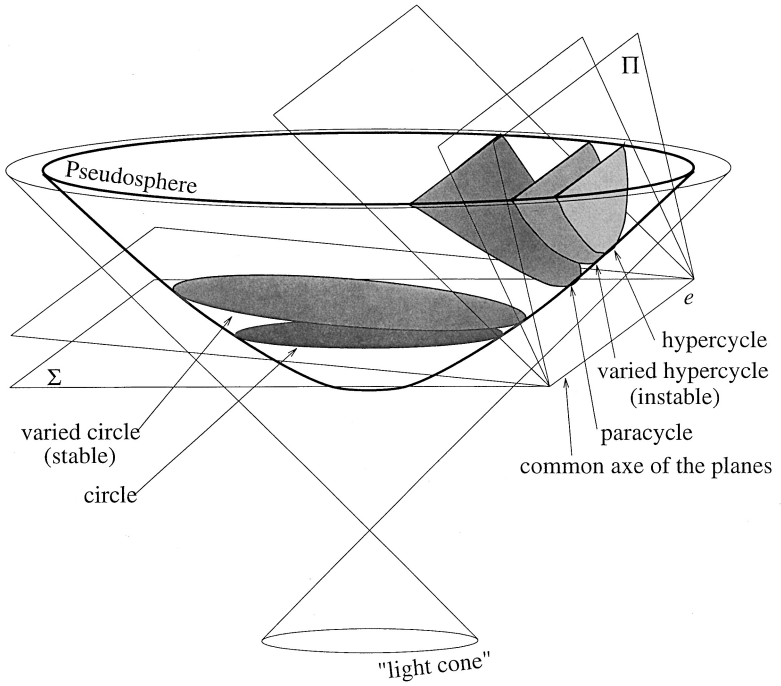

FIG. 3. The variation of a hypercycle and a circle.

e with Σ and Π. (If Σ and Π are parallel, then all the other planes are parallel with them, and e is the ideal line.)

Similar considerations can be followed for constant positive curvature. In the case of $r=1$, the two-dimensional manifold is the unit sphere embedded into a three-dimensional Euclidean vector space. The trajectories of curvature β/v are just the circles of radius $\operatorname{arcctg}(\beta/v)$ (measured on the sphere), and these curves are also the plane sections of the unit sphere.

For $r=0$ the trajectories are the usual circles on the two-dimensional Euclidean plane.

IV. THE EFFECT OF THE BOUNCES

Till now the behavior of nearby trajectories of charged particles in magnetic systems has been studied during the bounceless segments. However, in billiards the reflections also strongly influence the separation of close trajectories. At the bouncing point(s) neither the *variation* nor the *infinitesimal variation of a bouncing trajectory* is smooth, the variation is continuous there, and the Jacobi field and its first derivative have certain jump at the reflection point. In the ongoing section this effect is investigated in detail for two-dimensional systems, and a formula is derived which gives the jump of the Jacobi field and its derivative in terms of the magnetic field, the angle of reflection, and the curvature of the billiard wall at the reflection point.

For this purpose the definition of the variation and infinitesimal variation (Definitions 1 and 2) should be slightly modified for bouncing trajectories. [The bouncing trajectories are continuous curves, which are everywhere smooth, except at the bouncing point, they satisfy the equation of motion (1) for parameter values before and after the reflection, and obey the law of elastic reflection at the bouncing point.]

Definition 7: The mapping δ: $\mathfrak{R}\times(-\varepsilon_0,\varepsilon_0)\to M$ $(\varepsilon_0>0)$ is a *variation of the bouncing trajectory* γ_0, if the varied trajectories $\gamma_\varepsilon(t)=\delta(t,\varepsilon)$ $(|\varepsilon|<\varepsilon_0)$ are also trajectories of charged particles bouncing on the billiard wall according to the law of elastic reflection, and δ is smooth on its domain before and after the reflection. The *infinitesimal variation* V_0 *of the bouncing trajectory*

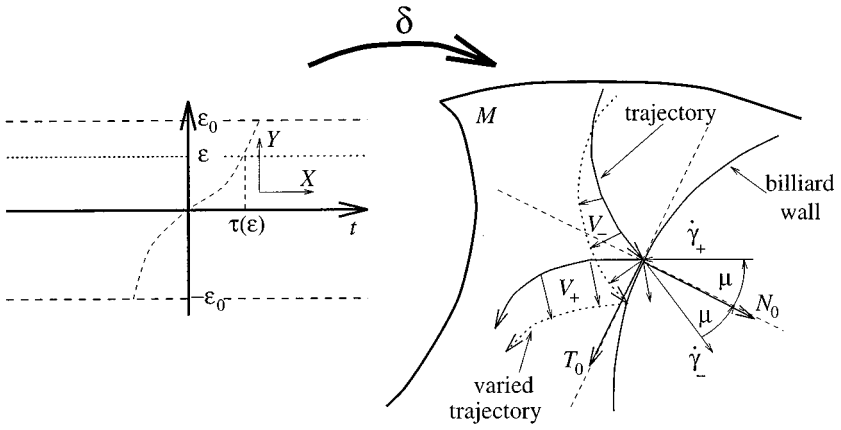

FIG. 4. The variation of a bouncing trajectory.

γ_0 corresponding to the variation δ is defined similarly as in Definition 2, $V_0(t)=\partial/\partial\varepsilon|_{(t,0)}\delta(t,\varepsilon)$, but in this case V_0 has a jump at the reflection point, since the variation δ is not smooth there.

The letters ω, Ω, and $B=\beta\Omega$ $[\beta\in\mathscr{F}(M)]$ denote the same tensor fields on the two-dimensional Riemannian manifold $(M,\langle\cdot,\cdot\rangle)$ as in the previous section. Let $\nu\colon \mathfrak{R}\to M$ be the billiard wall parametrized in such a way that $T:=\dot{\nu}$ is its unit tangent vector and the unit normal vector $N:=\Omega(\dot{\nu})$ points outwards of the billiard (Fig. 4). Let $\gamma\colon \mathfrak{R}\to M$ be the trajectory of a particle of unit speed bouncing on ν at the point $\nu(0)=\gamma(0)$, and let V be an infinitesimal variation of it. The values of the vector fields T, $N\in\mathscr{V}_\nu$ at the bouncing point are denoted by $T_0,N_0\in T_{\nu(0)}(M)$. Since γ obeys the law of elastic reflection,

$$\dot{\gamma}_+=\dot{\gamma}_- -2\langle\dot{\gamma}_-,N_0\rangle N_0, \tag{28}$$

where (and in the remaining sections further on) the subscripts ''$-$'' and ''$+$'' distinguish the vectors (and coordinates) just before and just after the reflection, respectively. The coordinates $a_\pm,b_\pm\in\mathfrak{R}$ of $V_\pm\in T_{\gamma(0)}(M)$ are defined by the following two formulas:

$$V_-=a_-\dot{\gamma}_-+b_-\dot{\gamma}_-^{\perp}, \tag{29}$$

$$V_+=a_+\dot{\gamma}_++b_+\gamma_+^{\perp}, \tag{30}$$

where $\dot{\gamma}_\pm^{\perp}=\Omega(\dot{\gamma}_\pm)\in T_{\gamma(0)}(M)$, like before. Let the angle of reflection, directed from the velocity vector $\dot{\gamma}_-$ (just before the reflection) to the normal vector N_0, be denoted by μ, as it is shown in Fig. 4. This means that

$$N_0=\dot{\gamma}_-\cos(\mu)+\dot{\gamma}_-^{\perp}\sin(\mu), \tag{31}$$

$$T_0=\dot{\gamma}_-\sin(\mu)-\dot{\gamma}_-^{\perp}\cos(\mu). \tag{32}$$

Let β and q be the value of the magnetic field and the curvature of the billiard wall at the bouncing point, respectively, where the curvature q is defined by the equation

$$\nabla_{T_0}T=-qN_0. \tag{33}$$

Since N points outwards of the billiard, q is positive if the billiard wall is focusing at the reflection point and negative if it is defocusing.

The following theorem gives the jump of the Jacobi field and its first derivative.

Theorem 8: Using the notations introduced above, the infinitesimal variation V_+ of a bouncing trajectory γ of unit speed and its first derivative V'_+ just after the reflection can be calculated by the following formulas:

$$V_+ = V_- - 2\langle V_-, N_0\rangle N_0, \tag{34}$$

$$V'_+ = V'_- - 2\langle V'_-, N_0\rangle N_0 + 2\frac{\langle \beta N_0 + q\dot{\gamma}_-^{\perp}, V_-\rangle}{\cos(\mu)}\,(\dot{\gamma}_-\,\sin(2\mu) - \dot{\gamma}_-^{\perp}\,\cos(2\mu)), \tag{35}$$

where V_- and V'_- are the infinitesimal variation and its first derivative just before the reflection.

These equations result in the following connections between the coordinates and their derivatives at the reflection point:

$$a_+ = a_-, \quad b_+ = -b_-; \tag{36}$$

$$a'_+ = a'_- - 2\beta b_-, \quad b'_+ = -b'_- + 2b_-\frac{q+\beta\,\sin(\mu)}{\cos(\mu)}. \tag{37}$$

We remark that Eq. (34) or (36) means that V_+ is simply the reflection of V_- in the line of T_0.

Proof: First we prove the assumptions (34) and (35). Let δ be a variation of γ corresponding to the infinitesimal variation V, and let X,Y and $H_{\leftarrow}, V_{\leftarrow}$ (or $H_{\rightarrow}, V_{\rightarrow}$) be the canonical vector fields on the parameter plane and the longitudinal, transverse vector field before (or after) the bounce, respectively. [This means that $H_{\leftarrow}(0,0)=\dot{\gamma}_-$, $H_{\rightarrow}(0,0)=\dot{\gamma}_+$, $V_{\leftarrow}(0,0)=V_-$ and $V_{\rightarrow}(0,0)=V_+$.] To avoid unnecessary technical difficulties, let us suppose that δ is regular at the point $t=\varepsilon=0$, and let $Z=\xi X+\eta Y$ be the vector on the parameter plane, for which $\delta_* Z = T_0$ holds. This means that

$$T_0 = \xi\dot{\gamma}_- + \eta V_- = \xi\dot{\gamma}_+ + \eta V_+. \tag{38}$$

Since the velocity vector $\dot{\gamma}_+$ is the reflection of the vector $\dot{\gamma}_-$ in the line of T_0, it follows from the previous equation that the infinitesimal variation vector V_+ is also the reflection of the vector V_- in this axis; this proves assumptions (34) and (36) of the theorem. [In the second equation of (36) the negative sign appears because the reflection of $\dot{\gamma}_-^{\perp}$ in T_0 is $-\dot{\gamma}_+^{\perp}$.]

With the help of the formulas (31), (32), and (29) the factors ξ,η can be easily expressed in terms of the angle of reflection and the (coordinates of the) infinitesimal variation vector before the bounce:

$$\xi = \frac{\langle N_0, V_-\rangle}{\langle \dot{\gamma}_-^{\perp}, V_-\rangle} = \sin(\mu) + \frac{a_-}{b_-}\cos(\mu),$$
$$\eta = -\frac{\cos(\mu)}{\langle \dot{\gamma}_-^{\perp}, V_-\rangle} = -\frac{\cos(\mu)}{b_-}. \tag{39}$$

Since the varied trajectories satisfy the law of elastic reflection,

$$H_{\rightarrow}(\tau(\varepsilon),\varepsilon) = H_{\leftarrow}(\tau(\varepsilon),\varepsilon) - 2\langle H_{\leftarrow}(\tau(\varepsilon),\varepsilon), N\rangle N, \tag{40}$$

where the function $\tau(\varepsilon)$ gives the parameter value corresponding to the bounce of the varied trajectory γ_ε. Differentiating this equation with respect to the vector $Z=\xi X+\eta Y$ at the point $t=\varepsilon=0$, and using Eq. (28) as well as the expressions

$$\widetilde{\nabla}_Z H_{\leftrightarrow} = \xi \widetilde{\nabla}_X H_{\leftrightarrow} + \eta \widetilde{\nabla}_Y H_{\leftrightarrow} = \beta \xi \dot{\gamma}_{\pm}^{\perp} + \eta V'_{\pm}, \tag{41}$$

$$\widetilde{\nabla}_Z N = \Omega(\widetilde{\nabla}_Z T) = -q\Omega(N_0) = qT_0, \tag{42}$$

we obtain

$$V'_+ = V'_- - 2\langle V'_-, N_0\rangle N_0 + \frac{-2(\xi\beta+q)}{\eta}(\langle \dot{\gamma}_-, N_0\rangle T_0 + \langle \dot{\gamma}_-, T_0\rangle N_0). \tag{43}$$

[For deriving the expressions (41) and (42) and Eq. (43), the connection (9), the equation of motion (1), and the properties (19) of the tensor Ω are to be used.]

With the help of Eqs. (31) and (32), it is easy to show that

$$\langle \dot{\gamma}_-, N_0\rangle T_0 + \langle \dot{\gamma}_-, T_0\rangle N_0 = \dot{\gamma}_- \sin(2\mu) - \dot{\gamma}_-^{\perp} \cos(2\mu). \tag{44}$$

Using this, and substituting ξ, η from (the coordinate free expression of) (39) into Eq. (43), Eq. (35) of the theorem can be obtained.

Differentiating the expressions (29) and (30) at $t=0$ with respect to $\dot{\gamma}_-$ and $\dot{\gamma}_+$, respectively, and in the second equation replacing the vectors $\dot{\gamma}_+, \dot{\gamma}_+^{\perp}$ in terms of the vectors $\dot{\gamma}_-, \dot{\gamma}_-^{\perp}$ using the low of elastic reflection (28), one can express the vectors V'_- and V'_+ in the basis $\{\dot{\gamma}_-, \dot{\gamma}_-^{\perp}\} \subset T_{\gamma(0)}(M)$:

$$V'_- = (a'_- - \beta b_-)\dot{\gamma}_- + (b'_- + \beta a_-)\dot{\gamma}_-^{\perp}, \tag{45}$$

$$\begin{aligned} V'_+ = {} & (-(a'_+ + \beta b_-)\cos(2\mu) + (b'_+ + \beta a_-)\sin(2\mu))\dot{\gamma}_- \\ & + (-(a'_+ + \beta b_-)\sin(2\mu) - (b'_+ + \beta a_-)\cos(2\mu))\dot{\gamma}_-^{\perp}. \end{aligned} \tag{46}$$

Substituting these expressions, as well as expression (29), into Eq. (35) and using the conditions (31) and (32), after straightforward calculations one can derive Eqs. (37).

This completes the proof of Theorem 8.

Q.E.D.

It can be seen from Eqs. (37) [or (35)] that the presence of the magnetic field really influences the behavior of nearby trajectories at the instant of the bounce. A reflection at an angle μ on a wall of curvature q in magnetic field β causes the same jump in the transverse part of the infinitesimal variation and its first derivative, as a reflection on a wall of curvature $q' = q + \beta\sin(\mu)$, without magnetic field. If $|\beta| > |q|$, at appropriate value of μ the magnetic field can even change the focusing or defocusing character of the wall.

In Appendix C we give an elementary proof of Eqs. (36) and (37) in a special case, where b'_- and the curvature q of the billiard wall are zero.

V. RELATION WITH THE CURVATURE OF THE HOROCYCLES

In this section we relate our method for calculating the separation of nearby trajectories in billiard systems to the earlier method of Bunimovich and Sinai[5,6,8] according to which the transverse separation of the trajectories can be obtained by integrating the curvature of the *horocycles* along the trajectory investigated.

Let $\gamma: \mathfrak{R} \to M$ be a trajectory of unit speed in the two-dimensional manifold $(M, \langle\cdot,\cdot\rangle)$ with magnetic field $B = \beta\Omega$, let δ be a variation of γ corresponding to the infinitesimal variation $V_0 = a\dot{\gamma} + b\dot{\gamma}^{\perp} \in \mathscr{V}_{\gamma}$, and let X, Y and $H, V \in \mathscr{V}_{\delta}$ be the canonical base fields on the parameter plane and the longitudinal, transverse vector fields, respectively. The vector field $\Omega(H) \in \mathscr{V}_{\delta}$ perpendicular to H is denoted by $H^{\perp}$.

Definition 9: The *horocycles* corresponding to the variation δ of the trajectory γ (of unit speed) are the integral curves of the vector field $H^{\perp}$ perpendicular to the varied trajectories. Assuming that δ is regular at the point $(t,0)$, the *curvature* $\kappa(t)$ *of the horocycle* at the point $\gamma(t)$ is defined by the following equation:

$$\widetilde{\nabla}_{P(t)} \frac{H^{\perp}}{|H^{\perp}|} = -\kappa(t)\dot{\gamma}(t), \tag{47}$$

where $P(t)$ is the vector of the parameter plane, for which $\delta_* P(t) = \Omega(\dot{\gamma}(t)) = \dot{\gamma}^{\perp}(t)$ holds. [Due to the negative sign in Eq. (47), the curvature κ is positive, if the varied trajectories diverge.]

In the following theorem we calculate the curvature κ of the horocycles as a function of the infinitesimal variation, and give expressions describing the evolution of κ along the trajectory as well as at the bouncings.

Theorem 10: Using the notations introduced above, the curvature κ is given by the following equation:

$$\kappa = \frac{\langle V_0', \dot{\gamma}^{\perp}\rangle - \beta_{\gamma}\langle V_0, \dot{\gamma}\rangle}{\langle V_0, \dot{\gamma}^{\perp}\rangle} = \frac{b'}{b} = (\ln|b|)', \tag{48}$$

where $\beta_{\gamma} = \beta \circ \gamma$.

The curvature κ_+ just after a reflection at an angle μ on a wall of curvature q is

$$\kappa_+ = \kappa_- - 2\frac{q + \beta\,\sin(\mu)}{\cos(\mu)}, \tag{49}$$

where κ_- is the curvature of the horocycle just before the bounce and β is the value of the magnetic field at the reflection point.

Assuming that the horocycles correspond to a special variation, their curvature obey the following differential equation:

$$\kappa' = -r - \beta_{\gamma}^2 + \beta_{\gamma}^{\perp} - \kappa^2, \tag{50}$$

where $r:\mathfrak{R}\to\mathfrak{R}$ is the scalar curvature of M along γ, and $\beta_{\gamma}^{\perp}(t) = \dot{\gamma}^{\perp}(t)(\beta)$ is the derivative of β in the direction perpendicular to $\dot{\gamma}(t)$.

[We emphasize that the statements (48) and (49) are valid for any variation, while the last formula is valid only for special variations.]

Proof: Let $P(t) = \chi(t)X + \psi(t)Y$ be the vector of the parameter plane for which $\delta_* P(t) = \dot{\gamma}^{\perp}(t)$ holds. This means, that $\dot{\gamma}^{\perp} = \chi\dot{\gamma} + \psi V_0$, and a simple calculation shows that

$$\chi = -\frac{\langle V_0, \dot{\gamma}\rangle}{\langle V_0, \dot{\gamma}^{\perp}\rangle}, \quad \psi = \frac{1}{\langle V_0, \dot{\gamma}^{\perp}\rangle}. \tag{51}$$

The curvature κ of the horocycles is calculated directly, according to its definition:

$$\widetilde{\nabla}_P \frac{H^{\perp}}{|H^{\perp}|} = -P(|H^{\perp}|)\dot{\gamma}^{\perp} + \widetilde{\nabla}_P H^{\perp}, \tag{52}$$

where the differentiations $P(|H^{\perp}|)$ and $\widetilde{\nabla}_P H^{\perp}$ can be further simplified:

$$P(|H^{\perp}|) = (\chi X + \psi Y)(|H|) = \psi \left.\frac{\partial}{\partial\varepsilon}\right|_{\varepsilon=0} |H| = \psi\langle V_0', \dot{\gamma}\rangle = \psi p, \tag{53}$$

$$\tilde{\nabla}_P H^{\perp} = \Omega(\tilde{\nabla}_P H) = \chi\Omega(\tilde{\nabla}_X \dot{\gamma}) + \psi\Omega(\tilde{\nabla}_Y H) = -\chi\beta_\gamma \dot{\gamma} + \psi\Omega(V_0'). \tag{54}$$

[We have used Eqs. (1), (9), (18), and (19).] Substituting $\Omega(V_0')$ with $\langle V_0', \dot{\gamma}\rangle \dot{\gamma}^{\perp} - \langle V_0', \dot{\gamma}^{\perp}\rangle \dot{\gamma}$ in Eq. (54) and putting the expressions (53) and (54) into Eq. (52), we obtain

$$\tilde{\nabla}_P \frac{H^{\perp}}{|H^{\perp}|} = -(\chi\beta_\gamma + \psi\langle V_0', \dot{\gamma}^{\perp}\rangle)\dot{\gamma}. \tag{55}$$

With the help of this equation, using expressions (51) and Eqs. (22) and (25) for χ,ψ and V_0, V_0', respectively, it is easy to prove assumption (48) of the theorem.

The conjecture (49) describing the jump of the curvature κ at the reflection can be proved by dividing the second equation of (37) with $b_+ = -b_-$.

Differentiating Eq. (48) we get $\kappa' = (b''b - b'^2)/b^2$, from which $b'' = b(\kappa' + \kappa^2)$ follows. Substituting it into the second equation of (23), and using that $p = 0$ for special variations, assumption (50) of the theorem can be also proved.

Q.E.D.

The results of Theorem 10 are in accordance with the earlier results of Bunimovich and Sinai[5,6,8] in the case of $\beta = 0$.

Following a given bunch of trajectories in a billiard system, with the help of the equations (49) and (50) the evolution of the curvature κ of the horocycles can be determined as a function of time, and, according to the connection (48), the integral $\int_0^t \kappa(t)dt = \ln(|b(t)|/|b(0)|)$ gives the logarithm of the transverse stretching. [Due to the second equation of (36), the absolute value of the transverse coordinate is continuous at the bounces.]

VI. CONCLUSIONS

In the present article the behavior of nearby trajectories has been investigated in classical magnetic billiard systems on Riemannian manifolds with a method which is similar to that of Jacobi fields for geodesic flows. The relative motion of two particles moving infinitesimally close to each other is described by the *infinitesimal variation* vector field along one of the trajectories (Definitions 2 and 7). In the bounceless segments the infinitesimal variations of the trajectories satisfy a second-order ordinary differential equation, which is the usual Jacobi equation in the lack of magnetic field (Theorem 4). Restricting our studies to two-dimensional systems, differential equations describing the transverse as well as the longitudinal behavior of nearby trajectories have been derived (Theorem 5). The transverse behavior depends on the (Gaussian) curvature of the manifold, on the value of the magnetic field, and its derivative in transverse direction. The positive curvature and the presence of the magnetic field suppress chaos.

The bouncing effects have been also investigated in two-dimensional billiards, and a formula describing the jump of the infinitesimal variation and its derivative at the reflections has been given (Theorem 8). These jumps depend not only on the curvature of the wall and on the angle of incidence, but also on the value of the magnetic field at the bouncing point. The magnetic field can even change the focusing or defocusing character of the wall.

We have expressed the curvature κ of the curves perpendicular to a bunch of trajectories (*horocycles*, Definition 9) in terms of the infinitesimal variation. It has been shown that in the bounceless segments κ obeys a first-order differential equation containing the (Gaussian) curvature of the manifold, the magnetic field, and its derivative in transverse direction, and at the reflections κ has a definite jump depending on the curvature of the wall, the angle of incidence, and the value of the magnetic field (Theorem 10). In the lack of magnetic field our results are in accordance with the known properties of κ.

After finishing this work the author was informed that another paper[14] is being published on partially similar topics on two-dimensional Euclidean surface. The author of Ref. 14 has also obtained Eq. (49) of theorem 10 describing the jump of the curvature κ of the horocycles at reflections in presence of magnetic field, and he has given the bounceless evolution of κ in

homogeneous magnetic field. [It is the solution of Eq. (50) in the special case of $r=\beta_\gamma^\perp=0$.] Furthermore, Ref. 14 contains nice applications for the evaluation of the Lyapunov exponent in different magnetic billiard systems.

APPENDIX A: VECTOR FIELDS ALONG DIFFERENTIABLE MAPPINGS

In this Appendix the basic properties of the *vector fields along differentiable mappings* are summarized.

Definition 11: Let $f:N\to M$ be a smooth mapping. A differentiable mapping $X:N\to T(M)$ is a (differentiable) *vector field along* f, if $\pi_M\circ X=f$ holds. The set of vector fields along f is denoted by $\mathscr{T}_f$.

The most common examples for this concept are $f_*U\in\mathscr{T}_f$ and $V\circ f\in\mathscr{T}_f$, where $U\in\mathscr{T}(N)$, $V\in\mathscr{T}(M)$. For vector fields along f essentially the same calculus can be developed as for those on M. A covariant derivation $\nabla:\mathscr{T}(M)\times\mathscr{T}(M)\to\mathscr{T}(M)$ of M can be naturally extended to one $\tilde{\nabla}:\mathscr{T}(N)\times\mathscr{T}_f\to\mathscr{T}_f$ on $\mathscr{T}_f$, so it is reasonable to derivate an element of $\mathscr{T}_f$ with respect to a vector field on N. If δ is regular at the point $n\in N$, then for every $P\in T_n(N)$ and $U\in\mathscr{T}(N)$

$$\tilde{\nabla}_P\delta_*U=\nabla_{(\delta_*)_nP}V, \tag{A1}$$

where $V\in\mathscr{T}(M)$ is an arbitrary vector field on M, for which $V\circ\delta=\delta_*U$ holds in an open neighborhood of $n\in N$. The derivation $\tilde{\nabla}$ satisfies the usual algebraic axioms [$\mathscr{F}(N)$-linearity in its first and Leibnitz rule in its second argument], and for the torsion tensor T and curvature tensor R of M it is also valid that

$$(f^*T)(X,Y)=T(f_*X,f_*Y)=\tilde{\nabla}_Xf_*Y-\tilde{\nabla}_Yf_*X-f_*[X,Y], \tag{A2}$$

$$R(f_*X,f_*Y)Z=\tilde{\nabla}_X\tilde{\nabla}_YZ-\tilde{\nabla}_Y\tilde{\nabla}_XZ-\tilde{\nabla}_{[X,Y]}Z, \tag{A3}$$

where $X,Y\in\mathscr{T}(N)$ and $Z\in\mathscr{T}_f$. The detailed proofs of these properties can be found in Ref. 19.

APPENDIX B: THE PSEUDOSPHERE MODEL AND SOME PROPERTIES OF THE HYPERBOLIC PLANE

In this Appendix the pseudosphere model of the hyperbolic plane is introduced, and using it in a series of lemmas with short proofs or references the basic properties of the isometries and the cycles of the Bolyai–Lobatchewski plane are summarized.

Let $(\mathbf{V},\langle\cdot,\cdot\rangle)$ be an oriented, arrow-oriented three-dimensional vector space with an indefinite scalar product $\langle\cdot,\cdot\rangle$ of signature $(-,+,+)$ on it. For the sake of simplicity we use the attributes introduced in the theory of special relativity (spacelike, lightlike, timelike, future/past oriented) for characterizing the vectors and hyperplanes of $\mathbf{V}$. Let $S\subset\mathbf{V}$ be the set of future-oriented timelike unit vectors.

Lemma 12: S is a two-dimensional, oriented, noncompact, simply connected embedded submanifold of $\mathbf{V}$, which inherits a (positive definite) Riemannian metrics from $\mathbf{V}$. Equipped with this Riemannian structure (denoted also by $\langle\cdot,\cdot\rangle$), S is diffeomorphic with the hyperbolic plane.

The inherited metrics is positive definite because of the fact that the tangent plane $T_x(S)$ at any point $x\in S$ is just the spacelike affine hyperplane through x orthogonal to the vector $x\in\mathbf{V}$. It is also easy to show that S is homogeneous and isotropic (see Lemma 14), so it has constant curvature. The detailed proof of Lemma 12 can be found in Ref. 10.

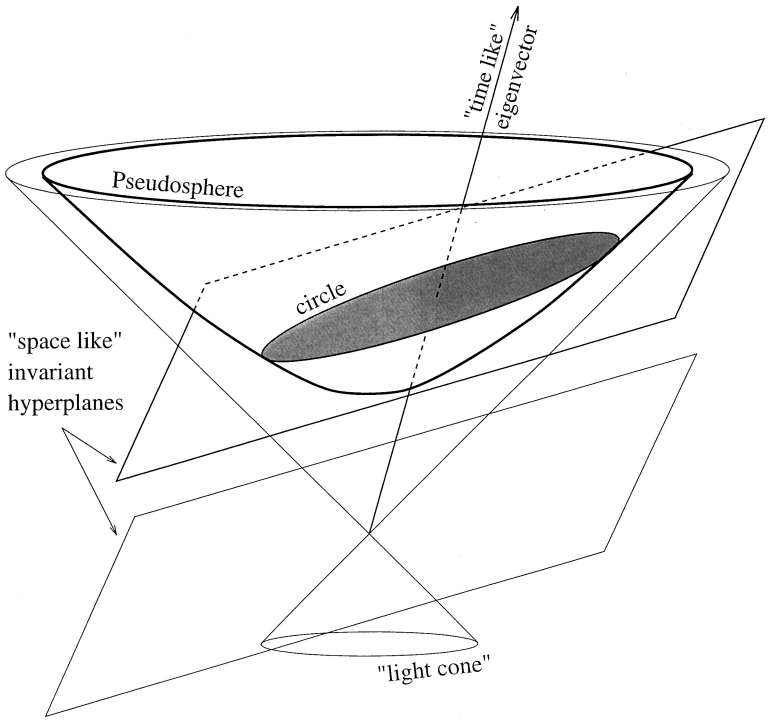

FIG. 5. The elliptic isometries.

Definition 13: The set S equipped with its inherited Riemannian structure is called the *pseudosphere*.

The following lemma gives a survey of the isometries of the hyperbolic plane using the pseudosphere model.

Lemma 14: Every arrow-orientation-preserving $\langle\cdot,\cdot\rangle$-orthogonal transformation of $\mathbf{V}$ leaves S fixed, and induces and isometry on the pseudosphere S. Conversely, every isometry of S can be uniquely extended to an arrow-orientation-preserving orthogonal transformation of $\mathbf{V}$. An isometry of S is orientation-preserving if and only if it is induced by an orientation-preserving orthogonal transformation of $\mathbf{V}$.

Every orientation and arrow-orientation-preserving transformation $\mathbf{O}$ of $\mathbf{V}$ which is not the identity can be put into one of the following three classes:

(i) The characteristic equation of $\mathbf{O}$ has three different roots; one of them is 1, which belongs to a timelike eigenvector, and the other two eigenvalues are complex numbers of unit absolute values conjugate to each other. The (spacelike) affine hyperplanes perpendicular to the timelike eigenspace are invariant under the effect of $\mathbf{O}$. (The effect of $\mathbf{O}$ is simply a rotation in the invariant planes around the timelike eigenvector.) The isometries of the hyperbolic plane induced by this kind of orthogonal transformations are called *elliptic isometries (rotations)*. The elliptic isometries have one fixed point (the center of the rotation), which is the intersection of S and the timelike eigenspace of $\mathbf{O}$. The rotations having the same center form a one-parameter subgroup of the isometry group of S. (See Fig. 5.)

(ii) The characteristic equation of $\mathbf{O}$ has three different real roots; one of them is 1, which belongs to a spacelike eigenvector, the other two real eigenvalues are reciprocal to each other, and the corresponding eigenvectors are lightlike vectors perpendicular to the spacelike eigenspace. The (timelike) affine hyperplanes perpendicular to the spacelike eigenvec-

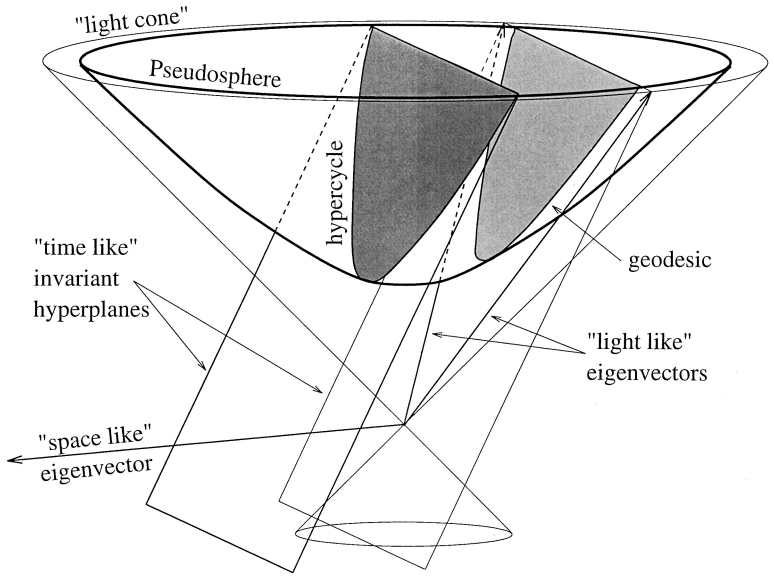

FIG. 6. The hyperbolic isometries.

tor are invariant under the transformation **O**. (This transformation is similar to the Lorentz boosts in the theory of special relativity.) The isometries of the hyperbolic plane induced by this kind of orthogonal transformations are called *hyperbolic isometries (translations)*. The hyperbolic isometries do not have fixed points, but they have a (not pointwise) fixed line, which is the intersection of S and the hyperplane spanned by the two lightlike eigenspaces. The translations having the same invariant line form a one-parameter subgroup of the isometry group of S. (See Fig. 6.)

(iii) The 1 is a three times degenerate root of the characteristic equation of **O**. **O** has only one lightlike eigenspace, and the (lightlike) hyperplanes orthogonal to it are invariant under the transformation. (In the invariant plane the effect of **O** is a shearing along the lightlike eigenvector.) The isometries of the hyperbolic plane induced by this kind of orthogonal transformations are called *parabolic isometries*. The parabolic isometries have neither fixed points nor invariant lines, but they have a fixed ideal point lying ''infinitely far'' in the direction of the lightlike eigenvector of the transformation. (This means that for every line directed towards this ideal point, the transformed image of the line also tends to this point.) The parabolic transformations having the same ideal point (or the same lightlike eigenvector) form a one-parameter subgroup of the isometry group of S. (See Fig. 7.)

The statements of this lemma can be proved step by step using standard linear algebraic methods.

It follows from Lemma 14 that for every pair of unit tangent vectors of the pseudosphere S there exists exactly one isometry of S, which transforms the first vector into the second vector. This means that the hyperbolic plane is homogeneous and isotropic, and its isometry group is a three-dimensional Lie group.

Now let us overview the properties of the most important curves (called the *cycles*) of the hyperbolic plane on the pseudosphere model.

Definition 15: The set of points lying at a distance $r>0$ from a fixed point o of the hyperbolic plane is called the *circle* of center o and radius r. The set of points lying at a distance $d\geqslant 0$ from a fixed geodesic line γ; on one side of γ is called the hypercycle of base line γ and altitude d. (Specially the geodesic lines are hypercycles of altitude zero.) A curve perpendicular to a bunch of

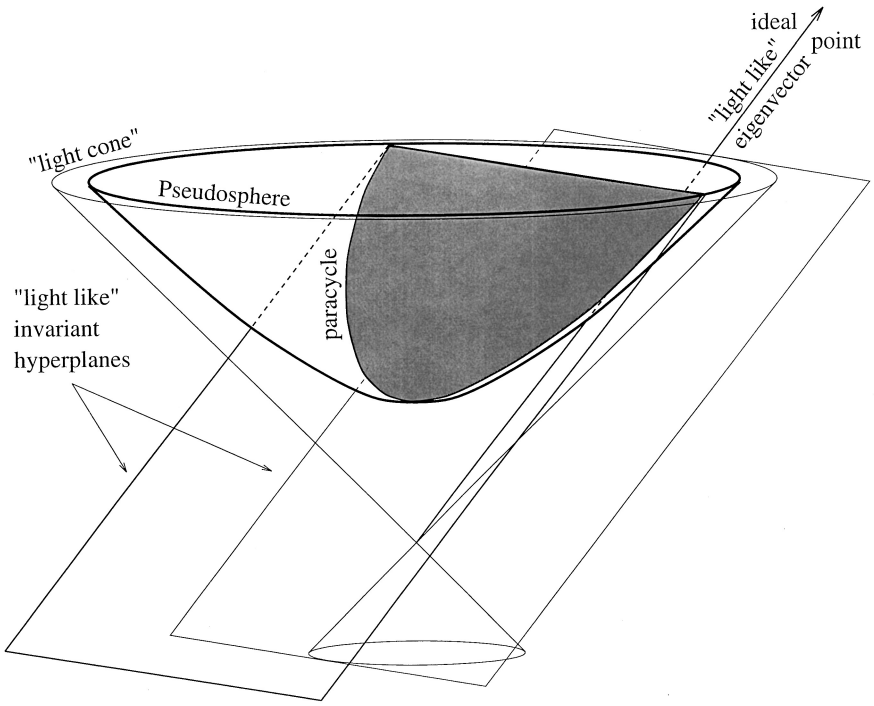

FIG. 7. The parabolic isometries.

geodesic lines tending towards the same ideal point in one direction is called *paracycle* (or sometimes *horocycle*). The circles, hypercycles, and paracycles together are named *cycles*.

Definition 16: A curve γ on a Riemannian manifold M is said to be *translatable along itself*, if there exists a one parameter subgroup of the isometry group of M, every element of which transforms the curve onto itself.

Lemma 17: Every cycle of the hyperbolic plane can be translated along itself. For circles, this translation is realized by a one-parameter subgroup of elliptic isometries, for hypercycles by hyperbolic isometries, and the subgroups of parabolic isometries translate the paracycles along themselves. [In other words, the circles (resp. the hypercycles, paracycles) are the orbits of the action of one-parameter subgroups of elliptic (resp. hyperbolic, parabolic) isometries.] Every cycle is a curve of constant curvature, a circle of radius r has curvature $\coth(r)$, a horocycle of altitude d has curvature $\tanh(d)$, and the curvature of the paracycles is 1. On the contrary, every (unextendable) curve of the hyperbolic plane, which has constant curvature, or which is translatable along itself, is a cycle.

On the pseudosphere model of the hyperbolic plane the cycles are exactly the sections of S with affine hyperplanes of $\mathbf{V}$. The intersections of hyperplanes containing the origin of $\mathbf{V}$ give the geodesic lines, the timelike affine hyperplanes intersect the pseudosphere in hypercycles, the lightlike affine hyperplanes in paracycles, and the intersections of S with spacelike affine hyperplanes are the circles. (See Figs. 5–7.)

It follows immediately from Definition 15 and lemma 14 that the cycles are translatable curves along themselves, and for the three different types of cycles the translations are realized by different types of isometries as stated in the lemma. It also means that the curvature of the cycles is constant, and a direct calculation using elementary techniques gives its value. It is also easy to show the converse of the first two statements. The assertion in the second paragraph of the lemma can be proved with the help of Lemma 14. For every cycle there is a one-parameter isometry

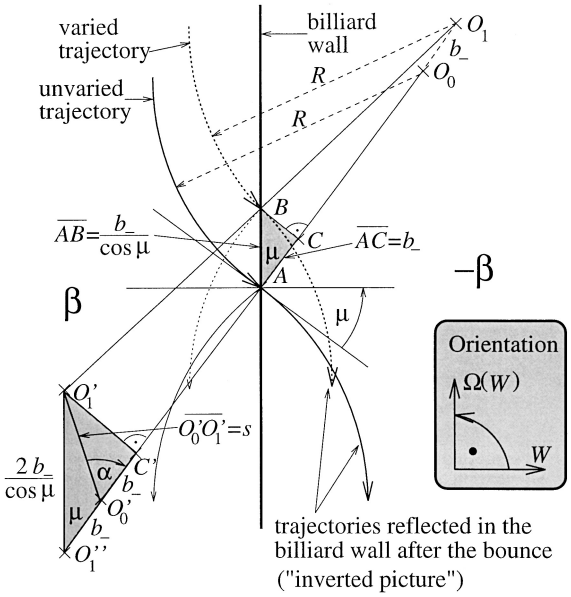

FIG. 8. The ''inverted picture'' of the bouncing trajectories for straight billiard wall.

subgroup of S, which transforms the cycle along itself. According to Lemma 14, there is a family of affine hyperplanes parallel to each other in $\mathbf{V}$, which are invariant under the one-parameter isometry subgroup. The investigated cycle is the intersection of S and one of these invariant affine planes.

APPENDIX C: ELEMENTARY ILLUSTRATION OF THE BOUNCING EFFECT

In this Appendix we give an elementary demonstration of the equations (36) and (37) describing the jump of the infinitesimal variation and its first derivative at the bounce in a special case, where the derivative of the transverse infinitesimal variation b' and the curvature q of the billiard wall are zero at the reflection point. Since the curvature of the manifold M does not play any role in the bouncing effects, it is assumed furthermore that $(M,\langle\cdot,\cdot\rangle)$ is the Euclidean plane. For the sake of simplicity, we deal only with special variations.

It is better to work in an ''*inverted picture,*'' i.e., reflect the trajectories after the bounce in the wall of the billiard. In this case the billiard wall can be considered as the boundary between two domains of opposite magnetic field, which the particles cross without changing their velocities (Fig. 8). It can be also seen that the infinitesimal variation is everywhere continuous in the inverted picture.

Let us use the usual notations $a_-, b_- \in \mathfrak{R}$ and $a'_-, b'_- \in \mathfrak{R}$ (introduced in Sec. IV) for describing the coordinates of the (special) infinitesimal variation and their derivatives just before the bounce, respectively. For distinguishing the coordinates (and their derivatives) in the inverted picture from the ordinary ones after the bounce, we use a tilde above the letters. Since the reflection in the billiard wall changes the orientation of the plane, the transverse coordinate changes sign in the inverted picture, but the longitudinal one remains unaltered, i.e.,

$$a_+ = \tilde{a}_+, \quad a'_+ = \tilde{a}'_+, \quad b_+ = -\tilde{b}_+, \quad b'_+ = -\tilde{b}'_+. \tag{C1}$$

As the infinitesimal variation is continuous in the inverted picture, $a_- = \tilde{a}_+$, $b_- = \tilde{b}_+$, and this together with (C1) proves Eqs. (36).

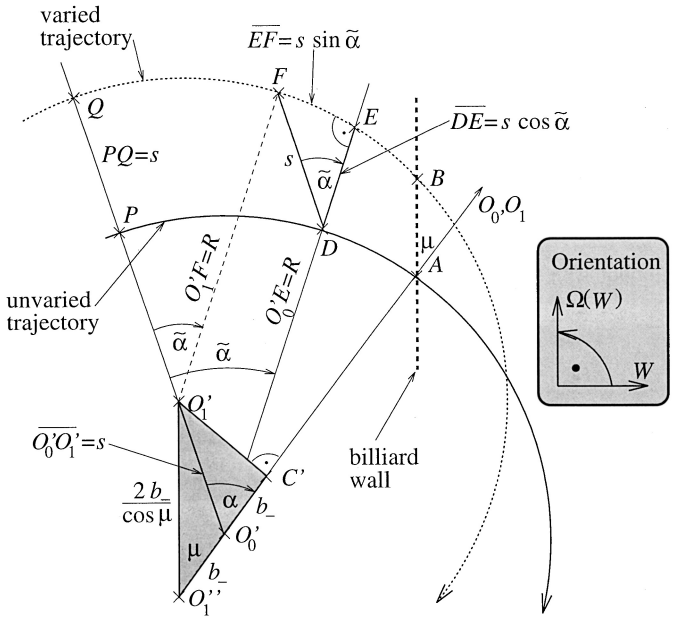

FIG. 9. The trajectories after the bounce in the ''inverted picture.''

To prove the equations (37) in the special case of $b'_- = q = 0$, let us consider the two infinitesimally close trajectories of unit speed in Fig. 8, where $0<\mu<\pi/2$ is the angle of reflection, $\beta>0$ is the magnetic field, and $R=1/\beta$ is the radius of the trajectories. Since $b'_- = 0$, the centers O_0, O_1 of the incident trajectories and the reflection point A of the unvaried trajectory are collinear, and $\overline{O_0O_1} = b_- > 0$. The centers O_0', O_1' of the trajectories after the bounce (in the inverted picture) are obtained by reflecting the centers O_0, O_1 of the incident trajectories in the bouncing points A,B, respectively. Let O_1'' be the central inverse image of O_1 in the point A, and let C, resp. C' be the foot of the perpendicular dropped from the points B, resp. O_1', to meet the line O_0O_0'. The triangles ABC and $O_1''O_1'C'$ are similar in the ratio of 2. Further on we assume that the variation is small, i.e., the angle $\angle BO_1A \ll 1$ or equivalently $b_- \ll R\cot(\mu)$. This means that the angle of incidence of the varied trajectory is also (approximately) μ, and $\overline{AC} \approx \overline{C'O_0'} \approx b_- = \overline{O_0O_1} = \overline{O_0'O_1''}$.

It can be seen in Fig. 8 that $\overline{AB} \approx b_-/\cos(\mu)$, so $\overline{O_1'O_1''} \approx 2b_-/\cos(\mu)$, and the angle $\angle O_0'O_1''O_1' = \mu$. Let us denote the angle $\angle O_1'O_0'O_0$ with α (directed in the way shown in Figs. 8 and 9), and let $s := \overline{O_0'O_1'}$ (Fig. 9). Applying the sine rule to the triangle $O_0'O_1'O_1''$,

$$s\,\sin(\alpha) = \sin(\mu)\,\frac{2b_-}{\cos(\mu)}. \tag{C2}$$

In order to determine the derivatives $\tilde{a}'_+, \tilde{b}'_+$ of the coordinates of the (special) infinitesimal variation just after the bounce (in the inverted picture), let us consider two particles starting from the points P,Q and moving along the trajectories shown in Fig. 9 at unit speed. (The points P, Q, O_0', and O_1' are collinear.) After the time $R\tilde{\alpha}$, where $\tilde{\alpha} = \angle QO_1'F = \angle PO_0'D$ is the angle of the arcs covered, the particles are at the points D, F, and the longitudinal, resp. transverse, distance between them are $\tilde{a}_+(\tilde{\alpha}) = -\overline{EF} = -s\,\sin(\tilde{\alpha})$, resp. $\tilde{b}_+(\tilde{\alpha}) = \overline{DE} = s\,\cos(\tilde{\alpha})$. (Since the variation is small, DEF is a right triangle.) Differentiating these expressions with respect to time (i.e., with respect to $R\tilde{\alpha}$) at $\tilde{\alpha}=\alpha$,

$$\tilde{a}'_+ = \frac{d}{d(R\tilde{\alpha})}\bigg|_\alpha (-s\,\sin(\tilde{\alpha})) = -s\beta\,\cos(\alpha) = -\beta\overline{O'_0C'} = -\beta b_-\,, \tag{C3}$$

$$\tilde{b}'_+ = \frac{d}{d(R\tilde{\alpha})}\bigg|_\alpha (s\,\cos(\tilde{\alpha})) = -s\beta\,\sin(\alpha) = -\beta\,\sin(\mu)\,\frac{2b_-}{\cos(\mu)}. \tag{C4}$$

[The right triangle $O'_0C'O'_1$ shows that $s\,\cos(\alpha)=b_-$, and we used expression (C2) in Eq. (C4).]

Inserting the connections (C1) into Eqs. (C3) and (C4), and using the fact that for special variations $a'_\pm = \beta b_\pm$ [see the first equation of (23) in Theorem 5, with $p=0$], it is easy to obtain Eqs. (37) in the special case of $b'_- = q = 0$.

(Received 6 September 1995; accepted for publication 19 June 1996)

The problem of exact integration of the Einstein–Dirac equation is studied. To solve this set of equations metrics admitting complete separation of variables in the Dirac equation are considered. At the first stage Stäckel spaces of types (3.1) and (3.0) are studied. For the first case obtained solutions contain arbitrary functions depending on one variable only (five real functions for the Einstein–Weyl equations and four real functions for the Einstein–Dirac ones). For the second one all solutions belonging to the diagonal metrics of Bianchi type 1 are found. © *1996 American Institute of Physics.* [S0022-2488(96)02909-X]

I. INTRODUCTION

Exact integration of the Einstein–Dirac equations is one of the complicated problems in the modern mathematical physics. As far as we know at this writing only few exact solutions of these equations have been found (see, for example Refs. 1, 2 and references therein). Our approach is based on using metrics of the space-times for which the Dirac equation can be integrated by complete separation of variables method. Many authors studied these metrics (see Refs. 3–9). In the papers, metrics admitting Yano–Killing tensors or Yano vectors were studied. Using these geometrical objects one can construct symmetry operators of the Dirac equation. These spaces have been found in Ref. 10. Other trend was investigate in Ref. 11 where all spaces for which the Dirac equations can be integrated by diagonalization and separation of variables have been found. In the paper[12] it was proved that if the Dirac equation admits complete separation of variables the Hamilton–Jacobi equation can be integrated by complete separation of variables in the same coordinate set too. In other words, spaces for which Dirac equation can be separated belong to the class of Stäckel spaces (Riemannian space is called the Stäckel one if in this space the Hamilton–Jacobi equation can be integrated by the complete separation of variables[13,14]). Recall the main states of the theory of Stäckel spaces (see Refs. 14–16). Let g_{ij} be a metric tensor of the Riemannian space V_n. The Hamilton–Jacobi equation

$$g^{ij}S_{,i}S_{,j}=m^2 \tag{1.1}$$

admits complete separation of variables if coordinate set $\{u^i\}$ exists for which the complete integral can be presented in the form:

$$S=\sum_{i=1}^{n} S_i(u^i,\lambda_1,\ldots,\lambda_n). \tag{1.2}$$

It was proved that the separation takes place if and only if the metric tensor g_{ij} can be put in the form

$$g_{ij}=\sum_{\nu=N}^{n} (\Phi^{-1})^{\nu}_{n} h^{ij}_{\nu}(u^{\nu}), \tag{1.3}$$

$$\Phi^{\mu}_{\nu}=\Phi^{\mu}_{\nu}(u^{\nu}), \quad h^{ij}_{\nu}=\delta^i_{\nu}\delta^j_{\nu}h^{\nu\nu}_{\nu}+(\delta^i_{\nu}\delta^j_{p}+\delta^i_{p}\delta^j_{\nu})h^{ij}_{\nu}+\delta^i_{p}\delta^j_{q}h^{pq}_{\nu},$$

$$p,q=1,\ldots N, \quad \nu,\mu=N+1,\ldots,n.$$

One can verify, that V_n admits mutually commuting Killing vectors and tensors:

$$Y^i_p=\delta^i_p, \quad Y^{ij}_\nu=\sum_{\nu=N}^{n}(\Phi^{-1})^\mu_\nu h^{ij}_\mu. \tag{1.4}$$

These geometrical objects form a so called compete set. Next designations are adopted in the theory. Riemannian space is called the Stäckel one of type (N,N_0) if the metric tensor can be presented in the form (1.3). N is the number of the Killing vectors entering into the complete set,

$$N_0=N-\mathrm{rank}|g_{ij}Y^i_pY^j_q|. \tag{1.5}$$

If V_n has the Lorentz signature $(+,-,-,-)$, number N_0 may take a value of 0 or 1. Hence there are seven types of Stäckel spaces with signature $(+,-,-,-)$: four non-null types (N,0) and three null types (N,1).

According to the definition the Dirac equation

$$(\gamma^i(x)\hat{D}_i-m)\Psi=0 \tag{1.6}$$

can be integrated by complete separation of variables if any Ψ may be present in the separated form:

$$\Psi=\hat{S}(u)\hat{\varphi}_0(u^0,\lambda),\hat{\varphi}_1(u^1,\lambda),\hat{\varphi}_2(u^2,\lambda),\hat{\varphi}_3(u^3,\lambda). \tag{1.7}$$

Here

$$\det\hat{S}(u)\neq 0, \quad [\hat{\varphi}_i,\hat{\varphi}_j]=0.$$

(The analogous definition takes place for the squared Dirac equation.[11,12] Another approach to the problem of separation of variables for the Dirac equation has been studied in Ref. 17.) In Ref. 3 it was proved that the existence of Yano vectors or Yano–Killing tensors is the necessary condition of the separation. Moreover, g_{ij} must have the form (1.3). (The space belongs to the Stäckel one.) In Ref. 10 it was found that only spaces $(2,N_0)$ can admit Yano vectors or Yano–Killing tensors. Hence only six types of spaces for which Ψ can be present in the form (1.7) exist. There are two types $(3,N_0)$ and four types $(2,N_0)$ (two types with Yano vector and two types with Yano–Killing tensor) satisfying these conditions. Thus all appropriate metrics are known now and it is possible to consider the problem of integration of the Einstein–Dirac equations for the case when the Dirac equation can be integrated by complete separation of variables. We try to solve the problem of the complete classification of the Einstein–Dirac spaces for which the Dirac equation admits complete separation of variables. Note that a similar problem has been solved for the case when gravitational field interacts with a vector one (Einstein–Maxwell equation[18–20]). Therefore the problem of classification for the interacting spinor and gravitational fields can be regarded as a part of the general classification problem. We begin our investigation from the spaces of types (3,1) and (3,0). (For the last type we restrict ourselves to the case when the metric has Bianchi type I form.) Other types will be considered in the next papers. Moreover, at the first stage it is possible to suppose that solutions of the Dirac equation have separate forms.

II. FIELD EQUATIONS

In the present section we restrict our attention to the case when the space-time has a form of Stäckel space of type (3.1). The Metric tensor for this case has a form:

$$g^{\mu\nu}=g^{\nu\mu}(x^0), \quad g^{00}=0, \quad \nu,\mu=0,1,2,3.$$

Obviously the space admits three Killing vectors $Y_p{}^i$. To write Einstein–Dirac equations one has to use Newman–Penrose formalism.[21,22] Let us introduce the complex tetrad in the form

$$\begin{gathered} l^i=(1,0,0,0), \ \ n^i=(0,1,\beta_2,\beta_3), \quad m^i=(0,0,v,u) \\ l_i=(0,1,0,0), \quad n_i=(1,0,0,0), \\ m_i=(0,i(\beta_3 u-\beta_2 v)/G,-iu/G,iv/G)), \\ G\equiv i(u\overline{v}-\overline{u}v), \quad \overline{\beta_2}=\beta_2, \quad \overline{\beta_3}=\beta_3. \end{gathered} \tag{2.1}$$

All functions depend on x^0 only, bar means complex conjugation. From (2.1) it follows

$$D=\partial_0, \quad \Delta=\partial_1+\beta_2\partial_2+\beta_3\partial_3, \quad \delta=v\partial_2+u\partial_3 (\partial_i\equiv\partial/\partial x^i), \tag{2.2}$$

$$\begin{gathered} \kappa=\lambda=\nu=\mu=0, \quad \alpha=i(\dot{\beta}_3\overline{v}-\dot{\beta}_2\overline{u})/4G, \quad 2\overline{\beta}=\overline{\tau}=\overline{\lambda}=2\alpha, \\ \sigma=i(\dot{v}u-\dot{u}v)/G, \quad \rho=i(\mathring{v}u-\mathring{u}v+\dot{u}\overline{v}-\dot{v}\overline{u})/2G=\dot{G}/2G, \\ \varepsilon=i(\mathring{u}v-\mathring{v}u+\dot{u}\overline{v}-\dot{v}\overline{u})/4G. \end{gathered} \tag{2.3}$$

Dots mean derivatives with respect to the variable x^0. Using (2.2) and (2.3) one can find spinor components of the Weyl tensor

$$\begin{gathered} \psi_0=\dot{\sigma}-\sigma(2\rho+4\varepsilon), \quad \psi_1=\mathring{\alpha}-(\rho+2\varepsilon)\overline{\alpha}-3\sigma\alpha, \\ 3\psi_2=-16\alpha\overline{\alpha}, \quad \psi_3=\psi_4=0, \end{gathered} \tag{2.4}$$

and spinor components of the Ricci tensor

$$\begin{gathered} \Phi_{00}=\dot{\rho}-\rho^2-\sigma\overline{\sigma}, \quad \Phi_{01}=\dot{\overline{\alpha}}-(3\rho+2\varepsilon)\overline{\alpha}-\sigma\alpha, \\ \Phi_{11}=-6\alpha\overline{\alpha}, \quad \Phi_{02}=-4\alpha^2, \quad 3\Lambda=2\alpha\overline{\alpha}, \quad \Phi_{12}=\Phi_{22}=0. \end{gathered} \tag{2.5}$$

In this formalism the Einstein–Dirac equations have the form

$$\Phi_{\alpha\beta'\gamma\delta'}+\varepsilon_{\alpha\gamma}\varepsilon_{\beta'\delta'}H=aT_{\alpha\beta'\gamma\delta'}, \tag{2.6}$$

$$\nabla_{\alpha\beta'}\xi^{\alpha}=m_0\eta_{\beta'}, \quad \nabla_{\alpha'\beta}\eta^{\alpha'}=m_0\xi_{\beta}. \tag{2.7}$$

Here $m_0=m/\sqrt{2}$, m is the mass of a spinor particle, $\Phi_{00'00'}=\Phi_{00}$, $\Phi_{00'01'}=\Phi_{01}$, $\Phi_{01'01'}=\Phi_{02}$, $\Phi_{01'11'}=\Phi_{12}$, $\Phi_{11'11'}=\Phi_{22}$, $\Phi_{00'11'}=2(\Phi_{11}-3\Lambda)$, $\Phi_{01'10'}=-2(\Phi_{11}+3\Lambda)$, $\xi_{\alpha'}=\overline{\xi_{\alpha}}$, $\alpha,\beta,\gamma,\delta=0,1$, H is the cosmological constant, $a=$const, and $T_{\alpha\beta'\gamma\delta'}$ is the stress-energy tensor of the particle with spin 1/2. It has the form

$$T_{\alpha\beta'\gamma\delta'}=ik[T(\xi)_{\alpha\beta'\gamma\delta'}-T(\eta)_{\alpha\beta'\gamma\delta'}], \tag{2.8}$$

$$T(\varphi)_{\alpha\beta'\gamma\delta'}=\varphi_{\delta'}\nabla_{\alpha\beta'}\varphi_{\gamma}+\varphi_{\beta}\nabla_{\gamma\delta'}\varphi_{\alpha}-\varphi_{\alpha}\nabla_{\alpha\beta'}\varphi_{\delta'}-\varphi_{\alpha}\nabla_{\gamma\delta'}\varphi_{\beta'}. \tag{2.9}$$

Here

$$\nabla_{00'}\varphi_0=D\varphi_0-\varepsilon\varphi_0+\kappa\varphi_1, \quad \nabla_{00'}\varphi_1=D\varphi_1-\pi\varphi_0+\varepsilon\varphi_1,$$

$$\nabla_{01'}\varphi_0=\delta\varphi_0-\beta\varphi_0+\sigma\varphi_1,\quad \nabla_{01'}\varphi_1=\delta\varphi_1-\mu\varphi_0+\beta\varphi_1,$$
$$\nabla_{10'}\varphi_0=\overline{\delta}\varphi_0-\alpha\varphi_0+\rho\varphi_1,\quad \nabla_{10'}\varphi_1=\overline{\delta}\varphi_1-\lambda\varphi_0+\alpha\varphi_1, \tag{2.10}$$
$$\nabla_{11'}\varphi_0=\Delta\varphi_0-\gamma\varphi_0+\tau\varphi_1,\quad \nabla_{11'}\varphi_1=\Delta\varphi_1-\nu\varphi_0+\gamma\varphi_1,$$
$$\nabla_{\alpha\beta'}\varphi_{\gamma'}=\overline{(\nabla_{\beta\alpha'}\varphi_{\gamma})}.$$

For the Einstein–Weyl case $m=\eta_\alpha=0$. Using (2.10) one can find function $T(\varphi)_{\alpha\beta'\gamma\delta'}$:

$$T(\varphi)_{00'00'}=\varphi_{0'}D\varphi_0-\varphi_0D\varphi_{0'}-(\varepsilon-\overline{\varepsilon})\varphi_0\varphi_{0'}+\kappa\varphi_{0'}\varphi_1-\overline{\kappa}\varphi_0\varphi_{1'},$$
$$2T(\varphi)_{00'01'}=\varphi_{1'}D\varphi_0-\varphi_0D\varphi_{1'}+\varphi_{0'}\delta\varphi_0-\varphi_0\delta\varphi_{0'}+\varphi_0\varphi_{0'}(\overline{\alpha}-\beta+\overline{\pi})$$
$$+\kappa\varphi_1\varphi_{1'}-(\varepsilon+\overline{\varepsilon}+\overline{\rho})\varphi_0\varphi_{1'}+\sigma\varphi_{0'}\varphi_1,$$
$$T(\varphi)_{01'01'}=\varphi_{1'}\delta\varphi_0-\varphi_0\delta\varphi_{1'}+\sigma\varphi_1\varphi_{1'}+\overline{\lambda}\varphi_0\varphi_{0'}-(\beta+\overline{\alpha})\varphi_0\varphi_{1'},$$
$$2T(\varphi)_{01'11'}=\varphi_{1'}\delta\varphi_1-\varphi_1\delta\varphi_{1'}+\varphi_{1'}\Delta\varphi_0-\varphi_0\Delta\varphi_{1'}+\overline{\nu}\varphi_0\varphi_{0'}$$
$$+(\beta-\overline{\alpha}+\tau)\varphi_1\varphi_{1'}-(\overline{\gamma}+\gamma+\mu)\varphi_0\varphi_{1'}+\overline{\lambda}\varphi_1\varphi_{0'},$$
$$T(\varphi)_{11'11'}=\varphi_{1'}\Delta\varphi_1-\varphi_1\Delta\varphi_{1'}+(\gamma-\overline{\gamma})\varphi_1\varphi_{1'}-\nu\varphi_0\varphi_{1'}+\overline{\nu}\varphi_1\varphi_{0'},$$
$$2T(\varphi)_{00'11'}=\varphi_{1'}D\varphi_1-\varphi_1D\varphi_{1'}+\varphi_{0'}\Delta\varphi_0-\varphi_0\Delta\varphi_{0'}+(\varepsilon-\overline{\varepsilon})\varphi_1\varphi_{1'}$$
$$+(\overline{\gamma}-\gamma)\varphi_0\varphi_{0'}-(\overline{\tau}+\pi)\varphi_0\varphi_{1'}+(\tau+\overline{\pi})\varphi_1\varphi_{0'},$$
$$2T(\varphi)_{01'10'}=\varphi_{0'}\delta\varphi_1-\varphi_0\overline{\delta}\varphi_{1'}+\varphi_{1'}\overline{\delta}\varphi_0-\varphi_1\delta\varphi_{0'}+(\overline{\mu}-\mu)\varphi_0\varphi_{0'}$$
$$+(\rho-\overline{\rho})\varphi_1\varphi_{1'}+(\beta+\overline{\alpha})\varphi_{0'}\varphi_1-(\alpha+\overline{\beta})\varphi_0\varphi_{1'}.$$

Let us transform tetrad (2.1) in the following manner:

$$\widetilde{l}\to l,\quad \widetilde{n}\to n,\quad \widetilde{m}\to m\ \exp i\theta(x^0). \tag{2.11}$$

Then

$$\widetilde{\alpha}\to\alpha\ \exp-i\theta,\quad \widetilde{\beta}\to\beta\ \exp i\theta,\quad \widetilde{\tau}\to\tau\ \exp i\theta,\quad \widetilde{\pi}\to\pi\ \exp-i\theta. \tag{2.12}$$

Other spin coefficients do not transform. If function θ will be chosen in the form

$$2\theta=-i\ \ln(\alpha/\overline{\alpha})$$

coefficients α,β,τ,π become real functions

$$\overline{\alpha}=\alpha=\beta=\tau/2=\pi/2. \tag{2.13}$$

Then Einstein–Dirac equations can be present in the form

$$(D+\varepsilon-\rho)\xi_1-(\overline{\delta}+\alpha)\xi_0=m_0\eta_{0'},\quad (\delta-\alpha)\xi_1-\Delta\xi_0=m_0\eta_{1'},$$
$$(D-\varepsilon-\rho)\eta_{1'}-(\delta+\alpha)\eta_{0'}=m_0\xi_0,\quad (\overline{\delta}-\alpha)\eta_{1'}-\Delta\eta_{0'}=m_0\xi_1; \tag{2.14}$$

$$\xi_{1'}\Delta\xi_1-\xi_1\Delta\xi_{1'}-\eta_{1'}\Delta\eta_1+\eta_1\Delta\eta_{1'}=0; \tag{2.15}$$

$$\xi_{1'}\delta\xi_1-\xi_1\delta\xi_{1'}+\xi_{1'}\Delta\xi_0-\xi_0\Delta\xi_{1'}+2\alpha\xi_1\xi_{1'}$$
$$-[\eta_{1'}\delta\eta_1-\eta_1\delta\eta_{1'}+\eta_{1'}\Delta\eta_0-\eta_0\Delta\eta_{1'}+2\alpha\eta_1\eta_{1'}]=0; \tag{2.16}$$

$$iak[\xi_{1'}D\xi_0-\xi_0D\xi_{1'}+\xi_{0'}\delta\xi_0-\xi_0\delta\xi_{0'}+2\alpha\xi_0\xi_{0'}-\rho\xi_0\xi_{1'}+\sigma\xi_{0'}\xi_1-\eta_{1'}D\eta_0+\eta_0D\eta_{1'}$$
$$-\eta_{0'}\delta\eta_0+\eta_0\delta\eta_{0'}-2\alpha\eta_0\eta_{0'}+\rho\eta_0\eta_{1'}-\sigma\eta_{0'}\eta_1]=4[\alpha(3\rho+2\varepsilon+\sigma)-\dot{\alpha}]; \tag{2.17}$$

$$ika\{\xi_1[(D+\varepsilon-\rho)\xi_1-(\overline{\delta}+\alpha)\xi_0]-\xi_1[(D-\varepsilon-\rho)\xi_{1'}-(\delta+\alpha)\xi_{0'}]+\xi_{0'}[\Delta\xi_0-(\delta-\alpha)\xi_1]$$
$$-\xi_0[\Delta\xi_{0'}-(\overline{\delta}-\alpha)\xi_{1'}]-\eta_{1'}[(D-\varepsilon-\rho)\eta_1-(\overline{\delta}+\alpha)\eta_0]+\eta_1[(D-\varepsilon-\rho)\eta_{1'}$$
$$-(\delta+\alpha)\eta_{0'}]-\eta_{0'}[\Delta\eta_0-(\delta-\alpha)\eta_1]+\eta_0[\Delta\eta_{0'}-(\overline{\delta}-\alpha)\eta_{1'}]\}=16\alpha^2-4H; \tag{2.18}$$

$$ika[\xi_{0'}\delta\xi_1-\xi_0\overline{\delta\xi}_{1'}-\xi_{1'}\overline{\delta\xi}_0-\xi_1\delta\xi_{0'}+2\alpha(\xi_{0'}\xi_1-\xi_0\xi_{1'})-\eta_{0'}\delta\eta_1+\eta_0\overline{\delta\eta}_{1'}$$
$$-\eta_{1'}\overline{\delta\eta}_0+\eta_1\delta\eta_{0'}-2\alpha(\eta_{0'}\eta_1-\eta_0\eta_{1'})]=-32\alpha^2+2H. \tag{2.19}$$

Separated solutions of Eqs. (2.13) have the form

$$\xi_a=\varphi_a\ \exp\ i(\lambda_1x^1+\lambda_2x^2+\lambda_3x^3),\quad \eta_a=\psi_a\ \exp-i(\lambda_1x^1+\lambda_2x^2+\lambda_3x^3),$$
$$\varphi_a=\varphi_a(x^0),\quad \psi_a=\psi_a(x^0),\quad \lambda_1,\lambda_2,\lambda_3=\text{const}. \tag{2.20}$$

One can show that Eqs. (2.6) are compatible if and only if $\lambda_p=0$. That is why we shall suppose that

$$\xi_\alpha=\xi_\alpha(x^0),\quad \eta_\alpha=\eta_\alpha(x^0). \tag{2.21}$$

III. EINSTEIN–WEYL EQUATIONS

First we consider the case when $m=\eta_a=0$. Then Eqs. (2.6) and (2.7) have the form

$$ika[\xi_{0'}\dot{\xi}_0-\xi_0\dot{\xi}_{0'}-2\varepsilon\xi_0\xi_{0'}]=-2(\dot{\rho}-\rho^2-\sigma\overline{\sigma}); \tag{3.1}$$

$$\xi_{1'}\dot{\xi}_0-\xi_0\dot{\xi}_{1'}-\rho\xi_0\xi_{1'}+\sigma\xi_{0'}\xi_1=0; \tag{3.2}$$

$$\sigma\xi_1\xi_{1'}=0; \tag{3.3}$$

$$H=0; \tag{3.4}$$

$$\dot{\xi}_1=(\rho-\varepsilon)\xi_1+\alpha\xi_0; \tag{3.5}$$

$$\alpha\xi_1=0. \tag{3.6}$$

From Eqs. (3.5) and (3.6) it follows that $\alpha=0$. If function $\xi_1\neq 0$ from Eq. (3.4) it follows $\sigma=0$. Using Eqs. (3.2) and (3.5) one can show that

$$\xi_{0'}\dot{\xi}_0-\xi_0\dot{\xi}_{0'}-2\varepsilon\xi_0\xi_{0'}=0. \tag{3.7}$$

By this is meant that $T_{\alpha\beta'\gamma\delta'}\equiv 0$. That is why from Eq. (3.4) it follows that $\xi_1=0$. To find ξ_0 one has to solve Eq. (3.1). Let us present ξ_0 in the form

$$\xi_0=X\ \exp\ iY\quad (\overline{X}=X,\ \ \overline{Y}=Y). \tag{3.8}$$

Then Eq. (3.1) can be written in the form

$$akX^2[\dot{Y}+i\varepsilon]=\dot{\rho}-\rho^2-\sigma\overline{\sigma}. \tag{3.9}$$

Obviously $\dot{Y}+i\varepsilon \neq 0$ (otherwise $T_{\alpha\beta'\gamma\delta'}\equiv 0$). Then

$$X=[(\dot{\rho}-\rho^2-\sigma\overline{\sigma})/ak(\dot{Y}+i\varepsilon)]^{1/2}. \tag{3.10}$$

Let us consider condition

$$\alpha=0.$$

From Eq. (2.3) it follows

$$\dot{\beta}_3\overline{v}-\dot{\beta}_2\overline{u}=0\Rightarrow\dot{\beta}_2=\dot{\beta}_3=0\Rightarrow\beta_2,\beta_3=\text{const}.$$

These conditions are equivalent to $\beta_2=\beta_3=0$. Thus obtained solution can be written in the form

$$l^i=(1,0,0,0),\quad n^i=(0,1,0,0),\quad m^i=(0,0,v,u),$$

$$\xi_\alpha=\delta_{\alpha 0}[(\dot{\rho}-\rho^2-\sigma\overline{\sigma})/ak(\dot{Y}+i\varepsilon)]^{1/2}\exp iY,\quad H=0.$$

Here Y,v,u are arbitrary functions depending on X^0 only, $\overline{Y}=Y$. Functions ρ,σ,ε can be found from Eq. (2.3). Note that the obtained metric belongs to Petrov type N.

IV. EINSTEIN–DIRAC EQUATIONS

Using (2.21) one can present Dirac equations in the following form:

$$\begin{aligned}(D+\varepsilon-\rho)\xi_1-\alpha\xi_0&=m_0\eta_{0'},\\ (D-\varepsilon-\rho)\eta_{1'}-\alpha\eta_{0'}&=m_0\xi_0;\end{aligned} \tag{4.1}$$

$$\left.\begin{aligned}\alpha\xi_1+m_0\eta_{1'}&=0,\\ m_0\xi_1+\alpha\eta_{1'}&=0;\end{aligned}\right\}\Rightarrow\alpha=m_0,\quad \eta_{1'}=-\xi_1. \tag{4.2}$$

Let us put (4.2) into (4.1). In result we shall obtain

$$\begin{aligned}(D-\rho)\eta_1=0\Rightarrow\eta_1&=c|G|^{1/2},\quad c=\text{const},\\ \xi_0&=-(\eta_{0'}+\varepsilon\eta_{1'}/m_0).\end{aligned} \tag{4.3}$$

From Eqs. (2.18), (2.19) and (4.3) it follows

$$H=8m_0^2, \tag{4.4}$$

$$ika(\eta_0\eta_{1'}-\eta_1\eta_{0'}-\varepsilon\eta_1\eta_{1'}/m_0)=4m_0. \tag{4.5}$$

Thus cosmological constant H is determined by the mass of a spinor. Other equations have the form

$$\begin{aligned}ika[\eta_1\dot{\eta}_{0'}-\eta_{1'}\dot{\eta}_0+\varepsilon\eta_1\dot{\eta}_{1'}/m_0+\rho(\eta_0\dot{\eta}_{1'}-\eta_1\dot{\eta}_{0'}+(\eta_0\eta_{1'}-\eta_{0'}\eta_1-\varepsilon\eta_1\eta_{1'}/m_0)\\ \times(2\varepsilon+\sigma+\rho)]=4m_0(3\rho+2\varepsilon+\sigma);\end{aligned} \tag{4.6}$$

$$ika[2(\eta_0\dot{\eta}_{0'}-\eta_{0'}\dot{\eta}_0)+(\dot{\varepsilon}+\varepsilon\rho)(\eta_1\eta_{0'}+\eta_0\eta_{1'})/m_0-2\varepsilon^2(\eta_0\eta_{1'}-\eta_{0'}\eta_1-\varepsilon\eta_1\eta_{1'}/m_0)$$
$$-\varepsilon(\eta_1\dot{\eta}_{0'}+\dot{\eta}_0\eta_{1'})/m_0]=-2(\dot{\rho}-\rho^2-\sigma\overline{\sigma}). \tag{4.7}$$

Equation (4.6) is consequent from Eqs. (4.3) and (4.7). Indeed from Eqs. (4.3) and (4.7) it follows

$$\dot{\varepsilon}\eta_1\dot{\eta}_{1'}=m_0[\dot{\eta}_0\eta_{1'}-\dot{\eta}_{0'}\eta_1+\rho(\eta_0\eta_{1'}-\eta_1\eta_{0'})]-2\varepsilon\rho\eta_1\eta_{1'}. \tag{4.8}$$

Using Eq. (4.8) one can present Eq. (4.6) in the form

$$\rho[iak(\eta_0\eta_{1'}-\eta_{0'}\eta_1-\varepsilon\eta_1\eta_{1'}/m_0)-4m_0]=0.$$

The left-hand side of Eq. (4.7) can be transformed in the following way:

$$ik[2(\eta_0\dot{\eta}_{0'}-\eta_{0'}\dot{\eta}_0)+(\dot{\varepsilon}+\varepsilon\rho)(\eta_1\eta_{0'}+\eta_0\eta_{1'})/m_0-\varepsilon(\eta_1\dot{\eta}_{0'}+\dot{\eta}_0\eta_{1'})/m_0]-8\varepsilon^2$$
$$=ika[2(\eta_0\dot{\eta}_{0'}-\eta_{0'}\dot{\eta}_0)+(\eta_1\eta_{0'}+\eta_0\eta_{1'})(\dot{\eta}_0\eta_{1'}-\dot{\eta}_{0'}\eta_1+\rho(\eta_0\eta_{1'}-\eta_1\eta_{0'}))/\eta_1\eta_{1'}$$
$$-2\varepsilon\rho/m_0-\varepsilon(\eta_1\dot{\eta}_{0'}+\dot{\eta}_0\eta_{1'})/m_0+\varepsilon\rho(\eta_1\eta_{0'}+\eta_{1'}\eta_0)/m_0]-8\varepsilon^2$$
$$=4m_0(\eta_1\eta_{0'}+\eta_0\eta_{1'})^{\cdot}/\eta_1\eta_{1'}-8\varepsilon^2.$$

Thus Eq. (4.7) is equivalent to

$$(\eta_0\eta_{1'}+\eta_{0'}\eta_1)^{\cdot}=\eta_1\eta_{1'}(\rho^2-\dot{\rho}+\sigma\overline{\sigma}+4\varepsilon^2)/2m_0. \tag{4.9}$$

Let us present function η_0 in the form

$$\eta_0=\eta_1 X=cXG^{1/2}.$$

Then from Eqs. (4.5) and (4.8) it follows

$$X=\frac{1}{2}\left\{\frac{1}{\eta_1\eta_{1'}}\left[\int(\rho^2+\sigma\overline{\sigma}+4\varepsilon^2-\dot{\rho})\ \frac{\eta_1\eta_{1'}}{2m_0}\ dx^0-\frac{4im_0}{ka}\right]+\frac{\varepsilon}{m_0}\right\}.$$

Here $\eta_1=c|G|^{1/2}$ functions ρ, σ, and ε have the form (2.3). To determine tetrad one has to solve Eq. (4.2):

$$\alpha=(\dot{\beta}_3\overline{v}-\dot{\beta}_2\overline{u})/(u\overline{v}-\overline{u}v)=4m_0. \tag{4.10}$$

From Eq. (4.9) it follows

$$\dot{\beta}_2=4m_0(v+\overline{v}),\quad \dot{\beta}_3=4m_0(u+\overline{u}).$$

Thus

$$v=(\dot{\beta}_2+iq_2)/8m_0,\quad u=(\dot{\beta}_3+iq_3)/8m_0, \tag{4.11}$$

q_2 and q_3 are arbitrary functions depending on x^0.

Let us present obtained solutions in the final form

$$l^i=(1,0,0,0),\quad n^i=(0,1,\beta_2,\beta_3),$$

$$m^i=(1,0,(\dot{\beta}_3+iq_3)/8m_0,(\dot{\beta}_3+iq_3)/8m_0),$$

$$\xi_1=-4m_0\overline{p}(\dot{\beta}_3q_2-\dot{\beta}_2q_3),\quad \eta_1=4m_0p(\dot{\beta}_3q_2-\dot{\beta}_2q_3);$$

$$\xi_0=\frac{-\overline{p}(\dot\beta_3q_2-\dot\beta_2q_3)^{-1/2}}{2}\left\{-(\dot\beta_3q_2-\dot\beta_2q_3)^{\cdot}+2\int\left(\frac{[(\dot\beta_3q_2-\dot\beta_2q_3)^{\cdot}]^2}{\dot\beta_3q_2-\dot\beta_2q_3}+\ddot\beta_2\dot q_3-\ddot\beta_3\dot q_2\right)dx^0\right.$$
$$\left.+i\left[\ddot\beta_3\dot\beta_2-\ddot\beta_2\dot\beta_3+\dot q_3q_2-\dot q_2q_3+\frac{1}{kap\overline{p}}\right]\right\};$$

$$\eta_0=\frac{p(\dot\beta_3q_2-\dot\beta_2q_3)^{-1/2}}{2}\left\{-(\dot\beta_3q_2-\dot\beta_2q_3)^{\cdot}+2\int\left(\frac{[(\dot\beta_3q_2-\dot\beta_2q_3)^{\cdot}]^2}{\dot\beta_3q_2-\dot\beta_2q_3}+\ddot\beta_2\dot q_3-\ddot\beta_3\dot q_2\right)dx^0\right.$$
$$\left.+i\left[\ddot\beta_3\dot\beta_2-\ddot\beta_2\dot\beta_3+\dot q_3q_2-\dot q_2q_3-\frac{1}{kap\overline{p}}\right]\right\}.$$

Here $p=\text{const}$, β_2, β_3, q_2, q_3 are arbitrary functions depending on x^0 only, and $H=8m_0^2=(2m)^3$.

V. BIANCHI TYPE I METRIC

We intend to consider others types of the Stäckel spaces in the next paper. In this paper we consider in addition to the spaces of type (3,1) the special case of the spaces of type (3.0) for which the Killing vectors entering into the complete set are spacelike and non-null. These metrics are known as Bianchi type I. The diagonal metrics of this type has a form:

$$dS^2=dx^{0^2}-\sum_{i=1}^{3}(dx^i\exp\alpha_i)^2,\quad \alpha_i=\alpha_i(x^0).$$

Let us introduce the complex tetrad:

$$l^\alpha=\frac{1}{\sqrt2}(\delta_0^\alpha-\delta_1^\alpha\exp-\alpha_1),\quad l_\alpha=\frac{1}{\sqrt2}(\delta_\alpha^0+\delta_\alpha^1\exp\alpha_1),$$

$$n^\alpha=\frac{1}{\sqrt2}(\delta_0^\alpha+\delta_1^\alpha\exp-\alpha_1),\quad n_\alpha=\frac{1}{\sqrt2}(\delta_\alpha^0-\delta_\alpha^1\exp\alpha_1),\tag{5.1}$$

$$m^\alpha=\frac{1}{\sqrt2}(\delta_2^\alpha\exp-\alpha_2-i\delta_3^\alpha\exp-\alpha_3),\quad m_\alpha=-\frac{1}{\sqrt2}(\delta_\alpha^2\exp\alpha_2-i\delta_\alpha^3\exp\alpha_3).$$

Using (5.1) let us find the spin coefficients the spinor components of the Ricci tensor and the Weyl one,

$$\kappa=\alpha=\beta=\tau=\pi=\nu=0,$$

$$\mu=-\rho=\frac{1}{2\sqrt2}(\dot\alpha_2+\dot\alpha_3),\quad \sigma=-\lambda=\frac{1}{2\sqrt2}(-\dot\alpha_2+\dot\alpha_3),\tag{5.2}$$

$$\varepsilon=-\gamma=\frac{\dot\alpha_1}{2\sqrt2},$$

$$\Phi_{00}=\Phi_{22}=\frac{1}{4}\,(-\ddot{\alpha}_2-\ddot{\alpha}_3-\dot{\alpha}_2^2-\dot{\alpha}_3^2-\dot{\alpha}_1(\dot{\alpha}_2+\dot{\alpha}_3)),$$

$$\Phi_{01}=\Phi_{21}=0,\quad \Phi_{11}=\frac{1}{4}\,(\dot{\alpha}_2\dot{\alpha}_3-\dot{\alpha}_1^2-\ddot{\alpha}_1), \tag{5.3}$$

$$12\Lambda=\ddot{\alpha}_1+\ddot{\alpha}_2+\ddot{\alpha}_3+\dot{\alpha}_1^2+\dot{\alpha}_2^2+\dot{\alpha}_3^2+\dot{\alpha}_1\dot{\alpha}_2+\dot{\alpha}_1\dot{\alpha}_3+\dot{\alpha}_2\dot{\alpha}_3,$$

$$4\Phi_{02}=\ddot{\alpha}_2-\ddot{\alpha}_3+(\dot{\alpha}_2-\dot{\alpha}_3)(\dot{\alpha}_2+\dot{\alpha}_3+\dot{\alpha}_1),$$

$$\Psi_0=\Psi_4=\frac{1}{4}\,(-\ddot{\alpha}_2+\ddot{\alpha}_3-\dot{\alpha}_2^2+\dot{\alpha}_3^2+\dot{\alpha}_1(\dot{\alpha}_2-\dot{\alpha}_3)),\quad \Psi_1=\Psi_3=0, \tag{5.4}$$

$$6\Psi_2=-\ddot{\alpha}_1-\dot{\alpha}_1^2-\dot{\alpha}_2\dot{\alpha}_3+\frac{1}{2}\,(\ddot{\alpha}_2+\ddot{\alpha}_3+\dot{\alpha}_2^2+\dot{\alpha}_3^2+\dot{\alpha}_1\dot{\alpha}_2+\dot{\alpha}_1\dot{\alpha}_3).$$

One can show that Einstein equations (2.6)–(2.7) are simultaneous only if $\xi_a=\xi_a(x^0)$, $\eta_a=\eta_a(x^0)$. In this case Dirac equation (2.7) will take the form:

$$\dot{\xi}_0=-\frac{(\dot{\alpha}_1+\dot{\alpha}_2+\dot{\alpha}_3)}{2}\,\xi_0-m\eta_{1'},\quad \dot{\eta}_{0'}=-\frac{(\dot{\alpha}_1+\dot{\alpha}_2+\dot{\alpha}_3)}{2}\,\eta_{0'}-m\xi_1$$

$$\dot{\xi}_1=-\frac{(\dot{\alpha}_1-\dot{\alpha}_2+\dot{\alpha}_3)}{2}\,\xi_1+m\eta_{0'},\quad \dot{\eta}_{1'}=-\frac{(\dot{\alpha}_1+\dot{\alpha}_2+\dot{\alpha}_3)}{2}\,\eta_{1'}+m\xi_0. \tag{5.5}$$

Let us denote

$$\xi_a=\varphi_\alpha\,\exp-\frac{\Omega}{2},\quad \eta_{a'}=i\varepsilon_{a'b'}\chi^{b'}\,\exp-\frac{\Omega}{2}.$$

Using (5.5) one can find that φ_a,χ_a have the form

$$\varphi_a=p_a\,\exp imx^0+q_a\,\exp-imx^0,\quad \chi^{a'}=p_a\,\exp imx^0+q_a\,\exp-imx^0,$$

$$p_a,q_a=\text{const},\quad p_{a'}=\overline{p_a},\quad \overline{q_{a'}}=q_a. \tag{5.6}$$

Let us enumerate all components of the tensor $T_{ab'cd'}$:

$$T_{00'11'}=T_{11'11'}=T_{00'00'}, \tag{5.7}$$

$$T_{00'00'}=\frac{ikm_0}{\sqrt{2}}\,(\xi_0\eta_1-\xi_{0'}\eta_{1'}+\eta_{0'}\xi_{1'}-\eta_0\xi_1),$$

$$T_{01'01'}=\frac{ik}{2\sqrt{2}}\,(-\dot{\alpha}_2+\dot{\alpha}_3)(\xi_1\xi_{1'}-\xi_0\xi_{0'}-\eta_1\eta_{1'}+\eta_0\eta_{0'}), \tag{5.8}$$

$$T_{00'01'}=T_{01'11'}=T_{01'10'}=0.$$

Now Einstein equations can be present in the equivalent form

$$\ddot{\alpha}_p+\dot{\alpha}_p^2-\dot{\alpha}_s\dot{\alpha}_q=c\,\exp-\Omega,\quad (p,q,s\neq),$$

$$\dot{\alpha}_1\dot{\alpha}_2+\dot{\alpha}_1\dot{\alpha}_3+\dot{\alpha}_2\dot{\alpha}_3=-H-c\ \exp-\Omega, \tag{5.9}$$

$$p,q,s\neq 1,2,3 c=\sqrt{2}m_0 a k(q_0 q_{0'}+q_1 q_{1'}-p_0 p_{0'}-p_1 p_{1'}),$$

$$\begin{aligned}(\dot{\alpha}_1-\dot{\alpha}_2)(p_0p_{1'}+q_0q_{1'}+p_{0'}p_1+q_{0'}q_1)&=(\dot{\alpha}_1-\dot{\alpha}_3)(p_0p_{1'}+q_0q_{1'}+p_{0'}p_1+q_{0'}q_1)\\&=(\dot{\alpha}_2-\dot{\alpha}_3)(p_0p_{0'}+q_0q_{0'}+p_{1'}p_1+q_{1'}q_1)=0.\end{aligned} \tag{5.10}$$

Equations (5.9) can be integrated:

$$\begin{aligned}\alpha_p&=-\frac{1}{3}\left[\varepsilon b_p\int\ \frac{\exp\ \Omega d\Omega}{\sqrt{l^2\ \exp 2\Omega-3H-3c\ \exp\ \Omega}}+\Omega\right],\\ \varepsilon x^0&=\int\ \frac{d\Omega}{\sqrt{l^2\ \exp 2\Omega-3H-3c\ \exp\ \Omega}}.\\ b_1&=l_1+l_2, b_2=l_3-2l_2,\quad b_3=l_2-2l_3,\\ l_q&=\text{const},\quad \varepsilon=\pm 1,\quad l^2=l_2^2+l_3^2-l_2l_3.\end{aligned} \tag{5.11}$$

One can show that the conditions (5.10) lead to the next variants

$$\text{I.}\ \ \alpha_1=\alpha_2=\alpha_3\Rightarrow l_p=0,\quad \text{II.}\ \ \alpha_2=\alpha_3\Rightarrow l_2=l_3=l.$$

Let us enumerate all obtained solutions:

$$\xi_a=\varphi_a Q^{1/3},\quad \eta_{a'}=i\varepsilon_{a'b'}\chi^{b'}Q^{1/3}$$

$[\phi_a,\chi^b$ have the form (5.6)]

$$\text{I.}\ \ dS^2=dx^{0^2}-Q^{2/3}[dx^{1^2}+dx^{2^2}+dx^{3^2}],$$

$$(1)\ \ H=0,\quad c<0,\quad Q=\frac{3|c|}{4}\ x^{0^2}, \tag{5.12}$$

$$(2)\ \ H<0,\quad c>0,\quad Q=|\frac{c}{H}|\mathrm{ch}^2\left(\frac{\sqrt{3|H|}}{2}\ x^{0^2}\right), \tag{5.13}$$

$$(3)\ \ H>0,\quad c<0,\quad Q=|\frac{c}{H}|\sin^2\left(\frac{\sqrt{3|H|}}{2}\ x^{0^2}\right), \tag{5.14}$$

$$\text{II.}\ \ dS^2=dx^{0^2}-Q^{2/3}[W^{-4/3}dx^{1^2}+W^{2/3}(dx^{2^2}+dx^{3^2})],\quad c=\xi|c|,\quad \xi^2=1,$$

$$(1)\quad H=0\quad Q=\frac{3c}{4}\left(\frac{4l^2}{9c^2}-x^{0^2}\right),\quad W=\frac{2l/3c+x^0}{2l/3c-x^0}, \tag{5.16}$$

$$(2)\quad H<0,\quad y^2=-1-\frac{4Hl^2}{3c^2},\quad Q=\frac{\xi|c|}{2H}\ (\xi-y\ \mathrm{sh}\ \sqrt{3|H|}x^0), \tag{5.17}$$

$$W=\frac{\xi y+\mathrm{sh}(\sqrt{3|H|}x^0)+(2l\sqrt{3|H|}/3c)\ \mathrm{ch}\ \sqrt{3|H|}x^0}{\xi-y\ \mathrm{sh}\ \sqrt{3|H|}x^0},$$

$$(3)\quad H<0,\quad y^2=1+\frac{4Hl^2}{3c^2},\quad Q=-\frac{\xi c}{2H}\ (y\ \mathrm{ch}(\sqrt{3|H|}x^0)-\xi), \tag{5.18}$$

$$W=\frac{-\xi y+\mathrm{ch}(\sqrt{3|H|}x^0)+(2l\sqrt{3|H|}/3c)\ \mathrm{sh}\ \sqrt{3|H|}x^0}{\xi-y\ \mathrm{ch}\ \sqrt{3|H|}x^0},$$

$$(4)\quad H>0,\quad y^2=1+\frac{4Hl^2}{3c^2},\quad Q=\frac{\xi c}{2H}\ (y\ \cos(\sqrt{3|H|}x^0)-\xi), \tag{5.19}$$

$$W=\frac{\xi y-\cos(\sqrt{3/|H|}x^0)+(2l\sqrt{3|H|}/3c)\ \sin\ \sqrt{3|H|}x^0}{\xi-y\ \cos\sqrt{3|H|}x^0}.$$

VI. CONCLUSION

(1) One can show that if for solutions obtained in Sec. III and IV spinor fields will be directed to zero $\xi_a, \eta_a \to 0$ the metrics take the form

$$dS^2=2dx^0x^1-g_{pq}(x^0)dx^pdx^q,\quad p,q=2,3. \tag{6.1}$$

Moreover $R_{\alpha\beta}=0$. It is known that such metrics describe a gravitational plain wave. Thus the obtained solution can be interpreted as plain gravitational wave interacting with a spinor field. As functions determining metric tensor are arbitrary one can find solutions with or without singularity. Solutions with neutrinos belong to Petrov type N. They can be regarded as a model of interacting plain gravitational and plain neutrino waves.

Solutions with massive spinor belong to Petrov type II (or D). Nevertheless they can be regarded as a plain wave too. All functions in this case depend on x^0 only. Let us transform the coordinate set in the following manner

$$x^0=u^0-u^1,\quad x^1=u^0+u^1,\quad x^2=u^2,\quad x^3=u^3.$$

Then all functions will depend on (u^0-u^1) only. In these coordinates $T_{00}>0$ and (u^0-u^1) have the same sense as for the electromagnetic wave in the flat space-time.

(2) Bianchi type I case. The spaces of this type for the general case describe the heterogeneous cosmological model. (Note that case when cosmological constant equals to zero was considered in).[23] They can be regarded as a generalization of the Kasner solutions. All of them have the

singular points. Apparently pulsating solution (5.19) is the same. It has infinitely large number of the repeating singular points. Let us calculate components $T_{\alpha\beta}$ for all obtained solutions

$$T_{00}=\frac{ikm}{\sqrt{2}}\,\frac{(q_0q_{0'}+q_1q_{1'}-p_0p_{0'}-p_1p_{1'})}{\exp(\alpha_1+\alpha_2+\alpha_3)}=\frac{c}{2G}\,\exp 2\Omega,$$

$$T_{0i}=T_{ij}=0,\quad i,j=1,2,3.$$

If $c>0$ T_{00} and energy are positive. Note in conclusion that (5.12)–(5.15) belong to the class of the conformally flat spaces, solutions (5.16)–(5.19) to Petrov type D ones.

Topology changing processes in the WKB approximation of four dimensional quantum cosmology with a negative cosmological constant are investigated. As Riemannian manifolds, which describe quantum tunnelings of space–time, constant negative curvature solutions of the Einstein equation, i.e., hyperbolic geometries are considered. Using four dimensional polytopes, one can explicitly construct hyperbolic manifolds with topologically nontrivial boundaries which describe topology changes. These instantonlike solutions are constructed out of 8-cells, 16-cells, or 24-cells and have several points at infinity called cusps. The hyperbolic manifolds are noncompact because of the cusps but have finite volumes. Topology change amplitudes in the WKB approximation in terms of the volumes of these manifolds are evaluated and it was found that the more complicated the topology changes, the more likely are suppressed. © *1996 American Institute of Physics.* [S0022-2488(96)04409-X]

I. INTRODUCTION

In classical gravity the topology change of the universe can be considered only in the case where a normally assumed principle like causality is violated.[1] In quantum gravity, on the other hand, topology changing processes are rather ubiquitous. For example, topology changes can happen in the birth of the universe, in the evaporation of a black hole, and so on. Moreover, the topology changes, if possible by any mechanism either in classical or quantum gravity, may induce important physical effects.

Recently there have been new progress in the investigation of topology changes. In $(2+1)$-dimensional simplified models, the topology changes have been demonstrated to happen indeed by some explicit examples. In three dimensional space–times with a negative cosmological constant, two kinds of topology changes have been investigated. The first one was associated with the existence of a compactified three dimensional black hole solution (or a higher genus universe with a negative cosmological constant). One of present authors (M.S.) showed that its analytical continuation around the coordinate singularity of the space–time may provide a process of topology change.[2] The second one was in the context of quantum cosmology. Siino *et al.*[3] constructed topology changing solutions by quantum tunneling. To discuss more physical topology changes these works should be generalized to four dimensional space–times. The former will be generalized to the $(3+1)$-dimensional compact hyperbolic cosmology.[4] The purpose of the present article is the generalization of the latter. That is to say, we investigate quantum topology changes in a cosmological model through tunneling processes in four dimensions.

According to Gibbons and Hartle,[5] a quantum tunneling space–time is semiclassically ap-

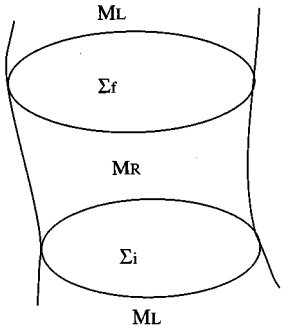

FIG. 1. A manifold with a Euclidean signature M_R interpolates the two manifolds with a Lorentz signature M_L through $\Sigma_{i,f}$.

proximated by a Riemannian manifold with totally geodesic boundaries. In Ref. 3, the authors found some constantly curved Riemannian manifolds with topologically nontrivial, totally geodesic boundaries. If such a manifold has two connected pieces of boundary components with different topologies, it describes a process of topology change between the two Lorentzian space–times connected on the boundaries. Such 3-manifolds were constructed out of regular truncated polyhedra embedded in a hyperbolic 3-space. In the present article, we discuss the topology change of the universe along the same line but in four dimensions. The four dimensional analog of polyhedra is called polytope and we shall construct four dimensional Riemannian manifolds by four dimensional regular truncated polytopes embedded in a hyperbolic 4-space.[6] The resultant manifolds describe topology change of a vacuum universe with a negative cosmological constant.

In Sec. II we briefly review quantum tunnelings of space–times in general, and give a mathematical preliminary for hyperbolic space and quotient manifolds. Section III gives topology changing solutions in four dimensional space–times of a constant negative curvature. We investigate their amplitudes and discuss the strong rigidity of the tunneling manifolds in Sec. IV. Section V is devoted to summary and discussions.

II. QUANTUM TUNNELING OF SPACE–TIMES AND HYPERBOLIC MANIFOLDS

A. Quantum tunneling of space–times: Formalism

In the context of quantum cosmology, a quantum tunneling should be described by Riemannian path integral formalism proposed by Hartle and Hawking.[7] We would like to appeal to the WKB approximation to compute tunneling amplitudes, since exact computations are almost hopeless in four dimensions. In this case, a quantum tunneling means a transition (classically forbidden) from a spatial hypersurface Σ_i to another spatial hypersurface Σ_f. By topology change of space–time it is meant that Σ_f is topologically different from Σ_i. These hypersurfaces may consist of some disconnected components.

Gibbons and Hartle[5] showed that, in the WKB approximation, the tunneling process is described by a Riemannian manifold which has the boundary components Σ_i and Σ_f. In the ADM formalism, a spatial hypersurface Σ is characterized by a spatial metric h_{ij} and an extrinsic curvature K_{ij} on it. In a semiclassical picture, an ordinary space–time manifold M_L with a Lorentzian signature (Lorentzian manifold) and a quantum tunneling manifold M_R with a Euclidean signature (Riemannian manifold) are connected on the hypersurface Σ (see Fig. 1). The spatial metric h_{ij} can be uniquely defined from the viewpoints of both regions, because it is independent of the time coordinates. However, the hypersurfaces connecting M_L and M_R cannot be arbitrarily chosen. Now we work out the condition the connecting hypersurfaces should satisfy. By a lapse function N and a shift vector N^i, the extrinsic curvature of Σ is defined as

$$K_{ij}=-\frac{1}{2N}\left(\frac{\partial h_{ij}}{\partial \tau}-D_{(i}N_{j)}\right), \tag{1}$$

in the Riemannian manifold, where τ is the time coordinate in this region, and it is defined as

$$K_{ij}=-\frac{1}{2N}\left(\frac{\partial h_{ij}}{\partial t}-D_{(i}N_{j)}\right), \tag{2}$$

in the Lorentzian manifold, where t is the time coordinate in this region. In these definitions, D_i is the covariant derivative with respect to h_{ij}. Since the time τ in M_R is analytically continued to the time t in M_L as $\tau=it$ at Σ, the analytical continuation of geometrical variables, h_{ij} and K_{ij}, requires vanishing K_{ij} and N_i at Σ. Hereafter the boundary hypersurfaces with vanishing extrinsic curvature will be called totally geodesic boundaries. Then on the connecting hypersurface, it must be totally geodesic.

For the sake of cosmological interest and simplicity, in the present article, we consider a vacuum space–time with a cosmological constant. If we further assume vanishing Weyl curvature, the space–time has a geometry with constant curvature. Thus the Riemannian tunneling manifold M_R becomes locally isometric to one of the following cases, S^4 (4-sphere), R^4 (4-plane), or H^4 (4-hyperboloid). In Ref. 5, however, it was proved that if a 4-manifold has two pieces of disconnected boundaries Σ_i and Σ_f, the space–time should violate the energy condition at some points. The energy condition states

$$R_{\mu\nu}V^{\mu}V^{\nu}>0 \tag{3}$$

for all vector V^{μ}. Therefore, we can exclude S^4 from our considerations of topology changing manifolds because the curvature of it is positive definite.

From the Gauss–Codazzi equation, the vanishing extrinsic curvature makes Σ_i and Σ_f also have constant curvatures (locally isometric to S^3, R^3, or H^3) if the 4-manifold has a constant curvature. To consider topology changes we need a variety of topologies. The Riemannian manifold locally isometric to R^4 does not satisfy this requirement because the topology of Σ is too restricted (see Ref. 8). On the other hand, since the variety of hyperbolic 3-manifolds (Riemannian manifolds locally isometric to H^3) is very rich, we will consider the Riemannian manifolds which are locally isometric to H^4. A vacuum space–time with a negative cosmological constant can serve our purpose. Then the main question we want to answer is: Can we construct a hyperbolic 4-manifold with totally geodesic boundaries Σ_i and Σ_f which have different topologies?

Mathematically, hyperbolic 4-manifolds are quotient manifolds of a 4-hyperboloid H^4 by discrete subgroups of its isometry group SO(4,1). The fundamental region of this quotient 4-manifold is a 4-polytope (four dimensional objects bounded by a collection of polyhedra) embedded into H^4. Intuitively, a quotient manifold means taking some copies of the fundamental regions with their faces identified pairwisely. If we need a 4-manifold with boundaries, some of the 3-faces of the fundamental regions should remain unidentified which form the 3-boundaries of the 4-manifold. Previously, some $(2+1)$-dimensional analog of this have been discussed.[3] Although it is more complicated in four dimensions, by similar procedures, we can determine the fundamental region and then the identifications of its 3-faces in hyperbolic geometry.[6]

B. Hyperbolic geometry and the Klein model

To give a hyperbolic, structure of four dimensional polytopes we embed them into H^4. In our constructions, we use an n-dimensional Klein model (projective model)[6] as the model of hyperbolic geometry. The n-Klein model is a model on an open n-disk

$$D^n=\{x^i\in R^n | x^i x_i<1\}, \tag{4}$$

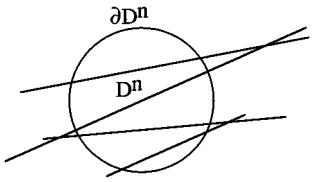

FIG. 2. A two dimensional example. There are some lines not intersecting each other inside the Klein model D^n. They are parallel lines and intersect outside the sphere at infinity ∂D^n.

in which a metric is

$$ds^2=\frac{1}{1-r^2}\left(\frac{dr^2}{1-r^2}+r^2d\Omega_{n-1}^2\right). \tag{5}$$

As r goes to 1, one approaches a sphere at infinity ∂D^n. This metric gives a constant sectional curvature -1 and has a hyperbolic structure. Then this Klein model is isometric to the spatial hypersurface of the well-known n-dimensional open-universe ($k=-1$).

Here, we briefly review the important properties of this model. First, it is easy to find that all totally geodesic (extrinsic curvature vanishing) $m(<n)$-hypersurfaces are m-planes in this model. Then we can construct totally geodesic boundaries by connecting such m-planes. For example, if $m=n-1$, the m-planes bound a polytope. We know that each m-plane can be identified with another by the isometry SO(n,1) of H^n. By these identifications we shall construct quotient manifolds. A more important property arises when we consider ideal points outside the sphere at infinity ∂D^n. As depicted in Fig. 2, most of ''parallel'' $(n-1)$-planes, which do not intersect each other inside the Klein model D^n but intersect outside the sphere at infinity ∂D^n. For our purpose we consider situations in which some $(n-1)$-planes share only one point ''a'' outside the sphere at infinity. The $(n-1)$-planes form a pyramid with the vertex a. There ought to exist a special cone which is tangent to the sphere at infinity. There exists an (n-1)-plane which intersects the cone at the tangent points (exemplified in Fig. 3). The virtue of the Klein model is that this $(n-1)$-plane is orthogonal to all of the planes forming the pyramid.

These facts facilitate our procedure of construction of tunneling manifolds. As an example, we show a simple case of a 2-Klein model of H^2. In Fig. 4, two regular triangles are drawn in the 2-Klein model so that each vertex protrudes from D^2. As mentioned above, we can draw dotted lines which are orthogonal to the edges of the triangle and truncate off the vertices along these dotted lines. We call such a truncation a regular truncation. Gluing the triangles so that the labeled

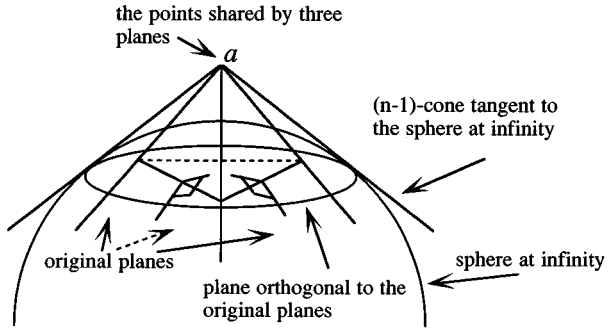

FIG. 3. Three planes share the point a outside the sphere. The cone with the vertex a, is tangent to the sphere at infinity. Then the plane through the tangent points is perpendicular to the three planes.

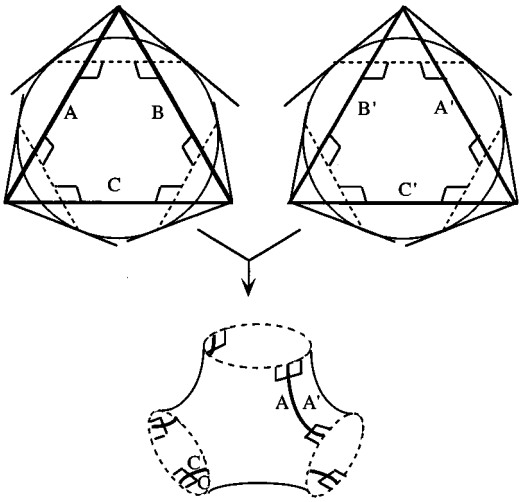

FIG. 4. Two hexagons made by regular truncations of triangles are glued. The resultant space is one of the simplest topology changing manifolds.

edges match each other, we get a hyperbolic manifold with three S^1 boundaries. Since the lines composing the boundaries are geodesic and orthogonal to the edges of the regular triangle, the boundaries become smooth totally geodesic S^1.[9]

Finally, we should remark upon the relation between the size of an object bounded by planes and the angles between these planes. In the hyperbolic geometry, if we enlarge the size of the object, the angles decrease. When the size approaches zero, the angles become the same values in Euclidean geometry. An angle on the sphere at infinity ∂D^n vanishes. We have no well-defined angle outside the sphere at infinity ∂D^n.

C. Four dimensional polytopes

First we prepare regular truncated 4-polytopes in the 4-Klein model of hyperbolic 4-space H^4. Regular 4-polytopes are 5-cell, 8-cell, 16-cell, 24-cell, 120-cell, and 600-cell.[10] For example, ''5-cell'' means that there are five congruent polyhedra which bound the 4-polytope. We shall consider large polytopes in the 4-Klein model in the following sense:

(1) All the vertices are outside of the sphere at infinity.
(2) Each edge of polytopes has intersection with the sphere at infinity.

The above conditions guarantee that a single ideal vertex shared by 3-planes which are cells (polyhedra) bounding the polytope can be regularly truncated off. As a generalization of the discussion in the last subsection, to a vertex, there is a unique 3-plane which is perpendicular to the polyhedra bounding the polytope. Also as mentioned in the previous subsection, the dicellular angle (the angle between two adjacent polyhedra in a 4 dimensional space) decreases as the size of the polytope increases in the hyperbolic geometry. To produce a regular and smooth structure after gluing of polytopes, we choose the size of the polytope to make dicellular angles become $2\pi/n$ (n is an integer). Then the size of the polytopes are restricted further to some discrete values. From a geometrical calculation we can find the allowed dicellular angles of the polytopes. The allowed polytopes are shown in Table I.

The first column gives the names of polytopes and the second column the polyhedra which bound the polytope. Allowed dicellular angles are shown in the third column. The fourth column shows polyhedra produced by regular truncations. The solid angles of these polyhedra at their

TABLE I. The first column is the name of polytopes, which are bounded by the polyhedra on the second column. The third column gives possible dicellular angles. After regular truncation, there appear new polyhedra shown in the fourth column whose vertices have a solid angle on the fifth column.

Polytope	Bounding polyhedra	Dicellular angle	Polyhedra made by truncation	Solid angle around the vertices
5-cell	5 tetrahedra	$\pi/3$	5 tetrahedra	0
8-cell	8 hexahedra	$\pi/3$	16 tetrahedra	0
16-cell	16 tetrahedra	$\pi/2$	8 octahedra	0
24-cell	24 octahedra	$2\pi/5$	24 hexahedra	$4\pi/20$
	24 octahedra	$\pi/3$	24 hexahedra	0
120-cell	120 dodecahedra	$\pi/3$	600 tetrahedra	0
600-cell	600 tetrahedra	$2\pi/3$	120 icosahedra	$4\pi/12$

vertices are in the fifth column. Here, it should be noted that the edges of the polytope are tangent to the sphere at infinity except for the cases of a 24-cell with a dicellular angle $2\pi/5$ and a 600-cell with a dicellular angle $2\pi/3$. Therefore, in most situations, vertices made by the truncation are on the sphere at infinity. (This aspect is reflected in the fifth column since the vertices at infinity have vanishing solid angles.) In these cases, the truncated polytopes are of course noncompact (exemplified for the case of 8-cell in the next section). Calculating the volume, however, in the next section, we find that their volumes are finite. In the present article, we only consider these noncompact cases. By allowing the points at infinity, the construction of the tunneling manifold becomes much easier. Because a constructed object is required to be a manifold, we should consider completeness of the construction which gives a restriction at every vertex generally. However, in the special cases with vertices on the sphere at infinity, these restrictions do not exist.

In the next section we shall demonstrate some examples of constructions of Riemannian manifolds which describe topology changing processes. One of such Riemannian manifolds is constructed from 12 8-cells which are 4-polytopes bounded by eight congruent hexahedra. The development of such an 8-cell on 3-space is shown in Fig. 5. Gluing faces in four dimensions according to the arrows in Fig. 5, we get a 4-dimensional polytope bounded by these eight hexahedra, which has 16 vertices.

III. RIEMANNIAN MANIFOLDS WITH TOTALLY GEODESIC BOUNDARIES

A. Construction from an 8-cell

We can adjust the size of the embedded 8-cell so that all the dicellular angles are $\pi/3$. Then we can show that all vertices are located outside the sphere at infinity ∂D^4. This 8-cell satisfies the two conditions given in the previous section. The edges of the 8-cell are coincidentally tangent to

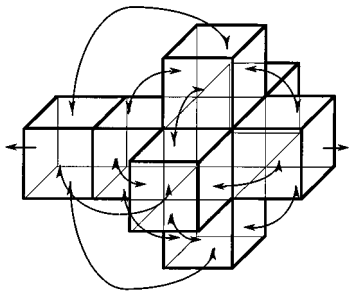

FIG. 5. The development of an 8-cell. Gluing the faces of the hexahedra along the arrows in four dimensions, we get the 8-cell of a 4-dimensional polytope.

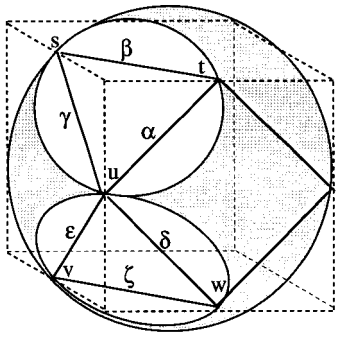

FIG. 6. The shaded sphere is a sphere at infinity in the 3-Klein model. Each edge of the hexahedra is tangent to the sphere at $s,t,u\cdots$. The sphere is cut by planes through $s,t,u\cdots$. Along these planes we truncate the vertices of the hexahedron.

the sphere at infinity. Each hexahedron of the 8-cell is embedded into an induced 3-Klein model (sub-model of the 4-Klein model) as shown in Fig. 6. In this three dimensional figure, all vertices are also outside the sphere at infinity ∂D^3 and all edges are tangent to the sphere.

To get smooth totally geodesic boundary hypersurfaces, we truncate every vertex of the 8-cell in an analogous way as we did in the 2-dimensional example in Sec. II B. Let us pay attention to the four hexahedra having a vertex in common in Fig. 5. The property of the Klein model guarantees the existence of a unique 3-hyperplane which is perpendicular to all of the four hexahedra as mentioned in the previous section. In this way we cut out the regions near the 16 vertices of the 8-cell by these perpendicular 3-hyperplanes to get a regular truncated 8-cell embedded completely in the 4-Klein model. The truncation of 8-cell induces truncation on every hexahedron bounding the 8-cell. The resultant hexahedron is shown in Fig. 6. On each hexahedron the truncation of the vertex of the 8-cell makes a triangle with its vertices on the sphere at infinity ∂D^3. It is noticed that the triangles share vertices with adjacent triangles [for example, the vertex (u) is shared by the two adjacent triangles Δstu and Δuvw in Fig. 6]. In this case, any edge of the original hexahedron can be completely truncated off by the two truncations of the two adjacent vertices connected by the edge (see Fig. 6).

Because four hexahedra share one vertex in an 8-cell (see Fig. 7), each 3-boundary of the

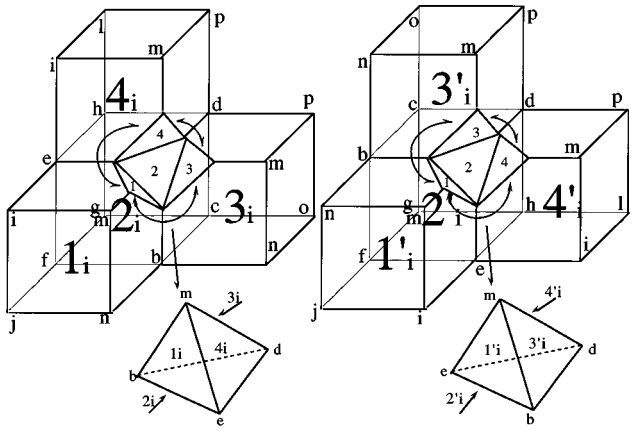

FIG. 7. A part of the 8-cell in Fig. 5. Four hexahedra meet at a vertex. When we truncate the vertex, a tetrahedron appears. We label the faces and the vertices of the tetrahedra at the vertices (a) by the index number of the cell which the face belongs to and the vertices of the 8-cells on the opposite side of (a), respectively.

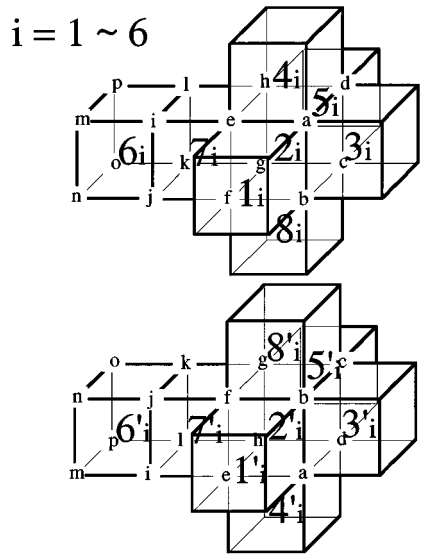

FIG. 8. Two types of 8-cells. Upper ones are left-handed while lower ones (with primes) are right-handed. The corresponding cells with the same number which are primed and unprimed are identified (for example, 1_1 and $1_1'$, 4_1 and $4_3'\cdots$).

8-cell made by the truncation of a vertex is bounded by four triangles. From Fig. 7 we see that the 3-boundary is a tetrahedron whose vertices are on the sphere at infinity. (To the cases of other 4-polytopes, see the fourth column of the Table I). Since each tetrahedron is orthogonal to the hexahedra in the hyperbolic 4-space, the dihedral angle of the tetrahedron, which equals the dicellular angle of the 8-cell, is $\pi/3$. The volume integration tells us that such tetrahedra have finite volumes[6] though they are noncompact. A single 8-cell includes 16 vertices and therefore has 16 tetrahedra as the boundary after regular truncations.

The next step is to find a certain gluing of appropriate number of regular truncated hyperbolic 8-cells by identifying the hexahedra, so that the resultant space becomes a smooth manifold and the collection of the tetrahedra produced by regular truncations form smooth 3-boundaries of the manifold. In mathematical language, we want to find a discrete subgroup of the isometry group SO(4,1) so that the quotient space of H^4 by the discrete subgroup is a manifold. First, we would like to try a generalization to four dimensions of what was illustrated in the simple two dimensional example and see whether a manifold can be formed or not. Below is an example of the trial.

We prepare two regular truncated 8-cells and put them in the position so that they have a reflection symmetry as depicted in Fig. 8. Gluing the hexahedra $X(=1\text{–}8)$ and $X'(=1'\text{–}8')$ so that all vertices $(a)\text{–}(p)$ match, we get a 4-space with 16 boundary components. To make sure smoothness of this 4-space in terms of hyperbolic geometry, it is sufficient to check the smoothness on the boundaries since the dicellular angles of the 8-cell equal the dihedral angles of the tetrahedra on the boundaries. The inside of a truncated hyperbolic 8-cell is smooth and regular. We can nicely glue the two hexahedra in four dimensions because the hexahedra are totally geodesic. Therefore, singular structures possibly appear only on the faces, edges and/or vertices of each hexahedron. From Fig. 6 we see that the singularity should appear on the boundary tetrahedra if any. The gluing of the hexahedra induces the gluing on the boundary tetrahedra. Fig. 7, for example, shows that the gluing of two tetrahedra corresponding to the vertex (a) both in the unprimed and primed 8-cells is determined by the identifications of the truncated hexahedra around the vertex (a). Since each unprimed hexahedron is identified with its primed partner, every face of unprimed tetrahedron is glued with its primed partner so that all vertices match. In this

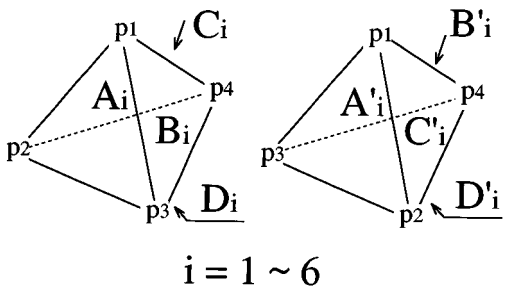

FIG. 9. Six unprimed tetrahedra and six primed tetrahedra. Twelve tetrahedra constitute $M_B 8$.

configuration, the topology of this space composed of the two tetrahedra is S^3. Nevertheless, we have only $2\pi/3$ turning around each edge of the tetrahedra after gluing, since only two edges of the tetrahedra with the dihedral angle $\pi/3$ are identified into one edge. This means a singularity by the deficit angle $2\pi-2\times\pi/3=4\pi/3$. Therefore, we fail to get a smooth manifold by a simple minded generalization of the 2-dimensional example in the previous section.

However, there is a way to improve the construction so that we can get a neat manifold, i.e., without a deficit angle. We consider a branched covering space of this singular space. The appropriate branched covering space can be given by a sixfold cover (12 tetrahedra) of the original singular space. The faces and vertices of the twelve tetrahedra are labeled as Fig. 9 ($i=1$–6). The following pairs of the faces of unprimed and primed tetrahedra are glued so that all labeled vertices match:

$$
\begin{aligned}
&A_1-A_1'B_1-B_3'C_1-C_2'D_1-D_4', \quad A_2-A_2'B_2-B_1'C_2-C_4'D_2-D_3',\\
&A_3-A_3'B_3-B_2'C_3-C_5'D_3-D_6', \quad A_4-A_4'B_4-B_6'C_4-C_1'D_4-D_5',\\
&A_5-A_5'B_5-B_4'C_5-C_6'D_5-D_1', \quad A_6-A_6'B_6-B_5'C_6-C_3'D_6-D_2'.
\end{aligned}
\tag{6}
$$

For instance, A_1 is matched with A_1'. All the vertices p_1,p_2,p_3 of A_1 are identified to the vertices p_1,p_2,p_3 of A_1', respectively.

Figure 10 shows consistency of the gluing around every edge. There are twelve edges in the sixfold covering space after the gluing. There are six dihedral angles which meet at one edge so that there is no deficit angle since each dihedral angle is $\pi/3$.

On the other hand, the vertices of the tetrahedra are on the sphere at infinity ∂D^3. By the gluing, these vertices are identified into four points at infinity, p_1,p_2,p_3,p_4. Such points at infinity are called cusps in the hyperbolic geometry. They are not singularities of the manifold but open boundaries at infinity.[6] Topologically a cusp looks like a torus crossing a half-open interval (see Fig. 11). The boundary space composed of twelve tetrahedra is a noncompact smooth manifold, which is called M_{B8} in the present paper.

The cusp will not cause any serious physical problem because one cannot observe the infinity of the universe. On the contrary, the existence of such structures at infinity renders the manifold of primary importance. It is a known fact in mathematics that there is a family of almost isometric compact manifolds limiting a cusped manifold.[11] It is expected that the limiting cusped manifold shares common characters of the family. Furthermore, the cusped manifold is the simplest one among the family in some sense. Hence, admitting the cusp to our manifold, we get the following simplest example of topology changing of space–time by quantum tunneling.

Now we expect that the branched covering proceeded above can be straightforwardly extended to the whole of 8-cells. Since the sixfold cover of the boundary 3-space produced by the simple minded identification is the smooth 3-manifold M_{B8}, the sixfold cover of the 4-space

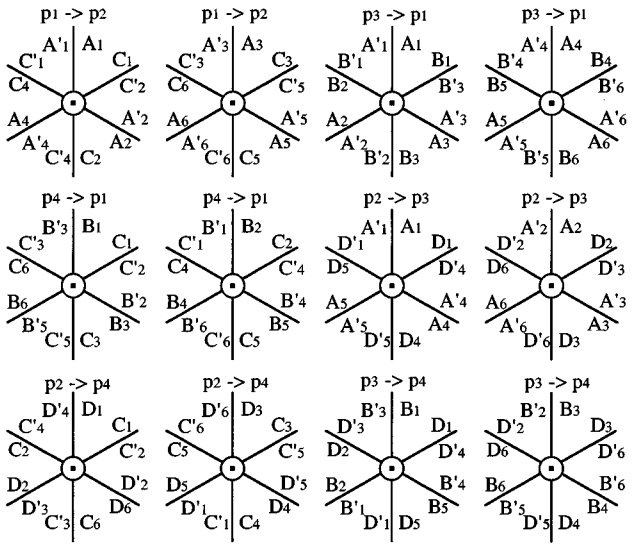

FIG. 10. The consistency check of the manifold which is composed of the tetrahedra in Fig. 9 with the rule of Eq. (6). Six dihedral angles meet at the edges in Fig. 9. Since each dihedral angle is $\pi/3$, there is no deficit angle.

produced by the simple minded identification will have smooth boundary manifolds, M_{B8}s. We prepare six pairs of unprimed and primed 8-cells as Fig. 8 (the pairs are labeled by $i=1$–6). Every vertex and cell (hexahedron) of the 8-cells are also labeled in Fig. 8. All subsequent gluings will be done so that these labeled vertices are matched. We determine the gluing of hexahedra around each vertex (a) of 8-cells (cell 1_i–cell 4_i, so that they induce gluing (6) on a tetrahedron made by the truncation of the vertex (a) to form M_{B8}. Figure 7 shows the tetrahedron by the truncation of each vertex (a). In this figure, each face of a tetrahedron is labeled by an index of the cell which the face belongs to, and each vertex of the tetrahedron is labeled by the same character as that of the nearest vertex of the hexahedron.

From Figs. 7 and 9 we find a correspondence, $1_i \equiv A_i$, $4_i \equiv B_i$, $3_i \equiv C_i$, $2_i \equiv D_i$. By Eq. (6), the gluing of the hexahedra, which constructs M_{B8} from the tetrahedra produced by the truncation of the vertex (a) are the following:

$$1_1-1_1'4_1-4_3'3_1-3_2'2_1-2_4', \quad 1_2-1_2'4_2-4_1'3_2-3_4'2_2-2_3',$$
$$1_3-1_3'4_3-4_2'3_3-3_5'2_3-2_6', \quad 1_4-1_4'4_4-4_6'3_4-3_1'2_4-2_5', \tag{7}$$

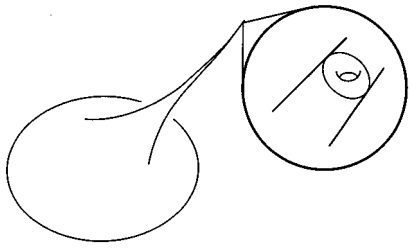

FIG. 11. An intuitive picture of a cusped hyperbolic manifold. The cusp topologically looks like a torus cross a half-open interval.

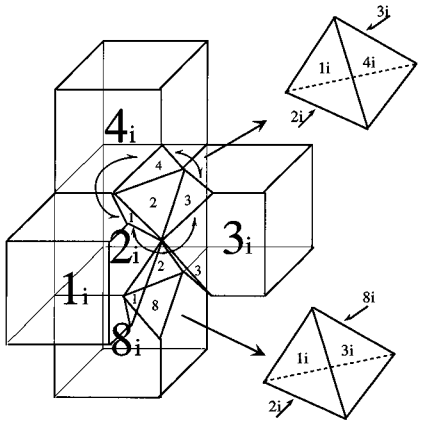

FIG. 12. If we treat 8_i as if it were 4_i, a tetrahedron from vertex (a) and a tetrahedron from vertex (b) would be symmetric under the inversion.

$$1_5-1_5'4_5-4_4'3_5-3_6'2_5-2_1', \quad 1_6-1_6'4_6-4_5'3_6-3_3'2_6-2_2'.$$

It is a nontrivial problem to determine whether it is possible or not for the tetrahedra produced by the truncations of the other vertices $(b)-(p)$ to form M_{B8}s by appropriate choices of gluing of the other cells (cell 5–cell 8). Determining the other gluings as shown below, we can see that two adjacent tetrahedra, e.g., formed by the truncations of vertices (a) and (b) (see Fig. 12), are symmetric under the inversion because of the symmetry of the 8-cell

$$\begin{aligned}
&5_1-5_1'8_1-8_3'7_1-7_2'6_1-6_4', \quad 5_2-5_2'8_2-8_1'7_2-7_4'6_2-6_3',\\
&5_3-5_3'8_3-8_2'7_3-7_5'6_3-6_6', \quad 5_4-5_4'8_4-8_6'7_4-7_1'6_4-6_5',\\
&5_5-5_5'8_5-8_4'7_5-7_6'6_5-6_1', \quad 5_6-5_6'8_6-8_5'7_6-7_3'6_6-6_2'.
\end{aligned} \tag{8}$$

Since the inversion of one M_{B8} gives another M_{B8}, each group of 12 tetrahedra forms one M_{B8} at each vertex $(b)-(p)$. Therefore, the glued twelve 8-cells have 16 M_{B8}s on their boundary. Here, a fact should be noticed that the tetrahedra are orthogonal to the cells (hexahedra) of the 8-cell, which guarantees that the M_{B8} is smooth at the points at which the tetrahedra join. Then M_{B8} on the boundary is a totally geodesic smooth manifold in H^4.

Of course, these identifications are orientation preserving isometry transformation because of the reflection symmetry between the unprimed and primed 8-cells. The resultant space is orientable.

To check that this 4-space is a complete smooth 4-manifold, we consider the neighborhood of the faces, edges and vertices. In four dimensions, when we turn around each face completely, the total angle should be 2π for consistency. We shall check this consistency on the boundary of it. On the boundary 3-hypersurface, we should check whether it is 2π or not around the edges (α,β,γ... in Fig. 6) of the tetrahedra. This consistency is guaranteed by our previous analysis where we have shown that the boundary consists of several pieces of the manifolds M_{B8} (see Fig. 10). The remaining vertices after the regular truncation (s,t,u... in Fig. 6) cause no problem since they form 4-cusps at infinity. Hence this space is a complete smooth non-compact hyperbolic 4-manifold with totally geodesic 3-boundaries. The boundaries are sixteen M_{B8}s.

B. Other solutions

As shown in Table I, there are seven kinds of 4-polytopes admitting regular truncations. Geometrical calculations reveal that two of them, 24-cell with a dicellular angle $2\pi/5$ and 600-cell with a dicellular angle $2\pi/3$, are compact and the others are noncompact after regular truncations. We can apply our method for the 12 noncompact 8-cells to these noncompact cases. By a similar method, we can successfully get complete smooth hyperbolic 4-manifolds with totally geodesic 3-boundaries in the two cases. One of them is the case of a 16-cell (bounded by 16 tetrahedra) with a dicellular angle $\pi/2$ and the other is the case of a 24-cell (bounded by 24 octahedra) with a dicellular angle $\pi/3$. Four 16-cells form a manifold whose 3-boundaries are eight M_{B16}s (we consider a twofold cover of a simple minded identifications), where an M_{B16} with six cusps is composed of four octahedra. Similarly, 6 24-cells also constitute a manifold whose 3-boundaries are 24 M_{B24}s (we consider a threefold cover of a simple minded identifications), where an M_{B24} with eight cusps is composed of six hexahedra.

Here, we would like to point out a peculiarity of the hyperbolic manifold by referring to a mathematical fact. For three or four dimensional hyperbolic manifold $M_{3,4}$, the fundamental group $\pi_1(M_{3,4})$ determines $M_{3,4}$ uniquely up to an isometry and a choice of normalizing constants.[12] This has been known as the Mostow rigidity. Then it is sometimes sufficient to determine the homology group H_1 of the hyperbolic manifold in order to distinguish the manifolds, where H_1 is an Abelian group such that $H_1=\pi_1/[\pi_1,\pi_1]$. To characterize the boundaries topologically we calculate the corresponding homology groups,[13]

$$H_1(M_{B8})=Z+Z+Z+Z; \tag{9}$$

$$H_1(M_{B16})=Z+Z+Z+Z+Z+Z; \tag{10}$$

$$H_1(M_{B24})=Z+Z+Z+Z+Z+Z+Z+Z. \tag{11}$$

Clearly they are topologically inequivalent. Since the rank of the free finite Abelian group part of H_1 counts the number of two dimensional holes,[13] M_{Bn} has a more complicated topological structure than M_{Bm} has if $n>m$. On the other hand, the torsion-free property may be considered as a pleasant feature of the universe because otherwise the universe might be non-orientable. If we had a method which can produce a solution whose boundaries have torsion part, much more solutions could be found.

Incidentally, it is impossible to construct a solution from 5-cells or 120-cells in our way. The remaining regular truncated polytopes are compact. In the compact case, we should check consistency also around the vertices of the regular truncated polytopes. However, it is too complicated for us to work out this consistency check and we need more advanced techniques. This is our project in future.[14]

IV. TOPOLOGY CHANGING AMPLITUDE AND STRONG RIGIDITY

We have constructed three hyperbolic 4-manifolds with totally geodesic boundaries. From Gibbons and Hartle[5] and Siino *et al.*,[3] these manifolds can be regarded as instantons causing topology changes by quantum tunneling. For example, the manifold of 12 8-cells can describe the topology changes: ''from nothing to sixteen M_{B8}s,'' ''from one M_{B8} to fifteen M_{B8}s'' or ''from two M_{B8}s to fourteen M_{B8}s,'' and so on (see Fig. 13). It is also worthy of notice that by plumbing them we can get infinite series of topology changing solutions as exemplified in Fig. 13. Since each boundary is totally geodesic, the gluing is perfect to make a neat manifold when we identify two boundary components of the same shape and size.

We have demonstrated topology changing processes between nontrivial spatial topologies in four dimensions by quantum tunneling, which cannot be reduced to a lower dimensional subspace. Brill constructed a 4-dimensional topology changing solution which, in fact, is effectively a direct

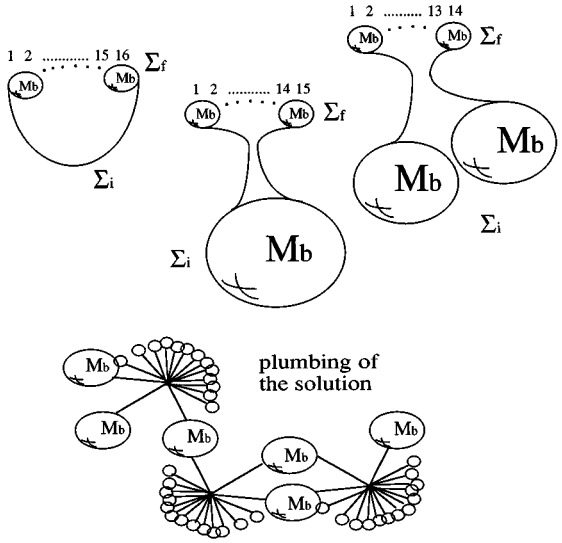

FIG. 13. A Riemannian manifold with 16 boundaries is regarded as a topology change solution ''from nothing to sixteen M_{B8}s'' ''from one M_{B8} to fifteen M_{B8}s,'' or ''from two M_{B8}'s to fourteen M_{B8}s,'' and so on. Furthermore, by plumbing of the solution we can obtain various types of topology change solutions.

product of a topology changing two dimensional space–time and the other two dimensional space.[9] Of course, the pair creation of charged black holes,[15] in an extended sense, is also a process of topology change. The Riemannian manifold for that process has a single totally geodesic 3-boundary which can be interpreted as a topology change from ''nothing'' to the space containing a pair of black holes. However, the present paper gives descriptions of processes which include not only the creation of the universe from ''nothing'' but also the change from n M_B to m $M_B (n \neq m)$. Both of initial and final spatial hypersurfaces (Σ_i and Σ_f) have nontrivial topologies.

Now let us evaluate the tunneling amplitude for these topology changes. In the context of the Hawking's Riemannian path integral, the amplitude can be formally described as

$$T(h_i, h_f) = \sum_{M_R} \int \mathscr{D}g \, \exp(-S_E[g]), \tag{12}$$

where h_i and h_f are the 3-dimensional metrics on the initial and final spatial hypersurfaces Σ_i and Σ_f, respectively. S_E is the Euclidean action,

$$S_E = -\frac{1}{16\pi G} \int_{M_R} (R - 2\Lambda) \sqrt{g} d^4x + \frac{1}{8\pi G} \int_{\partial M_R} K \sqrt{h} d^3x. \tag{13}$$

The path integral is over smooth 4-metric g on the Riemannian manifold M_R which has appropriate boundaries Σ_i and Σ_f by assumption. In our cases, M_R is one of the 4-manifolds which have been constructed in the previous section. Then we can evaluate the path integral (12) in the WKB approximation for the topology changing processes. The second term comes from the contribution of the boundaries other than $\Sigma_{i,f}$, namely, that of the open boundaries at the cusps. It is easy to see by explicit calculation that K vanishes at the cusps. Since our solution has a constant negative curvature $R = 4\Lambda < 0$, the classical action S_E is proportional to the 4-volume of the space–time and is given by

TABLE II. The topology changing manifolds that we have constructed. The first column is the polytope we have used. The resultant manifolds have the boundaries on the second column whose homology group H_1 are shown in the third column. The volume of solutions are displayed on the fourth column.

Building block	Boundary $\Sigma_{i,f}$	$H_1(\Sigma)$	The volume of solutions
8-cell×12	$16\times M_{B8}$	$Z+Z+Z+Z$	$\frac{4\pi^2}{3}\times 12$
16-cell×4	$8\times M_{B16}$	$Z+Z+Z+Z+Z+Z$	$\frac{4\pi^2}{3}\times 4$
24-cell×6	$24\times M_{B24}$	$Z+Z+Z+Z+Z+Z+Z+Z$	$\frac{4\pi^2}{3}\times 30$

$$\overline{S_E}=\frac{1}{8\pi G}\frac{V}{|\Lambda|}, \tag{14}$$

where V is a numerical value of the volume of M_R in the case of $\Lambda=-3$. It follows from Eq. (14) that the WKB approximation of the tunneling amplitude is exponentially suppressed for a tunneling manifold of a large volume. Then we intuitively expect that the topology change between more complicated topologies requires a larger volume of tunneling manifold and is more suppressed provided that the WKB prefactors are of the same order.

Though our manifolds have cusps, their volumes are finite. Following Kellerhals,[16] the hyperbolic volumes of the 4-polytopes that we have used are calculated as

$$\text{Volume(truncated 8-cells)}=\frac{4\pi^2}{3}, \tag{15}$$

$$\text{Volume(truncated 16-cells)}=\frac{4\pi^2}{3}, \tag{16}$$

$$\text{Volume(truncated 24-cells)}=\frac{20\pi^2}{3}, \tag{17}$$

and the volume of the manifolds are summarized in Table II.

The volume of a constant curvature space is given by the Gauss–Bonnet theorem,[17]

$$\chi(M)=\frac{1}{32\pi^2}\int_M \epsilon_{abcd}\mathscr{R}^{ab}\wedge\mathscr{R}^{cd}-\frac{1}{32\pi^2}\int_{\partial M}\epsilon_{abcd}\left(2\theta^{ab}\wedge\mathscr{R}^{cd}-\tfrac{4}{3}\theta^{ab}\wedge\theta^c_e\wedge\theta^c_e\wedge\theta^{ed}\right), \tag{18}$$

where $\mathscr{R}^{ab}$ and θ^{ab} are the curvature 2-form and the second fundamental form. Since the boundary ∂M is totally geodesic, θ^{ab} vanishes there. The Euler numbers $\chi(M)$ are combinatorially determined as

$$\chi(\text{tunneling manifold consisting of 12 8-cells})=12, \tag{19}$$

$$\chi(\text{tunneling manifold consisting of 4 16-cells})=4, \tag{20}$$

$$\chi(\text{tunneling manifold consisting of 6 24-cells})=30, \tag{21}$$

and agree with Eq. (18) and the volumes given in Table II.

Roughly speaking, more polytopes are needed to get a manifold with a more complicated topological structure. Then we expect that the volumes are largely related to the topological structure (just the Euler number in a constant curvature space). The larger volume will imply a

more complicated topological structure. Now let us recall one of the peculiarities of the hyperbolic manifold, Mostow rigidity. For three or four dimensional hyperbolic manifold $M_{3,4}$, the fundamental group $\pi_1(M_{3,4})$ determines $M_{3,4}$ uniquely up to an isometry and a choice of normalizing constant.[12] Therefore, our tunneling manifolds include no degrees of freedom of deformation[8] as long as the manifold is hyperbolic. If we include nonzero Weyl curvature, the manifold can become inhomogeneous and the degrees of freedom of deformation becomes dynamical. In such a situation, the quantum theory of the dynamical degrees of freedom have to be developed for a quantum topology change theory.

V. SUMMARY AND DISCUSSIONS

In the present paper, we have found instantons which describe topology changing processes by quantum tunneling of spatial hypersurfaces of space–times which are locally anti-de Sitter. Here we summarize our results in the Table II.

It may be intuitively expected that the more complicated is the topology of the universe which topologically changes, the larger is the volume of the tunneling manifold. Let us investigate whether this is the case in our examples. From Table II, however, we cannot easily draw a conclusion directly since the number of boundary manifolds are different. Quantitatively, we can compare a set of three topology changing manifolds with $16\times M_{B8}$, a set of six topology changing manifolds with $8\times M_{B16}$ and a set of two topology changing manifolds with $24\times M_{B24}$. All the sets have 48 boundaries though they are not arcwise connected. Then the corresponding manifolds have volumes $48\pi^2$, $32\pi^2$, and $80\pi^2$, respectively. The result is just not what we expected. Although the third one is much larger than the other two, which means that M_{B24} is more unlikely to appear comparing to the other two, the first one and the second one are comparable. What is more, the probability for the first one to appear is smaller than that for the second one. Since $H_1(\Sigma)$ characterizes the topological structure of Σ by Eqs. (9), (10), and (11), the boundary of the first one is simpler than that of the second one. However, their volumes imply that the topology of the first one is more complicated than the topology of the second one. Nevertheless, we cannot conclude that the tunneling of M_{B16} has the maximum of probability. There might be a smaller manifold describing the topology change of M_{B8}s. If we could find the relation between the volume of the solution (the Euler number) and the boundary of it, the relation would explain this.

One might think that our constructions are too restricted. First, the identification is determined so as to preserve the symmetry of the polytope. Second, the resultant polytopes are identical with each other. From these restrictions, for example, one cannot consistently identify the polyhedra which bound a single polytope. Our restrictions made the construction simple. However, it may well be the case that there are much more solutions which have been ruled out by the restrictions. To complete the discussion about the topology change by quantum tunneling, we should relax these restrictions. Then the structure of the tunneling manifold becomes more involved. Constructing such complicated cases will need the aid of computer.

When we evaluate the topology changing amplitude, the formalism of Hartle and Hawking has been used. However, the exact no-boundary condition in the original formalism of Hartle and Hawking does not allow the existence of boundary at infinity. In our solutions, the tunneling manifolds have cusped boundaries at infinity. Since the cusped boundaries are infinitely small and the manifolds have finite volumes, we may generalize the formalism of Hartle and Hawking to such a case. If we stick to impose the no-boundary condition in a strict sense, we need compact tunneling manifolds. An investigation in this direction is also in progress.[14]

People might be disturbed by the existence of the cusps. If we study the effect of ''matter fields'' or fluctuations of the metric (''one-loop corrections''), the boundary conditions at the cusps are needed. The conditions and the effects will be studied in appropriately simplified situation.[18] Furthermore, some people might insist that the cusps do not allow one to use Einstein–Hilbert action and the idea of a smooth manifold in this arbitrary small scale. A calculation in the $(2+1)$-dimensional gravity will reveal something about this as a simplified case. On the other

hand, it observationally causes no problem since the cusps are at infinity and we cannot ''see'' them. We see only the pattern of spatial periodicity.[19] If we observe the pattern of the spatial periodicity as the super large scale structure of the universe, we may be able to determine the topology of our universe and to know whether the universe has the cusps or not.

In the case of the topology change in $(2+1)$-dimensional quantum tunneling, the rigidity of the hyperbolic manifold is easier to understand. While hyperbolic 2-boundaries have moduli parameters as the dynamical degrees of freedom, the tunneling manifolds do not allow any deformation corresponding to them, which is consistent with the rigidity. In four dimensional case, however, the situation is different because the 3-boundary is also rigid as well as the tunneling manifold itself. The dynamical degrees of freedom will appear only when we allow nonzero Weyl curvature. In such a case the gravitational degrees of freedom should be considered. As a first step we can consider the linear perturbation of them. If we quantize these degrees of freedom, we expect particles be created. This might cause a quantum instability of topology changing solutions if the backreaction to the space–time is too large.

Einstein's equations in the presence of signature change

Tevian Dray[a)]

We discuss Einstein's field equations in the presence of signature change using variational methods, obtaining a generalization of the Lanczos equation relating the distributional term in the stress tensor to the discontinuity of the extrinsic curvature. In particular, there is no distributional term in the stress tensor, and hence no surface layer, precisely when the extrinsic curvature is continuous, in agreement with the standard result for constant signature. © *1996 American Institute of Physics.* [S0022-2488(96)02611-4]

I. INTRODUCTION

Classical cosmological models containing an initial region of Euclidean signature joined to a final region with the usual Lorentzian signature were introduced by Ellis *et al.*[1,2] A basic feature of this work is the use of the Darmois junction conditions at the surface where the signature changes. This assumption has been questioned by Hayward,[3] who prefers to assume the stronger conditions appropriate for quantum cosmology. We argue here in favor of the Darmois approach by *deriving* these junction conditions from the Einstein-Hilbert action.

What are Einstein's equations in the presence of signature change? Formal computation quickly goes astray: A signature-changing metric is necessarily degenerate at the hypersurface of signature change. The Geroch-Traschen conditions[4] for the existence of a distributional curvature tensor thus fail to be satisfied, and it is not clear whether a preferred connection exists. Supposing that a suitable distributional connection is available, the distributional curvature tensor could be readily constructed, but it would still be unclear at best how to reverse its trace with the degenerate metric to obtain a distributional Einstein tensor.

We adopt instead a variational approach, and begin with the natural generalization of the Einstein-Hilbert action to signature change, subtracting the standard surface term used in the nondegenerate case in the presence of boundaries. We choose to work with a discontinuous metric, as this permits the introduction of a frame which is orthonormal almost everywhere. Having made these choices, we find that the variations proceed unchanged from the degenerate case, and we recover the identical result: The Darmois conditions (continuity of the extrinsic curvature) ensure the absence of a surface layer, and the Lanczos equation relates the discontinuity of the extrinsic curvature to the surface stress tensor. The former result agrees with one of Embacher's variational principles;[5] the latter result is new.

The paper is organized as follows. In Section II we introduce the necessary notation for dealing with signature change, and introduce the concept of an ''almost'' orthonormal frame. In Section III we review the standard Einstein-Hilbert variational principle for Einstein's equations, showing that the usual derivation applies without change. Finally, in Section IV we discuss our results.

II. NOTATION

Let Σ be a (smooth) hypersurface in a smooth n-dimensional manifold M which divides M into disjoint open regions $M^\pm$ with smooth, nondegenerate metric tensors $g^\pm$. We will assume that the limits $g^\pm|_\Sigma$ exist, and that the pullbacks of $g^\pm|_\Sigma$ to Σ agree. The common pullback is the induced metric on Σ, which will be further assumed to be nondegenerate and which will be denoted by h. In particular, we are assuming that Σ is not null.

A tensor field F is said to be *regularly discontinuous*[6,7] if F is continuous on $M^\pm$ and if the one-sided limits,

$$F^\pm|_\Sigma = \lim_{\to\Sigma^\pm} F, \tag{1}$$

exist. The *discontinuity* of F is the tensor on Σ defined by

$$[F]_\Sigma = F^+|_\Sigma - F^-|_\Sigma . \tag{2}$$

Note that F itself need only be defined on $M^\pm$. In the *continuous metric* approach, one assumes that $[g]_\Sigma = 0$; this is the standard assumption for constant signature. If the signatures of $g^\pm$ differ, $g^\pm|_\Sigma$ will necessarily be degenerate ($\det g^\pm|_\Sigma = 0$) in this approach, whereas for constant signature one can also assume that $g^\pm|_\Sigma$ is nondegenerate. In the *nondegenerate metric* approach, one instead assumes that $g^\pm|_\Sigma$ are not degenerate. If the signatures of $g^\pm$ differ, this necessarily implies that $[g]_\Sigma \neq 0$; in this case, we will refer to this approach as the *discontinuous metric* approach. The two approaches are mutually exclusive in the presence of signature change, whereas for constant signature one normally makes both sets of assumptions.

Introduce an orthonormal (with respect to h) frame on Σ, i.e. a basis $\{\hat{e}^i, i = 1 \ldots n-1\}$ of 1-forms on Σ. In each of $M^\pm$ separately, we can extend this to a smooth orthonormal frame $\{e^a_\pm\} = \{e^0_\pm, e^i_\pm\}$ with $e^i|_\Sigma = \hat{e}^i$. We have $[e^i]_\Sigma = 0$ by construction, and we will further *assume* that $[e^0]_\Sigma = 0$. This can always be done in the continuous metric approach, although if the signature changes we have $e^0_\pm|_\Sigma = 0$. For discontinuous metrics, this is a further restriction on $g^\pm$, which amounts to assuming that both 1-sided notions of the unit normal vector to Σ are the same—which would imply continuity of the metric if the signature were constant—or equivalently that proper time/distance from Σ is a C^1 coordinate. Let $\{X^\pm_a\}$ denote the basis of vector fields on $M^\pm$ which is dual to $\{e^a_\pm\}$. Note that in the presence of signature change, $X^\pm_0$ will admit limits to Σ only in the discontinuous case.

Consider the separate Hodge dual operators defined by $g^\pm$ on $M^\pm$, both written as $*$, and the Hodge dual operator defined by h on Σ, written as $\hat{*}$. The metric volume element on Σ is

$$\hat{*}1 = e^1_\pm \wedge \cdots \wedge e^{n-1}_\pm, \tag{3}$$

and the metric volume elements on $M^\pm$ are

$$*1 = e^0_\pm \wedge e^1_\pm \wedge \cdots \wedge e^{n-1}_\pm, \tag{4}$$

which admit continuous limits to Σ by assumption. For discontinuous metrics, this provides the usual Leray decomposition,

$$*1 = e^0 \wedge \hat{*}1, \tag{5}$$

where e^0 here denotes the common limit of $e^0_\pm$ to Σ. However, in the continuous metric approach for a signature-changing metric, these limits are identically zero!

We therefore take the nondegenerate metric approach in the remainder of the paper, resulting in discontinuous metrics if the signature changes. We emphasize that this choice means that both

$$[e^0]_\Sigma = 0 = [X_0]_\Sigma\,, \tag{6}$$

so that there is a continuous ''orthonormal'' frame on all of M, which in turn defines a continuous, nondegenerate, volume element on all of M.

Metric-compatible connection 1-forms $\omega^a_{\pm b}$ on $M^\pm$ satisfy

$$dg_{ab} = \omega^m{}_a g_{mb} + \omega^m{}_b g_{ma}\,, \tag{7}$$

and have torsion

$$T^a = de^a + \omega^a{}_b \wedge e^b, \tag{8}$$

where we have dropped the $\pm$ index. For an orthonormal frame $\{e^a\}$,

$$dg_{ab} = 0, \tag{9}$$

and the unique metric-compatible, torsion-free connection is given by[8]

$$2g_{am}\omega^m{}_b = g_{mn}e^m i_{X_a}(i_{X_b}(de^n)) + g_{an}i_{X_b}(de^n) - g_{mb}i_{X_a}(de^m), \tag{10}$$

where

$$g_{ab} = g(X_a, X_b). \tag{11}$$

By assumption, g_{ab} is regularly discontinuous. We will further assume that the connection 1-forms $\omega^a{}_b$ are regularly discontinuous. Physically, this means that not only $g^\pm$ but also their derivatives admit 1-sided limits to Σ, so that $M^\pm \cup \Sigma$ are (pseudo) Riemannian manifolds-with-boundary.

III. VARIATIONAL APPROACH

We first review the Palatini formalism for obtaining Einstein's equations in vacuum for nondegenerate metrics. We then show by example how to include matter fields, and finally consider degenerate metrics.

A. Nondegenerate metrics

The Einstein-Hilbert action on a manifold with nondegenerate metric but without boundary can be written in terms of the Lagrangian density

$$\mathscr{L}_{EH} = g_{ac}R^c{}_b \wedge *(e^a \wedge e^b), \tag{12}$$

where the curvature 2-forms $R^a{}_b$ are defined by

$$R^a{}_b = d\omega^a{}_b + \omega^a{}_c \wedge \omega^c{}_b\,, \tag{13}$$

We adopt the Palatini approach and vary the action separately with respect to e^a and $\omega^a{}_b$, noting that g_{ac} is constant, $R^c{}_b$ is independent of e^a, and the remaining factor is independent of $\omega^a{}_b$.

Taking the ω variation first, if $\omega \mapsto \omega + \delta\omega$ then

$$\begin{aligned}\delta_\omega R^a{}_b &= \delta(d\omega^a{}_b + \omega^a{}_c \wedge \omega^c{}_b) \\ &= d(\delta\omega^a{}_b) + \delta\omega^a{}_c \wedge \omega^c{}_b + \omega^a{}_c \wedge \delta\omega^c{}_b\,.\end{aligned} \tag{14}$$

Thus,

$$\delta_\omega \mathscr{L}_{EH} = g_{ac}\delta_\omega R^c{}_b \wedge *(e^a \wedge e^b)$$

$$= g_{ac} d(\delta\omega^c{}_b \wedge *(e^a \wedge e^b)) + g_{ac}\delta\omega^c{}_b \wedge d*(e^a \wedge e^b)$$
$$+ g_{ac}\delta\omega^c{}_d \wedge \omega^d{}_b \wedge *(e^a \wedge e^b) - g_{ac}\delta\omega^d{}_b \wedge \omega^c{}_d \wedge *(e^a \wedge e^b). \quad (15)$$

Since there is no boundary, the surface term does not contribute. Furthermore, using (7) in the last term yields

$$-g_{ac}\delta\omega^d{}_b \wedge \omega^c{}_d = g_{cd}\delta\omega^d{}_b \wedge \omega^c{}_a, \quad (16)$$

so that requiring that $\delta_\omega R^a{}_b$ vanish for arbitrary variations in ω results in

$$D*(e^a \wedge e^b) := g_{ac}\delta\omega^c{}_b (d*(e^a \wedge e^b) + \omega^b{}_m \wedge *(e^a \wedge e^m) + \omega^a{}_m \wedge *(e^m \wedge e^b)) = 0. \quad (17)$$

Working in 4 dimensions for convenience and introducing the totally antisymmetric tensor η_{abcd} with $\eta_{0123} = 1$, whose indices are raised and lowered with g_{ab} we have

$$*(e^a \wedge e^b) = \frac{1}{2!}\eta^{ab}{}_{cd}(e^c \wedge e^d), \quad (18)$$

which leads directly to

$$D*(e^a \wedge e^b) = *(T^a \wedge e^b + e^a \wedge T^b) = 2*(T^a \wedge e^b). \quad (19)$$

The result of the ω variation is thus that the connection must be torsion-free

$$T^a = 0. \quad (20)$$

(We have assumed that the connection is metric-compatible. A similar computation starting instead from the assumption that the connection is torsion-free leads to the requirement that the connection be metric-compatible. A general computation, making no *a priori* restriction on the connection, results in an equation relating the nonmetricity of the connection to its torsion.[9])

Moving on to the e variation, we obtain

$$\delta_e *(e^a \wedge e^b) = \delta_e\left(\frac{1}{2!}\eta^{ab}{}_{cd}e^c \wedge e^d\right)$$

$$= \eta^{ab}{}_{cd}e^c \wedge \delta e^d$$

$$= -*(e^a \wedge e^b \wedge e^m g_{md}) \wedge \delta e^d$$

$$= -i_{X_d} *(e^a \wedge e^b) \wedge \delta e^d, \quad (21)$$

where we have used[8]

$$*(\phi \wedge X^\flat) = i_X * \phi, \quad (22)$$

where $X^\flat$ denotes the 1-form which is the metric dual of the vector field X. Thus

$$\delta_e \mathscr{L}_{EH} = 2g_{ac}R^c{}_b \wedge i_{X_d} *(e^a \wedge e^b) \wedge \delta e^d$$

$$= 2G_d \wedge \delta e^d, \quad (23)$$

where the right-hand-side defines[8] the Einstein 1-form G_d, which is related to the Einstein tensor G by

$$G_a = G(X_a, X_b)e^b. \tag{24}$$

Thus, in the absence of a matter Lagrangian, we obtain the vacuum Einstein equations

$$G_a = 0. \tag{25}$$

B. Matter terms

Before considering boundaries, we show by example what changes need to be made in the presence of matter. Consider for simplicity a massless scalar field Φ, with Lagrangian density

$$2\,\mathscr{L}_\Phi = d\Phi \wedge *d\Phi. \tag{26}$$

The field equations

$$d*d\Phi = 0 \tag{27}$$

are derived by varying $\mathscr{L}_\Phi$ with respect to Φ.[10] The stress 1-forms are obtained by varying $\mathscr{L}_\Phi$ with respect to e^a. We first note that

$$\begin{aligned} 0 = \delta_e d\Phi &= \delta_e(X_a(\Phi)e^a) \\ &= \delta X_a(\Phi)e^a + X_a(\Phi)\,\delta e^a. \end{aligned} \tag{28}$$

The variation is thus essentially a variation of $*$, and we obtain

$$\begin{aligned} \delta_e *d\Phi &= \delta_e(X_a(\Phi)*e^a) \\ &= \delta_e\left(X_a(\Phi)\frac{1}{3!}\,\eta^a_{bcd}e^b \wedge e^c \wedge e^d \right) \\ &= \delta X_a(\Phi)*e^a + X_a(\Phi)\frac{1}{2}\,\eta^a_{bcd}e^b \wedge e^c \wedge \delta e^d \\ &= -X_a(\Phi)*\delta e^a + X_a(\Phi)*(e^a \wedge e^m g_{md}) \wedge \delta e^d \\ &= -i_{X_a}(d\Phi)*\delta e^a + X_a(\Phi)i_{X_d}(*e^a) \wedge \delta e^d, \end{aligned} \tag{29}$$

where we have again used (22). Thus,

$$\begin{aligned} 2\,\delta_e\mathscr{L}_\Phi &= d\Phi \wedge \delta_e *d\Phi \\ &= -i_{X_a}(d\Phi)d\Phi \wedge *\delta e^a + d\Phi \wedge i_{X_d}(*d\Phi) \wedge \delta e^d \\ &= -i_{X_a}(d\Phi)\,\delta e^a \wedge *d\Phi + d\Phi \wedge i_{X_a}(*d\Phi) \wedge \delta e^a \\ &= i_{X_a}(d\Phi)*d\Phi \wedge \delta e^a + d\Phi \wedge i_{X_a}(*d\Phi) \wedge \delta e^a, \end{aligned} \tag{30}$$

so that the stress 1-forms are

$$2*\tau_a = 2\frac{\delta \mathscr{L}}{\delta e^a} = i_{X_a}(d\Phi)*d\Phi + d\Phi \wedge i_{X_a}(*d\Phi). \tag{31}$$

The stress 1-forms are related to the stress tensor T by

$$\tau_a = T(X_a, X_b)e^b \tag{32}$$

[compare (24)]. If we now take as our total Lagrangian

$$\mathscr{L} = \mathscr{L}_{EH} - 16\pi G \mathscr{L}_\Phi, \tag{33}$$

then the variation with respect to ω is unchanged, and the variation with respect to e yields Einstein's equations in the form

$$G_a = 8\pi G \tau_a. \tag{34}$$

C. Signature change

We now consider a manifold M divided as before into disjoint open regions $M^\pm$ by a hypersurface Σ. We will take as our Lagrangian the piecewise sum of the Einstein-Hilbert Lagrangians. For variations with support away from Σ, everything is as before, and we obtain Einstein's equations separately in the two regions. But for variations of ω in a neighborhood of Σ, the surface term which we previously discarded would now contribute, and we do not wish to impose any *a priori* conditions on the smoothness of the variations of ω, and thus implicitly on ω itself. We thus modify the Einstein-Hilbert action by adding a surface term,

$$\mathscr{L}_g = \mathscr{L}_{EH} - d(g_{ac}\omega^c{}_b \wedge *(e^a \wedge e^b)), \tag{35}$$

and note that this will precisely cancel the surface term in the variation of ω. We emphasize that this change in the action has nothing to do with signature change, and is required for the standard, constant signature case.[5,11]

We thus consider the theory with action,

$$\mathscr{S} = \int_{M^+} \mathscr{L}_g^+ + \int_{M^-} \mathscr{L}_g^-, \tag{36}$$

and reiterate that variations with support away from Σ lead as expected to Einstein's equations and the torsion-free condition separately in the two regions. If we now assume that

$$[e^a]_\Sigma = 0, \tag{37}$$

and consider continuous variations of e^a across the boundary, we obtain on each side a surface term of the form

$$-\int_\Sigma \delta_e(g_{ac}\omega^c{}_b \wedge *(e^a \wedge e^b)) = \int_\Sigma g_{ac}\omega^c{}_b \wedge i_{X_d} *(e^a \wedge e^b) \wedge \delta e^d, \tag{38}$$

where we have used (21). Consider the term

$$\rho_d := g_{ac}\omega^c{}_b \wedge i_{X_d} *(e^a \wedge e^b), \tag{39}$$

and note that only the pullback $\hat{\rho}_d$ of ρ_d occurs in (38). A tedious but straightforward computation making repeated use of identities like

$$g_{am}g_{bn}*(e^m\wedge e^n)=g_{bn}i_{X_a}*e^n=i_{X_a}i_{X_b}*1, \tag{40}$$

$$\omega^a{}_b\wedge i_{X_c}\alpha=-i_{X_c}(\omega^a{}_b\wedge\alpha)+i_{X_c}\omega^a{}_b\wedge\alpha, \tag{41}$$

$$g_{00}*(e^0\wedge e^i)=\hat{*}e^i, \tag{42}$$

shows that

$$\hat{\rho}_0=-2\omega^i{}_j(X_i)\hat{*}e^j, \tag{43}$$

$$\hat{\rho}_i=(2\omega^0{}_j(X_i)-2\delta_{ij}\delta^{kl}\omega^0{}_k(X_l))\hat{*}e^j, \tag{44}$$

and we see at once that $\hat{\rho}_0$ is continuous, as it only depends on the frame at Σ. Requiring that (38) vanish for arbitrary variations, we thus obtain the boundary condition

$$[\hat{\rho}_i]_\Sigma=0. \tag{45}$$

The extrinsic curvature of Σ is defined by (the 1-sided limits to Σ of)

$$K(X,Y)=-\nabla_X e^0(Y). \tag{46}$$

(One usually assumes X_0 is geodesic to ensure that K only has components tangent to Σ; it is in any case only these components which matter. One can therefore without loss of generality restrict X and Y to the tangent space to Σ, which is spanned by $\{X_i:i=1,\ldots,n-1\}$.) We have

$$K(X_i,X_j)=-(\nabla_{X_i}e^0)(X_j)=\omega^0{}_c(X_i)e^c(X_j)=\omega^0{}_j(X_i). \tag{47}$$

We define the trace of K by

$$\text{tr } K:=h^{ij}K(X_i,X_j)=\delta^{ij}K(X_i,X_j). \tag{48}$$

Inserting (47) and (48) into (45) and (44), we see that the e variation yields

$$0=[\hat{\rho}_i]_\Sigma=(2[K(X_i,X_j)]_\Sigma-2\delta_{ij}[\text{tr}]_\Sigma K)\hat{*}e^j, \tag{49}$$

which is equivalent to

$$[K(X_i,X_j)]_\Sigma=0, \tag{50}$$

so that the extrinsic curvature must be continuous.

D. Lanczos equation

If the matter Lagrangian contains a surface term of the form

$$\mathscr{S}_\Sigma=\int_\Sigma \mathscr{L}_\Sigma, \tag{51}$$

then there will be a surface stress tensor of the form

$$\hat{*}\tau_i^\Sigma=\frac{\delta\mathscr{L}_\Sigma}{\delta e^i}. \tag{52}$$

Relating this to the variation of the (surface term of the) Einstein-Hilbert action yields the Lanczos equation[12,13] in the form

$$[\hat{\rho}_i]_\Sigma = 16\pi G \tau_i^\Sigma , \tag{53}$$

or equivalently

$$([K(X_i,X_j)]_\Sigma - \delta_{ij}[\mathrm{tr}]_\Sigma K)e^j = 8\pi G \tau_i^\Sigma , \tag{54}$$

relating the discontinuity in the extrinsic curvature to the surface stress tensor. This equation is identical in form to that obtained when the metric is nondegenerate.

IV. DISCUSSION

We reiterate that there are no canonical ''Einstein's equations'' in the presence of signature change. One can try to construct a theory by formal substitution of a signature-changing metric into equations derived for constant signature, but it is not at all obvious that the resulting theory could be derived from an appropriate starting principle. For instance, for continuous, signature-changing metrics there is no (metric) volume element at the surface of signature change, so in this approach it is not clear what one should mean by a surface layer. And for discontinuous metrics, it is not even clear whether a (distributional) metric-compatible connection exists, since the standard computational techniques involve contracting the distributional derivatives of the metric with the discontinuous metric. One intriguing possibility involves a connection which is merely discontinuous but not metric-compatible.[14] Even with a discontinuous (as opposed to distributional) connection, however, the formal computation of Einstein's equations fails in general: While a distributional curvature tensor (or 2-form) can be constructed, with a signature-changing metric there is no way to take the trace to obtain the Einstein tensor.

Our results agree with Embacher[5] that the boundary condition obtained from the action (35) is precisely that the extrinsic curvature be continuous, which is the well-known Darmois junction condition for the absence of a surface layer.[15] Our derivation thus supports the work of several authors[1,2,16,17] who postulate the Darmois conditions for Einstein's equations in the presence of signature change. Hellaby and Dray[16–18] have pointed out, however, that in the presence of signature change the Darmois junction conditions are not sufficient to obtain the usual conservation laws, in contrast to the usual situation.[4,19–22] We note in particular that the Kossowski and Kriele claim[23] that the Darmois conditions lead to a surface layer which was missed by Ellis is incorrect,[24] as it is based on a smoothness assumption which does not hold in the Darmois approach.

We emphasize that not only does our work support our previous claims that the Darmois junction conditions are precisely the conditions for there to be no surface layer in the presence of signature change, but it also derives the precise relationship between the discontinuity in the extrinsic curvature and the stress tensor of the surface layer, namely the Lanczos equation.

Our theory is constructed using standard variational techniques from a straightforward generalization of the standard Einstein-Hilbert Lagrangian. A surface term is added to avoid having to specify continuity conditions on the connection variations without knowing anything in advance about the continuity of the connection itself. It is remarkable that even though our metric is discontinuous, there is still a continuous frame which is orthonormal almost everywhere, and we work with this frame to avoid having to vary the metric.

One might question whether our variations of the frame e^a are indeed arbitrary. There are two separate issues here, the first being that we have restricted our variations so that away from Σ the frame remains orthonormal. This is merely a reflection of the gauge freedom in Einstein's theory to work with a preferred category of frames, such as coordinate bases, null tetrads, or orthonormal frames. The second issue is at first sight more worrisome: Our class of nearly orthonormal frames for signature-changing metrics uniquely determines e^0 at Σ, so that

$$\delta e^0|_\Sigma = 0 \tag{55}$$

(which also restricts the variations $\delta e^i|_\Sigma$ to be tangent to Σ). The careful reader will have noticed that we have not tried to *derive* the condition $[\hat{\rho}_0]=0$ from the variational principle; we now see that this can not in fact be done. Fortunately, this condition is identically satisfied. This is just a reflection of the fact that we have fixed the hypersurface Σ, so that $X_0|_\Sigma$ is a geometric object, the normal vector field to the given surface. So long as Σ is fixed, there is no physical or geometric content to varying X_0, or equivalently varying its dual e^0. This point of view is supported by the fact that, if one permits such variations in the nondegenerate case, one obtains no new information. In any case, we expect our results to generalize directly to permit continuous variations of an arbitrary (non-orthonormal) frame e^a, yielding the same results. Strong evidence for this claim is provided by the fact that Embacher[5] obtains the same results as we do by varying (35) with respect to the metric and connection in a coordinate basis.

Similar results to those obtained here were derived earlier for the scalar field[10,25] from several different approaches, including a variational principle. These results agree with those obtained by Ellis *et al.*[1,2] for the coupled Einstein-Klein/Gordon system. Carfora and Ellis[26] have recently given a an elegant approach to signature changing spacetimes, in which the Darmois conditions are generalized to allow a diffeomorphism of the surface Σ of signature change.

(Received 6 June 1996; accepted for publication 28 June 1996)

The problem of geodesic incompleteness is examined for space–times with Finkelstein–Misner kinks. A discussion of spherically symmetric kink space–times is followed by specific examples in which geodesics, initially incomplete in the original space–time, are shown to be extendible by the Kruskal technique. The structure of the two Kruskal patches and their matching at the patch boundaries are worked out in detail for one such example. Comments are made concerning a possible link between extendibility and energy conditions. It is shown that the kinds of spherically symmetric kink space–times examined in the present paper do not satisfy the strong energy condition. © *1996 American Institute of Physics.* [S0022-2488(96)01711-2]

I. INTRODUCTION

Kink space–times were originally discovered by Finkelstein and Misner[1] and were further studied by Finkelstein and McCollum[2] who showed how kink space–times which were geodesically incomplete when presented in terms of so-called ''rotational'' coordinates could sometimes be extended by performing a Kruskal transformation[3] to obtain new coordinates which range over a larger geodesically complete manifold. Finkelstein and McCollum also raised the question of whether a geodesically complete kink space–time could arise from a physically reasonable source, and they formulated a set of conditions that (a certain class of) spherically symmetric kink space–times would need to satisfy if the source were to be physically reasonable.

More recently, Chamblin (Ref. 4, pp. 376–377) has raised questions concerning the relationship between kinking and geodesic incompleteness. In further work, Chamblin[5] studies chronological asymptotically flat kink space–times that satisfy the strong and generic energy conditions (and are already maximally extended). He argues that such a space–time will be timelike and null (i.e., nonspacelike) geodesically incomplete *in an absolute sense*. That is to say, the space–time cannot be further extended to a geodesically complete space–time. The de Sitter kink space–time, which does not satisfy the energy conditions, was previously extended by Dunn, Harriott, and Williams.[6] The purpose of the present paper is to pursue this tie between incompleteness and energy conditions by examining other examples of spherically symmetric kink space–times. Such space–times are characterized by a tipping over of the light cones as r varies from 0 to ∞. The angle of tilt of the light cones will be denoted by α, which will be assumed to be a function of r, but not of t. Although it is always possible to find a *local* coordinate system in which $\alpha(r)$ is zero, it is not possible to do this *globally* when there are kinks. Throughout the present paper, we shall

a)Electronic mail address: kdunn@is.dal.ca
b)Electronic mail address: tina.harriott@msvu.ca
c)Electronic mail address: williams@brandonu.ca

impose the boundary conditions $\alpha(0)=0$ and $\alpha(\infty)=\pi$, which correspond to a kink number of one.

II. SIMPLEST SPHERICALLY SYMMETRIC KINKS

The simplest spherically symmetric space–time with a kink present is given by[2,6–11]

$$ds^2=-\cos 2\alpha\ dt^2-2\sin 2\alpha\ dt\ dr+\cos 2\alpha\ dr^2+r^2\ d\Omega^2.$$

This is a special case of the space–time discussed by Letelier and Wang.[12,13] The Christoffel symbols and the Ricci and Einstein tensors are listed in Appendix A. Examples of such space–times include the de Sitter kink space–time[9,10] and the Tolman–Hawking and Schwarzschild kink space–times discussed by González-Díaz.[11] (See also Ref. 14.)

Since α varies from 0 to π, there will be two horizons: one at $\alpha=\pi/4$ and the other at $\alpha=3\pi/4$. For the example of the de Sitter kink space–time, the horizons are of the cosmological kind and the geodesics can be straightened by transforming to Kruskal coordinates.[6] For other examples, it may not be possible to extend the geodesics at $\alpha=\pi/4$ and $\alpha=3\pi/4$, but if it is possible, since one cannot expect to find a coordinate system that will straighten the geodesics at both $\alpha=\pi/4$ and $\alpha=3\pi/4$ simultaneously, two coordinate patches will be needed to describe the resulting geodesically complete space–time with Kruskal coordinates.[2] In terms of the original α, the coordinate patches correspond to the ranges $0\leqslant\alpha\leqslant\pi/2$ (first patch) and $\pi/2\leqslant\alpha\leqslant\pi$ (second patch). There is a further difficulty concerning the joining together of the two patches. The smooth joining of such patches requires the metric and its first derivatives to be continuous at the boundary (the Lichnerowicz junction conditions[15]) or alternatively, and more covariantly, that the first and second fundamental forms of the boundary three-manifold be the same for both patches (the Darmois junction conditions[16–18]). This is not the case for the de Sitter kink space–time.[19]

The two patches are most easily described in terms of a new time coordinate[2,6]

$$\overline{t}=t+h(r),$$

with $h(r)$ chosen to satisfy

$$\frac{dh}{dr}=\frac{\sin 2\alpha-\kappa}{\cos 2\alpha},$$

where $\kappa=+1$ for the first patch and $\kappa=-1$ for the second patch. The apparent singularities at $\alpha=\pi/4$ for $\kappa=+1$ and at $\alpha=3\pi/4$ for $\kappa=-1$ (i.e., for $\sin\alpha=\kappa\cos\alpha$) can be removed by using the identities

$$\sin 2\alpha\mp 1\equiv(\cos\alpha\mp\sin\alpha)^2,$$

$$\cos 2\alpha\equiv(\cos\alpha-\sin\alpha)(\cos\alpha+\sin\alpha)$$

to rewrite the derivative dh/dr as

$$\frac{dh}{dr}=\frac{\kappa\sin\alpha-\cos\alpha}{\sin\alpha+\kappa\cos\alpha}.$$

This is clearly well defined and hence $h(r)$ is also well defined, thus ensuring that the kink number will not be affected by the transformation to the new time coordinate $\overline{t}$. The metric is transformed to

$$ds^2=-\cos 2\alpha\ d\overline{t}^2-2\kappa\ d\overline{t}\ dr+r^2\ d\Omega^2,$$

and will be geodesically incomplete at $\alpha=\pi/4$ for $\kappa=+1$ and at $\alpha=3\pi/4$ for $\kappa=-1$, angles which correspond to the same $\sin\alpha=\kappa\cos\alpha$ condition under which trouble originally arose for dh/dt.

Kruskal coordinates,[3] U, V, are given by[2,6]

$$U=\mp e^{\gamma t}\exp\left(2\gamma\kappa\int_{0/A}^{r}\frac{dr}{\cos 2\alpha}\right),$$

$$V=\mp\frac{1}{\gamma a_\kappa}e^{-\gamma t},$$

where the lower limit of integration $0/A$ refers to the choices $r=0$ or $r=A$ at the start of the first or second patches, respectively, where a_κ denotes the values of r at the horizons which occur at a_{+1} in the first patch and at a_{-1} in the second patch, and where γ is a constant. The metric becomes

$$ds^2=-2F(U,V)dU\,dV+r^2\,d\Omega^2,$$

with F given by

$$F=\frac{-a_\kappa\cos 2\alpha}{2\gamma}\exp\left(-2\gamma\kappa\int_{0/A}^{r}\frac{dr}{\cos 2\alpha}\right).$$

(The factor of $-a_\kappa$ in this expression for F was omitted by error in our earlier paper.)[6] The constant γ, which has so far been undetermined, must be chosen so that the function F is finite and nonzero when $\sin\alpha=\kappa\cos\alpha$ (i.e., as $r\to a_\kappa$). When γ is chosen in this way, the extension process is complete. If no such γ can be found, then the Kruskal extension fails.

If the possibility of extending a nonspacelike geodesically incomplete kink space–time to one that is geodesically complete hinges, in part, on the energy conditions being satisfied,[5] then it is appropriate to review these energy conditions and also the physical conditions that were put forward by Finkelstein and McCollum.[2] Following the procedure of Hawking and Ellis (Ref. 20, p. 89), consider the eigenvalue equation

$$(G_{\mu\nu}-\lambda g_{\mu\nu})\xi^\nu=0.$$

The components G_μ^ν of the Einstein tensor are listed in Appendix A. In terms of the function

$$\mu(r):=\tfrac{1}{2}(r-r\cos 2\alpha)=r\sin^2\alpha,$$

introduced by Finkelstein and McCollum,[2] the eigenvalues are given by

$$\lambda_0=\lambda_1=2r^{-2}\,\partial_r\mu,\quad \lambda_2=\lambda_3=-r^{-1}\,\partial_r^2\mu.$$

Corresponding eigenvectors are

$$E_0=(\cos\alpha,\sin\alpha,0,0),\quad E_1=(\sin\alpha,-\cos\alpha,0,0),$$

$$E_2=(0,0,r^{-1},0),\quad E_3=(0,0,0,(r\sin\theta)^{-1}).$$

The eigenvector E_0 is timelike (with the remaining eigenvectors being spacelike) and so, of the four canonical forms listed by Hawking and Ellis (Ref. 20, p. 89), this situation is *Type I*. The $\{E_\alpha\}$ form an orthonormal basis and the tetrad components of the metric tensor are computed according to

$$\overline{g}_{\alpha\beta}=g(E_\alpha,E_\beta)=g_{\mu\nu}E^\mu_\alpha E^\nu_\beta=\mathrm{diag}(-1,1,1,1).$$

Note that $\overline{g^{\alpha\beta}}=\overline{g}_{\alpha\beta}$. It is straightforward to calculate the tetrad components $\overline{G}^{\alpha\beta}$ of the Einstein tensor and hence, using the Einstein equations $G^{\alpha\beta}=T^{\alpha\beta}$, the tetrad components $T^{\alpha\beta}$ of the energy-momentum tensor are found to be $\|T^{\alpha\beta}\|=\mathrm{diag}(\rho,p_1,p_2,p_3)$, where

$$\rho=2r^{-2}\,\partial_r\mu,\quad p_1=-2r^{-2}\,\partial_r\mu,\quad p_2=p_3=-r^{-1}\,\partial_r^2\mu.$$

The weak energy condition states that the energy density as measured by any observer is non-negative, and this is equivalent to requiring $\rho\geqslant 0$ and $\rho+p_\alpha\geqslant 0$, for $\alpha=1, 2, 3$ (Ref. 20, p. 90). These inequalities imply $\partial_r\mu\geqslant 0$ and $\partial_r(r^{-2}\,\partial_r\mu)\leqslant 0$. The strong energy condition holds for a *Type I* energy-momentum tensor provided that, for $\alpha=1, 2, 3$, $\rho+p_\alpha\geqslant 0$ and $\rho+\Sigma p_\alpha\geqslant 0$ (Ref. 20, p. 95). The latter condition is equivalent to $\partial_r^2\mu\leqslant 0$. Note that the strong energy condition does *not* imply the weak energy condition (Ref. 21, p. 219). We now list some physical conditions for $\mu(r)$:

(a) $\partial_r\mu\geqslant 0$ for all r,
(b) $\partial_r(r^{-2}\partial_r\mu)\leqslant 0$ for all r,
(c) $\mu=O(r^3)$ as $r\to 0$ (i.e., $|G^\nu_\mu|<\infty$ at $r=0$),
(d) $0\leqslant\mu/r\leqslant 1$ (i.e., $0\leqslant\sin^2\alpha\leqslant 1$),
(e) $\partial_r^2\mu\leqslant 0$ for all r.

Taken together, conditions (a) and (b) have been shown to be equivalent to the weak energy condition. From Appendix A,

$$G^t_t=G^r_r=-2r^{-2}\partial_r\mu,$$

$$G^\theta_\theta=G^\varphi_\varphi=-r^{-1}\partial_r^2\mu,$$

and so requiring $\mu=O(r^3)$ as $r\to 0$ will ensure that G^ν_μ, and hence T^ν_μ, is finite at the origin. This is condition (c). Condition (d) follows from the definition $\mu:=r\sin^2\alpha$. For present purposes, one needs a somewhat stronger condition than (d) since, to ensure the presence of a kink, we are imposing the boundary conditions $\alpha(0)=0$ and $\alpha(\infty)=\pi$. Thus we require μ to satisfy

(f) $\lim_{r\to 0}(\mu/r)=\lim_{r\to\infty}(\mu/r)=0$,

with μ/r attaining its maximum value of 1 at the value of r corresponding to $\alpha=\pi/2$. Our conditions (a), (c), and (d) agree with the corresponding conditions given by Finkelstein and McCollum (Ref. 2, p. 2253). However, our condition (b) differs from Finkelstein and McCollum's condition (b).

Taken together, conditions (b) and (e) have been shown to be equivalent to the strong energy condition. However, for the kind of spherically symmetric one-kink metrics being discussed, conditions (d) and (f) *must* be satisfied. From condition (f), $\lim_{r\to 0}(\mu/r)=0$ implies that, for small r, $\mu=O(r^{1+c})$ with $c>0$. Hence, for small $r>0$, $\partial_r\mu=O(r^c)>0$ and $\partial_r^2\mu=O(r^{c-1})>0$. The latter inequality violates condition (e), thus showing that the strong energy condition cannot be satisfied by kink metrics of this kind.

In the present paper, the space–times considered are spherically symmetric and have one kink on each hypersurface of constant t. Note that Alty[22] has given a formula for counting the number of kinks on a closed three-manifold or hypersurface within any nonsingular (3+1)-dimensional space–time. An alternative formula has been given by Torre.[23] (See also Ref. 24 for an earlier approach and Ref. 25 for a formula that is valid in 1+1 dimensions.) This concludes the analysis for general α. In Secs. III–V, specific functional forms for α will be chosen.

III. STEREOGRAPHIC KINK

Let the functional form of $\alpha(r)$ be given by

$$\tan(\alpha/2)=r/a,$$

where a is a positive constant and $0\leqslant r<\infty$. Since α varies continuously from $\alpha(0)=0$ to $\alpha(\infty)=\pi$, the resulting metric describes a one-kink space–time. The function $\mu(r)$ is given by

$$\mu=\frac{4a^2r^3}{(a^2+r^2)^2}.$$

Of conditions (a)–(f), only conditions (c), (d), and (f) hold. Thus not even the *weak* energy condition is satisfied. This space–time can be aptly called the ''stereographic kink space–time,'' since the angle α is mapped into a radial distance r in accordance with the usual stereographic projection from a sphere onto a plane with radial coordinate r. The first patch corresponds to the range $0\leqslant r\leqslant a$, and the second patch corresponds to the range $a\leqslant r<\infty$. The $r=a_\kappa$ (i.e., $\sin\alpha=\kappa\cos\alpha$) horizons are located at $r=a_\pm=a(2^{1/2}\mp1)$, where we are abbreviating a_{+1} to a_+ and a_{-1} to a_-. The derivative dh/dr is given by

$$\frac{dh}{dr}=\frac{\kappa 2ar-(a^2-r^2)}{2ar+\kappa(a^2-r^2)},$$

and it is straightforward to show (Ref. 26, §2.103, p. 57) that, to within an arbitrary constant,

$$h(r)=-\kappa r-2^{1/2}\{a_+\ \ln(r+\kappa a_+)+a_-\ \ln(-\kappa r+a_-)\}.$$

Both dh/dr and $h(r)$ are well defined everywhere.

The constants a_+ and a_- satisfy the equations

$$a_+a_-=a^2,$$

$$a_+^2=[3-2(2^{1/2})]a^2,$$

$$a_-^2=[3+2(2^{1/2})]a^2,$$

$$a_-^{-2}-a_+^{-2}=-4(2^{1/2})a^{-2},$$

which lead to

$$\begin{aligned}\frac{1}{\cos 2\alpha}&=\frac{(a^2+r^2)^2}{(a^2-r^2)^2-(2ar)^2}\\&=1+\frac{8a^2r^2}{(a^2-r^2)^2-(2ar)^2}\\&=1+\frac{8a^2r^2}{(r^2-a_+^2)(r^2-a_-^2)}\\&=1-2^{1/2}a^4\left\{\frac{a_-^{-2}}{r^2-a_+^2}-\frac{a_+^{-2}}{r^2-a_-^2}\right\}\\&=1-2^{-1/2}a^2\left\{a_-^{-1}\left(\frac{1}{r-a_+}-\frac{1}{r+a_+}\right)-a_+^{-1}\left(\frac{1}{r-a_-}-\frac{1}{r+a_-}\right)\right\},\end{aligned}$$

and hence, ignoring the constant factor coming from the lower integration limit, to

$$\int^r \frac{dr}{\cos 2\alpha} = r - 2^{-1/2}a^2\{a_-^{-1}(\ln|r-a_+| - \ln|r+a_+|) - a_+^{-1}(\ln|r-a_-| - \ln|r+a_-|)\}.$$

This expression is undefined at $r=a_+$ which occurs in the first patch, and at $r=a_-$ which occurs in the second patch. The constant γ must now be chosen (if possible) so that F is nowhere zero and nowhere infinite. Since

$$\cos 2\alpha = (r^2+a^2)^{-2}(r-a_+)(r+a_+)(r-a_-)(r+a_-),$$

it follows from the equation for F given in Sec. II that the appropriate choices for γ are $\gamma=-2^{-1/2}a^{-2}a_-$ in the first patch, and $\gamma=-2^{-1/2}a^{-2}a_+$ in the second patch. More concisely, $\gamma=-2^{-1/2}a^{-2}a_{-\kappa}$. Since the resulting F is a complicated function of r, it will not be easy to express F as an explicit function of U and V (as was done in the de Sitter case[6]).

IV. NEWTONIAN KINK

The example

$$\mu = \frac{2ar^2}{a^2+r^2}$$

was considered some years ago[7] and was shown to reproduce the Newtonian potential for large r. We shall call it the ''Newtonian kink.'' Conditions (a), (b), (d), and (f) are satisfied, but not conditions (c) or (e). Thus the weak energy condition is satisfied. The angle α is related to r by

$$\sin\alpha = \left(\frac{2ar}{a^2+r^2}\right)^{1/2}, \quad \cos\alpha = \frac{a-r}{(a^2+r^2)^{1/2}},$$

so that the boundary between patches is located at $r=a$. The roots of $\cos 2\alpha$ are $a_\pm = a(2\mp 3^{1/2})$. From

$$a_+a_- = a^2, \quad a_+ + a_- = 4a, \quad a_-^{-1} - a_+^{-1} = -2a^{-1}3^{1/2},$$

it follows that

$$\cos 2\alpha = 1 - \frac{4ar}{r^2+a^2} = \frac{(r-a_+)(r-a_-)}{r^2+a^2},$$

and

$$\frac{1}{\cos 2\alpha} = 1 + \frac{4ar}{(r-a_+)(r-a_-)} = 1 - 2a^2 3^{1/2}\left\{\frac{1}{a_-(r-a_+)} - \frac{1}{a_+(r-a_-)}\right\}.$$

Hence, neglecting the constant factor coming from the lower integration limit,

$$\int^r \frac{dr}{\cos 2\alpha} = r - 2a^2 3^{-1/2}(a_-^{-1}\ln|r-a_+| - a_+^{-1}\ln|r-a_-|).$$

It follows from the equation for F given in Sec. II that F will be nowhere zero and nowhere infinite if we choose $\gamma=-(3^{1/2}/4)a^2a_-$ in the first patch and $\gamma=-(3^{1/2}/4)a^2a_+$ in the second patch.

V. FINKELSTEIN–McCOLLUM KINK

Finkelstein and McCollum[2] proposed

$$\mu=\left(\frac{3}{2+1/r}\right)^3=\frac{27r^3}{8r^3+12r^2+6r+1},$$

which violates condition (e) but satisfies the remaining conditions. Hence μ satisfies the weak but not the strong energy condition. It is interesting to note that Finkelstein and McCollum's condition (b) is also satisfied. The above μ implies

$$\cos 2\alpha=\frac{8r^3-42r^2+6r+1}{8r^3+12r^2+6r+1}.$$

The numerator factorizes as

$$8r^3-42r^2+6r+1=8(r+b)(r-a_+)(r-a_-),$$

where

$$b=\tfrac{1}{2}(3^{3/2}-5)\approx 0.0981,\quad a_+=\tfrac{1}{4},\quad a_-=\tfrac{1}{2}(3^{3/2}+5)\approx 5.0981,$$

so that problems with geodesic incompleteness arise at a_+ in the first patch and at a_- in the second patch. The boundary between patches occurs at $r=1$.

$$\begin{aligned}\frac{1}{\cos 2\alpha}&=1+\frac{27r^2}{4(r+b)(r-a_+)(r-a_-)}\\&=1+\frac{27}{4}\left[\frac{1}{r+b}+\frac{(a_++a_-)r-a_+a_-}{(r+b)(r-a_+)(r-a_-)}\right]\\&=1+\frac{27}{4}\left[\frac{b^2}{(a_++b)(a_-+b)(r+b)}-\frac{a_+^2}{(b+a_+)(a_--a_+)(r-a_+)}\right.\\&\quad\left.+\frac{a_-^2}{(b+a_-)(a_--a_+)(r-a_-)}\right].\end{aligned}$$

Requiring F to be nowhere zero and nowhere infinite in the two patches implies

$$\gamma=-\frac{2(b+a_\kappa)(a_--a_+)}{27a_\kappa^2}.$$

This gives $\gamma=-2$ in the first patch ($\kappa=+1$), and $\gamma\approx-0.0718$ in the second patch ($\kappa=-1$). The above values of a_+ and a_- agree with those of Finkelstein and McCollum but the above values of γ do not [Ref. 2, Eqs. (37) and (38), p. 2256].

VI. SPHERICALLY SYMMETRIC KINKS WITH $\chi\neq 0$

A slightly more general form of metric than that of Sec. II is given by

$$ds^2=-e^{\chi}\cos 2\alpha\ dt^2-2\sin 2\alpha\ dt\ dr+e^{-\chi}\cos 2\alpha\ dr^2+r^2\ d\Omega^2.$$

Again, this is a special case of the metric discussed by Letelier and Wang.[12,13] The Christoffel symbols and the Ricci and Einstein tensors are listed in Appendix B. After a change of time coordinate,

$$\overline{t}=t+h(r), \quad \frac{dh}{dr}=\frac{\sin 2\alpha-\kappa}{e^{\chi}\cos 2\alpha},$$

the method of extension proceeds as in Sec. II, with

$$U=\mp e^{\gamma \overline{t}}\exp\left(2\gamma\kappa\int_{0/A}^{r}\frac{dr}{e^{\chi}\cos 2\alpha}\right),$$

$$V=\mp\frac{1}{\gamma a_{\kappa}}e^{-\gamma \overline{t}},$$

$$F=\frac{-a_{\kappa}e^{\chi}\cos 2\alpha}{2\gamma}\exp\left(-2\gamma\kappa\int_{0/A}^{r}\frac{dr}{e^{\chi}\cos 2\alpha}\right).$$

The function μ defined in Sec. II will now be generalized by defining

$$\mu(r):=\tfrac{1}{2}(r-re^{\chi}\cos 2\alpha).$$

The eigenvalue analysis is similar to before and the energy-momentum tensor can be shown to be of *Type I*, with the elements of $\|T^{\alpha\beta}\|=\mathrm{diag}(\rho,p_1,p_2,p_3)$ being related to $\partial_r\mu$ and $\partial_r^2\mu$ exactly as before, except that the generalized μ is now being used. The form of conditions (a), (b), and (e) is unchanged, as is the relationship between these conditions and the weak and strong energy conditions. However, for the generalized μ, the other conditions listed in Sec. II must be modified:

(c′) $|G^{\nu}_{\mu}|<\infty$ at $r=0$,
(d′) $0\leqslant\sin^2\alpha\leqslant 1$,
(f′) $\alpha(0)=\lim_{r\to 0}(\sin\alpha)=\lim_{r\to\infty}(\sin\alpha)=0$,

with, as before, the understanding that the presence of the kink will force α to pass through $\pi/2$ so that $\sin\alpha$ will attain its maximum value of 1. The discussion of the strong energy condition that was presented at the end of Sec. II can be adapted to the present situation by noting that a space–time with a well-defined kink number requires the metric to be continuous, and so e^{χ} must be a regular function of r in the neighborhood of $r=0$. The fact that e^{χ} is regular at $r=0$ implies that, for small r, the (generalized) μ satisfies $\mu=O(r^{1+c})$ with $c>0$. One can now deduce, following the argument of Sec. II, that the strong energy condition cannot be satisfied by the more general spherically symmetric kink metrics discussed in this section.

VII. EXAMPLE

As an example, let α be the same as for the ''Newtonian'' kink of Sec. IV and let e^{χ} be given by

$$e^{\chi}=\frac{2(r^2+a^2)}{a(a_{-}-a_{+})}.$$

The (r^2+a^2) in the numerator is chosen so that it will cancel with the similar term in the denominator of $\cos 2\alpha$. The constant factors are chosen for later convenience, remembering also that e^{χ} must be dimensionless. Conditions (a), (c′), and (e) are violated. Conditions (b), (d′), and (f′) are satisfied.

It follows from Sec. IV that

$$e^{\chi}\cos 2\alpha=\frac{2(r-a_+)(r-a_-)}{a(a_--a_+)},$$

where $a_\pm=a(2\mp 3^{1/2})$ and $a_+<a<a_-$. Horizons occur at $r=a_+$ in the first patch and at $r=a_-$ in the second patch. The boundary between the two patches occurs at $r=a$.

$$\int_{0/a}^{r}\frac{dr}{e^{\chi}\cos 2\alpha}=\frac{1}{2}\,a\int_{0/a}^{r}\left(\frac{1}{r-a_-}-\frac{1}{r-a_+}\right)dr=\frac{1}{2}\,a\left[\ln\left|\frac{r-a_-}{r-a_+}\right|\right]_{0/a}^{r}.$$

Consider the first patch, $0\leqslant r\leqslant a$;

$$\int_0^r\frac{dr}{e^{\chi}\cos 2\alpha}=\frac{1}{2}\,a\left[\ln\left(\frac{a_--r}{a_+-r}\right)\right]_0^r=\frac{1}{2}\,a\,\ln\left(\frac{a_+(a_--r)}{a_-(a_+-r)}\right).$$

From the equation for F given in Sec. VI, it follows that F will be finite and nonzero if $\gamma=-a^{-1}$. This leads to

$$F=\frac{a_+^2(r-a_-)^2}{a_-(a_--a_+)}.$$

Recall that $a=(a_+a_-)^{1/2}$ and define

$$\lambda:=\left(\frac{a_-}{a_+}\right)^{1/2}=\frac{a_--a}{a-a_+}\approx 3.732.$$

It follows that

$$U=\mp\lambda^2 e^{-\overline{t}/a}\left(\frac{a_+-r}{a_--r}\right),\quad V=\pm\lambda e^{\overline{t}/a},\quad UV=-\lambda^3\left(\frac{a_+-r}{a_--r}\right).$$

These formulas for F, U, V, and UV are valid for $0\leqslant r\leqslant a$. It follows that, for the first patch,

$$r=a_+\lambda^2\left(\frac{\lambda+UV}{\lambda^3+UV}\right)$$

and

$$F=\frac{a_+\lambda^4(a_--a_+)}{(\lambda^3+UV)^2}.$$

The first patch is illustrated in Fig. 1. Regions I_+ and II_+ are *original* regions. (Following González-Díaz,[14] a $\pm$ subscript indicates that the region is in the first/second patch.) Within $I_+\cup II_+$, $r=0$ corresponds to the hyperbola $UV=-\lambda$; $r=a_+$ corresponds to the line $U=0$ (for $V>0$), and $r=a$ corresponds to the hyperbola $UV=\lambda^2$. The extension is performed by allowing V to be negative in the formulas above. This creates the *new* regions III_+ and IV_+ of Fig. 1. The line $r=a_+$, $t=-\infty$ (i.e., $V=0$) forms the boundary between the original and the new regions.

Now consider the second patch, $a\leqslant r<\infty$:

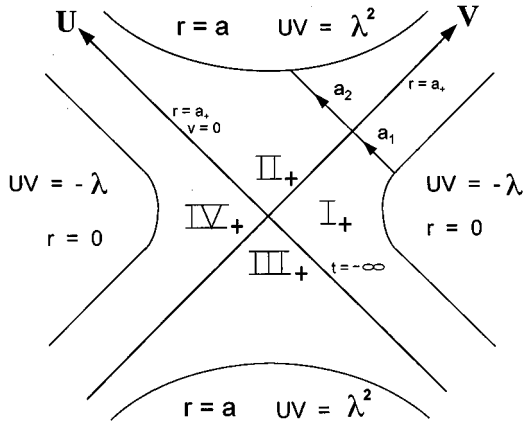

FIG. 1. First patch.

$$\int_a^r \frac{dr}{e^{\chi}\cos 2\alpha} = \frac{1}{2}\,a\left[\ln\left(\frac{a_- - r}{r - a_+}\right)\right]_a^r = \frac{1}{2}\,a\,\ln\left(\frac{a_- - r}{\lambda(r-a_+)}\right).$$

From the equation for F given in Sec. VI, it follows that F will be finite and nonzero if $\gamma = -a^{-1}$. This leads to

$$F = \frac{-\lambda a_-(r-a_+)^2}{a_- - a_+},$$

$$U = \mp\lambda^{-1}e^{-\overline{t/a}}\left(\frac{a_- - r}{r-a_+}\right), \quad V = \pm\lambda^{-1}e^{\overline{t/a}}, \quad UV = -\lambda^{-2}\left(\frac{a_- - r}{r-a_+}\right),$$

and

$$r = \frac{a_-(1-UV)}{1-\lambda^2 UV}, \quad F = \frac{-a_-\lambda(a_- - a_+)}{(1-\lambda^2 UV)^2}.$$

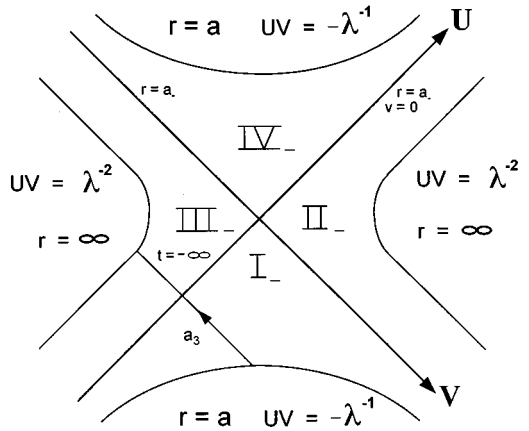

FIG. 2. Second patch.

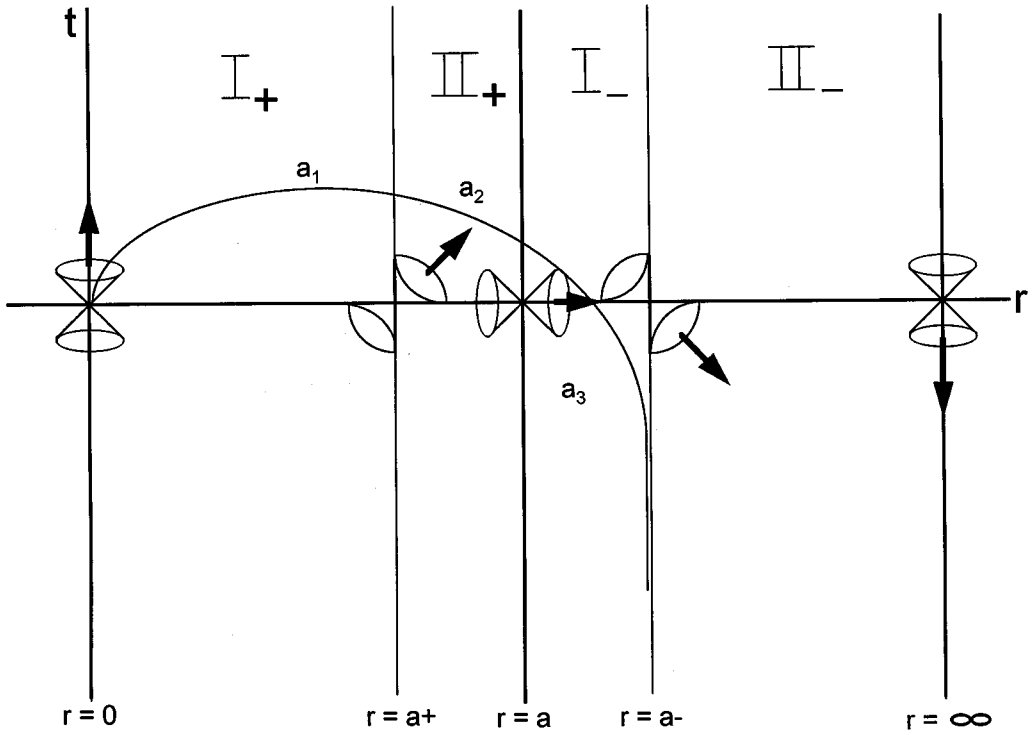

FIG. 3. Kink in rotational coordinates.

The second patch is illustrated in Fig. 2. Regions I_- and II_- are *original* regions. The line $r=a_-$, $t=-\infty$ (i.e., $V=0$) forms the boundary between $I_-\cup II_-$ and the union $III_-\cup IV_-$ of the two *new* regions, III_- and IV_-. The two $UV=\lambda^{-2}$ hyperbolas correspond to $r=\infty$ and the two $UV=-\lambda^{-1}$ hyperbolas correspond to $r=a$. The lower of the two latter hyperbolas (i.e., the $UV=-\lambda^{-1}$ hyperbola of region I_-) is to be joined with the corresponding $r=a$, $UV=\lambda^2$ hyperbola of region II_+ in the upper part of Fig. 1. Physical time is measured upwards in Figs. 1 and 2, and an example of a null geodesic $a_1a_2a_3$ is pictured starting from $r=0$, crossing from I_+ into II_+ and then into I_-, and finally into the new region III_-. The part of this geodesic that is within the original region $I_+\cup II_+\cup I_-$ is illustrated in rotational coordinates in Fig. 3.

Let Σ^+ denote the upper $UV=\lambda^2$ hyperbola in region II_+ of the first patch and let Σ^- denote the lower $UV=-\lambda^{-1}$ hyperbola in region I_- of the second patch. In constructing the kink space–time, one needs to show that Σ^+ and Σ^- can be smoothly joined. The rotational coordinates t,r,θ,φ span $II_+\cup I_-$ and it is easily shown that, in these coordinates, $g_{\mu\nu}$ and $\partial_\lambda g_{\mu\nu}$ are continuous across $\Sigma^\pm$. Thus the Lichnerowicz junction conditions[15] are satisfied and so smooth joining is possible. Although this implies that the Darmois junction conditions[16–18] are also satisfied, it is instructive to check these conditions in the UV-coordinate systems of the two patches. Following Lake,[18] let Σ denote a three-space within the (3+1)-dimensional space–time manifold and let the coordinates intrinsic to Σ be denoted by ξ^i, $i=1,2,3$. Let the equation for Σ be given in terms of the space–time coordinates by $x^\mu=x^\mu(\xi^i)$. Now define the intrinsic metric of Σ (Gauss' first fundamental form) by

$$\gamma_{ij} := \frac{\partial x^\mu}{\partial \xi^i}\frac{\partial x^\nu}{\partial \xi^j} g_{\mu\nu},$$

and the extrinsic curvature of Σ (Gauss' second fundamental form) by

$$K_{ij} := \frac{\partial x^\mu}{\partial \xi^i} \frac{\partial x^\nu}{\partial \xi^j} \nabla_\mu n_\nu,$$

where the unit vector n^λ is normal to Σ and can be found by writing the equation for Σ in the form $f(x^\mu(\xi^i))=0$ and putting

$$n_\lambda = \pm \left| g^{\mu\nu} \frac{\partial f}{\partial x^\mu} \frac{\partial f}{\partial x^\nu} \right|^{-1/2} \frac{\partial f}{\partial x^\lambda}.$$

An alternative and more convenient formula for K_{ij} is given by[17,18]

$$K_{ij} = -n_\lambda \left(\frac{\partial^2 x^\lambda}{\partial \xi^i \partial \xi^j} + \frac{\partial x^\mu}{\partial \xi^i} \frac{\partial x^\nu}{\partial \xi^j} \Gamma^\lambda_{\mu\nu} \right).$$

For the first patch, choose the intrinsic coordinates on Σ^+ to be $(\xi^1,\xi^2,\xi^3)=(V,\theta,\varphi)$ and note that, on Σ^+, $\partial U/\partial V = -\lambda^2 V^{-2}$. The first and second fundamental forms on Σ^+ will be denoted by γ^+_{ij} and K^+_{ij}, respectively. For the second patch, choose the intrinsic coordinates on Σ^- to be $(\xi^1,\xi^2,\xi^3)=(V,\theta,\varphi)$ and note that, on Σ^-, $\partial U/\partial V = \lambda^{-1} V^{-2}$. The first and second fundamental forms on Σ^- will be denoted by γ^-_{ij} and K^-_{ij}, respectively. The two Darmois conditions are $\gamma^+_{ij}=\gamma^-_{ij}$ and $K^+_{ij}=K^-_{ij}$, for $i,j=1,2,3$. It is straightforward to show that

$$\gamma^+_{VV} = \gamma^-_{VV} = \tfrac{1}{3} a (a_- - a_+) V^{-2},$$

$$\gamma^+_{\theta\theta} = \gamma^-_{\theta\theta} = a^2, \quad \gamma^+_{\varphi\varphi} = \gamma^-_{\varphi\varphi} = a^2 \sin^2\theta,$$

with the remaining components of $\gamma^\pm_{ij}$ being zero. Thus the first Darmois condition is satisfied.

The components of the unit normal vector on Σ^+ and Σ^- are, respectively,

$$n^+_U = (\lambda^2 C)^{-1} V, \quad n^+_V = (CV)^{-1} \quad n^+_\theta = n^+_\varphi = 0,$$

$$n^-_U = \lambda C^{-1} V, \quad n^-_V = -(CV)^{-1}, \quad n^-_\theta = n^-_\varphi = 0,$$

where

$$C = 2^{1/2} a^{-1} (a_-^{1/2} + a_+^{1/2})(a_- - a_+)^{-1/2}.$$

Care has been taken to choose the signs of $n^\pm_\mu$ so that n^+_μ is directed outwards from II_+ and n^-_μ is directed into I_-. It can now be shown that

$$K^+_{VV} = K^-_{VV} = -2C^{-1}(\lambda-1)(\lambda+1)^{-1} V^{-2},$$

$$K^+_{\theta\theta} = K^-_{\theta\theta} = -2C^{-1},$$

with $K^\pm_{\varphi\varphi} = \sin^2\theta K^\pm_{\theta\theta}$ and the remaining components of $K^\pm_{ij}$ being zero. Thus the second Darmois condition is satisfied.

VIII. SUMMARY

The problem of geodesic incompleteness was considered for two kinds of spherically symmetric kink space–times. Conditions that these space–times might satisfy were discussed in relation to the weak and strong energy conditions, and it was shown that the strong energy condition could not be satisfied. Examples were introduced and, in each case, the constant γ necessary to

perform the Kruskal extension was computed. In the most complicated of these examples, a judicious choice of the function e^{χ} enabled the transformation between tr-coordinates and UV-coordinates to be calculated explicitly and the Kruskal patches to be constructed. The junction conditions were shown to hold across the hypersurface located at the join of the two patches.

APPENDIX A: EINSTEIN TENSOR FOR SIMPLEST SPHERICALLY SYMMETRIC KINK

For the metric

$$ds^2 = -\cos 2\alpha\ dt^2 - 2\sin 2\alpha\ dt\ dr + \cos 2\alpha\ dr^2 + r^2\ d\Omega^2,$$

with $\alpha = \alpha(r)$, the nonzero Christoffel symbols are as follows:

$$\Gamma^t_{tt} = \sin^2 2\alpha\ \partial_r\alpha, \quad \Gamma^t_{tr} = \Gamma^r_{tt} = -\sin 2\alpha\ \cos 2\alpha\ \partial_r\alpha,$$

$$\Gamma^t_{rr} = (1 + \cos^2 2\alpha)\partial_r\alpha, \quad \Gamma^r_{tr} = -\sin^2 2\alpha\ \partial_r\alpha,$$

$$\Gamma^t_{\theta\theta} = r\ \sin 2\alpha, \quad \Gamma^t_{\varphi\varphi} = r\ \sin^2\ \theta\ \sin 2\alpha,$$

$$\Gamma^r_{rr} = \sin 2\alpha\ \cos 2\alpha\ \partial_r\alpha, \quad \Gamma^r_{\theta\theta} = -r\ \cos 2\alpha,$$

$$\Gamma^\theta_{r\theta} = \Gamma^\varphi_{r\varphi} = r^{-1}, \quad \Gamma^r_{\varphi\varphi} = -r\ \sin^2\ \theta\ \cos 2\alpha,$$

$$\Gamma^\theta_{\varphi\varphi} = -\sin\ \theta\ \cos\ \theta, \quad \Gamma^\varphi_{\theta\varphi} = \cot\ \theta.$$

With Δ defined as

$$\Delta := 2r^{-2}\partial_r(r\ \sin^2\ \alpha),$$

the nonzero components of the Ricci tensor are

$$R_{tt} = -R_{rr} = -(2r)^{-1}\ \cos 2\alpha\ \partial_r(r^2\Delta),$$

$$R_{tr} = -(2r)^{-1}\ \sin 2\alpha\ \partial_r(r^2\Delta),$$

$$R_{\theta\theta} = r^2\Delta, \quad R_{\varphi\varphi} = r^2\ \sin^2\ \theta\Delta,$$

with the curvature scalar being given by

$$R = 2r^{-2}\partial_r^2(r^2\ \sin^2\ \alpha) = 2\Delta + r^{-1}\partial_r(r^2\Delta).$$

The nonzero mixed components of the Einstein tensor are

$$G^t_t = G^r_r = -\Delta, \quad G^\theta_\theta = G^\varphi_\varphi = -(2r)^{-1}\partial_r(r^2\triangle).$$

The $\mu(r)$ of Finkelstein and McCollum[2] is related to $\triangle$ by

$$\Delta := 2r^{-2}\partial_r\mu,$$

whence

$$G^t_t = G^r_r = -2r^{-2}\partial_r \mu, \quad G^\theta_\theta = G^\varphi_\varphi = -r^{-1}\partial_r^2 \mu.$$

APPENDIX B: EINSTEIN TENSOR FOR SPHERICALLY SYMMETRIC KINK WITH $\chi=0$

For the metric

$$ds^2 = -e^\chi \cos 2\alpha \; dt^2 - 2 \sin 2\alpha \; dt \; dr + e^{-\chi} \cos 2\alpha \; dr^2 + r^2 \; d\Omega^2,$$

with $\alpha=\alpha(r)$ and $\chi=\chi(r)$, the nonzero Christoffel symbols are as follows:

$$\Gamma^t_{tt} = e^\chi \sin 2\alpha (\sin 2\alpha \; \partial_r \alpha - \tfrac{1}{2} \cos 2\alpha \; \partial_r \chi),$$

$$\Gamma^t_{tr} = \cos 2\alpha (-\sin 2\alpha \partial_r \alpha + \tfrac{1}{2} \cos 2\alpha \; \partial_r \chi),$$

$$\Gamma^r_{tt} = e^{2\chi} \cos 2\alpha (-\sin 2\alpha \; \partial_r \alpha + \tfrac{1}{2} \cos 2\alpha \; \partial_r \chi),$$

$$\Gamma^t_{rr} = e^{-\chi}[(1+\cos^2 2\alpha)\partial_r \alpha + \tfrac{1}{2} \sin 2\alpha \; \cos 2\alpha \partial_r \chi],$$

$$\Gamma^r_{tr} = e^\chi \sin 2\alpha (-\sin 2\alpha \partial_r \alpha + \tfrac{1}{2} \cos 2\alpha \; \partial_r \chi),$$

$$\Gamma^t_{\theta\theta} = r \; \sin 2\alpha, \quad \Gamma^t_{\varphi\varphi} = r \; \sin^2 \; \theta \sin 2\alpha,$$

$$\Gamma^r_{rr} = \cos 2\alpha (\sin 2\alpha \; \partial_r \alpha - \tfrac{1}{2} \cos 2\alpha \; \partial_r \chi),$$

$$\Gamma^r_{\theta\theta} = -re^\chi \cos 2\alpha, \quad \Gamma^\theta_{r\theta} = \Gamma^\varphi_{r\varphi} = r^{-1},$$

$$\Gamma^r_{\varphi\varphi} = -re^\chi \sin^2 \; \theta \cos 2\alpha, \quad \Gamma^\theta_{\varphi\varphi} = -\sin \; \theta \cos \; \theta,$$

$$\Gamma^\varphi_{\theta\varphi} = \cot \; \theta.$$

Define Φ by

$$\Phi = r^{-2}\partial_r (r - re^\chi \cos 2\alpha)$$

(noting that $\Phi=\Delta$ whenever $\chi=0$). The nonzero Ricci tensor components and the Ricci scalar are

$$R_{tt} = -(2r)^{-1} e^\chi \cos 2\alpha \; \partial_r (r^2 \Phi),$$

$$R_{tr} = -(2r)^{-1} \sin 2\alpha \; \partial_r (r^2 \Phi),$$

$$R_{rr} = (2r)^{-1} e^{-\chi} \cos 2\alpha \; \partial_r (r^2 \Phi),$$

$$R_{\theta\theta} = r^2 \Phi, \quad R_{\varphi\varphi} = r^2 \sin^2 \; \theta \Phi, \quad R = 2\Phi + r^{-1} \; \partial_r (r^2 \Phi).$$

The nonzero mixed components of the Einstein tensor are

$$G^t_t = G^r_r = -\Phi, \quad G^\theta_\theta = G^\varphi_\varphi = -(2r)^{-1} \partial_r (r^2 \Phi).$$

Topological properties of single gravisolitons

Reinaldo J. Gleiser, Alexander Garate, and Carlos O. Nicasio

(Received 10 July 1995; accepted for publication 30 May 1996)

The possibility of assigning topological properties to gravisolitons has been recently discussed by Belinsky, who considered perturbations of certain diagonal metrics with two commuting Killing vectors. The discussion given by Belinsky relies on the properties of the solitonic part of the projection of the four-dimensional space–time metric onto the two-dimensional space spanned by the Killing vectors. In that context, for single soliton perturbations, he finds two types of, in principle, disjoint solutions, characterized respectively by the functions $\mu_{\rm in}$ and $\mu_{\rm out}$, such that one can assign a ''topological charge'' to the corresponding space–time. In this article we analyze this problem, studying in detail the single soliton perturbation of a Bianchi-type VI_0 background, and prove that when we consider the full four-dimensional metric, it is possible to construct locally smooth extensions that connect sectors associated to $\mu_{\rm in}$ to sectors associated to $\mu_{\rm out}$. Therefore, the concept of ''topological charge'' for this type of gravisolitons needs to be revised. Some ideas in this direction are discussed in this paper. We also show that this behavior is not restricted to the particular case of a Bianchi-type VI_0 background, but holds in general for the whole set of diagonal background metrics considered by Belinsky. An interesting side result is that the soliton perturbation ''erases'' the ''cosmological'' singularity that appears naturally in the background metrics, and that they can be extended to regions not covered in the original charts. In the particular case of a Bianchi-type VI_0 background, the resulting extended metric is regular everywhere. Finally we present an extension of the soliton metric to the background by matching these metrics through a null hypersurface. This extension requires the presence of a ''null dust'' on the matching hypersurface, and therefore the resulting space–time is not a vacuum everywhere. © *1996 American Institute of Physics.* [S0022-2488(96)01911-1]

I. INTRODUCTION

The possibility of assigning topological properties to gravisolitons has been recently discussed by Belinsky,[1] who considered perturbations of certain diagonal metrics with two commuting Killing vectors. These are of the form

$$ds^2=f_0(-dt^2+dz^2)+\alpha e^{u_0}(dx^1)^2+\alpha e^{-u_0}(dx^2)^2, \tag{1}$$

where f_0, α, and u_0 are functions of t and z. If we set $t=\xi-\eta$ and $z=\xi+\eta$, α and u_0 satisfy the equations

$$\alpha_{,\xi\eta}=0, \tag{2}$$

$$(\alpha u_{o,\xi})_{,\eta}+(\alpha u_{o,\eta})_{,\xi}=0. \tag{3}$$

We may then write

0022-2488/96/37(11)/5652/13/$10.00

$$\alpha = a(\xi) + b(\eta), \tag{4}$$

where a and b are arbitrary functions, and define

$$\beta = a(\xi) - b(\eta) \tag{5}$$

so that α and β are linearly independent solutions of the wave equation (2).

According to Ref. 1, the one-soliton metric on this background can be written in the form

$$ds^2 = f(t,z)(dz^2 - dt^2) + g_{ab}dx^a dx^b, \tag{6}$$

where $a,b = 1,2$ ($x^1 = x$, $x^2 = y$), and we have

$$g = \begin{pmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{pmatrix} = \frac{1}{2|\mu|\cosh(\rho)} \begin{pmatrix} (\mu^2 e^{\rho} + \alpha^2 e^{-\rho}) e^{u_0} & \alpha^2 - \mu^2 \\ \alpha^2 - \mu^2 & (\alpha^2 e^{\rho} + \mu^2 e^{-\rho}) e^{-u_0} \end{pmatrix} \tag{7}$$

and

$$f = c_0 f_0 \alpha^{1/2} |\mu| \cosh(\rho) (\alpha^2 - \mu^2)^{-1}. \tag{8}$$

We notice that any solution of the vacuum Einstein equations that can be written in the form (6) is defined up to an arbitrary constant multiplying the coefficient f. On this account, and for further convenience, we have explicitly included the real parameter c_0 in (8). The sign of this constant will determine the timelike or spacelike nature of the vectors $\partial/\partial t$ and $\partial/\partial z$.

The function $\mu(t,z)$ is a solution of the quadratic equation

$$\mu^2 + 2(\beta - w)\mu + \alpha^2 = 0 \tag{9}$$

in which w is an arbitrary real constant and the function $\rho(t,z)$ can be found by quadratures from the differential equations

$$\begin{aligned} \rho_{,\xi} &= (\alpha + \mu)(\alpha - \mu)^{-1} u_{0,\xi}, \\ \rho_{,\eta} &= (\alpha - \mu)(\alpha + \mu)^{-1} u_{0,\eta}. \end{aligned} \tag{10}$$

Following the notation of Ref. 1, the solutions of (9) can be written as

$$\begin{aligned} \mu_{\text{in}} &= (w - \beta)\{1 - [1 - \alpha^2 (w - \beta)^{-2}]^{1/2}\}, \\ \mu_{\text{out}} &= (w - \beta)\{1 + [1 - \alpha^2 (w - \beta)^{-2}]^{1/2}\}. \end{aligned} \tag{11}$$

These definitions are motivated by the fact that if $\mu = \mu_{\text{in}}$, then the values of μ are inside the interval $[-\alpha, \alpha]$, while for $\mu = \mu_{\text{out}}$ the corresponding values are outside that interval. It is clear from the previous expressions that the property, e.g., $\mu = \mu_{\text{in}}$ (or $\mu = \mu_{\text{out}}$), is maintained in any neighborhood where (7) and (8) are well defined and regular, since the functions f and ρ are singular when $\mu = \pm\alpha$.

The discussion given by Belinsky in Ref. 1 relies on the properties of the solitonic part of the projection of the four-dimensional space–time metric onto the two-dimensional space spanned by the Killing vectors. In that context, for single soliton perturbations, and in accordance with the previous discussion, he finds two types of, in principle, disjoint solutions, characterized respectively by having either $\mu = \mu_{\text{in}}$ or $\mu = \mu_{\text{out}}$, in such a way that one can assign a ''topological charge'' to the corresponding space–time.

There are, however, some difficulties in this interpretation when we look at the complete set of metric coefficients characterizing the solitonic solutions. As indicated in Ref. 1, we have

$$\mu_{\text{in}}\mu_{\text{out}}=\alpha^2. \tag{12}$$

Then, if we call ρ_{in} and ρ_{out} the functions ρ, defined by (10), associated respectively with μ_{in} and μ_{out}, it is easy to check that for any ρ_{in} we may choose ρ_{out} such that $\rho_{\text{in}}=-\rho_{\text{out}}$. However, as can be seen by making the appropriate replacements in (7) and (8), this means that if we call f_{in} and g^{in}_{ab} the metric coefficients in (7) and (8) corresponding to a solution with μ_{in} and ρ_{in}, and f_{out} and g^{out}_{ab} those corresponding to a solution with μ_{out} and ρ_{out}, and the same c_0, we have

$$g^{\text{in}}_{11}=g^{\text{out}}_{11}, \quad g^{\text{in}}_{12}=-g^{\text{out}}_{12},$$

$$g^{\text{in}}_{22}=g^{\text{out}}_{22}, \quad f^{\text{in}}=-f^{\text{out}}.$$

Since a change in sign in g_{12} corresponds to an isometry where we change the sign of either x^1 or x^2, we conclude that a solution with μ_{in} and ρ_{in}, and a certain choice of c_0, is indistinguishable from that corresponding to μ_{out} and ρ_{out} and the opposite sign of c_0. This discrete symmetry bears a certain formal resemblance to that present for the kink and anti-kink solitons in the Sine–Gordon equation, in the sense that one is formally indistinguishable from the other if we include the change $x\rightarrow -x$ as a symmetry operation. We also remark that a change in sign in c_0 corresponds to a change in the choice of which of $\partial/\partial t$ or $\partial/\partial z$ is timelike.

In this article we analyze these properties in detail, studying the particular example of the single soliton perturbation of a Bianchi-type VI_0 background. We show that when we consider the full four-dimensional metric, it is possible to construct locally smooth extensions that connect sectors associated to μ_{in} to sectors associated to μ_{out}. Furthermore, by some rather natural restrictions on the coordinate ranges, it is possible to give a simple and interesting geometrical interpretation to the soliton metric, where we find sectors with $\mu=\mu_{\text{in}}$ and sectors with $\mu=\mu_{\text{out}}$. Therefore, our results seem to indicate that the concept of ''topological charge'' for this type of gravisolitons needs to be revised. Some ideas in this direction are discussed in this paper in Sec. V, where the present case is compared to that of the Sine–Gordon equation.[2]

We also show that this behavior is not restricted to the particular case of a Bianchi-type VI_0 background, but holds likewise for the whole set of diagonal background metrics considered by Belinsky. An interesting general property, obtained as a side result in our derivation, is that the soliton perturbation ''erases'' the ''cosmological'' singularity that appears naturally in the background metrics. The proofs are given in two Appendices.

Finally we present an extension of the soliton metric to the background, by matching these metrics through the null hypersurfaces $\mu^2=\alpha^2$. These extensions require the presence of a ''null dust'' on the matching hypersurface, and therefore the resulting space–time is not a vacuum everywhere.

II. THE METRIC

We consider a single real pole soliton perturbation of a seed metric that is a particular case of the metrics of the form (1), and corresponds to a vacuum Bianchi-type VI_0 metric.[3] This seed metric can be written in the form

$$ds^2=f_0(dz^2-dt^2)+te^{2kz}dx^2+te^{-2kz}dy^2, \tag{13}$$

where $f_0=\exp(k^2t^2)/\sqrt{t}$ *and* $k>0$.

In the case of (13), $\alpha=t$, we may take $\beta=z$, and the functions μ and ρ can be written as

$$\mu_\epsilon = \omega - z + \epsilon[(\omega - z)^2 - t^2]^{1/2}, \tag{14}$$

$$\rho = 2k\epsilon[(\omega - z)^2 - t^2]^{1/2}, \tag{15}$$

where ω is an arbitrary constant and $\epsilon = \pm 1$. Comparing with Ref. 1, we have $\mu_{+1} = \mu_{\text{in}}$ and $\mu_{-1} = \mu_{\text{out}}$. Without loss of generality, we may set $\omega = 0$ in what follows, on account of the homogeneity of the background.

It is clear from these definitions that the coefficients g_{ij} depend only on t^2. Replacing the definitions of μ and ρ in (8), we have

$$f = c_0 \exp(k^2 t^2)|\mu|\cosh(\rho)/(\alpha^2 - \mu^2). \tag{16}$$

Therefore, the metric depends only on t^2, and any region with t restricted to $t<0$ is isometric to an appropriate region where $t>0$. Since there is, in principle, a singularity for $t=0$, on account of the vanishing of $\alpha = \det(g)^{1/2}$, we only need to consider $t>0$ in our analysis of the geometrical properties of the metric.

The single soliton metric resulting from (13) is a well-defined vacuum solution of Einstein's equations, only if we restrict to $z^2 > t^2$, because μ is complex when $z^2 < t^2$, and the metric is no longer real. Therefore, the regions $z>0$ and $z<0$ correspond to separate charts in the (t,z) plane. It is not difficult to show, however, that a single soliton metric defined for certain fixed c_0 and ϵ, in the region $z<0$, is isometric to a single soliton metric with the same c_0, but the opposite sign for ϵ, defined in the region $z>0$.[4] Since we are considering both signs for ϵ, we may, without loss of generality, restrict our discussion to the sector $z>0$, $t>0$, with $z>t$.

We now notice that, besides those already mentioned, there is also a singularity in f for $z^2 = t^2$, since in that case we have $\alpha^2 = \mu^2$, and the denominator vanishes. The consequences of the presence of this type of singularity in solitonic solutions have been analyzed in detail in Ref. 5. In the present case, the procedures developed in Ref. 5 to handle this problem may be applied as follows: if we consider the general form of the metric (6), together with the restriction $z>0$, $t>0$, which defines a sector whose boundaries are at $t=0$ corresponding to the vanishing of $\det(g)$, and $t=z$, where the square root in μ vanishes, we notice that we still have two possible choices for ϵ, and two signs for c_0. With the given restrictions, the coefficient f may be written as

$$f = c_0 \epsilon \frac{\exp(k^2 t^2)\cosh(\rho)}{2(z^2 - t^2)^{1/2}}. \tag{17}$$

This implies that $\partial/\partial t$ is timelike if $c_0\epsilon > 0$, corresponding to the choice made in Ref. 1, but $\partial/\partial t$ is spacelike when $c_0\epsilon > 0$, which is also a solution, not considered in Ref. 1.

We take first the case $c_0\epsilon > 0$, and notice that μ can be written in the form

$$\mu_\epsilon = -[(z-t)^{1/2} - \epsilon(z+t)^{1/2}]^2/2. \tag{18}$$

This suggests[5] the introduction of new coordinates u and v, given by

$$u = +(z+t)^{1/2}, \quad v = -(z-t)^{1/2}. \tag{19}$$

The region $z>t>0$ in the t,z plane is then mapped one-to-one to the region $u>-v>0$ in the u,v plane, and using (19) we find

$$\mu_\epsilon = -(u + \epsilon v)^2/2, \tag{20}$$

$$\rho = -2k\epsilon uv, \tag{21}$$

$$\alpha = t = (u^2 - v^2)2, \tag{22}$$

$$z=(u^2+v^2)/2. \tag{23}$$

The metric coefficients g_{ab} in the coordinate system $\{u,v,x,y\}$ are simply obtained by replacing, in the corresponding functions, the appropriate functional dependencies in u and v [Eqs. (20)–(23)]. Taking into account that $\epsilon=\pm 1$, this gives the following expressions for g_{ab}:

$$g_{11}=\frac{(u+v)^2\ \exp(k(u-v)^2)+(u-v)^2\ \exp(k(u+v)^2)}{4\cosh(2kuv)},$$

$$g_{12}=-\frac{\epsilon uv}{\cosh(2kuv)}, \tag{24}$$

$$g_{22}=\frac{(u+v)^2\exp(-k(u-v)^2)+(u-v)^2\ \exp(-k(u+v)^2)}{4\cosh(2kuv)}.$$

Then, using the relation $-dt^2+dz^2=4uv\,du\,dv$, after the coordinate transformation (19), we find

$$ds^2=-2\tilde{f}(u,v)\,du\,dv+\tilde{g}_{ab}(u,v)\,dx^a dx^b, \tag{25}$$

with $\tilde{g}_{ab}(u,v)=g_{ab}(t(u,v),z(u,v))$ and

$$\tilde{f}=\mathscr{C}_0\ \cosh(2kuv)\exp(k^2(u^2-v^2)^2/4), \tag{26}$$

where $\mathscr{C}_0=c_0\epsilon$ is a positive constant, on account of our choice $c_0\epsilon>0$.

The results summarized in (24) and (26), though rather surprising, because it is apparent that almost all information on ϵ (and, therefore, on μ_{in} and μ_{out}) has been lost, except for the sign of the coefficient g_{12}, are in agreement with the discussion in Sec. I. Moreover, as indicated, even this sign has no *a priori* (local) geometrical meaning, because it can be changed to the opposite by a linear isometry in x^1 and x^2. The situation may be different, however, if we consider global properties of the solitonic solutions.

We remark again that (25) is isometric to (6) in the region $u>-v>0$. However, it is clear from (24) and (26) that the solitonic metric (25) is well defined and regular for $v=0$ (that is, $z=t$) and for $u>v>0$. The region $u>v>0$ in (25) corresponds, therefore, to a locally smooth extension of (6) through the hypersurface $z=t$, where the coordinate system of (6) is singular.

To clarify the nature of this extension to $v>0$, we consider again the metric in (t,z) coordinates, but now in the case $c_0\epsilon<0$, where $\partial/\partial t$ is spacelike. We define new coordinates u and v by

$$u=+(z+t)^{1/2},\quad v=(z-t)^{1/2}, \tag{27}$$

which now map one-to-one the region $z>t>0$ in the t,z plane to the region $u>v>0$ in the u,v plane. If we carry out the same procedures as in the previous case, we find exactly the same forms (24) and (26) for the transformed metric coefficients (up to an isometry of the form $x\to -x$), provided we define, in this case, the positive constant $\mathscr{C}_0$ by $\mathscr{C}_0=-c_0\epsilon$. This metric is, in this case, defined for $v>0$, but, on account of the previous discussion, it is trivially smoothly extended to the region $v<0$. Thus, if we consider the metric defined by (24) and (26) in the whole region $u>0$, $-u<v<u$, we find that all the single soliton metrics derived from (13), with a given value of $|c_0|$, and any ϵ, can be isometrically mapped to either the region $v>0$, or the region $v<0$, of a single (u,v) chart, where the metric takes the form (24) and (26), with $\mathscr{C}_0=|c_0|$. In other words, all forms of the single soliton metrics derived from (13) are contained in the extended (u,v) chart.

Going back to the question of the distinction between μ_{in} and μ_{out}, we notice that going from $v<0$ to $v>0$ corresponds formally to the change $v\to -v$. However, a change in sign in the

coordinate v is equivalent to the change $\epsilon \to -\epsilon$ along with a change of sign in f. Therefore, the original sector $z>t>0$ of an ϵ-type single soliton metric is smoothly extended to a similar sector, $z>t>0$, of a $-\epsilon$-type single soliton metric, but with the opposite sign for the c_0 parameter, that is, to a sector where $\partial/\partial t$ is spacelike and $\partial/\partial z$ is timelike. Thus, the metric (25) smoothly matches a region of space–time where $\mu=\mu_{\text{in}}$ with a region where $\mu=\mu_{\text{out}}$, a result that does not agree, in principle, with that described in Ref. 1. We shall comment more on this below, but first we will consider further extensions of (25), and show the interesting fact that in these the solitonic perturbation ''erases'' the ''cosmological singularity'' present in (13) for $t=0$.

As a final comment on this section, we remark that the possibility of smoothly extending the soliton metric through the hypersurfaces $\mu^2=\alpha^2$ is not restricted to the Bianchi-type VI_0 metrics, but, as shown in Appendix B, holds for general single soliton transformations of background metrics of the form (1).

III. GEOMETRICAL INTERPRETATION

The metric (25) is regular everywhere in the region $u>|v|$, but, since we have $\det(g)^{1/2}=(u^2-v^2)/2$, it is singular for $u=\pm v$. In this section we analyze the nature of these singularities of the soliton solution and show that with appropriate choices and restrictions on the coordinate systems, the metric can be made regular both for $u=v$ and $u=-v$.

The analysis is simplified if we introduce new coordinates, τ and R, related to u and v by

$$\tau=u+v, \quad R=u-v. \tag{28}$$

In terms of these coordinates, the metric coefficients take the form

$$2\tilde{f}(u,v)du\,dv=F(\tau,R)(-d\tau^2+dR^2)=\tfrac{1}{2}\mathscr{C}_0\cosh[k(R^2-\tau^2)/2]\exp(k^2R^2\tau^2/4)(-d\tau^2+dR^2) \tag{29}$$

and

$$g=\frac{1}{4\cosh[k(R^2-\tau^2)/2]}\begin{pmatrix}\tau^2\exp(kR^2)+R^2\exp(k\tau^2) & \epsilon(R^2-\tau^2)\\ \epsilon(R^2-\tau^2) & \tau^2\exp(-kR^2)+R^2\exp(-k\tau^2)\end{pmatrix}. \tag{30}$$

We notice that $\det(g_{ab})=R^2\tau^2/4$. That is, the singularities for $u=v$ and $u=-v$ appear in this coordinate system as singularities for $R=0$ and $\tau=0$. To analyze their structure, we consider the behavior of the metric coefficients in the limits $R\to 0$ and $\tau\to=0$.

We first notice that near $R=0$ we have

$$g\simeq\frac{1}{4\cosh[k\tau^2/2]}\begin{pmatrix}\tau^2+R^2\exp(k\tau^2) & -\epsilon\tau^2\\ -\epsilon\tau^2 & \tau+R^2\exp(-k\tau^2)\end{pmatrix} \tag{31}$$

while

$$2F(\tau,R)\simeq\mathscr{C}_0\cosh[k\tau^2/2], \tag{32}$$

These results suggest that we may ''diagonalize'' the metric (near $R=0$ and to order R^2) by introducing a ''rotation'' in the x,y plane, defining new coordinates η and Φ by the relations

$$x=\Phi-\epsilon\eta, \quad y=\Phi+\epsilon\eta. \tag{33}$$

With this change of coordinates the Killing part of the metric becomes

$$g_{\Phi\Phi}=\frac{R^2\ \cosh(k\tau^2)+\tau^2\cosh(kR^2)+(R^2-\tau^2)}{2\ \cosh(k(R^2-\tau^2)/2)}, \tag{34}$$

$$g_{\eta\Phi}=\frac{R^2\ \sinh(k\tau^2)+\tau^2\ \sinh(kR^2)}{2\ \cosh(k(R^2-\tau^2)/2)}, \tag{35}$$

$$g_{\eta\eta}=\frac{R^2\ \cosh(k\tau^2)+\tau^2\ \cosh(kR^2)-(R^2-\tau^2)}{2\ \cosh(k(R^2-\tau^2)/2)}, \tag{36}$$

and in the limit $R\to 0$, the leading orders of the metric coefficients are of the form

$$F=\tfrac{1}{2}\mathscr{C}_0\ \cosh(k\tau^2/2)+\mathscr{O}(R^2), \tag{37}$$

$$g_{\Phi\Phi}=\cosh(k\tau^2/2)R^2+\mathscr{O}(R^4), \tag{38}$$

$$g_{\Phi\eta}=\mathscr{O}(R^2), \tag{39}$$

$$g_{\eta\eta}=\frac{\tau^2}{\cosh(k\tau^2/2)}+\mathscr{O}(R^2). \tag{40}$$

However, then the singularity for $R=0$ is removed if we choose $C_0=2$, restrict Φ and R to the ranges $0\leqslant R<\infty$, $0\leqslant\Phi\leqslant 2\pi$, and identify $\Phi=0$ and $\Phi=2\pi$, because in this case, for $\tau\neq 0$, the singularity along $R=0$ can be interpreted as the coordinate singularity along a regular symmetry axis in cylindrical spatial coordinates.[6]

Similarly, taking as before $\mathscr{C}_0=2$, near $\tau=0$, the leading orders of the metric coefficients are of the form

$$\begin{aligned} F&=\cosh(kR^2/2)+O(\tau^2),\\ g_{\Phi\Phi}&=\frac{R^2}{\cosh(kR^2/2)}+O(\tau^2),\\ g_{\Phi\eta}&=O(\tau^2),\\ g_{\eta\eta}&=\cosh(kR^2/2)\,\tau^2+O(\tau^4). \end{aligned} \tag{41}$$

This form of the metric coefficients implies that the singularity for $\tau=0$ is of the Rindler type. It can be removed by the following coordinate transformation:[7]

$$T=\tau\ \cosh(\eta),\quad Z=\tau\ \sinh(\eta). \tag{42}$$

This transformation maps the region $\tau>0$, $-\infty<\eta<+\infty$, of the (τ,η) plane to the region $T\geqslant|Z|$ of the (T,Z) plane. However, after replacing the new coordinates in the metric coefficients, it is easy to check that the new metric is defined for *all* values of T and Z, and the already defined ranges for Φ and R, and can be, therefore, naturally extended to the regions $|T|<|Z|$.

We notice, however, that the extended regions $|T|<|Z|$ do not correspond to any of the regions defined by the ''canonical'' chart (t,z,x^1,x^2). This is easily seen if we transform the metric to new coordinates $\tilde{\tau}$ and $\tilde{\eta}$ defined by

$$T=\tilde{\tau}\ \sinh(\tilde{\eta}), \tag{43}$$

$$Z=\tilde{\tau}\ \cosh(\tilde{\eta}). \tag{44}$$

In this case the new metric coefficients corresponding to the regions $|T|<|Z|$ have the same formal expressions as (29) and (30) but with the (formal) replacement $\tau\to i\tilde{\tau}$. Since the metric depends on τ only through τ^2, the net effect is that $\partial/\partial\tilde{\tau}$ is now *spacelike*. Moreover, the determinant of g_{ab}, namely α^2, is now given by $-\tilde{\tau}^2R^2$, and becomes negative. Therefore, one of the Killing vectors changes from spacelike to timelike when we cross the boundary $\tau^2=0$, and the metric is actually *stationary* in the regions $|T|<|Z|$.

This dependence of the metric on τ^2 implies also that the solitonic metric is symmetric also with respect to T, where the metric is regular for $T=0$. Therefore $T=0$ corresponds to a moment of time symmetry for the whole space–time.

One may shed more light on the nature of the symmetries of this space–time by considering the Killing vector $\partial/\partial\eta$. In the chart (τ,η,R,Φ), its norm is given by $g_{\eta\eta}$. In the coordinate chart (T,R,Φ,Z), in the overlap region $T^2>Z^2$, we have

$$\frac{\partial}{\partial\eta}=T\,\frac{\partial}{\partial Z}+Z\,\frac{\partial}{\partial T}, \tag{45}$$

but it is clear that the right-hand side of (45) provides a smooth, well-defined extension for $\partial/\partial\eta$ to the whole (T,R,Φ,Z) chart, which is also a Killing vector field. We shall retain the name $\partial/\partial\eta$ for this extended field. Its norm is given by

$$\frac{\partial}{\partial\eta}\cdot\frac{\partial}{\partial\eta}=\frac{R^2\,\sinh[k(T^2-Z^2)]+(T^2-Z^2)\sinh(kR^2)}{2\,\cosh[k(R^2+Z^2-T^2)/2]} \tag{46}$$

and, therefore, $\partial/\partial\eta$ is spacelike for $T^2>Z^2$, timelike when $T^2<Z^2$, and null on the hypersurface $T^2=Z^2$.

In particular, in the region $T^2>Z^2$, for fixed τ, the trajectories of $\partial/\partial\eta$ generate a spacelike hypersurface that nowhere touches the null hypersurfaces $T^2=Z^2$. This latter hypersurface, which corresponds to $\tau=0$ is, in turn, smoothly generated by the trajectories of the *extended* $\partial/\partial\eta$, but has no image on the (τ,η,R,Φ) chart, since $\tau=0$ is outside that chart.

It is interesting to look at the form of the fronts corresponding to either $u=0$ or $v=0$. From the equalities

$$-4\epsilon uv=\tau^2-R^2=T^2-Z^2-R^2, \tag{47}$$

we find that these null hypersurfaces correspond to (topological) spheres which are contracting for $T<0$ and expanding for $T>0$. The constant T two-dimensional sections of these hypersurfaces approach a spherical shape for small $|T|$, but their form is distorted in general, on account of the nonflat nature of the background where they propagate. However, suppose now that we look at the functions $\mu_{\rm in}$ and $\mu_{\rm out}$ in the region $u>-v>0$, with u and v considered as functions of T, R, and Z. We have

$$\mu_{\rm in}=-\tfrac{1}{2}(T^2-Z^2), \tag{48}$$

$$\mu_{\rm out}=-\tfrac{1}{2}R^2, \tag{49}$$

$$\alpha^2=\tfrac{1}{4}(T^2-Z^2)R^2. \tag{50}$$

As we approach and cross the boundary $v=0$ from $v<0$ to $v>0$, we move from the region $T^2-Z^2>R^2$, where $|\mu_{\rm in}|<\alpha$ to the region $T^2-Z^2>R^2$, where $|\mu_{\rm in}|>\alpha$, while the opposite is true for $|\mu_{\rm out}|$. This confirms our assertion that the extension through $v=0$ connects a region associated to $\mu_{\rm in}$ to one associated to $\mu_{\rm out}$. However, as we have already indicated, there seems to be no natural isometrically invariant way of assigning either μ to the extended soliton metric. We shall comment more on this below.

Summarizing results, we have found that the solitonic metrics can be extended to define a space–time where the metric is regular everywhere. These space–times contain, in general, two stationary regions separated by a nonstationary region, isometric to the original soliton metric. The hypersurface where we have the transition from stationary to nonstationary corresponds to the original ''cosmological singularity,'' which is, therefore, eliminated by the soliton transformation. This behavior is not restricted to the Bianchi-type VI_0 background. In Appendix A we show that this ''cosmological singularity'' appears, in general, for background metrics of the form (1), and that it is ''cancelled'' in the soliton transformation.

IV. MATCHING THE SOLITON SOLUTION TO THE BACKGROUND

We have already indicated that in the original chart $\{t,z,x,y\}$ there is a singularity in the coefficient f when $\mu\to\pm\alpha$. However, since we also have in this case $\rho\to 0$, the remaining coefficients g_{ab} $(a,b=x,y)$ have a finite limit which coincides with that of the corresponding coefficients in the background metric. It is then tempting to try to find an extension of the soliton metric that matches it to the background through the hypersurfaces $z=\pm t$, where we have $\mu^2=\alpha^2$.

Let us consider again the soliton metric in the sector $z>t>0$. The coordinate singularity in f can be eliminated if we apply the coordinate transformation (19). The matching hypersurface $z=t$ is then approached by taking the limit $v=0$ from the region $v<0$, and we have the following expansions for the solitonic metric coefficients near $v=0$:

$$\tilde{f}=c_0\epsilon\,\exp(k^2u^4/4)+\mathcal{O}(v^2), \tag{51}$$

$$g_{11}=\frac{u^2}{2}\exp(ku^2)+\mathcal{O}(v^2), \tag{52}$$

$$g_{12}=\epsilon uv+\mathcal{O}(v^2), \tag{53}$$

$$g_{22}=\frac{u^2}{2}\exp(-ku^2)+\mathcal{O}(v^2). \tag{54}$$

We may, on the other hand, introduce the coordinate change

$$u=+(z+t)^{1/2},\quad v=-(z-t) \tag{55}$$

in the region $t>z>0$ of the background metric. The matching surface is then approached by taking the limit $v=0$ from positive values of v. In this case, the expansions for the seed metric coefficients for $v>0$, near $v=0$, are

$$\tilde{f}=\sqrt{2}\,\exp(k^2u^4/4)+\sqrt{2}\,\exp(k^2u^4/4)\,\frac{1-k^2u^4}{2u^2}\,v+\mathcal{O}(v^2), \tag{56}$$

$$g_{11}=\frac{u^2-v}{2}\exp(ku^2)+\mathcal{O}(v^2), \tag{57}$$

$$g_{12}=0, \tag{58}$$

$$g_{22}=\frac{u^2-v}{2}\exp(-ku^2)+\mathcal{O}(v^2). \tag{59}$$

Therefore, we conclude that, if we take $c_0\epsilon=\sqrt{2}$ in (51), the solitonic metric and the background metric can be matched continuously through the null hypersurface $v=0$. We notice, how-

ever, that although the metric coefficients are continuous in $v=0$, their first derivatives have finite jumps on this hypersurface. Since this is a null hypersurface, this type of behavior of the metric can be interpreted in terms of the presence of a matter shell (null dust) or of an impulsive gravitational wave, depending on the detailed structure of the singularity. This interpretation can be inferred from the fact that the Ricci tensor may, in this case, contain terms of the form[8] $\delta(v)$ or $\theta(v)$. On the other hand, because of the continuity of the metric coefficients, there will be terms containing a $\delta(v)$ function only in those components of the Ricci tensor that contain a second derivative of a metric coefficient with respect of the v coordinate. The only component of the Ricci tensor satisfying this requirement is R_{vv}, which, for a general metric of the form (7) and (8), can be written as

$$R_{vv}=\frac{\alpha_{,vv}}{\alpha}+\text{terms with lower derivatives in } v, \tag{60}$$

where the ''terms with lower derivatives in v'' give actually a vanishing contribution, on account of the fact that the metric is a vacuum solution for $v\neq 0$.

To compute R_{vv}, near the hypersurface $v=0$, we write α in the form

$$\alpha=\frac{u^2}{2}-\frac{v^2}{2}\,(1-\theta(v))-\frac{v}{2}\,\theta(v), \tag{61}$$

which leads to

$$R_{vv}=\frac{\delta(v)}{u^2}, \tag{62}$$

while the other components of the Ricci tensor vanish. The corresponding energy-momentum tensor can be interpreted as representing surface distribution of null dust located on $v=0$ with a positive energy density ρ proportional to u^{-2}.

In order to have a more symmetric space–time, we may consider the solitonic solution (6) in the region $-z>t>0$ and match it again to the background metric on the hypersurface $z=-t$. This is easily achieved by a simple modification of the previous procedure. The result is that, for any $t\neq 0$, we have two solitonic regions, one for $z>t$ and the other for $-z>t$, matched to the background metric through the hypersurfaces $|z|=t$. The matching requires the presence of surface distributions of null dust, with nonvanishing positive energy density, confined to the hypersurfaces $|z|=t$.

We notice that again the matching does not impose any condition on the functions μ, and it is possible to have solitons of the same or opposite sign for ϵ in the solitonic regions.

V. FINAL COMMENTS

The analysis carried out in this paper shows that the solitonic metrics considered by Belinsky in Ref. 1 can be locally (smoothly) extended in such a way that in a single chart the function μ satisfies, e.g., $|\mu|<|\alpha|$ in one region, and $|\mu|>|\alpha|$ in another. The distinction between μ_{in} and μ_{out} as indicating a topological characteristic of the solution does not appear then to be as clear as inferred from the considerations given in Ref. 1.

This situation is somewhat worsened if we consider also the equivalence of the metrics under isometric mappings, for, in this case, we have shown that a metric obtained using, say, μ_{in}, is isometric to a metric obtained starting with μ_{out}.

There is here, however, an important point that makes again contact with the topological character of some classical solitons. Consider, for instance, the Sine–Gordon equation,

$$\frac{\partial^2\phi(x,t)}{\partial t^2}-\frac{\partial^2\phi(x,t)}{\partial x^2}+\sin\ \phi(x,t)=0. \tag{63}$$

As is well known, it is possible to construct soliton solutions of this equation, known as *kinks* and *antikinks*, which are different solutions as long as we do not consider as equivalent situations related by the transformation $x\rightarrow -x$, which leaves the equation invariant, but changes a *kink* into an *antikink*. In other words, even though (63) is invariant under $x\rightarrow -x$, to be able to distinguish between the two types of topological solitons, we must exclude this *discrete* transformation[9] for there is no *intrinsic* property that we can use to distinguish between a kink and an antikink. Therefore, if we consider that solutions of (63) related by coordinate transformations (discrete or not) are equivalent, then the only apparent way of deducing the existence of two different solutions is by introducing some additional structure that defines a preferential orientation on the x axis. This structure could be the result of the presence of fields in the physical situation considered, or we could consider a solution of (63) with a kink and an antikink. In the latter case, we could easily recognize the difference between the kink and antikink solutions in the asymptotic regions of the multi-kink solution.

Similarly, the isometry that makes the solutions related to $\mu_{\rm in}$ and to $\mu_{\rm out}$ equivalent is a *discrete* transformation that corresponds to change in the orientation of the space axis. If we exclude these changes, we still have *two* types of soliton, and, although the reference to $\mu_{\rm in}$ and to $\mu_{\rm out}$ is essentially lost, they in some sense resemble even more the *kink* and *antikink* solutions of (63) because they are indistinguishable under certain discrete symmetry of their governing equation, but correspond to different solutions for a given *fixed* orientation of the space axis. Again, just as in the case of (63), where, assuming that $\phi(x,t)$ represents some physical quantity, we would not know if the situation corresponds to a kink or an antikink until we fix an orientation for the x axis, we have in the gravisoliton case a sort of ''rotation'' or ''twist'' that allows us to distinguish between a ''gravisoliton'' and an ''antigravisoliton,'' only after we have somehow fixed the orientation of the space axis of our reference system, but there is no intrinsic feature that we can use to distinguish one from the other.

Finally, it is also possible that, as in the case of the solutions of (63), in the gravitational case we could note the differences between the two types of gravisolitons analyzing multisoliton solutions, along lines similar to those given in Ref. 1. This possibility will be considered elsewhere.

APPENDIX A: BEHAVIOR NEAR $\alpha=0$

In this Appendix we consider the behavior of a general metric of the form (1) near $\alpha=0$. We assume that $g^{\mu\nu}\alpha_{,\nu}$ is timelike. It is clear from (1) and (4) that in any neighborhood here both $a(\xi)$ and $b(\eta)$ and their first derivatives are nonvanishing we may choose coordinates t and z that preserve the form (1) and where $\alpha=t$. We impose the (mild) restriction that there is such a coordinate system in a neighborhood of $\alpha=0$. Then, the vacuum Einstein equations for (1) can be put in the form

$$\frac{\partial^2 u_0(t,z)}{\partial z^2}-\frac{\partial^2 u_0(t,z)}{\partial t^2}-\frac{1}{t}\frac{\partial u_0(t,z)}{\partial t}=0 \tag{A1}$$

and

$$\frac{1}{f_0}\frac{\partial f_0}{\partial z}=t\,\frac{\partial u_0}{\partial t}\frac{\partial u_0}{\partial z}, \tag{A2}$$

$$\frac{1}{f_0}\frac{\partial f_0}{\partial t}=-\frac{1}{2t}+\frac{t}{2}\left(\frac{\partial u_0}{\partial t}\right)^2+\frac{t}{2}\left(\frac{\partial u_0}{\partial z}\right)^2. \tag{A3}$$

It is easily checked that (A1) is precisely the integrability condition for the system (A2) and (A3). We therefore assume that $u_0(t,z)$ is regular near $t=0$. Then we may write

$$u_0(t,z)=u_{00}(z)+u_{01}(z)t+u_{02}(z)t^2+u_{03}(z)t^3+u_{04}(z)t^4+\cdots . \tag{A4}$$

Replacing in (A1) we find that the coefficients of odd powers of t should be zero. The function $u_{00}(z)$ is arbitrary, and the other coefficients are determined once u_{00} is given. In particular we have

$$u_{02}(z)=\frac{1}{4}\frac{d^2u_{00}}{dz^2};\quad u_{04}(z)=\frac{1}{64}\frac{d^4u_{00}}{dz^4};\quad \cdots . \tag{A5}$$

We notice that the simplest choice for u_{00}, namely $u_{00}=2kz$, corresponds to the Bianchi-type VI_0 background.

Using this result in (A2) and (A3), we find the behavior of f_0 near $t=0$. This is given by

$$\ln f_0=\ln C_0-\frac{1}{2}\ln t+\frac{1}{4}t^2\left(\frac{du_{00}}{dz}\right)^2+\mathcal{O}(t^4). \tag{A6}$$

Therefore, for a general $u_0(t,z)$, regular near $t=0$, the function f_0 is the product $t^{-1/2}$ times a regular part. In other words, in all these metrics f_0 contains a factor $\alpha^{-1/2}$, which can be associated to a ''cosmological'' singularity. This factor is precisely cancelled in the single soliton transformation, which, therefore, has the effect of ''erasing'' the singularity.

APPENDIX B: BEHAVIOR NEAR $|\mu|=|\alpha|$

In this Appendix we consider the behavior of a general metric of the form (1) near $|\mu|=|\alpha|$. We assume that $g^{\mu\nu}\alpha_{,\nu}$ is timelike. In particular, we assume that $da/d\xi$ and $db/d\eta$ are nonvanishing in a neighborhood of the region where $|\mu|=|\alpha|$. We may then define new coordinates u and v, given by

$$u=[2a(\xi)-w]^{1/2},\quad v=-[-2b(\eta)-w]^{1/2}. \tag{B1}$$

In these new coordinates we have

$$\alpha=\tfrac{1}{2}(u^2-v^2),\quad \mu=-\tfrac{1}{2}(u+\epsilon v)^2,\quad \beta=\tfrac{1}{2}(u^2-v^2)+w, \tag{B2}$$

and the condition $|\mu|=|\alpha|$ is satisfied for either $u=0$ or $v=0$.

It is easy to check that the equations for ρ can be written in the form

$$\rho_{,u}=-\epsilon\frac{v}{u}u_{0,u},\quad \rho_{,v}=-\epsilon\frac{u}{v}u_{0,v}. \tag{B3}$$

The integrability condition for ρ is

$$2\alpha u_{0,}uv+\alpha_{,u}u_{0,v}+\alpha_{,v}u_{0,u}=0, \tag{B4}$$

which is equivalent to (3), in u,v coordinates.

We shall analyze the behavior of the metric coefficients near $v=0$. We assume regularity of u_0 in the sense that it admits an expansion of the form

$$u_0(u,v)=u_{o0}(u)+u_{o1}(u)v+u_{o2}(u)v^2+u_{o3}(u)v^3+\cdots . \tag{B5}$$

Then, (B4) puts no restriction on $u_{o0}(u)$, but u_{o1} must be of the form $u_{o1}=C/u$, where C is a constant, while the other terms should satisfy equations such as

$$2u^2\frac{du_{o2}}{du}+2uu_{o2}=\frac{du_{o0}}{du}, \tag{B6}$$

which do not mix coefficients of even and odd powers of v. If we replace (B5) in (B3), we find that ρ should be of the form

$$\rho(u,v)=-\epsilon uu_{o1}\ln v-2\epsilon uu_{o2}v+\cdots . \tag{B7}$$

If we further require regularity of u_0 near $u=0$, we should have $u_{o1}=0$, and all coefficients of odd powers of v should also vanish. The coefficients of even powers of v can, on the other hand, be chosen such that the expansion (B5) is regular and nontrivial near $u=0$. With this restriction we have that ρ vanishes at least as v for $v=0$. A simple example is, of course, the Bianchi-type VI_0 case analyzed in this paper, where $\rho=-2k\epsilon uv$.

Going back to the general form of the metric, if, as required by the regularity conditions on u_0, $\rho=0$ when $v=0$, that is, when $\mu^2=\alpha^2$, then g_{ab} is regular in a neighborhood of $v=0$, and coincides with the background metric for $v=0$. However, the full metric is not regular because there is a vanishing denominator and, therefore, a singularity in f. It is easy to show that singularity is related to coordinate choice and can be eliminated by an adequate change of coordinates. Namely, if we consider u and v as new coordinates, it is easy to verify that

$$\begin{aligned} f(t,z)(dz^2-dt^2)&=c_0f_0\alpha^{1/2}|\mu|\,\frac{\cosh(\rho)}{(\alpha^2-\mu^2)}\,d\xi d\eta \\ &=\sqrt{2}\epsilon c_0f_0(u^2-v^2)^{1/2}\cosh(\rho)\left(\frac{db}{d\eta}\frac{da}{d\xi}\right)^{-1}dudv, \end{aligned}$$

and, clearly, the last expression is regular for $v=0$, and the singularity has been cancelled.

Initial and final singularities in the closed Friedman world model are typical examples of *malicious* singularities. They form the single point of Schmidt's *b*-boundary of this model and are not Hausdorff separated from the rest of space–time. The method of noncommutative geometry, developed by A. Connes and his co-workers, is applied to this case. We rephrase Schmidt's construction in terms of the groupoid G of orthonormal frames over space–time and carry out the ''desingularization'' process. We define the line bundle $\tau:\Omega^{1/2}\rightarrow G$ over G and change the space of its cross sections into an involutive algebra. This algebra is represented in the space of operators on a Hilbert space and, with the norm inherited from these operators, it becomes a C^*-algebra. The initial and final singularities of the closed Friedman model are given by two distinct representations of this C^*-algebra in the space of operators acting on the Hilbert space $L^2(O(3,1))$. © *1996 American Institute of Physics.* [S0022-2488(96)01009-2]

I. INTRODUCTION

The problem of correctly defining singularities which appear in relativistic cosmology and relativistic astrophysics has been recently less investigated than it deserves. This is probably so because of the prevailing opinion that in the quantum gravity theory singularities will be irrevocably eliminated. However, this is not at all certain,[1] and—as we shall argue in the present paper—it may turn out that the study of classical singularities could suggest some indications concerning the looked for quantum gravity theory. Besides, the nature of classical singularities is interesting from the mathematical point of view and certainly deserves further study.

In the famous theorems of Hawking and Penrose on the existence of singularities, the latter were effectively identified with the geodesic incompleteness of space–time.[2] It was Schmidt[3] who proposed a very elegant construction of a singular boundary of space–time. Singularities were understood by him as points of this boundary, called *b-boundary* of space–time, and identified not only with the endpoints of (timelike and null) incomplete geodesics but also with the endpoints (in the generalized affine parameter) of timelike curves of bounded acceleration. This definition of singularities was soon accepted as the best available one within the framework of relativistic theories of gravitation. However, its popularity suddenly ended when Bosshard[4] and Johnson[5] demonstrated that in the closed Friedman world model the initial and final singularities formed the single point of the *b*-boundary, and that *b*-boundaries of the closed Friedman model and of the Schwarzschild solution are not Hausdorff separated from the rest of space–time. Some attempts to modify Schmidt's construction were lacking either the required generality or the original elegance.[6] In practice, Schmidt's construction was soon eliminated from current research.

We have returned to Schmidt's definition of singularities by looking at it from a slightly

different perspective. In our previous works[7] we have demonstrated that all troubles connected with the b-boundary construction have their origin in the fact that it is carried out in the bad category, namely in the category of smooth manifolds, whereas space–times with their singularities, from their very nature, go beyond this category. We have also shown that one can effectively work with the b-completed closed Friedman model (i.e., with its space–time together with its b-boundary) within the category of structured spaces. The structured space concept is based on the idea of ''algebraization'' of geometry, and it was Koszul who, in his classical paper,[8] gave a dictionary for translating geometry into algebra. By a *structured space* we mean the pair (M,C), where M is a topological space and C the sheaf of algebras of real functions on M such that, for any open set $U \in M$ and any functions $f_1,\ldots,f_n \in C(U)$, $\omega \in C^\infty(\mathbf{R})$, one has $\omega \circ (f_1,\ldots,f_n) \in C(U)$. The sheaf C is called the *differential structure* on M. The theory of structured spaces, developed in Ref. 9, is a strong generalization of the theory of smooth manifolds (any function belonging to the differential structure is *ex definitione* assumed to be smooth). By using the theory of structured spaces one can safely work with the b-completed closed Friedman M space–time as long as one deals with local cross sections of $C(U)$ and local vector fields on $U \subset M$. However, one must be cautious since there exists the unique differential structure which can be prolonged to the b-completed space–time, namely the one consisting only of constant functions. If one ''touches'' either of the two singularities (i.e., if one prolongs the differential structure to the singularity), pathologies immediately occur: the differential structure consists only of constant functions, there exist only zero derivations of such functions, i.e., zero vector fields, and consequently the ''bundle length'' of a curve joining the singularity with any point in space–time is zero, and everything shrinks to the single point.

To deal with similar ''pathological situations,'' Alain Connes[10] developed his noncommutative approach to geometry. This approach is a further generalization as compared with our structured space theory. Functional algebras appearing in the differential structure of structured spaces, being functional, are always commutative. In Connes' approach, the entire information about a given geometry is encoded in a non-necessarily commutative algebra. If this algebra happens to be commutative, it is essentially equivalent to the complex counterpart of our differential structure. Noncommutative algebras are indispensable in dealing with strongly singular situations. The aim of the present paper is to analyze space–times with b-boundaries, and in particular b-completed space–time of the closed Friedman model, within the framework of Connes' noncommutative geometry. We strictly follow Connes method; our only modification consists in replacing the ordinary concept of smoothness (in the manifold category) by its generalized counterpart in the theory of differential spaces.

In Sec. II we give a short account of Schmidt's construction and rephrase it in terms of the groupoid theory. In Sec. III we discuss the groupoid counterpart of singular fibers. By constructing the suitable line bundle on this groupoid we perform what could be called the *desingularization* process. Cross sections of this line bundle with suitably defined convolution (as ''multiplication'' of cross sections) and involution form a (noncommutative) involutive algebra. This algebra can be represented in the space of operators on a Hilbert space and, with the norm inherited from these operators, it becomes a C^*-algebra. With the help of this algebra we gain the insight into the structure of the initial and final singularities in the Friedman model. All this is presented in Sec. IV. Section V contains a discussion of the obtained results. Both initial and final singularities are given in terms of the algebra of operators acting on the Hilbert space $L^2(O(3,1))$ of square integrable functions defined on the Lorentz group [let us notice that by replacing $O(3,1)$ by its double covering we are led to the spinorial formalism]. It might well be that classical singularities are not entirely classical; they somehow seem to know that in the extreme conditions of shrinking quantum structures must be used to model physical processes.

II. FRAME BUNDLE OVER SPACE–TIME AS A GROUPOID

Schmidt's construction of the b-boundary of space–time can be summarized in the following way (details can be found in Ref. 3). Let M be a space–time carrying the Lorentz metric, and OM

(the connected component of) the orthonormal frame bundle over M, $\pi:OM\to M$. The Levi–Civita connection in M determines the family of uniformly equivalent Riemannian (positive definite) metrics on OM. We select one of them and notice that further construction does not depend of the particular choice. With the help of this metric we determine the distance function on OM and construct, in the usual way, the Cauchy completion $\overline{OM}$ of OM. The Lorentz group acts on OM to the right, $OM\times O(3,1)\to OM$, and since this action maps Cauchy sequences into Cauchy sequences, we can naturally extend the action of $O(3,1)$ into $\overline{OM}$, i.e., $\overline{OM}\times O(3,1)\to\overline{OM}$. The quotient space $\overline{M}:=\overline{OM}/O(3,1)$ is called the b-*completion* of space–time M. Here M turns out to be open and dense in $\overline{M}$, and $\partial_b M=\overline{M}\backslash M$ is said to be the b-*boundary* of M. (The above construction in the category of structured spaces is presented in Refs. 7 and 9.)

To treat M as a noncommutative space we shall apply Connes' method to our case and regard the fiber bundle of orthonormal frames over M as a groupoid. This could look like a slight change of perspective, but it has important consequences. Our construction applies to any space–time with its b-boundary, but in what follows we can think about the b-completed space–time of the closed Friedman world model, and regard it as a typical case to which noncommutative methods have to be applied.

For the groupoid definition, see Ref. 10 or 11; here we shall describe the groupoid $\overline{G}=\overline{OM}\lhd O(3,1)$ called the groupoid of orthonormal frames over $\overline{M}$. Elements of G are pairs of orthonormal frames. Therefore, an element $\gamma=(p,pg)$ of G (one can also write $\gamma=(p,g)$) can be interpreted as an arrow beginning at the orthonormal frame $p\in\overline{OM}$ and ending at the frame $pg\in\overline{OM}$, or equivalently as the element g of the group $O(3,1)$ transforming p into pg. Two arrows (p,g_1) and (q,g_2) can be composed if $pg_1=q$. The set of all composable arrows is denoted by $G^{(2)}$. Elements of the form (p,pe), where e is the unit of $O(3,1)$, should be regarded as loops beginning and ending at p. The set of all such loops is denoted by $G^{(0)}$. This interpretation is obvious for $p\in OM$. It can also be extended to ''singular fibers'' $\overline{OM}\backslash OM$ with a suitable understanding of ''singular frames,'' as it is discussed below.

It should be noticed that the groupoid G of orthonormal frames over $\overline{M}$ is smooth as a structured space. Indeed, the differential structure on $\overline{OM}$ can be pulled back from the Euclidean space in which it is embedded, and $O(3,1)$ itself carries the smooth manifold structure. In fact $\overline{G}$ is a D_0 structured space of constant dimension (for details concerning smooth structured spaces see Ref. 9). We thus have the following.

Proposition 2.1: The semidirect product $\overline{G}=\overline{OM}\lhd O(3,1)$, where $\overline{OM}$ is the Cauchy completed total space of the fiber bundle of orthonormal frames over the b-completion $\overline{M}$ of space–time M, is a groupoid. □

The above construction can locally be presented in the following way. Let φ be a map of an atlas on the manifold M (for the time being we consider space–time M without its b-boundary). To every point $p\in OM$, i.e., to every frame at $x\in M$, there corresponds its matrix representation $A_{p,\varphi}$ in the local map φ. The matrix representation of the point $pg\in\pi^{-1}(x)$ is the matrix $A_{pg,\varphi}$, and consequently the arrow $\gamma=(p,pg)$ can be represented by the matrix $A_{\gamma,\varphi}=A_{p,\varphi}+iA_{pg,\varphi}$.

Our strategy in the following will be to extend this representation to singular frames and then to define a suitable (complex) C^*-algebra which would encode the geometric information about space–time with its b-boundary.

III. THE STRUCTURE OF SINGULAR FIBERS

Let us consider a singular fiber $\overline{G}^{(2)}_{x_0}\subset\overline{G^{(2)}}$ where $x_0\in\partial_b M:=\overline{M}\backslash M$. The pairs belonging to $\overline{G}^{(2)}_{x_0}$ are no longer the pairs of orthonormal frames, but rather the pairs of limits of Cauchy sequences of orthonormal frames. Let $\overline{p}=\lim_{n\to\infty}p_n$ and $\overline{pg}=\lim_{n\to\infty}p_ng$, $g\in O(3,1)$, where p_n and p_ng are Cauchy sequences in OM. From Schmidt's construction[3] it follows that these limits always exist.

To see how singularities of this kind can be analyzed, let us consider the most pathological situation that can arise. Let us suppose that the singular fiber $\pi^{-1}(x_0)$, where $x_0 \in \partial_b M$, degenerates to a single point. In Refs. 7 and 9 such singularities were called *malicious singularities*. They appear in the closed Friedman model and in the Schwarzschild solution (Refs. 4 and 5). We immediately have the following.

Lemma 3.1: The following conditions are equivalent:

(i) $x_0 \in \partial_b M$ is a malicious singularity,
(ii) $G^{(2)}_{x_0} = \{(p,e)\} = \overline{G^{(0)}_{x_0}}$,
(iii) the isotropy group Γ_p of the point $p \in \pi^{-1}(x_0)$ coincides with the group $O(3,1)$. ■

Proof: To see the equivalence of (i) and (ii) it is enough to notice that if $p = \pi^{-1}(x_0)$, then, for every $g \in O(3,1)$, one has $pg = p$, and the equivalence of (i) and (iii) follows from the fact that p is a fixed point of the action of $O(3,1)$. □

The following sets will be useful in the sequel

$$G^p = \{\gamma \in \overline{G} : r(\gamma) = p\} = \{(p,g) : g \in O(3,1)\},$$

$$G_q = \{\gamma \in \overline{G} : s(\gamma) = q\} = \{(qg^{-1}, q) : g \in O(3,1)\}.$$

The first of these sets consists of all arrows that begin at $p \in \overline{OM}$, the second of all arrows that end at $q \in \overline{OM}$.

Lemma 3.2: The sets G^p and G_q can be given the structure of the group manifold $O(3,1)$. ■

Proof: The sets G^p and G_p can be written in the form $G^p = \{p\} \times O(3,1)$, $G_q = \{qg^{-1}\} \times O(3,1)$ from which the bijection between these sets and the set $O(3,1)$ is evident. With the help of this bijection the manifold structure can be carried out from $O(3,1)$ to G^p and G_q. □

It should be noticed that this structure of the sets G^p and G_q is preserved also in the malicious singularity.

Let $\varphi : M \to \mathbf{R}^n$ be a map belonging to an atlas on M and D_φ its domain. The map $\tilde{\varphi}$ on OM is said to be *associated* to the map φ if it is of the form $\tilde{\varphi} : \pi^{-1}(D_\varphi) \to \mathbf{R}^n \times \mathbf{R}^d$, where $d = \dim O(3,1)$. The map φ is said to be *accessible* (*to the singularity*) if $\mathrm{cl}\, D_{\tilde{\varphi}} \cap \partial_c OM \neq \varnothing$, where $\partial_c OM$ is the Cauchy boundary of OM. From Schmidt's construction[3] it follows that for every $x_0 \in \partial_b M$ there exists an accessible map (i.e., a map from the domain of which x_0 can be reached). It should be noticed that the set $\mathrm{cl}\, D_{\tilde{\varphi}}$ is $O(3,1)$-saturated, i.e., $\mathrm{cl}\, D_{\tilde{\varphi}} \cap \pi^{-1}(x_0) \supset \pi^{-1}(x_0)$, $x_0 \in \partial_b M$.

If p is an element of a singular fiber (not necessarily over the malicious singularity), from the Schmidt's construction one has $p = \lim_{n\to\infty} p_n$, where $p_n \in \pi^{-1}(D_\varphi)$, φ being an accessible map, and correspondingly $\gamma_n = (p_n, g)$. This gives us the local matrix representation of the singular fiber

$$A_{\gamma,\varphi} = \lim_{n\to\infty} A_{\gamma_n, p},$$

where

$$A_{\gamma_n,\varphi} = A_{p_n,\varphi} + iA_{p_n g,\varphi}.$$

The convergence of matrices should be understood in the following way. The obvious bijection $A_{p,\varphi} \mapsto p$ can be treated as a homeomorphism with the help of which we can pull back the Riemannian metric from OM to the space of matrices. The ''limit matrices'' $A_{\gamma,\varphi}$ should be understood as equivalence classes of the corresponding matrix sequences. Let us notice that if $x_0 \in \partial_b M$ is a malicious singularity, the singular fiber $\pi^{-1}(x_0)$ has the local matrix representation

$A_{p,\varphi} + iA_{p,\varphi}$, where φ is an accessible map on M. This trivially follows from the fact that the singular fiber consists of the one ''limit frame'' p which is represented by a loop.

IV. DESINGULARIZATION OF SPACE–TIME

Now—strictly following Connes's method—we construct the line bundle $\tau:\Omega^{1/2}\to\overline{G}$ over the groupoid G where $\Omega^{1/2} = \cup_{\gamma\in\overline{G}}\Omega^{1/2}_{\gamma}$ and $\Omega^{1/2}_{\gamma}$ is of the form

$$\Omega^{1/2}_{\gamma}=\{\rho:\wedge^k T_{\gamma}(G^p)\otimes\wedge^k T_{\gamma}(G_q)\to\mathbf{C}:$$

$$\rho(\lambda\nu)=|\lambda|^{1/2}\rho(\nu),\quad \lambda\in\mathbf{R},\quad \nu\in\wedge^k T_{\gamma}(G^p)\otimes\wedge^k T_{\gamma}(G_q)\}$$

for $\gamma=(p,q)=(p,pg)$. Here $k=\dim(G^p)=\dim(G_q)$ and, for $G^p = G_q=O(3,1)$, $k=6$. For $\gamma=(p,pg)$, one has $T_{\gamma}(O(3,1))\simeq o(3,1)$, where $o(3,1)$ is the Lie algebra of the Lorentz group $O(3,1)$. It can be easily seen that the line bundle τ: $\Omega^{1/2}\to G$ is trivial. It should be emphasized that the trivial structure of this line bundle is preserved at singularities (even malicious ones). This is the first important step in the process of ''desingularization of space–time.''

Let $C^{\infty}_c(G,\Omega^{1/2})$ denote the space of smooth sections with compact support of the bundle τ: $\Omega^{1/2}\to G$. In the space of sections $C^{\infty}_c(G,\Omega^{1/2})$ we define the *convolution* in the following way:

$$(s*t)(\gamma)=\int_{G_p} s(\gamma_1)t(\gamma_2),$$

where $s,t\in C^{\infty}_c(\overline{G},\Omega^{1/2})$, and $\gamma=(p,pg)$, $\gamma=\gamma_1\circ\gamma_2$. The integral is well defined since $s(\gamma_1)t(\gamma_2)$ is a one-density and it does not depend on the particular composition $\gamma=\gamma_1\circ\gamma_2$.

For each $s\in C^{\infty}_c(G,\Omega^{1/2})$ we also define the *involution* $s\mapsto s^*$ by $s^*(\gamma)=\overline{s(\gamma^{-1})}$.

Now we can formulate our final result:

Theorem 4.1: Let $G=\overline{OM}\triangleleft O(3,1)$ be the groupoid of orthonormal frames over space–time M with its b-boundary.

(1) With convolution and involution defined above $C^{\infty}_c(\overline{G},\Omega^{1/2})$ is an involutive algebra.

(2) For each $q\in G^{(0)}$ the expression

$$(\pi_q(s)\xi)\gamma=\int_{G_q} s(\gamma_1)\xi(\gamma_1^{-1}\gamma),$$

$\gamma\in G_q$, $\xi\in L^2(G_q)$, $s\in C^{\infty}_c(\overline{G},\Omega^{1/2})$, defines an involutive (nongenerate) representation

$$\pi_q: C^{\infty}_c(\overline{G},\Omega^{1/2})\to \mathrm{End}\, L^2(G_q)$$

of $C^{\infty}_c(\overline{G},\Omega^{1/2})$ in the Hilbert space $L^2(G_q)$ of the square integrable functions on the manifold G_q.

(3) The completion of $C^{\infty}_c(\overline{G},\Omega^{1/2})$ with respect to the norm

$$\|s\|=\sup_{q\in G^{(0)}}\|\pi_q(s)\|$$

is a C^*-algebra; it will be denoted by $C^*(\overline{OM})$. ■

Proof is the repetition of the proof given by Connes[12] with minor changes following from the fact that G is smooth in the sense of structured spaces. □

Every representation π_q, $q \in \overline{OM}$, can be prolonged to the representation of $C^*(\overline{OM})$, and part (2) of theorem 4.1 remains valid also for $C^*(\overline{OM})$. The C^*-algebra $C^*(\overline{OM})$ is a noncommutative counterpart of the algebra of functions on a given space, and it conveys all relevant information about space–time with singularities.

V. INTERPRETATION

How is the noncommutative C^*-algebra $C^*(\overline{OM})$ related to the geometry of space–time $\overline{M} = M \cup \partial_b M$ with its b-boundary? In noncommutative geometry there is no concept of point, but in some respects it could be replaced by the concept of state. If $\mathscr{A}$ is a C^*-algebra, π a representation of $\mathscr{A}$ in the Hilbert space $\mathscr{H}$, and $\xi \in \mathscr{H}$, then $a \mapsto (\pi(a)\xi,\xi)$ is a positive form on $\mathscr{A}$. If additionally this positive form is suitably normed, it is called a *state*. We have, therefore, a correspondence between (equivalence classes of) representations of $\mathscr{A}$ in a Hilbert space and states of $\mathscr{A}$ (the state is pure if and only if the corresponding representation is nonzero and irreducible).[13] In the present work we have shown that the initial and final singularities of the closed Friedman world model, understood as the b-boundary points, are distinct structures given by two representations

$$\pi_{p_i}: C^*(\overline{OM}) \to \text{End } L^2(G_{p_i}),$$

$i=1,2$, where p_1 is the single ''limit frame'' in the singular fiber over the initial singularity, and p_2 is the single ''limit frame'' in the singular fiber over the final singularity. Therefore, although the initial and final singularities, in the sense of Schmidt, cannot be regarded as points (or regions) in space–time (even if space–time is modelled by a structured space), they can be treated as the states of the universe.

Of course, we can apply the above-presented method to space–time M with no singularities. In such a case, we obtain a noncommutative C^*-algebra $C^*(OM)$; being noncummutative this algebra loses information about individual points and their neighborhoods, but instead it informs us about the states of the closed Friedman universe. As should be expected, such states coincide with space sections $t=$const of the Friedman model [indeed, because of the maximal symmetry of such space sections, it is easy to show that all corresponding representations of the algebra $C^*(OM)$ are equivalent]. Consequently, if we look at the history of the closed Friedman universe as a sequence of states, the initial and final singularities are full rights elements of this history.

The C^*-algebra $C^*(OM)$ must be strongly related to the (commutative) algebra $\mathscr{F}(M)$ of complex functions on the manifold M. Mathematically speaking $C^*(OM)$ and $\mathscr{F}(M)$ are strongly Morita equivalent. The concept of strong Morita equivalence plays the role of the isomorphism in the theory of C^*-algebras. In particular, two strongly Morita equivalent C^*-algebras have the same space of equivalence classes of irreducible representations.

Since the closed Friedman space–time M is a solution to Einstein field equations, the algebra $C^*(OM)$ contains full information about this solution. Using our former terminology[14] we can say that $C^*(OM)$ is a *noncommutative Einstein algebra of the closed Friedman world model*. Consequently, $C^*(\overline{OM})$ is the extension of this Einstein algebra to the b-completed closed Friedman space–time, and as such it can be regarded as a generalization of Einstein equations to the space–time with singularities. In this sense, the noncommutative approach to general relativity leads to its essential generalization.

Let us notice that the pathological behavior of the closed Friedman space–time with b-boundary is produced by forming the quotient $M = \overline{OM}/O(3,1)$. In the desingularization process, described in the preceding sections, this quotient has nowhere been used. Moreover, based on the C^*-algebra $C^*(\overline{OM})$ one can develop the measure theory, the K-theory, differential and integral calculi, as it has been done by Connes himself[10,15] and his co-workers.[16] In this sense, singularities, even the malicious ones, are no longer geometrically nontractable entities.

The method of dealing with singularities presented in this paper can be applied to any singularities understood as b-boundary points but, of course, it would be rather meaningless to apply this method to milder types of singularities which could be analyzed with the help of simpler and more standard strategies. On the other hand, the present method seems to be the only possible one as far as the malicious singularities are concerned. Singularities of this type, as proved in Refs. 7 and 9, always lead to typically nonlocal (non-Hausdorff) situations.

It is a striking fact that classical singularities are represented by typically quantum object $\mathrm{End}\, L^2(G_p)$, the algebra of operators on the Hilbert space of square integrable functions. Moreover, if we replace the Lorentz group $O(3,1)$ by its double covering $SL(2,\mathbf{C})$ we are automatically led to the spinor formalism. We should also notice that in the construction of the object $\mathrm{End}\, L^2(G_p)$ typically relativistic concepts (Lorentz frame bundle, Lorentz metric, connection, etc.) are involved and they nicely interact with typically quantum concepts (Hilbert space with its scalar product, bounded operators, etc.). We would like to emphasize that this interaction of relativistic and quantum structures was not put into our model by hand (it was not even intended), but it came to surface quite unexpectedly. It seems as if classical singularities knew something about quantum phenomena acting in the beginning and in the end of the closed Friedman universe.

It is tempting to speculate that beneath the Planck threshold smooth (commutative) geometry breaks down and essentially global, perhaps strongly singular, noncommutative geometry (with no points and no time instances) takes over. The space of states of such a quantum noncommutative universe (the counterpart of superspace in quantum canonical theory) would be the space of states of the corresponding C^*-algebra $\mathscr{A}$, and (Hermitian) elements of $\mathscr{A}$ could be regarded as the quantum gravity counterpart of observables in the usual quantum theory. Then one could try to proceed in analogy with the standard quantization methods.

(Received 28 May 1996; accepted for publication 21 June 1996)

A distributional method to solve the Einstein's field equations for thin shells is formulated. The familiar field equations and jump conditions of Darmois-Israel formalism are derived. A careful analysis of the Bianchi identities shows that, for cases under consideration, they make sense as distributions and lead to jump conditions of Darmois-Israel formalism. © *1996 American Institute of Physics.* [S0022-2488(96)03711-5]

I. INTRODUCTION

The study of hypersurfaces of discontinuity in general relativity began in the early twenties.[1–3] But it has been revived through new questions raised in cosmology and black-hole physics. Domain walls separating two coexisting different phases in inflationary scenarios,[4] bubble dynamics,[5] wormholes,[6] signature changes,[7] and interior structures of black-holes[8] are just some of the recent applications of the thin shell formalism of general relativity.

The traditional and most widely used method of handling such problems is that of Darmois-Israel (DI), based on the Gauss-Kodazzi decomposition of space-time.[9,10] It expresses the surface properties in terms of the jump of extrinsic curvature across the layer directly as functions of the layer's intrinsic coordinates. Thus the four-dimensional coordinates may be chosen freely and independently, adapted to the symmetry requirements, on the two sides of the layer. This is the very practical advantage of that method which has found its final formulation in the outstanding paper of Israel.[9] The geometric conditions for the layer to be considered as a boundary of two different manifolds glued together at this boundary were first formulated by Darmois.[3] Those are the minimum conditions which had been assumed by Israel. There are other conditions formulated by Lichnerowicz,[11,12] which means basically continuous coordinates across the layer, and seems to be necessary for using distributional tensor calculus. It is interesting to note that Sen,[2] in this relatively unknown paper, used the same conditions, without any further discussion, derived the reduced Einstein's equations for the general case, and solved it for the spheric symmetric $2+1$ dimensional mass distribution. The O'Brien-Synge conditions[13,14] are in most cases equivalent to the Lichnerowicz ones, so we are not going to consider them here.[15] Because of the restrictive choice of coordinates the Lichnerowicz conditions are not usually used. But there are cases where the distributional method, and therefore the Lichnerowicz conditions, are more suitable for calculation. The case of a cylindrically symmetric thin layer, for example, has been solved by the distributional method using these conditions.[16]

There have been attempts to formulate the problem of a thin layer in general relativity using distributional methods, familiar in other part of physics. In fact many physical systems, classical and relativistic, undergo very rapid transitions of their state of motion. Think of shock waves in hydrodynamics. Although the state of the system need not be described by discontinuous functions

of space and time, or by functions having discontinuity in their first or second derivatives, a mathematical description of the system which is based on the distribution valued states of the system gives an accurate picture of some important aspects of the physical problem. Usually such a description is more amenable to treatment than the treatment which contains a smooth description of the physical state. This has not only been used in classical hydrodynamics, but also has been applied in the relativistic case. Lichnerowicz[11,12] has given a discussion of hydrodynamic and gravitational shock wave problems by using curvature tensors for space-time which contain a Dirac δ function with support on a submanifold. Y. Choquet-Bruhat has used similar methods to treat high-frequency gravitational waves.[17]

Rapid changes of physical quantities occur also in electromagnetism. One might have, for example, some charge distribution which is confined to a one- or two-dimensional region of space that is small compared with characteristic distances of the problem. This distribution of charge can be replaced by a concentrated source, and the problem can be formulated in the sense of distributions, but not of smooth functions. There is a natural mathematical framework in electromagnetism. Recall that linear operations, including differentiations, make sense when applied to distributions. Hence, Maxwell's equations, by virtue of their linearity in both fields and sources, make sense as equations on these distributions. This means that the machinery of distribution theory is available in electromagnetism, and guarantees that distributional Maxwell fields with distributional charge-currents make physical sense, and at the same time gives a well defined and detailed sense in which a distributional charge density must approximate our real smooth charge density distribution.

In general relativity, where the field equations are non-linear, the use of distributional objects seem not to be trivial. Although Raju[18] claims to give an analytical formalism to deal with the occurrence of jump discontinuities in the metric across a hypersurface, using a non-linear theory of distributions,[18,19] his method does not seem to be conclusive. The application he mentions is for a continuous metric where no non-linear distributional operations are needed. Anyhow, here the mathematical framework cannot be as simple as for electromagnetism. Efforts to implement distributional methods in general relativity go back to works of Papapetrou and Treder.[20] Nariai,[21] aiming to understand the O'Brien-Synge junction conditions, and demanding the Einstein's tensor to be free of δ functions, uses continuous metrics and so brings in distributions in the formalism, which is consequently used by Kumar.[22] Papapetrou and Hamoui[23,24] then try to formulate a general method with application to a spherical symmetric thin layer. Their method has then been reformulated and corrected by Evans.[25] Lichnerowicz[12] gives a detailed mathematical analysis of distributions in curved space-time and comes to the conclusion that the classical properties of the covariant derivatives and all of the corresponding formulas are valid for tensor distributions. Barrabes[26] uses tensor distributions specially to include null hyper-surfaces in the shell dynamics.

Taub[27] is interested in relativistic hydrodynamics and shock waves but also discusses the previous accounts on the concentrated 2- and 3-dimensional sources. Israel[28] and Taub[27] give a formulation for a 2-dimensional concentrated mass distribution. These attempts have been criticized by Geroch and Traschen[29] who gave an extensive and thorough analysis of concentrated mass distributions in general relativity. This work is a milestone in all the discussions about the validity of distributional Einstein's field equations and its applications to concentrated sources. There the authors define some regularity conditions for metrics, for which the distributional tensor calculations are allowed. Hence, for example, the line source case should be handled with care, although some authors have criticized it.[30] The $(2+1)$-dimensional case, as a result of this work, should not cause any problem, as far as the continuity of the metric is assured. We have thereafter used distributional tensors to solve Einstein's equations directly, without any use of Gauss-Kodazzi decompositions. The coordinates have to be prepared to make them continuous at the hypersurface of discontinuity, but the method has been applied easily for several cases.[16,31,32] Naturally, there should be no difference in the results using either the distributional- or Gauss-Kodazzi-method. But the complete equivalence has never been demonstrated explicitly, and the

role of jump conditions by using the distributional method has never been clearly stated.

With the results of Geroch and Traschen in mind, we show here that all the dynamical- and constraint-equations derived by the DI-formalism results very naturally in the distributional method, without any need to define a new covariant derivative. For the sake of transparency, we limit ourselves to the non-null shells. The null case can be treated along the same line as this paper.[33]

In section II we review shortly the DI formalism and give the necessary formulae. Section III begins with the formulation of the distributional method. Covariant derivative of distributions and some useful formulae are given in section III A, and the Einstein's equations for a thin shell in section III B. Section III C deals with the conservation laws and the Bianchi identities. In this section we will see the full equivalence of the two methods. We end with a conclusion in section IV.

Conventions and definitions: We use the signature $(-+++)$, and follow the curvature conventions of Misner, Thorn, and Wheeler (MTW).[10] However, our sign convention for extrinsic curvature is that of Israel,[9] which is the opposite of MTW. The Greek indices run from 0 to 3 and Latin indices from 1 to 3. A semicolon indicates covariant derivatives with respect to either the four-metric of the whole space-time or the three-metric of the layer. There will, however, be no confusion because the kind of indices and objects used makes the difference transparent. The symbol $\nabla^{\pm}$ denotes the covariant derivative with respect to either of the metrics of partial manifolds $M^{\pm}$ which are to be glued together.

The square brackets $[F]$ are used to indicate the jump of any quantity F at the layer, and bars $\overline{F}$ the arithmetic mean of it. As we are going to work with distributional valued tensors, there may be terms in a tensor quantity F proportional to some δ-function. These terms are indicated by $\underline{F}$.

II. DARMOIS-ISRAEL FORMALISM

Assume two space-times M^+ and M^- with boundaries Σ^+ and Σ^-. M^+ and M^- may have been cut from space-times M_1 and M_2, respectively, but this is irrelevant for our task of glueing these together. Coordinates on the two space-time manifolds are defined independently as x_+^μ and x_-^μ, and the metrics denoted by $g^+_{\alpha\beta}(x_+^\mu)$ and $g^-_{\alpha\beta}(x_-^\mu)$. The induced metrics on the boundaries are called $g^+_{ij}(\xi_+^k)$ and $g^-_{ij}(\xi_-^k)$, where $\xi_\pm^k$ are intrinsic coordinates on $\Sigma_\pm$, respectively. Bringing these 3- and 4-dimensional quantities in connection is trivially done with the help of tetrads defining on Σ.[34]

Now, to paste the manifolds together we demand that the boundaries be isometric having the same coordinates

$$\xi_+^k = \xi_-^k = \xi^k.$$

The identification

$$\Sigma_+ = \Sigma_- =: \Sigma$$

gives us the single glued manifold $M = M_+ \cup M_-$.

This is the minimum requirement for glueing two manifolds together. Formulated as

$$[g_{ij}] = 0 \tag{1}$$

gives together with the continuity of the second fundamental form on Σ

$$[K_{ij}] = 0 \tag{2}$$

the Darmois conditions. Both conditions should be satisfied if Σ is just a boundary surface. But in the case of a thin shell we do not expect the second condition to be satisfied. In fact, the matter content of the shell should lead to a jump in the extrinsic curvature K_{ij}.

The condition (1) leaves the coordinates in $M^{\pm}$ free. If we assume the continuity of the coordinates $x_{\pm}^{\mu}$ at Σ we then have to require

$$[g_{\mu\nu}]=0, \tag{3}$$

which together with the corresponding equation for derivatives of the metric

$$\left[\frac{\partial g_{\mu\nu}}{\partial x^{\alpha}}\right]=0 \tag{4}$$

gives the Lichnerowicz conditions. In the following we just assume condition (1) or (3), respectively.

On Σ we define a three-bein

$$e_i=\frac{\partial}{\partial \xi^i}$$

having the components

$$e_i^{\mu}=\frac{\partial x^{\mu}}{\partial \xi^i}\ . \tag{5}$$

The induced metric on Σ is given by the scalar product

$$g_{ij}=e_i\cdot e_j=g_{\mu\nu}e_i^{\mu}e_j^{\nu}\ . \tag{6}$$

Note that, because of the assumed isometry, this metric is the same on both faces Σ_+ and Σ_-. We note that the subscripts of the three-beins on Σ are not the component indices, but as this distinction is trivial we prefer for the sake of simplicity not to use parentheses to distinguish them, as is usually done.

We choose the parametric equation for Σ in the form

$$\Phi(x^{\mu}(\xi^i))=0, \tag{7}$$

having the unit normal four-vector n^{μ} given by

$$n_{\mu}=\alpha^{-1}\partial_{\mu}\Phi, \tag{8}$$

where

$$\alpha=\pm\sqrt{\left(\left|g^{\nu\gamma}\frac{\partial f}{\partial x^{\nu}}\frac{\partial f}{\partial x^{\gamma}}\right|\right)}. \tag{9}$$

Therefore

$$n_{\mu}e_i^{\mu}=0, \tag{10}$$

and

$$n_{\mu}n^{\mu}=\epsilon, \tag{11}$$

where $\epsilon=+1$ or -1 for Σ to be time- or space-like, respectively. We suppose n^μ to be directed from M^- to M^+, i.e., in the direction of increasing a space- or time-like coordinate corresponding to time- or space-like Σ. Therefore we have to take the positive (negative) sign in (9) for time-(space-)like Σ. This choice gives us the useful relation

$$\text{sign } \alpha=\frac{|\alpha|}{\alpha}=\epsilon.$$

The choice of the Lichnerowicz condition (3) makes it possible to have a unique normal vector for each case. As we want to concentrate on the formulation of the distributional method and avoid any undue complications, we leave aside the case of null hypersurfaces.

Now, in general the metrics in M^+ and M^- need not to be continuous at Σ, but they could be. However, the normal extrinsic curvature (second fundamental form) is not continuous for a thin shell. It is defined by

$$K^\pm_{ij}=e^\mu_i e^\nu_j \nabla^\pm_\mu n_\nu=-n_\mu e^\nu_j \nabla^\pm_\nu e^\mu_i=-n_\mu e^\nu_i \nabla^\pm_\nu e^\mu_j=K^\pm_{ji}. \tag{12}$$

Now, we have all the prerequisites to write the Einstein's equation for the hypersurface. These are 10 equations which will be written in components normal and tangent to the hypersurface. The first and second contracted Gauss-Kodazzi equations are[9,10]

$$G_{\mu\nu}n^\mu n^\nu=\tfrac{1}{2}\,(K^2-K_{ij}K^{ij}-\epsilon^3 R), \tag{13}$$

$$G_{\mu\nu}e^\mu_i n^\nu=K^j_{i;j}-K_{,i}, \tag{14}$$

where ${}^3R$ and ${}^3G$ are the Ricci scalar and Einstein tensor of the three metric g_{ij}, respectively. Now, to discover the effect the energy-momentum tensor S_{ij} of Σ on the space-time geometry, we perform a ''pill-box'' integration of Einstein's equations across Σ:

$$S_{\mu\nu}=\lim_{\Sigma\to 0}\int_{-\Sigma}^{\Sigma}\left(T_{\mu\nu}-g_{\mu\nu}\frac{\Lambda}{\kappa}\right)dn=\frac{1}{\kappa}\lim_{\Sigma\to 0}\int_{-\Sigma}^{\Sigma}G_{\mu\nu}dn, \tag{15}$$

where n is the proper distance through Σ in the direction of the normal n_μ. $S_{\mu\nu}$ is the associated 4-tensor of energy momentum of the shell. The equations (13), (14) have the physical meaning that no moment associated with the surface layer flows out of Σ. Therefore $S_{\mu\nu}$ vanishes off the hypersurface Σ, which is expressed as

$$S_{\mu\nu}n^\nu=0. \tag{16}$$

The energy momentum 4- and 3-tensors are related as

$$S^{\mu\nu}=e^\mu_i e^\nu_j S^{ij}. \tag{17}$$

The covariant derivative of such a tensor relative to the corresponding connections is given by[9]

$$\nabla^\pm_\nu S^{\mu\nu}=e^\mu_i S^{ij}_{;j}-\epsilon S^{ij}K^\pm_{ij}n^\mu, \tag{18}$$

which leads to the following useful relation

$$e^\mu_i \nabla_\nu S^\nu_\mu=S^j_{i:j}. \tag{19}$$

Similarly we can associate to the 3-tensor K_{ij} defined on Σ, the corresponding 4-dimensional tensor:

$$K^{\mu\nu}=K^{ij}e_i^\mu e_j^\nu, \tag{20}$$

satisfying

$$K^{\mu\nu}n_\nu=0. \tag{21}$$

The remaining components of the Einstein's equations lead to the following non-vanishing result

$$\lim_{\Sigma\to 0}\int_{-\Sigma}^{\Sigma} G_{\mu\nu}e_i^\mu e_j^\nu dn=\epsilon([K_{ij}]-g_{ij}[K])=\kappa S_{ij}. \tag{22}$$

This distributional equivalent of Einstein's equations is called *Lanczos* equation, which partly determines the dynamic of the thin shell. The other dynamical equations come from the defining equation of the matter contents of the shell. Now, the two Gauss-Kodazzi equations act as constraints. The first one (13) is the so-called ''Hamiltonian''- and the second one (14) the ''ADM''-constraint. Note however that these equations are valid in M^+ and M^- on taking the limits as one approaches the layer Σ. Therefore we are actually faced with 8 equations, the sum and difference of which give us the junction conditions. The Hamiltonian constraint along with the Einstein's or Lanczos equations then give the *evolution identity*:

$$S^{ij}\overline{K_{ij}}=-[T_{\mu\nu}n^\mu n^\nu-\Lambda/\kappa] \tag{23}$$

and

$${}^3R+(\overline{K_{ij}}\,\overline{K^{ij}}-K^2)=2\epsilon\kappa\overline{(T_{\mu\nu}n^\mu n^\nu-\Lambda/\kappa)}+\frac{\epsilon\kappa^2}{4}\left(S^{ij}S_{ij}-\frac{S^2}{2}\right). \tag{24}$$

The ADM constraint gives the *conservation identity*

$$S^i_{j;i}=-\epsilon[T_{\mu\nu}n^\mu e_j^\nu] \tag{25}$$

and

$$\overline{K^i_{j;i}}-\overline{K_{,j}}=\kappa\overline{(T_{\mu\nu}n^\mu e_i^\nu)}. \tag{26}$$

Not all of these jump conditions are independent. Usually one takes the evolution identity (23) and the conservation identity (25) as the proper junction conditions, which in addition to the Lanczos equation should be satisfied.[35]

III. DISTRIBUTIONAL METHOD

Here we intend to give a formulation of the Einstein's equations for the case where there exists a hypersurface of concentrated source immersed in an otherwise arbitrary space-time, not necessarily vacuum. We assume the metric to be continuous at the hypersurface:

$$[g_{\mu\nu}]=0. \tag{27}$$

Otherwise we would have to consider non-linear operations of distributions such as $\delta\theta$ or $\delta\delta$. The disadvantage of having a continuous metric across the shell pays off by the simplicity of the method to calculate specific solutions.[16,31,32]

Write the metric in the following form

$$g_{\mu\nu}=g^+_{\mu\nu}\theta(\Phi(x))+g^-_{\mu\nu}\theta(-\Phi(x)), \tag{28}$$

where θ is the step function and

$$g^{+}_{\mu\nu}|_{\Phi(x)=0}=g^{-}_{\mu\nu}|_{\Phi(x)=0}. \tag{29}$$

This condition guarantees the smoothness of the metric on the hypersurface. Should this not be the case we try a coordinate transformation $x=x(x')$ having a jump in the first derivative:

$$\frac{\partial x^{\mu}}{\partial x'^{\rho}}=\alpha^{+\mu}_{\rho}\theta(\Phi(x))+\alpha^{-\mu}_{\rho}\theta(-\Phi(x)). \tag{30}$$

The condition for the new metric to be continuous comes out to be

$$\alpha^{+\mu}_{\rho}\alpha^{+\nu}_{\sigma}g^{+}_{\mu\nu}|_{\Phi(x)=0}=\alpha^{-\mu}_{\rho}\alpha^{-\nu}_{\sigma}g^{-}_{\mu\nu}|_{\Phi(x)=0}. \tag{31}$$

We assume from now on that the metric is smooth everywhere, C^1 at the hypersurface and C^{∞} on both sides of it.

Although the metric is continuous on Σ, its derivatives, and so the corresponding connections, are discontinuous. Nevertheless the connection corresponding to the metric $g_{\mu\nu}$ can be written in the following compact form:

$$\Gamma^{\rho}_{\mu\nu}=\tfrac{1}{2}\ g^{\rho\sigma}(g_{\mu\sigma,\nu}+g_{\nu\sigma,\mu}-g_{\mu\nu,\sigma})=\theta(\Phi(x))\Gamma^{+\rho}{}_{\mu\nu}+\theta(-\Phi(x))\Gamma^{-\rho}{}_{\mu\nu}, \tag{32}$$

where $\Gamma^{\pm\rho}{}_{\mu\nu}$ are the ordinary connections on $M^{\pm}$. The above connection has jump discontinuities on Σ.

To write the field equations for the hypersurface we need the formulation of the energy-momentum tensor of the shell. Generally it can be written in the form

$$\breve{T}_{\mu\nu}=CS_{\mu\nu}\delta(\Phi(x)), \tag{33}$$

where C is a constant to be calculated. We integrate the above equation in the direction of the normal to the hypersurface

$$\int \breve{T}_{\mu\nu}dn=CS_{\mu\nu}\int \delta(\Phi(x))dn=CS_{\mu\nu}\left|\frac{dn}{d\Phi}\right|. \tag{34}$$

Therefore, using the definition (15), we obtain

$$C=\left|\frac{d\Phi}{dn}\right| \tag{35}$$

and

$$\breve{T}_{\mu\nu}=S_{\mu\nu}\left|\frac{d\Phi}{dn}\right|\delta(\Phi(x)). \tag{36}$$

Note that in the literature one usually takes $C=1$, which is correct just for special cases. But in general the factor C is necessary (see also Ref. 33). Now, the derivative of Φ in the normal direction can be written in terms of unit normal vector n^{μ}:

$$C=\left|\frac{d\Phi}{dn}\right|=|n^{\mu}\partial_{\mu}\Phi|=|\epsilon\alpha|=|\alpha|, \tag{37}$$

where we have used (8)–(11). Therefore (33) will be written in the form

$$\check{T}_{\mu\nu}=S_{\mu\nu}|n^{\sigma}\partial_{\sigma}\Phi|\,\delta(\Phi(x))=CS_{\mu\nu}\delta(\Phi(x))=|\alpha|S_{\mu\nu}\delta(\Phi(x)). \tag{38}$$

A. Covariant derivative of distributional valued tensors

There is no need to change the ordinary concept of covariant derivative, as it has been carefully shown by Lichnerowicz.[12] In fact, all the known properties of covariant derivative and the corresponding formulae in a pseudo-Riemannian manifold are valid for tensor distributions. But for the sake of convenience of calculation we refer to some useful formulae. Consider first an arbitrary vector A^{μ} defined as

$$A^{\mu}=\theta(\Phi)A^{+}+\theta(-\Phi)A^{-}, \tag{39}$$

where $A^{\pm}$ has the support on $M^{\pm}$. It is therefore useful to define the operator

$$\nabla=\theta(\Phi)\nabla^{+}+\theta(-\Phi)\nabla^{-}. \tag{40}$$

We can now write the covariant derivative of a distributional valued vector A^{μ} in terms of the covariant derivatives of its defining parts in $M^{\pm}$. The following relation is easily obtained:

$$A^{\mu}_{;\nu}=\nabla_{\nu}A^{\mu}+[A^{\mu}]\partial_{\nu}\Phi\,\delta(\Phi). \tag{41}$$

This relation can be generalized easily for a distributional tensor of any rank. The covariant derivative of the tensor

$$T^{(\rho)}=\theta(\Phi)T^{+(\rho)}+\theta(-\Phi)T^{-(\rho)}, \tag{42}$$

where (ρ) stands for any number of indices, is calculated to be

$$T^{(\rho)}{}_{;\nu}=\nabla_{\nu}T^{(\rho)}+[T^{(\rho)}]\partial_{\nu}\Phi\,\delta(\Phi). \tag{43}$$

In case a tensor has the support on Σ its covariant derivative is in the usual form. Take the tensor $\check{T}^{\mu\nu}$ from (33). Its covariant derivative can be written

$$(\check{T}^{\mu\nu})_{;\rho}=(CS^{\mu\nu})_{;\rho}\delta(\Phi)+CS^{\mu\nu}(\delta(\Phi))_{,\rho}=(CS^{\mu\nu})_{;\rho}\delta(\Phi)+CS^{\mu\nu}\partial_{\rho}\Phi\,\delta'(\Phi). \tag{44}$$

We will need this relation later to discuss the conservation laws.

B. The field equations

Einstein's field equations are valid on both sides of the hypersurface as usual. So we concentrate our procedure on Σ, where we expect the curvature and Einstein tensor to be proportional to δ. That means that in calculating the connection coefficients and the components of the Ricci tensor we can ignore terms not proportional to δ. Hence, e.g., the terms in the Ricci tensor

$$R_{\mu\nu}=\Gamma^{\rho}_{\mu\rho,\nu}-\Gamma^{\rho}_{\mu\nu,\rho}+\Gamma^{\sigma}_{\mu\rho}\Gamma^{\rho}_{\sigma\nu}-\Gamma^{\sigma}_{\mu\nu}\Gamma^{\rho}_{\rho\sigma} \tag{45}$$

proportional to Γ's can be ignored. The only relevant terms are

$$\check{R}_{\mu\nu}=\check{\Gamma}^{\rho}_{\mu\rho,\nu}-\check{\Gamma}^{\rho}_{\mu\nu,\rho}. \tag{46}$$

Now,

$$\Gamma^{\rho}_{\mu\rho}=\frac{1}{2g}\,g_{,\mu}, \tag{47}$$

where g is the determinant of the metric. The δ distribution can only occur in the second derivatives of the metric. Therefore

$$\breve{\Gamma}^{\rho}_{\mu\rho,\nu}=\frac{1}{2g}\,\breve{g}_{,\mu\nu}. \tag{48}$$

Similarly, for the second term in the Ricci tensor we have

$$\breve{\Gamma}^{\rho}_{\mu\nu,\rho}=\tfrac{1}{2}\,g^{\rho\sigma}(\breve{g}_{\sigma\mu,\nu\rho}+\breve{g}_{\sigma\nu,\mu\rho}-\breve{g}_{\mu\nu,\sigma\rho}). \tag{49}$$

Having the metric in the form (28) we obtain

$$\breve{g}_{\alpha\beta,\mu\nu}=[g_{\alpha\beta,\mu}](\partial_\nu\Phi)\,\delta(\Phi(x)) \tag{50}$$

and

$$\breve{g}_{,\mu\nu}=[g_{,\mu}]\partial_\nu\Phi\,\delta(\Phi(x)). \tag{51}$$

As a result we obtain for terms in the Ricci tensor proportional to δ

$$\begin{aligned}\breve{R}_{\mu\nu}&=\left(\frac{1}{2g}\,[g_{,\mu}]\partial_\nu\Phi-g^{\rho\sigma}([g_{\sigma\mu,\nu}]+[g_{\sigma\nu,\mu}]-[g_{\mu\nu,\sigma}])\partial_\rho f\right)\delta(f(x))\\&=\left(\frac{1}{2g}\,[g_{,\mu}]\partial_\nu\Phi-[\Gamma^{\rho}_{\mu\nu}]\partial_\rho\Phi\right)\delta(\Phi(x)).\end{aligned} \tag{52}$$

This enables us to write the Einstein's equations for the layer:

$$\breve{G}_{\mu\nu}=\kappa\breve{T}_{\mu\nu}. \tag{53}$$

Defining

$$Q_{\mu\nu}=(\alpha)^{-1}\left(\frac{1}{2g}\,[g_{,\mu}]\delta^{\rho}_{\nu}-[\Gamma^{\rho}_{\mu\nu}]\right)\partial_\rho\Phi=\left(\frac{1}{2g}\,[g_{,\mu}]\delta^{\rho}_{\nu}-[\Gamma^{\rho}_{\mu\nu}]\right)n_\rho \tag{54}$$

we obtain, using (38) and (52) for the energy momentum tensor, the field equations in the 4-dimensional form

$$Q_{\mu\nu}-\tfrac{1}{2}\,g_{\mu\nu}Q=\epsilon\kappa S_{\mu\nu}, \tag{55}$$

where $Q=Q_{\mu\nu}g^{\mu\nu}$, and we have used the relation $\epsilon=|\alpha|/\alpha$. Note that $Q_{\mu\nu}$ is a tensor with support on Σ. This equation, for the time-like case, has been first derived, without using the hitherto unknown distributional calculus, by Sen.[2] We would like, therefore, to coin it by *Sen equation*. The three dimensional form of the Sen equation is readily obtained by decomposing it to tangential- and normal-components to Σ. Multiplying (54) with n^μ we obtain

$$S_{\mu\nu}n^\nu=0, \tag{56}$$

which is the same relation as (16). This tells us immediately that the components corresponding to $S_{\mu\nu}n^\mu n^\nu$ and $S_{\mu\nu}n^\mu e^\nu_i$ identically vanishes. To obtain the proper 3-dimensional components we notice first that

$$Q_{ij}=Q_{\mu\nu}e^\mu_i e^\nu_j=-[\Gamma^{\rho}_{\mu\nu}]n_\rho e^\mu_i e^\nu_j=[K_{ij}]. \tag{57}$$

Therefore, we obtain from the Sen equation

$$Q_{ij}=\epsilon\kappa(S_{ij}-\tfrac{1}{2}\,g_{ij}S), \tag{58}$$

which is equivalent to the Lanczos equation (22).

We have therefore seen that the explicit method of writing the Einstein's field equations for a regular metric which is continuous without having continuous derivatives leads to the equation (55) and is equivalent to the DI-formalism based on the Gauss-Codazzi formalism. In practice, one begins with known solutions of the Einstein's equations in $M^{\pm}$, and after making sure the continuity of the metric on Σ, tries to solve equations (55). In the following we will show that the jump conditions of DI-formalism follows from the Bianchi identities corresponding to the metric (28), and are therefore implicit in the equations we have used.

C. Conservation laws

We have now all the prerequisites to evaluate the Bianchi identities and the conservation of energy momentum tensor of our pasted space-time. The energy momentum of the whole space-time, including the cosmological terms $\Lambda^{\pm}$ is

$$T^{\mu\nu}=\breve{T}^{\mu\nu}+(T^{+\mu\nu}-\Lambda^{+}/\kappa g^{+\mu\nu})\,\theta(\Phi)+(T^{-\mu\nu}-\Lambda^{-}/\kappa g^{-\mu\nu})\,\theta(-\Phi), \tag{59}$$

where $\breve{T}^{\mu\nu}$ is defined in (38). Having in mind that the covariant divergences of $T^{\pm\mu\nu}$ and $g^{\pm\mu\nu}$ with respect to the corresponding connections vanishes, we obtain

$$T^{\mu\nu}{}_{;\nu}=(\breve{T}^{\mu\nu})_{;\nu}+[T^{\mu\nu}-\Lambda/\kappa]\partial_{\nu}\Phi\,\delta(\Phi), \tag{60}$$

where we have used the relation (43). Now inserting for $\breve{T}^{\mu\nu}$ from (38) and using (44) we obtain an equation having terms proportional to $\delta(\Phi)$ and $\delta'(\Phi)$. Each term vanishes independently. The term proportional to $\delta'(\Phi)$ gives

$$(S^{\mu\nu}\partial_{\nu}\Phi)(n^{\sigma}\partial_{\sigma}\Phi)=0, \tag{61}$$

which leads to the (56) and ensures the orthogonality of the energy-momentum tensor of Σ to the hypersurface normal n^{μ}. We use in the following this relation to simplify the remaining calculations. The term proportional to δ is

$$(CS^{\mu\nu})_{,\nu}+CS^{\mu\rho}\Gamma^{\nu}_{\nu\rho}+CS^{\rho\nu}\Gamma^{\mu}_{\rho\nu}+[T^{\mu\nu}-\Lambda/\kappa g^{\mu\nu}]\partial_{\nu}\Phi)\,\delta(\Phi)=0. \tag{62}$$

We have left $\delta(\Phi)$ as proportionality factor to stress its influence especially on terms containing Γ's and $g^{\mu\nu}$'s. Note that the third term containing Γ's contains terms like $\theta\cdot\delta$, i.e., product of distributions. This is in analogy to the elementary problem of evaluating the electrostatic force on a sheet of charge.[5] There the linearity of electrostatic equation resolve the ambiguity. But how about our case where the Einstein equations are non-linear? We have already shown that in the case of thin shells the only terms contributing to the Einstein tensor are the derivatives of the connection, or the second derivative of the metric, which appear linearly. It is then easily seen that in the case of a layer the Einstein's equations leads to a Poisson-like equation corresponding to the Sen equation (55) for concentrated distribution, where the second derivative can be replaced by (50) and (51). Therefore, in analogy to the electromagnetic case, we can use the linearity of (55) to show that

$$\Gamma^{\mu}_{\rho\nu}\delta(\Phi)=\tfrac{1}{2}\,(\Gamma^{+\mu}{}_{\rho\nu}+\Gamma^{-\mu}{}_{\rho\nu})\,\delta(\Phi). \tag{63}$$

Using this result and multiplying equation (62) by n_μ, we obtain the component in the normal direction.

$$(CS^{\mu\nu})_{,\nu}n_\mu + CS^{\rho\nu}\overline{\Gamma^{\mu}_{\rho\nu}}n_\mu = \epsilon[T^{\mu\nu} - \Lambda/\kappa g^{\mu\nu}]n_\mu \partial_\nu \Phi. \tag{64}$$

Using the relations (63) and the definition of the extrinsic curvature (12), we obtain the final result

$$S^{ij}\overline{K_{ij}} = \epsilon[T^{\mu\nu}n_\mu n_\nu - \Lambda/\kappa]. \tag{65}$$

This is the evolution identity (23) derived as one of the jump conditions in the Darmois-Israel method. Here it is just a consequence of the Bianchi identities. To obtain the remaining three equations we multiply (64) by e^i_μ. Using (19) we obtain

$$S^i_{j;i} = -\epsilon[T_{\mu\nu}n^\mu e^\nu_i], \tag{66}$$

which is the conservation identity (25). It gives the conservation law for the energy momentum tensor of the layer. We therefore see that our explicit distributional method of solving the Einstein's equations gives all the dynamical and constraint equations of the Darmois-Israel method, and is therefore equivalent to it.

IV. CONCLUSION

We have seen that, based on the Lichnerowicz condition (3), a distributional method can be formulated to solve Einstein's field equations for a thin shell, which is equivalent to the Darmois-Israel formalism, and gives all the necessary equations and jump conditions formulated there. In fact, it has been shown that the jump conditions are a consequence of the Bianchi identities, and therefore implicit in the formalism, once the Lichnerowicz condition is satisfied. This makes the distributional formalism easy to apply, especially when explicit solutions are to be found, and it pays off the disadvantage of the continuity of the coordinates across the shell.

Gravitational and electromagnetic perturbations of the Schwarzschild solution

G. F. Torres del Castillo
Departamento de Física Matemática, Instituto de Ciencias de la Universidad Autónoma de Puebla, 72000 Puebla, Pue., México

(Received 18 April 1996; accepted for publication 22 May 1996)

It is shown that the complete metric and vector potential perturbations of the Schwarzschild solution can be expressed in terms of radial functions that share several differential properties. The energy flux of the incident, reflected, and absorbed gravitational and electromagnetic waves is given and the polarization changes are also analyzed. © *1996 American Institute of Physics.* [S0022-2488(96)03609-2]

I. INTRODUCTION

The perturbations of space–times describing black holes have been the subject of numerous investigations, making use of diverse methods (see, e.g., Ref. 1). The simplest of these space–times corresponds to the Schwarzschild solution, which describes a static, uncharged black hole, and the study of its perturbations was initiated some time ago, originally in connection with the stability of the Schwarzschild black hole[2–4] (see also Refs. 5–7 and the references cited therein). Although it is generally believed that the perturbations of the Schwarzschild solution are fairly well understood, as we shall show below, some existing results are wrong or incomplete.

The aim of this paper is twofold; we show that the gravitational and the electromagnetic perturbations of the Schwarzschild solution can be expressed in terms of radial functions that obey sets of equations of the same form. This allows us to show that the Teukolsky–Starobinsky identities, which in the case of the gravitational and the electromagnetic perturbations involve differential operators of order four and two, respectively, follow from a single basic identity [Eq. (30) below]. We also give expressions for all the components of the perturbed conformal curvature and of the electromagnetic perturbations. The energy fluxes at spatial infinity and at the horizon are then calculated and it is *explicitly* shown that the energy carried by the gravitational or electromagnetic waves is conserved. We show that an ingoing circularly polarized gravitational wave produces an elliptically polarized scattered wave, even though the black hole does not rotate. Throughout this paper we make use of the Newman–Penrose notation.

II. DEBYE POTENTIALS

As shown in Refs. 8–11, the metric perturbations of an algebraically special solution of the Einstein vacuum field equations, in a frame such that $\Psi_0=\Psi_1=0$ (or, equivalently, $\kappa=\sigma=0$), are given by

$$\begin{aligned} h_{\mu\nu}=2\{&l_\mu l_\nu[(\delta+3\beta+\overline{\alpha}-\tau)(\delta+4\beta+3\tau)-\overline{\lambda}(D+4\epsilon+3\rho)]\\ &+m_\mu m_\nu(D+3\epsilon-\overline{\epsilon}-\rho)(D+4\epsilon+3\rho)-l_{(\mu}m_{\nu)}[(D+3\epsilon+\overline{\epsilon}-\rho+\overline{\rho})(\delta+4\beta+3\tau)\\ &+(\delta+3\beta-\overline{\alpha}-\tau-\overline{\pi})(D+4\epsilon+3\rho)]\}\psi_{\mathrm{G}}+\text{c.c.}, \end{aligned} \tag{1}$$

up to the gauge transformations $h_{\mu\nu}\mapsto h_{\mu\nu}-2\nabla_{(\mu}\xi_{\nu)}$, where ξ_μ is an arbitrary vector field, with the complex scalar potential ψ_{G} governed by the equation

$$[(\Delta+3\gamma-\overline{\gamma}+\overline{\mu})(D+4\epsilon+3\rho)-(\overline{\delta}+3\alpha+\overline{\beta}-\overline{\tau})(\delta+4\beta+3\tau)-3\Psi_2]\psi_{\mathrm{G}}=0. \tag{2}$$

0022-2488/96/37(11)/5684/11/$10.00

The Schwarzschild solution can be specified by the null tetrad,

$$l^\mu\partial_\mu=\partial_r+\frac{r^2}{\chi}\,\partial_t,\quad n^\mu\partial_\mu=-\frac{1}{2}\,\frac{\chi}{r^2}\left(\partial_r-\frac{r^2}{\chi}\,\partial_t\right),$$
$$m^\mu\partial_\mu=\frac{1}{\sqrt{2}r}\,(\partial_\theta+i\,\mathrm{cosec}\;\theta\partial_\varphi),\quad \overline{m^\mu}\partial_\mu=\frac{1}{\sqrt{2}r}\,(\partial_\theta-i\,\mathrm{cosec}\;\theta\partial_\varphi), \tag{3a}$$

with

$$\chi\equiv r^2-2Mr. \tag{3b}$$

The nonvanishing spin coefficients can be conveniently expressed as

$$\rho=-D\,\ln r,\quad \mu=\Delta\,\ln r,\quad \gamma=\Delta\,\ln r\chi^{-1/2},$$
$$\beta=\delta\,\ln\sin^{1/2}\theta,\quad \alpha=-\overline{\delta}\,\ln\sin^{1/2}\theta, \tag{4}$$

and the only nonvanishing component of the Weyl spinor is

$$\Psi_2=-\frac{M}{r^3}. \tag{5}$$

Since ψ_{G} has spin weight -2, we seek solutions of Eq. (2) of the form

$$\psi_{\mathrm{G}}=r^3Y_{-2}(r)e^{-i\omega t}{}_{-2}Y_{jm}(\theta,\varphi), \tag{6}$$

where the ${}_sY_{jm}$ are spin-weighted spherical harmonics.[12] Substituting Eqs. (3)–(6) into Eq. (2) one obtains the ordinary differential equation,

$$\mathscr{D}^*\,\frac{r^6}{\chi}\,\mathscr{D}Y_{-2}=\eta^2\,\frac{r^6}{\chi^2}\left(1+\frac{6M}{\eta^2r}\right)Y_{-2}, \tag{7}$$

where

$$\mathscr{D}^*\equiv\partial_r+\frac{i\omega r^2}{\chi},\quad \mathscr{D}\equiv\partial_r-\frac{i\omega r^2}{\chi} \tag{8}$$

and

$$\eta\equiv[(j-1)(j+2)]^{1/2}. \tag{9}$$

If one introduces the function[13]

$$X_{-1}\equiv\frac{r^6}{\eta^2\chi}\,\mathscr{D}\,Y_{-2}, \tag{10}$$

then Eq. (7) is equivalent to the system of first-order equations,

$$\mathscr{D}\,Y_{-2}=\eta^2\,\frac{\chi}{r^6}\,X_{-1},\quad \mathscr{D}^*X_{-1}=\frac{r^6}{\chi^2}\left(1+\frac{6M}{\eta^2r}\right)Y_{-2}. \tag{11}$$

On the other hand, the vector potential perturbations of an algebraically special solution of the Einstein vacuum field equations, in a frame such that $\Psi_0=\Psi_1=0$ are given by[14,9,10]

$$b_\mu = l_\mu(\delta+2\beta+\tau)\psi_{\mathrm{E}} - m_\mu(D+2\epsilon+\rho)\psi_{\mathrm{E}} + \text{c.c.}, \tag{12}$$

where the complex scalar potential ψ_{E} satisfies

$$[(\Delta+\gamma-\overline{\gamma}+\overline{\mu})(D+2\epsilon+\rho) - (\overline{\delta}+\alpha+\overline{\beta}-\overline{\tau})(\delta+2\beta+\tau)]\psi_{\mathrm{E}} = 0. \tag{13}$$

Commuting the derivatives acting on ψ_{E}, making use of the fact that $\kappa=\sigma=\Psi_1=0$, one obtains

$$[(D+3\epsilon+\overline{\epsilon}+2\rho-\overline{\rho})(\Delta+2\gamma+\mu) - (\delta+3\beta-\overline{\alpha}+2\tau+\overline{\pi})(\overline{\delta}+2\alpha+\pi) - 6\Psi_2]\psi_{\mathrm{E}} = 0. \tag{14}$$

Using the fact that ψ_{E} has spin weight -1, we look for solutions of Eq. (14) of the form

$$\psi_{\mathrm{E}} = \frac{\chi}{r^3} X_{-2}(r) e^{-i\omega t}\, {}_{-1}Y_{jm}(\theta,\varphi). \tag{15}$$

Then, substituting Eqs. (3a), (4), and (15) into Eq. (14), one finds that

$$\mathscr{D}\frac{\chi^2}{r^6}\mathscr{D}^* X_{-2} = \eta^2 \frac{\chi}{r^6}\left(1+\frac{12M}{\eta^2 r}\right) X_{-2}. \tag{16}$$

Therefore, introducing the function

$$Y_{-1} \equiv \frac{\chi^2}{r^6}\mathscr{D}^* X_{-2}, \tag{17}$$

Eq. (16) is equivalent to

$$\mathscr{D} Y_{-1} = \eta^2 \frac{\chi}{r^6}\left(1+\frac{12M}{\eta^2 r}\right) X_{-2}, \quad \mathscr{D}^* X_{-2} = \frac{r^6}{\chi^2} Y_{-1} \tag{18}$$

[cf. Eqs. (11)].

Equations (11) and (18) can be written in the common form

$$\mathscr{D} Y_{-k} = \eta^2 \frac{\chi}{r^6}\left(1+\frac{2q_k}{\eta^2 r}\right) X_{-l}, \quad \mathscr{D}^* X_{-l} = \frac{r^6}{\chi^2}\left(1+\frac{q_l}{\eta^2 r}\right) Y_{-k} \quad (k,l=1,2;\ k\neq l), \tag{19}$$

where

$$q_1 \equiv 6M, \quad q_2 \equiv 0. \tag{20}$$

In the study of the perturbations of the Reissner–Nordström solution, Chandrasekhar[15,5] obtained a set of equations identical to Eqs. (19). It must be noticed, however, that in the present case there is no need to make infinitesimal tetrad rotations as in Refs. 15 and 5. The solution of Eqs. (19) can be expressed in terms of a single function $Z_k^{(+)}$ or $Z_k^{(-)}$, which obeys the Schrödinger-type equation,[15,5]

$$\left(-\frac{d^2}{dr_*^2} + V_k^{(\pm)}\right) Z_k^{(\pm)} = \omega^2 Z_k^{(\pm)}, \tag{21}$$

where r_* is defined by $dr_*/dr=r^2/\chi$ and

$$V_k^{(\pm)}\equiv \pm q_l \frac{df_k}{dr_*}+q_l^2 f_k^2+\eta^2(\eta^2+2)f_k,$$
$$f_k\equiv \frac{\chi}{r^3(\eta^2 r+q_l)} \quad (k,l=1,2;\ \ k\neq l). \tag{22}$$

The solution of Eqs. (19) is given by

$$Y_{-k}=V_k^{(\pm)}Z_k^{(\pm)}+(W_k^{(\pm)}+2i\omega)\left(\frac{d}{dr_*}+i\omega\right)Z_k^{(\pm)},$$
$$\eta^2 X_{-l}=\mp q_l Z_k^{(\pm)}+f_k^{-1}\left(\frac{d}{dr_*}+i\omega\right)Z_k^{(\pm)} \quad (k\neq l), \tag{23}$$

with

$$W_k^{(\pm)}\equiv -\frac{d}{dr_*}\ln f_k\mp q_l f_k \quad (k\neq l). \tag{24}$$

It may be noticed that, since q_2 vanishes, the potentials $V_1^{(+)}$ and $V_1^{(-)}$, which correspond to the electromagnetic perturbations, coincide and, similarly, that $W_1^{(+)}=W_1^{(-)}$; therefore, Eqs. (21)–(24) yield only one expression for Y_{-1} and X_{-2}. On the other hand, Eqs. (3b), (20), and (22) give two distinct potentials,

$$V_2^{(+)}=\frac{\chi}{r^5}\frac{\eta^4(\eta^2+2)r^3+6\eta^4 Mr^2+36\eta^2M^2r+72M^3}{(\eta^2 r+6M)^2} \tag{25}$$

and

$$V_2^{(-)}=\frac{\chi}{r^5}[(\eta^2+2)r-6M]. \tag{26}$$

The potentials $V_2^{(+)}$ and $V_2^{(-)}$ were originally obtained by Zerilli[3] and by Regge and Wheeler,[2] respectively, in the study of the polar and axial metric perturbations of the Schwarzschild metric. Chandrasekhar and Detweiler[16] proved that the reflection and transmission coefficients corresponding to the potential barriers $V_2^{(+)}$ and $V_2^{(-)}$ are the same (also see Refs. 5 and 15 and Sec. IV).

In the present treatment, the functions $Z_2^{(+)}$ and $Z_2^{(-)}$ lead to the same set of solutions of Eqs. (11) and, as we shall show in Sec. IV, the reflection and transmission coefficients for the gravitational waves impinging on a Schwarzschild black hole coincide with those of the potential barrier employed to express the solution of Eqs. (11) [Eqs. (23)]; therefore, without any further calculation or without having to relate the functions $Z_2^{(+)}$ and $Z_2^{(-)}$ that produce a given perturbation, it follows that the reflection and transmission coefficients for $V_2^{(+)}$ and $V_2^{(-)}$ must coincide. (It may be remarked that in Ref. 5 it is shown that the perturbed value of Ψ_4, with respect to the tetrad (3), can be expressed in terms of the radial functions Y_{-2}, which are given in terms of either $Z_2^{(+)}$ or $Z_2^{(-)}$ by Eq. (23); this fact alone does not imply the equality of the reflection and transmission coefficients for $V_2^{(+)}$ and $V_2^{(-)}$ since the computation of the reflection and transmission coefficients of the black hole requires the knowledge of the corresponding perturbed value of Ψ_0 [see Eqs. (51), (53) and (56) below].) Note also that the meaning of the functions Y_{-k} and X_{-l} appearing in the present treatment differs from that of analogous functions introduced by Chandrasekhar.[15,5]

III. THE DIFFERENTIAL IDENTITIES

Since the complete perturbations (gravitational or electromagnetic) are given in terms of derivatives of a single scalar potential, there must exist differential identities relating the perturbed quantities. In fact, some differential relations of this type (called Teukolsky–Starobinsky identities) were obtained in the study of the Kerr metric perturbations. In terms of the notation used here, the Teukolsky–Starobinsky identities can be expressed as[17–19,5]

$$\chi^2\mathscr{D}^*\mathscr{D}^*\mathscr{D}^*\mathscr{D}^*r^3Y_{+2}\propto r^3Y_{-2}, \quad \chi^2\mathscr{D}\mathscr{D}\mathscr{D}\mathscr{D}r^3Y_{-2}\propto r^3Y_{+2}, \tag{27}$$

for the gravitational perturbations, and

$$\chi\mathscr{D}^*\mathscr{D}^*\frac{\chi}{r^3}X_{+2}\propto\frac{\chi}{r^3}X_{-2}, \quad \chi\mathscr{D}\mathscr{D}\frac{\chi}{r^3}X_{-2}\propto\frac{\chi}{r^3}X_{+2}, \tag{28}$$

in the case of the electromagnetic perturbations, where Y_{+k} and X_{+l} are radial functions satisfying the differential equations

$$\mathscr{D}^*Y_{+k}=\eta^2\frac{\chi}{r^6}\left(1+\frac{2q_k}{\eta^2 r}\right)X_{+l}, \quad \mathscr{D}X_{+l}=\frac{r^6}{\chi^2}\left(1+\frac{q_l}{\eta^2 r}\right)Y_{+k} \quad (k\neq l), \tag{29}$$

[cf. Eqs. (19)].

Since the radial dependence of the scalar potentials ψ_{G} and ψ_{E} is determined by similar equations [Eqs. (19)], it is not surprising that the identities (27)–(28) can be derived from a single relation. Indeed, the functions $X_{\pm k}$ can be normalized in such a way that[20]

$$\eta^2r^3\mathscr{D}^*\mathscr{D}^*\frac{\chi}{r^3}X_{+k}+q_kr^2\mathscr{D}^*\frac{1}{r}\mathscr{D}^*\frac{\chi}{r^2}X_{+k}=C_kX_{-k} \tag{30}$$

and

$$\eta^2r^3\mathscr{D}\mathscr{D}\frac{\chi}{r^3}X_{-k}+q_kr^2\mathscr{D}\frac{1}{r}\mathscr{D}\frac{\chi}{r^2}X_{-k}=\widetilde{C}_kX_{+k}, \tag{31}$$

where C_k and $\widetilde{C}_k$ are constants such that

$$\widetilde{C}_k=\overline{C_k}, \quad \text{for } \omega \text{ real.} \tag{32}$$

When $k=2$, owing to the fact that $q_2=0$, Eqs. (30) and (31) reduce to

$$\chi\mathscr{D}^*\mathscr{D}^*\frac{\chi}{r^3}X_{+2}=\frac{C_2}{\eta^2}\frac{\chi}{r^3}X_{-2}, \quad \chi\mathscr{D}\mathscr{D}\frac{\chi}{r^3}X_{-2}=\frac{\widetilde{C}_2}{\eta^2}\frac{\chi}{r^3}X_{+2}, \tag{33}$$

which correspond to Eqs. (28).

On the other hand, applying the operator $\mathscr{D}^*$ to both sides of Eq. (30) and making use of Eq. (19), one readily finds that

$$\eta^2\frac{\chi^2}{r^4}\mathscr{D}^*\mathscr{D}^*\mathscr{D}^*\frac{\chi}{r^2}X_{+k}=C_kY_{-l} \quad (k\neq l). \tag{34}$$

In an analogous manner, one obtains the identity

$$\eta^2 \frac{\chi^2}{r^4} \mathscr{D}\mathscr{D}\mathscr{D} \frac{\chi}{r^2} X_{-k} = \widetilde{C}_k Y_{+l} \quad (k \neq l). \tag{35}$$

Setting $k=1$ in Eqs. (34) and (35), and eliminating $X_{\pm 1}$ in favor of $Y_{\pm 2}$, making use of Eqs. (19) and (29), one obtains

$$\chi^2 \mathscr{D}^* \mathscr{D}^* \mathscr{D}^* \mathscr{D}^* r^3 Y_{+2} = C_1 r^3 Y_{-2}, \quad \chi^2 \mathscr{D}\mathscr{D}\mathscr{D}\mathscr{D} r^3 Y_{-2} = \widetilde{C}_1 r^3 Y_{+2}, \tag{36}$$

which correspond to Eqs. (27).

From Eqs. (19) and (29) one can derive two additional useful identities,

$$r^2 \mathscr{D}^* \mathscr{D}^* \mathscr{D}^* r^2 Y_{+k} = \eta^2 r \mathscr{D}^* \mathscr{D}^* \frac{\chi}{r^3} X_{+l} + 2q_k \mathscr{D}^* \mathscr{D}^* \frac{\chi}{r^3} X_{+l} - 4q_k \mathscr{D}^* \frac{\chi}{r^4} X_{+l} \quad (k \neq l) \tag{37}$$

and

$$r^2 \mathscr{D}\mathscr{D}\mathscr{D} r^2 Y_{-k} = \eta^2 r \mathscr{D}\mathscr{D} \frac{\chi}{r^3} X_{-l} + 2q_k \mathscr{D}\mathscr{D} \frac{\chi}{r^3} X_{-l} - 4q_k \mathscr{D} \frac{\chi}{r^4} X_{-l} \quad (k \neq l). \tag{38}$$

The value of $C_k \widetilde{C}_k$ can be obtained by eliminating X_{+k} from Eqs. (30) and (31) and making use repeatedly of Eqs. (19), this gives

$$C_k \widetilde{C}_k = \eta^4 (\eta^2 + 2)^2 + 4\omega^2 q_k^2. \tag{39}$$

The phase of C_k depends on the relative normalization of the functions X_{-k} and X_{+k}.

IV. REFLECTION, TRANSMISSION, AND ABSORPTION OF GRAVITATIONAL AND ELECTROMAGNETIC WAVES

All the components of the perturbed Weyl spinor, distinguished with a superscript B, can be calculated making use of Eq. (1) and the relation[21]

$$\Psi^{\mathrm{B}}_{ACDE} = \tfrac{1}{2} \nabla_{(A}{}^{R'} \nabla_C{}^{S'} h_{DE)R'S'} + \tfrac{1}{4} h^{\mu}{}_{\mu} \Psi_{ACDE}. \tag{40}$$

Then, by means of a straightforward but lengthy computation, using Eqs. (1), (3), (4), and (6) one obtains

$$\begin{aligned}
\overline{\Psi^{\mathrm{B}}_0} &= (\mathscr{D}\mathscr{D}\mathscr{D}\mathscr{D} r^3 Y_{-2}) e^{-i\omega t} {}_{-2}Y_{jm}(\theta,\varphi), \\
\overline{\Psi^{\mathrm{B}}_1} &= -\frac{\eta}{\sqrt{2}} (\mathscr{D}\mathscr{D}\mathscr{D} r^2 Y_{-2}) e^{-i\omega t} {}_{-1}Y_{jm}(\theta,\varphi), \\
\overline{\Psi^{\mathrm{B}}_2} &= \frac{\eta\sqrt{\eta^2+2}}{2r} (\mathscr{D} r^2 \mathscr{D}\, Y_{-2}) e^{-i\omega t} Y_{jm}(\theta,\varphi), \\
\overline{\Psi^{\mathrm{B}}_3} &= -\frac{\eta(\eta^2+2)}{2\sqrt{2}} \mathscr{D}\, Y_{-2} e^{-i\omega t} {}_1Y_{jm}(\theta,\varphi), \\
\overline{\Psi^{\mathrm{B}}_4} &= \frac{\eta^2(\eta^2+2)}{4r} Y_{-2} e^{-i\omega t} {}_2Y_{jm}(\theta,\varphi) - \frac{3iM\omega}{r} \overline{Y_{-2}} e^{i\omega t}\ \overline{{}_{-2}Y_{jm}(\theta,\varphi)}.
\end{aligned} \tag{41}$$

[In order to obtain the reduced expression for $\overline{\Psi_4^{\mathrm{B}}}$ given by Eq. (41) one has to employ repeatedly Eq. (2) or (11).[22,23]] Similarly, from Eqs. (3), (4), (12), (13), and (15) it follows that the components of the electromagnetic field perturbations are given by

$$\overline{\varphi_0}=\left(\mathscr{D}\mathscr{D}\frac{\chi}{r^3}X_{-2}\right)e^{-i\omega t}{}_{-1}Y_{jm}(\theta,\varphi),$$

$$\overline{\varphi_1}=-\frac{\sqrt{\eta^2+2}}{\sqrt{2}}\left(\frac{1}{r}\mathscr{D}\frac{\chi}{r^3}X_{-2}\right)e^{-i\omega t}Y_{jm}(\theta,\varphi), \tag{42}$$

$$\overline{\varphi_2}=\frac{(\eta^2+2)}{2}\frac{\chi}{r^5}X_{-2}e^{-i\omega t}{}_1Y_{jm}(\theta,\varphi).$$

Alternative expressions for the perturbations (41) and (42) can be obtained, making use of the differential relations (11), (33), (36), and (38). In particular, Ψ_0^{B} and Ψ_4^{B}, which are invariant under the gauge transformations $h_{\mu\nu}\mapsto h_{\mu\nu}-2\nabla_{(\mu}\xi_{\nu)}$ and represent the ingoing and outgoing gravitational radiation, respectively (see below), are given by

$$\overline{\Psi_0^{\mathrm{B}}}=\widetilde{C}_1\frac{r^3}{\chi^2}Y_{+2}e^{-i\omega t}{}_{-2}Y_{jm}(\theta,\varphi), \tag{43a}$$

$$\overline{\Psi_4^{\mathrm{B}}}=\frac{1}{4r}\{\eta^2(\eta^2+2)Y_{-2}e^{-i\omega t}{}_2Y_{jm}(\theta,\varphi)-12iM\omega\overline{Y_{-2}}e^{i\omega t}\ \overline{{}_{-2}Y_{jm}(\theta,\varphi)}\}. \tag{43b}$$

Equations (43) correspond to Eqs. (362) and (363) of Sec. 32 of Ref. 5; however, Eq. (43b) is not equivalent to the corresponding expression given in Ref. 5.

Since the potentials $V_k^{(\pm)}$ are of short range, $Z_k^{(\pm)}$ have the asymptotic behaviors $e^{\pm i\omega r_*}$ both for $r_*\to\infty$ and $r_*\to-\infty$ (the horizon of the black hole) and from Eqs. (23) one can find the asymptotic forms of Y_{-k} and X_{-l}.[5] If the functions $Z_k^{(\pm)}$ have the asymptotic behavior $e^{-i\omega r_*}$ for $r\to\infty$, then Eqs. (41) and (42) show that

$$\Psi_i^{\mathrm{B}}=O\left(\frac{1}{r^{1+i}}\right),\quad \varphi_i=O\left(\frac{1}{r^{1+i}}\right),$$

which means that, for ingoing waves, Ψ_0^{B} and φ_0 represent the ingoing fields and that these perturbations satisfy the ''peeling property'' (see Ref. 24). Similarly, if $Z_k^{(\pm)}$ have the asymptotic behavior $e^{i\omega r*}$ for $r_*\to\infty$,

$$\Psi_i^{\mathrm{B}}=O\left(\frac{1}{r^{5-i}}\right),\quad \varphi_i=O\left(\frac{1}{r^{3-i}}\right);$$

hence, at spatial infinity, Ψ_4^{B} and φ_2 represent the outgoing fields.

By definition, under a rotation through an angle ϕ determined by $m^\mu\mapsto e^{i\phi}m^\mu$, a quantity ξ with spin weight s transforms as $\xi\mapsto e^{is\phi}\xi$; therefore, since $\overline{\Psi_0^{\mathrm{B}}}$, $\overline{\Psi_4^{\mathrm{B}}}$, $\overline{\varphi_0}$, and $\overline{\varphi_2}$ have spin weight -2, 2, -1, and 1, respectively, if any of these quantities is proportional to $e^{i\omega t}$ or to $e^{-i\omega t}$, the corresponding field has circular polarization, while the presence of both factors, $e^{i\omega t}$ and $e^{-i\omega t}$, means that the field has elliptic polarization. Thus, at spatial infinity, the ingoing gravitational waves and the (ingoing and outgoing) electromagnetic waves given by Eqs. (41) and (42) have right (left) circular polarization if $\omega>0$ ($\omega<0$). (Note that φ_0 and φ_2 have opposite spin weights, but they represent waves propagating in opposite directions.) On the other hand, the outgoing gravitational waves given by Eqs. (41) will be elliptically polarized (unless $M\omega Y_{-2}$ vanishes).

Equation (43b) deserves some comments. First, the presence of a term proportional to $e^{i\omega t}$ is a consequence of considering *real* metric perturbations [Eq. (1)]. Second, unless $M\omega Y_{-2}$, or $M\omega Y_{+2}$, vanishes, there are no real gravitational perturbations such that all the components of the perturbed Weyl spinor have a time dependence of the form $e^{i\omega t}$ (or $e^{-i\omega t}$). Third, the presence of both factors $e^{i\omega t}$ and $e^{-i\omega t}$ in Ψ_4^{B} has an objective physical meaning: it signifies that the outgoing gravitational waves are elliptically polarized if the ingoing gravitational waves are circularly polarized. In most previous investigations on black hole perturbations (see, e.g., Ref. 5) it is assumed that all the perturbed quantities have a time dependence of the form $e^{-i\omega t}$, which, as remarked above, is not consistent if the metric perturbations are real [see also Ref. 7, Eqs. (3.97) and (3.98)] and, furthermore, it amounts to assuming that the helicity of the gravitational waves is left unchanged by the scattering from the black hole. Note that in the case of the scattering of electromagnetic waves, a circularly polarized ingoing wave gives rise to a circularly polarized outgoing wave (a result that is not obvious).

Assuming that there are no waves emerging from the horizon, the functions $Z_k^{(\pm)}$ have the asymptotic forms

$$\begin{aligned} Z_k^{(\pm)} &\to A_k^{(\pm)} e^{-i\omega r_*} + B_k^{(\pm)} e^{i\omega r_*} \quad (r_* \to +\infty), \\ &\to D_k^{(\pm)} e^{-i\omega r_*} \qquad\qquad\quad (r_* \to -\infty). \end{aligned} \tag{44}$$

Since the potentials $V_k^{(\pm)}$ are real, from Eq. (21) it follows that the amplitudes

$$R_k^{(\pm)} \equiv \frac{B_k^{(\pm)}}{A_k^{(\pm)}}, \quad T_k^{(\pm)} \equiv \frac{D_k^{(\pm)}}{A_k^{(\pm)}}, \tag{45}$$

satisfy

$$|R_k^{(\pm)}|^2 + |T_k^{(\pm)}|^2 = 1. \tag{46}$$

Expressing the radial functions Y_{-k}, X_{-l} in terms of $Z_k^{(\pm)}$, by means of Eqs. (23), and assuming that $Z_k^{(\pm)}$ have the asymptotic forms (44), from Eqs. (41) and (42) one finds that when $r_* \to \infty$,

$$\begin{gathered} \frac{1}{4} r\overline{\Psi_0^{\mathrm{B}}} \to -\omega^2[\eta^2(\eta^2+2) \pm 12iM\omega] A_2^{(\pm)} e^{-i\omega(t+r_*)}\, {}_{-2}Y_{jm}, \\ r\overline{\Psi_4^{\mathrm{B}}} \to -\omega^2[\eta^2(\eta^2+2) B_2^{(\pm)} e^{-i\omega(t-r_*)}\, {}_2Y_{jm} - 12iM\omega \overline{B_2^{(\pm)}} e^{i\omega(t-r_*)}\ \overline{{}_{-2}Y_{jm}}], \\ \frac{1}{2} r\overline{\varphi_0} \to -i\omega\eta(\eta^2+2) A_1 e^{-i\omega(t+r_*)}\, {}_{-1}Y_{jm}, \\ r\overline{\varphi_2} \to i\omega\eta(\eta^2+2) B_1 e^{-i\omega(t-r_*)}\, {}_1Y_{jm}. \end{gathered} \tag{47}$$

Similarly, when $r_* \to -\infty$ (the horizon of the black hole),

$$\begin{gathered} \chi^2 \overline{\Psi_0^{\mathrm{B}}} \to 4i\omega\left(i\omega + \frac{1}{4M}\right)(2M)^3[\eta^2(\eta^2+2) \pm 12iM\omega] D_2^{(\pm)} e^{-i\omega(t+r_*)}\, {}_{-2}Y_{jm}, \\ \chi\overline{\varphi_0} \to -4iM\omega\eta(\eta^2+2) D_1 e^{-i\omega(t+r_*)}\, {}_{-1}Y_{jm}. \end{gathered} \tag{48}$$

(We have supressed the superscript $(\pm)$ in the coefficients A_1, B_1, and D_1, since there is no difference between $Z_1^{(+)}$ and $Z_1^{(-)}$ [see Eqs. (21)–(24)].)

From Eqs. (47) and (48) it follows that the functions $Z_2^{(+)}$ and $Z_2^{(-)}$, satisfying the boundary conditions (44), give rise to the same gravitational perturbations, provided that the coefficients $A_2^{(\pm)}$, $B_2^{(\pm)}$, and $D_2^{(\pm)}$ are related by

$$\begin{gathered}[\eta^2(\eta^2+2)+12iM\omega]A_2^{(+)}=[\eta^2(\eta^2+2)-12iM\omega]A_2^{(-)},\\ B_2^{(+)}=B_2^{(-)},\\ [\eta^2(\eta^2+2)+12iM\omega]D_2^{(+)}=[\eta^2(\eta^2+2)-12iM\omega]D_2^{(-)},\end{gathered} \tag{49}$$

which, among other things, implies that [see Eqs. (45)]

$$R_2^{(+)}=\frac{\eta^2(\eta^2+2)+12iM\omega}{\eta^2(\eta^2+2)-12iM\omega}\,R_2^{(-)},\quad T_2^{(+)}=T_2^{(-)}. \tag{50}$$

(An alternative proof of these relations was given by Chandrasekhar.[15,5])

Using Eqs. (47) one finds that the flux of energy per unit time of the gravitational or electromagnetic radiation coming from infinity is given by

$$\frac{dE_{\text{in}}^{\text{grav}}}{dt}=\frac{1}{4\pi\omega^2}\lim_{r\to\infty}\int\left|\frac{1}{4}\,r\Psi_0^{\text{B}}\right|^2 d\Omega=\frac{\omega^2}{4\pi}\,[\eta^4(\eta^2+2)^2+144M^2\omega^2]|A_2^{(\pm)}|^2 \tag{51}$$

and

$$\frac{dE_{\text{in}}^{\text{em}}}{dt}=\frac{1}{2\pi}\lim_{r\to\infty}\int\left|\frac{1}{2}\,r\varphi_0\right|^2 d\Omega=\frac{\omega^2}{2\pi}\,\eta^2(\eta^2+2)^2|A_1|^2, \tag{52}$$

respectively. Similarly, since the power flux per unit solid angle of the outgoing gravitational and electromagnetic waves is

$$\frac{d^2E_{\text{out}}^{\text{grav}}}{dt\,d\Omega}=\frac{1}{4\pi\omega^2}\lim_{r\to\infty}|r\Psi_4^{\text{B}}|^2,\quad \frac{d^2E_{\text{out}}^{\text{em}}}{dt\,d\Omega}=\frac{1}{2\pi}\lim_{r\to\infty}|r\varphi_2|^2, \tag{53}$$

respectively, the *time-averaged* flux of energy per unit time of the outgoing gravitational waves is

$$\left\langle\frac{dE_{\text{out}}^{\text{grav}}}{dt}\right\rangle=\frac{\omega^2}{4\pi}\,[\eta^4(\eta^2+2)^2+144M^2\omega^2]|B_2^{(\pm)}|^2, \tag{54}$$

and the flux of energy per unit time of the outgoing electromagnetic waves is

$$\frac{dE_{\text{out}}^{\text{em}}}{dt}=\frac{\omega^2}{2\pi}\,\eta^2(\eta^2+2)^2|B_1|^2. \tag{55}$$

Finally, using the fact that the flux of energy across the event horizon is given by

$$\begin{gathered}\frac{d^2E_{\text{hole}}^{\text{grav}}}{dt\,d\Omega}=\frac{1}{64\pi}\lim_{r\to 2M}\frac{|\chi^2\Psi_0^{\text{B}}|^2}{(2M)^6[\omega^2+1/(4M)^2]},\\ \frac{d^2E_{\text{hole}}^{\text{em}}}{dt\,d\Omega}=\frac{1}{8\pi}\lim_{r\to 2M}\frac{|\chi\varphi_0|^2}{(2M)^2}\end{gathered} \tag{56}$$

[see Ref. 17 and Ref. 5, Eq. (258) of Chap. 8 and Eq. (516) of Chap. 9], from Eqs. (48) one obtains

$$\frac{dE^{\text{grav}}_{\text{hole}}}{dt}=\frac{\omega^2}{4\pi}\,[\,\eta^4(\,\eta^2+2)^2+144M^2\omega^2]|D_2^{(\pm)}|^2, \tag{57}$$

$$\frac{dE^{\text{em}}_{\text{hole}}}{dt}=\frac{\omega^2}{2\pi}\,\eta^2(\,\eta^2+2)^2|D_1|^2. \tag{58}$$

Thus, Eqs. (45), (46), (51), (52), (54), (55), (57), and (58) explicitly show that the energy carried by the gravitational or the electromagnetic perturbations is conserved. (Note that in order for these conservation relations to hold, it may be necessary to consider the time-averaged flux of energy [see Eq. (54)].) Furthermore, one has

$$\frac{\langle dE^{\text{grav}}_{\text{out}}/dt\rangle}{dE^{\text{grav}}_{\text{in}}/dt}=|R_2^{(\pm)}|^2,\quad \frac{dE^{\text{grav}}_{\text{hole}}/dt}{dE^{\text{grav}}_{\text{in}}/dt}=|T_2^{(\pm)}|^2 \tag{59}$$

and

$$\frac{dE^{\text{em}}_{\text{out}}/dt}{dE^{\text{em}}_{\text{in}}/dt}=|R_1|^2,\quad \frac{dE^{\text{em}}_{\text{hole}}/dt}{dE^{\text{em}}_{\text{in}}/dt}=|T_1|^2, \tag{60}$$

which means that the energy reflection and transmission coefficients for the gravitational and electromagnetic waves do coincide with the reflection and transmission coefficients for the potential barriers $V_2^{(\pm)}$ and V_1, respectively, in the Schrödinger-type equations (21). Note that the ''conservation relations'' (46) can be properly interpreted as expressions of the conservation of energy only after the energy fluxes (51), (52), (54), (55), (57), and (58) are derived, which requires, in particular, the knowledge of Ψ_0^{B} and Ψ_4^{B} with the correct relative normalization.

V. CONCLUDING REMARKS

As pointed out in Sec. II, Eqs. (19), which we take as the basic equations for the (uncoupled) gravitational and electromagnetic perturbations of the Schwarzschild solution, possess the form of a set of equations found in the study of the coupled gravitational and electromagnetic perturbations of the Reissner–Nordström solution,[15,5] although with a different meaning for the functions Y_{-k} and X_{-l}. This fact suggests that, going in the opposite direction, the equations for the gravitational and electromagnetic perturbations of some solutions of the Einstein vacuum field equations can be written in a form useful in the study of the coupled perturbations of the charged version of the background solution.

The derivations presented here illustrate the many simplifications that follow from the use of the Debye potentials in the study of perturbations.

A null-tetrad approach to Kerr–Schild gravitational fields in matter

Elisa Brinis Udeschini and Giulio Magli
Dipartimento di Matematica del Politecnico di Milano,
Piazza Leonardo Da Vinci 32, 20133 Milano, Italy

(Received 5 March 1996; accepted for publication 10 June 1996)

The null tetrad formalism is used to investigate the structure of the Einstein field equations for Kerr–Schild gravitational fields in the presence of an elastic solid source. It is shown that such equations may be reduced to five nonlinear partial differential equations for five variables. It turns out that, when the interior solutions admit the same preferred null congruence of the vacuum ones and some compatibility conditions hold, it is possible to reduce them to a linear system and to develop a method of solution which closely resembles the ''variation of the arbitrary constants'' for ordinary differential equations. In the present paper, the above technical framework is developed in general and applied to two simple examples, deferring to future work the approach to the Kerr–interior problem. © *1996 American Institute of Physics.* [S0022-2488(96)02509-1]

I. INTRODUCTION

In a recent paper[1] a new approach to the problem of finding the sources of the Kerr metric was presented. The key idea of such a paper was to search for elastic-solid sources within the same algebraic class to which the Kerr metric itself belongs, namely the Kerr–Schild[2] one (KS in what follows). In that paper it was shown that any stationary KS field in elastic matter may be obtained by solving three *linear* partial differential equations for the gravitational field and a set of six nonlinear, but algebraic, relations for the stresses. Such results lead to a new class of exact solutions which may be interpreted as describing elastic sources of the Kerr metric, the matching surface being an oblate spheroid. However, some open problems remain. First, the matching of the interior solution with the Kerr vacuum is not smooth, so that it is necessary to interpret the corresponding jump of the exterior curvature as a surface distribution; this fact strongly depends on the specific choice of the matching surface, but if one tries to change this choice one has to face a very difficult potential problem in Newtonian theory. Moreover, it is difficult to study the physical behavior of the stresses when the rotation rate becomes high.

The above results were obtained by means of a coordinate-dependent method. However, it is well known that the use of the Newman–Penrose (NP) formalism[3] proves very useful in dealing with KS gravitational fields. Recent developments in this area regard the ''generalized'' Kerr–Schild problem both in vacuum[4] and in presence of matter[5] and the generalization of the Kerr theorem to the nonstationary case.[6] The suitability of the NP formalism arises essentially because the preferred null direction of the KS geometry is a natural candidate for one of the null vectors of the NP tetrad. In fact, this observation was the starting point of the work by Debney, Kerr, and Schild (DKS)[7] who characterized the KS solutions of the Einstein and Einstein–Maxwell equations having a nonvanishing complex expansion. Here arises also the idea of the present paper, in which the search for exact KS solutions for the gravitational equations in elastic matter is conducted by making use of the tetrad formalism. Our main result is that, assuming as a source a non-prestressed elastic material, the gravitational field equations in the tetrad formalism can be reduced to five partial differential equations for five variables which have interesting properties. Such equations may in fact be written in a form which makes them directly comparable to that of vacuum, and this comparison suggests the possibility of constructing some nonvacuum solutions starting from the DKS vacuum ones. This may be done with a method which closely recalls the

J. Math. Phys. **37** (11), November 1996

''variation of the arbitrary constants'' for ordinary differential equations. It consists of choosing a vacuum solution and imposing that the corresponding nonvacuum one have the same preferred null congruence. This fixes two of the three quantities that characterize the gravitational field and, whenever the appropriate compatibility conditions hold, the determination of the field variables can be reduced to the integration of two suitable, linear differential forms. This quite unexpected result shows the way in which linearity comes into play using the null-tetrad formalism.

The present paper presents the framework of this null-tetrad approach to KS gravitational fields in elastic matter; the method described above is thus developed in general but only applied to two simple examples, deferring to a future work the application to the problem of the sources of the Kerr and the Kerr–Newman metric. To construct our examples we start from a Newman–Unti–Tamburino (NUT)[8] vacuum solution having a null Killing vector and from the Schwarzschild solution, respectively. The first choice gives rise to an independent derivation of a class of solutions originally due to Kowalczyński and Plebański,[9] while the second one produces a new class of (generally singular) nonstationary solutions, which, for certain choices of the integration parameters, reduces to an already known regular, static and spherically symmetric subclass.[10]

The paper is structured as follows. The null-tetrad formalism for KS fields is briefly recalled in Sec. II. The energy-momentum tensor and the Einstein field equations in the tetrad form are obtained in Secs. III and IV. Section V contains an overview on the vacuum DKS solutions, while the method of reduction of the nonvacuum field equations is presented in Sec. VI. The two examples are finally treated in Secs. VII and VIII, respectively. The paper ends with some concluding remarks and an outline about future work on this subject.

II. NULL-TETRAD FORMALISM FOR KERR–SCHILD FIELDS

Let $\mathscr{M}$ be the general-relativistic space–time equipped with the pseudo-Riemannian metric tensor $g_{\mu\nu}$ [$\mu,\nu=0,1,2,3$, signature $(-,+,+,+)$].[11]

Introduce at each point of $\mathscr{M}$ a tetrad of independent vectors $e_a{}^\mu$ ($a,b=1,2,3,4$) such that $e_a{}^\mu e^b{}_\mu=\delta_a^b$, where $e^b{}_\mu$ is the dual tetrad. We denote by e^a the linear differential forms $e^a{}_\mu dx^\mu$. The tetrad components of a tensor $T_{\mu\nu}$ are given by $T_{ab}=T_{\mu\nu}e_a{}^\mu e_b{}^\nu$. The directional derivatives along tetrad vectors will always be denoted by a comma preceding the index a, so that, for example,

$$f_{,a}:=e_a{}^\mu\partial_\mu f$$

for any scalar function f. The tetrad components of the covariant derivatives $e_a{}^\mu\boldsymbol{\nabla}_\mu$ will instead be denoted by a semicolon, while the symbol ''∂'' with a subscript will be always reserved for the partial derivative.

In the tetrad formalism the role of the Christoffel symbols is played by the Ricci rotation coefficients, defined by

$$\Gamma^a{}_{bc}:=-e^a{}_{\mu;\nu}e_b{}^\mu e_c{}^\nu.$$

For instance, the covariant derivative of a tensor reads

$$T^a{}_{b;c}=T^a{}_{b,c}-\Gamma^d{}_{bc}T^a{}_d+\Gamma^a{}_{dc}T^d{}_b\,.$$

The Ricci coefficients also determine the commutator between directional derivatives along tetrad vectors:

$$T^{\cdot\cdot}_{\cdot\cdot,[ab]}:=\tfrac{1}{2}\,(T^{\cdot\cdot}_{\cdot\cdot,ab}-T^{\cdot\cdot}_{\cdot\cdot,ba})=T^{\cdot\cdot}_{\cdot\cdot,c}\Gamma^c{}_{[ab]}\,.$$

We adopt the Newman–Penrose choice for the tetrad, which consists of using four null vectors such that $\underline{e}_1$ and $\underline{e}_2$ are complex conjugates while $\underline{e}_3$ and $\underline{e}_4$ are real. However, we will not

use the Newman–Penrose notations and conventions but rather that used by Debney, Kerr, and Schild. The scalar products between the tetrad vectors are therefore given by

$$g_{ab}=g_{\mu\nu}e_a{}^{\mu}e_b{}^{\nu}=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix} \tag{2.1}$$

whereas in the standard convention g_{34} equals *minus* one.

The numerical values 1,2,3,4 will always refer to tetrad indexes. These are raised and lowered by performing the permutation 1,2,3,4↦2,1,4,3. The complex conjugate of a real geometrical object may be obtained by applying the permutation 1,2,3,4↦2,1,3,4.

We are going to consider here only space–times which are of the Kerr–Schild type, namely we assume that the metric tensor may be put into the form

$$g_{\mu\nu}=\eta_{\mu\nu}+2hl_{\mu}l_{\nu},$$

where $\eta_{\mu\nu}$ is the metric tensor of Minkowski space, h is a scalar function, and l^{μ} is a null vector with respect to both the flat and the curved metric. It is therefore natural to pick l^{μ} as one of the null real vectors of the tetrad, say $\underset{\sim}{e}_4$. Starting with a system of pseudo-Cartesian coordinates $x^{\mu}=(x,y,z,t)$ such that the Minkowski metric assumes its canonical form, and introducing the null coordinates

$$\xi=\frac{x+iy}{\sqrt{2}},\quad \overline{\xi}=\frac{x-iy}{\sqrt{2}},$$

$$u=\frac{z+t}{\sqrt{2}},\quad v=\frac{z-t}{\sqrt{2}},$$

the line element reads

$$ds^2=2\ d\xi\ d\overline{\xi}+2\ du\ dv+2h(e^3)^2. \tag{2.2}$$

It is well known that a general field of null directions in Minkowski space may be parametrized in the form

$$e^3=du+\overline{Y}d\xi+Yd\overline{\xi}-\overline{Y}Ydv,$$

where Y is a complex function, so far arbitrary. The null tetrad may be completed as follows:

$$e^1=d\xi-Ydv,\qquad e^2=d\overline{\xi}-\overline{Y}dv,\qquad e^4=dv+he^3.$$

The directional derivatives of a scalar function f therefore read

$$\begin{aligned}f_{,1}&=\partial_{\xi}f-\overline{Y}\partial_u f,\\ f_{,2}&=\partial_{\overline{\xi}}f-Y\partial_u f,\qquad f_{,3}=\partial_u f-hf_{,4},\\ f_{,4}&=\partial_v f+Y\partial_{\xi}f+\overline{Y}\partial_{\overline{\xi}}f-Y\overline{Y}\partial_u f.\end{aligned} \tag{2.3}$$

The tetrad components R_{ab} of the Ricci tensor can now be calculated in terms of the three unknowns $h, Y, \overline{Y}$ and their derivatives in the following way. Starting from the first Cartan equation

$$de^a = \Gamma^a{}_{bc} e^b \wedge e^c,$$

one can calculate the quantities $\Gamma_{a[bc]}$ (listed in Appendix A). The Ricci rotation coefficients $\Gamma^a{}_{bc}$ are then obtained by

$$\Gamma_{abc} = -\Gamma_{bac} = \Gamma_{a[bc]} + \Gamma_{b[ca]} - \Gamma_{c[ab]},$$

and, finally, the tetrad components of the Riemann and the Ricci tensor can be deduced from the second Cartan equation

$$\tfrac{1}{2} R^a{}_{bcd} e^c \wedge e^d = d\Gamma^a_b + \Gamma^a_c \wedge \Gamma^c_b,$$

where $\Gamma^a_b = \Gamma^a{}_{bc} e^c$.

We shall consider KS fields characterized by the following properties of the congruence of null curves having $\underline{e}_4$ as the tangent vector:

(1) the curves are geodesic, so that

$$\Gamma_{424} = -Y_{,4} = 0; \tag{2.4}$$

(2) the complex expansion (expansion $+i$ rotation),

$$Z := -\Gamma_{421} = Y_{,1}, \tag{2.5}$$

is nonzero.

For such gravitational fields, the tetrad components R_{ab} of the Ricci tensor may be easily calculated. Any real, symmetric tensor in the null tetrad formalism is completely identified by four real components (with the values 12,33,34,44 of the indexes) and three complex components, the remaining three being obtainable by complex conjugation. In particular, for the Ricci tensor we have the following seven independent components:

$$R_{24} = 0, \qquad R_{44} = 0, \qquad R_{22} = -2Y_{,2}[h_{,4} + h(\overline{Z} - Z)],$$

$$R_{34} = -[h_{,4} + h(\overline{Z} - Z)],4 - 2Z[h_{,4} + h(\overline{Z} - Z)],$$

$$R_{12} = -(Z + \overline{Z})[h_{,4} + h(\overline{Z} - Z)] - 2hZ^2 + 2hY_{,2}\overline{Y}_{,1}, \tag{2.6}$$

$$R_{23} = -[h_{,4} + h(\overline{Z} - Z)]_{,2} + [h_{,4} + h(\overline{Z} - Z)]Y_{,3} - 2Y_{,3}hZ + 2Y_{,2}(h_{,1} - h\overline{Y}_{,3}),$$

$$R_{33} = -2(hZ)_{,3} + 2Z\overline{Z}h^2 - 2(h_{,1} - h\overline{Y}_{,3})Y_{,3} - 2hZ[h_{,4} + h(\overline{Z} - Z)] + 2(h_{,1} - h\overline{Y}_{,3})_{,2} + 2h^2\overline{Y}_{,1}Y_{,2}.$$

III. THE "CONSTITUTIVE CONSTRAINT" EQUATION AND THE STRUCTURE OF THE ENERGY-MOMENTUM TENSOR

In this section we obtain the structure of the energy-momentum tensor, which is obviously needed to write the Einstein field equations, in the case of an elastic material acting as a source of a KS geometry. This problem has been extensively treated in a recent paper,[1] so here we simply

express the main results in the tetrad formalism. For a detailed discussion and a brief introduction on the basic structures of relativistic elasticity we refer the reader to that paper.

The energy tensor of an elastic body may be written as

$$T_{\mu\nu}=\epsilon u_\mu u_\nu+\Pi_{\mu\nu}, \tag{3.1}$$

where ϵ is the energy density, u^μ is the velocity field of the material, and $\Pi_{\mu\nu}$ is the stress tensor (sometimes called the ''pressures tensor''). It is symmetric and orthogonal to the velocity ($\Pi_{\mu\nu}u^\nu=0$). The state of strain of the material is characterized by another symmetric, orthogonal tensor $H_{\mu\nu}$ and, in order to describe the physical state of the material, the relation connecting the strain and the stress must be given. For a generic, isotropic material such a relation may be obtained observing that the energy density is a function of three independent strain invariants, for which we choose the following definition:

$$I_1:=\tfrac{1}{2}(\mathrm{Tr}\ K-4),$$

$$I_2:=\tfrac{1}{4}[\mathrm{Tr}\ K^2-(\mathrm{Tr}\ K)^2]+3,$$

$$I_3:=\tfrac{1}{2}(\det K-1),$$

where the symbols $\det K$ and $\mathrm{Tr}\,K$ denote the determinant and the trace, respectively, of the auxiliary tensor

$$K^\mu_\nu:=H^\mu_\nu-u^\mu u_\nu.$$

The resulting stress–strain relation is the following:

$$\Pi_{\mu\nu}=\left(\frac{\partial\epsilon}{\partial I_3}\det K-\epsilon\right)(g_{\mu\nu}+u_\mu u_\nu)+\left(\frac{\partial\epsilon}{\partial I_1}-\mathrm{Tr}\ K\,\frac{\partial\epsilon}{\partial I_2}\right)H_{\mu\nu}+\frac{\partial\epsilon}{\partial I_2}H_{\mu\rho}H^\rho_\nu. \tag{3.2}$$

In order to calculate the tetrad expression of the above quantities, it is convenient to start with the pseudo-Cartesian coordinates x,y,z,t. Greek indexes will always refer to such coordinates; no confusion between their numerical values and that of tetrad indexes may occur since we shall only need the ''temporal'' components (i.e., zero-components) of the tetrad vectors.

It may be shown that relativistic elasticity has a ''gauge invariance'' which allows the choice of the ''comoving gauge'' or, in other words, the kinematical description of the material such that the velocity field has the simple form

$$u^\mu=(1/\sqrt{-g_{00}})\,\delta^\mu_0.$$

In what follows, we consider only the case of non-prestressed materials, deferring a more general treatment to a future paper in which the problem of the sources of the Kerr field will be analyzed in details. For non-prestressed bodies, it may be shown that the expression of the strain in the comoving frame is simply given by

$$H_{\mu\nu}=\delta_{ij}\delta^{\ i}_\mu\delta^{\ j}_\nu.$$

We can now calculate the required tetrad expression of the energy tensor. First of all, we observe that

$$u^a=\Gamma e^a{}_0, \qquad u_a=\Gamma(-e_a{}^0+2hk\delta^3_a),$$

where we have defined

$$\Gamma := \frac{1}{\sqrt{-g_{00}}} = \sqrt{\frac{1}{1-2hk^2}},$$

$$k := l_0 = \frac{1}{\sqrt{2}}\,(1+Y\overline{Y}).$$

The tetrad version of the strain reads

$$H_{ab} = g_{ab} + e_a{}^0 e_b{}^0 - 2h\,\delta_a^3\delta_b^3.$$

The square of such a tensor is then

$$H_{ac}H_b^c = H_{ab} - 2hQ_{ab},$$

where

$$Q_{ab} := \delta_a^3\delta_b^3 - k(e_a{}^0\delta_b^3 + e_b{}^0\delta_a^3) + k^2 e_a{}^0 e_b{}^0.$$

From $K_{ab} = H_{ab} - u_a u_b$ it follows

$$\det K = 1/\Gamma^2, \qquad \mathrm{Tr}\, K = 4 - 2hk^2.$$

Inserting the above results in (3.1) and (3.2), one readily obtains the tetrad version of the energy-momentum tensor:

$$T_{ab} = \epsilon u_a u_b + \left(\frac{1}{\Gamma^2}\frac{\partial\epsilon}{\partial I_3} - \epsilon\right)(g_{ab} + u_a u_b) + \left[\frac{\partial\epsilon}{\partial I_1} - (3-2hk^2)\,\frac{\partial\epsilon}{\partial I_2}\right]H_{ab} - 2h\,\frac{\partial\epsilon}{\partial I_2}\,Q_{ab}.$$

It may be shown that, if the null vector l^μ of a KS metric is geodesic, then it is an eigenvector of the Einstein tensor.[12] All the KS space–times considered here have a geodesic null vector [Eq. (2.4)], so that the energy tensor of the material has to satisfy $T^\mu_\nu l^\nu = -\epsilon l^\mu$. This equation may be interpreted as a condition on the state equation of the body, and therefore has been called ''constitutive constraint.'' [1] The tetrad version of such a constraint reads

$$T_{a4} = -\epsilon g_{a4}, \tag{3.3}$$

that is,

$$-(\delta_a^3 + k e_a{}^0)\left(\frac{\partial\epsilon}{\partial I_3} + \frac{\partial\epsilon}{\partial I_1} - 3\,\frac{\partial\epsilon}{\partial I_2}\right) = 0.$$

Therefore, the constraint implies

$$\frac{\partial\epsilon}{\partial I_3} + \frac{\partial\epsilon}{\partial I_1} = 3\,\frac{\partial\epsilon}{\partial I_2}. \tag{3.4}$$

This result obviously agrees with that previously obtained[1] using a coordinate-dependent method.

From now on, we assume that the energy density, regarded as a function of the strain invariants, satisfies (3.4). Using such an equation to eliminate $\partial\epsilon/\partial I_1$ in the expression of the energy tensor, we obtain

$$T_{ab} = -(\epsilon + k^2\mathscr{P})g_{ab} - k\mathscr{P}\,(e_a{}^0\delta_b^3 + e_b{}^0\delta_a^3) + \mathscr{P}\,(1+2hk^2)\,\delta_a^3\delta_b^3, \tag{3.5}$$

where

$$\mathscr{P} := 2h\left(\frac{\partial \epsilon}{\partial I_3} - \frac{\partial \epsilon}{\partial I_2}\right).$$

We stress that the material described by Eq. (3.5) is *not* a perfect fluid. In fact, although such a material is described by the energy density and only one principal stress $\mathscr{P}$, it may be easily verified that the corresponding energy tensor (3.5) is anisotropic. It becomes isotropic only if $\mathscr{P}$ vanishes. In this case, however, the energy tensor turns out to be proportional to the metric ($T_{ab} = -\epsilon g_{ab}$) and it follows from $T^b_{a;b} = 0$ that ϵ has to be a constant. Thus the resulting ''perfect fluid'' is formally equivalent to a cosmological constant term in the vacuum Einstein field equations.

IV. THE EINSTEIN FIELD EQUATIONS

We consider here the Einstein field equations in the form $G_{ab} = -T_{ab}$ owing to our choice of units and to the useful convention $T_{ab} = 8\pi T^{\text{true}}_{ab}$ (in other words, we adsorb the factor 8π into the definition of ϵ and $\mathscr{P}$). Due to $R^a_a = 2(R_{12} + R_{34})$, one has $G_{12} = -R_{34}$, $G_{34} = -R_{12}$, while $G_{ab} = R_{ab}$ for the other components. From the constitutive constraint (3.3) we have $T_{24} = T_{44} = 0$. But, from (2.6), one has $R_{24} = R_{44} = 0$ and therefore the corresponding field equations hold identically. Using (3.5) and (2.6) the field equations to be satisfied turn out to be the following:

$$\begin{gathered} R_{22} = 0, \qquad R_{12} = -\epsilon, \qquad R_{34} = -(\epsilon + k^2\mathscr{P}), \\ R_{13} = -(k\overline{Y}/\sqrt{2})\mathscr{P}, \qquad R_{23} = -(kY/\sqrt{2})\mathscr{P}, \qquad R_{33} = Y\overline{Y}\mathscr{P}. \end{gathered} \tag{4.1}$$

We start considering equation $R_{22} = 0$. From (2.6) we obtain either $Y_{,2} = 0$ or $h_{,4} + h(\overline{Z} - Z) = 0$. We remind the reader that, in the vacuum case, the Goldberg–Sachs theorem assures that $Y_{,2}$ vanishes and therefore the e^3 congruence is shear-free. In the nonvacuum case, the vanishing of $h_{,4} + h(Z - Z)$ gives $R_{34} = 0$, which is consistent with the sources only if $\epsilon + k^2\mathscr{P}$ vanishes too. It may be verified that this situation corresponds to a very particular case in which the energy-momentum tensor has limiting (stringlike or monopolelike) properties.[13] We shall not further investigate this case in the present paper, and therefore, from now on, we proceed assuming $\epsilon + k^2\mathscr{P}$ to be nonvanishing. This implies that the e^3 congruence is shear-free:

$$Y_{,2} = 0, \tag{4.2}$$

so that

$$dY = Y_{,a}e^a = Ze^1 + Y_{,3}e^3. \tag{4.3}$$

The field equation $R_{22} = 0$ is now satisfied. Due to (4.2), the remaining equations reduce to the following:

$$\begin{gathered} [R_{12}] \mapsto (Z + \overline{Z})[h_{,4} + h(\overline{Z} - Z)] + 2hZ^2 = \epsilon, \\ [R_{34}] \mapsto [h_{,4} + h(\overline{Z} - Z)]_{,4} + 2Z[h_{,4} + h(\overline{Z} - Z)] = \epsilon + k^2\mathscr{P}, \\ [R_{13}] \mapsto [h_{,4} + h(Z - \overline{Z})]_{,1} - [h_{,4} + h(Z - \overline{Z})]\overline{Y}_{,3} + 2\overline{Y}_{,3}h\overline{Z} = k\overline{Y}\mathscr{P}/\sqrt{2}, \\ [R_{23}] \mapsto [h_{,4} + h(\overline{Z} - Z)]_{,2} - [h_{,4} + h(\overline{Z} - Z)]Y_{,3} + 2Y_{,3}hZ = kY\mathscr{P}/\sqrt{2}, \\ [R_{33}] \mapsto 2(hZ)_{,3} - 2Z\overline{Z}h^2 + 2(h_{,1} - h\overline{Y}_{,3})Y_{,3} + 2hZ[h_{,4} + h(\overline{Z} - Z)] - 2(h_{,1} - h\overline{Y}_{,3})_{,2} = -Y\overline{Y}\mathscr{P}. \end{gathered} \tag{4.4}$$

The equations above are a system of five partial differential equations for the five unknowns (three real and two complex conjugate) $\epsilon,\mathscr{P},h,Y,\overline{Y}$. Therefore, we expect them to allow the determination of such fields.

We shall now elaborate the field equations ending up with a form which makes them directly comparable with the DKS vacuum ones.

Rewrite the equation $[R_{12}]$ in the form

$$h_{,4}+h\,\frac{Z^2+\overline{Z^2}}{Z+\overline{Z}}=\frac{\epsilon}{Z+\overline{Z}}.$$

If $\epsilon=0$, this is obviously a vacuum equation and, from the DKS work, we know that its general solution is proportional to $Z+\overline{Z}$, the factor of proportionality having zero fourth tetrad derivative (this is a consequence of the commutation relation $Z_{,4}=-Z^2$, see Appendix B). Then, we can write

$$h=\tfrac{1}{2}M(Z+\overline{Z}), \tag{4.5}$$

where

$$M_{,4}=\frac{2\epsilon}{(Z+\overline{Z})^2}. \tag{4.6}$$

The field equation $[R_{12}]$ is thus equivalent to the above equation. It is easy to check that, using (4.5) and (4.6) in the equation $[R_{34}]$, one obtains

$$\epsilon_{,4}=k^2\mathscr{P}(Z+\overline{Z}). \tag{4.7}$$

This equation, as we shall see, coincides with the ''conservation'' equation $T^b_{4;b}=0$.

Consider now the equation $[R_{23}]$ and its complex conjugate. Using Eqs. (4.5) and (4.6), it reduces to

$$M_{,2}-3\,\frac{\overline{Z}}{Z}\,Y_{,3}M=\Lambda,$$

where we have defined

$$\Lambda:=\frac{1}{Z^2}\left[\left(\frac{\epsilon}{Z+\overline{Z}}\right)_{,2}-\frac{\epsilon}{Z+\overline{Z}}Y_{,3}-\frac{Yk\mathscr{P}}{\sqrt{2}}\right]. \tag{4.8}$$

The real equation $[R_{33}]$ may finally be simplified using all the previous results. A rather cumbersome but straightforward calculation (in which the commutation relations listed in Appendix B play a key role) leads to

$$M_{,3}-\frac{Y_{,3}}{Z}\,M_{,1}-\frac{\overline{Y_{,3}}}{\overline{Z}}M_{,2}=-\frac{\epsilon}{Z+\overline{Z}}M+\mathscr{K}$$

with

$$\mathscr{K}:=\frac{1}{2Z\overline{Z}}[-Y\overline{Y}\mathscr{P}+(Z\Lambda)_{,1}+(\overline{Z\Lambda})_{,2}-Z\Lambda\overline{Y}_{,3}-\overline{Z\Lambda}Y_{,3}]. \tag{4.9}$$

Summarizing, the field equations (4.4) may be rewritten as follows:

$$M_{,1}=3\frac{Z}{\overline{Z}}\overline{Y}_{,3}M+\overline{\Lambda},\qquad M_{,2}=3\frac{\overline{Z}}{Z}Y_{,3}M+\Lambda,$$

$$M_{,3}=\frac{Y_{,3}}{Z}M_{,1}+\frac{\overline{Y}_{,3}}{\overline{Z}}M_{,2}-\frac{\epsilon}{Z+\overline{Z}}M+\mathscr{K},\tag{4.10}$$

$$M_{,4}=\frac{2\epsilon}{(Z+\overline{Z})^2},\qquad \epsilon_{,4}=k^2\mathscr{P}(Z+\overline{Z}).$$

Together with the Einstein field equations, obviously we have to take into account their compatibility conditions (due to Bianchi identities), which in the presence of matter fields are equivalent to the ''conservation'' equations $T^b_{a;b}=0$ for the energy tensor.

In our case, these equations may be written as follows:

$$(\epsilon+k^2\mathscr{P})_{,1}=k^2\overline{Y}_{,3}\mathscr{P}+\frac{k\mathscr{P}\overline{Y}}{\sqrt{2}}(Z+2\overline{Z})+\frac{k\overline{Y}}{\sqrt{2}}\mathscr{P}_{,4},$$

$$(\epsilon+k^2\mathscr{P})_{,2}=k^2Y_{,3}\mathscr{P}+\frac{k\mathscr{P}Y}{\sqrt{2}}(\overline{Z}+2Z)+\frac{kY}{\sqrt{2}}\mathscr{P}_{,4},\tag{4.11}$$

$$\hat{D}\epsilon=0,\qquad \epsilon_{,4}=k^2\mathscr{P}(Z+\overline{Z}),$$

where we have introduced the differential operator $\hat{D}$ whose action on a scalar function f is given by

$$\hat{D}f:=(1/\sqrt{2})[Yf_{,1}+\overline{Y}f_{,2}+k\sqrt{2}f_{,3}+(hk\sqrt{2}-1)f_{,4}].\tag{4.12}$$

It is easy to check that this expression is the tetrad version of the partial derivative with respect to the pseudo-Cartesian t-coordinate. Therefore, owing to the Bianchi identity $\hat{D}\epsilon=0$, the energy of the source must be a stationary function.

V. THE VACUUM CASE: AN OVERVIEW ON THE DEBNEY–KERR–SCHILD SOLUTIONS

In the present section, we briefly overview the integration of the vacuum equations originally due to Debney, Kerr, and Schild.[14] This account is essential for our purposes, and, moreover, we hope that it may be useful for the readers.

When no matter is present, $\epsilon=\mathscr{P}=0$ and therefore Λ and $\mathscr{K}$ vanish. As a consequence, Eqs. (4.10) reduce to

$$M_{,1}=3\frac{Z}{\overline{Z}}\overline{Y}_{,3}M,\qquad M_{,2}=3\frac{\overline{Z}}{Z}Y_{,3}M,$$

$$M_{,3}=\frac{Y_{,3}}{Z}M_{,1}+\frac{\overline{Y}_{,3}}{\overline{Z}}M_{,2},\qquad M_{,4}=0.\tag{5.1}$$

Observe now that, as a consequence of (2.4) and (4.3), the three functions Y, $\overline{Y}$, and M each satisfy the same pair of partial differential equations

$$X_{,4}=0, \quad X_{,3}-\frac{Y_{,3}}{Z}X_{,1}-\frac{\overline{Y}_{,3}}{\overline{Z}}X_{,2}=0. \tag{5.2}$$

However, the base space on which such functions are defined is four dimensional, and Y and $\overline{Y}$ are functionally independent according to the hypothesis of a nonvanishing Z. Therefore, any other function satisfying (5.2) must be functionally dependent on Y and $\overline{Y}$. Thus, we can put

$$M=\frac{m}{P^3}, \tag{5.3}$$

where m is a constant and $P=P(Y,\overline{Y})$ is a real function. The equations for $M_{,3}$ and $M_{,4}$ are now satisfied while the equation for $M_{,2}$ may be rewritten as

$$Y_{,3}=-\frac{ZP_{\overline{Y}}}{P}, \tag{5.4}$$

where $P_{\overline{Y}}=\partial P/\partial\overline{Y}$. It follows that also $Y_{,3}/Z=-P_{\overline{Y}}/P$ depends only on Y and $\overline{Y}$, so that

$$\left(\frac{Y_{,3}}{Z}\right)_{,2}=\overline{Z}\left(\frac{Y_{,3}}{Z}\right)_{\overline{Y}},$$

and, using the commutation relations of Appendix B,

$$\left(\frac{Y_{,3}}{Z}\right)_{\overline{Y}}=\frac{1}{\overline{Z}}\left(\frac{Y_{,3}}{Z}\right)_{,2}=\frac{1}{\overline{Z}}\left(\frac{Y_{,32}}{Z}-\frac{Y_{,3}}{Z^2}Z_{,2}\right)=\left(\frac{Y_{,3}}{Z}\right)^2.$$

Thus, (5.4) implies

$$P_{\overline{Y}Y}=-\left(P\,\frac{Y_{,3}}{Z}\right)_{\overline{Y}}=0.$$

Since P is real. P_{YY} vanishes, too, and therefore P must be a bilinear function in Y and $\overline{Y}$:

$$P=pY\overline{Y}+qY+\overline{q}\overline{Y}+c \tag{5.5}$$

with p and c real constants and q complex constant. Finally, one reaches the following formula for dY:

$$dY=\frac{Z}{P}\,(Pe^1-P_{\overline{Y}}e^3), \tag{5.6}$$

that is, using the explicit expression of the tetrad vectors,

$$dY=\frac{Z}{P}\,[(qY+c)(d\xi-Ydv)-(pY+\overline{q})(du+Yd\overline{\xi})]. \tag{5.7}$$

This differential equation may now be integrated and the general solution is given in implicit form by

$$F=0,$$
$$F:=\phi(Y)+(qY+c)(\xi-Yv)-(pY+\overline{q})(u+Y\overline{\xi}), \tag{5.8}$$

where $\phi(Y)$ is an arbitrary analytic function. This result, not completely straightforward in our opinion, is given without an explicit proof in the original DKS paper; we sketch then a proof in what follows.

The function Y defined by (5.7) identifies a particular class of geodesic, shear-free congruences characterized by (4.3). However, Kerr's theorem[15] states that all such congruences are given implicitly by an equation of the form

$$\mathscr{F}(Y,\lambda_1,\lambda_2)=0, \tag{5.9}$$

where $\mathscr{F}$ is a *completely arbitrary* analytic function of the quantities

$$\lambda_1=\xi-Yv, \quad \lambda_2=u+Y\overline{\xi}.$$

Therefore, all we have to do is to identify which further restrictions are imposed on $\mathscr{F}$ by the Einstein field equations. Comparing (4.3) with (5.6), we see that Y satisfies *one* more equation besides $Y_{,2}=Y_{,4}=0$ (which are the hypotheses of Kerr's theorem), namely (5.4). Using $Z=\partial_\xi Y-Y\partial_u Y$ and (5.5), such equation gives

$$(pY+\overline{q})\partial_\xi Y=-(qY+c)\partial_u Y.$$

However, if Y is defined implicitly by (5.9), one has

$$\partial_\xi Y=-\frac{1}{\mathscr{F}_Y}\frac{\partial\mathscr{F}}{\partial\lambda_1}, \quad \partial_u Y=-\frac{1}{\mathscr{F}_Y}\frac{\partial\mathscr{F}}{\partial\lambda_2},$$

and therefore $\mathscr{F}$ must be a solution of

$$(pY+\overline{q})\frac{\partial\mathscr{F}}{\partial\lambda_1}+(qY+c)\frac{\partial\mathscr{F}}{\partial\lambda_2}=0.$$

This linear partial differential equation in three independent variables fixes only the dependence of $\mathscr{F}$ on λ_1 and λ_2. Thus, it is easy to check that its general solution is given by

$$\mathscr{F}(Y,\lambda_1,\lambda_2)=\tilde{\mathscr{F}}(Y,\tau),$$

where $\tilde{\mathscr{F}}$ is a new arbitrary analytic function, and

$$\tau:=(qY+c)\lambda_1-(pY+\overline{q})\lambda_2.$$

It follows that the general solution of (5.7) is given by

$$\tilde{\mathscr{F}}(Y,(qY+c)(\xi-Yv)-(pY+\overline{q})(u+Y\overline{\xi}))=0.$$

This equation defines Y as a function of τ, but also τ as a function of Y, and therefore one can substitute it (without loss or gain in generality) with the DKS formula (5.8).

Returning to the solution of the field equations, and differentiating (5.8), we readily obtain

$$Z=-\frac{P}{F_Y}. \tag{5.10}$$

Summarizing, the vacuum DKS solutions are given by the following line element:

$$ds^2=2\ d\xi\ d\overline{\xi}+2\ du\ dv+m\ \frac{Z+\overline{Z}}{P^3}\ (du+\overline{Y}d\xi+Yd\overline{\xi}-Y\overline{Y}dv)^2, \tag{5.11}$$

where P, Y, and Z are defined by (5.5), (5.8), and (5.10), respectively. It may be shown[12] that all such solutions are algebraically special, the null vector $\underline{e}_4$ being a multiple principal null direction of the Weyl tensor.

The solutions (5.11) may be simplified by coordinate transformations because all of them admit at least one group of motions. In fact, introducing the real, linear differential operator

$$\hat{K}:=K^\mu\partial_\mu=c\,\partial_u+\overline{q\partial}_\xi+q\partial_{\overline{\xi}}-p\,\partial_v\,,$$

it is easy to check that $\hat{K}Y=0$. Moreover, $\hat{K}$ commutes with the directional derivatives along $\underline{e}_1$ and $\underline{e}_2$, so that $\hat{K}Z$ also vanishes. It follows that K^μ is a Killing vector of the DKS metrics. Since K^μ has constant components, it is also a translational Killing vector of flat space–time. In the three cases in which $\eta_{\mu\nu}K^\mu K^\nu$ is (a) negative, (b) positive, or (c) zero, one can, without loss of generality, make the following choice for the coefficients in P:

$$\text{(a)}p=c=1/\sqrt{2},q=0;\quad \text{(b)}p=-c=-1/\sqrt{2},q=0;\quad \text{(c)}p=q=0,c=1. \tag{5.12}$$

Correspondingly, one has

$$\text{(a)}P=k,\quad K^\mu\partial_\mu=(1/\sqrt{2})(\partial_u-\partial_v),$$

$$\text{(b)}P=(1/\sqrt{2})(1-Y\overline{Y}),\quad K^\mu\partial_\mu=(1/\sqrt{2})(\partial_u+\partial_v),$$

$$\text{(c)}P=1,\quad K^\mu\partial_\mu=\partial_u\,.$$

The case (a) evidently corresponds to stationary space–times ($K^\mu\partial_\mu=\hat{D}$).

One may now ask whether the DKS solutions admit additional Killing vectors. In particular, a physically interesting case is obviously that of axially symmetric space–times. The generator of rotations along the z axis written in the x,y,z,t coordinates is obviously given by

$$\hat{\Phi}:=\Phi^\mu\partial_\mu=\mathrm{x}\partial_\mathrm{y}-y\,\partial_\mathrm{x}=i(\overline{\xi\partial}_{\overline{\xi}}-\xi\partial_\xi).$$

It is not difficult to verify that Φ^μ is a Killing vector for the metric (2.2) if and only if

$$\hat{\Phi}Y=-iY,\quad \hat{\Phi}h=0.$$

In each of the three cases listed in (5.12), the first of such equations implies

$$\phi=Y\phi_Y\,.$$

Once this condition is satisfied, one has $\hat{\Phi}P=\hat{\Phi}Z=\hat{\Phi}\overline{Z}=0$ so that $\hat{\Phi}h=0$ holds identically due to the relation

$$h=\frac{1}{2}\ (Z+\overline{Z})\ \frac{m}{P^3}.$$

It follows that axisymmetric DKS solutions exist only if ϕ is a linear homogeneous function of Y. If the Killing vector K^μ is timelike, one obtains stationary, axially symmetric KS fields. In particular, the choice $\phi=-iaY$ with a real a leads to the Kerr solution of mass m and angular momentum ma, and therefore $\phi=0$ leads to the Schwarzschild solution.

VI. THE NONVACUUM CASE: A METHOD OF REDUCTION OF THE FIELD EQUATIONS

We turn now to the Einstein field equations in matter [Eqs. (4.10)]. Such equations are five highly nonlinear partial differential equations for the five unknowns $\epsilon, \mathscr{P}, M, Y, \overline{Y}$. We know a *particular* solution of them, namely the DKS vacuum field $\epsilon = \mathscr{P} = 0$ and $Y, \overline{Y}, M$ given by the equations (5.3), (5.5), and (5.8) above. In general, of course, knowledge of vacuum solutions is of little help in solving the coupled Einstein–matter problem. However, there are interesting cases in which generating techniques may be applied to vacuum solutions to obtain nonvacuum ones. We shall now try to construct one such technique to obtain some solutions of our equations. It will turn out that it is, in fact, possible to obtain solutions using an approach similar to the method of variation of the arbitrary constants familiar from the theory of ordinary differential equations.

The idea is the following. The first four equations in (4.10) look like the vacuum ones [Eqs. (5.1)] with the addition of a source term on the right-hand side. This suggests the ansatz

$$M = \frac{N}{\overline{P^3}},$$

where P is defined in (5.5) and N is a new unknown. Such a function is a ''variation of the constant'' m which appears in the vacuum case. The equation for $M_{,2}$ now gives

$$N_{,2} - 3\overline{Z}N\left(\frac{P\overline{_Y}}{P} + \frac{Y_{,3}}{Z}\right) = P^3\Lambda. \tag{6.1}$$

The above formula would effectively correspond to the result of a ''variation of the arbitrary constants'' with respect to the vacuum solution if the term in brackets vanishes. Evidently, this is possible whenever the equation (5.4) (which is a field equation for vacuum fields) holds in the nonvacuum case too. Therefore, in order to proceed with our construction, we have to *assume* the validity of such an equation as a condition on Y.[16] From now on, we introduce such a condition as an explicit assumption. It must, however, be remarked that (5.4) and its complex conjugate have now to be considered as additional partial differential equations ''superimposed'' on a system of five equations for five variables and must be compatible with such equations. Therefore, it is not guaranteed *a priori* that the resulting system does admit, in general, solutions different from the ''trivial'' vacuum ones.

Recall now that the field equations in vacuum give only one differential equation for Y, namely (5.4). Therefore, if (5.4) is satisfied also in the matter case, the function Y turns out to be the same as in vacuum. In such a case, in order to obtain a solution in matter, one can choose an explicit DKS solution for Y (choice of ϕ, p, q, c) as a ''seed.'' Then, the gravitational field turns out to be described by the *vacuum* fields Y and $\overline{Y}$ and by the function h, which is given in terms of N by the relation

$$h = \frac{1}{2}(Z + \overline{Z})\frac{N}{\overline{P^3}}. \tag{6.2}$$

The physical properties of the elastic material are described by the functions ϵ and $\mathscr{P}$, and the three unknowns $N, \epsilon, \mathscr{P}$ are governed by the following eight equations (Einstein+Bianchi):

$$\begin{gathered} N_{,1} = P^3\overline{\Lambda}, \qquad N_{,2} = P^3\Lambda, \\ N_{,3} = -P\overline{_Y}P^2\overline{\Lambda} - P_Y P^2\Lambda - \frac{\epsilon}{Z+\overline{Z}}N + P^3\mathscr{K}, \quad N_{,4} = P^3\frac{2\epsilon}{(Z+\overline{Z})^2}, \end{gathered} \tag{6.3}$$

$$(\epsilon+k^2\mathscr{P})_{,1}=-\frac{k^2P_Y\overline{Z}}{P}\mathscr{P}+\frac{k\mathscr{P}\overline{Y}}{\sqrt{2}}(Z+2\overline{Z})+\frac{k\overline{Y}}{\sqrt{2}}\mathscr{P}_{,4},$$

$$(\epsilon+k^2\mathscr{P})_{,2}=-\frac{k^2P_{\overline{Y}}Z}{P}\mathscr{P}+\frac{k\mathscr{P}Y}{\sqrt{2}}(\overline{Z}+2Z)+\frac{kY}{\sqrt{2}}\mathscr{P}_{,4}, \tag{6.4}$$

$$\hat{D}\epsilon=0, \qquad \epsilon_{,4}=k^2\mathscr{P}(Z+\overline{Z}).$$

As we have already stressed, once a seed solution has been explicitly chosen, one has to check whether this ''seed'' is such as to generate a nonvacuum solution. This requirement may be expressed in terms of the integrability conditions on the above equations, conditions which may be obtained using the commutation relations between tetrad derivatives (Appendix B). It turns out to be very complicated to identify *all* the compatible DKS seeds. Fortunately, however, the set of such ''seeds'' turns out to be not empty. In the present paper we shall concentrate only on two simple but interesting cases which are generated by two Petrov type D vacuum solutions and will be discussed in the next two sections.

VII. A SIMPLE EXAMPLE: THE KOWALCZYŃSKI–PLEBAŃSKI SOLUTIONS

As a first example of the procedure outlined above, we are going to deduce within our formalism a simple class of solutions originally due to Kowalczyński and Plebański.[9]

We start from vacuum solutions having a null Killing vector K^μ and restrict ourselves to the ''Kerr choice'' for ϕ, namely $\phi(Y)=-iaY$. These assumptions imply that $P=1$ and that the ''seed'' vacuum solution is

$$Y=Y(\xi,v)=\frac{\xi}{v+ia}. \tag{7.1}$$

It may be verified[17] that this seed corresponds to one of the NUT[8] solutions, the constant a being related to the NUT parameter.

As far as the material source is concerned, we consider only the case $\epsilon=\text{const}=\lambda$ and $\mathscr{P}=0$, so that the energy tensor ($T_{ab}=\lambda g_{ab}$) is formally equivalent to a cosmological constant term in the vacuum Einstein field equations. It follows that the ''conservation'' equations (6.4) hold identically.

From (7.1) one obtains that $Y_{,3}$ vanishes and that

$$Z=Z(v)=\frac{1}{v+ia};$$

thus $Z_{,1}$ and $Z_{,2}$ both vanish together with their complex conjugates due to Eqs. (2.3). In turn, this implies that Λ and $\mathscr{K}$ vanish [Eqs. (4.8) and (4.9)] and Eqs. (6.3) reduce to

$$N_{,1}=N_{,2}=0, \qquad N_{,3}=-\frac{\lambda}{Z+\overline{Z}}N, \qquad N_{,4}=\frac{2\lambda}{(Z+\overline{Z})^2}.$$

This system of equations is compatible, as one may readily check observing that

$$dN = N_{,3}e^3 + N_{,4}e^4 = \frac{1}{2}\lambda\left(\frac{v^2+a^2}{v}\right)^2 dv, \tag{7.2}$$

and thus N is a function of v only. Straightforward integration now yields

$$N(v) = \frac{\lambda}{2}\left(\frac{v^3}{3} + 2a^2 v - \frac{a^4}{v}\right) + m_0,$$

where m_0 is an arbitrary constant. Finally, due to (6.2), we end up with the Kowalczyński–Plebański result

$$h(v) = \frac{1}{2}(Z+\overline{Z})N(v) = \frac{1}{2}m_0(Z+\overline{Z}) + \frac{\lambda}{2}Z\overline{Z}\left(\frac{v^4}{3} + 2a^2v^2 - a^4\right).$$

VIII. GENERATION OF SOLUTIONS STARTING FROM THE SCHWARZSCHILD "SEED"

As we have seen, among the DKS solutions, the stationary ones contain the Kerr field and therefore the Schwarzschild one. It is of obvious physical interest to investigate whether the seeds corresponding to such solutions generate interior solutions. In the present paper we shall focus our attention only on the most simple case, namely the Schwarzschild one.

Letting $\phi=0$ and assuming stationariety ($P=k$), Eq. (5.8) reads

$$\overline{\xi}Y^2 + \mathrm{z}\sqrt{2}Y - \xi = 0,$$

[where $\mathrm{z}=(u+v)/\sqrt{2}$] so that Y is given by a quadratic equation. We choose the positive root and therefore set

$$Y = \frac{r-\mathrm{z}}{\overline{\xi}\sqrt{2}},$$

where $r = \sqrt{\mathrm{x}^2+\mathrm{y}^2+\mathrm{z}^2}$ is the radial coordinate of a spherical system in the flat base space.

It turns out that the complex expansion actually is real,

$$Z = \frac{r-\mathrm{z}}{\xi\overline{\xi}\sqrt{2}} = \overline{Z},$$

and the commutation relations then imply $Z_{,2} = \overline{Z}_{,2} = 0$ together with their complex conjugates. Moreover, one has

$$k = \frac{1}{\sqrt{2}}(1 + Y\overline{Y}) = rZ. \tag{8.1}$$

Applying the "$\hat{D}$" operator (4.12) to the last equation in (6.4), and observing that $\hat{D}$ commutes with the directional derivative along e_4 when DY vanishes, we see that $\mathscr{P}$ is stationary if ϵ and Y are. Therefore, the Bianchi identities (6.4) may be rearranged in terms of the tetrad derivatives of the auxiliary function

$$\eta := \epsilon + k^2\mathscr{P},$$

and read

$$\eta_{,1}=\frac{k\overline{Y}}{\sqrt{2}}\,[\mathscr{P}_{,4}+2Z\mathscr{P}], \qquad \eta_{,2}=\frac{kY}{\sqrt{2}}\,[\mathscr{P}_{,4}+2Z\mathscr{P}],$$
$$\hat{D}\,\eta=0, \qquad \eta_{,4}=k^2[\mathscr{P}_{,4}+2Z\mathscr{P}]. \tag{8.2}$$

The above equations may be rewritten (formally, at the present stage) as

$$d\,\eta=(\mathscr{P}_{,4}+2Z\mathscr{P})\left[\overline{Y}d\xi+Yd\overline{\xi}+\frac{1}{\sqrt{2}}\,(1-Y\overline{Y})dz\right]. \tag{8.3}$$

We remind the reader that, in the above formula, both Y and $\overline{Y}$ are *known* functions coming from the chosen seed solution. Using the seed explicitly, one obtains

$$d\,\eta=(\mathscr{P}_{,4}+2Z\mathscr{P})\,\frac{r-\mathrm{z}}{\xi\overline{\xi}\sqrt{2}}\,(\overline{\xi}\,d\xi+\xi\,d\overline{\xi}+\mathrm{z}\,dz)=(\mathscr{P}_{,4}+2Z\mathscr{P})Zr\,dr. \tag{8.4}$$

Therefore, in order to assure the compatibility of the above equation, η must be a function of r only and the relation

$$\mathscr{P}_{,4}+2Z\mathscr{P}=\frac{1}{rZ}\,\frac{d\,\eta}{dr} \tag{8.5}$$

must hold. Using (8.1) and $\mathscr{P}=(\eta-\epsilon)/k^2$, this gives

$$\eta_{,4}-\epsilon_{,4}+2Z(\,\eta-\epsilon)=Zr\,\frac{d\,\eta}{dr}. \tag{8.6}$$

It is now convenient to introduce the angles $\vartheta=\arctan(\sqrt{x^2+y^2}/z)$ and $\varphi=\arctan(y/x)$ of the spherical system of coordinates in the base space. It is easy to check that

$$r_{,4}=Zr, \quad \vartheta_{,4}=\varphi_{,4}=0.$$

and then

$$\epsilon_{,4}=\frac{\partial\epsilon}{\partial r}\,r_{,4}+\frac{\partial\epsilon}{\partial\vartheta}\,\vartheta_{,4}+\frac{\partial\epsilon}{\partial\varphi}\,\varphi_{,4}=Zr\,\frac{\partial\epsilon}{\partial r},$$

while

$$\eta_{,4}=Zr\,\frac{d\,\eta}{dr}.$$

It follows that (8.6) reads

$$\frac{\partial\epsilon}{\partial r}=\frac{2}{r}\,(\,\eta-\epsilon),$$

for every arbitrary choice of η. The general solution, denoting

$$\eta=f(r),$$

is then given by

$$\epsilon = \frac{E(\vartheta,\varphi)}{r^2} + \frac{2}{r^2}\int_{r_0}^{r} s f(s)\,ds,$$

$$\mathscr{P} = \frac{1}{(Zr)^2}\,(f(r) - \epsilon(r,\vartheta,\varphi)),$$

where $f(r)$ and $E(\vartheta,\varphi)$ are arbitrary functions.

The above procedure allowed us to calculate the material variables ϵ and $\mathscr{P}$ independently from N. Therefore, (6.3) now become linear differential equations in N only. Denoting by C the action of $\hat{D}$ on N, a simple calculation shows that such equations can be written as follows:

$$N_{,1} = \left(\frac{r^3\epsilon}{2}\right)_{,1} - \frac{\overline{Y}r^2 f(r)}{\sqrt{2}}, \qquad N_{,2} = \left(\frac{r^3\epsilon}{2}\right)_{,2} - \frac{Y r^2 f(r)}{\sqrt{2}},$$

$$N_{,3} = \left(\frac{r^3\epsilon}{2}\right)_{,3} + \frac{C}{rZ} - \frac{r f(r)}{2Z}\left(1 - Y\overline{Y} - 2\frac{N}{r}\right), \qquad N_{,4} = \left(\frac{r^3\epsilon}{2}\right)_{,4} - Z f(r) r^3.$$

Defining the auxiliary function

$$L := N - \frac{r^3\epsilon}{2},$$

we can write the following formula for the differential of L:

$$dL = \frac{1}{Zr}\,[C - r^2 f(r)]\left[\overline{Y}d\xi + Y d\overline{\xi} + \frac{1}{\sqrt{2}}\,(1 - Y\overline{Y})dz\right] + C\,dt = [C - r^2 f(r)]\,dr + C\,dt. \quad (8.7)$$

In order to assure the compatibility of the above equation we must calculate C explicitly. A quite long but straightforward calculation gives

$$C = \hat{D}N = \tfrac{1}{2}r^2(E_{,12} + E_{,21}) = \tfrac{1}{2}r^2\Delta E,$$

where Δ denotes the flat Laplace operator. Therefore $C = r^2\Delta E/2$ is a function of θ and φ only, and the necessary and sufficient condition for the compatibility of (8.7) is $C = \text{const}$. It follows that the function E must be a solution of the equation

$$\frac{\partial^2 E}{\partial\vartheta^2} + \frac{\cos\vartheta}{\sin\vartheta}\frac{\partial E}{\partial\vartheta} + \frac{1}{\sin^2\vartheta}\frac{\partial^2 E}{\partial\varphi^2} = 2C.$$

It is easy to check that such an equation admits a regular solution only if C vanishes, and in such a case the solution is constant. Therefore, nonsingular solutions of our problem exist only if C is zero and E is a constant or, in other words, if L depends on r only. In any case, we have

$$L(r,t) = C(r - r_0) - \int_{r_0}^{r} s^2 f(s)\,ds + Ct,$$

and finally

$$N(r,\vartheta,\varphi,t) = C(r - r_0) + \int_{r_0}^{r} s(r - s) f(s)\,ds + \frac{1}{2}\,rE(\vartheta,\varphi) + Ct. \quad (8.8)$$

The line element we have obtained reads, therefore, as follows:

$$ds^2 = -dt^2 + dr^2 + r^2(d\vartheta^2 + \sin^2\vartheta d\varphi^2) + \frac{2N(r,\vartheta,\varphi,t)}{r}(dt+dr)^2. \tag{8.9}$$

For $N=m=$const, this is the Schwarzschild line element (in the so-called Eddington form), as it must be. For $C=0$ and $E=$const, this is a static, spherically symmetric interior solution.[10] It satisfies the familiar mass-density relation for spherically symmetric static fields, namely

$$\frac{\partial N}{\partial r} = \frac{1}{2} r^2 \epsilon.$$

In the general case in which C is nonvanishing, the line element (8.9) describes an interior Kerr–Schild geometry which has no easily recognizable symmetries. As far as we are aware such metrics are new, but their physical meaning is doubtful because they are necessarily singular in $\theta=0$ or $\theta=\pi$.

IX. CONCLUDING REMARKS

The main problems in solving the Einstein field equations are obviously due to their intrinsic nonlinearity. However, since the work by Gürses and Gürsey,[18] it is known that an underlying linear structure exists in the case of Kerr–Schild space–times both in the vacuum and in the electrovacuum case. As was recently shown,[1] this linear structure comes into play also in the case of elastic matter, and allows the decoupling of the equations governing the gravitational field (which are linear partial differential equations) from those governing the material quantities (which turn out to be algebraic).

In the present paper we have shown that, if the same problem is approached using the null-tetrad formalism, linearity appears under the quite unexpected form of the possibility of ''variation of the arbitrary constants.'' This result appears to be promising in the perspective of solving some of the open problems left unsolved in Ref. 1. In fact, approaching the field equations using the coordinate-dependent method, one has to solve a boundary value problem for an elliptic, although linear, equation. Therefore, one is immediately faced with the absence of explicit sets of eigenfunctions if the boundary is not trivial. Here instead, although the null-tetrad machinery is somewhat intricate, the ''variation of arbitrary constants'' should allow us to study, for example, the matching problem with the Kerr metric, starting with a seed metric whose principal null direction satisfies the boundary conditions however complicated they can be. We think, in addition, that the possibility of expressing the stresses in terms of invariant tetrad components should result in facilitating the analysis of the physical properties of the sources even in the general case of prestressed bodies. It might be necessary to consider such bodies in order to satisfy the compatibility conditions in the Kerr case. Work in this direction is now in progress.

ACKNOWLEDGMENT

We are grateful to the referee whose valuable comments led us to improve the paper.

APPENDIX A: $\Gamma_{a[bc]}$ COEFFICIENTS

The nonvanishing skew-symmetric part of the Ricci rotation coefficients in the case of a geodesic ($Y_{,4}=0$) Kerr–Schild geometry are given by

$$
\begin{array}{llll}
2\Gamma_{1[14]}=-\overline{Y}_{,1}, & 2\Gamma_{1[34]}=-\overline{Y}_{,3}, & 2\Gamma_{2[24]}=-Y_{,2}, & 2\Gamma_{3[32]}=hY_{,3}-h_{,2},\\
2\Gamma_{1[13]}=h\overline{Y}_{,1}, & 2\Gamma_{2[14]}=-Z, & 2\Gamma_{2[34]}=-Y_{,3}, & 2\Gamma_{3[43]}=h_{,4},\\
2\Gamma_{1[23]}=h\overline{Z}, & 2\Gamma_{2[13]}=hZ, & 2\Gamma_{3[12]}=h(\overline{Z}-Z), & 2\Gamma_{4[12]}=\overline{Z}-Z,\\
2\Gamma_{1[24]}=-\overline{Z}, & 2\Gamma_{2[23]}=hY_{,2}, & 2\Gamma_{3[31]}=hY_{,3}-h_{,1}, & 2\Gamma_{4[31]}=\overline{Y}_{,3}.
\end{array}
$$

APPENDIX B: COMMUTATION RULES IN THE SHEAR-FREE CASE

For $Y_{,2}=0$, the commutation rules coming from the above Ricci coefficients read

$$2f_{[12]}=(Z-\overline{Z})(f_{,3}+hf_{,4}),$$

$$2f_{[13]}=hZf_{,1}-\overline{Y}_{,3}(f_{,3}+hf_{,4})+f_{,4}h_{,1},$$

$$2f_{[14]}=-Zf_{,1},$$

$$2f_{[34]}=-(Y_{,3}f_{,1}+\overline{Y}_{,3}f_{,2}+h_{,4}f_{,4}),$$

$$2f_{[23]}=h\overline{Z}f_{,2}-Y_{,3}(f_{,3}+hf_{,4})+f_{,4}h_{,2}.$$

Applying such formulas to Y, it follows

$$Z_{,2}=(Z-\overline{Z})Y_{,3}, \qquad Z_{,3}=Y_{,31}+hZ^2-Y_{,3}\overline{Y}_{,3},$$

$$Z_{,4}=-Z^2, \qquad Y_{,34}=-ZY_{,3}, \qquad Y_{,32}=(Y_{,3})^2.$$

Heat kernel for nonminimal operators on a Kähler manifold

Sergei Alexandrov

(Received 9 January 1996; accepted for publication 29 May 1996)

The heat kernel expansion for a general nonminimal operator on the spaces $C^\infty(\Lambda^k)$ and $C^\infty(\Lambda^{p,q})$ is studied. The coefficients of the heat kernel asymptotics for this operator are expressed in terms of the Seeley coefficients for the Hodge–de Rham Laplacian. © *1996 American Institute of Physics.* [S0022-2488(96)01509-5]

Let M be a compact Reimannian manifold of dimension m without boundary. If M is equipped with integrable complex structure, one can split tagential indices into holomorphic and antiholomorphic ones and define space of differential forms $C^\infty(\Lambda^{p,q})$. The exterior differential d can be also split into a sum $d=\partial+\bar\partial$ of anticommuting nilpotent operators: $\partial^2=\bar\partial^2=\partial\bar\partial+\bar\partial\partial=0$. If M is a Kähler manifold, the corresponding ''Laplacians'' can be reduced to the Hodge–de Rham Laplacian:

$$\partial\partial^*+\partial^*\partial=\overline{\partial\,\partial^*}+\overline{\partial^*\partial}=\tfrac{1}{2}\Delta=\tfrac{1}{2}(\delta d+d\delta). \tag{1}$$

Using these first order differential operators one can construct a (nonminimal) second order differential operator:

$$\mathscr{D}=g_1\partial\partial^*+g_2\partial^*\partial+g_3\overline{\partial\,\partial^*}+g_4\overline{\partial^*\partial}+g_5\partial\bar\partial^*+g_5^*\bar\partial\partial^*, \tag{2}$$

with real constants $g_1,\ldots,g_4$ and a complex constant g_5. For some values of the constants this operator reduces to that considered previously in the paper,[1] where one can find some motivations for studying nonminimal operators. Such operators appear naturally in quantum gauge theories after imposing gauge conditions.[2–5]

For a self-adjoint second order operator L with non-negative eigenvalues $\{\lambda_\nu\}$ one can define the integrated heat kernel

$$\mathrm{Tr}(e^{-tL})=\sum_\nu e^{-t\lambda_\nu}. \tag{3}$$

As $t\to 0_+$, there is an asymptotic expansion of the form

$$\mathrm{Tr}(e^{-tL})=\frac{1}{(4\pi)^{m/2}}\sum_{n=0}^{\infty}a_n(L)t^{(2n-m)/2}. \tag{4}$$

In this paper, we study the heat kernel expansion for the nonminimal operator $\mathscr{D}$ (2) and relate the Seeley coefficients $a_n(\mathscr{D})$ to that for the Laplace operator $a_n(\Delta)$. General expressions for $a_n(\Delta)$, $n=0,1,2,3$ suitable for the spaces of differential forms can be found in the paper.[6] In particular cases, this problem was solved in Refs. 1, 3–5. In a sense, we suggest an extension of the Theorem 1.2 of Ref. 1 for the case of complex geometry.

First we study the heat kernel for $\mathscr{D}$ acting on the space of k forms, $C^\infty(\Lambda^k)$. Next the case $\mathscr{D}$: $C^\infty(\Lambda^{p,q})\to C^\infty(\Lambda^{p,q})$ is considered. This assumes some restrictions on the constants in Eq. (2), but a more detailed information can be obtained.

Consider the heat kernel for nonminimal operators acting on the space $C^\infty(\Lambda^k)$ of k forms. Let us discuss some properties of first order operators D_1 and D_2, which will be used later to build up a general nonminimal second order operator $\mathscr{D}$.

Lemma 1: Let D_1 and D_2 be operators on $C^\infty(\Lambda)$ having the following properties: (a) D_1, D_2: $C^\infty(\Lambda^k)\to C^\infty(\Lambda^{k+1})$, (b) $D_1^2=D_2^2=0$, (c) $D_1D_2 + D_2D_1 = D_1D_2^* + D_2^*D_1 = 0$, (d) $D_1D_1^* + D_1^*D_1=\alpha\Delta,\ D_2D_2^*+D_2^*D_2=\beta\Delta,\ \alpha,\beta\neq 0$. Then

(1) $C^\infty(\Lambda^k)=\mathrm{Ker}(\Delta)\oplus\mathrm{im}(D_1)\oplus\mathrm{im}(D_1^*)=\mathrm{Ker}(\Delta)\oplus\mathrm{im}(D_2)\oplus\mathrm{im}(D_2^*)$,
(2) $C^\infty(\Lambda^k)=\mathrm{Ker}(\Delta)\oplus(D_1D_2)_k\oplus(D_1D_2^*)_k\oplus(D_1^*D_2)_k\oplus(D_1^*D_2^*)_k$.
(3) The following mappings are isomorphisms:

$$(D_1D_2)_k \overset{D_1D_1^*}{\leftrightarrow} (D_1^*D_2)_{k-1},\quad (D_1^*D_2)_k \overset{D_2D_2^*}{\leftrightarrow} (D_1^*D_2^*)_{k-1},$$

$$(D_1D_2^*)_k \overset{D_1D_1^*}{\leftrightarrow} (D_1^*D_2^*)_{k-1},\quad (D_1D_2)_k \overset{D_2D_2^*}{\leftrightarrow} (D_1D_2^*)_{k-1},$$

where operators D act from right to left, and D^* act from left to right. We introduced the notation $(AB)_k=\mathrm{im}(A)\cap\mathrm{im}(B)\cap C^\infty(\Lambda^k)$.

(4) Let $\Delta_k=\Delta\big|_{C^\infty(\Lambda^k)}$, $f(t,D)=\mathrm{Tr}\,\exp(-tD)f(t,A,B,k)=\mathrm{Tr}\,\exp[-t\Delta|_{(AB)_k}]$. Then in these notations

$$f(t,D_1^*,D_2^*,k)=\sum_{l=0}^{k}(-1)^l(l+1)(f(t,\Delta_{k-l})-\beta_{k-l}), \tag{5}$$

where β_k denote Betti numbers.

Proof: The proof of the first statement repeats standard proof[7] of the same property for operator d. The decomposition 2. can be obtained by repeating twice the decompositions 1. The third statement follows from the anticommutativity properties (b) and (c). To prove the last statement observe that all spaces appearing in the second statement of Lemma 1 are eigenspaces of the Laplace operator. Hence,

$$f(t,\Delta_k)=\beta_k+f(t,D_1,D_2,k)+f(t,D_1^*,D_2,k)+f(t,D_1,D_2^*,k)+f(t,D_1^*,D_2^*,k), \tag{6}$$

$$f(t,D_1,D_2,k)=f(t,D_1^*,D_2,k-1)=f(t,D_1,D_2^*,k-1)=f(t,D_1^*,D_2^*,k-2). \tag{7}$$

Now we can express $f(t,D_1^*,D_2^*)$ from Eq. (6) and by repeated use of Eq. (7) obtain

$$f(t,D_1^*,D_2^*,k)=-f(t,D_1^*,D_2^*,k-1)+\sum_{l=0}^{k}(-1)^l(f(t,\Delta_{k-l})-\beta_{k-l}). \tag{8}$$

Now the statement of the Lemma follows by induction. □

It is easy to see that the operators

$$D_1 = x_1\partial + y_1\overline{\partial}, \quad D_2 = x_2\partial + y_2\overline{\partial}, \tag{9}$$

satisfy conditions of Lemma 1 provided the equation $x_1x_2^* + y_1y_2^* = 0$ holds for complex parameters x_1, x_2, y_1, and y_2. The constants α and β are real and positive: $\alpha = \frac{1}{2}(|x_1|^2 + |y_1|^2)$, $\beta = \frac{1}{2}(|x_2|^2 + |y_2|^2)$. The nonminimal operator

$$\begin{aligned}\mathscr{D} &= aD_1D_1^* + bD_1^*D_1 + cD_2D_2^* + dD_2^*D_2 \\ &= (a|x_1|^2 + c|x_2|^2)\partial\partial^* + (b|x_1|^2 + d|x_2|^2)\partial^*\partial + (a|y_1|^2 + c|y_2|^2)\overline{\partial\,\partial^*} \\ &\quad + (b|y_1|^2 + c|y_2|^2)\overline{\partial^*}\,\overline{\partial} + [(a-b)x_1y_1^* + (c-d)x_2y_2^*]\partial\overline{\partial^*} + [(a-b)y_1x_1^* + (c-d)y_2x_1^*]\overline{\partial}\partial^*\end{aligned} \tag{10}$$

with real constants a, b, c, d is the most general hermitian operator on $C^\infty(\Lambda^k)$ which can be constructed using ∂, ∂, ∂^*, and ∂^*. This operator has the form (2).

The following Theorem gives the heat kernel asymptotics for $\mathscr{D}$.

Theorem 1. Let D_1 and D_2 satisfy conditions of Lemma 1. Then the coefficients a_n of the heat kernel expansion for the operator $\mathscr{D}$ (10) have the form

$$\begin{aligned}a_n[\mathscr{D}|_{C^\infty(\Lambda^k)}] &= (\alpha a + \beta c)^{n-(m/2)}\sum_{l=0}^{k-2}(-1)^{k-l}(k-l-1)a_n(\Delta_l) - [(\alpha a + \beta d)^{n-(m/2)} \\ &\quad + (\alpha b + \beta c)^{n-(m/2)}]\sum_{l=0}^{k-1}(-1)^{k-l}(k-l)a_n(\Delta_l) + (\alpha b + \beta d)^{n-(m/2)}\sum_{l=0}^{k}(-1)^{k-l} \\ &\quad \times (k-l+1)a_n(\Delta_l).\end{aligned}$$

Proof consists in repeated use of Lemma 1. Note, that to ensure existence of all traces of exponentials for positive t one should take non-negative a, b, c, d.

Consider nonminimal operators on $C^\infty(\Lambda^{p,q})$. To ensure that $\mathscr{D}$ maps $C^\infty(\Lambda^{p,q})$ on itself we should choose $D_1 = \partial$, $D_2 = \partial$. The following notations will be useful:

$$(AB)_{p,q} = \mathrm{im}(A) \cap \mathrm{im}(B) \cap C^\infty(\Lambda^{p,q}), \quad \Delta_{p,q} = \Delta|_{C^\infty(\Lambda^{p,q})}. \tag{11}$$

Other notations are modified by replacing k by p,q in Lemma 1. $\beta_{p,q}$ will denote Hodge numbers.

Next Lemma replaces the Lemma 1.

Lemma 2. 1: $C^\infty(\Lambda^{p,q}) = \mathrm{Ker}(\Delta_{p,q}) \oplus (\partial\overline{\partial})_{p,q} \oplus (\partial\overline{\partial^*})_{p,q} \oplus (\partial^*\overline{\partial})_{p,q} \oplus (\partial^*\overline{\partial^*})_{p,q}$.

2. The following maps are isomorphisms:

$$(\partial\overline{\partial})_{p,q} \overset{\partial,\partial^*}{\leftrightarrow} (\partial^*\overline{\partial})_{p-1,q}, \quad (\partial^*\overline{\partial})_{p,q} \overset{\overline{\partial\,\partial^*}}{\leftrightarrow} (\partial^*\overline{\partial^*})_{p,q-1},$$

$$(\partial\overline{\partial^*})_{p,q} \overset{\partial,\partial^*}{\leftrightarrow} (\partial^*\overline{\partial^*})_{p-1,q}, \quad (\partial\overline{\partial})_{p,q} \overset{\overline{\partial\,\partial^*}}{\leftrightarrow} (\partial\overline{\partial^*})_{p,q-1},$$

where the operators ∂ and $\overline{\partial}$ act from right to left, and the operators ∂^* and $\overline{\partial^*}$ act from left to right.

4. $f(t,\partial^*,\overline{\partial^*},p,q) = \Sigma_{k,l=0}^{p,q}(-1)^{k+l}(f(t,\Delta_{p-k,q-l}) - \beta_{p-k,q-l})$.

The proof repeats that of Lemma 1 with minor modifications Now we can prove the following theorem.

Theorem 2: Let $\mathscr{D} = a\,\partial\partial^* + b\,\partial^*\partial + c\,\overline{\partial\,\partial^*} + d\,\overline{\partial^*}\,\overline{\partial}$ on $C^\infty(\Lambda^{p,q})$. Then

$$a_n(\mathscr{D}) = \left(\frac{b+d}{2}\right)^{n-(m/2)} a_n(\Delta_{p,q}) + \left[\left(\frac{b+c}{2}\right)^{n-(m/2)} - \left(\frac{b+d}{2}\right)^{n-(m/2)}\right] a_n(\Delta_{p,q-1}) + \left[\left(\frac{a+d}{2}\right)^{n-(m/2)} - \left(\frac{b+d}{2}\right)^{n-(m/2)}\right] a_n(\Delta_{p-1,q}) + \left[\left(\frac{a+c}{2}\right)^{n-(m/2)} + \left(\frac{b+d}{2}\right)^{n-(m/2)} - \left(\frac{a+d}{2}\right)^{n-(m/2)} - \left(\frac{b+c}{2}\right)^{n-(m/2)}\right] \sum_{k,l=0}^{p-1,q-1} (-1)^{p+q-k-l} a_n(\Delta_{k,l}).$$

In this paper, we expressed the heat kernel coefficients for nonminimal operators on $C^\infty(\Lambda^k)$ and $C^\infty(\Lambda^{p,q})$ in terms of the Seeley coefficients for the Laplace operators on the same spaces. Expressions for the heat kernel asymptotics applicable for Laplacian on differential forms can be found in the literature.[6]

The fact that underlying manifold is Kählerian was used only to relate $\partial\partial^* + \partial^*\partial$ and $\partial\partial^* + \partial^*\partial$ to $\Delta = \delta d + d\delta$. With some modifications our results can be extended to a general complex manifold. Another generalization could consist in adding an endomorphism E to the operator $\mathscr{D}$.

Towards the canonical tensor operators of $u_q(3)$. I. The maximal null space case

Sigitas Ališauskas
Institute of Theoretical Physics and Astronomy, A. Goštauto 12, Vilnius 2600, Lithuania

(Received 27 February 1995; accepted for publication 20 May 1996)

Generalizing the SU(3) canonical tensor operator concept (Biedenharn and Louck) to the quantum algebra $u_q(3)$, the Wigner–Clebsch–Gordan coefficients of $u_q(3)$ with repeating irreducible representations are considered. Extremal projectors of the quantum algebra $u_q(3)$ in terms of the ordered generator polynomials are used for evaluation of the bilinear combinations of the $u_q(3)$ canonical isoscalar factors. Explicit expressions of the $u_q(3)$ isofactors, corresponding to the maximal null space case of the $u_q(3)$ unit canonical tensor operators, and their normalization factors (denominator functions) are presented. The transposition and conjugation phase factors for the SU(3) and $u_q(3)$ canonical isofactors are correlated with phases and zeros of boundary isofactors. Invariance of the canonical isofactors (or absence of such invariance) under interchange of the tensor operator and the initial or final state parameters is correlated with the existence and invariance (or numerical degeneracy) of the usual splitting (distinctive) conditions. Some oversights of previous publications are disclosed. © *1996 American Institute of Physics.* [S0022-2488(96)00509-9]

I. INTRODUCTION

The matrix elements of the canonical unit SU(3) tensor operators[1–4] provide the most universal complete algebraic system of the orthonormal coupling (Wigner–Clebsch–Gordan) coefficients of SU(3) group with the repeating irreducible representations (irreps) in the direct product decomposition. The canonical SU(3) tensor operators are determined by the null space inclusion property,[4–6] together with their Hermitian and conjugation properties and vanishing conditions[2,3,6] of certain SU(3):U(2) projective operators and corresponding maximal shift isoscalar factors (isofactors). Biedenharn, Louck, and collaborators solved explicitly[5–7] the normalization problem of the canonical SU(3) isofactors. The definite advance for the evaluation of the explicit canonical SU(3) isofactors is presented by the recursive construction of the SU(3) tensor operators,[8] although an additional orthogonalization procedure is necessary in the general case.

With the growing interest in the Wigner–Racah irreducible tensor calculus of the quantum groups, some elementary coupling coefficients for the quantum algebra $u_q(3)$ were considered by Smirnov *et al.*[9,10] and Lienert and Butler.[11] Some multiplicity-free isoscalar factors (isofactors) for the unitary quantum algebra $u_q(n)$ of an arbitrary rank were considered by Gould and Biedenharn[12] (with presented pattern calculus rules) and by Ališauskas and Smirnov[13] (for the coupling of arbitrary and one-parametric irreps, and for the semistretched and stretched coupling). Ališauskas[14] proposed alternative recursive constructions for the biorthogonal systems of $u_q(n)$ isofactors with the repeating irreps in the coproduct decomposition.

Biedenharn and Tarlini[15] presented a definition of the q-tensor operators transforming under representations of q-deformed universal enveloping algebras and compatible with the coproduct expansion rules and Klimyk[16] reconsidered the Wigner–Eckart theorem for the quantum group as dual to $u_q(n)$ Hopf algebra. In both cases their matrix elements are proportional to the coupling (Wigner–Clebsch–Gordan) coefficients of the quantum algebra. The explicit symmetric (multiplicity-free) tensor operators of $u_q(k)$ were expressed[13] in terms of the $u_q(k+1)$ generators. However, contrary to the $u_q(2)$ case[17,18] and the SU(3) case, even for the rank (1 1) the separate

components of the self-conjugate minimal null space canonical tensor operator of $u_q(3)$ are rather complicated (and, as a rule, nonlinear) functions[19] of $u_q(3)$ generators. Hence, the matrix elements of the simplest non-multiplicity-free $u_q(3)$ unit canonical tensor operator of the rank (1 1), presented by Smirnov and Kharitonov,[19] cannot be written straightforwardly from the matrix elements of the $u_q(3)$ generators, as it was done in the SU(3) case.[20,21]

In general, the external multiplicity labels of the all orthonormal analytical systems of the SU(3)⊃U(2) isofactors (including the matrix elements of the unit canonical tensor operators, the paracanonical[22,23] and pseudocanonical[22] isofactors) may be associated with solution of the internal SU(3)⊃U(2)⊃U(1)⊗U(1) weight multiplicity problem and represented by the operator (Gelfand–Weyl–Biedenharn) patterns[2–7] (or by the external isospin type parameters[22]) with the different distribution of the null spaces [which inclusion property[5,6] is not exceptional[24] just for the canonical tensor operators and defining condition (1.26b) of Ref. 6 is insufficient]. In all these cases isofactors [matrix elements of the SU(3):U(2) projective operators] with the fixed multiplicity label may be expressed[6] in terms of the definite numerator polynomials (or the multiple terminated series) in the free irrep parameters of SU(3) and U(2), with the linear numerator pattern calculus factors and the corresponding SU(3) and U(2)-invariant denominator polynomials under the square root sign. For all three analytical systems,[22] the guessed denominator functions[5,7,23,24] and the boundary[23,24] SU(3)⊃U(2) isofactors are determined completely by their polynomial, reduction, and symmetry properties and zeros [associated with the null spaces and the additional selection rules in frames of SU(2)]. Since the overlaps of the biorthogonal systems of $u_q(3)$ isofactors[14] are expressed in terms of the multiple balanced terminated basic hypergeometric series [and are invariant with respect to the substitution $q \to q^{-1}$, similarly as the $u_q(2)$ Racah coefficients], the analogical unambiguous extrapolation is possible for the paracanonical and pseudocanonical isofactors of $u_q(3) \supset u_q(2)$, although the proof is rather problematic.

For the fixed rank, shifts, and multiplicity label of the $u_q(3)$ canonical tensor operators, we may also deduce the analogical structure of their matrix elements, with rational numerator functions and the corresponding q-pattern calculus factors and $u_q(3)$ denominator functions under the square root sign, such that the expressions are valid for the entire values of parameters of initial state and give zeros in the null space region. However, appearing q-phases provide serious difficulties for the extrapolation of the SU(3) denominator G-function[7,25] for the $u_q(3)$ canonical tensor operators. {Note, that the role of Milne's[26] q-analog $[G]_m^{(3)}$ or, respectively, the well-poised multiple series $W_m^{(3)}$, cf. introduced by Holman *et al.*[27] SU(3) invariant G-function, for the $u_q(3)$ irreducible tensor operators[15] is not clear.}

In this paper, some important constructive elements of the explicit matrix elements of the $u_q(3)$ canonical tensor operators are presented and some distinction and symmetry problems of the $u_q(3)$ canonical isofactors are considered [together with some questionable aspects of the SU(3) case]. Unambiguous orthonormal systems of the $u_q(3) \supset u_q(2)$ isofactors may be derived from special bilinear combinations of isofactors, including, respectively, single, two, or other restricted number of values of the multiplicity labels, i.e., by means of the Gram-Schmidt process. Such bilinear combinations (presented for the paracanonical and pseudocanonical cases in Ref. 14) could be expressed by means of the integration of three qD-matrices, if the q-integration technique[28] could be extended to the quantum group space of $u_q(3)$, or using the q-boson realizations of the $u_q(3) \supset u_q(2)$ basis states. In Sec. II of this paper, we apply an easier approach—the generalized projection operator technique[8,9] and $u_q(2)$-irreducible properties[13] of the $u_q(3)$ generator powers and their ordered products for the explicit construction of the restricted bilinear combinations of the $u_q(3)$ canonical isofactors, equivalent to the SU(3) canonical isofactors for $q=1$.

The different $u_q(3)$ tensor operators may be constructed in analogy with (2.10) of Ref. 8 by means of the stretched coupling [see Eq. (4.10) of Ref. 13] of the maximal null space canonical tensor operator and the (q-self-adjoint) minimal null space canonical tensor operator, varying each rank. Since both the auxiliary q-tensor operators are still available[19] only in the case of rank (1 1),

it may be suitable to use construction (2.10) of Ref. 8 step by step, taking $k=1$, and to postpone the final (correct) construction of the orthogonal SU(3) and $u_q(3)$ canonical isofactors to a later publication, reconsidering below only some questionable aspects of orthogonality. Therefore, in Sec. III, the expressions for the product of isofactors with a single (extreme) value of the canonical multiplicity label are considered. Some of our results are different in formal structure from those[8] of SU(3) only by the appearance of rather complicated q-phases, but the explicit expressions for the square of the extreme maximal null space isofactor and the corresponding normalization factors, presented in Sec. III [as well as the expression for the most general bilinear combinations of the $u_q(3)$ canonical isofactors in Sec. II], were never published before, even in the SU(3) version. After unsuccessful efforts to rearrange this normalization factor in the generic $q\neq 1$ case into form, related to the G-function,[7,25] we observed that the first presented solution does not cover all the cases of the matrix elements of the maximal null space $u_q(3)$ canonical tensor operators, unless the normalization factor is expressed in a more convenient form, which was eliminated from the product of two different extreme canonical isofactors. The second version of the projection operator and the symmetries of the $u_q(3)$ canonical isofactors were indispensable for this purpose.

The essential advantage of the canonical tensor operators consists of their elementary behavior under conjugation and transposition. The symmetry properties of their matrix elements in the $u_q(3)$ case should be consistent with their depending on the multiplicity label phase relations of the SU(3) canonical isofactors[1,8] and include the corresponding q-factors,[29] but unquestionable (cf. Refs. 8 and 30) complete phase factors are correlated with the conjugation and transposition ($1\leftrightarrow 3$) invariant extreme isofactors, derived in Sec. III. In Sec. IV, we (re)consider the symmetry phase factors of the SU(3) and $u_q(3)$ canonical isofactors, correlating them also with the definite zeros of the SU(3) isofactors [similar to zeros of $C_{000}^{l_1 l_2 l}$ for l_1+l_2+l odd in the SU(2) case[31]]. Besides, we anticipate conditions for the existence or absence of the $1\leftrightarrow 2$ and $2\leftrightarrow 3$ S_2-irreducible transposition symmetry[32] of the $u_q(3)$ and SU(3) canonical isofactors, associated with the observed invariance or the degeneracy of the distinctive conditions. We also discuss the contradictions between the Derome[32] and Biedenharn *et al.*[30] approaches to this problem, when some parameters before and after transposition coincide.

We use here the same notations for irreps and basis states of $u_q(3)$ as were used in Ref. 8 for SU(3), with $(a\ \ b)$ for the mixed tensor irreps (more convenient to catch symmetries in the presented below results),

$$a=m_{13}-m_{23},\quad b=m_{23}-m_{33}\ \text{ where }\ [m_{13},m_{23},m_{33}] \tag{1.1a}$$

is a Young frame (partition). The basis states are labeled by the hypercharge y, the isospin i and its projection i_z:

$$y=m_{12}+m_{22}-\tfrac{2}{3}\,(m_{13}+m_{23}+m_{33}),\quad i=\tfrac{1}{2}\,(m_{12}-m_{22}),\quad i_z=m_{11}-\tfrac{1}{2}\,(m_{12}+m_{22}), \tag{1.1b}$$

where m_{ij} are the Gelfand–Tsetlin parameters. Sometimes the parameter

$$z=\tfrac{1}{3}\,(b-a)-\tfrac{1}{2}\,y=m_{23}-\tfrac{1}{2}\,(m_{12}+m_{22}) \tag{1.1c}$$

is more convenient than y, because

$$i\pm z\geqslant 0,\quad a+z-i\geqslant 0,\quad b-z-i\geqslant 0 \tag{1.1d}$$

are integers. For the state of irrep $(a\ \ b)$ in the coproduct $(a'b')\otimes(a''b'')$ decomposition,

$$z=z'+z''+v\ \ \text{where}\ \ v=\tfrac{1}{3}\,(a'-b'+a''-b''-a+b). \tag{1.2}$$

The multiplicity r of irrep $(a\ \ b)$ in the coproduct $(a'b')\otimes(a''b'')$ decomposition (intertwining number) is equal to[8,22]

$$r=\min r_{\alpha\beta\gamma}+1 \quad (\alpha=1,2,3;\beta=1,2,3;\gamma=1,2) \tag{1.3a}$$

where integers $r_{\alpha\beta\gamma}$ form the following $3\times3\times2$ array (the third dimension of which is represented by a skew shift in plane):

$$|r_{\alpha\beta\gamma}|=\begin{vmatrix} b'-a''+a+v & & b-v & & b' & \\ & a'-b''+b-v & & b & & b'+v \\ a & & a-a'+b''+v & & a''-v & \\ & a+v & & a''-b'+b-v & & a'' \\ a'-v & & b'' & & b'+b''-b+v & \\ & a' & & b''+v & & a'+a''-a-v \end{vmatrix} \tag{1.3b}$$

with equidistant parameters in the layers, rows, and columns:

$$r_{\alpha\beta2}-r_{\alpha\beta1}=r_{\alpha'\beta'2}-r_{\alpha'\beta'1}=v, \quad r_{\alpha\beta\gamma}-r_{\alpha\beta'\gamma}=r_{\alpha'\beta\gamma}-r_{\alpha'\beta'\gamma}. \tag{1.3c}$$

Similar to the SU(3) canonical tensor operators,[1–6] the matrix elements of $u_q(3)$ canonical unit tensor operators coincide with the coupling coefficients of $u_q(3)$,

$$\left\langle \begin{matrix} ab \\ yii_z \end{matrix} \middle| T^{(a''b'')t,q}_{y''i''i''_z} \middle| \begin{matrix} a'b' \\ y'i'i'_z \end{matrix} \right\rangle_q = \begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (a\ \ b) \\ y'i' & y''i'' & y\ \ i \end{bmatrix}^{(3)}_q \begin{bmatrix} i' & i'' & i \\ i'_z & i''_z & i_z \end{bmatrix}^{(2)}_q, \tag{1.4}$$

which are expressed on the rhs in terms of the $u_q(3)\downarrow u_q(3)$ isofactors (with the external canonical multiplicity label t written over the irrep which corresponds to the irreducible tensor operator) and Clebsch–Gordan coefficients of $u_q(2)$. In order to escape some ambiguities and complications in the analytical expressions and, especially, in the phases,[30] we prefer to use the linear external multiplicity label $t=\min(m''_{13}-\gamma_{12},\gamma_{22}-m''_{33})+1$ instead of the operator Gelfand–Weyl–Biedenharn pattern[3–7] $\Gamma_t=\left(\begin{smallmatrix}\gamma_{11}\\ \gamma_{12}\ \ \gamma_{22}\end{smallmatrix}\right)$, usual in the case of the partition type notations. In accordance with (2.7) of Ref. 8 [cf. (1.11) of Ref. 6], the multiplicity label t of the canonical tensor operator $T^{(a''b'')t,q}_{y''i''i''_z}$ accepts values 1,2,...,$\mathscr{M}$, where $\mathscr{M}$ is the number of independent tensor operators,

$$\mathscr{M}=\min r_{\alpha'\beta'\gamma}+1 (\alpha'=2,3;\beta'=2,3;\gamma=1,2), \tag{1.5a}$$

with the tensor operator characterizing parameters, presented as $2\times2\times2$ subarray

$$|r_{\alpha'\beta'\gamma}|=\begin{vmatrix} \Delta_1 & & p-\Delta_2 & \\ & p-\Delta_3 & & a'' \\ b'' & & \Delta_3 & \\ & \Delta_2 & & p-\Delta_1 \end{vmatrix}, \tag{1.5b}$$

expressed in terms of the shift parameters $\Delta_1,\Delta_2,\Delta_3(p=a''+b'')$ used in Refs. 5–7.

The null space property of the $u_q(3)$ canonical tensor operator $T^{(a''b'')t,q}_{y''i''i''_z}$ with the definite shifts of $u_q(3)$ irrep parameters means the complete vanishing of its matrix elements (and canonical isofactors) for[4,6,8]

$$t \leqslant \mathscr{M} - r, \tag{1.6}$$

when acting on the subspace $\mathscr{N}_t$ of an infinite dimensional Hilbert space $\mathscr{H}$ of all irreps $(a'b')$. Vanishing of the $u_q(3)$ canonical isofactors for

$$i'' + |i - i'| > a'' + b'' - t + 1 \tag{1.7a}$$

is another important generalization of the distinctive property[6] of the SU(3) canonical tensor labeling scheme. Particularly, in analogy with the SU(3) case,[2,3,8,33] it may be supposed that the complete system of the independent $u_q(3)$ isofactors is ensured by their vanishing condition for the sufficient shifts of the q-isospin,

$$|i - i'| > i''_{\mathrm{m}} - t + 1 \tag{1.7b}$$

[i.e., the $u_q(3){:}u_q(2)$ projective operators with the definite shifts of the $u_q(2)$ irrep parameters are zero operators[6]]. To some extension, a sufficient distinction may be ensured even by vanishing (i.e., equal to zero values) of isofactors for

$$i_{\mathrm{m}} - i' > i''_{\mathrm{m}} - t + 1, \tag{1.7c}$$

where isospin accepts the maximal values

$$i = i_{\mathrm{m}} \equiv \tfrac{1}{2}(a+b), \quad i'' = i''_{\mathrm{m}} \equiv \tfrac{1}{2}(a''+b'').$$

We are using also the notations

$$y_{\mathrm{m}} = \tfrac{1}{3}(a-b), \quad z_{\mathrm{m}} = \tfrac{1}{2}(b-a).$$

At first, conditions (1.7a)–(1.7c) may be proved by induction for the $u_q(3)$ self-adjoint tensor operator of the rank $(k\ \ k)$ in the minimal null space case with $t = k+1$. In order to prove that vanishing condition (1.7c) yields the vanishing conditions (1.7b) and (1.7a) for the general $u_q(3)$ canonical isofactors, we use the recursive construction (cf. Ref. 8) of the independent tensor operators

$$\widetilde{T}^{(a''b'')t,q}_{y''i''i''_z} = \left[T^{(t-1,t-1)t,q} T^{(a''-t+1,b''-t+1)1,q} \right]^{(a''b'')t,q}_{y''i''i''_z}, \tag{1.8}$$

derived by means of the stretched coupling of the self-adjoint minimal null space tensor operator $T^{(t-1,t-1)t,q}_{y_3 j_3 m_3}$ [with trivial shift of $u_q(3)$ irreps and restricted shift of $u_q(2)$ irreps for special $j_3 = t-1$] and maximal null space tensor operator $T^{(a''-t+1,b''-t+1)1,q}_{y_1 j_1 m_1}$ [which ensure the null space properties of the full operator (1.8)]. However, contrary to conjecture presented in Ref. 8, the orthogonalization process begun from the maximal value of t is as a rule necessary. Otherwise, the null space condition (1.6) is mainly (but incompletely) ensured by construction (1.8). Therefore, the superfluous tensor operators that appeared should be eliminated and the canonical tensor operators can be obtained only by the Gram–Schmidt process begun from the maximal value of t, although the tensor operators (1.8) with $t=1$ and $\mathscr{M}$ (after normalization) are always canonical.

Of course, conditions (1.7a)–(1.7c) are trivially satisfied (and, therefore, they seemed meaningless[6]) for the maximal null space tensor operators. Nevertheless, for the complete proof of the canonical distinctiveness, we need to find such triplet of parameters $i', i'' = i''_{\mathrm{m}}$, and i with

$$|i-i'|=i''_{\rm m}-t+1 \quad (\text{at least } i_{\rm m}-i'=i''_{\rm m}-t+1 \text{ and/or } i'_{\rm m}-i=i''_{\rm m}-t+1), \tag{1.9}$$

for which isofactor does not vanish and a Gram–Schmidt process from the bilinear combinations of isofactors may be ensured. However, in Secs. III and IV, some ambiguous situations (associated to the absence of the transposition $1\leftrightarrow 2$ or $2\leftrightarrow 3$ symmetry of the canonical isofactors) will be demonstrated, for which condition (1.9) (and beginning of any numerical Gram–Schmidt procedure) is impossible, because the corresponding values of parameters in triplet are not allowed (e.g., they are nonlexical[4,6]) for any value of t. Hence, the distinction properties (1.7a)–(1.7c) for special values of the irrep parameters may be degenerated, since the null space of the SU(3):U(2) and $u_q(3):u_q(2)$ projective operators may exceed the corresponding null space of the SU(3) and $u_q(3)$ canonical operators, contrary to Lemma 1.1, postulated in Ref. 6. Theorems 1.1 and 1.2 of Ref. 6 also turned out to be questionable. Nevertheless, Theorem 1.2 may be correct under the additional restrictions, when isofactors or matrix elements are conjugation invariant and expressed as ratios of the most simple non-singular functions. In such degenerated cases the analytical continuation procedure from the generic (non-degenerated) region may be helpful, as well as the remaining universal properties[1–7] of the canonical tensor operators.

II. EXTREMAL PROJECTORS AND BILINEAR COMBINATIONS OF $U_q(3)$ ISOFACTORS

As in Refs. 9 and 13, we use the Cartan–Weyl generators $E_{ik}(i,j,k=1,2,3)$ of the unitary quantum algebra $u_q(3)=U_q(u(3))$, which satisfy the commutation relations

$$[E_{ii},E_{kk}]=0, \quad [E_{ii},E_{jk}]=\delta_{ij}E_{ik}-\delta_{ik}E_{ji}, \tag{2.1a}$$

$$[E_{ik},E_{ki}]=[E_{ii}-E_{kk}], \tag{2.1b}$$

where $[x]$ and $[x]!$ are q-numbers and q-factorials, respectively:

$$[x]=\frac{(q^x-q^{-x})}{(q-q^{-1})}, \quad [x]!=[x][x-1]\ldots[2][1], \quad [1]!=[0]!=1. \tag{2.2}$$

The composite generators may be expressed in terms of the q-deformed commutators

$$E_{13}=[E_{12},E_{23}]_q\equiv E_{12}E_{23}-qE_{23}E_{12}, \tag{2.3a}$$

$$E_{31}=[E_{32},E_{21}]_{q^{-1}}\equiv E_{32}E_{21}-q^{-1}E_{21}E_{32}, \tag{2.3b}$$

and satisfy the Serre identities

$$[E_{ik},[E_{ik},E_{kl}]_q]_{q^{-1}}=0 \quad (i,k,l=1,2,3, \text{ or } 3,2,1), \tag{2.4a}$$

$$[E_{12},E_{32}]=[E_{21},E_{23}]=0. \tag{2.4b}$$

Generators E_{12} and E_{21} are chosen for the canonical $u_q(2)$ subalgebra, used for labeling of the basis states.

We use the coproduct expansion rules[9]

$$\Delta(E_{ii})=E_{ii}\otimes 1+1\otimes E_{ii}, \tag{2.5a}$$

$$\Delta(E_{ii+1})=E_{ii+1}\otimes q^{1/2(E_{ii}-E_{i+1,i+1})}+q^{-1/2(E_{ii}-E_{i+1,i+1})}\otimes E_{ii+1}, \tag{2.5b}$$

$$\Delta(E_{i+1i})=E_{i+1i}\otimes q^{1/2(E_{ii}-E_{i+1,i+1})}+q^{-1/2(E_{ii}-E_{i+1,i+1})}\otimes E_{i+1i}, \tag{2.5c}$$

as well as special coproduct formulas

$$\Delta(E_{13})=[\Delta(E_{12}),\Delta(E_{23})]_q=E_{13}\otimes q^{1/2(E_{11}-E_{33})}-(q-q^{-1})q^{-1/2(E_{22}-E_{33})}E_{12}\otimes E_{23}q^{1/2(E_{11}-E_{22})}+q^{-1/2(E_{11}-E_{33})}\otimes E_{13}, \tag{2.6a}$$

$$\Delta(E_{31})=[\Delta(E_{32}),\Delta(E_{21})]_{q^{-1}}=E_{31}\otimes q^{1/2(E_{11}-E_{33})}+(q-q^{-1})q^{-1/2(E_{11}-E_{22})}E_{32}\otimes E_{21}q^{1/2(E_{22}-E_{33})}+q^{-1/2(E_{11}-E_{33})}\otimes E_{31} \tag{2.6b}$$

for the composite generators E_{13} and E_{31} [see Eqs. (7.5) and (7.6) of Ref. 9] and the corresponding q-binomial and q-trinomial expansions[9] of the generator powers.

For the maximal isospin state $|aby_{\rm m}i_{\rm m}i_{\rm m}\rangle_q$ with $y_{\rm m}=1/3(a-b)$, $i_{\rm m}=1/2(a+b)$, $z_{\rm m}=1/2(b-a)$, the maximal projector of the quantum algebra $u_q(3)$ accepts the following form:

$$\mathscr{P}^{(ab)q}_{y_{\rm m}i_{\rm m}i_{\rm m},y_{\rm m}i_{\rm m}i_{\rm m}}=\sum_{n_1n_2n_3}\frac{(-1)^{n_1+n_2+n_3}q^{n_3}[a+1]![b+1]![a+b+2]!}{[n_1]![a+n_1+1]![n_2]![b+n_2+1]![n_3]![a+b+n_3+2]!}\times E_{31}^{n_1}E_{13}^{n_1}E_{21}^{n_3}E_{12}^{n_3}E_{23}^{n_2}E_{32}^{n_2}. \tag{2.7}$$

Contrary to the SU(3) case, we cannot go immediately from the highest weight projector[9] to (2.7) by a simple relabeling of subscripts in generators, but we need to check the identities

$$E_{13}\mathscr{P}^{(ab)q}_{i_{\max},i_{\max}}=E_{32}\mathscr{P}^{(ab)q}_{i_{\max},i_{\max}}=\mathscr{P}^{(ab)q}_{i_{\max},i_{\max}}E_{31}=\mathscr{P}^{(ab)q}_{i_{\max},i_{\max}}E_{23}=0, \tag{2.8}$$

using the generator transposition formulas, similarly as it was done in Ref. 9.

We may write a more universal projection operator as

$$\mathscr{P}^{(ab)q}_{y_{\rm m}i_{\rm m}i_{\rm m};yii}=\langle aby_{\rm m}i_{\rm m}i_{\rm m}|E_{13}^{a+z-i}E_{32}^{b-z-i}|abyii\rangle_q^{-1}\mathscr{P}^{(ab)q}_{y_{\rm m}i_{\rm m}i_{\rm m},y_{\rm m}i_{\rm m}i_{\rm m}}E_{13}^{a+z-i}E_{32}^{b-z-i}\mathscr{P}^{i,q}_{ii} \tag{2.9a}$$

$$=d_3[ab]\left(\frac{[a]![b]![a+b+1]![i+z]![i-z]![a+z+i+1]![b-z+i+1]!}{[2i+1]![a+z-i]![b-z-i]!}\right)^{1/2}\times\sum_{n_1n_2n_3}\frac{(-1)^{n_1+n_2}q^{(n_1+1)n_3}[a+b+n_1+n_2+n_3+2]!}{[n_1]![a+n_1+1]![n_2]![b+n_2+n_3+1]![n_3]![a+b+n_1+n_3+2]!}\times\frac{1}{[a+b+n_2+n_3+2]!}E_{21}^{n_3}E_{31}^{n_1}E_{23}^{n_2}E_{13}^{a+z-i+n_1+n_3}E_{32}^{b-z-i+n_2+n_3}\mathscr{P}^{i,q}_{ii} \tag{2.9b}$$

where $d_3[ab]=[a+1][b+1][a+b+2]$ and

$$\mathscr{P}^{i,q}_{ii}=\sum_{n'}\frac{(-1)^{n'}[2i+1]!}{[n']![2i+n'+1]!}E_{21}^{n'}E_{12}^{n'} \tag{2.10}$$

is the maximal projector of $u_q(2)$. For the rearrangement of (2.9a) [as well as (2.7)] to (2.9b), we use the transposition formulas presented in Appendix of Ref. 9, condition $E_{12}\mathscr{P}^{i,q}_{i}=0$, and summation formula (cf. Ref. 34)

$$\sum_s\frac{q^{s(a+b+c)}}{[s]![b-s]![c-s]![a+s]!}=\frac{q^{bc}[a+b+c]!}{[b]![c]![a+b]![a+c]!}. \tag{2.11}$$

By the way, we may also write the weight lowering operator for acting into the maximal isospin state:

$$\widetilde{F}\begin{pmatrix} ab \\ yii \end{pmatrix}|aby_{\rm m}i_{\rm m}i_{\rm m}\rangle_q=|abyii\rangle_q \tag{2.12a}$$

where

$$\widetilde{F}\begin{pmatrix} ab \\ yii \end{pmatrix}=\left(\frac{[2i+1]![a+z-i]![a+z+i+1]![b-z-i]![b-z+i+1]![i-z]!}{[a]![b]![a+b+1]![i+z]!}\right)^{1/2}$$
$$\times\sum_s \frac{q^{-s(2i+s+1)}[i+z+s]!}{[s]![a+z-i-s]![b-z-i-s]![2i+s+1]!}E_{21}^{s}E_{31}^{a+z-i-s}E_{23}^{b-z-i-s}. \tag{2.12b}$$

In accordance with condition (1.7c), we may express the bilinear combinations of isofactors as follows:

$$\sum_{t=1}^{\hat{I}'-i_{\rm m}+i''_{\rm m}+1}\begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (a\ \ b) \\ y'i' & y''i'' & y\ \ i \end{bmatrix}_q^{(3)}\begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (a\ \ b) \\ \hat{y}'\hat{I}' & y''_{\rm m}i''_{\rm m} & y_{\rm m}i_{\rm m} \end{bmatrix}_q^{(3)}$$
$$=\left(\begin{bmatrix} \hat{I}' & i''_{\rm m} & i_{\rm m} \\ i_{\rm m}-i''_{\rm m} & i''_{\rm m} & i_{\rm m} \end{bmatrix}_q^{(2)}\right)^{-1}\sum_{m'}\begin{bmatrix} i' & i'' & i \\ m' & i-m' & i \end{bmatrix}_q^{(2)}$$
$$\times\left\langle \begin{matrix}(a'b')\\ \hat{y}'\hat{I}'i_{\rm m}-i''_{\rm m}\end{matrix}\right|_q\left\langle \begin{matrix}(a''b'')\\ y''_{\rm m}i''_{\rm m}i''_{\rm m}\end{matrix}\right|_q\mathscr{P}^{(ab)q}_{y_{\rm m}i_{\rm m}i_{\rm m};y\ i\ i}\left|\begin{matrix}(a'b')\\ y'i'm'\end{matrix}\right\rangle_q\left|\begin{matrix}(a''b'')\\ y''i''i-m'\end{matrix}\right\rangle_q. \tag{2.13}$$

Although (2.13) provides an overcomplete system of non-orthogonal $u_q(3)$ isofactors, the direct canonical resolution of the multiplicity problem from the triangular system of equations (2.13) (i.e., by means of the Gram–Schmidt process) is not always possible (see Sec. IV).

We expand the powers of generators in (2.9b) when substituted into (2.13) in accordance with coproduct rules.[9] Operators $E_{21}^{n_3}$, $E_{31}^{n_1}$ and $E_{23}^{n_2}$ give only a single term in the coproduct expansion of (2.13) in accordance with formulas (7.9), (7.11) and (7.8) of Ref. 9, respectively, with the operators

$$q^{n_3(E_{11}-E_{22})/2+n_1(E_{11}-E_{33})/2+n_2(E_{22}-E_{33})/2},$$

acting in the space of the second irrep $(a''b'')$. Expansion of E_{13}^{k} $(k=a+z-i+n_1+n_3)$ in accordance with (7.10) of Ref. 9 gives a sum with a single summation parameter, as well as expansion of E_{32}^{l} $(l=b-z-i+n_2+n_3)$ in accordance with (7.9). Moreover, the powers of operators E_{13} and E_{32} acting in the second space are fixed by the shift conditions for the isospin projection and the hypercharge. Thus, the total number of sums (seven) does not exceed the SU(3) case[8] and we may write

$$\sum_t \begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (a\ \ b) \\ y'i' & y''i'' & y\ \ i \end{bmatrix}_q^{(3)} \begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (a\ \ b) \\ \hat{y}'\hat{I}' & y''_{\rm m} i''_{\rm m} & y_{\rm m} i_{\rm m} \end{bmatrix}_q^{(3)}$$

$$= (-1)^{\hat{I}'+i''_{\rm m}-i_{\rm m}} q^{(\hat{I}'-i_{\rm m}+i''_{\rm m})(\hat{I}'-i''_{\rm m}+i_{\rm m}+1)/2} ([i_{\rm m}+i''_{\rm m}-\hat{I}']![i_{\rm m}+i''_{\rm m}+\hat{I}'+1]!)^{1/2} d_3[a\ \ b]$$

$$\times \left(\frac{[a]![b]![i+z]![i-z]![a+z+i+1]![b-z+i+1]!}{[2i+1]![a+z-i]![b-z-i]![a''+b'']!} \right)^{1/2}$$

$$\times \sum_{n_1,n_2,n_3,m'} \frac{(-1)^{n_1+n_2} q^{Q_1} [a+b+n_1+n_2+n_3+2]!}{[n_1]![n_2]![n_3]![a+n_1+1]![b+n_2+n_3+1]!}$$

$$\times \frac{[a+z-i+n_1+n_3]![b-z-i+n_2+n_3]!}{[a+b+n_1+n_3+2]![a+b+n_2+n_3+2]![a''+z''-i+m']!} \begin{bmatrix} i' & i'' & i \\ m' & i-m' & i \end{bmatrix}_q^{(2)}$$

$$\times \frac{1}{[a-a''+v+z'-m'+n_1+n_3]![b''-z''-i+m']![b-b''-z'-v-m'+n_2+n_3]!}$$

$$\times \left\langle \begin{matrix} (a'b') \\ \hat{y}'\hat{I}' i_{\rm m} - i''_{\rm m} \end{matrix} \middle| E_{21}^{n_3} E_{31}^{n_1} E_{23}^{n_2} E_{13}^{a-a''+v+z'-m'+n_1+n_3} E_{32}^{b-b''-z'-v-m'+n_2+n_3} \middle| \begin{matrix} (a'b') \\ y'i'm' \end{matrix} \right\rangle_q$$

$$\times \left\langle \begin{matrix} (a''b'') \\ y''_{\rm m} i''_{\rm m} i''_{\rm m} \end{matrix} \middle| E_{13}^{a''+z''-i+m'} E_{32}^{b''-z''-i+m'} \middle| \begin{matrix} (a''b'') \\ y''i''i-m' \end{matrix} \right\rangle_q , \tag{2.14}$$

where

$$\hat{y}' = y_{\rm m} - y''_{\rm m} = \tfrac{1}{3}(a-b-a''+b'') = \tfrac{1}{3}(a'-b') - v$$

and q-phase

$$\begin{aligned} Q_1 = {} & (n_1+1)n_3 - \tfrac{1}{2}(a''+z''-i+m')(a-a''+2n_1-n_2+n_3) \\ & + \tfrac{1}{2} a''(a-a''+v+z'-m'+n_1+n_3) \\ & + \tfrac{1}{2}(b-b''-z'-v-m'+n_2+n_3)(b''-a''-3z''+m'-i) \\ & - \tfrac{1}{2}(b'-a'-3z'-m')(b''-z''-i+m') \\ & + \tfrac{1}{2}(a''+b'')n_3 + \tfrac{1}{2} a''n_1 - \tfrac{1}{2} b''n_2; \end{aligned} \tag{2.15}$$

$$(b'-a'-3z' = \tfrac{3}{2} y',\ \ b''-a''-3z'' = \tfrac{3}{2} y'')$$

appeared from the above mentioned coproduct expansion of the generator powers, after substituting the proper values of E_{ii}.

We express the matrix elements of the generator powers as follows:[13]

$$\left\langle \begin{matrix} (ab) \\ yim \end{matrix} \middle| E_{21}^n \middle| \begin{matrix} (ab) \\ yim+n \end{matrix} \right\rangle_q = \left(\frac{[i+m+n]![i-m]!}{[i+m]![i-m-n]!} \right)^{1/2}, \tag{2.16}$$

$$\left\langle \begin{matrix}(ab)\\ y'i'm'\end{matrix}\middle| E_{23}^{r}E_{13}^{p-r}\middle|\begin{matrix}(ab)\\ yim\end{matrix}\right\rangle_q = \delta_{z-p/2,z'}\delta_{m+p/2-r,m'}q^{(i+p/2-i')(i+p/2+i'+1)/2-p(i-m)/2-rm} \times\frac{\Gamma[abiz]([p-r]![r]![2i+1])^{1/2}}{\nabla[\frac{1}{2}p,i,i']\Gamma[abi'z']}\begin{bmatrix} i & \frac{1}{2}p & i' \\ m & \frac{1}{2}p-r & m'\end{bmatrix}^{(2)}_{q^{-1}}, \tag{2.17a}$$

$$\left\langle \begin{matrix}(ab)\\ y'i'm'\end{matrix}\middle| E_{31}^{r}E_{32}^{p-r}\middle|\begin{matrix}(ab)\\ yim\end{matrix}\right\rangle_q = \delta_{z+p/2,z'}\delta_{m+p/2-r,m'}(-1)^{i+p/2-i'+r} \times q^{(i+p/2-i')(i-p/2+i'+1)/2-p(i'-m')/2-r(m'+1)} \times\frac{\Gamma[abi'z'](p-r]![r]![2i+1])^{1/2}}{\nabla[\frac{1}{2}p,i,i']\Gamma[abiz]}\begin{bmatrix} i & \frac{1}{2}p & i' \\ m & \frac{1}{2}p-r & m'\end{bmatrix}^{(2)}_{q}, \tag{2.17b}$$

where the Clebsch–Gordan coefficients of $u_q(2)$ are presented in Refs. 13, 35, 36, and

$$\nabla[abc]=\left(\frac{[a+b-c]![a-b+c]![a+b+c+1]!}{[b+c-a]!}\right)^{1/2}, \tag{2.18}$$

$$\Gamma[abiz]=\left(\frac{[i+z]![a+z-i]![a+z+i+1]!}{[i-z]![b-z-i]![b-z+i+1]!}\right)^{1/2}. \tag{2.19}$$

The last matrix element on the rhs of Eq. (2.14) may be expressed without sum as follows:

$$\begin{aligned}&\left\langle \begin{matrix}(a''b'')\\ y''_{\rm m}i''_{\rm m}i''_{\rm m}\end{matrix}\middle| E_{13}^{a''+z''-i+m'}E_{32}^{b''-z''-i+m'}\middle|\begin{matrix}(a''b'')\\ y''i''i-m'\end{matrix}\right\rangle_q \\ &\quad=\frac{[a''+z''-i+m']![b''-z''-i+m']!}{[i-z''-m']!} \\ &\quad\times\left(\frac{[i''-z'']![a'']![b'']!}{[i''+z'']![a''+z''-i'']![b''-z''-i'']!}\right. \\ &\quad\left.\times\frac{[a''+b''+1]![2i''+1][i''+i-m']!}{[a''+z''+i''+1]![b''-z''+i''+1]![i''-i+m']!}\right)^{1/2}.\end{aligned} \tag{2.20}$$

Finally, the total number of sums in (2.14) is seven, including two isospin-type parameters of the intermediate states (which appear after acting with a power of E_{32} into $|a'b'\rangle_q$, but before acting with $E_{31}^{n_1}$) and a single sum of the $u_q(2)$ Clebsch–Gordan coefficient, appearing in accordance with Eq. (2.17a).

III. ISOFACTORS CHARACTERIZED BY THE MAXIMAL NULL SPACE

The three sums vanish in Eq. (2.14) for the canonical tensor operators, characterized by the maximal null space, when $\hat{I}' = i_{\rm m} - i''_{\rm m} \geqslant |\hat{z}'|$ [here $\hat{z}' \equiv 1/2(b'-a'+v)$] and label t accepts the single value $t=1$. Hence, we obtain

$$\begin{aligned}
&\left[\begin{matrix}\overset{t=1}{(a'b')} & (a''b'') & (ab)\\ y'i' & y''i'' & yi\end{matrix}\right]^{(3)}_{q}\left[\begin{matrix}\overset{t=1}{(a'b')} & (a''b'') & (ab)\\ \hat{y}'\hat{I}' & y''_{\mathrm{m}}i''_{\mathrm{m}} & y_{\mathrm{m}}i_{\mathrm{m}}\end{matrix}\right]^{(3)}_{q}\\
&\quad=\mathscr{N}_{(a''b'')}[a'b';ab]\,\frac{([a+1][b+1][a+b+2])^{1/2}}{\nabla[ii'i'']\Gamma[a'b'i'z']R[a''b''i''z'']}\\
&\quad\times\left(\frac{[2i'+1][i''-z'']![a+z+i+1]![b-z+i+1]![i+z]![i-z]!}{[i''+z'']![a+z-i]![b-z-i]!}\right)^{1/2}\\
&\quad\times\sum_{n_1,n_2,m',j'}\frac{(-1)^{(b''+v-b+z'+m'+n_2)/2-i'+j'+n_1}q^{Q_2}[2j'+1]}{[n_1]![n_2]![a+n_1+1]![b+n_2+1]![a+b+n_1+2]![a+b+n_2+2]!}\\
&\quad\times\frac{[a+b+n_1+n_2+2]![a+z-i+n_1]![b-z-i+n_2]!}{[i-m'-z'']![i''-i+m']![a'+a''-a-v-n_1]!}\\
&\quad\times\frac{[i''+i-m']![a-a''+v+n_1]![b'-a''+a+v+n_1+1]!}{\nabla^2[\frac{1}{2}(a-a''+v+z'-m'+n_1),i_{\mathrm{m}}-i''_{\mathrm{m}}+\frac{1}{2}(n_1+n_2),j']}\\
&\quad\times\frac{\Gamma^2[a',b',j',\frac{1}{2}(b-b''-v+z'-m'+n_2)]}{\nabla^2[\frac{1}{2}(b-b''-v-z'-m'+n_2),j',i']}
\end{aligned}\tag{3.1}$$

where the summation parameters satisfy the conditions[8]

$$\max(0,a''-a-v)\leqslant n_1\leqslant a'+a''-a-v,\quad 0\leqslant n_2\leqslant b'+b''-b+v,$$

$$i-i''\leqslant m'\leqslant\min(i',i-z''),$$

$$\max\{\tfrac{1}{2}(b-b''-v-z'+m'+n_2),\tfrac{1}{2}|b-b''-v+z'-m'+n_2|\}\leqslant j',$$

$$j'\leqslant\min\{b'-\tfrac{1}{2}(b-b''-v+z'-m'+n_2),\tfrac{1}{2}(b-b''-v-z'-m'+n_2)+i'\}$$

and are restricted by the non-negative integer values of the denominator q-factorial arguments. Besides, in (3.1) notations (2.18) and (2.19), together with those presented below, are used:

$$\begin{aligned}
&\mathscr{N}_{(a''b'')}[a'b';ab]\\
&\quad=\left(\frac{[a+1]![b+1]![a+b+2]![2i_{\mathrm{m}}-2i''_{\mathrm{m}}+1]![a'+\hat{z}'-\hat{I}']![b'-\hat{z}'-\hat{I}']!}{[\hat{I}'+\hat{z}']![\hat{I}'-\hat{z}']![a'+\hat{z}'+\hat{I}'+1]![b'-\hat{z}'+\hat{I}'+1]!}\right)^{1/2}
\end{aligned}\tag{3.2a}$$

$$=\left(\frac{[a+1]![b+1]![a+b+2]![a'+a''-a-v]![b'+b''-b+v]![a+b-a''-b''+1]!}{[a-a''+v]![b-b''-v]![a'-b''+b-v+1]![b'-a''+a+v+1]!}\right)^{1/2},\tag{3.2b}$$

$$R[abiz]=\left(\frac{[a+z-i]![a+z+i+1]![b-z-i]![b-z+i+1]!}{[2i+1][a]![b]![a+b+1]!}\right)^{1/2}, \tag{3.3}$$

$$\begin{aligned}Q_2=&(n_1-n_2)(i+z''-m')-\tfrac{1}{2}(a''+z''-i+m')(a-a'')-\tfrac{1}{2}(b''-z''-i+m')(\tfrac{3}{2}y'-m')\\&+\tfrac{1}{2}(\tfrac{3}{2}y''-i+m')(b-b''-v-z'-m')+\tfrac{1}{2}a''(a-a''+v+z'-m')+\tfrac{1}{2}(i'+i''-i)\\&\times(i-i'+i''+1)-(i+1)(i'-m')+j'(j'+1)-\tfrac{1}{4}(b-b''-v-z'+m'+n_2)\\&\times(b-b''-v-z'+m'+n_2+2)-2n_1z''.\end{aligned} \tag{3.4}$$

Notation (3.3) is also used in the expression[13] for the stretched $u_q(3)$ isofactors:

$$\begin{aligned}\begin{bmatrix}(a'b') & (a''b'') & (a'+a'',b'+b'')\\ (z')i' & (z'')i'' & (z'+z'')i\end{bmatrix}^{(3)}_q&=q^{(a'b''-a''b')/2+z'(a''+b'')-z''(a'+b')}\\&\times\frac{R[a'+a'',b'+b'',i,z'+z'']}{R[a'b'i'z']R[a''b''i''z'']}\begin{bmatrix}i' & i'' & i\\ z' & z'' & z\end{bmatrix}^{(2)}_q,\end{aligned} \tag{3.5}$$

which, of course, corresponds to a multiplicity-free case of (3.1).

The following particular case of (3.1) with $i'=i-i''_{\mathrm{m}}$ is especially important for the solution of its normalization problem:

$$\begin{aligned}&\begin{bmatrix}(a'b') & \overset{t=1}{(a''b'')} & (ab)\\ y'i-i''_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & yi\end{bmatrix}^{(3)}_q\begin{bmatrix}(a'b') & \overset{t=1}{(a''b'')} & (ab)\\ \hat{y}'i_{\mathrm{m}}-i''_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & y_{\mathrm{m}}i_{\mathrm{m}}\end{bmatrix}^{(3)}_q\\&=\left(\frac{[2i'+1]![i+z]![i-z]![a'+z'+i']![b'-z'-i']![a+z+i+1]![b-z+i+1]!}{[2i+1]![i'+z']![i'-z']![a+z-i]![b-z-i]![a'+z'+i'+1]![b'-z'+i'+1]!}\right)^{1/2}\\&\times q^{a''(a+z-i)/2-b''(b-z-i)/2}(d_3[ab])^{1/2}\mathscr{N}_{(a''b'')}[a'b';ab]\mathscr{D}^2\begin{pmatrix}q,t=1\\ a''b''\end{pmatrix}[a'b';ab],\end{aligned} \tag{3.6}$$

where

$$\begin{aligned}&\mathscr{D}^2\begin{pmatrix}q,t=1\\ a''b''\end{pmatrix}[a'b';ab]\\&=\mathscr{D}^2\begin{pmatrix}q^{-1},t=1\\ b''a''\end{pmatrix}[b'a';ba]\end{aligned} \tag{3.7a}$$

$$=\sum_{n_1,n_2}\frac{(-1)^{n_1+n_2}q^{a''n_1-b''n_2}[a+b+n_1+n_2+2]!}{[n_1]![n_2]![a+n_1+1]![b+n_2+1]![a+b+n_1+2]![a+b+n_2+2]!}$$

$$\times\frac{[a-a''+v+n_1]![b'-a''+a+v+n_1+1]![b-b''-v+n_2]![a'-b''+b-v+n_2+1]!}{[a'+a''-a-v-n_1]![b'+b''-b+v-n_2]![a+b-a''-b''+n_1+n_2+1]!}. \tag{3.7b}$$

Taking $i=i_{\mathrm{m}}, y=y_{\mathrm{m}}$, we obtain square of isofactor

$$\begin{bmatrix} (a'b') & \overset{t=1}{(a''b'')} & (ab) \\ \hat{y}'i_{\mathrm{m}}-i''_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & y_{\mathrm{m}}i_{\mathrm{m}} \end{bmatrix}^{(3)}_{q} = \mathscr{N}_{(a''b'')}[a'b';ab]\mathscr{D}\begin{pmatrix} q,t=1 \\ a''b'' \end{pmatrix}[a'b';ab]. \tag{3.8}$$

Now (3.8) may be inserted into the lhs of (3.1) to express the normalized isofactor of the maximal null space case, but some reasoning was necessary for choice of the sign of the boundary canonical isofactor. Acceptance of the separate isofactors (3.8) being positive requires use of the supplementary phase factors $(-1)^{b'-b}$ or $(-1)^{v}$ for the multiplicity-free[13] isofactors of $u_q(3)$ (with parameter $b''=0$, or in the semistretched case, respectively). We see that the denominator q-factorials $[a-a''+v]!$ and $[b-b''-v]!$, restricting the regions of non-vanishing for (3.1) and (3.6)–(3.8), cancel and the matrix elements of the $u_q(3)$ canonical tensor operator with $t=1$ may be obtained by an analytical continuation procedure and may exist also for $a-a''+v$ or $b-b''-v$ negative. Really, the sum over n_1,n_2,m',j' on the rhs of (3.1) is restricted only by the triangular and betweenness conditions (1.1d), but the rhs of (3.7b) is indefinite for negative $a-a''+v$ or $b-b''-v$. The latter problem was escaped in Ref. 8 for the SU(3) isofactors, after the corresponding double sum (at first rearranged into the $G^1_{b'+b''-b+v}$-function) has been transformed by means of its reduction formulas[6,7] into the $G^1_{b''}$-function.[5,7,25]

We tried to replace some ratios of q-factorials in the first and the last rows of Eq. (3.7b) separately by the q-analogs of the Vandermonde formulas,[34] in analogy with (3.17) of Ref. 8, but we failed to transform the double sum (3.7b) into another form, related to the denominator polynomials[5–7] of the SU(3) maximal null space tensor operators.[25] Unfortunately, after summation over n_1 (or n_2), it was impossible to take the sum over the second original summation parameter n_2 (or n_1) because of the non-balanced (i.e., non-correlated with the difference of the factorial argument sums in numerator and denominator) q-power, unless $b''=0$ (or $a''=0$).

In order to obtain more convenient expressions for the denominator function $\mathscr{D}^2\left(\begin{smallmatrix} q,t=1 \\ a''b'' \end{smallmatrix}\right)$, let us consider another product (trivial bilinear combination) of isofactors, corresponding to the maximal null space tensor operator:

$$\begin{bmatrix} (a'b') & \overset{t=1}{(a''b'')} & (ab) \\ y'_{\mathrm{m}}i'_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & \hat{y}i'_{\mathrm{m}}-i''_{\mathrm{m}} \end{bmatrix}^{(3)}_{q}\begin{bmatrix} (a'b') & \overset{t=1}{(a''b'')} & (ab) \\ \hat{y}'i_{\mathrm{m}}-i''_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & y_{\mathrm{m}}i_{\mathrm{m}} \end{bmatrix}^{(3)}_{q}. \tag{3.9}$$

Formula (3.1) gives a triple sum for (3.9), which is not preferable to (3.7b). Otherwise, an alternative expression (3.15) of Ref. 8, together with the Vandermonde formula, gives a double sum in the corresponding denominator function of the SU(3) maximal null space tensor operator. Hence, it is expedient to derive a q-analog of the projection operator (3.3b) of Ref. 8:

$$\mathscr{P}^{(ab)q}_{yii;y_{\rm m}i_{\rm m}i_{\rm m}}$$

$$=\widetilde{F}\begin{pmatrix} ab \\ yii \end{pmatrix}\mathscr{P}^{(ab)q}_{y_{\rm m}i_{\rm m}i_{\rm m};y_{\rm m}i_{\rm m}i_{\rm m}} \tag{3.10a}$$

$$=d_3[ab]([a]![b]![a+b+1]![2i+1]![i-z]![a+z-i]!$$

$$\times[a+z+i+1]![b-z-i]![b-z+i+1]!/[i+z]!)^{1/2}$$

$$\times\sum_{n_1n_2ur}\frac{(-1)^{n_1+n_2}q^{u(i+z+1)+r(a-2i+n_1-r)}[a+b+n_1+n_2-u+2]!}{[u]![a+n_1-u+1]![n_2-u]![b+n_2+1]![a+b+n_1+2]![a+b+n_2+2]!}$$

$$\times\frac{1}{[b-z-i-r+u]!}\sum_s\frac{q^{-s(a+n_1-u+1)}[i+z+s]!}{[s]![a+z-i-s]![r-s-u]![n_1-r+s]![2i+s+1]!}$$

$$\times E_{21}^rE_{31}^{a+z-i-r+n_1}E_{23}^{b-z-i-r+n_2}E_{13}^{n_1}E_{32}^{n_2}\mathscr{P}^{i_{\rm m},q}_{i_{\rm m}i_{\rm m}}. \tag{3.10b}$$

Formula (3.10b) is obtained, using in (3.10a) our formulas (2.9b), (2.12b), and the generator transposition formulas.[9] The sum over s is more convenient if transformed (cf. Refs. 8 and 34) into

$$\sum_s\ldots=\frac{[i+z]!q^{-(r-u)(a+z-i)}}{[i-z]![n_1-u]![a+z-i-r+n_1]!}$$

$$\times\sum_s(-1)^s\frac{q^{s(i+z-n_1+r)}[i-z+s]![a+z-i+n_1-s-u]!}{[s]![a+z-i-s]![r-s-u]![2i+s+1]!}. \tag{3.11}$$

However, the coproduct expansions (2.6a) and (2.6b) of the E_{31} and E_{13} powers in the matrix elements of projector (3.10b) give some additional sums in the expression of (3.9) to compare with the SU(3) case [see Eq. (3.3b) of Ref. 8]. An expression without additional sums may be obtained for the following bilinear combination of isofactors:

$$\sum_t\begin{bmatrix}(a'b') & \overset{t}{(a''b'')} & (ab)\\ y'_{\rm m}i'_{\rm m} & y''_{\rm m}i''_{\rm m} & \hat{y}i''_{\rm m}-i'_{\rm m}\end{bmatrix}^{(3)}_q\begin{bmatrix}(a'b') & \overset{t}{(a''b'')} & (ab)\\ y'_{\rm m}i'_{\rm m} & \hat{y}''i_{\rm m}-i''_{\rm m} & y_{\rm m}i_{\rm m}\end{bmatrix}^{(3)}_q. \tag{3.12}$$

After permutation of the both states to be coupled in (3.12), relabeling of the parameters $a',b',y',i'\leftrightarrow a'',b'',y'',i''$, and q-inversion: $q\rightarrow q^{-1}$ (together with an elementary phase factor), product (3.9) may be presented as

$$\begin{bmatrix}(a'b') & \overset{t=1}{(a''b'')} & (ab)\\ y'_{\rm m}i'_{\rm m} & y''_{\rm m}i''_{\rm m} & \hat{y}i'_{\rm m}-i''_{\rm m}\end{bmatrix}^{(3)}_q\begin{bmatrix}(a'b') & \overset{t=1}{(a''b'')} & (ab)\\ \hat{y}'i_{\rm m}-i''_{\rm m} & y''_{\rm m}i''_{\rm m} & y_{\rm m}i_{\rm m}\end{bmatrix}^{(3)}_q$$

$$=(-1)^{b''+v}q^{-Q_3}\left(\frac{d_3[ab][a'+b'+1]}{d_3[a'b'][2i'_{\rm m}-2i''_{\rm m}+1]}\right)^{1/2}\mathscr{N}_{(a''b'')}[a'b';ab]$$

$$\times\mathscr{N}_{(a''b'')}[ba;b'a']\mathbf{D}^2\begin{pmatrix}q,t=1\\ a''b''\end{pmatrix}[a'b';ab] \tag{3.13}$$

with

$$\mathbf{D}^2\begin{pmatrix} q,t=1 \\ a''b'' \end{pmatrix}[a'b';ab]$$

$$= q^{b''(a'-b''+b-v+2)-a''(b'-a''+a+v+2)}\mathbf{D}^2\begin{pmatrix} q^{-1},t=1 \\ a''b'' \end{pmatrix}[ba;b'a'] \tag{3.14a}$$

$$= (-1)^{b'-b+v}q^{a''(a''-a-v-1)-b''(b''-b+v-1)+b'-b+v}$$
$$\times\frac{[a'']![b'']![a'-b''+b-v+1]![b'-a''+a+v+1]![b'-a''+v]!}{[b'+b''+v+1]![a'+a''+b-v+2]![b'+b''+a+v+2)]!}$$
$$\times\sum_{s,u}\ \frac{(-1)^{s+u}q^{s(b''-b+v)-u(a''+b-v+2)}[a''+b''-s-u]![s+u]!}{[s]![a-a'+b''+v-s]![b-b'+a''-v-s]![b'-b+v+s]!}$$
$$\times\frac{[a'-b''-v+s]!}{[a'+b'-a''-b''+s+1]![u]![a'+a''-a-v-u]![b'+b''-b+v-u]!}$$
$$\times\frac{[a'+b'+a''+b''-u+2]!}{[b-b'-v+u]![a'+a''-v-u+1]!} \tag{3.14b}$$

and

$$Q_3=\tfrac{1}{2}\,b''(a'-b''+b-v+1)-\tfrac{1}{2}\,a''(b'-a''+a+v+1). \tag{3.15}$$

The factors in the first row of the rhs of Eq. (3.13) are mainly motivated by the symmetry properties of the $u_q(3)$ canonical isofactors, presented in the last section of this paper, but the equivalence question for the denominator functions (3.7b) and (3.14b), including the above presented distribution of q-powers between (3.13) and (3.14b), should be considered separately, unless $q=1$.

Taking into account the generic structure of the $t=1$ isofactors with the extreme shift of $u_q(2)$ irreps, grounded on the pattern calculus[12] principles, the ratio of such isofactors may be expressed as follows:

$$\begin{bmatrix} & \overset{t=1}{} & \\ (a'b') & (a''b'') & (ab) \\ \hat{y}'i_{\mathrm{m}}-i''_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & y_{\mathrm{m}}i_{\mathrm{m}} \end{bmatrix}^{(3)}_{q}\left(\begin{bmatrix} & \overset{t=1}{} & \\ (a'b') & (a''b'') & (ab) \\ y'_{\mathrm{m}}i'_{\mathrm{m}} & y''_{\mathrm{m}}i''_{\mathrm{m}} & \hat{y}i'_{\mathrm{m}}-i''_{\mathrm{m}} \end{bmatrix}^{(3)}_{q}\right)^{-1}$$
$$= (-1)^{b''+v}q^{Q_3}\left(\frac{d_3[a'b'][2i'_{\mathrm{m}}-2i''_{\mathrm{m}}+1]}{d_3[ab][a'+b'+1]}\right)^{1/2}\frac{\mathscr{N}_{(a''b'')}[a'b';ab]}{\mathscr{N}_{(a''b'')}[ba;b'a']}. \tag{3.16}$$

Particularly, the q-power in formula (3.16) is extrapolated from the multiplicity-free isofactors,[13] respectively, with $a=a'+a''-v$, or $b=b'+b''+v$, or $b''=0$, or $a''=0$. The single sums remaining in the corresponding formulas (4.5), (3.4), or (3.16) of Ref. 13 were taken, respectively, by means of the basic generalizations[34] of the Vandermonde, balanced, and Carlson formulas [see, for example, (3.11) and (3.15) of Ref. 13].

However, (3.14b) is also indefinite for $b'-a''+v<0$, or $a'-b''-v<0$ and $a-a''+v<0$. It is evident that the infinities (poles) of the denominator function, appearing together with the negative arguments of the numerator q-factorials, determine the null space for

$$a'-b''-v<0 \quad \text{and} \quad a-a''+v<0 \quad \text{both together} \tag{3.17a}$$

(i.e., $r_{\alpha 1\gamma}<r_{\alpha 2\gamma}$ and $r_{\alpha 1\gamma}<r_{\alpha 3\gamma}$), or

$$b-b''-v<0 \quad \text{and} \quad b'-a''+v<0 \quad \text{both together} \tag{3.17b}$$

(i.e., $r_{1\beta\gamma}<r_{3\beta\gamma}$ and $r_{1\beta\gamma}<r_{2\beta\gamma}$). Otherwise, if the null space situation is excluded, we should use the symmetry relations (3.7a) or (3.14a) of the denominator functions for $b'-a''+v<0$ in order to get expressions without indefinities, unless both $b'-a''+v<0$ and $a-a''+v<0$, when Eq. (3.14b) can be used only together with relation (3.14a). In general, for the fixed rank $(a''b'')$ and shifts $\Delta_1,\Delta_2,\Delta_3$ [see array (1.5b)] of the q-tensor operator $T^{(a''b'')1,q}$, we may choose such a version of the denominator function, where indefinities appear only together with singularities (poles). Hence, the left (generic) isofactor with $t=1$ on the lhs of (3.1) may accept non-zero values, although $i_{\mathrm{m}}-i''_{\mathrm{m}}<0$ and the right isofactor is equal to 0. In this case we get the null space of the $u_q(3):u_q(2)$ extreme projective operator, exceeding the null space of the corresponding canonical tensor operator.

For final fixation of the phases in the symmetry relations (4.2a) and (4.2b), it is expedient to write the following expression of special isofactors:

$$\begin{bmatrix} & {\scriptstyle t=1} & \\ (a'b') & (a''b'') & (ab) \\ y'_{\mathrm{m}}i'_{\mathrm{m}} & \hat{y}''i'' & y_{\mathrm{m}}i_{\mathrm{m}} \end{bmatrix}^{(3)}_{q}$$

$$=\frac{(-1)^{v+i''+\hat{z}''}q^{Q_4}}{\mathscr{D}\begin{pmatrix} q,t=1 \\ a''b'' \end{pmatrix}[a'b';ab]R[a''b''i''\hat{z}'']}$$

$$\times\left(\frac{[a'+b'+1][a+b+2][a+1]![b+1]![a']![b']![i_{\mathrm{m}}+i'_{\mathrm{m}}-i'']![i_{\mathrm{m}}+i'_{\mathrm{m}}+i''+1]!}{[2i'_{\mathrm{m}}+2i''_{\mathrm{m}}+3][a'+a''-v+1]![b'+b''+v+1]![b+a''-v+1]![a+b''+v+1]!}\right)^{1/2}$$

$$\times\frac{([2i''_{\mathrm{m}}+i_{\mathrm{m}}+i'_{\mathrm{m}}-i''+2]![2i''_{\mathrm{m}}+i_{\mathrm{m}}+i'_{\mathrm{m}}+i''+3]!)^{1/2}}{[a'+a''+b-v+2]![b'+b''+a+v+2]!}\begin{bmatrix} i''_{\mathrm{m}}+i_{\mathrm{m}}+1 & i'' & i'_{\mathrm{m}}+i''_{\mathrm{m}}+1 \\ \hat{z}' & \hat{z}'' & \hat{z} \end{bmatrix}^{(2)}_{q}, \tag{3.18}$$

where

$$Q_4=\tfrac{1}{2}\{\hat{z}''(a+b+4)+b''(b-b'-v)-a''(a-a'+v)+i''_{\mathrm{m}}(b'-a'+a''-b'')+v(i''_{\mathrm{m}}-i'_{\mathrm{m}})\},$$

$$\hat{z}'=\tfrac{1}{2}(b'-a'+v), \quad \hat{z}''=\tfrac{1}{2}(b''-a''+v), \quad \hat{z}=\tfrac{1}{2}(b-a-v). \tag{3.19}$$

Formula (3.18) may be derived directly from Eq. (3.15) of Ref. 8 in the $q=1$ case, but for arbitrary q we use projector (3.10b), together with transformations, applied between (3.12) and (3.13), explicit expressions[36] and symmetry properties[35] of the $u_q(2)$ Clebsch–Gordan coefficients.

Let us consider the simplest non-trivial example—special cases of the denominator function (3.7b) and (3.14b) for $a''=b''=1$, $a'=a$, $b'=b$, $v=0$. It may be written as

$$\mathscr{D}^2\begin{pmatrix} q,t=1 \\ 11 \end{pmatrix}[ab;ab]=\frac{f_2[ab]}{[a+b+1][a+b+2][a+b+3][a][a+1][a+2][b][b+1][b+2]} \tag{3.20}$$

in terms of function

$$f_2[ab]=[a+b+3][b+2]([a+b][a+2]-q[a][a+b+1])+[a+b+1][b]([a][a+b+4] -q^{-1}[a+2][a+b+3]) \tag{3.21a}$$

$$=q^{b-a}\{[2][a+b+4][a+b]-q^{-b+1}[a][a+b+4] -q^{-b-3}[a+b][a+2]+[2][a][a+2]\} \tag{3.21b}$$

$$=[2]([a+1][a+b+2]q^{-a-1}+[b+1]^2q^{a+b+2}-q^{a+b+2}-q^{b-a}-q^{-a-b-2}) \tag{3.21c}$$

$$=[2]([a-b][a+b+2]q^{-a-b-2}+[b+1][a+2b+3]-q^{a+b+2}-q^{b-a}-q^{-a-b-2}), \tag{3.21d}$$

where (3.21a) (where 4 is the initial formal total degree of a,b in the $q=1$ case polynomial) is obtained, respectively, from (3.7b) and reduced with considerable efforts to (3.21c) and (3.21d); the corresponding version (3.21b) of Eq. (3.14b) is more simple *ab initio*. Perhaps, function $f_2[ab]$ accepts the simplest form after the multiplication by q^{b+1} and substitution $q\to q^{-1}$ into the normalization factor[19] $g_{\lambda\mu}(q)$ of the canonical tensor operators of rank (1 1):

$$f_2[ab]=[2]\{q^{-a-1}([a+b+3][a]+[b])+q^{a+b+2}[b][b+2]\}. \tag{3.22}$$

It is invariant with respect to interchange $a\leftrightarrow b$, together with substitution $q\to q^{-1}$. For $q=1$, function $f_2[ab]$ turns into the usual quantity, related to the eigenvalue of the SU(3) Casimir operator

$$f_2(ab)=2(a^2+ab+b^2+3a+3b). \tag{3.23}$$

Some blocks of (3.14b) may be associated with the rhs of (2.11), but the rearrangement of the denominator function $\mathbf{D}^2\binom{q,t=1}{a''b''}$ into an analogue of G-function[7,25] is possible only in the $q=1$ case.[37] The requirement of the $q\to q^{-1}$ antisymmetry for the normalization factors makes any straightforward extrapolation of the denominator functions[5,7] of the SU(3) canonical tensor operators rather problematic. The necessity to fix two parameters from subarray (1.5b) in Eqs. (3.7b) and (3.14b) also restricts the possibility of introducing q-analog of G-function (for which fixation of a single parameter is sufficient).

We considered also the properties of Milne's[26] q-analog $[G]^{(3)}_m$ of the introduced by Holman *et al.*[27] invariant G-function (in terms of the well-poised series $W^{(3)}_m$), using Ref. 38 for agreement of notations. [Note that the G-functions, as introduced in Ref. 27, satisfy the complete explicit symmetry under permutations of array (1.5b), but present problems when reducing the total degree of polynomial, i.e., rearranging sums of fractions into polynomials of minimal degree]. However, we didn't find any coincidence of the generic q case even with our Eq. (3.21) or (3.22). Non-balanced and quadratic in the summation parameters q-powers of the well-poised series $[W]^{(3)}_m$, when presented in terms of the symmetrical q-factorials (2.2), appear in contradiction with the requirement of the $q\to q^{-1}$ antisymmetry under conjugation.

IV. SOME SYMMETRIES AND DISTINCTION PROBLEM OF THE SU(3) AND $u_q(3)$ CANONICAL ISOFACTORS

The symmetry properties of the matrix elements of the $u_q(3)$ canonical tensor operators should be consistent with the symmetry properties of the SU(3) canonical isofactors[1,8] (cf. also Ref. 30) and include the corresponding q-factors.[29] We prefer to use the SU(3) conjugation relation

$$|abyii_z\rangle_q^* = (-1)^{a+b+z+i_z}|b,a,-y,i,-i_z\rangle_{q^{-1}} \tag{4.1}$$

[with the phase factor $(-1)^{\rho(3)}$, $\rho(n)=\Sigma_{j=1}^{n}\Sigma_{i=1}^{j}m_{ij}$, in the Gelfand–Tsetlin parameters, cf. Ref. 1] instead of (2.20) of Ref. 30 [which gives the phase factor $(-1)^{a+b}$ if applied twice]. The $u_q(3)$ unit tensor operator conjugation and transposition (Hermitian) properties give the following $S_2\times S_2$ symmetry of isofactors:

$$\begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (ab) \\ y'i' & y''i'' & yi \end{bmatrix}_q^{(3)} = (-1)^{t-1+i'+i''-i}\begin{bmatrix} (b'a') & \overset{t}{(b''a'')} & (ba) \\ -y'i' & -y''i'' & -yi \end{bmatrix}_{q^{-1}}^{(3)} \tag{4.2a}$$

$$= (-1)^{a''+b''+v+t-1+i''-z''}q^{-3y''/2} \times \left(\frac{[2i'+1]d_3[ab]}{[2i+1]d_3[a'b']}\right)^{1/2}\begin{bmatrix} (ba) & \overset{t}{(a''b'')} & (b'a') \\ -yi & y''i'' & -y'i' \end{bmatrix}_{q^{-1}}^{(3)} \tag{4.2b}$$

together with q-inversion. Dependencies of the phase factors on the basis labels are the same as for other external labeling schemes of SU(3) isofactors[22,23,39] [e.g., labeled by means of SU(3) invariant operators[22,39] in the SU(3)⊗SU(3) enveloping algebra] and for the multiplicity-free isofactors[13] of $u_q(3)$. Dependence of the phase factors on the multiplicity label t is completely determined by the number $t-1$ of the self-adjoined minimal null space operators in the canonical tensor operator[1,8,30,33] under consideration, but the total phase factors in (4.2a) and (4.2b) are consistent with (3.18), as well as with (4.1). In accordance with (4.2a) or (4.2b), the SU(3) canonical isofactors with the sign change and coinciding after permutation parameters should be equal to 0.

However, the phase factors, obtained by extrapolation from the matrix elements of the elementary self-adjoined tensor operators and presented in Eq. (2.16b) of Ref. 8, should be corrected, as well as the phase factors of the SU(3) 3-j coefficients.[30] Of course, some alternatives in the phase choice are possible for different phase systems, but the conjugation properties of the evidently non-vanishing SU(3) isofactors

$$\begin{bmatrix} \overset{t=1}{(a'a')} & (a''a'') & (aa) \\ 0i_{\mathrm{m}}-i''_{\mathrm{m}} & 0i''_{\mathrm{m}} & 0i_{\mathrm{m}} \end{bmatrix}^{(3)} \quad (a\geqslant a'') \tag{4.3a}$$

[see Eq. (3.8)] should not contradict with phase factor in Eq. (4.2a). Especially, the phase factor asymmetry with respect to the permutation $a'\leftrightarrow b'$, $a''\leftrightarrow b''$, $a\leftrightarrow b$ [contrary to proposition (4.11) of Ref. 30] cannot be allowed, because it sometimes induces improper sign changes of the conjugation invariant canonical isofactors or 3-j coefficients, e.g., for the triplet of irreps (5 5), (3 3), and (4 4) with the shifts $\Delta_1=2$, $\Delta_2=3$, $\Delta_3=4$ and the operator pattern $\Gamma_1=(_5{}^2{}_0)$ of the rank [6 3 0] tensor operator in the partition-type notations. Besides, for this triplet (and in the all cases with $\Delta_1\neq\Delta_3$) the use of $\Gamma_1=(_0{}^{-2}{}_{-5})$ as multiplicity label in the coproduct $[0,-5,-10]\otimes[0,-3,-6]\rightarrow$

$[-4,-8,-12]$ decomposition is incompatible with condition (2.11) of Ref. 30 between the weights and shifts. The conjugation of irreps (in the partition-type notations) interchanges the order and signs of shifts, but formal conjugation of the operator pattern changes only the signs of shifts. Of course, the equivalence relation $\Gamma_1 \cong (_6{}^4{}_1) \neq (_5{}^2{}_0)$ (used together with $[0,-3,-6] \cong [6,3,0]$) does not improve the situation, but the operator pattern $(_6{}^4{}_1)$ is consistent with the transposed triplet of irreps (4 4), (3 3), and (5 5), as well as the general Γ_1 is consistent with the triplet $(ba)\otimes(a''b'') \rightarrow (b'a')$.

Otherwise, the phase factor $(-1)^{a''+b''+v} = (-1)^{a'-b'-a+b}$ in (4.2b) is determined by explicit isofactors (3.18) and does not contradict with the explicit multiplicity-free isofactors[13] after correlation of the fixed signs of the corresponding boundary cases. It is also consistent with the vanishing properties of special SU(3) isofactors

$$\begin{bmatrix} & \overset{t=1}{} & \\ (ba) & (a''b'') & (ab) \\ -y_{\mathrm{m}} i_{\mathrm{m}} & \hat{y}'' i'' & y_{\mathrm{m}} i_{\mathrm{m}} \end{bmatrix}^{(3)}, \tag{4.3b}$$

[with $\hat{y}'' = 2y_{\mathrm{m}}$, $i'' \geqslant |\frac{1}{2}(b''-a''+v)| = |b-a-v)|$], corresponding to zeros of the Clebsch–Gordan coefficients of SU(2) on the rhs of Eq. (3.18), related in frames of the Regge symmetry to the SU(2) Wigner coefficients with equal to 0 projections of angular momentum. In its turn, the q-power in (3.14a) may be found using the general version of (4.2b), together with (3.18).

Using elementary $u_q(3)$ Wigner–Clebsch–Gordan coefficients for the coupling $(b'''a''')\otimes(a'''b''') \rightarrow (0\ 0)$ [which are consistent with (4.2b) in the $a=b=0$ case], together with the phase factor $(-1)^{a'+a''+a'''}$, we may introduce the $u_q(3)$ 3-j coefficients (cf. Refs. 30 and 40)

$$\begin{pmatrix} & \overset{t}{} & \\ (a'b') & (a''b'') & (a'''b''') \\ y'i'i'_z & y''i''i''_z & y'''i'''i'''_z \end{pmatrix}^{(3)}_{q} = (-1)^{\psi+a'+a''+b'''+z'''+i'''_z} q^{-(3y'''+i'''_z)/2} \left(\frac{[2]}{d_3[a'''b''']} \right)^{1/2} \times \begin{bmatrix} & \overset{t}{} & \\ (a'b') & (a''b'') & (b'''a''') \\ y'i' & y''i'' & -y'''i''' \end{bmatrix}^{(3)}_{q} \begin{bmatrix} i' & i'' & i''' \\ i'_z & i''_z & -i'''_z \end{bmatrix}^{(2)}_{q} \tag{4.4}$$

for coupling of three irreps $(a'b')\otimes(a''b'')\otimes(a'''b''') \rightarrow (0\ 0)$. In accordance with Pluhař *et al.*[39] and Biedenharn *et al.*[30] (see Sec. V) for $\psi=0$ or v we obtain coinciding (but not equivalent with that presented in Ref. 30) conjugation and transposition $1 \leftrightarrow 3$ phase factors $(-1)^{v+t-1}$ [here $v = \frac{1}{3}(a'+a''+a'''-b'-b''-b''')$] of the $u_q(3)$ 3-j coefficients (together with the q-inversion $q \rightarrow q^{-1}$ in the both cases). However, these phase factors are different, if $\psi = a'+a''+a'''$ or $b'+b''+b'''$. Note, that our self-consistent conjugation phase factor (4.1) is sufficient for motivation (but, of course, not for the proof) of the phase factors in (4.2a) and (4.2b) in the $t=1$ case.

There are two different possible approaches to the permutations $1 \leftrightarrow 2$ or $1 \leftrightarrow 3$ in the canonical isofactors and 3-j coefficients of $u_q(3)$ or SU(3). Extending results discussed in Sec. VI and the conclusion of Ref. 22 about three versions of the canonical labeling, we may write explicitly also the relations between the isofactors with the permuted first and second irreps or the permuted and conjugated third and second irreps:

$$\begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (ab) \\ y'i' & y''i'' & yi \end{bmatrix}^{(3)}_{q} = (-1)^{\varphi_{12}+t-1+i'+i''-i} \begin{bmatrix} \overset{t}{(a''b'')} & (a'b') & (ab) \\ y''i'' & y'i' & yi \end{bmatrix}^{(3)}_{q^{-1}} \tag{4.5a}$$

$$= (-1)^{\varphi_{32}+t-1+i'+z'} q^{3y'/2} \left(\frac{[2i''+1]d_3[ab]}{[2i+1]d_3[a''b'']} \right)^{1/2} \times \begin{bmatrix} (a'b') & (ba) & \overset{t}{(b''a'')} \\ y'i' & -yi & -y''i'' \end{bmatrix}^{(3)}_{q^{-1}}, \tag{4.5b}$$

but in this case we are also transposing the multiplicity label t of the tensor operator of rank $(a''b'')$, together with selection rules (1.7). Hence, this operation means transition to a labeling scheme[22] different from the canonical one, similar to transition between two versions of the paracanonical[22,23] labeling or between six versions of the pseudocanonical[22] labeling. We are not able to specify phases φ_{12} and φ_{32} until we have concrete applications of (4.5a) and (4.5b) with fixed phase systems of these new labeling schemes.

Invariance in the absolute value of SU(3) 3-j coefficients under transposition of the irrep parameters, without special attachment to any definite labeling scheme, was usual according to de Swart,[40] although Derome[32] warned care should be taken when some transposed irreps are equivalent. Transposition of the isofactor parameters and multiplicity label, together with the change of its labeling scheme, was also used for the different labeling schemes[22,23] of the SU(3) isofactors and may be used without restriction (but with some distrust if irreps before and after transposition coincide) for isofactors of arbitrary non-multiplicity-free group, derived by means of the definite Gram–Schmidt process. Similar to any transformation of an arbitrary vector together with its coordinate system, these two dual operations both together give an identity (up to a possible sign change) and always may be associated[30] with the one-dimensional irrep of S_3, although the proof presented in Ref. 30 is unquestionable only when the below-discussed distinctive (splitting) conditions (factually always associated with a definite Gram–Schmidt process) are not spoiled. Nevertheless, it is not evident how the operations of different nature (4.2a), (4.2b), (4.5a), and (4.5b) (which leave invariant or change the labeling scheme) may be joined into a single representation of S_3, since unambiguous Derome's[32] character analysis of the S_3 or S_2 irreducible structure cannot be applied to relations (4.5a) or (4.5b) [unlike as to Eqs. (4.2a) or (4.2b)] (neither zeros of isofactors may be predicted).

Otherwise, instead of Eq. (4.5a) or (4.5b), we may write the numerical symmetry relations[29,30]

$$\begin{bmatrix} (a'b') & \overset{t}{(a''b'')} & (ab) \\ y'i' & y''i'' & yi \end{bmatrix}^{(3)}_{q} = \sum_{t'} B_{t,t'} (-1)^{i'+i''-i} \begin{bmatrix} (a''b'') & \overset{t'}{(a'b')} & (ab) \\ y''i'' & y'i' & yi \end{bmatrix}^{(3)}_{q^{-1}}, \tag{4.6a}$$

$$= \sum_{t''} \widetilde{B}_{t,t''} (-1)^{i'+z'} q^{3y'/2} \left(\frac{[2i''+1]d_3[ab]}{[2i+1]d_3[a''b'']} \right)^{1/2} \times \begin{bmatrix} (a'b') & \overset{t''}{(ba)} & (b''a'') \\ y'i' & -yi & -y''i'' \end{bmatrix}^{(3)}_{q^{-1}}, \tag{4.6b}$$

preserving the canonical (or other fixed) labeling scheme. When irreps before and after transposition coincide, the orthogonal (unitary) expansion matrices $B_{t,t'}$ and/or $\widetilde{B}_{t,t''}$ are representation matrices[32,41] with definite S_2 or S_3 irreducible (or reducible) structure, similar to the antidiagonal transition matrices in the case of the odd permutations for the external labeling scheme of Ref. 39. (Note that for isofactors of some groups[32] the two-dimensional irreducible representation of S_3 may also appear.)

As the simplest situation with non-trivial transition matrices $B_{t,t'}$ and $\widetilde{B}_{t,t''}$, the following example may be considered: In agreement with the presented-above and transposed conditions (1.7b) and (1.7c) and tabulated[19] expressions of the $u_q(3)$ canonical tensor operators, we may write the following evident relations:

$$\begin{bmatrix} & \overset{t=2}{} & \\ (2\ \ 1) & (1\ \ 1) & (2\ \ 1) \\ \frac{1}{3}\ \frac{3}{2} & 00 & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} \neq 0, \quad \begin{bmatrix} & \overset{t=2}{} & \\ (2\ \ 1) & (1\ \ 1) & (2\ \ 1) \\ \frac{1}{3}\ \frac{3}{2} & 01 & \frac{1}{3}\ \frac{1}{2} \end{bmatrix}^{(3)}_{q} = 0, \tag{4.7a}$$

$$\begin{bmatrix} & \overset{t=2}{} & \\ (1\ \ 1) & (2\ \ 1) & (2\ \ 1) \\ 00 & \frac{1}{3}\ \frac{3}{2} & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} = 0, \quad \begin{bmatrix} & \overset{t=2}{} & \\ (1\ \ 1) & (2\ \ 1) & (2\ \ 1) \\ 01 & \frac{1}{3}\ \frac{3}{2} & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} \neq 0, \tag{4.7b}$$

when for a ''transposed'' canonical labeling scheme we obtain

$$\begin{bmatrix} \overset{t=2}{} & & \\ (2\ \ 1) & (1\ \ 1) & (2\ \ 1) \\ \frac{1}{3}\ \frac{3}{2} & 00 & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} = 0, \quad \begin{bmatrix} \overset{t=2}{} & & \\ (2\ \ 1) & (1\ \ 1) & (2\ \ 1) \\ \frac{1}{3}\ \frac{3}{2} & 01 & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} \neq 0, \tag{4.7c}$$

$$\begin{bmatrix} \overset{t=2}{} & & \\ (1\ \ 1) & (2\ \ 1) & (2\ \ 1) \\ 00 & \frac{1}{3}\ \frac{3}{2} & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} \neq 0, \quad \begin{bmatrix} \overset{t=2}{} & & \\ (1\ \ 1) & (2\ \ 1) & (2\ \ 1) \\ 01 & \frac{1}{3}\ \frac{3}{2} & \frac{1}{3}\ \frac{3}{2} \end{bmatrix}^{(3)}_{q} = 0. \tag{4.7d}$$

Hence, we verify that even 2×2 matrix $B_{t,t'}$ is non-diagonal. A similar situation [and non-diagonal matrix $B_{t,t'}$ in (4.6a)] occurs for the $u_q(3)$ canonical isofactors with $(a''b'')=(1\ 1)$, $(a'b')=(a\ \ b)$, $a>1$, $b\geqslant 1$ or $a\geqslant 1$, $b>1$, with exception of the $a=b$ case for SU(3).

Favorably for the SU(3) and $u_q(3)$ canonical labeling scheme (but never for the non-trivial cases of the paracanonical[22,23] and some other labeling schemes), these expansion matrices $B_{t,t'}$ are usually diagonal for an elementary transposition (odd permutation) of the coinciding irreps in the canonical isofactors and always diagonal (what will be proved below) when the all three irreps in the canonical 3-j coefficient of SU(3) or $u_q(3)$ are equivalent. Otherwise, the antidiagonal form of the expansion matrices for the odd permutations of the SU(3) isofactors in the labeling scheme of Ref. 25 ensures the appearance of the two-dimensional reducible representations and solely one-dimensional irreps of S_3 for the all values of representation parameters of the SU(3) isofactors, in addition to the special cases, considered by Derome.[32]

Moreover, the sufficient conditions of the one-to-one correspondence between the isofactors on the lhs and the rhs of (4.6a) and (4.6b), labeled by t and t' [associated, respectively, with irreps $(a''b'')$ and $(a'b')$ and taking values, as a rule, in the different intervals], may be strictly formulated for the SU(3) and $u_q(3)$ canonical tensor operators. For this purpose, let us reconsider

conditions (1.7b) and (1.7c). Following Hecht[20] and Refs. 8, 22, and 30, it may be supposed that for a given triplet $(a'b')(a''b'')(a\ \ b)$ of SU(3) or $u_q(3)$ irreps at least one triplet of the basis state labels (the initiation point) exists, for which only a single value of the external multiplicity label with non-vanishing isofactor is possible. (Usually, from such point a Gram–Schmidt process is begun). For example, exactly three initiation points exist for the (non-trivial) paracanonical[22,23] external labeling scheme. For the SU(3) and $u_q(3)$ canonical isofactors, sometimes many such initiation points may be chosen, with the parameters $i',i''_{\mathrm{m}},i,y',y''_{\mathrm{m}},y$, satisfying the following conditions:

$$|i-i'|=i''_{\mathrm{m}}-\mathscr{M}+r, \quad y=y'+y''_{\mathrm{m}} \tag{4.8}$$

and, possibly, forming two isolated sets (for $i-i'>0$ and $i-i'<0$, respectively), when the multiplicities $\mathscr{M}=r$. For example, represented by (4.7) isofactors have more than two initiation points for tensor of rank (1 1) and a mutually shared initiation point for the both tensor operators of rank (2 1).

Specifying the parameters $i=i_{\mathrm{m}}$, $y=y_{\mathrm{m}}$ as in (2.13), (2.14), and (3.1) and taking into account possible additional restrictions in the null space case, we may write condition (4.8) for the first main initiation point as

$$i'_{\mathrm{init.}}=i_{\mathrm{m}}-i''_{\mathrm{m}}+\mathscr{M}-r\geqslant|\hat{z}'|, \quad \hat{z}'=\tfrac{1}{2}(b'-a'+v), \quad \text{and } i'_{\mathrm{init.}}\geqslant i''_{\mathrm{m}}-i_{\mathrm{m}}$$
$$\text{if } i_{\mathrm{m}}-i''_{\mathrm{m}}<0 \quad \text{in addition.} \tag{4.9a}$$

Otherwise, condition (4.8) with special parameters $i'=i'_{\mathrm{m}}$, $y'=y'_{\mathrm{m}}$ gives the second main initiation point

$$i_{\mathrm{init.}}=i'_{\mathrm{m}}-i''_{\mathrm{m}}+\mathscr{M}-r\geqslant|\hat{z}|, \quad \hat{z}=\tfrac{1}{2}(b-a-v), \quad \text{and } i_{\mathrm{init}}\geqslant i''_{\mathrm{m}}-i'_{\mathrm{m}} \quad \text{if } i'_{\mathrm{m}}-i''_{\mathrm{m}}<0 \quad \text{in addition.} \tag{4.9b}$$

However, the above discussed problems with the normalization factor (3.7b) or (3.14b) are caused by the absence of some initiation points. We see that such triplets $(a'b'),(a''b''),(a\ \ b)$ of SU(3) or $u_q(3)$ irreps are also possible, for which the initiation points of the canonical splitting scheme are missing, since neither (4.8), nor at least (4.9a) or (4.9b) may be satisfied. [Of course, the initiation points presented as (3.1)–(3.3) of Ref. 30, perhaps with intention to escape the ambiguities of attaching the operator pattern to the first or third irrep, may also be non-existent, when $a''+b''>a+b$ and $a''+b''>a'+b'$ without the null space situation.] Contrary to the paracanonical and pseudocanonical isofactors[22,23] (for which the numerical transitions from the biorthogonal to orthogonal sets are always possible), the canonical isofactors cannot always be obtained immediately from the bilinear combinations of isofactors (solving the triangular systems of equations in numerical or analytical forms, i.e., by a Gram–Schmidt process) but only by an analytical continuation procedure (extrapolation) from the region with infinite (but countable) number of points, in which initiation points are existing. (Note that the numerical approach of Draayer and Akiyama[42] and its analytical generalization[8] are independent of our initiation problem.)

Using array (1.3b), together with its equidistantness properties (1.3c) and relations

$$i_{\mathrm{m}}-i''_{\mathrm{m}}=\tfrac{1}{2}(r_{111}-r_{331}), \quad \hat{z}'=\tfrac{1}{2}(r_{131}-r_{311}),$$

$$i'_{\mathrm{m}}-i''_{\mathrm{m}}=\tfrac{1}{2}(r_{111}-r_{221}), \quad \hat{z}=\tfrac{1}{2}(r_{121}-r_{211}),$$

it may be shown that the initiation points of each [either (4.9a) or (4.9b)] type may disappear and the nearest allowed value of $\hat{i}'_{\mathrm{min}}>i'_{\mathrm{init.}}$ or $\hat{i}_{\mathrm{min}}>i_{\mathrm{init.}}$ (with the remaining parameters chosen as above) is not distinctive (i.e., not sufficient) for the canonical labeling of the external multiplicity

with fixed position of the tensor operator labels. For example, only one initiation point from two sets exists when non-diagonal parameter $r_{13\gamma}$ (respectively, $r_{12\gamma}$, or $r_{31\gamma}$, or $r_{21\gamma}$) from array (1.3b) strictly exceeds eight remaining parameters $r_{\alpha\beta\gamma}$ in the same layer of (1.3b). Separately for concrete versions of $\mathscr{M}-r$ we also prove that both inequalities (4.9a) and (4.9b) have no solutions when non-diagonal parameter $r_{32\gamma}$, i.e., b'' or $b''+v$ (or, respectively, $r_{23\gamma}$, i.e., a'' or $a''-v$), strictly exceeds eight remaining parameters $r_{\alpha\beta\gamma}$ in the same layer of (1.3b), i.e.,

$$r_{32\gamma}>r_{\alpha\beta\gamma}>0 \quad \text{unless} \quad \alpha=3,\ \beta=2 \quad \text{both together}, \tag{4.10a}$$

or

$$r_{23\gamma}>r_{22\gamma}, \quad r_{23\gamma}>r_{33\gamma}, \quad r_{23\gamma}>r_{21\gamma}, \quad r_{23\gamma}>r_{13\gamma}. \tag{4.10b}$$

(The both conditions, for maximal $r_{32\gamma}$ and for maximal $r_{23\gamma}$, are written above in the different, but equivalent forms).

Hence, we found the regions of the irrep parameters $(a'b')(a''b'')(a\ \ b)$, for which conditions (1.7a)–(1.7c) are not sufficient for the canonical splitting. We see that initiation points may be absent without the null space situation for parameters $r_{1\beta\gamma}$ or $r_{\alpha1\gamma}$ accepting intermediate values, respectively, between $r_{2\beta\gamma}$ and $r_{3\beta\gamma}$, or between $r_{\alpha2\gamma}$ and $r_{\alpha3\gamma}$, for example, in the case of the coproduct decomposition $(12)\otimes(31)\to(21)$ or $(24)\otimes(51)\to(42)$. Using recursive construction (2.13) of Ref. 8 [which is equivalent for $t=\mathscr{M}$ with algorithm of Draayer and Akiyama[42] in the SU(3) case], we see that isofactor

$$\begin{bmatrix} & \overset{t}{} & \\ (1\ \ 2) & (3\ \ 1) & (2\ \ 1) \\ -\frac{1}{3}\,\frac{1}{2} & \frac{2}{3}\,2 & \frac{1}{3}\,\frac{3}{2} \end{bmatrix}^{(3)}_{q} \tag{4.11a}$$

does not vanish for the both values of the multiplicity label $t=1,2$. Of course, their parameters with the maximal shift $|i'-i|=2$ are impossible and system of equations (2.13) is unsolvable in terms of the canonical isofactors, without using results of Sec. III. Otherwise, labels of (4.11a) corresponds to an initiation point, associated with the last tensor of rank $(2\ \ 1)$ or, respectively, with the isofactor

$$\begin{bmatrix} & \overset{t=1}{} & \\ (1\ \ 2) & (1\ \ 2) & (1\ \ 3) \\ -\frac{1}{3}\,\frac{1}{2} & -\frac{1}{3}\,\frac{3}{2} & -\frac{2}{3}\,2 \end{bmatrix}^{(3)}_{q}. \tag{4.11b}$$

Since (4.11a) has a definite symmetry, described by (4.2b), the transposition matrix $B_{t,t'}$ of (4.6a) for (4.11b) [and in the all cases, described by the conditions (4.10a) or (4.10b)] is non-diagonal, in spite of the coinciding first and second irreps, and corresponds to a reducible representation of S_2 according Derome.[32]

Therefore, dependency (4.10a) or (4.10b) between the isofactor parameters forbids any symmetries associated with the interchange of the SU(3) tensor operator and initial or final labels, even if the corresponding irreducible representations coincide. For example, recursive construction (2.13) of Ref. 8 (equivalent with the approach of Ref. 42) never gives 0 for isofactors

$$\begin{bmatrix} & \overset{t=2}{} & \\ (3\ \ 2) & (3\ \ 2) & (5\ \ 3) \\ \frac{1}{3}\,\frac{5}{2} & \frac{1}{3}\,\frac{5}{2} & \frac{2}{3}\,i \end{bmatrix}^{(3)} \quad (1\leqslant i\leqslant 4), \tag{4.11c}$$

which should appear at least for two values of i in the case of diagonal matrix $B_{t,t'}$ in (4.3c). Thus, the canonical resolution of the SU(3) external multiplicity problem sometimes is not optimal with respect to Derome's[32] approach.

Let us consider another concrete example of the irrep parameters with absent initiation points of the canonical isofactors. We take the canonical tensor operator of rank (6 4) for the coproduct decomposition $(2\ 4)\otimes(6\ 4)\rightarrow(3\ 3)$, with non-vanishing isofactors for $t=4$ and 5. The initiation points for the tensor operators of the rank (3 3) and (2 4) exist (but are not common for the both operators) and correspond to the isofactors of the alternative labeling schemes

$$\begin{bmatrix} & \overset{1}{} & \\ (2\ 4) & (6\ 4) & (3\ 3) \\ -\frac{1}{3}2 & \frac{1}{3}5 & 0\ 3 \end{bmatrix}_q^{(3)} \quad \text{and} \quad \begin{bmatrix} \overset{1}{} & & \\ (2\ 4) & (6\ 4) & (3\ 3) \\ -\frac{1}{3}3 & \frac{1}{3}5 & 0\ 2 \end{bmatrix}_q^{(3)}. \tag{4.12a}$$

The corresponding canonical isofactors cannot be extracted immediately from the bilinear combinations of the type (2.14) by any Gram–Schmidt process, but generalized to $u_q(3)$ recursive construction (2.13) of Ref. 8 (see also Ref. 42) may be useful, when applying our Eq. (2.14) for normalization (unless the q-analog for the denominator function[5,7] will be derived). This construction, together with non-vanishing values of the multiplicity-free isofactors[13]

$$\begin{bmatrix} (2\ 4) & (2\ 0) & (3\ 3) \\ -\frac{1}{3}2 & \frac{1}{3}1 & 0\ 3 \end{bmatrix}_q^{(3)} \quad \text{and} \quad \begin{bmatrix} (2\ 4) & (2\ 0) & (3\ 3) \\ -\frac{1}{3}3 & \frac{1}{3}1 & 0\ 2 \end{bmatrix}_q^{(3)}, \tag{4.12b}$$

allows us to prove that

$$\begin{bmatrix} & \overset{t=5}{} & \\ (2\ 4) & (6\ 4) & (3\ 3) \\ -\frac{1}{3}2 & \frac{1}{3}5 & 0\ 3 \end{bmatrix}_q^{(3)} \neq 0, \quad \begin{bmatrix} & \overset{t=5}{} & \\ (2\ 4) & (6\ 4) & (3\ 3) \\ -\frac{1}{3}3 & \frac{1}{3}5 & 0\ 2 \end{bmatrix}_q^{(3)} \neq 0. \tag{4.12c}$$

Finally, the absence of the initiation points for this case of the canonical coupling is also proved, taking into account that triplets satisfying (4.8) (1, 5, 3 or 3, 5, 1) are not allowed.

Similar to formula (3.6) with inserted Eq. (3.8) and the non-singular version of the denominator function (3.14b), expression (4.7) of Ref. 43 for the SU(3) isofactors with extreme shifts of the SU(2) irreps [or Eq. (5.8) of Ref. 8 which, nevertheless, is correct] may give zero for parameters satisfying conditions (4.10a) or (4.10b) [e.g., for triplet $(2\ 4)\otimes(6\ 2)\rightarrow(4\ 2)$], without the null space situation of the canonical tensor operator. Hence, we conclude that the null space of SU(3):U(2) and $u_q(3):u_q(2)$ projective operators may exceed the null space of the SU(3) and $u_q(3)$ canonical tensor operators, contrary to Lemma 1.1 and Theorem 1.1 of Ref. 6. Since the tertium non datur principle now is questionable in the proof of Theorem 1.2 of Ref. 6, the defining conditions (1.26b) of the canonical tensor operators[6] should be replenished. Particularly, now it is not evident that the isofactor vanishing condition (1.7a) is completely determined by the null space inclusion property $\mathcal{N}_1 \supset \mathcal{N}_2 \supset \cdots \supset \mathcal{N}_{\mathcal{M}}$, just together with the conjugation invariance, without any supplementary condition. Paradoxically, we see that construction (2.13) of Ref. 8 is conjugation invariant (up to sign) independently on its orthogonality, as well as the isofactors on the left-hand and right-hand sides of Eqs. (4.6a) and (4.6b), although matrices $B_{t,t'}$ and $\widetilde{B}_{t,t''}$ may be non-diagonal. The author did not find any reason why some unitary transformation with the non-diagonal matrix elements, vanishing on the disjunctive complement of $\mathcal{N}_{t'}$ in $\mathcal{N}_t$, for $t'>t$ cannot be invented, similar to the transformation between the canonical and pseudocanonical isofactors.

Hence, together with the arguments versus the null space inclusion property being sufficient for the canonical splitting, the author understood that the SU(3) isofactors with $t\neq 1$ or $\mathcal{M}$,

constructed by means of (2.13) of Ref. 8, may be non-orthogonal. Besides, the Gram–Schmidt process begun from $t=1$ (actually from $t=2$) spoils for $\mathscr{M}>2$ (when the set of isofactors is overcomplete), the null space inclusion property [perhaps, with exception of the rank (2 2) case]. [In this last case, (2.13) of Ref. 8 does not contradict with the results, tabulated in Ref. 44, but the null spaces also coincide.] The overlaps of the SU(3) isofactors from Ref. 8 were considered for the tensor operators of the multiplicity 4 and rank (3 3) and were expanded in terms of the overlaps (3.6) of the dual (biorthogonal) SU(3) coupled states[22] by means of the expansion coefficients (5.1) from Ref. 8 and expressed in terms of polynomials and linear functions in a,b by means of the computer algebra. Since the non-diagonal overlaps with unequal $t=2,3,4$ were expressed purely in terms of the linear functions in a,b, without any non-trivial polynomials, our approach of Ref. 8 does not seem hopeless for the final explicit construction of the SU(3) and $u_q(3)$ canonical tensor operators.

We see that some oversights of Ref. 8 and Refs. 6 and 30 are ''dual'' in a similar sense as the biorthogonal coupled bases:[22] the bases with subscripts are overcomplete and the bases with superscripts present additional definition problems. Hence, our Eq. (2.13) and the corresponding algorithm from Ref. 30, or used in Sec. VI of Ref. 22 distinctive conditions (6.1a,b), do not ensure sometimes the null space inclusion properties, when the corresponding initiation points are not correlated as above with the canonical splitting. Nevertheless, our Eq. (2.13) is overcomplete for the algorithm, consistent with the Braunschweig conjecture.[45,46] Particularly, the Williams[46] construction of the orthogonal SU(3) coupling coefficients is also equivalent to the numerical Gram-Schmidt procedure, whose initiation points may be either associated with some ''transposed'' version of the canonical labeling scheme [in analogy with (1.9), or (4.9a,b)], or may not be correlated with any considered analytical solution of the external multiplicity problem (although isofactors with the coinciding irreps should be equivalent up to sign with the canonical ones for the multiplicity 2). The above presented arguments may show some transposition symmetry of the coupling coefficients[46] being not universal, although the alternative symmetry relations[46] under definite restrictions may be equivalent to our results.

It is evident that matrix $B_{t,t'}$ accepts in (4.6a) a shift-diagonal form, if the initiation points for the tensor operators of rank $(a''b'')$ and $(a'b')$ are mutually related by the same transposition $(a'b')\leftrightarrow(a''b'')$. This is possible when $i'_{\mathrm{m}}-i''_{\mathrm{m}}-\mathscr{M}+r=i''_{\mathrm{m}}-i'_{\mathrm{m}}$, or in the inverse situation (appearing after the transposition), also when the null space appears before and/or after transposition (and Lemma 1.1 of Ref. 6 is valid). Thus, relation (4.6a) may be reduced to the phase factor when diagonal parameter $r_{33\gamma}$ of array (1.3b) exceeds all the remaining parameters of the same layer:

$$r_{33\gamma}\geqslant r_{\alpha\beta\gamma} \tag{4.13a}$$

with the corresponding shift $r_{11\gamma}-r_{22\gamma}$ or $r_{22\gamma}-r_{11\gamma}$ between t and t'. Similarly, the transposition $(b\ \ a)\leftrightarrow(a''b'')$ [with the antidiagonal transposition of the both layers of array (1.3b)] gives only phase factor in (4.6b) when

$$r_{22\gamma}\geqslant r_{\alpha\beta\gamma} \tag{4.13b}$$

with the corresponding shift $\pm\,2(i_{\mathrm{m}}-i''_{\mathrm{m}})$ of t. Supremacy of the parameter $r_{11\gamma}$ determines the possibility of transposition $(b'a')\leftrightarrow(a\ \ b)$ for the external multiplicity label, associated with tensor operator of rank $(a'b')$ or $(a\ \ b)$. Relations (4.13a) and (4.13b) turn into equalities and determine the S_3 transposition invariance (up to sign) of the SU(3) or $u_q(3)$ canonical 3-j coefficients, when the all three irreps are equivalent. Of course, conditions (4.13a) and (4.13b) are satisfied and Lemma 1.1 of Ref. 6 is not violated for the self-conjugated tensor operators with $v=0$ and in some their vicinity.

The vanishing (non-vanishing) properties of the canonical SU(3) isofactors with coinciding parameters allows us to fix some phases also in (4.6a) and (4.6b), when $B_{t,t'}$ or $\widetilde{B}_{t,t''}$ are diagonal. For example, non-vanishing of isofactors

$$\begin{bmatrix} & \overset{t=1}{} & \\ (a'b') & (a'b') & (a\ \ b) \\ y'_{\mathrm{m}}i'_{\mathrm{m}} & y'_{\mathrm{m}}i'_{\mathrm{m}} & \frac{2}{3}(b-a)0 \end{bmatrix}^{(3)} \quad \text{for } v=a'-b'=b-a \tag{4.14a}$$

or, in general,

$$\begin{bmatrix} & \overset{t_0}{} & \\ (a'b') & (a'b') & (a\ \ b) \\ y'_{\mathrm{m}}i'_{\mathrm{m}} & y'_{\mathrm{m}}i'_{\mathrm{m}} & 2y'_{\mathrm{m}}\ \ t_0-1 \end{bmatrix}^{(3)} \quad \text{with } t_0=|b'-a'+v|+1 \tag{4.14b}$$

do not contradict with (4.6a), if we include into $B_{t,t'}$ the phase factor $(-1)^{v+t-t_0}$, together with the corresponding shifts of t, determined by (4.13a) and $t_0=\mathscr{M}-r+1$ in the general $[(a'b')\neq(a''b'')]$ case. The same phase factor $(-1)^v$ appears for transposition $1\leftrightarrow 2$ in the multiplicity-free cases, without dependence on condition (4.13a).

We see that alternatives in the symmetry properties of the canonical isofactors and possibilities in abbreviating tables depend on what—diagonal or non-diagonal—position is accepted by the maximal entry of array (1.3b), when the external multiplicity of the SU(3) or $u_q(3)$ tensor operator or in the isofactors is determined by the minimal entry [in the opposite row, column, and layer of subarray (1.5b)]. Note that only diagonal entries belong to two different subarrays $2\times2\times2$ of the type (1.5b), or related with (1.5b) by the corresponding transposition. Remember that the denominator functions[5–7] and the boundary SU(3) isofactors (orthogonalization of which leads in a shortest way to the canonical ones—see Sec. V of Ref. 8) are dermined only for a fixed integer value of at least single entry of subarray (1.5b) and the multiplicity label t. Thus, the interchange of the tensor operator and initial (or, respectively, final) basis labels in the canonical SU(3) or $u_q(3)$ isofactors may give the coinciding (when the Gram–Schmidt processes are allowed before and after transposition) or alternative (transposed) numerical versions of the canonical splitting (with changed position of the tensor operator in its matrix element). The differences of the t shifts after such interchange and the different alternatives between the Gram–Schmidt and analytical continuation processes forbid speaking about the uniqueness of the canonical resolution of the external multiplicity problem analytical in all 12 isofactor parameters, unless (before) the position of the tensor operator in isofactor is fixed. The definition ambiguity of the canonical tensor operators may be excluded, if the null space inclusion property is used together with the linear independence condition of the all non-zero $u_q(3):u_q(2)$ [or SU(3):U(2)] projective operators.

Nevertheless, in addition to the symmetries, induced by conditions (4.13a), and (4.13b), some simple symmetries of the canonical isofactors may be caused by accidental initiation points. For example, vanishing of special SU(3) isofactors

$$\begin{bmatrix} & \overset{t=2}{} & \\ (1\ \ 1) & (a\ \ a) & (a\ \ a) \\ 0\ \ 0 & 0\ \ a & 0\ \ a \end{bmatrix}^{(3)}=0, \quad \begin{bmatrix} & \overset{t=2}{} & \\ (a\ \ a) & (1\ \ 1) & (a\ \ a) \\ 0\ \ a & 0\ \ 0 & 0\ \ a \end{bmatrix}^{(3)}=0 \tag{4.15a}$$

[in accordance with condition (1.7c) in the first case, and in accordance with the conjugation symmetry (4.2a), or with the tabulated isofactor expressions in the second case] induces the complete $S_3\times S_2$ symmetry of the canonical SU(3) isofactors for coupling $(a\ \ a)\otimes(1\ \ 1)\rightarrow(a\ \ a)$. In accordance with (3.18) and (4.2b), accidental initiation points exist also for SU(3) isofactors

$$\left[\begin{array}{ccc} & \overset{t}{} & \\ (1\ \ 2) & (3\ \ 1) & (2\ \ 1) \\ -\frac{1}{3}\frac{3}{2} & \frac{2}{3}\,i'' & \frac{1}{3}\frac{3}{2} \end{array}\right]^{(3)} \tag{4.15b}$$

with $t=1$ and 2 for $i''=0$ (or 2) and 1, respectively [cf. isofactors (4.11a) and (4.11b)].

In general, when all three irreps are self-adjoint, i.e., for coupling $(a'a')\otimes(a''a'')\to(a\ \ a)$, one or two independent versions of the canonical labeling may exist in accordance with satisfied condition (4.13a) or (4.13b). Anyway, the elements of matrices $B_{t,t'}$ and $\widetilde{B}_{t,t''}$ with the positions of different parity in rows and columns are 0, since the transpositions do not mix states with the different irreducible behavior under conjugation. Returning to the triplet of irreps (5 5), (3 3), and (4 4), we may predict that the canonical labeling scheme is completely invariant under transposition for $t=2$, but $t=1$ and $t=3$ states of the rank (3 3) tensor mix after transposition. [There is one-to-one correspondence between the all matrix elements of the rank (4 4) and (5 5) tensors]. However, the symmetries of this type are not satisfied by the corresponding $u_q(3)$ isofactors.

In spite of absent initiation point on the lhs or rhs of Eq. (4.6a) or (4.6b), zeros may be found in unitary matrices $B_{t,t'}$ and $\widetilde{B}_{t,t''}$ from the analysis of the original and transposed conditions (1.7). Distribution and number of zeros depend on the degree to which (4.9a) or (4.9b) are spoiled and determine some restrictions for the remaining non-vanishing matrix elements. For example, isofactor without any initiation point

$$\left[\begin{array}{ccc} & \overset{t}{} & \\ (2\ \ 3) & (4\ \ 2) & (3\ \ 2) \\ -\frac{1}{3}\frac{5}{2} & \frac{2}{3}3 & \frac{1}{3}\,\hat{i} \end{array}\right]^{(3)}_{q} \qquad \left(\hat{i}=\frac{1}{2},\frac{3}{2},\frac{5}{2}\right) \tag{4.16}$$

may be expanded according (4.6a) by means of the matrix $B_{t,t'}$ with $B_{31}=0$ and some dependencies (e.g., $B_{12}B_{23}=B_{13}B_{22}$) between the remaining matrix elements.

(Received 6 March 1995; accepted for publication 2 May 1996)

A general theory of quantum Clifford algebras is presented, based on a quantum generalization of the Cartan theory of spinors. We concentrate on the case when it is possible to apply the quantum-group formalism of bicovariant bimodules. The general theory is then singularized to the quantum SL(n,$\mathbb{C}$) group case, to generate explicit forms for the whole class of braidings required. The corresponding spinor representations are introduced and investigated. Starting from our Clifford algebras we introduce the quantum-Euclidean underlying spaces compatible with different choices of *-structures from where the analogues of Dirac and Laplace operators are built. Using the formalism developed, quantum Spin(n) groups are defined. © *1996 American Institute of Physics.* [S0022-2488(96)01709-4]

I. INTRODUCTION

In this paper we present a general theory of quantum Clifford algebras and spinors based on the incorporation, into the quantum context, of Cartan's theory of spinors.[1,2] Our approach depends essentially on constructing the ''spinor representation'' that would lead us to the proper way of defining the abstract algebra.

In Cartan's classical theory, spinors are considered as elements of the graded exterior algebra over one of the two isotropic subspaces into which the underlying $2n$ or $2n+1$-dimensional Euclidean or pseudo-Euclidean space W decomposes. These two isotropic subspaces are mutually dual and hence we can write $W=V\oplus V'$ for even-dimensional spaces and $W=M\oplus V\oplus V'$ for odd-dimensional spaces, where dim $V=$dim $V'=n$, and dim $M=1$. Spinors are based on V, and if any vector $\mathbf{w}$ in W is written as the unique decomposition $\mathbf{w}=x^0\hat{e}_0+x+f$, where $\hat{e}_0$ is a unit vector in M and $x\in V$, $f\in V'$, then the generators of the Clifford algebra acting on a spinor ξ are determined by the relations

$$H(\mathbf{w})\xi=x\wedge\xi+\iota_f\xi+x^0S\xi, \tag{1}$$

where S is the parity operator which acts on homogeneous spinors $\xi^{(p)}\in V^{\wedge p}$ according to

$$S\xi^{(p)}=(-1)^p\xi^{(p)}. \tag{2}$$

In our quantum construction we shall start from a vector space V endowed with a braiding $\sigma:V^{\otimes 2}\to V^{\otimes 2}$ satisfying the Hecke condition $\sigma^2=(1-q)\sigma+q1$ for some $q\in\mathbb{R}$, such that V and σ

(together with the dual V' and $\mathbb{C}$) with the usual tensor products (and appropriate subspaces and factor-spaces) generate a braided monoidal category. Moreover, we ask that the contraction map between V' and V is functorial [see diagrams (32) and (33)].

We can define $V^{\wedge}$, the exterior braided algebra of V, as $T(V)/J$ where $T(V)$ is the tensor algebra of V and J is the ideal of $T(V)$ generated by $\ker(A)$. Here $A=\Sigma_{k\geqslant 0}^{\oplus}A_k$, and A_k is defined on $V^{\otimes k}$ by $A_k=\Sigma_{\pi\in S_k}(-1)^{l(\pi)}\sigma_\pi$, where σ_π are operators obtained by replacing transpositions in the minimal decomposition of π by the corresponding σ-twists, and $l(\pi)$ is the length of π. We then have $A_k^2=c_kA_k$ with $c_k\neq 0$. Under our assumptions $T(V)=\ker(A)\oplus\mathrm{Im}(A)$, therefore $T(V)/J\simeq\mathrm{Im}(A)$, so we can identify $V^{\wedge}$ with $\mathrm{Im}(A)$, a subspace of $T(V)$. Explicitly, we will assume the following identifications:

$$[\varphi+\ker(A)]\leftrightarrow A(\varphi),$$

where $\varphi\in T(V)$.

This identification allows us to define a transformation $\iota_f:V^{\wedge}\to V^{\wedge}$ for any $f\in V'$ given by $\iota_f(\eta)=\Sigma f(\eta_{i_1})\eta_{i_2}\otimes\cdots\otimes\eta_{i_k}$ for $\eta=\Sigma\eta_{i_1}\otimes\eta_{i_2}\otimes\cdots\otimes\eta_{i_k}$. Having this operation we can define, for any $\mathbf{w}\in W$, an action on $V^{\wedge}$ by means of the relation (1), so we have a map $H:W\to L(V^{\wedge})$. We then find that $Cl(W)$, the algebra generated by $H(W)$, is isomorphic to $T(W)/J$ where J is the ideal generated by the elements $x\otimes y+(1/q)\sigma(x\otimes y)$; $x\otimes f+\sigma(x\otimes f)-\langle\sigma(x\otimes f)\rangle$; $f\otimes x+\sigma^{-1}(f\otimes x)-f(x)$; $f\otimes g+(1/q)\sigma(f\otimes g)$. Here $x,y\in V$; $f,g\in V'$, while $\langle,\rangle:V'\otimes_{\mathbb{C}}V\to\mathbb{C}$ denotes the contraction map and the symbol σ is used for all the braidings in the above-mentioned braided monoidal category.

We recall that $T(W)$ is a *filtered algebra* with filtration

$$T^d(W)=\sum_{i\leqslant d}W^{\otimes i}.$$

This filtration induces a filtration in $Cl(W)$. The corresponding graded algebra

$$\mathrm{gr}[Cl(W)]=\sum{}^{\oplus}Cl(W)^{i+1}/Cl(W)^i,$$

is naturally isomorphic, as a vector space, to $V^{\wedge}\otimes V'^{\wedge}$, while the product is appropriately ''deformed'' with the help of σ.

Moreover, it is possible to introduce a braiding τ in W, which depends exclusively on the initial braiding σ, such that the mentioned graded algebra is isomorphic, in a natural manner, to the corresponding τ-exterior algebra $W^{\wedge}$. From this point of view, our Clifford algebra can be interpreted as a *Chevalley–Kähler-type deformation* of the exterior algebra. It is worth noticing that this fact can be used as a starting point[3] for constructing quantum Clifford algebras, as in the classical theory. Such a generalization of the Chevalley–Kähler construction works for arbitrary braids.

The paper is organized in the following way. In Sec. II we shall review some basic facts about Hecke algebras and quantum groups, which are then applied to the cases of (general) quantum $\mathrm{SL}(n)$ groups. We shall also explain why it is possible to apply the theory of compact quantum groups in the noncompact context. In Sec. III a general theory of quantum Clifford algebras is given, together with some concrete examples and computations. Section IV is devoted to a more detailed study of the spinor representation. We shall prove that this representation is faithful and irreducible, as in the classical theory. Questions related to the spinor scalar product and the associated *-structure on the Clifford algebras will be discussed also. In Sec. V we construct the flip-over operators starting from the fundamental representation of $\mathrm{SL}_q(n,\mathbb{C})$. In Sec. VI we intro-

duce and investigate quantum Euclidean underlying spaces induced by our Clifford algebras. We also discuss different choices of *-structures. Finally, in Sec. VII we use our formalism to describe briefly the general procedure for defining quantum Spin(n) groups.

As a concrete example of constructing the braided monoidal category generated by V, V', $\mathbb{C}$, and $\sigma: V\otimes V\to V\otimes V$, we shall consider the case when a quantum group formalism of bicovariant bimodules can be applied. More specifically, we let G be a quantum group and $\mathscr{A}$ be the associated Hopf algebra of ''polynomial functions'' on G. We then take V as a right $\mathscr{A}$-module and right $\mathscr{A}$-comodule. Under some necessary and sufficient conditions we have that $V\simeq\Gamma_{\text{inv}}$=left invariant elements of a bicovariant bimodule Γ. Then, if in the category of bicovariant bimodules $\mathscr{T}_G$ we take the braided monoidal category generated by Γ, Γ' (dual to Γ), $\mathscr{A}$, (including the appropriate submodules and factor-modules) and consider the left invariant part of the objects of this last category we obtain the required braided monoidal category.

Our approach differs from others appearing in the literature (Refs. 4–6) in that the procedure followed in these papers consists essentially in deforming $Cl(W)$ by stressing its presentation in terms of generators and relations rather than its representation in $V^{\wedge}$. In this case if we consider an appropriate (Hecke) braiding $\sigma: W\otimes W\to W\otimes W$, it is natural to define the corresponding Clifford algebra $\widetilde{Cl}(W)$ as the factor algebra $T(W)/K$ where K is the ideal generated by elements $x\otimes y+(1/q)\sigma(x\otimes y)-(x,y)1$, where $x,y\in W$ and $(,)$ is an appropriate (σ-symmetric) bilinear form. Thus the corresponding graded algebra is simply $W^{\wedge}$. A problem with this approach is that if $W=V\oplus V'$, then it is not possible to have a representation of $\widetilde{Cl}(W)$ a la Cartan, because it is not possible to have that $\sigma(V\otimes V')=V'\otimes V$ and $\sigma(V'\otimes V)=V\otimes V'$ at the same time (the Hecke relation is incompatible with that, if the braid is not symmetric).

Another approach for deforming Clifford algebras is due to Hayashi,[7] where an analogy is made between the usual presentation of $Cl(W)$ by generators and relations with the Chevalley generators of the enveloping algebra $\mathscr{U}(X)$ of a symmetrizable generalized Cartan matrix X. The corresponding quantum Clifford algebra is then obtained in analogy with the quantized enveloping algebra. In this case a representation of the quantum Clifford algebra is given on a usual exterior algebra. The resulting quantum Clifford algebra turns out to be a direct product of classical Clifford algebras. It is worth noticing that our Clifford algebra is also isomorphic to the full endomorphism algebra $L(V^{\wedge})$, via the representation H (if $V^{\wedge}$ is finite dimensional).

It is interesting to consider possible physical applications of the formalism of quantum Clifford algebras from the point of view of introducing ''quantized'' space–time models. Logically, several possibilities are open. Perhaps the most natural approach is to define the corresponding space–time algebra starting from relations defining the quantum Clifford algebra. The space–time algebra is then generated by W, and quadratic relations obtained by requiring that the square of the generic vector from W is the space–time ''distance.'' In this picture the deviation from classical of the generating relations for quantum Clifford algebras is responsible for the noncommutativity of the space–time algebra. However, given a compatible *-structure, the space–time algebra is uniquely fixed. Essentially, it will be a variant of a ''quantum plane.''

On the other hand, it is possible to relax such a relation between the Clifford algebra and the ''space–time,'' and to introduce axiomatically the analogues of spin bundles. The advantage of such approach is in its flexibility, since the ''horizontal'' and the ''vertical'' parts of the formalism become relatively independent. In particular, it is possible to introduce a concept of a classical spinor structure on a quantum space.[8] The material presented here constitutes a base for further studies related to these matters.

II. HECKE ALGEBRAS, BICOVARIANT BIMODULES, AND INTERTWINERS FOR QUANTUM GROUPS

A. On Hecke algebras

Let $q\in\mathbb{C}\setminus\{0\}$ be a complex number and $n\geqslant 2$ an integer. By definition in Ref. 9, the corresponding Hecke algebra $H_{n,q}$ is described by generators $\sigma_1,\ldots,\sigma_{n-1}$ and relations

$$\sigma_i^2=(1-q)\sigma_i+q1, \tag{3}$$

$$\sigma_i\sigma_j=\sigma_j\sigma_i, \quad \text{if } |i-j|\geqslant 2, \tag{4}$$

$$\sigma_i\sigma_{i+1}\sigma_i=\sigma_{i+1}\sigma_i\sigma_{i+1}. \tag{5}$$

In what follows, it will be assumed that $q>0$. The algebra $H_{n,q}$ is finite dimensional, moreover $\dim H_{n,q}=n!$. It can be understood as a deformation of the functional algebra of the symmetric group S_n. A natural basis in $H_{n,q}$ is given by elements $([\pi]_q)_{\pi\in S_n}$, where $[\pi]_q$ denotes the element obtained by replacing transpositions in a *minimal* decomposition of the permutation π with the corresponding generators σ_i.

In this article Hecke algebras will appear via their representations, which will be of the following particular kind: Let V be a vector space and $\sigma: V\otimes V\to V\otimes V$ be an arbitrary braid operator satisfying the Hecke relation of the form (3). Then there exists the unique representation D_σ of the algebra $H_{n,q}$ in the space $V^{\otimes n}$ satisfying $D_\sigma(\sigma_i)=id^{i-1}\otimes\sigma\otimes id^{n-i-1}$. For our purposes, we shall further assume that the space V is a carrier of an irreducible representation υ of an appropriate quantum group G, such that σ intertwines the square of this representation. This condition will ensure that all entities constructed intrinsically from V and σ are G-covariant, in a natural manner. In fact, we shall go beyond this and assume that V, υ, and σ are interpretable in the framework of the theory of bicovariant bimodules[10] over G. More precisely, it will be assumed that V consists of left-invariant elements of some bicovariant bimodule Γ over G such that the representation υ can be viewed as the restriction of the right action of G on Γ, and such that σ becomes (the ''left-invariant part'' of) the canonical flip-over operator.

In our considerations, the main object associated to σ and V will be the corresponding *braided exterior algebra* $V^\wedge$. This algebra can be described as the factor algebra of the tensor algebra $V^\otimes$ through the ideal J generated by $\ker(I-\sigma)$. This ideal coincides with the kernel of the corresponding ''total antisymmetrizer'' $A: V^\otimes\to V^\otimes$, which is explicitly given by

$$A=\sum_{n\geqslant 0}^{\oplus} A_n,$$

where $A_n: V^{\otimes n}\to V^{\otimes n}$ are operators given by

$$A_n=\sum_{\pi\in S_n}(-1)^{l(\pi)}\sigma_\pi,$$

and σ_π are operators obtained by replacing transpositions in the minimal decomposition of π by the corresponding σ-twists. In other words,

$$\sigma_\pi=D_\sigma([\pi]_q).$$

In consequence, the following decomposition holds:

$$V^\otimes=\ker(A)\oplus\mathrm{Im}(A).$$

In fact, due to the Hecke relation, it follows that A is a projection operator, up to a multiplication constant in each $V^{\otimes k}$. Explicitly, we have

$$A_k^2=c_kA_k, \tag{6}$$

where

$$c_k=\left(\sum_{\pi\in S_k} q^{l(\pi)}\right). \tag{7}$$

The algebra $V^{\wedge}$ can be naturally identified, with the help of A, with the space $\mathrm{Im}(A)$. In what follows it will be assumed that the identification

$$V^{\wedge}\ni(\varphi+J)\leftrightarrow A(\varphi)\in V^{\otimes}$$

is made.

It is very important to observe that all our considerations apply for general Hecke braidings (with $q>0$), and in particular it is not necessary to assume that dimensions of braided exterior algebra spaces $V^{\wedge k}$ are classical (for example, classical *symmetric* algebras are included trivially in the procedure).

B. On bicovariant bimodules

In this subsection we shall summarize the most important elements of the theory of bicovariant bimodules over (compact matrix) quantum groups. We shall basically follow Ref. 10, in a slightly different notation.

1. Structure of bicovariant bimodules

Let Γ be a bicovariant bimodule over G, and let ${}_\Gamma\phi:\Gamma\to\Gamma\otimes\mathscr{A}$ and $\phi_\Gamma:\Gamma\to\mathscr{A}\otimes\Gamma$ be the right and the left action of G on Γ, respectively. These maps satisfy the following identities

$$(id\otimes\epsilon)_\Gamma\phi=id, \tag{8}$$

$$(\epsilon\otimes id)\phi_\Gamma=id, \tag{9}$$

$${}_\Gamma\phi(a\theta)=\phi(a)_\Gamma\phi(\theta), \tag{10}$$

$${}_\Gamma\phi(\theta a)={}_\Gamma\phi(\theta)\phi(a), \tag{11}$$

$$\phi_\Gamma(a\theta)=\phi(a)\phi_\Gamma(\theta), \tag{12}$$

$$\Phi_\Gamma(\theta a)=\phi_\Gamma(\theta)\phi(a), \tag{13}$$

$$(id\otimes\phi)_\Gamma\phi=({}_\Gamma\phi\otimes id)_\Gamma\phi, \tag{14}$$

$$(\phi\otimes id)\phi_\Gamma=(id\otimes\phi_\Gamma)\phi_\Gamma, \tag{15}$$

$$(\phi_\Gamma\otimes id)_\Gamma\phi=(id\otimes_\Gamma\phi)\phi_\Gamma. \tag{16}$$

Let $V=\Gamma_{\mathrm{inv}}$ be the space of left-invariant elements of Γ. The space V possesses a natural right $\mathscr{A}$-module structure. This structure is given by

$$\theta\circ a=\kappa(a^{(1)})\theta a^{(2)}, \tag{17}$$

where $\kappa:\mathscr{A}\to\mathscr{A}$ is the antipode map. Equivalently, we have

$$\theta\circ a=P(\theta a), \tag{18}$$

where $P:\Gamma\to V$ is the canonical projection onto left-invariant elements. This map is given by

$$P(\varphi)=\sum_i \kappa(a_i)\varphi_i,$$

where $\Sigma_i a_i\otimes\varphi_i=\phi_\Gamma(\varphi)$.

The space V is right-invariant in the sense that

$$_\Gamma\phi(V)\subseteq V\otimes\mathscr{A}. \tag{19}$$

Let $v:V\to V\otimes\mathscr{A}$ be the restriction of $_\Gamma\phi$ on V. This map is a representation of G (in other words V is a right $\mathscr{A}$-comodule).

The module and comodule structures on V are mutually related in the following way:

$$v(\theta\circ a)=\sum_k (\theta_k\circ a^{(2)})\otimes\kappa(a^{(1)})c_k a^{(3)}, \tag{20}$$

where

$$v(\theta)=\sum_k \theta_k\otimes c_k. \tag{21}$$

The map $I:\mathscr{A}\otimes V\to\Gamma$ given by

$$I(a\otimes\theta)=a\theta \tag{22}$$

is a left $\mathscr{A}$-module isomorphism. If we identify the two spaces (with the help of I), then the right $\mathscr{A}$-module structure on Γ is given by

$$(a\otimes\theta)b=ab^{(1)}\otimes(\theta\circ b^{(2)}). \tag{23}$$

Further, left and right actions of G on Γ are given by

$$\phi_\Gamma(a\otimes\theta)=a^{(1)}\otimes a^{(2)}\theta, \tag{24}$$

$$_\Gamma\phi(a\otimes\theta)=\sum_k a^{(1)}\otimes\theta_k\otimes a^{(2)}c_k. \tag{25}$$

Consequently, Γ is completely determined by $(V,v,\circ)$.

Let $\sigma:V\otimes V\to V\otimes V$ be (the left-invariant part of) the canonical flip-over operator.[10] The following identities hold:

$$\sigma(\eta\otimes\theta)=\sum_k \theta_k\otimes(\eta\circ c_k), \tag{26}$$

$$\sigma^{-1}(\theta\otimes\eta)=\sum_k [\eta\circ\kappa^{-1}(c_k)]\otimes\theta_k. \tag{27}$$

The map σ intertwines the square $v^2:V\otimes V\to V\otimes V\otimes\mathscr{A}$ with itself.

2. Reconstruction problematics

Let V be a vector space, $v:V\to V\otimes\mathscr{A}$ be a representation of G on V, and $\circ$ be a right $\mathscr{A}$-module structure on V. Let us assume that (20) holds, and let us define a left $\mathscr{A}$-module Γ as the free structure $\Gamma=\mathscr{A}\otimes V$.

It then follows that formula (23) defines a right module structure on Γ, while formulas (24) and (25) define the left and the right action of G on Γ. Endowed with all these structures, Γ becomes a bicovariant bimodule. Moreover, $V=\Gamma_{\text{inv}}$ and the initial $\circ$ and v are understood as associated right $\mathscr{A}$-module and comodule structures on V, respectively. In such a way, the circle is closed.

3. Some technical criteria for compatibility between the module and the comodule structure on V

Let us assume that a (finite-dimensional) vector space V is endowed with a right $\mathscr{A}$-comodule structure $v:V\to V\otimes\mathscr{A}$ as well as with a right $\mathscr{A}$-module structure $\circ$. Let $\sigma:V\otimes V\to V\otimes V$ be a linear map given by (26). This map is always bijective (independently of mutual compatibility between $\circ$ and v) and its inverse is given by (27).

Let us assume that the matrix elements of the representation v together with the matrix elements of the contragradient representation $\kappa(v)^{\mathrm{T}}$ generate the algebra $\mathscr{A}$.

Lemma II.1: The following conditions are equivalent:

(i) Equality (20) holds for each $\theta\in V$ and $a\in\mathscr{A}$.

(ii) The map σ intertwines v^2.

Proof: If equality (20) holds, then $\Gamma=\mathscr{A}\otimes V$ becomes in a natural manner a bicovariant bimodule over G and σ becomes its canonical flip-over operator. Therefore (ii) holds.

Conversely, let us assume that (ii) holds.

Let us fix a basis $e_1,\ldots e_n\in V$. Matrix elements v_{ij} of v are given by

$$v(e_i)=\sum_j e_j\otimes v_{ji}. \tag{28}$$

The intertwining property of σ can be expressed as

$$v^{\otimes 2}\sigma(e_i\otimes e_j)=\sum_k v^{\otimes 2}[e_k\otimes(e_i\circ v_{kj})]=\sum_{k,n}(e_n\otimes v_{nk})v[e_i\circ v_{kj}]=(\sigma\otimes id)v^{\otimes 2}(e_i\otimes e_j)$$

$$=\sum_{k,l}\sigma(e_k\otimes e_l)\otimes v_{ki}v_{lj}=\sum_{k,l,n}e_n\otimes(e_k\circ v_{nl})\otimes v_{ki}v_{lj}.$$

In other words,

$$\sum_{k,l}(e_k\circ v_{nl})\otimes v_{ki}v_{lj}=\sum_k(1\otimes v_{nk})v[e_i\circ v_{kj}].$$

Now multiplying by $1\otimes\kappa(v_{mn})$ both sides, and summing over the n we obtain

$$\sum_{k,l,n}(e_k\circ v_{nl})\otimes\kappa(v_{mn})v_{ki}v_{lj}=v[e_i\circ v_{mj}].$$

Hence, (20) holds for all a of the form v_{ij}.

Similarly, using (26) and the intertwining property of σ^{-1} we conclude that (20) holds for all a of the form $\kappa^{-1}(v_{ij})$. To complete the proof it is sufficient to observe that v_{ij} and $\kappa^{-1}(v_{ij})$ generate $\mathscr{A}$, and that if (20) holds for $a,b\in\mathscr{A}$, then it holds also for $a+\alpha b$ and ab.

Let us now assume that the matrix elements v_{ij} are mutually linearly independent.

Lemma II.2: If (20) holds for each $a\in\mathscr{A}$ and for one nonzero vector $\theta\in V$, then it holds for all vectors θ (and for all $a\in\mathscr{A}$).

Proof: Without a lack of generality we can assume that $\theta=e_i$, for some fixed i. Equation (20) (for this choice of θ) implies

$$(1\otimes a^{(1)})v(e_i\circ a^{(2)})(1\otimes\kappa(a^{(3)}))=\sum_j (e_j\circ a)\otimes v_{ji}.$$

Acting by $v\otimes id$ on both sides of the above equality, and using the comodule property and (20) we obtain

$$\sum_{kn} (e_k\circ a^{(4)})\otimes\kappa(a^{(3)})v_{kn}a^{(5)}\otimes a^{(1)}\kappa(a^{(2)})v_{ni}a^{(6)}\kappa(a^{(7)})$$

$$=\sum_{kn} (e_k\circ a^{(2)})\otimes\kappa(a^{(1)})v_{kn}a^{(3)}\otimes v_{ni}=\sum_j v(e_j\circ a)\otimes v_{ji}.$$

Hence

$$v(e_j\circ a)=\sum_k (e_k\circ a^{(2)})\otimes\kappa(a^{(1)})v_{kj}a^{(3)},$$

for an arbitrary j (because of linear independence of the v_{ij}). □

4. The dual bimodule

Assume now that a bicovariant bimodule Γ over G is specified by $(V,v,\circ)$. Then the corresponding *dual bimodule* Γ' can be specified by the triple $(V',v^c,\circ)$ where $v^c:V'\to V'\otimes A$ is the conjugate representation, while $\circ$ is the right $\mathscr{A}$-module structure on V defined by

$$\langle f\circ a,\theta\rangle=\langle f,\theta\circ\kappa^{-1}(a)\rangle. \tag{29}$$

Here, $f\in V'$, $\theta\in V$, and $\langle,\rangle$ is the contraction map. By a straightforward generalization of Woronowicz's considerations, we conclude that for any two bicovariant bimodules Γ_1 and Γ_2 there exists the canonical bimodule isomorphism $\sigma:\Gamma_1\otimes_{\mathscr{A}}\Gamma_2\to\Gamma_2\otimes_{\mathscr{A}}\Gamma_1$. Let V_i be the space of left-invariant elements of Γ_i. The left invariant part of this flip-over operator is an operator σ: $V_1\otimes V_2\to V_2\otimes V_1$, explicitly given by (26), where now $\eta\in V_1$ and $\theta\in V_2$ [with the inverse given by (27)]. Under these conditions all possible braid-type equations are satisfied.

We shall denote by $\mathscr{T}_G$ the *category* of bicovariant bimodules over G. Morphisms in this category are bimodule homomorphisms intertwining the corresponding right and left actions of G. Endowed with canonical braidings, $\mathscr{T}_G$ becomes a *braided monoidal category*.[11] Every *bicovariant algebra* is automatically an algebra in the category $\mathscr{T}_G$ (the product map is functorial with respect to all braidings). In what follows we shall use, without risk of confusion, the same symbol σ for all possible braidings appearing in the category $\mathscr{T}_G$.

If Γ_1 and Γ_2 are bicovariant bimodules determined by $(V_1, v_1, \circ)$ and $(V_2, v_2, \circ)$, respectively, then the product bimodule $\Gamma=\Gamma_1\otimes_{\mathscr{A}}\Gamma_2$ is determined by $(V,v,\circ)$ where $V=V_1\otimes V_2$, while v is the product of v_1 and v_2 and $\circ$ is given by

$$(\theta\otimes\eta)\circ a=(\theta\circ a^{(1)})\otimes(\eta\circ a^{(2)}). \tag{30}$$

If Γ is a bicovariant algebra, then Γ_{inv} is its subalgebra and we have

$$(\theta\eta)\circ a=(\theta\circ a^{(1)})(\eta\circ a^{(2)}), \tag{31}$$

for each θ, $\eta\in\Gamma_{\text{inv}}$.

It is also worth noticing that the contraction map between V and V' is functorial, in a natural manner. In other words,

Lemma II.3. The diagrams

$$\begin{array}{ccccc} V'\otimes & V & \otimes\Psi & \xrightarrow{(\sigma\otimes id)(id\otimes\sigma)} & \Psi\otimes & V' & \otimes V \\ \langle,\rangle\otimes id & \downarrow & & & & \downarrow & id\otimes\langle,\rangle, \\ \mathbb{C} & \otimes & \Psi & \xrightarrow[\cong]{} & \Psi & \otimes & \mathbb{C} \end{array} \tag{32}$$

$$\begin{array}{ccccc} \Psi\otimes & V' & \otimes V & \xrightarrow{(id\otimes\sigma)(\sigma\otimes id)} & V'\otimes & V & \otimes\Psi \\ id\otimes\langle,\rangle & \downarrow & & & & \downarrow & \langle,\rangle\otimes id \\ \Psi & \otimes & \mathbb{C} & \xrightarrow[\cong]{} & \mathbb{C} & \otimes & \Psi \end{array} \tag{33}$$

are commutative. Here $\Psi\in\{V,V'\}$.

Proof: Let us check diagrams (32). Diagrams (33) can be checked similarly. By direct computation we have

$$\begin{aligned} (id\otimes\langle,\rangle)(\sigma\otimes id)(id\otimes\sigma)(f\otimes\theta\otimes\eta) &= (id\otimes\langle,\rangle)(\sigma\otimes id)\Big(f\otimes\sum_l \eta_l\otimes(\theta\circ d_l)\Big) \\ &= (id\otimes\langle,\rangle)\Big(\sum_l \eta_l\otimes(f\circ d_l^{(1)})\otimes(\theta\circ d_l^{(2)})\Big) \\ &= \sum_l \eta_l\otimes\langle f\circ d_l^{(1)},\theta\circ d_l^{(2)}\rangle \\ &= \sum_l \eta_l\otimes\langle f,(\theta\circ d_l^{(2)})\circ\kappa^{-1}(d_l^{(1)})\rangle \\ &= \sum_l \eta_l\otimes\langle f,\theta\circ(d_l^{(2)}\kappa^{-1}(d_l^{(1)}))\rangle \\ &= \sum_l \eta\otimes\langle f,\theta e(d_l)\rangle = \eta\otimes\langle f,\theta\rangle, \end{aligned}$$

where $\Sigma_l \eta_l\otimes d_l = v(\eta)$ or $v^c(\eta)$ depending on the choice of Ψ. □

In fact, the above diagrams hold for an arbitrary $\Psi\in\mathscr{T}_G$.

C. Quantum SL(n,$\mathbb{C}$) groups

For application of the above general theory to the construction of the quantum Clifford algebras, which we present in Sec. III, we shall require the consideration of the specific case of the special linear groups. Following Ref. 12, let us consider a vector space $V=\mathbb{C}^n$, and a linear operator $\sigma: V\otimes V\to V\otimes V$ given by

$$\sigma(e_i\otimes e_j)=\mu(e_j\otimes e_i),\quad i<j,$$

$$\sigma(e_i\otimes e_i)=e_i\otimes e_i,$$

$$\sigma(e_i\otimes e_j)=\mu(e_j\otimes e_i)+(1-\mu^2)(e_i\otimes e_j),\quad i>j,$$

where $\mu\in(-1,1)\backslash\{0\}$. This operator is a Hecke braiding with $q=\mu^2$. A quantum deformation of the SL(n) group can be described as follows (it is obviously equivalent to the R-matrix definition[13]). Let $\mathscr{H}$ be the algebra generated by the elements $u_{ij}(i,j\in\{1,\ldots,n\})$ and the following relations

$$\sum_{kl}\sigma_{kl}^{ij}u_{km}u_{ln}=\sum_{kl}u_{ik}u_{jl}\sigma_{mn}^{kl}, \tag{34}$$

$$\sum_{\pi\in S_n}(-\mu)^{l(\pi)}u_{\pi_1\zeta_1}\cdots u_{\pi_n\zeta_n}=(-\mu)^{l(\zeta)}. \tag{35}$$

The meaning of relation (34) is that σ intertwines the square of the ''fundamental representation'' $v:V\to V\otimes\mathscr{A}$ [$v(e_i)=\Sigma_j e_j\otimes u_{ji}$, where e_i are the absolute basis vectors]. Relation (35) corresponds to the classical determinant requirement. Geometrically, it means that the reduction of the nth power of v on the one-dimensional subspace $V^{\wedge n}\subseteq V^{\otimes n}$ gives a trivial representation. Condition (35) can be also rewritten in the form

$$\sum_{\pi\in S_n}(-\mu)^{l(\pi)}u_{\zeta_1\pi_1}\cdots u_{\zeta_n\pi_n}=(-\mu)^{l(\zeta)}. \tag{36}$$

The Hopf algebra structure, the coproduct ϕ: $\mathscr{H}\to\mathscr{H}\otimes\mathscr{H}$, the counit ϵ: $\mathscr{H}\to\mathbb{C}$, and the antipode κ: $\mathscr{H}\to\mathscr{H}$ are specified by

$$\phi(u_{ij})=\sum_k u_{ik}\otimes u_{kj},\quad \epsilon(u_{ij})=\delta_{ij},$$

$$\kappa(u_{ij})=(-\mu)^{i-j}\sum_{\pi\in S_{n-1}}u_{\pi_1 1}\cdots u_{\pi_{i-1}i-1}u_{\pi_{i+1}i+1}\cdots u_{\pi_n n}.$$

In the formula for the antipode, permutations $\pi\in S_{n-1}$ are represented by sequences $(\pi_1,\ldots,\pi_{i-1},\pi_{i+1},\pi_n)$ of numbers $(1,\ldots,j-1,j+1,\ldots,n)$.

All operators of the form $D_\sigma(\varphi)$ (where $\varphi\in H_{n,q}$) intertwine the nth power of the fundamental representation u. Let us observe that the flip-over operator σ is borrowed from the theory of quantum SU(n) groups,[14] which are *compact quantum objects* (σ is a canonical intertwiner of the square of the fundamental representation of this group). In particular,[14] operators belonging to the image of the corresponding Hecke algebra representations are the only intertwiners of u^n.

Moreover, in all algebraic considerations with the above-described quantum SL(n,$\mathbb{C}$) group it is possible to deal with its *compact form* $S_\mu U(n)$. This is based on the fact that the Hopf algebras representing these two groups are isomorphic, the only difference being that the algebra $\mathscr{A}$ representing $S_\mu U(n)$ possesses the *-structure. Speaking in classical terms, the elements of the algebra $\mathscr{H}$ correspond to *holomorphic* polynomial functions on the quantum space SL(n) (and in the framework of this picture it is not possible to introduce the *-conjugation). On the other hand the elements of $\mathscr{A}$ correspond to all polynomial functions on $S_\mu U(n)$.

It is important to stress that the above argumentation only applies for the ''holomorphic part'' of the theory of the quantum SL(n) group. For example, if the full theory is considered (as for

example in Ref. 15), then the corresponding ''functional algebra'' $\mathscr{B}$ on the quantum SL(n) group is much larger (because then $\mathscr{B}$ represents all polynomial functions), and there exists the canonical Hopf algebra epimorphism $j:\mathscr{B}\to\mathscr{A}$ (the dualized inclusion map).

III. ON QUANTUM CLIFFORD ALGEBRAS

In this section we shall present a general construction of quantum Clifford algebras (for even-dimensional vector spaces), together with the corresponding spinor representation. The main geometrical classical idea that will be incorporated into the quantum context is that the spinor space is interpretable as the exterior algebra built over one of two isotropic (with respect to a given quadratic form) subspaces, into which the initial vector space decomposes. These subspaces are mutually dual, in a natural manner. The duality between them is realized via the scalar product. Therefore we can *start* from a vector space V (endowed with the appropriate structures) and *define* the ''total'' vector space as the direct sum $W=V\oplus V'$.

In the next subsection general considerations will be given. After that, the theory will be illustrated for the concrete example of four-dimensional spinors built from the quantum SL(2,$\mathbb{C}$) group, and its fundamental representation.

A. General considerations

Let G be a compact matrix quantum group. The algebra of polynomial functions on G will be denoted by $\mathscr{A}$. The quantum group structure is specified by the coproduct $\phi:\mathscr{A}\to\mathscr{A}\otimes\mathscr{A}$, the counit $\epsilon:\mathscr{A}\to\mathbb{C}$, and the antipode $\kappa:\mathscr{A}\to\mathscr{A}$. The result of an $(n-1)$-fold coproduct of $a\in\mathscr{A}$ will be denoted by $a^{(1)}\otimes\cdots\otimes a^{(n)}$.

Let $v:V\to V\otimes\mathscr{A}$ be an irreducible representation of G in a (finite dimensional) unitary vector space V. Let us assume that the space V possesses a unital right $\mathscr{A}$-module structure $\circ$, such that the compatibility condition (20) holds. In other words, V is understood as the left-invariant part of a bicovariant bimodule Γ over G, and v is the restriction on V of the corresponding right action of G on Γ. Let us assume that the corresponding canonical flip-over operator σ (eventually modified by an inessential multiplication constant) satisfies the Hecke condition

$$\sigma^2=(1-q)\sigma+qI,$$

for some $q>0$ (however, this assumption is not essential for our constructions).

Let $V^\wedge$ be the corresponding exterior algebra. This algebra is also naturally isomorphic to the subalgebra of left-invariant elements of the bicovariant[10] exterior algebra $\Gamma^\wedge$.

The following identities hold:

$$\sigma(m^\wedge\otimes id)=(id\otimes m^\wedge)(\sigma\otimes id)(id\otimes\sigma), \tag{37}$$

$$\sigma(id\otimes m^\wedge)=(m^\wedge\otimes id)(id\otimes\sigma)(\sigma\otimes id), \tag{38}$$

where $m^\wedge:V^\wedge\otimes V^\wedge\to V^\wedge$ is the multiplication map in $V^\wedge$. These identities express ''functoriality'' of $m^\wedge$, with respect to the natural braiding in $V^\wedge$, and follow directly from the fact that $V^\wedge\cong\Gamma^\wedge_{\mathrm{inv}}$. Indeed, using (31) we find

$$\begin{aligned}\sigma(m^\wedge\otimes id)(\theta\otimes\eta\otimes\zeta)&=\sum_k\ \zeta_k\otimes(\theta\eta)\circ c_k=\sum_k\ \zeta_k\otimes(\theta\circ c_k^{(1)})(\eta\circ c_k^{(2)})\\&=\sum_k\ (id\otimes m^\wedge)(\sigma\otimes id)(\theta\otimes\zeta_k\otimes(\eta\circ c_k))\\&=(id\otimes m^\wedge)(\sigma\otimes id)(id\otimes\sigma)(\theta\otimes\eta\otimes\zeta),\end{aligned}$$

for each $\zeta,\theta,\eta\in V^\wedge$, where $\Sigma_k\zeta_k\otimes c_k=v^\wedge(\zeta)$ and $v^\wedge:V^\wedge\to V^\wedge\otimes\mathscr{A}$ is the natural multiplicative extension of v (the restriction of the right action of G on $V^\wedge$). Property (37) follows similarly.

Let us now define the action $H: W \to L(V^{\wedge})$ of vectors from $V \oplus V' = W$ on $V^{\wedge}$ by the following formulas:

$$H(x)\xi = x \wedge \xi, \tag{39}$$

$$H(f\ )\xi = (f \otimes id)\xi = \iota_f \xi, \tag{40}$$

where $x \in V$, $f \in V'$ and in (40) the space $V^{\wedge}$ is realized as a subspace in $V^{\otimes}$ (with the help of the antisymmetrizer A).

For each $f \in V'$ the map $\iota_f : V^{\wedge} \to V^{\wedge}$ satisfies the following ''braided'' Leibniz rule:

$$\iota_f(\theta\eta) = \iota_f(\theta)\eta + (-1)^{\partial\theta} m\sigma^{-1}(\iota_f \otimes id)\sigma(\theta \otimes \eta). \tag{41}$$

This follows easily from the definition of ι_f as a contraction, as well as from the definition of the embedding $V^{\wedge} \hookrightarrow V^{\otimes}$.

Proposition III.1: The following identities hold:

$$H(x)H(y) + \frac{1}{q}\sum_k H(y_k)H(x_k) = 0, \tag{42}$$

$$H(f\ )H(g) + \frac{1}{q}\sum_l H(g_l)H(f_l) = 0, \tag{43}$$

$$H(f\ )H(x) + \sum_i H(x_i')H(f_i') = f(x), \tag{44}$$

$$H(y)H(g) + \sum_j H(g_j')H(y_j') = \sum_j g_j'(y_j'). \tag{45}$$

Here, $x, y \in V$ and $f, g \in V'$, while

$$\sum_k y_k \otimes x_k = \sigma(x \otimes y), \quad \sum_l g_l \otimes f_l = \sigma(f \otimes g),$$

$$\sum_i x_i' \otimes f_i' = \sigma^{-1}(f \otimes x), \quad \sum_j g_j' \otimes y_j' = \sigma(y \otimes g).$$

Proof: Identities (42) and (43) follow directly from the definition of exterior algebras over V and V', as well as from the fact that $I + \sigma/q$ is the projector on the space of σ-symmetric elements of $V \otimes V$ and $V' \otimes V'$. Identities (44) and (45) are mutually equivalent. Let us check (44). First, observe that the introduced ''contraction'' between V' and $V^{\wedge}$ can be naturally extended to a map $\iota: V'^{\wedge} \otimes V^{\wedge} \to V^{\wedge}$ such that

$$\iota_{uw} = \iota_u \iota_w \tag{46}$$

for each $u, w \in V'^{\wedge}$, where $\iota_{uw}(x) = \iota(u, w \otimes x)$.

Now, by the use of the braided Leibniz rule (41) and the identities

$$\sigma(\iota \otimes id) = (id \otimes \iota)(\sigma \otimes id)(id \otimes \sigma), \tag{47}$$

$$\sigma(id \otimes \iota) = (\iota \otimes id)(id \otimes \sigma)(\sigma \otimes id), \tag{48}$$

we obtain, by a direct computation,

$$\begin{aligned} H(f\ )H(x)\xi &= f(x)\xi - m^{\wedge}\sigma^{-1}(\iota_f \otimes id)\sigma(x\otimes\xi) \\ &= f(x)\xi - m^{\wedge}\sigma^{-1}(\iota\otimes id)(id\otimes\sigma)(f\otimes x\otimes\xi) \\ &= f(x)\xi - m^{\wedge}(id\otimes\iota)(\sigma^{-1}\otimes id)(f\otimes x\otimes\xi) = f(x)\xi - \sum_i H(x_i')H(f_i')\xi. \end{aligned}$$

□

Motivated by the above proposition we can *define* abstract quantum Clifford algebras. In fact, let $Cl(W)$ be a unital associative algebra generated by the vector space $W=V\oplus V'$ and the following relations

$$xy + \frac{1}{q}\sum_k y_k x_k = 0, \tag{49}$$

$$fg + \frac{1}{q}\sum_l g_l f_l = 0, \tag{50}$$

$$fx + \sum_i x_i' f_i' = f(x). \tag{51}$$

Definition III.1: The constructed algebra is called the quantum Clifford algebra associated to (V,σ).

The relations defining the algebra $Cl(W)$ can be written in a compact form as

$$\vartheta\eta + \sum_k \eta_k\vartheta_k = f(\vartheta,\eta).$$

Here, $\Sigma_k \eta_k\otimes\vartheta_k = \tau(\vartheta\otimes\eta)$ and $\tau: W^{\otimes 2}\to W^{\otimes 2}$ is a braiding given by the block matrix

$$\tau = \begin{pmatrix} \sigma/q & 0 & 0 & 0 \\ 0 & 0 & \sigma^{-1} & 0 \\ 0 & \sigma & 0 & 0 \\ 0 & 0 & 0 & \sigma/q \end{pmatrix},$$

and f is the corresponding bilinear form on W, extending the contraction map [uniquely determined by relations (49)–(51)].

To end this section, we observe that a quantum analogue of the Clifford algebra for the odd-dimensional case can be introduced as follows. We put

$$W = V\oplus V'\oplus M,$$

where M is a one-dimensional space, and define $Cl(W,\sigma)$ to be the abstract algebra generated by the spaces V and V', the corresponding relations (42)–(45), as well as by an element S satisfying $S^2=1$, $Sx+xS=0$, and $Sf+fS=0$, for each $x\in V$ and $f\in V'$.

IV. SPINOR REPRESENTATIONS

In this section we shall introduce the spinor representation. The braided exterior algebra $V^{\wedge}$ will play the role of the space of algebraic spinors.

A. Algebraic spinors

From the relations defining $Cl(W)$ and the braided Leibniz rule (41) for ι, it follows that the map $H:W\to L(V^{\wedge})$ can be uniquely extended to a unital homomorphism $H:Cl(W)\to L(V^{\wedge})$.

Definition IV.1: The introduced homomorphism H is called the spinor representation.

Proposition IV.1: The algebra $Cl(W)$ acts on $V^{\wedge}$ faithfully and irreducibly.

Proof: We shall prove that each nonzero vector $\xi\in V^{\wedge}$ is cyclic for H, which immediately implies that H is irreducible.

Without a lack of generality we can assume that ξ is homogeneous ($\xi\in V^{\wedge k}$).

Let us first observe that the spaces $V'^{\wedge}$ and $V^{\wedge}$ are mutually dual, in a natural manner. The corresponding pairing $\langle,\rangle:V'^{\wedge}\otimes V^{\wedge}\to\mathbb{C}$ can be explicitly constructed by taking the restriction of the natural pairing $\langle,\rangle:V'^{\otimes}\otimes V^{\otimes}\to\mathbb{C}$. Second, we have

$$\langle\varphi,\xi\rangle=c_k\iota(\varphi\otimes\xi), \tag{52}$$

for each $\varphi\in V'^{\wedge k}$. In particular, there exists $f\in V'^{\wedge}$ such that $\iota(f\otimes\xi)=1$. In other words, 1 can be obtained by acting with the operators $H(f)$ (where $f\in V'$) on ξ, and taking appropriate linear combinations. Consequently, ξ is cyclic for H, because 1 is cyclic for the left regular representation of $V^{\wedge}$ on itself.

Let us prove that H is faithful. From the relations defining $Cl(W)$ it follows that the inclusions $V\hookrightarrow W$ and $V'\hookrightarrow W$ can be extended to inclusions of algebras $V^{\wedge}\hookrightarrow Cl(W)$ and $V'^{\wedge}\hookrightarrow Cl(W)$. Moreover, from the same relations we conclude that the map $\mu:V^{\wedge}\otimes V'^{\wedge}\to Cl(W)$, given by

$$\mu(\xi\otimes\varphi)=\xi\varphi,$$

is bijective. Using this, Eq. (52), and the fact that $V^{\wedge}$ and $V'^{\wedge}$ are mutually dual, it is easy to see that the vectors ξ distinguish elements of $V^{\wedge}\otimes V'^{\wedge}$. More precisely, let us consider the maps of the form $\delta_{\xi}:V^{\wedge}\otimes V'^{\wedge}\to V^{\wedge}$ given by

$$\delta_{\xi}(\Theta)=H[\mu(\Theta)]\xi.$$

If $\Theta\in\ker(\delta_{\xi})$ for each $\xi\in V^{\wedge}$, then we have $\Theta=0$. In other words, the representation H is faithful. □

In the odd-dimensional case, the corresponding spinor representation can be constructed essentially in the same way as in the even-dimensional case. The additional generator S acts as the parity operator. According to Proposition IV.1 (applied to the Clifford algebra generated by V and V'), the operator $H(S)$ can be expressed algebraically through the operators $H(x)$, where $x\in V,V'$, if $V^{\wedge}$ is finite dimensional.

To end this section we shall briefly consider other possible approaches for introducing spinors, following Ref. 3. First, we give a more concise general definition.

Let $\varpi:V'^{\wedge}\to\mathbb{C}$ be a linear multiplicative functional, specified by $\varpi(1)=1$ and $\varpi(V')=\{0\}$. This gives a left $V'^{\wedge}$-module structure on the number field $\mathbb{C}$. On the other hand, $Cl(W)$ is naturally a right $V'^{\wedge}$-module (the multiplication on the right). Let $\mathscr{S}$ be a left $Cl(W)$-module, given by

$$\mathscr{S}=Cl(W)\otimes_{*}\mathbb{C},$$

where the tensor product is taken over $V'^{\wedge}$.

Proposition IV.2: The modules $(V^{\wedge},H)$ and $\mathscr{S}$ are naturally isomorphic. The isomorphism is explicitly given by

$$V^{\wedge} \ni \xi \leftrightarrow \xi \otimes_* 1 \in \mathscr{S}.$$

Proof: The statement follows from the relations defining the quantum Clifford algebra. □

Let us now assume for a moment that we are dealing with classical Clifford algebras. Then spinors can be viewed in another (but equivalent) way as elements of the left $Cl(W)$-ideal, generated by a volume element of V'.

An analogous description of spinors works in the quantum context if there exists a ''volume element'' in the braided exterior algebra $V'^{\wedge}$. More precisely, let us assume that there exists (a volume element) $\omega \in V'^{\wedge} \setminus \{0\}$ satisfying $x\omega = 0$, for each $x \in V'$.

Proposition IV.3: Let $\mathscr{I}_\omega$ be a left ideal in $Cl(W)$ generated by ω. Then there exists the unique $Cl(w)$-module map $i_\omega : V^{\wedge} \to \mathscr{I}_\omega$ satisfying $i_\omega(1) = \omega$.

Proof: The statement easily follows from the definition of the spinor module $\mathscr{I} = (\mathrm{V}^{\wedge}, \mathrm{H})$, and its simplicity. □

B. Scalar products and *-structures

In this subsection we shall introduce a natural scalar product in the spinor space, and investigate its properties. With the help of this scalar product, a *-structure on the corresponding quantum Clifford algebra will be introduced. The construction generalizes classical considerations in the case when the underlying space is endowed with an Euclidean (strictly positive) scalar product. Pseudo-Euclidean spaces are dealt with in a forthcoming paper.

Let us assume that the space V is endowed with a unitary structure, such that the braiding σ: $V^{\otimes 2} \to V^{\otimes 2}$ is Hermitian with respect to the corresponding scalar product. Let $j : V \to V'$ be the canonical antilinear map (induced by the scalar product). In what follows it will be assumed that V' is endowed with the corresponding j-induced scalar product (so that j is antiunitary).

We can now introduce a *-involution in the main vector space $W = V \oplus V'$, by means of the block matrix.

$$* = \begin{pmatrix} 0 & j^{-1} \\ j & 0 \end{pmatrix}.$$

We shall prove that this involution can be extended to a *-structure on the Clifford algebra $Cl(W)$.

Assume that $V^{\wedge}$ is realized as a subspace of completely σ antisymmetric elements of the tensor algebra $V^{\otimes}$. Furthermore, let us assume that $V^{\wedge}$ is endowed with the scalar product $\langle , \rangle$ given by

$$\langle \varphi, \psi \rangle = c_n(\varphi, \psi),$$

where $(,)$ is the scalar product in $V^{\otimes}$, and $\varphi, \psi \in V^{\wedge n}$, while

$$c_n = (n_q)!, \quad n_q = \frac{1 - q^n}{1 - q}, \quad \text{for } q \neq -1.$$

By definition, the elements of different degrees are orthogonal.

Lemma IV.1: We have

$$\langle H(x)\varphi, \psi \rangle = \langle \varphi, H(x^*)\psi \rangle, \tag{53}$$

for each $x \in W$ and $\varphi, \psi \in V^{\wedge}$.

Proof: Clearly, it is sufficient to check the above equation for elements $x \in V$, $\varphi \in V^{\wedge n-1}$, and $\psi \in V^{\wedge n}$. A direct calculation gives

$$\langle H(x)\varphi,\psi\rangle = c_n(A_{1n-1}(x\otimes\varphi),\psi) = c_n(x\otimes\varphi,A^{\dagger}_{1n-1}\psi) = c_n\left(\sum_{i=0}^{n-1} q^i\right)(x\otimes\varphi,\psi)$$
$$= c_{n-1}(\varphi,H(x^*)\psi) = \langle\varphi,H(x^*)\psi\rangle.$$

□

Therefore, the *-involution is compatible with the spinor representation H. Having in mind that the H is an isomorphism between $Cl(W)$ and $L(V^{\wedge})$, we can define a *-structure on the whole $Cl(W)$ by requiring that

$$\langle H(a)\varphi,\psi\rangle = \langle\varphi,H(a^*)\psi\rangle,$$

for each $a\in Cl(W)$. Evidently, this gives an antimultiplicative and involutive extension of the previously introduced map.

V. FLIP-OVER OPERATOR AND *q*-CLIFFORD ALGEBRA

In order to obtain concrete relations that will enable a comparison of our results with those of other authors, we focus our attention on the q-Clifford algebra for a $2n$-dimensional total vector space W, with basis $\{e_i,e_i'\}_{i=1}^n$, and quantum group $\mathrm{SL}_q(n,\mathbb{C})$ with metric representation on V given by $v(e_i)=\Sigma_j e_j\otimes u_{ji}$.

Following the methodology developed in the general theory contained in Sec. II, one arrives at the following results:

$$H(e_i')H(e_j)+\sum_{k,l}(\sigma^{-1})_{ij}{}^{kl}H(e_k)H(e_l') = \delta_{ij}E, \tag{54}$$

where

$$\sigma^{-1}(e_i'\otimes e_j) = \sum_{k,l}(\sigma^{-1})_{ij}{}^{kl}e_k\otimes e_l', \tag{55}$$

and E is the identity operator. The inverse relation is given by

$$H(e_i)H(e_j')+\sum_{k,l}(\sigma)_{ij}{}^{kl}H(e_k')H(e_l) = \eta_{ij}E, \tag{56}$$

with

$$\sigma(e_i\otimes e_j') = \sum_{k,l}(\sigma)_{ij}{}^{kl}e_k'\otimes e_l \quad\text{and}\quad \eta_{ij}\equiv\sum_{l}(\sigma)_{ij}{}^{ll}. \tag{57}$$

We also have

$$H(e_i)H(e_j)+\frac{1}{\mu^2}\sum_{k,l}(\sigma)_{ij}{}^{kl}H(e_k)H(e_l) = 0, \tag{58}$$

where

$$\sigma(e_i\otimes e_j) = \sum_{k,l}(\sigma)_{ij}{}^{kl}e_k\otimes e_l, \tag{59}$$

and

$$H(e_i')H(e_j')+\frac{1}{\mu^2}\sum_{k,l}(\sigma)_{ij}{}^{kl}H(e_k')H(e_l')=0, \tag{60}$$

where

$$\sigma(e_i'\otimes e_j')=\sum_{k,l}(\sigma)_{ij}{}^{kl}e_k'\otimes e_l'. \tag{61}$$

To compute the flip-over operators, we use the formalism of bicovariant bimodules. Here, we shall denote by $\tilde{\sigma}$ the canonical intertwiners given by formula (26). Up to a multiplication constant, $\tilde{\sigma}:V\otimes V\to V\otimes V$ coincides with the flip-over operator $\sigma:V\otimes V\to V\otimes V$. In fact, the condition $\tilde{\sigma}=\beta\sigma$ with $\beta\in\mathbb{R}^+$ uniquely fixes the corresponding right $\mathscr{A}$-module structure $\circ$ on V. Applying (26) and (27) and making use of the fact that

$$\kappa^{-1}(u)=F^{-1}\kappa(u)F, \tag{62}$$

where $\kappa(u)=u^\dagger$, and $F:V\to V$ is the canonical intertwiner[16] between u and its double contragradient u^{cc}, which in our case is explicitly given by $Fe_k=\mu^{2k-n-1}e_k$, we obtain expressions for $e_i\circ u_{kj}$ and $e_i\circ u_{kj}^*$. Using the definition (29) of $\circ$ in the dual space we obtain the expressions for $e_i'\circ u_{kj}$ and $e_i'\circ u_{kj}^*$.

The right $\mathscr{A}$-module structures on V and V' (cf. equations given in the Appendix) enable us to compute the remaining three flip-over operators. A direct calculation based on (26) and (27) gives

$$\tilde{\sigma}(e_i\otimes e_i')=\frac{1}{\beta}e_i'\otimes e_i+\frac{1-\mu^{-2}}{\beta}\sum_{k<i}\mu^{2(i-k)}e_k'\otimes e_k,$$

$$\tilde{\sigma}(e_i\otimes e_j')=\frac{1}{\beta\mu}e_j'\otimes e_i,\quad i\neq j,$$

$$\tilde{\sigma}^{-1}(e_i'\otimes e_i)=\beta e_i\otimes e_i'+\beta(1-\mu^2)\sum_{k<i}e_k\otimes e_k',$$

$$\tilde{\sigma}^{-1}(e_i'\otimes e_j)=\beta\mu e_j\otimes e_i',\quad i\neq j,$$

$$\tilde{\sigma}(e_i'\otimes e_i)=\frac{1}{\beta}e_i\otimes e_i'+\frac{1-\mu^{-2}}{\beta}\sum_{k>i}e_k\otimes e_k', \tag{63}$$

$$\tilde{\sigma}(e_i'\otimes e_j)=\frac{1}{\beta\mu}e_j\otimes e_i',\quad i\neq j,$$

$$\tilde{\sigma}(e_i'\otimes e_i')=\beta e_i'\otimes e_i',$$

$$\tilde{\sigma}(e_i'\otimes e_j')=\beta(1-\mu^2)e_i'\otimes e_j'+\mu\beta e_j'\otimes e_i',\quad i<j,$$

$$\tilde{\sigma}(e_i'\otimes e_j')=\beta\mu e_j'\otimes e_i',\quad i>j.$$

We can renormalize these flip-over operators $\tilde{\sigma}$ in such a way that they become extensions of the initial Hecke braiding $\sigma:V\otimes V\to V\otimes V$. This involves multiplying by β the ''mixing operators'' acting on $V\otimes V'$ and $V'\otimes V$ and, dividing by β the braid operator in $V'\otimes V'$. We denote by

σ all these new operators. From the quantum determinant condition (35) it is straightforward to determine that $\beta=\mu^{(1-n)/n}$. For the four-dimensional case, the q-Clifford algebra generated by $H(W)$ becomes

$$H(e_i)H(e'_j)+L_{ij}{}^{kl}H(e'_k)H(e_l)=\eta_{ij}E, \tag{64}$$

with

$$L=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & \mu^{-1} & 0 \\ 0 & \mu^{-1} & 0 & 0 \\ (\mu^2-1) & 0 & 0 & 1 \end{pmatrix}$$

and

$$\eta=\begin{pmatrix} 1 & 0 \\ 0 & \mu^2 \end{pmatrix};$$

$$H(e_i)H(e_j)+M_{ij}{}^{kl}H(e_k)H(e_l)=0,$$

with

$$M=\mu^{-2}\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & \mu & 0 \\ 0 & \mu & (1-\mu^2) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix};$$

$$H(e'_i)H(e'_j)+M'_{ij}{}^{kl}H(e'_k)H(e'_l)=0, \tag{65}$$

with

$$M'=\mu^{-2}\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & (1-\mu^2) & \mu & 0 \\ 0 & \mu & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

For the four-dimensional case, it is also possible to arrive at the above q-Clifford algebra by a stepwise procedure, which consists of making use of the definition of the action of the operator H on each element of the basis, applied twice on a spinor $\xi=\xi^0+\xi^1e_1+\xi^2e_2+\xi^3e_1\wedge e_2$. For example, the double action of $H(e_1)H(e'_1)$ on ξ results in

$$H(e_1)H(e'_1)\xi=e_1\wedge(\iota_{e'_1}\xi)=\xi^1e_1+\xi^3e_1\wedge e_2, \tag{66}$$

and, similarly,

$$H(e'_1)H(e_1)\xi=\iota_{e'_1}(e_1\wedge\xi)=\xi^0+\xi^2e_2. \tag{67}$$

Adding these two expressions yields

$$(H(e_1)H(e_1')+H(e_1')H(e_1))\xi=E\xi, \tag{68}$$

which coincides with our previous result.

Finally we consider the matrix $\hat{R}=PR$ [corresponding to the quantum group $\mathrm{SL}_q(2,\mathbb{C})$[13]] that satisfies both the Hecke condition and the braid equation. In matrix form we have

$$\hat{R}=\begin{pmatrix} \mu^{-1} & 0 & 0 & 0 \\ 0 & \mu^{-1}-\mu & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & \mu^{-1} \end{pmatrix}.$$

Furthermore, since for this case

$$\mu^{-1}\sigma=\begin{pmatrix} \mu^{-1} & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & \mu^{-1}-\mu & 0 \\ 0 & 0 & 0 & \mu^{-1} \end{pmatrix},$$

with σ corresponding to the flip-over operator on $V\otimes V$, which also satisfies the Hecke condition, both matrices are related by the similarity transformation

$$S\hat{R}S^{-1}=\mu^{-1}\sigma, \tag{69}$$

with

$$S=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

This enables us to obtain a relation between the R matrix, which determines the quantum group $\mathrm{SL}_q(2,\mathbb{C})$, and the operator σ, which establishes the anticommutation relations of the Clifford algebra.

VI. *q*-CLIFFORD ALGEBRAS AND *q*-DIRAC OPERATOR

In this section we use the q-Clifford algebra to construct a real q-space and a differential calculus associated to this space. We also build up the q-Dirac and the q-Klein–Gordon scalar operators from the dual q-Clifford algebra.

We shall introduce a formal background for the coordinates and the derivation operators, based on our q-Clifford algebras, and define a consistent *-structure which will allow us to describe real q-Euclidean spaces and the corresponding differential calculi. We also describe an interesting and purely quantum phenomenon which appears in the presented theory, which is related to a certain nonuniqueness of our q-Clifford algebras, as well as of the algebras of coordinates and derivations.

A. Differential calculus in isotropic basis

Consider a bilinear map $\langle,\rangle: W\times W\to\mathbb{C}$, given by the matrix elements figuring in the q-Clifford algebra relations

$$2\langle e_\alpha, e_\beta\rangle=f_{\alpha\beta}=(e_\alpha e_\beta+m\tau(e_\alpha\otimes e_\beta)), \tag{70}$$

with $e_\alpha = \{e_i, e_i'\}_{i=1}^n$. The introduced ''scalar product'' is τ-symmetric $\langle \mathbf{w}\otimes\mathbf{z}\rangle = \langle \tau(\mathbf{w}\otimes\mathbf{z})\rangle$, and nondegenerate, because the only contributions of the braid τ to (70) come from the part which mixes elements in V with elements in V', which is involutive due to relations (63).

Following the classical Cartan theory, we would like to satisfy the fundamental property of spinor transformations $H(\mathbf{w})$ associated with a vector $\mathbf{w}$, that is,

$$H(\mathbf{w})H(\mathbf{w}) = \langle \mathbf{w},\mathbf{w}\rangle E. \tag{71}$$

Maintaining the above relation for the quantum case will make it also possible to preserve the geometric interpretation of the spinor transformations $H(\mathbf{u})$ as ''plane inversions'' in a subspace perpendicular to the unit vector $\mathbf{u}$. This in turn will be important for the construction of a spinor algebra, a natural q-spinor bilinear inner product, and its relations to the Hermitian product introduced in the previous section.

Relation (71) implies

$$\sum_{\alpha\beta} w^\alpha w^\beta \otimes e_\alpha \otimes e_\beta \in \mathscr{B}\otimes \mathrm{Im}(1+\tau), \tag{72}$$

where $\mathscr{B}$ is the algebra generated by the coordinates $w^\alpha = \{w^1,\ldots,w^n,w'^1,\ldots,w'^n\}$ in the isotropic basis.

The above relation is equivalent to

$$0 = [id\otimes(1-\tau_1)](w^\alpha w^\beta \otimes e_\alpha \otimes e_\beta), \tag{73}$$

where τ_1 is an operator on W satisfying

$$\ker(1-\tau_1) = \mathrm{Im}(1+\tau).$$

An explicit solution for this is given by a braiding

$$\tau_1 = \begin{pmatrix} \sigma & 0 & 0 & 0 \\ 0 & 0 & \sigma^{-1} & 0 \\ 0 & \sigma & 0 & 0 \\ 0 & 0 & 0 & \sigma \end{pmatrix}, \tag{74}$$

where, as already mentioned, σ denotes all functorial extensions of the original σ (the domain is clear from the context).

From (73) we immediately obtain the following algebra for the coordinates w^α:

$$w^\alpha w^\beta = m\,\tau_1^\tau(w^\alpha\otimes w^\beta). \tag{75}$$

In explicit form,

$$\begin{aligned} w^i w^j &= \mu w^j w^i, \quad i<j, \\ w'^i w'^j &= \mu^{-1} w'^j w'^i, \quad i<j, \\ w^i w'^j &= \mu w'^j w^i, \quad i\neq j, \\ w^i w'^i &= w'^i w^i + \sum_{l>i} (1-\mu^2) w'^l w^l. \end{aligned} \tag{76}$$

Note that essentially the same algebra is obtained in Ref. 17 for the four-dimensional case. The basic difference being that in our approach the commutation relations (76) on the underlying base space are imposed by the ansatz (71) on the q-Clifford algebra.

To complete the algebra, we also need an algebra Σ of q-symbolic derivations $\{\partial_i,\partial_i'\}_{i=1}^n$. Relations for the algebra Σ follow by dualizing relations (75) and noting that for an arbitrary braiding η there corresponds a braiding $\psi\eta^{\tau}\psi$ acting in the dual space. Here ψ denotes the standard transposition operator (if we include the dual spaces in the braided monoidal category generated by η and require the functoriality of the contraction map). Thus we get the following symmetric algebra for the Σ space of q-derivations

$$\begin{aligned}
&\partial_i\partial_j=\mu^{-1}\partial_j\partial_i, \quad i<j,\\
&\partial_i'\partial_j'=\mu\partial_j'\partial_i', \quad i<j,\\
&\partial_i\partial_j'=\mu\partial_j'\partial_i, \quad i\neq j,\\
&\partial_i\partial_i'=\partial_i'\partial_i+\sum_{l<i}(1-\mu^2)\partial_l'\partial_l.
\end{aligned} \tag{77}$$

We shall be needing in addition the braided Leibniz rule with actions of q-derivations both from the left and from the right. The braided Leibniz rule with derivations from the left is given by

$$\partial_\alpha w^\beta=\delta_\alpha^\beta+(\mathscr{T}^{-1})_{\alpha\epsilon}^{\beta\gamma}w^\epsilon\partial_\gamma. \tag{78}$$

To determine the coefficients in (78) we use the functoriality relation

$$(id\otimes c)(\mathscr{T}^{-1}\otimes id)(\partial_\alpha\otimes w^\beta\otimes w^\gamma)=(c\otimes id)(id\otimes\eta)(\partial_\alpha\otimes w^\beta\otimes w^\gamma), \tag{79}$$

where c denotes contraction. This enables us to find the relation between $\mathscr{T}^{-1}$ and the braiding η in the space of coordinates. We obtain

$$(\mathscr{T}^{-1})_{\alpha\epsilon}^{\beta\gamma}=\eta^{\beta\gamma}{}_{\alpha\epsilon}, \tag{80}$$

with

$$\eta\equiv\begin{cases}
\mu^{-2}\sigma^{\tau} \;:\; (\alpha,\beta)=(i,j),\\
\mu^{-2}(\sigma)^{\tau} \;:\; (\alpha,\beta)=(i',j'),\\
(\tilde{\sigma}^{-1})^{\tau} \;:\; (\alpha,\beta)=(i',j),\\
(\sigma)^{\tau} \;:\; (\alpha,\beta)=(i,j').
\end{cases}$$

In explicit form, using (78)–(80), the Leibniz rule with action from the left is

$$\partial_i w^j=\mu^{-1}w^j\partial_i, \quad i\neq j$$

$$\partial_i w^i=1+\mu^{-2}w^i\partial_i+(\mu^{-2}-1)\sum_{k<i}w^k\partial_k,$$

$$\partial_i' w'^j=\mu^{-1}w'^j\partial_i', \quad i'\neq j',$$

$$\partial_i' w'^i=1+\mu^{-2}w'^i\partial_i'+(\mu^{-2}-1)\sum_{k>i}w'^k\partial_k',$$

$$\begin{aligned}
\partial_i' w^j &= \mu w^j \partial_i', \quad i<j,\\
\partial_i' w^j &= \mu w^j \partial_i' + (1-\mu^2) w^i \partial_j', \quad i>j,\\
\partial_i' w^i &= w^i \partial_i',\\
\partial_i w'^j &= \mu^{-1} w'^j \partial_i,\\
\partial_i w'^j &= \mu^{-1} w'^j \partial_i + (1-\mu^{-2}) \mu^{2(i-j)} w'^i \partial_j, \quad i>j,\\
\partial_i w'^i &= w'^i \partial_i.
\end{aligned} \tag{81}$$

In a similar manner, we obtain the Leibniz rule with q-derivation action from the right. Thus

$$w^\beta \overleftarrow{\partial}_\alpha = \delta_\alpha^\beta + \eta_{\epsilon\alpha}^{\gamma\beta} \overleftarrow{\partial}_\gamma w^\epsilon, \tag{82}$$

where

$$\eta \equiv \begin{cases} \mu^{-2}\sigma^\tau \ : \ (\beta,\alpha)=(j,k),\\ \mu^{-2}(\sigma)^\tau \ : \ (\beta,\alpha)=(j',k'),\\ (\sigma^{-1})^\tau \ : \ (\beta,\alpha)=(j',k),\\ (\sigma)^\tau \ : \ (\beta,\alpha)=(j,k'). \end{cases}$$

Explicitly, we have

$$w^j \overleftarrow{\partial}_k = \mu^{-1} \overleftarrow{\partial}_k w^j, \quad j \neq k, \tag{83}$$

$$w^j \overleftarrow{\partial}_j = 1 + \mu^{-2} \overleftarrow{\partial}_j w^j + (\mu^{-2}-1) \sum_{i>j} \overleftarrow{\partial}_i w^i, \tag{84}$$

$$w'^j \overleftarrow{\partial}_k' = \mu^{-1} \overleftarrow{\partial}_k' w'^j, \quad j \neq k, \tag{85}$$

$$w'^j \overleftarrow{\partial}_j' = 1 + \mu^{-2} \overleftarrow{\partial}_j' w'^j + (\mu^{-2}-1) \sum_{i<j} \overleftarrow{\partial}_i' w'^i, \tag{86}$$

$$w'^j \overleftarrow{\partial}_k = \mu \overleftarrow{\partial}_k w'^j + (1-\mu^2) \overleftarrow{\partial}_j w'^k, \quad j<k \tag{87}$$

$$w'^j \overleftarrow{\partial}_k = \mu \overleftarrow{\partial}_k w'^j, \quad j>k, \tag{88}$$

$$w'^j \overleftarrow{\partial}_j = \overleftarrow{\partial}_j w'^j, \tag{89}$$

$$w^j \overleftarrow{\partial}_k' = \mu^{-1} \overleftarrow{\partial}_k' w^j + (1-\mu^{-2}) \mu^{2(k-j)} \overleftarrow{\partial}_j w^k, \quad j<k \tag{90}$$

$$w^j \overleftarrow{\partial}_k' = \mu^{-1} \overleftarrow{\partial}_k' w^j, \quad j>k, \tag{91}$$

$$w^j \overleftarrow{\partial}_j' = \overleftarrow{\partial}_j' w^j. \tag{92}$$

The left and right partial derivatives used above are related to the differential by the following symbolic expression

$$d=\sum_{\alpha} dw^{\alpha}\,\partial_{\alpha}=\sum_{\alpha}\overleftarrow{\partial}_{\alpha}\,dw^{\alpha}. \tag{93}$$

Note that all the expressions derived in this section are automatically consistent, because all constructions are intrinsic, and are performed in a braided monoidal category. An alternative and explicit way to check consistency could be based on an approach similar to that followed by Pusz and Woronowicz[12] and Wess and Zumino.[18] Essentially such a procedure consists of introducing a flip operator C between differentials and coordinates which is required to satisfy the relations

$$E+C=\tau_1^{\tau}+C\tau_1^{\tau}, \tag{94}$$

$$(id\otimes\tau_1^{\tau})(C\otimes id)(id\otimes C)=(C\otimes id)(id\otimes C)(\tau_1^{\tau}\otimes id). \tag{95}$$

B. On two natural Clifford algebras

As we have seen, starting from $Cl(W)$ it is possible to construct a q-analogue of the polynomial algebra over W. This algebra is generated by W and relations resulting from the requirement that the expression

$$\left(\sum_i e_i' x_i' + e_i x_i\right)^2=\langle \mathbf{x},\mathbf{x}\rangle$$

be scalar. This leads to the braided-symmetric algebra $\mathscr{B}$ over W, based on the operator τ_1^{τ}. However, using the induced commutation relations for the partial derivatives, it is easy to show that the square of the symbolic ''Dirac operator''

$$\boldsymbol{\nabla}=\sum_i e_i'\,\partial_i' + e_i\partial_i$$

is not a scalar operator.

On the other hand, it is possible to adopt a different point of view, which consists of introducing a new Clifford algebra, starting from the explicit requirement that ∇^2 be a scalar operator and that relations between partial derivatives are assumed the same as in (77).

In other words we should look for such a braiding $\widetilde{\tau}: W^{\otimes 2}\to W^{\otimes 2}$ which is related to $\psi\tau_1\psi$ in the same way as τ is to τ_1^{τ} [see Eqs. (73) and (74)]. Explicitly

$$\widetilde{\tau}=\psi\tau^{\tau}\psi.$$

This leads to the following expression for the Laplacian:

$$\Delta=\nabla^2=\sum_i \partial_i'\partial_i\,. \tag{96}$$

Note, however, that this new Clifford algebra would exchange the role of coordinates and derivatives figuring in their commutation relations and when applying twice the procedure we would return to the starting point.

In the classical case both Clifford algebras coincide. However, from the point of view of introducing quantum space models, there is *a priori* no reason to favor one q-Clifford algebra over the other. Furthermore, from the perspective of developing an analogue of the Hamiltonian for-

malism, it may be desirable to work simultaneously with the two Clifford algebras, since one of them is intrinsically connected with coordinates, and the other is connected with derivation operators.

C. Real *q*-space and corresponding differential calculus

Let $\mathscr{W}$ be the algebra generated by the coordinates w^α, the left and right partial derivatives, and all the above-mentioned relations. We can now extend the antimultiplicative $*$-involution introduced in Sec. IV to the whole algebra $\mathscr{W}$.

For simplicity in what follows we shall restrict ourselves to the four-dimensional case. Clearly the results can be readily generalized to arbitrary dimensions.

In the isotropic basis $\{e_i, e_i'\}_{i=1}^2$ of the vector space W, the $*$-operation is given by

$$e_1^* = e_1', \quad e_1'^* = e_1, \tag{97}$$

$$e_2^* = e_2', \quad e_2'^* = e_2. \tag{98}$$

This *-operation induces the following *-operation for partial derivatives:

$$(\partial_1)^* = \overleftarrow{\partial}_1', \quad (\partial_2)^* = \overleftarrow{\partial}_2', \tag{99}$$

$$(\partial_1')^* = \overleftarrow{\partial}_1, \quad (\partial_2')^* = \overleftarrow{\partial}_2. \tag{100}$$

The $*$ is extended to the whole algebra $\mathscr{W}$ by making use of the properties

$$*^2 = id, \quad (w^\alpha w^\beta)^* = w^{\beta *} w^{\alpha *},$$

$$(\partial_\alpha w^\beta)^* = w^{\beta *} (\partial_\alpha)^*, \quad (w^\alpha \overleftarrow{\partial}_\beta)^* = (\overleftarrow{\partial}_\beta)^* w^{\alpha *}.$$

It is easy to verify that, with these relations, the algebra is consistent. Furthermore, defining reality by means of the condition $\mathbf{w}^* = \mathbf{w}$, we can apply the above formalism to construct the Dirac and Klein–Gordon operators for the case of q-deformed Euclidean spaces.

Clearly, to the generator level, the resulting expressions will reproduce the ones in the classical case. However, for computations with these operators involving higher-order terms in the generators, the quantum nature of the algebra will appear.

It is important to mention that the above *-structure is not unique. Another natural choice is to adopt a ''quantum plane'' viewpoint, and to consider the $*$ invariant under the natural action of a certain quantum group. In the considered case, the group is $S_\mu U(2)$. Explicitly, the *-structure is then given by

$$w^{1*} = w'^1, \quad w'^{1*} = w^1, \quad w^{2*} = \mu^2 w'^2, \quad w'^{2*} = \mu^{-2} w^2, \tag{101}$$

and

$$(\partial_1)^* = \mu^2 \overleftarrow{\partial}'_1, \quad (\partial_2)^* = \overleftarrow{\partial}'_2, \quad (\partial_1')^* = \mu^{-2} \overleftarrow{\partial}_1, \quad (\partial_2')^* = \overleftarrow{\partial}_2. \tag{102}$$

From this we construct the ''real'' basis of vectors $\{a_i\}_{i=1}^4$:

$$a_1 = e_1 + e_1', \tag{103}$$

$$a_2 = e_2 + \mu^2 e_2', \tag{104}$$

$$a_3 = i(e_1 - e_1'), \tag{105}$$

$$a_4 = i(\mu^2 e_2 - e_2'). \tag{106}$$

Making use of (106) it immediately follows that

$$\langle a_i, a_j \rangle \equiv g_{ij} \equiv \begin{cases} 1 \ : \ i=j=1 \ \text{ or } \ i=j=3, \\ \frac{1}{2}(1+\mu^{-2}) \ : \ i=j=2, \\ \dfrac{\mu^2}{2}(1+\mu^2) \ : \ i=j=4, \\ \dfrac{i}{2}(1-\mu^2) \ : \ i=2, \ j=4, \\ \dfrac{-i}{2}(1-\mu^2) \ : \ i=4, \ j=2, \\ 0 \ : \ \text{otherwise.} \end{cases}$$

Note that the g_{ij} can be seen as the coefficients of a ''q-metric,'' appearing in the corresponding q-Clifford algebra

$$a_i a_j + m\tau(a_i \otimes a_j) = 2g_{ij}. \tag{107}$$

In the basis (106), the coordinates of any ''real'' vector $\mathbf{A} \in W$ are given in terms of the former isotropic coordinates by

$$A^1 = \tfrac{1}{2}(w^1 + w'^1), \tag{108}$$

$$A^2 = \tfrac{1}{2}(w^2 + \mu^2 w'^2), \tag{109}$$

$$A^3 = \frac{i}{2}(w'^1 - w^1), \tag{110}$$

$$A^4 = \frac{i}{2}(-\mu^{-2} w^2 + w'^2). \tag{111}$$

Substituting (108)–(111) in the algebra (76), we obtain the following commutation relations for the A^i:

$$A^2 A^4 = A^4 A^2, \tag{112}$$

$$A^2 A^1 - iA^2 A^3 = \mu(A^1 A^2 - iA^3 A^2), \tag{113}$$

$$A^3 A^4 + iA^1 A^4 = \mu^{-1}(A^4 A^3 + iA^4 A^1), \tag{114}$$

$$A^1 A^3 - A^3 A^1 = \frac{i}{2}(\mu^{-2} - 1)(A^2 A^2 + \mu^4 A^4 A^4). \tag{115}$$

Note that from the relations (76) and (101), it follows that the ''q-distance'' defined as the fundamental bilinear form is ''real,'' i.e.,

$$\langle w, w \rangle = w'^1 w^1 + w'^2 w^2 = \langle w, w \rangle^*, \tag{116}$$

and it is also central to the algebra $\mathscr{B}$.

If we now write the q-distance in terms of the ''real'' coordinates, we have

$$\langle w,w\rangle = A^i A^j g_{ij} = A^1 A^1 + A^3 A^3 + \tfrac{1}{2}(1+\mu^{-2})(A^2 A^2 + \mu^4 A^4 A^4). \tag{117}$$

Observe that (117) has the Euclidean metric as the classical limit. The q-derivations $\{\partial/\partial A^i\}$, corresponding to the real coordinates A^i, follow directly from the chain rule

$$\frac{\partial}{\partial A^i} = \frac{\partial w^j}{\partial A^i}\frac{\partial}{\partial w^j} \equiv \frac{\partial w^j}{\partial A^i}\,\partial_j\,. \tag{118}$$

We thus obtain

$$\frac{\partial}{\partial A^1} = \partial_1 + \partial_1'\,, \tag{119}$$

$$\frac{\partial}{\partial A^2} = \partial_2 + \mu^{-2}\partial_2'\,, \tag{120}$$

$$\frac{\partial}{\partial A^3} = i(\partial_1 - \partial_1'), \tag{121}$$

$$\frac{\partial}{\partial A^4} = i(\mu^2\partial_2 - \partial_2'), \tag{122}$$

and $\partial A^i/\partial A^j = \delta_{ij}$, $(\partial/\partial A^i)^* = \overleftarrow{\partial}/\partial A^i$.

Note also that, in contrast to the solution suggested in Ref. 19, where conjugation of partial derivatives involves nonlinear terms of arbitrary order, our *-operation preserves the space of partial derivatives, intertwining the left and right differential structures.

Another approach in constructing a differential calculus is given in Ref. 20, where analogues of the Laplacian (see Sec. VI B) and the metric observable are similar to the entities considered here. On the other hand, our approach is fully based on the general theory of Clifford algebras, and does not presume a unique *-structure, since quantum groups are used mainly as auxiliary entities for the construction of the corresponding braidings (via the formalism of bicovariant bimodules). Thus we believe that our formalism would be less restrictive because one could exploit the nonuniqueness of the *-operator to investigate several possible q-Euclidean spaces with the same classical limit, as we commented before.

VII. QUANTUM GROUPS FROM CLIFFORD ALGEBRAS

Our above described general theory of quantum Clifford algebras based on a deformation of Cartan's theory of spinors can be readily applied to the construction of the different q-groups associated with the underlying Euclidean and pseudo-Euclidean spaces, as well as to the construction of their corresponding double covering quantum spin groups.

Indeed, by requiring that the fundamental property of spinor transformations [Eq. (71)] be preserved in the quantum case, and using the linearity of $H(\mathbf{w})$, a noncommutative algebra $\mathscr{B}$ with a consistent *-structure can be imposed for which the generators are the ''coordinates'' of the underlying (pseudo)-Euclidean space.

The fundamental representation of the corresponding quantum group comes from providing the algebra $\mathscr{B}$ with the structure of a comodule on which this quantum group coacts. By further requiring that the resulting quantum group leaves invariant the fundamental quadric $\langle \mathbf{x},\mathbf{x}\rangle$ results in the $O_q(n-h,h)$ groups associated to the possible signatures $(n-h,h)$ of the q-spaces.

To derive the corresponding double-covering q-spin groups, we use our Clifford algebra to define a q-spinor representation by

$$\xi=\sum_{p=0}^{\nu}\sum_{k_1<\cdots<k_p}\xi^{k_1\cdots k_p}\otimes H_{k_1}\cdots H_{k_p}\cdot 1. \tag{123}$$

The spinor components $\xi^{k_1\cdots k_p}$ generate a noncommutative algebra.

We also introduce the involutive and antimultiplicative τ-transpose operation, $\xi\in S\to\xi^{\tau}\in S'$, which maps linearly spinors in S to spinors in the dual space S'. This operation is uniquely defined by its action on the generators of the Clifford algebra:

$$1^{\tau}=1',H_i^{\tau}=H_i',(H_i')^{\tau}=H_i,(H_iH_j\cdots H_l\cdots H_p)^{\tau}=H_p'\cdots H_l'\cdots H_j'H_i', \tag{124}$$

which defines a right action of the initial Clifford algebra in the dual space.

Hence

$$\xi^{\tau}=\sum_{p=0}^{\nu}\sum_{k_1<\cdots<k_p}\xi^{k_1\cdots k_p}\otimes 1'\cdot H_{k_p}'\cdots H_{k_1}'. \tag{125}$$

Note that by virtue of (39)–(40) and (124) the elements $\{(H_{k_1}\cdots H_{k_p}\cdot 1)^{\tau}=1'\cdot H_{k_p}'\cdots H_{k_1}'\}$ form a basis reciprocal to $\{H_{k_1}\cdots H_{k_p}\cdot 1\}$, $k_1<\cdots<k_p$, which allows us to define a scalar product for homogeneous spinors of p-degree, given by

$$\begin{aligned}[(\xi^{(p)})^{\tau},\ \eta^{(p)}]:&=\sum_{k_1<\cdots<k_p}\xi^{k_1\cdots k_p}\eta^{k_1\cdots k_p}[1'\cdot H_{k_p}'\cdots H_{k_1}',H_{k_1}\cdots H_{k_p}\cdot 1]\\&=\sum_{k_1<\cdots<k_p}\xi^{k_1\cdots k_p}\eta^{k_1\cdots k_p}1'\cdot H_{k_p}'\cdots H_{k_1}'\cdot H_{k_1}\cdots H_{k_p}\cdot 1\\&=\sum_{k_1<\cdots<k_p}\xi^{k_1\cdots k_p}\eta^{k_1\cdots k_p}.\end{aligned} \tag{126}$$

Requiring that the scalar product of any two spinors respects gradation, we thus have

$$[\xi^{\tau},\ \eta]=\sum_{p=0}^{\nu}\sum_{k_1<\cdots<k_p}\xi^{k_1\cdots k_p}\eta^{k_1\cdots k_p}. \tag{127}$$

(Note that the above formula for the scalar product reduces to the definition used in Sec. IV when the spinor components become $\mathbb{C}$-numbers). Now, in analogy to the classical Cartan spinor theory, we introduce a spinor metric operator C, acting on spinors via the q-Clifford product, by

$$C=\sum_{p=0}^{\nu}(-1)^{p(p+1)/2}\sum_{\substack{\pi\in S_{\nu}\\ \pi(1)<\cdots<\pi(p)\\ \pi(p+1)<\cdots<\pi(\nu)}}(-1)^{l(\pi)}a^{p}_{\pi(1)\cdots\pi(p)}(\mu)H_{\pi(1)}\cdots H_{\pi(p)}(H_{\pi(p+1)}\cdots H_{\pi(\nu)})^{\tau}, \tag{128}$$

where $a^{p}_{\pi(1)\cdots\pi(p)}(\mu)$ are μ-parameter-valued commuting quantities such that in the classical limit they are equal to one.

This allows us to define a fundamental spinor bilinear by means of

$$(\xi,\xi)=[\xi^{\tau},C\cdot\xi]. \tag{129}$$

The quantum Spin (n) groups can then be constructed by introducing a matrix with block-diagonal entries, giving these entries the structure of a Hopf algebra and requiring that:

(1) each block sub-matrix should be unimodular,
(2) the fundamental spinor bilinear be central in the spinor components algebra,
(3) the fundamental spinor bilinear be invariant under the coaction map,
(4) we have

$$\delta:(\xi,H_\alpha\xi)\mapsto\sum_\beta t_{\alpha\beta}\otimes(\xi,H_\beta\xi),$$

where $t_{\alpha\beta}$ are the elements of the corresponding q-orthogonal groups.

Conditions (2) and (3) fix uniquely and consistently the parameters in (128), while (4) establishes the covering character of the q-spin groups.

The details of this procedure, which applies to arbitrary dimensions, are beyond the scope of this work, and will be presented in a forthcoming separate paper.

APPENDIX: RIGHT $\mathscr{A}$-MODULE STRUCTURES ON V AND V' FOR SL(n,$\mathbb{C}$)

From (26)–(29) we get the following right $\mathscr{A}$-module structure on V:
for $i<j$,

$$e_i\circ u_{kj}=\delta_{kj}\beta\mu e_i,\quad e_j\circ u^*_{ii}=\frac{1}{\mu\beta}\,e_j,$$

$$e_j\circ u^*_{ij}=\frac{\mu^2-1}{\beta\mu^{2(1+i-j)}}\,e_i,\quad e_j\circ u^*_{ik}=0,\quad k\neq\{i,j\};$$

for $i>j$,

$$e_i\circ u_{ij}=\beta(1-\mu^2)e_j,\quad e_i\circ u_{jj}=\beta\mu e_i,$$

$$e_i\circ u_{kj}=0,\quad k\neq\{i,j\},\quad e_j\circ u^*_{ik}=\frac{\delta_{ki}}{\beta\mu}\,e_j;$$

and finally, for $i=j$,

$$e_i\circ u^*_{ik}=\frac{1}{\beta}\,\delta_{ik}e_i,\quad e_i\circ u_{ki}=\delta_{ki}\beta e_i,$$

where $\beta=\mu^{1-n/n}$ (as follows from the quantum determinant condition).

Now using the definition (29) of $\circ$ in the dual space V' we obtain for $i\neq j$,

$$e'_i\circ u^*_{ji}=0,\quad e'_i\circ u^*_{ij}=\begin{cases}\beta(1-\mu^2)e'_j & \text{if } i<j,\\ 0 & \text{if } i>j,\end{cases}$$

$$e'_i\circ u^*_{jj}=\beta\mu e'_i,\quad e'_i\circ u^*_{kj}=0,\quad k\neq\{i,j\},\quad e'_i\circ u_{kj}=0,\quad k\neq\{i,j\},$$

$$e_i' \circ u_{ij} = 0, \quad e_i' \circ u_{jj} = \frac{1}{\beta\mu}\, e_i', \quad e_i' \circ u_{ji} = \begin{cases} \dfrac{\mu^2 - 1}{\beta\mu^2}\, e_j' & \text{if } j > i, \\ 0 \quad \text{if } j < i, \end{cases}$$

and the relations

$$e_i' \circ u_{ii} = \frac{1}{\beta}\, e_i', \quad e_i' \circ u_{ii}^* = \beta e_i',$$

when $i = j$.

The right $\mathscr{A}$-module structures on V and V' enable us to compute in an analogous way the remaining three flip-over operators. We shall omit listing them.

An ill-posed problem of the continuation of transient data for a hyperbolic equation in a three-dimensional inhomogeneous half-space

Jiasu Cao, Sailing He, and Vaughan H. Weston[a)]
Department of Electromagnetic Theory, Royal Institute of Technology, S-100 44 Stockholm, Sweden

(Received 26 January 1996; accepted for publication 30 April 1996)

A time-domain data continuation problem for a second order hyperbolic equation in a three-dimensional inhomogeneous half-space, which is a common problem in time-domain layer-stripping, is considered. Two different approaches, namely the local continuation approach and the wave-splitting approach, are used to propagate the surface data (the Dirichlet and Neumann data) to the data at deeper planes. The local continuation approach requires a regularization in order to obtain a stable numerical result. The wave-splitting approach uses larger transverse spatial domain of dependence, and gives reasonably stable results even without any additional smoothing process. © *1996 American Institute of Physics.*
[S0022-2488(96)00811-0]

I. INTRODUCTION AND STATEMENT OF THE PROBLEM

For any time-domain layer-stripping approach to an inverse problem, one has to propagate the transient wave field (the Dirichlet data) and its normal derivative (the Neumann data) to the next layer below (layer by layer) starting from the surface data which can be obtained from experimental measurements. In the present paper we treat such a data continuation problem for the following second order hyperbolic equation:

$$(\partial_t^2-\partial_z^2)u=F(x,y,z,t;u), \tag{1}$$

where

$$F(x,y,z,t;u)=a_1\partial_x^2u+a_2\partial_y^2u+A_1\partial_xu+A_2\partial_yu+A_3\partial_zu-b\partial_tu, \tag{2}$$

and where the coefficients a_1, a_2, A_j $(j=1,2,3)$, b are functions of spatial variables (x,y,z). The data continuation problem is to determine the internal field u and its normal derivative $\partial_z u$ from the surface data, i.e., $u|_{z=0}$ and $(\partial_z u)|_{z=0}$. Such a data continuation problem is in general ill-posed in the high-dimensional case. The ill-posedness can be illustrated by a simple example in homogeneous space with $a_1=a_2=1$ and $A_1=A_2=A_3=b=0$. Assume that the exact surface data are $u|_{z=0}=v_0(x,y,t),(\partial_z u)|_{z=0}=0$ and the corresponding solution to the internal field is $u=w(x,y,z,t)$. Now if there is a small perturbation (error) to the field at the surface such that $u|_{z=0}=v_0(x,y,t)+\epsilon\sin(k_1x)\sin(k_2y)\sin(kt)$ (ϵ is a small constant, and $k_1^2+k_2^2>k^2$), then the solution to the internal field becomes $u = w + \epsilon \sin(k_1x)\sin(k_2y)\sin(kt)\cosh(\sqrt{k_1^2+k_2^2-k^2}z)$, which has an exponentially growing error as the depth z increases. Some mathematical aspects of the propagation problem in a homogeneous space have been considered in Refs. 1 and 2. In the present paper, we give two alternative approaches to the ill-posed problem of the continuation of the transient data in an three-dimensional inhomogeneous half-space. The first approach is to use the local continuation formulas for which a regularization process is necessary. The second ap-

0022-2488/96/37(11)/5776/16/$10.00

proach is to use the dynamic integro-differential equations for the split fields (see, e.g., Refs. 3–8 for wave-splittings and their applications to inverse problems). In the wave-splitting approach, a larger transverse spatial domain of dependence is used, and the continuation results are reasonably stable even without any additional smoothing process. Once a successful continuation approach has been established, one can use the wave front condition, which relates the split fields at the wave front to the material parameters, to reconstruct these parameters.[7]

II. APPROACH ONE: LOCAL CONTINUATION FORMULAS

A. Local continuation theorem

In order to obtain a local continuation formula that can be employed in the next subsection, we prove a continuation theorem for the hyperbolic equation (1).

The continuation problem involves determining the values of u in some region of the half-space $z>0$ for a range of value of t, given the Dirichlet and Neumann values of u on the plane $z=0$,

$$u=v_0(x,y,t), \quad \frac{\partial u}{\partial z}=v_1(x,y,t); \quad z=0, \quad |t-t_0|<T. \tag{3}$$

To specify the conditions on the data and the coefficients of Eq. (1), we need to introduce the local Banach space A_s of analytic functions $w(x,y)$ in the transverse variables (x,y), whose norm is defined as follows:

$$\|w\|_s=\sum_{l=0}^{\infty}\sum_{p=0}^{\infty}\frac{s^{l+p}}{l!p!}\left|\frac{\partial^{l+p}w(0,0)}{\partial^p x\partial^l y}\right|, \tag{4}$$

where s is real and $s>0$. We will assume that v_0, v_1 belong to A_{s_0}, and v_0 is a C^1, v_1 a C^0 function of time. For $|t-t_0|\leqslant\tau$, $v_0\in C^1(A_{s_0},[t_0-\tau,t_0+\tau])$, $v_1\in C^0(A_{s_0},[t_0-\tau,t_0+\tau])$.

We will also assume that the coefficients a_1, a_2, A_j $(j=1,2,3)$ and b belong to A_{s_0} and are continuous functions of z for $0\leqslant z\leqslant T$, and so the solution of Eq. (1) will be in the following (z,t) domain:

$$D_T=\{(z,t)|0\leqslant z\leqslant T, \ z-T<t-t_0<T-z\}. \tag{5}$$

We use the following norm:

$$\|u\|_{s,D_T}=\max_{(z,t)\in D_T}\|u\|_s(z,t), \tag{6}$$

for functions $u(x,y,z,t)$, which are analytic in (x,y) and continuous in (z,t) in the domain D_T.

Equation (1) can be transformed in the following integral differential form:

$$u(x,y,z,t)=u_0(x,y,z,t)-\frac{1}{2}\int_0^z\int_{t-z+z'}^{t+z-z'}F(x,y,z',t';u)dt'dz', \tag{7}$$

where

$$u_0=\frac{1}{2}[v_0(x,y,t+z)+v_0(x,y,t-z)]+\frac{1}{2}\int_{t-z}^{t+z}v_1(x,y,t')dt'. \tag{8}$$

Differentiating Eq. (7) with respect to z and t, we obtain the additional equations

$$\frac{\partial u}{\partial z}=\frac{\partial u_0}{\partial z}-\frac{1}{2}\int_0^z [F(x,y,z',t+z-z';u)+F(x,y,z',t-z+z';u)]dz', \tag{9}$$

and

$$\frac{\partial u}{\partial t}=\frac{\partial u_0}{\partial t}-\frac{1}{2}\int_0^z [F(x,y,z',t+z-z';u)-F(x,y,z',t-z+z';u)]dz'. \tag{10}$$

By setting

$$U=\begin{bmatrix} u \\ \partial_z u \\ \partial_t u \end{bmatrix}, \quad U^0=\begin{bmatrix} u_0 \\ \partial_z u_0 \\ \partial_t u_0 \end{bmatrix}, \tag{11}$$

the systems of Eqs. (7)–(10) can be expressed in the following operator form:

$$U=U^0+T[U]. \tag{12}$$

As will be shown in a subsequent theorem, the above system of equations can be solved by successive approximation,

$$U^{n+1}=U^0+T[U^n], \quad n=0,1,2,\ldots, \tag{13}$$

starting from U^0 [given by Eq. (11)]. To show convergence of the iteration process, we need to introduce the sequence V^n,

$$V^n=U^{n+1}-U^n, \quad n=0,1,2,\ldots . \tag{14}$$

Obviously, we have

$$V^0=T[U^0], \tag{15}$$

$$V^n=T[V^{n-1}], \quad n=1,2,3,\ldots . \tag{16}$$

From the definitions (4)–(6), and Eq. (8), it follows that there exists a positive real constant α such that for $0<s\leqslant s_0$,

$$\max\left\{\|u_0\|_{s,D_T}, \left\|\frac{\partial u_0}{\partial z}\right\|_{s,D_T}, \left\|\frac{\partial u_0}{\partial t}\right\|_{s,D_T}\right\}\leqslant\alpha. \tag{17}$$

Thus, the components of U^0 satisfy the inequality

$$\|U_j^0\|_{s,D_T}\leqslant\alpha, \quad 0<s\leqslant s_0, \quad j=1,2,3. \tag{18}$$

To obtain estimates for $V^{(n)}$ we need to introduce the constant β such that

$$\max\{\|a_1\|_{s_0,D_T},\|a_2\|_{s_0,D_T},\|A_j\|_{s_0,D_T}(j=1,2,3),\|b\|_{s_0,D_T}\}\leqslant\beta. \tag{19}$$

Set

$$\rho_0=\beta(32+6s_0), \tag{20}$$

and choose the positive real constant a_0 such that

$$a_0\rho_0<1,\ \ a_0^2\rho_0<1,\ \ a_0s_0<T,\ \ a_0<T. \tag{21}$$

Let

$$\rho=\max[a_0\rho_0,a_0^2\rho_0], \tag{22}$$

it then follows that $\rho<1$. In the following lemma we will need the following decreasing sequence

$$a_n=a_{n-1}/[1+1/n^2],\quad n=1,2,3,\ldots\ . \tag{23}$$

Note that the sequence $\{a_n\}$ is bounded away from zero.

Lemma: For $0\leqslant z<a_n(s_0-s)$, $|t-t_0|\leqslant z$, the following inequalities hold:

$$\|V_1^n\|_s(z,t)<\lambda_0\rho^n z/[a_n(s_0-s)-z], \tag{24}$$

$$\|V_j^n\|_s(z,t)<\lambda_0\rho^n a_n z/[a_n(s_0-s)-z]^2,\quad j=2,3, \tag{25}$$

where

$$\lambda_0=4\beta\alpha[8+s_0+s_0^2/2]\max[a_0,a_0^2]. \tag{26}$$

See the Appendix for the proof of the above lemma.

It can now be shown that the method of successive approximation (13) converges.

Restricting (z,t) to the region $0\leqslant z<a_{n+1}(s_0-s)$, $|t-t_0|\leqslant z$, it follows from the lemma that

$$\sum_{k=0}^{n}\|V_1^k\|_s\leqslant\lambda_0\sum_{k=0}^{n}\frac{\rho^k z}{[a_k(s_0-s)-z]},$$

$$\sum_{k=0}^{n}\|V_j^k\|_s\leqslant\lambda_0\sum_{k=0}^{n}\frac{\rho^k a_k z}{[a_k(s_0-s)-z]^2},\quad j=2,3.$$

Using the result that $z<a_{n+1}(s_0-s)\leqslant a_0(s_0-s)$, and relation (23), it follows that

$$\sum_{k=0}^{n}\|V_1^k\|_s\leqslant\lambda_0\sum_{k=0}^{n}\frac{\rho^k a_{k+1}}{[a_k-a_{k+1}]}\leqslant\lambda_0\sum_{k=0}^{n}\rho^k(k+1)^2, \tag{27}$$

$$\sum_{k=0}^{n}\|V_j^k\|_s\leqslant\frac{\lambda_0}{(s_0-s)}\sum_{k=0}^{n}\frac{\rho^k a_{k+1}a_k}{(a_k-a_{k+1})^2}\leqslant\frac{\lambda_0}{(s_0-s)}\sum_{k=0}^{n}\rho^k[(k+1)^4+(k+1)^2],\quad j=2,3. \tag{28}$$

Since the constant a_0 has been chosen so that $\rho<1$, the series on the right-hand sides of the above two inequalities converge. Thus, it follows from the above two inequalities that the left-hand sides converge. From Eq. (14) it follows that

$$U^{n+1}=U^0+\sum_{k=0}^{n}V^k. \tag{29}$$

Thus for $n>m$,

$$\|U_j^n - U_j^m\|_s = \left\| \sum_{k=m+1}^{n} V_j^k \right\| \leqslant \sum_{k=m+1}^{n} \|V_j^k\|, \quad j=1,2,3, \tag{30}$$

which implies that U_j^n, $j=1,2,3$, converge. We can now state the theorem.

Local Continuation Theorem: For $0 \leqslant z < a_\infty(s_0 - s)$, $|t - t_0| \leqslant z$, where $a_\infty = \lim_{n\to\infty} a_n$, the sequence $\{U^n\}$ converges, and the solution $u(x,y,z,t)$ to the system of Eqs. (1)–(3) exists such that $u(x,y,z,t)$ is an analytic function in A_s and a C^1 function in z and t.

B. Finite-difference formulas

Here we give the finite-difference formulas of the local continuation theorem for the following acoustic wave equation:

$$\partial_t^2 u - \rho \nabla \cdot \left(\frac{1}{\rho} \nabla u \right) + b \partial_t u = 0, \tag{31}$$

where $\rho(x,y,z)$ is the density, and $b(x,y,z)$ is the dissipation coefficient (the velocity has a value of unity). Consider the problem of determining the value of u and $\partial u/\partial z$ on $z=h$ (h is small for use in a finite-difference formula) for Eq. (31), given the data $u = v_0$, $\partial u/\partial z = v_1$ on the plane $z=0$. We will assume that the data v_0, v_1, are piecewise analytic in the transverse variables (x,y), with v_0, v_1 being C^1 and C^0 functions of t, respectively, over certain intervals, with the discontinuities in x, y and t being of a wave front type (on the intersection of a characteristic surface and the plane $z=0$). In this paper we will treat the case where the discontinuity is a wave front moving in the positive z-direction. For the wave front moving in the opposite direction or combined directions, the theorem in the previous subsection has to be properly modified.

To apply the theorem in the previous subsection, we take $a_1 = a_2 = 1$, $(A_1, A_2, A_3) = -\nabla(\ln \rho)$. For small values of $z=h$, we take the approximate solution of system (12), given by the iterate $U^1 = U^0 + T(U^0)$, where U^0 is given by Eq. (11). Thus, it follows from Eqs. (2), (7), (8), and (9) that the solution to the above order is

$$u(x,y,h,t) = u_0(x,y,h,t) - \frac{1}{2} \int_0^h \int_{t-h+z'}^{t+h-z'} F(x,y,z',t';u_0)\, dt'\, dz', \tag{32}$$

$$\partial_z u(x,y,h,t) = \partial_z u_0(x,y,h,t) - \frac{1}{2} \int_0^h [F(x,y,z',t+h-z';u_0) + F(x,y,z',t-h+z';u_0)]\, dz', \tag{33}$$

where

$$\begin{aligned} u_0(x,y,z,t) &= \frac{1}{2}[v_0(x,y,t+z) + v_0(x,y,t-z)] + \frac{1}{2} \int_{t-z}^{t+z} v_1(x,y,t')\, dt', \\ F(x,y,z,t;u_0) &= (\partial_x^2 + \partial_y^2) u_0 - \nabla(\ln \rho) \cdot \nabla u_0 - b \partial_t u_0. \end{aligned} \tag{34}$$

Therefore, the sought-for expressions for u and $\partial u/\partial z$ at $z=h$ are

$$\begin{aligned} u(x,y,h,t) = {} & \frac{1}{2}[v_0(x,y,t+h) + v_0(x,y,t-h)] + \frac{1}{2} \int_{t-h}^{t+h} v_1(x,y,t')\, dt' - \frac{h^2}{2} [(\partial_x^2 + \partial_y^2) v_0 \\ & - (\partial_x v_0) \partial_x (\ln \rho)|_{z=0} - (\partial_y v_0) \partial_y (\ln \rho)|_{z=0} - v_1 \partial_z (\ln \rho)|_{z=0} - b \partial_t v_0] + O(h^3), \end{aligned} \tag{35}$$

$$[\partial_z u](x,y,h,t)=\tfrac{1}{2}[\partial_t v_0(x,y,t+h)-\partial_t v_0(x,y,t-h)]+\tfrac{1}{2}[v_1(x,y,t+h)+v_1(x,y,t-h)]$$
$$-h[(\partial_x^2+\partial_y^2)v_0-(\partial_x v_0)\partial_x(\ln\rho)|_{z=0}-(\partial_y v_0)\partial_y(\ln\rho)|_{z=0}$$
$$-v_1\partial_z(\ln\rho)|_{z=0}-b\partial_t v_0]+O(h^2). \tag{36}$$

Repeatedly applying the above two formulas, one can propagate the data $(u,\partial_z u)$ layer by layer (from the surface data) to the data at the planes $z=nh$, $n=1,2,3,\ldots$. Note that in the repeated application of the formulas, the smoothness parameter s_0 has to be replaced by s_n, $n=1,2,3,\ldots$, which is related to h through the constant $h<a_\infty(s_n-s_{n+1})$, $n=1,2,3,\ldots$. This limits the range of continuation with respect to z.

In order to obtain some reliable reference data to compare with our continuation results, we generate the data with either an explicit solution (in the case of a homogeneous medium) or a finite-difference time-domain method. In all the numerical examples, we assume that the medium above the surface $z=0$ is homogeneous and non-dissipative, and a point source is located at the point $\mathbf{r}_0=(0,0,z_0)(z_0<0)$ in the homogeneous upper half-space $z<0$ (the inhomogeneity is confined in the lower half-space $z>0$). The incident field in an entirely homogeneous space satisfies the following equation:

$$\partial_t^2 p^i-\nabla^2 p^i=\delta(\mathbf{r}-\mathbf{r}_0)f(t), \tag{37}$$

which has the solution

$$p^i=\frac{f(t-|\mathbf{r}-\mathbf{r}_0|)}{4\pi|\mathbf{r}-\mathbf{r}_0|}. \tag{38}$$

In all the numerical examples in the present paper, we choose the position of the point source to be $z_0=-0.5$, and $f(t)$ to be

$$f(t)=\begin{cases}\sin^2(\pi t/t_0), & \text{when } 0\leqslant t\leqslant t_0,\\ 0, & \text{otherwise,}\end{cases}$$

where $t_0=0.4$.

Numerical example 1 (case of a homogeneous medium): Consider the simplest case when the whole space is homogeneous and non-dissipative. The surface fields and their normal derivatives can be obtained from the explicit solution (38). We choose $\Delta x=\Delta y=\Delta z=2\Delta t=0.005$, and calculate the field and its normal derivative at the point (0,0,0.1), which is on the 20th layer, using the local continuation formulas (35) and (36). The continuation results are given by the dotted lines in Figs. 1(a) and 1(b), where the corresponding exact values [obtained from (38)] are given by the solid lines. Numerical results in Figs. 1(a) and 1(b) show that the continuation scheme is not stable, which is mainly due to the second order transverse spatial derivatives of the fields in the formulas (35) and (36). Thus, one needs to regularize[9] (smooth) the data before using the finite-difference formulas (35) and (36). In the next subsection, we describe a way to regularize the data.

C. Regularization

To obtain reliable second order transverse spatial derivatives of the field u, we need to smooth u to at least twice differentiable in respect with the transverse spatial variables $\mathbf{x}=(x,y)$. Define a function

$$S(\mathbf{x})=\frac{e^{-2\gamma\sqrt{|\mathbf{x}|+4}}}{2\pi\sqrt{|\mathbf{x}|+4}}. \tag{39}$$

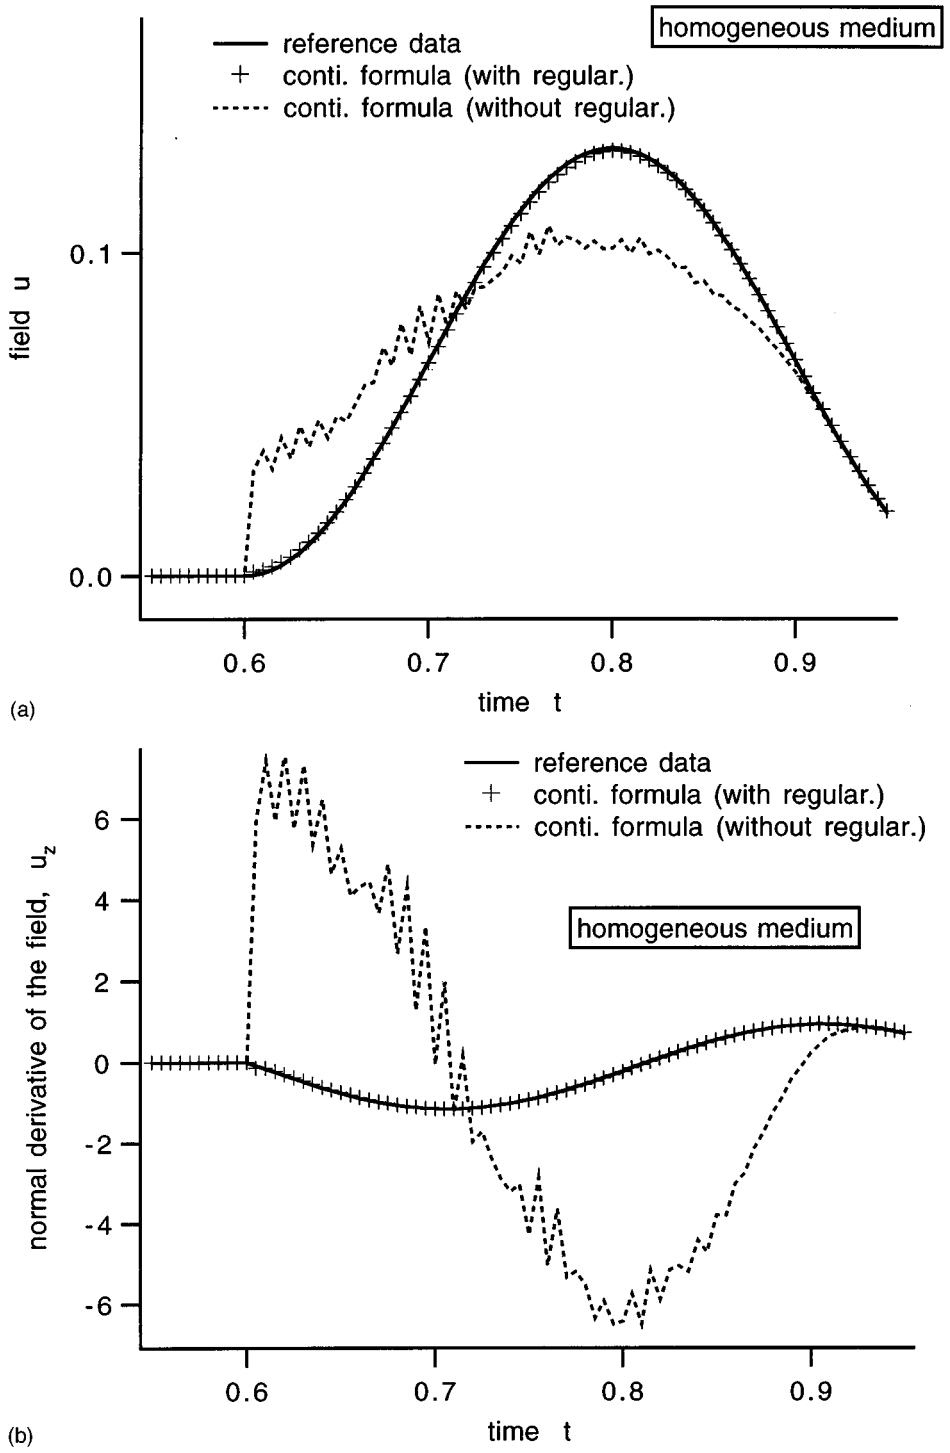

FIG. 1. (a) and (b) The local continuation formulas for data continuation in a homogeneous space. The solid lines are the exact reference data at a point (0,0,0.1) obtained from Eq. (38). The dotted lines are the corresponding continuation results using the local continuation formulas (35) and (36) without regularization. Here we choose $\Delta x=\Delta y=\Delta z=2\Delta t=0.005$, and the point (0,0,0.1) is at the 20th layer. The crosses are the corresponding continuation results using the regularization formula (43) with $d=0.005$.

Its Fourier transformation is

$$\widetilde{S}(\overline{\mathbf{x}})\equiv(\mathbf{F}^{-1}S)(\overline{\mathbf{x}})=\int S(\mathbf{x})e^{i\mathbf{x}\overline{\mathbf{x}}}d\mathbf{x}=2\pi\int_0^\infty S(\mathbf{x})J_0(|\mathbf{x}||\overline{\mathbf{x}}|)|\mathbf{x}|d|\mathbf{x}|=\frac{\exp(-2\sqrt{|\overline{\mathbf{x}}|^2+(2\gamma)^2})}{\sqrt{|\overline{\mathbf{x}}|^2+(2\gamma)^2}}. \tag{40}$$

If we choose γ such that it satisfies $\gamma=1/2e^{-4\gamma}$, i.e.,

$$\gamma=0.21315138, \tag{41}$$

then $S(\mathbf{x})$ and $\widetilde{S}(\overline{\mathbf{x}})$ are a pair of Fejer kernels (cf. e.g., Ref. 10), since $\widetilde{S}(0)=1$, $S(-\mathbf{x})=S(\mathbf{x})$, and $S,\ \widetilde{S}\in L_1$.

Define

$$S_d(\mathbf{x})\equiv\frac{1}{d^2}\,S\left(\frac{\mathbf{x}}{d}\right)=\frac{1}{2\pi}\cdot\frac{\exp[(-2\gamma/d)(\sqrt{|\mathbf{x}|^2+(2d)^2})]}{d\sqrt{|\mathbf{x}|^2+(2d)^2}}, \tag{42}$$

then we have the following theorem.

Regularization Theorem: If $u\in L_1$ and is bounded, then the following formula holds:

$$\lim_{d\to+0}\int_{R^2}S_d(\mathbf{x}-\overline{\mathbf{x}})u(\overline{\mathbf{x}})d\overline{\mathbf{x}}=u(\mathbf{x}). \tag{43}$$

Proof: Introduce the Fejer mean of u defined as

$$u_d(\mathbf{u})=\int_{R^2}e^{-i\mathbf{x}\overline{\mathbf{x}}}\widetilde{S}_d(d\overline{\mathbf{x}})\widetilde{u}(\overline{\mathbf{x}})d\overline{\mathbf{x}}, \tag{44}$$

where $\widetilde{S}_d$ and $\widetilde{u}$ are the inverse Fourier transform of S_d and u, respectively. Since $u\in L_1$, according to Theorem 1.13 in Ref. 10, we have

$$u_d(\mathbf{u})\equiv\int_{R^2}S_d(\mathbf{x}-\overline{\mathbf{x}})u(\overline{\mathbf{x}})d\overline{\mathbf{x}}. \tag{45}$$

Also since $u\in L_1$ and is bounded, we have (cf. Theorem 1.15 in Ref. 10),

$$\lim_{d\to+0}u_d(\mathbf{x})=u(\mathbf{x}). \tag{46}$$

Equation (43) follows immediately from the above two equations. The regularization theorem is thus proved.

Note that if the sources have spatial compact support (e.g., in a point source case), the field $u(x,y,z,t)$ is non-zero only within a finite region $\sqrt{x^2+y^2}<D_0$ on a plane $z=z_0$ at any finite time $t=t_0$, and thus obviously $u\in L_1(R^2)$. Using the regularization formula (43), we first test the homogeneous case as described in the numerical example 1. The crosses in Figs. 1(a) and 1(b) are the continuation results using the local continuation formulas (35) and (36) with u being smoothed [using the formula (43) with $d=0.005$] for each time at each layer. These numerical results indicate that the local continuation formulas give quite good continuation results in a homogeneous space if the regularization formula (43) is also used. In the next example we test the local continuation formulas (with the regularization) for a case of an inhomogeneous medium.

Numerical example 2 (the case of an inhomogeneous medium): In this numerical example, we consider an inhomogeneous half-space with the following synthetic density profile:

$$\rho(x,y,z)=1+2\sin^2(\pi z)\exp[-(x^2+y^2/4+z^2/9)], \quad z\geqslant 0. \tag{47}$$

The dissipation coefficient is chosen to be $b=0$ in the whole space. The reference data for the fields and their normal derivatives are calculated with a finite-difference time-domain method, in which one computes the fields step by step in time starting from the trivial initial condition for the fields (see Refs. 11 and 12) for a detailed description; our Connection machine with a memory of 2 GByte in RAM has enough memory to set all the boundary surfaces in x-, y-, and z- directions of the computation domain to be far enough away so that putting the fields to zero at the boundary surfaces will have no effect on the fields at the receiving points and during the time periods of interest). We then use the local continuation formulas (35) and (36) to migrate the surface data (obtained from the finite-difference time-domain method) to the data at the plane $z=0.1$ inside the inhomogeneous medium with $\Delta x=\Delta y=\Delta z=2\Delta t=0.005$. The formula (43) is used to regularize the data at each time and at each layer with $d=0.005$. The crosses in Figs. 2(a) and 2(b) are the continuation results at the point $(x,y)=(0,0)$ on the plane $z=0.1$ (the solid lines are the corresponding reference data). The continuation results appear to be quite good.

Note that in the local continuation formulas, one has to do the regularization (spatial convolution) at each time and at each layer (the spatial convolution is done only after computing u and $\partial_z u$ for all time steps and locations). As shown in Ref. 13, the analyticity of the data can guarantee the stability of the solution to the inverse problem. By such a spatial convolution, the analyticity of the data can be restored after the data continuation in deeper layers. In the next section, we give another approach for the data continuation, which does not require such a regularization.

III. APPROACH TWO: WAVE-SPLITTING FORMULAS

The acoustic wave equation (31) can be written in matrix form as

$$\partial_z\begin{bmatrix} u \\ \partial_z u\end{bmatrix}=\begin{bmatrix} 0 & 1 \\ \Box+(\nabla^T \ln\rho)\cdot\nabla^T+b\partial_t & (\partial_z \ln\rho)\end{bmatrix}\begin{bmatrix} u \\ \partial_z u\end{bmatrix}\equiv D\begin{bmatrix} u \\ \partial_z u\end{bmatrix}, \tag{48}$$

where $\Box=\partial_t^2-\partial_x^2-\partial_y^2$, and $\partial^T=(\partial_x,\partial_y)$. The total field can be decomposed into a down-going component u^+ and an up-going component u^- as follows:

$$\begin{bmatrix} u^+ \\ u^-\end{bmatrix}=\frac{1}{2}\begin{bmatrix} 1 & -K \\ 1 & K\end{bmatrix}\begin{bmatrix} u \\ \partial_z u\end{bmatrix}\equiv T\begin{bmatrix} u \\ \partial_z u\end{bmatrix}, \tag{49}$$

where K is the wave-splitting operator, which has the following explicit expression (see Ref. 4 for a detailed mathematical description of the wave-splitting operator):

$$\mathbf{K}u=\frac{1}{2\pi}\int_0^t\int_0^{2\pi} u(x+(t-s)\cos\theta, y+(t-s)\sin\theta, z, s)\,d\theta\,ds. \tag{50}$$

Differentiating Eq. (49) with respect to z and using Eq. (48), yields

$$\partial_z\begin{bmatrix} u^+ \\ u^-\end{bmatrix}=TDT^{-1}\begin{bmatrix} u^+ \\ u^-\end{bmatrix}. \tag{51}$$

After a formal matrix calculation, one obtains[7]

$$(\partial_z+K^{-1})u^+=f, \tag{52}$$

$$(\partial_z-K^{-1})u^-=-f, \tag{53}$$

where K^{-1} is the inverse of K, and

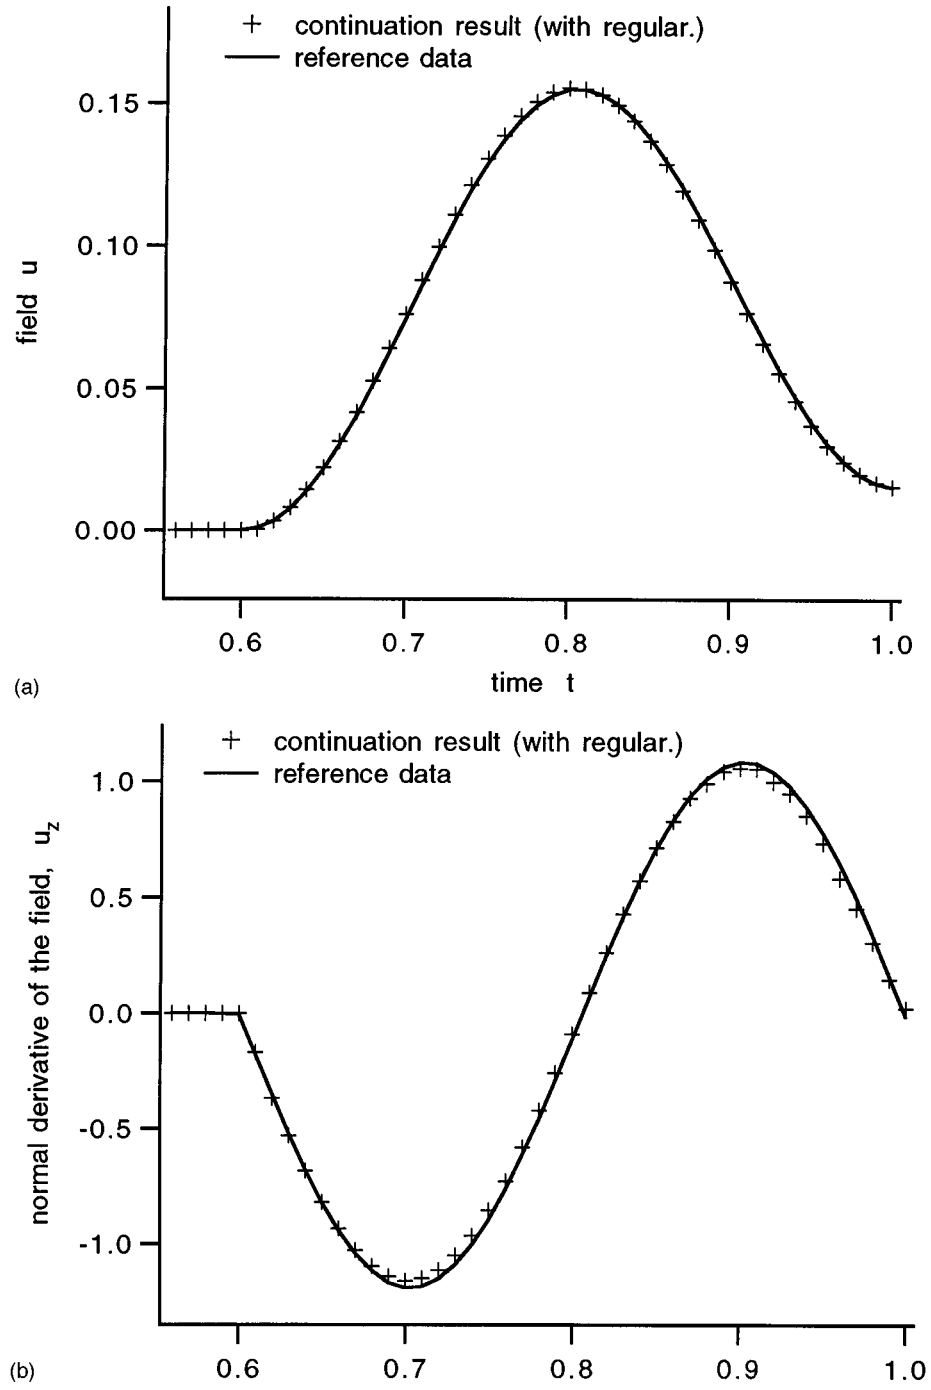

FIG. 2. (a) and (b) Data continuation using the local continuation formulas (with the regularization) in an inhomogeneous half-space with a synthetic density profile $\rho(x,y,z)=1+2\sin^2(\pi z)\exp[-(x^2+y^2/4+z^2/9)]$, for $z\geqslant 0$ (the dissipation coefficient $b\equiv 0$). The solid lines are the reference data at a point $(x,y)=(0,0)$ on the plane $z=0.1$, calculated with a finite-difference time-domain method. The crosses are the corresponding continuation results using the local continuation formulas with $\Delta x=\Delta y=\Delta z=2\Delta t=0.005$. The regularization parameter is chosen to be $d=0.005$.

$$f=-\tfrac{1}{2}K[(\nabla^T \ln \rho)\cdot\nabla^T+b\partial_t](u^+ +u^-)+\tfrac{1}{2}K[(\partial_z \ln \rho)K^{-1}](u^+ -u^-). \tag{54}$$

The operator K^{-1} can be expressed in the following form:[12]

$$\mathbf{K}^{-1}=\partial_t-\mathbf{L}, \tag{55}$$

where

$$\mathbf{L}u=\frac{1}{2\pi}[\partial_x^2(\mathbf{L}_1u)+\partial_y^2(\mathbf{L}_2u)-2\partial_{xy}^2(\mathbf{L}_3u)], \tag{56}$$

with

$$\mathbf{L}_1u=\int_0^t\int_0^{2\pi}\sin^2\theta\, u(x+(t-s)\cos\theta, y+(t-s)\sin\theta, z, s)\,d\theta ds, \tag{57}$$

$$\mathbf{L}_2u=\int_0^t\int_0^{2\pi}\cos^2\theta\, u(x+(t-s)\cos\theta, y+(t-s)\sin\theta, z, s)\,d\theta ds, \tag{58}$$

$$\mathbf{L}_3u=\int_0^t\int_0^{2\pi}\sin\theta\cos\theta\, u(x+(t-s)\cos\theta, y+(t-s)\sin\theta, s)\,d\theta ds. \tag{59}$$

Note that the integrations in the expressions (57)–(59) have a smoothing effect to the data u, and thus the spatial second order derivatives in the expression (56) is not a serious problem in the numerical evaluation of the operator $\mathbf{L}$.

From the dynamic integro-differential equations (52) and (53) for the split fields, we obtain the following approximations:

$$u^+(x,y,z+h,t)=\frac{1}{2\pi}\int\int_{D(x,y,t)}\frac{h}{R^3}[u^+(x',y',z,t-R)+R\partial_t u^+(x',y',z,t-R)]dx'dy' + hf(x,y,z,t)+O(h^2), \tag{60}$$

$$u^-(x,y,z+h,t)=u^-(x',y',z,t+h)-h[\mathbf{L}u^- +f](x,y,z,t)+O(h^2), \tag{61}$$

where $R=\sqrt{(x-x')^2+(y-y')^2+h^2}$, and $D(x,y,t)$ is a disk with center (x,y) and radius t at the z plane. Note that if $f=0$, then Eq. (60) gives the free-space integral formula.[6]

When both u^+ and u^- are calculated at a plane, the internal field u and its normal derivative $\partial_z u$ at that plane can be immediately obtained by

$$u=u^+ +u^-, \tag{62}$$

$$\partial_z u=K^{-1}[u^- -u^+]. \tag{63}$$

Numerical example 3 (using wave-splitting approach). In this numerical example, we consider an inhomogeneous half-space with the following synthetic profile for the dissipation coefficient:

$$b(x,y,z)=100\sin^2(\pi z)\exp[-(x^2+y^2/4+z^2/9)], \quad z\geq 0 \tag{64}$$

(the density ρ is a constant everywhere). The solid and dashed lines are the reference data for the fields at points (0,0,0.1) and (0.2,0,0.1), respectively, calculated with the finite-difference time-domain method. The dotted line is the free-space (i.e., when $b\equiv 0$) solution for the field u at the point (0,0,0.1), and the difference between the solid line and the dotted line indicates the magni-

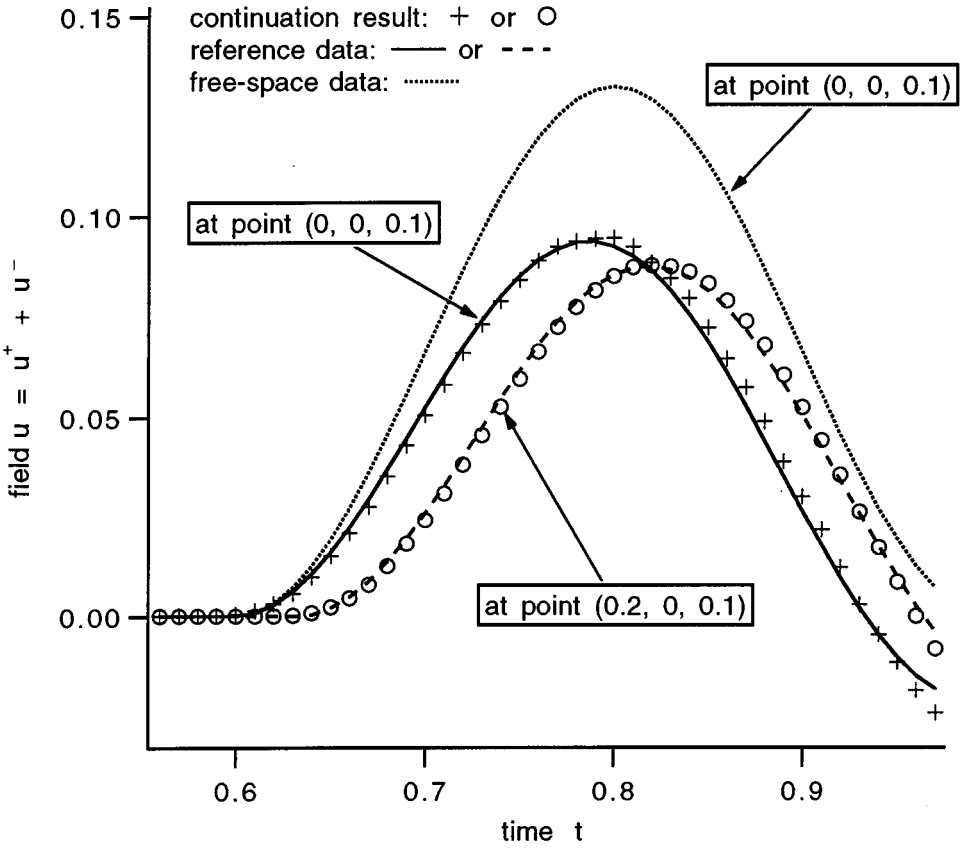

FIG. 3. Data continuation using the wave-splitting formulas (60) and (61) in an inhomogeneous half-space with a synthetic dissipation coefficient profile $b(x,y,z)=100\sin^2(\pi z)\exp[-(x^2+y^2/4+z^2/9)]$, $z\geqslant 0$ (the density ρ is constant everywhere). The solid and dashed lines are the reference data at points (0,0,0.1) and (0.2,0,0.1), respectively, calculated with a finite-difference time-domain method. The crosses and circles are the corresponding continuation data using the wave-splitting formulas with $\Delta x=\Delta y=\Delta z=2\Delta t=0.02$.

tude of scattering due to the dissipation. We use the wave-splitting formulas (60) and (61) to propagate the split fields at the surface (i.e., the incident field, and the reflected field obtained from the finite-difference time-domain method) to the split fields at the plane $z=0.1$ inside the inhomogeneous medium, with $\Delta x=\Delta y=\Delta z=2\Delta t=0.02$. The continuation results are output at two points (0,0,0.1) and (0.2,0,0.1) by the crosses and circles, respectively, in Fig. 3. One sees from Fig. 3 that the continuation data using the wave-splitting approach is smooth, even without any additional smoothing process. To compare with the local continuation approach described in the previous section, we plot the fields at a plane $z=0.1$ with a fixed time $t=0.8$ in Figs. 4(a)–4(c). Figure 4(a) is the reference data calculated by the finite-difference time-domain method. Figure 4(b) is the continuation result obtained by the wave-splitting formulas. Figure 4(c) is the continuation result obtained by the local continuation formulas (with regularization). Both the local continuation approach (with regularization) and the wave-splitting approach give quite good continuation results.

The reason why the wave-splitting approach gives stable results even without any additional smoothing process, is that it takes a larger transverse spatial domain of dependence. Notice that the transverse spatial domain of dependence of the operator K or L is a disk area with radius t. Therefore, if one wants to calculate the field at a point x on the plane $z=h$ up to the time $t=T$, the

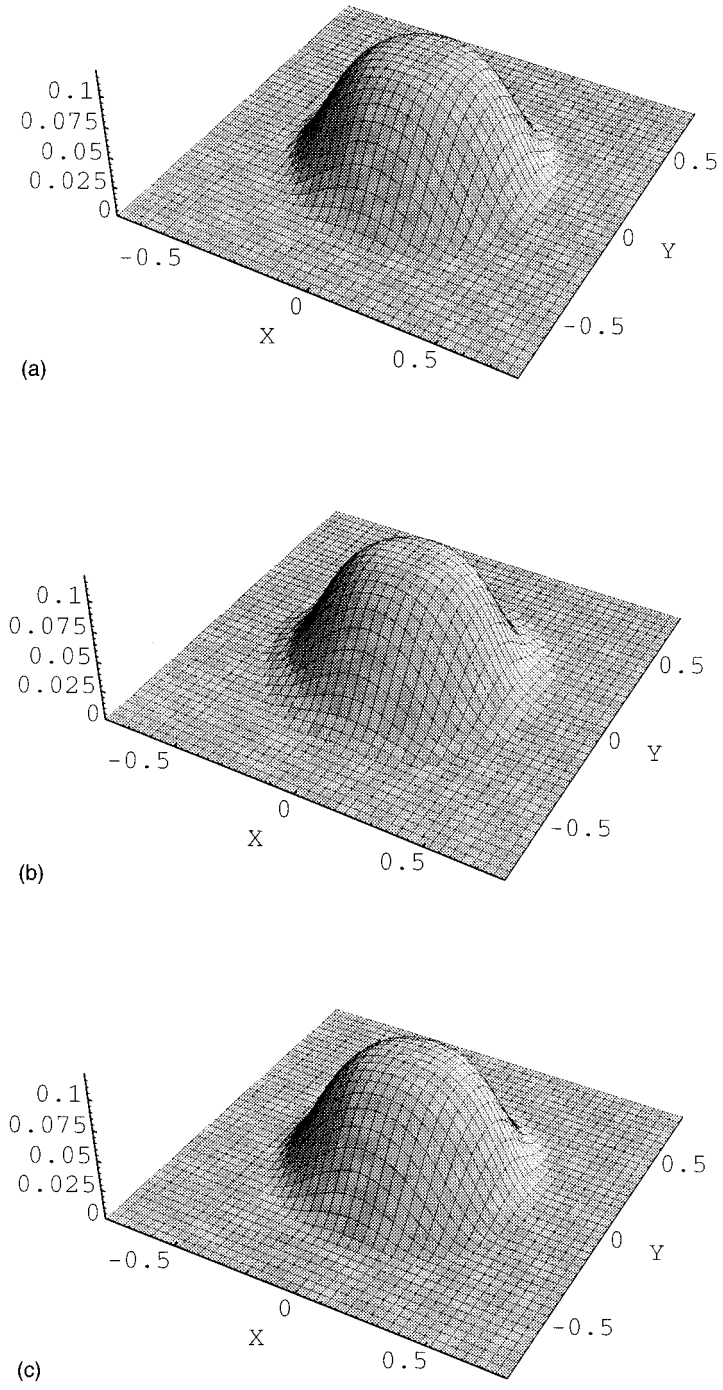

FIG. 4. (a)–(c) Data continuation results at a plane $z=0.1$ with a fixed time $t=0.8$ in an inhomogeneous half-space with a synthetic dissipation coefficient profile $b(x,y,z)=100\sin^2(\pi z)\exp[-(x^2+y^2/4+z^2/9)]$, $z\geqslant 0$ (then density ρ is constant everywhere). (a) is the reference data calculated by the finite-difference time-domain method. (b) and (c) are the corresponding continuation results obtained from the wave-splitting formulas and the local continuation formulas (with the regularization), respectively.

transverse spatial domain of dependence on the surface data is a disk area centered at x with radius T for the wave-splitting formulas (60) and (61), while for the local continuation formulas (35) and (36) the transverse spatial domain of dependence on the surface data is merely a disk centered at x with radius h. Thus, in a sense, the wave-splitting approach stabilizes the ill-posedness by using a larger transverse spatial domain of dependence.

IV. CONCLUSION

In the present paper we have considered the ill-posed problem of the time-domain data continuation for a second order hyperbolic equation in a three-dimensional inhomogeneous half-space. Two different approaches, namely the local continuation approach and the wave-splitting approach, have been used to propagate the surface data (the fields and their normal derivatives) to the data at deeper planes. A local continuation theorem has been given, and its finite-difference form has been used for the data continuation. To obtain a stable continuation result, a regularization process at each time at each plane is necessary in the local continuation approach. The wave-splitting approach uses a larger transverse spatial domain of dependence, and gives reasonably stable results even without any additional smoothing process. Numerical implementations for both the local continuation and the wave-splitting approaches are very suitable for parallel computing (without a parallel machine, the computation time for obtaining the results in Numerical examples 2 and 3 will be several years).

APPENDIX: PROOF OF THE LEMMA IN SECTION II A

Since

$$F(x,y,z,t;V)=(a_1\partial_x^2+a_2\partial_y^2+A_1\partial_x+A_2\partial_y)V_1+A_3V_2-bV_3, \tag{A1}$$

it follows for $0<s\leqslant s_0,(z,t)\in D_T$, on using the following properties of analytic functions in A_{s_0} (see, e.g., Ref. 13):

$$\|\partial_x^2 u\|_s,\|\partial_y^2 u\|_s\leqslant \frac{4}{(s'-s)^2}\,\|u\|_{s'},\quad 0<s<s'<s_0,$$

$$\|\partial_x u\|_s,\|\partial_y u\|_s\leqslant \frac{1}{s'-s}\,\|u\|_{s'},\quad 0<s<s'<s_0,$$

$$\|u\|_s\leqslant\|u\|_{s'},\quad 0<s<s'<s_0,$$

that

$$\|F(x,y,z,t;V)\|_s(z,t)\leqslant\beta\left[\frac{8}{(s'-s)^2}+\frac{2}{(s'-s)}\right]\|V_1\|_{s'}+\beta\|V_2\|_{s'}+\beta\|V_3\|_{s'}. \tag{A2}$$

Thus, from the relation [the first component of Eq. (16)],

$$V_1^n(x,y,z,t) = -\frac{1}{2}\int_0^z \int_{t-z+z'}^{t+z-z'} F(x,y,z',t';V^{n-1})\,dz'\,dt', \tag{A3}$$

where $n=1,2,...$, it follows that for $(z,t)\in D_T$,

$$\|V_1^n\|_s(z,t) \leqslant \frac{1}{2}\,\beta\int_0^z \int_{t-z+z'}^{t+z-z'} \left\{ \left[\frac{8}{(s'-s)^2} + \frac{2}{(s'-s)} \right] \|V_1^{n-1}\|_{s'} + \|V_2^{n-1}\|_{s'} + \|V_3{}^{n-1}\|_{s'} \right\} dt'\,dz'. \tag{A4}$$

When $n=0$, V_j^{n-1}, $j=1,2,3$, on the right-hand side of Eq. (A4) should be replaced by U_j^0.

In a similar manner, it can be shown using the second and third components of Eq. (16) that of $j=2,3$,

$$\|V_j^n\|_s(z,t) \leqslant \max_{|t'-t|\leqslant z-z'} \beta\int_0^z \left\{ \left[\frac{8}{(s'-s)^2} + \frac{2}{(s'-s)} \right] \|V_1^{n-1}\|_{s'} + \|V_2^{n-1}\|_{s'} + \|V_3^{n-1}\|_{s'} \right\} dz', \tag{A5}$$

for $n=1,2,...$, and when $n=0$, V_j^{n-1} on the right-hand side of Eq. (A5) should be replaced by U_j^0.

Define the following sequence:

$$s_n'(z) = (s_0 + s - z/a_n)/2, \quad n=0,1,2,3,\ldots\ . \tag{A6}$$

The lemma can now be proved by induction. For $n=0$, take $s' = s_0'(z') = (s + s_0 - z'/a_0)/2$ in expressions (A4), (A5), and restrict z so that $0\leqslant z < a_0(s_0-s)$, $|t-t_0|\leqslant z$. Using Eq. (18) and the inequality $s_0(z')-s \leqslant s_0/2$, it can be shown that

$$\|V_1^0\|_s(z,t) \leqslant 4a_0^2\beta\alpha\left(8 + s_0 + \frac{s_0^2}{2}\right)\int_0^z \frac{(z-z')\,dz'}{[a_0(s_0-s)-z']^2} \leqslant \lambda_0 \cdot \frac{z}{[a_0(s_0-s)-z]}. \tag{A7}$$

In a similar manner, it can be shown that

$$\|V_j^0\|_s(z,t) \leqslant \lambda_0 a_0 \int_0^z \frac{dz'}{[a_0(s_0-s)-z']^2} \leqslant \frac{\lambda_0 z a_0}{[a_0(s_0-s)-z]^2}, \tag{A8}$$

for $0\leqslant z < a_0(s_0-s)$.

Hence, inequalities (24) and (25) hold for $n=0$.

Assume that inequalities (24) and (25) hold for $n-1$. Then set $s' = s_n'(z') = (s + s_0 - z'/a_n)/2$ in Eq. (A4), restrict z so that $0\leqslant z < a_n(s_0-s)$, use the inequalities $a_n \leqslant a_{n-1} \leqslant \cdots \leqslant a_0$, and $[a_{n-1}(s_0-s)-z'] \geqslant [a_n(s_0-s)-z']$ valid for $0\leqslant z' < a_n(s_0-s)$ to obtain

$$\|V_1^n\|_s(z,t) \leqslant a_n a_0 \beta\lambda_0\rho^{n-1}(32+6s_0)\int_0^z \frac{(z-z')z'\,dz'}{[a_0(s_0-s)-z']^3} \leqslant \lambda_0\rho^n \cdot \frac{z}{[a_0(s_0-s)-z]}. \tag{A9}$$

The last inequality is obtained by straightforward integration.

In a similar manner, it can be shown from Eq. (A5) for $0\leqslant z < a_n(s_0-s)$, $|t-t_0 \leqslant z|$, that

$$\|V_j^n\|_s(z,t) \leqslant a_0 a_n \lambda_0 \rho^{n-1}\rho_0 \int_0^z \frac{z'\,dz'}{[a_0(s_0-s)-z']^3} \leqslant \lambda_0\rho^n \cdot \frac{z a_n}{[a_0(s_0-s)-z]^2}. \tag{A10}$$

The lemma is thus proved.

(Received 26 April 1996; accepted for publication 21 June 1996)

In relativity, planes and two-forms play important roles in the description of physical configurations or objects. When these configurations or objects interact, or are superposed, the corresponding planes or two-forms appear associated by pairs, and the *relative position* of the pair allows the classification of the particular form of the interaction. Here it is shown that in Minkowski space a pair of planes may adopt 35 relative positions. This result allows the almost complete characterization of the dimension of the Lie (sub)algebras (of the Lorentz group) generated by a pair of two-forms in terms of the relative position of their invariant planes. Furthermore, it is shown that, apart from Patera *et al.* algebras F_2 and F_5 (for which the eigenvalues' ratios have to be computed as well), the position of their invariant planes is also sufficient to determine the algebra itself generated by two two-forms. © *1996 American Institute of Physics.* [S0022-2488(96)03811-X]

I. INTRODUCTION

A smooth surface, the evolution of a rod, a string, a point mass with spin, a polarized photon; any of these objects define, in relativistic macroscopic physics, a (two-dimensional) *plane* at every point of its space–time support.[1]

Consequently, the study of shocks, diffusion, or interaction of any two of these elements involves the analysis of the different *relative positions* that the associated planes may have in Minkowski space–time.

Planes appear also naturally in relativity in many other domains, such as perfect fluids with heat flow,[2] anisotropic fluids,[3] tilted cosmologies,[4] magnetohydrodynamics,[5] two perfect fluid sources,[6] or regular or pure radiative electromagnetic fields.[7]

Thus, their junctions, shocks, phase changes, or chemical reactions across a hypersurface, their interactions,[8] or superpositions in a domain are processes that involves the study of the relative position of the pair of planes that they define. And so is also the description of the evolution of any of the above objects in these media.

The study of the variety of these relative positions not only induces a classification of the corresponding physical situations, allowing an easier analysis of them, but may help, in some cases, in the search of first integrals of the motion.[9]

Here we show that there exist 35 different relative positions for a pair of planes in Minkowski space–time (Theorem 1).

Relativistic Helmholtz vorticity of fluid currents,[10] Minkowski description of electromagnetic fields,[11] or infinitesimal generators (algebra) of Lorentz transformations[12] are perhaps the best-known examples of space–time two-forms. However, many other important two-forms have been considered in relativity, such as principal Riemann,[13] Killing–Yano,[14] Hertz potential,[15] or Frenkel intrinsic angular momentum[16] two-forms.

As two-forms in space–time univocally determine nonspacelike planes, our Theorem 1 di-

0022-2488/96/37(11)/5792/13/$10.00

rectly applies to the characterization of the *relative position of two two-forms*, and may help to find conserved quantities for the corresponding field equations.[17]

At any point of the space–time, a two-form amounts to an infinitesimal generator (element of its algebra) of a local Lorentz transformation; this interpretation of *any* two-form may be of interest in some problems related to adapted observers or frames.[12] Moreover, the determination of a Lorentz transformation by the corresponding Lorentz algebra two-form reduces the parametrization to its intrinsic elements.[18] In Ref. 19 it was shown a striking property of the commutator of two two-forms, namely that it defines an internal binary operation on the space of planes: the invariant planes of the commutator depend exclusively on the invariant planes of the two-forms (and not on their eigenvalues).

This last property strongly suggests that the Lie (sub)algebra (of the Lorentz group) generated by two two-forms depends essentially on the relative position of its invariants planes, and very little on their eigenvalues. In the second part of the article we examine this question. Our main result (Theorem 3) is that, apart from a special case of regular two-forms for which the ratio of eigenvalues are needed, the algebra generated by two two-forms *depends exclusively* on the relative position of the principal planes of the two-forms.

In the above-mentioned interpretation of any two-form as generator of a Lorentz transformation, but also in other situations,[20] one is naturally lead to consider the Baker–Campbell–Hausdorff formula[21] for the two-form associated to a product of two Lorentz transformations. Our Theorem 3 directly applies to simplify its general expression; this will be seen in a later work.

II. PRELIMINARIES

Let (V_4,g) be Minkowski space and P and Q be two planes (two-dimensional linear subspaces of V_4). In order to render easier the study of their relative position, it is convenient to range the intersections of them and their (biunivocally determinated) orthogonal planes $P^\perp$ and $Q^\perp$ as a 2×2 matrix:

$$\mathscr{D}(P,Q)\equiv\begin{pmatrix} P\cap Q & P\cap Q^\perp \\ P^\perp\cap Q & P^\perp\cap Q^\perp \end{pmatrix}.$$

The set of these matrices $\mathscr{D}(P,Q)$ will be denoted by $\mathscr{D}$. These matrices have the following properties $\forall P,Q$ (Proposition 2 of Ref. 19):

$$\begin{gathered}(\mathscr{D}(P,Q))_{ij}\ \perp(\mathscr{D}(P,Q))_{mn}\quad\forall(i,j)\neq(m,n),\\ \dim(\mathscr{D}(P,Q))_{11}=\dim((P,Q))_{22},\\ \dim(\mathscr{D}(P,Q))_{22}=\dim(\mathscr{D}(P,Q))_{21}.\end{gathered}\tag{1}$$

By reasons explained in Ref. 19 we are interested by the following transformations of $\mathscr{D}$ (bijections of $\mathscr{D}$):

$$\begin{aligned}&\mathrm{t}:\mathscr{D}(P,Q)\mapsto\mathscr{D}^{\mathrm{t}}(P,Q)\equiv\mathscr{D}(Q,P),\\ &\mathrm{c}:\mathscr{D}(P,Q)\mapsto\mathscr{D}^{\mathrm{c}}(P,Q)\equiv\mathscr{D}(P,Q^\perp),\\ &\mathrm{r}:\mathscr{D}(P,Q)\mapsto\mathscr{D}^{\mathrm{r}}(P,Q)\equiv\mathscr{D}(P^\perp,Q),\\ &\mathrm{l}:\mathscr{D}(P,Q)\mapsto\mathscr{D}^{\mathrm{l}}(P,Q)\equiv\mathscr{D}(l(P),l(Q)),\end{aligned}\tag{2}$$

where $\mathrm{l}\in\mathscr{L}$, $\mathscr{L}$ being the Lorent group.

TABLE I. Planes determined by $\mathscr{D}(P,Q)$.

m_0	m_{10}^0	m_{10}^2	m_1^0	m_1^3	m_1^1	m_{20}	m_{21}
$\begin{pmatrix}0&0\\0&0\end{pmatrix}$	$\begin{pmatrix}a&0\\0&b\end{pmatrix}$	$\begin{pmatrix}i&0\\0&p\end{pmatrix}$	$\begin{pmatrix}a&b\\c&d\end{pmatrix}$	$\begin{pmatrix}i&i\\p&q\end{pmatrix}$	$\begin{pmatrix}i&i\\i&i\end{pmatrix}$	$\begin{pmatrix}R&0\\0&R^\perp\end{pmatrix}$	$\begin{pmatrix}I&i\\i&I^\perp\end{pmatrix}$
Undetermined	$P=a+c'$ $Q=a+c''$	$P=i+i'$ $Q=i+i''$	$P=a+b$ $Q=a+c$	$P=i+i'$ $Q=i+p$	$P=i+p$ $Q=i+p'$	$P=R$ $Q=R$	$P=I$ $Q=I$

Let us consider the subgroups of transformations of $\mathscr{D}$ generated by the elements {t}, {t,cr}, {t,c,r}, and {l}, respectively. Apart from those given by (2), the images of the matrix $\mathscr{D}(P,Q)$ by the transformations of the subgroup generated by {t,c,r} are

$$\begin{aligned}&\mathscr{D}^{\mathrm{tr}}(P,Q)=\mathscr{D}(Q^\perp,P),\quad \mathscr{D}^{\mathrm{cr}}(P,Q)=\mathscr{D}(P^\perp,Q^\perp),\\&\mathscr{D}^{\mathrm{tcr}}(P,Q)=\mathscr{D}(Q^\perp,P^\perp),\quad \mathscr{D}^{\mathrm{tc}}(P,Q)=\mathscr{D}(Q^\perp,P).\end{aligned}\tag{3}$$

This subgroup, which is the same as the one generated by {tr,t}, is the dihedral group D_4. The subgroups generated by {t,cr} and {t} are, respectively, the dihedral group D_2 and the permutation group S_2.

Two results are needed. The first result says (Proposition 3 of Ref. 19) that *in Minkowski space the elements of* $\mathscr{D}/(D_4\times\mathscr{S})$ *are*

$$\begin{gathered}\left[\begin{pmatrix}0&0\\0&0\end{pmatrix}\right]\equiv m_0,\quad \left[\begin{pmatrix}a&0\\0&b\end{pmatrix}\right]\equiv m_{10}^0,\quad \left[\begin{pmatrix}i&0\\0&p\end{pmatrix}\right]\equiv m_{10}^2,\\ \left[\begin{pmatrix}a&b\\c&d\end{pmatrix}\right]\equiv m_1^0,\quad \left[\begin{pmatrix}i&i\\p&q\end{pmatrix}\right]\equiv m_1^3,\quad \left[\begin{pmatrix}i&i\\i&i\end{pmatrix}\right]\equiv m_1^1,\\ \left[\begin{pmatrix}R&0\\0&R^\perp\end{pmatrix}\right]\equiv m_{20},\quad \left[\begin{pmatrix}I&i\\i&I^\perp\end{pmatrix}\right]\equiv m_{21},\end{gathered}\tag{4}$$

where a, b, c, d, p, and q *are non-null directions,* i *is a null one, and* R *and* I *are respectively a non-null and a null plane.*

The second result says (Proposition 4 of Ref. 19) that *the components of the matrix* $\mathscr{D}(P,Q)$ *determine the planes* P *and* Q *as indicated in Table I, where* $\{a,b,c,d,\}$ *is a tetrad of orthogonal directions,* $\{a,b,c'\}$ *and* $\{a,b,c''\}$ *are different orthogonal triads,* $\{i,i',i''\}$ *is a triad of null directions, and* p *and* p' *are different and nonorthogonal directions which are orthogonal to the null directions of each case.*

III. RELATIVE POSITION

In a linear space, the relative position of two planes (P,Q) is determined by the dimension of their common elements, $\dim(P\cap Q)$; thus *in* V_4 *there are three relative positions for a pair of planes.*

If the linear space is endowed with a Euclidean metric, which associates to every plane its orthogonal, the (qualitative) relative positions of two planes are determined by the dimensions of relevant intersections of pairs of planes taken from the set $\{P,Q,P^\perp,Q^\perp\}$; i.e., by the dimension matrix $\mathrm{D}(P,Q)$ such that $(\mathrm{D}(P,Q))_{ij}=\dim(\mathscr{D}(P,Q))_{ij}$. Thus, from (1) it is easy to see that *in four-dimensional Euclidean space* (V_4,g_e), *there are six relative positions for a pair of planes,* corresponding to the dimension matrices

$$\begin{pmatrix}0&0\\0&0\end{pmatrix}\begin{pmatrix}1&0\\0&1\end{pmatrix}\begin{pmatrix}0&1\\1&0\end{pmatrix}\begin{pmatrix}1&1\\1&1\end{pmatrix}\begin{pmatrix}2&0\\0&2\end{pmatrix}\begin{pmatrix}0&2\\2&0\end{pmatrix}.$$

If the linear space is endowed with a Lorentzian metric, which associates to every plane also a causal character, the (qualitative) relative position of a pair of planes will be determined by the corresponding matrix $\mathrm{D}(P,Q)$ but also by the causal character of P and Q and the elements of $\mathscr{D}(P,Q)$. The object of this section is to characterize all of them.

Let us be slightly more precise. The six above-mentioned relative positions of the Euclidean case correspond to elements of $\mathscr{D}/(D_2\times O)$, bijectively related to the set D of dimension matrices $\mathrm{D}(P,Q)$. Here D_2 appears because the pairs (P,Q), (Q,P), $(P^\perp,Q^\perp)$, and $(Q^\perp,P^\perp)$ have the same relative position. However, in Minkowski space because of the causal character, we have to distinguish between (P,Q) and $(P^\perp,Q^\perp)$. Thus, in addition to the causal character of P and Q, we have to consider the group S_2 in place of D_2 (and, of course, $\mathscr{L}$ in place of O).

Denoting by c_P the causal character of the plane P ($c_P=-,0,+$, resp. if P is timelike, null, spacelike), by $c(P,Q)$ the couple of causal characters of P and Q, $c(P,Q)\equiv(c_P,c_Q)$, and by $\mathscr{C}$ the set $\{c(P,Q)\}\forall P,Q$, we are led to give the following definition:

Definition 1. The relative position of two planes P *and* Q *is the element of* $\mathscr{C}/S_2\times\mathscr{D}/(S_2\times\mathscr{L})$ *that contains* $(c(P,Q),\mathscr{D}(P,Q))$.

From (2)–(4) it is easy to compute the elements of $\mathscr{D}/(S_2\times\mathscr{L})$; one has[22]

$$\begin{gathered}
\left[\begin{pmatrix}0&0\\0&0\end{pmatrix}\right]\equiv m_0,\\
\left[\begin{pmatrix}0&t\\e&0\end{pmatrix}\right]\equiv m_{01}^{-+},\quad \left[\begin{pmatrix}0&e\\e'&0\end{pmatrix}\right]\equiv m_{01}^{++},\quad \left[\begin{pmatrix}0&i\\e&0\end{pmatrix}\right]\equiv m_{01}^{0+},\\
\left[\begin{pmatrix}t&0\\0&e\end{pmatrix}\right]\equiv m_{10}^{-+},\quad \left[\begin{pmatrix}e&0\\0&e'\end{pmatrix}\right]\equiv m_{10}^{++},\quad \left[\begin{pmatrix}e&0\\0&t\end{pmatrix}\right]\equiv m_{10}^{-+},\\
\left[\begin{pmatrix}i&0\\0&e\end{pmatrix}\right]\equiv m_{10}^{0+},\quad \left[\begin{pmatrix}e&0\\0&i\end{pmatrix}\right]\equiv m_{10}^{+0},\\
\left[\begin{pmatrix}t&e\\e'&e''\end{pmatrix}\right]\equiv m_1^{-+},\quad \left[\begin{pmatrix}e&e'\\e''&t\end{pmatrix}\right]\equiv m_1^{+-},\quad \left[\begin{pmatrix}e&t\\e'&e''\end{pmatrix}\right]\equiv m_1^{++},\\
\left[\begin{pmatrix}i&i\\e&e'\end{pmatrix}\right]\equiv m_1^{0+},\quad \left[\begin{pmatrix}e&i\\e'&i\end{pmatrix}\right]\equiv m_1^{+0},\quad \left[\begin{pmatrix}i&i\\i&i\end{pmatrix}\right]\equiv m_1^{00},\\
\left[\begin{pmatrix}T&0\\0&E\end{pmatrix}\right]\equiv m_{20}^{-+},\quad \left[\begin{pmatrix}E&0\\0&T\end{pmatrix}\right]\equiv m_{20}^{+-},\quad \left[\begin{pmatrix}0&T\\E&0\end{pmatrix}\right]\equiv m_{02},\\
\left[\begin{pmatrix}I&i\\i&I^\perp\end{pmatrix}\right]\equiv m_{21},\quad \left[\begin{pmatrix}i&I\\I^\perp&i\end{pmatrix}\right]\equiv m_{12},
\end{gathered}\tag{5}$$

where t and i are, respectively, a timelike and a null direction; e, e', and e'' are spacelike directions, and T, I, and E are, respectively, a timelike plane, a null plane, and a spacelike plane. We are thus able to prove the following result:

Theorem 1: *In Minkowski space there are 35 relative positions for a pair of planes. They are characterized in Table II.*

	m_{1}^{+-}	$\Pi_{3,13}$
	m_{20}^{+-}	$\Pi_{1,3}$

Proof: Suppose $[\mathscr{D}(P,Q)]=m_0$; let $\{a,b,a',b'\}$ be its characteristic tetrad (Definition 1 of Ref. 19) and $\{K,K^{\perp}\}$ its characteristic planes (Definition 2 of Ref. 19); then $a+a'=K$, $b+b'=K^{\perp}$, $P=a+b$, and $Q=a'+b'$. Taking into account that the characteristic planes are not null and that $a\not\perp a'$ and $b\not\perp b'$ one has that $[c(P,Q)]$ can be any element of $\mathscr{C}/S_2$.

Suppose $[\mathscr{D}(P,Q)]=m_{10}^{++}$; from the Table I one has $P=e+c'$ and $Q=e+c''$, verifying $c'\perp e\perp c''$ and $c'\not\perp c''$. Then P has the causal character of c' and Q has the character of c''. As c' and c'' can have any causal character, $[c(P,Q)]$ can be any element of $\mathscr{C}/S_2$.

Suppose $[\mathscr{D}(P,Q)]=m_{01}^{++}$. Then, one has $[\mathscr{D}(P^{\perp},Q)]=m_{10}^{++}$; by the preceding argument $[c(P^{\perp},Q)]$ is any element of $\mathscr{C}/S_2$, so that $[c(P,Q)]$ do as well.

Finally, let us take any other element m of $\mathscr{D}/(S_2\times\mathscr{S})$. It is easily deduced from (2), (3), (5), and Table I that $\mathscr{D}(P,Q)\in m$ implies that $[c(P,Q)]$ is univocally determined.

Then, Table II follows. □

IV. BASIC NOTIONS ABOUT TWO-FORMS

Every two-form F has two independent *invariant scalars*, namely $\phi_F \equiv (F,*F)$ and $\psi_F \equiv (F,F)$, where $*$ is the Hodge dual operator and $(.,.)$ stands for the scalar product induced by g: $(F,G) \equiv -(1/2)\mathrm{tr}(FG)$, tr being the trace operator and FG the (cross-)product of two-forms.[23]

A nonvanishing two-form F is called *null* if $\phi_F^2 + \psi_F^2 = 0$, *regular* otherwise, *simple* if $\phi_F = 0$, and *unitary* if it is simple and $\psi_F = -1$.

The *principal directions* of F are the common eigendirections of F and $*F$, which are necessarily null. Let $\pm\alpha$ and $\pm i\tilde{\alpha}$ be the eigenvalues of a regular two-form verifying $\alpha > 0$, $\phi_F = -2\alpha\tilde{\alpha}$, and $\psi = -\alpha^2 + \tilde{\alpha}^2$. Then F admits a unique decomposition of the form $F = \alpha U - \tilde{\alpha} * U$, where U is unitary. The pair $\{U, *U\}$ is called the *geometry* of F. For a null F, it is the pair $\{F, *F\}$ itself which is called the *geometry* of F.

It is *always* possible to write univocally any two-form F in terms of its geometry $\{U, *U\}$ as $F = \alpha U - \tilde{\alpha} * U$, where the *weights* α and $\tilde{\alpha}$ take the values $\alpha = 1$ and $\tilde{\alpha} = 0$ when U is null. This decomposition is useful when (as in the present case) only algebraic calculations are involved.

An *inner direction* x of a simple two-form F is a direction such that any of its elements $\hat{x}$ verifies $\hat{x} \wedge F = 0$, where $\wedge$ stands for the exterior product. The plane of inner directions will be noted $\pi(F)$. The *invariant planes* of a two-form F are the planes of inner directions of its geometry: $\{\pi(U), \pi(*U)\}$. It is clear that $\pi(*U) = \pi(U)^{\perp}$.

There are six invariant scalars for a pair of two-forms, F and G, namely ϕ_F, ψ_F, ϕ_G, ψ_G, and the two *mixed invariant scalars* $\rho_{FG} \equiv (F,*G)$ and $\sigma_{FG} \equiv (F,G)$. The geometrical meaning of the mixed invariant scalars is as follows (see Lemma 2 in Ref. 19 for a proof):

Lemma 1: The planes $\pi(F)$ and $\pi(G)$ of simple two-forms F and G have common directions if, and only if, the mixed invariant ρ_{FG} vanishes.

It is to be noted that, because of the identity $\sigma_{FG} = -\rho_{F*G}$, this lemma also asserts that $\pi(F)$ and $\pi(*G)$ have common directions if, and only if, $\sigma_{FG} = 0$.

Let us recall that two-forms build the Lie algebra of Lorentz group with the commutator as the Lie bracket

$$[F,G] = FG - GF;$$

the properties of its geometry have been studied in Ref. 19. Now we are concerned with the subalgebras $\mathscr{A}(F,G)$ of the Lie algebra of Lorentz group generated by two-forms F and G.

V. A BASIS FOR THE SUBALGEBRAS GENERATED BY TWO TWO-FORMS

Let us consider the set

$$\mathscr{G}(F,G) \equiv \{F, G, *F, *G, [F,G], *[F,G]\}$$

associated to two-forms F and G and let $\mathscr{L}(\mathscr{G}(F,G))$ denote the linear space generated by $\mathscr{G}(F,G)$.

Taking into account the identities $FG - *G*F = -\sigma_{FG} g$ and $[F,*G] = *[F,G]$, one has

$$\begin{aligned} [[F,G],F] &= -\sigma_{FG} F + \psi_F G + \rho_{FG} *F - \phi_F *G, \\ [[F,G],G] &= -\psi_G F + \sigma_{FG} G + \phi_G *F - \rho_{FG} *G, \end{aligned} \tag{6}$$

and it is clear that all the elements of $\mathscr{A}(F,G)$ may be expressed as a linear combination of the elements of $\mathscr{G}(F,G)$. Therefore, the following holds:

Lemma 2: For any two-forms F and G, one has $\mathscr{A}(F,G) \subset \mathscr{L}(\mathscr{G}(F,G))$.

Thus we can always select a basis of $\mathscr{A}(F,G)$ from $\mathscr{G}(F,G)$. Concerning the dimension of $\mathscr{L}(\mathscr{G}(F,G))$, we have the following.

Proposition 1: For nonproportional two-forms F and G, one has

$$\dim \mathscr{L}(\mathscr{G}(F,G)) \in \{2,4,6\}.$$

This dimension is 2 if, and only if, they have the same principal directions, it is 4 if, and only if, they have one common principal direction and at least one that is not common, and it is 6 if, and only if, they have no common principal directions.

Proof: Let $\{U,*U\}$ and $\{V,*V\}$ be the geometries of F and G, respectively. As the elements of $\mathscr{G}(F,G)$ may be expressed as linear combinations of the elements of $\mathscr{G}(U,V)$ and vice versa, it is clear that $\dim \mathscr{L}(\mathscr{G}(F,G))=\dim \mathscr{L}(\mathscr{G}(U,V))$. Hence, we only have to prove the proposition for the two-forms U and V.

Let us remember that U and V have same principal directions iff $U=\lambda V+\mu *V$ ($\lambda=1$ and $\mu=0$ if they are regular). Hence, if they have the same principal directions $\dim \mathscr{L}\{U,V,*U,*V\}=2$; and as $[U,\ V]=0$ (Proposition 8 from Ref. 19), $\dim \mathscr{L}(\mathscr{G}(U,V))=2$.

If U and V have one common principal direction and at least one noncommon, $\dim \mathscr{L}\{U,V,*U,*V\}=4$. Then there exist some vectors x, y, and z verifying $U=x\wedge y$, $V=x\wedge z$, and $(x,x)=0$. Since

$$[U,\ V]=-(x,x)y\wedge z-(x,z)U+(x,y)V=-(x,z)U+(x,y)V, \tag{7}$$

it follows that $\dim \mathscr{L}(\mathscr{G}(U,V))=4$.

If U and V have no common principal directions, $\dim \mathscr{L}\{U,V,*U,*V\}=4$ and $\dim \mathscr{L}(\mathscr{G}(U,V))\geqslant 4$. Suppose $\dim \mathscr{L}(\mathscr{G}(U,V))=4$ so that

$$[U,\ V]=\lambda U+\mu V+\nu *U+\xi *V,$$

and then

$$[[U,\ V],\ U]=-(\lambda\mu-\xi\nu)U-(\mu^2-\xi^2)V-(\lambda\xi+\mu\nu)*U-2\mu\xi *V,$$

$$[[U,\ V],\ V]=(\lambda^2-\nu^2)U+(\lambda\mu-\xi\nu)V-2\lambda\nu *U+(\lambda\xi+\mu\nu)*V.$$

However, from (6), $\phi_U=2\mu\xi=0$ and $\phi_V=-2\lambda\nu=0$, so that all the solutions for λ, μ, ν, and ξ lead to expressions of the form (7) implying the existence of common principal directions. Thus $\dim \mathscr{L}(\mathscr{G}(U,V))>4$. Suppose $\dim \mathscr{L}(\mathscr{G}(U,V))=5$, and then either $\dim \mathscr{L}\{U,V,*U,*V,[U,V]\}=5$ or $\dim \mathscr{L}\{U,V,*U,*V,*[U,V]\}=5$ or both. Assume the first condition verified so that

$$*[U,\ V]=\lambda U+\mu V+\nu *U+\xi *V+\chi[U,\ V]$$

and call $A\equiv\lambda U+\mu V+\nu *U+\xi *V$. It follows

$$[U,\ V]=-*A-\chi *[U,\ V]=-\chi A-*A-\chi^2[U,\ V],$$

and we obtain

$$(\chi\lambda-\nu)U+(\chi\mu-\xi)V+(\chi\nu+\lambda)*U+(\chi\xi+\mu)*V+(1+\chi^2)[U,\ V]=0.$$

Following our assumption this expression leads to the incompatibility $1+\chi^2=0$. The same conclusion is obtained assuming the other conditions, so that $\dim \mathscr{L}(\mathscr{G}(U,V))=6$ for U and V having no common principal directions. □

VI. DIMENSION OF THE ALGEBRAS GENERATED BY TWO SIMPLE TWO-FORMS

Let U and V be simple noncommuting two-forms (they do not have the same principal directions; see Proposition 8 in Ref. 19), and let ψ, ψ', ρ, and σ be their nonzero invariant scalars. From (6) we obtain

$$[[U,\ V],\ U]=-\sigma U+\psi V+\rho *U,\quad [[U,\ V],\ V]=-\psi' U+\sigma V-\rho *V. \tag{8}$$

Therefore, $\rho=0$ implies $\dim \mathscr{A}(U,V)\leqslant 3$. Conversely, when $\dim \mathscr{A}(U,V)\leqslant 3$, from (8) we have either $\rho=0$ or

$$*U=\lambda U+\mu V+\nu[U,\ V],\quad *V=\lambda' U+\mu' V+\nu'[U,\ V]. \tag{9}$$

However, if (9) is verified, then $\nu\nu'\neq 0$; hence we can obtain $[U,\ V]$ in two different ways from (9) and, equating them, we have

$$(\lambda'\nu-\lambda\nu')U+\nu' *U=(\mu\nu'-\mu'\nu)V+\nu *V,$$

and so U and V would have same geometry. Thus $\dim \mathscr{A}(U,V)\leqslant 3\Leftrightarrow\rho=0$. Then, from Lemma 1 and (7), we have the following:

Lemma 3: For noncommuting simple two-forms U and V, one has

(i) $\dim \mathscr{A}(U,V)=2$ *if, and only if, they have one common inner principal direction, and*
(ii) $\dim \mathscr{A}(U,V)=3$ *if, and only if, they have one common non-null inner direction.*

Let us suppose now $\dim \mathscr{A}(U,V)=4$. The last lemma implies $\rho\neq 0$, and, from (8), we get

$$[[[U,\ V],\ U],\ V]=-\sigma[U,\ V]+\rho *[U,\ V]; \tag{10}$$

hence, $\dim \mathscr{A}(U,V)=4\ \Rightarrow\ \dim \mathscr{L}(\mathscr{G}(U,V))=4$. Therefore, from Proposition 1 and Lemma 3, U and V must have one common principal direction and no common inner directions for both two-forms. Conversely, when U and V have a common principal direction and no common inner directions, $\dim \mathscr{L}(\mathscr{G}(U,V))=4$ (Proposition 1) and $\dim \mathscr{A}(U,V)\leqslant 4$ (Lemma 2). As $\rho\neq 0$, $\dim \mathscr{A}(U,V)=4$ (Lemma 3). Thus, the following lemma has been proved:

Lemma 4: The necessary and sufficient condition for $\dim \mathscr{A}(U,V)=4$ *is that the simple two-forms U and V have one common principal direction and no common inner directions.*

Finally, suppose $\dim \mathscr{A}(U,V)=6$.[24] By Lemmas 3 and 4, the two-forms U and V have neither common principal directions nor common inner directions. Conversely, by Proposition 1 when U and V have neither common principal directions nor common inner directions, $\dim \mathscr{L}(\mathscr{G}(U,V))=6$. As $\rho\neq 0$, from (8) and (10), the two-forms U, V, $[U,\ V]$, $[[U,\ V],U]$, $[[U,\ V],V]$ and $[[[U,V],U],V]$ are linearly independent; hence[24] $\dim \mathscr{A}(U,V)=6$. We have shown the following result:

Lemma 5: The necessary and sufficient condition for $\dim \mathscr{A}(U,V)=6$ *is that the simple two-forms U and V have neither common principal directions nor common inner directions.*

As a corollary of the last results and Proposition 8 of Ref. 19 we have the next proposition:

Proposition 2: Let U and V be nonproportional simple two-forms. It holds that

(i) $\dim \mathscr{A}(U,V)=2$ *and* $[U,\ V]=0$ *if, and only if, all principal directions are common;*
(ii) $\dim \mathscr{A}(U,V)=2$ *and* $[U,\ V]\neq 0$ *if, and only if, there is one common principal direction and at least one noncommon principal direction;*
(iii) $\dim \mathscr{A}(U,V)=3$ *if, and only if, there is only one common non-null inner direction;*
(iv) $\dim \mathscr{A}(U,V)=4$ *if, and only if, there is only one common principal direction and no common inner directions; and*
(v) $\dim \mathscr{A}(U,V)=6$ *if, and only if, there are neither common principal directions nor common inner directions.*

Hence, the following is now evident.

Corollary 1: The dimension of the algebra $\mathscr{A}(U,V)$ *generated by the simple two-forms U and V is d when the relative position of the planes of inner directions is* Π_d, *as given in Table II.*

VII. DIMENSION OF THE ALGEBRA GENERATED BY ANY TWO TWO-FORMS

Here we shall consider pairs of noncommuting two-forms such that at least one is not simple, say $F=\alpha U-\tilde{\alpha}*U$ and $G=\beta V-\tilde{\beta}*V$ such that $\psi_U=-1$ and $\psi_V\in\{-1,0\}$.

Suppose that F and G have only one common principal direction; then lemma 2 and proposition 1 imply $\dim \mathscr{A}(F,G)\leqslant 4$. Since U is unitary but V is unitary or null, (7) gives

$$[U,\ V]=\gamma U+\delta V \tag{11}$$

(note that $\gamma^2\in\{1,0\}$, $\delta^2=1$, and that $\gamma=0$ iff V is null). Hence,

$$[F,\ G]=\gamma\beta F+\delta\alpha G-\gamma\tilde{\beta}*F-\delta\tilde{\alpha}*G. \tag{12}$$

For F not simple and $\dim \mathscr{L}\{F,G,*F,*G\}=4$, $\dim \mathscr{A}(F,G)\geqslant 3$. Then, $\dim \mathscr{A}(F,G)\in\{3,4\}$. In order to have $\dim \mathscr{A}(F,G)=3$ we must impose $[[F,\ G],\ F]$, $[[F,\ G],\ G]\in\mathscr{L}\{F,G,[F,\ G]\}$. Taking into account (11) and (12) we get

$$[[f,\ G],\ G]=\gamma\delta(\alpha\beta-\tilde{\alpha}\tilde{\beta})F-(\alpha^2-\tilde{\alpha}^2)G+\gamma\delta(\alpha\tilde{\beta}+\tilde{\alpha}\beta)*F+2\alpha\tilde{\alpha}*G,$$

$$[[F,\ G],\ F]=(\beta^2-\tilde{\beta}^2)F+\gamma\delta(\alpha\beta-\tilde{\alpha}\tilde{\beta})G-2\beta\tilde{\beta}*F-\gamma\delta(\alpha\tilde{\beta}+\tilde{\alpha}\beta)*G,$$

so, $\dim \mathscr{A}(F,G)=3$ iff $\gamma(\alpha\tilde{\beta}-\tilde{\alpha}\beta)=0$; equivalently, G is null or the ratio of the weights of F equals the ratio of the weights of G.

Lemma 6: Let F and G be two-forms such that at least one is not simple. Then

(i) $\dim \mathscr{A}(F,G)=3$ *if, and only if, there is only one common principal direction and either one of the two-forms is null or, being regular, their weights' ratios coincide, and*

(ii) $\dim \mathscr{A}(F,G)=4$ *if, and only if, they are regular, have only one common principal direction and their weights' ratios are different.*

Finally, assume that they have no common principal direction. By Proposition 1 $\dim \mathscr{L}(\mathscr{I}(F,G))=6$ and by Lemma 6 $\dim \mathscr{A}(F,G)>4$, hence[24] it is 6. Conversely, when $\dim \mathscr{A}(F,G)=6$, from Lemma 2 and Proposition 1 they do not have any common principal direction. We have shown the following result:

Lemma 7: Let F and G be two-forms such that at least one is not simple. Then, the necessary and sufficient condition for $\dim \mathscr{A}(F,G)=6$ *is that they do not have common principal directions.*

As a corollary of proposition 8 of Ref. 19, and due to Lemmas 3–7 we have the following theorem:

Theorem 2: *Let F and G be nonproportional two-forms. Then*

(i) $\dim \mathscr{A}(F,G)=2$ *and* $[F,\ G]=0$ *if, and only if, they have the same principal directions;*

(ii) $\dim \mathscr{A}(F,G)=2$ *and* $[F,\ G]\neq 0$ *if, and only if, they are simple, have only one common principal direction, and at least one noncommon principal one;*

(iii) $\dim \mathscr{A}(F,G)=3$ *if, and only if, either they are simple and have only one non-null common direction or they are not simple, have one common principal direction and their weights' ratios coincide, or one is null, the other is not simple and have one common principal direction;*

(iv) $\dim \mathscr{A}(F,G)=4$ *if, and only if, they are both regular, have one common principal direction and their weights' ratios do not coincide; and*

(v) $\dim \mathscr{A}(F,G)=6$ *if, and only if, there are not common principal directions and, when they are simple, neither common inner directions.*

This theorem shows that the relative position of the geometries of a pair of two-forms determines the dimension of the algebra that they generate except in the case of regular two-forms

TABLE III. Subalgebras of the Lie algebra of Lorentz group.

Dimension	Type		Basis
0	R_1	F_{15}	
1	R_2	F_{13}	A_1
1	R_3	F_{14}	A_3
1	R_4	F_{12}	A_2
1	R_5	F_{11}	$A_1+\lambda A_2$ $(\lambda\neq 0)$
2	R_6	F_8	$A_1,\ A_3$
2	R_7	F_9	$A_1,\ A_2$
2	R_8	F_{10}	$A_3,\ A_4$
3	R_9	F_7	$A_1,\ A_3,\ A_4$
3	R_{10}	F_4	$A_1,\ A_3,\ A_5$
3	R_{11}	F_6	$A_2,\ A_3,\ A_4$
3	R_{12}	F_5	$A_1+\lambda A_2,\ A_3,\ A_4$ $(\lambda\neq 0)$
3	R_{13}	F_3	$A_2,\ A_3-A_5,\ A_4-A_6$
5	R_{14}	F_2	$A_1,\ A_2,\ A_3,\ A_4$
6	R_{15}	F_1	$A_1,\ A_2,\ A_3,\ A_4,\ A_5,\ A_6$

verifying the conditions that only one is simple and have one common principal direction. In this case we have to compute the weights' ratio of each one to discriminate between dimensions 3 and 4.

VIII. ALGEBRAS GENERATED BY TWO TWO-FORMS

Table III gives the subalgebras of the Lie algebra of Lorentz group. Each type corresponds to a class of conjugation by the orthochronous proper Lorentz group (connected component of the identity), except for the types where it the real number λ appears; each λ defines a different conjugation class. In the type column the Rs and the Fs correspond, respectively, to notations by Schell (see Ref. 25) and by Patera *et al.* (see Ref. 26); the last column includes a basis of each type in terms of the two-forms associated to a real null tetrad $\{l,m,p,q\}$.[27] We have made use of the notation:

$$\begin{aligned} &A_1=l\wedge m, \quad A_3=l\wedge p, \quad A_5=m\wedge p,\\ &A_2=p\wedge q, \quad A_4=l\wedge q, \quad A_6=m\wedge q. \end{aligned} \tag{13}$$

In this section we will see which types of these algebras can be generated by a pair of two-forms and which are the necessary and sufficient conditions for a pair of two-forms to generate a given type. These conditions will be expressed in terms of the geometric ingredients of the two-forms.

There are four types of subalgebras of dimension 1. Three of them (R_2,R_3,R_4) correspond to each causal character (resp., timelike, null, spacelike) of the plane of inner directions of a simple two-form. Type R_5 corresponds to classes of algebras generated by a nonsimple two-form, where λ is related to the weights' ratio of the two-form. It is clear that these types can be generated by two proportional two-forms with the characteristics listed above.

There are three types of subalgebras of dimension 2: R_6 is nonconmutative and R_7 and R_8 are conmutative; the former corresponds to regular geometry, and the latter to null geometry. From Theorem 2 we obtain the following result:

Lemma 8: For nonproportional two-forms F and G,

TABLE IV. The three-dimensional algebras of the Lorentz group.

Schell type	R_9	R_{10}	R_{11}	R_{12}	R_{13}
Bianchi type	V	VIII	VII_0	VII_h $(h\neq 0)$	IX

(i) *$\mathscr{A}(F,G)$ is an R_6-algebra if, and only if, they are simple, have only one common principal direction and at least one noncommon principal one,*

(ii) *$\mathscr{A}(F,G)$ is an R_7-algebra if, and only if, they are regular and have the same geometry, and*

(iii) *$\mathscr{A}(F,G)$ is an R_8-algebra if, and only if, they are null and have the same principal direction.*

Table IV shows the three-dimensional subalgebras of the Lorentz group and the correspondence between the Schell types and the Kramer *et al.*[29] notation of Bianchi[28] types.

The three planes of inner directions of the elements of the basis of R_{10}, R_{11}, and R_{13} (see Table III) generate a timelike, null, and spacelike hyperplane, respectively; for R_9 they generate all Minkowski space. Moreover, for types R_9, R_{10}, R_{11}, and R_{13}, any linear combination of the elements of the basis is simple, but this does not hold for R_{12}. We deduce that R_9, R_{10}, R_{11}, and R_{13} can only be generated by a pair of simple two-forms and that R_{12} can only be generated by a pair where at least one is not simple. By Proposition 2, the two-forms generating R_9, R_{10}, R_{11}, and R_{13} have a non-null common inner direction; taking into account (7), these two-forms and their commutator belong to a hyperplane; consequently R_9 cannot be generated by a pair of two-forms.

For algebras R_{10}, R_{11}, and R_{13} it is verified that

$$\pi([F,G])=(\mathrm{tr}\ \mathscr{D}(\pi(F),\pi(G)))^{\perp}.$$

This follows directly from the theorem of Ref. 19 and 7. Then, with the aid of Table II and relations (5), the relative position of the plane of inner directions of F and G that generate algebras R_{10}, R_{11}, and R_{13} may be obtained without difficulty. The result is given by the following lemma:

Lemma 9: The algebra $\mathscr{A}(F,G)$ generated by the two-forms F and G is never R_9 and it is R_{10}, R_{11} or *R_{13} if, and only if, F and G are simple and the relative position of the planes of inner directions is $\Pi_{3,r}$ with $r\in\{1,2,3,4,5,6,7,8,10\}$, $r\in\{9,11\}$, or $r\in\{12,13\}$, respectively.*

For R_{12} we have the result of part (i) of Lemma 6:

Lemma 10: Let F and G be two-forms with geometries $\{U,*U\}$ and $\{V,*V\}$, respectively. Then, $\mathscr{A}(F,G)$ is a R_{12} if, and only if, F and G are such that at least one is not simple and the relative position of $(\pi(U),\pi(V))$ is $\Pi_{2,2}$ or is $\Pi_{2,1}$ and their weights' ratio coincide.

Here R_{14} and R_{15} are the only algebras of dimension 4 and 6, respectively, so we only have to use Table II and (5) to express the conditions of Theorem 2 in terms of the relative position of the geometry. Then, taking into account Lemmas 8–10, we have the following theorem:

Theorem 3: *Let F and G be nonproportional two-forms and $\pi(U)$ and $\pi(V)$ the nonspacelike planes of its geometries. The algebra $\mathscr{A}(F,G)$ generated by F and G is*

(i) *never R_9,*

(ii) *R_7 or R_8 if the relative position of $(\pi(U),\pi(V))$ is $\Pi_{1,1}$ or $\Pi_{2,r}$ with $r\in\{1,2\}$,*

(iii) *R_6, R_{10}, R_{11}, R_{13}, R_{14},* or *R_{15}, if F and G are simple and the relative position of $(\pi(F),\pi(G))$ is $\Pi_{2,\cdot}$ for R_6, $\Pi_{3,r}$ with $r\in\{1,2,3,4,5,6,7,8,10\}$ for R_{10}, $\Pi_{3,r}$ with $r\in\{9,11\}$ for R_{11}, $\Pi_{3,r}$ with $r\in\{12,13\}$ for R_{13}, Π_4 for R_{14}, or $\Pi_{6,\cdot}$ for R_{15}, and*

(iv) *R_{12} or R_{15} if F and G are not both simple and the relative position of the planes $(\pi(U),\pi(V))$ is $\Pi_{2,2}$ for R_{12} or $\Pi_{3,r}$, $r\in\{1,2,3,4,7\}$, or $\Pi_{6,r'}$, $r'\in\{1,2,3,4,8,9\}$ for R_{15}. R_{12}, or R_{14} if they are not both simple, the relative position of the planes $(\pi(U),\pi(V))$ is $\Pi_{2,1}$ and their weights' ratios, respectively, coincide or differ.*

F. San José Martínez has been partially supported by Universisdad Complutense PR 180/91-3547 and DGICYT PB 92-0220.

[1] For a surface, this plane is the tangent one at the point, which, depending on its physical materialization, may have any causal orientation. For the rod or the string, the plane at every point is the one determined by the orientation of the object and its space–time velocity. For the point mass with spin, the appropriate plane is that defined by the spin two-form [see Ref. 16 or, for example, J. Ibañez, J. Martin, and E. Ruiz, Gen. Rel. Grav. **16**(3), 225 (1984) and references therein]. For the photon, it is the lightlike plane determined by the polarization and its null direction of propagation.

[2] In Landau and Lifchitz's as well as in Eckart's schemes; in both cases the plane is that defined by the velocity and the heat flow vectors. Such fluids may be of interest in the study of inhomogeneous universes; see, for example, J. Triginer and D. Pavón, Class. Quant. Grav. **12**, 689 (1995).

[3] The anisotropic fluids concerned here are those that, like in spherical symmetry, admit an isotropic two-surface, the plane in question being then that containing the fluid velocity and the anisotropic direction.

[4] That is, cosmologies in which the velocity of the cosmological (usually perfect) fluid does not coincide with that of the observers at rest with respect to the *instants* (spacelike hypersurfaces) of symmetry.

[5] In (perfect) relativistic magnetohydrodynamics, the plane is that determined by the velocity of the fluid and the magnetic field. For the subject, see, for example, B. Coll, Ann. Inst. Henri Poincaré **25**(4), 363 (1976) and references therein.

[6] Some astrophysical and cosmological situations seem to correspond to the sum of two perfect fluids. See G. S. Hall and D. A. Negm, Int. J. Theo. Phys. 25(4), 405 (1986); J. J. Ferrando, J. A. Morales, and M. Portilla, Gen. Rel. Grav. **22**(9), 1021 (1990) and references therein. In this case the plane is necessarily the spacelike eigenplane of the energy tensor.

[7] An electromagnetic field is described by a two-form (see Ref. 11), and it is well known [G. Y. Rainich, Trans. Am. Math. Soc. **27**, 106 (1925)] that a regular (resp. null) two-form in space–time is strictly equivalent to a $2+2$ weighted (resp. degenerated) local almost product structure, which may always be determined by its nonspacelike field of planes.

[8] Of particular importance is that of fluids (or magnetofluids) in the presence of pure radiative electromagnetic fields (relativistic cosmology), that of regular fields with radiation or that of two beam pure radiative interferences (relativistic optics) or that of the interaction of two spinning particles (relativistic mechanics and astronomy).

[9] Consider a system of two interacting point particles in Newtonian gravity, and let us associate to every one of them the plane containing its velocity and the relative position vector. In this case there are only two relative positions for the planes: they coincide or they cut each other. The statement that every one of these relative positions is *permanent* is equivalent to that of the *conservation* of the direction of the angular momentum. In some other more complicated relativistic systems for which we do not know first integrals, the analysis of the evolution of each of the possible relative positions of associate planes, easier to do in general, may help us to find some of these integrals.

[10] The classical Helmholtz vorticity [H. Helmholtz, Crelle's J. **55**, 25 (1858)], was extended to relativity by Synge [J. L. Synge, Proc. Lond. Math. Soc. **43**, 376 (1937)], and appears at present in all the studies involving relativistic fluids.

[11] Minkowski was the first to show that the electric and magnetic fields are in fact the components of a second-order skew-symmetric form (Nach. der K. Gessellschaft der Wissenschaften zu Göttingen Math. Phys. Klas. 53–111 (1908).

[12] Lorentz transformations in the exponential domain may be expressed in terms of the corresponding Lie algebra element, which is represented in Minkowski space by a constant antisymmetric form. In many problems in relativity, mainly those related to adapt *observers* (timelike directions) or *reference systems* (tetrads) to particular data, *local* Lorentz transformations (point dependent) are needed; they are then defined by an (exterior) two-form.

[13] These forms (antidual eigenforms of the Riemann tensor, or their real part), omnipresent in complex formalisms of general relativity, seem to have been first considered by Pirani in his analysis of the three Petrov types [F. A. E. Pirani, Phys. Rev. **105** (3), 1089 (1957)] and by Bel in his completion to five of those three types [Ll. Bel, Cahiers Phys. **138**, 59 (1962)].

[14] The Killing–Yano two-forms are potentiallike generators of some second-order Killing tensors (see for instance, Ref. 29). They are of importance in questions related to the symmetries of the space–time and in the problem of separation of variables of the Laplacian or the geodesic equations [see, for instance, S. Benenti, ''L'intégration de l'équation d'Hamilton-Jacobi par séparation des variables: histoire et résultats récents,'' in *La ''Mécanique analytique'' de Lagrange et son héritage* (Acta Acad. Scient. Taurinensis, Torino, 1990), pp. 119–144, and references therein].

[15] That Hertz potentials for electromagnetic field [H. Hertz, Ann. Phys. Lpz. **36**, 1 (1889)] can be defined in any space–time (Debye particular Hertz potentials cannot) was shown in J. M. Cohen and L. S. Kegeles, Phys. Rev. D **10**(4), 1070 (1974).

[16] The introduction in relativity of the spin two-form was due to J. Frenkel [Zeit. Phys. **37**, 243 (1926)], the equations of motions for spinning particles in a gravitational field were due to A. Papapetrou, [Proc. R. Soc. Lond., A **209**, 248 (1951)], and the interaction of two such particles was studied by Ibañez, Martin, and Ruiz (see reference in Ref. 1).

[17] By the same method indicated in Ref. 9.

[18] See comments on this subject in Ref. 19.

[19] B. Coll and F. San José, J. Math. Phys. **38**, 4350 (1995).

[20] For example, those given rise to effects of the *Thomas precession* type [cf. L. M. Thomas, Nature **117** (2945), 514 (April, 1926)].

[21] Let $L \equiv \exp F$ and $M \equiv \exp G$ be two (field of) Lorentz transformations generated by the two-forms F and G, respec-

tively. The product transformation $N \equiv LM$ is of the form $N \equiv \exp H$ where $H \equiv F \bullet G$ is given by the so-called BCH formula. See Ref. 19 for references.

[22] Subscripts denote dimension of a component of each diagonal and superscripts the causal character of the elements of the principal diagonal if they are not zero and of the second one otherwise.

[23] In local coordinates one has $(*F)_{\alpha\beta} \equiv (1/2)\,\eta_{\alpha\beta\gamma\delta} F^{\gamma\delta}$ and $(FG)_{\alpha\beta} \equiv F_{\alpha\rho} G^{\rho}_{\beta}$, where $\eta_{\alpha\beta\gamma\delta}$ is the volume element induced by the Minkowski metric g.

[24] It is well known that the Lorentz group has no subgroup of dimension 5; see, for instance, Ref. 25.

(Received 2 January 1996; accepted for publication 23 February 1996)

We study functional determinants for Dirac operators on manifolds with boundary. We give, for local boundary conditions, an explicit formula relating these determinants to the corresponding Green's functions. We finally apply this result to the case of a bidimensional disk under baglike conditions. © *1996 American Institute of Physics.* [S0022-2488(96)00306-4]

I. INTRODUCTION

It is well known that functional determinants have wide application in quantum and statistical physics. Typically, one faces the necessity of defining a regularized determinant for elliptic differential operators. In this context, the Dirac first-order differential operator plays a central role.

Seeley's construction of complex powers of elliptic differential operators provides a powerful tool to regularize such determinants: the so-called ζ-function method.[1]

In the case of boundaryless manifolds, this construction has been largely studied and applied (see, for instance, Ref. 2 and references therein).

For manifolds with boundary, the study of complex powers was performed in Refs. 3 and 4 for the case of local boundary conditions, while for the case of nonlocal conditions, this task is still in progress (see, for example, Ref. 5).

In general, the regularized determinant turns out to be nonlocal and, so, it cannot be expressed in terms of just a finite number of Seeley's coefficients. However, such determinant can always be obtained from the Green's function in a finite number of steps involving these coefficients. For boundaryless manifolds this was proved in Ref. 6, while for a particular type of local boundary condition the procedure was introduced in Ref. 7.

The aim of this paper is to give the explicit relationship between determinants and the corresponding Green's functions of Dirac operators under general local elliptic boundary conditions.

Dirac operators defined on manifolds with boundaries have been the subject of a vast literature (see, for instance, Refs. 8 and 9 and references therein), mainly concerning anomalies and index theorems. However, in these papers, the emphasis was put on nonlocal boundary conditions of the type introduced in Ref. 10. We leave for a forthcoming publication the treatment of such conditions.

The outline of this paper is as follows:

In Sec. II we introduce some general definitions and conventions concerning elliptic boundary problems for Dirac operators.

In Sec. III we present a formula relating the determinant of the Dirac operator with its Green's function for the case of local boundary conditions.

In Sec. IV, an explicit computation of the determinant of a Dirac operator in a bidimensional disk with baglike boundary conditions is performed, making use of the results in Sec. III.

II. ELLIPTIC BOUNDARY PROBLEMS, COMPLEX POWERS, AND REGULARIZED DETERMINANTS

Throughout this paper we will be concerned with boundary value problems associated to first-order elliptic operators

$$D: C^{\infty}(M,E) \to C^{\infty}(M,F), \tag{1}$$

where M is a bounded closed domain in $\mathbf{R}^{\nu}$ with smooth boundary ∂M, and E and F are k-dimensional complex vector bundles over M.

In a collar neighborhood of ∂M in M, we will take coordinates $\underline{\underline{x}}=(x,t)$, with t the inward normal coordinate and x local coordinates for ∂M (that is, $t>0$ for points in $M\backslash\partial M$ and $t=0$ on ∂M), and conjugated variables $\underline{\underline{\xi}}=(\xi,\tau)$.

As stated in the Introduction, we will mainly consider the Euclidean Dirac operator. Let us recall that the free Euclidean Dirac operator $i\not{\partial}$ is defined as

$$i\not{\partial} = \sum_{\mu=0}^{\nu-1} i\gamma_{\mu} \frac{\partial}{\partial x_{\mu}}, \tag{2}$$

where the matrices γ_{μ} satisfy

$$\gamma_{\mu}\gamma_{\alpha} + \gamma_{\alpha}\gamma_{\mu} = 2\delta_{\mu\alpha}, \tag{3}$$

and that, given a gauge potential $A=\{A_{\mu},\ \mu=0,...,\nu-1\}$ on M, the coupled Dirac operator is defined as

$$D(A) = i\not{\partial} + \not{A}, \tag{4}$$

with $\not{A}=\Sigma_{\mu=0}^{\nu-1}\gamma_{\mu}A_{\mu}$.

One of the most suitable tools for studying boundary problems is the Calderón projector Q.[11,12] For the case we are interested in, D of order 1 as in (1), Q is a (not necessarily orthogonal) projection from $[L^2(\partial M, E_{/\partial M})]$ onto the subspace $\{(T\varphi/\varphi)\in\ker(D)\}$, being T: $C^{\infty}(M,E)\to C^{\infty}(\partial M, E_{/\partial M})$ the trace map.

As shown in Ref. 11, Q is a zeroth-order pseudodifferential operator and its principal symbol $q(x;\xi)$, which depends only on the principal symbol of D, $\sigma_1(D)=a_1(x,t;\xi,\tau)$, turns out to be the $k\times k$ matrix

$$q(x;\xi) = \frac{1}{2\pi i} \int_{\Gamma} (a_1^{-1}(x,0;0,1)a_1(x,0;\xi,0) - z)^{-1}\, dz, \tag{5}$$

where Γ is any simple closed contour oriented clockwise and enclosing all poles of the integrand in $\mathrm{Im}(z)<0$.

Here Q is not unique, since it can be constructed from any fundamental solution of D, but its principal symbol $q(x;\xi)$ is uniquely determined.[11]

According to Calderón[11] and Seeley,[12] elliptic boundary conditions can be defined in terms of $q(x;\xi)$.

Definition 1: Let us assume that the *rank* of $q(x;\xi)$ is a constant r (as is always the case for $\nu\geqslant 3$).[11]

A zeroth-order pseudodifferential operator B: $[L^2(\partial M,E_{/\partial M})]\to[L^2(\partial M,G)]$, with G an r-dimensional complex vector bundle over ∂M, gives rise to an *elliptic boundary condition* for a first-order operator D as in (1) if, $\forall\xi{:}|\xi|\geqslant 1$,

$$\operatorname{rank}(b(x;\xi)q(x;\xi))=\operatorname{rank}(q(x;\xi))=r, \tag{6}$$

where $b(x;\xi)$ coincides with the principal symbol of B for $|\xi|\geqslant 1$.

In this case we say that

$$D\varphi=\chi \ \text{ in } \ M, \quad BT\varphi=f \ \text{ on } \ \partial M, \tag{7}$$

is an *elliptic boundary problem*, and denote by D_B the closure of D acting on the sections $\varphi\in C^\infty(M,E)$ satisfying $B(T\varphi)=0$.

An elliptic boundary problem such as (7) has a solution $\varphi\in H^1(M,E)$ for any (χ,f) in a subspace of $L^2(M,E)\times H^{1/2}(\partial M,G)$ of finite codimension. Moreover, this solution is unique up to a finite-dimensional kernel.[11] In other words, the operator

$$(D,BT){:}H^1(M,E)\to L^2(M,E)\times H^{1/2}(\partial M,G) \tag{8}$$

is Fredholm.

When B is a local operator, Definition 1 yields the classical local elliptic boundary conditions, also called Lopatinsky–Shapiro conditions (see, for instance, Ref. 13).

For Euclidean Dirac operators on $\mathbf{R}^\nu$, $E_{/\partial M}=\partial M\times\mathbf{C}^k$, local boundary conditions arise when the action of B is given by the multiplication by a $k/2\times k$ matrix of functions defined on ∂M.

Owing to *topological obstructions*, chiral Dirac operators in even dimensions, $\mathscr{D}$, do not admit local elliptic boundary conditions (see, for example, Ref. 14). Nevertheless, it is easy to see from Definition 1 that local boundary conditions can be defined for the full, either free or coupled, Euclidean Dirac operator

$$D(A)=\begin{pmatrix} 0 & \mathscr{D}^\dagger \\ \mathscr{D} & 0 \end{pmatrix}$$

on M.

We now sketch Seeley's construction of the complex powers of the operator D under a local elliptic boundary condition B.[3,4,15]

Definition 2: The elliptic boundary problem (7) admits a cone of Agmon's directions if there is a cone Λ in the λ-complex plane such that

(1) $\forall\overline{x}\in M$, $\forall\overline{\xi}\neq 0$, Λ contains no eigenvalues of the matrix $\sigma_1(D)(\overline{x,\xi})$,
(2) $\forall\xi{:}|\xi|\geqslant 1$, $\operatorname{rank}(b(x;\xi)q(\lambda)(x;\xi))=\operatorname{rank}(q(\lambda)(x;\xi))$, $\forall\lambda\in\Lambda$,

where $q(\lambda)$ denotes the principal symbol of the Calderón projector $Q(\lambda)$ associated to $D-\lambda I$, with λ included in $\sigma_1(D-\lambda I)$ [i.e., considering λ of degree one in the expansion of $\sigma(D-\lambda I)$ in homogeneous functions].[3,15]

An expression for $q(\lambda)(x;\xi)$ is obtained from (5):

$$q(\lambda)(x;\xi)=\frac{1}{2\pi i}\int_\Gamma (a_1^{-1}(x,0;0,1;0)a_1(x,0;\xi,0;\lambda)-z)^{-1}\,dz, \tag{9}$$

where $a_1(x;t;\xi,\tau;\lambda)=\sigma_1(D-\lambda I)$, with λ considered of degree one as stated above.

Henceforth, we assume the existence of an Agmon's cone Λ. Moreover, we will consider only boundary conditions B giving rise to a discrete spectrum $\operatorname{sp}(D_B)$. Note that this is always the case

for elliptic boundary problems unless $\mathrm{sp}(D_B)$ is the whole complex plane (see, for instance, Ref. 13). Now, for $|\lambda|$ large enough, $\mathrm{sp}(D_B)\cap\Lambda$ is empty, since there is no λ in $\mathrm{sp}(\sigma_1(D_B))\cap\Lambda$. Then, $\mathrm{sp}(D_B)\cap\Lambda$ is a finite set.

The usual definition of elliptic boundary conditions through ordinary differential equations in the normal variable can be recovered from Defn. 1 by introducing the ''partial symbol'' at the boundary:[3] Let us write

$$\sigma(D-\lambda I)=a_0(x,t;\xi,\tau;\lambda)+a_1(x,t;\xi,\tau;\lambda), \tag{10}$$

with a_l homogeneous of degree l in $(\overline{\xi,\lambda})$. We replace the coefficients of D by their Taylor expansions in powers of t, and group the resulting terms according to their degree of homogeneity in $(1/t,\xi,-i\partial_t,\lambda)$. More precisely, we set

$$a^{(j)}=a^{(j)}(x,t,\xi,-i\partial_t,\lambda)=\sum_{l-k=j}\frac{t^k}{k!}\,a_l^k(x,0,\xi,-i\partial_t,\lambda), \tag{11}$$

with $a_l^k=\partial_t^k a_l$.

Let us denote $\sigma'(D-\lambda I)=\Sigma_j a^{(j)}$ the partial symbol of $D-\lambda I$ at the boundary.

Now, condition (2) is equivalent to the following:

(2′) $\forall\lambda\in\Lambda$, $\forall x\in\partial M$, $\forall g\in\mathbf{C}^r$, the initial value problem

$$\sigma_1'(D)(x;\xi)u(t)=\lambda u(t),$$

$$b(x;\xi)u(t)\big|_{t=0}=g,$$

has, for each $\xi\neq 0$, a unique solution satisfying $\lim_{t\to\infty}u(t)=0$. This is the form under which this condition is stated in Ref. 3.

For $\lambda\in\Lambda$ not in $\mathrm{sp}(D_B)$, an asymptotic expansion of the symbol of $R(\lambda)=(D_B-\lambda I)^{-1}$ can be explicitly given:[3]

$$\sigma(R(\lambda))\sim\sum_{j=0}^{\infty}c_{-1-j}-\sum_{j=0}^{\infty}d_{-1-j}, \tag{12}$$

where the *Seeley coefficients* c_{-1-j} and d_{-1-j} satisfy

$$\sum_{j=0}^{1}a_{1-j}\circ\sum_{j=0}^{\infty}c_{-1-j}=I \tag{13}$$

with a_{1-j} as in (10), $\circ$ denoting the usual composition of homogeneous symbols, and

$$\sigma'(D-\lambda)\circ\sum_{j=0}^{\infty}d_{-1-j}=0,$$

$$\sigma'(B)\circ\sum_{j=0}^{\infty}d_{-1-j}=\sigma(B)\circ\sum_{j=0}^{\infty}c_{-1-j}\quad\text{at}\quad t=0, \tag{14}$$

$$\lim_{t\to\infty}d_{-1-j}=0.$$

Note that condition (2′) implies the existence and unicity of the solution of (14).

The coefficients $c_{-1-j}(x,t;\xi,\tau;\lambda)$ and $d_{-1-j}(x,t;\xi,\tau;\lambda)$ are meromorphic functions of λ with poles at those points where $\det[\sigma_1(D-\lambda)(x,t;\xi,\tau)]$ vanishes. The c_{-1-j}s are homogeneous of degree $-1-j$ in (ξ,τ,λ); the d_{-1-j}s are also homogeneous of degree $-1-j$, but in $(1/t,\xi,\tau,\lambda)$.[3]

This gives an approximation to $(D_B-\lambda)^{-1}$, a parametrix constructed as[3]

$$P_K(\lambda)=\sum_{\varphi}\ \psi\left[\sum_{j=0}^{K} Op(\theta_2 c_{-1-j})-\sum_{j=0}^{K} Op'(\theta_1 d_{-1-j})\right]\varphi, \tag{15}$$

where φ is a partition of the unity, $\psi\equiv 1$ in $\mathrm{Supp}(\varphi)$,

$$\begin{aligned}\theta_2(\xi,\tau,\lambda)&=\chi(|\xi|^2+|\tau|^2+|\lambda|^2),\\ \theta_1(\xi,\lambda)&=\chi(|\xi|^2+|\lambda|^2),\end{aligned} \tag{16}$$

with

$$\chi(t)=\begin{cases}0, & t\leqslant\frac{1}{2},\\ 1, & t\geqslant 1,\end{cases} \tag{17}$$

and

$$\begin{aligned}Op(\sigma)h(x,t)&=\int \sigma(x,t;\xi,\tau)\hat{h}(\xi,\tau)e^{i(x\xi+t\tau)}\,\frac{d\xi}{(2\pi)^{\nu-1}}\,\frac{d\tau}{2\pi},\\ Op'(\sigma)h(x,t)&=\int\int \tilde{\sigma}(x,t;\xi,s)\tilde{h}(\xi,s)e^{ix\xi}\,\frac{d\xi}{(2\pi)^{\nu-1}}\,\frac{ds}{2\pi},\end{aligned} \tag{18}$$

where $\hat{h}(\xi,\tau)$ is defined in (30) and

$$\tilde{h}(\xi,s)=\int h(x,s)e^{-ix\xi}\,dx. \tag{19}$$

Moreover, it can be proved from (12) that, for $\lambda\in\Lambda$,

$$\|R(\lambda)\|_{L^2}\leqslant C|\lambda|^{-1}, \tag{20}$$

with C a constant.[3,15]

The estimate (20) allows for expressing the complex powers of D_B as

$$D_B^z=\frac{i}{2\pi}\int_\Gamma \lambda^z R(\lambda)\,d\lambda \tag{21}$$

for $\mathrm{Re}\,z<0$, where Γ is a closed path lying in Λ, enclosing the spectrum of D_B.[4] Note that such a curve Γ always exists for $\mathrm{sp}(D_B)\cap\Lambda$ finite.

For $\mathrm{Re}\,z\geqslant 0$, one defines

$$D_B^z=D^l\circ D_B^{z-l}, \tag{22}$$

for l a positive integer such that $\mathrm{Re}(z-l)<0$.

If $\mathrm{Re}(z)<-\nu$, the power D_B^z is an integral operator with continuous kernel $J_z(x,t;y,s)$ and, consequently, it is trace class. As a function of z, $\mathrm{Tr}(D_B^z)$ can be extended to a meromorphic

function in the whole complex plane **C**, with only simple poles at $z=j-\nu$, $j=0,1,2,...$, and vanishing residues when $z=0,1,2,...$.[4] Throughout this paper, analytic functions and their meromorphic extensions will be given the same name.

The function $\mathrm{Tr}(D_B^z)$ is usually called $\zeta_{(D_B)}(-z)$ because of its similarity with the classical Riemann ζ-function: if $\{\lambda_j\}$ are the eigenvalues of D_B, $\{\lambda_j^z\}$ are the eigenvalues of D_B^z; so $\mathrm{Tr}(D_B^z)=\Sigma\lambda_j^z$ when D_B^z is a trace class operator.

A regularized determinant of D_B can then be defined as

$$\mathrm{Det}(D_B)=\exp\left[-\frac{d}{dz}\,\mathrm{Tr}(D_B^z)\right]\Bigg|_{z=0}. \tag{23}$$

Now, let $D(\alpha)$ be a family of elliptic differential operators on M sharing their principal symbol and analytically depending on α. Let B give rise to an elliptic boundary condition for all of them, in such a way that $D(\alpha)_B$ is invertible and the boundary problems they define have a common Agmon's cone. Then, the variation of $\mathrm{Det}\,D(\alpha)_B$ with respect to α is given by (see, for example, Refs. 10 and 16)

$$\frac{d}{d\alpha}\ln\mathrm{Det}\,D(\alpha)_B=\frac{d}{dz}\left[z\mathrm{Tr}\left\{\frac{d}{d\alpha}\,(D(\alpha)_B)D(\alpha)_B^{z-1}\right\}\right]\Bigg|_{z=0}. \tag{24}$$

Note that, under the assumptions made, $(d/d\alpha)(D(\alpha)_B)$ is a multiplication operator.

Given α_0 and α_1, the quotient $\mathrm{Det}(D(\alpha_1))_B/\mathrm{Det}(D(\alpha_0))_B$ can be obtained by integrating the variation in (24) along a path from α_0 to α_1.

Although $J_z(x,t;x,t;\alpha)$, the kernel of $D(\alpha)_B^z$ evaluated at the diagonal, can be extended to the whole z-complex plane as a meromorphic function, the rhs in (24) cannot be simply written as the integral over M of the finite part of

$$\mathrm{tr}\left\{\frac{d}{d\alpha}\,(D(\alpha)_B)J_{z-1}(x,t;x,t;\alpha)\right\} \tag{25}$$

at $z=0$ (where tr means matrix trace). In fact, $J_{z-1}(x,t;x,t;\alpha)$ is in general nonintegrable in the variable t near ∂M for $z\approx 0$.

Nevertheless, an integral expression for the rhs in (24) will be constructed in Sec. (III), from the integral expression for $\mathrm{Tr}(D(\alpha)_B^{z-1})$ holding in a neighborhood of $z=0$ and obtained in the following way:[4]

if $T>0$ is small enough, the function $j_z(x;\alpha)$, defined as

$$j_z(x;\alpha)=\int_0^T J_z(x,t;x,t;\alpha)\,dt \tag{26}$$

for $\mathrm{Re}\,z<1-\nu$, admits a meromorphic extension to **C** as a function of z. So, if V is a neighborhood of ∂M defined by $t<\epsilon$, with ϵ small enough, $\mathrm{Tr}(D(\alpha)_B^{z-1})$ can be written as the finite part of

$$\int_{M/V}\mathrm{tr}\;J_{z-1}(x,t;x,t;\alpha)dx\;dt+\int_{\partial M}\mathrm{tr}\;j_{z-1}(x;\alpha)dx, \tag{27}$$

where a suitable partition of the unity is understood.

III. GREEN'S FUNCTIONS AND DETERMINANTS

In this section, we will give an expression for $(d/d\alpha)\ln\mathrm{Det}[D(\alpha)_B]$ in terms of $G_B(x,t;y,s;\alpha)$, the Green's function of $D(\alpha)_B$ [i.e., the kernel of the operator $D(\alpha)_B^{-1}$].

With the notation of Sec. II, (24) can be rewritten as

$$\frac{d}{d\alpha}\ln \operatorname{Det} D(\alpha)_B = \operatorname*{F.P.}_{z=0}\int_M \operatorname{tr}\left[\frac{d}{d\alpha}(D(\alpha)_B)J_{-z-1}(x,t;x,t;\alpha)\right]d\overline{x}, \tag{28}$$

where the rhs must be understood as the finite part of the meromorphic extension of the integral at $z=0$.

The finite part of $J_{-z-1}(x,t;x,t;\alpha)$ at $z=0$ does not coincide with the regular part of $G_B(x,t;y,s;\alpha)$ at the diagonal, since the former is defined through an analytic extension.

However, it can be shown that there exists a relation between them, involving a finite number of Seeley's coefficients. In fact, for boundaryless manifolds this problem has been studied in Ref. 6, by comparing the iterated limits F.P. $\lim_{z\to -1}\{\lim_{\overline{y}\to\overline{x}} J_z(x,t;y,s;\alpha)\}$ and R.P. $\lim_{\overline{y}\to\overline{x}}\{\lim_{z\to -1} J_x(x,t;y,s;\alpha)\}=$R.P. $\lim_{\overline{y}\to\overline{x}} G_B(x,t;y,s;\alpha)$.

In the case of manifolds with boundary, the situation is more involved owing to the fact that the finite part of the extension of $J_z(x,t;x,t;\alpha)$ at $z=-1$ is not integrable near ∂M. (A first approach to this problem appears in Ref. 7). Nevertheless, as mentioned in Sec. II, a meromorphic extension of $\int_0^T J_z(x,t;x,t;\alpha)dt$, with T small enough, can be performed and its finite part at $z=-1$ turns to be integrable in the tangential variables. A similar result holds, *a fortiori*, for $\int_0^T t^n J_z(x,t;x,t;\alpha)dt$, with $n=1,2,3...$. Then, near the boundary, the Taylor expansion of the function $A_\alpha=(d/d\alpha)D(\alpha)_B$ will naturally appear, and the limits to be compared are F.P. $\lim_{z\to -1}\{\lim_{\overline{y}\to\overline{x}}\int_0^T t^n J_z(x,t;y,s;\alpha)dt\}$ and R.P. $\lim_{\overline{y}\to\overline{x}}\{\lim_{z\to -1}\int_0^T t^n J_z(x,t;y,s;\alpha)dt\}$ $=$R.P. $\lim_{\overline{y}\to\overline{x}}\int_0^T t^n G_B(x,t;y,s;\alpha)dt$.

The starting point for this comparison is to carry out asymptotic expansions and to analyze the terms for which the iterated limits do not coincide (or do not even exist).

An expansion of $G_B(x,t,y,s)$ in $M\backslash\partial M$ in homogeneous and logarithmic functions of $(\overline{x}-\overline{y})$ can be obtained from (12) for $\lambda=0$:

$$G_B(x,t,y,s)=\sum_{j=1-\nu}^{0} h_j(x,t,x-y,t-s)+M(x,t)\log|(x,t)-(y,s)|+R(x,t,y,s), \tag{29}$$

with h_j the Fourier transform $\mathscr{F}^{-1}(c_{-\nu-j})$ of $c_{-\nu-j}$ for $j>0$ and $h_0=\mathscr{F}^{-1}(c_{-\nu})-M(x,t)\log|(x,t)-(y,s)|$. The function $M(x,t)$ will be explicitly defined below [see (35)]. Our convention for the Fourier transform is

$$\begin{aligned}\mathscr{F}(f\,)(\overline{\xi})&=\hat{f}(\overline{\xi})=\int f(\overline{x})e^{-i\overline{x}\cdot\overline{\xi}}\,d\overline{x},\\ \mathscr{F}^{-1}(\hat{f}\,)(\overline{x})&=f(\overline{x})=\frac{1}{(2\pi)^\nu}\int \hat{f}(\overline{\xi})e^{i\overline{x}\cdot\overline{\xi}}\,d\overline{\xi}.\end{aligned} \tag{30}$$

For $t>0$, $R(x,t,y,s)$ is continuous even at the diagonal $(y,s)=(x,t)$. Nevertheless, $R(x,t,y,s)|_{(y,s)=(x,t)}$ is not integrable because of its singularities at $t=0$. On the other hand, the functions $t^n R(x,t,y,t)$ are integrable with respect to the variable t for $y\neq x$ and $n=0,1,2,...$. An expansion of $\int_0^\infty t^n R(x,t,y,t)dt$ in homogeneous and logarithmic functions of $(x-y)$ can also be obtained from (12):

$$\int_0^\infty t^n R(x,t,y,t)dt=\sum_{j=n+2-\nu}^{0} g_{j,j+n+2-\nu}(x,x-y)+M_n(x)\log(|x-y|)+R_n(x,y), \tag{31}$$

where $R_n(x,y)$ is continuous even at $y=x$, and $g_{j,j+n+2-\nu}$ is the Fourier transform of the (homogeneous extension of) $\int_0^\infty t^n \widetilde{d}_{-1-j}(x,t,\xi,t,0)dt$, with

$$\tilde{d}_{-1-j}(x,t,\xi,s,\lambda)=-\int_{\Gamma^-} e^{-is\tau}\, d_{-1-j}(x,t,\xi,\tau,\lambda)\,d\tau \tag{32}$$

for Γ^- a closed path enclosing the poles of $d_{-1-j}(x,t,\xi,\tau,\lambda)$ lying in $\{\mathrm{Im}\,\tau>0\}$.

Since $\tilde{d}_{-1-j}$ is homogeneous of degree $-j$ in $(1/t,\xi,1/s,\lambda)$, $g_{j,j+n+2-\nu}$ turns out to be homogeneous of degree $j+n+2-\nu$ in $x-y$.

From the forementioned comparison, the following Theorem can be shown to hold (the proof will be given in Ref. 17):

Theorem 1: *Let M be a bounded closed domain in $\mathbf{R}^\nu$ with smooth boundary ∂M and E a k-dimensional complex vector bundle over M.*

Let $(D_\alpha)_B$ *be a family of elliptic differential operators of first order, acting on the sections of E, with a fixed local boundary condition B on ∂M, and denote by $J_z(x,t;x,t;\alpha)$ the meromorphic extension of the evaluation at the diagonal of the kernel of $(D_\alpha)_B^z$.*

Let us assume that, for each α, $(D_\alpha)_B$ is invertible, the family is differentiable with respect to α, and $\partial/\partial\alpha(D_\alpha)_B f = A_\alpha f$, with A_α a differentiable function.

If V is a neighborhood of ∂M defined by $t<\epsilon$ and $T>0$ small enough, then

(a)

$$\frac{\partial}{\partial\alpha}\ln\mathrm{Det}(D_\alpha)_B=\operatorname*{F.P.}_{z=-1}\left[\int_{\partial M}\int_0^T \mathrm{tr}\{A_\alpha(x,t)J_z(x,t;x,t;\alpha)\}dt\,dx\right]$$
$$+\operatorname*{F.P.}_{z=-1}\left[\int_{M/V}\mathrm{tr}\{A_\alpha(\overline{x})J_z(\overline{x;x;\alpha})\}d\overline{x}\right], \tag{33}$$

where a suitable partition of the unity is understood. (This expression must be understood as the finite part at $z=-1$ of the meromorphic extension.)

(b) For every α, the integral $\int_0^T A_\alpha(x,t)J_z(x,t;x,t;\alpha)dt$ is a meromorphic function of z, for each $x\in\partial M$, with a simple pole at $z=-1$. Its finite part (dropping, from now on, the index α for the sake of simplicity) is given by

$$\operatorname*{F.P.}_{z=-1}\int_0^T A(x,t)J_z(x,t;x,t)dt=-\int_0^T A(x,t)\int_{|(\xi,\tau)|=1}\frac{i}{2\pi}\int_\Gamma\frac{\ln\lambda}{\lambda}\,c_{-\nu}(x,t;\xi,\tau;\lambda)d\lambda\,\frac{d\sigma_{\xi,\tau}}{(2\pi)^\nu}\,dt$$
$$+\sum_{l=0}^{\nu-2}\frac{\partial_t^l A(x,0)}{l!}\int_{|\xi|=1}\int_0^\infty t^l\,\frac{i}{2\pi}$$
$$\times\int_\Gamma\frac{\ln\lambda}{\lambda}\,\tilde{d}_{-(\nu-1)+l}(x,t;\xi,t;\lambda)d\lambda\,dt\,\frac{d\sigma_\xi}{(2\pi)^{\nu-1}}+\lim_{y\to x}\left\{\int_0^T A(x,t)\right.$$
$$\times\left[G_B(x,t;y,t)-\sum_{l=1-\nu}^{0}h_l(x,t;x-y,0)-M(x,t)\,\frac{\Omega_\nu}{(2\pi)^\nu}\,(\ln|x\right.$$
$$\left.-y|^{-1}+\mathscr{K}_\nu)\right]dt+\sum_{j=0}^{\nu-2}\sum_{l=0}^{\nu-2-j}\frac{\partial_t^l A(x,0)}{l!}\,g_{j,l-(\nu-2-j)}(x,x-y)$$
$$\left.+\sum_{l=0}^{\nu-2}\frac{\partial_t^l A(x,0)}{l!}\,M_{\nu-2-l}(x)\,\frac{\Omega_{\nu-1}}{(2\pi)^{\nu-1}}\,(\ln|x-y|^{-1}+\mathscr{K}_{\nu-1})\right\}, \tag{34}$$

with

$$M(x,t)=\frac{1}{\Omega_\nu}\int_{|(\xi,\tau)|=1} c_{-\nu}(x,t;\xi,\tau;0)\,d\sigma_{\xi,\tau},$$
$$M_j(x)=\frac{1}{\Omega_{\nu-1}}\int_{|\xi|=1}\int_0^\infty t^{\nu-2-j}\tilde{d}_{-1-j}(x,t;\xi,t;0)\,dt\;d\sigma_\xi, \tag{35}$$

where $\Omega_n=\mathrm{Area}(S^{n-1})$, $\mathscr{K}_\nu=\ln 2-\frac{1}{2}\gamma+\frac{1}{2}\Gamma'(\nu/2)/\Gamma(\nu/2)$ *with* γ *the Euler's constant and where* h_l *and* g_l *are related to the Green's function* G_B *as in (29) and (31),*

$$h_{1-\nu+j}(x,t;w,u)=\mathscr{F}^{-1}_{(\xi,\tau)}[c_{-1-j}(x,t;(\xi,\tau)/|(\xi,\tau)|;0)|(\xi,\tau)|^{-1-j}](w,u),$$
$$h_0(x,t;w,u)=\mathscr{F}^{-1}_{(\xi,\tau)}[\mathrm{P.V.}\{(c_{-\nu}(x,t;(\xi,\tau)/|(\xi,\tau)|;0)-M(x,t))|(\xi,\tau)|^{-\nu}\}](w,u),$$
$$g_{j,l}(x,w)=\mathscr{F}^{-1}_{\xi}\left[\int_0^\infty t^n\tilde{d}_{-1-j}(x,t;\xi/|\xi|,t;0)\,dt\,|\xi|^{-1-j-n}\right](w),$$

with

$$l=j+n-\nu+2,$$

and

$$g_{j,0}(x,w)=\mathscr{F}^{-1}_{\xi}\left[\mathrm{P.V.}\left[\int_0^\infty t^{\nu-j-2}\tilde{d}_{-1-j}(x,t;\xi/|\xi|,t;0)\,dt-M_j(x)\right]|\xi|^{-(\nu-1)}\right](w). \tag{36}$$

(c) The integral $\int_{M\setminus V}\mathrm{tr}[A(\overline{x})J_z(\overline{x;x})]d\overline{x}$ in the second term on the rhs of (33) is a meromorphic function of z with a simple pole at $z=-1$. Its finite part is given by

$$\begin{aligned}\underset{z=-1}{\mathrm{F.P.}}\int_{M\setminus V}\mathrm{tr}[A(\overline{x})J_z(\overline{x;x})]d\overline{x}=&\int_{M\setminus V}A(\overline{x})\int_{|\overline{\xi}|=1}\frac{i}{2\pi}\int\frac{\ln\lambda}{\lambda}\,c_{-\nu}(\overline{x,\xi};\lambda)d\lambda\,\frac{d\overline{\xi}}{(2\pi)^\nu}\\&+\int_{M\setminus V}\lim_{y\to\overline{x}}A(\overline{x})\Bigg[G_B(\overline{x,y})-\sum_{l=1-\nu}^{0}h_l(\overline{x,x-y})\\&-M(\overline{x})\frac{\Omega_\nu}{(2\pi)^\nu}(\ln|\overline{x-y}|^{-1}+\mathscr{K}_\nu)\Bigg]d\overline{x}.\end{aligned} \tag{37}$$

This Theorem gives a closed expression for the evaluation of the determinant when the associated Green's function is known.

Awful as it looks, (34) is not so complicated: In the first place, all terms can be systematically evaluated. Moreover, the terms containing h_l subtract the singular part of the Green's function in the interior of the manifold [see (29)] and can thus be easily identified from the knowledge of G_B. $R(x,t,y,t)$, the regular part so obtained, is still nonintegrable near the boundary. Those terms containing $g_{j,l}$ subtract the singular part of the integrals $\int_0^T t^n R(x,t,y,t)\,dt$ [see (31)]. Finally, the terms containing $c_{-\nu}$ and $d_{-\nu+1}$ arise as a consequence of having replaced an analytic regularization by a *point splitting* one.

Even though Seeley's coefficients c and $\tilde{d}$ are to be obtained through an iterative procedure, which can make their evaluation a tedious task, in the cases of physical interest only the few first of them are needed. In fact, for the two-dimensional example in Sec. IV we will only need two such coefficients.

IV. TWO-DIMENSIONAL DIRAC OPERATOR ON A DISK

In this section, we will use the method previously discussed to evaluate the determinant of the operator $D=i\not{\partial}+\not{A}$ acting on functions defined on a two-dimensional disk of radius R. A family of local baglike[18] elliptic boundary conditions will be assumed.

We take A_μ to be an Abelian field in the Lorentz gauge; as it is well known, it can be written as $A_\mu=\epsilon_{\mu\nu}\partial_\nu\phi$ ($\epsilon_{01}=-\epsilon_{10}=1$). For ϕ we choose a smooth bounded function $\phi=\phi(r)$. Notice that, with these assumptions, $A_r=0$ and $A_\theta(r)=-\partial_r\phi(r)$. We call

$$\Phi=\oint_{r=R} A_\theta R\, d\theta=-2\pi R\partial_r\phi(r)\big|_{r=R}. \tag{38}$$

The free Dirac operator in polar coordinates is

$$i\not{\partial}=i\left(\gamma_r\partial_r+\frac{1}{r}\,\gamma_\theta\partial_\theta\right), \tag{39}$$

with

$$\gamma_r=\begin{pmatrix}0 & e^{-i\theta}\\ e^{i\theta} & 0\end{pmatrix},\quad \gamma_\theta=\begin{pmatrix}0 & -ie^{-i\theta}\\ ie^{i\theta} & 0\end{pmatrix}. \tag{40}$$

With these conventions, the full Dirac operator can be written as

$$D=e^{-\gamma_5\phi(r)}i\not{\partial}e^{-\gamma_5\phi(r)}. \tag{41}$$

Now, in order to perform our calculations, we consider the family of operators

$$D_\alpha=i\not{\partial}+\alpha\not{A}=e^{-\alpha\gamma_5\phi(r)}i\not{\partial}e^{-\alpha\gamma_5\phi(r)},\quad \text{with } 0\leqslant\alpha\leqslant 1, \tag{42}$$

which will allow us to go smoothly from the free to the full Dirac operator. If we call

$$W(\alpha)=\ln\,\mathrm{Det}(D_\alpha)_B, \tag{43}$$

where B represents the elliptic boundary condition, we have

$$\frac{\partial}{\partial\alpha}\,W(\alpha)=\mathrm{F.P.}_{z=0}[\mathrm{Tr}(\not{A}(D_\alpha)_B^{-z-1})]. \tag{44}$$

From the Theorem in Sec. III we obtain

$$\frac{\partial}{\partial\alpha}W(\alpha)=\frac{1}{(2\pi)^2}\,\mathrm{tr}\Bigg\{\int\lim_{y\to x}\Bigg[\int\Bigg[\not{A}(t)\Bigg(4\pi^2G_B(x,t,y,t)-\frac{1}{|x-y|}\int e^{i\xi(x-y)/|x-y|}c_{-1}$$
$$\times\Bigg(x,t;\frac{(\xi,\tau)}{|(\xi,\tau)|};0\Bigg)d\xi\,d\tau-\int_{|(\xi,\tau)|\geqslant 1}e^{i\xi(x-y)}c_{-2}(x,t;\xi,\tau;0)d\xi\,d\tau$$
$$-\int\frac{i}{2\pi}\int_\Gamma\frac{\ln\lambda}{\lambda}\,c_{-2}$$
$$\times\Bigg(x,t;\frac{(\xi,\tau)}{|(\xi,\tau)|};\lambda\Bigg)d\lambda\,d\sigma_{\xi,\tau}\Bigg)+\not{A}(0)\Bigg(\int_{|\xi|\geqslant 1}e^{i\xi(x-y)}\tilde{d}_{-1}(x,t;\xi,t;0)d\xi$$
$$+\int\frac{i}{2\pi}\int_\Gamma\frac{\ln\lambda}{\lambda}\,\tilde{d}_{-1}$$
$$\times\Bigg(x,t;\frac{\xi}{|\xi|},t;\lambda\Bigg)d\lambda\,d\sigma_\xi\Bigg)\Bigg]dt\Bigg]dx\Bigg\},\tag{45}$$

where the Fourier transforms of c_{-2} and $\tilde{d}_{-1}$ have been left explicitly indicated.

Now, the coefficients c and $\tilde{d}$ in the previous equation are those appearing in the asymptotic expansion of the resolvent $(D_\alpha-\lambda I)^{-1}$.

From (41), the symbol of $(D_\alpha-\lambda I)$ is

$$\sigma(D_\alpha-\lambda I)=(-\not{\xi}-\lambda I)+\alpha\not{A}=a_1(\theta,t,\xi,\tau,\lambda)+a_0(\theta,t,\xi,\tau,\lambda),\tag{46}$$

where

$$a_1=-\not{\xi}-\lambda I,\quad a_0=\alpha\not{A}.\tag{47}$$

The required Seeley's c-coefficients are given by[2]

$$c_{-1}=\frac{1}{(\lambda^2-\xi^2-\tau^2)}\,(\not{\xi}-\lambda I),$$
$$c_{-2}=\frac{\alpha}{(\lambda^2-\xi^2)^2}\,(2\lambda\xi_\mu A_\mu I-(\lambda^2-\xi^2)\not{A}-2\xi_\mu A_\mu\not{\xi}),\tag{48}$$

where $\not{\xi}=\xi\gamma_\theta+\tau\gamma_t$.

As regards the boundary contributors to the parametrix, i.e., the coefficients d_{-1-j}, they are the solutions of (14). In our case, the equation to be solved is

$$(-\lambda I-\xi\gamma_\theta+i\gamma_t\partial_t)d_{-1}=0,\tag{49}$$

with boundary conditions

$$b_0d_{-1}=b_0c_{-1}\quad\text{at } t=0,\tag{50}$$

plus the vanishing of d_{-1} as $t\to+\infty$. Equation (49) can be recast in the form

$$\partial_td_{-1}=-Md_{-1},\tag{51}$$

where $M=\xi\gamma_5+i\lambda\gamma_t$. It can be easily verified that

$$\mathrm{tr}(M)=0, \quad M^2=(\xi^2-\lambda^2)I. \tag{52}$$

So, M has eigenvalues $\pm\sqrt{\xi^2-\lambda^2}$, corresponding to the eigenvectors

$$u_{\pm}=\begin{pmatrix} ie^{-i\theta}(\xi\pm\sqrt{\xi^2-\lambda^2}) \\ \lambda \end{pmatrix}. \tag{53}$$

Since $d_{-1}\to 0$ for $t\to\infty$, we obtain

$$d_{-1}(x,t;\xi,\tau;\lambda)=e^{-t\sqrt{\xi^2-\lambda^2}}u_{+}\otimes\begin{pmatrix} f \\ g \end{pmatrix}^{\dagger}, \tag{54}$$

where the vector $\binom{f}{g}$ must be determined from the boundary condition at $t=0$ ($r=R$), given by (50).

We now consider a parametric family of baglike local boundary conditions leading to an elliptic boundary problem,

$$b_0=(1,we^{-i\theta}), \tag{55}$$

with w a nonzero complex constant. (Notice that these boundary conditions reduce to those of an MIT bag[18] when $w=\pm 1$.)

We define the operator $(D_\alpha)_B$ as the differential operator in (41), acting on the dense subspace of functions satisfying

$$B\psi\equiv b_0\psi|_{t=0}=0. \tag{56}$$

It is easy to verify that this operator has no normalizable zero modes. (Notice that these are not the most general local elliptic boundary conditions. In fact, zero modes would in general arise if one allowed w to depend on θ.)

Now, from (50) and the expression for c_{-1} given in (48), it turns out that

$$\begin{pmatrix} f \\ g \end{pmatrix}^{\dagger}=\frac{e^{i\theta}}{(\xi^2+\tau^2-\lambda^2)(\lambda w+i\xi+i\sqrt{\xi^2-\lambda^2})}\,(\lambda+w(-i\xi+\tau) \quad e^{-i\theta}(i\xi+\tau+\lambda w)). \tag{57}$$

Placing this expression into (54), and taking into account (32), we finally obtain

$$\begin{aligned}\tilde{d}_{-1}=&\pi i\,\frac{e^{-(u+t)\sqrt{\xi^2-\lambda^2}}}{\sqrt{\xi^2-\lambda^2}(iw\lambda-\xi-\sqrt{\xi^2-\lambda^2})}\\ &\times\begin{pmatrix} (\xi+\sqrt{\xi^2-\lambda^2})(i\lambda+w(\xi+\sqrt{\xi^2-\lambda^2})) & e^{-i\theta}(\xi+\sqrt{\xi^2-\lambda^2})(iw\lambda-\xi+\sqrt{\xi^2-\lambda^2}) \\ -i\lambda e^{i\theta}(i\lambda-w(\xi+\sqrt{\xi^2-\lambda^2})) & -i\lambda(iw\lambda-\xi+\sqrt{\xi^2-\lambda^2}) \end{pmatrix}.\end{aligned} \tag{58}$$

In order to apply (45), we look for the function $G_B(x,y)$ satisfying

$$D_\alpha G_B(x,y)=\delta(x,y), \quad BG_B(x,y)|_{x\in\partial\Omega}=0, \tag{59}$$

where D_α and B are given by Eqs. (41) and (56), respectively. Now, with the notation

$$\begin{aligned} x=(x_0,x_1)=(r\ \cos\ \theta, r\ \sin\ \theta), \quad X=x_0+ix_1=re^{i\theta}, \\ y=(y_0,y_1)=(\rho\ \cos\ \varphi,\rho\ \sin\ \varphi), \quad Y=y_0+iy_1=\rho e^{i\varphi}, \end{aligned} \tag{60}$$

it is easy to see that $G_B(x,y)$ is given by

$$G_B(x,y)=\frac{1}{2\pi i}\begin{pmatrix} \dfrac{Rwe^{\alpha(\phi(x)+\phi(y)-2\phi(R))}}{XY^*-R^2} & \dfrac{e^{\alpha(\phi(x)-\phi(y))}}{X-Y} \\ \dfrac{e^{-\alpha(\phi(x)-\phi(y))}}{(X-Y)^*} & \dfrac{Re^{-\alpha(\phi(x)+\phi(y)-2\phi(R))}}{w(XY^*-R^2)^*} \end{pmatrix}. \tag{61}$$

With these elements at hand, we now perform the calculation of the determinant.

From (61), one can see that

$$G_B(\theta,r,\varphi,r)\underset{\varphi\to\theta}{\sim}\ \text{diagonal matrix}+\frac{1}{2\pi ir(\theta-\varphi)}\,\gamma_\theta. \tag{62}$$

When placed into (45), we obtain for the first term on the rhs

$$\mathrm{tr}\{A_\theta\gamma_\theta G_B(\theta,r,\varphi,r)\}\underset{\varphi\to\theta}{\sim}\frac{A_\theta}{\pi ir(\theta-\varphi)}. \tag{63}$$

For the second term in (45)

$$-\frac{1}{4\pi^2|x-y|}\int d\xi\,d\tau\,e^{i\xi(x-y)/|x-y|}c_{-1}\left(x,t;\frac{(\xi,\tau)}{|(\xi,\tau)|};\lambda=0\right)\underset{\varphi\to\theta}{\sim}\frac{-1}{2\pi ir(\theta-\varphi)}\,\gamma_\theta, \tag{64}$$

which exactly cancels the singularity of the Green's function. Therefore, the contribution of the first two terms in (45) vanishes.

As regards the third term,

$$\begin{aligned}
&\frac{-1}{(2\pi)^2}\,\mathrm{tr}\int \lim_{y\to x}\mathcal{A}(t)\int_{|(\xi,\tau)|\geqslant 1}e^{i\xi(x-y)}c_{-2}(x,t;\xi,\tau;0)\,d\xi\,d\tau\,dx\,dt\\
&\quad=\frac{-\alpha}{2\pi^2}\lim_{y\to x}\int A_\theta^2 d^2x\int_{|(\xi,\tau)|\geqslant 1}e^{i\xi(x-y)}\,\frac{(\tau^2-\xi^2)}{(\xi^2+\tau^2)^2}\,d\xi\,d\tau\\
&\quad=-\frac{\alpha}{\pi}\int A_\theta^2 d^2x\,\lim_{y\to x}\int_{|x-y|}^{\infty}J_2(u)\,\frac{du}{u}\\
&\quad=\frac{-\alpha}{2\pi}\int A_\nu A_\nu\,d^2x.
\end{aligned} \tag{65}$$

where $J_2(u)$ is the Bessel function of order two.

Now, the fourth term in (45) is

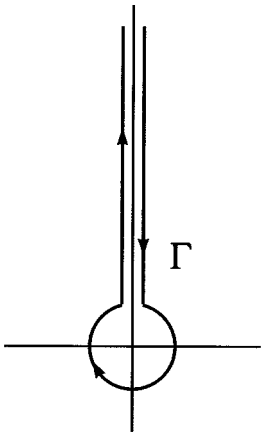

FIG. 1. The Contour Γ.

$$\frac{-1}{(2\pi)^2}\,\mathrm{tr}\int \mathcal{A}(t)\int\ \frac{i}{2\pi}\int_\Gamma \ln\lambda\, c_{-2}\left(x,t;\frac{(\xi,\tau)}{|(\xi,\tau)|};\lambda\right)\frac{d\lambda}{\lambda}\,d\sigma_{\xi,\tau}\,dx\,dt$$
$$=\frac{-i\alpha}{4\pi^3}\int A_\theta^2\,d^2x\int_\Gamma\frac{\ln\lambda}{(\lambda^2-1)^2}\int(1-\lambda^2-2\xi^2)d\sigma_{\xi,\tau}\,\frac{d\lambda}{\lambda}$$
$$=\frac{i\alpha}{2\pi^2}\int A_\theta^2\,d^2x\,2\pi i\int_0^\infty\frac{\mu\,d\mu}{(\mu^2+1)^2}$$
$$=\frac{-\alpha}{2\pi}\int A_\nu A_\nu\,d^2x. \tag{66}$$

This term gives rise to a contribution identical to that of (65).

The last term in (45) is

$$\frac{i}{(2\pi)^3}\,\mathrm{tr}\int\mathcal{A}(0)\sum_{\xi=\pm1}\int_\Gamma\ln\lambda\,\tilde{d}_{-1}\left(x,t;\frac{\xi}{|\xi|},t;\lambda\right)\frac{d\lambda}{\lambda}\,dx\,dt$$
$$=\frac{i\Phi}{(2\pi)^2}\int_\Gamma\frac{u\,\ln\lambda}{(1+u^2\lambda^2)}\left[\lambda\sqrt{1+u^2}-i\sqrt{1-\lambda^2}\right]\frac{d\lambda}{\sqrt{1-\lambda^2}}, \tag{67}$$

where $u=(1-w^2)/2w$. We choose the curve Γ as in Fig. 1.

Therefore, (67) reads

$$-\frac{\Phi}{2\pi}\,u\int_0^\infty\frac{1}{(1-u^2\mu^2)}\left[\mu\,\frac{\sqrt{1+u^2}}{\sqrt{1+\mu^2}}-1\right]d\mu=\frac{-\Phi}{4\pi}\ln w^2. \tag{68}$$

Putting all pieces together [(65), (66), and (68)], we finally find

$$\ln \mathrm{Det}(D)_B - \ln \mathrm{Det}(i\partial\!\!\!/)_B = -\frac{1}{2\pi}\int_\Omega A_\nu A_\nu \, d^2x - \frac{\Phi}{4\pi}\ln w^2$$

$$= -\frac{1}{2\pi}\int_\Omega A_\nu A_\nu \, d^2x$$

$$-\frac{1}{4\pi}\ln w^2 \int_{\partial\Omega} A_\nu \, dx_\nu . \tag{69}$$

The first term is the integral, restricted to the region Ω, of the same density appearing in the well-known case of the whole plane.[19] The second term is well defined for every $w \neq 0$, and vanishes for a null total flux, $\Phi = 0$. For $w = 0$, b_0 in (55) does not define an elliptic boundary problem. It is also interesting to notice that this term vanishes in the case of MIT bag boundary conditions, i.e., $w = \pm 1$.

This calculation is to be compared with the case of the compactified plane,[2] where the determinant can be expressed in terms of just the kernel of the z-power of the operator analytically extended to $z = 0$, which is a local quantity. The presence of boundaries makes the evaluation more involved, since even in simple cases as the present (or the half-plane treated in Ref. 7), the knowledge of the Green's function of the problem is needed.

The differential calculus on n-dimensional ($n\geqslant 3$) quantum Minkowski space covariant with respect to left action of κ-Poincaré group is constructed and its uniqueness is shown. © *1996 American Institute of Physics.* [S0022-2488(96)03909-6]

I. INTRODUCTION

The κ-Poincaré algebra, introduced in Ref. 1, provides a Hopf algebra deformation of standard Poincaré algebra which depends on dimensionful parameter κ. Its global counterpart, κ-Poincaré group P_κ has been constructed by Zakrzewski.[2] It is a free *-algebra generated by the hermitean elements $\Lambda^\mu{}_\nu$, a^μ, subject to the following conditions:

$$
\begin{gathered}
(g^{\mu\nu}=\mathrm{diag}(+---)):\quad [a^\mu,a^\nu]=\frac{i}{\kappa}\,(\delta^\mu_0 a^\nu-\delta^\nu_0 a^\mu),\\
[\Lambda^\mu{}_\nu,\Lambda^\alpha{}_\beta]=0,\quad [\Lambda^\mu{}_\nu,a^\alpha]=-\frac{i}{\kappa}\,((\Lambda^\mu{}_0-\delta^\mu_0)\Lambda^\alpha{}_\nu+(\Lambda^0{}_\nu-\delta^0_\nu)g^{\mu\alpha}),\\
\Delta(\Lambda^\mu{}_\nu)=\Lambda^\mu{}_\alpha\otimes\Lambda^\alpha{}_\nu,\quad \Delta(\alpha^\mu)=\Lambda^\mu{}_\nu\otimes a^\nu+a^\mu\otimes I,\quad S(\Lambda^\mu{}_\nu)=\Lambda_\nu{}^\mu,\\
S(a^\mu)=-\Lambda_\nu{}^\mu a^\nu.\quad \epsilon(\Lambda^\mu{}_\nu)=\delta^\mu_\nu,\quad \epsilon(a^\mu)=0.
\end{gathered}
\tag{1}
$$

It appears[2,3] that one can also define a noncommutative generalization of Minkowski spacetime—the κ-Minkowski space $\mathcal{M}_\kappa$. The κ-Poincaré group acts on $\mathcal{M}_\kappa$ covariantly from the left. Once one accepts the idea that the κ-deformed Poincaré symmetry can have something to do with reality, the next step is to find the natural generalizations of standard geometric notions related to Minkowski space. The first step toward this directions was made by Sitarz[4] who showed that one cannot construct four-dimensional differential calculus on $\mathcal{M}_\kappa$ which is covariant with respect to infinitesimal left action of $\mathcal{P}_\kappa$. He sketched also the construction of five-dimensional covariant calculus.

In the present paper we consider the problem of the classification of differential calculi on $\mathcal{M}_\kappa$ which are covariant with respect to the left *global* action of κ-Poincaré group on $\mathcal{M}_\kappa$. No restriction is made concerning the dimensionality of spacetime (i.e., the indices μ, ν, etc., in Eq. (1) run from 0 to $n-1$) except $n\geqslant 3$. We show that the lowest dimensional nontrivial left-covariant calculus is $n+1$-dimensional and is unique. Its construction is given explicitly and the result coincides with the suggestion of Sitarz.

As a main tool we use the beautiful Woronowicz theory of differential calculi.[5] In Sec. II we show that the Woronowicz theory can be immediately extended to deal with the problem of covariant differential calculi on quantum spaces. This natural extension provides a nice framework to discuss our problem. In Sec. III we use the scheme developed in Sec. II to show that there is a

0022-2488/96/37(11)/5820/8/$10.00

unique $n+1$-dimensional calculus on $\mathcal{M}_\kappa$ which is left-covariant with respect to the action of $\mathcal{P}_\kappa$. This calculus is explicitly constructed and shown to be lowest-dimensional nontrivial calculus on $\mathcal{M}_\kappa$.

The results obtained here were briefly reported in Ref. 6. Let us also mention that the differential calculi on quantum spacetimes covariant with respect to other deformations of Poincaré group were considered by Podleś.[7]

II. COVARIANT DIFFERENTIAL CALCULI

Let us first indicate how one can extend the Woronowicz theory of differential calculi[5] to the following situation: Assume that the quantum group $\mathcal{B}$ acts on quantum space $\mathcal{A}$; one looks for differential calculi on $\mathcal{A}$ on which the covariant action of $\mathcal{B}$ can be defined as ''induced'' by the action of $\mathcal{B}$ on $\mathcal{A}$. All proofs are omitted as being a straightforward extension of those given by Woronowicz.

Let $\mathcal{A}$ be an algebra with unity (quantum space). The starting point in Woronowicz construction is the universal bimodule $\mathcal{A}^2 \subset \mathcal{A}\otimes\mathcal{A}$ defined by

$$\mathcal{A}^2 = \left\{ \sum_k a_k \otimes b_k \in \mathcal{A}\otimes\mathcal{A} \Big| \sum_k a_k b_k = 0 \right\},$$

$$c\left(\sum_k a_k \otimes b_k\right) = \sum_k c a_k \otimes b_k, \quad \left(\sum_k a_k \otimes b_k\right) c = \sum_k a_k \otimes b_k c. \tag{2}$$

The universal differential $D: \mathcal{A} \to \mathcal{A}^2$ is given by $da = I\otimes a - a\otimes I$.

It can be easily shown that any other calculus is obtained from the universal one by dividing by an appropriately chosen sub-bimodule $\mathcal{N} \subset \mathcal{A}^2$.

Let now ρ_L be a left action of a quantum group $\mathcal{B}$ on $\mathcal{A}$, i.e., a homomorphism $\rho_L : \mathcal{A} \to \mathcal{B}\otimes\mathcal{A}$ obeying

$$(\mathrm{id}\otimes\rho_L)\circ\rho_L = (\Delta\otimes\mathrm{id})\circ\rho_L, \quad (\epsilon\otimes\mathrm{id})\circ\rho_L = \mathrm{id}. \tag{3}$$

Let us define the action $\tilde{\rho}_L$ of $\mathcal{B}$ on $\mathcal{A}^2$ as follows: Let

$$q = \sum_i x_i \otimes y_i \in \mathcal{A}\otimes\mathcal{A}, \quad \rho_L(x_i) = \sum_k a_i{}^k \otimes x_i{}^k \in \mathcal{B}\otimes\mathcal{A},$$

$$\rho_L(y_i) = \sum_l b_i{}^l \otimes y_i{}^l \in \mathcal{B}\otimes\mathcal{A}; \tag{4a}$$

then

$$\tilde{\rho}_L(q) = \sum_{i,k,l} a_i{}^k b_i{}^l \otimes x_i{}^k \otimes y_i{}^l. \tag{4b}$$

Obviously, $\tilde{\rho}_L : \mathcal{A}\otimes\mathcal{A} \to \mathcal{B}\otimes\mathcal{A}\otimes\mathcal{A}$; however, it is straightforward to show that $\tilde{\rho}_L : \mathcal{A}^2 \to \mathcal{B}\otimes\mathcal{A}^2$. Following the same lines as in Ref. 5, one easily proves the following properties of $\tilde{\rho}_L$

(i_L) for $x \in \mathcal{A}$, $y \in \mathcal{A}^2$

$$\tilde{\rho}_L(xy) = \rho_L(x)\tilde{\rho}_L(y), \quad \tilde{\rho}_L(yx) = \tilde{\rho}_L(y)\rho_L(x)$$

(ii_L)

$$\tilde{\rho}_L \circ D = (\mathrm{id} \otimes D) \circ \rho_L \tag{5}$$

(iii_L)

$$(\mathrm{id} \otimes \tilde{\rho}_L) \circ \tilde{\rho}_L = (\Delta \otimes \mathrm{id}) \circ \tilde{\rho}_L, \quad (\epsilon \otimes \mathrm{id}) \circ \tilde{\rho}_L = \mathrm{id}.$$

Property (iii_L) means that $\tilde{\rho}_L$ is the left action of $\mathscr{B}$ on $\mathscr{A}^2$ while (i), (ii) can be summarized by saying that $\tilde{\rho}_L$ is the lift of ρ_L to $\mathscr{A}^2$ ($\tilde{\rho}_L$ is the left action of $\mathscr{B}$ on universal differential calculus on $\mathscr{A}$ induced from the left action ρ_L). Moreover, let us note that the following formula holds:

$$\tilde{\rho}_L \left(\sum_i x_i D y_i \right) = \sum_i \rho_L(x_i)(\mathrm{id} \otimes D) \rho_L(y_i) \tag{6}$$

which is a counterpart of Eq. (1.15) of Ref. 5.

Now, assume that $\mathscr{N} \subset \mathscr{A}^2$ is a subbimodule such that

$$\tilde{\rho}_L(\mathscr{N}) \subset \mathscr{B} \otimes \mathscr{N}. \tag{7}$$

Then the differential calculus (Γ, d) determined by $\mathscr{N}$ has the following property:

$$\sum_i x_i \, dy_i = 0 \Rightarrow \sum_i \rho_L(x_i)(\mathrm{id} \otimes d) \rho_L(y_i) = 0. \tag{8}$$

Therefore,

$$\tilde{\rho}_L \left(\sum_i x_i \, dy_i \right) = \sum_i \rho_L(x_i)(\mathrm{id} \otimes d) \rho_L(y_i) \tag{9}$$

is well defined linear mapping from Γ into $\mathscr{B} \otimes \Gamma$. Formulate (i_L)–(iii_L) and Eq. (6) hold upon replacing $\mathscr{A}^2$ by Γ and D by d.

We shall say that (Γ, d) is left-covariant with respect to the action of $\mathscr{B}$.

All the above results can be extended mutatis mutandis to right actions. Let $\rho_R : \mathscr{A} \to \mathscr{A} \otimes \mathscr{B}$ be right action of $\mathscr{B}$ on $\mathscr{A}$

$$(\rho_R \otimes \mathrm{id}) \circ \rho_R = (\mathrm{id} \otimes \Delta) \circ \rho_R, \quad (\mathrm{id} \otimes \epsilon) \circ \rho_R = \mathrm{id}. \tag{10}$$

For

$$q = \sum_i x_i \otimes y_i \in \mathscr{A} \otimes \mathscr{A}, \quad \rho_R(x_i) = \sum_k x_i{}^k \otimes a_i{}^k \in \mathscr{A} \otimes \mathscr{B},$$

$$\rho_R(y_i) = \sum_l y_i{}^l \otimes b_i{}^l \in \mathscr{A} \otimes \mathscr{B}, \tag{11a}$$

we put

$$\tilde{\rho}_R(q) = \sum_{i,k,l} x_i{}^k \otimes y_i{}^l \otimes a_i{}^k b_i{}^k, \tag{11b}$$

Again $\tilde{\rho}_R : \mathscr{A}^2 \to \mathscr{A}^2 \otimes \mathscr{B}$ obeys

(i_R) for $x \in \mathscr{A}$, $y \in \mathscr{A}^2$

$$\tilde{\rho}_R(xy)=\rho_R(x)\tilde{\rho}_R(y), \quad \tilde{\rho}_R(yx)=\tilde{\rho}_R(y)\rho_R(x),$$

(ii_R)

$$\tilde{\rho}_R\circ D=(D\otimes \mathrm{id})\circ\rho_R \tag{12}$$

(iii_R)

$$(\tilde{\rho}_R\otimes \mathrm{id})\circ\tilde{\rho}_R=(\mathrm{id}\otimes\Delta)\circ\tilde{\rho}_R, \quad (id\otimes\epsilon)\circ\tilde{\rho}_R=\mathrm{id}$$

as well as

$$\tilde{\rho}_R\left(\sum_i x_i D y_i\right)=\sum_i \rho_R(x_i)(D\otimes \mathrm{id})\rho_R(y_i). \tag{13}$$

Now assume $\mathcal{N}\in\mathcal{A}^2$ to be a sub-bimodule such that $\tilde{\rho}_R(\mathcal{N})\subset\mathcal{N}\otimes\mathcal{B}$. Then, for the calculus (Γ,d) determined by $\mathcal{N}$, (i_R)–(iii_R) and Eq. (13) hold with appropriate replacements $\mathcal{A}^2\to\Gamma$, $D\to d$.

Finally, let the pair (ρ_L,ρ_R) of actions of $\mathcal{B}$ on $\mathcal{A}$ be given. We assume that ρ_L,ρ_R commute

$$(\mathrm{id}\otimes\rho_R)\circ\rho_L=(\rho_L\otimes \mathrm{id})\circ\rho_R. \tag{14}$$

We say that (Γ,d) is bicovariant with respect to the action of $\mathcal{B}$ on $\mathcal{A}$ if it is left- and right-covariant. Then, it has all properties of left- and right-covariant calculi together with the following one [cf. Eq. (1.20) of Ref. 5];

$$(\mathrm{id}\otimes\tilde{\rho}_R)\circ\tilde{\rho}_L=(\tilde{\rho}_L\otimes \mathrm{id})\circ\tilde{\rho}_R. \tag{15}$$

Let us now discuss the problem of infinitesimal action of $\mathcal{B}$ on $\mathcal{A}$. Let χ be any element of the Hopf algebra dual to $\mathcal{B}$. We put

$$\chi_{\rho_L}=(\chi\otimes \mathrm{id})\circ\rho_L, \quad \chi_{\tilde{\rho}_L}=(\chi\otimes \mathrm{id})\circ\tilde{\rho}_L. \tag{16}$$

The first definition, introduced by Woronowicz,[8] coincides with the one used by Majid and Ruegg.[3] The second one is equivalent to the proposal of Sitarz[4]

$$\begin{aligned}\chi_{\tilde{\rho}_L}(x\ dy)&=(\chi\otimes \mathrm{id})(\rho_L(x)(\mathrm{id}\otimes d)\rho_L(y))\\&=[(\chi_{(1)}\otimes \mathrm{id})\rho_L(x)](\mathrm{id}\otimes d)[(\chi_{(2)}\otimes \mathrm{id})\rho_L(y)]\\&=\chi_{(1)\rho_L}(x)(\mathrm{id}\otimes d)\chi_{(2)\rho_L}(y),\end{aligned} \tag{17}$$

where $\Delta\chi=\chi_{(1)}\otimes\chi_{(2)}$. Analogous definitions can be given for ρ_R and $\tilde{\rho}_R$.

From the above discussion it follows then that in order to check whether a calculus on $\mathcal{A}$ is consistent with the action of $\mathcal{B}$ on $\mathcal{A}$ it is sufficient to check the property $\tilde{\rho}_L(\mathcal{N})\subset\mathcal{B}\otimes\mathcal{N}$ $(\tilde{\rho}_R(\mathcal{N})\subset\mathcal{N}\otimes\mathcal{B})$.

This simplifies considerably if $\mathcal{A}$ itself is a quantum group and $\mathcal{N}$ defines (say) left-covariant calculus on it. Then $\mathcal{N}=r^{-1}(\mathcal{A}\otimes\mathcal{R})$ where $\mathcal{R}$ is a right ideal in $\ker\epsilon$; any element of $\mathcal{A}\otimes\mathcal{R}$ can be written as

$$t=\sum_i a_i\otimes x_i b_i, \tag{18}$$

where $a_i, b_i \in \mathscr{A}$ and x_i are generators of $\mathscr{R}$. From the very definition of the operation r^{-1} the following formula follows immediately:[5]

$$r^{-1}(t) = \sum_{i,l} a_i S(b^{l'}{}_i) r^{-1}(I \otimes x_i) b^{l''}{}_i, \tag{19a}$$

where

$$\Delta(b_i) = \sum_{l} b^{l'}{}_i \otimes b^{l''}{}_i. \tag{19b}$$

The properties (5) applied to the universal calculus imply

$$\widetilde{\rho}_L(r^{-1}(t)) = \sum_{i,l} \rho_L(a_i S(b^{l'}{}_i) \widetilde{\rho}_L(r^{-1}(I \otimes x_i)) \rho_L(b^{l''}{}_i). \tag{20}$$

Therefore it is sufficient to check that

$$\widetilde{\rho}_L(r^{-1}(I \otimes x_i)) \subset \mathscr{B} \otimes \mathscr{N} \tag{21}$$

for all generators x_i of $\mathscr{R}$.

Let us now pass to the external algebra. Given $\widetilde{\rho}_L : \Gamma \to \mathscr{B} \otimes \Gamma$ we define $\widetilde{\rho}_L^{\otimes 2} : \Gamma^{\otimes 2} \to \mathscr{B} \otimes \Gamma^{\otimes 2}$ by

$$\widetilde{\rho}_L^{\otimes 2}(\omega_1 \otimes \omega_2) = \sum_{k,l} a_{1k} a_{2l} \otimes \omega_{1k} \otimes \omega_{2l} \tag{22}$$

extended by linearity; here $\omega_i \in \Gamma$ and

$$\widetilde{\rho}_L(\omega_i) = \sum_{k} a_{ik} \otimes \omega_{ik}, \quad i = 1,2. \tag{23}$$

Let us assume that $\mathscr{A}$ is a quantum group, (Γ, d)—a bicovariant calculus on it and let σ be the module homomorphism defined in Proposition 3.1 of Ref. 5. Then $\Gamma^{\wedge 2}$ is defined as

$$\Gamma^{\wedge 2} = \Gamma^{\otimes 2} / \ker(I - \sigma) \tag{24}$$

and, in order to have a consistent action of $\mathscr{B}$ on $\Gamma^{\wedge 2}$ we must only check that

$$(\mathrm{id} \otimes \sigma) \circ \widetilde{\rho}_L^{\otimes 2} = \widetilde{\rho}_L^{\otimes 2} \circ \sigma. \tag{25}$$

Due to the property

$$\widetilde{\rho}_L^{\otimes 2}(xy) = \rho_L(x) \widetilde{\rho}_L^{\otimes 2}(y), \quad x \in \mathscr{A}, \quad y \in \Gamma^{\otimes 2} \tag{26}$$

it is sufficient to verify Eq. (25) for the basic elements only.

III. LEFT-COVARIANT CALCULI ON κ-MINKOWSKI SPACE

The n-dimensional κ-Minkowski space $\mathscr{M}_\kappa$ is an $*$-algebra with unity generated by n hermitian elements x^μ subject to the following conditions:[2,3]

$$[x^\mu, x^\nu] = \frac{i}{\kappa} (\delta_0^\mu x^\nu - \delta_0^\nu x^\mu). \tag{27}$$

$\mathcal{M}_\kappa$ can be equipped with the structure of the quantum group by putting

$$\Delta x^\mu = I\otimes x^\mu + x^\mu \otimes I, \quad S(x^\mu) = -x^\mu, \quad \epsilon(x^\mu) = 0. \tag{28}$$

The left action of n-dimensional κ-Poincaré group $\mathcal{P}_\kappa$ on $\mathcal{M}_\kappa$ can be defined as follows:

$$\rho_L(I) = I\otimes I, \quad \rho_L(x^\mu) = \Lambda^\mu{}_\nu \otimes x^\nu + a^\mu \otimes I \tag{29}$$

extended by linearity and multiplicativity.

We want to find a left-covariant (with respect to action of $\mathcal{P}_\kappa$) calculi on $\mathcal{M}_\kappa$. The proof will be given for $n=4$. However, for general $n\geqslant 3$ the proof goes along the same way. As the first step let us note that $\mathcal{M}_\kappa$ is a subgroup of $\mathcal{P}_\kappa$. Indeed, $\Pi:\mathcal{P}_\kappa \to \mathcal{M}_\kappa$ given

$$\Pi(a^\mu) = x^\mu, \quad \Pi(\Lambda^\mu{}_\nu) = \delta^\mu_\nu I \tag{30}$$

is an epimorphism obeying

$$\Delta_{\mathcal{M}} \circ \Pi = (\Pi\otimes\Pi)\circ\Delta_{\mathcal{P}}. \tag{31a}$$

Moreover, it is immediate to check that

$$(\Pi\otimes \mathrm{id})\circ\rho_L = \Delta_{\mathcal{M}}. \tag{31b}$$

Let $\tilde{\rho}_L$ be the extension of ρ_L to $\mathcal{M}^2_\kappa$. Equations (8), (31), and the results contained in Ref. 5 imply that any calculus on $\mathcal{M}_\kappa$ left-covariant with respect to action of $\mathcal{P}_\kappa$ is also left-covariant with respect to action of $\mathcal{M}_\kappa$ on itself. Therefore the relevant sub-bimodule $\mathcal{N}$ is of the form $r^{-1}(\mathcal{M}_\kappa\otimes\mathcal{R})$ where $\mathcal{R}$ is a right ideal in $\ker\epsilon_{\mathcal{M}}$.

Let $\mathcal{R}$ be any ideal in $\ker\epsilon_{\mathcal{M}}$. Any $a\in\mathcal{R}$ can be written as ($\boldsymbol{\mu}\equiv(\mu_0,\mu_k)$)

$$a = \sum_{\mu_0,\mu_k} c_{\boldsymbol{\mu}} (x^0)^{\mu_0} \prod_{k=1}^{n-1} (x^k)^{\mu_k}. \tag{32}$$

Let us call $|\mu| = \mu_0 + \Sigma_{k=1}^{n-1}\mu_k$; obviously, $c_{\boldsymbol{\mu}}=0$ for $|\mu|=0$; further, let

$$\mu(a) = \max_{c_{\boldsymbol{\mu}}\neq 0} |\mu|, \quad \mu(\mathcal{R}) = \min_{a\in\mathcal{R}} \mu(a). \tag{33}$$

Obviously, $\mu(\mathcal{R})\geqslant 1$; let us first assume that $\mu(\mathcal{R})=1$. This means that $c_0 x^0 + c_k x^k \in \mathcal{R}$ for some (not all zero) constants c_0, c_k. But

$$\tilde{\rho}_L(r^{-1}(I\otimes c_\mu x^\mu)) = c_\mu \Lambda^\mu{}_\nu \otimes r^{-1}(I\otimes x^\nu). \tag{34}$$

Therefore, $x^\mu\in\mathcal{R}$ for all μ, i.e., $\mathcal{R}=\ker\epsilon_{\mathcal{M}}$ and the corresponding calculus is trivial.

As the next step let us take $\mu(\mathcal{R})=2$. It is straightforward to check that

$$\tilde{\rho}_L(r^{-1}(I\otimes x^{\mu\nu})) = \Lambda^\mu{}_\alpha \Lambda^\nu{}_\beta \otimes r^{-1}(I\otimes x^{\alpha\beta}), \tag{35}$$

where

$$x^{\mu\nu} \equiv x^\mu x^\nu + \frac{i}{\kappa}(g^{\mu\nu}x^0 - g^{0\mu}x^\nu). \tag{36}$$

Due to the fact that Λ's commute among themselves we can write a standard representation theory of Lorentz group. First of all, we note that $r^{-1}(I\otimes x^{\mu\nu})$ transform as a second order symmetric [$x^{\mu\nu}=x^{\nu\mu}$ due to Eqs. (27) and (36)] tensor. It carries $D^{(1,1)}\oplus D^{(0,0)}$ representation of

Lorentz group. Let us first take all $x^{\mu\nu}$ as generators of $\mathscr{R}$. Then $(x^0)^2=x^{00}\in\mathscr{R}$ and $x^ix^0=x^{i0}\in\mathscr{R}$, i.e., $[(x^0)^2,x^i]\in\mathscr{R}$; therefore $x^ix^0+x^0x^i\in\mathscr{R}$ and $x^0x^i\in\mathscr{R}$. However, $x^{0i}=x^0x^i-(i/\kappa)x^i\in\mathscr{R}$ which implies $x^i\in\mathscr{R}$. Then Poincaré invariance implies $x^0\in\mathscr{R}$ and our calculus is trivial.

To improve the situation we can only, due to condition (21), subtract $D^{(0,0)}$ or $D^{(1,1)}$. Obviously, subtracting $D^{(1,1)}$ gives larger calculus, so we will subtract $D^{(0,0)}$.

It is not difficult to check that for general $n\geqslant 3$ the following lemma holds.

Lemma: Let $\mathscr{R}\subset\ker\epsilon_{\mathscr{M}}$ be right ideal generated by the elements

$$x^\mu x^\nu+\frac{i}{\kappa}(g^{\mu\nu}x^0-g^{0\mu}x^\nu)-\frac{1}{n}g^{\mu\nu}\left(x^2+\frac{i(n-1)}{\kappa}x^0\right). \tag{37}$$

Then

(a) $\mathscr{R}$ defines a left-$\mathscr{P}_\kappa$-covariant calculus on $\mathscr{M}_\kappa$,

(b) $a\in\mathscr{R}$ implies $S(a)^*\in\mathscr{R}$,

(c) $\ker\epsilon_{\mathscr{M}}/\mathscr{R}$ is spanned by x^μ and by

$$\varphi\equiv x^2+\frac{i}{\kappa}(n-1)x^0. \tag{38}$$

Now, we can construct the relevant calculus. The left-invariant forms are

$$\tau^\mu=\pi r^{-1}(I\otimes x^\mu)=dx^\mu,\quad \tau=\pi r^{-1}(I\otimes\varphi)=d\varphi-2x_\mu dx^\mu \tag{39}$$

and they appear to be also right-invariant. The commutation rules are easily derived according to the standard procedure of Ref. 5

$$[\tau^\mu,x^\nu]=\frac{i}{\kappa}g^{0\mu}\tau^\nu-\frac{i}{\kappa}g^{\mu\nu}\tau^0+\frac{1}{n}g^{\mu\nu}\tau,\quad [\tau,x^\mu]=-\frac{n}{\kappa^2}\tau^\mu \tag{40}$$

while the hermicity properties read

$$(\tau^\mu)^*=\tau^\mu,\quad \tau^*=-\tau. \tag{41}$$

The left action of $\mathscr{P}_\kappa$ on $\mathscr{M}_\kappa$ is easily calculated to be

$$\tilde{\rho}_L(\tau^\mu)=\Lambda^\mu{}_\nu\otimes\tau^\nu,\quad \tilde{\rho}_L(\tau)=I\otimes\tau. \tag{42}$$

In order to construct the external algebra we first verify property (25) for the bimodule homomorphism σ: $\sigma(\tau^\mu\otimes\tau^\nu)=\tau^\nu\otimes\tau^\mu$, $\sigma(\tau\otimes\tau^\mu)=\tau^\mu\otimes\tau$, $\sigma(\tau^\mu\otimes\tau)=\tau\otimes\tau^\mu$. The external algebra implied by σ takes the standard form

$$\tau^\mu\wedge\tau^\nu=-\tau^\nu\wedge\tau^\mu,\quad \tau\wedge\tau^\mu=-\tau^\mu\wedge\tau. \tag{43}$$

Moreover,

$$d\tau^\mu=0,\quad d\tau=-2\,d\tau^\mu\wedge d\tau_\mu. \tag{44}$$

From the discussion carried out above it follows that the $n+1$-dimensional calculus described by Eqs. (39)–(43) is the lowest dimensional nontrivial calculus on $\mathscr{M}_\kappa$ covariant with respect to the left action of $\mathscr{P}_\kappa$. This is due to the fact that all differential calculi with $\mu(\mathscr{R})\geqslant 3$ have higher dimensions.

Finally, let us compare our calculus with that proposed by Sitarz.[4] Our Eqs. (40) agree with Eqs. (60) of Ref. 4 under the identification: $x^\mu \to ix^\mu$, $\tau \to (4/\kappa^2)\varphi$. In the two-dimensional case there is also an agreement provided the replacement $\tau \to (2/\kappa^2)\varphi$ is made; also the multiplication rules for one-forms [Eqs. (58) of Ref. 4] coincide in this case.

(Received 19 March 1996; accepted for publication 21 June 1996)

A general method to map a polynomial recursion on a matrix linear one is suggested. The solution of the recursion is represented as a product of a matrix multiplied by the vector of initial values. This matrix is product of *transfer* matrices whose elements depend only on the polynomial and not on the initial conditions. The method is valid for systems of polynomial recursions and for polynomial recursions of arbitrary order. The only restriction on these recurrent relations is that the highest-order term can be written in explicit form as a function of the lower-order terms (existence of a normal form). A continuous analog of this method is described as well. © *1996 American Institute of Physics.*

I. INTRODUCTION

Recurrent relations take a central place in various fields of science. For example, numerical solution of differential equations and models of evolution of a system involve, in general, recursions.

By now, only linear recursions could be solved[1–3] while even the simplest nonlinearity usually made an analytic solution impossible. A good example for this is a rather simple recursion, the logistic map, $y_{n+1}=\lambda y_n(1-y_n)$. The analysis of its behavior, while based on roundabout approaches, has revealed many unusual features.

In this paper we propose a new approach to the solution of polynomial recursions. It turns out that the coefficients of the i-th iteration of the polynomial depend linearly on the coefficients of the $(i-1)$-th iteration. Using this fact we succeed in writing down the general solution of the recursion.

To make this paper more readable we include some auxiliary material on linear recursions as well as an introductory example.

II. INTRODUCTORY EXAMPLE: LOGISTIC MAPPING

To demonstrate our approach we begin with the recursion equation known as the logistic mapping:

$$y_{n+1}=\lambda y_n(1-y_n) \quad \text{with} \quad y_0\equiv y. \tag{1}$$

Very recently it was shown by Rabinovich *et al.*[4] that the solution of this recursion is given by

$$y_n=\langle \mathbf{e}|\mathbf{T}^n|\mathbf{y}\rangle, \tag{2}$$

where $\mathbf{T}$ is a transfer matrix with elements

$$T_{jk}=(-1)^{k-j}\binom{j}{k-j}\lambda^j. \tag{3}$$

0022-2488/96/37(11)/5828/9/$10.00

The vectors $|\mathbf{y}\rangle$ and $\langle\mathbf{e}|$ are correspondingly a set of y's powers and the first ort defined as

$$|\mathbf{y}\rangle=\{y^j\}_{j=1}^{2^n} \quad \text{and} \quad \langle\mathbf{e}|=[\delta_{j1}]_{j=1}^{2^n}, \tag{4}$$

where δ_{jk} is the Kronecker symbol.

Equations (2) and (3) were derived in Ref. 4 by consideration of a branching process. However, knowing the representation of the solution (2) one can obtain the matrix elements (3) in a ''one-line'' way. Namely, we have to find a matrix $\mathbf{T}$ that transforms a column $\{y^j\}$ to a column $\{[\lambda y(1-y)]^j\}$. Expanding this last expression

$$[\lambda y(1-y)]^j=\sum_{i=0}^{j}(-1)^i\binom{j}{i}\lambda^j y^{j+i}=\sum_{k=j}^{2j}(-1)^{k-j}\binom{j}{k-j}\lambda^j y^k=\sum_{k=j}^{2j}T_{jk}y^k$$

and extending the last summation over all natural numbers {due to the vanishing of the binomials $\binom{j}{k-j}$ for k outside the interval $[j,2j]$} we immediately recover Eq. (3) for the elements of the matrix $\mathbf{T}$.

III. GENERAL CASE OF FIRST-ORDER POLYNOMIAL RECURSION

Here we consider a first-order recursion equation in its normal form

$$y_{n+1}=P(y_n), \tag{5}$$

where $P(x)$ is a polynomial of degree m:

$$P(x)=\sum_{k=0}^{m}a_k x^k, \quad a_m\neq 0. \tag{6}$$

Let $y_0\equiv y$ be an initial value for the recursion (5). We denote by $|\mathbf{y}\rangle$ the column vector of powers of y

$$|\mathbf{y}\rangle=\{y^j\}_{j=0}^{\infty}$$

and the vector $\langle\mathbf{e}|$ is a row vector

$$\langle\mathbf{e}|=[\delta_{j1}]_{j=0}^{\infty}.$$

It should be emphasized that j runs from 0, since in the general case $a_0\neq 0$. In this notation $\langle\mathbf{e}|\mathbf{y}\rangle$ is a scalar product that yields

$$\langle\mathbf{e}|\mathbf{y}\rangle=y. \tag{7}$$

Theorem: For any recursion of the type of Eq. (5) there exists a matrix $\mathbf{T}=\{T_{jk}\}_{j,k=0}^{\infty}$ such that

$$y_n=\langle\mathbf{e}|\mathbf{T}^n|\mathbf{y}\rangle. \tag{8}$$

Proof: For $n=0$ the statement of the theorem is valid [see Eq. (7)]. We introduce the column vector $|\mathbf{y}_1\overset{\text{def}}{=}\{y_1^j\}_{j=0}^{\infty}$, where $y_1=P(y)$. Let $\mathbf{T}$ be a matrix such that

$$|\mathbf{y}_1\rangle=\mathbf{T}|\mathbf{y}\rangle. \tag{9}$$

The existence of this matrix will be proven later on. If such a matrix exists, then, analogically to Eq. (7), we have

$$y_1 = \langle \mathbf{e}|\mathbf{y}_1\rangle = \langle \mathbf{e}|\mathbf{T}|\mathbf{y}\rangle.$$

Therefore, the statement of the theorem is true for $n=1$ as well.

Assume that Eq. (8) is valid for $n=l$ and any initial value y. Then y_{l+1} can be represented as $y_{l+1}=\langle \mathbf{e}|\mathbf{T}^l|\mathbf{y}_1\rangle$, where $y_1=P(y)$ is considered as a new initial value of the recursion. Then, using Eq. (9) one gets

$$y_{l+1} = \langle \mathbf{e}|\mathbf{T}^l|\mathbf{y}_1\rangle = \langle \mathbf{e}|\mathbf{T}^l\mathbf{T}|\mathbf{y}\rangle = \langle \mathbf{e}|\mathbf{T}^{l+1}|\mathbf{y}\rangle.$$

To prove the existence of the matrix $\mathbf{T}$ we use $|\mathbf{y}_1\rangle \overset{\text{def}}{=} \{P^j(y)\}_{j=0}^{\infty}$. In turn, $P^j(y)$ is the jm-th degree polynomial

$$P^j(y) = \left(\sum_{i=0}^{m} a_i y^i\right)^j = \sum_{k=0}^{jm} T_{jk} y^k, \tag{10}$$

and we infer that $\mathbf{T}=\{T_{jk}\}_{j,k=0}^{\infty}$ obeys Eq. (9).

Note that for j and k satisfying $k \geqslant jm$ we have $T_{jk}\equiv 0$. Therefore, each row is finite (i.e., there is only a finite number of nonzero matrix elements in each row). This proves the existence of powers of $\mathbf{T}$ and completes the proof.

The method of this section can be generalized to an arbitrary analytic function in the right-hand side of Eq. (5).[5]

IV. SPECIAL CASES

A. The binomial case, $P(x)=a_p x^p + a_q x^q$

As one can see, in the general case elements of the matrix $\mathbf{T}$ have a form of rather complicated sums. However, they are degenerated to a fairly simple expression, when the polynomial (6) has only two terms. In this case one gets

$$P^j(y) = (a_p y^p + a_q y^q)^j = \sum_{i=0}^{j} \binom{j}{i} a_p^{j-i} a_q^i y^{p(j-i)+qi}.$$

Denoting

$$k = p(j-i)+qi, \quad i = l(k) = (q-p)^{-1}(k-pj),$$

we have

$$P^j(y) = \sum_{k=jp}^{jq} y^k \binom{j}{l(k)} a_p^{j-l(k)} a_q^{l(k)}.$$

Thus, the matrix elements T_{jk} are

$$T_{jk} = \binom{j}{l(k)} a_p^{j-l(k)} a_q^{l(k)}.$$

By substituting here $p=1$, $q=2$, $a_p=-a_q=\lambda$, we immediately recover the solution for the logistic map, Eq. (3).

B. The trinomial case, $P(x)=a_0+a_px^p+a_qx^q$, $a_0\neq 0$

Here, the transfer matrix $\mathbf{T}$ admits the following decomposition:

$$\mathbf{T}=\mathbf{A}\mathbf{T}_0,$$

where $\mathbf{T}_0$ is the matrix corresponding to the polynomial $P_0(x)=a_px^p+a_qx^q$ and $\mathbf{A}$ is an upper-triangular matrix. Indeed, let us consider $P_0(x)=a_px^p+a_qx^q$ and the corresponding matrix $\mathbf{T}_0$. It yields

$$\mathbf{T}_0|\mathbf{y}\rangle=|\mathbf{y}_1'\rangle\overset{\text{def}}{=}\{P_0^j(y)\}_{j=0}^{\infty}.$$

For the matrix $\mathbf{T}$ one gets

$$\mathbf{T}|\mathbf{y}\rangle=|\mathbf{y}_1\rangle\overset{\text{def}}{=}\{P(y)^j\}_{j=0}^{\infty},$$

$$P^j(y)=\sum_{i=0}^{j}\binom{j}{i}a_0^{j-i}(a_py^p+a_qy^q)^i.$$

Denoting in the last line $A_{ji}\equiv\binom{j}{i}a_0^{j-i}$ one obtains $|\mathbf{y}_1\rangle=\mathbf{A}|\mathbf{y}_1'\rangle=\mathbf{A}\mathbf{T}_0|\mathbf{y}\rangle=\mathbf{T}|\mathbf{y}\rangle$, and $\mathbf{T}=\mathbf{A}\mathbf{T}_0$.

V. NONCONSTANT COEFFICIENTS

As shown in Ref. 4 a generalization of Eq. (1),

$$y_{n+1}=\lambda_n y_n(1-y_n)\quad\text{with}\quad y_0\equiv y,\tag{11}$$

can be solved using a similar approach. The solution is

$$y_n=\langle\mathbf{e}|\mathbf{T}_n\cdots\mathbf{T}_2\mathbf{T}_1|\mathbf{y}\rangle,\tag{12}$$

where the matrix elements of $\mathbf{T}_i$ are now i-dependent:

$$(T_i)_{jk}=(-1)^{k-j}\binom{j}{k-j}(\lambda_i)^j.\tag{13}$$

The same argument is valid for an arbitrary recursion $y_{n+1}=P_n(n,y_n)$ and therefore solution Eq. (8) takes the form of Eq. (12) with the obvious changes ($a_0,\ldots,a_m$ become i-dependent functions) in the corresponding matrix elements.

VI. THE RICCATI RECURSION

This name is commonly used for the equation

$$y_{n+1}y_n+a_n'y_{n+1}+b_n'y_n+c_n'=0.$$

However, by a proper change of variable[1,2] this equation can be reduced to a linear one and then treated by conventional techniques. Here we shall be dealing with the following recursion:

$$y_{n+1}=a_n+b_ny_n+c_ny_n^2\quad\text{with}\quad y_0\equiv y.$$

This is a possible (asymmetric) discrete analog of the Riccati differential equation.[6] It is well known that the latter cannot be solved in quadratures.

The general results of the two previous sections can be employed to write down the solution of this recursion. Namely, the solution reads

$$y_n = \langle \mathbf{e} | \mathbf{T}_n \cdots \mathbf{T}_2 \mathbf{T}_1 | \mathbf{y} \rangle,$$

where the matrix $\mathbf{T}_i$ is a product of two matrices

$$\mathbf{T}_i = \mathbf{A}_i \mathbf{S}_i$$

with matrix elements

$$(\mathbf{A}_i)_{jk} = \binom{j}{k} a_i^{j-k} \quad \text{and} \quad (\mathbf{S}_i)_{jk} = \binom{j}{k-j} b_i^{2j-k} c_i^{k-j}.$$

VII. SYSTEM OF LINEAR FIRST-ORDER RECURSIONS

The next three sections deal with linear recursions. They are well known,[1,2] but we include those sections to help the understanding of subsequent sections, devoted to systems of nonlinear recursions.

The solution of a system of linear first-order recursions in the most general case is rather trivial, but for the sake of clarity we shall demonstrate it on a 2×2 homogeneous system

$$\begin{aligned} u_{n+1} &= (\lambda_{11})_n u_n + (\lambda_{12})_n v_n \quad \text{with} \quad u_0 \equiv u, \\ v_{n+1} &= (\lambda_{21})_n u_n + (\lambda_{22})_n v_n \quad \text{with} \quad v_0 \equiv v. \end{aligned} \tag{14}$$

Introducing the vector $\langle \mathbf{x}_n | = (u_n, v_n)$ and the matrix

$$\mathbf{\Lambda}_n = \begin{pmatrix} (\lambda_{11})_n & (\lambda_{12})_n \\ (\lambda_{21})_n & (\lambda_{22})_n \end{pmatrix},$$

one rewrites Eq. (14) as follows:

$$|\mathbf{x}_{n+1}\rangle = \mathbf{\Lambda}_n |\mathbf{x}_n\rangle$$

and, thus,

$$|\mathbf{x}_{n+1}\rangle = \mathbf{\Lambda}_n \ldots \mathbf{\Lambda}_0 |\mathbf{x}_0\rangle,$$

where $\langle \mathbf{x}_0 | = (u, v)$ is an initial vector.

Further generalization to a homogeneous system of N linear equations of first order is straightforward.

VIII. LINEAR EQUATION WITH NONCONSTANT COEFFICIENTS

The result of the previous section allows one to solve linear recursions of an arbitrary order with nonconstant coefficients. As usual, we start with the simplest case—a second-order equation

$$x_{n+1} + \lambda_n x_n + \mu_{n-1} x_{n-1} = 0. \tag{15}$$

Denoting $y_n \equiv \mu_{n-1} x_{n-1}$ we obtain the system

$$x_{n+1} = -\lambda_n x_n - y_n, \quad y_{n+1} = \mu_n x_n. \tag{16}$$

The solution of this equation is written as in the previous section but now

$$\mathbf{\Lambda}_n=\begin{pmatrix} -\lambda_n & -1 \\ \mu_n & 0 \end{pmatrix}$$

and the initial vector is $(x_1,\mu_0 x_0)$, where x_0 and x_1 are initial values of the recursion (15).

The method we used to transform Eq. (15) to Eq. (16) is well known in the theory of differential equations,[7] but it is useful for the simplest case of constant coefficients only.

Again, the generalization of (16) for a linear equation of arbitrary order is quite simple.

IX. SYSTEM OF LINEAR HIGHER-ORDER RECURSIONS

The generalization to higher orders is rather obvious. The simplest example is

$$\begin{aligned} &x_{n+1}+(\lambda_{11})_n x_n+(\lambda_{12})_n x_{n-1}+(\mu_{11})_n y_n+(\mu_{12})_n y_{n-1}=0, \\ &y_{n+1}+(\mu_{21})_n y_n+(\mu_{22})_n y_{n-1}+(\lambda_{21})_n x_n+(\lambda_{22})_n x_{n-1}=0. \end{aligned} \tag{17}$$

One proceeds as in the previous section with new variables $u_n=x_{n-1}$ and $v_n=y_{n-1}$. Then, the system (17) takes the form

$$\begin{gathered} x_{n+1}+(\lambda_{11})_n x_n+(\lambda_{12})_n u_n+(\mu_{11})_n y_n+(\mu_{12})_n v_n=0, \\ y_{n+1}+(\mu_{21})_n y_n+(\mu_{22})_n v_n+(\lambda_{21})_n x_n+(\lambda_{22})_n u_n=0, \\ u_{n+1}-x_n=0, \quad v_{n+1}-y_n=0, \end{gathered}$$

i.e., the vector (x_n,y_n,u_n,v_n) is transformed by the transfer matrix

$$\mathbf{\Lambda}_n=\begin{pmatrix} -(\lambda_{11})_n & -(\mu_{11})_n & -(\lambda_{12})_n & -(\mu_{12})_n \\ -(\lambda_{21})_n & -(\mu_{21})_n & -(\lambda_{22})_n & -(\mu_{22})_n \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

and subject to appropriate initial conditions.

X. SYSTEM OF NONLINEAR FIRST-ORDER RECURSIONS

Actually, very little is known about systems of nonlinear recursions.[8] We now extend our method of Sec. III to deal with systems of nonlinear equations. Let us demonstrate it on the following example:

$$\begin{aligned} &u_{n+1}=\lambda u_n(1-v_n) \quad \text{with } u_0\equiv u, \\ &v_{n+1}=\mu v_n(1-u_n) \quad \text{with } v_0\equiv v. \end{aligned} \tag{18}$$

Proceeding here as in Sec. III, we are checking the transformation of a product $u^j v^k$:

$$\begin{aligned} [\lambda u(1-v)]^j[\mu v(1-u)]^k &= \sum_{r,s} \lambda^j u^j (-1)^r \binom{j}{r} v^r \mu^k v^k (-1)^s \binom{k}{s} u^s \\ &= \sum_{p,q} u^p v^q (-1)^{(p-j)+(q-k)} \binom{j}{q-k} \binom{k}{p-j} \lambda^j \mu^k. \end{aligned} \tag{19}$$

We prefer to proceed with the aid of multidimensional matrices[9] as being the most natural way. However, a possibility of using traditional two-dimensional matrices also exists.[5]

Indeed, introducing here a four-dimensional matrix $\mathbf{T}$ with the elements

$$T_{jkpq}=(-1)^{(p-j)+(q-k)}\binom{j}{q-k}\binom{k}{p-j}\lambda^j\mu^k$$

(it can also be viewed as an ordinary matrix on the space of index pairs) we basically return to the familiar transfer-matrix construction but for more complex objects. Namely, we shall operate with a two-dimensional matrix $\mathbf{X}$, defined as a direct product of vectors $|\mathbf{u}\rangle$ and $|\mathbf{v}\rangle$:

$$X_{jk}=u^j v^k.$$

Here the matrix $\mathbf{X}$ plays the same role as the vector $|\mathbf{y}\rangle$ in Sec. III. The four-dimensional matrix $\mathbf{T}$ is analogous to its two-dimensional relative $\mathbf{T}$. The multiplication of such matrices is defined rather naturally:

$$\mathbf{X}_1\mathbf{X}_2=\sum_{p,q}(X_1)_{pq}(X_2)_{pq},\quad (\mathbf{TX})_{jk}=\sum_{p,q}T_{jkpq}X_{pq},\quad (\mathbf{T}_1\mathbf{T}_2)_{jkpq}=\sum_{rs}(T_1)_{jkrs}(T_2)_{rspq}.$$

Note that the matrix analog of the scalar product of vectors is just a contraction, $\mathbf{X}_1\mathbf{X}_2$, in the tensor algebra nomenclature.

As in Sec. X, one can obtain the solution of the system in the form

$$u_n=\mathbf{E}_1\mathbf{T}^n\mathbf{X},\quad v_n=\mathbf{E}_2\mathbf{T}^n\mathbf{X},$$

where, as usual,

$$(\mathbf{E}_1)_{jk}=\delta_{1j}\delta_{0k},\quad (\mathbf{E}_2)_{jk}=\delta_{0j}\delta_{1k}.$$

Further generalization of this approach is also rather simple. In the general case of m first-order nonlinear equations

$$x_{n+1}^{(i)}=P_i(x_n^{(1)},\ldots,x_n^{(m)}),\quad i=1,\ldots,m, \tag{20}$$

one has to consider the $2m$-dimensional transfer matrix $\mathbf{T}$. To construct it we are checking as before the product

$$P_{j_1,\ldots,j_m}\equiv P_1^{j_1}\cdots P_m^{j_m},$$

and the m-dimensional matrix $\mathbf{X}$, defined as a direct product of m vectors of initial values $|\mathbf{x}^{(1)}\rangle,\ldots,|\mathbf{x}^{(m)}\rangle$.

The polynomial $P_{j_1,\ldots,j_m}$ depends on m variables $x^{(1)},\ldots,x^{(m)}$ and therefore can be represented as

$$P_{(j_1,\ldots,j_m)}(x^{(1)},\ldots,x^{(m)})=\mathbf{T}_{(j_1,\ldots,j_m)}\mathbf{X},$$

where $\mathbf{T}_{j_1,\ldots,j_m}$ is a constant multidimensional matrix of coefficients of the polynomial $P_{j_1\ldots,j_m}$. This matrix $\mathbf{T}_{j_1,\ldots,j_m}$ is the $(j_1,\ldots,j_m)$-th m-section of the transfer matrix $\mathbf{T}$.

Then defining the matrix $\mathbf{E}_i$ by

$$(\mathbf{E}_i)_{j_1,\ldots,j_i,\ldots,j_m}=\delta_{0j_1}\ldots\delta_{1j_i}\ldots\delta_{0j_m}$$

one can write down the solution of the system in the form

$$x_n^{(i)} = \mathbf{E}_i \mathbf{T}^n \mathbf{X}.$$

XI. SYSTEM OF NONLINEAR HIGHER-ORDER RECURSIONS

We are not going to write down even the simplest example, but the scheme is quite obvious: introduction of new variables to bring each equation to the first-order structure and, then, construction of a transfer matrix (as in the two previous sections).

XII. CONTINUOUS ANALOG OF THE TRANSFER MATRIX

In this section we present a continuous generalization of our transfer matrix technique. We consider the general case, the multivariable function, $f:\mathbf{R}^n \to \mathbf{R}^n$. We do not try to establish the exact conditions for existence of all the functions involved, but merely describe the algorithm.

Let

$$F_{x\to s}[\varphi(\mathbf{x},\mathbf{t})] = (2\pi)^{-n} \int_{\mathbf{R}^n} \exp(-i\langle \mathbf{x},\mathbf{s}\rangle)\varphi(\mathbf{x},\mathbf{t})d\mathbf{x},$$

where $\langle \mathbf{x},\mathbf{s}\rangle$ is the scalar product of two real vectors $\mathbf{x}$ and $\mathbf{s}$, be the Fourier transform of the function $\varphi:\mathbf{R}^{2n}\to\mathbf{C}$, $\mathbf{s},\mathbf{x},\mathbf{t}\in\mathbf{R}^n$ and $F_{s\to x}^{-1}$ be the corresponding inverse Fourier transform.[10] Then, we define the transfer kernel of the function $f:\mathbf{R}^n\to\mathbf{R}^n$ as Fourier transform $T(\mathbf{t},\mathbf{s}) = F_{x\to s}\exp[i\langle f(\mathbf{x}),\mathbf{t}\rangle]$.

For example, let us consider the logistic map, $f(x)=\lambda x(1-x)$. Then the transfer kernel is the function[11]

$$T(t,s) = \int_{-\infty}^{\infty} \exp[-ixs + it\lambda x(1-x)]dx = \sqrt{\frac{\pi}{t\lambda}} \exp\left[-\frac{i\pi}{4} + \frac{i(t\lambda - s)^2}{4t\lambda}\right].$$

We define the product of the transfer kernels $S(\mathbf{t},\mathbf{s})$ and $T(\mathbf{t},\mathbf{s})$ of the functions $g(\mathbf{x})$ and $f(\mathbf{x})$ by

$$S\odot T(\mathbf{t},\mathbf{s}) \overset{\text{def}}{=} \int_{\mathbf{R}^n} S(\mathbf{t},\tau)T(\tau,\mathbf{s})d\tau.$$

Theorem: The product, $S\odot T(\mathbf{t},\mathbf{s})$, of the transfer kernels $S(\mathbf{t},\mathbf{s})$ and $T(\mathbf{t},\mathbf{s})$ is the transfer kernel of the composition $g\circ f(\mathbf{x})$, where $g\circ f(\mathbf{x})\equiv g(f(\mathbf{x}))$.

Indeed, performing the inverse Fourier transform for the function $S\odot T(\mathbf{t},\mathbf{s})$ one gets

$$F_{s\to x}^{-1}[S\odot T(\mathbf{t},\mathbf{s})] = \int_{\mathbf{R}^n} S(\mathbf{t},\tau)F_{s\to x}^{-1}[T(\tau,\mathbf{s})]d\tau = \int_{\mathbf{R}^n} S(\mathbf{t},\tau)\exp[i\langle f(\mathbf{x}),\tau\rangle]d\tau$$
$$= F_{\tau\to f(\mathbf{x})}^{-1}[S(\mathbf{t},\tau)] = \exp[i\langle g\circ f(\mathbf{x}),t\rangle].$$

One can see that the product of the transfer kernels is defined in analogy to the matrix product and we can obtain the solution of the recursion (see Sec. III) in the form

$$y_n^{(j)} = -\ln\{F_{s\to y}^{-1}[\mathbf{T}^n(\mathbf{t},\mathbf{s})]\big|_{\mathbf{t}=i\mathbf{e}_j}\}$$

where $\mathbf{e}_j = \{\delta_{jk}\}_{k=1}^n$.

XIII. SUMMARY

In this paper we have presented a new method to obtain the solution of arbitrary polynomial recursions. The method has been generalized to systems of multivariable recursions and recursions of arbitrary order, in analogy to the solution of linear recursions, also presented in this paper.

Generally, the solution is obtained in the form of a matrix power, applied to the vectors of initial values. We have presented a way to construct such a matrix.

Famous and important examples, such as the logistic map and the Riccati recursion, have been considered and the corresponding matrices have been written down explicitly.

We also generalized the method in another direction. It is shown that instead of transfer matrix one can use transfer kernel which can be considered as a continuous matrix.[12]

While the investigation of the solutions found is beyond the scope of the paper this challenging task deserves a few words. For example, the logistic map solution (2) can be used to construct a generating function.[4] Unfortunately, this latter may have an essential singularity. Therefore, it is more natural to construct an exponential generating function $\phi(z) \equiv \Sigma_n^{\infty}(1/n!) y_n z^n = \langle \mathbf{e} | \exp(z\mathbf{T}) | \mathbf{y} \rangle$. Then, one can try to understand the parametric dependence of the logistic map asymptotics from a steepest descent of the Cauchy integral

$$y_n = \frac{1}{2\pi i} \oint_{C_0} \frac{\phi(z)}{z^{n+1}}\, dz,$$

where the contour C_0 includes the origin of coordinates.

I. INTRODUCTION

The notion of a generalized spectral decomposition of self-adjoint operators on a Hilbert space goes back to Dirac,[1] who assumed that a given self-adjoint operator A must be of the form

$$A=\int_{\sigma(A)} d\lambda\ \lambda|\lambda)(\lambda|, \tag{1}$$

where $\sigma(A)$ is the spectrum of the operator A. This formula is a straightforward generalization of the familiar decomposition of a self-adjoint operator on a finite-dimensional Hilbert space

$$A=\sum_i \lambda_i|e_i)(e_i|, \tag{2}$$

where λ_i and e_i are the eigenvalues and eigenvectors of A, respectively. In infinite-dimensional Hilbert spaces, however, the situation is not so simple. The notion of an eigenvalue is replaced by the spectrum, but eigenvectors can be associated only with the discrete part of the spectrum. Nevertheless, a precise meaning can be given to the decomposition (1), if we replace eigenvectors by ''generalized eigenvectors,'' which will, in general, lie outside the given Hilbert space. This is achieved by replacing the initial Hilbert space $\mathscr{H}$ by a dual pair $(\Phi,\Phi^\times)$, where Φ is a locally convex space, which is a dense subspace of $\mathscr{H}$ endowed with a topology, stronger than the Hilbert space topology. This procedure is referred to as rigging and the triple

$$\Phi\subset\mathscr{H}\subset\Phi^\times \tag{3}$$

is called a *rigged Hilbert space* (see Refs. 2–5 for details). Gelfand[3,4] was the first to give a precise meaning to the generalized eigenvectors, which was later elaborated by Maurin.[5] Although generalized eigenvectors have a very natural physical interpretation, generalized spectral decompositions have not been used in physics for a long time. Only a few papers had appeared by the end of the 1960s (see, for example, Refs. 6–8), followed by a series of papers by Bohm and Gadella (see Ref. 2 and references therein). The latter publications are particularly significant, because they provide the basis for a rigorous and systematic approach to the problems of irreversibility and resonances in unstable quantum systems like the Friedrichs model.[9] The same ideas can be extended to chaotic dynamical systems, like Kolmogorov systems or exact systems.[10,11] The observable phase functions of dynamical systems evolve according to the Koopman operator[10]

$$Vf(x)=f(Sx),$$

where S is an endomorphism or an automorphism of a measure space, and f is a square-integrable phase function.

The spectrum of the Koopman operator determines the time scales of the approach to equilibrium very much in analogy with quantum unstable systems, where the spectra of the Hamiltonians determine the decay rates. More precisely, the eigenvalues of the Koopman operator or that of its adjoint, known as the Frobenius–Perron operator, are the resonances of the power spectrum.[12–15] Eigenvalues and eigenvectors of simple chaotic systems have recently been constructed by several authors.[16–24]

The question of the existence of a generalized spectral decomposition of extensions of the Koopman operator was raised and resolved by Antoniou and Tasaki.[17–19] This issue is delicate, because the original Gelfand–Maurin theory was constructed for operators which admit a spectral theorem,[25] like normal operators, giving a generalized spectrum identical with the Hilbert space spectrum. The Koopman operator of unstable systems, however, either does not admit a spectral theorem, as in the case of exact systems,[18] or the generalized spectrum is very different from the Hilbert space spectrum, as in the case of Kolmogorov systems.[19] The original Gelfand–Maurin theory had to be extended[17–19] to arbitrary dual pairs $(\Phi,\Phi^{\times})$ of linear topological spaces.

Summarizing for the reader's convenience, a dual pair $(\Phi,\Phi^{\times})$ of linear topological spaces constitutes a rigged Hilbert space for the linear endomorphism V of the Hilbert space $\mathscr{H}$ if the following conditions are satisfied:

(1) Φ is a dense subspace of $\mathscr{H}$.
(2) Φ is complete and its topology is stronger than the one induced by $\mathscr{H}$.
(3) Φ is stable with respect to the adjoint $V^{\dagger}$ of V, i.e., $V^{\dagger}\Phi\subset\Phi$.
(4) The adjoint $V^{\dagger}$ is continuous on Φ

The extension V_{ext} of V to the dual $\Phi^{\times}$ of Φ is then defined in the standard way as follows:

$$(\phi|V_{\text{ext}}f)=(V^{\dagger}\phi|f),$$

for every $\phi\in\Phi$.

In the sequel we shall not distinguish between V and V_{ext} if confusion is unlikely to arise.

The choice of the test function space Φ depends on the specific operator V and on the physically relevant questions to be asked about the system. For self-adjoint operators V, for example, the generalized spectral theorem can be justified for nuclear test function spaces; for normal operators this condition may be relaxed.[26,27]

Here, we shall discuss the problem of rigging for the generalized spectral decompositions of the Koopman operators for two specific but typical models of chaotic systems, namely, the Renyi maps and the baker maps.

In the case of the Renyi map various riggings exist[28] and our task will be to choose a tight rigging within spaces of analytic test functions. We call a rigging ''tight'' if the test function space

is the (set theoretically) largest possible within a chosen family of test function spaces, such that the physically relevant spectral decomposition is meaningful. This notion of tightness is more general than that of Fredricks.[7] It turns out that the topology of this rigged Hilbert space enjoys some of the properties of a strict inductive limit of Banach spaces, which greatly simplifies convergence arguments.

The construction of the rigged Hilbert space for the baker map, on the other hand, reveals a different aspect of the problem of rigging. In fact, here the problem is to understand the very nature of the rigging, since the test function space is the tensor product of the space of polynomials with the space of square-integrable functions corresponding to the expanding and contracting fibers. Our task will be to investigate the properties of this rigged Hilbert space.

II. RIGGED HILBERT SPACES FOR THE RENYI MAPS

In this section we discuss the rigged Hilbert spaces for the Koopman operator of the general β-adic Renyi map.

The β-adic Renyi map S on the interval $[0,1)$ is the multiplication, modulo 1, by the integer $\beta \geqslant 2$

$$S:[0,1)\to[0,1): \quad x\mapsto Sx=\beta x(\mathrm{mod}\ 1).$$

The probability densities $\rho(x)$ evolve according to the Frobenius–Perron operator U (Ref. 11):

$$U\rho(x)\equiv \sum_{y,S(y)=x} \frac{1}{|S'(y)|}\,\rho(y)=\frac{1}{\beta}\sum_{r=0}^{\beta-1}\rho\left(\frac{x+r}{\beta}\right).$$

The Frobenius–Perron operator is a partial isometry on the Hilbert space L^2 of all square integrable functions over the unit interval; it is, moreover, the dual of the isometric Koopman operator V:

$$V\rho(x)=U^{\dagger}\rho(x)=\rho(Sx).$$

In Ref. 18 two of us (I.A. and S.T.) constructed a spectral decomposition of the Koopman operator using a general algorithm based on the subdynamics decompositions. The Koopman operator can be expressed as follows:

$$V=\sum_{n=0}^{\infty} \frac{1}{\beta^n}\,|\widetilde{B}_n)(B_n|, \tag{4}$$

where $B_n(x)$ is the nth-degree Bernoulli polynomial defined by the generating function (Ref. 29, §9)

$$\frac{ze^{zx}}{e^z-1}=\sum_{n=0}^{\infty}\frac{B_n(x)}{n!}\,z^n$$

and

$$|\widetilde{B}_n)=\begin{cases} |1), & n=0,\\ \dfrac{(-1)^{(n-1)}}{n!}\{\delta^{(n-1)}(x-1)-\delta^{(n-1)}(x)\}), & n=1,2,\ldots . \end{cases}$$

The bras $(\cdot|$ and kets $|\cdot)$ denote linear and antilinear functionals, respectively. Formula (4) defines a spectral decomposition for the Koopman and Frobenius–Perron operators in the following sense:

$$(\rho|Vf)=(U\rho|f)=\sum_{n=0}^{\infty}\frac{1}{\beta^n}(\rho|\widetilde{B}_n)(B_n|f),$$

for any density function ρ and observable f in the appropriate pair (Φ,Φ^x). Consequently, the Frobenius–Perron operator acts on density functions as

$$U\rho(x)=\int_0^1 dx'\ \rho(x')+\sum_{n=1}^{\infty}\frac{\rho^{(n-1)}(1)-\rho^{(n-1)}(0)}{n!\beta^n}B_n(x).$$

The orthonormality of the system $|\widetilde{B}_n)$ and $(B_n|$ follows immediately, while the completeness relation is just the Euler–MacLaurin summation formula for the Bernoulli polynomials (Ref. 29, §9)

$$\rho(x)=\int_0^1 dx'\ \rho(x')+\sum_{n=1}^{\infty}\frac{\rho^{(n-1)}(1)-\rho^{(n-1)}(0)}{n!}B_n(x). \tag{5}$$

The Bernoulli polynomials are the only polynomial eigenfunctions as any polynomial can be uniquely expressed as a linear combination of the Bernoulli polynomials.

The spectral decomposition (4) has no meaning in the Hilbert space L^2, as the derivatives $\delta^{(n)}(x)$ of Dirac's delta function appear as right eigenvectors of V. A natural way to give meaning to formal eigenvectors of operators which do not admit eigenvectors in Hilbert space is to extend the operator to a suitable rigged Hilbert space. A suitable test function space is the space $\mathscr{P}$ of polynomials. The space $\mathscr{P}$ fulfills the following conditions:

(i) $\mathscr{P}$ is dense in L^2 (see Ref. 30, ch. 15),
(ii) $\mathscr{P}$ is a nuclear LF-space (Ref. 30, ch. 51) and thus, complete and barreled,
(iii) $\mathscr{P}$ is stable with respect to the Frobenius–Perron operator U, and
(iv) U is continuous with respect to the topology of $\mathscr{P}$, because U preserves the degree of polynomials.

It is, therefore, an appropriate rigged Hilbert space, which gives meaning to the spectral decomposition of V.

We shall, however, look for a tight rigging. The test functions should at least provide a domain for the Euler–MacLaurin summation formula (5). The requirement of absolute convergence of the series (5) means that

$$\sum_{n=1}^{\infty}\left|\frac{\phi^{(n-1)}(y)}{n!}B_n(x)\right|<\infty\quad(y=0,1).$$

This implies[18] that the appropriate test functions are restrictions on $[0,1)$ of entire functions of exponential type c with $0<c<2\pi$. For simplicity we identify the test functions space with the space $\mathscr{E}_c$ of entire functions $\phi(z)$ of exponential type $c>0$ such that

$$|\phi(z)|\leqslant Ke^{c|z|},\quad \forall z\in\mathbb{C},\quad \text{for some } K>0.$$

Each member of the whole family $\mathscr{E}_c$, $0<c<2\pi$, is a suitable test function space, since properties (1)–(4) are fulfilled. Indeed, each space $\mathscr{E}_c$ is a Banach space with norm (Ref. 30, ch. 22):

$$\|\phi\|_c\equiv\sup_{z\in\mathbb{C}}|\phi(z)|e^{-c|z|},$$

which is dense in the Hilbert space L^2, as $\mathscr{E}_c$ includes the polynomial space $\mathscr{P}$. Each $\mathscr{E}_c$ is stable under the Frobenius–Perron operator U, and it is easily verified that U is continuous on $\mathscr{E}_c$. Now, observe that the spaces are ordered

$$\mathscr{E}_c \subset \mathscr{E}_{c'}, \quad c<c',$$

and consider the space

$$\tilde{\mathscr{E}}_{2\pi} \equiv \bigcup_{c<2\pi} \mathscr{E}_c.$$

The space $\tilde{\mathscr{E}}_{2\pi}$, also preserved by U, is the (set theoretically) largest test function space in our case. Since $\tilde{\mathscr{E}}_{2\pi}$ is a natural generalization of the space $\mathscr{P}$ of polynomials, we want to equip it with a topology which is a generalization of the topology of $\mathscr{P}$.

Recall that $\mathscr{P}$ was given the strict inductive limit topology of the spaces $\mathscr{P}^n$ of all polynomials of degree $\leqslant n$. A very important property of this topology is that the strict inductive limit of complete spaces is complete. Moreover, it is exceptionally simple to describe convergence in this topology. For example, a sequence $\{w_n\}$ of polynomials converges in $\mathscr{P}$ if and only if the degrees of all w_n are uniformly bounded by some n_0 and $\{w_n\}$ converges in $\mathscr{P}^{n_0}$.

We cannot, however, define the strict inductive topology on $\tilde{\mathscr{E}}_{2\pi}$ because for $c<c'$ the topology on $\mathscr{E}_c$ induced by $\mathscr{E}_{c'}$ is essentially stronger than the initial one. Nevertheless, as we shall see in the theorem below, it is possible to define a topology on $\tilde{\mathscr{E}}_{2\pi}$, which is a natural extension of the topology on $\mathscr{P}$ in the following sense.

Theorem 1: There is a locally convex topology $\mathscr{T}$ on $\tilde{\mathscr{E}}_{2\pi}$ for which it is a nuclear, complete Montel space. Moreover, a sequence $\{f_n\} \subset \tilde{\mathscr{E}}_{2\pi}$ is convergent in the $\mathscr{T}$ topology if and only if there is $c_0 \in (0,2\pi)$ such that 1° f_n, $n=1,2,...$, are of exponential type c_0 and 2° $\{f_n\}$ converges in $\|\cdot\|_{c_0}$-norm.

Proof: Denote by $\hat{f}$ the Fourier transform of a function f and by $\check{f}$ its converse. By Schwartz's extension of the Paley–Wiener theorem (Ref. 31, vol. II, p. 106) a function f belongs to $\mathscr{E}_c$ if and only if $\hat{f}$ is a distribution with compact support contained in the interval $[-c, c]$.

Note that, if the function $f \in \tilde{\mathscr{E}}_{2\pi}$ is integrable or square integrable, then $\hat{f}$ is a function. However, for an arbitrary function its Fourier transform is correctly defined only as a distribution with compact support, i.e., as a continuous linear functional on the space $C^\infty(\Omega)$ of all infinitely differentiable functions on the interval $\Omega=(-2\pi, 2\pi)$, endowed with the topology of uniform convergence on compact subsets of Ω of functions together with all their derivatives.

The Fourier transform, therefore, establishes an isomorphism between $\tilde{\mathscr{E}}_{2\pi}$ and the topological dual $C^\infty(\Omega)^x$ of the space $C^\infty(\Omega)$. Consequently, the strong dual topology of $C^\infty(\Omega)^x$ can be transported through the inverse Fourier transform to the space $\tilde{\mathscr{E}}_{2\pi}$. The strong dual topology is the topology of uniform convergence on bounded subsets of $C^\infty(\Omega)$. Then $C^\infty(\Omega)^x$ is nuclear (Ref. 30, p. 530), complete (Ref. 31, vol I, p. 89), and a Montel space (Ref. 30, prop. 34.4 and 36.10). In this way we obtain on $\tilde{\mathscr{E}}_{2\pi}$ a topology with the same properties.

We shall now prove the second part of the theorem. Let $\{f_n\}$ be convergent to zero in $\tilde{\mathscr{E}}_{2\pi}$. This means that $\{\check{f}_n\}$ converges in $C^\infty(\Omega)^x$. Therefore $\{\check{f}_n\}$ is a bounded subset of $C^\infty(\Omega)^x$, which implies (Ref. 30, th. 34.4, p. 359) that the supports of all f_n are contained in a compact set $K \subset \Omega$.

Take c with $c<2\pi$ and $K \subset (-c,c)$. Therefore [see Ref. 31, vol. I, th. XXVI and the remark afterwards which remains true if we replace $\mathbb{R}^1$ by the open set $\Omega=(-2\pi,2\pi)$], there is a number $p \geqslant 0$ and a family of continuous functions $g_{j,n}$ such that the supports of $g_{j,n}$ are contained in the interval $(-c,c)$,

$$\check{f}_n = \sum_{j \leqslant p} D^j g_{j,n}$$

(D^j denotes the jth derivative, classical or in the sense of distributions) and $g_{j,n}(x)$ converges uniformly to zero as $n\to\infty$.

Using the above representation of $\check{f}_n$ we obtain that $\check{f}_n$ converges to zero uniformly on each set U_A:

$$U_A\equiv\left\{ f\in C^\infty(\Omega):\ \sup_{x\in[-c,c]}\left|\frac{d^j}{dx_j}f(x)\right|\leqslant A,\quad j=0,1,\ldots,p\right\},$$

where $A>0$. Indeed, for each j

$$|\langle D^j g_{j,n},f\rangle|=\left|(-1)^j\int_{-c}^{c}g_{j,n}(x)\,\frac{d^j}{dx_j}f(x)dx\right|$$

$$\leqslant A\int_{-c}^{c}|g_{j,n}(x)|dx\to 0,$$

as $n\to\infty$.

Let us take any $c_0\in(c,2\pi)$. Then for each $z\in\mathbb{C}$ the function

$$x\mapsto e^{izx}e^{-c_0|z|},\quad |x|\leqslant c, \tag{6}$$

belongs to U_A. Indeed

$$\left|\frac{d^j}{dx_j}\left(e^{izx}e^{-c_0|z|}\right)\right|\leqslant|z|^j e^{|z|(|x|-c_0)}=|z|^j e^{|z|(|x|-c)}e^{-(c_0-c)|z|}$$

$$\leqslant|z|^j e^{-(c_0-c)|z|}.$$

The right-hand side is bounded, for each $j=0,1,\ldots,p$, by some constant A_j. Thus taking $A=\max_{0\leqslant j\leqslant p}A_j$ we see that the functions (6) belong to U_A, for each $z\in\mathbb{C}$.

From

$$f_n(z)=(\check{f}_n)\hat{}\,(z)$$

and uniform convergence of $\check{f}_n$ on U_A we have

$$\sup_{z\in\mathbb{C}}|f_n(z)|e^{-c_0|z|}=\sup_{z\in\mathbb{C}}|\langle\,\check{f}_n,e^{iz}e^{-c_0|z|}\rangle|\to 0,$$

as $n\to\infty$, which means that $\|f_n\|_{c_0}\to 0$. This proves 2°. Condition 1° is also satisfied because we have chosen $c_0>c$. Thus, the supports of the $\check{f}_n$s are also contained in $(-c_0,c_0)$ and by the Paley–Wiener–Schwartz theorem the f_ns are of exponential type c_0.

The converse of the second part of the theorem is now trivial. If $\{f_n\}$ satisfies 1° and 2°, then by applying the Paley–Wiener–Schwartz theorem again we obtain convergence of $\{\check{f}_n\}$ in $C^\infty(\Omega)^x$.

Remark 1: Using the above method one can show an analogous criterion of convergence for bounded nets in $\tilde{\mathscr{E}}_{2\pi}$ but not for an arbitrary net.

Remark 2: Note that it is not always possible to obtain convergence of the type given in the above theorem. Actually, to prove the second part of the theorem we needed the following property:

Let F be a Frechet space and let $\{x_n'\}$ be a sequence in its dual F' which converges to zero in the strong dual topology. Then there exists an open subset U of F such that

$$|\langle x_n', x\rangle| \to 0, \quad \text{uniformly for } x \in U. \tag{7}$$

As mentioned in Ref. 32, some concrete F-spaces have this property although it is not true in general. It was stated there as an open problem to describe those F-spaces for which (7) is true. This situation motivated us to include the full proof.

Remark 3: An alternative but less constructive proof of the theorem can be found in Ref. 28. It is based on a theorem by Raikov[33] and the nuclearity of the imbedding

$$\mathscr{E}_c \hookrightarrow \mathscr{E}_{c'}, \quad c < c'.$$

III. THE RIGGED HILBERT SPACE FOR THE BAKER TRANSFORMATIONS

The β-adic, $\beta = 2,3,...$, baker's transformation B on the unit square $[0, 1)\times[0, 1)$ is a two-step operation: (1) squeeze the 1×1 square to a $\beta\times 1/\beta$ rectangle and (2) cut the rectangle into β $(1\times 1/\beta)$ rectangles and pile them up to form another 1×1 square:

$$(x,y) \mapsto B(x,y) = \left(\beta x - r, \frac{y+r}{\beta}\right), \quad \text{for } \frac{r}{\beta} \leqslant x < \frac{r+1}{\beta}, \quad r = 0,\ldots,\beta-1.$$

The invariant measure of the β-adic baker transformation is the Lebesgue measure on the unit square. The probability densities $\rho(x,y)$ evolve according to the Frobenius–Perron operator U (Ref. 11):

$$U\rho(x,y) \equiv \rho(B^{-1}(x,y)) = \rho\left(\frac{x+r}{\beta}, \beta y - r\right), \quad \text{for } \frac{r}{\beta} \leqslant y < \frac{r+1}{\beta}, \quad r = 0,\ldots,\beta-1.$$

The Frobenius–Perron and Koopman operators are unitary on the Hilbert space $L^2_{x,y}$ of square integrable functions over the unit square and has a countably degenerate Lebesgue spectrum on the unit circle plus the simple eigenvalue 1 associated with the equilibrium (as is the case for all Kolmogorov automorphisms).

The β-adic baker automorphism B is the natural extension[34] of the β-adic Renyi map on the unit interval $[0, 1)$, described in the previous section.

It was shown in Ref. 19 that the Koopman operator V has a spectral decomposition involving Jordan blocks

$$V = |\tilde{f}_{00})(f_{00}| + \sum_{\nu=1}^{\infty} \left\{ \sum_{r=0}^{\nu} \frac{1}{\beta^\nu} |\tilde{f}_{\nu,r})(f_{\nu,r}| + \sum_{r=0}^{\nu-1} |\tilde{f}_{\nu,r+1})(f_{\nu,r}| \right\}. \tag{8}$$

The vectors $f_{\nu,j}$ and $\tilde{f}_{\nu,j}$ are linear functionals over the spaces $L^2_x \otimes \mathscr{P}_y$ and $\mathscr{P}_x \otimes L^2_y$, respectively, with well-defined inner product $(f_{\nu,r}|\tilde{f}_{\nu',r'}) = \delta_{\nu\nu'}\delta_{rr'}$, and $\Sigma_{\nu=0}^{\infty}\Sigma_{r=0}^{\nu}|\tilde{f}_{\nu,r})(f_{\nu,r}| = I$. Moreover,

$$(f_{\nu,r}|V = \begin{cases} \frac{1}{\beta^\nu}((f_{\nu,r}| + (f_{\nu,r+1}|), & r = 0,\ldots,\nu-1, \\ \frac{1}{\beta^\nu} f_{\nu,r}, & r = \nu, \end{cases}$$

$$V|\tilde{f})_{\nu,r} = \left\{ \frac{1}{\beta^\nu}(|\tilde{f}_{\nu,r}) + |\tilde{f}_{\nu,r-1})), \quad r = 1,\ldots,\nu, \right.$$

$$\left. \frac{1}{\beta^\nu} \tilde{f}_{\nu,r}, \quad r = 0. \right.$$

While the Koopman operator V is unitary in the Hilbert space $L^2_{x,y}$ and thus has spectrum on the unit circle $|z|=1$ in the complex plane, the spectral decomposition (8) includes the numbers $1/\beta^{\nu}<1$ which are not in the Hilbert space spectrum. The spectral decomposition (8) also shows that the Frobenius–Perron operator has Jordan-block parts despite the fact that it is diagonalizable in the Hilbert space. As both $f_{\nu,j}$ and $\tilde{f}_{\nu,j}$ contain distributions, the spectral decomposition (8) has no meaning in the Hilbert space $L^2_{x,y}$ but only on the subspaces $L^2_x \otimes \mathscr{P}_y$ and $\mathscr{P}_x \otimes L^2_y$. Therefore, our purpose is to define an appropriate topology on these spaces. We shall give the construction for $\mathscr{P}_x \otimes L^2_y$ only; a similar argument applies to $L^2_x \otimes \mathscr{P}_y$.

We will start from the most natural, i.e., the strict inductive limit topology, which coincides with other, apparently stronger, tensor product topologies.

Let us consider the space $\mathscr{P}\otimes L^2$ (for simplicity we omit the subscripts x and y), where $\mathscr{P}$ is the space of all polynomials w of finite degree:

$$w=\sum_{k=0}^{n} a_k x^k, \tag{9}$$

L^2_y is the space of all square integrable functions on the space $Y=[0, 1]$.

Let $\mathscr{P}^n$ be the space of all polynomials of degree $\leqslant n$. For a w of the form (9),

$$\|w\|_n = \max_{0\leqslant k\leqslant n} |a_k|$$

defines a norm on $\mathscr{P}^n$. Then $\mathscr{P}$ is defined as the union $\cup_n \mathscr{P}^n$ with the strict inductive limit topology (Ref. 30, sec. 13).

Similarly $\mathscr{P}\otimes L^2$ was defined in Ref. 19 as the strict inductive limit of the spaces $\mathscr{P}^n \otimes L^2$ endowed with the topology τ, generated by the norms

$$\left\| \sum_{k=1}^{n} x^k \otimes \phi_k \right\|_n = \max_{0\leqslant k\leqslant n} \|\phi\|_{L^2}. \tag{10}$$

It is very easy to see that $(\cup_n \mathscr{P}^n)\otimes L^2 = \cup_n (\mathscr{P}^n \otimes L^2)$. Thus, we have, *algebraically*,

$$\mathscr{P}\otimes L^2 = (\varinjlim \mathscr{P}^n)\otimes L^2 = \varinjlim (\mathscr{P}^n \otimes L^2),$$

and, as we will see below, also topologically.

In fact, it will be shown that the τ-topology defined by the seminorms (10) is also, roughly speaking, the only natural locally convex tensor product topology on the space $\mathscr{P}\otimes L^2$.

This will be done in three steps:

(1) τ is a cross-seminorm topology, i.e., the tensor product seminorm (10) is a cross-norm[35] when restricted to the Banach spaces $\mathscr{P}^n$ and L^2. Indeed, for $w\in\mathscr{P}^n$, $f\in L^2$,

$$\begin{aligned}\|w\otimes f\|_n &= \left\| \sum_{k=1}^{n} a_k x^k \otimes f \right\|_n = \left\| \sum_{k=1}^{n} x^k \otimes (a_k f) \right\|_n \\ &= \max_{0\leqslant k\leqslant n} \|a_k f\|_{L^2} = \max_{0\leqslant k\leqslant n} |a_k| \|f\|_{L^2} \\ &= \|w\|_n \|f\|_{L^2}.\end{aligned}$$

(2) The τ-topology is weaker than the projective topology (shortly π-topology) on the tensor product $\mathscr{P}\otimes L^2$ (see Ref. 30, sec. 43, for the definition). Indeed, consider an element $\tilde{f}=\Sigma_{i=1}^{N} w_i\otimes f_i$ of the space $\mathscr{P}\otimes L^2$ and let n be the maximal degree of $w_i, i=1,\ldots,N$. Then we can write $w_i=\Sigma_{k=0}^{N} a_k^{(i)}x^k$, $i=1,\ldots,N$ (some $a_k^{(i)}$ can be zero). Therefore

$$\begin{aligned}\tilde{f}&=\left\|\sum_{i=1}^{N} w_i\otimes f_i\right\|_n=\left\|\sum_{i=1}^{N}\left(\sum_{k=0}^{n} a_k^{(i)}x^k\right)\otimes f_i\right\|_n\\&=\left\|\sum_{k=0}^{n}\left(\sum_{i=1}^{N} a_k^{(i)}f_i\right)\otimes x^k\right\|_n\\&=\max_{0\leq k\leq n}\left\|\sum_{i=1}^{N} a_k^{(i)}f_i\right\|_{L^2}\leq\max_{0\leq k\leq n}\sum_{i=1}^{N}|a_k^{(i)}|\|f_i\|_{L^2}.\end{aligned}$$

Denote by R the right-hand side in the above inequalities and let k_0 be the index which realizes the maximum of R. Then

$$\begin{aligned}R&=\sum_{i=1}^{N}|a_{k_0}^{(i)}|\|f_i\|_{L^2}\leq\sum_{i=1}^{N}\max_{0\leq k\leq n}|a_k^{(i)}|\|f_i\|_{L^2}\\&=\sum_{i=1}^{N}\|w_i\|_n\|f_i\|_{L^2}.\end{aligned}$$

Therefore, we obtain the inequality

$$\|\tilde{f}\|_n\leq\sum_{i=1}^{N}\|w_i\|_n\|f_i\|_{L^2},$$

which does not depend on the particular representation of $\tilde{f}$. Thus $\|\tilde{f}\|_n\leq\|\tilde{f}\|_{\pi,n}$, where $\|\cdot\|_{\pi,n}$ denotes the π-seminorm corresponding to the seminorm $\|\cdot\|_n$ on $\mathscr{P}$ and $\|\cdot\|_{L^2}$.

(3) The τ-topology is stronger than the ε-topology (see Ref. 30, sec. 43 for the definition) on $\mathscr{P}\otimes L^2$. To see this let us first note that the space $\mathscr{P}$ with its topology can be identified with the space $C_c^0(X)$ of continuous functions on X with compact support (Ref. 30, p. 132), provided we take as the locally compact space the set $\mathbb{N}\cup\{0\}$ with the discrete topology. In such a case, functions with compact support are just sequences with at most finitely many nonzero elements and the family of seminorms is here precisely the same as that for $\mathscr{P}$ described above. Similarly, $\mathscr{P}\otimes L^2$ with the τ-topology can be identified with $C_c^0(X;L^2)$ which is a subspace of the space $C^0(X;L^2)$ of all continuous functions on X with values in L^2 (see Ref. 30, p. 412 for the definition of the topology).

On the other hand, $C_c^0(X;L^2)$ is topologically isomorphic with $C_c^o(X)\,\hat{\otimes}_\epsilon L^2$ ($\hat{}$ denotes completion). Since the topology induced by $C^0(X;L^2)$ on $C_c^0(X;L^2)$ is weaker than the τ-topology we obtain that *the ε-topology on $\mathscr{P}\otimes L^2$ is weaker than τ-topology.*

Therefore after completion we obtain

$$\mathscr{P}\hat{\otimes}_\pi L^2\subset\mathscr{P}\hat{\otimes}_\tau L^2\subset\mathscr{P}\hat{\otimes}_\epsilon L^2.$$

However, since $\mathscr{P}$ is a nuclear space we have (Ref. 30, th. 50.1)

$$\mathscr{P}\hat{\otimes}_e L^2\cong\mathscr{P}\hat{\otimes}_\pi L^2$$

($\cong$ denotes topological isomorphism). Because $\mathscr{P}\otimes L^2$ is already complete in the τ-topology[19] we obtain the following.

Theorem 2: The τ-topology on $\mathscr{P}\otimes L^2$ coincides with the ε and the π topology.

IV. CONCLUDING REMARKS

(1) We have characterized the natural rigged Hilbert spaces of analytic functions associated with the prototype of dynamical systems, namely the Renyi and the baker transformations. In the case of the Renyi map, we constructed a tight rigged Hilbert space $\tilde{\mathscr{E}}_{2\pi}$ within the spaces of analytic functions, which gives meaning to the simple resonance spectrum. We have shown that $\tilde{\mathscr{E}}_{2\pi}$ inherits the crucial properties of strict inductive limits of Banach spaces without being a strict inductive limit itself. For the baker maps we characterized the topology of the tensor product which gives meaning to the multiple resonance spectrum.

(2) We expect that these rigged Hilbert space topologies are typical for chaotic maps, if the evolution of analytic densities is considered. In the case of nonanalytic densities we may have test function spaces satisfying properties (1)–(4) with different extension properties.

ACKNOWLEDGMENTS

A structure theorem concerning projective quaternionic representations is stated and proved. A corollary to the structure theorem is then proved, answering a question recently posed by Adler. © *1996 American Institute of Physics.* [S0022-2488(96)01309-6]

I. INTRODUCTION

In a recent paper,[1] Adler builds on some of the material in his book,[2] specifically that which concerns general, multicentral and central quaternionic projective representations. He asks if a multicentral representation can be constructed that is not central or if it can be proved that a multicentral representation must always be central. For a given Lie group G, the answers to these questions depend on the connectedness of the group. If G is not connected, it is possible to construct a multicentral representation that is not central and we provide an example of such in this paper. Our main result, however, is to prove that if G is connected, then a multicentral representation must also be central. This is actually a corollary to a structure theorem that divides irreducible representations into three types according to the reality and commutativity of the projective phases.

II. USEFUL TERMS AND COMMON THEMES

For a general introduction to quaternions and their application to quantum mechanics, we refer the reader to Adler's book.[2]

The quaternions include both real and complex numbers, and by a suitable categorization the commutativity properties of the different types of quaternion can be concisely summarized. In this paper, we use the following categories in the proof of the structure theorem and of its corollary.

Definition 1: A real number has vanishing i, j, and k coefficients.

Definition 2: A complex number has vanishing j and k coefficients. It is the most general α-symplectic quaternion.

Definition 3: A strictly complex number has vanishing j and k coefficients but nonvanishing i coefficient.

Definition 4: A skew-complex number has vanishing 1 and i coefficients. It is a purely β-symplectic quaternion.

Definition 5: A strictly quaternionic number has nonvanishing β-symplectic part.

It should be noted that these definitions are dependent on the choice of i, j, and k, so the quaternionic basis must be specified before the above terms can be used.

Other useful quaternionic quantities are phases. A phase is a real, complex or quaternionic number that has unit norm, in other words it is an element of, respectively, $U(1,\mathbb{R})$, $U(1,\mathbb{C})$ or $U(1,\mathbb{H})$. A real phase must then be ± 1 while a complex phase can be parametrised as the familiar $\exp(i\theta)$.

The connectedness of G is crucial to the structure theorem and is used several times in the proof. Typically, we will deduce that, for each a in G, a certain quantity dependent on a must

0022-2488/96/37(11)/5848/10/$10.00

have one of two mutually exclusive ''disconnected'' properties, P or Q. We use disconnected to mean that it is impossible to have a smooth transition from P to Q. Since G is connected, either property P holds for all a or property Q holds for all a; there cannot be one region of G where P is satisfied and one where Q is since the regions' boundary would be a discontinuity. To determine which property holds for all a, it then suffices to test which property holds for some particular a, such as the multiplicative identity 1.

As a tool for applying the consequences of connectedness, it is useful to be able to perturb group elements by a small amount. If we perturb a group element a by a small amount, we write the new group element as $a\delta a$ where δa is a group element in some neighborhood of the identity; letting δa tend to 1 then defines a limiting process that generates elements tending to a.

III. THE STRUCTURE THEOREM AND ITS COROLLARY

Let G be a connected Lie group with identity element 1, and suppose that V is a quaternionic Hilbert space with a privileged set of (quaternionic) orthonormal basis elements $\{|f\rangle\}$. Let

$$U: G \to U(V, \mathscr{H})$$

be a smooth assignment from a group element a to a unitary right-linear operator U_a on V. We say that U is a projective quaternionic representation if $U_1 = 1$ and

$$\Omega(b,a) = U_{ba}^{-1} U_b U_a$$

is diagonal on the basis $\{|f\rangle\}$ for all group elements b and a, that is

$$\Omega(b,a) = \sum_f |f\rangle \omega(f,b,a) \langle f|$$

for some quaternionic phase $\omega(f,b,a)$ called the projective phase. The above definition of a representation is partially dependent on the choice of basis; a representation which is projective with respect to one basis need not be projective with respect to another. However, one can safely reray a basis

$$|f\rangle \mapsto |f\rangle \phi_f$$

$$\omega(f,b,a) \mapsto \overline{\phi_f} \omega(f,b,a) \phi_f,$$

where the ϕ_f are quaternionic phases, without changing the projective nature of the map U—this reraying affects the ω but not the Ω. Let us also make the technical assumption that U is irreducible, in the sense that there does not exist a partition of the basis elements into two sub-bases with respect to which the operators U_a are block-diagonal for all group elements a. A reducible representation can easily be expressed as the direct sum of irreducible ones, so this is not a severe restriction. There are three obvious ways to make such a representation. The first way is to start with a genuine representation (so that

$$U_{ba} = U_b U_a$$

for all b and a); this is, of course, automatically a quaternionic projective representation in any basis. We can modestly generalize this by requiring only that the representation be real-projective, that is, so that

$$U_{ba} = \pm U_b U_a.$$

A second way is to start with a complex projective representation on a complex space $V_{\mathbb{C}}$, so that one has complex operators $U_a^{\mathbb{C}}$ such that

$$U_{ba}^{\mathbb{C}}\omega(b,a)=U_b^{\mathbb{C}}U_a^{\mathbb{C}}$$

for some complex phase $\omega(b,a)$, and extend it to a projective quaternionic representation on $V_{\mathbb{C}} \oplus V_{\mathbb{C}}j$ in the canonical manner. The third way is to start with a real projective representation, $U_a^{\mathbb{R}}$ on a real space $V_{\mathbb{R}}$ and tensor product it with an otherwise arbitrary phase map

$$\sigma: G \to U(1,\mathbb{H})$$

to obtain a quaternionic projective representation on the quaternionic space $V_{\mathbb{R}} \otimes \mathbb{H}$. The following theorem states that these three methods are, up to a reraying, the only ways to create irreducible projective quaternionic representations.

Structure Theorem: *Let U be an irreducible projective representation of a connected Lie group G. There then exists a reraying of the basis $|f\rangle$ under which one of the following three possibilities must hold.*

(1) U is a real projective representation (type I). That is, $\omega(f,b,a)=\omega(b,a)$ is independent of $|f\rangle$ and is equal to ± 1 for each b and a.
(2) U is the extension of a complex projective representation (type II). That is, the matrix elements $\langle f|U_a|f'\rangle$ are complex and $\omega(f,b,a)=\omega(b,a)$ is independent of $|f\rangle$ and is a complex phase.
(3) U is the tensor product of a real projective representation and a quaternionic phase (type III). That is, there exists a decomposition

$$U_a = U_a^{\mathbb{R}} \sum_f |f\rangle \sigma_a \langle f|,$$

where the unitary operator $U_a^{\mathbb{R}}$ has real matrix elements, σ_a is a quaternionic phase and

$$U_{ba}^{\mathbb{R}} = \pm U_b^{\mathbb{R}} U_a^{\mathbb{R}}$$

for all b and a.

It should be noted that the three cases are not mutually exclusive; for example, a one-dimensional type I representation is a type III representation with real σ_a and a one-dimensional type II representation is a type III representation with complex σ_a.

We use this structure theorem to answer Adler's question. Let a multicentral projective representation be one in which $\Omega(b,a)$ commutes with U_b and U_a for all b and a, and let a central projective representation be one in which $\Omega(b,a)$ commutes with U_c for all a, b, and c. Our answer is then as follows.

Corollary 1: Any multicentral quaternionic projective representation of a connected Lie group is central.

The requirement that G is connected is not redundant, as shown in the following example. Set G to be the union of two copies of the quaternionic phase group $U(1,\mathbb{H})$ labeled by $+$ and $-$, respectively, with these labels combining under Z_2. Let U be the one-dimensional representation defined by $U_{a_+} = a$ and $U_{a_-} = 1$ for all $a \in U(1,\mathbb{H})$. The whole system is now a quaternionic projective representation of $Z_2 \times U(1,\mathbb{H})$, which is not connected, the operators multiplying according to Table I. By inspection, for each row $\Omega(b,a)$ commutes with U_a and with U_b, so the representation is multicentral, but $\Omega(b,a)$ does not generally commute with all U_c, so the representation is not central.

TABLE I. Representation for $Z_2 \times U(i,\mathscr{H})$.

a	b	ba	U_a	U_b	U_{ba}	$\Omega(b,a)$
a_+	b_+	ba_+	a	b	ba	1
a_+	b_-	ba_-	a	1	1	a
a_-	b_+	ba_-	1	b	1	b
a_-	b_-	ba_+	1	1	ba	ba

IV. PROOF OF THE STRUCTURE THEOREM

Following Adler's analysis,[1] we begin with the crucial observation that

Statement 1:

$$U_a^{-1}\Omega(b,c)U_a=\Omega(bc,a)^{-1}\Omega(b,ca)\Omega(c,a),$$

is unitary and diagonal for all a, b, and c.
We may therefore, write this unitary diagonal operator as

$$U_a^{-1}\Omega(b,c)U_a=\sum_f |f\rangle \nu(f,a,b,c)\langle f|, \tag{1}$$

where the ν are quaternionic phases that are formed from the ω,

$$\nu(f,a,b,c)=\omega(f,bc,a)^{-1}\omega(f,b,ca)\omega(f,c,a).$$

We multiply Eq. (1) on the left by U_a and take matrix elements to give

$$\omega(f,b,c)\langle f|U_a|f'\rangle=\langle f|U_a|f'\rangle \nu(f',a,b,c). \tag{2}$$

If the underlying algebra was commutative and the matrix elements of U_a were invertible, we could cancel the matrix elements and conclude that the ω were independent of f. Since the quaternions are not commutative, we can only expect to show that the conjugacy class of the ω is independent of f.

We shall use Eq. (2) for various values of f and f' to derive a relationship that involves the ω but not the ν. However, it is necessary to first ensure that the matrix elements of U_a are invertible for suitable a, $|f\rangle$ and $|f'\rangle$. This motivates the following.

Definition 6: We say that two basis states $|f_1\rangle$ and $|f_2\rangle$ are directly connected if there exists a basis state $|f_3\rangle$ (which may be equal to $|f_1\rangle$ or $|f_2\rangle$ or both) and a group element a such that $\langle f_1|U_a|f_3\rangle$ and $\langle f_2|U_a|f_3\rangle$ are both nonzero (and hence invertible).

The relationship of direct connectivity is symmetric but is not necessarily an equivalence relation. In order to form equivalence classes, we shall also define a completion of direct connectivity.

Definition 7: We say that two basis states $|f\rangle$ and $|f'\rangle$ are indirectly connected if there exists a non-negative integer n and a sequence of basis states $|f_0\rangle,\ldots,|f_n\rangle$ with $|f_0\rangle=|f\rangle$ and $|f_n\rangle=|f'\rangle$ such that $|f_i\rangle$ and $|f_{i+1}\rangle$ are directly connected for all $0\leqslant i<n$.

It can easily be verified that indirect connectivity is an equivalence relation. Note, that two states which are directly connected are automatically indirectly connected. This allows us to propose the following.

Proposition 1: All basis states are indirectly connected to each other.

Suppose this were not true. Then one can partition the basis states into two nonempty classes A and A' such that no state in A is directly connected to any state in A'. To do this, pick any basis state $|f_0\rangle$ and let A be the set of all states indirectly connected to $|f_0\rangle$; by the hypothesis that not

all states are indirectly connected, A and its complement A' are nonempty. Let V_A and $V_{A'}$ be the subspaces of V spanned by the states of A and those of A' respectively, so that $V = V_A \oplus V_{A'}$. Choose a basis state $|f\rangle$ from A and a group element a. Then the Hilbert space state $U_a|f\rangle$ can have components from states in A or components from states in A' but not both, since that would contradict the fact that A and A' are not directly connected. Since $|f\rangle$ is normalized and since U_a is unitary, $U_a|f\rangle$ is also normalized and hence lies either in the unit sphere of V_A or in the unit sphere of $V_{A'}$ for each a. When a is the multiplicative group identity 1, $U_a|f\rangle$ lies in (the unit sphere of) V_A; by the connectivity argument, $U_a|f\rangle$ lies in V_A for all a, and since $|f\rangle$ was an arbitrary basis state of A, this means that U maps V_A to V_A. Similarly it must map $V_{A'}$ to $V_{A'}$. Hence U is reducible, contradicting the assumptions of the theorem, and the proposition is proved.

Corollary 2: For any basis states $|f_1\rangle$ and $|f_2\rangle$ there exists a quaternionic phase $\phi(f_1, f_2)$ such that

$$\omega(f_2, b, c) = \phi(f_1, f_2)\omega(f_1, b, c)\overline{\phi(f_1, f_2)}, \tag{3}$$

for all b and c.

Since $|f_1\rangle$ and $|f_2\rangle$ are indirectly connected by the previous proposition, it is sufficient to prove this corollary for the case when the states are directly connected and then to use induction. (The claim is trivial when the states are the same.) We may thus assume the existence of a group element a and a state $|f_3\rangle$ such that $\langle f_1|U_a|f_3\rangle$ and $\langle f_2|U_a|f_3\rangle$ are invertible. Substituting f_1 for f and f_3 for f' and then f_2 for f and f_3 for f' in Eq. (2) and eliminating the ν dependence yields Eq. (3) with

$$\phi(f_1, f_2) = \frac{\langle f_2|U_a|f_3\rangle[\langle f_1|U_a|f_3\rangle]^{-1}}{|\langle f_2|U_a|f_3\rangle[\langle f_1|U_a|f_3\rangle]^{-1}|} = \overline{\phi(f_2, f_1)}.$$

Corollary 2 can now be used to simplify the problem as follows. Choose a fixed basis state $|f_0\rangle$; all other basis states may now be rerayed,

$$|f\rangle \mapsto |f\rangle\phi(f, f_0),$$

without changing the projective nature of the representation U. Under this reraying, Eq. (3) implies that

$$\omega(f, b, c) \mapsto \omega(f_0, b, c);$$

in other words, $\omega(f, b, c) = \omega(b, c)$ is independent of the basis state $|f\rangle$.

There are then three cases depending on the range of the ω. We list them here and then consider each in turn.

(1) The $\omega(b, c)$ are real for all b and c.
(2) The ω are not always real, but they commute with each other.
(3) There exist $\omega(b, c)$ and $\omega(b', c')$ which do not commute with each other.

For the first case, since the ω must have unit magnitude, each is therefore, ± 1—this is the first case of the structure theorem so the representation is of type I.

Another way to state the second case is to say that there exists a single reraying under which the ω are all complex. In this case, we must re-examine Eq. (2), which is an identity of the form $pr = rq$. Now the ν are each the product of three of the ω; in particular, the ν are also complex. We can then use the following fact.

Quaternionic Identity 1: If the p is strictly complex, q are complex and r is quaternionic such that

$$pr = rq,$$

then either $p=q$, in which case r is also complex, or $p=q^*$, in which case r is skew-complex. (This is easily proved by decomposing all quantities into complex and skew-complex components.) Since it is assumed that $\omega(b,c)$ is not real for at least one pair b and c, this means that, for each a, U_a either has all complex matrix elements or all skew-complex matrix elements. However, since U_a never completely vanishes and is complex when $a=1$, we can use the connectedness of G as before to show that U_a must be complex for all a—this is the second case of the structure theorem so the representation is of type II.

For the third case, we must again re-examine Eq. (2). Since the ω are independent of $|f\rangle$ and the ν are formed from the ω, the ν are also independent of $|f\rangle$. Thus, whenever x is any matrix element of U_a, we have

$$\omega(b,c)x=x\nu(a,b,c). \tag{4}$$

When x and y are two nonzero matrix elements of U_a, a double application of Eq. (4) gives, after some manipulation, that

$$\omega(b,c)xy^{-1}=x\nu(a,b,c)y^{-1}=xy^{-1}\omega(b,c),$$

in other words, xy^{-1} commutes with $\omega(b,c)$. Similarly, xy^{-1} commutes with $\omega(b',c')$. Now we use the following fact.

Quaternionic Identity 2: If p, q, and r are quaternions such that r commutes with both p and q, but p and q do not themselves commute, then r must be real.

Hence, xy^{-1} is real for all pairs of nonzero matrix elements x and y of U_a. This is equivalent to saying that the nonzero matrix elements of U_a all have the same quaternionic phase, so we can separate U_a into the product of a real matrix $U_a^{\mathbb{R}}$ and a quaternionic phase matrix Σ_a,

$$\Sigma_a=\sum_f |f\rangle\sigma_a\langle f|,$$

so that

$$U_a=U_a^{\mathbb{R}}\Sigma_a=\Sigma_a U_a^{\mathbb{R}}.$$

Since U_a and Σ_a are unitary, $U_a^{\mathbb{R}}$ must also be unitary. Repeatedly using the fact that real matrices commute with constant diagonal ones (we recall that the Ω are constant diagonal), we find that

$$(U_{ba}^{\mathbb{R}})^{-1}U_b^{\mathbb{R}}U_a^{\mathbb{R}}$$

is simultaneously real unitary and constant diagonal and must, therefore, be plus or minus the identity. Thus, we have achieved the third case of the structure theorem and the representation is of type III.

Since these are the only three possibilities for the ω, the structure theorem is proved.

V. PROOF OF THE STRUCTURE THEOREM'S COROLLARY

We may again assume without loss of generality that the representation is irreducible, in which case the structure theorem applies. Representations of type I and type II are automatically central, so we immediately pass to consideration of type III representations. Here, we effectively have a one-dimensional projective quaternionic representation

$$a\mapsto\sigma_a.$$

Since the real part $U_a^{\mathbb{R}}$ of the representation is real-projective and commutes with constant diagonal operators, the multicentrality condition reduces to the quaternion-valued constraint

$$[\sigma_{ba}^{-1}\sigma_b\sigma_a,\sigma_a]=[\sigma_{ba}^{-1}\sigma_b\sigma_a,\sigma_b]=0. \tag{5}$$

One immediate consequence of multicentrality is

Statement 2: If any two of σ_a, σ_b, and σ_{ba} commute, then all three commute.

Our task is to show that in fact $\sigma_{ba}^{-1}\sigma_b\sigma_a$ commutes with all σ_c, meaning that the representation is also central. We may assume that the σ_a do not all commute with one another as if they did, the representation would be of type II which is always central. This lack of total commutativity may be stated as follows.

Statement 3: For any choice of i, there is an a such that σ_a is strictly quaternionic and so does not commute with any strictly complex number.

In particular, this means that we can always find an a such that σ_a is not real.

Given that there are some noncommuting phases, centrality is equivalent to the statement that

$$\sigma_{ba}=\pm\sigma_b\sigma_a \tag{6}$$

for all a and b, in other words the representation must, after all, be of type I. We begin by observing that from Eq. (5) and from quaternionic identity 2, we have that

Statement 4: $\sigma_{ba}=\pm\sigma_b\sigma_a$ is true whenever σ_a and σ_b do not commute.

This is actually a special case of a more general statement.

Proposition 2: Unless exactly two of σ_a, σ_b, and σ_{ba} are real, it is true that $\sigma_{ba}=\pm\sigma_b\sigma_a$.

In other words, if none of, one of, or all three of σ_a, σ_b, and σ_{ba} are real, then Eq. (6) holds. By statement 4, we may begin by assuming that σ_a and σ_b commute and hence by statement 2, they also commute with σ_{ba}. We can then reray them to be complex, in which case, statement 3 allows us to find a c such that σ_c does not commute with any of σ_a, σ_b, or σ_{ba}.

If all three of σ_a, σ_b, and σ_{ba} are real, then the proposition is trivially true, so we can assume that at most one of them is real. This gives four cases as follows.

(1) σ_b, σ_a, and σ_{ba} are all strictly complex.
(2) σ_b is real but σ_a and σ_{ba} are strictly complex.
(3) σ_a is real but σ_b and σ_{ba} are strictly complex.
(4) σ_{ba} is real but σ_b and σ_a are strictly complex.

In the first case, we have from statement 4 that

$$\sigma_{cb}=\pm\sigma_c\sigma_b;$$

since this is the product of something strictly complex and something strictly quaternionic, it is also strictly quaternionic. Hence, by statement 4 again,

$$\sigma_{cba}=\pm\sigma_{cb}\sigma_a=\pm\sigma_c\sigma_b\sigma_a,$$

On the other hand, another application of statement 4 gives that

$$\sigma_{cba}=\pm\sigma_c\sigma_{ba},$$

which on canceling σ_c means that Eq. (6) holds and the proposition is true.

In the second case, we again have from statement 4 that

$$\sigma_{cba}=\pm\sigma_c\sigma_{ba},$$

so σ_{cba} is strictly quaternionic and does not commute with σ_a. Hence, by statement 2, none of σ_{cba}, σ_{cb}, or σ_a can commute with each other and hence by statement 4,

$$\sigma_{cba}=\pm\sigma_{cb}\sigma_a;$$

therefore,

$$\sigma_c \sigma_{ba} = \pm \sigma_{cb} \sigma_a$$

or, after rearrangement,

$$\sigma_a \sigma_{ba}^{-1} = \pm \sigma_{cb}^{-1} \sigma_c .$$

However, the left-hand side of this equation is the product of two strictly complex quantities and hence is complex while the right-hand side commutes with σ_c by statement 2; thus, both sides must be equal to ± 1 or, since σ_b is real, to $\pm \sigma_b$. Hence Eq. (6) holds and the proposition is again true.

The third and fourth cases are handled in a similar manner to the above treatment of the second case, although σ_{bac} is considered instead of σ_{cba} in the third case.

We now develop an important corollary to this proposition by introducing the following definitions.

Definition 8: σ is locally constant at x if there is a neighborhood V_x around x such that $\sigma_x = \sigma_y$ for all y in V_x.

Definition 9: If σ_x is real and σ is locally constant at x, then σ_x is strongly real.

The corollary to proposition 2 is then as follows.

Corollary 3: Unless exactly two of σ_a, σ_b, and σ_{ba} are strongly real, it is true that $\sigma_{ba} = \pm \sigma_b \sigma_a$.

This is trivially true if σ_a, σ_b, and σ_{ba} are all strongly real, since they are then real and Eq. (6) holds. Suppose, then, that neither σ_a nor σ_b are strongly real: then we can find (multiplicative) perturbations $a\,\delta a$ and $b\,\delta b$ of a and b for which $\sigma_{a\,\delta a}$ and $\sigma_{b\,\delta b}$ are not real so that proposition 2 applies. Letting δa and δb tend to 1 and using the continuity of σ, Eq. (6) continues to hold and hence the proposition is true. The other two cases are handled similarly.

We wish to prove that Eq. (6) always holds, and we shall do this by showing that there is no a such that σ_a is strongly real, allowing us to apply corollary 3. A convenient origin for our argument is the multiplicative identity of G.

Proposition 3: σ_1 is real but is not strongly real.

Since σ_a commutes with itself, statement 2 implies that σ_1 commutes with all σ_a. Since not all σ commute, quaternionic identity 2 means that σ_1 is real. We will now prove that σ_1 is not strongly real.

Suppose that σ_1 is strongly real, so that

$$\sigma_{\delta a} = \pm 1 \tag{7}$$

for all δa in the neighborhood V_1. Let a be any group element such that σ_a is not real; by continuity, we can then find a neighborhood V_1^a of 1 such that $\sigma_{a\,\delta a}$ is also not real and is not equal to $-\sigma_a$ for all δa in V_1^a. Then, by proposition 2, we may conclude that

$$\sigma_{a\,\delta a} = \sigma_a$$

for all δa in $V_1 \cap V_1^a$—in other words, σ is locally constant at a whenever σ_a is not real. We will now generate a contradiction to the supposition that σ_1 is strongly real.

We use the connectedness of G to construct a trajectory from a, where σ_a is not real, to the identity,

$$\{a(t) : t \in [0,1]\}; \quad a(0) = a, \quad a(1) = 1.$$

At $t=0$, $\sigma_{a(t)} = \sigma_a$ but at $t=1$, $\sigma_{a(t)} \neq \sigma_a$. Let t_0 be the first time that $\sigma_{a(t)}$ departs from σ_a; more precisely,

$$t_0 = \sup\{s : \sigma_{a(t)} = \sigma_a \forall 0 \leqslant t < s\}.$$

By continuity, we then have that $\sigma_{a(t_0)} = \sigma_a$ so that $\sigma_{a(t_0)}$ is not real. Now, by the argument in the previous paragraph, which we recall follows from the supposition that σ_1 is strongly real, σ is locally constant at a. However, this means that

$$\sigma_{a(t_0+\delta t)} = \sigma_{a(t_0)}$$

for all sufficiently small δt. However, this contradicts the definition of t_0, which means that σ_1 cannot be strongly real, proving the proposition.

Since σ_1 is not strongly real, we ought to be able to prove the converse result of the conclusion of the second paragraph of the above proof, and this is in fact the case.

Corollary 4: If σ_a is not real, then σ is not locally constant at a.

If σ is locally constant at a, then for all $a\,\delta a$ in the neighborhood V_a of a,

$$\sigma_{a\,\delta a} = \sigma_a;$$

now, σ_a is not real and so by proposition 2,

$$\sigma_{a\,\delta a} = \pm \sigma_a \delta_{\delta a},$$

which, with the previous equation, means that Eq. (7) is again true. However, that implies that σ_1 is strongly real, which contradicts the proposition.

Corollary 5: If at least two of σ_a, σ_b, and σ_{ba} are not strongly real, then all three phases are not strongly real.

Suppose that σ_a and σ_b are not strongly real but that σ_{ba} is. Since σ_a is not strongly real, corollary 4 implies that σ is not locally constant at a. Thus, we can find a δa close to 1 such that $\sigma_{a\,\delta a}$ is not equal to $\pm\sigma_a$ or ± 1; in particular $\sigma_{a\,\delta a}$ is not strongly real, so by corollary 3,

$$\sigma_b \sigma_{a\,\delta a} = \pm \sigma_{ba\,\delta a}.$$

However, since σ_{ba} is strongly real,

$$\sigma_{ba\,\delta a} = \pm \sigma_{ba} = \pm \sigma_b \sigma_a,$$

contradicting the fact that $\sigma_{a\,\delta a} \neq \pm \sigma_a$. The other two cases are handled similarly.

Corollary 6: For δa sufficiently close to 1, $\sigma_{\delta a}$ is not strongly real.

Choose a such that σ_a is not real. By continuity, $\sigma_{a\,\delta a}$ is also not real for δa sufficiently close to 1. Since σ_a and $\sigma_{a\,\delta a}$ are not real, they are not strongly real, so by corollary 5, $\sigma_{\delta a}$ is also not strongly real.

With one main step remaining, we are now very close to our goal.

Proposition 4: There is no a such that σ_a is strongly real.

Suppose there exists an a such that σ_a is strongly real. We use the connectedness of G to construct a trajectory from a to the identity,

$$\{a(t) : t \in [0,1]\}; \quad a(0) = a, \quad a(1) = 1.$$

At $t=0$, $\sigma_{a(t)} = \sigma_a$ and hence is strongly real, but at $t=1$, $\sigma_{a(t)} = \sigma_1$ which is not strongly real. Let t_0 be the first time that $\sigma_{a(t)}$ is not strongly real; more precisely,

$$t_0 = \sup\{s : \sigma_{a(t)} \text{ is strongly real } \forall 0 \leqslant t < s\}.$$

The definition of t_0 means that $\sigma_{a(t)}$ is strongly real for all $t < t_0$ and that, for all $\epsilon > 0$, we can find $\delta t \in [0, \epsilon]$ such that $\sigma_{a(t_0+\delta t)}$ is not strongly real.

Suppose $\sigma_{a(t_0)}$ was itself strongly real. There is then a neighborhood $V_{a(t_0)}$ such that σ is real and constant in that neighborhood. However, this lets us choose an $\epsilon>0$ such that $a(t_0 + \delta t) \in V_{a(t_0)}$ for all $\delta t \in [0,\epsilon]$; since σ is real and constant in this neighborhood, this means that $\sigma_{a(t_0+\delta t)}$ is also strongly real, contradicting the definition of t_0.

Suppose, then, that $\sigma_{a(t_0)}$ is not strongly real. Choose δa near 1 such that

$$a(t_0)\,\delta a = a(t_0 - \delta t),$$

where δt is, as usual, small and positive. Since $\sigma_{a(t_0)}$ and, by corollary 6, $\sigma_{\delta a}$ are not strongly real, by corollary 5, $\sigma_{a(t_0-\delta t)}$ is not strongly real, again contradicting the definition of t_0.

Since $\sigma_{a(t_0)}$ must be either strongly real or not strongly real, the supposition that σ_a was strongly real is false and we have proved the proposition. By corollary 3, therefore, Eq. (6) is always true, so that the representation is central, in the case that the σ_a do not all commute. All cases now having been covered, we have also proved the main corollary.

An alternative to the last couple of steps is to form H, the set of all $a \in G$ such that σ_a is not strongly real. H is then a subgroup of G by corollary 5. We then prove that H is an open subset of G, and that $G\backslash H$, the set of all $a \in G$ such that σ_a is strongly real, is also an open subset of G. However, by the definition of connectedness, there is no way to partition G as the union of two disjoint nonempty open sets, and since 1 is in H by proposition 3, it must be $G\backslash H$ that is empty, proving proposition 4.

The above proof of the corollary to the structure theorem shows that for a multicentral (and hence central) type III representation, either all the σ_a commute and can thus be rerayed to be complex—so the representation is type II—or the σ satisfy Eq. (6)—so the representation is type I. The only irreducible multicentral projective quaternionic representations are, therefore, either real projective representations or extensions of complex projective representations.

ACKNOWLEDGMENT

The authors would like to thank S. L. Adler for suggesting we look into the question of multicentrality implying centrality and for his useful suggestions while reading this paper as it developed.

(Received 22 March 1996; accepted for publication 8 May 1996)

We prove that the second cohomology group with coefficients in the adjoint module of both the infinite-dimensional Lie superalgebras $k(1)$ and $k^+(1)$, as well as their unique central extensions, which are known as the Neveu–Schwarz and the Ramond superalgebras, respectively, is equal to zero. This particularly implies that all these Lie superalgebras are rigid, i.e. they can only be deformed in a trivial manner. © *1996 American Institute of Physics.* [S0022-2488(96)03809-1]

I. INTRODUCTION

From the general theory on deformations of algebraic structures (see, e.g., Ref. 1), we learn that constructions of deformations involve cohomology computations. The infinitesimal part of an algebra deformation can be represented as an element of the second cohomology group with coefficients in the adjoint representation. An algebra is called rigid if all its deformations are trivial, i.e. any algebra that is obtained from it by deformation is isomorphic to the original algebra by means of an isomorphism that depends on the deformation parameter, which reduces to the identity mapping when this deformation parameter is set equal to zero. A sufficient condition for the rigidity of an algebra is that its second cohomology group is equal to zero. Therefore, algebras that satisfy this condition are usually called absolutely rigid.

In recent years quite a number of papers have been written on the topic of deformations of nilpotent subalgebras of graded infinite-dimensional Lie algebras (see, e.g., Refs. 2–6). These works show that the nilpotent subalgebras have several nontrivial deformations that have a fairly simple algebraic description. In Refs. 7 and 8 the author shows that the situation is similar in the case of graded infinite-dimensional Lie superalgebras. With respect to the corresponding graded Lie (super)algebras, one could say there is common consent that these Lie (super)algebras are rigid. In this paper we show that the results of the cohomology computations for the positive nilpotent part of the Neveu–Schwarz and the Ramond Lie superalgebras presented in Ref. 7, can be fruitfully used to prove that these Lie superalgebras are absolutely rigid. In fact, the presented method of rigidity proving is another illustration of the usefulness of studying these nilpotent subalgebras.

The Neveu–Schwarz and Ramond superalgebras are usually called super-Virasoro algebras since they can be viewed as superanalogs of the Virasoro algebra. As the Virasoro algebra arises as the unique (up to equivalence) central extension of the Witt algebra, they are the unique central extensions of the simple Lie superalgebras $k(1)$ and $k^+(1)$, respectively (see, e.g., Ref. 9). Both superalgebras appear in mathematical physics (see, e.g., Refs. 10 and 11). For instance, in superstring theory (see, e.g., Ref. 12) the Neveu–Schwarz algebra describes the super-Virasoro algebra in the bosonic sector, whereas the Ramond algebra describes the super-Virasoro algebra in the fermionic sector.

[a)]Electronic mail: nico@cwi.nl

0022-2488/96/37(11)/5858/11/$10.00

The Neveu–Schwarz algebra can be presented as the $\mathbb{Z}_2$-graded vector space with $\{L_p, D\}_{p\in\mathbb{Z}}$ as a basis of the even homogeneous part and $\{G_q\}_{q+1/2\in\mathbb{Z}}$ as a basis of the odd homogeneous part. Its commutator is defined by

$$\begin{aligned}
[L_p, L_q] &= (p-q)L_{p+q} + \tfrac{1}{8}(p^3-p)\,\delta_{p+q,0}D,\\
[L_p, G_q] &= (\tfrac{1}{2}p-q)G_{p+q},\\
[G_p, G_q] &= 2L_{p+q} + \tfrac{1}{2}(p^2-\tfrac{1}{4})\,\delta_{p+q,0}D,
\end{aligned} \tag{1}$$

and the property that D is a central element. The Ramond algebra has $\{L_p, D\}_{p\in\mathbb{Z}}$ as a basis of the even homogeneous part and $\{F_q\}_{q\in\mathbb{Z}}$ as a basis of the odd homogeneous part. It is equipped with the commutator

$$\begin{aligned}
[L_p, L_q] &= (p-q)L_{p+q} + \tfrac{1}{8}p^3\,\delta_{p+q,0}D,\\
[L_p, F_q] &= (\tfrac{1}{2}p-q)F_{p+q},\\
[F_p, F_q] &= 2L_{p+q} + \tfrac{1}{2}p^2\,\delta_{p+q,0}D,
\end{aligned} \tag{2}$$

where D is defined to be central.

II. THE RIGIDITY OF $k(1)$ AND NS

The Lie superalgebra $k(1)$ (see Ref. 9) is defined as the $\mathbb{Z}_2$-graded vector space $\mathbb{C}[t,t^{-1},\theta]$ equipped with the commutator

$$[f,g] = \left(2f - \theta\frac{\partial f}{\partial\theta}\right)\frac{\partial g}{\partial t} - \frac{\partial f}{\partial t}\left(2g - \theta\frac{\partial g}{\partial\theta}\right) - (-1)^{|f|}\frac{\partial f}{\partial\theta}\frac{\partial g}{\partial\theta}, \quad f,g\in\mathbb{C}[t,t^{-1},\theta]. \tag{3}$$

The parameter t is even and the parameter θ is odd. The symbol $|f|$ denotes the parity of the element f in $\mathbb{C}[t,t^{-1},\theta]$. As basis of $k(1)$ we choose $\{e_p\}_{p\in\mathbb{Z}}$ where

$$e_{2p} = t^{p+1}, \quad e_{2p-1} = \theta t^p \quad (p\in\mathbb{Z}). \tag{4}$$

Note that the elements in this basis are homogeneous, in particular, the parity of e_p equals p modulo 2. The unique central extension of $k(1)$, which we denote by NS, is determined by the 2-cocycle $c\in Z^2(k(1))$, defined as

$$c(f\wedge g) = \mathrm{Res}\left\{\left(\frac{\partial f}{\partial\theta} - \theta\frac{\partial f}{\partial t}\right)\frac{\partial^2 g}{\partial t^2} - (-1)^{|f|}\frac{\partial^2 f}{\partial t^2}\left(\frac{\partial g}{\partial\theta} - \theta\frac{\partial g}{\partial t}\right)\right\}. \tag{5}$$

In this formula the symbol Res denotes the residue, i.e., $\mathrm{Res}(h)$ is the coefficient of the term θt^{-1} in $h\in\mathbb{C}[t,t^{-1},\theta]$. The wedge ($\wedge$) in formula (5) denotes the $\mathbb{Z}_2$-graded antisymmetric tensor product, so for homogeneous elements f and g in $k(1)$ we have

$$f\wedge g = f\otimes g - (-1)^{|f||g|}g\otimes f = -(-1)^{|f||g|}g\wedge f.$$

Naturally a basis for NS is found by adding the central element γ to the given basis of $k(1)$. The linear map φ defined by

$$\varphi(t^{p+1}) = 2L_{-p}, \quad \varphi(\theta t^q) = G_{1/2-q}, \quad \varphi(\gamma) = \tfrac{1}{4}D \quad (p,q\in\mathbb{Z}) \tag{6}$$

is an isomorphism that explicitly describes the connection between the description of the Neveu–Schwarz algebra given in (1) and the one presented above. Besides the $\mathbb{Z}_2$ grading of NS,

$$NS=\bigoplus_{j\in\mathbb{Z}_2} NS_j, \quad NS_0=(\bigoplus_{j\in\mathbb{Z}}\langle e_{2j}\rangle)\oplus\langle\gamma\rangle, \quad NS_1=\bigoplus_{j\in\mathbb{Z}}\langle e_{2j-1}\rangle,$$

which describes NS as a superspace, the element e_0 defines an inner grading on $k(1)$ and NS by means of its adjoint action. The basis elements are homogeneous with respect to this inner $\mathbb{Z}$ grading. We denote the eigenspace of $ad(e_0)$ corresponding to the eigenvalue λ by $NS_{(\lambda)}$; then we have

$$NS=\bigoplus_{\lambda\in\mathbb{Z}} NS_{(\lambda)}, \quad NS_{(0)}=\langle e_0,\gamma\rangle, \quad NS_{(\lambda)}=\langle e_\lambda\rangle \quad (\lambda\in\mathbb{Z}\backslash\{0\}). \tag{7}$$

We remark that the inner grading is compatible with the $\mathbb{Z}_2$ grading in the sense that a homogeneous element of degree λ has parity λ modulo 2. For later use we write out explicitly the commutators of the basis elements:

$$\begin{aligned}
[e_{2j},e_{2k}]&=2(k-j)e_{2j+2k}+2k(k^2-1)\delta_{j+k,0}\gamma,\\
[e_{2j-1}e_{2k}]&=(k-2j+1)e_{2j+2k-1},\\
[e_{2j-1},e_{2k-1}]&=e_{2j+2k-2}+2k(k-1)\delta_{j+k,1}\gamma,\\
[e_j,\gamma]&=0.
\end{aligned} \tag{8}$$

The commutators in $k(1)$ are the same with the omission of all terms involving the central element γ.

Theorem 1: *The second cohomology group of $k(1)$ with coefficients in the adjoint representation is equal to zero:*

$$H^2(k(1);k(1))=0.$$

Proof: The $\mathbb{Z}$ grading of $k(1)$ induces a $\mathbb{Z}$ grading on the cochain complex $(C^\bullet(k(1);k(1)),d)$, so we can write

$$C^q(k(1);k(1))=\prod_{\lambda\in\mathbb{Z}} C^q(k(1);k(1))_{(\lambda)} \quad (q\in\mathbb{Z}),$$

and similarly for the corresponding cohomology groups. For details on the coboundary operator on this cochain complex and the corresponding cohomology groups we simply refer to Refs. 8, 13, and 14. Since nonzero cohomology classes can only exist at degree zero (see, e.g., Ref. 8 or 15), we know that

$$H^q(k(1);k(1))_{(\lambda)}=0 \quad (q\in\mathbb{Z}),$$

for all degrees λ not equal to zero. This observation reduces the work to be done considerably; we can confine ourselves to studying homogeneous 2-cocycles of degree zero.

An arbitrary 2-cocycle of degree zero can be written as

$$c(e_j\wedge e_k)=\alpha_{j,k}e_{j+k} \quad (j,k\in\mathbb{Z}), \tag{9}$$

with coefficients $\alpha_{j,k}\in\mathbb{C}$ satisfying $\alpha_{j,k}=-(-1)^{jk}\alpha_{k,j}$. A cocycle represents a cohomology class, in general; it is, however, not unique since there exist other cohomologically equivalent cocycles.

By application of coboundary corrections, we will determine a set of conditions for the coefficients $\alpha_{j,k}$ such that each cohomology class has a unique representative with coefficients that satisfy these specific conditions.

Lemma 1: An arbitrary cohomology class of $H^2(k(1);k(1))_0$ *can be represented by a 2-cocycle as described by formula (9), with coefficients* $\alpha_{j,k}$ *satisfying*

$$\alpha_{-1,1}=\alpha_{0,1}=0, \quad \alpha_{j,k}=0 \quad (jk>0).$$

Proof: We perform coboundary corrections in several steps. We refer to each step by the condition it imposes on the coefficients $\alpha_{j,k}$.

Step 1: $\alpha_{j,k}=0 \quad (j,k\in\mathbb{Z}_{>0})$

We define the Lie supersubalgebra of $k(1)$ spanned by the homogeneous elements of positive degree and denote it by

$$k(1)_+ = \bigoplus_{\lambda\in\mathbb{Z}_{>0}} k(1)_{(\lambda)}.$$

In Ref. 7 we proved (by application of the Feigin–Fuchs spectral sequence; for its definition see Ref. 16) that $H^2(\mathrm{k}(1)_+;\mathrm{k}(1)_+)_{(0)}=0$; hence the restriction of c to $\wedge^2(k(1)_+)$ is a coboundary. So there exists an element b_1 in $C^1(\mathrm{k}(1)_+;\mathrm{k}(1)_+)_{(0)}$ such that $d(b_1)(e_j\wedge e_k)=c(e_j\wedge e_k)$ for all $j,k\in\mathbb{Z}_{>0}$. We expand b_1 trivially from $k(1)_+$ to $k(1)$ by defining $b_1(e_j)=0$ for all $j\in\mathbb{Z}_{\leqslant 0}$ and we replace c by $c'=c-d(b_1)$. The 2-cocycle c' has coefficients $\alpha'_{j,k}$ satisfying $\alpha'_{j,k}=0$ for all $j,k\in\mathbb{Z}_{>0}$. From here on we will denote c' again by c.

Step 2: $\alpha_{j,k}=0 \quad (j,k\in\mathbb{Z}_{<0})$

Similar to the previous step, we define

$$k(1)_- = \bigoplus_{\lambda\in\mathbb{Z}_{<0}} k(1)_{(\lambda)};$$

this is the Lie supersubalgebra of $k(1)$ spanned by the homogeneous elements of negative degree. It is isomorphic to $k(1)_+$ by the isomorphism φ: $k(1)_+\to k(1)_-$, satisfying

$$\begin{cases} \varphi(e_{2j})=-e_{-2j} \\ \varphi(e_{2j-1})=ie_{1-2j} \end{cases} \quad (j\in\mathbb{Z}_{>0}).$$

Hence, $H^2(k(1)_-;k(1)_-)_{(0)}=0$ and there exists an element b_2 in $C^1(k(1);k(1))_{(0)}$ such that $(d(b_2)-c)(e_j\wedge e_k)=0$, $(j,k\in\mathbb{Z}_{<0})$, and $b_2(e_j)=0$, $(j\in\mathbb{N})$. In particular, we have $d(b_2)(e_j\wedge e_k)=0$ for all $j,k\in\mathbb{Z}_{>0}$, so $d(b_2)$ respects the previous conditions for the coefficients $\alpha_{j,k}$. We adjust c to $c-d(b_2)$ and obtain $\alpha_{j,k}=0$ for all $j,k\in\mathbb{Z}_{<0}$.

Step 3: $\alpha_{0,1}=0$

We define the element b_3 in $C^1(k(1);k(1))_{(0)}$ by $b_3(e_j)=\delta_{j,0}e_0 \quad (j\in\mathbb{Z})$. The coboundary $d(b_3)$ satisfies $d(b_3)(e_j\wedge e_k)=0 \quad (jk>0)$, so it respects the preceding conditions for the coefficients $\alpha_{j,k}$. Since $d(b_3)(e_0\wedge e_1)=e_1$ we can adjust c such that $\alpha_{0,1}$ becomes zero.

Step 4: $\alpha_{-1,1}=0$

Define $b_4\in C^1(k(1);k(1))_{(0)}$ by $b_4(e_j)=je_j \quad (j\in\mathbb{Z}_{>0})$ and $b_4(e_j)=0 \quad (j\in\mathbb{Z}_{\leqslant 0})$. One easily verifies that $d(b_4)(e_j\wedge e_k)=0$ for $jk\geqslant 0$, hence the coboundary $d(b_4)$ respects the preceding conditions for $\alpha_{j,k}$. On account of $d(b_4)(e_{-1}\wedge e_1)=e_0$ it is possible to adjust c such that $\alpha_{-1,1,}=0$. □

It is not yet clear that a representative of the form described in the previous lemma is unique. We will prove that any 2-cocycle that satisfies these conditions is equal to zero. The cocycle condition $d(c)=0$ gives rise to four types of equations for the coefficients $\alpha_{j,k}$. Since we will need them frequently we write down these equations explicitly: $d(c)(e_{2j}\wedge e_{2k}\wedge e_{2l})=0$ gives

$$(k-j)\alpha_{2j+2k,2l}-(l-j)\alpha_{2j+2l,2k}+(l-k)\alpha_{2l+2k,2j}$$
$$-(l+k-j)\alpha_{2k,2l}+(j+l-k)\alpha_{2j,2l}-(j+k-l)\alpha_{2j,2k}=0; \tag{10}$$

$d(c)(e_{2j-1}\wedge e_{2k}\wedge e_{2l})=0$ gives

$$(k-2j+1)\alpha_{2j+2k-1,2l}-(l-2j+1)\alpha_{2j+2l-1,2k}+2(l-k)\alpha_{2k+2l,2j-1}$$
$$-(l+k-2j+1)\alpha_{2k,2l}+(2l+2j-k-1)\alpha_{2j-1,2l}-(2j+2k-l-1)\alpha_{2j-1,2k}=0; \tag{11}$$

$d(c)(e_{2j-1}\wedge e_{2k-1}\wedge e_{2l})=0$ gives

$$\alpha_{2j+2k-2,2l}-(l-2j+1)\alpha_{2j+2l-1,2k-1}-(l-2k+1)\alpha_{2k+2l-1,2j-1}$$
$$-\alpha_{2k-1,2l}-\alpha_{2j-1,2l}-2(j+k-l-1)\alpha_{2j-1,2k-1}=0; \tag{12}$$

and $d(c)(e_{2j-1}\wedge e_{2k-1}\wedge e_{2l-1})=0$ gives

$$\alpha_{2j+2k-2,2l-1}+\alpha_{2j+2l-2,2k-1}+\alpha_{2k+2l-2,2j-1}-(k+l-2j)\alpha_{2k-1,2l-1}$$
$$-(j+l-2k)\alpha_{2j-1,2l-1}-(j+k-2l)\alpha_{2j-1,2k-1}=0. \tag{13}$$

By substituting specific values for j, k, and l in these equations we prove in several steps that all coefficients $\alpha_{j,k}$ are equal to zero. Again we refer to each step by the condition it imposes on the coefficients.

Step 1: $\alpha_{0,p}=0$ $(p\in\mathbb{Z})$

We substitute $(j,l)=(k,0)$ in (12) and find $\alpha_{4k-2,0}=2\alpha_{2k-1,0}$. In particular $k=1$ yields $\alpha_{0,2}=0$, then by substituting $(j,k,l)=(0,\mathbb{Z}_{>0},\mathbb{Z}_{>0})$ in (10) we find $(l-k)(\alpha_{2l+2k,0}-\alpha_{2l,0}-\alpha_{2k,0})=0$ and $\alpha_{0,2l}=l\alpha_{0,2}=0$ for all $l\in\mathbb{Z}_{>0}$. A similar proof can be given for $l\in\mathbb{Z}_{<0}$ since putting $(j,k,l)=(0,1,0)$ in (12) yields $\alpha_{-1,0}=0$.

Step 2: $\alpha_{-1,p}=\alpha_{1,p}=0$ $(p\in\mathbb{Z})$

We already have $\alpha_{-1,p}=0$ for $p\leqslant 1$; in order to show that $\alpha_{-1,p}=0$ for $p\geqslant 2$ we take $(j,k,l)=(0,1,\mathbb{Z}_{>0})$ and $(j,k,l)=(0,\mathbb{Z}_{>0},1)$ in (12), yielding $-(l-1)\alpha_{-1,2l+1}-\alpha_{-1,2l}=0$ and $-2(1-k)\alpha_{-1,2k+1}-\alpha_{-1,2}-2(k-2)\alpha_{-1,2k-1}=0$. The choice $l=1$ in the first equation gives $\alpha_{-1,2}=0$, and by that the second one yields $\alpha_{-1,2k+1}=(k-2)\alpha_{-1,2k-1}/(k-1)$. The choice $k=2$ gives $\alpha_{-1,5}=0$ and by induction we find $\alpha_{-1,2p+1}=0$ for $p\geqslant 2$. Then again, the first implies $\alpha_{-1,p}=0$ for all $p\geqslant 4$. The last case $\alpha_{-1,3}=0$ follows from substituting $(j,k,l)=(10,0,2)$ in (13). The case $\alpha_{1,p}=0$ for all $p\in\mathbb{Z}$ can be handled similarly.

Step 3: $\alpha_{2,2p}=\alpha_{-2,2p}=0$ $(p\in\mathbb{Z})$

We consider $\alpha_{2,2p}$ with $p\in\mathbb{Z}_{<0}$. Putting $(j,k,l)=(1,1,-1)$ in (12) yields $\alpha_{-2,2}=0$ and $(j,k,l)=(-1,\mathbb{Z}_{<0},1)$ in (10) gives $(k+1)\alpha_{2k-2,2}-(k+2)\alpha_{2k,2}=0$. So by taking $k=-2$ we obtain $\alpha_{2,-6}=0$ and inductively $\alpha_{2,2p}=0$ for all $p\leqslant -3$. The condition $\alpha_{2,-4}=0$ follows from $(j,k,l)=(-3,-2,1)$ in (10). The case $\alpha_{-2,2p}$ can be handled similarly.

Step 4: $\alpha_{4,2p}=0$ $(p\in\mathbb{Z})$

We only need to consider $p<-1$. We substitute $(j,k,l)=(-1,\mathbb{Z}_{<0},2)$ in (10) and obtain $(k+1)\alpha_{2k-2,4}-(k+3)\alpha_{2k,4}=0$. The choice $k=-3$ yields $\alpha_{4,2p}=0$ for $p\leqslant -4$. By combining $k=-2$ with $(j,k,l)=(-3,-2,2)$ in (10), we obtain $\alpha_{4,-6}=\alpha_{4,-4}=0$ and hence $\alpha_{4,2p}=0$ for all p in $\mathbb{Z}$.

Step 5: $\alpha_{2n,2p}=0$ $(n,p\in\mathbb{Z})$

We only need to consider $\alpha_{2n,2p}$ with $n\in\mathbb{N}$ and $p\in\mathbb{Z}$. The cases $n=0,1,2$ are already evident. We proceed by induction, assuming that $\alpha_{2j,2p}=0$ for all $j\leqslant n$. Substituting $(j,k,l)=(p,1,n)$ in (10) gives $(n-1)\alpha_{2n+2,2p}=0$.

Step 6: $\alpha_{2,p}=0$, $(p\in\mathbb{Z})$

We only need to consider odd p. Put $(k,l)=(1,1)$ in (13), then $\alpha_{2,2j-1}=0$.

Step 7: $\alpha_{3,p}=0$ $(p\in\mathbb{Z})$

We put $(j,k)=(2,0)$ in (12) and (13) and find $\alpha_{2l,3}-(l+1)\alpha_{3,2l-1}=0$ and $\alpha_{2l-2,3}-(l+2)\alpha_{3,2l-1}=0$. Setting $l=-2$ yields by induction $\alpha_{3,p}=0$ for $p\leqslant -6$. The case $p=-4$ follows from, e.g., $(j,k,l)=(2,-10,-12)$ in (11) and putting $l=-1$ and $l=-2$ in the equations above yield $\alpha_{3,-3}=\alpha_{3,-5}=0$. By this and previous steps all coefficients $\alpha_{3,p}$ are equal to zero.

Step 8: $\alpha_{n,p}=0$ $(n,p\in\mathbb{Z})$

We only need to prove this for $n\in\mathbb{N}$ and $p\in\mathbb{Z}$. We use induction on n. The cases $n=0,1,2,3$ are evident on account of previous steps. It is completed by the substitutions

$$(j,k,l)=(1,p,n) \text{ in } (11), \quad (1-n)\alpha_{2n+1,2p}=0 \quad (n\geqslant 2),$$

$$(j,k,l)=(p+1,1,n) \text{ in } (12), \quad (1-n)\alpha_{2n+1,2p+1}=0 \quad (n\geqslant 2),$$

$$(j,k,l)=(p+1,1,n) \text{ in } (13), \quad \alpha_{2n,2p+1}=0.$$

This completes the proof that any 2-cocycle of degree zero is a coboundary. So by the previous remarks on the inner grading we have $H^2(k(1);k(1))=0$.

We will use the same technique to prove that the central extension NS is rigid.

Theorem 2: *The second cohomology group of NS with coefficients in the adjoint representation is equal to zero*:

$$H^2(NS;NS)=0.$$

Proof: Due to the inner grading of NS it suffices to prove that $H^2(NS;NS)_0=0$. An arbitrary 2-cocycle of degree zero can be written as

$$\begin{aligned} c(e_j\wedge e_k)&=\alpha_{j,k}e_{j+k}+\delta_{j+k,0}\beta_k\gamma \quad (j,k\in\mathbb{Z}),\\ c(\gamma\wedge e_j)&=\lambda_j e_j+\delta_{j,0}\mu\gamma \quad (j\in\mathbb{Z}), \end{aligned} \tag{14}$$

where $\alpha_{j,k}$, β_k, λ_j, and μ are complex numbers satisfying

$$\alpha_{j,k}=-(-1)^{jk}\alpha_{k,j} \quad (j,k\in\mathbb{Z}), \quad \beta_{-k}=-(-1)^k\beta_k \quad (k\in\mathbb{Z}).$$

Again we use coboundary corrections to choose representatives of a specific form. The notation will be similar to the one in Theorem 1.

Lemma 2: An arbitrary cohomology class of $H^2(NS;NS)_0$ *can be represented by a 2-cocycle as described by formula (14), with coefficients satisfying*

$$\alpha_{-1,1}=\alpha_{0,1}=\beta_1=\beta_3=\lambda_1=0, \quad \alpha_{j,k}=0 \quad (jk>0).$$

Proof:

Step 1: $\alpha_{-1,1}=\alpha_{0,1}=0$ $\alpha_{j,k}=0$ $(jk>0)$

Use the coboundaries $d(b_l)$ $(1\leqslant l\leqslant 4)$, where b_l is the extension of the element b_l given in Theorem 1, defined by $b_l(\gamma)=0$.

Step 2: $\lambda_1=0$

We define b_5 in $C^1(NS;NS)_{(0)}$ by $b_5(\gamma)=e_0$, $b_5(e_j)=0$, $(j\in\mathbb{Z})$; then $d(b_5)(\gamma\wedge e_1)=e_1$ so we obtain $\lambda_1=0$.

Step 3: $\beta_1=0$

We define b_6 in $C^1(NS;NS)_{(0)}$ by $b_6(\gamma)=0$, $b_6(e_l)=\delta_{l,0}\gamma$, $(l\in\mathbb{Z})$, and we see that $d(b_6)(e_{-1}\wedge e_1)=-\gamma$. By this β_1 becomes zero.

Step 4: $\beta_3=0$

Define b_7 in $C^1(NS;NS)_{(0)}$ by $b_7(\gamma)=\gamma$, $b_7(e_l)=0$, $(l\in\mathbb{Z})$; then $d(b_7)(e_{-3}\wedge e_3)=-4\gamma$; hence β_3 becomes zero.

It can easily be verified that all these corrections respect the preceding ones. □

We will prove that any representative c of this form is equal to zero. For that purpose we write out some consequences of the cocycle condition $d(c)=0$:

$$d(c)(\gamma\wedge e_{2j-1}\wedge e_{2k-1})=(\lambda_{2j+2k-2}-\lambda_{2k-1}-\lambda_{2j-1})e_{2j+2k-2}+\delta_{j+k,1}(\mu-\lambda_{2j-1}2j(j-1)-\lambda_{2k-1}2k(k-1))\gamma=0, \tag{15}$$

$$d(c)(\gamma\wedge e_{2j-1}\wedge e_{2k})=(k-2j+1)(\lambda_{2j+2k-1}-\lambda_{2k}-\lambda_{2j-1})e_{2j+2k-1}=0, \tag{16}$$

$$d(c)(\gamma\wedge e_{2j}\wedge e_{2k})=2(k-j)(\lambda_{2j+2k}-\lambda_{2j}-\lambda_{2k})e_{2j+2k}+2k\delta_{j+k,0}(2\mu-(k^2-1)(\lambda_{2j}+\lambda_{2k}))\gamma=0. \tag{17}$$

We take $(j,k)=(1,0)$ in (15) and $k=0$ in (16) and obtain $\mu=\lambda_0=0$. By substituting $j=1$ in (15) and (16), we find $\lambda_k=\lambda_1=0$ for all $k\in\mathbb{Z}$. Since the equations (10)–(13) still hold, we conclude that $\alpha_{j,k}=0$ for all j and k in $\mathbb{Z}$. Finally, we prove that the coefficients β_j are equal to zero,

$$d(c)(e_{2j-1}\wedge e_{2k-1}\wedge e_{2-2j-2k})=-\{\beta_{2-2j-2k}+(3j+k-2)\beta_{2k-1}+(3k+j-2)\beta_{2j-1}\}\gamma=0, \tag{18}$$

$$d(c)(e_{2j}\wedge e_{2k}\wedge e_{-2j-2k})=2\{(k-j)\beta_{2j+2k}-(2j+k)\beta_{2k}+(2k+j)\beta_{2j}\}\gamma=0. \tag{19}$$

We substitute $(j,k)=(1,1)$ and $(j,k)=(1,2)$ in (18) and obtain $\beta_2=\beta_4=0$. The choice $j=1$ in (19) yields $\beta_{2k+2}=[(k+2)/(k-1)]\beta_{2k}$ $(k\neq 1)$, and by induction all β_{2k} are equal to zero. Then $j=k$ in (18) implies $\beta_{2k-1}=0$ for all k in $\mathbb{Z}$ and the proof is complete. □

III. THE RIGIDITY OF $k^+(1)$ AND R

The Lie superalgebra $k^+(1)$ (see Ref. 9) looks quite similar to $k(1)$; it consists of the $\mathbb{Z}_2$-graded vector space $\mathbb{C}[t,t^{-1},\theta\sqrt{t}]$ equipped with the commutator of formula (3). We define a basis of $k^+(1)$ by $\{e_p\}_{p\in\mathbb{Z}}$, where

$$e_{2p}=t^{p+1},\quad e_{2p-1}=\theta t^p\sqrt{t}\quad (p\in\mathbb{Z}).$$

The elements in this basis are homogeneous; the parity of e_p is p modulo 2. The Ramond algebra is the unique central extension of $k^+(1)$. It is described by the 2-cocycle of formula (5) and we shall denote it by R. Let γ denote the central element of R. An isomorphism that relates this description with the one presented by formula (2) in the Introduction can be given by

$$\varphi(t^{p+1})=2L_{-p}+\tfrac{1}{16}\delta_{p,0}D,\quad \varphi(\theta t^q\sqrt{t})=F_{-q},\quad \varphi(\gamma)=\tfrac{1}{4}D\quad (p,q\in\mathbb{Z}). \tag{20}$$

We will use the inner grading of R corresponding to the special element $\frac{1}{2}e_0$. This boils down to

$$R=\bigoplus_{\lambda\in\mathbb{Z}}R_{(\lambda)},\quad R_{(\lambda)}=\langle e_{2l-1},e_{2\lambda}\rangle\quad (\lambda\in\mathbb{Z}\backslash\{0\}),\quad R_{(0)}=\langle e_{-1},e_0,\gamma\rangle.$$

The basis elements are homogeneous with respect to this $\mathbb{Z}$ grading, however, the $\mathbb{Z}_2$ grading of R is not compatible with this $\mathbb{Z}$ grading. To be more precise, we have

$$R_{(\lambda)}=R_{(\lambda),0}\oplus R_{(\lambda),1}=\langle e_{2\lambda}\rangle\oplus\langle e_{2\lambda-1}\rangle\quad (\lambda\neq 0)$$

and

$$R_{(0)}=R_{(0),0}\oplus R_{(0),1}=\langle e_0,\gamma\rangle\oplus\langle e_{-1}\rangle.$$

This makes the rigidity proof in this case slightly more technical than the one presented in the previous section. For later use we write out the commutators of the basis elements:

$$\begin{aligned}
[e_{2j},e_{2k}]&=2(k-j)e_{2j+2k}+2k(k^2-1)\,\delta_{j+k,0}\gamma,\\
[e_{2j-1},e_{2k}]&=(k-2j)e_{2j+2k-1},\\
[e_{2j-1},e_{2k-1}]&=e_{2j+2k}+2(k^2-\tfrac{1}{4})\,\delta_{j+k,0}\gamma,\\
[e_j,\gamma]&=0.
\end{aligned}\tag{21}$$

The commutators in $k^+(1)$ are as described above with the omission of all the terms involving the central element γ.

Theorem 3: *The even part of the second cohomology group of $k^+(1)$ with coefficients in the adjoint representation is equal to zero:*

$$H^2(k^+(1);k^+(1))=0.$$

Proof: Due to the inner grading of $k^+(1)$, we only need to prove $H^2(k^+(1);k^+(1))_{(0),0}=0$, i.e. we can restrict ourselves to studying even 2-cocycles of degree zero. We will use the same technique as described in the two proofs of the previous section, therefore we will confine ourselves to shortly indicating the various steps without discussing them in detail.

An even 2-cocycle c of degree zero is of the following form:

$$\begin{aligned}
c(e_{2j}\wedge e_{2k})&=\alpha_{2j,2k}e_{2j+2k},\\
c(e_{2j-1}\wedge e_{2k})&=\alpha_{2j-1,2k}e_{2j+2k-1},\\
c(e_{2j-1}\wedge e_{2k-1})&=\alpha_{2j-1,2k-1}e_{2j+2k},
\end{aligned}\tag{22}$$

with $\alpha_{j,k}\in\mathbb{C}$ and $\alpha_{j,k}=-(-1)^{jk}\alpha_{k,j}$ $(j,k\in\mathbb{Z})$.

Lemma 3: An arbitrary cohomology class of $H^2(k^+(1);k^+(1))_{(0),0}$ can be represented by a 2-cocycle as described by formula (22), with coefficients $\alpha_{j,k}$ satisfying

$$\alpha_{-2,-1}=\alpha_{-2,1}=\alpha_{0,1}=0,\quad \alpha_{j,k}=0\quad (j,k>0;j,k<-1).$$

Proof:

Step 1: $\alpha_{j,k}=0$ $(j,k>0)$

Define

$$k^+(1)_+=\bigoplus_{\lambda\in\mathbb{Z}_{>0}}k^+(1)_{(\lambda)};$$

this is the Lie supersubalgebra of $k^+(1)$ spanned by the homogeneous elements of positive degree. From Ref. 7 we know that $H^2(k^+(1)_+;k^+(1)_+)_{(0)}=0$; hence the restriction of c to $\wedge^2(k^+(1)_+)$ is a coboundary. By subtracting $d(b_1)$ from c, where b_1 denotes the trivial expansion of the element that yields the coboundary mentioned above, we obtain a 2-cocycle with coefficients $\alpha_{j,k}$ satisfying the described property.

Step 2: $\alpha_{j,k}=0$ $(j,k<-1)$

Define

$$k^+(1)_- = \bigoplus_{\lambda \in \mathbb{Z}_{<0}} k^+(1)_{(\lambda)}$$

and note that $k^+(1)_-$ is isomorphic to $k^+(1)_+$ by the isomorphism $\varphi: k^+(1)_+ \to k^+(1)_-$, given by

$$\begin{cases} \varphi(e_{2j}) = -e_{-2j} \\ \varphi(e_{2j-1}) = ie_{-2j-1} \end{cases} \quad (j \in \mathbb{Z}_{>0}).$$

By a similar argument as given in Step 1, we obtain $\alpha_{j,k}=0$ for $j,k<-1$.

Step 3: $\alpha_{0,1}=0$

Use $d(b_2)$ with $b_2(e_j)=\delta_{j,0}e_0$ $(j \in \mathbb{Z})$; then $d(b_2)(e_0 \wedge e_1)=2e_1$.

Step 4: $\alpha_{-2,-1}=0$

Use $d(b_3)$ with $b_3(e_j)=\delta_{j+1,0}e_{-1}$ $(j \in \mathbb{Z})$; then $d(b_3)(e_{-2} \wedge e_{-1})=e_{-3}$.

Step 5: $\alpha_{-2,1}=0$

Define b_4 by $b_4(e_{2j})=je_{2j}, b_4(e_{2j-1})=je_{2j-1}$ $(j \in \mathbb{Z}_{\leqslant 0})$, and $b_4(e_j)=0$ $(j \in \mathbb{Z}_{>0})$; then $d(b_4)(e_{-2} \wedge e_1)=-3e_{-1}$.

One can easily verify that each coboundary respects the conditions that have been imposed on the coefficients $\alpha_{j,k}$ in preceding steps. □

By similar inductive arguments, as demonstrated in the preceding theorems, one can prove that any 2-cocycle of the form described in the lemma is equal to zero. By that the proof is complete. □

Theorem 4: *The even part of the second cohomology group of R with coefficients in the adjoint representation is equal to zero*:

$$H^2(R;R)_0=0.$$

Proof: Due to the inner grading of R, it is sufficient to prove that $H^2(R;R)_{(0),0}=0$. An arbitrary even 2-cocycle of degree zero can be written as

$$\begin{gathered} c(e_{2j} \wedge e_{2k}) = \alpha_{2j,2k}e_{2j+2k} + \delta_{j+k,0}\beta_{2k}\gamma, \\ c(e_{2j-1} \wedge e_{2k}) = \alpha_{2j-1,2k}e_{2j+2k-1}, \\ c(e_{2j-1} \wedge e_{2k-1}) = \alpha_{2j-1,2k-1}e_{2j+2k} + \delta_{j+k,0}\beta_{2k-1}\gamma, \\ c(c\gamma \wedge e_j) = \lambda_j e_j + \delta_{j,0}\mu\gamma, \end{gathered} \tag{23}$$

where $\alpha_{j,k}, \beta_k, \lambda_j$, and μ are complex numbers such that

$$\alpha_{j,k} = -(-1)^{jk}\alpha_{k,j} \quad (j,k \in \mathbb{Z}), \quad \beta_{-2k} = -\beta_{2k}, \quad \beta_{2k-1} = \beta_{-2k-1} \quad (k \in \mathbb{Z}).$$

Lemma 4: An arbitrary cohomology class of $H^2(R;R)_{(0),0}$ can be represented by a 2-cocycle as described by formula (23), with coefficients $\alpha_{j,k}$ satisfying

$$\alpha_{-2,-1}=\alpha_{-2,1}=\alpha_{0,1}=0, \quad \alpha_{j,k}=0 \quad (j,k>0; j,k<-1),$$

and coefficients β_k and λ_j that satisfy

$$\beta_1=\beta_2=\lambda_2=0.$$

Proof: It is evident that the restrictions from Step 1–5 from Theorem 3 can also be obtained for $\alpha_{j,k}$ in this case. Furthermore, we perform the following steps.

Step 1: $\beta_2=0$

Use $d(b_1)$ with $b_1(e_j)=\delta_{j,0}\gamma$ $(j \in \mathbb{Z})$, and $b_1(\gamma)=0$; then $d(b_1)(e_{-2} \wedge e_2)=-4\gamma$.

Step 2: $\beta_1=0$

Use $d(b_2)$ with $b_2(\gamma)=\gamma$ and $b_2(e_j)=0$ $(j\in\mathbb{Z})$; then $d(b_2)(e_{-3}\wedge e_1)=-\frac{3}{2}\gamma$.

Step 3: $\lambda_2=0$

Use $d(b_3)$ with $b_3(\gamma)=e_0$ and $b_3(e_j)=0$ $(j\in\mathbb{Z})$; then $d(b_3)(\gamma\wedge e_2)=2e_2$. □

We will prove that any 2-cocycle c given by (23), with coefficients satisfying the conditions of the preceding lemma, is equal to zero,

$$d(c)(\gamma\wedge e_{2j}\wedge e_{2k})=2(k-j)(\lambda_{2j+2k}-\lambda_{2j}-\lambda_{2k})e_{2j+2k}+\delta_{j+k,0}2k(2\mu-(k^2-1)(\lambda_{2j}+\lambda_{2k}))\gamma=0, \tag{24}$$

$$d(c)(\gamma\wedge e_{2j-1}\wedge e_{2k})=(k-2j)(\lambda_{2j+2k-1}-\lambda_{2j-1}-\lambda_{2k})e_{2j+2k-1}=0, \tag{25}$$

$$d(c)(\gamma\wedge e_{2j-1}\wedge e_{2j-1})=(\lambda_{4j}-2\lambda_{2j-1})e_{4j}+\delta_{j,0}(\mu+\lambda_{-1})\gamma=0. \tag{26}$$

From the substitution $(j,k)=(-1,1)$ in (24), we obtain $\mu=0$. Then $j=0$ in (26) yields $\lambda_{-1}=0$. From $k=1$ in (25) we conclude $\lambda_{2j-1}=\lambda_{-1}=0$ for all $j\in\mathbb{Z}$. Finally, Eq. (25) implies $\lambda_{2k}=0$ for all $k\in\mathbb{Z}$.

Since the conditions for the coefficients $\alpha_{j,k}$ from Lemma 4 coincide with the conditions in Lemma 3, the proof of the preceding theorem implies that all coefficients $\alpha_{j,k}$ are equal to zero. In order to show that β_k equals zero for all $k\in\mathbb{Z}$, we write out the following two expressions:

$$d(c)(e_{2j}\wedge e_{2k}\wedge e_{-2j-2k})=2\{(k-j)\beta_{2j+2k}-(k+2j)\beta_{2k}+(2k+j)\beta_{2j}\}\gamma=0, \tag{27}$$

$$d(c)(e_{2j-1}\wedge e_{2k-1}\wedge e_{-2j-2k})=\{\beta_{2j+2k}-(k+3j)\beta_{2k-1}-(j+3k)\beta_{2j-1}\}\gamma=0. \tag{28}$$

We take $(j,k)=(1,1)$ in (28) and obtain $\beta_4=0$. Then by inductive use of Eq. (27) we conclude that $\beta_{2k}=0$ for all $k\in\mathbb{Z}$. Finally, $j=1$ in (28) gives $\beta_{2k-1}=0$ for all $k\in\mathbb{Z}$. This completes the proof that any even 2-cocycle of degree zero is a coboundary. □

IV. SOME FINAL REMARKS

The even parts of the Lie superalgebras NS and R are isomorphic to the Virasoro algebra. Therefore one could consider the rigidity proofs of these superalgebras, as extensions of a rigidity proof for the Virasoro algebra. In fact, this is how the presented technique has arisen. This technique can also be used with respect to W algebras, work on this is in progress.

In the introductory part of this paper we mentioned the possibility of deforming Lie superalgebras. A deformation of a Lie superalgebra L is defined by a new commutator on L, which is a power series in a formal parameter, with the zeroth-order term equal to the bracket of L. Since the parameter involved is usually even, it is only the even part of the cohomology group of L that is of interest with respect to the rigidity of L. Nevertheless, one can formally carry out the construction of a deformation of L by using an odd parameter, such deformations are therefore called odd deformations. For details on this we refer to Ref. 8. On account of $\mathbb{Z}$ homogeneity; the cocycle that describes an odd deformation needs to be odd. By consequence, a sufficient condition for the rigidity of a Lie superalgebra with respect to these kinds of odd deformations is that the odd component of its second cohomology group with coefficients in the adjoint module is equal to zero. From Theorems 1 and 2 we learn that $k(1)$ and NS satisfy this condition. We can give proofs similar to the ones given in Theorems 3 and 4, to show that $H^2(k^+(1);k^+(1))_1=0$ and $H^2(R;R)_1=0$. Hence, we can conclude that the Lie superalgebras $k(1)$, $k^+(1)$, NS, and R are also rigid with respect to odd deformations.

Asymptotics of oscillatory Riemann–Hilbert problems

G. G. Varzugin[a)]
Laboratory of Complex System Theory, Physics Institute of St. Petersburg University, St. Petersburg, Peterhof, Ulyanovskaya 1, 198904 Russia

(Received 14 September 1995; accepted for publication 1 July 1996)

A classical method of stationary phase for oscillatory integrals is generalized to oscillatory Riemann–Hilbert problems of the kind arising in the theory of integrable nonlinear equations. The proposed approach is developed for the phase with N first-order stationary points, and the final formulas can immediately be applied to the problem of long-time behavior of the solutions of equations such as the NLS, KdV, mKdV sine-Gordon, and others. © *1996 American Institute of Physics.* [S0022-2488(96)01111-5]

I. INTRODUCTION

It is well known that the Riemann–Hilbert problem (RHP) plays an important role in the study of a certain class of nonlinear evolution equations.[1] In particular, the long-time behavior of the solution of the initial value problem for the evolution equation can be found by finding a viable method of asymptotic analysis of the RHP. A great progress has already been made when that is the 2×2 matrix RHP on the real axis with oscillations in its conjugation matrix: this will also be treated here. However, the results obtained in this paper are more general, and the approach used allows us to formulate these results in the spirit of the method of stationary phase.

The mentioned oscillatory Riemann–Hilbert problem is a search for a matrix $M(\lambda)$ analytic in λ for $\operatorname{Im}\lambda\neq0$, satisfying a conjugation condition on the real axis, and normalized at infinity:

$$M_+(\lambda)=M_-(\lambda)G(\lambda,t),\quad \lambda\in R,$$

$$M(\infty)=I, \tag{1.1}$$

where the jump (conjugation) matrix, $G(\lambda,t)$ is given by

$$G(\lambda,t)=\begin{pmatrix} 1+p(\lambda)q(\lambda) & p(\lambda)e^{-it\theta(\lambda)} \\ q(\lambda)e^{it\theta(\lambda)} & 1 \end{pmatrix}. \tag{1.2}$$

Solving a nonlinear wave equation by the inverse scattering method, one looks for potentials

$$u(t)=\lim_{\lambda\to\infty}\lambda M_{12}(\lambda),\quad v(t)=\lim_{\lambda\to\infty}\lambda M_{21}(\lambda). \tag{1.3}$$

In this paper, we study (1.1) with general phase, assuming that it has N first-order stationary phase points. More precisely, it is supposed that

(A) $p(\lambda)$, $q(\lambda)$ belong to the Schwartz space.

(B) $\theta\in C^\infty(R)$, $\operatorname{Im}\theta(\lambda)=0$, $\theta(\lambda)\sim\lambda^d$ as $\lambda\to\pm\infty$, where d is some integer. The asymptotics are differentiable.

(C) The first derivative of θ vanishes only in points $\lambda_1,\ldots,\lambda_N$, where $\theta''(\lambda_n)\neq0$.

(D) $1+p(\lambda)q(\lambda)>0$ for all $\lambda\in R$.

Conditions A and B can be chosen weaker but we use them in order to simplify formulations of some results. On the contrary, assumptions C and D are strict.

[a)]Electronic mail: varzugin@phim.niif.spb.su

Theorem: Let conditions A, B, C, and D be satisfied. Then, there is a number t_0 such that the solution of the RHP exists at least for $t \geqslant t_0$. The leading asymptotics of the potentials are given as the sum of contributions from the distinct stationary phase points:

$$u(t)=\sum_{n=1}^{N} u_0^n(t)+O(t^{-3/4}\ln t), \quad v(t)=\sum_{n=1}^{N} v_0^n(t)+O(t^{-3/4}\ln t). \tag{1.4}$$

The functions u_0^n and v_0^n are determined by

$$u_0^n=\frac{i\nu_n}{\varepsilon_n\sqrt{|\nu_n\theta''(\lambda_n)t|}}\frac{p(\lambda_n)}{\sqrt{|p(\lambda_n)q(\lambda_n)|}}\exp\{-it\theta(\lambda_n)-i\nu_n\ln|\theta''(\lambda_n)t|+i\alpha_n(\lambda_1,\ldots,\lambda_N)\}, \tag{1.5a}$$

$$v_0^n=\frac{i\nu_n}{\varepsilon_n\sqrt{|\nu_n\theta''(\lambda_n)t|}}\frac{q(\lambda_n)}{\sqrt{|p(\lambda_n)q(\lambda_n)|}}\exp\{it\theta(\lambda_n)+i\nu_n\ln|\theta''(\lambda_n)t|-i\alpha_n(\lambda_1,\ldots,\lambda_N)\}, \tag{1.5b}$$

where

$$\varepsilon_n=\operatorname{sgn}\theta''(\lambda_n), \quad \nu_n=-\frac{1}{2\pi}\varepsilon_n\ln(1+p(\lambda_n)q(\lambda_n)),$$

and

$$\alpha_n(\lambda_1\cdots\lambda_N)=\varepsilon_n\frac{\pi}{4}+\arg\Gamma(i\nu_n)+\sum_{k=1,k\neq n}^{N}2\nu_k\ln|\lambda_n-\lambda_k| + \frac{1}{\pi}\int_{\theta'(z)<0}\ln|z-\lambda_n|d\ln(1+p(z)q(z))$$

(here Γ is the standard gamma function). Moreover, for $|\operatorname{Im}\lambda|\geqslant a>0$, one has

$$M(\lambda)=\begin{pmatrix} \delta(\lambda) & \delta^{-1}(\lambda)\sum_{n=1}^{N} u_0^n/(\lambda-\lambda_n) \\ \delta(\lambda)\sum_{n=1}^{N} v_0^n/(\lambda-\lambda_n) & \delta^{-1}(\lambda) \end{pmatrix}+O(t^{-3/4}\ln t), \tag{1.6}$$

where

$$\delta(\lambda)=\exp\left\{\frac{1}{2\pi i}\int_{\theta'(z)<0}\frac{\ln(1+p(z)q(z))}{z-\lambda}\,dz\right\}.$$

The order of decay of the corrections in formulas (1.4) and (1.6) is not the best possible one: the estimates for these corrections in (1.4) and (1.6) for the nondiagonal elements of $M(\lambda)$ can be improved to order $t^{-3/2}\ln t$. The error term for the diagonal part of $M(\lambda)$ in (1.6) must be $O(t^{-1}\ln t)$.

The first *direct* method for analyzing the asymptotics of the factorization problem (1.1) was proposed by Its.[2] Its considered the nonlinear Schrödinger equation (NLS) [the phase, $\theta(\lambda)=(\lambda-\lambda_0)^2$, has one stationary point in this case] and showed that problem (1.1) could be reduced, up to small errors which decay as $t\to\infty$, to a model RHP, which in turn was explicitly

solvable. The extension of those ideas to the phase with more then one stationary point led to the necessity of involving the technique (which is quite difficult itself) from the theory of isomonodromic deformations.[3]

The second was presented by Deift and Zhou[4] who investigated the modified Korteweg–de Vries equation (mKdV). The phase, $\theta(\lambda)=4(\lambda^3-3\lambda_0^2\lambda)$, has two stationary points in this case. They separated the contribution from the distinct stationary phase points and derived the model RH problem by deforming contours in the spirit of the classical method of steepest descent. In other words, they reduced the situation with two stationary phase points to the situation with one stationary phase point. The Deift–Zhou procedure is a general and rigorous approach to analyzing oscillatory RHPs of the form (1.1).

We emphasize that only the direct approaches to (1.1) have been described, i.e., those not involving *a priori* ansatz for the asymptotic form of the solution of an integrable nonlinear equation (the further references can be found in Refs. 3 and 4). We mention also that formulas (1.4) and (1.5) have already appeared in the literature[5] but as a hypothesis.

Before describing the background of this paper and its relationship with earlier works, let us recall the classical theory of oscillatory integrals. Note that if $p(\lambda)=0$, we derive that

$$v(t)=\frac{i}{2\pi}\int_{-\infty}^{\infty} q(\lambda)e^{it\theta(\lambda)}\,d\lambda, \quad u(t)=0. \tag{1.7}$$

For studying (1.7) there exist two commonly known approaches: the method of steepest descent and the method of stationary phase. The main idea of the first is an appropriate deformation of the contour of integretion. This method can be applied only if q and θ are analytic, but it may give more detailed information about the asymptotic behavior of (1.7) and can be used when the contour is not the real axis. The method of stationary phase is based on integration by parts and is applicable when q and θ are smooth functions. In this paper, we advocate the point of view that all results obtained for oscillatory integrals can be generalized to oscillatory RHPs (1.1). Indeed, it has been shown by the authors of Ref. 4 that one can investigate (1.1) by deforming the conjugation contour of (1.1). It is worth mentioning that in Ref. 4 a special technique of rational approximations of q was developed to include not only analytic q. The theorem posed in this Introduction establishes a result which, in the classical theory, is stated by the method of stationary phase. It is interesting to note that formulas (1.4) and (1.5) become classical if one passes to the limit $p\to 0$ and takes into account that the potentials in this case are given by (1.7).

The present paper is closely related to Refs. 2 and 4. We proceed by conjugating the original RHP (1.1) to

$$\begin{gathered} M_+^{\Phi}(\lambda)=M_-^{\Phi}(\lambda)\Phi_-^{-1}(\lambda)G(\lambda,t)\Phi_+(\lambda), \quad \lambda\in R, \\ M^{\Phi}(\infty)=I, \end{gathered} \tag{1.1}$$

where piecewise analytical matrix function Φ is constructed explicitly: this is a way of Ref. 2 as well. The transformation (1.8) is employed both to localize the problem and to derive the model RHP. The latter was introduced in Ref. 2. The scheme of proof in the method of Ref. 2 was not developed rigorously. As it was demonstrated in Ref. 4, the most successful way for justification of asymptotics is to use the operator approach to the RHP of Beals and Coifman.[6] This is also applied here in a manner similar to Ref. 4, however, on the basis of completely different estimates.

As a final remark, we say a few words on the relationship between the steepest descent method and the method of stationary phase. Suppose it is desired to evaluate an integral

$$I(t)=\int_a^b q(\lambda)e^{it\theta(\lambda)}\,d\lambda$$

as $t\to\infty$, where $q(\lambda)$ and $\theta(\lambda)$ are smooth, and $\theta(\lambda)$ is real. If $q(\lambda)$ is analytic, and $\theta(\lambda)$ is real analytic, and if, in addition, for some (small) $\varepsilon>0$,

$$\text{Im } \theta(\lambda)>0 \quad \text{for } a<\text{Re } \lambda<b, \quad 0<\text{Im } \lambda<\varepsilon, \tag{1.8}$$

then the above integral can be deformed to an integral on a contour lying in $a<\text{Re}\,\lambda<b$, $0<\text{Im}\,\lambda<\varepsilon$. But then $\text{Re}\, i\theta(\lambda)<0$, and as $t\to\infty$, the leading contributions to $I(t)$ clearly arises from small neighborhoods of a and b. These observations, in particular, are taken for the ground of the method in Ref. 4.

Now as $\theta(\lambda)$ is real analytic, it follows from (1.8) and the Cauchy–Riemann equations that

$$\theta'(\lambda)=\frac{\partial \text{ Re } \theta}{\partial(\text{Re } \lambda)}(\lambda)=\frac{\partial \text{ Im } \theta}{\partial(\text{Im } \lambda)}(\lambda)>0,$$

and hence as $\theta'(\lambda)\neq 0$ in (a,b) one can evaluate $I(t)$ asymptotically simply integrating by parts on the real axis. In other words analyticity is not needed to evaluate $I(t)$ as $t\to\infty$: all that is needed are familiar to (1.8) conditions on the signature of $\theta'(\lambda)$ on appropriate subintervals of R. This is the basis of the method in the present paper.

II. THE SCALAR RIEMANN–HILBERT PROBLEM

In this section, we discuss the properties of the solution of the scalar factorization problem:

$$\begin{gathered}\delta_+(\lambda)=\delta_-(\lambda)(1+p(\lambda)q(\lambda)), \quad \lambda\in D_-,\\ \delta_+(\lambda)=\delta_-(\lambda), \quad \lambda\in D_+,\\ \delta(\infty)=1,\end{gathered} \tag{2.1}$$

where

$$D_+=\{\lambda:\lambda\in R,\theta'(\lambda)>0\}, \quad D_-=\{\lambda:\lambda\in R,\theta'(\lambda)<0\}. \tag{2.2}$$

The role of $\delta(\lambda)$ will be made clear in the sequel.

The problem (2.1) has a unique solution in the class of bounded functions. It is given by the following formula:

$$\ln\,\delta(\lambda)=\frac{1}{2\pi i}\int_{D_-}\frac{\ln(1+p(\lambda)q(\lambda))}{z-\lambda}\,dz. \tag{2.3}$$

Standard theorems concerning singular integrals reveal that $\delta_\pm$ are smooth functions in the domain $D_+\cup D_-$. The preceding as well as following statements are a consequence of conditions A and D.

Assume for the moment that

$$\nu(\lambda)=-\frac{1}{2\pi}\ln(1+p(\lambda)q(\lambda)) \tag{2.4}$$

is analytic in some small neighborhood of the stationary phase point λ_n. Then, one can verify calculating the jump on the left-hand side of

$$\ln\,\delta(\lambda)-i\varepsilon_n\nu(\lambda)\ln(\varepsilon_n(\lambda-\lambda_n))=\Lambda(\lambda) \tag{2.5}$$

that Λ is analytic in a neighborhood of λ_n. We choose the principle branch of the logarithm, and ε_n denotes sgn $\theta''(\lambda_n)$.

Now, consider the general case. Let $\varphi(\lambda)$ be a finite function whose support contains only one stationary phase point λ_n and $\varphi(\lambda)=1$ if $|\lambda-\lambda_n|\leqslant r, r>0$. Furthermore, split $\nu(\lambda)$ as follows:

$$\begin{gathered}\nu(\lambda)=\nu^1(\lambda)\varphi(\lambda)+(\nu(\lambda)-\nu^1(\lambda))\varphi(\lambda)+\nu(\lambda)(1-\varphi(\lambda)),\\ \nu^1(\lambda)=\sum_{k=0}^{m+1}\frac{\nu^{(k)}(\lambda_n)}{k!}(\lambda-\lambda_n)^k.\end{gathered}\tag{2.6}$$

Divide (2.3) into three Cauchy integrals in accordance with (2.6). The density of the third Cauchy integral is zero when $z\in I_n$ (I_n denotes the interval $|z-\lambda_n|<r$), hence analytic in the circle $|\lambda-\lambda_n|<r$. The density of the second Cauchy integral can be extended by zero from $D_-\cap I_n$ to I_n: the extension belongs to $C^{m+1}(I_n)$. Therefore, this integral produces the piecewise analytic function whose boundary values are in $C^m(I_n)$. The first term in (2.6) is analytic in the circle $|\lambda-\lambda_n|<r$. Thus (2.5) and (2.6) give rise to the proceeding representation for $\delta(\lambda)$ in a small neighborhood of λ_n:

$$\ln\,\delta(\lambda)=i\varepsilon_n\nu^1(\lambda)\ln\,\varepsilon_n(\lambda-\lambda_n)+\Lambda^1(\lambda).\tag{2.7}$$

In (2.7), Λ^1 is analytic for $\operatorname{Im}\lambda\neq 0$, $|\lambda-\lambda_n|<r$, and its boundary values, $\Lambda^1_\pm$, belong to $C^m(I_n)$. Note also that

$$\Lambda^1_+(\lambda_n)=\Lambda^1_-(\lambda_n)\equiv i\gamma(\lambda_n).\tag{2.8}$$

From (2.7) it is easy to see that the local behavior of $\delta(\lambda)$ at λ_n is described by

$$\begin{gathered}\delta^{\,n}(\lambda)=(\lambda-\lambda_n)^{i\nu_n}\varepsilon_n^{i\nu_n}e^{i\gamma(\lambda_n)},\quad -\pi<\arg\,\varepsilon_n(\lambda-\lambda_n)<\pi,\\ \nu_n=\varepsilon_n\nu(\lambda_n)\equiv\operatorname{sgn}\,\theta''(\lambda_n)\nu(\lambda_n).\end{gathered}\tag{2.9}$$

We summarize the results as follows:

Proposition 2.1: Let $\delta(\lambda)$ be a solution of (2.1) in the class of bounded functions. Then,

(1) it is unique, and $\delta_\pm$ are smooth functions in $D_+\cup D_-$, and

(2) in a sufficiently small neighborhood of the stationary phase point λ_n, the following estimates are valid:

$$\left|\frac{d^k}{d\lambda^k}\,\delta_\pm(\lambda)\right|\leqslant\frac{C}{|\lambda-\lambda_n|^k},\tag{2.10}$$

$$|\delta(\lambda)-\delta^n(\lambda)|\leqslant C|\lambda-\lambda_n|\ln|\lambda-\lambda_n|.\tag{2.11}$$

A simple way to derive an explicit expression for $\gamma(\lambda_n)$ is to obtain it through

$$e^{2i\gamma(\lambda_n)}=\lim_{\lambda\to\lambda_n}|\lambda-\lambda_n|^{-2i\nu_n}\delta_+(\lambda)\delta_-(\lambda).\tag{2.12}$$

Direct calculations lead to

$$\gamma(\lambda_n)=\sum_{k=1,k\neq n}^{N}\nu_k\,\ln|\lambda_n-\lambda_k|+\frac{1}{2\pi}\int_{D_-}\ln|z-\lambda_n|d\,\ln(1+p(z)q(z)).\tag{2.13}$$

Here we have used the fact that

$$\ln\ \delta_+(\lambda)\delta_-(\lambda)=\sum_{k=1}^{N} 2i\nu_k \ln|\lambda-\lambda_k|-2i\int_{D_-} \ln|z-\lambda|\,d\nu(z). \tag{2.14}$$

Identity (2.14) is found by integration by parts.

In later sections, we shall thoroughly investigate the piecewise analytic matrix

$$m(\lambda)=M(\lambda)e^{-\sigma_3 \ln \delta(\lambda)}. \tag{2.15}$$

It satisfies the following factorization problem:

$$m_+(\lambda)=m_-(\lambda)(b^-)^{-1}b^+, \quad m(\infty)=I, \tag{2.16}$$

where $b^{\pm}$ are triangular matrices,

$$b^+(\lambda)=\begin{pmatrix} 1 & 0 \\ \overline{\rho(\lambda,t)} & 1 \end{pmatrix}, \quad b^-(\lambda)=\begin{pmatrix} 1 & -\rho(\lambda,t) \\ 0 & 1 \end{pmatrix} \tag{2.17a}$$

if $\lambda\in D_+$,

$$b^+(\lambda)=\begin{pmatrix} 1 & \rho(\lambda,t) \\ 0 & 1 \end{pmatrix}, \quad b^-(\lambda)=\begin{pmatrix} 1 & 0 \\ -\overline{\rho(\lambda,t)} & 1 \end{pmatrix} \tag{2.17b}$$

if $\lambda\in D_-$. Here, we have introduced the notations:

$$\rho(\lambda,t)=p(\lambda)\delta_+(\lambda)\delta_-(\lambda)e^{-it\theta(\lambda)}, \quad \overline{\rho(\lambda,t)}=q(\lambda)\delta_+^{-1}(\lambda)\delta_-^{-1}(\lambda)e^{it\theta(\lambda)}. \tag{2.18}$$

It is clear that one may find the potentials, u and v, through the solutions of (2.16) by the same formulas (1.3) with $m(\lambda)$ in place of $M(\lambda)$.

III. OPERATOR FORMULATION OF THE RHP

As in Ref. 4 we shall employ the method of Beals and Coifman[6] in order to construct the singular integral equation associated with (2.16). It will be the basis for later proofs. All the results in this section can be found in Ref. 6. They are given here merely for convenience of subsequent use.

We begin with classical properties of Cauchy operators,

$$(C_\pm f\ )(\lambda)=\frac{1}{2\pi i}\lim_{\varepsilon\to 0}\int_{-\infty}^{\infty}\frac{f(z)}{z-(\lambda\pm i\varepsilon)}\,dz, \quad \varepsilon>0. \tag{3.1}$$

A natural way of treating $C_\pm$ is to regard them as operators in $L_2(R)$. The Fourier transform gives

$$(C_\pm f\ )(\lambda)=\pm\int_{-\infty}^{\infty}\hat{f}(s)H(\mp s)e^{-is\lambda}\,ds, \tag{3.2}$$

where $H(s)$ is the Heavyside unit symbol. It follows trivially from (3.2) that $\pm C_\pm$ are bounded operators from $L_2(R)$ to $L_2(R)$; moreover, they are mutually complementary orthogonal projection operators.

Introduce

$$C_w f=C_+(fw^-)+C_-(fw^+), \tag{3.3}$$

where

$$w^{\pm}=\pm(b^{\pm}-I) \tag{3.4}$$

and

$$w=w^{+}+w^{-}. \tag{3.5}$$

The operator C_w in (3.3) acts on the space of 2×2 matrix-valued functions. It is understood throughout the article that the L_2 and L_∞-norms, respectively, in this space are conventionally given by

$$\|f\|^2_{L_2(R)}=\int_{-\infty}^{\infty}\text{trace } ff^{*}\, d\lambda, \quad \|f\|_{L_\infty(R)}=\sup_{\lambda}|f(\lambda)|,$$

and $|f|$ denotes $\max_{ij}|f_{ij}|$. The matrices $w^{\pm}$ are ambiguously determined by the jump matrix of the RHP. However, we shall call them the data of the RHP, pointing out explicitly the chosen factorization of the jump matrix.

Let μ be a solution of the basic integral equation

$$\mu=I+C_w\mu. \tag{3.6}$$

If the solution of Eq. (3.6) exists, then one defines the solution of RHP (2.16) as

$$m(\lambda)=I+\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{\mu(z)w(z)}{z-\lambda}\,dz. \tag{3.7}$$

Indeed, simple calculations show that

$$m_{\pm}(\lambda)=I+C_{\pm}(\mu w^{+})+C_{\pm}(\mu w^{-})=\pm\mu w^{\pm}+I+C_w\mu=\mu(I\pm w^{\pm})=\mu b^{\pm}(\lambda), \tag{3.8}$$

which implies (2.16). It is not necessary, but sufficient, to suppose that $w^{\pm}\in L_2(R)\cap L_\infty(R)$. Then, C_w is a bounded map from $L_\infty(R)$ to $L_2(R)$; hence, $C_w(I)\in L_2(R)$,

$$\|C_w(I)\|_{L_2(R)}\leqslant\|w^{-}\|_{L_2(R)}+\|w^{+}\|_{L_2(R)}. \tag{3.9}$$

This fact, along with the uniqueness of the solution of the RHP, reveals that Eq. (3.6) has a unique solution if $id-C_w$ is invertible as an operator from $L_2(R)$ to $L_2(R)$. As an operator in $L_2(R)$, C_w has norm dominated by

$$\|C_w\|\leqslant\|w^{-}\|_{L_\infty}\|C_{+}\|+\|w^{+}\|_{L_\infty}\|C_{-}\|\leqslant\|w^{-}\|_{L_\infty}+\|w^{+}\|_{L_\infty}. \tag{3.10}$$

In particular, the solution of the RHP exists when $\|w^{-}\|_{L_\infty}+\|w^{+}\|_{L_\infty}<1$. In addition, note that if Eq. (3.6) has a solution μ, then $\mu-I\in L_2(R)$.

Examine the question of what happens if the factorization data of the jump matrix $(b^{\pm})$ are changed. Set $b^{\pm}=Ub'^{\pm}$, where the matrix U is invertable. Then one has the following relation:[7]

$$(id-C_w)=(id-C_{w'})\hat{U}, \tag{3.11}$$

here $\hat{U}$ is an operator of right multiplication by U $(\hat{U}f=fU)$. In fact,

$$\begin{aligned}(id-C_{w'})\hat{U}f&=fU-C_{+}(fU(I-b'^{-}))+C_{-}(fU(I-b'^{+}))\\&=fU-C_{+}(f(U-b^{-}))-C_{-}(f(b^{+}-U))\\&=f-C_{+}(fw^{-})-C_{-}(fw^{+})=(id-C_w)f.\end{aligned}$$

IV. LOCALIZATION PRINCIPLE

In this section, we shall show that only small neighborhoods of the stationary phase points give an essential contribution to the potentials. This fact will help us to reduce the original Riemann–Hilbert problem to some RHPs with one stationary phase point. First, we shall discuss some asymptotic properties of singular integrals. The method of stationary phase based on integration by parts[8] is the most useful for this purpose.

Lemma 1: Let $f\in C^{2k-1}(R)$, $k>1$, and

(1) supp $f\subset D_+$ or supp $f\subset D_-$.

Suppose also that for any set of non-negative integers β, α_i such that $\Sigma_{m=0}^{n}\ \alpha_m=\Sigma_{m=0}^{n}\ m\alpha_m=n-\beta$,

(2) $f^n_{\beta,\alpha_0,\ldots,\alpha_n}\to 0$ as $\lambda\to\pm\infty$, $n<k$.

(3) $f^k_{\beta,\alpha_0,\ldots,\alpha_k}|\theta'|^d\in L_1$ at $\pm\infty$, $d=1,\ \frac{1}{2}$, where $f^n_{\beta,\alpha_0,\ldots,\alpha_n}=|f^{(\beta)}||\theta'|^{\beta+d-2n}|\theta'|^{\alpha_0}\cdots|\theta^{(n+1)}|^{\alpha_n}$. Then,

$$\lim_{\varepsilon\to 0}\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{f(z)e^{it\theta(z)}}{z-(\lambda+i\varepsilon)}\,dz=\operatorname{sgn}\varepsilon H(\operatorname{sgn}\varepsilon\theta'(\lambda))f(\lambda)e^{it\theta(\lambda)}+I_0(\lambda),\tag{4.1}$$

where $H(\lambda)$ is the Heavyside unit symbol, and for $I_0(\lambda)$, one has the estimates

$$\|I_0\|_{L_\infty(R)}\leqslant\frac{C}{t^{k-1}},\quad \|I_0\|_{L_2(R)}\leqslant\frac{C}{t^{k-1/2}}.\tag{4.2}$$

Proof: It is sufficient to prove the lemma for supp $f\subset D_+$, since the proof when supp $f\subset D_-$ is similar. It is enough to prove the result for $\varepsilon<0$, since for $\varepsilon>0$ it follows immediately from the fact that $\pm C_\pm$ are complementary orthogonal projection operators.

Represent the left-hand side of (4.1) in the form (3.2):

$$I_0(\lambda)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{f(z)e^{it\theta(z)}}{z-(\lambda-i0)}\,dz=-\int_0^{\infty}\hat f_t(s)e^{-is\lambda}\,ds.$$

Applying integration by parts, we get

$$\hat f_t(s)=\frac{1}{2\pi}\int_{-\infty}^{\infty}f(\lambda)e^{it\theta(\lambda)+is\lambda}\,d\lambda=\frac{(-1)^k}{2\pi i^k}\int_{-\infty}^{\infty}f_k(\lambda,s,t)e^{it\theta(\lambda)+is\lambda}\,d\lambda,$$

where

$$f_k(\lambda,s,t)=\frac{d}{d\lambda}\left(\frac{1}{\omega(\lambda)}\,f_{k-1}(\lambda,s,t)\right),\quad f_0(\lambda)=f(\lambda),$$

$$\omega(\lambda)=t\theta'(\lambda)+s>0\quad\text{for}\quad\lambda\in\operatorname{supp}f,\quad s>0.$$

Note that

$$f_k(\lambda,s,t)=\sum_{\beta=0}^{k}f^{(\beta)}(\lambda)\omega^{\beta-2k}C^k_\beta(\omega,\omega',\ldots,\omega^{(k)}),$$

where C^k_β are homogeneous polynomials of order $k-\beta$ whose coefficients, $C^k_{\beta\alpha_0\cdots\alpha_k}\omega^{\alpha_0}\cdots(\omega^{(k)})^{\alpha_k}$, are nonzero only if $\Sigma^k_{m=0}m\alpha_m=k-\beta$. We now use the Minkowski integral inequality,

$$\left(\int_0^\infty |\hat{f}_t(s)|^p \, ds \right)^{1/p} \leqslant \frac{1}{2\pi} \int_{-\infty}^{\infty} d\lambda \left(\int_0^\infty ds |f_k(\lambda,s,t)|^p \right)^{1/p}. \tag{4.3}$$

Since $\omega^{(m)}$ does not depend on s for $m>0$, the first integral on the right-hand side of (4.3) can be easily calculated; one derives

$$\|I_0\|_{L_\infty} \leqslant \int_0^\infty |\hat{f}_t(s)| ds \leqslant \frac{1}{t^{k-1}} \frac{1}{2\pi} \frac{1}{k-1} \sum_{\beta=0}^{k} \int_{-\infty}^{\infty} |f^{(\beta)}(\lambda)| |\theta'(\lambda)|^{\beta+1-2k} |C_\beta^k(\lambda)| d\lambda,$$

$$\|I_0\|_{L_2} = \sqrt{2\pi} \left(\int_0^\infty |\hat{f}_t(s)|^2 ds \right)^{1/2} \leqslant \frac{1}{t^{k-1/2}} \frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{2k-1}} \sum_{\beta=0}^{k} \int_{-\infty}^{\infty} |f^{(\beta)} \times (\lambda)| |\theta'(\lambda)|^{\beta+1/2-2k} |C_\beta^k(\lambda)| d\lambda.$$

In the above inequalities, $|C_\beta^k(\lambda)|$ denote $\Sigma_{\alpha_0 \cdots \alpha_k} |C^k_{\beta\alpha_0\cdots\alpha_k}| |\theta'(\lambda)|^{\alpha_0} |\theta''(\lambda)|^{\alpha_1} \cdots |\theta^{(k+1)}(\lambda)|^{\alpha_k}$. The lemma is evident.

To separate the contributions from the distinct stationary phase points, we shall employ a partition of unity:

$$\sum_{n=1}^{N} \varphi_n(\lambda) + \varphi(\lambda) + \psi(\lambda) = 1,$$

where φ, ψ, $\varphi_n \in C^\infty(R)$, $\varphi_n(\lambda)=1$ if $|\lambda-\lambda_n| \leqslant 3\epsilon/4$, $\varphi_n(\lambda)=0$ if $|\lambda-\lambda_n|>\epsilon$, supp $\varphi \subset D_+$, supp $\varphi \subset D_-$, and ϵ is some positive number such that there is only one stationary phase point λ_n in supp φ_n.

Set

$$\begin{aligned} \rho_\pm^\varphi &= C_\pm(\varphi\rho), \quad \rho_\pm^\psi = C_\pm(\psi\rho), \\ \overline{\rho}_\pm^{\,\varphi} &= C_\pm(\varphi\overline{\rho}), \quad \overline{\rho}_\pm^{\,\psi} = C_\pm(\psi\overline{\rho}). \end{aligned} \tag{4.4}$$

One can apply Lemma 1 to (4.4). Indeed, Proposition 2.1 shows that $\varphi\rho$, $\psi\rho$, $\varphi\overline{\rho}$, and $\psi\overline{\rho}$ are smooth functions whose supports are in D_+ or D_-. Conditions A and B imposed on θ, p, and q make premises (2) and (3) of the lemma fulfilled as well. It is convenient to summarize the properties of (4.4) as follows:

Proposition 4.1: For any given k, there are constants $C(k)$ independent on t such that

$$\rho_-^\varphi = -\rho\varphi + \rho_+^\varphi, \quad \|\rho_+^\varphi\| \leqslant \frac{C(k)}{t^k}, \quad \rho_+^\psi = \rho\psi + \rho_-^\psi, \quad \|\rho_-^\psi\| \leqslant \frac{C(k)}{t^k},$$

$$\overline{\rho}_+^{\,\varphi} = \overline{\rho\varphi} + \overline{\rho}_-^{\,\varphi}, \quad \|\overline{\rho}_-^{\,\varphi}\| \leqslant \frac{C(k)}{t^k}, \quad \overline{\rho}_-^{\,\psi} = -\overline{\rho\psi} + \overline{\rho}_+^{\,\psi}, \quad \|\overline{\rho}_+^{\,\psi}\| \leqslant \frac{C(k)}{t^k}.$$

Here, $\|\rho\|$ denotes the L_∞- or L_2-norms.

Suppose that $m^L(\lambda)$ is a solution of the RHP

$$m_+^L(\lambda) = m_-^L(\lambda)(b_L^-)^{-1} b_L^+, \quad m^L(\infty) = I, \tag{4.5}$$

where $b_L^{\pm}$ are related to the data $w_L^{\pm}$ given by $w_L^{\pm}=\Sigma_{n=1}^{N}\varphi_n w^{\pm}$ [see (3.4)]. It is clear that these data are not zero only in neighborhoods of the stationary phase points. In the following sections, we shall prove that the operator $id - C_{w_L}$ associated with (4.5) is invertible as an operator in L_2 if t is large enough, and the norm of its inverse is bounded when $t\to\infty$.

Proposition 4.2: There is a number t_0 such that the solution of the RHP (2.16) exists at least for $t\geqslant t_0$. Moreover, for any given k, one has

$$|m(\lambda)-m^L(\lambda)|\leqslant\frac{C(k)}{t^k}\quad\text{if } |\mathrm{Im}\,\lambda|\geqslant a>0, \tag{4.6}$$

and

$$u(t)=u^L(t)+O\left(\frac{1}{t^k}\right),\quad v(t)=v^L(t)+O\left(\frac{1}{t^k}\right). \tag{4.7}$$

Proof: Introduce the piecewise analytical matrix function

$$\Phi(\lambda)=\begin{pmatrix}1 & 0\\ -\overline{\rho}^{\varphi}_{+}(\lambda) & 1\end{pmatrix}\begin{pmatrix}1 & -\rho^{\psi}_{+}(\lambda)\\ 0 & 1\end{pmatrix},\quad \mathrm{Im}\,\lambda>0,$$

$$\Phi(\lambda)=\begin{pmatrix}1 & -\rho^{\varphi}_{-}(\lambda)\\ 0 & 1\end{pmatrix}\begin{pmatrix}1 & 0\\ -\overline{\rho}^{\psi}_{-}(\lambda) & 1\end{pmatrix},\quad \mathrm{Im}\,\lambda<0.$$

Because $|\Phi(\lambda)-I|\leqslant Ct^{-k}$ when $|\mathrm{Im}\,\lambda|\geqslant a>0$, it is sufficient to prove the results for matrix

$$m^{\Phi}(\lambda)=m(\lambda)\Phi(\lambda), \tag{4.8}$$

which satisfies the factorization problem

$$\begin{gathered}m^{\Phi}_{+}(\lambda)=m^{\Phi}_{-}(\lambda)(b^{-}_{\Phi})^{-1}b^{+}_{\Phi},\quad b^{\pm}_{\Phi}=b^{\pm}\Phi_{\pm},\\ m^{\Phi}(\infty)=I.\end{gathered} \tag{4.9}$$

It follows from Proposition 4.1 that the data of the RHP (4.9) can be decomposed in the form

$$w^{\pm}_{\Phi}=w^{\pm}_{L}+w^{\pm}_{R}, \tag{4.10}$$

where $w_R^{\pm}$ are small in the sense of the L_2- or L_∞-norms, viz.,

$$\|w^{\pm}_{R}\|_{L_\infty(R)},\|w^{\pm}_{R}\|_{L_2(R)}\leqslant\frac{C}{t^k}. \tag{4.11}$$

The basic integral equation,

$$\mu^{\Phi}=I+C_{w_\Phi}\mu^{\Phi}, \tag{4.12}$$

can be equivalently rewritten as

$$\begin{gathered}A(\mu^{\Phi}-\mu^{L})=(id-C_{w_L})^{-1}C_{w_R}\mu^{L},\\ A=id-(id-C_{w_L})^{-1}C_{w_R},\end{gathered} \tag{4.13}$$

provided that $id - C_{w_L}$ is invertible. The norm of C_{w_R} converges to zero as $t\to\infty$. Therefore, the operator A has an inverse if t is large enough. This leads to the desired existence of the solution of (4.12) and hence of (4.9).

From (3.7) and (4.10), one has

$$m^{\Phi}(\lambda)-m^{L}(\lambda)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{w_R(z)}{z-\lambda}\,dz+\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{(\mu^{\Phi}-\mu^{L})w_{\Phi}}{z-\lambda}\,dz+\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{(\mu^{L}-I)w_R}{z-\lambda}\,dz, \tag{4.14}$$

and for $|\mathrm{Im}\,\lambda|\geqslant a>0$

$$|m^{\Phi}(\lambda)-m^{L}(\lambda)|\leqslant C\{\|w_R\|_{L_2}+\|\mu^{\Phi}-\mu^{L}\|_{L_2}\|w_{\Phi}\|_{L_2}+\|\mu^{L}-I\|_{L_2}\|w_R\|_{L_2}\}. \tag{4.15}$$

Inserting (4.11) and the estimate

$$\|\mu^{\Phi}-\mu^{L}\|_{L_2}\leqslant C(\|w_R^{+}\|_{L_2}+\|w_R^{-}\|_{L_2}+(\|w_R^{+}\|_{L_\infty}+\|w_R^{-}\|_{L_\infty})\|\mu^{L}-I\|_{L_2}), \tag{4.16}$$

which is a consequence of (4.13), in (4.15), one derives (4.6).

To complete the proof, observe that

$$w_R=\begin{pmatrix}0 & \rho_{+}^{\varphi}-\rho_{-}^{\psi}\\ \overline{\rho_{+}^{\psi}}-\overline{\rho_{-}^{\varphi}} & 0\end{pmatrix}+w_I. \tag{4.17}$$

In the splitting of (4.17), each element of w_I belongs to $L_1(R)$ as a sum of the functions like $\rho\varphi\overline{\rho_{+}^{\psi}},\rho_{+}^{\varphi}\overline{\rho_{+}^{\psi}}\cdots$; its L_1-norm is dominated by $\|\rho_{+}^{\varphi}\|_{L_2}+\|\rho_{-}^{\psi}\|_{L_2}+\|\overline{\rho_{+}^{\varphi}}\|_{L_2}+\|\overline{\rho_{-}^{\psi}}\|_{L_2}\leqslant C(k)t^{-k}$. Multiply (4.14) by λ and pass to the limit $\lambda\to\infty$. In the process of estimating this limit, only the first term of (4.14) is troublesome. However, note that

$$\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{w^{R}-w^{I}}{z-\lambda}\,dz=\begin{pmatrix}0 & \rho_{+}^{\varphi}(\lambda)\\ \overline{\rho_{+}^{\psi}}(\lambda) & 0\end{pmatrix},$$

if $\mathrm{Im}\,\lambda\geqslant 0$. The above formula and analogous one for $\mathrm{Im}\,\lambda\leqslant 0$, together with (4.17), say that

$$\left|\lim_{\lambda\to\infty}\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{\lambda w^{R}(z)}{z-\lambda}\,dz\right|\leqslant\frac{C}{t^{k}},\quad \mathrm{Im}\,\lambda\neq 0.$$

Now, the asymptotics of (4.7) are evident.

The proof of Proposition 4.2 illuminates the reason why the original RHP (1.1) was conjugated to the RHP (2.16) in which the jump matrix had factorization (2.17). To have a better grasp of that, it is useful to review the proof for the phase with no stationary points. Let $\theta'(\lambda)>0$ for definiteness. Then, one must choose the factorization (2.17a). Split $\rho(\overline{\rho})$ in the form $\rho=\rho_{+}-\rho_{-}$ $(\overline{\rho}=\overline{\rho_{+}}-\overline{\rho_{-}})$. Since ρ_{+}, $\overline{\rho_{-}}$ are small while $\rho_{-}(\overline{\rho_{+}})$ can be incorporated into m_{-} (m_{+}), we conclude that $\Phi(\psi=0)$ is an approximating solution of (2.16), and the potentials decrease to higher order in t.

In the rest of this section, we pursue the study of oscillatory singular integrals. Before formulating our results, let us introduce some notations. Set

$$\begin{aligned}\rho_n&=p(\lambda_n)e^{-it\theta(\lambda_n)}\delta_{+}^{n}(\lambda)\delta_{-}^{n}(\lambda)e^{-it\varepsilon_n\kappa_n(\lambda-\lambda_n)^2},\\ \overline{\rho_n}&=q(\lambda_n)e^{it\theta(\lambda_n)}(\delta_{+}^{n}(\lambda))^{-1}(\delta_{-}^{n}(\lambda))^{-1}e^{it\varepsilon_n\kappa_n(\lambda-\lambda_n)^2},\end{aligned} \tag{4.18}$$

and

$$h(\lambda)=H(\varepsilon_n(\lambda-\lambda_n)),\quad e(\lambda)=H(-\varepsilon_n(\lambda-\lambda_n)), \tag{4.19}$$

where $\kappa_n=\frac{1}{2}|\theta''(\lambda_n)|$ and $\epsilon_n=\operatorname{sgn}\theta''(\lambda_n)$. Then, define

$$\begin{aligned}&\rho_{\pm}^{h}=C_{\pm}((\rho\varphi_n-\rho_n)h),\quad \rho_{\pm}^{e}=C_{\pm}((\rho\varphi_n-\rho_n)e),\\ &\overrightarrow{\rho}_{\pm}^{h}=C_{\pm}((\overrightarrow{\rho\varphi}_n-\overrightarrow{\rho_n})h),\quad \overrightarrow{\rho}_{\pm}^{e}=C_{\pm}((\overrightarrow{\rho\varphi}_n-\overrightarrow{\rho_n})e).\end{aligned} \tag{4.20}$$

Proposition 4.3:

$$\rho_{-}^{h}=-(\rho\varphi_n-\rho_n)h+\rho_{+}^{h},\quad \|\rho_{+}^{h}\|_{L_\infty}\leqslant Ct^{-1/2}\ln t,\quad \|\rho_{+}^{h}\|_{L_2}\leqslant Ct^{-3/4}\ln t,$$

$$\rho_{+}^{e}=(\rho\varphi_n-\rho_n)e+\rho_{-}^{e},\quad \|\rho_{-}^{e}\|_{L_\infty}\leqslant Ct^{-1/2}\ln t,\quad \|\rho_{-}^{e}\|_{L_2}\leqslant Ct^{-3/4}\ln t,$$

$$\overrightarrow{\rho}_{+}^{h}=(\overrightarrow{\rho\varphi}_n-\overrightarrow{\rho_n})h+\overrightarrow{\rho}_{-}^{h},\quad \|\overrightarrow{\rho}_{-}^{h}\|_{L_\infty}\leqslant Ct^{-1/2}\ln t,\quad \|\overrightarrow{\rho}_{-}^{h}\|_{L_2}\leqslant Ct^{-3/4}\ln t,$$

$$\overrightarrow{\rho}_{-}^{e}=-(\overrightarrow{\rho\varphi}_n-\overrightarrow{\rho_n})e+\overrightarrow{\rho}_{+}^{e},\quad \|\overrightarrow{\rho}_{+}^{e}\|_{L_\infty}\leqslant Ct^{-1/2}\ln t,\quad \|\overrightarrow{\rho}_{+}^{e}\|_{L_2}\leqslant Ct^{-3/4}\ln t.$$

Proof: We prove the estimates for ρ_{-}^{e} in the case when $\varepsilon_n=-1$, because the proofs for the other estimates are similar. Notice that $\rho\varphi_n$ can be rewritten for $\lambda-\lambda_n\geqslant 0$ in the form

$$\rho\varphi_n=\varphi_n e^{-it\theta}\delta_{+}^{2}r,\quad r(\lambda)=\frac{p(\lambda)}{1+p(\lambda)q(\lambda)}.$$

Set

$$\rho^{1}\varphi_n=\varphi_n e^{-it\theta}\delta_{+}^{2}r^{1},\quad r^{1}(\lambda)=\sum_{m=0}^{3}\frac{r^{(m)}(\lambda_n)}{m!}(\lambda-\lambda_n)^m.$$

Since

$$\rho\varphi_n-\rho^{1}\varphi_n=\operatorname{Re}^{-it\theta},\quad R(\lambda)=\varphi_n(\lambda)\,\delta_{+}^{2}(\lambda)(r(\lambda)-r^{1}(\lambda)),$$

$e(\lambda)R(\lambda)$ belongs to $C^{3}(R)$ [because of (2.10)], and $\operatorname{supp} eR\subset D_{-}$, Lemma 1 yields

$$\|C_{-}((\rho-\rho^{1})\varphi_n e)\|_{L_\infty}\leqslant Ct^{-1},\quad \|C_{-}((\rho-\rho^{1})\varphi_n e)\|_{L_2}\leqslant Ct^{-3/2}. \tag{4.21}$$

Now we replace the phase by its Taylor's series:

$$\theta^{1}(\lambda)=\sum_{m=0}^{5}\frac{\theta^{(m)}(\lambda_n)}{m!}(\lambda-\lambda_n)^m.$$

Let

$$\rho^{\tau}=e^{-it\theta^{\tau}}\delta_{+}^{2}r^{1},\quad \theta^{\tau}(\lambda)=\theta^{1}(\lambda)+\tau(\theta(\lambda)-\theta^{1}(\lambda)).$$

Then

$$C_{-}((\rho^{1}-\rho^{0})\varphi_n e)=-it\int_{0}^{1}d\tau C_{-}((\theta-\theta^{1})\rho^{\tau}\varphi_n e). \tag{4.22}$$

Recall that $\varphi_n(\lambda)=0$ for $|\lambda-\lambda_n|\geqslant\varepsilon$. Until now, ε was arbitrary; at this point, however, choose ε such that

$$\frac{\theta^{1\prime}(\lambda)}{\theta'(\lambda)}\geqslant a>0 \quad \text{for } |\lambda-\lambda_n|\leqslant\varepsilon.$$

This condition guarantees that $\theta^{\tau}(\lambda)$ has only one stationary point λ_n in supp φ_n. Application of Lemma 1, taken together with the Minkowski integral inequality, to (4.22) results in

$$\|C_-((\rho^1-\rho^0)\varphi_n e)\|_{L_\infty}\leqslant Ct^{-1}, \quad \|C_-((\rho^1-\rho^0)\varphi_n e)\|_{L_2}\leqslant Ct^{-3/2}. \tag{4.23}$$

By virtue of Lemma 1, it is also easy to show that the L_2- and L_∞-norms of $C_-(\rho_n(1-\varphi_n)e)$ decay to higher order as $t\to\infty$.

To conclude the proof, it remains to evaluate $C_-((\rho^0-\rho_n)\varphi_n e)$. Note that $(\rho^0-\rho_n)\varphi_n$ has an analytic continuation in the quadrant $|\lambda-\lambda_n|<\frac{3}{4}\varepsilon$, $\mathrm{Re}(\lambda-\lambda_n)>0$, $\mathrm{Im}\,\lambda>0$ [indeed, $\varphi_n(\lambda)=1$ if $|\lambda-\lambda_n|\leqslant\frac{3}{4}\varepsilon$, $\delta_+^n\delta_-^n=(\delta_+^n)^2/(1+p(\lambda_n)q(\lambda_n))$ if $\lambda-\lambda_n>0$]. Let $\Gamma=\Gamma_1\cup\Gamma_2\cup\Gamma_3$ be the contour which consists of an interval joining λ_n with $\lambda_n+\varepsilon' e^{i\pi/4}$ (Γ_1), an arc joining $\lambda_n+\varepsilon' e^{i\pi/4}$ with $\lambda_n+\varepsilon'$ (Γ_2), and a ray joining $\lambda_n+\varepsilon'$ with $+\infty$ (Γ_3). Here, ε' is a positive number less than $\frac{3}{4}\varepsilon$. Write

$$C_-((\rho^0-\rho_n)\varphi_n e)=\frac{1}{2\pi i}\int_{\lambda_n}^{\infty}\frac{(\rho^0(z)-\rho_n(z))\varphi_n(z)}{z-(\lambda-i0)}\,dz=\frac{1}{2\pi i}\int_{\Gamma_1}\frac{\rho^0(z)-\rho_n(z)}{z-\lambda}\,dz$$
$$+\frac{1}{2\pi i}\int_{\Gamma_2\cup\Gamma_3}\frac{(\rho^0(z)-\rho_n(z))\varphi_n(z)}{z-(\lambda-i0)}\,dz. \tag{4.24}$$

It is possible to choose ε' such that $\mathrm{Im}\,\theta^1(\lambda)\leqslant 0$ as $\lambda\in\Gamma_1\cup\Gamma_2$, $\mathrm{Im}\,\theta^1(\varepsilon' e^{i\pi/4})<0$, and $\theta^{1\prime}(\lambda)\neq 0$ as $\lambda\in\Gamma_2$. Therefore, the second integral on the right-hand side of (4.24) can be estimated by integration by parts for $\lambda\notin[\varepsilon',\varepsilon]$. However, notice that the variation of ε leads to the appearance in (4.24) of a small correction described by Lemma 1. Eventually, one derives appropriate L_2 and L_∞ evaluations for this integral.

Consider the first integral on the right-hand side of (4.24). Since

$$|\delta_+^2(\lambda)r^1(\lambda)-(\delta_+^n(\lambda))^2 r^1(\lambda_n)|\leqslant C|\lambda-\lambda_n|\ln|\lambda-\lambda_n|,$$

which is true because of (2.11), and since

$$|e^{-it\theta^1(\lambda)}-e^{it\theta^0(\lambda)}|\leqslant t|\theta^1(\lambda)-\theta^0(\lambda)|,$$

which is true if $\mathrm{Im}\,\theta^1(\lambda)$ and $\mathrm{Im}\,\theta^0(\lambda)\leqslant 0$, one obtains

$$\left|\frac{1}{2\pi i}\int_{\Gamma_1}\frac{\rho^0(z)-\rho_n(z)}{z-\lambda}\,dz\right|\leqslant C_1\int_0^{\varepsilon' e^{i\pi/4}}\frac{|z|\ln|z|e^{it\kappa_n\,\mathrm{Im}\,z^2}}{|z-(\lambda-\lambda_n)|}\,dz+C_2 t\int_0^{\varepsilon' e^{i\pi/4}}\frac{|z|^3 e^{it\kappa_n\,\mathrm{Im}\,z^2}}{|z-(\lambda-\lambda_n)|}\,dz$$
$$\leqslant C\,\frac{\ln t}{\sqrt{t}}\int_0^{\infty e^{i\pi/4}}\frac{(|z|\ln|z|+|z|^3)e^{i\kappa_n\,\mathrm{Im}\,z^2}}{|z-\xi|}\,dz=\frac{\ln t}{\sqrt{t}}f(\xi), \tag{4.25}$$

where $\xi=\sqrt{t}(\lambda-\lambda_n)$. The function f, determined through (4.25), is a function of ξ only obviously belonging to $L_2\cap L_\infty$. This completes the proof.

It should be pointed out that the above proof is a combination of ideas from Refs. 8 and 9.

V. MODEL RIEMANN–HILBERT PROBLEM

It has been explained that the asymptotic investigation of the RHP (2.16) is equivalent to the RHP (4.5). That the jump matrix in (4.5) is unity everywhere except small neighborhoods of the stationary phase points allows us to divide the factorization problem (4.5) into N simpler problems. As it turns out, the solution of (4.5) can be expressed, up to small errors, in terms of the solutions of the following RH problems:

$$\begin{gathered}\phi_+^n(\lambda)=\phi_-^n(\lambda)(b_n^-)^{-1}b_n^+, \quad n=1,\ldots,N,\\ \phi(\infty)=I,\end{gathered} \tag{5.1}$$

where $b_n^\pm$ are associated with the data $w_n^\pm=\varphi_n w^\pm$ ($b_n^\pm=I\pm\varphi_n w^\pm$). More precisely, it is a product of ϕ^n, while the potentials, u^L and v^L are a sum of potentials of (5.1). Before proving these statements rigorously, we shall conduct a comprehensive asymptotic analysis of (5.1).

On the other hand, problems (5.1) can be reduced, again up to small errors, to explicitly solvable ones. It is suitable to begin with these problems. To produce them, ρ and $\overline{\rho}$ in (2.16) should be replaced by ρ_n and $\overline{\rho_n}$ of (4.18), respectively. In new notations, after this substitution, one gets

$$\begin{aligned}\psi_+^M(\lambda)&=\psi_-^M(\lambda)(b_M^-)^{-1}b_M^+\\ &=\psi_-^M(\lambda)\begin{pmatrix}1 & \rho_n(\lambda)\\ 0 & 1\end{pmatrix}\begin{pmatrix}1 & 0\\ \overline{\rho_n}(\lambda) & 1\end{pmatrix}, \quad \varepsilon_n(\lambda-\lambda_n)>0\\ &=\psi_-^M(\lambda)\begin{pmatrix}1 & 0\\ \overline{\rho_n}(\lambda) & 1\end{pmatrix}\begin{pmatrix}1 & \rho_n(\lambda)\\ 0 & 1\end{pmatrix}, \quad \varepsilon_n(\lambda-\lambda_n)<0,\\ \psi^M(\infty)&=I.\end{aligned} \tag{5.2}$$

A more clear form of (5.2) is obtained with the following change of variables. Set

$$\xi=\varepsilon_n\sqrt{2\kappa_n t}(\lambda-\lambda_n), \quad -\pi<\arg\,\xi<\pi. \tag{5.3}$$

Then

$$\rho_n=p^0\xi_+^{i\nu_n}\xi_-^{i\nu_n}e^{-i\varepsilon_n\xi^2/2}, \quad \overline{\rho_n}=q^0\xi_+^{-i\nu_n}\xi_-^{-i\nu_n}e^{i\varepsilon_n\xi^2/2}, \tag{5.4}$$

where

$$p^0=p(\lambda_n)e^{-i\beta(\lambda_n)}, \quad q^0=q(\lambda_n)e^{i\beta(\lambda_n)}, \quad \beta=t\theta(\lambda_n)-2\gamma(\lambda_n)+\nu_n\ln 2\kappa_n t. \tag{5.5}$$

Inserting (5.3)–(5.5) into (5.2), we learn that

$$\psi_+^0(\xi)=\psi_-^0(\xi)\xi_-^{i\nu_n\sigma_3}\exp\left\{-i\sigma_3\varepsilon_n\frac{\xi^2}{2}\right\}v^{\varepsilon_n}\exp\left\{i\sigma_3\varepsilon_n\frac{\xi^2}{2}\right\}\xi_+^{-i\nu_n\sigma_3}. \tag{5.6}$$

Here, $\psi^0(\xi)$ is determined by the identity $\psi^M(\lambda)=\psi^0(\xi)$, and

$$v^1=\begin{pmatrix}1+p^0q^0 & p^0\\ q^0 & 1\end{pmatrix}, \quad v^{-1}=\begin{pmatrix}1 & -p^0\\ -q^0 & 1+p^0q^0\end{pmatrix}.$$

One thing which is worth mentioning is that, in the case when $\varepsilon_n=-1$, the substitution (5.3) maps the upper half-plane onto the lower half-plane and vice versa. This means that it is necessary to invert the jump matrix of (5.2) in deriving (5.6), whereas $\psi^M(\lambda\pm i0)=\psi^0(\xi\mp i0)$.

A natural method for solving (5.6) is to consider the piecewise analytic function $\Psi(\xi) = \psi_0(\xi)\xi^{i\nu_n\sigma_3}\exp(-i\sigma_3\varepsilon_n\xi^2/2)$. It happens that the jump matrix of Ψ is independent on ξ; hence, $(d\Psi/d\xi)\Psi^{-1}$ is an analytic function easily calculated through its known behavior at infinity. This results in a linear equation for Ψ which can be solved explicitly in terms of parabolic-cylinder functions. However, we shall find the solution of (5.6) directly, without calling on the linear equation.

Let

$$D_{i\nu}(z), \quad D_{i\nu}(-z), \quad D_{-i\nu-1}(iz), \quad D_{-i\nu-1}(-iz) \tag{5.7}$$

be the standard notations for the parabolic-cylinder functions. Recall that they are entire for any ν. Introduce

$$\Psi_1(\xi)=\begin{pmatrix} e^{\pi\nu/2}D_{i\nu}(i\alpha\xi) & ye^{-\pi\nu}D_{-i\nu-1}(-\alpha\xi) \\ -\overline{y}e^{\pi\nu/2}D_{i\nu-1}(i\alpha\xi) & e^{-\pi\nu}D_{-i\nu}(-\alpha\xi)\end{pmatrix}\alpha^{-i\nu\sigma_3},$$

$$\Psi_2(\xi)=\begin{pmatrix} e^{\pi\nu/2}D_{i\nu}(i\alpha\xi) & -yD_{-i\nu-1}(\alpha\xi) \\ -\overline{y}e^{\pi\nu/2}D_{i\nu-1}(i\alpha\xi) & D_{-i\nu}(\alpha\xi)\end{pmatrix}\alpha^{-i\nu\sigma_3},$$

$$\Psi_3(\xi)=\begin{pmatrix} e^{-\pi\nu/2}D_{i\nu}(-i\alpha\xi) & -yD_{-i\nu-1}(\alpha\xi) \\ \overline{y}e^{-\pi\nu/2}D_{i\nu-1}(-i\alpha\xi) & D_{-i\nu}(\alpha\xi)\end{pmatrix}\alpha^{-i\nu\sigma_3},$$

$$\Psi_4(\xi)=\begin{pmatrix} e^{-\pi\nu/2}D_{i\nu}(-i\alpha\xi) & ye^{\pi\nu}D_{-i\nu-1}(-\alpha\xi) \\ \overline{y}e^{-\pi\nu/2}D_{i\nu-1}(-i\alpha\xi) & e^{\pi\nu}D_{-i\nu}(-\alpha\xi)\end{pmatrix}\alpha^{-i\nu\sigma_3},$$

where y, $\overline{y}$, and ν satisfy the constraint $\nu=y\overline{y}$. Any three of the functions from the set (5.7) are linearly dependent as solutions of the same second-order linear differential equation. The exact connection formulas can be found in Ref. 10. Using them, one easily checks

$$\Psi_2(\xi)=\Psi_1(\xi)S_1, \quad \Psi_3(\xi)=\Psi_2(\xi)S_2, \quad \Psi_4(\xi)=\Psi_3(\xi)S_3, \tag{5.8}$$

where S_k are triangular matrices given by

$$S_1=\alpha^{i\nu\sigma_3}\begin{pmatrix} 1 & \dfrac{i\sqrt{2\pi}e^{-\pi\nu}}{\overline{y\Gamma}(i\nu)} \\ 0 & 1\end{pmatrix}\alpha^{-i\nu\sigma_3}, \quad S_2=\alpha^{i\nu\sigma_3}\begin{pmatrix} 1 & 0 \\ \dfrac{i\sqrt{2\pi}}{y\Gamma(-i\nu)} & 1\end{pmatrix}\alpha^{-i\nu\sigma_3},$$

$$S_3=\alpha^{i\nu\sigma_3}\begin{pmatrix} 1 & -\dfrac{i\sqrt{2\pi}e^{\pi\nu}}{\overline{y\Gamma}(i\nu)} \\ 0 & 1\end{pmatrix}\alpha^{-i\nu\sigma_3}, \quad \sigma_3=\begin{pmatrix} 1 & 0 \\ 0 & -1\end{pmatrix}.$$

Taking the asymptotic expansion of $D_{i\nu}(z)$ as $z\to\infty$,

$$D_{i\nu}(z)=z^{i\nu}e^{-z^2/4}\left(1+O\left(\frac{1}{z^2}\right)\right), \quad |\arg z|<\frac{3\pi}{4}, \tag{5.9}$$

and setting $\alpha = e^{-i\varepsilon_n\pi/4}$, one observes

$$\Psi_k(\xi)=\left(\begin{pmatrix} 1 & -ye^{i\varepsilon_n\pi/4}/\xi \\ -\varepsilon_n\overline{y}e^{-i\varepsilon_n\pi/4}/\xi & 1\end{pmatrix}+O\left(\frac{1}{|\xi|^2}\right)\right)e^{-i\varepsilon_n(\xi^2/4)\sigma_3+i\nu\sigma_3\ln\xi} \tag{5.10}$$

if $\xi\in\Omega_k(\varepsilon_n)$, $\xi\to\infty$,

$$\Omega_k(1)=\left\{\xi:-\frac{3\pi}{2}+\frac{k\pi}{2}<\arg\,\xi<-\frac{\pi}{2}+\frac{k\pi}{2}\right\},$$

$$\Omega_k(-1)=\left\{\xi:-2\pi+\frac{k\pi}{2}<\arg\,\xi<-\pi+\frac{k\pi}{2}\right\},\quad k=1,2,3,4.$$

Ending our construction, we demand that y, $\overline{y}$, and ν be chosen so that

$$\nu=\nu_n,\quad p^0=\frac{i\sqrt{2\pi}e^{-\varepsilon_n\pi\nu_n/2}}{\overline{y\Gamma}(i\nu_n)},\quad q^0=\frac{\varepsilon_n i\sqrt{2\pi}e^{-\varepsilon_n\pi\nu_n/2}}{y\Gamma(-i\nu_n)}. \tag{5.11}$$

Identities (5.11) are consistent with the constraint $\nu=y\overline{y}$. Indeed,

$$p^0q^0=-\varepsilon_n\frac{2\pi e^{-\varepsilon_n\pi\nu_n}}{\nu_n\Gamma(i\nu_n)\Gamma(-i\nu_n)}=-\varepsilon_n 2i\,\sin(i\pi\nu_n)e^{-\varepsilon_n\pi\nu_n}=-1+e^{-\varepsilon_n 2\pi\nu_n}.$$

Now, there are no obstacles to achieve the desired goal of solving (5.6). In fact, from (5.8), (5.10), and (5.11) it is seen that

$$\psi^0(\xi)=\begin{cases}\Psi_3(\xi)\xi^{-i\nu_n\sigma_3}e^{i(\xi^2/4)\sigma_3}, & \text{Im }\xi>0,\\ \Psi_1(\xi)\xi^{-i\nu_n\sigma_3}e^{i(\xi^2/4)\sigma_3}, & \text{Im }\xi<0,\end{cases}$$

is a solution of (5.6) when $\varepsilon_n=1$, while

$$\psi^0(\xi)=\begin{cases}\Psi_4(\xi)\xi^{-i\nu_n\sigma_3}e^{-i(\xi^2/4)\sigma_3}, & \text{Im }\xi>0,\\ \Psi_2(\xi)\xi^{-i\nu_n\sigma_3}e^{-i(\xi^2/4)\sigma_3}, & \text{Im }\xi<0,\end{cases}$$

is a solution of (5.6) when $\varepsilon_n=-1$.

The solution of (5.2) has been found explicitly. At this point, consider the operator $id-C_{w_M}$ related to (5.2) $[w_M^{\pm}=\pm(b_M^{\pm}-I), w_M=w_M^{+}+w_M^{-}]$. Dealing with the operator form of the RHP which was discussed in Sec. III, the following result from Refs. 4 and 7 is very useful:

Lemma 2: Let $\phi(\lambda)$ be a piecewise analytic invertible matrix, with $\phi(\infty)=I$. Define

$$w_\phi=w_\phi^{+}+w_\phi^{-},\quad w_\phi^{\pm}=\pm(b_\phi^{\pm}-I),$$

$$b^{\pm}=b_\phi^{\pm}\phi_{\pm},\quad w^{\pm}=\pm(b^{\pm}-I).$$

Then

$$(id-C_w)=(id-C_\phi)(id-C_{w_\phi}),$$

$$(id-C_{\phi^{-1}})(id-C_\phi)=(id-C_\phi)(id-C_{\phi^{-1}})=id,$$

where

$$C_\phi f=C_+(f(I-\phi_-))+C_-(f(\phi_+-I)),$$

$$C_{\phi^{-1}}f=C_+(f(I-\phi_-^{-1}))+C_-(f(\phi_+^{-1}-I)).$$

Proof: In fact,

$$
\begin{aligned}
C_\phi C_{w_\phi} &= C_\phi(C_+(\cdot w_\phi^-)+C_-(\cdot w_\phi^+)) \\
&= C_+[(C_+(\cdot w_\phi^-)+C_-(\cdot w_\phi^+))(I-\phi_-)]+C_-[(C_+(\cdot w_\phi^-)+C_-(\cdot w_\phi^+))(\phi_+-I)] \\
&= C_+(C_+(\cdot w_\phi^-)(I-\phi_-))+C_-(C_-(\cdot w_\phi^+)(\phi_+-I)) \\
&= C_+(\cdot w_\phi^-(I-\phi_-))-C_-(\cdot w_\phi^+(\phi_+-I))=C_{w_\phi}-C_w+C_\phi,
\end{aligned}
$$

whereas

$$
w_\phi^-(I-\phi_-)=w_\phi^- - w^- + (I-\phi_-), \quad w_\phi^+(\phi_+-I)=w^+ - w_\phi^+ + (I-\phi_+).
$$

The rest of the lemma is proved with similar calculations.

Return to the operator $(id - C_{w_M})$. Application of Lemma 2 in the case when $\phi(\lambda)=\psi^M(\lambda)$ and $b^\pm = b_M^\pm$ leads to

$$
(id-C_{w_M})^{-1}=\hat{\mu}^M(id-C_{\phi^{-1}}). \tag{5.12}
$$

In the above formula, $\hat{\mu}^M$ denotes right multiplication by μ^M ($\hat{\mu}^M f = f\mu^M$),

$$
(\mu^M)^{-1}=b_M^+(\psi_+^M)^{-1}=b_M^-(\psi_-^M)^{-1}=b_\phi^\pm. \tag{5.13}
$$

We have also used the identity

$$
(id-C_{w_\phi})f=f(\mu^M)^{-1}.
$$

From (5.12) one concludes that $(id - C_{w_M})^{-1}$ exists and is bounded as $t\to\infty$. In addition, since $C_{\phi^{-1}}I = 0$, μ^M is a solution of the basic integral equation.

Formula (5.13) gives a useful representation for μ^M which, after simplification by (5.8) and (5.11), takes the form

$$
\mu^M(\lambda;\varepsilon_n=1)=\begin{cases}\Psi_2(\xi)\xi^{-i\nu_n\sigma_3}e^{i(\xi^2/4)\sigma_3}, & \xi>0,\\ \Psi_4(\xi)\xi_+^{-i\nu_n\sigma_3}e^{i(\xi^2/4)\sigma_3}, & \xi<0,\end{cases} \tag{5.14a}
$$

$$
\mu^M(\lambda;\varepsilon_n=-1)=\begin{cases}\Psi_3(\xi)\xi^{-i\nu_n\sigma_3}e^{-i(\xi^2/4)\sigma_3}, & \xi>0,\\ \Psi_1(\xi)\xi_-^{-i\nu_n\sigma_3}e^{-i(\xi^2/4)\sigma_3}, & \xi<0.\end{cases} \tag{5.14b}
$$

From (5.10) and (5.14) we learn that

$$
\mu^M(\lambda)=\tilde{\mu}^M(\xi)=I+O(1/\xi) \quad \text{as} \quad \xi\to\pm\infty,
$$

whence

$$
\|\mu^M-I\|_{L_2}\leqslant Ct^{-1/4}. \tag{5.15}
$$

Let u^n, v^n and u_0^n, v_0^n be potentials of the RHPs (5.1) and (5.2), respectively. Note that u_0^n and v_0^n can be obtained from (5.5), (5.10), and (5.11). The result of these calculations is given by (1.5).

Proposition 5.1. There is a number t_0 such that the solution of RHP (5.1) exists at least for $t\geqslant t_0$. Moreover,

$$
|\phi^n(\lambda)-\psi^M(\lambda)|\leqslant Ct^{-3/4}\ln t \quad \text{if } |\operatorname{Im}\lambda|\geqslant a>0 \tag{5.16}
$$

and

$$u^n(t)=u_0^n(t)+O(t^{-3/4}\ln t),\quad v^n(t)=v_0^n(t)+O(t^{-3/4}\ln t). \tag{5.17}$$

Proof: The proof is virtually the same as the proof of Proposition (4.2). Here we use the piecewise analytical matrix $\Phi(\lambda)$ determined by

$$\Phi(\lambda)=\begin{pmatrix} 1 & 0 \\ -\overline{\rho^h_+}(\lambda) & 1 \end{pmatrix}\begin{pmatrix} 1 & -\rho^e_+(\lambda) \\ 0 & 1 \end{pmatrix},\quad \operatorname{Im}\lambda>0,$$

$$\Phi(\lambda)=\begin{pmatrix} 1 & -\rho^h_-(\lambda) \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ -\overline{\rho^e_-}(\lambda) & 1 \end{pmatrix},\quad \operatorname{Im}\lambda<0.$$

Passing to the new RHP (4.9) with $b\pm$ replaced by $b_n^{\pm}$ and with

$$m^{\Phi}(\lambda)=\phi^n(\lambda)\Phi(\lambda),$$

one deduces from Proposition 4.3 that the data of (4.9) can be decomposed in the form

$$w_{\Phi}^{\pm}=w_M^{\pm}+w_R^{\pm},$$

where $w_M^{\pm}$ are the data of (5.2) while $w_R^{\pm}$ have small L_2- and L_∞-norms which are dominated by

$$\|w_R^{\pm}\|_{L_2}\leqslant Ct^{-3/4}\ln t,\quad \|w_R^{\pm}\|_{L_\infty}\leqslant Ct^{-1/2}\ln t. \tag{5.18}$$

Due to the estimates (4.15) and (4.16) with ψ^M,μ^M in place of m^L,μ^L and due to inequalities (5.15) and (5.18), one gets

$$|m^{\Phi}(\lambda)-\psi^M(\lambda)|\leqslant Ct^{-3/4}\ln t \quad \text{if } |\operatorname{Im}\lambda|\geqslant a>0,$$

$$\|\mu^{\Phi}-\mu^M\|_{L_2}\leqslant Ct^{-3/4}\ln t. \tag{5.19}$$

To derive (5.16), it is sufficient to note that

$$|\Phi(\lambda)-I|\leqslant Ct^{-1}\ln t \quad \text{if } |\operatorname{Im}\lambda|\geqslant a>0.$$

Instead of the splitting (4.17), we now have

$$w_R=\begin{pmatrix} -\overline{\rho^e_+}\rho_n h-\rho^h_+\overline{\rho_n}e & \rho^h_+-\rho^e_- \\ \overline{\rho^e_+}-\overline{\rho^h_-} & -\overline{\rho^h_-}\rho_n e-\rho^e_-\overline{\rho_n}h \end{pmatrix}+w_I,$$

where again each element of w_I belongs to $L_1(R)$ but with L_1-norm decaying as $t^{-3/4}\ln t$. Since the diagonal elements of w_R-w_I do not play any role in the evaluation of the potentials u^n and v^n, the end of the proof is similar to that of Proposition 4.2.

Proposition 5.2: The operator $id-C_{w_n}$ related to (5.1) has an inverse at least for large t, and this is bounded as $t\to\infty$.

Proof: Let $(id-C_{w_\Phi})$ be the operator associated with the new RHP (4.9). Because of the identity

$$id-C_{w_\Phi}=(id-C_{w_M})(id-(id-C_{w_M})^{-1}C_{w_R})$$

and estimates (5.18), $(id-C_{w_\Phi})$ is invertible at least for large t. Using Lemma 2, the proof is complete.

Proposition 5.3: Let μ^n be the solution of the basic integral equation related to (5.1). Then

$$\|\mu^n-\mu^M\|_{L_2}\leqslant Ct^{-3/4}\ln t. \tag{5.20}$$

Proof: From (3.8) it is easily seen that $\mu^\Phi=\mu^n$, where Φ was determined in the proof of Proposition 5.1. Therefore, inequality (5.19) implies (5.20).

Proposition 5.4: For any real λ which is not in the support of φ_n, the following estimate is valid:

$$\begin{aligned}\mu^n(\lambda)=\phi_+^n(\lambda)=\phi_-^n(\lambda)&=\mu^M(\lambda)+O(t^{-3/4}\ln t)\\&=I+\begin{pmatrix}0 & u_0^n/(\lambda-\lambda_n)\\ v_0^n/(\lambda-\lambda_n) & 0\end{pmatrix}\\&\quad+O(t^{-3/4}\ln t).\end{aligned} \tag{5.21}$$

Proof: Take the representation (3.7) for the solution of the RHP:

$$\phi_+^n(\lambda)=\phi_-^n(\lambda)=I+\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{\mu^M(z)w_n(z)}{z-\lambda}\,dz+\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{(\mu^n(z)-\mu^M(z))w_n(z)}{z-\lambda}\,dz. \tag{5.22}$$

The second integral in the above formula is evaluated by

$$\frac{1}{2\pi}\frac{1}{|\lambda-\lambda_n|-\varepsilon}\|\mu^n-\mu^M\|_{L_2}\|w_n\|_{L_2}\leqslant Ct^{-3/4}\ln t.$$

The first is equal to $C_{w_n}(\mu^M)(\lambda)$, whereas $w_n^{\pm}(\lambda)=0$. Hence, one may show that

$$\phi_+^n(\lambda)=\phi_-^n(\lambda)=\mu^M(\lambda)+C_{w_n-w_M}(\mu^M)(\lambda)+O(t^{-3/4}\ln t). \tag{5.23}$$

Define

$$R^n(\lambda)=C_{w_n-w_M}(\mu^M)(\lambda)=C_+(\mu^M(w_n^--w_M^-))(\lambda)+C_-(\mu^M(w_n^+-w_M^+))(\lambda).$$

It turns out that

$$|R^n(\lambda)|\leqslant C\frac{\ln t}{t}; \tag{5.24}$$

thus (5.21) follows from (5.23). To obtain (5.24), one should consider each element of the matrix $R^n(\lambda)$ distinguishing two cases: $\varepsilon_n=1$, and $\varepsilon_n=-1$; for instance, we illustrate the proof of (5.24) for $R_{12}^n(\lambda)$, assuming that $\varepsilon_n=1$.

A straightforward calculation yields

$$\mu^M(w_n^--w_M^-)=\begin{pmatrix}\mu_{12}^M(\overline{\rho\varphi}_n-\overline{\rho}_n)e & \mu_{11}^M(\rho\varphi_n-\rho_n)h\\ \mu_{22}^M(\overline{\rho\varphi}_n-\overline{\rho}_n)e & \mu_{21}^M(\rho\varphi_n-\rho_n)h\end{pmatrix},$$

$$\mu^M(w_n^+-w_M^+)=\begin{pmatrix}\mu_{12}^M(\overline{\rho\varphi}_n-\overline{\rho}_n)h & \mu_{11}^M(\rho\varphi_n-\rho_n)e\\ \mu_{22}^M(\overline{\rho\varphi}_n-\overline{\rho}_n)h & \mu_{21}^M(\rho\varphi_n-\rho_n)e\end{pmatrix}.$$

Therefore,

$$R_{12}^n(\lambda)=C_+(\mu_{11}^M(\rho\varphi_n-\rho_n)h)(\lambda)+C_-(\mu_{11}^M(\rho\varphi_n-\rho_n)e)(\lambda)$$
$$=C_+(d^h(\rho_+^h-\rho_-^h))(\lambda)+C_-(d^e(\rho_+^e-\rho_-^e))(\lambda),$$

where we have used (5.14a) and replaced μ_{11}^M by

$$d^h=(\Psi_2)_{11}\xi^{-i\nu_n}e^{i\xi^2/4}=e^{\pi\nu_n/4}D_{i\nu_n}(i\alpha\xi)\xi^{-i\nu_n}e^{i\xi^2/4}$$

or

$$d^e=(\Psi_4)_{11}\xi_+^{-i\nu_n}e^{i\xi^2/4}=e^{-3\pi\nu_n/4}D_{i\nu_n}(-i\alpha\xi)\xi^{-i\nu_n}e^{i\xi^2/4}.$$

Notice that $d^h(d^e)$ is an analytic bounded function in the sector $-\pi<\arg(\lambda-\lambda_n)<\pi/2$ $[0<\arg(\lambda-\lambda_n)<3\pi/2]$ with unit behavior at infinity [see (5.9)],

$$d^h(\lambda)=1+O\left(\frac{1}{|\xi|^2}\right),\quad d^e(\lambda)=1+O\left(\frac{1}{|\xi|^2}\right).$$

Hence, $d^h\rho_-^h(d^e\rho_+^e)$ belongs to the null space of $C_+(C_-)$. This means that

$$R_{12}^n=C_+(d^h\rho_+^h)(\lambda)-C_-(d^e\rho_-^e)(\lambda)$$
$$=\rho_+^h(\lambda)+\rho_-^e(\lambda)+C_+((d^h-1)\rho_+^h)(\lambda)-C_-((d^e-1)\rho_-^e)(\lambda).$$

Let

$$\Gamma_{\lambda_n}^+=\{\lambda:\lambda=\lambda_n+ze^{i\pi/4},z\in R\},\quad \Gamma_{\lambda_n}^-=\{\lambda:\lambda=\lambda_n+ze^{-i\pi/4},z\in R\}.$$

Recall that $\rho_+^h(\rho_-^e)$ is the boundary value of the analytic, in the complex plane with the cut $\lambda-\lambda_n\geqslant 0(\lambda-\lambda_n\leqslant 0)$, function $\rho^h(\rho^e)$. Deforming the contour of integration, we deduce

$$R_{12}^n(\lambda)=\rho_+^h(\lambda)+\rho_-^e(\lambda)+(d^h(\lambda)-1)\rho_+^h(\lambda)h(\lambda)+(d^e(\lambda)-1)\rho_-^e(\lambda)e(\lambda)$$
$$+\frac{1}{2\pi i}\int_{\Gamma_{\lambda_n}^+}\frac{(d^h(z)-1)\rho^h(z)}{z-\lambda}\,dz+\frac{1}{2\pi i}\int_{\Gamma_{\lambda_n}^+}\frac{(d^e(z)-1)\rho^e(z)}{z-\lambda}\,dz.$$

The last identity reveals that

$$|R_{12}^n(\lambda)|\leqslant C_1(|\rho_+^h(\lambda)|+|\rho_-^e(\lambda)|)+C_2\frac{t^{-1/4}}{|\lambda-\lambda_n|}(\|\rho^h\|_{L_2(\Gamma_{\lambda_n}^+)}+\|\rho^e\|_{L_2(\Gamma_{\lambda_n}^+)}).\qquad(5.25)$$

Reviewing the proof of Proposition 4.3, one sees that

$$|\rho_+^h(\lambda)|,|\rho_-^e(\lambda)|\leqslant C\frac{\ln t}{t},\quad \|\rho^h\|_{L_2(\Gamma_{\lambda_n}^+)},\|\rho^e\|_{L_2(\Gamma_{\lambda_n}^+)}\leqslant Ct^{-3/4}\ln t.$$

Thus, estimate (5.25) implies

$$|R_{12}^n(\lambda)|\leqslant C\frac{\ln t}{t}.$$

The contour $\Gamma_{\lambda_n}^-$ is needed when the case $\varepsilon_n=-1$ is considered.

VI. THE PROOF OF THE THEOREM

We take up the investigation of the RHP (2.16), which is equivalent to the original one (1.1). In Sec. IV, (2.16) was reduced, without loss of asymptotic information, to the factorization problem (4.5), provided the operator associated with (4.5) was invertible at least for large t. The data of the RHP (4.5) had support localized in neighborhoods (which could be chosen arbitrarily small) of the stationary phase points. This result, namely, Proposition (4.2), is in complete correspondence with analogous ones from the asymptotic theory of oscillatory integrals, known as the localization principle. The next problem is to separate the contributions from the distinct stationary phase points. The present section is dedicated to it.

Consider the piesewise analytic matrix $m^{L\phi}$ defined through

$$m^L(\lambda)=m^{L\phi}(\lambda)\phi^1(\lambda), \tag{6.1}$$

where ϕ^1 is the solution of (5.1) with $n=1$. It evidently satisfies the following factorization problem:

$$m_+^{L\phi}(\lambda)=m_-^{L\phi}(\lambda)(b_{L\phi}^-)^{-1}b_{L\phi}^+, \quad m^{L\phi}(\infty)=I. \tag{6.2}$$

We choose the decomposition of the jump matrix in the form

$$b_{L\phi}^-=\mu^1 b_L^-(\phi_-^1)^{-1}, \quad b_{L\phi}^+=\mu^1 b_L^+(\phi_+^1)^{-1}. \tag{6.3}$$

Since $(\mu^1)^{-1}=b_1^-(\phi_-^1)^{-1}=b_1^+(\phi_+^1)^{-1}$, it occurs that

$$w_{L\phi}^{\pm}=\sum_{n=2}^{N}\varphi_n\mu^1 w^{\pm}(\mu^1)^{-1}. \tag{6.4}$$

Furthermore, estimate (5.21) gives rise to the splittings

$$w_{L\phi}^{\pm}=\sum_{n=2}^{N}\varphi_n w^{\pm}+w_R^{\pm}\equiv w_{L'}^{\pm}+w_R^{\pm}, \tag{6.5}$$

in which the corrections $w_R^{\pm}$ are small, viz.,

$$\|w_R^{\pm}\|_{L_2},\|w_R^{\pm}\|_{L_\infty}\leqslant Ct^{-1/2}. \tag{6.6}$$

Moreover,

$$w_R^{\pm}=\sum_{n=2}^{N}\varphi_n(V_1w^{\pm}-w^{\pm}V_1)+w_I^{\pm}\equiv w_V^{\pm}+w_I^{\pm}, \tag{6.7}$$

where

$$V_1=\begin{pmatrix}0 & u_0^1/(\lambda-\lambda_1)\\ v_0^1/(\lambda-\lambda_1) & 0\end{pmatrix}, \quad \|w_I^{\pm}\|_{L_1},\|w_I^{\pm}\|_{L_2},\|w_I^{\pm}\|_{L_\infty}\leqslant Ct^{-3/4}\ln t. \tag{6.8}$$

Let $m^{L'}(\lambda)$ be the solution of the RHP with data $w_{L'}^{\pm}$,

$$\begin{gathered}m_+^{L'}(\lambda)=m_-^{L}(\lambda)(b_{L'}^-)^{-1}b_{L'}^+, \quad b_{L'}^{\pm}=I\pm w_{L'}^{\pm},\\ m^{L'}(\infty)=I,\end{gathered} \tag{6.9}$$

and let $id - C_{w_{L'}}$ have an inverse which is bounded as $t\to\infty$. Then, rewriting the basic integral equation related to (6.2) in the form (4.13), one gets

$$\|\mu^{L\phi}-\mu^{L'}\|_{L_2}\leqslant C(\|C_{w_R}I\|_{L_2}+(\|w_R^+\|_{L_\infty}+\|w_R^-\|_{L_\infty})\|\mu^{L'}-I\|_{L_2}). \tag{6.10}$$

Inequalities (6.6) and (6.10) imply that

$$\|\mu^{L\phi}-\mu^{L'}\|_{L_2}\leqslant Ct^{-1/2}. \tag{6.11}$$

To proceed, we must suppose that $\|\mu^k\|_{L_\infty}\leqslant C$. Then, Lemma 2 and relation (3.11) reveal

$$(id-C_{w_L})^{-1}=\hat{\mu}^1(id-C_{w_{L\phi}})^{-1}(id-C_{\phi^{-1}}), \tag{6.12}$$

where $\phi=\phi^1$, $\hat{\mu}^1 f=f\mu^1$. Thus $id - C_{w_L}$ is invertible at least for large t [see (6.5) and (6.6)], and $(id - C_{w_L})^{-1}$ is bounded as $t\to\infty$. In addition, $\mu^L=\mu^{L\phi}\mu^1$ because $C_{\phi^{-1}}I = 0$. The last identity and (6.11) show

$$\|\mu^L-\mu^{L'}\mu^1\|_{L_2}\leqslant Ct^{-1/2};$$

hence

$$\|\mu^L-I\|_{L_2}\leqslant\|\mu^1-I\|_{L_2}+\|\mu^1\|_{L_\infty}\|\mu^{L'}-I\|_{L_2}+Ct^{-1/2}.$$

It is clear that the same arguments work with respect to $id - C_{w_{L'}}$. Continuing the induction, which consist of a finite number of steps, we find

$$\|\mu^L-I\|_{L_2}\leqslant\sum_{k=1}^{N} C_k\|\mu^k-I\|_{L_2}+C_0t^{-1/2}\leqslant Ct^{-1/4},\quad \|\mu^{L'}-I\|_{L_2}\leqslant Ct^{-1/4}. \tag{6.13}$$

We now want to improve estimate (6.11). Note that the leading terms of $w_R^{\pm}$ have been found explicitly. These are of order $t^{-1/2}$ but contain oscillations as well. Taking this into account, one observes

$$\|C_{w_V}I\|_{L_2}\leqslant Ct^{-3/4},\quad \|C_{w_R}I\|_{L_2}\leqslant Ct^{-3/4}\ln t. \tag{6.14}$$

Hence

$$\|\mu^{L\phi}-\mu^{L'}\|_{L_2}\leqslant Ct^{-3/4}\ln t. \tag{6.15}$$

Return to the RHP (4.5). Using the analogous of formula (4.14), we derive

$$m^{L\phi}(\lambda)-m^{L'}(\lambda)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{w_V(z)}{z-\lambda}\,dz+O(t^{-3/4}\ln t)=O(t^{-3/4}\ln t), \tag{6.16}$$

provided $|\mathrm{Im}\,\lambda|\geqslant a>0$. Here, the oscillations in $w_V^{\pm}$ have been taken into account again. Then

$$m^L(\lambda)=m^{L'}(\lambda)\phi^1(\lambda)+O(t^{-3/4}\ln t),\quad |\mathrm{Im}\,\lambda|\geqslant a>0, \tag{6.17}$$

and

$$u^L=u^{L'}+u^1+O(t^{-3/4}\ln t),\quad v^L=v^{L'}+v^1+O(t^{-3/4}\ln t), \tag{6.18}$$

where $u^{L'}$ and $v^{L'}$ are the potentials of (6.9). It is obvious from (6.17) that, applying induction on the number of stationary phase points, we eventually obtain

$$m^L(\lambda)=\phi^N(\lambda)\cdots\phi^1(\lambda)+O(t^{-3/4}\ln t),\quad |\mathrm{Im}\,\lambda|\geqslant a>0, \tag{6.19}$$

and

$$u^L=\sum_{n=1}^{N} u^n+O(t^{-3/4}\ln t),\quad v^L=\sum_{n=1}^{N} v^n+O(t^{-3/4}\ln t). \tag{6.20}$$

The evaluations from Propositions (4.2) and (5.1) and the above ones complete the proof of the theorem.

Since there is one hole in the above proof, we describe briefly another approach in the end of this section. First, note that the assumption $\|\mu^k\|_{L_\infty}\leqslant C$ has been used in two places. One is the existence proof of $(id-C_{w_L})^{-1}$. Second, it has been needed in the proof of estimates (6.13). However, it is possible to state these results independently of whether $\mu^k\in L_\infty$ or not. Indeed, we know that the operators associated with the RHP (5.1), $id-C_{w_n}$, are invertible. Further, inspection reveals the following identities:

$$\begin{aligned}
&(id-C_{w_L})\left(id+\sum_{k=1}^{N} C_{w_k}(id-C_{w_k})^{-1}\right)=id-\sum_{k,n,k\neq n}^{N} C_{w_k}C_{w_n}(id-C_{w_n})^{-1},\\
&\left(id+\sum_{k=1}^{N} C_{w_k}(id-C_{w_k})^{-1}\right)(id-C_{w_L})=id-\sum_{k,n,k\neq n}^{N} (id-C_{w_k})^{-1}C_{w_k}C_{w_n}.
\end{aligned} \tag{6.21}$$

Recall that $C_{w_L}=\Sigma_{k=1}^{N}C_{w_k}$. Evidently, if the operators on the right-hand side of (6.21) are invertible, then $(id-C_{w_L})^{-1}$ exists. The former is true for large t because of the inequalities

$$\|C_{w_k}C_{w_n}\|_{L_2\to L_2}\leqslant Ct^{-1/4},\quad k\neq n.$$

The latter can be found by the method of stationary phase since $C_{w_n}f$ is an analytic function whose derivatives are bounded in t for any $f\in L_2$ in some neighborhood of $\mathrm{supp}\,w_k$ ($\mathrm{supp}\,w_k\cap\mathrm{supp}\,w_n=\varnothing$, $n\neq k$). The desired evaluations (6.13) are now consequence of

$$\|C_{w_L}I\|_{L_2}\leqslant Ct^{-1/4}.$$

We have developed our approach, assuming that the phase of the RHP (1.1) is a smooth function on the real axis; however, the RHPs which arise in the theory of integrable nonlinear equations (e.g., sine–Gordon) may have a phase with poles on the real axis. These cases can easily be incorporated into the method presented here if we assume that $p(\lambda)$ and $q(\lambda)$ have zeros of appropriate order at the poles of the phase. Therefore, the theorem is still valid for such p, q, and θ.

The one-dimensional Schrödinger equation and two of its generalizations are considered, as they arise in quantum mechanics, wave propagation in a nonhomogeneous medium, and wave propagation in a nonconservative medium where energy may be absorbed or generated. Generically, the zero-energy transmission coefficient vanishes when the potential is nontrivial, but in the exceptional case this coefficient is nonzero, resulting in tunneling through the potential. It is shown that any nontrivial exceptional potential can always be fragmented into two generic pieces. Furthermore, any nontrivial potential, generic or exceptional, can be fragmented into generic pieces in infinitely many ways. The results remain valid when Dirac delta functions are included in the potential and other coefficients are added to the Schrödinger equation. For such Schrödinger equations, factorization formulas are obtained that relate the scattering matrices of the fragments to the scattering matrix of the full problem. © *1996 American Institute of Physics.*

I. INTRODUCTION

In this paper we consider the one-dimensional Schrödinger equation and two of its generalizations. The Schrödinger equation (2.1) describes the quantum mechanical behavior of a particle interacting with the potential $V(x)$. From the corresponding transmission coefficient $T(k)$ we obtain the probability $|T(k)|^2$ that a particle of energy k^2 can tunnel through this potential. Generically, the zero-energy transmission coefficient is zero and hence a zero-energy particle cannot tunnel through a nontrivial potential. However, in the exceptional case, the transmission coefficient does not vanish at zero energy. In this paper, we analyze certain aspects of this exceptional case. With the help of a factorization formula, we show that a nontrivial exceptional potential can always be fragmented into generic pieces; i.e., a nontrivial potential allowing tunneling at zero energy can always be decomposed into pieces none of which allow such tunneling. The factorization formula (2.17) used to obtain this result allows us to express the scattering coefficients corresponding to a potential in terms of the scattering coefficients corresponding to its fragments. We show that similar factorization formulas hold for certain generalized Schrödinger equations describing the wave propagation in one-dimensional nonhomogeneous or nonconservative media. For such generalized Schrödinger equations, the generic and exceptional cases are again determined by the zero-energy behavior of the transmission coefficients.

The generalized Schrödinger equation (3.3) can be analyzed by locally transforming it into a finite number of Schrödinger equations; the results obtained in Sec. II show that each of these Schrödinger equations can be chosen to have generic potentials. In Sec. III we obtain the corresponding factorization formula for Eq. (3.3). This formula, Eq. (3.15), brings insight to the analy-

sis of wave scattering in a one-dimensional nonhomogeneous medium and allows us to see how the scattering process can be viewed as resulting both from ''soft scatterers''[1] (responsible for continuous changes in the medium parameters) and from ''hard scatterers''[1] (responsible for discontinuous changes in the medium parameters). This formula also explains how the total scattering matrix can be obtained in terms of the scattering matrices of the individual fragments localized in space.

In Sec. IV, we generalize the factorization formula (2.17) in a different way to analyze how the scattering process takes place in a one-dimensional nonconservative medium governed by the generalized Schrödinger equation (4.1), where energy absorption or generation may occur. Although the scattering matrix is no longer unitary when energy absorption or generation is present, we still have a factorization formula, namely Eq. (4.5), showing how the scattering resulting from the fragments is superposed to give the total scattering.

The small-energy analysis of the exceptional case for these three equations usually requires elaborate calculations. In addition to giving insight into the scattering process, the factorization formulas associated with these equations are expected to simplify the small-energy analysis of the wavefunctions and scattering coefficients.

II. SCHRÖDINGER EQUATION

Consider the one-dimensional Schrödinger equation

$$\frac{d^2\psi(k,x)}{dx^2}+k^2\psi(k,x)=V(x)\psi(k,x), \tag{2.1}$$

where k^2 is energy, x is the space coordinate, and $V(x)$ is a real-valued potential belonging to $L_1^1(\mathbf{R})$, i.e., $\int_{-\infty}^{\infty} dx\ (1+|x|)|V(x)|$ is finite. The scattering solutions of Eq. (2.1) are those that behave like $e^{\pm ikx}$ as $x\to+\infty$ and $x\to-\infty$. There are two linearly independent scattering solutions $f_l(k,x)$ and $f_r(k,x)$ of Eq. (2.1), known as the Jost solutions from the left and from the right, respectively, satisfying the boundary conditions

$$f_l(k,x)=\begin{cases} e^{ikx}+o(1), & x\to+\infty, \\ \dfrac{1}{T(k)}\,e^{ikx}+\dfrac{L(k)}{T(k)}\,e^{-ikx}+o(1), & x\to-\infty, \end{cases} \tag{2.2}$$

$$f_r(k,x)=\begin{cases} \dfrac{1}{T(k)}\,e^{-ikx}+\dfrac{R(k)}{T(k)}\,e^{ikx}+o(1), & x\to+\infty, \\ e^{-ikx}+o(1), & x\to-\infty, \end{cases} \tag{2.3}$$

where $T(k)$ is the transmission coefficient and $R(k)$ and $L(k)$ are the reflection coefficients from the right and from the left, respectively. The scattering matrix associated with Eq. (2.1) is defined as

$$\mathbf{S}(k)=\begin{bmatrix} T(k) & R(k) \\ L(k) & T(k) \end{bmatrix}, \tag{2.4}$$

and it satisfies

$$\mathbf{S}(-k)=\overline{\mathbf{S}(k)}, \quad k\in\mathbf{R}, \tag{2.5}$$

where the overline denotes complex conjugation. The scattering matrix is unitary; thus,

$$|T(k)|^2+|R(k)|^2=|T(k)|^2+|L(k)|^2=1, \quad k\in\mathbf{R}, \tag{2.6}$$

and from Eq. (2.5) we see that

$$R(k)T(-k)+L(-k)T(k)=0, \quad k\in\mathbf{R}. \tag{2.7}$$

It is also known that the determinant of $\mathbf{S}(k)$ is given by

$$T(k)^2-R(k)L(k)=\frac{T(k)}{T(-k)}, \quad k\in\mathbf{R}. \tag{2.8}$$

For a potential in $L^1_1(\mathbf{R})$, the corresponding scattering matrix is well understood. Generically, the transmission coefficient vanishes linearly as $k\to 0$ and $R(0)=L(0)=-1$. In the exceptional case, we have $T(0)\neq 0$ and hence $|R(0)|=|L(0)|<1$. There are other characterizations of these two cases. For example, the potential $V(x)$ is exceptional if and only if $f_l(0, x)$ and $f_r(0, x)$ are linearly dependent. Equivalently, $V(x)$ is exceptional if and only if at least one of $f_l(0, x)$ and $f_r(0, x)$ is bounded; in that case both of these functions are bounded for $x\in\mathbf{R}$. Furthermore, the potential $V(x)$ is exceptional if and only if

$$\int_{-\infty}^{\infty} dx\ V(x)f_l(0, x)=0, \tag{2.9}$$

which is equivalent to $\int_{-\infty}^{\infty} dx\ V(x)f_r(0, x)=0$ because $f_l(0, x)$ and $f_r(0, x)$ are linearly dependent in the exceptional case. Moreover, the exceptional case occurs if and only if $f_l'(0, -\infty)=0$ or $f_r'(0, +\infty)=0$. Here and throughout the paper the prime denotes the spatial derivative and we interpret $f_l'(0, -\infty)$ as $\lim_{x\to-\infty} f_l'(0, x)$ and interpret $f_r'(0, +\infty)$ as $\lim_{x\to+\infty} f_r'(0, x)$.

If the potential has support on a half-line, i.e., if $V(x)=0$ for $x>b$ or $x<a$ for some constants a and b, we have the exceptional case if and only if $f_r'(0, x)=0$ for all $x\geqslant b$ or $f_l'(0, x)=0$ for all $x\leqslant a$, respectively. For example, when $V(x)=0$ for $x>b$, the linear dependence of $f_l(0, x)$ and $f_r(0, x)$ in the exceptional case requires that $f_r(0, x)$ is a constant for $x\geqslant b$ and hence $f_r'(0, b)=0$; in the generic case, since $f_r(0, x)$ is linear for $x\geqslant b$ and linearly independent of $f_l(0, x)$, it follows that $f_r'(0, b)\neq 0$. Note that $f_l(0, x)$ and $f_l'(0, x)$ cannot simultaneously vanish at the same x value; otherwise, we would have $f_l(0, x)=0$ for $x\in\mathbf{R}$ contradicting $f_l(0,+\infty)=1$. Similarly, $f_r(0, x)$ and $f_r'(0, x)$ cannot simultaneously vanish at the same x value. Thus, if $V(x)=0$ for $x<a$ and if $f_l(0, a)=0$, then $V(x)$ must be generic. Similarly, if $V(x)=0$ for $x>b$ and $f_r(0, b)=0$, then $V(x)$ must be generic.

In the exceptional case, let γ denote the constant

$$\gamma=\frac{f_l(0, x)}{f_r(0, x)}. \tag{2.10}$$

We have[2]

$$\begin{bmatrix} f_l(-k,x) \\ f_r(-k,x) \end{bmatrix}=\begin{bmatrix} T(k) & -R(k) \\ -L(k) & T(k) \end{bmatrix}\begin{bmatrix} f_r(k,x) \\ f_l(k,x) \end{bmatrix}, \quad k\in\mathbf{R}, \tag{2.11}$$

and hence from Eqs. (2.10) and (2.11) at $k=0$ we get

$$\gamma=\frac{T(0)}{1+R(0)}=\frac{1+L(0)}{T(0)}. \tag{2.12}$$

Using Eqs. (2.7), (2.8), and (2.12), we obtain

$$T(0)=\frac{2\gamma}{\gamma^2+1}, \quad L(0)=-R(0)=\frac{\gamma^2-1}{\gamma^2+1}. \tag{2.13}$$

Further information on the generic and exceptional cases can be found in Refs. 2–6. For later reference, we summarize some of the necessary and sufficient conditions for the exceptional case.

Proposition 2.1: A potential $V\in L_1^1(\mathbf{R})$ is exceptional if and only if $f_l'(0,-\infty)=0$ or equivalently if and only if $f_r'(0,+\infty)=0$. If $V(x)$ vanishes for $x>b$, it is exceptional if and only if $f_r'(0,b)=0$. Similarly, if $V(x)$ vanishes for $x<a$, it is exceptional if and only if $f_l'(0,a)=0$.

The trivial potential $V(x)=0$ is exceptional. If $V(x)$ is nontrivial and $V(x)\geqslant 0$, then $V(x)$ is generic. The exceptional case is unstable in the sense that a small change in the potential usually makes the case generic. As an example, consider the square-well potential: the exceptional case occurs at the exact depths when a bound state is added to the potential; at any other depth the square-well potential is generic.

The distinction between the generic and exceptional cases becomes relevant when the small-energy behavior of the scattering coefficients and of the wavefunctions is considered. In many instances one has to deal with quantities involving the factor $T(k)/k$. In the generic case this factor remains bounded and continuous as $k\to 0$, but in the exceptional case it behaves as $T(0)/k$ with $T(0)\neq 0$. In some applications the factor $T(k)/k$ is multiplied by a continuous function $g(k)$ and one has to prove, for example, the integrability of the product $g(k)T(k)/k$ as $k\to 0$. In the generic case this integrability holds automatically, but in the exceptional case one has to prove, for instance, that $g(k)$ is of order $|k|^{\gamma}$ for some $\gamma\in(0,1]$ as $k\to 0$. This is one of the reasons why proofs tend to be more elaborate in the exceptional case than in the generic case. In this Section we show among other things that an exceptional potential can always be ''fragmented'' into two generic pieces and that a matrix closely related to the scattering matrix can be written as a product of factors, where each factor carries the information pertaining to one fragment. The term ''fragment'' will be made precise below. We expect our results to offer simplifications in dealing with exceptional potentials.

We now consider Eq. (2.1) and first explain the term fragment used in this paper. Choose a partition $-\infty<x_1<x_2<\cdots<x_n<+\infty$ of the real line $\mathbf{R}$ and define

$$V_{j,j+1}(x)=\begin{cases} V(x), & x\in(x_j,x_{j+1}),\\ 0, & x\notin(x_j,x_{j+1}),\end{cases}$$

so that

$$V(x)=\sum_{j=0}^{N} V_{j,j+1}(x), \tag{2.14}$$

where in Eq. (2.14) and below we use the convention that $x_0=-\infty$ and $x_{N+1}=+\infty$. We call $V_{j,j+1}(x)$ a fragment of $V(x)$. In analogy to Eq. (2.4) we let

$$\mathbf{S}_{j,j+1}(k)=\begin{bmatrix} T_{j,j+1}(k) & R_{j,j+1}(k)\\ L_{j,j+1}(k) & T_{j,j+1}(k)\end{bmatrix}$$

denote the scattering matrix associated with the potential $V_{j,j+1}(x)$, where each matrix $\mathbf{S}_{j,j+1}(k)$ only carries the information pertaining to the fragment $V_{j,j+1}(x)$. Using the scattering coefficients, we introduce the matrices

$$\Lambda(k)=\begin{bmatrix} \dfrac{1}{T(k)} & -\dfrac{R(k)}{T(k)} \\ \dfrac{L(k)}{T(k)} & \dfrac{1}{T(-k)} \end{bmatrix}, \quad \Lambda_{j,j+1}(k)=\begin{bmatrix} \dfrac{1}{T_{j,j+1}(k)} & -\dfrac{R_{j,j+1}(k)}{T_{j,j+1}(k)} \\ \dfrac{L_{j,j+1}(k)}{T_{j,j+1}(k)} & \dfrac{1}{T_{j,j+1}(-k)} \end{bmatrix}. \tag{2.15}$$

Note that each matrix in Eq. (2.15) can be written as the product of two matrices in the following way:

$$\Lambda(k)=\begin{bmatrix} \dfrac{1}{T(k)} & -\dfrac{R(k)}{T(k)} \\ \dfrac{L(k)}{T(k)} & \dfrac{1}{T(-k)} \end{bmatrix}=\begin{bmatrix} 1 & 0 \\ L(k) & T(k) \end{bmatrix}\begin{bmatrix} \dfrac{1}{T(k)} & -\dfrac{R(k)}{T(k)} \\ 0 & 1 \end{bmatrix}. \tag{2.16}$$

Note also that using Eq. (2.7) it is possible to express the entries of each matrix in Eq. (2.15) in terms of the transmission coefficient and only one of the reflection coefficients; for example, we have

$$\Lambda(k)=\begin{bmatrix} \dfrac{1}{T(k)} & -\dfrac{R(k)}{T(k)} \\ -\dfrac{R(-k)}{T(-k)} & \dfrac{1}{T(-k)} \end{bmatrix}=\begin{bmatrix} \dfrac{1}{T(k)} & \dfrac{L(-k)}{T(-k)} \\ \dfrac{L(k)}{T(k)} & \dfrac{1}{T(-k)} \end{bmatrix}.$$

It is known[7] that $\Lambda(k)$ can be written as the product

$$\Lambda(k)=\Lambda_{0,1}(k)\Lambda_{1,2}(k)\cdots\Lambda_{N,N+1}(k). \tag{2.17}$$

It can be proved that Eq. (2.17) remains valid if we allow the potential $V(x)$ to contain a finite number of Dirac delta functions. When delta functions are included, the proof of Eq. (2.17) can be obtained from Eqs. (3.15) and (3.16) in the special case $H(x)\equiv 1$. If all the fragments in Eq. (2.14) are delta-function potentials, Eq. (2.17) reduces to Eq. (3.17). In Sec. III we will elaborate on the inclusion of delta functions.

The matrices $\Lambda(k)$ and $\Lambda_{j,j+1}(k)$ are usually called transition matrices. The reason for this terminology is as follows, which at the same time proves Eq. (2.17). Any scattering solution $\psi(k,x)$ of (2.1) obeys $\psi(k,x)=c_1e^{ikx}+c_2e^{-ikx}+o(1)$ as $x\to+\infty$ and $\psi(k,x)=d_1e^{ikx}+d_2e^{-ikx}+o(1)$ as $x\to-\infty$, where c_1,c_2,d_1,d_2 are function of k alone. By using Eqs. (2.2), (2.3), and (2.8), we can relate the vectors $[c_1\ c_2]$ and $[d_1\ d_2]$ corresponding to each of the Jost solutions $f_l(k,x)$ and $f_r(k,x)$, and hence we obtain $[d_1\ d_2]^t=\Lambda(k)[c_1\ c_2]^t$. We use the superscript t to denote the transpose. Hence $\Lambda(k)$ provides the link between the asymptotics of the solutions of Eq. (2.1) at $+\infty$ and those at $-\infty$ when the functions $e^{\pm ikx}$ are chosen as an (asymptotic) basis. Now let $N=1$, i.e., the partition is simply $-\infty<x_1<+\infty$. Let $\psi_{1,2}(k,x)$ be the solution of Eq. (2.1) with the potential $V_{1,2}(x)$ that satisfies $\psi_{1,2}(k,x)=\psi(k,x)$ for $x\geqslant x_1$, and let $\psi_{0,1}(k,x)$ be the solution of Eq. (2.1) with the potential $V_{0,1}(x)$ such that $\psi_{0,1}(k,x)=\psi(k,x)$ for $x\leqslant x_1$. Then $\psi_{1,2}(k,x)=\tilde{d}_1e^{ikx}+\tilde{d}_2e^{-ikx}$ for $x\leqslant x_1$, where $[\tilde{d}_1\ \tilde{d}_2]^t=\Lambda_{1,2}(k)[c_1\ c_2]^t$. Since $\psi(k,x_1)=\psi_{0,1}(k,x_1)=\psi_{1,2}(k,x_1)$ and $\psi'(k,x_1)=\psi'_{0,1}(k,x_1)=\psi'_{1,2}(k,x_1)$, it follows that $\psi_{0,1}(k,x)=\tilde{d}_1e^{ikx}+\tilde{d}_2e^{-ikx}$ for $x\geqslant x_1$. So $\Lambda_{0,1}(k)[\tilde{d}_1\ \tilde{d}_2]^t=[d_1\ d_2]^t$, and hence $[d_1\ d_2]^t=\Lambda_{0,1}(k)\Lambda_{1,2}(k)[c_1\ c_2]^t$. Thus, $\Lambda(k)=\Lambda_{0,1}(k)\Lambda_{1,2}(k)$, proving Eq. (2.17) when $N=1$. For $N\geqslant 2$ the result follows by induction.

For later use we note that when $N=1$, from Eqs. (2.15) and (2.17) we obtain

$$\frac{1}{T(k)}=\frac{1-R_{0,1}(k)L_{1,2}(k)}{T_{0,1}(k)T_{1,2}(k)}. \tag{2.18}$$

Now we return to Eq. (2.1) and discuss some consequences of Eqs. (2.17) and (2.18). The first result concerns resonant energies. These are energies at which the potential is perfectly transparent; in other words, energies $k_i^2 \geq 0$ where $|T(k_i)|=1$. Because of Eq. (2.5), $T(-k) = \overline{T(k)}$ for real k, and hence it is sufficient to consider the resonant frequencies only for $k_i \geq 0$. Typically, if $V(x)$ is a square-well potential, the existence of such resonant energies is well known (p. 94 of Ref. 8). There are also some general existence results[9] concerning resonances for potentials that are symmetric with respect to the midpoint of the potential barrier. The resonant energies play an important role in tunneling spectroscopy.[10] Here we consider a related but somewhat different problem. We consider the one-parameter family of potentials

$$V_\xi(x)=V_{0,1}(x+\xi)+V_{1,2}(x-\xi), \tag{2.19}$$

where $\xi>0$ is a real parameter. In other words, we take a potential $V(x)$ consisting of two fragments $V_{0,1}(x)$ and $V_{1,2}(x)$ and vary the distance between them by changing ξ. The goal is to adjust the distance between the fragments so that the transmission coefficient has magnitude 1. Let $T_\xi(k)$ denote the transmission coefficient for $V_\xi(x)$, and fix any $k=k_0 \geq 0$. Then we ask: are there any values of ξ for which $|T_\xi(k_0)|=1$? The answer when $k_0>0$ is contained in the next theorem. The analysis for $k_0=0$ will be given at the end of this section.

Theorem 2.2: Consider the potential $V_\xi(x)$ defined in Eq. (2.19) with the corresponding transmission coefficient $T_\xi(k)$. For any fixed $k_0>0$, there are three possibilities: (i) $|T_\xi(k_0)|=1$ for all $\xi>0$, (ii) there is no $\xi>0$ for which $|T_\xi(k_0)|=1$, (iii) the values $\xi>0$ for which $|T_\xi(k_0)|=1$ form an infinite sequence tending to $+\infty$.

Proof: Before starting the proof we remark that case (i) occurs when both of the fragments have a common resonant energy, that is when $|T_{0,1}(k_0)|=|T_{1,2}(k_0)|=1$; case (ii) occurs when $|T_{0,1}(k_0)|\neq|T_{1,2}(k_0)|$; case (iii) occurs when $|T_{0,1}(k_0)|=|T_{1,2}(k_0)|\neq 1$. For example, if $V(x)$ is symmetric about $x=x_1$ and hence $V_{0,1}(x_1-x)=V_{1,2}(x_1+x)$, then we are either in case (i) or case (iii); the same is true if $V_{1,2}(x)$ is a translate of $V_{0,1}(x)$.

The reflection coefficients from the right and left associated with the potentials $V_{0,1}(x+\xi)$ and $V_{1,2}(x-\xi)$ are given by $R_{0,1}(k)e^{2ik\xi}$ and $L_{1,2}(k)e^{2ik\xi}$, respectively. The transmission coefficients of the individual fragments are not affected by the shifts $\pm\xi$. Thus, by Eq. (2.18), $|T_\xi(k_0)|=1$ if and only if

$$|T_{0,1}(k_0)||T_{1,2}(k_0)|=|1-R_{0,1}(k_0)L_{1,2}(k_0)e^{4ik_0\xi}|. \tag{2.20}$$

Clearly, if $R_{0,1}(k_0)=L_{1,2}(k_0)=0$, then, by Eq. (2.6), $|T_{0,1}(k_0)|=|T_{1,2}(k_0)|=1$, and Eq. (2.20) holds independently of ξ, which is case (i). If $R_{0,1}(k_0)=0$ but $L_{1,2}(k_0)\neq 0$ (or vice versa), then $|T_{0,1}(k_0)|=1$ and $|T_{1,2}(k_0)|<1$ (or vice versa). Then Eq. (2.20) does not hold for any ξ. This is a special case of case (ii). Now suppose that $R_{0,1}(k_0)$ and $L_{1,2}(k_0)$ are both nonzero. Note the inequality

$$1-ab \geq (1-a^2)^{1/2}(1-b^2)^{1/2}, \quad a,b\in[0,1],$$

with the equality holding if and only if $a=b$. Using this inequality with $a=|R_{0,1}(k_0)|$ and $b=|L_{1,2}(k_0)|$, we see that Eq. (2.20) holds if and only if $|R_{0,1}(k_0)|=|L_{1,2}(k_0)|$ and

$$R_{0,1}(k_0)L_{1,2}(k_0)e^{4ik_0\xi}=|R_{0,1}(k_0)||L_{1,2}(k_0)|.$$

Hence, if $|R_{0,1}(k_0)|\neq|L_{1,2}(k_0)|$, then we are in case (ii). If $|R_{0,1}(k_0)|=|L_{1,2}(k_0)|$, then we set

$$R_{0,1}(k_0)L_{1,2}(k_0)=|R_{0,1}(k_0)||L_{1,2}(k_0)|e^{i\varphi(k_0)},$$

and we see that the values ξ are given by $4k_0\xi+\varphi(k_0)=2\pi n$, where n is any integer large enough to ensure $\xi>0$. Hence $\xi_n=\pi n/(2k_0)-\varphi(k_0)/(4k_0)$ is the desired sequence in case (iii). ■

Next we give some results concerning the nature of the point $k=0$. Let $f_{l;j,j+1}(k,x)$ and $f_{r;j,j+1}(k,x)$ denote the Jost solutions from the left and from the right, respectively, for the potentials $V_{j,j+1}(x)$. Since the potentials $V_{j,j+1}(x)$ have compact support for $j=1,\ldots,N-1$, using Proposition 2.1 we can conclude that $V_{j,j+1}(x)$ is generic if and only if $f'_{l;j,j+1}(k,x_j)\neq 0$ or if and only if $f'_{r;j,j+1}(k,x_{j+1})\neq 0$. Equivalently, $V_{j,j+1}(x)$ is exceptional if and only if $f'_{l;j,j+1}(k,x_j)=0$ or if and only if $f'_{r;j,j+1}(k,x_{j+1})=0$. This characterization also applies to the fragments $V_{0,1}(x)$ and $V_{N,N+1}(x)$ if we use $f'_{l;0,1}(k,x_0)$ and $f'_{r;N,N+1}(k,x_{N+1})$, respectively.

Theorem 2.3: Consider a potential $V(x)$ given in Eq. (2.14) with $N\geqslant 1$. Then:

(i) $\Rightarrow$ If all $N+1$ of the fragments are exceptional, then $V(x)$ is exceptional.

(ii) $\Rightarrow$ If exactly one fragment is generic, then $V(x)$ is generic.

Proof: (i) We give two proofs of (i) illustrating different aspects of the problem. First let $N=1$. Then, from Eq. (2.18) we see that if both $T_{0,1}(0)$ and $T_{1,2}(0)$ are nonzero, then the transmission coefficient $T(k)$ corresponding to $V(x)$ cannot vanish at $k=0$. Using induction, it then follows from Eq. (2.18) that if none of the transmission coefficients $T_{j,j+1}(k)$ vanish at $k=0$, then $T(k)$ cannot vanish at $k=0$. Hence (i) is proved. Alternatively, one can argue by using the zero-energy Jost solutions. Let $M_{j,j+1}$ denote the transfer matrix such that

$$\begin{bmatrix} \psi(0,x_j) \\ \psi'(0,x_j)\end{bmatrix}=M_{j,j+1}\begin{bmatrix} \psi(0,x_{j+1}) \\ \psi'(0,x_{j+1})\end{bmatrix},\quad j=1,\ldots,N-1,$$

for any zero-energy solution of Eq. (2.1). Notice that

$$f_{l;j,j+1}(0,x_{j+1})=1,\quad f'_{l;j,j+1}(0,x_{j+1})=0.$$

Hence, if $V_{j,j+1}(x)$ is exceptional, then $[1\ 0]^t$ is an eigenvector of $M_{j,j+1}$ corresponding to the eigenvalue $f_{l;j,j+1}(0,x_j)$; if $V_{j,j+1}(x)$ is generic, then $[1\ 0]^t$ is not an eigenvector of $M_{j,j+1}$, since in that case $f'_{l;j,j+1}(0,x_j)\neq 0$ and $f'_{l;j,j+1}(0,x_{j+1})=0$. Furthermore, we have $f_l(0,x_N)=f_{l;N,N+1}(0,x_N)$ for $x\in[x_N,+\infty)$ and hence $f'_l(0,x_N)=0$ whenever $V_{N,N+1}(x)$ is exceptional. Since all fragments are assumed exceptional, and hence $[1\ 0]^t$ is a common eigenvector of all matrices $M_{j,j+1}$, it follows that

$$\begin{bmatrix} f_l(0,x_1) \\ f'_l(0,x_1)\end{bmatrix}=M_{1,2}\cdots M_{N-1,N}\begin{bmatrix} f_l(0,x_N) \\ 0\end{bmatrix}=c\begin{bmatrix} 1 \\ 0\end{bmatrix},$$

where $c=\Pi_{n=1}^{N} f_{l;n,n+1}(0,x_n)$. Now notice that $f_l(0,x)$ satisfies $f''_l(0,x)=V_{0,1}(x)f_l(0,x)$ with the boundary conditions $f_l(0,x_1)=c$ and $f'_l(0,x_1)=0$; since $V_{0,1}(x)$ is exceptional, $f_l(0,x)$ must be a constant multiple of $f_r(0,x)$ in the interval $(-\infty,x_1]$. Hence $V(x)$ is exceptional.

(ii) When $N=1$ and exactly one of the two fragments is generic, then the assertion immediately follows from Eq. (2.18). Indeed, from Eqs. (2.15) and (2.17) we have

$$\frac{1}{T_{1,2}(k)}=\frac{1-L_{0,1}(-k)L(k)}{T_{0,1}(-k)T(k)},$$

and hence if $T(0)\neq 0$ and $T_{0,1}(0)\neq 0$, we must have $T_{1,2}(0)\neq 0$. Consequently, if both $V(x)$ and $V_{0,1}(x)$ are exceptional, $V_{1,2}(x)$ has to be exceptional. A similar argument shows that if $T(0)\neq 0$ and $T_{1,2}(0)\neq 0$, we must have $T_{0,1}(0)\neq 0$. When $N\geqslant 2$, assume that the generic fragment is $V_{j_0,j_0+1}(x)$. Multiply Eq. (2.17) by $T_{j_0,j_0+1}(k)$ so that

$$T_{j_0,j_0+1}(k)\Lambda(k)=\Lambda_{0,1}(k)\cdots[T_{j_0,j_0+1}(k)\Lambda_{j_0,j_0+1}(k)]\cdots\Lambda_{N,N+1}(k). \tag{2.21}$$

Now let $k\to 0$ in Eq. (2.21). Since in the generic case, $\lim_{k\to 0} T(k)/k = ic_0$ for some real, nonzero constant c_0 (p. 303 of Ref. 5), we have $T_{j_0,j_0+1}(0)/\overline{T_{j_0,j_0+1}(0)} = -1$. Also, $R(0)=L(0)=-1$ in the generic case. Thus on the right-hand side of Eq. (2.21) we get

$$\lim_{k\to 0}\,[T_{j_0,j_0+1}(k)\Lambda(k)] = \Lambda_{0,1}(0)\Lambda_{1,2}(0)\cdots\begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix}\cdots\Lambda_{N,N+1}(0).$$

Since $\det \Lambda_{j,j+1}(k)=1$, the matrices $\Lambda_{j,j+1}(0)$ are invertible and hence it follows that the matrix product in Eq. (2.21) is nonzero as $k\to 0$. This implies that $\lim_{k\to 0}[k\Lambda(k)]\neq 0$ and hence $V(x)$ must be generic. As in (i), one could also use the transfer matrices to give an alternate proof of part (ii). ■

Theorem 2.4: Any nontrivial potential, generic or exceptional, can be fragmented into at least two generic pieces. There are infinitely many different ways of fragmenting a nontrivial potential into generic pieces.

Proof: If suffices to show that if a given portion contains an exceptional piece that is not identically zero, then that piece can further be partitioned into infinitely many generic pieces. Suppose that $V_{j,j+1}(x)$ is exceptional and not identically zero. Then there is a subinterval of (x_j, x_{j+1}) on which $f_l'(0, x) \neq 0$. Choosing any point in this subinterval to partition $V_{j,J+1}(x)$ yields two fragments that are both generic.

An alternate proof can be given as follows. Let $f_{l;j,j+1}(k,x)$ be the corresponding Jost solution from the left for the potential $V_{j,j+1}(x)$. From Eq. (2.9) we have

$$\int_{x_j}^{x_{j+1}} dx\; V_{j,j+1}(x) f_{l;j,j+1}(0, x) = 0. \tag{2.22}$$

Then for any $z\in\mathbf{R}$, consider the fragmentation of $V_{j,j+1}(x)$ given by

$$V_{j,j+1}(x) = \theta(z-x)V_{j,j+1}(x) + \theta(x-z)V_{j,j+1}(x), \tag{2.23}$$

where $\theta(x)$ is the Heaviside function, i.e., $\theta(x)=1$ if $x>0$ and $\theta(x)=0$ if $x<0$. The fragments given in Eq. (2.23) have to be generic for an infinite number of values $z\in(x_j,x_{j+1})$, because $V_{j,j+1}(x)$ is nontrivial and so the integral obtained by replacing the lower limit in (2.22) by z has to be nonzero for some z, and hence, by continuity, for infinitely many z. ■

One can also consider fragmentations that contain exceptional pieces. From Theorem 2.3 we already know that a generic potential cannot be divided into two exceptional fragments. A generic potential can be divided into one generic and one exceptional piece if and only if there is a point x_1 where either $f_l'(0, x_1) = 0$ or $f_r'(0, x_1) = 0$. In the first case, the piece to the right of x_1 is exceptional while the piece to the left of x_1 is generic. In the second case, the types of the pieces are reversed. We may or may not be able to fragment a nontrivial exceptional potential into two nontrivial exceptional pieces. For example, the square-well potential supported on $0<x<a$ becomes exceptional at the depths $-j^2\pi^2/a^2$ with $j=1, 2, 3,...$, and hence the square-well potential given by

$$V(x) = \begin{cases} -\pi^2, & x\in(0,1), \\ 0, & \text{elsewhere}, \end{cases}$$

cannot be fragmented into two nontrivial exceptional pieces. A nontrivial exceptional potential can be cut into two nontrivial exceptional pieces if and only if there is a point x_1 where $f_l'(0, x_1) = 0$. If we have an exceptional potential we can choose each zero of $f_l'(0, x)$ as a separation point.

This will give the partition into the largest possible number of exceptional pieces, and that number may be finite or infinite. Example 3.1 demonstrates that an exceptional potential can be fragmented into an infinite number of exceptional pieces. If $V(x)$ is generic, then choosing the zeros of $f_l'(0,x)$ [respectively, $f_r'(0,x)$] as separation points, we obtain a partition where all pieces are exceptional except one, namely $V_{0,1}(x)$ [respectively, $V_{N,N+1}(x)$].

We note that if more than one fragment of $V(x)$ is generic, then $V(x)$ may be generic or exceptional. The following example illustrates this point.

Example 2.5: Assume

$$V_{0,1}(x)=\frac{-4e^{\sqrt{2}x}}{(1+e^{\sqrt{2}x})^2}\,\theta(-x),\quad V_{1,2}(x)=\frac{-4e^{-\sqrt{2}x}}{(1+e^{-\sqrt{2}x})^2}\,\theta(x).$$

Both $V_{0,1}(x)$ and $V_{1,2}(x)$ are generic, and in fact we have

$$T_{0,1}(k)=T_{1,2}(k)=\frac{k(k+i/\sqrt{2})}{k^2+1/4},\quad R_{0,1}(k)=L_{1,2}(k)=\frac{-1}{4k^2+1}.$$

Note that corresponding to $V(x)=V_{0,1}(x)+V_{1,2}(x)$ we have

$$T(k)=\frac{k+i/\sqrt{2}}{k-i/\sqrt{2}},\quad R(k)=0,$$

which is the exceptional case.

On the other hand, in terms of $u(x)$ and $v(x)$ given by

$$u(x)=8[4(3+2\sqrt{2})e^{\sqrt{2}x}-64e^{2x}+8e^{(2+\sqrt{2})x}-e^{(2+2\sqrt{2})x}+4(3-2\sqrt{2})e^{(4+\sqrt{2})x}],$$

$$v(x)=8+8e^{2x}-(3+2\sqrt{2})e^{\sqrt{2}x}-(3-2\sqrt{2})e^{(2+2\sqrt{2})x},$$

let us define

$$V_{0,1}(x)=\frac{u(x)}{v(x)^2}\,\theta(-x),\quad V_{1,2}(x)=\frac{-e^{-\sqrt{2}x}}{(1+e^{-\sqrt{2}x}/4)^2}\,\theta(x),$$

both of which are generic with the corresponding transmission coefficients

$$T_{0,1}(k)=\frac{50k(k+i)(\sqrt{2}k+i)}{50\sqrt{2}k^3+70ik^2+13\sqrt{2}k+31i},\quad T_{1,2}(k)=\frac{25k(\sqrt{2}k+i)}{25\sqrt{2}k^2+15ik+4\sqrt{2}}.$$

The sum $V(x)=V_{0,1}(x)+V_{1,2}(x)$ is a generic potential with the scattering coefficients given by

$$T(k)=\frac{2k(k+i)}{2k^2+1},\quad R(k)=\frac{-1}{2k^2+1}.$$

Finally, we analyze $T_\xi(0)$ corresponding to the potential $V_\xi(x)$ given in Eq. (2.19), as the analysis of $T_\xi(k)$ for $k=0$ was omitted from Theorem 2.2. In order to have $|T_\xi(0)|=1$, it is necessary that $V_\xi(x)$ is exceptional, and hence we first analyze the conditions for which $V_\xi(x)$ is exceptional. Let $F_l(k,x)$ and $F_r(k,x)$ denote the Jost solutions from the left and from the right, respectively, for the potential $V_\xi(x)$. Let us also use $f_l(k,x)$ and $f_r(k,x)$ to denote the Jost solutions from the left and from the right, respectively, for the potential $V(x)$. Note that $V_\xi(x)=0$ for $x\in(x_1-\xi,x_1+\xi)$, and hence we have

$$F_l(0,x)=\begin{cases} f_l(0,x+\xi)\left[1-2\xi\dfrac{f_l'(0,x_1)}{f_l(0,x_1)}-2\xi f_l'(0,x_1)^2\displaystyle\int_{x+\xi}^{x_1}\frac{dt}{f_l(0,t)^2}\right], & x\leqslant x_1-\xi,\\ (x-x_1-\xi)f_l'(0,x_1)+f_l(0,x_1), & x\in[x_1-\xi,\,x_1+\xi],\\ f_l(0,x-\xi), & x\geqslant x_1+\xi, \end{cases} \tag{2.24}$$

$$F_r(0,x)=\begin{cases} f_r(0,x+\xi), & x\leqslant x_1-\xi,\\ (x-x_1+\xi)f_r'(0,x_1)+f_r(0,x_1), & x\in[x_1-\xi,\,x_1+\xi],\\ f_r(0,x-\xi)\left[1+2\xi\dfrac{f_r'(0,x_1)}{f_r(0,x_1)}-2\xi f_r'(0,x_1)^2\displaystyle\int_{x_1}^{x-\xi}\frac{dt}{f_r(0,t)^2}\right], & x\geqslant x_1+\xi. \end{cases} \tag{2.25}$$

From Eqs. (2.24) and (2.25) we see that $V_\xi(x)$ is exceptional if and only if the ratio $F_r(0,x)/F_l(0,x)$ is independent of x; since $F_l(0,x)$ and $F_r(0,x)$ are linear functions in the interval $x\in[x_1-\xi,x_1+\xi]$, we can conclude that $V_\xi(x)$ is exceptional if and only if

$$\frac{F_r(0,x_1+\xi)}{F_l(0,x_1+\xi)}=\frac{F_r(0,x_1-\xi)}{F_l(0,x_1-\xi)},$$

from which we obtain

$$\xi=\frac{[f_l(0,x_1);f_r(0,x_1)]}{2f_l'(0,x_1)f_r'(0,x_1)}=\frac{d_r-d_l}{2d_rd_l}, \tag{2.26}$$

where $[f;g]=fg'-f'g$ denotes the Wronskian and we have defined

$$d_l=\frac{f_l'(0,\ x_1)}{f_l(0,\ x_1)},\quad d_r=\frac{f_r'(0,\ x_1)}{f_r(0,\ x_1)}.$$

The cases in which $f_l(0,x_1)=0$ and $f_r(0,x_1)=0$ are included by setting $d_l=\infty$ and $d_r=\infty$, respectively.

(a) If $d_l\neq0$ and $d_r\neq0$, then there is exactly one value of ξ given by Eq. (2.26) for which $V_\xi(x)$ is exceptional provided the right-hand side of Eq. (2.26) is positive. Otherwise, $V_\xi(x)$ is generic.

(b) If $d_l=d_r=0$, i.e., if $f_l'(0,x_1)=f_r'(0,x_1)=0$, then both fragments and hence also $V(x)$ are exceptional. Thus, $V_\xi(x)$ is exceptional for all $\xi\geqslant0$.

(c) If $d_l\neq0$ and $d_r=0$, then $V_{0,1}(x)$ is exceptional and $V_{1,2}(x)$ is generic. Thus, $T_{0,1}(0)\neq0$, $T_{1,2}(0)=0$, $R_{1,2}(0)=-1$, and $|L_{0,1}(0)|<1$, and Eq. (2.18) shows that $T_\xi(0)=0$ and hence we are in the generic case for all $\xi\geqslant0$. This is also in agreement with Theorem 2.3 (ii).

(d) If $d_l=0$ and $d_r\neq0$, then the analysis is similar to case (c); thus $V_\xi(x)$ is generic for all $\xi\geqslant0$.

(e) If $d_l\neq0$ and $d_r=\infty$, then $f_l'(0,x_1)\neq0$ and $f_r(0,x_1)=0$; both fragments are generic. From Eq. (2.26) we see that $V_\xi(x)$ is exceptional only when $\xi=1/(2d_l)$ provided that $d_l>0$. Otherwise $V_\xi(x)$ is generic, and in particular $V(x)$ is generic.

(f) If $d_l=\infty$ and $d_r\neq0$, the analysis is similar to case (e). Then, from Eq. (2.26) we see that $V_\xi(x)$ is exceptional only when $\xi=-1/(2d_r)$ provided that $d_r<0$. Otherwise $V_\xi(x)$ is generic, and in particular $V(x)$ is generic.

(g) If $d_l=0$ and $d_r=\infty$, from (2.26) in the limiting case it is seen that no ξ exists for which $V_\xi(x)$ is exceptional. Similarly, if $d_l=\infty$ and $d_r=0$, $V_\xi(x)$ is always generic.

(h) If $d_l=d_r=\infty$, we have $f_l(0,x_1)=f_r(0,x_1)=0$ and hence $f_l(0,x)$ and $f_r(0,x)$ are linearly dependent. Thus, $V(x)$ is exceptional. However, as seen from Eq. (2.26), $V_\xi(x)$ is generic for every $\xi>0$. In other words, $T_\xi(0)\neq0$ for $\xi=0$ but $T_\xi(0)=0$ for all $\xi>0$.

Once all the ξ values are obtained in cases (a), (b), (e), and (f) for which V_ξ is exceptional, one needs to determine which of these ξ values correspond to $|T_\xi(0)|=1$. For example, in case (b), we can proceed as follows. From Eq. (2.18) we have

$$\frac{1}{T_\xi(0)}=\frac{1-R_{0,1}(0)L_{1,2}(0)}{T_{0,1}(0)T_{1,2}(0)}, \tag{2.27}$$

and hence $T_\xi(0)$ is independent of ξ. Let $\gamma_{0,1}$ be the constant defined as in Eq. (2.10) giving the ratio of the zero-energy Jost solutions for the potential $V_{0,1}(x)$, and let $\gamma_{1,2}$ be defined similarly for the potential $V_{1,2}(x)$. As in Eq. (2.13), we have

$$R_{0,1}(0)=\frac{1-\gamma_{0,1}^2}{1+\gamma_{0,1}^2}, \quad L_{1,2}(0)=\frac{\gamma_{1,2}^2-1}{1+\gamma_{1,2}^2}. \tag{2.28}$$

Using Eq. (2.28) in Eq. (2.27) we obtain

$$T_\xi(0)=\frac{2\gamma_{0,1}\gamma_{1,2}}{1+\gamma_{0,1}^2\gamma_{1,2}^2},$$

from which we see that $|T_\xi(0)|=1$ if and only if $\gamma_{0,1}\gamma_{1,2}=\pm 1$.

III. WAVE PROPAGATION IN A NONHOMOGENEOUS MEDIUM

The fragmentation of an exceptional potential into two generic pieces has important consequences in direct and inverse scattering problems associated with wave propagation, where the governing equations are related to the Schrödinger equation or its variants. One such differential equation is given by

$$\frac{d^2\psi(k,x)}{dx^2}+\frac{k^2}{c(x)^2}\,\psi(k,x)=Q(x)\psi(k,x), \tag{3.1}$$

or by its time domain equivalent

$$\frac{\partial^2\phi(t,x)}{\partial x^2}-\frac{1}{c(x)^2}\,\frac{\partial^2\phi(t,x)}{\partial t^2}=Q(x)\phi(t,x). \tag{3.2}$$

Equation (3.1) describes the quantum mechanical behavior of a particle when the potential also depends on its energy. Equations (3.1) and (3.2) describe the propagation of waves in a one-dimensional nonhomogeneous, nonabsorptive medium where the wavespeed is $c(x)$ and the restoring force density is $Q(x)$. These equations can be analyzed by transforming them into Schrödinger equations by using local Liouville transformations.[11] In the special (but still significant) case $Q(x)=0$, the potential in the transformed Schrödinger equation is always exceptional. One important outcome of Theorem 2.4 is that it is possible to choose the local Liouville transformations in such a way that all the resulting fragments of the transformed Schrödinger equations are either generic or pertain to a potential vanishing identically. This leads to considerable simplifications in the small-k analysis of Eqs. (3.1) and (3.2). For example, consider Eq. (3.25) of Ref. 11 where the Jost solutions and their space derivatives are expressed as a product of matrices, each of which is expressed in terms of the quantities related to one fragment only. The matrices in Eq. (3.25) of Ref. 11 contain the factor $t_{j-1,j}(k)/k$, where $t_{j-1,j}(k)$ is the transmission coefficient corresponding to the jth fragment; that factor remains continuous as $k\to 0$ if the jth piece is generic and it is singular if the jth piece is exceptional. Hence, by fragmenting the exceptional pieces into generic ones, it becomes obvious that the Jost solutions and their space derivatives are continuous at $k=0$.

Let us write Eq. (3.1) as

$$\psi''(k,x)+k^2H(x)^2\psi(k,x)=Q(x)\psi(k,x), \quad x\in\mathbf{R}. \tag{3.3}$$

Our assumptions on $Q(x)$ and $H(x)$ are as follows:

(H1) $H(x)$ is strictly positive, piecewise continuous with possible discontinuities in $H(x)$ or $H'(x)$ occurring at the N points $x_1<\cdots<x_N$.

(H2) $H(x)\to H_\pm$ as $x\to\pm\infty$, where $H_\pm$ are positive constants.

(H3) $H-H_\pm\in L^1(\mathbf{R}^\pm)$, where $\mathbf{R}^-=(-\infty,0)$ and $\mathbf{R}^+=(0,+\infty)$.

(H4) H' is absolutely continuous on (x_n,x_{n+1}) and $2H''H-3(H')^2\in L^1_1(x_n,x_{n+1})$ for $n=0,\ldots,N$, where $x_0=-\infty$ and $x_{N+1}=+\infty$.

(H5) $Q(x)$ is real valued and of the form $Q(x)=W(x)+\Sigma_{j=1}^N c_j\delta(x-x_j)$, where $W\in L^1_1(\mathbf{R})$ and $\delta(x)$ is the Dirac delta function.

Conditions (H1)–(H5), without the delta-function terms in (H5), were introduced in Ref. 11, where the inverse scattering problem for Eq. (3.3), namely the recovery of the coefficient $H(x)$ from an appropriate set of scattering data, was studied. Hypothesis (H1) allows for abrupt changes in the material properties of the medium in which the wave propagates. In (H5) we have now included delta functions because they are often useful in working out explicitly solvable examples. Moreover, it is of interest to see how some of the results are affected by delta functions superimposed on discontinuities in $H(x)$ and $H'(x)$. The delta-function potential $V(x)=\alpha\delta(x-a)$ corresponds to

$$T(k)=\frac{k}{k+i\alpha/2}, \quad R(k)=\frac{-i\alpha/2}{k+i\alpha/2}\,e^{2ika}, \quad L(k)=\frac{-i\alpha/2}{k+i\alpha/2}\,e^{-2ika}, \tag{3.4}$$

from which we see that it is a generic potential.

As for Eq. (2.1), Eq. (3.3) also has two linearly independent scattering solutions, namely the Jost solutions $f_l(k,x)$ and $f_r(k,x)$ satisfying the boundary conditions

$$f_l(k,x)=\begin{cases} e^{ikH_+x}+o(1), & x\to+\infty,\\ \dfrac{1}{T_l(k)}\,e^{ikH_-x}+\dfrac{L(k)}{T_l(k)}\,e^{-ikH_-x}+o(1), & x\to-\infty,\end{cases}$$

$$f_r(k,x)=\begin{cases} \dfrac{1}{T_r(k)}\,e^{-ikH_+x}+\dfrac{R(k)}{T_r(k)}\,e^{ikH_+x}+o(1), & x\to+\infty,\\ e^{-ikH_-x}+o(1), & x\to-\infty.\end{cases}$$

Here, $T_l(k)$ and $T_r(k)$ are the transmission coefficients from the left and from the right, respectively, and $L(k)$ and $R(k)$ are the reflection coefficients from the left and from the right, respectively. Associated with Eq. (3.3) is the scattering matrix

$$\mathbf{S}(k)=\begin{bmatrix} T_l(k) & R(k)\\ L(k) & T_r(k)\end{bmatrix}. \tag{3.5}$$

The matrix $\mathbf{S}(k)$ is not unitary unless $H_+=H_-$; we have $\mathbf{S}(-k)=\overline{\mathbf{S}(k)}$ for real k, and

$$H_+T_l(k)=H_-T_r(k), \quad \text{Im } k\geqslant 0,$$

$$T_r(-k)T_l(k)+|R(k)|^2=T_r(k)T_l(-k)+|L(k)|^2=1, \quad k\in\mathbf{R},$$

$$R(k)T_r(-k)+L(-k)T_r(k)=0, \quad k\in\mathbf{R}.$$

In the study of the scattering matrix $\mathbf{S}(k)$ given in Eq. (3.5), one again has to distinguish between the generic case and the exceptional case. As in Sec. II, in the generic case the transmission coefficients vanish linearly as $k\to 0$, whereas in the exceptional case we have $T_l(0)\neq 0$ and $T_r(0)\neq 0$. Furthermore, in the generic case $R(0)=L(0)=-1$, while in the exceptional case $|R(0)|=|L(0)|<1$. The coefficient $H(x)$ in Eq. (3.3) has no influence on the leading behavior of the transmission coefficients as $k\to 0$, and hence the generic and exceptional cases are determined by the potential $Q(x)$ only. All the characterizations of the two cases for the Schrödinger equation hold verbatim also for Eq. (3.3). If $Q(x)=0$ in Eq. (3.3), we have the exceptional case. If $Q(x)$ is nontrivial and $Q(x)\geqslant 0$ in Eq. (3.3), then we have the generic case. All the differences between the two cases as $k\to 0$ outlined in Sec. II also exist[11–13] in the wave propagation problem associated with Eq. (3.3).

Let us generalize the factorization formula (2.17) to the scattering problem for Eq. (3.3). Under the Liouville transformation

$$y=y(x)=\int_0^x ds\ H(s), \quad \psi(k,x)=\frac{1}{\sqrt{H(x)}}\ \phi(k,y), \tag{3.6}$$

Eq. (3.3) is transformed into

$$\frac{d^2\phi(k,y)}{dy^2}+k^2\phi(k,y)=V(y)\,\phi(k,y), \tag{3.7}$$

where

$$V(y)=V(y(x))=\frac{H''(x)}{2H(x)^3}-\frac{3}{4}\frac{H'(x)^2}{H(x)^4}+\frac{Q(x)}{H(x)^2}. \tag{3.8}$$

Since, by (H1), $H(x)$ and $H'(x)$ are allowed to have jump discontinuities at x_j for $j=1,\ldots,N$, the function $V(y)$ is undefined at $y_j=y(x_j)$ for $j=1,\ldots,N$. In agreement with Eq. (3.6), we set $y_0=y(x_0)=-\infty$ and $y_{N+1}=y(x_{N+1})=+\infty$. Then $V(y)$ is well defined in each of the intervals (y_j,y_{j+1}) for $j=0,\ldots,N$, and (H4) ensures that $V\in L_1^1$ on these intervals. In view of (H5), the solutions of Eq. (3.3) satisfy the conditions

$$\psi(k,x_n-0)=\psi(k,x_n+0), \quad \psi'(k,x_n+0)-\psi'(k,x_n-0)=c_n\psi(k,x_n). \tag{3.9}$$

As a result, by using Eqs. (3.6) and (3.9), we deduce that the solutions of Eq. (3.7) satisfy the self-adjoint boundary conditions

$$\phi(k,y_n-0)=\sqrt{q_n}\ \phi(k,y_n+0), \tag{3.10}$$

$$\frac{d\phi(k,y_n-0)}{dy}=\nu_n\phi(k,y_n+0)+\frac{1}{\sqrt{q_n}}\frac{d\phi(k,y_n+0)}{dy}, \tag{3.11}$$

where

$$q_n=\frac{H(x_n-0)}{H(x_n+0)},$$

$$\nu_n=\frac{1}{2\sqrt{H(x_n-0)H(x_n+0)}}\left[\frac{H'(x_n-0)}{H(x_n-0)}-\frac{H'(x_n+0)}{H(x_n+0)}-2c_n\right]. \tag{3.12}$$

The scattering matrix corresponding to Eq. (3.7) equipped with these boundary conditions is known as the ''reduced scattering matrix''[11] and is given by

$$\sigma(k)=\begin{bmatrix}\tau(k) & \rho(k)\\ \ell(k) & \tau(k)\end{bmatrix},$$

where $\tau(k)$ is the reduced transmission coefficient and $\rho(k)$ and $\ell(k)$ are the reduced reflection coefficients from the right and from the left, respectively. The reduced scattering matrix is unitary and its entries are related to the scattering matrix $\mathbf{S}(k)$ given in Eq. (3.5) as follows:[11]

$$\tau(k)=\sqrt{\frac{H_+}{H_-}}\,T_l(k)e^{ikA}=\sqrt{\frac{H_-}{H_+}}\,T_r(k)e^{ikA}, \tag{3.13}$$

$$\rho(k)=R(k)e^{2ikA_+}, \quad \ell(k)=L(k)e^{2ikA_-},$$

where

$$A_\pm=\pm\int_0^{\pm\infty} ds\,[H_\pm-H(s)], \quad A=A_++A_-.$$

The points y_j generate a partition of the real line, and so we define

$$V_{j,j+1}(y)=\begin{cases}V(y), & y\in(y_j,y_{j+1}),\\ 0, & \text{elsewhere.}\end{cases}$$

We let $\tau_{j,j+1}(k)$, $\rho_{j,j+1}(k)$, and $\ell_{j,j+1}(k)$ denote the transmission coefficient and the reflection coefficients from the right and from the left, respectively, for the potential $V_{j,j+1}(y)$, and, as in Eq. (2.15), we define

$$\Lambda(k)=\begin{bmatrix}\dfrac{1}{\tau(k)} & -\dfrac{\rho(k)}{\tau(k)}\\ \dfrac{\ell(k)}{\tau(k)} & \dfrac{1}{\tau(-k)}\end{bmatrix}, \quad \Lambda_{j,j+1}(k)=\begin{bmatrix}\dfrac{1}{\tau_{j,j+1}(k)} & -\dfrac{\rho_{j,j+1}(k)}{\tau_{j,j+1}(k)}\\ \dfrac{\ell_{j,j+1}(k)}{\tau_{j,j+1}(k)} & \dfrac{1}{\tau_{j,j+1}(-k)}\end{bmatrix}. \tag{3.14}$$

By suppressing the k-dependence of the transition matrices in Eq. (3.14), we have the generalization of Eq. (2.17) in the case of Eq. (3.3) given by[13]

$$\Lambda=\Lambda_{0,1}F_1\Lambda_{1,2}F_2\Lambda_{2,3}\cdots F_N\Lambda_{N,N+1}, \tag{3.15}$$

where F_j for $j=1,\ldots,N$ are the matrices defined by

$$F_j(k)=\begin{bmatrix}\alpha_n+\dfrac{\nu_n}{2ik} & \left(\beta_n+\dfrac{\nu_n}{2ik}\right)e^{-2iky}\\ \left(\beta_n-\dfrac{\nu_n}{2ik}\right)e^{2iky_n} & \alpha_n-\dfrac{\nu_n}{2ik}\end{bmatrix},$$

with

$$\alpha_n=\frac{1}{2}\left[\sqrt{\frac{H(x_n-0)}{H(x_n+0)}}+\sqrt{\frac{H(x+0)}{H(x_n-0)}}\right], \quad \beta_n=\frac{1}{2}\left[\sqrt{\frac{H(x_n-0)}{H(x_n+0)}}-\sqrt{\frac{H(x_n+0)}{H(x_n-0)}}\right],$$

and where the constants ν_n are given in Eq. (3.12).

The matrices F_j account for the internal boundary conditions (3.10) and (3.11). In order to justify Eq. (3.15), again consider the case $N=1$ first. Using notations similar to those used below Eq. (2.17), we let $\phi(k,y)$ be a solution of Eq. (3.7) such that $\phi(k,y)=c_1e^{iky}+c_2e^{-iky}$ as $y\to+\infty$, and we define $\phi_{1,2}(k,y)$ and $\phi_{0,1}(k,y)$ as solutions of Eq. (3.7) for the fragments $V_{0,1}(y)$ and $V_{1,2}(y)$ such that $\phi_{1,2}(k,y)=\phi(k,y)$ for $y>y_1$ and $\phi_{0,1}(k,y)=\phi(k,y)$ for $y<y_1$. Then, $\phi_{1,2}(k,y)=\tilde{d}_1e^{iky}+\tilde{d}_2e^{-iky}$ for $y<y_1$ and $\phi_{0,1}(k,y)=\tilde{c}_1e^{iky}+\tilde{c}_2e^{-iky}$ for $y>y_1$, with suitable constants $\tilde{d}_1$, $\tilde{d}_2$, $\tilde{c}_1$, and $\tilde{c}_2$. Now the coefficients $\tilde{d}_1$ and $\tilde{d}_2$ are related to the coefficients $\tilde{c}_1$ and $\tilde{c}_2$ through the boundary conditions (3.10) and (3.11) by setting $\phi(k,y_1-0)=\phi_{0,1}(k,y_1)$, $\phi'(k,y_1-0)=\phi'_{0,1}(k,y_1)$, and $\phi(k,y_1+0)=\phi_{1,2}(k,y_1)$, $\phi'(k,y_1+0)=\phi'_{1,2}(k,y_1)$. This yields

$$\begin{bmatrix} e^{iky_1} & e^{-iky_1} \\ ike^{iky_1} & -ike^{-iky_1} \end{bmatrix}\begin{bmatrix} \tilde{c}_1 \\ \tilde{c}_2 \end{bmatrix}=\begin{bmatrix} \sqrt{q_1} & 0 \\ \nu_1 & \dfrac{1}{\sqrt{q_1}} \end{bmatrix}\begin{bmatrix} e^{iky_1} & e^{-iky_1} \\ ike^{iky_1} & -ike^{-iky_1} \end{bmatrix}\begin{bmatrix} \tilde{d}_1 \\ \tilde{d}_2 \end{bmatrix},$$

from which we obtain $[\tilde{c}_1\ \tilde{c}_2]^t=F_1[\tilde{d}_1\ \tilde{d}_2]^t$. This proves Eq. (3.15) when $N=1$, and the general case follows by induction. Note that F_n can be written as a product of three matrices, namely

$$F_n=\Lambda(x_n-0,\,x_n)\Lambda[x_n,x_n]\Lambda(x_n,x_n+0), \tag{3.16}$$

where

$$\Lambda(x_n-0,\,x_n)=\begin{bmatrix} \alpha_n^-+\dfrac{\nu_n^-}{2ik} & \left(\beta_n^-+\dfrac{\nu_n^-}{2ik}\right)e^{-2iky_n} \\ \left(\beta_n^--\dfrac{\nu_n^-}{2ik}\right)e^{2iky_n} & \alpha_n^--\dfrac{\nu_n^-}{2ik} \end{bmatrix},$$

$$\Lambda[x_n,x_n]=\begin{bmatrix} 1-\dfrac{c_n}{2ik} & \dfrac{c_n}{2ik}\,e^{-2iky_n} \\ -\dfrac{c_n}{2ik}\,e^{2iky_n} & 1+\dfrac{c_n}{2ik} \end{bmatrix},$$

$$\Lambda(x_n,x_n+0)=\begin{bmatrix} \alpha_n^++\dfrac{\nu_n^+}{2ik} & \left(\beta_n^++\dfrac{\nu_n^+}{2ik}\right)e^{-2iky_n} \\ \left(\beta_n^+-\dfrac{\nu_n^+}{2ik}\right)e^{2iky_n} & \alpha_n^+-\dfrac{\nu_n^+}{2ik} \end{bmatrix},$$

with

$$\alpha_n^{\mp}=\frac{1}{2}\left[\sqrt{H(x_n\mp0)}+\frac{1}{\sqrt{H(x_n\mp0)}}\right],\quad \beta_n^{\mp}=\pm\frac{1}{2}\left[\sqrt{H(x_n\mp0)}-\frac{1}{\sqrt{H(x_n\mp0)}}\right],$$

$$\nu_n^{\mp}=\frac{\pm1}{2\sqrt{H(x_n\mp0)}}\,\frac{H'(x_n\mp0)}{H(x_n\mp0)}.$$

We remark that the transition matrix $\Lambda(x_n-0,x_n)$ is due to the hard scatterer caused by a jump in $H(x)$ from $H(x_n-0)$ to 1 and a jump in $H'(x)$ from $H'(x_n-0)$ to 0. The transition matrix $\Lambda[x_n,x_n]$ is due to the hard scatterer $c_n\delta(x-x_n)$, as seen from Eq. (3.4). The transition matrix $\Lambda(x_n,x_n+0)$ is due to the hard scatterer caused by a jump in $H(x)$ from 1 to $H(x_n+0)$ and a

jump in $H'(x)$ from 0 to $H'(x_n+0)$. The transition matrices $\Lambda_{n,n+1}(k)$ in Eq. (3.15) are due to the soft scatterers $V_{n,n+1}(y)$. In the special case when $H(x)=1$ and $W(x)=0$ in (H5), Eq. (3.15) takes the form

$$\Lambda=\Lambda[x_1,x_1]\cdots\Lambda[x_N,x_N], \tag{3.17}$$

which describes scattering by a superposition of delta functions located at $x_1,\ldots,x_N$.

We mention one application of the factorization formula (3.15) in the inverse scattering problem for Eq. (3.3) concerning the large-k asymptotics of $\tau(k)$, $\rho(k)$, and $\ell(k)$; we refer the reader to Refs. 11–13 for details: it is known that from the large-k asymptotics of a reduced reflection coefficient one can recover the ratios q_n and ν_n (cf. Ref. 13, where the case $c_n=0$ was studied). It is seen from Eq. (3.12) that the coefficients c_n affect the large-k asymptotics through the constants ν_n and thus contribute in the same manner as the jumps in the derivative of $H(x)$. We also see that c_n can be chosen suitably to cancel the contribution from a jump in $H'(x)$.

In the recovery of $H(x)$ in Eq. (3.3), the distinction between the exceptional and generic cases is important. For example, in the absence of bound states, given the scattering data consisting of a reduced reflection coefficient and $Q(x)$, one obtains a one-parameter family of $H(x)$ in the exceptional case and a unique $H(x)$ in the generic case.[11–13] Therefore, in the exceptional case one must include either H_+ or H_- in the scattering data for the unique recovery of $H(x)$; however, in the generic case, H_+ or H_- cannot be specified in the scattering data and instead these constants are themselves recovered during the inversion procedure.

Finally in this section we give an example of an exceptional potential that can be fragmented into an infinite number of only exceptional pieces.

Example 3.1: In Eq. (3.3) choose $Q(x)=0$ and

$$H(x)=\begin{cases}1+\left(\dfrac{\sin x}{x}\right)^3, & x\neq 0,\\ 2, & x=0.\end{cases} \tag{3.18}$$

Note that $H(x)$ is strictly positive and bounded, $H_\pm=1$, and

$$H'(x)=\begin{cases}\dfrac{3\sin^2 x}{x^4}\,[x\cos x-\sin x], & x\neq 0,\\ 0, & x=0,\end{cases}$$

$$H''(x)=\begin{cases}\dfrac{3\sin x}{x^5}\,[x^2(3\cos^2 x-1)-6x\cos x\sin x+4\sin^2 x], & x\neq 0,\\ 0, & x=0,\end{cases}$$

and hence H, H', and H'' are all continuous on $\mathbf{R}$. Since $Q(x)=0$, we are in the exceptional case, and hence the transmission coefficients $T_l(k)$ and $T_r(k)$ cannot vanish at $k=0$. Note that $H(n\pi)=1$, $H'(n\pi)=0$, and $H''(n\pi)=0$ for any integer n. Using Eq. (3.6) let us define $y_n=y(n\pi)$. Now consider the potential $V(y)$ obtained by using Eq. (3.18) and $Q(x)=0$ in Eq. (3.8). That potential must be exceptional, and in fact from Eq. (3.13) it can be seen that the transmission coefficient $\tau(k)$ corresponding to the potential $V(y)$ cannot vanish at $k=0$. Now let us fragment $V(y)$ as $V(y)=\sum_{n=-\infty}^{\infty}V_{n,n+1}(y)$, where we have defined

$$V_{n,n+1}(y)=\begin{cases}V(y), & y\in(y_n,y_{n+1}),\\ 0, & \text{elsewhere.}\end{cases} \tag{3.19}$$

The following argument shows that each $V_{n,n+1}(y)$ is exceptional. Since $Q(x)=0$ in Eq. (3.3), the corresponding zero-energy Jost solution is given by $f_l(0,x)=1$ for $x\in\mathbf{R}$. Using Eq. (5.1) of Ref. 11, we see that the zero-energy Jost solution from the left of Eq. (3.7) is given by

$$g_l(0,y)=g_l(0,y(x))=\sqrt{H(x)}.$$

Hence, we obtain

$$g_l'(0,y)=\frac{dg_l(0,y)}{dy}=\frac{dx}{dy}\,\frac{d\sqrt{H(x)}}{dx}=\frac{H'(x)}{2H(x)^{3/2}}. \tag{3.20}$$

Since $H'(n\pi)=0$, from Eq. (3.20) we see that $g_l'(0,y_n)=0$, and hence we can choose y_n as the separation points to fragment $V(y)$ into only exceptional pieces, which are given by Eq. (3.19).

IV. WAVE PROPAGATION IN A NONCONSERVATIVE MEDIUM

The wave propagation in a one-dimensional nonconservative medium is described, in the frequency domain, by the generalized Schrödinger equation

$$\psi''(k,x)+k^2\psi(k,x)=[ikP(x)+Q(x)]\psi(k,x),\quad x\in\mathbf{R}, \tag{4.1}$$

where k is the wave number, $P(x)$ represents the joint effect of energy absorption and generation, and $Q(x)$ stands for the restoring force density. In the time domain Eq. (4.1) corresponds to

$$\frac{\partial^2 u}{\partial x^2}-\frac{\partial^2 u}{\partial t^2}-P(x)\,\frac{\partial u}{\partial t}=Q(x)u,\quad t,x\in\mathbf{R},$$

where the wavespeed is equal to one. We will assume that $Q(x)$ is real valued and belongs to $L_1^1(\mathbf{R})$, and that $P(x)$ is real valued and belongs to $L^1(\mathbf{R})$. We have energy absorption when $P(x)\leqslant 0$ and energy generation when $P(x)\geqslant 0$; however, our results in this section are valid without assuming that $P(x)$ is positive or negative.

The scattering solutions of Eq. (4.1) are those behaving like e^{ikx} or e^{-ikx} as $x\to\pm\infty$, and such solutions occur when $k^2>0$. Among the scattering solutions are the Jost solution from the left $f_l(k,x)$ and the Jost solution from the right $f_r(k,x)$ satisfying the boundary conditions (2.2) and (2.3), respectively. The scattering matrix $\mathbf{S}(k)$ associated with Eq. (4.1) has the form (2.4). When $P(x)$ is purely imaginary, the inverse scattering problem for Eq. (4.1) was analyzed by Jaulent and Jean;[14–17] in this case the scattering matrix $\mathbf{S}(k)$ is unitary and hence the reflection coefficients cannot exceed one in absolute value. An incomplete study of the same problem when $P(x)$ is real was outlined in Ref. 18. In that case the differential equation (4.1) is no longer self-adjoint and the scattering matrix $\mathbf{S}(k)$ is no longer unitary. Consequently, the analysis of the direct and inverse scattering problems for real $P(x)$ is much more complicated than for imaginary $P(x)$.

We are interested in the analog of the factorization formula (2.17). As in Sec. II, let us partition the real axis $\mathbf{R}$ into $x_0<x_1<x_2<\cdots<x_N<x_{N+1}$ with $x_0=-\infty$ and $x_{N+1}=+\infty$. Consider the analog of Eq. (4.1) given by

$$\psi''(k,x)+k^2\psi(k,x)=[ikP_{j,j+1}(x)+Q_{j,j+1}(x)]\psi(k,x), \tag{4.2}$$

where we have defined the fragments

$$P_{j,j+1}(x)=\begin{cases}P(x), & x\in(x_j,x_{j+1}),\\ 0, & \text{elsewhere},\end{cases} \tag{4.3}$$

$$Q_{j,j+1}(x)=\begin{cases} Q(x), & x\in(x_j,x_{j+1}),\\ 0, & \text{elsewhere.}\end{cases} \tag{4.4}$$

Let the scattering matrix associated with Eq. (4.2) be given by

$$\mathbf{s}_{j,j+1}(k)=\begin{bmatrix} t_{j,j+1}(k) & r_{j,j+1}(k)\\ l_{j,j+1}(k) & t_{j,j+1}(k)\end{bmatrix}.$$

Proceeding as in the previous sections or as in Ref. 7 or Ref. 13 we obtain

$$\Lambda(k)=\Lambda_{0,1}(k)\Lambda_{1,2}(k)\cdots\Lambda_{N,N+1}(k), \tag{4.5}$$

where we have defined the transition matrices

$$\Lambda(k)=\begin{bmatrix} \dfrac{1}{T(k)} & -\dfrac{R(k)}{T(k)}\\ \dfrac{L(k)}{T(k)} & \dfrac{T(k)^2-L(k)R(k)}{T(k)}\end{bmatrix}, \tag{4.6}$$

$$\Lambda_{j,j+1}(k)=\begin{bmatrix} \dfrac{1}{t_{j,j+1}(k)} & -\dfrac{r_{j,j+1}(k)}{t_{j,j+1}(k)}\\ \dfrac{l_{j,j+1}(k)}{t_{j,j+1}(k)} & \dfrac{t_{j,j+1}(k)^2-l_{j,j+1}(k)r_{j,j+1}(k)}{t_{j,j+1}(k)}\end{bmatrix}. \tag{4.7}$$

As in the previous sections, the transition matrix given in Eq. (4.6) provides the link between the asymptotics of the scattering solutions of Eq. (4.1) at $+\infty$ and those at $-\infty$ when $e^{\pm ikx}$ are chosen as an asymptotic basis; the transition matrices in Eq. (4.7) have similar interpretations. Again, each of the matrices in Eqs. (4.6) and (4.7) can be decomposed as in Eq. (2.16). Note that the (2,2) entry in Eq. (4.6) is analytic in the lower-half complex plane $\mathbf{C}^-$ and in general cannot be replaced by $1/T(-k)$; however, it is known that[14] this entry is equal to $1/\mathscr{T}(-k)$, where $\mathscr{T}(k)$ is the transmission coefficient associated with the differential equation obtained from Eq. (4.1) by changing the sign of $P(x)$.

Again one has to distinguish between the generic and exceptional cases in studying the scattering and inverse scattering problems for Eq. (4.1). As for Eq. (3.3), the potential $Q(x)$ alone determines whether we have the generic case or the exceptional case. The difficulties arising in proofs in the exceptional case outlined in the previous sections remain true also for Eq. (4.1), and by choosing each fragment in the partitioning (4.3) and (4.4) to be either generic or identically zero we expect simplifications in the small k-analysis of the direct and inverse scattering problems for Eq. (4.1).

(Received 30 January 1996; accepted for publication 23 May 1996)

We derive a set of inequalities which relate the translation invariant problem of N identical particles with pairwise interactions to an independent particle problem. These inequalities apply to attractive power law potentials $V(r)=r^q$, $1\leqslant q\leqslant\infty$, and superpositions of such potentials; they become identities in the harmonic oscillator case $q=2$. We use the inequalities to derive new upper and lower bounds for the ground state energies of fermion systems, which interact through these potentials. These bounds improve all previous results in the range $1\leqslant q\leqslant\infty$; they reduce to the exact answer in the harmonic oscillator case. © *1996 American Institute of Physics.* [S0022-2488(96)01109-7]

I. INTRODUCTION

Since the pioneering works of Fischer and Ruelle on the thermodynamic limit,[1] of Dyson and Lenard on the stability of matter,[2] and of Lévy-Leblond on the nonsaturation of gravitational forces,[3] a great deal of interest has been devoted to the derivation of lower bounds for the ground state energies of many particle systems in terms of two particle spectra.

In Ref. 4 we have shown that for boson systems, or particles of different masses, previous bounds could be considerably improved by a simple technique. The improved bounds coincide with the exact answer for harmonic interactions. This has a number of applications, for instance in relating baryon to meson masses in the quark model.

Pairwise interacting N fermion systems present a variety of interesting applications. In that case, however, the methods introduced in Ref. 4 are not able to produce any improvements to the bounds obtained by the Fischer–Ruelle–Dyson–Lenard–Lévy-Leblond (FRDL3)[1–3] technique. This is quite frustrating in the harmonic oscillator case which can be solved exactly, and where the FRDL3 bound differs from the exact result by a factor of $\sqrt{2}$. Similarly, the attractive Coulomb case can be calculated for large N with the Thomas–Fermi method. In that case, the FRDL3 result is off by a factor of ~ 3.

One reason for this difficulty in improving the FRDL3 bounds can be traced back to the known difficulty of constructing an orthogonal set of N particle wavefunctions which satisfies the three conditions of being completely antisymmetric, translationally invariant, and of being eigenfunctions of an independent particle Hamiltonian. This can only be done in the harmonic case.

In this paper, we present a new approach to the N fermion problem with pairwise interactions which deals with the particular class of potentials

$$V(r)=\int_1^\infty r^q \mu(q)\,dq, \quad \mu \geqslant 0.$$

Although, this class does not include some cases of practical interest such as the Coulomb and Yukawa potentials, or the quark–quark confining potentials, the results are nevertheless very interesting insofar as (1) they systematically improve the FRDL3 results; (2) they produce *both* upper *and* lower bounds; and (3) they reduce to the exact answer in the harmonic case.

The derivation of these new bounds relies on the existence of a set of inequalities which is interesting as such. The proof of these inequalities is nontrivial, it requires the techniques of $\mathcal{L}^P$ interpolation, and the Riesz–Thorin interpolation theorem. For the class of potentials under consideration, these inequalities allow us to relate an N-body problem with pairwise interactions and translation invariance to an independent particle problem whose solution is known.

In Sec. I, we state the problems under consideration and recall previous bounds. In Sec. II, we use the inequalities to derive the upper and lower bounds on fermion systems, and we draw our first conclusions. Finally, in Sec. III, we give the derivation of the inequalities themselves.

II. POSITION OF THE PROBLEM

Consider a system of N identical particles with pairwise interactions $V_{ij} \equiv V(r_i - r_j)$, of Hamiltonian

$$H^N = \sum_{i=1}^N p_i^2 + \sum_{i=1}^N \sum_{j=i+1}^N V_{ij} \tag{1}$$

(for simplicity we have set the mass equal to $\frac{1}{2}$).

We denote by $\epsilon_n(\mu)$ the energy levels of a particle of mass $\mu/2$ placed in the potential $V(r)$ centered at the origin, of Hamiltonian $h = p^2/\mu + V(r)$, by g_n their degeneracies, and by $f_N(\mu)$ the ground state energy of N independent fermions, of spin s and mass $\mu/2$, each placed in this potential, of Hamiltonian

$$\tilde{H}^N = \sum_{i=1}^N h_i = \sum_{i=1}^N \left(\frac{p_i^2}{\mu} + V(r_i) \right). \tag{2}$$

We have

$$f_N(\mu) = (2s+1) \sum_{n=1}^k g_n \epsilon_n(\mu) + r\,\epsilon_{k+1}(\mu), \tag{3}$$

where the integer k is defined in terms of N by

$$(2s+1) \sum_{n=1}^k g_n + r = N < (2s+1) \sum_{n=1}^{k+1} g_n, \quad r \geqslant 0. \tag{4}$$

In the Coulomb case, $V = -1/r$, we have $\epsilon_n(\mu) = -\mu/4n^2$, $g_n = n^2$, and, for large N, $f_N(\mu) \approx -(\mu/4)(2s+1)^{2/3}(3N)^{1/3}$.

In the three-dimensional harmonic oscillator $V = r^2$, $\epsilon_n(\mu) = (2n+1)/\sqrt{\mu}$, $g_n = n(n+1)/2$, and, for large N, $f_N(\mu) \approx (6N)^{4/3}/((2s+1)^{1/3} 4\sqrt{\mu})$.

Following an argument due originally to Fischer and Ruelle,[1] one can obtain a lower bound on the N-particle ground state energy E^N, in terms of the two-particle spectrum, by rewriting the Hamiltonian (1) as a sum of N terms

$$H^N=\frac{1}{2}\sum_{i=1}^{N} H_i, \tag{5}$$

$$H_i=\sum_{j=1,j\neq i}^{N}\left(\frac{2p_j^2}{(N-1)}+V_{ij}\right). \tag{6}$$

If $|\Omega\rangle$ is the N particle ground state, $E^N=\langle\Omega|H^N|\Omega\rangle$, and therefore

$$E^N=\frac{N}{2}\langle\Omega|H_i|\Omega\rangle. \tag{7}$$

In Eq. (6), H_i appears as the Hamiltonian of $N-1$ independent particles of mass $\mu/2=(N-1)/4$, placed in the field of particle i considered as infinitely massive. Since $\langle H_i\rangle$ is larger than the ground state energy of this system, one obtains the desired lower bounds.

For bosons, we have

$$E_B^N\geqslant\frac{N(N-1)}{2}\,\epsilon_1(\mu=(N-1)/2), \tag{8}$$

which yields in the Coulomb and harmonic cases

$$E_B^N\geqslant 3N\sqrt{(N-1)/2}\quad(V=r^2), \tag{9a}$$

$$E_B^N\geqslant -N(N-1)^2/16\quad(V=1/r). \tag{9b}$$

In the case of fermions, the antisymmetry of $|\Omega\rangle$ imposes retention of only those levels of H_i which correspond to antisymmetric states in the $N-1$ particles $j=1,\ldots,N,j\neq i$. The minimal requirement is therefore to distribute evenly the $N-1$ particles over the $N-1$ lowest eigenstates of the one-particle Hamiltonian. One thus obtains

$$E_F^N\geqslant\frac{N}{2}\,f_{N-1}(\mu=(N-1)/2). \tag{10}$$

For large N, in the harmonic and Coulomb cases, respectively, one obtains

$$E_F^N\geqslant\frac{6^{4/3}}{2^{1/2}4(2s+1)^{1/3}}\,N^{11/6}\quad(V=r^2), \tag{11a}$$

$$E_F^N\geqslant-\frac{(2s+1)^{2/3}3^{1/3}}{16}\,N^{7/3}\quad(V=-1/r). \tag{11b}$$

These bounds are off by factors of $\sqrt{2}$ (harmonic case, which is exactly soluble) and ≈ 3 (Coulomb case, which can be treated by the Thomas–Fermi method for large N).

In the case of bosons (more generally, nonidentical particles), we have improved the above bounds[4] in what we believe is an optimal way.

We use the identity

$$N\sum_{i=1}^{N} p_i^2=\sum_{1\leqslant i<j\leqslant N}\sum(p_i-p_j)^2+\left(\sum_{i=1}^{N} p_i\right)^2, \tag{12}$$

valid for any set of N vectors p_i, $i=1,\ldots,N$ of R^k, to separate out the center-of-mass motion in (1) as

$$H^N = H^N_{\rm rel} + P^2/N, \tag{13}$$

where the relative Hamiltonian is

$$H^N_{\rm rel} = \sum_{1\leqslant i<j\leqslant N}\sum \left(\frac{1}{N}(p_i-p_j)^2 + V_{ij}\right) \tag{14}$$

and $P=\Sigma p_i$ is the total momentum.

In the N body center-of-mass frame $\langle P\rangle = 0$ [this can be made rigorous by adding, e.g., a term $\alpha^2(\Sigma r_i/N)^2$ which commutes with $H^N_{\rm rel}$ and letting α^2 tend to zero], and therefore

$$E^N = \frac{N(N-1)}{2}\langle\Omega|\left(\frac{4}{N}\left(\frac{p_i-p_j}{2}\right)^2 + V_{ij}\right)|\Omega\rangle. \tag{15}$$

Since $(p_i-p_j)/2$ and (r_i-r_j) satisfy canonical commutation relations, one obtains, for bosons

$$E^N_B \geqslant \frac{N(N-1)}{2}\,\epsilon_1(\mu = N/4), \tag{16}$$

which improves (8) since $\epsilon_n(\mu)$ increases with $1/\mu$.

This new lower bound becomes the exact answer for a harmonic interaction: $E^N = 3(N-1)\sqrt{N}$, and we have shown[4] that it is very close to the exact answer for the power-law potentials $V=r^q$, $-1\leqslant q\leqslant 5$, including the Coulomb case (we thank J. M. Richard for making new tests for $q>3$, $N=3$).

In fermion systems, however, this procedure does not help. We can, of course, perform a decomposition of H^N similar to (5) and (6):

$$H^N = \frac{1}{2}\sum_{i=1}^{N} H_i, \tag{17}$$

$$H_i = \sum_{j=1, j\neq i}^{N}\left(\frac{4}{N}\left(\frac{p_j-p_i}{2}\right)^2 + V_{ij}\right), \tag{18}$$

but H_i is no longer an independent particle Hamiltonian, and it cannot be diagonalized in general. In fact, although $(p_j-p_i)/2$ and (r_j-r_i) have canonical commutation relations, (p_j-p_i) and (r_k-r_i) do not commute.

Here H_i can be viewed as describing the motion of $N-1$ independent particles of mass $N/2$, placed in the field of a much lighter particle i of mass $N/(2(N+1))$. This problem has no simple solution in general. The difficulty we meet here is also related to the known difficulty of constructing fully antisymmetric N-particle wavefunctions which are both eigenstates of an $N-1$ independent particle Hamiltonian and translationally invariant.

No recasting of the kinetic term, such as (12) or the many analogous formulas one can write, can do the job, and it seems impossible to improve the fermionic bound (10) in a simple way without further specifying the potential.

This situation is rather frustating with regards to the harmonic interaction, where we know the exact answer and the bound (10) is off by a factor of $\sqrt{2}$.

A naïve conjecture, following from the inspection of Eq. (14), and assuming the first $N-1$ levels of the Hamiltonian $(4/N)p^2+V(r)$ are equally populated, such as what would occur in a Slater determinant, would lead to

$$E_F^N \geqslant \frac{N}{2} f_{N-1}(\mu = N/4), \tag{19}$$

which, in the harmonic case, reduces to $\sqrt{N} f_{N-1}(1)$, giving the right answer asymptotically in N. However, it does not seem possible to prove such a conjecture in a simple way.

III. DERIVATION OF NEW FERMIONIC BOUNDS

Improved bounds on fermion systems may be obtained by further specifying the potential. In what follows, we restrict ourselves to power-law potentials,

$$V(r) = r^q, \quad 1 \leqslant q \leqslant \infty, \tag{20}$$

which include the harmonic case $q=2$ and the infinite square well $q=\infty$, and superpositions of such potentials.

It is instructive to recall the solution of the harmonic case. Consider the independent particle Hamiltonian

$$\widetilde{H}^N = \sum_{i=1}^N p_i^2 + N \sum_{i=1}^N r_i^2; \tag{21}$$

the ground-state energy of the totally antisymmetric solution is

$$\widetilde{E}^N = \sqrt{N} f_N \tag{22}$$

[from now on we write f_N instead of $f_N(1)$ since we know that the eigenvalues of $ap^2 + br^q$ scale as $a^{q/(q+2)} b^{2/(q+2)}$, and therefore $f_N(\mu)$ can be expressed in terms of $f_N(1)$].

Using the identity (12) both for the kinetic and potential terms, we obtain

$$\widetilde{H}^N = H_{\mathrm{rel}}^N + \left(\frac{P^2}{N} + N^2 X^2 \right), \tag{23}$$

where $X = \Sigma r_i / N$ is the center of gravity of the system. The second term on the right-hand side of (23) is a one-particle Hamiltonian which commutes with H_{rel}^N. Therefore the ground state energy of $\widetilde{H}^N$ is the sum of ground state energies $\widetilde{E}^N = E^N + \sqrt{N} \epsilon_1$, that is to say,

$$E^N = \sqrt{N}(f_N - \epsilon_1). \tag{24}$$

In order to derive upper and lower bounds for fermion systems with $V(r) = r^q$ potentials, we will follow a similar procedure, and we will make use of the following inequalities.

Consider N vectors r_i, $i = 1, \ldots, N$, of R^3, and $1 \leqslant q \leqslant \infty$. Then

$$4 \sum_{1 \leqslant i < j \leqslant N} \sum \left| \frac{r_i - r_j}{2} \right|^q + N^2 \left| \frac{\Sigma_{i=1}^N r_i}{N} \right|^q \geqslant N \sum_{i=1}^N |r_i|^q, \tag{25}$$

$$\sum_{1 \leqslant i < j \leqslant N} \sum |r_i - r_j|^q + \left| \sum_{i=1}^N r_i \right|^q \leqslant N \sum_{i=1}^N |r_i|^q, \tag{26}$$

where the upper inequality holds for $1 \leqslant q \leqslant 2$, and the lower one for $2 \leqslant q \leqslant \infty$; $|r|$ is the Euclidean norm of $r \in R^3$.

The proof of these inequalities is given in the next section. Notice that both of them become identities for $q=2$ since they reduce to (12).

The physical interest of such inequalities lies in the fact that they allow us to relate a problem of translationally invariant pairwise interaction to an independent particle problem.

Indeed, both inequalities are of the form

$$\sum_{1\leqslant i<j\leqslant N}\sum |r_i-r_j|^q+a|X|^q\geqslant b\sum_{i=1}^{N}|r_i|^q, \tag{27}$$

where $X=\Sigma r_i/N$ is the position of the center of gravity. We therefore have the *operator* inequalities

$$\sum_{i=1}^{N} p_i^2+\sum\sum |r_i-r_j|^q+a|X|^q\geqslant\sum_{i=1}^{N}(p_i^2+b|r_i|^q). \tag{28}$$

The right-hand side of (28) is an independent-particle Hamiltonian whose (antisymmetric) ground state energy is

$$\widetilde{E}_f^N=b^{2/(q+2)}f_N. \tag{29}$$

Using (12) the left-hand side can be rewritten as the sum of two commuting Hamiltonians, the Hamiltonian we are interested in $H_{\rm rel}^N$, and a one-particle Hamiltonian

$$h=\frac{P^2}{N}+a|X|^q \tag{30}$$

whose ground state energy is $a^{2/(q+2)}N^{-q(q+2)}\epsilon_1$. $H_{\rm rel}^N$ and h commute, their eigenstates factorize, and their eigenvalues add.

Since (28) is an operator inequality, we therefore have the bounds

$$E_f^N+a^{2/(q+2)}N^{-q/(q+2)}\epsilon_1\geqslant b^{2/(q+2)}f_N. \tag{31}$$

Inserting the actual values of the coefficients a and b, as can be read from Eqs. (25) and (26), we obtain the following upper and lower bounds for the ground state energy E_1^N of a N fermion system with pairwise interactions $|r_i-r_j|^q$. For $1\leqslant q\leqslant 2$,

$$2^{[2(q-2)]/(q+2)}[N^{2/(q+2)}f_N-N^{(4-q)/(q+2)}\epsilon_1]\leqslant E_F^N\leqslant N^{2/(q+2)}f_N-N^{q/(q+2)}\epsilon_1 \tag{32}$$

and, for $2\leqslant q\leqslant\infty$, the inequalities are reversed. At $q=2$, we recover the exact harmonic oscillator results.

Since, for $V=r^q, f_N\sim N^{(5q+6)/(3q+6)}$ as $N\to\infty$ in three dimensions, as it can be shown from semi-classical estimates valid in the large N limit for power potentials, the f_N terms dominate over the ϵ_1 terms at large N, and, for simplicity, we concentrate on this limit for the discussion:

$$2^{[2(q-2)]/(q+2)}\leqslant\lim_{N\to\infty}[E_F^N/N^{2/(q+2)}f_N]\leqslant 1, \tag{33}$$

the upper and lower inequalities corresponding respectively to $1\leqslant q\leqslant 2$ and to $2\leqslant q\leqslant\infty$.

For $q=1$, the upper and lower bounds differ by a factor $2^{2/3}=1.59$; the lower bound is the same as the previous result (10). For $q=\infty$ (infinite square well) the upper and lower bounds differ by a factor of 4 and again the lower bound coincides with (10).

In all the range $1<q<\infty$, the previous result (10) is improved. The maximal improvement occurs for the harmonic case $q=2$, where these bounds reduce to the exact answer.

This approach provides *both* upper and lower bounds.

We shall exploit this fact in turning to the more general class of potentials which are linear superpositions of power law potentials (20):

$$V(r)=\int_1^\infty r^q \mu(q)\ dq. \tag{34}$$

In principle, since we have both upper and lower inequalities in the two ranges $1\leqslant q\leqslant 2$ and $2\leqslant q\leqslant\infty$, we should be able to write upper and lower bounds for this class of potentials.

Consider first the simplest case which corresponds to linear superpositions (34) with positive weights and $q\geqslant 2$,

$$V(r)=\int_2^\infty r^q \mu(q)\ dq, \quad \mu(q)\geqslant 0, \tag{35}$$

a particular case of which is entire functions with positive expansion coefficients and no linear term (a constant can always be subtracted out).

From the inequalities (25) and (26), we readily obtain, writing down (35) on both sides,

$$\sum_{1\leqslant i<j\leqslant N}\sum V(r_i-r_j)+V\left(\sum\ r_i\right)\geqslant N\sum_{i=1}^N\ V(r_i), \tag{36}$$

$$\sum\sum\ V(r_i-r_j)+\frac{N^2}{4}\ V\left(\frac{2\Sigma r_i}{N}\right)\leqslant\frac{N}{4}\sum_{i=1}^N\ V(2r_i). \tag{37}$$

Adding the kinetic terms and taking into account that the eigenvalues of $ap^2+bV=b(a/bp^2+V)$ are directly expressed in terms of those of V: $\epsilon_n(\mu=b/a)$, and that multiplying r by a constant is equivalent to rescaling the mass by the inverse squared of this constant, one obtains the bounds

$$E_F^N\geqslant N f_N(\mu=N)-\epsilon_1(\mu=1/N), \tag{38}$$

$$E_F^N\leqslant\frac{N}{4}\ f_N\left(\mu=\frac{N}{16}\right)-\frac{N^2}{4}\ \epsilon_1\left(\mu=\frac{N^3}{16}\right). \tag{39}$$

For potentials of the class

$$V(r)=\int_1^2 r^q\mu(q)dq, \quad \mu\geqslant 0, \tag{40}$$

the signs of these two bounds are simply reversed.

The bounds (38) and (39) are quite remarkable in that they hold for any potential of the classes (35) and (40), and are expressed in terms of the two-particle spectrum. They reduce to the particular cases (32) for power law potentials, and become exact for a harmonic potential.

We notice that, although (38) reproduces the harmonic result, it is different from the naïve conjecture (19). It is only for potentials of the class (35) that (38) is an improvement over the result (10).

For the more general superposition (34) with positive weights, one can obtain similar formulas but these are more complicated to write. The N-body results are expressed in terms of two-body spectra corresponding not to the original potential but to a modified one:

$$\tilde{V}(r)=\int_1^2 \frac{(2r)^q}{4}\,\mu(q)dq+\int_2^\infty r^q\mu(q)dq=V(r)-\int_1^2\left(1-\frac{2^q}{4}\right)r^q\mu(q)dq. \tag{41}$$

For weights of alternating signs, sticking to the class (35) for simplicity, one can write the potential $V(r)$ as

$$V(r)=V_+(r)-V_-(r) \tag{42}$$

with

$$V_\pm(r)=\int_2^\infty r^q\mu_\pm(q)\,dq, \quad \mu_\pm(q)\geqslant 0. \tag{43}$$

In order to write lower bounds, for instance, one uses inequality (36) for V_+ and inequality (37) for V_- in order to obtain

$$H^N+\frac{P^2}{N}+V_+(NX)-\frac{N^2}{4}\,V_-(2X)\geqslant\sum_{i=1}^N\left[p_i^2+NV_+(r_i)-\frac{N}{4}\,V_-(2r_i)\right]. \tag{44}$$

Leaving aside the one-particle Hamiltonian for the center-of-mass variable X in the left-hand side, this inequality allows us to relate H^N to an independent-particle Hamiltonian where the potential is no longer $V(r)$ but the effective potential

$$\tilde{V}(r)=V_+(r)-\tfrac{1}{4}V_-(2r). \tag{45}$$

In general, however, this is of no use in deriving lower bounds because in many cases of interest $\tilde{V}(r)$ is unbounded from below. Consider, for instance

$$V=-\lambda r^2\,\exp(-r), \tag{46}$$

which possesses two-body bound states for λ large enough, and pertains to the class under consideration. For this potential, one has

$$V_+(r)=r^2\,\sinh r, \quad V_-(r)=r^2\,\cosh r, \tag{47}$$

therefore the effective potential $\tilde{V}(r)$ entering on the right-hand side of (44) is

$$\tilde{V}(r)=r^2\,\sinh r-r^2\,\cosh 2r, \tag{48}$$

which is unbounded from below.

Upper bounds can nevertheless be obtained in such cases.

Lower bounds can only be obtained if $\mu(q)$ oscillates in a bounded region in q (for instance, if V is a polynomial in r).

IV. PROOF OF THE INEQUALITIES

We now give the proof of the inequalities (25) and (26). The keypoint in this proof is due to Jean-Michel Bony.

Consider N_1 vectors x_i, $i=1,\ldots,N_1$, of R^3 (or R^k in general) and let $|x_i|$ denote the usual Euclidean norm of x_i.

The set $X=\{x_1,x_2,\ldots,x_{N_1}\}$ can be considered as a point in $(R^3)^{N_1}$. In this latter space one defines the $\mathcal{L}^P$ norm of X, noted $\|x\|_p$, $p\geqslant 1$, associated with the positive coefficients $\gamma_1,\gamma_2,\ldots,\gamma_{N_1}$ as

$$\|X\|_p=(\gamma_1|x_1|^p+\gamma_2|x_2|^p+\cdots+\gamma_{N_1}|x_{N_1}|^p)^{1/p}. \tag{49}$$

Consider a point $Y=\{y_1,y_2,\ldots,y_{N_2}\}$ of $(R^3)^{N_2}$ with the ℓ^p norm $\|Y\|_p=(\Sigma_{i=1}^{N_2}\delta_i|y_i|^p)^{1/p}$, δ_i positive, and an injective linear transformation L from $X\in(R^3)^{N_1}$ to $Y\in(R^3)^{N_2}$ noted $Y=LX$, such that, for $1\leqslant p_2\leqslant p_1\leqslant+\infty$,

$$\|LX\|_{p_1}\leqslant c_1\|X\|_{p_1}, \tag{50a}$$

$$\|LX\|_{p_2}\leqslant c_2\|X\|_{p_2}. \tag{50b}$$

The Riesz–Thorin interpolation theorem[5] states that for all p between p_2 and p_1

$$p_1\geqslant p\geqslant p_2,\quad \|LX\|_p\leqslant C_p\|X\|_p, \tag{51}$$

with

$$C_p=C_2^{1-\theta}C_1^{\theta}, \tag{52}$$

θ being given in terms of p, p_2, and p_1 by

$$\frac{1}{p}=\frac{\theta}{p_1}+\frac{1-\theta}{p_2}. \tag{53}$$

Returning to our problem, we first consider $X=\{x_1,x_2,\ldots,x_N\}\in(R^3)^N$ with the ℓ^P norm

$$\|X\|_p=\left(N\sum_{i=1}^{N}|x_i|^p\right)^{1/p} \tag{54}$$

and $Y=\{\{v_{ij}\},w\}\in(R^3)^{N'}$, $N'=N(N-1)+1$, where

$$v_{ij}=\frac{x_i-x_j}{2},\quad w=\sum_{i=1}^{N}\frac{x_i}{N}, \tag{55a}$$

the inverse transformation being

$$x_i=\frac{(w+2\Sigma_{j=1}^{N}v_{ij})}{N}. \tag{55b}$$

Equations (55a) and (55b) provide a bijection of $(R^3)^N$ and its image $\mathcal{J}$ in $(R^3)^{N'}$ which is such that

$$v_{ij}+v_{ji}=0,\quad v_{ij}+v_{jk}+v_{ki}=0.$$

The ℓ^p norm of Y is defined by

$$\|Y\|_p+\left(2\sum_{i=1}^{N}\sum_{\substack{j=1\\ i\neq j}}^{N}|v_{ij}|^p+N^2|w|^p\right)^{1/p}. \tag{56}$$

For $p=2$, these norms are equal since they reduce to the identity (12): $\|X\|_2=\|Y\|_2$.

For $p=1$, using the identity

$$x_i=\frac{1}{N}\left(\sum_{j=1}^{N}(x_i-x_j)+\sum_{j=1}^{N}x_j\right),$$

one has

$$|x_i|\leqslant\frac{1}{N}\left(\sum_{j=1}^{N}|x_i-x_j|+\left|\sum_{j=1}^{N}x_j\right|\right).$$

Therefore, by summing over i,

$$N\sum|x_i|\leqslant 2\sum_{\substack{i=1\\ i\neq j}}^{N}\sum_{j=1}^{N}\left|\frac{x_i-x_j}{2}\right|+N^2\left|\frac{\Sigma x_i}{N}\right|. \tag{57}$$

In other words, $\|X\|_1\leqslant\|Y\|_1$, and by the Riesz–Thorin interpolation theorem

$$\|X\|_p\leqslant\|Y\|_p, \quad 1\leqslant p\leqslant 2,$$

which proves the inequality (25) in this case.

For $p>2$, the inequality is reversed. Indeed

$$\|X\|_\infty\geqslant\|Y\|_\infty, \tag{58}$$

which can be seen as follows. Let $|x_i|=\sup_j|x_j|$. It is obvious that $|x_i|\geqslant|x_j-x_k|/2\ \forall j,k$ and $|x_i|\geqslant|\Sigma x_i|/N$.

So, $\sup_j|x_j|\geqslant\sup(|v_{ij}|,|w|)$.

The only case we need to consider is when all vectors are collinear and of equal moduli. If all vectors are equal, both sides of (58) are equal. If p vectors are equal to x and $(N-p)$ to $-x$, one easily checks that $N\Sigma|x_i|\geqslant 2\Sigma\Sigma|v_{ij}|$, this becoming an inequality for $p=N/2$.

Therefore, (58) holds and, since $\|X\|_2=\|Y\|_2$,

$$\|X\|_p\geqslant\|Y\|_p \quad \text{for } p\geqslant 2,$$

which completes the proof of inequality (25). This inequality is *saturated*, i.e., it becomes an equality, when either all x_i are equal, or $N/2$ of the x_i are equal to x and the other $N/2$ are equal to $-x$ (N even).

Turning to inequality (26), we now replace (55) by

$$v_{ij}=(x_i-x_j), \quad w=\sum_{i=1}^{N}x_i, \tag{59}$$

and we define the ℓ^p norm of Y by

$$\|Y\|_p=\left(\frac{1}{2}\sum_{\substack{i=1\\ i\neq j}}^{N}\sum_{j=1}^{N}|x_i-x_j|^p+\left|\sum_{i=1}^{N}x_i\right|^p\right)^{1/p}, \tag{60}$$

$\|X\|_p$ being defined as previously.

For $p=2$ we still have $\|X\|_2=\|Y\|_2$, of course.

The proof that $\|Y\|_1\geqslant\|X\|_1$ is straightforward. We have

$$|x_i-x_j|\leqslant|x_i|+|x_j|, \quad \left|\sum\ x_i\right|\leqslant\sum\ |x_i|.$$

Therefore

$$\frac{1}{2}\sum_{\substack{i=1\\ i\neq j}}^{N}\sum_{j=1}^{N}|x_i-x_j|+\left|\sum_{i=1}^{N}x_i\right|\leqslant N\sum_{i=1}^{N}|x_i|.$$

and

$$\|Y\|_p\leqslant\|X\|_p \tag{61}$$

for $1\leqslant p\leqslant 2$, which proves (26) in that range of values of p.

Notice that we also have for any $\lambda\geqslant 0$

$$\frac{1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N}|x_i-x_j|+\lambda^2\left|\frac{\Sigma x_i}{\lambda}\right|\leqslant(N-1+\lambda)\sum_{i=1}^{N}|x_i|,$$

$$\frac{1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N}|x_i-x_j|^2+\lambda^2\left|\frac{\Sigma x_i}{\lambda}\right|^2\leqslant N\sum_{i=1}^{N}|x_i|^2,$$

which lead to a set of λ-dependent inequalities valid for $1\leqslant p\leqslant 2$ where one makes full use of the Riesz–Thorin interpolation theorem, in particular Eq. (52).

In practice, we have found out that, by optimizing in λ, one does improve the upper bound in the range $1\leqslant p\leqslant 2$, but not asymptotically in N. One can readily check that, for $p=1$, the upper bound can be brought down to $E_F^N\leqslant(N-1)^{2/3}\,(f_N^3-N\epsilon_1^3)^{1/3}$ instead of $E_F^N\leqslant N^{2/3}\,f_N-N^{1/3}\epsilon_1$. The improvement is only felt for small values of N.

Finally, for $p\to+\infty$ we want to prove that

$$\left(\frac{1}{2}\sum\sum\ |x_i-x_j|^p+\left|\sum\ x_i\right|^p\right)^{1/p}\geqslant N^{1/p}\left(\sum\ |x_i|^p\right)^{1/p}. \tag{62}$$

Let x_1 be one of the vectors of largest norm $|x_1|\geqslant|x_i|$, $i=2,\ldots,N$. If one other vector, x_2, of nonvanishing norm points in the backward hemisphere of x_1, that is to say $x_1\cdot x_2/|x_1||x_2|<0$, then $|x_1-x_2|\geqslant|x_1|$ and the inequality holds.

If all vectors x_i, $i\neq 1$, point in the forward hemisphere of x_1 and at least one is of nonzero norm, then $|\Sigma x_i|>|x_1|$ and the inequality holds.

If all vectors vanish except x_1, both sides of (62) are equal.

Therefore, $\|X\|_\infty\leqslant\|Y\|_\infty$, and $\|X\|_p\leqslant\|Y\|_p$ for $p\geqslant 2$, which completes the proof of inequality (26). This inequality is saturated when all x_i vanish except one of them.

One can derive, in a similar manner, a variety of other inequalities, for instance by using Jacobi variables.

The Riesz–Thorin interpolation theorem actually applies to a much larger class of problems since it applies to measure spaces, with positive measure, in general. Notice, for instance, by dividing Eq. (25) by N^2, one can rewrite it in integral form as

$$2\int\int\left|\frac{x(u)-x(v)}{2}\right|^p d\mu(u)d\mu(v)+\left|\int x(u)d\mu(u)\right|^p\geqslant\int|x(u)|^p\,d\mu(u),$$

where we have introduced a positive measure such that $\int d\mu(u)=1$. In order to recover (25) we set

$$d\mu(u)=\frac{1}{N}\sum_{i=1}^{N}\delta(u-x_i)du.$$

In this more general formulation, these inequalities may turn out to be useful in dealing with systems with an infinite number of degrees of freedom.

ACKNOWLEDGMENTS

We are indebted to Jean-Michel Bony and the Centre de Mathématiques de l'Ecole Polytechnique for many enlightening discussions and for providing the proof of a conjecture which appeared very difficult to establish within R^3 geometry. One of us (A.M.) would like to acknowledge the hospitality of Professor J. P. Bourguignon and the Institut des Hautes Etudes Scientifiques (IHES), where part of this work was done. The other author (J.L.B.) wishes to thank Professor E. Predazzi and the Institute of Theoretical Physics of the University of Torino, where part of this work was completed, for their kind hospitality.

Interchannel resonances at a threshold

B. Baumgartner
Institut für Theoretische Physik, Universität Wien, Boltzmanngasse 5, A-1090 Wien, Austria

(Received 29 February 1996; accepted for publication 20 June 1996)

Fermi's Golden Rule, the perturbation theoretic formula for calculating the half-width of a resonance, is not applicable to the case of a transition from a bound state into an open channel, when the energy of the bound state is exactly at the threshold of the continuum. We study solvable models of this phenomenon. The exact results coincide in leading order with the formulas found by modifying Fermi's Golden Rule. © *1996 American Institute of Physics.* [S0022-2488(96)03011-3]

I. INTRODUCTION

An interchannel resonance in quantum mechanical scattering is considered as arising by a perturbation of a bound state in a closed channel, with the bound state energy lying in a region where other channels are open.[1] In the case of a small perturbation, the half-width of the resonance is in general calculated with **Fermi's Golden Rule** (FGR).[2–4] If the unperturbed Hamiltonian H_0 (which is the kinetic energy plus interchannel potentials) with a bound state $|\varphi\rangle$ in the closed channel and continuum wavefunctions ψ_k in the open channel (we will consider only one open channel) is perturbed by αV, then FGR gives the imaginary part of the resonance energy as a product of

(1) α^2,
(2) the absolute square of the transition matrix element $\langle\varphi|V\psi_k\rangle$,
(3) the spectral density in the open channel, and
(4) the constant π.

A mathematical treatment, using complex scaling,[5] confirms Fermi's Golden Rule as the contribution to perturbation theory in second order, with the exception of *the case where the energy of the bound state does coincide with the threshold of the continuous spectrum in the open channel*. When trying to apply FGR to such a case, one observes the following facts:

(a) The transition matrix element is zero in general; only in the case of an open s-channel with a zero-energy inner-channel resonance may it be nonvanishing at the threshold.
(b) The spectral density at the threshold is infinite.

So FGR gives either infinity or an undecided value of zero times infinity; up to now we don't know for sure whether the bound state turns into a resonance, and, in case it should do so, we don't have a perturbation-theoretic formula for its lifetime.

Such cases actually do occur with atoms.[6] In principle they could also appear with nuclei or in solid state physics, where the channels are the bands of electron states, and where a bound state is located at an impurity. For semiconductors just the resonances near a band edge (=threshold) are of particular importance.[7]

In this paper we study simple solvable models: first, a one-dimensional lattice model with two bands. Then we make a comparison with a simplified model, which keeps only the barest essentials. This serves as an argument for the validity of the solvable continuum models with a separable potential for coupling of the channels. The continuum models are one-dimensional or the radial parts of a rotation-invariant three-dimensional system.

The leading term in an expansion of the lifetime turns out to be proportional to a half-integer-

0022-2488/96/37(12)/5928/11/$10.00

exponentiated coupling constant. We end up with a conjecture how to modify FGR to get a generally valid formula for the imaginary part of the resonance energy.

II. A ONE-DIMENSIONAL LATTICE MODEL

We consider a one-dimensional lattice $\mathbf{Z}$, carrying two channels, which would be translation invariant, if there were not an impurity at the point denoted by $n=0$. We consider only a local action of the impurity, so we can restrict the Hilbert space for each channel to the space of even functions. (The odd functions are zero at $n=0$ and are not affected by the impurity.) So it is enough to consider the half-space with points $n\geqslant 0$, and the even wavefunctions can be represented by elements of the Hilbert space $\ell^2(\mathbf{N})$ with the norm for $\psi=(\psi_n)\in\ell^2(\mathbf{N})$ given by

$$\|\psi\|^2=|\psi_0|^2=2\sum_{n=1}^{\infty}|\psi_n|^2. \tag{1}$$

In each channel there is a kinetic energy K:

$$(K\psi)_n=\begin{cases}2\psi_n-\psi_{n-1}-\psi_{n+1}, & n\geqslant 1\\ 2\psi_0-2\psi_1, & n=0.\end{cases}$$

The complete system with two bands is modelled in the Hilbert space $\ell^2(\mathbf{N})\oplus\ell^2(\mathbf{N})$. One channel gives a band shifted by a positive energy b, so, without impurity, the Hamiltonian would be $(K+b\mathbf{1})\oplus K$. The impurity is represented by a negative local inner-channel potential $(-w\delta_{n,0})\oplus(-v\delta_{n,0})$, where w is positive.

We are interested in the bound state in the upper band. It has the wavefunction

$$\varphi_n=ce^{-n\gamma_0},\quad c=(\coth\ \gamma_0)^{-1/2}, \tag{2}$$

where

$$2\sinh\ \gamma_0=w \tag{3}$$

and a binding energy which we consider as exactly equal to the relative shift of the bands:

$$b=2\cosh\ \gamma_0-2. \tag{4}$$

Now we collect all these contributions as the unperturbed Hamiltonian H_0. In matrix notation

$$H_0=\begin{pmatrix}b\mathbf{1}+K-w\delta_{n,0} & 0\\ 0 & K-v\delta_{n,0}\end{pmatrix} \tag{5}$$

it has the bound state $\binom{\varphi_n}{0}$ with energy zero, which equals the lower band edge of the lower channel.

Next we add a perturbation αV by an impurity at the point $n=0$, which introduces a coupling of the channels. For explanations see the discussion in Sec. III. We define

$$H_\alpha=H_0+\alpha V,\quad V=\delta_{n,0}\begin{pmatrix}\mathbf{1} & t^*\\ t & u\end{pmatrix},\quad t\in\mathbf{C},\quad u\in\mathbf{R}. \tag{6}$$

In the open channel the resonance state should behave like a Gamow function,[8] so, to solve the equation, we make the ansatz

$$\psi_n = \begin{pmatrix} e^{-n\gamma} \\ a \cdot e^{ikn} \end{pmatrix}, \tag{7}$$

$$(H_\alpha - E)\psi = 0, \tag{8}$$

and search for solutions with $\mathrm{Im}(k) < 0$, $E \to 0$, $a \to 0$, and $\gamma \to \gamma_0$ as $\alpha \to 0$.

Inserting (7) into (8) gives for the components $((H_\alpha - E)\psi)_n$ for $n \geqslant 1$ the equations

$$E = 2 - 2\cosh\,\gamma + b = 2 - 2\cos\,k, \tag{9}$$

$$\begin{aligned} b + 2 - 2e^{-\gamma} - w - E + \alpha(1 + t^* a) &= 0, \\ (2 - 2e^{ik} - v - E)a + \alpha(ua + t) &= 0. \end{aligned} \tag{10}$$

Expressing E by the appropriate parts of (9) we transform (10) to

$$a = \frac{-\alpha t}{\alpha u - v - 2i\,\sin\,k} = \frac{\alpha - w + 2\sinh\,\gamma}{-t^* \alpha} \tag{11}$$

and

$$\alpha^2(t^* t - u) + \alpha(f + ug) - fg = 0, \tag{12}$$

where we have introduced

$$\begin{aligned} f &:= v + 2i\,\sin\,k, \\ g &:= w - 2\sinh\,\gamma. \end{aligned} \tag{13}$$

Considering, by way of Eq. (9), E, γ, f, and g as analytic functions of the uniformizing complex variable k,

$$\gamma = \gamma(k) = \mathrm{arcosh}(b/2 + \cos\,k) \tag{14}$$

with

$$\lim_{k \to 0} \gamma(k) = \gamma_0 > 0,$$

we will be mainly interested in the behavior of these functions of k near zero. The expansions are

$$\begin{aligned} E &= k^2 - \frac{k^4}{12} + O(k^6), \\ f &= v + 2ik - \frac{i}{3}\,k^3 + O(k^5), \\ g &= k^2\,\coth\,\gamma_0 + \left(\frac{1}{w} + \frac{2}{w^3} - \frac{\sqrt{w^2+4}}{12w}\right)k^4 + O(k^6) =: c^{-2}k^2 + dk^4 + O(k^6). \end{aligned} \tag{15}$$

The goal is to get E as a function of real α by way of k. Using Eq. (12) it seems easier first to consider α as a complex-valued function of k, and then to invert this to a function $k(\alpha)$. Four different cases have to be treated separately:

(a) If $t^* t - u = 0$,

$$\alpha=\frac{f\cdot g}{f+ug}\begin{cases}(c^{-2}k^2+dk^4)\left(1-\dfrac{t^*t}{c^2v}\,k^2+i\,\dfrac{2t^*t}{c^2v}\,k^3\right)+O(k^6), & \text{if } v\neq 0,\\ (c^{-2}k^2+dk^4)\left(1+i\,\dfrac{t^*t}{2c^2}\right)k+O(k^5), & \text{if } v=0.\end{cases}\tag{16a}$$

(b) If $t^*t-u\neq 0$, the solution of the quadratic equation with $\alpha\to 0$ as $k\to 0$ has to be chosen:

$$\begin{aligned}\alpha&=\frac{f+ug}{2(t^*t-u)}\left(\sqrt{1+\frac{4fg(t^*t-u)}{(f+ug)^2}}-1\right)\\&=\begin{cases}(c^{-2}k^2+dk^4)\left(1-\dfrac{t^*t}{c^2v}\,k^2+2it^*t\,\dfrac{c^{-2}}{v^2}\,k^3\right)+O(k^6), & \text{if } v\neq 0,\\ (c^{-2}k^2+dk^4)\left(1+i\,\dfrac{t^*t}{2c^2}\,k\right)+O(k^4), & \text{if } v=0.\end{cases}\end{aligned}\tag{16b}$$

The leading contributions to the power series for the case b are independent of u and identical to the power series in case a, where we may replace u by t^*t. However, the distinction between absence and presence of an impurity well, $v=0$ and $v\neq 0$, is important.
For $v\neq 0$,

$$\alpha=c^{-2}k^2-\left(\frac{t^*t}{vc^4}-d\right)+i\,\frac{2t^*t}{vc^4}\,k^5+O(k^6).$$

For $v=0$,

$$\alpha=c^{-2}k^2+i\,\frac{t^*t}{2c^4}\,k^3+O(k^4).\tag{17}$$

In all the cases $\alpha(k)$ is an analytic function of k in some neighborhood of $k=0$, which is a zero point of second order, so the function can be inverted to give k as an analytic function of the square root of α.[9,10] Its expansion is
for $v\neq 0$,

$$\begin{aligned}k&=c\alpha^{1/2}+\frac{1}{2}\left(t^*t\,\frac{c}{v}-c^5d\right)\alpha^{3/2}-it^*t\,\frac{c^2}{v^2}\,\alpha^2+O(\alpha^{5/2}),\\E&=c^2\alpha+\left(t^*t\,\frac{c^2}{v}-c^6d-\frac{c^4}{12}\right)\alpha^2-it^*t\,\frac{2c^3}{v^2}\,\alpha^{5/2}+O(\alpha^3);\end{aligned}\tag{18}$$

for $v=0$,

$$\begin{aligned}k&=c\alpha^{1/2}-i\,\frac{t^*t}{4}\,\alpha+O(\alpha^{3/2}),\\E&=c^2\alpha-it^*t\,\frac{c}{2}\,\alpha^{3/2}+O(\alpha^2).\end{aligned}\tag{19}$$

III. DISCUSSION

The model has been chosen to investigate the basic mathematical structure, with best possible ease in computation. The impurity's potential and the perturbation are therefore assumed to act locally at one point only. From there on everything is as general as possible. For the closed

channel the inner-channel part of the perturbing potential has been set equal to one in Eq. (6). The reason is the following: If it were zero, the bound state would under perturbation not turn into a resonance, but would remain a bound state. [This can be checked with the ansatz of a wavefunction $\Phi_n = \binom{e^{-\gamma n}}{a \cdot e^{-\kappa n}}$, and proceeding in a similar way as for the resonance.] So we are only interested in the case where this inner-channel perturbation is strictly positive, and we may use the freedom of shifting the normalization between the coupling constant and the potential V to set this matrix element equal to one.

The threshold behavior of the open channel, connected with the absence or presence of an impurity well, determines the leading term for the imaginary part: If $v \neq 0$, there is a nonvanishing effective range of the impurity and the continuum wavefunctions at low energy tend to stay away from it. The transition probability from the bound state to the continuum increases with the coupling constant α more slowly than in other cases. If $v=0$, there is no effective range, the transitions are not hindered, and the high spectral density of the continuum effects an increase of Im $(E(\alpha))$ faster than α^2. These effects will be discussed in closer detail for the continuum models.

IV. THE SIMPLIFIED LATTICE MODEL

To pave the way for simple continuum models, we simplify this two-band model by ignoring any inner-channel effects in the closed channel, except for the change in energy. So, we replace H_α by $PH_\alpha P$, with the projection operator

$$P = \begin{pmatrix} |\varphi\rangle\langle\varphi| & 0 \\ 0 & 1 \end{pmatrix}, \tag{20}$$

where $|\varphi\rangle$ is the unperturbed bound state (2).

So we work in the restricted Hilbert space $P[\ell^2(\mathbf{N}) \oplus \ell^2(\mathbf{N})] \cong \mathbf{C} \oplus \ell^2(\mathbf{N})$, where the closed channel is represented by only one state. Moreover, we feel free to replace the inner-channel part u of the perturbation V by t^*t, because the leading terms in the expansion of (16b) are identical to those of (16a).

The Hilbert space is $\mathscr{H} = \mathbf{C} \oplus \ell^2(\mathbf{N})$, the Hamiltonian $H_\alpha = H_0 + \alpha V$,

$$H_0 = \begin{pmatrix} 0 & 0 \\ 0 & K - v\,\delta_{n0} \end{pmatrix}, \quad V = \begin{pmatrix} c^2 & ct^*\delta_{n0} \\ ct\,\delta_{n0} & t^*t\,\delta_{n0} \end{pmatrix}. \tag{21}$$

With the ansatz for the unnormalized resonance wavefunction

$$\Psi = \begin{pmatrix} 1 \\ a \cdot e^{ikn} \end{pmatrix} \tag{22}$$

inserted into $(H_\alpha - E)\Psi = 0$, we get

$$\begin{aligned} E &= 2(1 - \cos k), \\ a &= (E/\alpha c - c)/t^*, \\ \alpha &= \frac{c^{-2}(1 - \cos k)(v + 2i \sin k)}{v/2 + i \sin k + t^*tc^{-2}(1 - \cos k)}. \end{aligned} \tag{23}$$

This α is an analytic function of k, with the power series in a neighborhood of the origin

$$\alpha=\begin{cases} c^{-2}k^2+\left(\dfrac{t^*t}{vc^4}-\dfrac{1}{12c^2}\right)k^4-ik^5+O(k^6) & \text{for } v\neq 0,\\ c^{-2}k^2+i\,\dfrac{t^*t}{2c^4}\,k^3+O(k^4) & \text{for } v=0. \end{cases} \tag{24}$$

These functions can be inverted to a function of $\sqrt{\alpha}$, analytic in a neighborhood of the origin: For $v\neq 0$,

$$\begin{aligned} k&=c\alpha^{1/2}+\left(\frac{t^*t}{2vc^2}-\frac{1}{24}\right)c^3\alpha^{3/2}-i\,\frac{t^*tc^2}{v^2}\,\alpha^2+O(\alpha^{5/2}),\\ E&=c^2\alpha+\frac{t^*tc^2}{v}\,\alpha^2-i\,\frac{2t^*tc^3}{v^2}\,\alpha^{5/2}+O(\alpha^3). \end{aligned} \tag{25}$$

For $v=0$,

$$\begin{aligned} k&=c\alpha^{1/2}-i\left(\frac{t^*t}{4}\right)\alpha+O(\alpha^{3/2}),\\ E&=c^2\alpha-i\,\frac{t^*tc}{2}\,\alpha^{3/2}+O(\alpha^2). \end{aligned} \tag{26}$$

The leading contributions both to the real part and to the imaginary part of the energy in (25) and (26) are identical to those in the formulas (18) and (19).

V. A SIMPLE CONTINUUM MODEL

The studies of the lattice model encourage us to use two simple building blocks: To keep only a single bound state, representing the closed channel, and to consider a rank one operator as the perturbation V, coupling the bound state to the open channel. In the open channel we consider the particle to be free. Everything is reflection or rotation invariant in one or three dimensions.

The Hilbert space is now

$$\mathscr{H}=\mathbf{C}\oplus\mathscr{L}^2(\mathbf{R}_+)=\left\{\begin{pmatrix} p\\ |\psi\rangle\end{pmatrix}, p\in\mathbf{C}, |\psi\rangle=\psi(x)\in\mathscr{L}^2(\mathbf{R}_+)\right\}.$$

As Hamiltonian we consider

$$H_\alpha=H_0+\alpha V,\quad H_0=\begin{pmatrix}0&0\\0&K_\nu\end{pmatrix},\quad V=\begin{pmatrix}c^2 & c\langle v|\\ c|v\rangle & |v\rangle\langle v|\end{pmatrix}, \tag{27}$$

with $c>0$, $v(x)=O(e^{-\kappa x})$ for some $\kappa>0$, as $x\to\infty$. The kinetic energy, plus the angular momentum barrier, is either

$$K_\nu=-\frac{d^2}{dx^2}+\frac{\ell(\ell+1)}{x^2},\quad \ell=\nu-\frac{1}{2}\in\mathbf{N} \tag{28}$$

with Dirichlet-boundary conditions (b.c.) at $x=0$, or $K_\nu=-d^2/dx^2$ with Neumann (b.c.) at $x=0$ and $\nu=-\frac{1}{2}$. The models in one dimension are either of parity -1 or $+1$, concerning the reflection at $x=0$ in $\mathscr{L}^2(\mathbf{R})$. They can thus be reduced to models on the half line $\mathbf{R}_+$, with $\nu=\pm\frac{1}{2}$, the sign of ν corresponding to the sign of the parity.

The index ν is chosen in such a way that it coincides with the standard indication of the Bessel functions, which, multiplied by $\sqrt{\pi kx/2}$, give the eigenfunctions of K_ν.

The **formal** ansatz for the resonance wavefunction at positive α is

$$\Psi_\alpha = \begin{pmatrix} 1 \\ \psi_\alpha(x) \end{pmatrix}, \tag{29}$$

supposed to be a solution of the differential equation

$$(H_\alpha - E(\alpha))\Psi_\alpha = 0, \tag{30}$$

with the asymptotic behavior

$$\psi_\alpha(x) \sim e^{ikx} \quad \text{at } x \to \infty, \text{ with } \mathrm{Im}(k) < 0, \quad \mathrm{Re}(k) > 0. \tag{31}$$

A discussion of this asymptotic behavior would involve mathematical subtleties, especially if $v(x)$ is not of compact support. So we will instead analyze these formulas first for negative coupling constants α. There we get unnormalized bound states Ψ_α with negative energies $E(\alpha)$, the asymptotic behavior as in (31), but with $k = k(\alpha) = i\sqrt{-E(\alpha)}$. Then we may consider the analytic continuation of $E(\alpha)$ and $\psi_\alpha(x)$ to positive α. This is again achieved by inverting the function $\alpha(k)$.

Inserting (27) and (29) into (30) gives the pair of equations

$$\begin{aligned} \alpha c^2 + \alpha c \langle v | \psi_\alpha \rangle - E = 0, \\ (K_\nu - E)|\psi_\alpha\rangle + \alpha(c + \langle v|\psi_\alpha\rangle)|v\rangle = 0. \end{aligned} \tag{32}$$

The second equation is transformed to

$$|\psi_\alpha\rangle = -\alpha(c + \langle v|\psi_\alpha\rangle)(K_\nu - E)^{-1}|v\rangle = -\frac{E}{c}(K_\nu - E)^{-1}|v\rangle. \tag{33}$$

Multiplying (33) by $\langle v|$, and eliminating $\langle v|\psi_\alpha\rangle$ from the pair of equations, we get

$$\alpha = \frac{E}{c^2 - E\langle v|(K_\nu - E)^{-1}|v\rangle}. \tag{34}$$

For negative real energies E, (34) gives negative real α. In the uniformizing variable k, this function $\alpha(k)$ can be analytically continued into the region $\mathrm{Im}(k) > -\kappa$ (Appendix A). In Appendix B we prove that the energies $E = k^2$ in the unphysical sheet, giving positive real $\alpha(k)$, are actually poles of the resolvent of H_α. In Appendix A it is shown that

$$\langle v|(K_\nu - k^2)^{-1}|v\rangle = F(k) - ik^{2\nu}G(k), \tag{35}$$

with $F(k)$ and $G(k)$ analytic functions of k, real and even for $k \in \mathbf{R}$. $G(0)$ is the absolute square of a scaled transition matrix element from $|v\rangle$ into the continuum of K_ν at energy zero: $|t|^2 = G(0)$. The analytic function $\alpha(k)$ can be split into a real and an imaginary part, for $k \in \mathbf{R}$, and expanded in powers of k:

$$\alpha(k) = \frac{k^2}{c^2 - k^2F(k) - ik^{2\nu+2}G(k)} = \frac{k^2}{c^2} + O(k^4) + i\left[\frac{|t|^2}{c^4}k^{2\nu+4} + O(k^{2\nu+6})\right]. \tag{36}$$

To invert it, we have to form the square root:

$$\alpha^{1/2}(k)=\frac{k}{c}+O(k^3)+i\left[\frac{|t|^2}{2c^3}\,k^{2\nu+3}+O(k^{2\nu+5})\right]. \tag{37}$$

In both equations the remaining contributions, which we indicate by the order of their leading terms, have real-valued expansion coefficients. The inversion of this function near $k=0$ gives the searched for expansions of k and of E in the square root of the coupling constant:

$$k(\alpha^{1/2})=c\,\alpha^{1/2}+O(\alpha^{3/2})-i\left[\frac{c^{2\nu+1}}{2}\,|t|^2\alpha^{\nu+3/2}+O(\alpha^{\nu+5/2})\right], \tag{38}$$

$$E(\alpha^{1/2})=c^2\alpha+O(\alpha^2)-i[c^{2\nu+2}|t|^2\alpha^{\nu+2}+O(\alpha^{\nu+3})]. \tag{39}$$

VI. DISCUSSION

The leading term in the expansion of the real part of the resonance energy is precisely as in ordinary first-order perturbation theory. The leading term in the expansion of the negative imaginary part increases as $\alpha^{3/2}$ for $\nu=-\frac{1}{2}$, where standard FGR would give infinity times α^2. In the other cases, for $\nu\geqslant\frac{1}{2}$, the increase is slower than α^2. Now it turns out that the leading term in the expansion can be calculated with a **modified FGR**:

As a *first step* one has to take into account the shift in energy of the bound state to $E_\alpha=c^2\alpha$.

Then as a *second step* one has to proceed with standard FGR, applied to the bound state with the shifted energy.

In the present case this procedure gives the transition matrix element to the wavefunction $b_\nu(kx)$ in the open channel (see Appendix A)

$$t_k:=\sqrt{\frac{2}{\pi}}\,c\int_0^\infty v^*(x)b_\nu(kx)dx\overset{k\to0}{\sim}ck^{\nu+1/2}\sqrt{\frac{2}{\pi}}\,t. \tag{40}$$

The spectral density is $1/2k$. Evaluating all the contributions at $k=\sqrt{E_\alpha}$, one gets

$$\frac{\Gamma}{2}=|\mathrm{Im}\;E(\alpha)|=\frac{\pi}{2k}\,|t_k|^2\alpha^2=c^{2\nu+2}|t|^2\alpha^{\nu+2}, \tag{41}$$

precisely the leading term in (39).

Concerning the relevance of the model for physics, one has to observe that the wavefunctions in the continuum of an open channel with a short range potential behave as in the open channel without a potential and with Dirichlet b.c., *unless there is a zero energy bound state or inner-channel resonance*. In an open channel with $l=0$ and a zero-energy resonance, the wavefunctions behave as in the open channel with Neumann b.c. and the transition matrix element into the continuum stays finite at $E=0$.

The exponential falloff of the perturbing potential in the model corresponds to the exponential decrease of the bound state wavefunction to be incorporated in the model: Consider the case of two particles with the bound state Φ in the closed channel,

$$\Phi(\mathbf{x},\mathbf{y})=\varphi_1(\mathbf{x})\varphi_2(\mathbf{y})$$

perturbed by an interaction $\alpha W(\mathbf{x}-\mathbf{y})$. It enables transitions into an open channel, where the second particle with y-coordinate is still bounded with the wavefunction $\varphi_3(\mathbf{y})$, but the first particle is free. In this open channel the general wavefunction is

$$\Psi(x,y)=\psi(\mathbf{x})\varphi_3(\mathbf{y}),$$

the transition matrix element is

$$\langle \Psi | \alpha W | \Phi \rangle = \langle \psi | \alpha v \rangle$$

with

$$v(\mathbf{x}) = \varphi_1(\mathbf{x}) \int d^3y\, W(\mathbf{x}-\mathbf{y}) \varphi_3^*(\mathbf{y}) \varphi_2(\mathbf{y}).$$

The decay of $v(\mathbf{x})$ is thus determined by the decay of the bound state wavefunction $\varphi_1(\mathbf{x})$.

There remains the problem of the behavior of continuum wavefunction in the open channel in the presence of a long range potential.

APPENDIX A: ANALYTIC CONTINUATION

The solutions to the differential equation

$$((K_\nu - k^2) f\ )(x) = 0$$

are given by the transformed Bessel and Hankel functions b_ν and e_ν:

$$\begin{aligned} b_\nu(kx) &:= (\pi kx/2)^{1/2} J_\nu(kx), \\ e_\nu(kx) &:= (\pi kx/2)^{1/2} H_\nu^{(1)}(kx). \end{aligned} \tag{A1}$$

The asymptotic behavior is[11]

$$b_\nu(kx) \overset{kx\to 0}{\sim} \frac{\sqrt{\pi}}{\Gamma(\nu+1)} \left(\frac{kx}{2}\right)^{\nu+1/2}, \tag{A2}$$

$$e_\nu(kx) \overset{kx\to\infty}{\sim} e^{i(kx - \pi(\nu+1/2)/2)}. \tag{A3}$$

The Wronskian

$$b_\nu \frac{d}{dx} e_\nu - e_\nu \frac{d}{dx} b_\nu = ik. \tag{A4}$$

The Green's function $G_{\nu,k}(x,y)$, the kernel of the resolvent $(K_\nu - k^2)^{-1}$ for $\mathrm{Im}\, k > 0$, is thus

$$G_{\nu,k}(x,y) = \frac{i}{k} [\Theta(y-x) b_\nu(kx) e_\nu(ky) + \Theta(x-y) b_\nu(ky) e_\nu(kx)]. \tag{A5}$$

For half-integer-valued ν, it is an entire function of k.

Since in the limit $x\to\infty$ $v(x) = O(e^{-\kappa x})$, the integration

$$\int_0^\infty dx \int_0^\infty dy\, v^*(x) G_{\nu,k}(x,y) v(y)$$

converges for $\mathrm{Im}\, k > -\kappa$. So does the integration with $G_{\nu,k}$ replaced by the kernel $(d/dk)(kG_{\nu,k})$, and the existence of a continuation of the analytic function

$$kQ(x) := k\langle v | (K_\nu - k^2)^{-1} | v \rangle$$

is established for Im $k>-\kappa$. In order to distinguish between real and imaginary coefficients of the expansions, we use the transformed Neumann functions

$$n_\nu(kx):=(\pi kx/2)^{1/2}N_\nu(kx)$$

and split

$$e_\nu=b_\nu+in_\nu. \tag{A6}$$

The Green's function is now written as

$$G_{\nu,k}(x)=\frac{i}{k}\,b_\nu(ky)b_\nu(kx)+\frac{1}{k}\,[\Theta(y-x)n_\nu(ky)b_\nu(kx)+\Theta(x-y)b_\nu(ky)n_\nu(kx)]. \tag{A7}$$

The Bessel and Neumann functions take real values at positive real arguments. So, *for positive real* k, we may split $Q(k)$ into real and imaginary parts:

$$Q(k)=F(k)+ik^{2\nu}G(k), \tag{A8}$$

$$F(k)=-\frac{1}{k}\int_0^\infty dx\int_0^\infty dy\,\Theta(y-x)n_\nu(ky)b_\nu(kx)[v^*(y)v(x)+v(y)v^*(x)]. \tag{A9}$$

The product $n_\nu(ky)b_\nu(kx)$ lifts the singularity of $1/k$. For half-integer-valued ν, $F(k)$ has an analytic expansion in powers of k^2:

$$G(k)=k^{-(2\nu+1)}\left|\int_0^\infty dx v^*(x)b_\nu(kx)\right|^2 \overset{k\to0}{\to}|t|^2, \tag{A10}$$

with the ''scaled transition matrix element''

$$t:=\lim_{k\to0}k^{-(\nu+1/2)}\int_0^\infty dx v^*(x)b_\nu(kx)=\frac{\sqrt{\pi}}{2^{\nu+1/2}\Gamma(\nu+1)}\int_0^\infty dx v^*(x)x^{\nu+1/2}. \tag{A11}$$

At $k\sim0$, $G(k)$ has an analytic expansion in powers of k^2.

APPENDIX B: POLES OF THE RESOLVENT

We split the Hamiltonian H_α as

$$H_\alpha=L+W,\quad L:=\begin{pmatrix}\alpha c^2 & 0\\ 0 & K+\alpha|v\rangle\langle v|\end{pmatrix},\quad W:=\begin{pmatrix}0 & \alpha c\langle v|\\ \alpha c|v\rangle & 0\end{pmatrix} \tag{B1}$$

(we simply write K instead of K_ν) and use the iterated resolvent equation in the Hilbert space $\mathbf{C}\oplus\mathscr{L}^2(\mathbf{R})$,

$$(H_\alpha-E)^{-1}=(L-E+W)^{-1}=\frac{1}{L-E}-\frac{1}{L-E}\,W\,\frac{1}{L-E+W}=\frac{1}{L-E}-\frac{1}{L-E}\,W\,\frac{1}{L-E}$$
$$+\frac{1}{L-E}\,W\,\frac{1}{L-E}\,W\,\frac{1}{L-E+W} \tag{B2}$$

to calculate the matrix element with $(\,{}^1_{|0\rangle})$:

$$r:=(1,\langle 0|)\,\frac{1}{L+W-E}\begin{pmatrix}1\\|0\rangle\end{pmatrix}. \tag{B3}$$

We get

$$r=\frac{1}{\alpha c^2-E}+\frac{\alpha^2 c^2}{\alpha c^2-E}\,\langle v|\frac{1}{K+\alpha|v\rangle\langle v|-E}\,|v\rangle r. \tag{B4}$$

Again we use the resolvent equation, now in the smaller Hilbert space $\mathscr{L}^2(\mathbf{R}_+)$:

$$\frac{1}{K-E+\alpha|v\rangle\langle v|}=\frac{1}{K-E}-\frac{\alpha}{K-E}\,|v\rangle\langle v|\,\frac{1}{K-E+\alpha|v\rangle\langle v|}. \tag{B5}$$

Taking the expectation value of (B5) with $|v\rangle$, we get an equation, to be transformed to

$$\langle v|\,\frac{1}{K-E+\alpha|v\rangle\langle v|}\,|v\rangle=\frac{\langle v|\,\frac{1}{K-E}\,|v\rangle}{1+\alpha\langle v|\,\frac{1}{K-E}\,|v\rangle}. \tag{B6}$$

Inserting (B6) in (B4) and solving for r results in

$$r=\frac{1+\alpha\langle v|(K-E)|v\rangle}{\alpha c^2-E-\alpha E\langle v|(K-E)^{-1}|v\rangle}. \tag{B7}$$

Due to the asymptotic bound at large x

$$v(x)=O(e^{-\kappa x}), \tag{B8}$$

the matrix element $\langle v|(K-k^2)^{-1}|v\rangle$ can be continued to an analytic function of k, for $\mathrm{Im}\,k>-\kappa$. The poles of the matrix element $r=r(k)$ in this region are the zeroes of the denominator of (B7). Finding these zeroes amounts to solving Eq. (34).

Other matrix elements of the resolvent involve the same denominator.

Transmission of conduction electrons through a symmetric pair of delta-barriers or delta-wells embedded in a semiconductor or a metal

V. Bezák
Department of Solid State Physics, Faculty of Mathematics and Physics, Comenius University, 84215 Bratislava, Slovakia

(Received 26 June 1996; accepted for publication 12 August 1996)

The transmission coefficient $T(k_0)$ is calculated for conduction electrons incident with a wave vector k_0 upon a double barrier (double well) formed of two equal delta-barriers (of two equal delta-wells) embedded in a one-dimensional (1-D) semiconductor or in a 1-D metal. The stationary Schrödinger–Wannier equation $E(-i\partial/\partial x)\psi+V(x)\psi=\mathscr{E}\psi$ is solved for $V(x)=\gamma[\delta(x+a/2)+\delta(x-a/2)]$ (with real and time-independent parameters γ, a) and $\mathscr{E}=E(k_0)>0$. (The interband transitions are neglected.) The operator $E(-i\partial/\partial x)$ corresponds to a given (possibly nonquadratic) dispersion function $E(k)$ of the conduction electrons $[E(0)=0]$. It is shown that $T(k_0)$ is an oscillating function reaching the maximum value $[T(k_0)\to 1]$ on an infinite set $\{K^{(j)}\}$ of values of k_0. The shape of $T(k_0)$ depends on the shape of the dispersion function $E(k)$ in a simple way: $T(k_0)=T_{\rm par}(mv(k_0)/\hbar))$ where $T_{\rm par}(k_0)$ means the transmission coefficient in the special case when the dispersion function is quadratic, $E_{\rm par}(k)=\hbar^2k^2/2m$, and $v(k)=(1/\hbar)\partial E(k)/\partial k$ is the group velocity due to $E(k)$. [Here $E(k)$ is taken as an increasing function.]

I. INTRODUCTION

A. Physical motivation

The use of delta-function pseudopotentials is an old and frequent approach in the solid state physics. For instance, in general discussions of the behavior of conduction electrons in metallic polycrystals, interfaces between crystalline grains were often interpreted as very thin potential energy barriers (cf. e.g., Refs. 1 and 2) and afterwards, from mathematical grounds, simplified as delta-barriers.[3] Similarly, a narrow quantum well (e.g., a sandwich structure with a very thin inner layer) can be approximated as a delta-well. In the literature, we could find examples that even the potential energy of point defects was sometimes modelled as a delta-potential, or (more correctly) as $\sim-(2\pi\sigma^2)^{-3/2}\exp[-(\mathbf{r}-\mathbf{r}_i)^2/2\sigma^2]$, where σ is a small real parameter. Such a point-defect potential may correspond to a deep level in a 3-D semiconductor and we can put it into conformity with the spirit of the well-known Koster–Slater theory.[4,5] (For brief information about this theory cf. e.g., Ref. 6.) If these point defects are densely packed along a plane (and at present there are modern techniques of the so-called delta-doping enabling to implant atomically thin layers of dopants in a crystalline structure), we may approximately replace the sum $\sim-\Sigma_i(2\pi\sigma^2)^{-1/2}\exp[-(\mathbf{r}-\mathbf{r}_i)^2/2\sigma^2]$ by an averaged function approximated as $\gamma\delta(x)$ (with $\gamma<0$).

Generally, if we can verify that a quantum mechanical method is adequate for solving a problem in which the potential energy is taken as a delta-function, we may believe that the same method is also applicable for solving more realistic (and potentially more difficult) problems.

Thus, there is good motivation to study Bloch electrons near a delta-barrier or a delta-well embedded in a crystalline lattice.

In this paper, we will consider the delta-barrier or the delta-well as an abstraction in a context of the mesoscopic quantum physics. Therefore, we will not focus attention on the Bloch wavefunctions themselves. Instead, we will pay heed to envelope wavefunctions. The only fact which

we will explicitly take into account from the Bloch theory is the existence of dispersion functions $E_n(\mathbf{k})$ defining the electron energy bands. For the sake of simplicity, we will consider one energy band only, the conduction band; therefore, we omit the band index n and write the dispersion function as $E(\mathbf{k})$. We assume that $E(\mathbf{k})$ is an analytical function of the variable $\mathbf{k}$.

Obviously, the equation $E(-i\boldsymbol{\nabla})\psi_0(\mathbf{r})=\mathscr{E}\psi_0(\mathbf{r})$ is satisfied by the plane waves $\psi_0(\mathbf{r})\sim\exp(i\mathbf{k}\cdot\mathbf{r})$ if $\mathscr{E}=E(\mathbf{k})$. In spite of this fact, it is not trivial to solve the delta-barrier or delta-well problem if $E(\mathbf{k})$ is a general function. That is why papers which dealt with delta-potentials $\gamma\delta(x)$ in crystals specified, as a rule, the dispersion law, i.e., the dependence $E=E(\mathbf{k})$, in the parabolic form,

$$E_{\mathrm{par}}(\mathbf{k})=\hbar^2k^2/2m.$$

However, there are only a few cases where the parabolic dispersion law of the conduction electrons is actually a good approximation. First of all, we can mention two such cases:

(1) the $A^{\mathrm{III}}B^{\mathrm{V}}$ semiconductors (if energies of the conduction electrons are close to the lower boundary of the conduction band) and
(2) the alkaline metals (then the electron energies may be as high as the Fermi energy).

In the majority of other cases, we have to assume that the dispersion function $E(\mathbf{k})$ of the conduction electrons is not quadratic.

In our recent papers[7,8] where we have already gone beyond the quadratic approximation of the function $E(\mathbf{k})$, we have derived, having employed the one-band Schrödinger–Wannier equation[9] (the same equation which has been used in the Koster–Slater theory[4,5] for the envelope wave-functions of the conduction electrons), general formulas for the reflection (transmission) coefficient from (through) a *single* delta-barrier or a *single* delta-well. The one-band Schrödinger–Wannier equation differs from the usual Schrödinger equation solely in the kinetic energy term: in the **r**-representation, we have to use the operator $E(-i\boldsymbol{\nabla})$ instead of the usual kinetic energy operator $-\hbar^2\nabla^2/2m$. In general, the McLaurin development of the function $E(\mathbf{k})$ may involve an infinite number of terms; in other words, $E(-i\boldsymbol{\nabla})$ may mean a functional differential operator. Therefore, if the potential energy is of the form $\gamma\delta(x)$, it is uneasy to formulate correct boundary conditions at $x=0$. Fortunately, these conditions can be avoided (as we have shown right in Refs. 7 and 8) if one uses the **k**-representation.

The purpose of the present paper is to show that our former analysis[7,8] can readily be extended. Now we will consider *two* equal delta-barriers ($\gamma>0$) or *two* equal delta-wells ($\gamma<0$) instead of one. To avoid formal complications, we will solve the problem in the one-dimensional version.

Before formulating our problem mathematically, let us mention some relevant configurations on which it may have a special bearing. First, there are planar faults of the crystalline periodicity consisting of two closely positioned parallel defect planes. Such faults were really observed. Here we can discuss, e.g., pairs of stacking faults or pairs of twin planes. For example, recently Rosová *et al.*[10–12] presented thorough electron microscopic observations of pairs of twin planes (the so-called twin lamellae in the electron micrographs) in YBaCuO—in the material most reputed as one of the high-temperature superconductors. We believe that the idea of modelling an effective potential energy of conduction electrons by pairs of delta-functions in such a case can be supported by arguments of the theory of pseudopotentials[13] well known to solid state theorists.

Second, in view of interesting applications in the semiconductor electronics, there is one specifically good reason why a detailed analysis of the situation with the potential energy defined as a sum of two delta-functions may be worth doing: if a conduction electron is to travel across a double barrier or a double well, its transmission coefficient $T(k_0)$ has to manifest the phenomenon of the ideal transparency at ''resonances.'' Indeed, microelectronic structures in which the potential energy of electrons is modelled as a symmetric double barrier are nowadays a matter to which

great attention is being paid in connection with the *resonant tunnelling transistors*.[14–17] Until now, any theoretical analysis of the resonant tunnelling through pairs of equal barriers was always confined to the case when the dispersion dependence $E=E(k)$ was taken parabolic. Moreover, if the shape of these barriers was not taken as rectangular, the tunnelling probability through them was almost always calculated approximately, mainly within the framework of the WKB approximation. Notwithstanding, if these barriers are taken as delta-barriers, the calculations can be done without resorting to such an approximation. That is why we may consider even solutions concerning the simplified situation where the symmetric double barrier is composed of delta-functions as truly archetypal for the theory of the resonant tunnelling transistors.

Admittedly, we must say that if $E(k)\equiv E_{\mathrm{par}}(k)$, the problem of deriving the transmission probability [then we write it as $T_{\mathrm{par}}(k_0)$] with the potential energy in the form of two equal delta-functions is not new: for instance, Galindo and Pascual devote much attention to this problem in their monograph.[18] Nevertheless, without repeating their way of derivations, we intend to generalize their results. Our intent is to show a general way of deriving the oscillating transmission coefficient $T(k_0)$ under the assumption that $E=E(k)$ may be a nonparabolic dependence.

B. Mathematical preliminaries

In accordance to what has just been said, the majority of calculations in the present paper concern the Hamiltonian

$$H(x)=E\left(-\mathrm{i}\,\frac{\partial}{\partial x}\right)+\gamma\left[\delta\left(x+\frac{a}{2}\right)+\delta\left(x-\frac{a}{2}\right)\right]. \tag{1}$$

(Only at the end of this paper, the Hamiltonian will be written in a more general form.)

We assume that the function $E(k)$ (a real function if k is real) is known in advance. We take $E(0)=0$ and

$$E(-k)\equiv E(k). \tag{2}$$

For the sake of simplicity, we take $E(k)$ as a growing function if $k>0$.

Condition (2) implies that

$$E(k)=\sum_{n=1}^{\infty} a_n k^{2n}. \tag{3}$$

As in Ref. 7, we do not confine the definition region of $E(k)$ to the (first) Brillouin zone and stipulate formally that

$$E(k)/|k|\to\infty \tag{4}$$

if $|k|\to\infty$. Of course, we assume that the function $E(k)$ is realistic enough if values of $|k|$ are not too high, namely if the energies $E(k)$ lie still well below the upper boundary of the band under consideration. Therefore, condition (4) corresponds to nothing more than to a mathematical extrapolation.

In particular, if $E(k)$ defines the conduction band in a narrow-gap semiconductor, we may exemplify our derivations by taking $E(k)$ in the form of the well-known Kane function[19–23]

$$E_{\mathrm{Kane}}(k)=\frac{E_g}{2}\left[\left(1+\frac{2\hbar^2k^2}{mE_g}\right)^{1/2}-1\right], \tag{5}$$

where E_g is the width of the forbidden gap. [In the case of metals for which our calculations are also applicable, $E(k)$ should be exemplified by another function.]

Before ending this Section, let us make two remarks.

First, even if the Kane function does not respect condition (4), we can easily make a mathematical amendment: to secure the fulfillment of condition (4), it is sufficient to multiply $E_{\mathrm{Kane}}(k)$ by a convenient formal factor $\Phi(u)$, fulfilling the conditions $\Phi(0)=1$, $\Phi(u)\to\infty$, with $u=\varepsilon k^2$, where $\varepsilon>0$ is a very small constant. Essentially, as we have shown in Refs. 7 and 8, condition (4) is only to guarantee that there is a finite lower bound for all eigenenergies of $H(x)$ even in the case when $\gamma<0$ and that the transmission coefficient $T(k_0)$ does not tend (on the average) to a value different from unity if $|k_0|\to\infty$.

Second, $E(k)$ need not be an entire function (i.e., a function analytical on the whole complex k-plane $\mathscr{D}_\infty$) and the function $E_{\mathrm{Kane}}(k)$ is really not. We stipulate, however, the existence of a domain $\mathscr{D}$ involving both the real k-semiaxes (the point zero may be excluded) and the infinite point and assume that the function $E(k)$ is analytical in $\mathscr{D}$. In the case of the Kane function, we define $\mathscr{D}=\mathscr{D}_\infty-\mathscr{I}$, where $\mathscr{I}$ is an interval on the imaginary k-axis with boundaries defined by the values $\mathrm{Im}\,k_d=-(1/\hbar)\sqrt{mE_g/2}-\varepsilon$ and $\mathrm{Im}\,k_u=+(1/\hbar)\sqrt{mE_g/2}+\varepsilon$. If k is complex in formula (5), we might formally discuss two separated analytical branches of the function $E_{\mathrm{Kane}}(k)$ in $\mathscr{D}$. From physical reasons, however, we do only accept the branch for which $E_{\mathrm{Kane}}(k)>0$ if $k\neq 0$ is real.

II. THE TRANSMISSION COEFFICIENT

A. Some relations formulated via the *x*-representation

In the x-representation, the stationary one-band Schrödinger–Wannier equation reads

$$\left\{E\left(-\mathrm{i}\frac{\partial}{\partial x}\right)+\gamma\left[\delta\left(x+\frac{a}{2}\right)+\delta\left(x-\frac{a}{2}\right)\right]\right\}\psi_{k_0}(x)=E(k_0)\psi_{k_0}(x). \tag{6}$$

Without loss of generality, we may confine ourselves to considering a conduction electron incident upon the pair of the delta-barriers or of the delta-wells from the left (i.e., we may take $k_0>0$). Then we take the (envelope) wavefunction in the form

$$\psi_{k_0}(x)=[1-\Theta(x+a/2)][\exp(\mathrm{i}k_0x)+B\ \exp(-\mathrm{i}k_0x)]+[\Theta(x+a/2)-\Theta(x-a/2)]$$
$$\times[F\ \cos(k_0x)+G\ \sin(k_0x)]+\Theta(x-a/2)C\ \exp(\mathrm{i}k_0x) \tag{7}$$

or

$$\psi_{k_0}(x)=\exp(\mathrm{i}k_0x)+B\ \exp(-\mathrm{i}k_0x)+\Theta(x+a/2)[F\ \cos(k_0x)+G\ \sin(k_0x)-\exp(\mathrm{i}k_0x)$$
$$-B\ \exp(-\mathrm{i}k_0x)]+\Theta(x-a/2)[C\ \exp(\mathrm{i}k_0x)-F\ \cos(k_0x)-G\ \sin(k_0x)]. \tag{8}$$

Here, $\Theta(x)$ is the Heaviside step function: $\Theta(x)=0$ if $x<0$ and $\Theta(x)=1$ if $x>0$. Since the function $\psi_{k_0}(x)$ is continuous at $x=\pm a/2$, we obtain the equations

$$\psi_{k_0}(-a/2)=\exp(-\mathrm{i}k_0a/2)+B\ \exp(\mathrm{i}k_0a/2)=F\ \cos(k_0a/2)-G\ \sin(k_0a/2), \tag{9}$$

$$\psi_{k_0}(a/2)=C\ \exp(\mathrm{i}k_0a/2)=F\ \cos(k_0a/2)+G\ \sin(k_0a/2). \tag{10}$$

From them, we obtain the expressions

$$F=\frac{\exp(-\mathrm{i}k_0a/2)+(C+B)\exp(\mathrm{i}k_0a/2)}{2\cos(k_0a/2)}, \tag{11}$$

$$G=\frac{-\exp(-\mathrm{i}k_0a/2)+(C-B)\exp(\mathrm{i}k_0a/2)}{2\sin(k_0a/2)}. \tag{12}$$

When inserting (11) and (12) into (8), we obtain $\psi_{k_0}(x)$ as a function of two complex coefficients: $B \equiv B(k_0)$ and $C \equiv C(k_0)$.

The transmission coefficient is

$$T = \frac{|C|^2}{|B|^2 + |C|^2}. \tag{13}$$

However, since

$$|B|^2 + |C|^2 = 1 \tag{14}$$

(we will verify this explicitly), then

$$T(k_0) = |C(k_0)|^2. \tag{15}$$

The complementary probability, i.e.,

$$R(k_0) = 1 - T(k_0) = |B(k_0)|^2, \tag{16}$$

is the reflection coefficient.

Thus, the basic problem is to calculate the coefficients B and C.

B. Form of the wavefunction in the *k*-representation

Let $M_K(k)$, $N_K(k)$, $P_K(k)$, etc., be the Fourier originals to $m_K(x)$, $n_K(x)$, $p_K(x)$:

$$m_K(x) = \int_{-\infty}^{\infty} \mathrm{d}k M_K(k) \exp(\mathrm{i}kx), \tag{17}$$

etc.

We assume that K is a real parameter. The Fourier original to the exponential

$$m_K(x) = \exp(\mathrm{i}Kx) \tag{18}$$

is the delta function

$$M_K(k) = \delta(k - K). \tag{19}$$

The Fourier original to the generalized analytical function

$$n_K(x) = \Theta(x) \exp(\mathrm{i}Kx) \tag{20}$$

is

$$N_K(k) = \frac{1}{2}\,\delta(k-K) - \frac{\mathrm{i}}{2\pi}\,\mathrm{v.p.}\,\frac{1}{k-K} = \frac{1}{2}\,\delta(k-K) - \frac{\mathrm{i}}{4\pi}\left(\frac{1}{k-K-\mathrm{i}\epsilon} + \frac{1}{k-K+\mathrm{i}\epsilon}\right). \tag{21}$$

(In the last relation, ϵ is a positive infinitesimal quantity. The symbol v.p. means the Cauchy principal value.[24])

In the wavefunction (8), we have also got the terms of the type

$$p_K(x) = \Theta(x-b) \exp(\mathrm{i}Kx), \tag{22}$$

$$q_{k_0}(x) = \Theta(x-b) \cos(k_0 x), \tag{23}$$

$$r_{k_0}(x)=\Theta(x-b)\sin(k_0x). \tag{24}$$

Respectively, they correspond to the Fourier originals

$$P_K(k)=\exp[-\mathrm{i}(k-K)b]N_K(k), \tag{26}$$

$$\begin{aligned}Q_{k_0}(k)&=\tfrac{1}{2}(\exp[-\mathrm{i}(k-k_0)b]N_{k_0}(k)+\exp[-\mathrm{i}(k+k_0)b]N_{-k_0}(k))\\&=\tfrac{1}{2}\exp(-\mathrm{i}k_0b)(\exp(\mathrm{i}k_0b)N_{k_0}(k)+\exp(-\mathrm{i}k_0b)N_{-k_0}(k)),\end{aligned} \tag{27}$$

$$\begin{aligned}R_{k_0}(k)&=\frac{1}{2\mathrm{i}}\,(\exp[-\mathrm{i}(k-k_0)b]N_{k_0}(k)-\exp[-\mathrm{i}(k+k_0)b]N_{-k_0}(k))\\&=\frac{1}{2\mathrm{i}}\exp(-\mathrm{i}k_0b)(\exp(\mathrm{i}k_0b)N_{k_0}(k)-\exp(-\mathrm{i}k_0b)N_{-k_0}(k)),\end{aligned} \tag{28}$$

where $N_K(k)$ is given by expression (21). (In our case, b is equal either to $-a/2$ or to $a/2$.)

We define the Fourier original $\phi_{k_0}(k)$ to $\psi_{k_0}(x)$ as well:

$$\psi_{k_0}(x)=\int_{-\infty}^{\infty}\mathrm{d}k\,\phi_{k_0}(k)\exp(\mathrm{i}kx). \tag{29}$$

When employing the wavefunction (8) on the lhs of (29) and utilizing correspondingly, term by term, the Fourier originals (19), (21), (26), (27), and (28), we obtain the decomposition

$$\phi_{k_0}(k)=\phi^{\delta}_{k_0}(k)+\phi^{\mathrm{vp}}_{k_0}(k) \tag{30}$$

where

$$\phi^{\delta}_{k_0}(k)=\tfrac{1}{2}[(1+C)\,\delta(k-k_0)+B\,\delta(k+k_0)] \tag{31}$$

is the ''delta function part.'' The ''valeur principale part'' $\phi^{\mathrm{vp}}_{k_0}(k)$ will be calculated in the next section.

C. Solution of the Schrödinger–Wannier equation in the *k*-representation

The function $\phi_{k_0}(k)$ has to obey the Schrödinger–Wannier equation

$$[E(k)-E(k_0)]\phi_{k_0}(k)=-\frac{\gamma}{2\pi}\int_{-\infty}^{\infty}\mathrm{d}k'\,\phi_{k_0}(k')\left\{\exp\left[-\mathrm{i}(k'-k)\,\frac{a}{2}\right]+\exp\left[\mathrm{i}(k'-k)\,\frac{a}{2}\right]\right\}. \tag{32}$$

Equation (32) results directly from Eq. (6) if the convolution theorem is applied. [Note that the Fourier original to $\delta(x-b)$ is $\exp(-\mathrm{i}kb)/2\pi$.] However, according to (29), we have

$$\psi_{k_0}\left(-\frac{a}{2}\right)=\int_{-\infty}^{\infty}\mathrm{d}k'\,\phi_{k_0}(k')\exp\left(-\mathrm{i}k'\,\frac{a}{2}\right), \tag{33a}$$

$$\psi_{k_0}\left(\frac{a}{2}\right)=\int_{-\infty}^{\infty}\mathrm{d}k'\,\phi_{k_0}(k')\exp\left(\mathrm{i}k'\,\frac{a}{2}\right), \tag{33b}$$

and thus we may write the Schrödinger–Wannier equation in the form

$$[E(k)-E(k_0)]\phi_{k_0}(k)=-\frac{\gamma}{2\pi}\left[\psi_{k_0}\left(-\frac{a}{2}\right)\exp\left(\mathrm{i}k\,\frac{a}{2}\right)+\psi_{k_0}\left(\frac{a}{2}\right)\exp\left(-\mathrm{i}k\,\frac{a}{2}\right)\right]. \tag{34}$$

Obviously,

$$[E(k)-E(k_0)]\phi^{\delta}_{k_0}(k)=0. \tag{35}$$

Therefore, instead of (34), we may write the equation

$$[E(k)-E(k_0)]\phi^{\mathrm{vp}}_{k_0}(k)=-\frac{\gamma}{2\pi}\left[\psi_{k_0}\left(-\frac{a}{2}\right)\exp\left(\mathrm{i}k\,\frac{a}{2}\right)+\psi_{k_0}(a)\exp\left(-\mathrm{i}k\,\frac{a}{2}\right)\right]. \tag{36}$$

According to the very definition of the function $\phi^{\mathrm{vp}}_{k_0}(k)$, if any product of this function with an analytical function is to be integrated with respect to the variable k, the integration has to be done in the Cauchy sense. So we have to exempt two infinitesimally short intervals centered in the points $\pm k_0$, i.e., $(-k_0-\epsilon,-k_0+\epsilon)$ and $(k_0-\epsilon,k_0+\epsilon)$, from the real k-axis. Then, as $E(k)\neq E(k_0)$ for all values of k outside these intervals, we may divide Eq. (36) by $E(k)-E(k_0)$. Thus we obtain the expression

$$\phi^{\mathrm{vp}}_{k_0}(k)=-\frac{\gamma}{2\pi}\,\mathrm{v.p.}\left[\psi_{k_0}\left(-\frac{a}{2}\right)\,\frac{\exp(\mathrm{i}ka/2)}{E(k)-E(k_0)}+\psi_{k_0}\left(\frac{a}{2}\right)\,\frac{\exp(-\mathrm{i}ka/2)}{E(k)-E(k_0)}\right]. \tag{37}$$

Its Fourier image is

$$\psi^{\mathrm{vp}}_{k_0}(x)=\int_{-\infty}^{\infty}\mathrm{d}k\,\phi^{\mathrm{vp}}_{k_0}(k)\exp(\mathrm{i}\,kx). \tag{38}$$

Formulas (37) and (38) imply that we have to cope with the calculation of the integral

$$\mathrm{v.p.}\int_{-\infty}^{\infty}\mathrm{d}k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k)-E(k_0)}=\frac{1}{2}\int_{-\infty}^{\infty}\mathrm{d}\,k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k-\mathrm{i}\,\epsilon)-E(k_0)}+\frac{1}{2}\int_{-\infty}^{\infty}\mathrm{d}\,k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k+\mathrm{i}\,\epsilon)-E(k_0)}. \tag{39}$$

In Sec. IB, we have defined (for k taken as a complex variable) the domain $\mathscr{D}$ and the interval $\mathscr{I}$. Now we add the definition of the subdomain $\mathscr{D}^{+}\subset\mathscr{D}$ and of the subinterval $\mathscr{I}^{+}\subset\mathscr{I}$ by the condition $\mathrm{Im}\,k>0$. (Analogically, we say that $k\in\mathscr{D}^{-}\subset\mathscr{D}$ or $k\in\mathscr{I}^{-}\subset\mathscr{I}$ if $\mathrm{Im}\,k<0$.) The function $1/[E(k-\mathrm{i}\epsilon)-E(k_0)]$ has two single poles, $k^{+}_{1,2}=\pm k_0+\mathrm{i}\epsilon$, lying in $\mathscr{D}^{+}$, while $1/[E(k+\mathrm{i}\epsilon)-E(k_0)]$ has two single poles, $k^{-}_{1,2}=\pm k_0-\mathrm{i}\epsilon$, lying in $\mathscr{D}^{-}$. If $x>b$, we define a closed contour Γ^{+} consisting of five parts as follows. The first part is the negative half of the real k-axis. The second and third parts of Γ^{+} are the left-hand and right-hand boundaries of $\mathscr{I}^{+}$. The fourth part is the positive half of the real k-axis. The final (fifth) part is an infinitely large semicircle (centered at $k=0$) lying in $\mathscr{D}^{+}$. Similarly, if $x<b$, we define the closed contour Γ^{-} as the mirror image (with respect to the real k-axis) of Γ^{+}. Then, using the theorem of residua, we obtain the results

$$\frac{1}{2}\int_{-\infty}^{\infty}\mathrm{d}k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k-\mathrm{i}\epsilon)-E(k_0)}$$
$$=\frac{1}{2}\oint_{\Gamma^+}\mathrm{d}k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k-\mathrm{i}\epsilon)-E(k_0)}$$
$$=\mathrm{i}\pi\Theta(x-b)(\mathrm{res}_{k=k_0+\mathrm{i}\epsilon}+\mathrm{res}_{k=-k_0+\mathrm{i}\epsilon})\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k-\mathrm{i}\epsilon)-E(k_0)}$$
$$=i\pi\Theta(x-b)\,\frac{\exp[\mathrm{i}k_0(x-b)]-\exp[-\mathrm{i}k_0(x-b)}{E'(k_0)},\tag{40+}$$

$$\frac{1}{2}\int_{-\infty}^{\infty}\mathrm{d}k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k+\mathrm{i}\epsilon)-E(k_0)}=-\frac{1}{2}\oint_{\Gamma^-}\mathrm{d}k\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k+\mathrm{i}\epsilon)-E(k_0)}$$
$$=-\mathrm{i}\pi[1-\Theta(x-b)](\mathrm{res}_{k=k_0-\mathrm{i}\epsilon}+\mathrm{res}_{k=-k_0-\mathrm{i}\epsilon})\,\frac{\exp[\mathrm{i}k(x-b)]}{E(k+\mathrm{i}\epsilon)-E(k_0)}$$
$$=-\mathrm{i}\pi[1-\Theta(x-b)]\,\frac{\exp[\mathrm{i}k_0(x-b)]-\exp[-\mathrm{i}k_0(x-b)]}{E'(k_0)}.\tag{40-}$$

Here we have introduced the symbol $\oint$ in the usual sense, i.e., we have reserved it for the anticlockwise integration. When integrating along Γ^+ (Γ^-), we observe that the contributions due to the left-hand and right-hand sides of $\mathscr{T}^+$ ($\mathscr{T}^-$) exactly cancel out.

For brevity, we have introduced the symbol

$$E'(k)=\frac{\mathrm{d}E(k)}{\mathrm{d}k}.\tag{41}$$

[Note that $E'(k)>0$ and $E'(-k)=-E'(k)$.]

In this way we have derived the formula

$$\mathrm{v.p.}\int_{-\infty}^{\infty}\mathrm{d}k\,\frac{\exp(\mathrm{i}kX)}{E(k)-E(k_0)}=-2\pi[2\Theta(X)-1]\,\frac{\sin(k_0X)}{E'(k_0)}.\tag{42}$$

With its aid, formulas (37) and (38) yield us the function

$$\psi_{k_0}^{\mathrm{vp}}(x)=-\frac{\gamma}{E'(k_0)}\left\{\psi_{k_0}\left(-\frac{a}{2}\right)\left[2\Theta\left(x+\frac{a}{2}\right)-1\right]\sin\left[k_0\left(x+\frac{a}{2}\right)\right]\right.$$
$$\left.+\psi_{k_0}\left(\frac{a}{2}\right)\left[2\Theta\left(x-\frac{a}{2}\right)-1\right]\sin\left[k_0\left(x-\frac{a}{2}\right)\right]\right\}.\tag{43}$$

Hence

$$\psi_{k_0}^{\mathrm{vp}}\left(-\frac{a}{2}-0\right)=\frac{\gamma}{E'(k_0)}\,\psi_{k_0}\left(\frac{a}{2}\right)\sin(k_0a)=\frac{\gamma}{E'(k_0)}\,C\,\exp\left(\mathrm{i}k_0\,\frac{a}{2}\right)\sin(k_0a),\tag{44}$$

$$\psi_{k_0}^{\mathrm{vp}}\left(\frac{a}{2}+0\right)=\frac{\gamma}{E'(k_0)}\,\psi_{k_0}\left(-\frac{a}{2}\right)\sin(k_0a)=\frac{\gamma}{E'(k_0)}\left[\exp\left(-\mathrm{i}k_0\,\frac{a}{2}\right)+B\,\exp\left(\mathrm{i}k_0\,\frac{a}{2}\right)\right]\sin(k_0a).\tag{45}$$

[Here we have employed formulas (9) and (10).]

However, the respective Fourier images to functions (30) and (31) are

$$\psi_{k_0}(x)=\psi^{\delta}_{k_0}(x)+\psi^{\mathrm{vp}}_{k_0}(x), \tag{46}$$

$$\psi^{\delta}_{k_0}(x)=\tfrac{1}{2}[(C+1)\exp(\mathrm{i}k_0x)+B\ \exp(-\mathrm{i}k_0x)]. \tag{47}$$

The function (46) is continous. When taking x equal to $-a/2-0$ and to $a/2+0$, and bearing in mind expressions (44) and (45), we obtain the following two linear algebraic equations for the coefficients B and C:

$$\exp\left(-\mathrm{i}k_0\frac{a}{2}\right)+B\ \exp\left(\mathrm{i}k_0\frac{a}{2}\right)=\frac{1}{2}\left[(C+1)\exp\left(-\mathrm{i}k_0\frac{a}{2}\right)+B\ \exp\left(\mathrm{i}k_0\frac{a}{2}\right)\right]$$
$$+\frac{\gamma}{E'(k_0)}\ C\ \exp\left(\mathrm{i}k_0\frac{a}{2}\right)\sin(k_0a), \tag{48}$$

$$C\ \exp\left(\mathrm{i}k_0\frac{a}{2}\right)=\frac{1}{2}\left[(C+1)\exp\left(\mathrm{i}k_0\frac{a}{2}\right)+B\ \exp\left(-\mathrm{i}k_0\frac{a}{2}\right)\right]$$
$$+\frac{\gamma}{E'(k_0)}\left[\exp\left(-\mathrm{i}k_0\frac{a}{2}\right)+B\ \exp\left(\mathrm{i}k_0\frac{a}{2}\right)\right] \tag{49}$$

[cf. again (9) and (10)].
Their solution is

$$B(k_0)=\exp(-\mathrm{i}k_0a)\ \frac{2\gamma[E'(k_0)\cos(k_0a)+\gamma\ \sin(k_0a)]}{D(k_0)}, \tag{50}$$

$$C(k_0)=\mathrm{i}\ \exp(-\mathrm{i}k_0a)\ \frac{[E'(k_0)]^2}{D(k_0)}, \tag{51}$$

where

$$D(k_0)=-2\gamma E'(k_0)\cos(k_0a)+[[E'(k_0)]^2-2\gamma^2]\sin(k_0a)$$
$$+\mathrm{i}E'(k_0)[E'(k_0)\cos(k_0a)+2\gamma\ \sin(k_0a)]. \tag{52}$$

D. General result for the transmission coefficient $T(k_0)$

The square of the absolute value of (52) is

$$|D(k_0)|^2=[E'(k_0)]^4+4\gamma^2[E'(k_0)\cos(k_0a)+\gamma\ \sin(k_0a)]^2. \tag{53}$$

When calculating $|C(k_0)|^2$, we obtain the formula

$$T(k_0)=\frac{[E'(k_0)]^4}{[E'(k_0)]^4+4\gamma^2[E'(k_0)\cos(k_0a)+\gamma\ \sin(k_0a)]^2} \tag{54}$$

giving the probability with which a conduction electron with the wavevector k_0 can travel across the system of two equal delta-barriers or delta-wells that are the distance a apart. The complementary probability, i.e., the reflection coefficient which is equal to $|B(k_0)|^2$, then is

$$R(k_0)=\frac{4\gamma^2[E'(k_0)\cos(k_0a)+\gamma\,\sin(k_0a)]^2}{[E'(k_0)]^4+4\gamma^2[E'(k_0)\cos(k_0a)+\gamma\,\sin(k_0a)]^2}. \tag{55}$$

The identity $T+R=1$ proves exactly the validity of identity (14).

III. DISCUSSION AND CONCLUDING REMARKS

A. The oscillations of the transmission coefficient $T(k_0)$

When introducing the group velocity

$$v(k)=\frac{1}{\hbar}\,E'(k), \tag{56}$$

we may rewrite formula (54) in the form

$$T(k_0)=\frac{[\hbar v(k_0)]^4}{[\hbar v(k_0)]^4+4\gamma^2[\hbar v(k_0)\cos(k_0a)+\gamma\,\sin(k_0a)]^2}. \tag{57}$$

According to this formula, there are values of k_0 at which $T(k_0)$ is equal to unity. This ideal transparency of the symmetric delta-function double barrier or double well takes place at all values of k_0 that are equal to the roots $K^{(j)}$ of the equation

$$\hbar v(K^{(j)})=-\gamma\,\tan(K^{(j)}a). \tag{58}$$

Notice that

$$v_{\rm par}(k)=\frac{\hbar k}{m}, \tag{59}$$

while

$$v_{\rm Kane}(k)=\frac{\hbar k}{m}\left[1+\frac{2\hbar^2k^2}{mE_g}\right]^{-1/2}. \tag{60}$$

Let us introduce the dimensionless parameters

$$\kappa=k_0a, \tag{61}$$

$$\beta=\frac{m\gamma a}{\hbar^2}. \tag{62}$$

Then we define the dimensionless function $\eta(\kappa)$,

$$E(k_0)=\frac{\hbar^2}{ma^2}\,\eta(\kappa). \tag{63}$$

In particular,

$$\eta_{\rm par}(\kappa)=\tfrac{1}{2}\kappa^2, \tag{64}$$

$$\eta_{\rm Kane}(\kappa)=\frac{\eta_g}{2}\left[\left(1+\frac{2\kappa^2}{\eta_g}\right)^{1/2}-1\right]. \tag{65}$$

In the latter formula, we have used η_g instead of E_g:

$$E_g=\frac{\hbar^2}{ma^2}\,\eta_g\,. \tag{66}$$

Clearly, $\hbar^2/ma^2$ and a are, respectively, the units for energies and distances. After defining the dimensionless group velocity

$$v(\kappa)=\frac{\mathrm{d}\eta(\kappa)}{\mathrm{d}\kappa}, \tag{67}$$

we obtain the functions

$$v_{\mathrm{par}}(\kappa)=\kappa, \tag{68}$$

$$v_{\mathrm{Kane}}(\kappa)=\frac{\kappa}{(1+2\kappa^2/\eta_g)^{1/2}}. \tag{69}$$

Thus, according to formula (57), we obtain the function

$$\mathscr{T}(\kappa)=\frac{[v(\kappa)]^4}{[v(\kappa)]^4+4\beta^2[v(\kappa)\cos(\kappa)+\beta\,\sin(\kappa)]^2} \tag{70}$$

so that

$$\mathscr{T}_{\mathrm{par}}(\kappa)=\frac{\kappa^4}{\kappa^4+4\beta^2[\kappa\,\cos(\kappa)+\beta\,\sin(\kappa)]^2} \tag{71}$$

[cf. formula (A12) in the Appendix] and

$$\mathscr{T}_{\mathrm{Kane}}(\kappa)=\frac{\kappa^4}{\kappa^4+4\beta^2(1+2\kappa^2/\eta_g)[\kappa\,\cos(\kappa)+\beta(1+2\kappa^2/\eta_g)^{1/2}\,\sin(\kappa)]^2}. \tag{72}$$

In Fig. 1, we compare $\mathscr{T}_{\mathrm{par}}(\kappa)$ (the upper frame) with $\mathscr{T}_{\mathrm{Kane}}(\kappa)$ (the lower frame). Both the frames are equally scaled. The vertical dashed lines correspond to $\kappa=j\pi$, while the dotted lines correspond to $\kappa=(j-1/2)\pi$, $j=1,2,\ldots$. The full curved lines correspond to the double delta-function barrier with $\beta=5$ and the dashed curved lines correspond to the double delta-function well with $\beta=-5$. The curves showing $\mathscr{T}_{\mathrm{Kane}}(\kappa)$ concern the value $\eta_g=120$.

As it is seen from formula (70), the values $\mathscr{T}(j\pi/2)$ (with an arbitrary integer j) are always for β and for $-\beta$ equal to one another. (In both the frames of Fig. 1, the full curved line and the dashed curved line intersect one another just at $\kappa=j\pi/2$.)

In the dimensionless variables that we are now using formula (58) reads

$$v(\kappa^{(j)})=-\beta\,\tan(\kappa^{(j)}), \tag{73}$$

so that

$$v_{\mathrm{par}}(\kappa^{(j)})=\kappa^{(j)}, \tag{74}$$

$$v_{\mathrm{Kane}}(\kappa^{(j)})=\kappa^{(j)}[1+2\kappa^{(j)^2}/\eta_g]^{-1/2}. \tag{75}$$

If $\beta>0$ and $j\to\infty$, the position $\kappa_{\mathrm{par}}^{(j)}$ of the jth maximum of the function $\mathscr{T}_{\mathrm{par}}(\kappa)$ $(=1)$ tends to the value $(j-1/2)\pi$ from the right. In the double-well case, however, for $j\to\infty$, we find that

$\kappa_{\rm par}^{(j)} \to (j + 1/2)\pi$ from the left for $-1<\beta<0$ if $-1<\beta<0$ and $\kappa_{\rm par}^{(j)} \to (j - 1/2)\pi$ from the left if $\beta<-1$. On the other hand, the asymptotic behavior of the position $\kappa_{\rm Kane}^{(j)}$ of the jth maximum of the function $\mathscr{T}_{\rm Kane}(\kappa)$ $(=1)$ is different. Formula (75) implies that $\upsilon_{\rm Kane}(\kappa) \to \kappa(\eta_g/2)^{1/2}$ if $\kappa \to \infty$. Therefore, if $\beta>0$ and $j \to \infty$, the position $\kappa_{\rm Kane}^{(j)}$ of the jth maximum of the function $\mathscr{T}_{\rm par}(\kappa)$ $(=1)$ tends to the value $j\pi - \arctan[(\eta_g/2)^{1/2}/\beta)]$ from the right. In the double-well case, we find for $j \to \infty$ that $\kappa_{\rm Kane}^{(j)} \to j\pi + \arctan[(\eta_g/2)^{1/2}/|\beta|]$ from the left if $-1<\beta<0$ and $\kappa_{\rm Kane}^{(j)} \to j\pi - \arctan[(\eta_g/2)^{1/2}/|\beta|]$ from the left if $\beta<-1$.

B. The transmission coefficient as a function of energy

If we depict the transmission coefficient T as a function of the energy $E(k_0)$, and not as function of k_0 (in contrast to the Sec. III A), the difference between $T_{\rm par}$ and $T_{\rm Kane}$ becomes even more visible.

Since $E(k)$ has been taken as a growing function of $|k|$, we may equally say that $|k|$ is a growing function of E. In particular, after inverting formulas (64) and (65), we obtain the functions

$$\kappa_{\rm par}(\eta) = (2\eta)^{1/2}, \tag{76}$$

$$\kappa_{\rm Kane}(\eta) = (2\eta)^{1/2}[1 + \eta/\eta_g]^{1/2}. \tag{77}$$

Correspondingly, we define the functions

$$\tilde{\mathscr{T}}_{\rm par}(\eta) \equiv \mathscr{T}(\kappa_{\rm par}(\eta)), \tag{78}$$

$$\tilde{\mathscr{T}}_{\rm Kane}(\eta) \equiv \mathscr{T}(\kappa_{\rm Kane}(\eta)). \tag{79}$$

These functions are shown in Fig. 2. The vertical dashed lines are erected at $\eta = \eta_{\rm par}(j\pi)$ (in the upper frame) and at $\eta = \eta_{\rm Kane}(j\pi)$ (in lower frame). Respectively, the vertical dotted lines are erected at $\eta = \eta_{\rm par}((j-1/2)\pi)$ and at $\eta = \eta_{\rm Kane}((j-1/2)\pi)$. The shifts of the vertical dashed (dotted) lines of the lower frame against the corresponding vertical dashed (dotted) lines of the upper frame demonstrate the extent of the deviation from the parabolicity if $E_{\rm par}(k)$ is replaced by $E_{\rm Kane}(k)$ with preserving the same effective mass m at $k=0$:

$$\frac{1}{m} = \frac{1}{\hbar^2}\left.\frac{\partial^2 E_{\rm par}(k)}{\partial k^2}\right|_{k=0} = \frac{1}{\hbar^2}\left.\frac{\partial^2 E_{\rm Kane}(k)}{\partial k^2}\right|_{k=0}. \tag{80}$$

Evidently, the number of the maxima in the lower frame is higher than in the upper frame, in correspondence with the fact that the curve $E = E_{\rm Kane}(k)$ lies below the curve $E = E_{\rm par}(k)$.

C. The limiting case when $a \to 0$

In our previous paper,[7] we have calculated the transmission coefficient $T_\gamma^{\rm single}(k_0)$ for conduction electrons incident upon a single delta-function potential of the strength γ:

$$T_\gamma^{\rm single}(k_0) = \frac{[\hbar\upsilon(k_0)]^2}{[\hbar\upsilon(k_0)]^2 + \gamma^2}. \tag{81}$$

According to formula (57), if $a \to +0$, i.e., if two delta-potentials of the strength γ join together, the pair of these delta-potentials gives the same transmission probability $T(k_0)$ as one single delta-potential but with the strength 2γ :

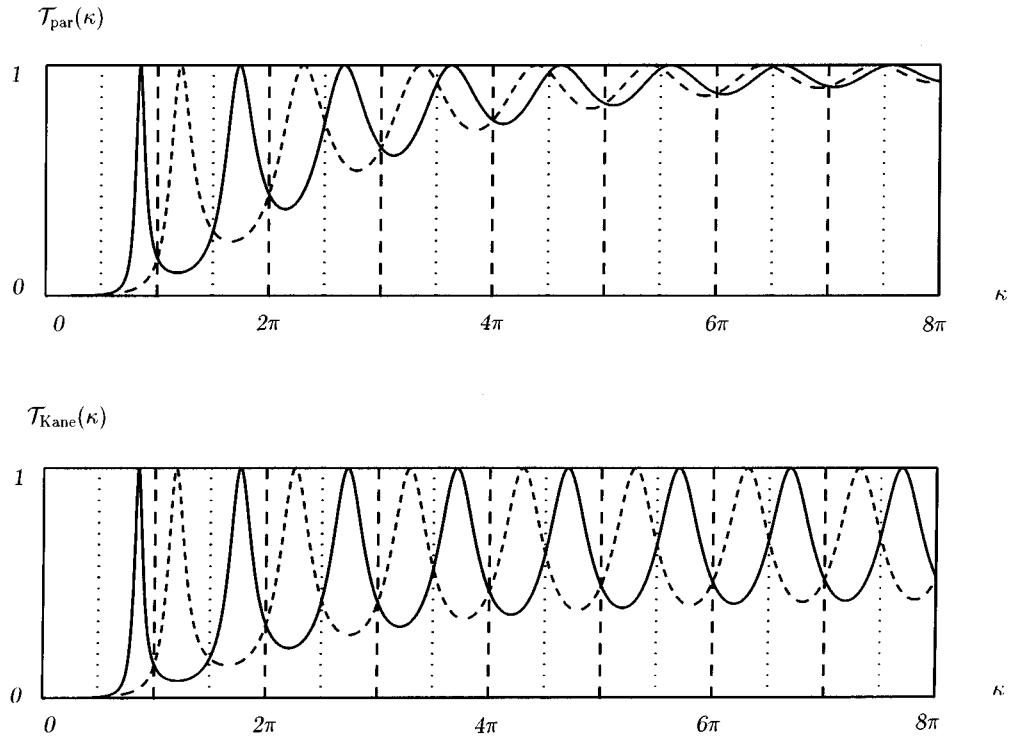

FIG. 1. The upper frame: the transmission coefficient $\mathcal{T}=\mathcal{T}_{\mathrm{par}}(\kappa)$ [i.e., if $E(k)=E_{\mathrm{par}}(k)$] for $\beta=5$ (full curved line) and for $\beta=-5$ (dashed curved line). The lower frame: the transmission coefficient $\mathcal{T}=\mathcal{T}_{\mathrm{Kane}}(\kappa)$ [i.e., if $E(k)=E_{\mathrm{Kane}}(k)$] for $\beta=5$ (full curved line) and for $\beta=-5$ (dashed curved line) ($\eta_g=120$).

$$\lim_{a\to+0} T(k_0)=T_{2\gamma}^{\mathrm{single}}(k_0). \tag{82}$$

D. Difficulties with boundary conditions in the *x*-representation

Our main intent in the present paper was to demonstrate explicitly that it is really advantageous to solve the Schrödinger–Wannier equation in the k-representation since then we are free of difficulties which otherwise arise with boundary conditions in the x-representation whenever the potential energy term of the Hamiltonian involves at least one delta-function, provided that $E(k)$ is a nonquadratic function. (Of course, there are no difficulties with boundary conditions followed from the overall continuity of any envelope wavefunction; actually, problems arise only with boundary conditions formulated for derivatives—and not only for the first-order derivative but also for higher-order derivatives—of the envelope wavefunction.)

Fortunately, if we focus attention on eigenfunction $\psi(x)\equiv\psi_{k_0}(x)$ due to positive eigenenergies $\mathscr{E}=E(k_0)$, then for any position x_s of the delta-function potential $\sim\delta(x-x_s)$, we *may* write a relation which looks like a boundary condition involving derivatives of $\psi_{k_0}(x)$.

We will now briefly elucidate this statement with a more general Hamiltonian than (1). We define the Hamiltonian

$$H_S(x)=E\left(-\mathrm{i}\frac{\partial}{\partial x}\right)+\sum_{s=1}^{\infty}\gamma_s\delta(x-x_s), \tag{83}$$

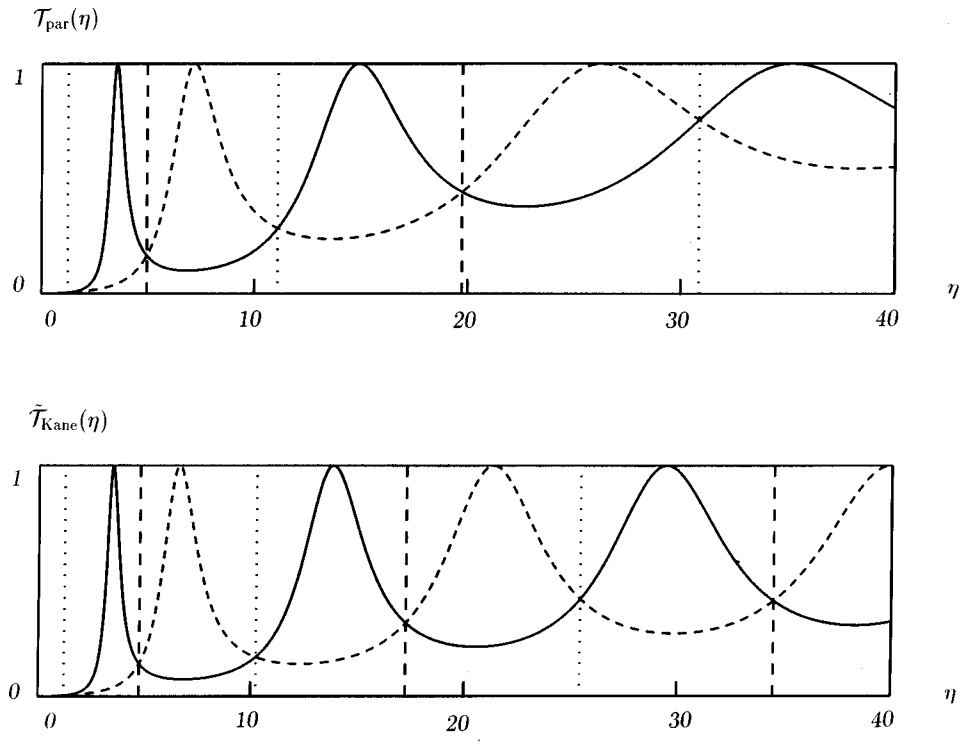

FIG. 2. The same as in Fig. 1 ($\beta=\pm 5$) but the corresponding transmission coefficients are taken as functions of the energy parameter η: $\tilde{\mathcal{T}}_{\rm par}(\eta)=\mathcal{T}_{\rm par}(\kappa)$, $\tilde{\mathcal{T}}_{\rm Kane}(\eta)=\mathcal{T}_{\rm Kane}(\kappa)$ ($\eta_g=120$).

assuming that the (real) values γ_s and x_s are arbitrary but $x_1<x_2<\ldots<x_S$. In (83), we assume that the operator $E(-\mathrm{i}\partial/\partial x)$ corresponds to an arbitrary dispersion function $E(k)$. [Regard only condition (4).] In particular, we define also

$$H_{S,\rm par}(x)=-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2}+\sum_{s=1}^{\infty}\gamma_s\delta(x-x_s). \tag{84}$$

Let $\Psi_{\rm par}(x,t)$ be an arbitrary wavefunction satisfying the Schrödinger–Wannier equation

$$\mathrm{i}\hbar\,\frac{\partial\Psi_{\rm par}(x,t)}{\partial t}=H_{S,\rm par}(x)\Psi_{\rm par}(x,t). \tag{85}$$

Since $H_{S,\rm par}(x)$ is a second-order differential operator, we may write down the boundary conditions

$$-\frac{\hbar^2}{2m}\left[\left.\frac{\partial\Psi_{\rm par}(x,t)}{\partial x}\right|_{x=x_s+0}-\left.\frac{\partial\Psi_{\rm par}(x,t)}{\partial x}\right|_{x=x_s-0}\right]+\gamma_s\Psi_{\rm par}(x_s)=0. \tag{86}$$

If we prefer to use the group velocity $v_{\rm par}(k)$ [cf. formula (59)], we can rewrite equation (86) into the form

$$-\mathrm{i}\left(\frac{\hbar}{2}\right)\left[v_{\mathrm{par}}\left(-\mathrm{i}\,\frac{\partial}{\partial x}\right)\Psi_{\mathrm{par}}(x,t)\Big|_{x=x_s+0}-v_{\mathrm{par}}\left(-\mathrm{i}\,\frac{\partial}{\partial x}\right)\Psi_{\mathrm{par}}(x,t)\Big|_{x=x_s-0}\right]+\gamma_s\Psi_{\mathrm{par}}(x_s,t)=0. \tag{87}$$

[The envelope wavefunction $\Psi_{\mathrm{par}}(x,t)$ itself is continuous but its first derivative $\partial\Psi_{\mathrm{par}}(x,t)/\partial x$ is discontinuous at $x=x_s$.]

Let us now discuss stationary wavefunctions

$$\Psi_{\mathscr{E}}(x,t)=\exp(-\mathrm{i}\,\mathscr{E}t/\hbar)\,\tilde{\psi}_{\mathscr{E}}(x) \tag{88}$$

in the case when $E(k)$ [satisfying condition (4)] is not a quadratic function.

In accordance with the way of derivations which we have decided to follow in Sec. II, we may make the following general statement:

if $\mathscr{E}=E(k_0)>0$, then for $\tilde{\psi}_{\mathscr{E}}(x)=\psi_{k_0}(x)$ we may write the identities

$$-\mathrm{i}\left(\frac{\hbar}{2}\right)\left[v\left(-\mathrm{i}\frac{\partial}{\partial x}\right)\psi_{k_0}(x)\Big|_{x=x_s+0}-v\left(-\mathrm{i}\frac{\partial}{\partial x}\right)\psi_{k_0}(x)\Big|_{x=x_s-0}\right]+\gamma_s\psi_{k_0}(x_s)=0 \tag{89}$$

where the operator $v(-\mathrm{i}\partial/\partial\mathrm{x})$ derives from the group velocity $v(k)$ [cf. formula (54)] by replacing the argument k by $-\mathrm{i}\partial/\partial\mathrm{x}$.

We do not call equalities (89) boundary conditions since generally, if $E(k)$ is not quadratic, equalities (89) cannot be employed in the case when $\mathscr{E}<0$ [if $\psi_{k_0}(x)$ is replaced by $\tilde{\psi}_{\mathscr{E}}(x)$]. [In general, the localized wavefunctions $\tilde{\psi}_{\mathscr{E}}(x)$ for $\mathscr{E}<0$ cannot be constructed as finite sums of exponentials. Therefore, if $\mathscr{E}<0$, not only that is it dubious whether equalities (89) are valid but it is also questionable for which functions these equalities are usable at all.]

To conclude this discussion, we state that in the case of the equation

$$\mathrm{i}\hbar\,\frac{\partial\Psi(x,t)}{\partial t}=H_S(x)\Psi(x,t) \tag{90}$$

concerning a nonquadratic dispersion function $E(k)$, we may surely rely upon the equalities

$$-\mathrm{i}\left(\frac{\hbar}{2}\right)\left[v\left(-\mathrm{i}\,\frac{\partial}{\partial x}\right)\Psi(x,t)\Big|_{x=x_s+0}-v\left(-\mathrm{i}\frac{\partial}{\partial x}\right)\Psi(x,t)\Big|_{x=x_s-0}\right]+\gamma_s\Psi(x_s,t)=0,\quad s=1,\ldots,S \tag{91}$$

provided that none of the constants γ_s is negative.

E. The possibility of a direct translation of results from the case when the dispersion law $E=E(k)$ is parabolic to the case when it is nonparabolic

In this section hand in hand with equalities (89), we will state the validity of the following corollary:

Corollary: Let $\mathscr{A}_{\mathrm{par}}$ be a quantum mechanical coefficient determining the nonlocalized wavefunction $\psi_{k_0}(x)$ derived from the equation

$$H_{S,\mathrm{par}}(x)\,\psi_{k_0,\mathrm{par}}(x)=E(k_0)\,\psi_{k_0,\mathrm{par}}(x) \tag{92}$$

[$E(k_0)>0$ and k_0 is an arbitrary real fixed value]. After introducing the variables $\kappa_s=k_0x_s$ ($s=1,2,\ldots,S$), we consider $\mathscr{A}_{\mathrm{par}}$ as a function of $S+1$ *independent* variables $k_0,\kappa_1,\ldots,\kappa_S$: $\mathscr{A}_{\mathrm{par}}\equiv\mathscr{A}_{\mathrm{par}}(k_0,\kappa_1,\ldots,\kappa_S)$.

If $H_{S,\mathrm{par}}(x)$ is replaced by $H_S(x)$ [respecting condition (4)], the function $\mathscr{A}_{\mathrm{par}}(k_0,\kappa_1,\ldots,\kappa_S)$ is transformed into another function, $\mathscr{A}(k_0,\kappa_1,\ldots,\kappa_S)$, in correspondence with the equation

$$H_S(x)\psi_{k_0}(x)=E(k_0)\psi_{k_0}(x). \tag{93}$$

Then

$$\mathscr{A}(k_0,\kappa_1,\ldots,\kappa_S)\equiv\mathscr{A}_{\mathrm{par}}(mv(k_0)/\hbar,\kappa_1,\ldots,\kappa_S). \tag{94}$$

(Recall that $k_0=mv_{\mathrm{par}}(k_0)/\hbar$.)

Undoubtedly, identity (94) is of appreciable practical value since to solve the Wannier–Schrödinger equation in the case when $E(-\mathrm{i}\partial/\partial x)$ is a second-order differential operator is evidently an easier task [because of the possibility to use the x-representation and the boundary conditions (87)] than to solve this equation in any other case where $E(-\mathrm{i}\partial/\partial x)$ corresponds to a nonquadratic function $E(k)$. A general way of how to obtain the exact solution of the Schrödinger equation [for $E(k)\equiv E_{\mathrm{par}}(k)$ and $\mathscr{E}>0$] with δ-function potentials of arbitrary position and strength has been presented by Reading and Sigel.[25] (For a simplified alternative to their derivations cf. Ref. 26.)

To suggest the proof of formula (94), let us dissect the real x-axis on $S+1$ intervals $\equiv(x_{j-1},x_j)$ $(j=1,2,\ldots,S+1)$ with $x_0=-\infty$ and $x_{S+1}=\infty$. Taking $k_0>0$, we write

$$\psi_{k_0}(x)=[1-\Theta(x-x_1)][\exp(\mathrm{i}k_0x)+B\ \exp(-\mathrm{i}k_0x)]+\sum_{s=1}^{S-1}[\Theta(x-x_s)-\Theta(x-x_{s+1})]$$
$$\times[F_s\ \cos(k_0x)+G_s\ \sin(k_0x)]+\Theta(x-x_S)C\ \exp(\mathrm{i}k_0x). \tag{95}$$

As it is seen, here we have $2S$ coefficients: B, $\{F_s,G_s\}$ and C; $s=1,\ldots,S-1$. For these coefficients, we obtain S linear algebraic equations simply from the continuity of function (95). Subsequently we can carry out analogical calculations as in Sec. II C. This means that we are to solve the Schrödinger–Wannier equation in the k-representation at first and afterwards return to the x-representation. If we choose $x=x_s-0$ (or $x=x_s+0$) in the wavefunction $\psi_{k_0}(x)$ obtained in this way, we arrive at S new linear equations (independent of the former ones) for B, $\{F_s,G_s\}$ and C. These equations involve the derivative $E'(k_0)$ as a parameter. Thus, we can indeed derive $2S$ independent linear algebraic equations for $2S$ coefficients of the wavefunction $\psi_{k_0}(x)$. Each coefficient is derived uniquely and whichever dispersion function $E(k)$ is used, the formal expression for each coefficient is the same: it a function of the variables $\kappa_s=k_0x_s$ (which occur as arguments in sines and cosines; $s=1,\ldots,S$) and of $E'(k_0)=\hbar v(k_0)$. However, this function can also be obtained in a different way if we use the function $E_{\mathrm{par}}(k)$ in the role of $E(k)$. If we prefer to express any coefficient—let us call it $\mathscr{A}$—as a function of k_0 and κ_s instead of $v(k)$ and κ_s $(s=1,,\ldots,S)$, we obtain right equality (94).

Simultaneously, we can clarify the validity of identities (89). If we take into consideration any interval x_{j-1},x_j [cf. the definition of $\psi_{k_0}(x)$ by expression (95)], we may state that

$$v\left(-\mathrm{i}\frac{\partial}{\partial x}\right)\exp(\pm ik_0x)=\pm v(k_0)\exp(\pm ik_0x). \tag{96}$$

In the special case when $E(k)\equiv E_{\mathrm{par}}(k)$, these equalities, when respected in relations (89), have yielded correct values for each coefficient $\mathscr{A}_{\mathrm{par}}(k_0,\kappa_1,\ldots,\kappa_S)$. Then, if the dependence of the corresponding coefficient $\mathscr{A}(k_0,\kappa_1,\ldots,\kappa_S)$ on $v(k)$ is to be [according to formula (94)] the same for nonquadratic functions $E(k)$ as for the quadratic one, it is only then possible if relations (89) are valid generally, i.e., not only in the case when $E(k)\equiv E_{\mathrm{par}}(k)$.

Finally, it is instructive to exemplify identity (94) with the transmission coefficient $T(k_0)$ which we have calculated so carefully in this paper for the double delta-function potential. In the

Appendix, we present the calculation of $T_{\rm par}(k_0)$ within the framework of the x-representation as well. Now we have $S=2$, $\gamma_1=\gamma_2=\gamma$, $\kappa_1=-k_0a/2$, $\kappa_2=k_0a/2$. According to (A12), we have the function

$$T_{\rm par}(k_0)=\frac{k_0^4}{k_0^4+4(m\gamma/\hbar^2)^2[k_0\ \cos(\kappa_2-\kappa_1)+(m\gamma/\hbar^2)\sin(\kappa_2-\kappa_1)]^2}. \tag{97}$$

If we substitute $mv(k_0)/\hbar$ for k_0 in the rhs (retaining the variables κ_1 and κ_2 intact), we obtain the expression

$$T_{\rm par}\left(\frac{mv(k_0)}{\hbar}\right)=\frac{[\hbar v(k_0)]^4}{[\hbar v(k_0)]^4+4\gamma^2[\hbar v(k_0)\cos(\kappa_2-\kappa_1)+\gamma\ \sin(\kappa_2-\kappa_1)]^2}. \tag{98}$$

However, the rhs of (98) is nothing but the expression for $T(k_0)$ according to formula (57). Thus, we have indeed verified that

$$T(k_0)\equiv T_{\rm par}(mv(k_0)/\hbar), \tag{99}$$

in full concordance with the general equality (94).

We close this paper by expressing our hope that the line of thought as it has been presented here may have rewarding potentialities especially in view of some interesting problems occurring in the theory of mesoscopic phenomena.

ACKNOWLEDGMENT

APPENDIX: COEFFICIENT $T_{\rm par}(k_0)$ FOR THE PARABOLIC DISPERSION LAW $E=E_{\rm par}(k)$

Within the framework of the x-representation, the traditional way of calculating $T_{\rm par}(k_0)$ for a symmetric delta-function double barrier (double well), if $E=\hbar^2k^2/(2m)$, is as follows.

We solve the Schrödinger equation

$$-\frac{{\rm d}^2}{{\rm d}\xi^2}\psi+2\beta[\,\delta(\xi+1/2)+\delta(\xi-1/2)\,]\psi=\kappa^2\psi. \tag{A1}$$

Here we have introduced the dimensionless parameters (59) and (60) and the dimensionless variable

$$\xi=x/a. \tag{A2}$$

We assume that the solution is of the form

$$\psi(\xi)=\Theta(\xi+\tfrac{1}{2})[\exp({\rm i}\kappa\xi)+B\ \exp(-{\rm i}\kappa\xi)]+[\Theta(\xi+\tfrac{1}{2})-\Theta(\xi-\tfrac{1}{2})]$$
$$\times[F\ \cos(\kappa\xi)+G\ \sin(\kappa\xi)]+\Theta(\xi-\tfrac{1}{2})C\ \exp({\rm i}\kappa\xi). \tag{A3}$$

From the continuity of the wavefunction $\psi(\xi)$, we obtain the equations

$$\exp\left(-\frac{{\rm i}\kappa}{2}\right)+B\ \exp\left(\frac{{\rm i}\kappa}{2}\right)=F\ \cos\left(\frac{\kappa}{2}\right)-G\ \sin\left(\frac{\kappa}{2}\right), \tag{A4}$$

$$C\ \exp\left(\mathrm{i}\frac{\kappa}{2}\right)=F\ \cos\left(\frac{\kappa}{2}\right)+G\ \sin\left(\frac{\kappa}{2}\right). \tag{A5}$$

Equations (A4) and (A5) are, of course, equally correct whichever dispersion function $E(k)$ is taken into consideration.

However, the usability of the following step which we are now intending to do is strictly limited to the parabolicity of the dependence $E=E(k)$ [or $\eta=\eta(\kappa)$].

When integrating (A1) with respect to ξ from $-a/2-\varepsilon$ to $-a/2+\varepsilon$ and from $a/2-\varepsilon$ to $a/2+\varepsilon$ (where $\varepsilon>0$ is an infinitesimal quantity), we obtain, respectively, the equations

$$\frac{2\beta+\mathrm{i}\kappa}{\kappa}\exp\left(\frac{-\mathrm{i}\kappa}{2}\right)+\frac{2\beta-\mathrm{i}\kappa}{\kappa}\exp\left(\frac{\mathrm{i}\kappa}{2}\right)B=F\ \sin\left(\frac{\kappa}{2}\right)+G\ \cos\left(\frac{k}{2}\right), \tag{A6}$$

$$\frac{2\beta-\mathrm{i}\kappa}{\kappa}\exp\left(\frac{\mathrm{i}\kappa}{2}\right)C=F\ \sin\left(\frac{\kappa}{2}\right)-G\ \cos\left(\frac{\kappa}{2}\right). \tag{A7}$$

Equation (A6) represents a linear relation between the left-hand and right-hand first derivatives of $\psi(\xi)$ at $\xi=-\frac{1}{2}$. Similarly, Eq. (A7) is a linear relation between the left-hand and right-hand first derivatives of $\psi(\xi)$ at $\xi=\frac{1}{2}$. If $E(k)$ is quadratic, then it is needless to try to find relations between higher-order derivatives of $\psi(\xi)$ at $\xi=\pm\frac{1}{2}$. Only if $E(k)$ were a nonquadratic function, then higher-order derivatives of $\psi(\xi)$ would have indispensably to be reckoned with. Nevertheless, the method of the k-representation, as we have employed it in Sec. II, has enabled us fully to miss any complications with the higher-order derivatives in boundary conditions at all.

Equations (A5) and (A7) imply the relations

$$F=C\ \exp\left(\frac{\mathrm{i}\kappa}{2}\right)\left[\cos\left(\frac{\kappa}{2}\right)+\frac{2\beta-\mathrm{i}\kappa}{\kappa}\sin\left(\frac{\kappa}{2}\right)\right], \tag{A8}$$

$$G=C\ \exp\left(\frac{\mathrm{i}\kappa}{2}\right)\left[\sin\left(\frac{\kappa}{2}\right)-\frac{2\beta-\mathrm{i}\kappa}{\kappa}\cos\left(\frac{\kappa}{2}\right)\right]. \tag{A9}$$

After inserting (A8) and (A9) into (A4) and (A6), we obtain two linear equations for C and B. Their solutions are

$$C=\mathrm{i}\,\frac{\kappa^2\ \exp(-\mathrm{i}\kappa)}{-2\beta\kappa\ \cos\ \kappa+(\kappa^2-2\beta^2)\sin\ \kappa+\mathrm{i}\kappa(\kappa\ \cos\ \kappa+2\beta\ \sin\ \kappa)}. \tag{A10}$$

$$B=\frac{2\beta\ \exp(-\mathrm{i}\kappa)(\kappa\ \cos\ \kappa+\beta\ \sin\ \kappa)}{-2\beta\kappa\ \cos\ \kappa+(\kappa^2-2\beta^2)\sin\ \kappa+\mathrm{i}\kappa(\kappa\ \cos\ \kappa+2\beta\ \sin\ \kappa)}. \tag{A11}$$

Correspondingly, denoting $\mathscr{T}_{\mathrm{par}}(\kappa)\equiv|C|^2$ and $\mathscr{R}_{\mathrm{par}}(\kappa)\equiv|B|^2$, we obtain the functions

$$\mathscr{T}_{\mathrm{par}}(\kappa)=\frac{\kappa^4}{\kappa^4+4\beta^2(\kappa\ \cos\ \kappa+\beta\ \sin\ \kappa)^2}, \tag{A12}$$

$$\mathscr{R}_{\mathrm{par}}(\kappa)=\frac{4\beta^2(\kappa\ \cos\ \kappa+\beta\ \sin\ \kappa)^2}{\kappa^4+4\beta^2(\kappa\ \cos\ \kappa+\beta\ \sin\ \kappa)^2}. \tag{A13}$$

When returning to the variables k_0 and γ and using the denotation

$$E'_{\mathrm{par}}(k_0)=\frac{\mathrm{d}E_{\mathrm{par}}(k_0)}{\mathrm{d}k_0}=\frac{\hbar^2 k_0}{m}, \tag{A14}$$

we may state that formulas (A12) and (A13) are in full agreement with formulas (54) and (55) if $E(k)\equiv E_{\mathrm{par}}(k)$.

Finally, let us point out that Galindo and Pascual[18] have derived expression (A12) for the transmission coefficient [cf. their formula (4.133)] by means of another method. Their calculation has relied on Jost functions.

(Received 25 March 1994; accepted for publication 8 May 1996)

We obtain phase space representations of the Poincaré group for zero mass particles of all helicities, including photons. A natural quantization scheme for massless particles arises, and a covariant phase space localization operator is found.
 [S0022-2488(96)02311-0]

I. INTRODUCTION

In this paper we investigate the particle-like nature of the photon and other massless relativistic objects.

An elementary particle in relativistic theory is, according to Newton and Wigner,[1] described mathematically by a unitary, irreducible representation of the Poincaré group together with a collection of localization operators transforming covariantly. The conventional view adheres to two specific tenets: (i) the localization operators are described through the use of a Borel structure on the space or the space–time of the theory, and covariance is with respect to the Euclidean subgroup; (ii) the localization operators are to be projection operators.

While maintaining the assumption regarding the representation, we advance an extension of the conventional view concerning the localization operators, proposing that (i) the localization operators be described through the use of a Borel structure in the phase space of the theory, and covariance be with respect to the full Poincaré group; (ii) the localization operators are not *a priori* restricted to be projection operators.

It appears that a completely satisfactory description is not to be found in either of the conventional formulations of classical relativistic particle mechanics in space–time or of relativistic quantum mechanics. Employing a framework reflecting but extending and unifying these two formulations, we take as fundamental a phase space formulation of relativistic particle mechanics. We also allow a measurement theory in quantum mechanics based upon unsharp measurement (positive operator-valued measures, systems of covariance) rather than one based solely on sharp measurement (projection-valued measures, systems of imprimitivity). Our position is founded upon recent developments in classical relativistic particle mechanics and quantum mechanics as outlined in the following.

In the realm of classical mechanics we adopt the apparatus of symplectic geometry to describe Hamiltonian systems.[2–5] We follow generally the treatment of relativistic particle mechanics as advanced by Künzle,[6] Souriau,[7] and exposited further by Woodhouse.[8]

In the domain of quantum mechanics, we recall that elementary relativistic systems are associated with irreducible representations of the Poincaré group,[9] and that elementary particles require, in addition, a covariant notion of localizability.[1] For localization describable by projection operators[10] these two characteristics of elementary particles merge to form a system of imprimitivity[11] with respect to a Euclidean subgroup of the Poincaré group.[12] Within this scheme the photon fails to be localizable. Hegerfeldt[13] proved more generally that covariant localization of elementary relativistic systems by projection operators is inconsistent even for massive systems. In order to treat localizability of the photon it was suggested[14,15] that positive operator-valued measures be employed. Positive operator-valued measures are now an essential ingredient in quantum measurement theory.[16–20] Independent of these developments, phase space representations of the

0022-2488/96/37(12)/5958/29/$10.00

Poincaré group with a concept of unsharp localizability for massive particles were discovered by Prugovečki[21] and further elaborated by Ali and Prugovečki.[22]

The following is our strategy:

(i) identify symplectic homogeneous spaces (phase spaces) of the Poincaré group relevant to massless particles;
(ii) construct unitary representations of the Poincaré group on Hilbert spaces of functions on these phase spaces;
(iii) define the phase space localization operators on such Hilbert spaces;
(iv) carry out harmonic decompositions of these representations into irreducible components on which the projected localization operators define covariant positive operator-valued measures.

Summary of the results:

(i) We construct informationally complete covariant localization operators for elementary massless particles of arbitrary *helicity/spin* in explicit form.
(ii) The operator for localization within a region of phase space is realized as an integral with respect to a density; consequently, to a measurable function on classical phase space there corresponds an operator obtained by averaging the function with respect to this density, itself an operator. This correspondence defines a natural quantization scheme bearing some similarity to suggestions of Berezin,[23] Prugovečki,[24] Ali and Prugovečki,[25] Schroeck,[26,27] Ali and Emch,[28] and Ali and Doebner.[29]

In quantum mechanics over phase space, a quantization scheme may also be defined as follows: to each measurable function f, associate the operator of multiplication by f, and restrict this operator to the irreducible subspace which is the Hilbert space of the physical system. Choosing f to be the characteristic function for a measurable set, one obtains a localization operator. The localization operator so obtained may be used to produce a quantization scheme in the manner outlined in the previous paragraph. The result is the same quantization scheme with which we began. In this sense, there is a natural equivalence between quantization and localization. This equivalence is both conceptual and practical.

This formalism also yields a dequantization scheme whereby a classical probability density on phase space is naturally associated with a density operator in conventional quantum mechanics so that classical and quantum expectations agree. In this respect these two correspondences are dual.

II. GROUP STRUCTURE, GEOMETRIC STRUCTURE, DEFINITIONS, AND NOTATION

Minkowski space–time and energy-momentum space are both identified with $\mathbb{R}^4$ equipped with the Minkowski metric $g \equiv \mathrm{diag}(1,-1,-1,-1)$. We identify $\mathbb{R}^4$ with the set of 2×2 Hermitian matrices according to the correspondence:

$$(p^0,p^1,p^2,p^3) \leftrightarrow \begin{pmatrix} p^0+p^3 & p^1-ip^2 \\ p^1+ip^2 & p^0-p^3 \end{pmatrix} \tag{1}$$

using the boldface notation $\mathbf{p}$ in either situation. The Minkowski inner product $g(\mathbf{p},\mathbf{p})$ is expressed

$$g(\mathbf{p},\mathbf{p}) = \det\begin{pmatrix} p^0+p^3 & p^1-ip^2 \\ p^1+ip^2 & p^0-p^3 \end{pmatrix}. \tag{2}$$

The Minkowski inner product is abbreviated

$$\mathbf{p}\cdot\mathbf{q} \equiv g(\mathbf{p},\mathbf{q}). \tag{3}$$

The identification in (1) permits a flexible expression of the natural action of elements A of $SL(2,\mathbb{C})$, the double cover of the Lorentz group on $\mathbb{R}^4$, as follows:

$$\mathbf{p} \mapsto A \cdot \mathbf{p} \equiv A\mathbf{p}A^{\dagger}. \tag{4}$$

The Poincaré group, $\mathscr{P}$, is taken to be the semi-direct product:

$$\mathscr{P} = \mathbb{R}^4 \oslash \mathscr{L}, \quad \mathscr{L} \equiv SL(2,\mathbb{C}). \tag{5}$$

Two closed subgroups of $\mathscr{P}$ of particular relevance in the representation theory of massless spinning particles are

(a) $H_1 \equiv \mathbb{R}^4 \oslash SL(2,\mathbb{C})_{\mathbf{p}}$,
(b) $H_2 \equiv \mathbb{R}\mathbf{p} \oslash SL(2,\mathbb{C})_{\mathbf{p}}$,

where $SL(2,\mathbb{C})_{\mathbf{p}}$, the stability subgroup of the future-pointing null vector $\mathbf{p}$ in $\mathbb{R}^4$ viewed as energy-momentum space, consists of those $A \in SL(2,\mathbb{C})$ satisfying the condition $A \cdot \mathbf{p} = \mathbf{p}$. Case (a) occurs in the theory of induced irreducible representations where the homogeneous space $\mathscr{P}/H_1$ is the conventional momentum space (future null cone). Topologically, $\mathscr{P}/H_1$ is homeomorphic to $\mathbb{R}^1 \times S^2$. In case (b), $\mathscr{P}/H_2$ is the symplectic homogeneous space identified by Souriau[3] (see also Ref. 8) as the phase space of the photon. Topologically, $\mathscr{P}/H_2$ is homeomorphic to $\mathbb{R}^3 \times \mathbb{R}^1 \times S^2$.

The orbit $\mathscr{O}_{\mathbf{p}}$ of $\mathbf{p}$ under $SL(2,\mathbb{C})$ consists of all points $A \cdot \mathbf{p}$, $A \in SL(2,\mathbb{C})$. When $\mathbf{p}$ is a future-pointing null vector ($p^0 > 0$), then $\mathscr{O}_{\mathbf{p}}$ is the future null cone V_0^+:

$$V_0^+ = \{\mathbf{p} | g(\mathbf{p},\mathbf{p}) = 0,\ p^0 > 0\}. \tag{6}$$

Henceforth, $\mathbf{p}_o$ denotes the point $(1,0,0,1) \in V_0^+$.

If $\mathbf{q}$ belongs to $\mathscr{O}_{\mathbf{p}}$ with $\mathbf{q} = A \cdot \mathbf{p}$, then the stabilizers of $\mathbf{q}$ and $\mathbf{p}$ are related:

$$SL(2,\mathbb{C})_{\mathbf{q}} = A SL(2,\mathbb{C})_{\mathbf{p}} A^{-1}.$$

A computation shows that $SL(2,\mathbb{C})_{\mathbf{p}_o}$ is the subgroup of matrices A of the form $A = \left(\begin{smallmatrix} 1 & z \\ 0 & 1 \end{smallmatrix}\right) \times \left(\begin{smallmatrix} \tau & 0 \\ 0 & \tau^{-1} \end{smallmatrix}\right)$, $|\tau| = 1$, $z \in \mathbb{C}$. If θ is the angle of right-hand rotation about the (0,0,1)-axis in $\mathbb{R}^3$ when A acts on $\mathbb{R}^4$ by (4), then $\tau = e^{-i\theta/2}$; the matrices of the type $\left(\begin{smallmatrix} \tau & 0 \\ 0 & \tau^{-1} \end{smallmatrix}\right)$ form a group isomorphic to $O(2)^{\sim}$, a double cover of $O(2)$. The matrices of the type $\left(\begin{smallmatrix} 1 & z \\ 0 & 1 \end{smallmatrix}\right)$ form a group isomorphic to $\mathbb{R}^2$. Therefore, the group $SL(2,\mathbb{C})_{\mathbf{p}_o}$ is isomorphic to $E(2)^{\sim} = \mathbb{R}^2 \oslash O(2)^{\sim}$, a double cover of the Euclidean group of $\mathbb{R}^2$.[9] For any $\mathbf{p} = (p^0, \vec{p}) \in V_0^+$, an element of $SL(2,\mathbb{C})_{\mathbf{p}} \cong E(2)^{\sim}$ factorizes similarly into a product of a translation preceded by a rotation in $\mathbb{R}^3$ about the axis $\vec{p}$.

We now describe the homogeneous spaces $\mathscr{P}/H_1$ and $\mathscr{P}/H_2$ and their left-invariant measures in coordinates. For this, we use the general fact that $G/G_{\mathbf{x}}$ is diffeomorphic to $\mathscr{O}_{\mathbf{x}}$ the G-orbit of $\mathbf{x}$ under the action of the group G through the diffeomorphism $AG_{\mathbf{x}} \mapsto A \cdot \mathbf{x}$, $A \in G$. Let $H_0 \equiv SL(2,\mathbb{C})_{\mathbf{p}_o}$ so that $\mathscr{L}/H_0 = SL(2,\mathbb{C})/SL(2,\mathbb{C})_{\mathbf{p}_o}$. In the present case, $SL(2,\mathbb{C})/SL(2,\mathbb{C})_{\mathbf{p}_o}$ is diffeomorphic to V_0^+ by the mapping

$$A\ SL(2,\mathbb{C})_{\mathbf{p}_o} \mapsto A \cdot \mathbf{p}_o. \tag{7}$$

Since $SL(2,\mathbb{C})$ and $E(2)^{\sim} = \mathbb{R}^2 \oslash O(2)^{\sim}$ are unimodular Lie groups, the homogeneous space $SL(2,\mathbb{C})/SL(2,\mathbb{C})_{\mathbf{p}_o}$ has an $SL(2,\mathbb{C})$-invariant measure unique up to scalar multiples. On the other hand, V_0^+ also has the $SL(2,\mathbb{C})$-invariant measure ν, which when V_0^+ is identified with $\mathbb{R}^3$ by $\mathbf{p} = (p^0, \vec{p}) = (p^0, p^1, p^2, p^3) \mapsto \vec{p}$, is given by

$$d\nu(\mathbf{p}) = (p^0)^{-1} dp^1 \wedge dp^2 \wedge dp^3, \tag{8}$$

where $p^0=|\vec{p}|$, and which, when V_0^+ is identified with $\mathbb{R}^+\times\mathbb{R}^2$ by $\mathbf{p}\mapsto(p^0+p^3,p^1,p^2)$, is given by

$$d\nu(\mathbf{p})=(p^0+p^3)^{-1}d(p^0+p^3)\wedge dp^1\wedge dp^2. \tag{9}$$

The diffeomorphism (7) identifies these three invariant measures. From this, we obtain the following:

(a) The homogeneous space $\mathscr{L}/H_0 = \mathrm{SL}(2,\mathbb{C})/\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o}$ is diffeomorphic to V_0^+ and possesses the $\mathrm{SL}(2,\mathbb{C})$-invariant measure ν.

(b) The homogeneous space $\mathscr{P}/H_1 = \mathbb{R}^4\circledcirc\mathrm{SL}(2,\mathbb{C})/\mathbb{R}^4\circledcirc\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o}$ is diffeomorphic to $\mathrm{SL}(2,\mathbb{C})/\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o}$ and hence $\mathscr{P}/H_1$ is also diffeomorphic to V_0^+. From (7) and (8) $\mathscr{P}/H_1$ possesses the $\mathscr{P}$-invariant measure ν.

(c) The homogeneous space $\mathscr{P}/H_2 = \mathbb{R}^4\circledcirc\mathrm{SL}(2,\mathbb{C})/\mathbb{R}\mathbf{p}_o\circledcirc\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o}$ may be described as the space of cosets $(\mathbf{a},A)(\mathbb{R}\mathbf{p}_o\circledcirc\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o}) = (\mathbf{a}+\mathbb{R}A\cdot\mathbf{p}_o, A\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o})$ which corresponds by (7) to $(\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p})$ where $\mathbf{p}=A\cdot\mathbf{p}_o$. Thus, $\mathscr{P}/H_2$ is seen to be diffeomorphic to the bundle $\cup_{\mathbf{p}\in V_0^+}\mathbb{R}^4/\mathbb{R}\mathbf{p}$. Consequently, a $\mathscr{P}$-invariant measure on $\mathscr{P}/H_2$ is seen to be

$$d\mu(\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p})=d\lambda_{\mathbf{p}}(\mathbf{a})d\nu(\mathbf{p}), \tag{10}$$

where $d\lambda_{\mathbf{p}}(\mathbf{a})$ is the Lebesgue measure on the three-dimensional quotient space $\mathbb{R}^4/\mathbb{R}\mathbf{p}$ of $\mathbb{R}^4$. We stress that in using this measure, one must necessarily integrate over the $\mathbb{R}^4/\mathbb{R}\mathbf{p}$ coordinates first.

We turn now to a brief description of the symplectic structure of the homogeneous space $\mathscr{P}/H_2$ by paralleling results obtained for the case of relativistic massive spinning particles (Refs. 30–32). For $\lambda\in\mathbb{R}$, let $\mathscr{E}_\lambda$ denote the evolution space of triples (Ref. 7): $(\mathbf{q},\ \mathbf{p},\ \mathbf{s})\in\mathbb{R}^4\times\mathbb{R}^4\times\mathbb{R}^4$, satisfying the conditions: $\mathbf{p}\in V_0^+$, $\mathbf{s}=\lambda\mathbf{p}$. The origin of the latter condition is the classical mechanical requirement that $g(\mathbf{p},\mathbf{s})=0$ and the additional requirement that $\mathbf{s}$ be a null vector (Ref. 33). Spacelike $\mathbf{s}$ leads to continuous spin representations which are not treated here. If $\lambda\neq0$, then λ is the classical counterpart of *helicity/spin*; the sign of λ labels the two circular polarizations (Ref. 3). If $\lambda=0$, $\mathscr{E}_0$ will be understood to be the set of pairs: $(\mathbf{q},\mathbf{p})\in\mathbb{R}^4\times\mathbb{R}^4$, $\mathbf{p}\in V_0^+$. For $\lambda\neq0$, $\mathscr{E}_\lambda$ is topologically $\mathbb{R}^4\times\mathbb{R}\times S^2$.

For the Minkowski space–time $M=(\mathbb{R}^4,g)$ and any point $\mathbf{q}\in M$, define $V_0^+(\mathbf{q})\equiv\{\mathbf{p}\in T_{\mathbf{q}}^*M:\mathbf{p}$ is future pointing and null$\}$. This is essentially the V_0^+ introduced earlier. If $(\mathbf{e}_0,\ \mathbf{e}_1,\ \mathbf{e}_2,\ \mathbf{e}_3)$ is a Lorentz frame at $\mathbf{q}$ [i.e., $g(\mathbf{e}_a,\mathbf{e}_b)=g_{ab}$] and $(\boldsymbol{\theta}^0,\ \boldsymbol{\theta}^1,\ \boldsymbol{\theta}^2,\ \boldsymbol{\theta}^3)$ is the dual frame at $\mathbf{q}$, any $\mathbf{p}\in V_0^+(\mathbf{q})$ may be expressed $\mathbf{p}=p_a\boldsymbol{\theta}^a$. We may always choose a Lorentz frame so that $\mathbf{p}=\boldsymbol{\theta}^0-\boldsymbol{\theta}^3$. In arbitrary coordinates, this may be written $p_\mu=\theta^0_\mu-\theta^3_\mu$, or $p^\mu=e^\mu_0+e^\mu_3$. Define

$$\mathbf{S}\equiv\lambda\,\boldsymbol{\theta}^1\wedge\boldsymbol{\theta}^2;\quad \text{i.e.,}\ \ S_{\rho\sigma}=\lambda(\theta^1_\rho\theta^2_\sigma-\theta^1_\sigma\theta^2_\rho). \tag{11}$$

With this choice, regarding $\mathbf{S}$ as the angular momentum tensor relative to the origin $\mathbf{q}$ of the frame $(\mathbf{e}_a)$, one computes the corresponding Pauli-Lubanski spin vector

$$s^\mu=\tfrac{1}{2}\epsilon^{\mu\rho\sigma\tau}S_{\rho\sigma}p_\tau. \tag{12}$$

In coordinate free terms,

$$\mathbf{s}=*(\mathbf{p}\wedge\mathbf{S}), \tag{13}$$

where $*$ denotes the Hodge dual mapping for M. From the definition of $\mathbf{S}$ we find that $\mathbf{s}=\lambda\mathbf{p}$.

On the bundle $\mathrm{Lor}(M)$ of Lorentz frames over M, with coordinates (q^α,e^α_a), define the two-form

$$\Omega = dp_\mu \wedge dq^\mu + (2\lambda^2)^{-1}(dS^\alpha_\beta \wedge S^\beta_\gamma dS^\gamma_\alpha), \tag{14}$$

where, as before, $S^{\alpha\beta}=\lambda(e_1^\alpha e_2^\beta - e_1^\beta e_2^\alpha)$ and $p_\mu = \theta^0_\mu - \theta^3_\mu$. (See Ref. 3, p. 190, equation ♣, with "η"$=+1$ and Ref. 6.) Regard the evolution space $\mathscr{E}_\lambda$ as a subset of the Lorentz bundle by the injection

$$\begin{gathered} \iota: \mathscr{E}_\lambda \to \mathrm{Lor}(M), \\ \iota: (\mathbf{q},\mathbf{p},\mathbf{s}) \mapsto (q^\alpha, e^\alpha_a), \end{gathered} \tag{15}$$

where

$$\mathbf{p} = \boldsymbol{\theta}^0 - \boldsymbol{\theta}^3 \quad \text{and} \quad \lambda \mathbf{p} = *(\mathbf{p} \wedge \mathbf{S}). \tag{16}$$

Then we pull back Ω to obtain the two-form $\iota^*\Omega$ on $\mathscr{E}_\lambda$. On $\mathscr{E}_\lambda$, $\iota^*\Omega$ is degenerate, with a one-dimensional kernel. Thus, Ω induces a symplectic structure on the six-dimensional phase space $\mathscr{E}_\lambda/\ker(\iota^*\Omega)$. The action of $\mathscr{P}$ on $\mathscr{E}_\lambda$ is given by

$$(a,A)(\mathbf{q},\mathbf{p},\mathbf{s}) = (A^{-1}\cdot(\mathbf{q}-\mathbf{a}),\ A^{-1}\cdot\mathbf{p},\ A^{-1}\cdot\mathbf{s}). \tag{17}$$

This induces an action on $\mathscr{E}_\lambda/\ker(\iota^*\Omega)$, and shows (see Ref. 3, pp. 189–192 and Ref. 5, pp. 341–343) that $\mathscr{E}_\lambda/\ker(\iota^*\Omega)$ may be identified with the bundle $\cup_{\mathbf{p}\in V_0^+}\mathbb{R}^4/\mathbb{R}\mathbf{p}$ and hence with $\mathscr{P}/H_2$. Alternatively, the phase space $\mathscr{E}_\lambda/\ker(\iota^*\Omega)$ and its symplectic structure may be identified with the coadjoint orbit of the Poincaré group corresponding to the point $(\mathbf{p}, S)$ as in (16) and its canonical symplectic structure (Ref. 34).

The following notation will be used for the canonical projections π_i and (local) Borel cross sections σ_i:

(0)

$$\begin{gathered} \pi_0: \mathrm{SL}(2,\mathbb{C}) \to \mathrm{SL}(2,\mathbb{C})/\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o} \cong V_0^+ \ \text{ by } \ \pi_0(A) = A\cdot\mathbf{p}_o; \\ \sigma_0: \mathrm{SL}(2,\mathbb{C})/\mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o} \to \mathrm{SL}(2,\mathbb{C}) \ \text{ with } \ \pi_0\circ\sigma_0(\mathbf{p}) = \mathbf{p}. \end{gathered} \tag{18}$$

(1)

$$\begin{gathered} \pi_1: \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C}) \to \mathbb{R}^4 \oslash \mathrm{SL}(2;\mathbb{C})/\mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o} \cong V_0^+ \ \text{ by } \ \pi_1(\mathbf{a},A) = A\cdot\mathbf{p}_o; \\ \sigma_1: \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C})/\mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o} \to \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C}) \ \text{ with } \ \pi_1\circ\sigma_1(\mathbf{p}) = \mathbf{p}. \end{gathered} \tag{19}$$

(2)

$$\begin{gathered} \pi_2: \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C}) \to \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C})/\mathbb{R}\mathbf{p}_o \oslash \mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o} \ \text{ by } \ \pi_2(\mathbf{a},A) = (\mathbf{a}+\mathbb{R}A\cdot\mathbf{p}_o, A\cdot\mathbf{p}_o); \\ \sigma_2: \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C})/\mathbb{R}\mathbf{p}_o \oslash \mathrm{SL}(2,\mathbb{C})_{\mathbf{p}_o} \to \mathbb{R}^4 \oslash \mathrm{SL}(2,\mathbb{C}) \ \text{ with } \ \pi_2\circ\sigma_2(\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p}) = (\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p}). \end{gathered} \tag{20}$$

III. INDUCED MASSLESS REPRESENTATIONS OF THE POINCARÉ GROUP

In this section we develop the representations of the Poincaré group induced from irreducible representations of the two subgroups H_1 and H_2. These are respectively the standard irreducible representation on the null cone, and the phase space representation.

A. Induced massless representations of the Poincaré group on the null cone

The Mackey[11] procedure of induced representations will be employed to obtain massless unitary irreducible representations of $\mathscr{P}$. In this way we will recover not only the ''standard'' irreducible representations for massless spinning particles, but also unitarily equivalent representations that are analogous to the phase space representations.

The unitary irreducible representations M_λ of $O(2)^\sim$ are parametrized by $\lambda \in \frac{1}{2}\mathbb{Z}$ and act on $\mathscr{H}_0 = \mathbb{C}$. If $R(\psi)$ denotes rotation by ψ, then $M_\lambda(R(\psi)) = \exp(i\lambda\psi)$.

The unitary irreducible representation Λ_λ of $E(2)^\sim = \mathbb{R}^2 \circledcirc O(2)^\sim$ induced from M_λ is given by

$$\Lambda_\lambda(z,\tau) \equiv \Lambda(\chi_0, M_\lambda; (z,\tau)) = \chi_0(z) M_\lambda(\tau) = \tau^\lambda, \tag{21}$$

where, using the notation from Sec. II, (z,τ) denotes an element of $E(2)^\sim$. The representation space of Λ_λ is $\mathscr{H}_0 = \mathbb{C}$.

We are now ready to describe the unitary irreducible representations of the subgroup H_1 of the Poincaré group corresponding to massless particles with quantized spin (helicity). Continuous spin representations will not be considered.

Massless discrete spin unitary irreducible representations of $H_1 = \mathbb{R}^4 \circledcirc [\mathrm{SL}(2,\mathbb{C})]_{\mathbf{p}_o} = \mathbb{R}^4 \circledcirc E(2)^\sim$ arise from the choice of a character $\chi_{\boldsymbol{\xi}}$ where $\boldsymbol{\xi}$ is any vector in the $\mathrm{SL}(2,\mathbb{C})$-orbit of $\mathbf{p}_o$, and one of the representations Λ_λ, $\lambda \in \frac{1}{2}\mathbb{Z}$, of $E(2)^\sim$. Denoting this representation by $\Lambda_{\boldsymbol{\xi}\lambda}$ and using the notation of Sec. II, we have

$$\Lambda_{\boldsymbol{\xi}\lambda}(\mathbf{k},(z,\tau)) \equiv \Lambda(\chi_{\boldsymbol{\xi}}, \Lambda_\lambda; (\mathbf{k},(z,\tau))) = \chi_{\boldsymbol{\xi}}(\mathbf{k}) \Lambda_\lambda(z,\tau) = \exp\{i\boldsymbol{\xi}\cdot\mathbf{k}\}\tau^\lambda. \tag{22}$$

We induce a representation of $\mathscr{P}$ from this representation of H_1.

Theorem 3.1: *Let $\boldsymbol{\xi} \in V_0^+$, and $\lambda \in \frac{1}{2}\mathbb{Z}$. The Hilbert space of the representation is*

$$\mathscr{H}_{\mathrm{mom}}^{\boldsymbol{\xi}\lambda} = L^2_\nu(\mathscr{P}/H_1). \tag{23}$$

The induced unitary irreducible representation $U^{\boldsymbol{\xi}\lambda}$ of $\mathscr{P}$ is given by

$$[U^{\boldsymbol{\xi}\lambda}(\mathbf{a},A)F](\mathbf{p}) = \exp\{i[\sigma_0(\mathbf{p})\cdot\boldsymbol{\xi}]\cdot\mathbf{a}\} M_\lambda(\sigma_0(\mathbf{p})^{-1} A \sigma_0(A^{-1}\cdot\mathbf{p})) F(A^{-1}\cdot\mathbf{p}). \tag{24}$$

To obtain the familiar representation,[9] one identifies $\mathscr{P}/H_1 = V_0^+$ with $\mathbb{R}^3$ by $\mathbf{p} = (p^0, \vec{p}) \mapsto \vec{p}$ and $\mathscr{H}_{\mathrm{mom}}^{\boldsymbol{\xi}\lambda}$ with $L^2_\nu(\mathbb{R}^3)$, $d\nu(\vec{p}) = \|\vec{p}\|^{-1} d\vec{p}$, and one chooses $\boldsymbol{\xi} = \mathbf{p}_o$ to obtain

$$[U^{\mathbf{p}_o\lambda}(\mathbf{a},A)F](\mathbf{p}) = \exp\{i\mathbf{p}\cdot\mathbf{a}\} M_\lambda(\sigma_0(\mathbf{p})^{-1} A \sigma_0(A^{-1}\cdot\mathbf{p})) F(A^{-1}\cdot\mathbf{p}). \tag{25}$$

A unitarily equivalent representation is obtained by choosing $\boldsymbol{\xi} = \mathbf{q}_o \equiv (\frac{1}{2}, 0, 0, -\frac{1}{2})$ (that is, $\mathbf{q}_o$ is a future null vector $\mathbf{k}$ such that $\mathbf{k}\cdot\mathbf{p}_o = 1$), and $\mathbf{q} = \sigma_0(\mathbf{p})\cdot\mathbf{q}_o$, to obtain

$$[U^{\mathbf{q}_o\lambda}(\mathbf{a},A)F](\mathbf{p}) = \exp\{i\mathbf{q}\cdot\mathbf{a}\} M_\lambda(\sigma_0(\mathbf{p})^{-1} A \sigma_0(A^{-1}\cdot\mathbf{p})) F(A^{-1}\cdot\mathbf{p}). \tag{26}$$

The choices $\lambda = \pm\frac{1}{2}$ have been identified as the neutrino representations, and the cases $\lambda = \pm 1$ as the photon representations (Refs. 9 and 35–37). The graviton has been associated with $\lambda = \pm 2$. The choices ''$\pm$'' reflect the two-valued nature of helicity.

B. Induced massless representations of the Poincaré group on phase space

Because the phase space representations will be induced from representations of $H_2 \equiv \mathbb{R}\mathbf{p}_o \circledcirc [\mathrm{SL}(2,\mathbb{C})]_{\mathbf{p}_o} \cong \mathbb{R} \circledcirc E(2)^\sim$, $\mathbf{p}_o = (1,0,0,1)$, it is useful to describe the unitary irreducible representations of H_2.

In the notation of Sec. II, let $(\kappa\mathbf{p}_o,(z,\tau))\in\mathbb{R}\mathbf{p}_o\oslash E(2)^{\sim}=\mathbb{R}\mathbf{p}_o\oslash[\mathrm{SL}(2,\mathbb{C})]_{\mathbf{p}_o}\equiv H_2$. Let χ_β be a character for $\mathbb{R}$: $\chi_\beta(\kappa)=\exp\{i\beta\kappa\}$, $\beta\in\mathbb{R}$. Again, we denote irreducible unitary representations of $E(2)^{\sim}$ by M_λ, as in (21). We obtain then the irreducible unitary representation $\Lambda_{\beta\lambda}$ of H_2:

$$\Lambda_{\beta\lambda}(\kappa,(z,\tau))=\Lambda(\chi_\beta,M_\lambda;(\kappa\mathbf{p}_o,(z,\tau)))=\chi_\beta(\kappa)M_\lambda(z,\tau)=\exp\{i\beta\kappa\}\tau^\lambda, \tag{27}$$

where β is any real number, $\lambda\in\frac{1}{2}\mathbb{Z}$.

From these representations of H_2, we now obtain phase space representations of $\mathscr{P}$.

Theorem 3.2: *Let $\beta\in\mathbb{R}$, and $\lambda\in\frac{1}{2}\mathbb{Z}$. The Hilbert space of the representation is*

$$\mathscr{H}_{\mathrm{phase}}^{\beta\lambda}=L^2_\mu(\mathscr{P}/H_2), \tag{28}$$

where μ is the $\mathscr{P}$-invariant measure on $\mathscr{P}/H_2$ defined in (10). Recalling from Sec. II the identification of $\mathscr{P}/H_2$ with $\mathbb{R}^3\times V_0^+$ by $(\mathbf{k}+\mathbb{R}\mathbf{p},\mathbf{p})\mapsto(\mathbf{k},\mathbf{p})$, we identify elements of $\mathscr{H}_{\mathrm{phase}}^{\beta\lambda}$ as functions F: $\mathbb{R}^3\times V_0^+\to\mathbb{C}$ satisfying $F(\mathbf{k}+\alpha\mathbf{p},\mathbf{p})=F(\mathbf{k},\mathbf{p})$, for all $\alpha\in\mathbb{R}$. The induced unitary irreducible representation $U^{\beta\lambda}$ of $\mathscr{P}$ is given by

$$[U^{\beta\lambda}(\mathbf{a},A)F](\mathbf{k},\mathbf{p})=\Lambda_{\beta\lambda}(h_2(\mathbf{b},B)[h_2((\mathbf{a},A)^{-1}(\mathbf{b},B))]^{-1})F((\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p})), \tag{29}$$

where, for $(\mathbf{k},\mathbf{p})$, $(\mathbf{b},B)$ is any element of $\mathscr{P}$ such that $\pi_2(\mathbf{b},B)=(\mathbf{k}+\mathbb{R}\mathbf{p},\mathbf{p})$ and where h_2: $\mathscr{P}\to H_2$ by $g\mapsto[\sigma_2\circ\pi_2(g)]^{-1}g$.

Proof: The induced representation space $\mathscr{H}_{\mathrm{phase}}^{\beta\lambda}\equiv L^2_\mu(\mathscr{P}/H_2)$ consists of functions f: $\mathscr{P}\to\mathbb{C}$ such that $f\circ\sigma_2$ is square integrable on $\mathscr{P}/H_2$ and

$$f(gh)=\Lambda_{\beta\lambda}(h^{-1})f(g) \tag{30}$$

for all $h\in H_2$, $g\in\mathscr{P}$. On such functions we define the left quasi-regular representation $U^{\Lambda_{\beta\lambda}}\equiv U^{\beta\lambda}$ by

$$[U^{\beta\lambda}(g)f](g')=f(g^{-1}g') \tag{31}$$

for all $g,g'\in\mathscr{P}$. Since $h_2(g)=[\sigma_2\circ\pi_2(g)]^{-1}g$ is an element in H_2, (30) becomes

$$f(g)=\Lambda_{\beta\lambda}(h_2(g)^{-1})f(\sigma_2\circ\pi_2(g)). \tag{32}$$

It follows that

$$[U^{\beta\lambda}(g)f](g')=f(g^{-1}g')=\Lambda_{\beta\lambda}([h_2(g^{-1}g')]^{-1})f(\sigma_2\circ\pi_2(g^{-1}g')).$$

Then, by replacing f with $U^{\beta\lambda}(g)f$ in (32), we obtain

$$\begin{aligned}[U^{\beta\lambda}(g)f](\sigma_2\circ\pi_2(g'))&=\Lambda_{\beta\lambda}(h_2(g'))[U^{\beta\lambda}(g)f](g')\\&=\Lambda_{\beta\lambda}(h_2(g'))\Lambda_{\beta\lambda}([h_2(g^{-1}g')]^{-1})f(\sigma_2\circ\pi_2(g^{-1}g'))\\&=\Lambda_{\beta\lambda}(h_2(g')[h_2(g^{-1}g')]^{-1})f(\sigma_2(g^{-1}\pi_2(g'))).\end{aligned} \tag{33}$$

Note that, in (33), $\Lambda_{\beta\lambda}(h_2(g')[h_2(g^{-1}g')]^{-1})$ depends on g' only through $\pi_2(g')$. In order to simplify (33), define

$$F(\mathbf{k},\mathbf{p})\equiv f(\sigma_2(\mathbf{k}+\mathbb{R}\mathbf{p},\mathbf{p})). \tag{34}$$

It follows that $F(\mathbf{k}+\alpha\mathbf{p},\mathbf{p})=F(\mathbf{k},\mathbf{p})$ for all $\alpha\in\mathbb{R}$, and also, from (33), that such functions F are form invariant under the action of $\mathscr{P}$ defined by

$$[U^{\beta\lambda}(g)F](\mathbf{k},\mathbf{p})\equiv[U^{\beta\lambda}(g)f](\sigma_2(\mathbf{k}+\mathbb{R}\mathbf{p},\mathbf{p})). \tag{35}$$

Equation (33) becomes

$$[U^{\beta\lambda}(\mathbf{a},A)F](\mathbf{k},\mathbf{p})=\Lambda_{\beta\lambda}(h_2(\mathbf{b},B)[h_2((\mathbf{a},A)^{-1}(\mathbf{b},B))]^{-1})F(A^{-1}\cdot(\mathbf{k}-\mathbf{a}),A^{-1}\mathbf{p}), \quad (36)$$

for any $(\mathbf{b},B)$ such that $\pi_2(\mathbf{b},B)=(\mathbf{k}+\mathbf{R}\mathbf{p},\mathbf{p})$. Since $f\circ\sigma_2\in L^2_\mu(\mathscr{P}/H_2)\equiv\mathscr{H}^{\beta\lambda}_{\text{phase}}$, by an abuse of notation, we write $F\in\mathscr{H}^{\beta\lambda}_{\text{phase}}$.

Equation (36) may, in turn, be simplified by lifting the action of $\mathscr{P}$ on $\mathscr{P}/H_2$ to an action of $\mathscr{P}$ on $\mathbb{R}^4\times V_0^+$ defined by

$$(\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p})\equiv(A^{-1}\cdot(\mathbf{k}-\mathbf{a}),A^{-1}\mathbf{p}). \quad (37)$$

This results in

$$[U^{\beta\lambda}(\mathbf{a},A)F](\mathbf{k},\mathbf{p})=\Lambda_{\beta\lambda}(h_2(\mathbf{b},B)[h_2((\mathbf{a},A)^{-1}(\mathbf{b},B))]^{-1})F((\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p})), \quad (38)$$

for any $(\mathbf{b},B)$ such that $\pi_2(\mathbf{b},B)=(\mathbf{k}+\mathbb{R}\mathbf{p},\mathbf{p})$ with $F\in\mathscr{H}^{\beta\lambda}_{\text{phase}}$.□

The expression (38) is a general phase space representation of $\mathscr{P}$ depending on the arbitrary choice of section σ_2. Any section σ_2 may be expressed in the form

$$\sigma_2(\mathbf{k}+\mathbb{R}\mathbf{p},\mathbf{p})=(\mathbf{k},-\kappa(\mathbf{k},\mathbf{p})\mathbf{p},A(\mathbf{k},\mathbf{p})) \quad (39)$$

where

$$\mathbf{p}=A(\mathbf{k},\mathbf{p})\cdot\mathbf{p}_o,\quad \kappa(\mathbf{k}+\alpha\mathbf{p},\mathbf{p})=\kappa(\mathbf{k},\mathbf{p})+\alpha,\quad A(\mathbf{k}+\alpha\mathbf{p},\mathbf{p})=A(\mathbf{k},\mathbf{p}) \quad (40)$$

for all $\alpha\in\mathbb{R}$. From this one computes

$$h_2(\mathbf{b},B)\equiv(\kappa(\mathbf{b},\mathbf{p})\mathbf{p}_o,A(\mathbf{b},\mathbf{p}))^{-1}B),\quad \mathbf{p}=B\cdot\mathbf{p}_o,$$

and

$$\begin{aligned}&h_2(\mathbf{b},B)[h_2((\mathbf{a},A)^{-1}(\mathbf{b},B))]^{-1}\\&\quad=([\kappa(\mathbf{b},\mathbf{p})-\kappa((\mathbf{a},A)^{-1}(\mathbf{b},\mathbf{p}))]\mathbf{p}_o,[A(\mathbf{b},\mathbf{p})]^{-1}A[A((\mathbf{a},A)^{-1}(\mathbf{b},\mathbf{p}))]).\end{aligned} \quad (41)$$

Equation (38) now reads

$$\begin{aligned}[U^{\beta\lambda}(\mathbf{a},A)F](\mathbf{k},\mathbf{p})&=\exp\{i\beta(\kappa(\mathbf{k},\mathbf{p})-\kappa[(\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p})])\}\\&\quad\times M_\lambda\{[A(\mathbf{k},\mathbf{p})]^{-1}A[A((\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p}))]\}F((\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p})).\end{aligned} \quad (42)$$

In order to compare (42) with (26), we choose

$$A(\mathbf{k},\mathbf{p})=\sigma_0(\mathbf{p}),\quad \kappa(\mathbf{k},\mathbf{p})=\mathbf{k}\cdot\mathbf{q}, \quad (43)$$

where $\mathbf{q}$ is a null vector such that $\mathbf{p}\cdot\mathbf{q}=1$. This special choice of section yields

$$[U^{\beta\lambda}(\mathbf{a},A)F](\mathbf{k},\mathbf{p})=\exp\{i\beta\mathbf{a}\cdot\mathbf{q}\}M_\lambda(\sigma_0(\mathbf{p})^{-1}A\sigma_0(A^{-1}\mathbf{p}))F((\mathbf{a},A)^{-1}(\mathbf{k},\mathbf{p})) \quad (44)$$

with $F\in\mathscr{H}^{\beta\lambda}_{\text{phase}}$ and $M_\lambda(\tau)$ given by (21). By setting $\beta=1$, the representation (44) is strikingly similar to the representation (26). Note also that (40) precludes the choice $\kappa(\mathbf{k},\mathbf{p})=\mathbf{k}\cdot\mathbf{p}$; so, we may not obtain such a similarity between (42) and (26), the standard irreducible representation.

The choice (43) for the section is special, leading directly to the orthogonality relations which follow. Other choices give more complicated relations. The variety of results so obtainable have been worked out for the 1+1-dimensional Poincaré group but only in representations with trivial multiplier (Ref. 38).

IV. ORTHOGONALITY RELATIONS

We now introduce an isometry from $L^2_\nu(\mathscr{P}/H_1)$ to a closed subspace of $L^2_\mu(\mathscr{P}/H_2)$ by first deriving an appropriate orthogonality relation. The orthogonality relation will play many additional roles subsequently.

For this, it is convenient to establish a coordinate system, so that some of the computations are easier to follow. As always, we choose $\mathbf{p}_o=(1,0,0,1)$; then $\mathbf{p}_o\cdot\mathbf{p}_o=0$. We also choose $\mathbf{q}_o$, $\mathbf{u}_o$, $\mathbf{v}_o\in\mathbb{R}^4$ such that $\mathbf{q}_o\cdot\mathbf{q}_o=0$, $\mathbf{u}_o\cdot\mathbf{u}_o=\mathbf{v}_o\cdot\mathbf{v}_o=-1$, $\mathbf{p}_o\cdot\mathbf{q}_o=1$, $\mathbf{p}_o\cdot\mathbf{u}_o=\mathbf{p}_o\cdot\mathbf{v}_o=\mathbf{q}_o\cdot\mathbf{u}_o=\mathbf{q}_o\cdot\mathbf{v}_o=\mathbf{u}_o\cdot\mathbf{v}_o=0$. Define, for $\mathbf{p}\in V_0^+$, $\mathbf{q}_\mathbf{p}\equiv\sigma_0(\mathbf{p})\cdot\mathbf{q}_o$, $\mathbf{u}_\mathbf{p}\equiv\sigma_0(\mathbf{p})\cdot\mathbf{u}_o$, $\mathbf{v}_\mathbf{p}\equiv\sigma_0(\mathbf{p})\cdot\mathbf{v}_o$. Then any vector $\mathbf{a}\in\mathbb{R}^4$ may be written in coordinates as

$$\mathbf{b}=(\mathbf{b}\cdot\mathbf{q}_\mathbf{p})\mathbf{p}+(\mathbf{b}\cdot\mathbf{p})\mathbf{q}_\mathbf{p}-(\mathbf{b}\cdot\mathbf{u}_\mathbf{p})\mathbf{u}_\mathbf{p}-(\mathbf{b}\cdot\mathbf{v}_\mathbf{p})\mathbf{v}_\mathbf{p}; \tag{45}$$

i.e., by (43),

$$\mathbf{b}-\kappa(\mathbf{b},\mathbf{p})\mathbf{p}=(\mathbf{b}\cdot\mathbf{p})\mathbf{q}_\mathbf{p}-(\mathbf{b}\cdot\mathbf{u}_\mathbf{p})\mathbf{u}_\mathbf{p}-(\mathbf{b}\cdot\mathbf{v}_\mathbf{p})\mathbf{v}_\mathbf{p}. \tag{46}$$

In this coordinate system, the invariant measure (10) on $\mathbb{R}^3\times\mathbb{R}^1\times S^2$ becomes

$$d\mu(\mathbf{b}+\mathbb{R}\mathbf{p},\mathbf{p})=d\lambda_\mathbf{p}(\mathbf{b})\,d\nu(\mathbf{p})=d(\mathbf{b}\cdot\mathbf{p})d(\mathbf{b}\cdot\mathbf{u}_\mathbf{p})d(\mathbf{b}\cdot\mathbf{v}_\mathbf{p})(p^0)^{-1}dp^1\wedge dp^2\wedge dp^3. \tag{47}$$

Theorem 4.1: *(Orthogonality) Let $U^{\mathbf{p}_o\lambda}$ be the irreducible zero mass representation of the Poincaré group on $L^2_\nu(\mathscr{P}/H_1)$ as in Theorem 3.1, (25). Let $\mathscr{E}$ be the multiplication operator on $L^2_\nu(\mathscr{P}/H_1)$ given by*

$$(\mathscr{E}\psi)(\mathbf{k})=\mathscr{E}(\mathbf{k})\,\psi(\mathbf{k}). \tag{48}$$

Let η_1, η_2, φ_1, $\varphi_2\in L^2_\nu(\mathscr{P}/H_1)$. Let W_η be defined by

$$W_\eta: L^2_\nu(\mathscr{P}/H_1)\to\mathbb{C}^\mathscr{P}, \tag{49}$$

$$[W_\eta(\varphi)](\mathbf{b},B)=\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\mathbf{b},B)\,\eta,\varphi\rangle. \tag{50}$$

For any section σ_2 given by (39) with $\kappa(\mathbf{k},\mathbf{p})=\mathbf{k}\cdot\mathbf{q}$, $W_\eta(\varphi)$ as a function on $\mathscr{P}/H_2$ is defined by

$$[W_\eta(\varphi)](\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p})\equiv[W_\eta(\varphi)](\sigma_2(\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p})). \tag{51}$$

Define positive operator C on $L^2_\nu(\mathscr{P}/H_2)$ by

$$(C^2\eta)(\mathbf{p})\equiv 4(2\pi)^3(p^0+p^3)^{-2}\eta(\mathbf{p}). \tag{52}$$

If

$$\mathscr{E}(\mathbf{k})=\sqrt{k^0}=((k^1)^2+(k^2)^2+(k^3)^2)^{1/4}, \tag{53}$$

then

$$\langle W_{\eta_2}(\varphi_2),W_{\eta_1}(\varphi_1)\rangle_{L^2_\mu(\mathscr{P}/H_2)}=\langle\eta_1,C^2\eta_2\rangle_{L^2_\nu(\mathscr{P}/H_1)}\langle\varphi_2,\varphi_1\rangle_{L^2_\nu(\mathscr{P}/H_1)}; \tag{54}$$

conversely (54) holds for all η_1, $\eta_2\in D(C)$, φ_1, $\varphi_2\in L^2_\nu(\mathscr{P}/H_1)$ iff $|\mathscr{E}(\mathbf{p})|=\sqrt{p^0}$.

Proof: In the computation below, we shall use a delta function property; we begin with a derivation of this property: From (46) we compute,

$$(\mathbf{p}-\mathbf{t})\cdot(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k})=(\mathbf{b}\cdot\mathbf{k})((\mathbf{p}-\not{\ell})\cdot\mathbf{q}_\mathbf{k})-(\mathbf{b}\cdot\mathbf{u}_\mathbf{k})((\mathbf{p}-\not{\ell})\cdot\mathbf{u}_\mathbf{k})-(\mathbf{b}\cdot\mathbf{v}_\mathbf{k})((\mathbf{p}-\not{\ell})\cdot\mathbf{v}_\mathbf{k}). \tag{55}$$

Hence

$$\int d\lambda_{\mathbf{k}}(\mathbf{b})\exp\{i(\mathbf{p}-\mathbf{t})\cdot(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k})\} = \int d(\mathbf{b}\cdot\mathbf{k})d(\mathbf{b}\cdot\mathbf{u}_{\mathbf{k}})d(\mathbf{b}\cdot\mathbf{v}_{\mathbf{k}})\exp\{i[(\mathbf{b}\cdot\mathbf{k})((\mathbf{p}-\mathbf{t})\cdot\mathbf{q}_{\mathbf{k}}) - (\mathbf{b}\cdot\mathbf{u}_{\mathbf{k}})((\mathbf{p}-\mathbf{t})\cdot\mathbf{u}_{\mathbf{k}})]\}\exp\{-i(\mathbf{b}\cdot\mathbf{v}_{\mathbf{k}})((\mathbf{p}-\mathbf{t})\cdot\mathbf{v}_{\mathbf{k}})]\}$$
$$= (2\pi)^3\delta((\mathbf{p}-\mathbf{t})\cdot\mathbf{q}_{\mathbf{k}})\delta((\mathbf{p}-\mathbf{t})\cdot\mathbf{u}_{\mathbf{k}})\delta((\mathbf{p}-\mathbf{t})\cdot\mathbf{v}_{\mathbf{k}}). \quad (56)$$

Now if $\mathbf{p}$ is any null vector, from (45) we may write

$$\mathbf{p} = (\mathbf{p}\cdot\mathbf{k})\mathbf{q}_{\mathbf{k}} + (\mathbf{p}\cdot\mathbf{q}_{\mathbf{k}})\mathbf{k} - (\mathbf{p}\cdot\mathbf{u}_{\mathbf{k}})\mathbf{u}_{\mathbf{k}} - (\mathbf{p}\cdot\mathbf{v}_{\mathbf{k}})\mathbf{v}_{\mathbf{k}}.$$

Then, for purposes of integration after applying the δ-functions in (56), one obtains

$$0 = \mathbf{p}\cdot\mathbf{p} = 2(\mathbf{p}\cdot\mathbf{k})(\mathbf{p}\cdot\mathbf{q}_{\mathbf{k}}) - (\mathbf{p}\cdot\mathbf{u}_{\mathbf{k}})^2 - (\mathbf{p}\cdot\mathbf{v}_{\mathbf{k}})^2 = 2(\mathbf{p}\cdot\mathbf{k})(\mathbf{t}\cdot\mathbf{q}_{\mathbf{k}}) - (\mathbf{t}\cdot\mathbf{u}_{\mathbf{k}})^2 - (\mathbf{t}\cdot\mathbf{v}_{\mathbf{k}})^2.$$

If also $\mathbf{t}\cdot\mathbf{t}=0$, then

$$0 = 2(\mathbf{t}\cdot\mathbf{k})(\mathbf{t}\cdot\mathbf{q}_{\mathbf{k}}) - (\mathbf{t}\cdot\mathbf{u}_{\mathbf{k}})^2 - (\mathbf{t}\cdot\mathbf{v}_{\mathbf{k}})^2;$$

consequently,

$$\mathbf{p}\cdot\mathbf{k} = \mathbf{t}\cdot\mathbf{k}.$$

We may therefore restate (56) in the symbolic form

$$\int d\lambda_{\mathbf{k}}(\mathbf{b})\exp\{-i(\mathbf{p}-\mathbf{t})\cdot(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k})\} = (2\pi)^3\delta(\mathbf{p}-\mathbf{t}). \quad (57)$$

We see from this form that the result is independent of the choice made for the basis elements $\mathbf{q}_o$, $\mathbf{u}_o$, $\mathbf{v}_o$.

We now use (57) to prove the theorem. Initially assume either that η_1,η_2 are such that $U^{\mathbf{p}_o\lambda}(\sigma_2\circ\pi_2(\mathbf{b},B))\eta_i$ is in the domain of $\mathscr{E}$ for all $(\mathbf{b},B)\in\mathscr{P}$, or that φ_1,φ_2 are in the domain of $\mathscr{E}$. We have, for $\mathbf{k}\equiv B\cdot\mathbf{p}_o$,

$$\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2\circ\pi_2(\mathbf{b},B))\eta_i,\varphi_i\rangle = \langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k},\sigma_0(\mathbf{k}))\eta_i,\varphi_i\rangle$$
$$= \int d\nu(\mathbf{p})\mathscr{E}(\mathbf{p})\exp\{-i\mathbf{p}\cdot(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k})\}$$
$$\times\overline{M_\lambda(\sigma_0(\mathbf{p})^{-1}B\sigma_0(B^{-1}\cdot\mathbf{p})\eta_i(\sigma_0(\mathbf{k})^{-1}\mathbf{p}))}\varphi_i(\mathbf{p}). \quad (58)$$

However,

$$\langle W_{\eta_2}(\varphi_2),W_{\eta_1}(\varphi_1)\rangle_{L^2_\mu(\mathscr{P}/H_2)} = \int_{\mathscr{P}/H_2} d\mu((\pi^2(\mathbf{b},B))\overline{[W_{\eta_1}(\varphi_1)](\sigma_2(\pi_2(\mathbf{b},B)))}$$
$$\times[W_{\eta_2}(\varphi_2)](\sigma_2(\pi_2(\mathbf{b},B)))$$
$$= \int_{\mathscr{P}/H_2} d\mu(\pi_2(\mathbf{b},B))\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\pi_2(\mathbf{b},B)))\eta_1,\varphi_1\rangle$$
$$\times\langle\varphi_2,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\pi_2(\mathbf{b},B)))\eta_2\rangle$$
$$= \int_{\mathscr{P}/H_2} d\mu(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k},\mathbf{k})\int d\nu(\mathbf{p})d\nu(\mathbf{t})$$

$$
\begin{aligned}
&\times \exp\{-i(\mathbf{p}-\mathbf{t})\cdot(\mathbf{b}-\kappa(\mathbf{b},\mathbf{k})\mathbf{k})\}\overline{M_\lambda(\sigma_0(\mathbf{p})^{-1}B\sigma_0(B^{-1}\cdot\mathbf{p}))}\\
&\times M_\lambda(\sigma_0(\mathbf{t})^{-1}B\sigma_0(B^{-1}\cdot\mathbf{t}))\overline{\mathscr{E}(\mathbf{p})}\mathscr{E}(\mathbf{t})\\
&\times\overline{\eta_1(\sigma_0(\mathbf{k})^{-1}\mathbf{p})}\,\eta_2(\sigma_0(\mathbf{k})^{-1}\mathbf{t})\varphi_1(\mathbf{p})\overline{\varphi_2(\mathbf{t})}\\
=&\int d\nu(\mathbf{p})d\nu(\mathbf{t})\overline{\mathscr{E}(\mathbf{p})}\mathscr{E}(\mathbf{t})\varphi_1(\mathbf{p})\overline{\varphi_2(\mathbf{t})M_\lambda(\sigma_0(\mathbf{p})^{-1}B\sigma_0(B^{-1}\cdot\mathbf{p}))}\\
&\times M_\lambda(\sigma_0(\mathbf{t})^{-1}B\sigma_0(B^{-1}\cdot\mathbf{t}))\delta(\mathbf{p}-\mathbf{t})(2\pi)^3\\
&\times\int d\nu(\mathbf{k})\overline{\eta_1(\sigma_0(\mathbf{k})^{-1}\mathbf{p})}\,\eta_2(\sigma_0(\mathbf{k})^{-1}\mathbf{t})\\
=&\int d\nu(\mathbf{p})\varphi_1(\mathbf{p})\overline{\varphi_2(\mathbf{p})}|\mathscr{E}(\mathbf{p})|^2(p^0)^{-1}\\
&\times\left[(2\pi)^3\int d\nu(\mathbf{k})\overline{\eta_1(\sigma_0(\mathbf{k})^{-1}\mathbf{p})}\,\eta_2(\sigma_0(\mathbf{k})^{-1}\mathbf{p})\right]\\
=&\int d\nu(\mathbf{p})\varphi_1(\mathbf{p})\overline{\varphi_2(\mathbf{p})}|\mathscr{E}(\mathbf{p})|^2(p^0)^{-1}N_{12}(\mathbf{p})\\
=&\langle\varphi_2,EN_{12}\varphi_1\rangle_{L^2_\nu(P/H_1)},
\end{aligned}
\tag{59}
$$

where

$$
N_{12}(\mathbf{p})\equiv(2\pi)^3\int d\nu(\mathbf{k})\overline{\eta_1(\sigma_0(\mathbf{k})^{-1}\mathbf{p})}\,\eta_2(\sigma_0(\mathbf{k})^{-1}\mathbf{p})
\tag{60}
$$

and

$$
E(\mathbf{p})=|\mathscr{E}(\mathbf{p})|^2(p^0)^{-1}.
$$

We shall show that N_{12} is independent of $\mathbf{p}$. Recall $\eta(\mathbf{k})=f(0,\sigma_0(\mathbf{k}))$ for some f transforming under $U^{\mathbf{p}_o\lambda}$ as in (25). Then

$$
N_{12}=(2\pi)^3\int d\nu(\mathbf{k})\overline{f_1(0,\sigma_0(\mathbf{k})^{-1}\sigma_0(\mathbf{p}))}f_2(0,\sigma_0(\mathbf{k})^{-1}\sigma_0(\mathbf{p})).
\tag{61}
$$

Define F by $F(0,\sigma_0(\mathbf{p}))=f(0,\sigma_0(\mathbf{p})^{-1})$. Then, by the SL(2,$\mathbb{C}$) invariance of ν,

$$
\begin{aligned}
N_{12}&=(2\pi)^3\int d\nu(\mathbf{k})\overline{F_1(0,\sigma_0(\mathbf{p})^{-1}\sigma_0(\mathbf{k}))}F_2(0,\sigma_0(\mathbf{p})^{-1}\sigma_0(\mathbf{k}))\\
&=(2\pi)^3\int d\nu(\mathbf{k})\overline{F_1(0,\sigma_0(\mathbf{k}))}F_2(0,\sigma_0(\mathbf{k}))=(2\pi)^3\int d\nu(\mathbf{k})\overline{f_1(0,\sigma_0(\mathbf{k})^{-1})}f_2(0,\sigma_0(\mathbf{k})^{-1}).
\end{aligned}
$$

Also, we have from (7) and (18), $\sigma_0(\mathbf{k})^{-1}=\sigma_0(\tilde{\mathbf{k}})h(\mathbf{k})$ for some null vector $\tilde{\mathbf{k}}$, and some element $h(\mathbf{k})$ of $E(2)^{\sim}$. Using (22) and the analog of (30) common to any induction procedure, we obtain

$$
N_{12}=(2\pi)^3\int d\nu(\mathbf{k})\overline{f_1(\sigma_0(\tilde{\mathbf{k}})h(\mathbf{k}))}f_2(0,\sigma_0(\tilde{\mathbf{k}})h(\mathbf{k}))=(2\pi)^3\int d\nu(\mathbf{k})\overline{f_1(0,\sigma_0(\tilde{\mathbf{k}}))}f_2(0,\sigma_0(\tilde{\mathbf{k}})).
$$

With a similar computation, one also shows that the last expression is independent of any particular choice for σ_0, any other choice again differing by an $E(2)\tilde{}$-valued function acting on the right. To proceed, it then suffices to compute $\tilde{\mathbf{k}}$ using any convenient choice of section σ_0. We do this in the Appendix in order to extract the Jacobian $d\tilde{\mathbf{k}}/d\mathbf{k}$, which is all we need for what follows. We obtain

$$[(\tilde{k})^0]^{-1} d\tilde{\mathbf{k}}/d\mathbf{k} = -4[k^0]^{-1}[k^0+k^3]^{-2}. \tag{62}$$

Using this, and substituting $\tilde{\mathbf{k}}=\mathbf{r}$, we compute

$$\begin{aligned} N_{12} &= (2\pi)^3 \int d\nu(\mathbf{k}) \overline{f_1(0,\sigma_0(\tilde{\mathbf{k}}))} f_2(0,\sigma_0(\tilde{\mathbf{k}})) = (2\pi)^3 \int d\nu(\mathbf{k}) \overline{\eta_1(\tilde{\mathbf{k}})}\, \eta_2(\tilde{\mathbf{k}}) \\ &= (2\pi)^3 \int \frac{d\mathbf{k}}{k^0} \overline{\eta_1(\tilde{\mathbf{k}})}\, \eta_2(\tilde{\mathbf{k}}) = (2\pi)^3 \int d\mathbf{k}\, \frac{d\mathbf{k}}{d\tilde{\mathbf{k}}} \frac{1}{k^0} \overline{\eta_1(\tilde{\mathbf{k}})}\, \eta_2(\tilde{\mathbf{k}}) \\ &= (2\pi)^3 \int d\mathbf{r}\, \frac{d\tilde{\mathbf{r}}}{d\mathbf{r}} \frac{1}{\tilde{r}^0} \overline{\eta_1(\mathbf{r})}\, \eta_2(\mathbf{r}) = 4(2\pi)^3 \int \frac{d\mathbf{r}}{r^0} (r^0+r^3)^{-2} \overline{\eta_1(\mathbf{r})}\, \eta_2(\mathbf{r}) \\ &= \langle \eta_1, C^2 \eta_2 \rangle_{L^2_\nu(P/H_1)}. \end{aligned} \tag{63}$$

Then (59) becomes

$$\langle W_{\eta_2}(\varphi_2), W_{\eta_1}(\varphi_1) \rangle_{L^2_\mu(\mathscr{P}/H_2)} = \langle \varphi_2, E\varphi_1 \rangle_{L^2_\nu(P/H_1)} \langle \eta_1, C^2 \eta_2 \rangle_{L^2_\nu(P/H_1)}$$

which equals

$$\langle \varphi_2, \varphi_1 \rangle_{L^2_\nu(P/H_1)} \langle \eta_1, C^2 \eta_2 \rangle_{L^2_\nu(P/H_1)}$$

iff $E(\mathbf{p})=1$, i.e., $|\mathscr{E}(\mathbf{p})| = \sqrt{p^0}$.

This proves (54) under the initial assumptions on η_1,η_2 or φ_1,φ_2. However, C^2 acting on $L^2_\nu(\mathscr{P}/H_1)$, being an operator of pointwise multiplication by a function that is nonzero, has dense range. Thus (54) and (52) have unique bounded linear extensions. □

The integral (63) is geometrically more transparent if one uses the coordinates $\{p^0+p^3, p^1, p^2\}$ rather than $\{p^1,p^2,p^3\}$. Here as in (10), there is the constraint $p^0+p^3 \geqslant 0$. The Jacobian for this transformation is $p^0/(p^0+p^3)$ and (63) becomes

$$\begin{aligned} N_{12} &= 4(2\pi)^3 \int \frac{dp^1 dp^2 dp^3}{p^0} (p^0+p^3)^{-2} \overline{\eta_1(\mathbf{p})}\, \eta_2(\mathbf{p}) \\ &= 4(2\pi)^3 \int d(p^0+p^3) dp^1 dp^2 (p^0+p^3)^{-3} \overline{\eta_1(\mathbf{p})}\, \eta_2(\mathbf{p}) \end{aligned} \tag{64}$$

where the integral is over the half-space $p^0+p^3 \geqslant 0$.

Corollary 4.2: With the notation above and choosing $\eta_1=\eta_2=\eta$ so that $N_{11} \equiv \|C\eta\|^2 = 1$, then W_η is an isometry: $W_\eta : L^2_\nu(\mathscr{P}/H_1) \to L^2_\mu(\mathscr{P}/H_2)$. Defining the representation $U^{\eta,\lambda}$ of $\mathscr{P}$ on the range of W_η in $L^2_\mu(\mathscr{P}/H_2)$ by intertwining,

$$U^{\eta,\lambda} \equiv W_\eta U^{\mathbf{p}_o \lambda} W_\eta^{-1}, \tag{65}$$

then $U^{\eta,\lambda}$ is an irreducible representation of $\mathscr{P}$.

Proof: One need only show that W_η is a closed operator, the proof of which is straightforward. Then the range of W_η is closed subspace $\mathscr{H}_\eta$ of $L^2_\mu(\mathscr{P}/H_2)$. □

In a similar fashion, one could begin with the representation $U^{\beta\lambda}$ on $L^2_\mu(\mathscr{P}/H_2)$ as in (29), and form the pull-back representation $W_\eta^{-1}U^{\beta\lambda}W_\eta$ on $L^2_\nu(\mathscr{P}/H_1)$. Since $U^{\beta\lambda}$ is not irreducible, as we show below, this is not as useful.

Notation: Henceforth, we shall say that η is admissible if $N\equiv\|C\eta\|^2<\infty$. Furthermore, the symbol η will henceforth be reserved to denote an admissible vector.

The projection: $L^2_\mu(\mathscr{P}/H_2)\to$the range of W_η will be denoted P^η.

V. PHASE SPACE LOCALIZATION AND INTERTWINING WITH PHASE SPACE REPRESENTATIONS

We recall the familiar result that, for massive irreducible representations of the Poincaré group, there are Euclidean covariant Euclidean space localization operators[1,12] allowing one to define ''massive elementary particles.'' This result has been generalized to show the existence of phase space localization operators covariant under the action of the entire Poincaré group.[31] On the other hand, it was also shown[1,12] that no Euclidean covariant Euclidean space localization operator existed for the photon or for other massless particles of helicity greater than 1. We shall next show that this precludes intertwining the standard irreducible massless representations with any left-quasiregular representation on phase space such as is given in (44). Nevertheless, we shall exhibit explicitly the phase space representation intertwined via the W_η given above.

Definition: Define the family $A\equiv\{A(\Delta)|\Delta$ a Borel set in $\mathscr{P}/H_2\}$ on $L^2_\mu(\mathscr{P}/H_2)$ through multiplication by characteristic functions χ_Δ for Borel sets Δ:

$$\begin{aligned}&\Delta\mapsto A(\Delta)=M_{\chi_\Delta};\\ &[A(\Delta)f](\mathbf{y})=\chi_\Delta(\mathbf{y})f(\mathbf{y})a.e.\mathbf{y},\quad f\in L^2_\mu(\mathscr{P}/H_2).\end{aligned}\tag{66}$$

On $L^2_\nu(\mathscr{P}/H_1)$ define the family A_η by

$$A_\eta\equiv\{A_\eta(\Delta)|\Delta=\text{Borel set of } \mathscr{P}/H_2\},\tag{67}$$

where

$$A_\eta(\Delta)\equiv W_\eta^{-1}P^\eta A(\Delta)W_\eta\equiv W_\eta^{-1}P^\eta A(\Delta)P^\eta W_\eta.\tag{68}$$

Since A is the phase space localization operator on $L^2_\mu(\mathscr{P}/H_2)$, and A_η is its pullback to the irreducible representation space $L^2_\nu(\mathscr{P}/H_1)$, A_η is the natural choice for a phase space localization operator for massless particles.

Definition: Let G be a group on $\mathscr{P}/H_2$ and let U be a representation of G on $L^2_\mu(\mathscr{P}/H_2)$. The phase space localization operator A is said to be G-covariant with respect to U if and only if

$$U(g)A(\Delta)U(g)^{-1}=A(g\cdot\Delta)\ \text{ for all }\ \Delta\in\text{Borel}(\mathscr{P}/H_2),\quad g\in G.$$

Theorem 5.1: *The family $A=\{A(\Delta)|\Delta=$Borel set in $\mathscr{P}/H_2\}$ is a $\mathscr{P}$-covariant projection-valued measure (PVM) on $L^2_\mu(\mathscr{P}/H_2)$ with respect to $U^{\beta\lambda}$ of (44) [and not with respect to $U^{\eta,\lambda}$ of (65)]. A_η is a positive operator-valued measure (POVM) on $L^2_\nu(\mathscr{P}/H_1)$.*

Proof: That A is a PVM is trivial. To see the covariance, choose $f\in L^2_\mu(\mathscr{P}/H_2)$. Now, from (44) we have, for $\varphi\equiv\kappa(\mathbf{k},\mathbf{p})-\kappa((\mathbf{b},B)^{-1}(\mathbf{k},\mathbf{p}))$,

$$\begin{aligned}&[U^{\beta\lambda}(\mathbf{b},B)A(\Delta)U^{\beta\lambda}(\mathbf{b},B)^{-1}F](\mathbf{k},\mathbf{p})\\ &\quad=\exp\{i\beta\varphi\}M_\lambda(\sigma_0(\mathbf{p})^{-1}B\sigma_0(B^{-1}\mathbf{p}))[A(\Delta)U^{\beta\lambda}(\mathbf{b},B)^{-1}F](B^{-1}\cdot(\mathbf{k}-\mathbf{b}),B^{-1}\cdot\mathbf{p})\end{aligned}$$

$$= \begin{cases} 0 & \text{if } (B^{-1}\cdot(\mathbf{k}-\mathbf{b}), B^{-1}\cdot\mathbf{p}) \notin \Delta \\ F(\mathbf{k},\mathbf{p}) & \text{if } (B^{-1}\cdot(\mathbf{k}-\mathbf{b}), B^{-1}\cdot\mathbf{p}) \in \Delta \end{cases}$$

$$= [A((\mathbf{b},B)\circ\Delta)F](\mathbf{k},\mathbf{p}) \tag{69}$$

where

$$(\mathbf{k},\mathbf{p}) \in (\mathbf{b},B)\circ\Delta \quad \text{iff} \quad (\mathbf{b},B)^{-1}(\mathbf{k},\mathbf{p}) = (B^{-1}\cdot(\mathbf{k}-\mathbf{b}), B^{-1}\cdot\mathbf{p}) \in \Delta.$$

Hence, A is $\mathscr{P}$-covariant with respect to $U^{\beta\lambda}$. Since A_η is the projection of a PVM, it is a POVM. □

As a consequence of Theorem 5.1, we have the following:

Result: Let U be an irreducible representation of $\mathscr{P}$ on a Hilbert space $\mathscr{H}$. Let W intertwine U with the left-regular representation V of $\mathscr{P}$ on $L^2_\mu(\mathscr{P}/H_2)$. Let P denote the projection of $L^2_\mu(\mathscr{P}/H_2)$ onto the range of W. Let B be defined by

$$B(\Delta) = W^\dagger P A(\Delta) W, \quad \Delta \in \text{Borel}(\mathscr{P}/H_2),$$

where A is the phase space localization operator defined above. Then B is a $\mathscr{P}$-covariant localization operator on $\mathscr{H}$.

Proof: Since $WU(g) = V(g)W$ for all $g \in \mathscr{P}$, one has $U(g)W^\dagger W = W^\dagger W U(g)$ for all $g \in \mathscr{P}$. Since U is irreducible, $W^\dagger W = \gamma \mathbf{1}$ for some $\gamma > 0$. Then

$$(\gamma^{-1} W W^\dagger) W\phi = \gamma^{-1} W(W^\dagger W)\phi = W\phi$$

for all $\phi \in \mathscr{H}$. Therefore, if $f \in L^2_\mu(\mathscr{P}/H_2)$ is orthogonal to the range of W, then

$$\langle \gamma^{-1} W W^\dagger f, W\phi\rangle = \gamma^{-1}\langle W^\dagger f, W^\dagger W\phi\rangle = \langle W^\dagger f, \phi\rangle = \langle f, W\phi\rangle = 0.$$

Thus, $\gamma^{-1} W W^\dagger = P$. It follows by intertwining that $V(g)P = PV(g)$ for all $g \in \mathscr{P}$. Hence, for all $g \in \mathscr{P}$,

$$U(g^{-1})B(\Delta)U(g) = U(g^{-1})W^\dagger P A(\Delta) W U(g) = W^\dagger V(g^{-1}) P A(\Delta) V(g) W$$
$$= W^\dagger P V(g^{-1}) A(\Delta) V(g) W = W^\dagger P A(g\cdot\Delta) W = B(g\cdot\Delta).$$

□

In particular, if we take W to be W_η defined through (51) and $B = A_\eta$, then if W_η intertwined the irreducible representation $U^{\xi\lambda}$ in (24) with $U^{\beta\lambda}$ in (29) or (44), it follows that A_η would define a $\mathscr{P}$-covariant configuration space localization operator, and hence a Euclidean space localization operator covariant under the Euclidean subgroup of $\mathscr{P}$. This would contradict the result of Wightman (Ref. 12, pp. 850, 862). One concludes that W_η cannot intertwine $U^{\xi\lambda}$ with any phase space representation of $\mathscr{P}$ such as $U^{\beta\lambda}$.

To obtain the same result without relying on Wightman's result, we may do the following: Define a Euclidean subgroup of $\mathscr{P}$, by first picking a preferred time axis. In the basis defining the notation of (45), the time direction corresponds to $\mathbf{p}+2\mathbf{q}_\mathbf{p}$. Then, $(\mathbf{u}_\mathbf{p}, \mathbf{v}_\mathbf{p}, \mathbf{p}-2\mathbf{q}_\mathbf{p})$ forms a basis of spacelike vectors in what may viewed as ordinary momentum space. This identification of ''ordinary space'' is not Poincaré invariant, but is invariant under the subgroup $\text{SL}(2,\mathbb{C})_{\mathbf{p}+2\mathbf{q}_\mathbf{p}} \cong O(3)$ of $\text{SL}(2,\mathbb{C})$. Then $\mathbb{R}^4 \circledcirc \text{SL}(2,\mathbb{C})_{\mathbf{p}+2\mathbf{q}_\mathbf{p}} \cong \mathbb{R}^4 \circledcirc O(3)$ includes the Euclidean group $E(3) = [\mathbb{R}^4/(\mathbf{p}+2\mathbf{q}_\mathbf{p})] \circledcirc \text{SL}(2,\mathbb{C})_{\mathbf{p}+2\mathbf{q}_\mathbf{p}}$.

The next theorem isolates the desired intertwining condition.

Theorem 5.2: *For $U^{p_o\lambda}$ as in (25), $U^{\beta\lambda}$ as in (29), and W_η as in (49) and (50), then*

$$W_\eta U^{\mathbf{p}_o\lambda}(g) = U^{\beta\lambda}(g) W_\eta \tag{70}$$

iff $g \in \mathscr{P}$ *satisfies*

$$\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(g^{-1}\cdot\mathbf{x}))\eta = U^{\mathbf{p}_o\lambda}(g^{-1})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \quad a.e. \quad \mathbf{x}. \tag{71}$$

Proof: We have

$$\begin{aligned}[W_\eta U^{\mathbf{p}_o\lambda}(g)\varphi](\mathbf{x}) &\equiv [W_\eta U^{\mathbf{p}_o\lambda}(g)\varphi](\sigma_2(\mathbf{x})). = \langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o\lambda}(g)\varphi\rangle \\ &= \langle U^{\mathbf{p}_o\lambda}(g^{-1})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \varphi\rangle. \end{aligned} \tag{72}$$

On the other hand,

$$\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(g^{-1}\cdot\mathbf{x}))\eta, \varphi\rangle = [W_\eta\phi](\sigma_2(g^{-1}\cdot\mathbf{x})) \equiv [W_\eta\phi](g^{-1}\cdot\mathbf{x}) = U^{\beta\lambda}(g)[W_\eta\varphi](\mathbf{x}). \tag{73}$$

Since both (72) and (73) hold for all φ, then (70) is equivalent to (71). □

The condition (71) is the source of the general failure of achieving Euclidean covariance in the massless representations of the Poincaré group. To see this, suppose $g \in \mathbb{R}^4 \circledcirc \mathrm{SL}(2,\mathbb{C})_{\mathbf{p}+2\mathbf{q}_\mathbf{p}}$. It follows that $\mathscr{E}U^{\mathbf{p}_o\lambda}(g) = U^{\mathbf{p}_o\lambda}(g)\mathscr{E}$. Then (71) reduces to showing that

$$U^{\mathbf{p}_o\lambda}(\sigma_2(g^{-1}\cdot\mathbf{x}))\eta = U^{\mathbf{p}_o\lambda}(g^{-1}\sigma_2(\mathbf{x}))\eta, \quad a.e. \quad \mathbf{x}.$$

By using σ_2 as defined in (39) and (43) and setting $\mathbf{x}=(\mathbf{k},\mathbf{p})$ and $g=(\mathbf{b},B)$, one shows that this is equivalent to

$$U^{\mathbf{p}_o\lambda}((-\mathbf{b}\cdot\mathbf{q})\mathbf{p}, A(\mathbf{k},\mathbf{p})^{-1}BA(B^{-1}(\mathbf{k}-\mathbf{b}), B^{-1}\mathbf{p}))\eta = \eta \quad \text{for all } (\mathbf{k},\mathbf{p}).$$

For $U^{\mathbf{p}_o\lambda}$ as in (25), this requires $\eta=0$.

For comparison, we note that a similar analysis in the massive case has a nontrivial solution, namely that η be rotation invariant (Ref. 31).

We exhibit precisely the form of the irreducible unitary phase space representation intertwined from $U^{\mathbf{p}_o\lambda}$ by (65).

Theorem 5.3: *The irreducible representation* $U^{\eta,\lambda}$ *intertwined from* $U^{\mathbf{p}_o\lambda}$ *by (65) is given, for* $N=\|C\eta\|^2$*, by the integral representation*

$$[U^{\eta,\lambda}(g)(P^\eta f)](\mathbf{x}) = N^{-1}\int d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\pi, U^{\mathbf{p}_o\lambda}(g)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle(P^\eta f)(\mathbf{y}). \tag{74}$$

Proof: From (72) we have

$$[W_\eta U^{\mathbf{p}_o\lambda}(g)\varphi](\mathbf{x}) = \langle U^{\mathbf{p}_o\lambda}(g^{-1})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \varphi\rangle.$$

Using the orthogonality relation (54), this reads

$$\begin{aligned}[W_\eta U^{\mathbf{p}_o\lambda}(g)\varphi](\mathbf{x}) &= N^{-1}\langle W_\eta U^{\mathbf{p}_o\lambda}(g^{-1})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, W_\eta\varphi\rangle \\ &= N^{-1}\int d\mu(\mathbf{y})\overline{[W_\eta U^{\mathbf{p}_o\lambda}(g^{-1})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta](\mathbf{y})}[W_\eta\varphi](\mathbf{y}).\end{aligned}$$

From the definition (50) of W_η, this may be written

$$\begin{aligned}&[W_\eta U^{\mathbf{p}_o\lambda}(g)W_\eta^{-1}W_\eta\varphi](\mathbf{x}) \\ &\quad = [W_\eta U^{\mathbf{p}_o\lambda}(g)\varphi](\mathbf{x})\end{aligned}$$

$$= N^{-1} \int d\mu(\mathbf{y}) \langle \mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o \lambda}(g)\mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{y}))\eta \rangle [W_\eta \varphi](\mathbf{y}).$$

By (65), (74) follows. □

Again we see that (74) does not correspond to the left-quasiregular representation for the action of g unless (72) is satisfied.

VI. QUANTIZATION AND DEQUANTIZATION

With the results above, we may define a natural quantization scheme. On $L^2_\mu(\mathscr{P}/H_2)$, and for f a measurable function on $\mathscr{P}/H_2$, define the operator M_r by

$$[M_r f](\mathbf{y}) \equiv r(\mathbf{y}) f(\mathbf{y}). \tag{75}$$

For $\psi \in L^2_\nu(\mathscr{P}/H_1)$, define $A_\eta(r)\psi$ by

$$A_\eta(r)\psi \equiv W_\eta^{-1} P^\eta M_r W_\eta \psi. \tag{76}$$

Theorem 6.1: (Quantization):

$$A_\eta(r) = \int_{\mathscr{P}/H_2} r(\mathbf{x}) |\mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta\rangle\langle \mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta| d\mu(\mathbf{x}). \tag{77}$$

Proof: Let ψ, $\varphi \in L^2_\nu(\mathscr{P}/H_1)$. We have,

$$\begin{aligned}\langle \varphi, A_\eta(r)\psi\rangle &= \langle \varphi, W_\eta^{-1} P^\eta M_r W_\eta \psi\rangle = \langle W_\eta \varphi, P^\eta M_r W_\eta \psi\rangle = \langle W_\eta \varphi, M_r W_\eta \psi\rangle \\ &= \int \overline{[W_\eta \phi](\mathbf{x})} [M_r W_\eta \psi](\mathbf{x}) d\mu(\mathbf{x}) \\ &= \int \langle \varphi, \mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta\rangle r(\mathbf{x}) \langle \mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta, \psi\rangle d\mu(\mathbf{x}).\end{aligned}$$

□

Remark: If $r(\mathbf{x}) \equiv 1$, a.e. $\mathbf{x}$, then (77) shows that $A_\eta(r) = 1$. Alternatively,

$$\int_{\mathscr{P}/H_2} |U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta\rangle\langle U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta| d\mu(\mathbf{x}) = \mathscr{E}^{-2}. \tag{78}$$

We introduce the notation

$$T^\eta(\mathbf{x}) \equiv |\mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta\rangle\langle \mathscr{E} U^{\mathbf{p}_o \lambda}(\sigma_2(\mathbf{x}))\eta|. \tag{79}$$

Then Theorem 6.1 may be reexpressed

$$A_\eta(r) = \int_{\mathscr{P}/H_2} r(\mathbf{x}) T^\eta(\mathbf{x}) d\mu(\mathbf{x}). \tag{80}$$

There is also a natural dequantization scheme:

Theorem 6.2. *(Dequantization): Let ρ be a density operator in $L^2_\nu(\mathscr{P}/H_1)$, and define*

$$R_\rho(\mathbf{x}) \equiv \mathrm{Tr}(\rho T^\eta(\mathbf{x})). \tag{81}$$

Then R_ρ is a classical probability density over the phase space $\mathscr{P}/H_2$ and, moreover,

$$\mathrm{Tr}(\rho A_\eta(r)) = \int_{\mathscr{P}/H_2} R_\rho(\mathbf{x}) r(\mathbf{x}) d\mu(\mathbf{x}); \tag{82}$$

i.e., the quantum and classical expectations agree, making the quantization map and the dequantization map dual in the sense of (82).

Proof: The theorem follows from (80), (81), and the interchangeability of trace with the integral. □

Two questions which we now ask are:

(1) Which operators in $L^2_\nu(\mathscr{P}/H_1)$ may be written in the form (76) and (80) for some measurable function r?
(2) Does the set of expressions in (81), $\{R_\rho(\mathbf{x}) \equiv \mathrm{Tr}(\rho T^\eta(\mathbf{x})) | \mathbf{x} \in \mathscr{P}/H_2\}$, uniquely determine ρ?

To analyze this, we introduce the concept of ''informational completeness:''

Definition: A collection $\{A_\alpha | \alpha \in I\}$ of operators acting on Hilbert space $\mathscr{H}$ is said to be informationally complete iff, for ρ_1 and ρ_2 any positive trace class operators of trace one on $\mathscr{H}$, the equality $\mathrm{Tr}(\rho_1 A_\alpha) = \mathrm{Tr}(\rho_2 A_\alpha)$ for all $\alpha \in I$, implies $\rho_1 = \rho_2$.

A result of P. Busch[39] shows that, if $\{A_\alpha | \alpha \in I\}$ is informationally complete, then the closure of the span of $\{A_\alpha | \alpha \in I\} \cup \{\mathbf{1}\}$ [in the sense of a topology related to the form $A \mapsto \mathrm{Tr}(\rho A)$] includes all of $\mathscr{B}(\mathscr{H})$. In this sense, possessing the informational completeness property implies a positive response to both questions. This has a physical interpretation if the A_α are all quantum observables (that is, they are self-adjoint, or at least symmetric operators), since the positive traceclass operators of trace one on $\mathscr{H}$ are the quantum statistical density operators and $\mathrm{Tr}(\rho A)$ is just quantum expectation. The question of informational completeness is addressed as we introduce families of localization operators below.

VII. INFORMATIONAL COMPLETENESS OF THE LOCALIZATION OPERATOR

To demonstrate the informational completeness property, we will use the mathematical trick of introducing an action of the Heisenberg group on an extension of the phase space representation of zero mass particles. Then we will employ the known informational completeness property of the Wigner coefficients of the Heisenberg group:

Consider $\phi \in L^2(V_0^+, d\nu)$, $d\nu(\mathbf{k}) = d(\mathbf{k}\cdot\mathbf{q}_0) d(\mathbf{k}\cdot\mathbf{u}_0) d(\mathbf{k}\cdot\mathbf{v}_0)/\mathbf{k}\cdot\mathbf{q}_0$. Since, for $\mathbf{k} \in V_0^+$, $\mathbf{k}\cdot\mathbf{p}_0 = [(\mathbf{k}\cdot\mathbf{u}_0)^2 + (\mathbf{k}\cdot\mathbf{v}_0)^2]/2\mathbf{k}\cdot\mathbf{q}_0$, we may consider $V_0^+ \cong \mathbb{R}^+ \times \mathbb{R}^2$, and functions ϕ in V_0^+ to be functions ϕ of $(\mathbf{k}\cdot\mathbf{q}_0, \mathbf{k}\cdot\mathbf{u}_0, \mathbf{k}\cdot\mathbf{v}_0)$ in $\mathbb{R}^+ \times \mathbb{R}^2$ which are extended to all of $\mathbb{R}^3$ with support on the closure of V_0^+. We set

$$j: V_0^+ \to \mathbb{R}^3, \quad j(\mathbf{k}) = (\mathbf{k}\cdot\mathbf{q}_0, \mathbf{k}\cdot\mathbf{u}_0, \mathbf{k}\cdot\mathbf{v}_0). \tag{83}$$

Similarly, j^{-1}: $\mathbb{R}^3 \to V_0^+ \cup V_0^- \cup \{\mathbf{0}\}$, and j^{-1} maps $\mathbf{x} \in \mathbb{R}^3$ into V_0^+ iff $\mathbf{x} = (x_0, x_1, x_2)$ with $x_0 > 0$.

We may now define the bijective isometry

$$J: L^2(V_0^+, d\nu) \to L^2(\mathbb{R}^3), \quad J: \phi(\mathbf{k}) \to |\mathbf{k}\cdot\mathbf{q}_0|^{-1/2} \widetilde{\phi}(j(\mathbf{k})). \tag{84}$$

By (64), η is admissible iff

$$\int_{\mathbb{R}^2} d(\mathbf{k}\cdot\mathbf{u}_0) d(\mathbf{k}\cdot\mathbf{v}_0) \int_{\mathbb{R}^+} d(\mathbf{k}\cdot\mathbf{q}_0) (\mathbf{k}\cdot\mathbf{q}_0)^{-3} |\eta(\mathbf{k})|^2 < \infty.$$

Thus, as a function of $\mathbf{k}\cdot\mathbf{q}_0$, if η is smooth, it may be extended smoothly to a function on $\mathbb{R}^3$.

Now, for $t \in \mathbb{R}$, $\mathbf{r}' \in V_0^+$, $\mathbf{r}'\cdot\mathbf{q}_0 = 0$ (the ''prime'' $'$ will henceforth signal this condition), define

$$l(\mathbf{r}') = (\mathbf{r}'\cdot\mathbf{p}_0, -\mathbf{r}'\cdot\mathbf{u}_0, -\mathbf{r}'\cdot\mathbf{v}_0) \in \mathbb{R}^3. \tag{85}$$

These are the coordinates of $\mathbf{r}\prime=(\mathbf{r}\prime\cdot\mathbf{p}_0)\mathbf{q}_0-(\mathbf{r}\prime\cdot\mathbf{u}_0)\mathbf{u}_0-(\mathbf{r}\prime\cdot\mathbf{v}_0)\mathbf{v}_0$ *relative to the basis* $\{\mathbf{q}_0,\mathbf{u}_0,\mathbf{v}_0\}$; *with respect to the Minkowski metric, this basis is dual to the basis* $\{\mathbf{p}_0, -\mathbf{u}_0, -\mathbf{v}_0\}$ *for which the coordinates are given by the map* j.

Next, for such $\mathbf{r}\prime$ *and for* $\mathbf{s}\in\mathbb{R}^4$, *define a representation* W *of the Heisenberg group by*

$$W(t,l(\mathbf{r}'),j(\mathbf{s})):L^2(\mathbb{R}^3)\to L^2(\mathbb{R}^3),$$

$$[W(t,l(\mathbf{r}'),j(\mathbf{s}))J\phi](\mathbf{x})=e^{-i\pi l(\mathbf{r}')\cdot j(\mathbf{s})}e^{i2\pi(t+l(\mathbf{r}')\cdot(\mathbf{x}+j(\mathbf{s})))}[J\phi](\mathbf{x}+j(\mathbf{s})),\quad \mathbf{x}\in\mathbb{R}^3, \tag{86}$$

where $l(\mathbf{r}')\cdot j(\mathbf{s})$ and $l(\mathbf{r}')\cdot(\mathbf{x}+j(\mathbf{s}))$ employs the usual inner product in $\mathbb{R}^3$. Because $\mathbf{r}'\cdot\mathbf{q}_0=0$, these two inner products agree with the Minkowski inner products $\mathbf{r}'\cdot\mathbf{s}$ and $\mathbf{r}'\cdot(j^{-1}(\mathbf{x})+\mathbf{s})$, and we may write

$$[W(t,l(\mathbf{r}'),j(\mathbf{s}))J\phi](\mathbf{x})=e^{-i\pi\mathbf{r}'\cdot\mathbf{s}}e^{i2\pi(t+\mathbf{r}'\cdot(j^{-1}(\mathbf{x})+\mathbf{s}))}[J\phi](\mathbf{x}+j(\mathbf{s})). \tag{87}$$

One verifies the Heisenberg relation

$$W(t,l(\mathbf{r}'),j(\mathbf{s}))W(u,l(\mathbf{q}'),j(\mathbf{p}))=W(t+u+(\mathbf{q}'\cdot\mathbf{s}+\mathbf{r}'\cdot\mathbf{p})/2,l(\mathbf{r}')+l(\mathbf{q}'),j(\mathbf{s})+j(\mathbf{p})),$$

$$\mathbf{q}'\cdot\mathbf{q}_0=0. \tag{88}$$

The Heisenberg orthogonality relations are computed and expressed as

$$\int_{\mathbb{R}^6}d(\mathbf{r}'\cdot\mathbf{p}_0)d(\mathbf{r}'\cdot\mathbf{u}_0)d(\mathbf{r}'\cdot\mathbf{v}_0)d(\mathbf{s}\cdot\mathbf{q}_0)d(\mathbf{s}\cdot\mathbf{u}_0)d(\mathbf{s}\cdot\mathbf{v}_0)\langle J\phi_1,W(0,l(\mathbf{r}'),j(\mathbf{p}))J\phi_2\rangle_{L^2(\mathbb{R}^3)}$$
$$\times\langle W(0,l(\mathbf{r}'),j(\mathbf{s}))J\phi_3,J\phi_4\rangle_{L^2(\mathbb{R}^3)}=\langle J\phi_3,J\phi_2\rangle_{L^2(\mathbb{R}^3)}\langle J\phi_1,J\phi_4\rangle_{L^2(\mathbb{R}^3)}. \tag{89}$$

If we denote by U the action of the Poincaré group on $L^2(V_0^-)$ with invariant measure $d\nu(\mathbf{k})=d(\mathbf{k}\cdot\mathbf{q}_0)d(\mathbf{k}\cdot\mathbf{u}_0)d(\mathbf{k}\cdot\mathbf{v}_0)/|\mathbf{k}\cdot\mathbf{q}_0|$ corresponding to the same helicity as the representation U on $L^2(V_0^+)$, then the Heisenberg operators are computed to have the following covariance with respect to our section of the Poincaré group:

Theorem 7.1: For $\mathbf{x}=(\mathbf{a}+\mathbb{R}\mathbf{p},\mathbf{p})$, $\sigma(\mathbf{x})=(\mathbf{a}',A_{\mathbf{p}})$, $\mathbf{a}'=\mathbf{a}-(\mathbf{a}\cdot\mathbf{q}_{\mathbf{p}})\mathbf{p}$ (*hence* $\mathbf{a}'\cdot\mathbf{q}_0=0$), *then*

$$U(\sigma(\mathbf{x}))^{-1}J^{-1}W(0,l(\mathbf{r}'),j(\mathbf{s}))JU(\sigma(\mathbf{x}))=e^{i\mathbf{a}'\cdot\mathbf{s}}J^{-1}W(0,l(A_{\mathbf{p}}^{-1}\mathbf{r}'),j(A_{\mathbf{p}}^{-1}\mathbf{s}))J. \tag{90}$$

We may now reexpress the expected values of the phase space localization operators as follows:

$$\begin{aligned}
&\langle\phi_2,T_\eta(\mathbf{x})\phi_1\rangle_{L^2(V_0^+)}\\
&\quad=\langle U(\sigma(\mathbf{x}))\eta,\phi_1\rangle_{L^2(V_0^+)}\langle\phi_1,U(\sigma(\mathbf{x}))\eta\rangle_{L^2(V_0^+)}\\
&\quad=\langle JU(\sigma(\mathbf{x}))\eta,J\phi_1\rangle_{L^2(\mathbb{R}^3)}\langle J\phi_1,JU(\sigma(\mathbf{x}))\eta\rangle_{L^2(\mathbb{R}^3)}\\
&\quad=\int_{\mathbb{R}^6}d(\mathbf{r}'\cdot\mathbf{p}_0)d(\mathbf{r}'\cdot\mathbf{u}_0)d(\mathbf{r}'\cdot\mathbf{v}_0)d(\mathbf{s}\cdot\mathbf{q}_0)d(\mathbf{s}\cdot\mathbf{u}_0)d(\mathbf{s}\cdot\mathbf{v}_0)\\
&\qquad\times\langle J\phi_2,W(0,l(\mathbf{r}'),j(\mathbf{s}))J\phi_1\rangle_{L^2(\mathbb{R}^3)}\langle W(0,l(\mathbf{r}'),j(\mathbf{s}))JU(\sigma(\mathbf{x}))\eta,JU(\sigma(\mathbf{x}))\eta\rangle_{L^2(\mathbb{R}^3)}\\
&\quad=\int_{\mathbb{R}^6}d(\mathbf{r}'\cdot\mathbf{p}_0)d(\mathbf{r}'\cdot\mathbf{u}_0)d(\mathbf{r}'\cdot\mathbf{v}_0)d(\mathbf{s}\cdot\mathbf{q}_0)d(\mathbf{s}\cdot\mathbf{u}_0)d(\mathbf{s}\cdot\mathbf{v}_0)\\
&\qquad\times\langle J\phi_2,W(0,l(\mathbf{r}'),j(\mathbf{s}))J\phi_1\rangle_{L^2(\mathbb{R}^3)}e^{-i\mathbf{a}'\cdot\mathbf{s}}\langle W(0,l(A_{\mathbf{p}}^{-1}\mathbf{r}'),j(A_{\mathbf{p}}^{-1}\mathbf{s}))J\eta,J\eta\rangle_{L^2(\mathbb{R}^3)}
\end{aligned}$$

$$
\begin{aligned}
&= \int_{\mathbb{R}^6} d(\mathbf{r}'\cdot\mathbf{p}_0)d(\mathbf{r}'\cdot\mathbf{u}_0)d(\mathbf{r}'\cdot\mathbf{v}_0)d(\mathbf{s}\cdot\mathbf{q}_0)d(\mathbf{s}\cdot\mathbf{u}_0)d(\mathbf{s}\cdot\mathbf{v}_0)e^{-il(\mathbf{a}')\cdot j(\mathbf{s})} \\
&\quad\times\langle J\phi_2, W(0,l(\mathbf{r}'-\mathbf{q}_\mathbf{p}),j(\mathbf{s}))J\phi_1\rangle_{L^2(\mathbb{R}^3)} \\
&\quad\times\langle W(0,l(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p})),j(A_\mathbf{p}^{-1}\mathbf{s}))J\eta, J\eta\rangle_{L^2(\mathbb{R}^3)},
\end{aligned}
\tag{91}
$$

where we have introduced the shift $\mathbf{r}'\to\mathbf{r}'-\mathbf{q}_\mathbf{p}$, $\mathbf{q}_\mathbf{p}=A_\mathbf{p}\mathbf{q}_0$, in order to ''center'' the last factor in $j(V_0^+)$.

Next, as in the informational completeness proof for the affine group,[40] we introduce a ''chirp,'' c. Define

$$
c(\mathbf{t}) = e^{i\pi\mathbf{t}\cdot\mathbf{t}}, \quad \mathbf{t}\in\mathbb{R}^3. \tag{92}
$$

Take

$$
J\eta = cg, \quad \text{some } g\in L^2(\mathbb{R}^3). \tag{93}
$$

Then

$$
\begin{aligned}
&\langle W(0,l(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p}),j(A_\mathbf{p}^{-1}\mathbf{s})))J\eta, J\eta\rangle_{L^2(\mathbb{R}^3)} \\
&\quad=\langle W(0,l(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p}),j(A_\mathbf{p}^{-1}\mathbf{s})))cg, cg\rangle_{L^2(\mathbb{R}^3)} \\
&\quad=\int_{\mathbb{R}^3} d^3\mathbf{t}\overline{c(\mathbf{t})g(\mathbf{t})}e^{-i\pi(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p}))\cdot A_\mathbf{p}^{-1}\mathbf{s}}e^{i2\pi(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p}))\cdot(j^{-1}\mathbf{t}+A_\mathbf{p}^{-1}\mathbf{s})}c(\mathbf{t}+j(\mathbf{s}))g(\mathbf{t}+j(\mathbf{s})) \\
&\quad=\langle W(0,l(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p})+j(A_\mathbf{p}^{-1}\mathbf{s}),j(A_\mathbf{p}^{-1}\mathbf{s})))g, g\rangle_{L^2(\mathbb{R}^3)} \\
&\quad=\langle W(0,l(A_\mathbf{p}^{-1}\mathbf{r}'-\mathbf{q}_0)+j(A_\mathbf{p}^{-1}\mathbf{s}),j(A_\mathbf{p}^{-1}\mathbf{s}))g, g\rangle_{L^2(\mathbb{R}^3)}.
\end{aligned}
\tag{94}
$$

Finally, also as in the informational completeness proof for the affine group, we show that by replacing η with a delta sequence $\{\eta_\lambda\}$, we may isolate the Fourier transform of all Wigner coefficients $\langle W(0,l(A_\mathbf{p}^{-1}\mathbf{r}' - \mathbf{q}_0) + j(A_\mathbf{p}^{-1}\mathbf{s}),j(A_\mathbf{p}^{-1}))g, g\rangle_{L^2(\mathbb{R}^3)}$. As an example, if one takes $g=g_\lambda\in L^2(\mathbb{R}^3)$,

$$
g_\lambda(\mathbf{t}) = Ne^{-\pi\mathbf{t}\cdot\mathbf{t}/\lambda^2}, \tag{95}
$$

N a normalization constant, then one obtains

$$
\begin{aligned}
&\langle W(0,l(A_\mathbf{p}^{-1}\mathbf{r}'-\mathbf{q}_0)+j(A_\mathbf{p}^{-1}\mathbf{s}),j(A_\mathbf{p}^{-1}\mathbf{s}))g_\lambda, g_\lambda\rangle_{L^2(\mathbb{R}^3)} \\
&\quad=e^{-i\pi j(A_\mathbf{p}^{-1}\mathbf{s})\cdot j(A_\mathbf{p}^{-1}\mathbf{s})/(2\lambda^2)}e^{-\pi\lambda^2\{l[A_\mathbf{p}^{-1}\mathbf{r}'-\mathbf{q}_0]+j(A_\mathbf{p}^{-1}\mathbf{s})\}\cdot\{l[A_\mathbf{p}^{-1}\mathbf{r}'-\mathbf{q}_0]+j(A_\mathbf{p}^{-1}\mathbf{s})\}/2} \\
&\quad=e^{-\pi j(A_\mathbf{p}^{-1}\mathbf{s})\cdot j(A_\mathbf{p}^{-1}\mathbf{s})/(2\lambda^2)}\lambda^{-3}2^{-5/2}K_\lambda(l[A_\mathbf{p}^{-1}\mathbf{r}'-\mathbf{q}_0]+j[A_\mathbf{p}^{-1}\mathbf{s}])
\end{aligned}
\tag{96}
$$

where $\{K_\lambda|\lambda>0,\lambda^{-1}\to0^+\}$ is a delta sequence (Ref. 27, pp. 309–310). Also, in the limit $\lambda^{-1}\to0^+$, the first exponential converges to 1. We therefore have

$$
\begin{aligned}
&\lambda^3 2^{5/2}\langle\phi_2, T_{\eta_\lambda}(\mathbf{x})\phi_1\rangle_{L^2(V_0^+)} \\
&=\lambda^3 2^{5/2}\int_{\mathbb{R}^6} d(\mathbf{r}'\cdot\mathbf{p}_0)d(\mathbf{r}'\cdot\mathbf{u}_0)d(\mathbf{r}'\cdot\mathbf{v}_0)d(\mathbf{s}\cdot\mathbf{q}_0)d(\mathbf{s}\cdot\mathbf{u}_0)d(\mathbf{s}\cdot\mathbf{v}_0)e^{-il(\mathbf{a}')\cdot j(\mathbf{s})} \\
&\quad\times\langle J\phi_2, W(0,l(\mathbf{r}'-\mathbf{q}_\mathbf{p}),j(\mathbf{s}))J\phi_1\rangle_{L^2(\mathbb{R}^3)}\langle W(0,l(A_\mathbf{p}^{-1}(\mathbf{r}'-\mathbf{q}_\mathbf{p}),j(A_\mathbf{p}^{-1}\mathbf{s}))cg_\lambda, cg_\lambda\rangle_{L^2(\mathbb{R}^3)}
\end{aligned}
$$

$$= \int_{\mathbb{R}^6} d(\mathbf{r}'\cdot\mathbf{p_0})d(\mathbf{r}'\cdot\mathbf{u_0})d(\mathbf{r}'\cdot\mathbf{v_0})d(\mathbf{s}\cdot\mathbf{q_0})d(\mathbf{s}\cdot\mathbf{u_0})d(\mathbf{s}\cdot\mathbf{v_0})e^{-il(\mathbf{a}')\cdot j(\mathbf{s})}$$
$$\times\langle J\phi_2, W(0,l(\mathbf{r}'-\mathbf{q_p}),j(\mathbf{s}))J\phi_1\rangle_{L^2(\mathbb{R}^3)} e^{-\pi j(A_{\mathbf{p}}^{-1}\mathbf{s})\cdot j(A_{\mathbf{p}}^{-1}\mathbf{s})/(2\lambda^2)}$$
$$\times K_\lambda(l[A_{\mathbf{p}}^{-1}\mathbf{r}'-\mathbf{q}_0]+j[A_{\mathbf{p}}^{-1}\mathbf{s}])$$
$$\to_{\lambda^{-1}\to 0^+} \int_{\mathbb{R}^3} d(\mathbf{s}\cdot\mathbf{q_0})d(\mathbf{s}\cdot\mathbf{u_0})d(\mathbf{s}\cdot\mathbf{v_0})e^{-il(\mathbf{a}')\cdot j(\mathbf{s})}\langle J\phi_2, W(0,l(\mathbf{r}'\cdot\mathbf{q_p}),j(\mathbf{s}))J\phi_1\rangle_{L^2(\mathbb{R}^3)}. \quad (97)$$

Similarly, for

$$\rho = \sum_k \gamma_k P_{\phi_k}$$

any density operator in $L^2_\nu(V_0^+)$,

$$\lambda^3 2^{5/2}\mathrm{Tr}_{L^2_\nu(V_0^+)}(\rho T_{\eta_\lambda}(\mathbf{x})) \to_{\lambda^{-1}\to 0^+} \int_{\mathbb{R}^3} d(\mathbf{s}\cdot\mathbf{q_0})d(\mathbf{s}\cdot\mathbf{u_0})d(\mathbf{s}\cdot\mathbf{v_0})e^{-il(\mathbf{a}')\cdot j(\mathbf{s})}$$
$$\times \mathrm{Tr}_{L^2(\mathbb{R}^3)}[J\rho J^{-1}W(0,l(\mathbf{r}'-\mathbf{q_p}),j(\mathbf{s}))]. \quad (98)$$

Here $\mathbf{r}'$ is given by

$$l[A_{\mathbf{p}}^{-1}\mathbf{r}'-\mathbf{q}_0]+j[A_{\mathbf{p}}^{-1}\mathbf{s}]=0; \quad (99)$$

i.e.,

$$(A_{\mathbf{p}}^{-1}\mathbf{r}'\cdot\mathbf{p_0}+1, -A_{\mathbf{p}}^{-1}\mathbf{r}'\cdot\mathbf{u_0}, -A_{\mathbf{p}}^{-1}\mathbf{r}'\cdot\mathbf{v_0})+(A_{\mathbf{p}}^{-1}\mathbf{s}\cdot\mathbf{q_0}, A_{\mathbf{p}}^{-1}\mathbf{s}\cdot\mathbf{u_0}, A_{\mathbf{p}}^{-1}\mathbf{s}\cdot\mathbf{v_0})=0; \quad (100)$$

so,

$$\mathbf{r}'\cdot\mathbf{p_0} = (\mathbf{p}\cdot\mathbf{q_0})^{-1}[1+(\mathbf{r}'\cdot\mathbf{u_0})(\mathbf{p}\cdot\mathbf{u_0})+(\mathbf{r}'\cdot\mathbf{v_0})(\mathbf{p}\cdot\mathbf{v_0})]-\mathbf{s}\cdot\mathbf{q_0},$$
$$\mathbf{r}'\cdot\mathbf{u_0} = \mathbf{s}\cdot\mathbf{u_0}-(\mathbf{p}\cdot\mathbf{u_0})(\mathbf{s}\cdot\mathbf{q_0})(\mathbf{p}\cdot\mathbf{q_0})^{-1}, \quad (101)$$
$$\mathbf{r}'\cdot\mathbf{v_0} = \mathbf{s}\cdot\mathbf{v_0}-(\mathbf{p}\cdot\mathbf{v_0})(\mathbf{s}\cdot\mathbf{q_0})(\mathbf{p}\cdot\mathbf{q_0})^{-1}.$$

Hence

$$l(\mathbf{r}'-\mathbf{q_0}) = (-\mathbf{p}\cdot\mathbf{q_0}+(\mathbf{p}\cdot\mathbf{q_0})^{-1}+(\mathbf{p}\cdot\mathbf{q_0})^{-1}[(\mathbf{s}'\cdot\mathbf{u_0})(\mathbf{p}\cdot\mathbf{u_0})+(\mathbf{s}'\cdot\mathbf{v_0})(\mathbf{p}\cdot\mathbf{v_0})]-(\mathbf{s}\cdot\mathbf{q_0})$$
$$\times(\mathbf{p}\cdot\mathbf{q_0})^{-2}[(\mathbf{p}\cdot\mathbf{u_0})^2+(\mathbf{p}\cdot\mathbf{v_0})^2]-\mathbf{s}\cdot\mathbf{q_0},\ \mathbf{s}\cdot\mathbf{u_0}-(\mathbf{p}\cdot\mathbf{u_0})(\mathbf{s}\cdot\mathbf{q_0})(\mathbf{p}\cdot\mathbf{q_0})^{-1},$$
$$\mathbf{s}\cdot\mathbf{v_0}-(\mathbf{p}\cdot\mathbf{v_0})(\mathbf{s}\cdot\mathbf{q_0})(\mathbf{p}\cdot\mathbf{q_0})^{-1}). \quad (102)$$

Therefore, the map $(\mathbf{p},\mathbf{s})\mapsto(l(A_{\mathbf{p}}^{-1}\mathbf{r}'-\mathbf{q}_0), j(\mathbf{s}))$, $V_0^+\times\mathbb{R}^4\to\mathbb{R}^6$ is surjective, and all Wigner coefficients $\mathrm{Tr}_{L^2(\mathbb{R}^3)}[J\rho J^{-1}W(0,l(\mathbf{r}'-\mathbf{q_p}),j(\mathbf{s}))]$ may be obtained by Fourier transform. By the informational completeness of these coefficients[40] $J\rho J^{-1}$, and hence ρ, is determined uniquely.

For consistency with the original problem in $L^2_\nu(V_0^+)$, one needs to work with a slightly different delta sequence than this Gaussian net $\{\eta_\lambda\}$ for the informational completeness since none of these η_λ are supported on V_0^+; however, as the example shows, it is enough for the distribution to be centered at $\mathbf{q_p}\in V_0^+$, and this may be accomplished with suitably supported delta sequences.

VIII. EXPLICIT FORMULAS FOR P^η AND W_η^{-1}

To simplify subsequent analysis, we present explicit expressions for P^η and W_η^{-1}.

Theorem 8.1: *Let $f\in L^2_\mu(\mathscr{P}/H_2)$. Define P by*

$$(Pf)(\mathbf{z})\equiv\|C\eta\|^{-2}\int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle f(\mathbf{x}). \tag{103}$$

Then P is the projection P^η from $L^2_\mu(\mathscr{P}/H_2)$ to the range of W_η.

Proof: (1) $Pf\in$Range of W_η since we may rewrite the integral in (103) in the form

$$\int d\mu(\mathbf{x})f(\mathbf{x})[W_\eta(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta)](\mathbf{z}).$$

$$(2)\quad (PW_\eta\varphi)(\mathbf{z})=\|C\eta\|^{-2}\int d\mu(\mathbf{x})\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta,\varphi\rangle$$
$$=\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\varphi\rangle=(W_\eta\varphi)(\mathbf{z}).$$

Therefore P is the identity on the range of W_η.

$$(3)\quad (PPf)(\mathbf{z})=\|C\eta\|^{-2}\int d\mu(\mathbf{x})\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle(Pf)(\mathbf{x})$$
$$=\|C\eta\|^{-4}\int d\mu(\mathbf{x})d\mu(\mathbf{y})\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle$$
$$\times\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle f(\mathbf{y})$$
$$=\|C\eta\|^{-2}\int d\mu(\mathbf{y})\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle f(\mathbf{y})$$
$$=(Pf)(\mathbf{z}).$$

Therefore

$$P^2=P.$$

(4) P is an integral operator with kernel K such that $\overline{K(\mathbf{x},\mathbf{y})}=K(\mathbf{y},\mathbf{x})$. Thus

$$P=P^\dagger. \qquad \square$$

Theorem 8.2: *$W_\eta^{-1}:P^\eta L^2_\mu(\mathscr{P}/H_2)\to L^2_\nu(\mathscr{P}/H_1)$ is given by*

$$W_\eta^{-1}(P^\eta f)=N^{-1}\int (P^\eta f)(\mathbf{x})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\, d\mu(\mathbf{x}), \tag{104}$$

where $N=\|C\eta\|^2$.

Proof: Recall, $(W_\eta\varphi)(\mathbf{x})=\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta,\varphi\rangle$. Also, since for $f\in L^2_\mu(\mathscr{P}/H_2)$, there exists a unique $\varphi\in L^2_\nu(\mathscr{P}/H_1)$ such that $P^\eta f=W_\eta\varphi$, then for any $\psi\in L^2_\nu(\mathscr{P}/H_1)$ we compute

$$\left\langle\psi,N^{-1}\int (P^\eta f)(\mathbf{x})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\, d\mu(\mathbf{x})\right\rangle=\left\langle\psi,N^{-1}\int (W_\eta\varphi)(\mathbf{x})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\, d\mu(\mathbf{x})\right\rangle$$
$$=N^{-1}\int (W_\eta\varphi)(\mathbf{x})\overline{(W_\eta\psi)(\mathbf{x})}d\mu(\mathbf{x})=\langle\psi,\varphi\rangle$$
$$=\langle\psi,W_\eta^{-1}P^\eta f\rangle. \qquad \square$$

Theorem 8.3: *For P^{η} and W_{η} as above,*

$$P^{\eta}=\|C\eta\|^{-2}W_{\eta}W_{\eta}^{\dagger}. \tag{105}$$

Proof: From the orthogonality theorem we have

$$[W_{\eta}W_{\eta}^{\dagger}W_{\eta}\varphi](\mathbf{x})=\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, W_{\eta}^{\dagger}W_{\eta}\varphi\rangle=\langle W_{\eta}\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, W_{\eta}\varphi\rangle$$
$$=\|C\eta\|^2\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta,\varphi\rangle=\|C\eta\|^2[W_{\eta}\varphi](\mathbf{x}).$$

Thus $\|C\eta\|^{-2}W_{\eta}W_{\eta}^{\dagger}$ is the identity on the range of W_{η}. If f is orthogonal to the range of W_{η}, then

$$W_{\eta}W_{\eta}^{\dagger}f(\mathbf{x})=\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, W_{\eta}^{\dagger}f\rangle=\langle W_{\eta}\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, f\rangle=0. \qquad \square$$

With these results, we may present an alternate proof of the integral representation for $U^{\eta,\lambda}$ as intertwined from $U^{\mathbf{p}_o\lambda}$ and given in Theorem 5.3, (74).

Alternative Proof of Theorem 5.3:

$$[U^{\eta,\lambda}(g)(P^{\eta}f\ )](\mathbf{x})=(W_{\eta}U^{\mathbf{p}_o\lambda}(g)W_{\eta}^{-1}P^{\eta}f\ )(\mathbf{x})=\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o\lambda}(g)W_{\eta}^{-1}P^{\eta}f\rangle$$
$$=N^{-1}\left\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o\lambda}(g)\int (P^{\eta}f\ )(\mathbf{y})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\, d\mu(\mathbf{y})\right\rangle$$
$$=N^{-1}\int d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o\lambda}(g)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle(P^{\eta}f\ )(\mathbf{y}). \qquad \square$$

Corollary 8.4: Theorem 5.3 (74) may also be written, using Theorem 8.1, to read

$$[U^{\eta,\lambda}(g)(P^{\eta}f\ )](\mathbf{x})=N^{-1}\int d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o\lambda}(g)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle\|C\eta\|^{-2}$$
$$\times\int d\mu(\mathbf{z})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta\rangle f(\mathbf{z})$$
$$=N^{-1}\int d\mu(\mathbf{z})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, U^{\mathbf{p}_o\lambda}(g)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta\rangle f(\mathbf{z}). \tag{106}$$

This provides a explicit integral representation.

IX. COVARIANCE ASPECTS OF THE LOCALIZATION OPERATOR

We next determine the covariance properties of the phase space localization operators for the photon and other zero mass particles. For notation, see Sec. V.

Theorem 9.1: $A_{\eta}(\Delta)\varphi = N^{-1}\int_{\Delta}d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta,\varphi\rangle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta$; *i.e.,*

$$A_{\eta}(\Delta)=N^{-1}\int_{\Delta}d\mu(\mathbf{y})|\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta|=N^{-1}\int_{\Delta}d\mu(\mathbf{y})T^{\eta}(\mathbf{y}). \tag{107}$$

Proof: In fact, (107) follows immediately from (80); but for reasons given below, we offer an independent proof here:

$$A_{\eta}(\Delta)\varphi=W_{\eta}^{-1}P^{\eta}A(\Delta)W_{\eta}\varphi=N^{-1}\int_{\mathscr{P}/H_2}d\mu(\mathbf{x})(P^{\eta}A(\Delta)W_{\eta}\varphi)(\mathbf{x})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta$$

$$
\begin{aligned}
&= N^{-2}\int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\int_{\mathscr{P}/H_2} d\mu(\mathbf{y})\\
&\quad\times\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle (A(\Delta)W_\eta\varphi)(\mathbf{y})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\\
&= N^{-2}\int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\int_{\Delta} d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle\\
&\quad\times(W_\eta\varphi)(\mathbf{y})\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\\
&= N^{-2}\int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\int_{\Delta} d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle\\
&\quad\times\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta,\varphi\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\\
&= N^{-2}\int_{\Delta} d\mu(\mathbf{y})\int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta,\varphi\rangle\\
&\quad\times\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\\
&= N^{-1}\int_{\Delta} d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta,\varphi\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta. \qquad \square
\end{aligned}
$$

Equation (107) proves that $\Delta\to A_\eta(\Delta)$ is an absolutely continuous POVM with respect to the invariant measure, and A_η has operator density T^η. Then using the theory of integration with respect to a POVM one may establish a quantization scheme.[41] The specific quantization scheme from that theory gives precisely (80). Hence, one could have defined A and A_η by (66) and (68), and then derived the quantization scheme. In contrast, in Sec. V the localization is derived from the quantization scheme (75) and (76). *Theorem* 6.1 shows the equivalence of these two approaches.

Theorem 9.2: *As an operator on* $L^2_\nu(\mathscr{P}/H_1)$, A_η *satisfies*

$$\mathscr{E}U^{\mathbf{p}_o\lambda}(g)\mathscr{E}^{-1}A_\eta(\Delta)\mathscr{E}^{-1}U^{\mathbf{p}_o\lambda}(g)^{-1}\mathscr{E}=A_\eta(g[\Delta]). \tag{108}$$

Proof:

$$
\begin{aligned}
\mathscr{E}U^{\mathbf{p}_o\lambda}(g)\mathscr{E}^{-1}A_\eta(\Delta)\varphi &= \mathscr{E}N^{-1}\int_{\Delta} d\mu(\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta,\varphi\rangle U^{\mathbf{p}_o\lambda}(g\sigma_2(\mathbf{y}))\eta\\
&= \mathscr{E}N^{-1}\int_{y\in\Delta} d\mu(g\cdot\mathbf{y})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(g^{-1}\sigma_2(g\cdot\mathbf{y}))\eta,\varphi\rangle U^{\mathbf{p}_o\lambda}(\sigma_2(g\cdot\mathbf{y}))\eta\\
&= N^{-1}\int_{g[\Delta]} d\mu(\mathbf{z})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(g^{-1}\sigma_2(\mathbf{z}))\eta,\varphi\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta\\
&= N^{-1}\int_{g[\Delta]} d\mu(\mathbf{z})\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta,\mathscr{E}^{-1}U^{\mathbf{p}_o\lambda}(g)\mathscr{E}\varphi\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{z}))\eta\\
&= A_\eta(g[\Delta])\mathscr{E}^{-1}U^{\mathbf{p}_o\lambda}(g)\mathscr{E}\varphi.
\end{aligned}
$$

Thus

$$\mathscr{E}U^{\mathbf{p}_o\lambda}(g)\mathscr{E}^{-1}A_\eta(\Delta)=A_\eta(g[\Delta])\mathscr{E}^{-1}U^{\mathbf{p}_o\lambda}(g)\mathscr{E}. \qquad \square$$

Corollary 9.3: $\Delta\to\mathscr{E}^{-1}A_\eta(\Delta)\mathscr{E}^{-1}$ *defines a non-normalized POVM transforming covariantly under* $U^{\mathbf{p}_o\lambda}$:

$$U^{\mathbf{p}_o\lambda}(g)(\mathscr{E}^{-1}A_\eta(\Delta)\mathscr{E}^{-1})U^{\mathbf{p}_o\lambda}(g^{-1})=\mathscr{E}^{-1}A_\eta(g[\Delta])\mathscr{E}^{-1}. \tag{109}$$

Proof: From (108), the covariance follows. For the normalization

$$\mathscr{E}^{-1}A_\eta(\mathscr{P}/H_2)\mathscr{E}^{-1}=\mathscr{E}^{-2}, \quad \text{not } \mathbf{1}. \qquad \square$$

Remark: Equation (109) may be reexpressed

$$\mathscr{E}^{-1}A_\eta(\Delta)\mathscr{E}^{-1}\varphi=N^{-1}\int_\Delta d\mu(\mathbf{y})\langle U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta,\varphi\rangle U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta, \tag{110}$$

or

$$\mathscr{E}^{-1}A_\eta(\Delta)\mathscr{E}^{-1}=N^{-1}\int_\Delta d\mu(\mathbf{y})|U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta\rangle\langle U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{y}))\eta|. \tag{111}$$

It is not known at this time if this family of phase space localization operators reduces, by marginality, to the family of configuration space localization operators of Kraus[42] in the photon case.

X. THE ANALOG OF THE WIGNER TRANSFORM

We define a transform in analogy to the Wigner transform of nonrelativistic massive quantum theory:

Definition: The Wigner transform will be defined in the massless Poincaré case by

$$\rho\mapsto\{\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\rho)|\mathbf{x}\in\mathscr{P}/H_2\}, \tag{112}$$

and the Weyl dequantization by

$$B\mapsto\{\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))B)|\mathbf{x}\in\mathscr{P}/H_2\} \tag{113}$$

where B is any operator such that almost every $\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))B)$ exists.

Remark: As in the massive, nonrelativistic case, the right-hand side of (112) does not generally define a probability density, and (112) does not define a proper dequantization scheme.

Theorem 10.1: *Let $\eta\in D(C^2)$ and let η be admissible. Then the one-dimensional projection $P_{C^2\eta}$ is given by*

$$P_{C^2\eta}=\|C^2\eta\|^{-2}\int_{\mathscr{P}/H_2}\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x})),C^2\eta\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x}). \tag{114}$$

Proof: Let $\psi,\ \varphi\in D(\mathscr{E})$. Then

$$\begin{aligned}&\langle\psi,\|C^2\eta\|^{-2}\int_{\mathscr{P}/H_2}\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta,C^2\eta\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x})\varphi\rangle\\&=\|C^2\eta\|^{-2}\int_{\mathscr{P}/H_2}d\mu(\mathbf{x})\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta,C^2\eta\rangle\langle\psi,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\varphi\rangle\\&=\|C^2\eta\|^{-2}\langle C^2\eta,\varphi\rangle\langle\psi,C^2\eta\rangle=\langle\psi,P_{C^2\eta}\varphi\rangle\end{aligned}$$

for a dense set of φ,ψ. Hence, it holds for all $\varphi,\ \psi\in L^2_\nu(\mathscr{P}/H_1)$. $\square$

Theorem 10.2: *Let ρ be a density operator in $L^2_\nu(\mathscr{P}/H_1)$. Then*

$$\rho=\int_{\mathscr{P}/H_2}\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\rho)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x}); \tag{115}$$

i.e., $\{\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}|\mathbf{x}\in\mathscr{P}/H_2\}$ *is informationally complete in* $L^2_\nu(\mathscr{P}/H_1)$.

Proof: Begin with $\rho=\Sigma\rho_i P_{\psi_i}$, ψ_i in the range of C^2. Then, write $\psi_i=C^2\varphi_i$:

$$\begin{aligned}\rho&=\sum_i \rho_i\|C^2\varphi_i\|^{-2}\int_{\mathscr{P}/H_2}\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\varphi_i,C^2\varphi_i\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x})\\&=\sum_i \rho_i\|\psi_i\|^{-2}\int_{\mathscr{P}/H_2}\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\psi_i,\psi_i\rangle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x})\\&=\int_{\mathscr{P}/H_2}\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\sum_i \rho_i\|\psi_i\|^{-2}|\psi_i\rangle\langle\psi_i|)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x})\\&=\int_{\mathscr{P}/H_2}\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\rho)\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))d\mu(\mathbf{x}).\end{aligned}$$ □

This theorem does not carry direct physical meaning since physical observables are self-adjoint or symmetric operators, while the operators $\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}$ are not even symmetric.

Theorem 10.3:

$$\mathrm{Tr}(\rho B)=\int_{P/H_2}\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\rho)\mathrm{Tr}(\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))B)d\mu(\mathbf{x}); \tag{116}$$

that is, the quantum expectation and the analog of the classical expectation coincide.

Theorem 10.4: *For section* σ_2 *as in (39) and (40), operators* $U^{\mathbf{p}_o\lambda}$ *as in (25), and* $\mathscr{E}$ *as in (48) and (53), the set*

$$\{\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))|\mathbf{x}\in\mathscr{P}/H_2\} \tag{117}$$

is informationally complete in $L^2_\nu(\mathscr{P}/H_1)$. *Furthermore, the reconstruction of vector states* P_ψ *from the set* $\{\mathrm{Tr}(P_\psi\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x})))|\mathbf{x}\in\mathscr{P}/H_2\}$ *is particularly simple.*

Proof: Informational completeness follows from Theorem 10.2 and the invertibility of C^{-2}.

For the reconstruction of vector states, let $\{e_j|j=1,2,3,...\}$ be an orthonormal basis for $L^2_\nu(\mathscr{P}/H_1)$. Then

$$\begin{aligned}&\int_{\mathscr{P}/H_2}d\mu(\mathbf{x})\langle e_j,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle\mathrm{Tr}(P_\psi\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x})))\\&\quad=\int_{\mathscr{P}/H_2}d\mu(\mathbf{x})\langle e_j,\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle\langle\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\psi,\psi\rangle\\&\quad=\langle\psi,C^2\eta\rangle\langle e_j,\psi\rangle.\end{aligned}$$

Since

$$\langle\psi,C^2\eta\rangle\psi=\sum_j\langle\psi,C^2\eta\rangle\langle e_j,\psi\rangle e_j,$$

one can construct normalized vector ψ up to a constant phase from the set

$$\{\mathrm{Tr}(P_\psi\mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x})))|\mathbf{x}\in\mathscr{P}/H_2\}.$$ □

This approach also gives a formula for reconstructing P_ψ from its Wigner transform (112). In particular,

$$\int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\langle e_j, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle \mathrm{Tr}(P_\psi \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x})))$$

$$= \int_{\mathscr{P}/H_2} d\mu(\mathbf{x})\langle e_j, \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))\eta\rangle\langle \mathscr{E}U^{\mathbf{p}_o\lambda}(\sigma_2(\mathbf{x}))C^{-2}\psi, \psi\rangle = \langle \psi, \eta\rangle\langle e_j, \psi\rangle, \tag{118}$$

from which we can determine normalized ψ up to a constant phase, and hence P_ψ.

XI. COMPARISON WITH OTHER RESULTS

The methods used here are closest to those of Ali and Antoine[38,43] and Ali, Antoine, and Gazeau[44] in their treatment of the Poincaré group in two dimensions, but differ in several essential ways. First of all, in our treatment we intertwine irreducible representations with representations in $L^2_\mu(\mathscr{P}/H_2)$, but not with the left-quasiregular representation on $L^2_\mu(\mathscr{P}/H_2)$. Second, our orthogonality result (54) exhibits a factoring into a factor involving only the resolution generators and a second term that is independent of the resolution generators; this factorization plays a role in the proof of informational completeness. Furthermore, their treatment of the Poincaré group in two dimensions deals only with the massive case with a recent extension to the massless case,[45] while the present work deals with the massless case in the full four dimensions. In a sequel paper, we shall treat the massive case as well, but even there our two approaches will differ, this latter difference occurring since we use methods parallel to the general scheme employed to discuss informational completeness of Wigner coefficients and localization operators in the Heisenberg, affine, and Galilei groups;[40] in that setting, the presence of nontrivial cocycles requires a modification of the standard process. In the four-dimensional Poincaré group there are no nontrivial cocycles; however, for the two-dimensional Poincaré group, there is a one-dimensional manifold of inequivalent multiplier representations based on distinct cocycles (Ref. 46, pp. 478–484). For this reason, two-dimensional Galilean theory is closer to the two-dimensional Poincaré theory than the corresponding four-dimensional cases (and may be related by group contraction). Ali *et al.* discuss only the representation based on the trivial multiplier representation. The difference is in the nature of the approaches, ours beginning with the identification of the physically relevant and classically motivated homogeneous spaces, after which all related induced representations play a role. Fourth, the inclusion of all three spatial dimensions allows for spin and helicity. The nontrivial restrictions on the resolution generators under rotations that derive from the intertwining property are inherently connected with the identification of the value of *spin/helicity*. This simply cannot be discussed in the two-dimensional setting.

Points of similarity of their approach and ours are also manifold and include: the operator $\mathscr{E}$ appearing in (48) and (50), as well as the choice between the localization operator A_η transforming under a nonunitary representation of the group $\mathscr{P}$ [Eq. (108)] versus $\mathscr{E}^{-1}A_\eta\mathscr{E}^{-1}$ transforming covariantly under the ''proper'' unitary representation but being normalized to $\mathscr{E}^{-2}$ [Eq. (109)] are both consistent with the results of Ali *et al.* and would not be anticipated from results of others known to us.

Our approach here is different in spirit from all prior treatments based on deforming results in the massive case to massless ones by taking ''suitable'' limits. The treatment of the massive case, in particular, will be seen in the sequel to have no terms corresponding to the $\mathscr{E}$ factors here; therefore, the essential introduction of this $\mathscr{E}$ will not be obtained by any such limiting process, nor will the travelling coordinate system introduced in (64) arise in such a limit. In fact, essential

structural differences should occur between the massive and massless cases, since the geometry of the corresponding homogeneous spaces is different because the little groups for the two cases are different.

APPENDIX: CHOICE OF CROSS SECTION FOR $SL(2,\mathbb{C})/[SL(2,\mathbb{C})]_{(1,0,0,1)}$

If $a\neq 0$, then the element $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ of $SL(2,\mathbb{C})$ may be factored uniquely in the form

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} |a| & 0 \\ |a|ca^{-1} & |a|^{-1} \end{pmatrix} \begin{pmatrix} a|a|^{-1} & b|a|^{-1} \\ 0 & a^{-1}|a| \end{pmatrix}. \tag{A1}$$

The last factor is in $H_1=[SL(2,\mathbb{C})]_{(1,0,0,1)}$.

The set of elements for which this decomposition fails ($a=0$) is of Haar measure zero; consequently, we may impose the condition $a\neq 0$ when integrating over the group.

Henceforth, for $A=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, we define

$$\theta_A \equiv a|a|^{-1} \tag{A2}$$

and almost everywhere choose the canonical projection π_0 and Borel section σ_0 by

$$\pi_0 : SL(2,\mathbb{C}) \to SL(2,\mathbb{C})/[SL(2,\mathbb{C})]_{(1,0,0,1)}, \tag{A3}$$

$$\pi_0(A) = \pi_0\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) = \begin{pmatrix} a & b \\ c & d \end{pmatrix} H_1 = \begin{pmatrix} |a| & 0 \\ |a|ca^{-1} & |a|^{-1} \end{pmatrix} H_1$$

$$\equiv \left\{ \begin{pmatrix} |a| & 0 \\ |a|ca^{-1} & |a|^{-1} \end{pmatrix} \begin{pmatrix} \theta & z \\ 0 & \theta^{-1} \end{pmatrix}, \ |\theta|=1, z\in\mathbb{C} \right\};$$

$$\sigma_0 : SL(2,\mathbb{C})/[SL(2,\mathbb{C})]_{(1,0,0,1)} \to SL(2,\mathbb{C}),$$

$$\sigma_0 = \pi_0\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) \mapsto \sigma_0 \circ \pi_0\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) \equiv \begin{pmatrix} |a| & 0 \\ |a|ca^{-1} & |a|^{-1} \end{pmatrix}. \tag{A4}$$

We may parametrize the cosets with the parameters $ca^{-1}\in\mathbb{C}$, $|a|\in\mathbb{R}^+$ up to a set of measure zero. Next, set

$$\mathbf{p}_0 = \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix} \tag{A5}$$

and

$$\mathbf{p} \equiv A\cdot\mathbf{p}_0. \tag{A6}$$

Then

$$\begin{pmatrix} p^0+p^3 & p^1-ip^2 \\ p^1+ip^2 & p^0-p^3 \end{pmatrix} = A\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}A^\dagger = 2\begin{pmatrix} |a|^2 & a\overline{c} \\ \overline{ac} & |c|^2 \end{pmatrix}; \tag{A7}$$

so;

$$\begin{gathered} p^0>0, \quad \mathbf{p}\cdot\mathbf{p}=0, \\ p^0+p^3=2|a|^2, \quad p^1+ip^2=2\overline{ac}. \end{gathered} \tag{A8}$$

Conversely, every future-pointing null vector $\mathbf{p}\in\mathbb{R}^4$ uniquely determines a class in $\mathrm{SL}(2,\mathbb{C})/\mathrm{SL}(2,\mathbb{C})_{(1,0,0,1)}$ and a unique $\sigma_0\circ\pi_0(A)$. For such $\mathbf{p}$ we define $A_{\mathbf{p}}$ by

$$A_{\mathbf{p}}\equiv\begin{pmatrix}((p^0+p^3)/2)^{1/2} & 0\\ (p^1+ip^2)/(2(p^0+p^3))^{1/2} & (2/(p^0+p^3))^{1/2}\end{pmatrix}=\sigma_0\circ\pi_0(A). \tag{A9}$$

In this way, we may identify $\mathrm{SL}(2,\mathbb{C})/\mathrm{SL}(2,\mathbb{C})_{(1,0,0,1)}$ with V_0^+. From (A9),

$$A_{\mathbf{p}}^{-1}\equiv\begin{pmatrix}(2/(p^0+p^3))^{1/2} & 0\\ (-p^1-ip^2)/(2(p^0+p^2))^{1/2} & ((p^0+p^3)/2)^{1/2}\end{pmatrix}\equiv A_{\tilde{\mathbf{p}}}, \tag{A10}$$

where

$$\begin{aligned}\tilde{p}^{\,0}+\tilde{p}^{\,3}&=4(p^0+p^3)^{-1},\\ \tilde{p}^{\,1}&=-2p^1(p^0+p^3)^{-1},\\ \tilde{p}^{\,2}&=-2p^2(p^0+p^3)^{-1},\\ \tilde{p}^{\,0}-\tilde{p}^{\,3}&=p^0-p^3.\end{aligned} \tag{A11}$$

From (A11), the Jacobian (62) follows.

(Received 8 May 1996; accepted for publication 28 June 1996)

We construct the path integral formula in terms of a ''multi-periodic'' coherent state as an extension of the Nielsen–Rohrlich formula for spin. We make an exact calculation of the formula and show that, when a parameter corresponding to the magnitude of spin becomes large, the leading order term of the expansion coincides with the exact result. We also give an explicit correspondence between the trace formula in the multi-periodic coherent state and the one in the ''generalized'' coherent state. © *1996 American Institute of Physics.* [S0022-2488(96)03911-4]

I. INTRODUCTION

Spin, a system being subject to the SU(2) group, is a simple and pedagogical model so that many useful results and discussions have been made. In the framework of the path integral, it is applied to, for example, the explanation of the Fermi–Bose transmutation.[1–3]

In quantum mechanics there exist few systems which are solved exactly, so various approximations such as the perturbation or the variational method have been invented to give useful results. The most suitable one in the path integral formalism is the WKB approximation, which can be stated as the stationary phase method in quantum mechanics. Although the WKB approximation is useful, the result differs from the exact one in general. However, it is known that there exist some systems in which they coincide with each other, for example, the harmonic oscillator: this is a kind of trivial example since the approximation gives the same form with the original action which is the Gaussian to be integrated exactly.

In the stationary phase approximation in finite dimensions, the conditions that an approximation gives the exact result of the integral has been discovered by Duistermaat and Heckman,[4,5] so that the fact is called as the DH theorem.

Recently there have been some discussions[6–9] that the WKB approximation gives the exact result (we call this fact the **WKB exactness**) in the trace formula of spin in connection with the DH theorem. However, there are some unsatisfactory points in the preceding discussions, for example, the manner of construction of the trace formula and the use of the continuum path integral. By paying attention to the above points, we have shown the WKB exactness in terms of the spin coherent state[10] with the form

$$Z=\lim_{N\to\infty}\int\prod_{i=1}^{N}d\mu(\xi_i,\xi_i^*)\exp\left[iJ\sum_{k=1}^{N}\left\{2i\,\log\left(\frac{1+\xi_k^*\xi_k}{1+\xi_k^*\xi_{k-1}}\right)+\Delta th\,\frac{1-\xi_k^*\xi_{k-1}}{1+\xi_k^*\xi_{k-1}}\right\}\right]\Bigg|_{\xi_N=\xi_0},\tag{1.1}$$

where J is the magnitude of spin and h is the external magnetic field. We have also extended the WKB exactness in terms of the ''generalized'' coherent state.[11]

As for path integrals for spin, there exists another expression, the Nielsen–Rohrlich formula,[12,13] which is constructed in terms of the periodic coherent state. Its trace formula is

[a)]Electronic-mail address: fujii@yokohama-cu.ac.jp
[b)]Electronic-mail address: fnhs1scp@mbox.nc.kyushu-u.ac.jp

$$Z=\sum_{n=-\infty}^{\infty}\lim_{N\to\infty}\int_{2n\pi}^{2(n+1)\pi}\frac{d\varphi_N}{2\pi}\int_{-\infty}^{\infty}\prod_{i=1}^{N-1}\frac{d\varphi_i}{2\pi}\int_{-J-1/2+\varepsilon}^{J+1/2-\varepsilon}\prod_{j=1}^{N}\frac{dp_j}{2\pi}$$
$$\times\exp\left[i\sum_{k=1}^{N}(p_k+J)(\varphi_k-\varphi_{k-1})-\Delta t\sum_{k=1}^{N}h(k)p_k\right]\Bigg|_{\varphi_N=\varphi_0+2n\pi}, \tag{1.2}$$

where ε is positive infinitesimal. On the other hand, the trace formula of the spin coherent state is (1.1). The two representations look quite different despite starting from the same Hamiltonian. The integration domain of ps and the existence of infinite sum lead to the observation that the phase space is considered to be the ''punctured sphere'', while the phase space of the spin coherent state is $CP^1\simeq S^2$, the ''sphere.'' In the latter case, the WKB exactness holds. However, in the former case, from (1.2), the equations of motion are

$$\begin{aligned}\varphi_k-\varphi_{k-1}&=h(k)\Delta t,\\ p_k-p_{k-1}&=0,\end{aligned} \tag{1.3}$$

which does not meet the boundary condition $\varphi_N=\varphi_0+2n\pi$ in a general $h(k)$. Thus there seems to be no classical solutions. We have clarified this puzzle in Ref. 14. The phase space of the Nielsen–Rohrlich formula is not ''punctured'' and the appearance of the infinite sum is superficial. The trace formula is equivalent to that of the spin coherent state. By rewriting (1.2) to

$$Z=\sum_{n=-\infty}^{\infty}e^{i2n\pi J}\lim_{N\to\infty}\int_{2n\pi}^{2(n+1)\pi}\frac{d\varphi_N}{2\pi}\int_{-\infty}^{\infty}\prod_{i=1}^{N-1}\frac{d\varphi_i}{2\pi}\int_{0}^{\pi}\prod_{j=1}^{N}\lambda\sin\theta_j d\theta_j$$
$$\times\exp\left\{i\lambda\sum_{k=1}^{N}\cos\theta_k(\varphi_k-\varphi_{k-1}-h\Delta t)\right\}\Bigg|_{\varphi_N=\varphi_0+2n\pi}, \tag{1.4}$$

the WKB exactness also holds in this case.

Although the extension of the Nielsen–Rohrlich formula has been attempted,[15] the explicit form has not yet been obtained. In this paper we construct the path integral formula and clarify the WKB exactness.

The contents of this paper are as follows. In Sec. II, we define the ''multi-periodic'' coherent state to construct the path integral formula. In Sec. III, we make an exact calculation of the trace formula. We establish a relationship with the trace formula to that of the generalized coherent state in Sec. IV. Then we perform the WKB approximation to confirm the WKB exactness in Sec. V. The last section is devoted to the discussion.

II. CONSTRUCTION OF THE TRACE FORMULA

First we make up the $u(N+1)$ algebra and the representation space by means of $N+1$ harmonic oscillators. The method is called the Schwinger boson method.[16] The commutation relations of oscillators are

$$[a_\alpha,\ a_\beta^\dagger]=\delta_{\alpha\beta},\quad [a_\alpha,\ a_\beta]=[a_\alpha^\dagger,\ a_\beta^\dagger]=0,\quad \alpha,\beta=1,\ldots,N+1, \tag{2.1}$$

and the Fock space is

$$\{|m^1,\ldots,m^{N+1}\rangle\},\quad m^\alpha=0,1,2,\ldots,\ \text{with}\ \alpha=1,\ldots,N+1,$$

$$|m^1,\ldots,m^{N+1}\rangle\equiv\frac{1}{\sqrt{m^1!\cdots m^{N+1}!}}(a_1^\dagger)^{m^1}\cdots(a_{N+1}^\dagger)^{m^{N+1}}|0\rangle,\tag{2.2}$$

$$a_\alpha|0\rangle=0.$$

By putting

$$E_{\alpha\beta}=a_\alpha^\dagger a_\beta,\quad \alpha,\beta=1,\ldots,N+1,\tag{2.3}$$

the $u(N+1)$ algebra

$$[E_{\alpha\beta},\,E_{\gamma\delta}]=\delta_{\beta\gamma}E_{\alpha\delta}-\delta_{\delta\alpha}E_{\gamma\beta}\tag{2.4}$$

is realized.

The Fock space (2.2) is too large to be the representation space of $U(N+1)$. We restrict the representation space with the identity operator

$$\mathbf{1}_Q\equiv\sum_{\|m\|=Q}|m^1,\ldots,m^{N+1}\rangle\langle m^1,\ldots,m^{N+1}|,\tag{2.5}$$

where we have used the abbreviation

$$\|m\|\equiv\sum_{\alpha=1}^{N+1}m^\alpha.\tag{2.6}$$

Now we introduce the highest weight vector defined by

$$\begin{aligned}&E_{N+1,N+1}|Q;N+1\rangle\rangle=Q|Q;N+1\rangle\rangle,\\&E_{N+1,\alpha}|Q;N+1\rangle\rangle=0,\quad \alpha=1,\ldots,N,\end{aligned}\tag{2.7}$$

where $E_{\alpha,N+1}(E_{N+1,\alpha})$ is the lowering (raising) operator of $u(N+1)$. We can identify

$$|Q;N+1\rangle\rangle\equiv|\overset{1}{0},\ldots,\overset{N}{0},\ \overset{N+1}{Q}\ \rangle.\tag{2.8}$$

The ''multi-periodic'' coherent state is defined by

$$\begin{aligned}|\boldsymbol{\varphi}\rangle\equiv|\varphi^1,\varphi^2,\ldots,\varphi^N\rangle&\equiv\frac{1}{(2\pi)^{N/2}}\sum_{\|m\|=Q}\sqrt{\frac{m^{N+1}!}{m^1!\cdots m^N!Q!}}\prod_{\alpha=1}^{N}(e^{-im^\alpha\varphi^\alpha}(E_{\alpha,N+1})^{m^\alpha})|Q;N+1\rangle\rangle\\&=\frac{1}{(2\pi)^{N/2}}\sum_{\|m\|=Q}e^{-i\Sigma_{\alpha=1}^N m^\alpha\varphi^\alpha}|m^1,m^2,\ldots,m^{N+1}\rangle,\end{aligned}\tag{2.9}$$

which satisfies periodicity

$$|\varphi^1,\ldots,\varphi^\alpha+2n\pi,\ldots,\varphi^N\rangle=|\varphi^1,\ldots,\varphi^\alpha,\ldots,\varphi^N\rangle,\quad n:\text{integer}.\tag{2.10}$$

The inner product is

$$\langle \boldsymbol{\varphi}|\boldsymbol{\varphi}'\rangle = \frac{1}{(2\pi)^N} \sum_{\|m\|=Q} e^{i\Sigma_{\alpha=1}^N m^\alpha(\varphi^\alpha - \varphi^{\alpha'})}, \tag{2.11}$$

and the resolution of unity is

$$\int_0^{2\pi} d\boldsymbol{\varphi}|\boldsymbol{\varphi}\rangle\langle\boldsymbol{\varphi}| = \mathbf{1}_Q, \tag{2.12}$$

where

$$\int_0^{2\pi} d\boldsymbol{\varphi} \equiv \int_0^{2\pi} \prod_{\alpha=1}^N d\varphi^\alpha. \tag{2.13}$$

To construct the path integral formula, we utilize the next relation: For $m_0, m_1 \in \mathbf{Z}$,

$$\sum_{m=m_0}^{m_1} e^{im\varphi} f(m) = \sum_{n=-\infty}^{\infty} \int_{m_0-\varepsilon}^{m_1+\varepsilon} dp e^{ip(\varphi+2n\pi)} f(p), \quad 0<\varepsilon<1. \tag{2.14}$$

We rewrite (2.11) with the aid of (2.14) to

$$\begin{aligned}
\langle \varphi|\varphi'\rangle &= \frac{1}{(2\pi)^N} \sum_{m^1=0}^{Q} \sum_{m^2=0}^{Q-m^1} \cdots \sum_{m^N=0}^{Q-\Sigma_{\alpha=1}^{N-1} m^\alpha} e^{i\Sigma_{\alpha=1}^N m^\alpha(\varphi^\alpha-\varphi^{\alpha'})} \\
&= \frac{1}{(2\pi)^N} \sum_{m^1=0}^{Q} \sum_{m^2=0}^{Q-m^1} \cdots \sum_{m^{N-1}=0}^{Q-\Sigma_{\alpha=1}^{N-2} m^\alpha} e^{i\Sigma_{\alpha=1}^N m^\alpha(\varphi^\alpha-\varphi^{\alpha'})} \\
&\quad \times \sum_{n^N=-\infty}^{\infty} \int_{-\varepsilon_N}^{Q-\Sigma_{\alpha=1}^{N-1} m^\alpha+\varepsilon_N} dp^N e^{ip^N(\varphi^N-\varphi^{N\prime}+2n^N\pi)} \\
&= \cdots = \frac{1}{(2\pi)^N} \sum_{n^1=-\infty}^{\infty} \cdots \sum_{n^N=-\infty}^{\infty} \int_{-\varepsilon_1}^{Q+\varepsilon_1} dp^1 \int_{-\varepsilon_2}^{Q-p^1+\varepsilon_2} dp^2 \cdots \int_{-\varepsilon_{N-1}}^{Q-\Sigma_{\alpha=1}^{N-2} p^\alpha+\varepsilon_{N-1}} dp^{N-1} \\
&\quad \times \int_{-\varepsilon_N}^{Q-\Sigma_{\alpha=1}^{N-1} p^\alpha+\varepsilon_N} dp^N e^{i\Sigma_{\alpha=1}^N p^\alpha(\varphi^\alpha-\varphi^{\alpha'}+2n^\alpha\pi)},
\end{aligned} \tag{2.15}$$

where we restrict $0<\varepsilon_\alpha \leqslant 1/(2^{\alpha-1}(N+1))$ for later convenience. We make a change of variables such that

$$\tilde{p}^\alpha = p^\alpha + \frac{1}{2^{\alpha-1}(N+1)}, \tag{2.16}$$

with

$$\lambda \equiv \frac{Q}{2} + \frac{1}{N+1},$$

$$\tilde{\varepsilon}_\alpha \equiv -\varepsilon_\alpha + \frac{1}{2^{\alpha-1}(N+1)}, \quad 0 \leqslant \tilde{\varepsilon}_\alpha < \frac{1}{2^{\alpha-1}(N+1)}, \tag{2.17}$$

which leads to

$$\int_{-\varepsilon_\alpha}^{Q-\Sigma_{\beta=1}^{\alpha-1}p^\beta+\varepsilon_\alpha} dp^\alpha \to \int_{\tilde{\varepsilon}_\alpha}^{2\lambda-\Sigma_{\beta=1}^{\alpha-1}\tilde{p}^\beta-\tilde{\varepsilon}_\alpha} d\tilde{p}^\alpha. \tag{2.18}$$

Equation (2.15) then becomes

$$\begin{aligned}\langle\boldsymbol{\varphi}|\boldsymbol{\varphi}'\rangle = \frac{1}{(2\pi)^N}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}\int_{\varepsilon_1}^{2\lambda-\varepsilon_1}dp^1\int_{\varepsilon_2}^{2\lambda-p^1-\varepsilon_2}dp^2\cdots\int_{\varepsilon_{N-1}}^{2\lambda-\Sigma_{\alpha=1}^{N-2}p^\alpha-\varepsilon_{N-1}}dp^{N-1}\\ \times\int_{\varepsilon_N}^{2\lambda-\Sigma_{\alpha=1}^{N-1}p^\alpha-\varepsilon_N}dp^N e^{i\Sigma_{\alpha=1}^{N}[p^\alpha-1/(2^{\alpha-1}(N+1))](\varphi^\alpha-\varphi^{\alpha\prime}+2n^\alpha\pi)},\end{aligned} \tag{2.19}$$

where the tildes have been omitted.

We adopt a Hamiltonian as

$$\hat{H}\equiv\sum_{\alpha=1}^{N+1}c_\alpha a_\alpha^\dagger a_\alpha, \tag{2.20}$$

where we have assumed that all cs are different from each other and independent of time. The matrix element of the Hamiltonian is

$$\begin{aligned}\langle\boldsymbol{\varphi}|\hat{H}|\boldsymbol{\varphi}'\rangle &= \left\{\sum_{\alpha=1}^{N}(c_\alpha-c_{N+1})\frac{1}{i}\frac{\partial}{\partial\varphi^\alpha}+c_{N+1}Q\right\}\langle\boldsymbol{\varphi}|\boldsymbol{\varphi}'\rangle\\ &= \frac{1}{(2\pi)^N}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}\int_{\varepsilon_1}^{2\lambda-\varepsilon_1}dp^1\cdots\int_{\varepsilon_N}^{2\lambda-\Sigma_{\alpha=1}^{N-1}p^\alpha-\varepsilon_N}\\ &\quad\times dp^N e^{i\Sigma_{\alpha=1}^{N}[p^\alpha-1/(2^{\alpha-1}(N+1))](\varphi^\alpha-\varphi^{\alpha\prime}+2n^\alpha\pi)}\left[\sum_{\alpha=1}^{N}\mu_\alpha\left(p^\alpha-\frac{1}{2^{\alpha-1}(N+1)}\right)+c_{N+1}Q\right],\end{aligned} \tag{2.21}$$

where $\mu_\alpha\equiv c_\alpha-c_{N+1}$.

From now on we put $\tilde{\varepsilon}_\alpha=0$ for simplicity. [See (2.17) for the range of $\tilde{\varepsilon}_\alpha$.]

The Feynman kernel is defined by

$$K(\boldsymbol{\varphi}_F,\boldsymbol{\varphi}_I;T)\equiv\langle\boldsymbol{\varphi}_F|e^{-i\hat{H}T}|\boldsymbol{\varphi}_I\rangle=\lim_{M\to\infty}\langle\boldsymbol{\varphi}_F|(1-i\Delta t\hat{H})^M|\boldsymbol{\varphi}_I\rangle,\quad \Delta t\equiv T/M, \tag{2.22}$$

or explicitly

$$
\begin{aligned}
K(\boldsymbol{\varphi}_F,\boldsymbol{\varphi}_I;T) &= \lim_{M\to\infty}\int_0^{2\pi}\prod_{i=1}^{M-1} d\boldsymbol{\varphi}_i \prod_{j=1}^{M}\langle\boldsymbol{\varphi}_j|(1-i\Delta t\hat{H})|\boldsymbol{\varphi}_{j-1}\rangle\Bigg|_{\boldsymbol{\varphi}_0=\boldsymbol{\varphi}_I}^{\boldsymbol{\varphi}_M=\boldsymbol{\varphi}_F} \\
&= \lim_{M\to\infty}\int_0^{2\pi}\prod_{i=1}^{M-1} d\boldsymbol{\varphi}_i \prod_{j=1}^{M}\Bigg[\frac{1}{(2\pi)^N}\sum_{n_j^1=-\infty}^{\infty}\cdots\sum_{n_j^N=-\infty}^{\infty}\int_0^{2\lambda} dp_j^1\cdots \\
&\quad\times\int_0^{2\lambda-\Sigma_{\alpha=1}^{N-1}p_j^\alpha} dp_j^N e^{i\Sigma_{\alpha=1}^{N}[p^\alpha-1/(2^{\alpha-1}(N+1))](\Delta\varphi_j^\alpha+2n_j^\alpha\pi)}\Bigg[1-i\Delta t \\
&\quad\times\Bigg\{\sum_{\alpha=1}^{N}\mu_\alpha\Bigg(p_j^\alpha-\frac{1}{2^{\alpha-1}(N+1)}\Bigg)+c_{N+1}Q\Bigg\}\Bigg]\Bigg]\Bigg|_{\varphi_0=\varphi_I}^{\varphi_M=\varphi_F} \\
&= \lim_{M\to\infty}\int_0^{2\pi}\prod_{i=1}^{M-1} d\boldsymbol{\varphi}_i \prod_{j=1}^{M}\Bigg\{\frac{1}{(2\pi)^N}\sum_{n_j^1=-\infty}^{\infty}\cdots\sum_{n_j^N=-\infty}^{\infty}\int_0^{2\lambda} dp_j^1\cdots\int_0^{2\lambda-\Sigma_{\alpha=1}^{N-1}p_j^\alpha} dp_j^N\Bigg\} \\
&\quad\times\exp\Bigg[i\sum_{k=1}^{M}\Bigg\{\sum_{\alpha=1}^{N}\Bigg(p_k^\alpha-\frac{1}{2^{\alpha-1}(N+1)}\Bigg)(\Delta\varphi_k^\alpha+2n_k^\alpha\pi) \\
&\quad-\Delta t\Bigg\{\sum_{\alpha=1}^{N}\mu_\alpha\Bigg(p_k^\alpha-\frac{1}{2^{\alpha-1}(N+1)}\Bigg)+c_{N+1}Q\Bigg\}\Bigg\}\Bigg]\Bigg|_{\varphi_0=\varphi_I}^{\varphi_M=\varphi_F},
\end{aligned}
\tag{2.23}
$$

where the resolution of unity (2.12) has been inserted in the first equality and $\Delta\varphi_k^\alpha\equiv\varphi_k^\alpha-\varphi_{k-1}^\alpha$ has been put and $O((\Delta t)^2)$ terms, which finally vanish in $M\to\infty$ limit, have been omitted in the last equality. We introduce new variables such that

$$
\begin{aligned}
n_k^{\alpha'} &= \sum_{l=1}^{k} n_l^\alpha, \\
\varphi_k^{\alpha'} &= \varphi_k^\alpha+2n_k^{\alpha'}\pi,
\end{aligned}
\tag{2.24}
$$

to give

$$
\begin{aligned}
\Delta\varphi_k^\alpha+2n_k^\alpha\pi &= \Delta\varphi_k^{\alpha'}, \\
\sum_{n_i^{\alpha'}=-\infty}^{\infty}\int_{2n_i^{\alpha'}\pi}^{2(n_i^{\alpha'}+1)\pi} d\varphi_i^{\alpha'} &= \int_{-\infty}^{\infty} d\varphi_i^{\alpha'}.
\end{aligned}
\tag{2.25}
$$

The kernel is then rewritten

$$
\begin{aligned}
K(\boldsymbol{\varphi}_F,\boldsymbol{\varphi}_I;T)=&\lim_{M\to\infty}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}d\boldsymbol{\varphi}_i\sum_{n_M^1=-\infty}^{\infty}\cdots\sum_{n_M^N=-\infty}^{\infty}\prod_{j=1}^{M}\\
&\times\left\{\int_0^{2\lambda}\frac{dp_j^1}{2\pi}\cdots\int_0^{2\lambda-\Sigma_{\alpha=1}^{N-1}p_j^\alpha}\frac{dp_j^N}{2\pi}\right\}\exp\left[i\sum_{k=1}^{M}\left\{\sum_{\alpha=1}^{N}\left(p_k^\alpha-\frac{1}{2^{\alpha-1}(N+1)}\right)\Delta\varphi_k^\alpha\right.\right.\\
&\left.\left.-\Delta t\left\{\sum_{\alpha=1}^{N}\mu_\alpha\left(p_k^\alpha-\frac{1}{2^{\alpha-1}(N+1)}\right)+c_{N+1}Q\right\}\right\}\right]\Bigg|_{\varphi_0^\alpha=\varphi_I^\alpha}^{\varphi_M^\alpha=\varphi_F^\alpha+2n_M^\alpha\pi}\\
=&e^{-iQc_{N+1}T+i\Sigma_{\alpha=1}^{N}[1/(2^{\alpha-1}(N+1))]\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}\\
&\times e^{-i\Sigma_{\alpha=1}^{N}[1/(2^{\alpha-1}(N+1))](\varphi_F^\alpha-\varphi_I^\alpha+2n^\alpha\pi)}\lim_{M\to\infty}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}d\boldsymbol{\varphi}_i\prod_{j=1}^{M}\\
&\times\left\{\int_0^{2\lambda}\frac{dp_j^1}{2\pi}\cdots\int_0^{2\lambda-\Sigma_{\alpha=1}^{N-1}p_j^\alpha}\frac{dp_j^N}{2\pi}\right\}\exp\left[i\sum_{k=1}^{M}\sum_{\alpha=1}^{N}p_k^\alpha\Phi_k^\alpha\right]\Bigg|_{\varphi_0^\alpha=\varphi_I^\alpha}^{\varphi_M^\alpha=\varphi_F^\alpha+2n^\alpha\pi},
\end{aligned}
\tag{2.26}
$$

where primes have been omitted and n_M^α has been written as n^α and $\Phi_k^\alpha\equiv\Delta\varphi_k^\alpha-\Delta t\mu_\alpha$ in the last equality.

Further, we make a change of variables such that

$$
\begin{aligned}
p^{1\prime}&=p^1-\lambda,\\
p^{2\prime}&=p^2-\frac{\lambda-p^{1\prime}}{2},\\
&\vdots\\
p^{\alpha\prime}&=p^\alpha-\frac{\lambda-\Sigma_{\beta=1}^{\alpha-1}2^{\beta-1}p^{\beta\prime}}{2^{\alpha-1}},\\
&\vdots\\
p^{N\prime}&=p^N-\frac{\lambda-\Sigma_{\beta=1}^{N-1}2^{\beta-1}p^{\beta\prime}}{2^{N-1}},
\end{aligned}
\tag{2.27}
$$

which leads to

$$
\int_0^{2\lambda-\Sigma_{\beta=1}^{\alpha-1}p^\beta}dp^\alpha\to\int_{-(\lambda-\Sigma_{\beta=1}^{\alpha-1}2^{\beta-1}p^{\beta\prime})/2}^{(\lambda-\Sigma_{\beta=1}^{\alpha-1}2^{\beta-1}p^{\beta\prime})/2}dp^{\alpha\prime},
\tag{2.28}
$$

where we use the notations

$$\left.\begin{array}{l}\displaystyle\sum_{\beta=a}^{b} f(\beta)=0\\ \displaystyle\prod_{\beta=a}^{b} f(\beta)=1\end{array}\right\} \quad \text{for } b<a \tag{2.29}$$

for simplicity. We then obtain the kernel

$$\begin{aligned}K(\boldsymbol{\varphi}_F,\boldsymbol{\varphi}_I;T)=&e^{-iQc_{N+1}T+i\Sigma_{\alpha=1}^{N}1/(2^{\alpha-1}(N+1))\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}\\ &\times e^{-i\Sigma_{\alpha=1}^{N}1/(2^{\alpha-1}(N+1))(\varphi_F^\alpha-\varphi_I^\alpha+2n^\alpha\pi)}\\ &\times\lim_{M\to\infty}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}d\boldsymbol{\varphi}_i\prod_{j=1}^{M}\left\{\int_{-\lambda}^{\lambda}\frac{dp_j^1}{2\pi}\int_{-(\lambda-p_j^1)/2}^{(\lambda-p_j^1)/2}\frac{dp_j^2}{2\pi}\cdots\right.\\ &\left.\times\int_{-(\lambda-\Sigma_{\beta=1}^{N-1}2^{\beta-1}p_j^\beta)/2^{N-1}}^{(\lambda-\Sigma_{\beta=1}^{N-1}2^{\beta-1}p_j^\beta)/2^{N-1}}\frac{dp_j^N}{2\pi}\right\}\\ &\times\exp\left[i\sum_{k=1}^{M}\sum_{\alpha=1}^{N}\left(p_k^\alpha+\frac{\lambda-\Sigma_{\beta=1}^{\alpha-1}2^{\beta-1}p_k^\beta}{2^{\alpha-1}}\right)\Phi_k^\alpha\right]\Bigg|_{\varphi_0^\alpha=\varphi_I^\alpha}^{\varphi_M^\alpha=\varphi_F^\alpha+2n^\alpha\pi},\end{aligned} \tag{2.30}$$

where we have again omitted primes.

To compare with the θ-expression of the Nielsen–Rohrlich formula (1.4), we make a change of variables such that

$$p_k^\alpha=\lambda\left(\prod_{\beta=1}^{\alpha-1}\sin^2\frac{\theta_k^\beta}{2}\right)\cos\theta_k^\alpha,\quad \alpha=1,\ldots,N, \tag{2.31}$$

with the Jacobian

$$\frac{\partial(p)}{\partial(\theta)}=(-1)^N\lambda^N\prod_{\alpha=1}^{N}\left\{\left(\sin^2\frac{\theta_k^\alpha}{2}\right)^{N-\alpha}\sin\theta_k^\alpha\right\}, \tag{2.32}$$

to obtain

$$\begin{aligned}K(\boldsymbol{\varphi}_F,\boldsymbol{\varphi}_I;T)=&e^{-iQc_{N+1}T+i\Sigma_{\alpha=1}^{N}[1/(2^{\alpha-1}(N+1))]\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}\\ &\times e^{-i\Sigma_{\alpha=1}^{N}[1/(2^{\alpha-1}(N=1))](\varphi_F^\alpha-\varphi_I^\alpha+2n^\alpha\pi)}\\ &\times\lim_{M\to\infty}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}d\boldsymbol{\varphi}_i\prod_{j=1}^{M}\left\{\lambda^N\int_0^\pi\left(\sin^2\frac{\theta_j^1}{2}\right)^{N-1}\right.\\ &\left.\times\sin\theta_j^1\frac{d\theta_j^1}{2\pi}\cdots\int_0^\pi\sin^2\frac{\theta_j^{N-1}}{2}\sin\theta_j^{N-1}\frac{d\theta_j^{N-1}}{2\pi}\int_0^\pi\sin\theta_j^N\frac{d\theta_j^N}{2\pi}\right\}\\ &\times\exp\left[i\sum_{k=1}^{M}\sum_{\alpha=1}^{N}2\lambda\left(\prod_{\beta=1}^{\alpha-1}\sin^2\frac{\theta_k^\beta}{2}\right)\cos^2\frac{\theta_k^\alpha}{2}\Phi_k^\alpha\right]\Bigg|_{\varphi_0^\alpha=\varphi_I^\alpha}^{\varphi_M^\alpha=\varphi_F^\alpha+2n^\alpha\pi}.\end{aligned} \tag{2.33}$$

The trace formula is defined by

$$Z \equiv \int_0^{2\pi} d\boldsymbol{\varphi} \langle \boldsymbol{\varphi} | e^{-i\hat{H}T} | \boldsymbol{\varphi} \rangle = \int_0^{2\pi} d\boldsymbol{\varphi} K(\boldsymbol{\varphi}, \boldsymbol{\varphi}; T), \tag{2.34}$$

whose explicit form is

$$\begin{aligned} Z = & e^{-iQc_{N+1}T + i[1/(N+1)]\Sigma_{\alpha=1}^{N} 2^{-\alpha+1}\mu_\alpha T} \sum_{n^1=-\infty}^{\infty} \cdots \sum_{n^N=-\infty}^{\infty} e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N} 2^{-\alpha+2} n^\alpha \pi} \\ & \times \lim_{M\to\infty} \prod_{\alpha=1}^{N} \left\{ \int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi} d\varphi_M^\alpha \right\} \int_{-\infty}^{\infty} \prod_{i=1}^{M-1} d\boldsymbol{\varphi}_i \prod_{j=1}^{M} \left\{ \lambda^N \int_0^\pi \left(\sin^2 \frac{\theta_j^1}{2} \right)^{N-1} \right. \\ & \left. \times \sin\, \theta_j^1 \frac{d\theta_j^1}{2\pi} \cdots \int_0^\pi \sin^2 \frac{\theta_j^{N-1}}{2} \sin\, \theta_j^{N-1} \frac{d\theta_j^{N-1}}{2\pi} \int_0^\pi \sin\, \theta_j^N \frac{d\theta_j^N}{2\pi} \right\} \\ & \times \exp\left[2i\lambda \sum_{k=1}^{M} \sum_{\alpha=1}^{N} \left(\prod_{\beta=1}^{\alpha-1} \sin^2 \frac{\theta_k^\beta}{2} \right) \cos^2 \frac{\theta_k^\alpha}{2}\, \Phi_k^\alpha \right] \Bigg|_{\varphi_0^\alpha = \varphi_M^\alpha - 2n^\alpha\pi} . \end{aligned} \tag{2.35}$$

This is the counterpart of the θ-expression of the Nielsen–Rohrlich formula. Actually, in the $N=1$ case, by putting $Q=2J$ and $c_1=-c_2=h/2$, (2.35) becomes

$$\begin{aligned} Z = & \sum_{n=-\infty}^{\infty} e^{i2n\pi J} \lim_{M\to\infty} \int_{2n\pi}^{2(n+1)\pi} \frac{d\varphi_M}{2\pi} \int_{-\infty}^{\infty} \prod_{i=1}^{M-1} \frac{d\varphi_i}{2\pi} \prod_{j=1}^{M} \\ & \times \left\{ \lambda \int_0^\pi \sin\, \theta_j d\theta_j \right\} \exp\left[i\lambda \sum_{k=1}^{M} \cos\, \theta_k (\Delta\varphi_k - h\Delta t) \right], \end{aligned} \tag{2.36}$$

which is just the Nielsen–Rohrlich formula (1.4).

III. EXACT CALCULATION

To claim the WKB exactness, we need the exact calculation to be compared with the result of the WKB approximation. We have already obtained the exact result in another expression (the generalized coherent state).[11] However, we make an exact calculation in this expression to be self-contained.

By changing variables such that

$$p_k^\alpha = \left(\prod_{\beta=1}^{\alpha-1} \sin^2 \frac{\theta_k^\beta}{2} \right) \cos^2 \frac{\theta_k^\alpha}{2}, \tag{3.1}$$

with the Jacobian

$$\frac{\partial(p)}{\partial(\theta)} = (-1)^N 2^{-N} \prod_{\alpha=1}^{N} \left\{ \left(\sin^2 \frac{\theta_k^\alpha}{2} \right)^{N-\alpha} \sin\, \theta_k^\alpha \right\}, \tag{3.2}$$

the trace formula (2.35) becomes

$$Z=e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}$$
$$\times\lim_{M\to\infty}\prod_{i=1}^{M}\left\{(2\lambda)^N\int_0^1 dp_i^1\cdots\int_0^{1-\Sigma_{\alpha=1}^{N-1}p_i^\alpha}dp_i^N\right\}$$
$$\times\prod_{\alpha=1}^{N}\left\{\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}\frac{d\varphi_M^\alpha}{2\pi}\int_{-\infty}^{\infty}\prod_{j=1}^{M-1}\frac{d\varphi_j^\alpha}{2\pi}\right\}\prod_{\alpha=1}^{N}e^{2i\lambda\Sigma_{k=1}^{M}p_k^\alpha\Phi_k^\alpha}. \tag{3.3}$$

Rewriting the exponent to

$$\sum_{k=1}^{M}p_k^\alpha\Phi_k^\alpha=\sum_{k=1}^{M-1}(p_k^\alpha-p_{k-1}^\alpha)\varphi_k^\alpha+(p_M^\alpha-p_1^\alpha)\varphi_M^\alpha+p_1^\alpha 2n^\alpha\pi-\Delta t\mu_\alpha\sum_{k=1}^{M}p_k^\alpha, \tag{3.4}$$

and performing the φ_i-integrals ($i=1,\ldots,N-1$) as the δ-functions, we obtain

$$Z=e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}2n^\alpha\pi}$$
$$\times\lim_{M\to\infty}\prod_{i=1}^{M}\left\{(2\lambda)^N\int_0^1 dp_i^1\cdots\int_0^{1-\Sigma_{\alpha=1}^{N-1}p_i^\alpha}dp_i^N\right\}$$
$$\times\prod_{\alpha=1}^{N}\left[\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}\frac{d\varphi_M^\alpha}{2\pi}e^{2i\lambda\{(p_M^\alpha-p_1^\alpha)\varphi_M^\alpha+p_1^\alpha 2n^\alpha\pi-\Delta t\mu_\alpha\Sigma_{k=1}^{M}p_k^\alpha\}}\prod_{j=1}^{M-1}\left\{\frac{1}{2\lambda}\,\delta(p_j^\alpha-p_{j+1}^\alpha)\right\}\right]$$
$$\times e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}2n^\alpha\pi}(2\lambda)^N$$
$$\times\int_0^1 dp_M^1\cdots\int_0^{1-\Sigma_{\alpha=1}^{N-1}p_M^\alpha}dp_M^N e^{2i\lambda\Sigma_{\alpha=1}^{N}(2n^\alpha\pi-\mu_\alpha T)p_M^\alpha}. \tag{3.5}$$

By applying the integral relation (1.7) with $I=0$, $L=1$, $u=2\lambda$, and $\Phi^\alpha=2n^\alpha\pi-\mu_\alpha T$, (3.5) becomes

$$Z=e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}2n^\alpha\pi}$$
$$\times\left[\sum_{\alpha=1}^{N}\frac{e^{i2\lambda(2n^\alpha\pi-\mu_\alpha T)}}{i(2n^\alpha\pi-\mu_\alpha T)\Pi_{\substack{\beta=1\\\beta\neq\alpha}}^{N}i\{2(n^\alpha-n^\beta)\pi-(\mu_\alpha-\mu_\beta)T\}}+\frac{(-1)^N}{\Pi_{\alpha=1}^{N}i(2n^\alpha\pi-\mu_\alpha T)}\right]. \tag{3.6}$$

First we calculate each term of the α-sum. We set

$$
\begin{aligned}
Z_\alpha &= e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\beta=1}^{N}2^{-\beta+1}\mu_\beta T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\beta=1}^{N}2^{-\beta+1}2n^\beta\pi}\\
&\quad\times\frac{e^{2i\lambda(2n^\alpha\pi-\mu_\alpha T)}}{i(2n^\alpha\pi-\mu_\alpha T)}\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N}\frac{1}{i\{2(n^\alpha-n^\beta)\pi-(\mu_\alpha-\mu_\beta)T\}}\\
&= e^{-iQc_\alpha T}e^{-i[1/(N+1)]2^{-N+1}\mu_\alpha T}\sum_{n^\alpha=-\infty}^{\infty}\frac{e^{i[1/(N+1)]2^{-N+1}2n^\alpha\pi}}{i(2n^\alpha\pi-\mu_\alpha T)}\\
&\quad\times\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N}\left[e^{i[1/(N+1)]2^{-\beta+1}\tilde{\mu}_\beta T}\sum_{\tilde{n}^\beta=-\infty}^{\infty}\frac{e^{i[1/(N+1)]2^{-\beta+1}2\tilde{n}^\beta\pi}}{i(2\tilde{n}^\beta\pi+\tilde{\mu}_\beta T)}\right],
\end{aligned}
\tag{3.7}
$$

where $\tilde{n}^\beta=n^\alpha-n^\beta$ and $\tilde{\mu}_\beta\equiv c_\beta-c_\alpha=\mu_\beta-\mu_\alpha$ $(\beta\neq\alpha)$. We apply the formula

$$
\sum_{n=-\infty}^{\infty}\frac{e^{2n\pi i\varepsilon}}{2n\pi+\varphi}=\frac{e^{i(1/2-\varepsilon)\varphi}}{2\sin\varphi/2},\quad 0<\varepsilon<1,
\tag{3.8}
$$

with

$$
\begin{aligned}
&\varepsilon=\frac{1}{N+1}2^{-N+1},\quad \varphi=-\mu_\alpha T\quad\text{for }\alpha,\\
&\varepsilon=\frac{1}{N+1}2^{-\beta+1},\quad \varphi=\tilde{\mu}_\beta T\quad\text{for }\beta\neq\alpha,
\end{aligned}
\tag{3.9}
$$

to find

$$
Z_\alpha=e^{-iQc_\alpha T}\frac{1}{1-e^{i\mu_\alpha T}}\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N}\frac{1}{1-e^{-i\tilde{\mu}_\beta T}}=\frac{e^{-iQc_\alpha T}}{\Pi_{\substack{\beta=1\\ \beta\neq\alpha}}^{N+1}(1-e^{-i\tilde{\mu}_\beta T})},
\tag{3.10}
$$

where $\tilde{\mu}_{N+1}\equiv c_{N+1}-c_\alpha=-\mu_\alpha$. Next the calculation of the last term in (3.6) is

$$
\begin{aligned}
Z_{N+1}&\equiv e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\\
&\quad\times\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}2n^\alpha\pi}\frac{(-1)^N}{\Pi_{\alpha=1}^{N}i(2n^\alpha\pi-\mu_\alpha T)}\\
&= e^{-iQc_{N+1}T}\prod_{\alpha=1}^{N}\left[e^{i[1/(N+1)]2^{-\alpha+1}\mu_\alpha T}\sum_{\tilde{n}^\alpha=-\infty}^{\infty}\frac{e^{i[1/(N+1)]2^{-\alpha+1}2\tilde{n}^\alpha\pi}}{i(2\tilde{n}^\alpha\pi+\mu_\alpha T)}\right]=\frac{e^{-iQc_{N+1}T}}{\Pi_{\alpha=1}^{N}(1-e^{-i\mu_\alpha T})},
\end{aligned}
\tag{3.11}
$$

where we have put $\tilde{n}^\alpha=-n^\alpha$ in the second equality and applied (3.8) in the last equality. Thus

$$
Z=\sum_{\alpha=1}^{N+1}Z_\alpha=\sum_{\alpha=1}^{N+1}\frac{e^{-iQc_\alpha T}}{\Pi_{\substack{\beta=1\\ \beta\neq\alpha}}^{N+1}\{1-e^{-i(c_\beta-c_\alpha)T}\}}.
\tag{3.12}
$$

This is the exact result of the trace formula and just the same as that of the generalized coherent state. We here note that (3.12) can be written in the determinant form:

$$Z=\left|\begin{array}{cccc} 1 & 1 & \cdots & 1 \\ e^{-ic_1T} & e^{-ic_2T} & \cdots & e^{-ic_{N+1}T} \\ \vdots & \vdots & \ddots & \vdots \\ e^{-i(N-1)c_1T} & e^{-i(N-1)c_2T} & \cdots & e^{-i(N-1)c_{N+1}T} \\ e^{-i(Q+N)c_1T} & e^{-i(Q+N)c_2T} & \cdots & e^{-i(Q+N)c_{N+1}T} \end{array}\right| \Bigg/ \left|\begin{array}{cccc} 1 & 1 & \cdots & 1 \\ e^{-ic_1T} & e^{-ic_2T} & \cdots & e^{-ic_{N+1}T} \\ \vdots & \vdots & \ddots & \vdots \\ e^{-i(N-1)c_1T} & e^{-i(N-1)c_2T} & \cdots & e^{-i(N-1)c_{N+1}T} \\ e^{-iNc_1T} & e^{-iNc_2T} & \cdots & e^{-iNc_{N+1}T} \end{array}\right|.$$

For detailed calculation, see Appendix B.

IV. RELATIONSHIP TO THE GENERALIZED COHERENT STATE

In this section we establish a relationship with (2.35) to the trace formula in terms of the generalized coherent state by an explicit calculation.

By definition, the trace formula in terms of the multi-periodic coherent state is

$$Z=\lim_{M\to\infty}\int_0^{2\pi}\prod_{i=1}^{M} d\boldsymbol{\varphi}_i \prod_{k=1}^{M}\langle\boldsymbol{\varphi}_k|(1-i\Delta t\hat{H})|\boldsymbol{\varphi}_{k-1}\rangle\Big|_{\boldsymbol{\varphi}_M=\boldsymbol{\varphi}_0}. \tag{4.1}$$

Inserting the completeness

$$\mathbf{1}_Q=\sum_{\|m\|=Q}|m^1,\ldots,m^{N+1}\rangle\langle m^1,\ldots,m^{N+1}|, \tag{4.2}$$

and noting

$$\begin{aligned}\langle\boldsymbol{\varphi}|m^1,\ldots,m^{N+1}\rangle&=\frac{1}{(2\pi)^{N/2}}\,e^{i\Sigma_{\alpha=1}^{N}m^\alpha\varphi^\alpha},\\ \hat{H}|m^1,\ldots,m^{N+1}\rangle&=\left(\sum_{\alpha=1}^{N}\mu_\alpha m^\alpha+c_{N+1}Q\right)|m^1,\ldots,m^{N+1}\rangle,\end{aligned} \tag{4.3}$$

and putting

$$\theta_i^\alpha=-\varphi_i^\alpha+2\pi, \tag{4.4}$$

we rewrite (4.1) as

$$Z=\lim_{M\to\infty}\prod_{i=1}^{M}\left[\sum_{\|m_i\|=Q}\int_0^{2\pi}\frac{d\boldsymbol{\theta}_i}{(2\pi)^N}\,e^{-i\Sigma_{\alpha=1}^{N}m_i^\alpha\Delta\theta_i^\alpha}\left\{1-i\Delta t\left(\sum_{\alpha=1}^{N}\mu_\alpha m_i^\alpha+c_{N+1}Q\right)\right\}\right]\Bigg|_{\varphi_M=\varphi_0}, \tag{4.5}$$

where

$$\int_0^{2\pi} d\boldsymbol{\theta}_i \equiv \int_0^{2\pi} \prod_{\alpha=1}^{N} d\theta_i^\alpha ,$$
$$\Delta\theta_i^\alpha \equiv \theta_i^\alpha - \theta_{i-1}^\alpha . \tag{4.6}$$

If we write (4.5) as

$$Z = \lim_{M\to\infty} \prod_{i=1}^{M} \left[\sum_{\|m_i\|=Q} \int_0^{2\pi} \frac{d\boldsymbol{\theta}_i}{(2\pi)^N} e^{-i\Sigma_{\alpha=1}^{N}(m_i^\alpha - m_{i+1}^\alpha)\theta_i^\alpha} \left\{ 1 - i\Delta t \left(\sum_{\alpha=1}^{N} \mu_\alpha m_i^\alpha + c_{N+1}Q \right) \right\} \right] \Bigg|_{\varphi_M=\varphi_0} , \tag{4.7}$$

we find $m_i^\alpha = m_{i+1}^\alpha$ from the $\boldsymbol{\theta}$-integrals (δ-functions). By inserting the identity[11]

$$\frac{(N+Q)!}{\mathbf{l}!} \int_0^{\infty} \prod_{\alpha=1}^{N} du^\alpha \frac{(u^1)^{l^1}\cdots(u^N)^{l^N}}{(1+u^1+\cdots u^N)^{N+Q+1}} = 1,$$
$$l! \equiv l^1!\ldots l^{N+1}!, \tag{4.8}$$

into (4.5), the trace formula becomes

$$\begin{aligned} Z = \lim_{M\to\infty} \prod_{i=1}^{M} \Bigg[\sum_{\|m_i\|=Q} & \frac{(N+Q)!}{Q!} \int_0^{2\pi} \frac{d\boldsymbol{\theta}_i}{(2\pi)^N} \int_0^{\infty} \frac{\Pi_{\alpha=1}^{N} du_i^\alpha}{(1+u_i^1+\cdots+u_i^N)^{N+1}} \\ & \times \frac{((u_i^1)^{1/2}e^{-i\theta_i^1})^{m_i^1}\cdots((u_i^N)^{1/2}e^{-i\theta_i^N})^{m_i^N}}{(1+u_i^1+\cdots+u_i^N)^{Q/2}} \\ & \times \frac{((u_{i-1}^1)^{1/2}e^{i\theta_{i-1}^1})^{m_i^1}\cdots((u_{i-1}^N)^{1/2}e^{i\theta_{i-1}^N})^{m_i^N}}{(1+u_{i-1}^1+\cdots+u_{i-1}^N)^{Q/2}} \frac{Q!}{\mathbf{m}!} \left\{ 1 - i\Delta t \left(\sum_{\alpha=1}^{N} \mu_\alpha m_i^\alpha + c_{N+1}Q \right) \right\} \Bigg] \Bigg|_{\boldsymbol{\theta}_M=\boldsymbol{\theta}_0} , \end{aligned} \tag{4.9}$$

where $m_i^\alpha = m_{i+1}^\alpha$ and $u_0^\alpha = u_M^\alpha$ have been used. Then putting

$$(u_i^\alpha, \theta_i^\alpha) \to \xi_i^\alpha ; \quad \xi_i^\alpha = \sqrt{u_i^\alpha} e^{i\theta_i^\alpha}, \tag{4.10}$$

we obtain

$$
\begin{aligned}
Z=&\lim_{M\to\infty}\prod_{i=1}^{M}\left[\sum_{\|m_i\|=Q}\int d\mu(\boldsymbol{\xi}_i,\boldsymbol{\xi}_i^{\dagger})\right.\\
&\times\sqrt{\frac{Q!}{\mathbf{m}!}}\frac{(\xi_i^{1*})^{m_i^1}\cdots(\xi_i^{N*})^{m_i^N}}{(1+\boldsymbol{\xi}_i^{\dagger}\boldsymbol{\xi}_i)^{Q/2}}\sqrt{\frac{Q!}{\mathbf{m}!}}\frac{(\xi_{i-1}^{1})^{m_i^1}\cdots(\xi_{i-1}^{N})^{m_i^N}}{(1+\boldsymbol{\xi}_{i-1}^{\dagger}\xi_{i-1})^{Q/2}}\\
&\left.\times\left\{1-i\Delta t\left(\sum_{\alpha=1}^{N}\mu_\alpha m_i^\alpha+c_{N+1}Q\right)\right\}\right]\Bigg|_{\boldsymbol{\xi}_M=\boldsymbol{\xi}_0}\\
=&\lim_{M\to\infty}\prod_{i=1}^{M}\left[\sum_{\|m_i\|=Q}\int d\mu(\boldsymbol{\xi}_i,\boldsymbol{\xi}_i^{\dagger})\langle\boldsymbol{\xi}_i|(1-i\Delta t\hat{H})|m^1,\ldots,m^{N+1}\rangle\langle m^1,\ldots,m^{N+1}|\boldsymbol{\xi}_{i-1}\rangle\right]\Bigg|_{\boldsymbol{\xi}_M=\boldsymbol{\xi}_0}\\
=&\lim_{M\to\infty}\prod_{i=1}^{M}d\mu(\boldsymbol{\xi}_i,\boldsymbol{\xi}_i^{\dagger})\prod_{j=1}^{M}\langle\boldsymbol{\xi}_j|(1-i\Delta t\hat{H})|\boldsymbol{\xi}_{j-1}\rangle\Bigg|_{\boldsymbol{\xi}_M=\boldsymbol{\xi}_0},
\end{aligned}
\tag{4.11}
$$

which is nothing but the trace formula in terms of the generalized coherent state.[11]

V. THE WKB APPROXIMATION

In the Nielsen–Rohrlich formula, the WKB approximation is applicable to the θ-expression instead of the p-expression. In this section we perform the WKB approximation to the θ-expression of the trace formula in terms of the multi-periodic coherent state. The WKB approximation in this case is the large $Q(\lambda)$ expansion.

Writing (2.35) as

$$
\begin{aligned}
Z=&\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}\lim_{M\to\infty}\prod_{\alpha=1}^{N}\left\{\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}d\varphi_M^\alpha\right\}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}d\boldsymbol{\varphi}_i\prod_{j=1}^{M}\\
&\times\left\{\lambda^N\int_0^\pi\left(\sin^2\frac{\theta_j^1}{2}\right)^{N-1}\sin\theta_j^1\frac{d\theta_j^1}{2\pi}\cdots\int_0^\pi\left(\sin^2\frac{\theta_j^{N-1}}{2}\right)\right.\\
&\left.\times\sin\theta_j^{N-1}\frac{d\theta_j^{N-1}}{2\pi}\int_0^\pi\sin\theta_j^N\frac{d\theta_j^N}{2\pi}\right\}e^{iS^{(n^\alpha)}}
\end{aligned}
\tag{5.1}
$$

with the action

$$
\begin{aligned}
S^{(n^\alpha)}\equiv&-Qc_{N+1}T+\frac{1}{N+1}\sum_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T-\frac{1}{N+1}\sum_{\alpha=1}^{N}2^{-\alpha+2}n^\alpha\pi\\
&+2\lambda\sum_{k=1}^{M}\sum_{\alpha=1}^{N}\left(\prod_{\beta=1}^{\alpha-1}\sin^2\frac{\theta_k^\beta}{2}\right)\cos^2\frac{\theta_k^\alpha}{2}\Phi_k^\alpha,
\end{aligned}
\tag{5.2}
$$

we find the equations of motion;

$$
\left(\prod_{\beta=1}^{\alpha-1}\sin^2\frac{\theta_k^\beta}{2}\right)\cos^2\frac{\theta_k^\alpha}{2}-\left(\prod_{\beta=1}^{\alpha-1}\sin^2\frac{\theta_{k+1}^\beta}{2}\right)\cos^2\frac{\theta_{k+1}^\alpha}{2}=0,
\tag{5.3a}
$$

$$\left(\prod_{\beta=1}^{\alpha-1}\sin^2\frac{\theta_k^\beta}{2}\right)\sin\theta_k^\alpha\left[-\Phi_k^\alpha+\sum_{\gamma=\alpha+1}^{N}\left(\prod_{\delta=\alpha+1}^{\gamma-1}\sin^2\frac{\theta_k^\delta}{2}\right)\cos^2\frac{\theta_k^\gamma}{2}\,\Phi_k^\gamma\right]=0. \tag{5.3b}$$

Now we solve the first equation(s), (5.3a). In the $\alpha=1$ case the equation is

$$\cos^2\frac{\theta_k^1}{2}=\cos^2\frac{\theta_{k+1}^1}{2}, \tag{5.4}$$

and its solution is

$$\theta_k^1=\theta_{k+1}^1=\theta^1=\text{const.} \tag{5.5}$$

In the $\alpha=2$ case the equation is

$$\sin^2\frac{\theta^1}{2}\left(\cos^2\frac{\theta_k^2}{2}-\cos^2\frac{\theta_{k+1}^2}{2}\right)=0, \tag{5.6}$$

and its solutions are

(i) $\theta^1=0$ [in this case the remaining equations of (5.3a) hold with arbitrary θ^α for $\alpha\geqslant 2$],
(ii) $\theta^1=C_1\neq 0,\ \theta_k^2=\theta_{k+1}^2=\theta^2=\text{const.}$

By a similar consideration, we obtain the solutions

$$\begin{aligned}(\theta^1,\theta^2,\ldots,\theta^N)&=(0,*,*,\ldots,*,*),\\&=(C_1,0,*,\ldots,*,*),\\&=(C_1,C_2,0,\ldots,*,*),\\&\ \ \vdots\\&=(C_1,C_2,C_3,\ldots,C_{N-1},0),\end{aligned} \tag{5.7}$$

where $C_\alpha=\text{const}\neq 0$ $(1\leqslant\alpha\leqslant N-1)$, and $*$ denotes an arbitrary number. Next we solve (5.3b). The solution $(C_1,C_2,\ldots,C_{I-1},0,*,\ldots,*)$ of (5.7) satisfies the equations for $\alpha\geqslant I$ because $\theta_k^I=0$. In the $\alpha=I-1$ case the equation is

$$\sin C_{I-1}(-\Phi_k^{I-1}+\Phi_k^I)=0. \tag{5.8}$$

Because $-\Phi_k^{I-1}+\Phi_k^I=-(\Delta\varphi_k^{I-1}-\mu_{I-1}\Delta t)+(\Delta\varphi_k^I-\mu_I\Delta t)=0$ is not compatible with the boundary condition for any given T, the solution is

$$C_{I-1}=\pi. \tag{5.9}$$

Therefore we obtain

$$C_1=C_2=\cdots=C_{I-1}=\pi. \tag{5.10}$$

Considering about all Is, finally we obtain the solutions of (5.3):

$$
\begin{aligned}
(\theta_k^1,\theta_k^2,\ldots,\theta_k^N) &= (0,*,*,\ldots,*,*),\\
&= (\pi,0,*,\ldots,*,*),\\
&= (\pi,\pi,0,\ldots,*,*),\\
&\ \ \vdots\\
&= (\pi,\pi,\pi,\ldots,\pi,0),\\
&= (\pi,\pi,\pi,\ldots,\pi,\pi),
\end{aligned}
\tag{5.11}
$$

with φs being arbitrary for all α and κ.

First we consider the WKB approximation around $(\theta_k^1,\ldots,\theta_k^N)=(\pi,\pi,...,\pi)$. Putting

$$
\theta_k^\alpha = \pi - \frac{x_k^\alpha}{\sqrt{\lambda}}, \quad \alpha = 1,\ldots,N, \tag{5.12}
$$

we write the trace formula as

$$
\begin{aligned}
Z = e^{-iQc_{N+1}T + i[1/(N+1)]\Sigma_{\alpha=1}^N 2^{-\alpha+1}\mu_\alpha T} & \sum_{n^1=-\infty}^{\infty} \cdots \sum_{n^N=-\infty}^{\infty} e^{-i[1/(N+1)]\Sigma_{\alpha=1}^N 2^{-\alpha+2} n^\alpha \pi}\\
\times \lim_{M\to\infty} \prod_{\alpha=1}^N & \left\{ \int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi} d\varphi_M^\alpha \right\} \int_{-\infty}^{\infty} \prod_{i=1}^{M-1} d\boldsymbol{\varphi}_i \prod_{j=1}^{M} \left\{ \lambda^N \int_0^\infty \left(\cos^2 \frac{x_j^1}{2\sqrt{\lambda}} \right)^{N-1} \right.\\
\times \sin \frac{x_j^1}{\sqrt{\lambda}} & \left. \frac{dx_j^1}{2\pi\sqrt{\lambda}} \cdots \int_0^\infty \cos^2 \frac{x_j^{N-1}}{2\sqrt{\lambda}} \sin \frac{x_j^{N-1}}{\sqrt{\lambda}} \frac{dx_j^{N-1}}{2\pi\sqrt{\lambda}} \int_0^\infty \sin \frac{x_j^N}{\sqrt{\lambda}} \frac{dx_j^N}{2\pi\sqrt{\lambda}} \right\}\\
\times \exp & \left[2i\lambda \sum_{k=1}^M \sum_{\alpha=1}^N \left(\prod_{\beta=1}^{\alpha-1} \cos^2 \frac{x_k^\beta}{2\sqrt{\lambda}} \right) \left(\sin^2 \frac{x_k^\alpha}{2\sqrt{\lambda}} \right) \Phi_k^\alpha \right].
\end{aligned}
\tag{5.13}
$$

The leading order term ($O((1/\lambda)^0)$) becomes

$$
\begin{aligned}
Z_{N+1} \equiv e^{-iQc_{N+1}T + i[1/(N+1)]\Sigma_{\alpha=1}^N 2^{-\alpha+1}\mu_\alpha T} & \sum_{n^1=-\infty}^{\infty} \cdots \sum_{n^N=-\infty}^{\infty} e^{-i[1/(N+1)]\Sigma_{\alpha=1}^N 2^{-\alpha+2} n^\alpha \pi}\\
\times \lim_{M\to\infty} \prod_{\alpha=1}^N & \left[\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi} \frac{d\varphi_M^\alpha}{2\pi} \int_{-\infty}^{\infty} \prod_{i=1}^{M-1} \frac{d\varphi_i^\alpha}{2\pi} \int_0^\infty \prod_{j=1}^{M} x_j^\alpha dx_j^\alpha \right.\\
\times \exp & \left. \left\{ \frac{i}{2} \sum_{k=1}^M (x_k^\alpha)^2 (\Phi_k^\alpha + i\delta_M) \right\} \right],
\end{aligned}
\tag{5.14}
$$

where δ_M has been introduced, which is given for each M and finally put as zero, to ensure the convergence of the x-integrals. By the form of (5.14), each x_j^α-integral can be performed independently to give

$$Z_{N+1}=e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+2}n^\alpha\pi}$$
$$\times\lim_{M\to\infty}\prod_{\alpha=1}^{N}\left[\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}\frac{d\varphi_M^\alpha}{2\pi}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}\frac{d\varphi_i^\alpha}{2\pi}\prod_{j=1}^{M}\frac{1}{i(\mu_\alpha\Delta t-\Delta\varphi_j^\alpha-i\delta_M)}\right]. \quad (5.15)$$

Noting that

$$\int_{-\infty}^{\infty}\frac{d\varphi_i^\alpha}{2\pi i}\frac{1}{\mu_\alpha\Delta t-\varphi_{j+1}^\alpha+\varphi_j^\alpha-i\delta_M}\frac{1}{\mu_\alpha\Delta t-\varphi_j^\alpha+\varphi_{j-1}^\alpha-i\delta_M}=\frac{1}{\mu_\alpha 2\Delta t-\varphi_{j+1}^\alpha+\varphi_{j-1}^\alpha-2i\delta_M}, \quad (5.16)$$

we perform the φ-integrals to obtain

$$Z_{N+1}=e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\prod_{\alpha=1}^{N}\left[i\sum_{n^\alpha=-\infty}^{\infty}\frac{e^{i[1/(N+1)]2^{-\alpha+2}n^\alpha\pi}}{2n^\alpha\pi-\mu_\alpha T}\right]$$
$$=e^{-iQc_{N+1}T}\prod_{\alpha=1}^{N}\left[e^{i[1/(N+1)]2^{-\alpha+1}\mu_\alpha T}\sum_{\tilde{n}^\alpha=-\infty}^{\infty}\frac{e^{i2\tilde{n}^\alpha\pi[1/(N+1)]2^{-\alpha+1}}}{i(2\tilde{n}^\alpha\pi+\mu_\alpha T)}\right], \quad (5.17)$$

where we have put $\delta_M=0$ and $\tilde{n}^\alpha=-n^\alpha$ in the second equality. Application of the formula (3.8), noting

$$0<\frac{1}{N+1}2^{-\alpha+1}<1, \quad (5.18)$$

gives the final form

$$Z_{N+1}=e^{-iQc_{N+1}T}\prod_{\alpha=1}^{N}\left[e^{i[1/(N+1)]2^{-\alpha+1}\mu_\alpha T}\frac{e^{i(1/2-2^{-\alpha+1}/(N+1))\mu_\alpha T}}{2i\sin\frac{\mu_\alpha T}{2}}\right]$$
$$=\frac{e^{-iQc_{N+1}T}}{\Pi_{\alpha=1}^{N}(1-e^{-i\mu_\alpha T})}=\frac{e^{-iQc_{N+1}T}}{\Pi_{\alpha=1}^{N}\{1-e^{-i(c_\alpha-c_{N+1})T}\}}. \quad (5.19)$$

Next we perform the WKB approximation around

$$(\theta_k^1,\ldots,\theta_k^N)=(\overset{1}{\pi},\overset{2}{\pi},\ldots,\overset{I-1}{\pi},\overset{I}{0},\overset{I+1}{*},\ldots,\overset{N}{*}), \quad (5.20)$$

for $I=1,\ldots,N$ [$(\theta_k^1,\ldots,\theta_k^N)=(\pi,\pi,...,\pi,0)$ is a special case of (5.20)]. We put

$$\theta_k^\alpha=\pi-\frac{x_k^\alpha}{\sqrt{\lambda}},\quad \alpha=1,\ldots,I-1,\quad \theta_k^I=\frac{x_k^I}{\sqrt{\lambda}}, \quad (5.21)$$

and leave $\theta_\kappa^\alpha(\alpha=I+1,\ldots,N)$ unchanged because they are arbitrary numbers which have no expansion points. The leading order term of the trace formula then becomes

$$
\begin{aligned}
Z_I = & e^{-iQc_{N+1}T+i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}\mu_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{-i[1/(N+1)]\Sigma_{\alpha=1}^{N}2^{-\alpha+1}2n^\alpha\pi} \\
& \times\lim_{M\to\infty}\prod_{\alpha=1}^{N}\left\{\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}d\varphi_M^\alpha\right\}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}d\varphi_i \\
& \times\prod_{j=1}^{M}\left\{\int_0^\infty x_j^1\frac{dx_j^1}{2\pi}\cdots\int_0^\infty x_j^{I-1}\frac{dx_j^{I-1}}{2\pi}\int_0^\infty 2^{-2(N-I)}\right. \\
& \left.\times(x_j^I)^{2(N-I)+1}\frac{dx_j^I}{2\pi}\int_0^\pi\left(\sin^2\frac{\theta_j^{I+1}}{2}\right)^{N-I-1}\sin\theta_j^{I+1}\frac{d\theta_j^{I+1}}{2\pi}\cdots\int_0^\pi\sin\theta_j^N\frac{d\theta_j^N}{2\pi}\right\} \\
& \times e^{2i\lambda(2n^I\pi-\mu_I T)}\exp\left[\frac{i}{2}\sum_{k=1}^{M}\sum_{\alpha=1}^{I-1}(x_k^\alpha)^2(\Phi_k^\alpha-\Phi_k^I)-\frac{i}{2}\sum_{k=1}^{M}(x_k^I)^2\Phi_k^I\right. \\
& \left.+\frac{i}{2}\sum_{k=1}^{M}(x_k^I)^2\sum_{\alpha=I+1}^{N}\left(\prod_{\beta=I+1}^{\alpha-1}\sin^2\frac{\theta_k^\beta}{2}\right)\cos^2\frac{\theta_k^\alpha}{2}\Phi_k^\alpha\right] \\
= & e^{-iQc_IT}\hat{Z}_I e^{-i[1/(N+1)]2^{-I+1}\mu_I T+i[1/(N+1)]\Sigma_{\alpha=I+1}^{N}2^{-\alpha+1}\mu_\alpha T} \\
& \times\sum_{n^I=-\infty}^{\infty}\cdots\sum_{n^N=-\infty}^{\infty}e^{i[1/(N+1)]2^{-I+1}2n^I\pi-[1/(N+1)]\Sigma_{\alpha=I+1}^{N}2^{-\alpha+1}2n^\alpha\pi} \\
& \times\lim_{M\to\infty}\prod_{\alpha=I}^{N}\left\{\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}\frac{d\varphi_M^\alpha}{2\pi}\int\prod_{i=1}^{M-1}\frac{d\varphi_i^\alpha}{2\pi}\right\} \\
& \times\prod_{j=1}^{M}\left\{2^{-(N-I)}\int_0^\infty(x_j^I)^{2(N-I)+1}dx_j^I e^{-(i/2)(x_j^I)^2\Phi_j^I}\int_0^\pi\left(\sin^2\frac{\theta_j^{I+1}}{2}\right)^{N-I-1}\right. \\
& \left.\times\sin\theta_j^{I+1}d\theta_j^{I+1}\cdots\int_0^\pi\sin\theta_j^N d\theta_j^N\exp\left[\frac{i}{2}(x_j^I)^2\sum_{\alpha=I+1}^{N}\left(\prod_{\beta=I+1}^{\alpha-1}\sin^2\frac{\theta_j^\beta}{2}\right)\cos^2\frac{\theta_j^\alpha}{2}\Phi_j^\alpha\right]\right\},
\end{aligned}
\tag{5.22}
$$

where

$$
\begin{aligned}
\hat{Z}_I \equiv & e^{i[1/(N+1)]\Sigma_{\alpha=1}^{I-1}2^{-\alpha+1}\tilde{\mu}_\alpha T}\sum_{n^1=-\infty}^{\infty}\cdots\sum_{n^{I-1}=-\infty}^{\infty}e^{i[1/(N+1)]\Sigma_{\alpha=1}^{I-1}2^{-\alpha+1}2(n^I-n^\alpha)\pi} \\
& \times\lim_{M\to\infty}\prod_{\alpha=1}^{I-1}\left\{\int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi}\frac{d\varphi_M^\alpha}{2\pi}\int_{-\infty}^{\infty}\prod_{i=1}^{M-1}\frac{d\varphi^\alpha}{2\pi}\int_0^\infty\prod_{j=1}^{M}x_j^\alpha dx_j^\alpha\right. \\
& \left.\times\exp\left[\frac{i}{2}\sum_{k=1}^{M}(x_k^\alpha)^2(\Phi_k^\alpha-\Phi_k^I)\right]\right\},
\end{aligned}
\tag{5.23}
$$

with $\tilde{\mu}_\alpha\equiv\mu_\alpha-\mu_I$. We can calculate $\hat{Z}_I$ by the way similar to the $(\theta_k^1,\ldots,\theta_k^N)=(\pi,\ldots,\pi)$ case by substituting $N\to I-1$ and $\Phi_k^\alpha\to\Phi_k^\alpha-\Phi_k^I$ to obtain

$$\hat{Z}_I = e^{i[1/(N+1)]\Sigma_{\alpha=1}^{N-1} 2^{-\alpha+1}\tilde{\mu}_\alpha T} \sum_{n^1=-\infty}^{\infty} \cdots \sum_{n^{I-1}=-\infty}^{\infty} e^{i[1/(N+1)]\Sigma_{\alpha=1}^{I-1} 2^{-\alpha+1} 2(n^I - n^\alpha)\pi}$$
$$\times \prod_{\alpha=1}^{I-1} \left[\frac{1}{-i\{2(n^\alpha - n^I)\pi - (\mu_\alpha - \mu_I)T\}} \right]$$
$$= \prod_{\alpha=1}^{I-1} \left[e^{i[1/(N+1)]2^{-\alpha+1}\tilde{\mu}_\alpha T} \sum_{\tilde{n}^\alpha=-\infty}^{\infty} \frac{e^{i[1/(N+1)]2^{-\alpha+1} 2\tilde{n}^\alpha \pi}}{i(2\tilde{n}^\alpha + \tilde{\mu}_\alpha T)} \right] = \prod_{\alpha=1}^{I-1} \frac{1}{1 - e^{-i\tilde{\mu}_\alpha T}}, \tag{5.24}$$

where $\tilde{n}^\alpha = n^I - n^\alpha$. For the remaining part of (5.22), changing variables such that

$$p_k^\alpha = \left(\prod_{\beta=I+1}^{\alpha-1} \sin^2 \frac{\theta_k^\beta}{2} \right) \cos^2 \frac{\theta_k^\alpha}{2}, \quad \alpha = I+1, \ldots, N, \tag{5.25}$$

with the Jacobian

$$\frac{\partial(\pi)}{\partial(\theta)} = (-1)^{N-I} 2^{-N+I} \prod_{\alpha=I+1}^{N} \left\{ \left(\sin^2 \frac{\theta_k^\alpha}{2} \right)^{N-\alpha} \sin \theta_k^\alpha \right\}, \tag{5.26}$$

gives the form of the leading order term

$$Z_I = e^{-iQc_I T} \hat{Z}_I e^{-i[1/(N+1)]2^{-I+1}\mu_I T + i[1/(N+1)]\Sigma_{\alpha=I+1}^{N} 2^{-\alpha+1}\mu_\alpha T}$$
$$\times \sum_{n^I=-\infty}^{\infty} \cdots \sum_{n^N=-\infty}^{\infty} e^{i[1/(N+1)]2^{-I+1} 2n^I \pi - i[1/(N+1)]\Sigma_{\alpha=I+1}^{N} 2^{-\alpha+1} 2n^\alpha \pi}$$
$$\times \lim_{M\to\infty} \prod_{\alpha=1}^{N} \left\{ \int_{2n^\alpha \pi}^{2(n^\alpha+1)\pi} \frac{d\varphi_M^\alpha}{2\pi} \int_{-\infty}^{\infty} \prod_{i=1}^{M-1} \frac{d\varphi_i^\alpha}{2\pi} \right\}$$
$$\times \prod_{j=1}^{M} \left\{ \int_0^\infty (x_j^I)^{2(N-I)+1} dx_j^I e^{-(i/2)(x_j^I)^2 \Phi_j^I} \int_0^1 dp_j^{I+1} \int_0^{1-p_j^{I+1}} dp_j^{I+2} \cdots \right.$$
$$\left. \times \int_0^{1-\Sigma_{\alpha=I+1}^{N-1} p_j^\alpha} dp_j^N \exp\left[\frac{i}{2} (x_j^I)^2 \sum_{\alpha=I+1}^{N} p_j^\alpha \Phi_j^\alpha \right] \right\}. \tag{5.27}$$

By putting $u_j = \frac{1}{2}(x_j^I)^2$ and applying the integral relation (1.7) with $L = I+1$, $u = u_j$, $\Phi^\alpha = \Phi_j^\alpha$, u-integrals becomes

$$\int_0^\infty (u_j)^{N-I} du_j e^{-iu_j\Phi_j^I} \int_0^1 dp_j^{I+1} \cdots \int_0^{1-\Sigma_{\alpha=I+1}^{N-1} p_j^\alpha} dp_j^N e^{iu_j \Sigma_{\alpha=I+1}^N p_j^\alpha \Phi_j^\alpha}$$

$$= \int_0^\infty (u_j)^{N-I} du_j e^{-iu_j\Phi_j^I} (iu_j)^{-N+(I+1)-1} \left[\sum_{\alpha=I+1}^N \frac{1}{\Phi_j^\alpha \Pi_{\substack{\beta=I+1 \\ \beta\neq\alpha}}^N (\Phi_j^\alpha - \Phi_j^\beta)} e^{iu_j\Phi_j^\alpha} \right.$$

$$\left. + \frac{(-1)^{N-(I-1)+1}}{\Pi_{\beta=I+1}^N \Phi_j^\beta} \right] = \lim_{\delta\to 0} i^{-N+I} \left[\sum_{\alpha=I+1}^N \frac{1}{\Phi_j^\alpha \Pi_{\substack{\beta=I+1 \\ \beta\neq\alpha}}^N (\Phi_j^\alpha - \Phi_j^\beta)} \int_0^\infty du_j e^{iu_j(\Phi_j^\alpha - \Phi_j^I + i\delta)} \right.$$

$$\left. + \frac{(-1)^{N-I}}{\Pi_{\beta=I+1}^N \Phi_j^\beta} \int_0^\infty du_j e^{-iu_j(\Phi_j^I - i\delta)} \right] = i^{-N+I-1} \left\{ -\sum_{\alpha=I+1}^N \frac{1}{\Phi_j^\alpha \Pi_{\substack{\beta=I \\ \beta\neq\alpha}}^N (\Phi_j^\alpha - \Phi_j^\beta)} \right.$$

$$\left. + \frac{(-1)^{N-I}}{\Pi_{\beta=I}^N \Phi_j^\beta} \right\} = \frac{1}{i\Phi_j^I \Pi_{\beta=I+1}^N i(\Phi_j^I - \Phi_j^\beta)}, \tag{5.28}$$

where the regularization parameter δ has been introduced for the u_j-integrals to converge in the third equality and the relation (1.6) has been applied in the last equality. Thus (5.27) becomes

$$Z_I = e^{-iQc_I T} \hat{Z}_I e^{-i[1/(N+1)]2^{-I+1}\mu_I T + i[1/(N+1)]\Sigma_{\alpha=I+1}^N 2^{-\alpha+1}\mu_\alpha T}$$

$$\times \sum_{n^I=-\infty}^\infty \cdots \sum_{n^N=-\infty}^\infty e^{i[1/(N+1)]2^{-I+1}2n^I\pi - i[1/(N+1)]\Sigma_{\alpha=I+1}^N 2^{-\alpha+1}2n^\alpha\pi}$$

$$\times \lim_{M\to\infty} \int_{2n^I\pi}^{2(n^I+1)\pi} \frac{d\varphi_M^I}{2\pi} \int_{-\infty}^\infty \prod_{i=1}^{M-1} \frac{d\varphi_i^I}{2\pi} \prod_{j=1}^M \frac{1}{i\Phi_j^I} \prod_{\alpha=I+1}^N$$

$$\times \left\{ \int_{2n^\alpha\pi}^{2(n^\alpha+1)\pi} \frac{d\varphi_M^\alpha}{2\pi} \int_{-\infty}^\infty \prod_{i=1}^{M-1} \frac{d\varphi_i^\alpha}{2\pi} \prod_{j=1}^M \frac{1}{(\Phi_j^I - \Phi_j^\alpha)} \right\}$$

$$= e^{-iQc_I T} \hat{Z}_I e^{-i[1/(N+1)]2^{-I+1}\mu_I T + i[1/(N+1)]\Sigma_{\alpha=I+1}^N 2^{-\alpha+1}\mu_\alpha T}$$

$$\times \sum_{n^I=-\infty}^\infty \cdots \sum_{n^N=-\infty}^\infty e^{i1/(N+1)2^{-I+1}2n^I\pi - i[1/(N+1)]\Sigma_{\alpha=I+1}^N 2^{-\alpha+1}2n^\alpha\pi}$$

$$\times \frac{1}{i(2n^I\pi - \mu_I T)} \prod_{\alpha=I+1}^N \frac{1}{i\{2(n^I - n^\alpha)\pi - (\mu_I - \mu_\alpha)T\}}, \tag{5.29}$$

where the φ-integrals have been performed by noting (5.16). Putting

$$\tilde{n}^\alpha = n^I - n^\alpha, \quad \tilde{\mu}_\alpha \equiv c_\alpha - c_I = \mu_\alpha - \mu_I, \quad \alpha = I+1,\ldots,N,$$

$$\tilde{\mu}_{N+1} \equiv c_{N+1} - c_I = -\mu_I, \tag{5.30}$$

we obtain

$$
\begin{aligned}
Z_I &= e^{-iQc_I T}\hat{Z}_I e^{i[1/(N+1)]2^{-N+1}\tilde{\mu}_{N+1}T} \sum_{n^I=-\infty}^{\infty} \frac{e^{i[1/(N+1)]2^{-N+1}2n^I\pi}}{i(2n^I\pi+\tilde{\mu}_{N+1}T)} \\
&\quad \times \prod_{\alpha=I+1}^{N} \left[e^{i[1/(N+1)]2^{-\alpha+1}\tilde{\mu}_\alpha T} \sum_{\tilde{n}^\alpha=-\infty}^{\infty} \frac{e^{i[1/(N+1)]2^{-\alpha+1}2\tilde{n}^\alpha\pi}}{i(2\tilde{n}^\alpha\pi+\tilde{\mu}_\alpha T)} \right] \\
&= e^{-iQc_I T}\hat{Z}_I e^{i[1/(N+1)]2^{-N+1}\tilde{\mu}_{N+1}T} \frac{e^{i(1/2-[1/(N+1)]2^{-N+1})\tilde{\mu}_{N+1}T}}{2i\,\sin\dfrac{\tilde{\mu}_{N+1}T}{2}} \\
&\quad \times \prod_{\alpha=I+1}^{N} \left[e^{i1/(N+1)2^{-\alpha+1}\tilde{\mu}_\alpha T} \frac{e^{i(1/2-[1/(N+1)]2^{-\alpha+1})\tilde{\mu}_\alpha T}}{2i\,\sin\dfrac{\tilde{\mu}_\alpha T}{2}} \right] \\
&= e^{-iQc_I T}\hat{Z}_I \frac{1}{1-e^{-i\tilde{\mu}_{N+1}T}} \prod_{\alpha=I+1}^{N} \frac{1}{1-e^{-i\tilde{\mu}_\alpha T}} = \frac{e^{-iQc_I T}}{\prod_{\substack{\alpha=1 \\ \alpha\neq I}}^{N+1}(1-e^{-i\tilde{\mu}_\alpha T})},
\end{aligned}
\tag{5.31}
$$

where we have applied the formula (3.8) in the second equality and put the explicit form of $\hat{Z}_I$, (5.24), in the last equality. Thus the total contribution of the WKB approximation becomes

$$
Z_{\mathrm{WKB}} = \sum_{\alpha=1}^{N+1} Z_\alpha = \sum_{\alpha=1}^{N+1} \frac{e^{-iQc_\alpha T}}{\prod_{\substack{\beta=1 \\ \beta\neq\alpha}}^{N+1}\{1-e^{-i(c_\beta-c_\alpha)T}\}},
\tag{5.32}
$$

which is the same with the exact calculation (3.12). Therefore we can conclude that *the WKB exactness holds in the multi-periodic coherent state*.

VI. DISCUSSION

In this paper we have constructed the trace formula in terms of the multi-periodic coherent state as an extension of the Nielsen–Rohrlich formula for spin. We have made an exact calculation of the trace formula and performed the WKB approximation to show the WKB exactness. We have also clarified a connection between the trace formula and that of the generalized coherent state.

The result obtained in this paper is perfectly parallel with the generalized coherent state.[11] Similar argument in terms of another coherent state may be possible. However, the WKB exactness will not hold in arbitrary coherent states. Now we have the problem that *what kind of coherent states make the system WKB exact.*

The extension to the Grassmann manifold from CP^N have been made.[17] The corresponding extension from the multi-periodic coherent state will be also possible.

The extension to supersymmetric $CP^1(CP^N)$ model is also attractive. There is an expectation that by the fermion contribution the result of the continuum path integral coincides with the discrete one.

The extension to field theories is more important. There are some attempts in this field.[18–20] However, they still seem to be insufficient in the mathematical point of view.

APPENDIX A: SOME USEFUL RELATIONS

1. The Vandermonde's determinant

We define

$$\Delta_k \equiv \prod_{\alpha=k}^{n} \prod_{\beta=k}^{\alpha-1} (a_\alpha - a_\beta) = \begin{vmatrix} 1 & 1 & \cdots & 1 \\ a_k & a_{k+1} & \cdots & a_n \\ a_k^2 & a_{k+1}^2 & \cdots & a_n^2 \\ \vdots & \vdots & \ddots & \vdots \\ a_k^{n-k} & a_{k+1}^{n-k} & \cdots & a_n^{n-k} \end{vmatrix},$$

$$\Delta_k(\alpha) \equiv \begin{vmatrix} a_k & a_{k+1} & \cdots & a_{\alpha-1} & a_{\alpha+1} & \cdots & a_n \\ a_k^2 & a_{k+1}^2 & \cdots & a_{\alpha-1}^2 & a_{\alpha+1}^2 & \cdots & a_n^2 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_k^{n-k} & a_{k+1}^{n-k} & \cdots & a_{\alpha-1}^{n-k} & a_{\alpha+1}^{n-k} & \cdots & a_n^{n-k} \end{vmatrix}, \tag{A1}$$

$$\tilde{\Delta}_k(\alpha) \equiv \begin{vmatrix} 1 & \cdots & 1 & 1 & \cdots & 1 \\ a_k & \cdots & a_{\alpha-1} & a_{\alpha+1} & \cdots & a_n \\ a_k^2 & \cdots & a_{\alpha-1}^2 & a_{\alpha+1}^2 & \cdots & a_n^2 \\ \vdots & & \vdots & \vdots & & \vdots \\ a_k^{n-k-1} & \cdots & a_{\alpha-1}^{n-k-1} & a_{\alpha+1}^{n-k-1} & \cdots & a_n^{n-k-1} \end{vmatrix} = \prod_{\substack{\beta=k \\ \beta\neq\alpha}}^{n} \prod_{\substack{\gamma=k \\ \gamma\neq\alpha}}^{\beta-1} (a_\beta - a_\gamma),$$

$$P_k \equiv \prod_{\alpha=k}^{n} a_\alpha = a_k a_{k+1} \cdots a_n .$$

Here Δ_k is known as the Vandermonde's determinant and $\Delta_k(\alpha)$ is its cofactor apart from sign factor $(-1)^{\alpha-k}$. We then find the relations (Laplace expansion)

$$\Delta_k = \sum_{\alpha=k}^{n} (-1)^{\alpha-k} \Delta_k(\alpha),$$

$$\Delta_k(\alpha) = \frac{P_k}{a_\alpha} \tilde{\Delta}_k(\alpha). \tag{A2}$$

We rewrite $\Delta_k(\alpha)$ by another expression. Since

$$\prod_{\substack{\beta=k \\ \beta\neq\alpha}}^{n} (a_\alpha - a_\beta) = (-1)^{n-\alpha} \Delta_k \frac{1}{\tilde{\Delta}_k(\alpha)} = (-1)^{n-\alpha} \frac{P_k}{a_\alpha} \frac{\Delta_k}{\Delta_k(\alpha)}, \tag{A3}$$

we have

$$\Delta_k(\alpha) = (-1)^{n-\alpha} \frac{P_k}{a_\alpha \prod_{\substack{\beta=k \\ \beta\neq\alpha}}^{n} (a_\alpha - a_\beta)} \Delta_k . \tag{A4}$$

Substituting (A4) into the first relation in (A2), we then find

$$\sum_{\alpha=k}^{n} \frac{P_k}{a_\alpha \Pi_{\substack{\beta=k \\ \beta\neq\alpha}}^{n}(a_\alpha - a_\beta)} = (-1)^{n-k}, \tag{A5}$$

and, picking out the $\alpha=k$ term,

$$\frac{1}{a_k \Pi_{\beta=k+1}^{n}(a_k - a_\beta)} = -\sum_{\alpha=k+1}^{n} \frac{1}{a_\alpha \Pi_{\substack{\beta=k \\ \beta\neq\alpha}}^{n}(a_\alpha - a_\beta)} + \frac{(-1)^{n-k}}{P_k}. \tag{A6}$$

2. Some integral

We claim

$$\begin{aligned} A(L) &\equiv \int_0^{1-\Sigma_{\gamma=I+1}^{L-1} p^\gamma} dp^L e^{iu\Phi^L p^L} \cdots \int_0^{1-\Sigma_{\gamma=I+1}^{N-1} p^\gamma} dp^N e^{iu\Phi^N p^N} \\ &= (iu)^{-N+L-1} \left[\sum_{\alpha=L}^{N} \frac{1}{\Phi^\alpha \Pi_{\substack{\beta=L \\ \beta\neq\alpha}}^{N}(\Phi^\alpha - \Phi^\beta)} e^{iu(1-\Sigma_{\gamma=I+1}^{L-1} p^\gamma)\Phi^\alpha} + \frac{(-1)^{N-L+1}}{\Pi_{\beta=L}^{N}\Phi^\beta} \right], \\ &\quad \text{for } L = N, N-1, \ldots, I+1. \end{aligned} \tag{A7}$$

We prove this relation by mathematical induction. In the $L=N$ case we can examine (A7) by an explicit calculation. Now we assume that (A7) holds in L. We then calculate in the $L-1$ case:

$$\begin{aligned} A(L-1) &\equiv \int_0^{1-\Sigma_{\gamma=I+1}^{L-2} p^\gamma} dp^{L-1} e^{iu\Phi^{L-1} p^{L-1}} \cdots \int_0^{1-\Sigma_{\gamma=I+1}^{N-1} p^\gamma} dp^N e^{iu\Phi^N p^N} \\ &= \int_0^{1-\Sigma_{\gamma=I+1}^{L-2} p^\gamma} dp^{L-1} A(L) \\ &= (-1)^{-N+L-1} \left[\sum_{\alpha=L}^{N} \frac{1}{\Phi^\alpha \Pi_{\substack{\beta=L \\ \beta\neq\alpha}}^{N}(\Phi^\alpha - \Phi^\beta)} e^{iu(1-\Sigma_{\gamma=I+1}^{L-2} p^\gamma)\Phi^\alpha} \right. \\ &\quad \times \int_0^{1-\Sigma_{\gamma=I+1}^{L-1} p^\gamma} dp^{L-1} e^{iu(\Phi^{L-1}-\Phi^\alpha)p^{L-1}} \\ &\quad \left. + \frac{(-1)^{N-L+1}}{\Pi_{\beta=L}^{N}\Phi^\beta} \int_0^{1-\Sigma_{\gamma=I+1}^{L-2} p^\gamma} dp^{L-1} e^{iu\Phi^{L-1} p^{L-1}} \right] \\ &= (iu)^{-N+(L-1)-1} \left[\sum_{\alpha=L}^{N} \frac{1}{\Phi^\alpha \Pi_{\substack{\beta=L-1 \\ \beta\neq\alpha}}^{N}(\Phi^\alpha - \Phi^\beta)} e^{iu\Phi^\alpha(1-\Sigma_{\gamma=I+1}^{L-2})p^\gamma} \right. \\ &\quad \left. + \left\{ -\sum_{\alpha=L}^{N} \frac{1}{\Phi^\alpha \Pi_{\substack{\beta=L-1 \\ \beta\neq\alpha}}^{N}(\Phi^\alpha - \Phi^\beta)} + \frac{(-1)^{N-L+1}}{\Pi_{\beta=L-1}^{N}\Phi^\beta} \right\} \right. \end{aligned}$$

$$\times e^{iu\Phi^{L-1}(1-\Sigma_{\gamma=I+1}^{L-2}p^{\gamma})}+\frac{(-1)^{N-(L-1)+1}}{\Pi_{\beta=L-1}^{N}\Phi^{\beta}}\Bigg]$$

$$=(iu)^{-N+(L-1)-1}\Bigg[\sum_{\alpha=L}^{N}\frac{1}{\Phi^{\alpha}\Pi_{\substack{\beta=L-1\\ \beta\neq\alpha}}^{N}(\Phi^{\alpha}-\Phi^{\beta})}$$

$$\times e^{iu\Phi^{\alpha}(1-\Sigma_{\gamma=I+1}^{L-2})p^{\gamma}}+\frac{1}{\Phi^{L-1}\Pi_{\beta=L}^{N}(\Phi^{L-1}-\Phi^{\beta})}$$

$$\times e^{iu\Phi^{L-1}(1-\Sigma_{\gamma=I+1}^{L-2}p^{\gamma})}+\frac{(-1)^{N-(L-1)+1}}{\Pi_{\beta=L-1}^{N}\Phi^{\beta}}\Bigg]$$

$$=(-1)^{-N+(L-1)-1}\Bigg[\sum_{\alpha=L-1}^{N}\frac{1}{\Phi^{\alpha}\Pi_{\substack{\beta=L-1\\ \beta\neq\alpha}}^{N}(\Phi^{\alpha}-\Phi^{\beta})}$$

$$\times e^{-u\Phi^{\alpha}(1-\Sigma_{\gamma=I+1}^{L-2}p^{\gamma})}+\frac{(-1)^{N-(L-1)+1}}{\Pi_{\beta=L-1}^{N}\Phi^{\beta}}\Bigg]. \tag{A8}$$

Equation (A8) indicates that (A7) in the $L-1$ case holds if it holds in the L case. Thus we conclude that (A7) holds for $L=N,N-1,\ldots,I+1$.

APPENDIX B: THE DETERMINANT FORM OF THE EXACT RESULT

Utilizing the relation in Appendix A, we rewrite the exact result of the trace formula in the determinant form.

By assigning

$$k=1,\quad n=N+1,\quad a_{\alpha}=e^{-ic_{\alpha}T}, \tag{B1}$$

(A3) becomes

$$\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N+1}(e^{-ic_{\alpha}T}-e^{-ic_{\beta}T})=(-1)^{N+1-\alpha}\frac{\Delta_1}{\tilde{\Delta}_1(\alpha)}. \tag{B2}$$

By means of (B2), we rewrite (3.12) to

$$Z=\sum_{\alpha=1}^{N+1}\frac{e^{-iQc_\alpha T}}{\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N+1}\{1-e^{-i(c_\beta-c_\alpha)T}\}}=\sum_{\alpha=1}^{N+1}\frac{e^{-iQc_\alpha T}}{e^{iNc_\alpha T}\prod_{\substack{\beta=1\\ \beta\neq\alpha}}^{N+1}(e^{-ic_\alpha T}-e^{-ic_\beta T})}$$

$$=\sum_{\alpha=1}^{N+1}\frac{e^{-i(Q+N)c_\alpha T}}{(-1)^{N+1-\alpha}\dfrac{\Delta_1}{\tilde{\Delta}_1(\alpha)}}=\frac{1}{\Delta_1}\sum_{\alpha=1}^{N+1}$$

$$\times(-1)^{N+1+\alpha}e^{-i(Q+N)c_\alpha T}\begin{vmatrix} 1 & \cdots & 1 & 1 & \cdots & 1 \\ e^{-ic_1T} & \cdots & e^{-ic_{\alpha-1}T} & e^{-ic_{\alpha+1}T} & \cdots & e^{-ic_{N+1}T} \\ e^{-i2c_1T} & \cdots & e^{-i2c_{\alpha-1}T} & e^{-i2c_{\alpha+1}T} & \cdots & e^{-i2c_{N+1}T} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ e^{-i(N-1)c_1T} & \cdots & e^{-i(N-1)c_{\alpha-1}T} & e^{-i(N-1)c_{N+1}T} & \cdots & e^{-i(N-1)c_{N+1}T} \end{vmatrix}$$

$$=\frac{1}{\Delta_1}\begin{vmatrix} 1 & 1 & \cdots & 1 \\ e^{-ic_1T} & e^{-ic_2T} & \cdots & e^{-ic_{N+1}T} \\ \vdots & \vdots & \ddots & \vdots \\ e^{-i(N-1)c_1T} & e^{-i(N-1)c_2T} & \cdots & e^{-i(N-1)c_{N+1}T} \\ e^{-i(Q+N)c_1T} & e^{-i(Q+N)c_2T} & \cdots & e^{-i(Q+N)c_{N+1}T} \end{vmatrix}. \tag{B3}$$

This is the determinant form (3.13).

(Received 11 April 1996; accepted for publication 11 June 1996)

A third order Monge-Ampère type equation of associativity that Dubrovin has obtained in 2-d topological field theory is formulated in terms of a variational principle subject to second class constraints. Using Dirac's theory of constraints this degenerate Lagrangian system is cast into Hamiltonian form and the Hamiltonian operator is obtained from the Dirac bracket. There is a new type of Kac-Moody algebra that corresponds to this Hamiltonian operator. In particular, it is not a W-algebra. © *1996 American Institute of Physics.* [S0022-2488(96)01811-7]

I. INTRODUCTION

Witten has introduced model-independent recursion relations which can be regarded as the qualitative definition of the topological phase of two dimensional gravity.[1] The validity of these relations is based on purely geometrical considerations such as intersection theory and makes no reference to the details of the physical model. The equations of associativity for the Frobenius algebra satisfied by the n-point function are third order Monge-Ampère equations. In this paper we shall consider the Hamiltonian structure of

$$u_{ttt}=u_{xtt}u_{xxx}-u_{txx}{}^2 \tag{1}$$

that Dubrovin[2] has obtained as an equation of associativity in 2-d topological field theory. Our approach will closely follow the discussion of the multi-Hamiltonian structure of the Monge-Ampère equation,[3] starting with a field theory formulation of Dubrovin's equation (1) itself.

We shall show that Eq. (1) can be derived from a variational principle with a degenerate Lagrangian and using Dirac's theory of constraints[4] cast it into Hamiltonian form. The resulting Dirac bracket yields the Hamiltonian operator. The Kac-Moody algebra associated with this Hamiltonian operator is not a W-algebra.

The Hamiltonian structure of Eq. (1) has also been discussed by Mokhov and Ferapontov[5] who based their considerations on a system of equations of hydrodynamic type.[6] They found that Eq. (1) is equivalent to a non-diagonizable 3-component Hamiltonian system of hydrodynamic type and obtained a first order Hamiltonian operator of Dubrovin-Novikov type. The Hamiltonian operator that results from our approach is different from that of Mokhov and Ferapontov.

II. SYSTEM OF EVOLUTION EQUATIONS

Dubrovin's equation (1) is third order in time and in order to cast it into Hamiltonian form we need to express it as a triplet of first order nonlinear evolution equations. For this purpose we introduce auxiliary variables

$$p=u_x, \quad q=u_t, \quad r=u_{tt}, \tag{2}$$

which results in

0022-2488/96/37(12)/6012/6/$10.00

$$\begin{aligned} p_t &= q_x, \\ q_t &= r, \\ r_t &= p_{xx} r_x - {q_{xx}}^2 \end{aligned} \tag{3}$$

and it is worth noting that this split of Eq. (1) into the system (3) is not unique. Now the vector field

$$\mathbf{X} = q_x \frac{\partial}{\partial p} + r \frac{\partial}{\partial q} + (p_{xx} r_x - {q_{xx}}^2) \frac{\partial}{\partial r} \tag{4}$$

defines the flow. In the discussion of the Hamiltonian structure of this system we shall use $u^i, i = 1,2,3$, for the variables p, q, r, respectively.

III. DIRAC BRACKET

It can be verified directly that the Lagrangian density which yields the first order equations of motion (3) is given by

$$\mathscr{L} = p r_t - \tfrac{1}{2} q_x q_t - p_x p_{xx} q_t - p_x q_{xx} p_t - q r_x - \tfrac{1}{2} q_x^2 p_{xx} \tag{5}$$

and we note that it is linear in the velocities. Thus the canonical momenta

$$\begin{aligned} \pi_p &= -p_x q_{xx}, \\ \pi_q &= -p_x p_{xx} - \tfrac{1}{2} q_x, \\ \pi_r &= p \end{aligned} \tag{6}$$

cannot be inverted for the velocities and we have a degenerate Lagrangian system. They satisfy the canonical Poisson bracket relations

$$\{\pi_k(x), u^i(y)\} = \delta_k^i \delta(x-y) \tag{7}$$

with all others vanishing. The passage to a Hamiltonian formulation of this system requires the use of Dirac's theory of constraints[4] since the Lagrangian (5) is degenerate.

Following Dirac we introduce the primary constraints from Eqs. (6)

$$\begin{aligned} \phi_1 &= \pi_p + p_x q_{xx}, \\ \phi_2 &= \pi_q + p_x p_{xx} + \tfrac{1}{2} q_x, \\ \phi_3 &= \pi_r - p \end{aligned} \tag{8}$$

and calculating the Poisson brackets of the constraints

$$\begin{aligned} \{\phi_1(x), \phi_1(y)\} &= q_{xx} \delta_x(x-y) - q_{yy} \delta_y(y-x), \\ \{\phi_1(x), \phi_2(y)\} &= p_y \delta_{xx}(y-x) + p_x \delta_{yy}(x-y) - p_{xx} \delta_y(x-y) \\ \{\phi_1(x), \phi_3(y)\} &= \delta(x-y), \\ \{\phi_2(x), \phi_2(y)\} &= \tfrac{1}{2} \delta_x(x-y) - \tfrac{1}{2} \delta_y(y-x), \\ \{\phi_2(x), \phi_3(y)\} &= 0, \\ \{\phi_3(x), \phi_3(y)\} &= 0 \end{aligned} \tag{9}$$

we find that the constraints (8) are second class as they do not vanish modulo the constraints.

The total Hamiltonian of Dirac is given by

$$H_T=\int\left(\frac{1}{2}q_x^2p_{xx}+qr_x+c^i\phi_i\right)dx, \tag{10}$$

where summation over $i=1,2,3$ is implied and c^i are Lagrange multipliers. The condition that the constraints are maintained in time

$$\{\phi_i(x),H_T\}=0 \tag{11}$$

gives rise to no further constraints. Instead, using Eqs. (9), we find that the Lagrange multipliers are determined from Eq. (11)

$$c^1=q_x,\quad c^2=r,\quad c^3=p_{xx}r_x-q_{xx}{}^2$$

and finally from Eq. (10) we have

$$H_T=\int\left\{q_x\pi_p+r\pi_q+(p_{xx}r_x-q_{xx}{}^2)\pi_r-\frac{1}{2}rq_x-pq_{xx}{}^2+pr_xp_{xx}\right\}dx \tag{12}$$

for the total Hamiltonian. Given any smooth function of the canonical variables $\mathscr{A}$, all the equations of motion are satisfied in the form of Hamilton's equations

$$\mathscr{A}_t=\{\mathscr{A}(x),H_T\} \tag{13}$$

with this total Hamiltonian.

In order to construct the Dirac bracket we need the inverse J^{ik} of the matrix of Poisson brackets of the constraints. The definition of the inverse is simply

$$\int\{\phi_i(x),\phi_k(z)\}J^{kj}(z,y)dz=\delta_i^j\delta(x-y), \tag{14}$$

which results in a set of differential equations for J^{ik}. Starting with the Poisson bracket relations (9) we find that Eq. (14) can be solved readily to yield

$$\begin{aligned}
J^{11}(x,y)&=0,\\
J^{12}(x,y)&=0,\\
J^{13}(x,y)&=\delta(x-y),\\
J^{22}(x,y)&=-\theta(x-y),\\
J^{23}(x,y)&=p_{xx}\delta(x-y),\\
J^{33}(x,y)&=(p_{xx}^2-2q_{xx})\delta_x(x-y)+(p_{xx}p_{xxx}-q_{xxx})\delta(x-y)
\end{aligned} \tag{15}$$

for the inverse of (9). From this result the Dirac bracket can be constructed readily.

IV. HAMILTONIAN OPERATOR

The transition from the Dirac bracket to the Hamiltonian operator is given by

$$\{u^i(x),u^k(y)\}_D=J^{ik}(x,y)\equiv J^{ik}(x)\,\delta(x-y) \tag{16}$$

and from Eqs. (16) and (15) it follows that the Hamiltonian operator corresponding to the degenerate Lagrangian (5) is

$$J=\begin{pmatrix} 0 & 0 & -1 \\ 0 & D_x^{-1} & -p_{xx} \\ 1 & p_{xx} & D_x q_{xx}+q_{xx}D_x-p_{xx}D_x p_{xx} \end{pmatrix}, \tag{17}$$

where D_x^{-1} the inverse of D_x. We refer to Ref. 7 for the definition and properties of D_x^{-1} in particular,

$$D_x^{-1}f=\frac{1}{2}\left(\int_{-\infty}^{x}-\int_{x}^{\infty}\right)f(\xi)d\xi \tag{18}$$

and the integrals are taken in the principal value sense. We should note that the Hamiltonian operator (17) is not a truly nonlocal operator. In the variables p,q,r for which there is a local expression for the Lagrangian (5) there is a nonlocal piece in the Hamiltonian operator, but this operator will become a local operator if in place of p,q,r we use variables that contain higher x-derivatives of u.

Finally, in Dirac's theory second class constraints hold as strong equations and therefore one can eliminate the momenta from Eqs. (6) to obtain the total Hamiltonian density

$$\mathscr{H}_D=\tfrac{1}{2}q_x^2 p_{xx}+rq_x \tag{19}$$

of Dirac. It can be directly verified that this quantity is conserved for the flow (4) and this is the Hamiltonian function appropriate to the operator (17). That is, the equations of motion (3) are cast into the form

$$u_t^i=\mathbf{X}(u^i)=J^{ik}\delta_k H_D \tag{20}$$

of Hamilton's equations, where δ_k denotes the variational derivative with respect to u^k and H_D is the integral of the density $\mathscr{H}_D$.

The proof of the Jacobi identities for (17) follows from the fact that it is simply the Hamiltonian operator corresponding to the Dirac bracket according to Eq. (16) and there is a general proof of the Jacobi identities for Dirac brackets.[4]

There are two additional conserved densities for Eqs. (3),

$$\begin{aligned} \mathscr{C} &= r-q_x p_{xx}, \\ \mathscr{P} &= \tfrac{1}{2}q_x^2+rp_x+\tfrac{1}{2}p_x^2 q_{xx}, \end{aligned} \tag{21}$$

which consist of the Casimir and momentum, respectively. Inserting P in place of H_D in Eq. (20) we end up with the trivial flow.

V. SYMPLECTIC STRUCTURE

The symplectic structure of the equations of motion (3) is obtained by integrating the 2-form density[8]

$$\omega=\tfrac{1}{2}du^i\wedge K_{ij}du^j \tag{22}$$

over the spatial variable, where K is the ''inverse'' of J. This is just the Poisson bracket of the constraints (9), or we may invert (17) to obtain

$$K=\begin{pmatrix} q_{xx}D_x+D_x q_{xx} & -p_{xx}D_x & 1 \\ -D_x p_{xx} & D_x & 0 \\ -1 & 0 & 0 \end{pmatrix} \tag{23}$$

and we find the symplectic 2-form

$$\omega = dp \wedge dr + q_{xx} dp \wedge dp_x - p_{xx} dp \wedge dq_x + \frac{1}{2} dq \wedge dq_x , \tag{24}$$

which can be directly verified to be a closed 2-form. By invoking the Poincaré lemma, in a local neighborhood we can write

$$\omega = d\alpha, \quad \alpha = (q_x p_{xx} - r) dp - \tfrac{1}{2} q_x dq, \tag{25}$$

where the coefficient of dp is essentially the Casimir of (17). The closure of the symplectic 2-form (24) is equivalent to the satisfaction of the Jacobi identities by the Hamiltonian operator (17).

VI. KAC-MOODY ALGEBRA

Hamiltonian operators associated with integrable nonlinear evolution equations give rise to Kac-Moody (KM) algebras.[9] There is an explicit algorithm for the construction of the KM algebra from the Hamiltonian operator which is essentially based on Fourier analysis. Thus using

$$p(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{i}{n^2} \mathscr{P}_n e^{inx} dn, \quad q(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{1}{n^2} \mathscr{Q}_n e^{inx} dn,$$

$$r(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \mathscr{R}_n e^{inx} dn,$$

we find

$$\begin{aligned}
&[\mathscr{P}_m, \mathscr{P}_n] = 0, \\
&[\mathscr{P}_m, \mathscr{Q}_n] = 0, \\
&[\mathscr{P}_m, \mathscr{R}_n] = m^2 \delta_{n,-m}, \\
&[\mathscr{Q}_m, \mathscr{Q}_n] = m^3 \delta_{n,-m}, \\
&[\mathscr{Q}_m, \mathscr{R}_n] = -m^2 \mathscr{P}_{m+n}, \\
&[\mathscr{R}_m, \mathscr{R}_n] = (m-n) \mathscr{Q}_{m+n} + \Sigma_{k=-\infty}^{\infty} k \mathscr{P}_{m-k} \mathscr{P}_{k+n} ,
\end{aligned} \tag{26}$$

which is not a W-algebra, but rather of a new type. We note that no normal ordering is needed in the last one of Eqs. (26) because all the $\mathscr{P}_n$ commute.

VII. CONCLUSION

We have presented a Hamiltonian formulation of Dubrovin's equation of associativity in 2-d topological field theory. A different Hamiltonian structure for this equation was obtained by Mokhov and Ferapontov earlier. In a subsequent paper[11] we shall show that these two Hamiltonian structures can be combined to yield the bi-Hamiltonian structure of Dubrovin's equation, which by the theorem of Magri[10] will provide a proof of its complete integrability.

(Received 30 June 1995; accepted for publication 1 July 1996)

The causality structure of two-dimensional manifolds with degenerate metrics is analyzed in terms of global solutions of the massless wave equation. Certain novel features emerge. Despite the absence of a traditional Lorentzian Cauchy surface on manifolds with a Euclidean domain, it is possible to uniquely determine a global solution (if it exists), satisfying well-defined matching conditions at the degeneracy curve, from Cauchy data on certain spacelike curves in the Lorentzian region. In general, however, no global solution satisfying such matching conditions will be consistent with this data. Attention is drawn to a number of obstructions that arise prohibiting the construction of a bounded operator connecting asymptotic single particle states. The implications of these results for the existence of a unitary quantum field theory are discussed. © *1996 American Institute of Physics.* [S0022-2488(96)01311-4]

I. INTRODUCTION

If S is a spacelike (acausal) domain in a space–time M, then one defines its domain of dependence $D(S)$ as the set of points p such that all nonterminating timelike curves from p intersect S.[1] Furthermore, one says that an acausal hypersurface S is a Cauchy hypersurface if $D(S)=M$. The existence of a Cauchy hypersurface is equivalent to M being globally hyperbolic.

Kundt first[2] discussed the nonexistence of certain topologically nontrivial space–times assuming that every geodesic is complete. Geroch[1] exploited the notion of global hyperbolicity to reach a similar conclusion. There has been recent interest in the behavior of both classical and quantum fields on background manifolds that admit metrics with both Euclidean[3] and variable signatures[1,2,4–16] as well as in space–times that are not globally hyperbolic.[17]

For information that propagates according to the wave equation for a scalar field, a specification of the field and its normal derivative on any spacelike surface S is sufficient to determine a unique solution to the equation on the domain of dependence of S. A manifold with a degenerate metric is not globally hyperbolic and it is therefore of interest to investigate the influence of this degeneracy on the propagation of massless scalar fields satisfying

$$d\star d\psi=0, \tag{1}$$

where $\star$ is the Hodge map associated with an ambient metric tensor field g.

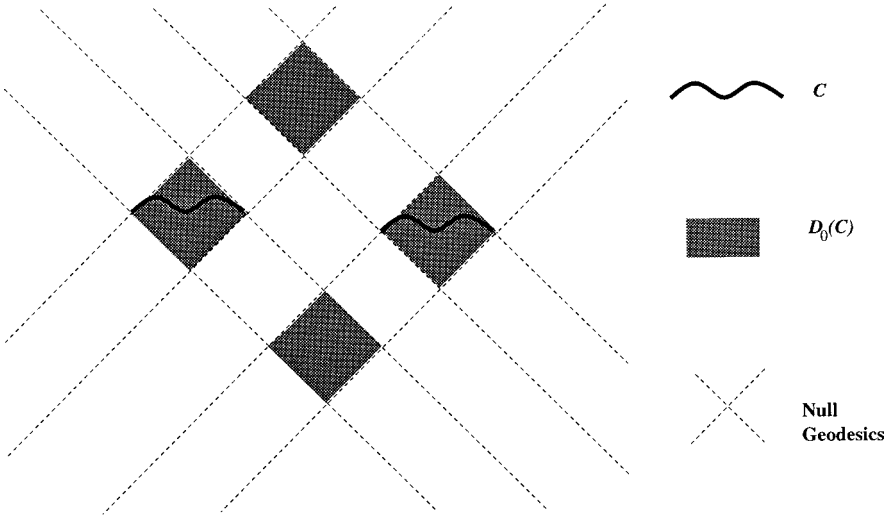

FIG. 1. Domain of null dependence of C, $D_0(C)\subset L\cup\Sigma$.

In this article we address this question in the context of a metric that partitions a two-dimensional manifold into three disjoint sets: a Lorentzian region L, a Euclidean region E, and a one-dimensional subset Σ where the metric is degenerate.

In a region where g has Euclidean signature (1) is the (elliptic) Laplace equation. The traditional data for this equation is the specification of ψ on the boundary of any Euclidean domain since this will fix a solution uniquely in such a region. However, we show below that a specification of ψ and its normal derivative on any arc of the boundary is also sufficient to uniquely determine the interior solution should it exist. This result proves of relevance when we discuss the propagation of hyperbolic data from a Lorentzian to a Euclidean domain.

In a region where g has Lorentzian signature (1) is the (hyperbolic) *massless* wave equation, and it is possible to contemplate data on disjoint spacelike curves (Fig. 1).

Since information travels along null geodesics we redefine the domain of dependence. Thus if C is a spacelike (acausal) domain in a Lorentzian region $L\subset M$, then its *domain of null dependence* $D_0(C)$ is the set of points p such that all nonterminating null curves from p intersect C. For $C\subset L$ and $\Sigma'\subset\Sigma$ we define $D_0(C\cup\Sigma')$ to be all the points $p\in L$ where both null geodesics that intersect at p either intersect C or terminate on Σ', where they are not tangent.

From Fig. 1 we see that if C is not connected, then $D_0(C)$ may contain regions disjoint from C.

Consider now a spacelike arc $C\subset L$ on which standard Cauchy data for (1) is prescribed (Fig. 2). Furthermore, suppose that the domain of null dependence of C intersects Σ nontrivially, i.e., the intersection is one-dimensional. Then we show below that if a global solution exists and agrees with the data on C, then it is unique in E. Such a solution provides Cauchy data on Σ which together with that on C enables one to construct the solution on the domain of null dependence $D_0(C\cup\Sigma)$. In general no such global solution exists, as will be illustrated in example 1 below.

If the intersection $D_0(C)\cap\Sigma$ is trivial, then the theorem below is not applicable. In this case more than one global solution may exist compatible with the Cauchy data on C. Example 2 will illustrate this situation.

In Sec. V we review the standard prescription that is adopted to construct a quantum field theory on a fixed globally hyperbolic manifold. With the aid of explicit examples, we draw attention to the obstructions that arise when one attempts to implement this prescription on a two-dimensional manifold with a degenerate metric. We offer reasons why we believe that a

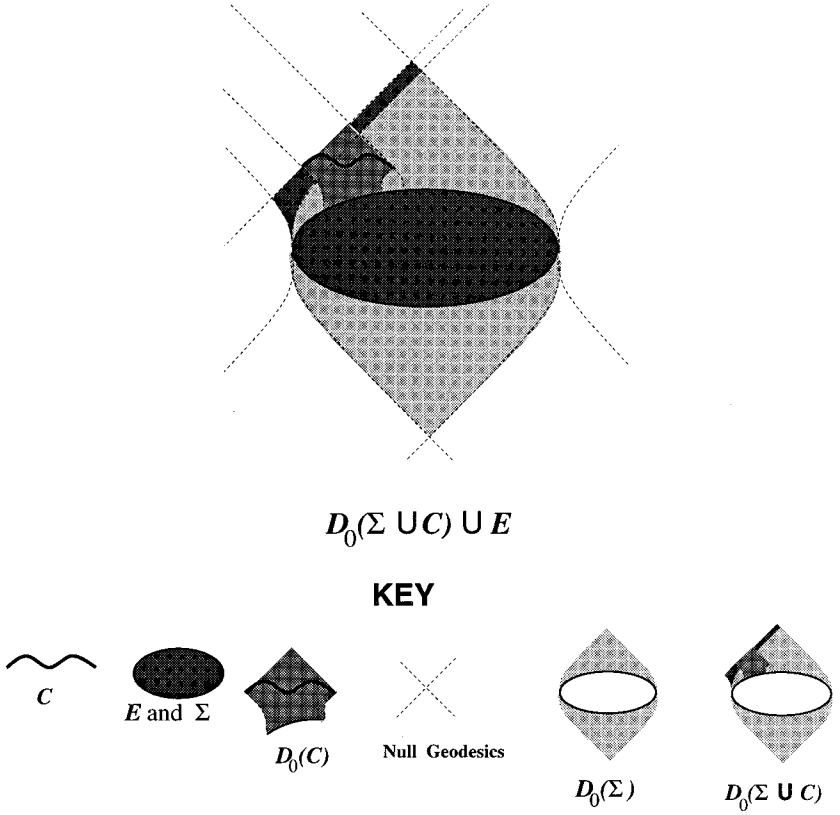

FIG. 2. $D_0(C\cup\Sigma)\cup E$.

bounded unitary scattering matrix in the presence of nondynamical signature change may not exist.

II. CONSTRUCTION OF COORDINATE SYSTEMS

Given a two-dimensional manifold (L,g^L) with a (nondegenerate) Lorentzian metric g^L, a *null coordinate system* (η_+,η_-) is one in which the metric may be written

$$g^L=\Omega^L(\eta_+,\eta_-)(d\eta_+\otimes d\eta_- + d\eta_-\otimes d\eta_+), \tag{2}$$

where Ω^L is a real function. Similarly for a two-dimensional manifold (E,g^E) with a (nondegenerate) Euclidean metric g^E, a *complex isothermal coordinate system* $(z,\overline{z})$ is one in which the metric may be written

$$g^E=\Omega^E(z,\overline{z})(dz\otimes d\overline{z}+dz\otimes d\overline{z}), \tag{3}$$

where Ω^E is a real positive function. It is known that one can construct a null coordinate system about any point in $p\in L$ and that one can construct a complex isothermal coordinate system about any point $p\in E$.

In this section we give conditions for the construction of null and complex isothermal coordinate systems for a two-dimensional manifold $M=L\cup\Sigma\cup E$ with a signature changing metric g.

We assume that Σ is (locally) parametrized by a C^ω monotonic function $\Sigma:I\mapsto\Sigma$, with $\sigma\in I\subset\mathbb{R}$. (The symbol Σ will be used for both the map and its image.) Given $p\in\Sigma$, we say Σ is *null at* p if

$$g\left(\Sigma_\star \frac{\partial}{\partial\sigma},\ \Sigma_\star \frac{\partial}{\partial\sigma}\right)\Big|_p = 0. \tag{4}$$

If Σ is null at p, then null geodesics in $L\cup\Sigma$ are tangent to Σ at p.

For $p\in\Sigma$ such that Σ is not null at p, Lemma 1 below shows that there exists a coordinate system about p in L which can be extended to Σ, and Lemma 2 below shows that there exists a complex isothermal coordinate system about p that extends to Σ.

Lemma 2 is a modification of the standard proof for the existence of isothermal coordinates (Ref. 18, Vol. IV, pp. 455–460). However, to simplify matters we restrict our attention to the case where g is analytic and can be written in *absolute time* form[9] about a point $p\in\Sigma$; that is there exist coordinates (t,x) about p such that the metric can be written

$$g = tdt\otimes dt + h(t,x)^2 dx\otimes dx, \tag{5}$$

where h is a real positive C^ω function. In this coordinate system the curve Σ is given by $t=0$. Then g^E is given by the restriction

$$g^E = g|_{t>0}. \tag{6}$$

From Ref. 9 (theorem 1) we know that sufficient conditions for writing g in absolute time form about $p\in\Sigma$ are

(i) Σ is not null at p,
(ii) with respect to any coordinate system, $\det(g_{ab})$ has a nonzero differential at p, and
(iii) $\{g_{ab}\}$ is C^ω in a neighborhood of p.

With respect to both the null and complex isothermal coordinate system we then derive the general solution of (1), specifying both its value and *normal derivative* on Σ. This data is used to match the solutions across Σ.

Lemma 1: Extension of Null Coordinate System: Given $p\in\Sigma$ such that Σ is not null at p, there exists a neighborhood of p, $U^L\subset L\cup\Sigma$ and a C^0 function

$$\Phi^L: U^L \mapsto \{(\eta_+,\eta_-)\in\mathbb{R}^2 |\, \eta_- \leqslant \eta_+\} \tag{7}$$

such that the restriction

$$\Phi^L|_L : U^L\cap L \mapsto \{(\eta_+,\eta_-)\in\mathbb{R}^2 |\, \eta_- < \eta_+\} \tag{8}$$

is a C^∞ diffeomorphism and a null coordinate system. Also

$$\Phi^L|_\Sigma : U^L\cap\Sigma \mapsto \{(\eta_+,\eta_-)\in\mathbb{R}^2 |\, \eta_- = \eta_+\}, \tag{9}$$

where

$$\eta_+\circ\Sigma(\sigma) = \eta_-\circ\Sigma(\sigma) = \sigma. \tag{10}$$

Proof: Every point $x\in L$ near p lies on the intersection of two null geodesics. We can choose U^L such that for all $x\in U^L\cap L$, both the null geodesics that intersect x also intersect Σ near p where they are not tangent. Thus for each x this gives two points, $q_1,q_2\in\Sigma$ (See Fig. 3). Let $\eta_+(x)$ be the larger of $\{\Sigma^{-1}(q_1),\Sigma^{-1}(q_2)\}$ and $\eta_-(x)$ the smaller. This construction gives a well-defined C^∞ map Φ^L, which is a diffeomorphism in the set described. Furthermore, since $\eta_\pm$=constant are null geodesics, $\partial/\partial\eta_\pm$ are null, so the metric is given by (2). ■

With respect to a null coordinate system the Lorentzian Hodge maps are given by

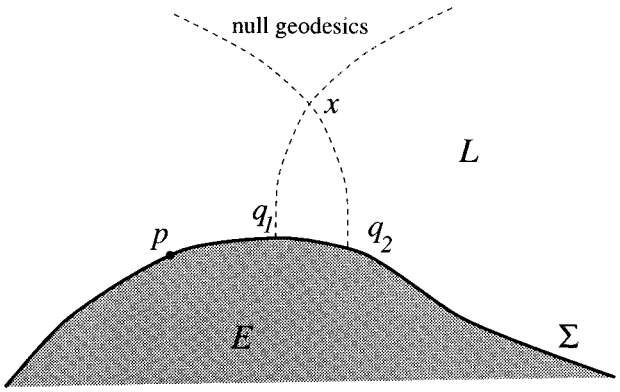

FIG. 3. Intersection of the null geodesics from x with Σ at q_1 and q_2.

$$\star 1 = \Omega^L d\eta_+ \wedge d\eta_- , \tag{11}$$

$$\star d\eta_+ = -d\eta_+ , \tag{12}$$

$$\star d\eta_- = d\eta_- , \tag{13}$$

so the wave equation (1) for $\psi^L : U^L \to \mathbb{C}$ is

$$\frac{\partial^2 \psi^L}{\partial \eta_+ \partial \eta_-} d\eta_+ \wedge d\eta_- = 0, \tag{14}$$

and its solution in this region is

$$\psi^L = \psi^L_+(\eta_+) + \psi^L_-(\eta_-), \tag{15}$$

where $\psi^L_\pm : U^L \to \mathbb{C}$. We define the value of the ψ^L on Σ and the normal derivative $\mathcal{N}\psi^L_\Sigma$ of ψ^L on Σ by

$$\psi^L_\Sigma : \Sigma \mapsto \mathbb{C}, \quad \psi^L_\Sigma(x) = \lim_{y \to x, y \in L} \psi^L(y), \tag{16}$$

$$\mathcal{N}\psi^L_\Sigma : \Sigma \mapsto \mathbb{C}, \quad \mathcal{N}\psi^L_\Sigma(x) = i_{\partial/\partial\sigma}\left(\Sigma^\star \left(\lim_{y \to x, y \in L} \star d\psi^L|_y \right) \right). \tag{17}$$

With respect to the coordinate systems (η_+, η_-) given in Lemma 1, these are given by

$$\psi^L_\Sigma(x) = \psi^L_+(\eta_+(x)) + \psi^L_-(\eta_-(x)), \tag{18}$$

$$\begin{aligned}
\mathcal{N}\psi^L_\Sigma(x) &= i_{\partial/\partial\sigma}\left(\Sigma^\star \lim_{y \to x, y \in L} \star d(\psi^L_+(\eta_+) + \psi^L_-(\eta_-))|_y \right) \\
&= i_{\partial/\partial\sigma}\left(\Sigma^\star \lim_{y \to x, y \in L} (\psi^{L\prime}_+ \star d\eta_+ + \psi^{L\prime}_- \star d\eta_-)|_y \right) \\
&= i_{\partial/\partial\sigma}\left(\Sigma^\star \lim_{y \to x, y \in L} (-\psi^{L\prime}_+ d\eta_+ + \psi^{L\prime}_- d\eta_-)|_y \right) \\
&= i_{\partial/\partial\sigma}(\Sigma^\star(-\psi^{L\prime}_+ d\eta_+ + \psi^{L\prime}_- d\eta_-)|_x) \\
&= -\psi^{L\prime}_+ \frac{\partial \eta_+ \circ \Sigma}{\partial \sigma} + \psi^{L\prime}_- \frac{\partial \eta_- \circ \Sigma}{\partial \sigma} \\
&= -\psi^{L\prime}_+(\eta_+(x)) + \psi^{L\prime}_-(\eta_-(x)),
\end{aligned} \tag{19}$$

since $\partial\eta_{\pm}\circ\Sigma/\partial\sigma=1$. Thus the normal derivative exists so long as Σ is not null.

Lemma 2: Extension of Complex Isothermal Coordinate System: Given $p\in\Sigma$ such that g is analytic and can be written in absolute time form (5) about a point $p\in\Sigma$, then there exists a neighborhood of p, $U^E\subset E\cup\Sigma$ and a C^0 function

$$\Phi^E: U^E\mapsto\{z\in\mathbb{C}|\mathrm{Im}(z)\geqslant 0\} \tag{20}$$

such that the restriction

$$\Phi^E|_E: U^E\cap E\mapsto\{z\in\mathbb{C}|\mathrm{Im}(z)>0\} \tag{21}$$

is a C^ω diffeomorphism, and a complex isothermal coordinate. Also

$$\Phi^E|_\Sigma: U^E\cap\Sigma\mapsto\mathbb{R}. \tag{22}$$

Proof: Let g be written as in (5), so that p is given by $t=0$, $x=x_0$, and g^E is given by (6). Let

$$\omega=h dx+i\sqrt{t}dt \tag{23}$$

so that

$$g^E=\omega\otimes\overline{\omega}+\overline{\omega}\otimes\omega. \tag{24}$$

We seek a nonvanishing integrating factor $\lambda(t,x)$, and a complex coordinate $z(t,x)$ such that

$$\omega\lambda=dz. \tag{25}$$

Consider the extension of ω to $\mathbb{R}^+\times\mathbb{C}$ given by

$$\omega=h(t,\xi)d\xi+i\sqrt{t}dt, \tag{26}$$

where $t\in\mathbb{R}$, $t>0$, and $\xi\in\mathbb{C}$, and where $h(t,\xi)$ is the analytic extension of $h(t,x)$ with respect to its second argument. Let

$$X=\frac{-i\sqrt{t}}{h}\frac{\partial}{\partial\xi}+\frac{\partial}{\partial t}, \tag{27}$$

a vector field on $\mathbb{R}^+\times\mathbb{C}$, which is an annihilator of ω, i.e., $\omega(X)=0$. The solution curves of X are the set of curves $t\mapsto(t,\xi(t))$, where $\xi(t)$ are solutions to the differential equation

$$\frac{dx}{dt}=-i\frac{\sqrt{t}}{h(x,t)}. \tag{28}$$

We note that the component of X in the t direction is 1, and the component of X in the imaginary ξ direction is

$$-\frac{\sqrt{t}\ \mathrm{Re}(h)}{|h|^2}, \tag{29}$$

which, near $t=0$, $\xi=x_0$, is bounded above by $\sqrt{t}$ times some factor. Therefore, near $p=(0,x_0)$, all solution curves of (28) that intersect the half-plane $\{t=0,\ \mathrm{Im}(\xi)>0\}$ also intersect the plane $\{\mathrm{Im}(\xi)=0,\ t>0\}$ and visa versa (see Fig. 4). Thus we have the map

$$\Phi^E: U^E\mapsto\{z\in\mathbb{C}|\mathrm{Im}(z)\geqslant 0\},\quad \Phi^E:(t,x)\mapsto z, \tag{30}$$

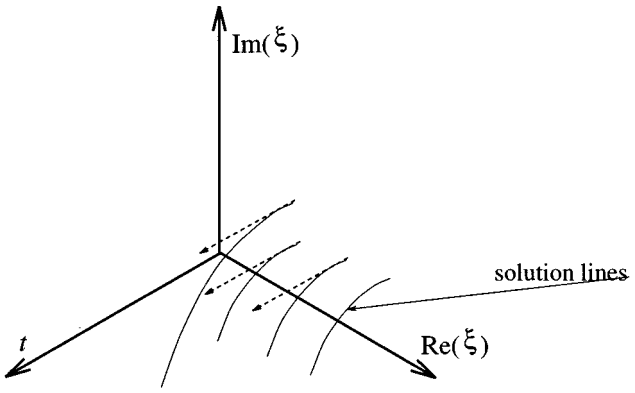

FIG. 4. The solution lines of X intersecting with the half-plane $\{\mathrm{Im}(\xi)=0,\ t>0\}$ and the half-plane $\{t=0,\ \mathrm{Im}(\xi)>0\}$ where they are parallel to the field $\partial/\partial t$.

where the solution curve connects the point $(t=t,\mathrm{Re}(\xi)=x,\mathrm{Im}(\xi)=0)\in\{\mathrm{Im}(\xi)=0,t>0\}$ to the point $(t=0,\xi=z)\in\{t=0,\mathrm{Im}(\xi)>0\}$. This map satisfies (21), and (22). Since z now labels each solution curve, and is thus a constant along it, $X(z)\equiv dz(X)=0$. In general

$$dz=\lambda\,\omega+\mu_1\overline{\omega}+\mu_2 dt, \tag{31}$$

but contracting with $\partial/\partial\overline{\xi}$ implies that $\mu_1=0$ since z and ω are analytic. Contracting with X gives $\mu_2=0$ so (25) holds.

Substituting dz into (24) gives (3) with $\Omega^E=1/\lambda\overline{\lambda}$. ■

The Euclidean Hodge maps are given with respect to the $(z,\overline{z})$ coordinate system by

$$\star 1=\Omega^2 dz\wedge d\overline{z}, \tag{32}$$

$$\star dz=-i dz, \tag{33}$$

$$\star d\overline{z}=i d\overline{z}, \tag{34}$$

so Laplace's equation for $\psi^E:U\to\mathbb{C}$ is

$$\frac{\partial^2\psi^E}{\partial z\,\partial\overline{z}}dz\wedge d\overline{z}=0 \tag{35}$$

and its solution in this region is

$$\psi^E=\psi^E_+(z)+\overline{\psi^E_-(z)}, \tag{36}$$

where $\psi^E_\pm:U\to\mathbb{C}$. Since $\partial\psi^E_\pm/\partial\overline{z}=0$ these are analytic functions. We define ψ^E_Σ and $\mathscr{N}\psi^E_\Sigma$ by replacing the symbol L with E in (16) and (17). These are given by

$$\psi^E_\Sigma(p)=\psi^E_+(p)+\overline{\psi^E_-(p)}, \tag{37}$$

$$\mathscr{N}\psi^E_\Sigma(p)=-i\psi^{E\prime}_+\frac{\partial z}{\partial\sigma}+\overline{i\psi^{E\prime}_-}\,\frac{\partial\overline{z}}{\partial\sigma}. \tag{38}$$

We have

$$\frac{\partial z}{\partial \sigma} = \frac{dx}{d\sigma} \in \mathbb{R} - \{0\}, \tag{39}$$

hence

$$\mathcal{N}\psi^E_\Sigma(p) = i\,\frac{dx}{d\sigma}\,(-\psi^{E\prime}_+ + \overline{\psi^{E\prime}_-}). \tag{40}$$

So the normal derivative exists about the point $p \in \Sigma$ so long as Σ is not null.

III. UNIQUENESS LEMMA

Lemma 3: Let $(E \cup \Sigma, g)$ be a closed pathwise connected manifold with boundary $\Sigma = \partial E$, with a Riemannian metric g which is degenerate on Σ and analytic in a neighborhood of Σ. Let there be only isolated points on Σ about which g cannot be written in absolute time form. Given a nontrivial curve $C: I \mapsto \Sigma$ where I is some interval in $\mathbb{R}$ parametrized by s and two functions $u^E, v^E: E \mapsto \mathbb{C}$ that satisfy Laplace's equation $d \star d\psi = 0$ on the interior of E, then $u^E_\Sigma|_C = v^E_\Sigma|_C$ and $\mathcal{N}u^E_\Sigma|_C = \mathcal{N}v^E_\Sigma|_C$ if and only if $u^E = v^E$.

In these equations $u^E_\Sigma(x), \mathcal{N}u^E_\Sigma(x)$ are defined by replacing ψ by the symbol u in the Euclidean version of (16) and (17).

Proof: Let (U^E, Ψ^E) be a complex isothermal chart of E about a point $p \in C(I)$ given by Lemma 2 above. For the solution $w^E = u^E - v^E$, it follows that $w^E_\Sigma|_C = 0$ and $\mathcal{N}w^E_\Sigma|_C = 0$. Thus from (37) and (40) we have

$$w^E_\pm(z) = 0 \quad \forall z \in \Psi^E \circ C(I). \tag{41}$$

Hence $w^E_\pm$ are analytic functions on the domain $\Psi^E(U^E \cap E) \subset \mathbb{C}$ where $\mathrm{Im}(\Psi^E(U^E \cap E)) > 0$. They are continuous functions on the domain $\Psi^E(U^E) \subset \mathbb{C}$ where $\mathrm{Im}(\Psi^E(U^E \cap \Sigma)) = 0$. One can perform a Schwartz reflection[19] about $\mathrm{Im}(z) = 0$ to produce an analytic function on a domain with a nontrivial subset of $\Psi^E(\Sigma)$ in its interior. Since $\Psi^E(C)$ is not a distinct collection of points

$$w^E_\pm(z) = 0 \quad \forall z \in \Psi^E(U^E). \tag{42}$$

For any other chart $(\widetilde{U}, \widetilde{\Psi})$ where $U \cap \widetilde{U} \neq \varnothing$, since

$$w^E_\pm(z) = 0 \quad \forall z \in \widetilde{\Psi}(\widetilde{U} \cap U), \tag{43}$$

then

$$w^E_\pm(z) = 0 \quad \forall z \in \widetilde{\Psi}(\widetilde{U}). \tag{44}$$

Thus $w^E_\pm = 0$, or $u^E = v^E$ on E. ■

This is a uniqueness proof, not an existence proof. Given two functions $f_1, f_2: C(I) \mapsto \mathbb{C}$ there will in general be no solution $u: E \mapsto \mathbb{C}$ to Laplace's equation such that $u|_C = f_1$ and $i_{C\star}\partial/\partial s \star u = f_2$ for any neighborhood of $C(I)$.

Example 1: Let $\Psi^E(U^E) = \{z \in \mathbb{C} | \mathrm{Im}(z) < 0\}$ and $\Psi^E(C) = \{z \in \mathbb{C} | \mathrm{Im}(z) = 0\}$. Let

$$\psi^E_\Sigma(x) = \begin{cases} e^{(-1/x^2)}, & x > 0, \\ 0, & x \leqslant 0, \end{cases}$$
$$\mathcal{N}\psi^E_\Sigma(x) = 0 \quad \forall x \in \mathbb{R}, \tag{45}$$

where $x \in \Psi^E(C)$. According to Lemma 3, the data on $x<0$ implies that $\psi(z)=0\ \forall z \in \Psi^E(U^E)$, while the data on $x>0$ implies that $\psi(z)=\exp(-1/x^2)\ \forall z \in \Psi^E(U^E)$. Thus there is no solution to Laplace's equation on $\Psi^E(U^E)$ consistent with this boundary data.

This does not contradict the Cauchy–Kowalewski theorem[20,21] on the existence of solutions to PDE's with analytic Cauchy data since the data (45) is not analytic.

IV. UNIQUENESS THEOREM

In order to match Euclidean solutions to Lorentzian solutions, we must adopt some boundary conditions along the degeneracy curve Σ.

The class of boundary conditions adopted here relate boundary data in a **linear** and **pointwise invertible** manner. Thus for $J:\Sigma \mapsto GL_2(\mathbb{C})$

$$\begin{pmatrix} \psi^L_\Sigma(x) \\ \mathcal{N}\psi^L_\Sigma(x) \end{pmatrix} = J(x) \begin{pmatrix} \psi^E_\Sigma(x) \\ \mathcal{N}\psi^E_\Sigma(x) \end{pmatrix}. \tag{46}$$

The ''natural'' boundary conditions given by continuity of ψ and its normal derivative across Σ correspond to

$$J(x)=\mathbf{1}. \tag{47}$$

We note in passing that the theorem below is applicable even when ψ is restricted such that $\mathcal{N}\psi^E_\Sigma(x)=\mathcal{N}\psi^L_\Sigma(x)=0$.

Theorem: *Let (M,g) be a two-dimensional manifold M with a metric g that is degenerate along a curve Σ, partitioning M into a Lorentzian domain L and a connected Euclidean domain E. Let g be analytic in a neighborhood of Σ, and let there only be isolated points on Σ where g cannot be written in absolute time form. Let $C \subset L$ be an acausal curve, parametrized by s, such that $D_0(C)\cap\Sigma$ contains an arc. Given two solutions of (1) $u,v:M\mapsto\mathbb{C}$ satisfying any boundary condition in the class above, then $u|_C=v|_C$ and $(C^\star \star du)(\partial/\partial s)=(C^\star \star dv)(\partial/\partial s)$ if and only if $u|_{D_0(C\cup\Sigma)\cup E} = v|_{D_0(C\cup\Sigma)\cup E}$, i.e., u and v agree on the entire shaded area indicated in Fig. 2.*

Proof: Since u and v have the same Cauchy data on C, then if $w=u-v$ it follows that $w|_{D_0(C)} = 0$. Hence w has zero Cauchy data on the Lorentzian side of $D_0(C)\cap\Sigma$, i.e.,

$$w^L_\Sigma(x)=0 \quad \text{and} \quad \mathcal{N}w^L_\Sigma(x)=0 \quad \forall x \in D_0(C)\cap\Sigma. \tag{48}$$

In these equations $w^L_\Sigma(x)$, $\mathcal{N}w^L_\Sigma(x)$, $w^E_\Sigma(x)$, and $\mathcal{N}w^E_\Sigma(x)$ are defined by replacing ψ by w in (16) and (17). Since the boundary conditions are linear and pointwise invertible, we have zero Cauchy data for w on the Euclidean side of $D_0(C)\cap\Sigma$, i.e.,

$$w^E_\Sigma(x)=0 \quad \text{and} \quad \mathcal{N}w^E_\Sigma(x)=0 \quad \forall x \in D_0(C)\cap\Sigma. \tag{49}$$

Hence $w|_E=0$ from Lemma 3. This now implies zero Cauchy data for w on the Euclidean side of the whole of Σ, i.e.,

$$w^E_\Sigma(x)=0 \quad \text{and} \quad \mathcal{N}w^E_\Sigma(x)=0 \quad \forall x \in \Sigma. \tag{50}$$

Thus these boundary conditions give zero Cauchy data for w on the Lorentzian side of the *whole* of Σ. Since the Cauchy data for w on C is zero as well, it follows that $w|_{D_0(C\cup\Sigma)\cup E} = 0$. ■

Again we note that this is a uniqueness theorem. In general no solution to (1) on M will exist satisfying (46) with Cauchy data on some C satisfying the conditions of this theorem. The requirement that $D_0(C)\cap\Sigma$ is nontrivial is necessary. If the domain of null dependence of C contains a single point in common with the Euclidean domain E, it is not difficult to construct a situation in which there exists more than one solution on E compatible with the Cauchy data.

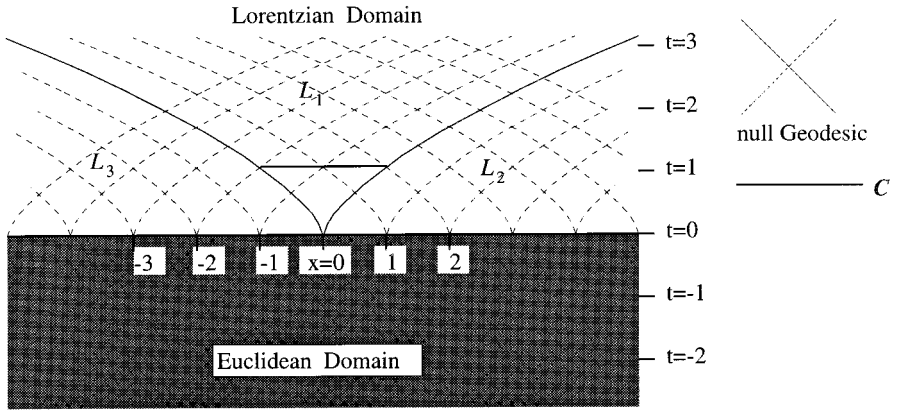

FIG. 5. Example where $D_0(C)\cap\Sigma$ is trivial.

Example 2: Let $M=\mathbb{R}^2$ and $g=-\frac{9}{4}tdt\otimes dt+dx\otimes dx$. We wish to find solutions that have zero Cauchy data on $C=\{(-1,x),-1\leqslant x\leqslant 1\}$. The null geodesics (denoted by dotted lines in Fig. 5) are given by $x\pm t^{(3/2)}=$const. Clearly one solution that also satisfies the natural boundary conditions (47) is $\psi=0$ on M. However, one readily verifies that another solution is

$$\psi|_L(x,t)=\begin{cases}0, & x+t^{3/2}>0, x-t^{3/2}<0 \quad (L_1 \text{ in Fig. 5}),\\ (1-i)\sqrt{x-t^{3/2}}, & x-t^{3/2}>0, t>0 \quad (L_2 \text{ in Fig. 5}),\\ (1-i)\sqrt{-x-t^{3/2}}, & x+t^{3/2}>0, t>0 \quad (L_3 \text{ in Fig. 5}),\end{cases} \tag{51}$$

$$\psi|_E(x,t)=(\sqrt{x+it^{3/2}})+i\overline{(\sqrt{x+it^{3/2}})}, \tag{52}$$

where $\sqrt{\ }:\{z\in\mathbb{C}:\mathrm{Im}(z)\leqslant 0\}\mapsto\{z\in\mathbb{C}:\mathrm{Re}(z)\geqslant 0,\mathrm{Im}(z)\leqslant 0\}$.

In a two-dimensional universe with a known degenerate metric one might imagine one could use the theorem above to predict the behavior of the scalar field beyond causally connected regions. However, realistic Cauchy data that is obtained from physical measurements will contain errors. Since it is possible to find global solutions that lie arbitrarily close to such data in the domain of the Cauchy curve but are arbitrarily disparate elsewhere, one must conclude that the propagation of such errors cannot be controlled.

Example 3: Referring to Fig. 5, enlarge C to $\hat{C}=\{(t=1,x):|x|<2\}$. Assume the ''experimental'' data given on $\hat{C}$ prescribes that a function and its normal derivative are zero to an accuracy ϵ. If ϵ is zero, then the theorem above implies that the only global solution is identically zero. For $\epsilon>0$, given any continuous function $f:\mathbb{R}\mapsto\mathbb{C}$ such that $f(x)=0$, $\forall|x|\leqslant 3$, then from the Boltzano–Wiesstrass theorem there exists a polynomial $\mathscr{P}:\mathbb{R}\mapsto\mathbb{C}$ such that $|\mathscr{P}(x)-f(x)|<\epsilon/2$, $\forall x\leqslant 5$. The function $\mathscr{P}(x+it^{3/2})$ solves Laplace's equation (1) in the Euclidean domain and $|\mathscr{P}(x)|<\epsilon/2$ on the interval $\{(t=0,x):|x|<3\}$. However, this function extends to a global solution of (1) on $\mathbb{R}^2$ and is consistent with the ''experimental'' Cauchy data on $\hat{C}$ within the prescribed error. This is similar to Hadamard's example[22] demonstrating that certain initial value problems are not *well posed* for Laplace's equation.

V. IMPLICATIONS FOR QUANTIZATION

The standard method[23–25] for constructing a quantum field theory in a curved space–time is to consider a globally hyperbolic manifold M possessing Cauchy surfaces C^{in} and C^{out} in (asymptotically) flat regions upon which one sets up Hilbert spaces $\mathscr{H}(C^{\text{in}})\oplus\overline{\mathscr{H}(C^{\text{in}})}$ and $\mathscr{H}(C^{\text{out}})\oplus\overline{\mathscr{H}(C^{\text{out}})}$ of solutions to local field equations.

The Klein–Gordon Hermitian bilinear form is defined as

$$\langle u,v\rangle_C=\frac{1}{2\pi i}\int_C \overline{u}\star dv - v\star d\overline{u}, \tag{53}$$

where u,v are Cauchy data on a Cauchy surface C for solutions to the scalar wave (Klein–Gordon) equation. For C in a flat region of space–time, the (maximal) subspace of positive frequencies, $\mathscr{H}(C)$, is defined by some timelike vector field which is Killing in this region, such that the restriction of $\langle,\rangle_C$ to $\mathscr{H}(C)$ is positive definite. The restriction of $\langle,\rangle_C$ to its conjugate $\overline{\mathscr{H}(C)}=\{\overline{u}|u\in\mathscr{H}(C)\}$ is negative definite. We have

$$\langle u,v\rangle_C=\langle u_+,v_+\rangle_C+\langle\overline{u_-},\overline{v_-}\rangle_C \tag{54}$$

where $u=u_+ +\overline{u_-}$, $v=v_+ +\overline{v_-}$, and $u_\pm,v_\pm\in\mathscr{H}(C)$. The Hilbert space $\mathscr{H}(C)\oplus\overline{\mathscr{H}(C)}$ is defined with respect to the ''true'' inner product

$$\langle\langle u,v\rangle\rangle_C=\langle u_+,v_+\rangle_C-\langle\overline{u_-},\overline{v_-}\rangle_C. \tag{55}$$

For any solution $u:M\mapsto\mathbb{C}$ there is Cauchy data associated with $u^{\text{in}}\in\mathscr{H}(C^{\text{in}})\oplus\overline{\mathscr{H}(C^{\text{in}})}$ for u, and Cauchy data associated with $u^{\text{out}}\in\mathscr{H}(C^{\text{out}})\oplus\overline{\mathscr{H}(C^{\text{out}})}$. The corresponding quantum system is said to be *unitary* if $\langle u^{\text{in}},v^{\text{in}}\rangle_{C^{\text{in}}}=\langle u^{\text{out}},v^{\text{out}}\rangle_{C^{\text{out}}}$. This is guaranteed for a globally hyperbolic manifold since the current $\overline{u}\star du-u\star d\overline{u}$ is conserved. The linear map $\mathscr{A}:\mathscr{H}(\mathscr{C}^{\text{in}})\oplus\overline{\mathscr{H}(\mathscr{C}^{\text{in}})}\mapsto\mathscr{H}(\mathscr{C}^{\text{out}})\oplus\overline{\mathscr{H}(\mathscr{C}^{\text{out}})}$ defined by $u^{\text{in}}\mapsto u^{\text{out}}=\mathscr{A}u^{\text{in}}$ may be represented as

$$\mathscr{A}=\begin{pmatrix}\alpha & \beta\\ \overline{\beta} & \overline{\alpha}\end{pmatrix} \tag{56}$$

and defines the Bogolubov transformations:

$$\alpha:\mathscr{H}(C^{\text{in}})\mapsto\mathscr{H}(C^{\text{out}}), \tag{57}$$

$$\beta:\mathscr{H}(C^{\text{in}})\mapsto\overline{\mathscr{H}(C^{\text{out}})}. \tag{58}$$

From these one may construct the Scattering matrix in a Fock space basis of many particle states in the quantum theory. The expectation value of the particle number density with respect to the image of a Fock space vacuum state under this Scattering matrix can be shown to be $\Sigma_{ij}|\beta_{ij}|^2$. For a finite theory β must be Hilbert–Schmidt, i.e., $\Sigma_{ij}|\beta_{ij}|^2<\infty$ (Ref. 23, p. 140). This implies that $\mathscr{A}$ must be bounded.

It is of interest to see to what extent the formalism above breaks down in the context of a quantum field theory of massless scalar particles in a background two-dimensional space–time with a degenerate metric. We approach this by considering a simple example in which we can readily calculate the Bogolubov coefficients. Let M be a cylinder with coordinates $\{(\tau,\theta)|-\infty<\tau<\infty,0\leqslant\theta<2\pi\}$, together with the axially symmetric metric

$$g=g_{\tau\tau}(\tau)d\tau\otimes d\tau+g_{\theta\theta}(\tau)d\theta\otimes d\theta, \tag{59}$$

where $g_{\theta\theta}(\tau)>0$ for all τ. Here M has a Euclidean region E (where $g_{\tau\tau}>0$) sandwiched between two Lorentzian regions labelled L^{in} and L^{out} (where $g_{\tau\tau}<0$). Let there be a flat region $L^{\text{in}}_{\text{flat}}\subset L^{\text{in}}$, i.e., where $g_{\tau\tau}=-1$, $g_{\theta\theta}=1$, containing the Cauchy surface $C^{\text{in}}\subset L^{\text{in}}_{\text{flat}}$. Similarly let $C^{\text{out}}\subset L^{\text{out}}_{\text{flat}}\subset L^{\text{out}}$. Let Σ^{in} be the degeneracy ring $\tau=\tau^{\text{in}}$ that partitions E from L^{in}. Similarly suppose Σ^{out} is the degeneracy ring $\tau=\tau^{\text{out}}>\tau^{\text{in}}$ that partitions E from L^{out}. See Ref. 15 for explicit details of such a construction.

A transformation to complex coordinates, such that the metric may be written as (3), is given by

$$z=\Psi(\tau,\theta)=e^{i\theta}\exp\left(\int_{\tau^{\rm in}}^{\tau}\left(\frac{g_{\tau\tau}(\tau')}{g_{\theta\theta}(\tau')}\right)^{1/2}d\tau'\right)\quad\text{where}\quad \tau^{\rm in}\leqslant\tau\leqslant\tau^{\rm out},\quad 0\leqslant\theta<2\pi. \tag{60}$$

Thus $\Psi(E)$ is an annulus about the origin with radii 1 and e^{ξ} where

$$\xi=\int_{\tau^{\rm in}}^{\tau^{\rm out}}\left(\frac{g_{\tau\tau}(\tau')}{g_{\theta\theta}(\tau')}\right)^{1/2}d\tau'. \tag{61}$$

A convenient basis of nonzero mode solutions to (1) in the Lorentzian flat domain $L^{\rm in}_{\rm flat}$ is

$$\{e^{\rm in}_k=|2\pi k|^{-1/2}e^{-i(|k|\tau+k\theta)},\overline{e^{\rm in}_k}=|2\pi k|^{-1/2}e^{i(|k|\tau+k\theta)}\}_{k\in\mathbb{Z},k\neq 0}, \tag{62}$$

where (τ,θ) lie in $L^{\rm in}_{\rm flat}$. This basis is in 1-to-1 correspondence with the set of Cauchy data on $C^{\rm in}$ and hence provides a basis of one-particle in-states for $\mathscr{H}(C^{\rm in})\oplus\overline{\mathscr{H}(C^{\rm in})}$, with $\{e^{\rm in}_k\}$ giving a basis for $\mathscr{H}(C^{\rm in})$. A basis of one-particle out-states is likewise defined from $\{e^{\rm out}_k,\overline{e^{\rm out}_k}\}$ where (τ,θ) lie in $L^{\rm out}_{\rm flat}$.

The Bogolubov coefficients can easily be calculated from the matching conditions (47):

$$\alpha_{kk}=\cosh(k\xi)\quad \alpha_{kj}=0,\quad j\neq k, \tag{63}$$

$$\beta_{kk}=i\,\sinh(k\xi),\quad \beta_{kj}=0,\quad j\neq k. \tag{64}$$

It is obvious that β is not Hilbert–Schmidt. Furthermore, it is easy to verify that the linear map $\mathscr{A}:\mathscr{H}(C^{\rm in})\oplus\overline{\mathscr{H}(C^{\rm in})}\mapsto\mathscr{H}(C^{\rm out})\oplus\overline{\mathscr{H}(C^{\rm out})}$ is not even bounded. This follows since one can construct a solution u on M which has a pole on $\Sigma^{\rm out}$, e.g.,

$$u(\tau,\theta)=\frac{1}{\Psi(\tau,\theta)-\Psi(\tau^{\rm out},0)}. \tag{65}$$

Now $\|u^{\rm in}\|_{C^{\rm in}}<\infty$ but $\|u^{\rm out}\|_{C^{\rm out}}=\infty$, which could not happen if $\mathscr{A}$ were bounded. ($\|\mathscr{A}(u^{\rm in})\|_{C^{\rm out}}=\|u^{\rm out}\|\leqslant\|\mathscr{A}\|\|u^{\rm in}\|_{C^{\rm in}}$.) However on the subspace consisting of finite sums of basis elements above, the mapping $\mathscr{A}$ has a unitary restriction. Furthermore, it can be shown that if $u:M\mapsto\mathbb{C}$ is bounded, and $u^{\rm in}\in\mathscr{H}(C^{\rm in})\oplus\overline{\mathscr{H}(C^{\rm in})}$ is associated Cauchy data, then $\langle u^{\rm in},u^{\rm in}\rangle_{C^{\rm in}}=\langle\mathscr{A}u^{\rm in},\mathscr{A}u^{\rm in}\rangle_{C^{\rm out}}$.

In order to construct $\mathscr{A}$ from initial Cauchy data $u^{\rm in}\in\mathscr{H}(C^{\rm in})\oplus\overline{\mathscr{H}(C^{\rm in})}$, one or more of the following obstructions may arise when attempting to calculate the corresponding element $u^{\rm out}\in\mathscr{H}(C^{\rm out})\oplus\overline{\mathscr{H}(C^{\rm out})}$:

(1) There is no compatible solution in any Euclidean neighborhood of $\Sigma^{\rm in}$. An illustration of this has been given in example 1.

(2) Although a solution in a neighborhood of $\Sigma^{\rm in}$ exists, this solution has a ''natural boundary'' which prevents it propagating to $\Sigma^{\rm out}$. For example, consider the analytic function $f:\mathbb{D}\mapsto\mathbb{C}$,

$$f(z)=\sum_{n=0}^{\infty}\left(\frac{z}{R}\right)^{(n!)}, \tag{66}$$

where $\mathbb{D}\subset\mathbb{C}$ is the open disk of radius R. This function is infinite for all $z=Re^{p/q}$, $p,q\in\mathbb{Z}$, and is therefore said to have a natural boundary on $\partial\mathbb{D}$. It cannot be analytically continued beyond $\partial\mathbb{D}$. If $1<R<e^{\xi}$, then $\Psi(\Sigma^{\rm in})\subset\mathbb{D}$ and $\Psi(\Sigma^{\rm out})\not\subset\mathbb{D}$, hence the state in $\mathscr{H}(C^{\rm in})\oplus\overline{\mathscr{H}(C^{\rm in})}$ corresponding to f cannot be propagated to $\Sigma^{\rm out}$.

(3) The state propagates to Σ^{out} but contains a singularity on Σ^{out}. This may give an infinite norm for the state at C^{out}.

(4) An analytic continuation of the state on Σ^{in} to Σ^{out} exists with singularities in E. Such singularities can give rise to nontrivial de Rham periods and contribute to the breakdown of unitarity. In Ref. 15 it is suggested that a resolution to this problem is to excise those domains where such solutions are singular by attaching extra tubes to the manifold. This correlates the space of allowable Cauchy data to the global topology of the manifold. One can then restore unitarity for this particular initial state by labelling some of the tubes as ''in'' and the others as ''out.'' This resolution works for any particular state but cannot be applied to the entire space of states without removing the entire Euclidean domain.

VI. CONCLUSIONS

One of the most striking results of the theorem above is that a space–time with a Euclidean domain does not necessarily require a traditional Cauchy surface in order for one to be able to predict a global solution of the (scalar) wave equation. Cauchy data on any acausal curve may be sufficient. To effect such a prediction it is only necessary that (i) the domain of null dependence of the acausal curve has a nontrivial intersection with the Euclidean domain, (ii) the solution in the two domains is connected by ''linear pointwise-invertible'' junction conditions, and (iii) the boundary of the Euclidean domain is a Cauchy curve for the whole Lorentzian domain. If the degenerate metric possesses a spacelike Killing isometry in the Lorentzian domain, then (iii) is automatic.

For example, a two-dimensional cosmology may be modelled with a metric that is induced by appropriately immersing a paraboloid in Minkowski three-space. If the Euclidean domain corresponds to a parabolic cap, then the ring of signature change is a Cauchy curve for the prediction of solutions to the wave equation for the whole paraboloid. However, every acausal segment in the Lorentzian region provides a family of (disconnected) domains of null determination. If one such domain has a nontrivial intersection with the ring of signature change, then any global solution satisfying the junction conditions above can be calculated from just the Cauchy data on the original segment. However, in general, given arbitrary Cauchy data on such a segment, there may be no such global solution.

Although our results have relied fundamentally on the conformal structure of the scalar wave equation and the dimensionality of the background manifold, we speculate that many of these features will persist in theories that lack conformal symmetry, such as the massive Klein–Gordon equation in three or more dimensions. The extension of our methods would exploit the general theory of elliptic partial differential equations.[20–22,27]

The traditional construction of a local quantum field theory on a space–time relies on a number of features that are conspicuously absent on manifolds with a degenerate metric. Most notably it proves difficult to construct a space of asymptotic quantum states that can be connected by a unitary Scattering matrix.

Although it is not difficult to find subspaces of bounded Lorentzian solutions, such solutions may become singular when continued to a Euclidean region via a broad class of matching conditions. Thus a well-behaved Lorentzian solution can propagate into the future without attenuation and pass smoothly into a Euclidean domain where it may rapidly explode. For example, for any $0<r<1$ consider the sum of two packets

$$u(\tau,\theta)=\frac{1}{1-re^{i(\theta+\hat{\tau})}}+\frac{1}{1-re^{i(\theta-\hat{\tau})}}, \tag{67}$$

where

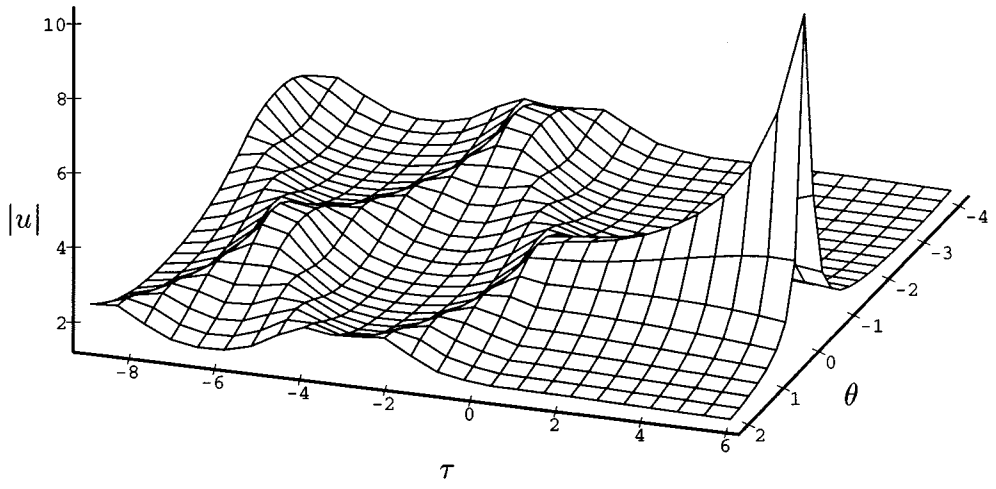

FIG. 6. Evolution with τ of the modulus of a pair of counterrotating Lorentzian wavepackets u across a metric degeneracy at $\tau=0$. The angular coordinate for the cylindrical manifold is denoted by $0\leqslant\theta<2\pi$.

$$\hat{\tau}=\int_{\tau}^{\tau^{\mathrm{in}}}\left(\frac{-g_{\tau\tau}(\tau')}{g_{\theta\theta}(\tau')}\right)^{1/2}d\tau' \tag{68}$$

for $(\tau,\theta)\in L^{\mathrm{in}}$, and

$$u(\tau,\theta)=\frac{1}{1-z}+\frac{\overline{z}}{\overline{z}-r^2} \tag{69}$$

for $(\tau,\theta)\in E$ where $z=\Psi(\tau,\theta)$ is given by (60). This is illustrated in Fig. 6, with $r=0.4$, for the cylindrical manifold M above. For $\tau<\tau^{\mathrm{in}}$, the bounded Lorentzian wave packets counterrotate around the cylinder unattenuated, until they reach the signature ring at $\tau^{\mathrm{in}}=0$. This Lorentzian solution is then matched to the Euclidean one using the junction condition (47), but with the additional constraint that the normal derivatives on either side of the degeneracy curve vanish. The solution clearly becomes an exploding peak as it diffuses into the Euclidean region, becoming singular before escaping to the Lorentzian domain.

We have also explicitly demonstrated several other obstructions than can arise when trying to construct unitary operators in a basis of asymptotic states. Although we cannot prove that no such construction is possible, the results above lead us to strongly suspect that without a radical departure from traditional methods a local unitary quantum field theory on a background with a fixed topology and degenerate metric does not exist. This conclusion does not necessarily rule out classical geometries with signature change. A more comprehensive analysis would consider a coupled field and geometry system with dynamic topology. Such a quantum geometry would then allow classical histories describing a manifold with a topology consistent with the corresponding bounded global field configuration. In the weak-field semi-classical limit such coupled states might select a self-consistent classical background geometry with a degenerate metric upon which one could construct an approximate quantum matter field description.

We formulate scattering in one dimension due to the coupled Schrödinger equation in terms of the S matrix, the unitarity of which leads to constraints on the scattering amplitudes. Levinson's theorem is seen to have the form $\eta(0)=\pi(n_b+\frac{1}{2}n-\frac{1}{2}N)$, where $\eta(0)$ is the phase of the S matrix at zero energy, n_b the number of bound states with nonzero binding energy, n the number of half-bound states, and N the number of coupled equations. In view of the effects due to the half-bound states, the threshold behaviour of the scattering amplitudes is investigated in general, and is also illustrated by means of particular potential models. © *1996 American Institute of Physics.* [S0022-2488(96)03112-X]

I. INTRODUCTION

The quantum mechanics of one-dimensional scattering describes many actual physical phenomena to a good approximation. (For example, see Ref. 1 for a review of tunneling times.) One-dimensional models are furthermore often employed to gain deeper insight into the approximations used in order to make the more complex three-dimensional systems tractable. It is therefore not surprising that there have been many articles, also in this journal, dealing with various aspects of such scattering. In particular a number of papers have appeared in recent years on the threshold behaviour of one-dimensional scattering and Levinson's theorem.[2–7] These studies have been limited to systems without coupling.

In this paper we wish to investigate scattering described by a system of coupled differential equations with a particular interest in developing a formulation for Levinson's theorem and in gaining insight into the threshold properties of the scattering amplitudes. This work can be seen as a special case of multichannel scattering for which the threshold energies are equal. In subsequent work, we intend to generalize to the case of differing threshold energies. Although in previous work on one-dimensional scattering one has at times employed a ''partial wave'' analysis[7,8] or a parity-eigenstate representation,[2,6] we have chosen to use the traditional, more ''physical,'' approach involving states with incident waves coming from a single direction.

In Sec. II we express the scattering properties in terms of the S matrix, the unitarity of which leads to specifiable constraints on the scattering amplitudes. For the proof of the generalized Levinson's theorem we make use of the complete set of orthonormal states of the Hamiltonian; this is an alternative to the approach involving the analyticity of the scattering amplitudes. The proof of Levinson's theorem depends on the threshold properties of the scattering amplitudes. These properties are of interest in their own right, especially in connection with scattering time delay and advance,[6] and therefore we discuss the zero-energy behaviour of the amplitudes at some length.

The factorization of the S matrix is generalized to the coupled system in Sec. III. We also

indicate that there is a class of finitely periodic matrix potentials for which the scattering amplitudes can be found in a way analogous to the case with no coupling.

In Sec. IV we discuss a number of specific potential models to elucidate and amplify general results. We conclude with a brief discussion of our results in Sec. V.

II. *S*-MATRIX FORMULATION

The one-dimensional scattering problem has been studied in terms of the S matrix by a number of authors. (See, for example, Refs. 7, 9–12.) We extend the formalism to include a matrix potential function. The Schrödinger equation for a stationary state of such a system is

$$-\frac{d^2\Psi}{dx^2}+V(x)\Psi=k^2\Psi, \tag{2.1}$$

where $V(x)$ is a real, symmetric $N\times N$ matrix, k^2 the energy of the system, and $\Psi(k,x)$ the wave function, which is an N-dimensional column vector. For large values of $|x|$ the potential matrix $V(x)$ approaches zero sufficiently fast, so that in the asymptotic region $\Psi(k,x)$ represents a free-particle wave function. To ensure this we will take $V(x)=\mathbf{0}$ for $|x|>R$, R being the range of the potential. (The boldface $\mathbf{0}$ and $\mathbf{1}$ refer to the zero and identity $N\times N$ matrices, respectively.) Furthermore, we assume that $|V_{ij}(x)|$ is integrable for $i,j=1,\ldots,N$.

The physical scattering solutions of Eq. (2.1) at a given energy k^2 can be written as the columns of $N\times N$ matrices $\psi(k,x)$ and $\tilde{\psi}(k,x)$ which are uniquely determined by the boundary conditions,

$$\psi(k,x)\sim\begin{cases}\mathbf{1}e^{ikx}+\rho(k)e^{-ikx}, & x\to-\infty\\ \tau(k)e^{ikx}, & x\to\infty\end{cases} \tag{2.2}$$

and

$$\tilde{\psi}(k,x)\sim\begin{cases}\tilde{\tau}(k)e^{-ikx}, & x\to-\infty\\ \mathbf{1}e^{-ikx}+\tilde{\rho}(k)e^{ikx}, & x\to\infty.\end{cases} \tag{2.3}$$

We will refer to ψ and $\tilde{\psi}$ as the solution matrices. Note that the columns of ψ contain the wave functions with an incident wave from the left, whereas the columns of $\tilde{\psi}$ include those with an incident wave from the right. The $N\times N$ matrices $\rho,\tilde{\rho},\tau,\tilde{\psi}$ are generalizations of the usual reflection and transmission amplitudes.[13,14] The set of N-dimensional column vectors of matrices ψ and $\tilde{\psi}$ represent solutions of Eq. (2.1). The linear independency of these solutions can be shown by considering the $2N\times 2N$ matrix,

$$W(\psi,\tilde{\psi})=\begin{pmatrix}\psi & \tilde{\psi}\\ \psi' & \tilde{\psi}'\end{pmatrix}, \tag{2.4}$$

in which the prime indicates the derivative with respect to x. In Appendix A we show that the $\det W(\psi,\tilde{\psi})$ is a constant, which is nonzero if and only if the solutions are linearly independent. Its value, determined from the asymptotic forms of ψ and $\tilde{\psi}$, is

$$\det W(\psi,\tilde{\psi})=\det(\tau(k))(-2ik)^N. \tag{2.5}$$

Thus when both k and $\det\tau(k)$ are nonzero, the columns of ψ and $\tilde{\psi}$ give $2N$ linearly independent solutions.

In order to define the S matrix, we consider the general solution matrix in the asymptotic region,

$$\Phi(k,x)\sim\begin{cases}Ae^{ikx}+B'e^{-ikx}, & x\to-\infty\\ A'e^{ikx}+Be^{-ikx}, & x\to\infty,\end{cases} \tag{2.6}$$

where A,A',B,B' are $N\times N$ matrices. Since the unprimed matrices are associated with incoming waves and the primed matrices with outgoing waves, the S matrix can be defined as the matrix that transforms the coefficients of the incoming waves into those of the outgoing waves,[7,15] so that

$$\begin{pmatrix}A'\\ B'\end{pmatrix}=S\begin{pmatrix}A\\ B\end{pmatrix}=\begin{pmatrix}S_{aa} & S_{ab}\\ S_{ba} & S_{bb}\end{pmatrix}\begin{pmatrix}A\\ B\end{pmatrix}. \tag{2.7}$$

Clearly, S is a $2N\times 2N$ matrix. We can write it in terms of the transmission and reflection amplitudes by making use of the special cases for which $(A,B)=(\mathbf{1},\mathbf{0})$ and $(A,B)=(\mathbf{0},\mathbf{1})$. The result is

$$S=\begin{pmatrix}S_{aa} & S_{ab}\\ S_{ba} & S_{bb}\end{pmatrix}=\begin{pmatrix}\tau & \tilde{\rho}\\ \rho & \tilde{\tau}\end{pmatrix}. \tag{2.8}$$

The S matrix contains $4N^2$ complex elements or $8N^2$ real parameters. As we will see below there are a number of relations between the transmission and reflection amplitudes, which will reduce the number of independent real parameters.

A. Relation between reflection and transmission amplitudes

Constraints on the transmission and reflection amplitudes follow from the Schrödinger equation (2.1). Consider two solution matrices $\psi_1(k,x)$ and $\psi_2(k,x)$, then

$$\psi_2''=(k^2-V)\psi_2 \quad \text{and} \quad \psi_2^{\dagger\prime\prime}=\psi_2^\dagger(k^2-V), \tag{2.9}$$

so that

$$\psi_2^{\dagger\prime\prime}\psi_1=\psi_2^\dagger(k^2-V)\psi_1. \tag{2.10}$$

The Schrödinger equation, Eq. (2.1), for ψ_1 premultiplied by $\psi_2^\dagger$ yields

$$\psi_2^\dagger\psi_1''=\psi_2^\dagger(k^2-V)\psi_1. \tag{2.11}$$

Subtracting Eqs. (2.10) and (2.11), we obtain

$$\psi_2^{\dagger\prime\prime}\psi_1-\psi_2^\dagger\psi_1''=\frac{d}{dx}[\psi_2^{\dagger\prime}\psi_1-\psi_2^\dagger\psi_1']=0, \tag{2.12}$$

which leads to

$$\psi_2^{\dagger\prime}\psi_1-\psi_2^\dagger\psi_1'=\text{ constant matrix}. \tag{2.13}$$

If we now insert the asymptotic forms of ψ or $\tilde{\psi}$ for ψ_1 or ψ_2 into Eq. (2.13) and equate the expression at $-\infty$ to that at $+\infty$, we obtain the following relations:

$$\tau^\dagger\tau+\rho^\dagger\rho=\tilde{\tau}^\dagger\tilde{\tau}+\tilde{\rho}^\dagger\tilde{\rho}=\mathbf{1}, \tag{2.14}$$

$$\rho^\dagger\tilde{\tau}+\tau^\dagger\tilde{\rho}=\tilde{\tau}^\dagger\rho+\tilde{\rho}^\dagger\tau=\mathbf{0}. \tag{2.15}$$

Equations (2.14) and (2.15) are equivalent to the statement that $S^\dagger S = I$, where I is the $2N \times 2N$ identity matrix.

Further relations are found by using the time-reversal symmetry of the system. Since $V(x)$ is real, the complex conjugate solution matrices ψ^* and $\tilde{\psi}^*$ are also solutions of the Schrödinger equation. By complex conjugating Eq. (2.6), we see that the roles of the incoming and outgoing asymptotic waves are reversed, and indeed Eq. (2.7) is valid when $A \to B'^*$, $B \to A'^*$, $A' \to B^*$, and $B' \to A^*$. Thus Eq. (2.7) may be written as

$$\begin{pmatrix} B^* \\ A^* \end{pmatrix} = S \begin{pmatrix} B'^* \\ A'^* \end{pmatrix}. \tag{2.16}$$

Multiplying on the left by $S^\dagger$ and using $S^\dagger S = I$, we find that

$$\begin{pmatrix} B'^* \\ A'^* \end{pmatrix} = S^\dagger \begin{pmatrix} B^* \\ A^* \end{pmatrix}, \tag{2.17}$$

which leads to

$$\begin{pmatrix} A' \\ B' \end{pmatrix} = \begin{pmatrix} \mathbf{0} & \mathbf{1} \\ \mathbf{1} & \mathbf{0} \end{pmatrix} S^T \begin{pmatrix} \mathbf{0} & \mathbf{1} \\ \mathbf{1} & \mathbf{0} \end{pmatrix} \begin{pmatrix} A \\ B \end{pmatrix}, \tag{2.18}$$

where S^T is the transpose of S. Thus

$$S = \begin{pmatrix} \mathbf{0} & \mathbf{1} \\ \mathbf{1} & \mathbf{0} \end{pmatrix} S^T \begin{pmatrix} \mathbf{0} & \mathbf{1} \\ \mathbf{1} & \mathbf{0} \end{pmatrix}, \tag{2.19}$$

from which it follows that

$$\tilde{\tau} = \tau^T, \quad \rho = \rho^T, \quad \text{and} \quad \tilde{\rho} = \tilde{\rho}^T. \tag{2.20}$$

Inserting these expressions into Eqs. (2.14) and (2.15), we obtain

$$\tilde{\tau}\tilde{\tau}^\dagger + \rho\rho^\dagger = \tau\tau^\dagger + \tilde{\rho}\tilde{\rho}^\dagger = \mathbf{1}, \tag{2.21}$$

$$\tau\rho^\dagger + \tilde{\rho}\tilde{\tau}^\dagger = \rho\tau^\dagger + \tilde{\tau}\tilde{\rho}^\dagger = \mathbf{0}. \tag{2.22}$$

These equations yield the other half of the unitarity condition of the S matrix, so that

$$S^\dagger S = S S^\dagger = I. \tag{2.23}$$

For a parity-invariant potential function, i.e., $V(-x) = V(x)$, there are further constraints on the transmission and reflection amplitudes. In that case the amplitudes are symmetric matrices and the two types of amplitudes are the same, i.e.,

$$\rho = \tilde{\rho} = \rho^T = \tilde{\rho}^T, \quad \text{and} \quad \tau = \tilde{\tau} = \tilde{\tau}^T = \tau^T. \tag{2.24}$$

There is also a useful relation between the scattering amplitudes at k and at $-k$, which is easily obtained by generalizing the result for uncoupled potentials.[7] Since $\psi^*(-k,x)$ and $\tilde{\psi}^*(-k,x)$ are solution matrices of the Schrödinger equation with the same boundary conditions as $\psi(k,x)$ and $\tilde{\psi}(k,x)$ respectively, we find that

$$\tau^*(-k) = \tau(k), \quad \rho^*(-k) = \rho(k), \quad \tilde{\tau}^*(-k) = \tilde{\tau}(k), \quad \tilde{\rho}^*(-k) = \tilde{\rho}(k). \tag{2.25}$$

From these relations it follows immediately that the reflection and transmission amplitudes at threshold (i.e., $k=0$) are real.

B. Levinson's theorem

Levinson's theorem in its most common formulation for a spherically symmetric potential gives a relationship of the scattering phase shifts at zero and infinite energy. The theorem has also been studied for one-dimensional systems without coupling.[2,5] We generalize the theorem to the matrix-potential case. Levinson's theorem is a consequence of the orthogonality and completeness relation of the eigenstates of the total Hamiltonian.

The scattering states of the Schrödinger equation (2.1) defined by Eqs. (2.2) and (2.3) along with the bound states can be used to form a complete orthonormal set of eigenstates. Suppose that there are n_b bound states whose orthonormal wave functions are denoted by the column vectors $\psi_{E_j}(x)$ with $E_j(<0)$ referring to the bound state energy. In case of degenerate bound states, we label the state vectors with subscript E_j, but allow the possibility of different subscripts j for the same energy in order to include all independent bound-state vectors. For example, one could have $E_j=E_i$ where $i \neq j$ when E_i is a degenerate energy eigenvalue. The orthonormality relations are

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dx\,\psi_j^{\dagger}(k,x)\,\psi_i(k',x)=\frac{1}{2\pi}\int_{-\infty}^{\infty} dx\,\tilde{\psi}_j^{\dagger}(k,x)\,\tilde{\psi}_i(k',x)=\delta_{ij}\delta(k'-k), \tag{2.26}$$

$$\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dx\,\psi_j^{\dagger}(k,x)\,\psi_{E_i}(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dx\,\tilde{\psi}_j^{\dagger}(k,x)\,\psi_{E_i}(x)=0, \tag{2.27}$$

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dx\,\tilde{\psi}_j^{\dagger}(k,x)\,\psi_i(k',x)=0 \quad \text{and} \quad \int_{-\infty}^{\infty} dx\,\psi_{E_j}^{\dagger}(x)\,\psi_{E_i}(x)=\delta_{ij}\,, \tag{2.28}$$

where ψ_i and $\tilde{\psi}_i$ are the ith columns of the ψ and $\tilde{\psi}$ matrices, respectively. Thus the completeness relation is

$$\sum_{j=1}^{n_b}\psi_{E_j}(x)\,\psi_{E_j}^{\dagger}(x')+\sum_{i=1}^{N}\frac{1}{2\pi}\int_0^{\infty} dk\,\psi_i(k,x)\,\psi_i^{\dagger}(k,x')$$

$$+\sum_{i=1}^{N}\frac{1}{2\pi}\int_0^{\infty} dk\,\tilde{\psi}_i(k,x)\,\tilde{\psi}_i^{\dagger}(k,x')=\mathbf{1}\delta(x-x'). \tag{2.29}$$

The completeness relation may be written in a more compact form in terms of the matrices themselves rather than the column vectors, i.e.,

$$\sum_{j=1}^{n_b}\psi_{E_j}(x)\,\psi_{E_j}^{\dagger}(x')+\frac{1}{2\pi}\int_0^{\infty} dk[\,\psi(k,x)\,\psi^{\dagger}(k,x')+\tilde{\psi}(k,x)\,\tilde{\psi}^{\dagger}(k,x')\,]=\mathbf{1}\delta(x-x'). \tag{2.30}$$

For the free-particle case when $V(x)=\mathbf{0}$, there are no bound states and the completeness relation is

$$\frac{1}{2\pi}\int_0^{\infty} dk[\,\psi^0(k,x)\,\psi^{0\dagger}(k,x')+\tilde{\psi}^0(k,x)\,\tilde{\psi}^{0\dagger}(k,x')\,]=\mathbf{1}\delta(x-x'). \tag{2.31}$$

We now subtract Eq. (2.31) from Eq. (2.30), set $x'=x$, and integrate over x from $-\mathscr{R}$ to $\mathscr{R}$. The resulting equation may be written as

$$\int_0^\infty dk \int_{-\mathscr{R}}^{\mathscr{R}} dx [\psi(k,x)\psi^\dagger(k,x) + \widetilde{\psi}(k,x)\widetilde{\psi}^\dagger(k,x) - \psi^0(k,x)\psi^{0\dagger}(k,x) - \widetilde{\psi}^0(k,x)\widetilde{\psi}^{0\dagger}(k,x)]$$

$$= -2\pi \int_{-\mathscr{R}}^{\mathscr{R}} dx \sum_{j=1}^{n_b} \psi_{E_j}(x)\psi_{E_j}^\dagger(x). \tag{2.32}$$

The trace of Eq. (2.32) in the limit as $\mathscr{R}$ approaches infinity gives

$$-2\pi n_b = \lim_{\mathscr{R}\to\infty} \int_0^\infty dk \int_{-\mathscr{R}}^{\mathscr{R}} dx \, \mathrm{Tr}[\psi(k,x)\psi^\dagger(k,x) + \widetilde{\psi}(k,x)\widetilde{\psi}^\dagger(k,x)$$

$$- \psi^0(k,x)\psi^{0\dagger}(k,x) - \widetilde{\psi}^0(k,x)\widetilde{\psi}^{0\dagger}(k,x)]. \tag{2.33}$$

To perform the integration over x in the right side of Eq. (2.33), we use the identity

$$\mathrm{Tr}[\psi\psi^\dagger] = \frac{1}{2k}\frac{\partial}{\partial x}\left\{ \mathrm{Tr}\left[\frac{\partial\psi}{\partial k}\frac{\partial\psi^\dagger}{\partial x} - \frac{\partial^2\psi}{\partial x \partial k}\psi^\dagger \right] \right\}, \tag{2.34}$$

which may be obtained by taking the derivative with respect to k of the Schrödinger equation (2.1). Since in the limit $\mathscr{R}$ exceeds the range of the potential, we can insert the asymptotic forms of the wave functions in Eq. (2.33) to obtain

$$-2\pi n_b = \lim_{\mathscr{R}\to\infty} \int_0^\infty \frac{dk}{2k} \mathrm{Tr}\Bigg[-2ik\left(\frac{\partial\tau}{\partial k}\tau^\dagger + \frac{\partial\rho}{\partial k}\rho^\dagger + \frac{\partial\widetilde{\tau}}{\partial k}\widetilde{\tau}^\dagger + \frac{\partial\widetilde{\rho}}{\partial k}\widetilde{\rho}^\dagger \right)$$

$$- i(\rho + \widetilde{\rho})e^{2ik\mathscr{R}} + i(\rho^\dagger + \widetilde{\rho}^\dagger)e^{-2ik\mathscr{R}} \Bigg]. \tag{2.35}$$

Following Newton and Jost[16] we define the phase as

$$\eta(k) = \frac{1}{2i} \ln \det S(k), \tag{2.36}$$

where we require $\eta(k)$ to be continuous for $k \in (0,\infty)$. Since the S matrix is unitary, we may write $S = U^\dagger S_D U$, where U is a real orthogonal matrix and S_D is the diagonal matrix $S_D = \mathrm{diag}(e^{i\delta_1}, \ldots, e^{i\delta_{2N}})$ where the δ_j's are real phases.[17] Let us write therefore $S = e^{i\Delta}$ where $\Delta = U^\dagger \Delta_D U$ for $\Delta_D = \mathrm{diag}(\delta_1, \ldots, \delta_{2N})$. Then

$$2i\,\eta(k) = \ln \det S(k) = \ln \det S_D(k) = \sum_{j=1}^{2N} i\,\delta_j(k) = \mathrm{Tr}[i\Delta_D(k)] \tag{2.37}$$

and

$$2i\frac{\partial\eta}{\partial k} = \mathrm{Tr}\left[\frac{\partial i\Delta_D}{\partial k}\right] = \mathrm{Tr}\left[S_D^\dagger \frac{\partial S_D}{\partial k}\right] = \mathrm{Tr}\left[S^\dagger \frac{\partial S}{\partial k}\right] = \mathrm{Tr}\left[\frac{\partial\tau}{\partial k}\tau^\dagger + \frac{\partial\rho}{\partial k}\rho^\dagger + \frac{\partial\widetilde{\tau}}{\partial k}\widetilde{\tau}^\dagger + \frac{\partial\widetilde{\rho}}{\partial k}\widetilde{\rho}^\dagger\right]. \tag{2.38}$$

Thus Eq. (2.35) may be written as

$$\eta(0) - \eta(\infty) = \pi n_b - \lim_{\mathscr{R}\to\infty} X(\mathscr{R}), \tag{2.39}$$

where

$$X(\mathscr{R})=\frac{1}{2}\int_0^\infty \frac{dk}{2k}\,\mathrm{Tr}[\,i(\rho(k)+\tilde{\rho}(k))e^{2ik\mathscr{R}}-i(\rho^\dagger(k)+\tilde{\rho}^\dagger(k))e^{-2ik\mathscr{R}}] \tag{2.40}$$

$$=\frac{i}{4}\int_{-\infty}^{\infty}\frac{dk}{k}\,\mathrm{Tr}[\rho(k)+\tilde{\rho}(k)]e^{2ik\mathscr{R}}. \tag{2.41}$$

In the next section we show that $\rho(k)\sim O(1/k)$ for large $|k|$, so that the integration in Eq. (2.41) converges for large $|k|$. We now take the limit as $\mathscr{R}$ approaches ∞, using the relation

$$\lim_{\mathscr{R}\to\infty}\frac{e^{2ik\mathscr{R}}}{k}=i\pi\delta(k), \tag{2.42}$$

where $\delta(k)$ is the Dirac delta function. In that limit $X(\mathscr{R})$ goes to $-(\pi/4)\,\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)]$, so that the statement of Levinson's theorem now is

$$\eta(0)=\pi n_b+\frac{\pi}{4}\,\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)], \tag{2.43}$$

where we have set $\eta(\infty)$ equal to zero. In the next section we also show that

$$\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)]=-2(N-n), \tag{2.44}$$

where n is the number of ''half-bound states.''[10,11,18] Thus in its final form Levinson's theorem states,

$$\eta(0)=\pi(n_b+\tfrac{1}{2}n-\tfrac{1}{2}N). \tag{2.45}$$

This expression of the theorem is consistent with that for the uncoupled case given in Ref. 11.

C. Threshold behaviour of ρ and τ

The threshold behaviour of reflection and transmission amplitudes and coefficients has been discussed recently in several articles.[2,4,6,7] In order to study the behaviour of the ρ and τ matrices at $k=0$, we introduce a different set of solutions of the Schrödinger equation, since according to Eq. (2.5) the columns of ψ and $\tilde{\psi}$ fail to be linearly independent at $k=0$. Let $\phi(k,x)$ and $\chi(k,x)$ be solution matrices of Eq. (2.1) which satisfy the boundary conditions,

$$\begin{aligned}\phi(k,-R)&=\chi'(k,-R)=\mathbf{1}\\ \phi'(k,-R)&=\chi(k,-R)=\mathbf{0},\end{aligned} \tag{2.46}$$

where R is the range of the potential as defined at the beginning of Sec. II. By evaluating $\det W(\phi,\chi)$ at $x=-R$ and using the results of Appendix A, we readily show that for all x and k the $\det W(\phi,\chi)=1$, where the matrix W is defined as in Eq. (2.4). Thus unlike the column vectors of ψ and $\tilde{\psi}$, the column vectors of ϕ and χ are linearly independent at zero energy.

In order to obtain the scattering amplitudes, we expand ψ in terms of ϕ and χ so that

$$\psi(k,x)=\phi(k,x)B(k)+\chi(k,x)C(k), \tag{2.47}$$

where $B(k)$ and $C(k)$ are matrices of expansion coefficients. Evaluating ψ and ψ' at $\pm R$ using Eqs. (2.2) and (2.47), we obtain four equations involving $B(k),C(k),\rho(k)$ and $\tau(k)$. By eliminating three of these we find that ρ can expressed in terms of ϕ and χ and their derivatives evaluated at R. Thus

$$\rho(k)=\{k^2\chi(k,R)+ik[\chi'(k,R)+\phi(k,R)]-\phi'(k,R)\}^{-1}$$
$$\times\{k^2\chi(k,R)+ik[\chi'(k,R)-\phi(k,R)]+\phi'(k,R)\}e^{-2ikR}. \tag{2.48}$$

Similarly by expanding $\tilde{\psi}$ in terms of ϕ and χ we obtain

$$\tilde{\rho}(k)=\{k^2\chi(k,R)-ik[\chi'(k,R)-\phi(k,R)]+\phi'(k,R)\}$$
$$\times\{k^2\chi(k,R)+ik[\chi'(k,R)+\phi(k,R)]-\phi'(k,R)\}^{-1}e^{-2ikR}, \tag{2.49}$$

$$\tilde{\tau}(k)=2ik\{k^2\chi(k,R)+ik[\chi'(k,R)+\phi(k,R)]-\phi'(k,R)\}^{-1}e^{-2ikR}, \tag{2.50}$$

and, since $\tau(k)=\tilde{\tau}^T(k)$,

$$\tau(k)=2ik\{k^2\chi^T(k,R)+ik[\chi'^T(k,R)+\phi^T(k,R)]-\phi'^T(k,R)\}^{-1}e^{-2ikR}. \tag{2.51}$$

Thus all four scattering amplitudes, and consequently the S matrix, are determined by ϕ and χ and their derivatives evaluated at R. In Appendix B it is shown that $\phi(k,x)$ and $\chi(k,x)$ are entire functions of complex k for all $x\in[-R,R]$ so that the analytic properties of the scattering amplitudes can be determined using these wave functions. By inserting the expressions for the large real k behaviour of the wave functions, Eqs. (B16) and (B17), into the expressions for the scattering amplitudes, we obtain

$$\tau(k)\sim\mathbf{1}+O(1/k) \quad \text{and} \quad \rho(k)\sim\mathbf{0}+O(1/k) \quad \text{for } k\to\infty, \tag{2.52}$$

and similar expressions for $\tilde{\tau}$ and $\tilde{\rho}$.

If $\det[\phi'(0,R)]\neq 0$, the reflection and transmission amplitudes at zero energy are

$$\rho(0)=\tilde{\rho}(0)=-\mathbf{1} \quad \text{and} \quad \tau(0)=\tilde{\tau}(0)=\mathbf{0}. \tag{2.53}$$

The case for which $\det[\phi'(0,R)]=0$ needs special attention. In order to understand the significance of this condition, we look at the bound states of the system. In the Schrödinger equation (2.1) for bound states, we denote the bound-state energy as $\alpha^2=-k^2$ with $\alpha>0$. The bound-state wave functions can be expressed as column vectors of a matrix $\psi_b(\alpha,x)$ with the asymptotic boundary conditions,

$$\psi_b(\alpha,x)\sim\begin{cases}e^{\alpha x}Q, & x\leqslant -R\\ e^{-\alpha x}T, & x\geqslant R\end{cases} \tag{2.54}$$

where Q and T are matrices of constants. The number of independent bound states at a given energy will depend on the rank of the matrix ψ_b, and consequently cannot exceed N. Proceeding as we did for the scattering states, we expand the bound-state wave functions in terms of the functions $\phi_b(\alpha,x)$ and $\chi_b(\alpha,x)$ which are solution matrices of the Schrödinger equation with energy $-\alpha^2$ and satisfy the boundary conditions

$$\phi_b(\alpha,-R)=\chi_b'(\alpha,-R)=\mathbf{1}, \quad \chi_b(\alpha,-R)=\phi_b'(\alpha,-R)=\mathbf{0}. \tag{2.55}$$

Thus

$$\psi_b(\alpha,x)=\phi_b(\alpha,x)\beta(\alpha)+\chi_b(\alpha,x)\gamma(\alpha), \tag{2.56}$$

where β and γ are matrices of expansion coefficients. At R and $-R$ we match the asymptotic form of the wave function, Eq. (2.54), and its derivative to the expanded form, Eq. (2.56), and its derivative. Eliminating T,Q and γ from the four equations so obtained, we are left with the equation

$$\{\alpha^2\chi_b(\alpha,R)+\alpha[\chi_b'(\alpha,R)+\phi_b(\alpha,R)]+\phi_b'(\alpha,R)\}\beta(\alpha)=0. \tag{2.57}$$

Since one of the four matching equations is $Q=\beta(\alpha)e^{\alpha R}$, there will be bound states only if the matrix $\beta(\alpha)$ contains nonzero entries. Such a nontrivial matrix exists only when

$$\det\{\alpha^2\chi_b(\alpha,R)+\alpha[\chi_b'(\alpha,R)+\phi_b(\alpha,R)]+\phi_b'(\alpha,R)\}=0. \tag{2.58}$$

This is the bound-state eigenvalue equation for energy $-\alpha^2$. In contrast to the case with no coupling, the bound-state eigenenergies can be degenerate.

Let us consider the eigenstates when $\alpha=0$. These will occur only if $\det[\phi_b'(0,R)]=0$. In general the solutions represented by the columns vectors of $\psi_b(0,x)$ are bounded but not square integrable; hence they are referred to as half-bound states.[19] The restriction on the potential function that it vanishes for $|x|\geqslant R$, precludes the possibility of having normalizable state functions at zero energy. For this to be the case a linear combination of the columns of ψ_b would yield $\Psi(0,x)=0$ for $|x|\geqslant R$. Such a boundary condition would lead to the trivial solution of Eq. (2.1). Normalizable zero-energy bound states can exist for potentials which are less restrictive than those of this paper.[18]

Since $\phi(0,x)$ and $\phi_b(0,x)$ are solutions of the same system of differential equations and both have the same boundary conditions, $\phi_b(0,x)=\phi(0,x)$. Thus the condition that

$$\det[\phi'(0,R)]=0 \tag{2.59}$$

is equivalent to the condition for the existence of half-bound states.

Consider the matrix eigenvalue equation,

$$\phi'(0,R)\tilde{\beta}=\lambda\tilde{\beta}, \tag{2.60}$$

where $\tilde{\beta}$ is a column vector and λ is its eigenvalue. There will be a nontrivial solution only if

$$\det[\phi'(0,R)-\lambda\mathbf{1}]=0. \tag{2.61}$$

Suppose the eigenvalues obtained are $\lambda_1,\cdots,\lambda_N$. At least one of these must be zero if there is a half-bound state. Actually there may be $n(\leqslant N)$ zero eigenvalues. We can order these in the following way: $0,\ldots,0,\lambda_{n+1},\ldots,\lambda_N$. These n zero eigenvalues will have n linearly independent eigenvectors associated with them, which represent n distinct half-bound states.

We now return to the discussion of reflection and transmission amplitudes. The inverse of $\tilde{\tau}$ of Eq. (2.50) can be written as

$$2ik\,\tilde{\tau}^{-1}(k)=\{k^2\chi(k,R)+ik[\chi'(k,R)+\phi(k,R)]-\phi'(k,R)\}e^{2ikR}. \tag{2.62}$$

If this equation is combined with Eq. (2.49), we obtain

$$2ik\tilde{\rho}(k)\tilde{\tau}^{-1}(k)=\{k^2\chi(k,R)-ik[\chi'(k,R)-\phi(k,R)]+\phi'(k,R)\}. \tag{2.63}$$

The factor in the curly brackets of Eq. (2.62) is precisely that in the determinant of Eq. (2.58) (with $k=i\alpha$), i.e., it is the factor which determines the bound states of the system. In Appendix B we show that matrices ϕ and χ are elementwise entire functions of k. From Eq. (2.62) and the fact that $\tilde{\tau}^T=\tau$ we see that $2ik\tau^{-1}(k)$ and $(2ik)^N$ det $\tau^{-1}(k)$ are also entire functions of k. According to Eqs. (2.58) and (2.62) det $\tau^{-1}(k)$ has a zero at $k=i\alpha$ when $-\alpha^2$ is the energy of a bound state. Thus det $\tau(k)$ has poles (possibly multiple) on the positive imaginary axis of the complex k plane. In the absence of a half-bound state, det $\tau^{-1}(k)$ has an Nth order pole at $k=0$ and det τ has an Nth order zero at $k=0$. Since there can be no more than N half-bound states det $\tau(k)$ and $\tau(k)$ are analytic in a neighborhood of $k=0$.

In the following we consider real k. Taking the limits as k goes to zero of Eqs. (2.62) and (2.63) we obtain

$$\lim_{k\to 0} 2ik\tilde{\tau}^{-1}(k) = -\phi'(0,R) \quad \text{and} \quad \lim_{k\to 0} 2ik\tilde{\rho}(k)\tilde{\tau}^{-1}(k) = \phi'(0,R). \tag{2.64}$$

Similarly using Eq. (2.51) and the transpose of Eq. (2.48), we get

$$\lim_{k\to 0} 2ik\tau^{-1}(k) = -\phi'^{T}(0,R) \quad \text{and} \quad \lim_{k\to 0} 2ik\rho(k)\tau^{-1}(k) = \phi'^{T}(0,R). \tag{2.65}$$

We introduce unitary matrices $U(k)$ and $V(k)$ which diagonalize τ (Ref. 20), so that

$$\tau_D(k) = U^{\dagger}(k)\tau(k)V(k) \quad \text{and} \quad 2ik\tau_D^{-1} = V^{\dagger}(k)2ik\tau^{-1}(k)U(k). \tag{2.66}$$

In the limit as k approaches zero $U(0)$ and $V(0)$ also diagonalize $\phi'^{T}(0,R)$, i.e., $\phi_D'^{T}(0,R) = V^{\dagger}(0)\phi'^{T}(0,R)U(0)$, so that

$$\lim_{k\to 0} 2ik\tau_D^{-1}(k) = -\phi_D'^{T}(0,R). \tag{2.67}$$

We define the matrix

$$r(k) \equiv V^{\dagger}(k)\rho(k)V(k), \tag{2.68}$$

so that

$$\lim_{k\to 0} 2ikr(k)\tau_D{}^{-1}(k) = \phi_D'^{T}(0,R). \tag{2.69}$$

Combining Eqs. (2.67) and (2.69) gives

$$r(0)\phi_D'^{T}(0,R) = -\phi_D'^{T}(0,R). \tag{2.70}$$

The matrices $\phi'^{T}(0,R)$ and $\phi_D'^{T}(0,R)$ have the same rank (Ref. 20). Thus $\phi_D'^{T}(0,R)$ will have the same number of nonzero diagonal elements as there are nonzero eigenvalues of $\phi'^{T}(0,R)$ or $\phi'(0,R)$. Writing $\phi_D'^{T}(0,R) = \mathrm{diag}(0,\cdots,0,s_{n+1},\cdots,s_N)$ and using Eq. (2.70) we see that the matrix $r(0)$ must have the form

$$r(0) = \begin{pmatrix} R_{11} & \mathbf{0} \\ R_{21} & -\mathbf{1} \end{pmatrix}, \tag{2.71}$$

where the matrices R_{11}, R_{21}, $\mathbf{0}$ and $\mathbf{1}$ have dimensions $n\times n$, $(N-n)\times n$, $n\times(N-n)$ and $(N-n)\times(N-n)$, respectively.

To study the behaviour of $\tau_D(k)$ near $k=0$, we consider the Hermitian positive semi-definite matrix $T(k) = \tau^{\dagger}(k)\tau(k)$, whose real nonnegative eigenvalues we denote by $t_1^2(k),\ldots,t_N^2(k)$. The singular values of $\tau(k)$ are defined as the nonnegative square root of these, i.e., $t_1(k),\ldots,t_N(k)$, and they form the diagonal elements of $\tau_D(k)$ in Eq. (2.66), so that $\tau_D(k) = \mathrm{diag}(t_1(k),\ldots,t_N(k))$. (Ref. 20) Since $\tau(k)$ is analytic in the neighborhood of $k=0$, so is $T(k)$. For small real $k>0$, we invoke a theorem of Rellich[21] which states that the eigenvalues of $T(k)$ are convergent power series of k. Furthermore, using Eq. (2.25), we note that $T(k) = T^{T}(-k)$ and the eigenvalues of $T(k)$ and $T(-k)$ are the same. Thus taking the eigenvalues in the same order, we find that $t_i^2(-k) = t_i^2(k)$. Hence the $t_i^2(k)$'s are power series of k^2 and the

$t_i(k)$'s are power series of k. Thus we may write $\tau_D(k) = \mathrm{diag}(t_1 + t_{11}k + \cdots, \ldots, t_N + t_{N1}k + \cdots)$ and $\tau_D^{-1}(k) = \mathrm{diag}((t_1 + t_{11}k + \cdots)^{-1}, \ldots, (t_N + t_{N1}k + \cdots)^{-1})$, where the t_i's and t_{ij}'s are constants. In order that

$$\lim_{k\to 0} 2ik\tau_D^{-1}(k) = \lim_{k\to 0} \mathrm{diag}(2ik(t_1 + t_{11}k + \cdots)^{-1}, \ldots, 2ik(t_N + t_{N1}k + \cdots)^{-1}) \tag{2.72}$$

$$= \mathrm{diag}(0, \ldots, 0, -s_{n+1}, \ldots, -s_N), \tag{2.73}$$

the quantities $t_1, \ldots, t_n \neq 0$ and $t_{n+1} = \cdots = t_N = 0$. The matrix $\tau_D(0)$ therefore has the form $\tau_D(0) = \mathrm{diag}(t_1, \ldots, t_n, 0, \ldots, 0)$ where the first n diagonal elements are nonzero.

Recall that $\tau^T = \tilde{\tau}$ and therefore $(\tau^T)^{-1} = \tilde{\tau}^{-1}$, and that $\tilde{\rho} = \tilde{\rho}^T$. The second part of Eq. (2.64) becomes

$$\lim_{k\to 0} 2ik\tau^{-1}(k)\tilde{\rho}(k) = \phi'^T(0,R). \tag{2.74}$$

The same U and V can be used to obtain

$$\lim_{k\to 0} 2ik\tau_D{}^{-1}(k)\tilde{r}(k) = \phi_D'^T(0,R), \tag{2.75}$$

where

$$\tilde{r}(k) = U^\dagger(k)\tilde{\rho}(k)U(k). \tag{2.76}$$

As before the structure of $\tilde{r}(0)$ may be determined, and it is

$$\tilde{r}(0) = \begin{pmatrix} \tilde{R}_{11} & \tilde{R}_{12} \\ \mathbf{0} & -\mathbf{1} \end{pmatrix}. \tag{2.77}$$

In order to simplify Eq. (2.43) we write

$$\begin{aligned} \mathrm{Tr}[\rho(0) + \tilde{\rho}(0)] &= \mathrm{Tr}[r(0) + \tilde{r}(0)] \\ &= -2(N-n) + \mathrm{Tr}[R_{11}^{n\times n} + \tilde{R}_{11}^{n\times n}], \end{aligned} \tag{2.78}$$

where the superscripts refer to the dimensions of the matrices. All that remains is to evaluate the last term of the right side of this equation. At zero energy the scattering amplitudes are real. Using this fact along with the relations that $\tilde{\tau} = \tau^T$ and $\rho = \rho^T$ in Eq. (2.15), we obtain

$$\tau(0)\rho(0) + \tilde{\rho}(0)\tau(0) = \mathbf{0}. \tag{2.79}$$

By applying the diagonalization transformation of τ, we find that

$$\tau_D(0)r(0) + \tilde{r}(0)\tau_D(0) = \mathbf{0}. \tag{2.80}$$

In matrix form this equation may be written

$$\begin{pmatrix} A_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix}\begin{pmatrix} R_{11} & \mathbf{0} \\ R_{21} & -\mathbf{1} \end{pmatrix} + \begin{pmatrix} \tilde{R}_{11} & \tilde{R}_{12} \\ \mathbf{0} & -\mathbf{1} \end{pmatrix}\begin{pmatrix} A_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} = \mathbf{0}, \tag{2.81}$$

where $A_1 = \mathrm{diag}(t_1, \cdots, t_n)$ and the block matrices have the appropriate dimensions. From Eq. (2.81) it follows that

$$A_1 R_{11} + \tilde{R}_{11} A_1 = \mathbf{0}^{n\times n}. \tag{2.82}$$

Consequently, the second term in the right side of Eq. (2.78) is zero, and we have the simple relation

$$\mathrm{Tr}[\rho(0) + \tilde{\rho}(0)] = -2(N-n) \tag{2.83}$$

In light of the discussion of the $N=1$ normal and anomalous threshold behaviour,[4,7] our result seems surprising since the right side of Eq. (2.83) is an integer, whereas the anomalous threshold effect for parity-noninvariant potentials gives values for $\rho(0)$ which lie between 0 and 1. However, if one considers the sum of $\rho(0)$ and $\tilde{\rho}(0)$ in the uncoupled case, one obtains an even integer. For a parity-invariant potential, i.e., $V(-x)=V(x)$, ρ and $\tilde{\rho}$ are equal and the zero-energy value of ρ will always be an integer.

III. SEGMENTED POTENTIALS AND FACTORIZATION OF THE *S* MATRIX

For the Schrödinger equation without coupling it is well known that the reflection and transmission amplitudes satisfy a factorization formula. That is, if the potential is subdivided into a number of sections, then the total transmission and reflection amplitudes for the system can be expressed in terms of the amplitudes for each of the truncated pieces of the potential. The recent proof of Aktosun[22] may be generalized immediately to the case of N coupled equations.

Following Aktosun, then, we subdivide the real line into J pieces. The boundaries of the segments are denoted by x_i, $i=0,\ldots,J$, with $-R=x_0<x_1<\ldots<x_{J-1}<x_J=R$. The potential may then be written as a sum of truncated potentials as follows:

$$V(x) = \sum_{j=0}^{J-1} V_j(x), \tag{3.1}$$

where

$$V_j(x) = \begin{cases} V(x), & x_j<x<x_{j+1} \\ 0, & \text{otherwise.} \end{cases} \tag{3.2}$$

The single indices on the truncated potentials should not be confused with the implicit double indices which label the various elements of the potential matrix.

For a given j, then, let us define the matrix

$$\Lambda_j(k) = \begin{pmatrix} \tau_j^{-1}(k) & -\tau_j^{-1}(k)\tilde{\rho}_j(k) \\ \rho_j(k)\tau_j^{-1}(k) & (\tilde{\tau}_j^{\dagger}(k))^{-1} \end{pmatrix}, \tag{3.3}$$

where $\tau_j(k)$, $\tilde{\tau}_j(k)$, $\rho_j(k)$, $\tilde{\rho}_j(k)$ represent the various amplitude matrices for the truncated potentials with the usual boundary conditions. The amplitudes for the original potential are similarly arranged into a matrix,

$$\Lambda(k) = \begin{pmatrix} \tau^{-1}(k) & -\tau^{-1}(k)\tilde{\rho}(k) \\ \rho(k)\tau^{-1}(k) & (\tilde{\tau}^{\dagger}(k))^{-1} \end{pmatrix}, \tag{3.4}$$

and the factorization formula is then simply given by

$$\Lambda(k) = \prod_{j=0}^{J-1} \Lambda_j(k), \tag{3.5}$$

where the factors on the right side of the equation are ordered so that factors with lower subscripts occur to the left of the ones with higher subscripts. The proof of Eq. (3.5) is completely analogous to that advanced by Aktosun in the $N=1$ case and so we shall not review it here. The only added complication is the fact that the various amplitude matrices do not generally commute, but this has been properly accounted for in the definitions of the Λ matrices. The utility of Eq. (3.5) will become apparent below when we use it to derive the amplitudes for scattering from two different delta-function matrix potentials in terms of the amplitudes for scattering from each of them separately.

This approach effectively factorizes the S matrix in the sense that if the S matrix of the jth potential segment, i.e.,

$$S_j(k)=\begin{pmatrix} \tau_j(k) & \tilde{\rho}_j(k) \\ \rho_j(k) & \tilde{\tau}_j(k) \end{pmatrix}, \tag{3.6}$$

is known, then the scattering amplitudes of the potential segment are determined, and from them $\Lambda_j(k)$. Using Eq. (3.5) we can obtain $\Lambda(k)$ for the whole potential, and this allows us to solve for the scattering amplitudes and the S matrix of the whole potential.

Another generalization of the uncoupled to the coupled problem involves the finitely periodic potentials, recently discussed by a number of authors.[3,23–25] In the derivation of the factorization formula, Eq. (3.5), we have to be careful in the ordering of the products such as $\rho\tau^{-1}$. This non-commutativity of the amplitude matrices would typically prevent us from generalizing the closed-form solutions of the finitely periodic potentials. There are however classes of potentials for which the various amplitude matrices do commute with each other and for which the results for no coupling *can* be generalized.

An example of such a class of potentials consists of those potentials which can be expressed as

$$V(x)=U\ \mathrm{diag}[v_1(x),v_2(x),\ldots,v_N(x)]U^T, \tag{3.7}$$

where U is a constant (real) orthogonal matrix. Note that the potentials of Eq. (3.7) include as a subclass those of the form $V(x)=v(x)M$, where $v(x)$ is a real-valued function of x and M is a constant symmetric matrix. Such potentials have been used previously in various applications (see, for example, Ref. 26). It is easy to prove that when the potential is diagonalizable by a constant orthogonal matrix, then all of the amplitude matrices (as well as their inverses and hermitian conjugates) commute with each other.

If we use potentials of this type to construct finitely periodic potentials with nonoverlapping subpotentials, the analysis of Rozman *et al.*[23,24] follows in the same way for the matrix potential problem and the expressions for the amplitude matrices are straight forward generalizations of their results.

IV. POTENTIAL MODELS

Below we consider some potential models which lend themselves to solutions in closed form. These models help to elucidate some of the results obtained in the previous sections.

A. Constant potential matrix

An example of a potential for which solutions can be obtained in closed form is the square-well or square-barrier potential matrix for which

$$V(x)=\begin{cases} V_0 & \text{for } a\leqslant x\leqslant b \text{ where } a\geqslant -R \text{ and } b\leqslant R \\ 0 & \text{otherwise,} \end{cases} \tag{4.1}$$

where V_0 is a real symmetric $N\times N$ matrix. The Schrödinger equation (2.1) is equivalent to a first-order differential equation of the matrix function $W(x)=W(\phi,\chi)$ of Eq. (A2), i.e.,

$$W'(x)=F(x)W(x), \tag{4.2}$$

where

$$F(x)=\begin{pmatrix} \mathbf{0} & \mathbf{1} \\ V(x)-k^2 & \mathbf{0} \end{pmatrix}, \tag{4.3}$$

with the boundary condition $W(-R)=I$. As we saw earlier the function $W(x)$ provides the advantage of giving solutions that are linearly independent at $k=0$. In addition, Eq. (4.2) gives us an initial value problem, rather than the two-point boundary condition problem of the original Schrödinger equation. Solving for the scattering amplitudes numerically is simpler for the initial value problem. An alternative to this approach is the variable amplitude formulation which also casts the problem into a system of first order differential equations with an initial value condition.[13,14] In principle, Eq. (4.2) can be used to solve the Schrödinger equation for any arbitrary potential matrix.

For the constant potential matrix the differential equation Eq. (4.2) can be integrated starting at $x=-R$ over the three regions $(-R,a),(a,b)$ and (b,R) in turn.[27] The result is

$$\begin{aligned} W(R)=&\begin{pmatrix} \cos\, k(R-b) & k^{-1}\sin k(R-b) \\ -k\sin k(R-b) & \cos\, k(R-b) \end{pmatrix}\begin{pmatrix} \cosh\, K(b-a) & K^{-1}\sinh K(b-a) \\ K\sinh K(b-a) & \cosh\, K(b-a) \end{pmatrix} \\ &\times\begin{pmatrix} \cos\, k(a+R) & k^{-1}\sin k(a+R) \\ -k\sin k(a+R) & \cos\, k(a+R) \end{pmatrix}, \end{aligned} \tag{4.4}$$

where $K^2=V_0-k^2$. To simplify matters, but still to allow us to study a model with a potential function without definite parity, we set $a=-R$, so that we obtain explicit forms for the wave functions at $x=R$.

$$\begin{aligned} \phi(k,R)&=\cos\, k(R-b)\cosh\, K(R+b)+k^{-1}\sin k(R-b)K\sinh K(R+b), \\ \phi'(k,R)&=-k\sin k(R-b)\cosh\, K(R+b)+\cos\, k(R-b)K\sinh K(R+b), \\ \chi(k,R)&=\cos\, k(R-b)K^{-1}\sinh K(R+b)+k^{-1}\sin k(R-b)\cosh\, K(R+b), \\ \chi'(k,R)&=-k\sin k(R-b)K^{-1}\sinh K(R+b)+\cos\, k(R-b)\cosh\, K(R+b). \end{aligned} \tag{4.5}$$

These expressions can be inserted in the equations for ρ, $\tilde{\rho}$, τ, $\tilde{\tau}$, Eqs. (2.48) to (2.51), to obtain the scattering amplitudes.

Note that $K^2=V_0-k^2$ is a real symmetric matrix and may therefore be diagonalized by an orthogonal transformation U, giving $K_D^2=UK^2U^T$. The diagonal matrix K_D has the square root of the diagonal elements of K_D^2 along its diagonal. Thus $K=U^TK_DU$, which is a symmetric matrix. Consequently, ϕ,ϕ',χ,χ' are symmetric matrices, which leads to $\tau=\tilde{\tau}$. Furthermore, since each of the wave-function matrices or their derivatives at R is a power series (or polynomial) of the matrix K, the wave-function matrices commute. It is not difficult to show that in the case of $b=R$, i.e., when the potential function has even parity, $\rho(k)=\tilde{\rho}(k)$.

The threshold behaviour of the transition amplitudes for a potential lacking specific parity can be studied explicitly with this model. Since Levinson's theorem involves the trace of the ampli-

tudes at zero energy, we need to consider the diagonalized forms of the amplitudes only. We diagonalize each of the wave-function matrices of Eq. (4.5) using the same orthogonal matrix U for each, and we denote the diagonal matrices at zero energy as

$$\begin{aligned}\phi_D(0,R) &= \mathrm{diag}(p_1,\ldots,p_N), \phi_D'(0,R) = \mathrm{diag}(\lambda_1,\ldots,\lambda_N),\\ \chi_D(0,R) &= \mathrm{diag}(x_1,\ldots,x_N), \chi_D'(0,R) = \mathrm{diag}(x_1',\ldots,x_N').\end{aligned} \tag{4.6}$$

When there is no half-bound state, we obtain, by inserting these expressions into Eqs. (2.48) and (2.51),

$$\rho(0)=\rho_D(0)=-\mathbf{1} \quad \text{and} \quad \tau(0)=\tau_D(0)=\mathbf{0}. \tag{4.7}$$

When there are n half-bound states and $\det \phi'(0,R)=0$, we write $\phi_D'(0,R) = \mathrm{diag}(0,\ldots,0,\lambda_{n+1},\ldots,\lambda_N)$. Using Eq. (2.13) we find that

$$\phi^{\dagger\prime}(k,x)\chi(k,x)-\phi^{\dagger}(k,x)\chi'(k,x)=-\mathbf{1}. \tag{4.8}$$

In general the matrices ϕ and χ are real and for the constant potential matrix they are symmetric as well. Thus

$$\phi'(0,R)\chi(0,R)-\phi(0,R)\chi'(0,R)=\phi_D\prime(0,R)\chi_D(0,R)-\phi_D(0,R)\chi_D\prime(0,R)=-\mathbf{1}. \tag{4.9}$$

From this relation it follows that $x_i'=1/p_i$ for $i=1,\ldots,n$, and furthermore,

$$\rho_D(0)=\mathrm{diag}\left(\frac{1-p_1^2}{1+p_1^2},\ldots,\frac{1-p_n^2}{1+p_n^2},-1,\ldots,-1\right), \tag{4.10}$$

$$\tilde{\rho}_D(0)=\mathrm{diag}\left(-\frac{1-p_1^2}{1+p_1^2},\ldots,-\frac{1-p_n^2}{1+p_n^2},-1,\ldots,-1\right), \tag{4.11}$$

$$\tau_D(0)=\tilde{\tau}_D(0)=\mathrm{diag}\left(\frac{2p_1}{1+p_1^2},\ldots,\frac{2p_n}{1+p_n^2},0,\ldots,0\right). \tag{4.12}$$

Clearly the relation (2.83) is satisfied by Eqs. (4.10) and (4.11). For the parity-invariant potential obtained by setting $b=R$ in Eq. (4.5) , $\phi(0,R)=\chi'(0,R)$. Hence $p_i=x_i'$ for $i=1,\ldots,N$, and it follows that $p_i^2=1$. Such a potential therefore yields transition amplitudes of the form

$$\rho_D(0)=\tilde{\rho}_D(0)=\mathrm{diag}(0,\ldots,0,-1,\ldots,-1) \quad \text{and} \quad \tau_D(0)=\mathrm{diag}(\pm 1,\ldots,\pm 1,0,\ldots,0). \tag{4.13}$$

When the ith diagonal element of $\phi_D(0,x)$ is an even (odd) function, then the ith diagonal element of $\tau_D(0)$ will have a plus (minus) sign with the one. The converse is not necessarily true.

Consider the special case of $N=1$. For the parity-invariant potential with a half-bound state, one has $\rho(0)=0$ and $\tau(0)=\pm 1$. The plus sign corresponds to $\phi(0,x)$ being an even solution and the negative sign to it being an odd solution. When there is no half-bound state, then $\rho(0)=-1$ and $\tau(0)=0$. In the case of a potential without definite parity, $\rho(0)=\tilde{\rho}(0)=-1$ and $\tau(0)=\tilde{\tau}(0)=0$ when the potential does not support a half-bound state. When there is a half-bound state, $\tau(0)$ and $\tilde{\tau}(0)$ are not equal to zero, nor are the ρ's equal to -1. However, the sum of the ρ's is an integer, i.e., $\rho(0)+\tilde{\rho}(0)=0$. These results, which are clearly valid for the square-well potential, are actually valid for any $N=1$ potential function.

B. Models involving delta-function potentials

We now consider two examples involving delta functions for which results can be obtained in closed form. The results exhibit qualitative features which are also found in much more complicated examples. First we examine the case of a single delta-function matrix potential positioned at the origin. Then we will use the factorization formula derived earlier to look at the case for which there are two delta-function matrices symmetrically positioned on both sides of the origin.

1. Delta function at the origin

We write the Schrödinger equation for this case as

$$\left(-\frac{d^2}{dx^2}+\delta(x)\lambda\right)\psi=k^2\psi, \tag{4.14}$$

where λ is an $N\times N$ symmetric matrix, and ψ can be taken to be either a column vector solution or a solution matrix. The former approach will be used when we consider bound states and the latter when we examine scattering solutions.

First consider the scattering solutions. Since the potential has even parity, we immediately have the result that $\tilde{\rho}=\rho$ and $\tilde{\tau}=\tau$. Thus we need only consider the solution with the incident wave from the left,

$$\psi(k,x)=\begin{cases}\mathbf{1}e^{ikx}+\rho e^{-ikx}, & x\leqslant 0\\ \tau e^{ikx}, & x\geqslant 0.\end{cases} \tag{4.15}$$

Here we see the utility of working directly with a matrix of column eigenvectors (as opposed to working with individual column vectors); ρ and τ may be solved for directly in terms of matrix operations. The scattering amplitudes are

$$\rho(k)=(2ik-\lambda)^{-1}\lambda, \tag{4.16}$$

$$\tau(k)=\mathbf{1}+\rho(k)=2ik(2ik-\lambda)^{-1}. \tag{4.17}$$

Of particular interest to us, due to its connection with the version of Levinson's theorem given in Eq. (2.43), is the quantity $\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)]$. If λ^{-1} exists, then $\rho(0)=-\mathbf{1}$ and $\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)]=2\,\mathrm{Tr}[\rho(0)]=-2N$, as expected. If λ is not invertible, however, we must be a bit more careful.

In order to determine the significance of the noninvertibility of λ, consider the bound-state solutions of Eq. (4.14). Setting $\alpha^2=-k^2$ and insisting that $\alpha\geqslant 0$, we find that the column eigenvector for the bound state is

$$\Psi_b(\alpha,x)=\begin{cases}Ae^{\alpha x}, & x\leqslant 0\\ Ae^{-\alpha x}, & x\geqslant 0,\end{cases} \tag{4.18}$$

where A is a normalized column matrix. By integrating Eq. (4.14) over an infinitesimal interval including the origin, we obtain an expression between the derivatives of $\Psi_b(\alpha,x)$ on both sides of the origin, which leads to the relation

$$(2\alpha+\lambda)A=0. \tag{4.19}$$

In order to avoid the trivial solution, we demand that

$$\det(2\alpha+\lambda)=0. \tag{4.20}$$

The nonnegative values of α which solve the above equation define the bound-state energies. Clearly there is at least one half-bound state if $\det \lambda = 0$.

Returning to the scattering problem, we find that the easiest way to proceed is to first diagonalize the matrix λ. Since λ is real and symmetric, the diagonalization can be accomplished by using an orthogonal matrix U, so that

$$\lambda_D = U \lambda U^{-1}, \tag{4.21}$$

where λ_D is diagonal and $U^{\mathrm{T}} = U^{-1}$. If we now define

$$\psi_D \equiv U \psi U^{-1}, \tag{4.22}$$

we see that Eq. (4.14) may be rewritten as

$$\left(-\frac{d^2}{dx^2} + \delta(x) \lambda_D \right) \psi_D = k^2 \psi_D . \tag{4.23}$$

The orthogonal transformation similarly transforms the boundary conditions, Eq. (4.15), to

$$\psi_D(k,x) = \begin{cases} \mathbf{1} e^{ikx} + \rho_D(k) e^{-ikx}, & x \leqslant 0 \\ \tau_D(k) e^{ikx}, & x \geqslant 0. \end{cases} \tag{4.24}$$

We see here another advantage of working directly with square matrices. If we had been working with column-vector wave functions, the transformed wave functions would have been given by $U\Psi$, so that the normalization of the incoming wave would in general have been changed. Working with $N \times N$ wave-function matrices gives the above result that the form of the boundary conditions is unchanged under the transformation. In fact the transformed wave function is itself a diagonal matrix, and we essentially have N decoupled copies of the problem with no coupling, with (possibly) different potential strengths. [Note that this same trick can be employed any time the potential is of the form $V(x) = v(x) M$, where M is a real symmetric matrix. Diagonalizing M gives N decoupled systems with potentials $V_i(x) = m_i v(x)$, $i = 1,\ldots,N$, where the m_i are the eigenvalues of the matrix M.]

Suppose now that $\det \lambda = 0$. Then it follows that λ has at least one zero eigenvalue. Let us again suppose that there are in fact n zero eigenvalues, so that

$$\lambda_D = \mathrm{diag}(0,\ldots,0,\lambda_{n+1},\ldots,\lambda_N), \tag{4.25}$$

where the λ_i, $i = n+1,\ldots,N$, are the remaining (nonzero) eigenvalues. Then the diagonalized reflection and transmission amplitude matrices are given by

$$\rho_D(k) = \mathrm{diag}\left(0,\ldots,0, \frac{\lambda_{n+1}}{2ik - \lambda_{n+1}}, \ldots, \frac{\lambda_N}{2ik - \lambda_N} \right) \tag{4.26}$$

and

$$\tau_D(k) = \mathrm{diag}\left(1,\ldots,1, \frac{2ik}{2ik - \lambda_{n+1}}, \ldots, \frac{2ik}{2ik - \lambda_N} \right), \tag{4.27}$$

so that

$$\mathrm{Tr}[\rho(0) + \tilde{\rho}(0)] = 2\,\mathrm{Tr}[\rho_D(0)] = -2(N-n). \tag{4.28}$$

Thus we see in this example how the trace of $\rho(0)+\tilde{\rho}(0)$ keeps track of the number of half-bound states in the system. In fact it is easy to verify that Levinson's theorem holds for the coupled system, since it holds separately for each decoupled equation of the diagonalized problem. (The proof follows on noting that the determinant of the S matrix is unchanged under the transformation which diagonalizes ρ and τ.)

It is instructive to consider the relation

$$2ik\tau_D^{-1}(k)=\ \mathrm{diag}(2ik,\ldots,2ik,2ik-\lambda_{n+1},\ldots,2ik-\lambda_N), \tag{4.29}$$

which follows from Eq. (4.27). It demonstrates for this model that in the limit as $k\to 0$ the expression Eq. (2.65) is real, as expected.

2. Potential with two delta functions

We now turn to a slightly more complicated example, in which there are two delta-function matrix potentials, one at $x=a$ and the other at $x=-a$. The $N=1$ version of this model was studied by Senn.[4] The Schrödinger equation for this case is given by

$$\left(-\frac{d^2}{dx^2}+\delta(x+a)\lambda+\delta(x-a)\tilde{\lambda}\right)\psi=k^2\psi, \tag{4.30}$$

with boundary conditions

$$\psi(k,x)=\begin{cases}\mathbf{1}e^{ikx}+\rho(k)e^{-ikx}, & x\leqslant -a\\ \tau(k)e^{ikx}, & x\geqslant a,\end{cases} \tag{4.31}$$

for the wave incident from the left and

$$\tilde{\psi}(k,x)=\begin{cases}\tilde{\tau}(k)e^{-ikx}, & x\leqslant -a\\ \mathbf{1}e^{-ikx}+\tilde{\rho}(k)e^{ikx}, & x\geqslant a,\end{cases} \tag{4.32}$$

for the wave incident from the right. Rather than solve the Schrödinger equation again, we may now simply substitute the results of the previous section into the factorization formula, Eq. (3.5). (Some care must be taken with the reflection amplitude matrices, for they acquire a phase when the potential is translated. The transmission amplitude matrices are, however, unchanged.) An evaluation of the resulting expressions yields

$$\rho(k)=(\lambda e^{-4ika}+(2ik+\lambda)(2ik-\tilde{\lambda})^{-1}\tilde{\lambda})\Gamma^{-1}(k,a;\lambda,\tilde{\lambda})\lambda^{-1}, \tag{4.33}$$

$$\tau(k)=-4k^2e^{-2ika}(2ik-\tilde{\lambda})^{-1}\Gamma^{-1}(k,a;\lambda,\tilde{\lambda})\lambda^{-1}, \tag{4.34}$$

$$\tilde{\rho}(k)=(2ik-\tilde{\lambda})^{-1}\Gamma^{-1}(k,a;\lambda,\tilde{\lambda})((2ik-\lambda)\lambda^{-1}\tilde{\lambda}e^{-4ika}+2ik+\tilde{\lambda}), \tag{4.35}$$

$$\tilde{\tau}(k)=\tau^T(k), \tag{4.36}$$

where

$$\Gamma(k,a;\lambda,\tilde{\lambda})=(2ik-\lambda)\lambda^{-1}e^{-2ika}-(2ik-\tilde{\lambda})^{-1}\tilde{\lambda}e^{2ika}. \tag{4.37}$$

Let us assume for the moment that both λ^{-1} and $\tilde{\lambda}^{-1}$ exist so that the above expressions are well defined. (For $k>0$, it is actually sufficient that only one or the other exists—it is possible to rewrite the expressions so that they contain only $\tilde{\lambda}^{-1}$ and not λ^{-1}.) Performing a Taylor expansion of ρ and $\tilde{\rho}$ for small k, we find that in the typical case $\rho(0)=\tilde{\rho}(0)=-\mathbf{1}$, so that

$\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)]=-2N$, as expected. The atypical case is defined by the condition $\det(\lambda^{-1}+\tilde{\lambda}^{-1}+2a)=0$, which, as we shall see, is also the condition for a half-bound state.

Let us then work out the bound-state condition. This may be done in a manner similar to that for the single delta-function case to obtain

$$\det \Gamma(i\alpha,a;\lambda,\tilde{\lambda})=0. \tag{4.38}$$

Solutions of Eq. (4.38) with $\alpha>0$ correspond to bound states. As $\alpha\to 0$, Eq. (4.38) yields the half-bound-state condition,

$$\det(\lambda^{-1}+\tilde{\lambda}^{-1}+2a)=0. \tag{4.39}$$

Alternatively, if we employ the wave functions ϕ and χ of Sec. II C. for the model potential and use Eq. (2.58) as the condition for the bound state, we obtain the equation

$$\det([(\lambda+2\alpha)(\tilde{\lambda}+2\alpha)-\lambda\tilde{\lambda}e^{-4\alpha a}]/2\alpha)=0, \tag{4.40}$$

which in the limit as α approaches zero reduces to

$$\det(\lambda+\tilde{\lambda}+2a\lambda\tilde{\lambda})=0. \tag{4.41}$$

This equation is preferred over Eq. (4.39) since it is not artificially singular when one of the inverse matrices does not exist.

Let us now consider an explicit example with $N=2$. Since one of the two matrices λ or $\tilde{\lambda}$ may always be diagonalized by an orthogonal transformation, we will let λ be diagonal right from the start. An example which gives a half-bound state for $a=1$ is one for which

$$\lambda=\begin{pmatrix} -\frac{1}{2} & 0 \\ 0 & -1 \end{pmatrix}, \quad \tilde{\lambda}=\begin{pmatrix} -6 & -2 \\ -2 & -1 \end{pmatrix}. \tag{4.42}$$

Figure 1 shows a parametric plot of $\rho_{11}(k)$ as a function of k in the complex plane for the cases $a=0.95$, $a=1.00$, and $a=1.05$. In the two typical cases ($a=0.95,1.05$), $\rho_{11}(0)=-1$, while for the atypical case ($a=1$), $\rho_{11}(0)=0.777\cdots$. This is then the analog of Senn's ''threshold anomaly'' for the generalized matrix version of his model.[4] Examination of the other diagonal reflection amplitudes yields the expected result that $\mathrm{Tr}[\rho(0)+\tilde{\rho}(0)]$ is equal to -4 in the typical case and -2 in the case where one half-bound state exists.

The behaviour of $\rho_{11}(k)$ as a function of k may strike the reader as being somewhat peculiar: for sufficiently large k as k increases, $\rho_{11}(k)$ traces out a never-ending counter-clockwise spiral towards the origin. A plot of the argument of $\rho_{11}(0)$ for the three cases would show that the phase shifts are not bounded—they keep on increasing to infinity. This peculiar feature does not exist when there is no coupling (the phase shifts are bounded due to Levinson's theorem), but is a rather generic feature of $N>1$ models. The important thing to bear in mind when $N>1$ is that the phase shift which obeys Levinson's theorem is defined as being proportional to the logarithm of the determinant of the S matrix. This phase shift can in general be a nontrivial function of the ''physical'' phase shifts associated with the scattering amplitudes.

Figure 2 shows a plot of

$$f(\alpha,a;\lambda,\tilde{\lambda})=\det([(\lambda+2\alpha)(\tilde{\lambda}+2\alpha)-\lambda\tilde{\lambda}e^{-4\alpha a}]/2\alpha), \tag{4.43}$$

as a function of α for $a\approx 1$. The inset in this figure shows an expanded view of the function near the origin for the three cases $a=0.95,1.00$, and 1.05. In addition to the two regular bound states

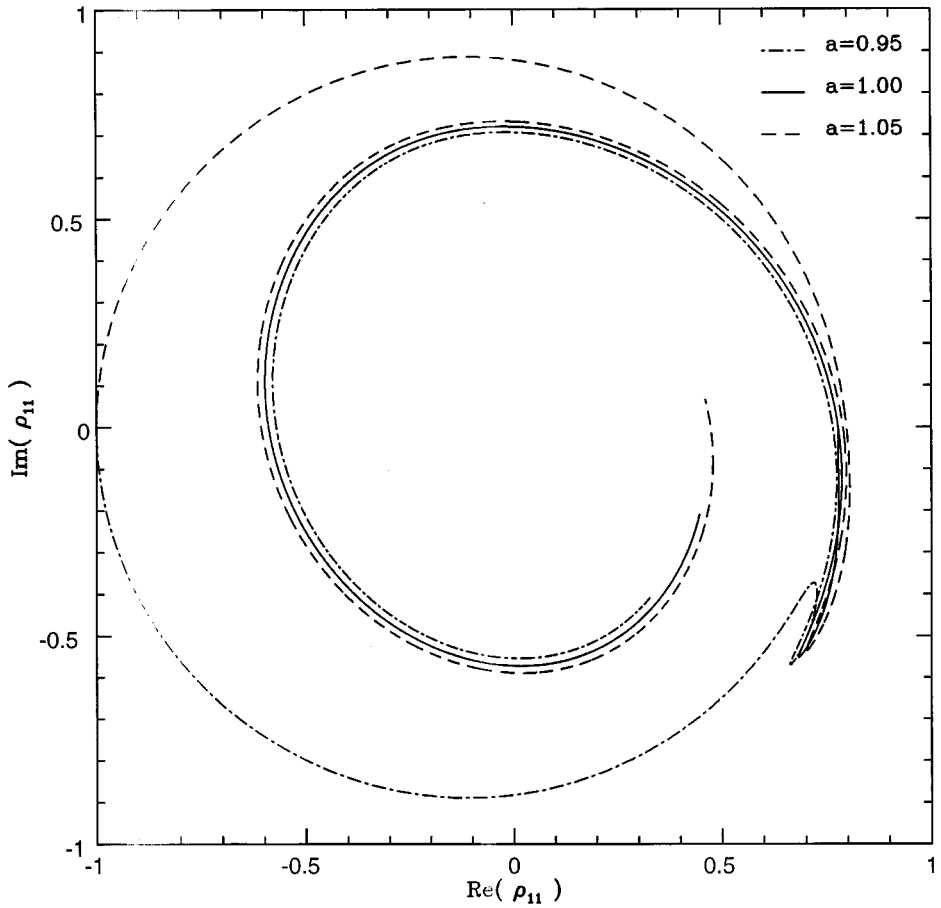

FIG. 1. Plot of the $\mathrm{Im}(\rho_{11}(k))$ vs the $\mathrm{Re}(\rho_{11}(k))$ for $k=0$ to $k=5$ for double delta-function matrix potential. For the $a=1.05$ case the curve reverses the direction of travel around the origin when $k\simeq 1.1$.

that all three cases possess (near $\alpha=0.5164$ and $\alpha=3.3508$), the $a=1.05$ case has an extra bound state near $\alpha=0.0259$, and the $a=1.00$ case has a new bound state just emerging at $\alpha=0$.

Finally, Fig. 3 shows a plot of the ''Levinson's theorem'' phase shift as a function of k for the three cases. Clearly this phase shift is well-behaved and is bounded. As the potential ''strength'' is adjusted so that the system goes through a half-bound state the phase shift at $k=0$ jumps by π in two increments of $\pi/2$.

V. DISCUSSION

In this section we make a few observations. The problem of one-dimensional coupled-equation scattering using a representation of wave functions which have incoming waves from the left or the right is readily solvable. Despite the advantages of a ''partial wave'' representation[7,8] or a parity-eigenstate representation[2,6] for parity-invariant potential functions, our analysis (which is valid for any potential) is quite manageable.

The use of wave function matrices (see Refs. 16 and 28 for three-dimensional scattering and also Refs. 13 and 14 for one-dimensional scattering) rather than column-vector wave functions, leads to simplified notation for a number of relations, e.g., the closure relation, Eq. (2.30). One also finds that performing a unitary transformation on the scattering wave function matrix does not

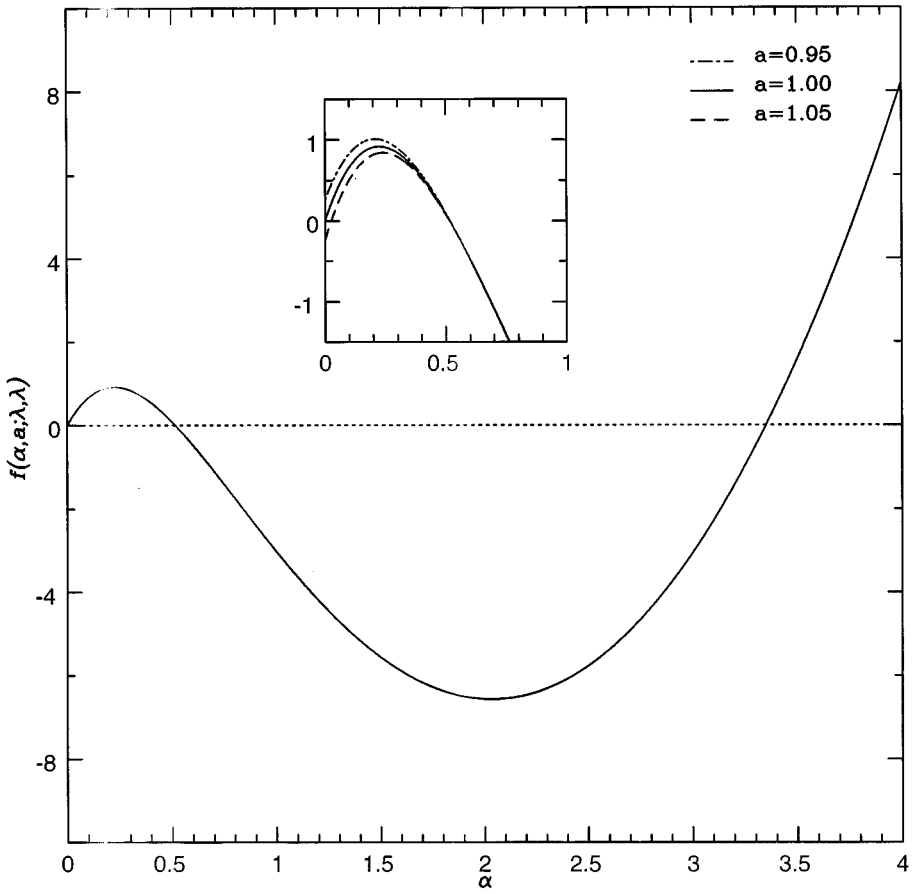

FIG. 2. The determinant function for the double delta-function potential graphed as a function of α.

alter the normalization of the incoming waves, whereas it does for column wave functions. The introduction of the real matrix wave function solutions ϕ and χ has two distinct advantages. In the first place the Schrödinger equation for the scattering problem can be reduced to a system of first-order differential equations with one-point boundary conditions, Eq. (4.2). The scattering amplitudes (and the S matrix) are algebraic expressions of these functions evaluated at R. Furthermore, unlike the solution matrices ψ and $\tilde{\psi}$, matrices ϕ and χ have linearly independent columns at threshold and consequently are convenient for investigating threshold behaviour.

Our starting point with the wave functions ψ and $\tilde{\psi}$, which gives the definition of the reflection amplitudes ρ and $\tilde{\rho}$, yields a generalized and simplified understanding of threshold behaviour. Whereas previous work[4,7] indicates that for parity-noninvariant potentials the reflection amplitude at threshold can have noninteger values, unlike that for parity-invariant potentials, we find that $\mathrm{Tr}[\rho(k)+\tilde{\rho}(k)]$ at threshold is always an integer [see Eq. (2.83)]. The results of de Bianchi,[2] however, already imply such a relation, as well as noninteger reflection amplitudes at threshold, for some parity-noninvariant potentials with no coupling.

Finally, the phases of the reflection and transmission amplitudes of the coupled system are not simple functions of k, as is the case for uncoupled scattering, for which these phases satisfy the appropriate form of Levinson's theorem. The phase η of the S matrix, which appears in Levinson's theorem, is in general a nontrivial function of the phases of the scattering amplitudes.

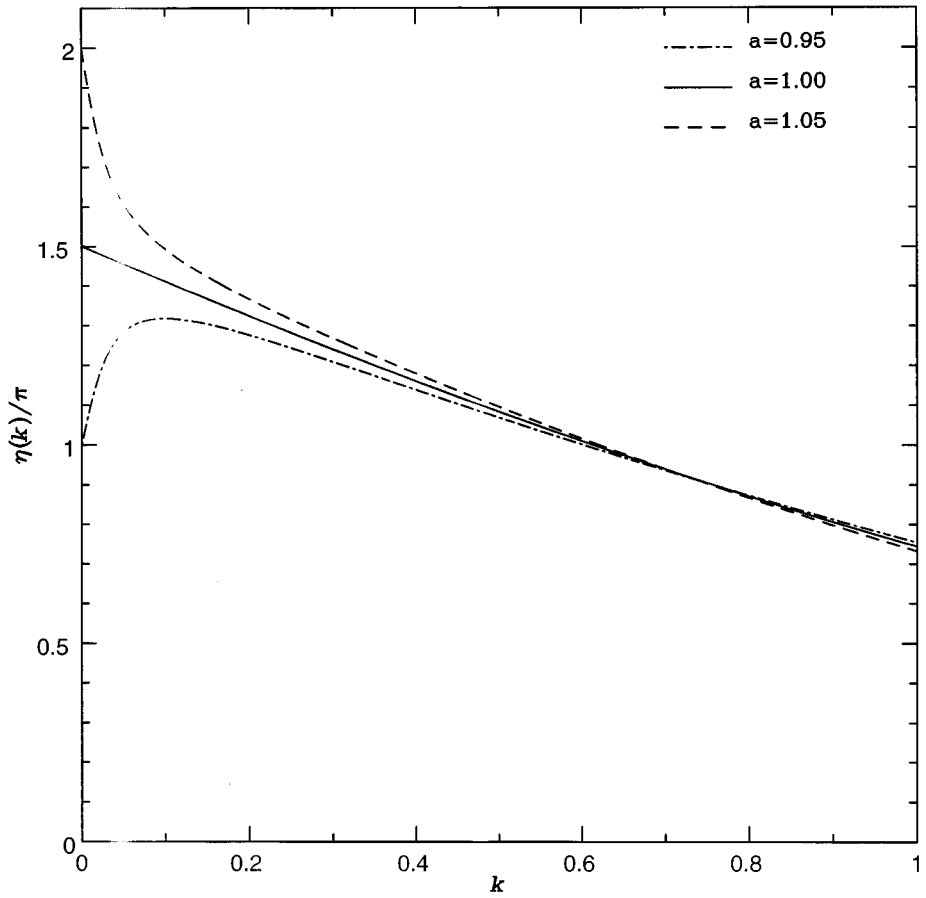

FIG. 3. The phase of the S matrix (divided by π) of the double delta-function potential as a function of k. For k larger than shown on the graph the three curves remain close to one another and approach zero as $k\to\infty$.

Furthermore, the function $\eta(k)$ is bounded, unlike the phases of the scattering amplitudes which are not necessarily bounded.

ACKNOWLEDGMENTS

It is a pleasure to thank Professor Yuki Nogami for helpful discussions. K.A.K. also benefitted from discussions with B. Leduc, J. Oppenheim, and L. Paniak. APPENDIX A: SOME PROPERTIES OF SOLUTIONS OF THE SCHRÖDINGER EQUATION

In this Appendix we determine the condition for linear independence of the solutions of the Schrödinger equation. Consider the matrix Schrödinger equation

$$-\frac{d^2\psi}{dx^2}+V(x)\psi=k^2\psi, \tag{A1}$$

where ψ is the $N\times N$ solution matrix whose columns are solutions to Eq. (2.1). Suppose we have two such solution matrices, f and $\tilde{f}$. We define a $2N\times 2N$ matrix functional

$$W(f,\tilde{f})=\begin{pmatrix} f & \tilde{f} \\ f' & \tilde{f}' \end{pmatrix}, \tag{A2}$$

in which the prime indicates the derivative with respect to x. Since f and $\tilde{f}$ satisfy Eq. (A1) the matrix W is a solution of the matrix equation,

$$W'=FW, \tag{A3}$$

where

$$F=\begin{pmatrix} \mathbf{0} & \mathbf{1} \\ V-k^2 & \mathbf{0} \end{pmatrix}. \tag{A4}$$

Lemma 1: $(\det\ W)'=0$ for all $x\in(-\infty,\infty)$.

Proof: Let us write f and $\tilde{f}$ in terms of their N-component row vectors:

$$f=\begin{pmatrix} f_1 \\ f_2 \\ \vdots \\ f_N \end{pmatrix} \quad \text{and} \quad \tilde{f}=\begin{pmatrix} \tilde{f}_1 \\ \tilde{f}_2 \\ \vdots \\ \tilde{f}_N \end{pmatrix}. \tag{A5}$$

We then obtain (Ref. 27)

$$(\det\ W)'=\det\begin{pmatrix} f_1' & \tilde{f}_1' \\ f_2 & \tilde{f}_2 \\ \vdots & \vdots \\ f_N & \tilde{f}_N \\ f_1' & \tilde{f}_1' \\ f_2' & \tilde{f}_2' \\ \vdots & \vdots \\ f_N' & \tilde{f}_N' \end{pmatrix}+\cdots+\det\begin{pmatrix} f_1 & \tilde{f}_1 \\ f_2 & \tilde{f}_2 \\ \vdots & \vdots \\ f_N' & \tilde{f}_N' \\ f_1' & \tilde{f}_1' \\ f_2' & \tilde{f}_2' \\ \vdots & \vdots \\ f_N' & \tilde{f}_N' \end{pmatrix}+\det\begin{pmatrix} f_1 & \tilde{f}_1 \\ f_2 & \tilde{f}_2 \\ \vdots & \vdots \\ f_N & \tilde{f}_N \\ f_1'' & \tilde{f}_1'' \\ f_2' & \tilde{f}_2' \\ \vdots & \vdots \\ f_N' & \tilde{f}_N' \end{pmatrix}+\cdots+\det\begin{pmatrix} f_1 & \tilde{f}_1 \\ f_2 & \tilde{f}_2 \\ \vdots & \vdots \\ f_N & \tilde{f}_N \\ f_1' & \tilde{f}_1' \\ f_2' & \tilde{f}_2' \\ \vdots & \vdots \\ f_N'' & \tilde{f}_N'' \end{pmatrix}. \tag{A6}$$

The first N determinants in the sum on the right are zero because they have two equivalent rows. In order to show that the remaining terms are also zero, we write the Schrödinger equation, Eq. (A1), as

$$\psi''(x)=M(x)\psi(x), \tag{A7}$$

where $M(x)$ is an $N\times N$ matrix. Furthermore we write $M(x)$ in terms of row vectors

$$M(x)=\begin{pmatrix} m_1(x) \\ m_2(x) \\ \vdots \\ m_N(x) \end{pmatrix}. \tag{A8}$$

Then the matrix in the ith second-derivative term of Eq. (A6) may be written as

$$\begin{pmatrix} f_1 & \tilde{f}_1 \\ \vdots & \vdots \\ f_N & \tilde{f}_N \\ f_1' & \tilde{f}_1' \\ \vdots & \vdots \\ f_i'' & \tilde{f}_i'' \\ \vdots & \vdots \\ f_N' & \tilde{f}_N' \end{pmatrix} = \begin{pmatrix} \mathbf{1} & & & & \mathbf{0} & & \\ & 1 & & & & & \\ & & \ddots & & & & \\ & & & 1 & & & \\ m_i(x) & & & & 0 & & \\ & & & & & 1 & \\ & & & & & & \ddots \\ & & & & & & & 1 \end{pmatrix} (W). \tag{A9}$$

The determinant of the matrix on the right side of Eq. (A9) is zero, and consequently the $(\det W)' = 0$. The $\det W$ is a constant function of x.

Lemma 2: The solutions contained in the columns of f and $\tilde{f}$ are linearly independent if and only if $\det W \neq 0$ for all $x \in (-\infty, \infty)$.

Proof: First suppose that $\det W \neq 0$. We consider a linear combination of solutions which is equal to the trivial solution,

$$f\mathbf{h} + \tilde{f}\tilde{\mathbf{h}} = \mathbf{o} \quad \text{for all } x, \tag{A10}$$

where $\mathbf{h}$ and $\tilde{\mathbf{h}}$ are N-component column vectors of constants and $\mathbf{o}$ is the N-component zero column vector. A similar relation holds for the derivatives of f and $\tilde{f}$, so that

$$W\mathbf{c} = \mathbf{o}, \tag{A11}$$

where

$$\mathbf{c} = \begin{pmatrix} \mathbf{h} \\ \tilde{\mathbf{h}} \end{pmatrix}, \tag{A12}$$

and $\mathbf{c}$ and $\mathbf{o}$ are now $2N$-component column vectors. If $\det W \neq 0$ for some x, which according to the previous result means it is nonzero for all x, $\mathbf{c} = \mathbf{o}$ and the column solutions contained in f and $\tilde{f}$ are linearly independent.

Suppose now that $\det W = 0$. If $\det W = 0$ for some $x = x_0$, then the system of linear equations $W(x_0)\mathbf{c} = \mathbf{o}$ has a nontrivial solution $\mathbf{c}$. We form a column solution of the system of differential equations, Eq. (A3), $\mathbf{w}(x) = W(x)\mathbf{c}$ which vanishes at x_0. This is the trivial solution of Eq. (A3); $\mathbf{w}(\mathrm{x}) = \mathbf{o}$ for all x. It follows that the column solutions contained in f and $\tilde{f}$ are linearly dependent.

APPENDIX B: ANALYTIC PROPERTIES OF THE SOLUTION MATRICES ϕ AND χ

We consider solution matrices $\phi(k,x)$ and $\chi(k,x)$ of Eq. (A1) with boundary conditions $\phi(k,-R) = \chi'(k,-R) = \mathbf{1}$ and $\phi'(k,-R) = \chi(k,-R) = \mathbf{0}$, where R is the range of the potential. According to a theorem of Poincaré an ordinary differential equation containing an entire function of some parameter has solutions which are entire functions of the parameter provided these solutions have boundary conditions which are independent of the parameter. We will show that ϕ and χ are entire functions of k, following a similar derivation for partial-wave solutions in three-dimensional scattering.[28,29]

It is straightforward to verify that the matrix functions ϕ and χ with the given boundary conditions are solutions of integral equations of the Volterra type,

$$\phi(k,x)=\mathbf{1}\cos k(x+R)+\int_{-R}^{x}dx'\,\frac{\sin k(x-x')}{k}V(x')\phi(k,x') \tag{B1}$$

$$\chi(k,x)=\mathbf{1}\frac{\sin k(x+R)}{k}+\int_{-R}^{x}dx'\,\frac{\sin k(x-x')}{k}V(x')\chi(k,x'). \tag{B2}$$

In order to show that each element of the solution matrices is an entire function of k, we rewrite Eq. (B1) in the form

$$\phi(k,x)=\mathbf{1}\cos k(x+R)+\int_{-R}^{x}dx'\int_{0}^{x-x'}dt\,\cos ktV(x')\phi(k,x'). \tag{B3}$$

We solve Eq. (B3) by successive approximations of the form

$$\phi(k,x)=\sum_{s=0}^{\infty}\phi^{(s)}(k,x), \tag{B4}$$

where

$$\phi^{(s)}(k,x)=\int_{-R}^{x}dx'\int_{0}^{x-x'}dt\,\cos ktV(x')\phi^{(s-1)}(k,x'),\quad s\geqslant 1$$

and

$$\phi^{(0)}(k,x)=\mathbf{1}\cos k(x+R). \tag{B5}$$

Thus

$$|\phi_{ij}^{(s)}(k,x)|\leqslant\int_{-R}^{x}dx'\int_{0}^{x-x'}dt|\cos kt|\sum_{l}|V_{il}(x')||\phi_{lj}^{(s-1)}(k,x')|,\quad s\geqslant 1 \tag{B6}$$

and

$$|\phi_{ij}^{(0)}(k,x)|=\delta_{ij}|\cos k(x+R)|. \tag{B7}$$

Denoting $\Im k$ for the imaginary part of k and using the relation $|\cos kt|\leqslant\cosh \Im kt$ for t real, we obtain upon iteration

$$\begin{aligned}|\phi_{ij}^{(s)}(k,x)|&\leqslant\sum_{i'j'}|\phi_{i'j'}^{(s)}(k,x)|\\&\leqslant\left(\frac{\sinh(2\Im kR)}{\Im k}\right)^{s}\cosh(2\Im kR)\int_{-R}^{x}dx_1\int_{-R}^{x_1}dx_2\cdots\int_{-R}^{x_{s-1}}dx_s\\&\quad\times\sum_{i',j',l_1,\ldots,l_s}|V_{i'l_1}(x_1)||V_{l_1l_2}(x_2)|\cdots|V_{l_sj'}(x_s)|.\end{aligned} \tag{B8}$$

Since the integrand is a symmetric function under the interchange of any pair (x_i,x_j),

$$|\phi_{ij}^{(s)}(k,x)| \leqslant \left(\frac{\sinh(2\Im kR)}{\Im k}\right)^s \cosh(2\Im kR)\frac{1}{s!} \times \sum_{i',j',l_1,\ldots,l_s} \int_{-R}^{x} dx_1 |V_{i'l_1}(x_1)| \cdots \int_{-R}^{x} dx_s |V_{l_s j'}(x_s)|. \tag{B9}$$

Let

$$M_0 = \max_{i,j} \int_{-R}^{R} dx' |V_{ij}(x')| < \infty. \tag{B10}$$

Then

$$|\phi_{ij}^{(s)}(k,x)| \leqslant \left(\frac{\sinh(2\Im kR)}{\Im k}\right)^s \cosh(2\Im kR)\frac{N^{s+2}}{s!} M_0^s. \tag{B11}$$

Thus the series $\Sigma_s \phi_{ij}^{(s)}$ converges absolutely and uniformly for $x \in [-R,R]$ and for every region in the complex k plane. To determine the existence of $(\partial\phi/\partial k)(k,x)$, we differentiate Eq. (B3) with respect to k,

$$\frac{\partial \phi}{\partial k}(k,x) = -(x+R)\mathbf{1}\sin k(x+R) - \int_R^x dx' \int_0^{x-x'} dt\, t \sin kt V(x')\phi(k,x') + \int_R^x dx' \int_0^{x-x'} dt \cos kt\, V(x')\frac{\partial \phi}{\partial k}(k,x'). \tag{B12}$$

When Eq. (B4) is differentiated with respect to k it yields

$$\frac{\partial \phi}{\partial k}(k,x) = \sum_{s=0}^{\infty} \frac{\partial \phi^{(s)}}{\partial k}(k,x), \tag{B13}$$

where now we have

$$\frac{\partial \phi^{(s)}}{\partial k}(k,x) = \int_R^x dx' \int_0^{x-x'} dt \cos kt\, V(x')\frac{\partial \phi^{(s-1)}}{\partial k}(k,x') \tag{B14}$$

with

$$\frac{\partial \phi^{(0)}}{\partial k}(k,x) = -(x+R)\mathbf{1}\sin k(x+R) - \int_R^x dx' \int_0^{x-x'} dt\, t \sin kt\, V(x')\phi(k,x'). \tag{B15}$$

It is not difficult to show that

$$\left|\frac{\partial \phi_{ij}^{(0)}}{\partial k}(k,x)\right|$$

is bounded, and the convergence of series (B13) follows in the same manner as that of $\phi(k,x)$. Since $\phi(k,x)$ and its derivative with respect to k exist for all k, $\phi(k,x)$ is an entire function of k. Similarly $\chi(k,x)$ can be shown to be an entire function of k.

For real k the behaviour of $\phi(k,x)$ and $\chi(k,x)$ as k becomes very large can be determined by iterating Eqs. (B1) and (B2). Thus

$$\phi(k,x)\underset{k\to\infty}{\sim}\mathbf{1}\cos k(x+R)+\frac{1}{k}\int_{-R}^{x}dx'\sin k(x-x')V(x')\cos k(x'+R)+O(1/k^2) \tag{B16}$$

and

$$\chi(k,x)\underset{k\to\infty}{\sim}\mathbf{1}\frac{\sin k(x+R)}{k}+\frac{1}{k^2}\int_{-R}^{x}dx'\sin k(x-x')V(x')\sin k(x'+R)+O(1/k^3). \tag{B17}$$

Special-relativistic harmonic oscillator modeled by Klein–Gordon theory in anti-de Sitter space

D. J. Navarro[a] and J. Navarro-Salas[b]
Departamento de Física Teórica and IFIC, Centro Mixto Universidad de Valencia-CSIC, Facultad de Física, Universidad de Valencia, Burjassot-46100, Valencia, Spain

(Received 12 June 1995; accepted for publication 5 August 1996)

It is shown that the one-particle sector of the Klein–Gordon theory in the universal covering space of the anti-de Sitter space (CAdS) can be interpreted, in a natural way, as a special-relativistic oscillator in Minkowski space. The quantum wave functions have a significantly different behavior with respect to the nonrelativistic ones. The energy spectrum coincides, up to the ground state energy, with that of the nonrelativistic oscillator. The requirement of having the adequate nonrelativistic limit for the special-relativistic oscillator theory turns out to be equivalent to the imposition of the Dirichlet-type boundary condition at spatial infinity on CAdS Klein–Gordon functions. © *1996 American Institute of Physics.*

I. INTRODUCTION

The nonrelativistic oscillator is one of the simplest and most useful system in physics. However, despite its simplicity, there is not a well-established relativistic generalization in the literature. The first proposal for a special-relativistic harmonic oscillator was given by Yukawa,[1] followed by the work of Feynman *et al.*[2] and further developed in Ref. 3. These works are all based on the naive covariant generalization $x^\mu x_\mu$ of the nonrelativistic potential thus leading to quantum timelike excitations, the interpretation of which presents some difficulties. On the other hand, Itô *et al.*[4] (see also Refs. 5 and 6) introduced a Dirac equation which is linear in both coordinates and momenta. In the nonrelativistic limit, the equation satisfied by the large components is that of ordinary oscillator with a spin-orbit coupling term.

Recently a new proposal for the special-relativistic harmonic oscillator was outlined in Ref. 7 (see also Ref. 8). It is based in the natural generalization of the symmetry algebra of quantum operators of a relativistic free system (i.e., the Poincaré algebra)

$$[\hat{E},\,\hat{x}]=-i\,\frac{\hbar}{m}\,\hat{p},\quad [\hat{E},\,\hat{p}]=0,\quad [\hat{x},\,\hat{p}]=i\hbar\left(1+\frac{1}{mc^2}\,\hat{E}\right),\tag{1}$$

and that of a nonrelativistic harmonic oscillator (i.e., the Lie algebra of the Newton group)

$$[\hat{E},\,\hat{x}]=-i\,\frac{\hbar}{m}\,\hat{p},\quad [\hat{E},\,\hat{p}]=im\omega^2\hbar\hat{x},\quad [\hat{x},\,\hat{p}]=i\hbar.\tag{2}$$

Here $\hat{E}$, $\hat{p}$, and $\hat{x}$ are the energy (with the rest-mass energy subtracted), momentum, and boost operators in the center of momentum frame. The proposed symmetry for the $(1+1)$ special-relativistic oscillator was defined in terms of the unique Lie algebra which allows it to be contracted to the above algebras

[a]Electronic mail address: dnavarro@lie.uv.es
[b]Electronic mail address: jnavarro@lie.uv.es

0022-2488/96/37(12)/6060/14/$10.00

$$[\hat{E},\,\hat{x}]=-i\,\frac{\hbar}{m}\,\hat{p},\quad [\hat{E},\,\hat{p}]=im\omega^2\hbar\hat{x},\quad [\hat{x},\,\hat{p}]=i\hbar\left(1+\frac{1}{mc^2}\,\hat{E}\right). \tag{3}$$

This Lie algebra corresponds to that of the SO(1,2) group. Related approaches can be seen in Ref. 9.

The aim of this paper is to further elaborate on this proposal. In Sec. II we shall interpret it geometrically showing that a static (1+1) anti-de Sitter metric can be used to simulate a one-dimensional special-relativistic oscillator. More precisely, we shall show that the one-particle sector of the Klein–Gordon field theory on the universal covering space of the anti-de Sitter space (CAdS), with the positive frequencies defined with respect to the global timelike Killing vector, can be interpreted in terms of a special-relativistic oscillator in Minkowski space. The results obtained in this way can be seen as complementary to those found by group theoretical methods[10–12] for the one-dimensional oscillator.[7,13] The main goal of this paper is to extend to three spatial dimensions the proposal (3) for a (1+1) special-relativistic oscillator. This will be done in Sec. III by making use of the geometrical interpretation developed in Sec. II. Obviously, the proper space–time of the special-relativistic oscillator theory is Minkowski space (CAdS is just an auxiliary concept) and this should be taken into account in the interpretation of the corresponding wavefunctions. We will show that a specific boundary condition, usually required as a way to recover a well-defined Cauchy problem[14] in AdS, is now needed to recover the quantum mechanics of the nonrelativistic harmonic oscillator. Moreover, the adequate physical interpretation of the special-relativistic oscillator wave functions involves some sort of Newton–Wigner type transformation of the associated Klein–Gordon functions. In Sec. IV we shall state our conclusions.

II. ANTI-DE SITTER SPACE AND THE ONE-DIMENSIONAL SPECIAL-RELATIVISTIC OSCILLATOR

The basic ingredient in the proposal of Ref. 7 for a special-relativistic oscillator is the SO(1,2) group symmetry. The Lie algebra commutators of this group can be thought of as the natural generalization of those of the relativistic free particle and the nonrelativistic oscillator. Due to anti-de Sitter (AdS) space is a homogeneous space of the SO(1,2) group. It is therefore natural to regard the harmonic oscillator interaction in (1+1) Minkowski space as equivalent to a free system in AdS space (more precisely, in its universal covering space, which has the topology of $\mathbb{R}^2$).[15] However, this definition for a special-relativistic oscillator is incomplete. Owing to general covariance we must specify which particular CAdS metric properly simulates the relativistic oscillator interaction in Minkowski space. To solve this ambiguity we can resort to the nonrelativistic limit. To adjust the nonrelativistic limit we have to choose g_{00} as

$$g_{00}=1+\frac{\omega^2}{c^2}\,x^2. \tag{4}$$

Assuming now a static form for the metric, the requirement of having a CAdS geometry determines the remaining component of the metric:

$$ds^2=\left(1+\frac{\omega^2}{c^2}\,x^2\right)c^2dt^2-\frac{1}{1+(\omega^2/c^2)x^2}\,dx^2. \tag{5}$$

The timelike geodesic trajectories of motion can be obtained from the Lagrangian

$$\mathscr{L}=-mc\,\sqrt{1-\frac{1}{1+(\omega^2/c^2)x^2}\,\frac{v^2}{c^2}+\frac{\omega^2}{c^2}\,x^2}, \tag{6}$$

where m is the (reduced) mass of the system. Moreover, it is easy to see that the timelike geodesics in the metric (5) are periodic and with a period $2\pi/\omega$ independent of the amplitude. The underlying SO(1,2) symmetry is realized by Poisson brackets between the three constants of motion

$$C_{(a)}=mg_{\mu\nu}f^{\mu}_{(a)}\frac{dx^{\nu}}{d\tau}, \tag{7}$$

where $f^{\mu}_{(a)}$, $a=1,2,3$, are the Killing vectors of (5).

$$f^{\mu}_{1}=(1,0), \tag{8}$$

$$f^{\mu}_{2}=\left(\frac{(\omega/c)\,x}{\sqrt{1+(\omega^2/c^2)\,x^2}}\cos\,\omega t,\sqrt{1+\frac{\omega^2}{c^2}\,x^2}\,\sin\,\omega t\right), \tag{9}$$

$$f^{\mu}_{3}=\left(-\frac{(\omega/c)x}{\sqrt{1+(\omega^2/c^2)x^2}}\sin\,\omega t,\sqrt{1+\frac{\omega^2}{c^2}\,x^2}\cos\,\omega t\right). \tag{10}$$

The Killing vectors realize the algebra (3). Here f^{μ}_{1}, f^{μ}_{2}, and f^{μ}_{3} lead to the energy, boost, and momentum generators, respectively. It is also interesting to note that the periodic character of the trajectories of motion of the oscillator can be traced back to the existence of closed timelike lines in AdS space.

From (6) it is straightforward to compute the Hamiltonian of the model

$$H^2=m^2c^4+p^2c^2+m^2\omega^2c^2x^2+2\omega^2x^2p^2+\frac{\omega^4}{c^2}\,x^4p^2. \tag{11}$$

Physically we can think of this Hamiltonian as the one describing the dynamics of a (special-relativistic) harmonic oscillator system in the center of the momentum frame. The AdS symmetry is the responsiblility of the nonlinear terms in (11). We must remark that (11) differs essentially from the naive definition[16]

$$(H-\tfrac{1}{2}m\omega^2x^2)^2=m^2c^4+p^2c^2. \tag{12}$$

In contrast with (12), our model (11) will lead to square-integrable quantum wavefunctions. With the standard substitutions $H\to i\hbar\partial/\partial t$, $p\to -i\hbar\partial/\partial x$, $x\to x$ [we have used the same notation for the ''position'' operator and the ''boost'' operator $\hat{x}$ of (3)] and introducing the parameters α and β to account for the normal ordering ambiguities of the classical function (11):

$$x^4p^2\to -\hbar^2\left(x^4\frac{d^2}{dx^2}+4x^3\frac{d}{dx}+\alpha x^2\right), \tag{13}$$

$$x^2p^2\to -\hbar^2\left(x^2\frac{d^2}{dx^2}+2x\frac{d}{dx}+\beta\right). \tag{14}$$

The quantum counterpart of (11) yields to

$$\left\{ \frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \left(1+\frac{\omega^2}{c^2}x^2\right)^2 \frac{\partial^2}{\partial x^2} - 4\frac{\omega^2}{c^2}x\left(1+\frac{\omega^2}{c^2}x^2\right)\frac{\partial}{\partial x} + \left[\left(\frac{mc}{\hbar}\right)^2 - 2\beta\frac{\omega^2}{c^2}\right]\left(1+\frac{\omega^2}{c^2}x^2\right) - (\alpha-2\beta)\frac{\omega^4}{c^4}x^2\right\}\Psi(x,t)=0. \tag{15}$$

This equation turns out be the Klein–Gordon equation in AdS space[17]

$$\left(\Box + \frac{m^2c^2}{\hbar^2} + \xi R\right)\phi = 0, \tag{16}$$

where $\Box$ is the D'Alembertian operator for the AdS metric (5), $R=-2\omega^2/c^2$ is the scalar curvature, and ξ is a numerical factor. The equivalence is obtained through the transformation

$$\Psi = \frac{1}{\sqrt{1+(\omega^2/c^2)x^2}}\,\phi, \tag{17}$$

and requires a restriction on the parameters α and β: $\alpha=\xi+\frac{1}{2}$ and $\beta=2\xi+2$.

It is worthwhile to remark that the transformation (17) can be understood in terms of the Klein–Gordon scalar product in curved space (see, for instance Ref. 17)

$$\langle \phi_1 | \phi_2 \rangle = i\int_\Sigma d\sigma_\mu \sqrt{g} g^{\mu\nu}(\phi_1 \overleftrightarrow{\partial}_\nu \phi_2^*), \tag{18}$$

where Σ is the initial value hypersurface. For the line element (5) and choosing Σ as $t=0$, (18) becomes

$$\langle \phi_1 | \phi_2 \rangle = -i\int \frac{dx}{1+(\omega^2/c^2)x^2}(\phi_1 \overleftrightarrow{\partial}_0 \phi_2^*). \tag{19}$$

For stationary states the scalar product (19) is proportional to the standard $L^2(\mathbb{R},dx)$ scalar product of Schrödinger-type wavefunctions

$$\langle \Psi_1 | \Psi_2 \rangle = \int dx \Psi_1^* \Psi_2. \tag{20}$$

In general a sort of Newton–Wigner-type transformation is required to convert (19) into (20). From now on we shall be mainly concerned with the Klein–Gordon equation although the physical wavefunctions are the Schrödinger-type wavefunctions verifying the equation (15).

The D'Alembertian operator for the AdS metric (5) is

$$\Box = \frac{1}{1+(\omega^2/c^2)x^2}\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - 2\frac{\omega^2}{c^2}x\frac{\partial}{\partial x} - \left(1+\frac{\omega^2}{c^2}x^2\right)\frac{\partial^2}{\partial x^2}. \tag{21}$$

To solve the Klein–Gordon equation we shall first look for positive frequency states. To find the spatial dependence of the wavefunctions we shall further propose the ansatz

$$\phi(x,t) = e^{-i\lambda\omega t}\left(1+\frac{\omega^2}{c^2}x^2\right)^{-\lambda/2}\phi^\lambda(x), \tag{22}$$

where λ is an arbitrary positive parameter. The wavefunction (22) verifies the Klein–Gordon equation (16) if the function $\phi^\lambda(x)$ satisfies the following differential equation;

$$\left\{\left(1+\frac{\omega^2}{c^2}x^2\right)\frac{d^2}{dx^2}-2\frac{\omega^2}{c^2}(\lambda-1)x\frac{d}{dx}+\frac{\omega^2}{c^2}(\lambda(\lambda-1)-N^2+2\xi)\right\}\phi^{\lambda}(x)=0, \tag{23}$$

where $N=mc^2/\hbar\omega$. In terms of the variable $w=-(\omega^2/c^2)x^2$, (23) is a standard hypergeometric equation

$$\left\{(1-w)w\frac{d^2}{dw^2}+\left(\frac{1}{2}-\left(\frac{3}{2}-\lambda\right)w\right)\frac{d}{dw}-\frac{1}{4}(\lambda(\lambda-1)-N^2+2\xi)\right\}\phi^{\lambda}(w)=0. \tag{24}$$

The vanishing of the Klein–Gordon functions at infinity restricts the allowed values of the λ parameter. We obtain

$$\lambda=\tfrac{1}{2}+n+\gamma, \tag{25}$$

where $n=0,1,2,...$, and

$$\gamma=\pm\tfrac{1}{2}\sqrt{1+4N^2-8\xi}. \tag{26}$$

So mathematically we obtain two distinct set of states according to the positive and negative sign of γ. However, in order to obtain the nonrelativistic limit of the eigenenergies we must choose the positive sign. Therefore the energy spectrum of the (1+1) relativistic oscillator is given by

$$E_n=\left(\frac{1}{2}+n+\frac{1}{2}\sqrt{1+4\frac{m^2c^4}{\hbar^2\omega^2}-8\xi}\right)\hbar\omega. \tag{27}$$

In the limit $c\to\infty$ the spectrum behaves as

$$E_n\to E_n^{NR}+mc^2, \tag{28}$$

where $E_n^{NR}=(\frac{1}{2}+n)\hbar\omega$ are the standard eigenenergies of the (1+1) nonrelativistic oscillator. The equation (27) makes clear the physical meaning of the ξ parameter. It is related with the zero-point energy of the relativistic oscillator. The consistence of theory is related to the unitarity of the representation of the AdS algebra (3) which only requires the positivity of the energy (27) (see later on in this section). Therefore the range of ξ is naturally restricted as $1+4(m^2c^4/\hbar^2\omega^2)-8\xi>0$.

Introducing the variable $z=-i\frac{\omega}{c}x$ and for the discrete values (25), the equation (23) turns out to be the equation of Gegenbauer polynomials[18]

$$\left\{(1-z^2)\frac{d^2}{dz^2}-(1-2(n+\gamma))z\frac{d}{dz}-n(n+2\gamma)\right\}\phi_n^{\lambda}(z)=0. \tag{29}$$

Therefore the Klein–Gordon energy-eigenstates are

$$\phi_n^{\gamma}(x,t)=N_n^{\gamma}e^{-i(E/\hbar)t}\left(1+\frac{\omega^2}{c^2}x^2\right)^{-\lambda/2}C_n^{-(n+\gamma)}\left(-i\frac{\omega}{c}x\right), \tag{30}$$

where N_n^{γ} are appropriate normalization constants

$$(N_n^{\gamma})^{-2}=\sqrt{\pi}\frac{c}{\omega}\frac{4^n}{n!}\frac{(2\gamma)!}{(2\gamma+n)!}\left[\frac{(\gamma+n)!}{(\gamma)!}\right]^2\frac{1}{\gamma+n+\frac{1}{2}}\frac{\Gamma(\gamma+1)}{\Gamma(\gamma+\frac{1}{2})}. \tag{31}$$

Let us now consider the interpretation of the solutions of the wave equations (15) and/or (16). It is well known that the Klein–Gordon wavefunctions—with the scalar product (18)—cannot be interpreted as probability density amplitudes. The definition of ''position'' observable is problem-

atical, even for the free relativistic particle.[19] One has to introduce a new field—representing the same abstract state—with respect to which the scalar product takes the L^2-form (see, for instance, Refs. 20 and 21).

A positive-frequency solution of the Klein–Gordon equation [with the energy spectrum (27)] is given by

$$\phi(x,t)=\sum_{n=0}^{\infty} \frac{1}{\sqrt{2E_n/\hbar}}\,\tilde{c}_n\phi_n^{\gamma}(x)e^{-iE_nt/\hbar}, \tag{32}$$

where $\tilde{c}_n$ are complex numbers. The inner product on these states is

$$\|\phi\|^2=\sum_{n=0}^{\infty}|\tilde{c}_n|^2. \tag{33}$$

Given the state $\{\tilde{c}_n\}\in l^2$, one can define the Newton–Wigner field[20]

$$\phi_{\mathrm{NW}}(x,t)=\sum_{n=0}^{\infty}\tilde{c}_n\phi_n^{\gamma}(x)e^{-iE_nt/\hbar}, \tag{34}$$

with respect to which the scalar product turns out to be

$$\|\phi_{\mathrm{NW}}\|^2=\int_{-\infty}^{+\infty}|\phi_{\mathrm{NW}}(x,t)|^2\rho(x)dx, \tag{35}$$

where $\rho(x)=(1+(\omega^2/c^2)x^2)^{-1}$. Since our special-relativistic oscillator lies in flat Minkowski space, $|\phi_{\mathrm{NW}}|^2$ cannot be properly interpreted as a probability density in position space and a further transformation is required. Defining now the ''Schrödinger''-type wavefunction

$$\Psi(x,t)=\sum_{n=0}^{\infty}\frac{\tilde{c}_n}{\sqrt{1+(\omega^2/c^2)x^2}}\,\phi_n^{\gamma}(x)e^{-iE_nt/\hbar}=\frac{1}{\sqrt{1+(\omega^2/c^2)x^2}}\,\phi_{\mathrm{NW}}(x,t), \tag{36}$$

the inner product takes now the adequate form (20)

$$\|\Psi\|^2=\int_{-\infty}^{+\infty}|\Psi(x,t)|^2dx \tag{37}$$

to properly interpret $|\Psi(x,t)|^2$ as the probability density for observations of x at time t. Therefore, both the Newton–Wigner and Schrödinger-type states are (generalized) eigenfunctions of the position operator $\hat{x}$ ($\hat{x}\phi_{\mathrm{NW}}=x\phi_{\mathrm{NW}}$). In analogy with the analysis of Ref. 19 we can push down this action on the solution space. In our case this leads to a complicated expression in terms of the enveloping algebra of the AdS Lie algebra.

The normalized energy-eigenstates represented by Schrödinger wave functions are

$$\Psi_n^{\gamma}(x,t)=N_n^{\gamma}e^{-i(E/\hbar)t}\left(1+\frac{\omega^2}{c^2}\,x^2\right)^{-(\lambda+1)/2}C_n^{-(n+\gamma)}\left(-i\,\frac{\omega}{c}\,x\right), \tag{38}$$

with the orthonormality relations

$$\langle \Psi_n^\gamma | \Psi_m^\gamma \rangle = N_n^\gamma N_m^\gamma \int_{-\infty}^{\infty} \frac{dx}{1+(\omega^2/c^2)x^2} \left(1+\frac{\omega^2}{c^2}\,x^2\right)^{-(1+2\gamma+n+m)/2}$$
$$\cdot\, C_n^{-(n+\gamma)}\left(-i\,\frac{\omega}{c}\,x\right) C_m^{-(m+\gamma)}\left(-i\,\frac{\omega}{c}\,x\right) = \delta_{nm}\,. \tag{39}$$

We must stress that the Hermite polynomials $H_n(\zeta)$, where $\zeta = \sqrt{m\omega/\hbar}\;x$, are naturally recovered in the nonrelativistic limit

$$\lim_{c\to\infty} \frac{i^n n!}{N^{n/2}}\, C_n^{-(n+\gamma)}\left(-i\,\frac{\zeta}{\sqrt{N}}\right) = H_n(\zeta). \tag{40}$$

We also have

$$\lim_{c\to\infty} \frac{N^n}{(n!)^2}\,(N_n^\gamma)^2 = \sqrt{\frac{m\omega}{\hbar\pi}}\,\frac{1}{n!\,2^n}, \tag{41}$$

where the rhs of (41) has the normalization constants of the Hermite polynomials. Therefore, the lhs of (40), without the limit, can be seen as a relativistic generalization of the Hermite polynomials. In fact, it is not difficult to check that they are proportional to the so-called relativistic Hermite polynomials of Refs. 7, 13, and 22.

We would like to remark at this point that, although the expression (38) allows us to show the proper nonrelativistic limit of the relativistic wave functions, the formula (39) is not the standard orthogonality relation for the Gegenbauer polynomials. However, introducing a new variable $y = [(\omega/c)x]/\sqrt{1+(\omega^2/c^2)x^2} \in [-1,1]$, and using the following relation between Gegenbauer polynomials,

$$C_n^{-(n+\gamma)}\left(-i\,\frac{\omega}{c}\,x\right) = i^n 2^n\,\frac{(2\gamma)!(\gamma+n)!}{(\gamma)!(2\gamma+n)!}\left(1+\frac{\omega^2}{c^2}\,x^2\right)^{n/2} C_n^{\gamma+1/2}\left(\frac{(\omega/c)x}{\sqrt{1+(\omega^2/c^2)x^2}}\right), \tag{42}$$

the expression (39) can be converted into the standard orthogonality relation[18]

$$\langle \Psi_n^\gamma | \Psi_m^\gamma \rangle = N_n^\gamma N_m^\gamma\,\frac{c}{\omega}\,2^{(n+m)}\left(\frac{(2\gamma)!}{(\gamma)!}\right)^2 \frac{(\gamma+n)!(\gamma+m)!}{(2\gamma+n)!(2\gamma+m)!}$$
$$\cdot \int_{-1}^{1} dy\,(1-y^2)^\gamma C_n^{\gamma+1/2}(y) C_m^{\gamma+1/2}(y) = \delta_{nm}\,. \tag{43}$$

This result can be used to characterize immediately the Hilbert $\mathscr{H}$ space of the theory. The completeness theorem (see, for instance Ref. 23) for the orthogonal polynomials of compact support in the space of square-integrable functions implies that the set of wavefunctions Ψ_n^γ provides an orthonormal basis for the Hilbert space $\mathscr{H} \equiv L^2([-1,1],(c/\omega)[1/(1-y^2)^{3/2}]dy) \approx L^2(\mathbb{R},dx)$.

To finish this section we shall consider the construction of the quantum physical operators. One is tempted to propose the Killing vectors

$$\hat{C}_{(a)} = i\hbar f^\mu_{(a)}\,\frac{\partial}{\partial x^\mu}, \tag{44}$$

acting on Newton–Wigner functions ϕ_{NW} (they are solutions of the invariant Klein–Gordon equation), as the quantum operators associated to the classical observables (7). The operators $\hat{C}_{(a)}$ do not leave invariant the measure $d\mu = dx/[1+(\omega^2/c^2)x^2] = \rho(x)dx$ of the scalar product (35)

$$\langle \phi_{1_{\mathrm{NW}}} | \phi_{2_{\mathrm{NW}}} \rangle = \int d\mu \phi^*_{1_{\mathrm{NW}}} \phi_{2_{\mathrm{NW}}}. \tag{45}$$

Therefore, the representation $g \to U(g)$ defined by

$$U(g)\phi_{\mathrm{NW}}(x,t) = \phi_{\mathrm{NW}}(g^{-1}(x,t)), \tag{46}$$

where $g(x,t)$ is the finite group action in the space–time, is not unitary. Nevertheless, the representation defined by

$$U(g)\phi_{\mathrm{NW}}(x,t) = \left(\frac{d\mu_g}{d\mu}\right)^{1/2} \phi_{\mathrm{NW}}(g^{-1}(x,t)), \tag{47}$$

where $d\mu_g/d\mu$ is the Radon–Nikodim derivative of μ_g with respect to μ, is unitary. A straightforward calculation leads to the following expression;

$$U(g)\phi_{\mathrm{NW}}(x,t) = \sqrt{\frac{1+x'^2}{1+x^2}}\, \phi_{\mathrm{NW}}(g^{-1}(x,t)), \tag{48}$$

where $(x',t') \equiv g(x,t)$. This corrects the expression of the operators (44) and then the proper quantum operators acting on $\phi_{\mathrm{NW}}(x,t)$ read as

$$\hat{C}_1 = i\hbar \frac{\partial}{\partial x^0}, \tag{49}$$

$$\begin{aligned}\hat{C}_2 = {} & i\hbar \frac{(\omega/c)x}{\sqrt{1+(\omega^2/c^2)x^2}} \cos \omega t \frac{\partial}{\partial x^0} + i\hbar \sqrt{1+\frac{\omega^2}{c^2}x^2} \sin \omega t \frac{\partial}{\partial x} \\ & + i\hbar \frac{(\omega/c)\, x}{\sqrt{1+(\omega^2/c^2)x^2}} \sin \omega t \frac{\partial}{\partial \phi_{\mathrm{NW}}},\end{aligned} \tag{50}$$

$$\begin{aligned}\hat{C}_3 = {} & i\hbar \frac{-(\omega/c)x}{\sqrt{1+(\omega^2/c^2)x^2}} \sin \omega t \frac{\partial}{\partial x^0} + i\hbar \sqrt{1+\frac{\omega^2}{c^2}x^2} \cos \omega t \frac{\partial}{\partial x} \\ & + i\hbar \frac{(\omega/c)x}{\sqrt{1+(\omega^2/c^2)x^2}} \cos \omega t \frac{\partial}{\partial \phi_{\mathrm{NW}}}.\end{aligned} \tag{51}$$

Finally, the transformation (36) allows us to obtain the action of the quantum operators on the physical (relativistic oscillator) wavefunctions Ψ.

In conclusion, the Schrödinger wavefunctions (38) provide an orthonormal basis of the carrier space for unitary, lowest-weight representations of the symmetry algebra so(1,2). Moreover, the lowest-weight representation of the so(1,2) algebra are characterized by a unique parameter,[24] $E_0/\hbar\omega = \frac{1}{2} + \gamma$ in our case, and, therefore, our Hilbert space construction is unique, up to unitary equivalence, if we assume the existence of a ground state (i.e., a lowest weight state). Finally we want to comment on the issue of the zero-point energy. For the (1+1) relativistic oscillator we

have $E_0/\hbar\omega > \frac{1}{2}$. This means that not all the lowest-weight representations ($E_0/\hbar\omega \in [0, +\infty]$) can be realized physically. The natural barrier $E_0/\hbar\omega = \frac{1}{2}$ corresponds to the so-called Mock representation.[24]

III. THE THREE-DIMENSIONAL SPECIAL-RELATIVISTIC OSCILLATOR

In this section we shall extend our study of the one-dimensional special-relativistic oscillator to the three-dimensional case. To this end we shall first find out the appropriate form of the (1+3) metric. Imposing the nonrelativistic limit and assuming the static form for the metric and the spherical symmetry of the (1+3) AdS space we can write

$$ds^2 = \left(1 + \frac{\omega^2}{c^2} r^2\right) c^2 dt^2 - F(r) dr^2 - G(r)(d\theta^2 + \sin^2 \theta d\varphi^2), \tag{52}$$

where $0 \leqslant \theta \leqslant \pi$ and $0 \leqslant \varphi \leqslant 2\pi$ are the usual spherical coordinates. Moreover, to recover the one-dimensional oscillator when the angular coordinates are frozen we have to choose the function $F(r)$ as follows:

$$F(r) = \frac{1}{1 + (\omega^2/c^2) r^2}. \tag{53}$$

Imposing now the anti-de Sitter geometry we find that the appropriate line element should read as

$$ds^2 = \left(1 + \frac{\omega^2}{c^2} r^2\right) c^2 dt^2 - \frac{dr^2}{1 + (\omega^2/c^2) r^2} - r^2(d\theta^2 + \sin^2 \theta d\varphi^2). \tag{54}$$

The geodesics of (54) can be derived from the Lagrangian

$$\mathscr{L} = -mc \sqrt{1 + \frac{\omega^2}{c^2} r^2 - \frac{v^2}{c^2} + \frac{\omega^2}{c^4} \frac{(\mathbf{x}\cdot\mathbf{v})^2}{1 + (\omega^2/c^2) r^2}}, \tag{55}$$

and, according with our scheme, we can view the above Lagrangian as defining a three-dimensional special-relativistic oscillator in Minkowski space. The SO(3,2) symmetry (i.e., the generalisation of the three-dimensional Poincaré and Newton algebras),

$$[\hat{E}, \hat{x}^i] = -i \frac{\hbar}{m} \hat{p}^i, \quad [\hat{E}, \hat{p}^i] = im\omega^2 \hbar \hat{x}^i, \quad [\hat{x}^i, \hat{p}^j] = i\hbar \left(1 + \frac{1}{mc^2} \hat{E}\right) \delta^{ij} \tag{56}$$

(we have omitted the rotation generators), can be realized now by the Killing vectors of (54).

The next step now is to compute the Hamiltonian. We obtain

$$H^2 = \left(1 + \frac{\omega^2}{c^2} r^2\right) (m^2 c^4 + p^2 c^2 + \omega^2 (\mathbf{x}\cdot\mathbf{p})^2). \tag{57}$$

As in the one-dimensional oscillator it is not difficult to test that the wave equation associated with the Hamiltonian (57) can be transformed, with a particular normal-ordering prescription, into a Klein–Gordon equation. Introducing the parameters α, β, η, and ϱ for the operator ordering ambiguities of the classical function (57),

$$x_i^4 p_i^2 \to -\hbar^2 \left(x_i^4 \frac{\partial^2}{\partial x_i^2} + 4x_i^3 \frac{\partial}{\partial x_i} + \alpha x_i^2\right), \tag{58}$$

$$x_i^2 p_i^2 \to -\hbar^2 \left(x_i^2 \frac{\partial^2}{\partial x_i^2} + 2x_i \frac{\partial}{\partial x_i} + B \right), \tag{59}$$

$$x_i^3 p_i \to -i\hbar \left(x_i^3 \frac{\partial}{\partial x_i} + \eta x_i^2 \right), \tag{60}$$

$$x_i p_i \to -i\hbar \left(x_i \frac{\partial}{\partial x_i} + \varrho \right), \tag{61}$$

the Schrödinger equation leads to the Klein–Gordon equation in AdS space with metric (54) ($R=-12\omega^2/c^2$). The Schrödinger and Newton–Wigner-type wavefunctions are related by

$$\Psi = \frac{1}{\sqrt{1+(\omega^2/c^2)r^2}}\, \phi_{\mathrm{NW}}. \tag{62}$$

The normal ordering parameters are then fixed as

$$\alpha = \frac{11}{2} + 8\xi, \quad \beta = \frac{1}{2} + 2\xi, \quad \eta = \frac{3}{2}, \quad \varrho = \frac{1}{2}. \tag{63}$$

So, there is only one free parameter left, which is essentially the curvature factor ξ.

Now we want to solve the corresponding Klein–Gordon equation. The D'Alembertian operator is given by

$$\Box = \frac{1}{1+(\omega^2/c^2)r^2} \frac{1}{c^2} \frac{\partial^2}{\partial t^2} - 2\frac{\omega^2}{c^2} r \frac{\partial}{\partial r} - \left(1 + \frac{\omega^2}{c^2} r^2 \right) \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) + \frac{\mathbf{L}^2}{r^2}, \tag{64}$$

where $\mathbf{L}^2$ is the orbital angular momentum operator

$$\mathbf{L}^2 = -\frac{1}{\sin\theta} \frac{\partial}{\partial\theta} \left(\sin\theta \frac{\partial}{\partial\theta} \right) - \frac{1}{\sin^2\theta} \frac{\partial^2}{\partial\varphi^2}. \tag{65}$$

Separation of variables and an ansatz analogous to that of (22) leads to the following set of positive frequency modes:

$$\phi(\mathbf{x},t) = e^{-i\lambda\omega t} Y_m^l(\theta,\varphi) \left(1 + \frac{\omega^2}{c^2} r^2 \right)^{-\lambda/2} r^l \phi_l^\lambda(r), \tag{66}$$

where $Y_m^l(\theta,\varphi)$ are the spherical harmonics and the functions $\phi_l^\lambda(r)$ are required to verify the equation

$$\left\{ \left(1 + \frac{\omega^2}{c^2} r^2 \right) \frac{d^2}{dr^2} - 2\frac{\omega^2}{c^2} r(\lambda - l - 2) \frac{d}{dr} + 2\frac{l+1}{r} \frac{d}{dr} + \frac{\omega^2}{c^2} \left(\lambda(\lambda - 2l - 3) + l(l+3) - N^2 + 12\xi \right) \right\} \phi_l^\lambda(r) = 0. \tag{67}$$

In terms of the variable $\rho = -(\omega^2/c^2)r^2$, the above equation turns out to be a hypergeometric differential equation

$$\left\{(1-\rho)\rho\,\frac{d^2}{d\rho^2}+\left(l+\frac{3}{2}-\left(l+\frac{5}{2}-\lambda\right)\rho\right)\frac{d}{d\rho}-\frac{1}{4}\,(\lambda(\lambda-2l-3)+l(l+3)-N^2+12\xi)\right\}\phi_l^{\lambda}(\rho)=0. \tag{68}$$

The ordinary regularity condition at the origin and the square integrability of the functions yield to the following energy spectrum ($\lambda=E/\hbar\omega$):

$$E_n=\left(\frac{3}{2}+2n+l+\frac{1}{2}\,\sqrt{9+4\,\frac{m^2c^4}{\hbar^2\omega^2}-48\xi}\right)\hbar\omega, \tag{69}$$

where $n,l=0,1,2,3,\ldots$. We have chosen the positive sign of the square root of (69) ($\gamma = +\frac{1}{2}\times\sqrt{9+4N^2-48\xi}$) to fit the nonrelativistic approximation

$$E_n \xrightarrow{c\to\infty} E_n^{NR}+mc^2, \tag{70}$$

where $E_n^{NR}=(\frac{3}{2}+2n+l)\hbar\omega$ is the ordinary energy spectrum of three-dimensional nonrelativistic oscillator. The range of ξ is now restricted as $9+4N^2-48\xi>0$.

We must mention at this point that the choice of the positive sign of the square root of (69) parallels the Dirichlet-type boundary conditions imposed on the solution of the Klein–Gordon equation on the Einstein static universe in $1+3$ dimensions associated with AdS space[14] (see also Ref. 25 for the $1+2$ case). The negative sign corresponds to the Newmann boundary condition. Both boundary conditions allow us to solve the problem of the lack of global hyperbolicity in the standard AdS theory. However, in our relativistic oscillator interpretation the Dirichlet-type boundary condition emerges as the natural one to properly recover the quantum nonrelativistic oscillator.

For the values (69) the regular hypergeometric functions solving (68) are

$$\phi_{nl}^{\lambda(r)}={}_2F_1\left(-n,n+l+\frac{3}{2}-\lambda,l+\frac{3}{2};-\frac{\omega^2}{c^2}\,r^2\right). \tag{71}$$

Rewriting the dimensionless parameter $(\omega^2/c^2)r^2$ as $(m\omega/\hbar N)r^2$, it is easy to check that, in the limit $c\to\infty$, the functions (71) become the confluent hypergeometric ones appearing in the nonrelativistic wavefunctions

$$\lim_{c\to\infty}{}_2F_1\left(-n,n+l+\frac{3}{2}-\lambda,l+\frac{3}{2};-\frac{m\omega}{\hbar}\,\frac{r^2}{N}\right)={}_1F_1\left(-n,l+\frac{3}{2};\,\frac{m\omega}{\hbar}\,r^2\right). \tag{72}$$

Taking into account the relation of Jacobi polynomials with the hypergeometric functions[18]

$${}_2F_1(-n,n+\alpha+\beta+1,\alpha+1;z)=\frac{n!}{(\alpha+1)_n}\,P_n^{(\alpha,\beta)}(1-2z), \tag{73}$$

we obtain the following set of wavefunctions

$$\Psi_{nlm}^{\gamma}(\mathbf{x},t)=C_{nl}^{\gamma}e^{-t(E/\hbar)t}Y_m^l(\theta,\varphi)\left(1+\frac{\omega^2}{c^2}\,r^2\right)^{-(\lambda+1)/2}r^lP_n^{[l+1/2,-\lambda]}\left(1+2\,\frac{\omega^2}{c^2}\,r^2\right). \tag{74}$$

where C_{nl}^{γ} are appropriate normalization constants

$$(C_{nl}^{\gamma})^{-2}=\frac{1}{2(\omega/c)^{2l+3}(2l+3)}\,\frac{\Gamma(\gamma+n+1)\Gamma(n+l+\frac{3}{2})}{n!\Gamma(2n+l+\frac{3}{2}+\gamma)\;\Gamma(n+l+\frac{3}{2}+\gamma)}, \tag{75}$$

with respect to the scalar product

$$\langle \Psi^{\gamma}_{nls} | \Psi^{\gamma}_{ml's'} \rangle = C^{\gamma}_{nl} C^{\gamma}_{ml'} \int_{-1}^{1} \int_{0}^{2\pi} \int_{0}^{\infty} d(\cos\,\theta) d\varphi \, \frac{r^2 dr}{1+(\omega^2/c^2) r^2}$$
$$\cdot \left(1+\frac{\omega^2}{c^2}\, r^2 \right)^{-(3+2\gamma+n+(m)+2l+2l')/2} r^{(l+l')} Y^{l}_{s}(\theta,\varphi) Y^{l'}_{s'}(\theta,\varphi)$$
$$\cdot P^{[l+1/2,-\lambda]}_{n}\left(1+2\frac{\omega^2}{c^2} r^2 \right) P^{[l'+1/2,-\lambda]}_{m}\left(1+2\,\frac{\omega^2}{c^2}\, r^2 \right). \tag{76}$$

Observe that the polynomials $P^{[l+1/2,-\lambda]}_{n}$ have the appropriate $c\to\infty$ limit

$$\lim_{c\to\infty} P^{[l+1/2,-\lambda]}_{n}\left(1+2\,\frac{m\omega}{\hbar}\,\frac{r^2}{N} \right) = L^{(l+1/2)}_{n}\left(\frac{m\omega}{\hbar}\, r^2 \right), \tag{77}$$

where $L^{(l+1/2)}_{n}$ are the generalized Laguerre polynomials. To illustrate our special-relativistic generalization of them we give the first few polynomials

$$P^{[l+1/2,-(l+3/2+\gamma)]}_{0}\left(1+2\,\frac{\zeta^2}{N} \right) = 1, \tag{78}$$

$$P^{[l+1/2,-(l+5/2+\gamma)]}_{1}\left(1+2\,\frac{\zeta^2}{N} \right) = \left(l+\frac{3}{2} \right) - 2\,\frac{\gamma}{N}\,\zeta^2, \tag{79}$$

$$P^{[l+1/2,-(l+7/2+\gamma)]}_{2}\left(1+2\,\frac{\zeta^2}{N} \right) = \frac{1}{2}\left(l+\frac{3}{2} \right)\left(l+\frac{5}{2} \right) - \frac{1}{2}\,\frac{\gamma(l+\frac{5}{2})}{N}\,\zeta^2 + \frac{1}{8}\,\frac{\gamma(\gamma+1)}{N^2}\,\zeta^4. \tag{80}$$

Although the relation (73) leads to a set of polynomials with the appropriate nonrelativistic limit, the scalar product (76) is not the standard orthogonality relation of the Jacobi polynomials. However, introducing an alternative relation between the hypergeometric functions and the Jacobi polynomials

$${}_2F_1\left(-n,-n-\alpha,\beta+1;\,\frac{x+1}{x-1} \right) = \frac{n!}{(\beta+1)n}\left(\frac{2}{x-1} \right)^{n} P^{(\alpha,\beta)}_{n}(x), \tag{81}$$

we can rewrite the wavefunctions as

$$\Psi^{\gamma}_{nlm}(\mathbf{x},t) = C^{\gamma}_{nl} e^{-i(E/\hbar)t} Y^{l}_{m}(\theta,\varphi) \cdot \left(1+\frac{\omega^2}{c^2}\, r^2 \right)^{-(\lambda+1)/2+n} r^{l} P^{[\gamma,l+1/2]}_{n}\left(\frac{-1+(\omega^2/c^2) r^2}{1+(\omega^2/c^2) r^2} \right). \tag{82}$$

In terms of the new variable $x=[-1+(\omega^2/c^2)r^2]/[1+(\omega^2/c^2)r^2]\in[-1,1]$, the scalar product (76) turns out to be

$$\langle \Psi^{\gamma}_{nls} | \Psi^{\gamma}_{ml's'} \rangle = C^{\gamma}_{nl} C^{\gamma}_{ml'} 2^{-(\gamma+l+5/2)} \left(\frac{\omega}{c} \right)^{-(2l+3)} \delta_{ll'}\,\delta_{ss'}$$
$$\cdot \int_{-1}^{1} dx (1-x)^{\gamma} (1+x)^{l+1/2} P^{[\gamma,l+1/2]}_{n}(x) P^{[\gamma,l+1/2]}_{m}(x). \tag{83}$$

As in the (1+1) case, we observe again that the inner product (83) reproduces the standard orthogonality relation for Jacobi polynomials. The completeness theorem for orthogonal polynomials implies that states Ψ^{γ}_{nlm} constitutes an orthonormal basis for the Hilbert space $L^2(\mathbb{R}^3, r^2 dr d\varphi d(\cos\theta))$. Finally we would like to remark that the irreducible representations of the (1+3) AdS algebra are determined up to equivalence by two parameters:[26] the lowest eigenvalue of the Hamiltonian and the spin of the particle. Since we are dealing with a spinless particle our construction is uniquely characterized by the ground state energy.

IV. CONCLUSIONS AND FINAL COMMENTS

In this paper we have provided a physical interpretation of the one-particle sector of the Klein–Gordon theory in terms of a special-relativistic oscillator in Minkowski space. The system is exactly solvable and leads to radial energy eigenfunctions composed of a weight-function

$$\left(1+\frac{\omega^2}{c^2}\,r^2\right)^{-(3/2+2n+1+(1/2)\sqrt{9+4(m^2c^4/\hbar^2\omega^2)-48\xi}+1)/2}, \tag{84}$$

reducing to the Gaussian one $e^{-(1/2)(m\omega/\hbar)r^2}$ in the limit $c\to\infty$, and a polynomial

$$r^l P_n^{[l+1/2,-\lambda]}\left(1+2\,\frac{\omega^2}{c^2}\,r^2\right), \tag{85}$$

going to its nonrelativistic counterpart.

We observe from the expression (84) that the probability density for the relativistic oscillator is less confined in the classical region than the corresponding one of the nonrelativistic oscillator. It penetrates more appreciably in the classically forbidden region. This can be understood in terms of the behavior of the null geodesics in AdS. They go to infinity in a finite lapse of the coordinate time t used in the metrics (5) and (54). So, that, in the limit $N=0$, the geodesics are not confined in a finite region of space and this fact is partially reflected by the asymptotic behavior of the wave functions. Despite this, the spacing of the energy levels is identical to the nonrelativistic one. However, for the ground state energy we have

$$E_0=\hbar\omega\left(\tfrac{3}{2}+\tfrac{1}{2}\sqrt{9+4N^2-48\xi}\right), \tag{86}$$

representing some sort of mixing between the nonrelativistic zero-point energy $\frac{3}{2}\hbar\omega$ and the relativistic rest mass energy. The mixing is just parametrized by the curvature factor ξ.

It is remarkable that the lack of global hyperbolicity of AdS space is physically incorporated by choosing those solutions with the adequate nonrelativistic limit. This way of truncating the space of solutions, which is natural in our special-relativistic oscillator theory, turns out to be equivalent to the imposition of the Dirichlet-type boundary condition at infinity.

Another point which merits some comment is the question of how to extend our approach to spinning particles. When dealing with spin $\frac{1}{2}$ particles one could construct the corresponding wave equation by means of Dirac equation in the AdS background, i.e.,

$$(i\gamma^{\mu}(\partial_{\mu}-\Gamma_{\mu})-mc/\hbar)\Psi=0, \tag{87}$$

where $\gamma^{\mu}=e^{\mu}_{\alpha}\gamma^{\alpha}$ are the Dirac matrices in AdS space (e^{μ}_{α} are the vierbeins) and Γ_{μ} is the spin connection. Using the identity

$$R_{\mu\nu\sigma\rho}\gamma^{\mu}\gamma^{\nu}\gamma^{\sigma}\gamma^{\rho}=-2R, \tag{88}$$

where $R_{\mu\nu\sigma\rho}$ is the Riemann curvature tensor, it is not difficult to see that the Dirac equation (87) implies a Klein–Gordon equation with $\xi=\frac{1}{4}$:

$$\left(\Box+\left(\frac{mc}{\hbar}\right)^2+\frac{1}{4}R\right)\Psi=0. \tag{89}$$

The term $\frac{1}{4}R$ plays the role of the standard spin-dependent term $(q/2)F_{\mu\nu}\sigma^{\mu\nu}$ which appears when coupling the Dirac field with an electromagnetic potential. Note that this term is now diagonal in the spin components and then the energy spectrum should be similar to that of the spinless oscillator.

Prepotential of $N=2$ SU(2) Yang–Mills gauge theory coupled with a massive matter multiplet

Yűji Ohta
Department of Mathematics, Faculty of Science, Hiroshima University, Higashi-Hiroshima 739, Japan

(Received 4 April 1996; accepted for publication 22 May 1996)

We discuss the $N=2$ SU(2) Yang–Mills theory coupled with a massive matter in the weak coupling. In particular, we obtain the instanton expansion of its prepotential. Instanton contributions in the mass-less limit are completely reproduced. We study also the double scaling limit of this massive theory and find that the prepotential with instanton corrections in the double scaling limit coincides with that of $N=2$ SU(2) Yang–Mills theory without matter. © *1996 American Institute of Physics.* [S0022-2488(96)04511-2]

I. INTRODUCTION

As is well-known, low energy properties of $N=2$ supersymmetric Yang–Mills gauge theory are dominated by a holomorphic function (prepotential) and were recently studied by Seiberg and Witten.[1,2] In particular, they showed that the quantum moduli space was described by a kind of special geometry[3] and identified the quantum moduli space of $N=2$ SU(2) Yang–Mills theory without matter with the moduli space of a certain elliptic curve. Though they did not explicitly calculate the prepotential with instanton corrections, they qualitatively discussed the monopole and dyon masses, the metric on the quantum moduli space and a version of Olive–Montonen electric-magnetic duality and found that the strongly coupled vacuum turned out to be a weakly coupled theory of monopoles.

After the discovery of Seiberg and Witten,[1,2] generalizations for other gauge group theories coupled with or without several matters[4–9] have been discussed. The instanton expansion of the prepotential for pure SU(2) and SU(3) theories[6] and SU(2) theory with mass-less matters[10] have been found, but prepotentials of the massive SU(2) thories have not been established quantitatively so far. For this reason, we can not say that the non-perturbative aspects of quantum moduli space have been understood in detail even for the case of $N=2$ SU(2) Yang–Mills theory when massive N_f matters[11] are introduced. In fact, instanton calculations for massive theory do not seem to be discussed in the literature. Thus we will study the quantum moduli spaces of $N=2$ SU(2) Yang–Mills gauge theories coupled with massive matters in this and subsequent papers.[12] In particular, we will study the quantum moduli space of $N=2$ SU(2) Yang–Mills theory coupled with a massive matter at weak coupling in this paper.

The paper organizes as follows. In the next section, we derive the Picard–Fuchs equation for massive $N_f=1$ $N=2$ SU(2) Yang–Mills theory and discuss the property of its solutions. It is noteworthy that the order of the differential equation is three in contrast with that of the mass-less theory whose order of the Picard–Fuchs equation is two. We also obtain the monodromy matrix near the weak coupling limit. In Sec. III, we derive the prepotential and its instanton expansion. The result coincides with the previous result[10] if the matter is mass-less. Considerations on double scaling limit of the $N_f=1$ massive theory are done in Sec. IV. We will see that we can reproduce the instanton expansion of the $N_f=0$ theory. Section V is a summary.

II. THE PICARD–FUCHS EQUATION

Quantum moduli space of $N_f=1$, $N=2$ SU(2) Yang–Mills theory can be described by a kind of hyperelliptic curve

0022-2488/96/37(12)/6074/12/$10.00

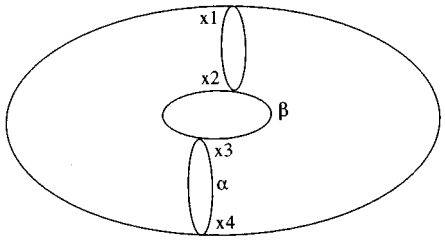

FIG. 1. The hyperelliptic curve as a genus 1 Riemann surface.

$$y^2=(x^2-u)^2-\Lambda_1^3(x+m), \tag{2.1}$$

and the meromorphic 1-form[13] which is given by

$$\lambda_1=\frac{\sqrt{2}xdx}{4\pi iy}\left[\frac{x^2-u}{2(x+m)}-2x\right], \tag{2.2}$$

where $x, y\in\mathbf{C}$, u is the gauge invariant parameter, Λ_1 is the dynamical mass scale of this theory and m is the bare mass of the hypermultiplet.[9] Formulation by an elliptic curve can also be found.[2]

This curve has four branching points. In particular, near the weak coupling limit ($u=\infty$), they will be

$$\begin{aligned}
x_1&=-\sqrt{u}-\frac{i\Lambda_1^{3/2}}{2u^{1/4}}+\frac{i\Lambda_1^{3/2}m}{4u^{3/4}}+\ldots,\\
x_2&=-\sqrt{u}+\frac{i\Lambda_1^{3/2}}{2u^{1/4}}-\frac{i\Lambda_1^{3/2}m}{4u^{3/4}}+\ldots,\\
x_3&=\sqrt{u}-\frac{\Lambda_1^{3/2}}{2u^{1/4}}-\frac{\Lambda_1^{3/2}m}{4u^{3/4}}+\ldots,\\
x_4&=\sqrt{u}+\frac{\Lambda_1^{3/2}}{2u^{1/4}}+\frac{\Lambda_1^{3/2}m}{4u^{3/4}}+\ldots\ .
\end{aligned} \tag{2.3}$$

Since we can take the cuts to run from x_1 to x_2 and x_3 to x_4, we may identify this curve as a genus one Riemann surface, as shown in Fig. 1. We then identify α-cycle as a loop going around the cut from x_4 to x_3 counterclockwise and β-cycle from x_3 to x_2. As is obvious from the figure, the intersection of these cycles is $\alpha\cap\beta=1$.

Now we can define periods $a(u), a_D(u)$ of λ_1 by

$$a(u)=\oint_\alpha \lambda_1, \tag{2.4}$$

$$a_D(u)=\oint_\beta \lambda_1. \tag{2.5}$$

$a(u)$ is identified with the scalar component of the $N=1$ chiral multiplet and $a_D(u)$ is its dual. We are interested in their evaluation, but it is not so easy to accomplish it exactly. So we take a method of the Picard–Fuchs equation. It is given by

$$\frac{d^3\Pi_1}{du^3}+\frac{3\Delta_1(m)+\Delta_1'(m)(4m^2-3u)}{\Delta_1(m)(4m^2-3u)}\frac{d^2\Pi_1}{du^2} - \frac{8[4(2m^2-3u)(4m^2-3u)+3(3\Lambda_1^3m-4u^2)]}{\Delta_1(m)(4m^2-3u)}\frac{d\Pi_1}{du}=0, \tag{2.6}$$

where

$$\Delta_1(m)=27\Lambda_1^6+256\Lambda_1^3m^3-288\Lambda_1^3mu-256m^2u^2+256u^3, \tag{2.7}$$

and $\Pi_1=\int_\gamma \lambda_1$, γ is a suitable 1-cycle and $\Delta_1' = d\Delta_1/du$. Note that $\Delta_1(m)$ is the discriminant of the curve (2.1). It is easy to find that (2.6) has no symmetry over the u-plane and the mass plays a role to break the symmetry. Equation (2.6) has obviously regular singular points which are solutions to $\Delta_1(m)=0$ and $4m^2-3u=0$. These singular points correspond to mass-less states. Since we are going to treat only weak coupling limit in this paper, we do not discuss the behaviour of the moduli space near these singular points, but they should be discussed elsewhere. We have checked that (2.6) can also be obtained as a result of the double scaling limit of the Picard–Fuchs equation of the massive $N_f=2$ theory.[12]

In the case of mass-less limit ($m\to 0$), this third order differential equation reduces to the second one,

$$\frac{d^3\Pi_1}{du^3}-\frac{\Delta_1(0)-\Delta_1'(0)u}{\Delta_1(0)u}\frac{d^2\Pi_1}{du^2}+\frac{64u}{\Delta_1(0)}\frac{d\Pi_1}{du}=0, \tag{2.8}$$

i.e.,

$$(27\Lambda_1^6+256u^3)\frac{d^2\Pi_1}{du^2}+64u\Pi_1=0, \tag{2.9}$$

where we set the integration constant as 0 because it can be shown directly. This equation has already been obtained and solved.[10]

The mechanism of this reduction is explained as follows. When the matter is massive, λ_1 will acquire an extra simple pole corresponding to $x=-m$ in contrast with the mass-less case. At first sight, even if $m=0$, λ_1 seems to have a pole at $x=0$, but the locus of the pole can be canceled out between denominator and numerator of λ_1. Accordingly, in general, the number of poles of massive meromorphic 1-form is equal to that of the mass-less meromorphic 1-form plus 1. Since the differentiation reduces the order[14] by 1, the reduction will require one step more when λ_1 is massive. Therefore the order of the differential equation which the periods of λ_1 should satisfy will increase one more than that of mass-less λ_1, i.e., the order will be three and this observation is consistent with (2.6) and (2.9).

In order to get the solutions to (2.6) near $u=\infty$, we take $z=1/u$. After this change of variable, we use Frobenius's method. Then we find that its indicial equation has three roots, i.e., 0, $-1/2$, $-1/2$ (double roots). The solution $\rho_0(z)$ corresponding to the index 0 is in fact trivial, i.e., it is a constant,

$$\rho_0(z)=\epsilon. \tag{2.10}$$

However, this constant ϵ may depend on Λ_1 or m and will be determined below. Geometrically, ϵ corresponds to the residue contribution of the pole of the meromorphic 1-form. Of course, ϵ must

vanish in the mass-less limit because the mass-less theory does not have such a pole. Thus ϵ is a function of the mass. On the other hand, there are two independent solutions corresponding to the index $-1/2$. One of them is

$$\rho_1(z)=z^{-1/2}\sum_{i=0}^{\infty} a_i z^i, \tag{2.11}$$

where the first several expansion coefficients a_i are given in appendix A. We find that a_n can be represented by a polynomial of $\Lambda_1^{3i}m^j$ with $2n=3i+j$, where i and j are some non-negative integers. The other solution behaves logarithmically. It is

$$\rho_2(z)=\rho_1(z)\ln z+z^{-1/2}\sum_{i=1}^{\infty} b_i z^i, \tag{2.12}$$

where the first several coefficients b_i are given in appendix B. Note that b_n can also be represented by a polynomial of $\Lambda_1^{3i}m^j$ with $2n=3i+j$. But this time, non-negative integers i and j must move over all combinations.

Since we would like to get $a(u)$ and $a_D(u)$, let us consider whether we can express them as linear combinations of ρ_0, ρ_1 and ρ_2. First, in order to see an asymptotic behaviour of $a(u)$ near $u=\infty$, we must calculate the lower order expansion of the integral (2.4). This is done in appendix C. Making a comparison ρ_1 and ρ_0 with (C4), we can see that

$$a(u)=n\rho_0(z)+\frac{\rho_1(z)}{\sqrt{2}}, \tag{2.13}$$

where we identified

$$\rho_0(z)=-\frac{\sqrt{2}}{4}\,m. \tag{2.14}$$

It is easy to find that $a(u)$ can be expressed by a hypergeometric function in the mass-less limit.[10] $a_D(u)$ can be written as a linear combination of ρ_0, ρ_1 and ρ_2 by comparison it with (C7),

$$a_D(u)=A\rho_2(z)+B\rho_1(z)+n'\rho_0(z), \tag{2.15}$$

where

$$A=-\frac{i3\sqrt{2}}{4\pi}, \quad B=\frac{i\sqrt{2}}{4\pi}\,c, \tag{2.16}$$

and $c=-6+8\ln 2-i\pi-6\ln\Lambda_1$.

From these explicit expressions for the periods, we can easily find that the monodromy matrix near $u=\infty$ acts to the three objects ${}^t(a_D,a,\epsilon)$ as

$$\begin{pmatrix} a_D \\ a \\ \epsilon \end{pmatrix} \to \begin{pmatrix} -1 & 3 & 2n'-3n \\ 0 & -1 & 2n \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} a_D \\ a \\ \epsilon \end{pmatrix}. \tag{2.17}$$

Note that the monodromy matrix is now quantized by the winding number n and n'. Since these winding numbers are arbitrary, we may say that there are ''many'' monodromy matrices near $u=\infty$. This observation will be valid even near the regular singular points.

III. PREPOTENTIAL

Let us try to construct the prepotential $\mathscr{F}_1$ which is a solution to the following differential equation

$$a_D(u)=\frac{d\mathscr{F}_1}{da}, \tag{3.1}$$

but we use a new variable $\tilde{a}=a-n\epsilon$ for convenience. For that purpose, first, we must express u as a series of $\tilde{a}$. We can easily get it from (2.13), i.e.,

$$\begin{aligned} u=&2\tilde{a}^{\,2}+\frac{\Lambda_1^3 m}{16\tilde{a}^{\,2}}-\frac{3\Lambda_1^6}{2048\tilde{a}^{\,4}}+\frac{5\Lambda_1^6 m^2}{4096\tilde{a}^{\,6}}-\frac{7\Lambda_1^9 m}{65536\tilde{a}^{\,8}}+\frac{1}{\tilde{a}^{\,10}}\left(\frac{153\Lambda_1^{12}}{67108864}+\frac{9\Lambda_1^9 m^3}{131072}\right)\\ &-\frac{715\Lambda_1^{12}m^2}{67108864\tilde{a}^{\,12}}+\frac{1}{\tilde{a}^{\,14}}\left(\frac{1131\Lambda_1^{15}m}{2147483648}+\frac{1469\Lambda_1^{12}m^4}{268435456}\right)-\frac{1}{\tilde{a}^{\,16}}\left(\frac{1155\Lambda_1^{18}}{137438953472}\right.\\ &\left.+\frac{2625\Lambda_1^{15}m^3}{2147483648}\right)-\frac{1}{\tilde{a}^{\,18}}\left(\frac{667879\Lambda_1^{18}m^2}{1099511627776}+\frac{148819\Lambda_1^{15}m^5}{17179869184}\right)+\cdots . \end{aligned} \tag{3.2}$$

Inserting (3.2) into (2.15) and integrating it over $\tilde{a}$, we can obtain the prepotential

$$\mathscr{F}_1=\frac{i\tilde{a}^{\,2}}{\pi}\left[\frac{3}{4}\ln\left(\frac{\tilde{a}}{\Lambda_1}\right)^2+\frac{3}{4}\left(-1+\frac{c}{3}+\ln 2\right)-\frac{\sqrt{2}\pi}{4i\tilde{a}}n'm-\frac{m^2}{4\tilde{a}^{\,2}}\ln\tilde{a}+\sum_{i=2}^{\infty}\mathscr{F}_i^{\,1}\tilde{a}^{\,-2i}\right], \tag{3.3}$$

where the first several coefficients $\mathscr{F}_i^{\,1}$ are recorded in appendix D. Note that $\mathscr{F}_n^{\,1}$ is expressed again by a polynomial of $\Lambda_1^{3i}m^j$ with $2n=3i+j$. We can find that our result (3.3) is consistent with the mass-less $N_f=1$ theory[10] when $m=0$. It is interesting to note that (3.3) has a curious term proportional to $(\ln\tilde{a})/\tilde{a}^{\,2}$ in the brackets. However, we can find that[15]

$$\begin{aligned} \mathscr{F}_s^{\,1}=&\left(\tilde{a}-\frac{m}{\sqrt{2}}\right)^2\ln\left(\tilde{a}-\frac{m}{\sqrt{2}}\right)+\left(\tilde{a}+\frac{m}{\sqrt{2}}\right)^2\ln\left(\tilde{a}+\frac{m}{\sqrt{2}}\right)\\ =&2\tilde{a}^{\,2}\ln\tilde{a}+m^2\ln\tilde{a}+\frac{3}{2}m^2-\frac{m^4}{24\tilde{a}^{\,2}}-\frac{m^4}{240\tilde{a}^{\,4}}-\cdots . \end{aligned} \tag{3.4}$$

Thus we may rewrite (3.3) as

$$\begin{aligned} \mathscr{F}_1=&\frac{i\tilde{a}^{\,2}}{\pi}\left[\frac{3}{4}\ln\left(\frac{\tilde{a}}{\Lambda_1}\right)^2+\frac{3}{4}\left(-1+\frac{c}{3}+\ln 2\right)-\frac{\sqrt{2}\pi}{4i\tilde{a}}n'm-\frac{1}{4\tilde{a}^{\,2}}\mathscr{F}_s^{\,1}+\frac{1}{2}\ln\tilde{a}+\frac{3m^2}{8\tilde{a}^{\,2}}\right.\\ &\left.+\sum_{i=2}^{\infty}\tilde{\mathscr{F}}_i^{\,1}\tilde{a}^{\,-2i}\right], \end{aligned} \tag{3.5}$$

where $\tilde{\mathscr{F}}_i^{\,1}$ is the Λ_1 dependent part of $\mathscr{F}_i^{\,1}$.

IV. DOUBLE SCALING LIMIT

In this section, we examine the double scaling limit of the massive $N_f=1$ theory discussed in previous sections.

To begin with, let us discuss the Picard–Fuchs equation. Since the $N_f=1$ curve turns to the $N_f=0$ curve in the double scaling limit ($m\to\infty$, $\Lambda_1\to 0$, $m\Lambda_1^3=\Lambda_0^4$ fixed, where Λ_0 is a dynamical parameter of the $N_f=0$ theory), in other words, $N=2$ SU(2) Yang–Mills theory is considered as a low energy theory of the massive $N_f=1$ theory,[2] we may expect that (2.6) reduces to the Picard–Fuchs equation of the $N_f=0$ theory. In fact, we find that (2.6) in the double scaling limit is given by

$$\frac{d^3\Pi_1}{du^3}+\frac{3\cdot 256m^2(\Lambda_0^4-u^2)-2\cdot 256m^2u\cdot 4m^2}{256m^2(\Lambda_0^4-u^2)\cdot 4m^2}\frac{d^2\Pi_1}{du^2}-\frac{32\cdot 8m^4}{256m^2(\Lambda_0^4-u^2)\cdot 4m^2}\frac{d\Pi_1}{du}=0, \tag{4.1}$$

i.e.,

$$\frac{d^2\Pi_1}{du^2}-\frac{1}{4(\Lambda_0^4-u^2)}\Pi_1=\text{constant}. \tag{4.2}$$

Equation (4.2) shows the global $\mathbf{Z}_2$ symmetry over the u-plane. At first sight, this can be seen as the Picard–Fuchs equation of $N=2$ SU(2) Yang–Mills theory without matter.[6,16] However, we can not say that Π_1 also reduces to that of $N_f=0$ Picard–Fuchs equation because there is no reason why the relation

$$\Pi_1(u,m,\Lambda_1)\quad\overset{\text{double scaling limit}}{\longrightarrow}\quad\Pi_0(u,\Lambda_0) \tag{4.3}$$

should hold, where Π_0 is a representative of the $N_f=0$ period integral. So we can not insist that the integration constant on the right hand side of (4.2) must be 0.

More precisely speaking, the meromorphic 1-form λ_1 in the double scaling limit will behave as

$$\begin{aligned}\lambda_1&\to\frac{\sqrt{2}xdx}{4\pi i\tilde{y}}\left[\frac{x^2-u}{2m}\left(1-\frac{x}{m}+\frac{x^2}{m^2}-\cdots\right)-2x\right]\\&=\frac{\sqrt{2}x(x^2-u)dx}{8\pi im\tilde{y}}\left(1-\frac{x}{m}+\frac{x^2}{m^2}-\cdots\right)-\frac{\sqrt{2}x^2dx}{2\pi i\tilde{y}},\end{aligned} \tag{4.4}$$

where $\tilde{y}^2=(x^2-u)^2-\Lambda_0^4$ is the curve for the $N_f=0$ theory. The first term in the last expression is an ''extra'' 1-form which depends on the mass m while the second is nothing other than the meromorphic 1-form of the $N_f=0$ theory. Therefore, naively speaking, the solutions to (2.6) consist of the contributions originating from this extra 1-form and λ_0, in the double scaling limit. In fact, (2.10) and (2.12) diverge to infinity in the double scaling limit as is easy to find. Accordingly, when we discuss the low energy version of $N_f=1$ theory, we must carefully treat (4.3). Though ρ_0, ρ_1 and ρ_2 are indeed solutions to (2.6) for finite Λ_1 and m, nothing gives an assurance that they constitute fundamental solutions even for infinitely large Λ_1 or m. Recall that we have obtained the solutions to (2.6), assuming that Λ_1 and m are finite. Consequently, there must be a gap between Π_1 in the double scaling limit and Π_0. This gap will appear as divergence due to the large mass.

Next, let us directly examine the above observations, focusing on the periods $a(u)$ and $a_D(u)$. As for the residue part of the periods, i.e., ρ_0, it moves to infinity due to $m\to\infty$. However, the heavy quark with large mass can be integrated out,[2] so we can eliminate the residue dependence of the periods. We can see that among the expansion coefficients $a_n(n>1)$ of $a(u)$, only the coefficients of even degree survive in the double scaling limit and those of the odd degrees vanish.

Accordingly, we may then say that $a(u)$ converges to a solution to (4.2). In other words, $a(u)$ is not affected by the contributions from the extra 1-form. This fact suggests that $a(u)$ has a nice property which is valid under the double scaling. It is easy to check that the period $a(u)$ in the double scaling limit can be again expressed as a hypergeometric function. In order to see the behaviour of $a_D(u)$, on the other hand, we must rewrite it as a series of $a(u)$ and then take the double scaling limit. We can easily see that the expansion coefficients b_n's diverge to infinity in the double scaling limit. This means that the contributions for $a_D(u)$ from the extra 1-form are non-trivial. Since it is hard to see the difference with the period over β-cycle of the $N_f=0$ theory in this situation, we should first arrange $a_D(u)$ with some ''good'' variable. For that purpose, we take $a(u)$ as the good variable. From (3.2), $a_D(u)$ will be expanded as

$$a_D(u)=n'\epsilon+\sqrt{2}a[B-A\ \ln 2-2A\ \ln a]+\frac{A}{\sqrt{2}}\left[\frac{m^2}{3a}+\frac{m}{72a^3}\,(-3\Lambda_1^3+2m^3)\right.$$
$$\left.+\frac{1}{46080a^5}\,(45\Lambda_1^6+256m^6)+\frac{m^2}{86016a^7}\,(-105\Lambda_1^6+128m^6)+\cdots\right], \tag{4.5}$$

where ϵ, A and B are given in (2.14) and (2.16). Note that each coefficient of $a^{-2i+1}(i>0)$ consists of a finite part and a ''divergent'' part and the latter is always proportional to m^{2l}, $l\in\mathbf{N}$. However, since the heavy quark with large mass must be integrated out[2] as has been mentioned above, it would be enough to consider the finite parts. The divergence due to the large mass can be eliminated in that sense. Accordingly, if we extract only finite contributions we can arrive at a correct answer to get the periods $a_D(u)$ of the $N_f=0$ theory. The reader may ask how to deal with the constants A and B in (4.5) under the double scaling. These constants should be replaced with those of the $N_f=0$ theory. This is because the initial conditions for the Picard–Fuchs equation of the $N_f=1$ theory are different from those of the $N_f=0$ theory. In this way, Π_1 reduces to Π_0 and under this situation the integration constant in (4.2) will be 0. Then (4.2) is nothing other than the Picard–Fuchs equation of the $N_f=0$ theory. Of course, this time we must change Π_1 to Π_0 in (4.2).

Let us examine the double scaling limit of the prepotential. From the above discussions, we can drop the large mass dependence of the prepotential. Then, the procedure to do it consists of two steps. The first one is to take the double scaling limit of the first six terms in the brackets in (3.5). The second one is to consider the double scaling limit of the instanton expansion coefficients.

In order to accomplish the first step, we use a trick. Recall that we can add or subtract infinity related to the mass because of the reason described before. Thus,

$$\frac{3}{4}\ln\left(\frac{a}{\Lambda_1}\right)^2+\frac{3}{4}\,C=\frac{3}{4}\ln\left(\frac{a}{\Lambda_1}\right)^2+\frac{3}{4}\,C+\ln\left[\left(\frac{a}{m}\right)^{1/2}\cdot e^{D/2-3C/4}\right]$$
$$=\ln\left(\frac{a}{\Lambda_0}\right)^2+\frac{D}{2}, \tag{4.6}$$

where[17] $C=-1+\ln 2+c/3$, $D=-6+6\ln 2$ and $\tilde{a}$ is now replaced with a. Note that this trick essentially corresponds to the replacement of the ''initial'' conditions described above. Since the remaining two terms can be integrated out, we have dropped them here.

For the expansion coefficients $\tilde{\mathcal{F}}_i^1$, we can easily find that they will then be

$$\tilde{\mathcal{F}}_2^1\to-\frac{\Lambda_0^4}{64},\quad \tilde{\mathcal{F}}_3^1\to 0,\quad \tilde{\mathcal{F}}_4^1\to-\frac{5\Lambda_0^8}{32768},\quad \tilde{\mathcal{F}}_5^1\to 0,$$
$$\tilde{\mathcal{F}}_6^1\to-\frac{3\Lambda_0^{12}}{524288},\quad \tilde{\mathcal{F}}_7^1\to 0,\quad \tilde{\mathcal{F}}_8^1\to-\frac{1469\Lambda_0^{16}}{4294967296},\quad \tilde{\mathcal{F}}_9^1\to 0. \tag{4.7}$$

Then we can get the following ''renormalized'' prepotential $\hat{\mathcal{F}}_1$ in the double scaling limit:

$$\hat{\mathscr{F}}_1=\frac{ia^2}{\pi}\left[\ln\left(\frac{a}{\Lambda_0}\right)^2+\frac{D}{2}-\frac{\Lambda_0^4}{2^6\cdot a^4}-\frac{5\Lambda_0^8}{2^9\cdot a^6}-\frac{3\Lambda_0^{12}}{2^{19}\cdot a^8}-\frac{1469\Lambda_0^{16}}{2^{32}\cdot a^{10}}-\cdots\right]. \tag{4.8}$$

This agrees with the result of $N_f=0$ pure Yang–Mills theory.[6]

V. SUMMARY

We have studied the moduli space of $N=2$ SU(2) Yang–Mills theory coupled with a matter multiplet at weak coupling. In particular, we have determined its prepotential and monodromy matrix. For general values of Λ_1 and m, we have established that the two periods of the meromorphic 1-form can be written as

$$\begin{aligned} a(u)&=-\frac{\sqrt{2}}{4}nm+\frac{1}{2}\sqrt{2u}\left[1+\sum_{i=2}^{\infty}a_i(\Lambda_1^3,m)u^{-i}\right],\\ a_D(u)&=-\frac{\sqrt{2}}{4}n'm+\frac{3i}{2\pi}\tilde{a}(u)\ln\left(\frac{u}{\Lambda_1^2}\right)+\sqrt{u}\sum_{i=0}^{\infty}a_{D_i}(\Lambda_1^3,m)u^{-i}, \end{aligned} \tag{5.1}$$

where $a_i(\Lambda_1^3,m)$ and $a_{D_i}(\Lambda_1^3,m)$ are homogeneous polynomials of order $2i$, instead of the formulas noted before.[2,10] And we have proposed the exact expression for the prepotential as in (3.5). The coefficients of instanton expansion in the mass-less limit completely recovered. On the other hand, we have succeeded in constructing the $N_f=0$ theory as a low energy theory of the massive $N_f=1$ and have found that we can recover the instanton expansion of the prepotential of the $N_f=0$ theory.

Finally, we give some comments. Since the massive $N_f=1$ theory can be considered as a low energy theory of the massive $N_f=2$ theory,[2] all our results will be expected to be reproduced from it. In addition to this, it will be interesting to reconstruct our results in the languages of integrable systems such as Whitham hierarchy and so on.[16,18] The discussions in this paper should be compared with those approaches, but such considerations unfortunately are not proceeded at present.

ACKNOWLEDGMENT

The author would like to give his thanks to Dr. H. Kanno for helpful comments and suggestions.

APPENDIX A: EXPANSION COEFFICIENTS (1)

The first several coefficients of ρ_1 are

$$\begin{aligned} &a_0=1,\quad a_1=0,\quad a_2=-\frac{\Lambda_1^3 m}{16},\\ &a_3=\frac{3\Lambda_1^6}{1024},\quad a_4=-\frac{15\Lambda_1^6 m^2}{1024},\quad a_5=\frac{35\Lambda_1^9 m}{16384},\\ &a_6=-\frac{105\Lambda_1^9}{4194304}(3\Lambda_1^3+256m^3),\quad a_7=\frac{3465\Lambda_1^{12}m^2}{2097152},\\ &a_8=-\frac{3003\Lambda_1^{12}m}{67108864}(3\Lambda_1^3+80m^3),\quad a_9=\frac{15015\Lambda_1^{15}}{4294967296}(\Lambda_1^3+384m^3). \end{aligned} \tag{A1}$$

APPENDIX B: EXPANSION COEFFICIENTS (2)

The first several coefficients of ρ_2 are

$$b_1=\frac{1}{3}\,m^2,\quad b_2=\frac{m}{72}\,(3\Lambda_1^3+4m^3),$$

$$b_3=\frac{1}{23040}\,(-45\Lambda_1^6+480\Lambda_1^3m^3+512m^6),$$

$$b_4=\frac{m^2}{21504}\,(-21\Lambda_1^6+224\Lambda_1^3m^3+256m^6),$$

$$b_5=\frac{m}{276480}\,(-120\Lambda_1^9+1575\Lambda_1^6m^3+1920\Lambda_1^3m^6+2048m^9), \tag{B1}$$

$$b_6=\frac{1}{415236096}\,(9801\Lambda_1^{12}-937728\Lambda_1^9m^3+1419264\Lambda_1^6m^6+2162688\Lambda_1^3m^9+2097152m^{12}),$$

$$b_7=\frac{m^2}{5725224960}\,(323505\Lambda_1^{12}+13453440\Lambda_1^9m^3+15375360\Lambda_1^6m^6 +23855104\Lambda_1^3m^9+20971520m^{12}),$$

$$b_8=\frac{m}{3019898880}\,(45837\Lambda_1^{15}-5636520\Lambda_1^{12}m^3+4392960\Lambda_1^9m^6 +7028736\Lambda_1^6m^9+10485760\Lambda_1^3m^{12}+8388608m^{15}),$$

$$b_9=\frac{1}{13799729922048}\,(-9689337\Lambda_1^{18}+3483611712\Lambda_1^{15}m^3+16467010560\Lambda_1^{12}m^6 +16728391680\Lambda_1^9m^9+29198647296\Lambda_1^6m^{12}+41070624768\Lambda_1^3m^{15}+30064771072m^{18}).$$

APPENDIX C: LOWER ORDER EXPANSION OF THE PERIODS

In this appendix, we show that the lower order expansion of the period integral (2.4) in detail as an example. However, we must treat (2.4) carefully because this α-cycle is defined to be a usual homology basis. Recall that the meromorphic 1-form was constructed under the assumption such that the asymptotic behaviour of $a(u)$ at $u=\infty$ was to be $a(u)\sim\sqrt{u/2}$ even if the theory was massive.[9] Therefore even if we evaluate the period (2.4) by direct calculation, we can not obtain the correct contribution from the pole.[2] When the cycle may cross the pole, then the integration must pick up the residue of the pole. However, since the α-cycle in (2.4), as we have stated above, avoids the pole, we must study the case such that the cycle deforms from α to α', which encloses the pole and the two branching points x_3 and x_4 as shown in Fig. 2. As is easily seen from this figure, the direction of α' is the same as that of δ, which encloses only the pole. However, taking into account an effect for topological deformation, we can find that the α-cycle can be identified with the loop α'' in the figure. Namely, if the α-cycle should move on another covering of this x-plane and back onto the original one, it will enclose x_1 and x_2, i.e., another cut. But this time, the directions of α and α'' will be different. Therefore when α'' crosses the pole, the direction of α''' which is a deformation of α'' and that of δ will be different. This fact causes the sign of the residue to change. The reader may ask that the sign of the integral over the α'' should be reflected.

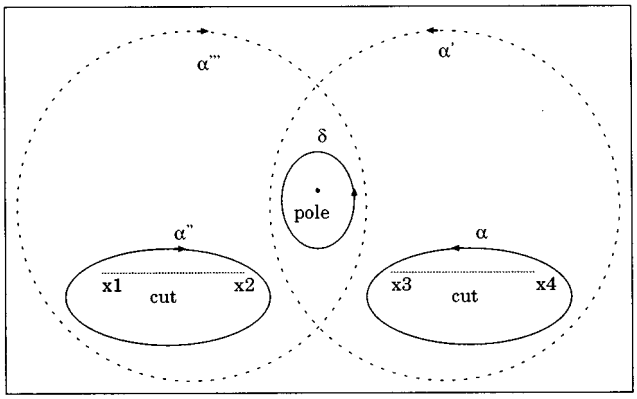

FIG. 2. Deformations of α-cycle on the x-plane.

Of course it is right. But since we usually use the convention such that the overall sign of $a(u)$ without the residue contribution, for example, to be $+$, e.g., $a(u) \sim +\sqrt{u/2}$ in $N=2$ $SU(2)$ Yang-Mills theory, we should change the sign of the residue instead of that of the integral in order to preserve the convention.

From these discussions, the true expression for the massive period $a(u)$ should be defined by

$$a(u):\ \oint_{\tilde{\alpha}} \lambda_1 = \oint_{\alpha} \lambda_1 + \oint_{\delta} \lambda_1$$

$$= \oint_{\alpha} \lambda_1 + 2\pi i n \cdot \mathrm{Res}(\lambda_1)|_{\text{at } x=-m}, \tag{C1}$$

where $\tilde{\alpha}$ is a certain member of the family of α-cycle which may include the pole and the cut inside the loop, δ is a small loop around the pole and $n=0,\pm 1$. If $\tilde{\alpha}$ avoids the pole, then $\tilde{\alpha}=\alpha$ and $n=0$. If $\tilde{\alpha}$ encloses the pole and the directions of $\tilde{\alpha}$ and δ coincide, $n=+1$. If the directions are different while $\tilde{\alpha}$ encloses the pole, then $n=-1$. To clarify, we should further comment on the number n. We have treated only the case such that $\tilde{\alpha}$ winds once around the pole, but we may also allow the case such that it winds several times around the pole. In this time, n can be interpreted as winding number and will be $n \in \mathbf{Z}$.

Now, let us evaluate (C1). First, note that

$$\oint_{\alpha} \lambda_1 = 2\int_{x_4}^{x_3} \lambda_1. \tag{C2}$$

On the right hand side, the factor 2 is required because the integral over α-cycle contains an integral from x_4 to x_3 and from x_3 to x_4 on the other side of the cut. In order to calculate (C2), we introduce a new variable t such as$x = \sqrt{u}t$. Then (C2) will be

$$\oint_{\alpha} \lambda_1 = \frac{2\sqrt{2}}{4\pi i} \int_{x_4/\sqrt{u}}^{x_3/\sqrt{u}} \frac{utdt}{\sqrt{u^2(t^2-1)^2 - \Lambda_1^3(\sqrt{u}t+m)}} \left[\frac{u(t^2-1)}{2(\sqrt{u}t+m)} - 2\sqrt{ut} \right]$$

$$= \frac{i}{4\pi} \sqrt{2u} \int_{x_4/\sqrt{u}}^{x_3/\sqrt{u}} \frac{(3\sqrt{u}t^3 + 4mt^2 + \sqrt{u}t)}{\sqrt{u}t+m} \left[\frac{1}{t^2-1} + \frac{\Lambda_1^3 m}{2u^2(t^2-1)^3} + \frac{3\Lambda_1^6 t^2}{8u^3(t^2-1)^5} + \cdots \right] dt$$

$$= \frac{1}{2} \sqrt{2u} \left(1 - \frac{\Lambda_1^3 m}{16u^2} + \cdots \right). \tag{C3}$$

Taking the contribution from the pole into account, we can arrive at

$$a(u)=-\frac{\sqrt{2}}{4}nm+\frac{1}{2}\sqrt{2u}\left(1-\frac{\Lambda_1^3 m}{16u^2}+\cdots\right). \tag{C4}$$

On the other hand, the integration over β-cycle is not well-defined, as well. This can be seen by evaluating its lower order expansion. (2.5) will be

$$\oint_\beta \lambda_1=\frac{i}{4\pi}\sqrt{2u}\left(3\ln u+8\ln 2-i\pi-6-6\ln\Lambda_1+\frac{im\pi}{\sqrt{u}}+\cdots\right). \tag{C5}$$

At first sight, this integration seems to be $a_D(u)$ with the contribution from the pole. In fact, this observation is not wrong. However, (C5) does not contain the possibilities such that the β-cycle does not enclose the pole, for example. In other words, the topological deformation of β-cycle as in the case of α-cycle is (partially) ignored. Since the pole merely contributes as only a constant term, (C5) will be well-defined as the period over the β-cycle avoiding the pole, if the constant term is extracted. Therefore the true definition of $a_D(u)$ will be

$$\begin{aligned} a_D(u):&=\oint_{\tilde\beta}\lambda_1 \\ &=\oint_\beta\lambda_1+\oint_\delta\lambda_1 \\ &=\oint_\beta\lambda_1+2\pi i n'\cdot\mathrm{Res}(\lambda_1)\big|_{\text{at } x=-m}, \end{aligned} \tag{C6}$$

where $\tilde\beta$ is a certain member of β-cycle which may enclose the pole and the cut, β in (C6) means now a loop avoiding the pole and $n'=0,\pm1$. If the loop $\tilde\beta$ winds around the pole several times, then $n'\in\mathbf{Z}$. In this way we can arrive at

$$a_D(u)=-\frac{\sqrt{2}}{4}n'm+\frac{i}{4\pi}\sqrt{2u}(3\ln u+8\ln 2-i\pi-6-6\ln\Lambda_1+\cdots). \tag{C7}$$

APPENDIX D: EXPANSION COEFFICIENTS (3)

The first several coefficients of the prepotential (3.3) are listed below:

$$\begin{gathered} \mathscr{F}_2^1=-\frac{1}{64}\Lambda_1^3 m+\frac{m^4}{96},\quad \mathscr{F}_3^1=\frac{3\Lambda_1^6}{16384}+\frac{m^6}{960}, \\ \mathscr{F}_4^1=-\frac{5\Lambda_1^6 m^2}{32768}+\frac{m^8}{5376},\quad \mathscr{F}_5^1=\frac{7\Lambda_1^9 m}{786432}+\frac{m^{10}}{23040}, \\ \mathscr{F}_6^1=-\frac{153\Lambda_1^{12}}{1073741824}-\frac{3\Lambda_1^9 m^3}{524288}+\frac{m^{12}}{84480}, \\ \mathscr{F}_7^1=\frac{715\Lambda_1^{12}m^2}{1073741824}+\frac{m^{14}}{279552}, \\ \mathscr{F}_8^1=-\frac{1131\Lambda_1^{15}m}{42949672960}-\frac{1469\Lambda_1^{12}m^4}{4294967296}+\frac{m^{16}}{860160}, \\ \mathscr{F}_9^1=\frac{385\Lambda_1^{18}}{1099511627776}+\frac{525\Lambda_1^{15}m^3}{8589934592}+\frac{m^{18}}{2506752}. \end{gathered} \tag{D1}$$

The relation between $\mathscr{F}_i^1$ and $\tilde{\mathscr{F}}_i^1$ is

$$\tilde{\mathscr{F}}_i^1:=\mathscr{F}_i^1-(\text{term proportional to } m^{2i}). \tag{D2}$$

Symmetry and history quantum theory: An analog of Wigner's theorem

S. Schreckenberg[a)]
Blackett Laboratory, Imperial College, South Kensington, London SW7 2BZ, United Kingdom

(Received 29 May 1996; accepted for publication 29 July 1996)

The basic ingredients of the ''consistent histories'' approach to quantum theory are a space $\mathcal{UP}$ of ''history propositions'' and a space $\mathcal{D}$ of ''decoherence functionals.'' In this article we consider such history quantum theories in the case where $\mathcal{UP}$ is given by the set of projectors $\mathcal{P}(\mathcal{V})$ on some Hilbert space $\mathcal{V}$. We define the notion of a ''physical symmetry of a history quantum theory'' (PSHQT) and specify such objects exhaustively with the aid of an analog of Wigner's theorem. In order to prove this theorem we investigate the structure of $\mathcal{D}$, define the notion of an ''elementary decoherence functional,'' and show that each decoherence functional can be expanded as a certain combination of these functionals. We call two history quantum theories that are related by a PSHQT ''physically equivalent'' and show explicitly, in the case of history quantum mechanics, how this notion is compatible with one that has appeared previously. © *1996 American Institute of Physics.* [S0022-2488(96)00212-5]

I. INTRODUCTION

In this paper we discuss the mathematical aspects of a notion of ''symmetry'' in a history quantum theory, such as the decoherent histories approach to quantum theory initiated by Griffiths,[1] Omnès,[2] and Gell-Mann and Hartle.[3] Given the major importance symmetries play in almost every physical theory, one would like to know what the counterpart of this concept is in theories who place the emphasis on ''histories'' and ''decoherence functionals'' rather than propositions and states at a fixed time point (as is done in standard quantum theory). This involves the problem of giving a meaning to the notion of two history theories being equivalent, when consistent sets can be called equivalent, etc.[4]

These matters are not settled yet, but I will show that, in case we adopt a particular notion of ''symmetry,'' it is possible to assign a well-defined meaning to such concepts. In order to understand where these ideas fit into the structure of such history quantum theories, we have to rewrite the decoherent histories approach in a way that describes the ingredients of such a theory in a more transparent way.

The clarification of the structural content of history quantum theories (HQT) is due to C. J. Isham,[5] who extracted the basic features of these theories in the form of a set of axioms which determine the mathematical content of the framework of such theories. The aim is to place history quantum theories—as an entirely new approach to the problem of defining and constructing quantum theories—on an equally firm mathematical base as other, already existing approaches to quantum theories. The explanation of why the axioms take the particular form chosen is a very deep one and is partly motivated by problems arising in the area of quantum gravity, in particular the so-called ''problem of time;'' it uses ideas of ''quasi-temporal'' logic and much more. These matters have been discussed at some length by Isham,[5] Isham and Linden,[6] and Schreckenberg,[7] and the reader is referred to those sources for a deeper appreciation of ''history quantum theories.''

In this paper I will adopt a working, practical approach. I will mainly restrict myself to the case of the history version of finite-dimensional quantum mechanics. This will prove to be an ideal model to illustrate the concept of ''symmetry'' introduced in this article.

Our discussion will be based on an investigation of how the mathematical structure of history quantum theories suggests a notion of ''physical symmetries of history quantum theories.'' It is striking—and indeed very satisfying—that the concept developed here is compatible with a definition and a result presented by Gell-Mann and Hartle in Ref. 4, even though this was not the original goal of the enterprise. This speaks on the one hand for the physical insight and arguments which led Gell-Mann and Hartle to the notion of 'physical equivalence', and, on the other hand, it shows the strength of the mathematical formalism developed by Isham[5] in order to capture the main ideas of the decoherent histories program in a precise manner. Because of this relation among the results, the physical arguments presented in Ref. 4 can, to some extent, be regarded as *physical* arguments in favor of the notion developed here and, vice versa, the arguments presented here as a precise *mathematical* statement about such objects, which possess a *very* transparent description.

We will begin with an introduction to the formalism introduced in Ref. 5, recall the classification theorem for decoherence functionals proven in Ref. 8, and remind the reader of the content of Wigner's theorem, which will be central to our investigation. In Sec. II we reformulate the standard requirements for ''physical symmetries'' given by Wigner in a way that is more suited to our problem in that it avoids some of the interpretative difficulties that arise when one is trying to induce a notion of symmetry in history quantum theories from symmetries defined at a single time point. We proceed by defining ''physical symmetries of a history quantum theory'' (PSHQT) and show that a particular subset of PSHQT can be induced by unitary or antiunitary operators $\hat{U}$ on $\mathscr{V}$, which I call ''homogeneous symmetries.'' We show that these symmetries possess a characterization *à la* Wigner. We investigate the structure of the space $\mathscr{D}$ in some detail to show in Sec. III that, in fact, PSHQT are in one-to-one correspondence with homogeneous symmetries and can thus be characterized by an analog of Wigner's theorem. We call two history quantum theories which are related by a physical symmetry of a history quantum theory *physically equivalent*. This expression first appeared in Ref. 4 and we show explicitly, for history quantum mechanics, how the notion of ''physical equivalence''—as introduced in Ref. 4—is naturally induced by a subset of the set of PSHQT. In the closing section IV we mention some ways one could try to proceed in order to find a satisfactory *physical* interpretation of the symmetries considered in this article.

A. Decoherent histories and history quantum theory

1. The algebraic structure for HQT

In the decoherent histories approach the two main ingredients are the so-called ''histories,'' namely sequences of Schrödinger picture projection operators $\alpha := (\alpha_{t_1}, \alpha_{t_2}, \ldots, \alpha_{t_n})$, with $t_1 < t_2 < \cdots < t_n$, defined on the single time Hilbert space $\mathscr{H}$, and ''decoherence functionals,'' namely a complex-valued functional d of pairs of histories. For normal quantum mechanics the latter is given by

$$d_{(H,\rho)}(\alpha,\beta) := \mathrm{tr}_{\mathscr{H}}(\widetilde{C}_\alpha^\dagger \rho_{t_0} \widetilde{C}_\beta), \tag{I.1}$$

where the ''class'' operator $\widetilde{C}_\alpha$ (Ref. 3) is defined to be

$$\widetilde{C}_\alpha := \alpha_{t_1}(t_1)\alpha_{t_2}(t_2)\cdots\alpha_{t_n}(t_n) \tag{I.2}$$

with $\{\alpha_{t_i}(t_i) := e^{(i/\hbar)H(t_i-t_0)}\alpha_{t_i}e^{-(i/\hbar)H(t_i-t_0)}\}$ being the associated Heisenberg picture operators. For the ease of exposition, all histories α will be defined on n arbitrary, but fixed, time points.

This functional $d(\alpha,\beta)$ is an extension of the formula $d(\alpha,\alpha)$ in standard quantum mechanics for the joint probability of finding all the properties $\alpha := (\alpha_{t_1},\alpha_{t_2},\ldots,\alpha_{t_n})$ with $t_1<t_2<\cdots<t_n$ in a time-ordered sequence of measurements. The aim is to determine with the aid of certain ''consistency conditions'' on $d(\alpha,\beta)$ such histories, on which $d(\alpha,\alpha)$ defines a probability distribution.

The expression for the decoherence functional is rather messy: it is difficult to isolate the contribution of the histories α and β to the evaluation. Whereas before they were defined as sequences of Schrödinger operators, they enter now as a product of Heisenberg operators. Hence the evolution operator should belong intrinsically to the decoherence functional as does the density matric ρ.

The separation that I have in mind of the contribution to $d_{(H,\rho)}(\alpha,\beta)$ of (i) the histories, and (ii) a part which encodes all the properties of the decoherence functional, is best illustrated by an analogous expression in standard quantum mechanics. Namely, the probability $p(x\in[a,\,b])$ of finding that the eigenvalue x of an observable X lies in the interval $[a,b],a,b\in\mathbb{R}$, given the state ρ of the system, is evaluated as

$$p(x\in[a,b],\rho)=\mathrm{tr}_{\mathscr{H}}(P^X_{[a,b]}\rho). \tag{I.3}$$

One can immediately refer to the density operator to describe the contribution of the state and to the projection operator $P^X_{[a,b]}$—as the mathematical representation of the question asked—to describe the contribution of the corresponding observable to the value $p(x\in[a,b],\rho)$. This is, of course, due to Gleason's theorem which establishes a one-to-one correspondence between states and density operators.

The appropriate rewriting of the expression for $d_{(H,\rho)}(\alpha,\beta)$, which is described in detail in Ref. 8, relies on the mathematical identity

$$\mathrm{tr}_{\mathscr{H}}(A_1A_2\ldots A_m)=\mathrm{tr}_{\otimes\mathscr{H}^m}(A_1\otimes\cdots\otimes A_mS), \tag{I.4}$$

which allows us to express the trace of a product of m operators $\{A_m\}$ by means of the trace of a single operator $A_1\otimes\cdots\otimes A_m$ on the m-fold tensor product space $\mathscr{V}_m:=\otimes\mathscr{H}^m$ and a universal operator S.

Forgetting for a moment the ρ in (I,1), $d_{(H,\rho)}(\alpha,\beta)$ is given by the product of $2n$ Heisenberg operators. Using formula (I.4) we deduce that histories enter the decoherence functional in the following way:

$$\tilde{\alpha}=\alpha_{t_1}(t_1)\otimes\alpha_{t_2}(t_2)\otimes\cdots\otimes\alpha_{t_n}(t_n). \tag{I.5}$$

Heisenberg operators are just Schrödinger operators multiplied on the left and right by the evolution operators $U(t_i,t_0)$ and its inverse. Expression (I.4) shows that this dependence can be thrown onto the universal operator S, allowing us to represent histories by Schrödinger-picture operators

$$\alpha=\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}\in P(\mathscr{V}_n), \tag{I.6}$$

which contribute to the value for $d_{(H,\rho)}(\alpha,\beta)$ through

$$d_{(H,\rho)}(\alpha,\beta)=\mathrm{tr}_{\mathscr{V}_n\otimes\mathscr{V}_n}(\alpha\otimes\beta X_{(H,\rho)}), \tag{I.7}$$

for some operator $X_{(H,\rho)}$ defined on $\mathscr{V}_n\otimes\mathscr{V}_n$. The time-ordered strings of projection operators $(\alpha_{t_1},\alpha_{t_2},\ldots,\alpha_{t_n})$ are now represented by a homogeneous projection operator $\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ on the n-fold tensor product space $\mathscr{V}_n=\otimes_{i=1}^n\mathscr{H}_{t_i}$ and one can easily see that this association is

one-to-one. This motivates the definition of a space $\mathcal{UP}$ of ''history propositions'' (also called ''universal propositions'' or ''propositions about the universe''), which is given by the set of *all* projection operators $\alpha \in \mathcal{P}(\mathcal{V}_n)$ on the n-fold tensor product space.

By these means we have achieved the aim of separating the contribution of the histories to the value $d_{(H,\rho)}(\alpha,\beta)$ in that the operator $X_{(H,\rho)}$ encodes now all of the dynamical information and the initial conditions of the system under investigation.

One can also convince oneself that the decoherence functional (I.7) satisfies the following properties:

$$\begin{aligned} &\circ \text{Hermiticity: } d(\alpha,\beta) = d(\beta,\alpha)^* \quad \forall\, \alpha,\beta \in \mathcal{P}(\mathcal{V}_n), \\ &\circ \text{Positivity: } d(\alpha,\alpha) \geqslant 0 \quad \forall\, \alpha \in \mathcal{P}(\mathcal{V}_n), \\ &\circ \text{Additivity: } d(\alpha \oplus \beta,\gamma) = d(\alpha,\gamma) + d(\beta,\gamma), \\ &\circ \text{Normalization: } d(1,1) = 1, \end{aligned} \tag{I.8}$$

which are the usual requirements for decoherence functionals in the consistent histories approach when expressed in this formalism. The operation ''$\oplus$'' is given by the addition of two orthogonal projectors, i.e., history propositions, in $\mathcal{P}(\mathcal{V}_n)$.

This example seems to suggest that it might be worth trying to define a *history quantum theory* as a theory which has two main ingredients: A space of history propositions $\mathcal{UP}$ which, in this paper, will be the space of propositions $\mathcal{P}(\mathcal{V})$ onto a Hilbert space $\mathcal{V}$; and a decoherence functional $d \in \mathcal{D}$, where $\mathcal{D}$ denotes the space of all decoherence functionals, that is, all those functionals defined on $\mathcal{P}(\mathcal{V}) \times \mathcal{P}(\mathcal{V})$ which possess the properties (I.8) mentioned above. Thus $\mathcal{V}$ does not necessarily have to be of the tensor-product form $\mathcal{V}_n$, and $d \in \mathcal{D}$ will in general not be of the form $d_{(H,\rho)}$. In this formalism, *consistent sets of history propositions with respect to a* $d \in \mathcal{D}$ correspond to certain partitions of the unit operator on $\mathcal{V}$ into mutually orthogonal projectors $\{\alpha_i\}_{i=1}^{m \leqslant \dim \mathcal{V}}$ such that

$$d(\alpha_i,\alpha_j) = \delta_{ij} d(\alpha_i,\alpha_i) \quad \forall\, i,j \in \{1,2,\ldots,m\}. \tag{I.9}$$

The properties (I.8) of $d \in \mathcal{D}$ ensure that the values $d(\alpha_i,\alpha_i)$ determine a probability distribution on the Boolean algebra generated by the $\{\alpha_i\}_{i=1}^{m \leqslant \dim \mathcal{V}}$.

2. The classification theorem

We want to base our investigations of symmetries on the expression (I.7) of the decoherence functional. However, in order to do so, we must first be sure that it is not only a lucky coincidence that we are able to cast this *particular* decoherence functional for the history version of quantum mechanics in the above form. The formalism for decoherent histories is not simply restricted to models with unitary evolution, inclusions of final density matrices, and the like. Therefore, in order to formulate a notion of symmetry that is valid for all these cases, we have to find out whether every decoherence functional, i.e., every functional satisfying the properties (I.8) listed above, can be written in the form (I.7). The clear cut answer to this is given by the following theorem (see Ref. 8), which is valid for any theory in which the history propositions are given by projectors on a finite-dimensional Hilbert space $\mathcal{V}$.

Theorem:[8] If $\dim \mathcal{V} > 2$, decoherence functionals d are in one-to-one correspondence with operators $X = X_1 + iX_2$ on $\mathcal{V} \otimes \mathcal{V}$ according to the rule

$$d(\alpha,\beta) = \mathrm{tr}_{\mathcal{V}\otimes\mathcal{V}}(\alpha \otimes \beta X) \tag{I.10}$$

with the restriction that

$$(a) X^\dagger = MXM \quad \text{with} \quad M(|v\rangle \otimes |w\rangle) := |w\rangle \otimes |v\rangle, \quad \forall |v\rangle, |w\rangle \in \mathscr{V}, \tag{I.11}$$

$$(b) \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha \otimes \alpha X_1) \geq 0, \tag{I.12}$$

$$(c) \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(X_1) = 1. \tag{I.13}$$

The restrictions on the operator X on $\mathscr{V}\otimes\mathscr{V}$ reflect the requirements (I.8). We denote by $\mathscr{X}_{\mathscr{D}}$ the set of all such operators X. This theorem which has been extended to arbitrary von Neumann algebras without factor of type II in Ref. 9, is the cornerstone of the forthcoming investigation. It allows us to shift the investigation of the properties of decoherence functionals $d \in \mathscr{D}$, where $\mathscr{D}$ denotes the space of all decoherence functionals, to an analysis of the properties of the associated operator $X_d \in \mathscr{X}_{\mathscr{D}}$, which, as we emphasize once again, carries all of the ''dynamical'' content as well as the ''initial conditions'' of the model under investigation.

It is important to understand the origin of these requirements. Condition (I.11) reflects the Hermiticity requirement. The action of M on $\alpha\otimes\beta$ is given by $M(\alpha\otimes\beta)M = (\beta\otimes\alpha)$. Equation (I.11) follows then from the condition

$$d(\alpha,\beta) = \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\beta X) = \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\beta\otimes\alpha X^\dagger) = d(\beta,\alpha)^*.$$

Condition (I.12) stems from the fact that, since $X^\dagger = MXM$ is equivalent to the pair of conditions

$$X_1 = MX_1M, \quad X_2 = -MX_2M, \tag{I.14}$$

it follows that

$$\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\alpha X_2) = -\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\alpha MX_2M) = -\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(M(\alpha\otimes\alpha)MX_2) = -\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\alpha X_2), \tag{I.15}$$

and so $\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\alpha X_2) = 0$ is implied already by the Hermiticity requirement (I.11).

It will be advantageous later to think of $d(\alpha,\beta)$ as the value of the complex-valued functional

$$\begin{aligned} &\mathrm{tr}: \mathscr{P}(\mathscr{V})\otimes\mathscr{P}(\mathscr{V}) \times \mathscr{X}_{\mathscr{D}} \to \mathbb{C} \\ &(\alpha\otimes\beta; X_d) \mapsto \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\beta X_d). \end{aligned} \tag{I.16}$$

B. Wigner's theorem

In order to understand fully the importance of Wigner's result it is crucial to distinguish between the notion of a *symmetry* and that of a *physical symmetry*.

Definition: On a complex Hilbert space $\mathscr{H}$ a *symmetry* is a unitary or antiunitary operator U. Thus it leaves invariant the modulus of the inner product of any pair of two vectors $|v\rangle, |w\rangle \in \mathscr{H}$, that is

$$|\langle v,w\rangle|^2 = |\langle Uv, Uw\rangle|^2, \quad \forall |v\rangle, |w\rangle \in \mathscr{H}. \tag{I.17}$$

This definition is only a mathematical one; it has, *a priori*, no motivation by physical arguments. Note also that it does *not* impose any further defining properties on U, such as commutativity with the Hamiltonian operator. Such requirements only enter at a much later stage, motivated by analogs of the assumption in classical mechanics, that a particular physical system evolves along the flowlines of a specific, Hamiltonian, vector field.

On the other hand, a physical system at a *fixed moment of time* is described in quantum mechanics by a state $\sigma \in \mathscr{S}: \mathscr{P}(\mathscr{H}) \to \mathbb{R}$, that is, a normalized $[\sigma(1)=1]$, positive-valued functional which is additive on disjoint projectors. The states are, via Gleason's theorem, in one-to-one correspondence with density operators ρ on $\mathscr{H}$ according to the rule

$$\sigma(\alpha,\rho)=\mathrm{tr}_{\mathscr{H}}(\alpha\rho),\quad \forall\,\alpha\in\mathscr{P}(\mathscr{H}), \tag{I.18}$$

where ρ is defined by the properties

$$\rho=\rho^{\dagger},\quad \rho\geqslant 0,\quad \mathrm{tr}_{\mathrm{H}}(\rho)=1. \tag{I.19}$$

The set of all density operators is often denoted by $\mathscr{W}_{\mathscr{S}}$.

The *physical* assumption is now that all that matters are the relations among the states, which can be entirely described by means of their overlaps, that is the transition amplitudes $\mathrm{tr}_{\mathscr{H}}(\rho_1\rho_2)$.

In the finite-dimensional case the self-adjointness of ρ implies that for every density operator there exists an orthonormal basis $\{|\psi_i\rangle\}$ such that

$$\rho=\sum\, r_i P_{|\Psi_i\rangle},\quad \sum\, r_i=1,\quad r_i\geqslant 0. \tag{I.20}$$

Density operators of the form $P_{|\Psi_i\rangle}:=|\,\Psi_i\rangle\langle\Psi_i|\in\mathscr{W}_{\mathscr{SP}}$ are called *pure*. Every density operator possesses an expansion in terms of pure density operators, also representing ''rays'' of $\mathscr{H}$; instead of $\mathscr{W}_{\mathscr{SP}}$ we also use sometimes the notation $\mathscr{R}(\mathscr{H})$. Therefore, the invariance requirement on the transition amplitude between two arbitrary states ρ_1 and ρ_2 can be reduced to the requirement that

$$\mathrm{tr}_{\mathscr{H}}(P_{|\Psi^1\rangle}P_{|\Psi^2\rangle})=\mathrm{tr}_{\mathscr{H}}(P^{\xi}_{|\Psi^1\rangle}P^{\xi}_{|\Psi^2\rangle}), \tag{I.21}$$

for arbitrary one-dimensional pure density operators $P_{|\Psi^1\rangle}$ and $P_{|\Psi^2\rangle}$ and an affine map ξ: $\mathscr{W}_{\mathscr{SP}}\to\mathscr{W}_{\mathscr{SP}}$, that is a map satisfying $\xi(\Sigma_i c_i P_{|\Psi^i\rangle})=\Sigma_i c_i\xi(P_{|\Psi^i\rangle})\equiv\Sigma_i c_i P^{\xi}_{|\Psi^i\rangle}, c_i\in\mathbb{C}$.

Definition: A *physical symmetry* is an affine bijection $\xi:\mathscr{W}_{\mathscr{SP}}\to\mathscr{W}_{\mathscr{SP}}$; $P_{|\Psi\rangle}\mapsto P^{\xi}_{|\Psi\rangle}$, such that the transition amplitude between pure density operators remains invariant, i.e., that

$$\mathrm{tr}_{\mathscr{H}}(P_{|\Psi_1\rangle}P_{|\Psi_2\rangle})=\mathrm{tr}_{\mathscr{H}}(P^{\xi}_{|\Psi_1\rangle}P^{\xi}_{|\Psi_2\rangle}),\quad \forall|\Psi_1\rangle,|\Psi_2\rangle\in\mathscr{H}. \tag{I.22}$$

Theorem:[10] (*Wigner*) Every symmetry induces a physical symmetry and, conversely, every one-to-one map $\xi:\mathscr{W}_{\mathscr{SP}}\to\mathscr{W}_{\mathscr{SP}}$ preserving orthogonality between rays is a physical symmetry and can be implemented by a unitary or antiunitary operator U on $\mathscr{H}$.

II. SYMMETRY AND HISTORY QUANTUM THEORY

The notion of symmetry discussed in the last section arose from discussing quantum mechanics at a single, fixed time point $t\in\mathbb{R}$ with a corresponding Hilbert space $\mathscr{H}$. At a single time point physics is described in terms of the pair $(\mathscr{S},\mathscr{L})$, where $\mathscr{S}$ is the set of states and $\mathscr{L}$ is the lattice of projection operators on $\mathscr{H}$. In order to define physical symmetries in quantum mechanics—in the sense specified by Wigner—only the knowledge of one part of this pair was required, namely the knowledge of the properties of the set of states $\mathscr{S}$, via the map

$$\mathrm{tr}:\mathscr{W}_{\mathscr{SP}}\times\mathscr{W}_{\mathscr{SP}}\to\mathbb{R}$$

$$(P_{|\Psi_1\rangle}:P_{|\Psi_2\rangle})\mapsto\mathrm{tr}_{\mathscr{H}}(P_{|\Psi_1\rangle}P_{|\Psi_2\rangle}). \tag{II.1}$$

The properties of the lattice of propositions $\mathscr{L}=\mathscr{P}(\mathscr{H})$ did not enter in full.

In order to arrive at a notion of symmetry for HQTs, recall that in a history quantum theory the pair $(\mathscr{UP},\mathscr{D})$ can be seen as a formal analogue of the pair $(\mathscr{L},\mathscr{S})$. Comparing the two expressions

$$\mathrm{tr}_{\mathscr{H}}(\rho_1\rho_2)\quad and\quad \mathrm{tr}_{\mathscr{T}\otimes\mathscr{T}}(\alpha\otimes\beta X_d) \tag{II.2}$$

reveals immediately the mathematical difference between them. In contrast to the quantum mechanical case at a single time point, in HQTs the map

$$\mathrm{tr}:\mathscr{P}(\mathscr{V})\otimes\mathscr{P}(\mathscr{V})\times\mathscr{X}_{\mathscr{D}}\to\mathbb{C}$$

$$(\alpha\otimes\beta)\times X_d\mapsto\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\beta X_d) \tag{II.3}$$

intertwines the properties of $\mathscr{UP}=\mathscr{P}(\mathscr{V})$ and $\mathscr{X}_{\mathscr{D}}$. This is not surprising, since the classification theorem is more to be regarded as an analog of Gleason's theorem, which in a similar manner intertwines properties of $\mathscr{L}$ and $\mathscr{S}$.

The invariance requirement for the expression $\mathrm{tr}_{\mathscr{H}}(\rho_1\rho_2)$ has a direct physical meaning. In HQTs the formal analog of a density operator ρ is an operator $X_d\in\mathscr{X}_{\mathscr{D}}$ so that the first guess for symmetries might be to look for transformations which leave ''transition amplitudes between different X_d'' invariant. However, such a requirement would be hard to interpret since HQTs deal with ''history propositions'' as entities in their own right. The theory is completely specified by choosing *a particular* decoherence functional, which is kept fixed throughout. Since the notion of ''time'' in a specific history quantum theory is determined by the choice of the structure of the space of history propositions—for example, the nature of ''time'' as a parameter $t\in\mathbb{R}$ in quantum mechanics is mirrored in the definition of $\mathscr{P}(\mathscr{V}_n)=\mathscr{P}(\otimes_{i=1}^{n}\mathscr{H}_{t_i})$—and decoherence functionals associate numbers with these pairs of history propositions *as an entity*, a change of the decoherence functional must not occur.

How can we nonetheless use, at least at the mathematical level, the existing notion of a physical symmetry and later on Wigner's theorem, to define a corresponding notion for HQTs that does not suffer from the difficulty mentioned above? The main idea is to characterize the notion of a *physical symmetry* in a form which exploits the pairing (I.18) between density operators $\rho\in\mathscr{W}_{\mathscr{S}}$ and propositions $\alpha\in\mathscr{P}(\mathscr{H})$ given by Gleason's theorem.

A. Alternative specification of physical symmetries

We start by neglecting entirely the considerations from which the expression

$$\mathrm{tr}_{\mathscr{H}}(P_{|\Psi\rangle}P_{|\Phi\rangle}) \tag{II.4}$$

originally arose. Pure density operators belong trivially to the space of projection operators $\mathscr{P}(\mathscr{H})$ and therefore, instead of thinking of the map (II.1) as a pairing between states, one can think of it as a map

$$\mathrm{tr}:\{\mathscr{R}(\mathscr{H})\subset\mathscr{P}(\mathscr{H})\}\times\mathscr{W}_{\mathscr{S}^p}\to\mathbb{R}$$

$$P_{|\Psi\rangle}\times P_{|\Phi\rangle}\mapsto\mathrm{tr}_{\mathscr{H}}(P_{|\Psi\rangle}P_{|\Phi\rangle}) \tag{II.5}$$

that establishes a pairing between a subset of the space of propositions and the set of pure states. Therefore, we see immediately that Wigner's result can be read as follows: Wigner's theorem determines all bijections

$$\xi:\mathscr{R}(\mathscr{H})\times\mathscr{W}_{\mathscr{S}^p}\to\mathscr{R}(\mathscr{H})\times\mathscr{W}_{\mathscr{S}^p}$$

$$(P_{|\Phi\rangle},P_{|\Psi\rangle})\mapsto(P^{\xi}_{|\Phi\rangle},P^{\xi}_{|\Psi\rangle}) \tag{II.6}$$

that leave invariant the pairing

$$\mathrm{tr}_{\mathscr{H}}(P_{|\Psi\rangle}P_{|\Phi\rangle})=\mathrm{tr}_{\mathscr{H}}(P^{\xi}_{|\Psi\rangle}P^{\xi}_{|\Phi\rangle}). \tag{II.7}$$

Now, when seen from this perspective, it is natural to ask whether or not Wigner's theorem specifies completely all affine one-to-one maps

$$V:\mathscr{P}(\mathscr{H})\times\mathscr{W}_{\mathscr{S}}\rightarrow\mathscr{P}(\mathscr{H})\times\mathscr{W}_{\mathscr{S}}$$

$$(\alpha,\rho)\mapsto(\alpha^V,\rho^V) \tag{II.8}$$

such that the pairing between propositions and density operators is left invariant for all $\alpha\in\mathscr{P}(\mathscr{H})$ and all $\rho\in\mathscr{W}_{\mathscr{S}}$, i.e.,

$$\mathrm{tr}_{\mathscr{H}}(\alpha\rho)=\mathrm{tr}_{\mathscr{H}}(\alpha^V\rho^V). \tag{II.9}$$

The map is required to be affine since the space $\mathscr{W}_{\mathscr{S}}$ is a convex space. Convex combinations of elements of $\mathscr{W}_{\mathscr{S}}$ are again density operators.

Note that the question posed is not trivial: The space of projectors $\mathscr{P}(\mathscr{H})$ is a disjoint union of compact Grassmann manifolds and therefore allows for a much wider class of transformation than just unitary or antiunitary operators U on $\mathscr{H}$. The three conditions these maps have to satisfy are

$$^*V:\mathscr{P}(\mathscr{H})\rightarrow\mathscr{P}(\mathscr{H}), \tag{II.10}$$

$$^*V:\mathscr{W}_{\mathscr{S}}\rightarrow\mathscr{W}_{\mathscr{S}}, \tag{II.11}$$

$$^*\mathrm{tr}_{\mathscr{H}}(\alpha\rho)=\mathrm{tr}_{\mathscr{H}}(\alpha^V\rho^V). \tag{II.12}$$

If we consider transformations on $\mathscr{P}(\mathscr{H})$, the interesting transformations are given by transforming projectors of different dimensions to each other. So consider, for example, the transformation

$$G:\mathscr{P}(\mathscr{H})\rightarrow\mathscr{P}(\mathscr{H})$$

$$\alpha\mapsto G[\alpha], \tag{II.13}$$

whereby a particular one-dimensional projector $P_{|\Phi\rangle}$ is mapped into an m-dimensional one, $G[P_{|\Phi\rangle}]$, $m>1$. Such a transformation might be bijective on $P(\mathscr{H})$ and even obey requirement (II.12).

Now, regarding $P_{|\Phi\rangle}$ as a pure *density operator*, we see immediately that the trace of its image under G is $\mathrm{tr}_{\mathscr{H}}(G[P_{|\Phi\rangle}])=m$. Therefore, such a map does not comply with the requirement (II.11). Thus, only maps which map rays into rays are allowed and, therefore, all maps obeying the conditions (II.8) and (II.9) are determined by Wigner's theorem.

This reformulation of ''physical symmetries'' in terms of the intersection of different sets of transformations fulfilling (II.10), (II.11), or (II.12), respectively, possesses the advantage of never having to consider ''transition amplitudes between states at a fixed moment of time.'' Physical symmetries just preserve the intertwining between $(\mathscr{L},\mathscr{S})$ via Gleason's theorem by transforming $\mathscr{L}$ *and* $\mathscr{S}$ by the same transformation *into itself*.

This fact justifies trying to define symmetries of a history quantum theory by exact analogs of the requirements (II.10)–(II.12), i.e., by replacing

$$\{\mathscr{P}(\mathscr{H});\mathscr{W}_{\mathscr{S}};\mathrm{tr}_{\mathscr{H}}(\alpha\rho)\}\leftrightarrow\{\mathscr{P}(\mathscr{V})\otimes\mathscr{P}(\mathscr{V});\mathscr{X}_{\mathscr{D}};\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\beta X_d)\}. \tag{II.14}$$

This notion of a ''symmetry of a history quantum theory'' does not suffer from the interpretative difficulty mentioned above.

Through this choice, we will build in an invariance requirement for the values $d(\alpha,\beta)$ of the decoherence functional from the very start. Some physical arguments for such a choice can be found in Refs. 4, 11, and 12. I will discuss its relevance at various stages in this paper.

B. Definition and proposition

Definition: A *physical symmetry of a history quantum theory* (PSHQT) is any affine one-to-one map

$$\mathcal{Q}:\mathcal{P}(\mathcal{V})\otimes\mathcal{P}(\mathcal{V})\times\mathcal{X}_{\mathcal{G}}\to\mathcal{P}(\mathcal{V})\otimes\mathcal{P}(\mathcal{V})\times\mathcal{X}_{\mathcal{G}}$$

$$([\alpha\otimes\beta],X_d)\mapsto([\alpha\otimes\beta]^{\mathcal{Q}},X_d^{\mathcal{Q}}) \tag{II.15}$$

that preserves the value of the pairing between history propositions and operators associated with decoherence functionals, i.e.,

$$\mathrm{tr}_{\mathcal{V}\otimes\mathcal{V}}(\alpha\otimes\beta X_d)=\mathrm{tr}_{\mathcal{V}\otimes\mathcal{V}}([\alpha\otimes\beta]^{\mathcal{Q}}X_d^{\mathcal{Q}}). \tag{II.16}$$

We state once again the three requirements such a map has to fulfill:

$$*\mathcal{Q}:\mathcal{P}(\mathcal{V})\otimes\mathcal{P}(\mathcal{V})\to\mathcal{P}(\mathcal{V})\otimes\mathcal{P}(\mathcal{V}), \tag{II.17}$$

$$*\mathcal{Q}:\mathcal{X}_{\mathcal{G}}\to\mathcal{X}_{\mathcal{G}}, \tag{II.18}$$

$$*\mathrm{tr}_{\mathcal{V}\otimes\mathcal{V}}(\alpha\otimes\beta X_d)=\mathrm{tr}_{\mathcal{V}\otimes\mathcal{V}}([\alpha\otimes\beta]^{\mathcal{Q}}X_d^{\mathcal{Q}}). \tag{II.19}$$

Each condition separately determines a set of transformations, but only the intersection of these sets may be called a PSHQT. The word *physical* is chosen since this definition parallels the one for physical symmetries given by Wigner. Again, the history propositions $\alpha\in\mathcal{P}(\mathcal{V})$ *and* the decoherence functionals, represented by $X_d\in\mathcal{X}_{\mathcal{G}}$, are transformed *together* by the same transformation. We call two history quantum theories that are related by a physical symmetry of a history quantum theory *physically equivalent*. Furthermore, as will be shown later, this definition encompasses the notion of ''physical equivalence,'' first introduced and justified through physical arguments by Gell-Mann and Hartle in Ref. 4. It is easy to see that the following Lemma holds.

Lemma: The relation among two history quantum theories (hqt_1,hqt_2) of being *physically equivalent*, denoted by $hqt_1\sim hqt_2$, is an equivalence relation. Thus it is (i) reflexive: $hqt_1\sim hqt_1$, (ii) symmetric: $hqt_1\sim hqt_2\Rightarrow hqt_2\sim hqt_1$, and (iii) transitive: $(hqt_1\sim hqt_2)$ and $(hqt_2\sim hqt_3)\Rightarrow(hqt_1\sim hqt_3)$.

There is an obvious class of transformations on $\mathcal{V}\otimes\mathcal{V}$ that fulfills all three conditions (II.17)–(II.18) stated above:

Definition: A *homogeneous symmetry* on $\mathcal{V}\otimes\mathcal{V}$ is a unitary operator $\hat{U}\otimes\hat{U}$ where $\hat{U}$ may be a unitary or antiunitary operator on $\mathcal{V}$.

Lemma: Every homogeneous symmetry induces a PSHQT, i.e., {HS}⊂{PSHQT}.

Proof: A homogeneous symmetry induces the maps

$$\begin{aligned}\alpha\otimes\beta&\mapsto\hat{U}\otimes\hat{U}[\alpha\otimes\beta]\hat{U}^{\dagger}\otimes\hat{U}^{\dagger},\\ X_d&\mapsto\hat{U}\otimes\hat{U}X_d\hat{U}^{\dagger}\otimes\hat{U}^{\dagger},\end{aligned} \tag{II.20}$$

so that for all $\alpha\otimes\beta\in\mathcal{P}(\mathcal{V})\otimes\mathcal{P}(\mathcal{V})$ and all $X_d\in\mathcal{X}_{\mathcal{G}}$ it holds that

$$d(\alpha,\beta)=\mathrm{tr}_{\mathcal{V}\otimes\mathcal{V}}[(\hat{U}\alpha\hat{U}^{\dagger}\otimes\hat{U}\beta\hat{U}^{\dagger})(\hat{U}\otimes\hat{U}X_d\hat{U}^{\dagger}\otimes\hat{U}^{\dagger})]. \tag{II.21}$$

One can easily check that $\hat{U}\otimes\hat{U}X_d\hat{U}^{\dagger}\otimes\hat{U}^{\dagger}$ fulfills the defining properties for an operator $X_{d'}\in\mathcal{X}_{\mathcal{G}}$ given by the classification theorem. □

Homogeneous symmetries possess a different characterization, which can easily be derived from Wigner's theorem for quantum mechanics. Recall the definition of the map M used in the classification theorem for decoherence functionals:

$$M:\mathscr{V}\otimes\mathscr{V}\to\mathscr{V}\otimes\mathscr{V}$$

$$|u\rangle\otimes|v\rangle\mapsto|v\rangle\otimes|u\rangle, \tag{II.22}$$

for all $|u\rangle,|v\rangle\in\mathscr{V}\otimes\mathscr{V}$. As a result, its action on projection operators of the form $\alpha\otimes\beta$ is given by

$$M(\alpha\otimes\beta)M=(\beta\otimes\alpha),\quad \forall\,\alpha\otimes\beta\in P(\mathscr{V})\otimes P(\mathscr{V}). \tag{II.23}$$

In particular, this holds true for $\alpha,\beta\in\mathscr{R}(\mathscr{V})$, i.e., projection operators belonging to the space $\mathscr{R}(\mathscr{V})$ of rays of $\mathscr{V}$.

Let $\tau=\tau_1\otimes\tau_2$ denote a map

$$\tau:\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})\to\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})$$

$$P_{|\Psi\rangle}\otimes P_{|\Phi\rangle}\mapsto[P_{|\Psi\rangle}\otimes P_{|\Phi\rangle}]^{\tau}:=P_{|\Psi\rangle}^{\tau_1}\otimes P_{|\Phi\rangle}^{\tau_2}, \tag{II.24}$$

where τ_1 and τ_2 denote transformations on the space of pure density operators. A map τ is said to *commute* with M if $(M\circ\tau)[P_{|\Psi\rangle}\otimes P_{|\Phi\rangle}]=(\tau\circ M)[P_{|\Psi\rangle}\otimes P_{|\Phi\rangle}]$ for all elements $P_{|\Psi\rangle}\otimes P_{|\Phi\rangle}\in\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})$, written symbolically as $[\tau, M]=0$.

Definition: A homogeneous symmetry of a history quantum theory (HSHQT) is a one-to-one map $\tau:\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})\to\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})$ that preserves the transition amplitude between two elements, i.e.,

$$\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}([P_{|\Psi_1\rangle}\otimes P_{|\Phi_1\rangle}][P_{|\Psi_2\rangle}\otimes P_{|\Phi_2\rangle}])=\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}([P_{|\Psi_1\rangle}\otimes P_{|\Phi_1\rangle}]^{\tau}[P_{|\Psi_2\rangle}\otimes P_{|\Phi_2\rangle}]^{\tau}),$$

and commutes with the map M, that is $[\tau, M]=0$.

Proposition: Every homogeneous symmetry induces a HSHQT and, conversely, every one-to-one map $\tau:\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})\to\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})$ that preserves orthogonality between the rays and commutes with M is a HSHQT and can be implemented by a unitary or antiunitary operator $\hat{U}\otimes\hat{U}$ on $\mathscr{V}\otimes\mathscr{V}$. Symbolically,

$$\{\mathrm{HSHQT}\}\cong\{\mathrm{HS}\}.$$

Proof: The transition amplitude between two elements $[P_{|\Psi_1\rangle}\otimes P_{|\Phi_1\rangle}],[P_{|\Psi_2\rangle}\otimes P_{|\Phi_2\rangle}]\in\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})$ is given by

$$\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}([P_{|\Psi_1\rangle}\otimes P_{|\Phi_1\rangle}][P_{|\Psi_2\rangle}\otimes P_{|\Phi_2\rangle}])=\mathrm{tr}_{\mathscr{V}}(P_{|\Psi_1\rangle}P_{|\Psi_2\rangle})\mathrm{tr}_{\mathscr{V}}(P_{|\Phi_1\rangle}P_{|\Phi_2\rangle}). \tag{II.25}$$

Therefore, by Wigner's theorem, all transformations preserving orthogonality and the transition amplitude can be implemented by operators $\hat{U}\otimes\hat{V}$, where $\hat{U}$ and $\hat{V}$ are either unitary or antiunitary operators on $\mathscr{V}$. Requiring these transformations to commute with M concludes the proof. □

Remark: It is important to understand why only transformations of the form $\hat{U}\otimes\hat{U}$ are admitted, and not, for example, operators of the form

$$\sum_i c_i\hat{U}_i\otimes\hat{U}_i,\quad \sum_i c_i=1,\quad c_i\in\mathbb{R}. \tag{II.26}$$

The reason is that, starting from $d(\alpha,\beta)$, only those transformations $\tilde{T}:\alpha\otimes\beta\mapsto\tilde{T}(\alpha\otimes\beta)\tilde{T}^{\dagger}$ on $\mathscr{V}\otimes\mathscr{V}$ are allowed for which

$$\tilde{T}(\alpha\otimes\beta)\tilde{T}^{\dagger}=\alpha'\otimes\beta'. \tag{II.27}$$

It is possible for these transformations only to write them as $d(\alpha,\beta)\mapsto d'(\alpha',\beta')$.

We have therefore established the following relation among the three sets of transformations:

$$\{\text{HSHQT}\}\cong\{\text{HS}\}\subset\{\text{PSHQT}\}. \tag{II.28}$$

We argued that PSHQTs determined by conditions (II.17)–(II.19) is an appropriate notion for symmetries of history quantum theories. What we want to show now is that all PSHQTs are given by homogeneous symmetries of the form $\hat{U}\otimes\hat{U}$. In view of (II.28) it remains to be shown that $\{\text{HS}\}\supset\{\text{PSHQT}\}$.

C. The structure of $\mathscr{D}$

In order to show that all PSHQTs can be characterized by means of rays in $\mathscr{R}(\mathscr{V})\otimes\mathscr{R}(\mathscr{V})$, we have to discuss in more detail the structure of the space of decoherence functionals. Comparison with the case in standard quantum mechanics shows that what we now have to look for is a notion of ''elementary decoherence functionals,'' out of which all other decoherence functionals can be built by a certain superposition. The requirement (II.19) for PSHQT,

$$\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\beta X_d)=\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}([\alpha\otimes\beta]^{\mathbb{C}}X_d^{\mathbb{C}}),$$

can then be reduced to a requirement that has to hold only for all elementary decoherence functionals. We start our investigation with the following observation:

Lemma: For any finite set $\{d^{(i)}\}_{i=1}^{n}$, $d^{(i)}\in\mathscr{D}$, it holds that $d:=\Sigma_i r_i d^{(i)}\in\mathscr{D}, r_i\in\mathbb{R}$, provided that

$$r_i\in\mathbb{R}\quad\forall i\in\{1,2,\ldots,n\},$$

$$\sum_i r_i d^{(i)}(\alpha,\alpha)\geqslant 0\quad\forall\alpha\in\mathscr{UP}, \tag{II.29}$$

$$\sum_i r_i=1.$$

These conditions reflect the requirements for d of Hermiticity, positivity, and normalization. We call such superpositions of decoherence functionals a *weak convex combination* of decoherence functionals. All convex combinations are weak convex combinations, but the converse is not true. For a convex combination it is required that $r_i\geqslant 0$; the second condition in (II.29) does not imply $r_i\geqslant 0$. It seems natural to look for so-called ''pure decoherence functionals'' which can not be written as weak convex combination of other decoherence functionals. An argument first given by N. Linden[13] shows that *any* decoherence functional can be written as the sum of two other decoherence functionals. Thus there can be no pure decoherence functionals. Nonetheless, in this context we are only interested in a convenient expansion of an arbitrary decoherence functional by what I will call *elementary decoherence functionals*. This will suffice to prove an analog of Wigner's theorem in the next section. I will show explicitly how these elementary decoherence functionals reflect Linden's argument. The same notions apply *mutatis mutandis* for the associated operators $X_d\in\mathscr{X}_{\mathscr{D}}$.

By the classification theorem[8] we know that for every decoherence functional $d\in\mathscr{D}$ its associated operator X_d can be written as a sum of two self-adjoint operators $X_d=X_1+iX_2$ subject to the conditions

$$X_1=MX_1M;\quad X_2=-MX_2M;\quad \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\alpha X_1)\geqslant 0;\quad \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(X_1)=1. \tag{II.30}$$

We seek an expansion for the real part X_1 and the imaginary part X_2 of X_d as a weak convex combination of decoherence functionals d^e that can not be written as a weak convex combination.

Proposition: For each $X=X_1+iX_2\in\mathscr{X}_{\mathscr{D}}$ there exist two orthonormal bases (ONB) $\{|e_i\rangle\}$ and $\{|b_i\rangle\}$ on $\mathscr{V}$ such that X can be written as

$$X=\sum_{i,j}\lambda_{ij}X_1^{(ij)}+i\sum_{l,m}\kappa_{lm}X_2^{[lm]}, \tag{II.31}$$

where

$$X_1^{(ij)}=\tfrac{1}{2}(P_{|e_i\rangle}\otimes P_{|e_j\rangle}+P_{|e_j\rangle}\otimes P_{|e_i\rangle});$$
$$\lambda_{ij}=\lambda_{ji},\quad \sum_{i,j}\lambda_{ij}=1,\quad \sum_{i,j}a_{ii}\lambda_{ij}a_{jj}\geqslant 0,\quad \lambda_{ij}\in\mathbb{R}, \tag{II.32}$$

and

$$X_2^{[lm]}=\tfrac{1}{2}(P_{|b_l\rangle}\otimes P_{|b_m\rangle}-P_{|b_m\rangle}\otimes P_{|b_l\rangle});$$
$$\kappa_{lm}=-\kappa_{ml},\quad \kappa_{lm}\in\mathbb{R}. \tag{II.33}$$

Remark: The positivity requirement $\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\alpha X_1)\geqslant 0$ gives rise to the condition $\Sigma_{i,j}a_{ii}\lambda_{ij}a_{jj}\geqslant 0$ for an arbitrary projector $\alpha=\Sigma_{ij}a_{ij}|e_i\rangle\langle e_j|$ on $\mathscr{V}$ when expanded in the basis $\{|e_i\rangle\langle e_j|\}$.

Proof: The proof is a constructive one; it follows the proof of the classification theorem in Ref. 8.

For each $\alpha\in\mathscr{P}(\mathscr{V})$ define a function $d_\alpha(\beta)\colon\mathscr{P}(\mathscr{V})\to\mathbb{C}$ where $d_\alpha(\beta):=d(\alpha,\beta)$. Let $\mathfrak{R}d_\alpha$ and $\mathfrak{T}d_\alpha$ denote the real and imaginary parts of d_α, so that

$$d_\alpha(\beta)=\mathfrak{R}d_\alpha(\beta)+i\mathfrak{T}d_\alpha(\beta) \tag{II.34}$$

with $\mathfrak{R}d_\alpha(\beta)\in\mathbb{R}$ and $\mathfrak{T}d_\alpha(\beta)\in\mathbb{R}$. We will develop the argument only for the real part $\mathfrak{R}d_\alpha(\beta)$. The biadditivity condition on the $d\in\mathscr{D}$ requires that $\mathfrak{R}d_\alpha(\beta_1\oplus\beta_2)=\mathfrak{R}d_\alpha(\beta_1)+\mathfrak{R}d_\alpha(\beta_2)$ for any orthogonal pair of projectors β_1 and β_2. Since d is assumed to be bounded, the same holds true for its real part $\mathfrak{R}d_\alpha$. For any $r\in\mathbb{R}$, the quantity

$$\kappa_r(\beta):=r\ \dim(\beta)=r\ \mathrm{tr}(\beta) \tag{II.35}$$

is a real additive function of β, and hence so are $\mathfrak{R}d_\alpha+\kappa_r$ for any $r\in\mathbb{R}$.

In Ref. 8 it was shown that there exists for each $\alpha\in\mathscr{P}(\mathscr{V})$ two real numbers $r_\alpha,\mu_a\in\mathbb{R}$ such that there exists a density operator $\rho_\alpha^{\mathfrak{R}}$ on $\mathscr{V}$ for which it holds that

$$\mathfrak{R}d_\alpha(\beta)=\mathrm{tr}_{\mathscr{V}}\left(\left(\frac{1}{\mu_\alpha}\rho_\alpha^{\mathfrak{R}}-r_\alpha\right)\beta\right)=\mathrm{tr}_{\mathscr{V}}(Y_\alpha^{\mathfrak{R}}\beta), \tag{II.36}$$

where $Y_\alpha^{\mathfrak{R}}:=(1/\mu_\alpha)\rho_\alpha^{\mathfrak{R}}-r_\alpha$. Since $\rho_\alpha^{\mathfrak{R}}$ is a density operator, there exists an orthonormal basis $\{|e_i\rangle\}_{i=1}^{\dim\mathscr{V}}$ and positive numbers $w_\alpha^i\in\mathbb{R}$ such that $\rho_\alpha^{\mathfrak{R}}=\Sigma_i w_\alpha^i P_{|e_i\rangle}$ and therefore

$$Y_\alpha^{\mathfrak{R}}=\sum_i\left(\frac{w_\alpha^i}{\mu_a}-r_\alpha\right)P_{|e_i\rangle}. \tag{II.37}$$

The additivity condition $d(\alpha_1\oplus\alpha_2,\beta)=d(\alpha_1,\beta)+d(\alpha_2,\beta)$ implies that

$$\mathrm{tr}_{\mathscr{V}}(Y_{\alpha_1\oplus\alpha_2}^{\mathfrak{R}}\beta)=\mathrm{tr}_{\mathscr{V}}(Y_{\alpha_1}^{\mathfrak{R}}\beta)+\mathrm{tr}_{\mathscr{V}}(Y_{\alpha_2}^{\mathfrak{R}}\beta), \tag{II.38}$$

which, since it is true for all $\beta \in \mathscr{P}(\mathscr{V})$ (and hence for all operators on $\mathscr{V}$), implies that the operator-valued map $\alpha \mapsto Y_\alpha^{\mathfrak{R}}$ is itself additive in the sense that

$$Y_{\alpha_1 \oplus \alpha_2}^{\mathfrak{R}} = Y_{\alpha_1}^{\mathfrak{R}} + Y_{\alpha_2}^{\mathfrak{R}} \tag{II.39}$$

for all disjoint pairs of projectors α_1 and α_2 on the Hilbert space $\mathscr{V}$.

Let $\{|c_i\rangle\}_{i=1}^{\dim \mathscr{V}}$ be an orthonormal basis of $\mathscr{V}$; let $\{\langle c_i|\}_{i=1}^{\dim \mathscr{V}}$ denote its dual basis. Let $\{B_{ij} := |c_i\rangle\langle c_j|;\ i,j=1,2,\ldots,N\}$ be a vector-space basis for the operators on $\mathscr{V}$, so that the operators $Y_\alpha^{\mathfrak{R}}$ can be expanded as $Y_\alpha^{\mathfrak{R}} = \Sigma_{i,j=1} y_{ij}^{\mathfrak{R}}(\alpha) B_{ij}$. Then relation (II.39) shows that the complex expansion coefficients $y_{ij}^{\mathfrak{R}}(\alpha)$, $i,j=1,2,\ldots,\dim \mathscr{V}$, must satisfy the additivity condition:

$$y_{ij}^{\mathfrak{R}}(\alpha_1 \oplus \alpha_2) = y_{ij}^{\mathfrak{R}}(\alpha_1) + y_{ij}^{\mathfrak{R}}(\alpha_2). \tag{II.40}$$

Since $Y_\alpha^{\mathfrak{R}}$ is a bounded operator, its expansion coefficient functions $\alpha \mapsto y_{ij}^{\mathfrak{R}}(\alpha) \forall\, \alpha \in \mathscr{P}(\mathscr{V})$ are bounded as well. It was shown[8] that there exists an operators $\Lambda_{ij}^{\mathfrak{R}}$ on $\mathscr{V}$ such that

$$y_{ij}(\alpha) = \mathrm{tr}_{\mathscr{V}}(\alpha \Lambda_{ij}^{\mathfrak{R}}), \tag{II.41}$$

and therefore

$$Y_\alpha = \sum_{i,j=1}^{N} \mathrm{tr}_{\mathscr{V}}(\alpha \Lambda_{ij}^{\mathfrak{R}}) B_{ij}. \tag{II.42}$$

In particular,

$$\mathfrak{R}d(\alpha,\beta) = \mathrm{tr}_{\mathscr{V}}\left\{ \sum_{i,j} (\mathrm{tr}_{\mathscr{V}}(\alpha \Lambda_{ij}^{\mathfrak{R}})) B_{ij} \beta \right\} = \sum_{i,j} \mathrm{tr}_{\mathscr{V}}(\alpha \Lambda_{ij}^{\mathfrak{R}}) \mathrm{tr}_{\mathscr{V}}(B_{ij}\beta). \tag{II.43}$$

We define an operator $X^{\mathfrak{R}}$ on $\mathscr{V} \otimes \mathscr{V}$ by

$$X^{\mathfrak{R}} := \sum_{ij} \Lambda_{ij}^{\mathfrak{R}} \otimes B_{ij}, \tag{II.44}$$

for which it holds that $\mathfrak{R}d(\alpha,\beta) = \mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha \otimes \beta X^{\mathfrak{R}})$.

From now on we choose the particular set of $\{|e_i\rangle\}$ of eigenvectors of the operator $\rho_\alpha^{\mathfrak{R}}$ as an orthonormal basis for $\mathscr{V}$, i.e., $B_{ij} = |e_i\rangle\langle e_j|$. As an operator on $\mathscr{V}$, $\Lambda_{ij}^{\mathfrak{R}}$ possesses an expansion

$$\Lambda_{ij}^{\mathfrak{R}} = \sum_{k,l} \lambda_{kl}^{ij} B_{kl}, \tag{II.45}$$

so that

$$X^{\mathfrak{R}} = \sum_{i,j,k,l} \lambda_{kl}^{ij} B_{kl} \otimes B_{ij}. \tag{II.46}$$

However, from Eq. (II.37) we see that, by using the basis $\{|e_i\rangle\}$, this sum reduces to

$$X^{\mathfrak{R}} = \sum_{i,k,l} \lambda_{kl}^{ii} B_{kl} \otimes b_{ii}, \tag{II.47}$$

since only the $B_{ii} = P_{|e_i\rangle}$ appear in the expansion of $Y_\alpha^{\mathfrak{R}}$.

Remember now that $X^{\mathfrak{R}}$ stands for the real part X_1 of X_d, the operator associated with a decoherence functional $d \in \mathscr{D}$. As such it has to fulfill that

$$X^{\mathfrak{R}} = M X^{\mathfrak{R}} M, \tag{II.48}$$

where M was defined through the action $M(A \otimes B)M = (B \otimes A)$ for arbitrary operators A and B on $\mathscr{V}$. This requirement is strong enough to reduce (II.47) to

$$X^{\mathfrak{R}} = \sum_{i,k} \lambda^{ii}_{kk} B_{kk} \otimes B_{ii}\,. \tag{II.49}$$

Since $B_{ii} = |e_i\rangle\langle e_i| = P_{|e_i\rangle}$, we see that the real part $X^{\mathfrak{R}} \equiv X_1$ of the operator X_d associated with a decoherence functional $d \in \mathscr{D}$ can be written as

$$X_1 \equiv X^{\mathfrak{R}} = \sum_{i,j} \lambda_{ij} P_{|e_1\rangle} \otimes P_{|e_j\rangle}\,, \tag{II.50}$$

where $\lambda_{ij} := \lambda^{ii}_{jj}$. It is easy to see that these coefficients must obey

$$\lambda_{ij} = \lambda_{ji}\,, \quad \sum_{i,j} \lambda_{ij} = 1, \quad \sum_{i,j} a_{ii} \lambda_{ij} a_{jj} \geqslant 0, \tag{II.51}$$

which follow from the requirements of Hermiticity, normalization, and positivity. The $a_{ii} \in \mathbb{R}$ are expansion coefficients of an arbitrary projector $\alpha = \Sigma_{ij} a_{ij} |e_i\rangle\langle e_j|$ on $\mathscr{V}$ when expanded in the basis $\{|e_i\rangle\langle e_j|\}$.

Note that the operators $P_{|e_i\rangle} \otimes P_{|e_j\rangle}$ are not themselves operators associated with decoherence functionals. They do not obey the $X^{\dagger} = MXM$ requirement. By defining

$$X_1^{(ij)} := \tfrac{1}{2}(P_{|e_i\rangle} \otimes P_{|e_j\rangle} + P_{|e_j\rangle} \otimes P_{|e_i\rangle}), \tag{II.52}$$

we see that $X_1^{(ij)}$ is an operator that can be associated with a decoherence functional. This concludes the proof of the proposition for the real part.

By the same procedure we obtain the expansion (II.33) for the imaginary part X_2 of X_d in terms of projectors $P_{|b_i\rangle}$ for a different orthonormal basis $\{|b_i\rangle\}$. This concludes the proof. □

Note that the imaginary part X_2 in itself is not an operator that can be associated with a $d \in \mathscr{D}$. Thus, we have shown the following Corollary.

Corollary: There exists a one-to-one correspondence between elementary decoherence functionals $d^e \in \mathscr{D}$ and operators $X_{d^e} \in \mathscr{X}_{\mathscr{D}}$ which are given by the following expression:

$$X^{(ij)[lm]}_{d^e} = X_1^{(ij)} + i \kappa_{lm} X_2^{[lm]}, \quad \kappa_{lm} \in \mathbb{R}, \tag{II.53}$$

where the operators $X_1^{(ij)}$ and $X_2^{[lm]}$ are defined as above. Note that there is no sum over repeated indices.

We have thus shown that every decoherence functional can be written as a weak convex combination of elementary decoherence functionals. I now want to show why these X_{d^e} must not be called ''pure decoherence functionals.''

We show that every elementary decoherence functional can be written as the sum of two decoherence functionals as follows. Due to the fact that the imaginary part X_2' of an operator $X' \in \mathscr{X}_{\mathscr{D}}$ associated with arbitrary decoherence functional $d' \in \mathscr{D}$ can be added to the operator X_{d^e} associated with an elementary decoherence functional $d^e \in \mathscr{X}_{\mathscr{D}}$ to produce a new decoherence functional, one can calculate that

$$X_{d^e} = \tfrac{1}{2}(X_{d^e} + iX_2') + \tfrac{1}{2}(X_{d^e} - iX_2'). \tag{II.54}$$

Both terms $(X_{d^e} + iX_2')$ and $(X_{d^e} - iX_2')$ in this expression are proper decoherence functionals, even though iX_2' in itself is *not* a decoherence functional. Thus, elementary decoherence functionals are not pure, but they still account for the simplest expansion of an arbitrary decoherence functional and this is all that is needed for the proof of the analog of Wigner's theorem.

We have now all the tools at hand to prove the following theorem.

III. AN ANALOG OF WIGNER'S THEOREM

Recall that, up to this point, we know about the following relation between the sets of ''homogeneous symmetries of a history quantum theory, ''homogeneous symmetries,'' and ''physical symmetries of a history quantum theory:''

$$\{\text{HSHQT}\} \cong \{\text{HS}\} \subset \{\text{PSHQT}\}. \tag{III.1}$$

We are now going to show that the sets {HS} and {PSHQT} are identical.

A. The theorem

Theorem: There exists a one-to-one correspondence between homogeneous symmetries and physical symmetries of history quantum theories. Thus each PSHQT is given by an operator $\hat{U} \otimes \hat{U}$ and induces a HSHQT; conversely, every one-to-one map τ: $\mathscr{R}(\mathscr{V}) \otimes \mathscr{R}(\mathscr{V}) \to \mathscr{R}(\mathscr{V}) \otimes \mathscr{R}(\mathscr{V})$ that preserves orthogonality between the rays and commutes with M can be implemented by a unitary operator $\hat{U} \otimes \hat{U}$ on $\mathscr{V} \otimes \mathscr{V}$, where $\hat{U}$ may be unitary or antiunitary.

Proof: We will first look for one-to-one maps which leave invariant the pairing between history propositions and decoherence functionals and map the set of rays into itself, *and then* restrict those transformations to homogeneous symmetries via the condition that they must map $\mathscr{X}_{\mathscr{D}}$ into itself.

We first consider the invariance requirement for the values of $d(\alpha,\beta)$. This has to hold true for *all* decoherence functionals. In particular, for the functionals $X_1^{(ij)}$ the relevant number is

$$2\,\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha \otimes \beta X_1^{(ij)}) = \mathrm{tr}_{\mathscr{V}}(\alpha P_{|e_i\rangle})\mathrm{tr}_{\mathscr{V}}(\alpha P_{|e_j\rangle}) + \mathrm{tr}_{\mathscr{V}}(\alpha P_{|e_j\rangle})\mathrm{tr}_{\mathscr{V}}(\beta P_{|e_i\rangle}), \tag{III.2}$$

for some ONB $\{|e_i\rangle\}$ of $\mathscr{V}$.

Recall that the requirement of the invariance of the imaginary part of a decoherence functional leads us to consider

$$2\,\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha \otimes \beta X_2^{[ij]}) = \mathrm{tr}_{\mathscr{V}}(\alpha P_{|b_i\rangle})\mathrm{tr}_{\mathscr{V}}(\beta P_{|b_j\rangle}) - \mathrm{tr}_{\mathscr{V}}(\alpha P_{|b_j\rangle})\mathrm{tr}_{\mathscr{V}}(\beta P_{|b_i\rangle}), \tag{III.3}$$

for some ONB $\{|b_i\rangle\}$ of $\mathscr{V}$.

Therefore, considering those decoherence functionals X_d for which $|b_i\rangle = |e_i\rangle$ for all $i \in \{1,2,\ldots,\dim \mathscr{V}\}$, and $\lambda_{ij} = \kappa_{ij}$ for all $i,j \in \{1,2,\ldots,\dim \mathscr{V}\}$, we see that the invariance requirement amounts to requiring that

$$\mathrm{tr}_{\mathscr{V}}(\alpha P_{|e_i\rangle})\mathrm{tr}_{\mathscr{V}}(\beta P_{|e_j\rangle}) \tag{III.4}$$

should remain invariant under the appropriate transformations. At first we take the case when $\alpha \otimes \beta \in \mathscr{R}(\mathscr{V}) \otimes \mathscr{R}(\mathscr{V})$. By Wigner's theorem, the transformations leaving (III.4) invariant are given by operators $\hat{U} \otimes \hat{V}$ whereby $\hat{U}$ and $\hat{V}$ are unitary or antiunitary operators on $\mathscr{V}$. Even though these transformations leave the value of $d(\alpha,\beta)$ invariant, they do not comply with the condition of mapping the set $\mathscr{X}_{\mathscr{D}}$ into itself.

To see this, recall that an element $X_d \in \mathscr{X}_{\mathscr{D}}$ is required to satisfy the condition $X_d^\dagger = MX_dM$, which is equivalent to $X_1^{(ij)} = MX_1^{(ij)}M$ and $X_2^{[ij]} = -MX_2^{[ij]}M$. Consider the following particular decoherence functional $X_1^{(ii)}$ under such a mapping:

$$\mathscr{X}_{\mathscr{D}} \ni P_{|e_i\rangle} \otimes P_{|e_i\rangle} \mapsto P^{\hat{U}}_{|e_i\rangle} \otimes P^{\hat{V}}_{|e_i\rangle}. \tag{III.5}$$

Since

$$M[P^{\hat{U}}_{|e_i\rangle} \otimes P^{\hat{V}}_{|e_i\rangle}]M \neq P^{\hat{U}}_{|e_i\rangle} \otimes P^{\hat{V}}_{|e_i\rangle}, \tag{III.6}$$

we see that its image under the map $\hat{U} \otimes \hat{V}$ does not belong to $\mathscr{X}_{\mathscr{D}}$. To comply with this requirement we need to require that $[\hat{U} \otimes \hat{V}, M] = 0$, i.e., consider only those operators of the form $\hat{U} \otimes \hat{U}$.

What is now left to show is that there can be no other transformations obeying conditions (II.17)–(II.19), even if we allow for arbitrary transformations $G = (G_0, G_0)$:

$$G: \mathscr{P}(\mathscr{V}) \otimes \mathscr{P}(\mathscr{V}) \to \mathscr{P}(\mathscr{V}) \otimes \mathscr{P}(\mathscr{V})$$

$$\alpha \otimes \beta \mapsto \alpha^{G_0} \otimes \beta^{G_0}. \tag{III.7}$$

The argument is much the same as in the standard quantum mechanical case: consider a transformation $G = (G_0, G_0)$ that maps a one-dimensional projector $\alpha \in \mathscr{P}(\mathscr{V})$ into $\alpha^{G_0} \in \mathscr{P}(\mathscr{V})$, an m-dimensional one, $m > 1$. Therefore,

$$\alpha \otimes \alpha \mapsto \alpha^{G_0} \otimes \alpha^{G_0}.$$

It is easy to see that there exists a $d \in \mathscr{D}$ such that $X_d = \alpha \otimes \alpha$ (see also Ref. 14). However, since $\mathrm{tr}_{\mathscr{V} \otimes \mathscr{V}}(\alpha^{G_0} \otimes \alpha^{G_0}) = m^2$, there exists no decoherence functional $d^{G_0} \in \mathscr{D}$ for which $\alpha^{G_0} \otimes \alpha^{G_0}$ is the associated operator $X_{d^{G_0}}$. This concludes the proof. □

B. Discussion

The result of the theorem shows that every PSHQT can be induced by a unitary or antiunitary operator $\hat{U}$ on $\mathscr{V}$ as follows:

$$\begin{aligned} \mathscr{UP}: \quad & \alpha \mapsto \tilde{\alpha} := \hat{U} \alpha \hat{U}^\dagger, \\ \mathscr{D}: \quad & X_d \mapsto X_{\tilde{d}} := \tilde{X}_d \equiv \hat{U} \otimes \hat{U} X_d \hat{U}^\dagger \otimes \hat{U}^\dagger. \end{aligned} \tag{III.8}$$

As a consequence of this transformation, the invariance

$$d(\alpha, \beta) = \tilde{d}(\tilde{\alpha}, \tilde{\beta}) \tag{III.9}$$

for all $d \in \mathscr{D}$ and all $\alpha, \beta \in P(\mathscr{V})$ follows by the property of the trace.

By looking at the definition for a PSHQT from which this theorem arose, it seems rather unnecessary to proceed via the use of elementary decoherence functionals. We could have started immediately by looking for all transformations obeying condition (II.17); then, restrict to those which map $\mathscr{X}_{\mathscr{D}}$ into itself. However, since it was not known to which extent $\mathscr{X}_{\mathscr{D}}$ can accommodate more general transformations G on $\mathscr{P}(\mathscr{V})$, it seems a sensible way to follow this hybrid path. In particular, we circumvented the problem of specifying all transformations that map $\mathscr{X}_{\mathscr{D}}$ into itself.

A central requirement in the proof of the theorem was the invariance of the value $d(\alpha, \beta) \in \mathbb{C}$ for all pairs $\alpha, \beta \in \mathscr{P}(\mathscr{V})$. A closer inspection reveals that the existence of *complex*-valued functionals makes it possible to reduce the invariance requirement to the form (III.4). However, it is

neither necessary to consider *complex*-valued functionals nor to require invariance for *all* pairs (α,β). We can investigate the possibility of softening the invariance requirement to hold only for the ''diagonal'' values of $d\in\mathscr{D}$, i.e., $d(\alpha,\alpha)$. Then we are led to the condition that

$$\mathrm{tr}_{\mathscr{T}\otimes\mathscr{T}}(\alpha\otimes\alpha X_1^{(ij)})=\mathrm{tr}_{\mathscr{T}}(\alpha P_{|e_i\rangle})\mathrm{tr}_{\mathscr{T}}(\alpha P_{|e_j\rangle}) \tag{III.10}$$

has to remain invariant. In this case we see that we will end up with the same transformations $\hat{U}\otimes\hat{U}$ on $\mathscr{T}\otimes\mathscr{T}$ as requiring $d(\alpha,\beta)$ to remain invariant for *all* pairs (α,β). This is due to the fact that restricting to projectors of the form $\alpha\otimes\alpha$ can be formulated with the aid of the same operator M which is used to formulate the defining property $X^\dagger=MXM$ for decoherence functionals. Therefore, the requirement on the diagonal part only is strong enough to enforce it onto the value of d on any pair (α,β).

The particular feature of physical symmetries of history quantum theories is their property of being implemented by a unitary or antiunitary operator $\hat{U}$ on $\mathscr{T}$. As a consequence, each partition of the unit operator in $\mathscr{T}$ into mutually orthogonal projectors, that is a set of projectors $\{\alpha_i\}$, such that

$$\{\alpha_i\}_{i=1}^{m\leqslant\dim\mathscr{T}},\quad \oplus_{i=1}^m\alpha_i=1, \tag{III.11}$$

is mapped into another partition of unity. In particular, the cardinality of this set is preserved. Now, much emphasis in the decoherent histories approach is placed on finding consistent sets of history propositions with respect to a particular decoherence functional $d\in\mathscr{D}$. In the formalism used here, consistent sets are naturally associated with particular partitions of unity,[14] namely those for which it holds that

$$d(\alpha_i,\alpha_j)=\delta_{ij}d(\alpha_i,\alpha_i)\quad\forall i,j\in\{1,2,\ldots,m\}. \tag{III.12}$$

We see therefore that a PSHQT will always map consistent sets into sets of the *same* cardinality. There has been some discussion[11,12] whether or not one should allow for transformations between consistent sets of different cardinality. We see that, at least in this context, this possibility is excluded if one agrees on the definition of PSHQT presented in this article.

C. Physical symmetries of history quantum mechanics

The main aim of this section is to show that the notion of ''physical equivalence,'' introduced in Ref. 4, is—when expressed in this formalism—a particular example of a physical symmetry of history quantum mechanics. It also serves the purpose of providing the explicit form of the decoherence functional for this theory.

Remember that, for standard quantum mechanics when looked at from the perspective of the history program, the space of history propositions $\alpha\in\mathscr{UP}$ is given by projectors $\alpha\in\mathscr{P}(\mathscr{V}_n)=\mathscr{P}(\otimes_{i=1}^n\mathscr{H}_{t_i})$. The particular decoherence functional is associated with an operator

$$X_{(H,\rho_{t_0},\rho_{t_f})}=\frac{1}{\mathrm{tr}_{\mathscr{H}}(\rho_{t_0}\rho_{t_f}(t_f))}\,\tilde{X}_{(H,\rho_{t_0},\rho_{t_f})} \tag{III.13}$$

on $\mathscr{V}_n\otimes\mathscr{V}_n$, where I also have inserted a final density operator at time t_f. When evaluated on homogeneous projectors $\alpha_h=\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$, the value of $d_{(H,\rho_{t_0},\rho_{t_f})}(\alpha_h,\beta_h)$ is given by

$$d_{(H,\rho_{t_0},\rho_{t_f})}(\alpha_h,\beta_h)=\frac{1}{\mathrm{tr}_{\mathscr{H}}(\rho_{t_0}\rho_{t_f}(t_f))}\,\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha_h\otimes\beta_h\widetilde{X}_{(H,\rho_{t_0},\rho_{t_f})})$$

$$=\frac{1}{\mathrm{tr}_{\mathscr{H}}(\rho_{t_0}\rho_{t_f}(t_f))}\,\mathrm{tr}_{\mathscr{H}}(\widetilde{C}^{\dagger}_{\alpha_h}\rho_{t_0}\widetilde{C}_{\beta_h}\rho_{t_f}(t_f)),\tag{III.14}$$

which coincides with the form of the decoherence functional usually employed in the histories approach. However, note once again that $d_{(H,\rho_{t_0},\rho_{t_f})}(\alpha,\beta)$ is defined *for all* $\alpha,\beta\in\mathscr{P}(\mathscr{V})$. By following the procedure outlined in Ref. 8, one shows that the operator $\widetilde{X}_{(H,\rho_{t_0},\rho_{t_f})}$ is given by

$$\begin{aligned}\widetilde{X}_{(H,\rho_{t_0},\rho_{t_f})}=&[U(t_1,t_0)^{\dagger}\rho_{t_0}U(t_1,t_0)\otimes U(t_2,t_1)^{\dagger}\otimes\cdots\otimes U(t_n,t_{n-1})^{\dagger}]\\&\otimes[U(t_2,t_1)\otimes U(t_3,t_2)\otimes\cdots\otimes U(t_n,t_{n-1})\otimes U(t_f,t_n)\rho_{t_f}U(t_f,t_n)^{\dagger}]\\&\times(R_{(n)}\otimes 1_{t_1}\otimes 1_{t_2}\otimes\cdots\otimes 1_{t_n})S_{(2n)}(R_{(n)}\otimes 1_{t_1}\otimes 1_{t_2}\otimes\cdots\otimes 1_{t_n}).\end{aligned}\tag{III.15}$$

The last three lines involve universal operators $R_{(n)}$ and $S_{(2n)}$ that arise by rewriting products of operators in terms of tensor-products.[8] Thus they are system independent. This operator is defined on $\mathscr{V}_n\otimes\mathscr{V}_n$ and encodes the initial and final density operators as well as the dynamical evolution in the form of the evolution operator $U(t_i,t_{i-1})$. This is the purest description of the content of the decoherence functional one can write down. It has a very transparent form.

Recall[4] that ''two triples $(\{C_\alpha\},H,\rho)$ and $(\{\widetilde{C}_\alpha\},\widetilde{H},\widetilde{\rho})$ are called 'physically equivalent' if there are fields and conjugate momenta $(\Phi(x),\pi(x))$ and $(\Phi(x),\widetilde{\pi}(x))$, respectively, in which the triples' histories, Hamiltonian, and initial condition take the same form.'' As an example, the explicit transformation $(\alpha_{t_i}(t_i)\mapsto V\alpha_{t_i}(t_i)V^{\dagger},H\mapsto VHV^{\dagger},\rho\mapsto V\rho V^{\dagger})$ for a fixed unitary operator V on $\mathscr{H}$ was shown to lead to physically equivalent triples.

Remark: In order not to use the same symbol twice, I used the notation V instead of U as in Ref. 4 for the unitary operator; in the context of history quantum mechanics $U(t_i,t_{i-1})$ already denotes the evolution operator.

First, notice that a transformation of the Heisenberg projection operators

$$\alpha_{t_i}(t_i)\mapsto V\alpha_{t_i}(t_i)V^{\dagger}\quad\forall i\in\{1,2,\ldots,n\}\tag{III.16}$$

is identical to the transformation

$$\alpha_{t_i}(t_i)\mapsto VU(t_i,t_0)V^{\dagger}[V\alpha_{t_i}V^{\dagger}]VU(t_i,t_0)V^{\dagger},\quad\forall i\in\{1,2,\ldots,n\}\tag{III.17}$$

that is a pair of transformations

$$\alpha_{t_i}\mapsto V\alpha_{t_i}V^{\dagger}\quad\forall i\in\{1,2,\ldots,n\};\quad H\mapsto VHV^{\dagger},\tag{III.18}$$

where the α_{t_i} denote the Schrödinger projection operators. This is important since in the formalism used here only a string $\alpha_h=\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ of *Schrödinger projection operators* corresponds to a homogeneous history proposition $\alpha_h\in\mathscr{UP}=\mathscr{P}(\mathscr{V}_n)$. Now, defining the unitary operator $\hat{U}_V:=V\otimes V\otimes\cdots\otimes V$, n times, remembering that $\rho\mapsto V\rho V^{\dagger}$ and that the decoherence functional is given by Eq. (III.15), we see that the effect of this transformations on $\widetilde{X}_{(H,\rho_{t_0},\rho_{t_f})}$ is given by $\widetilde{X}_{(H,\rho_{t_0},\rho_{t_f})}\mapsto(\hat{U}_V\otimes\hat{U}_V)\widetilde{X}_{(H,\rho_{t_0},\rho_{t_f})}(\hat{U}_V^{\dagger}\otimes\hat{U}_V^{\dagger})$. Thus, this transformation between physically equivalent triples can be described as follows:

The transformation of the history propositions $\alpha_h \in \mathscr{P}(\mathscr{V}_n)$ as well as the operator $X_{(H,\rho_{t_0},\rho_{t_f})}$ by a unitary $\hat{U}_V \in B(\mathscr{V}_n)$ clearly leaves invariant the values of $d(\alpha_h,\beta_h)$ since

$$d(\alpha_h,\beta_h)=\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}[(\hat{U}_V\alpha_h\hat{U}_V^\dagger\otimes\hat{U}_V\beta_h\hat{U}_V^\dagger)(\hat{U}_V\otimes\hat{U}_V X_{(H,\rho_{t_0},\rho_{t_f})}\hat{U}_V^\dagger\otimes\hat{U}_V^\dagger)], \qquad \text{(III.19)}$$

which is the definition of physical symmetry of a history quantum theory for which $\mathscr{UP}=P(\mathscr{V}_n)$. Note that, in general, not all unitary operators $\hat{U}$ on $\mathscr{V}_n$ need to be of the form $\hat{U}_V$ for a unitary operator V on the single-time Hilbert space $\mathscr{H}$.

IV. SUMMARY AND OUTLOOK

In this article we proposed a notion of a ''homogeneous symmetry'' (HS) and of a ''physical symmetry of a history quantum theory'' (PSHQT). We proved an analog of Wigner's theorem which states that there exists a one-to-one correspondence between both HS and PSHQT. It has been shown that each PSHQT can be induced by a unitary or antiunitary operator $\hat{U}$ on $\mathscr{V}$. History quantum theories that are related by a PSHQT are called ''physically equivalent'' and we showed explicitly in the case of history quantum mechanics how this notion encompasses the notion of physical equivalence introduced by Gell-Mann and Hartle in Ref. 4 in case one is dealing with a finite-dimensional, single-time Hilbert space $\mathscr{H}_t$ at a finite number of time points $(t_1,t_2,\ldots,t_n)$. An extension to infinite-dimensional $\mathscr{H}_t$ as well as to a continuous range of time points is clearly desirable since such spaces occur naturally in the context of *continuous histories*.[15,16]

In this article we also investigated the structure of the space of decoherence functionals; in particular, we defined the notion of an ''elementary decoherence functional'' in terms of which every decoherence functional can be expanded. We showed that these decoherence functionals are not pure, an observation that agrees with a result by Linden[13] that there exist no pure decoherence functionals. These elementary decoherence functionals were employed in order to perform some proofs but have *never* been assigned any status other than a technical one. In particular, we never calculated ''transition amplitudes between decoherence functionals,'' something that entirely contradicts the spirit of history quantum theories. Do these elementary decoherence functionals possess any physical interpretation?

While the definition of symmetry presented here has very convenient properties, it does not treat consistent sets of history propositions in any way preferred to other elements $\alpha \in \mathscr{P}(\mathscr{V})$. However, since these are the sets one ultimately wants to determine, it is reasonable to ask for a notion of symmetry which mirrors their importance. Reflecting a moment about the structure of consistent sets, one notices that this amounts to asking for an approach which places its emphasis on Boolean subalgebras of the space $\mathscr{P}(\mathscr{V})$. Via the use of the consistency conditions on the values of the decoherence functional, some of these Boolean algebras, namely the ones associated with consistent sets, are selected. Within each of these algebras classical reasoning without running into logical paradoxes is possible, whereas reasoning about elements belonging to different consistent sets leads, in general, to inconsistencies in the use of the values $d(\alpha,\alpha)$ of the decoherence functional as probabilities. The theory of ''Boolean manifolds,'' [17] which seem to be the most appropriate objects to describe history quantum theories,[7,18] allows one to describe the structure of $\mathscr{P}(\mathscr{V})$ in these terms and therefore, one is led to the problem of defining a transformation theory on Boolean manifolds. This is a task for future research.

By proving a classification theorem for decoherence functionals—an analog of Gleason's theorem in the context of history quantum theories—and the analog of Wigner's theorem presented here, we have laid the mathematical foundations for an approach to quantum theory from the point of view of the history program.

In history quantum theories the decoherence functional can be thought of as providing the ''dynamical'' content of the theory. In standard quantum mechanics, when investigated from the point of view of the history program, this is manifest in that the space of history propositions $\mathscr{UP}$

is given by Schrödinger picture projection operators and thus represents the ''kinematical''—as opposed to ''dynamical''—ingredient of the theory. In contrast, the decoherence functional (III.15) contains the evolution operator and the initial and final density operators and thus provides the ''dynamical'' specification of the model under investigation. In a companion paper[19] we will use the analog of Wigner's theorem presented in this article to define and to investigate the properties of ''symmetries of decoherence functionals.''

Lie algebra cohomology and group structure of gauge theories

Hyun Seok Yang and Bum-Hoon Lee[a)]
Department of Physics, Hanyang University, Seoul 133-791, Korea

(Received 18 October 1995; accepted for publication 28 June 1996)

We explicitly construct the adjoint operator of coboundary operator and obtain the Hodge decomposition theorem and the Poincaré duality for the Lie algebra cohomology of the infinite-dimensional gauge transformation group. We show that the adjoint of the coboundary operator can be identified with the BRST adjoint generator $Q^\dagger$ for the Lie algebra cohomology induced by BRST generator Q. We also point out an interesting duality relation—Poincaré duality—with respect to gauge anomalies and Wess–Zumino–Witten topological terms. We consider the consistent embedding of the BRST adjoint generator $Q^\dagger$ into the relativistic phase space and identify the noncovariant symmetry recently discovered in QED with the BRST adjoint Nöther charge $Q^\dagger$. © *1996 American Institute of Physics.*

I. INTRODUCTION

The theory of gauge fields is based on symmetry principles and the hypothesis of locality of fields. The principle of local gauge invariance determines all the forms of the interactions and allows the geometrical description of the interactions.[1] However the quantization of gauge fields leads to difficulties due to the constraints arising from the gauge symmetry. These difficulties of the quantization of constrained systems can be circumvented by the extension of phase space including the anticommuting ghost variables.[2] In this approach, the original gauge symmetry is transformed into the so-called BRST symmetry in the extended phase space.[3,4] The BRST symmetry will determine all the forms of the interactions and the algebraic and topological properties of the fields in the quantum theory.[5]

The question that comes naturally to mind is how we recover the original gauge invariant space consisting of only physical degrees of freedom from the extended phase space with ghosts[4–6] and what is the physical spectrum with the group invariant structure. In order to study the algebraic and topological structures of gauge theories, we follow the point of view of Ref. 7 about the ghost fields and the BRST transformation. That is, we identify the ghost field with the Cartan–Maurer form on an infinite-dimensional Lie group G_∞—the group of gauge transformation—and the BRST generator Q with the coboundary operator s on its Lie algebra $\mathcal{G}$. Through these identifications, we have the natural framework to construct the Lie algebra cohomology induced by the BRST generator Q. This Lie algebra cohomology will be related to the group invariants of the configuration space of gauge fields and matter fields.

The organization of this paper is as follows. In Sec. II, we construct the cochain complex on $\mathcal{G}$ with values in a $\mathcal{G}$-module.[8–10] With the pairing between Lie algebra $\mathcal{G}$ and its dual space $\mathcal{G}^*$, we define a chain as an element of the dual space to the cochain and a dual operation s_* of s. We define a positive-definite inner product and construct an adjoint operator $s^\dagger$ of s using the Hodge duality operation. We obtain the Hodge decomposition theorem, Poincaré duality, and Künneth formula analogous to the de Rham cohomology.[11]

In Sec. III, we show that the adjoint of the coboundary operator can be identified with the BRST adjoint generator $Q^\dagger$ for the Lie algebra cohomology induced by BRST generator Q and

each cohomology class on a polynomial space is characterized by the gauge invariant polynomials with a particular group invariant structure imposed on the cochain (or chain) space. We discuss the physical implications of the Lie algebra cohomology in the contexts of gauge anomaly and the effective action with the symmetry group G spontaneously broken to a subgroup H. The Lie algebra cohomology allows us algebraic and topological characterization of them and provides an interesting duality relation—Poincaré duality—between them. In Sec. IV, we apply this cohomology to QED and QCD. In order to consider the consistent embedding of the BRST adjoint generator $Q^\dagger$ into the relativistic phase space, we introduce the nonminimal sector of BRST generator.[4] Through this procedure, we find the BRST-like Nöther charge $Q^\dagger$ corresponding to the adjoint of the BRST generator Q, which generates a new kind of noncovariant symmetry in QED in Refs. 12 and 13. Section V contains discussion and some comments.

II. LIE ALGEBRA COHOMOLOGY

Let P be a principal bundle with a structure group G (a compact Lie group with the invariant inner product defined on its Lie algebra g) over a differentiable manifold M (flat Minkowski space or Euclidean space $\mathbf{R}^n$). The gauge transformation group G_∞—an automorphism of P—and its Lie algebra $\mathcal{G}$ can be identified with the set of C^∞-functions on M taking values in the structure group G and its Lie algebra g, respectively. One defines the dual spaces g^* of g and $\mathcal{G}^*$ of $\mathcal{G}$ as follows:[10]

$$\langle x,X\rangle=\sum_{a=1}^{dimG} X^a x_a, \quad \text{for } X\in g(\mathcal{G}),\ x\in g^*(\mathcal{G}^*). \tag{2.1}$$

The space–time dependence of the elements of G_∞, $\mathcal{G}$, and $\mathcal{G}^*$ will be suppressed unless otherwise explicitly indicated and an L^2-norm will be assumed in the inner product (2.1) between $\mathcal{G}$ and $\mathcal{G}^*$.[14] Using the pairing between Lie algebra g ($\mathcal{G}$) and its dual space g^* ($\mathcal{G}^*$), the coadjoint action of G (G_∞) on g^* ($\mathcal{G}^*$) is defined by

$$\langle X,Ad_g^* x\rangle=\langle Ad_{g^{-1}}X,x\rangle \quad \text{for } g\in G(G_\infty),\ x\in g^*(\mathcal{G}^*). \tag{2.2}$$

Consider a p-cochain w^p, an element of $C^p(\mathcal{G};R)$, where C^p is an antisymmetric p-linear map on $\mathcal{G}$ with values in a left $\mathcal{G}$-module R with the ring structure.[8–11] The space of cochains on $\mathcal{G}$ is the direct sum of the spaces of p-cochains:

$$C^*=\oplus_{p=0}^{dimG} C^p. \tag{2.3}$$

We introduce on C^* the operators $i(\vartheta)(x)$ and $\epsilon(\vartheta^*)(x)$ on a point $x\in M$ defined as follows:

$$i(\vartheta): C^p\to C^{p-1}, \quad \forall\,\vartheta\in\mathcal{G}$$

by

$$(i(\vartheta)(x)w^p)(\vartheta_1,\ldots,\vartheta_{p-1})(y)=w^p(\vartheta,\vartheta_1,\ldots,\vartheta_{p-1})(y)\,\delta(x-y), \quad w^p\in C^p; \tag{2.4}$$

and

$$\epsilon(\vartheta^*): C^p\to C^{p+1}, \quad \forall\,\vartheta^*\in\mathcal{G}^*$$

by

$$(\epsilon(\vartheta^*)(x)w^p)(\vartheta_1,\ldots,\vartheta_{p+1})(y)=\sum_{l=1}^{p+1}(-1)^{l+1}\langle\vartheta^*(x),\vartheta_l(y)\rangle w^p(\vartheta_1,\ldots,\hat{\vartheta}_l,\ldots,\vartheta_{p+1})(y), \tag{2.5}$$

where $\hat{}$ indicates omission. Denote by $\{\theta_a\}$, $a=1,\ldots,N\equiv dim G$, a basis of $\mathscr{G}$ and by $\{\theta^{*a}\}$ the basis of $\mathscr{G}^*$ such that

$$\langle\theta^{*a}(x),\theta_b(y)\rangle=\delta^a_b\delta(x-y). \tag{2.6}$$

Then straightforward calculations using the definitions (2.4) and (2.5) lead to the following relations:[10]

$$\{i(\theta_a),i(\theta_b)\}\equiv i(\theta_a)\circ i(\theta_b)+i(\theta_b)\circ i(\theta_a)=0,$$

$$\{\epsilon(\theta^{*a}),\epsilon(\theta^{*b})\}=0,$$

$$\{\epsilon(\theta^{*a}),i(\theta_b)\}=\langle\theta^{*a},\theta_b\rangle\mathbf{1}=\delta^a_b\mathbf{1}, \tag{2.7}$$

where $\circ$ denotes the map composition. Then, for example, the p-cochain $w^p\in C^p$ can be constructed using the operator $\epsilon(\theta^*)$ as follows:

$$w^p=\sum\ \frac{1}{p!}\underbrace{\epsilon(\theta^{*a})\circ\epsilon(\theta^{*b})\circ\cdots\circ\epsilon(\theta^{*c})}_{p\ \text{elements}}\phi^{(p)}_{ab\ldots c},\quad\text{where}\quad\phi^{(p)}_{ab\ldots c}\in R. \tag{2.8}$$

It must be kept in mind that the operations in Eqs. (2.4)–(2.8) must be understood as defined on a point $x\in M$ and we have omitted delta-function on M in Eq. (2.7). This shorthand notation will be used throughout this paper if it raises no confusion.

Let $s:C^p\to C^{p+1}$ be the coboundary operator, i.e., $s^2=0$ (Refs. 7–10) defined on $C^*(\mathscr{G};R)$ by

$$(sw^p)(\theta_1,\ldots,\theta_{p+1})(x)=\sum_{l=1}^{p+1}(-1)^{l+1}\theta_l\cdot w^p(\theta_1,\ldots,\hat{\theta}_l,\ldots,\theta_{p+1})(x)$$

$$+\sum_{l<n}(-1)^{l+n}w^p([\theta_l,\theta_n],\theta_1,\ldots,\hat{\theta}_l,\ldots,\hat{\theta}_n,\ldots,\theta_{p+1})(x), \tag{2.9}$$

where a dot means the linear transformation of R defined by an element of $\mathscr{G}$. The coboundary operator s can then be expressed in terms of $\epsilon(\theta^*)$ and $i(\theta)$ as follows:

$$s=\sum_{a=1}^{N}\int_M\theta_a\cdot\epsilon(\theta^{*a})-\sum_{a<b}^{N}\int\int_M i([\theta_a,\theta_b])\circ\epsilon(\theta^{*a})\circ\epsilon(\theta^{*b}), \tag{2.10}$$

where the integrations are defined over M.

Now we define a chain complex C as the dual space of the cochain complex C^* using the duality (2.1),[9,11] namely,

$$\langle,\rangle:C^p\times C_p\to R$$

by

$$(w^p,v_p)\mapsto\langle w^p,v_p\rangle=\int_{v_p} w^p,\quad w^p\in C^p \text{ and } v_p\in C_p, \tag{2.11}$$

where we set $\langle w^p,v_q\rangle=0$ if $p\neq q$, and C^* and C are augmented compleces, that is, $C^p=C_p=0$ for $p<0$.[8,11] The duality (2.11) allows us to define an operator $s_*:C_p(\mathcal{G}^*;R)\to C_{p-1}(\mathcal{G}^*;R)$ dual to s:

$$\langle sw^{p-1},v_p\rangle=\langle w^{p-1},s_*v_p\rangle,\quad w^{p-1}\in C^{p-1} \text{ and } v_p\in C_p. \tag{2.12}$$

Obviously, Eq. (2.12) shows us $s^2=0$ implies $s_*^2=0$. Thus we will identify s_* with the boundary operator acting on the chains $\{v_p\}$. Of course, the above procedures defining the chain complex is completely analogous to the ordinary homology theory.[8,9,11]

Let us introduce the Hodge star duality operation whose action on the cochain space is defined as follows:

$$*:C^p\to C^{N-p} \tag{2.13}$$

by

$$(*w^p)(\theta_{a_{p+1}},\ldots,\theta_{a_N})=\sum\frac{1}{p!}w^p(\theta_{b_1},\ldots,\theta_{b_p})\epsilon^{b_1\ldots b_p}{}_{a_{p+1}\ldots a_N}. \tag{2.14}$$

As the de Rham cohomology, we want to define the adjoint operator $s^\dagger$ of s (Refs. 9 and 15) under the new nondegenerate inner product defined by

$$(w_1,w_2)=\int_{u_N} w_1\wedge *w_2 \tag{2.15}$$

with the N-chain u_N satisfying $s_*u_N=0$. Then

$$(sw_1,w_2)=(w_1,s^\dagger w_2), \tag{2.16}$$

and $s^\dagger:C^p\to C^{p-1}$ is given by

$$s^\dagger=(-1)^{N\cdot p+N+1}*\circ s\circ *. \tag{2.17}$$

For convenience, we have taken the Cartan–Killing metric g_{ab} of the semi-simple Lie subalgebra as positive definite:

$$g_{ab}=-\tfrac{1}{2}c^l_{ad}c^d_{bl}=\delta_{ab},$$

where $[\theta_a(x),\theta_b(y)]=c^l_{ab}\theta_l(x)\delta(x-y)$. The operator $s^\dagger$ is nilpotent since $s^{\dagger 2}\propto *s^2*=0$. Using the definitions in Eqs. (2.17), (2.9), and (2.14), one can determine the action of $s^\dagger$ on a p-cochain w^p:

$$\begin{aligned}(s^\dagger w^p)(\theta_1,\ldots,\theta_{p-1})(x)=&-\sum_{l=p}^{N}\theta_l\cdot w^p(\theta_l,\theta_1,\ldots,\theta_{p-1})(x)\\&-\sum_{l=1}^{p-1}\sum_{a<b}(-1)^{l+1}c^l_{ab}w^p(\theta_a,\theta_b,\theta_1,\ldots,\hat{\theta}_l,\ldots,\theta_{p-1})(x).\end{aligned} \tag{2.18}$$

Similarly, the adjoint operator $s^\dagger$ can be expressed in terms of $\epsilon(\theta^*)$ and $i(\theta)$ as follows

$$s^{\dagger}=-\sum_{a=1}^{N}\int_{M}\theta_a\cdot i(\theta_a)+\sum_{a<b,c}^{N}\int_{M}c_{ab}^{c}\epsilon(\theta^{*c})\circ i(\theta_a)\circ i(\theta_b). \tag{2.19}$$

Let us define an operator $\delta\equiv s\circ s^{\dagger}+s^{\dagger}\circ s$ corresponding to the Laplacian, which clearly takes p-cochains back into p-cochains as

$$\delta: C^p\rightarrow C^p.$$

The straightforward calculation using Eq. (2.7) and the Jacobi identity for c_{ab}^{c} leads to the following expression for the Laplacian δ:

$$\delta=-\int_{M}\left(\sum\ \theta_a\cdot\theta_a+\sum\ c_{ab}^{c}\theta_a\cdot\epsilon(\theta^{*c})\circ i(\theta_b)+\frac{1}{2}\sum\ c_{ab}^{c}c_{ae}^{d}\epsilon(\theta^{*c})\circ i(\theta_b)\cdot\epsilon(\theta^{*d})\circ i(\theta_e)\right). \tag{2.20}$$

Considering the formal resemblance to the de Rham cohomology, it will be sufficient to state, without proof, only the important results which are necessary for later applications. For mathematical details of homology and cohomology theory, see Refs. 8, 9, and 11.

We define the p-th cohomology group of the Lie algebra $\mathcal{G}$ by the equivalence class of the p-cochains $C^p(\mathcal{G};R)$, that is, the kernel of s modulo its image:

$$H^p(\mathcal{G};R)\equiv Ker^p s/\mathrm{Im}^p s,\quad p=0,\ldots,N. \tag{2.21}$$

Then the nondegenerating inner product (2.11) provides a natural pairing between p-th cohomology group $H^p(\mathcal{G};R)$ and p-th homology group $H_p(\mathcal{G}^*;R)$,

$$H^p(\mathcal{G};R)\otimes H_p(\mathcal{G}^*;R)\rightarrow R,$$

so that *the inner product (2.11) establishes the duality of the vector spaces* $H^p(\mathcal{G};R)$ *and* $H_p(\mathcal{G}^*;R)$, the de Rham theorem.[11]

The following result is the direct consequence of the positive definiteness of the inner product (2.15):

The ''harmonic'' p-cochain $w^p\in Harm(\mathcal{G};R)$, *i.e.,* $\delta w^p=0$ *is satisfied if and only if it is exact, i.e.,* $sw^p=0$ *and co-exact, i.e.,* $s^{\dagger}w^p=0$.

The adjointness of the operator s and $s^{\dagger}$ under the nondegenerate inner product (2.15) and their nilpotency leads to the so-called Hodge decomposition theorem in the cochain space in a unique way:[9,15]

Any p-cochain w^p *can be uniquely decomposed as a sum of exact, co-exact, and harmonic forms, i.e.,*

$$w^p=\delta_H^p\oplus sw^{p-1}\oplus s^{\dagger}w^{p+1},\quad p=0,\ldots,N, \tag{2.22}$$

where δ_H^p is a harmonic p-cochain. The Hodge decomposition theorem (2.22) implies *the isomorphism between the p-th cohomology space* $H^p(\mathcal{G};R)$ *and the p-th harmonic space* $Harm^p(\mathcal{G};R)$.

The Hodge star operator $*$ maps $C^p\rightarrow C^{N-p}$ and commute with the Laplacian δ. Thus $*$ induces an isomorphism

$$Harm^p(\mathcal{G};R)\approx Harm^{N-p}(\mathcal{G};R).$$

Consequently, $H^{N-p}(\mathcal{G};R)$ *and* $H^p(\mathcal{G};R)$ *are isomorphic as vector spaces,*

$$H^{N-p}(\mathcal{G};R)\approx H^p(\mathcal{G};R). \tag{2.23}$$

This is just the Poincaré duality.[11]

If the Lie algebra $\mathcal{G}$ is a direct sum of semi-simple Lie algebras and/or Abelian $u(1)$ algebras, that is, $\mathcal{G}=\mathcal{G}_1\oplus\mathcal{G}_2$ and thus each of these algebras $\mathcal{G}_\alpha$ is an ideal of $\mathcal{G}$, then a total p-cochain C^p will be a sum of a tensor product of cochains corresponding to each Lie algebra $\mathcal{G}_\alpha$,

$$C^p=\oplus_{q+r=p}C_1^q\otimes C_2^r,$$

and $w^p\in C^p$ will be given by

$$w^p=\sum_{q=0}^{p} w_1^q\times w_2^{p-q},\quad w_1^q\in C_1^q,\quad w_2^{p-q}\in C_2^{p-q}.$$

The map $w^p\in C^p$ on $\mathcal{G}$ is defined by

$$w^p(\theta_1,\ldots,\theta_q;\xi_1,\ldots,\xi_{p-q})=w_1^q(\theta_1,\ldots,\theta_q)w_2^{p-q}(\xi_1,\ldots,\xi_{p-q}),\quad \theta_i\in\mathcal{G}_1,\quad \xi_i\in\mathcal{G}_2.$$

Then $H^p(\mathcal{G};R)$ can be decomposed into a sum of a product of each $H^q(\mathcal{G}_1;R)$ and $H^{p-q}(\mathcal{G}_2;R)$:

$$H^p(\mathcal{G};R)=\oplus_{q=0}^{p}[H^q(\mathcal{G}_1;R)\otimes H^{p-q}(\mathcal{G}_2;R)]. \tag{2.24}$$

This is known as the Künneth formula for a product space (in our case, a product group $G_1\otimes G_2$).[11,15]

III. GROUP STRUCTURE OF GAUGE THEORIES

In this section we will show that the group invariant structures of the gauge theory can be described by the Lie algebra cohomology induced by the BRST generator Q in the algebra of invariant polynomials on $\mathcal{G}$ with the generalized Poisson bracket,[4] taking the complete correspondence with the results of Sec. II. It will provide the algebraic and the topological characterization with respect to group invariant structures in the gauge theory and exhibit a very remarkable connection between the BRST symmetry and the differential and algebraic geometry.

Consider any physical system with gauge transformation group G_∞ and its compact Lie algebra $\mathcal{G}$ with N generators G_a, $a=1,\ldots,N$, satisfying the following Lie algebra:

$$[G_a(x),G_b(y)]=gf_{ab}^cG_c(x)\delta(x-y),\quad a,b,c=1,\ldots,N. \tag{3.1}$$

Corresponding to each generator, we introduce a ghost $\eta^a(x)$ and an antighost $\rho_a(x)$ which satisfy the following Poisson bracket relations:

$$\{\eta^a,\eta^b\}=\{\rho_a,\rho_b\}=0,\quad \{\eta^a,\rho_b\}=\delta_b^a. \tag{3.2}$$

Then we can construct the nilpotent BRST generator[4]

$$Q=\int_M G_a\eta^a-\frac{1}{2}g\int_M f_{ab}^c\rho_c\eta^a\eta^b, \tag{3.3}$$

and its nilpotency

$$Q^2=0 \tag{3.4}$$

follows from the Lie algebra (3.1) together with the Jacobi identity.

If one identifies the operators $\epsilon(\theta^{*a})(x)$ and $i(\theta_a)(x)$ in Sec. II with the ghost $\eta^a(x)$ and the antighost $\rho_a(x)$, respectively,[10] the expression (2.10) about the coboundary operator s exactly agrees with the BRST generator Q, where structure constants $c^l_{ab}=gf^l_{ab}$ and G_a is any representation for θ_a. Rewrite the BRST generator as

$$Q=\int_M\left(J_a\eta^a-\frac{1}{2}\,\tau_a\eta^a\right), \tag{3.5}$$

where $J_a=G_a+\tau_a$. $\tau_a=g\rho_m f^m_{al}\eta^l$ satisfies the same algebra as G_a and commutes with it. Then BRST s-transformation law with respect to a field $\mathscr{F}(x)$ is defined as follows,

$$s.\mathscr{F}(x)=[Q,.\mathscr{F}(x)\}, \tag{3.6}$$

where the symbol $[,\}$ is the generalized Poisson bracket. Thus the s-transformations with respect to the ghost field η and ρ by Q are

$$s\,\eta^a=-\tfrac{1}{2}\,gf^a_{bc}\eta^b\eta^c,\quad s\rho_a=J_a. \tag{3.7}$$

According to Ref. 7, we identify the ghost field $\eta(x)$ with a left-invariant Cartan–Maurer form on the group G_∞. With this interpretation of the ghost field $\eta(x)$, the first equation in Eq. (3.7) is just the Cartan–Maurer equation with respect to ''exterior derivative'' s for forms $\eta(x)$ on G_∞. It is also obvious that the adjoint operator $s^\dagger$ of s introduced in Sec. II can be constructed in terms of η and ρ. We define the corresponding generator by $Q^\dagger$ and it is given by

$$Q^\dagger=-\int_M\left(G^a\rho_a-\frac{1}{2}\,gf^{ab}_c\eta^c\rho_a\rho_b\right)=-\int_M\left(J^a\rho_a-\frac{1}{2}\,\tau^a\rho_a\right). \tag{3.8}$$

One can easily check this generator is also nilpotent, i.e., $Q^{\dagger 2}=0$ as stated in Sec. II.

The generator $Q^\dagger$ first appeared in Ref. 16 to find the gauge invariant interactions in string theory and then in Ref. 17 to construct the BRST complex and the cohomology of compact Lie algebra. The Lie algebra cohomology in this paper is quite different from the BRST cohomology constructed in Ref. 18, so we use the nomenclature, Lie algebra cohomology, in order to avoid confusion with the BRST cohomology since these two cohomologies have been often confused in the literature. In fact, the cohomology of Ref. 17 corresponds to the Lie algebra cohomology in this paper as long as the space–time dependences of the Lie group G_∞ and the Lie algebra $\mathscr{G}$ are fixed. However, it is necessary to consider the infinite-dimensional Lie group and Lie algebra in order that the BRST generator may be viewed as the coboundary operator for the Lie algebra cohomology.[7]

The $s^\dagger$-transformation with respect to a field $\mathscr{F}(x)$ is defined by

$$s^\dagger.\mathscr{F}(x)=[Q^\dagger,.\mathscr{F}(x)\}. \tag{3.9}$$

Then the $s^\dagger$-transformations with respect to the ghost fields η and ρ are

$$s^\dagger\eta^a=-J^a,\quad s^\dagger\rho_a=\tfrac{1}{2}\,gf^{bc}_a\rho_b\rho_c. \tag{3.10}$$

The above equations show that one can identify the antighost ρ_a with the Cartan–Maurer form with respect to the ''exterior derivative'' $s^\dagger$ as well.

Since Q and $Q^\dagger$ are nilpotent, it follows that Q and $Q^\dagger$ invariant by G_∞, i.e.,

$$[Q,J_a]=0,\quad [Q^\dagger,J_a]=0. \tag{3.11}$$

One finds that Q and $Q^\dagger$ satisfy the supersymmetrylike algebra that closes into a Laplacian generator Δ,

$$\{Q,Q^\dagger\}=-\Delta, \quad [\Delta,Q]=0, \quad [\Delta,Q^\dagger]=0, \tag{3.12}$$

where the Laplacian Δ can be computed in terms of the Casimir generators[16]

$$\Delta=\frac{1}{2}\int_M (J^a J_a+G^a G_a). \tag{3.13}$$

The operator δ: $C^p\to C^p$ in Sec. II corresponds to this generator and it has exactly the same expression as Δ if it is rewritten in terms of Casimir operators.

Following the same scheme as those in Refs. 19 and 20, we construct the cochains on $\mathcal{G}$ spanned by the polynomial $\omega_{(p)}=Tr\,\eta^p$, where $\eta=\eta^a T_a$ and T_a is a generator of g. That is, a p-dimensional cochain $C^p(\mathcal{G};R)$ corresponding to Eq. (2.8) is spanned by elements of the space of $w^p=\wedge^r\omega_{(p_r)}\cdot\phi(\Sigma p_r=p)$, where ϕ is an element of R, i.e., $\mathcal{G}$-module of symmetric polynomials on $\mathcal{G}$ without (anti-)ghosts. Then $\omega_{(p)}=0$ if p is even and $\omega_{(p)}$ is a ''closed'' p-form - a p-cocycle, i.e., $s\omega_{(p)}=0$ by Eq. (3.7). Notice, for semi-simple groups G, $\omega_{(1)}=0$.[15] Let us reexpress the p-cochain w^p as the following form:

$$w^p=\sum \frac{1}{p!}\,\eta^{a_1}\eta^{a_2}\cdots\eta^{a_p}\cdot\phi^{(p)}_{a_1a_2\cdots a_p}. \tag{3.14}$$

Note that the results such as Hodge decomposition theorem, Poincaré duality, and Künneth formula in Sec. II will be reproduced here in the same manner as well. In Sec. II, we stated the isomorphism between the p-th cohomology space $H^p(\mathcal{G};R)$ and the p-th harmonic polynomial space $Harm^p(\mathcal{G};R)$. Therefore, the BRST invariant polynomial space can be summarized as the *harmonic* polynomial space $\delta w^p=0$, whose solutions are represented by

$$[G_a,w^p]=0, \tag{3.15}$$

and

$$[\tau_a,w^p]=[g\rho_m f^{\ m}_{al}\eta^l,w^p]=0. \tag{3.16}$$

The second condition reads, in components,

$$f^{\ m}_{a[a_1}\phi^{(p)}_{a_2\cdots a_p]m}=0, \tag{3.17}$$

where the square bracket denotes complete antisymmetrization over the enclosed indices.[17] The first condition (3.15) imposes the G-invariance—G-singlet—on the polynomial ($\mathcal{G}$-module) and the second one imposes very important constraints about the group invariant structures. For the $p=0$ and $p=N$, the conditions (3.15) and (3.16) are always satisfied trivially as long as they are associated with the G-invariant polynomials, which leads to the conclusion that the zeroth and the N-th cohomology spaces require only the space of G-singlet. For semi-simple groups G, there are no solutions satisfying the condition (3.16) for $p=1,2,4$ since there is no cohomology basis $\wedge^r\omega_{(p_r)}$ to be closed and for $p=N-1$, $N-2$, $N-4$ by Poincaré duality (2.23), so that their cohomologies $H^p(\mathcal{G};R)$ vanish. Note that the gauge group SU(2) is cohomologically trivial so that the group invariant structure in the SU(2) gauge theory is similar to electrodynamics. In this respect, we would like to refer to the interesting analysis[21] which arrives at the same conclusion under the different approach. If one $U(1)$ factor is present (for example, $SU(2)\times U(1)$, $U(2)$, etc.),

then $H^1(\mathcal{G};R)$ is non-trivial since $\omega_{(1)}$ is nonzero.[15,19] For $G=\mathrm{SU}(N)$, $N\geqslant 3$, there exist nontrivial cohomologies $H^3(\mathcal{G};R)$ and $H^5(\mathcal{G};R)$ whenever the symmetric polynomials $\phi^{(3)}$ and $\phi^{(5)}$ are proportional to the structure constants as follows, respectively:

$$\phi^{(3)}_{abc}=f_{abc}\cdot\phi, \quad \phi^{(5)}_{abcde}=d_{amn}f_{mbc}f_{nde}\cdot\phi, \tag{3.18}$$

where $d_{abc}=1/2TrT_a\{T_b,T_c\}$ and ϕ is any G-singlet. These follow directly from the expansion (3.14)[7,22] or Eq. (3.17) with the Jacobi identity.

It is worth mentioning, for $G=\mathrm{SU}(3)$, the nontrivial cohomologies $H^3(\mathcal{G};R)$ and $H^5(\mathcal{G};R)$ are related with each other by Poincaré duality (2.23). The solution of the descent equations corresponding to the Wess–Zumino consistency conditions in gauge theories[23] shows that the polynomials $\omega_{(3)}$ and $\omega_{(5)}$ corresponding to the third and the fifth cohomologies (3.18) respectively generate the two dimensional and the four dimensional gauge anomaly[7,19] (see also recent analysis[24] by Sorella, where the cohomology basis $\omega_{(3)}$ and $\omega_{(5)}$ have a fundamental importance on solving the descent equations). Thus, from the results of these literatures, we can conclude that two and four dimensional $SU(3)$ anomalies are related to each other by the Poincaré duality; in other words, the gauge anomaly in two dimensional QCD implies the existence of the anomaly in four dimensional QCD as long as d-cohomology is trivial.[7,19,20] This observation is also applied to the problem yielding the general G-invariant effective action[25] with the symmetry group G spontaneously broken to the subgroup H since the G-invariant effective actions for homogeneous spaces G/H can be understood as the Lie algebra cohomology problem of the manifold G/H. For example, in the case for $\mathrm{SU}(3)\times\mathrm{SU}(3)$ spontaneously broken to the subgroup SU(3), the two dimensional Poincaré-dual of the Wess–Zumino–Witten term in four dimensional theory is the Goldstone–Wilczek topological current.[26]

IV. COHOMOLOGY IN QED AND QCD

In this section, we want to see whether it is possible to find a corresponding adjoint generator $Q^\dagger$ of the nilpotent Nöther charge Q in relativistic theories and what the role of the adjoint $Q^\dagger$ in the Lagrangian formulation is. That is, the solution we want to find out is how to embed the adjoint $Q^\dagger$ of Q into the relativistic phase space. In order to construct the relativistic phase space, it is then necessary to incorporate the Lagrange multipliers and their conjugate momenta and the associated ghost pairs into the phase space.[4,27] In that case we will have the two kinds of first-class constraints composed of Gauss constraints and gauge-fixing constraints in the extended phase space. Thus the consistent embedding of the BRST adjoint generator $Q^\dagger$ into the relativistic phase space means that the $Q^\dagger$ is the adjoint generator with respect to the total Lie algebra $\mathcal{G}$ composed of a direct sum of two ideals $\mathcal{G}_1$ and $\mathcal{G}_2$ corresponding to the Gauss and the gauge-fixing constraint algebras, respectively, and it can be realized as a Nöther charge in configuration space.

First, consider the BRST (and anti-BRST) invariant effective QED Lagrangian. (Our BRST treatments are parallel with those of Baulieu's paper.[5])

$$\begin{aligned}\mathcal{L}_{\mathrm{eff}}&=-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}+\overline{\psi}(i\gamma^\mu D_\mu-m)\psi-\tfrac{1}{2}\,\overline{ss}(A_\mu^2+\alpha\overline{cc})\\&=-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}+\overline{\psi}(i\gamma^\mu D_\mu-m)\psi+A_\mu\partial^\mu b+\frac{\alpha}{2}\,b^2-\partial_\mu\overline{c}\partial^\mu c,\end{aligned} \tag{4.1}$$

where $D_\mu=\partial_\mu+ieA_\mu$ is the covariant derivative with the metric $g_{\mu\nu}=(1,-1,-1,-1)$. The explicit BRST transformations are

$$sA_\mu=\partial_\mu c, \quad sc=0,$$

$$s\overline{c}=b, \quad sb=0,$$

$$s\psi = -iec\psi. \tag{4.2}$$

We introduced an auxiliary field b to achieve off-shell nilpotency of the BRST (and the anti-BRST) transformation. Then the nilpotent Nöther charge generated by the BRST symmetry reads as

$$Q = \int d^3x\{(\partial_i F^{io} - J_0)c + b\dot{c}\}, \tag{4.3}$$

where J_0 is a charge density defined by

$$J_0 = e\overline{\psi}\gamma_0\psi. \tag{4.4}$$

The constraint functions G^i consist of two commuting groups, $G^i = (\Phi, b)$, $i = 1,2$, where $\Phi = \partial_i F^{io} - J_0$ is a Gauss law constraint in the theory and b is the momentum canonically conjugate to the Lagrange multiplier A_0 so that it generates a gauge transformation, δA_0. Thus adding the nonminimal sector in the BRST generator, the Lie algebra $\mathcal{G}$ is composed of a direct sum of two Abelian ideals $\mathcal{G}_1$ and $\mathcal{G}_2$ corresponding to the $u(1)$ generators Φ and b, respectively. In a similar fashion, let the ghost fields split as follows:

$$\eta^i = (c, \pi_{\bar{c}} = \dot{c}), \quad \rho^i = (\pi_c = -\dot{\bar{c}}, c). \tag{4.5}$$

Then the BRST charge Q with respect to the total Lie algebra $\mathcal{G}$ can be written as a linear combination of each $u(1)$ subalgebra sectors

$$Q = \int d^3x G^i \alpha_{ij} \eta^j, \tag{4.6}$$

where

$$\alpha_{ij} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Since the constraints in the relativistic phase space for Abelian gauge theories impartially generate $u(1)$ Lie algebras and the Künneth formula (2.24) shows $H(\mathcal{G};R)$ is the product of each $H(\mathcal{G}_1;R)$ and $H(\mathcal{G}_2;R)$, we expect that the adjoint $Q^\dagger$ corresponding to the total Lie algebra $\mathcal{G}$ similarly should be a linear combination of each subalgebra sector. Therefore, according to Eq. (3.8), one can guess the form of the generator $Q^\dagger$ must be the following: $Q^\dagger = -\int d^3x G^i \beta_{ij} \rho^j$. Note that we have a degree of freedom to the extent of multiplicative factor in defining the BRST generator Q or its adjoint generator $Q^\dagger$ for a given Lie algebra $\mathcal{G}$ as long as it does not affect the nilpotency of Q or $Q^\dagger$. Using this degree of freedom either in the Lie algebra $\mathcal{G}_2$ or in the $\mathcal{G}_1$ sector in defining the adjoint generator $Q^\dagger$, we take the following choices for the matrix β_{ij} which will allow the well-defined canonical mass dimension for $Q^\dagger$:

$$\beta_{ij} = \begin{pmatrix} 1 & 0 \\ 0 & -\nabla^2 \end{pmatrix} \text{or} \begin{pmatrix} -\nabla^{-2} & 0 \\ 0 & 1 \end{pmatrix}. \tag{4.7}$$

These choices make the BRST adjoint $Q^\dagger$ the symmetry generator of the Lagrangian (4.1) and so complete the consistent embedding of $Q^\dagger$ into the relativistic phase space.

Alternatively, in the case of the Abelian gauge theory, we can also obtain the BRST adjoint generator $Q^\dagger$ through an appropriate redefinition about the constraint functions G^i and the ghost fields (4.5) as follows:

$$G^i=(\Phi,\sqrt{-\nabla^2}b),\quad \eta^i=\left(c,\frac{1}{\sqrt{-\nabla^2}}\dot{c}\right),\quad \rho^i=(-\overrightarrow{\dot{c}},\sqrt{-\nabla^2}\overline{c}),$$

$$G^i=\left(\frac{1}{\sqrt{-\nabla^2}}\Phi,b\right),\quad \eta^i=(\sqrt{-\nabla^2}c,\dot{c}),\quad \rho^i=\left(-\frac{1}{\sqrt{-\nabla^2}}\overrightarrow{\dot{c}},c\right), \tag{4.8}$$

and $\beta_{ij}=\alpha_{ij}$ since the redefinition does not affect their algebra.

Then the adjoint generator $Q^\dagger$ can take the local expression in Ref. 13 or the nonlocal one in Ref. 12. The explicit form of the BRST adjoint generator $Q^\dagger$ for the local type is

$$Q^\dagger=\int d^3x\{(\partial_i F^{io}-J_0)\overrightarrow{\dot{c}}+b\nabla^2\overline{c}\}. \tag{4.9}$$

Thus the explicit transformations defined by (3.9) are that

$$s^\dagger A_0=-\nabla^2\overline{c},\quad s^\dagger A_1=-\partial_0\partial_i\overline{c},$$

$$s^\dagger c=(\partial_i F^{io}-J_0),\quad s^\dagger\overline{c}=0,$$

$$s^\dagger\psi=ie\overrightarrow{c}\psi,\quad s^\dagger b=0. \tag{4.10}$$

In Ref. 13, it has been shown that this noncovariant transformation is a symmetry of the Lagrangian (4.1) and there also exists the same kind of symmetry in the Landau–Ginzburg and the Chern–Simons theories and the Nöther charge $Q^\dagger$ imposes strong constraint on state space. As discussed in Ref. 13, the symmetry generated by $Q^\dagger$ is realized in quite a different way compared to the BRST symmetry: while the gauge-fixing term in the effective QED Lagrangian (4.1), i.e., $A_\mu\partial^\mu b+(\alpha/2)b^2\rightarrow-(1/2\alpha)(\partial_\mu A^\mu)^2$, remains invariant under the transformation (4.10), the variation from the ghost term is canceled up to the total derivative by the variation from the original gauge-invariant classical Lagrangian which remains invariant under the BRST transformation (4.2). These differences in the way of realizing the symmetries imply that the BRST adjoint symmetry can give the different superselection sector from the BRST symmetry[28] (as it is also seen from the Hodge decomposition theorem (2.22) which is a canonical decomposition into a direct sum of linearly independent subspaces) unlike the recent comment.[29]

If we use, instead, the matrix

$$\beta_{ij}=\begin{pmatrix}\frac{1}{-\nabla^2} & 0\\ 0 & 1\end{pmatrix}$$

in Eq. (4.9), we will obtain the nonlocal symmetry in Ref. 12. Of course, in this case, we must impose the good boundary conditions on fields. But there is no reason to introduce the nonlocality and it seems unnatural since the generator $Q^\dagger$ must be the adjoint of the generator Q of the local gauge transformation.

In non-Abelian gauge theory, the BRST charge Q incorporated with a compactifiable gauge fixing (e.g., the covariant or the Coulomb gauge) can generate a well-defined gauge transformation only on the interior of a bounded region, whose boundary is so-called the Gribov horizon, because of the existence of the Gribov copies.[30] The adjoint generator in the configuration space can be understood as the generator of transformation consistent with the gauge fixing condition.[12,13] Thus, in the configuration space, there may not exist the globally well-defined expression of the adjoint generator $Q^\dagger$ of non-Abelian gauge theory compatible with the gauge fixing condition unlike QED

on account of the topological obstructions such as the Gribov ambiguity. But it does not imply that there can not exist the local expression of $Q^{\dagger}$, because the difficulty posed by the Gribov ambiguity can be avoided[31] by finding a local cross section on a finite local covering and using the Faddeev–Popov trick locally. Nevertheless, it seems a nontrivial problem to find the solution for the consistent embedding into the relativistic phase space for the non-Abelian gauge theory such as QCD. This problem remains for a future work. We want to focus our attention on the construction of su(3) Lie algebra cohomology in QCD.

Consider the BRST (and anti-BRST) invariant effective QCD Lagrangian:

$$\begin{aligned}\mathscr{L}_{\text{eff}} &= -\tfrac{1}{4} F^a_{\mu\nu} F^{a\mu\nu} + \overline{\Psi}(i\gamma^\mu D_\mu - M)\Psi - \tfrac{1}{2}\,\overline{ss}(A^a_\mu A^{a\mu} + \alpha \overline{C^a} C^a) \\ &= -\frac{1}{4} F^2_{\mu\nu} + \overline{\Psi}(i\gamma^\mu D_\mu - M)\Psi + A_\mu \partial^\mu B + \frac{\alpha}{2} B^2 + \frac{\alpha}{2} gB[C,\overline{C}] \\ &\quad - \partial_\mu \overline{C} D^\mu C + \frac{\alpha}{2} g^2 [\overline{C}, C]^2, \end{aligned} \tag{4.11}$$

where quark fields Ψ are taken to transform according to the fundamental $SU(3)$ representation, the Yang–Mills vector potential A_μ, a pair of anticommuting ghosts C,C and the auxiliary field B take values in the adjoint representation of a SU(3) Lie group. The QCD Lagrangian (4.11) is invariant with respect to the following BRST transformations:[5]

$$\begin{aligned} &sA_\mu = D_\mu C, \quad sC = -\frac{g}{2}[C,C], \\ &s\overline{C} = B, \quad sB = 0, \\ &s\Psi = -gC\Psi. \end{aligned} \tag{4.12}$$

D_μ defines the covariant derivatives of $SU(3)$ Yang–Mills symmetry group. The corresponding conserved nilpotent BRST generator is given by

$$Q = \int d^3x \left\{ (D_i F^{io} - J_0 + g[\overleftarrow{\overline{C}}, C])^a C^a + B^a (D_0 C)^a - \frac{1}{2} g[\overleftarrow{\overline{C}}, C]^a C^a \right\}, \tag{4.13}$$

where J^a_0 is a matter color charge density defind by

$$J^a_0 = -ig\overline{\Psi}\gamma_0 T^a \Psi. \tag{4.14}$$

The constraint functions G^A are composed of two commuting groups, $G^A = (\Phi^a, B^a)$, where $\Phi^a = (D_i F^{io} - J_0)^a$ is the original Gauss-law constraints in the theory generating $su(3)$ Lie algebra:

$$[\Phi_a, \Phi_b] = g f^c_{ab} \Phi_c, \tag{4.15}$$

and B^a is the momenta canonically conjugate to the Lagrange multiplier A^a_0 and generates $u(1)$ Lie algebras. In the similar fashion as QED, one can split the ghosts as follows:

$$\eta^A = (C^a, \Pi^a_C = (D_0 C)^a), \quad \rho^A = (\Pi^a_C = -\overleftarrow{\overline{C^a}}, \overline{C^a}). \tag{4.16}$$

Note that $s\Pi^a_{\bar{C}} = 0$, so that we can identify the ghost $\Pi^a_{\bar{C}}$ with the Cartan–Maurer form on $U(1)$ group. Of course, the BRST generator Q in Eq. (4.13) is exactly the same form of Eq. (3.3). Let us rewrite the BRST generator Q as the form of Eq. (3.5),

$$Q = \int d^3x \left\{ J_a C^a + B_a \Pi^a_{\bar{C}} - \frac{1}{2}\, \tau_a C^a \right\}, \tag{4.17}$$

where the generator J^a and the generator of the ghost representation τ_a (Ref. 16) are given by

$$J^a = (D_i F^{io} - J_0 + g[\overleftarrow{\bar{C}}, C])^a = \Phi^a + \tau^a, \quad \tau^a = g[\overleftarrow{\bar{C}}, C]^a. \tag{4.18}$$

The generators J_a and τ_a satisfy the same $su(3)$ algebra:

$$[J_a, J_b] = g f^{\ c}_{ab} J_c, \quad [\tau_a, \tau_b] = g f^c_{ab} \tau_c. \tag{4.19}$$

The nontriviality of the principal fiber bundle does not admit a global section which would provide a global gauge fixing. The nonexistence of a global section of the bundle entails that it is not possible to continuously fix the gauge globally. Then the Gribov ambiguity is a consequence of the fact that there exists a topological obstruction to the existence of a global gauge fixing condition.[31] This means that a global gauge fixing must contain discontinuities coming from the global geometry of the gauge theory. Thus the BRST charge (4.13) or (4.17) will also contain these discontinuities as long as it is not restricted to a fundamental modular region because it is involved with the global gauge fixing.

Since the two groups of the constraint functions $G^A = (\Phi^a, B^a)$ commute with each other, the total Lie algebra $\mathcal{G}$ including the nonminimal sectors B^a is composed of the $su(3)$ non-Abelian ideal and the eight $u(1)$ Abelian ideals:

$$\mathcal{G} = \oplus su(3) \oplus \oplus_{\alpha=1}^{8} u(1)_\alpha. \tag{4.20}$$

In order to construct only the cohomology of the color $su(3)$ Lie algebra for the reasons explained above, we drop the Abelian sectors from the BRST generator Q through the direct restriction on the cochain space (3.14), in other words, considering only $su(3)$ subcochain complex. Note that this restriction to a subalgebra sector of the cochain space is always possible in terms of the Künneth formula (2.24). The BRST adjoint $Q^\dagger$ defined on the cochain $C^*(su(3);R)$ is equal to

$$Q^\dagger = -\int d^3x \left\{ J^a \Pi^a_C - \frac{1}{2}\, \tau^a \Pi^a_C \right\}. \tag{4.21}$$

Then the Laplacian Δ of the $su(3)$ subalgebra sector can be represented in terms of the generators J_a and the original constraints Φ_a,

$$\Delta = \tfrac{1}{2} \int d^3x \{ J^a J_a + \Phi^a \Phi_a \}, \tag{4.22}$$

which is equal to the expression given by Eq. (3.13) for $su(3)$ cohomology. Thus the harmonic polynomials of the $su(3)$ algebra sector must satisfy the following conditions,

$$[\Phi^a, w^p] = [(D_i F^{io} - J_0)^a, w^p] = 0, \quad a = 1, \ldots, 8, \tag{4.23}$$

and

$$[\tau^a, w^p] = [g f^a_{bc} \overleftarrow{\bar{C}^b} C^c, w^p] = 0, \quad a = 1, \ldots, 8. \tag{4.24}$$

From the arguments in Sec. III, we see that the solutions of Eqs. (4.23) and (4.24) exist trivially for $p=0$ and $p=8$ as long as they are given by the gauge invariant polynomials because they are singlets under the adjoint representation of the su(3) Lie algebra. But the cohomologies $H^p(\mathrm{su}(3);R)$ for $p=1$, 2, 4, 6, and 7 vanish. For $p=3$ and 5, there always exist non-trivial cohomologies $H^3(\mathrm{su}(3);R)$ and $H^5(\mathrm{su}(3);R)$ whose structures are given by Eq. (3.18) and they are related to each other by the Poincaré duality (2.23). Since the Lie algebra cohomology proves the nontrivial property of group invariant structures, the nonvanishing Lie algebra cohomologies $H^p(\mathrm{su}(3);R)$ can be related to the gauge invariants in $SU(3)$ gauge theory. It remains to investigate the deep relation between the gauge invariant configuration of gauge and matter fields in the space–time and the Lie algebra cohomology.

V. DISCUSSION

We have constructed the Lie algebra cohomology of the group of gauge transformation and obtained the Hodge decomposition theorem and the Poincaré duality. As long as a Lie algebra has a nondegenerate Cartan–Killing metric so that the underlying manifold is orientable, we can always define a unique (up to a multiplicative factor) adjoint of the coboundary operator under a nondegenerate inner product using a Hodge duality. However, for Lie algebras such as the Virasoro algebra for which no Cartan–Killing metric exists, the adjoint can not be unique. Indeed, for the Virasoro algebra, the adjoint of BRST generator defined by Niemi[32] is different from ours and that in Ref. 16.

We also considered the consistent extension of the Lie algebra cohomology into the relativistic phase space in order to obtain the Lagrangian formulation. In order to do that, we extended the Lie algebra by including the nonminimal sector of BRST generator and defined the adjoint generator with respect to the total Lie algebras corresponding to the constraint algebras in the extended phase space. We have pointed out that the generator $Q^\dagger$ constructed through this procedure corresponds to the adjoint of the BRST generator Q generating local gauge transformation and generates the noncovariant local or nonlocal symmetry in QED in Refs. 12 and 13 and there is no reason to introduce the nonlocality necessarily.

We have remarked that, in non-Abelian gauge theory, there may not exist the globally well-defined expression of the adjoint generator compatible with the gauge fixing condition due to the Gribov ambiguity being a topological obstruction coming from the global geometry of the gauge theory. But, as explained in Sec. IV, the adjoint $Q^\dagger$ in the non-Abelian gauge theory can exist locally (or perturbatively), so that it can generate new symmetry at least locally (or perturbatively). Then it will be interesting to study the role of the symmetry generated by the generator $Q^\dagger$ and the Ward identity of this symmetry in the local (or perturbative) sense and we think they are the important topics to need further study, including the relation between the Lie algebra cohomology and the global geometry of the gauge theory.

Note that the Lie algebra cohomology constructed here is quite different from the BRST cohomology in Refs. 6, 18, and 33. In the two cohomologies, the role of ghost fields is quite different and each inner product to obtain Hodge theory is defined by the definitely different schemes. It can be shown[34] that there is no paired singlet in the BRST cohomology so that higher cohomologies with nonzero ghost number vanish as long as the asymptotic completeness is assumed. Therefore the ghost number characterizing cohomology classes in this paper has different meaning from the ghost number of state space. The distinction between the BRST cohomology and the Lie algebra cohomology will be further clarified.[34]

In QCD, there are nontrivial cohomologies $H^p(\mathrm{su}(3);R)$ for $p=0$, 8 and $p=3$, 5 and they are, respectively, related to each other by the Poincaré duality. Since the Lie algebra cohomology proves the nontrivial property of group invariant structures, the nonvanishing Lie algebra cohomologies $H^p(\mathrm{su}(3);R)$ may be deeply related to the colorless combination of $SU(3)$ color charges which satisfy the su(3) Lie algebra. Then it will be very interesting to investigate the relation between the color confinement and the su(3) cohomology.

(Received 22 April 1996; accepted for publication 12 June 1996)

Based on the idea of quantum groups and para-Grassmannian variables, we present a generalization of supersymmetric classical mechanics with a deformation parameter $q=\exp(2\pi i/k)$ dealing with the $k=3$ case. The coordinates of the q-superspace are a commuting parameter t and a para-Grassmannian variable θ, where $\theta^3=0$. The generator and covariant derivative are obtained, as well as the action for some possible superfields. © *1996 American Institute of Physics.* [S0022-2488(96)00812-2]

I. INTRODUCTION

In the last few years, quasi triangular Hopf algebras or quantum groups[1–3] have attracted alot of attention from physicists. One of the most interesting features is that such structures can be related to underlying symmetries on spaces where the coordinates are noncommutative.[4]

It has been shown that the creation and annihilation operators of the q-deformed harmonic oscillator,[5]

$$aa^{\dagger}-qa^{\dagger}a=q^{-N}, \tag{1}$$

possess a classical limit where these operators can be understood as coordinates obeying[6]

$$\theta^k=0, \tag{2}$$

where k is an integer, and the q-factor of the deformation is a prime root of unity, $q^k=1$. In general, the properties of these coordinates are generalizations of the associated with Grassmannian variables. Promoting these coordinates to functions of a (nondeformed) parameter t, it was shown that it is possible to write down an action for such fields that, when added to the action of a commuting field, has a symmetry resembling supersymmetry,[7] and it has also been how to functional integrate on a heterotic quantum field theory.[8] The aim of this article is to show a way to understand the transformations on such fields and the action invariances, as resulting from a superspace formulation of a classical mechanical model where its coordinates are the para-Grassmann variables (a q-superspace) and noncommuting fields.

In the next section we briefly review para-Grassmann variables and also how we construct coordinates and actions from them. Section III is devoted to the construction of the q-superspace, transformations between its coordinates, and the induced transformations on the q-superfields defined on it. Invariant quadratic actions are constructed in Sec IV, in particular for a free particle and the harmonic oscillator. We leave some final comments to the last section.

II. PARA-GRASSMANNIAN VARIABLES AND THEIR RELATION TO QUERMIONIC COORDINATES

We start this section by introducing a para-Grassmannian variable θ and its derivative, $\partial/\partial\theta \equiv \partial_\theta$ obeying[9]

$$\theta^k = 0, \quad \partial_\theta{}^k = 0, \tag{3}$$

for a positive integer k.

If we demand that the action of ∂_θ on θ^n is proportional to θ^{n-1}, it turns out that it becomes necessary to deform the Leibnitz rule to be

$$\partial_\theta(ab) = (\partial_\theta a)b + g(a)(\partial_\theta b), \tag{4}$$

where a and b are arbitrary polynomials in θ, and $g(a)$ is an automorphism of the algebra satisfying

$$g(\alpha a + \beta b) = \alpha g(a) + \beta g(b), \quad g(ab) = g(a)g(b), \tag{5}$$

where α and β are c-numbers.

Choosing $a = \theta$ in (4), we see that ∂_θ and θ must obey a q-deformed commutation (q-commutation) relation

$$[\partial_\theta, \theta]_q \equiv \partial_\theta\theta - q\,\theta\partial_\theta = 1, \tag{6}$$

implying for θ the automorphism

$$g(\theta) = q\,\theta. \tag{7}$$

This derivative, however, is not unique. Indeed, we could change the power 1 in Eq. (6) by any other integer, thus for each value of k one can define $k-1$ different derivatives. For the specific case $k=3$, one may also define another derivative δ_θ (Ref. 10) that q-commutes with θ as

$$[\delta_\theta, \theta]_{q^2} \equiv \delta_\theta\theta - q^2\,\theta\delta_\theta = 1, \tag{8}$$

and its Leibnitz rule differs from Eq. (4) by changing $g(a)$ to $g(g(a))$. These two derivatives have the following q-commutation relation

$$\partial_\theta\delta_\theta - q\,\delta_\theta\partial_\theta = 1.$$

As in the Grassmannian case, it is not possible to define the integral over θ as the inverse of the derivative. However, if we impose translation invariance and homogenity for the integral, it must be of the form

$$\int d\theta\ \theta^n \alpha\,\delta_{n,k-1}. \tag{9}$$

It is interesting to notice that, for $k=2$ and $q=-1$, Eq. (1) becomes the usual anticommutator, consistent with Eqs. (3) and (6), which are the conditions for Grassmannian variables. Taking $k\to\infty$, Eq. (1) becomes the usual commutator. The meaning of this limit in Eq. (3) is that, if we Taylor expand a function of these variables, it will become a series [obviously, if $\theta^k=0$, k finite, a Taylor expansion will be a polynomial of degree $(k-1)$] being

$$f = a_0 + \theta a_1 + \theta^2 a_2 + \cdots + \theta^{k-1} a_{k-1}, \tag{10}$$

where we can promote the functions of a (commuting) parameter t.

Let us recall that in the Grassmannian case we have two different coordinates: one that behaves like θ (a fermionic coordinate), and another that behaves like θ^0, a bosonic (commuting) coordinate. In the para-Grassmannian case, we will have k different types of coordinates, each one corresponding to a power of θ, and again θ^0 being a commuting one. We call $\psi^{(i)}(t)$ the q-fermionic generalization of the coordinates or, simply, the quermionic coordinates, and its label (i) indicates the sector to which it belongs.

In a recent work,[7] it was emphasized that two quermions of different sectors obey the q-commutation relation

$$\psi^{(i)}\psi^{(j)}=q_{(i,j)}\psi^{(j)}\psi^{(i)}, \tag{11}$$

where the parameters $q_{(i,j)}$ are simply powers of q, $q^k=1$.

The particular case $k=3$ was taken, and an action which extends the supersymmetric point particle through the use of these generalized fields was constructed. This generalized particle was described by the coordinates $(x(t),\psi^{(1)}(t),\psi^{(2)}(t))$, in the same way as a supersymmetric point particle is described by the coordinates $(x(t),\psi(t))$. The shown action involving the quermions was given by

$$S=\int dt\left(\frac{1}{2}\dot{x}^2-qC^{(s)^2}\dot{\psi}^{(2)}\psi^{(1)}\right), \tag{12}$$

with the mass equal to one. The second term in (12) resembles the classical fermionic equation of motion. The cocycle-type factor $C^{(s)^2}$ was required because the product of two objects of different sectors, $A^{(r)}B^{(s)}$, must behave like an object of the sector $(r+s)$ mod 3. In that work, it emphasized the necessity of the factor Cq-superfield, paying the price of writing a suitable ''algebra'' of this factors. For instance, the cocycle-type factor $C^{(s)}$ that could be seen as a sector-counter had a relation

$$C^{(s)}A^{(i)}=q^iA^{(i)}C^{(s)}, \tag{13}$$

and adding the choice $[\psi^{(1)},\psi^{(2)}]_q=0$, which takes all the fields as real, the second term in the action equation (12) was left real and a zeroth sector representative.

Another interesting feature to recall was the transformation (the variations of a field, from now on, will be written as Δ to one not to be confused with the derivative δ)

$$\Delta x=qC^{(s)}\epsilon^{(1)}\psi^{(2)},\quad \Delta\psi^{(1)}=q^2C^{(s)^2}\epsilon^{(1)}\dot{x},\quad \Delta\psi^{(2)}=\pm q\epsilon^{(1)}\psi^{(1)}, \tag{14}$$

on the action (12) reaching

$$\Delta S=\pm\int dt\,\frac{d}{dt}\,(\epsilon^{(1)}\psi^{(1)^2}), \tag{15}$$

where $[\epsilon^{(1)},\psi^{(1)}]_q=[\psi^{(2)},\epsilon^{(1)}]_q=0$ was used. Such a transformation is similar to a supersymmetric one: the parameter $\epsilon^{(1)}$ is a noncommuting one, the action transforms as a total derivative, and one of the fields, $\psi^{(1)}$, transforms as a total derivative, which can be taken as indicating that $\psi^{(1)}$ is the highest term in a θ-expansion of some superfield. One could also write transformations among the fields with a parameter belonging to the sector two. However, it can be shown that this transformation is not a symmetry of the action (12).[7]

III. THE q-SUPERSPACE AND q-SUPERFIELDS

We begin to construct a q-superspace formulation that will recover the structure concerning the quermionic coordinates presented in the last section. As previously stated, we will consider in detail only the $k=3$ case, which represents the nilpotency and produces an interesting expression $1+q+q^2=0$. It emphasizes that the q and q^2 cases have no crucial difference. Some of the ideas discussed here and in the next section have been discussed also in Refs. 11 and 12 and more recently in Ref. 13 (this interesting work appeared when we had just finished this paper).

The q-superspace coordinates are $(t;\theta)$, where t is a c-number to be identified with time and θ is a para-Grassmannian variable obeying $\theta^3=0$, and both are taken as real parameters.

Let us now introduce transformations between these coordinates that are translations on the q-superspace. We write them as

$$\theta' = \theta + \varepsilon, \quad t' = t + q^C \theta^2 \varepsilon, \tag{16}$$

where ε is an infinitesimal constant in the same sector as θ and C can assume the values 1,2,3. Clearly, the exponent 3 will give us a trivial factor restricting then our set of possible choices. The translation in q-superspace fixes the mass dimensions of θ and ε to be $-\frac{1}{3}$. Although the translation term in t does not commute with the infinitesimal parameter ε, it still belongs to the same sector as t. [Remember that we met this issue when we wrote down the action for the quermionic components, Eq. (12), and we introduced the cocycle-like factor $C^{(s)}$ to correct the statistics.] We will say that two terms are homogeneous if both belong to the same sector. Defining the q-commutator to be

$$[A,B]_q \equiv AB - qBA, \tag{17}$$

we choose

$$[\theta,\varepsilon]_{q^{2C}} = 0. \tag{18}$$

It is after determining these q-commutation relations that we set the q factors in (16) to preserve the reality condition for the coordinates. We could choose q^C instead of q^{2C} in (18) (i.e., take $[\varepsilon,\theta]_{q^{2C}} = 0$). With this choice we necessarily have to change $q \leftrightarrow q^2$ in Eq. (16).

After introducing the q-superspace (t,θ), our next step is to write down a function of these variables. As in the supersymmetric case, let us expand this function in a Taylor series on θ. This expansion is a polynomial of degree 2 [for the generic case $\theta^k=0$, the polynomial goes up to the order $(k-1)$],

$$X(t;\theta) = x(t) + q^{B_2}\theta\psi^{(2)}(t) + q^{2B_1}\theta^2\psi^{(1)}(t). \tag{19}$$

The coordinate $x(t)$ is a commuting function, the $\psi^{(i)}(t)$ are the q-supersymmetric partners of the coordinate $x(t)$, and their dimensions are $[\psi^{(j)}] = -j/3$. We take their quommutators to be

$$[\psi^{(1)},\psi^{(2)}]_{q^A}=0, \quad [\varepsilon,\psi^{(j)}]_{q^{D_j}}=0, \quad [\theta,\psi^{(j)}]_{q^{B_j}}=0, \tag{20}$$

where the last expression guarantees that X is real and the others complete a deformed algebra.

The infinitesimal coordinate transformations (16) induce a variation on the q-superfield $X(t,\theta)$ of the form

$$X(t',\theta') - X(t,\theta) = \Delta X = \varepsilon Q X. \tag{21}$$

We can get the realization of the q-supersymmetric generator transformation, Q, by Taylor expanding the lhs of this equation. Choosing the factors to keep the reality condition we have

$$X(\theta',t')-X(\theta,t)=\varepsilon\frac{\partial X}{\partial\theta}+q^{2C}\varepsilon\theta^2\frac{\partial X}{\partial t}. \tag{22}$$

With this expansion, and using Eq. (16), Q becomes

$$Q=q^{2C}\theta^2\frac{\partial}{\partial t}+\frac{\partial}{\partial\theta}. \tag{23}$$

We notice that the generator is in the θ^2 sector, and its canonical dimension is $[Q]=\frac{1}{3}$. A straightforward calculation shows that $Q^3=-\partial_t$. This means that the q-supersymmetric transformations are the cubic roots of time translations.

Explicitly computing the rhs of (21), we obtain the X variation as

$$\Delta X=q^{B_2}\varepsilon\psi^{(2)}-q^{2B_1+2+C}\theta\varepsilon\psi^{(1)}+q^{2C}\theta^2\varepsilon\hat{x}. \tag{24}$$

Bearing in mind the reality condition we find from ΔX and X itself some relations among the q exponents. Finally we reach

$$2C=2B_2=B_1,\quad D_2=D_1+1. \tag{25}$$

The above relations do not fix completely the q-commutators among the variables [see (20)] we are considering, since we still have at our disposal three free coefficients. We may choose the variables $2C=D_2=1$ and $A=2$, thus fixing all the other ones (remember that for the $k=3$ nilpotency we have only two relevant choices for the exponents). With such a choice, the q-superspace translation becomes

$$\theta'=\theta+\varepsilon,\quad t'=t+q^2\theta^2\varepsilon, \tag{26}$$

while the q-su becomes

$$X(t)=x+q^2\theta\psi^{(2)}+q^2\theta^2\psi^{(1)}. \tag{27}$$

The q-SUSY generator,

$$Q=q\theta^2\partial_t+\partial_\theta, \tag{28}$$

yields the transformation

$$\Delta X=q\varepsilon\theta^2\dot{x}+q^2\varepsilon\psi^{(2)}-q\varepsilon\theta\psi^{(1)}, \tag{29}$$

or in components

$$\Delta x=q^2\varepsilon\psi^{(2)},\quad \Delta\psi^{(1)}=\varepsilon\dot{x},\quad \Delta\psi^{(2)}=q\varepsilon\psi^{(1)}. \tag{30}$$

Moreover, they have the q-commutators

$$\varepsilon\theta=q^2\theta\varepsilon,\quad \theta\psi^{(j)}=q^j\psi^{(j)}\theta,\quad \varepsilon\psi^{(j)}=q^j\psi^{(j)}\varepsilon, \tag{31}$$

which let on the same structure as the one present in Sec. II. This structure allows us to take the q-commutation relation between the two quermionic coordinates, which read

$$\psi^{(1)}\psi^{(2)}=q^2\psi^{(2)}\psi^{(1)}. \tag{32}$$

Having written down the q-superspace transformations and the variations on the q-superfield, let us now construct a q-covariant derivative, D, that is, a differential operator that obeys

$$[D,Q]_q=0, \tag{33}$$

$$D(\Delta X)=\Delta(DX). \tag{34}$$

We could try for D the same structure that appears in the q-SUSY generator, i.e., to take $D=q^{\alpha}\theta^2\partial_t+aq^{\beta}\partial_\theta$, $(\alpha,\beta=1,2,3;\ a\in C)$. However, it turns out not to be possible to find an operator with this structure and q-commuting with Q. The only operator that obeys (34) is Q itself, but it obviously does not obey (33).

To construct the coordinates of level 3 permit us to introduce two differential operators, ∂_θ and δ_θ. Using the second one it is possible to show that the operator

$$D=\theta^2\partial_t+q\,\delta_\theta \tag{35}$$

satisfies the conditions (33) and (34).

As in the supersymmetric case, the component fields can be defined by projecting the superfield on different sectors, using the covariant derivatives on $\theta=0$:

$$X|_{\theta=0}=x, \quad DX|_{\theta=0}=\psi^{(2)}, \quad D^2X|_{\theta=0}=-\psi^{(1)}. \tag{36}$$

From now on, we will neglect the subscript $\theta=0$.

We also notice some relations between different powers of D and Q that will become useful later:

$$D.|=q^2Q.|, \quad D^2.|=qQ^2.|, \quad D^3.|=-\partial_t.|. \tag{37}$$

Besides the above-defined bosonic superfield, we can also construct sectors one and two superfields. Their θ expansion can be taken to be

$$\Lambda^{(1)}=\lambda^{(1)}+\theta A+q\,\theta^2\lambda^{(2)} \tag{38}$$

and

$$\Xi^{(2)}(t)=\xi^{(2)}+q\,\theta\xi^{(1)}+\theta^2F, \tag{39}$$

where the superscripts indicate the sectors to which the fields belongs, and A and F are bosonic fields.

The dimension of the q-superfield $\Xi^{(2)}$ is taken to be $\frac{2}{3}$, its bosonic component F being dimensionless and, as we will see later, behaving as an auxiliary field. We cannot, however, take the dimension of the q-superfield $\Lambda^{(1)}$ to be $\frac{1}{3}$, since this would imply a negative dimension for the component field $\lambda^{(2)}$. Thus take its dimension to be $\frac{4}{3}$. This, however, will produce different equations of motion for its quermionic components, as we will see in the next section.

We assume that the fields $\xi^{(j)}$ have the same behavior as $\psi^{(j)}$ with respect to the q-commutations relations with each other, with θ and with ϵ.

IV. EXAMPLES OF SUPERACTIONS

In this section, we are going to make a general discussion about simply quadratic actions that are functions of the q-superfields introduced in the previous section and give some examples of them.

The action for a generic superfield Φ must be of the form

$$S=\int dtd\theta\mathscr{L}(\Phi,\dot{\Phi},D\Phi,D^2\Phi), \tag{40}$$

where $\mathscr{P}$ is a polynomial in Φ and its derivatives. $\mathscr{P}$ must behave like θ^2, belonging to the sector two (since $\int d\theta = \partial_\theta^2$, and S is scalar), and since the measure has mass dimension $-\frac{1}{3}$ and S is dimensionless, its dimension must be $\frac{1}{3}$.

By comparing the expression for the covariant derivative and the θ-integration, we notice the rule

$$\int d\theta = q^2 D^2|. \tag{41}$$

Let us now perform a transformation on the action

$$\Delta S = \int dt\ d\theta\ \Delta\mathscr{P}(\Phi, \dot{\Phi}, D\Phi, D^2\Phi), \tag{42}$$

since the Jacobian is one, which can be seen by the t independence of the θ translation. Since $\mathscr{P}$ is a superfield, its variation is of the form of Eq. (21). Using this and Eq. (41), we arrive at the conclusion

$$\Delta S = -q\varepsilon \int dt\ \alpha_t \mathscr{P}. \tag{43}$$

and the transformations Eq. (16) generates symmetries of the action.

Let us now write an action of the q-superfields X, $\Lambda^{(1)}$, and $\Xi^{(2)}$ defined in Sec. III, and compute their equations of motion. We begin with the bosonic superfield X. Its quadratic action is

$$S_X = -\frac{m}{2} \int dt\ d\theta\ q^2 (D^2 X)(D^2 X), \tag{44}$$

where m is a commuting mass parameter. By explicit computation of its θ integral, or by use of Eq. (41), this action can be written down in components as

$$S_X = m \int dt \left(\frac{1}{2} \dot{x}^2 - 2q \dot{\psi}^{(2)} \psi^{(1)} \right), \tag{45}$$

where the difference with the Sec. I action is due to the different initial superactions in these cases.

Although the variational calculus of the quermionic coordinates presents several difficulties to overcome (for instance, how to do the variation with respect to a quermion), it is clear that the equation of motion arising from the above Lagrangian is, up to multiplicative factors $D\dot{X} = 0$, giving in components $\ddot{x} = \psi^{(j)} = 0$ $(j = 1,2)$. Computing its q-supersymmetric variation, we obtain

$$\Delta S^X = q\varepsilon \int dt\ \frac{\partial \psi^{(1)^2}}{\partial t}. \tag{46}$$

We notice that the action given by Eq. (44), its variation Eq. (46), and the variation of the component fields Eq. (30) are, up to factors, equal to Eqs. (12), (15), and (14), respectively, recalling that the presence of such cocycle-type factors was because the q-commutation homogeneity assumption had been used. Thus we see that the q-superfield X describes the dynamics of a free particle partners.

The quadratic action for the q-superfield $\Lambda^{(1)}$ is

$$S_\Lambda = -\frac{m}{2} \int dt d\theta (\dot{\Lambda}^{(1)})^2. \tag{47}$$

By convenience the mass parameter was taken to be the same as in the X action. In components, the action turns out to be

$$S_\Lambda = \frac{m}{2} \int dt(\dot{A}^2 + 2q\dot{\lambda}^{(2)}\dot{\lambda}^{(1)}) \tag{48}$$

It is interesting to notice that the equation of motion for $\Lambda^{(1)}$, obtained from its action, $\ddot{\Lambda}^{(1)}=0$, gives in component $\ddot{A}=\ddot{\lambda}^{(i)}=0$. Thus this q-superfield also represents a free particle, but its quermionic partners obey an equation of motion that is of second order in the time derivative, whereas in the case of q-superfield X it is of first order. The q-supersymmetric variation of the S_Λ is

$$\Delta S_\Lambda = \varepsilon \int dt \frac{\partial(\dot{\Lambda}^{(1)})^2}{\partial t}. \tag{49}$$

We now consider the quadratic action for the q-superfield $\Xi^{(2)}$. It is

$$S_\Xi = m \int dt\ d\theta (D\Xi^{(2)})^2. \tag{50}$$

In component fields, the action reads

$$S_\Xi = m \int dt[2q\dot{\xi}^{(2)}\xi^{(1)} + F^2]. \tag{51}$$

The equation of motion for $\Xi^{(2)}$ is $D^2\Xi^{(2)}=0$, giving $F=\dot{\xi}^{(j)}=0$, meaning, as it was anticipated, that the bosonic coordinate F is an auxiliary one. The variation of S_Ξ is

$$\Delta S_\Xi = -\varepsilon \int dt\ \frac{\alpha \xi^{(1)^2}}{\partial t}. \tag{52}$$

The superfields X and $\Xi^{(2)}$ can have a quadratic action with a mixed term

$$S_{X\Xi} = m\omega \int dt d\theta q^2 X \Xi^{(2)}, l \tag{53}$$

where ω has a mass^{-1} dimension. In components we write this action as

$$S_{X\Xi} = m\omega \int dt(Fx + q^2\psi^{(1)}\xi^{(2)} + q\psi^{(2)}\xi^{(1)}). \tag{54}$$

Summing up the actions (44), (50), and (54), $S_{HO}=S_X+S_\Xi+S_{X\Xi}$, and its bosonic part is

$$S_{HO} = \int dtm\left(\frac{1}{2}\dot{x}^2 + \frac{1}{2}F^2 + \omega F x\right). \tag{55}$$

Computing the equation of motion of the auxiliary field F and reintroducing it in the action, it becomes

$$S_x = \int dt\left[\frac{1}{2}m\dot{x}^2 - \frac{1}{2}m\omega x\right], \tag{56}$$

which is the action for the harmonic oscillator.

V. CONCLUSIONS

In this article, we presented a generalization of some supersymmetric classical mechanical models where the superspace has a noncommuting coordinate nilpotent of order 3, and the commutation relations among the several objects of the model are deformed by powers of a parameter q. Translations on the q-superspace induce transformations on the fields, and the operational realization of the supersymmetric generator is obtained by a suitable Taylor expansion. The covariant derivative was also introduced, in which we used a second kind of partial para-Grassmannian derivative. In spite of the supersymmetric structure similarity, we are facing a slightly different situation. In fact, because of the presence of two derivatives, such as the forward and the backward one, it resembles a lattice approach. In a recent work,[13] the authors showed the roles played by the covariant derivative D and the symmetry generator Q, present in this work, are the left and right action of G_3 group.

After introducing superfields belonging to different sectors, we were able to construct quadratic actions for each one. These actions are, up to total derivatives, invariant under the q-supersymmetric transformations. Using a naive approach, it is possible to extract from these actions the equations of motion since there is no, up to now, well-defined differential calculus on these quermionic coordinates. We intend to discuss this subject in a forthcoming publication. We also showed that imposing the ''on-shell'' constraint to the auxiliary fields, it is possible to get the harmonic oscillator as a bosonic sector of a simple suitable linear combination of the actions.

It should also be interesting to study this formulation from a field theoretical point of view, in particular in the $(2+1)$-dimensional case. We might also try to understand if such fields are representations of some q-deformed algebra, either a q-Poincaré or a q-Clifford one.

Inverse problem in nonstationary multidimensional medium

Boris M. Shevtsov
Radio Science Laboratory, Pacific Oceanological Institute, 43, Baltiyskay St., Vladivostok, 690041, Russia

(Received 8 March 1995; accepted for publication 1 July 1996)

The problem of a scalar wave propagation from the point impulsive source in the layer of a nonstationary multidimensional medium is considered. The boundary problem for the wave equation is reformulated in the problem with the initial condition using the invariant imbedding method. The integral-differential inverse procedures of the various orders were obtained from the imbedding equations using the singularities method. The order of inverse procedure is defined by the degree of a polynomial in the analytical representation of the medium characteristic near the layer boundary. It was shown that the coefficients of the polynomial are calculated with the help of the differential characteristics of the point impulsive source in the inhomogeneous medium. The cause and character of the multidimensional inverse problem overdefiniteness are considered. The application of the proposed procedure for a statistical problem is discussed. © *1996 American Institute of Physics.* [S0022-2488(96)04311-3]

I. INTRODUCTION

For the study of direct and inverse wave problems in the regular and random media, the imbedding method[1,2] has been developed which allows simultaneously the creation of the strict inverse procedures[3–5] and the employment of the effective statistical approaches using the Markov process approximation.[1,2,6] This is different from the integral equation method[7,8] and the deferential method,[9,10] both of which have some difficulties pertaining to the application in statistical theory.[1,2]

The nature of most of the media examined in optics, acoustics, plasma physics, and radio science is described by mathematical models with spatial and time inhomogeneous refractive index. The inverse procedure obtained by the imbedding method was considered for multidimensional stationary[11,12] and one-dimensional nonstationary[13] media. The subject of the present paper is to extend the previous results on common case for the promotion of the inverse problem research in remote sensing based on the statistical approach,[14] which is a strict alternative to the line radiation transfer theory, which uses the usual transfer equation[15] and does not account for the statistical effects.[16,17]

In the present paper, the mathematical model accepted in statistical theory[1,2] is employed. The boundary-value wave problem for this model is reformulated in the problem with the initial condition and the imbedding equation is written. The inverse procedure is obtained from the imbedding equation by a singularities method.[5,18]

The main step of the inverse procedure is the ''layer stripping'' process,[11,12] which can be realized in the different versions. In conclusion, the extension of the obtained procedure on statistical problems and the derivation way of the evolution equations for the statistical characteristics of backscattering are discussed.

II. THE STATEMENT OF THE PROBLEM

The scalar wave propagation in the layer of inhomogeneous nonstationary medium that occupies the part of the space $L_0 \leqslant x \leqslant L$ will be considered. The wave is created by the point impulsive source on the boundary of the layer $x = L$ and is described by the equation[15]

0022-2488/96/37(12)/6130/9/$10.00

$$\left[\frac{\partial^2(1+\varepsilon(x,\boldsymbol{\rho},t))}{\partial t^2}-c^2\Delta\right]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)=\delta(x-L)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\,\delta(t-t_0), \tag{1}$$

where $\varepsilon(x,\boldsymbol{\rho},t)$ is the continuous and smooth characteristic of the scattering medium in the layer $L_0\leqslant x\leqslant L$, $\boldsymbol{\rho}$ and $\boldsymbol{\rho}_0$ are the vectors in the plane of constant x, c is the signal velocity in the homogeneous medium outside of the layer, where $\varepsilon=0$, Δ is Laplacian, and the Dirac δ-functions are in the right part of this equation.

It will be assumed that $-1<\varepsilon(x,\boldsymbol{\rho},t)<\mu$ and all first partial derivatives of $\varepsilon(x,\boldsymbol{\rho},t)$ are bounded. However, when some variants of the inverse procedure will be discussed in Sec. VII, the existence and bound of higher derivatives will be supposed.

Equation (1) is used in the different areas of physics, for example, in optics, acoustics, radio science, etc., where the wave propagation is considered in the medium with a transient impedance or refractive index. The wave equation is taken here in a simpler form to show an approach, which may be extended to the waves of a more complex nature.

The solution of the mixed (initial and boundary values) problem for Eq. (1) will be analyzed. There are the discontinuities of $\varepsilon(x,\boldsymbol{\rho},t)$ on two planes $x=L_0$ and $x=L$, which divide the space into three areas. It will be supposed that G and $\partial G/\partial x$ are continuous on the boundaries of the layer and there are only the going away waves outside of the layer. These six boundary values for three space areas are enough to solve the above-mentioned problem, if they are completed by the initial conditions: $G=0$ for $t<t_0$. In Sec. IV, this mixed problem will be represented in the convenient form for obtaining the imbedding equations in Sec. V. First, the wave operator in (1) will be written through the Neumann operator[12] in Sec. III.

We shall proceed from the existence of a solution of the above-formulated problem for the Eq. (1),[15] which is a Green's function describing the field of the point impulsive source. This solution is the generalized function,[19] which will be considered on the plane $x=L$. The evolution equations of the solution, when L is a variable parameter, will be found in Sec. V. The behavior of singularities and the regular part of the solution will be considered in Sec. VI with the intention of creating the inverse procedure in Sec. VII.

III. THE CASE OF THE HOMOGENEOUS SPACE

The factorization of the wave operator (1) in the free space will be needed below. In the homogeneous space, (see for example Ref. 15) the solution of (1) is

$$g(x-L,\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)=\frac{\theta(t-t_0)}{4\pi c^2(t-t_0)}\,\delta[c(t-t_0)-\sqrt{(x-L)^2+(\boldsymbol{\rho}-\boldsymbol{\rho}_0)^2}]$$

$$\equiv\frac{\theta(t-t_0)}{2\pi c}\,\delta[c^2(t-t_0)^2-(x-L)^2-(\boldsymbol{\rho}-\boldsymbol{\rho}_0)^2], \tag{2a}$$

where $\theta(t-t_0)$ is the Heaviside function. Let us write the equation for (2). If $\epsilon=0$ everywhere, Eq. (1) may be presented in the form

$$\left[\frac{\partial}{\partial x}+\hat{M}(\boldsymbol{\rho},t)\right]\left[\frac{\partial}{\partial x}-\hat{M}(\boldsymbol{\rho},t)\right]g(x-L,\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)=-\delta(x-L)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\,\delta(t-t_0)/c^2, \tag{2b}$$

where the introduced operator is defined as[2]

$$\hat{M}^2(\boldsymbol{\rho},t)=\frac{\partial^2}{c^2\partial t^2}-\Delta_{\boldsymbol{\rho}},\quad \Delta_{\boldsymbol{\rho}}=\partial^2/\partial y^2+\partial^2/\partial z^2.$$

In the regions $x>L$ and $x<L$ the function g satisfies the first-order equations $[\partial/\partial x \pm \hat{M}(\boldsymbol{\rho},t)]g=0$, which describe the free going away waves. The signs correspond to the directions of the waves. The solutions of these equations we can write as[2]

$$g(x-L,\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)=\exp[-|x-L|\hat{M}(\boldsymbol{\rho},t)]g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0), \tag{3}$$

where $g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)=g(0,\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)$. Differentiating (3) twice with respect to x we shall find

$$[\partial^2/\partial x^2-\hat{M}^2(\boldsymbol{\rho},t)]g(x-L,\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)=-2\,\delta(x-L)\hat{M}(\boldsymbol{\rho},t)g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0). \tag{4}$$

Then we see that it follows from the comparison of (2b) with (4)

$$\hat{M}(\boldsymbol{\rho},t)g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)=(1/2c^2)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\,\delta(t-t_0). \tag{5}$$

We shall present the operator $\hat{M}(\boldsymbol{\rho},t)$ in the integral form by the identity

$$\hat{M}(\boldsymbol{\rho},t)f(\boldsymbol{\rho},t)=\int d\boldsymbol{\rho}_1 dt_1 \hat{M}(\boldsymbol{\rho},t)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_1)\,\delta(t-t_1)f(\boldsymbol{\rho}_1,t_1). \tag{6}$$

Hence we defined the kernel of the operator as

$$M(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1)=\hat{M}(\boldsymbol{\rho},t)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_1)\,\delta(t-t_1). \tag{7}$$

Acting by $\hat{M}(\boldsymbol{\rho},t)$ on (5) we can obtain also for the kernel of the operator

$$M(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1)=2c^2\hat{M}^2(\boldsymbol{\rho},t)g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1). \tag{8}$$

Differentiating in the right part of (8), we yield the explicit form of the kernel[2]

$$M(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1)=-\frac{2}{(t-t_1)}\frac{\partial}{\partial t}\,g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1). \tag{9a}$$

Substituting second expression (2a) in (9a) and differentiating it here, using the formulas,

$$\delta'(t-t_1)=-\delta(t-t_1)/(t-t_1) \quad \text{and} \quad \int d\boldsymbol{\rho}_1\delta[c^2(t-t_1)^2-(\boldsymbol{\rho}-\boldsymbol{\rho}_1)^2]|_{t\to t_1}=\pi,$$

which may be derived by the standard technique of the generalized functions,[15,19] it can be shown that

$$\hat{M}(\boldsymbol{\rho},t)f(\boldsymbol{\rho},t)=\frac{1}{c}\frac{\partial}{\partial t}\,f(\boldsymbol{\rho},t)-\frac{2c}{\pi}\int d\boldsymbol{\rho}_1 dt_1\,\theta(t-t_1)\,\delta'[c^2(t-t_1)^2-(\boldsymbol{\rho}-\boldsymbol{\rho}_1)^2]f(\boldsymbol{\rho}_1,t_1), \tag{9b}$$

where δ' is the derivative of the δ-function and, in the agreement with its definition,[15] is the spatial derivative of $f(\boldsymbol{\rho}_1,t_1)$ normal to the nonstationary circle $c^2(t-t_0)^2-(\boldsymbol{\rho}-\boldsymbol{\rho}_0)^2=0$. The example (9b) of two members decomposition of the kernel (9a) will be used in Sec. VI.

By the action of inverse operator $\hat{M}^{-1}(\boldsymbol{\rho},t)$ on (5), the kernel of the inverse operator is obtained:

$$M^{-1}(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1)=\hat{M}^{-1}(\boldsymbol{\rho},t)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_1)\,\delta(t-t_1)=2c^2g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_1,t-t_1). \tag{9c}$$

Substituting the first expression of (2a) in (9c), we come exactly to the result (2.3) of Ref. 12. It is clear that the $\hat{M}^{-1}(\boldsymbol{\rho},t)$ is the Neumann operator in free space, hence the $\hat{M}(\boldsymbol{\rho},t)$ is its inversion.

IV. THE BOUNDARY CONDITIONS

Following the method[1,2] we shall write the noted above (in Sec. II) boundary conditions in the convenient form for obtaining the imbedding equations. The solution of (1) is $G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)=\exp[-(x-L)\hat{M}(\boldsymbol{\rho},t)]G(L,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)$ for $x>L$ and $G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)=\exp[(x-L)M(\boldsymbol{\rho},t)]G(L_0,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)$ for $x<L_0$. Differentiating these expressions with respect to x and accounting for the jump $\partial/\partial x G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L-0}^{x=L+0}=-(1/c^2)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\delta(t-t_0)$ and the continuity of G and $\partial/\partial x G$, we obtain the relations in the layer on the inside of the boundaries. After this evolution, we have the problem in the layer instead of (1).

$$\left[\frac{\partial^2}{\partial x^2}-\hat{M}^2(\boldsymbol{\rho},t)\right]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)=\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\,\varepsilon(x,\boldsymbol{\rho},t)G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0),$$

$$\left[\frac{\partial}{\partial x}+\hat{M}(\boldsymbol{\rho},t)\right]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L-0}=(1/c^2)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\,\delta(t-t_0), \tag{10}$$

$$\left[\frac{\partial}{\partial x}-\hat{M}(\boldsymbol{\rho},t)\right]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L_0+0}=0.$$

The imbedding method allows us to reformulate this boundary problem to the problem with the initial conditions. Following Refs. 1 and 2, we shall obtain the imbedding equations, which will be used for the investigation of the inverse problem below.

V. IMBEDDING EQUATIONS

Having in mind that L is a variable parameter in a correspondence with the essence of the imbedding method,[1,2] we differentiate (10) with respect to L. The equation and the second boundary condition give directly the necessary result. The first boundary condition yields

$$\left[\frac{\partial}{\partial x}+\hat{M}(\boldsymbol{\rho},t)\right]\left[\frac{\partial}{\partial x}+\frac{\partial}{\partial L}\right]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L}=0. \tag{11}$$

Two components in (11) $[\partial/\partial x+\hat{M}(\boldsymbol{\rho},t)]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L}$ are found by using Eq. (10) and the operation of $\hat{M}(\boldsymbol{\rho},t)$ on the first boundary condition (10). Its obtained instead of (10).

$$\left[\frac{\partial^2}{\partial x^2}-\hat{M}^2(\boldsymbol{\rho},t)\right]\frac{\partial}{\partial L}\,G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)=\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\,\varepsilon(x,\boldsymbol{\rho},t)\,\frac{\partial}{\partial L}\,G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0),$$

$$\left[\frac{\partial}{\partial x}+\hat{M}(\boldsymbol{\rho},t)\right]\frac{\partial}{\partial L}\,G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L}=-\frac{1}{c^2}\,\hat{M}(\boldsymbol{\rho},t)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\,\delta(t-t_0)$$

$$-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\,\varepsilon(L,\boldsymbol{\rho},t)G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0), \tag{12}$$

$$\left[\frac{\partial}{\partial x}-\hat{M}(\boldsymbol{\rho},t)\right]\frac{\partial}{\partial L}\,G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L_0}=0,$$

where $G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)=G(L,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)$.

We see from the comparison of (10) with (12) that the solution of (10) is a Green's function for the problem (12). It means that $\partial G/\partial L$ is expressed through G by the integral relationship, which yields with respect to (6) and (7) the expression

$$\left[\frac{\partial}{\partial L}+\hat{M}(\boldsymbol{\rho}_0,t_0)\right]G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)$$

$$=-\int d\boldsymbol{\rho}_1 dt_1 G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_1,t_1)\,\frac{\partial^2}{\partial t_1^2}\,\varepsilon(L,\boldsymbol{\rho}_1,t_1)G_L(\boldsymbol{\rho}_1,t_1;\boldsymbol{\rho}_0,t_0). \tag{13}$$

$\hat{M}(\boldsymbol{\rho}_0,t_0)$ is defined above in (7)–(9); it operates on $\boldsymbol{\rho}_0,t_0$. We have to exchange in (7) $\boldsymbol{\rho}\to\boldsymbol{\rho}_1$, $\boldsymbol{\rho}_1\to\boldsymbol{\rho}_0$ (and the same for t). The expression (13) may be considered as the equation for $G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)$, if it be completed by the initial condition

$$G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{L=x}=G_x(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0). \tag{14}$$

We need the equation for $G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ and write

$$\frac{\partial G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)}{\partial L}=\left(\frac{\partial}{\partial x}+\frac{\partial}{\partial L}\right)G(x,\boldsymbol{\rho},t;L,\boldsymbol{\rho}_0,t_0)|_{x=L}\,.$$

Here the first component is found using the first boundary condition (10); the second is calculated by the using of (13). A result is obtained as

$$\left[\frac{\partial}{\partial L}+\hat{M}(\boldsymbol{\rho},t)+\hat{M}(\boldsymbol{\rho}_0,t_0)\right]G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$$

$$=\frac{1}{c^2}\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0)\,\delta(t-t_0)-\int d\boldsymbol{\rho}_1 dt_1 G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_1,t_1)\,\frac{\partial^2}{\partial t_1^2}\,\varepsilon(L,\boldsymbol{\rho}_1,t_1)G_L(\boldsymbol{\rho}_1,t_1;\boldsymbol{\rho}_0,t_0) \tag{15}$$

with the obvious initial condition $G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)|_{L=L_0}=g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)$.

How it will be shown that the value $G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ plays the main role in the inverse problem. This is a field on the plane $x=L$ from the point impulsive source on same plane, which may be measured in the remote sensing. The difference $G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)-g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)$ is a backscattering field from the layer of the inhomogeneous medium. Below we shall consider the solution of Eq. (1) only on the plane $x=L$ and Eq. (15) will be used only.

VI. THE METHOD OF THE SINGULARITIES

The important element of the differential approach for inverse problems is the method of the singularities.[5,18,20] In order to make its generalization for the multidimensional problem, we shall perform the solution of (15) as

$$G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)=\theta(t-t_0)H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0), \tag{16}$$

where $\theta(t-t_0)$ is the Heaviside function.

The substitution of (16) in (15) and the application of (9b) give the expression with two kinds of singularities $\theta(t-t_0)$ and $\delta(t-t_0)$. Comparing the coefficients before these singularities to zero, we obtain two equations:

$$\frac{\partial}{\partial L}\,H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)+\frac{1}{c}\,\frac{\partial}{\partial t}\,H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)-\frac{1}{c}\,\frac{\partial}{\partial t_0}\,H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$$

$$-\frac{2c}{\pi}\int_{t_0}^{t}dt_1\int \boldsymbol{\rho}_1 H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_1,t_1)\,\delta'[c^2(t_1-t_0)^2-(\boldsymbol{\rho}_1-\boldsymbol{\rho}_0)^2]$$

$$-\frac{2c}{\pi}\int_{t_0}^{t}dt_1\int \boldsymbol{\rho}_1 \delta'[c^2(t-t_1)^2-(\boldsymbol{\rho}-\boldsymbol{\rho}_1)^2]H_L(\boldsymbol{\rho}_1,t_1;\boldsymbol{\rho}_0,t_0)$$

$$=h_L(\boldsymbol{\rho}_0,t_0)\varepsilon(L,\boldsymbol{\rho}_0,t_0)\frac{\partial}{\partial t_0}H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$$

$$-h_L(\boldsymbol{\rho},t)\frac{\partial}{\partial t}[\varepsilon(L,\boldsymbol{\rho},t)H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)]$$

$$+\int_{t_0}^{t}dt_1\int d\boldsymbol{\rho}_1\frac{\partial}{\partial t_1}[H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_1,t_1)]\frac{\partial}{\partial t_1}\varepsilon(L,\boldsymbol{\rho}_1,t_1)H_L(\boldsymbol{\rho}_1,t_1;\boldsymbol{\rho}_0,t_0), \quad (17a)$$

$$c^2\varepsilon(L,\boldsymbol{\rho}_0,t_0)h_L^2(\boldsymbol{\rho}_0,t_0)+2c\cdot h_L(\boldsymbol{\rho}_0,t_0)-1=0. \quad (17b)$$

The value $h_L(\boldsymbol{\rho}_0, t_0)$ in (17b) is determined by the relationship

$$H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)|_{t\to t_0}=h_L(\boldsymbol{\rho}_0,t_0)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0), \quad (18)$$

which is the distribution of the source field in the initial moment t_0. The amplitude $h_L(\boldsymbol{\rho}_0,t_0)$ of this distribution is defined, in the agreement with (17b), by the characteristic of the medium $\varepsilon(L,\boldsymbol{\rho}_0,t_0)$ in the point of the source,

$$h_L(\boldsymbol{\rho}_0,t_0)=\frac{(\sqrt{1+\varepsilon(L,\boldsymbol{\rho}_0,t_0)}-1)}{c\varepsilon(L,\boldsymbol{\rho}_0,t_0)}. \quad (19)$$

Note, a sign before the square root in (19) is chosen so that for the homogeneous medium

$$H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)|_{t\to t_0}=g_0(\boldsymbol{\rho}-\boldsymbol{\rho}_0,t-t_0)|_{t\to t_0}=(1/2c)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0).$$

The δ' in (17a) is the derivative of the δ-function. In the agreement with its definition,[15] the expressions under the integrals in the left part of (17a) are the spatial derivative of $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ normal to the nonstationary circles $c^2(t_1-t_0)^2-(\boldsymbol{\rho}_1-\boldsymbol{\rho}_0)^2=0$ or $c^2(t-t_1)^2-(\boldsymbol{\rho}-\boldsymbol{\rho}_1)^2=0$ in the plane $x=L$. These terms describe the transverse propagation of the wave and are written in (17a) formally as the longitudinal terms, which simplifies the analysis of the multidimensional problem.

Equation (17a) allows us to obtain the relation between the partial derivative of $\varepsilon(L,\boldsymbol{\rho}_0,t_0)$ with respect to L and the partial derivatives of $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ with respect to t and t_0 for $t=t_0$. Putting in (17a) $t=t_0$, we have

$$\frac{\partial h_L(\boldsymbol{\rho}_0,t_0)}{\partial L}+\frac{A_L(\boldsymbol{\rho}_0,t_0)}{c}-\frac{B_L(\boldsymbol{\rho}_0,t_0)}{c}=h_L(\boldsymbol{\rho}_0,t_0)\varepsilon(L,\boldsymbol{\rho}_0,t_0)[B_L(\boldsymbol{\rho}_0,t_0)-A_L(\boldsymbol{\rho}_0,t_0)]$$
$$-\frac{[h_L(\boldsymbol{\rho}_0,t_0)]^2\partial\varepsilon(L,\boldsymbol{\rho}_0,t_0)}{\partial t_0}. \quad (20)$$

The values A and B introduced here are the characteristics of the point source on the boundary of the inhomogeneuos medium in initial moment. They are defined by the expressions

$$\left.\frac{\partial H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)}{\partial t}\right|_{t\to t_0}=A_L(\boldsymbol{\rho}_0,t_0)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0), \quad (21)$$

$$\left.\frac{\partial H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)}{\partial t_0}\right|_{t\to t_0} = B_L(\boldsymbol{\rho}_0,t_0)\,\delta(\boldsymbol{\rho}-\boldsymbol{\rho}_0).$$

Using (17b), (19), and (20), we can obtain

$$\frac{\partial \varepsilon(L,\boldsymbol{\rho}_0,t_0)}{\partial L} = \frac{2(1-ch_L(\boldsymbol{\rho}_0,t_0))^2[A_L(\boldsymbol{\rho}_0,t_0) - 2\partial h_L(\boldsymbol{\rho}_0,t_0)/\partial t_0 - B_L(\boldsymbol{\rho}_0,t_0)]}{[ch_L(\boldsymbol{\rho}_0,t_0)]^4}. \tag{22}$$

Hence the derivative of $\varepsilon(L,\boldsymbol{\rho}_0,t_0)$ with respect to L is defined by the time derivatives of the field on the boundary of the medium in initial moment.

Differentiating (17a) with respect to t and t_0, putting $t=t_0$, and combining the obtained expressions, we can find $\partial^2\varepsilon(L,\boldsymbol{\rho}_0,t_0)/\partial L^2$, which will be defined by second time derivatives of the field on the boundary in initial moment.

The procedure of the differentiation may be repeated over and over again and the higher derivatives of ε with respect to L can be found. In principle, from the time behavior of the field on the plane $x=L$ in initial moment, all L derivatives of ε can be calculated and the Taylor series of ε can be completed, which allows us to reconstruct the behavior of ε to the left from the plane $x=L$. It can be considered like the inverse procedure, but the nonlinearity of Eq. (17a) creates the difficulties in calculation of very high derivatives. The more effective way will be discussed in next section.

Note the some features of the wave propagation. On the plane $x=L$, the value of $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ is singular on the front of the wave. Behind the front, the wave can have also the singularities, when the reflection of the wavefront from the medium or from the plane $x=L_0$ comes to the surface $x=L$. This moment and greater time were not considered above. To do it, the solution of (15), instead of (16), would have to be presented in the form

$$G_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0) = \theta(t-t_0)H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0) + \theta(t-t_0')\widetilde{H}_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0',t_0'), \tag{23}$$

where $\boldsymbol{\rho}_0'$ and t_0' are the point on the plane $x=L$ and the moment of the reflection appearance. Substituting (23) in (15) and separating the singularities as above, we can obtain the equation for $\widetilde{H}_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0',t_0')$, which is not closed, because the value H presents there. (We have to define H and $\widetilde{H}$ jointly.) The separation of the singularities was considered in detail for the one-dimensional case in Ref. 20.

When the second wavefront reflection appears on the plane $x=L$, the third term has to be included in (23) and the third equation has to be obtained, etc. This approach allows us to separate and to observe individually the moves of all singularities, which will promote the development of the algorithms and numerical methods.

With the purpose of simplifying the examination of an inverse procedure, the case when the reflections of the wavefront are absent will be considered below.

VII. INVERSE PROBLEM

The inverse procedure for the multidimensional nonstationary medium may be obtained by the use of the evolution equations (17a) and (17b). These equations allow us to apply the ''layer stripping'' process for the value $H_L(\boldsymbol{\rho},t;\ \boldsymbol{\rho}_0,t_0)$, which is used so successfully in other simpler cases.[11–13] The main step in the ''layer stripping'' process is to employ Eq. (17a) to obtain a value of $H_{L-\delta L}(\boldsymbol{\rho},\ t;\boldsymbol{\rho}_0,t_0)$ on a surface $x=L-\delta L(\,\delta L>0)$ for a finite time interval, from knowledge of this value $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ on an adjacent surface $x=L$, where two surface are an infinitesimal distance apart.

The field $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ on the plane $x=L$ of the point source on the same plane for finite time interval may be measured. The $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ is observed on the bounded region in R^6, which is

chosen in an agreement with the condition where $\varepsilon(x,\boldsymbol{\rho},t)$ have to be reconstructed. The feature of the inverse problem with the nonstationary medium is a necessity to repeat the experiments with the medium many times and to make the measurements in every case for the different t_0, which is the initial moment of the source action. For example, the time periodical media are comfortable to examine. The $\boldsymbol{\rho}_0$ is another free variable parameter in an experiment. When the scattering data $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ are obtained, the step of inverse procedure is carried out.

Putting $t\to t_0$ in $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ and using (17b), we find $\varepsilon(L,\boldsymbol{\rho}_0,t_0)$ on the plane $x=L$. Substituting $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ and $\varepsilon(L,\boldsymbol{\rho}_0,t_0)$ in Eq. (17a) and determining $\partial H_L/\partial L$, the value of $H_{L-\delta L}(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ is obtained so $H_{L-\delta L}=H_L-(\partial H_L/\partial L)\cdot\delta L$. The operation $t\to t_0$ in $H_{L-\delta L}(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ takes $\varepsilon(L-\delta L,\boldsymbol{\rho}_0,t_0)$ on the surface $x=L-\delta L$.

This step may be repeated many times and $\varepsilon(x,\boldsymbol{\rho},t)$ can be reconstructed to the left from $x=L$. The procedure stops in two cases. We arrive at the plane $x=L_0$ or the definition region of $H_{L-n\times\delta L}(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ is tightened to the point in R^6 where n is the number of a procedure step and $n\times\delta L$ is the transference distance of the right layer boundary. The structure of Eq. (17a) is such that a definition region of $H_{L-n\times\delta L}(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ is decreased on every procedure step. If the distance $n\times\delta L$ of an inversion is not enough, we have to make the observation region of $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ in the measurements more broad.

Above we had in view the line ''layer stripping'' process for the value $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ so that $H_{L-\delta L}=H_L-(\partial H_L/\partial L)\cdot\delta L$ and the value $\varepsilon(L,\boldsymbol{\rho},t)$ was constant in δL infinitesimal layer. We discussed the scheme of first order. There is an opportunity to create the higher order procedure. The value $\varepsilon(L,\boldsymbol{\rho},t)$ may be presented in the δL-layer by a k-polynomial in L, whose coefficient calculations are considered in the previous section. Substituting this polynomial in Eq. (17a), solving it in the δL-layer, and getting $H_{L-\delta L}(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ from $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$, we realize the k-order ''layer stripping'' process and accordingly the same inverse procedure. The address to a high-order procedure will promote the improvement of the stability and convergence of inversion. In principle, the questions of stability and convergence of the procedure may be considered as in the well-researched one-dimensional case,[3,4] and the complete analysis of the procedure features will be carried out in the future, when an algorithm will be created and the numerical experiments will be realized.

The $H_L(\boldsymbol{\rho},t;\boldsymbol{\rho}_0,t_0)$ in R^6 is used for the reconstruction of the $\varepsilon(x,\boldsymbol{\rho},t)$ in R^4. We see a over-definiteness that is the attribute and characteristic property of the multidimensional inverse problem,[21] which comes from the structure of Eq. (17a) and is explained physically by the transverse propagation, in the direction across to the x-axis.

VIII. CONCLUSION

The same application of the obtained results will be discussed here. Equation (17a) is a differential equation of a first order with respect to L. This allows us to apply the approximation of the Markov process[1,2] for the analysis of the statistical inverse problem.[6] Hence, the proposed above inverse procedure may be used directly in the statistical transfer theory[1,2] for a determination of a multidimensional random medium characteristics. The apparatus of a Markov process approximation developed in Refs. 16 and 17 for a derivation of an evolution equation for the backscattering statistical characteristics may be applied to (17a) and the generalization of the present procedure for statistical inverse problem may be obtained.

A temperature and mass dependence of the linear Boltzmann collision operator from group theory point of view

Vladimir Saveliev
Institute of Ionosphere, Almaty, 480068, Kazakhstan

(Received 22 March 1996; accepted for publication 20 May 1996)

The Lie group of the transformations affecting the parameters of the linear Boltzmann collision operator such as temperature of background gas and ratio of masses of colliding particles and molecules is discovered. The group also describes the conservation laws for collisions and main symmetries of the collision operator. New algebraic properties of the collision operator are derived. Transformations acting on the variables and parameters and leaving the linear Boltzmann kinetic equation invariant are found. For the constant collision frequency the integral representation of solutions for nonuniform case in terms of the distribution function of particles drifting in a gas with zero temperature is deduced. The new exact relaxation solutions are obtained too. © *1996 American Institute of Physics.*

I. INTRODUCTION

Last year's steady interest remains in studying groups of symmetry of the mathematical physics equations. It is so especially in the case where the transformations taken into consideration affect the parameters of an equation as well as its variables, that is, the basis of the renormgroup ideology.[1] Here, we will study the linear kinetic equation that in particular describes nonuniform spatial drift of charged particles through a gas in the electromagnetic field. It is useful, first, to consider (from the group theory point of view) the character of dependence on parameters of the collision integral as the most complicated term of this equation. Also, such a consideration is interesting, because it results in quite remarkable mathematical constructions, and permits us to understand deeper properties of the collision operator. The evolution due to collisions of the distribution function of particles having mass m_1 (for example, ions) with particles of mass m_2 (molecules), distributed on speed according to the distribution function $\Psi(\boldsymbol{u})$, is defined by the operator of collisions[2] $\hat{I}$:

$$\left(\frac{\partial f}{\partial t}\right)_C = \hat{I}(\Psi) f, \tag{1}$$

where

$$[\hat{I}f](\boldsymbol{v}) = \int \nu(\mathrm{v})\chi(\mu,\mathrm{v})[f(\boldsymbol{v}')\Psi(\boldsymbol{u}') - f(\boldsymbol{v})\Psi(\boldsymbol{u})]d\Omega_{\boldsymbol{v}'}d\boldsymbol{u}, \tag{2}$$

$\mathbf{v}=\boldsymbol{v}-\boldsymbol{u}$ is relative velocity, $\mu=(\mathbf{v}\cdot\mathbf{v}')/\mathrm{v}^2$ is the cosine of scattering angle: $d\Omega_{\mathbf{v}'}$ is the element of solid angle near $\mathbf{v}'$, $\nu=N\mathrm{v}\sigma$ and $\chi=(1/\sigma)d\sigma/d\Omega$ are the frequency of collisions and probability of scattering into solid angle; $\boldsymbol{v},\boldsymbol{v}'$; $\boldsymbol{u},\boldsymbol{u}'$ are velocities of ions and molecules before and after a collision; $\boldsymbol{v}$, $\boldsymbol{u}$, $\mathbf{v}'$ and $\boldsymbol{v}'$, $\boldsymbol{u}'$, $\boldsymbol{v}$ are connected with the idempotent transformation:

$$\boldsymbol{v}' = \frac{m\boldsymbol{v} + \boldsymbol{u} + \mathbf{v}'}{1+m}, \quad \boldsymbol{v} = \frac{m\boldsymbol{v}' + \boldsymbol{u}' + \mathbf{v}}{1+m},$$

$$\boldsymbol{u}' = \frac{m\boldsymbol{v} + \boldsymbol{u} - m\mathbf{v}'}{1+m}, \quad \boldsymbol{u} = \frac{m\boldsymbol{v}' + \boldsymbol{u}' - m\boldsymbol{v}}{1+m}, \tag{3}$$

$$\mathbf{v} = \boldsymbol{v} - \boldsymbol{u}, \quad \mathbf{v}' = \boldsymbol{v}' - \boldsymbol{u}',$$

where $m = m_1/m_2$.

We will consider only elastic collisions. Because of this we will have

$$\mathrm{v} = \mathrm{v}'. \tag{4}$$

Many properties of the collision operator can be found more easily for the conjugate operator and then they can be transferred on the collision operator. If the scalar product is defined as

$$(\varphi, f) = \int \varphi(\boldsymbol{v}) f(\boldsymbol{v}) d\boldsymbol{v}, \tag{5}$$

then the conjugate operator determined by the condition

$$(\varphi, \hat{I} f) = (\tilde{\hat{I}} \varphi, f), \tag{6}$$

obviously ($d\mathbf{v} d\mathbf{u} d\Omega_{\mathbf{v}'} = d\mathbf{v}' d\mathbf{u}' d\Omega_{\mathbf{v}}$), will have the form

$$[\tilde{\hat{I}} \varphi](\boldsymbol{v}) = \int \nu(\mathrm{v}) \chi(\mathrm{v}, \mu) [\varphi(\boldsymbol{v}') - \varphi(\boldsymbol{v})] \Psi(\boldsymbol{u}) d\Omega_{\mathbf{v}'} d\boldsymbol{u}. \tag{7}$$

II. TEMPERATURE DEPENDENCE OF THE COLLISION OPERATOR

Let us introduce special notation $\hat{J}$ for the collision operator for collisions with scattering centers that are at rest before a collision, i.e., when $\Psi(\boldsymbol{u}) = \delta(\boldsymbol{u})$:

$$\hat{J} = \hat{I}(\delta(\boldsymbol{u})). \tag{8}$$

The collision operator $\hat{I}$ can be expressed through the operator $\hat{J}$ with the help of a simple transformation[3,4] $F: \hat{J} \to \hat{I}$. This transformation has a clear physical meaning consisting in that the process of scattering on moving center can be considered in the system of reference where this center is at rest. Indeed, the action of the collision operator can be reduced to the next operations. The scattering centers should be separated on groups according to the velocity, and one should get over to the system where scattering centers of a chosen group are at rest, act by the collision operator $\hat{J}$, return to the initial system, and integrate over all groups, i.e.,

$$\hat{I} = F(\hat{J}) = \int d\boldsymbol{u} \Psi(\boldsymbol{u}) e^{-\boldsymbol{u}\nabla} \hat{J} e^{\boldsymbol{u}\nabla}, \tag{9}$$

where $e^{\boldsymbol{u}\nabla}$ is the operator of translation on the vector $\boldsymbol{u}$ in the velocity space,

$$e^{\boldsymbol{u}\nabla} f(\boldsymbol{v}) = f(\boldsymbol{v} + \boldsymbol{u}), \quad \text{where } \nabla = \frac{\partial}{\partial \boldsymbol{v}}. \tag{10}$$

The transformation F has an interesting algebraic property. The successive action of the transformations F_{Ψ_1} and F_{Ψ_2}, induced by the distribution functions $\Psi_1(\boldsymbol{u})$ and $\Psi_2(\boldsymbol{u})$, is the transformation induced by convolution of the input distribution functions:

$$F_{\Psi_1}\otimes F_{\Psi_2}=F_{\Psi_2}\otimes F_{\Psi_1}=F_{\Psi_{12}},$$
$$\Psi_{12}=\Psi_1\circ\Psi_2=\Psi_2\circ\Psi_1=\int \Psi_1(\boldsymbol{u}-\boldsymbol{u}')\Psi_2(\boldsymbol{u}')d\boldsymbol{u}'. \tag{11}$$

In practicality, in the important case when a distribution of scattering centers (molecules) is the Maxwellian distribution with temperature T,

$$\Psi(\boldsymbol{u})=\Psi_T(u)=\left(\frac{m_2}{2\pi kT}\right)^{3/2} e^{-m_2u^2/2kT}, \tag{12}$$

the family of the transformations F_T, $0\leqslant T<\infty$, is an Abelian semigroup:

$$F_{T=0}=1, \quad F_{T_1}\otimes F_{T_2}=F_{T_2}\otimes F_{T_1}=F_{T_1+T_2}. \tag{13}$$

Property (13) follows from a closure of the family of the Maxwellian distributions, $\Psi_T(\boldsymbol{u})$, $0\leqslant T<\infty$, relatively to the convolution:

$$\int d\boldsymbol{u}'\Psi_{T_1}(\boldsymbol{u}-\boldsymbol{u}')\Psi_{T_2}(\boldsymbol{u}')=\Psi_{T_1+T_2}(\boldsymbol{u}). \tag{14}$$

Differentiating transformation F_T (9) with respect to temperature T at zero, bearing in mind the property of Maxwellians,

$$\frac{\partial}{\partial T}\Psi_T(\boldsymbol{v})=\frac{k}{2m_2}\nabla^2\Psi_T(\boldsymbol{v}), \tag{15}$$

we will have an expression for the generator q of the temperature transformations' semigroup. An action of the generator q on the operator $\hat{I}$ is expressed through the double commutator $(\hat{a}*\hat{b}\equiv[\hat{a},\hat{b}]\equiv\hat{a}\hat{b}-\hat{b}\hat{a})$:

$$q(\hat{I})=\frac{k}{2m_2}\boldsymbol{\nabla}*\boldsymbol{\nabla}*\hat{I}\equiv\frac{k}{2m_2}[\boldsymbol{\nabla},[\boldsymbol{\nabla},\hat{I}]]=\frac{k}{2m_2}(\nabla^2\hat{I}-2\boldsymbol{\nabla}\hat{I}\boldsymbol{\nabla}+\hat{I}\nabla^2). \tag{16}$$

According to expression (16), the collision operator satisfies the differential equation:

$$\frac{\partial}{\partial T}\hat{I}=\frac{k}{2m_2}\boldsymbol{\nabla}*\boldsymbol{\nabla}*\hat{I}\equiv\frac{k}{2m_2}[\boldsymbol{\nabla},[\boldsymbol{\nabla},\hat{I}]]. \tag{17}$$

We will denote by the operator belonging to some algebra K marked from the right side with the sign $*$ (i.d. $\hat{a}*$, $\hat{a}\subseteq K$) the linear map $\hat{a}*$: $K\rightarrow\hat{a}*K$ of the algebra K into itself:

$$\hat{a}*\hat{b}\equiv\hat{a}\hat{b}-\hat{b}\hat{a}, \quad \hat{a},\hat{b}\subseteq K. \tag{18}$$

Later we will need the next simple properties of such maps:

$$[\hat{a}*,\hat{b}*]=[\hat{a},\hat{b}]*, \quad [\hat{a}*,\hat{b}]=[\hat{a},\hat{b}*]=[\hat{a},\hat{b}],$$
$$\hat{a}\hat{b}*+\hat{b}\hat{a}*=\hat{a}*\hat{b}*+(\hat{b}\hat{a})*. \tag{19}$$

Taking into account definitions (18), we can express the collision operator in terms of the collision operator of the scattering on molecules at rest before the collision with the help of the transformation F_T:

$$\hat{I}=e^{(kT/2m_2)\nabla*\nabla*}\hat{J}. \tag{20}$$

III. MASS DEPENDENCE OF THE COLLISION OPERATOR

It can be seen from Eq. (3) that the derivative of the velocity after collision with respect to the variable $\ln(1+m)$ is equal to a difference of the velocities before and after the collision:

$$\xi=\ln(1+m), \quad \frac{\partial \boldsymbol{v}'}{\partial \xi}=\boldsymbol{v}-\boldsymbol{v}'. \tag{21}$$

So,

$$\frac{\partial}{\partial \xi}\tilde{\hat{I}}=(\boldsymbol{v}\tilde{\hat{I}}-\tilde{\hat{I}}\boldsymbol{v})\boldsymbol{\nabla}=(\boldsymbol{v}*\tilde{\hat{I}})\boldsymbol{\nabla}=(\boldsymbol{\nabla}\boldsymbol{v}*-\boldsymbol{\nabla}*\boldsymbol{v}*)\tilde{\hat{I}}. \tag{22}$$

Conjugating expression (22) and using the usual properties of conjugation,

$$(\hat{a}\hat{b})\tilde{}=\tilde{\hat{b}}\tilde{\hat{a}} \quad \text{and} \quad \tilde{\boldsymbol{\nabla}}=-\boldsymbol{\nabla}, \quad \tilde{\boldsymbol{v}}=\boldsymbol{v}, \tag{23}$$

one gets a formula for differentiation of the collision operator $\hat{I}$ on ξ:

$$\frac{\partial}{\partial \xi}\hat{I}=\boldsymbol{\nabla}\boldsymbol{v}*\hat{I}. \tag{24}$$

Thus, the semigroup of the transformations, $e^{\xi\boldsymbol{\nabla}\boldsymbol{v}*}$, $\infty>\xi\geqslant 0$, describes the mass dependence of the collision operator and together with the transformation F_T allows the expression of the operator $\hat{I}$ in terms of the operator $\hat{\chi}$ that describes a process of scattering on the infinitely heavy ($m=0$) centers being at rest. The operator $\hat{\chi}$ is the simplest collision operator. So, we have

$$\hat{I}=e^{(kT/2m_2)\boldsymbol{\nabla}*\boldsymbol{\nabla}*+\ln(1+m)\boldsymbol{\nabla}\boldsymbol{v}*}\hat{\chi}, \tag{25}$$

$$[\hat{\chi}f](\boldsymbol{v})=\int \nu(\mathrm{v})\chi(\mu,\mathrm{v})[f(\mathbf{v}')-f(\boldsymbol{v})]d\Omega_{\mathbf{v}'}, \quad \text{here } \mathbf{v}'^2=\mathbf{v}^2=\boldsymbol{v}^2, \quad \tilde{\hat{\chi}}=\hat{\chi}. \tag{26}$$

One can notice that the generators of the temperature and mass transformations commutate:

$$[\boldsymbol{\nabla}*\boldsymbol{\nabla}*,\boldsymbol{\nabla}\boldsymbol{v}*]=0. \tag{27}$$

Due to (17), (23), and (22), the conjugate collision operator can be represented in the form

$$\tilde{\hat{I}}=e^{(kT/m_2)\boldsymbol{\nabla}*\boldsymbol{\nabla}*+\ln(1+m)(\boldsymbol{\nabla}\boldsymbol{v}*-\boldsymbol{\nabla}*\boldsymbol{v}*)}\hat{\chi}. \tag{28}$$

IV. ENERGY CONSERVATION LAW

The energy conservation law for scattering on an infinitely heavy center being at rest is reduced to the fact that the squares of velocities before and after collision remain equal, or in other words,

$$\boldsymbol{v}^2 * \hat{\chi} = 0, \tag{29}$$

and the operator $\hat{\chi}$ is a stationary object with respect to the group of transformations defined by generator $\boldsymbol{v}^2 *$:

$$e^{\alpha \boldsymbol{v}^2 *} \hat{\chi} = \hat{\chi}. \tag{30}$$

One more property of symmetry is added in the case of the constant collision frequency ($\nu = \text{const}$, the so-called Maxwell's particles) frequently used in the kinetic theory:

$$\nabla^2 * \hat{\chi} = 0, \quad \text{when} \quad \nu = \text{const}, \quad \chi(\mu, \mathrm{v}) = \chi(\mu). \tag{31}$$

V. LIE ALGEBRA AND GROUP

To create from the set of generators $\boldsymbol{\nabla} * \boldsymbol{\nabla} *$, $\boldsymbol{\nabla} \boldsymbol{v} *$, $v^2 *$, $\boldsymbol{\nabla}^2 *$ the basis of Lie algebra, one needs to add to it three more elements: $\boldsymbol{\nabla} * \boldsymbol{v} *$, $\boldsymbol{v} * \boldsymbol{v} *$ $(\boldsymbol{v} \boldsymbol{\nabla}) *$. This seven-dimensional Lie algebra is determined by commutative relations that look most simple in the bases:

$$P_1 = \frac{1}{\sqrt{8}} \nabla * \nabla *, \quad P_2 = \frac{1}{2} \nabla * \boldsymbol{v} *, \quad P_3 = \frac{1}{\sqrt{8}} \boldsymbol{v} * \boldsymbol{v} *,$$

$$Q_1 = \frac{1}{\sqrt{8}} \nabla^2 *, \quad Q_2 = \frac{1}{2} (\boldsymbol{v} \nabla) *, \quad Q_3 = \frac{1}{\sqrt{8}} v^2 *, \tag{32}$$

$$S = M - Q_2 - P_2,$$

where

$$M = \nabla \boldsymbol{v} *,$$

and can be represented in the form

$$[P_i, P_k] = 0,$$

$$[Q_i, P_k] = e_{ikl} b_{lm} P_m, \quad [Q_i, Q_k] = e_{ikl} b_{lm} Q_m, \tag{33}$$

$$[S, P_k] = P_k, \quad [S, Q_k] = 0,$$

where e_{ikl} is the antisymmetric Levi-Civita tensor and b_{lm} is an antidyogonal matrix

$$b = \begin{pmatrix} 0 & 0 & 1 \\ 0 & -1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \tilde{b} = b, \quad b^2 = 1. \tag{34}$$

Explicit values of commutators (32) are given in Table I. For convenience we give commutative relations for the generator of mass transformations M separately:

TABLE I. Values of the commutators $[A_\alpha, A_\beta]$.

$A_\alpha \backslash A_\beta$	P_1	P_2	P_3	Q_1	Q_2	Q_3	S
$P_1=\frac{1}{\sqrt{8}}\nabla*\nabla*$	0	0	0	0	P_1	P_2	$-P_1$
$P_2=\frac{1}{2}\nabla*\boldsymbol{v}*$	0	0	0	$-P_1$	0	P_3	$-P_2$
$P_3=\frac{1}{\sqrt{8}}\boldsymbol{v}*\boldsymbol{v}*$	0	0	0	$-P_2$	$-P_3$	0	$-P_3$
$Q_1=\frac{1}{\sqrt{8}}\nabla^2*$	0	P_1	P_2	0	Q_1	Q_2	0
$Q_2=\frac{1}{2}(\boldsymbol{v}\nabla)*$	$-P_1$	0	P_3	$-Q_1$	0	Q_3	0
$Q_3=\frac{1}{\sqrt{8}}v^2*$	$-P_2$	$-P_3$	0	$-Q_2$	$-Q_3$	0	0
$S=\nabla\boldsymbol{v}*-\frac{1}{2}(\boldsymbol{v}\nabla)*-\frac{1}{2}\nabla*\boldsymbol{v}*$	P_1	P_2	P_3	0	0	0	0

$$[M,P_1]=0,\quad [M,P_2]=P_2,\quad [M,P_3]=2P_3,$$
$$[M,Q_1]=-Q_1-P_1,\quad [M,Q_2]=0,\quad [M,Q_3]=Q_3+P_3. \tag{35}$$

As it follows from Table I, AP, AQ, APQ, and APS (where AP is the Lie algebra with bases elements P_i, APS is the Lie algebra with bases elements P_i, S, and so on) are subalgebras of Lie algebra $APQS$ (32). Moreover APQ and APS are ideals, and AP is commutative ideal. Matrices T_{ik} of adjoint representation[5] of the subgroup GQ, defined by the expression

$$G^{-1}(q)Q_iG(q)=T_{ik}(q)Q_k,\quad G(q)=e^{q_1Q_1}e^{q_2Q_2}e^{q_3Q_3}, \tag{36}$$

can be obtained with the help of the formula

$$e^ABe^{-A}=B+\frac{1}{1!}[A,B]+\frac{1}{2!}[A,[A,B]]+\cdots. \tag{37}$$

These matrixes have the form

$$T(q)=\begin{vmatrix} e^{q_2} & q_3e^{q_2} & \frac{q_3^2}{2}e^{q_2} \\ -q_1e^{q_2} & 1-q_1q_3e^{q_2} & q_3\left(1-\frac{q_1q_3}{2}e^{q_2}\right) \\ \frac{q_1^2}{2}e^{q_2} & -q_1\left(1-\frac{q_1q_3}{2}e^{q_2}\right) & \left(1-\frac{q_1q_3}{2}e^{q_2}\right)^2e^{-q_2} \end{vmatrix}. \tag{38}$$

One can see from (33) that the generators P_i are being transformed according to the same representation:

$$G^{-1}(q)P_iG(q)=T_{ik}(q)P_k. \tag{39}$$

Matrices of the conjugated representation $\overline{T_{ik}}(q)$,

$$G(q)Q_kG^{-1}(q)=Q_i\overline{T_{ik}}(q),\quad G(q)P_kG^{-1}(q)=P_i\overline{T_{ik}}(q), \tag{40}$$

accordingly have the form

$$\overline{T(q)}=\widetilde{T}^{-1}(q)=\begin{vmatrix} \left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)^2 e^{-q_2} & q_1\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right) & \frac{q_1^2}{2}\,e^{q_2} \\ -q_3\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right) & 1-q_1q_3e^{q_2} & q_1e^{q_2} \\ \frac{q_3^2}{2}\,e^{q_2} & -q_3e^{q_2} & e^{q_2} \end{vmatrix}. \tag{41}$$

Parameters of the product of two elements from subgroup GQ,

$$G(q)G(q')=G(q''),\quad G(q'),G(q''),G(q)=e^{q_1Q_1}e^{q_2Q_2}e^{q_3Q_3}\in GQ, \tag{42}$$

are defined by formulas

$$q_1''=q_1+\frac{q_1'}{1-q_3q_1'/2}\,e^{-q_2},\quad q_2''=(q_2+q_2')\ln\left(1-\frac{q_3q_1'}{2}\right)^2,\quad q_3''=q_3'+\frac{q_3}{1-q_3q_1'/2}\,e^{-q_2'}; \tag{43}$$

parameters of the inverse element have the form

$$G^{-1}(q)=G(q'),$$
$$q_1'=\frac{q_1e^{q_2}}{(q_1q_2/2)e^{q_2}-1},\quad q_2'=-q_2\,\ln\left(\frac{q_1q_2}{2}\,e^{q_2}-1\right)^2,\quad q_3'=\frac{q_3e^{q_2}}{(q_1q_2/2)e^{q_2}-1}. \tag{44}$$

The connection with parameters of the exponential parametrization for a group element from GQ is given by formula

$$e^{q_1Q_1}e^{q_2Q_2}e^{q_3Q_3}=e^{q_1'Q_1+q_2'Q_2+q_3'Q_3},$$
$$q_1'=\frac{q_1q_2}{1-e^{-q_2}},\quad q_2'=\frac{q_1q_2q_3}{2(1-e^{-q_2})}+q_2,\quad q_3'=\frac{q_2q_3}{1-e^{-q_2}}. \tag{45}$$

The summands of the element S are a basis of the subalgebra:

$$[Q_2,M]=[Q_2,P_2]=0,\quad [M,P_2]=P_2. \tag{46}$$

The multiplication formula,

$$e^{q_2Q_2}e^{\xi M}e^{p_2P_2}e^{q_2'Q_2}e^{\xi' M}e^{p_2'P_2}=e^{q_2''Q_2}e^{\xi'' M}e^{p_2''P_2},$$
$$p_2''=p_2'+p_2e^{-\xi'},\quad \xi''=\xi+\xi',\quad q_2''=q_2+q_2', \tag{47}$$

and the correspondence formula,

$$e^{p_2P_2}e^{\xi M}=e^{p_2'P_2+\xi' M},$$
$$\xi'=\xi,\quad p_2'=\frac{\xi p_2}{\exp(\xi)-1},\quad p_2=\frac{\exp(\xi')-1}{\xi'}\,p_2', \tag{48}$$

follow from (46). That yields useful relations:

$$e^{sS}=e^{-sQ_2}e^{(1-\exp(s))P_2}e^{sM}=e^{(1-\exp(s))P_2}e^{sM}e^{-sQ_2},$$
$$e^{\ln(1+m)(M-2P_2)}=e^{-2mP_2}e^{\ln(1+m)M}. \tag{49}$$

For the entire group $GPQS$, the formula of two elements' product reads

$$G(p,q,s)=e^{p_iP_i}e^{q_1Q_1}e^{q_2Q_2}e^{q_3Q_3}e^{sS}=e^{p_iP_i}e^{sS}e^{q_1Q_1}e^{q_2Q_2}e^{q_3Q_3}\in GPQS,$$
$$G(p,q,s)G(p',q',s')=G(p'',q'',s''),$$
$$p_i''=p_i+e^s\overline{T_{ik}}(q)p_k', \tag{50}$$
$$q_1''=q_1+\frac{q_1'e^{-q_2}}{1-q_3q_1'/2},\quad q_2''=q_2+q_2'+\ln\left(1-\frac{q_3q_1'}{2}\right)^2,\quad q_3''=q_3'+\frac{q_3e^{-q_2'}}{1-q_3q_1'/2},$$
$$s''=s+s'.$$

The representation conjugated with adjoint one of the group is given by the formulas

$$G(p,q,s)P_kG^{-1}(p,q,s)=P_ie^s\overline{T_{ik}}(q),$$
$$GQ_kG^{-1}=Q_i\overline{T_{ik}}+P_1(p_1\overline{T_{2k}}-p_2\overline{T_{1k}})+P_2(p_1\overline{T_{3k}}-p_3\overline{T_{1k}})+P_3(p_2\overline{T_{3k}}-p_3\overline{T_{2k}}), \tag{51}$$
$$GSG^{-1}=-P_ip_i+S.$$

VI. SOME CONSEQUENCES

We will call as extended collision operator the following operator:

$$\hat{I}_g(p,q,s)=e^{p_iP_i}e^{sS}e^{q_1Q_1}e^{q_2Q_2}e^{q_3Q_3}\hat{\chi}, \tag{52}$$

which one can obtain acting by a transformation from the group $GPQS$ (50) on the simplest collision operator $\hat{\chi}$ for collisions with infinitely heavy centers being at rest.

As follows from (28) and (49) and also from property (30) and formulas (54), (55), and (37), the conjugated operator is connected with the collision operator by the relation

$$\tilde{\hat{I}}=e^{-2mP_2}\hat{I}=e^{\sqrt{2}(m_1/kT)Q_3}\hat{I}. \tag{53}$$

Taking into account (25), (49), and the first part of (53), one can express the collision operator $\hat{I}$ and the conjugated collision operator $\tilde{\hat{I}}$ in terms of the extended operator $\hat{I}_g$ with accordingly chosen parameters:

$$\hat{I}=\hat{I}_g(p,q,s),$$
$$p_1=\sqrt{2}\,\frac{kT}{m_2},\quad p_2=m,\quad p_3=0;\quad q_1=0,\quad q_2=\ln(1+m),\quad q_3=0;\quad s=\ln(1+m); \tag{54}$$

$$\tilde{\hat{I}}=\hat{I}_g(p,q,s), \tag{55}$$

$$p_1=\sqrt{2}\,\frac{kT}{m_2},\quad p_2=-m,\quad p_3=0;\quad q_1=0,\quad q_2=\ln(1+m),\quad q_3=0;\quad s=\ln(1+m).$$

Energy conservation law (29) yields the identity for the extended collision operator:

$$G(p,q,s)Q_3G^{-1}(p,q,s)\hat{I}_g(p,q,s)=0. \tag{56}$$

An explicit form of (56) can be obtained with the help of (51) and (41):

$$\left\{\frac{q_1^2}{2}\,Q_1+q_1Q_2+Q_3+q_1\left(p_1-p_2\,\frac{q_1}{2}\right)P_1+\left(p_1-p_3\,\frac{q_1^2}{2}\right)P_2+(p_2-p_3q_1)P_3\right\}\hat{I}_g(p,q,s)=0. \tag{57}$$

In the case of the constant collision frequency, we add two more identities due to (31), (29), and (33):

$$G(p,q,s)Q_1G^{-1}(p,q,s)\hat{I}_g(p,q,s)=0,\quad G(p,q,s)Q_2G^{-1}(p,q,s)\hat{I}_g(p,q,s)=0,$$
$$\text{when}\quad \nu=\text{const},\quad \chi(\mu,v)=\chi(\mu). \tag{58}$$

We can get the explicit form of them using (51) and (41) accordingly:

$$\left\{\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)^2e^{-q_2}Q_1-q_3\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)Q_2+\frac{q_3^2}{2}\,e^{q_2}Q_3+\left[-p_1q_3\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)\right.\right.$$
$$\left.-p_2\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)^2e^{-q_2}\right]P_1+\left[p_1\,\frac{q_3^2}{2}\,e^{q_2}-p_3\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)^2e^{-q_2}\right]P_2$$
$$\left.+\left[p_2\,\frac{q_3^2}{2}\,e^{q_2}+p_3q_3\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)\right]P_3\right\}\hat{I}_g(p,q,s)=0,$$
$$\text{when}\quad \nu=\text{const},\quad \chi(\mu,v)=\chi(\mu); \tag{59}$$

$$\left\{q_1\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)Q_1+(1-q_1q_3e^{q_2})Q_2-q_3e^{q_2}Q_3+\left[p_1(1-q_1q_3e^{q_2})\right.\right.$$
$$\left.-p_2q_1\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)\right]P_1-\left[p_1q_3e^{q_2}+p_3q_1\left(1-\frac{q_1q_3}{2}\,e^{q_2}\right)\right]P_2$$
$$\left.-[p_2q_3e^{q_2}+p_3(1-q_1q_3e^{q_2})]P_3\right\}\hat{I}_g(p,q,s)=0;$$
$$\text{when}\quad \nu=\text{const},\quad \chi(\mu,v)=\chi(\mu). \tag{60}$$

Identities (57), (59), and (60) with the parameters given by (54) for the operator $\hat{I}$ are reduced to the form

$$\left(v^{2}*+\frac{2kT}{m_2}\,\nabla*\boldsymbol{v}*+m\boldsymbol{v}*\boldsymbol{v}*\right)\hat{I}=0; \tag{61}$$

$$(\nabla^{2}*-m\nabla*\nabla*)\hat{I}=0,\quad \text{when}\quad \nu=\text{const},\quad \chi(\mu,\text{v})=\chi(\mu); \tag{62}$$

$$\left((\boldsymbol{v}\boldsymbol{\nabla})*+\frac{kT}{m_2}\boldsymbol{\nabla}*\boldsymbol{\nabla}*\right)\hat{I}=0,\quad \text{when}\quad \nu=\text{const},\quad \chi(\mu,\text{v})=\chi(\mu). \tag{63}$$

The temperature transformation that gets the collision operator $\hat{I}$ can be represented by the similitude

$$\begin{aligned}\hat{I}&=Ge^{[(1+m)/m](\sqrt{2}kT/m_2)Q_1}G^{-1}Ge^{[-(1+m)/m](\sqrt{2}kT/m_2)Q_1}\hat{\chi}=e^{(kT/2m_1)\nabla^2}*\hat{J}'\\&=e^{(kT/2m_1)\nabla^2}\hat{J}'e^{-(kT/2m_1)\nabla^2},\end{aligned} \tag{64}$$

where

$$\hat{J}'=e^{\ln(1+m)M}\hat{\chi}',$$

$$\hat{\chi}'=e^{-(1+m)(kT/2m_1)\nabla^2}\hat{\chi}e^{(1+m)(kT/2m_1)\nabla^2}.$$

In the case the collision frequency does not depend on the velocity, we have $\hat{\chi}'=\hat{\chi}$ due to property (31) and consequently $\hat{J}'=\hat{J}$. Therefore, for that case the collision operator $\hat{I}$ is expressed in terms of the collision operator $\hat{J}$ for collisions with molecules at rest with the help of the simple similitude:

$$\hat{I}=e^{(kT/2m_1)\nabla^2}*\hat{J}=e^{(kT/2m_1)\nabla^2}\hat{J}e^{-(kT/2m_1)\nabla^2},\quad \text{when}\quad \nu=\text{const},\quad \chi(v,\mu)=\chi(\mu), \tag{65}$$

which is based on the Gauss transformation:[6]

$$e^{(kT/2m_1)\nabla^2}f(\boldsymbol{v})=\left(\frac{m_1}{2\pi kT}\right)^{3/2}\int d\boldsymbol{v}'e^{-m_1(\boldsymbol{v}-\boldsymbol{v}')^2/2kT}f(\boldsymbol{v}'). \tag{66}$$

VII. TRANSFORMATIONS FROM THE RENORMGROUP OF THE BOLTZMANN LINEAR KINETIC EQUATION

We use the term *renormgroup* here to underline that the group transformations affect not only the variables $\boldsymbol{v}$, $\boldsymbol{r}'$, t, but the problem's parameters T, m, $\mathbf{w}$, too. Thus, we use the renormgroup ideology.[1]

Let us consider nonuniform drift of charged particles through the gas of heated molecules in the electric and magnetic fields.[7] The distribution function of charged particles $f(\boldsymbol{v},\boldsymbol{r},t)$ satisfies the Boltzmann kinetic equation with the extended operator parameters p, q, s taken from (54):

$$\frac{\partial f}{\partial t}+\boldsymbol{v}\boldsymbol{\nabla}_{\boldsymbol{r}}f+(\boldsymbol{w}+\boldsymbol{v}\times\Omega)\boldsymbol{\nabla}f=\hat{I}_g(p,q,s)f, \tag{67}$$

where $\mathbf{w}=e\boldsymbol{E}/m$, $\Omega=e\boldsymbol{B}/mc$, $\boldsymbol{\nabla}_{\boldsymbol{r}}=\partial/\partial\boldsymbol{r}$, $\boldsymbol{\nabla}=\partial/\partial\boldsymbol{v}$.

The operator of the left part of Eq. (67),

$$\hat{L}=\frac{\partial}{\partial t}+\boldsymbol{v}\nabla_{\boldsymbol{r}}+(\boldsymbol{w}+\boldsymbol{v}\times\Omega)\boldsymbol{\nabla},$$

is transformed by generators from the AQ algebra as follows:

$$Q_1\hat{L}=\frac{1}{\sqrt{8}}\,[\nabla^2,\hat{L}]=\frac{1}{\sqrt{2}}\,\boldsymbol{\nabla}\boldsymbol{\nabla}_{\boldsymbol{r}},$$

$$Q_2\hat{L}=\tfrac{1}{2}\,[\boldsymbol{v}\boldsymbol{\nabla},\hat{L}]=\tfrac{1}{2}\,(\boldsymbol{v}\boldsymbol{\nabla}_{\mathbf{r}}-\boldsymbol{w}\boldsymbol{\nabla}), \tag{68}$$

$$Q_3\hat{L}=\frac{1}{\sqrt{8}}\,[v^2,\hat{L}]=-\frac{1}{\sqrt{2}}\,\boldsymbol{w}\boldsymbol{v}.$$

It is easy to see that the action of the operators affecting the problem's parameter $\boldsymbol{w}$ and spatial variable $\boldsymbol{r}$ leads to the same results:

$$\frac{1}{\sqrt{2}}\,(\boldsymbol{\nabla}_{\boldsymbol{r}}\nabla_{\boldsymbol{w}})*\hat{L}=\frac{1}{\sqrt{2}}\,[\boldsymbol{\nabla}_{\boldsymbol{r}}\boldsymbol{\nabla}_{\boldsymbol{w}},\hat{L}]=\frac{1}{\sqrt{2}}\,\boldsymbol{\nabla}\boldsymbol{\nabla}_{\boldsymbol{r}},$$

$$-\tfrac{1}{2}\,(\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}})*\hat{L}=-\tfrac{1}{2}\,[(\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}}),\hat{L}]=\tfrac{1}{2}\,(\boldsymbol{v}\boldsymbol{\nabla}_{\boldsymbol{r}}-\boldsymbol{w}\boldsymbol{\nabla}), \tag{69}$$

$$\frac{1}{\sqrt{2}}\,(\boldsymbol{w}\boldsymbol{r})*\hat{L}=\frac{1}{\sqrt{2}}\,[\boldsymbol{w}\boldsymbol{r},\hat{L}]=-\frac{1}{\sqrt{2}}\,\boldsymbol{w}\boldsymbol{v}.$$

Therefore, the difference of the operators from (68) and (69) gives us the set of generators commutating with operator $\hat{L}$. The group constructed on their base keeps the operator $\hat{L}$ invariant,

$$e^{(\overline{q_1}/\sqrt{8})\,(\nabla^2-2\boldsymbol{\nabla}_{\boldsymbol{r}}\boldsymbol{\nabla}_{\boldsymbol{w}})*}\hat{L}=e^{(\overline{q_1}/\sqrt{8})(\nabla^2-2\boldsymbol{\nabla}_{\boldsymbol{r}}\boldsymbol{\nabla}_{\boldsymbol{w}})}\hat{L}\,e^{-(\overline{q_1}/\sqrt{8})(\nabla^2-2\boldsymbol{\nabla}_{\boldsymbol{r}}\boldsymbol{\nabla}_{\boldsymbol{w}})}=\hat{L},$$

$$e^{(\overline{q_2}/2)\,(\boldsymbol{v}\boldsymbol{\nabla}+\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}})*}\hat{L}=e^{(\overline{q_2}/2)\,(\boldsymbol{v}\boldsymbol{\nabla}+\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}})}\hat{L}\,e^{-(\overline{q_2}/2)(\boldsymbol{v}\boldsymbol{\nabla}+\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}})}=\hat{L}, \tag{70}$$

$$e^{(\overline{q_3}/\sqrt{8})(v^2-2\boldsymbol{w}\boldsymbol{r})*}\hat{L}=e^{(\overline{q_3}/\sqrt{8})(v^2-2\boldsymbol{w}\boldsymbol{r})}\hat{L}\,e^{-(\overline{q_3}/\sqrt{8})(v^2-2\boldsymbol{w}\boldsymbol{r})}=\hat{L}.$$

The extended collision operator $\hat{I}_g(p,q,s)$ is transformed under the GQ group, because operators (69) do not affect the velocity and commutate with $\hat{I}_g(p,q,s)$:

$$e^{(\overline{q_1}/\sqrt{8})(\nabla^2-2\boldsymbol{\nabla}_{\boldsymbol{r}}\boldsymbol{\nabla}_{\boldsymbol{w}})*}\hat{I}_g(p,q,s)=e^{\overline{q_1}Q_1}\hat{I}_g(p,q,s)=\hat{I}_g(p',q',s'),$$

$$e^{(\overline{q_2}/2)(\boldsymbol{v}\boldsymbol{\nabla}+\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}})*}\hat{I}_g(p,q,s)=e^{\overline{q_2}Q_2}\hat{I}_g(p,q,s)=\hat{I}_g(p',q',s'), \tag{71}$$

$$e^{(\overline{q_3}/\sqrt{8})(v^2-2\boldsymbol{w}\boldsymbol{r})*}\hat{I}_g(p,q,s)=e^{\overline{q_3}Q_3}\hat{I}_g(p,q,s)=\hat{I}_g(p',q',s').$$

Therefore, the kinetic equation (67) is invariant regarding the transformations with parameters $\overline{q_1}$, $\overline{q_2}$, and $\overline{q_3}$ due to properties (70), (71), (42), and (43). The transformations have the form

$$p_i'=\overline{T_{ik}}(\overline{q})p_k,\quad s'=s,$$

$$q_1'=\overline{q_1}+\frac{q_1e^{-\overline{q_2}}}{1-\overline{q_3}q_1/2},\quad q_2'=\overline{q_2}+q_2+\ln\left(1-\frac{\overline{q_3}q_1}{2}\right)^2,\quad q_3'=q_3+\frac{\overline{q_3}e^{-q_2}}{1-\overline{q_3}q_1/2},$$

$$f'(\boldsymbol{v},\boldsymbol{r},t;\boldsymbol{w},p',q',s')=e^{(\overline{q_1}/\sqrt{8})(\nabla^2-2\boldsymbol{\nabla}_{\boldsymbol{r}}\boldsymbol{\nabla}_{\boldsymbol{w}})}e^{(\overline{q_2}/2)(\boldsymbol{v}\boldsymbol{\nabla}+\boldsymbol{r}\boldsymbol{\nabla}_{\boldsymbol{r}}+\boldsymbol{w}\boldsymbol{\nabla}_{\boldsymbol{w}})}e^{(\overline{q_3}/\sqrt{8})(v^2-2\boldsymbol{w}\boldsymbol{r})}f(\boldsymbol{v},\boldsymbol{r},t;\boldsymbol{w},p,q,s,). \tag{72}$$

We will give three simple examples of using the transformation (72).

Example 1: If we change the parameters p, q, and s in problem (67) and take them from (55), we will have $\hat{I}_g(p,q,s)=\tilde{\hat{I}}$. For these parameters a constant N_0 becomes the solution of Eq. (67)

due to the property of the conjugated collision operator, $\tilde{\hat{I}}N_0 = 0$. Transformation (72) with parameters $\overline{q_3} = -\sqrt{2}m_1/kT$ and $\overline{q_1} = \overline{q_2} = 0$ transforms [see (53)] $\tilde{\hat{I}}$ into $\hat{I}$ so that, with the help of this transformation, we can get the classic Maxwell–Boltzmann solution for problem (67):

$$f = N_0 e^{-(m_1/2kT)(v^2 - 2\mathbf{wr})}. \tag{73}$$

Example 2: The extended collision operator with parameters p, q, and s given by formula (54) at $T=0$ is the collision operator $\hat{J}$ for collisions with molecules being at rest before collision. In the case of the constant collision frequency, transformation (72) with parameters $\overline{q_1} = \sqrt{2}kT/m_1$ and $\overline{q_2} = \overline{q_3} = 0$ transforms the operator $\hat{J}$ into $\hat{I}$ due to property (65). Therefore, transformation (72) with those parameters makes it possible to express the distribution function of charged particles drifting in a heated gas ($T \neq 0$) in terms of the distribution function of charged particles drifting in a cold gas ($T=0$):

$$f(\mathbf{v},\mathbf{r},t;\mathbf{w},T) = e^{(kT/2m_1)(\nabla^2 - 2\nabla_r \nabla_w)} f(\mathbf{v},\mathbf{r},t;\mathbf{w},\ T=0), \quad \text{when} \quad \nu = \text{const}, \quad \chi(\mu,\text{v}) = \chi(\mu). \tag{74}$$

Using the property of the Fourier transformation,

$$\hat{F}\nabla_r \hat{F}^{-1} = i\mathbf{k}, \quad [\hat{F}f](\mathbf{k}) = \frac{1}{(2\pi)^{3/2}} \int d\mathbf{r} e^{-i\mathbf{kr}} f(\mathbf{r}), \tag{75}$$

and formulas (66), (10), we get the integral representation of transformation (74):

$$f(\mathbf{v},\mathbf{r},t;\mathbf{w},T) = \left(\frac{m_1}{2\pi kT}\right)^{3/2} \int \frac{d\mathbf{v}'\, d\mathbf{r}'\, d\mathbf{k}}{(2\pi)^3} e^{-m_1(\mathbf{v}-\mathbf{v}')^2/2kT + i\mathbf{k}(\mathbf{r}-\mathbf{r}')} \times f\left(\mathbf{v}',\mathbf{r}',t;\mathbf{w} - i\frac{kT}{m_1}\mathbf{k},\ T=0\right) \quad \text{when} \quad \nu = \text{const}, \quad \chi(\mu,\text{v}) = \chi(\mu). \tag{76}$$

Formula (76) gives a generalization of the Wannier[8] theorem of convolution on the spatial not uniform case with presence of the magnetic field.

Example 3: When $\nu = \text{const}$, and $\chi(\mu,\text{v}) = \chi(\mu)$, a class of the exact solutions of the equation

$$\frac{\partial f}{\partial t} + \mathbf{v}\nabla_r f + (\mathbf{w} + \mathbf{v} \times \Omega)\nabla f = \hat{I} f, \tag{77}$$

describing spatial and velocity relaxation of the plasma charged component in the electric and magnetic fields has the form

$$f(\mathbf{v},\mathbf{r},t) = e^{-(m_1/2kT)(v^2 - 2\mathbf{wr})} e^{-(kT/2m_1)(\nabla^2 - 2\nabla_r\nabla_w)} e^{t[\tilde{\hat{J}} - \mathbf{v}\nabla_r - (\mathbf{w}+\mathbf{v}\times\Omega)\nabla]} p_n(\mathbf{v},\mathbf{r}), \tag{78}$$

where $p_n(\mathbf{v},\mathbf{r})$ is an arbitrary polynomial of the order n of the velocity and radius vector components, and the function

$$\varphi(\mathbf{v},\mathbf{r},t) = e^{t[\tilde{\hat{J}} - \mathbf{v}\nabla_r - (\mathbf{w}+\mathbf{v}\times\Omega)\nabla]} p_n(\mathbf{v},\mathbf{r}) \tag{79}$$

is a solution of the equation

$$\frac{\partial \varphi}{\partial t} + \mathbf{v}\nabla_r \varphi + (\mathbf{w} + \mathbf{v} \times \Omega)\nabla\varphi = \tilde{J}\varphi. \tag{80}$$

In fact, the linear vector space of polynomials of the order not greater than n is invariant with respect to the operator

$$\hat{H}=\tilde{\tilde{J}}-\boldsymbol{v}\boldsymbol{\nabla}_{\boldsymbol{r}}-(\boldsymbol{w}+\boldsymbol{v}\times\Omega)\boldsymbol{\nabla},$$

and therefore the operator is represented by the matrix in that space. Thus the exponential in (78) and (79) is a function in terms of the matrix and its action on a polynomial is defined by the usual rules.[9] A simple example of a solution (nonpositive) from class (78) is the solution ($n=1$)

$$f=e^{-(m_1/2kT)(v^2-2\boldsymbol{w}\boldsymbol{r})}\left\{c_0+\boldsymbol{c}_1[(\lambda+\Omega\times)\boldsymbol{r}+\boldsymbol{v}-\boldsymbol{w}t]+\boldsymbol{c}_{2+}\left(\boldsymbol{v}-\frac{\boldsymbol{w}}{\lambda-i\Omega}\right)e^{(\lambda-i\Omega)t}\right.$$
$$\left.+\boldsymbol{c}_{2-}\left(\boldsymbol{v}-\frac{\boldsymbol{w}}{\lambda+i\Omega}\right)e^{(\lambda+i\Omega)t}+\boldsymbol{c}_{2\mathrm{II}}\left(\boldsymbol{v}-\frac{\boldsymbol{w}}{\lambda}\right)e^{\lambda t}\right\}, \tag{81}$$

where c_0 is an arbitrary constant, $\boldsymbol{c}_1$ is an arbitrary vector constant, $\boldsymbol{c}_{2+}$, $\boldsymbol{c}_{2-}$, $\boldsymbol{c}_{2\mathrm{II}}$ are the cyclic components of an arbitrary vector constant those can be effectively used[10] for description the ionospheric magnetoactive plasma dynamic,

$$\boldsymbol{c}_{2\pm}=-\frac{\Omega\times(\Omega\times\pm i\Omega)}{2\Omega^2}\boldsymbol{c}_2,\quad \boldsymbol{c}_{2\mathrm{II}}=\frac{\Omega\times\Omega\times+\Omega^2}{\Omega^2}\boldsymbol{c}_2,$$

where $\lambda=\lambda_1^0$ is the eigenvalue[4,11] of the conjugated collision operator, $\tilde{\tilde{J}}\boldsymbol{v}=\lambda_1^0\boldsymbol{v}$.

(Received 22 December 1995; accepted for publication 21 February 1996)

We derive rigorous bounds on the length scale of determining local averages (volume elements) for the 3-D Navier-Stokes Equations. These length scale estimates are related to Kolmogorov's notion of a dissipation length scale in turbulent flows.
 [S0022-2488(96)00711-6]

I. INTRODUCTION

We consider the Navier-Stokes Equations (NSE)

$$\begin{cases} \dfrac{\partial}{\partial t}u-\nu\Delta u+(u\cdot\nabla)u+\nabla p=f \\ \nabla\cdot u=0 \end{cases},$$

in the cube $\Omega=[0,L]^3$. The above equations are subject to either periodic or Dirichlet boundary conditions. Let us divide Ω into N^3 small sub-cubes, $\{Q_j\}_{j=1}^{N^3}$, each with side of length $\ell=LN^{-1}$. Let us denote by

$$\overline{w_j}=\frac{1}{|Q_j|}\int_{Q_j} w(x)dx, \quad \text{for } j=1,2,\ldots,N^3,$$

the average of the function w in the small cube Q_j, and we set

$$\overline{\eta(w)}=\left(\sum_{j=1}^{N^3}|\overline{w_j}|^2\right)^{1/2}.$$

Following Ref. 1 (see also Ref. 2) we say that the set of sub-cubes $\{Q_j\}_{j=1}^{N^3}$ is a set of determining volume elements if for any two solutions $u(t),v(t)$ of the NSE, $\overline{\eta((u(t)-v(t)))}\to 0$, $t\to\infty$, implies $\|u(t)-v(t)\|\to 0$ as $t\to\infty$, in some reasonable norm $\|\cdot\|$. This concept was inspired by the notions of determining modes and determining nodes which were introduced by Foias and Prodi in Ref. 3 and by Foias and Temam in Ref. 4, respectively. These ideas were developed in an attempt to identify and study the finite number of degrees of freedom in turbulent flows. Rigorous *global* estimates on the number of determining modes, determining nodes and determining volume elements were established in Refs. 5, 6, and 2, respectively. An

0022-2488/96/37(12)/6152/5/$10.00

improvement of these global estimates was recently reported in Ref. 7. Moreover, a unified treatment of these concepts and more general ones, such as determining finite elements, has been recently developed in Refs. 8 and 9.

The above mentioned estimates are global in the sense that they are independent of the individual solution. In this paper, however, we give an upper bound on the minimal number of determining volume elements, N^3, or equivalently a lower bound on the size of determining finite volume elements (cubes), ℓ, in terms of the viscosity, and a modified mean rate of dissipation. The latter is a function of the individual solution. It is noteworthy that estimates for the number of determining volume elements that we provide here are the same as those established in Ref. 10 for the number of determining modes. This study is complementary to other rigorous work identifying small length scales in solutions of the NSE.[10–14]

II. PRELIMINARIES

We denote by $L^p(D)$ the usual Lebesgue spaces in the domain D, and by $H^k(D)$ the usual L^2 Sobolev spaces of index k in the domain D. Hereafter c_i, for $i=1,2,\ldots$, will denote positive dimensionless universal constants.

First let us prove the following version of the Poincaré inequality.

Lemma 2.1: *For every* $w \in H^1(Q_j)$ *we have*

$$\|w\|^2_{L^2(Q_j)} \leq 2|\overline{w_j}|^2 \ell^3 + c_1 \ell^2 \|\nabla w\|^2_{L^2(Q_j)}, \tag{1}$$

$$\|w\|^2_{L^2(\Omega)} \leq 2(\overline{\eta(w)})^2 \ell^3 + c_1 \ell^2 \|\nabla w\|^2_{L^2(\Omega)}. \tag{2}$$

Proof: By the Poincaré inequality we have

$$\|w - \overline{w_j}\|_{L^2(Q_j)} \leq c_1 \ell \|\nabla w\|_{L^2(Q_j)},$$

where c_1 is a universal constant independent of w and Q_j. From the above we get

$$\|w\|_{L^2(Q_j)} \leq |Q_j|^{1/2} |\overline{w_j}| + c_1 \ell \|\nabla w\|_{L^2(Qj)},$$

which establishes (1). To prove (2) we sum the (1) over $j=1,\ldots,N^3$.

Let us recall the following Lemma from Ref. 5 (see also Ref. 2).

Lemma 2.2: *Let* α *be a locally integrable real valued function on* $(0,\infty)$ *satisfying, for some* $0<T<\infty$, *the following conditions:*

$$\liminf_{t\nearrow\infty} \frac{1}{T}\int_t^{t+T} \alpha(\tau)\,d\tau = \gamma > 0,$$

$$\limsup_{t\to\infty} \frac{1}{T}\int_t^{t+T} \alpha^-(\tau)\,d\tau = \Gamma < \infty,$$

where $\alpha^- = \max\{-\alpha,0\}$. *Further, let* β *be a real valued locally integrable function defined on* $(0,\infty)$ *such that*

$$\lim_{t\to\infty} \frac{1}{T}\int_t^{t+T} \beta^+(\tau)\,d\tau = 0,$$

where $\beta^+ = \max\{\beta,0\}$. *Suppose that* ξ *is an absolutely continuous non-negative function on* $(0,\infty)$ *such that*

$$\frac{d}{dt}\xi+\alpha\xi\leqslant\beta, \qquad \text{a.e. on } (0,\infty).$$

Then $\xi(t)\to 0$ *as* $t\to\infty$.

III. MAIN RESULTS

We now state our main result:

Theorem 3.1: *Let* u *be any solution of the NSE. Suppose that the length of the side of* Q_j, *for* $j=1,\ldots,N^3$, *is small enough so that*

$$\ell^{-2}\geqslant\frac{4c_1}{\nu}\inf_{T>0}\left(\limsup_{t\to\infty}\frac{1}{T}\int_t^{t+T}\|\nabla u(s)\|_{L^\infty(\Omega)}ds\right). \tag{3}$$

Then for any solution v *of the NSE for which* $\overline{\eta}((u(t)-v(t)))\to 0$, *as* $t\to\infty$, *we have* $\|u(t)-v(t)\|_{L^2(\Omega)}\to 0$, *as* $t\to\infty$.

Proof: Let us set $w=u-v$. Then, w satisfies

$$\frac{\partial w}{\partial t}-\nu\Delta w+(u\cdot\nabla)w+(w\cdot\nabla)u-(w\cdot\nabla)w+\nabla(p_u-p_v)=0,$$

where p_u and p_v are the pressure fields corresponding to the solutions u and v respectively. Multiply the above equation by w and integrate over Ω to obtain

$$\frac{1}{2}\frac{d}{dt}\|w\|^2_{L^2(\Omega)}-\nu\int_\Omega\Delta w(x)\cdot w(x)dx+\int_\Omega((w(x)\cdot\nabla)u(x))\cdot w(x)dx+\int_\Omega((u(x)\cdot\nabla)w(x))\cdot w(x)dx-\int_\Omega((w(x)\cdot\nabla)w(x))\cdot w(x)dx=0.$$

Notice that $\int_\Omega\nabla(p_u(x)-p_v(x))\cdot w(x)dx=0$ because $\nabla\cdot w=0$ and $w|_{\partial\Omega}=0$ (or periodic). Integrate by parts the above equations and use again the facts that $\nabla\cdot u=\nabla\cdot w=0$ and that $w|_{\partial\Omega}=0$ (or periodic) to get

$$\frac{1}{2}\frac{d}{dt}\|w\|^2_{L^2(\Omega)}+\nu\|\nabla w\|^2_{L^2(\Omega)}=-\int_\Omega[(w(x)\cdot\nabla)u(x)]\cdot w(x)dx. \tag{4}$$

Now, we estimate the right hand side

$$\left|\int_\Omega((w(x)\cdot\nabla)u(x))\cdot w(x)dx\right|\leqslant\|\nabla u\|_{L^\infty(\Omega)}\|w\|^2_{L^2(\Omega)}.$$

Hence equation (4) becomes:

$$\frac{1}{2}\frac{d}{dt}\|w\|^2_{L^2(\Omega)}+\nu\|\nabla w\|^2_{L^2(\Omega)}\leqslant\|w\|^2_{L^2(\Omega)}\|\nabla u\|_{L^\infty(\Omega)},$$

and from (2) we have

$$\frac{1}{2}\frac{d}{dt}\|w\|^2_{L^2(\Omega)}+\left(\frac{\nu}{c_1\ell^2}-\|\nabla u\|_{L^\infty(\Omega)}\right)\|w\|^2_{L^2(\Omega)}\leqslant\frac{2\nu\ell}{c_1}(\overline{\eta}(w))^2.$$

Let $T_*>0$ be chosen such that

$$\inf_{T>0}\left(\limsup_{t\to\infty}\frac{1}{T}\int_t^{t+T}\left\|\nabla u(s)\right\|_{L^\infty(\Omega)}ds\right)\leqslant\limsup_{t\to\infty}\frac{1}{T_*}\int_t^{t+T_*}\|\nabla u(s)\|_{L^\infty(\Omega)}ds\leqslant\frac{\nu}{2c_1\ell^2}.$$

Now, we apply Lemma 2.2 with $\alpha(t)=\nu/c_1\ell^2-\|\nabla u(t)\|_{L^\infty(\Omega)}$, $\beta(t)=(2\nu\ell/c_1)(\overline{\eta}(w))^2$ and $T=T_*$ to conclude the Theorem.

Let u be any solution of the NSE. Following the conventional theory of turbulence we set

$$\epsilon=\frac{\nu}{L^3}\langle\|\nabla u\|^2_{L^2(\Omega)}\rangle,$$

the mean rate of energy dissipation, where $\langle\cdot\rangle$ denotes some kind of ensemble average (usually taken to be time average). Following Kolmogorov[15] we identify a small length scale in the flow to be

$$\ell_K\sim\left(\frac{\nu^3}{\epsilon}\right)^{1/4}.$$

By analogy let us define a modified mean rate of energy dissipation,

$$\epsilon_\infty=\nu\inf_{T>0}\left(\limsup_{t\to\infty}\frac{1}{T}\int_t^{t+T}\|\nabla u(s)\|^2_{L^\infty(\Omega)}ds\right),$$

and a modified small length scale:

$$\ell_{K,\infty}=\frac{1}{\sqrt{4c_1}}\left(\frac{\nu^3}{\epsilon_\infty}\right)^{1/4}.$$

As a corollary of the above Theorem we have:

Corollary 3.2: *If the side of each of the cubes Q_j, for $j=1,\ldots,N^3$, is small enough, in particular if $\ell\leqslant\ell_{K,\infty}$, then the cubes are determining volume elements.*

Explicit solutions of supersymmetric KP hierarchies: Supersolitons and solitinos

A. Ibort, L. Martínez Alonso, and E. Medina Reus
Departamento de Física Teórica, Universidad Complutense, E-28040 Madrid, Spain

(Received 13 December 1995; accepted for publication 8 July 1996)

Wide classes of explicit solutions of the Manin-Radul and Jacobian supersymmetric KP hierarchies are constructed by using line bundles over complex supercurves based on the Riemann sphere. Their construction extends several ideas of the standard KP theory, such as wave functions, ∂-equations and τ-functions. Thus, supersymmetric generalizations of N-soliton solutions, including a new purely odd ''solitino'' solution, as well as rational solutions, are found and characterized. © *1996 American Institute of Physics.* [S0022-2488(96)02112-3]

I. INTRODUCTION

The most appealing aspects of the theory of the KP hierarchy have a rich geometrical content and it is likely that this fact is at the heart of the relevance of integrable systems in modern theoretical physics.[1,2] For example, a common feature of the explicit methods of solutions is that they frequently involve geometric objects such as Grassmannians, algebraic curves, Abelian functions, and holomorphic line bundles.[3–9] This also happens to be true in the context of supersymmetric KP (SKP) hierarchies[10,11] and it is expected that some of these integrable systems are to find applications in string theory and quantum gravity.[12–14] The aim of this article is to show how line bundles over complex supercurves can be used to provide efficient methods of solution for the SKP hierarchies formulated by Manin and Radul (MRKP)[15] and Mulase and Rabin (JKP).[10,11] Both hierarchies have attracted much attention because of their important mathematical content. Apart from sharing many of the standard integrability properties, among their reductions they have a supersymmetric generalization of the KdV hierarchy with a rich Hamiltonian structure[15–17] and they are relevant from the point of view of superconformal algebra.[18–20] A basic goal of our study is to generalize some of the standard methods of solution arising in the KP theory and to characterize the classes of solutions they determine. In particular we want to investigate solutions of soliton type and their relationship with the standard KP solitons. To this end we extend some strategies of the Grassmannian approach for constructing several types of solutions and apply them to the SKP hierarchies.

This work is based on the concept of super-wave function for a system of Sato equations of supersymmetric type. As it is known from our experience with the KP hierarchy, the notion of wave function is what allows us to derive methods of solution based on the resolution of analytic problems. Despite the seemingly great diversity of these methods, they exhibit a common ingredient: the presence of holomorphic line bundles[6–8] whose sections turn to be the wave functions. Actually, the wave functions are special types of sections satisfying certain conditions as functions of the spectral parameter. These conditions are formulated in several forms depending on the particular approach which is being adopted. For example, they may be expressed by means of a ∂-equation[21,22] or by selecting a subspace of an infinite-dimensional Grassmanian.[7] In this article we characterize the super-wave functions as certain sections of deformations of holomorphic line bundles over complex supercurves based on the Riemann sphere together with the corresponding points in the super-Grassmannian. Finally we also offer a ∂-equation description of them. Then we compute several families of solutions including supersymmetric N-soliton solutions possessing an interesting composite odd structure, and a genuine supersymmetric family of solutions without a bosonic counterpart, unrelated to any class of solution of the standard KP theory, that we call *solitino* solutions. They exhibit a remarkable nonlinear superposition principle and a Fourier-like

J. Math. Phys. **37** (12), December 1996

dependence on the bosonic variables. It is worth mentioning that the solutions found in the present work can also be determined, although in a less straigthforward way, through the bilinear formalism proposed in Ref. 23.

The first part of Section II is concerned with a brief review of SKP hierarchies in terms of pseudodifferential operators, including the formulation of Sato equations. The notion of super-wave function is analyzed in the second part of this section. In particular, we describe in detail the derivation of the corresponding expressions for the vacuum super-wave functions. The characterization of super-wave functions as sections of (super) holomorphic line bundles over complex supermanifolds is described in the first part of Section III, and finally in Section IV we relate the above constructions to the supergroup and bilinear formalism.

II. SUPER KP HIERARCHIES

A. Sato equations for super KP hierarchies

The MRKP and JKP hierarchies can be described in a unified way with the help of an algebra $\mathscr{E}$ of super-pseudodifferential operators:[24]

$$X=\sum_{n\leqslant N} a_n(x,\theta,\mathbf{t},\boldsymbol{\tau})D^n, \quad N\in\mathbb{N}, \tag{1}$$

where the coefficients a_n are elements of a supercommutative algebra

$$\mathscr{S}=\mathbb{C}[[x,\mathbf{t}]]\otimes\Lambda(\theta,\boldsymbol{\tau})\otimes\mathscr{A}.$$

Here, x is an even variable, θ is an odd variable, $\mathbf{t}=\{t_n\}_{n=1}^{\infty}$ and $\boldsymbol{\tau}=\{\tau_n\}_{n=1}^{\infty}$ are infinite sets of even and odd variables, respectively, and $\mathscr{A}$ denotes a given complex Grassmann algebra of finite or infinite dimension. The superdifferential operator D is defined as the derivation on $\mathscr{S}$ given by

$$D=\frac{\partial}{\partial\theta}+\theta\frac{\partial}{\partial x},$$

satisfying the identity

$$D^2=\partial\equiv\frac{\partial}{\partial x}.$$

We will denote by $X=X_+ + X_-$ the decomposition of elements $X\in\mathscr{E}$ into positive ($n\geqslant 0$) and negative ($n<0$) powers D^n of D.

Both algebras $\mathscr{S}$ and $\mathscr{E}$ have natural $\mathbb{Z}_2$-graduations

$$\mathscr{S}=\mathscr{S}_{\bar{0}}\oplus\mathscr{S}_{\bar{1}}, \quad \mathscr{E}=\mathscr{E}_{\bar{0}}\oplus\mathscr{E}_{\bar{1}}.$$

An operator (1) is said to have parity p if and only if ($\forall n\leqslant N$) the coefficients a_n have parity $n+p$ mod 2. We may also introduce body maps ϵ on $\mathscr{S}$ and $\mathscr{E}$ (Ref. 24) and, in particular, the body of an operator (1) is given by

$$\epsilon(X)=\sum_{n\ \text{even}}\epsilon(a_n)D^n.$$

Notice that $\epsilon(X)$ is not the even part of X.

The Sato equations for the SKP hierarchies can be written as

$$\frac{\partial K}{\partial t_n} = -(K\partial^n K^{-1})_- K,$$
$$\frac{DK}{D\tau_n} = -(KA_n K^{-1})_- K, \quad n \geqslant 1, \tag{2}$$

for an even $K \in \mathscr{E}$ of the form

$$K = 1 + \sum_{n=1}^{\infty} w_n(x, \theta, \mathbf{t}, \boldsymbol{\tau}) D^{-n}. \tag{3}$$

Notice that $p(w_{2n}) = 0$ and $p(w_{2n+1}) = 1$ so that $p(K) = 0$.

For the MRKP hierarchy the superderivations $D/D\tau_n$ and the operators A_n in (2) are

$$\frac{D}{D\tau_n} = \frac{\partial}{\partial \tau_n} - \sum_{m \geqslant 1} \tau_m \frac{\partial}{\partial t_{n+m-1}}, \quad A_n = D^{2n-1}.$$

while for the JKP version

$$\frac{D}{D\tau_n} = \frac{\partial}{\partial \tau_n}, \quad A_n = (D - \theta D^2) D^{2n-2} = \frac{\partial}{\partial \theta} D^{2n-2}.$$

These hierarchies generalize the standard KP hierarchy in the sense that, as one easily shows, the body $\epsilon(K)$ of a solution K of (2) satisfies the Sato equations for the KP hierarchy in the variables t_n.

By identifying the coefficients of the powers of D in the system (2) one finds infinite systems of superdifferential equations involving the superfunctions $\{w_n\}$. Simpler equations can be obtained by imposing a reduction condition of the type[15]

$$\frac{\partial K}{\partial t_r} = 0, \tag{4}$$

for some $r \geqslant 2$. Indeed, if one introduces the operator

$$L = KDK^{-1} = D + \sum_{n=1}^{\infty} u_n D^{-n+1}, \tag{5}$$

the constraint (4) is equivalent to

$$(L^{2r})_- = (KD^{2r}K^{-1})_- = 0,$$

and it turns out that the operator

$$\mathscr{L} = L^{2r}$$

satisfies the Lax equations

$$\frac{\partial \mathscr{L}}{\partial t_n} = [(\mathscr{L}^{n/r})_+, \mathscr{L}]. \tag{6}$$

The coefficients of the expansion of $(\mathscr{L}^{n/r})_+$ in powers of D are differential polynomials in the coefficients of $\mathscr{L}$ (Ref. 15), so that (6) leads to a system of superdifferential equations for the coefficients of $\mathscr{L}$ which constitutes a supersymmetric generalization of the rth KdV hierarchy.

For example if we asssume (4) for $r=2$, then the operator $\mathscr{L}=L^4$ is of the form

$$\mathscr{L}=D^4+v_1D+v_0,$$

where v_0 and v_1 can be expressed in terms of the coefficients of K as

$$v_0=-2[\partial w_2+(\partial w_1)w_1], \quad v_1=-2\partial w_1. \tag{7}$$

Furthermore, it is easy to find

$$(\mathscr{L}^{3/2})_+=D^6+\frac{3}{2}v_1D^3+\frac{3}{2}v_0D^2+\frac{3}{4}\partial v_1D+\frac{3}{4}\partial v_0,$$

so that the equation corresponding to (6) for $n=3$ reads ($t=t_3$)

$$\begin{aligned}\frac{\partial v_0}{\partial t}&=\frac{1}{4}[\partial(\partial^2v_0+3v_1Dv_0+3v_0^2)],\\ \frac{\partial v_1}{\partial t}&=\frac{1}{4}[\partial(\partial^2v_1+3v_1Dv_1+6v_0v_1)],\end{aligned} \tag{8}$$

which is the supersymmetric Korteweg-de Vries (SKdV) equation of Manin-Radul.[15]

B. Super-wave functions for super KP hierarchies

The notion of super-wave function for a SKP hierarchy requires the introduction of a spectral parameter (z,α), where z denotes a complex variable and α is a new Grassmann variable. The superparameter (z,α) represents local supercoordinates on a complex supercurve $\mathscr{C}$ (see for instance, Ref. 25, and references therein for the notions of supergeometry used in the following) with structure sheaf $\mathscr{O}$ and not being necessarily a super-Riemann surface (SRS). Let p be a point in the body of $\mathscr{C}$ and D a disk containing p. We shall denote by $\mathscr{O}^*$ the restriction of sheaf of superfunctions $\mathscr{O}$ to $D-\{p\}$.

Definition 1:[11–20,24] *A vacuum super-wave function is a superfunction* $f_0\in\mathscr{O}^*\otimes\mathscr{S}$ *that satisfies*

$$\begin{aligned}\frac{\partial f_0}{\partial t_n}&=\partial^n f_0,\\ \frac{Df_0}{D\tau_n}&=A_nf_0, \quad n\geqslant 1.\end{aligned} \tag{9}$$

Hence, a super-wave function f_0 depends on the variables $(z,\alpha;x,\theta,\mathbf{t},\boldsymbol{\tau})$, and is a solution of the linear system (9). We can find solutions of (9) using the ansazt,

$$f_0=Ve^{zx+\alpha\theta}, \tag{10}$$

with V a super-pseudodifferential operator in $\mathscr{E}$ and satisfying the initial condition $V|_{\mathbf{t}=\mathbf{0},\boldsymbol{\tau}=\mathbf{0}}=1$. Then, V must verify

$$\frac{\partial V}{\partial t_n}=\partial^n\cdot V,$$

$$\frac{DV}{D\tau_n}=A_n\cdot V,\quad n\geqslant 1.$$

It is easy to see that for the MRKP hierarchy

$$V=\exp\left[\sum_{n=1}^{\infty} t_n\partial^n\right]\cdot\left[1+\sum_{n=1}^{\infty}\tau_n D^{2n-1}\right]$$

and

$$f_0=\exp\left[zx+\alpha\theta+\sum_{n=1}^{\infty} z^n t_n+(\alpha-z\theta)\sum_{n=1}^{\infty} z^{n-1}\tau_n\right].$$

Respectively for the JKP hierarchy

$$V=\exp\left[\sum_{n=1}^{\infty} t_n\partial^n+\sum_{n=1}^{\infty}\tau_n\frac{\partial}{\partial\theta}D^{2n-2}\right]$$

and

$$f_0=\exp\left[zx+\alpha\theta+\sum_{n=1}^{\infty} z^n t_n+\alpha\sum_{n=1}^{\infty} z^{n-1}\tau_n\right].$$

Henceforth we will write both expressions of the vacuum super-wave function f_0 as

$$f_0=\exp\left[zx+\sum_{n=1}^{\infty} z^n(t_n+\theta\tau_n)+(\alpha-\lambda)\left(\theta+\sum_{n=1}^{\infty} z^{n-1}\tau_n\right)\right],\tag{11}$$

where $\lambda=\lambda(z,\theta,\boldsymbol{\tau})$ denotes a function which for the MRKP hierarchy is

$$\lambda(z,\theta,\boldsymbol{\tau})=z\theta-\sum_{n=1}^{\infty} z^n\tau_n,\tag{12}$$

and for the JKP hierarchy is given by

$$\lambda(z,\theta,\boldsymbol{\tau})=z\theta.\tag{13}$$

For brevity's sake, we will often omit the arguments of the superfunctions which are irrelevant or clear from the context.

It should be noticed that

$$Df_0=(\lambda-\alpha)f_0,\quad D^2f_0=zf_0,\tag{14}$$

so that the action of inverse powers of D on f_0 may be defined as

$$D^{-1}f_0=D\cdot D^{-2}f_0=(\lambda-\alpha)z^{-1}f_0.\tag{15}$$

It is now evident that we can ''dress'' the vacuum super-wave function to obtain solutions of Sato's equations (2) introducing the notion of a super-wave function.

Let $H(\Omega)$ denote the set of complex valued holomorphic functions of z on a certain region Ω of the complex plane, and $\mathcal{O}_\Omega=H(\Omega)\otimes\Lambda(\alpha)$ the superalgebra of superfunctions of the trivial $(1|1)$-superspace over Ω.

Definition 2: Let Ω *and* $\mathscr{O}_\Omega$ *as before. A super-wave function for a SKP hierarchy is an even element* $f=f(z,\alpha;x,\theta;\mathbf{t},\boldsymbol{\tau})$ *of the algebra*

$$\mathscr{O}_\Omega\otimes\mathbb{C}[[x,\mathbf{t}]]\otimes\Lambda(\theta,\boldsymbol{\tau})\otimes\mathscr{A},$$

which satisfies the properties:
(P1) f *is a solution of an infinite system of equations:*

$$\begin{aligned}\frac{\partial f}{\partial t_n}&=P_n f,\\ \frac{Df}{D\tau_n}&=Q_n f,\quad n\geqslant 1,\end{aligned}\tag{16}$$

with $P_n,Q_n\in\mathscr{E}$ *being superdifferential operators*

$$(P_n)_-=(Q_n)_-=0.$$

(P2) f *can be decomposed as a product:*

$$f=f'\cdot f_0,\tag{17}$$

where f' *admits a Laurent expansion on* $r<|z|<r'$ *of the form:*

$$f'=1+\sum_{n=1}^{\infty}w_{2n}z^{-n}+(\alpha-\lambda)\sum_{n=1}^{\infty}w_{2n-1}z^{-n},\tag{18}$$

with $w_n\in\mathscr{S}$ *for all* $n\geqslant 1$.

Then a super-wave function f is obtained by dressing the vacuum super-wave function f_0 using an operator K satisfying Sato's equations.

Theorem 1: *Let* f *be a super-wave function for an SKP hierarchy and* f_0 *the vacuum super-wave function (11), then there is an operator* K *such that*

$$f=Kf_0.\tag{19}$$

and K *verifies Sato's equations (2). Conversely, any solution of Sato's equations (2) provides a super-wave function* f *for a SKP hierarchy by means of Eq. (19).*

Proof: To prove this fact, we observe that as a consequence of properties (14) and (15) of f_0, the operator K in (19) has the required form (3) with the coefficients w_n being the same as those of the expansion (18) of f'. On the other hand (16), (19) and (9) imply

$$\frac{\partial K}{\partial t_n}f_0+K\partial^n f_0=P_nKf_0,$$

so that we deduce

$$\frac{\partial K}{\partial t_n}K^{-1}=P_n-K\partial^nK^{-1}.$$

But this equation obviously leads to

$$P_n=(K\partial^nK^{-1})_+$$

and

$$\frac{\partial K}{\partial t_n} = -(K\partial^n K^{-1})_- K.$$

In the same way one shows that K satisfies the Sato equations for the flows associated with the variables τ_n. Thus, we have obtained in this way a one-to-one correspondence between solutions K of Sato's equation and super-wave functions f_0.

Conversely, if $f=Kf_0$, then because of (2), and (9), f verifies (16) with $P_n=(K\partial^n K^{-1})_+$ and $Q_n=(KA_nK^{-1})_+$. Moreover, because of the expansion (3) of the operator K follows the expansion (18) of the transition superfunction f'.

It is worth noticing that, as it should be expected, the body of a super-wave function for a SKP hierarchy constitutes a wave function for the standard KP hierarchy.

III. LINE BUNDLES AND EXPLICIT SOLUTIONS OF THE SKP HIERARCHIES

A. Super-wave functions as sections of line bundles

Contrary to the situation in the bosonic case, the description of the SKP flows must be done not on line bundles over a supercurve but on line bundles over a family of supercurves parametrized by θ, $\boldsymbol{\tau}$. To be precise, we are going to consider a family $\mathscr{M}(\theta, \tau)$ of compact complex supermanifolds of dimension (1,1) *parametrized* by the set of global Grassmann variables $(\theta,\boldsymbol{\tau})$. We will describe this structure in detail. Let $\mathscr{U}=(U;z,\alpha)$ and $\mathscr{U}'=(U';z',\alpha')$ be two charts, where the pair $\{U,U'\}$ is a covering of the Riemann sphere, for instance,

$$U=\{z\in\mathbb{C}\,|\,|z|<r\},\quad U'^0=\{z\in\mathbb{C}\,|\,|z|>r'\},\quad 0<r'<r,$$

with the two systems of coordinates being related through the equations

$$z'=\frac{1}{z},\quad \alpha'=\alpha-\lambda(z,\theta,\boldsymbol{\tau}). \tag{20}$$

Here $\lambda(z,\theta,\boldsymbol{\tau})$ is the function defined in (12) and (13) and the transformation $\alpha\mapsto\alpha'$ will be called a super-Schiffer transformation. Notice that these supermanifolds are of extended type in the sense of Rogers[26] because superfunctions on $\mathscr{M}(\theta,\boldsymbol{\tau})$ depend not only on the local coordinates (z,α) of the supermanifold but also on the global variables $(\theta,\boldsymbol{\tau})$. In general, the equation (20) for the super-Schiffer transformation $\alpha\mapsto\alpha'$ does not extend holomorphically throughout U', generically it has a pole of order 1 at ∞, and the supermanifold structures defined by the transition superfunctions (20) are not equivalent to the trivial super-Riemann sphere.

Thus we can think on the supermanifold structures defined by the $(\theta,\boldsymbol{\tau})$-dependent transition functions (20) as tracing a path on the moduli space of complex supercurves. See Ref. 27 for the description of universal deformations on the supermoduli space of supercurves. We could consider further deformations of our complex supercurves but we will simplify the description of super-wave functions by considering only the supercurves parametrized by θ and $\boldsymbol{\tau}$ by means of (20).

We shall consider then the family $\mathscr{L}(x,\mathbf{t})$ of holomorphic line bundles over $\mathscr{M}(\theta,\boldsymbol{\tau})$ with transition function given by the vacuum super-wave function f_0 of a SKP hierarchy. Our purpose now will be to characterize holomorphic sections of these bundles. Such sections will be determined by pairs

$$(\mathscr{U},\phi),\quad (\mathscr{U}',\phi'),$$

defined on the patches U and U', and where ϕ and ϕ' are even superfunctions

$$\phi\in M(U)\otimes\Lambda(\alpha)\otimes\mathbb{C}[[x,\mathbf{t}]]\otimes\Lambda(\theta,\boldsymbol{\tau})\otimes\mathscr{A},$$

$$\phi'\in M(U')\otimes\Lambda(\alpha')\otimes\mathbb{C}[[x,\mathbf{t}]]\otimes\Lambda(\theta,\boldsymbol{\tau})\otimes\mathscr{A},$$

verifying the overlapping condition,

$$\phi=\phi'\cdot f_0,\quad \forall z\in U\cap U'. \tag{21}$$

Here, $M(U)$ and $M(U')$ denote the sets of complex valued meromorphic functions of z on U and U', respectively.

Comparing our last equation (21) with the factorization property for a super-wave function (17), we immediately see that wide classes of super-wave functions for the SKP hierarchies can be obtained from special sections of $\mathscr{L}(x,\mathbf{t})$. We will search for the conditions defining subsets

$$\mathscr{W}\subset M(U)\otimes\Lambda(\alpha)\otimes\mathbb{C}[[x,\mathbf{t}]]\otimes\Lambda(\theta,\boldsymbol{\tau})\otimes\mathscr{A}, \tag{22}$$

whose elements will be super-wave functions.

Definition 3: A subspace $\mathscr{W}$ of the the superalgebra $M(U)\otimes\Lambda(\alpha)\otimes\mathbb{C}[[x,\mathbf{t}]]\otimes\Lambda(\theta,\boldsymbol{\tau})\otimes\mathscr{A}$ will be called an asympotic super-module if it verifies:

(C1) *$\mathscr{W}$ is a left-module over the algebra of superdifferential operators generated by D and $\{(\partial/\partial t_n),(\partial/\partial\tau_n)\}_{n\geqslant 1}$ with coefficients in $\mathscr{S}$.*

(C2) *There is only one even section of the line superbundle $\mathscr{L}(x,\mathbf{t})$ given by the local expressions,*

$$(\mathscr{U},f),\quad (\mathscr{U}',f'), \tag{23}$$

such that $f\in\mathscr{W}$ and f' is holomorphic on U' with $f'|_{\{z=\infty\}}=1$.

In Section III we will construct explicitly several examples of asymptotic super-modules for complex supercurves with body manifold the Riemann sphere. For more general complex supercurves $\mathscr{M}$ with body manifold an arbitrary compact Riemann surface Σ, the previous characterization works similarly. To construct the subspaces $\mathscr{W}$ we should choose first a line bundle $\mathscr{L}$ over $\mathscr{M}$ such that $\dim H^0(\mathscr{M},\mathscr{L})=\dim H^1(\mathscr{M},\mathscr{L})=0$. Then, fixing a point $p\in\Sigma$ and a local trivialization in a neighborhood of it, we define the new bundle $\mathscr{L}\otimes\mathscr{L}_p$ possessing the required properties. Notice that the cohomological requirements on $\mathscr{L}$ implies that $\deg E=0$ where E is the underlying complex line bundle over the Riemann surface. For the Riemann sphere case, this implies that $\deg\mathscr{L}=-1$ and the complex supercurve is not a SRS.

We can prove now the following theorem characterizing super-wave functions using asymptotic super-modules.

Theorem 2: *Given an asymptotic super-module $\mathscr{W}$, the superfunction*

$$f=f'\cdot f_0,\quad z\in U\cap U',$$

defined by the unique section associated to it is a super-wave function for the associated SKP hierarchy.

Proof: To see this, observe that from (C2) in Def. 3 we deduce

$$f'=1+\sum_{n=1}^{\infty}w_{2n}(z')^n+\alpha'\cdot\sum_{n=1}^{\infty}w_{2n-1}(z')^n=1+\sum_{n=1}^{\infty}w_{2n}z^{-n}+(\alpha-\lambda)\sum_{n=1}^{\infty}w_{2n-1}z^{-n}.$$

Therefore f satisfies the condition (P2) for super-wave functions. On the other hand, by using (14) we get that for $z\in U\cap U'$

$$\begin{aligned} D^{2n}f-w_1D^{2n-1}f&=[z^n+O(z^{n-1})]f_0,\\ D^{2n+1}f+w_1D^{2n}f&=[-(\alpha-\lambda)z^n+O(z^{n-1})]f_0. \end{aligned} \tag{24}$$

As a consequence, we may determine superdifferential operators $P_n, Q_n \in \mathscr{E}$ such that

$$\frac{\partial f}{\partial t_n} - P_n f = O\left(\frac{1}{z}\right) \cdot f_0,$$
$$\frac{Df}{D\tau_n} - Q_n f = O\left(\frac{1}{z}\right) \cdot f_0, \quad n \geqslant 1. \tag{25}$$

Then, it is easy to see that (C2) implies that both $\partial f/\partial t_n - P_n f$ and $Df/D\tau_n - Q_n f, n \geqslant 1$, vanish, and therefore f satisfies the condition (P1) for super-wave functions.

Solutions to a reduced hierarchy (4) can be obtained by imposing on $\mathscr{W}$ the additional condition

$$z^r \cdot \mathscr{W} \subset \mathscr{W}. \tag{26}$$

Indeed, in that case the super-wave function f associated with $\mathscr{W}$ satisfies

$$\frac{\partial f}{\partial t_r} = z^r \cdot f,$$

so that f' and K are independent on t_r.

B. Solitons and solitinos

We will now construct several examples of asymptotic super-modules and the corresponding super-wave functions.

Let us consider the subset of superfunctions ϕ which are analytic for all $z \in U$, with the possible exception of simple poles contained in a fixed subset $\{q_i\}_{i=1}^N$, and such that the corresponding residues satisfy

$$\mathrm{Res}(\phi, q_i) = (c_i + \alpha\omega_i) \cdot \phi(p_i, \alpha), \quad i = 1, \ldots, N, \tag{27}$$

where $\{c_i\}_{i=1}^N \in \mathscr{A}_0$ and $\{\omega_i\}_{i=1}^N \in \mathscr{A}_1$ are given, and $\{p_i\}_{i=1}^N$ is a fixed subset of points of U different from $\{q_i\}_{i=1}^N$. This subspace will be denoted by $\mathscr{W}(\mathbf{q}, \mathbf{p}; \mathbf{c}, \boldsymbol{\omega})$, where $\mathbf{q} = (q_1, \ldots, q_N)$, etc.

Theorem 3: *The subspace $\mathscr{W}(\mathbf{q}, \mathbf{p}; \mathbf{c}, \boldsymbol{\omega})$ is an asymptotic super-module and its elements are super-wave functions for a SKP hierarchy.*

Proof: In order to prove that $\mathscr{W}(\mathbf{q}, \mathbf{p}; \mathbf{c}, \boldsymbol{\omega})$ verifies the required conditions (C1) and (C2) of Def. 3, let us note that the corresponding superfunction f must be of the form

$$f = \left[1 + \sum_{i=1}^{N} \frac{a_i + (\alpha - \lambda)\beta_i}{z - q_i}\right] \cdot f_0, \tag{28}$$

where the unknown coefficients a_i and β_i are even and odd elements of $\mathscr{S}$, respectively. Thus computing the residues, (27) implies

$$a_i + (\alpha - \lambda(q_i))\beta_i = (b_i + \alpha\gamma_i)\left[1 + \sum_{j=1}^{N} \frac{a_j + (\alpha - \lambda(p_i))\beta_j}{p_i - q_j}\right], \tag{29}$$

for all $i = 1, \ldots, N$, where $b_i, \gamma_i \in \mathscr{S}$ are given by

$$b_i = e(p_i) c_i e(q_i)^{-1}, \quad \gamma_i = e(p_i)\left[\omega_i + c_i \sum_{n \geqslant 1} (p_i^{n-1} - q_i^{n-1})\tau_n\right] e(q_i)^{-1},$$

and with $e(z)$ denoting the superfunction

$$e(z)=\exp\left[zx+\sum_{n\geqslant 1} z^n(t_n+\theta\tau_n)-\lambda(z)\left(\theta+\sum_{n\geqslant 1} z^{n-1}\tau_n\right)\right].$$

From (29) the following linear system for the coefficients a_i and β_i follows

$$\begin{aligned}&\sum_j\left[\delta_{ij}-\frac{b_i}{p_i-q_j}\right]\cdot a_j-\sum_j\left[\delta_{ij}\lambda(q_i)-\frac{b_i\lambda(p_i)}{p_i-q_j}\right]\cdot\beta_j=b_i,\\ &-\sum_j\frac{\gamma_i}{p_i-q_j}\cdot a_j+\sum_j\left[\delta_{ij}+\frac{\gamma_i\lambda(p_i)-b_i}{p_i-q_j}\right]\cdot\beta_j=\gamma_i.\end{aligned}\tag{30}$$

This is a uniquely solvable system since the body of the matrix of coefficients is the invertible numerical matrix,

$$\begin{pmatrix}\delta_{ij}-\dfrac{\epsilon(b_i)}{p_i-q_j} & 0\\ 0 & \delta_{ij}-\dfrac{\epsilon(b_i)}{p_i-q_j}\end{pmatrix}.\tag{31}$$

Therefore we conclude that (28) is a super-wave function.

Theorem 1 allows the identification of the coefficients of the expansion of the super-wave function with the coefficients of the expansion of the operator K solving Sato's equations (2). Observe then for f given by eq. (28), the first two coefficients of the expansion of the associated solution K of Sato equations are

$$w_1=\sum_{i=1}^{N}\beta_i,\quad w_2=\sum_{i=1}^{N}a_i.\tag{32}$$

We consider the following two different cases for the system (30).

1. Supersoliton solutions: $\epsilon(c_i)=0,\forall i\neq 1,\ldots,N$

From (30) it is easy to see that the body of f is the wave function associated with the N-soliton solution of the KP hierarchy. Therefore the solution of the SKP hierarchy provided by f is a supersymmetric generalization of the standard multisoliton solutions. For example, it is rather simple to derive the explicit solution for $N=1$. In this case, the constraints (27) reduce to

$$\mathrm{Res}(\phi,q)=(c+\alpha\omega)\phi(p,\alpha).$$

Then one finds

$$f=\left[1+\frac{a+(\alpha-\lambda)\beta}{z-q}\right]\cdot f_0,$$

with

$$\begin{aligned}a&=\frac{(q-p)b}{q-p+b}+\frac{\lambda(p)b+(q-p)\lambda(q)}{(q-p+b)^3}(q-p)^2\gamma,\\ \beta&=\frac{(p-q)^2}{(q-p+b)^2}\gamma.\end{aligned}\tag{33}$$

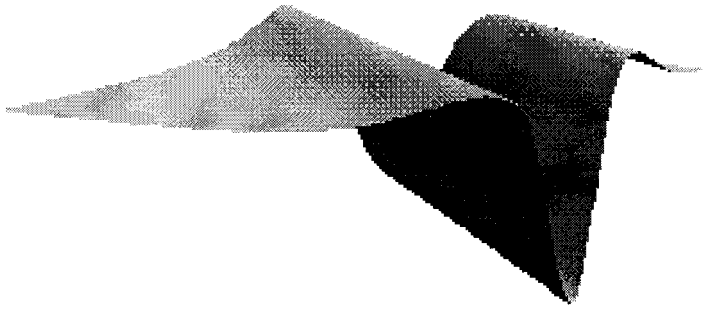

FIG. 1. Composite structure of a single supersoliton, $(h_1(x,t), q=1, x_0=1)$.

If we take $p=-q$, then it follows that $z^2\cdot\mathscr{W}\subset\mathscr{W}$, so that f becomes a super-wave function for the supersymmetric KdV hierarchy. In particular, it provides a solution of the SKdV equation (8). To simplify the expression of this solution we set $t_n=0$, $\forall n\neq 3$, and $\tau_n=0$, $\forall n\geqslant 1$. Thus, from (7), (32) and (33), we find

$$\begin{aligned} v_0&=2\left(q^2+\theta\omega\frac{q^3}{c}\right)\operatorname{sech}^2[q(x-x_0+q^2t)]-3\,\theta\omega\frac{q^3}{c}\operatorname{sech}^4[q(x-x_0+q^2t)],\\ v_1&=\omega\frac{2q^2}{c}\sinh[q(x-x_0+q^2t)]\operatorname{sech}^3[q(x-x_0+q^2t)], \end{aligned} \tag{34}$$

where

$$x_0=\frac{1}{q}\log\left(\frac{c}{2q}\right).$$

The expression of v_0 may be described as a supersymmetric dressing of the standard soliton of the KdV equation. Writing $v_0=h_0(x,t)+h_1(x,t)\,\theta\omega$ and $v_1=h_2(x,t)\,\omega$, in Fig. 1 we show the composite structure of h_1, the $\theta\omega$ component of the superfunction v_0.

On the other hand, it is worth noticing that the odd superfunction v_1 is proportional to a function h_2 of (x,t) which represents also a composite structure (see Fig. 2) which propagates without deformation along the x axis.

2. Solitino solutions: $c_i=0, \forall i=1,\ldots,N$

In this case (29) and (30) reduces to

$$\begin{aligned} a_i&=\lambda(q_i)\cdot\beta_i,\\ \gamma_i&=\sum_{j=1}^{N}\left[\delta_{ij}+\gamma_i\frac{\lambda(p_i)-\lambda(q_j)}{p_i-q_j}\right]\beta_j. \end{aligned} \tag{35}$$

This system can be solved in terms of the nilpotent matrix

$$\Delta_{ij}=\frac{\lambda(p_i)-\lambda(q_j)}{p_i-q_j}\gamma_i. \tag{36}$$

Indeed, as $\Delta^N\boldsymbol{\gamma}=0$ the solution of (35) is

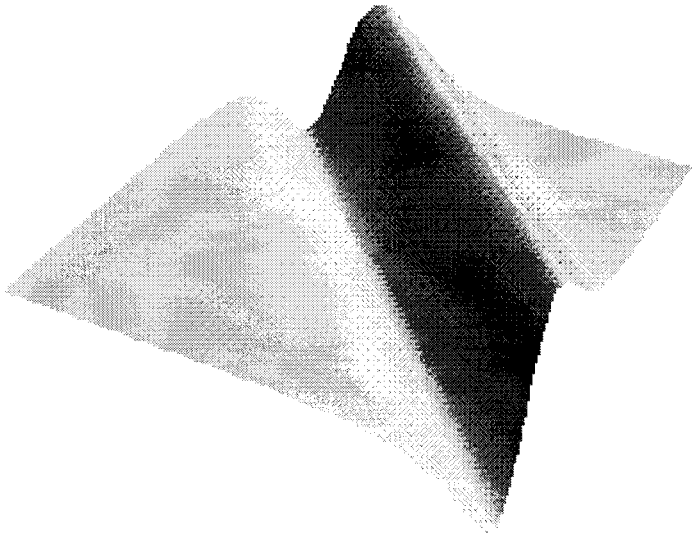

FIG. 2. Odd component of a supersoliton $(h_2(x,t), q=1, x_0=1)$.

$$\boldsymbol{\beta}=\sum_{n=0}^{N-1}\Delta^n\boldsymbol{\gamma}, \tag{37}$$

where $\boldsymbol{\beta}=(\beta_1,\ldots,\beta_N)$ and $\boldsymbol{\gamma}=(\gamma_1,\ldots,\gamma_N)$. It must be observed that the body of f vanishes, so that this class of solutions is not related to any class of the standard KP theory. We will refer to these solutions as *solitino* solutions. The single solitino solution corresponds to $N=1$ and takes the form

$$f=\left[1+\frac{a+(\alpha-\lambda)\beta}{z-q}\right]\cdot f_0,$$

$$w_1=\beta=\omega\ \exp\ r, \quad w_2=a=\lambda(q)\omega\ \exp\ r,$$

where

$$\exp\ r=e(p)e(q)^{-1}=\exp\Bigg[(p-q)x+\sum_{n\geqslant 1}(p^n-q^n)(t_n+\theta\tau_n)-(\lambda(p)-\lambda(q))\theta$$

$$-\sum_{n\geqslant 1}(\lambda(p)p^{n-1}-\lambda(q)q^{n-1})\tau_n\Bigg]. \tag{38}$$

If we take $p_i=-q_i$, $\forall i=1,\ldots,N$, then $z^2\cdot\mathscr{W}\subset\mathscr{W}$ and we obtain a solution of (8). It adopts a convenient way by setting, as we did before, $t_n=0, \forall n\neq 3$ and $\tau_n=0, \forall n\geqslant 1$. Thus the matrix (36) reduces to

$$\Delta_{ij}=\theta\omega_i\ \exp[-2q_i(x+q_i^2t)]$$

and

$$\gamma_i=\omega_i\ \exp[2q_i(x+q_i^2t)],$$

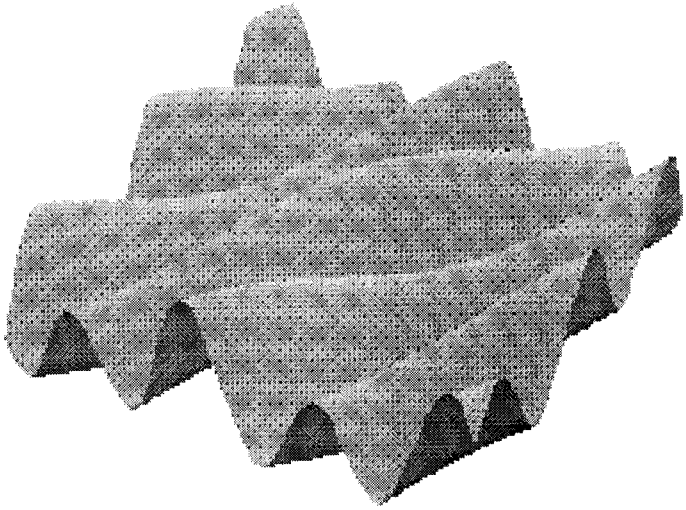

FIG. 3. An even component of a bisolitino solution.

and we find the following multisolitino solution of the SKdV equation (8):

$$v_0 = 4\theta \sum_i q_i^2 \omega_i \exp[-2q_i(x+q_i^2 t)] + 4\sum_{i,j} q_i \omega_i \omega_j \exp[-2q_i(x+q_i^2 t) - 2q_j(x+q_j^2 t)], \tag{39}$$

$$v_1 = 4\sum_i q_i \omega_i \exp[-2q_i(x+q_i^2 t)]. \tag{40}$$

In particular the single solitino solution takes the form

$$v_0 = 4q^2 \theta\omega \exp[-2q(x+q^2 t)], \quad v_1 = 4q\omega \exp[-2q(x+q^2 t)].$$

It is not a localized solution as a function of x. In fact, for imaginary q it is a plane wave.

The multisolitino solution (39) represents a superposition of solitinos which is of a nonlinear character, as it is shown by the presence of quadratic terms in the expression for v_0. See Fig. 3 for a representation of a component of the even part of a bisolitino solution.

C. Rational solutions

A solution K of the SKP hierarchy (2) is said to be rational if the coefficients w_n of its expansion (3) are rational functions of the even coordinates $(x,\mathbf{t})$. Solutions of this kind can be derived by means of asymptotic super-modules similar to those used for solitons and solitinos by imposing instead of the conditions (27) constraints of the type

$$\left(\alpha \frac{\partial}{\partial \alpha} \frac{\partial^{n_i}}{\partial z^{n_i}} + c_i \frac{\partial^{m_i}}{\partial z^{m_i}}\right) \phi(p_i, \alpha) = 0.$$

For example, let us take $\mathscr{W}$ to be the set of superfunctions ϕ analytic on U with the possible exception of a simple pole at a given point $q \neq 0$, and such that

$$\alpha \frac{\partial}{\partial \alpha} \frac{\partial \phi}{\partial z}(0,\alpha) + \phi(0,\alpha) = 0. \tag{41}$$

It is straightforward to get

$$f=\left[1+\frac{a+(\alpha-\lambda)\beta}{z-q}\right]\cdot f_0, \tag{42}$$

with

$$a=q, \quad \beta=-\frac{q(\theta+\tau_1)}{1+q(x+t_1+1)}.$$

As $z^2\cdot\mathscr{W}\subset\mathscr{W}$ this construction leads to a solution of (8) which turns out to be given by

$$v_0=0, \quad v_1=-\frac{2q^2(\theta+\tau_1)}{[1+q(x+t_1+1)]^2}.$$

Another simple example is obtained by replacing (41) by

$$\frac{\partial\phi}{\partial z}(0,\alpha)=0, \tag{43}$$

then the superfunctions a and β in (42) take the form

$$a=q\left(1-\frac{1}{s}+\frac{r\tau_2}{s^3}\right), \quad \beta=\frac{q^2\tau_2}{s^2},$$

where for the MRKP hierarchy

$$s=q(x+t_1+\tau_1\theta)+1, \quad r=q^2(\theta-\tau_1),$$

and for the JKP hierarchy

$$s=q(x+t_1)+1, \quad r=q^2\theta.$$

The condition $z^2\cdot\mathscr{W}\subset\mathscr{W}$ keeps on being satisfied and the corresponding solution of (8) is

$$v_0=-\frac{2q^2}{s^2}+\frac{6q^2r\tau_2}{s^4}, \quad v_1=\frac{4q^3\tau_2}{s^3}.$$

We notice that this solution is a supersymmetric dressing of the elementary rational solution

$$v=\frac{-2q^2}{(qx+1)^2}$$

of the KdV equation.

IV. SUPERGROUP THEORETICAL DESCRIPTION

It is well known the use of $\bar{\partial}$-equations to obtain wave functions for the KP hierarchy.[21,22] This theory was extended to the supersymmetric situation in Ref. 23.

We shall consider solutions of the $\bar{\partial}$-equation,

$$\frac{\partial}{\partial\bar{z}}f(z,\alpha;x,\theta;\mathbf{t},\boldsymbol{\tau})=\int d^2z'\,d\alpha'\,a(z',\alpha';z,\alpha)f(z',\alpha';x,\theta;\mathbf{t},\boldsymbol{\tau}), \tag{44}$$

with $a(z',\alpha';z,\alpha)$ a given distribution of odd parity. We shall denote by $\mathscr{F}$ the space of solutions of Eq. (44) having an asymptotic expansion, $z\to\infty$, of the form

$$F=\left(\sum_{n=-\infty}^{N} u_n z^n+(\alpha-\lambda)\sum_{n=-\infty}^{M} v_n z^n\right) f_0,$$

with coefficients u_n, v_n in $\mathscr{S}$.

By using the properties (9) of the vacuum super-wave function f_0 and the isospectrality of the $\bar{\partial}$-equation (44) (the kernel a of the equation (44) does not depend on x,t), it is immediate that $\mathscr{F}$ is a left module for the algebra of superdifferential operators $\mathscr{E}$. Then, if a unique even solution f of Eq. (44) with the asymptotic expansion Eq. (18) exists, then by Thm. 2, it will be a super-wave equation for a SKP hierarchy.

It was shown in Ref. 23 that solutions of the $\bar{\partial}$-equation are related with the τ-function of the SKP hierarchy generated from the action of the element

$$g=\exp\frac{1}{\pi}\int d^2z'\,d\alpha'\,d^2z\,d\alpha B(z',\alpha')a(z',\alpha';z,\alpha)C(z,\alpha) \tag{45}$$

of the supergroup $GL(\infty|\infty)$ on the vacuum. The quantum fields B, C form a superghost system with commutation and anticommutation relations given by

$$[B(z,\alpha),B(z',\alpha')]=\{C(z,\alpha),C(z',\alpha')\}=0;\quad [B(z,\alpha),C(z',\alpha')]=(\alpha-\alpha')\hat{\delta}_\gamma(z-z'),$$

and $\hat{\delta}_\gamma(z)$ denotes the delta function with support on the circle γ acting on test functions as

$$\int d^2z\,\hat{\delta}_\gamma(z)\phi(z)=\oint_\gamma z\phi(z).$$

One of the advantages of the τ-function formalism for integrable systems is that it allows us to classify the solutions in terms of orbits of symmetry groups. For the SKP hierarchies considered in this paper a τ-function description is already available which exhibits their invariance under the supergroup $GL(\infty|\infty)$.[23] We can thus conclude form the above discussion that the τ-function of the SKP hierarchy generated from the action of (45) on the vacuum is associated with the super-wave function which satisfies the corresponding $\bar{\partial}$ equation.

As for the solutions analyzed in this paper, it is easy to derive the $\bar{\partial}$-equation verified by their associated super-wave functions. For example, the solutions that arise from the constraints (27) and (41) give rise to the kernels

$$a(z',\alpha';z,\alpha)=\pi\sum_{i=1}^{N}(\alpha'-\alpha)(c_i+\alpha'\omega_i)\delta(z-q_i)\delta(z'-p_i) \tag{46}$$

and

$$a(z',\alpha';z,\alpha)=\frac{\delta(z-q)}{2\pi i}\left[\pi(\alpha'-\alpha)\hat{\delta}_{\gamma_1}(z')+\left(\frac{\alpha'-\alpha}{z'}-\frac{\alpha}{(z')^2}\right)\hat{\delta}_{\gamma_2}(z')\right], \tag{47}$$

respectively. Here $\delta(z-q)$ is the usual delta function on the plane and $\hat{\delta}_{\gamma_i}(z)$, $i=1,2$, denotes the delta functions with support on the circles γ_i ($|z|=r_i$), with $r_1>|q|>r_2$. Consequently, we have provided two additional different characterizations for our solutions of the SKP hierarchies. First, from Eq. (45) every solution is associated with an element of $GL(\infty|\infty)$. Second, Eq. (44) shows that the kernel a supplies the spectral description of the solutions.

(Received 22 November 1995; accepted for publication 16 July 1996)

The relationship between Lax and bi-Hamiltonian formulations of dynamical systems on finite- or infinite-dimensional phase spaces is investigated. The Lax–Nijenhuis equation is introduced and it is shown that every operator that satisfies that equation satisfies the Lenard recursion relations, while the converse holds for an operator with a simple spectrum. Explicit higher-order Hamiltonian structures for the Toda system, a second Hamiltonian structure of the Euler equation for a rigid body in n-dimensional space, and the quadratic Adler–Gelfand–Dickey structure for the KdV hierarchy are derived using the Lax–Nijenhuis equation. © *1996 American Institute of Physics.* [S0022-2488(96)03411-1]

I. INTRODUCTION

We present an explanation of a long-standing problem: What is the relationship between the Lax formulation of an integrable system and the existence of a bi-Hamiltonian structure?

When considering differential equations in Lax form[1] on a finite- or infinite-dimensional phase-space manifold, according to the problem at hand, one introduces either a matrix of a given size, or a differential operator of a given degree, or, more generally, a pseudo-differential operator whose coefficients are functions of the phase-space coordinates. In other words, the ''Lax operator'' is an A-valued map on phase space, where A is an associative algebra that has to be determined in each problem.

We study the case where the phase-space manifold admits a pair of compatible Poisson structures, i.e., has a bi-Hamiltonian structure.[2–4] (See also Refs. 5–7, and Ref. 8 for a complete exposition and further references.) The term ''Poisson structure'' is most frequently used for finite-dimensional manifolds such as the phase space of dynamical systems defined by evolution ordinary differential equations, while the term ''Hamiltonian structure'' is commonly used in the case of infinite-dimensional manifolds, e.g., manifolds of functions, such as the phase spaces of systems described by evolution partial differential equations. When two Poisson structures satisfying a compatibility condition are present, the term ''bi-Hamiltonian structure'' will be applied. We shall mainly consider the finite-dimensional case, but the extension to the infinite-dimensional situation is straightforward, in the setting of the formal calculus of variations in the sense of Gelfand, Dickey, and Dorfman. (See Refs. 9, 10, and 8.)

As the defining property of a matrix-valued Lax operator, L, in the presence of a bi-Hamiltonian structure (P,Q) we take the so-called Lenard recursion relations,

$$Q\left(d\ \mathrm{tr}\,\frac{L^k}{k}\right)=P\left(d\ \mathrm{tr}\,\frac{L^{k+1}}{k+1}\right). \tag{1.1}$$

When L has distinct eigenvalues, λ_i, these relations imply that

a)Electronic mail address: yks@math.polytechnique.fr
b)Electronic mail address: magri@vmimat.mat.unimi.it

$$Q(d\lambda_i)=\lambda_i P(d\lambda_i),$$

and in all cases they imply the pairwise involutivity of the eigenvalues of L with respect to both Poisson brackets. Moreover, the traces of powers of L, and hence the eigenvalues of L, are conserved along the flow of each evolution equation in Lax form, $\dot{L}=[L,B]$.

The recursion relations for differential equations in Lax form first appeared in the context of evolution partial differential equations, and they are actually due to Lax.[1] [It is surprising that it has become customary to call them the Lenard recursion relations, probably because, in his paper of 1976, Lax[11] refers to Lenard's contribution to the derivation of the infinite family of higher-order Korteweg–de Vries (KdV) equations as reported in the 1974 article by Gardner, Greene, Kruskal, and Miura.[12] Actually, Gardner *et al.* derived this ''infinite family of equations that leave the eigenvalues of the Schrődinger equation invariant in time'' and they also give ''an alternate derivation of this family due to Lenard,'' and both derivations reveal the recursion operator explicitly but do not relate it to any Hamiltonian property. In that same paper, Lax ascribes the involutivity property of the conserved quantities to Gardner (Ref. 13), where it is not explicit at all! Actually the factorization of the recursion operator as the composition of a Poisson and a symplectic operator is in Lax,[11] Magri,[2] Gelfand and Dorfman,[3] and Fokas and Fuchssteiner.[14]]

In this paper, we show that, under suitable conditions on its spectrum, a Lax operator on a bi-Hamiltonian manifold satisfies a universal equation which we call the Lax–Nijenhuis equation because the vanishing of the Nijenhuis torsion of the recursion operator of a bi-Hamiltonian structure appears as a particular case of this property. Conversely, if L satisfies the Lax–Nijenhuis equation, then L is a Lax operator. We then study the converse problem of determining compatible Hamiltonian structures from Lax–Nijenhuis equations. We treat the Toda system (see Refs. 15–20), the rigid body, the KdV hierarchy (see Refs. 21, 22, and 16), and, more generally, Lax equations that are Hamiltonian with respect to a Poisson bracket defined by an R-matrix (see Ref. 23).

In Sec. II we recall the definition of Hamiltonian and bi-Hamiltonian structures and we prove that functions that satisfy recursion relations (1.1), where P and Q are compatible Poisson structures, are pairwise in involution with respect to either Hamiltonian structure. Nijenhuis operators appear in the theory of bi-Hamiltonian structures (P,Q) when one considers the (1,1)-tensor $N=QP^{-1}$, where the first Poisson structure is assumed to be invertible, i.e., symplectic. (See Refs. 24–27). We analyze the properties of Nijenhuis operators and we observe that the vanishing of the Nijenhuis torsion[28] of a (1,1)-tensor implies the fundamental equation (2.5) that is the prototype of the Lax–Nijenhuis equation that we introduce in (3.6).

Section III contains the main results concerning the relationship between Lax and bi-Hamiltonian formulations of dynamical systems. It is natural to require that the traces of powers of the Lax operator satisfy the Lenard recursion relations (Definition 3.1). It then follows that, under the assumption of the simplicity of its spectrum, such a Lax operator satisfies the Lax–Nijenhuis equation (3.6). Conversely, we show in Proposition 3.5 that, if an operator satisfies the Lax–Nijenhuis equation, it satisfies the Lenard recursion relations, and therefore the traces of its powers are in involution. In addition, we prove that this property remains valid for negative and fractional powers, when they are defined.

The hereditary properties of Nijenhuis operators and of Lax operators compatible with a bi-Hamiltonian structure are derived in Sec. IV. We show that the Lax formulation exists for all vector fields,

$$X_k=Q\alpha_k=P\alpha_{k+1},$$

where α_k is a sequence of differential one-forms satisfying the Lenard recursion relations, provided that X_0 admits a Lax formulation. When all α_ks are closed, the X_ks constitute a bi-Hamiltonian hierarchy, i.e., a sequence of commuting bi-Hamiltonian vector fields, and we state a further commutation property in Proposition 4.3.

The fifth and last section is devoted to examples. For the nonperiodic Toda system, we explicitly determine a sequence of skewsymmetric higher-order bivectors satisfying Lax–Nijenhuis equations. The first three elements of this sequence coincide with the known linear, quadratic, and cubic Poisson structures. We treat the case of the Euler equations for the n-dimensional rigid body rotating about a fixed point, and some generalizations of it. We then study the Lax–Nijenhuis equation for the KdV equation, and, more generally, for the first equation in the nth KdV hierarchy, where the Lax operator takes values in a manifold of nth-order differential operators in the graded, associative algebra of formal pseudodifferential operators, and we obtain the second Adler–Gelfand–Dickey Hamiltonian structure from the first one. Finally, this construction is further generalized to determine the quadratic bracket associated with the linear Poisson bracket defined by an R-matrix, i.e., a solution of the modified classical Yang–Baxter equation.

For background and many results on integrable systems, we refer to Refs. 29 and 30. See Ref. 31 for a discussion closely connected with ours, but undertaken from a different point of view.

II. LENARD RECURSION RELATIONS ON A BI-HAMILTONIAN MANIFOLD

In this section, we recall some well-known results on Lenard recursion relations which we shall need for the study of Lax operators in Sec. III. First we introduce the concept of a bi-Hamiltonian manifold.

A Poisson manifold (also called a Hamiltonian manifold) is a manifold equipped with a Poisson bracket. We recall that a Poisson bracket can be defined in terms of a field of bivectors (a bivector for short) called the Poisson bivector. If P is a bivector on a manifold M, we identify P with the linear bundle map,

$$P: T^*M \to TM,$$

defined by $\langle \beta, P\alpha \rangle = P(\alpha, \beta)$, for $\alpha, \beta \in T^*M$. We set $X_f = Pdf$, for any function $f \in C^\infty(M)$, and we call X_f the Hamiltonian vector field with Hamiltonian f. We also define the Poisson bracket,

$$\{f,g\}_P = X_f \cdot g,$$

for f and $g \in C^\infty(M)$. Recall that a bivector P on M is a Poisson bivector if and only if one of the following equivalent conditions is satisfied:

(1) $[P,P]=0$, where $[\ ,\ ]$ is the Schouten bracket,
(2) the Poisson bracket $\{\ ,\ \}_P$ satisfies the Jacobi identity,
(3) $[X_f, X_g] = X_{\{f,g\}_P}$, for $f, g \in C^\infty(M)$.

These conditions are equivalent because, by the definition of the Schouten and Poisson brackets,

$$\begin{aligned} -\tfrac{1}{2}[P,P](df,dg,dh) &= \{f,\{g,h\}_P\}_P + \{g,\{h,f\}_P\}_P + \{h,\{f,g\}_P\}_P \\ &= ([Pdf, Pdg] - Pd(P(df,dg))).h \\ &= ([X_f, X_g] - X_{\{f,g\}_P}).h, \end{aligned}$$

for $f, g, h \in C^\infty(M)$.

Definition 2.1: A bi-Hamiltonian manifold (M,P,Q) is a manifold M equipped with Poisson structures, P and Q, which are compatible, i.e., such that any linear combination of P and Q is a Poisson structure. A (locally) bi-Hamiltonian vector field on (M,P,Q) is a vector field leaving P and Q invariant.

Thus, on a bi-Hamiltonian manifold there exists a pencil of Poisson structures, $P_\lambda = Q - \lambda P$, for $\lambda \in \mathbb{R} \cup \{\infty\}$. A sufficient condition for a vector field X to be (locally) bi-Hamiltonian is that

there exist closed differential one-forms α and β such that $X=P\beta=Q\alpha$. In particular, if there exist functions f and g such that $X=P(dg)=Q(df)$, then X is bi-Hamiltonian.

Lemma 2.2: Let P and Q be Poisson structures on M. Then P and Q are compatible if and only if one of the following equivalent conditions is satisfied:

(i) $[P, Q]=0$,
(ii) $\circlearrowleft(\{f,\{g,h\}_P\}_Q+\{f,\{g,h\}_Q\}_P)=0$, *where* $\circlearrowleft$ *denotes the sum over the circular permutations of* f,g,h,
(iii) $[X_f, Y_g]+[Y_f, X_g]=X_{\{f,g\}_Q}+Y_{\{f,g\}_P}$,

for $f,g\in C^\infty(M)$, *where* $X_f=Pdf$ *and* $Y_f=Qdf$.

Proof: In fact, each of these conditions is the polarization of the corresponding condition for a single Poisson structure, and each is obtained by bilinearity from the corresponding conditions for P,Q and $P+Q$. ■

For a Hamiltonian system on a symplectic manifold—the phase space—to be completely integrable in the sense of Liouville and Arnold,[32] there must exist a number of independent conserved quantities, equal to half the dimension of the symplectic manifold, which are pairwise in involution. Here we consider the case where the phase space is a bi-Hamiltonian manifold, and we show that when a sequence of functions defined on it satisfies the Lenard recursion relations, these functions are pairwise in involution. We shall denote the positive integers by $\mathbb{N}^*$.

Proposition 2.3: Let P and Q be Poisson structures on a manifold, M, and let $(f_k), k\in\mathbb{N}^*$, be a sequence of complex-valued functions on M that satisfy the Lenard recursion relation,

$$Q(df_k)=P(df_{k+1}), \tag{2.1}$$

for $k\in\mathbb{N}^*$. Then the functions, f_k, are pairwise in involution with respect to both Poisson brackets.

Proof: Let m be a non-negative integer, and let (C_m) be the property that, for all $k\geqslant 1$, $P(df_k,df_{k+m})=0$ and $Q(df_k,df_{k+m})=0$. Clearly (C_0) holds. Now for any $k\geqslant 1, m\geqslant 0$,

$$P(df_k,df_{k+m+1})=-\langle df_k,P(df_{k+m+1})\rangle=-\langle df_k,Q(df_{k+m})\rangle,$$

and

$$Q(df_k,df_{k+m+1})=\langle df_{k+m+1},Q(df_k)\rangle=\langle df_{k+m+1},P(df_{k+1})\rangle.$$

Thus it is clear that (C_{m+1}) holds if (C_m) holds. Therefore (C_m) is proved for all non-negative integers, m. Thus $P(df_k,df_l)=Q(df_k,df_l)=0$ for any $k,l\in\mathbb{N}^*$. ■

We remark that this proof uses only (2.1) and the skewsymmetry of P and Q. However, the assumption that P and Q are compatible Poisson structures is essential in order to guarantee the existence of functions, f_k, fulfilling the Lenard recursion relations (2.1). The question of the existence of such functions in the case of an arbitrary bi-Hamiltonian structure is a difficult problem which is beyond the scope of the present paper. Here, we shall demonstrate their existence in a special case, that of a bi-Hamiltonian manifold, (M,P,Q), where P is an *invertible* Poisson structure, i.e., a symplectic structure. The field of (1,1)-tensors,

$$N=QP^{-1}, \tag{2.2}$$

is called the *recursion operator* or the *Nijenhuis operator* of the bi-Hamiltonian structure. The first name is justified by the fact that N maps symmetries of a bi-Hamiltonian system into symmetries of the same system (see Sec. IV), while the second name is justified by the well-known result proved in Lemma 2.5 below. Nijenhuis operators provide the basic examples of the Lax–Nijenhuis operators to be defined in Sec. III B.

We recall that the Nijenhuis torsion of a field of (1,1)-tensors N on a manifold M is the vector-valued two-form $T(N)$ on M defined by

$$T(N)(X,\ Y)=[NX,\ NY]-N([NX,\ Y]+[X,\ NY])+N^2[X,\ Y], \tag{2.3}$$

for all vector fields X,Y on M.

Definition 2.4: A field of (1,1)*-tensors with vanishing Nijenhuis torsion is called a Nijenhuis tensor or Nijenhuis operator.*

Lemma 2.5: If (P,Q) *is a bi-Hamiltonian structure on* M*, and* $Q=NP$*, where* N *is a* (1,1)*-tensor on* M*, then the Nijenhuis torsion,* $T(N)$*, of* N *vanishes on the image of* P*. In particular, if* (P,Q) *is a bi-Hamiltonian structure, with* P *invertible, then the recursion operator,* $N=QP^{-1}$*, is a Nijenhuis operator.*

Proof: Assume that $Q=NP$. It is enough to show that $T(N)$ vanishes on any pair of vectors (Pdf,Pdg) where $f,g\in C^\infty(M)$. In fact, using the notations of Lemma 2.2,

$$\begin{aligned}T(N)(Pdf,Pdg)&=[NPdf,\ NPdg]-N([NPdf,\ Pdg]+[Pdf,\ NPdg])+N^2[Pdf,\ Pdg]\\&=[Y_f,\ Y_g]-N([Y_f,\ X_g]+[X_f,\ Y_g])+N^2[X_f,\ X_g].\end{aligned}$$

Using the results of Lemma 2.2, we obtain

$$T(N)(Pdf,Pdg)=Y_{\{f,g\}_Q}-N(X_{\{f,g\}_Q}+Y_{\{f,g\}_P})+N^2X_{\{f,g\}_P},$$

which vanishes since $NX_h=Y_h$, for $h\in C^\infty(M)$. ■

The condition that $T(N)=0$ is equivalent to the condition that

$$\mathscr{L}_{NX}N-N\mathscr{L}_XN=0, \tag{2.4}$$

for all vector fields X on M, where $\mathscr{L}_X$ denotes the Lie derivative with respect to X. In fact,

$$T(N)(X,Y)=\mathscr{L}_{NX}(NY)-N\mathscr{L}_{NX}Y-N(\mathscr{L}_X(NY)-N(\mathscr{L}_XY))=(\mathscr{L}_{NX}N)Y-N(\mathscr{L}_XN)Y.$$

Therefore the following proposition holds.

Proposition 2.6: Let N *be a Nijenhuis tensor on a manifold* M*. Then*

$$\mathscr{L}_{NX}N-\mathscr{L}_X\left(\frac{N^2}{2}\right)=\left[N,\ \frac{1}{2}\,\mathscr{L}_XN\right], \tag{2.5}$$

for all vector fields, X*, on* M*.*

Proof: Relation (2.5) follows from the preceding expression of $T(N)$ and the assumption that $T(N)=0$. ■

For the Nijenhuis operator, $N=QP^{-1}$, of a bi-Hamiltonian structure, (P,Q), where P is invertible, Eq. (2.5) becomes

$$\mathscr{L}_{Q\alpha}\,N-\mathscr{L}_{P\alpha}\left(\frac{N^2}{2}\right)=[N,\ \hat{N}(\alpha)] \tag{2.6}$$

for all differential forms α on M, where $\hat{N}(\alpha)=\frac{1}{2}\mathscr{L}P_\alpha N$. This property is the prototype of that of Lax operators on bi-Hamiltonian manifolds.

III. LAX OPERATORS

We first describe the development of the notion of Lax operator from the simplest case to that of Lax operators on Hamiltonian and bi-Hamiltonian phase spaces. We then motivate our definition of Lax–Nijenhuis operators.

A. Lax operators on Hamiltonian and bi-Hamiltonian phase spaces

A dynamical system, $dx/dt=X(x)$, on a manifold M is said to admit a Lax formulation if there exist square matrices L and B, by no means unique, whose coefficients depend on x, such that the given dynamical system is equivalent to

$$\frac{dL}{dt}=[L,\ B], \tag{3.1}$$

where $[L,\ B]=LB-BL$ is the usual commutator. Usually, L is called the Lax operator or the Lax matrix. In fact, both L and B are maps from the manifold M (the space of dependent variables) to the associative algebra of square matrices of a given size. The existence of a Lax formulation for a given dynamical system is important because it implies the existence of a sequence of conserved quantities,

$$J_k=\frac{1}{k}\ \mathrm{tr}\ L^k, \tag{3.2}$$

for $k\in\mathbb{N}^*$, where tr denotes the trace of a matrix. (These conserved quantities need not be functionally independent.) In fact,

$$\frac{dJ_k}{dt}=\mathrm{tr}\ L^{k-1}\ \frac{dL}{dt}=\mathrm{tr}\ L^{k-1}[L,\ B]=\mathrm{tr}(L^kB-L^{k-1}BL)=0.$$

If, moreover, the Lax mapping L is defined on a phase space with a Hamiltonian structure, i.e., on a Poisson manifold, then it is natural to require that the traces of powers of L, which are conserved quantities, be pairwise in involution. In this case, this requirement becomes part of the definition of a Lax operator.

Let us now consider the case where the phase space is a bi-Hamiltonian manifold (M,P,Q). We have seen in Sec. II that, on a bi-Hamiltonian manifold, recursion relations (2.1) for functions f_k imply the pairwise involutivity of these functions. It is natural to require that a Lax operator L defined on a bi-Hamiltonian phase space (M,P,Q) be such that quantities J_k defined by (3.2), proportional to the traces of powers of L, satisfy the so-called Lenard recursion relations

$$Q(dJ_k)=P(dJ_{k+1}), \tag{3.3}$$

for $k\in\mathbb{N}^*$. So, we are led to introduce the following definition of Lax operators on a bi-Hamiltonian phase space (M,P,Q).

Recall that a trace on an associative algebra A over the field of real or complex numbers is a linear form, tr, on A, such that

$$\mathrm{tr}\ L_1L_2=\mathrm{tr}\ L_2L_1, \tag{3.4}$$

for all L_1 and L_2 in A.

Definition 3.1: Let (M,P,Q) be a bi-Hamiltonian manifold. A Lax operator compatible with (P,Q) is an A-valued function L on M, where A is an associative algebra with unit and trace, such that the functions, $J_k=(1/k)\mathrm{tr}\ L^k$, $k\in\mathbb{N}^*$, satisfy the Lenard recursion relations (3.3).

Under this definition, by Proposition 2.3, the traces of the powers of a Lax mapping compatible with (P,Q) are pairwise in involution with respect to both P and Q.

B. Lax–Nijenhuis operators

To understand what relates L to P and Q, we shall consider the simplest case where L is a matrix, but we shall first review some facts about the geometry of associative algebras.

Let A be an associative algebra with a trace. We assume that the symmetric bilinear form on A, $(L_1,L_2)=\operatorname{tr} L_1L_2$, defines an isomorphism of A with its dual A^* and, by means of this isomorphism, we identify A^* with A. We equip A with the Lie algebra structure defined by the associative product,

$$[L_1,\ L_2]=L_1L_2-L_2L_1.$$

Since $\operatorname{tr} L_1L_2L_3=\operatorname{tr} L_3L_1L_2$, the symmetric bilinear form $(\ ,\ )$ is invariant, i.e.,

$$(L_1,[L_2,\ L_3])=([L_1,\ L_2],L_3),$$

Thus the coadjoint action of the Lie algebra A on A^* is identified with the adjoint action of A on itself, and the tangent space at L in A to the coadjoint orbit of L is $\{[L,B]|B\in A\}$. (See also VIII.4 of Ref. 33 for the role of coadjoint orbits in the theory of Lax operators.)

Proposition 3.2: Let A be the algebra of square $n\times n$ matrices, where n is a positive integer. Let L be an A-valued Lax operator compatible with the bi-Hamiltonian structure (P,Q). We assume that L is semi-simple. Then, at each point where the eigenvalues of L are distinct, and for each differential one-form α on M, there exists a matrix $\widetilde{L}(\alpha)$ such that

$$\mathscr{L}_{Q\alpha}L-L\mathscr{L}_{P\alpha}L=[L,\ \widetilde{L}(\alpha)]. \tag{3.5}$$

Proof: Let α be any differential one-form on M. Then, by the definition of a Lax operator, L, compatible with (P,Q), and the skewsymmetry of P and Q, for all one-forms α and for all $k\in\mathbb{N}^*$,

$$\frac{1}{k}\operatorname{tr}\mathscr{L}_{Q\alpha}L^k=\frac{1}{k+1}\operatorname{tr}\mathscr{L}_{P\alpha}L^{k+1},$$

and therefore we obtain

$$\operatorname{tr} L^{k-1}(\mathscr{L}_{Q\alpha}L-L\mathscr{L}_{P\alpha}L)=0.$$

This condition expresses the fact that for all k, the vector field with value $\mathscr{L}_{Q\alpha}L-L\mathscr{L}_{P\alpha}L$ at L leaves $\operatorname{tr} L^k$ invariant, which implies that it leaves all eigenvalues of L invariant. This condition is clearly satisfied if $\mathscr{L}_{Q\alpha}L-L\mathscr{L}_{P\alpha}L$ is tangent to the coadjoint orbit of L, and the converse holds if L is semi-simple with distinct eigenvalues. Thus, under the assumptions of the proposition on the spectrum of L, for each α there exists a matrix, $\widetilde{L}(\alpha)$, such that Eq. (3.5) is satisfied. ■

We shall now allow L to be a section of an associative algebra bundle with trace, $\mathscr{A}$, over M. By this we mean a vector bundle over M such that each fiber $\mathscr{A}_x$ of $\mathscr{A}$, for x in M, is an associative algebra with unit and trace, depending smoothly on x. Obviously an A-valued function L on M corresponds to the case where $\mathscr{A}$ is the trivial vector bundle, $\mathscr{A}=M\times A$. However, we formulate our definition in this more general situation in order to include the case of the Nijenhuis operators that was considered in Sec. II. At each point x in M, $\operatorname{End}(T_xM)$ is an associative algebra with trace, to which we can apply the preceding remarks. Equation (3.5) means that for each differential form α on M, and for each x in M, the vertical vector, $(\mathscr{L}_{Q\alpha}L-L(\mathscr{L}_{P\alpha}L))(x)$, is tangent to the coadjoint orbit of $L(x)$ in $\mathscr{A}_x$. It is easy to show that this is equivalent to the fact

that the vertical vector, $(\mathscr{L}_{Q\alpha} L - \mathscr{L}_{P\alpha}(L^2/2))(x)$, is tangent to this orbit. We assume that M has a bi-Hamiltonian structure, (P,Q). Motivated by the discussion in the previous subsections, we define the following.

Definition 3.3: A section L of an associative algebra bundle $\mathscr{A}$ with trace over a bi-Hamiltonian manifold (M,P,Q) is a Lax–Nijenhuis operator if, for all differential forms α on M, $\mathscr{L}_{Q\alpha}L - \mathscr{L}_{P\alpha}(L^2/2)$ is tangent to the coadjoint orbit of $L(x)$ in the fiber $\mathscr{A}_x$ of $\mathscr{A}$, for each x in M.

Identifying a section of $T^*\mathscr{A}$ over L with a section of $T\mathscr{A}$ over L and using the identification of the dual of the vertical space at x, $(V(\mathscr{A}_x))^* = \mathscr{A}_x^*$, with the vertical space $V(\mathscr{A}_x) = \mathscr{A}_x$, we obtain immediately the following.

Proposition 3.4: A section $L: M \to \mathscr{A}$ is a Lax–Nijenhuis operator if there exists a lifting of L into a section $\hat{L}: T^*M \to T^*\mathscr{A}$ such that

$$\mathscr{L}_{Q\alpha} L - \mathscr{L}_{P\alpha}\left(\frac{L^2}{2}\right) = [L,\ \hat{L}(\alpha)], \tag{3.6}$$

for each section α of T^*M.

Equation (3.6) is called the *Lax–Nijenhuis equation.*

Examples. By (2.6), the recursion operator of a bi-Hamiltonian manifold (M,P,Q) with P invertible is a Lax–Nijenhuis operator.

Proposition 3.2 shows that any matrix-valued Lax operator with a simple spectrum compatible with (P,Q) is a Lax–Nijenhuis operator.

C. Properties of Lax–Nijenhuis operators

We shall now prove that the traces of powers of any matrix-valued Lax–Nijenhuis operator on a bi-Hamiltonian manifold, (M,P,Q), satisfy the Lenard recursion relations (3.3), and that the operator is therefore, by Definition 3.1, a Lax operator compatible with (P,Q).

Proposition 3.5: Let L be a matrix-valued Lax–Nijenhuis operator on a bi-Hamiltonian manifold (M,P,Q). Then the functions $J_k = (1/k)\operatorname{tr} L^k$, $k \in \mathbb{N}^*$, satisfy the Lenard recursion relations (3.3), and L is a Lax operator compatible with (P,Q). Moreover, if L is invertible, relation (3.3) holds when k is a negative integer, and, if L admits a fractional power, $L^{1/r}$, relation (3.3) also holds when k is an integral multiple of $1/r$.

Proof: Relation (3.6) implies that, for any $k \in \mathbb{N}^*$,

$$L^{k-1}\mathscr{L}_{Q\alpha} L - L^{k-1}\mathscr{L}_{P\alpha}\left(\frac{L^2}{2}\right) = [L,\ L^{k-1}\hat{L}(\alpha)],$$

for any α. Taking traces of both sides implies that

$$\mathscr{L}_{Q\alpha}\left(\frac{1}{k}\operatorname{tr} L^k\right) = \mathscr{L}_{P\alpha}\left(\frac{1}{k+1}\operatorname{tr} L^{k+1}\right),$$

or, with the notation of (3.2),

$$\langle Q\alpha, dJ_k\rangle = \langle P\alpha, dJ_{k+1}\rangle.$$

Since this relation holds for any differential form α, we obtain relation (3.3) by the skewsymmetry of P and Q. It follows from Definition 3.1 that L is a Lax operator compatible with (P,Q).

We now show that relation (3.3) holds for negative and fractional powers of Lax–Nijenhuis operators, when they are defined. When α is a fixed differential form, we introduce the convenient notations

$$\mathscr{L}_{P\alpha} L = \frac{dL}{dt_1}, \quad \mathscr{L}_{Q\alpha} L = \frac{dL}{dt_2}, \quad \hat{L}(\alpha) = B.$$

Using the following elementary formulas, valid for L, $B \in A$ and $k \in \mathbb{N}^*$,

$$[L^k, B] = \sum_{j=0}^{k-1} [L, L^j B L^{k-1-j}] = \sum_{j=0}^{k-1} L^j [L, B] L^{k-1-j} \tag{3.7}$$

and

$$\frac{dL^k}{dt} = \sum_{j=0}^{k-1} L^j \frac{dL}{dt} L^{k-1-j}, \tag{3.8}$$

we obtain from (3.6), by induction on k,

$$\frac{dL^k}{dt_2} - \frac{1}{2}\left(L \frac{dL^k}{dt_1} + \frac{dL^k}{dt_1} L \right) = [L^k, B], \tag{3.9}$$

for k a positive integer. Let us prove that, if L is invertible, (3.9) is also valid for k a negative integer. In fact, for $k = -1$,

$$\begin{aligned}
&\frac{dL^{-1}}{dt_2} - \frac{1}{2}\left(L \frac{dL^{-1}}{dt_1} + \frac{dL^{-1}}{dt_1} L \right) = -L^{-1} \frac{dL}{dt_2} L^{-1} + \frac{1}{2}\left(\frac{dL}{dt_1} L^{-1} + L^{-1} \frac{dL}{dt_1} \right) \\
&= -\frac{1}{2} L^{-1}\left(L \frac{dL}{dt_1} + \frac{dL}{dt_1} L \right) L^{-1} + \frac{1}{2}\left(\frac{dL}{dt_1} L^{-1} + L^{-1} \frac{dL}{dt_1} \right) - L^{-1}[L, B] L^{-1} \\
&= -BL^{-1} + L^{-1} B = [L^{-1}, B],
\end{aligned}$$

and, more generally, formula (3.9) for $k < -1$ is proved by recursion.

We now assume that L admits a fractional power D, namely $D^r = L$, for some positive integer r. Then using (3.7) and (3.8), we obtain

$$\begin{aligned}
0 &= \frac{dD^r}{dt_2} - \frac{1}{2}\left(D^r \frac{dD^r}{dt_1} + \frac{dD^r}{dt_1} D^r \right) - [D^r, B] \\
&= \sum_{j=1}^{r} \left(D^{r-j} \frac{dD}{dt_2} D^{j-1} - \frac{1}{2}\left(D^r D^{r-j} \frac{dD}{dt_1} D^{j-1} + D^{r-j} \frac{dD}{dt_1} D^{j-1} D^r \right) - D^{r-j}[D,B] D^{j-1} \right),
\end{aligned}$$

thus

$$\sum_{j=1}^{r} D^{r-j}\left(\frac{dD}{dt_2} - \frac{1}{2}\left(L \frac{dD}{dt_1} + \frac{dD}{dt_1} L \right) - [D, B] \right) D^{j-1} = 0. \tag{3.10}$$

Still more generally, if $D^r = L$, and h is a positive integer, we can prove

$$\sum_{j=1}^{r} D^{r-j}\left(\frac{dD^h}{dt_2} - \frac{1}{2}\left(L \frac{dD^h}{dt_1} + \frac{dD^h}{dt_1} L \right) - [D^h, B] \right) D^{j-1} = 0. \tag{3.11}$$

In fact, we first write (3.10), left-multiply by D^{h-1-i}, then right-multiply by D^i, and sum from $i=0$ to $h-1$. In the resulting equality, we use (3.7) and (3.8) to obtain (3.11). Taking traces in (3.11) and using

$$\frac{1}{b}\,\mathrm{tr}\,D^a\,\frac{dD^b}{dt}=\frac{1}{a+b}\,\mathrm{tr}\,\frac{dD^{a+b}}{dt},$$

we obtain

$$\frac{1}{r+h-1}\,\mathrm{tr}\,\frac{dD^{r+h-1}}{dt_2}=\frac{1}{2r+h-1}\,\mathrm{tr}\,\frac{dD^{2r+h-1}}{dt_1}. \tag{3.12}$$

Setting $(r+h-1)/r=k$, we obtain relation (3.3) for any k that is an integral multiple of $1/r$. Combining the previous results, we see that this formula also holds for negative rational numbers, when such powers of L are defined. ■

IV. BI-HAMILTONIAN HIERARCHIES AND LAX FORMULATION

We have emphasized the striking analogies between the properties of a Lax operator compatible with a bi-Hamiltonian structure and those of a Nijenhuis operator. In this section, we shall continue by considering the ''hereditary properties'' of both types of operators.

The simplest hereditary property of a Nijenhuis operator, N, is that it maps symmetries of N into symmetries of N. In fact, if a vector field X is a symmetry of N, i.e., is such that

$$\mathscr{L}_X N=0,$$

then, by relation (2.4), and as a consequence of the vanishing of the torsion of N,

$$\mathscr{L}_{NX} N=0.$$

Thus, if X is a symmetry of N, so are NX and, more generally, N^kX, for $k\in\mathbb{N}$. The property has been ''inherited'' by the iterated vector fields $NX, N^2X,\ldots$.

We now consider a sequence of differential one-forms, α_k, $k\in\mathbb{N}$, on a bi-Hamiltonian manifold, (M,P,Q), that satisfy the recursion relations,

$$Q\alpha_k=P\alpha_{k+1}. \tag{4.1}$$

Let us consider the sequence of vector fields,

$$X_k=Q\alpha_k=P\alpha_{k+1}. \tag{4.2}$$

If P is invertible, then, by Lemma 2.5, $N=QP^{-1}$ is a Nijenhuis operator and it satisfies

$$X_{k+1}=NX_k. \tag{4.3}$$

If we now assume that the vector field X_0 is a symmetry of the Nijenhuis operator N, then so is X_k, for each $k\in\mathbb{N}$, by the hereditary property of N, recalled above.

Let us now examine the corresponding property for Lax–Nijenhuis operators. Let L be a matrix-valued Lax–Nijenhuis operator on a bi-Hamiltonian manifold (M,P,Q), in the sense of Definition 3.3, and let α_k and X_k be forms and vectors as above. We assume that the vector field X_0 is such that there exists a matrix-valued mapping A_0 on M satisfying

$$\frac{dL}{dt_0}=[L,\,A_0],\quad \text{where } \frac{dL}{dt_0}=\mathscr{L}_{X_0}L. \tag{4.4}$$

We shall prove by recursion that, for any vector field X_k in the associated sequence, there exists a matrix-valued mapping A_k on M satisfying

$$\frac{dL}{dt_k}=[L,\ A_k], \quad \text{where } \frac{dL}{dt_k}=\mathscr{L}_{X_k}L. \tag{4.5}$$

In fact, let us assume (4.5) for 0,1,...,$k-1$. Then, from (3.6), we obtain

$$\begin{aligned}\mathscr{L}_{X_k}L=\mathscr{L}_{Q\alpha_k}L&=\mathscr{L}_{P\alpha_k}\frac{L^2}{2}L+[L,\ \hat{L}(\alpha_k)]\\&=\tfrac{1}{2}(L\mathscr{L}_{X_{k-1}}L+(\mathscr{L}_{X_{k-1}}L)L)+[L,\ \hat{L}(\alpha_k)]\\&=[L,\ \tfrac{1}{2}(LA_{k-1}+A_{k-1}L)+\hat{L}(\alpha_k)].\end{aligned}$$

Setting $A_k=\frac{1}{2}(LA_{k-1}+A_{k-1}L)+\hat{L}(\alpha_k)$, we obtain (4.5) for k.

Remark: Setting $\hat{L}(\alpha_k)=C_k$, $k\in\mathbb{N}$, an explicit expression for A_k, $k\in\mathbb{N}^*$, is

$$A_k=\frac{1}{2^k}\sum_{h=0}^{k}\binom{k}{h}L^hA_0L^{k-h}+\sum_{h=0}^{k-1}\sum_{p=0}^{h}\frac{1}{2^h}\binom{h}{p}L^pC_{k-h}L^{h-p}.$$

In fact, this formula is valid for $k=1$ and is proved by recursion.

The following proposition summarizes this discussion.

Proposition 4.1: Let α_k, $k\in\mathbb{N}$, be a sequence of differential one-forms on the bi-Hamiltonian manifold (M,P,Q), with α_k satisfying recursion relations (4.1) and let $X_k=Q\alpha_k=P\alpha_{k+1}=d/dt_k$ be the corresponding sequence of vector fields. If the vector field $X_0=d/dt_0$ admits a Lax formulation,

$$\frac{dL}{dt_0}=[L,\ A_0],$$

where L is a matrix-valued Lax–Nijenhuis operator, then for each $k\in\mathbb{N}$, there exists a matrix-valued mapping A_k on M satisfying (4.5).

In particular, we shall consider the case when there exists a sequence of closed differential one-forms α_k satisfying recursion relations (4.1). When P is invertible, we set $N=QP^{-1}$, and we denote the transpose of N by ${}^tN$. Then (4.1) is written

$$\alpha_{k+1}={}^tN(\alpha_k) \quad \text{or} \quad \alpha_k=({}^tN)^k\alpha_0,$$

and (4.3) is written

$$X_k=N^k(X_0).$$

Proposition 4.2: Let (M,P,Q) be a bi-Hamiltonian manifold with P invertible. Assume that the differential one-forms α_0 and α_1 are closed. Then all α_k's are closed and the vector fields X_k, $k\in\mathbb{N}$, are (locally) bi-Hamiltonian vector fields which commute in pairs.

Proof: Using the fact that N has vanishing Nijenhuis torsion (Lemma 2.5), we find that

$$d\alpha_k(X,Y)=d\alpha_{k-1}(NX,Y)+d\alpha_{k-1}(X,NY)-d\alpha_{k-2}(NX,NY),$$

for $k\geqslant 2$ and for all vector fields X,Y on M. Thus all the α_k's are closed.

Therefore each vector field X_k is (locally) bi-Hamiltonian.

$$\mathscr{L}_{X_k}P=0, \quad \mathscr{L}_{X_k}Q=0,$$

and hence each X_k is a symmetry of N,

$$\mathscr{L}_{X_k}N=0.$$

(This fact also follows from $\mathscr{L}_{X_0}N = 0$ and the hereditary property of N.)

Thus

$$\begin{aligned}[X_k, X_l]=\mathscr{L}_{X_k}(N^lX_0)&=(\mathscr{L}_{X_k}N^l)X_0+N^l\mathscr{L}_{X_k}X_0\\&=-N^l\mathscr{L}_{X_0}(N^kX_0)\\&=-N^l(\mathscr{L}_{X_0}N^k)(X_0)-N^{l+k}\mathscr{L}_{X_0}X_0=0.\end{aligned}$$ ■

Remark: If X is any (locally) bi-Hamiltonian vector field, then $\mathscr{L}_XN=0$. It follows that if Y is a symmetry of X, so is NY. This justifies the term ''recursion operator'' for the Nijenhuis operator N of a bi-Hamiltonian structure (P,Q), with P invertible.

Remark: Let k and l be non-negative integers. For any Nijenhuis operator N and vector field X, it follows from (2.4) by recursion that

$$\mathscr{L}_{NX}(N^l)=N\mathscr{L}_X(N^l)$$

and that

$$\mathscr{L}_{N^kX}(N^l)=N^k\mathscr{L}_X(N^l).$$

For $k=l$, we recover the well-known fact that any positive power of a Nijenhuis operator is a Nijenhuis operator, and that negative and fractional powers of a Nijenhuis operator, when they are defined, are also Nijenhuis operators.

A sequence of commuting bi-Hamiltonian vector fields is called a *bi-Hamiltonian hierarchy*. When X_k, $k\in\mathbb{N}$, is a bi-Hamiltonian hierarchy, we obtain further properties for the sequence of Lax equations (4.5). In fact, writing that $\mathscr{L}_{X_j}\mathscr{L}_{X_k}L - \mathscr{L}_{X_k}\mathscr{L}_{X_j}L = 0$ for all $j, k\in\mathbb{N}$, we obtain

$$\begin{aligned}0&=\mathscr{L}_{X_j}[L, A_k]-\mathscr{L}_{X_k}[L, A_j]\\&=\left[\frac{\partial L}{\partial t_j}, A_k\right]+\left[L, \frac{\partial A_k}{\partial t_j}\right]-\left[\frac{\partial L}{\partial t_k}, A_j\right]-\left[L, \frac{\partial A_j}{\partial t_k}\right]\\&=[[L, A_j], A_k]-[[L, A_k], A_j]+\left[L, \frac{\partial A_k}{\partial t_j}-\frac{\partial A_j}{\partial t_k}\right]\\&=\left[L, [A_j, A_k]+\frac{\partial A_k}{\partial t_j}-\frac{\partial A_j}{\partial t_k}\right],\end{aligned}$$

by the Jacobi identity. Thus the operator, which can be called the curvature of the connection defined by A_k,

$$[A_j, A_k]+\frac{\partial A_k}{\partial t_j}-\frac{\partial A_j}{\partial t_k}$$

commutes with L. Summarizing, we obtain the following.

Proposition 4.3: When X_k is a bi-Hamiltonian hierarchy with Lax formulation (4.5), the curvature of the connection with components A_k commutes with the Lax operator L.

V. EXAMPLES

In this section, we give four examples showing how the Lax–Nijenhuis equation can be used to compute higher-order Hamiltonian structures associated with a Hamiltonian system admitting a Lax formulation. We write the Lax–Nijenhuis equation (3.6) in the form

$$\mathscr{L}_{Q\alpha} L = \tfrac{1}{2}(L\mathscr{L}_{P\alpha} L + (\mathscr{L}_{P\alpha} L)L) + [L, \hat{L}(\alpha)], \tag{5.1}$$

and we use the information on L and the arbitrariness of α to split this equation into two parts: the first determines the unknown map $\hat{L}$, up to some still arbitrary constants, the second part determines $\mathscr{L}_{Q\alpha} L$ and then Q. The condition of skewsymmetry on Q then determines the constants. The discussion is quite similar to a problem with constraints coming from the restrictions imposed on L, where the role of the Lagrange multipliers is played by the mapping $\hat{L}$.

A. The Toda system

We shall consider the Toda system and its well-known Lax formulation. Let $M = \mathbb{R}^{2n+1}$ with coordinates $x^I = (a_j, b_l)$, $j = 1,\ldots,n$, $l = 1,\ldots,n+1$, $I = 1,\ldots,2n+1$. We consider the Poisson bivector P_0 defined by

$$\begin{aligned} \{a_j, b_j\} &= -a_j, \quad j = 1,2,\ldots,n \\ \{a_j, b_{j+1}\} &= a_j, \quad j = 1,2,\ldots,n, \end{aligned} \tag{5.2}$$

all other Poisson brackets being equal to 0. Thus the Poisson bivector P_0 has matrix

$$(P_0^{IJ}) = \begin{pmatrix} & & & & & a_1 & -a_1 & & & \\ & & & & & & a_2 & -a_2 & & 0 \\ & & & 0 & & & & \ddots & \ddots & \\ & & & & & & 0 & & \ddots & \ddots \\ & & & & & & & & & a_n & -a_n \\ -a_1 & & & & & & & & & & \\ a_1 & -a_2 & & 0 & & & & & & & \\ & a_2 & \ddots & & & & & & & & \\ & & \ddots & \ddots & & & & 0 & & & \\ & 0 & & \ddots & -a_n & & & & & & \\ & & & & a_n & & & & & & \end{pmatrix}.$$

When $H = \Sigma_{j=1}^{n} a_j^2 + 1/2\Sigma_{l=1}^{n+1} b_l^2$, the Hamiltonian vector field $X = P_0 dH$ is the Toda vector field. In fact, the evolution equation $dx/dt = X(x)$ is the system

$$\frac{da_j}{dt} = \{a_j, H\}, \quad j = 1,2,\ldots,n,$$

$$\frac{db_l}{dt} = \{b_l, H\}, \quad l = 1,2,\ldots,n+1,$$

and, setting $a_0 = a_{n+1} = 0$, this system becomes

$$\frac{da_j}{dt}=a_j(b_{j+1}-b_j), \quad j=1,2,\ldots,n,$$
$$\frac{db_l}{dt}=2(a_l^2-a_{l-1}^2), \quad l=1,2,\ldots,n+1, \tag{5.3}$$

which are the equations of the Toda system in Flaschka coordinates.[15] A Lax formulation for the Toda system is

$$\frac{dL}{dt}=[L, A],$$

where

$$L=\begin{pmatrix} b_1 & a_1 & & & & & \\ a_1 & b_2 & a_2 & & & 0 & \\ & a_2 & b_3 & a_3 & & & \\ & & a_3 & \ddots & \ddots & & \\ & & & \ddots & \ddots & \ddots & \\ & 0 & & & \ddots & b_n & a_n \\ & & & & & a_n & b_{n+1} \end{pmatrix}, \quad A=\begin{pmatrix} 0 & a_1 & & & & & \\ a_1 & 0 & a_2 & & & 0 & \\ & a_2 & 0 & a_3 & & & \\ & & a_3 & \ddots & \ddots & & \\ & & & \ddots & \ddots & \ddots & \\ & 0 & & & \ddots & 0 & a_n \\ & & & & & a_n & 0 \end{pmatrix}. \tag{5.4}$$

Now let P and Q be Poisson structures such that (5.1) is satisfied for L symmetric and tridiagonal, as above. We assume that P is known, and we consider Q to be an unknown, higher-order, Poisson structure. We shall assume that $\hat{L}(\alpha)$ depends linearly on α, and we shall denote the matrix $\hat{L}(dx^I)$ of order $n+1$ by C^I. Then (5.1) becomes

$$L\left(P^{IJ}\frac{\partial L}{\partial x^J}+2C^I\right)+\left(P^{IJ}\frac{\partial L}{\partial x^J}-2C^I\right)L=2Q^{IJ}\frac{\partial L}{\partial x^J}, \tag{5.5}$$

where the summation over $J=1,2,\ldots,2n+1$ is understood.

We shall assume that C^I is a skewsymmetric tridiagonal matrix, for each $I=1,\ldots,2n+1$,

$$C^I=\begin{pmatrix} 0 & c^{I1} & & & & & \\ -c^{I1} & 0 & c^{I2} & & & 0 & \\ & -c^{I2} & 0 & c^{I3} & & & \\ & & -c^{I3} & \ddots & \ddots & & \\ & & & \ddots & \ddots & \ddots & \\ & 0 & & & \ddots & 0 & c^{In} \\ & & & & & -c^{In} & 0 \end{pmatrix}, \tag{5.6}$$

where $c_1^I,\ldots,c_n^I$ are to be determined. This choice is the simplest possible and it guarantees that $[L, C^I]$ is a symmetric penta-diagonal matrix. Any other choice of C^I would yield a matrix $[L, C^I]$ with more entries, and so with more constraints to be imposed.

For each $I=1,\ldots,2n+1$, $P^{IJ}(\partial L/\partial x^J)$ is the symmetric tridiagonal matrix

$$\begin{pmatrix} P^{I,n+1} & P^{I1} & & & 0 \\ P^{I1} & P^{I,n+2} & P^{I2} & & \\ & P^{I2} & \ddots & \ddots & \\ & & \ddots & P^{I,2n} & P^{In} \\ 0 & & & P^{In} & P^{I,2n+1} \end{pmatrix},$$

and therefore $(P^{IJ}(\partial L/\partial x^J)-2C^I)L$ is the transpose of $L(P^{IJ}(\partial L/\partial x^J)+2C^I)$. Thus condition (5.5) implies that, for fixed I, matrix C^I is such that the symmetric part of $L(P^{IJ}(\partial L/\partial x^J)+2C^I)$ is tridiagonal. Writing this condition explicitly, one obtains

$$\sum_{k=1}^{n-1}(a_k(P^{J,k+1}+2c^{J,k+1})+a_{k+1}(P^{Jk}-2c^{Jk}))=0.$$

Solving this system for c^{Jk} in terms of P^{Jk} yields the existence of multipliers λ_k^J, $k=1,2,\ldots,n$, such that

$$2c^{Jk}=P^{Jk}+2\lambda_k^J a_k\,.$$

We assume that P^{Jk} is divisible by a_k. This assumption is satisfied for $P=P_0$ defined by (5.2). Setting $\lambda_1^J=\lambda^J$, we obtain

$$2c^{Jk}=P^{Jk}+2a_k\left(\lambda^J-\sum_{j=2}^{k}\frac{P^{Jj}}{a_j}\right).$$

(By convention, here and below the last sum vanishes if $k<2$.)

From relations (5.5), we then obtain the coefficients of the higher-order Poisson structure Q,

$$Q^{Jk}=\tfrac{1}{2}a_k(P^{J,n+k}+P^{J,n+k+1})+\tfrac{1}{2}b_k(P^{Jk}+2c^{Jk})+\tfrac{1}{2}b_{k+1}(P^{Jk}-2c^{Jk}),$$

$$Q^{J,n+l}=a_l(P^{Jl}-2c^{Jl})+a_{l-1}(P^{J,l-1}+2c^{J,l-1})+b_lP^{J,n+l}.$$

We now replace the c^{Jk}s by their values in terms of the parameters λ^J, and we impose the conditions that the diagonal terms of Q vanish. These $2n+1$ conditions imply

$$2(b_{k+1}-b_k)\left(\lambda^k-\sum_{j=2}^{k-1}\frac{P^{kj}}{a_j}\right)=P^{k,n+k}+P^{k,n+k+1},$$

$$a_1^2\lambda^{n+1}=0,$$

$$(a_l^2-a_{l-1}^2)\left(\lambda^{n+l}-\sum_{j=2}^{l-1}\frac{P^{n+l,j}}{a_j}\right)=a_{l-1}P^{n+l,l-1}+a_lP^{n+l,l},$$

for $l=2,\ldots,n+1$.

Thus, we have obtained

$$Q^{Jk}=\frac{1}{2}\,a_k(P^{J,n+k}+P^{J,n+k+1})+b_kP^{Jk}+a_k(b_k-b_{k+1})\left(\lambda^J-\sum_{j=2}^{k-1}\frac{P^{Jj}}{a_j}\right),$$

$$Q^{J,n+l}=2(a_{l-1}P^{J,l-1}+a_lP^{Jl})+b_lP^{J,n+l}+2(a_{l-1}^2-a_l^2)\left(\lambda^J-\sum_{j=2}^{l-1}\frac{P^{Jj}}{a_j}\right),$$

where the λ^Js are given above in terms of a_k, b_l, and P^{IJ}.

Let us assume that all a_ks are nonvanishing and let us introduce the matrix M of order $2n+1$, depending on $a_1,\ldots,a_n,b_1,\ldots,b_{n+1}$, such that M applied to the column with entries $A_1,\ldots,A_n,B_1,\ldots,B_{n+1}$, is the column with entries

$$\overline{A_k}=\frac{1}{2}\,a_k(B_k+B_{k+1})+b_kA_k+a_k(b_{k+1}-b_k)\sum_{j=2}^{k}\frac{A_j}{a_j},$$

$$\overline{B_1}=b_1B_1,\quad \overline{B_2}=b_2B_2+2(a_1A_1+a_2A_2), \tag{5.7}$$

$$\overline{B_l}=b_lB_l+2(a_{l-1}A_{l-1}+a_lA_l)+2(a_l^2-a_{l-1}^2)\sum_{j=2}^{l-1}\frac{A_j}{a_j},$$

for $l=3,\ldots,n+1$.

We see that

$$Q=MP+X\otimes\lambda,$$

where X is the Toda vector field with components

$$a_1(b_2-b_1),a_2(b_3-b_2),\ldots,a_n(b_{n+1}-b_n),2a_1^2,2(a_2^2-a_1^2),\ldots,-2a_n^2,$$

and λ is the vector with components $\lambda^1,\ldots,\lambda^n,\lambda^{n+1},\ldots,\lambda^{2n+1}$. We observe that, although Q is skewsymmetric, this expression does not constitute a decomposition of Q into a sum of skewsymmetric two-tensors.

Thus the Lax–Nijenhuis equation yields an explicit determination of the bivector Q in terms of P. For $P=P_0$, we see that the corresponding vector $\lambda=\lambda_{(0)}$ is the row-matrix with entries

$$\lambda_{(0)}^J=-\tfrac{1}{2}\delta_{n+2}^J. \tag{5.8}$$

It is easy to check that

$$P_1=MP_0+X\otimes\lambda_{(0)}$$

coincides with the second Poisson structure of the Toda system.[17,19,20] For example, if $n=3$, the matrix MP_0 is equal to

$$\begin{pmatrix} b_1 & 0 & 0 & \frac{a_1}{2} & \frac{a_1}{2} & 0 & 0 \\ 0 & b_3 & 0 & 0 & \frac{a_2}{2} & \frac{a_2}{2} & 0 \\ 0 & U & b_4 & 0 & 0 & \frac{a_3}{2} & \frac{a_3}{2} \\ 0 & 0 & 0 & b_1 & 0 & 0 & 0 \\ 2a_1 & 2a_2 & 0 & 0 & b_2 & 0 & 0 \\ 0 & 2\frac{a_3^2}{a_2} & 2a_3 & 0 & 0 & b_3 & 0 \\ 0 & -2\frac{a_3^2}{a_2} & 0 & 0 & 0 & 0 & b_4 \end{pmatrix} \begin{pmatrix} & & & a_1 & -a_1 & 0 & 0 \\ & 0 & & 0 & a_2 & -a_2 & 0 \\ & & & 0 & 0 & a_3 & -a_3 \\ -a_1 & 0 & 0 & & & & \\ a_1 & -a_2 & 0 & & & & \\ 0 & a_2 & -a_3 & & & 0 & \\ 0 & 0 & a_3 & & & & \end{pmatrix},$$

where $U=(a_3/a_2)(b_4-b_3)$, and

$$X\otimes\lambda_{(0)}=\begin{pmatrix} a_1(b_2-b_1) \\ a_2(b_3-b_2) \\ a_3(b_4-b_3) \\ 2a_1^2 \\ 2(a_2^2-a_1^2) \\ 2(a_3^2-a_2^2) \\ -2a_3^2 \end{pmatrix} \otimes {}^t(0 \quad 0 \quad 0 \quad 0 \quad -\tfrac{1}{2} \quad 0 \quad 0),$$

so that

$$P_1=MP_0+X\otimes\lambda_{(0)}=\begin{pmatrix} 0 & -\frac{1}{2}a_1a_2 & 0 & a_1b_1 & -a_1b_2 & 0 & 0 \\ \frac{1}{2}a_1a_2 & 0 & -\frac{1}{2}a_2a_3 & 0 & a_2b_2 & -a_2b_3 & 0 \\ 0 & \frac{1}{2}a_2a_3 & 0 & 0 & 0 & a_3b_3 & -a_3b_4 \\ -a_1b_1 & 0 & 0 & 0 & -2a_1^2 & 0 & 0 \\ a_1b_2 & -a_2b_2 & 0 & 2a_1^2 & 0 & -2a_2^2 & 0 \\ 0 & a_2b_3 & -a_3b_3 & 0 & 2a_2^2 & 0 & -2a_3^2 \\ 0 & 0 & a_3b_4 & 0 & 0 & 2a_3^2 & 0 \end{pmatrix}.$$

Repeating the process, we have to compute the bivector

$$P_2=MP_1+X\otimes\lambda_{(1)},$$

where $\lambda_{(1)}$ is the vector corresponding to P_1. We can show that

$$\lambda_{(1)}=M\lambda_{(0)}.$$

For example, if $n=3$,

$$\lambda_{(1)}=(-\tfrac{1}{4}a_1,-\tfrac{1}{4}a_2,0,0,-\tfrac{1}{2}b_2,0,0)$$

and P_2 is the skewsymmetric matrix

$$P_2 = MP_1 + X \otimes \lambda_{(1)}$$

$$= \begin{pmatrix} 0 & -a_1a_2b_2 & 0 & a_1b_1^2+a_1^3 & -a_1b_2^2-a_1^3 & -a_1a_2^2 & 0 \\ & 0 & -a_2a_3b_3 & a_1^2a_2 & a_2b_2^2+a_2^3 & -a_2b_3^2-a_2^3 & -a_2a_3^2 \\ & & 0 & 0 & a_2^2a_3 & a_3b_3+a_3^2 & -a_3b_4^2-a_3^2 \\ & & & 0 & -2a_1^2(b_1+b_2) & 0 & 0 \\ & & & & 0 & -2a_2^2(b_2+b_3) & 0 \\ & & & & & 0 & -2a_3^2(b_3+b_4) \\ & & & & & & 0 \end{pmatrix}.$$

In this case, P_2 coincides with the opposite of the third Poisson structure of the Toda system described in Refs. 17 and 20.

Thus if M is the matrix of order $2n+1$ defined by (5.7), the bivectors P_i obtained from the Lax–Nijenhuis equation satisfy

$$P_{i+1} = MP_i + X \otimes \lambda_{(i)},$$

where X is the Toda vector field and $\lambda_{(i)}$ is the vector corresponding to P_i.

In particular, it follows that each coefficient P_i^{Jk} of the bivector P_i is divisible by a_k, so the iteration can be carried out.

Let us show that in fact the skewsymmetry of P_i and P_{i+1} implies that

$$\lambda_{(i+1)} = M\lambda_{(i)}.$$

Thus we consider

$$P_i = MP_{i-1} + X \otimes \lambda_{(i-1)},$$

$$P_{i+1} = MP_i + X \otimes \lambda_{(i)}.$$

Since P_{i+1} is assumed to be skewsymmetric, $\lambda_{(i)}$ must satisfy

$$P_i{}^tM - MP_i = X \otimes \lambda_{(i)} + \lambda_{(i)} \otimes X.$$

Moreover, from the skewsymmetry of P_i, we obtain

$$P_i = MP_{i-1} + X \otimes \lambda_{(i-1)} = P_{i-1}{}^tM - \lambda_{(i-1)} \otimes X,$$

where

$$P_i{}^tM - MP_i = X \otimes M\lambda_{(i-1)} + M\lambda_{(i-1)} \otimes X.$$

We thus obtain $\lambda_{(i)} = M\lambda_{(i-1)}$. The following proposition summarizes this discussion.

Proposition 5.1: Let M be the matrix of order $2n+1$ defined by (5.7). The bivectors obtained from the Lax–Nijenhuis equation satisfy

$$P_{i+1} = MP_i + X \otimes M^i\lambda_{(0)},$$

where $\lambda_{(0)}$ is the vector given by (5.8).

B. The *n*-dimensional rigid body

The Euler equations for the n-dimensional rigid body rotating about a fixed point can be written

$$\dot{M} = [M,\ \Omega],$$

where M is the angular momentum, a time-dependent element of the Lie algebra so(n), and

$$M = J\Omega + \Omega J.$$

Here J is a diagonal matrix with positive entries $J_1, J_2, \ldots, J_n$ defined in terms of the principal moments of inertia, and Ω is the angular velocity. These equations admit a Lax formulation, with a spectral parameter,

$$\dot{L} = [L,\ B],$$

where $L = M/\lambda + J^2$ and $B = \Omega + \lambda J$.

Moreover, it is well known (see, e.g., Refs. 10 and 34) that these equations can be written in Hamiltonian form, with respect to the linear Poisson structure of so(n) induced by the identification of the Lie algebra so(n) with its dual by means of the trace of the product of matrices. Making use of this identification, this Poisson structure P is defined by P_M:so(n)$\to$so(n), for each M in so(n), where

$$P_M = ad_M.$$

If $K(M) = \frac{1}{2}\,\mathrm{tr}(M\Omega)$, then the gradient of K [the differential of K identified with a matrix in so(n)] is the constant matrix Ω, and therefore the Euler equations can be written as the Hamiltonian equation

$$\dot{M} = P(dK).$$

Let us use the Lax–Nijenhuis equation in order to find a possible form of a second Hamiltonian structure that will make this equation a bi-Hamiltonian system. Setting $\dot{L} = dL/dt_1$, it follows from the definitions and from the Euler equation that

$$\frac{d(L^2)}{dt_1} = \frac{1}{\lambda}\,(L[M,\ \Omega] + [M,\ \Omega]L),$$

and therefore, by a simple computation,

$$\frac{1}{2}\,\frac{d(L^2)}{dt_1} = \frac{1}{2\lambda}\,[L,\ M\Omega + \Omega M] + \frac{1}{\lambda}\,(M\Omega L - L\Omega M).$$

By the definition of L, $M\Omega L - L\Omega M = M\Omega J^2 - J^2\Omega M$. This suggests that we should set

$$\frac{dM}{dt_2} = M\Omega J^2 - J^2\Omega M.$$

We observe that if M and Ω are skewsymmetric, so is dM/dt_2. In fact, Q defined by

$$Q_M(V) = MVJ^2 - J^2VM,$$

for $M, V \in$ so(n), is the second, compatible Poisson structure on so(n) that was recently found by Morosi and Pizzocchero.[34] This second Poisson structure Q is actually a deformation of the first, linear one, P, under the linear map $M \to JMJ$. The Euler equation can be written

$$\dot{M} = Q(dH),$$

where $H(M)=-\frac{1}{2}\,\mathrm{tr}(J^{-1}MJ^{-1}\Omega)$, since the gradient of H is $-J^{-1}\Omega J^{-1}$.

We now show how to extend this procedure to the determination of Poisson structures compatible with the linear Poisson structures on the sum of several copies of a simple Lie algebra, considered in Refs. 30 and 35. Let us consider, for instance, the Hamiltonian system

$$\frac{dM_0}{dt_1}=[M_0,\ V_1],$$

$$\frac{dM_1}{dt_1}=[M_0,\ V_0]+[M_1,\ V_1],$$

where V_0 and V_1 are the components of the gradient of a Hamiltonian function K. We introduce the Lax matrix depending on the spectral parameter λ,

$$L=\frac{M_0}{\lambda^2}+\frac{M_1}{\lambda}+A.$$

Computing the derivative of the square of this matrix, we find that

$$\frac{1}{2}\,\frac{d(L^2)}{dt_1}=\left[L,\ \frac{(M_0V_1+V_1M_0)}{2\lambda^2}+\frac{(M_0V_0+V_0M_0)+(M_1V_1+V_1M_1)}{2\lambda}\right]$$

$$+\frac{1}{\lambda^2}\,(M_0V_0M_1-M_1V_0M_0+M_0V_1A-AV_1M_0)$$

$$+\frac{1}{\lambda}\,(M_0V_0A-AV_0M_0+M_1V_1A-AV_1M_1).$$

Therefore the Lax–Nijenhuis equation suggests that we should set

$$\frac{dM_0}{dt_2}=(M_0V_0M_1-M_1V_0M_0)+(M_0V_1A-AV_1M_0),$$

$$\frac{dM_1}{dt_2}=(M_0V_0A-AV_0M_0)+(M_1V_1A-AV_1M_1).$$

A computation shows that this is actually a Poisson structure on the direct sum of two copies of so(n). It is clearly compatible with the first, because it can be obtained by deforming A into $A+\lambda I$.

C. The KdV equation

We now enter the field of nonlinear partial differential equations by considering the Korteweg–de Vries (KdV) equation

$$\frac{du}{dt}=u_{xxx}-6uu_x.$$

We use the notations of the formal calculus of variations.[9,10,8] As is well known, the KdV equation is Hamiltonian since it can be written in the form

$$\frac{\partial u}{\partial t}=\partial\,\frac{\delta H}{\delta u},$$

where

$$H(u)=-\int\left(\frac{1}{2}\,u_x^2+u^3\right)dx,$$

and $\partial=d/dx$ is the Gardner Hamiltonian structure.[13] It admits a Lax representation, $du/dt=[L,\,B]$, with

$$L=\partial^2-u,\quad B=4\partial^3-3(u\partial+\partial u).$$

We now want to use the Lax–Nijenhuis equation (5.1), where $P=\partial$, to find the second Hamiltonian structure of the KdV equation. Since L is a second-order differential operator, we assume that $\hat{L}(\alpha)$ is a first-order differential operator,

$$\hat{L}(\alpha)=\lambda+\mu\partial,$$

where λ and μ depend linearly on the one-form α. A simple computation yields

$$\tfrac{1}{2}\mathscr{L}_{P\alpha}(L^2)=-\alpha_x\partial^2-\alpha_{xx}\partial+(u\alpha_x-\tfrac{1}{2}\alpha_{xxx}),$$

$$[L,\,\hat{L}(\alpha)]=2\mu_x\partial^2+(2\lambda_x+\mu_{xx})\partial+(\lambda_{xx}+\mu u_x).$$

By inserting these formulas into the Lax–Nijenhuis equation and by equating the coefficients of ∂^2, ∂, and ∂^0, we get

$$(2\mu-\alpha)_x=0,$$

$$(2\lambda+\mu_x-\alpha_x)_x=0,$$

$$-\mathscr{L}_{Q\alpha}(u)=u\alpha_x-\tfrac{1}{2}\alpha_{xxx}+\lambda_{xx}+\mu u_x\,.$$

The first two equations yield the solution $\mu=\frac{1}{2}\alpha$, $\lambda=\frac{1}{4}\alpha_x$, while the third one yields the second Hamiltonian structure of the KdV equation,

$$Q_u(\alpha)=\tfrac{1}{4}\alpha_{xxx}-u\alpha_x-\tfrac{1}{2}u_x\alpha.$$

The recursion operator is the nonlocal operator, $R_u=\frac{1}{4}\partial^2-u-\frac{1}{2}u_x\partial^{-1}$.

D. The second Adler–Gelfand–Dickey bracket

We now generalize the previous example to the first equation of the nth KdV hierarchy. The unknowns are functions $u_0,u_1,\ldots,u_{n-1}$ on the circle, whose time evolution is being studied. It admits a Lax formulation,

$$\frac{dL}{dt}=[L,B],$$

where

$$L=\partial^n+u_{n-1}\partial^{n-1}+\cdots+u_0\,,$$

and B is a suitable differential operator of order $n+1$. Here L takes values in a manifold $\mathscr{L}_n$ of invertible elements in the algebra A_n of formal pseudodifferential operators of order $\leqslant n$ on the circle.[36] This equation is Hamiltonian with respect to the Poisson structure P on $\mathscr{L}_n$ which, in the operator formalism, is defined by

$$P_L(\alpha)=[\alpha,L]_+\,, \tag{5.9}$$

where α is the pseudodifferential operator,

$$\alpha=\partial^{-1}\alpha_0+\partial^{-2}\alpha_1+\cdots+\partial^{-n}\alpha_{n-1}\,,$$

which is considered as a one-form on $\mathscr{S}_n$. The value of α on any tangent vector $U=U_{n-1}\partial^{n-1}+\cdots+U_1\partial+U_0$ is, by definition,

$$\langle\alpha,U\rangle=\int \operatorname{res}_{\partial^{-1}}(\alpha\circ U)=\int(\alpha_0U_0+\cdots+\alpha_{n-1}U_{n-1})dx.$$

In Eq. (5.9) the symbol $[L,\alpha]_+$ means that we consider the differential part of the pseudodifferential operator obtained by computing the commutator of the operators L and α by the usual (formal) rules of the algebra of pseudodifferential operators. See, e.g., Refs. 36 and 37.

The Lax–Nijenhuis equation (5.1) then takes the form

$$\mathscr{S}_{Q\alpha}(L)=\tfrac{1}{2}(L[\alpha,L]_+-[\alpha,L]_+L)+[L,\hat{L}(\alpha)].$$

Since L is a monic differential operator of order n and

$$\mathscr{S}_{Q\alpha}(L)=\mathscr{S}_{Q\alpha}(u_0)+\mathscr{S}_{Q\alpha}(u_1)\partial+\cdots+\mathscr{S}_{Q\alpha}(u_{n-1})\partial^{n-1},$$

we can solve this equation by looking for operators

$$\hat{L}(\alpha)=\lambda_0+\lambda_1\partial+\cdots+\lambda_{n-1}\partial^{n-1}.$$

(The reasons for this choice and that made in the case of the Toda system are similar.) Then we observe that the Lax–Nijenhuis equation can also be written in the form

$$\mathscr{S}_{Q\alpha}(L)=[\alpha,L]_+L+[L,M(\alpha)] \tag{5.10}$$

if we set

$$M(\alpha)=\hat{L}(\alpha)+\tfrac{1}{2}[\alpha,L]_+\,.$$

To split Eq. (5.10) in two parts, one determining $M(\alpha)$ and the other determining $\mathscr{S}_{Q\alpha}(L)$, we observe that the constraints on L imply that

$$(\mathscr{S}_{Q\alpha}(L)L^{-1})_+=0.$$

Then we get

$$(\mathscr{S}_{Q\alpha}(L)\cdot L^{-1})_+=([\alpha,\,L]_++[L,\,M(\alpha)L^{-1}])_+=0,$$

$$(\mathscr{S}_{Q\alpha}(L)\cdot L^{-1})_-=([\alpha,L]_++[L,M(\alpha)L^{-1}])_-$$

or

$$[L,(M(\alpha)-\alpha L)L^{-1}]_+=0, \tag{5.11}$$

$$\mathscr{S}_{Q\alpha}(L)=[L,M(\alpha)L^{-1}]_-\cdot L. \tag{5.12}$$

Now $[L,(\alpha L)_-L^{-1}]_+=0$, since

$$(L(\alpha L)_- L^{-1} - (\alpha L)_-)_+ = (L(\alpha L)_- L^{-1})_+ = 0.$$

In fact, we know that for any strictly pseudodifferential operator X, such that $X_+ = 0$,

$$(LXL^{-1})_+ = 0.$$

The constraint equation (5.11) can therefore be written in the form

$$[L, (M(\alpha) - (\alpha L)_+) L^{-1}]_+ = 0,$$

and the simplest solution of (5.11) is thus

$$M(\alpha) = (\alpha L)_+ .$$

If we now insert this solution into Eq. (5.12), we get

$$\mathscr{S}_{Q\alpha}(L) = [L, (\alpha L)_+ L^{-1}]_- \cdot L,$$

or

$$\begin{aligned} Q_L(\alpha) = (L(\alpha L)_+ L^{-1})_- L &= L(\alpha L)_+ L^{-1} L - (L(\alpha L)_+ L^{-1})_+ L \\ &= L(\alpha L)_+ - (L\alpha L L^{-1} - L(\alpha L)_- L^{-1})_+ L \\ &= L(\alpha L)_+ - (L\alpha)_+ L. \end{aligned}$$

This is the second Adler–Gelfand–Dickey bracket.[21,16,10,37]

E. The *R*-matrix bracket

It is well known that the Poisson structure (5.9) on $\mathscr{S}_n$ is a particular case of the Poisson structure P defined by

$$P_L(\alpha) = R([L, \alpha]) - [L, R\alpha] \tag{5.13}$$

associated with any skewsymmetric R-matrix satisfying the modified classical Yang–Baxter equation,

$$[RX, RY] - R([RX, Y] + [X, RY]) = -[X, Y].$$

Indeed to obtain (5.9) from (5.13) it is enough to choose as an R-matrix on the algebra of formal pseudodifferential operators half the difference,

$$R = \tfrac{1}{2}(\pi_+ - \pi_-),$$

between the projections π_+ and π_- onto the positive and negative parts into which the algebra of formal pseudodifferential operators naturally splits. In fact

$$R([L, \alpha]) - [L, R\alpha] = \tfrac{1}{2}[L, \alpha]_+ - \tfrac{1}{2}[L, \alpha]_- + \tfrac{1}{2}[L, \alpha] = [L, \alpha]_+ .$$

Therefore, it is natural to try to generalize the previous example by solving the Lax–Nijenhuis equation corresponding to

$$\mathscr{S}_{P\alpha}(L) = R([L, \alpha]) - [L, R(\alpha)].$$

To this end we remark that

$$\mathscr{L}_{P\alpha}(L^2)=LR([L,\alpha])+R([L,\alpha])L-[L,LR(\alpha)+R(\alpha)L]$$

so that the Lax–Nijenhuis condition takes the form

$$\mathscr{L}_{Q\alpha}(L)=\tfrac{1}{2}(LR([L,\alpha])+R([L,\alpha])L)+[L,\hat{L}(\alpha)-\tfrac{1}{2}(LR(\alpha)+R(\alpha)L)].$$

In this case we have no obvious supplementary conditions on L to be used to determine $\hat{L}(\alpha)$. However, to do this we can use the skewsymmetry of Q (as in the Toda example). The idea is to split the linear operator

$$M_L(\alpha)=LR([L,\alpha])+R([L,\alpha])L$$

into its symmetric and skewsymmetric parts. Since

$${}^tM_L(\alpha)=[L,R(\alpha L+L\alpha)],$$

we can write

$$\mathscr{L}_{Q\alpha}(L)=\tfrac{1}{2}(M_L(\alpha)-{}^tM_L(\alpha))+[L,\hat{L}(\alpha)+\tfrac{1}{2}(R(\alpha L+L\alpha))-LR(\alpha)-R(\alpha)L].$$

Now we can choose

$$\hat{L}(\alpha)=\tfrac{1}{2}(LR(\alpha)+R(\alpha)L)-\tfrac{1}{2}R(\alpha L+L\alpha)$$

so as to annihilate the commutator and to get $\mathscr{L}_{Q\alpha}(L)=\tfrac{1}{2}(M_L(\alpha)-{}^tM_L(\alpha))$, a manifestly skewsymmetric mapping. The explicit result that we finally get is

$$\mathscr{L}_{Q\alpha}(L)=\tfrac{1}{2}(LR([L,\alpha])+R([L,\alpha])L-[L,R(\alpha L+L\alpha)]),$$

and thus

$$Q_L(\alpha)=R(L\alpha)L-LR(\alpha L).$$

This is the well known form[23] of the second (quadratic) Poisson bivector associated with the R-bracket (5.13).

VI. CONCLUSION

These examples may help to explain the role of the Lax–Nijenhuis equation and its limits. This equation does not define the second (''quadratic'') Poisson bracket, Q, associated with a Lax operator, but it provides a systematic way of deriving this bracket. The previous examples show that, in many cases, the form of L and the form of the first, given Poisson tensor suggest natural choices for the form of $\hat{L}(\alpha)$ which make Q uniquely defined. This is the value of the method. Its limits are that it does not provide a proof of the fact that we indeed obtain a second Poisson tensor compatible with the given one.

In Ref. 38, there appears a Lax formulation for the evolution of the recursion operator of the KdV hierarchy, whose geometric interpretation along the lines of the present exposition remains to be clarified.

A geometrical method towards first integrals for dynamical systems

Simon Labrunie[a] and Robert Conte
Service de physique de l'état condensé, CEA Saclay, 91191 Gif-sur-Yvette Cedex, France

(Received 5 April 1996; accepted for publication 5 July 1996)

We develop a method, based on Darboux's and Liouville's works, to find first integrals and/or invariant manifolds for a physically relevant class of dynamical systems, without making any assumption on these elements' forms. We apply it to three dynamical systems: Lotka–Volterra, Lorenz and Rikitake. © *1996 American Institute of Physics.* [S0022-2488(96)03511-6]

I. HISTORICAL OVERVIEW

In Refs. 1 and 2, Roger Liouville and A. Tresse developed a method for deciding whether two differential equations of the form

$$\frac{d^2y}{dx^2}+a_1(x,y)\left(\frac{dy}{dx}\right)^3+3\,a_2(x,y)\left(\frac{dy}{dx}\right)^2+3\,a_3(x,y)\frac{dy}{dx}+a_4(x,y)=0, \tag{1}$$

where the a_i are arbitrary functions of the real or complex variables x and y, are geometrically equivalent, i.e., can be transformed into each other by the most general dependent and independent variable change

$$x'=\varphi(x,y), \quad y'=\psi(x,y). \tag{2}$$

This method was based on the construction of a ''relative invariant'' function called ν_5 of the a_i and of their derivatives, such that in any transformation (2) it becomes $\nu_5'=J(x,y)^{-5}\nu_5$ where $J(x,y)$ is the Jacobian of the transformation. In the general case, two equations such that their ν_5 are non-zero and proportional to each other are indeed equivalent. If $\nu_5=0$ for both, however, one cannot conclude at first, and other invariants, involving higher derivatives of the a_i, must be calculated in order to decide. As an application, Liouville proposed the effective reduction of Equation (1) into its simplest canonical form, which in most cases leads to an explicit integration.

Here we will adopt another point of view. We have derived from these theories a method for finding out first integrals for a wide and physically important class of dynamical systems without having to make any ansatz on their functional form. In the rest of this section, we shall recall some mathematical results of Darboux,[3] Liouville and Tresse. Then we explain our method in Section II, and apply it in Section III to three well-known dynamical systems. Finally, Section IV discusses our results summarised in Table I.

A. Essentials of Liouville theory

Consider a differential equation like (1). Liouville[1] defined the following functions — which are seen as functions of (x,y), forgetting the supposed relation between those variables:

$$L_2=\frac{\partial}{\partial x}\left(\frac{\partial a_1}{\partial x}-3\,a_1a_3\right)+\frac{\partial}{\partial y}\left(\frac{\partial a_3}{\partial y}-2\,\frac{\partial a_2}{\partial x}+a_1a_4\right)$$
$$-3\,a_2\left(\frac{\partial a_3}{\partial y}-2\,\frac{\partial a_2}{\partial x}+a_1a_4\right)+a_1\left(\frac{\partial a_4}{\partial y}+3\,a_2a_4\right), \tag{3}$$

$$L_1=\frac{\partial}{\partial y}\left(\frac{\partial a_4}{\partial y}+3\,a_2a_4\right)-\frac{\partial}{\partial x}\left(2\,\frac{\partial a_3}{\partial y}-\frac{\partial a_2}{\partial x}+a_1a_4\right)$$
$$-3\,a_3\left(2\,\frac{\partial a_3}{\partial y}-\frac{\partial a_2}{\partial x}+a_1a_4\right)-a_4\left(\frac{\partial a_1}{\partial x}-3\,a_1a_3\right), \tag{4}$$

$$\nu_5=L_2\left(L_1\frac{\partial L_2}{\partial x}-L_2\frac{\partial L_1}{\partial x}\right)+L_1\left(L_2\frac{\partial L_1}{\partial y}-L_1\frac{\partial L_2}{\partial y}\right)-a_1L_1^3+3\,a_2L_1^2L_2-3\,a_3L_1L_2^2+a_4L_2^3. \tag{5}$$

The equation $\nu_5=0$ means that

$$L_1dx+L_2dy=0 \tag{6}$$

defines a particular solution of Equation (1). We shall call (6) a *subequation* of Equation (1), i.e., (1) is a differential consequence of (6). Notice that in the case $L_2\equiv 0$ the solution is *not* $L_1\equiv 0$ — which would mean an unexpected lowering of this equation's differential order — but $dx=0$, an absurdity as x is seen as the independent variable. Similarly if $L_1\equiv 0$, the solution is $dy=0$, a solution possibly present in Equation (1) but not very interesting.

Now suppose neither L_1 nor L_2 vanish identically and define $\alpha=-L_2/L_1$. Then

$$\nu_5=L_1^3\left(\alpha\frac{\partial\alpha}{\partial y}+\frac{\partial\alpha}{\partial x}+a_1\alpha^3+3\,a_2\alpha^2+3\,a_3\alpha+a_4\right) \tag{7}$$

and Equation (6) can be rewritten $dy/dx=\alpha(x,y)$. Conversely suppose there is a first-order subequation to Equation (1), namely $dy/dx=A(x,y)$. Then A is a solution to the first-order non-linear PDE

$$A\frac{\partial A}{\partial y}+\frac{\partial A}{\partial x}+a_1A^3+3\,a_2A^2+3\,a_3A+a_4=0 \tag{8}$$

we shall discuss later. Liouville theory is a finite effort tool for finding particular solutions to Equation (8).

B. Darboux polynomials and first integrals for polynomial dynamical systems

Consider an autonomous polynomial dynamical system

$$\dot{x}_i=V_i(x),\quad i=1,\ldots,n. \tag{9}$$

We say that a polynomial $f(x_1,\ldots,x_n)$ is a *Darboux polynomial*[3] of (9) if there exists a polynomial ''eigenvalue'' p such that

$$\frac{df}{dt}\equiv\sum_{i=1}^{n}V_i\frac{\partial f}{\partial x_i}=pf.$$

In other words, there is an algebraic variety, defined by $f(x_1,\ldots,x_n)=0$, which is invariant by the flow of V. In this respect, this notion is a neighbour of the notion of subequation we have seen.

Darboux polynomials are tools for finding out,[4,5] but also proving the non-existence (cf. Ref. 6 for an example) of first integrals to polynomial dynamical systems. We shall not enter into the details. Let us just notice that a polynomial first integral is simply a Darboux polynomial with eigenvalue 0, and that a Darboux polynomial f with constant eigenvalue α gives rise to the time-dependent first integral $f\,e^{-\alpha t}$. More rational and algebraic first integrals can be built with the ''basic blocks'' of Darboux polynomials,[4,5] and, conversely, a theorem of Bruns[7] says there cannot be an algebraic first integral of (9) unless there is a rational one, which in turn implies the existence of Darboux polynomials.

In brief, the problems of existence of first integrals and Darboux polynomials for a polynomial dynamical system are very tightly linked. Notice also that all these objects, like ordinary eigenvectors and -values of linear endomorphisms, naturally live in $\mathbf{C}$.

II. PRINCIPLE OF THE METHOD

We shall draw our interest to autonomous three-dimensional polynomial dynamical systems which are of *first degree* in one of their three variables, e.g., z. Their general form is thus

$$\dot{x}=V_x^0(x,y)+zV_x^1(x,y),\quad \dot{y}=V_y^0(x,y)+zV_y^1(x,y),$$

$$\dot{z}=V_z^0(x,y)+zV_z^1(x,y), \tag{10}$$

which we may abbreviate as $\dot{X}=V(X)$. Dynamical systems of this kind are frequently met in physics: well-known examples are the Lorenz model, or the various three-wave interaction prob-

lems (Rabinovich, etc.). Very often they are indeed of first degree in *all* their variables. We can use this feature for harvesting more information — an example is given in the paragraph about the Lorenz model.

We assume to have found out and studied all solutions with $x=$ cst. Assuming x nonconstant, we shall transform the system (10) into a non-autonomous second-order differential equation linking y and x which will turn out to be of type (1).

Now we settle in a region of space where $\dot{x} \neq 0$ and take x as the independent variable, parametrising the integral curves of (10). The relation

$$(V_x^0(x,y)+zV_x^1(x,y))\frac{dy}{dx}=V_y^0(x,y)+zV_y^1(x,y) \tag{11}$$

is satisfied along all integral curves. Hence, writing $p=dy/dx$,

$$z(V_x^1 p-V_y^1)=V_y^0-pV_x^0. \tag{12}$$

These equations define the mappings $\phi:(x,y,z)\mapsto(x,y,p)$ and $\phi^*:(x,y,p)\mapsto(x,y,z)$, which are homographic and hence:

(1) They are one-to-one wherever they are defined and their determinant $C(x,y)=V_x^0V_y^1-V_y^0V_x^1$ is non-zero; as it involves only the variables x and y the surface $\Sigma=\{C(x,y)=0\}$ can be seen either as a submanifold in the (x,y,z) space or in the (x,y,p) space.

(2) The surfaces $S_1=\{V_x^0(x,y)+zV_x^1(x,y)=0\}$ in the (x,y,z) space and $S_2=\{V_x^1(x,y)p-V_y^1(x,y)=0\}$ in the (x,y,p) space are singular. Any point on $S_1\backslash\Sigma$ is sent to $p=\infty$: this happens when $\dot{x}=0$, and the tangent to the integral curve is orthogonal to the x-axis, i.e., ''vertical'' in (x,y) representation $(dy/dx=\infty)$. Similarly any point on $S_2\backslash\Sigma$ is sent to $z=\infty$.

(3) On Σ, ϕ and ϕ^* are ''constant along fibres,'' i.e., two points of Σ having different z (or p) are sent to the same image, having the same (x,y) as the original point, hence lying on Σ. Thus it is always possible to get it as the image of a point on $\Sigma\backslash S_1$ and calculating it that way shows that $\phi(\Sigma)=\Sigma\cap S_2$; and similarly $\phi^*(\Sigma)=\Sigma\cap S_1$.

Since we are concerned with a differential problem, we have to study what the vector field $V(X)$ becomes under the action of the tangent map $T_X\phi$. And, indeed, points X on Σ differing only in the z coordinate have the same image by ϕ, but different $V(X)$ such that the corresponding $T_X\phi(V(X))$ also generally differ. As all these vectors are attached to the common image of the points X, this can cause a loss of information, leading, as we shall see, to important practical difficulties.

Similarly, we find that

$$(V_x^0(x,y)+zV_x^1(x,y))\frac{dz}{dx}=V_z^0(x,y)+zV_z^1(x,y).$$

We calculate dz/dx by differentiating (12) with respect to x, putting the result into the previous formula, and then replacing z itself with its value in function of p given by Equation (12). This leads to a differential equation in p which, in Cauchy form, reads

$$\frac{dp}{dx}=\frac{N(x,y,p)}{C(x,y)^2}, \tag{13}$$

where N is polynomial in (x,y,p) and of degree three in p. Interpreting p as dy/dx, we see Equation (13) as a differential equation of Liouville type like (1). There are two essential facts in

these computations. One is that the denominator of (13) is exactly the square of the determinant $C(x,y)$ of ϕ, so Equation (13) will not set any further problem as long as its construction is valid. The other one is that Equations (10) are of degree one in z: it ensures not only the good behaviour of the $z \leftrightarrow p$ correspondence but also the Liouville form of the differential equation (13).

We intend to apply Liouville theory to Equation (13) in order to obtain subequations for it. Now, we must take care of their possible relationships with the forbidden surfaces. If a subequation defines a curve in the (x,y,p) space which is not contained in Σ or S_2, there is no problem: it will be pulled back into the (x,y,z) space by the ϕ^* map, which coincides then with the reciprocal of ϕ.

But in the computation of Equation (13), we have used the $z=\phi^*(x,y,p)$ map, and then suppressed the denominator $V_x^1 p - V_y^1$. Thus, the singular manifold at S_2 has disappeared in (13). But consider a curve plotted on S_2 (i.e., $V_x^1 p - V_y^1 \equiv 0$) which is, moreover, a *jet* (i.e., $p \equiv dy/dx$). Then, identically

$$\frac{dy}{dx} = A(x,y) = \frac{V_y^1(x,y)}{V_x^1(x,y)}.$$

We can check that this A is always a solution to Equation (8), whatever the vector field V may be. Hence *any jet plotted on S_2 is a subequation of Equation (13).* However, this jet cannot yield an invariant manifold in the (x,y,z) space unless it is made of images by ϕ of points in this space. Now, it is easy to show that the only points on S_2 that can be written as $\phi(x,y,z)$ are those on $\Sigma \cap S_2$; therefore, as we have seen, they are images of points also lying on Σ.

Yet we know that the pullback of the vector field V is not necessarily well-behaved on Σ. Thus, the system (10) and the differential equation (13) can behave quite differently on Σ.

If we find as Equation (6) the equation of a jet on S_2, we have to check independently whether Σ is an invariant manifold for V or not. In dynamical systems containing parameters, this can be rephrased as: *find at what condition on the system's parameters the equation denominator $C(x,y)$ is a Darboux polynomial for the system (10).*

III. RESULTS FOR SEVERAL DYNAMICAL SYSTEMS

We have applied the method exposed in Section II to three different dynamical systems of type (10) depending on real parameters: Lotka–Volterra, Lorenz, Rikitake. We shall discuss the results obtained in the rest of this section.

A. The (a,b,c) Lotka–Volterra system

This remarkably symmetric system

$$\dot{x} = x(cy+z), \quad \dot{y} = y(az+x), \quad \dot{z} = z(bx+y), \tag{14}$$

appeared first as a model for three-species competition, yet has been found later in plasma physics. A considerable amount of research has been done on it, using many techniques.[6,8–10] Here we shall follow the process exposed in Section II.

Since Equations (14) are invariant by simultaneous circular permutations of (x,y,z) and (a,b,c), it is equivalent to perform the method with any couple of variables. Once this is done, more results can be obtained by the above symmetry. There is also a symmetry in taking $x=x'/b, y=z'/c, z=y'/a$ and $a=1/c', b=1/b', c=1/a'$, which will appear in the distribution of the $\nu_5=0$ cases.

So, we take z as the independent variable and eliminate x, and find

$$L_1 = \frac{(b-1)(1+abc)Q_{abc}^1(y,z)}{z(y-abz)^4} \tag{15}$$

and

$$L_2=\frac{(b-1)(1+abc)Q^2_{abc}(y,z)}{z(y-abz)^4} \tag{16}$$

and

$$\nu_5=\frac{(b-1)^3(1+abc)^3P_{abc}(y,z)}{z^2y^2(y-abz)^{10}}, \tag{17}$$

where $P_{abc},Q^1_{abc},Q^2_{abc}$ are polynomials whose coefficients depend on (a,b,c) and which we do not write down for the sake of brevity. The cases $1+abc=0$ and $b=1$ are known: the first one is the full integrability of the system, with, in particular, the first integral $abx+y-az$; in the second one we have the Darboux polynomial $y-az$ whose eigenvalue is x. We remark this Darboux polynomial is exactly the denominator. Notice also that in those two cases, L_1 and L_2 vanish together with ν_5 so that Equation (6) is an identity and cannot be used for finding out Darboux polynomials.

Now the cases where all coefficients of P_{abc} are zero are listed below in Table I. We notice the presence of the symmetry $a=1/c',b=1/b',c=1/a'$ in this list; one case $(a=1,b=1,c=1)$ is self-symmetric. We shall handle in some detail one of these ''exotic'' cases, viz. $(a=1/4,b=2,c=-5)$. The subequation (6) reads

$$y(-3z^2+16zy-32y^2)+4z\frac{dy}{dz}(z^2-7zy+16y^2)=0. \tag{18}$$

Reverting to the original variables (x,y,z) changes this equation in

$$y(z-2y)(16y^2-2xz-8yz+z^2)=0. \tag{19}$$

The expression $z-2y$ is proportional to the equation denominator; its presence here is an artefact due, as we have seen, to a former suppression of denominator. It should not be taken in account since it corresponds to $b=1$. On the other hand, the other two factors are Darboux polynomials, since their derivatives with respect to the system (14) are $\dot{y}=y(z/4+x)$ and

$$\frac{d}{dt}(16y^2-2xz-8yz+z^2)=2x(16y^2-2xz-8yz+z^2).$$

This illustrates the validity of the method in the general case. The results for all cases are summarised in Table I. We get no information for the self-symmetric case since it is a specialisation of $b=1$, so our method cannot be applied.

B. The Lorenz model

Another well-known and intensively studied[11–15] dynamical system, the Lorenz model

$$\dot{x}=\sigma(y-x),\quad \dot{y}=\varrho x-y-xz,\quad \dot{z}=xy-bz, \tag{20}$$

originally thought of as a simple model for atmospheric turbulence, was the first example of a low-dimensional chaotic deterministic dynamical system.[11] All known first integrals have been obtained or reobtained by Kuś,[13] using the non-decisive procedure of Carleman embedding. Here we shall recover some of them *methodically* by the means of Liouville theory.

Since there is no symmetry among variables here, we can proceed three times to the calculation of the $L_{1,2}$ and ν_5 functions, eliminating each time one of the three variables. Indeed, the

Liouville equation like (13) contains no more information than the dynamical system like (10) does, but it has more singularities; yet, as we have seen, these singularities often contain useful matter about the dynamical system's invariant manifold structure.

Eliminating z and choosing x as the independent variable yields $C(x,y)=\sigma x(y-x)$. Neither $x=0$ nor $y-x=0$ can be interesting invariant manifolds, since both imply $\dot{x}=0$, so $x=$ cst and $y=$ cst. This, in turn, also implies that z is constant, and the manifold reduces to a fixed point.

The functions L_2 and ν_5 are (cf. Ref. 16)

$$L_2=\frac{1+b+\sigma}{\sigma(y-x)^3} \tag{21}$$

and

$$\nu_5=\frac{(1+b+\sigma)P_{b\sigma\varrho}(x,y)}{\sigma^5x^2(y-x)^{10}}. \tag{22}$$

In the obvious case $1+b+\sigma=0$, we also have $L_2=0$. Thus, as explained in Section I, our choice of variables was a bad one. Looking for other cases, we only get three points in the (b,σ,ϱ) space, viz. $(b=0,\sigma=-1)$, $(b=2/3,\sigma=1/3)$ and $(b=-16/5,\sigma=-1/5,\varrho=-7/5)$. They are specialisations either of known cases[13] or of the $1+b+\sigma=0$ case. In those cases, we get subequations that do not give rise to Darboux polynomials, i.e., equations that represent jets plotted on the surface S_2.

Now, if we eliminate y and choose x as the independent variable, we get as equation denominator $C(x,z)=bz-x^2$. Its derivative with respect to the system (20) is

$$\begin{aligned}\frac{d}{dt}(bz-x^2)&=(b-2\,\sigma)xy-(b^2z-2\,\sigma x^2)\\&=-2\,\sigma(bz-x^2)+(b-2\,\sigma)(xy-bz).\end{aligned} \tag{23}$$

The remainder is of degree one in x. Thus C is a Darboux polynomial iff $b=2\,\sigma$; then the eigenvalue is $-2\,\sigma$, so $I=(x^2-2\,\sigma z)\,\mathrm{e}^{2\,\sigma t}$ is a first integral.[12]

We have calculated ν_5 and found

$$\nu_5=\frac{(b-2\,\sigma)(1+b+\sigma)P_{b\sigma\varrho}}{\sigma^5(bz-x^2)^{10}}, \tag{24}$$

$P_{b\sigma\varrho}$ being such that its coefficients never simultaneously vanish. In the case $b=2\,\sigma$, Equation (6) yields $x-\sigma dz/dx=0$. This is the equation of a jet on S_2, and since we are in the good case, we find Σ as the invariant surface.

When $1+b+\sigma=0$, Equation (6) still yields $x-\sigma dz/dx=0$. But in this case, Σ is not invariant and we do not have a Darboux polynomial.

Finally, we have taken z as the independent variable and eliminated x. We find $C(y,z)=b\varrho z-bz^2-y^2$ and

$$\begin{aligned}\frac{dC}{dt}&=xy((b-2)\varrho+2\,(1-b)z)+2\,y^2+2\,b^2z^2-b^2\varrho z\\&=-2\,(b\varrho z-bz^2-y^2)+R(x,y,z),\end{aligned} \tag{25}$$

the remainder R being of first degree in y; hence C is a Darboux polynomial iff $b=1$ and $\varrho=0$. Then, $dC/dt=-2\,C$ and we get that way the first integral $I=(z^2+y^2)\,\mathrm{e}^{2t}$.[12]

As for ν_5, it is equal to

$$\nu_5=\frac{(1+b+\sigma)yP_{b\sigma\varrho}(y,z)}{(b\varrho z-bz^2-y^2)^{10}}, \tag{26}$$

where $P_{b\sigma\varrho}(y,z)\equiv 0$ iff $b=1$ and $\varrho=0$. Let us handle first the latter case. In that case, $L_1=-\sigma zy/(z^2+y^2)^2$ and $L_2=-\sigma y^2/(z^2+y^2)^2$, so Equation (6) simplifies as $zdz+ydy=0$. This is the equation of a jet on S_2, and we get Σ as invariant manifold.

Now, in the case $1+b+\sigma=0$, there is another simplification in Equation (6), namely $yL_1\equiv(z-\varrho)L_2$ and hence $(z-\varrho)dz+ydy=0$. But this is the jet on S_2, so we get no information in this case.

C. The Rikitake dynamo

This dynamical system[8]

$$\dot{x}=-\mu x+y(z+\beta),\quad \dot{y}=-\mu y+x(z-\beta),\quad \dot{z}=\alpha-xy, \tag{27}$$

models the variation of the earth's magnetic field with time.

Let us take x as the privileged variable and eliminate z. The denominator in Equation (13) is $C(x,y)=\mu(y^2-x^2)+2\,\beta xy$, and

$$\nu_5=\frac{\beta^2\mu^2P_{\alpha\beta\mu}(x,y)}{(\mu(y^2-x^2)+2\,\beta xy)^{10}}, \tag{28}$$

where the coefficients of $P_{\alpha\beta\mu}$ cannot vanish together unless $\beta=0$ or $\mu=0$.

The derivative of $C(x,y)$ with respect to the system (27) is

$$\frac{dC}{dt}=(y^2-x^2)(2\,\beta^2-2\,\mu^2)-2\,\beta xy+2\,\beta z(x+y). \tag{29}$$

Assume C is a Darboux polynomial of eigenvalue $P(x,y,z)=A(x,y)+zB(x,y)$. Then the identification of the z terms in Equation (29) gives $BC=2\,\beta(x+y)$. Since C is of second degree, this is impossible unless $\beta=0$.

When $\beta=0$, Equation (29) reads $dC/dt=-2\,\mu C$, so C is a Darboux polynomial of this system, which gives the first integral $(y^2-x^2)\,\mathrm{e}^{2\mu t}$. On the other hand,

$$L_1=\frac{4\,x^2y}{\mu^2(x^2-y^2)^2},\quad L_2=\frac{-4\,xy^2}{\mu^2(x^2-y^2)^2},$$

hence Equation (6) becomes $-xdx+ydy=0$. This is a jet on S_2, but we are in the ''good'' case, and we recover the Darboux polynomial y^2-x^2.

If now $\mu=0$, then

$$L_1=\frac{-\alpha(3\,x^4+2\,x^2y^2+3\,y^4)}{4\,\beta^2x^3y^4},\quad L_2=\frac{\alpha(3\,x^4+2\,x^2y^2+3\,y^4)}{4\,\beta^2x^4y^3},$$

so the subequation is once more $-xdx+ydy=0$, the jet on S_2. Hence we do not obtain any Darboux polynomial unless $\beta=0$.

We have also performed the computations with the other two couples of variables. They have not given more information than the previous ones.

IV. CONCLUSION

We have obtained, *by a methodic procedure*, numerous cases of Darboux polynomials for the Lotka–Volterra system. This ''Darboux polynomial searcher'' can be seen as an input to algorithms which need Darboux polynomials, such as the Prelle–Singer procedure. Up to now, that procedure began with a systematic search, which obliged to set an *a priori* limit on the polynomial's degree in all its variables.[4] Some new results[5] allow the refinement of the search by restricting the choice of the possible highest-degree homogeneous components of the tentative Darboux polynomials, while speeding it up when the system's coefficients are rational numbers. Yet they are valid for dynamical systems of dimension 2, and until now have no counterpart in dimension 3.

Our method has also reobtained some known first integrals for the Lorenz and Rikitake systems, though all cases have not been found, and despite the ''divergence enigma'' we now explain.

In both Lorenz and Rikitake systems, the divergence is a constant, respectively $-1-b-\sigma$ and $-2\,\mu$. In both cases, its vanishing triggers the vanishing of ν_5, but also the reduction of Equation (6) to a singularity from which no information can be extracted. However, the Rikitake dynamo possesses when $\mu=0$ a time-dependent first integral $I=x^2-y^2+4\,\beta z-4\,\alpha\beta t$; this kind of first integral cannot be detected by our method, since it does not arise from a Darboux polynomial, but from a polynomial $f(x,y,z)$ such that $df/dt=$ cst. Such a first integral may exist only for dynamical systems having a constant term, so there is no chance to find any for the Lorenz model. But there may be a first integral of some special kind — indeed, numerical experiments exhibit a regular behaviour when $1+b+\sigma=0$.

Table I summarises the results obtained by our method. Abbreviations are: DS for ''dynamical system,'' FI for ''first integral,'' and DE for ''Darboux element,'' i.e., a couple of polynomials (f,p) such that $df/dt=pf$.

The Kadomtsev–Petviashvili equation as a source of integrable model equations

Attilio Maccari
Technical Institute ''G. Cardano,'' Piazza della Resistenza 1, 00015 Monterotondo Rome, Italy

(Received 2 April 1996; accepted for publication 5 June 1996)

A new integrable and nonlinear partial differential equation (PDE) in 2+1 dimensions is obtained, by an asymptotically exact reduction method based on Fourier expansion and spatiotemporal rescaling, from the Kadomtsev–Petviashvili equation. The integrability property is explicitly demonstrated, by exhibiting the corresponding Lax pair, that is obtained by applying the reduction technique to the Lax pair of the Kadomtsev–Petviashvili equation. This model equation is likely to be of applicative relevance, because it may be considered a consistent approximation of a large class of nonlinear evolution PDEs. © *1996 American Institute of Physics.* [S0022-2488(96)03109-X]

I. INTRODUCTION

In the last years, various authors have studied the wave modulation induced by weak nonlinear effects, for a large class of nonlinear evolution equations in 1+1 and 2+1 dimensions, with a dispersive linear part. The most interesting result is that only a very limited number of model equations are necessary. These model equations are usually of applicative relevance (in plasma physics, nonlinear optics, hydrodynamics), because they are obtained by means of a reduction method from a large class of nonlinear evolution equations, under opportune approximations.[1–6]

It is clear from this method that the property of integrability is inherited through this limit technique and then our model equations are integrable, being sufficient that only an integrable equation is present in the large class from which they have been obtained. This method can be also applied to the weakly nonlinear ordinary differential equations.[7]

The first step of the reduction method (in 2+1 dimensions) is to use a moving frame of reference via the transformation

$$\xi=\epsilon^{p_1}(x-V_1t),\quad \eta=\epsilon^{p_2}(y-V_2t),\quad \tau=\epsilon^{q}t, \tag{1.1}$$

where $p_1,p_2>0$, $q>0$, and $V_1=V_1(K_1,K_2)$, $V_2=V_2(K_1,K_2)$ are the components of the group velocity $\mathbf{V}(\mathbf{K})\equiv(V_1(K_1,K_2),V_2(K_1,K_2))$ of the linearized equation, i.e. of the equation obtained after neglecting all the nonlinear terms and ϵ is the expansion parameter, supposed to be sufficiently small. The linear evolution is most appropriately described in terms of Fourier modes, which have a constant amplitude and a well-defined group velocity (the speed with which a wave packet peaked at that Fourier mode would move in ordinary space). To identify the nonlinear effects, we consider a specific Fourier mode and the frame of reference (1.1), which moves with the corresponding group velocity. We study the modulation, in terms of the variables defined above, of the amplitude of the Fourier mode, due to nonlinear effects. The modulation (that would remain constant in the absence of nonlinear effects) is best described in terms of the rescaled variables ξ,η,τ, that account for the need to look on larger space and time scales, to obtain a not negligible contribution from the nonlinear term.

In a precedent paper, this method has been applied to the Boussinesq equation and a new integrable nonlinear evolution PDE in 1+1 dimensions has been derived.[8] This line of research is now applied in 2+1 dimensions and the variable change (1.1) can be used, in case with a different

rescaling in the spatial variables ($p_1 \neq p_2$): if $p_1 > p_2$, the spatial scale for X is greater than the scale for Y, and *vice versa* if $p_1 < p_2$. In particular, we consider the Kadomtsev–Petviashvili (KP) equation[9] (integrable by means of the spectral transform[10]):

$$U_{xt}(x,y,t) + U_{xxxx}(x,y;t) + sU_{yy}(x,y,t) - 3(U^2(x,y,t))_{xx} = 0, \tag{1.2}$$

where $U = U(x,y,t)$ is real, $s = \pm 1$, and the subscripts denote differentiation. In the second section, we demonstrate that the modulation is governed by a model equation of nonlinear Schrodinger type, if $p_1 = p_2$:

$$i\Psi_\tau(\xi,\eta,\tau) + L_1\Psi(\xi,\eta,\tau) + \Psi(\xi,\eta,\tau)\Phi(\xi,\eta,\tau) = 0, \tag{1.3a}$$

$$L_2\Phi(\xi,\eta,\tau) = 2L_1(|\Psi(\xi,\eta,\tau)|^2), \tag{1.3b}$$

with $\Psi = \Psi(\xi,\eta,\tau)$ complex, $\Phi = \Phi(\xi,\eta,\tau)$ real, and the linear differential operators L_1 and L_2 given by

$$L_1 = \frac{1}{4}(1 - s\lambda^2)\frac{\partial^2}{\partial\xi^2} + s\lambda\frac{\partial}{\partial\xi}\frac{\partial}{\partial\eta} - s\frac{\partial^2}{\partial\eta^2}, \tag{1.3c}$$

$$L_2 = -\frac{1}{4}(1 + s\lambda^2)\frac{\partial^2}{\partial\xi^2} + s\lambda\frac{\partial}{\partial\xi}\frac{\partial}{\partial\eta} - s\frac{\partial^2}{\partial\eta^2}, \tag{1.3d}$$

with $\lambda = K_2/\sqrt{3}K_1^2$. The equation (1.3) belongs to a class first studied by Shulman.[11] If $p_1 \neq p_2$, a new model equation can be derived,

$$i\Psi_\tau(\xi,\eta,\tau) + \Psi_{\xi\xi}(\xi,\eta,\tau) + \Psi(\xi,\eta,\tau)\Phi(\xi,\eta,\tau) = 0, \tag{1.4a}$$

$$\Phi_\tau(\xi,\eta,\tau) + \Phi_\eta(\xi,\eta,\tau) + (|\Psi(\xi,\eta,\tau)|^2)_\xi = 0, \tag{1.4b}$$

with $\Psi = \Psi(\xi,\eta,\tau)$ complex and $\Phi = \Phi(\xi,\eta,\tau)$ real. Taking into account the above-mentioned reasons, it is expected that the equation (1.4) is of applicative relevance. If we take $\xi = \eta$, we recover the integrable equation in $1+1$ dimensions obtained in a precedent paper.[8]

In the third section, the Lax pair relative to Eqs. (1.4) is deduced from the Lax pair of the KP equation. Note that if we eliminate $\Phi_\eta(\xi,\eta,\tau)$ in the last equation (1.4b) by means of a trivial change of variables, at the same time a term $\Psi_\eta(\xi,\eta,\tau)$ appears in the first equation (1.4a).

Finally, in the last section the most important results are recapitulated and some possible extensions and generalizations indicated.

II. MODEL NONLINEAR PDEs OBTAINED FROM THE KADOMTSEV–PETVIASHVILI EQUATION

The linear dispersive part of the Kadomtsev–Petviashvili equation (1.2) is simply described in terms of Fourier modes, with a group velocity $\mathbf{V}(\mathbf{K}) = (V_1(K_1,K_2), V_2(K_1,K_2))$,

$$V_1(K_1,K_2) = -3K_1^2 - s\frac{K_2^2}{K_1^2}, V_2(K_1,K_2) = \frac{2sK_2}{K_1}. \tag{2.1}$$

We introduce a formal asymptotic Fourier expansion,

$$U(x,y,t) = \sum_{n=-\infty}^{n=+\infty} \epsilon^{\gamma_n}\psi_n(\xi,\eta,\tau;\epsilon)\exp\{in(K_1x + K_2y - \omega t)\}, \tag{2.2}$$

with $\gamma_n=|n|$, $\gamma_0=1+r$ a real number to be determined later on, and $\psi_{-n}(\xi,\eta,\tau;\epsilon)=\psi_n^*(\xi,\eta,\tau;\epsilon)$, because $U(x,y,t)$ is real. It is assumed that the limit of $\psi_n(\xi,\eta,\tau,\epsilon)$'s, for $\epsilon\to 0$, exists and is finite.

The final goal is to obtain the evolution equation for the modulation amplitude $\psi_1(\xi,\eta,\tau,\epsilon\to 0)=\Psi(\xi,\eta,\tau)$ and to understand how it is modified by choosing different wave numbers. In particular, an interesting result shall be derived, if the special condition $3K_1^4-K_2^2=0$ is verified.

The standard procedure is to consider the different equations obtained from the coefficients of the Fourier modes. To simplify the treatment, it is more convenient to separate the contributions from the linear and nonlinear parts: $\epsilon^{\gamma_n}[D_n\psi_n]=\epsilon^2 F_n$, where D_n is a linear differential operator acting on $\psi_n(\xi,\eta,\tau)$ and F_n is the contribution of the nonlinear part. The operator D_n is

$$D_n=|(-in\omega+\epsilon^q\partial_\tau-V_1(K_1,K_2)\epsilon^{p_1}\partial_\xi-V_2(K_1,K_2)\epsilon^{p_2}\partial_\eta)\times(\epsilon^{p_1}\partial_\xi+inK_1)+(inK_1+\epsilon^{p_1}\partial_\xi)^4+s(inK_2+\epsilon^{p_2}\partial_\eta)^2. \tag{2.3}$$

It is easily seen that the first F_n has the following explicit form:

$$F_0=6(|\Psi(\xi,\eta,\tau|^2)_{\xi\xi}\epsilon^{2p_1}+o(\epsilon^{2p_1+2},\epsilon^{2p_1+2r}), \tag{2.4a}$$

$$F_2=-12K_1^2\Psi^2(\xi,\eta,\tau)+o(\epsilon^{p_1}), \tag{2.4b}$$

$$F_1=-6K_1^2\Phi(\xi,\eta,\tau)\Psi(\xi,\eta,\tau)\epsilon^r-6K_1^2\psi_2(\xi,\eta,\tau)\Psi^*(\xi,\eta,\tau)\epsilon+O(\epsilon^{p_1+r},\epsilon^{p_1+1}), \tag{2.4c}$$

where $\Phi(\xi,\eta,\tau)=\psi_0(\xi,\eta,\tau)$. After taking $q=2$, $p_1=p_2=1$, $r=1$ for the proper balance of terms, we obtain for $n=0$,

$$V_1(K_1,K_2)\Phi_{\xi\xi}(\xi,\eta,\tau)+V_2(K_1,K_2)\Phi_{\xi\eta}(\xi,\eta,\tau)-s\Phi_{\eta\eta}(\xi,\eta,\tau)+6(|\Psi(\xi,\eta,\tau)|^2)_{\xi\xi}=0, \tag{2.5a}$$

and for $n=1$,

$$iK_1\Psi_\tau(\xi,\eta,\tau)-(6K_1+V_1(K_1,K_2))\Psi_{\xi\xi}(\xi,\eta,\tau)-V_2(K_1,K_2)\Psi_{\xi\eta}(\xi,\eta,\tau)+s\Psi_{\eta\eta}(\xi,\eta,\tau)+6(K_1^2\Phi(\xi,\eta,\tau)\Psi(\xi,\eta,\tau)-|\Psi(\xi,\eta,\tau)|^2\Psi(\xi,\eta,\tau))=0. \tag{2.5b}$$

After a trivial rescaling we arrive at the model equation (1.3). Note that for $K_2=\lambda=0$, we reproduce the Davey–Stewartson equation,[12] whose integrability is well known.[13] However, even if $\lambda\neq 0$, by means of a trivial transformation in the spatial variables, the λ can be eliminated, reducing thereby (1.3) to the Davey–Stewartson equation.

If $p_2>p_1$, a different result is obtained for $n=0$,

$$\Phi(\xi,\eta,\tau)=\frac{6K_1^2}{3K_1^4-K_2^2}\,|\Psi(\xi,\eta,\tau)|^2, \tag{2.6a}$$

with $\gamma_0=1+r=2$, and for $n=1$,

$$i\Psi_\tau(\xi,\eta,\tau)+A(K_1,K_2)\Psi_{\xi\xi}(\xi,\eta,\tau)+6K_1(\Phi(\xi,\eta,\tau)\times\Psi(\xi,\eta,\tau)+\psi_2(\xi,\eta,\tau)\Psi^*(\xi,\eta,\tau))=0, \tag{2.6b}$$

with $2p_1=q=2$. The standard unidimensional nonlinear Schrödinger equation is obtained,

$$i\Psi_\tau(\xi,\eta,\tau)+A(K_1,K_2)\Psi_{\xi\xi}(\xi,\eta,\tau)+B(K_1,K_2)|\Psi(\xi,\eta,\tau)|^2\Psi(\xi,\eta,\tau)=0, \tag{2.7a}$$

with

$$A(K_1,K_2)=-\frac{(3K_1^4+K_2^2)}{K_1^3}, \quad B(K_1,K_2)=\frac{6(3K_1^4+K_2^2)}{(3K_1^5-K_2^2K_1)}. \tag{2.7b}$$

If the relation $3K_1^4=K_2^2$ is verified, then $B(K_1,K_2)$ diverges and another derivation is necessary. For $n=0$ a new equation arises:

$$\Phi_\tau(\xi,\eta,\tau)+2K_1\sqrt{3}\Phi_\eta(\xi,\eta,\tau)-6(|\Psi(\xi,\eta,\tau)|^2)_\xi=0, \tag{2.8a}$$

with $p_2=q$, $r=1+p_1-p_2$.

Taking $n=1$, a new model nonlinear PDE is obtained:

$$i\Psi_\tau(\xi,\eta,\tau)-6K_1\Psi_{\xi\xi}(\xi,\eta,\tau)+6K_1\Psi(\xi,\eta,\tau)\Phi(\xi,\eta,\tau)=0, \tag{2.8b}$$

with $r+1=2p_1$, i.e., $p_1=\frac{2}{3}$, $p_2=\frac{4}{3}$, $r=\frac{1}{3}$, $q=\frac{4}{3}$.

After a trivial rescaling, we arrive at the nonlinear model equation (1.4). It is expected that it is integrable, taking into account that it has been obtained from an equation integrable by the spectral transform.

III. THE LAX PAIR FOR THE MODEL NONLINEAR PDE

The reduction method can be applied to the Lax pair of the Kadomtsev–Petviashvili equation, in order to demonstrate the integrability of (1.3) and (1.4) by the spectral transform. The Lax operators are

$$L=\frac{i}{\sqrt{3}}\frac{\partial}{\partial y}+\frac{\partial^2}{\partial x^2}-U(x,y,t), \quad L\varphi(x,y,t)=0, \tag{3.1}$$

$$A=4\frac{\partial^3}{\partial y^3}-6U(x,y,t)\frac{\partial}{\partial x}-3U_x(x,y,t)+i\sqrt{3}W(x,y,t), \tag{3.2}$$

with $W_x(x,y,t)=U_y(x,y,t)$ and

$$\varphi_t(x,y,t)+A\varphi(x,y,t)=0. \tag{3.3}$$

We introduce an asymptotic Fourier expansion,

$$\varphi(x,y,t)=\sum_{n=-\infty}^{n=+\infty}\epsilon^{\tilde{\gamma}_n}\varphi_n(\xi,\eta,\tau;\epsilon)\exp\left[i\frac{n}{2}z+i(\lambda_1x+\lambda_2y+\lambda_3t)\right], \tag{3.4}$$

where n is odd, $z=K_1x+K_2y-\omega t$, $\tilde{\gamma}_{n+2}=1+\tilde{\gamma}_n$ for $n>0$, $\tilde{\gamma}_{n-2}=\tilde{\gamma}_n+1$ for $n<0$, $\varphi_n(\xi,\eta,\tau,\epsilon)$'s are functions that parametrically depend on ϵ and remain finite if $\epsilon\to0$, and $\lambda_1,\lambda_2,\lambda_3$ are real constants to be determined later on. Inserting now the expression for $\sigma(x,y,t)$ in (3.1), the coefficients of the Fourier modes generate a series of relations; each relation must be valid for a given order of approximation in ϵ. In particular, for the fundamental harmonics $\varphi_\pm(x,y,t)=\varphi_{\pm1}(x,y,t)$, considering terms $O(\epsilon^0)$ in (3.1) and (3.3), the constants $\lambda_1,\lambda_2,\lambda_3$ can be fixed:

$$\lambda_1 = -\frac{K_1}{2}, \quad \lambda_2 = -\frac{\sqrt{3}}{2} K_1^2, \quad \lambda_3 = -2K_1^3. \tag{3.5}$$

The new spectral problem is obtained by means of the successive order ϵ for the equation (3.1), after choosing $\tilde{\gamma}_{-1} = \tilde{\gamma}_1 + \frac{1}{3}$ for the proper balance of terms,

$$i\varphi_{+,\eta}(\xi,\eta,\tau) - \varphi_{+,\xi\xi}(\xi,\eta,\tau) - \Phi(\xi,\eta,\tau)\varphi_+(\xi,\eta,\tau) + \Psi(\xi,\eta,\tau)\varphi_-(\xi,\eta,\tau) = 0, \tag{3.6a}$$

$$i\varphi_{-,\xi}(\xi,\eta,\tau) - \tfrac{1}{2}\Psi^*(\xi,\eta,\tau)\varphi_+(\xi,\eta,\tau) = 0. \tag{3.6b}$$

If the other equation (3.3) is considered, the spectral problem can be again obtained. The temporal evolution can be revealed, taking into account the next order of approximation of (3.3), but in doing so new quantities, the corrections $\tilde{\varphi}_\pm(\xi,\eta,\tau)$ of order ϵ to the fundamental harmonics $\varphi_\pm(\xi,\eta,\tau)$, appear. These unknown quantities can be eliminated in (3.3) taking advantage of the relation obtained from (3.1), considering terms of order ϵ^2. This elimination is possible only because Eqs. (3.1) and (3.3) are identical at the first order. The Lax pair of (1.4) is then

$$L = iD_1 \frac{\partial}{\partial\eta} + iD_2 \frac{\partial}{\partial\xi} + D_3 \frac{\partial^2}{\partial\xi^2} - \tilde{\Psi}(\xi,\eta,\tau), \quad L\hat{\varphi}(\xi,\eta,\tau) = 0, \tag{3.7a}$$

with

$$D_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad D_2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad D_3 = \begin{pmatrix} -1 & 0 \\ 0 & 0 \end{pmatrix}, \tag{3.7b}$$

$$\tilde{\Psi}(\xi,\eta,\tau) = \begin{pmatrix} \Phi(\xi,\eta,\tau) & -\Psi(\xi,\eta,\tau) \\ \frac{1}{2}\Psi^*(\xi,\eta,\tau) & 0 \end{pmatrix}, \quad |\hat{\varphi}(\xi,\eta,\tau) = \begin{pmatrix} \varphi_+ \\ \varphi_- \end{pmatrix}, \tag{3.7c}$$

and

$$A = -iD_1\Phi(\xi,\eta,\tau) - iD_1 \frac{\partial^2}{\partial\xi^2} - \hat{\Psi}(\xi,\eta,\tau) \frac{\partial}{\partial\xi} + \hat{\Psi}_\xi(\xi,\eta,\tau), \tag{3.7d}$$

with

$$\hat{\varphi}_\tau(\xi,\eta,\tau) + A\hat{\varphi}(\xi,\eta,\tau) = 0, \tag{3.7e}$$

$$\hat{\Psi}(\xi,\eta,\tau) = \begin{pmatrix} 0 & 0 \\ \frac{1}{2}\Psi^*(\xi,\eta,\tau) & 0 \end{pmatrix}. \tag{3.7f}$$

A similar calculation permits us to obtain the well-known Lax pair of the Davey–Stewartson equation (1.3).

IV. CONCLUSION

The results obtained in this paper identify a research line devoted to discovery nonlinear evolution PDEs, which are integrable and of applicative relevance. In particular, a new integrable nonlinear evolution PDE has been derived from the Kadomtsev–Petviashvili equation, by means of a reduction method based on Fourier decomposition and space–time rescalings [see (1.4)]. Moreover, the integrability property is explicitly demonstrated, because the Lax pair has been deduced, by applying the reduction method to the Lax pair of the original equation. Possible extensions and generalizations are now indicated: (i) study of the characteristics of the solutions of

(1.3); (ii) research of universal and integrable nonlinear PDEs in 2+1 and 3+1 dimensions obtained by the reduction method; (iii) approximate solution of a physically relevant nonlinear equation through the study of the correspondent integrable model equation.

Wronskian solutions of the constrained Kadomtsev–Petviashvili hierarchy

Walter Oevel[a] and Walter Strampp
Fachbereich 17-Mathematik/Informatik, Universität-GH Kassel, Holländische Str. 36, 34109 Kassel, Germany

(Received 22 September 1995; accepted for publication 12 June 1996)

The integrable Kadomtsev–Petviashvili (KP) hierarchy is compatible with generalized k-constraints of the type $(L^k)_- = \Sigma_i\, q_i \partial_x^{-1} r_i$. A large class of solutions—among them solitons—can be represented by Wronskian determinants of functions satisfying a set of linear equations. In this paper we shall obtain additional conditions for these functions imposed by the constraints. © *1996 American Institute of Physics.* [S0022-2488(96)04111-4]

I. THE CONSTRAINED KP HIERARCHY

The dynamics of the KP hierarchy is defined by the Lax equations

$$L_{t_n} = [L, (L^n)_-], \tag{I.1}$$

with the micro-differential operator $L = \partial_x + u_2 \partial_x^{-1} + u_3 \partial_x^{-2} + \ldots$. The dressing operator $W = 1 + w_1 \partial_x^{-1} + w_2 \partial_x^{-2} + \ldots$, related to the Lax operator by $L = W \partial_x W^{-1}$, satisfies Sato's equations

$$W_{t_n} = -(W \partial_x^n W^{-1})_- W. \tag{I.2}$$

The essence of Sato's theory[1–5] is the fact that solutions of Sato's equations can be expressed by a single function τ, which has to satisfy a hierarchy of *bilinear* equations. It is well-known[6–11] that the KP dynamics (I.1) is compatible with generalized k-constraints of the form

$$(L^k)_- = \sum_{i=1}^{M} q_i \partial_x^{-1} r_i \tag{I.3}$$

with suitable functions q_i and r_i. We note that such Lax operators are characterized by the existence of an M-th order differential operator

$$A = \partial_x^M + a_{M-1} \partial_x^{M-1} + \cdots + a_0$$

such that AL^k is a differential operator. The factor A needs to annihilate the functions q_i, i.e., $A(q_1) = \cdots = A(q_N) = 0$. Since an operator may be reconstructed from its kernel, A is uniquely determined if the Wronskian determinant $\mathscr{W}(q_1, \ldots, q_N)$ does not vanish. Similarly, there exists

$$B = \partial_x^M + b_{M-1} \partial_x^{M-1} + \cdots + b_0$$

such that $L^k B$ is a differential operator. The functions r_i span the kernel of the adjoint B^*. The constraint (1.3) reduces the KP dynamics to the hierarchy

$$(L^k)_{t_n} = [L^k, (L^n)_-], \quad (q_i)_{t_n} = (L^n)_+ (q_i), \quad (r_i)_{t_n} = -(L^{*n}) + (r_i)$$

[a]Permanent address: FB 17-Mathematik, University of Paderborn, 33095 Paderborn, Germany.

of 1+1-dimensional integrable equations. For $M=1$ the first three constraints yield the the AKNS hierarchy ($k=1$), the Yajima–Oikawa hierarchy ($k=2$) and a coupled Boussinesq type ($k=3$) hierarchy.[6–11]

II. WRONSKIAN SOLUTIONS

In the following we consider linearly independent functions $f_1,\ldots,f_N$ satisfying the infinite set of linear equations

$$\frac{\partial f_i}{\partial t_n}=f_i^{(n)}\equiv\frac{\partial^n f_i}{\partial x^n}. \tag{II.1}$$

Their Wronskian determinant

$$\mathscr{W}(f_1,\ldots,f_N)=\begin{vmatrix} f_1^{(0)} & \cdots & f_1^{(N-1)} \\ \vdots & \ddots & \vdots \\ f_N^{(0)} & \cdots & f_N^{(N-1)} \end{vmatrix}$$

is a τ-function of the KP hierarchy.[4] This implies that the N-th order differential operator $W=\partial_x^N+w_1\partial_x^{N-1}+\cdots+w_N$ given by

$$W=\frac{1}{\mathscr{W}(f_1,\ldots,f_N)}\begin{vmatrix} f_1^{(0)} & f_1^{(1)} & \cdots & f_1^{(N)} \\ \vdots & \vdots & \ddots & \vdots \\ f_N^{(0)} & f_N^{(1)} & \cdots & f_N^{(N)} \\ 1 & \partial_x & \cdots & \partial_x^N \end{vmatrix} \tag{II.2}$$

provides a dressing operator satisfying (1.2). [The finite micro-differential operator $W\partial_x^{-N}=1+w_1\partial_x^{-1}+\cdots+w_N\partial_x^{-N}$ also satisfies (I.2) and is the dressing operator of Sato's theory.] In this formal determinant an expansion with respect to the last row is understood, in which all subdeterminants are collected on the left of the differential symbols. With this representation it is clear that the action of W on an arbitrary function g is given by

$$W(g)=\frac{\mathscr{W}(f_1,\ldots,f_N,g)}{\mathscr{W}(f_1,\ldots,f_N)}. \tag{II.3}$$

In particular, $W(f_1)=\cdots=W(f_N)=0$, so that formula (II.2) provides the reconstruction of a normalized ordinary differential operator from its kernel.

We shall study the effect of the k-constraint on the entries of the Wronskian τ-function. We will make use of the following technical lemma:

Lemma: The micro-differential inverse of the dressing operator (II.2) *is given by*

$$W^{-1}=\sum_{i=1}^{N} f_i\partial_x^{-1}g_i$$

with

$$g_i=(-1)^{N-i}\,\frac{\mathscr{W}(f_1,\ldots,f_{i-1},f_{i+1},\ldots,f_N)}{\mathscr{W}(f_1,\ldots,f_N)}. \tag{II.4}$$

Proof: The functions g_i are the solutions of the linear system

$$\begin{pmatrix} f_1^{(0)} & \cdots & \cdots & f_N^{(0)} \\ \vdots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ f_1^{(N-1)} & \cdots & \cdots & f_N^{(N-1)} \end{pmatrix} \begin{pmatrix} g_1 \\ \vdots \\ \vdots \\ g_N \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}.$$

From these equations and using the algebraic rule

$$f\partial_x^{-1} = \partial_x^{-1} f + \partial_x^{-2} f^{(1)} + \partial_x^{-3} f^{(2)} + \ldots,$$

for the symbol ∂_x^{-1} one finds

$$\left(W \sum_{i=1}^{N} f_i \partial_x^{-1} g_i \right)_+ = \left(W \sum_{k=0}^{\infty} \partial_x^{-k-1} \sum_{i=1}^{N} f_i^{(k)} g_i \right)_+ = \left(W \partial_x^{-N} \left(1 + \sum_{k=N}^{\infty} \partial_x^{N-k-1} \sum_{i=1}^{N} f_i^{(k)} g_i \right) \right)_+ = 1.$$

On the other hand,

$$\left(W \sum_{i=1}^{N} f_i \partial_x^{-1} g_i \right)_- = \sum_{i=1}^{N} (W(f_i)) \partial_x^{-1} g_i = 0,$$

whence $W\Sigma_i f_i \partial_x^{-1} g_i = 1$. Q.E.D.

The following theorem provides a simple criterion for the Wronskian entries $f_1, \ldots, f_N$ leading to k-constrained KP flows:

Theorem: *The KP solution $L = W\partial_x W^{-1}$ generated by the Wronskian τ-function $\mathscr{W}(f_1, \ldots, f_N) \neq 0$ satisfies the k-constraint (I.3) with some suitable functions $q_1, \ldots, q_M$ and $r_1, \ldots, r_M$ if and only if*

$$\mathscr{W}(f_1, \ldots, f_N, f_{i_1}^{(k)}, \ldots, f_{i_{M+1}}^{(k)}) = 0 \tag{II.5}$$

for all $(M+1)$-tupel of indices $1 \leqslant i_1 < \cdots < i_{M+1} \leqslant N$, which is equivalent to

$$\mathscr{W}\left(\frac{\mathscr{W}(f_1, \ldots, f_N, f_{i_1}^{(k)})}{\mathscr{W}(f_1, \ldots, f_N)}, \ldots, \frac{\mathscr{W}(f_1, \ldots, f_N, f_{i_{M+1}}^{(k)})}{\mathscr{W}(f_1, \ldots, f_N)} \right) = 0 \tag{II.6}$$

for all such indices.

Proof: The equivalence between (II.5) and (II.6) is provided by the Wronskian identity

$$\mathscr{W}\left(\frac{\mathscr{W}(f_1, \ldots, f_N, h_1)}{\mathscr{W}(f_1, \ldots, f_N)}, \ldots, \frac{\mathscr{W}(f_1, \ldots, f_N, h_{M+1})}{\mathscr{W}(f_1, \ldots, f_N)} \right) = \frac{\mathscr{W}(f_1, \ldots, f_N, h_1, \ldots, h_{M+1})}{\mathscr{W}(f_1, \ldots, f_N)}, \tag{II.7}$$

which holds for arbitrary functions $f_1, \ldots, f_N$ and $h_1, \ldots, h_{M+1}$. It is proven in the appendix.

Using the previous lemma one finds

$$(L^k)_- = (W\partial_x^k W^{-1})_- = \sum_{i=1}^{N} (W(f_i^{(k)})) \partial_x^{-1} g_i \tag{II.8}$$

with g_i defined by (II.4). Hence, the constraint (I.3) with $M = N$ is always satisfied for KP solutions generated by $N \times N$-Wronskians. It is claimed that the conditions (II.5)/(II.6) reduce the sum from N to M terms.

First, we show that (II.6) follows from (I.3). As already remarked in Section I, for L satisfying (I.3) there exists an M-th order differential operator A such that AL^k is a differential operator. Application to $W(f_i)=0$ yields

$$0=AL^k(W(f_i))=AW\partial_x^k(f_i)=A(W(f_i^{(k)})).$$

Formula (II.3) leads to

$$W(f_i^{(k)})=\frac{\mathscr{W}(f_1,\ldots,f_N,f_i^{(k)})}{\mathscr{W}(f_1,\ldots,f_N)}\in kernel\ \ (A).$$

Since the kernel of A has dimension M, at most M of these functions can be linearly independent, whence (II.6) obtains. Conversely, if (II.6) holds, then at most M of the functions $W(f_i^{(k)})$ are linearly independent. Consequently, they can be expressed by M functions $q_1,\ldots,q_M$:

$$\frac{\mathscr{W}(f_1,\ldots,f_N,f_i^{(k)})}{\mathscr{W}(f_1,\ldots,f_N)}=\sum_{i=1}^{M} c_{ij}q_j,\quad i=1,\ldots,N,$$

with some constants c_{ij} and (II.8) reduces to

$$(L^k)=\sum_{i=1}^{N}\left(\sum_{j=1}^{M} c_{ij}q_j\right)\partial_x^{-1}g_i=\sum_{j=1}^{M} q_j\partial_x^{-1}\left(\sum_{i=1}^{N} c_{ij}g_i\right). \tag{II.9}$$

$Q.E.D.$

III. EXAMPLE

We consider 2×2-Wronskians $\tau=\mathscr{W}(f_1,f_2)$ with

$$f_1=\exp(c_1+\lambda_1 x+\lambda_1^2 y+\lambda_1^3 t)+\exp(d+\mu x+\mu^2 y+\mu^3 t),$$

$$f_2=\exp(c_2+\lambda_2 x+\lambda_2^2 y+\lambda_2^3 t)+\exp(c_3+\lambda_3 x+\lambda_3^2 y+\lambda_3^3 t)$$

with arbitrary constants c_i,λ_i,d,μ. These functions satisfy the linear equations (II.1) with $t_1=x,t_2=y$ and $t_3=t$, whence $u(x,y,t)=\ln(\tau)_{xx}$ satisfies the KP equation

$$4u_{tx}=(u_{xxx}+12uu_x)_x+3u_{yy}. \tag{III.1}$$

Using the theorem in the last section we will derive conditions on the parameters such that the k-constraint (I.3) with $M=1$ is satisfied. The criterion (II.5) yields a single equation

$$0=\mathscr{W}(f_1,f_2,f_1^{(k)},f_2^{(k)})=(\mu^k-\lambda_1^k)(\lambda_2^k-\lambda_3^k)V(\lambda_1,\lambda_2,\lambda_3,\mu)e^{c_1+c_2+c_3+d}e^{(\lambda_1+\lambda_2+\lambda_3+\mu)x}e^{(\lambda_1^2+\lambda_2^2+\lambda_3^2+\mu^2)y}e^{(\lambda_1^3+\lambda_2^3+\lambda_3^3+\mu^3)t}$$

with the Vandermonde determinant

$$V(\lambda_1,\lambda_2,\lambda_3,\mu)=\begin{vmatrix}1&\lambda_1&\lambda_1^2&\lambda_1^3\\1&\lambda_2&\lambda_2^2&\lambda_2^3\\1&\lambda_3&\lambda_3^2&\lambda_3^3\\1&\mu&\mu^2&\mu^3\end{vmatrix}.$$

It may be satisfied by the choice $\mu=\lambda_2$. Putting $d=c_2$, the τ-function yields

$$\tau=(\lambda_2-\lambda_1)e^{\eta_1+\eta_2}+(\lambda_3-\lambda_2)e^{\eta_2+\eta_3}+(\lambda_3-\lambda_1)e^{\eta_1+\eta_3},$$

where

$$\eta_i=c_i+\lambda_i x+\lambda_i^2 y+\lambda_i^3 t, \quad i=1,2,3.$$

The constraint $(L^k)_-=q\partial_x^{-1}r$ is satisfied with

$$q:=(\lambda_3^k-\lambda_2^k)\frac{\mathscr{W}(f_1,f_2,f_1^{(k)})}{\mathscr{W}(f_1,f_2)}=(\lambda_1^k-\lambda_2^k)\frac{\mathscr{W}(f_1,f_2,f_2^{(k)})}{\mathscr{W}(f_1,f_2)}$$
$$=\frac{(\lambda_1-\lambda_2)(\lambda_2-\lambda_3)(\lambda_3-\lambda_1)(\lambda_1^k-\lambda_2^k)(\lambda_3^k-\lambda_2^k)}{(\lambda_2-\lambda_1)e^{-\eta_3}+(\lambda_3-\lambda_1)e^{-\eta_2}+(\lambda_3-\lambda_2)e^{-\eta_1}},$$

and, according to (II.9)/(II.4),

$$r:=\left(\frac{f_2}{(\lambda_2^k-\lambda_3^k)}+\frac{f_1}{(\lambda_1^k-\lambda_2^k)}\right)\frac{1}{\mathscr{W}(f_1,f_2)}$$
$$=\frac{e^{-\eta_1-\eta_2-\eta_3}}{(\lambda_1^k-\lambda_2^k)(\lambda_3^k-\lambda_2^k)}\frac{(\lambda_3^k-\lambda_2^k)e^{\eta_1}+(\lambda_3^k-\lambda_1^k)e^{\eta_2}+(\lambda_2^k-\lambda_1^k)e^{\eta_3}}{(\lambda_3-\lambda_2)e^{-\eta_1}+(\lambda_3-\lambda_1)e^{-\eta_2}+(\lambda_2-\lambda_1)e^{-\eta_3}}.$$

These functions are regular for $\lambda_1<\lambda_2<\lambda_3$ and, for fixed y and t, bounded in x, if $\lambda_1<0$, $\lambda_2=0$, $\lambda_3>0$. The KP solution $u=\ln(\tau)_{xx}$ consists of three solitary waves located in (x,y,t)-space along the planes $\eta_1\approx\eta_2$, $\eta_2\approx\eta_3$ and $\eta_1\approx\eta_3$, respectively. In particular, choosing $\lambda_1=$, $\lambda_2=0$, $\lambda_3=-\lambda$, $c_1=c$, $c_2=0$, $c_3=-c$ one finds

$$q=\frac{(-1)^k\lambda^{2(k+1)}}{1+e^{-\lambda^2 y}\cosh(c+\lambda x+\lambda^3 t)}$$

and

$$r=\begin{cases}-\dfrac{1}{\lambda^{k+1}}\dfrac{e^{-\lambda^2 y}+\cosh(c+\lambda x+\lambda^3 t)}{e^{\lambda^2 y}+\cosh(c+\lambda x+\lambda^3 t)} & \text{for odd } k,\\ -\dfrac{1}{\lambda^{k+1}}\dfrac{\sinh(c+\lambda x+\lambda^3 t)}{e^{\lambda^2 y}+\cosh(c+\lambda x+\lambda^3 t)} & \text{for even } k.\end{cases}$$

For $k=1$ one has $L=\partial_x+q\partial_x^{-1}r$, whence q,r satisfy the first flows of the AKNS hierarchy

$$q_y=q_{xx}+2q^2r, \quad r_y=-r_{xx}-2qr^2$$

and

$$q_t=q_{xxx}+6qrq_x, \quad r_t=r_{xxx}+6qrr_x,$$

respectively. A solution of the KP equation (III.1) is given by $u=qr$. Plots of u and q in the (x,y)-plane at time $t=0$ are given in Figures 1 and 2 for $\lambda_1=-1$, $\lambda_2=0$, $\lambda_3=1$, $c_1=c_2=c_3=0$.

IV. CONCLUDING REMARKS

We have found necessary and sufficient conditions reducing a Wronskian solution of the general KP hierarchy to solutions of the k-constrained hierarchy. We have relied on properties of differential operators resulting from *finite* dressing operators. Of course, the same goal could have

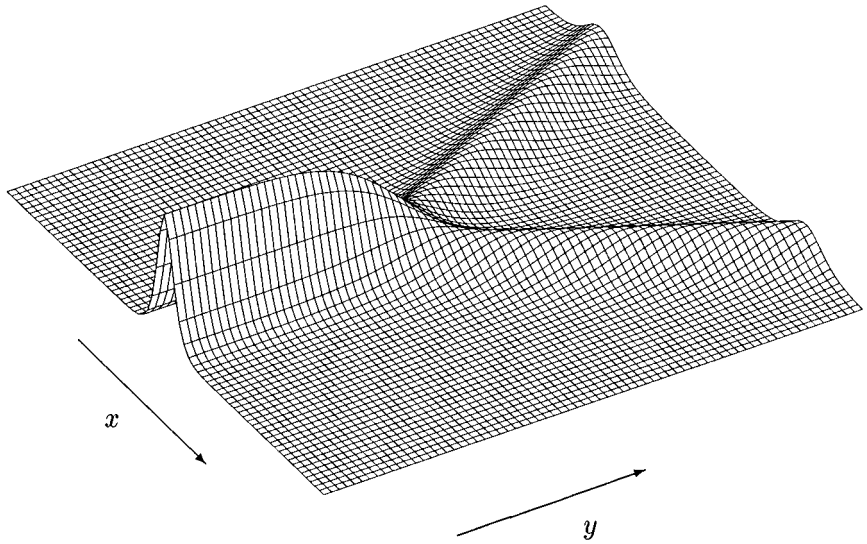

FIG. 1. $u(x,y,t)$ for $t = 0$.

been achieved by formulating additional equations for general τ-functions which then might be specialized to τ-functions of Wronskian type. The constraints for general τ-functions, however, are technically more involved. For special cases some results exist: the simplest additional condition on the τ-function in the cases $k=1$ and 2, respectively, is a trilinear form[12,13] and a quattrolinear form,[13,14] respectively. For Wronskian τ-functions these general conditions reduce to the results of the theorem in Sec. II.

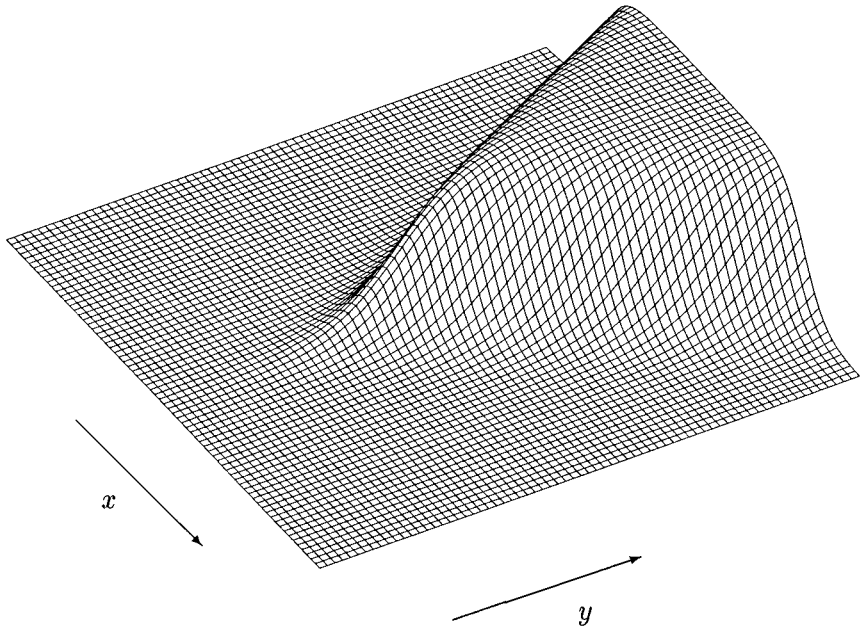

FIG. 2. $q(x,y,t)$ for $t = 0$.

APPENDIX: PROOF OF THE WRONSKIAN IDENTITY (II.7)

With some given family of functions $f_{n+1}^{[n]}, f_{n+2}^{[n]}, \ldots$, one considers ''iterated Darboux transformations'' defined by the recursion

$$f_i^{[k+1]} := \frac{\mathscr{W}(f_{k+1}^{[k]}, f_i^{[k]})}{f_{k+1}^{[k]}}, \quad i,k = n, n+1, \ldots .$$

Crum's classical result[15] is that after K such recursive steps the resulting functions have the Wronskian representation

$$f_i^{[n+K]} = \frac{\mathscr{W}(f_{n+1}^{[n]}, \ldots, f_{n+k}^{[n]}, f_i^{[n]})}{\mathscr{W}(f_{n+1}^{[n]}, \ldots, f_{n+K}^{[n]})}. \tag{A.1}$$

Comparing the results for $(n,K) = (0, N+m)$ and $(n,K) = (N,m)$ one finds for $i = N+m+1$:

$$f_{N+m+1}^{[N+m]} = \frac{\mathscr{W}(f_1^{[0]}, \ldots, f_{N+m+1}^{[0]})}{\mathscr{W}(f_1^{[0]}, \ldots, f_{N+m}^{[0]})} = \frac{\mathscr{W}(f_{N+1}^{[N]}, \ldots, f_{N+m+1}^{[N]})}{\mathscr{W}(f_{N+1}^{[N]}, \ldots, f_{N+m}^{[N]})}. \tag{A.2}$$

Denoting $f_i^{[0]} = f_i$ for $i = 1, \ldots, N$ and $f_{N+i}^{[0]} = h_i$ for $i = 1, \ldots, m+1$ one has

$$f_{N+i}^{[N]} = \frac{\mathscr{W}(f_1, \ldots, f_N, h_i)}{\mathscr{W}(f_1, \ldots, f_N)}, \quad i = 1, \ldots, m+1$$

from (A.1) with $n=0$, $K=N$ and (A.2) yields

$$f_{N+m+1}^{[N+m]} = \frac{\mathscr{W}(f_1, \ldots, f_N, h_1, \ldots, h_{m+1})}{\mathscr{W}(f_1, \ldots, f_N, h_1, \ldots, h_m)} = \frac{\mathscr{W}\left(\frac{\mathscr{W}(f_1, \ldots, f_N, h_1)}{\mathscr{W}(f_1, \ldots, f_N)}, \ldots, \frac{\mathscr{W}(f_1, \ldots, f_N, h_{m+1})}{\mathscr{W}(f_1, \ldots, f_N)}\right)}{\mathscr{W}\left(\frac{\mathscr{W}(f_1, \ldots, f_N, h_1)}{\mathscr{W}(f_1, \ldots, f_N)}, \ldots, \frac{\mathscr{W}(f_1, \ldots, f_N, h_m)}{\mathscr{W}(f_1, \ldots, f_N)}\right)}.$$

Multiplication of these identities with $m = 0, \ldots, M$ yields (II.7). Q.E.D.

(Received 16 January 1996; accepted for publication 15 August 1996)

In this paper, we study adiabatic Hamiltonian systems including those subject to small-amplitude forcing and damping. It is known that simple zeroes of the adiabatic Poincare–Arnold–Melnikov function imply the existence of primary intersection points of the stable and unstable manifolds of hyperbolic orbits. Here, we present an Nth-order Melnikov function whose simple zeroes correspond to Nth-order transverse intersection points and hence to N-pulse homoclinic orbits. Using this function, it can be shown that N-pulse homoclinic orbits arise in a plethora of adiabatic models, including systems with slowly varying potentials. The theory is illustrated on a damped Hamiltonian system with a slowly varying cubic potential. In addition, the Nth-order adiabatic Melnikov function is useful for showing the existence of multi-pulse resonant periodic orbits in the special class of slow, time-periodic systems. © *1996 American Institute of Physics.*

I. INTRODUCTION

Adiabatic invariance theory in mechanics has a long and rich history; see, e.g., Ref. 1. Adiabatic invariance theory was developed for slowly varying $[\mathcal{O}(\varepsilon)]$ Hamiltonian systems, and it applies to all orbits in regions where the ratio of the small parameter ε to the instantaneous orbit frequency is small. The terms in the series for the adiabatic invariant become disordered and the expansion ceases to be valid, however, near slowly-varying separatrices where the instantaneous orbital frequency approaches zero.

The dynamics of special and general orbits in these separatrix-swept regions has been the object of much recent study, for applications and development of the theory (see, e.g., Refs. 1–10 and also the references in Ref. 11). In time-periodic adiabatic systems, the existence of many resonant hyperbolic periodic orbits in these regions has been established via topological shooting,[7,8] and via matched asymptotic expansions,[4,12] among others. Moreover, for general adiabatic systems with general, not necessarily periodic, hyperbolic orbits in these regions, adiabatic separatrix crossing theory gives the change in a general orbit's adiabatic invariant and the canonically conjugate phase variable after it crosses an instantaneous separatrix. See Refs. 1, 5, and 6 for the full development and references to earlier works; see also Ref. 13.

For time periodic systems, chaos has been discovered in these regions.[3] The existence of the periodic orbits and bounded nonperiodic orbits in a Smale–Birkhoff horseshoe, as well as a kneading theory, have been established in two examples via topological shooting.[7,8] Moreover, the presence of Smale–Birkhoff homoclinic chaos can also be shown using the adiabatic Melnikov function.[2,4,14,15] Further studies of the chaotic structure in these separatrix-swept regions—including lobe area, homoclinic tangle geometry, island size, and the genericity of these results—are presented in Refs. 9, 16, and 17. The main tools used in these later works include an adiabatic separatrix crossing map[16] and an action theoretic derivation of the adiabatic Melnikov function.[9,17] See also Ref. 18.

Many of the physical problems modeled by slowly varying systems are not purely Hamiltonian, however, and are instead subject to small amplitude forcing and damping. For example, the slowly varying system arising in the model of resonant sloshing[7,12] is only Hamiltonian when viscosity is neglected. The presence of viscosity results in small amplitude dissipation in the governing equations.[12] Dissipation also plays an important role in capture-into-resonance, particle

0022-2488/96/37(12)/6220/30/$10.00

dynamics in modulated waves, transport in charged particle beams, and other physical systems.

While one expects many of the homoclinic and periodic orbits to survive when forcing and damping are added, there exists a general need to detect precisely which ones do, and where they lie in phase space and for what range of forcing and damping they exist. The Hamiltonian methods used in Refs. 9, 16, and 17 are not applicable when dissipation is included. In contrast, the adiabatic Melnikov function still applies, and hence the existence of persistent homoclinic orbits can still be demonstrated. Also, numerical evidence is presented in Ref. 12 showing that the resonant periodic orbits in the sloshing model can be continued into the nonzero dissipation regime, and it is thought that the topological shooting method can be extended, as well, as indicated in Ref. 7.

Many questions, however, remain open. How can one detect multiple pulse homoclinic orbits? For what parameter values do they occur? Near which parameter values do homoclinic tangencies occur? For special time-periodic systems, what is the geometry of the single-pulse and multi-pulse periodic orbits near these homoclinic orbits?, just to name a few.

In this paper, we develop a method to answer some of these questions. In particular, we establish a higher-order adiabatic Melnikov theory for slowly modulated Hamiltonian systems, which may also be subject to forcing and damping:

$$\dot{q}=\frac{\partial H}{\partial p}(q,p,z)+\varepsilon\mu f_1(q,p,z),\quad \dot{p}=-\frac{\partial H}{\partial q}(q,p,z)+\varepsilon\mu f_2(q,p,z),\quad \dot{z}=\varepsilon, \tag{1.1}$$

where $0<\varepsilon\ll 1$, $\mu>0$, the Hamiltonian H is four times continuously differentiable with a slowly varying parameter z, and f_1, f_2 are $\mathcal{C}^3$. When $\varepsilon=0$, (1.1) is a one-parameter family of ''frozen'' or unperturbed systems. Under the assumption that for each z in a finite interval this system possesses an orbit that is homoclinic (or heteroclinic) to a saddle fixed point(s), we construct a function of ε and z that we call the Nth-order adiabatic Melnikov function. Our main result shows that simple zeroes of this function imply the existence of transverse Nth-order homoclinic intersections of stable and unstable manifolds of (1.1) corresponding to N-pulse homoclinic orbits for the full system (1.1), provided ε is sufficiently small. First-order intersection points are points at which the finite segments of the local manifolds between the fixed point and the intersection point have only the intersection point in common, and these first-order intersections correspond to one-pulse homoclinic orbits. Secondary intersection points are points at which a segment of one manifold between two adjacent (as measured by arclength) first intersection points intersects the other local manifold, and they correspond to two-pulse homoclinic orbits, and so forth for all finite N.

Of course, in the special case of H being periodic in z, the existence of one principal intersection point automatically implies the existence of infinitely many of them, as Poincare showed. However, this new higher-order function is needed to establish the existence of higher-order intersection points for general H.

Also, in the special case of H being periodic in z, the existence and local uniqueness of periodic orbits of all periods automatically follows from the Smale–Birkhoff Homoclinic Theorem (see, e.g., Ref. 19). The precise geometric location of these periodic orbits can be determined using the Lambda Lemma (for scalar z) or by geometric singular perturbation theory (in the case of scalar z, and also for vector valued z) in conjunction with the Nth-order Melnikov function (see Ref. 10 for applications). These periodic orbits make one or more fast excursions away from a hyperbolic periodic solution. In this way, the Nth-order adiabatic Melnikov function enables one to generalize the results of Refs. 7, 8, and 12 for special conservative cases of slowly varying sinusoidal and cubic potentials to the entire class of systems (1.1), even to those with dissipation. During their fast excursions, the multi-pulse resonant periodic orbits stay close to the multi-pulse homoclinic orbits studied here. Thus, precise asymptotic information about the location of many N-pulse periodic orbits can also be gained with the Nth-order adiabatic Melnikov function.

In the global bifurcations at which segments of stable and unstable manifolds are tangent to each other, pairs of stable and unstable periodic orbits are created. Tangencies of these manifolds occur when the Nth-order adiabatic Melnikov function has higher-order zeroes. Hence, the Nth-order adiabatic Melnikov function can also be used to detect homoclinic tangencies and the associated creation of resonant periodic orbits.

The theory developed here is illustrated on an example of a Hamiltonian system, including dissipation, with a cubic potential whose slow variation in z is periodic. We identify and classify all the higher-order intersection points—and their corresponding multi-pulse homoclinic orbits—obtained by the intersection of a segment of the unstable manifold and a segment of the stable manifold. We find several different types of multi-pulse homoclinic orbits, including those that make their fast excursions in rapid succession and those that spend a longer amount of time in between excursions.

In the special case when $\mu=0$ in (1.1) and when H is periodic in z, the general theoretical method developed here is similar to the adiabatic separatrix-crossing map used in Ref. 16. In their vertex–intervertex map, the energy and time variables for an orbit are updated using the slow rate of change of the action and the period, respectively, evaluated at the appropriate vertices. By comparison, in our work, the energy change is measured by the adiabatic Melnikov function, and the period is essential for measuring the time between vertices, and hence for calculating the slow time at which to evaluate the Melnikov function. The methods yield the same result since the adiabatic Melnikov function is equal to the rate of pulsation of the critical (instantaneous separatrix) action, as shown in Refs. 9 and 17. Thus, the set of zeroes of M_A corresponds to the set Λ_e in Ref. 16, and the exact location of higher-order intersection points may be determined either by applying the separatrix-crossing map as demonstrated in Sec. 3.5 of Ref. 16 or by computing the appropriate higher-order adiabatic Melnikov function.

Finally, we remark that our work was inspired in part by the recently developed[20] higher-order Melnikov theory for planar Hamiltonian systems subject to general, small-amplitude, time-periodic perturbations:

$$\dot{x}=\frac{\partial H}{\partial y}(x,y)+\delta g_1(x,y,t), \quad \dot{y}=-\frac{\partial H}{\partial y}(x,y)+\delta g_2(x,y,t),$$
