where the convergence of the series is intended in the usual matrix norm, which also implies convergence in the $\tau_{\mathscr{F}}$ topology. Furthermore, in the Ising model and in the Heisenberg model, if we restrict to $\mathscr{F}_0$, it is certainly possible to define the algebraic dynamics as the following infinite sum:

$$\alpha_t(A)=\sum_{k=0}^{\infty}\frac{t^k}{k!}\,(\delta^{(k)}(A)),$$

since one can prove that the series again converges with respect to the $\tau_{\mathscr{F}}$ or $\tau_{\mathscr{F}_0}$ topology, respectively. Obviously we have $\alpha_t(A)\in\mathfrak{U}$ for all $A\in\mathfrak{U}_0$.

As mentioned in Sec. II, for each $\{n\}\in\mathscr{F}$ the problem of the existence of the thermodynamical limit of α_V^t can be considered in each CQ^*-algebra $(\mathscr{B}(\mathscr{H}_M,\mathscr{H}_{\overline{M}}),*,\mathscr{B}(\mathscr{H}_M),\flat)$. This can be useful when the family $\mathscr{F}$ of states is so poor as to consist of only one state.

This is not the case of the (almost) mean-field models, since for them the family $\mathscr{F}$ is quite rich. Nevertheless, it still makes sense to consider for these models this CQ^*-algebraic approach.

From the first part of this section we know, in fact, that the almost ergodic means S_V^i converge in the topology $\tau_{\mathscr{F}}$, so that they converge with respect to each norm $\|\cdots\|_{M_{\{n\}},\overline{M}_{\{n\}}}=\|\,e^{-M_{\{n\}}}\cdots e^{-M_{\{n\}}}\|$ for any choice of the sequence $\{n\}$ in the set $\mathscr{F}$, and the same obviously holds true, even for the finite volume dynamics α_V^t. Therefore, in each of these CQ^*-algebras the thermodynamical limit of α_V^t is well defined, even if it is necessarily representation dependent. This is not a major problem in the models we are considering since something nice happens here: as far as the sequence $\{n\}$ is chosen in $\mathscr{F}$, or in $\mathscr{F}_0$ for the Heisenberg model, $\alpha_V^t(A)$ converges always to the same element, modulo $\pi_{\{n\}}(I)$. For instance, in the Ising model, $\pi_{\{n\}}(S_V^3)$ converges to $2Jt\eta n_3\pi_{\{n\}}(I)$ in any norm $\|\ \|_{M_{\{n\}},\overline{M}_{\{n\}}}$, where η and n_3 are fixed by the definition of $\mathscr{F}$. A consequence of this fact is the convergence of $\pi_{\{n\}}(\alpha_V^t(A))$ for each $A\in\mathfrak{U}_0$.

Of course, this procedure strongly relies on the specific models we are considering, since there is no reason *a priori* to be sure that the limit of a certain α_V^t does not depend on the way in which this limit is performed!

B. Spin models with bubbles

In this section we discuss some more models with a direct physical meaning that are unitarily equivalent to those discussed above and whose thermodynamical behavior can easily be determined. We will see that the models below still give rise to finite volume algebraic dynamics converging when $|V|\to\infty$.

We start with proving a first *equivalence* result, which relates different Hamiltonians. Let us consider a certain finite lattice region Ω, which we may suppose to be contained in any volume V for $|V|>|\Omega|$.

Let us now define the finite volume Hamiltonian,

$$H_V^{\rm tr}=\frac{1}{|V|^{\gamma}}\sum_{p,q\in V} T_pT_q\,, \tag{3.5}$$

where $T_p=(\gamma\cdot\sigma)_p$

We have the following.

Proposition III.1: Let H_V^{tr} be as in (3.5) and suppose that, $\forall p\notin\Omega, T_p=\sigma_p^3$. A unitary operator U of the form

$$U=\exp\left\{i\sum_p m_p\cdot\sigma_p\right\},$$

such that $H_V^{tr}=UH_V^{\mathcal{T}}U^*$ exists if and only if each vector γ_p has a norm equal to unity. In this case one finds explicitly

$$m_p=\begin{cases}\left(\dfrac{\pi\sqrt{2}\,\gamma_p^1}{4\sqrt{1+\gamma_p^3}},\dfrac{\pi\sqrt{2}\,\gamma_p^2}{4\sqrt{1+\gamma_p^3}},\dfrac{\pi\sqrt{2}\,\gamma_p^3}{4\sqrt{1+\gamma_p^3}}\right), & \forall p\in\Omega,\\ 0, \quad otherwise.\end{cases} \tag{3.6}$$

Proof: We prove first the necessity. If such a U exists it must necessarily transform σ_p^3 into T_p, so that $T_p=U\sigma_p^3U^*$, $\forall p\in V$. Indicating with $\|\ \|_V$ the vector norm and with $\|\ \|$ the C^* norm, and using some easy properties of the σ matrices, we must have simultaneously $\|T_p\|=\|(\gamma\cdot\sigma)_p\,,\|=\|\gamma_p\|_V$ and $\|T_p\|=\|U\sigma_p^3U^*\|=\|\sigma_p^3\|=1$.

Vice versa, let us suppose that $\|\gamma_p\|=1$. We want to show that it is possible to choose an operator U as above that maps one Hamiltonian into the other. The proof is straightforward. We have to solve the following system (in which we have omitted the lattice site index):

$$\begin{cases}-\dfrac{\sin(2m)}{m}\,m_2+2m_3m_1\left(\dfrac{\sin(m)}{m}\right)^2=\gamma_1,\\ \dfrac{\sin(2m)}{m}\,m_1+2m_3m_2\left(\dfrac{\sin(m)}{(m)}\right)^2=\gamma_2,\\ \cos(2m)+2m_3^2\left(\dfrac{\sin(m)}{m}\right)^2=\gamma_3.\end{cases} \tag{3.7}$$

where $m^2=m_1^2+m_2^2+m_3^2$. It is now very easy to verify that the solution (3.6) satisfies, in the hypothesis $\|\gamma_p\|_V=1$, the above system and corresponds to $m=\pi/2$. □

The models described by $H_V^{\rm tr}$ can all be thought of as *bubble* models. They describe, in fact, a situation in which inside a certain bubble of finite size, Ω, the spin variables are not necessarily in the z direction, while outside this region all the spins are polarized along z. From the

literature,[11,5,6] it is reasonable to expect that the algebraic dynamics of this bubble model still converges. This should essentially follow from the fact that the family $\mathscr{F}$ is closed under local transformations.

Here we will adopt a different approach, which allows us to conclude directly that the thermodynamical limit exists. Let us define

$$\widetilde{\alpha}^t_V(A) \equiv e^{iH^{\mathrm{tr}}_V t} A e^{-iH^{\mathrm{tr}}_V t},$$

where $A \in \mathfrak{U}_0$. We now verify that, for each $A \in \mathfrak{U}_0$, $\widetilde{\alpha}'_V(A)$ is a Cauchy net in the topology $\tau_{\mathscr{F}}$. This depends on the fact that $\alpha'_V(A)$ is, in turn, a $\tau_{\mathscr{F}}$-Cauchy net. We have, indeed,

$$\begin{aligned}\|\pi_{\{n\}}(\widetilde{\alpha}^t_V(A) - \widetilde{\alpha}^t_{V'}(A))\|_{M_{\{n\}},\overline{M_{\{n\}}}} &= \|\pi_{\{n\}}(U(\alpha^t_V(\widetilde{A}) - \alpha^t_{V'}(\widetilde{A}))U^*)\|_{M_{\{n\}},\overline{M_{\{n\}}}} \\ &\leqslant \|\pi_{\{n\}}(\alpha^t_V(\widetilde{A}) - \alpha^t_{V'}(\widetilde{A}))\|_{M_{\{n\}},\overline{M_{\{n\}}}} \to 0,\end{aligned}$$

where $\widetilde{A} \equiv U^* A U$. Here we took into account the inequality

$$\|\pi_{\{n\}}(XY)\|_{M_{\{n\}},\overline{M_{\{n\}}}} \leqslant \|\pi_{\{n\}}(X)\|_{M_{\{n\}},\overline{M_{\{n\}}}} \|Y\|, \quad \forall X, Y \in \mathfrak{U}_0,$$

and we made use of the fact that $e^{iH^{\mathrm{tr}}_V t} A e^{-iH^{\mathrm{tr}}_V t} = U e^{iH_V t} \widetilde{A} e^{-iH_V t} U^*$. Convergence to zero of the above limit when both V and V' diverge is ensured by the existence of the dynamics α_t on the whole $\mathfrak{U}_0$.

Of course, the group property of α_t is also shared by $\widetilde{\alpha}_t$, like the other properties discussed for the original model.

A similar conclusion can also be stated for the Heisenberg model. Even in this case it is possible to consider bubble models related to this and to study the thermodynamical limit of the algebraic dynamics.

Proposition III.2: Let H^{tr}_V be

$$H^{\mathrm{tr}}_V = \frac{1}{|V|^\gamma} \sum_{p,q \in V} \sum_{i=1}^{3} T^i_p T^i_q,$$

and suppose that $\forall p \notin \Omega, T^i_p = \sigma^i_p$. *A unitary operator* U *of the form*

$$U = \exp\left\{ i \sum_p m_p \cdot \sigma_p \right\},$$

such that $H^{\mathrm{tr}}_V = U H^{\mathscr{H}}_V U^*$ *exists only if the vectors* γ^i_p *form, for any* $p \in V$, *a set of right-handed versors*.

The proof is very simple and will be omitted here. It is more useful to notice that we can only prove a necessary condition for the transformation between the two Hamiltonians to be possible. Nevertheless, it is reasonable to expect that the above condition is also sufficient for the existence of the operator U. Its geometrical interpretation is clear: we start with an orthonormal system of normalized vectors and we obtain another analogous system of vectors. *Vice versa*, to get an orthonormal system of normalized vectors we expect that the starting point should be a triplet of similar versors.

Then, in conclusion, also these bubble models, as well as any other unitarily equivalent model, can be setted in the framework discussed in Sec. II.

APPENDIX A: AN OVERVIEW OF MATHEMATICAL DEFINITIONS

In this appendix we collect some basic facts on partial *-algebras, quasi *-algebras, and CQ^*-algebras, which are needed for a better understanding of the paper. For more details we refer to Refs. 14, 15, 16, 2, 3, and 4 and to Refs. 17 and 18 for reviews.

A partial *-algebra is a vector space $\mathfrak{A}$ with involution $A\to A^*$ [i.e., $(A+\lambda B)^*=A^*+\overline{\lambda}B^*$; $A=A^{**}$] and a subset $\Gamma\subset\mathfrak{A}\times\mathfrak{A}$, such that (i) $(A,B)\in\Gamma$ implies $(B^*,A^*)\in\Gamma$; (ii) (A,B) and $(A,C)\in\Gamma$ imply $(A,B+\lambda C)\in\Gamma$; and (iii) if $(A,B)\in\Gamma$, then there exists an element $AB\in\mathfrak{A}$, and for this multiplication the distributive property holds in the following sense: if $(A,B)\in\Gamma$ and $(A,C)\in\Gamma$ then

$$AB+AC=A(B+C).$$

Furthermore $(AB)^*=B^*A^*$.

The product is not required to be associative.

The partial *-algebra $\mathfrak{A}$ is said to have a unit if there exists an element I (necessarily unique) such that $I^*=I$, $(I,A)\in\Gamma$, $IA=AI=A$, $\forall A\in\mathfrak{A}$.

If $(A,B)\in\Gamma$ then we say that A is a left multiplier of B [and write $A\in L(B)$] or B is a right multiplier of A [$B\in R(A)$]. For $\mathscr{S}\subset\mathfrak{A}$ we put $L.\mathscr{S}=\cap_{A\in\mathscr{S}}L(A)$; the set $R.\mathscr{S}$ is defined in an analogous way. The set $M.\mathscr{S}=L.\mathscr{S}\cap R.\mathscr{S}$ is called the set of universal multipliers of $\mathscr{S}$.

Following Lassner,[2,3] we call quasi *-algebras a special family of partial *-algebras: namely, those for which the set $M\mathfrak{A}$ of universal multipliers is a *-algebra.

Let $\mathfrak{A}$ be a linear space and $\mathfrak{A}_0$ a *-algebra contained in $\mathfrak{A}$. We say that $\mathfrak{A}$ is a quasi *-algebra with distinguished *-algebra $\mathfrak{A}_0$ (or, simply, over $\mathfrak{A}_0$) if (i) the right and left multiplications of an element of $\mathfrak{A}$ and an element of $\mathfrak{A}_0$ are always defined and linear; and (ii) an involution * (which extends the involution of $\mathfrak{A}_0$) is defined in $\mathfrak{A}$ with the property $(AB)^*=B^*A^*$ whenever the multiplication is defined.

A quasi *-algebra $(\mathfrak{A},\mathfrak{A}_0)$ is said to have a unit I if there exists an element $I\in\mathfrak{A}_0$ such that $AI=IA=A$, $\forall A\in\mathfrak{A}$.

A quasi *-algebra $(\mathfrak{A},\mathfrak{A}_0)$ is said to be a topological quasi *-algebra if in $\mathfrak{A}$ is defined a locally convex topology ξ such that (a) the involution is continuous and the multiplications are separately continuous; and (b) $\mathfrak{A}_0$ is dense in $\mathfrak{A}[\xi]$.

In Ref. 4 we considered a special class of quasi *-algebras, called CQ^*-algebras, which arise as completions of C^*-algebras.

*Definition 1: A rigged quasi *-algebra $\mathfrak{A}$ is a partial *-algebra for which there exist two vector subspaces $\mathfrak{A}_\flat$ and $\mathfrak{A}_\sharp$, such that* (i) $(\mathfrak{A}_\flat)^*=\mathfrak{A}_\sharp$; (ii)

$$\Gamma\{(A,B)\in\mathfrak{A}\times\mathfrak{A}:A\in\mathfrak{A}_\sharp \quad or \quad B\in\mathfrak{A}_\flat\};$$

and (iii) *both $\mathfrak{A}_\flat$ and $\mathfrak{A}_\sharp$ are algebras with respect to the partial multiplication $(A,B)\in\Gamma\to AB\in\mathfrak{A}$ defined in $\mathfrak{A}$.*

The multiplication $(A,B)\in\Gamma\to AB\in\mathfrak{A}$ is supposed to be (weakly) semiassociative; *i.e.* $(AB)C=A(BC)\forall A\in\mathfrak{A}$ *and* $\forall B,C\in\mathfrak{A}_\flat$.

*Definition 2: A rigged quasi *-algebra $\{\mathfrak{A},*,\mathfrak{A}_\flat,\flat\}$ is called a CQ^*-algebra if (i) $\mathfrak{A}$ is a Banach space under the norm and $\|A^*\|=\|A\|$, $\forall A\in\mathfrak{A}$; (ii) $\mathfrak{A}_\flat$ is a C^*-algebra with respect to the norm $\|\ \|_\flat$ and to the involution $\flat$; (iii) $\mathfrak{A}_\sharp$ carries the norm $\|\ \|_\sharp$, defined by $\|A\|_\sharp\equiv\|A^*\|_\flat$ (thus the involution * is an isometric anti-isomorphism of $\mathfrak{A}_\flat$ onto $\mathfrak{A}_\sharp$) and $A^{\sharp *}=A^{*\flat}$, $\forall A\in\mathfrak{A}_\sharp$; (iv) $\|B\|_\flat=\sup_{\|A\|\le 1}\|AB\|$; and (v) $\mathfrak{A}_0=\mathfrak{A}_\flat\cap\mathfrak{A}_\sharp$ is $\|\ \|_\flat$ dense in $\mathfrak{A}_\flat$ and $\mathfrak{A}_\flat$ is $\|\ \|$ dense in $\mathfrak{A}$.*

A very interesting example of CQ^*-algebras is provided by the families of bounded operators acting in a triplet of Hilbert spaces.

Let $\mathscr{H}$ be a Hilbert space with scalar product $\langle\cdot,\cdot\rangle$ and $\lambda(\cdot,\cdot)$ a positive sesquilinear closed form defined on a dense domain $\mathscr{D}_\lambda\subset\mathscr{H}$. Then $\mathscr{D}_\lambda$ becomes a Hilbert space, that we denote by $\mathscr{H}_\lambda$, with respect to the scalar product

$$\langle f,g\rangle_\lambda = \langle f,g\rangle + \lambda(f,g).$$

Let $\mathscr{H}_\lambda^-$ be the Hilbert space of conjugate linear forms on $\mathscr{H}_\lambda$.

In this way one gets the triplet of Hilbert spaces,

$$\mathscr{H}_\lambda \subset \mathscr{H} \subset \mathscr{H}_\lambda^-.$$

Let $\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$ be the Banach space of bounded operators from $\mathscr{H}_\lambda$ into $\mathscr{H}_\lambda^-$ and let us denote with $\|A\|_{\lambda\lambda}^-$ the natural norm of $A \in \mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$.

The involution in $\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$, is defined in the following way: to each element $A \in \mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$, we associate the linear map A^* from $\mathscr{H}_\lambda$ into $\mathscr{H}_\lambda^-$, defined by the equation

$$\langle A^* f,g\rangle = \overline{\langle Ag,f\rangle}, \quad \forall f,g \in \mathscr{H}_\lambda.$$

Then one has $A^* \in \mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$ and $\|A^*\|_{\lambda\lambda}^- = \|A\|_{\lambda\lambda}^-, \forall A \in \mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$.

Let $\mathscr{B}(\mathscr{H}_\lambda)$ denotes the C^*-algebra of bounded operators on $\mathscr{H}_\lambda$ [the usual involution of $\mathscr{B}(\mathscr{H}_\lambda)$ will be denoted here as $\flat$] and $\mathscr{B}(\mathscr{H}_\lambda^-)$ the C^*-algebra of bounded operators on $\mathscr{H}_\lambda^-$ [the natural involution of $\mathscr{B}(\mathscr{H}_\lambda^-)$ is denoted as $\sharp$]. Then, both $\mathscr{B}(\mathscr{H}_\lambda)$ and $\mathscr{B}(\mathscr{H}_\lambda^-)$ are contained in $\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$ and $A \in \mathscr{B}(\mathscr{H}_\lambda)$ if, and only if, $A^* \in \mathscr{B}(\mathscr{H}_\lambda^-)$. Moreover, $B^\flat{}^* = B^{*\sharp}, \forall B \in \mathscr{B}(\mathscr{H}_\lambda)$.

With the algebraic operations defined in the natural way $(\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-), *, \mathscr{B}(\mathscr{H}_\lambda), \flat)$ is a rigged quasi *-algebra. The distinguished *-algebra of $\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$ is

$$\mathscr{B}^+(\mathscr{H}_\lambda) = \{A \in \mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-) : A, A^* \in \mathscr{B}(\mathscr{H}_\lambda)\}.$$

Moreover, $(\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-), *, \mathscr{B}(\mathscr{H}_\lambda), \flat)$ is a CQ^*-algebra if $\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$ and $\mathscr{B}(\mathscr{H}_\lambda)$ carry their natural norms. In fact, $\mathscr{B}^+(\mathscr{H}_\lambda)$ is dense in $\mathscr{B}(\mathscr{H}_\lambda, \mathscr{H}_\lambda^-)$, and the other requirements of the definition of CQ^*-algebra are also fulfilled. For the details see Ref. 4, Example 3.3.

The CQ^*-algebras considered in Secs. I and II of this paper are all of this kind. They are obtained when the form λ is taken as the form associated to the closed operator e^M.

The general structure of CQ^*-algebras simplifies for the so-called proper CQ^*-algebras.

Definition 3: A CQ^*-algebra $\{\mathfrak{U}, *, R\mathfrak{U}, \flat\}$ is called proper if $R\mathfrak{U} = L\mathfrak{U}$ and if $A^\flat = A^\sharp, \forall A \in R\mathfrak{U}$.

In Ref. 4 it is proved that from the above definition it follows that (i) $\|A\|_\sharp = \|A\|_\flat, \forall A \in R\mathfrak{U}$; (ii) all the Abelian CQ^*-algebras (i.e., $R\mathfrak{U} = L\mathfrak{U}$ and $AB = BA, \forall A \in \mathfrak{U}, B \in R\mathfrak{U}$) are proper.

As said before, CQ^*-algebras arise naturally as completions of C^*-algebras with respect to a weaker norm. Indeed the following is true.

Proposition 4: Let $\mathscr{C}$ be a C^*-algebra with norm $\|\ \|_1$ and involution $*$. Let $\|\ \|$ be another norm on $\mathscr{C}$, weaker than $\|\ \|_1$ and such that (i) $\|A\| = \|A^*\|, \forall A \in \mathscr{C}$; (ii) $\|AB\| \leq \|A\| \|B\|_1, \forall A, B \in \mathscr{C}$. *Then the completion $\hat{\mathscr{C}}$ of $\mathscr{C}$, with its natural norm, is a proper CQ^*-algebra over $\mathscr{C}$, with $* = \flat$.*

A more detailed study of CQ^*-algebras has been undertaken in Ref. 19.

(Received 20 February 1996; accepted for publication 20 May 1996)

The space of analytical test functions ξ, rapidly decreasing on the real axis (i.e., Schwartz test functions of the type $\mathscr{S}$ on the real axis), is used to construct the rigged Hilbert space (RHS) $(\xi,\mathscr{H},\xi')$. Gamow states (GS) can be defined in RHS starting from Dirac's formula. It is shown that the expectation value of a self-adjoint operator acting on a GS is real. We have computed exactly the probability of finding a system in a GS and found that it is finite. The validity of recently proposed approximations to calculate the expectation value of self-adjoint operators in a GS is discussed. © *1996 American Institute of Physics.* [S0022-2488(96)00209-5]

I. INTRODUCTION

The proper treatment of the continuum and the inclusion of decaying states belonging to it in the definition of Green's functions of physical interest is a long-standing problem in various fields of physics. The mathematical consequences of the inclusion of the continuum in the scattering of particles by a central potential have been explored by Gamow long ago.[1] A modern review of the scattering theory can be found in Ref. 2 where the basic elements of the involved radial differential equations are presented in great detail. The use of these states, as it has been shown by Gamow,[1] is of central importance in building the physical interpretation of the α-decay mode of heavy atomic nuclei.[3] The so-called Gamow resonant states [for simplicity Gamow states (GS)] fulfill purely outgoing boundary conditions with an exponential behavior at infinity.[2] Several methods have been proposed since the publication of Gamow's work,[4] particularly in connection with the normalizability of Green's functions in the presence of GS and in the treatment of completeness relations.[5] The mathematical equivalence between some of these methods has been discussed recently and the correspondence between Bergreen's and Mittag-Lefler's representations has been explored at length.[6] Presently a rich literature is available regarding the application of these concepts to nuclear reactions and to nuclear structure problems.[7]

The amount of information about mathematical properties of representations which include GS is also very rich. The use of decaying states of complex energy in the framework of the Hamiltonian formalism, and the use of deformed contours to compute survival amplitudes, has been reported in Ref. 8 by Sudarshan and co-workers. The formulation of quantum mechanics in the rigged Hilbert space (RHS) has been also studied by Bohm.[9] In Ref. 10 it is shown that idealized resonances are described, within the RHS, by generalized eigenvectors of a self-adjoint Hamiltonian with complex eigenvalues and a Breit–Wigner energy distribution. Similar arguments have been advanced by Gadella.[11,12,13] Among the difficulties posed by the use of GS one can mention the appearance of the exponential catastrophe and the need to include nonphysical

states of negative energy in the definition of GS by an integral on the real axis.[14] A nonrigorous cure for the exponential catastrophe would be the use of some regularization techniques, such as the one proposed by Zel'dovich.[15] However, and with reference to explicit numerical applications, the use of these techniques does not guarantee the stability of the results since the onset of the exponential dominance of the GS can manifest itself at physical scales.[5] Among the recent references on GS we shall mention the work of T. Berggren,[16] where the possibility of defining expectation values of operators in a resonant state is considered. In the present work we shall focus our attention on the mathematical aspects of representations which include Gamow states. At variance with the usually adopted approach, i.e., by using the class of functions known as Hardy class functions,[11–13] we shall use tempered ultradistributions.[17,–20] The space of analytical functionals ξ' (tempered ultradistributions) is the minimal space whose Fourier antitransform accomodates real exponential functions as distributions. In the first part of this work the definition of the space of analytical test functions ξ is given and the corresponding RHS is constructed. Then Dirac's formulation of quantum mechanics in RHS is shown, the structure of GS is given explicitly, and the norm of GS in RHS is calculated. The contribution of GS to $P(E)$, the probability distribution of a system at energy E, is obtained and the relation with the Breit–Wigner weighted energy distribution is studied. Next, some examples of GS as analytical functionals are given. Finally, a comparison with Berggren's results on expectation values with resonant states is presented.

II. THE RIGGED HILBERT SPACE ($\xi,\mathscr{H},\xi'$)

Let us consider the space ξ of entire analytical test functions $\hat{\phi}(z)$ rapidly decreasing on the real axis, i.e., $\hat{\phi}(z)|_{y=0}=\phi(x)$ is a test function of the Schwartz space $\mathscr{S}$ (see Refs. 17–21).

The structure of a countable normed space of ξ is given by the family of norms

$$\|\hat{\phi}\|_n=\sup_{|z|=n}|\hat{\phi}(z)|, \quad n\in\mathscr{N}. \tag{1}$$

These norms are compatible since

$$\|\hat{\phi}\|_n<\|\hat{\phi}\|_{n+1}. \tag{2}$$

In ξ we define the scalar product

$$\langle\hat{\psi},\hat{\phi}\rangle=\int_{-\infty}^{+\infty}dE\ \overline{\hat{\psi}}(E)\hat{\phi}(E) \tag{3}$$

and the norm

$$\|\hat{\phi}\|^2=\langle\hat{\phi},\hat{\phi}\rangle. \tag{4}$$

The space ξ is completed by using the norm of Eq. (4); the resulting space is the Hilbert space $\mathscr{H}$ of square-integrable functions ($\xi\subset\mathscr{H}$).

If ξ' are linear continuous functionals (distributions) over ξ, we have (Refs. 17–21)

$$\xi\subset\mathscr{H}\subset\xi'. \tag{5}$$

Here ξ is a nuclear space (see Ref. 22) and $(\xi,\mathscr{H},\xi')$ is a RHS or a Guelfand's triplet (GT). In this RHS a linear and symmetric operator A acting on ξ, which admits a self-adjoint prolongation $\overline{A}$ acting on $\mathscr{H}$, has a complete set of eigen-functionals on ξ' with real generalized eigenvalues.[23,24] Let us introduce the GT $(\tilde{\xi},\mathscr{H},\tilde{\xi}')$ which is related to the GT given in Eq. (5) by the Fourier transform

$$\phi(t)=\mathscr{F}^{-1}\{\hat{\phi}(E)\}=\frac{1}{2\pi}\int_{-\infty}^{+\infty}e^{iEt}\hat{\phi}(E)dE. \tag{6}$$

If $\hat{\psi}(E)\in\xi'$, we define $\psi(t)$ by

$$\langle\psi(t),\phi(t)\rangle=\frac{1}{2\pi}\langle\hat{\psi}(E),\hat{\phi}(E)\rangle. \tag{7}$$

Consequently, one has

$$\psi(t)=\mathscr{F}^{-1}\{\hat{\psi}(E)\} \tag{8}$$

with

$$\phi(t)\in\widetilde{\xi},\quad \psi(t)\in\widetilde{\xi}'. \tag{9}$$

The Schwartz space $\mathscr{S}'$ (of tempered distributions) is included in ξ' and in $\widetilde{\xi}'$ ($\mathscr{S}'\subset\xi'$). The distributions of $\mathscr{S}'$ fulfill Dirac's formula[17]

$$S(x)=\int_{-\infty}^{+\infty}\delta(x-y)S(y)dy. \tag{10}$$

The extension to ξ' of Dirac's formula is given by[17]

$$\hat{\psi}_c(z)=\frac{1}{2\pi i}\int_{-\infty}^{+\infty}\frac{1}{E-z}\,\hat{\psi}(E)dE, \tag{11}$$

where

$$\hat{\psi}(E)=\hat{\psi}_c(E+i0)-\hat{\psi}_c(E-i0). \tag{12}$$

Related to the RHS $(\widetilde{\xi},\mathscr{H},\widetilde{\xi}')$ [and $(\xi,\mathscr{H},\xi')$], it exists the abstract GT $(\xi_a,\mathscr{H}_a,\xi_a')$. This relation is established with the help of the operator $\hat{x}$, representing in $\mathscr{H}_a$ the position operator x of $\mathscr{H}$. The operator $\hat{x}$ has a complete set of eigenfunctions in ξ_a'. We use for them Dirac's notation $|x\rangle$. To each abstract ket $|\phi\rangle\in\xi_a$ it corresponds a function $\langle x|\phi\rangle=\phi(x)\in\widetilde{\xi}$. In other words, to each function $\phi(x)\in\widetilde{\xi}$, it corresponds an abstract ket $|\phi\rangle\in\xi_a$, such that $\langle x|\phi\rangle=\phi(x)$. This procedure establishes the above-mentioned relation between $\widetilde{\xi}$ and ξ_a. When the space ξ is completed we obtain the Hilbert space $\mathscr{H}$, while the correspondence just established leads to the complete abstract space $\mathscr{H}_a(\supset\xi_a)$. Finally, any linear continuous functional ψ in $\widetilde{\xi}'$ is made to correspond to that abstract ket, $|\psi\rangle\in\xi_a'$, such that

$$\psi(\phi)=\langle\psi|\phi\rangle \tag{13}$$

for all $\phi\in\widetilde{\xi}$.

These relations represent Dirac's formalism of quantum mechanics in a RHS. For more details see the works cited in Ref. 25.

The principal difference between the triplets defined above and those considered in Ref. 11 are due to the fact that our space ξ is formed by ''ultra analytic'' test functions; i.e., any $\phi\in\xi$ is entire-analytic and rapidly decreasing on the real axis. The dual space ξ' is formed by ''ultradistributions'' (see Refs. 17–20). The space $\widetilde{\xi}'$ is the minimal space that contains real exponentials. It also allows the representation of any ultradistribution by a pair of analytic functions that can be determined by Eqs. (11) and (12).

Let us now introduce a self-adjoint operator $H \in \mathscr{H}$, such that

$$H|E\rangle = E|E\rangle, \quad E_0 < E < E_1. \tag{14}$$

We shall consider all the $\hat{\psi} \in \xi'$ with support (in the sense of Ref. 17) in the interval (E_0, E_1). This means that $\hat{\psi}$ can be determined from the discontinuity $\psi(E)$ of the pair of analytic functions on the real axis. Furthermore, $\psi(E) = 0$ if $E \notin (E_0, E_1)$.

Following Eq. (11) one can write

$$\hat{\psi}(E_G) = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E - E_G} \hat{\psi}(E) dE \tag{15}$$

and

$$(\hat{\psi}(E_G))^* = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E_G^* - E} (\hat{\psi}(E))^* \, dE \tag{16}$$

with

$$E_G = E_D + i\Gamma, \quad \Gamma > 0.$$

In Dirac's notation, $\hat{\psi}(E) = \langle E|\psi\rangle$. Thus

$$\hat{\psi}(E_G) = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E - E_G} \langle E|\psi\rangle dE, \tag{17}$$

$$(\hat{\psi}(E_G))^* = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E_G^* - E} \langle \psi|E\rangle dE. \tag{18}$$

We can also write Eq. (17) as

$$\hat{\psi}(E_G) = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E - E_G} \langle E|dE|\psi\rangle.$$

We now define

$$\langle E_G| = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E - E_G} \langle E|dE \tag{19}$$

and

$$|E_G^*\rangle = \frac{1}{2\pi i} \int_{E_0}^{E_1} \frac{1}{E_G^* - E} |E\rangle dE. \tag{20}$$

In consequence,

$$\hat{\psi}(E_G) = \langle E_G|\psi\rangle, \tag{21}$$

$$(\hat{\psi}(E_G))^* = \langle \psi|E_G^*\rangle. \tag{22}$$

The state $|E_G^*\rangle$ is by definition a Gamow state. Note that if $\hat{\psi}(E)$ is the discontinuity of $\hat{\psi}_c(z)$ on the real axis, then $E^n \hat{\psi}(E)$ is the discontinuity of $z^n \hat{\psi}(z)$ also on the real axis.

Then we have [cf. Eq. (20)]

$$E_G{}^{*n}|E_G{}^*\rangle = \frac{1}{2\pi i}\int_{E_0}^{E_1}\frac{1}{E_G{}^*-E}\,E^n|E\rangle dE,$$

i.e.,

$$H^n|E_G{}^*\rangle = \frac{1}{2\pi i}\int_{E_0}^{E_1}\frac{1}{E_G{}^*-E}\,H^n|E\rangle dE \tag{23}$$

$$= E_G{}^{*n}|E_G{}^*\rangle, \tag{24}$$

and $|E_G{}^*\rangle$ is an eigenstate of H.

The states $|E_G{}^*\rangle$ are normalizable and the norm is given by

$$\langle E_G|E_G^*\rangle = \frac{1}{4\pi^2\Gamma}\left[\arctan\left(\frac{E_1-E_D}{\Gamma}\right)-\arctan\left(\frac{E_0-E_D}{\Gamma}\right)\right]. \tag{25}$$

With this normalization, and for the $E_1\to\infty$ and $E_0\to-\infty$, the normalized GS can be cast in the more familiar form of Ref. 14.

In consequence, the diagonal matrix element of H between GS is given by the expression

$$\langle E_G|H|E_G^*\rangle = E_D+\frac{\Gamma}{2}\,\frac{\ln\left[\dfrac{(E_1-E_D)^2+\Gamma^2}{(E_0-E_D)^2+\Gamma^2}\right]}{\left[\arctan\left(\dfrac{E_1-E_D}{\Gamma}\right)-\arctan\left(\dfrac{E_0-E_D}{\Gamma}\right)\right]}. \tag{26}$$

With this result it is readily seen that the imaginary part of the diagonal matrix element satisfies

$$\mathrm{Im}\langle E_G|H|E_G^*\rangle = 0, \tag{27}$$

and that for the limits $E_0\to-\infty$ and $E_1\to+\infty$ one has

$$\langle E_G|H|E_G^*\rangle = E_D\,. \tag{28}$$

The time evolution of a GS is given by

$$\langle\psi|e^{-iHt}|E_G{}^*\rangle = e^{-iE_G{}^*t}(\hat{\psi}(E_G))^* \tag{29}$$

as a consequence of Eqs. (11) and (23).

The probability distribution associated to a GS is given by

$$P(E)=|\langle E|E_G^*\rangle|^2=\frac{\Gamma}{(E-E_D)^2+\Gamma^2}\cdot\frac{1}{\left[\arctan\left(\dfrac{E_1-E_D}{\Gamma}\right)-\arctan\left(\dfrac{E_0-E_D}{\Gamma}\right)\right]}. \tag{30}$$

In the limit $E_1\to+\infty$, $E_0\to-\infty$, the above equation yields

$$P(E)=\frac{\Gamma/\pi}{(E-E_D)^2+\Gamma^2}, \tag{31}$$

which is the Breit–Wigner form proposed by Ref. 16.

Let us introduce the self-adjoint operator A, which is acting on $\mathscr{H}_a$,

$$A=\int_{-\infty}^{+\infty}|\lambda\rangle\lambda\, d\sigma_a(\lambda)\langle\lambda|, \tag{32}$$

where $\sigma_a(\lambda)$ is given by

$$\sigma_a(\lambda)=\begin{cases}\displaystyle\sum_{n=-\infty}^{+\infty}\Theta(\lambda-\lambda_n), & \lambda<\lambda_0\\ \lambda, & \lambda_0<\lambda<\lambda_1,\end{cases} \tag{33}$$

and where Θ is a Heaviside step function. The expectation value of A between GS

$$\langle E_G|A|E_G{}^*\rangle=\int_{-\infty}^{+\infty}\langle E_G|\lambda\rangle\lambda\, d\sigma_a(\lambda)\langle\lambda|E_G{}^*\rangle \tag{34}$$

is real since $\langle E_G|\lambda\rangle=(\langle\lambda|E_G^*\rangle)^*$. So far, the results which we have presented are based on the use of the theory of tempered ultradistributions. In order to illustrate them we shall discuss some simple examples.

For the first case we have adopted the plane waves

$$\langle E|x\rangle=\frac{e^{-iEx}}{\sqrt{2\pi}}.$$

From Eq. (11) one obtains

$$\langle E_G|x\rangle=\sqrt{2\Gamma}\ \mathrm{sgn}[\mathrm{Im}(E_G)]e^{-iE_Gx} \tag{35}$$

for the wavefunction of a GS.[26]

The second example is given by the function

$$\langle E|x\rangle=[\Theta(E-E_0)-\Theta(E-E_1)]\frac{e^{-iEx}}{\sqrt{2\pi}},$$

and for this case Eq. (11) yields

$$\langle E_G|x\rangle=\frac{C}{2\pi i}\,[\ln(E_G-E_1)-\ln(E_G-E_0)]e^{-iE_Gx}, \tag{36}$$

where C is a constant.[26]

As it can be seen from these examples, the GS can be obtained as tempered ultradistributions.

III. BERGGREN APPROXIMATION

In the following we shall discuss the validity of the approximation proposed by Berggren[16] to calculate the expectation value of an operator in a resonant state. Following Berggren's notation, let us introduce the state $|k,\hat{k},l\rangle$ and the continuum wavefunction $\langle\mathbf{x}|k,\hat{k},l\rangle=\phi_k^{(+)}(\mathbf{r})$.

Then, since the energy E is given by

$$E(\mathbf{k})=\frac{k^2}{2m}, \tag{37}$$

the GS can be defined by

$$|E_G{}^*\rangle = \frac{\sqrt{\Gamma}}{i\sqrt{\pi/2}} \int_0^{+\infty} \frac{|E(\mathbf{k}),\hat{k},l\rangle}{E_G{}^* - E}\, dE. \tag{38}$$

One can write

$$|k,\hat{k},l\rangle = \sqrt{\frac{k}{m}}\, |E(\mathbf{k}),\hat{k},l\rangle \tag{39}$$

and, consequently,

$$|E_G{}^*\rangle = \frac{\sqrt{\Gamma}}{i\sqrt{\pi/2}} \int_0^{+\infty} \sqrt{\frac{k}{m}}\, \frac{|k,\hat{k},l\rangle}{E_G{}^* - E(\mathbf{k})}\, dk, \tag{40}$$

$$\langle E_G|A|E_G{}^*\rangle = \frac{2\Gamma}{\pi} \sum_{l,l'} \int_0^{+\infty} dk \int_0^{+\infty} dk'\, \frac{\sqrt{kk'}}{m}\, \frac{\langle k',\hat{k}',l'|A|k,\hat{k},l\rangle}{(E(\mathbf{k}') - E_G)(E(\mathbf{k}) - E_G{}^*)} \tag{41}$$

[see Eq. (2) of Ref. 16]. We are now in a position to compare the result provided by the present method, about the expectation value of an operator in a resonant GS, and Berggren's conjecture, namely,

$$\langle A\rangle = \mathrm{Re}\langle E_G{}^*|A|E_G{}^*\rangle, \tag{42}$$

where

$$\langle E_G{}^*|A|E_G{}^*\rangle = \frac{2\Gamma}{\pi} \sum_{l,l'} \int_0^{+\infty} dk \int_0^{+\infty} dk'\, \frac{\sqrt{kk'}}{m}\, \frac{\langle k',\hat{k}',l'|A|k,\hat{k},l\rangle}{(E(\mathbf{k}') - E_G{}^*)(E(\mathbf{k}) - E_G{}^*)}. \tag{43}$$

The relation between Eqs. (40) and (42) can be expressed as

$$\begin{aligned}\langle A\rangle = \langle E_G|A|E_G{}^*\rangle = \mathrm{Re}\langle E_G{}^*|A|E_G{}^*\rangle &- \frac{2i\Gamma^2}{\pi} \sum_{l,l'} \int_0^{+\infty} dk \int_0^{+\infty} dk'\, \frac{\sqrt{kk'}}{m}\, [E(\mathbf{k}) - E(\mathbf{k}')] \\ &\times \frac{\langle k',\hat{k}',l'|A|k,\hat{k},l\rangle}{|E(\mathbf{k}') - E_G|^2 |E(\mathbf{k}) - E_G|^2} \\ &+ \frac{4\Gamma^3}{\pi} \sum_{l,l'} \int_0^{+\infty} dk \int_0^{+\infty} dk'\, \frac{\sqrt{kk'}}{m}\, \frac{\langle k',\hat{k}',l'|A|k,\hat{k},l\rangle}{|E(\mathbf{k}') - E_G|^2 |E(\mathbf{k}) - E_G|^2}.\end{aligned} \tag{44}$$

It means that the result obtained by Berggren[16] is valid at leading order in Γ. At this order one obtains, from the above equation,

$$\langle A\rangle = \langle E_G|A|E_G{}^*\rangle = \mathrm{Re}\langle E_G{}^*|A|E_G{}^*\rangle. \tag{45}$$

The contributions of higher-order terms, for any value of Γ, is given by Eq. (43). From this equation it is seen that the expectation value of the operator A in a GS differs from the estimate $\mathrm{Re}\langle E_G{}^*|A|E_G{}^*\rangle$ and that it shows a power-law dependence upon Γ.

IV. CONCLUSIONS

In this work we have presented a mathematical representation of GS based on the theory of tempered ultradistributions. The use of them has been shown to be useful, particularly in discussing the normalization of GS. The connection with Berggren's approximation, concerning the expectation value of an operator on a resonant state, has been established. We have shown that Berggren's expansion is valid at leading order in the imaginary part of the energy E_G. A general expression for this expectation value has been introduced which is not restricted by any prior assumption about the order of magnitude of the imaginary part of E_G as compared with the value of the real part of it. These results show that the space of ultradistributions together with the RHS discussed seems to be an appropriate framework for the description of GS and its main properties.

Solvable quantum versions of the classical dynamical system characterized by the Hamiltonian $H=\Sigma_{j,k=1}^{n}\ p_j p_k[\lambda+\mu\cos(q_j-q_k)]$ are presented. The eigenvalues of the quantum Hamiltonians are exhibited, as well as the corresponding eigenfunctions. © *1996 American Institute of Physics.* [S0022-2488(96)04009-1]

I. INTRODUCTION

It has been recently pointed out that the dynamical system characterized by the Hamiltonian

$$H=\sum_{j,k=1}^{n}\ p_j p_k\ \exp(-|q_j-q_k|) \tag{1.1}$$

is completely integrable.[1,2] Motivated by this remarkable discovery, one of us investigated the integrability of analogous systems and found that the Hamiltonian

$$H=\sum_{j,k=1}^{n}\ p_j p_k[\lambda+\mu\ \cos(q_j-q_k)] \tag{1.2}$$

is integrable.[3] Subsequently, it was shown that the more general Hamiltonian

$$H=\sum_{j,k=1}^{n}\ p_j p_k[\lambda+\mu\ \cos(q_j-q_k)+\mu'\ \sin|q_j-q_k|] \tag{1.3}$$

of which H (1.1) and H (1.2) are special cases, is also integrable.[4]

Not only is the system characterized by the Hamiltonian (1.2) completely integrable, it also turns out that the corresponding equations of motion *can be solved explicitly in terms of elementary functions*. This result led to the suggestion that there might exist *solvable quantum versions* of this model.[3] In the present paper this conjecture is validated.

Below, in Sec. II, three quantum versions of H (1.2) are introduced. For the special case $n=2$, the eigenvalues and eigenfunctions of these three quantum Hamiltonians are displayed in Sec. III. For the third of these quantum versions, the solution to the eigenvalue problem is exhibited for arbitrary n in Sec. IV; for the second, in Sec. V. In both these cases, the solutions live in the Hilbert space characterized by periodic boundary conditions (of period 2π), with the additional restriction that *all momenta be non-negative*; as explained below, this latter restriction is a rather natural requirement in the former case (third model), less so in the latter (second model). The proofs of these results are given in Sec. VI. In Sec. VII we conclude the paper by briefly listing some open problems.

Let us end this introduction by mentioning that the analogous classical dynamical system characterized by the Hamiltonian

---

[a]On leave while serving as Secretary General, Pugwash Conferences on Science and World Affairs, Geneva, London, Rome.

$$H=\lambda n\sum_{j=1}^{n} p_j+\mu\sum_{j,k=1}^{n}(p_jp_k)^{1/2}\cos(q_j-q_k) \tag{1.4}$$

is also explicitly solvable in terms of elementary functions,[5] and that also for this system there exists a solvable quantum version.[6]

II. QUANTUM HAMILTONIANS

The quantization is generally achieved via the standard representation

$$p_j=\frac{\hbar}{i}\frac{\partial}{\partial q_j}, \tag{2.1}$$

which entails the commutation rule

$$[q_j,p_k]=i\hbar\,\delta_{jk}. \tag{2.2}$$

Hereafter we generally set $\hbar=1$, except when we deem appropriate to display explicitly the dependence on $\hbar$.

A natural quantum version of the Hamiltonian (1.2) is given by

$$H^{(1)}=\lambda P^2+\mu\sum_{j,k=1}[\alpha\cos(q_j-q_k)\,p_jp_k+\beta\,p_jp_k\cos(q_j-q_k)+(1-\alpha-\beta)\,p_j\cos(q_j-q_k)\,p_k], \tag{2.3}$$

where α and β denote two arbitrary constants. Here, and always below

$$P=\sum_{j=1}^{n} p_j. \tag{2.4}$$

It is clear that the quantum Hamiltonian $H^{(1)}$, see Eq. (2.3), is Hermitian if λ,μ,α,β are real and $\alpha=\beta$.

Two other quantizations of the classical Hamiltonian H (1.2) read as follows:

$$H^{(2)}=\lambda P^2+\mu A^+A \tag{2.5a}$$

with

$$A=\sum_{j=1}^{n} a_j,\quad A^+=\sum_{j=1}^{n} a_j^+, \tag{2.6a}$$

$$a_j=\exp(-iq_j)p_j,\quad a_j^+=p_j\exp(iq_j), \tag{2.6b}$$

and

$$H^{(3)}=\lambda P^2+\tfrac{1}{4}\mu B^+B \tag{2.7a}$$

with

$$B=\sum_{j=1}^{n} b_j^2,\quad B^+=\sum_{j=1}^{n}(b_j^+)^2, \tag{2.8a}$$

$$b_j = \exp(-iq_j/2)(2p_j)^{1/2}, \quad b_j^+ = (2p_j)^{1/2}\exp(iq_j/2). \tag{2.8b}$$

Clearly, both $H^{(2)}$ and $H^{(3)}$ are Hermitian (provided λ and μ are real), because A^+ is the Hermitian conjugate of A and B^+ is the Hermitian conjugate of B. In terms of the original operators q_j, p_j the latter two Hamiltonians read as follows:

$$H^{(2)} = \lambda P^2 + \mu \sum_{j,k=1}^{n} p_j \exp[i(q_j - q_k)]p_k \tag{2.5b}$$

$$= \lambda P^2 + \mu \sum_{j,k=1}^{n} p_j \cos(q_j - q_k)p_k + \mu \frac{\hbar}{2} \sum_{j,k=1, j\neq k}^{n} \cos(q_j - q_k)(p_j + p_k), \tag{2.5c}$$

and

$$H^{(3)} = \lambda P^2 + \mu \sum_{j=1}^{n} p_j(p_j - \hbar/2) + \mu \sum_{j,k=1, j\neq k}^{n} \exp[i(q_j - q_k)][(p_j + \hbar)(p_j + \hbar/2)p_k(p_k - \hbar/2)]^{1/2}. \tag{2.7b}$$

To obtain the formula for $H^{(3)}$ we used the formal operator identity

$$(p_j + a)^{1/2}\exp(ibq_k) = \exp(ibq_k)(p_j + a + b\hbar\delta_{jk})^{1/2}. \tag{2.9}$$

It is obvious from the above expressions that the Hamiltonians $H^{(r)}$, $r = 1,2,3$, reduce to the classical Hamiltonian (1.2) when $\hbar = 0$ and q_j, p_j are treated as ordinary variables instead of (noncommuting) operators.

The rest of this paper is devoted to the investigation of the eigenvalue (or Schrödinger) equations,

$$H^{(r)}\Psi^{(r)}(\mathbf{q}) = E^{(r)}\Psi^{(r)}(\mathbf{q}), \quad r = 1,2,3, \tag{2.10}$$

for these 3 quantum Hamiltonians.

III. SOLUTIONS IN THE TWO-BODY CASE ($n=2$)

In this section we exhibit the eigenvalues $E^{(r)}$ and the eigenfunctions $\Psi^{(r)}(\mathbf{q})$ of the quantum Hamiltonians of the preceding Section, see Eq. (2.10), in the special case of two particles ($n=2$). The verification of these results is left as an exercise for the diligent reader (in the cases of $H^{(3)}$ and $H^{(2)}$ see also below)

$$E^{(1)} = \lambda k^2 + \mu[k^2 + 2\alpha m - 2\beta(m+1) - m(m+1)] \tag{3.1a}$$

$$\Psi^{(1)} = \exp[ik(q_1 + q_2)/2]\ \sin^m[(q_1 - q_2)/2]\ F(a_+, a_-, c; \sin^2[(q_1 - q_2)/2]), \tag{3.1b}$$

$$a_\pm = (1 + m - \alpha + \beta \pm [k^2 - 4\beta + (1 - \alpha + \beta)^2]^{1/2})/2, \tag{3.1c}$$

$$c = a_+ + a_- + 1/2 = m - \alpha + \beta + 3/2. \tag{3.1d}$$

$$E^{(2)} = \lambda k^2 + \mu[k^2 + k - m(m+1)], \tag{3.2a}$$

$$\Psi^{(2)} = \exp[ik(q_1 + q_2)/2]\ \sin^m[(q_1 - q_2)/2]\ F(a, b, c; \sin^2[(q_1 - q_2)/2]), \tag{3.2b}$$

$$a=1+(m+k)/2, \quad b=(m-k)/2, \quad c=a+b+1/2=m+3/2. \tag{3.2c}$$

$$E^{(3)}=\lambda k^2+\mu(k^2-m^2), \tag{3.3a}$$

$$\Psi^{(3)}=\exp(ikq_2)\, f(q_1-q_2), \tag{3.3b}$$

$$f(q)=\sum_{l=0}^{k} c_l \exp(ilq), \tag{3.3c}$$

$$c_l=\{(2l)![2(k-l)]!\}^{1/2} \sum_{l'=0}^{\min(k-m,l)} (-1)^{l-l'} \binom{k-m}{l'} \binom{2m}{2(l-l')}. \tag{3.3d}$$

In the above formulas m and k are the two quantum numbers that identify the eigenvalues and the eigenfunctions. The significance of k is revealed by the formula [see Eq. (2.4)]

$$P\Psi^{(r)}(\mathbf{q})=k\Psi^{(r)}(\mathbf{q}), \quad r=1,2,3. \tag{3.5}$$

In Eqs. (3.1b) and (32.b), $F(-,-,-;-)$ denotes the Gauss hypergeometric function;[7] note that in both cases the hypergeometric function belongs to the special class for which there holds a quadratic transformation [see Eq. (2.11.2) of Ref. 7]. The functions $\Psi^{(1)}(\mathbf{q})$ and $\Psi^{(2)}(\mathbf{q})$ satisfy the eigenvalue equation (2.10) for *any* value of m and k. However, the restriction that (the real part of) m be *non-negative* is required to avoid that these wave functions diverge at $q_1=q_2$, and the requirement that m and k be *integers* with $m+k$ *even* is necessary and sufficient to guarantee that these wave functions are periodic in q_1 and q_2 with period 2π. Under these conditions the quantities a,b in (3.2c) are also *integers*; if either of them in *not positive* then the hypergeometric function in the r.h.s. of Eq. (3.2b) becomes a *polynomial*. Likewise, the constants $a_{\pm}$, see Eq. (3.1c), become *integers* if $\alpha=(s-1)^2$ and $\beta=s^2$ with s integer; then $a_{\pm}=s+(m\pm k)/2$.

For the eigenvalue problem (2.10) with $r=3$, see Eq. (3.3), we have assumed that the quantum numbers k and m are *non-negative integers* with $m\leqslant k$. As a consequence, the eigenfunction $\Psi^{(3)}(\mathbf{q})$, see Eqs. (3.3b)–(3.3d) is periodic with period 2π in q_1,q_2, and it moreover contains *only non-negative powers* of $\exp(iq_1)$ and $\exp(iq_2)$. The significance of this restriction is discussed in the next section.

IV. EIGENVALUES AND EIGENFUNCTIONS OF $H^{(3)}$

When investigating the eigenvalues and eigenfunctions of the quantum Hamiltonian $H^{(3)}$, see Eq. (2.7), we restrict consideration to the Hilbert space spanned by the basis

$$\exp(i\mathbf{m}\cdot\mathbf{q})\equiv\exp\left(i\sum_{j=1}^{n} m_j q_j\right), \quad \mathbf{m}\equiv(m_1,\ldots,m_n)\in\mathbf{N}^n \tag{4.1}$$

(i.e., with $m_1,\ldots,m_n$ being *non-negative integers*), endowed with the standard inner product for square integrable functions with period 2π ($\langle f,g\rangle=\int_0^{2\pi}\cdots\int_0^{2\pi} f^*(\mathbf{q})g(\mathbf{q})dq_1\cdots dq_n$). Requiring that all components m_j of $\mathbf{m}$ be *integers* corresponds to imposing *periodic* boundary conditions (with period 2π, for all the variables q_j); the restriction that they be *non-negative* is to avoid any difficulty with the definition of the pseudo-differential operators $p_j^{1/2}$ [see Eq. (2.8b)], whose action on the basis (4.1) is specified by the formula [see Eq. (2.1)]

$$p_j^{1/2}\exp(i\mathbf{m}\cdot\mathbf{q})=m_j^{1/2}\exp(i\mathbf{m}\cdot\mathbf{q}). \tag{4.2}$$

The restriction to this ''non-negative momenta'' subspace is *self-consistent*, because acting with $H^{(3)}$, see Eq. (2.7), on any function that is representable as a superposition of these basis elements

yields a function that is again representable as a superposition of these basis elements; indeed, this is clearly a property inherited from the operators b_j, b_j^+ [see Eqs. (2.8) and (4.2)].

Let us now turn to a description of the eigenvalues and eigenfunctions of $H^{(3)}$ in the above mentioned Hilbert space. The proofs of the following results are given in Sec. VI.

The solution of the eigenvalue equation (2.10) for $r=3$ and *arbitrary* particle number $n \geqslant 2$ is given by the eigenvalues

$$E^{(3)} = \lambda k^2 + \mu[k^2 + (\tfrac{n}{2} - 1)k - m(m + \tfrac{n}{2} - 1)], \tag{4.3}$$

and by the eigenfunctions

$$\Psi^{(3)}(\mathbf{q}) = \sum_{l_1,\ldots,l_n=0, l_1+\ldots+l_m=k}^{n} c(\mathbf{m},\mathbf{l}) \left(\prod_{j=1}^{n} (2l_j)! \right)^{1/2} \exp\left(i \sum_{j=1}^{n} l_j q_j \right), \tag{4.4a}$$

where the coefficients $c(\mathbf{m},\mathbf{l})$ are defined by the expansion formula

$$\left(\sum_{j=1}^{n} x_j^2 \right)^{k-m} H_{2m}(\mathbf{x}) = \sum_{l_1,\ldots,l_n=0, l_1+\ldots+l_n=k}^{k} c(\mathbf{m},\mathbf{l}) \prod_{j=1}^{n} x_j^{2l_j}. \tag{4.4b}$$

Just as in the treatment of $H^{(3)}$ given in Sec. III (for $n=2$), the numbers k and m are *non-negative integers* with $m \leqslant k$; they are the quantum numbers labeling the eigenvalues $E^{(3)}$, see Eq. (4.3). One again has [see Eq. (3.5)]

$$P\Psi^{(3)}(\mathbf{q}) = k\Psi^{(3)}(\mathbf{q}). \tag{4.5}$$

The function $H_{2m}(\mathbf{x})$ in the defining relation (4.4b) for the coefficients $c(\mathbf{m},\mathbf{l})$ denotes a *harmonic* polynomial of degree $2m$, i.e., an even homogeneous polynomial of degree $2m$ in the variables $x_1,\ldots,x_n$ satisfying the (n-dimensional) Laplace equation

$$\Delta H_{2m}(\mathbf{x}) = 0. \tag{4.6}$$

For a given m (and $n \geqslant 3$) there exist $(4m+n-2)!(2m+n-3)!/[(n-2)!(2m)!]$ such *independent* harmonic polynomials [see Eq. (11.2.2) of Ref. 7]; this is, therefore, also the multiplicity of the eigenvalue $E^{(3)}$, see Eq. (4.3), in the generic case (λ and μ incommensurate); note that the multiplicity does not depend on k. Rather explicit formulas for these polynomials (in terms of Gegenbauer polynomials) can be found in Eq. (11.2.21) of Ref. 7.

V. EIGENVALUES AND EIGENFUNCTIONS OF $H^{(2)}$

In this section we exhibit the eigenvalues and eigenfunctions of the Hamiltonian $H^{(2)}$, see Eq. (2.5), again in the Hilbert space spanned by the basis (4.1). The restriction to *integer* values of the quantum numbers m_j corresponds again to the imposition of *periodic* boundary conditions (of period 2π, for all the variables q_j); the additional restriction that they all be *non-negative* (namely, the restriction to work in the space with only *non-negative momenta*), although *self-consistent* (as in the previous case), has no cogent justification (contrary to the previous case).

The proofs of the following results are given in Sec. VI.

The eigenvalues $E^{(2)}$ of $H^{(2)}$, see Eq. (2.10), are given by the formula

$$E^{(2)} = \lambda k^2 + \mu[k^2 + (n-1)k - m(m+n-1)], \tag{5.1}$$

with k and m *non-negative integers* and $m \leqslant k$; note the analogy, and yet the difference, of $E^{(2)}$, see Eq. (5.1), with $E^{(3)}$, see Eq. (4.3).

The corresponding eigenfunctions of $\Psi^{(2)}$, see Eq. (2.10), are again also eigenfunctions of P,

$$P\Psi^{(2)}=k\Psi^{(2)}, \tag{5.2}$$

so that the quantum number k has the same significance as in the preceeding sections [see Eqs. (3.5) and (4.5)]; and they are given by the explicit formulas

$$\Psi^{(2)}(\mathbf{q})=(A^{+})^{k-m}\Phi(\mathbf{q}), \tag{5.3}$$

$$\Phi(\mathbf{q})=\left[\sum_{j=1}^{n}\gamma_j\exp(iq_j)\right]^m, \tag{5.4a}$$

with A^{+} defined by Eqs. (2.6) and (2.1), and where the n constants γ_j are arbitrary except for the single restriction

$$\sum_{j=1}^{n}\gamma_j=0. \tag{5.4b}$$

For $n=2$ the simultaneous validity of Eq. (3.2b), and of Eq. (5.3) with Eq. (5.4), entails the following intriguing (possibly new!?) representation of (even) Gegenbauer polynomials:[8]

$$C_{2p}^{m+1}(\cos x)=(-)^p 2^{-2p}[(2p)!]^{-1}(\sin x)^{-m}\exp[-i(m+2p)y]\cdot\left\{\left(\frac{\partial}{\partial y}+\frac{\partial}{\partial x}\right)\exp[i(x+y)]+\left(\frac{\partial}{\partial y}-\frac{\partial}{\partial x}\right)\exp[i(y-x)]\right\}^{2p}\cdot\exp(imy)(\sin x)^m, \tag{5.5a}$$

$$C_{2p}^{m+1}(\cos x)=[(2p)!]^{-1}(\sin x)^{-m}\cdot\left\{\left[(m+2p+1)\cos x+(\sin x)\frac{\partial}{\partial x}\right]\times\left[(m+2p)\cos x+(\sin x)\frac{\partial}{\partial x}\right]\cdot\left[(m+2p-1)\cos x+(\sin x)\frac{\partial}{\partial x}\right]\cdots\left[(m+3)\cos x+(\sin x)\frac{\partial}{\partial x}\right]\cdot\left[(m+2)\cos x+(\sin x)\frac{\partial}{\partial x}\right]\right\}(\sin x)^m, \tag{5.5b}$$

with m and p *non-negative integers*. The formula (5.5a) has been obtained by setting $k-m=2p$, $q_1=y+x$, $q_2=y-x$, and using the second of Eqs. (10.9.21) of Ref. 8. The formula (5.5b) is easily obtained from (5.5a) using the (operator) identity

$$\left(\frac{\partial}{\partial y}+\frac{\partial}{\partial x}\right)\exp[i(x+y)]+\left(\frac{\partial}{\partial y}-\frac{\partial}{\partial x}\right)\exp[i(y-x)]=2\left[\frac{\partial}{\partial y}\cos x+i\frac{\partial}{\partial x}\sin x\right]\exp(iy). \tag{5.6}$$

The normalization constant for these equations has been determined by setting $\cos x=z$ in Eq. (5.5b) and then evaluating the dominant term (as z diverges).

Of course an equivalent representation to Eqs. (5.4) reads

$$\Phi(\mathbf{q})=\left\{\sum_{j=1,j\neq k}^{n}\gamma_j[\exp(iq_j)-\exp(iq_k)]\right\}^m, \tag{5.7}$$

with k arbitrary, $1 \leqslant k \leqslant n$, and now with the $n-1$ arbitrary constants γ_j, $j=1,\ldots,n$, $j \neq k$, unrestricted. By expanding the right-hand-side in powers of the constants γ_j, one obtains $N(n,m)=\binom{n+m-2}{m} \equiv (n+m-2)!/[(n-2)!m!]$ different functions, as coefficients of different powers of the $n-1$ constants γ_j; all these functions yield, via Eq. (5.3), different eigenfunctions, all of which satisfy both eigenvalue equations, (5.2), and (2.10) with $r=2$ and with Eq. (5.1). Hence $N(n,m)$ gives the multiplicity (or at least, a lower bound to the multiplicity) of the eigenvalue (5.1) (in the generic case with λ and μ incommensurate).

VI. PROOFS

To derive the results of Sec. IV one first observes that the operators b_j^+ and b_j, see Eq. (2.8b), satisfy the commutation rules

$$[b_j,\ b_j^+]=\delta_{jk}. \tag{6.1}$$

Hence another representation for these operators, also consistent with these commutation relations, is given by

$$b_j^+ = x_j, \quad b_j = \frac{\partial}{\partial x_j}. \tag{6.2}$$

In the latter representation the Hamiltonian (2.7a) reads

$$H^{(3)} = \tfrac{1}{4}(\lambda N + \mu r^2 \Delta), \tag{6.3a}$$

with

$$N = \sum_{j=1}^{n} x_j \frac{\partial}{\partial x_j}, \quad r^2 = \sum_{j=1}^{n} x_j^2, \quad \Delta = \sum_{j=1}^{n} \frac{\partial^2}{\partial x_j^2}. \tag{6.3b}$$

Now let $H_{2m}(\mathbf{x})$ be a *harmonic* polynomial of degree $2m$ and define

$$\phi(\mathbf{x}) = r^{2(k-m)} H_{2m}(\mathbf{x}), \tag{6.4}$$

so that $\phi(\mathbf{x})$ is a homogeneous *polynomial* in the x_j's of degree $2k$ (here the assumption $k-m \geqslant 0$ plays an essential role). Then it is clear from the representation (6.3a) that

$$H^{(3)}\phi(\mathbf{x}) = E^{(3)}\phi(\mathbf{x}), \tag{6.5}$$

with $E^{(3)}$ given by Eq. (4.3).

It remains to transform back to the variables q_j, $j=1,\ldots,n$. To this end one observes that in both representations the ground state wave function is a constant [constant functions are annihilated by both representations of b_j, see Eqs. (2.8b) and (6.2)]. By comparing the action of the creation operators b_j^+ on the ground state in both representations one arrives at the transformation rule

$$x_j^{2l} \to [(2l)!]^{1/2} \exp(ilq_j). \tag{6.6}$$

Hence, to obtain the eigenfunction $\Psi^{(3)}(\mathbf{q})$ one must first expand $\phi(\mathbf{x})$, see Eq. (6.4), in powers of the variables x_j, and then perform the substitution (6.6). This yields Eq. (4.4).

Let us now proceed to prove the results of Sec. V.

It is easily seen that the following formulas are implied by the definitions (2.6) with Eqs. (2.1), (2.2), (2.4):

$$[a_j, a_k^+] = \delta_{jk}(1+2p_j), \tag{6.7}$$

$$[P, A^m] = -mA^m, \quad m = 0,1,2,\ldots, \tag{6.8a}$$

$$[P, (A^+)^m] = m(A^+)^m, \quad m = 0,1,2,.., \tag{6.8b}$$

$$[A, (A^+)^m] = (A^+)^{m-1} m(m+n-1+2P), \quad m = 0,1,2,.., \tag{6.9a}$$

$$[A^+A, (A^+)^m] = (A^+)^m m(m+n-1+2P), \quad m = 0,1,2,\ldots, \tag{6.9b}$$

$$[P, A^+A] = 0. \tag{6.10}$$

Using the explicit definition (5.4) of $\Phi(\mathbf{q})$ it is easy to show that this function satisfies the two equations

$$P\Phi(\mathbf{q}) = m\Phi(\mathbf{q}), \tag{6.11}$$

$$A\Phi(\mathbf{q}) = 0. \tag{6.12}$$

Hence, using Eqs. (6.8b) and (6.9b), it is easy to show that $\Psi^{(2)}$, see Eq. (5.3), satisfies Eq. (5.2) as well as Eq. (2.10) with Eq. (5.1).

VII. OUTLOOK

We conclude by briefly mentioning some open problems associated with these quantum versions of the Hamiltonian (1.2) (for a list of open problems extant in the classical context see Ref. 4).

For the two-body case ($n=2$), the results of Sec. III provide the complete solution of the quantum problem for the 3 Hamiltonians $H^{(r)}$, $r=1,2,3$, introduced in Sec. II, in the guise of rather explicit solutions of the relevant Schrödinger equations. This opens the possibility to investigate other prescriptions for quantization (for instance, different boundary conditions) than those detailed above; a task that we consider sufficiently easy, for $n=2$, not to warrant any additional elaboration here. The question of exploring more fully other quantizations in the many-body case ($n>2$) is on the other hand an interesting open problem; and also open and interesting is the problem to solve, in some appropriate Hilbert space, the eigenvalue equation (2.10) with $r=1$ (for $n>2$), as well as the problem to solve Eq. (2.10) with $r=2$ (for $n>2$) in the larger Hilbert space characterized by the basis (4.1) *without* the restriction that the integers m_j be *non-negative* (note that, in the $n=2$ case, the eigenfunctions are then given by Eq. (3.2b) with a *nonpolynomial* hypergeometric function).

Let us end by mentioning that the question of the existence of a *solvable* quantum version of the more general Hamiltonian (1.3) constitutes an interesting, and probably difficult, open problem.

Coherent state path-integral representation of supersymmetric lattice models

Zhe Chang[a)]
International Centre for Theoretical Physics, Trieste, Italy and
INFN, Sezione di Trieste, Trieste, Italy

(Received 28 November 1994; accepted for publication 10 May 1996)

A kind of high-temperature superconductivity related lattice model is investigated within the framework of supergroup coherent state path-integral representation. Symmetry properties are analyzed and the Hamiltonians are written in the symmetric form explicitly in terms of generators of the supergroup $U(N/M)$. By a standard approach, general supergroup coherent states are constructed. Holstein–Primakoff realizations of the supergroup $U(N/M)$ on the coset space $U(N/M)/[U(1)\otimes U(N-1/M)]$ are obtained. Vacuum persistence amplitudes are expressed in terms of parameters on the coset space $U(2/M)/[U(1)\otimes U(1/M)]$. Symmetry-breaking terms in the Hamiltonian are taken into account separately. The Lagrangians of these models are quadratic in Grassmann variables. Thus fermionic fields can be integrated out. The nonlinear σ model is arrived at as effective continuum field theory describing the low-energy excitations of the supersymmetric lattice models.

I. INTRODUCTION

It is well known that the Bardeen, Cooper, and Schrieffer (BCS) theory[1] gives viable mechanisms for superconductivity in metals and superfluidity of liquid He_3. This theory has also successfully explained a variety of related phenomena in diverse areas of physics. However, the discovery of copper-oxide superconductivity[2,3] with critical temperature as high as 120 K raised doubts about it. Due to the nature of the phonon-mediated electron–electron interaction in BCS theory, there are upper bounds on the critical temperatures much lower than those achieved with the copper oxides. The lack of a significant isotope effect with substitution of the oxygen sites seems to rule out the possibility that the phonon Debye frequency is the characteristic energy scale entering in the fundamental equations of the high-temperature superconductivity. Because the superconductiviting phase occurs near a metal-insulator transition, an antiferromagnetic as well as a structural instability, the phase diagram of high T_c superconductivity materials is rich. There is a growing suspicion that a different mechanism may be responsible for the high T_c superconductivity. Anderson[4,5] suggested that the novel quantum spin fluctuations in the CuO_2 planes may be responsible for the superconductivity. Interesting magnetic properties revealed by neutron-scattering experiments provide further support for this idea. It was conjectured that such fluctuations might destroy the antiferromagnetic long-range order in the ground state, giving rise to a new state of the spin system, a quantum spin-liquid state. The superconductivity in these materials was then conjectured to arise from the behavior of a novel quantum fluid created out of a highly correlated set of electronic degrees of freedom.

Anderson argued that the appropriate model for the high T_c superconductivity is the two-dimensional single-band Hubbard model[6] in the strong on-site Coulomb repulsion limit,

$$H_{\text{Hubb.}}=-t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^{\dagger}c_{k\sigma}+c_{k\sigma}^{\dagger}c_{j\sigma})+U\sum_{j}\ c_{j1}^{\dagger}c_{j1}c_{j,-1}^{\dagger}c_{j,-1}, \tag{1}$$

[a)]Electronic mail: changz@ictp.trieste.it

0022-2488/96/37(9)/4252/22/$10.00

where t is the hopping matrix elements and U is the on-site Coulomb interaction. In this model the fermion creation operators create electrons at the outer $d_{x^2-y^2}$ orbital of the Cu atoms, which is hybridized in an antibonding symmetry with the P_x and P_y orbitals of the two oxygen atoms in the CuO_2 cell.

Standard strong-coupling perturbation treatment of the single-band Hubbard Hamiltonian produces the effective $t-J$ model[7,8] with the superexchange coupling $J=4t^2/U$,

$$H_{t-J}=-t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^{\dagger}c_{k\sigma}+c_{k\sigma}^{\dagger}c_{j\sigma})+J\sum_{\langle jk\rangle}(S_j^{\dagger}S_k+S_k^{\dagger}S_j+2S_j^3S_k^3). \tag{2}$$

The $t-J$ Hamiltonian is an interesting model on its own. This model can be obtained in the strong-coupling limit from a more realistic model that takes into account the more detailed orbital structure of the CuO_2 cell, even when the holes created by doping sit primarily on the oxygen sites.[9]

At half-filling, apart from a constant, the $t-J$ Hamiltonian is equivalent to the spin-$\frac{1}{2}$ antiferromagnetic Heisenberg model on a square lattice,

$$H_{\text{Heisen.}}=J\sum_{\langle jk\rangle}(S_j^{\dagger}S_k+S_k^{\dagger}S_j+2S_j^3S_k^3). \tag{3}$$

The spin model has been studied for many years.[10,11] Since the 1950s, the importance of field theory to condensed matter physics, and vice versa, has been recognized based on the pioneer works of Landau and Feynman. Conformal field theory describes effectively critical phenomena. The renormalization group, which is developed initially by field theorists, has become the main tool for the interpretations of experimental data, the conceptual framework, and the computational algorithm in condensed matter physics. Haldane first used the $SU(2)$ group coherent state path-integral representation[12] to map the spin operators to unit 3-vectors on the large spin limit,

$$\mathbf{S}_j\rightarrow s\boldsymbol{\varphi}_j,\quad \boldsymbol{\varphi}_j\cdot\boldsymbol{\varphi}_j=1, \tag{4}$$

and the system becomes classical. On the other hand, in the long-wavelength limit the system approaches a continuum field theory appropriate for the study of low-energy excitations. When both approximations are used in conjunction the system is described by a nonlinear σ model,

$$L=\frac{1}{2g}\,\partial_\mu\boldsymbol{\varphi}\cdot\partial^\mu\boldsymbol{\varphi}, \tag{5}$$

with the constraint $\boldsymbol{\varphi}\cdot\boldsymbol{\varphi}=1$.

Semiclassically we assume spontaneous symmetry breaking[13] and write

$$\boldsymbol{\varphi}=\left(\varphi_1,\varphi_2,\sqrt{1-\sum_{i=1}^{2}\varphi_i\varphi_i}\right)\doteq(\varphi_1,\varphi_2,1). \tag{6}$$

Then we have

$$L=\frac{1}{2g}\sum_{i=1}^{2}2\,\partial_\mu\varphi_i\,\partial^\mu\varphi_i=\frac{1}{2g}\,\partial_\mu\phi\,\partial^\mu\phi^{\dagger}, \tag{7}$$

where we have used the notations $\phi=\varphi_1+i\varphi_2$, $\phi^{\dagger}=\varphi_1-i\varphi_2$.

It is widely believed that the quantum nonlinear σ model provides an accurate description of the long-wavelength, low-energy properties of the spin system, even in the small spin regime. Affleck and Randjbar-Daemi, Salam, and Strathdee (RSS) have generalized the approach to $SU(N)$ and general Lie group cases.[14,15]

By defining the so-called spin-hole coherent states,

$$|\Omega,\xi\rangle_s=|\Omega\rangle_s|0\rangle+|\Omega\rangle_{s-1/2}\xi f^\dagger|0\rangle, \tag{8}$$

Auerbach and Larson[16] used the coherent state representation to deal with the $t-J$ model. By a Hartree–Fock approximation, a model that is quadratic in the Grassmann variables is arrived. The effective Lagrangian of the $t-J$ model is of the form

$$L^{\rm eff}_{t-J}=\sum_j\ (2s-\rho_j)\mathbf{A}(\Omega_j)\cdot\dot{\Omega}_j-H^J(\Omega)-\beta^{-1}T\ \log\left[1+T_\tau\ \exp\left(-\int_0^\beta d\tau(H^f(\Omega_j)-\mu)\right)\right]. \tag{9}$$

However, no σ-type field theory was obtained explicitly. They argued that although the expansion around the Néel state is formally controlled by the large spin size s, at low doping the success of this approximation for the $s=\frac{1}{2}$ antiferromagnetism can be relied on.

The spin–spin interactions are essential to the high T_c superconductivity related lattice models. As Haldane has shown in the absence of doping the spin–spin interactions can be presented by the $2+1$-dimensional nonlinear σ model. It is natural to hope that, at least in the low doping case, the spin–spin interactions, in general, should be described by a σ-type field theory.

It is well known that the novel feature of supersymmetry is that it operates between bosons and fermions, the odd generators of the supergroup corresponding to transformations between bosons and fermions. Thus supersymmetry provides a unified description of mixed systems of bosons and fermions. Supersymmetry is introduced originally for applications in high-energy physics and becomes more and more popular in other fields of physics.

In this paper, we begin with discussing the symmetry properties of these models and rewrite the Hamiltonians in a supersymmetric form. Here the supergroup $U(N/M)$[17–19] plays a fundamental role. The Hamiltonians are written in terms of the generators of $U(N/M)$. For convenience, we introduce the Schwinger boson (slave fermion) representation.[20,21] This representation is widely used by condensed matter physicists in dealing with doping problems of high T_c superconductivity. The total particle number of bosons and fermions is used to label representations of $U(N/M)$. The elements of $U(N/M)$ are identified as transformations among states that have the same total particle number. To arrive at a path-integral representation of the supersymmetric models, we construct supergroup coherent states[18,22] from unitary irreducible representations of the supergroup. The supergroup coherent states have a natural topological coset space structure $U(N/M)/[U(1)\otimes U(N-1/M)]$. Parametrization of the coset space is presented explicitly. A complex projective representation of $U(N/M)/[U(1)\otimes U(N-1/M)]$ is introduced. We show that two important properties of ordinary group coherent states are maintained by the supergroup coherent states, i.e., they are, in general, nonorthogonal but are normalized to unity. According to Schurr's lemma, we also give the resolution of identity of the supergroup coherent states. This is crucial for obtaining a path-integral representation. Following the method of RSS,[15] we express the vacuum persistence amplitudes of the supersymmetric systems in terms of parameters on the coset space $U(2/M)/[U(1)\otimes U(1/M)]$ through the Holstein–Primakoff realizations.[23] To agree with the Néel character (at least short range) of the high T_c superconductivity materials, we give two kinds of parametrizations of the coset space on bipartite lattices. After taking account of the symmetry-breaking terms of the Hamiltonians, we get a Lagrangian that describes sensibly the spin fluctuations of the high T_c superconductivity materials. It should be noticed that the Lagrangian is quadratic in Grassmann variables. Thus we can integrate out the fermionic fields and get an

effective Lagrangian that only involves bosonic fields. This is just the familiar nonlinear σ model. This result proves the predictions of the weak-coupling mean-field theory in the Fermion coherent state path-integral representation.

This paper is organized as follows. In Sec. II, we show symmetry properties of the high T_c superconductivity related lattice models. Section III is devoted to discussing the Schwinger boson representations of the supergroup. Supergroup coherent states are constructed in Sec. IV. We give the supergroup coherent state path-integral representations of these models in Sec. V. Concluding remarks are given in Sec. VI.

II. HIGH T_c SUPERCONDUCTIVITY RELATED SUPERSYMMETRIC LATTICE MODELS

The existence of antiferromagnetism in the absence of doping is an evidence for strong electron correlations for the high T_c materials. The extended Hubbard model[24–26] is one of the simplest models for describing the electron correlations on a two-dimensional lattice, which includes nearest-neighbor interactions such as density–density and spin–spin coupling and additional interactions such as a bond charge term and a pair hopping term. The Hamiltonian of the model is given by

$$\begin{aligned} H_{\text{Hubb.}} = & -t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^{\dagger}c_{k\sigma}+c_{k\sigma}^{\dagger}c_{j\sigma})-\frac{t}{2}\sum_{\langle jk\rangle}(n_j-1)(n_k-1)+t\sum_{\langle jk\rangle}(c_{j1}^{\dagger}c_{j,-1}c_{k,-1}^{\dagger}c_{k1} \\ & +c_{j,-1}^{\dagger}c_{j1}c_{k1}^{\dagger}c_{k,-1})+t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^{\dagger}c_{k\sigma}+c_{k\sigma}^{\dagger}c_{j\sigma})(n_{j,-\sigma}+n_{k,-\sigma}) \\ & -t\sum_{\langle jk\rangle}(c_{j1}^{\dagger}c_{j,-1}^{\dagger}c_{k,-1}c_{k1}+c_{k1}^{\dagger}c_{k,-1}^{\dagger}c_{j-1}c_{j1})-4t\sum_{j}\left(n_{j1}-\frac{1}{2}\right)\left(n_{j,-1}-\frac{1}{2}\right) \\ & +U\sum_{j}c_{j1}^{\dagger}c_{j1}c_{j,-1}^{\dagger}c_{j,-1}, \end{aligned} \tag{10}$$

where the operator $c_{j\sigma}$ ($c_{j\sigma}^{\dagger}$) [$j=1,2,\ldots,L$ (total number of lattice sites)] describe electrons on the lattice and satisfy the anticommutation relation,

$$\{c_{j\sigma},c_{k\sigma'}\}=0,\quad \{c_{j\sigma},c_{k\sigma'}^{\dagger}\}=\delta_{jk}\delta_{\sigma\sigma'},\quad \{c_{j\sigma}^{\dagger},c_{k\sigma'}^{\dagger}\}=0. \tag{11}$$

Here we have used the notations $n_{j\sigma}=c_{j\sigma}^{\dagger}c_{j\sigma}$ and $n_j=\Sigma_{\sigma=\pm 1}n_{j\sigma}$, $\Sigma_{\langle jk\rangle}$ implies the sum over the nearest neighbors, in which the pairs (j,k) and (k,j) have to be counted once each so that the sum can be always considered as symmetric under interchanging $j\leftrightarrow k$.

The Hilbert space of the extended Hubbard model is spanned by the states of the form

$$|a_1\rangle\otimes|a_2\rangle\otimes\cdots\otimes|a_j\rangle\otimes\cdots\otimes|a_L\rangle, \tag{12}$$

where $|a_j\rangle\in\{|1_j\rangle=c_{j1}^{\dagger}|0\rangle_j,|2_j\rangle=c_{j,-1}^{\dagger}|0\rangle_j,|3_j\rangle=|0\rangle_j,|4_j\rangle=c_{j1}^{\dagger}c_{j,-1}^{\dagger}|0\rangle_j\}$. Here $|0\rangle_j$ is defined as $c_{j\sigma}|0\rangle_j=0$ and the vacuum $|0\rangle=\otimes|0\rangle_j$ satisfies $c_{j\sigma}|0\rangle=0$.

The system has $SU(2)$ spin symmetry. The spin operator $\mathbf{S}_j$ is defined by

$$\mathbf{S}_j=\frac{1}{2}\sum_{\sigma,\sigma'=\pm 1}c_{j\sigma}^{\dagger}\boldsymbol{\tau}_{\sigma\sigma'}c_{j\sigma'}, \tag{13}$$

where $\boldsymbol{\tau}$ are the three Pauli matrices,

$$\tau_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \tau_2=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \tau_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}. \tag{14}$$

Another symmetry of the system is the so-called η pairing[27,28] generated by

$$\eta_j = c_{j1}c_{j,-1}, \quad \eta_j^\dagger = c_{j,-1}^\dagger c_{j1}^\dagger, \quad \eta_j^3 = -\tfrac{1}{2}(n_j - 1). \tag{15}$$

Together with the spin $SU(2)$ symmetry, this gives an $SO(4)$ symmetry.

In terms of the operators of spin and η spin, the extended Hubbard Hamiltonian is of the form

$$\begin{aligned} H_{\text{Hub.}} = & -t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^\dagger c_{k\sigma} + c_{k\sigma}^\dagger c_{j\sigma}) - \frac{t}{2}\sum_{\langle jk\rangle}(n_j - 1)(n_k - 1) + t\sum_{\langle jk\rangle}(S_j^\dagger S_k + S_k^\dagger S_j + 2S_j^3 S_k^3) \\ & + t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^\dagger c_{k\sigma} + c_{k\sigma}^\dagger c_{j\sigma})(n_{j,-\sigma} + n_{k,-\sigma}) - t\sum_{\langle jk\rangle}(\eta_j^\dagger \eta_k + \eta_k^\dagger \eta_j + 2\eta_j^3 \eta_k^3) \\ & - 4t\sum_j \left(n_{j1} - \frac{1}{2}\right)\left(n_{j,-1} - \frac{1}{2}\right) + U\sum_j c_{j1}^\dagger c_{j1} c_{j,-1}^\dagger c_{j,-1}. \end{aligned} \tag{16}$$

The above Hamiltonian can be divided formally into two parts, the supersymmetric part $H_{\text{Hub.}}^0$ and the symmetry-breaking part $H_{\text{Hub.}}^{\text{int}}$,

$$\begin{aligned} H_{\text{Hub.}}^0 = & -t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^\dagger c_{k\sigma} + c_{k\sigma}^\dagger c_{j\sigma}) - \frac{t}{2}\sum_{\langle jk\rangle}(n_j - 1)(n_k - 1) + t\sum_{\langle jk\rangle}(S_j^\dagger S_k + S_k^\dagger S_j + 2S_j^3 S_k^3) \\ & + t\sum_{\langle jk\rangle}\sum_{\sigma=\pm 1}(c_{j\sigma}^\dagger c_{k\sigma} + c_{k\sigma}^\dagger c_{j\sigma})(n_{j,-\sigma} + n_{k,-\sigma}) - t\sum_{\langle jk\rangle}(\eta_j^\dagger \eta_k + \eta_k^\dagger \eta_j + 2\eta_j^3 \eta_k^3) \\ & - 4t\sum_j \left(n_{j1} - \frac{1}{2}\right)\left(n_{j,-1} - \frac{1}{2}\right), \\ H_{\text{Hub.}}^{\text{int}} = & U\sum_j c_{j1}^\dagger c_{j1} c_{j,-1}^\dagger c_{j,-1}. \end{aligned} \tag{17}$$

As we know there are four states at each lattice site, two of them are fermionic and the others are bosonic. The terms H_{jk}^0 $(t=1)$ act as a minus graded permutation[29] of the electron states at sides j and k. By ''graded'' we mean that there is an extra minus sign if the two states that are permuted are both single electron states. For example,

$$\begin{aligned} H_{jk}^0 c_{j1}^\dagger |0\rangle &= -c_{k1}^\dagger |0\rangle, \\ H_{jk}^0 c_{j1}^\dagger c_{k,-1}^\dagger |0\rangle &= c_{j,-1}^\dagger c_{k1}^\dagger |0\rangle. \end{aligned} \tag{18}$$

Thus the symmetric part $H_{\text{Hub.}}^0$ can be written as an invariant form in terms of generators of the supergroup $U(2/2)$,

$$H_{\text{Hub.}}^0 = -t\sum_{\langle jk\rangle}\sum_{\alpha,\beta=1}^{16} \text{Str}(X^\alpha X^\beta) X^\alpha X^\beta. \tag{19}$$

The supergroup $U(2/2)$ here is the group of the unitary rotations of the four allowed states, $|a_j\rangle$ $(a=1,\ldots,4)$, into one another.

It is easy to show that the off-diagonal matrix element $(j \neq k)$ $\langle \Phi_m | c_{j,-1}^\dagger c_{j1}^\dagger c_{k1} c_{k,-1} | \Phi_m \rangle / \langle \Phi_m | \Phi_m \rangle$ is constant for long distances $|j-k|$. Here $|\Phi_m\rangle = (\eta^\dagger)^m |0\rangle$. Indeed we have

$$\frac{\langle\Phi_m|c^\dagger_{j,-1}c^\dagger_{j1}c_{k1}c_{k,-1}|\Phi_m\rangle}{\langle\Phi_m|\Phi_m\rangle}=\frac{m(L-m)}{L(L-1)}. \tag{20}$$

This fact established the properties of off-diagonal-long-range-order (ODLRO) for the state $|\Phi_m\rangle$. In the thermodynamic limit we have ODLRO as soon as $m/L\to D$ becomes finite. The ODLRO is characteristic for superconductivity.[30]

If the double occupied sites are kinetically forbidden, the restricted Hilbert space of the system now consists of configurations made of empty sites (holes) and up and down spins ($|a_j\rangle$, $a=1,2,3$). The kinetic term will allow for charge motion since empty sites will be able to move. These holes carry electric charge but they have no spin. The effective Hamiltonian now has the form of the t-J model,

$$H_{t-J}=-t\sum_{\langle jk\rangle}\sum_{\sigma=\pm1}(c^\dagger_{j\sigma}c_{k\sigma}+c^\dagger_{k\sigma}c_{j\sigma})+J\sum_{\langle jk\rangle}\left(S^\dagger_jS_k+S^\dagger_kS_j+2S^3_jS^3_k-\frac{n_jn_k}{4}\right). \tag{21}$$

Notice that H_{t-J} acts on the Hilbert space, where no double occupancy of sites are allowed.

Also, the $t-J$ Hamiltonian can be divided into a symmetric part H^0_{t-J} and a symmetry-breaking part $H^{\rm int}_{t-J}$,[31–33]

$$\begin{aligned}H^0_{t-J}&=-t\sum_{\langle jk\rangle}\sum_{\sigma=\pm1}(c^\dagger_{j\sigma}c_{k\sigma}+c^\dagger_{k\sigma}c_{j\sigma})+2t\sum_{\langle jk\rangle}\left(S^\dagger_jS_k+S^\dagger_kS_j+2S^3_jS^3_k-\frac{n_jn_k}{4}\right),\\ H^{\rm int}_{t-J}&=(J-2t)\sum_{\langle jk\rangle}\left(S^\dagger_jS_k+S^\dagger_kS_j+2S^3_jS^3_k-\frac{n_jn_k}{4}\right).\end{aligned} \tag{22}$$

H^0_{t-J} is of $U(2/1)$ supersymmetric invariance. It generates the unitary rotations among the allowed states of the $t-J$ model, $|a_j\rangle$ ($a=1,2,3$). And the terms H^0_{jk} act as a minus graded permutations of these states.

At the half-filled case of the extended Hubbard model, only the spin up and down states $|a_j\rangle$ ($a=1,2$) are allowed and no fermionic states are left. The permutation group in this case becomes as the Lie group $U(2)$. And the symmetric Hamiltonian reduces to the usual spin-$\frac{1}{2}$ quantum Heisenberg Hamiltonian,

$$H_{\rm Heisen.}=J\sum_{\langle jk\rangle}(S^\dagger_jS_k+S^\dagger_kS_j+2S^3_jS^3_k). \tag{23}$$

Generally speaking, from n states $|a\rangle$ ($a=1,2,\ldots,n$), which satisfy

$$\langle a|b\rangle=\delta^{ab}, \tag{24}$$

one can construct $n\times n$ independent real operators X^{ab},

$$X^{ab}=|a\rangle\langle b|,\quad a,b=1,2,\ldots,n. \tag{25}$$

With the local states $|a_j\rangle$ that satisfy the relation

$$\langle a_j|b_k\rangle=\delta_{jk}\delta^{ab}, \tag{26}$$

we can define the local operators $X^{ab}_j=|a_j\rangle\langle b_j|$.

With the local Hubbard operators X^{ab}_j the extended Hubbard Hamiltonian can be cast into the following form:

$$H_{\text{Hub.}}=-t\sum_{\langle jk\rangle}\sum_{a,c=1}^{4}X_j^{ac}X_k^{ca}(-1)^{F(a)\cdot F(c)}+U\sum_j X_j^{44}, \tag{27}$$

where F is the graded number,

$$F(x)=\begin{cases}1, & \text{for } x=1,2,\\ 0, & \text{for } x=3,4.\end{cases}$$

The $t-J$ and Heisenberg Hamiltonians in terms of the local Hubbard operators are

$$H_{t-J}=-t\sum_{\langle jk\rangle}\sum_{a,c=1}^{3}X_j^{ac}X_k^{ca}(-1)^{F(a)\cdot F(c)}+(J-2t)\sum_{\langle jk\rangle}\sum_{a,c=1}^{2}X_j^{ac}X_k^{ca}; \tag{28}$$

$$H_{\text{Heisen.}}=J\sum_{\langle jk\rangle}\sum_{a,c=1}^{2}X_j^{ac}X_k^{ca}. \tag{29}$$

We clearly see that the extended Hubbard model, the t-J model, and Heisenberg model can be described in a unified manner. The Hamiltonians of these models can be written into a supersymmetric form explicitly in terms of the generators of the supergroup $U(2/M)$. In the following, we investigate the supergroup coherent state path-integral presentations of the $U(2/M)$ models.

It should be noticed that, so far, the discussion has been entirely about the $s=\frac{1}{2}$ case. Before going ahead further, we would like to generalize to high s. Let us imagine that the band electrons have an orbital degeneracy labeled by an index $a=1,2,\ldots,\mathcal{N}$, where $\mathcal{N}$ is the number of degenerate bands. The total band spin at a given site j is now given by $\mathbf{S}_j=\frac{1}{2}\Sigma_{\sigma,\sigma'=\pm1}\Sigma_{a=1}^{\mathcal{N}}c_{j\sigma,a}^{\dagger}\boldsymbol{\tau}_{\sigma\sigma'}c_{j\sigma',a}$. This system still has the global $SU(2)$ invariant of spin rotations. At the half-filling case, the local spin gets to be as large as possible. The equivalent Heisenberg model has a total spin quantum number s at each site equal to $s=\mathcal{N}/2$. The limit $\mathcal{N}\to\infty$ is the same as the semiclassical limit $s\to\infty$.[34]

III. SCHWINGER BOSONS (SLAVE FERMIONS) REPRESENTATIONS

Arovas and Auerbach[21] introduced two commuting Schwinger bosons b^i ($b^{i\dagger}$) ($i=1,2$) to describe states of spin. The operator b^i ($b^{i\dagger}$) obeys the commutation relation

$$[b^i,b^{j\dagger}]=\delta^{ij}, \tag{30}$$

and satisfies the constraint

$$\sum_{i=1}^{2}b^{i\dagger}b^i=1. \tag{31}$$

The bilinear forms of the Schwinger bosons yield the spin operators

$$\mathbf{S}=\frac{1}{2}(b^{1\dagger},b^{2\dagger})\boldsymbol{\tau}\begin{pmatrix}b^1\\ b^2\end{pmatrix}. \tag{32}$$

Furthermore, a slave fermion f ($f^{\dagger}$)[16] and the two Schwinger bosons can be used to represent the allowed states of the projected Hilbert space of the $t-J$ model. The slave fermion obeys the anticommutation relation

$$\{f^{\dagger},f\}=1, \tag{33}$$

and satisfies the constraints

$$\sum_{i=1}^{2} b^{i\dagger}b^{i}+f^{\dagger}f=1. \tag{34}$$

The $t-J$ model is faithfully represented by

$$H^{t-J}=t\sum_{\langle jk\rangle} f_j^{\dagger}f_k\mathscr{T}_{jk}-J\sum_{\langle jkl\rangle}(\delta_{jl}-f_l^{\dagger}f_j)\mathscr{A}_{lk}^{\dagger}\mathscr{A}_{lk}(1-f_k^{\dagger}f_k), \tag{35}$$

where

$$\mathscr{A}_{jk}=b_j^{1\dagger}b_k^{2\dagger}-b_j^{2\dagger}b_k^{1\dagger},\quad \mathscr{T}_{jk}=b_k^{1\dagger}b_j^{1\dagger}-b_k^{2\dagger}b_j^{2\dagger}.$$

Here $\langle jkl\rangle$ are triads of nearest neighbors.

In the general case, to denote the allowed states of the high-temperature superconductivity related lattice models, one can introduce a set of Schwinger bosons and slave fermions at each site, b^i $(b^{i\dagger})$ $(i=1,2,\ldots,N)$ and f^{α} $(f^{\alpha\dagger})$ $(\alpha=1,2,\ldots,M)$, which satisfy the following commutation (anticommutation) relations:

$$\begin{gathered}[b^i,b^{j\dagger}]=\delta^{ij},\quad i,j=1,2,\ldots,N,\\ \{f^{\alpha},f^{\beta\dagger}\}=\delta^{\alpha\beta},\quad \alpha,\beta=1,2,\ldots,M,\\ [b^i,f^{\alpha}]=0=[b^i,f^{\dagger\alpha}],\quad \{f^{\alpha},f^{\beta}\}=0=[b^i,b^j].\end{gathered} \tag{36}$$

For the sake of compactness, we denote the boson and fermion operators generically as ξ^A $(\xi^{\dagger A})$,

$$\begin{gathered}\xi^A(\xi^{A\dagger}),\quad A=1,2,\ldots,N+M,\\ \xi^i\equiv b^i,\quad i=1,2,\ldots,N,\\ \xi^{N+\alpha}\equiv f^{\alpha},\quad \alpha=1,2,\ldots,M,\end{gathered} \tag{37}$$

and write symbolically

$$[\xi^A,\xi^{B\dagger}\}=\delta^{AB}, \tag{38}$$

where the product [,} is to be understood as an anticommutator between any two fermionic components and as a commutator otherwise.

It is well known that the bosonic bilinears $b^ib^{j\dagger}$ and the fermionic bilinears $f^{\alpha}f^{\beta\dagger}$ generate the Lie algebras $u(N)$ and $u(M)$ under commutation, respectively. The Bose–Fermi bilinears $b^if^{\alpha\dagger}$ and $f^{\alpha}b^{i\dagger}$ close into the set $b^ib^{j\dagger}$ and $f^{\alpha}f^{\beta\dagger}$ under anticommutation,

$$\begin{gathered}\{f^{\alpha\dagger}b^i,b^{j\dagger}f^{\beta}\}=f^{\alpha\dagger}f^{\beta}\delta^{ij}+b^{j\dagger}b^i\delta^{\alpha\beta},\\ \{f^{\alpha\dagger}b^i,f^{\beta\dagger}b^j\}=0=\{b^{i\dagger}f^{\alpha},b^{j\dagger}f^{\alpha}\}.\end{gathered} \tag{39}$$

Thus, considering the boson-fermion bilinears as the odd generators and bosonic bilinears and fermionic bilinears as the even generators, one finds that the operators $\xi^{A\dagger}\xi^B$ form the superalgebra $u(N/M)$.[17,18]

Indeed, we have

$$\begin{gathered}X^{AB}=\xi^{A\dagger}\xi^B,\\ [X^{AC},X^{BD}\}=X^{AD}\delta^{BC}\pm X^{BC}\delta^{AD}.\end{gathered} \tag{40}$$

Thus X^{AB} generates the supergroup $U(N/M)$.

The Fock space of the system is of the form

$$
\begin{gathered}
|0\rangle = \text{vacuum}, \\
b^{i\dagger}|0\rangle, \quad f^{\alpha\dagger}|0\rangle = 1-\text{particle states}, \\
b^{i_1\dagger}b^{i_2\dagger}|0\rangle, \quad b^{i\dagger}f^{\alpha\dagger}|0\rangle, \quad f^{\alpha_1\dagger}f^{\alpha_2\dagger}|0\rangle = 2-\text{particle states}, \\
\vdots \\
b^{i_1\dagger}b^{i_2\dagger}\cdots b^{i_k\dagger}f^{\alpha_1\dagger}f^{\alpha_2\dagger}\cdots f^{\alpha_{\mathscr{L}-k}\dagger}|0\rangle = \mathscr{L}-\text{particle states}.
\end{gathered}
\tag{41}
$$

Generally, the $\mathscr{L}$-particle states may contain k bosons and $\mathscr{L}-k$ fermions, where $1\leqslant k\leqslant\mathscr{L}$.

It is easy to see that the total particle number operator,

$$
N_{bf} = \sum_i b^{i\dagger}b^i + \sum_\alpha f^{\alpha\dagger}f^\alpha = \sum_A \xi^{A\dagger}\xi^A, \tag{42}
$$

has the fixed eigenvalue $\mathscr{L}$ for the $\mathscr{L}$-particle states of any value of k, $1\leqslant k\leqslant\mathscr{L}$. It should be used to label the Fock space of the supersymmetric systems.

Supposing that the systems we are interested in are of $\mathscr{N}$-fold orbital degeneracy, we would focus on the $\mathscr{N}$-particle states of the Fock space. The $\mathscr{N}$-particle states may be written in terms of the operator $\xi^{A\dagger}$,

$$
\xi^{A_1\dagger}\xi^{A_2\dagger}\cdots\xi^{A_{\mathscr{N}}\dagger}|0\rangle. \tag{43}
$$

If we analyze the $\mathscr{N}$-particle state as a tensor in the boson and fermion indices, we find it is symmetric in bosonic indices $(i_1, i_2, \ldots, i_k)$ and antisymmetric in the fermionic indices $(\alpha_1, \alpha_2, \ldots, \alpha_{\mathscr{N}-k})$. Thus, in terms of Young tableau, we may represent it as

$$
\left(\begin{array}{ll} \underbrace{\heartsuit\,\heartsuit\cdots\heartsuit\,\heartsuit}_{k}, & \left.\begin{array}{l}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathscr{N}-k \end{array}\right). \tag{44}
$$

It indicates a direct product of a symmetric representation of $U(N)$ and an antisymmetric representation of $U(M)$. Thus, in terms of $U(N)\otimes U(M)$ representations, the $\mathscr{N}$-particle state are the direct sum,

$$
\left(\underbrace{\heartsuit\,\heartsuit\cdots\heartsuit\,\heartsuit}_{\mathscr{N}},0\right)\otimes\left(\underbrace{\heartsuit\,\heartsuit\cdots\heartsuit\,\heartsuit}_{\mathscr{N}\text{-}1},\heartsuit\right)\otimes\left(\underbrace{\heartsuit\,\heartsuit\cdots\heartsuit\,\heartsuit}_{\mathscr{N}\text{-}2},\begin{array}{l}\heartsuit\\ \heartsuit\end{array}\right)\otimes\cdots\otimes\left(0,\left.\begin{array}{l}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathscr{N}\right). \tag{45}
$$

We will indicate the supertensor by a super Young tableau,

$$\left(\underbrace{\spadesuit\spadesuit\cdots\spadesuit\spadesuit}_{\mathcal{N}} \right). \tag{46}$$

Thus, the $U(N/M)$ supertableau, if decomposed into its $U(N)\otimes U(M)$ parts, is seen to be Eq. (45).

Therefore, the $\mathcal{N}$-particle state may be understood as a collection of irreducible representations of the $U(N)\otimes U(M)$ subgroup. X^{ij} ($X^{\alpha\beta}$) kills a boson (fermion) and creates another boson (fermion) and $X^{\alpha i}$ ($X^{i\alpha}$) kills a boson (fermion) and creates a fermion (boson). Thus,

$$X^{ij}\left|\left(\begin{array}{c}\overbrace{\heartsuit\cdots\heartsuit *\cdots\heartsuit\heartsuit}^{j}\\ \underbrace{\qquad\qquad\qquad}_{k}\end{array},\ \left.\begin{array}{c}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k\right)\right\rangle\rangle=\left|\left(\begin{array}{c}\overbrace{\heartsuit\cdots\heartsuit *\cdots\heartsuit\heartsuit}^{i}\\ \underbrace{\qquad\qquad\qquad}_{k}\end{array},\ \left.\begin{array}{c}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k\right)\right\rangle\rangle,$$

$$X^{\alpha\beta}\left|\left(\underbrace{\heartsuit\heartsuit\cdots\heartsuit\heartsuit}_{k},\ \beta\left\{\begin{array}{c}\heartsuit\\ \vdots\\ \heartsuit *\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k\right)\right\rangle\rangle=\left|\left(\underbrace{\heartsuit\heartsuit\cdots\heartsuit\heartsuit}_{k},\ \alpha\left\{\begin{array}{c}\heartsuit\\ \vdots\\ \heartsuit *\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k\right)\right\rangle\rangle, \tag{47}$$

$$X^{\alpha i}\left|\left(\underbrace{\heartsuit\heartsuit\cdots\heartsuit\heartsuit}_{k},\ \left.\begin{array}{c}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k\right)\right\rangle\rangle=\left|\left(\underbrace{\heartsuit\heartsuit\cdots\heartsuit\heartsuit}_{k-1},\ \left.\begin{array}{c}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k+1\right)\right\rangle\rangle,$$

$$X^{i\alpha}\left|\left(\underbrace{\heartsuit\heartsuit\cdots\heartsuit\heartsuit}_{k},\ \left.\begin{array}{c}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k\right)\right\rangle\rangle=\left|\left(\underbrace{\heartsuit\heartsuit\cdots\heartsuit\heartsuit}_{k+1},\ \left.\begin{array}{c}\heartsuit\\ \heartsuit\\ \vdots\\ \heartsuit\\ \heartsuit\end{array}\right\}\mathcal{N}-k-1\right)\right\rangle\rangle,$$

so that the $X^{\alpha i}$ ($X^{i\alpha}$) acts as a ladder operator hopping to the right (left) in Eq. (45). If we apply all the operators X^{AB} taken to any power on the $\mathcal{N}$-particle state, we remain within the set of $\mathcal{N}$-particle states. This shows that the super-tableau (46) represents an irreducible set of states under all transformations of supergroup $U(N/M)$.

IV. SUPERGROUP COHERENT STATES

Consider an arbitrary quantum mechanical lattice model, whose Hamiltonian is expressed in terms of generators of a supergroup G, $X_j^l \in g$,

$$H = H(X_j^l). \tag{48}$$

We are now interested only in the case of the Hamiltonian involving linear and quadratic terms of X_j^l,

$$H = \sum_{j,k} \sum_{l,m} c_{lm}^{jk} X_j^l X_k^m + \sum_j \sum_l c_j^l X_j^l. \tag{49}$$

The superalgebra g spanned by the operators X_j^l is closed under commutation (anticommutation),

$$[X_j^k, X_j^l\} = \sum_k c_m^{kl} X_j^m, \tag{50}$$

where c_m^{kl} are the structure constants of g.

The group-theoretic approach to coherent states involves the use of unitary group representations.[35–37] We know that the standard supergroup elements connected to the identity are obtained by exponentiating superalgebra elements. There is thus one-to-one correspondence between such elements of the supergroup and points in the flat superspace $RM_L^{m,n}$,[38–40] which is the Cartesian product of m copies of RB_{L0} with n copies of RB_{L1}. A Grassmann algebra RB_L is an associative algebra generated by identity 1 and by L elements β_a ($a=1,2,\ldots,L$) obeying the anticommutation relations $\{\beta_a, \beta_b\} = 0$. The algebra is spanned by the identity and all independent nonvanishing products of β_a. There are 2^L linear independent basis elements. The subset of basis elements consisting of identity and all even products of the generators spans the even part RB_{L0} of RB_L; the remaining basis elements span the odd part RB_{L1}.

The set of left translations on a supergroup forms a supermodule W. This is the direct product of RB_L with a superalgebra. We denote the superalgebra generators[41] by X^1, $X^2,\ldots,X^m$; X^{m+1}, $X^{m+2},\ldots,X^{m+n}$. To obtain a unitary representation $T(g)$, we must work with the super-Hermitian basis of the superalgebra by choosing the generators so that $X^{j\dagger} = X^j$ for $j=1,2,\ldots,m$ and $X^{j\dagger} = -X^j$ otherwise. Thus, the operator

$$\begin{gathered} T(g) = \exp\left(\sum_{j=1}^{N^2+M^2} iA^j X^j + \sum_{j=1}^{2NM} i\theta^j X^{m+j} \right), \\ X^{j\dagger} = X^j, \quad \text{for } j = 1,2,\ldots,N^2+M^2, \\ X^{j\dagger} = -X^j, \quad \text{for } j = N^2+M^2+1,\ N^2+M^2+2,\ldots,(N+M)^2, \\ A^j \in RB_{L0}, \quad \theta^j \in RB_{L1}, \end{gathered} \tag{51}$$

defines an unitary representation of the supergroup $U(N/M)$.

To go to the super-Hermitian basis we must choose Hermitian combinations of the even generators and anti-Hermitian combinations of the odd ones. For the even generators we thus choose

$$X^k=\begin{cases} X^{ij}+X^{ji}, \\ i(X^{ij}-X^{ji}), \\ X^{\alpha\beta}+X^{\beta\alpha}, \\ i(X^{\alpha\beta}-X^{\beta\alpha}), \end{cases} \qquad k=1,2,\ldots,N^2+M^2. \tag{52}$$

And for the odd generators we choose the following anti-Hermitian operators:

$$X^k=\begin{cases} X^{\alpha i}-X^{i\alpha}, \\ i(X^{\alpha i}+X^{i\alpha}), \end{cases} \qquad k=N^2+M^2+1,\ldots,(N^2+M^2). \tag{53}$$

For the Hamiltonian (49), the Hilbert space V^Λ is a direct sum of unitary irreducible representations Γ_j of the supergroup G at each site of the lattice. In principle, we can choose an arbitrary state $|\Phi_0\rangle=|\Lambda\rangle$ within each unitary irreducible representation Γ_j^Λ, which can be normalized to unity $\langle\Phi_0|\Phi_0\rangle=1$. Acting by unitary representation Γ_j^Λ on the reference state Λ, we get the supergroup coherent states.

It should be noticed that there is a subgroup of $U(N/M)$ that consists of all the group elements h that leaves the reference state invariant up to a phase factor, called the maximum-stability subgroup H, i.e.,

$$h|\Lambda\rangle=|\Lambda\rangle e^{i\psi(h)}, \quad h\in H. \tag{54}$$

Every element g of the supergroup $U(N/M)$ can be uniquely decomposed into a product of two elements, one in H and the other in the quotient $U(N/M)/H$,

$$g=\Omega h, \quad g\in U(N/M), \quad h\in H, \quad \Omega\in U(N/M)/H, \tag{55}$$

so that we have

$$g|\Lambda\rangle=\Omega h|\Lambda\rangle=\Omega|\Lambda\rangle e^{i\psi(h)}. \tag{56}$$

$|SC\rangle\equiv\Omega|\Lambda\rangle$ is the supergroup coherent states. This definition of supergroup coherent states guarantees that there is a one-to-one correspondence with the coset space $U(N/M)/H$, so that the coordinates of the supergroup coherent states, $z^i\in RB_{L0}(\mu=1,2,\ldots,p)$, $z^\alpha\in RB_{L1}$ $[\alpha=1,2,\ldots,q$; and $p+q=\dim U(N/M)/H]$, may be chosen in any convenient parametrize representatives, $T(\Omega)$, from the cosets $U(N/M)/H$.

It is easy to see that

$$\begin{gathered} X^{\alpha\beta}\frac{1}{\sqrt{\mathcal{N}!}}(b^{1\dagger})^{\mathcal{N}}|0\rangle=0, \\ X^{ij}\frac{1}{\sqrt{\mathcal{N}!}}(b^{1\dagger})^{\mathcal{N}}|0\rangle=0, \quad \text{for } j\neq 1, \\ X^{i\alpha}\frac{1}{\sqrt{\mathcal{N}!}}(b^{1\dagger})^{\mathcal{N}}|0\rangle=0, \\ X^{\alpha i}\frac{1}{\sqrt{\mathcal{N}!}}(b^{1\dagger})^{\mathcal{N}}|0\rangle=0, \quad \text{for } i\neq 1. \end{gathered} \tag{57}$$

These operators span a subalgebra $u(1)\otimes u(N-1/M)$ of $u(N/M)$. The corresponding supergroup $U(1)\otimes U(N-1/M)$ is just the stability subgroup of $U(N/M)$, which leaves the state $(1/\sqrt{\mathcal{N}!})\times(b^{1\dagger})^{\mathcal{N}}|0\rangle$ invariant.

Choosing $(1/\sqrt{\mathcal{N}!})(b^{1\dagger})^{\mathcal{N}}|0\rangle$ as the reference state $|\Lambda\rangle$ in the representation denoted by the super Young tableau (46), we obtain the supergroup coherent states by acting

$$\Omega=\exp\left(\sum_{j=1}^{N}\eta^{j}X^{1j}+\sum_{\alpha=1}^{M}\eta^{\alpha}X^{1\alpha}-\sum_{j=1}^{N}\eta^{j\dagger}X^{j1}-\sum_{\alpha=1}^{M}\eta^{\alpha\dagger}X^{1\alpha}\right), \tag{58}$$

on the chosen reference state $(1/\sqrt{\mathcal{N}!})(b^{1\dagger})^{\mathcal{N}}|0\rangle$,

$$|SC\rangle=\Omega|\Lambda\rangle=\exp\left(\sum_{j=1}^{N}\eta^{j}X^{1j}+\sum_{\alpha=1}^{M}\eta^{\alpha}X^{1\alpha}-\sum_{j=1}^{N}\eta^{j\dagger}X^{j1}-\sum_{\alpha=1}^{M}\eta^{\alpha\dagger}X^{1\alpha}\right)\frac{1}{\sqrt{\mathcal{N}!}}(b^{1\dagger})^{\mathcal{N}}|0\rangle, \tag{59}$$

where $\eta^{j}\in CB_{L0}$, $\eta^{\alpha}\in CB_{L1}$, and CB_{L0}, CB_{L1} denotes the even and odd part of a complex Grassmann algebra with L elements, respectively.

These supergroup coherent states have a natural topological coset space $U(N/M)/[U(1)\otimes U(N-1/M)]$.

The fundamental representation of the superalgebra $u(N/M)$ is generated by the $(N+M)$-dimensional matrices,

$$(X^{AB})_{mn}=\delta^{A}_{m}\delta^{B}_{n}. \tag{60}$$

Thus, we have

$$\Omega=\exp\left(\sum_{j=1}^{N}\eta^{j}X^{1j}+\sum_{\alpha=1}^{M}\eta^{\alpha}X^{1\alpha}-\sum_{j=1}^{N}\eta^{j\dagger}X^{j1}-\sum_{\alpha=1}^{M}\eta^{\alpha\dagger}X^{1\alpha}\right)=\exp\begin{pmatrix}\bigcirc & \eta\\ -\eta^{\dagger} & \bigcirc\end{pmatrix}, \tag{61}$$

where η is an $(N+M-1)$-component rank vector with the first $(N-1)$ elements ordinary complex numbers while the last M elements complex Grassmann numbers. Therefore, in the fundamental representation, the finite transformation Ω is of the form

$$(\Omega)^{D}_{C}(z)=\begin{pmatrix}\sqrt{1-zz^{\dagger}} & z\\ -z^{\dagger} & \sqrt{1-z^{\dagger}z}\end{pmatrix}, \tag{62}$$

where $z=\eta(\sin\sqrt{\eta^{\dagger}\eta}/\sqrt{\eta^{\dagger}\eta})$, is also an $(N+M-1)$-component rank vector with the same grad with η. This is a supersymmetric generalization of the bosonic case discussed in Ref. 15.

If we explicitly introduce a complex projective representation τ of $U(N/M)/[U(1)\otimes U(N-1/M)]$,

$$\tau=\frac{z}{\sqrt{1-z^{\dagger}z}}, \tag{63}$$

any group transformation g acting on the coset space $U(N/M)/[U(1)\otimes U(N-1/M)]$ must be a holomorphic transformation,

$$\tau'=g\tau=\frac{A\tau+B}{C\tau+D}, \tag{64}$$

where

$$g=\begin{pmatrix} A & B \\ C & D \end{pmatrix} \in U(N+M),$$

$A(D)$ is a 1×1 $((N+M-1)\times(N+M-1))$ complex matrix, $B(C)$ is a $1\times(N+M-1)$ $((N+M-1)\times 1)$ matrix.

Just as the ordinary group coherent states, two important algebraic properties are maintained by the supergroup coherent states. From the definition of the supergroup coherent states, we have

$$\langle SC(z)|SC(z')\rangle=\langle\Lambda|\Omega^{-1}(z)\Omega(z')|\Lambda\rangle=\langle\Lambda|\Omega(z'')|\Lambda\rangle e^{i\psi}\neq 0, \tag{65}$$

and

$$\langle SC(z)|SC(z)\rangle=\langle\Lambda|\Omega^{-1}(z)\Omega(z)|\Lambda\rangle=\langle\Lambda|\Lambda\rangle=1. \tag{66}$$

Thus the supergroup coherent states are generally nonorthogonal but normalized to unity.

Define the operator O as

$$O=\int |SC(z)\rangle d\mu(\Omega(z))\langle SC(z)|, \tag{67}$$

we obtain that

$$gO=\int g|SC(z)\rangle d\mu(\Omega(z))\langle SC(z)|g^{-1}g=\int |SC(z')\rangle e^{i\phi'(h)}d\mu(\Omega(z'))e^{-i\phi'(h)}\langle SC(z')|g$$

$$=Og, \quad g\in U(N/M), \tag{68}$$

where $d\mu(\Omega)$ is the supergroup-invariant measure of $U(N/M)$ possessing the property $d\mu(\Omega(z))=d\mu(\Omega(z'))$.

Therefore, according to Schurr's lemma, the operator O must be proportional to the identity operator. Hence, with an appropriately normalized measure $d\mu$, we can get

$$\int |SC(z)\rangle d\mu(\Omega(z))\langle SC(z)|=1. \tag{69}$$

The supergroup coherent states can be expanded in a complete orthonormal basis $|\lambda\rangle$,

$$|SC(z)\rangle=\sum_{\lambda} |\lambda\rangle\langle\lambda|SC(z)\rangle, \tag{70}$$

and it is possible to project the orthonormal basis vectors from the supergroup coherent states by making use of Eq. (69),

$$|\lambda\rangle=\int d\mu(\Omega(z))|SC(z)\rangle\langle SC(z)|\lambda\rangle. \tag{71}$$

The supergroup coherent states therefore constitute an overcomplete basis.

V. PATH-INTEGRAL REPRESENTATIONS

Typically we are interested in studying both zero-temperature and finite-temperature properties of a system. At finite temperature, the equilibrium properties are determined by the partition function

$$Z=\mathrm{Tr}\ e^{-H/k_BT}. \tag{72}$$

At zero temperature we are interested in the vacuum persistence amplitudes,

$$Z=\mathrm{Tr}\ \hat{T}\ \exp\left(-\frac{i}{\hbar}\int_{-\infty}^{\infty}H\ d\tau\right), \tag{73}$$

where $\hat{T}$ is the time order operator.

In this section, we generalize the method of RSS[15] to supersymmetric systems and give the supergroup coherent state path-integral representation of the high T_c superconductivity related lattice models. For a supersymmetric system with the supergroup theoretic Hamiltonian H, the standard path integral is derived as follows. We first split up the time interval τ into N_τ segments of infinitesimal length $\Delta\tau$ such that $N_\tau\cdot\Delta\tau=\tau$. For infinitesimal intervals $\Delta\tau\to 0$, we can write

$$Z=\mathrm{Tr}\ \hat{T}\ \exp\left(-\frac{i}{\hbar}\sum_{j=1}^{N_\tau}H(\tau_j)\Delta\tau\right)=\mathrm{Tr}\ \hat{T}\prod_{j=1}^{N_\tau}\exp\left(-\frac{i}{\hbar}H(\tau_j)\Delta\tau\right). \tag{74}$$

Then we insert the resolution of identity (69) at each intermediate time τ_j. We get

$$\begin{aligned}
Z=&\lim_{\Delta\tau\to 0}\int\left\langle SC(z_f)\left|e^{-iH\,\Delta\tau/\hbar}\right|SC\left(z_f-\frac{dz}{d\tau}\Delta\tau\right)\right\rangle d\mu\left(\Omega\left(z_f-\frac{dz}{d\tau}\Delta\tau\right)\right)\\
&\times\left\langle SC\left(z_f-\frac{dz}{d\tau}\Delta\tau\right)\left|e^{-iH\,\Delta\tau/\hbar}\right|SC\left(z_f-\frac{dz}{d\tau}2\,\Delta\tau\right)\right\rangle d\mu\left(\Omega\left(z_f-\frac{dz}{d\tau}2\,\Delta\tau\right)\right)\\
&\times\left\langle SC\left(z_f-\frac{dz}{d\tau}2\,\Delta\tau\right)\right|\cdots\left|SC\left(z_i+\frac{dz}{d\tau}\Delta\tau\right)\right\rangle d\mu\left(\Omega\left(z_i+\frac{dz}{d\tau}\Delta\tau\right)\right)\\
&\times\left\langle SC\left(z_i+\frac{dz}{d\tau}\Delta\tau\right)\left|e^{-iH\,\Delta\tau/\hbar}\right|SC(z_i)\right\rangle\\
=&\int\mathscr{D}[d\mu(\Omega(\tau))]\exp\left(\frac{i}{\hbar}\int_{-\infty}^{\infty}L\ d\tau\right),
\end{aligned} \tag{75}$$

where $\mathscr{D}[d\mu(\Omega(\tau))]$ is the functional measure of the path integral and L is the Lagrangian of the system.

The overlap between neighboring coherent states is

$$\langle SC(z+dz)|SC(z)\rangle=\langle\Lambda|\Omega^{-1}(z+dz)\Omega(z)|\Lambda\rangle=1-\tfrac{1}{2}\mathscr{N}(z\ dz^\dagger-dz\ z^\dagger). \tag{76}$$

Hence, the Lagrangian of the system takes the form

$$L=-\frac{\hbar}{2i}\mathscr{N}(z\ \partial_\tau z^\dagger-\partial_\tau z\ z^\dagger)-H(z,z^\dagger). \tag{77}$$

The canonical momenta of the system are

$$\pi_i=\frac{\partial L}{\partial\dot{z}^i}=\frac{\hbar}{i}\mathscr{N}z^{i\dagger}. \tag{78}$$

Canonical quantization gives the commutation rules,

$$[z^i,z^j\}=0,\quad [z^i,z^{j\dagger}\}=\frac{1}{\mathcal{N}}\delta_{ij},\quad [z^{i\dagger},z^{j\dagger}\}=0. \tag{79}$$

To construct the generators out of these operators it is helpful to consider first their coherent state expectation values,

$$\begin{aligned}\langle SC(z)|X^{AB}|SC(z)\rangle&=\langle\Lambda|\Omega^{-1}(z)X^{AB}\Omega(z)|\Lambda\rangle=(\Omega^{-1}(z))^{AC}\langle\Lambda|X^{CD}|\Lambda\rangle(\Omega(z))^{DB}\\&=\mathcal{N}(\Omega^{-1}(z)Y\Omega(z))^{AB},\end{aligned} \tag{80}$$

where

$$Y=\begin{pmatrix}\mathcal{N} & 0\\ 0 & 0\end{pmatrix}.$$

With the matrices $\Omega(z)$ given by Eq. (62) one obtains

$$\langle SC(z)|X^{AB}|SC(z)\rangle=\begin{pmatrix}\mathcal{N}(1-zz^\dagger) & \mathcal{N}\sqrt{1-zz^\dagger}z\\ \mathcal{N}z^\dagger\sqrt{1-zz^\dagger} & \mathcal{N}z^\dagger z\end{pmatrix}. \tag{81}$$

The classical expressions on the rhs of the above equation suggest the following operator realization:

$$\begin{aligned}X^{11}(z)&=\mathcal{N}\left(1-\sum_{k=1}^{N+M-1}z^{k\dagger}z^k\right),\\ X^{1(j+1)}(z)&=\mathcal{N}\sqrt{1-\sum_{k=1}^{N+M-1}z^{k\dagger}z^k}z^j,\quad j=1,2,\ldots,N+M-1,\\ X^{(i+1)1}(z)&=\mathcal{N}z^{i\dagger}\sqrt{1-\sum_{k=1}^{N+M-1}z^{k\dagger}z^k},\quad i=1,2,\ldots,N+M-1,\\ X^{(i+1)(j+1)}(z)&=\mathcal{N}z^{i\dagger}z^j.\end{aligned} \tag{82}$$

It is easy to verify, using the commutation rules (79), that these operators satisfy the superalgebra $u(N/M)$.

From now on we discuss the high-temperature superconductivity related lattice models and so that we restrict ourselves at the case of $N=2$. We expect that the high-temperature superconductivity materials, at least the short-range order, should have Néel character, it is natural to consider the staggered and uniform components of the z field, i.e., on sublattice A we use the above z parametrization and on sublattice B we use another set of parametrization. Making use of a parameter transformation of the supergroup coherent states.

$$\begin{aligned}z^1&\to -z^1\sqrt{1-\sum_{i=1}^{1+M}z^{i\dagger}z^i},\quad z^{1\dagger}\to -\sqrt{1-\sum_{i=1}^{1+M}z^{i\dagger}z^i}z^{1\dagger},\\ z^i&\to\frac{z^{1\dagger}}{\sqrt{z^{1\dagger}z^1}}z^i,\quad i=2,3,\ldots,1+M,\\ z^{i\dagger}&\to z^{i\dagger}\frac{z^{1\dagger}}{\sqrt{z^{1\dagger}z^1}},\quad i=2,3,\ldots,1+M,\end{aligned} \tag{83}$$

we get the other set of expectations of X_j^{ac},

$$\langle SC(z')|X^{ac}|SC(z')\rangle$$

$$=\begin{pmatrix} \mathcal{N}z^{1\dagger}z^1 & -\mathcal{N}\sqrt{1-\sum_{i=1}^{1+M} z^{i\dagger}z^i}\,z^1 & \mathcal{N}z^{1\dagger}z' \\ -\mathcal{N}z^{1\dagger}\sqrt{1-\sum_{i=1}^{1+M} z^{i\dagger}z^i} & \mathcal{N}\left(1-\sum_{i=1}^{1+M} z^{i\dagger}z^i\right) & -\mathcal{N}\sqrt{1-\sum_{i=1}^{1+M} z^{i\dagger}z^i}\,z' \\ \mathcal{N}z'^{\dagger}z^1 & -\mathcal{N}z'^{\dagger}\sqrt{1-\sum_{i=1}^{1+M} z^{i\dagger}z^i} & \mathcal{N}z'^{\dagger}z' \end{pmatrix}, \tag{84}$$

where we have used the notation $z'=(z^2,z^3,\ldots,z^{1+M})$.

This set of expectations arise another Holstein–Primakoff realization of the superalgebra $u(2/M)$,

$$X^{11}(z)=\mathcal{N}z^{1\dagger}z^1,\quad X^{12}(z)=-\mathcal{N}\sqrt{1-\sum_{k=1}^{1+M} z^{k\dagger}z^k}\,z^1,$$

$$X^{1(j+1)}=\mathcal{N}z^{1\dagger}z^j,\quad j=2,3,\ldots,1+M,$$

$$X^{21}(z)=-\mathcal{N}z^{1\dagger}\sqrt{1-\sum_{k=1}^{1+M} z^{k\dagger}z^k},$$

$$X^{22}=\mathcal{N}\left(1-\sum_{k=1}^{1+M} z^{k\dagger}z^k\right),\quad X^{2(j+1)}=-\mathcal{N}\sqrt{1-\sum_{k=1}^{1+M} z^{k\dagger}z^k}\,z^j, \tag{85}$$

$$X^{(i+1)1}=\mathcal{N}z^{i\dagger}z^1,\quad i=2,3,\ldots,1+M,$$

$$X^{(i+1)2}=-\mathcal{N}z^{i\dagger}\sqrt{1-\sum_{k=1}^{1+M} z^{k\dagger}z^k},$$

$$X^{(i+1)(j+1)}(z)=\mathcal{N}z^{i\dagger}z^j.$$

Let H^0 be the Hamiltonian for the system with $U(2/M)$ symmetry on a two-dimensional lattice,

$$H^0=-t\sum_{\langle jk\rangle}\sum_{a,c=1}^{2+M} X_j^{ac}X_k^{ca}(-1)^{F(a)\cdot F(c)}, \tag{86}$$

where

$$F(x)=\begin{cases}1, & x=1,2,\\ 0, & x=3,4,\ldots,2+M.\end{cases}$$

Then we have

$$
\begin{aligned}
H^0(z)&=\langle SC(z)|H|SC(z)\rangle\\
&=-t\sum_{\langle jk\rangle}\sum_{a,c=1}^{2+M}\langle X_j^{ac}\rangle\langle X_k^{ca}\rangle(-1)^{F(a)\cdot F(c)}\\
&=\frac{t}{2}\sum_{\langle jk\rangle}\sum_{a,c=1}^{2}(\langle X_j^{ac}\rangle+\langle X_k^{ac}\rangle)(\langle X_j^{ca}\rangle+\langle X_k^{ca}\rangle)-t\sum_j\sum_{a,c=1}^{2}\langle X_j^{ac}\rangle\langle X_j^{ca}\rangle\\
&\quad+\frac{t}{2}\sum_{\langle jk\rangle}\sum_{a=1}^{2}\sum_{c=3}^{2+M}(\langle X_j^{ac}\rangle+\langle X_k^{ac}\rangle)(\langle X_j^{ca}\rangle-\langle X_k^{ca}\rangle)\\
&\quad+\frac{t}{2}\sum_{\langle jk\rangle}\sum_{a=3}^{2+M}\sum_{c=1}^{2}(\langle X_j^{ac}\rangle+\langle X_k^{ac}\rangle)(\langle X_j^{ca}\rangle-\langle X_k^{ca}\rangle)\\
&\quad+\frac{t}{2}\sum_{\langle jk\rangle}\sum_{a,c=3}^{2+M}(\langle X_j^{ac}\rangle-\langle X_k^{ac}\rangle)(\langle X_j^{ca}\rangle-\langle X_k^{ca}\rangle)-t\sum_j\sum_{a,c=3}^{2+M}\langle X_j^{ac}\rangle\langle X_j^{ca}\rangle. \qquad (87)
\end{aligned}
$$

We will not consider here frustrated systems. Thus, and for the sake of simplicity, we will consider the case of $U(2/M)$ models on bipartite lattices. We split the staggered z_j^1 field into a slowly very piece $\phi(j)$, the order parameter field, and a small rapidly varying part, $\xi(j)$,

$$
\begin{aligned}
z_j^1&=\phi(j)+a_0\xi(j), \quad \text{for sublattice } A,\\
z_j^1&=\phi(j)-a_0\xi(j), \quad \text{for sublattice } B,
\end{aligned} \qquad (88)
$$

where a_0 denotes the lattice spacing.

We work with the constraint that requires that

$$
\sum_{a,c=1}^{2+M}\langle X^{ac}(z)\rangle\langle X^{ca}(z)\rangle(-1)^{F(a)\cdot F(c)}=\sum_{a,c=1}^{2+M}\langle X^{ac}(\phi)\rangle\langle X^{ca}(\phi)\rangle(-1)^{F(a)\cdot F(c)}. \qquad (89)
$$

By making use of the large $\mathcal{N}$ approximation, we obtain

$$
H^0(\phi,\xi;z')=\frac{t\mathcal{N}^2}{2}\int dx\,dy\left(\partial_\mu\phi\;\partial^\mu\phi^\dagger+4\xi\xi^\dagger+4\sum_{k=2}^{1+M}z^{k\dagger}z^k\right), \qquad (90)
$$

where $\partial_\mu\phi\;\partial^\mu\phi^\dagger\equiv\partial_x\phi\;\partial_x\phi^\dagger+\partial_y\phi\;\partial_y\phi^\dagger$.

We know that the Lagrangian of the $U(2/M)$ model is

$$
L^0(z)=-\frac{i\hbar}{2}\mathcal{N}\sum_j\left\{(-1)^{S(j)}(z_j^1\;\partial_\tau z_j^{1\dagger}-\partial_\tau z_j^1\;z_j^{1\dagger})+\sum_{i=2}^{1+M}(z_j^i\;\partial_\tau z_j^{i\dagger}-\partial_\tau z_j^i\;z_j^{i\dagger})\right\}-H^0(z), \qquad (91)
$$

where

$$
S(j)=\begin{cases}0, & \text{for sublattice } A,\\ 1, & \text{for sublattice } B.\end{cases}
$$

To complete the discussion of the continuum limit, it is necessary to consider the kinetic term,

$$-\frac{i\hbar}{2}\mathcal{N}\sum_j\left\{(-1)^{S(j)}(z_j^1\ \partial_\tau z_j^{1\dagger}-\partial_\tau z_j^1\ z_j^{1\dagger})+\sum_{i=2}^{1+M}(z_j^i\ \partial_\tau z_j^{i\dagger}-\partial_\tau z_j^i\ z_j^{i\dagger})\right\}.$$

Substituting Eq. (88), we obtain, after discarding a total derivative,

$$-\frac{i\hbar}{2}\mathcal{N}\sum_j(-1)^{S(j)}(z_j^1\ \partial_\tau z_j^{1\dagger}-\partial_\tau z_j^1\ z_j^{1\dagger})\doteq\frac{-i\hbar\mathcal{N}}{a_0}\int dx\ dy(\xi\ \partial_\tau\phi^\dagger-\partial_\tau\phi\ \xi^\dagger).\tag{92}$$

Thus, the Lagrangian becomes as

$$L^0(\phi,\xi;z_i)=-\frac{i\hbar\mathcal{N}}{a_0}\int dx\ dy(\xi\ \partial_\tau\phi^\dagger-\partial_\tau\phi\ \xi^\dagger)-\frac{i\hbar\mathcal{N}}{2a_0^2}\int dx\ dy\sum_{i=2}^{1+M}(\partial_\tau z^i\ z^{i\dagger}+\partial_\tau z^{i\dagger}\ z^i)$$
$$-\frac{t\mathcal{N}^2}{2}\int dx\ dy\left(\partial_\mu\phi\ \partial^\mu\phi^\dagger+4\xi\xi^\dagger+4\sum_{i=2}^{1+M}z^{i\dagger}z^i\right).\tag{93}$$

The auxiliary fields ξ can be eliminated by solving the Euler–Lagrange equation $\delta L/\delta\xi=0$,

$$2t\mathcal{N}^2\xi^\dagger=-\frac{i\hbar\mathcal{N}}{a_0}\partial_\tau\phi^\dagger,\quad 2t\mathcal{N}^2\xi=\frac{i\hbar\mathcal{N}}{a_0}\partial_\tau\phi.\tag{94}$$

Therefore, we obtain

$$L^0(\phi,z_i)\doteq\int dx\ dy\left(\frac{\hbar^2}{2ta_0^2}\partial_\tau\phi\ \partial_\tau\phi^\dagger-\frac{t\mathcal{N}^2}{2}\partial_\mu\phi\ \partial^\mu\phi^\dagger\right)$$
$$-\int dx\ dy\sum_{i=2}^{1+M}\left(\frac{i\hbar\mathcal{N}}{2a_0^2}(\partial_\tau z^i\ z^{i\dagger}+\partial_\tau z^{i\dagger}\ z^i)+2t\mathcal{N}^2z^{i\dagger}z^i\right).\tag{95}$$

To deal with the realistic models related to high-temperature superconductivity, we must consider the interactive Hamiltonian. The whole Lagrangian of the two-dimensional (2-D) extended Hubbard model is

$$L_{\text{Hub.}}(\phi,z_i)\doteq\int dx\ dy\left(\frac{\hbar^2}{2ta_0^2}\partial_\tau\phi\ \partial_\tau\phi^\dagger-\frac{t\mathcal{N}^2}{2}\partial_\mu\phi\ \partial^\mu\phi^\dagger\right)$$
$$-\int dx\ dy\sum_{i=2}^{3}\left(\frac{i\hbar\mathcal{N}}{2a_0^2}(\partial_\tau z^i\ z^{i\dagger}+\partial_\tau z^{i\dagger}\ z^i)+2t\mathcal{N}^2z^{i\dagger}z^i\right)-\frac{U}{a_0^2}\int dx\ dy\ z^{3\dagger}z^3.\tag{96}$$

The Lagrangian of the $t-J$ model on the two-dimensional lattice is

$$L_{t-J}(\phi,z_i)\doteq\int dx\ dy\left(\frac{\hbar^2}{2Ja_0^2}\partial_\tau\phi\ \partial_\tau\phi^\dagger-\frac{J\mathcal{N}^2}{2}\partial_\mu\phi\ \partial^\mu\phi^\dagger\right)$$
$$-\int dx\ dy\left(\frac{i\hbar\mathcal{N}}{2a_0^2}(\partial_\tau z^2\ z^{2\dagger}+\partial_\tau z^{2\dagger}\ z^2)+2t\mathcal{N}^2z^{2\dagger}z^2\right).\tag{97}$$

And the Lagrangian of the 2-D Heisenberg model is simply

$$L_{\text{Heisen.}}(\phi,z_i)\doteq\int dx\ dy\left(\frac{\hbar^2}{2Ja_0^2}\partial_\tau\phi\ \partial_\tau\phi^\dagger-\frac{J\mathcal{N}^2}{2}\partial_\mu\phi\ \partial^\mu\phi^\dagger\right).\tag{98}$$

Making use of the property of Grassmann integrals,

$$\int \mathscr{D}z^{i\dagger}\,\mathscr{D}z^{i}\,\exp\left(-\int z^{i\dagger}Mz^{i}\right)=\mathrm{Det}\;M,\quad z^{i},z^{i\dagger}\in CB_{L1}, \tag{99}$$

we can integrate out the fermionic fields and obtain an effective Lagrangian that involves only a bosonic part,

$$L^{\mathrm{eff}}_{\mathrm{Hub.}}(\phi)=\int dx\;dy\left(\frac{\hbar^{2}}{2ta_{0}^{2}}\,\partial_{\tau}\phi\;\partial_{\tau}\phi^{\dagger}-\frac{t\mathscr{N}^{2}}{2}\,\partial_{\mu}\phi\;\partial^{\mu}\phi^{\dagger}\right)$$
$$-i\;\ln\left(\mathrm{Det}\left(\frac{i\hbar\mathscr{N}}{a_{0}^{2}}\,\partial_{\tau}+2t\mathscr{N}^{2}\right)\mathrm{Det}\left(\frac{i\hbar\mathscr{N}}{a_{0}^{2}}\,\partial_{\tau}+2t\mathscr{N}^{2}+\frac{U}{a_{0}^{2}}\right)\right); \tag{100}$$

$$L^{\mathrm{eff}}_{t-J}(\phi)=\int dx\;dy\left(\frac{\hbar^{2}}{2Ja_{0}}\,\partial_{\tau}\phi\;\partial_{\tau}\phi^{\dagger}-\frac{J\mathscr{N}^{2}}{2}\,\partial_{\mu}\phi\;\partial^{\mu}\phi^{\dagger}\right)-i\;\ln\,\mathrm{Det}\left(\frac{i\hbar\mathscr{N}}{a_{0}^{2}}\,\partial_{\tau}+2t\mathscr{N}^{2}\right). \tag{101}$$

Therefore, up to a constant, the low-energy excitations of the extended Hubbard model, $t-J$ model and Heisenberg model is described, in a unified manner, by the nonlinear σ model. In other words, the nonlinear σ model gives a sensible description of the spin fluctuations of the high T_c superconductivity materials. This agrees with the predictions of the weak-coupling mean-field theory.

VI. CONCLUDING REMARKS

In this paper, we have shown that the supergroup $U(N/M)$ plays an important role in a kind of high-temperature superconductivity related lattice model. To arrive at a continuum field theory description of these models, we constructed supergroup coherent states by a standard approach. A nonlinear σ model was obtained as an effective field theory of low-energy excitations of spin–spin interactions of high T_c superconductivity materials in the supergroup coherent state path-integral representation. This result is within our expectations, the spin–spin interactions can be described by the nonlinear σ model in the absence of doping and doping do not violate the Néel ground state, at least in the low doping case. This also proves the prediction of weak-coupling mean-field theory in fermion coherent state path-integral representation. In the fermion coherent state path-integral representation,[34,42,43] the Lagrangian of the Hubbard model is of the form

$$L=\frac{i}{\hbar}\sum_{\langle jk\rangle}\sum_{\sigma=\pm1}\Phi^{\dagger}_{j\sigma}\;\partial_{\tau}\Phi_{k\sigma}+2t\sum_{\langle jk\rangle}\sum_{\sigma=\pm1}\Phi^{\dagger}_{j\sigma}\Phi_{k\sigma}+\frac{U}{6}\sum_{j}\;(\Phi^{\dagger}_{j\sigma}\boldsymbol{\tau}_{\sigma\sigma'}\Phi_{j\sigma'})^{2}. \tag{102}$$

The associated path-integral contains quartic terms, the interaction, and hence we do not know how to complete the partition function. Introducing a vector real boson field $\boldsymbol{\phi}$ and using the Hubbard–Stratonovich transformation,[44,45]

$$\int d\boldsymbol{\phi}\,\exp\left(-\frac{i}{\hbar}\left(\frac{1}{2}\,\boldsymbol{\phi}^{2}+\lambda\,\boldsymbol{\phi}\Phi^{\dagger}\boldsymbol{\tau}\Phi\right)\right)=\mathrm{const}\times\exp\left(\frac{i}{2\hbar}\,\lambda^{2}(\Phi^{\dagger}\boldsymbol{\tau}\Phi)^{2}\right), \tag{103}$$

one can get an equivalent Lagrangian of the Hubbard model,

$$L'=\frac{i}{\hbar}\sum_{\langle jk\rangle}\sum_{\sigma=\pm1}\Phi^{\dagger}_{j\sigma}\;\partial_{\tau}\Phi_{k\sigma}+2t\sum_{\langle jk\rangle}\sum_{\sigma=\pm1}\Phi^{\dagger}_{j\sigma}\Phi_{k\sigma}-\sqrt{\frac{U}{3}}\sum_{j}\;\boldsymbol{\phi}_{j}\Phi^{\dagger}_{j\sigma}\boldsymbol{\tau}_{\sigma\sigma'}\Phi_{j\sigma'}-\frac{1}{2}\sum_{j}\;\boldsymbol{\phi}^{2}_{j}. \tag{104}$$

The $\boldsymbol{\phi}$ fields represent the collective modes associated with spin fluctuations. The effective Lagrangian is given by

$$L^{\text{eff}}(\boldsymbol{\phi}) = -\frac{1}{2}\sum_j \boldsymbol{\phi}^2 - i \ln \text{Det}\left(\frac{i}{\hbar}\partial_\tau - M(\boldsymbol{\phi})\right), \tag{105}$$

where $M(\boldsymbol{\phi})$ is a functional matrix of the $\boldsymbol{\phi}$ fields. On the mean-field-theory approximation, the effective Lagrangian shows the relevant nonlinear effects. The properties of the effective Lagrangian suggests that the nonlinear σ model,

$$L^{\text{eff}} = \frac{\rho}{2}\left(\partial_\tau \boldsymbol{\phi}\cdot\partial_\tau \boldsymbol{\phi} - v_s^2\ \partial_\mu \boldsymbol{\phi}\cdot\partial^\mu \boldsymbol{\phi}\right) + \cdots\ , \tag{106}$$

describes the slow spin fluctuations. In this paper we have proved the assumption but not used any approximation, except large spin and long wavelength.

Two-body wave equations in curved space–time

Philippe Droz-Vincent

(Received 14 July 1995; accepted for publication 3 May 1996)

Two scalar particles undergoing mutual interaction are considered in a prescribed curved space–time. Both masses are finite (recoil is not neglected). For a description of this system we propose a pair of coupled Klein–Gordon equations; they involve two-body-sector extensions of the Laplace–Beltrami operator, plus a term that takes mutual interaction into account. Besides the problem of compatibility, we discuss several requirements that seem more or less necessary from a physical point of view. Particular attention is devoted to the preservation of space–time symmetries (isometric invariance). Composition of curvature with mutual interaction is a nonlinear problem, but it can be explicitly solved in a toy model of static orthogonal space–time. Moreover, we check that isometric invariance and other physical requirements are satisfied in this example. © *1996 American Institute of Physics.* [S0022-2488(96)02708-9]

I. INTRODUCTION

The perturbation of energy levels of an atom in curved space–time is of considerable theoretical interest. Several years ago, Parker pointed out the possibility to consider a hydrogen atom as a probe of space–time curvature.[1] We would like to add that, *in principle*, also the elementary quark model of composite hadrons should be somehow affected by the presence of an extremely strong gravitational field.

Of course, curvature effects on the *internal* structure of composite systems are of very small magnitude and cannot be directly observed in accessible regions of space–time. For an atomic system, a significant effect would require a radius of curvature of the order of 10^{-3} cm (a molecule should be more sensitive).

Nevertheless, regions of such large curvature might exist in the neighborhood of small black holes left over from the early stage of the universe. And one must bear in mind that observations of more and more remote regions of space provides us with information about the early universe, a laboratory of large curvature.

All these reasons have motivated an abundant flow of papers about quantum mechanics of atoms in curved space–time.[1–3] Most authors have systematically neglected the recoil of the nucleus. It was the merit of Fischbach, Freeman, and Cheng[3] to point out that taking recoil into account may, in weak gravitational fields, introduce a correction of the same magnitude as the gravitational perturbations (and this remark is more drastically relevant for positronium). They realized that a fully relativistic treatment of two-body dynamics in the presence of gravity is a difficult problem, and they undertook to solve it along the lines of the Bakamjian–Thomas formalism.[4] In this context they devoted special attention to the problem of separating relative variables from the center-of-mass coordinates, a delicate question previously considered by Krajcik and Foldy.[5]

However, the modern developments of relativistic particle dynamics[6–9] allow for a more sophisticated and more efficient framework. In our opinion it has now become natural and reasonable to look after a *manifestly covariant* description of mutually interacting particles moving in a prescribed Riemannian space–time.

Insofar as pair creation can be neglected (and taking recoil into account does not change the conditions under which this approximation is valid, so one is referred to the literature quoted

0022-2488/96/37(9)/4274/18/$10.00

above in order to discuss this point) any arbitrary, but fixed, number of particles could be, in principle, considered. But in practice, we are in a position to undertake the study of *two-body* quantum mechanics because the progresses obtained up to now in flat space–time have essentially concerned the two-body sector.

Our approach to the quantum mechanics of composite systems was obtained by quantizing ''predictive relativistic mechanics.''[6] It agrees with the possibility of considering relativistic particle dynamics as a constraint theory[7] (papers in this field are currently referred to in the literature as constraint relativistic mechanics). This standpoint implies eliminating the field that underlies the mutual interaction, thus *only the particle degrees of freedom* are explicitly considered, and eventually coupled to gravity.

The basic equations for two interacting scalar particles are a pair of Klein–Gordon equations coupled by appropriate terms that carry the mutual interaction and must ensure compatibility.[6] This term can be either phenomenological or motivated by consideration of quantum field theory. In this latter case, the contact between coupled Klein–Gordon equations and the standard methods of quantum electrodynamics in the two-body sector has been firmly established, see Todorov for the quasipotential approach[9] and Sazdjian[10] for the relationship to Bethe–Salpeter equation (BS equation). In fact, the coupled equations of relativistic quantum mechanics present several advantages over the BS equation.

Turning now to the situation where gravity is present as an external field, we observe that, in spite of promising advances, quantum theory is not yet developed in curved space–time as far as to produce a tractable version of the BS equation, taking curvature effects into account. Thus, a formulation of two-body dynamics in curved space–time using a pair of wave equations would be very convenient.

In principle, generalizing quantum mechanics to a Lorentzian manifold M_4 is straightforward if the d'Alembert symbol is replaced by the Laplace Beltrami operator (for simplicity we consider minimal coupling). So let us write

$$2H_a\Psi = m_a^2\Psi, \quad a=1,2, \tag{1.1}$$

where the particle masses are m_1, m_2. The wave function Ψ depends on eight arguments, namely the coordinates of a couple q_1, q_2 taken in $M_4 \times M_4$. It is always possible to write $H_a = K_a + V_a$, where K_1, K_2, respectively, refer to particles 1 and 2, namely

$$K_a = -\tfrac{1}{2}\, g(a)^{\alpha\beta}\boldsymbol{\nabla}_{a\alpha}\boldsymbol{\nabla}_{a\beta}, \tag{1.2}$$

whereas V_1, V_2 are considered as describing the mutual interaction. In view of our knowledge of the flat-space–time theory,[6] we expect to have in most cases of interest the unipotential simplification $V_1 = V_2 = V$.

To avoid unnecessary complications we assume that space–time M_4 has the trivial topology. It is clear that Eqs. (1.1) must be mutually compatible. By natural generalization of the flat-space–time theory, we require a strong *compatibility condition*, namely

$$[H_1, H_2] = 0. \tag{1.3}$$

At this stage it is already a practical problem to determine in closed form which interaction term can be added to the Laplace–Beltrami operators without violating condition (1.3). This problem was solved years ago[6] for an isolated system in Minkowski space (the word isolated refers to the absence of an external field). Even if one remains in flat space–time, the presence of external fields is a difficulty, because *relativistic interactions cannot be linearly composed*. In the flat case however, some results have been obtained, for external potentials with special symmetries.[11–14]

In the present case we consider a system that is submitted to no external force but gravity. Physically, this situation is analogous to the flat case in the presence of an external potential. But we have a lot of extra complications due to the geometric nature of General Relativity.

Our main goal is to construct closed-form examples of a pair of wave equations, mutually consistent in the presence of a curvature field. But we shall also discuss the general features of such equations, with special care for a set of reasonable requirements one should impose to them. Among these conditions isometric invariance plays the role of a generalization of the Poincaré invariance usually required in the flat case.

We first recollect, in Sec. II, several well-known results about the manifestly covariant formulation of two-body dynamics in flat space–time. In this framework, and in order to make possible a contact with the work of Fishbach *et al.*, we propose a relativistic covariant version of the concept of center of mass, and we outline its connection with the separation of canonical variables we are currently using.

In Sec. III we address the general problem of two mutually interacting particles imbedded in a curved space–time. An axiomatic discussion (focusing on invariance properties) provides a set of necessary conditions restricting the possible choice of H_1 and H_2. Then it will be interesting to exhibit an example satisfying all (or part of) these minimal requirements. Keeping this goal in mind, a preliminary work is in order. That is why in Sec. IV we recall some standard facts about the motion of a test particle *alone* in a curved space–time with possible isometries. In addition, we systematically introduce a flat background metric and put special emphasis on the role of isometries.

We return to the two-body case in Sec. V. Finally, a specific form of the metric tensor will be assumed. The particular symmetry enjoyed by this metric singles out a natural flat background where standard methods of *special relativistic quantum mechanics in external fields* can be finally applied. Moreover, this metric is invariant under time translation in a strong sense, which allows for solving (in closed form) the compatibility problem. We ultimately discuss whether the outcome of this procedure satisfies the conditions we have previously demanded. Section VI will be devoted to concluding remarks.

Notation: Particle labels $a,b=1,2$. Space–time manifold M_4. Partial differentiation with respect to coordinates are noted as $\partial_\mu=\partial/\partial q^\mu$, $\partial_{a\mu}=\partial/\partial q_a^\mu$. The use of q_1,q_2 is not a typographic fancy; we mean to recall that in the classical limit ($\hbar\to 0$) the arguments of the wave function should, in principle, reduce to the canonical coordinates of a covariant Hamiltonian formulation and cannot coincide with the physical coordinates (say x_1,x_2) in the *large* (that is unconstrained) *phase space*, where the standard Poisson brackets are implemented.[6]

Greek labels are omitted whenever no confusion is possible. When we consider a flat background metric $\underline{g}_{\mu\nu}$, its reciprocal tensor is $\underline{g}^{\alpha\beta}$. The determinants are g and $\underline{g}$, respectively. Of course, Cartesian coordinates refer to $\underline{g}_{\mu\nu}$.

Scalar products indicated by a dot always refer to the flat metric. For instance $p^2=p\cdot p$ stands for $\underline{g}^{\mu\nu}p_\mu p_\nu$. Indices will be rised (lowered) with help of the flat metric only. $p_{a\alpha}$ is the operator with components $-i\partial/\partial q_a^\alpha$ in the Cartesian coordinates.

Angular momentum in flat space–time is $m^{\alpha\beta}=q^\alpha p^\beta-q^\beta p^\alpha$.

Dependence on the coordinates and/or momenta of particle a is indicated as in $g(a)=g(q_a)$, etc.

In Cartesian coordinates, we separate canonical variables in two groups as follows:

$$z^\alpha=q_1^\alpha-q_2^\alpha,\quad y=\tfrac{1}{2}(p_1-p_2), \tag{1.4}$$

$$P=p_1+p_2,\quad Q=\tfrac{1}{2}(q_1^\alpha+q_2^\alpha), \tag{1.5}$$

hence the commutators

$$[z^\alpha, y_\beta] = [Q^\alpha, P_\beta] = i\,\delta^\alpha_\beta. \tag{1.6}$$

The total angular momentum is defined as

$$M = q_1 \wedge p_1 + q_2 \wedge p_2 = Q \wedge P + z \wedge y,$$

which allows for checking that P and M actually generate the Lie algebra of the Poincaré group.

Projection orthogonal to P is performed with help of the tensor $\Pi^\mu_\nu = \delta^\mu_\nu - P^\mu P_\nu / P^2$. As in Ref. 12, we define

$$Z = z^2 P^2 - (z \cdot P)^2. \tag{1.7}$$

The superscript (0), like for instance in $V^{(0)}$, refers to the isolated system (no curvature involved).

Throughout this paper, *symmetric operators will be referred to as Hermitian*. Isometry always refers to the Riemannian metric, never to the metric of Hilbert space.

Definition: A flat metric $\overline{g}$ is said to be *isometrically admissible* with respect to g if any isometry of g is an isometry of $\overline{g}$.

II. TWO-BODY DYNAMICS IN FLAT SPACE–TIME

In order to avoid misunderstandings, the reader who is not familiar with constraint relativistic mechanics is cautioned that the field that carries mutual interaction does not explicitly appear in the system of coupled equations (1.1).

For the moment, let us postpone the question of coupling this picture to the curvature field, and consider the dynamics of an isolated two-body system in flat space–time.

One may think of two scalar particles of the same nature (like, e.g., pions undergoing electromagnetic interactions). Both constituent particles correspond to the same matter field. This field is considered in the two-body sector and interacts with some mediating field (like photon, gluon, etc.), which carries mutual interaction between the particles. Standard methods of quantum field theory allow for elimination of the mediating field. For instance, the quasipotential approach gives rise to a differential equation complemented with an extra equation, which handles the problem of relative time. Alternatively, one may use the integrodifferential Bethe–Salpeter equation (BS), which is characterized by its kernel. Of course, any term in the Lagrangian that couples the matter field with the mediating field will result in a contribution to the quasipotential equation, or equivalently a contribution to the BS kernel. So the analytic form of this kernel reflects the interaction between the matter field and the mediating field. Under reasonably general assumptions, it has been proved that the BS equation can be transformed into a pair of coupled *differential* equations of the form (1.1) (naturally approximations may be made, some diagrams may be considered as dominant, etc.; the reader is referred to Sazdjian[11] for details). In practice, any potential of the form $V^{(0)} = f(Z, P^2, y \cdot P)$ or simply $f(Z, P^2)$ is general enough to accommodate most relevant examples of interaction between scalar constituents.

We insist that our approach is self-contained within the two-body sector. Like in the BS equation, our wave function is a (c-number) scalar depending on two points of space–time. But in the absence of a mediating field, it would reduce to a superposition of products of (classical, complex) Klein–Gordon fields.

Wave equations are of the form (1.1). The couple q_1, q_2 has Cartesian coordinates q_1^α, q_2^β in $M_4 \times M_4$.

The multiplicative operators q_1, q_2 are canonically conjugate to the operators $p_1 = -i\partial/\partial q_1$, $p_2 = -i\partial/\partial q_2$. The Lie algebra of the Poincaré group has the generators $P = p_1 + p_2$, $M = q_1 \wedge p_1 + q_2 \wedge p_2$. Notice that these formulas are valid, irrespective of the mutual interaction exerted between the particles. P^α is interpreted as total momentum, since its components generate space–time translations. It is remarkable that if we define $z^\alpha = q_1^\alpha - q_2^\alpha$, this operator is invariant under translation. It is therefore natural to regard z as a relative quantity and to complete the

commuting set P^α, z^β by eight more variables in order to obtain a new set of 16 canonical variables. After this, we end up with two separate kinds of variables. In fact, the interpretation of z can be justified by a precise analysis in terms of the *physical* coordinates of the particles, provided one gets back to the level of *classical* (relativistic) mechanics, where the concept of world line still makes sense. For this purpose let us sketch the classical Hamiltonian formulation underlaying our description of two-particle systems by coupled wave equations. We follow the line of a two-time formalism, which considers the proper times as independent parameters. Phase space is a 16-dimensional symplectic space with *canonical* coordinates satisfying the standard Poisson bracket relations $\{q_a^\alpha, p_{b\beta}\} = \delta_{ab}\delta_\beta^\alpha$, etc. In terms of these canonical coordinates, the motion is governed by Hamiltonian equations of the form.

$$\frac{\partial A}{\partial \tau_a} = \{A, H_a\}, \tag{2.1}$$

where H_1, H_2 are the Hamiltonian generators and τ_1, τ_2 are proportional to the proper times (these Hamiltonians, identified as half-squared masses, should not be confused with the Dirac Hamiltonian H_{D}, which arises in the constraints approach and is numerically zero). They are mutually in involution, which ensures that equations of the form (2.1) are consistent. In fact, H_1, H_2 generate a two-parameter Abelian group. The orbits of this group are eventually identified as the Cartesian products $\Gamma_1 \times \Gamma_2$, where Γ_1 (resp., Γ_2) is the lift in phase space of the world line of particle 1 (resp., particle 2). A complication associated with the famous No-Interaction Theorem[15] is that, in general, Poincaré invariance implies that the physical positions x_1^α, x_2^β cannot be canonical. They coincide with the canonical coordinates *only* on a certain submanifold (Σ). [This point is sometimes hidden in the constraints formulation, because this alternative approach deals with a submanifold of (Σ).] The Poisson bracket $\{x_1^\alpha, x_2^\beta\}$ differs from the metric tensor $\eta^{\alpha\beta}$ (its precise value is model dependent). Throughout the whole phase space, x_1, x_2 may be complicated functions of the canonical variables. Specifying the manifold (Σ) is actually a boundary condition that achieves the definition of the system we consider. In a large class of models one assumes that the equation of (Σ) is simply $P \cdot z = 0$. It is clear that every point of (Σ) also satisfies

$$P \cdot (x_1 - x_2) = 0. \tag{2.2}$$

Provided P is time-like, this equation expresses that in the frame where $\mathbf{P}=0$ (rest frame of the system) one has $x_1^0 = x_2^0$. Therefore (Σ) is called the equal-time surface; the points located on it have equal-time coordinates in the system rest frame. Finally, the connection between z and the physical relative coordinates is as follows: *In restriction to* (Σ) *and in the rest frame*, $z^0 = 0$ and $\mathbf{z} = \mathbf{q}_1 - \mathbf{q}_2 = \mathbf{x}_1 - \mathbf{x}_2$.

We pursue the task of forming a new set of canonical coordinates by completion of P, z with conjugate quantities. Limiting ourselves to a linear transformation (from individual coordinates to the new set) we can define

$$Q = \lambda q_1 + (1-\lambda) q_2, \quad y = (1-\lambda) p_1 - \lambda p_2, \tag{2.3}$$

and we can check $\{Q^\alpha, P_\beta\} = \{z^\alpha, y_\beta\} = \delta_\beta^\alpha$, $\{Q^\alpha, Q^\beta\} = \{y^\alpha, y^\beta\} = 0$. For any choice of the positive constant $\lambda < 1$, we obtain two separate sets of canonical variables. With an obvious abuse of language, a popular terminology refers to Q, P and z, y, respectively, as center-of-mass variables and relative variables. For computational simplicity we take $\lambda = \frac{1}{2}$. Still, some explanation is necessary in order to somehow relate Q with the physical center of mass. Here we hit the delicate question of defining this concept in a covariant framework,[5,16,17] but we shall not discuss here the various definitions of relativistic center of mass. We simply propose to consider the quantities

$$\Xi = \frac{M\cdot P}{P^2} + \frac{P\cdot Q}{P^2}\,P, \tag{2.4}$$

as the space–time coordinates of the center of mass. This definition may be justified as follows:

(i) It is manifestly covariant.

(ii) Owing to the constancy of M and P, the quantities Ξ^α are the coordinates of a point that moves on a straight line when τ_1,τ_2 run from $-\infty$ to $+\infty$, and this line is parallel to P.

(iii) For the configurations taken on the equal-time surface, Ξ reduces to

$$\Xi^\alpha_\Sigma = \frac{P\cdot p_1}{P^2}\,x_1^\alpha + \frac{P\cdot p_2}{P^2}\,x_2^\alpha \tag{2.5}$$

[hint $P^2/2 \pm y\cdot P = P\cdot p_1$ (resp. $P\cdot p_2$)]. Therefore, in the rest frame (defined by P^α) the spatial component of Ξ_Σ coincides with definition (c) of Pryce[16] (average of the coordinates weighted by the energies).

(iv) One easily computes $\{(M\cdot P/P^2)^\alpha, P^\beta\} = \Pi^{\alpha\beta}$ and $\{T, P^\beta\} = P^\beta/P^2$, whence we derive equations of motion in single-particle form,

$$\{\Xi^\alpha, P^\beta\} = \eta^{\alpha\beta}, \quad \left\{\Xi^\alpha, \frac{P^2}{2}\right\} = P^\alpha, \quad P^\alpha = \text{const.} \tag{2.6}$$

However, the components of Ξ have nonvanishing Poisson brackets among themselves and cannot be taken as canonical coordinates. This is reminiscent of definition (c) in Pryce,[16] and agrees with a remark made by Llosa.[17]

In the rest frame and at equal times, the spatial piece of Ξ finally reduces to the object that is called ''center of energy'' by Feshman *et al.*,[3] and agrees with the definition of Lightman and Lee,[18] in the classical limit. Finally, it is easy to see how Ξ differs from Q, if we notice that Ξ can be equivalently written as

$$\Xi = Q + \left(\frac{y\cdot P}{P^2}\right) z + \left(\frac{z\cdot P}{P^2}\right) y. \tag{2.7}$$

The second term on the right-hand side expresses that Ξ involves a weighted average: this term vanishes in the case of equal masses (then $P\cdot p_1 = P\cdot p_2$). The last term on the right-hand side vanishes at equal times.

Ξ^α has four components, but the contraction $\Xi\cdot P$ is identical with $Q\cdot P$ and is trivially related to the proper time of the center of mass.

Still, we must remember that this picture is limited to isolated systems. In the presence of external fields, we naturally retain the interpretation that P is the total momentum, but it is not constant anymore. Moreover, the use of the surface $P\cdot z = 0$ for a boundary condition in this case is probably questionable, and no reasonable modification of it, adapted to the external field, is known for the moment. As a result, the relationship between z^α and $x_1^\alpha - x_2^\alpha$ is not anymore well defined when external coupling is turned on.

Also, it remains an open problem as to know how Eq. (2.6) are modified and whether they keep a single-particle form, in the presence of curvature. A similar question was earlier discussed in Refs. 3 and 18, but substantial differences existing between their formulation and ours make it difficult to transpose their conclusions.

Nevertheless, the variables Q, P, z, y introduced by (1.4), (1.5) remain canonical whatsoever and they split anyway into two separate groups. In the presence of an external field, like, for instance, gravity, their labeling as ''center-of-mass variables'' and ''relative variables'' is a manifest abuse of language, and should be avoided in a rigorous terminology.

Still, they provide a powerful tool in order to organize tractable calculations (see Ref. 12).

III. GENERAL FRAMEWORK

We now turn to the case where curvature is present (no other external force is being considered).

A. Compatibility

The wave equations have the form (1.1). We naturally require the strong condition (1.3), which ensures compatibility. Assuming that $V_1=V_2=V$, condition (1.3) reduces to

$$[K_1-K_2,V]=0. \tag{3.1}$$

B. Hermiticity

In order to have a consistent mathematical setting, the squared-mass operators on the left-hand side of (1.1) (and eventually the generators of transformations induced by space–time symmetries, if any) must be considered as acting in some well-defined Hilbert space; this remains true even if the wave function cannot actually belong to this Hilbert space.

Therefore we shall naturally assume that H_1,H_2 are operators in

$$L^2(\mathbf{R}^8)=L^2(\mathbf{R}^8,\sqrt{|g(1)|}\sqrt{|g(2)|}d^4q_1\ d^4q_2).$$

Here the following observation is in order. In the absence of mutual interaction we can write (1.1) in the form of independent Klein–Gordon equations,

$$2K_a\Psi=m_a^2\Psi, \tag{3.2}$$

where $2K_a$ is the Laplace Beltrami operator in terms of the coordinates of particle a. It is well known[19] that this operator is Hermitian when considered as acting in $L_a^2=L^2(\mathbf{R}^4,\sqrt{|g(a)|}d^4q_a)$, thus K_1 and K_2, extended as operators acting in $L^2(\mathbf{R}^8)=L_1^2\otimes L_2^2$ are both Hermitian. Despite the fact that the four-fold integrals defining L_1^2 and L_2^2 have no direct physical interpretation, this property of hermiticity is very fortunate from a formal point of view. Already in special relativity, it has been demonstrated that off-shell Hilbert spaces of the form $L^2(\mathbf{R}^4)$ or $L^2(\mathbf{R}^8)$ provide the most convenient framework for handling Feynmann's propagators in a manifestly covariant way [for instance, $1/(p^2+U-m^2\pm i\epsilon)$, where U is an external potential, naturally makes sense as the resolvent of an operator in $L^2(\mathbf{R}^4,d^4q)$, and similar observations can be made when interparticle interaction is considered[20]]. We extend this philosophy to curved space–time and require hermiticity as well in the presence of mutual interactions.

In other words, we demand that H_1,H_2 are Hermitian operators in the Hilbert space $L^2(\mathbf{R}^8)$.

At a deeper level of accuracy one would raise the question of self-adjointness, in connection with the possibility of developing a manifestly covariant scattering theory in terms of scalar evolution parameters. Indeed, there are two possibilities in relativistic dynamics.

(For simplicity of the present argument, let us provisionally consider the case of a single particle.) The most popular point of view consists in using the time coordinate as an indicator of evolution (say q^0 in some coordinate system); then the Klein–Gordon equation is interpreted as the relativistic generalization of the time-depending Schrödinger equation.

Another approach, in the spirit of Schwinger's ''proper time method''[21] assigns this role to a scalar parameter, which coincides with proper time (or a suitable generalization of it) in the classical limit $\hbar\to 0$; now the Klein–Gordon equation is a mass-shell reduction of the Stückelberg equation,[22] and the D'Alembert operator is trivially proportional to the generator of the motion. In this case, self-adjointness of the D'Alembert operator with respect to the *four-space* scalar product (involving integration over d^4q) would be a precious information in order to set up a complete quantum theory.

Although we have a preference for the latter point of view (which has been extended to many-body systems[20,23]), we shall not discuss further the evolutive aspects of the wave equations.

Returning to the problem of two-body quantum mechanics in curved space–time, we shall be contented, in this first attempt, with the property of hermiticity (symmetry) and leave the question of self-adjointness for future investigations (notice that even in the one-body case, self-adjointness in the four-space scalar product has received so far very little attention, if any).

C. Coupling separability

The above conditions are not yet sufficient from a physical point of view. Indeed, one expects to find the *correct limits when either the curvature or the mutual interaction is absent*.

When the curvature identically vanishes, one should recover an isolated system of particles interacting in Minkowski space–time.

When the mutual interaction is zero, the wave equations should describe independent particles, each one being free in curved space–time (in other words, submitted only to the curvature field associated with the metric).

These situations will be referred to as the *no-field limit* and the *independent-particles limit*, respectively.

As simple as it might seem, the formulation of correct limits is problematic in curved space–time. First of all, *the notion of an isolated system is generally ambiguous*. Strictly speaking, the absence of curvature does not correspond to a well-specified Minkowski space.

But, in practice, there are cases where this difficulty can be bypassed.

(i) One may consider a particular solution of the Einstein equations. This solution necessarily depends on the Newton constant, and we obtain a flat metric if we replace this constant by zero.

(ii) Particular symmetries may select a flat metric in a natural way (asymptotically flat space–times, plane waves, etc.). Another example: $ds^2=dt^2-d\sigma^2$, where $d\sigma^2$ enjoys spherical symmetry (but not more).

Besides this problem about the unicity of a flat background, additional care is needed because the most natural flat background and the Riemannian metric do not define the same Hilbert space. Indeed, the quotient $\overline{g/g}$ of scalar densities is a scalar, and, in general, it is not a constant (the case of a plane wave, in the weak field approximation and TT gauge, is an exception). One might be tempted to consider only flat metrics satisfying $\overline{g/g}=$const. as eligible for a flat background. But generally, this procedure does not respect the symmetries of the pseudo-Riemannian metric $g_{\mu\nu}$. Indeed, it may happen that none of the background metrics selected in this manner is isometrically admissible.

Fortunately, the technical complication of having distinct Hilbert spaces will be easily handled by a change of wave function that amounts to reformulating the wave equations in terms of a new wave function $\tilde{\Psi}$, an (improper) element of

$$\overline{L^2}(\mathbf{R}^8)=L^2(\mathbf{R}^8,\sqrt{\overline{g(1)}\,\overline{g(2)}}d^4q_1\,d^4q_2),$$

and in terms of modified operators that are Hermitian (symmetric) in this new Hilbert space. This approach can be considered as a change of representation, performed with the help of a unitary transformation from L^2 to $\overline{L^2}$. This method allows for application of flat-space techniques: Cartesian coordinates, etc.

D. Isometric invariance

It may happen that space–time admits some isometries. If we first consider the motion of a single test particle, each isometry of space–time is associated with a conserved quantity: its generator.

A natural generalization of flat-space theory consists in requiring that the generators of these isometries must be constants of the two-body motion, even in the presence of a mutual interaction.

Whereas an *isolated system* in Minkowski space is characterized by Poincaré symmetry (Poincaré invariance from the active point of view), *it is natural to require that an isolated system in curved space–time be at least invariant under the infinitesimal unitary transformations associated with space–time isometries*. This should hold true as well for two-body as for one-body systems, and also when the constituent particles undergo mutual interaction. For this aim it is not sufficient that the interaction term be Poincaré invariant in its no-field limit, say $V^{(0)}$. Indeed, this term is modified by the presence of curvature (namely $V \neq V^{(0)}$) in order to keep compatibility satisfied.

The question of whether this condition is sufficient goes beyond the scope of this paper (when space–time has no isometry at all, this condition becomes empty; is it still possible to define isolated systems?).

Remark: When we perform a change of wave function, some unitary transformation of the whole picture is necessary. This transformation maps $L^2(\mathbf{R}^8)$ either onto itself or onto a different Hilbert space, and obviously keeps the compatibility conditions satisfied. When identifying the no-field and independent-particle limits, one must take this change of representation into account. For instance, after transformation (4.5) below, the independent-particle limit is characterized by the half-squared-mass operators $\tilde{K}_1, \tilde{K}_2$, which are Hermitian in $L^2(\mathbf{R}^8)$. We first recall a few results of Riemannian geometry (see the Appendix).

If ξ generates infinitesimal isometries of g, then, in the standard notation of differential geometry the Lie derivative operator satisfies $\mathscr{L}_\xi \Delta = \Delta \mathscr{L}_\xi$. When f is a 0-form, that is a scalar function, we simply have $\mathscr{L}_\xi f = \xi^\alpha \partial_\alpha f$. Moreover, $\xi^\alpha \partial_\alpha$ is skew symmetric with respect to the scalar product that defines $L^2(\mathbf{R}^4)$.

Isometries are implemented as quantum operators in the following way. With any vector field ξ^α leaving $g_{\mu\nu}$ invariant, we associate the operator $X = -i\xi^\mu \partial_\mu$ acting in $L^2(\mathbf{R}^4, d^4q)$. It is clear that X is Hermitian.

In the two-body sector ones deal with $L^2(\mathbf{R}^8) = L_1 \otimes L_2$. The isometric vector ξ^α induces the operators

$$J_1 = -i\xi^\alpha(1)\partial_{1\alpha}, \quad J_2 = -i\xi^\alpha(2)\partial_{2\alpha}, \tag{3.3}$$

respectively acting in L_1, L_2. Then J_1, J_2 are extended to $L^2(\mathbf{R}^8)$ as $J_1 \otimes 1$ and $1 \otimes J_2$, respectively. Considered as operators in $L^2(\mathbf{R}^8)$, they are the *individual isometries* (for instance, in the limit of free motion in flat space–time, linear and angular momenta of each particle are trivial examples of individual isometries). Finally, the *total isometry* induced by ξ^μ is $J = J_1 + J_2$.

IV. THE ONE-BODY PROBLEM

In the Klein–Gordon equation $2K\psi = m^2\psi$, the D'Alembert symbol is replaced by the Laplace–Beltrami operator. In other words,

$$-2K\psi = \frac{1}{\sqrt{|g|}} \partial_\mu (\sqrt{|g|} g^{\mu\nu} \partial_\nu \psi).$$

K transforms as a scalar and is Hermitian[19] in the space $L^2(\mathbf{R}^4, \sqrt{|g|} d^4q)$. Moreover, if the contravariant vector field $\xi^\mu(q)$ is the infinitesimal generator of a one-parameter group of transformations leaving g invariant, then a *classical* constant of geodesic motion is the function $\xi^\mu \pi_\mu$, a scalar on the cotangent bundle $T^*(M_4)$ endowed with coordinates q^α, π_β and with the standard Poisson brackets.

Its quantum counterpart is the differential operator $X = -i\xi^\mu \partial_\mu$.

But the partial differentiation operator ∂_μ present in the above expression of $K\psi$ is neither a vector nor Hermitian in the sense of Hilbert space L^2.

Nevertheless, if we now introduce any flat metric $\overline{g_{\mu\nu}}$, then the operator defined as $p_\mu = -i\partial_\mu$ in the Cartesian coordinates associated with $\overline{g}$ does transform as a vector and is Hermitian in the space $\overline{L^2}(\mathbf{R}^4) = L^2(\mathbf{R}^4, \sqrt{|\overline{g}|}d^4q)$ endowed with the scalar product

$$\langle \chi, \omega \rangle = \int \chi^* \omega \sqrt{|\overline{g}|} d^4q. \tag{4.1}$$

Moreover, we have $X = \xi \cdot p$.

Using Cartesian coordinates makes it trivial to check that we can write

$$2K = \frac{1}{\sqrt{|g|}} p_\mu \sqrt{|g|} g^{\mu\nu} p_\nu. \tag{4.2}$$

This situation suggests a change of wave function, say

$$\widetilde{\psi} = \Gamma \psi,$$

where the ''bimetric'' scalar Γ is

$$\Gamma = |g/\overline{g}|^{1/4}, \tag{4.3}$$

that is to say, $\sqrt{|g|} = \Gamma^2 \sqrt{|\overline{g}|}$. The Klein–Gordon equation can now be written as

$$2\widetilde{K}\widetilde{\psi} = m^2 \widetilde{\psi}, \tag{4.4}$$

where, for all operator A,

$$\widetilde{A} = \Gamma A \Gamma^{-1}. \tag{4.5}$$

In this formula Γ is understood as a multiplicative operator acting on functions $f(q)$. Notice that $\widetilde{K}$ is Hermitian in $\underline{L^2}$, we say flat Hermitian. Equation (4.3) is a unitary transformation from $L^2(\mathbf{R}^4, \sqrt{|g|}d^4q)$ to $\underline{L^2}(\mathbf{R}^4)$. The multiplicative operator Γ (and, more generally, any function of q) is Hermitian in both $L^2(\mathbf{R}^4)$ and $L^2(\mathbf{R}^4)$.

Applying rule (4.5) to Eq. (4.1), we immediately find

$$2\widetilde{K} = \Gamma^{-1} p_\mu \Gamma g^{\mu\nu} \Gamma p_\nu \Gamma^{-1}, \tag{4.6}$$

which is manifestly flat Hermitian. We define an *effective* external potential F by setting

$$\widetilde{K} = \tfrac{1}{2}p^2 + F. \tag{4.7}$$

From its very definition, F is flat Hermitian. So finally, both $\widetilde{K}$ and F are Hermitian in $\overline{L^2}$.

Notice that we could write F down in closed form, by elementary commutator algebra, starting from (4.6) and splitting the contravariant metric tensor as $g^{\mu\nu} = \overline{g^{\mu\nu}} + h^{\mu\nu}$. Of course, the contravariant components of $\overline{g}$ reduce to $\eta^{\mu\nu} = \mathrm{diag}(1,-1,-1,-1)$ in Cartesian coordinates.

Let us now consider the behavior of infinitesimal isometries.

If ξ generates infinitesimal isometries of $g_{\mu\nu}$, it follows that $\xi^\alpha \partial_\alpha$ commutes with K [both being considered as operators in $L^2(\mathbf{R}^4)$]. After introduction of an auxiliary flat metric $\overline{g}$, we can write $X = -i\xi^\alpha \partial_\alpha = \xi \cdot p$ and $[\xi \cdot p, K] = 0$, where $\xi \cdot p$ and K are Hermitian in $L^2(\mathbf{R}^4)$.
Henceforth we assume that $\overline{g}$ is isometrically admissible.

Proposition 1: Assume that ξ is an isometry of both g and $\overline{g}$. Then transformation (4.5) leaves $X = \xi \cdot p$ unchanged, so $\widetilde{X} = X$. In other words, in the Poincaré Lie algebra associated with the flat

metric, any element that leaves also g invariant is unchanged by transformation (4.5). *Moreover,* $\tilde{K}$ *as well as* K *commutes with* X*, and* X *is Hermitian in both* L^2 *and* $\overline{L^2}$.

Proof: ξ being isometry of g and $\overline{g}$ implies that the Lie derivative of the bimetric scalar vanishes, say $\xi^\alpha \partial_\alpha \Gamma = 0$, thus the multiplicative operator Γ satisfies $[\xi\cdot p, \Gamma] = 0$. We have seen that $\xi^\alpha \partial_\alpha$ commutes with the Laplace Beltrami operator Δ. After transformation (4.5) we get $[\tilde{K}, \xi\cdot p] = 0$. We have already proved that $\xi\cdot p$ is Hermitian in L^2. But according to our assumption, there exist, *in Cartesian coordinates*, a constant vector C^α and a skew-symmetric tensor $C^{\alpha\beta}$, such that

$$X = \xi^\alpha p_\alpha = C^\alpha p_\alpha + C^{\alpha\beta} m_{\alpha\beta}. \tag{4.8}$$

In this form, it is manifest that $\xi\cdot p$ is Hermitian also in the sense of $\overline{L^2}$.

Corollary 2: If $\mathscr{L}_\xi g = \mathscr{L}_\xi \overline{g}$ *then* $[\xi\cdot p, F] = 0$. This is now obvious from Eq. (4.7) and shows the importance of having $\overline{g}$ isometrically admissible.

Example: We now consider a line element of the simple form,

$$ds^2 = d(q^0)^2 - R^2(r)\, d\mathbf{q}^2, \tag{4.9}$$

where $d\mathbf{q}^2$ is a shorthand notation for $\delta_{ij}\, dq^i\, dq^j$ and r is $\sqrt{\mathbf{q}^2}$. This metric defines a particular case of static orthogonal space–time. We assume that R is everywhere finite and differentiable as many times as necessary. Space sections are supposed to be isotropic but *not* homogeneous. They have a unique center of spherical symmetry; thus the form (4.9) of the metric is unique up to a change,

$$q'^k = \Lambda q^k, \quad R' = \Lambda^{-1} R,$$

but we fix the space coordinates by requiring that $R(\mathbf{q}=0) = 1$.

Our assumptions imply that

$$R^2 \neq \frac{\text{const}}{(1 + \frac{1}{4} k r^2)^2}.$$

This restriction excludes the particular case of an Einstein static space–time.

A preferred background metric is, of course, $d\overline{s^2} = d(q^0)^2 - d\mathbf{q}^2$.

Notice that the metrics $g_{\mu\nu}$ and $\overline{g_{\mu\nu}}$ coincide on the line $q^k = 0$, world line of the center of spherical symmetry.

Both metrics are invariant under time translation and space rotations, and $g_{\mu\nu}$ has no further symmetry. Each generator of these isometries (considered as a Hermitian operator in L^2) commutes with K.

Alternatively, when the state of the particle is represented by $\tilde{\psi}$ and its motion described by Eq. (4.4), the infinitesimal rotations and the time translation keep being represented by the same operators m_{ij}, p_0. Because Γ in (4.5) is rotational invariant, and does not depend on time, these operators are not affected by (4.5) and are Hermitian in both Hilbert spaces $L^2(\mathbf{R}^4)$ and $\overline{L^2}(\mathbf{R}^4)$.

According to this particular form of g and $\overline{g}$, p_0 and m_{ij} are unchanged by (4.5). In other words, $\tilde{p}_0 = p_0$ and $\tilde{m}_{ij} = m_{ij}$.

It is clear that $d\overline{s^2}$ defines $\overline{g_{\mu\nu}}$ as an isometrically admissible background metric. In the present example, Eq. (4.8) is satisfied with $C^\alpha = (1,0,0,0)$ and $C^{\alpha\beta}$ reduces to C^{jk}.

Now our claim is that, owing to the assumptions made on the line element (4.9), both $[F, p_0]$ and $[F, q^0]$ vanish. According to the terminology introduced in a previous work,[12] we formulate this statement as follows.

Proposition 3: Owing to the form (4.9) of the metric $g_{\mu\nu}$*, the effective potential* F *defined by (4.7) is strongly invariant by time translation.*

Proof: Commutation with p_0 is straightforward. Indeed Γ only depends on **q**, thus $[\Gamma,p_0]=0$; for a similar reason $[g^{\mu\nu},p_0]=0$, and obviously p_μ commutes with p_0.

According to (4.7), in order to prove that also $[F,q^0]$ vanishes it will be sufficient to prove that $[2\widetilde{K},q^0]$ coincides with $[p^2,q^0]$.

We observe that

$$[p^2,q^0]=-2ip_0.$$

Using (4.6) we easily compute

$$[2\widetilde{K},q^0]=-ig^{0\nu}\Gamma p_\nu\Gamma^{-1}-i\Gamma^{-1}p_\mu\Gamma g^{\mu 0}.$$

But g^{0j} is zero, thus only g^{00} survives. We are left with

$$2[\widetilde{K},q^0]=-i\Gamma p_0\Gamma^{-1}-i\Gamma^{-1}p_0\Gamma,$$

where $[\Gamma,p_0]$ vanishes, thus finally $2[\widetilde{K},p_0]=-2ip_0$, which completes the proof of our statement.

Loosely speaking, F depends only on **q** and **p**; we say that it is purely transverse.

Proposition 4: Owing to the form (4.9) of the metric, the effective potential F is (simply) invariant by space rotations.

Proof: From Proposition 1 we know that K and $\widetilde{K}$ commute with X, in particular, when $X=C^{ij}m_{ij}$. Obviously, p^2 is invariant under space rotations. Finally, a glance at (4.7) ensures rotation invariance of F.

V. THE TWO-BODY PROBLEM

Assuming the unipotential simplification, we write

$$H_a=K_a+V. \tag{5.1}$$

Our problem reduces to the determination of V by solving (3.1). Insofar as we consider gravity as an external field applied to the system, a natural approach consists in determining V by its no-field limit, say $V^{(0)}$. Indeed, in the absence of gravity, the most general form of $V^{(0)}$ allowing for compatibility and Poincaré invariance is well known.[6] As mentioned in Sec. II, a potential of the form $V^{(0)}=f(Z,P^2,y\cdot P)$ is general enough for our purpose.

Some care is needed, however, because, in general, for an arbitrarily specified metric $g_{\mu\nu}$, the no-field limit has no intrinsic meaning.

Anyway, this point of view requires introduction of an auxiliary flat metric $\overline{g_{\mu\nu}}$, and leads to the following developments.

Define $\Gamma_a=|g(a)/\overline{g(a)}|^{1/4}$ and $\Gamma_1\Gamma_2=\Gamma_{12}$.

Since $L^2(\mathbf{R}^8,\sqrt{g_1g_2}d^4q_1,d^4q_2)=L^2(\mathbf{R}^4,\sqrt{|g(1)|}d^4q_1)\otimes L^2(\mathbf{R}^4,\sqrt{|g(2)|}d^4q_2)$, there is no confusion if now $\widetilde{A}$ denotes the product $\Gamma_{12}A\Gamma_{12}^{-1}$ for all A acting in $L^2(\mathbf{R}^8)$. Indeed, when A is a product A_1A_2 of operators acting in $L^2(1)$ and $L^2(2)$, respectively, we can check that $\widetilde{A}=\widetilde{A}_1\widetilde{A}_2$.

The lack of Poincaré symmetry is partially redeemed by considering the operators induced in $\overline{L^2}(\mathbf{R}^8)$ by the isometries of g. Let the contravariant vector field ξ generate a one-parameter group of isometries of space–time. In Sec. III D we have introduced the operators J_1,J_2, respectively, acting in $L^2(\mathbf{R}^4\sqrt{|g(1)|},d^4q_1)$ and in $L^2(\mathbf{R}^4\sqrt{|g(2)|},d^4q_2)$. Their extension to $L^2(\mathbf{R}^8)$ is straightforward.

In the presence of an auxiliary flat metric we can write $J_1=\xi(1)\cdot p_1$, $J_2=\xi(2)\cdot p_2$. Provided the auxiliary metric $\overline{g}$ is isometrically admissible, we apply Proposition 1 and obtain

$$J_1=C\cdot p_1+C^{\mu\nu}m_{1\mu\nu}, \tag{5.2}$$

$$J_2 = C \cdot p_2 + C^{\mu\nu} m_{2\mu\nu}, \tag{5.3}$$

for some constant vector C^α and tensor $C^{\mu\nu}$.

Now consider the *total isometry* induced by ξ, say $J = J_1 + J_2$. Proposition 1 implies that $\tilde{J}_a = J_a$, hence $\tilde{J} = J$.

From the properties of the motion in the absence of mutual interaction, or equivalently from Proposition 1 extended by the tensor product, we obtain

$$[K_a, J_b] = [\tilde{K}_a, J_b] = 0, \quad a,b = 1,2. \tag{5.4}$$

It is clear that

$$J = C \cdot P + C^{\alpha\beta} M_{\alpha\beta}. \tag{5.5}$$

Existence of nonvanishing coefficients $C^\alpha, C^{\mu\nu}$ ensures that some elements of the Poincaré algebra survive as symmetries of the motion in the presence of curvature.

Axiom (D) of Sec. III (isometric invariance) can be precisely understood as follows: For all isometry-generating vector field ξ, the corresponding operator of total isometry J must be a constant of the two-body motion.

Later on, we shall apply the above formula in order to check that this condition is actually satisfied by two-body motion in the particular space–time (4.9).

Let us now turn to the problem of compatibility. Condition (3.1) is transformed into

$$[\tilde{K}_1 - \tilde{K}_2, \tilde{V}] = 0. \tag{5.6}$$

In view of (4.7) we define effective external potentials $F_a = F(q_a, p_a)$ by the formulas

$$\tilde{K}_a = \tfrac{1}{2} p_a^2 + F_a. \tag{5.7}$$

It is clear that $\tilde{K}_a$ and F_b are Hermitian in $\overline{L^2}(\mathbf{R}^8)$.

Example: In general, the decomposition (5.7) would have no intrinsic significance (assuming that we rely on General Relativity as the true theory of gravity). But we shall now specialize to the particular case of the line element (4.9). The assumptions made about the function $R^2(r)$ ensure without ambiguity a preferred flat background.

For the metric (4.9) we have seen that C has components (1,0,0,0) and C reduces to its space-by-space components. Any isometry of $g_{\mu\nu}$ satisfies

$$J = C^0 P_0 + C^{ij} M_{ij}. \tag{5.8}$$

Extension of Propositions 3 and 4 to the two-body sector is straightforward and implies that the effective potentials F_1, F_2 are strongly invariant under time translations, and simply invariant by space rotations.

As a result, compatibility can now be solved by a flat-space technique, using the Bijtebier ansatz.[11] Closed form expressions will be written at the price of a change of representation. The *external-field representation* is formally given by

$$A' = e^{iB} A e^{-iB}, \quad \forall A, \tag{5.9}$$

where $B = TL$ and

$$T = y_T \cdot P_T + F_1 - F_2, \tag{5.10}$$

$$L = L_\alpha z^\alpha, \quad L_\alpha = \frac{P_L^\alpha}{P_L^2}. \tag{5.11}$$

In order to keep contact with a generalized formulation of this method we use our notation of Ref. 12. The space of four-vectors is decomposed along longitudinal and transverse directions. Each four-vector has a unique transverse (resp., longitudinal) part. Subscripts T and L refer to this splitting.

But here, like in Ref. 11, the longitudinal part has only the time component. Longitudinal canonical variables commute with the transverse ones, F_1, F_2 depend only on transverse variables and $[T,L]=0$.

The wave equations will be now written as

$$2\widetilde{H}'_a\widetilde{\Psi}' = m_a^2\widetilde{\Psi}', \tag{5.12}$$

where $\widetilde{H}'_a = \widetilde{K}'_a + \widetilde{V}'$. In order to avoid cumbersome notation we systematically write $\widetilde{K}'$ for $(\widetilde{K})'$, etc. One must keep in mind that

$$\widetilde{\Psi}' = e^{iB}\Gamma\Psi, \quad \widetilde{H}'_a = e^{iB}\Gamma H_a \Gamma^{-1} e^{-iB}, \tag{5.13}$$

and so on.

In the present notation, (5.7) can be identified as (2.7) of Ref. 12, where K_a and G_a have been replaced by $\widetilde{K}_a$ and F_a, respectively. Along this line $\widetilde{K}'_a$ can be explicitly computed; see Eqs. (3.36) of Ref. 12, or Eqs. (2.24) and (2.25) of Ref. 14. One finds

$$\widetilde{K}'_a = \widetilde{K}_a - T(L\cdot y \pm \tfrac{1}{2}) + \tfrac{1}{2}T^2 L\cdot L, \tag{5.14}$$

with $+1$ (resp., -1) for $a=1$ (resp., $a=2$). Hence, using the identity $p_1^2+p_2^2 = \frac{1}{2}P^2 + 2y^2$, we get

$$\widetilde{K}'_1 + \widetilde{K}'_2 = \frac{P^2}{4} + y^2 + F_1 + F_2 - 2T(L\cdot y) + T^2 L\cdot L, \tag{5.15}$$

$$\widetilde{K}'_1 - \widetilde{K}'_2 = y_L \cdot P_L. \tag{5.16}$$

In fact, B was tailored in order to obtain (5.16). Now define

$$\mu = \tfrac{1}{2}(m_1^2 + m_2^2), \quad \nu = \tfrac{1}{2}(m_1^2 - m_2^2),$$

and replace the wave equations by their sum and difference. We get

$$(\widetilde{H}'_1 + \widetilde{H}'_2)\widetilde{\Psi}' = \mu\widetilde{\Psi}', \tag{5.17}$$

$$(\widetilde{H}'_1 - \widetilde{H}'_2)\widetilde{\Psi}' = \nu\widetilde{\Psi}'. \tag{5.18}$$

According to the assumptions made about the metric, there is a unique ''laboratory frame.'' Transverse and longitudinal decomposition simply refers to space and time splitting, thus B takes on the form given by Bijtebier in Ref. 11. In other words,

$$L\cdot L = \frac{1}{P_0^2}, \quad L\cdot y = \frac{y_0}{P_0}, \quad y_L\cdot P_L = y^0\cdot P^0, \tag{5.19}$$

$$T = -\mathbf{y}\cdot\mathbf{P} + F_1 - F_2, \quad L = \frac{z^0}{P^0}. \tag{5.20}$$

These expressions are inserted into (5.15) and (5.16), and one makes the ansatz

$$\widetilde{V}' = f(\hat{Z}, P^2, y^0 P^0), \tag{5.21}$$

$$\hat{Z} = -\mathbf{z}^2 P^2 - (\mathbf{z}\cdot\mathbf{P})^2. \tag{5.22}$$

We finally obtain

$$\widetilde{H}_1' + \widetilde{H}_2' = \frac{P^2}{4} + y^2 + F_1 + F_2 - 2T\,\frac{y_0}{P_0} + \frac{T^2}{P_0^2} + f(\hat{Z}, P^2, y^0 P^0), \tag{5.23}$$

whereas the difference of squared mass operators is simply

$$\widetilde{H}_1' - \widetilde{H}_2' = y_0 P_0 . \tag{5.24}$$

In these formulas T is simply $F_1 - F_2 - \mathbf{y}\cdot\mathbf{P}$ and F_1, F_2 are given by (5.7).

At this stage, *invariance under time translation and space rotations is manifest, which demonstrates, according to (5.8), that axiom D of Sec. III is actually satisfied*.

Since P_0 and $y_0 P_0$ are constants of the motion, the wave equations (5.17) and (5.18) undergo a reduction. The dependence on the ''relative time'' is factorized out by diagonalization of these quantities. If E is eigenvalue of P^0, we write

$$\widetilde{\Psi}'(z, Q) = \exp\, i\left(EQ^0 + \frac{\nu}{E}\, z^0 \right) \Phi(\mathbf{z}, \mathbf{Q}). \tag{5.25}$$

We are left with six degrees of freedom.

Remark: The line followed from Eq. (5.10) to Eqs. (5.15) and (5.24) was the most natural from a heuristic or pedagogic point of view. Let us, however, stress that the possibility of explicitly computing operators of the form $e^{iB} A e^{-B}$ without question about the self-adjointness of B is essentially founded on the fact that a multiple commutator,

$$[B^{[n]}, A] = [B[B \cdots [B, A] \cdots]],$$

vanishes for some finite integer n. Beside the case of squared-mass operators, a trivial example is given by P_0 and M_{ij}. Obviously, P_0' and M_{ij}' exist and simply $P_0' = P_0$, $M_{ij}' = M_{ij}$. It stems from (5.8) that J' exists and $J' = J$. But we have previously seen that $\widetilde{J} = J$, thus finally $\widetilde{J}' = J$. So the Lie algebra generated by the isometries of $g_{\mu\nu}$ is kept unchanged under transformations $A \to \widetilde{A} \to \widetilde{A}'$.

In our present knowledge, there is no evidence that B is essentially self-adjoint on some dense domain in $L^2(\mathbf{R}^8)$. This difficulty is not specific of a curvature field. We have already pointed it out, in the case where the external field is electromagnetic. In the present state of the art, we cannot discard the possibility that A' may not exist or may be ambiguously defined, *when A is an operator other than those we explicitly consider here*.

For instance, can we actually transform the generator of a Lorentz rotation mixing space and time? Fortunately we are not concerned with such an operator because it does not leave the metric (4.9) invariant and therefore is not a symmetry of our system.

All we need is to represent the pieces of Poincaré algebra that survive the application of a curvature field. And, in fact, the Lie algebra generated by H_1, H_2 and the total isometries of $g_{\mu\nu}$ is respected by the transformation (5.9).

Notice that $\widetilde{P}_0 = P_0$ and if $M = (q \wedge p)_1 + (q \wedge p)_2$ then $\widetilde{M}_{ij} = M_{ij}$.

In view of these considerations, a rigorous exposition should start with (5.17) and (5.18) from the outset, $\widetilde{H}_1'$ and $\widetilde{H}_2'$ being given by (5.23) and (5.24). Then checking that $\widetilde{H}_1'$ and $\widetilde{H}_2'$ commute

to each other is a mere exercise. In this approach we postulate the wave equation in the form (5.12). The squared mass operators are explicitly given by application of (5.23) and (5.24).

For the sake of the principles formulated in Sec. III, we may observe that it is always possible to construct a representation in terms of operators acting in L^2, making the change of wave function $\hat{\Psi}=\Gamma^{-1}\widetilde{\Psi}'$ and the operator transformation $\hat{H}_a = \Gamma^{-1}\widetilde{H}'_a\Gamma$, which maps $\overline{L^2}$ back onto L^2. (Beware that $[\Gamma, B]$ does not vanish. H does not coincide with $\hat{H}$.) But only the external-field representation is tractable.

A. No-field limit

In the absence of curvature, B does not vanish, but it reduces to

$$b=(y_T\cdot P_T)L=-\mathbf{y}\cdot\mathbf{P}\,\frac{z^0}{P^0},$$

which has been proved to be essentially self-adjoint in some dense domain of $\overline{L^2}$.[14] Thus, all operators of the form $e^{ib}Ae^{-ib}$ are well defined and the no-field limit of the external-field representation is unitarily equivalent to the customary representation describing two interacting particles in flat space–time.

However, the no-field limits of $\widetilde{H}'_1,\widetilde{H}'_2$, say $\widetilde{H}'^{(0)}_1,\widetilde{H}'^{(0)}_2$ do not show up the familiar form one usually encounters for a two-body system isolated in Minkowski space. In particular, their Poincaré invariance arises ''in disguise,'' owing to the fact that the generators of (flat) space–time displacements are not represented in the conventional fashion.

But one may easily revert to the primitive representation by the transformation

$$H^{(0)}_a=\Gamma^{-1}e^{-ib}\widetilde{H}'^{(0)}_a e^{ib}\Gamma.$$

This peculiarity is not characteristic of gravity. It already occurs when one turns off an external field in special relativity.[11,14]

B. Independent-particle limit

The case of two independent particles moving in curved space–time without mutual interaction is more tricky.

The wave equations of the external-field representation are given in terms of $\widetilde{K}'_1,\widetilde{K}'_2$.

But there is no rigorous evidence that these operators be unitarily equivalent to $\widetilde{K}_1,\widetilde{K}_2$. However, the important structure here is the Lie algebra generated by K_1,K_2 and the *individual isometries* of the form $J_1=-i\xi^\alpha\partial_{1\alpha}$, $J_2=-i\xi^\alpha\partial_{2\alpha}$. We wish to stress that in (5.9) the transformed version of all the individual isometries is well-defined. In fact, J_1,J_2 commute with Γ_{12} and with B, thus they keep their form unchanged under the transformations generated by these operators.

Finally, the commutation relations among $\widetilde{K}_1$, $\widetilde{K}_2$, P^0, M_{ij} are not altered when going over to $\widetilde{K}'_1$, $\widetilde{K}'_2$, P^0, M_{ij}.

VI. CONCLUSION

The equations of motion proposed here fully take into account the two-body structure of the system. Hence, some questions raised by Fishbach *et al.* are answered. The way we separate canonical variables in two sets was mainly motivated by computational simplicity. Insofar as the contact with noncovariant theories can be made explicit, our choice turns out to be more in the spirit of a ''center of energy'' according to Ref. 3 rather than of a center of mass in the sense of Krajcik and Foldy. More precisely, our canonical variable Q is simply related with Ξ through Eq.

(2.7). Then the spatial part of Ξ can be identified with the ''center of energy'' evoked by Fischer *et al.*,[3] following Ref. 18. After this reduction is made, the contact with the definition of Ref. 5 can be obtained like in Ref. 3.

In principle, our equations of motion could permit us to formulate as well the scattering of a bound state *by* the gravitational field (with some reservations about the intrinsic meaning of this concept, we may return to this question in future work) as the $1+1$ scattering of two particles *in the presence of* curvature. They also should allow for investigating changes in the spectrum of bound states.

Unfortunately it is generally not possible to write these equations in closed form; exact solutions of the compatibility condition are exceptional, they require a special symmetry of the metric tensor. But this complication is by no means a characteristic peculiarity of the gravitational field; it arises as well in special relativity when we consider two bodies interacting in an external field, as soon as recoil effects are taken into account. When the metric has the suitable symmetry, formulas (5.23) and (5.24) permit writing Eqs. (5.17) and (5.18) explicitly by a method that is, to a large extent, independent of the form of the mutual interaction.

In the absence of curvature, an essential structure was the Lie algebra spanned by the squared-mass operators and the generators of the Poincaré group. Here analogously, the algebra spanned by H_1, H_2 and the total isometries (if any) play a similar role.

In addition to compatibility, a list of physically reasonable conditions has been discussed. In order to implement these requirements in a tractable model, we have considered a special case of static orthogonal space–time. In this example, the existence of a preferred flat background allows for regarding the curvature field as an external field in Minkowski space–time. In a representation using Hilbert space L^2, we have applied standard methods of relativistic quantum mechanics of particles, and explicitly solved the compatibility problem in a way that respects the symmetries of the Riemannian metric. Relative time was finally eliminated.

In this model, Axioms A, B, and D are strictly satisfied. Axiom C is rigorously satisfied insofar as the no-field limit is concerned, and (at least) formally satisfied in the case of the independent-particle limit.

Of course, the example given in Sec. V is not very useful for practical applications because no reasonable stress-energy tensor is expected to support a line element of the form (4.9) through Einstein equations. For this reason we prefer to speak of a *curvature field* rather than of a gravitational field.

Nevertheless, one must realize that no other solution of the compatibility condition (1.3) is available in closed form at the present time, except in the trivial case of Minkowski space. The present example is at least nontrivial, as it has a nonzero curvature. Our model, being defined in closed form, ensures that the general framework developed in Sec. III is not empty. Moreover it is an illustration of the role of isometries.

If one wishes to consider realistic space–times, it is possible to seek for solutions in the form of series expansions.

In this paper, for simplicity, we have considered scalar particles only. The general framework can be set forth also for fermions, provided K_1, K_2 are replaced by Dirac operators and the right-hand side of (1.1) become linear in the masses. But adapting to fermions the method displayed in Sec. V requires further work.

APPENDIX: PROPERTIES OF ISOMETRIES

In standard notations of differential geometry, the four-dimensional Laplace–Beltrami operator is

$$\Delta = \delta d + d\delta.$$

Claim: If ξ is an isometry and f a differential form, then $\mathscr{L}_\xi \Delta f = \Delta \mathscr{L}_\xi f$.

For a p form, the general proof rests on the identities $\delta = *^{-1} d *$ and $* \mathscr{L} = (-1)^p \mathscr{L} *$. When f is a function, that is a 0 form, we simply have

$$2Kf = \Delta f = \delta\, df.$$

Claim: If ξ is an isometry, then $\xi^\alpha \partial_\alpha$ is skew Hermitian in $L^2(\mathbf{R}^4)$.
Proof:

$$\int_\Omega (\xi^\alpha\ \partial_\alpha \phi^*)\psi \sqrt{|g|}\, d^4q = \int_\Omega \nabla_\alpha \partial_\alpha (\xi^\alpha \phi^* \psi)\sqrt{|g|}\, d^4q - \int_\Omega (\xi^\alpha\ \partial_\alpha \psi)\phi^* \sqrt{|g|}\, d^4q$$

$$- \int_\Omega (\nabla_\alpha \xi^\alpha)\phi^* \psi \sqrt{|g|}\, d^4q.$$

The first term gets transformed into the flux of $\xi^\alpha \phi^* \psi$ across the three-dimensional surface $\partial\Omega$. In the limit where Ω extends to infinity *in all space–time directions*, then ϕ and ψ vanish on $\partial\Omega$ (they are supposed to be squared integrable), therefore this first term yields no contribution. The last term also vanishes since $\nabla \cdot \xi$ is obviously zero. We are left with

$$\int\ (\xi \cdot \partial \phi^*)\psi \sqrt{|g|}\, d^4q = -\int\ \phi^* (\xi \cdot \partial \psi)\sqrt{|g|}\, d^4q;$$

in other words, $\xi^\alpha \partial_\alpha$ is skew symmetric in L^2.

Squeezing Bogoliubov transformations on the infinite mode CCR-algebra

Reinhard Honegger and Alfred Rieckers
Institut für Theoretische Physik, Universität Tübingen, D-72076 Tübingen, Germany

(Received 31 October 1995; accepted for publication 18 March 1996)

A detailed analysis of and a general decomposition theorem for in general unbounded symplectic transformations on an arbitrary complex pre-Hilbert space (one–boson test function space) are given. The structure of strongly continuous symplectic groups on such spaces is determined. The connection between quadratic Hamiltonians, Bogoliubov transformations, and symplectic transformations is discussed in the Fock representation, and their relevance for squeezing operations in quantum optics is pointed out. The results for this rather general class of transformations are proved in a self-contained fashion. © *1996 American Institute of Physics.* [S0022-2488(96)01308-4]

I. INTRODUCTION

In recent developments in quantum optics the squeezed states of light have acquired a broad interest since by noise reduction they promise to increase the accuracy of certain measurement devices and to improve the transmission rate in optical communication techniques.

In the theoretical descriptions of squeezing processes the Hamiltonians most frequently are approximated by quadratic expressions

$$H_q=\frac{1}{2}\sum_{n=1}^{N}\left(\zeta_n a_n^* a_n^* + \overline{\zeta_n} a_n a_n\right) \tag{1.1}$$

of the light field (interaction picture), where the $\zeta_n \in \mathbb{C}$ arise from a classical (macroscopic) pumping field, and the $a_n^* \equiv a^*(e_n)$ are the creation [resp. the $a_n \equiv a(e_n)$ the annihilation] operators of the orthonormalized modes $\{e_1,\ldots,e_N\}$. Here N commonly is assumed to be finite.[1] In the literature the Hamiltonian (1.1) usually is referred to as the degenerate case of squeezing. However, in the smeared field formalism[2] the nondegenerate squeezing Hamiltonians may be transformed into the form (1.1) by superposing the idler and the signal modes.[3,4] There are also some investigations on infinite (resp. continuous) mode squeezing.[5] Calculating the time evolution associated with (1.1) leads to a one-parameter group of Bogoliubov transformations on the algebra of observables.

A rigorous smeared boson field theory is based on an arbitrary one-boson testfunction space E, which is a complex pre-Hilbert space with norm completion $\mathscr{H}$. The choice of E determines the specific boson system and the modes taken into account. For bosons with the spin s, E is a subspace of $\mathsf{L}^2(\Lambda)\otimes\mathbb{C}^{2s+1}$. For photons the quantization procedure in the Coulomb gauge leads to a test function space E consisting of divergence-free (i.e., $\boldsymbol{\nabla}\cdot f=0$), square-integrable functions f: $\Lambda\to\mathbb{C}^3$ on the quantization volume $\Lambda\subseteq\mathbb{R}^3$ in position space. The algebra of observables is the C^*-Weyl algebra $\mathscr{W}(E)$ over E generated by the unitary Weyl operators $W(f),f\in E$ (sometimes called displacement operators), which in regular representations are given in terms of the smeared creation and annihilation operators, $W(f)=\exp\{i2^{-1/2}(a^*(f)+a(f))\}$, and which satisfy the Weyl form of the canonical commutation relations (CCR), cf. the beginning of Sec. III.

The Bogoliubov transformations α on $\mathscr{W}(E)$ (as, e.g., those generated by the quadratic Hamiltonians from above) are in one-to-one correspondence with the symplectic transformations T on E (i.e., T acts real-linearly and bijectively on E and leaves the imaginary part of the scalar product $\langle .|. \rangle$ invariant), such that $\alpha(W(f))=W(Tf)\ \forall f\in E$, in which case we write $\alpha=\alpha_T$.

0022-2488/96/37(9)/4292/18/$10.00

Symplectic and Bogoliubov transformations belong to the basic structure of a boson quantum field theory. From the beginning of the operator-algebraic Weyl theory they have been studied with respect to different points of view. In the theoretical developments of squeezing for modern measurement and communication devices they are of a special importance (see above). Both for the structural investigations and for practical applications the use of unbounded symplectic transformations on an incomplete pre-Hilbert space E is unavoidable (as will be substantiated by future work).

Here, we present a new approach using the (unique) decompositions of real-linear operators into their complex-linear and complex-antilinear parts. The fixed complex structure inherent in the complex-linearity of the test function space E allows a systematic study of the general structure of symplectic transformations, especially of symplectic one-parameter groups with their generators and unitary implementations (here in Fock space). Beside new results we also collect and generalize some older ones, which are scattered in an incoherent fashion over a series of articles. Here we present a self-contained exposition, where all statements are proved by means of a direct and complete argumentation and are illustrated by several examples.

In Sec. II we first give a detailed analysis of the algebraic relations for the (complex) linear part and the antilinear (conjugate linear) part of a symplectic T. Then we verify that every symplectic T on E uniquely is decomposable into a unitary U, a self-adjoint positive S, and an antilinear involution J (as operators on $\mathscr{H}$), so that

$$T = U\,\cosh(S) + UJ\,\sinh(S). \tag{1.2}$$

This formula may be considered as the polar decomposition of the real-linear, symplectic T. It generalizes the special finite-dimensional examples, which gave rise to the developments of the squeezing theory.[1] If E is a proper dense subspace of $\mathscr{H}$, then T (or equivalently S) may be unbounded. For $E=\mathscr{H}$, however, T always has to be bounded (cf. Lemma 2.9). In Sec. II B we completely characterize strongly continuous symplectic one-parameter groups $\{T_t | t\in\mathbb{R}\}$ on $\mathscr{H}$ with the growth property $||T_t|| \leqslant \exp\{\beta|t|\} \forall t\in\mathbb{R}$ for some $\beta\geqslant 0$, as those which have a generator with bounded antilinear part.

The decomposition formula (1.2) is a useful tool for calculating squeezing properties (e.g., the variances) of Bogoliubov transformed (i.e., squeezed) states. This application is deferred to papers to follow.[6]

Section III is devoted to unitary implementations of the Bogoliubov transformations α_T with respect to the Fock representation of $\mathscr{W}(E)$. This investigation is inspired by Ref. 7 where, however, functional techniques are used exclusively. In Sec. III A we first give a slight generalization of Shale's result:[8] α_T is unitarily implementable in Fock space, if and only if the antilinear part of T is of Hilbert–Schmidt class, which especially yields T to be bounded. Then we calculate the transition probability of Glauber vectors with squeezed Glauber vectors [Lemma 3.4 and Eq. (A1)], a result which resembles a functional formula in Ref. 7. It is found for the one mode case also in some quantum optical articles.[1] Section III B deals with the connection between general quadratic Hamiltonians in Fock space and one-parameter groups of symplectic transformations on $\mathscr{H}$. Let $H := H_q + H_C$, where H_q is from (1.1) with $N=\infty$, and H_C denotes the free evolution Hamiltonian on Fock space uniquely associated with the self-adjoint linear one-boson Hamiltonian C on the complex one-boson Hilbert space $\mathscr{H}$. Then with the self-adjoint antilinear $D=\Sigma_{n=1}^{\infty}\zeta_n\langle .|e_n\rangle e_n$ on $\mathscr{H}$, we show the group $T_t := \exp\{ti(C-D)\}$, $t\in\mathbb{R}$, to consist of bounded symplectic transformations T_t on $\mathscr{H}$, which on the second quantized level are implemented by $\exp\{itH\}$, i.e.,

$$\exp\{itH\}W(f)\exp\{-itH\} = \alpha_{T_t}(W(f)) = W(T_t f) \quad \forall f\in\mathscr{H} \quad \forall t\in\mathbb{R}. \tag{1.3}$$

Here C may be unbounded. However, the condition that the Fock vacuum vector is contained in the domain of definition of the self-adjoint H on Fock space is equivalent to D being an antilinear Hilbert–Schmidt operator on $\mathscr{H}$, i.e., $\Sigma_{n=1}^{\infty}|\zeta_n|^2<\infty$, which also yields the Hilbert–Schmidt property of the antilinear parts of the symplectic transformations T_t.

Especially for $C=0$, and hence $H_C=0$, one obtains the formula (cf. Corollary 3.10)

$$T_t=\exp\{-itD\}=\cosh(tS)+J\,\sinh(tS)=\sum_{n=1}^{\infty}\left[\cosh(t|\zeta_n|)\langle e_n|.\rangle e_n-i\,\frac{\zeta_n}{|\zeta_n|}\,\sinh(t|\zeta_n|)\langle .|e_n\rangle e_n\right]$$

with $S=\Sigma_{n=1}^{\infty}|\zeta_n|\langle e_n|.\rangle e_n$ and $Je_n=-i(\zeta_n/|\zeta_n|)e_n\forall n\in\mathbb{N}$. Then Eq. (1.3) expressed in terms of annihilation and creation operators in Fock space gives for every $n\in\mathbb{N}$ and $t\in\mathbb{R}$

$$\exp\{itH_q\}a(e_n)\exp\{-itH_q\}=\cosh(t|\zeta_n|)a(e_n)-i\,\frac{\zeta_n}{|\zeta_n|}\,\sinh(t|\zeta_n|)a^*(e_n).$$

If $\Sigma_{n=1}^{\infty}|\zeta_n|^2=\infty$, then H_q has no meaning as an operator on Fock space.[4]

As indicated above, there occur on the one-particle level complex-linear, complex-antilinear, and real-linear operators. If not stated otherwise, we always mean with the expressions ''operator'' and ''linear operator'' complex-linear mappings. On the level of the second quantization (C^*-algebraic level, and operators on Fock space), however, we are concerned with complex-linear operators, only.

II. SYMPLECTIC TRANSFORMATIONS

Let E be an arbitrary complex pre-Hilbert space with (right-linear) scalar product $\langle .|.\rangle$ and norm-completion $\mathscr{H}$. The imaginary part of the scalar product is a nondegenerate symplectic form on E.

Definition 2.1 (Symplectic Transformation): A mapping $T: E\to E$ is called a symplectic transformation on E, if it is real-linear, surjective [that is, $T(E)=E$] and fulfills

$$\mathrm{Im}\langle Tf|Tg\rangle=\mathrm{Im}\langle f|g\rangle\quad\forall f,g\in E. \tag{2.1}$$

The set of all symplectic transformation on E we denote by $\mathscr{T}(E)$.

Relation (2.1) implies the injectivity of T, and thus each symplectic transformation T acts bijective on E. The inverse mapping $T^{-1}: E\to E$ is a symplectic transformation on E, too. Hence $\mathscr{T}(E)$ forms a group. We have, e.g., $U\in\mathscr{T}(E)$ for each unitary U on $\mathscr{H}$ with $U(E)=E$, which gives a subgroup of $\mathscr{T}(E)$.

A. The general form of a symplectic transformation

Since E and $\mathscr{H}$ are complex-linear vector spaces each real-linear operator $T: E\to\mathscr{H}$ decomposes uniquely into its (complex-) linear part T_l and its (complex-) antilinear part T_a, that is, $T=T_l+T_a$ with

$$T_l:=\tfrac{1}{2}(T-iTi)\quad\text{and}\quad T_a:=\tfrac{1}{2}(T+iTi). \tag{2.2}$$

In the following we consider T_l and T_a for a symplectic $T\in\mathscr{T}(E)$ as (not necessarily bounded) operators on the Hilbert space $\mathscr{H}$ with the dense domain of definition E and range contained in E.

Let us refer some common notations (cf. Ref. 9, Section VIII.1), which are used throughout the paper. The orthogonal complement of a subset $K\subseteq\mathscr{H}$ is denoted by $K^{\perp}$, its closure by $\bar{K}$. The (complex-) linear hull $\mathsf{LH}(K)$ of $K\subset\mathscr{H}$ consists of all finite linear combinations of elements of K. A linear (resp. antilinear) operator B on $\mathscr{H}$ is a linear (resp. antilinear) mapping from its domain $\mathscr{D}(B)$, a complex-linear subspace of $\mathscr{H}$, into $\mathscr{H}$. B is called densely defined, if $\mathscr{D}(B)$ is dense in $\mathscr{H}$. The adjoint B^* of a densely defined linear (resp. antilinear) operator B on $\mathscr{H}$ is given by

$$\mathscr{D}(B^*) := \{g \in \mathscr{H} | f \in \mathscr{D}(B) \mapsto \langle g|Bf\rangle \text{ is } \|.\|\text{-continuous}\}$$

and by setting $\langle B^*g|f\rangle := \langle g|Bf\rangle$ for linear B, and $\langle f|B^*g\rangle := \langle g|Bf\rangle$ for antilinear B, respectively. In general B^* is a closed linear (resp. antilinear) operator on $\mathscr{H}$, but not necessarily densely defined. $\ker(B)$ is the kernel and $\mathrm{ran}(B)$ the range of B. For closable B we write B for its closure. $B|_K$ denotes the restriction of B to the subspace $K \subseteq \mathscr{D}(B)$. K is a core for the closed B, if $\overline{B|_K} = B$. B leaves K invariant, if $K \subseteq \mathscr{D}(B)$ and $B(K) \subseteq K$. B is called positive, $B \geqslant 0$, if $\langle f|Bf\rangle \geqslant 0 \forall f \in \mathscr{D}(B)$. We write $A \subseteq B$, if $\mathscr{D}(A) \subseteq \mathscr{D}(B)$ and $A = B|_{\mathscr{D}(A)}$. A densely defined B is called symmetric if $B \subseteq B^*$, essentially self-adjoint if $B = B^*$, and self-adjoint if $B = B^*$. For closed densely defined B one has that $0 \leqslant B^*B$ is self-adjoint and linear, and one puts $|B| := \sqrt{B^*B}$. For the closed linear (resp. antilinear) B one has the (unique) polar decomposition $B = V|B|$ where V is the unique linear (resp. antilinear) partial isometry with initial space $(\ker(B))^\perp = \overline{\mathrm{ran}(|B|)}$ and final space $\overline{\mathrm{ran}(B)}$. For bounded linear (resp. antilinear) operators A on $\mathscr{H}$ we always assume $\mathscr{D}(A) = \mathscr{H}$, which gives $\mathscr{D}(A^*) = \mathscr{H}$ and $\|A\| = \|A^*\|$.

Theorem 2.2: *Let $T: E \to \mathscr{H}$ be a real-linear operator. We have the following equivalences:*

(*i*) $T \in \mathscr{T}(E)$ (*especially,* $T(E) = E$).

(*ii*) *T, T_l, and T_a fulfill the following relations:*

(*a*) $T(E) = E$ [*implying* $T_l(E) \subseteq E$, and $T_a(E) \subseteq E$], $E \subseteq \mathscr{D}(T_l^*)$, $E \subseteq \mathscr{D}(T_a^*)$ (*implying the closability of T_l and T_a*),

(b) $T_l^* T_a = T_a^* T_l$ and $T_l^* T_l - T_a^* T_a = \mathbb{1}_E$.

(*iii*) *T, T_l, and T_a fulfill the following relations:*

(a) $T(E) = E$,

(b) $\langle T_l f|T_a g\rangle = \langle T_l g|T_a f\rangle$ *and* $\langle T_l f|T_l g\rangle - \langle T_a g|T_a f\rangle = \langle f|g\rangle \forall f, g \in E$.

(iv) *T_l and T_a fulfill the following relations:*

(a) $E \subseteq \mathscr{D}(T_l^*)$, $E \subseteq \mathscr{D}(T_a^*)$, and, *$T_l, T_a, T_l^*, T_a^*$ leave E invariant,*

(b) $T_l^* T_a = T_a^* T_l$, $T_l^* T_l - T_a^* T_a = \mathbb{1}_E$,

(c) $T_l T_a^*|_E = T_a T_l^*|_E$ *and* $T_l T_l^*|_E - T_a T_a^*|_E = \mathbb{1}_E$.

Moreover, if T is a symplectic transformation on E, then

$$T_l^* \supseteq \tfrac{1}{2}(T^{-1} - iT^{-1}i), \quad T_a^* \supseteq -\tfrac{1}{2}(T^{-1} + iT^{-1}i), \tag{2.3}$$

and, for the symplectic transformation $T^{-1}: E \to E$, it holds

$$T^{-1} = T_l^*|_E - T_a^*|_E, \quad (T^{-1})_l = T_l^*|_E, \quad (T^{-1})_a = -T_a^*|_E. \tag{2.4}$$

Proof: (i)$\Rightarrow$(ii): Observing $\langle f|Tg\rangle = \mathrm{Im}(i\langle f|Tg\rangle) + i\,\mathrm{Im}\langle f|Tg\rangle$ one uses (2.1) to calculate

$$\langle f|(T - iTi)g\rangle = \langle (T^{-1} - iT^{-1}i)f|g\rangle, \quad \langle f|(T + iTi)g\rangle = -\langle g|(T^{-1} + iT^{-1}i)f\rangle,$$

which leads to (2.3) and (2.4), and also shows (ii)(a). Now (2.1) implies

$$\underbrace{(T_l^* T_l - T_a^* T_a - \mathbb{1}_E)}_{\text{linear}} f + \underbrace{(T_l^* T_a - T_a^* T_l)}_{\text{antilinear}} f = 0 \quad \forall f \in E.$$

Now observe that E is a complex-linear vector space, and we may replace f by if. (ii)$\Rightarrow$(iii): (iii)(b) is another formulation of (ii)(b). (iii)$\Rightarrow$(i): (iii)(b) yields (2.1). (i)$\Rightarrow$(iv) is obtained by applying (i)$\Leftrightarrow$(ii) to T and T^{-1} from (2.4). (iv)$\Rightarrow$(ii): Let $\widetilde{T} := T_l^*|_E - T_a^*|_E$. With (iv)(c) one easily checks $T\widetilde{T} = \mathbb{1}_E$, which proves (ii)(a). ∎

Corollary 2.3: Let $T \in \mathscr{T}(E)$. It holds $\||\overline{T_l}|f\| = \|\overline{T_l} f\| \geqslant \|f\| \forall f \in \mathscr{D}(|\overline{T_l}|) = \mathscr{D}(\overline{T_l})$, and $\overline{\mathrm{ran}(|\overline{T_l}|)} = \mathscr{H}$. If $\mathscr{H}$ is separable, or, if T_l is bounded, then $\mathrm{ran}(T_l) = \overline{\mathrm{ran}(T_l)} = \mathscr{H}$, i.e., *$|\overline{T_l}|^{-1}$ and $(T_l)^{-1}$ are bounded with domain $\mathscr{H}$.*

Proof: From Theorem 2.2(iv) follows $\||\overline{T_l}|f\| = \|\overline{T_l}f\| \geqslant \|f\| \forall f \in \mathscr{D}(|\overline{T_l}|) = \mathscr{D}(\overline{T_l})$ and $\|T_l^* f\| \geqslant \|f\| \forall f \in E$. Since $|\overline{T_l}|$ is self-adjoint we have $\mathscr{H} = \ker(|\overline{T_l}|)^\perp = \overline{\mathrm{ran}(|\overline{T_l}|)}$ (e.g., Ref. 10, Proposition X.1.13). Since also $|\overline{T_l}|^{-1}$ is closed and $\||\overline{T_l}|^{-1} g\| \leqslant \|g\|$, we actually have $\mathrm{ran}(|\overline{T_l}|) = \mathscr{H}$. The same argument for $\overline{T_l}$ yields $\mathrm{ran}(\overline{T_l}) = \mathrm{ran}(T_l) =: \mathscr{K}$ to be closed. Assume $\mathscr{K}$ to be a proper subspace of $\mathscr{H}$. Then there is an $f \in E$ with $f \notin \mathscr{K}$. Choose an ONB (orthonormal base) $\mathscr{O}$ of the linear hull $\mathsf{LH}\{\mathrm{ran}(T_l), f\} \subseteq E$, the existence of which is ensured by the separability of $\mathscr{H}$ (e.g., Ref. 11, Section 3.3). Then there exists an $e \in \mathscr{O}$ with $e \in E \cap \mathscr{K}^\perp$. But $\mathscr{K}^\perp = \ker(T_l^*)$, and thus $1 = \|e\| \leqslant \|T_l^* e\| = 0$, a contradiction. The proof for bounded T_l is obvious. ■

Corollary 2.4: Suppose $\mathscr{H}$ separable, and let $T \in \mathscr{T}(E)$. Then E is a core for T_l^*, T_a^*, $T_l^* \overline{T_l}$, $T_a^* \overline{T_a}$, $\overline{T_l} T_l^*$, and $\overline{T_a} T_a^*$.

Proof: Replacing T_a by $-T_a$ from Theorem 2.2(iv) follows that $\hat{T} := T_l - T_a \in \mathscr{T}(E)$ with $\hat{T}^{-1} = T_l^*|_E + T_a^*|_E \in \mathscr{T}(E)$. Hence $S := \hat{T}^{-1} T \in \mathscr{T}(E)$. But $S_l = T_l^* T_l + T_a^* T_a = 2 T_l^* T_l - \mathbb{1}_E$ is symmetric with $\mathrm{ran}(S_l) = \mathscr{H}$ by Corollary 2.3. Hence $\overline{S_l}$ is self-adjoint by Ref. 11, Theorem 5.19, and so is $\overline{T_l^* T_{le}} = \frac{1}{2}(\overline{S_l} + \mathbb{1})$. But $\overline{T_l^* T_l} \subseteq \overline{T_l^*}\,\overline{T_l}$, and thus $\overline{T_l^* T_l} = \overline{T_l^*}\,\overline{T_l}$ (e.g., Ref. 11, Theorem 5.31), which proves E to be a core for $\overline{T_l^* T_l}$. Because of $\mathrm{ran}(T_l) \subseteq E$ and $\mathscr{D}(T_l^*) \supseteq E$ this yields $T_l^* \overline{T_l} = \overline{T_l^*|_E}\,\overline{T_l}$. But $\overline{T_l^*|_E} \subseteq T_l^*$ gives $\overline{T_l} = \overline{T_l^{**}} \subseteq \overline{T_l^*|_E}^*$, and hence $T_l^* \overline{T_l} = \overline{T_l^*|_E}\,\overline{T_l^*|_E}^*$, which with Ref. 11, Theorem 5.40, leads to $\overline{T_l} = \overline{T_l^*|_E}^*$, respectively $T_l^* = \overline{T_l^*|_E}$. Now use $T_l^* T_l = T_a^* T_a + \mathbb{1}_E$, and the same argumentation for $T^{-1} \in \mathscr{T}(E)$. ■

Theorem 2.5 (Decomposition): *Let $T \in \mathscr{T}(E)$. Suppose $\mathscr{H}$ separable or T_l (or equivalently T_a) bounded. Then on $\mathscr{H}$ there exist a positive self-adjoint operator S, a unitary U, and an antilinear involution J (that is, $J = J^* = J^{-1}$), so that*

(a) *E is a subspace of the domains of $U \cosh(S)$, $UJ \sinh(S)$, $\cosh(S) U^*$, $J \sinh(S) U^*$, and these operators leave E invariant.*

(b) *J commutes with S in the sense of $J\phi(S) = \overline{\phi(S)} J$ for every Borel measurable function $\phi: [0,\infty[\to \mathbb{C}$ (here ϕ is the complex-conjugate function). Especially, $J(\ker(S)) = \ker(S)$ and $J(\ker(S)^\perp) = \ker(S)^\perp$.*

(c) *$T_l = U \cosh(S)|_E$ and $T_a = UJ \sinh(S)|_E$.*

(d) *E is a core for $\cosh(S)$, $\sinh(S)$, $\cosh(S)^2$, and $\sinh(S)^2$.*

(e) *Let $\widetilde{U}$ be a unitary, $\widetilde{S}$ a self-adjoint operator with $\mathscr{D}(\exp\{\pm\widetilde{S}\}) \supseteq E$, and $\widetilde{J}$ an antilinear involution on $\mathscr{H}$, such that $T = \widetilde{U} \cosh(\widetilde{S})|_E + \widetilde{U}\widetilde{J} \sinh(\widetilde{S})|_E$. We have $\widetilde{U} = U$, $|\widetilde{S}| = S$, $\widetilde{J}$ commutes with $\widetilde{S}$, $\widetilde{J} f = -Jf$ for $f \in \widetilde{P}(]-\infty, 0[)\mathscr{H}$, and $\widetilde{J} g = Jg$ for $g \in \widetilde{P}([0,\infty[)\mathscr{H}$, where $\widetilde{P}$ is the projection-valued measure associated with $\widetilde{S}$. Especially, if $\widetilde{S} \geqslant 0$, then $\widetilde{S} = S$ and $\widetilde{J} g = Jg \forall g \in \ker(S)^\perp$.*

Proof: $T_l^* T_l - T_a^* T_a = \mathbb{1}_E$ implies $\|\overline{T_l} f\|^2 = \|\overline{T_a} f\|^2 + \|f\|^2 \forall f \in D_1 := \mathscr{D}(\overline{T_l}) = \mathscr{D}(\overline{T_a})$. For the proof we drop the bar for the closures. We get $\mathscr{D}(|T_l|^2) = \mathscr{D}(|T_a|^2)$ and $|T_l|^2 = |T_a|^2 + \mathbb{1}$, which gives

$$\exp\{it|T_l|^2\} = \exp\{it\} \exp\{it|T_a|^2\} \quad \forall t \in \mathbb{R}, \tag{2.5}$$

and the closed subspace $\mathscr{K} := \ker(|T_a|) = \{f \in D_1 \,||T_l| f = f\}$. Thus, $\exp\{it|T_l|^2\}(\mathscr{K}) = \mathscr{K} \forall t \in \mathbb{R}$, and $\mathscr{K}$ is a reducing subspace for $|T_l|^2$ and for $|T_l|$ (cf. Ref. 11, Theorem 7.39). Since E is a core for T_l^* and T_a^* (Corollary 2.4), the same argumentation holds for $T^{-1} = T_l^*|_E - T_a^*|_E$ with $D_1^* := \mathscr{D}(T_l^*) = \mathscr{D}(T_a^*)$ and $\mathscr{K}^* := \ker(|T_a^*|)$.

Since cosh is bijective from $[0,\infty[$ onto $[1,\infty[$ we may define $S \geqslant 0$ by $|T_l| =: \cosh(S)$, and thus $|T_a| = \sinh(S)$. Obviously, $\mathscr{K} = \ker(S)$.

Let $T_l = U|T_l|$ be the polar decomposition, for which U is a unitary because of Corollary 2.3. From $T_l^* = |T_l| U^*$ it follows $U^*(D_1^*) = D_1$. From $|T_l^*| U = U|T_l|$ we obtain $|T_l^*| Uf = U|T_l| f = Uf \forall f \in \mathscr{K}$, and hence $U(\mathscr{K}) = \mathscr{K}^*$.

Let $T_a = V|T_a|$ be the polar decomposition with the antilinear partial isometry V from $\overline{\mathrm{ran}(|T_a|)} = \mathscr{K}^{\perp}$ onto $\overline{\mathrm{ran}(T_a)} = \mathscr{K}^{*\perp}$. We continue V to an antiunitary on $\mathscr{H}$: let I be an arbitrary antilinear involution on $\mathscr{K}$ and define $Vf := UIf$ for $f \in \mathscr{K}$.

With $|T_l^*|^2 = U|T_l|^2U^*$ and $|T_a^*|^2 = V|T_a|^2V^*$ and (2.5) we calculate

$$U\exp\{it|T_l|^2\}U^* = \exp\{it|T_l^*|^2\} = \exp\{it\}\exp\{it|T_a^*|^2\} = \exp\{it\}V\exp\{-it|T_a|^2\}V^*$$
$$= V\exp\{-it\}\exp\{-it|T_a|^2\}V^* = V\exp\{-it|T_l|^2\}V^* \quad \forall t \in \mathbb{R},$$

implying $V^*U\exp\{it|T_l|^2\} = \exp\{-it|T_l|^2\}V^*U$. With Fourier transformation and standard arguments one now easily checks (b) for $J := V^*U$.

Here $\mathscr{K}^{\perp}$ is a reducing subspace for $|T_l|$, hence $|T_a||T_l|\exp\{-2\tau|T_l|\}|_{\mathscr{K}^{\perp}}$ for $\tau > 0$ is a bounded, injective, self-adjoint operator on $\mathscr{K}^{\perp}$ with range dense in $\mathscr{K}^{\perp}$. Because J commutes with $|T_l|$, for all $f, g \in \mathscr{K}^{\perp}$ one easily calculates with Theorem 2.2(iii)

$$\langle f|J^*|T_a||T_l|\exp\{-2\tau|T_l|\}g\rangle$$
$$= \langle T_l\exp\{-\tau|T_l|\}f|T_a\exp\{-\tau|T_l|\}g\rangle$$
$$= \langle T_l\exp\{-\tau|T_l|\}g|T_a\exp\{-\tau|T_l|\}f\rangle$$
$$= \langle f|J|T_a||T_l|\exp\{-2\tau|T_l|\}g\rangle,$$

which yields $J = J^*$ on $\mathscr{K}^{\perp}$. $J = I$ on $\mathscr{K}$ is obvious, and thus $J = J^*$ on the whole of $\mathscr{H}$.

We prove (e): From the uniqueness of the decomposition (2.2) it follows $T_l|_E = \widetilde{U}\cosh(\widetilde{S})|_E = U\cosh(S)|_E$, which implies $\mathscr{D}(\overline{\cosh(\widetilde{S})|_E}) = D_1 = \mathscr{D}(\cosh(S))$. Since $\widetilde{U}$ is unitary and $\mathrm{ran}(T_l) = \mathscr{H}$, we have $\mathrm{ran}(\overline{\cosh(\widetilde{S})|_E}) = \mathscr{H}$, which by Ref. 11, Theorem 5.19 implies the self-adjointness of $\overline{\cosh(\widetilde{S})|_E}$ and finally $\overline{\cosh(\widetilde{S})|_E} = \cosh(\widetilde{S})$. The uniqueness of the polar decomposition now yields $U = U$ and $\cosh(\widetilde{S}) = \cosh(S)$, which gives $|\widetilde{S}| = S$ [since $\cosh(x) = \cosh(|x|)\forall x \in \mathbb{R}$]. The spectral calculus and $U^*T_a = J\sinh(\widetilde{S}) = J\sinh(S)$ proves the rest.

(a) is a consequence of Theorem 2.2(iv). (d) follows from Corollary 2.4. ■

For $T \in \mathscr{T}(E)$ part (e) of the above theorem gives the uniqueness of the decomposition $T = U\cosh(S)|_E + UJ\sinh(S)|_E$ with positive self-adjoint $S \geqslant 0$. Since J commutes with S, only its action on $\ker(S)^{\perp}$ is of interest, i.e., J is arbitrarily changeable on $\ker(S)$. We also give the converse statement, which is very helpful for explicit constructions of symplectic transformations T, which may be performed as in Example 2.7 below.

Corollary 2.6: Let be U a unitary, S a self-adjoint operator (not necessarily positive), and J an antilinear involution on $\mathscr{H}$*, so that* (a) *and* (b) *of Theorem 2.5 are fulfilled. Then* $U\cosh(S)|_E + UJ\sinh(S)|_E$ *is an element of* $\mathscr{T}(E)$.

Proof: T so defined being symplectic on E is a consequence of Theorem 2.2(iv). ■

Example 2.7: Let $m \in \mathbb{N}$ and $n \in \mathbb{N} \cup \{0, \infty\}$. *Assume* $E := \mathscr{C}_c^n(\mathbb{R}^m)$, *the complex-valued, n-times continuously differentiable functions on* $\mathbb{R}^m$ *with compact support. We choose* $\mathscr{H} = \mathsf{L}^2(\mathbb{R}^m)$ *with respect to the Lebesgue measure* $\mathrm{d}^m x$ *as the completion of E. Define S to be the operator of multiplication with the arbitrary but n-times continuously differentiable function* $s: \mathbb{R}^m \to \mathbb{R}$, *and J to be the complex conjugation,* $Jf = \bar{f}$, $f \in \mathscr{H}$. *The unitary U on* $\mathscr{H}$ *we construct by* $(Uf)(x) := \exp\{i\theta(x)\}f(Rx - a)$, $x \in \mathbb{R}^m$, $f \in \mathscr{H}$, *with some real-valued, n-times continuously differentiable function* θ, *the rotation* $R \in \mathsf{SO}(m)$, *and* $a \in \mathbb{R}^m$.

The operators U, J, $\cosh(S)$, *and* $\sinh(S)$ *leave E invariant, and consequently by the above corollary* $U\cosh(S)|_E + UJ\sinh(S)|_E =: T \in \mathscr{T}(E)$. *Moreover,* $\ker(S) = \mathsf{L}^2(N(S))$ *where* $N(S) := \{x \in \mathbb{R}^m | s(x) = 0\}$.

Sometimes we consider $\mathscr{H}$ as a real Hilbert space with scalar product $(.|.) := \mathrm{Re}\langle .|. \rangle$, which we denote by $\mathscr{H}_r$. The adjoint of the real-linear operator A on $\mathscr{H}_r$ is denoted by A^+, $(f|Ag) = (A^+f|g)$ for all $f \in \mathscr{D}(A)$ and $g \in \mathscr{D}(A^+)$. The absolute value of the closed real-linear A

on $\mathscr{H}_r$ is denoted by $|A|_r := \sqrt{A^+A}$. Similarly to the complex case, for a closed real-linear operator A on a real Hilbert space one has the (unique) polar decomposition $A = V|A|_r$, where the (unique) partial isometry is real-linear with initial space $\overline{\mathrm{ran}(|A|_r)}$ and final space $\overline{\mathrm{ran}(A)}$ (cf., e.g., Ref. 11).

Corollary 2.8: Let $T \in \mathscr{T}(E)$. Then T is a closable real-linear operator on the real Hilbert space $\mathscr{H}_r$. And the decomposition $T = U(\cosh(S)|_E + J \sinh(S)|_E)$ according Theorem 2.5 with the unitary U, the positive $S = S^*$, and the antilinear involution J on $\mathscr{H}$ gives the polar decomposition of the closure $T = U|T|_r$, $|T|_r = \cosh(S) + J \sinh(S)$.

Proof: Obviously, $T^+ \supseteq T_l^* + T_a^*$ is densely defined and hence T is closable. Now observe that $\cosh(S) + J \sinh(S)$ is a positive real-linear operator on $\mathscr{H}_r$. ■

B. Strongly continuous symplectic groups

We give here the case of bounded $T \in \mathscr{T}(E)$ a special treatment. If $\|Tf\| \leqslant c\|f\| \forall f \in E$ for some $c > 0$, then $\|\pm iTif\| \leqslant c\|f\|$, thus T_l and T_a are bounded. Conversely, T_l to be bounded is equivalent for T_a to be bounded, which implies T to be bounded. In this case T is continuously extendable to an element of $\mathscr{T}(\mathscr{H})$.

Lemma 2.9: Let $T \in \mathscr{T}(\mathscr{H})$. Then T, T_l and T_a are bounded.

Proof: Theorem 2.2 gives $\mathscr{D}(T_l) = \mathscr{D}(T_a) = \mathscr{D}(T_l^*) = \mathscr{D}(T_a^*) = \mathscr{H}$. The boundedness now follows from the closed graph theorem (e.g., Ref. 11, Theorem 5.7). ■

Let $C = C^*$ be a self-adjoint linear (possibly unbounded) operator on $\mathscr{H}$. Then $u_t := \exp\{itC\}$, $t \in \mathbb{R}$, defines a strongly continuous one-parameter group u of isometries on the real Hilbert space $\mathscr{H}_r$. We perturb u with the antilinear self-adjoint bounded $D = D^*$ on $\mathscr{H}$. The perturbed (strongly continuous) group on $\mathscr{H}_r$ is denoted by $\exp\{t(iC + D)\}$ with generator $iC + D$ and may be calculated by a perturbation expansion (cf. Ref. 12, Section 3.1). The linear part of $\exp\{t(iC + D)\}$ is given by summing over the even powers in the expansion series, and the antilinear part by summing over the odd ones.

Theorem 2.10: *The following statements are valid:*

(a) *Let $C = C^*$ be a linear operator on $\mathscr{H}$, and let $D = D^*$ be an antilinear bounded operator on $\mathscr{H}$. Then $T_t := \exp\{t(iC + D)\} \in \mathscr{T}(\mathscr{H})$ with $\|T_t\| \leqslant \exp\{\|D\||t|\}$ for all $t \in \mathbb{R}$.*

(b) *Let $\{T_t | t \in \mathbb{R}\} \subset \mathscr{T}(\mathscr{H})$ be a strongly continuous group with growth $\|T_t\| \leqslant \exp\{\beta|t|\} \forall t \in \mathbb{R}$ for some $\beta \geqslant 0$. Then there exists a unique linear $C = C^*$ and a unique antilinear bounded $D = D^*$ on $\mathscr{H}$ with $T_t = \exp\{t(iC + D)\} \forall t \in \mathbb{R}$.*

Proof: (a): $D = D^*$ implies $\mathrm{Im}\langle f | Dg\rangle = \mathrm{Im}\langle -Df | g\rangle \forall f, g \in \mathscr{H}$. Calculating with the perturbation series (e.g., Ref. 12, Theorem 3.1.33) gives $\mathrm{Im}\langle T_{-t} f | g\rangle = \mathrm{Im}\langle f | T_t g\rangle \forall f, g \in \mathscr{H}$. But $T_{-t} = T_t^{-1}$, thus $T_t \in \mathscr{T}(\mathscr{H})$. (b): From (2.4) follows $(T_{-t})_l + (T_{-t})_a = T_{-t} = T_t^{-1} = (T_t)_l^* - (T_t)_a^*$, which gives $(T_{-t})_l = (T_t)_l^*$ and $(T_{-t})_a = -(T_t)_a^*$. Let now all be as in Lemma A1 for our group T_t on the real Hilbert space $\mathscr{H}_r$. For the adjoint group T_t^+ we have $T_t^+ = (T_t)_l^* + (T_t)_a^* = (T_{-t})_l - (T_{-t})_a = -iT_{-t}i$, that is, $\exp\{tG^+\} = -i \exp\{-tG\}i \forall t \in \mathbb{R}$, which gives $f \in \mathscr{D}(G^+)$, if and only if $if \in \mathscr{D}(G)$. Hence, $\mathscr{D}(G) = \mathscr{D}(G^+)$ implies $\mathscr{D}(G)$ to be a complex dense subspace of $\mathscr{H}$, and, consequently, $G^+ = iGi$. Comparing with (2.2) gives $\Lambda = G_l$ to be (complex) linear and $D \supseteq G_a$ to be antilinear. Put $C := -i\Lambda$. From $\Lambda = -\Lambda^+$ and $D = D^+$ now follows $C = C^*$, and $D = D^*$, the adjoints with respect to the complex scalar product $\langle .|. \rangle$. ■

Theorem 2.10 completely characterizes the strongly continuous symplectic goups $\{T_t | t \in \mathbb{R}\} \subset \mathscr{T}(\mathscr{H})$ with growth $\|T_t\| \leqslant \exp\{\beta|t|\} \forall t \in \mathbb{R}$ for some $\beta \geqslant 0$. In general, a strongly continuous symplectic goup $\{V_t | t \in \mathbb{R}\} \subset \mathscr{T}(\mathscr{H})$ has the growth property $\|V_t\| \leqslant c \exp\{\beta|t|\} \forall t \in \mathbb{R}$ for some $\beta \geqslant 0$ and $c \geqslant 1$ (Ref. 12, Proposition 3.1.3). If there does not exist a $\beta \geqslant 0$ so that c may be chosen as $c = 1$, then by Theorem 2.10 the antilinear part, if it exists as a densely defined (closed) operator, of the generator of the group $\{V_t | t \in \mathbb{R}\}$ cannot be bounded.

Example 2.11. Let $\mathscr{H}$ be a separable complex Hilbert space with fixed ONB $\{e_k | k \in \mathbb{N}\}$, *and*

C,S,R positive, self-adjoint linear operators on $\mathscr{H}$ with $Ce_k=c_ke_k$, $Se_k=s_ke_k$, $Re_k=r_ke_k$ where $c_k>0$, $s_k\geqslant 0$, and $r_k>0\,\forall k\in\mathbb{N}$. S and R are supposed to be bounded. Finally let J be the antilinear involution on $\mathscr{H}$ satisfying $Je_k=e_k\,\forall k\in\mathbb{N}$. Obviously, C, S, R, and J mutually commute.

By Theorem 2.10 the exponentials $T_t:=\exp\{it(C-JS)\}$, $t\in\mathbb{R}$, define a strongly continuous one-parameter group of symplectic transformations $T_t\in\mathscr{T}(\mathscr{H})$. Another symplectic group of this kind is introduced by $\hat{T}_t:=TT_tT^{-1}$, where $T:=\exp\{JR\}=\cosh(R)+J\sinh(R)\in\mathscr{T}(\mathscr{H})$.

It holds $\hat{T}_t=\exp\{it(\hat{C}-J\hat{S})\}\,\forall t\in\mathbb{R}$ with the self-adjoint linear operators on $\mathscr{H}$

$$\begin{aligned}\hat{C}&:=2(\sinh(R)^2C+\cosh(R)\sinh(R)S)+C,\\ \hat{S}&:=2(\sinh(R)^2S+\cosh(R)\sinh(R)C)+S,\end{aligned}\tag{2.6}$$

which also have the e_k, $k\in\mathbb{N}$, as eigenvectors.

From (2.6) *it is seen that, for unbounded C, it may happen that $\hat{S}$ is unbounded, too. Hence the antilinear part $-iJ\hat{S}$ of the generator is unbounded* (e.g., *if $R\geqslant\mathbb{1}$, then $\hat{S}\geqslant C$*), *which by Theorem 2.10 implies the growth estimate $\|\hat{T}_t\|\leqslant c\exp\{\beta|t|\}\,\forall t\in\mathbb{R}$ with some $c>1$ and $\beta\geqslant 0$. Also, it is not possible to find a $\beta>0$ such that c may be chosen as $c=1$. Especially, because of $\|T\|=\|T^{-1}\|=\exp\{\|R\|\}$ and Theorem 2.10*(a), *we find the growth property $\|\hat{T}_t\|\leqslant\exp\{2\|R\|\}\exp\{\|S\||t|\}\,\forall t\in\mathbb{R}$.*

A continuation of this example is found at the end of Sec. III. The following lemma is used in the sequel.

Lemma 2.12: Let $D=D^*$ be an antilinear bounded operator on $\mathscr{H}$. Then there exists an antilinear involution J on $\mathscr{H}$ so that $D=J|D|$ and J commutes with D and $|D|$. Moreover, J is uniquely determined on $\ker(D)^\perp$.

Proof: The self-adjointness of D yields $\ker(|D|)=\ker(D)=\ker(D^*)$. Hence the initial space and final space is $\ker(D)^\perp$ for the antilinear partial isometry V occuring in the polar decomposition $D=V|D|$. The self-adjointness of D also yields V to commute with $|D|$ and D, and $V=V^*$. Hence V is an antilinear involution on $\ker(D)^\perp$, which we extend to an antilinear involution J on $\mathscr{H}$.

Example 2.13: Let D and J be as in Lemma 2.12. Then $T_t=\exp\{tD\}\in\mathscr{T}(\mathscr{H})$ with $(T_t)_l=\cosh(t|D|)$ and $(T_t)_a=J\sinh(t|D|)\,\forall t\in\mathbb{R}$.

III. UNITARY IMPLEMENTATIONS ON FOCK SPACE

The one-boson test function space E is a complex pre-Hilbert space with norm-completion $\mathscr{H}$. The C^*-algebra of the boson system is the Weyl algebra $\mathscr{W}(E)$ over E. $\mathscr{W}(E)$ is generated by the unitary Weyl operators $W(f)$, $f\in E$, satisfying (Ref. 12, Theorem 5.2.8)

$$W(f)W(g)=\exp\left\{-\frac{i}{2}\,\mathrm{Im}\langle f|g\rangle\right\}W(f+g),\quad W(f)^*=W(-f)\,\forall f,g\in E.\tag{3.1}$$

$\mathscr{S}\equiv\mathscr{S}(\mathscr{W}(E))$ denotes the state space of $\mathscr{W}(E)$. A state $\omega\in\mathscr{S}$ is called *regular*, if for each $f\in E$ the map $t\in\mathbb{R}\mapsto\langle\omega;W(tf)\rangle$ is continuous [$\langle\omega;M\rangle$ denotes the expectation value of ω with $M\in\mathscr{W}(E)$]. In the GNS representation $(\Pi_\omega,\mathscr{H}_\omega,\Omega_\omega)$ (e.g., Ref. 12, Subsection 2.3.3) of the regular $\omega\in\mathscr{S}$ the self-adjoint field operators are given by $\Phi_\omega(f):=-i(\mathrm{d}/\mathrm{d}t)\Pi_\omega(W(tf))|_{t=0}$, $f\in E$. The functional $f\in E\mapsto\Phi_\omega(f)$ is real-linear and the field operators satisfy the CCR on suitable dense domains, $[\Phi_\omega(f),\Phi_\omega(g)]\subseteq i\,\mathrm{Im}\langle f|g\rangle\mathbb{1}$, $\forall f,g\in E$. The CCR for the smeared annihilation and creation operators, $a_\omega(f):=2^{-1/2}(\Phi_\omega(f)+i\Phi_\omega(if))$ and $a_\omega^*(f):=2^{-1/2}(\Phi_\omega(f)-i\Phi_\omega(if))$, respectively, write as $[a_\omega(f),a_\omega(g)]=[a_\omega^*(f),a_\omega^*(g)]=0$, and $[a_\omega(f),a_\omega^*(g)]\subseteq\langle f|g\rangle\mathbb{1}$, where the $a_\omega^*(f)$ and $a_\omega(f)$, $f\in E$, are densely defined and closed. Furthermore, $a_\omega(f)^*=a_\omega^*(f)$, the map $f\in E\mapsto a_\omega(f)$ is antilinear, and $f\in E\mapsto a_\omega^*(f)$ is linear (e.g., Ref. 12, Lemma 5.2.12).

The Fock vacuum state $\omega_{\mathrm{F}}\in\mathscr{S}$ is given by its characteristic function

$$\langle \omega_F; W(f)\rangle = \exp\{-\tfrac{1}{4}\|f\|^2\} \quad \forall f \in E. \tag{3.2}$$

Its GNS representation $(\Pi_F, F_+(\mathscr{H}), \Omega_F)$ is identical to the usual Fock representation Π_F on the symmetric Fock space $F_+(\mathscr{H}) = \oplus_{n=0}^{\infty} \mathbb{P}_+(\otimes_n \mathscr{H})$, where $\mathbb{P}_+$ is the symmetrization operator and $\otimes_n \mathscr{H}$ the n-fold tensor product of $\mathscr{H}$ with itself, and with the vacuum vector $\Omega_F = (1,0,0,\ldots) \in F_+(\mathscr{H})$ as cyclic vector. $\mathbb{P}_+(\otimes_n \mathscr{H})$ is called the n-particle subspace of $F_+(\mathscr{H})$. The Fock field, creation, annihilation, and Weyl operators are denoted by $\Phi_F(f)$, $a_F^*(f)$, $a_F(f)$, and $W_F(f)$, $f \in \mathscr{H}$ [$\Pi_F(W(f)) = W_F(f)$ for $f \in E$], respectively. We remark that $a_F(g)\Omega_F = 0$ $\forall g \in \mathscr{H}$, and $a_F^*(g)\mathbb{P}_+(f_1 \otimes \cdots \otimes f_n) = \sqrt{n+1}\,\mathbb{P}_+(g \otimes f_1 \otimes \cdots \otimes f_n) \forall g, f_j \in \mathscr{H}, \forall n \in \mathbb{N} \cup \{0\}$ (e.g., Ref. 12, Subsection 5.2.1; Ref. 9, Section X.7).

For each $T \in \mathscr{T}(E)$ there is a (unique)*-automorphism α_T on the Weyl algebra $\mathscr{W}(E)$ with $\alpha_T(W(f)) = W(Tf) \forall f \in E$, the *Bogoliubov transformation* associated with T. The dual transformation ν_T, $\langle \nu_T(\omega); M\rangle = \langle \omega; \alpha_T(M)\rangle$, $\omega \in \mathscr{S}$, $M \in \mathscr{W}(E)$, is an affine bijection on $\mathscr{S}$. Obviously, $(\nu_T)^{-1} = \nu_{T^{-1}}$, and, the state $\omega \in \mathscr{S}$ is regular, if and only if $\nu_T(\omega)$ is so. Especially, $\nu_T(\omega_F)$ is regular.

A. Bogoliubov transformations in the Fock representation

Here we turn our interest to those cases for which the Bogoliubov transformation α_T is unitarily implementable in Fock space. For finite-dimensional $E = \mathscr{H}$ [for each $T \in \mathscr{T}(E)$] this is a consequence of the Stone–von Neumann uniqueness theorem (e.g., Ref. 12, Corollary 5.2.15), which implies the irreducible GNS representation $[\Pi_F \circ \alpha_T, F_+(\mathscr{H}), \Omega_F]$ of the pure state $\nu_T(\omega_F)$ to be unitarily equivalent to the Fock representation $(\Pi_F, F_+(\mathscr{H}))$. For separable $E = \mathscr{H}$ the problem is solved in Ref. 8 (cf. also Refs. 7 and 13, Section 9), which is equivalent to the result of Ref. 14. The formulation of Shale's theorem presented here makes no use of the separability of $\mathscr{H}$ and allows also E to be a proper, dense, complex subspace of $\mathscr{H}$ (cf. Lemma 2.9). It is derived in a way different from Refs. 8 and 14. We refer some common notions (e.g., Ref. 9, Section VI.6): A bounded linear (resp. antilinear) operator D on $\mathscr{H}$ is called Hilbert–Schmidt, if its Hilbert–Schmidt norm $\|D\|_{HS} := (\Sigma_{e \in \mathscr{O}} \|De\|^2)^{1/2}$ is finite, here $\|.\|_{HS}$ does not depend on the specific ONB $\mathscr{O}$ chosen for $\mathscr{H}$; D is called to be of trace class, if $\mathrm{tr}[|D|] < \infty$, where $\mathrm{tr}[.]$ denotes the usual trace on $\mathscr{H}$.

Theorem 3.1: *Let $T \in \mathscr{T}(E)$. We have the following equivalences:*

(i) *$\nu_T(\omega_F)$ is normal with respect to the Fock representation $(\Pi_F, F_+(\mathscr{H}))$;*

(ii) *α_T is unitarily implementable with respect to the Fock representation $(\Pi_F, F_+(\mathscr{H}))$, that is, there exists a unitary U_T on $F_+(\mathscr{H})$ with $\Pi_F(\alpha_T(M)) = U_T \Pi_F(M) U_T^* \forall M \in \mathscr{W}(E)$;*

(iii) *$|\overline{T_a}|$ is Hilbert–Schmidt on $\mathscr{H}$, which is equivalent for $|T_l| - \mathbb{1}$ to be of trace class;*

(iv) *$|T|_r - \mathbb{1}$ is a real-linear Hilbert–Schmidt operator on the real Hilbert space $\mathscr{H}_r$ (see Corollary 2.8), which is equivalent for $T^+T - \mathbb{1}$ to be Hilbert–Schmidt (cf. Refs. 8 and 13).*

If some of these assertions (and hence all) are valid, then U_T of (ii) is unique up to a phase. Moreover, $U_T\Omega_F = e^{i\vartheta}\Omega_F$ for some $\vartheta \in [0, 2\pi[$, if and only if $T_a = 0$.

Proof: (i)⇒(ii): $\nu_T(\omega_F)$ is pure. Hence, since $\nu_T(\omega_F)$ is Π_F-normal and by the irreducibility of Π_F (Ref. 12, Proposition 5.2.4), there exists a normalized $\eta_T \in F_+(\mathscr{H})$ so that $(\Pi_F, F_+(\mathscr{H}), \eta_T)$ is a GNS representation of $\nu_T(\omega_F)$. On the other side, $(\Pi_F \circ \alpha_T, F_+(\mathscr{H}), \Omega_F)$ is a GNS representation of $\nu_T(\omega_F)$, too, which has to be unitarily equivalent to $(\Pi_F, F_+(\mathscr{H}), \eta_T)$.

(ii)⇒(iii): First, $f \in E \mapsto \langle U_T^* \Omega_F | W_F(f) U_T^* \Omega_F\rangle = \exp\{-\tfrac{1}{4}\|Tf\|^2\}$ is continuous [e.g., Ref. 12, Proposition 5.2.4(4)], from which it follows that T is bounded. We extend the bounded T_l and T_a to all of $\mathscr{H}$ without changing the notation. From $\Phi_F(Tf) = U_T \Phi_F(f) U_T^*$ follows $U_T a_F(f) U_T^* = a_F(T_l f) + a_F^*(T_a f)$. Let $U_T\Omega_F = \oplus_{n=0}^{\infty} \xi_n$ with $\xi_n \in \mathbb{P}_+(\otimes_n \mathscr{H})$, especially, $\xi_0 = \alpha_0 \Omega_F$, i.e., $\alpha_0 = \langle \Omega_F | U_T \Omega_F\rangle$. Then $(a_F(T_l f) + a_F^*(T_a f)) U_T \Omega_F = U_T a_F(f) \Omega_F = 0 \; \forall f \in E$. With Corollary 2.3 we obtain the recursive system of equations: $a_F(g)\xi_{n+1} = -a_F^*(T_a (T_l)^{-1} g)\xi_{n-1}$ for all $g \in \mathscr{H}$

and each $n \geqslant 0$. Especially for $n=0$ it follows $\xi_1=0$, and thus, $\xi_{2k+1}=0\ \forall k \in \mathbb{N}$. $U_T\Omega_F \neq 0$ implies $\alpha_0 \neq 0$. For $n=1$ we have $a_F(g)\xi_2 = -\alpha_0 T_a (T_l)^{-1} g$, which with $\xi_2 = \mathbb{P}_+ \xi_2$ yields

$$\sqrt{2}\langle g \otimes h | \xi_2 \rangle = \langle a_F^*(g) h | \xi_2 \rangle = \langle h | a_F(g) \xi_2 \rangle = -\alpha_0 \langle h | T_a (T_l)^{-1} g \rangle. \tag{3.3}$$

With an ONB $\{e_j | j \in I\}$ of $\mathscr{H}$ we finally obtain

$$\infty > \frac{\|\xi_2\|^2}{|\alpha_0|^2} = \sum_{i,j \in I} |\langle e_i \otimes e_j | \alpha_0^{-1} \xi_2 \rangle|^2 = \frac{1}{2} \sum_{i,j \in I} |\langle e_j | T_a (T_l)^{-1} e_i \rangle|^2 = \frac{1}{2} \| |T_a| |T_l|^{-1} \|_{\mathrm{HS}}^2,$$

where we used the decomposition $T_l = U|T_l|$ and $T_a = UJ|T_a|$ with $|T_l| = \cosh(S)$ and $|T_a| = \sinh(S)$ from Theorem 2.5. Since $|T_l|$ is bounded, the assertion follows from the fact that the Hilbert–Schmidt class is a two-sided *-ideal in the bounded operators on $\mathscr{H}$.

$|T_l| \geqslant \mathbb{1}$ and $(|T_l|-\mathbb{1})(|T_l|+\mathbb{1}) = |T_l|^2 - \mathbb{1} = |T_a|^2$ imply $0 \leqslant |T_l| - \mathbb{1} \leqslant |T_a|^2$. Hence $|T_l| - \mathbb{1}$ is of trace class, if and only if $|T_a|^2$ is so (the trace class is a two-sided *-ideal in the bounded operators on $\mathscr{H}$).

(iii)$\Rightarrow$(i): The field, creation, and annihilation operators associated with the GNS representation $(\Pi_F \circ \alpha_T,\ F_+(\mathscr{H}),\ \Omega_F)$ of $\nu_T(\omega_F)$ we denote by $\Phi_T(f)$, $a_T^*(f)$, and $a_T(f)$, respectively. Obviously, $\Phi_T(f) = \Phi_F(Tf)$ and $a_T(f) = a_F(T_l f) + a_F^*(T_a f)\ \forall f \in E$. Since $|T_a|$ is Hilbert–Schmidt and commutes with J (Theorem 2.5) there exists an ONB $\mathscr{O}$ for $\mathscr{H}$ consisting of eigenvectors for $|T_a|$ with $Je = e\ \forall e \in \mathscr{O}$. Let $\mathscr{T}$ be a finite subset of $\mathscr{O}$, $P_{\mathscr{T}}$ the orthogonal projection onto $\mathsf{LH}\{\mathscr{T}\}$, and $h \in \mathsf{LH}\{\mathscr{T}\}$. Using the commutation relations

$$a_F(g) W_F(h) = W_F(h) \left(a_F(g) + \frac{i}{\sqrt{2}} \langle g | h \rangle \right), \quad a_F^*(g) W_F(h) = W_F(h) \left(a_F^*(g) - \frac{i}{\sqrt{2}} \langle h | g \rangle \right), \tag{3.4}$$

$|T_l|^2 = |T_a|^2 + \mathbb{1}$, and the Cauchy–Schwarz inequality, we obtain for each $g \in \mathscr{H}$

$$\|a_T(g) W_F(Uh) \Omega_F\|^2 = \tfrac{1}{2} |\langle g | (|T_l| - J|T_a|) h \rangle|^2 + \| |T_a| g \|^2 \leqslant \mathrm{tr}[|g\rangle\langle g| (c(h) P_{\mathscr{T}} + T_a^* T_a)]$$

with $c(h) \geqslant 0$ only depending on h. Let $\mathscr{F}$ be an ONB of the arbitrary finite-dimensional complex subspace $F \subseteq E$ with associated orthogonal projection P_F. Then

$$\sum_{e \in \mathscr{T}} \|a_T(e) W_F(Uh) \Omega_F\|^2 \leqslant \mathrm{tr}[P_F (c(h) P_{\mathscr{T}} + T_a^* T_a)] \leqslant \mathrm{tr}[c(h) P_{\mathscr{T}} + T_a^* T_a] < \infty.$$

But the set of vectors $W_F(Uh)\Omega_F$ with $h \in \mathsf{LH}(\mathscr{O})$ is total in $\mathscr{H}$. Hence a Fock-number operator for $\nu_T(\omega_F)$ exists and Ref. 12. Theorem 5.2.14 yields (i).

The equivalence (iii)$\Leftrightarrow$(iv) is easily checked with the decomposition of Theorem 2.5 and Corollary 2.8. Furthermore, the relations $|T|_r + \mathbb{1} \geqslant \mathbb{1}$ and $(|T|_r - \mathbb{1})(|T|_r + \mathbb{1}) = |T|_r^2 - \mathbb{1}$ imply $0 \leqslant |T|_r - \mathbb{1} \leqslant T^+ T - \mathbb{1}$. Hence $|T|_r - \mathbb{1}$ is Hilbert–Schmidt, if and only if $T^+ T - \mathbb{1}$ is so.

Let us prove the uniqueness of U_T: Assume U_T and $\widetilde{U}_T$ to implement α_T. Then $\widetilde{U}_T^* U_T$ is a unitary element of the commutant $\Pi_F(\mathscr{W}(E))'$. But Π_F is irreducible. Now, $T_a = 0$, if and only if T is unitary ($S=0$ in Theorem 2.5). This holds, if and only if $\nu_T(\omega_F) = \omega_F$, which is equivalent to $\eta_T = e^{i\vartheta} \Omega_F$ for some $\vartheta \in [0, 2\pi[$, where η_T is the cyclic vector from above. ■

Let us remark, that, e.g., Example 2.7 does not fulfill the requirements of Theorem 3.1.

Corollary 3.2: Let $T \in \mathscr{T}(E)$. Then the GNS representation of the pure state $\nu_T(\omega_F)$ is $(\Pi_F \circ \alpha_T, F_+(\mathscr{H}), \Omega_F)$, and the associated field and annihilation operators, $\Phi_T(f)$ resp. $a_T(f)$, are given as

$$\Phi_T(f) = \Phi_F(Tf), \quad a_T(f) = a_F(T_l f) + a_F^*(T_a f), \quad f \in E.$$

There exists a normalized vector $\xi_T \in F_+(\mathscr{H})$ with $a_T(f)\xi_T = 0 \forall f \in E$, *if and only if the equivalent assertions (i)–(iv) of Theorem 3.1 are valid, in which case* ξ_T *uniquely (up to a phase) is given by* $\xi_T = U_T\Omega_F$.

Definition 3.3: Let $\mathscr{T}_F(E)$ *be the subgroup of those symplectic transformations* $T \in \mathscr{T}(E)$ *for which* $|\overline{T_a}|$ *is a Hilbert–Schmidt operator on* $\mathscr{H}$.

Each $T \in \mathscr{T}_F(E)$ extends continuously to an element of $\mathscr{T}_F(\mathscr{H})$, in which sense $\mathscr{T}_F(E)$ is a subgroup of $\mathscr{T}_F(\mathscr{H})$. Because the unitaries U_T, $T \in \mathscr{T}_F(\mathscr{H})$, are unique up to a phase, $T \mapsto U_T$ is a projective representation of $\mathscr{T}_F(\mathscr{H})$; some properties of this are discussed in Ref. 8.

In the following we use the determinant $\det(R)$ of a bounded (linear) operator R on $\mathscr{H}$. $\det(R)$ exists if $R - \mathbb{1}$ is of trace class, and it is approximable from finite dimensions with the usual determinant. $\det(R) = 0$, if $0 \in \sigma(R)$, with $\sigma(R)$ the spectrum of R. If $0 \notin \sigma(R)$, we have the formula $\det(R) = \exp\{\mathrm{tr}[\ln(R)]\}$, where $\ln(R)$ is well defined (cf. Ref. 8 Lemma 2.1; Ref. 15, Sections VII.3 and XI.6; Ref. 7, p. 8; and Ref. 16, Subsection X.I.4).

Lemma 3.4: Let $T \in \mathscr{T}_F(\mathscr{H})$. *Then the unitary* U_T *implementing* α_T *in the Fock representation* $(\Pi_F, F_+(\mathscr{H}))$ *is characterized uniquely by the following transition amplitude, which holds for all* $g, h \in \mathscr{H}$:

$$\langle W_F(g)\Omega_F | U_T W_F(h)\Omega_F\rangle = \langle \Omega_F | U_T\Omega_F\rangle \exp\{\tfrac{1}{2}\langle (T_l)^{-1}g | h\rangle + \tfrac{1}{4}(\langle g | T_a (T_l)^{-1} g\rangle - \langle (T_l)^{-1} T_a h | h\rangle - \|g\|^2 - \|h\|^2)\} \tag{3.5}$$

with $|\langle \Omega_F | U_T\Omega_F\rangle| = (\det(|T_l|))^{-1/2}$. *One has* $\det(|T_l|) \neq 0$, *since* $0 \notin \sigma(T_l)$ *by Corollary 2.3.*

Proof: $U_T a_F(g) U_T^* = a_F(T_l g) + a_F^*(T_a g)$, and $-i\sqrt{2}(\mathrm{d}/\mathrm{d}t) W_F(tf)\Omega_F = W_F(tf) a_F^*(f)\Omega_F$, and (3.4) lead to the following differential equations (for each $f \in \mathscr{H}$ in dependence of the parameter $t \in \mathbb{R}$):

$$\begin{aligned} 0 &= \langle W_F(tf)\Omega_F | U_T a_F((T_l)^{-1} f)\Omega_F\rangle \\ &= \langle a_F^*(f) W_F(tf)\Omega_F | U_T\Omega_F\rangle + \langle a_F(T_a (T_l)^{-1} f) W_F(tf)\Omega_F | U_T\Omega_F\rangle \\ &= i\sqrt{2}\,\frac{\mathrm{d}}{\mathrm{d}t}\langle W_F(tf)\Omega_F | U_T\Omega_F\rangle + \frac{i}{\sqrt{2}}\, t(\|f\|^2 - \langle f | T_a (T_l)^{-1} f\rangle)\langle W_F(tf)\Omega_F | U_T\Omega_F\rangle, \end{aligned}$$

the solutions of which give (3.5) for $h = 0$. $U_T W_F(h)\Omega_F = W_F(Th) U_T\Omega_F$, the Weyl relations and the decomposition of Theorem 2.5, $T_l = U|T_l|$ and $T_a = UJ|T_a|$ with $|T_l|^2 = |T_a|^2 + \mathbb{1}$, and $[|T_l|, J] = 0$ imply (3.5) for every $g, h \in \mathscr{H}$. For determining $|\langle \Omega_F | U_T\Omega_F\rangle|$ we use Subsection B of the Appendix. Choose an ONB $\mathscr{O}$ for $\mathscr{H}$ consisting of eigenvectors of $|T_a|$ with $Je = e \forall e \in \mathscr{O}$. Let $\mathscr{L}$ be the set of all finite-dimensional complex subspaces $\mathscr{V} \subseteq \mathsf{LH}(U\mathscr{O})$. Then $1 = \| U_T\Omega_F\|^2 = \sup_{\mathscr{V} \in \mathscr{L}} \|\Gamma(P_{\mathscr{V}}) U_T\Omega_F\|^2$ ($\Gamma(P_{\mathscr{V}})$ is defined in Subsection B of the Appendix). For each $\mathscr{V} \in \mathscr{L}$ choose the ONB as a subset of $U\mathscr{O}$. Then with (3.5) by direct calculation of the integrals (A2) one obtains the result. ∎

B. Hamiltonians for symplectic one-parameter groups

Assume $\{T_t | t \in \mathbb{R}\}$ to be a strongly continuous one-parameter group of symplectic transformations $T_t \in \mathscr{T}_F(\mathscr{H})$ with associated Bogoliubov transformations α_{T_t} on the Weyl algebra $\mathscr{W}(\mathscr{H})$. Whenever the group $\{T_t | t \in \mathbb{R}\}$ is nontrivial, then the associated group $\{\alpha_{T_t} | t \in \mathbb{R}\}$ on $\mathscr{W}(\mathscr{H})$ is not strongly continuous, because of $\|W(f) - W(g)\| = 2$ for $f \neq g$ (e.g., Ref. 12, Theorem 5.2.8). Nevertheless it may be possible to implement this group of Bogoliubov transformations by a strongly continuous unitary group in some representations of $\mathscr{W}(\mathscr{H})$. In the present subsection we are asking for self-adjoint operators H on $F_+(\mathscr{H})$ such that $\exp\{itH\}$ unitarily implements α_{T_t} with respect to the Fock representation $(\Pi_F, F_+(\mathscr{H}))$ for every $t \in \mathbb{R}$, that is,

$$\exp\{itH\}W_{\mathrm{F}}(f)\exp\{-itH\}=W_{\mathrm{F}}(T_t f)=(\Pi_{\mathrm{F}}\circ\alpha_{T_t})(W(f)) \quad \forall f\in\mathscr{H}. \tag{3.6}$$

The next two theorems completely solve this problem for H satisfying the additional property $\Omega_{\mathrm{F}}\in\mathscr{D}(H)$. We need some preparatory considerations.

For the self-adjoint linear C on $\mathscr{H}$ the self-adjoint operator $a_{\mathrm{F}}^*Ca_{\mathrm{F}}$ on $F_+(\mathscr{H})$ is the second quantization of C, often also denoted by $\mathrm{d}\Gamma(C)$; especially $a_{\mathrm{F}}^*\mathbb{1}a_{\mathrm{F}}=:N$ is the number operator on the Fock space $F_+(\mathscr{H})$ (cf., e.g., Ref. 12, Subsection 5.2.1, or Ref. 9, Section X.7), whose eigenspace with eigenvalue $n\in\mathbb{N}$ consists just of the n-particle subspace $\mathbb{P}_+(\otimes_n\mathscr{H})$ of $F_+(\mathscr{H})$. We want to define the quadratic operators $a_{\mathrm{F}}^*Da_{\mathrm{F}}^*$ and $a_{\mathrm{F}}Da_{\mathrm{F}}$.

Definition 3.5: For each antilinear finite rank operator D on $\mathscr{H}$ [i.e., ran(D) *is of finite dimension; e.g., Ref. 11, Theorem 6.1] with (nonunique) decomposition* $D=\Sigma_{j=1}^p\langle\cdot|f_j\rangle g_j$ *(where* $p\in\mathbb{N}$, *and* $f_j,g_j\in\mathscr{H}$ for $j\in\{1,\ldots,p\}$) *we define*

$$a_{\mathrm{F}}^*Da_{\mathrm{F}}^*:=\sum_{j=1}^p a_{\mathrm{F}}^*(f_j)a_{\mathrm{F}}^*(g_j), \quad a_{\mathrm{F}}Da_{\mathrm{F}}:=\sum_{j=1}^p a_{\mathrm{F}}(f_j)a_{\mathrm{F}}(g_j).$$

We mention that this definition is independent from the specific decomposition of D, *and* that $\mathscr{D}(N)\subseteq\mathscr{D}(a_{\mathrm{F}}^*Da_{\mathrm{F}}^*)$ *and* $\mathscr{D}(N)\subseteq\mathscr{D}(a_{\mathrm{F}}Da_{\mathrm{F}})$.

Obviously, $(a_{\mathrm{F}}^*Da_{\mathrm{F}}^*)^*\supseteq a_{\mathrm{F}}Da_{\mathrm{F}}$ and $(a_{\mathrm{F}}Da_{\mathrm{F}})^*\supseteq a_{\mathrm{F}}^*Da_{\mathrm{F}}^*$. Because creation operators commute with each other, we have $a_{\mathrm{F}}^*Da_{\mathrm{F}}^*=a_{\mathrm{F}}^*D^*a_{\mathrm{F}}^*$, resp. $a_{\mathrm{F}}Da_{\mathrm{F}}=a_{\mathrm{F}}D^*a_{\mathrm{F}}$. Hence we may restrict ourselves to self-adjoint antilinear finite rank operators D. $\mathsf{HS}_a^{sa}(\mathscr{H})$ denotes the complex-linear vector space of self-adjoint antilinear Hilbert–Schmidt operators on $\mathscr{H}$. It is well known that the self-adjoint antilinear finite rank operators on $\mathscr{H}$ are $\|.\|_{\mathsf{HS}}$-dense in $\mathsf{HS}_a^{sa}(\mathscr{H})$.

Lemma 3.6: It holds:

(a) *Let D be an antilinear finite rank operator on $\mathscr{H}$. Then*

$$\|a_{\mathrm{F}}^*Da_{\mathrm{F}}^*\psi\|\leqslant\|D\|_{\mathsf{HS}}\|((N+1)(N+2))^{1/2}\psi\| \quad \forall\psi\in\mathscr{D}(N),$$

and the same inequality holds for $a_{\mathrm{F}}Da_{\mathrm{F}}$. Hence $a_{\mathrm{F}}^*Da_{\mathrm{F}}^*$ and $a_{\mathrm{F}}Da_{\mathrm{F}}$ can be defined for arbitrary $D\in\mathsf{HS}_a^{sa}(\mathscr{H})$ by continuous approximation of D by finite rank operators, with the domain $\mathscr{D}(a_{\mathrm{F}}^*Da_{\mathrm{F}}^*):=\mathscr{D}(N)=:\mathscr{D}(a_{\mathrm{F}}Da_{\mathrm{F}})$. The mapping $D\in\mathsf{HS}_a^{sa}(\mathscr{H})\mapsto a_{\mathrm{F}}^*Da_{\mathrm{F}}^*$ is (complex-) linear, and $D\in\mathsf{HS}_a^{sa}(\mathscr{H})\mapsto a_{\mathrm{F}}Da_{\mathrm{F}}$ is antilinear.

(b) *Let be $C=C^*$ linear with core $\mathscr{D}_C\subseteq\mathscr{H}$,* and $D=D^*\in\mathsf{HS}_a^{sa}(\mathscr{H})$. *Then*

$$H:=\tfrac{1}{2}(a_{\mathrm{F}}^*Da_{\mathrm{F}}^*+a_{\mathrm{F}}Da_{\mathrm{F}})+a_{\mathrm{F}}^*Ca_{\mathrm{F}}$$

is essentially self-adjoint on the linear hull L of vectors $\mathbb{P}_+(f_1\otimes\cdots\otimes f_n)$ with $f_1,\ldots,f_n\in\mathscr{D}_C$ and $n\in\mathbb{N}\cup\{0\}$. Especially, $\|H\Omega_{\mathrm{F}}\|=(1/\sqrt{2})\|D\|_{\mathsf{HS}}$.

Proof: We omit the index F standing for Fock. (a): We decompose $D=\Sigma_{j=1}^p\alpha_j\langle\cdot|f_j\rangle g_j$ with $\alpha_j\in\mathbb{C}$ and $f_j,g_j\in\mathscr{H}$ such that $\{f_1,\ldots,f_p\}$ is an orthonormal system of $\mathscr{H}$ and $\{g_1,\ldots,g_p\}$, too. Define the linear operator $X_n:\otimes_n\mathscr{H}\to\otimes_{n+2}\mathscr{H}$, $\xi\mapsto\sqrt{(n+1)(n+2)}\Sigma_{j=1}^p\alpha_j f_j\otimes g_j\otimes\xi$. Then $\|X_n\|=\sqrt{(n+1)(n+2)}\|D\|_{\mathsf{HS}}$. Now observe that $a^*Da^*=\oplus_n\mathbb{P}_+X_n\mathbb{P}_+$.

(b): We show that $\mathrm{ran}(H|_L-z)$ is dense in $F_+(\mathscr{H})$ for each $z\in\mathbb{C}$ with $\mathrm{Im}(z)\neq0$, which gives the essential self-adjointness of $H|_L$ (e.g., Ref. 11, Theorem 5.21). Let $\eta=\oplus_k\eta_k\in F_+(\mathscr{H})$, $\eta_k\in\mathbb{P}_+(\otimes_k\mathscr{H})$, with $\eta\perp\mathrm{ran}(H|_L-z)$. Because of (a) especially for vectors $\xi\in L\cap\mathbb{P}_+(\otimes_k\mathscr{H})$ we obtain $2\langle(a^*Ca-z)\xi|\eta_k\rangle+\langle\xi|aDa\,\eta_{k+2}\rangle+\langle\xi|a^*Da^*\eta_{k-2}\rangle=0$. But a^*Ca is essentially selfadjoint on $L\cap\mathbb{P}_+(\otimes_k\mathscr{H})$ as an operator on $\mathbb{P}_+(\otimes_k\mathscr{H})$, which implies $\eta_k\in\mathscr{D}(a^*Ca)$ and $2a^*Ca\,\eta_k+aDa\,\eta_{k+2}+a^*Da^*\eta_{k-2}=\overline{z}\,\eta_k\,\forall k\in\mathbb{N}$. Taking the imaginary part of the inner product with η_k, one obtains

$$\mathrm{Im}(z)\|\eta_k\|^2=\mathrm{Im}\langle\eta_{k+2}|a^*Da^*\eta_k\rangle-\mathrm{Im}\langle\eta_k|a^*Da^*\eta_{k-2}\rangle.$$

Consequently, $\mathrm{Im}(z)\Sigma_{k=0}^{n}\|\eta_k\|^2=\mathrm{Im}\langle\eta_{n+2}|a^*Da^*\eta_n\rangle+\mathrm{Im}\langle\eta_{n+1}|a^*Da^*\eta_{n-1}\rangle$. Hence with the estimations of (a) we get for each $n\in\mathbb{N}$

$$|\mathrm{Im}(z)|\sum_{k=0}^{n}\|\eta_k\|^2\leqslant\sqrt{(n+1)(n+2)}\||D|\|_{\mathsf{HS}}(\|\eta_{n+2}\|+\|\eta_{n+1}\|+\|\eta_n\|+\|\eta_{n-1}\|). \tag{3.7}$$

Assume $\eta\neq0$. Then there is an $n_0\in\mathbb{N}$ with $\Sigma_{k=0}^{n_0}\|\eta_k\|^2=:c>0$. Equation (3.7) now gives

$$4\sum_{n=n_0-1}^{\infty}\|\eta_n\|^2\geqslant\frac{|\mathrm{Im}(z)|c}{\||D|\|_{\mathsf{HS}}}\sum_{n=n_0}^{\infty}((n+1)(n+2))^{-1/2}=\infty,$$

which is a contradiction to $\|\eta\|^2=\Sigma_k\|\eta_k\|^2<\infty$. Thus $\eta=0$ and $\mathrm{ran}(H|_L-z)$ is dense.

Now use the decomposition (3.8) from below. Then $H\Omega_{\mathrm{F}}=\frac{1}{2}a^*Da^*\Omega_{\mathrm{F}}=2^{-1/2}\Sigma_k d_k e_k\otimes e_k$, which gives $\|H\Omega_{\mathrm{F}}\|^2=\frac{1}{2}\|D\|_{\mathsf{HS}}^2$. ∎

Let be $D=D^*\in\mathsf{HS}_a^{sa}(\mathscr{H})$ and J an antilinear involution on $\mathscr{H}$ from Lemma 2.12, i.e., $D=J|D|$ and J commutes with D and $|D|$. We select an ONB $\{e_k|k\in I\}$ of $\mathscr{H}$ consisting of eigenvectors for $|D|$ so that $Je_k=e_k\forall k\in I$, i.e., $|D|e_k=d_ke_k$ with $d_k\geqslant0\forall k\in I$ and $\Sigma_{k\in I}d_k^2<\infty$. Hence the antilinear $D\in\mathsf{HS}_a^{sa}(\mathscr{H})$ may be represented as $D=\Sigma_{k\in I}d_k\langle.|e_k\rangle e_k$, and by Lemma 3.6(a) we have

$$a_{\mathrm{F}}^*Da_{\mathrm{F}}^*\psi=\sum_{k\in I}d_ka_{\mathrm{F}}^*(e_k)a_{\mathrm{F}}^*(e_k)\psi\quad\forall\psi\in\mathscr{D}(N), \tag{3.8}$$

where the series converge with respect to the norm on $F_+(\mathscr{H})$ (the analogous equation is valid for $a_{\mathrm{F}}Da_{\mathrm{F}}$). This implies that, for $N=\infty$ in the case $\Sigma_{n=1}^{\infty}|\zeta_n|^2<\infty$, the Hamiltonian H_q from the introduction is a well-defined self-adjoint operator in the Fock representation (observe that, for each $n\in\mathbb{N}$, we have $\zeta_n\langle.|e_n\rangle e_n=|\zeta_n|\langle.|z_ne_n\rangle(z_ne_n)$ and $\zeta_na_n^*a_n^*\equiv\zeta_na_{\mathrm{F}}^*(e_n)^2=|\zeta_n|a_{\mathrm{F}}^*(z_ne_n)^2$, where $z_n:=\exp\{(i/2)\arg(\zeta_n)\}$), and the power series in (1.1) converges in the strong resolvent sense by Ref. 11, Theorem 9.16.

Theorem 3.7: *Let $C=C^*$ be a linear operator on $\mathscr{H}$ and $D=D^*$ an antilinear Hilbert–Schmidt operator on $\mathscr{H}$, and let $H=\frac{1}{2}(a_{\mathrm{F}}^*Da_{\mathrm{F}}^*+a_{\mathrm{F}}Da_{\mathrm{F}})+a_{\mathrm{F}}^*Ca_{\mathrm{F}}$ be the self-adjoint operator on $F_+(\mathscr{H})$ from Lemma 3.6. Then, for each $t\in\mathbb{R}$ it holds $T_t:=\exp\{it(C-D)\}\in\mathscr{T}_{\mathrm{F}}(\mathscr{H})$ (cf. Theorem 2.10), and $\exp\{itH\}$ unitarily implements α_{T_t} with respect to the Fock representation $(\Pi_{\mathrm{F}},F_+(\mathscr{H}))$ [see Eq. (3.6)].*

Moreover, $\langle\Omega_{\mathrm{F}}|\exp\{itH\}\Omega_{\mathrm{F}}\rangle=(\det((T_{-t})_l\exp\{itC\}))^{-1/2}$, where $(T_{-t})_l\exp\{itC\}-\mathbb{1}$ is of trace class, and $\langle W_{\mathrm{F}}(g)\Omega_{\mathrm{F}}|\exp\{itH\}W_{\mathrm{F}}(h)\Omega_{\mathrm{F}}\rangle$ is given by Eq. (3.5) with $U_{T_t}\equiv\exp\{itH\}$ for every $f,g\in\mathscr{H}$ and all $t\in\mathbb{R}$.

Proof: We omit the index F. That $T_t\in\mathscr{T}_{\mathrm{F}}(\mathscr{H})$ immediately follows from the Theorems 2.10 and 3.1 with the perturbation expansion. For antilinear $X=X^*$ of Hilbert–Schmidt class we put $H(X):=\frac{1}{2}(a^*Xa^*+aXa)$. Let $U_t:=\exp\{ita^*Ca\}$ and $u_t:=\exp\{itC\}$. We use $U_t\Phi(h)U_{-t}=\Phi(u_th)$ and (3.8) applied to X for deriving $U_tH(X)U_{-t}=H(u_tXu_{-t})$, and the CCR for checking $i[H(X),\Phi(h)]=\Phi(-iXh)$ for each $h\in\mathscr{H}$. With the Dyson expansion for the perturbation $H(D)$ (e.g., Ref. 12, Proposition 5.4.1) we obtain

$$\begin{aligned}&\exp\{itH\}\Phi(f\,)\exp\{-itH\}\\&\quad=\sum_{n=0}^{\infty}\int_0^t\mathrm{d}t_1\int_0^{t_1}\mathrm{d}t_2\cdots\\&\quad\times\int_0^{t_{n-1}}\mathrm{d}t_n i^n[U_{t_n}H(D)U_{-t_n},[\ldots[U_{t_n}H(D)U_{-t_n},U_t\Phi(f\,)U_{-t}]\ldots]]\end{aligned}$$

$$
\begin{aligned}
&= \sum_{n=0}^{\infty} \int_0^t \mathrm{d}t_1 \int_0^{t_1} \mathrm{d}t_2 \cdots \int_0^{t_{n-1}} \mathrm{d}t_n i^n [H(u_{t_n} D u_{-t_n}), [\ldots [H(u_{t_1} D u_{-t_1}), \Phi(u_t f)]\ldots]] \\
&= \sum_{n=0}^{\infty} \int_0^t \mathrm{d}t_1 \int_0^{t_1} \mathrm{d}t_2 \cdots \int_0^{t_{n-1}} \mathrm{d}t_n \Phi(u_{t_n}(-iD) u_{-t_n} \cdots u_{t_1}(-iD) u_{-t_1} u_t f) \\
&= \Phi(T_t f),
\end{aligned}
$$

which converges for small t on finite particle vectors because of the estimations of Lemma 3.6 (detailed estimations of the perturbation terms may be done analoguously to Ref. 17).

We calculate $\langle \Omega_{\mathrm{F}} | \exp\{itH\} \Omega_{\mathrm{F}} \rangle$. Equation (3.8) yields $H\Omega_{\mathrm{F}} = \frac{1}{2} a^* D a^* \Omega_{\mathrm{F}} = 2^{-1/2} \Sigma_k d_k e_k \otimes e_k$, from which with Eq. (3.3) we obtain the differential equation

$$
\begin{aligned}
\frac{1}{i} \frac{\mathrm{d}}{\mathrm{d}t} \langle \Omega_{\mathrm{F}} | \exp\{itH\} \Omega_{\mathrm{F}} \rangle &= \langle H\Omega_{\mathrm{F}} | \exp\{itH\} \Omega_{\mathrm{F}} \rangle \\
&= \sum_k \frac{d_k}{\sqrt{2}} \langle e_k \otimes e_k | \exp\{itH\} \Omega_{\mathrm{F}} \rangle \\
&\overset{(3.3)}{=} -\sum_k \frac{d_k}{2} \langle e_k | (T_t)_a ((T_t)_l)^{-1} e_k \rangle \langle \Omega_{\mathrm{F}} | \exp\{itH\} \Omega_{\mathrm{F}} \rangle \\
&= -\tfrac{1}{2} \overline{\mathrm{tr}[D(T_t)_a ((T_t)_l)^{-1}]} \langle \Omega_{\mathrm{F}} | \exp\{itH\} \Omega_{\mathrm{F}} \rangle. \qquad (3.9)
\end{aligned}
$$

Obviously, $\mathrm{d}(T_t)_l/\mathrm{d}t = (\mathrm{d}T_t/\mathrm{d}t)_l = i(C(T_t)_l - D(T_t)_a)$. Hence, putting $M_t := u_{-t}(T_t)_l$ we obtain $iM_t^{-1} \mathrm{d}M_t/\mathrm{d}t = ((T_t)_l)^{-1} D(T_t)_a$ to be of trace class, which with the formula $\det(M_t) = \exp\{\mathrm{tr}[\ln(M_t)]\}$ implies

$$
-2i\sqrt{\det(M_t)} \, \frac{\mathrm{d}(\det(M_t))^{-1/2}}{\mathrm{d}t} = \mathrm{tr}[((T_t)_l)^{-1} D(T_t)_a] = \mathrm{tr}[D(T_t)_a ((T_t)_l)^{-1}].
$$

Comparing with (3.9) yields $\langle \Omega_{\mathrm{F}} | \exp\{itH\} \Omega_{\mathrm{F}} \rangle = \overline{(\det(M_t))^{-1/2}} = (\det((T_t)_l^* u_t))^{-1/2}$. Now observe $T_{-t} = T_t^{-1}$, and hence $(T_t)_l^* = (T_{-t})_l$ by Eq. (2.4). That $(T_{-t})_l u_t - \mathbb{1}$ (resp. $M_t - \mathbb{1}$) are of trace class follows immediately from the perturbation expansion. ■

Theorem 3.8: *For each $t \in \mathbb{R}$ let $T_t \in \mathscr{T}_{\mathrm{F}}(\mathscr{H})$, and let H be a self-adjoint operator on $F_+(\mathscr{H})$ such that* $\exp\{itH\}$ *unitarily implements α_{T_t} with respect to $(\Pi_{\mathrm{F}}, F_+(\mathscr{H}))$ for every $t \in \mathbb{R}$* [cf. *Eq. (3.6)*]. *Then $\{T_t | t \in \mathbb{R}\}$ is a strongly continuous group, and we have the following equivalences*

(i) $\Omega_{\mathrm{F}} \in \mathscr{D}(H)$,

(ii) *there exists a linear operator $C = C^*$ on $\mathscr{H}$ and an antilinear Hilbert–Schmidt operator $D = D^*$ on $\mathscr{H}$ with $T_t = \exp\{it(C-D)\} \forall t \in \mathbb{R}$* (cf. *Theorem 2.10*).

If (i) and (ii) are fulfilled, then the (linear, resp. *antilinear) self-adjoint operators C and D are uniquely given, and it is $H = \frac{1}{2}(a_{\mathrm{F}}^* D a_{\mathrm{F}}^* + a_{\mathrm{F}} D a_{\mathrm{F}}) + a_{\mathrm{F}}^* C a_{\mathrm{F}} + \kappa \mathbb{1}$ for $a \kappa \in \mathbb{R}$.*

Proof: That $\{T_t | t \in \mathbb{R}\}$ forms a group is immediate. Let us check its strong continuity: With the Weyl relations (3.1) and (3.2) we obtain for each $f \in \mathscr{H}$

$$1=\lim_{t\to 0}|\langle W_{\mathrm{F}}(f\,)\Omega_{\mathrm{F}}|\exp\{itH\}W_{\mathrm{F}}(f\,)\exp\{-itH\}\Omega_{\mathrm{F}}\rangle|\overset{(3.6)}{=}\lim_{t\to 0}|\langle W_{\mathrm{F}}(f\,)\Omega_{\mathrm{F}}|W_{\mathrm{F}}(T_t f\,)\Omega_{\mathrm{F}}\rangle|$$

$$\overset{(3.1)}{=}\lim_{t\to 0}|\langle\Omega_{\mathrm{F}}|W_{\mathrm{F}}(T_t f-f\,)\Omega_{\mathrm{F}}\rangle|\overset{(3.2)}{=}\lim_{t\to 0}\exp\{-\tfrac{1}{4}\|T_t f-f\|^2\}.$$

Hence there exists the generator $G, T_t=\exp\{tG\}$, a closed real-linear operator on $\mathscr{H}$ with dense real-linear domain $\mathscr{D}(G)$.

Because of Theorem 3.7 and since the U_{T_t} are unique up to a phase by Theorem 3.1, it suffices to prove (i)⇒(ii). Let $H':=H-\langle\Omega_{\mathrm{F}}|H\Omega_{\mathrm{F}}\rangle\mathbb{1}$. Then Eq. (3.5) gives for each $g\in\mathscr{H}$ and all $t\in\mathbb{R}$

$$\langle W_{\mathrm{F}}(g)\Omega_{\mathrm{F}}|\exp\{itH'\}\Omega_{\mathrm{F}}\rangle=\langle\Omega_{\mathrm{F}}|\exp\{itH'\}\Omega_{\mathrm{F}}\rangle\exp\{\tfrac{1}{4}(\langle g|(T_t)_a((T_t)_l)^{-1}g\rangle-\|g\|^2)\}. \tag{3.10}$$

Since $\Omega_{\mathrm{F}}\in\mathscr{D}(H')$ we may differentiate $d/dt\cdots|_{t=0}$, and it follows that

$$\frac{d}{dt}\langle g|(T_t)_a((T_t)_l)^{-1}g\rangle\bigg|_{t=0}=\frac{d}{dt}\langle g|T_t((T_t)_l)^{-1}g\rangle\bigg|_{t=0}=:q(g)$$

exists for all $g\in\mathscr{H}$. But $q(g)=\langle g|Gg\rangle\forall g\in\mathscr{D}(G)$. We define the (complex-) bi-antilinear form $d(f,g):=\frac{1}{4}(q(f+g)-q(f-g))$ with $\mathscr{D}(d)=\mathscr{H}$, which satisfies $d(f,g)=d(g,f\,)\forall f,\ g\in\mathscr{H}$. Hence (3.10) implies $\langle W_{\mathrm{F}}(g)\Omega_{\mathrm{F}}|H'\Omega_{\mathrm{F}}\rangle=\frac{1}{4}d(g,g)\exp\{-\frac{1}{4}\|g\|^2\}\forall g\in\mathscr{H}$. Now let $\mathscr{V}$ be an arbitrary finite-dimensional complex subspace $\mathscr{V}\subseteq\mathscr{H}$ with ONB $\{e_1,\ldots,e_m\}$, where $m:=\dim_{\mathbb{C}}\mathscr{V}$. Then Proposition A3 and Lemma A2 from the Appendix yield

$$\|\Gamma(P_{\mathscr{V}})H'\Omega_{\mathrm{F}}\|^2=\frac{1}{2}\sum_{k,l=1}^{m}|d(e_k,e_l)|^2=\frac{1}{2}\|D_{\mathscr{V}}\|_{\mathsf{HS}}^2\geqslant\frac{1}{2}\|D_{\mathscr{V}}\|^2, \tag{3.11}$$

where $D_{\mathscr{V}}=D_{\mathscr{V}}^*$ is the antilinear operator on $\mathscr{V}$ with $d(f,g)=\langle f|D_{\mathscr{V}}g\rangle\forall f,\ g\in\mathscr{V}$. Consequently $|d(f,g)|\leqslant\sqrt{2}\|H'\Omega_{\mathrm{F}}\|\,\|f\|\,\|g\|\forall f,\ g\in\mathscr{H}$, and the form d is bounded, which implies the existence of an antilinear bounded $D=D^*$ on $\mathscr{H}$ with $d(f,g)=\langle f|-iDg\rangle\forall f,\ g\in\mathscr{H}$. Equation (3.11) finally gives $\||D|\|_{\mathsf{HS}}=\sqrt{2}\|H'\Omega_{\mathrm{F}}\|$, i.e., $|D|$ is Hilbert–Schmidt.

Now consider $\mathscr{H}$ as a real Hilbert space with scalar product $(.|.):=\mathrm{Re}\langle.|.\rangle$. Since $d(g,g)=q(g)=\langle g|Gg\rangle\forall g\in\mathscr{D}(G)$, we have that $\mathrm{Re}(d(f,g))$ is a real-bilinear form on $\mathscr{H}$ with

$$(f|-iDg)=(-iDf|g)=\mathrm{Re}(d(f,g))=\tfrac{1}{2}((f|Gg)+(Gf|g))\quad\forall f,g\in\mathscr{D}(G),$$

which for $\Lambda:=G+iD$ implies $0=(f|\Lambda g)+(\Lambda f|g)$. Hence $\Lambda=-\Lambda^+$ by Lemma A1, where Λ^+ is the adjoint of Λ with respect to the real scalar product $(.|.)$. Then, as in the proof of Theorem 2.10, it follows: $C:=-i\Lambda$ is complex-linear and self-adjoint with respect to the complex scalar product $\langle.|.\rangle$, i.e., $C=C^*$. ■

Corollary 3.9: Let $\{T_t|t\in\mathbb{R}\}\subset\mathscr{T}_{\mathrm{F}}(\mathscr{H})$ *be a strongly continuous group. Assume the existence of a* $T\in\mathscr{T}_{\mathrm{F}}(\mathscr{H})$ *such that* $T^{-1}T_tT=\exp\{it(C-D)\}\ \forall t\in\mathbb{R}$ *for some linear* $C=C^*$ *and* $D\in\mathsf{HS}_a^{sa}(\mathscr{H})$ (*or, equivalently* $T^{-1}GT=i(C-D)$ *for the generator* G *of* $T_t=\exp\{tG\}$). *Then* $\exp\{itH\}$ *unitarily implements* α_{T_t} *with respect to* Π_{F} *for every* $t\in\mathbb{R}$ [*cf. Eq. (3.6)*], *where* $H=U_T[\frac{1}{2}(a_{\mathrm{F}}^*Da_{\mathrm{F}}^*+a_{\mathrm{F}}Da_{\mathrm{F}})+a_{\mathrm{F}}^*Ca_{\mathrm{F}}]U_T^*$.

For $C=0$ the situation is somewhat simpler, which is shown by the following

Corollary 3.10: Let $D=D^*$ *be antilinear and bounded on* $\mathscr{H}$, *and* J *the antilinear involution from Lemma 2.12. Then*

$$T_t:=\exp\{-itD\}=\cosh(t|D|)-iJ\,\sinh(t|D|)\in\mathscr{T}(\mathscr{H})$$

for all $t\in\mathbb{R}$ (cf. *Example 2.13). Moreover, we have the following equivalences:*

(i) $|D|$ *is a Hilbert–Schmidt operator on* $\mathscr{H}$,

(ii) $T_t \in \mathscr{T}_{\mathrm{F}}(\mathscr{H})$ *for some real* $t \neq 0$,
(iii) $T_t \in \mathscr{T}_{\mathrm{F}}(\mathscr{H})$ *for all* $t \in \mathbb{R}$,
(iv) *there exists a unitary* U_{T_t} on $F_+(\mathscr{H})$, *which unitarily implements* α_{T_t} *with respect to* Π_{F} *for some real* $t \neq 0$.

If these conditions are valid, then U_{T_t} *from (iv) is uniquely (up to a phase) given by* $U_{T_t} = \exp\{itH\}$ with $H = \frac{1}{2}(a_{\mathrm{F}}^* D a_{\mathrm{F}}^* + a_{\mathrm{F}} D a_{\mathrm{F}})$.

Proof: The decomposition of T_t follows from the exponential series. Because of Theorems 3.7 and 3.8 it remains to prove and (iv)⇒(ii)⇒(i). However, V_t implementing α_{T_t} with respect to Π_{F} implies $T_t \in \mathscr{T}_{\mathrm{F}}(\mathscr{H})$ by definition. Theorem 3.1 yields $\sinh(t|D|)$ to be Hilbert–Schmidt for a $t \neq 0$. Thus there exists an ONB $\{e_k | k \in I\}$ for $\mathscr{H}$ consisting of eigenvectors for $|D|$, $|D| e_k = d_k e_k, d_k \geqslant 0$, satisfying

$$\infty > \sum_{n=1}^{\infty} \sinh(t d_k)^2 = \frac{1}{2} \sum_{n=1}^{\infty} (\cosh(2t d_k) - 1) \geqslant t^2 \sum_{n=1}^{\infty} d_k^2,$$

which gives (i). The rest follows from Theorems 3.1 and 3.7. ■

Let us continue Example 2.11.

Example 3.11: Let all be as in Example 2.11. In addition assume R to be Hilbert–Schmidt and $T \in \mathscr{T}_{\mathrm{F}}(\mathscr{H})$. *Then, by Theorem 3.1 the latter is equivalent with* $\sinh(R)$ *being Hilbert–Schmidt on* $\mathscr{H}$, *and Theorem 3.7 implies* $T_t \in \mathscr{T}_{\mathrm{F}}(\mathscr{H}) \forall t \in \mathbb{R}$. *Since* $\mathscr{T}_{\mathrm{F}}(\mathscr{H})$ *is a group, we have* $T_t \in \mathscr{T}_{\mathrm{F}}(\mathscr{H}) \forall t \in \mathbb{R}$.

Even in this case C may be chosen such that $\hat{S}$ *is unbounded. For example, define C by* $c_k := k/\sinh(r_k) \forall k \in \mathbb{R}$. *Then (2.6) yields* $\hat{S}$ *to be unbounded.*

APPENDIX

1. On generators of groups on real Hilbert spaces

For the proof of Theorem 2.10 we need some group theoretical results on real Hilbert spaces. Here in the first part of the Appendix we exclusively are concerned with a real Hilbert space $\mathscr{H}_r$ with scalar product $(.|.)$, and with real-linear operators having real-linear domains. The adjoint of the (real-linear) operator A on $\mathscr{H}_r$ is denoted by A^+. Let us mention that each weakly continuous (semi-) group on $\mathscr{H}_r$ is strongly continuous and its weak and strong generators coincide (Ref. 12, Corollary 3.1.8).

Lemma A1: Let $\{T_t | t \in \mathbb{R}\}$ *be a strongly continuous group on* $\mathscr{H}_r$ *with generator G*, i.e., $T_t = \exp\{tG\}$, $t \in \mathbb{R}$, *and growth* $\|T_t\| \leqslant \exp\{\beta|t|\} \forall t \in \mathbb{R}$ for some $\beta \geqslant 0$. *It follows* $\mathscr{D}(G) = \mathscr{D}(G^+)$, G^+ *is the generator of the adjoint group* $\{T_t^+ | t \in \mathbb{R}\}$, and G *decomposes uniquely as* $G = \Lambda + D$ *with the closed operator* $\Lambda = -\Lambda^+$ *and the bounded operator* $D = D^+$. *Especially,* $D \supseteq \frac{1}{2}(G + G^+)$ *and* $\Lambda = \frac{1}{2}(G - G^+)$.

Proof: G is closed with dense domain $\mathscr{D}(G)$ (Ref. 12, Theorem 3.1.22). Hence $\{T_{\pm t} \exp\{-\beta t\} | t \geqslant 0\}$ defines two semigroups of contractions. Differentiating $\|T_{\pm t} \exp\{-\beta t\} f\|^2 \leqslant \|f\|^2$ for $t \geqslant 0$ yields

$$0 \geqslant \frac{\mathrm{d}}{\mathrm{d}t} \| T_{\pm t} \exp\{-\beta t\} f \|^2 \Big|_{t=0} = 2(f | (\pm G - \beta) f) \quad \forall f \in \mathscr{D}(G),$$

which gives $-\beta \|f\|^2 \leqslant (f|Gf) \leqslant \beta \|f\|^2 \forall f \in \mathscr{D}(G)$. Let us define on $\mathscr{D}(G)$ the symmetric (real)-bilinear form $s(f,g) = \frac{1}{2}((f|Gg) + (Gf|g))$. Then $-\beta \|f\|^2 \leqslant s(f,f) \leqslant \beta \|f\|^2 \forall f \in \mathscr{D}(G)$ implies the boundedness of s (which we extend to all of $\mathscr{H}_r$) and the existence of a bounded operator $D = D^+$ on $\mathscr{H}_r$ with $s(f,g) = (f|Dg) \forall f,g \in \mathscr{H}_r$ (Ref. 9, Theorem VIII.15). Let $\Lambda := G - D$. Then

$$0 = \tfrac{1}{2}((f|Gg) + (Gf|g)) - (f|Dg) = \tfrac{1}{2}((f|\Lambda g) + (\Lambda f|g))$$

from which follows $\Lambda \subseteq -\Lambda^+$.

On the other side the adjoint group is weakly (and hence strongly) continuous with generator G^+. Now $G^+=\Lambda^+ + D$ and the same procedure as above yield $\Lambda^+ \subseteq -\Lambda^{++}$. But G is closed, and thus Λ is so, which gives $\Lambda^{++}=\Lambda$ (Ref. 11, Theorem 5.3). Uniqueness follows from $D \supseteq \frac{1}{2}(G+G^+)$ and $\Lambda=\frac{1}{2}(G-G^+)$. ■

2. Second quantized projections

Here we prove some results, which we need for Lemma 3.4 and Theorem 3.7. On $\mathbb{C}^m \cong \mathbb{R}^{2m}$ we denote by $d^{2m}\alpha$ the Lebesgue measure $\mathrm{dRe}(\alpha_1)\,\mathrm{dIm}(\alpha_1)\cdots\mathrm{dRe}(\alpha_m)\,\mathrm{dIm}(\alpha_m)$ for $\alpha=(\alpha_1,...,\alpha_m)\in\mathbb{C}^m$.

Lemma A2: For $m\in\mathbb{N}$ let $E:\mathbb{C}^m\to\mathbb{C}$, $\alpha\mapsto\exp\{-\frac{1}{2}\Sigma_{k=1}^m|\alpha_k|^2\}$. Then for every $p_k, q_k \in \mathbb{N}\cup\{0\}$ we have

$$\int_{\mathbb{R}^{2m}} E(\alpha)\overline{\alpha_1}^{p_1}\cdots\overline{\alpha_m}^{p_m}\alpha_1^{q_1}\cdots\alpha_m^{q_m}\,\mathrm{d}^{2m}\alpha=(\delta_{p_1,q_1}\cdots\delta_{p_m,q_m})(2\pi)^m(2^{p_1}(p_1!)\cdots 2^{p_m}(p_m!))$$

where $\delta_{k,l}=0$ for $k\neq l$ and $\delta_{k,l}=1$ for $k=1$.

Proof: We have $\overline{\alpha_k}E(\alpha) = -2(\partial E/\partial\alpha_k)(\alpha)$ and $\alpha_k E(\alpha) = -2(\partial E/\partial\overline{\alpha_k})(\alpha)$. Now use integration by parts, $\int(\partial E/\partial\alpha_k)F\,\mathrm{d}^{2m}\alpha=-\int E(\partial F/\partial\alpha_k)\mathrm{d}^{2m}\alpha$ and $\int(\partial E/\partial\overline{\alpha_k})F\,\mathrm{d}^{2m}\alpha = -\int E(\partial F/\partial\alpha_k)\mathrm{d}^{2m}\alpha$. ■

From now on we are exclusively concerned with complex-linear spaces and operators. Let $\mathscr{H}$ be a Hilbert space. On the Fock space $F_+(\mathscr{H})=\oplus_{n=0}^\infty \mathbb{P}_+(\otimes_n\mathscr{H})$ the Glauber vectors are given as $\mathscr{G}(h)=W_F(-i\sqrt{2}h)\Omega_\mathrm{F}$, $h\in\mathscr{H}$ (cf., e.g., Ref. 18, Section 8.1), where

$$W_\mathrm{F}(g)\Omega_\mathrm{F}=\exp\{-\tfrac{1}{4}\|g\|^2\}\left[\bigoplus_{n=0}^{\infty}\left(\frac{i}{\sqrt{2}}\right)^n\frac{1}{\sqrt{n!}}(\otimes_n g)\right],\quad g\in\mathscr{H}. \tag{A1}$$

For a subspace $\mathscr{V}$ of $\mathscr{H}$ with associated orthogonal projection $P_\mathscr{V}$ from $\mathscr{H}$ onto $\mathscr{V}$ let $\Gamma(P_\mathscr{V}):=\oplus_{n=0}^\infty(\otimes_n P_\mathscr{V})$ (second quantization, cf. Ref. 12, Subsection 5.2.1, or Ref. 9, Section X.7), which is an orthogonal projection in $F_+(\mathscr{H})$. As a consequence of Lemma A2 we obtain:

Proposition A3: Let $\mathscr{V}$ be an m-dimensional subspace of $\mathscr{H}$ with arbitrary ONB *$\{e_k|k=1,\ldots,m\}$, $m\in\mathbb{N}$. Then for each $\psi\in F_+(\mathscr{H})$ we have*

$$\|\Gamma(P_\mathscr{V})\psi\|^2=\frac{1}{(2\pi)^m}\int_{\mathbb{R}^{2m}}|\langle W_\mathrm{F}\left(\sum_{k=1}^m\alpha_k e_k\right)\Omega_\mathrm{F}|\psi\rangle|^2\,\mathrm{d}^{2m}\alpha. \tag{A2}$$

Proof: Let $\psi=\oplus_{n=0}^\infty\psi_n$ with $\psi_n\in\mathbb{P}_+(\oplus_n\mathscr{H})$. Then

$$\left\langle\otimes_n\left(\sum_{k=1}^m\alpha_k e_k\right)\middle|\psi_n\right\rangle=\sum_{\text{a.p.:}n_1,\ldots,n_m}\frac{n!}{n_1!\cdots n_m!}\,\alpha_1^{n_1}\cdots\alpha_m^{n_m}\langle\mathbb{P}_+(e_1\otimes\cdots e_m)|\psi_n\rangle,$$

where $\Sigma_{\text{a.p.:}n_1,\ldots,n_m}$ runs over all possibilities for $n_k\in\{0,\ldots,n\}$ with $\Sigma_{k=1}^m n_k=n$ and e_k appears n_k times in $\langle\mathbb{P}_+(e_1\otimes\cdots e_m)|\psi_n\rangle\equiv\langle n_1,\ldots,n_m|\psi_n\rangle$. Now for $M\in\mathbb{N}$ let

$$G_M(\alpha):=\sqrt{E(\alpha)}\sum_{n=0}^M\left(\frac{-i}{\sqrt{2}}\right)^n\frac{1}{\sqrt{n!}}\sum_{\text{a.p.:}n_1,\ldots,n_m}\frac{n!}{n_1!\cdots n_m!}\,\alpha_1^{n_1}\cdots\alpha_m^{n_m}\langle n_1,\ldots,n_m|\psi_n\rangle,$$

for which $\lim_{M\to\infty}G_M(\alpha)=\langle W_F(\Sigma_{k=1}^m\alpha_k e_k)\Omega_\mathrm{F}|\psi\rangle\forall\alpha\in\mathbb{C}^m$ by Eq. (A1). Now remember that $\{\sqrt{n!/n_1!\ldots n_m!}|n_1,\ldots,n_m\rangle|\Sigma_{k=1}^m n_k=n\}$ forms an ONB for $\mathbb{P}_+(\otimes_n\mathscr{H})$, and use Lemma A2 to deduce

$$\int_{\mathbb{R}^{2m}}|G_M(\alpha)|^2\,\mathrm{d}^{2m}\alpha=(2\pi)^m\sum_{n=0}^M\|\Gamma(P_\mathscr{V})\psi_n\|^2,$$

which implies that $\lim_M\int\cdots=\int\lim_M\cdots$. ■

Consider the linear space $\mathscr{M}$ of mappings $\Theta:\mathscr{H}\to\mathbb{C}$, $f\mapsto\Theta(f)$, for which for each finite-dimensional subspace $\mathscr{V}\subseteq\mathscr{H}$ the functions $\alpha\in\mathbb{C}^m\cong\mathbb{R}^{2m}\mapsto\Theta(\Sigma_{k=1}^m\alpha_k e_k)$ are measurable, where $\{e_k|k=1,\ldots,m\}$ is an ONB of $\mathscr{V}$. Obviously, $\int_{\mathbb{R}^{2m}}\Theta(\Sigma_{k=1}^m\alpha_k e_k)\mathrm{d}^{2m}\alpha$ does not depend on the ONB of $\mathscr{V}$, and thus one puts $[1/(2\pi)^m]\mathrm{d}^{2m}\alpha\equiv\mathrm{d}\mu_{\mathscr{V}}(f)$. If $\mathscr{S}$ is the collections of all finite-dimensional subspaces of $\mathscr{H}$ ordered by inclusion, one constructs the *continual integral* Hilbert space $\mathscr{K}_c(\mathscr{H})$ to consist of those $\Theta\in\mathscr{M}$ for which $\lim_{\mathscr{V}\in\mathscr{S}}\int_{\mathscr{V}}|\Theta(f)|^2\,d\mu_{\mathscr{V}}(f)<\infty$. Since $\lim_{\mathscr{V}\in\mathscr{S}}\|\Gamma(P_{\mathscr{V}})\psi\|=\|\psi\|\forall\psi\in F_+(\mathscr{H})$, from Eq. (A2) follows that $F_+(\mathscr{H})$ and $\mathscr{K}_c(\mathscr{H})$ are unitarily equivalent in the sense that $\psi\in F_+(\mathscr{H})$ corresponds to the functional $f\in\mathscr{H}\mapsto\langle W_{\mathrm{F}}(f)\Omega_{\mathrm{F}}|\psi\rangle$ in $\mathscr{K}_c(\mathscr{H})$ (cf., e.g., Ref. 7).

[2] In the smeared field formalism the creation and annihilation operators ''smeared'' by the ''test function'' $f\in\mathscr{H}$ are given as $a^*(f)=\Sigma_{n=1}^N\langle e_n|f\rangle a^*(e_n)$ resp. $a(f)=\Sigma_{n=1}^N\overline{\langle e_n|f\rangle}a(e_n)$, where $f=\Sigma_{n=1}^N\langle e_n|f\rangle e_n$ decomposes according to the orthonormal base $\{e_1,\ldots,e_N\}$ of the complex one-particle (test function) Hilbert space $\mathscr{H}$ with right-linear scalar product $\langle.|.\rangle$. Here $a(f)$ and $a^*(f)$ are adjoint to each other. The mapping $f\in\mathscr{H}\mapsto a^*(f)$ is complex-linear, $f\in\mathscr{H}\mapsto a(f)$ is complex-antilinear, and the canonical commutation relations (CCR) with the commutator $[A,B]=AB-BA$ written as

$$[a(f),a(g)]=[a^*(f),a^*(g)]=0,\quad [a(f),a^*(g)]=\langle f|g\rangle\mathbb{1},\quad \forall f,g\in\mathscr{H}.$$

[3] One has $\Sigma_k(\eta_k a^*(e_{s,k})a^*(e_{i,k})+\overline{\eta_k}a(e_{s,k})a(e_{i,k}))$ for the quadratic Hamiltonians associated with nondegenerate squeezing, where the index s stands for the signal modes $e_{s,k}$ and i for the idler modes $e_{i,k}$ (which all are supposed to be mutually orthogonal and normalized, and which generate the one-photon test function Hilbert space $\mathscr{H}$) and $\eta_k\in\mathbb{C}$. The combined orthonormalized modes e_n are chosen as $2^{-1/2}(e_{s,k}\pm e_{i,k})$, and the form (1.1) is obtained from the simple transformations $a^{\#}(f)a^{\#}(g)=4^{-1}(a^{\#}(f+g)^2-a^{\#}(f-g)^2)$ for arbitrary one-photon testfunctions $f,g\in\mathscr{H}$, which is valid for both the smeared creation [i.e., $a^{\#}(h)\equiv a^*(h)$] and annihilation operators [i.e., $a^{\#}(h)\equiv a(h)$ (Ref. 4)].

Path integral solution of the Schrödinger equation in curvilinear coordinates: A straightforward procedure

J. LaChapelle
Department of Physics and Center for Relativity, University of Texas, Austin, Texas 78712

(Received 24 April 1996; accepted for publication 7 June 1996)

A new axiomatic formulation of path integrals is used to construct a path integral solution of the Schrödinger equation in curvilinear coordinates. An important feature of the formalism is that a coordinate transformation in the variables of the wavefunction does not imply a change of variable of integration in the path integral. Consequently, a transformation from Euclidean to curvilinear coordinates is simple to handle; there is no need to introduce ''quantum corrections'' into the action functional. Furthermore, the paths are differentiable: hence, issues related to stochastic paths do not arise. The procedure for constructing the path integral solution of the Schrödinger equation is straightforward. The case of the Schrödinger equation in spherical coordinates for a free particle is presented in detail. © *1996 American Institute of Physics.* [S0022-2488(96)02809-5]

I. INTRODUCTION

The generalization of the Feynman path integral to non-Euclidean coordinates has been a long and sometimes confusing process. Already in 1948, Feynman[1] realized that a naive change of variables in the path integral would not yield the required result. Later, Edwards and Gulyaev,[2] working in configuration space, considered a free particle in polar coordinates and found that the correct Green's function for the associated Schrödinger equation could only be obtained if they kept terms of higher order in the expansion parameter than one would expect. On the other hand, Arthurs,[3] working on phase space, found that higher-order terms were not required as long as a suitable Hamiltonian was used. Peak and Inomata[4] also considered the path integral in polar coordinates (see also Ref. 5). *All of these studies found that extra terms were needed in the action functional to account for the change from Euclidean to polar coordinates.* The extra terms were later interpreted as a consequence of the stochastic nature of the paths used in the integration.

An added source of confusion was the ambiguity in the definition of the time-sliced path integral. The definition does not specify at which point of the time interval one is to evaluate the short-time propagator. Each choice leads to a different result. Eventually, it was realized that this ambiguity was directly related to the operator ordering ambiguity.[6–13]

Despite improved understanding, expressing the solution of a given Schrödinger equation in terms of the conventional definition of a path integral remains a difficult task in general.

An axiomatic formulation of path integrals currently being developed by Cartier and DeWitt-Morette[14] remedies this situation. (Alternative mathematical approaches to formulating the Feynman path integral can be found in the literature.[15–18]) The key to the formulation's *utility* is that it emphasizes the infinite-dimensional space of paths rather than the finite-dimensional manifold where the paths take their values. Moreover, in order that actions be finite, the paths are differentiable—unlike the continuous paths in conventional path integrals. A change of coordinates (on the manifold where the paths take their values) is easy to handle, and a key theorem allows for the construction of a path integral solution for the Schrödinger equation in curvilinear coordinates.

We will show that the construction requires only the transformation from Euclidean to curvilinear coordinates and knowledge of the free part of the action functional. Notably, no ''extra terms'' are needed in the action functional. The procedure is general and simple to use. Of course,

0022-2488/96/37(9)/4310/10/$10.00

the resulting path integral may not always be easy to evaluate. It can be solved exactly for a free particle in d-dimensions, and the three-dimensional spherical coordinate case is worked out in detail. The scope of this paper is confined to curvilinear coordinate systems so only *flat* configuration space will be considered.

II. TWO APPROACHES TO PATH INTEGRALS

In this section we present both the usual derivation of the path integral as a solution of the Schrödinger equation and the new axiomatic formulation of Cartier/DeWitt-Morette. Although the first derivation is thoroughly familiar to most physicists, we present a brief review: it is important to have the salient features in mind in order to better appreciate how the Cartier/DeWitt-Morette formalism handles the Schrödinger equation in curvilinear coordinates. The purpose of this section is not to give a thorough comparison between the formalisms but to point out two particularly relevant issues related to a change of coordinates on a flat configuration space.

A. The ''time-slicing'' method

The conventional definition of a path integral as the matrix elements of the evolution operator in quantum mechanics employs two principal ideas. First, the Trotter–Kato–Nelson product formula is used to represent the evolution operator, $\hat{U}(t_f,t_i):=\exp[-i(t_f-t_i)\hat{H}(q,p)]$ $=\exp[-i(t_f-t_i)\{\hat{T}(p)+\hat{V}(q)\}]$, in the form

$$\begin{aligned}\exp[-i(t_f-t_i)\hat{H}(q,p)/\hbar]&=(\exp[-i(t_f-t_i)\hat{H}(q,p)/N\hbar])^N\\&=\lim_{N\to\infty}(\exp[-i(t_f-t_i)\hat{T}(p)/N\hbar]\\&\quad\times\exp[-i(t_f-t_i)\hat{V}(q)/N\hbar])^N.\end{aligned}\tag{1}$$

Here (q,p) is a point in the phase space of the associated classical system, which we take to be the cotangent bundle T^*M of the d-dimensional configuration space M. We assume M is equipped with a metric g. More general Hamiltonians can be considered which will raise the issue of operator ordering.

Essentially, this is a time-slicing technique. That is, the time interval $[t_i,\ t_f]$ is divided into N small pieces $[t_i,\ t_1]\cup\cdots\cup[t_{N-1},\ t_f]$, and the effect of the evolution operator for the full time interval is replaced by the short-time evolution operators over each piece of the divided time interval. In the limit as the number of small intervals goes to infinity and their length goes to zero, the last line of Eq. (1) becomes exact.

The second step is to insert the mixed representation identity operator

$$\mathbf{1}=\int_{T^*M}\frac{dqdp}{2\pi\hbar}\,|q\rangle\langle q\|p\rangle\langle p|\tag{2}$$

a total of N times between each term in the product in the last line of Eq. (1). We remark that $dqd\tilde{p}:=dqdp/2\pi\hbar$ is the Liouville measure in the associated phase space.

In the coordinate basis, the final state $|q_f\rangle:=\hat{U}(t_f,t_i)|q_i\rangle$ can thus be represented as

$$\begin{aligned}|q_f\rangle=e^{[-i(t_f-t_i)\hat{H}(q,p)/\hbar]}|q_i\rangle&=\lim_{N\to\infty}(e^{[-i(t_f-t_i)\hat{T}(p)/N\hbar]}e^{[-i(t_f-t_i)\hat{V}(q)/N\hbar]})^N|q_i\rangle\\&=\lim_{N\to\infty}\prod_{n=1}^{N}\int_{T^*M}dq_nd\tilde{p}_n\,e^{[ip_n(q_n-q_{n-1})/\hbar]}\\&\quad\times e^{[-i(t_f-t_i)\{T(p_n)+V(q_{n-1})\}/N\hbar]}|q_N\rangle,\end{aligned}\tag{3}$$

where $q_n := q(\overline{t_n})$ and $p_n := p(\overline{t_n})$ for some $\overline{t_n} \in [t_n, t_{n+1}]$. If the q_n and p_n are interpreted as particular values of position and momentum along some trajectory in phase space, then Eq. (3) can be interpreted as an integral over all paths in phase space such that $q_0 = q_i$. Notice that we must integrate over all values of q_N so that Eq. (3) is an integration over paths with only one endpoint fixed.

From Eq. (3), the matrix elements of the evolution operator, $\langle q_f|\hat{U}(t_f,t_i)|q_i\rangle$, are given by

$$\langle q(t_f)|q(t_i)\rangle := \langle q_f|\hat{U}(t_f,t_i)|q_i\rangle = \langle q_f|e^{[-i(t_f-t_i)\hat{H}(q,p)/\hbar]}|q_i\rangle$$

$$= \lim_{N\to\infty} \prod_{n=1}^{N} \int_{T^*M} dq_n d\tilde{p}_n \delta(q_f - q_N)$$

$$\times e^{[ip_n(q_n-q_{n-1})/\hbar]} e^{[i(t_f-t_i)\{T(p_n)+V(q_{n-1})\}/N\hbar]}, \tag{4}$$

where we have used $\langle q_f|q_N\rangle = \delta(q_f - q_N)$. We emphasize that the integration is over paths with only one fixed endpoint—the other endpoint being fixed by the delta function.

For the special case of a flat configuration space, Eq. (4) is often written schematically as

$$\langle q(t_f)|q(t_i)\rangle = \int \mathscr{D}q\mathscr{D}p\, \delta(q_f - q_N) \exp\left(\frac{i}{\hbar}\int_{t_i}^{t_f} \{\mathbf{p}\cdot\dot{\mathbf{q}} - H(q,p)\}dt\right), \tag{5}$$

where the domain of integration is understood to be the space of paths which take their values in phase space and which have one fixed endpoint, i.e., $q_0 = q_i$. [It should be kept in mind that Eq. (5) is only a shorthand notation for Eq. (4).[19]]

Finally, if the Hamiltonian is quadratic in the momentum, the integration over momentum variables in Eq. (4) can be done explicitly, resulting in the usual configuration space path integral.

There are two important points to be made concerning this construction of the path integral. Both points are direct consequences of the use of the Trotter–Kato–Nelson product formula and the resolution of the identity operator.

The first point is that time-slicing introduces an ambiguity associated with the choice of $\overline{t_n}$. Should $\overline{t_n}$ be taken to be the beginning of the time interval, somewhere between, the end, or a combination of points? In fact, the ambiguity in the choice of $\overline{t_n}$ is related to the operator ordering problem; each choice of $\overline{t_n}$ corresponds to a different Hamiltonian operator (see, for example, Refs. 6–13).[20–22]

The second point is that the use of the resolution of the identity operator introduces an explicit choice of representation and, hence, an explicit choice of coordinates on phase space. Indeed, the whole time-sliced path integral game is played with particular values of paths *in phase space*. Changing coordinates on the phase space manifold changes the expression in Eq. (3). Exactly how to change the expression under a change of coordinates is not as straightforward as one might expect. In general, an extra ''quantum potential'' term must be added to the action functional to obtain the correct result. The extra term can be attributed to the stochastic nature of the time-sliced paths.

B. The new formalism

We will now contrast the time-slicing method with the Cartier/DeWitt-Morette formalism. In particular, we will see how the two points above do not become an issue. Only a general sketch of the relevant ideas is presented, and we will confine ourselves to paths which take their values in configuration space. More complete details can be found elsewhere.[14,23]

The new method is fundamentally different from the time-slicing technique. The underlying theme is an *emphasis on an infinite-dimensional space* of paths and a *shift away from the finite-*

dimensional manifold where the paths take their values. This allows for a solid mathematical formalism which, we believe, is advantageous despite the inherent complexity of working with the infinite-dimensional function (path) space.

1. Definition of the path integral

The generic path integral requires three well-defined components for its construction: (1) a domain of integration which is an infinite-dimensional function space, (2) an integrator defined on the domain of integration, and (3) an integrand or integrable functional. Given these three ingredients, a value can be assigned to the path integral.

The **domain of integration** $\boldsymbol{X}$ is a real, separable Banach space and $x \in \boldsymbol{X}$ are taken to be $L^{2,1}$ functions.[24] We denote the dual space of $\boldsymbol{X}$ by $\boldsymbol{X}'$ and the duality by $\langle x', x\rangle_{\boldsymbol{X}}$ where $x' \in \boldsymbol{X}'$.

Assume there exists a continuous, symmetric, nondegenerate linear map $D:\boldsymbol{X}\to\boldsymbol{X}'$ and denote its inverse by the map $G:\boldsymbol{X}'\to\boldsymbol{X}$. Then a quadratic form on $\boldsymbol{X}$ is defined by $Q(x)=\langle Dx, x\rangle_{\boldsymbol{X}}$, and a quadratic form on $\boldsymbol{X}'$ is defined by $W(x')=\langle x', Gx'\rangle_{\boldsymbol{X}}$. An **integrator** $\mathscr{D}_{Q,W}x$ for a path integral can be defined by the relation

$$\int_{\boldsymbol{X}} e^{\{\pi i Q(x) - 2\pi i \langle x', x\rangle_{\boldsymbol{X}}\}} \mathscr{D}_{Q,W}x = e^{\{-\pi i W(x')\}}. \tag{6}$$

We emphasize that the integrator is defined *implicitly* in terms of Q and W by Eq. (6). (More exotic integrators can be defined, but we choose the familiar example of a Gaussian integrator for illustration purposes.)

Now, since $\boldsymbol{X}'$ is separable and complete, it is possible to define complex Borel measures μ on $\boldsymbol{X}'$. This allows one to relate a class of **integrable functionals** Φ_Q to the fiducial integrand $\exp\{\pi i Q(x)\}$ by the relation

$$F_\mu(x) = \int_{\boldsymbol{X}'} e^{\{\pi i Q(x) - 2\pi i \langle x', x\rangle_{\boldsymbol{X}}\}} d\mu(x'), \tag{7}$$

where $F_\mu \in \Phi_Q$.

This construction implies the functional integral satisfies

$$\int_X F_\mu(x) \mathscr{D}_{Q,W}x = \int_{\boldsymbol{X}'} e^{\{-\pi i W(x')\}} d\mu(x'). \tag{8}$$

The right-hand side of Eq. (8) should not be construed as a means to evaluate the left-hand side. Indeed, the measure μ associated with a given $F_\mu \in \Phi_Q$ is not usually known. Equation (8) is a consequence of relations (6) and (7) and is useful for determining when the integral exists or for proving general theorems—neither of which requires the specific form of μ.

2. Parametrizing the space of paths

We need to say a few things about the domain of integration. For quantum mechanical applications, one is usually interested in a path integral over all paths $x:\mathrm{T}\to N$ where $\mathrm{T}=[t_i, t_f]\subset\mathbb{R}$ and N is an n-dimensional manifold. However, in general, the space of paths which take their values in a manifold N will not be a Banach space $\boldsymbol{X}$. For suppose that we are interested in all paths which have the same fixed endpoints at $t=t_i$. Then $x_1+x_2\in\boldsymbol{X}$ if and only if $x(t_i)=0 \forall x\in\boldsymbol{X}$. This follows because $(x_1+x_2)(t_i)=x_1(t_i)+x_2(t_i)$ for vanishing endpoints only. So the space of paths with nonvanishing fixed endpoints is not a vector space and, therefore, is not a Banach space.

However, if we restrict attention to the space of paths which have only one endpoint fixed in N (that is, a space of pointed paths), then the space of such paths is contractible. Consequently, it

can be parametrized by a space of pointed paths which take their values in a flat manifold $\mathbb{R}^n$ and have their fixed endpoint at the origin of $\mathbb{R}^n$. But, this parameter space of paths *is* a Banach space. Hence, *integration on a space of pointed paths can be defined in terms of integration on the parameter space*.[14]

The situation is analogous to integration on finite-dimensional manifolds. There one does not know how to integrate on a general manifold. Instead, one defines the integral by parametrizing points in the general manifold by points in flat manifolds where one knows how to integrate. For functional integrals, we do not know how to integrate over a general function space so we parametrize it with a Banach space where the rules of functional integration are established.

The details of the parametrization for our particular case follow. Let there be r linearly independent vector fields which generate a vector subspace $R_m \subseteq T_m M$ at each $m \in M$, and denote them by $\boldsymbol{X}_{(\alpha)}$ where $\alpha \in \{1,...,r\}$. Let $\mathscr{P}_f^R M$ denote the space of pointed $L^{2,1}$ paths with fixed *final* point $x(t_f) = m_f \in M \forall x \in \mathscr{P}_f^R M$ and such that $\dot{\mathbf{x}}(t) \in R_{x(t)}$. Denote by $\mathscr{P}_0 \mathbb{R}^d =: \boldsymbol{Z}_i$ the space of $L^{2,1}$ paths with fixed *initial* point $z(t_i) = 0 \in \mathbb{R}^d \ \forall z \in \boldsymbol{Z}_i$.[25]

Since the paths in $\mathscr{P}_f^R M$ are $L^{2,1}$ and since the set $\{\boldsymbol{X}_{(\alpha)}(x(t))\}$ spans $R_{x(t)}$, it follows that there exist functions $\dot{z}^\alpha(t)$ such that

$$\dot{\mathbf{x}}(t) = \boldsymbol{X}_{(\alpha)}(x(t))\dot{z}^\alpha(t), \quad x(t_f) = m_f. \tag{9}$$

This differential equation associates a path $z \in \boldsymbol{Z}_i$ with each path $x \in \mathscr{P}_f^R M$. If the map $x \mapsto z$ can be inverted, then, given some $z \in \boldsymbol{Z}_i$, Eq. (9) has a unique solution $x \in \mathscr{P}_f^R M$. Denote this solution by $x(t,z) = m_f \cdot \boldsymbol{\Sigma}(t,z)$ where $\Sigma(t,z): M \to M$ is a global transformation on M such that $x(t_i,z) = m_f \cdot \boldsymbol{\Sigma}(t_i,z) = m_f$.

We now have a parametrization $P: \boldsymbol{Z}_i \to \mathscr{P}_f^R M$ by the solution of Eq. (9). That is, we have parametrized the space of pointed paths $\mathscr{P}_f^R M$ by the space of paths $\boldsymbol{Z}_i$. Since we know how to do a functional integral on $\boldsymbol{Z}_i$, we simply define

$$\int_{\mathscr{P}_f^R M} F(x) \mathscr{D}x := \int_{\boldsymbol{Z}_i} F(x(z)) \mathscr{D}_{Q,W} z, \tag{10}$$

where $\mathscr{D}_{Q,W} z$ is characterized by Eq. (6) with $\boldsymbol{X} = \boldsymbol{Z}_i$. Of course, for this definition to be useful, the right-hand side must be independent of the parametrization used. That is, we must get the same answer if we use the parametrization $\widetilde{P}: \widetilde{\boldsymbol{Z}}_i \to \mathscr{P}_f^R M$ by $\widetilde{z} \mapsto x$. But, this just means that the functional integral must be invariant under a change of variable of integration.

Inspection of Eq. (9) shows that a change of variable of integration is not directly associated with a change of coordinates on the manifold M. A change of coordinates on M implies a change in the components of the vector fields $\dot{\mathbf{x}}$ and $\boldsymbol{X}_{(\alpha)}$ but there is no change in the coordinates of z: the parametrization changes, but the integration variables do not. The point is that, in contrast to the time-slicing method, a change of coordinates on the manifold M is *not* associated with a change of variable of integration.

3. Key theorem

A key result of Cartier/DeWitt-Morette is that the path integral which has been defined above is the solution of a Schrödinger-type partial differential equation:

Theorem[14]: Let $\mathscr{P}_f^R M$ be the space of $L^{2,1}$ paths with fixed endpoints $x(t_f) = m_f \in M$ whose velocity vectors are elements of $R \subseteq TM$. Parametrize $\mathscr{P}_f^R M$ by $\boldsymbol{Z}_i$. Let $S_0(x)$ be the free action of a particle given by $S_0(x) = \int_T g_{x(t)}(\dot{\mathbf{x}}(t), \dot{\mathbf{x}}(t)) dt$, and let $V: M \to \mathbb{R}$ be a well-behaved scalar potential. Let $\psi: M \to \mathbb{C}^n$ be any integrable $C^\infty(M)$ function with compact support. Then the path integral

$$\Psi(t_f,m_f):=(U_{t_f}\psi)(m_f):=\int_{\mathscr{P}_f^D M}\psi(x)e^{[\pi i S_0(x)+\int_T V(x)dt]}\mathscr{D}x$$

$$=\int_{\mathbf{Z}_i}\psi(x(t_f,z))e^{[\pi i S_0(x(z))+\int_T V(x(t,z))dt]}\mathscr{D}_{Q,W}z$$

$$=\int_{\mathbf{Z}_i}\psi(m_f\cdot\Sigma(t_f,z))e^{[\int_T V(m_f\cdot\Sigma(t,z))dt]}e^{[\pi i Q(z)]}\mathscr{D}_{Q,W}z \tag{11}$$

is a solution of the partial differential equation

$$\frac{\partial\Psi(t_f,m_f)}{\partial t_f}=\left[\frac{i}{4\pi}\,g^{\alpha\beta}\mathscr{L}_{\mathbf{X}_{(\alpha)}}\mathscr{L}_{\mathbf{X}_{(\beta)}}+V\right]\Bigg|_{m_f}\Psi(t_f,m_f),$$

$$\Psi(t_i,m_f)=\psi(m_f). \tag{12}$$

Moreover, the functional operator U_{t_f}, which evolves the function ψ from t_i to t_f, satisfies the group property $U_{t_2}\circ U_{t_1}=U_{t_2+t_1}$.

Here $g^{\alpha\beta}g_{\beta\gamma}=\delta^{\alpha}_{\gamma}$, $\mathscr{L}_{\mathbf{X}_{(\alpha)}}$ is the Lie derivative in the direction $\boldsymbol{X}_{(\alpha)}$, and $g_{\alpha\beta}$ is a symmetric nondegenerate matrix on $\boldsymbol{Z}_i$ defined by

$$S_0(x(z))=\int_T g_{x(t)}(\dot{\mathbf{x}}(t,z),\dot{\mathbf{x}}(t,z))dt=\int_T g_{x(t)}(\mathbf{X}_{(\alpha)}(x(t)),\boldsymbol{X}_{(\beta)}(x(t)))\dot{z}^{\alpha}(t)\dot{z}^{\beta}(t)dt$$

$$=:\int_T g_{\alpha\beta}\dot{z}^{\alpha}(t)\dot{z}^{\beta}(t)dt$$

$$=:Q(z). \tag{13}$$

Equation (11) is the Cartier/DeWitt-Morette analog of the time-sliced configuration space path integral. This theorem allows one to associate a *unique* action functional[25] with a Hamiltonian operator associated with a given Schrödinger equation. Again, this should be contrasted with the discussion above concerning the analogous situation for conventional path integrals.

III. CURVILINEAR COORDINATES

In this section we will first give a simple example—the Schrödinger equation for a free particle in spherical coordinates—to see how a change of coordinates is handled in the new formalism. Then we will present the recipe for the general case. Throughout this section we consider only flat configuration space path integrals. When configuration space is a nontrivial (pseudo)Riemannian manifold, one can use the Cartan development to parametrize the space of pointed paths on the manifold by the space of pointed paths on the tangent space at a point of the manifold.[14] This procedure does not alter the methods or results of this or the next section.

A. Spherical coordinates

Consider a free particle on $\mathbb{R}^3$. We want to calculate the Green's function of the Schrödinger equation in spherical coordinates $(r,\theta,\phi)=:\mathbf{r}$ on $\mathbb{R}^3$. This is equivalent to finding the point-to-point transition amplitude $\langle\mathbf{r}(t_f)|\mathbf{r}(t_i)\rangle=:\mathscr{K}(t_f,\mathbf{r}_f;t_i,\mathbf{r}_i)$. The point-to-point transition amplitude can be obtained from the path integral in Eq. (11) by taking the initial functional ψ to be a delta functional. This choice ''ties down'' the other ends of the paths (recall that we deal with pointed paths).

Cover $\mathbb{R}^3$ with an atlas of spherical coordinates such that $\mathbf{r}_f$ and $\mathbf{r}_i$ lie in the same patch. Note that the space of paths $\mathscr{P}_f^R\mathbb{R}^3$ is not a Banach space so we parametrize by the space of paths $\mathbf{Z}_i=\mathscr{P}_0\mathbb{R}^3$. According to Eq. (11), we have to solve the following functional integral:

$$\mathscr{K}(t_f,\mathbf{r}_f;t_i,\mathbf{r}_i)=\int_{\mathbf{Z}_i}\delta(\mathbf{r}_f\cdot\Sigma(t_f,z)-\mathbf{r}_i)e^{[\pi iS_0(\mathbf{r}(z))]}\mathscr{D}_{Q,W}z \tag{14}$$

where

$$S_0(\mathbf{r})=\frac{1}{2\pi\hbar}\int_{\mathrm{T}}(\dot{r}^2+r^2\dot{\theta}^2+r^2\sin^2\theta\dot{\phi}^2)dt.$$

The first step in solving Eq. (14) is to find a simplifying parametrization. From the form of the action functional, the indicated parametrization is fairly obvious. Take Euclidean coordinates for $z(t)\in\mathbb{R}^3$ [then Eq. (14) will be easy to solve] and consider the transformation between spherical and Euclidean coordinates:

$$\begin{aligned}
r&=\sqrt{(z^1)^2+(z^2)^2+(z^3)^2},\\
\theta&=\cos^{-1}\left(\frac{z^3}{\sqrt{(z^1)^2+(z^2)^2+(z^3)^2}}\right),\\
\phi&=\tan^{-1}\left(\frac{z^2}{z^1}\right).
\end{aligned} \tag{15}$$

Then the parametrization corresponding to Eq. (9) which transforms spherical coordinates to Euclidean coordinates is

$$\begin{aligned}
dr(t)&=\sin\theta(t)\cos\phi(t)dz^1(t)+\sin\theta(t)\sin\phi(t)dz^2(t)+\cos\theta(t)dz^3(t),\\
d\theta(t)&=\frac{\cos\theta(t)\cos\phi(t)}{r(t)}dz^1(t)+\frac{\cos\theta(t)\sin\phi(t)}{r(t)}dz^2(t)-\frac{\sin\theta(t)}{r(t)}dz^3(t),\\
d\phi(t)&=\frac{-\sin\phi(t)}{r(t)\sin\theta(t)}dz^1(t)+\frac{\cos\phi(t)}{r(t)\sin\theta(t)}dz^2(t),\\
r(t_f)&=r_f,\quad \theta(t_f)=\theta_f,\quad \phi(t_f)=\phi_f,
\end{aligned} \tag{16}$$

and the solution is

$$\begin{aligned}
r(t,z)&=\{(r_f\sin\theta_f\cos\phi_f+z^1(t))^2+(r_f\sin\theta_f\sin\phi_f+z^2(t))^2\\
&\quad+(r_f\cos\theta_f+z^3(t))^2\}^{1/2},\quad 0<r<\infty\\
\cos\theta(t,z)&=\left(\frac{r_f\cos\theta_f+z^3(t)}{r(t)}\right),\quad 0\leqslant\theta<\pi,\\
\tan\phi(t,z)&=\left(\frac{r_f\sin\theta_f\sin\phi_f+z^2(t)}{r_f\sin\theta_f\cos\phi_f+z^1(t)}\right),\quad 0\leqslant\phi<2\pi.
\end{aligned} \tag{17}$$

Hence, the parametrized action functional is given by

$$S_0(\mathbf{r}(z))=Q(z)=\frac{1}{2\pi\hbar}\int_{\mathrm{T}}\{(\dot{z}^1)^2+(\dot{z}^2)^2+(\dot{z}^3)^2\}dt \tag{18}$$

so that $g^{\alpha\beta}=(2\pi\hbar)\delta^{\alpha\beta}$.

The delta functional becomes

$$\begin{aligned}&\delta^3\{r(t_f,z)-r_i,\theta(t_f,z)-\theta_i,\phi(t_f,z)-\phi_i\}\\&\quad=r_i^2\sin\theta_i\delta^3\begin{pmatrix}r_f\sin\theta_f\cos\phi_f-r_i\sin\theta_i\cos\phi_i+z^1(t_f),\\ r_f\sin\theta_f\sin\phi_f-r_i\sin\theta_i\sin\phi_i+z^2(t_f),\\ r_f\cos\theta_f-r_i\cos\theta_i+z^3(t_f)\end{pmatrix},\end{aligned} \tag{19}$$

where the right-hand side follows from Eq. (17) and the well-known identity $\delta^3(f(x))=\Sigma_{x_0}\delta^3(x-x_0)/|\det f'(x_0)|$ with $f(x_0)=0$. Note that the delta functional depends only on a single value of the paths, i.e., $z(t_f)$. Thus it is actually just a delta *function*.

Substitute Eqs. (18) and (19) into Eq. (14). The integral can be simplified by making use of the linear map $L:\mathbf{Z}_i\to\mathbb{R}^3$ by $z^\alpha\mapsto u^\alpha=z^\alpha(t_f)$. The integral reduces to a finite integral (see, for example, Ref. 14)

$$\int_{\mathbb{R}^3}e^{[\pi iQ(u)]}r_i^2\sin\theta_i\delta^3\begin{pmatrix}r_f\sin\theta_f\cos\phi_f-r_i\sin\theta_i\cos\phi_i+u^1,\\ r_f\sin\theta_f\sin\phi_f-r_i\sin\theta_i\sin\phi_i+u^2,\\ r_f\cos\theta_f-r_i\cos\theta_i+u^3,\end{pmatrix}|\det 2\pi i\hbar G(t_f,t_f)|^{1/2}d^3u, \tag{20}$$

where $Q(\mathbf{u})=\mathbf{u}^2/2G(t_f,t_f)$. Here $G(t,s)$ is the Green's function for $Q(z)$ for $z\in\mathbf{Z}_i$. It is easy to check that $G(t,s)=\theta(t-s)(t-t_i)+\theta(s-t)(s-t_i)$ so that $G(t_f,t_f)=(t_f-t_i)$.

Therefore, the final expression for the transition amplitude is

$$\mathscr{K}(t_f,\mathbf{r}_f;t_i,\mathbf{r}_i)=r_i^2\sin\theta_i[2\pi i\hbar(t_f-t_i)]^{-3/2}\exp\left\{\frac{i}{\hbar}\frac{|\mathbf{r}_f-\mathbf{r}_i|^2}{2(t_f-t_i)}\right\}. \tag{21}$$

This is the propagator for a free particle in $\mathbb{R}^3$ expressed in spherical coordinates.

According to the key theorem, the transition amplitude (21) is the solution of a partial differential equation. By inspecting Eq. (16), we identify

$$\begin{aligned}\boldsymbol{X}_{(1)}&=\left(\sin\theta\cos\phi,\frac{\cos\theta\cos\phi}{r},\frac{-\sin\phi}{r\sin\phi}\right),\\ \boldsymbol{X}_{(2)}&=\left(\sin\theta\sin\phi,\frac{\cos\theta\sin\phi}{r},\frac{\cos\phi}{r\sin\theta}\right),\\ \boldsymbol{X}_{(3)}&=\left(\cos\theta,\frac{-\sin\theta}{r},0\right).\end{aligned} \tag{22}$$

The corresponding Lie derivatives are

$$\begin{aligned}\mathscr{L}_{\boldsymbol{X}_{(1)}}&=\sin\theta\cos\phi\frac{\partial}{\partial r}+\frac{\cos\phi}{r}\frac{\partial}{\partial\theta}-\frac{\sin\phi}{r\sin\theta}\frac{\partial}{\partial\phi},\\ \mathscr{L}_{\boldsymbol{X}_{(2)}}&=\sin\theta\sin\phi\frac{\partial}{\partial r}+\frac{\sin\phi}{r}\frac{\partial}{\partial\theta}+\frac{\cos\phi}{r\sin\theta}\frac{\partial}{\partial\phi},\\ \mathscr{L}_{\boldsymbol{X}_{(3)}}&=\cos\theta\frac{\partial}{\partial r}-\frac{\sin\theta}{r}\frac{\partial}{\partial\theta}.\end{aligned} \tag{23}$$

Substituting these Lie derivatives and the transition amplitude into Eq. (12) verifies the partial differential equation

$$\frac{\partial \mathscr{K}}{\partial t_f} = \frac{i\hbar}{2}\left(\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2}\right)\Bigg|_{\mathbf{r}_f}\mathscr{K},$$
$$\lim_{t_f\to t_i}\mathscr{K}(t_f,\mathbf{r}_f;t_i,\mathbf{r}_i) = \delta(r_f-r_i)\,\delta(\theta_f-\theta_i)\,\delta(\phi_f-\phi_i), \tag{24}$$

and we have succeeded in solving the Schrödinger equation in spherical coordinates. Note that the constant $r_i^2\sin\theta_i$ in Eq. (21) is consistent with Eq. (24) since

$$\begin{aligned}(r_i^2\sin\theta_i)^{-1}\lim_{t_f\to t_i}\mathscr{K}(t_f,\mathbf{r}_f;t_i,\mathbf{r}_i) &= (r_i^2\sin\theta_i)^{-1}\delta(r_f-r_i)\,\delta(\theta_f-\theta_i)\,\delta(\phi_f-\phi_i)\\ &= \delta(x_f-x_i)\,\delta(y_f-y_i)\,\delta(z_f-z_i)\\ &= \lim_{t_f\to t_i}\mathscr{K}(t_f,\mathbf{x}_f;t_i,\mathbf{x}_i).\end{aligned} \tag{25}$$

B. The general case

To obtain the path integral solution of the Schrödinger equation in *general* curvilinear coordinates for an interacting particle in Euclidean space, we just outline the necessary steps. The calculations follow the example in the previous section. Of course for generic interactions the path integral cannot be solved exactly.

(1) Write the equations for the transformation $x=f(z)$ from Euclidean to curvilinear coordinates.
(2) Use the derivatives $\mathbf{dx}=f'\mathbf{dz}$ to define the parametrization and to identify the vector fields $X_{(\alpha)}$, which will be the columns of f'.
(3) Use the free part of the action functional to define the quadratic form Q. Hence, determine $g_{\alpha\beta}$.
(4) Use Eq. (11) to solve the Schrödinger equation given by Eq. (12).
(5) If a point-to-point transition is desired, take the initial functional in the path integral to be a delta functional.

IV. CONCLUSIONS

A new formulation of path integrals has been used to study the relationship between coordinate transformations on a flat configuration space and the path integral solution of the transformed Schrödinger equation. The variables of the path integral are $L^{2,1}$ functions which do not share the stochastic properties of paths in the conventional path integral. In particular, no ''quantum potential'' corrections to the action functional are required under a change from Euclidean to curvilinear coordinates. Moreover, a unique integrator is associated with the Hamiltonian operator encoded in the Schrödinger equation. Given a coordinate transformation, it is straightforward to write down the path integral solution of the transformed Schrödinger equation.

[19] The usual text book derivation of Eq. (4) uses the delta function to do the integral over q_N. Hence, the number of dps and dqs is not equal in general. As a result, the integrand in Eq. (5) does not include a delta function, and the domain of integration is the space of paths with *both* endpoints fixed. Our approach, on the other hand, keeps the balance between the number of dps and dqs, but the domain of integration is the space of paths with *one* endpoint fixed and the integrand includes a delta function. This (equivalent) formulation allows for a more direct comparison with the new formalism described in Sec. II B.
[20] Closely related to the t_n ambiguity and operator ordering is the fact that the ''paths'' in Eq. (3) behave like Brownian paths in the sense that $(dx)^2 \sim dt$. This leads to an often fruitful analogy with stochastic calculus and Wiener integrals. However, analytically continuing Wiener integrals to include the case of quantum mechanics is not possible in general (see, for example, Refs. 21 and 22), and the correspondence between path integrals and Wiener integrals is strictly formal.

[24] A function is $L^{2,1}$ if $\int_T |dx/dt|^2 \, dt < \infty$. We choose $L^{2,1}$ functions because of their relevance to physics. Specifically, the Lagrangian density requires derivatives, and the kinetic energy must be finite.
[25] For our purpose, it is convenient but not necessary to fix the *final* endpoints for the paths $x \in \mathscr{P}_f^R M$ and the *initial* endpoints for the paths $z \in \boldsymbol{Z}_i$: fixing any combination of initial and/or final points is allowed.
[26] Strictly speaking, the action functional is only unique up to definition (13) which relates the free-particle action to the quadratic form that characterizes the integrator.

A symmetry of massless fields

Yu-Fen Liu[a] and Jaime Keller[b]
Centro de Investigaciones Teóricas, Facultad de Estudios Superiores-Cuautitlán, Universidad Nacional Autónoma de México, Apartado 70-528, 04510 México, D.F., Mexico

(Received 1 February 1996; accepted for publication 20 May 1996)

It is proved that there exists an additional intrinsic symmetry in the left-handed and right-handed fermions (and other fields). The corresponding group of transformations is induced by the Poincaré translations in the space–time manifold. This symmetry predicts an additional intrinsic energy-momentum for fermions. Considering this symmetry as local leads to introduction of a gauge field and of a nonintegrable phase angle, the corresponding Berry-type phase depends on the topology of the Riemannian space–time manifold as determined by the vierbein. This additional symmetry provides us with the possibility of considering the fermions as gauge fields on the nonvector bundle. © *1996 American Institute of Physics.* [S0022-2488(96)02109-3]

I. INTRODUCTION

In the theory of elementary particles we customarily invoke the principles of symmetry. The discovery of symmetries has brought order into the complexity of data and phenomena; it has made possible several developments of science. ''Symmetry is one idea by which man through the ages has tried to comprehend and create order, beauty, and perfection'' as H. Weyl has expressed it so concisely.

In elementary particle physics the inherent symmetries of the fields considered have allowed us either to derive or to incorporate many important properties of the particles, mainly through the conservation rules (the conserved quantities as invariants of the symmetry groups considered) and the associated selection rules for possible interactions.

In this paper we will analyze an additional intrinsic symmetry in the left-handed and right-handed fermion fields. The corresponding group transformation on the null twistor space can be induced by the Poincaré translation in the space–time manifold. This symmetry predicts an additional intrinsic energy-momentum for the fermion. By extension this could be applied to other massless fields.

It is known that gauge fields in physics are established as connections on a vector bundle. The theory of a gauge field on a nonvector bundle should deserve more attention.[1] We show that an additional symmetry provides us with the possibility to construct the theory where the fermionic fields, commonly regarded as matter fields, become the gauge fields on the nonvector bundle. This opens a new approach in the pursuit of great unification of physical fields.

First we show that the Poincaré group can be considered as a chiral group. The complexification of $R_{1,3}$, the Clifford algebra of space–time $R^{1,3}$, will be used for this purpose ($R_{1,3}$ is called space–time real geometrical algebra). This is the algebra generated by representing a space–time vector tetrad by γ_μ, $\mu=0,1,2,3$, and the definitions of the multiple index quantities and of geometric multiplication:

$$\gamma_\mu\gamma_\nu=g_{\mu\nu}\mathbf{1}+\gamma_{\mu\nu}, \quad \gamma_{\mu\nu}=-\gamma_{\nu\mu},$$

where $g_{\mu\nu}$ is the scalar metric, $\mathbf{1}$ is the unit of the algebra, the $\gamma_{\mu\nu}$ are bivectors;

0022-2488/96/37(9)/4320/13/$10.00

$$\gamma_{\mu\nu}\gamma_\lambda=\gamma_\mu g_{\nu\lambda}-g_{\mu\lambda}\gamma_\nu+\gamma_{\mu\nu\lambda},$$

defining the trivectors, totally antisymmetric in all three indexes,

$$\gamma_{\mu\nu\lambda}=-\gamma_{\mu\lambda\nu}=-\gamma_{\nu\mu\lambda}=\gamma_{\lambda\mu\nu};$$

and the pseudoscalar γ_5 or space–time volume tetravector

$$\gamma_{\mu\nu\lambda}\gamma_\rho=\gamma_{\mu\nu}g_{\lambda\rho}-\gamma_{\mu\lambda}g_{\nu\rho}+\gamma_{\nu\lambda}g_{\mu\rho}+\gamma_5.$$

The indexes are given a definite order and the definitions are consistent with the change of sign with the exchange of two adjacent indexes.

The reversion of all indexes is denoted by a tilde over a multivector $\tilde{\gamma}_{\mu\nu}=\gamma_{\nu\mu}$, $\tilde{\gamma}_{\mu\nu\lambda}=\gamma_{\lambda\nu\mu}$, etc.

Second we consider the symmetry generated by these quantities when combined in a form suitable to have a representation of the Poincaré group. This is then used to study fermion fields.

This brings the necessity of studying the gauge theory of the translation group as an extension of the simplest gauge groups for fermions.

We end with some final consideration about the significance of this analysis.

II. THE POINCARÉ GROUP REPRESENTATION AS A CHIRAL GROUP IN SPACE–TIME ALGEBRA

The equations describing physical relations in space–time (or in ordinary three-dimensional space) should be covariant under both Lorentz transformations $\mathbb{L}$ and changes of origin d of the coordinate system. This set of operations, called the Poincaré group, of which rotations and changes of origin in ordinary three-dimensional space are subgroups, is characterized by the pair $\{\mathbb{L},d\}$.

The group transformation is $\{\mathbb{L}_2,d_2\}\{\mathbb{L}_1,d_1\}=\{\mathbb{L}_3,d_3\}$. In the geometric algebra of space–time $R^{1,3}$ (the Clifford algebra $R_{1,3}$) a position vector $\chi_0=\chi^\mu\gamma_\mu$ is transformed. With the use of the boosters and rotors $\mathbb{L}$,

$$\chi_0\rightarrow\chi_1=\mathbb{L}_1\chi_0\tilde{\mathbb{L}}_1+d_1\rightarrow\chi_2=\mathbb{L}_2\chi_1\tilde{\mathbb{L}}_2+d_2, \tag{1}$$

or

$$\chi_2=\mathbb{L}_2\mathbb{L}_1\chi_0\tilde{\mathbb{L}}_1\tilde{\mathbb{L}}_2+\mathbb{L}_2d_1\tilde{\mathbb{L}}_2+d_2, \tag{2}$$

$$\chi_2=\mathbb{L}_3\chi_0\tilde{\mathbb{L}}_3+d_3, \tag{3}$$

defining (the tilde operation reverses the product of two multivectors)

$$\mathbb{L}_3=\mathbb{L}_2\mathbb{L}_1 \quad \text{and} \quad d_3=\mathbb{L}_2d_1\tilde{\mathbb{L}}_2+d_2. \tag{4}$$

The ''multiplication'' of the Poincaré group is well defined but cumbersome. There are several representations, some of which are reasonable to handle. For example, the use of the matrix form (here the $\mathbb{L}_i$ are square matrices and the χ_i and d_i column matrices, the 0^l are row matrices)

$$\begin{pmatrix}\mathbb{L}_1 & d_1\\ 0^l & \mathbf{1}\end{pmatrix}\begin{pmatrix}\chi_0\\ 1\end{pmatrix}=\begin{pmatrix}\mathbb{L}_1\chi_0+d_1\\ 1\end{pmatrix} \tag{5}$$

and

$$\begin{pmatrix} \mathbb{L}_2 & d_2 \\ 0^l & \mathbf{1} \end{pmatrix}\begin{pmatrix} \chi_1 \\ 1 \end{pmatrix}=\begin{pmatrix} \mathbb{L}_2\chi_1+d_2 \\ 1 \end{pmatrix} \tag{6}$$

or

$$\begin{pmatrix} \mathbb{L}_3 & d_3 \\ 0^l & \mathbf{1} \end{pmatrix}\begin{pmatrix} \chi_0 \\ 1 \end{pmatrix}=\begin{pmatrix} \mathbb{L}_2 & d_2 \\ 0^l & \mathbf{1} \end{pmatrix}\begin{pmatrix} \mathbb{L}_1 & d_1 \\ 0^l & \mathbf{1} \end{pmatrix}\begin{pmatrix} \chi_0 \\ 1 \end{pmatrix}. \tag{7}$$

Then

$$\begin{pmatrix} \mathbb{L}_3 & d_3 \\ 0^l & \mathbf{1} \end{pmatrix}=\begin{pmatrix} \mathbb{L}_2\mathbb{L}_1 & \mathbb{L}_2 d_1+d_2 \\ 0^l & \mathbf{1} \end{pmatrix} \tag{8}$$

clearly shows that the ''product'' of group elements are elements of the group. Group multiplication is matrix multiplication here.

In geometric algebra there is a representation of the elements of the group which allows *geometric multiplication* as the group (non-Abelian) multiplication:

$$\{\mathbb{L}_2,d_2\}\{\mathbb{L}_1,d_1\}=\{\mathbb{L}_3,d_3\}.$$

For this geometric algebra representation we use the product of the elements $(1+\varepsilon d)$ and $\mathbb{L}$, which separately have as group multiplication the geometric product

$$\mathbb{L}_3=\mathbb{L}_2\mathbb{L}_1 \quad \text{and} \quad (1+\varepsilon d_3)=(1+\varepsilon d_2)(1+\varepsilon d_1), \tag{9}$$

where $d_3=d_2+d_1$ and $\varepsilon d_2\varepsilon d_1=0$, requiring that either $\{\varepsilon^2=0,\ \varepsilon d=d\varepsilon\}$ or $\{\varepsilon_+\varepsilon_-=0,\ \varepsilon_+ d=d\varepsilon_-\}$. In the first case $\varepsilon^2=0$ is a nilpotent operation commuting with the vectors d. In the second case $\varepsilon_+(\varepsilon_-)$ is a projector operator

$$\varepsilon_+\varepsilon_-=\varepsilon_-\varepsilon_+=0, \quad \varepsilon_++\varepsilon_-=1, \tag{10}$$

which can be written in terms of a unit multivector e, $e^2=\mathbf{1}$ which, $ed=-de$, anticommutes with the vectors d. The $\varepsilon_+=\frac{1}{2}(1+e)$ and $\varepsilon_-=\frac{1}{2}(1-e)$. In general a suitable $\{\varepsilon;\varepsilon^2=0,\ \varepsilon d=d\varepsilon\}$ or $\{e;e^2=1,\ ed=-de\}$ can only be found in an algebra of a dimension higher than the Clifford algebra $R_{p,q}$ corresponding to the space $R^{p,q}$. The formal definition of ε or e is enough for the purpose of studying the Poincaré group but the possibility of physical usefulness or insight would be lost.

In the Dirac algebra $\mathscr{D}$ corresponding to $R_{1,3}$ one usually admits its complexification, corresponding to the use of $R_{0,5}\simeq R_{2,3}\simeq R_{4,1}$, that is $\mathscr{D}=\{R_{1,3}\oplus iR_{1,3}\simeq R_{0,5}\}$. The commonly used operators $i\gamma_5=i\gamma_0\gamma_1\gamma_2\gamma_3$ and $i\gamma_{12}=i\gamma_1\gamma_2$ are good examples of this complexification of the algebra. It is $i\gamma_5$ which has the property $i\gamma_5\gamma_\mu=-\gamma_\mu i\gamma_5$, and $(i\gamma_5)^2=1$ required for the use in (9) and (10). Then the group of translations Γ has two isomorphic representations $\Gamma:d\to d'$, which are $(1+\mathbb{P}_R d)$ and $(1+\mathbb{P}_L d)$ where

$$\begin{gathered} \mathbb{P}_R=\tfrac{1}{2}(1+i\gamma_5) \ \text{ and } \ \mathbb{P}_L=\tfrac{1}{2}(1-i\gamma_5), \\ \mathbb{P}_R+\mathbb{P}_L=1, \quad \mathbb{P}_R\mathbb{P}_L=\mathbb{P}_L\mathbb{P}_R=0 \quad \text{and} \quad \mathbb{P}_R\mathbb{P}_R=\mathbb{P}_R, \quad \mathbb{P}_L\mathbb{P}_L=\mathbb{P}_L, \quad \mathbb{P}_R d=d\mathbb{P}_L. \end{gathered} \tag{11}$$

Here the $\mathbb{P}_R$ and $\mathbb{P}_L$ are the operators for right-handed and left-handed projection, respectively: $\psi=\mathbb{P}_R\psi+\mathbb{P}_L\psi=R_0+L_0$.

The Lorentz transformations $\mathbb{L}$,

$$\mathbb{L}:\chi\to\chi'=\mathbb{L}\chi\tilde{\mathbb{L}}, \quad \mathbb{L}\tilde{\mathbb{L}}=\tilde{\mathbb{L}}\mathbb{L}=1, \tag{12}$$

do form a multiplication group

$$\mathbb{L}_3=\mathbb{L}_2\mathbb{L}_1, \quad \tilde{\mathbb{L}}_3=\tilde{\mathbb{L}}_1\tilde{\mathbb{L}}_2, \tag{13}$$

which can be used to construct, together with the $(1+\varepsilon d)$, a set of two *representations* of the Poincaré group.

The representations of the Poincaré group are

$$\mathbb{P}_i^{(L)}=(1+\mathbb{P}_L d_i)\mathbb{L}_i; \quad \mathbb{P}_i^{(R)}=(1+\mathbb{P}_R d_i)\mathbb{L}_i, \tag{14}$$

and ($A=L,R$ and, as a reminder, $\mathbb{L}_j\mathbb{P}_L=\mathbb{P}_L\mathbb{L}_j$)

$$\begin{aligned}\mathbb{P}_k^{(A)}&=\mathbb{P}_j^{(A)}\mathbb{P}_i^{(A)}=(1+\mathbb{P}_L d_j)\mathbb{L}_j(1+\mathbb{P}_L d_i)\mathbb{L}_i,\\ \mathbb{P}_k^{(A)}&=(1+\mathbb{P}_L(d_j+\mathbb{L}_j d_i\mathbb{L}_j))\mathbb{L}_j\mathbb{L}_i,\\ \mathbb{P}_k^{(A)}&=(1+\mathbb{P}_L d_k)\mathbb{L}_k.\end{aligned} \tag{15}$$

The operators $(1+\mathbb{P}_A d)$ then become an important part of the study of the invariances and the symmetries related to relativistic quantum theory of particle and interaction fields. Their use in constructing a new representation of the Poincaré Lie algebra (see below) is thus both straightforward and clarifies the reason for some features of the theory of elementary particles.

III. INTRINSIC SYMMETRY OF FERMION

In this section we will show now that there exists a new intrinsic symmetry for the left-handed and right-handed fermions, which corresponds to a special Poincaré translation in the phase space of the spinor space.

One knows that any fermion field can be written as a superposition of handness states:

$$\Psi=(\mathbb{P}_L+\mathbb{P}_R)\Psi=\left(\frac{1-i\gamma_5}{2}\right)\Psi+\left(\frac{1+i\gamma_5}{2}\right)\Psi=L_0+R_0. \tag{16}$$

In the standard Weinberg–Salam model,[2] the left-handed fermion L_0 and right-handed fermion R_0 are treated on different levels. All left-handed components L_0 are supposed to form SU(2) doublets while the right-handed components R_0 are SU(2) singlets. From the mathematical point of view they are mathematically independent quantities.

The Lagrangian in the standard model for a fermion field with electroweak interactions and a symmetry breaking mass term is

$$\begin{aligned}\mathbf{L}=&+\frac{1}{2}\overline{L_0}i\gamma^\mu\left(\frac{1-i\gamma_5}{2}\right)\left(\partial_\mu L_0+\frac{ig'}{2}B_\mu L_0-\frac{ig}{2}A_\mu^i\tau_i L_0\right)-\frac{1}{2}\left(\partial_\mu\overline{L_0}-\frac{ig'}{2}B_\mu\overline{L_0}\right.\\ &\left.+\frac{ig}{2}\overline{L_0}\tau_i A_\mu^i\right)i\gamma^\mu\left(\frac{1-i\gamma_5}{2}\right)L_0+\frac{1}{2}\overline{R_0}i\gamma^\mu\left(\frac{1+i\gamma_5}{2}\right)(\partial_\mu R_0+ig'B_\mu R_0)-\frac{1}{2}(\partial_\mu\overline{R_0}\\ &-ig'B_\mu\overline{R_0})i\gamma^\mu\left(\frac{1+i\gamma_5}{2}\right)R_0-g_e\left[\overline{R_0}\Phi^\dagger\left(\frac{1-i\gamma_5}{2}\right)L_0+\overline{L_0}\left(\frac{1+i\gamma_5}{2}\right)\Phi R_0\right],\end{aligned} \tag{17}$$

where the τ_i ($i=1,2,3$) are Pauli matrices, Φ is a Higgs–Goldstone field, and B_μ and A_μ^i are U(1) and SU(2) gauge fields, respectively.

By introducing new special arbitrary phase-angles (which do not change the Lagrangian), we can generalize the left-handed and right-handed spinors through a Clifford algebra valued phase factor in the following form:[3]

$$L_0 \to L \equiv \exp\left[b^a i\gamma_a \left(\frac{1-i\gamma_5}{2} \right) \right] L_0 = \left[1 + b^a i\gamma_a \left(\frac{1-i\gamma_5}{2} \right) \right] L_0 ,$$
$$R_0 \to R \equiv \exp\left[b^a i\gamma_a \left(\frac{1+i\gamma_5}{2} \right) \right] R_0 = \left[1 + b^a i\gamma_a \left(\frac{1+i\gamma_5}{2} \right) \right] R_0 . \tag{18}$$

The last equalities arise because the exponential has a truncated expansion from $\gamma_\alpha \mathbb{P}_L = \mathbb{P}_R \gamma_\alpha$ and $\mathbb{P}_L \mathbb{P}_R = \mathbb{P}_R \mathbb{P}_L = 0$. The corresponding Dirac conjugate spinors are

$$\overline{L} = \overline{L_0} \left[1 - b^a i\gamma_a \left(\frac{1-i\gamma_5}{2} \right) \right],$$
$$\overline{R} = \overline{R_0} \left[1 - b^a i\gamma_a \left(\frac{1+i\gamma_5}{2} \right) \right], \tag{19}$$

with $\overline{L}L = \overline{L_0} L_0$ and $\overline{R}R = \overline{R_0} R_0$.

In principle, L (resp. R) is not just a conventional left (resp. right)-handed spinor, as far as it includes left (resp. right)-handed ''phase angles b^a''. We choose to call L (resp. R) as ''generalized left (resp. right)-handed spinor''. In fact L (or R) are closely related to the ''null twistors'' which were studied early by Penrose.[4] (See Ref. 5 for the geometric algebra formulation of twistors.) The objects (18) and (19) are faithful representations of the full Poincaré group and not only, as spinors are, of the Lorentz group. The geometry of these spinors is clearest in the terms of projective twistor space. Considering L to be fixed and solving for real solutions $b^a \in M$ of Eq. (18), it turns out that a solution exists only if $LL = 0$. These solutions for b^a in real Minkowski space M constitute a null straight line (null geodesics), and every null straight line in Minkowski space M arises in this way. So a point in Minkowski space is said to be ''incident'' with the null twistor. This is the so-called standard flat-space twistor correspondence.

The generalized left (or right)-handed spinor (null twistor) can be defined by using (the idempotent) projector operator $P_L = [1 + b^\mu i\gamma_\mu((1-i\gamma_5)/2)]((1-i\gamma_5)/2)$, which satisfies $P_L P_L = P_L$. It can be considered as generalization of $(P_L)_0 = ((1-i\gamma_5)/2)$. We define its complement V by $P_L + V = 1$; it also satisfies $VV = V$. Any spinor can then be decomposed in two parts:

$$\psi = P_L(\psi) + V(\psi) = L + V(\psi). \tag{20}$$

It is important to notice that under a new $S^\alpha_{-\beta} \in G_T$ transformation of a chiral group G_T [see the definition of $S^\alpha_{-\beta}$ in Eq. (22)], the spinor ψ transforms as

$$\widetilde{\psi} = S_- \psi = S_-(L + V(\psi)) = S_- L + V(\psi). \tag{21}$$

This means that in the spinor space $S^\alpha_{-\beta} \in G_T$ acts only on its projective subspace (projective null twistor space), which can be considered as representation space of this group G_T.

Notice also that although we bear firmly in mind that L and R include arbitrary ''phase angles b^a'', these parameters will disappear from the Lagrangian (17) when we replace L_0 and R_0 by L and R. This means that the standard model is invariant under the following transformation[3]

$$\widehat{R^\alpha} = S^\alpha_{+\beta} R^\beta = \left[1 - k\sigma^\mu i\gamma_\mu \left(\frac{1+i\gamma_5}{2} \right) \right]^\alpha_\beta R^\beta ,$$
$$\widehat{L^\alpha} = S^\alpha_{-\beta} L^\beta = \left[1 - k\sigma^\mu i\gamma_\mu \left(\frac{1-i\gamma_5}{2} \right) \right]^\alpha_\beta L^\beta , \tag{22}$$

$$S_+\left[\gamma_\mu\left(\frac{1+i\gamma_5}{2}\right)\right](S_+)^{-1}=\gamma_\mu\left(\frac{1+i\gamma_5}{2}\right),$$

$$S_-\left[\gamma_\mu\left(\frac{1-i\gamma_5}{2}\right)\right](S_-)^{-1}=\gamma_\mu\left(\frac{1-i\gamma_5}{2}\right).$$

The matrices $S^{\alpha}_{\pm\beta}$ with parameters σ^μ constitute a four-dimensional Abelian subgroup of SU(2,2). For some physical considerations we can consider σ^μ as parameters of Poincaré translation in the phase space of the spinor space induced by translation $\widehat{x^\mu} = x^\mu + \sigma^\mu$ in the space–time manifold. The generators of Poincaré group can be taken[6,7] therefore as elements of the multivector Clifford algebra of the complex space–time geometric algebra $M=s+v+b+t+p$, where s denotes scalar, v denotes vector, b denotes bivector, t denotes trivector, and p denotes pseudoscalar part, as

$$P^{\pm}_{\mu}=i\partial_\mu-k\gamma_\mu\left(\frac{1\pm i\gamma_5}{2}\right),$$

$$L_{\mu\nu}=ix_\nu\partial_\mu-ix_\mu\partial_\nu+\frac{i}{4}(\gamma_\mu\gamma_\nu-\gamma_\nu\gamma_\mu). \tag{23}$$

We can verify that these sets of generators satisfy the usual commutation relations of the Poincaré Lie algebra (''Poisson brackets'' relations)

$$[P^{\pm}_{\mu},P^{\pm}_{\nu}]=0,$$

$$[L_{\mu\nu},L_{\lambda\rho}]=ig_{\mu\lambda}L_{\mu\rho}-ig_{\mu\lambda}L_{\nu\rho}+ig_{\nu\rho}L_{\lambda\mu}-ig_{\mu\rho}L_{\lambda\nu}, \tag{24}$$

$$[P^{\pm}_{\mu},L_{\nu\lambda}]=ig_{\mu\nu}P^{\pm}_{\lambda}-ig_{\mu\lambda}P^{\pm}_{\nu}.$$

These generators have been studied as generators of a subgroup of the conformal group by Barut and Raczka.[8] Some interesting results in this direction have previously been obtained by Dirac[9] and Hepner.[10] We remind the reader that a choice like (23) is in itself a dynamical model. Also, there exist representations of M suitable for any spin and not only for spin $\frac{1}{2}$ fermions.[5,7]

Returning to the consideration of the standard model, we know that, under the gauge group SU(2) transformations, L and R transform in completely different ways, and now we see that under the Poincaré translation they also transform in different ways. We can easily visualize this situation by the example of two different kinds of screws. When we screw both, the clockwise and the counterclockwise screws with the same rotation direction, we can observe that if the former is screwed (translated) in, the latter is screwed (translated) out. The phase angles involved by (22) correspond to a so-called complex duality rotation $v\rightarrow it$, $t'=i\gamma_5 v'$, where vectors and trivectors are mapped in the $v-t$ plane.

According to Dirac,[11] the task of constructing a relativistic dynamics is equivalent to constructing a representation of the inhomogeneous Lorentz group. In other words, ''to construct the theory of a dynamical system, one must obtain expressions for ten fundamental quantities that satisfy the 'Poisson brackets' relations [i.e., Eq. (24)]. The problem of finding a new dynamical system reduces to the problem of finding a new solution of these equations.''

The existence of an additional intrinsic symmetry introduced by enlarging the representation of P_μ predicts an additional intrinsic energy-momentum term for fermions, which is generated, as discussed below, by the additional second term $i\gamma_\mu((1\pm i\gamma_5)/2)$ in the $P^{\pm}_{\mu}$. However, since the additional term $i\gamma_\mu((1\pm i\gamma_5)/2)$ is nilpotent, it turns out that the rest mass corresponding to the additional intrinsic energy-momentum of a given handness fermion is zero.

Let

$$W_{\mu}^{\pm}=-\tfrac{1}{2}\epsilon_{\mu\nu\lambda\rho}L^{\nu\lambda}P^{\pm\rho} \tag{25}$$

be the new Pauli–Lubanski vector. Consider now the following linear combinations of $(P^{\pm})^2$ and $(W^{\pm})^2$,

$$\begin{aligned} C_1&=\tfrac{3}{2}(P_{\mu}^{\pm}+\tfrac{2}{3}W_{\mu}^{\pm})(P^{\pm\mu}+\tfrac{2}{3}W^{\pm\mu})=\tfrac{3}{2}(P^{\pm})^2+\tfrac{2}{3}(W^{\pm})^2=-\partial_{\mu}\partial^{\mu},\\ C_2^{\pm}&=\left(P_{\mu}^{\pm}+\frac{2}{\sqrt{3}}\,W_{\mu}^{\pm}\right)\left(P^{\pm\mu}+\frac{2}{\sqrt{3}}\,W^{\pm\mu}\right)=(P^{\pm})^2+\frac{4}{3}\,(W^{\pm})^2=4ki\,\gamma_{\mu}\left(\frac{1\pm i\gamma_5}{2}\right)\partial_{\mu}, \end{aligned} \tag{26}$$

which commute with all the ten generators of the Poincaré group. The first of these Casimir operators, which corresponds to the orbital energy-momentum, is associated with the rest mass m^2. The second is associated with an internal-orbital interaction. [The invariance of the $C_2^{\pm}$ depends on the invariance of the $\mathbb{P}_L$ and $\mathbb{P}_R$ (see Ref. 7).]

We can also approach these issues from an equivalent but different perspective. Since the Lagrangian (39) is invariant under the translational transformation (23), the Noether conserved quantity for the left-handed fermion is the energy-momentum tensor density

$$T_{\nu}^{-\mu}=\frac{i}{2}\,[(\overline{L_0}\gamma^{\mu}(\partial_{\nu}L_0)-(\partial_{\nu}\overline{L_0})\,\gamma^{\mu}L_0)]+\frac{ik_2}{2}\,[(\overline{L_0}\gamma_{\nu}(\partial^{\mu}L_0)-(\partial^{\mu}\overline{L_0})\,\gamma_{\nu}L_0))] \tag{27}$$

here k_2 depends on k_1 and k. The energy-momentum vector is

$$\begin{aligned} P_{\mu}^{-}&=\int d^3x T_{\mu}^{-0},\\ P_{\mu}^{-}&=\int d^3x\,\frac{i}{2}\,[\overline{L_0}\gamma^0(\partial_{\mu}L_0)-(\partial_{\mu}\overline{L_0})\,\gamma^0L_0+k_2(\overline{L_0}\gamma_{\mu}(\partial_0L_0)-(\partial_0\overline{L_0})\,\gamma_{\mu}L_0)]. \end{aligned} \tag{28}$$

The additional second part corresponds to the intrinsic energy momentum for the left-handed fermion. Its form is similar to the U(1) charged current. This opens the possibility that a chiral field behaves as a field with an intrinsic energy momentum current, and intrinsic charged current.

IV. GAUGE THEORY OF THE TRANSLATION GROUP

The gauge theory of the Poincaré group was brought into consideration by Kibble, Frolov and Sciama at the beginning of 1960s. Their work generalizes Utiyama's gauge version of gravity which left open the question on the gauge status of the tetrad gravitational fields.[12] In the same period of time, the gauge potentials of spatial translations were considered in the gauge theory of dislocations in continuous media.[13]

The Poincaré group combines the group of Lorentz rotations L_b^a and the group of translations σ^a in the four-dimensional Minkowski space–time in the form

$$\widehat{y^a}=L_b^a y^b+\sigma^a. \tag{29}$$

Localization, that is making this L_b^a and σ^a position-dependent $L_b^a(x)$ and $\sigma^a(x)$, of these transformations leads in the usual analysis to the introduction of gauge fields (notice that, different from the coordinate frame vectors x^{μ}, the free y^b are components of the nonvector bundle). The covariant derivative ∇_{μ} of the section $y^a(x)$ can be defined as the sum

$$\nabla_{\mu}(y^a)=\partial_{\mu}y^a-\Gamma_{\mu b}^a y^b-N_{\mu}^a. \tag{30}$$

The transformation properties of the above connections in relation to (29) are

$$\widehat{\nabla}_\mu(\widehat{y^a}) \equiv \left(\frac{\partial \widehat{y^a}}{\partial y^b}\right) \nabla_\mu y^b = L^a_b(\nabla_\mu y^b) \tag{31}$$

and (notice that the following are, in fact, definitions of Γ and N)

$$\widehat{\Gamma^a_{\mu b}} = L^a_d \Gamma^d_{\mu c}(L^{-1})^c_b + L^a_{d,\mu}(L^{-1})^d_b, \tag{32}$$

$$\widehat{N^a_\mu} = L^a_b N^b_\mu + \partial_\mu \sigma^a - [L^a_d \Gamma^d_{\mu c}(L^{-1})^c_b + L^a_{d,\mu}(L^{-1})^d_b]\sigma^b. \tag{33}$$

As it can be shown that the gauge fields $\Gamma^a_{\mu b}$ are related and can be expressed in terms of the Christoffel symbols and tetrads, it can be shown therefore that they correspond to the gravitational field. Also, and in the same way, from physical considerations it is possible to select a special, metric-compatible, gauge potential of the localized Poincaré translation such that

$$\nabla_\mu(y^a) = \partial_\mu y^a - \Gamma^a_{\mu b} y^b - N^a_\mu = e^a_\mu, \tag{34}$$

where e^a_μ is the vierbein field. This invariant condition implies that there is always a certain translation gauge where N^a_μ coincides with e^a_μ. In this case the curvature tensor corresponding to the translational connection

$$F^a_{\mu\nu} = N^a_{\nu,\mu} - N^a_{\mu,\nu} + \Gamma^a_{\nu b} N^b_\mu - \Gamma^a_{\mu b} N^b_\nu = e^a_{\nu,\mu} - e^a_{\mu,\nu} + \Gamma^a_{\nu b} e^b_\mu - \Gamma^a_{\mu b} e^b_\nu. \tag{35}$$

plays the role of the Cartan torsion.

Now we have stated the necessary definitions and we proceed to analyze the gauge theory of the Poincaré translation (23) in the phase space of the (chiral projected) spinor space which (as we mentioned in the previous section) is induced by translations in the tangent bundle of the space–time manifold. The covariant derivatives of generalized left-handed spinor are defined as

$$\nabla_\mu(L^\beta) \equiv \partial_\mu L^\beta - N^a_\mu i \left[\gamma_a\left(\frac{1-i\gamma_5}{2}\right)\right]^\beta_\gamma L^\gamma - \frac{1}{4}\Gamma^a_{\mu b}(\gamma_a\gamma^b - \gamma^b\gamma_a)^\beta_\gamma L^\gamma. \tag{36}$$

In analogy to (34), without losing the invariant property of the theory, we can consider only the metric compatible translation connection N^a_μ, i.e., assume that

$$\nabla_\mu(b^a) = \partial_\mu b^a - \Gamma^a_{\mu d} b^d - N^a_\mu = k_1 e^a_\mu, \tag{37}$$

where $b^a(x)$ are phase angles of generalized left-handed spinor

$$L = \exp\left[b^a i\gamma_a\left(\frac{1-i\gamma_5}{2}\right)\right] L_0 = \left[1 + b^a i\gamma_a\left(\frac{1-i\gamma_5}{2}\right)\right] L_0 \tag{38}$$

(see Ref. 14 for further discussions of this point and of the importance of twistor-spin $\frac{1}{2}$-fields). We now restrict ourselves to emphasize the new translational symmetry of the spinors to the case where the gravitational field and the torsion are zero (i.e., $\Gamma^a_{\mu d} = T^a_{\mu d} = 0$). We can rewrite the Lagrangian $\mathbf{L}$ of the Dirac field in the same form as that for bosons:

$$\mathbf{L} = \frac{-1}{k_1}(\overline{\nabla_\mu L})(\nabla_\mu L) + \frac{-1}{k_1}(\overline{\nabla_\mu R})(\nabla_\mu R) - m\left[\overline{L}\left(\frac{1+i\gamma_5}{2}\right)R + \overline{R}\left(\frac{1-i\gamma_5}{2}\right)L\right]. \tag{39}$$

In the torsion-free case, the curvature tensor corresponding to the above connection,

$$F^{\alpha}_{\beta\mu\nu}=F^{d}_{\mu\nu}i\left[\gamma_d\left(\frac{1\mp i\gamma_5}{2}\right)\right]^{\alpha}_{\beta}=0 \tag{40}$$

[here $F^{a}_{\mu\nu}$ is defined as (35)]. So we could naively state that the fermions have nowhere experienced any ''force.'' However, as the Aharonov–Bohm experiment shows, in quantum mechanics the actual value of the potential plays a role (i.e., in determining some observable effect such as interference) not expected on classical theories. As stressed by C. N. Yang, the knowledge on the field strengths $F_{\mu\nu}$ under-describes electromagnetism while the knowledge on the potential over-describes the physical situation, leading to the attempt of using the nonintegrable phases to characterize a gauge theory. The existence of Berry phases within the well-known framework of the adiabatic approximation requires the study of the question of phases and angles in quantum mechanics. The nonintegrable phases for left-handed fermion are defined as

$$L'=\exp\left\{\beta^a i\gamma_a\left(\frac{1-i\gamma_5}{2}\right)\right\}\cdot L_0=\exp\left\{\left(b^a+\int N^a_\mu dx^\mu\right)i\gamma_a\left(\frac{1-i\gamma_5}{2}\right)\right\}\cdot L_0, \tag{41}$$

where the N^a_μ are metric compatible and satisfy

$$\nabla_\mu(b^a)=\partial_\mu b^a-\Gamma^a_{\mu d}b^d-N^a_\mu=k_1 e^a_\mu. \tag{42}$$

We see then that the Berry-type phases in the fermion fields depend on the topology of the space–time manifold which is determined by the vierbein e^a_μ. Moreover the U(1) phase in $\exp(i\alpha)$ is determined only up to a term $\exp(i2n\pi)$ where n is *integer*. In contrast with the U(1) case, the 'phases β^a' in (41) are only determined to a *null straight line* in the Minkowski space–time.

It is interesting to notice that in the theory of continuous media,[13] $\Gamma^a_{\mu d}$ corresponds to the disclination and N^a_μ corresponds to the dislocation fields, both of which have their origin from line defects.

V. GAUGE FIELD THEORY FOR FERMION FIELDS

To study, under the previous point of view, the Lagrangian of chiral fermion fields, let us begin with the definition of the extended Poincaré group (we remind that this extension is different from the group used in supersymmetry theory) considering also the standard U(1)×SU(2) gauge groups in the spinor space:

$$\begin{aligned}
\widehat{y^d}&=y^d+h^d,\\
\widehat{y^A}&=\exp(ig_1h^5)S^A_B(\sigma^i)y^B,\\
\widehat{\theta^\beta}&=\exp(ig_2h^5)\left[1+h^d i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\beta}_{\alpha}\theta^\alpha+\xi^\beta,\\
\widehat{\overline{\theta_\beta}}&=\exp(-ig_2h^5)\overline{\theta_\alpha}\left[1-h^d i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\alpha}_{\beta}+\overline{\xi_\beta}.
\end{aligned} \tag{43}$$

Here h^d, h^5, σ^i, ξ^β, and $\overline{\xi_\beta}$ (for simplicity denoted sometimes as ξ and $\overline{\xi}$) are group parameters of the Poincaré translation, the U(1), the SU(2), and the spinor translation groups, respectively. Experimentalists assert that they have not observed fermions with $V+A$ weak interactions. So, for a reason that will be clear shortly, we will work here with left-Poincaré-translation only. The generators of the corresponding Lie algebra are

$$T_d=\partial_d+i\left[\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\beta}_{\alpha}\theta^{\alpha}\frac{\partial}{\partial\theta^{\beta}}-i\overline{\theta}\left[\gamma_a\left(\frac{1-i\gamma_5}{2}\right)\right]\frac{\partial}{\partial\overline{\theta}},$$

$$T_5=ig_1y^A\frac{\partial}{\partial y^A}+ig_2\theta^{\beta}\frac{\partial}{\partial\theta^{\beta}}-ig_2\overline{\theta}\frac{\partial}{\partial\overline{\theta}},$$

$$T_i=\tau^A_{iB}y^B\frac{\partial}{\partial y^A},\quad T_{\beta}=\frac{\partial}{\partial\theta^{\beta}},\quad \overline{T^{\beta}}=\frac{\partial}{\partial\overline{\theta}_{\beta}}. \tag{44}$$

The nonzero commutation relations among these generators are

$$\begin{aligned}
&[T_i,T_j]=c^k_{ij}T_k,\\
&[T_d,T_{\beta}]=-T_{\gamma}\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\gamma}_{\beta},\\
&[T_d,\overline{T^{\beta}}]=\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\beta}_{\gamma}\overline{T^{\gamma}},\\
&[T_5,T_{\beta}]=-ig_2T_{\beta},\quad [T_5,\overline{T^{\beta}}]=ig_2\overline{T^{\beta}}.
\end{aligned} \tag{45}$$

In the local coordinate neighborhood $E_u(x,y)$, where $y=(y^d,y^A,\theta^{\alpha},\overline{\theta_{\beta}})$ and $x=\{x^{\mu}\}$ are coordinates in the base space (Minkowski space–time), let

$$Z_{\mu}=\partial_{\mu}+N^d_{\mu}T_d+B^5_{\mu}T_5+A^i_{\mu}T_i+W^{\beta}_{\mu}T_{\beta}+\overline{W}_{\beta\mu}\overline{T^{\beta}} \tag{46}$$

be the horizontal vector. Then the functions $N^d_{\mu}(x)$, $B^5_{\mu}(x)$, $A^i_{\mu}(x)$, $W^{\beta}_{\mu}(x)$, and $\overline{W}_{\beta\mu}(x)$ define connections in a wider sense (gauge fields on nonvector bundle). The covariant derivatives of a section $y(x)=[y^d(x^{\mu}),y^A(x^{\mu}),\theta^{\beta}(x^{\mu}),\theta_{\beta}(x^{\mu})]$ can be defined as

$$\begin{aligned}
&\nabla_{\mu}(y^a)\equiv\partial_{\mu}y^a-N^a_{\mu},\\
&\nabla_{\mu}(y^A)\equiv\partial_{\mu}y^A-ig_1B^5_{\mu}y^A-A^i_{\mu}\tau^A_{iB}y^B,\\
&\nabla_{\mu}(\theta^{\beta})\equiv\partial_{\mu}\theta^{\beta}-ig_2B^5_{\mu}\theta^{\beta}-N^d_{\mu}\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\beta}_{\alpha}\theta^{\alpha}-W^{\beta}_{\mu},\\
&\nabla_{\mu}(\overline{\theta_{\beta}})\equiv\partial_{\mu}\overline{\theta_{\beta}}+ig_2B^5_{\mu}\overline{\theta_{\beta}}+N^d_{\mu}\overline{\theta_{\alpha}}\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\alpha}_{\beta}-\overline{W}_{\beta\mu}.
\end{aligned} \tag{47}$$

The corresponding curvature tensor is defined by

$$\begin{aligned}
[Z_{\mu},Z_{\nu}]&\equiv F^d_{\mu\nu}T_d+F^5_{\mu\nu}T_5+F^i_{\mu\nu}T_i+F^{\beta}_{\mu\nu}T_{\beta}+\overline{F}_{\beta\mu\nu}\overline{T^{\beta}}\\
&=(\partial_{\mu}N^d_{\nu}-\partial_{\nu}N^d_{\mu})T_d+(\partial_{\mu}B^5_{\nu}-\partial_{\nu}B^5_{\mu})T_5+(\partial_{\mu}A^i_{\nu}-\partial_{\nu}A^i_{\mu}+c^i_{jk}A^j_{\mu}A^k_{\nu})T_i\\
&\quad+\left\{\partial_{\mu}W^{\beta}_{\nu}-\partial_{\nu}W^{\beta}_{\mu}-ig_2B^5_{\mu}W^{\beta}_{\nu}+ig_2B^5_{\nu}W^{\beta}_{\mu}+N^d_{\nu}\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]^{\beta}_{\alpha}W^{\alpha}_{\mu}\right.
\end{aligned}$$

$$-N_\mu^d\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]_\alpha^\beta W_\nu^\alpha\Big\}T_\beta+\Big\{\partial_\mu\overline{W_{\beta\nu}}-\partial_\nu\overline{W_{\beta\mu}}+ig_2B_\mu^5\overline{W_{\beta\nu}}-ig_2B_\nu^5\overline{W_{\beta\mu}}$$

$$-N_\nu^d\overline{W_{\alpha\mu}}\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]_\beta^\alpha+N_\mu^d\overline{W_{\alpha\nu}}\left[i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]_\beta^\alpha\Big\}\overline{T^\beta}. \tag{48}$$

Here $F_{\mu\nu}^5$ and $F_{\mu\nu}^i$ are the electromagnetic field and the Yang–Mills fields, respectively. As we noted before, it is possible to choose a special metric-compatible gauge potential N_μ^d such that

$$\nabla_\mu(y^a)=\partial_\mu y^a-N_\mu^a=e_\mu^a. \tag{49}$$

The torsion-free case corresponds to $F_{\mu\nu}^d=0$. In the same way we can introduce a covariant condition for $\nabla_\mu(\theta^\alpha)$ (i.e., a restriction for the gauge field W_μ^β). According to Eq. (20), by using the projector operators $P_L=[1+y^a i\gamma_\mu((1-i\gamma_5)/2)]((1-i\gamma_5)/2)$ and V, it can be decomposed in to two parts $\nabla_\mu\theta^\alpha=P_L(\nabla_\mu\theta^\alpha)+V(\nabla_\mu\theta^\alpha)$. Under a $S_{-\beta}^\alpha\in G_T$ transformation

$$\widehat{\nabla_\mu\theta^\beta}=S_{-\alpha}^\beta[\nabla_\mu\theta^\alpha]=S_{-\alpha}^\beta[P_L(\nabla_\mu\theta^a)]+V(\nabla_\mu\theta^\beta), \tag{50}$$

which means that only the components $P_L(\nabla_\mu\theta^\alpha)$ are affected by the transformation $S_{-\beta}^\alpha\in G_T$. So, without losing the invariant properties of the theory, we can assume that $V(\nabla_\mu\theta^\alpha)=0$. In other words, the $\nabla_\mu\theta^\alpha$ can be assumed to have the following form:

$$\begin{aligned}\nabla_\mu\theta=L_\mu&=\left[1+y^d i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right]L_{0\mu},\\ \nabla_\mu\overline{\theta}=\overline{L}_\mu&=\overline{L_{0\mu}}\left[1-y^d i\gamma_d\left(\frac{1-i\gamma_5}{2}\right)\right].\end{aligned} \tag{51}$$

In this case, instead of W_μ^β and $\overline{W_{\beta\mu}}$, we can use $L_{0\mu}^\beta$ and $\overline{L_{0\mu\beta}}$ in $F_{\mu\nu}^\beta$ and $\overline{F_{\beta\mu\nu}}$. So the Yang–Mills-type Lagrangian is

$$\begin{aligned}\mathbf{L}&=-\tfrac{1}{4}F_{\mu\nu}^5F_{\mu\nu}^5-\tfrac{1}{4}F_{\mu\nu}^iF_{\mu\nu}^i-\tfrac{1}{2}\overline{F_{\beta\mu\nu}}F_{\mu\nu}^\beta\\ &=-\tfrac{1}{4}F_{\mu\nu}^5F_{\mu\nu}^5-\tfrac{1}{4}F_{\mu\nu}^iF_{\mu\nu}^i+6\overline{R_0}i\gamma_\mu(\partial_\mu R_0+ig_2B_\mu^5R_0)-6(\partial_\mu\overline{R_0}-ig_2B_\mu^5\overline{R_0})i\gamma_\mu R_0\\ &\quad-\overline{L_{0\nu}^T}i\gamma_\mu(\partial_\mu L_{0\nu}^T+ig_2B_\mu^5L_{0\nu}^T)+(\partial_\mu\overline{L_{0\nu}^T}-ig_2B_\mu^5\overline{L_{0\nu}^T})i\gamma_\mu L_{0\nu}^T-2[\overline{L_{0\mu}^T}R_0+\overline{R_0}L_{0\mu}^T]_{,\mu},\end{aligned} \tag{52}$$

where the vector-spinor $L_{0\mu}^\beta$ has been decomposed into two parts:

$$L_{0\mu}=L_{0\mu}^T+i\gamma_\mu\left(\frac{-i}{4}\gamma_\mu L_{0\mu}\right)=L_{0\mu}^T+i\gamma_\mu R_0. \tag{53}$$

We can verify that the above Lagrangian includes the Dirac Lagrangian of the charged right-handed fermion R_0. One can ignore the last divergence term, as this term may be integrated up to the topological quantum number. Performing the variation of this Lagrangian with respect to $L_{0\mu}^T$, and using the method of Lagrange multipliers, we can prove that $L_{0\mu}^T=L_{02\mu}^T+D_\mu L_{01}$ (here $D_\mu=\partial_\mu-ig_2B_\mu^5$) includes a spin $\frac{1}{2}$ charged left-handed spinor singlet $L_{01}\equiv\frac{1}{2}D_\nu L_{0\nu}^T$ which satisfies the massless Dirac equation and the spin $\frac{3}{2}$ charged left-handed vector-spinor field $L_{02\mu}^T$ (with the condition for Rarita–Schwinger fields $\gamma_\mu L_{02\mu}^T=0$) which satisfies $\gamma_\mu D_\mu L_{02\nu}^T=(\gamma_\nu+F_{\nu\mu}^5\gamma_\mu)L_{01}$.

If W_μ^β [in addition to Eq. (51)] satisfies following invariant condition (twistor equation),

$$\gamma_\nu\left(\frac{1-i\gamma_5}{2}\right)\nabla_\mu\theta+\gamma_\mu\left(\frac{1-i\gamma_5}{2}\right)\nabla_\nu\theta=\frac{1}{2}\,g_{\mu\nu}\gamma_\lambda\left(\frac{1-i\gamma_5}{2}\right)\nabla_\lambda\theta, \tag{54}$$

then we can prove that the above Lagrangian includes only a right-handed spinor singlet $R_0=(-i/4)\,\gamma_\mu L_{0\mu}$ (i.e., $L_{0\mu}=i\gamma_\mu R_0$).

VI. SOME FINAL CONSIDERATIONS

It is important to notice that if the base space is a Riemannian space with Christoffel connections $\{^{\nu}_{\mu}\}$, then the derivative of any space–time vector $\partial_\mu B_\nu$ must be replaced by the covariant derivative $D_\mu(B_\nu)\equiv\partial_\mu B_\nu+B_\lambda\{^{\lambda}_{\mu\nu}\}$.

Moreover, in analogy to the Kaluza–Klein[15] theory, the base space can be enlarged, and then more gauge components must be introduced.[16] Let us consider for example the case with five-dimensional base space. We know that the physical charged field has an arbitrary phase angle, denoted here by x^5, and subjected to the condition of cyclicity, i.e., $\Psi(x^\mu,x^5)=\Psi(x^\mu)\exp(-ig_1x^5)$. The Lagrangian does not depend on this phase angle. This condition reflects the independence of observed physical phenomena on the fifth coordinate of the base space and is called the condition of cylindricity. It implies the orthogonality of space–time manifold with the phase manifold. If we admit that in Eq. (43) the parameters of the (local) gauge group $\xi^\beta(x^\mu,x^5)$ are not only functions of the space–time coordinate x^μ but also functions of the phase angle x^5, that leads to the introduction of the additional gauge fields L_5^β and $L_{\beta5}$ such that

$$\begin{aligned} Z_\mu&=\partial_\mu+N_\mu^d T_d+B_\mu^5 T_5+A_\mu^i T_i+W_\mu^\beta T_\beta+\overline{W}_{\beta\mu}\overline{T^\beta},\\ Z_5&=\partial_5+a_1L_5^\beta T_\beta+a_2\overline{L}_{\beta5}\overline{T^\beta}. \end{aligned} \tag{55}$$

For simplicity let us consider only the case with $W_{0\mu}=i\gamma_\mu R_0$. As mentioned above, in analogy to the Kaluza–Klein theory, we can introduce the ansatz of ''dimensional reduction,'' i.e., taking the fields N_μ^d, B_μ, and A_μ^i to be independent of the extra coordinate x^5, and the fermion fields R_0 and L_5^β subjected to the condition of cyclicity. We get then additional components of the curvature tensor

$$[Z_\mu,\,Z_5]=F_{\mu5}^\beta T_\beta+\overline{F}_{\beta\mu5}\overline{T^\beta} \tag{56}$$

and additional Lagrangian terms $(\overline{F}_{\beta\mu5}F_{\mu5}^\beta)$ which include the Dirac Lagrangian of the left-handed fermion and the fermionic mass term.

In a similar form, we can enlarge the base space M to include the representation space of the SU(2) group, i.e., $\mathbf{x}=(x^\mu,x^5,x^A)$. And then, the total Lagrangian will include a left-handed SU(2) spinor-doublet and a doublet of a Higgs–Goldstone complex scalar field.

I. INTRODUCTION

The quantum Boltzmann equation (QBE) is derived for photons. As far as we know, this is the first derivation of this fundamental equation. We expect the main application of this result is to photon diffusion in matter. We distinguish the QBE from the usual Boltzmann equation. The latter has been studied widely. We explain below the differences between these two equations. We also show how the usual Boltzmann equation is derived from the QBE.

Photons diffuse through many different kinds of materials, such as clouds, stellar atmospheres, cermats, and human tissue.[1–7] The Boltzmann equation for photons is routinely used to describe the diffusion of light in these materials.

In the Boltzmann equation for photons, the usual practice is to have a differential equation for the number density of photons $f(\hat{q},\mathbf{r},t)$ of frequency ω, which depends upon the direction of the photons $\hat{q}$, the position in the medium $\mathbf{r}$ and the time t. The usual equation is

$$\left[\frac{\partial}{\partial t}+c\hat{q}\cdot\boldsymbol{\nabla}_r+\left(\frac{1}{\tau_a}+\frac{1}{\tau_s}\right)\right]f(\hat{q},\mathbf{r},t)=\frac{1}{\tau_s}\int\frac{d\Omega'}{4\pi}P(\hat{q},\hat{q}')f(\hat{q}',\mathbf{r},t), \tag{1}$$

where the lifetimes are for absorption τ_a and scattering τ_s. The scattering term on the right contains the information $P(\hat{q},\hat{q}')$ for scattering between $\mathbf{q}$ and $\mathbf{q}'$. The scattering integral is over all of the 4π solid angle of the $\hat{q}'$ variable. This equation is well-known and well studied.[1–7]

The quantum Boltzmann equation (QBE) is an equation of motion for the photon Green's function when the system is not in equilibrium. There are several types of correlation function, such as retarded, advanced, etc.[8] An important one is

$$\mathscr{D}^{<}_{\mu\nu}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2)=-i\langle A_\nu(\mathbf{r}_2,t_2)A_\mu(\mathbf{r}_1,t_1)\rangle, \tag{2}$$

where the vector potential is $A_\mu(\mathbf{r},t)$. From this definition one derives an equation of motion for the Wigner distribution function (WDF) $\mathscr{D}_{\mu\nu}(\mathbf{q},\omega;\mathbf{r},t)$. This equation is the QBE. It is different than the usual Boltzmann equation described in the previous paragraph. It is a tensor quantity, rather than a scalar. Also, it has more variables in its arguments, since $\mathbf{q}$ and ω are assumed to be independent variables. The QBE is the more fundamental equation. From it we derive the Boltzmann equation (1). This derivation gives us definitions of quantities such as the life times for absorption τ_a and scattering τ_s.

There has been prior work on the closely related problem of evaluating the correlation of the electric field with itself at two different points in space and time $\langle E^*(\mathbf{r}_1,t_1)E(\mathbf{r}_2,t_2)\rangle$. Zubairy and Wolf[9] derived an equation for the correlation function of free fields. Their result is very different than ours since they are not using Wigner distribution functions. Later work has discussed free

field propagation from partially coherent sources.[10] An important line of work was the development of theories on weak localization and coherent backscattering of photons.[11–13] There they evaluated the average electric field in the coherent potential approximation, and then used perturbation theory to get the correlation functions of the field with itself. We discuss these results further in the final section of this paper.

The general procedure is similar to that for phonons, since both particles are boson fields. There have been numerous derivations of the QBE for phonons.[14–21] However, the interaction between photons and matter is strong, so that several scattering terms must be retained in the interaction. The same terms are not kept in the QBE for phonons since the interaction there is weaker. Also, phonon scattering is dominated by anharmonic effects, and these processes are unimportant for photon diffusion. So the QBE for the two systems are different in detail.

The derivation proceeds in three stages. The next is to derive the QBE for noninteracting photons. This allows us to introduce the notation and to set up the general formalism. Sections III and IV discuss the interactions between the photon and the media. We derive the photon Green's function for systems in equilibrium. Here, we derive the important self-energy terms which also contribute to the nonequilibrium case. Section V has the case where photons diffuse through matter. Here, we assume the scattering centers are fixed. We identify the limits of coherent and incoherent scattering. The last section contains a brief discussion and summary of the results.

II. NONINTERACTING PHOTONS

The Green's function for photons is the correlation function of the vector potential $A_\mu(\mathbf{r},t)$ at two different points in space and time

$$\mathscr{D}^{<}_{\mu\nu}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2) = -i\langle A_\nu(\mathbf{r}_2,t_2)A_\mu(\mathbf{r}_1,t_1)\rangle. \tag{3}$$

The QBE for photons is the equation of motion for this correlation function. The derivation requires other correlation functions, which are defined as[8]

$$\mathscr{D}^{>}_{\mu\nu}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2) = -i\langle A_\mu(\mathbf{r}_1,t_1)A_\nu(\mathbf{r}_2,t_2)\rangle, \tag{4}$$

$$\mathscr{D}^{t}_{\mu\nu} = \theta(t_1-t_2)\mathscr{D}^{>}_{\mu\nu} + \theta(t_2-t_1)\mathscr{D}^{<}_{\mu\nu}, \tag{5}$$

$$\mathscr{D}^{\overline{t}}_{\mu\nu} = \theta(t_1-t_2)\mathscr{D}^{<}_{\mu\nu} + \theta(t_2-t_1)\mathscr{D}^{>}_{\mu\nu}, \tag{6}$$

$$\mathscr{D}^{r}_{\mu\nu} = \theta(t_1-t_2)[\mathscr{D}^{>}_{\mu\nu} - \mathscr{D}^{<}_{\mu\nu}]. \tag{7}$$

The superscripts $t,\overline{t},r$ denote the time-ordered, anti-time-ordered, and retarded Green's functions.

The Hamiltonian for photons depends upon the gauge. Here we use the gauge $\nabla\cdot\mathbf{A}=0$ which makes the scalar potential instantaneous. Then the noninteracting Hamiltonian for photons is given in terms of the electric and magnetic fields

$$H_0 = \int \frac{d^3r}{8\pi}\,[E^2+B^2], \tag{8}$$

$$\mathbf{E} = -\frac{1}{c}\frac{\partial \mathbf{A}}{\partial t}, \tag{9}$$

$$\mathbf{B} = \nabla\times\mathbf{A}. \tag{10}$$

The fields are quantized. The electric field is the conjugate momentum to the vector potential, so that the basic commutation relation is

$$[E_\mu(\mathbf{r}_1,t),A_\nu(\mathbf{r}_2,t)]=4\pi i\hbar c\,\delta_{\mu\nu}\delta^3(\mathbf{r}_1-\mathbf{r}_2). \tag{11}$$

The commutator is defined at equal times. The first equation of motion

$$\frac{\partial}{\partial t}A_\mu=i[H_0,A_\mu]=-cE_\mu \tag{12}$$

which reproduces Eq. (9). The second equation of motion is

$$\frac{\partial^2}{\partial t^2}\mathbf{A}=-ic[H_0,\mathbf{E}] \tag{13}$$

$$=c^2\boldsymbol{\nabla}\times(\boldsymbol{\nabla}\times\mathbf{A}). \tag{14}$$

The term on the right comes from the commutator of the electric and magnetic fields. We use the fact that $\boldsymbol{\nabla}\times(\boldsymbol{\nabla}\times\mathbf{A})=\nabla^2\mathbf{A}-\boldsymbol{\nabla}\boldsymbol{\nabla}\cdot\mathbf{A}$ and the second term is zero by our gauge condition. This expression is the standard equation of motion for the vector potential. For noninteracting photons, the equation of motion for the Green's functions are either of the two expressions

$$\left[\frac{\partial^2}{\partial t_1^2}-c^2\nabla_1^2\right]D^<_{\mu\nu}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2)=0, \tag{15}$$

$$\left[\frac{\partial^2}{\partial t_2^2}-c^2\nabla_2^2\right]D^<_{\mu\nu}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2)=0. \tag{16}$$

The above two expressions are equations of motion for the Green's function.

The equation we want is obtain by subtracting them. First we must go to a center-of-mass coordinate system.

$$\mathbf{r}=\mathbf{r}_1-\mathbf{r}_2, \tag{17}$$

$$\mathbf{R}=\frac{\mathbf{r}_1+\mathbf{r}_2}{2}, \tag{18}$$

$$t=t_1-t_2, \tag{19}$$

$$T=\frac{t_1+t_2}{2}, \tag{20}$$

$$\mathscr{D}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2)\rightarrow\mathscr{D}(\mathbf{r},t;\mathbf{R},T). \tag{21}$$

Here, the symbol T denotes center-of-mass time, and not temperature or time ordering. If we subtract our two equations (15) and (16), and convert to c.m. coordinates, then we find

$$2\left[\frac{\partial^2}{\partial t\partial T}-c^2\boldsymbol{\nabla}r\cdot\boldsymbol{\nabla}R\right]\mathscr{D}^<_{\mu\nu}(\mathbf{r},t;\mathbf{R},T)=0. \tag{22}$$

The next step is to Fourier transform the relative variables to $(\mathbf{q},\omega)$

$$\mathscr{D}^<(\mathbf{q},\omega;\mathbf{R},T)=\int d^3r\; e^{-i\mathbf{q}\cdot\mathbf{r}}\int dt\; e^{i\omega t}\mathscr{D}^<_{\mu\nu}(\mathbf{r},t;\mathbf{R},T) \tag{23}$$

$$\left[\omega\,\frac{\partial}{\partial T}+c^2\mathbf{q}\cdot\boldsymbol{\nabla}_R\right]\mathscr{D}^{<}_{\mu\nu}(\mathbf{q},\omega;\mathbf{R},T)=0. \tag{24}$$

Notice that the last equation is similar to a Boltzmann equation, in that there is a term with a derivative with respect to time (T) and another term with a derivative with respect to position ($\boldsymbol{\nabla}_R$). It is solved by any function of the form $f(\omega\mathbf{q}\cdot\mathbf{R}-c^2q^2T)$. Further terms are provided by the interactions.

In discussing the interactions it is useful to introduce a matrix formalism for the various Green's functions[8]

$$\widetilde{\mathscr{D}}=\begin{pmatrix}\mathscr{D}^{t} & -\mathscr{D}^{<}\\ \mathscr{D}^{>} & -\mathscr{D}^{\overline{t}}\end{pmatrix}, \tag{25}$$

$$\left(\omega\,\frac{\partial}{\partial T}+c^2\mathbf{q}\cdot\boldsymbol{\nabla}_R\right)\widetilde{\mathscr{D}}(\mathbf{q},\omega;\mathbf{R},T)=0. \tag{26}$$

Each Green's function obeys the homogeneous Boltzmann equation for noninteracting particles. Another equation we shall need is

$$\left(\frac{\partial^2}{\partial t_1^2}-c^2\nabla_1^2\right)\widetilde{\mathscr{D}}(\mathbf{r}_1,t_1;\mathbf{r}_2,t_2)=4\pi c^2\delta_{\mu\nu}\delta(t_1-t_2)\,\delta(\mathbf{r}_1-\mathbf{r}_2)\widetilde{I}, \tag{27}$$

where $\widetilde{I}$ is the unit matrix. We also give the noninteracting Green's functions, where η is infinitesimal

$$\mathscr{D}^{r}_{\mu\nu}(\mathbf{k},\omega)=\frac{4\pi c^2\hbar(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)}{\omega^2-c^2k^2+i\eta}, \tag{28}$$

$$\mathscr{D}^{<}_{\mu\nu}(\mathbf{k},\omega)=-iB(\mathbf{k},\omega)n(\omega), \tag{29}$$

$$\mathscr{D}^{>}_{\mu\nu}(\mathbf{k},\omega)=-iB(\mathbf{k},\omega)[n(\omega)+1], \tag{30}$$

$$B(\mathbf{k},\omega)=\frac{(2\pi c)^2\hbar}{ck}\,(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)[\delta(\omega-ck)-\delta(\omega+ck)], \tag{31}$$

$$n(\omega)=\frac{1}{e^{\beta\omega}-1}, \tag{32}$$

$$\mathscr{D}^{t}=\mathscr{D}^{r}+\mathscr{D}^{<}=\mathscr{D}^{>}+\mathscr{D}^{a}, \tag{33}$$

$$\mathscr{D}^{\overline{t}}=\mathscr{D}^{>}-\mathscr{D}^{r}=\mathscr{D}^{<}-\mathscr{D}^{a}. \tag{34}$$

III. PHOTONS INTERACTIONS WITH CELLS

We assume the scattering is done by particles located at points $\mathbf{R}_j$ which are fixed in position. Each scatterer is an object such as a droplet or cell which can absorb and scatter radiation. Let $\hbar\omega_l$ denote the energy of an optical transition which has a matric element $r_{l\mu}=\langle f|r_\mu|i\rangle$ between the initial and final state of that transition. The position and momentum operators for these optical transitions are[22]

$$X_\mu = \sum_l r_{l\mu}(b_l + b_l^\dagger), \tag{35}$$

$$P_\nu = -im\sum_l r_{l\nu}\omega_l(b_l - b_l^\dagger), \tag{36}$$

where b_l and $b_l^\dagger$ are the boson quantum operators of the Frenkel exciton. These position and momentum operators obey the usual commutation relation,

$$[X_\mu, P_\nu] = 2im\sum_l r_{l\mu}r_{l\nu}\omega_l = iN_c\hbar\delta_{\mu\nu}, \tag{37}$$

$$2m\sum_l r_{l\mu}r_{l\nu}\omega_l = \hbar N_c\delta_{\mu\nu}. \tag{38}$$

The last identity is the f-sum rule, where N_c is the number of electrons in the cell.

The dynamic dipole moment of the cell is eX_μ. The polarizability is the correlation of the dynamic moment with itself[22]

$$\alpha_{\mu\nu}(i\omega_n) = -\frac{e^2}{\hbar}\int_0^\beta d\tau\, e^{i\omega_n\tau}\langle T_\tau X_\mu(\tau)X_\nu(0)\rangle \tag{39}$$

$$= \frac{2e^2}{\hbar}\sum_l \frac{r_{l\mu}r_{l\nu}\omega_l}{(i\omega_n)^2 - \omega_l^2} \tag{40}$$

which has the units of volume. Here, we are using the formalism[23] at nonzero temperature, where the frequencies are imaginary $i\omega_n = 2\pi i k_B T n/\hbar$. The symbol T_τ denotes the τ-ordering operator. Our analysis will also require that we evaluate the correlation function of the momentum with itself. A short calculation gives

$$\mathscr{P}_{\mu\nu}(i\omega_n) = -\frac{e^2}{\hbar m^2}\int_0^\beta d\tau\, e^{i\omega_n\tau}\langle P(\tau)P(0)\rangle \tag{41}$$

$$= (i\omega_n)^2\alpha_{\mu\nu}(\omega_n) - \frac{e^2N_c}{m}\delta_{\mu\nu}, \tag{42}$$

where we have used the f-sum rule to derive the last expression.

The interaction between the photons and the electrons in the cell is written as

$$V = -\frac{e}{mc}\sum_j \mathbf{P}_j\cdot\mathbf{A}(\mathbf{R}_j, t) + \frac{e^2}{2mc^2}\sum_j A^2(\mathbf{R}_j, t). \tag{43}$$

The symbol $\mathbf{P}_j$ denotes the momentum operator (36) for the cell j at position $\mathbf{R}_j$. This momentum operator denotes the motion of the electrons within the cell or droplet. Another term, which we do not write, is contributed by the center-of-mass motion of the cell or droplet.

IV. HOMOGENEOUS SYSTEMS IN EQUILIBRIUM

A. Dyson's equation

First we discuss the result for homogeneous systems in equilibrium. Here, the only Green's function we need is found at complex frequencies $i\omega_n$.[8] There is no dependence upon the variables $(\mathbf{R},T)$. Dyson's equation in the Matsubara notation is

$$\mathscr{D}_{\mu\nu}(\mathbf{k},i\omega_n)=\mathscr{D}^{(0)}_{\mu\nu}(\mathbf{k},i\omega_n)+\mathscr{D}^{(0)}_{\mu\phi}(\mathbf{k},i\omega_n)M_{\phi\lambda}(\mathbf{k},i\omega_n)\mathscr{D}_{\lambda\nu}(\mathbf{k},i\omega_n), \tag{44}$$

$$\mathscr{D}^{(0)}_{\mu\nu}(\mathbf{k},i\omega_n)=\frac{4\pi c^2(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)}{(i\omega_n)^2-c^2k^2}. \tag{45}$$

The self-energy function of the photon is[22] $M_{\mu\nu}$. It is a matrix because the Green's function is also a matrix. Repeated indices imply summation.

The interaction in Eq. (43) has two types of self-energy terms. The first contains two factors of the $\mathbf{P}\cdot\mathbf{A}$ interaction, and contains the correlation function evaluated in Eq. (42). The second self-energy comes from the A^2 term in the interaction. It produces a term which is equal, and opposite in sign, to the second term in Eq. (42). The sum of the two self-energy terms is just the first term in Eq. (42) divided by c^2. When we solve Dyson's equation for homogeneous systems in equilibrium, we find the Green's function for photons of

$$\mathscr{D}_{\mu\nu}(\mathbf{k},i\omega_n)=\frac{4\pi c^2(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)}{(i\omega_n)^2\epsilon(\mathbf{k},i\omega_n)-c^2k^2}, \tag{46}$$

$$\epsilon(\mathbf{k},i\omega_n)=1+4\pi n_s\alpha(\mathbf{k},i\omega_n), \tag{47}$$

where n_s is the density of scattering centers. Here, we have derived the well-known result that the interactions produce a dielectric function $\epsilon(\mathbf{k},i\omega_n)$ which then modifies the dispersion of the photons.

B. Local field corrections

The above derivation does not include the Lorenz–Lorentz local field corrections to the dielectric function. This contribution can be included by a more careful derivation, as done in Ref. 22. One must add another interaction term which includes the dipole–dipole interaction between the fluctuations eX_j at different sites

$$V_d=e^2\sum_{ij}X_{i\mu}\phi_{\mu\nu}(\mathbf{R}_{ij})X_{j\nu}, \tag{48}$$

$$\phi_{\mu\nu}(\mathbf{R})=\frac{\delta_{\mu\nu}}{R^3}-\frac{3R_\mu R_\nu}{R^5}. \tag{49}$$

A wave vector dependent polarizability for the scattering media can be defined as

$$\alpha_{\mu\nu}(\mathbf{k},i\omega_n)=-e^2\sum_{j\neq i}e^{i\mathbf{k}\cdot\mathbf{R}_{ji}}\int_0^\beta d\tau\, e^{i\omega_n\tau}\langle T_\tau X_j(\tau)X(\tau)\rangle. \tag{50}$$

Here, one starts at one scattering site i and sums over all other scattering sites $j\neq i$. The technique for evaluating this sum, with random scattering centers, is explained in the next section. Now we show that one can derive a Dyson's equation for the polarizability using the dipole–dipole interaction plus the $p\cdot A$ interaction

$$\alpha_{\mu\nu}(\mathbf{k},i\omega_n)=\alpha_{\mu\nu}(i\omega_n)+\alpha_{\mu\phi}(i\omega_n)[t_{\phi\lambda}(\mathbf{k})+d_{\phi\lambda}(\mathbf{k},i\omega_n)]\alpha_{\lambda\nu}(\mathbf{k},i\omega_n), \tag{51}$$

$$t_{\mu\nu}(\mathbf{k})=\sum_{j\neq i} e^{i\mathbf{k}\cdot\mathbf{R}_{ji}}\phi_{\mu\nu}(\mathbf{R}_{ji}), \tag{52}$$

$$d_{\mu\nu}(\mathbf{k},i\omega_n)=\frac{\omega_n^2}{c^2}\sum_{j\neq i} e^{i\mathbf{k}\cdot\mathbf{R}_{ji}}\mathscr{D}_{\mu\nu}(\mathbf{R}_{ji},i\omega_n). \tag{53}$$

The symbol $\alpha_{\mu\nu}(i\omega_n)$ denotes the polarizability of a single scattering center, while $\alpha_{\mu\nu}(\mathbf{k},i\psi_n)$ denotes the polarizability in the actual media, including local field corrections. The Lorentz–Lorenz form of the dielectric function is obtained using the expressions

$$t_{\mu\nu}(\mathbf{k})=4\pi n_s[\hat{k}_\mu\hat{k}_\nu-\tfrac{1}{3}\delta_{\mu\nu}], \tag{54}$$

$$d_{\mu\nu}(\mathbf{k},i\omega_n)\ll 1. \tag{55}$$

Here, n_s is the density of scattering sites. This result is derived in the next section.

The photon polarization is perpendicular to the photon wave vector $\mathbf{k}$. This is ensured by the factor $(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)$. From now on we assume that all Green's functions have this factor and write

$$\mathscr{D}_{\mu\nu}(\mathbf{k},i\omega_n)=(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)\mathscr{D}(\mathbf{k},i\omega_n). \tag{56}$$

All Green's functions have a scalar factor $\mathscr{D}$ times this polarization factor. We also do this with our nonequilibrium Green's functions. Similarly, in Dyson's equation, the self-energy $M_{\mu\nu}$ becomes a scalar since its tensor components are averaged over the photon polarization. We also assume that the polarizability $\alpha_{\mu\nu}=\delta_{\mu\nu}\alpha$ is isotropic.

C. Averaging over scattering centers

Here, we wish to reexamine the above self-energy terms, and to consider carefully the method of averaging over the positions of the scattering sites $\mathbf{R}_j$. We discuss the averaging for the A^2 term in the interaction, since this self-energy is easier. However, exactly the same analysis applies to the $p\cdot A$ term. In evaluating the perturbation expansion for the S matrix, the first term which gives a self-energy has the factor

$$\frac{e^2N_c}{2mc^2}\sum_j\int d^3r_1\, e^{-i\mathbf{k}\cdot(\mathbf{r}_1-\mathbf{r}_2)}\int_0^\beta d\tau_1\int_0^\beta d\tau\, e^{i\omega_n\tau}\langle T_\tau A_\mu(\mathbf{r}_1,\tau)A^2(\mathbf{R}_j,\tau_1)A_\nu(\mathbf{r}_2,0)\rangle$$

$$=\frac{e^2N_c}{mc^2}\sum_j\int d^3r_1\, e^{-i\mathbf{k}\cdot(\mathbf{r}_1-\mathbf{r}_2)}\int_0^\beta d\tau_1\int_0^\beta d\tau\, e^{i\omega_n\tau}\mathscr{D}_{\mu\phi}(\mathbf{r}_1-\mathbf{R}_j,\tau-\tau_1)\mathscr{D}_{\phi,\nu}(\mathbf{R}_j-\mathbf{r}_2,\tau_1)$$

$$=\frac{e^2N_c}{mc^2}\mathscr{D}_{\mu\phi}(\mathbf{k},i\omega_n)\,\frac{1}{\Omega}\sum_{j\mathbf{q}} D_{\phi\nu}(\mathbf{q},i\omega_n)e^{i(\mathbf{k}-\mathbf{q})\cdot(\mathbf{R}_j-\mathbf{r}_2)},$$

where Ω is the volume. In the double sum over $(j,\mathbf{q})$, the nonzero term is where $\mathbf{q}=\mathbf{k}$ and then the sum over j gives N_s $(n_s=N_s/\Omega)$. Thus this term is

$$\frac{e^2N_cn_s}{mc^2}\mathscr{D}_{\mu\phi}(\mathbf{k},i\omega_n)\mathscr{D}_{\phi\nu}(\mathbf{k},i\omega_n). \tag{57}$$

This term leads to a self-energy of

$$\frac{e^2 N_c n_s}{m}\,\delta_{\mu\nu}. \tag{58}$$

This is the term in the first order of perturbation theory. It cancels the second term in Eq. (42).

Let us now examine the same interaction in the second order of perturbation theory. The correlation function is

$$\langle T_\tau A_\mu(\mathbf{r}_1,\tau)A^2(\mathbf{R}_i,\tau_1)A^2(\mathbf{R}_j,\tau_2)A_\nu(\mathbf{r}_2,0)\rangle \tag{59}$$

$$=4\mathscr{D}_{\mu\phi}(\mathbf{r}_1-\mathbf{R}_i,\tau-\tau_1)\mathscr{D}_{\phi\lambda}(\mathbf{R}_i-\mathbf{R}_j,\tau_1-\tau_2)\mathscr{D}_{\lambda\nu}(\mathbf{R}_j-\mathbf{r}_2,\tau_2). \tag{60}$$

There is now a double sum over the positions (i,j) of the scattering centers. We chose to omit the term where the photons successively interact with the same scattering center. This term does not contribute to scattering, and merely renormalizes the charge on the electron. So in the above expression we specify that $i\neq j$.

When we express the photon Green's functions of position as functions of wave vector, we find the factor

$$\sum_{i\neq j} e^{i(\mathbf{q}-\mathbf{k})\cdot(\mathbf{R}_i-\mathbf{R}_j)}=N_s^2\delta_{\mathbf{q}=\mathbf{k}}+N_s[S(\mathbf{q}-\mathbf{k})-1]. \tag{61}$$

The first term on the right $N_s^2\delta_{\mathbf{q}=\mathbf{k}}$ gives the square of the self-energy found in first-order. The second term gives a new contribution to the self-energy. The factor of $S(\mathbf{q}-\mathbf{k})$ is the *static structure factor*.[24] It is the term which depends on the arrangement and density of the scattering centers. The $p\cdot A$ term has a similar expression, and the again there is cancellation.

We must now determine the form for $S(q)$. There are three constraints:

(1) It vanishes at $q\to 0$.
(2) It goes to one at $qa\gg 1$ where a is a length typical of the separation between scattering centers.
(3) It obeys an important sum rule

$$\int \frac{d^3q}{(2\pi)^3}[1-S(q)]=n_s, \tag{62}$$

where n_s is the density of scattering centers.

A formula which obeys the second and third constraints is

$$1-S(q)=\frac{8\pi a^3 n_s}{[1+(qa)^2]^2}. \tag{63}$$

One can make it obey the first constraint by choosing $8\pi n_s a^3=1$ which serves to define a precisely. We do not assert that the random distribution of scattering centers always has this form for $S(q)$. Instead, we note that this choice is the simplest one which obeys all of the constraints. We shall use it in the evaluation of integrals. If the wave vector of light is k, our results for $(ka)\gg 1$ and also $(ka)\ll 1$ are independent of the choice of $S(q)$. However, having a specific form for $S(q)$ allows a reasonable interpolation between these limits.

We now can evaluate the sums over the scattering centers in Eqs. (52) and (53). First evaluate Eq. (52) which can be written

$$t_{\mu\nu}(\mathbf{k})=n_s\int d^3r\; g(\mathbf{r})\,\phi_{\mu\nu}(\mathbf{r}), \tag{64}$$

where $g(\mathbf{r})$ is the pair distribution function. We rewrite $g=(g-1)+1$. The ''1'' term is just the Fourier transform of $\phi_{\mu\nu}$ which is called $T_{\mu\nu}(\mathbf{k})$. The fourier transform of $n_s(g-1)$ is $(S-1)$ so that we derive the expression

$$T_{\mu\nu}(\mathbf{k})=4\pi\hat{k}_\mu\hat{k}_\nu, \tag{65}$$

$$t_{\mu\nu}(\mathbf{k})=n_sT_{\mu\nu}(\mathbf{k})-\int\frac{d^3q}{(2\pi)^3}[1-S(\mathbf{k}-\mathbf{q})]T_{\mu\nu}(\mathbf{q}) \tag{66}$$

$$=4\pi n_s\{\hat{k}_\mu\hat{k}_\nu-\tfrac{1}{2}[(1-\xi)\delta_{\mu\nu}-(1-3\xi)\hat{k}_\mu\hat{k}_\nu]\}, \tag{67}$$

$$\xi=\left[1+\frac{1}{\lambda^2}\right]\left[1-\frac{1}{\lambda}\tan^{-1}(\lambda)\right], \tag{68}$$

$$\lambda=ka. \tag{69}$$

A similar analysis for the summation over the photon Green's functions yields the expression

$$d_{\mu\nu}=q_n^2\left\{n_s\mathscr{D}_{\mu\nu}(\mathbf{k},i\omega_n)-\int\frac{d^3q}{(2\pi)^3}[1-S(\mathbf{q}-\mathbf{k})]\mathscr{D}_{\mu\nu}(\mathbf{q},i\omega_n)\right\}. \tag{70}$$

However, we drop the first term. We have already counted it in the self-energy of the photon, and including it here is double counting. The second term is new, and is the contribution we want

$$d_{\mu\nu}=-q_n^2\int\frac{d^3q}{(2\pi)^3}[1-S(\mathbf{q}-\mathbf{k})]\mathscr{D}_{\mu\nu}(\mathbf{q},i\omega_n) \tag{71}$$

$$=4\pi n_sz^2\left\{\frac{(\delta_{\mu\nu}-\hat{k}_\mu\hat{k}_\nu)}{\lambda^2+(1+z)^2}+\frac{\zeta}{2}(\delta_{\mu\nu}-3\hat{k}_\mu\hat{k}_\nu)\right\}, \tag{72}$$

$$\zeta=\frac{1}{\lambda^2z}-\frac{1}{\lambda^3z^2}\left[(1+\lambda^2)\tan^{-1}(\lambda)-(1+\lambda^2-z^2)\tan^{-1}\left(\frac{\lambda}{1+z}\right)\right], \tag{73}$$

$$z=aq_n=\frac{\omega_na}{c}. \tag{74}$$

These complicated expressions become simple in the two important limits.

1. $(ka)^2\ll 1$

Here, the scattering centers are close together on the scale of the wave length of light. Then one finds that $\xi=1/3+O(\lambda^2)$ and $\zeta=-2/[3(1+z)^2]$ which gives

$$t_{\mu\nu}(\mathbf{k})=-\frac{4\pi n_s}{3}[\delta_{\mu\nu}-3\hat{k}_\mu\hat{k}_\nu], \tag{75}$$

$$d_{\mu\nu}(\mathbf{k},i\omega_n)=\frac{8\pi n_s}{3}\delta_{\mu\nu}\frac{z^2}{(1+z)^2}. \tag{76}$$

Eventually we will analytically extend the imaginary frequency to the complex space $i\omega_n\to\omega$ and then $z^2\to-\lambda^2$. In this limit the term $d_{\mu\nu}$ is negligible while the term $t_{\mu\nu}$ gives a dielectric function

of the Lorentz–Lorenz form, with the local field correction. It is suitable for light propagating through fluids such as water, where the scattering centers are close together. The wavelets from the scattering add together to form a new wave, in agreement with Huygens principle.

2. $(ka)^2 \gg 1$

Here, the scattering centers are far apart on the scale of the wave length of light. In this limit we find that $\zeta \to O(1/\lambda^2 z)$ and

$$\xi \to 1 - \frac{\pi}{2\lambda} + O(1/\lambda^2), \tag{77}$$

$$t_{\mu\nu}(\mathbf{k}) = -\frac{\pi^2 n_s}{\lambda}[\delta_{\mu\nu} - 3\hat{k}_\mu \hat{k}_\nu]. \tag{78}$$

The factor $t_{\mu\nu}$ is now of order $O(1/\lambda)$ so the local field correction is small. There are not enough scattering centers, in the vicinity of each other, to provide such a correction. Similarly, the factor of $d_{\mu\nu}$ is also of $O(n_s/\lambda)$ or else $O(n_s/z)$ and is also negligible.

The case of photon diffusion has $\lambda, z \gg 1$. Here, there is no local field correction. So we generally neglect this contribution to the polarizability.

We end this section by giving the final expression for the dielectric function of the media in equilibrium

$$\epsilon(\mathbf{k}, i\omega_n) = 1 + 4\pi n_s \alpha_L(\mathbf{k}, i\omega_n)\left\{1 + 4\pi (i\omega_n)^2 \alpha_L(\mathbf{k}, i\omega_n) \int \frac{d^3q}{(2\pi)^3} \frac{\zeta(\hat{q}\cdot\hat{k})}{\omega_n^2 + c^2 q^2}[1 - S(\mathbf{q}-\mathbf{k})]\right\}, \tag{79}$$

$$\alpha_L(\mathbf{k}, i\omega_n) = \frac{\alpha(i\omega_n)}{1 + 4\pi n_s \alpha(i\omega_n) t_{\mu\mu}(\mathbf{k})}, \tag{80}$$

$$\zeta(\hat{q}\cdot\hat{k}) = \tfrac{1}{2}[1 + (\hat{q}\cdot\hat{k})^2]. \tag{81}$$

The polarization factor $\zeta(\hat{q}\cdot\hat{k})$ needs to be explained. We assume that the polarizabilities $\alpha_{\mu\nu}$ are isotropic. Then in Dyson's equation we have the combination of polarization factors

$$\rho_{\mu\nu} = (\delta_{\mu\phi} - \hat{k}_\mu \hat{k}_\phi)(\delta_{\phi\lambda} - \hat{q}_\phi \hat{q}_\lambda)(\delta_{\lambda\nu} - \hat{k}_\lambda \hat{k}_\nu) \tag{82}$$

$$= \delta_{\mu\nu} - \hat{k}_\mu \hat{k}_\nu - \hat{q}_\mu \hat{q}_\nu + (\hat{q}_\mu \hat{k}_\nu + \hat{k}_\mu \hat{q}_\nu)(\hat{q}\cdot\hat{k}) - \hat{k}_\mu \hat{k}_\nu (\hat{q}\cdot\hat{k})^2. \tag{83}$$

After doing the integrals over the variable d^3q we are left with a contribution to the Green's function which must have a net dependence of $(\delta_{\mu\nu} - \hat{k}_\mu \hat{k}_\nu)$. This latter expression can be averaged by taking the sum with $\mu = \nu$ which is two. Applying the same sum to $\rho_{\mu\nu}$ gives $1 + (\hat{q}\cdot\hat{k})^2$ and dividing by two gives ζ.

In the expression for the dielectric function, we treat differently the two factors of $t_{\mu\nu}$ and $d_{\mu\nu}$. The former contributes to the local field correction for the polarizability. The latter does not. Instead, it is just a correction to the dielectric constant. This difference occurs because $d_{\mu\nu}$ is a self-energy correction to the photon Green's function. Higher-order terms in the perturbation series are examined in Ref. 25.

V. NONEQUILIBRIUM

A. QBE

Now we consider how these interactions contribute to the QBE for photons. We assume here that the scattering centers are fixed in space.

We begin by writing Dyson's equation in real space, and introduce a four vector notation $x=(\mathbf{r},t)$. Then operating upon this equation with the left-hand side of Eq. (27)

$$\begin{aligned}\widetilde{\mathscr{D}}_{\mu\nu}(x_1;x_2)&=\widetilde{\mathscr{D}}^{(0)}_{\mu\nu}(x_1;x_2)+\int dx_3\ dx_4\ \widetilde{\mathscr{D}}^{(0)}_{\mu\phi}(x_1;x_3)\widetilde{M}_{\phi\lambda}(x_3;x_4)\widetilde{\mathscr{D}}_{\lambda\nu}(x_4;x_2)\\&\quad\times\left[\frac{\partial^2}{\partial t_1^2}-c^2\nabla_1^2\right]\widetilde{\mathscr{D}}_{\mu\nu}(x_1;x_2)\\&=4\pi c^2\delta_{\mu\nu}\delta(x_1-x_2)\widetilde{I}+4\pi c^2\\&\quad\times\int dx_3\ \widetilde{M}_{\mu\lambda}(x_1;x_3)\widetilde{\mathscr{D}}_{\lambda\nu}(x_3;x_2)\left[\frac{\partial^2}{\partial t_2^2}-c^2\nabla_2^2\right]\widetilde{\mathscr{D}}_{\mu\nu}(x_1;x_2)\\&=4\pi c^2\delta_{\mu\nu}\delta(x_1-x_2)\widetilde{I}+4\pi c^2\int dx_3\ \widetilde{\mathscr{D}}_{\mu\phi}(x_1;x_3)\widetilde{M}_{\phi\nu}(x_3;x_2).\end{aligned}$$

We have given the equations obtained when one takes derivatives either with respect to the x_1 or to the x_2 variable. The QBE is obtained by subtracting these last two equations, and then changing to center-of-mass variables

$$\begin{aligned}2i\left(\omega\frac{\partial}{\partial T}+c^2\mathbf{q}\cdot\boldsymbol{\nabla}\right)\widetilde{\mathscr{D}}(\mathbf{q},\omega;\mathbf{R},T)&=4\pi c^2[\widetilde{M}(\mathbf{q},\omega;\mathbf{R},T)\widetilde{\mathscr{D}}(\mathbf{q},\omega;\mathbf{R},T)\\&\quad-\widetilde{\mathscr{D}}(\mathbf{q},\omega;\mathbf{R},T)\widetilde{M}(\mathbf{q},\omega;\mathbf{R},T)].\end{aligned}\tag{84}$$

The matrix $\widetilde{M}$ has the same arrangement of elements as Eq. (25). We have neglected terms which contain derivatives with respect to the variables $\mathbf{R}$ and T. The left-hand side of this equation has the same terms we have for the noninteracting QBE. The terms on the right involving the self-energy operator $\widetilde{M}$ are the contributions of the interactions. This factor is nonzero since the two matrices do not commute. The various terms which contribute to the self-energy in equilibrium also contribute to the scattering and interactions in nonequilibrium. We now examine these various terms to see how they enter into the QBE for photons.

An important question is whether the scattering center remains in thermal equilibrium. When the photons diffuse they are not in thermal equilibrium. Whether the scattering centers remain in equilibrium depends upon their connection to the heat bath. If the scattering centers are the cells of the body, they are probably well connected to a heat bath. We will assume this to be the case. The cells absorb radiation, and convert it to heat. A counter example is when the scattering is done by individual atoms in a gas. The atoms have no place to dissipate their energy except by reradiating the absorbed photons. Then the atoms are out of equilibrium along with the photons.

B. First-order scattering

There are two scattering terms. As for the case of equilibrium, the lowest order term is from $\mathscr{P}(\omega)$ which gives $\widetilde{M}=n_s(\omega/c)^2\widetilde{\alpha}(\omega)$. The commutator of the two matrices is

$$\widetilde{\alpha}\widetilde{\mathscr{D}}-\widetilde{\mathscr{D}}\widetilde{\alpha}=[\alpha^{>}\mathscr{D}^{<}-\alpha^{<}\mathscr{D}^{>}]\begin{pmatrix}1&-1\\1&-1\end{pmatrix}.\tag{85}$$

In equilibrium we have that

$$\alpha^{<} = -in(\omega)A(\omega), \tag{86}$$

$$\alpha^{>} = -i[n(\omega)+1]A(\omega), \tag{87}$$

$$A(\omega) = 2\pi \frac{e^2}{\hbar} \sum_l r_{l\mu}^2 [\delta(\omega-\omega_l) - \delta(\omega+\omega_l)]. \tag{88}$$

We assume that the photons are only slightly out of equilibrium. The photon Green's functions $\mathscr{D}^{<}$ and $\mathscr{D}^{>}$ both equal their equilibrium part plus a nonequilibrium term $\delta\mathscr{D}$. The QBE for the nonequilibrium part is, including only the absorption term in the scattering part,

$$\left[\omega \frac{\partial}{\partial T} + c^2 \mathbf{q}\cdot\boldsymbol{\nabla}_R + 2\pi n_s \omega^2 A(\omega)\right]\delta\mathscr{D} = 0. \tag{89}$$

The last term in brackets is due to photon absorption at the cells, where n_s is the volume density of such scatterers, and $A(\omega)$ is the spectral function of the polarizability.

C. Second-order scattering

There is a self-energy term in the equilibrium case (60) which is due to a double scattering event. Here, we consider how the same term enters into the scattering term for the QBE. For this case we can write the matrix $\widetilde{M}$ as

$$\widetilde{M} = n_s \left(\frac{\omega}{c}\right)^4 \widetilde{\alpha}\widetilde{D}'\widetilde{\alpha}, \tag{90}$$

$$\widetilde{D}' = \frac{1}{2\Omega} \sum_{\mathbf{q}'} [1+(\hat{q}\cdot\hat{q}')^2][S(\mathbf{q}-\mathbf{q}')-1]\widetilde{\mathscr{D}}(\mathbf{q}',\omega;\mathbf{R},T). \tag{91}$$

In order to evaluate the scattering term we need the combination of matrix multiplications

$$\widetilde{N} = \widetilde{\alpha}\widetilde{D}'\widetilde{\alpha}\widetilde{\mathscr{D}} - \widetilde{\mathscr{D}}\widetilde{\alpha}\widetilde{D}'\widetilde{\alpha}. \tag{92}$$

This expression is complicated. For the QBE we only need the component N_{12} of the 2×2 matrix which gives the contribution to $\mathscr{D}^{<}$. After much algebra we find

$$N_{12} = -D^{<}[D_r'\alpha_r^2 - D_a'\alpha_a^2] + (D^{>}-D^{<})[\alpha^{<}(\alpha_r D_r' + \alpha_a D_a') + \alpha_r\alpha_a D^{<\prime}]. \tag{93}$$

Usually we assume that the system is only slightly out of equilibrium. Then we set the photon Green's functions to an equilibrium part plus a nonequilibrium part $D \to D + \delta D$, etc. The term containing only equilibrium factors vanishes. We linearize the equations and retain only the terms proportional to one power of the nonlinear component.

$$\delta N_{12} = \delta D'\alpha_r\alpha_a[D^{>}-D^{<}] - \delta\mathscr{D}[D_r'\alpha_r^2 - D_a'\alpha_a^2]. \tag{94}$$

Factors such as $D^{>}, D^{<}, D_r', D_a'$ are evaluated using their equilibrium values. The first term on the right is due to the nonequilibrium $\delta D'$. It is due to the photons scattering back into the distribution. The term proportional to $\delta\mathscr{D}$ is scattering out of the distribution of photons. The rates of these two process are not equal. However, we can rearrange this expression to give

$$\delta N_{12} = i\alpha_r\alpha_a[B\,\delta D' - B'\,\delta\mathscr{D}] + 2iA\,\delta\mathscr{D}\Re\{\alpha_r\mathscr{D}_r\}. \tag{95}$$

The last term on the right is a contribution to the absorption coefficient. The first two terms give the scattering in and out of the photons from the distribution. These terms are now symmetrical.

When photons diffuse they scatter without changing frequencies. In the expression for $[1-S(\mathbf{q}-\mathbf{k})]$ the two wave vectors will have the same magnitude: $|\mathbf{q}|=|\mathbf{k}|$. This factor depends mainly on the scattering angle θ between these two vectors. Define $\mu=\cos(\theta)$ so that $\mathbf{q}\cdot\mathbf{k}=k^2\mu$ then our expression for the structure factor becomes

$$[1-S(\mathbf{q}-\mathbf{k})]=\frac{1}{[1+2(ka)^2(1-\mu)]^2}. \tag{96}$$

In the diffusion regime, where $ka\gg 1$, then this function is highly peaked for forward scattering ($\mu\sim 1$). Thus we have shown that photon scattering is peaked in the forward direction. This is well known to workers in the field. However, they have attributed the forward scattering to the properties of a single cell, which is approximated as a water droplet. Here, we note that another contribution to the forward scattering is the distribution of cells.

D. *J* algebra

So far we have treated the self-energies in the first two orders of perturbation. We wish to sum subsets of diagrams to all orders of perturbation. We have found a simple method of doing this using an algebra based on a matrix we call $\tilde{J}$

$$\tilde{J}=\begin{pmatrix}1 & -1\\ 1 & -1\end{pmatrix}. \tag{97}$$

Now it is possible to prove some theorems

$$(1)\,\tilde{J}\tilde{J}=0, \tag{98}$$

$$(2)\,\tilde{\alpha}\tilde{J}=\alpha_r\tilde{J}, \tag{99}$$

$$(3)\,\tilde{J}\tilde{\alpha}=\alpha_a\tilde{J}, \tag{100}$$

where products of matrices imply matrix multiplication.

The first theorem is obvious by inspection. The second and third are proved similarly, and it is sufficient to prove one, say the second. From the definition of the matrices we get

$$\tilde{\alpha}\tilde{J}=\begin{pmatrix}\alpha^t & -\alpha^<\\ \alpha^> & -\overline{\alpha^t}\end{pmatrix}\begin{pmatrix}1 & -1\\ 1 & -1\end{pmatrix} \tag{101}$$

$$=\begin{pmatrix}\alpha^t-\alpha^< & -\alpha^t+\alpha^<\\ \alpha^>-\overline{\alpha^t} & -\alpha^>+\overline{\alpha^t}\end{pmatrix} \tag{102}$$

$$=\alpha^r\begin{pmatrix}1 & -1\\ 1 & -1\end{pmatrix}, \tag{103}$$

where we have used the identities that $\alpha^r=\alpha^t-\alpha^<=\alpha^>-\overline{\alpha^t}$.

These results allow us to evaluate in a simple way any product of matrices containing one $\tilde{J}$ matrix. An example is

$$\tilde{\alpha}\tilde{D}\tilde{J}\tilde{\alpha}=\alpha_r\alpha_a D_r\tilde{J}. \tag{104}$$

Any matrix to the left of $\tilde{J}$ gets replaced by its retarded function, and any matrix to the right of $\tilde{J}$ gets replaced by its advanced function. Any string with two of them is zero.

This simple algebra allows us to evaluate in a simple way the perturbation series for the photon self-energies. The photon Green's function matrix is evaluated as an equilibrium term plus a nonequilibrium term δD which is the same for every element of the matrix

$$\mathscr{D} \to \mathscr{D} + \delta D \tilde{J}. \tag{105}$$

The nonequilibrium term is proportional to the $\tilde{J}$ matrix. As an example, consider the second-order self-energy evaluated in the prior section

$$\tilde{N} = \tilde{\alpha}\tilde{D}'\tilde{\alpha}\tilde{D} - \tilde{D}\tilde{\alpha}\tilde{D}'\tilde{\alpha}. \tag{106}$$

We find the term proportional to one power of the nonequilibrium part

$$\delta\tilde{N} = \delta D[\tilde{\alpha}\tilde{D}'\tilde{\alpha}\tilde{J} - \tilde{J}\tilde{\alpha}\tilde{D}'\tilde{\alpha}] + \delta D'[\tilde{\alpha}\tilde{J}\tilde{\alpha}\tilde{D} - \tilde{D}\tilde{\alpha}\tilde{J}\tilde{\alpha}] \tag{107}$$

$$= \delta D[\alpha_r^2 D_r' - \alpha_a^2 D_a'] + \alpha_r \alpha_a \delta D'[D_a - D_r]. \tag{108}$$

This gives the prior result, and by a derivation which takes only a few lines. Similarly, in the next higher order of perturbation theory we find

$$\tilde{N} = \tilde{\alpha}\tilde{D}'\tilde{\alpha}\tilde{D}'\tilde{\alpha}\tilde{D} - \tilde{D}\tilde{\alpha}\tilde{D}'\tilde{\alpha}\tilde{D}'\tilde{\alpha}, \tag{109}$$

$$\delta\tilde{N} = \delta D\tilde{J}[\alpha_r^3 D_r'^2 - \alpha_a^3 D_a'^2] + \delta D'\tilde{J}\alpha_r\alpha_a[\alpha_r D_r' + \alpha_a D_a'][D_a - D_r]. \tag{110}$$

Continuing in his way we can easily derive the expressions for terms in the higher order of perturbation theory. Then it is possible to sum the series and we finally obtain the total result

$$\begin{aligned}
\delta\tilde{N} &= \delta D\tilde{J}\left[\frac{\alpha_r}{1-\alpha_r D_r'} - \frac{\alpha_a}{1-\alpha_a D_a'}\right] \\
&= \frac{\alpha_r\alpha_a\delta D'}{(1-\alpha_r D_r')(1-\alpha_a D_a')}\,\tilde{J}[D_r - D_a] \\
&= \frac{\alpha_r\alpha_a}{(1-\alpha_r D_r')(1-\alpha_a D_a')}\,\tilde{J}[\delta D(D_r' - D_a') - \delta D'(D_r - D_a)] + \frac{(\alpha_r - \alpha_a)\delta D}{(1-\alpha_r D_r')(1-\alpha_a D_a')}\,\tilde{J}.
\end{aligned} \tag{111}$$

We have presented two equivalent expressions. In the second expression, we have grouped them such that the first two terms describe scattering, while the last term describes absorption.

The effect of the higher-order terms is to provide terms in the denominator such as $(1 - \alpha_r D_r')$ and $(1 - \alpha_a D_a')$. These provide local field corrections to the polarizabilities of the scattering centers. As remarked earlier, for the case of photon diffusion these terms are negligible. We omit them since we are primarily interested in this case. Then the absorption term is given by the expression derived from the first-order scattering. The QBE we have derived so far, including second order terms, is

$$\begin{aligned}
&\left[\omega\,\frac{\partial}{\partial T} + c^2\mathbf{q}\cdot\boldsymbol{\nabla} + 2\pi c^2(\Gamma_a(\omega) + \Gamma_s(\mathbf{q},\omega)]\,\delta D(\mathbf{q},\omega;\mathbf{R},T)\right. \\
&\quad = 2\pi c^2 n_s B(\mathbf{q},\omega;\mathbf{R},T)\int \frac{d^3k}{(2\pi)^3}\,\delta D(\mathbf{k},\omega;\mathbf{R},T)\,\frac{d\sigma(\hat{q}\cdot\hat{k})}{d\Omega}\,[1 - S(\mathbf{q}-\mathbf{k})],
\end{aligned} \tag{112}$$

$$\Gamma_a(\omega) = n_s \left(\frac{\omega}{c}\right)^2 A(\omega), \tag{113}$$

$$\Gamma_s(\mathbf{q},\omega;\mathbf{R},T) = n_s \int \frac{d^3k}{(2\pi)^3} B(\mathbf{k},\omega;\mathbf{R},T) \frac{d\sigma(\hat{q}\cdot\hat{k})}{d\Omega} [1 - S(\mathbf{q}-\mathbf{k})], \tag{114}$$

$$\frac{d\sigma(\hat{q}\cdot\hat{k})}{d\Omega} = \left(\frac{\omega}{c}\right)^4 \alpha(\omega)^2 \frac{1}{2}[1 + (\hat{q}\cdot\hat{k})^2]. \tag{115}$$

This QBE is the main result of this calculation. In the next section we discuss various moments of this equation.

We have written the scattering in terms of the differential cross section for the photon scattering. We also give the cross section for Rayleigh scattering. Another important scattering source is Mie scattering from a dielectric sphere. Mie scattering is the correct theory if the scattering centers are spheres. Examples are water droplets in clouds or else latex balls suspended in water. The theory of Mie scattering is given in standard textbooks.[26] A very interesting test of the theory is given by Zaccanti and Bruscaglioni.[27] They show that the Mie scattering is highly peaked in the forward direction when $a \gg \lambda$, where a is the radius of the spheres.

VI. MOMENTS

One of our goals is to derive Eq. (1). Since it does not depend upon the frequency variable ω then this equation is obtained from our QBE by an integration over frequency.

''Moment equations'' are the name applied to macroscopic equations obtained by integrating the QBE over frequency, over wave vector, or both. Functions of frequency and wave vector are inserted into these integrals to give various macroscopic equations. We know in advance that we should obtain equations which depend upon macroscopic quantities such as

(1) The number density of photons $f(\mathbf{q},\mathbf{r},t)$.

(2) The photon energy density which depends upon electric **E** and magnetic **B** fields

$$\mathscr{E}(\mathbf{R},T) = \frac{1}{8\pi}[E^2(\mathbf{R},T) + B^2(\mathbf{R},T)]. \tag{116}$$

(3) The Poynting vector for energy flux

$$\mathbf{S}(\mathbf{R},T) = \frac{c}{4\pi} \mathbf{E}\times\mathbf{B}. \tag{117}$$

Since the last two quantities do not depend upon **q** or ω they are moments obtained by integrating over both $d\omega$ and d^3q.

A. Equilibrium moments

A useful introduction to this topic is obtained by taking moments of the equilibrium functions. They provide a guide to possible macroscopic variables. The basic definitions are in Eqs. (29) and (31). The polarization tensor $(\delta_{\mu\nu} - \hat{q}_\mu \hat{q}_\nu)$ is evaluated by taking its trace which is 2

$$i\sum_\mu \mathscr{D}^<_{\mu\nu}(\mathbf{q},\omega) = 2B(q,\omega)n(\omega), \tag{118}$$

$$B(q,\omega) = \frac{(2\pi c)^2\hbar}{\omega_q}[\delta(\omega-\omega_q) - \delta(\omega+\omega_q)], \tag{119}$$

$$\Lambda_n(q)=\int \frac{d\omega}{2\pi}\,\omega^n B(q,\omega)n(\omega), \tag{120}$$

$$\Lambda_0=\frac{(2\pi c)^2\hbar}{\omega_q}\,[2n(\omega_q)+1], \tag{121}$$

$$\Lambda_1=-(2\pi c)^2\hbar, \tag{122}$$

$$\Lambda_2=(2\pi c)^2\hbar\,\omega_q[2n(\omega_q)+1]. \tag{123}$$

The moment Λ_0 appears to be the particle density, while Λ_2 is the energy density. The moment Λ_1 is just a constant. The even moments are proportional to the photon occupation number $n(\omega_q)$. They are candidates for being a distribution function. The odd moments are not proportional to the photon density.

B. Nonequilibrium moments

Here, we evaluate the same moments using the nonequilibrium distributions. We define them as

$$\Xi_n(\mathbf{q},\mathbf{R},T)=i\int \frac{d\omega}{2\pi}\,\omega^n\sum_\mu \mathscr{D}^<_{\mu\mu}(\mathbf{q},\omega;\mathbf{R},T)$$
$$=i^n\int dt\,\delta(t)\int d^3r\; e^{-i\mathbf{q}\cdot\mathbf{r}}\frac{\partial^n}{\partial t^n}\sum_\mu\left\langle A_\mu\left(\mathbf{R}+\frac{\mathbf{r}}{2};T+\frac{t}{2}\right)A_\mu\left(\mathbf{R}-\frac{\mathbf{r}}{2};T-\frac{t}{2}\right)\right\rangle. \tag{124}$$

We have used the definition of the correlation functions as a Wigner distribution function. From now on, in this section, the summation over μ is intended, but is not written explicitly. The first moments are as follows.

1. $n=0$. Here, there are no time derivatives. This suggests the following definition for the photon density:

$$f(\mathbf{q},\mathbf{R},T)=\frac{\omega_q}{(2\pi c)^2\hbar}\int d^3r\; e^{-i\mathbf{q}\cdot\mathbf{r}}\left\langle A_\mu\left(\mathbf{R}+\frac{\mathbf{r}}{2};T\right)A_\mu\left(\mathbf{R}-\frac{\mathbf{r}}{2};T\right)\right\rangle. \tag{125}$$

2. $n=1$. Here, there is a single time derivative. We use the notation $A(\pm)$ to denote $A_\mu(\mathbf{R}\pm\frac{\mathbf{r}}{2},T)$. In the following equations, we use the fact that the time derivative of the vector potential is proportional to the electric field

$$\Xi_1=\frac{i}{2}\int d^3r\; e^{-i\mathbf{q}\cdot\mathbf{r}}\langle\dot{A}(+)A(-)-A(+)\dot{A}(-)\rangle \tag{126}$$

$$=-\frac{ic}{2}\int d^3r\; e^{-i\mathbf{q}\cdot\mathbf{r}}\langle E(+)A(-)-A(+)E(-)\rangle. \tag{127}$$

The quantity in brackets would be the commutator of the electric field with the vector potential, except that the space arguments in the last term are interchanged. So this moment has a complex behavior. It is not a simple constant, as it was for the equilibrium case.

3. $n=2$. There are two time derivatives which can be expressed as

$$\Xi_2=-\frac{1}{4}\int d^3r\; e^{-i\mathbf{q}\cdot\mathbf{r}}\langle\ddot{A}(+)A(-)+A(+)\ddot{A}(-)-2\dot{A}(+)\dot{A}(-)\rangle \tag{128}$$

$$= -\int d^3r\ e^{-i\mathbf{q}\cdot\mathbf{r}}\left[\frac{\partial^2}{4\partial T^2}\langle A(+)A(-)\rangle - \langle \dot{A}(+)\dot{A}(-)\rangle\right]. \tag{129}$$

The first term in brackets is the second time (i.e., T) derivative of $f(\mathbf{q},\mathbf{R},T)$. The last term in the bracket is just the correlation function of the electric field with itself $c^2\langle E(+)E(-)\rangle$ and is related to the energy density. For equilibrium moments the second moment was proportional to the density of photons

$$(2\pi)^2\hbar W(\mathbf{q},\mathbf{R},T) = \int d^3r\ e^{-i\mathbf{q}\cdot\mathbf{r}}\langle E_\mu(\mathbf{R}+\tfrac{1}{2}\mathbf{r},T)E_\mu(\mathbf{R}-\tfrac{1}{2}\mathbf{r},T)\rangle. \tag{130}$$

It is reasonable to suggest that the distribution W, from the energy density, is proportional to $f(\mathbf{q},\mathbf{R},T)$. We can express even moments in terms of this distribution function. However, the odd moments must be another function.

C. Boltzmann equation

Now we turn to the derivation of Eq. (1). The obvious way to obtain this equation is to integrate the QBE over all frequency: to take its zeroth moment. For this discussion, we focus initially on the first two terms in the QBE which are

$$\left[\omega\frac{\partial}{\partial T} + c^2\mathbf{q}\cdot\boldsymbol{\nabla}\right]\mathscr{D} = . \tag{131}$$

If we integrate this equation over all frequency, then there is a problem. The first term has the first moment while the second term has a zeroth moment. These two moments are fundamentally different, since one is proportional to the density of photons while the odd moment is something else. This problem is not corrected by multiplying the equation by any power of ω, since one term will be an even moment and the other will be an odd moment.

We examined the references on the QBE for phonons, to see how previous authors solved the problem there. They obtained a BE by a procedure which we regard as incorrect. They *assumed* that[9–16]

$$\mathscr{D}^< = C(q)\,\delta(\omega-\omega_q)f(\mathbf{q},\mathbf{R},T), \tag{132}$$

where $C(q)$ is a function of q. With this assumption, the zeroth moment of frequency gives an equation similar to Eq. (1). However, our moment analysis has shown this assumption is incorrect. There is no reason to omit the contribution from negative frequencies.

We decided to proceed by deriving two distribution functions. The first is $f(\mathbf{q},\mathbf{R},T)$ which is defined in Eq. (125), and which is related to the density of photons. The second we define as $g(\mathbf{q},\mathbf{R},T)$ is related to the odd moments of the distribution function

$$(2\pi c)^2\hbar g(\mathbf{k},\mathbf{R},T) = \int \frac{d\omega}{2\pi}\,\omega\mathscr{D}(\mathbf{k},\omega,\mathbf{R},T). \tag{133}$$

This correlation is proportional to the bracket in Eq. (127). Using this definition, we can now take moments of the Boltzmann equation. In doing the frequency integral, we examine the parity of the terms multiplying $\mathscr{D}$ in the frequency integrand. If these terms are even in frequency, such as ω^{2n} or else $\omega A(\omega)$, then this integral is proportional to $f(\mathbf{q},\mathbf{R},T)$. However, if these factors are odd functions of frequency, then we suppose the integral is proportional to $g(\mathbf{q},\mathbf{R},T)$. The division of terms into odd and even functions of frequency allows us to define the absorption and scattering terms.

1. n=0

We take the frequency integral of the QBE in Eq. (112) and derive

$$\frac{\partial}{\partial T}\, g + c\hat{q}\cdot\nabla f + \left(\frac{1}{\tau_a}+\frac{1}{\tau_s}\right) g = \frac{1}{\tau_s}\int \frac{d\Omega'}{4\pi}\, P(\hat{q}\cdot\hat{k}) g(\mathbf{k},\mathbf{R},T), \tag{134}$$

$$\frac{1}{\tau_a} = 2\pi n_s \omega_q A(\omega_q), \tag{135}$$

$$\frac{1}{\tau_s} = \frac{(2\pi)^3 c^4}{\omega_q^2}\, n_s \int \frac{d^3k}{(2\pi)^3}\, \delta(\omega_k-\omega_q)\, \frac{d\sigma(\hat{q}\cdot\hat{k})}{d\Omega}\, [1-S(\mathbf{q}-\mathbf{k})]$$

$$= c n_s \int d\Omega'\, \frac{d\sigma(\cos(\theta))}{d\Omega'}\, [1-S(2q\ \sin(\theta/2))], \tag{136}$$

$$P(\hat{q}\cdot\hat{k}) = c\tau_s n_s\, \frac{d\omega(\cos(\theta))}{d\Omega'}\, [1-S(2q\ \sin(\theta/2))]. \tag{137}$$

Note that the structure factor $1-S$ enters into the definition of the scattering function $P(\hat{q}\cdot\hat{k})$. Previous workers only included the scattering cross section in this function.

2. n=1

Here, we multiply the QBE by ω and integrate over all frequencies. Sorting integrands according to whether they are even or odd functions of frequency produces the following equation:

$$\frac{\partial}{\partial T}\left[W - \frac{1}{4\omega_q^2}\frac{\partial^2}{\partial T^2}\, f\right] + c\hat{q}\cdot\nabla g + \left(\frac{1}{\tau_a}+\frac{1}{\tau_s}\right) f = \frac{1}{\tau_s}\int \frac{d\Omega'}{4\pi}\, P(\hat{q}\cdot\hat{k}) f(\mathbf{k},\mathbf{R},T). \tag{138}$$

The terms for absorption and scattering are the same ones in Eq. (134). We make two approximations on this expression. First, we neglect the triple time derivative of f. Since we are interested in diffusion, then they should give a very small contribution. Second, we assume the energy density is just the phonon frequency multiplied by f. If this is true, then $W=f$. With these two assumptions, Eq. (138) becomes

$$\frac{\partial}{\partial T}\, f + c\hat{q}\cdot\nabla g + \left(\frac{1}{\tau_a}+\frac{1}{\tau_s}\right) f = \frac{1}{\tau_s}\int \frac{d\Omega'}{4\pi}\, P(\hat{q}\cdot\hat{k}) f(\mathbf{k},\mathbf{R},T). \tag{139}$$

When we compare Eqs. (134) and (139) we see they are similar. One is found from the other by exchanging f and g. It makes sense to alternately add these two equations, or subtract them

$$f^{(\pm)} = f \pm g,$$

$$\left[\frac{\partial}{\partial T} + c\hat{q}\cdot\nabla + \left(\frac{1}{\tau_a}+\frac{1}{\tau_s}\right)\right] f^{(+)} = \frac{1}{\tau_s}\int \frac{d\Omega'}{4\pi}\, P(\hat{q}\cdot\hat{k}) f^{(+)}(\mathbf{k},\mathbf{R},T),$$

$$\left[\frac{\partial}{\partial T} - c\hat{q}\cdot\nabla + \left(\frac{1}{\tau_a}+\frac{1}{\tau_s}\right)\right] f^{(-)} = \frac{1}{\tau_s}\int \frac{d\Omega'}{4\pi}\, P(\hat{q}\cdot\hat{k}) f^{(-)}(\mathbf{k},\mathbf{R},T). \tag{40}$$

The first of these two equations is the same as Eq. (1). Thus we have derived this equation, which was one of the goals of this paper. We now see that it is the Boltzmann equation for the combination $f^{(+)}=f+g$. We associate this function with photons of positive frequency. We have also derived a second equation for $f^{(-)}=f-g$. We associate this function with photons of negative

frequency. Without any interactions, then $f^{(+)}=F(\mathbf{q}\cdot\mathbf{R}-\omega T)$ while $f^{(-)}=F(\mathbf{q}\cdot\mathbf{R}+\omega T)$. Obviously $f^{(+)}$ corresponds to the physics convention that a wave of positive $\mathbf{q}$ and positive frequency moves in the direction $\mathbf{R}$ with increasing time.

VII. DISCUSSIONS

We have provided the first derivation of the quantum Boltzmann equation for photons. We have showed how the usual Boltzmann equation for the photon density can be derived from this QBE by taking moments. One result of this derivation is an explicit expression for the scattering term in the Boltzmann equation. This function contains a factor which relates to the distribution of scattering centers. We also showed that there are negligible local field corrections for the case of photon diffusion, which is the primary application of the QBE. Finally, we introduced a matrix $\tilde{J}$ which makes the discussion of perturbation expansions very easy.

Stephen[12] has discussed the phenomena of photon diffusion and coherent backscattering. His analysis is derived from the correlation function of the electric field with itself. His analysis starts from a different point, the electric field in the coherent potential approximation. We tried and failed to derive coherent backscattering using our formalism. We summed several sets of diagrams, besides those reported here. We summed every set we could imagine. But none gave coherent backscattering. We are still working on this problem.

The behavior of the nontruncated and truncated Efimov–Fradkin models ($\mathscr{L}_{\rm int}=-\Sigma_{n=3}^{N}\lambda_n\varphi^n$) at finite temperature in a generic D-dimensional flat space–time was investigated. The thermal contribution to the renormalized mass and coupling constants are obtained in the one-loop approximation by the use of a mix between dimensional and the Epstein zeta function analytic regularization and a modified minimal subtraction procedure. We proved that for $D_c(N-1)\leqslant D$ there is not a temperature for which at least one of the renormalized coupling constants becomes zero, where $D_c(N-1)$ is the critical spacetime dimension for the renormalized coupling constant λ_{N-1}. For $D_c(N)\leqslant D<D_c(N-1)$ only the renormalized coupling constant λ_{N-1} becomes zero at some temperature β_{N-1}^{-1}. For $D<D_c(N)$ the renormalized coupling constants $\lambda_{N-1}(\beta)$ and $\lambda_N(\beta)$ become zero at temperatures β_{N-1}^{-1} and β_N^{-1}, respectively. In the latter situation, for temperatures $\beta_{N-1}^{-1}<\beta^{-1}<\beta_N^{-1}$ the effective potential has a global minimum. For temperatures above β_N^{-1}, the system can develop a first order phase transition, where the origin corresponds to a metastable vacuum. In the nontruncated model, corresponding to a nonpolynomial Lagrange density, for $D\geqslant 2$ all the coupling constants remain positive for any temperature. © *1996 American Institute of Physics.*

I. INTRODUCTION

In this paper an attempt is made to understand the vacuum stability mechanism in scalar models at finite temperature assuming polynomial and nonpolynomial Lagrange densities. It is of common knowledge that the ultraviolet divergences that arise in models with nonpolynomial Lagrange densities are not worse graph by graph than those encountered in polynomial renormalizable models.[1] This result was obtained using a summation method introduced by Efimov and Fradkin.[2,3] The idea of the method is to investigate the Borel summability of the divergent perturbative series.[4] The interaction Lagrange density of these models may be expanded in a power series of the type,

$$\mathscr{L}_{\rm int}=-\lim_{N\to\infty}\sum_{n=3}^{N}\lambda_n\varphi^n(x), \tag{1}$$

where $\varphi(x)$ is a Hermitian scalar field and λ_n are the coupling constants of the model.

Instead of regularizing the model using a ultraviolet cutoff Λ in the Euclidean momenta, or assuming the existence of a spacetime microscopic structure, characterized by a lattice spacing a, we preferred to regularize it by using a combination of two different methods: the dimensional[5] and analytic regularization methods.[6] The advantage of this technique lies in the fact that the dependence of mass and coupling constant with the temperature appear in a very straightforward

way. A recent discussion on the relation between the cutoff method and analytical regularization procedures to obtain the Casimir energy in an arbitrary ultrastatic spacetime with or without boundaries, may be found in Svaiter and Svaiter.[7] Upon the application of the analytic regularization method, a mass parameter μ is introduced, in order to deal with dimensionless quantities in the analytic extensions. It is not difficult to show that the canonical dimension of the coupling constants of the model are given by

$$\lambda_n = \mu^{D-(n/2)(D-2)}, \tag{2}$$

where D is the space–time dimension. Each coupling constant in the expansion given by Eq. (1) has a critical dimension $D_c(n)$. By critical dimension of each coupling constant we mean a space–time dimension such that below it the coupling constant may be a large quantity due to its positive dimension $D-(n/2)(D-2)$ in terms of μ (or using the critical phenomena language, in terms of the original scale $1/a$, where a is the lattice spacing). We define the critical space–time dimension $D_c(n)=2n/(n-2)$, as the space–time dimension where the renormalized coupling constant λ_n is dimensionless. Below $D_c(n)$, the model is superrenormalizable. We demonstrate that in the superrenormalizable case above some temperature the system may suffer a first order phase transition.

In two recent papers studying the $\lambda\varphi^4$ model, the possibility of changing the sign of the renormalized coupling constant was raised.[8,9] In the first one, the thermal and topological contributions to the renormalized mass and renormalized coupling constant in the one-loop approximation were obtained.[8] In the second one we extended the study of the $\lambda\varphi^4$ model at finite temperature to a generic D-dimensional space–time with trivial topology of the spacelike section and we also discussed the behavior with the temperature of the Gross–Neveu model, which is an ultraviolet asymptotically free model. In the Gross–Neveu model, we proved that for $D=3$ the thermal contribution to the renormalized coupling constant is zero. On the other hand, for $D\neq 3$ our results are inconclusive.[9] Studying the $\lambda\varphi^4$, model we obtained more concrete results. Still using the effective potential and the one-loop approximation, we presented the thermal contribution to the renormalized mass and coupling constant. The thermal renormalized coupling constant is given by

$$\lambda(\beta)=\lambda(\infty)+\Delta\lambda(\beta), \tag{3}$$

where $\lambda(\infty)$ is the temperature independent renormalized coupling constant and $\Delta\lambda(\beta)$ is its thermal correction. Using the fact that $\Delta\lambda(\beta)$ is negative, we proved that for $D<4$, at sufficiently high temperatures, the system may suffer a first order phase transition with a metastable vacuum at the origin.

In the majority of the papers in the literature the temperature dependence of the renormalized coupling constant is neglected. This approach is reasonable if we are interested in studying a second order phase transition. In this case, the variation of the squared mass with the temperature is the most important fact. Therefore, it is sufficient to consider the renormalized coupling constant as independent of the temperature, and the sign of the squared mass drives the second order phase transition. The situation that we are interested in discussing here is quite different, since the goal of our investigation is not the behavior of the system in the neighborhood of a second order phase transition. Our intention is to study the model in the high temperature regime (far from a critical temperature), where the possibility of vanishing some renormalized coupling constant with a first order phase transition at some temperature arises.

We would like to emphasize that the study of the dependence of the coupling constant with the temperature is not new in the literature. Many authors have studied such dependence in scalar models[10] and also in non-Abelian gauge theories.[11] In the former case, since QCD is an asymptotically free theory, it can be shown that as the temperature increases, the temperature dependent renormalized coupling constant goes to zero. As we discussed, in the $\lambda\varphi^4$ model if $D<4$, for temperatures β^{-1} above the temperature β_T^{-1} the renormalized coupling constant $\lambda(\beta)$ becomes

negative and the origin is a metastable vacuum. This kind of problem occurs with nonasymptotical models. The growth of the coupling constant at large momenta corresponds to the temperature growth (in modulus) of the renormalized coupling constant.

Even in the absence of temperature, the instability of the vacuum of models using scalar fields has been discussed in the literature. An enlightening discussion has been done by Linde.[12] Studying the $O(N)$ model and performing an $1/N$ expansion of the effective potential, this author showed that the effective potential is a double-valued function of the field φ [where the field $\Phi=(\varphi_1,...,\varphi_N)$ has a classical part $\Phi=\sqrt{N}(\varphi,0,...,0)$]. In the upper branch appears a tachyonic pole that leads us to disregard it as a nonphysical one, remaining the effective potential described by a unique curve that for large values of the classical field is not bounded from below.

We would like to stress that the situation treated in this paper is very similar to the examples where renormalized quantities depend on the geometric parameters of the spacelike section. The simplest example is the renormalized vacuum energy of scalar fields confined in a parallelepipedal box, where the sign of the energy may depend on the relative lengths of the cavity. Indeed the sign of the Casimir energy may depend on the spacetime dimension, the type of boundary conditions, etc.,[13] but we would like to emphasize only the dependence of the Casimir energy on the ratio of the sizes of the box [imposing a Dirichlet boundary condition] to give a rough idea of what kind of behavior we expect in situations where regularization and renormalization procedures are obligatory. Note that the possibility of obtaining a negative renormalized coupling constant in the $\lambda\varphi^4$ model was conjectured by Nash a long time ago.[14]

In this paper, we will investigate the one-loop renormalization of the truncated and nontruncated Efimov–Fradkin model assuming thermal equilibrium with a reservoir at temperature β^{-1}. Using the one-loop effective potential discussed briefly in Refs. 8 and 9, we will show that if $D\geqslant D_c(N-1)$, all the renormalized coupling constants of the truncated model are positive for any temperature (note that for reasons of stability in the tree level N must be even). For $D_c(N-1)>D\geqslant D_c(N)$ only the renormalized coupling constant $\lambda_{N-1}(\beta)$ becomes zero at some temperature β_{N-1}^{-1}. For $D_c(N)>D$, the renormalized coupling constants $\lambda_{N-1}(\beta)$ and $\lambda_N(\beta)$ become zero at the temperatures β_{N-1}^{-1} and β_N^{-1}, respectively.

The outline of the paper is the following: in Sec. II the effective potential is presented. In Sec. III the thermal contribution to the renormalized mass and coupling constant are presented in the truncated model ($N=4$). In Sec. IV we repeat the calculations of the truncated model for $N>4$ and in the nontruncated model. Finally, we discuss some applications of our results in curved spacetime and high order behavior of perturbation theory. Conclusions are given in Sec. V. In this paper we use $\hbar=c=1$.

II. THE ONE-LOOP EFFECTIVE POTENTIAL OF THE EFIMOV–FRADKIN MODEL AT ZERO AND FINITE TEMPERATURE

In this section we will generalize some results obtained in Refs. 8 and 9. Suppose we have a D-dimensional flat space–time with trivial topology of the spacelike section and Bose fields in thermal equilibrium with a reservoir at temperature β^{-1}. Let us assume the following Lagrange density associated with a massive neutral scalar field,

$$\mathscr{L}=\frac{1}{2}(\partial_\mu\varphi)^2-\frac{1}{2}m^2\varphi^2-\sum_{n!}^{\infty}\frac{\lambda_n}{n!}\varphi^n+\text{counterterms}. \tag{4}$$

Since the model is nonrenormalizable, the counterterms have meaning only in the context of a finite number of loops. Note that we are not assuming inversion symmetry in the model, i.e., $V(\varphi_0)=V(-\varphi_0)$. If we assume it, the only surviving terms will be the even powers of the field. The time ordered products of the fields can be continued analytically to imaginary times, and we define a Euclidean action integrating the analytic continuation to imaginary times in the Lagrange

density. After a Wick rotation, defining the normalized expectation value of the field by $\varphi_0=\langle 0|\varphi|0\rangle/\langle 0|0\rangle$, the zero temperature effective potential is given in the one-loop approximation by

$$V(\varphi_0)=V_{\mathrm{I}}(\varphi_0)+V_{\mathrm{II}}(\varphi_0), \tag{5}$$

where

$$V_{\mathrm{I}}(\varphi_0)=\frac{1}{2}\,m^2\varphi_0^2+\sum_{n=3}^{\infty}\frac{\lambda_n}{n!}\,\varphi_0^n+\text{counterterms}, \tag{6}$$

and

$$V_{\mathrm{II}}(\varphi_0)=\sum_{s=1}^{\infty}\frac{(-1)^{s+1}}{2s}\left(\sum_{n=3}^{\infty}\frac{1}{(n-2)!}\,\lambda_n\varphi_0^{n-2}\right)^s\int\frac{d^Dq}{(2\pi)^D}\,\frac{1}{(\omega^2+\mathbf{q}^2+m^2)^s}. \tag{7}$$

There is no difficulty in extending the above results, assuming that the system is in thermal equilibrium with a reservoir at temperature β^{-1}. In the study of quantum fields at finite temperature two different approaches are currently used. The first one is the real time formalism in the canonical[15] or path integral approach.[16] The second one, is the Euclidian time formalism and will be used from now on in this paper. After a Wick rotation, the functional integral runs over the fields that satisfy periodic boundary conditions in Euclidian time. The effective action may be defined, as in the zero temperature case, by a functional Legendre transformation. Regularization and renormalization procedures follow the same steps taken in the zero temperature case, since temperature effects do not change the ultraviolet behavior of the model. Summing up, to study temperature effects in Bose fields we must perform the following replacements in the Euclidian region:

$$\int\frac{d\omega}{2\pi}\rightarrow\frac{1}{\beta}\sum_{n'}\,, \tag{8}$$

and

$$\omega\rightarrow\omega_{n'}=\frac{2\pi n'}{\beta}, \tag{9}$$

where $\omega_{n'}=2\pi n'/\beta$ are the Matsubara frequencies. Introducing a mass parameter μ and defining the dimensionless quantities,

$$c^2=\frac{m^2}{4\pi^2\mu^2}, \tag{10}$$

$$(\beta\mu)^2=a^{-1}, \tag{11}$$

and

$$k^i=\frac{q^i}{2\pi\mu}, \tag{12}$$

the Born terms plus the one-loop contributions to the effective potential are given by

$$V(\beta,\varphi_0)=V_{\mathrm{I}}(\varphi_0)+V_{\mathrm{II}}(\beta,\varphi_0),$$

where

$$V_{\mathrm{I}}(\beta,\varphi_0)=\frac{1}{2}\,m^2\varphi_0^2+\sum_{n=3}^{\infty}\,\frac{\lambda_n}{n!}\,\varphi_0^n+\text{counterterms},\tag{13}$$

and

$$V_{\mathrm{II}}(\beta,\varphi_0)=\sqrt{a}\mu^D\sum_{s=1}^{\infty}\,\frac{(-1)^{s+1}}{2s}\left(\sum_{n=3}^{\infty}\,\frac{\lambda_n\varphi_0^{n-2}}{4\pi^2\mu^2(n-2)!}\right)^s\sum_{n'=-\infty}^{\infty}\int d^dk\,\frac{1}{(an'^2+\mathbf{k}^2+c^2)^s}.\tag{14}$$

Owing to the discreteness of the Matsubara frequencies, an analytic regularization procedure will be used. Defining the inhomogeneous Epstein zeta function as

$$A_N^{c^2}(s,a_1,a_2,\ldots,a_N)=\sum_{n_1,n_2,\ldots,n_N=-\infty}^{\infty}(a_1n_1^2+a_2n_2^2+\cdots+a_Nn_N^2+c^2)^{-s},\tag{15}$$

we will see that its analytic continuation will be used to regularize the model. Before showing how this analytic continuation works, and in order to simplify Eq. (14), it is convenient to define g_n and ϕ as the new coupling constants and an adimensional (for $D=4$) vacuum expectation value of the field

$$g_n=\frac{\lambda_n}{4\pi^2\mu^{4-n}(n-2)!},\tag{16}$$

and

$$\frac{\varphi_0}{\mu}=\phi.\tag{17}$$

Substituting Eq. (16) and Eq. (17) in Eq. (14) we obtain

$$V_{\mathrm{II}}(\beta,\phi)=\mu^D\sqrt{a}\sum_{s=1}^{\infty}\,\frac{(-1)^{s+1}}{2s}\left(\sum_{n=3}^{\infty}\,g_n\phi^{n-2}\right)^s\sum_{n'=-\infty}^{\infty}\int d^dk\,\frac{1}{(an'^2+c^2+\mathbf{k}^2)^s}.\tag{18}$$

Since the spatial section of the space–time is noncompact, in order to deal with the divergences in the integral of Eq. (18), we will first use dimensional regularization. From the well-known formula,

$$\int\,\frac{d^dk}{(k^2+b^2)^s}=\frac{\pi^{d/2}}{\Gamma(s)}\,\Gamma\left(s-\frac{d}{2}\right)\,\frac{1}{b^{2s-d}},\tag{19}$$

and defining $f(D,s)$ as

$$f(D,s)=f(d+1,s)=\frac{(-1)^{s+1}}{2s}\,\pi^{d/2}\Gamma\left(s-\frac{d}{2}\right)\,\frac{1}{\Gamma(s)},\tag{20}$$

it is possible to write $V_{\mathrm{II}}(\beta,\phi)$ in terms of the inhomogeneous Epstein zeta function given by Eq. (15) as

$$V_{\mathrm{II}}(\beta,\phi)=\mu^{D}\sqrt{a}\sum_{s=1}^{\infty} f(D,s)\left(\sum_{n=3}^{\infty} g_n\phi^{n-2}\right)^{s} A_1^{c^2}\left(s-\frac{d}{2},a\right). \tag{21}$$

The terms $s\leqslant D/2$ are divergent, which implies that the effective potential is not yet regularized. To complete the regularization, let us assume that each term in the series of the one-loop effective potential $V(\beta,\phi)$ is replaced by its analytic extension, defined at the beginning in a open connected set of points of the complex plane s. Since we discussed carefully the process of the analytic continuation in the previous works, here we will only sketch this derivation. First, it is necessary to write Eq. (21) in terms of the modified inhomogeneous Epstein zeta function as we did in the above quoted works. For $\mathrm{Re}(s)>N/2$, the modified inhomogeneous Epstein zeta function, $E_N^{c^2}(s,a_1,a_2,\ldots,a_N)$ converges and represents an analytic function of s, so $\mathrm{Re}(s)>N/2$ is the largest possible convergence domain of the series. The next step is to establish a connection between the terms of the series defining the inhomogeneous Epstein zeta function and the Euler integral representation of the gamma function. For instance, in the case of only one sum this connection is of the type

$$\frac{1}{(n+a)^s}=\frac{1}{\Gamma(s)}\int_0^{\infty} t^{s-1}e^{-t(n+a)}dt.$$

Summing over n in both sides, we obtain in the left-hand side the inhomogeneous Riemann zeta function and in the right-hand side a still divergent integral. We split the integral into two parts, the first one defines an entire function $Q(s)$ and the second one $P(s)$ contains the divergences. Then we use a Bernoulli representation for the integrand of $P(s)$ and the Weierstrass theorem to exchange the sum and integral operations. This allows us to show that $P(s)$ extends to a meromorphic function of s having simple poles. The generalization the case of a multiple sum goes along the same lines.

Therefore, using the results of Ref. 17 we rewrite Eq. (21) as

$$V_{\mathrm{II}}(\beta,\phi)=\mu^{D}\sum_{s=1}^{\infty}\left(\sum_{n=3}^{\infty} g_n\phi^{n-2}\right)^{s} h(D,s)\left[\frac{1}{2^{D/2-s+2}}\,\Gamma\left(s-\frac{D}{2}\right)\left(\frac{m}{\mu}\right)^{D-2s}+\sum_{n'=1}^{\infty}\left(\frac{m}{\mu^2\beta n'}\right)^{D/2-s} K_{D/2-s}(mn'\beta)\right], \tag{22}$$

where

$$h(D,s)=\frac{1}{2^{D/2-s-1}}\,\frac{1}{\pi^{D/2-2s}}\,\frac{(-1)^{s+1}}{s}\,\frac{1}{\Gamma(s)}. \tag{23}$$

Although Eq. (22) is ill defined, in the one-loop approximation it is possible to find the exact form of the counterterms in such a way that, mass and coupling constants (and consequently) the effective potential are finite quantities. To extract the singularities from the analytic extensions, let us define the mass squared as the value of the inverse propagator at zero momentum and the coupling constant λ_n as the proper n-point function at zero external momentum. In fact, the true physical mass is defined as the value of p^2 at which the inverse propagator vanishes. However, the two values are related by a finite renormalization. In the next section, we will develop such an idea in a very simple case: the truncated ($N=4$) Efimov–Fradkin model and, subsequently, present the temperature dependent renormalized squared mass and coupling constants of the model.

III. THE RENORMALIZED MASS AND COUPLING CONSTANTS IN THE TRUNCATED ($N=4$) EFIMOV–FRADKIN MODEL

The goal of this section is to study how temperature effects lead to instabilities in scalar massive models. For the sake of simplicity and in order to obtain some insight about the thermal contribution to the renormalized mass and coupling constants in the nontruncated Efimov–Fradkin model, let us suppose the truncated model, i.e., $\lambda_n=0$ for $n>4$. We remark that the theory defined only with the term λ_3 is not consistent in any spacetime dimension since the energy is not bounded below, and so no ground state can exist in the interacting theory. The inclusion of λ_4 introduces a global minimum in the model. Defining

$$f(D,s)=\frac{1}{2^{D/2-s+2}}\,\Gamma\left(s-\frac{D}{2}\right),$$

it is possible to write $V_{\mathrm{II}}(\beta,\phi)$ as

$$V_{\mathrm{II}}(\beta,\phi)=\mu^D\sum_{s=1}^{\infty}\sum_{k=0}^{s}h(D,s)C_s^k g_3^{s-k}g_4^k\phi^{s+k}\left[f(D,s)\left(\frac{m}{\mu}\right)^{D-2s}+\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-s}K_{D/2-s}(mn\beta)\right]. \tag{24}$$

In order to find the exact form of the counterterms that will render the model finite, let us consider the renormalization conditions for the nontruncated model

$$\frac{\partial^2}{\partial\phi^2}\,V(\beta,\phi)\big|_{\phi=0}=\mu^2m^2, \tag{25}$$

and

$$\frac{\partial^n}{\partial\phi^n}\,V(\beta,\phi)\big|_{\phi=0}=\mu^n\lambda_n,\quad n=3,4,\ldots\ . \tag{26}$$

We should point out that, strictly speaking, there is no need for wave function renormalization because the vacuum expectation value of the field has been chosen to be a constant. Using Eqs. (6), (24), (25), and (26), it is possible to find the exact form of the counterterms in such a way that they cancel the pole contribution of the analytic extensions. In the neighborhood of the poles, the regular part of the analytic extension of the inhomogeneous Epstein zeta function has two contributions: one which is independent of the temperature (this contribution can be absorbed in the counterterms), and another that depends on it. The thermal contribution to the renormalized coupling constant is proportional to the regular part of the analytic extension of the inhomogeneous Epstein zeta function in the neighborhood of some poles for the ultraviolet divergent graphs. Of course, nonultraviolet divergent graphs do not need to be regularized giving a finite thermal contribution to the renormalized quantities.

Note that we are choosing the renormalization conditions at $\varphi_0=0$. This may be done in the truncated model even if the minimum of the effective potential is not at $\varphi_0=0$, since the renormalization point is totally arbitrary. The values of the renormalized quantities obtained using $\varphi_0=0$ as the renormalization point are related to the corresponding quantities obtained in the true vacuum $\varphi_0\neq0$ by the equations,

$$m^2\big|_{\varphi_0}=\tfrac{1}{2}\,m^2+\tfrac{1}{2}\,\lambda_3\varphi_0+\tfrac{1}{4}\,\lambda_4\varphi_0^2, \tag{27}$$

FIG. 1. The two graphs that contribute to the temperature dependent renormalized mass m^2. Note that they are ultraviolet divergent for $D=4$.

$$\lambda_3|_{\varphi_0}=\frac{1}{3!}\,(\lambda_3+\lambda_4\varphi_0), \tag{28}$$

and finally

$$\lambda_4|_{\varphi_0}=\lambda_4. \tag{29}$$

Analyzing the sign of the thermal corrections to the renormalized physical parameters evaluated at $\phi=0$, the sign of Eqs. (27) and (29) does not change. This is expected since the metastable behavior and the existence of a global minimum cannot depend upon the choice of the renormalization point. For the case of the coupling constant $\lambda_3(\beta)$ with the restrictive condition $|\varphi_0\lambda_4|<|\lambda_3|$, all the forthcoming conclusions also apply.

Let us call $\Delta m^2(D,\beta,m,\lambda_3,\lambda_4,\mu)$ and $\Delta\lambda_n(D,\beta,m,\lambda_3,\lambda_4,\mu)$, $n=3,4$ the thermal squared mass and thermal coupling constants, respectively. In the following, in order to simplify the notation we keep explicitly only the β dependence of the renormalized quantities. Thus,

$$m^2(\beta)=m^2+\Delta m^2(\beta), \tag{30}$$

$$\lambda_n(\beta)=\lambda_n+\Delta\lambda_n(\beta), \quad n=3,4, \tag{31}$$

and for the sake of simplicity in the notation in the rest of this section, we call $\lambda_3(\beta)=\sigma(\beta)$ and $\lambda_4(\beta)=\lambda(\beta)$. From now on we will disregard the combinatorics factors in front of Feynman diagrams, since they are always real positive numbers, and cannot change qualitatively the forthcoming results concerning the sign of the renormalized physical parameters. We are interested only in the connected one particle irreducible diagrams (1PI) which means that in the approximation we are making here, we have two graphs that contribute to the temperature dependent renormalized squared mass (see Fig. 1), the terms $s=1$, $k=1$ (of order λ) and $s=2$, $k=0$ (of order σ^2). It is not difficult to show that the case $s=1$, $k=1$ gives a positive contribution,

$$\Delta m^2_{g_4}(\beta)-\Delta m^2_{g_4}(\infty)=\mu^{D-2}h(D,1)g_4\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-1}K_{D/2-1}(mn\beta). \tag{32}$$

In the same way, the contribution from the term $s=2$, $k=0$ is negative and it is given by

$$\Delta m^2_{g_3}(\beta)-\Delta m^2_{g_3}(\infty)=\mu^{D-2}h(D,2)g_3^2\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-2}K_{D/2-2}(mn\beta). \tag{33}$$

Using general properties of the Bessel function $K_n(z)$, we obtain that the leading contribution comes from the graph given by Fig. 1(a), i.e., $\Delta m^2_{g_4}(\beta)-\Delta m^2_{g_4}(\infty)+\Delta m^2_{g_3}(\beta)-\Delta m^2_{g_3}(\infty)>0$, and the thermal correction to the renormalized squared mass is always positive. Using the proper time method, Braden obtained the same expression for the thermal mass in the $\lambda\varphi^4$ model [see Eq. (32)]. This author also discussed the two-loop correction to the mass and proved that the coun-

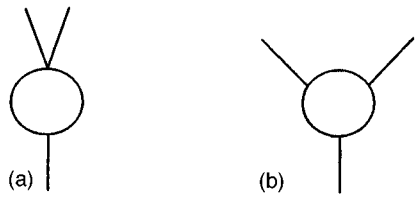

FIG. 2. The two graphs that contribute to the renormalized coupling constant $\sigma(\beta)$. Note that only the first one is ultraviolet divergent for $D=4$.

terterms are temperature independent.[18] Note that the nonleading contribution coming from the graph of Fig. 1(b) is negative, going in the direction of the vanishing of the mass. In other words, in the truncated model with only nonzero λ_3 coupling constant (disregarding the problem of the unboundedness of the effective potential even in the tree level approximation), the thermal squared mass will become zero and negative at high temperatures. Various investigations have been made in theories with cubic coupling. Gross, Perry, and Yaffe[19] calculated the thermal mass of a graviton coupled with massless fermions in the one-loop approximation. These authors found that the thermal mass squared was negative and the graviton developed an imaginary mass at some temperature. This lead the authors to conclude that the hot flat space–time is unstable. The thermal graviton one-loop correction was also analyzed by Kikuchi, Moriya, and Tsukahara and Holstein.[20] It was also shown that the thermal effects destabilize the hot curved space–time.

The situations that we are interested in discussing are the ones in which some renormalized coupling constant $\lambda_n(\beta)$ vanishes by temperature effects. As we discussed above, if $D<D_c(n)$ this situation can be realized. It is important to note that in this region the model is superrenormalizable, and when the fields are massless, perturbative expansion suffers from severe infrared divergences. Since the thermal squared mass is always positive and we are interested in the high temperature regime, this problem does not afflict us, i.e., infrared divergences never appear in our calculations at least in the one-loop aproximation. It should be noted that this fact does not occur in higher order-loop calculations. If we consider N self-energy insertions of $O(\lambda)$ (a ring correction) into a single loop, its contribution is infrared divergent in the case of the zero mass of the field. In other words, on the perturbative level the thermal mass generation does not prevent the appearance of infrared divergences in higher order loop diagrams.

Let us now study the thermal contribution to the renormalized coupling constants. Initially, for the thermal renormalized coupling constant $\sigma(\beta)$ we obtain,

$$\sigma(\beta)=\sigma(\infty)+\Delta\sigma_{g_3}(\beta)+\Delta\sigma_{g_3g_4}(\beta). \tag{34}$$

As in the previous case, it is necessary to study the cases $s=2$, $k=1$ and $s=3$, and $k=0$ (see Fig. 2). In the case of $s=2$, $k=1$ [of order $\sigma\lambda$, see Fig. 2(a)], it is not difficult to show that it gives a negative contribution,

$$\Delta\sigma_{g_3g_4}(\beta)-\Delta\sigma_{g_3g_4}(\infty)=2\mu^{D-3}h(D,2)g_3g_4\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-2}K_{D/2-2}(mn\beta). \tag{35}$$

For the second case, $s=3$, $k=0$ [of the order σ^3, see Fig. 2(b)] the contribution is positive,

$$\Delta\sigma_{g_3}(\beta)-\Delta\sigma_{g_3}(\infty)=\mu^{D-3}h(D,3)g_3^3\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-3}K_{D/2-3}(mn\beta). \tag{36}$$

The thermal correction to the renormalized coupling constant $\sigma(\beta)$ is given by

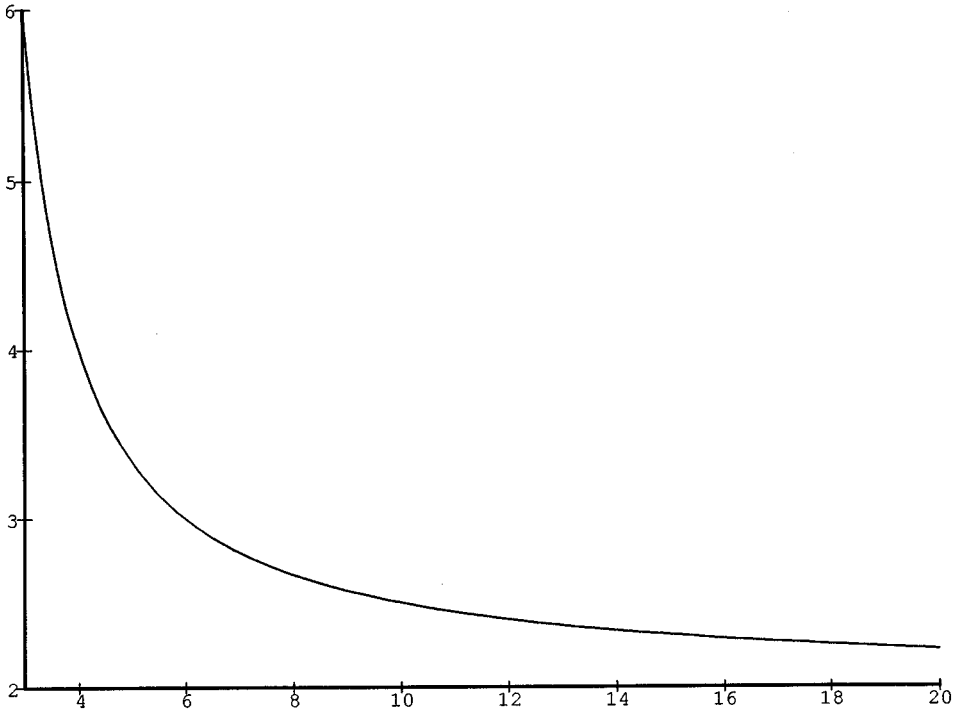

FIG. 3. The critical dimension as a function of n for each coupling constant λ_n.

$$[\Delta\sigma_{g_3g_4}(\beta)-\Delta\sigma_{g_3g_4}(\infty)]+[\Delta\sigma_{g_3}(\beta)-\Delta\sigma_{g_3}(\infty)]. \tag{37}$$

The term between the first brackets of Eq. (37) dominates over the second one, and the thermal correction to the renormalized coupling constant $\sigma(\beta)$ is negative. We have the interesting situation where the renormalized coupling constant $\sigma(\beta)$ attains its maximum at zero temperature ($\beta^{-1}=\infty$), and decreases monotonically as the temperature increases. In other words, the thermal contribution to the renormalized coupling constant $\Delta\sigma(\beta)$ is negative, and increases in modulus with the temperature. As we discussed in the previous sections, for $D<D_c(n)$ the coupling constant may be a large quantity. From Eq. (2), it is not difficult to show that $D_c(n)=2n/(n-2)$ (see Fig. 3). Since the thermal contribution to the renormalized coupling constant is negative, there is a temperature β_3^{-1} where $\sigma(\beta)$ vanishes if $D<6$. Above this temperature $\sigma(\beta)$ becomes negative. As we will see, even if $D<4$, there is a finite range of temperatures where $\lambda(\beta)$ is still positive. The thermal contribution to the renormalized coupling constant $\lambda(\beta)$ also can be calculated. The complete expression for $\lambda(\beta)$ is

$$\lambda(\beta)=\lambda(\infty)+\Delta\lambda_{g_3}(\beta)+\Delta\lambda_{g_3g_4}(\beta)+\Delta\lambda_{g_4}(\beta). \tag{38}$$

As in the previous case we need to study the graphs $s=2$, $k=2$, $s=3$, $k=1$, and $s=4$, $k=0$ (see Fig. 4). For the first case $s=2$, $k=2$ (of order λ^2), we get a negative contribution [see Fig. 4(a)],

$$\Delta\lambda_{g_4}(\beta)-\Delta\lambda_{g_4}(\infty)=\mu^{D-4}h(D,2)g_4^2\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-2}K_{D/2-2}(mn\beta). \tag{39}$$

For the case $s=3$, $k=1$ [of the order $\sigma^2\lambda$, Fig. 4(b)] we obtain a positive contribution

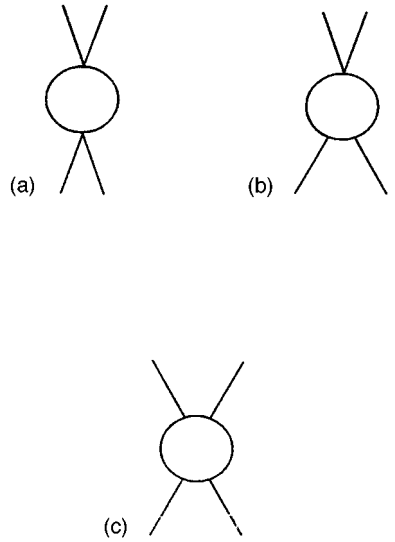

FIG. 4. The three graphs that contribute to the renormalized coupling constant $\lambda(\beta)$. Again, only the first is ultraviolet divergent in $D=4$.

$$\Delta\lambda_{g_3g_4}(\beta)-\Delta\lambda_{g_3g_4}(\infty)=3\mu^{D-4}h(D,3)g_3^2g_4\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-3}K_{D/2-3}(mn\beta). \tag{40}$$

Finally, in the last case, $s=4$, $k=0$ [of the order σ^4, Fig. 4(c)] we obtain a negative contribution given by

$$\Delta\lambda_{g_3}(\beta)-\Delta\lambda_{g_3}(\infty)=\mu^{D-4}h(D,4)g_3^4\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta}\right)^{D/2-4}K_{D/2-4}(mn\beta). \tag{41}$$

The thermal correction to the renormalized coupling constant $\lambda(\beta)$ is the sum of the contributions from the three graphs of Fig. 4, which gives

$$[\Delta\lambda_{g_3}(\beta)-\Delta\lambda_{g_3}(\infty)]+[\overline{\Delta\lambda}_{g_3g_4}(\beta)-\Delta\lambda_{g_3g_4}(\infty)]+[\Delta\lambda_{g_4}(\beta)-\Delta\lambda_{g_4}(\infty)]. \tag{42}$$

The term between the last brackets in Eq. (42) dominates over the others and, since its contribution is negative, the thermal correction to the renormalized coupling constant $\lambda(\beta)$ is negative. The important conclusion from the above discussion is the following: the critical dimension for λ is $D=4$, which implies that if we take $D<4$ there is a temperature such that $\lambda(\beta)$ becomes zero. Let us call β_4^{-1} this temperature. If the system is heated above this temperature β_4^{-1}, the renormalized coupling constant $\lambda(\beta)$ becomes negative. Note that we have two different temperatures (for $D<4$) where $\sigma(\beta)$ and $\lambda(\beta)$ vanish. First $\sigma(\beta)$ becomes zero at β_3^{-1} [where $\lambda(\beta)$ is still positive] and after at β_4^{-1} the renormalized coupling constant $\lambda(\beta)$ becomes zero [where $\sigma(\beta)$ is negative]. For temperatures $\beta^{-1}>\beta_4^{-1}$ the system can develop a first order phase transition with the decay of a false vacuum.[21]

Finally, the effective potential as a function of the temperature and the vacuum expectation value of the field for $D<4$, $m^2=\mu=\lambda=1$ may be plotted in a ''toy'' model. The temperature is the parameter that allows us to interpolate between the two configurations: a stable vacuum at low temperatures and a metastable state at temperatures $\beta^{-1}>\beta_4^{-1}$ (see Fig. 5). In the next section we

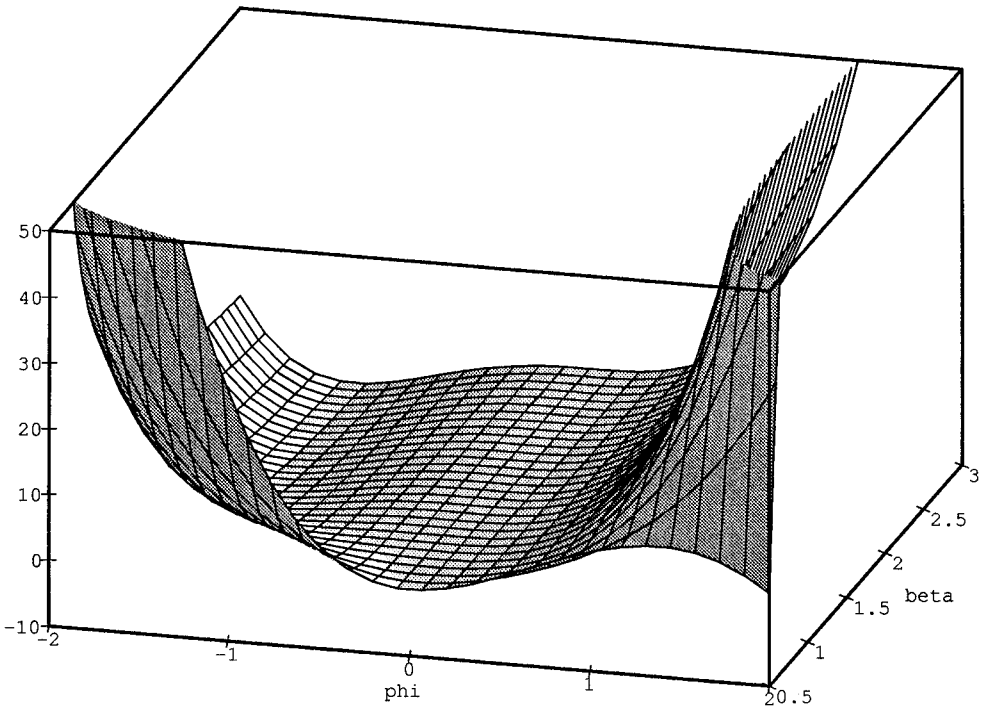

FIG. 5. The effective potential as a function of the vacuum expectation value of the field and the inverse of the temperature. For low temperatures, it has a global minimum and for temperature $\beta^{-1}>\beta_{g4}^{-1}$, the potential has a metastable vacuum.

will repeat the calculations that we have done in this section to the truncated ($N>4$) and also in the nontruncated modes.

IV. THE RENORMALIZED MASS AND COUPLING CONSTANTS IN THE TRUNCATED ($N>4$) AND THE NONTRUNCATED MODELS

In this section we will suppose a general truncated model, i.e., $\lambda_n=0$ for $n>N>4$. Since we intend to disregard at the tree level the problem of the unboundedness of the energy density, we assume that N is an even integer. The calculations are now formally identical to the previous ones. The only difference is the richness coming from the distinct graphs contributing to the thermal renormalized coupling constants. For reasons that will become clear later we will study two different situations,

$$\text{(i)}\quad D<D_c(N-1),$$

$$\text{(ii)}\quad D\geqslant D_c(N-1).$$

For $D<D_c(N-1)$, let us investigate the thermal renormalized coupling constants $\lambda_{N-2}(\beta)$, $\lambda_{N-1}(\beta)$ and $\lambda_N(\beta)$, separately. We must analyze the leading diagrams giving contributions to the renormalized coupling constants $\lambda_{N-2}(\beta)$, $\lambda_{N-1}(\beta)$, and $\lambda_N(\beta)$. In this case, it is not difficult to show that there is a positive contribution to the renormalized coupling constant $\lambda_{N-2}(\beta)$ given by the graph $s=1$ in Fig. 6. This is because the leading contribution comes from the graph with the smaller value of s. An example of nonleading contributions are those given by the graphs in Fig. 7. The leading thermal contribution gives

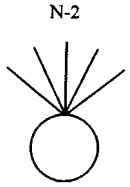

FIG. 6. The graph that gives the leading contribution to the renormalized coupling constant $\lambda_{N-2}(\beta)$.

$$\lambda_{N-2}(g_N,\beta)-\lambda_{N-2}(g_N,\infty)\cong\mu^{D-N+2}h(D,1)g_N\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-1}K_{D/2-1}(mn\beta). \quad (43)$$

The result above can be generalized to the other coupling constants $\lambda_3,...,\lambda_{N-3}$. Thus, the renormalized coupling constants $\lambda_3,...,\lambda_{N-2}$ are always positive, for any D space–time dimension. The situation changes in the case of the coupling constant $\lambda_{N-1}(\beta)$. In this case the leading graphs are given in Fig. 8. The thermal contribution from these graphs to the renormalized coupling constant λ_{N-1} is given by

$$\lambda_{N-1}(g_N,g_{N-1},\ldots,g_3,\beta)-\lambda_{N-1}(g_N,g_{N-1},\ldots,g_3,\infty)$$

$$\cong\mu^{D-N+1}h(D,2)(g_Ng_3+g_{N-1}g_4+\cdots)\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-2}K_{D/2-2}(mn\beta), \quad (44)$$

which is a negative expression, implying that for $D<D_c(N-1)$ it must have a temperature where $\lambda_{N-1}(\beta)$ vanishes. Finally, for the coupling constant $\lambda_N(\beta)$, the leading graphs are given by Fig. 9. A straightforward calculation gives for the thermal contribution to the renormalized coupling constant λ_N the value

$$\lambda_N(g_N,g_{N-1},\ldots,g_3,\beta)-\lambda_N(g_N,g_{N-1},\ldots,g_3,\infty)$$

$$=\mu^{D-N}h(D,2)(g_Ng_4+g_{N-1}g_5+\cdots)\sum_{n=1}^{\infty}\left(\frac{m}{\mu^2\beta n}\right)^{D/2-2}K_{D/2-2}(mn\beta). \quad (45)$$

As in the previous case, the coupling constant λ_N also becomes zero at the temperature β_N^{-1} if $D<D_c(N)$. From the same arguments related to the critical dimension of each coupling constant, for $D\geqslant D_c(N-1)$ all the renormalized coupling constants are positive for any temperature. A very interesting situation is the case where $D_c(N)\leqslant D<D_c(N-1)$. Although the coupling constant λ_{N-1} becomes negative above the temperature β_{N-1}^{-1}, the effective potential has a global

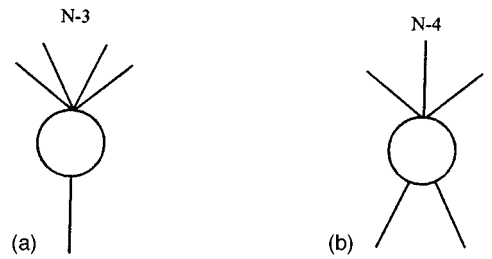

FIG. 7. The graphs that give nonleading contributions to the renormalized coupling constant $\lambda_{N-2}(\beta)$.

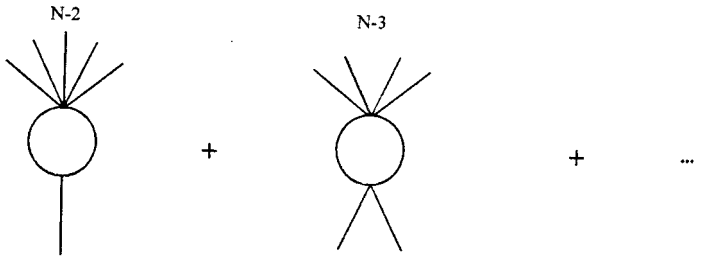

FIG. 8. The graphs that give the leading contribution to the renormalized coupling constant $\lambda_{N-1}(\beta)$.

minimum, since the renormalized coupling constant $\lambda_N(\beta)$ is positive for any temperature. In this case, the ground state of the model is stable. Note that we are using the renormalization conditions at $\phi=0$. Imposing only even powers of the field in Eq. (1), all the above conclusions apply. Including odd powers of the field, the global minimum of the effective potential is not at $\phi=0$. Let us suppose that the minimum occurs at some value $\phi\neq 0$. It is possible to show that the results concerning the sign of the renormalized coupling constant $\lambda_N(\beta)$ and squared mass do not change. From a physical point of view this could not be otherwise, since the critical behavior of the system and the existence or not of vacuum decay should not be affected by a change of the renormalization point. Summing up, in the truncated model we have tunneling between different vacua if $D<D_c(N)$, where $D_c(N)$ is the critical dimension of λ_N.

The above discussions can be summarized as follows. In a massive scalar superrenormalizable model at finite temperature, there is a temperature β_N^{-1} such that the renormalizable coupling constant $\lambda_N(\beta)$ becomes zero. Above such temperature there is tunneling between different vacua.

Particularly important is the connection between our investigations and instanton solutions in scalar models. It is well known that in $D=4$ the massive $\lambda\varphi^4$ model does not admit real instanton solutions. In the massless case, also, there are no real instanton solutions (with positive action), nevertheless, a complex instanton solution (with negative action) is known.[22] The instanton solution is related to the fact that the renormalized coupling constant λ is negative. It is not difficult to see the connection between the mechanism studied by us and the possible existence of instantons, since in our case the renormalized coupling constant may become negative as the temperature changes. In the simplest case of massive $\lambda\varphi^4$ and $D<4$, instantons could exist in the model for $\beta^{-1}>\beta_4^{-1}$.

As noted a long time ago by Dyson, in QED, for negative coupling constant e^2, the Hamiltonian is unbounded below and the vacuum is a metastable state.[23] In this situation, particles and antiparticles would repel each other, increasing the distance between them and pairs of particle, and antiparticles would be continually created. In the vacuum energy (the sum of all connected diagrams having n vertices and no external legs) appears an imaginary part. As it was noted originally by Bender and Wu studying the quantum anharmonic oscillator, there is a relation between the nth Rayleigh–Schrodinger coefficient and the lifetime of the unstable states of a negatively coupled anharmonic oscillator.[24] The idea was used also in field theory by Parisi and others.[25–27] Asymptotic estimates in perturbation theory can be obtained by computing the imaginary part of the Green's functions for small negative coupling constant. More recently, Fainberg and Yofa also calculated the high order corrections to the instantons contribution to the Green's functions in the regime $\lambda<0$.[28]

The effects we have described in this paper may also be applied to cosmological phase transition problems. The study of phase transition in cosmological models has been widely discussed in the literature. For a complete review see Ref. 29 and other references, therein. It is shown that in the evolution of the universe, metastable vacuum states may appear. The decay of such metastable states is materialized in the Lorentzian space–time as nucleation of a bubble of

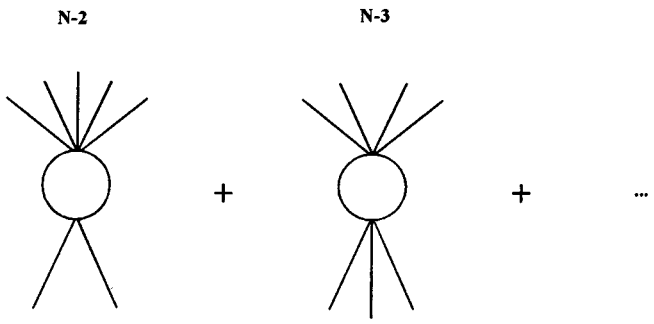

FIG. 9. The graphs that give leading contributions to the renormalized coupling constant $\lambda_N(\beta)$.

true vacuum in the false vacuum phase. Frequently, in the study of the false vacuum decay, it is assumed that the system is ''prepared'' in a metastable state. Such metastable states appear naturally in our formalism by temperature effects that change the sign of renormalized coupling constants. For instance, as we have seen before, in the truncated model ($N=4$) for $4\leqslant D<6$, the coefficient of the φ^3 term becomes negative above the temperature β_3^{-1}. This is a natural realization of the potential studied by Gleiser *et al.*[30] and Vilenkin and Ford.[31] If we assume that the universe expands and supercools, the possibility of the creation of bubbles of true vacuum arises, nevertheless, there are subtleties in this process. Back to Lorentzian time, let us define $\Delta\tau$ as the time necessary to the temperature of the environment to drop down to β_4^{-1}, where the vacuum state becomes stable. On the other hand, if the mean life of the metastable state Δt is larger than $\Delta\tau$ there is no nucleation of the bubbles at all. Only if $\Delta t<\Delta\tau$, there would be a finite probability of nucleation of bubbles.

In the case of ''real'' cosmological evolution, it is necessary to include gravity; nontrivial problems may appear, as for example the possibility of the presence of horizon. For a careful analysis of these situations, see Ref. 32. We cannot disregard the possibility that particle creation associated with the tunneling process will destroy the above scenario. Particle creation that occurs in the process of nucleation of bubbles was analyzed by Rubakov.[33] We still do not know how to introduce these effects in our model. The discussion of tunneling effects, instantons, and how they contribute to high order estimates in perturbation theory will be presented in a forthcoming paper.[34]

V. CONCLUSION

The purpose of this paper has been to discuss the effect of keeping local terms with higher powers of the field in the Lagrange density of a neutral scalar field. We also assume that the system is in thermal equilibrium with a reservoir at temperature β^{-1}. We proved that in the truncated Efimov–Fradkin model, (i) for $D\geqslant D_c(N-1)$ there is no a temperature where at least one of the coupling constants becomes zero; (ii) for $D_c(N-1)>D\geqslant D_c(N)$, there exists a temperature β_{N-1}^{-1}, where only the renormalized coupling constant $\lambda_{N-1}(\beta)$ becomes zero and all the other renormalized coupling constants remain positive; and (iii) for $D<D_c(N)$, the coupling constants $\lambda_{N-1}(\beta)$ and $\lambda_N(\beta)$ become zero at some temperatures β_{N-1}^{-1} and β_N^{-1}, respectively.

It is clear that in the nontruncated case, all the renormalized coupling constants remain positive for $D\geqslant 2$. We would like to point out that some care must be taken in order not to extrapolate the results of this paper to regions outside the domain of validity of the approximation we have done, i.e., beyond the one-loop level. As we discussed in the previous section, a natural extension of the ideas of the paper is to include gravitation, although there is some subtleness related to this approach. The techniques of the paper with the Euclidian path approach can only be implemented

in some special cases (for example, Schwarzschild or de Sitter spacetime), i.e., to continue analytically to Euclidian space the metric must have a section in the complexified spacetime on which the metric is real and positive-definite. In spacetime metrics where this property works, all the calculations can be repeated, of course, with the subtleness of the curved metric.

The Lax pair by dimensional reduction of Chern–Simons gauge theory

Oktay K. Pashaev[a)]
International School for Advanced Studies (SISSA/ISAS), Via Beirut 2, 34014 Trieste, Italy

(Received 11 December 1995; accepted for publication 10 May 1996)

We show that the Nonlinear Schrödinger Equation and the related Lax pair in $1+1$ dimensions can be derived from $2+1$-dimensional Chern–Simons Topological Gauge Theory. The spectral parameter, a main object for the Loop algebra structure and the Inverse Spectral Transform, has to appear as a homogeneous part (condensate) of the statistical gauge field, connected with the compactified extra space coordinate. In terms of solitons, a natural interpretation for the one-dimensional analog of Chern–Simons Gauss law is given. © *1996 American Institute of Physics.* [S0022-2488(96)02308-0]

I. INTRODUCTION

It has been known for many years that intimate relations between the dimensional reduction procedure and nonlinear models exist. A first example of such relations was suggested by Kaluza and Klein[1] for unification of gravitation and electromagnetism in a five-dimensional theory of gravity. Then, the idea was remarkably developed in the context of dual models and the string theory.[2] It turns out that the Yang–Mills theory in $4+N$ dimensions leads, via dimensional reduction, to a Yang–Mills+Higgs scalars coupled theory with specific couplings.[3] In this context we can suppose that the integrability of some nonlinear models can be related to the dimensional reduction procedure. This guess is indicated by a ''folk theorem'' that dimensional reduction from higher dimensions enlarges the symmetry G to its affine extension.[4,5] Then, some infinite-dimensional symmetries, appearing as the hidden symmetries of integrable models, shall have a geometrical meaning. Thus, by dimensional reduction, many $0+1$- and $1+1$-dimensional integrable models were embedded to the self-dual Yang–Mills (SDYM) equations.[6] By suitable reduction, the Lax pair associated with the corresponding low-dimensional model has appeared from the Lax pair for SDYM.[7] Moreover, one believes even that the self-dual Yang–Mills equations are a universal integrable system from which all the others could be obtained by proper reductions.[6] This program, still being intensively studied, requires that there should be a linear system for equations of the zero-curvature type (the Lax pair). However, the origin of the linear system remains a *terra incognita*. As well as the most mysterious part of the linear problem—the spectral parameter. From the algebraic point of view, the presence of a spectral parameter in the linear problem with Lie algebra $\mathcal{G}$ announces the appearance of an enlarged, loop algebra structure $\mathcal{G}\times C[\lambda,\lambda^{-1}]$, associated with the hidden non-Abelian symmetry of the model. An important point is that the spectral parameter is present in the linear problem and absent in the related evolution equation. Since the last one arises from the zero-curvature condition (ZCC) for the associated flat connections, it suggests a gauge-theoretical formulation of this phenomena. According to this observation we expect the existence of non-Abelian gauge theory, which includes the spectral parameter as a gauge degree of freedom. Hence, the isospectral deformation defined by the nonlinear evolution equation should appear as a gauge invariant condition.

Thus, we search for non-Abelian gauge theory with symmetries not less than the integrable one. Usually, in high-energy physics, the unification procedure means an embedding to a larger

symmetry group. Apparently most drastic possibilities for unification provide the Topological Field Theory (TFT).[8] As is well known,[9] TFT admits a huge diffeomorphism symmetry, which is realized by gauge transformations. Resulting reparametrization invariance of the model leads to the trivial dynamics, frozen in the reparametrization of gauge (unphysical) parameters. The dimensional reduction idea is very useful in the TFT.[10] Thus, three-dimensional Chern–Simons gauge field theory[11] can be reduced from four-dimensional TFT. By a subsequent reduction to two dimensions the conformal field theory was obtained.[12] A general reduction of CS theory leads to two-dimensional TFT, known as the BF theory.[13,14] Furthermore, two linear gravities—based on the de Sitter group or a central extension of the Poincaré group—were derived from three-dimensional TFT.[15] These results suggest that TFT could be a good candidate for the universal model, properly reducing which conformal invariant and integrable systems can be obtained. The question is how to constrain the model to have an integrable two-dimensional system.

Earlier we showed that for nonlinear σ models some constraint equations naturally arise. The idea, inspired by the gauge relation between one-dimensional integrable models, is to use variables from the tangent space to the nonlinear manifold.[16] By this approach, some evolution σ models like the Heisenberg Model (HM) and the Topological Magnet[17] are reformulated as the $U(1)$ gauge invariant field theory.[18–20] A mapping of the model to the three-dimensional zero-curvature condition (or to the CS theory) implies that the field connection should satisfy the proper constraint. In contrast with time reparametrization invariance of CS theory, the reduced system evolves according to the related σ model. For the integrable evolution,[19] it means a breaking of continual TFT symmetry up to a discrete time hierarchy of integrable models.

In the present paper we show that $2+1$-dimensional HM, considered as a constraint for CS theory, by dimensional reduction provides not only the integrable model, the Nonlinear Schrödinger Equation (NLSE), but also the corresponding Lax pair. The spectral parameter appears automatically in a correct way and has the meaning of the homogeneous (condensate) part for the statistical gauge field, related with the extra space dimension. Moreover, the nonhomogeneous structure of the field is related to the Bäcklund transformations for NLSE. In Sec. II, we present the general formalism of constructing the gauge invariant field theory, associated with the nonlinear σ model. Section III describes the related formulation of the non-Abelian CS theory. In Sec. IV, we illustrate the general approach with two important examples. Dimensional reduction for $2+1$ HM will be considered in Sec. V. In the conclusion we discuss some physical ideas to explain our results. We interpret the one-dimensional analog of CS Gauss law in terms of solitons for integrable models.

II. MOVING FRAME AND ADJOINT REPRESENTATION OF ZCC

In this section we present a general formalism connecting a zero curvature equations on A_1 algebra [$SU(2)$ or any noncompact version of it] in the adjoint representation with the moving trihedral.[21,22] This formalism allows us to formulate a nonlinear σ model as the Abelian gauge field theory.

Let us consider the group A_1 with element g, generated by τ_i $(i=1,2,3)$, satisfying

$$\tau_i \tau_j = h_{ij} + i c_{ijk} \tau_k , \tag{2.1}$$

where h_{ij} and c_{ijk} are the Killing metric and structure constants of A_1. We define an orthonormal trihedral set of unit vectors $\mathbf{n}_i$ and $\mathbf{e}_i$, and matrices N_i and E_i correspondingly, in the adjoint representation,

$$N_i = (\mathbf{n}_i, \tau) = \mathbf{n}_i^k \tau_k = h_{kl} \mathbf{n}_i^k \tau^l = g \tau_i g^{-1}, \tag{2.2a}$$

$$E_i = (\mathbf{e}_i, \tau) = \mathbf{e}_i^k \tau_k = h_{kl} \mathbf{e}^k \tau^l = g^{-1} \tau_i g. \tag{2.2b}$$

Using (2.1), the orthonormality of the trihedral are expressed by the relations

$$N_i N_j = h_{ij} + i c_{ijk} N_k , \tag{2.3a}$$

$$E_i E_j = h_{ij} + i c_{ijk} E_k . \tag{2.3b}$$

The Killing metric h_{ij} and structure constants $c_{ijk} = -c_{jik}$ defines the inner and cross products between three-vectors, transforming in the adjoint representation of A_1:

$$(\mathbf{n}_i \mathbf{n}_j) = h_{ij} , \tag{2.4a}$$

$$\mathbf{n}_i \wedge \mathbf{n}_j = c_{ijk} \mathbf{n}_k \tag{2.4b}$$

(and the similar equations for $\mathbf{e}_i$ vectors). Matrices N_i and E_i are connected by the similarity transformation,

$$N_i = g^2 E_i g^{-2}, \tag{2.5}$$

while related $\mathbf{n}_i$ and $\mathbf{e}_i$ vectors satisfy

$$(\mathbf{n}_i)^j h_{jj} = (\mathbf{e}_j)^i h_{ii} \tag{2.6}$$

(no summation). Due to this relation, in the present paper we restrict ourselves only with $\mathbf{n}_i$ vectors.

Let $\mathbf{n}_i = \mathbf{n}_i(x)$ are smooth vector fields that define at each space coordinate $\mathbf{x} = (x^1, x^2, x^3)$ of M the three vectors $(\mathbf{n}_1(x), \mathbf{n}_2(x), \mathbf{n}_3(x))$, forming an orthonormal basis called the moving frame.

We can introduce the left- and right-invariant chiral currents,

$$J^R_\mu = g^{-1} \partial_\mu g, \tag{2.7a}$$

$$J^L_\mu = \partial_\mu g \; g^{-1} \tag{2.7b}$$

($\mu = 1,2,3$). They are connected by simple transformation,

$$J^R_\mu = g^{-1} J^L_\mu g. \tag{2.8}$$

The trihedral moves according to the equations,

$$\partial_\mu N_i = [J^L_\mu, N_i] = g[J^R_\mu, \tau_i] g^{-1}, \tag{2.9a}$$

$$\partial_\mu E_i = g^{-1}[\tau_i, J^L_\mu] g = [E_i, J^R_\mu], \tag{2.9b}$$

or in the three-dimensional representation,

$$\partial_\mu N_i = (J^R_\mu)^{(ad)}_{ik} N_k , \tag{2.10a}$$

$$\partial_\mu E_i = -(J^L_\mu)^{(ad)}_{ik} E_k , \tag{2.10b}$$

where $(J^R_\mu)_{ik}$ and $(J^L_\mu)_{ik}$ are matrices in the adjoint representation,

$$(J^{R,L}_\mu)^{(ad)}_{ik} = -i c_{ijk} (J^{R,L}_\mu)_j = i (J^{R,L}_\mu)_j c_{jik} , \tag{2.11}$$

and $J^{R,L}_\mu = \Sigma (J^{R,L}_\mu)_j \frac{1}{2} \tau_j$. Related rotation of the moving frame is given by the equations

$$\partial_\mu \mathbf{n}_i = (J^R_\mu)^{(ad)}_{ik}\mathbf{n}_k, \quad \partial_\mu \mathbf{e}_i = -(J^L_\mu)^{(ad)}_{ik}\mathbf{e}_k.$$

Matrices $J^{R,L}_\mu$ have the symmetry property

$$(J^{R,L}_\mu)^{(ad)}_{ij} h_{jj} = -(J^{R,L}_\mu)^{(ad)}_{ji} h_{ii}.$$

For $SU(2)$ case $h_{ij}=\delta_{ij}$, $c_{ijk}=\epsilon_{ijk}$ and the matrices (2.11) are antisymmetric.

The zero-curvature conditions for chiral currents (2.7) have the form

$$\partial_\mu J^R_\nu - \partial_\nu J^R_\mu + [J^R_\mu, J^R_\nu] = 0, \tag{2.12a}$$

$$\partial_\mu J^L_\nu - \partial_\nu J^L_\mu - [J^L_\mu, J^L_\nu] = 0. \tag{2.12b}$$

In the following discussion we are concerned mainly on the J^R_μ matrix and skip the R index.

Let us decompose the matrix J_μ to the diagonal and off-diagonal parts,

$$J_\mu = J^{(0)}_\mu + J^{(1)}_\mu,$$

parametrized in the form

$$J^{(0)}_\mu = \frac{i}{4}\sigma_3 V_\mu, \tag{2.13a}$$

$$J^{(1)}_\mu = \begin{pmatrix} 0 & -\kappa^2\overline{q_\mu} \\ q_\mu & 0 \end{pmatrix}, \tag{2.13b}$$

where $\kappa^2=+1$ for $SU(2)$ and $\kappa^2=-1$ for $SU(1,1)$ case. Then,

$$c_{ijk} = \kappa^2 \epsilon_{ijk} h_{kk},$$

and in the adjoint representation we have

$$(J_\mu)^{(ad)} = \frac{1}{2}\begin{pmatrix} 0 & V_\mu & 4\kappa^2\,\mathrm{Re}(q_\mu) \\ -V_\mu & 0 & 4\kappa^2\,\mathrm{Im}(q_\mu) \\ -4\,\mathrm{Re}(q_\mu) & -4\,\mathrm{Im}(q_\mu) & 0 \end{pmatrix}. \tag{2.14}$$

The moving frame rotates with x variation according to equations

$$\partial_\mu \mathbf{n}_1 = -\tfrac{1}{2}V_\mu \mathbf{n}_2 - 2\kappa^2(\mathrm{Re}\ q_\mu)\mathbf{n}_3, \tag{2.15a}$$

$$\partial_\mu \mathbf{n}_2 = \tfrac{1}{2}V_\mu \mathbf{n}_1 - 2\kappa^2(\mathrm{Im}\ q_\mu)\mathbf{n}_3, \tag{2.15b}$$

$$\partial_\mu \mathbf{n}_3 = 2(\mathrm{Re}\ q_\mu)\mathbf{n}_1 + 2(\mathrm{Im}\ q_\mu)\mathbf{n}_2. \tag{2.15c}$$

If we denote $U_\mu \equiv (\mathrm{Re}(q_\mu), \mathrm{Im}(q_\mu))$, the system can be written in a more compact form,

$$\partial_\mu \mathbf{n}_i = -\tfrac{1}{2}V_\mu \epsilon_{ij}\mathbf{n}_j - 2\kappa^2 U_{i\mu}\mathbf{s}, \tag{2.16a}$$

$$\partial_\mu \mathbf{s} = 2U_{i\mu}\mathbf{n}_i. \tag{2.16b}$$

The vector $\mathbf{s}\equiv\mathbf{n}_3$ satisfies the constraint

$$(\mathbf{s}(x), \mathbf{s}(x)) = h_{33}, \tag{2.17}$$

where $h_{33}=1$ for $SU(2)$ and $SU(1,1)$ [and $h_{33}=-1$ for $SL(2,R)$]. It belongs to the two-dimensional sphere S^2 or pseudosphere $S^{1,1}$ correspondingly.

Fields V_μ and q_μ are given by projections,

$$V_\mu=-2\kappa^2(\mathbf{n}_2,\partial_\mu\mathbf{n}_1),\quad \mathrm{Re}(q_\mu)=-\frac{\kappa^2}{2}(\mathbf{s},\partial_\mu\mathbf{n}_1),\quad \mathrm{Im}(q_\mu)=-\frac{\kappa^2}{2}(\mathbf{s},\partial_\mu\mathbf{n}_2). \tag{2.18}$$

Two vector fields $(\mathbf{n}_1(x),\mathbf{n}_2(x))$ at each $\mathbf{x}$ form a basis in the tangent space to the corresponding manifold for $\mathbf{s}(x)$. But vectors $\mathbf{n}_1$ and $\mathbf{n}_2$ are not uniquely determined by Eq. (2.4).[16]

If we choose other $\mathbf{n}_1',\mathbf{n}_2'$ as a rotated basis,

$$\mathbf{n}_1'=\cos\alpha\mathbf{n}_1-\sin\alpha\mathbf{n}_2,\quad \mathbf{n}_2'=\cos\alpha\mathbf{n}_2+\sin\alpha\mathbf{n}_1, \tag{2.18}$$

related V_μ' and q_μ' defined by (2.18) are the $U(1)$ gauge transformed fields,

$$V_\mu'=V_\mu+2\partial_\mu\alpha,\quad q_\mu'=e^{i\alpha}q_\mu. \tag{2.19}$$

The expression for the q_μ field is simplified if we introduce a complex basis,

$$\mathbf{n}_+=\mathbf{n}_1+i\mathbf{n}_2,\quad \mathbf{n}_-=\mathbf{n}_1-i\mathbf{n}_2, \tag{2.20}$$

satisfying the following relations:

$$(\mathbf{n}_+,\mathbf{n}_+)=0=(\mathbf{n}_-,\mathbf{n}_-), \tag{2.20a}$$

$$(\mathbf{n}_+,\mathbf{n}_-)=2\kappa^2, \tag{2.20b}$$

$$\mathbf{n}_+\times\mathbf{s}=i\mathbf{n}_+,\quad \mathbf{n}_-\times\mathbf{s}=-i\mathbf{n}_-,\quad \mathbf{n}_-\times\mathbf{n}_+=2i\kappa^2\mathbf{s}. \tag{2.20c}$$

Then

$$q_\mu=\frac{\kappa^2}{2}(\partial_\mu\mathbf{s},\mathbf{n}_+),\quad \overline{q_\mu}=\frac{\kappa^2}{2}(\partial_\mu\mathbf{s},\mathbf{n}_-). \tag{2.21}$$

In terms of (2.20), the moving frame equations (2.16) become

$$D_\mu\mathbf{n}_+=-2\kappa^2q_\mu\mathbf{s}, \tag{2.22a}$$

$$\partial_\mu\mathbf{s}=q_\mu\mathbf{n}_-+\overline{q_\mu}\mathbf{n}_+, \tag{2.22b}$$

where $D_\mu\equiv\partial_\mu-i/2V_\mu$ is the covariant derivative.

This form is explicitly invariant under the local $U(1)$ gauge transformations,

$$\mathbf{s}\to\mathbf{s},\quad \mathbf{n}_+\to e^{i\alpha}\mathbf{n}_+,\quad \mathbf{n}_-\to e^{-i\alpha}\mathbf{n}_-, \tag{2.23}$$

which are just the local rotations in the tangent to the vector $\mathbf{s}$ plane.

As follows from Eqs. (2.22), fields V_μ and q_μ are subject to the system

$$D_\mu q_\nu=D_\mu q_\mu, \tag{2.24a}$$

$$[D_\mu,D_\nu]=-2\kappa^2(\overline{q_\mu}q_\nu-\overline{q_\nu}q_\mu). \tag{2.24b}$$

To describe a time evolution of the three-dimensional physical system, we need to introduce the space-time $M_3=T\times M_2$ decomposition, where T is associated with the time variable $x_3=t$ and M_2 is a two-dimensional space manifold. In this case a time evolution of the moving frame,

$$D_0\mathbf{n}_+ = -2\kappa^2 q_0 \mathbf{s}, \tag{2.25a}$$

$$\partial_0 \mathbf{s} = q_0 \mathbf{n}_- + \overline{q_0}\mathbf{n}_+ , \tag{2.25b}$$

is completely arbitrary due to the arbitrariness of q_0. We recall that q_0 as well as V_0 are Lagrange multipliers of the CS TFT appearing in front of the CS Gauss law of the theory [see Eq. (3.12)]. Moreover, Eq. (2.25b) shows that evolution of the spin vector $\mathbf{s}$ associated with CS TFT, $U(1)$ being gauge invariant, remains completely arbitrary. In this sense the TFT are related to the nonlinear σ model with an arbitrary evolution (reparametrization invariance) or, what is the same, without any evolution, modulo $U(1)$ gauge transformations.

Formally, we can represent Eq. (2.25b) as the spin precession equation,

$$\partial_0 \mathbf{s} = \mathbf{s} \times \mathbf{H}, \tag{2.26}$$

in an arbitrary $U(1)$ gauge invariant magnetic field,

$$\mathbf{H} = i(\overline{q_0}\mathbf{n}_+ - q_0 \mathbf{n}_-). \tag{2.27}$$

Nevertheless, to the above results a topological restriction on the possible spin configurations exists. Indeed, we can imagine that the space M_2 is compact. For example, if we suppose that the value of the spin vector $\mathbf{s} \in S^2$ [$SU(2)$ case] at infinity is fixed $\mathbf{s} \to (0,0,1)$. Then, all smooth configurations describing the mapping of (x_1, x_2) into $\mathbf{s}(x)$, independently of the evolution, are classified by the integer-valued degree of mapping of $S^2 \to S^2$, or the topological charge:

$$Q = \frac{1}{8\pi} \int \epsilon_{ij} \mathbf{s}(\partial_i \mathbf{s} \times \partial_j \mathbf{s}) d^2x = \frac{1}{8\pi} \int \epsilon_{ij}\, \partial_i V_j\, d^2x. \tag{2.28}$$

In terms of our gauge fields, the topological charge density has the form

$$\epsilon_{ij} \mathbf{s}(\partial_i \mathbf{s} \times \partial_j \mathbf{s}) = \epsilon_{ij} \partial_i V_j = B, \tag{2.29}$$

of the radial (along the $\mathbf{s}$) oriented magnetic field $\mathbf{B}$ associated with the vector potential V_j. As well known, Eq. (2.28) states that the winding number of mapping $S^2 \to S^2$ coincides with the winding number of the mapping of the circle S^1 at $x_1^2 + x_2^2 \to \infty$ into the Abelian gauge group manifold. It means that all $U(1)$ gauge transformations (2.19) also fall into topologicoal classes characterized by winding number (2.28). Just substituting (2.19) in to (2.28) we find that under Abelian gauge transformations

$$V_j \to V_j + 2\partial_j \alpha, \tag{2.30}$$

Q transforms as

$$Q \to Q + \frac{1}{4\pi} \int \epsilon_{ij} \partial_i \partial_j \alpha d^2x. \tag{2.31}$$

For a smooth gauge transformation the second term vanishes and Q is invariant.

More generally, if M_2 is a compact Riemann surface of genus g, $M_2 = \Sigma_g$, the charge Q in (2.28) is the first Chern class c_1, which is an integer.[23]

However, if M_2 admits some singular points, Q could be an arbitrary number. Let us consider a potential V_j with charge Q. We perform a singlar at $\mathbf{x}=0$ rotation (2.31) of $(\mathbf{n}_1, \mathbf{n}_2)$ with angle

$$\alpha(\mathbf{x}) = N\theta(\mathbf{x}), \tag{2.32}$$

where $\theta(\mathbf{x}) = \arctan(x_2/x_1)$. Then, using unconventional representation for the planar δ-function[24]

$$\epsilon_{ij}\partial_i\partial_j\theta=(\partial_1\partial_2-\partial_2\partial_1)\theta=2\pi\delta^2(x), \tag{2.33}$$

we find that $\Delta Q = N/2$.

As evident, instead of integer N we can use an arbitrary real number which gives us arbitrary Q. This singular gauge transformation is related with a point vortex creation at $\mathbf{x}=0$ and is described by the anyon potential

$$V_i^A=2\frac{\partial}{\partial x_i}\alpha(\mathbf{x})=2N\frac{\partial}{\partial x_i}\theta(\mathbf{x})=-2N\epsilon_{ij}\partial_j\ \ln|\mathbf{x}|=-2N\epsilon_{ij}\frac{x_j}{|\mathbf{x}|}. \tag{2.34}$$

In a more general situation, for n point vortices located at $\mathbf{x}_1, \ldots, \mathbf{x}_n$, with related strength $N_p(p = 1, \ldots, n)$, the vector potential

$$V_i^A(\mathbf{x};\mathbf{x}_1, \ldots, \mathbf{x}_n)=-2\epsilon_{ij}\sum_{p=1}^{n} N_p\frac{(x^j-x_p^j)}{|\mathbf{x}-\mathbf{x}_p|^2}=-2\epsilon_{ij}\partial_j\sum_{p=1}^{n} N_p\ \ln|\mathbf{x}-\mathbf{x}_p|, \tag{2.35}$$

produces the magnetic field vanishing almost everywhere,

$$B(\mathbf{x})=\epsilon_{ij}\ \partial_i V_j=4\pi\sum_{p=1}^{n} N_p\delta^2(x-x_p). \tag{2.36}$$

The corresponding charge changes as

$$\Delta Q=\frac{1}{2}\sum_{p=1}^{n} N_p. \tag{2.37}$$

III. CHERN–SIMONS GAUGE THEORY REDUCTION

In the previous section we introduced the chiral fields J_μ (2.7) satisfying the zero curvature condition (2.12). The last one, in term of components (2.13), is described by the system (2.24). For fields V_μ and q_μ, subject to (2.24), the moving frame can be reconstructed from Eq. (2.16). Moreover, the current J_μ can be considered as a non-Abelian pure gauge potential. Then, the zero-curvature equations (2.12) are of the Lagrangian form for the pure non-Abelian Chern–Simons functional.

The Chern–Simons action is defined as follows:

$$S[J]=\frac{k}{4\pi}\int_M \mathrm{Tr}\left(J\wedge dJ+\frac{2}{3}J\wedge J\wedge J\right), \tag{3.1}$$

where M is an oriented three-dimensional manifold, J is a gauge connection with values in the Lie algebra $\mathcal{G}$. Action (3.1) is manifestly independent from the space metric, so it was interpreted by Witten as a general covariant theory or topological field theory.[8]

The classical equations of motion following from action (3.1) have the form

$$F=dJ+J\wedge J=0, \tag{3.2}$$

of the zero-curvature condition.

To adopt the canonical approach to the problem, one considers a region of the three-manifold to be isomorphic to $M_3=T\times M_2$, where we interpret T as the time. Then, for the gauge field we have $J_\mu=(J_0,J_j)$, where J_0 is the time component and the action (3.1) takes the form

$$S(J)=-\frac{k}{4\pi}\int_{\Sigma}\int dt\ \epsilon^{ij}\ \mathrm{Tr}\left(J_i\frac{\partial}{\partial t}J_j-J_0F_{ij}\right), \tag{3.3a}$$

where

$$F_{ij}=\partial_iJ_j-\partial_jJ_i+[J_i,J_j]. \tag{3.3b}$$

In the basis

$$T_a=\tfrac{1}{2}\tau_a \quad (a=1,2,3), \tag{3.4a}$$

$$[T_a,T_b]=ic_{abc}T_c, \tag{3.4b}$$

with

$$\mathrm{Tr}(T_aT_b)=\tfrac{1}{2}h_{ab} \tag{3.4c}$$

[see Eq. (2.1)], we have the Poisson brackets for components $J_\mu=\Sigma_{a=1}^{3}(J_\mu)_aT_a$:

$$\{J_i^a(x),J_j^b(y)\}=\frac{4\pi}{k}\epsilon_{ij}h^{ab}\delta^2(x-y). \tag{3.5}$$

Then, in terms of V_μ and q_μ fields,

$$\{V_i(x),V_j(y)\}=-\frac{16\pi}{k}\epsilon_{ij}h_{33}\delta^2(x-y), \tag{3.6}$$

$$\{\mathrm{Re}(q_i(x)),\mathrm{Re}(q_j(y))\}=-\frac{\pi}{k}\epsilon_{ij}h_{11}\delta^2(x-y), \tag{3.7a}$$

$$\{\mathrm{Im}(q_i(x)),\mathrm{Im}(q_j(y))\}=-\frac{\pi}{k}\epsilon_{ij}h_{22}\delta^2(x-y). \tag{3.7b}$$

The last two relations have a more appropriate form if we introduce new fields (this idea was inspired by the gauge relation between 1+1-dimensional NLSE and HM),

$$\psi_\pm=\frac{1}{2\sqrt{\pi}}(q_1\pm iq_2). \tag{3.8}$$

They are directly related with the complex structure on the manifold M_2 in terms of

$$z=x_1+ix_2, \quad \overline{z}=x_1-ix_2. \tag{3.9}$$

The Poisson brackets for the $\psi_\pm$ fields are

$$\{\psi_+(x),\overline{\psi_+}(y)\}=\frac{i}{2k}(h_{11}+h_{22})\delta^2(x-y), \tag{3.10a}$$

$$\{\psi_-(x),\overline{\psi_-}(y)\}=-\frac{i}{2k}(h_{11}+h_{22})\delta^2(x-y). \tag{3.10b}$$

As evident, new fields defined by (3.8) are convenient only for $SU(2)$ and $SU(1,1)$ cases. For $SL(2,R)$ case brackets (3.10) are vanishing and more convenient to use other variables. We can rewrite the brackets in a compact form,

$$\{V_i(x),V_j(y)\}=-\frac{16\pi}{k}\,\epsilon_{ij}\delta^2(x-y), \tag{3.11a}$$

$$\{\psi_+(x),\overline{\psi_+}(y)\}=\frac{i}{k}\,\kappa^2\delta^2(x-y), \tag{3.11b}$$

$$\{\psi_-(x),\overline{\psi_-}(y)\}=-\frac{i}{k}\,\kappa^2\delta^2(x-y), \tag{3.11c}$$

where $\kappa^2=+1$ for $SU(2)$ and $\kappa^2=-1$ for $SU(1,1)$.

The brackets (3.11) allow us to interpret V_μ as an Abelian CS field (the statistical field) and ψ_+,ψ_- as charged matter fields.[18–20]

The action in terms of these fields on the plane has the form

$$\begin{aligned}S=\int dt\int d^2x\Big\{&-\frac{k}{32\pi}\,\epsilon^{\mu\nu\lambda}V_\mu\,\partial_\nu V_\lambda\\&+\frac{ik}{2}\,[(\psi_+\,\overline{D_0\psi_+}-\overline{\psi_+}\,D_0\psi_+)-(\psi_-\,\overline{D_0\psi_-}-\overline{\psi_-}\,D_0\psi_-)]\\&-\frac{k}{2\pi}\,iq_0(\overline{D_-}\,\overline{\psi_+}-\overline{D_+}\,\overline{\psi_-})+\frac{k}{2\pi}\,i\overline{q_0}(D_-\psi_+-D_+\psi_-)\Big\},\end{aligned} \tag{3.12}$$

where $D_\pm=D_1\pm iD_2=\partial_\pm-i/2V_\pm$, $V_\pm=V_1\pm iV_2$. From (3.3) we recognize that the time components V_0 and q_0 of the gauge potential J_0 are the Lagrange multipliers, arbitrariness of which guarantees the gauge invariance (covariance) of the topological action.

Related constraints (3.3a) in components $F=\Sigma_{a=1}^3F_aT_a$ generate $su(2)$ or $su(1,1)$ algebra,

$$\{G_a(\mathbf{x}),G_b(\mathbf{y})\}=c_{abc}G_c(\mathbf{x})\,\delta^2(x-y), \tag{3.13}$$

where rescaled constraints $G^a=-(ik/8\pi)F^a$ have the form

$$G_+=G_1+iG_2=-\frac{k}{2\pi}\,(D_-\psi_+-D_+\psi_-), \tag{3.14a}$$

$$G_-=G_1-iG_2=-\frac{k}{2\pi}\,(\overline{D_-}\,\overline{\psi_+}-\overline{D_+}\,\overline{\psi_-}), \tag{3.14b}$$

$$G_3=\frac{k}{8\pi}\,[(\partial_1V_2-\partial_2V_1)+8\pi(|\psi_+|^2-|\psi_-|^2)]. \tag{3.14c}$$

The physical subspace of the TFT is defined by the constraint surface

$$G_\pm=0,\quad G_0=0,$$

and any breaking of the topological symmetry relates with a deviation from this surface. Constraints (3.14) form a part of the Euler–Lagrange equations for the action (3.12):

$$D_0\psi_\pm=\frac{1}{2\sqrt{\pi}}D_\pm q_0, \tag{3.15a}$$

$$[D_+,D_-]=8\pi\kappa^2(|\psi_+|^2-|\psi_-|^2), \tag{3.15b}$$

$$[D_0,D_\pm]=-4\sqrt{\pi}\kappa^2(\overline{q_0}\psi_\pm-\overline{\psi_\pm}q_0), \tag{3.15c}$$

$$D_+\psi_-=D_-\psi_+. \tag{3.15d}$$

A solution of these equations defines the moving frame according to

$$D_0\mathbf{n}_+=-2q_0\mathbf{s}, \tag{3.16a}$$

$$\partial_0\mathbf{s}=q_0\mathbf{n}_-+\overline{q_0}\mathbf{n}_+, \tag{3.16b}$$

$$D_\pm\mathbf{n}_+=-4\sqrt{\pi}\psi_\pm\mathbf{s}, \tag{3.16c}$$

$$\partial_\pm\mathbf{s}=2\sqrt{\pi}(\psi_\pm\mathbf{n}_-+\overline{\psi_\mp}\mathbf{n}_+), \tag{3.16d}$$

where fields $V_0,V_\pm$, and $q_0,\psi_\pm$ are given by relations

$$V_0=-i(\partial_0\mathbf{n}_+,\mathbf{n}_-),\quad V_\pm=-i(\partial_\pm\mathbf{n}_+,\mathbf{n}_-), \tag{3.17a}$$

$$q_0=\frac{1}{2}(\partial_0\mathbf{s},\mathbf{n}_+),\quad \psi_\pm=\frac{1}{4\sqrt{\pi}}(\partial_\pm\mathbf{s},\mathbf{n}_+). \tag{3.17b}$$

We note that the system (3.15), as well as (3.16), is invariant under conformal transformations,

$$z'=f(z),\quad \overline{z'}=\overline{f(z)},\quad V_-=f'V'_-,\quad V_+=\overline{f'}V'_+,\quad \psi_-=f'\psi'_-,\quad \psi_+=\overline{f'}\psi'_+.$$

At the end of this section we reproduce some useful formulas,

$$(\partial_\pm\mathbf{s},\partial_\pm\mathbf{s})=16\pi\psi_\pm\overline{\psi_\mp}, \tag{3.18}$$

$$(\partial_+\mathbf{s},\partial_-\mathbf{s})=8\pi(|\psi_+|^2+|\psi_-|^2), \tag{3.19}$$

$$\partial_+\mathbf{s}\times\partial_-\mathbf{s}=8i\pi(|\psi_+|^2-|\psi_-|^2). \tag{3.20}$$

IV. NONLINEAR σ-MODEL EXAMPLES

In this section we describe some simple two-dimensional models in the formalism of Sec. II. The first model is conformal invariant, while the second one is just integrable. In both cases time evolution is defined by the Lagrange multipliers q_0,V_0 and has an arbitrary character. Imposing equations of motion for the model as constraints on the field variables, we restrict the phase space of CS TFT.

A. 2+0-dimensional σ model

As a first simple example we consider the Euclidean nonlinear σ model for the classical spin vector $\mathbf{s}$,

$$\partial_+\,\partial_-\mathbf{s}+(\partial_+\mathbf{s},\partial_-\mathbf{s})\mathbf{s}=0. \tag{4.1}$$

The model is conformal invariant. This fact guarantees that the conformal invariance of the CS TFT (3.12), supplied with Eq. (4.1), will be preserved.

Due to Eqs. (3.16c), (3.16d), (3.19), and the relation

$$\partial_+ \partial_- \mathbf{s} = 2\sqrt{\pi}[(D_-\psi_+)\mathbf{n}_- + (\overline{D_-}\,\overline{\psi_+})\mathbf{n}_+) - 8\pi(|\psi_+|^2 + |\psi_-|^2)\mathbf{s}, \tag{4.2}$$

the moving frame (3.16) and the field equations (3.15), consistent with Eq. (4.1), should be supplied with additional constraints

$$D_-\psi_+ = D_+\psi_- = 0. \tag{4.3}$$

The resulting system (3.15) decouples on the evolutionary part,

$$D_0\psi_\pm = \frac{1}{2\sqrt{\pi}} D_\pm q_0, \tag{4.4a}$$

$$[D_0, D_\pm] = -4\sqrt{\pi}\kappa^2(\overline{q_0}\psi_\pm - \overline{\psi_\pm} q_0), \tag{4.4b}$$

which contains arbitrary Lagrange multipliers q_0, V_0 and the spatial part

$$D_-\psi_+ = D_+\psi_- = 0, \tag{4.5a}$$

$$[D_+, D_-] = 8\pi\kappa^2(|\psi_+|^2 - |\psi_-|^2). \tag{4.5b}$$

The last system (4.5) is completely equivalent to the σ model (4.1) and has remarkable properties.[18] Most interesting for TFT may be that Eqs. (4.5), known as the Hitchin equations, can be formulated on an arbitrary Riemann surface.

The system (4.5) [in contrast to Eqs. (4.4)] is also invariant under simple transformation,

$$\psi_+ \to e^{i\gamma}\psi_+, \quad \psi_- \to e^{-i\gamma}\psi_-, \quad V_\pm \to V_\pm, \tag{4.6}$$

where γ=const. This transformation for the σ model is known as the Pohlmeyer's $R^{(\gamma)}$ transformation.[25] It relates to a ''hidden'' symmetry of the model and generates an infinite set of nonlocal conservation laws.[16] It seems not obvious as this symmetry acts in the CS TFT (3.12).

If we attempt to describe the symmetry transformation (4.6) as the global $U(1)$ gauge transformation (2.19), (2.23), we immediately obtain that one of the fields ψ_+, ψ_- should vanish. As a result, the system (4.5) reduces to the self-(anti-)dual Chern–Simons equations:[24]

$$D_\pm\psi_\mp = 0, \tag{4.7a}$$

$$[D_+, D_-] = \pm 8\pi\kappa^2|\psi_\mp|^2, \tag{4.7b}$$

related with the Liouville equation. The instantons (topological solitons) of the model (4.1) correspond to the Chern–Simons solitons of the model (4.7),[18] while the topological charge (2.28) becomes of the electric charge form

$$Q_\pm = \pm\int |\psi_\pm|^2 \, d^2x.$$

Solutions other than solitons, when both ψ_+ and $\psi_- \neq 0$, are described by the conformal Sinh-Gordon equation[26] (Toda hierarchy) reduced from (4.5).[18] It is worth noting that both of the systems (4.5) and (4.7) is conformal and R invariant. However, only the self-dual system (4.7)

admits the Pohlmeyer's symmetry (4.6), as a gauge symmetry. This fact intimately relates with the Darboux and C integrability of the Liouville equation[27,28] and with special properties of the CS action, admitting diffeomorphism invariance as the gauge invariance.

B. (1+1)-Heisenberg model

If in the previous case we considered the conformal invariant integrable model, now we like to break the conformal invariance, but preserve integrability. This is the well-known classical continuous isotropic Heisenberg model, describing precession of the spin **s** according to the Landau–Lifshitz equation,

$$\partial_0 \mathbf{s} = \mathbf{s} \times \partial_j \, \partial^j \mathbf{s}, \tag{4.8}$$

where **s** belongs to the two-dimensional sphere S^2 (or pseudosphere $S^{1,1}$).[31]

In this section we examine only the 1+1-dimensional case (the 2+1 -dimensional model is considered in Sec. V). We will treat here both coordinates as the space coordinates. Then the model

$$\partial_1 \mathbf{s} = \mathbf{s} \times \partial_2^2 \mathbf{s}, \tag{4.9}$$

is some kind of two-dimensional σ model.

Substituting

$$\partial_1 \mathbf{s} = q_1 \mathbf{n}_- + \overline{q_1} \mathbf{n}_+ , \tag{4.10a}$$

$$\partial_2^2 \mathbf{s} = D_2 \mathbf{n}_- + \overline{D_2} \mathbf{n}_+ - 4|q_2|^2 \mathbf{s}, \tag{4.10b}$$

to Eq. (4.9), we find the constraint between components,

$$q_1 = i \, D_2 q_2 , \tag{4.11}$$

where the covariant derivative $D_2 = \partial_2 - (i/2)V_2$. Equation (4.11) allows us to exclude the q_1 field from equations.

The moving frame equations (2.22) now read as

$$D_1 \mathbf{n}_+ = -2i\kappa^2 \, D_2 q_2 \, \mathbf{s}, \tag{4.12a}$$

$$D_2 \mathbf{n}_+ = -2\kappa^2 q_2 \mathbf{s}, \tag{4.12b}$$

$$\partial_1 \mathbf{s} = i \, D_2 q_2 \mathbf{n}_- - i \, \overline{D_2} \overline{q_2} \mathbf{n}_+ , \tag{4.12c}$$

$$\partial_2 \mathbf{s} = q_2 \mathbf{n}_- + \overline{q_2} \mathbf{n}_+ , \tag{4.12d}$$

while the field equations are

$$i \, D_1 q_2 + D_2^2 q_2 = 0, \tag{4.13a}$$

$$\partial_1 V_2 - \partial_2 V_1 = -4\kappa^2 \partial_2 |q_2|^2 . \tag{4.13b}$$

In terms of redefined fields,

$$A_1 = V_1 + 4\kappa^2 |q_2|^2, \quad A_2 = V_2 , \tag{4.14}$$

(4.13) becomes the $U(1)$ gauged Nonlinear Schrödinger Equation,

$$i\left(\partial_1-\frac{i}{2}A_1\right)q_2+\left(\partial_2-\frac{i}{2}A_2\right)^2 q_2-2\kappa^2|q_2|^2q_2=0, \tag{4.15a}$$

$$\partial_1 A_2-\partial_2 A_1=0. \tag{4.15b}$$

The second equation allows one to exclude the potentials A_1 and A_2 by the $U(1)$ gauge transformation. If $A_j=2\partial_j\lambda$, we define a new, gauge invariant $\Phi=qe^{i\lambda}$ subject to the Nonlinear Schrödinger equation,

$$i\ \partial_1\Phi+\partial_2^2\Phi-2\kappa^2|\Phi|^2\Phi=0. \tag{4.16}$$

As is well known, this equation is integrable and admits an infinite number of conservation laws, interpreted as continuity equations in our case.

The topological charge (2.28) appears now as

$$Q=-\kappa^2\frac{2}{\pi}\int d^2x\ \partial_2|\Phi|^2=-\kappa^2\frac{2}{\pi}\int dx_1(|\Phi(x_1,x_2=L_+)|^2-|\Phi(x_1,x_2=L_-)|^2),$$

where $L_\pm$ are the boundary values in the second space direction. The usual evolution form for NLSE, when $x_1=t$, $x_2=x$, gives the meaning of

$$Q=\frac{1}{4\pi}\int \mathbf{s}\ \partial_t\mathbf{s}\times\partial_x\mathbf{s}\ dt\ dx=-\kappa^2\frac{2}{\pi}\int_{x=C}dt|\Phi(x,t)|^2,$$

as a one dimensional Wess–Zumino term. It turns out that well-known soliton solutions on an infinite space line (the plane for M_2) and periodic solutions on the finite interval (the cylinder for M_2) always have vanishing Q. A nonvanishing contribution should appear for the compact on (x,t) boundary conditions (the Riemann surface for M_2).

It is worth noting that integrability of models (4.9) and (4.16) is connected with the Lax pair representation or ZCC with an arbitrary spectral parameter. The loop algebra structure provides nonlocal conserved quantities, generating non-Abelian algebra for the NLSE.[29] They arise as a hidden non-Abelian structure of the model (4.16). We understand now the geometrical meaning of this structure, since the model phase space can be considered as the tangent plane to the two-dimensional manifold, being a sphere for $\kappa^2=1$ and a pseudosphere for $\kappa^2=-1$.[31] Moreover, in the next section we show that the spectral parameter has an origin from the extra space direction.

V. DIMENSIONAL REDUCTION OF 2+1 HM

From the action (3.3) or (3.12) we conclude that evolution of the model is completely defined by Lagrange multipliers. Usually to fix gauge freedom one uses the Hamiltonian gauge, when

$$q_0=0,\quad V_0=0.$$

Thus, all considered field configurations are static. In this case reparametrization invariance of the theory corresponds to an arbitrary time dependence for parameters of the moduli space. But if we like to study an integrable deformation of the topological symmetry we need to consider less restricted gauge conditions, providing integrable dynamics.

In the present section we choose a different gauge condition. Since evolution equation for σ models in tangent space reduces to constraints on the phase space variables, we can choose this constraint as a new gauge condition. Then, in this gauge the resulting CS theory should have the corresponding time evolution.[18–20]

We consider the HM (4.8) in 2+1 dimensions,

$$\partial_0 \mathbf{s} = \mathbf{s} \times (\partial_1^2 + \partial_2^2)\mathbf{s}, \tag{5.1}$$

with $(\mathbf{s}, \mathbf{s}) = 1$.

From the moving frame equations (2.22), we conclude that Eq. (5.1) leads to the constraint on q_0:

$$q_0 = i\, D_1 q_1 + i\, D_2 q_2 . \tag{5.2}$$

This relation allows one to exclude q_0 from the system (2.22), and we have

$$D_0 \mathbf{n}_+ = -2i\kappa^2 (D_k q_k)\mathbf{s}, \tag{5.3a}$$

$$D_k \mathbf{n}_+ = -2\kappa^2 q_k \mathbf{s}, \tag{5.3b}$$

$$\partial_0 \mathbf{s} = i(D_k q_k)\mathbf{n}_- - i(\overline{D_k q_k})\mathbf{n}_+ , \tag{5.3c}$$

$$\partial_k \mathbf{s} = q_k \mathbf{n}_- + \overline{q_k}\mathbf{n}_+ \quad (k = 1,2). \tag{5.3d}$$

Remaining field variables should satisfy the system

$$iD_0 q_k + D_k D_l q_l = 0, \tag{5.4a}$$

$$D_k q_l = D_l q_k \quad (k,l = 1,2), \tag{5.4b}$$

$$[D_k, D_l] = -2\kappa^2 (\overline{q_k} q_l - q_k \overline{q_l}), \tag{5.4c}$$

$$[D_0, D_k] = 2i\kappa^2 (q_k\, \overline{D_l q_l} + \overline{q_k}\, D_l q_l). \tag{5.4d}$$

In terms of complex fields (3.8),

$$\psi_\pm = \frac{1}{2\sqrt{\pi}} (q_1 \pm i q_2), \tag{5.5}$$

we have for the moving frame

$$D_0 \mathbf{n}_+ = -4i\sqrt{\pi}(D_- \psi_+)\mathbf{s} + 4i\pi\kappa^2 (|\psi_+|^2 + |\psi_-|^2)\mathbf{n}_+ , \tag{5.6a}$$

$$D_\pm \mathbf{n}_+ = -4\sqrt{\pi}\psi_\pm \mathbf{s}, \tag{5.6b}$$

$$\partial_0 \mathbf{s} = 2i\sqrt{\pi}((D_- \psi_+)\mathbf{n}_- - (\overline{D_-}\,\overline{\psi_+})\mathbf{n}_+), \tag{5.6c}$$

$$\partial_\pm \mathbf{s} = 2\sqrt{\pi}(\psi_\pm \mathbf{n}_- + \overline{\psi_\mp}\mathbf{n}_+), \tag{5.6d}$$

and for the field equations,

$$i\, D_0 \psi_\pm + (D_1^2 + D_2^2)\psi_\pm + 8\pi\kappa^2 |\psi_\pm|^2 \psi_\pm = 0, \tag{5.7a}$$

$$D_- \psi_+ = D_+ \psi_- , \tag{5.7b}$$

$$[D_+, D_-] = 8\pi\kappa^2 (|\psi_+|^2 - |\psi_-|^2), \tag{5.7c}$$

$$[D_0, D_\pm] = 8i\pi\kappa^2 (\overline{\psi_\mp}\, D_\pm \psi_\mp + \psi_\pm\, \overline{D_\mp}\,\overline{\psi_\pm}) - 4i\pi\kappa^2 \partial_\pm (|\psi_+|^2 + |\psi_-|^2). \tag{5.7d}$$

The covariant derivatives in the system (5.6) and (5.7) are defined as before [see Eq. (3.12)]:

$$D_{\pm}=\partial_{\pm}-\frac{i}{2}A_{\pm},\quad D_0=\partial_0-\frac{i}{2}A_0, \tag{5.8}$$

with $A_{\pm}=V_{\pm}$, but redefined as

$$A_0=V_0-8\pi\kappa^2(|\psi_+|^2+|\psi_-|^2). \tag{5.9}$$

For the static field configurations, Eq. (5.1) reduces to the σ model (4.1), considered before. Now we are going to perform a dimensional reduction of the model to have an integrable evolution system. Let $M=T\times R\times S$, where R is the real line associated with the x_1 space coordinate and S is compactified on the circle second space coordinate x_2. As usual, for zero modes we are looking for equations independent of x_2,

$$i\ D_0\psi_{\pm}+\left[D_1^2+\left(\frac{i}{2}A_2\right)^2\right]\psi_{\pm}+8\pi\kappa^2|\psi_{\pm}|^2\psi_{\pm}=0, \tag{5.10a}$$

$$\left(\partial_1-\frac{i}{2}A_-\right)\psi_+=\left(\partial_1-\frac{i}{2}A_+\right)\psi_-, \tag{5.10b}$$

$$\partial_1 A_2=-8\pi\kappa^2(|\psi_+|^2-|\psi_-|^2), \tag{5.10c}$$

$$\partial_0 A_1-\partial_1 A_0=8\pi\kappa^2 A_2(|\psi_+|^2-|\psi_-|^2), \tag{5.10d}$$

$$\partial_0 A_2=-8i\pi\kappa^2[(\overline{\psi_+}\ \partial_1\psi_+-\psi_+\ \partial_1\overline{\psi_+})-(\overline{\psi_-}\ \partial_1\psi_--\psi_-\ \partial_1\overline{\psi_-})-iA_1(|\psi_+|^2-|\psi_-|^2)]. \tag{5.10e}$$

If instead of the potential A_0 we introduce

$$\mathscr{A}_0=A_0-\tfrac{1}{2}A_2^2,\quad \mathscr{A}_1=A_1,\quad \mathscr{A}_2=A_2, \tag{5.11}$$

Eq. (5.10d) becomes of the vanishing field strength form

$$\partial_0\mathscr{A}_1-\partial_1\mathscr{A}_0=0, \tag{5.12d}$$

and for the remain equations we have

$$i\ \mathscr{D}_0\psi_{\pm}+\mathscr{D}_1^2\psi_{\pm}+8\pi\kappa^2|\psi_{\pm}|^2\psi_{\pm}=0, \tag{5.12a}$$

$$\left(\partial_1-\frac{i}{2}\mathscr{A}_-\right)\psi_+=\left(\partial_1-\frac{i}{2}\mathscr{A}_+\right)\psi_-, \tag{5.12b}$$

$$\partial_1\mathscr{A}_2=-8\pi\kappa^2(|\psi_+|^2-|\psi_-|^2), \tag{5.12c}$$

$$\partial_0\mathscr{A}_2=-8i\pi\kappa^2[(\overline{\psi_+}\ \mathscr{D}_1\psi_+-\psi_+\ \overline{\mathscr{D}_1}\,\overline{\psi_+})-(\overline{\psi_-}\ \mathscr{D}_1\psi_--\psi_-\ \overline{\mathscr{D}_1}\,\overline{\psi_-}), \tag{5.12e}$$

where $\mathscr{D}_0=\partial_0-(i/2)\mathscr{A}_0$, $\mathscr{D}_1=\partial_1-(i/2)\mathscr{A}_1$. Comparing Eqs. (5.12a) and (5.12d) with gauged NLSE (4.15a)–(4.15b), we recognize complete equivalence. Using the same as before procedure, we can compensate the gauge potentials via $U(1)$ rotation,

$$\mathscr{A}_0=2\ \partial_0\lambda,\quad \mathscr{A}_1=2\ \partial_1\lambda,\quad \Phi_{\pm}=\psi_{\pm}e^{i\lambda}. \tag{5.13}$$

Thus, we find that both of the Φ_+, Φ_- fields satisfy the NLSE,

$$i\ \partial_0\Phi_\pm+\partial_1^2\Phi_\pm+8\pi\kappa^2|\Phi_\pm|^2\Phi_\pm=0, \tag{5.14}$$

and the set of relations connecting $\mathscr{A}_2$ with Φ_+, Φ_- fields,

$$\partial_1\Phi_+-\partial_1\Phi_-=1/2.\mathscr{A}_2(\Phi_++\Phi_-), \tag{5.15a}$$

$$\partial_1.\mathscr{A}_2=-8\pi\kappa^2(|\Phi_+|^2-|\Phi_-|^2), \tag{5.15b}$$

$$\partial_0.\mathscr{A}_2=-8i\pi\kappa^2[(\overline{\Phi}_+\ \partial_1\Phi_+-\Phi_+\ \partial_1\overline{\Phi}_+)-(\overline{\Phi}_-\ \partial_1\Phi_--\Phi_-\ \partial_1\overline{\Phi}_-)]. \tag{5.15c}$$

The system (5.15) allows one to define the $\mathscr{A}_2$ field in explicit form,

$$\mathscr{A}_2=\epsilon_\pm\sqrt{\alpha_0^2-16\pi\kappa^2|\Phi_+-\Phi_-|^2}, \tag{5.16}$$

where α_0 is an integration constant, $\epsilon_\pm=\pm1$. I can easily show that if both Φ_+ and Φ_- are solutions of the NLSE (5.14), then the evolution for $\mathscr{A}_2$ (5.16) is satisfied to Eq. (5.15c).

But Eq. (5.15a) with condition (5.16) is just the space part of the Bäcklund transformations for NLSE (5.14). The related time part can be easily reconstructed from the system (5.15). Thus, a surprising moment arising from the (2+1)-dimensional reduction is an interpretation of the Bäcklund transformation for NLSE in terms of the Abelian Chern–Simons gauge field, associated with the extra space coordinate x_2.

When $\Phi_+=\Phi_-$ the $\mathscr{A}_2=\epsilon_\pm\alpha_0=$const. As we show immediately, this constant has the meaning of the spectral parameter. When $\Phi_+\neq\Phi_-$, that means a soliton creation $\mathscr{A}_2$ is an inhomogeneous function measuring the departure of Φ_+ from Φ_-.

To clarify the meaning of the homogeneous part α_0, we turn now to the chiral current (2.7a),

$$J_\mu=g^{-1}\ \partial_\mu g=\frac{i}{4}\ \sigma_3V_\mu+\begin{pmatrix}0 & -\kappa^2\overline{q_\mu}\\ q_\mu & 0\end{pmatrix}. \tag{5.17}$$

We can carry out the $U(1)$ gauge transformation (5.13),

$$g\to ge^{(i/4)\lambda\sigma_3}. \tag{5.18}$$

As a result we have

$$J_1=\sqrt{\pi}\begin{pmatrix}0 & -\kappa^2(\overline{\Phi}_++\overline{\Phi}_-)\\ \Phi_++\Phi_- & 0\end{pmatrix},$$

$$J_2=\frac{i}{4}\ \sigma_3.\mathscr{A}_2-i\sqrt{\pi}\begin{pmatrix}0 & \kappa^2(\overline{\Phi}_+-\overline{\Phi}_-)\\ \Phi_+-\Phi_- & 0\end{pmatrix},$$

$$J_0=\frac{i}{8}\ \sigma_3[\mathscr{A}_2^2+16\pi\kappa^2(|\Phi_+|^2+|\Phi_-|^2)]+i\sqrt{\pi}\begin{pmatrix}0 & \kappa^2(\overline{\mathscr{D}}_-\overline{\Phi}_++\overline{\mathscr{D}}_+\overline{\Phi}_-)\\ \mathscr{D}_-\Phi_++\mathscr{D}_+\Phi_- & 0\end{pmatrix}.$$

Using (5.7b),

$$\mathscr{D}_-\Phi_+=\mathscr{D}_+\Phi_-,$$

we can rewrite it as

$$J_+=-\frac{1}{4}\ \sigma_3.\mathscr{A}_2+2\sqrt{\pi}\begin{pmatrix}0 & -\kappa^2\overline{\Phi}_-\\ \Phi_+ & 0\end{pmatrix}, \tag{5.19a}$$

$$J_0=\frac{i}{8}\,\sigma_3[\mathscr{A}_2^2+16\pi\kappa^2(|\Phi_+|^2+|\Phi_-|^2)]+2i\sqrt{\pi}\begin{pmatrix}0 & \kappa^2\,\overline{\mathscr{D}}_+\overline{\Phi}_-\\ \mathscr{D}_-\Phi_+ & 0\end{pmatrix}. \tag{5.19b}$$

Now, let

$$\Phi_+=\Phi_-\equiv\frac{1}{2\sqrt{\pi}}\,\Phi, \tag{5.20}$$

then, from (5.16),

$$\mathscr{A}_2=\epsilon_\pm\alpha_0\equiv 4\lambda_0. \tag{5.21}$$

As a result we have the well-known Lax pair for NLSE,

$$J_+=-\lambda_0\sigma_3+\begin{pmatrix}0 & -\kappa^2\overline{\Phi}\\ \Phi & 0\end{pmatrix}, \tag{5.22a}$$

$$J_0=i\sigma_3[2\lambda_0^2+\kappa^2|\Phi|^2]+i\begin{pmatrix}0 & \kappa^2(\partial_1+2\lambda_0)\overline{\Phi}\\ (\partial_1-2\lambda_0)\Phi & 0\end{pmatrix}. \tag{5.22b}$$

The Lax pair for the 1+1 HM model (4.9) can be constructed from (5.22) by the usual procedure of the gauge transformation, in terms of (2.2) trihedral N_3.[30,31]

It is clear now that constant λ_0 has a meaning of the spectral parameter. The remarkable fact is that J_+ consists of two parts: J_1 part is independent of the spectral parameter and J_2 is completely defined in terms of it.

As known, in order to investigate the infrared properties of the theory, we can expand the gauge field $\mathscr{A}_2$ in a Fourier series and separate out the part that plays the main role at long distances. This is the constant in space (x_1) term,

$$\mathscr{A}_2\cong 4\lambda_0\left(1+\frac{\pi\kappa^2}{2\lambda_0^2}\,|\Phi_+-\Phi_-|^2+\cdots\right). \tag{5.23}$$

Thus, we can interpret the spectral parameter as a condensate value for the Chern–Simons gauge field $\mathscr{A}_2$ associated with the extra dimension.

As we see, the Lax pair with the spectral parameter flow, defining all the miracles of soliton mathematics, has a simple interpretation in terms of an extra space direction and CS TFT.

VI. CONCLUSION

In conclusion I would like to emphasize some points. First, as shown above, the non-Abelian TFT (3.1) represented in the form (3.12) could be interpreted as the Abelian Chern–Simons gauge theory interacting with a doublet of matter fields.[20] Usually, the Abelian gauge field is called the ''statistical field'' since it defines the anyonic statistics for matter fields. For a more direct relation we need to rescale the ''matter'' fields,

$$\psi_\pm=\frac{1}{\sqrt{k}}\,\Psi_\pm,$$

to have normal canonical brackets (3.11). Then, the Chern–Simons Gauss law (3.15b) becomes

$$\partial_1 V_2 - \partial_2 V_1 = -\frac{8\pi\kappa^2}{k}\,(|\Psi_+|^2 - |\Psi_-|^2).$$

From this form we recognize that the coupling constant k for the non-Abelian theory (3.1) coincides with the statistical parameter for fractional statistics. It means that in quantized (3.1) theory the matter fields could appear (after singular gauge transformation) as anyons.[20]

The 1+1-dimensional reduction of the model (5.7) shows that two components $\mathscr{A}_0$, $\mathscr{A}_1$ of the statistical gauge field can be removed by gauge transformation. But component $\mathscr{A}_2$ (5.16) related to the extra space coordinate has a deep physical meaning. Thus, for infrared properties of the Chern–Simons theory (3.12), the constant in space vector potential,

$$A_i(x) = X_i(t) + \cdots,$$

depending only of time, is relevant. The corresponding Chern–Simons term in (3.12),

$$\frac{k}{16\pi}\,\dot{\mathbf{X}}\times\mathbf{X},$$

has a simple physical interpretation. If we consider (X_1, X_2) as coordinates of the charged particle in the plane, and switch on the magnetic field orthogonal to the plane, the Lorentz force will arise. It connects two directions X_1, X_2 in such a way that energy from the first direction will flow to the second one. In our case it means that due to the Chern–Simons structure in the topological action (3.12), our 1+1-dimensional gauge theory (5.14), (5.15) continue to feel an extra space coordinate. But all dependence of the extra space coordinate is hidden in the spectral parameter (5.21). Of course, the gauge invariant nonlinear equations (5.14) are independent of x_2 and λ_0.

Thus, the potential (5.16) generally includes two parts. A part with the spectral parameter only is a constant, and has meaning of the ''condensate'' for the statistical gauge field, while the nonhomogeneous part of $\mathscr{A}_2$ comes from the deviation between two solutions of the NLSE (5.14). We know that (5.15)–(5.16) is an elementary Bäcklund transformation for NLSE. If one of the fields is vanishing, it provides the one-soliton solution for the second one. Corresponding value of $\mathscr{A}_2$ we call the one-soliton gauge potential. This allows us to formulate a gauge invariance principle. The statistical gauge field is a homogeneous, globally defined field in the case (5.20). When condition (5.20) is broken, that means a soliton is created, the gauge field $\mathscr{A}_2$ becomes a local function of coordinate x_1. Hence, we observe that the statistical gauge field is an inseparable phenomena accompanying the soliton creation. It is a relic of the Chern–Simons Gauss law, which states the creation of magnetic flux by a particle creation. According to this, in anyon physics, we interpret the physical excitations as particles with an attached magnetic flux. Consequently, even the one-dimensional solitons are excitations attached with a statistical magnetic field. Indeed, if we put one of the fields, say $\Phi_- = 0$, from Eq. (5.15b) follows the one-dimensional (!) CS Gauss law,

$$B(x) = \frac{8\pi\kappa^2}{k}\,|\Psi_+|^2.$$

For a soliton with large amplitude $\eta = \mathrm{Im}\,\lambda_0$, we can write approximately

$$B(x) \approx \frac{16\pi\kappa^2}{k}\,\eta\,\delta(x).$$

This relation should be compared with a two-dimensional ''prototype'' (2.36). It shows explicitly that one soliton is always attached to the ''magnetic'' field. The line integral (''one-dimensional flux''),

$$\int B\, dx = \frac{8\pi\kappa^2}{k} \int |\Psi_+|^2\, dx = \frac{16\pi\kappa^2}{k}\, \eta,$$

is time independent and the well-known first integral of NLSE. It has a simple interpretation of the rescaled soliton amplitude Im λ_0 and really is inseparable from the soliton in any collisions.

The above discussion, appearing exactly 120 yr after Bäcklund's first paper on his transformation theory,[32] implies a new, physical interpretation of the Bäcklund transformation. It gives BT explicitly in terms of an inhomogeneous Abelian CS gauge field and indicates the deep relation between CS TFT and BT. We conjecture that results have the general meaning and are applicable to other integrable models. In fact, all that we need are constraints for CS theory, arising from the nonlinear σ model. Thus, earlier we showed[19] that the classical spin model in planar condensed media, the so-called Topological Magnet,[17] provides for gauge invariant fields the Davey–Stewartson equations. Dimensional reduction in this case also leads to the NLSE and related BT. Our result suggests that while the Lax pair depends on an additional spectral parameter, which is remnant of the three-dimensional theory, the reduced Nonlinear Evolution Equation is gauge invariant and independent of that parameter. It would be interesting to obtain in this way the Lax pair for the SDYM from proper TFT in higher then four dimensions.

Finally, we remark on the possibility of tracking the connection between quantum exactly soluble TFT and integrable models in the spirit of Ref. 33. In this case, ideas of dissipative dynamics associated with CS theory[34] could be relevant to treat the indefinite metric structure of TFT.

(Received 23 August 1995; accepted for publication 5 April 1996)

Studies of models of current flow behaviour in electrical impedance tomography (EIT) have shown that the current density distribution varies extremely rapidly near the edge of the electrodes used in the technique. This behaviour imposes severe restrictions on the numerical techniques used in image reconstruction algorithms. In this paper we have considered a simple two dimensional case and we have shown how the theory of end point/pinch singularities which was developed for studying the anomalous thresholds encountered in elementary particle physics can be used to give a complete description of the analytic structure of the current density near to the edge of the electrodes. As a byproduct of this study it was possible to give a complete description of the Riemann sheet manifold of the eigenfunctions of the logarithmic kernel. These methods can be readily extended to other weakly singular kernels. © *1996 American Institute of Physics.* [S0022-2488(96)02307-9]

I. INTRODUCTION

There are numerous examples of practical situations where electric current is used to probe the interior of some object of interest. One emerging technology which specifically uses this approach has become known as electrical impedance tomography (EIT). This is a method of medical and industrial imaging in which electrical currents are applied to the surface of an object and the induced surface voltage is measured. These data are then used to produce an image of the conductivity distribution in the interior of the object. An extensive literature exists on EIT.[1]

The particular feature of EIT which is of interest to us here is related to the observation that in practice the electric current can be applied only through a finite number of electrodes—currently in the range 16–64 for two dimensional applications. The consequences of this fact and the appropriate mathematical modelling of the electrodes have been discussed in a number of papers.[2–4]

In medical applications one of the significant problems for EIT is the existence of a thin layer of material of high, but unknown, contact impedance lying between the current drive electrodes and the body. Various models have been proposed to describe this phenomenon but one which has strong experimental support[5] is to suppose that on the (finite size) electrodes the electric potential, Φ, is related to the electric current $\sigma(\partial\Phi/\partial n)$ by

$$\Phi + \mathcal{Z}\sigma \frac{\partial \Phi}{\partial n} = V$$

where σ is the conductivity just below the electrode, $\mathcal{Z}$ is the contact impedance and V is the potential of the electrode (a constant). The induced voltage, Φ, is found by making measurements on high impedance electrodes, also attached to the surface.

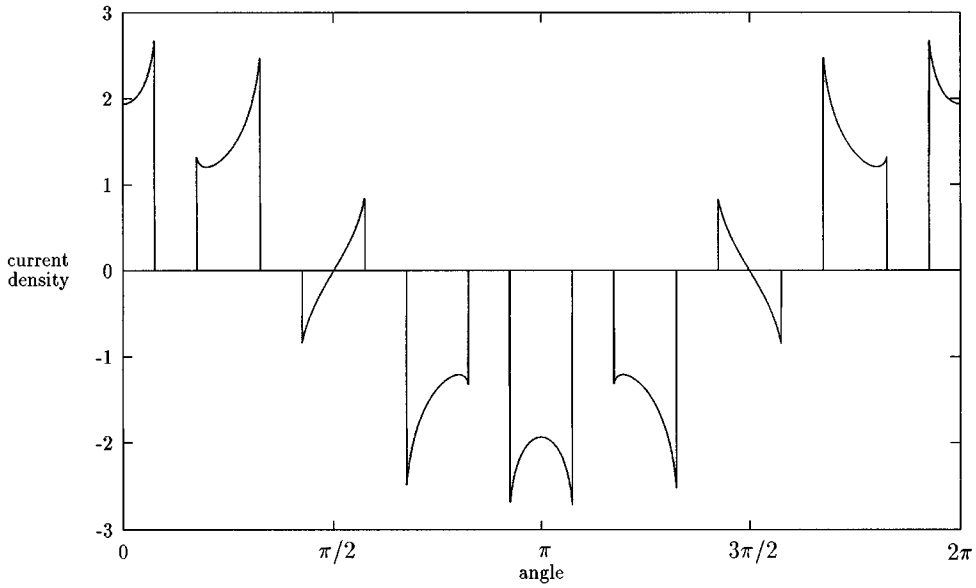

FIG. 1. The current density distribution obtained solving Eq. (6) numerically for the case of 8 electrodes, each having a contact impedance equal to 0.22.

This model has been studied numerically using a boundary Fourier technique[2] for the case of constant $\mathscr{Z}$ and an interesting phenomenon which was observed was the appearance of very sharp peaks in the current density distribution at the edge of the electrodes. More recently the model has been studied numerically for non-constant $\mathscr{Z}$ using the weakly singular integral equation described in Eq. (6) below. Although the singularity is weak, its existence has important consequences for the numerical treatment of this equation. Details of this work will be given elsewhere[6] but the point which we wish to emphasize here is that the distinctive sharp peak behaviour occurs for a wide range of conductivity distributions and contact impedance forms. In Fig. 1 we show typical results for the current density distribution in the case of eight electrodes with an input current on the lth electrode of $\cos\theta_l$.

An unwelcome consequence of the sharpness of these peaks is that the direct numerical modelling of the potential with the finite element method has become an excessively substantial task due to the high number of mesh points needed near to the edge of the electrodes in order to accommodate the rapid variation of the normal derivative of the potential. The aim of this article is to give an explicit analytic description of these singularities in a form which should substantially improve the speed of the numerical computation.

Since the appearance of the peaks is a boundary phenomenon which is very little influenced by the actual values of the conductivity σ inside the disk—see the discussion in Section III about the *dominant singular integral equation*—we shall focus our attention on the constant σ case. In this case the governing partial differential equation is Laplace's equation and our problem becomes one in potential theory. Consequently, we shall study the electrode model defined above for the standard domain of the unit disk. The importance of the unit disk stems from the fact that the potential problem for any simply connected two dimensional domain can be reduced to the unit disk by an appropriate conformal mapping.

In earlier investigations of these peaks it had been shown[4] that this problem can be solved explicitly in the *zero* contact impedance case ($\mathscr{Z}\equiv 0$), for the case of two electrodes. In this specific case one finds that near the edge of the electrodes

$$\frac{\partial \Phi}{\partial n} \sim \frac{1}{\sqrt{x}}$$

where x is the distance, along the boundary, from the edge of the electrode. Thus the normal derivative of Φ becomes infinite at the edge of the electrodes. However if the contact impedance $\mathcal{Z}$ is not zero, although $\partial\Phi/\partial n$ still has sharp peaks at the edge of the electrodes (see Fig. 1), it remains finite since both Φ and V are finite and since $\partial\Phi/\partial n \equiv (V-\Phi)/(\mathcal{Z}\sigma)$. This shows that the nature of the singularities in the $\mathcal{Z}\neq 0$ case *cannot* be obtained from that encountered in the soluble $\mathcal{Z}\equiv 0$ model. Thus, in order to have a correct understanding of these singularities some deeper investigations are necessary and this represents the main goal of the present paper.

Overview of the paper

After a short description of the mathematical model in Section II, in Section III we formulate the boundary problem as an integral equation. As shown there the kernel of this integral equation has a weak (logarithmic) singularity, and this has direct consequences for the singularities of the solution near the electrodes edges. We will describe these singularities in terms of an asymptotic series for the potential.

In pursuing this program we shall have to step off the real axis into the neighbouring complex plane. This will be necessary since we will write the solution of the integral equation as an infinite sum of the free term and the eigenfunctions of the weakly singular kernel. As one knows, there are many examples of series uniformly and absolutely convergent on the real axis which cannot be differentiated term by term [for example $\Sigma_{n=1}\cos(nx)/n^2$ converges uniformly, while the kth derivatives of its terms contain factors of the form n^{k-2} which spoil any convergence], but in deriving asymptotic expressions we will often have to perform this kind of operation. However, in contrast to what happens on a real interval, in the complex plane there exists a marvelous theorem which states that given a sequence $\{f_i\}$ of functions holomorphic in some domain Ω which converge uniformly, $f_i \to f$, on all compact subsets of Ω, then (a) f is a holomorphic function in Ω and (b) f_i' as well as the higher derivatives $f_i^{(n)}$ tend uniformly towards f' and $f^{(n)}$ on any compact subset of Ω. In some way by walking in the complex plane around the singularity one has a better view of what really happens there.

In studying the analytic properties of the free term (Section IV) and of the eigenfunctions (Section V), we shall use techniques similar to those from the ''pinch and end point singularities theory'' which was developed some time ago by Eden, Landshoff, Olive and Polkinghorne[7] in elementary particle physics. However our problem is more complex than that related to the Feynman graphs in two respects. First we will have to consider moving cuts rather than moving poles, and second we will no longer have integrals over some explicitly given functions, but integrals over the *a priori* unknown eigenfunctions whose singularities we are trying to find.

Handling infinite series can also be dangerous because spurious singularities may creep in as happens, for example, with the common geometric series. The proof that this does not happen in the neighbourhood of the singular point is given in the first subsection of the Section V. The analytic properties of the eigenfunctions and the recursive procedure to compute the coefficients in the asymptotic expansions are given in Section V B [see Eq. (67)]. From this expansion it follows that the spikes of the current density near the edge of the electrodes are of the form

$$\frac{\partial \Phi}{\partial n} \sim \sum_{m=1}^{r} \sum_{k=1}^{m} c_{mk} x^m \cdot \log^k(x) + \mathcal{O}(x^{r+1-\varepsilon}) + \text{regular part},$$

where x is the distance along the boundary from the edge of the electrode and c_{mk} some real coefficients. Since the derivative of $x\log(x)$ is $1+\log(x)$, this means that although these spikes are *finite* they have *infinite derivatives*.

II. THE MATHEMATICAL MODEL FOR EIT

The usual model used to describe the forward problem in EIT is obtained by considering the object as consisting of isotropic material with conductivity distribution σ contained in an open, simply connected region Ω surrounded by a reasonably smooth boundary $\partial\Omega$. On the surface, $\partial\Omega$, a number, L, of electrodes are attached and electrical current is applied.

In this case Maxwell's equations give:

$$\nabla\cdot(\sigma\nabla\Phi)=0 \quad \text{in} \quad \Omega. \tag{1}$$

Further, the total current driven on the lth electrode $I_l = \int_{\Gamma_l}\sigma(\partial\Phi/\partial n)$ is a known quantity and there is no current outflow outside the region covered by the electrodes, $\Gamma=\Gamma_1\cup\Gamma_2\cup\cdots\cup\Gamma_L$. If we now introduce our electrode model mentioned earlier to the case when σ is constant and Ω is the unit disk, the physical problem is equivalent to the mathematical problem of solving the following boundary value problem:

$$\nabla^2\Phi(z)=0 \quad \text{in} \quad \Omega, \tag{2}$$

$$\frac{\partial\Phi}{\partial n}=0 \quad \text{on} \quad \partial\Omega\backslash\Gamma,$$

$$\frac{\partial\Phi}{\partial n}=\frac{1}{\mathscr{Z}_l(z)}\,[V_l-\Phi(z)] \quad \text{on the electrode} \quad \Gamma_l\subset\partial\Omega, \tag{3}$$

$$\int_{\Gamma_l}\frac{\partial\Phi}{\partial n}\,d\theta=I_l, \quad l=1,\ldots,L,$$

for constant induced voltage, V_l, and total current driven, I_l, on each electrode. Here $\mathscr{Z}_l$ represents the contact (the ''skin'') impedance and $\Phi(z=e^{i\theta}\in\Gamma_l)$ is the potential just underneath ''the skin''.

III. THE INTEGRAL EQUATION

If the values of the normal derivative

$$\left.\frac{\partial\Phi}{\partial n}\right|_{z=e^{i\theta}}$$

were known everywhere on the boundary $\partial\Omega$ of the unit disk, we would be considering a classical Neumann problem, which is readily solved by means of the formula

$$\Phi(z)=\int_0^{2\pi}\mathscr{N}(z,e^{i\theta'};0)\left.\frac{\partial\Phi}{\partial n}\right|_{z'=e^{i\theta'}}d\theta'+\text{const.}, \tag{4}$$

where the Neumann kernel $\mathscr{N}(z,z';0)$ is

$$\mathscr{N}(z,z';0)=-\frac{1}{\pi}\log|z-z'|,$$

with $z'=e^{i\theta'}$ on the unit circle.

If we integrate the kernel with the values of the normal derivative $\partial\Phi/\partial n$ on the unit circle, we obtain a function Φ which is harmonic throughout the unit disk, which vanishes at $z=0$ and which

has the prescribed normal derivative values on the boundary. Similar kernels $\mathcal{N}(z,z';z_0)$ producing functions vanishing at $z=z_0$ rather that at $z=0$ can be written easily,[8] but the knowledge of the normal derivative determines Φ only up to a constant.

For what follows it is interesting to continue the Neumann integral (4) up to the boundary. Since

$$|e^{i\theta}-e^{i\theta'}|^2 \equiv 2[1-\cos(\theta'-\theta)],$$

if z and z' are of the form $z=e^{i\theta}$ and $z'=e^{i\theta'}$ the Neumann kernel on the unit circle reads:

$$\mathcal{N}(e^{i\theta},e^{i\theta'};0) = -\frac{1}{2\pi}\log\{2[1-\cos(\theta'-\theta)]\},$$

$$= -\frac{1}{\pi}\log\left|2\sin\left(\frac{\theta'-\theta}{2}\right)\right|. \tag{5}$$

In our case the normal derivative is known explicitly only on that part of the boundary which lies between the electrodes (i.e., on $\partial\Omega\backslash\Gamma$) where $\partial\Phi/\partial n$ is identical to zero. However, since the integral representation (4) can be continued up to the boundary, conditions (3) yield a linear integral equation for the boundary values $\rho(\theta)\equiv\Phi(e^{i\theta})$ of the potential:

$$\rho(\theta) = -\frac{1}{\pi}\sum_{l=1}^{L} V_l \int_{\Gamma_l}\frac{d\theta'}{\mathcal{Z}_l(\theta')}\log\left|2\sin\left(\frac{\theta'-\theta}{2}\right)\right| + \frac{1}{\pi}\sum_{l=1}^{L}\int_{\Gamma_l}\frac{d\theta'}{\mathcal{Z}_l(\theta')}\log\left|2\sin\left(\frac{\theta'-\theta}{2}\right)\right|\rho(\theta'). \tag{6}$$

Although the kernel

$$-\frac{1}{\pi}\log\left|2\sin\left(\frac{\theta'-\theta}{2}\right)\right|$$

becomes infinite each time θ' equals θ, this logarithmic singularity is weak enough to be L^2 integrable. The kernel is therefore of Hilbert–Schmidt type and so one can benefit from all the advantages of Fredholm integral equations of the second kind, namely the existence and uniqueness of an L^2 solution $\rho(\theta)$.

Equation (6) may be rewritten in a form which exhibits the logarithmic singularities of the kernel. Taking $e^{i\theta}\in\Gamma_{l_0}$ we may write

$$\begin{aligned}\rho(\theta) = &-\frac{1}{\pi}\sum_{l\neq l_0}\int_{\Gamma_l}\log\left|2\sin\left(\frac{\theta'-\theta}{2}\right)\right|\frac{[V_l-\rho(\theta')]}{\mathcal{Z}_l(\theta')}\,d\theta' \\ &-\frac{1}{\pi}\int_{\Gamma_{l_0}}\log\left|\frac{\sin\left(\frac{\theta'-\theta}{2}\right)}{\left(\frac{\theta'-\theta}{2}\right)}\right|\frac{[V_{l_0}-\rho(\theta')]}{\mathcal{Z}_{l_0}(\theta')}\,d\theta' - \frac{1}{\pi}V_{l_0}\int_{\Gamma_{l_0}}\frac{d\theta'}{\mathcal{Z}_{l_0}(\theta')}\log|\theta'-\theta| \\ &+\frac{1}{\pi}\int_{\Gamma_{l_0}}\frac{d\theta'}{\mathcal{Z}_{l_0}(\theta')}\log|\theta'-\theta|\rho(\theta').\end{aligned} \tag{7}$$

In order to study the local behaviour of the solution $\rho(\theta)$ near the edges of the l_0th electrode, we absorb the first two terms which are continuous into the ''free term'' of the so called *dominant singular integral equation*,[9] which is of the form:

$$f(x)=g(x)+\lambda\int_0^1 K(x,t)f(t)dt, \quad 0\leqslant x\leqslant 1, \tag{8}$$

$$K(x,t)\equiv\log|t-x|. \tag{9}$$

Here the points $x=0$ and $x=1$ correspond to the edges of the electrode under consideration. Equation (8) can be readily deduced from (7) by a suitable change of variables and functions in the $\mathscr{Z}_l(\theta)$ constant case, but as we shall show elsewhere[10] the discussion for the general case (non-constant $\mathscr{Z}_l$, non-constant σ) is fairly similar. When we follow this procedure we find that, as well as the first two terms from Eq. (7) which are regular, the function $g(x)$ contains the term

$$-V_{l_0}\Big/\pi\int_{\Gamma_{l_0}} d\theta'\log|\theta'-\theta|/\mathscr{Z}_{l_0}(\theta'),$$

so that after the changes of variables $g(x)$ has the form

$$g(x)=\int_0^1 \log|t-x|w(t)dt+\text{regular part}.$$

For the convenience of some subsequent proofs we shall also be interested in the iterated equations obtained by replacing $f(t)$ under the integral by the right hand side of the integral equation (8):

$$\begin{aligned} f(x)&=g_2(x)+\lambda^2\int_0^1 K_2(x,t)f(t)dt,\\ f(x)&=g_3(x)+\lambda^3\int_0^1 K_3(x,t)f(t)dt,\ldots \end{aligned} \tag{10}$$

and so on, where

$$\begin{aligned} g_2(x)&=g(x)+\lambda\int_0^1 K(x,t)g(t)dt,\\ g_3(x)&=g_2(x)+\lambda^2\int_0^1 K_2(x,t)g(t)dt,\ldots \end{aligned} \tag{11}$$

and

$$\begin{aligned} K_2(x,t)&=\int_0^1 K(x,\tau)K(\tau,t)d\tau,\\ K_3(x,t)&=\int_0^1 K_2(x,\tau)K(\tau,t)d\tau,\ldots\ . \end{aligned} \tag{12}$$

If this iteration had been continued indefinitely we would have found the Neumann series for f. Since these series usually converge only for very small values of λ, we shall not use them but stop after a finite number of terms and take advantage of the fact that the eigenvalues of $K_j(x,t)$ are the powers $\{\lambda_n^j\}$ of the eigenvalues $\{\lambda_n\}$ of $K(x,t)$. Indeed this will be quite helpful in some subsequent convergence proofs.

IV. SINGULARITY OF THE FREE TERM

In this and in the next section we shall try to find the analytic structure of the edge singularities of the solution without solving the integral equation, the latter being possible only numerically

or in some very special cases.[4] To this aim we shall use methods similar to those from the theory of the pinch or of the end point singularities,[7] well known to particle physicists working in analytic S-matrix theory. As a preparation to what follows it is probably helpful to look to the corresponding chapters from the classical book of Eden, Landshoff, Olive and Polkinghorne.[7]

In this section we shall deal with the free term $g(x)$ of Eq. (8). As mentioned in the Introduction, in order to find the analytic structure of the singularities we have to step into the neighbouring complex plane. We shall start our investigations with some negative values z_0 of z for which $\log|t-z|=\log(t-z)$ since the integration variable t is between 0 and 1. Having to perform analytic continuations we prefer to handle holomorphic expressions ($\log|t-z|$ *is not* a holomorphic function of z) and so, instead working with $g(x)$ we shall focus our attention on functions of the kind

$$F(z)=\int_0^1 \log(t-z)w(t)dt \tag{13}$$

where the weight $w(t)$ is a function of t, which is holomorphic (no cuts or other singularities) in neighbourhoods of $t=0$ and $t=1$. Although the holomorphic extension $F(z)$ is different from $g(x)$, it is closely related to it since, up to regular terms $\mathrm{Re}\,F(x\pm i\epsilon)=g(x)$ for $x\in[0,1]$ and $\epsilon\searrow 0$. Since the weight $w(t)$ may differ very much from one case to another, integral (13) cannot be performed explicitly. Therefore it will be interesting to have a mathematical procedure which should be able to predict the form of the singularity *without* actually performing the integrals. However, in order to have a partial check of the results which will be obtained below, we note that in the simplest case $w\equiv 1$ we obtain $F_{w\equiv 1}(z)=z\log(-z)+(1-z)\log(1-z)-1$.

As mentioned at the end of the last section, if λ is small enough the Neumann series converge and so the solution can be written in terms of the free terms g_j of the iterated equations. Therefore at the end of this section we shall discuss briefly the singularity of the iterated functions $g_j(x)$ since they provide a check of the results obtained in Section V in the general case.

A. Different ways of defining a cut

We recall that the features which are important when considering the cut structure of complex functions are the locations of the branch points and not the way in which the cut is taken. Indeed, the cut can be deformed or trailed as will become apparent below, in Figs. 3 to 5. As a first example, consider the function $F_{w\equiv 1}(z)$ given above. To define the cut of the first term $z\log(-z)$, we first introduce the function $Z(z)=-z$ and ask then that the cut of $\log Z(z)$ should run along the positive Z real axis. One achieves this by writing $Z=|Z|\exp(i\phi)$ and requiring ϕ to be in the range $[0,2\pi)$. With these conditions the cut of the first term, $z\log(-z)$, of $F_{w\equiv 1}(z)$ runs along the negative z real axis. The function $z\log(-z)$ is real and equal to $z\log|-z|\equiv-|z|\log|z|$ below the cut. Above the cut it will contain an additional imaginary part equal to $2i\pi z$. There will be no cut along the positive z real axis; here the value of $z\log(-z)$ is equal to $z\log|z|+i\pi z$ both above and below the real axis.

It is not compulsory to take the cut of the second term of $F_{w\equiv 1}(z)$ to the left. Indeed, if we define a new variable $Z(z)=1-z$, we can redefine the ''fundamental Riemann sheet'' of $\log Z$ by requiring that the argument ϕ of Z to be between $-\pi$ and π rather than between 0 and 2π, so that the cut of $\log Z=\log(1-z)$ will run along the negative real Z axis. Summarising $F_{w\equiv 1}(z)$ has no cut on the interval $[0,1]$ but two cuts running from $-\infty$ to 0 and from 1 to ∞.

The possible patterns for the cut of the logarithm are not exhausted by the cases discussed above. To have a further example let us consider for instance the function $Z(z)\equiv 1+z$ and begin with a cut of $\log Z$ running along the negative Z real axis. In this case the cut of $\log(z+1)$ looks as in Fig. 2a where the $\pm i\pi$ *zones* mean that the values just above or beneath the cut differ by $\pm i\pi$ from the mean value across the cut. (For illustration purposes we have slightly deplaced the cut: as it stands it corresponds to the function $\log[z-(-1-i\epsilon)]$, $\epsilon>0$.)

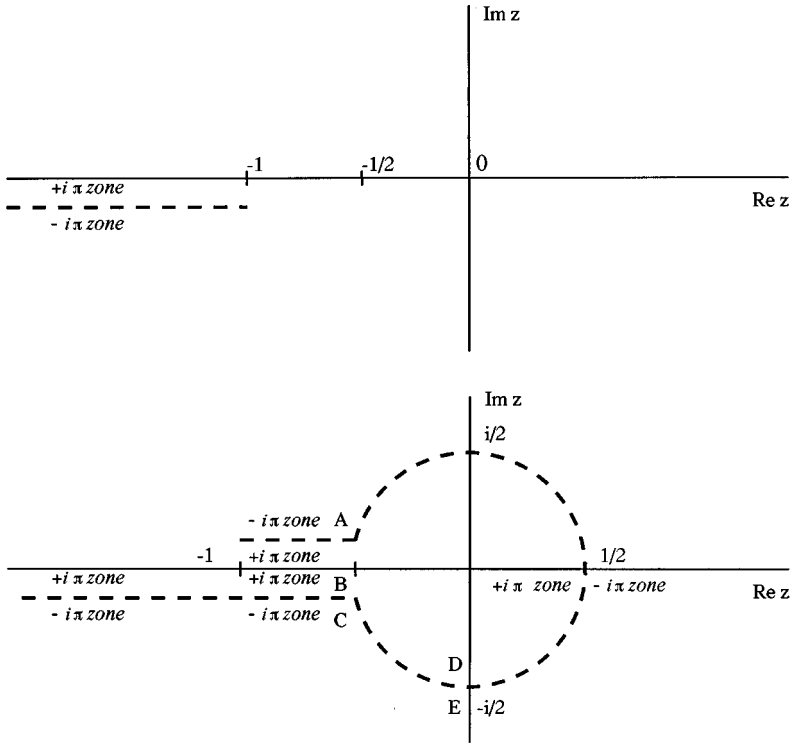

FIG. 2. (a) and (b) Example of two different definitions of the cut of $\log(z+1)$.

However we could alternatively define the cuts to run as in Fig. 2b where again the $\pm i\pi$ *zones* mean that the values of the logarithm differ by $\pm i\pi$ from the mean value across the cut (which is not necessarily real). With these specifications one finds immediately that the value of $\log(z+1)$ at the points A, B and C are, up to epsilons, equal respectively to $\log|z_A+1|$, to $\log|z_A+1|+2i\pi$ and again to $\log|z_A+1|$. As a further example, the values of $\log(z+1)$ at the points $D(z=-i/2+i\epsilon)$ and $E(z=-i/2-i\epsilon)$ are respectively $\log\sqrt{5/4} - (26.5/180)i\pi + 2i\pi$ and $\log\sqrt{5/4} - (26.5/180)i\pi$, while the mean value across the cut is there equal to $\log\sqrt{5/4} - (26.5/180)i\pi + i\pi$.

B. "Hooking" the integration contour

Let us come back to the function $F(z)$. In what follows it is important to consider separately the parameter (the "control") z-plane, and the complex t-plane where the integration is performed. As stated above, our aim is to find the singularities of $F(z)$, in the "control" z-plane, without performing the integration explicitly. Since our final goal is the description of the singularity of $F(z)$ at $z=0$, in this section we shall consider only analytic continuations performed in some neighborhood of the origin. A similar discussion can be made for the other end point $z=1$.

Suppose that initially z lies somewhere immediately below the negative real axis in the complex z-plane: $z=z_0\equiv x_0-i\epsilon$, where $x_0<0$ and $\epsilon>0$. The function $\log(t-z)$ from the integral of Eq. (13) has, *as a function of* t (i.e. in the complex t-plane where the integration is performed), a cut running parallel to the real t-axis from $t=-\infty$ to $t=z$ (see the dashed line in Fig. 3). From the point of view of the integration t-space, z is a parameter. Suppose now that z moves towards a point $z_a=x_a-i\epsilon$ ($x_a>0$) and then returns to z_0 ($x_0<0$) without crossing the integration contour.

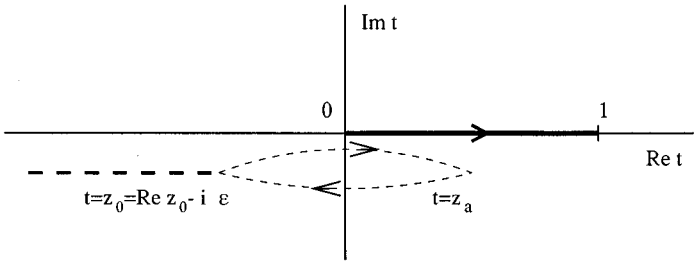

FIG. 3. Integration path (full line) and cut of the logarithm (dashed).

Correspondingly, the head of the cut of the logarithm (as a function of t) will move in the t-plane as shown in Fig. 3, but, since it will never cross the integration contour, the value of $F(z_0)$ will be identical with the value that the function $F(z)$ had before the point z began to move from z_0.

The situation is however different if the path followed by the point z in the control complex z-plane crosses the segment $[0,1]$ before returning to the initial position $z=z_0$. Here again the path followed by the ''head'' of the cut begins at z_0 and ends at the same point, but this time it winds around the integration end point $t=0$, crossing the real axis at $t=z_b$ as shown in Figs. 4 and 5.

A genuine analytic continuation of the function $F(z)$ should, of course, be at least continuous, i.e. have no jumps or other discontinuities. Therefore, even before the end point $t=z$ of the singularity of the logarithm reaches the point $t=z_b$ which lies on the real axis between 0 and 1 (see Fig. 4), we shall use the freedom we have to deform the integration contours inside the analyticity domain of the integrand without altering in any way the value of the integral $F(z)$.

Since the branch point $t=z$ ''trails'' behind it the cut of the logarithm when z moves further through points z_c in the upper half z-plane (Fig. 4) towards z_0, the value we obtain for the analytic continuation $F^{(1)}(z_0)$ of the initial integral will be given by the integral along the path C in Fig. 5 (the dashed line in Fig. 5 represents the cut of the logarithm; as it stands, the cut ends at the conjugate point $\overline{z_0}=x_0+i\epsilon$ rather than at z_0). Since the value of the logarithm on the lower lip of the emerging part of the cut contains an additional $2\pi i$ with respect to that on the upper lip (recall the discussions about the points A and B from Fig. 2b), the integral on the part of the contour around the cut (see Fig. 5) is

$$\int_0^{z_0}(\log|t-z_0|+i\pi)w(t)dt+\int_{z_0}^{0}(\log|t-z_0|-i\pi)w(t)dt=-2i\pi\int_{z_0}^{0}w(t)dt.$$

Here we have supposed that the weight $w(t)$ has no singularities at $z=0$. Such a point z_0 where the integration starts and which is below the initial integration threshold is called an ''anomalous threshold'' in elementary particle physics.

The new value $F^{(1)}(z_0)$ of $F(z)$ obtained by means of this analytic continuation process is hence

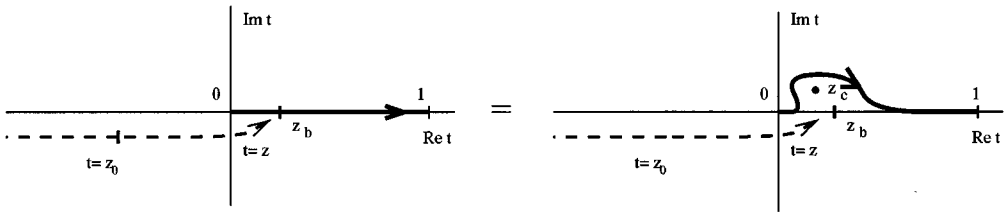

FIG. 4. The integrals over $[0,1]$ and over the deformed path are identical if $w(t)$ is holomorphic.

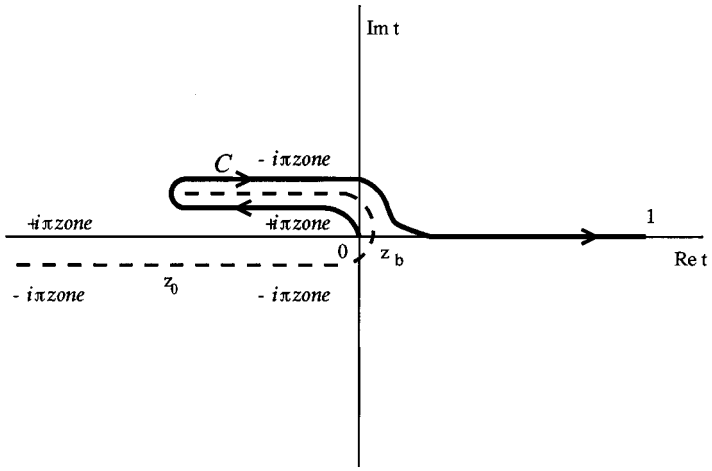

FIG. 5. The moving cut deforms the integration contour and produces an anomalous threshold.

$$F^{(1)}(z_0)=2i\pi\int_0^{z_0} w(t)dt+\int_0^1 \log(t-z_0)w(t)dt, \tag{14}$$

where the logarithm has the same determination as in Eq. (13) (i.e., a cut like in Fig. 3). There are many ways of defining the Riemann sheets of $F(z)$ but here we describe only two of them:

(i) If we define $F(x+iy)$ for any point in the upper half z-complex plane to coincide with the function $F^{(1)}(x+iy)$ defined above, i.e. $F(x+iy)\equiv F^{(1)}(x+iy)$ $(y>0)$, we have implicitly required that the function $F(z)$ should have no cuts on the segment [0,1] but only on other parts of the real axis. For instance, from the above discussion it follows that along the negative real axis $F(z)$ will have a discontinuity

$$\begin{aligned}\Delta F(x)&=F(x+i\epsilon)-F(x-i\epsilon)\equiv F^{(1)}(x+i\epsilon)-F(x-i\epsilon)\\&=2i\pi\int_0^x w(t)dt, \quad x\in\text{negative real axis},\end{aligned} \tag{15}$$

which means that $F(z)$ has indeed a cut along the negative real axis. This definition of the ''fundamental'' Riemann sheet of $F(z)$ coincides with that for the simple example of $F_{w\equiv 1}(z)$ discussed in the previous subsection.

(ii) Alternatively we could have required that the function $F(z)$ should have no cuts along the negative real axis. This amounts to redefining its ''fundamental'' Riemann sheet: we start again from our $z_0\equiv x_0-i\epsilon$ with $x_0<0$, ask that $F^{(0)}(z_0)\equiv F(z_0)$ but then require that the values of $F^{(0)}(z)$ above the real axis should merge, for $\mathrm{Re}\, z<0$, with those below the axis. We, therefore, *define* $F^{(0)}(z)$ for $\mathrm{Re}\, z<0$ as

$$F^{(0)}(z)=\int_0^1 \log(t-z)w(t)dt. \tag{16}$$

This definition which initially has been given only for $\mathrm{Re}\, z<0$ may then be extended to the whole complex plane cut along the real segment [0,1] (and further, along the positive real axis up to infinity; but, as mentioned at the beginning of this subsection, in order to keep the discussion simple we shall not consider what happens beyond the end point $z=1$). According to the definition (ii), the function $F^{(0)}(z)$ will have no cuts along the real negative axis, but in return, will have

different values along the upper and the lower lip of the real segment [0,1]. In the lower half plane $F^{(0)}(z)$ coincides with the function $F(z)$ corresponding to the previous definition (i) of the fundamental Riemann sheet, but not any longer for $\mathrm{Im}\, z>0$ where $F(z)$ was identical to $F^{(1)}(z)$. However, since by the construction of the function $F^{(1)}(z)$ [see the discussion preceding Eq. (14)] we had

$$F^{(0)}(x-i\epsilon)=F^{(1)}(x+i\epsilon)+\mathcal{O}(\epsilon), \quad \text{for } \epsilon>0 \quad \text{and } 0<x<1, \tag{17}$$

it follows that $F^{(1)}(z)$ represents now the analytic continuation of $F^{(0)}(z)$ on the next Riemann sheet—call it sheet (1)—when one crosses the segment [0,1] in the *upward* direction.

On the other hand, starting from the values $F^{(0)}(x+i\epsilon)$ from the upper lip of the segment [0,1] and continuing them *downwards*, one gets the function $F^{(-1)}(z)$:

$$F^{(-1)}(x-i\epsilon)=F^{(0)}(x+i\epsilon)+\mathcal{O}(\epsilon), \quad \text{for } \epsilon>0 \quad \text{and } 0<x<1, \tag{18}$$

which is obtained by deforming the integration contour in the lower half plane. Hence, $F^{(-1)}(z)$ will have the form

$$F^{(-1)}(z_0)=-2i\pi\int_0^{z_0} w(t)dt+\int_0^1 \log(t-z_0)w(t)dt, \tag{19}$$

where, again, the logarithm has the same determination as in Eqs. (13) and (16). Further, we see that the jump of $F^{(0)}$ across the cut [0,1] is

$$\Delta F^{(0)}(x)=-2i\pi\int_0^z w(t)dt, \quad \text{for } 0<x<1.$$

The functions $F^{(-1)}$, $F^{(0)}$, $F^{(1)}$ living on the Riemann sheets (-1), (0), (1) represent in fact a unique analytic function $F(z)$, the various branches $F^{(-1)}(z)$, $F^{(0)}(z)$, $F^{(1)}(z)$ being nothing but its values on a cutting up of the initial Riemann manifold along some arbitrarily given cuts.

If the function w is holomorphic in some neighbourhood of the origin it admits there an expansion of the form

$$w(t)=a_0+a_1t+a_2t^2+\cdots, \tag{20}$$

and so, from Eq. (15) we find

$$\Delta F(x)=2i\pi\left[a_0x+\frac{a_1}{2}x^2+\frac{a_2}{3}x^3+\cdots\right]. \tag{21}$$

A function which has precisely the same jump along the negative axis is given by

$$\left[a_0+\frac{a_1}{2}z+\frac{a_2}{3}z^2+\cdots\right]z\log z \tag{22}$$

which provides a mathematically correct and at the same time extremely simple description of the singularity of $F(z)$ near the point $z=0$.

Before closing this section we shall discuss briefly the structure of the singularities at the origin of the free terms $g_2(z)$, $g_3(z),\ldots,$ $g_j(z)$ of the iterated equations (10). In contrast to $g(z)$, these functions are written as integrals of the form (13) over weights $w(t)$ which are no longer holomorphic but contain the singularities of $g(z)$, $g_2(z),\ldots,$ $g_{j-1}(z)$ respectively. By straightforward integration we find that the general term of the iterated function $g_j(z)$ is

$$z^m \log^k(z), \quad \text{with } k=0,1,\ldots,j \text{ and } m\geqslant k. \tag{23}$$

At this stage we may wonder whether the left hand cuts of the powers of $\log(t)$ appearing under the integrals will not interfere with the above analytic continuation process. This does not occur since the real part of t becomes negative only along the loop in Fig. 5 around the emerging part of the cut of $\log(t-z)$ which is always at the same side of the negative real axis, i.e. always in the same ''$+i\pi$ *zone*'' of the function $\log(t)$. This means that

$$\Delta\left[\int_0^1 \log(t-z)t^m \log^k(t)dt\right]=2i\pi\int_0^z t^m(\log|t|+i\pi)^k dt, \quad z\in\text{negative real axis}. \tag{24}$$

V. SINGULARITIES OF THE SOLUTION OF THE FULL EQUATION

As mentioned in the Introduction, the specific difficulties of our problem are twofold. We have first to handle moving cuts; this question has been largely discussed in the previous section devoted to the free term. Second—and this is probably the main difference with respect to the classical papers on pinch and end point singularities—we will have to cope with the fact that the singularities of the function under the integral are *a priori* unknown, this function being the solution of the integral equation whose analytic properties we are trying to establish. In this section we shall address this second problem by solving it first for the eigenfunctions which are the natural building blocks of the solution, with the hope that their analytic properties (together with those of the free term) will be transmitted to the solution itself. Of course, this is not at all obvious since we will deal with infinite series and so new singularities may creep in. Therefore before we embark in Section V B on the study of the Riemann sheet structure and the asymptotic expansion of the eigenfunctions, we will first make sure in Section V A that the analytic properties of the eigenfunctions do exhaust the holomorphic characteristics of the solution. This is probably not entirely pedagogical, but reflects fairly well the way in which our work progressed. We shall have often to refer in Section V A to various analytic properties of the eigenfunctions which will be proved only later in Section V B.

This type of analysis presented here is not restricted to this particular integral equation, but we hope that it provides a working example of how one could proceed in problems involving other kinds of weakly singular kernels. To this end we tried to avoid as much as possible any special properties of the logarithmic kernel—for instance the fact that its null-space ker **K** is empty—and show how we can proceed in the general case. At a first reading or if not particularly interested in these mathematical proofs but only in the practical aspects of the asymptotic expansion, the reader may read only Section V A 1, skip the remainder of the Section V A and pass directly to Section V B.

A. The absence of summation singularities

We shall proceed in a number of stages:

In Section *V A 1* we discuss the role of eigenfunction expansions in describing the generic singularities of the solution. In both Sections *V A 1* and *V A 2* we recall some facts from the theory of integral equations and we identify a class of functions $\{\psi\}$ which can be expanded in terms of the eigenfunctions. We discuss also the possible appearance of additional singularities due to problems of convergence of infinite sums of functions.

The convergence proofs are provided in two separate subsections. In Section *V A 3* we discuss the continuity of these ψ-functions on the real segment $[0,1]$ and we show that their eigenfunction expansions converge uniformly there. However, in order to be able to consider the holomorphic properties of the solution $f(z)$ we need a number of results in the complex z-plane. These are derived in Section *V A 4* where, in particular, we prove that no additional singularities appear as a result of the summation of the series. The convergence of the asymptotic parts of the eigenfunctions is discussed in Section *V A 5*.

1. Generic singularities and eigenfunction expansions

When discussing the possible singularities of the solution of an integral equation we are faced with an apparent paradox. Independently of the specific form of the integral kernel, we may always proceed as a numerical analyst usually does when checking the correctness of computer code: start in the right hand side of Eq. (8) with some ''nice'' function $f(t)$ which has no singularities, integrate it with the kernel and then choose the free term $g(x)$ to recover the initial function $f(x)$. So, irrespective of the (integrable) singularities of the kernel, the solution $f(x)$ might be a polynomial, a simple trigonometric function or anything else. One may feel that this type of solution is quite exceptional but this example is enough to show that one *cannot* speak about ''the general singularity'' of the solution of an integral equation with a given singular kernel. However one is fully entitled to ask oneself what may happen in the non-exceptional situations, i.e. in the *generic* case.

To this end it is enlightening to express the solution of the integral equation (8) for our logarithmic kernel in terms of the eigenfunctions $u_n(x)$ of $K(x,t)$, defined by

$$u_n(x)=\lambda_n\int_0^1 K(x,t)u_n(t)dt, \quad \text{with } K(x,t)\equiv\log|t-x|, \tag{25}$$

as the series

$$f(x)=g(x)+\sum_{n=0}^{\infty}\frac{\lambda}{\lambda_n-\lambda}\,g_n u_n(x), \tag{26}$$

derived below in Section *V A 2*, where

$$g_n\overset{\text{def}}{=}\int_0^1 g(x)u_n(x)dx. \tag{27}$$

From expansion (26) it is obvious that in the generic case when small changes in the form of the function $g(x)$ and hence in $\{g_n\}$ are allowed, both the singularities of the free term $g(x)$ and of the eigenfunctions $u_n(x)$ will appear in the solution $f(x)$ since they will no longer cancel identically.

2. The functions $\psi(x)$

In what follows we shall use systematically the notation $\psi(x)$ for the functions from the range Ran **K** of the integral operator. The properties of these functions are used in the derivation of expansion (26) which plays a central role for the analytic properties of f as a superposition of those of g and of the u_n. However we should exercise great care at this point since additional singularities may creep in. We should have in mind the case of the sequence of functions $1,1+z,1+z+z^2,\ldots$. In the open unit disk this sequence tends to the function $1/(1-z)$ which has a pole at $z=1$, whereas all the functions in the sequence are holomorphic in an arbitrary large disk. Later in Section *V A 4* we will use a theorem of Vitali and/or of Morera to prove that no additional singularities appear in a neighbourhood of the origin. The theorem of Vitali, for instance, is partially based on the requirement that the elements of the sequence of partial sums should be uniformly bounded, which is clearly not valid in the counter-example with the geometric series if $|z|\geqslant 1$. Hence we have to make sure that in our case all the requirements of these theorems are fulfilled.

In order to obtain Eq. (26) we first multiply the integral equation (8) by an eigenfunction $u_n(x)$, integrate over the variable x and use the symmetry of the kernel to get

$$f_n=g_n+\frac{\lambda}{\lambda_n}f_n, \tag{28}$$

where the coefficients f_n are defined from $f(x)$ by integrals similar to those in Eq. (27).

From Eq. (28) we find $f_n=\lambda_n g_n/(\lambda_n-\lambda)$, but we should avoid expressing the solution $f(x)$ as a sum $\Sigma f_n u_n(x)$ since the latter might not converge pointwise and/or the eigenfunctions $\{u_n\}$ might not represent a complete system of orthonormal functions. In the special case of the logarithmic kernel (25) it happens (see Appendix) that the $\{u_n\}$ do represent such a complete orthonormal system, but for an arbitrary kernel K, $\ker \mathbf{K}$ is not empty and so they do not.

Many of the textbook theorems concerning expansions of the type (26) rely on the continuity of the kernel in the square $[0,1]\times[0,1]$. Since this is certainly not the case for our logarithmic kernel, some supplementary work is necessary to adapt the proofs to our specific conditions. In the simple cases where the kernel is continuous one usually takes advantage of this fact to prove that for any square integrable—even singular—function $\varphi(t)$, the function

$$\psi(x)\overset{\text{def}}{=}\int_0^1 K(x,t)\varphi(t)dt \tag{29}$$

from $\mathrm{Ran}\,\mathbf{K}$ is (a) continuous for $x\in[0,1]$, and (b) expressible in the form of an uniformly convergent expansion

$$\begin{aligned}\psi(x)&=\sum_{n=0}^{\infty}\psi_n u_n(x),\\ &\equiv\sum_{n=0}^{\infty}\varphi_n/\lambda_n u_n(x)\end{aligned} \tag{30}$$

where ψ_n and φ_n are defined by

$$\psi_n=\int_0^1\psi(t)u_n(t)dt,\quad \varphi_n=\int_0^1\varphi(t)u_n(t)dt.$$

Here the relation which connects the coefficients ψ_n and φ_n can be obtained by multiplying Eq. (29) by $u_n(x)$, integrating and using the symmetry of the kernel

$$\psi_n=\varphi_n/\lambda_n\,. \tag{31}$$

The solution $f(x)$ itself does not in general have a representation of the ψ-kind (29), but it is clear from the integral equation (8) that the difference $f(x)-g(x)$ is a true ψ-kind function. Hence it can be expanded as the sum $\Sigma(f_n-g_n)u_n(x)$, which in turn, using the relation (28) between f_n and g_n, yields the representation (26) for the solution of the integral equation in terms of the free term $g(x)$ and of the eigenfunctions $u_n(x)$.

In Section *V A 3* we shall prove that the properties (a) and (b) and hence the expandibility of $f(x)-g(x)$ are also valid in the case of the logarithmic kernel. Before showing that let us notice that if $\ker\mathbf{K}$ is empty as is the case—see the Appendix—with the logarithmic kernel, or if φ is chosen from the orthogonal complement $\ker^{\perp}\mathbf{K}$ of $\ker\mathbf{K}$, we also have

$$\left\|\varphi(x)-\sum_{n=0}^{\infty}\varphi_n u_n(x)\right\|_{L^2}=0. \tag{32}$$

However, in contrast with what happens with the ψ-kind functions, Eq. (32) represents only a convergence in the mean, i.e. $\varphi(x)$ does not have, in general, an expansion of the form (30) which converges uniformly. For the study of the analytic properties of the solution we shall need finer properties than those offered by L^2-space arguments, since, for instance, holomorphy and uniform convergence of the partial sums are essential for the Morera theorem to be used in Section *V A 4*.

3. Continuity of $\psi(x)$ in the logarithmic case and the uniform convergence of the $\psi^{(j)}(x)$ on the segment [0,1]

This section deals with the properties of the ψ-kind functions (29) on the segment $[0,1]$ for the logarithmic kernel (9). The arguments are quite similar to those which are used in the case of the continuous kernels, but we shall discuss them briefly here as a preparation for the next section and as well as to make this paper self-contained.

Our logarithmic kernel becomes infinite each time the integration variable t equals x. However, the continuity (a) of $\psi(x)$ on the interval $[0,1]$ (including at its end points) can be proved in a straightforward manner using the Schwarz inequality. Indeed, for any L^2 function $\|\varphi\|_{L^2} \leqslant M$ and for any points x and $x+\delta$ belonging to the (closed) segment $[0,1]$, we have

$$|\psi(x+\delta)-\psi(x)|^2 \leqslant \int_0^1 [\log|t-(x+\delta)|-\log|t-x|]^2 dt \times M^2, \tag{33}$$

where the integral $\int_0^1 |\varphi(t)|^2 dt$ has been replaced by the bound on the L^2-norm. If δ is small enough, it can be shown that the integral on the right hand side of (33) can be made smaller than any given nonzero ϵ^2/M^2, which proves the continuity of all the ψ-kind functions of the form (29). Since the eigenfunctions $u_n(x)$ by their very definition (25) are also functions of the ψ-kind, we have hence implicitly proved their continuity on the segment $[0,1]$, including at the end points $x=0$ and $x=1$.

We shall now show, (b), that for $x \in [0,1]$ the finite sums

$$\psi^{(j)}(x) = \sum_{n=0}^{j} \psi_n u_n(x) \tag{34}$$

converge uniformly to the function $\psi(x)$ defined in Eq. (29).

To this end we shall show first that the functions $\psi^{(j)}(x)$ converge uniformly to some (continuous) function $\psi^{(\infty)}(x)$: a similar proof may be used then for the uniform convergence of the analytic extensions $\Psi^{(j)}(z)$ which will be introduced in the next section. From Eq. (31) and from the definition (25) of the eigenfunctions $\{u_n(x)\}$ we have

$$\left|\sum_{j+1}^{j+k} \psi_n u_n(x)\right|^2 \equiv \left|\sum_{j+1}^{j+k} \frac{\varphi_n}{\lambda_n} \cdot \lambda_n \int_0^1 K(x,t) u_n(t) dt\right|^2 = \left|\int_0^1 K(x,t) \sum_{j+1}^{j+k} \varphi_n u_n(t) dt\right|^2,$$

which, using the Schwarz inequality and the fact that the basis $\{u_n(t)\}$ is orthonormal, yields

$$\left|\sum_{j+1}^{j+k} \psi_n u_n(x)\right|^2 \leqslant \int_0^1 \left|K(x,t)\right|^2 dt \cdot \int_0^1 \left|\sum_{j+1}^{j+k} \varphi_n u_n(t)\right|^2 dt = \int_0^1 |K(x,t)|^2 dt \cdot \sum_{j+1}^{j+k} \varphi_n^2. \tag{35}$$

For each fixed value of x, $0 \leqslant x \leqslant 1$, the kernel $K(x,t) \equiv \log|t-x|$ regarded as a function of t is in $L^2[0,1]$, and so,

$$\int_0^1 K^2(x,t) dt < M^2 < \infty.$$

Since the function φ is also in L^2, $\Sigma_{j+1}^{j+k} \varphi_n^2$ tends to zero for $\forall k$ as j increases. Hence the right hand side of (35) can be made arbitrarily small irrespective of the value of x. This means that the sequence $\psi^{(j)}(x)$ converges *uniformly* to some limit $\psi^{(\infty)}(x)$. Now from the continuity of the eigenfunctions $\{u_n(x)\}$ which we have proved above, it follows that the finite combinations $\{\psi^{(j)}(x)\}$ are continuous. Since the $\{\psi^{(j)}(x)\}$ converge *uniformly*, the limit $\psi^{(\infty)}(x)$ is also continuous.

On the other hand, by projecting the kernel onto the basis $\{u_n\}$ we obtain ''the coefficients'' $u_n(x)/\lambda_n$. Bessel's inequality then ensures that any sum over the $u_n^2(x)/\lambda_n^2$ is bounded:

$$\sum_{n=0}^{\infty} \frac{u_n^2(x)}{\lambda_n^2} \leqslant \int_0^1 K^2(x,t)dt (<\infty). \tag{36}$$

Integrating with respect to x we see that $\Sigma 1/\lambda_n^2$ must also converge and hence the $|\lambda_n|$ must tend to infinity with n. This fact will help us to prove that $\psi^{(\infty)}(x)$ is in fact identical to the function $\psi(x)$ defined in Eq. (29).

Indeed, since both functions $\psi(x)$ and $\psi^{(\infty)}(x)$ are continuous, it is enough to show that the L^2-norm of their difference is zero. To this end we notice that the difference between $\psi(x)$ and the functions $\psi^{(j)}(x)$ can be written as

$$\psi(x) - \psi^{(j)}(x) = \int_0^1 K^{(j+1)}(x,t)\varphi(t)dt \tag{37}$$

where $K^{(j+1)}(x,t)$ is the truncated kernel

$$K^{(j+1)}(x,t) = K(x,t) - \sum_{n=0}^{j} \frac{u_n(x)u_n(t)}{\lambda_n}, \tag{38}$$

where we have supposed that the eigenvalues have been labelled according their increasing moduli: $|\lambda_0| \leqslant |\lambda_1| \leqslant \cdots$. Unlike the procedure followed before, we shall not try to use the Schwarz inequality to prove directly the pointwise convergence of the $\psi^{(j)}(x)$, but we shall go instead through L^2-space arguments. Since the first $j+1$ eigenfunctions $u_0(x),\ u_1(x),\ldots,u_j(x)$ are all in the null space ker $\mathbf{K}^{(j+1)}$ of the truncated kernel (38), it follows that its eigenvalue with smallest absolute value is λ_{j+1}. If we denote by $K_2^{(j+1)}(x,y)$ the iterated truncated kernel

$$K_2^{(j+1)}(x,y) = \int K^{(j+1)}(x,t)K^{(j+1)}(t,y)dt, \tag{39}$$

its smallest eigenvalue μ will be λ_{j+1}^2. However for any symmetric Hilbert-Schmidt kernel $\mathscr{K}(x,y)$ we have

$$\sup_{\|\varphi\|=M} \left| \int \int \mathscr{K}(x,y)\varphi(x)\varphi(y)dxdy \right| = \frac{M^2}{|\mu|}$$

where μ is the smallest eigenvalue of $\mathscr{K}$. Hence, taking the integral over the square of the modulus of the left hand side of Eq. (37) we obtain

$$\|\psi - \psi^{(j)}\|_{L^2}^2 = \left| \int \int K_2^{(j+1)}(x,y)\varphi(x)\varphi(y)dxdy \right| \leqslant \frac{M^2}{\lambda_{j+1}^2} \tag{40}$$

which means that $\|\psi - \psi^{(j)}\|_{L^2} \leqslant M/|\lambda_{j+1}|$. Since $1/|\lambda_{j+1}|$ tends to zero as j increases, so does $\|\psi - \psi^{(j)}\|_{L^2}$. Now, from the uniform convergence $\|\psi^{(j)} - \psi^{(\infty)}\|_{L^{(\infty)}} \to 0$ which has proved above [see Eq. (35)], we have immediately also the L^2 convergence

$$\|\psi^{(j)} - \psi^{(\infty)}\|_{L^2} \to 0. \tag{41}$$

From the triangle inequality we have

$$\|\psi - \psi^{(\infty)}\|_{L^2} \leqslant \|\psi - \psi^{(j)}\|_{L^2} + \|\psi^{(j)} - \psi^{(\infty)}\|_{L^2}, \tag{42}$$

where from Eqs. (40) and (41) we see that the left hand side, which is independent of j, can be made arbitrarily small by a suitable choice of j in the right hand side. This means that $\|\psi - \psi^{(\infty)}\|_{L^2} \equiv 0$ which, since both $\psi(x)$ and $\psi^{(\infty)}(x)$ are continuous, proves that the two functions are identical.

4. The functions $\Psi^{(j)}(z)$ and the theorems of Morera and Vitali

In order to be able to study the nature of the singularities of the functions of ψ-kind, we will have to step off the real axis into the complex z-plane. We shall be particularly interested in the complex plane singularities and the asymptotic expansions near $z=0$ of eigenfunction expansions of the form (26), related to the solution $f(x)$ of the integral equation. To this end we shall need to know some analytic properties of the eigenfunctions $\{u_n\}$. These will be derived in section V B where, similarly to the function $F^{(0)}(z)$ [see Eq. (16) from Section IV], we shall define the analytic functions

$$U_n^{(0)}(z) \overset{\text{def}}{=} \lambda_n \int_0^1 \log(t-z) u_n(t)\, dt, \quad n=1,2,3,\ldots . \tag{43}$$

Although these functions do not yet represent the analytic continuation of the eigenfunctions $u_n(x)$ which are defined on the real segment $[0,1]$, they are closely related to them. This specific choice is based, as for $F^{(0)}(z)$, on the fact that for real negative z we have $\log(t-z) \equiv \log|t-z|$, since the integration variable t on the right hand side of Eq. (43) is always between 0 and 1. In contrast to the function $\log|t-z|$ (which is *not* holomorphic because of the modulus), the function $\log(t-z)$ can be extended analytically in the whole (cut) complex z-plane.

As will become apparent in Section V B, the analytic functions $U_n^{(0)}(z), U_n^{(1)}(z), U_n^{(-1)}(z),...$ which are the analogues of the functions $F^{(0)}(z), F^{(1)}(z), F^{(-1)}(z),...$, defined in Eqs. (16), (14) and (19), have an infinite Riemann sheet structure; the superscript in parentheses indicates the Riemann sheet under consideration. From the definition of the Riemann sheets and the continuity properties across the cut, we have, similar to Eqs. (17)–(18), for any real x between 0 and 1:

$$U_n^{(k)}(x+i\epsilon) = U_n^{(k-1)}(x-i\epsilon) + \mathcal{O}(\epsilon), \quad \epsilon > 0, \quad x \in [0,1]. \tag{44}$$

As will be shown in Section *V B 3*, the eigenfunctions $u_n(x)$ defined on the interval $[0,1]$ can be written as simple combinations of the boundary values of $U_n^{(0)}(z)$, $U_n^{(1)}(z)$ and $U_n^{(-1)}(z)$ on the upper and lower lips of the cut:

$$\begin{aligned} u_n(x) &= \frac{1}{2}\left[U_n^{(0)}(x+i\epsilon) + U_n^{(1)}(x+i\epsilon)\right], \quad \epsilon \searrow 0, \quad 0<x<1, \\ u_n(x) &= \frac{1}{2}\left[U_n^{(0)}(x-i\epsilon) + U_n^{(-1)}(x-i\epsilon)\right], \quad \epsilon \searrow 0, \quad 0<x<1. \end{aligned} \tag{45}$$

Hence, in analogy with the function $\psi(x)$ and the finite sums $\psi^{(j)}(x)$ defined in the previous subsection for $x \in [0,1]$, we shall define now for z in some given region Ω of the complex plane, the holomorphic functions

$$\Psi(z) \overset{\text{def}}{=} \int_0^1 \log(t-z)\varphi(t)\, dt, \quad \varphi \in L^2[0,1], \tag{46}$$

$$\Psi^{(j)}(z) \overset{\text{def}}{=} \sum_{n=0}^{j} \psi_n U_n^{(0)}(z) \equiv \sum_{n=0}^{j} \frac{\varphi_n}{\lambda_n} U_n^{(0)}(z). \tag{47}$$

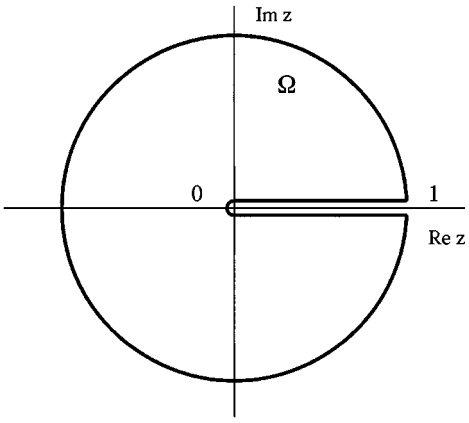

FIG. 6. The open set Ω.

Since we are mainly interested in the behavior of the solution near the origin, it is sufficient to take the region Ω to be the (open) unit disk cut along the real segment [0,1] (see Fig. 6), but any other (cut) disk of radius R is also acceptable. The holomorphy of $\Psi(z)$ in Ω follows from the theorem of Morera which states that iff[11,12] the function $\Psi(z)$ *is continuous* in the open set Ω and iff

$$\int_{\partial\Delta} \Psi(z)dz = 0 \tag{48}$$

along the border of *every* closed triangle $\Delta \subset \Omega$ (i.e. along any reasonable regular closed contour), then the function $\Psi(z)$ *is holomorphic* in Ω. It is clear that these two conditions are met by any function having the representation (46) for $z \in \Omega$. The continuity of $\Psi(z)$ can be established in a similar way to that of the functions $\psi(x)$ [see Eq. (33)], while the vanishing of the integrals (48) follows—after the interchange of the integral over $t \in [0,1]$ and integrals in the z complex plane—from the holomorphy of $\log(t-z)$ as a function of $z \in \Omega$. The theorem of Fubini[11] permits this interchange of the integration order since the function $F(z,t) \equiv \log(t-z)\varphi(t)$ is in $L^1[\partial\Delta \times [0,1]]$ we are interested in. The holomorphy of the functions $\Psi^{(j)}(z)$ is an immediate consequence of the fact that they are finite sums of holomorphic functions.

We denote by $\Psi^{\infty}(z)$ the limit of the sequence $\{\Psi^{(j)}(z)\}$ wherever this limit exists. We will show that *there are no new singularities* which enter the region Ω as a result of the summation process, i.e., that the limit $\Psi^{\infty}(z)$ is holomorphic in Ω. This is an important point: remember the counterexample with the geometric series from the beginning of Section *V A 2*.

In studying the analytic properties of the function $\Psi^{\infty}(z)$, the crucial property is again the uniform convergence—to be proved below—of the sequence $\{\Psi^{(j)}(z)\}$. This might seem surprising since on the real line there exist examples of sequences of infinitely differentiable functions which converge uniformly to functions which are nowhere differentiable. However, in the complex plane the uniform convergence of the sequences can be used in conjunction with the theorem of Morera to prove the holomorphy of their limits. Indeed, as a first consequence of the uniform convergence of the sequence $\{\Psi^{(j)}(z)\}$ one obtains the continuity of its limit $\Psi^{\infty}(z)$. Secondly, the identities

$$\int_{\partial\Delta} \Psi^{\infty}(z)dz = 0 \tag{49}$$

follow from the vanishing of the corresponding integrals over the holomorpic functions $\Psi^{(j)}(z)$ and from the fact that, because of uniform convergence, the integration and the limiting processes can be interchanged.

To prove the uniform convergence of $\{\Psi^{(j)}(z)\}$ for $z \in \Omega$ we shall proceed similarly to the method used on the interval [0,1]. Since the sums (47) are finite, they commute with the integral (43) from the definition of $U_n^{(0)}(z)$ and so

$$\Psi^{(j)}(z) \equiv \sum_{n=0}^{j} \frac{\varphi_n}{\lambda_n} U_n^{(0)}(z) = \int_0^1 \log(t-z) \sum_{n=0}^{j} \varphi_n u_n(t) dt. \tag{50}$$

Using arguments similar to those which led to Eq. (35), we find

$$\left| \sum_{j+1}^{j+k} \psi_n U_n^{(0)}(z) \right|^2 \leqslant \int_0^1 |\log(t-z)|^2 dt \cdot \sum_{j+1}^{j+k} \varphi_n^2 \tag{51}$$

where, for all $z \in \Omega$, the integral over the logarithm is bounded while the sum over the coefficients φ_n^2 tends to zero as j becomes large. This proves the uniform convergence of the sequence $\{\Psi^{(j)}(z)\}$ in Ω and hence, by the theorem of Morera, that the function $\Psi^{\infty}(z)$ has no singularities in the region Ω.

These results can also be proved using a theorem of Vitali[13] which states that if (a) the functions $\Psi^{(j)}(z)$ are holomorphic for $z \in \Omega$, (b) the sequence converges uniformly on some subset Σ of Ω which has an accumulation point inside Ω and (c) the functions $\Psi^{(j)}(z)$ are *uniformly bounded* in Ω, then the functions $\Psi^{(j)}(z)$ tend uniformly towards a function $\Psi^{\infty}(z)$ which is holomorphic in Ω. Note that the subset Σ may be the segment just above the real interval [0,1] where the uniform convergence has been proved in Section *V A 3*.

Using Vitali's theorem we can easily find the regions where $\Psi^{\infty}(z)$ is holomorphic, by looking at the sets where the $\Psi^{(j)}(z)$ are bounded. In this way we can verify that unlike the functions $U_n^{(0)}(z)$ which can be continued on higher Riemann sheets, the limit $\Psi^{\infty}(z)$ generally *does not exist* there. This is so because the uniform boundness condition (c) is no longer fulfilled outside the first Riemann sheet (unless the coefficients ψ_n decrease exponentially quickly). The reason is the existence of the factor $\exp[i\lambda_n(z-t)]$ in the higher Riemann sheet continuations $U_n^{(k)}(z)$ of the functions $U_n^{(0)}(z)$—see Eq. (65) from Section *V B 4*—which grows exponentially with λ_n if $(z-t)$ is complex.

Finally we shall show that, similar to $\psi^{(\infty)}$ on the real segment, the limit $\Psi^{\infty}(z)$ coincides inside Ω with the function $\Psi(z)$ defined in Eq. (46). This is a direct consequence of the fact that the set $\ker \mathbf{K}$ is empty in the case of the logarithmic kernel. Indeed, replacing $U_n^{(0)}(z)$ in Eq. (47) by its definition (43), Eq. (46) and the Schwarz inequality give

$$|\Psi(z) - \Psi^{(j)}(z)|^2 \leqslant \left\| \varphi(x) - \sum_{0}^{j} \varphi_n u_n(x) \right\|_{L^2}^2 \int_0^1 |\log(t-z)|^2 dt \tag{52}$$

where the right hand side tends to zero when j grows. [For kernels other than the logarithmic one with non empty null space, we can define appropriate Ψ-functions so that the corresponding φ-functions are contained in $\ker^{\perp}\mathbf{K}$. The simplest way to do this is to begin with a Neumann series but stop after few iterations so that the new $\varphi(x)$ should belong itself to Ran $\mathbf{K}$.]

5. Sums of asymptotic expressions

One of the goals of Section V B is to derive asymptotic expressions valid for $z \to 0$ for the analytic extensions $U_n^{(0)}(z)$ of the eigenfunctions:

$$U_n^{(0)}(z) = U_{n,\mathrm{asy}}^{(0)}(z) + U_{n,\mathrm{rem}}^{(0)}(z). \tag{53}$$

The remainder $U^{(0)}_{n,\mathrm{rem}}(z)$ behaves like $\mathcal{O}(|z|^{k-\eta})$ where k is some given positive integer and $\eta>0$ but otherwise arbitrary small. However, the coefficients of the asymptotic terms $U^{(0)}_{n,\mathrm{asy}}(z)$ contain some (fixed) positive power of the eigenvalue λ_n, depending on the value of the exponent k. Since the $\{\lambda_n\}$ tend to infinity with n, we should choose carefully an appropriate definition for the $\{\Psi^{(j)}_{\mathrm{asy}}\}$ in order to secure their convergence.

The simplest way to solve this problem is to use the iterated integral equations (10) discussed in Section III. The eigenfunctions of the iterated kernels $K_r(x,t)$ (12) are identical with those of the initial one, the only change being that the eigenvalues are now $(\lambda_n)^r$. This introduces a beneficial factor $1/\lambda_n^r$ in the coefficients $\psi_{r,n}$ of the new functions

$$\psi_r(x)=\int_0^1 K_r(x,t)\varphi(t)dt, \tag{54}$$

which are now

$$\psi_{r,n}=\frac{\varphi_n}{\lambda_n^r}. \tag{55}$$

This ensures the separate convergence of the series

$$\Psi^{(j)}_{\mathrm{asy}}(z)=\sum_{n=0}^{j}\psi_{r,n}U^{(0)}_{n,\mathrm{asy}}(z)=\sum_{n=0}^{j}\frac{\varphi_n}{\lambda_n^r}U^{(0)}_{n,\mathrm{asy}}(z) \tag{56}$$

and

$$\Psi^{(j)}_{\mathrm{rem}}(z)=\sum_{n=0}^{j}\psi_{r,n}U^{(0)}_{n,\mathrm{rem}}(z)=\sum_{n=0}^{j}\frac{\varphi_n}{\lambda_n^r}U^{(0)}_{n,\mathrm{rem}}(z).$$

As a result the asymptotic expansion of the solution of the integral equation will contain terms of the form $z^m\log^k(z)$, $k\leqslant r$, $m\geqslant k$, as do the iterated free term [see Eq. (23)] and the asymptotic terms $U^{(0)}_{n,\mathrm{asy}}(z)$.

The initial range of validity of the asymptotic expressions derived above is the cut open disk Ω and so does not yet extend on the real segment $[0,1]$. We are of course interested to show the correctness of these asymptotic series also on some small real interval $0\leqslant x\leqslant x_0$. As has been shown above, the theorem of Vitali fails to work on higher Riemann sheets since the functions $U^{(1)}_n(z)$ and $U^{(-1)}_n(z)$ are no longer uniformly bounded and so the sequence $\{\Psi^{(j)}(z)\}$ does not converge any more there. However it is interesting and important for what follows to note that the sequence $\{\Psi^{(j)}(z)\}$ related to our integral equation with logarithmic kernel converges uniformly also on the closure $\overline{\overline{\Omega}}$ of Ω, i.e. the function $\Psi^{\infty}(z)$ is well defined and continuous (because of the uniform convergence) on the real interval $[0,1]$, both when approached from above and below. We have used the symbol $\overline{\overline{\Omega}}$ to emphasize the fact that in all this discussion the open set Ω has to be considered as an open subset of the whole Riemann manifold of the solution of the integral equation rather than of the z complex plane (whereas normally the closure $\overline{\Omega}$ coincides with the unit disk $|z|\leqslant 1$). The set $\overline{\overline{\Omega}}$ contains the interval $[0,1]$ twice (see Fig. 7) corresponding to the fact that the function $\Psi(z)$ has different limits when z approaches the interval $[0,1]$ from above or below.

To prove that the sequence $\{\Psi^{(j)}(z)\}$ converges uniformly also on the interval $[0,1]$ it is sufficient to note that when $z\in[0,1]$, $|\log(t-z)|$ is equal to $|\log|t-z||$ if $t>z$, or to $|\log|t-z|\pm i\pi|$ if $t<z$. Here the sign of $i\pi$ depends on whether z approaches the real axis from above or from below. However in both cases the integral from Eq. (52) is bounded and hence, the right hand side of (52) can be made as small as one wishes by taking j to be sufficiently large.

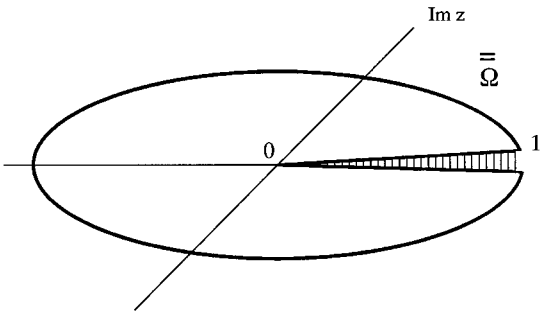

FIG. 7. The closure $\bar{\bar{\Omega}}$ of Ω drawn as a three dimensional picture in order to emphasize that the interval [0,1] is included twice.

It has been already shown in the previous subsection that limit $\Psi^{\infty}(z)$ coincides with the holomorphic function $\Psi(z)$ throughout the open set Ω. The limit $\Psi^{\infty}(z)$ does not exist beyond the two real segments [0,1] from the border of $\bar{\bar{\Omega}}$ but is continuous up to and on them, because of the uniform convergence of the sequence $\{\Psi^{(j)}(z)\}$. The function $\Psi^{\infty}(z)$ is hence defined, by continuity, in an unambiguous way on the two real intervals on the boundary of $\bar{\bar{\Omega}}$. It coincides there with $\Psi(z)$, as everywhere else in the closed set $\bar{\bar{\Omega}}$.

In this way we have shown that the asymptotic series $\Psi^{\infty}_{\text{asy}}(z)$ obtained using the asymptotic expansions of $U_n^{(0)}(z)$ are valid in a neighbourhood of the origin in $\bar{\bar{\Omega}}$, and therefore on the (two) real intervals $[0,x_0]$. This means that the remainder $\Psi^{\infty}_{\text{rem}}(z)$ of the asymptotic series is bounded by $\mathcal{O}(|z|^{k-\eta})$ on the real interval $[0,x_0]$ as well as in the open set Ω.

B. Continuation of the eigenfunctions to the complex plane

In this subsection we shall study the singularities of the eigenfunctions. To this end, similar to the analytic extension $F^{(0)}$ of the free term from Section IV we shall introduce in Section *V B 2* the analytic extensions $U_n^{(0)}$ of the eigenfunctions $u_n(x)$.

In trying to continue $U_n^{(0)}$ analytically on higher Riemann sheets, i.e. in trying to construct the function $U_n^{(1)}$ as we did with the free term in Section IV, we face a specific difficulty related to the fact that the eigenfunctions $u_n(x)$ as they stand are defined only on the segment [0,1]. This means that we could no longer ''hook'' the integration contour, as we did in Section IV where the weight $w(t)$, being analytic, was well defined not only on the real segment but also on the various complex plane deformations of the initial integration path.

This point will be solved in Section V B 3 where the eigenfunctions $u_n(x)$ will be expressed as linear combinations of $U_n^{(0)}$ and its Riemann sheet continuations. Another consequence of this fact will be the Volterra integral equation which relates $U_n^{(1)}$ to $U_n^{(0)}$ or vice versa (Section *V B 4*). This Volterra integral equation can be solved effectively, providing explicit expressions for $U_n^{(1)}$ or $U_n^{(-1)}$ in terms of $U_n^{(0)}$. Finally, in Section *V B 5* this integral equation is used in order to derive the asymptotic series which describe the singularities of the eigenfunctions around the origin.

1. Eigenfunctions of the logarithmic kernel

It has been proved in the Section *V A 3* that, in spite of the logarithmic singularity in the integrand, the eigenfunctions $\{u_n\}$ defined by

$$u_n(x)=\lambda_n\int_0^1 \log|t-x|u_n(t)dt \tag{57}$$

are continuous functions. The graphs of some of these eigenfunctions are depicted in Fig. 8 and

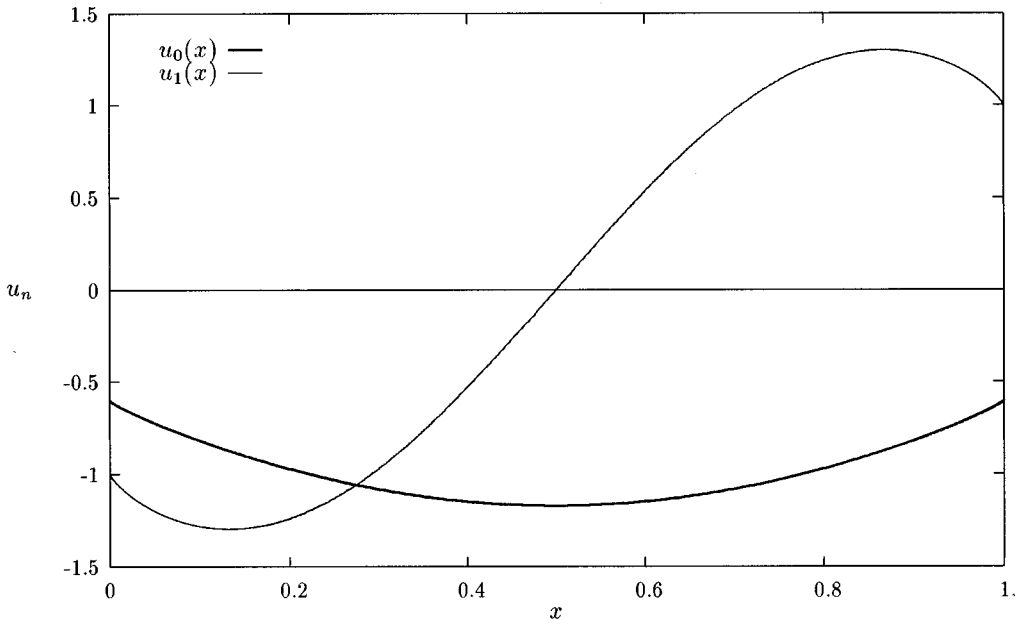

FIG. 8. The eigenfunctions $u_0(x)$ and $u_1(x)$.

Fig. 9. Although these eigenfunctions are finite and look well behaved at the end points 0 and 1 of the fundamental domain (they are there continuous), their derivatives are there infinite. It is the aim of the following subsections to give a full analytic description of the singularities of $u_n(x)$ at these end points.

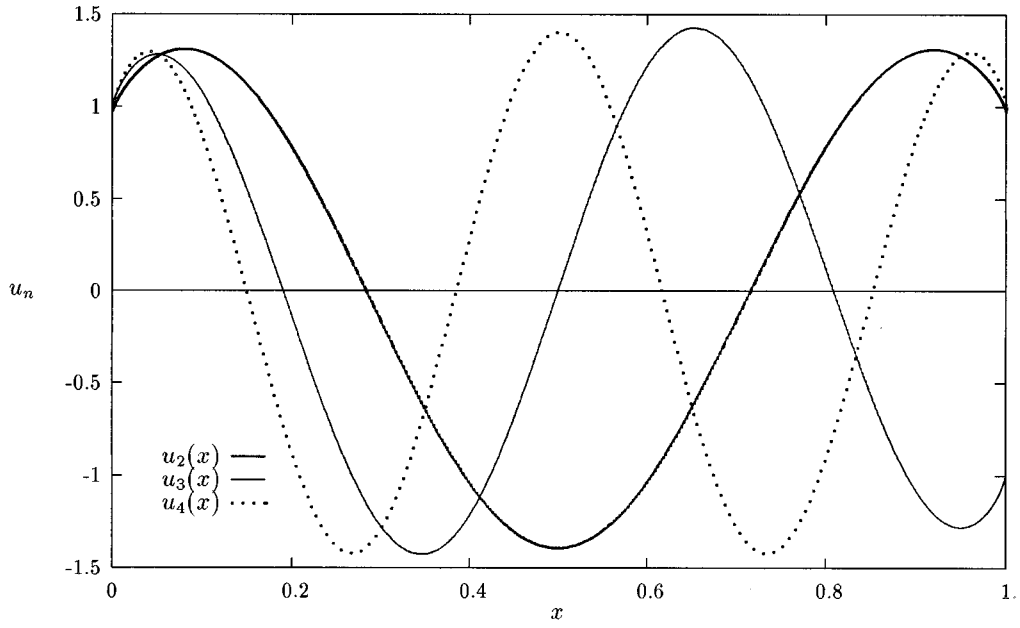

FIG. 9. The eigenfunctions $u_2(x)$, $u_3(x)$ and $u_4(x)$.

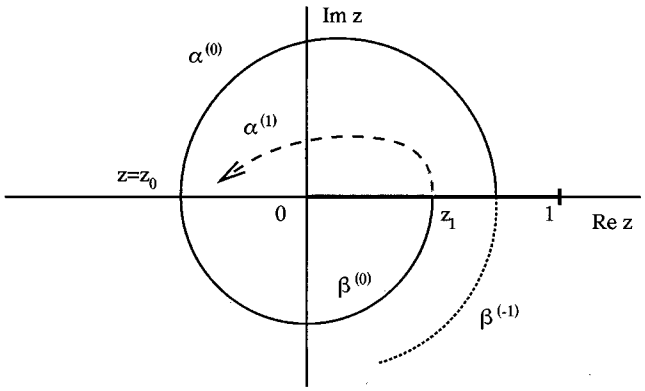

FIG. 10. Higher Riemann sheet continuations paths of $U_n^{(0)}$.

Notice that initially, in order to compute the eigenfunctions $u_n(x)$ it has been sufficient to take the range of the variable x to be the same as that of the integration variable t. Usually to compute the function from the left hand side of an integral equation for values of the variable x outside this initial range, we take the so-called Nystrøm continuation, which consists simply of substituting the new values of x in the right hand side of the equation. However this is possible *only* if the kernel is holomorphic in some given region and so this method is not applicable in our case because of the modulus function inside the logarithm which spoils holomorphy. Thus if in Eq. (57) we take x to be negative, the left hand side ''$u_n(x)$'' *is not* the analytic continuation of the function $u_n(t)$ which appears on the right hand side.

2. The functions $U_n^{(0)}(z)$ and their analytic continuations $U_n^{(\pm k)}(z)$

The function $u_n(x)$, which was defined in this naive way for negative values of x, may be used to introduce a new function $U_n^{(0)}(z)$ which is analytic and, although different from $u_n(x)$ when $x \in [0,1]$, is intimately related to it. Noticing that for $x<0$ *and* $\forall t \in [0,1]$ we have $\log|t-x| = \log(t-x)$, we shall define $U_n^{(0)}(z)$ by

$$U_n^{(0)}(z) \overset{\text{def}}{=} \lambda_n \int_0^1 \log(t-z) u_n(t)\, dt, \quad n=1,2,3,\ldots . \tag{58}$$

Taking the cut of $\log(Z) \equiv \log(t-z)$ along the real negative axis of the complex $Z \equiv t-z$ plane, $U_n^{(0)}(z)$ is a complex function of real type, $U_n^{(0)}(z) = \overline{U_n^{(0)}(\overline{z})}$, having, as we shall show later, a branch point at the origin and a cut lying on the positive real axis. Since we are interested in the singularity of the function near the origin we shall consider the detailed behaviour of $U_n^{(0)}(z)$ only in the neighbourhood of $z=0$. A similar analysis can be performed at the point $z=1$.

The superscript ($^{(0)}$ in the present case) of $U_n^{(k)}(z)$ denotes the Riemann sheet under consideration. Our notation will be such that, by crossing the cut of $U_n^{(k)}$ between $z=0$ and $z=1$ in *an anti-clockwise* way, the value of the superscript increases by 1: see, in Fig. 10, the full line $\alpha^{(0)}-\beta^{(0)}$ from the sheet (0), which is continued by the dashed line $\alpha^{(1)}$ lying on sheet (1). Conversely, crossing the cut between 0 and 1 in the *clockwise* direction, we pass from the full line $\alpha^{(0)}$ from the sheet (0) to the dotted line $\beta^{(-1)}$ from the sheet (-1).

We will want to continue the function $U_n^{(0)}(z)$ defined by the right hand side integral from Eq. (58), starting from some point $z=z_0$ ($z_0<0$), along the full line path $\beta^{(0)}$ and the dashed line $\alpha^{(1)}$, back to z_0, obtaining in this way the value $U_n^{(1)}(z_0)$ of $U_n(z)$ on the next Riemann sheet. But in so doing we will need to deform the integration contour on the right hand side of Eq. (58) into the upper half complex t-plane as we did in the case of the free term in Section IV. We are faced,

however, with the difficulty that $u_n(t)$, as it stands, is defined only on the real segment $0 \leqslant t \leqslant 1$. We therefore need to express $u_n(t)$ as the value of some analytic function on the upper edge of the cut. Here we will be interested only in the *upper lip* of the cut, since moving in an anti-clockwise direction, the analytic continuation path will hook and deform the integration contour into the *upper half* of the complex t-plane (see the curve C from Fig. 5).

3. Expressing $u_n(t)$, $0<t<1$, in terms of $U_n^{(0)}(t+i\epsilon)$ and $U_n^{(1)}(t+i\epsilon)$

Our first concern will be to rewrite the functions appearing under the integral sign of Eq. (58) as combinations of analytic functions. To this end we again use the definition (58) and start from some point $z=z_0$, $z_0<0$. We first continue $U_n^{(0)}(z)$ along a path lying in the lower half z-plane to a point $z_-=z_1-i\epsilon$, $0<z_1<1$, $\epsilon>0$, below the segment $[0,1]$ (along the path $\beta^{(0)}$ from Fig. 10). If the cut of $\log(Z)\equiv\log(t-z)$ is taken to run along the negative real Z-axis, we have

$$\lim_{\epsilon \searrow 0} \log[t-(z_1-i\epsilon)] = \begin{cases} \log|t-z_1|+i\pi & \text{if } t<z_1, \\ \log|t-z_1| & \text{if } t>z_1. \end{cases}$$

We now split the integral along the segment $[0,1]$ into one between 0 and z_1 (where, of course, $t<z_1$ and so the integral runs along the upper lip of the cut of the logarithm), and a second one, between z_1 and 1, where the integration points stay apart from the cut of the logarithm. In this way we get

$$\begin{aligned} U_n^{(0)}(z_1-i\epsilon) &= \lambda_n \int_0^{z_1} \log|t-z_1| u_n(t)dt + \pi i \lambda_n \int_0^{z_1} u_n(t)dt + \lambda_n \int_{z_1}^{1} \log|t-z_1| u_n(t)dt \\ &= u_n(z_1) + \pi i \lambda_n \int_0^{z_1} u_n(t)dt, \end{aligned} \tag{59}$$

where the last equality follows simply from the fact that the first and the third terms combine to give exactly the right hand side of Eq. (57).

Similarly we can make an analytic continuation from $z=z_0<0$ (along the path $\alpha^{(0)}$ from Fig. 10) to the point $z_+=z_1+i\epsilon$ above the cut, to obtain

$$\begin{aligned} U_n^{(0)}(z_1+i\epsilon) &= \lambda_n \int_0^{z_1} \log|t-z_1| u_n(t)dt - \pi i \lambda_n \int_0^{z_1} u_n(t)dt + \lambda_n \int_{z_1}^{1} \log|t-z_1| u_n(t)dt \\ &= u_n(z_1) - \pi i \lambda_n \int_0^{z_1} u_n(t)dt. \end{aligned} \tag{60}$$

The integral over $u_n(t)$ can be eliminated between Eqs. (59) and (60) by taking the sum of the right hand sides, so that

$$\begin{aligned} u_n(z_1) &= \frac{1}{2}\,[U_n^{(0)}(z_1+i\epsilon)+U_n^{(0)}(z_1-i\epsilon)] + \mathcal{O}(\epsilon) \\ &= \frac{1}{2}\,[U_n^{(0)}(z_1+i\epsilon)+U_n^{(1)}(z_1+i\epsilon)] + \mathcal{O}(\epsilon). \end{aligned} \tag{61}$$

Here the last line of Eq. (61) follows from the fact that the values of $U_n^{(1)}$ of the function U_n on the next Riemann sheet on the *upper lip* of the cut, merge, by definition [see also Eq. (17)], with those of $U_n^{(0)}$ *below* the cut:

$$U_n^{(0)}(z_1-i\epsilon) = U_n^{(1)}(z_1+i\epsilon) + \mathcal{O}(\epsilon), \quad 0<z_1<1.$$

4. A Volterra equation for $U_n^{(1)}(z)$

We shall now be able to deform the integration contour in the complex t-plane in the same way as we did in Section IV. Recalling that by the analytic continuation of $U_n^{(0)}(z)$ along the path $\beta^{(0)}-\alpha^{(1)}$ from Fig. 10 one obtains the function $U_n^{(1)}(z)$, we find

$$U_n^{(1)}(z_0)=\lambda_n\int_C \log(t-z_0)\,\frac{U_n^{(0)}(t)+U_n^{(1)}(t)}{2}\,dt, \tag{62}$$

where the integration contour C is shown in Fig. 5 and where we have replaced $u_n(t)$ under the integrand by its holomorphic expression (61). The dashed line represents the cut of $\log(t-z_0)$ in the complex t-plane, where, again, the $+i\pi$-*zone* and $-i\pi$-*zone* mean that the logarithm differs there by $+i\pi$ and $-i\pi$ with respect to its mean value across the cut. In the region $\mathrm{Re}\,t<0$, both $U_n^{(0)}$ and $U_n^{(1)}$ are holomorphic. So—recollect the discussion from Section IV which led to Eq. (14)—the integral over the $\mathrm{Re}\,t<0$ half-plane part of the contour C yields

$$-i\pi\lambda_n\int_{z_0}^{0}[U_n^{(0)}(t)+U_n^{(1)}(t)]dt,$$

while the rest of the integral, between $t=0$ and $t=1$, is identical with that from definition (58) of the function $U_n^{(0)}(z_0)$. So, Eq. (62) can be rewritten in the form

$$U_n^{(1)}(z)=U_n^{(0)}(z)+i\pi\lambda_n\int_0^z[U_n^{(0)}(t)+U_n^{(1)}(t)]dt, \tag{63}$$

which is valid for any z in the cut complex plane since it involves only analytic expressions. Equation (63) can be regarded as a Volterra integral equation for $U_n^{(1)}(z)$ if the function $U_n^{(0)}(z)$ is known, or equally, as a Volterra integral equation for $U_n^{(0)}(z)$ if $U_n^{(1)}(z)$ were known.

This equation can be solved by differentiation. We find immediately

$$\frac{dU_n^{(1)}(z)}{dz}-\frac{dU_n^{(0)}(z)}{dz}=+i\pi\lambda_n[U_n^{(0)}(z)+U_n^{(1)}(z)], \tag{64}$$

or, rearranging the terms,

$$\frac{dU_n^{(1)}(z)}{dz}-i\pi\lambda_nU_n^{(1)}(z)=\frac{dU_n^{(0)}(z)}{dz}+i\pi\lambda_nU_n^{(0)}(z).$$

This can be rewritten in the form

$$\exp(+i\pi\lambda_nz)\,\frac{d}{dz}\,[\exp(-i\pi\lambda_nz)U_n^{(1)}(z)]=\exp(-i\pi\lambda_nz)\,\frac{d}{dz}\,[\exp(+i\pi\lambda_nz)U_n^{(0)}(z)].$$

Now, from Eq. (63) it is obvious that $U_n^{(1)}(0)=U_n^{(0)}(0)$. This is an initial condition which permits us to write the solution of the Volterra equation as

$$U_n^{(1)}(z)=U_n^{(0)}(z)+2i\pi\lambda_n\int_0^z\exp[i\pi\lambda_n(z-t)]U_n^{(0)}(t)dt. \tag{65}$$

Similarly we can step backwards and express $U_n^{(0)}$ with respect to $U_n^{(1)}$, or $U_n^{(-1)}$ with respect to $U_n^{(0)}$:

$$U_n^{(-1)}(z)=U_n^{(0)}(z)-2i\pi\lambda_n\int_0^z \exp[-i\pi\lambda_n(z-t)]U_n^{(0)}(t)dt. \tag{66}$$

5. Asymptotic expansion

To begin with, we shall suppose that each of the functions $U_n^{(0)}(z)$ admits an expansion around the origin of the form

$$U_n^{(0)}(z)=U_{n,\mathrm{asy}}^{(0)}(z)+U_{n,\mathrm{rem}}^{(0)}(z)\equiv\sum_{k=0}^{r} a_k z^k+\sum_{m=1}^{r}\sum_{k=1}^{r} b_{mk}z^m\cdot\log^k(-z)+U_{n,\mathrm{rem}}^{(0)}(z), \tag{67}$$

where $U_{n,\mathrm{rem}}^{(0)}$ is $\mathcal{O}(|z|^{r+1-\eta})$. The choice of these series may look very restrictive, but once we have shown their consistency, their uniqueness follows from the uniqueness of the solution of a linear integral equation with a Hilbert-Schmidt kernel. In Eq. (67) the sum $\Sigma_{k=0}^{r}a_k z^k$ comes from the holomorphic part of $U_n^{(0)}$ around $z=0$. Taking as before the cut of $\log(Z)\equiv\log(-z)$ along the negative real Z-axis, the right hand side of Eq. (67) will be holomorphic throughout the domain Ω which has a cut running along the positive real axis (see Fig. 6). From the definition (58) we see that $U_n^{(0)}(z)$ is a real-analytic function [i.e. $U_n^{(0)}(z)=\overline{U_n^{(0)}(\overline{z})}$] and so the coefficients a_k ($k=0,1,2...$) and b_{mk} ($m,k=1,2,...$) have to be real. The coefficients b_{mk} are then determined in a recursive manner from the coefficients a_k of the regular part.

In order to find the coefficients b_{mk} we first notice that the analytic continuation of $U_{n,\mathrm{asy}}^{(0)}$ across the cut yields

$$U_{n,\mathrm{asy}}^{(1)}(z)=\sum_{k=0}^{r} a_k z^k+\sum_{m=1}^{r}\sum_{k=1}^{r} b_{mk}z^m\cdot[\log(-z)+2i\pi]^k. \tag{68}$$

Inserting the expressions (67) and (68) in Eq. (64) we may then compare the various terms appearing in the left and right hand sides. This comparison can be done for any z in the open set Ω, for instance for negative real z, in order to be away from the cut of $\log(-z)$. Taking the limit $z\to 0$ in both sides we remark that

$$b_{1k}=0,\quad k=2,3,\ldots, \tag{69}$$

as a consequence of the fact that the differences of terms of the type $z[\log(-z)+2i\pi]^k$ and $z\log^k(-z)$ from the left hand side of Eq. (64) yield, by differentiation, terms which tend to infinity and which are not compensated by similar terms from the right hand side. Looking at the constant terms we get

$$b_{11}=\lambda_n a_0. \tag{70}$$

Similarly, by differentiating with respect to z both sides of Eq. (64) we obtain

$$b_{mk}=0\quad \text{if } k\geqslant m+1, \tag{71}$$

while the coefficients b_{mk} with $k\leqslant m$ can be expressed iteratively by means of the coefficients a_k. So, for instance, we find

$$b_{21}=\frac{2a_1\lambda_n-a_0\lambda_n^2}{4},\quad b_{22}=\frac{a_0\lambda_n^2}{4}. \tag{72}$$

We tried to check numerically the accuracy of this asymptotic expansion in regions close to the singularity. To this end we took two terms from the holomorphic part of $U_{n,\mathrm{asy}}^{(0)}(z)$, and expressed

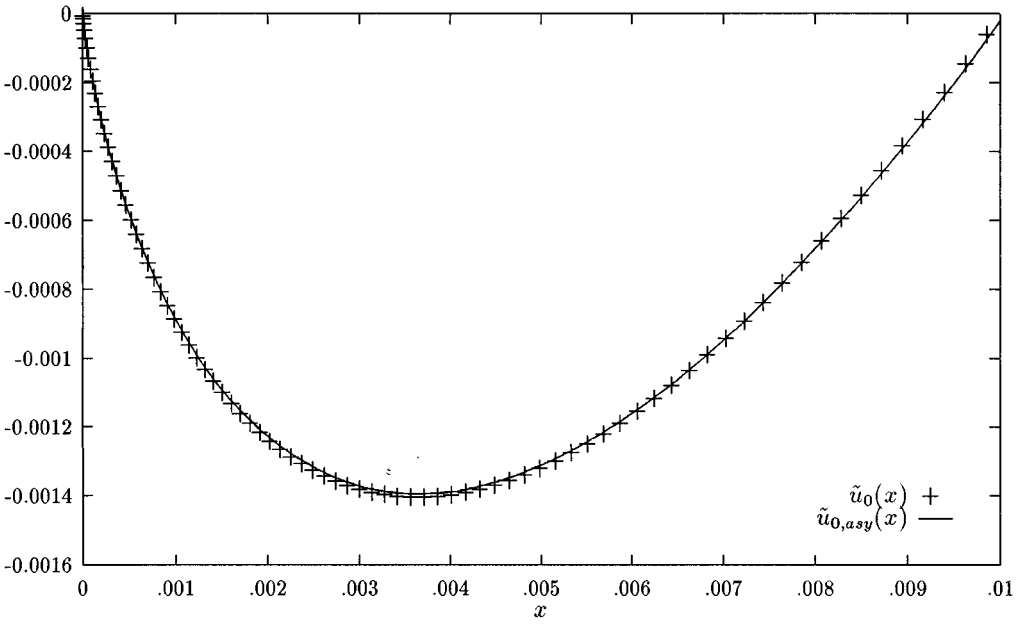

FIG. 11. One parameter asymptotic fit of $\tilde{u}_0(x)$.

the corresponding b_{mk} coefficients in terms of the first two coefficients a_0 and a_1. Since a_0 is determined by the value at $x=0$ of the eigenfunctions which, in turn, is determined by the normalization condition, we have in fact *only one free parameter*, the coefficient a_1. Using the above expressions for b_{11}, b_{21} and b_{22} in terms of a_0 (given) and a_1 (free), we have chosen a_1 to obtain the best fit to the first few eigenfunctions, in the region [0,0.01] near the origin where we expected the asymptotic expansion to hold. When we plot the function $u_n(x)$ together with our asymptotic expansion the two curves appear identical on the interval [0,0.01]. In order to show the slight difference in these functions we have defined a new function $\tilde{u}_n(x)=u_n(x)-u_n(0)-[u_n(x_1)-u_n(0)]x/x_1$ which has its end points $\tilde{u}_n(0)$ and $\tilde{u}_n(0.01)$ at the same height and so permits the use of a much enlarged y-axis scale. The corresponding plots for the two first eigenfunctions are presented in Figs. 11 and 12. Although as it has been already stressed, these curves are just one parameter fits and that moreover we have restricted ourselves only to the first terms in the asymptotic expression, the agreement between these asymptotic expressions (the full lines) with the computer calculated points of the eigenfunctions (the crosses) is really excellent.

VI. RESUME AND CONCLUSIONS

As indicated in the Introduction, the numerical calculations related to the solution of the inverse problem for EIT are seriously hampered by the high number of mesh points necessary to take into account the sharp peaks of the current density near the edge of the electrodes. Since these peaks seemed to be intrinsic objects describable by only a small numbers of parameters we have investigated the details of their analytic structure. To this end we have studied the Riemann sheet structure of the eigenfunctions of the dominant singular integral equation relating to the solution of the mixed boundary problem for the potential, and derived asymptotic expressions both for the eigenfunctions and for the solution of the integral equation. These asymptotic expressions provide very simple parametrisations for the anomalous thresholds, whose effectiveness can be judged from the Figs. 11 and 12.

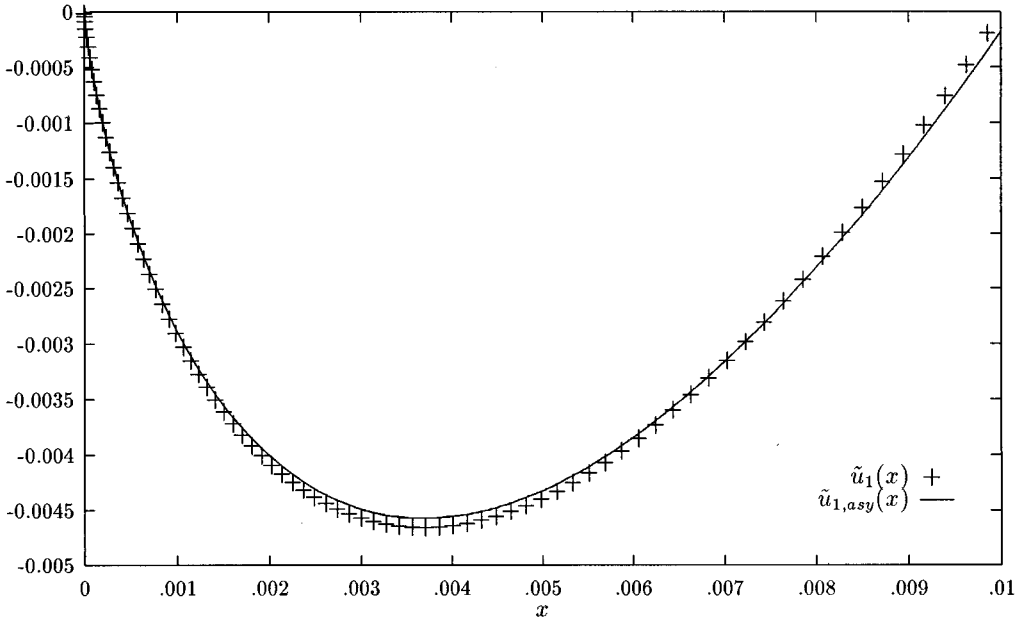

FIG. 12. One parameter asymptotic fit of $\tilde{u}_1(x)$.

The paper is constructed as follows: In the Introduction and in Section II the mathematics of the EIT modelling is discussed while the corresponding weakly singular integral equation is given in Section III. In Section IV we have discussed the effect on the singularities of the free term of the moving cut of the logarithm which ''hooks'' the integration contour. The *generic singularities* of the solution of the integral equation are then described as a superposition of those of the free term and of the eigenfunctions which were derived in Section V B. Section V A contains the proof that although we deal with infinite series, no new singularities appear in the neighbourhood of the origin, i.e. the singularities of the solution are really those of the eigenfunctions and of the free term. We also determine the limits of the domain where the eigenfunction sum converges unconditionally and show how one can extend the validity of the asymptotic series also on the real segment [0,1].

We hope that the discussion of the analytic properties of the eigenfunctions and solution of this quite special, logarithmic singular equation, will provide a working example which might be useful also for the study of the singularities of the solution of other weakly singular integral equations. The discontinuities across the cuts will certainly be different, but the general discussion will probably be fairly similar.

ACKNOWLEDGMENTS

The authors are grateful to Professor G. Auberson, Professor G. Mennessier, and Professor P. C. Sabatier for long discussions concerning the integral equation and other analytic aspects of this paper. One of the authors (M.K.P.) would like to thank The British Council for their support. Another author (S.I.) acknowledges a research grant from the Ministère de l'Enseignement Supérieur et de la Recherche and the help of Professor C. Duhamel from the French Embassy in Bucharest without whom this collaboration would not have been possible.

APPENDIX: COMPLETENESS OF THE BASIS $\{u_n\}$

Following a proof given by Auberson,[14] we shall show in what follows that ker **K**, the null space of the logarithmic kernel, is empty and so the eigenfunctions $\{u_n\}_{n=0,1,2\ldots}$ do span the whole Hilbert space of the L^2 functions on [0,1].

Suppose that ker $\mathbf{K}\neq\{0\}$, i.e. that there exists at least one non zero L^2-function ϕ such that

$$\int_0^1 \log|x-y|\,\phi(y)\,dy=0. \tag{A1}$$

Defining the function

$$v(x)\overset{\text{def}}{=}\int_0^x \phi(y)\,dy, \tag{A2}$$

we have

$$\text{(a)}\quad \frac{dv(x)}{dx}=\phi(x)\ \text{ almost everywhere,}$$

$$\text{(b)}\quad v(0)=0.$$

We can easily prove that the function $v(x)$ satisfies a Hölder condition of index 1/2

$$|v(x_1)-v(x_2)|\leqslant A|x_1-x_2|^{1/2},\quad \text{for } \forall x_1,x_2\in(0,1),$$

where A is a positive constant.

By integrating the left hand side of Eq. (A1) by parts we find

$$\int_0^1 \log|x-y|\,\phi(y)\,dy=v(1)\log(1-x)-\mathscr{P}\int_0^1 \frac{v(y)}{y-x}\,dy$$

so that from Eq. (A1) we obtain

$$\mathscr{P}\int_0^1 \frac{v(y)}{y-x}\,dy=v(1)\log(1-x), \tag{A3}$$

If we now consider the following function

$$F(z)\overset{\text{def}}{=}\sqrt{z(z-1)}\int_0^1 \frac{v(y)}{y-z}\,dy\quad \text{for } z\in D \tag{A4}$$

where D is the complex z-plane cut along the segment [0,1], we can show that

(i) F is a holomorphic function in D;
(ii) $\lim_{z\to\infty}F(z)=-\int_0^1 v(y)\,dy$;
(iii) $\operatorname{Im} F(x+i\epsilon)=\sqrt{x(1-x)}\,\mathscr{P}\int_0^1[v(y)/(y-x)]\,dy=\sqrt{x(1-x)}\,v(1)\log(1-x)$, for $x\in(0,1)$;
(iv) $\operatorname{Re} F(x+i\epsilon)=-\pi\sqrt{x(1-x)}\,v(x)$, for $x\in(0,1)$.

The properties (i)–(iii) imply that

$$F(z)=\frac{v(1)}{\pi}\int_0^1 \frac{\sqrt{y(1-y)}\log(1-y)}{y-z}\,dy-\int_0^1 v(y)\,dy,\quad z\in D, \tag{A5}$$

while from (iv) it follows that for $x \in (0,1)$ we have

$$-\pi\sqrt{x(1-x)}v(x)=\frac{v(1)}{\pi}\mathscr{P}\int_0^1 \frac{\sqrt{y(1-y)}\log(1-y)}{y-x}\,dy-\int_0^1 v(y)dy. \tag{A6}$$

Taking now the limits $x\searrow 0$ and $x\nearrow 1$ we find

$$\frac{v(1)}{\pi}\int_0^1 \sqrt{\frac{1-y}{y}}\log(1-y)dy-\int_0^1 v(y)dy=0, \tag{A7}$$

$$-\frac{v(1)}{\pi}\int_0^1 \sqrt{\frac{y}{1-y}}\log(1-y)dy-\int_0^1 v(y)dy=0. \tag{A8}$$

Subtracting (A8) from (A7) we see that $v(1)=0$ and hence, from Eq. (A6),

$$v(x)=\frac{1}{\pi\sqrt{x(1-x)}}\int_0^1 v(y)dy\equiv\frac{C}{\pi\sqrt{x(1-x)}}. \tag{A9}$$

Now, since $v(1)$ is zero, the constant C also has to be zero and so $v(x)$ has to vanish identically [it had to be so since neither the right hand side of Eq. (A9) and even less its derivative are L^2]. This implies that ker**K** is an empty set and so the eigenfunctions $\{u_n\}$ of the logarithmic kernel form a complete L^2 basis on the segment [0,1].

Localized solutions of the Dirac–Maxwell equations

C. J. Radford[a)]
Department of Mathematics, Statistics and Computing Science, The University of New England, Armidale, N.S.W, 2351, Australia

(Received 3 November 1995; accepted for publication 11 March 1996)

The full classical Dirac–Maxwell equations are considered in a somewhat novel form and under various simplifying assumptions. A reduction of the equations is performed in the case when the Dirac field is static. A further reduction of the equations is made under the assumption of spherical symmetry. These static spherically symmetric equations are examined in some detail and a numerical solution presented. Some surprising results emerge from this investigation: (i) Spherical symmetry necessitates the existence of a magnetic monopole. (ii) There exists a uniquely defined solution, determined only by the demand that the solution be analytic at infinity. (iii) The equations describe highly compact objects with an inner onion like shell structure. © *1996 American Institute of Physics.*

I. INTRODUCTION

It is an interesting exercise to compare the current development of a quantum theory of gravitation, from the fully non-linear Einstein theory, to the development of QED from the linearized Dirac–Maxwell theory. The most startling difference is the large body of work on the classical, non-linear, theory of gravitation (general relativity)—a theory which includes, in a self consistent manner, the interactions of the gravitational field itself. There is no comparable body of work on the full Dirac–Maxwell theory (Dirac equations with electromagnetic interaction, Maxwell equations with Dirac field source—the so-called ''self interaction''). Of course this situation arose, historically, because of the rapid development and stunning success of QED.

Einstein's equations provide a much better description of gravity than do the linear spin-2 equations. Indeed, one can ''derive'' classical general relativity from the linear, massless spin-2 theory by summing all the Feynman diagrams to tree level—see Refs. 1 and 2. The full Dirac–Maxwell equations should provide a much better description of electronic matter than their linearized counterparts (in which self terms are ignored).

Explicit solutions to the Dirac–Maxwell equations are rare, see Ref. 3. Uniqueness and existence results for this system have been known for some time, see Ref. 4 and references therein. More recently, existence results have been obtained for ''soliton like'' solutions.[5,6] Theorem 1 of Ref. 5 proves the existence of solutions to the Dirac–Maxwell equations as a critical point of the Dirac–Maxwell action functional in the Sobelev space $H^{1/2}(\mathbb{R}^3, \mathbb{C}^4)$; with the Dirac spinor being a smooth function exponentially decreasing at infinity, together with all its derivatives. The solutions presented here are quite different, they are singular at the origin and behave like $1/r^4$ near infinity.

There exist a number of solutions to the Yang–Mills–Dirac and Yang–Mills–Dirac–Higgs equations, see Ref. 7 and the comprehensive list of references contained therein.

The paper is organized as follows: in Sec. II we write the equations in 2-spinor form, this description then allows us to (covariantly) solve the Dirac equations for the electromagnetic potential and so write down a complete set of equations in terms of the Dirac field. In Sec. III we examine the static and spherically symmetric reductions of the equations. In Sec. IV we deal with

a)chris@neumann.une.edu.au

0022-2488/96/37(9)/4418/16/$10.00

some general properties of the static spherically symmetric system and in Sec. V present a numerical solution to this system.

II. The Dirac–Maxwell Equations

In standard notation the Dirac-Maxwell equations are

$$\gamma^{\alpha}(\partial_{\alpha}-ieA_{\alpha})\psi+im\psi=0, \quad F_{\alpha\beta}=A_{\beta,\alpha}-A_{\alpha,\beta},$$
$$\partial^{\alpha}F_{\alpha\beta}=-4\pi ej_{\beta}=-4\pi e\overline{\psi}\gamma_{\beta}\psi. \tag{1}$$

Employing the γ_5-diagonal or van der Waerden description, see for example Ref. 8, we have

$$\gamma^{\alpha}=\sqrt{2}\begin{pmatrix} 0 & \sigma^{\alpha}_{B\dot{B}} \\ \sigma^{\alpha A\dot{A}} & 0 \end{pmatrix},$$

with $\sigma^{\alpha}_{A\dot{A}}$ the van der Waerden symbols, i.e.

$$(\sigma^{0}_{A\dot{A}})=\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad (\sigma^{j}_{A\dot{A}})=\frac{1}{\sqrt{2}}\times \text{Pauli Matrix}, \quad j=1,2,3.$$

Where $A,B=0,1$ and $\dot{A},\dot{B}=\dot{0},\dot{1}$ are two-spinor indices (see Ref. 8). The Dirac bispinor, ψ is

$$\psi=\begin{pmatrix} u_A \\ \overline{v^{\dot{B}}} \end{pmatrix} \quad \text{and} \quad \overline{\psi}=(v^{B},\overline{u_{\dot{A}}}).$$

So that the Dirac equations become

$$(\partial^{A\dot{A}}-ieA^{A\dot{A}})u_A+\frac{im}{\sqrt{2}}\,\overline{v^{\dot{A}}}=0, \quad (\partial^{A\dot{A}}+ieA^{A\dot{A}})v_A+\frac{im}{\sqrt{2}}\,\overline{u^{\dot{A}}}=0, \tag{2}$$

where $\partial^{A\dot{A}}\equiv\sigma^{\alpha A\dot{A}}\partial_{\alpha}$, $A^{A\dot{A}}=\sigma^{\alpha A\dot{A}}A_{\alpha}$.

The Maxwell equations are

$$\partial^{\alpha}F_{\alpha\beta}=-4\pi ej_{\beta}=-4\pi e\sigma^{A\dot{A}}_{\beta}(u_A\overline{u_{\dot{A}}}+v_A\overline{v_{\dot{A}}}). \tag{3}$$

In the linearized theory the ''self current'' j_{β} is ignored. We now eliminate the potential $A^{A\dot{A}}$ using (2)-another approach is to eliminate ''A^{self}_{α}'' using the formal Green's function[3,9]—we will use purely algebraic methods. From Eqs. (2) we have

$$v^{A}\partial^{B\dot{A}}u_B+u^{A}\partial^{B\dot{A}}v_B+\frac{im}{\sqrt{2}}\,(v^{A}\overline{v^{\dot{A}}}+u^{A}\overline{u^{\dot{A}}})=ie[A^{B\dot{A}}(v^{A}u_B-u^{A}v_B)]. \tag{4}$$

However, because of the two-dimensionality of the 2-spinor space we have

$$v_Au_B-u_Av_B=\epsilon_{AB}(u^{C}v_C).$$

Here, $\epsilon_{01}=\epsilon^{01}=1$, $\epsilon_{10}=\epsilon^{10}=-1$, $\epsilon^{00}=\epsilon_{00}=\epsilon^{11}=\epsilon_{11}=0$; we define $\xi^{A}=\epsilon^{AB}\xi_B$ and $\xi_A=\epsilon_{BA}\xi^{B}$.

We assume that $u^{C}v_C\neq0$ almost everywhere. Now, $j^{\alpha}j_{\alpha}=|u^{A}v_A|^2$, so $u^{C}v_C\equiv0$ implies that the current vector, j, is null—a massive neutrino field.

We can now solve (4) for the electromagnetic potential A,

$$A^{A\dot{A}}=\frac{i}{e(u^c v_c)}\left\{v^A\partial^{B\dot{A}}u_B+u^A\partial^{B\dot{A}}v_B+\frac{im}{\sqrt{2}}\,(u^A\overline{u^{\dot{A}}}+v^A\overline{v^{\dot{A}}})\right\}. \tag{5}$$

Notice that, from (5), under the gauge transformation

$$\begin{pmatrix} u_A \\ \overline{v^{\dot{B}}}\end{pmatrix}\to e^{i\chi}\begin{pmatrix} u_A \\ \overline{v^{\dot{B}}}\end{pmatrix}\quad\text{we have}\quad A_\alpha\to A_\alpha+\frac{1}{e}\,\partial_\alpha\chi$$

as we should expect!

The four complex equations (2) actually over determine the four *real* quantities A_α. We must impose on (5) the condition that A_α is real. These reality conditions can be written as

$$\overline{(A^{A\dot{A}}u_A\overline{u_{\dot{A}}})}=A^{A\dot{A}}u_A\overline{u_{\dot{A}}},\quad \overline{(A^{A\dot{A}}v_A\overline{v_{\dot{A}}})}=A^{A\dot{A}}v_A\overline{v_{\dot{A}}},\quad \overline{(A^{A\dot{A}}u_A\overline{v_{\dot{A}}})}=A^{A\dot{A}}v_A\overline{u_{\dot{A}}}.$$

With the use of (5) these reality conditions become

$$\begin{aligned}\partial^{A\dot{A}}(u_A\overline{u_{\dot{A}}})&=-\frac{im}{\sqrt{2}}\,(u^C v_C-\overline{u^{\dot{C}}}\,\overline{v_{\dot{C}}}),\\ \partial^{A\dot{A}}(v_A\overline{v_A})&=\frac{im}{\sqrt{2}}\,(u^C v_C-\overline{u^{\dot{C}}}\,\overline{v_{\dot{C}}}),\\ u_A\partial^{A\dot{A}}\overline{v_{\dot{A}}}-\overline{v_{\dot{A}}}\partial^{A\dot{A}}u_A&=0.\end{aligned} \tag{6}$$

These equations constitute four real first order equations for the four complex quantities u^A and v^A. A further four real third order equations for these quantities is obtained upon substitution of (5) into the Maxwell equations (3). Note that adding the first two equations of (6) leads to the equation of conservation for j^α.

III. REDUCTION OF THE SYSTEM

A. The static equations

Firstly, we impose the condition that the field is static. We assume that there exists a Cartesian Lorentz frame in which $j^\alpha=\delta_0^\alpha j^0$. Imposing this condition one quickly finds that

$$v^A=e^{i\chi}\sqrt{2}\sigma^{0A\dot{A}}\overline{u_{\dot{A}}},\ \text{with}\ \chi\ \text{a real function.}$$

The current vector is now

$$j^\alpha=\sqrt{2}(u^0\overline{u^0}+u^1\overline{u^1})\,\delta_0^\alpha.$$

The reality conditions are

$$\begin{aligned}\partial_{A\dot{A}}(u^A\overline{u^A})&=\frac{-2m}{\sqrt{2}}\,(|u^0|^2+|u^1|^2)\sin\chi,\\ (\partial_{0\dot{0}}+\partial_{1\dot{1}})(|u^0|^2+|u^1|^2)&=0,\\ u^0(\partial_{0\dot{0}}+\partial_{1\dot{1}})u^1-u^1(\partial_{0\dot{0}}+\partial_{1\dot{1}})u^0&=i[u^0u^1(\partial_{0\dot{0}}-\partial_{1\dot{1}})+(u^1)^2\partial_{1\dot{0}}-(u^0)^2\partial_{1\dot{1}}]\chi,\end{aligned}$$

the expressions for the potential $A^{A\dot{A}}$ can now be written down, although we will not do this at this stage.

Now under a gauge transformation we have

$$u^A \to e^{i\mu} u^A \quad \text{and} \quad A_\alpha \to A_\alpha + \frac{1}{e}\,\partial_\alpha \mu.$$

We fix the gauge by defining real functions X, Y and η as follows:

$$u^0 = X e^{i/2(\chi+\eta)}, \quad u^1 = Y e^{i/2(\chi-\eta)}.$$

Our equations can be given in a particularly suggestive three vector form by writing (in our Cartesian coordinates)

$$l = (\sigma^{\alpha}_{A\dot{A}} u^A \overline{u^A}) = \left(l^0, \frac{1}{\sqrt{2}}\,\mathbf{V} \right)$$

with

$$l^0 = \frac{1}{\sqrt{2}}\,(X^2 + Y^2)$$

and

$$\mathbf{V} = (2XY\,\cos\,\eta, 2XY\,\sin\,\eta, X^2 - Y^2).$$

The reality conditions become

$$\frac{\partial}{\partial t}\,(X^2+Y^2) = 0, \quad \boldsymbol{\nabla}\cdot\mathbf{V} = -2m(X^2+Y^2)\sin\,\chi, \quad \frac{\partial \mathbf{V}}{\partial t} + (\boldsymbol{\nabla}\chi)\times\mathbf{V} = \mathbf{0}.$$

With electromagnetic potential

$$A^0 = \frac{m}{e}\,\cos\,\chi + \frac{(X^2-Y^2)}{2e(X^2+Y^2)}\,\frac{\partial \eta}{\partial t} + \frac{(\boldsymbol{\nabla}\chi)\cdot\mathbf{V}}{2e(X^2+Y^2)},$$

$$\mathbf{A} = \frac{1}{2e(X^2+Y^2)}\left[\frac{\partial \chi}{\partial t}\,\mathbf{V} + (X^2-Y^2)\boldsymbol{\nabla}\eta - \boldsymbol{\nabla}\times\mathbf{V} \right], \quad \text{where } \mathbf{A} = (A^1, A^2, A^3).$$

The full system is given by the above two sets of equations and the Maxwell equations.

B. Spherical symmetry

We now impose spherical symmetry upon our static system. A minimal requirement that the Dirac field be static and spherically symmetric (in any gauge) is that the vector l, above, is spherically symmetric. We require

$$[X_i, l] = 0,$$

where the X_i, $i=1,2,3$, are the three (vector) generators of rotations.

These conditions imply that l has time and radial components only and that these components are functions of (t,r) only, $r = \sqrt{(x^1)^2+(x^2)^2+(x^3)^2}$.

Using the notation above we have

$$X^2+Y^2=R=R(r), \quad \text{only} \quad \mathbf{V}=|\mathbf{V}|\hat{\mathbf{r}}=R\hat{\mathbf{r}},$$

where $\hat{\mathbf{r}}=(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta)$ in terms of the polar coordinates r, θ, ϕ. We have

$$X=\sqrt{R}\,\cos(\theta/2), \quad Y=\sqrt{R}\,\sin(\theta/2), \quad \eta=\phi.$$

The Dirac bispinor is now

$$\psi=\sqrt{R}\begin{pmatrix} -e^{(i/2)(\chi-\phi)}\sin(\theta/2) \\ e^{(i/2)(\chi+\phi)}\cos(\theta/2) \\ -e^{-(i/2)(\chi+\phi)}\sin(\theta/2) \\ e^{-(i/2)(\chi-\phi)}\cos(\theta/2) \end{pmatrix}.$$

The equations are now as follows

$$\chi=\chi(r), \quad R=R(r), \quad \mathbf{A}=\frac{1}{2e}\frac{\cot\theta}{r}\hat{\phi},$$

$$A^0=\frac{m}{e}\cos\chi+\frac{1}{2e}\frac{d\chi}{dr},$$

$$\frac{d}{dr}(r^2R)=-2mr^2R\sin\chi, \quad \frac{d}{dr}\left(r^2\frac{dA_0}{dr}\right)=4\sqrt{2}\pi e r^2R. \tag{7}$$

The really surprising result here is the unavoidable appearance of the magnetic monopole term

$$\mathbf{A}=\frac{1}{2e}\frac{\cot\theta}{r}\hat{\phi}.$$

Here $\hat{\phi}$ is the usual azimuthal unit vector, in terms of a coordinate basis $A=-(1/2e)\cos\theta d\phi$.

We should also impose a normalization condition (or finite total charge condition) on any solution

$$\int j^\alpha dS_\alpha<\infty$$

on any space like hypersurface. This leads to the condition

$$\int_{r=0}^{\infty} r^2Rdr<\infty.$$

To end this section we rewrite the determining radial equations in a more transparent form by introducing the following new (dimensionless) variables

$$\rho=2mr, \quad a=\frac{e}{m}A^0, \quad q=4\pi\sqrt{2}\,\frac{e^2}{m}\,r^2R.$$

$$\frac{d\chi}{d\rho}=a-\cos\chi, \quad \frac{d}{d\rho}\left(\rho^2\frac{da}{d\rho}\right)=q, \quad \frac{dq}{d\rho}=-q\sin\chi. \tag{8}$$

IV. STATIC SPHERICAL SYMMETRY: GENERAL PROPERTIES

The system of equations (8) possesses the discrete symmetry

$$\chi \to \pi - \chi, \quad a \to -a, \quad q \to -q. \tag{9}$$

This is just the operation of charge conjugation; q needs to be reinterpreted (it was originally defined as non-negative) to account for the change in sign of the charge which manifests itself on the right hand side of the second equation of (8). We write $q=\epsilon Q$, with $\epsilon^2=1$ and $Q \geqslant 0$, so $Q=\sqrt{2}(e^2/m)r^2R$; then, under (9), we have $\epsilon \to -\epsilon$ and $Q \to Q$.

Our equations read,

$$\frac{d\chi}{d\rho}=a-\cos\,\chi, \quad \frac{da}{d\rho}=\frac{\epsilon f}{\rho^2}, \quad \frac{df}{d\rho}=Q, \quad \frac{dQ}{d\rho}=-Q\,\sin\,\chi, \tag{10}$$

where we have introduced the new variable f to give a set of four first order, ordinary differential equations. This new variable is directly related to the magnitude total (Dirac field) charge contained in a ball of radius r, $B(r)$,

$$e\int_{B(r)} j^{\alpha}dS_{\alpha}=e\int_{B(r)} j^0 d^3x=4\pi e\sqrt{2}\int_{s=0}^{r} s^2R(s)ds=\frac{2\pi}{e}\int_{\sigma=0}^{\rho} Q d\sigma=\frac{1}{2e}\,(f(\rho)-f(0)).$$

In view of this—and the fact that $df/dp=Q=\epsilon q$ is proportional to the charge density on a shell of radius r—we will use the following condition on our system (10):

$$\left[\begin{array}{l}\text{On } \rho>0,\ f \text{ is a bounded } C^1 \text{ function, with bounded first derivative.}\\ \text{Both } f \text{ and } \dfrac{df}{d\rho} \text{ have well defined limits as } \rho\to\infty.\end{array}\right. \tag{C1}$$

We will now develop some qualitative results which indicate the types of solution which can exist under rather general (and physically reasonable) conditions.

Lemma 1: Suppose (χ,a,f,Q) is a solution of (10) on $\rho>0$, then under C1 the function a is C^2 on $\rho>0$ with a and $da/d\rho$ bounded on intervals $\rho\geqslant\rho_1>0$ and ρa bounded on $0\leqslant\rho\leqslant\rho_1<\infty$. If $f(0)\neq 0$ or $df/d\rho(0)=Q(0)>0$ then a is unbounded as $\rho\to 0$.

Proof: We first establish that Q and f have well defined limits as ρ approaches 0. We are assuming that the solution (χ,a,f,Q) exists on $\rho>0$, so for $\rho_2>\rho_1>0$ and using Eq. (10), we have

$$|Q(\rho_2)-Q(\rho_1)|=\left|\int_{\rho_1}^{\rho_2} Q(\sigma)\sin\,\chi(\sigma)d\sigma\right|$$

$$\leqslant\int_{\rho_1}^{\rho_2}|Q\,\sin\,\chi|d\sigma<M_1(\rho_2-\rho_1), \text{ here } M_1=\sup_{\mathbf{R}^+}Q<\infty.$$

Letting ρ_1 and ρ_2 approach zero, we have $|Q(\rho_2)-Q(\rho_1)|\to 0$. Using Cauchy's criterion we conclude that $Q(0^+)$ exists. A similar argument can be given to demonstrate the existence of $f(0^+)$.

The boundedness of $da/d\rho$, on $\rho\geqslant\rho_1$ follows from

$$\epsilon\frac{da}{d\rho}=f/\rho^2$$

Integrate this expression to bound a on $\rho\geqslant\rho_1>0$.

Write $\Omega=\epsilon\rho a$, then

$$\rho\,\frac{d\Omega}{d\rho}-\Omega=f,\ \text{ and }\quad \rho\,\frac{d^2\Omega}{d\rho^2}=Q.$$

From the second of these equations we have, on $(0,\rho_1]$,

$$-M_1\,\ln\!\left(\frac{\rho_1}{\rho}\right)+\frac{d\Omega}{d\rho}\,(\rho_1)\leqslant\frac{d\Omega}{d\rho}\,(\rho)\leqslant\frac{d\Omega}{d\rho}\,(\rho_1).$$

So we have (note as a is C^2 away from $\rho=0$ so is Ω)

$$\rho\,\frac{d\Omega}{d\rho}\to 0,\ \text{ as }\ \rho\to 0.$$

Hence from the first of the Ω equations we see that Ω has a well defined limit as $\rho\to 0$, in fact

$$\lim_{\rho\to 0}\,\Omega(\rho)=-f(0).$$

An immediate consequence is that if $f(0)\neq 0$ then a is unbounded as $\rho\to 0$.

Now from (10) we have $Q\geqslant Q(0)e^{-\rho}$, so that $f(\rho)-f(0)\geqslant(df/d\rho)(0)(1-e^{-\rho})$—recall $df/d\rho=\epsilon q=Q$. Given the earlier result we may $f(0)=0$ otherwise a is unbounded. We can now integrate our $da/d\rho$ equation with this bound for f,

$$\epsilon(a(\rho)-a(\rho_1))\leqslant-\frac{df}{d\rho}\,(0)\left[\frac{(1-e^{-\rho})}{\rho}-\frac{(1-e^{-\rho_1})}{\rho_1}\right]-\frac{df}{d\rho}\,(0)\int_{\sigma=\rho}^{\rho_1}\frac{e^{-\sigma}}{\sigma}\,d\sigma.$$

As $\rho\to 0$ the integral on the right side of the inequality diverges to $+\infty$.

Lemma 2: Suppose (χ,a,f,Q) is a solution of (10) on $\infty>\rho>0$, then under C1 the function χ is C^1 with $d\chi/d\rho$ bounded on intervals $\rho\geqslant\rho_1>0$. If $f(0)\neq 0$ then χ is unbounded as $\rho\to 0$.

Proof: The regularity of χ—on its presumed interval of existence—is established using standard theory (see, for example, Ref. 10 or 11) after first noting that the right side of

$$\frac{d\chi}{d\rho}=a-\cos\,\chi$$

is C^2 in ρ (treating a as a known function and using lemma 1) and C^∞ in χ.

From the above equation we also have

$$\epsilon a-1\leqslant\epsilon\,\frac{d\chi}{d\rho}\leqslant\epsilon a+1,$$

which gives the required bounds (using lemma 1). Working on $(0,\rho_1)$ we have (as in the proof of lemma 1)

$$C_0+\frac{f(0)}{\rho}\leqslant\epsilon\,\frac{d\chi}{d\rho}\leqslant C_1+\frac{f(\rho_1)}{\rho},$$

where $C_0=\epsilon a(\rho_1)-1-f(0)/\rho_1$ and $C_1=\epsilon a(\rho_1)+1-f(\rho_1)/\rho_1$.

Integrating,

$$C_2-C_1(\rho_1-\rho)+f(\rho_1)\ln(\rho)\leqslant\epsilon\chi\leqslant C_3-C_0(\rho_1-\rho)+f(0)\ln(\rho),$$

with $C_2=\epsilon\chi(\rho_1)-f(\rho_1)\ln(\rho_1)$ and $C_3=\epsilon\chi(\rho_1)-f(0)\ln(\rho_1)$. If $f(0)<0$ choose ρ_1 near 0 so that $f(\rho_1)<0$ and we have from our last inequality that $\epsilon\chi\to\infty$ as $\rho\to 0$. If $f(0)>0$ our inequality yields $\epsilon\chi\to-\infty$ as $\rho\to 0$.

There is one other condition which makes sense ''physically'': if we have an isolated system we expect the charge density should go to zero at infinity.

$$\left[\frac{df}{d\rho}=Q\to 0, \text{ as } \rho\to\infty. \tag{C2}\right.$$

Lemma 3: Suppose (χ,a,f,Q) is a solution of (10) on $\rho>0$ under conditions C1 and C2. Then $-1\leqslant a_\infty\leqslant 1$ where $a\to a_\infty$ as $\rho\to\infty$.

Proof: We first establish that a has a well defined limit, written as a_∞, as $\rho\to\infty$; for $\rho_2>\rho_1>0$, we have

$$|a(\rho_2)-a(\rho_1)|=\left|\int_{\rho_1}^{\rho_2}\frac{f(\sigma)d\sigma}{\sigma^2}\right|<M_2\left(\frac{1}{\rho_1}-\frac{1}{\rho_2}\right), \text{ where } M_2=\sup_{\mathbb{R}^+}|f|.$$

Letting ρ_1 and ρ_2 approach ∞, we conclude that the limit $a\to a_\infty$ exists.

From the first and second equations of (10) we have

$$\frac{d}{d\rho}\ln|a-\cos\chi|=\left(\frac{da}{d\rho}+\sin\chi\,\frac{d\chi}{d\rho}\right)\Big/(a-\cos\chi)=\sin\chi-\frac{f}{\rho^2(a-\cos\chi)}.$$

Consequently, on $\rho\geqslant\rho_1>0$, integrating the last equation of (10) we have

$$-\ln[Q/Q(\rho_1)]=\int_{\rho_1}^{\rho}\sin\chi(\sigma)d\sigma=\ln\left|\frac{a-\cos\chi}{a(\rho_1)-\cos\chi(\rho_1)}\right|+\int_{\rho_1}^{\rho}\frac{f(\sigma)d\sigma}{[\sigma^2(a(\sigma)-\cos\chi(\sigma))]}.$$

Now assume $a_\infty>1$. In fact, this also takes care of the case $a_\infty<-1$, since under the discrete conjugation symmetry, (9), $a\to -a$ and in particular $a_\infty\to -a_\infty$. Working on $\rho\geqslant\rho_1>0$ we have, for ρ_1 large enough,

$$a(\rho)>1+\alpha_0>0, \text{ for } \rho\geqslant\rho_1 \text{ and some constant } \alpha_0.$$

Then, as $a-1\leqslant(d\chi/d\rho)\leqslant a+1$, so

$$0<\alpha_0<\frac{d\chi}{d\rho}<M, \text{ where } M \text{ is a finite constant—see lemma 1,}$$

$$\text{i.e., } \quad \alpha_0<a-\cos\chi<M.$$

Clearly both terms on the right side of our equation for $-\ln[Q/Q(\rho_1)]$ are bounded. This contradicts our assumption C2 that $Q\to 0$ as $\rho\to\infty$.

The constant a_∞ can be removed from the potential via a gauge transformation. Under $\psi\to e^{-ima_\infty t}\psi$, we have $a\to a-a_\infty$. After this transformation the Dirac field ψ has time dependence e^{-iEt}, where $-m\leqslant E=\alpha_\infty m\leqslant m$.

The three lemmas give a basic characterization of the solutions obeying C1 and C2. If $f(0)\neq 0$ or $Q(0)>0$ then a diverges at the origin, these are solutions which can be pictured as a Dirac field surrounding a central charged monopole—the numerical solution of Sec. 4 is of this type. There is also the possibility of solutions with a and R (recall: $Q=\sqrt{2}(e^2/m)r^2R$) everywhere bounded, such solutions were suggested by the work of Wakano,[12] who examined numerical solutions for what could be called ''half linearized'' Dirac Maxwell equations—''half linearized'': if the elec-

trostatic potential is ''dominant'' ignore the Maxwell equation involving the electromagnetic vector potential and vice versa. In fact, as the following theorem demonstrates, no such solutions exist.

Theorem: *There does not exist a non-trivial solution of (10) on $\rho\geqslant 0$ under conditions C1 and C2 with a and $P=Q/\rho^2$ bounded on $\rho\geqslant 0$.*

Proof: From lemma 1 we have, $f(0)=Q(0)=0$. Next we establish that both χ and a have well defined limits as $\rho\to 0$. Note that $d\chi/d\rho=a+1-\cos\chi$ is bounded, under the hypothesis of the theorem, as $\rho\to 0$; hence, by an argument of the sort used previously, $\chi\to\chi(0)=\chi_0$, say, as $\rho\to 0$. We also have

$$f=\int_{\sigma=0}^{\rho} Q(\sigma)d\sigma=\int_{\sigma=0}^{\rho}\sigma^2 P(\sigma)d\sigma\geqslant 0.$$

Using the mean value theorem we have, for some $\rho_1,\rho>\rho_1>0$

$$f(\rho)=\rho\rho_1^2 P(\rho_1)<\rho^3 M_3,\quad \text{where}\quad M_3=\sup_{\mathbb{R}^+} P<\infty.$$

Thus

$$|a(\rho_2)-a(\rho_1)|=\left|\int_{\rho_1}^{\rho_2}\frac{f(\rho)d\rho}{\rho^2}\right|<\int_{\rho_1}^{\rho_2}\rho M_3 d\rho=\frac{1}{2}M_3(\rho_2^2-\rho_1^2).$$

Letting $\rho_1,\rho_2\to 0$ establishes the existence of the limit for a, we write

$$\lim_{\rho\to 0} a=a_0.$$

Now we use an argument similar to that used in the proof of lemma 3 to show that $d\chi/d\rho=a-\cos\chi\to 0$, as $\rho\to 0$. On $(0,\rho_1)$ we have

$$(*)-\ln[Q(\rho_1)/Q(\rho)]=\ln\left|\frac{a(\rho_1)-\cos\chi(\rho_1)}{a-\cos\chi}\right|+\int_{\sigma=\rho}^{\rho_1}\frac{f(\sigma)d\sigma}{\sigma^2[a(\sigma)-\cos\chi(\sigma)]}.$$

Assume, $(d\chi/d\rho)(0)=a_0-\cos\chi_0\neq 0$. Then, choosing ρ_1 near 0 so that $(d\chi/d\rho)(\rho)(d\chi/d\rho)(0)>0$, for $\rho_1>\rho>0$, we have

$$\left|\int_{\rho}^{\rho_1}\frac{f(\sigma)d\sigma}{\sigma^2[a(\sigma)-\cos\chi(\sigma)]}\right|<M_3\int_{\rho}^{\rho_1}\frac{\sigma d\sigma}{\left|\frac{d\chi}{d\rho}(\sigma)\right|}.$$

The right side of this inequality is bounded as $\rho\to 0$. Consequently, the right side of $(*)$ is bounded as $\rho\to 0$. But this contradicts the assumption of the theorem that $Q=\rho^2 P\to 0$ as $\rho\to 0$. Thus

$$\frac{d\chi}{d\rho}(0)=a_0-\cos\chi_0=0,\quad\text{or}\quad a_0=\cos\chi_0.$$

We now assume $\epsilon=+1$, the case $\epsilon=-1$ can (of course!) be obtained by conjugation. As $da/d\rho=f/\rho^2<0$ on $\rho>0$, so

$$a_0=\cos\chi_0<a<a_\infty\leqslant 1$$

on $\rho>0$.

Define new variables

$$U=\sqrt{Q}\,\cos(\chi/2),\quad\text{and}\quad V=\sqrt{Q}\,\sin(\chi/2).$$

We have

$$\frac{dU}{d\rho}=-\frac{1}{2}(a+1)V,\quad\text{and}\quad\frac{dV}{d\rho}=\frac{1}{2}(a-1)U.$$

The pair U and V also satisfy the following linear, second order equations

$$\frac{d^2U}{d\rho^2}-\frac{f}{\rho^2(a+1)}\frac{dU}{d\rho}+\frac{1}{4}(a^2-1)U=0,$$

and (11)

$$\frac{d^2V}{d\rho^2}-\frac{f}{\rho^2(a-1)}\frac{dV}{d\rho}+\frac{1}{4}(a^2-1)V=0.$$

We note that $f/\rho^2(a+1)$ is bounded on intervals $[0,\rho_2]$, with $0\leqslant\rho_2<\infty$ and that $f/\rho^2(a-1)$ is bounded on $(0,\infty]$—in the first case we may have $a_\infty=-2$, whereas we may have $a_0=0$ in the second; we also have

$$\tfrac{1}{4}(a^2-1)\leqslant 0,\quad\text{on}\quad\rho\geqslant 0.$$

From the definitions of U and V we have $U,V\to 0$ as $\rho\to 0$ or ∞. Thus, by the maximum principle for odes (see Ref. 13), we conclude $U\equiv V\equiv 0$, so $Q\equiv 0$. There do not exist non-trivial solutions.

V. NUMERICAL SOLUTIONS

Numerical solutions to the system (10), with $\epsilon=1$, were sought by first expanding in a power series from either $s=0$ ($\rho=\infty$, with $s=1/\rho$) or $\rho=0$ and then evolving the system in s or ρ, respectively, using a MATLAB interface to the NAG library.[14]

A. Solutions near $\rho=0$

In lemma 1 we found that $\Omega=\rho a$ was bounded, near $\rho=0$, with

$$\lim_{\rho\to 0}\Omega(\rho)=f(0)$$

It is natural then to seek solutions of the form $a=\Omega(\rho)/\rho$, near $\rho=0$, with Ω analytic in ρ. From (10) it can be seen that both f and Q must be analytic, with $Q(0)=0$.

However, with Q analytic and $Q(0)=0$, the last equation of (10) can only be satisfied with $Q\equiv 0$–which implies $a=c_0+c_1/\rho$, we will refer to such solutions as trivial. The behavior of the system near $\rho=0$ may be quite complex; from the proof of the theorem (see Eqs. (11)), with $a=\Omega/\rho$, we see that near $\rho=0$ the second order equations for U and V have indicial equation (see Ref. 15)

$$\lambda^2+\tfrac{1}{4}\Omega(0)^2=0.$$

This implies that U and V have behavior

$$U\ \text{ or }\ V\sim\omega_1(\rho)\cos\left(\frac{\Omega(0)}{2}\ln\rho\right)+\omega_2(\rho)\sin\left(\frac{\Omega(0)}{2}\ln\rho\right),\ \text{ near }\ \rho=0.$$

B. Solutions near $\rho=\infty$

Near $\rho=\infty$ we expect $a\sim a_\infty+c_1/\rho+c_2/\rho^2+\cdots$. Assuming a is analytic in $s=1/\rho$, near $s=0$, then implies that f, Q and $\sin\chi$ are also analytic in s, in fact

$$f=\frac{da}{ds},\quad Q=s^2\frac{d^2a}{ds^2},\quad \text{and}\quad \sin\chi=2s+s^2\left(\frac{d^3a/ds^3}{d^2a/ds^2}\right).$$

With the assumption that χ is analytic near $s=0$ a uniquely defined (up to conjugacy) power series results if we demand that the solution be non-trivial (χ does have the freedom to add integer multiples of 2π).

The resulting power series has no free parameters, it is uniquely determined. The lower order portion of the power series solution is as follows

$$\chi=\pi-2s-\frac{1}{21}s^3-\frac{3}{520}s^5+O(s^7),$$

$$a=-1+4s^2-\frac{3}{7}s^4+\frac{341}{5096}s^6+O(s^7),$$

$$f=-8s+\frac{12}{7}s^3-\frac{1023}{2548}s^5+O(s^7),$$

$$Q=8s^2-\frac{36}{7}s^4+\frac{5115}{2548}s^6+O(s^7).$$

Using the power series to determine initial conditions it was found that the numerical results were very stable for a good range of initial values for s ($s_0=0.000001$ to $s_0=0.01$), the results were somewhat unstable for $s_0<0.0000001$. The results presented in figures 1 to 4 were obtained by first shooting from near $s=0$ towards $\rho=0$ and then using the final values of this run as initial conditions to shoot from near $\rho=0$ towards $s=0$, to verify the solution. We also note, from the above power series, that $a_\infty=-1$. So in the gauge for which $a\to 0$ as $\rho\to\infty$ the Dirac field has time dependence e^{imt}.

In Figs. 1–4 χ, $a-a_\infty=a+1$, $f(r)-f(0)$ (proportional to the ''electron'' charge interior to a ball radius r) and Q are plotted against the radial distance measured in units of the Compton wavelength (i.e. against $\frac{1}{2}\rho=mr$).

Interpretation: The solution represented in Figs. 1–4 can be thought of as a central, charged monopole (point source), surrounded by an oppositely charged Dirac field-near ∞ the electrostatic potential behaves as $A^0=(m/e)a\sim -m/e+[1/(me)/r^2]$ and near $r=0$ the potential behaves as $A^0\sim -m/e+[(\gamma/e)r]$ (where $\gamma\approx 5.7037$ is the magnitude of the slope of the line in Fig. 5, where $a+1$ is plotted against $1/(mr)$).

At about one half the Compton wavelength from the center there is a shielding effect and the Coulomb nature of the central charge becomes apparent. [We assume that the constants appearing in the Dirac equation, i.e., e and m have there usual meaning—e the square root of the fine structure constant and m the inverse of the (reduced) Compton wavelength.]At large distances from the center the electrostatic charges ''cancel'' each other. We can calculate the magnitude of the total charge due to the Dirac field (see Sec. III A 3.1), with $f(0)$ calculated numerically ($f(\infty)=0$, in this case),

$$e\int_{\mathbb{R}^3}j^\alpha dS_\alpha=\frac{1}{2e}\,(f(\infty)-f(0))\approx\frac{1}{2e}\,11.407391.$$

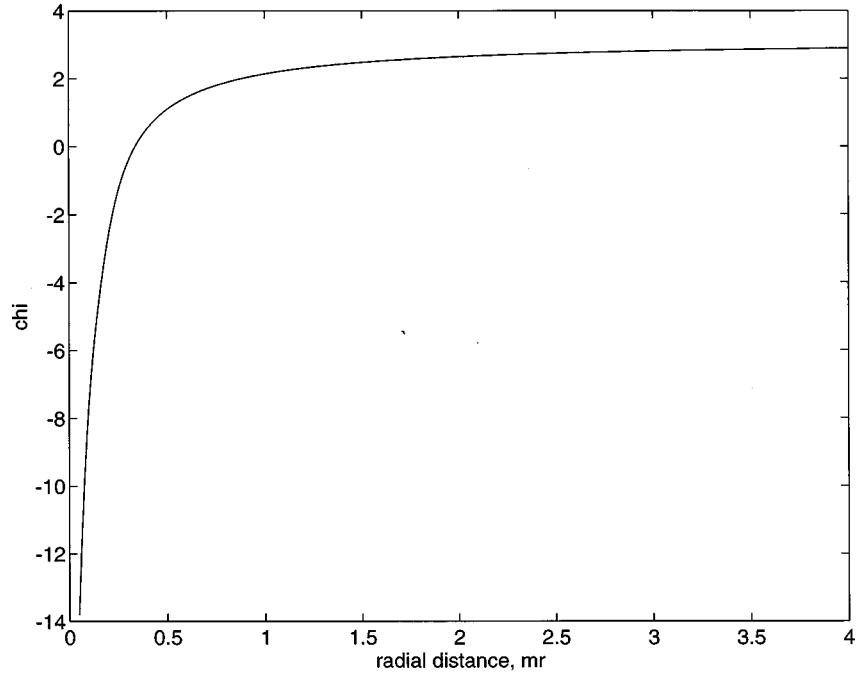

FIG. 1. The angular variable, χ.

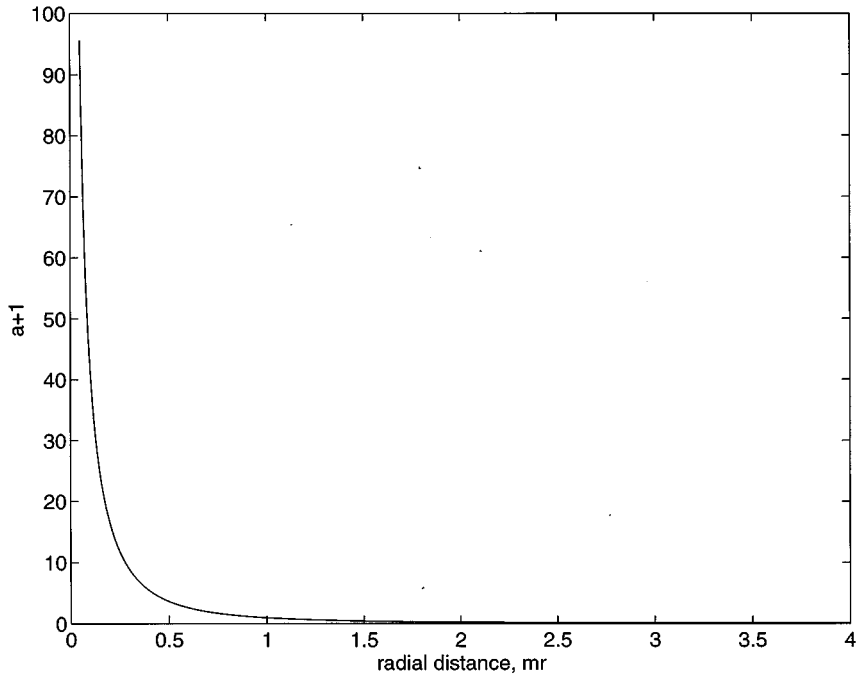

FIG. 2. The potential, $a+1$.

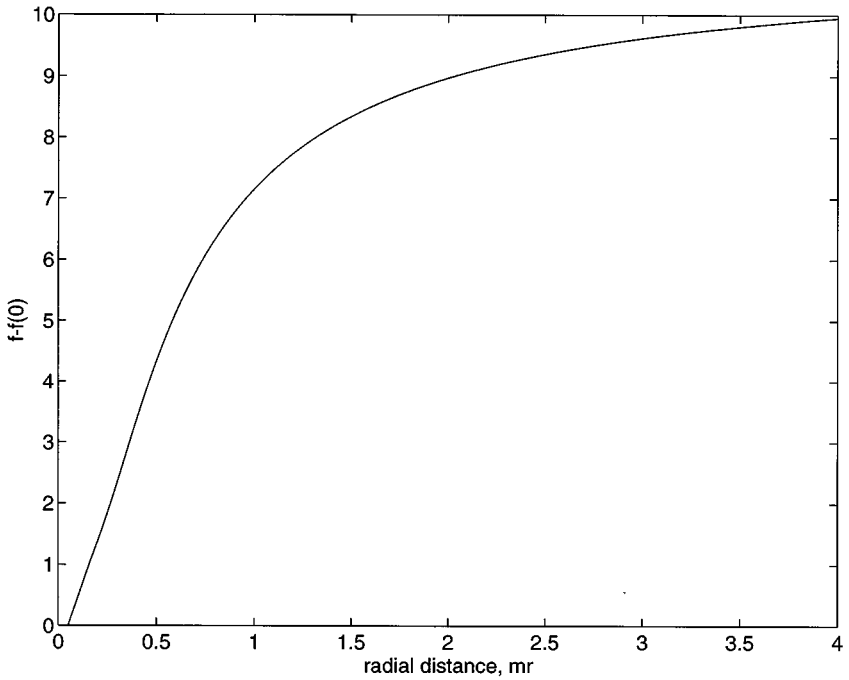

FIG. 3. The ''charge'' interior to $B(r)$, $f-f(0)$.

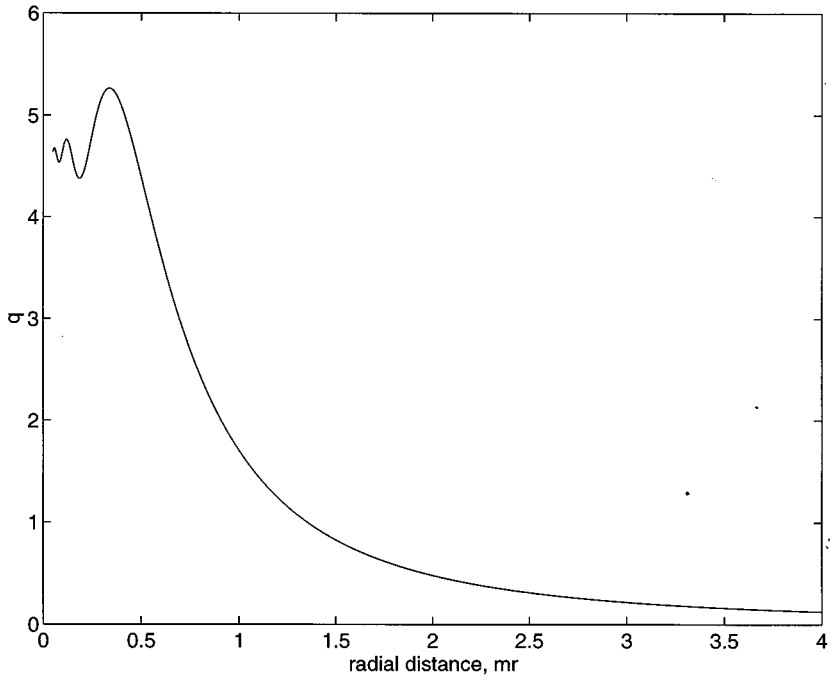

FIG. 4. The ''charge'' on a shell, radius mr, q.

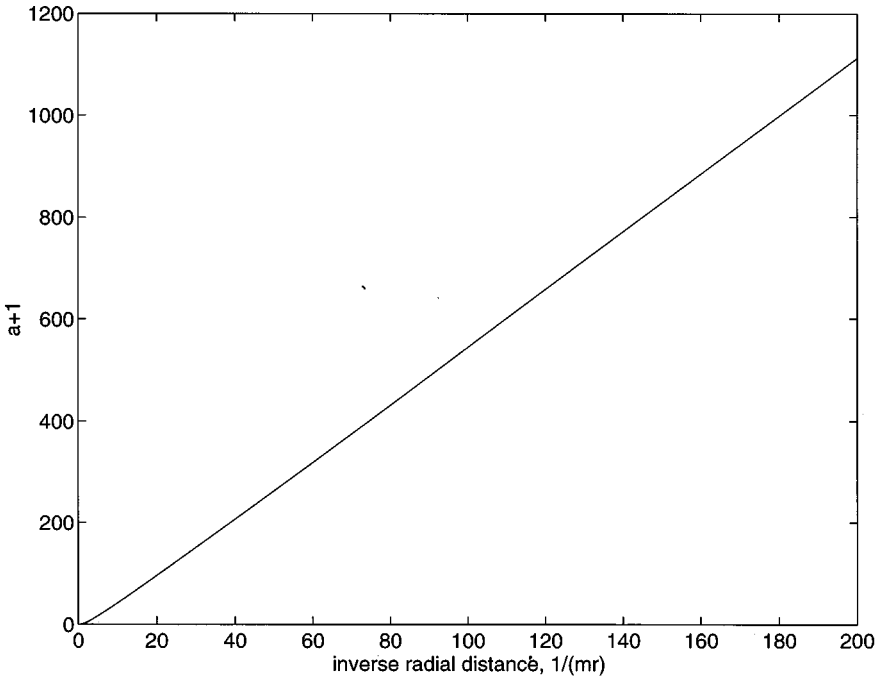

FIG. 5. The potential, a, from infinity.

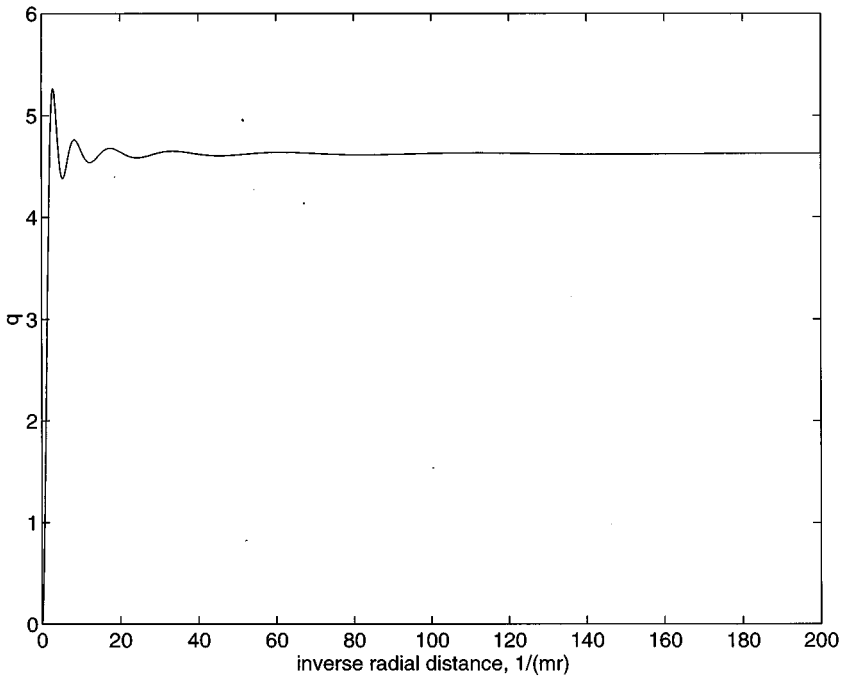

FIG. 6. The shell ''charge,'' q, from infinity.

This calculation results in a charge of the same magnitude as the central charge.

The object is highly compact, with a radius of about a (reduced) Compton wavelength—see Figs. 4 and 6. It has an onion like structure consisting of an infinite series of spherical shells—the local maxima of Q occur at points, $\rho=\rho_m$, where $\sin(\chi(\rho_m))=0$, however from lemma 2 we see that χ must diverge as $\rho\to 0$ (in the present case) so there will be an infinite number of shells.

The ''mass'' of the Dirac field may be defined as

$$m\int_{\mathbb{R}^3} j^\alpha dS_\alpha=\frac{m}{2e^2}\,(f(\infty)-f(0))\approx 11.407391\,\frac{m}{2e^2}.$$

To finish we calculate the energy-momentum of the system. The symmetric energy-momentum tensor is

$$T_{\alpha\beta}=T^D_{\alpha\beta}+T^{em}_{\alpha\beta},\quad \text{with}$$

$$T^D_{\alpha\beta}=\frac{i}{4}\,[\sigma_\alpha^{A\dot A}(\overline{u_{\dot A}}u_{A,\beta}+v_A\overline{v_{\dot A,\beta}})+\sigma_\beta^{A\dot A}(\overline{u_{\dot A}}u_{A,\alpha}+v_A\overline{v_{\dot A,\alpha}})$$

$$-\sigma_\alpha^{A\dot A}(u_A\overline{u_{\dot A,\beta}}+\overline{v_{\dot A}}v_{A,\beta})-\sigma_\beta^{A\dot A}(u_A\overline{u_{\dot A,\alpha}}+\overline{v_{\dot A}}v_{A,\alpha})]+eA_{(\alpha j\beta)},$$

$$T^{em}_{\alpha\beta}=-\frac{1}{4\pi}\left(F_{\alpha\gamma}F^\gamma_\beta-\frac{1}{4}\,\eta_{\alpha\beta}F_{\mu\nu}F^{\mu\nu}\right).$$

These expressions are derived from the Lagrangian

$$L=\frac{i}{2}\,(\overline{u_{\dot A}}\partial^{A\dot A}u_A-u_A\partial^{A\dot A}\overline{u_{\dot A}}-\overline{v_{\dot A}}\partial^{A\dot A}v_A+v_A\partial^{A\dot A}\overline{v_{\dot A}})-\frac{m}{\sqrt{2}}\,(u_Av^A+\overline{u_{\dot A}}\dot{\bar v}^{\dot A})+ej_\alpha A^\alpha-\frac{1}{16\pi}\,F_{\alpha\beta}F^{\alpha\beta}.$$

Notice that in the absence of the electromagnetic field, for a Dirac field with time dependence e^{-iEt}, the energy density T^D_{00} is

$$T^D_{00}=Ej_0.$$

In the present case we have

$$T^D_{00}=j_0eA_0=\frac{m^2}{e^2}\,\frac{Qa}{4\pi r^2},\qquad T^{em}_{00}=\frac{m^2}{2e^2}\left[\rho^2\left(\frac{da}{d\rho}\right)^2+\frac{1}{\rho^2}\right]\left(\frac{1}{4\pi r^2}\right).$$

These expressions include terms due to the central Coloumb and magnetic monopole fields, they lead to an infinite total energy when integrated over $\mathbb{R}^3$. Formally then, the total energy is

$$E=\frac{m}{4e^2}\int_0^\infty\left[\frac{f^2}{\rho^2}+\frac{1}{\rho^2}+2Qa\right]d\rho.$$

Finally, it is perhaps worth mentioning that the highly localized ''multi-electron fields'' described here may in fact have applications to objects described in recent experimental work[16]-''geonium'' or ''kilo-e'' objects-consisting of highly localized (point like, from the experimental viewpoint) collections of electrons in atomic traps.

A manifestly reciprocal theory of scattering in the presence of elastic media

Daniel Wurmser
Naval Research Laboratory, Washington, DC 20375-5350

(Received 27 February 1996; accepted for publication 8 May 1996)

The role of elastic waves in the scattering problem is examined in the context of modern field theory. This effort builds upon a previously published, and since successfully applied formalism for solving the acoustic and electromagnetic scattering problems. It specifically addresses the scattering of acoustic waves from a fluid-solid interface, as well as the scattering of elastodynamic waves from surfaces satisfying the zero-displacement, stress-free, and solid–solid boundary conditions. Expressions for the change in the scattering amplitude due to a perturbation in the scattering surface are derived directly from the requirement of time reversal symmetry (also known as reciprocity). These results constitute formal statements of the composite (or two-scale) model. In a typical application, the perturbation usually corresponds to Bragg scattering and is treated statistically, while the reference surface provides tilt, shadowing, and multiple scattering, and is usually treated deterministically. Used in this way, the new formalism effectively allows existing numerical and operator expansion methods to be used to calculate the scattering from rougher and/or higher dimensional surfaces than would otherwise be possible. An alternate application of the formalism is illustrated using the fluid-solid boundary as an example. A new manifestly reciprocal expression for the scattering amplitude is presented, as are the small slope and ''local'' two-scale approximations for this problem. (By local, it is meant that only local phenomena such as the tilt of the reference surface are automatically included. However, since the result is manifestly reciprocal, it is fairly straightforward to incorporate a non-local effect such as shadowing.) During the course of the discussion, the classical scattering problem is reexamined from an entirely new perspective. [S0022-2488(96)02009-9]

I. INTRODUCTION

A new approach for calculating the far-field scattering of acoustic and electromagnetic waves from rough surfaces has recently been developed[1–5]. The formalism is constructed around the property of time-reversal symmetry (also known as reciprocity). Well-known proofs for the reciprocity of acoustic and electromagnetic scattering in a time-independent environment were modified to produce formal statements of the composite-roughness (i.e., two-scale) model. These consist of approximate expressions for the change in the scattering amplitude corresponding to a small perturbation of a reference surface. The expressions are good to first order in the perturbation, but exact with respect to the reference surface. By construction, they manifestly exhibit reciprocity. Two basic strategies have been used to develop practically useful applications of this fundamental formal result.

On the one hand, the formal statement of the composite-roughness model can be used directly to generate an entirely new approach for calculating the field scattered from a rough surface. Let the unperturbed reference surface include those features of the scattering surface which are large compared to the wavelength of the field, and let the perturbation contain all the smaller features. Since the result is *exact* with respect to the large features, non-local effects such as shadowing, multiple scattering, and diffraction can be calculated using high-order perturbation theory,[1] or

non-perturbative numerical or analytic techniques.[6] Bragg scattering is associated with the small surface features, and it is calculated using perturbation theory, and typically treated stochastically. Note that non-perturbative techniques are usually considered to be inappropriate for use with very rough scattering surfaces, but in the two-scale context provided by the new formalism, these restrictions are effectively circumvented. Direct application of the new composite model also leads to another related line of development. If only local effects are of interest, the formal statements of the composite model can be used to generate entirely new expansions of the scattering amplitude good to second order in the ratio of the acoustic wavelength to the radius of curvature of the scattering surface, and, most significantly, also good to much higher orders in the slope.[3] (The distinctive feature of these results is the presence of an arctangent in the integrand.)

Following the alternate basic strategy, the formal statement of the composite model is used to generate a second fundamental result. The expressions for the *change* in the scattering amplitude, when applied to an infinitesimal translation, become generating functions for new representations of the scattering amplitude *itself*. Unlike the traditional representations of the scattering amplitude, these manifestly exhibit reciprocity. In the investigation of acoustic and electromagnetic scattering, approximation schemes such as perturbation theory, the small slope approximation, and the composite model were easily derived for a number of boundary conditions.[3] In some cases, this was the first time the results had been derived anywhere.

The utility of the manifestly reciprocal representations of the scattering amplitude is not restricted to the problem of scattering from rough surfaces alone. The formalism has also led to breakthroughs in the study of scattering from finite objects. When applied to planar objects, it provides an exact formula for the scattering amplitude in terms of a line integral around the edge of the scatterer. Useful approximations can be obtained by approximating the integrand with solutions to the local half-plane problem. These insights have recently been used by Dashen, Abawi, and Wandzura[7,8] to examine the scattering from planar objects, edges, and corners.

In this paper the formalism will be extended to include elastic solids. The formal statement of the composite model and the manifestly reciprocal representation of the scattering amplitude will be derived for scattering from a fluid–solid interface as well as for the interface between two elastic solids. In addition, the manifestly reciprocal expression for the scattering amplitude will be used to generate new composite model and small slope approximations for the case of the fluid–solid interface.

The limiting properties of these results will be considered. It will be shown that, in the limit as the shear waves disappear (i.e., as the shear velocity approaches zero), the results for scattering from a fluid–solid interface approach previously derived results for the fluid–fluid interface (see Ref. 3).

The formal mathematical results to be presented in this paper are applicable to several physical problems. A typical application of the results for scattering from a fluid–solid interface would be acoustic scattering from some parts of the ocean bottom. This would include areas where there is a solid rock layer either directly underwater, or submerged beneath a muddy bottom that acoustically behaves like a liquid. The solid–solid results may find application in the study of seismic waves, specifically where the scattering between layers of the Earth's crust is involved. These results may also find application in the field of non-destructive testing, where scattering from the interface between different materials would be described by the solid–solid scattering formalism.

II. A FORMAL STATEMENT OF THE COMPOSITE ROUGHNESS MODEL

A. The general procedure

The derivations in this paper parallel the procedure developed in Refs. 2 and 3. For additional insight into the notation, the strategy employed, and the underlying physical assumptions, the reader is referred to those references. Elements of the notation for elastodynamic wave scattering developed in Ref. 9 (pp. 46–50) and Refs. 10–12 will also be used below.

A small displacement of the material in an elastic solid is given by the vector $\vec{u}$ while the components of the stress tensor are defined to be

$$\tau_{ij} \equiv \lambda(\vec{\nabla}\cdot\vec{u})\,\delta_{ij} + \mu(\nabla_i u_j + \nabla_j u_i), \tag{2.1}$$

where λ and μ are the Lamé constants, physical parameters characteristic of the solid. In dyadic notation, this is written as

$$\overleftrightarrow{\tau} \equiv \lambda \overleftrightarrow{\mathbf{1}}(\vec{\nabla}\cdot\vec{u}) + \mu(\vec{\nabla}\vec{u} + \vec{u}\vec{\nabla}_{\hookleftarrow}), \tag{2.2}$$

(where the subscript ''$\hookleftarrow$'' indicates that the differential operator operates to the left). The environment is assumed to be time-independent. Then, considering each frequency ω independently, wave propagation is given by the equation

$$\vec{\nabla}\cdot\overleftrightarrow{\tau} = -\rho\omega^2\vec{u}, \tag{2.3}$$

where ρ is the density of the solid.

Reciprocity is proven using the elastodynamic equivalent of what is called Lorentz's Lemma in electromagnetic theory. This procedure is outlined in Ref. 12 (pp. 155–156). Recall that Lorentz's Lemma states that, for any two independent fields labeled 1 and 2 which satisfy the time-independent problem at a given fixed frequency ω, the vector

$$\vec{E}_1 \times \vec{H}_2 - \vec{E}_2 \times \vec{H}_1$$

must be a divergence-free vector. This follows from Maxwell's equations in the absence of free charges. The analogous divergence-free vector for elastodynamic waves is

$$\overleftrightarrow{\tau}_1\cdot\vec{u}_2 - \overleftrightarrow{\tau}_2\cdot\vec{u}_1.$$

This follows immediately from the equation of motion (2.3) and the equality

$$\overleftrightarrow{\tau}_1 : \vec{\nabla}\vec{u}_2 = \overleftrightarrow{\tau}_2 : \vec{\nabla}\vec{u}_1,$$

which in turn follows directly from the definition of the stress tensor (2.1). (Note that '':'' is the double dot product defined by $A:B \equiv A_{ij}B_{ji}$, where repeated indices are summed.) It follows that for any closed surface with normal $\hat{n}$ (we follow the convention that $\hat{n}$ points into the region bounded by S),

$$\int_S dS\hat{n}\cdot[\overleftrightarrow{\tau}_1\cdot\vec{u}_2 - \overleftrightarrow{\tau}_2\cdot\vec{u}_1] = 0. \tag{2.4}$$

Reciprocity follows from this equality as follows.

- S is chosen to be the sum of the scattering surface S_0 and the sphere at infinity S_∞ (or the hemisphere at infinity for a plane scatterer).
- The two solutions correspond to incoming plane waves labeled by the directions $\hat{k}_1$ and $\hat{k}_2$, respectively.
- $\hat{k}_2$ is identified with the negative of the normalized position vector of the observer (i.e., $\hat{k}_2 = -\hat{r}$). The solution labeled by ''2'' is then called the reciprocal solution. $\hat{r}$ is sometimes referred to below as the outgoing direction.

Evaluation of equation (2.4) shows that the scattering amplitude remains unchanged under the exchange $\hat{k}_1 \to \hat{k}_2$; $\hat{k}_2 \to \hat{k}_1$ (this step takes some effort; see Ref. 12). To put it another way, in the asymptotic limit, the magnitude and phase of the scattered wave are unchanged by reversing the

incoming and outgoing directions, and exchanging their roles. This is the reciprocity theorem. There are some minor complications related to the tensor nature of elastodynamic waves, but these will be addressed below as they become directly relevant to the discussion.

Following the technique outlined in Ref. 2, the new formalism emerges when the two solutions are chosen so that they correspond to not only to different incoming directions, *but also to scattering from different scattering surfaces*—the solution labeled by ''2'' scatters from a reference surface S_2 and the solution labeled by ''1'' scatters from a perturbed surface S_1. In equation (2.4), choose S to be S_2+S_∞ and define R_∞ to be the negative of the contribution from S_∞, the sphere (or hemisphere) at infinity (unless S_2 is a closed surface and the integrand is evaluated using the field *inside* S_2; then $S=S_2$, and just set $R_\infty=0$). We have

$$R_\infty=\int_{S_2} dS_2[\hat{n}_2\cdot\vec{\tau}_1(\vec{x_2})\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\tau}_2(\vec{x_2})\cdot\vec{u}_1(\vec{x_2})]. \tag{2.5}$$

Consider the following mapping from S_2 to S_1. At the point $\vec{x_2}$ draw a normal to S_2 and follow it until intersects S_1 at point $\vec{x_1}$. The normal distance ξ from $\vec{x_1}$ to $\vec{x_2}$ is positive if $\vec{x_1}$ lies within the scattering region for S_2 and negative if the opposite is true. (This geometry is sketched in Figure 1 of Ref. 2.) It is implicitly assumed that the perturbation is small enough with respect to the radius of curvature of the reference surface (i.e., the reference surface is smooth) that the transformation is single-valued, and that the solution can be analytically continued beyond the scattering surface (see Refs. 2 and 13 for a further discussion of this topic). We now calculate (2.5) to first order. The details are given in Appendix A.

Here

$$\begin{aligned}
R_\infty=&\int_{S_2} dS_2[\hat{n}_1\cdot\vec{\tau}_1(\vec{x_1})\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\tau}_2(\vec{x_2})\cdot\vec{u}_1(\vec{x_1})]-\int dS\xi\,\mathrm{Tr}(\vec{\varrho})\hat{n}\cdot\vec{\tau}_1\cdot\vec{u}_2\\
&+\int dS\xi[\hat{n}\cdot\vec{\tau}_2\cdot\vec{\varrho}\cdot\vec{u}_1+\hat{n}\cdot\vec{\tau}_1\cdot\vec{\varrho}\cdot\vec{u}_2]\\
&-\int dS\xi[\hat{n}\cdot\vec{\tau}_2\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\vec{u}_1\cdot\hat{n})+\hat{n}\cdot\vec{\tau}_1\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\vec{u}_2\cdot\hat{n})]-\int dS\xi[\vec{\nabla}\cdot(\vec{\tau}_1\cdot\vec{u}_2)]\\
&+\int dS\xi[\hat{n}\cdot\vec{\tau}_2\cdot\hat{n}[\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1]+\hat{n}\cdot\vec{\tau}_1\cdot\hat{n}[\hat{n}\hat{n}:\vec{\nabla}\vec{u}_2]]\\
&+2\int dS\xi\left[\frac{\hat{n}\cdot\vec{\tau}_2\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\tau}_1\cdot\hat{n}}{\mu}\right]+O(\xi^2).
\end{aligned} \tag{2.6}$$

The dyadic $\vec{\varrho}$ is the curvature tensor, and it is a geometrical characteristic of the scattering surface defined by equation (A9). (It should not be confused with the scalar ρ, which is the density of the material.) Equation (2.6) is an intermediate result. It is best thought of as a mathematical identity, presented here as a lemma, which underlies the results that will be presented later in this paper. Subsequent to equation (2.6), the calculations for scattering from a fluid–solid interface and a solid–solid interface part ways.

In what follows, $\vec{\nabla}\cdot(\vec{\tau}_1\cdot\vec{u}_2)$ will generally be rewritten as

$$\vec{\nabla}\cdot(\vec{\tau}_1\cdot\vec{u}_2)=(\vec{\nabla}\cdot\vec{\tau}_1)\cdot\vec{u}_2+\vec{\tau}_1:\vec{\nabla}\vec{u}_2=-\rho\omega^2\vec{u}_1\cdot\vec{u}_2+\vec{\tau}_1:\vec{\nabla}\vec{u}_2.$$

On terms which are manifestly $O(\xi)$ there is no need to specify whether the field is evaluated at $\vec{x_1}$ or at $\vec{x_2}$, because the resulting effect on R_∞ is of $O(\xi^2)$. It also does not matter whether the solutions correspond to scattering from the reference surface or from the perturbed surface, since

here too the difference contributes at $O(\xi^2)$. The labels ''1'' and ''2'' in this case only refer to properties of the incident fields such as the direction of the wavevector and sometimes, as we will see below, whether the incoming wave is longitudinal or transverse and specifying the incoming polarization for the latter case.

Because of its general nature, equation (2.6) and its components do not easily lend themselves to straightforward physical interpretation. However, there are some things we can say, even at this early stage of the calculation. In what follows, as was done in the reciprocity proof outlined earlier, the direction of the incident wavevector labeled by ''2'' will always be interpreted as being the negative of the direction of the observer in the original problem; thus, the solution labeled ''2'' almost corresponds to the reciprocal problem (''almost'' because it scatters from the reference surface, but we are just a step or two away from eliminating the only terms where the distinction still matters). Then, using very general arguments, it is shown in Appendix B that R_∞ is (more or less) proportional to δT, the difference between the scattering amplitude for the perturbed surface T and that for the reference surface T_0; i.e., symbolically,

$$R_\infty \propto \delta T \equiv T - T_0 .$$

(Recall that ''$\equiv$'' implies a definition.) Note that this implies that R_∞ must be at least first order in ξ, and that the first term on the right-hand side of equation (2.6), although it does not explicitly *appear* to be at least of $O(\xi)$, must reduce to an expression which is. It is also shown in Appendix B that if neither field ''1'' nor field ''2'' is incoming from a half-space, then the contribution from the hemisphere at ∞ bounding that half-space is zero (i.e., $R_\infty = 0$), even if there are transmitted waves in the half-space.

We are now in a position to recognize the power of this approach. Once the expression has been recast so that only terms manifestly proportional to ξ remain, then we have an expression for scattering from the perturbed surface, which can be evaluated using only solutions for scattering from the *un*perturbed surface. The proviso that only terms manifestly proportional to ξ remain is satisfied by invoking specific boundary conditions to evaluate the offending terms [i.e., the first line on the right hand side of (2.6)]. Four boundary conditions are of interest here (see e.g., Ref. 10, pp. 27–29):

- fixed rigid boundary: $\vec{u} = 0$ on the interface;
- free boundary: $\hat{n} \cdot \vec{\tau} = 0$ on the interface;
- boundary between two elastic solids (i.e., the solid–solid interface): $\vec{u}$ and $\hat{n} \cdot \vec{\tau}$ continuous on the interface;
- slip boundary condition (the fluid–solid interface is a special case of this condition): $\hat{n} \cdot \vec{u}$ and $\hat{n} \cdot \vec{\tau} \cdot \hat{n}$ are continuous and $\hat{n} \cdot \vec{\tau} \cdot (\vec{\mathbf{1}} - \hat{n}\hat{n}) = 0$ on the interface.

Note that the terms in equation (2.6) which are not manifestly proportional to ξ vanish automatically in the first two cases. For the solid–solid interface, subtract equation (2.6) for the region below the interface (i.e., corresponding to the half-space without an incoming plane wave, or the interior region for a finite scatterer) from the same equation evaluated for the solution above the interface (recalling that $R_\infty = 0$ in the former case, $R_\infty \propto \delta T$ in the latter case). The continuity conditions ensure that the first line on the right hand side of (2.6) cancels, and the result is an equation for δT with an integrand manifestly proportional to ξ. (Recall that δT was defined just above as the change in the scattering amplitude due to the perturbation of the surface.)

Thus, we have outlined how the first three boundary conditions may be used to eliminate the $O(\xi^{\,0})$ terms in equation (2.6). However, for the slip boundary condition, more work is needed. This will be considered in the next section, where the problem of scattering from a fluid–solid interface is considered.

B. The fluid–solid interface

The fluid–solid interface is subject to the fourth set of boundary conditions listed in the previous section, the slip boundary conditions. According to these conditions, $\hat{n}\cdot\vec{\vec{\tau}}$ and $\vec{u}$ are no longer required to be continuous along the interface. However, $\hat{n}\cdot\vec{\vec{\tau}}\cdot\hat{n}$ and $\hat{n}\cdot\vec{u}$ are continuous, and furthermore, we have $\hat{n}\cdot\vec{\vec{\tau}}=\hat{n}\cdot\vec{\vec{\tau}}\cdot\hat{n}\hat{n}$ on the surface, so that

$$R_\infty=\int_{S_2} dS_2[\hat{n}_1\cdot\vec{\vec{\tau}}_1(\vec{x_1})\cdot\hat{n}_1\hat{n}_1\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\vec{\tau}}_2(\vec{x_2})\cdot\hat{n}_2\hat{n}_2\cdot\vec{u}_1(\vec{x_1})]+O(\xi). \tag{2.7}$$

Next, use equation (A1) to match up $\vec{u}_2(\vec{x_2})$ with $\hat{n}_2$ and $\vec{u}_1(\vec{x_1})$ with $\hat{n}_1$, and then integrate by parts. The details are given in Appendix C, leading to the result

$$\begin{aligned}R_\infty=&\int_{S_2} dS_2[\hat{n}_1\cdot\vec{\vec{\tau}}_1(\vec{x_1})\cdot\hat{n}_1\hat{n}_2\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\vec{\tau}}_2(\vec{x_2})\cdot\hat{n}_2\hat{n}_1\cdot\vec{u}_1(\vec{x_1})]+\int dS\xi\,\mathrm{Tr}(\vec{\vec{\varrho}})\hat{n}\cdot\vec{u}_1\tau^2_{nn}\\&+\int dS\xi\rho\omega^2\vec{u}_1\cdot\vec{u}_2+\int dS\xi[\vec{u}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\tau^1_{nn})+\vec{u}_1\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\tau^2_{nn})]\\&-\int dS\xi\frac{\vec{\vec{\tau}}_1:\vec{\vec{\tau}}_2}{2\mu}+\int dS\xi\frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\vec{\vec{\tau}}_1)\,\mathrm{Tr}(\vec{\vec{\tau}}_2)}{3\lambda+2\mu}+\int dS\xi\left[\frac{\mathrm{Tr}(\vec{\vec{\tau}}_1)}{3\lambda+2\mu}\tau^2_{nn}+\frac{\mathrm{Tr}(\vec{\vec{\tau}}_2)}{3\lambda+2\mu}\tau^1_{nn}\right],\end{aligned} \tag{2.8}$$

where $\tau_{nn}\equiv\hat{n}\cdot\vec{\vec{\tau}}\cdot\hat{n}$. Note that the $O(\xi^0)$ terms are now continuous across the interface and may be canceled by subtraction of the equivalent equation below the surface.

Now, take the limit as the solid becomes a fluid (i.e., let $\mu\to 0$). It is shown in Appendix D that in this limit (2.8) reduces to

$$\begin{aligned}R_\infty=&\int_{S_2} dS_2[\hat{n}_1\cdot\vec{\vec{\tau}}_1(\vec{x_1})\cdot\hat{n}_1\hat{n}_2\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\vec{\tau}}_2(\vec{x_2})\cdot\hat{n}_2\hat{n}_1\cdot\vec{u}_1(\vec{x_1})]\\&+\int dS\xi\,\mathrm{Tr}(\vec{\vec{\varrho}})\hat{n}\cdot\vec{u}_1\tau^2_{nn}+\int dS\xi\rho\omega^2\hat{n}\cdot\vec{u}_1\hat{n}\cdot\vec{u}_2\\&-\int dS\xi\rho\omega^2\vec{u}_1\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{u}_2+\int dS\xi\frac{k^2}{\rho\omega^2}\tau^1_{nn}\tau^2_{nn}.\end{aligned} \tag{2.9}$$

Equations (2.8) and (2.9) will shortly be subtracted from one another to produce an expression for the change in the scattering amplitude δT corresponding to the perturbation of a fluid–solid interface. However, we first briefly digress to more closely examine equation (2.9). This is done in order to develop a better physical understanding of this equation, and to determine the precise relationship between R_∞ and δT, when the latter is defined in terms of the conventions used in reference 2 (which in turn are conventions commonly used in acoustics).

Thus, note that for an acoustic field in a fluid:

$$\vec{u}\to\frac{\vec{\nabla}P}{\rho\omega^2};\quad \vec{\vec{\tau}}\to -P\vec{\vec{1}},$$

where P is the pressure wave. Making these substitutions, we find

$$R_\infty = -\frac{1}{\rho\omega^2}\left\{ \int_{S_2} dS_2[P_1(\vec{x}_1)\hat{n}_2\cdot\vec{\nabla}P_2(\vec{x}_2) - P_2(\vec{x}_2)\hat{n}_1\cdot\vec{\nabla}P_1(\vec{x}_1)] + \int dS\xi\ \mathrm{Tr}(\overleftrightarrow{\mathcal{G}})(\hat{n}\cdot\vec{\nabla}P_1)P_2 \right.$$
$$\left. - \int dS\xi\hat{n}\cdot\vec{\nabla}P_1\hat{n}\cdot\vec{\nabla}P_2 + \int dS\xi[\vec{\nabla}P_1\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}P_2 - k^2P_1P_2] \right\}$$
$$= -\frac{1}{\rho\omega^2}R_\infty^{fluid} = -\frac{1}{\rho\omega^2}\delta T^{fluid}, \tag{2.10}$$

where R_∞^{fluid} and δT^{fluid} are analogous quantities for the problem of acoustic propagation through a fluid as discussed in reference 2. (Recall that δT represents the correction to the scattering amplitude for the perturbed surface; i.e., $T = T_0 + \delta T$ where T_0 is for scattering from the reference surface.) The identification of R_∞^{fluid} with δT^{fluid} implies that both the incoming and outgoing directions lie in the region bounded by S_2 and the sphere at infinity (i.e., we are looking at reflection back into the same medium, not transmission into the medium on the other side of the interface). We will implicitly continue to make this assumption in what follows.

Note that in Appendix B, we have the result

$$R_\infty = \frac{\rho\omega^2}{k_p^2}\delta T^{pp}, \tag{2.11}$$

where pp stands for ''scattering between scalar components of an elastodynamic wave.'' This gives the apparent result

$$\delta T^{pp} \overset{?}{=} -\frac{k_p^2}{(\rho\omega^2)^2}\delta T^{fluid}.$$

It is very important to note that this would be an erroneous conclusion! Equality (2.11) assumes that the incoming displacement wave has an amplitude of 1, whereas (2.10) assumes that the incoming pressure wave is normalized to unity. Once the different assumptions are accounted for, we indeed find

$$\delta T^{pp} = \delta T^{fluid}.$$

In our study of the fluid–solid interface, we will assume that there is a *normalized incoming pressure* wave in the fluid.

We now follow the strategy which was used in reference 2 to calculate the scattering from a two-fluid or a two-dielectric interface. Equation (2.8) is evaluated in the solid. Since it is assumed here that there is no incoming wave in the solid, and that the outgoing direction points somewhere into the fluid, it follows that $R_\infty^{solid} = 0$. Equation (2.9) is evaluated in the fluid, where $R_\infty = -\delta T/\rho_I\omega^2$ with ρ_I the density of the fluid. Henceforth, the superscript ''I'' refers to quantities evaluated on the fluid side, while the superscript ''II'' refers to those quantities evaluated on the solid side. (Later, when we consider the interface between two solids, this will, of course, be generalized, where I will refer to the side with an incoming wave.) Now, subtract the equations and use the boundary conditions (continuity of $\hat{n}\cdot\vec{u}, \tau_{nn}$) to simplify the result. Note that the continuity of τ_{nn} implies that the transverse derivative $(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{\nabla}\tau_{nn})$ must be continuous as well, so that

$$(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{\nabla}\tau_{nn}^{II}) = (\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{\nabla}\tau_{nn}^{I}) = -\rho_I\omega^2(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{u}^I.$$

(There is a minor point that may cause some confusion here. In the above derivations, it was always assumed that the normal points into the volume enclosed by S. Thus, strictly speaking, below the interface, $\hat{n}$ should be replaced by its negative. However, $\hat{n}\rightarrow-\hat{n}$ also implies that $\vec{\varrho}\rightarrow-\vec{\varrho}$ and $\xi\rightarrow-\xi$ and it turns out that all terms in these equations have the same parity! This makes comparison and subtraction of the two equations completely straightforward.)

Combining these results, we have the following equation applicable to the case when an acoustic wave is incident from the fluid side of a fluid–solid interface and scatters back into the fluid,

$$-\frac{\delta T}{\rho_I\omega^2}=\int dS\xi\omega^2(\rho_I-\rho_{II})\hat{n}\cdot\vec{u}_1\hat{n}\cdot\vec{u}_2+\int dS\xi\omega^2(\rho_I-\rho_{II})\vec{u}_1^{II}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{u}_2^{II}-\int dS\xi\rho_I\omega^2(\vec{u}_1^{I}-\vec{u}_1^{II})\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{u}_2^{I}-\vec{u}_2^{II})+\int dS\xi\left(\frac{k_I^2}{\rho_I\omega^2}+\frac{1}{2\mu_{II}}\right)\tau_{nn}^1\tau_{nn}^2+\int dS\xi\frac{\overleftrightarrow{\tau}_1^{TII}:\overleftrightarrow{\tau}_2^{TII}}{2\mu_{II}}-\int dS\xi\left(\frac{\lambda_{II}}{2\mu_{II}}\right)\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1^{II})\,\mathrm{Tr}(\overleftrightarrow{\tau}_2^{II})}{3\lambda_{II}+2\mu_{II}}-\int dS\xi\left[\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1^{II})}{3\lambda_{II}+2\mu_{II}}\tau_{nn}+\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_2^{II})}{3\lambda_{II}+2\mu_{II}}\tau_{nn}\right]. \tag{2.12}$$

The superscript ''T'' denotes the transverse components of τ defined by

$$\overleftrightarrow{\tau}^{T}\equiv(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\tau}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})=\begin{pmatrix}\tau_{t_1t_1}\tau_{t_1t_2}\\ \tau_{t_2t_1}\tau_{t_2t_2}\end{pmatrix}. \tag{2.13}$$

Implicit in the last equality is the choice of a *local* coordinate system such that

$$\hat{n}\perp\hat{t}_1\perp\hat{t}_2.$$

Often, $\hat{t}_1$ is chosen to be in the plane of incidence.

In (2.12), note that there are no I/II labels on $\hat{n}\cdot\vec{u}$ and τ_{nn}, since these quantities are the same on both sides. In interpreting this equation, it is also worthwhile to note that the labels 1 and 2 at this point refer to the fact that the quantities in question are, in the former case, solutions to the problem of scattering for an incoming plane wave with wave-vector $\vec{k}$, and in the latter case to the reciprocal problem with incoming wave-vector $-\vec{q}$. Also note that

$$\tau_{nn}=\frac{\mathrm{Tr}(\overleftrightarrow{\tau}^{I})}{3}.$$

The trace of the stress tensor is a physically significant quantity. Note that

$$\frac{\mathrm{Tr}(\overleftrightarrow{\tau})}{3\lambda+2\mu}=\vec{\nabla}\cdot\vec{u}=\Delta,$$

where Δ is the ''dilatation'' (i.e., the increase in volume per unit volume). Δ basically propagates with the longitudinal (i.e., p-, primary, or pressure) wave. Beyond this observation, the physical interpretation of the terms in equation (2.12) generally will become clear only gradually. Particularly helpful in this regard will be section III D, where certain limits are taken as the solid in region II becomes a liquid.

Result (2.12) is, in fact, more general than implied here. In deriving this equation, it was implicitly assumed that ρ_I is constant on the sphere at ∞, but nowhere was it assumed that ρ,

λ, or μ are constant in the vicinity of the scattering surface. The same applies for the results to follow in this section as well as those derived in section II C to follow. For a further discussion of this issue, see Ref. 2.

Following Ref. 2, let $\vec{d}$ be an infinitesimal constant translation so that consequently $\delta T = -i\vec{Q}\cdot\vec{d}\,T(\vec{q},\vec{k})$ and $\xi = -\hat{n}\cdot\vec{d}$ [where $T(\vec{q},\vec{k})$ is the scattering amplitude from the surface before it is translated and $\vec{Q}\equiv\vec{k}-\vec{q}$]. Parameterize the surface S using the 2-dimensional vector **x**, the projection of the coordinates of points on S onto a plane. Since $\vec{d}$ is arbitrary, we have

$$
\begin{aligned}
-\frac{iQ_z T(\vec{q},\vec{k})}{\rho_I\omega^2} &= \int d^2x(\rho_I-\rho_{II})\omega^2\hat{n}\cdot\vec{u}_1\hat{n}\cdot\vec{u}_2 + \int d^2x(\rho_I-\rho_{II})\omega^2\vec{u}_1^{II}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{u}_2^{II} \\
&\quad - \int d^2x\rho_I\omega^2(\vec{u}_1^{I}-\vec{u}_1^{II})\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{u}_2^{I}-\vec{u}_2^{II}) + \int d^2x\left(\frac{k_I^2}{\rho_I\omega^2}+\frac{1}{2\mu_{II}}\right)\tau_{nn}^1\tau_{nn}^2 \\
&\quad + \int d^2x\frac{\overleftrightarrow{\tau}_1^{TII}:\overleftrightarrow{\tau}_2^{TII}}{2\mu_{II}} - \int d^2x\left(\frac{\lambda_{II}}{2\mu_{II}}\right)\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1^{II})\,\mathrm{Tr}(\overleftrightarrow{\tau}_2^{II})}{3\lambda_{II}+2\mu_{II}} \\
&\quad - \int d^2x\left[\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1^{II})}{3\lambda_{II}+2\mu_{II}}\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_2^{I})}{3} + \frac{\mathrm{Tr}(\overleftrightarrow{\tau}_2^{II})}{3\lambda_{II}+2\mu_{II}}\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1^{I})}{3}\right],
\end{aligned}
\tag{2.14}
$$

where Q_z is the component of $\vec{Q}$ in the direction normal to the reference plane (with positive direction pointing into the fluid). Note that line 5 of equation (2.14) can be combined with the second term of line 4 using the following equality:

$$
\tau_{nn}^1\tau_{nn}^2 + \overleftrightarrow{\tau}_1^{TII}:\overleftrightarrow{\tau}_2^{TII} = \overleftrightarrow{\tau}_1^{II}:\overleftrightarrow{\tau}_2^{II}. \tag{2.15}
$$

This equality follows from equation (E2) and the boundary condition $\hat{n}\cdot\overleftrightarrow{\tau}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n}) = 0$.

Equation (2.14) is somewhat related to an important previous result obtained by Berman and Dacol and given by Ref. 5, equation (2). The latter is valid in general for the scattering of an acoustic wave, where both the incident wave and the observer are in the fluid (i.e., $-\vec{k}$ and $\vec{q}$ both point into the fluid, and the scattering is from an interface obeying either the Dirichlet, Neumann, impedance, fluid–fluid, or fluid–solid boundary conditions). The work outlined in Ref. 5 is also based on the technique proposed by Dashen and outlined in Refs. 1, 2, and consequently the resultant expression for the scattering amplitude manifestly exhibits reciprocity. Equation (2.14) and Ref. 5 [equation (2)] are both exact, and must ultimately be equivalent, but there are significant differences in their practical implementation. For example, the latter depends only on the field evaluated on the fluid (i.e., incoming) side, and this arguably leads to a (formal) simplification of the problem. On the other hand, the integrand of (2.14) depends on the displacement vector $\vec{u}$ and the stress tensor $\overleftrightarrow{\tau}$ only, both of which have a straightforward physical interpretation, while equation (2) of Ref. 5 explicitly depends on quantities such as $\vec{\nabla}\vec{u}$ which can be simplified further (see, for example, the last few lines of Appendix I). There is a great deal of physical information ''hiding'' in these terms. We will see in section III D that the comparative physical transparency of equation (2.14) leads, for example, to a straightforward examination of the difference between the Dirichlet, Neumann, fluid–fluid, and fluid–solid boundary value problems. Such an increase in physical transparency can also be a significant asset in simplifying the results. The scattering problem is potentially very complex, and the extensive use of physical intuition can be crucial in making the problem tractable (see once again, for example, section III below).

C. Full elastodynamic scattering

When the scattered wave is a full elastodynamic wave, then the problem involves a complication that does not seem at first glance to be present when the scattered wave is a (scalar) acoustic wave, namely that the scattering amplitude behaves as a tensor quantity. However, this property can be viewed as a straightforward generalization of concepts familiar from the scalar problem. For the acoustic problem, the scattering amplitude can be interpreted as a tensor, with the indices being the (continuous) variables specifying the direction of the incoming wave and the angular coordinates of the observer (i.e., the vectors $\vec{k}$ and $\vec{q}$, respectively). For the electromagnetic problem, the scattering amplitude is additionally labeled by the polarization of the incoming wave (having implicitly decomposed the incident wave into components of this form) and the polarization components of the outgoing wave being sampled by the observer (again assuming such a decomposition). Thus two more continuous tensor indices are added to the scattering amplitude. Finally, for elastodynamic waves, it is also necessary to decompose the incident field into scalar or vector components of the field and to similarly specify whether the observer is sampling the scalar or vector components of the outgoing waves. Now the new relevant tensor indices take on one of two discrete possible values (corresponding to ''scalar or vector'').

The decomposition of the field (in terms of plane waves, polarizations, etc.), which is necessary for defining the scattering amplitude as a tensor, is also intimately connected with the concept of reciprocity. In particular, it is the ''spectral'' components of the wave after it has been decomposed in this way, which are reciprocal. Conversely, a theory constructed from the reciprocity principle very naturally leads to the scattering amplitude tensor. As demonstrated below, the scattering amplitude can be written in terms of products of the solution to the problem at hand, and the solution of the reciprocal problem. The reciprocal problem is defined such that the incoming wave is characterized by the tensor quantities corresponding to those ''components'' of the outgoing solution of the original problem which are being sampled by the observer. The key insight which allows the formalism previously developed for the electromagnetic and acoustic problems (and in section II B above for the problem of scattering from the fluid–solid interface) to be extended to elastodynamic waves is the recognition that decomposing an elastodynamic wave into scalar and vector components is entirely analogous to specifying the polarization or the direction of propagation of the wave. (This insight is implicitly used, for example, in the reciprocity proof given on pp. 155–154 of Ref. 12.)

Armed with this insight, it is once again possible to derive a formal two-scale expression for the scattering amplitude of elastodynamic waves which is exact with respect to a reference surface, and good to first order in a perturbation. This is evaluated explicitly for the zero displacement boundary condition, the free boundary condition, and the continuity boundary condition found at the interface between two elastic solids. (The latter may be applicable to the study of scattering from sub-bottom layers. The two former are expected to apply to certain seismic problems.) These results are analogous to those obtained for scattering from the fluid–solid interface as well as for the electromagnetic and acoustic problems.

We are now ready to examine the details. It is shown in Appendix E that equation (2.6) reduces to

$$
\begin{aligned}
R_\infty = & \int_{S_2} dS_2[\hat{n}_1 \cdot \vec{\vec{\tau}}_1(\vec{x_1}) \cdot \vec{u}_2(\vec{x_2}) - \hat{n}_2 \cdot \vec{\vec{\tau}}_2(\vec{x_2}) \cdot \vec{u}_1(\vec{x_1})] - \int dS \xi \, \mathrm{Tr}(\vec{\vec{\varrho}}) \hat{n} \cdot \vec{\vec{\tau}}_1 \cdot \vec{u}_2 \\
& + \int dS \xi [\hat{n} \cdot \vec{\vec{\tau}}_2 \cdot \vec{\vec{\varrho}} \cdot \vec{u}_1 + \hat{n} \cdot \vec{\vec{\tau}}_1 \cdot \vec{\vec{\varrho}} \cdot \vec{u}_2] \\
& - \int dS \xi [\hat{n} \cdot \vec{\vec{\tau}}_2 \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{\nabla}(\vec{u}_1 \cdot \hat{n}) + \hat{n} \cdot \vec{\vec{\tau}}_1 \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{\nabla}(\vec{u}_2 \cdot \hat{n})]
\end{aligned}
$$

$$+\int dS\xi\rho\omega^2\vec{u}_1\cdot\vec{u}_1+\int dS\xi\frac{\tau^1_{nn}\tau^2_{nn}+2\hat{n}\cdot\vec{\tau}_1\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\tau}_2\cdot\hat{n}}{2\mu}$$

$$-\int dS\xi\frac{\vec{\tau}^T_1:\vec{\tau}^T_2}{2\mu}+\int dS\xi\frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\vec{\tau}^T_1)\ \mathrm{Tr}(\vec{\tau}^T_2)}{3\lambda+2\mu}-\int dS\xi\frac{\lambda}{2\mu}\frac{\tau^1_{nn}\tau^2_{nn}}{3\lambda+2\mu}. \tag{2.16}$$

Note that for the three elastodynamic boundary conditions being considered here (i.e., $\vec{u}=0$; $\hat{n}\cdot\vec{\tau}=0$; continuity of $\vec{u}$, $\hat{n}\cdot\vec{\tau}$) the first four lines of equation (2.16) are either zero, or cancel at the interface. [In particular, consider the 4th line of equation (2.16). For the zero-displacement boundary condition ($\vec{u}=0$), $\vec{u}\cdot\hat{n}=0$ on S implies that $\vec{\nabla}(\vec{u}\cdot\hat{n})\|\hat{n}$ and thus $(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\vec{u}\cdot\hat{n})=0$. For the stress-free boundary condition ($\hat{n}\cdot\vec{\tau}=0$) the term is trivially zero. For the solid–solid boundary condition, we have $\vec{u}$ continuous on S, which implies that $\hat{n}\cdot(\vec{u}^I-\vec{u}^{II})=0$ everywhere on S. Thus $\vec{\nabla}(\hat{n}\cdot(\vec{u}^I-\vec{u}^{II}))$ is proportional to $\hat{n}$, and

$$(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\hat{n}\cdot(\vec{u}^I-\vec{u}^{II}))=0,$$

establishing that $(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\hat{n}\cdot\vec{u})$ is continuous across the interface and the term in question cancels when contributions from the two sides are subtracted.]

Also note that from Appendix B we have $R_\infty=a^{ch}\delta T^{ch}$ where the superscript ch stands for the four possible channels pp, sp, ps, and ss; and a^{ch} is given by

$$a^{pp}=\rho\omega^2/k_p^2,\quad a^{sp}=\rho\omega^2/k_s^{1/2}k_p^{3/2},$$
$$a^{ps}=\rho\omega^2/k_s^{3/2}k_p^{1/2},\quad a^{ss}=\rho\omega^2/k_s^2, \tag{2.17}$$

where we are implicitly assuming that the *incoming* wave corresponding to the solution labeled by 1 contains only the type of wave (s or p) given by the 2nd label in ch, is normalized to unity, and approaches from a direction given by $\hat{k}$, while the *incoming* wave corresponding to the solution labeled by 2 contains only the type of wave given by the 1st label in ch, is also normalized to unity, and approaches from a direction given by $-\hat{q}=-\hat{r}$ (where $\hat{r}$ specifies the angular coordinates of the observer).

We are now ready to consider specific cases. Along with equation (2.12), they are the *fundamental results* of this paper.

1. The zero-displacement boundary condition

For the zero-displacement boundary condition, $\vec{u}=0$. This corresponds to scattering from an infinitely rigid wall. It is shown in Appendix F that in this case, equation (2.16) reduces to

$$a^{ch}\delta T^{ch}=\int dS\xi\left[\frac{\tau^1_{nn}\tau^2_{nn}}{\lambda+2\mu}+\frac{\hat{n}\cdot\vec{\tau}_1\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\tau}_2\cdot\hat{n}}{\mu}\right]. \tag{2.18}$$

2. The stress-free boundary condition

The stress-free boundary condition ($\hat{n}\cdot\vec{\tau}=0$) is relevant to the problem of scattering from a free surface (i.e., the boundary between a solid and a vacuum such as, for example, an air–rock interface). When this condition applies, equation (2.16) immediately reduces to

$$a^{ch}\delta T^{ch}=\int dS\xi\left[\rho\omega^2\vec{u}_1\cdot\vec{u}_2-\frac{\vec{\tau}^T_1:\vec{\tau}^T_2}{2\mu}+\frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\vec{\tau}^T_1)\ \mathrm{Tr}(\vec{\tau}^T_2)}{3\lambda+2\mu}\right]. \tag{2.19}$$

The reader should be aware of the availability of an additional technique for solving this type of boundary value problem. De Santo[14] has developed a diagrammatic approach for modeling the scattering of elastodynamic waves from surfaces obeying stress-free boundary conditions. Of particular relevance to the discussion here, it should be noted that this method may find use in solving for $\vec{u}$ and $\vec{\vec{\tau}}$ of the reference problem.

3. The solid–solid boundary condition

For the solid–solid boundary condition ($\vec{u}$, $\hat{n}\cdot\vec{\vec{\tau}}$ continuous) we subtract equation (2.16) on the two sides of the interface and use the continuity conditions to obtain

$$a^{ch}\delta T^{ch}=\int dS\xi(\rho_I-\rho_{II})\omega^2\vec{u}_1\cdot\vec{u}_2+\int dS\xi\left(\frac{1}{\mu_I}\frac{\lambda_I+\mu_I}{3\lambda_I+2\mu_I}-\frac{1}{\mu_{II}}\frac{\lambda_{II}+\mu_{II}}{3\lambda_{II}+2\mu_{II}}\right)\tau^1_{nn}\tau^2_{nn}$$
$$+\int dS\xi\left(\frac{1}{\mu_I}-\frac{1}{\mu_{II}}\right)\hat{n}\cdot\vec{\vec{\tau}}_1\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\vec{\tau}}_2\cdot\hat{n}-\int dS\xi\left[\frac{\vec{\vec{\tau}}_1^{TI}:\vec{\vec{\tau}}_2^{TI}}{2\mu_I}-\frac{\vec{\vec{\tau}}_1^{TII}:\vec{\vec{\tau}}_2^{TII}}{2\mu_{II}}\right]$$
$$+\int dS\xi\left[\frac{\lambda_I}{2\mu_I}\frac{\mathrm{Tr}(\vec{\vec{\tau}}_1^{TI})\,\mathrm{Tr}(\vec{\vec{\tau}}_2^{TI})}{3\lambda_I+2\mu_I}-\frac{\lambda_{II}}{2\mu_{II}}\frac{\mathrm{Tr}(\vec{\vec{\tau}}_1^{TII})\,\mathrm{Tr}(\vec{\vec{\tau}}_2^{TII})}{3\lambda_{II}+2\mu_{II}}\right]. \tag{2.20}$$

The off-diagonal element of $\vec{\vec{\tau}}^T$, $\tau_{t_1t_2}$ obeys the simple boundary condition given in Appendix G, but this does not lead to an apparent simplification of the formal result equation (2.20). Once again, note that De Santo[15] has developed a boundary integral equation approach, which facilitates numerical calculations modeling the scattering of elastodynamic waves from solid–solid interfaces. This method could be useful in solving the reference problem.

III. EXAMPLE: THE ''SMALL SLOPE'' AND '' 'LOCAL' TWO-SCALE'' APPROXIMATIONS FOR THE FLUID-SOLID INTERFACE

To illustrate the results obtained in section II, we now use the formalism for the fluid–solid boundary [specifically, equation (2.14)] to derive both the small slope and the ''local'' two-scale (i.e., composite model) approximations. The approach follows that pursued for the acoustic and electromagnetic problems as outlined in references 1, 3. For a more complete discussion concerning the origin of this type of approximation, see references 16–22.

The approximations considered here are used to model scattering from a fluid-elastic interface S which can naturally be parameterized by the coordinates $\vec{x}=(\mathbf{x},h(\mathbf{x}))$ where $\mathbf{x}$ is a 2-dimensional vector specifying coordinates in a plane, and $h(\mathbf{x})$ is a single-valued function which averages to zero when $\mathbf{x}$ is allowed to vary over the entire plane.

Note that in this paper, as in references 2–4, a bold-faced variable indicates a 2-dimensional vector, while a variable with an arrow on top represents a 3-dimensional vector. We are implicitly employing a Cartesian coordinate system oriented such that the direction of the positive z-axis (given by the unit vector $\hat{z}$) is given by $\hat{z}=\hat{n}$, where $\hat{n}$ is the unit vector normal to the plane pointing *into* the fluid. (Keep in mind that the wave is assumed to be incident from the fluid side.) Concerning an additional point of notation, the vector $\vec{r}$ will be used to denote an arbitrary point in space, while $\vec{x}$ (or $\vec{x}_0$) denotes the (3-dimensional) coordinates of a point on a scattering (or reference) surface.

Typically, $h(\mathbf{x})$ is a statistical quantity, often, but not necessarily always, characterized by Gaussian statistics (e.g., see reference 1). The formalism described in this section may, for example, be applicable to modeling acoustic scattering from the sea floor in certain regions of the world's oceans.

The small slope approximation is good to 2nd order in both the slope and the radius of curvature of the scattering surface [i.e., Error $= O(\nabla h, \nabla\nabla h/\kappa)$ where κ is the smallest of the various wavenumbers characterizing the field]. This approximation differs from 1st order perturbation theory primarily because it is good to all orders in $Q_z h$.

The ''local'' two-scale approximation assumes, in addition, the existence of a reference surface S_0 given by $\vec{x}_0=(\mathbf{x},h_0(\mathbf{x}))$. This approximation is here called ''local'' because the particular two-scale model being developed in this section measures the tilt of the reference surface, but does not include non-local effects such as shadowing and multiple scattering. It is formally accurate to 1st order in the radius of curvature of the *reference* surface S_0, but it retains accuracy to much higher orders with respect to the slope of S_0. Thus, the ''local'' two-scale approximation is typically appropriate for use when a reference surface is available so that most of the slope of S is due to the ''tilt'' of the reference surface [i.e., for $\delta h \equiv h(\mathbf{x})-h_0(\mathbf{x})$, we have $\nabla(\delta h)\ll\nabla h_0$], while the radius of the curvature of the reference surface S_0 remains small relative to all of the wavelengths associated with the field (see discussion in section II of Ref. 1). The ''local'' two-scale approximation is also well suited to instances when there are large scale features present which are best described deterministically, while superimposed on these one finds small scale surface features which can only be conveniently characterized statistically. Such a scenario may apply to some of the ocean bottom scattering problems referred to just above. In such cases, a non-local effect like shadowing, if important, must be inserted by hand. Since the formalism is manifestly reciprocal, this is not too difficult (see comments towards the end of section IV in reference 2). As will be shown below, following our approach, the ''local'' two-scale approximation turns out to be closely related to the small slope approximation.

A. The general procedure

We begin by deriving the small slope approximation, and then generalizing the result to the ''local'' two-scale approximation. In so doing, we follow a very general procedure developed in section II of reference 3. The starting point for this approach is the general form for the scattering amplitude given by equation (2.2) of reference 3:

$$T_0(\vec{q},\vec{k})=\frac{i}{Q_z}\int d^2x A_0(\vec{q},\vec{k}) \tag{3.1}$$

(recalling that $\vec{Q}\equiv\vec{k}-\vec{q}$). Note that the equation for a fluid–solid interface, equation (2.14), has this form, allowing A_0 to be expressed in terms of the displacement vector $\vec{u}$ and the stress tensor $\overleftrightarrow{\tau}$ evaluated on the two sides of the interface. T_0 and A_0 are taken to refer to the problem of scattering from a reference surface S_0. The scattering amplitude T corresponding to the surface $S=(\mathbf{x},h_0(\mathbf{x})+\delta h(\mathbf{x}))$ is given by equation (2.6) in reference 3:

$$T(\vec{q},\vec{k})=\frac{i}{Q_z}\int d^2x e^{iQ_z\delta h}A_0(\vec{q},\vec{k})+O\left((\nabla\delta h)^2,\left(\frac{\nabla\nabla\delta h}{\kappa}\right)^2\right) \tag{3.2}$$

[through $O(\delta h)$, this result follows directly from (2.12); higher orders in $Q_z\delta h$ essentially come by considering the phase shift associated with a constant translation, but some effort is needed to rigorously eliminate the possibility of cross-terms between higher orders of $Q_z\delta h$ and 1st order in derivatives of δh; see appendix A of Ref. 3]. The small slope follows when the reference surface is chosen to be the plane $h_0=0$. [This case is a little unusual since (3.1) will give δ-functions corresponding to specular scattering directions, but this does not invalidate the method.]

Thus, the small slope approximation can be obtained as follows. Set $A_0(\vec{q},\vec{k})$ equal to $\rho_I\omega^2$ times the integrand of equation (2.14), and evaluate it with $\vec{u}^I$, $\overleftrightarrow{\tau}^I$, $\vec{u}^{II}$, and $\overleftrightarrow{\tau}^{II}$ chosen to be the

solutions to the flat plane problem. Then insert the resulting expression for $A_0(\vec{q},\vec{k})$ into equation (3.2). Note that the effect of the phase factor $\exp(iQ_z\delta h)$ in equation (3.2) is simply to shift the phase to that of the incoming wave at the interface.

The ''local'' two-scale approximation is obtained from the small slope result when the normal to the plane $\hat{z}$ is replaced by $\hat{n}_0$, the normal to some reference surface S_0. Furthermore, the phase of all the components of the solution must now be set equal to the phase of the incoming wave evaluated on the reference surface S_0. In other words, define

$$\mathbf{k}\equiv(\vec{\mathbf{1}}-\hat{z}\hat{z})\cdot\vec{k}= \text{ horizontal component of } \vec{k}$$

and consider the solution to the flat plane problem. On the interface (i.e., the $z=0$ plane) the incident, reflected, and both the transmitted waves have the same phase given by $\exp(i\mathbf{k}\cdot\mathbf{x})$ (a more detailed discussion will be presented when the problem is solved below). In going from the small slope to the two-scale approximation, this gets replaced according to the prescription

$$e^{i\mathbf{k}\cdot\mathbf{x}}\rightarrow e^{i\mathbf{k}\cdot\mathbf{x}}e^{ik_zh_0}=e^{i\vec{k}\cdot\vec{x}_0}.$$

What has effectively been done here is to treat the reference surface as being locally flat, with an additional phase shift accounting for the fact that the origin is no longer on the plane. If there were no curvature to the surface, the result would be exact. (If this all seems unclear, see reference 3, section II for further discussion concerning this procedure.) Finally, note that once again, the phase factor $\exp(iQ_z\delta h)$ in equation (3.2) will effectively bring the phase up to $\exp(i\vec{k}\cdot\vec{x})$, where $\vec{x}$ is on the actual scattering surface.

Henceforth, we will conduct our calculation in a general notation which will apply to both the small slope and the two-scale approximation. This is possible essentially because the small slope is, formally speaking, a special case of the local two-scale approximation, although a close inspection of the procedure described in the preceding paragraph, as well as a comparison of the error terms, will indicate that some caution must be exercised before taking this connection too literally.

From now on, we will therefore use $\hat{n}$ to stand for either $\hat{z}$ (small slope) or $\hat{n}_0$ (''local'' two-scale). The phase on the reference interface is given by $\exp(i\vec{k}\cdot\vec{x}_0)$ where $\vec{x}=(\mathbf{x},0)$ for the small slope calculation, and $\vec{x}=(\mathbf{x},h_0)$ for the small slope calculation. It will also be useful to define the quantity

$$\mathbf{k}_\perp\equiv(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{k}.$$

This is the component of the vector in the tangent plane of the reference surface for the ''local'' two-scale approximation, and the horizontal component $\mathbf{k}$ (i.e., in the x-y plane) of the wave vector in the small slope approximation.

B. Solution for the flat plane problem

Keeping in mind that in the flat plane problem, the unit vector $\hat{n}$ is the constant vector $\hat{z}$, the general form of the pressure field resulting when a normalized incoming plane wave scatters from a flat interface is

$$P=e^{i\vec{k}_i\cdot\vec{r}}+Be^{i\vec{k}_R\cdot\vec{r}},$$
$$\vec{k}_i=(\mathbf{k}_\perp,k_{in});\quad \vec{k}_R\equiv(1-2\hat{n}\hat{n})\cdot\vec{k}_i=(\mathbf{k}_\perp,-k_{in}). \tag{3.3}$$

In presenting solutions to the flat plane problem, we will henceforth append the subscript i to the incoming wavevector (i.e., $\vec{k}\rightarrow\vec{k}_i$). As always, the time dependence $\exp(-i\omega t)$ has been dropped.

(Note that throughout this paper, we have implicitly decomposed the scattering problem for an arbitrary incoming field into the problem of scattering each individual plane wave component of the incoming field. This is a standard procedure for problems where the medium does not vary as a function of the time. See reference 1, section II for more details.)

B will be derived from the boundary conditions below. The general form of the solution and the definition of $\vec{k}_R$ follow from the requirement that the horizontal component of the wavenumber must be conserved at a flat interface. This is a well known result and can be deduced from very general arguments [see, for example, reference 23, equation (7.34)]. Note that $k_i=|\vec{k}_i|=|\vec{k}_R|=\omega/c_I$ where c_I is the speed of sound in the fluid.

Now, use

$$\vec{u}^I=\frac{\vec{\nabla}P}{\rho_I\omega^2}, \tag{3.4}$$

the definition of $\vec{\vec{\tau}}$ [equation (2.1)], and the Helmholtz equation for P to show

$$\vec{\vec{\tau}}^I=\lambda_I\vec{\nabla}\cdot\vec{u}^I=-P\vec{\vec{1}}, \tag{3.5}$$

and consequently

$$\vec{u}^I=\frac{i}{\rho_I\omega^2}(\vec{k}_i e^{i\vec{k}_i\cdot\vec{r}}+B\vec{k}_R e^{i\vec{k}_R\cdot\vec{r}}), \tag{3.6}$$

$$\vec{\vec{\tau}}^I=-(e^{i\vec{k}_i\cdot\vec{r}}+Be^{i\vec{k}_R\cdot\vec{r}})\vec{\vec{1}}. \tag{3.7}$$

Also in the solid, we have in general both outgoing primary (p) and secondary (s) waves:

$$\vec{u}^{II}=C[\hat{k}_p e^{i\vec{k}_p\cdot\vec{r}}-A_S\hat{t}e^{i\vec{k}_s\cdot\vec{r}}], \tag{3.8}$$

where C, A_S, and $\hat{t}$ will be determined below. Once again using the definition of $\vec{\vec{\tau}}$ equation (2.1) we have

$$\vec{\vec{\tau}}^{II}=iC[k_p(\lambda_{II}\vec{\vec{1}}+2\mu_{II}\hat{k}_p\hat{k}_p)e^{i\vec{k}_p\cdot\vec{r}}-\mu_{II}k_sA_S(\hat{k}_s\hat{t}+\hat{t}\hat{k}_s)e^{i\vec{k}_s\cdot\vec{r}}]. \tag{3.9}$$

Note that $k_p=|\vec{k}_p|=\omega/c_p$, $k_s=|\vec{k}_s|=\omega/c_s$, where

$$c_p=\sqrt{\frac{\lambda_{II}+2\mu_{II}}{\rho_{II}}},\quad c_s=\sqrt{\frac{\mu_{II}}{\rho_{II}}} \tag{3.10}$$

are the propagation speeds for the primary and secondary waves, respectively. We also have

$$\begin{aligned}\vec{k}_p&=(\mathbf{k}_\perp,k_{pn})\ \text{ with }\ k_{pn}=\operatorname{sgn}(k_{in})\sqrt{k_p^2-\mathbf{k}_\perp\cdot\mathbf{k}_\perp},\\ \vec{k}_s&=(\mathbf{k}_\perp,k_{sn})\ \text{ with }\ k_{sn}=\operatorname{sgn}(k_{in})\sqrt{k_s^2-\mathbf{k}_\perp\cdot\mathbf{k}_\perp},\end{aligned} \tag{3.11}$$

where the principal values of the square roots must be taken (i.e., positive if the argument of the square root is positive, a positive number times i if it is negative). Note that if the positive z-axis points *into* the fluid and therefore in the direction of the normal $\hat{n}$ (all this is generally assumed in this paper), then $\operatorname{sgn}(k_{in})$ corresponds to a ''$-$'' sign.

It is easily verified that the boundary condition $\hat{n}\cdot\vec{\vec{\tau}}^{\,II}\cdot(1-\hat{n}\hat{n})=0$ implies that $(1-\hat{n}\hat{n})\cdot\hat{t}\propto\mathbf{k}_\perp$ (independent of C or A_S). Note that this constrains $\hat{t}$ to the plane of incidence and therefore implies that the shear wave is linearly polarized for this (the flat plane) problem.

By additionally recognizing that $\hat{t}\perp\vec{k}_s$, and recalling that $\hat{t}$ is normalized to unity, we can conclude that $\hat{t}$ must (aside from an overall phase which can be absorbed in A_S) be given by

$$\hat{t}=\hat{k}_s\times\frac{\hat{n}\times\mathbf{k}_\perp}{|\mathbf{k}_\perp|}=\frac{\hat{n}|\mathbf{k}_\perp|^2-\mathbf{k}_\perp k_{sn}}{|\mathbf{k}_\perp|k_s}. \tag{3.12}$$

Substituting this result back into the equation $\hat{n}\cdot\vec{\tau}^{\,II}\cdot(1-\hat{n}\hat{n})=0$, applying some straightforward algebra, including the result

$$1-\frac{k_{sn}^2}{|\mathbf{k}_\perp|^2}=2\left(1-\frac{k_s^2}{2|\mathbf{k}_\perp|^2}\right),$$

we find

$$A_S=\frac{k_s k_{pn}}{|\mathbf{k}_\perp|k_p(1-k_s^2/2|\mathbf{k}_\perp|^2)}. \tag{3.13}$$

The continuity conditions on $\hat{n}\cdot\vec{u}$ and τ_{nn} provide two equations for the two remaining unknowns B and C. After some (mostly) straightforward algebra, we find

$$B=\frac{\alpha+\beta-\delta}{\alpha+\beta+\delta},\quad C=\frac{-2i}{\alpha+\beta+\delta},$$

where

$$\alpha=-k_p\left(\lambda_{II}+2\mu_{II}\frac{k_{pn}^2}{k_p^2}\right)=\frac{k_s}{k_p}\frac{2\mu_{II}}{A_S}\frac{k_{pn}}{k_p}|\mathbf{k}_\perp,$$

$$\beta=2\mu_{II}\left(\frac{k_{sn}}{k_s}\right)|\mathbf{k}_\perp|A_S,\quad \delta=\frac{\rho_I\omega^2}{k_{in}}\left(\frac{k_s}{2|\mathbf{k}_\perp|}\right)A_S, \tag{3.14}$$

where the expression for α in terms of A_S makes use of a lemma derived in Appendix H. This is the only tricky part related to the derivation of equation (3.14). The form of the solution given by this equation follows directly from the boundary conditions. It is also well suited for verification of energy conservation (i.e., $|B|^2\leqslant 1$) even when the transmitted waves become evanescent (i.e., k_{pn} imaginary, or k_{pn} and k_{sn} both imaginary; k_{sn} only imaginary is impossible).

For practical applications to be discussed below, it will also be useful to have the following alternate form of the solution available:

$$B=\frac{a-1}{a+1},\quad C=\frac{-b}{ik_p\mu_{II}(\lambda_{II}/2\mu_{II}+1)}\frac{1}{a+1},$$

where

$$a=\frac{\alpha+\beta}{\delta}=\frac{\rho_{II}}{\rho_I}\frac{k_{in}}{k_{pn}}\left[1-\frac{4|\mathbf{k}_\perp|^2k_{sn}(k_{sn}-k_{pn})}{k_s^4}\right],$$

$$b=\frac{\rho_{II}}{\rho_I}\frac{k_{in}}{k_{pn}}\left(1-\frac{2|\mathbf{k}_\perp|^2}{k_s^2}\right). \tag{3.15}$$

Generally straightforward algebra is needed to obtain result (3.15). The only ''tricky'' step comes in eliminating the explicit ω^2 from C by making the substitution

$$k_p^2=\frac{\rho_{II}\omega^2}{2\mu_{II}(1+\lambda_{II}/2\mu_{II})}. \tag{3.16}$$

C. Approximate representations of the scattering amplitude

1. Derivation

To evaluate the integrand A_0 in equation (3.2), it is necessary to evaluate the displacement vector and stress tensor on the reference surface. As stated above, for the small slope approximation, this means taking the flat plane solution [as given by equations (3.6)–(3.9], and evaluating it on the interface, which is called S_0 [recall, this is the plane $(\mathbf{x},0)$ for the small slope approximation]. Thus, we have

$$e^{i\vec{k}_i\cdot\vec{x}}|_{S_0}=e^{i\vec{k}_R\cdot\vec{x}}|_{S_0}=e^{i\vec{k}_p\cdot\vec{x}}|_{S_0}=e^{i\vec{k}_s\cdot\vec{x}}|_{S_0}=e^{i\mathbf{k}_\perp\cdot\vec{x}}. \tag{3.17}$$

For the ''local'' two-scale approximation, let $\hat{n}\rightarrow\hat{n}_0$ and make the following replacement (as discussed above):

$$\left.\begin{matrix} e^{i\vec{k}_R\cdot\vec{x}}|_{S_0} \\ e^{i\vec{k}_p\cdot\vec{x}}|_{S_0} \\ e^{i\vec{k}_s\cdot\vec{x}}|_{S_0} \end{matrix}\right\} \rightarrow e^{i\vec{k}_i\cdot\vec{x}}|_{S_0}+O\left(\frac{1}{R_c}\right), \tag{3.18}$$

where $1/R_c\propto\nabla\nabla h_0$ is the reciprocal of the radius of curvature of the reference surface S_0 given by $(\mathbf{x},h_0)$ (i.e., at each point, assume that the reference surface is locally flat). (For more information concerning the relationship of $\nabla\nabla h_0$ to the geometric quantity R_c, see reference 2, Appendix B.) Once again note that the extra phase in equation (3.2) formally implies that the phase is evaluated on the ''true'' scattering surface S rather than on the reference surface S_0, but the normal vector $\hat{n}$ is evaluated on the reference surface (i.e., $\hat{n}=\hat{z}$ for the small slope, $\hat{n}=\hat{n}_0$ for the ''local'' two-scale).

Thus effectively, for the small slope and two-scale approximations, we can now substitute the following quantities directly into equation (2.14):

$$\vec{u}_1^I=\frac{i}{\rho_I\omega^2}(\vec{k}_i+B\vec{k}_R)e^{i\vec{k}_i\cdot\vec{x}},\quad \vec{\vec{\tau}}_1^I=-(1+B)\vec{\vec{1}}e^{i\vec{k}_i\cdot\vec{x}},$$

$$\vec{u}_1^{II}=C[\hat{k}_p-A_S\hat{t}]e^{i\vec{k}_i\cdot\vec{x}}, \tag{3.19}$$

$$\vec{\vec{\tau}}_1^{II}=iC[k_p(\lambda_{II}\vec{\vec{1}}+2\mu_{II}\hat{k}_p\hat{k}_p)-\mu_{II}k_sA_S(\hat{k}_s\hat{t}+\hat{t}\hat{k}_s)]e^{i\vec{k}_i\cdot\vec{x}},$$

where the quantities $\hat{k}_R$, $\hat{k}_p$, $\hat{k}_s$, $\hat{t}$, B, C, and A_S are all evaluated using $\hat{n}$ of the reference surface ($\hat{z}$ or $\hat{n}_0$) and the position vector $\vec{x}$ in the phase lies on the scattering surface S. For the same quantities labeled by the subscript ''2,'' just replace $\vec{k}$ with $-\vec{q}$.

Recall that the error introduced when substitutions (3.19) are made into (2.14) is $O((\nabla h)^2, (\nabla\nabla h)^2)$ for the small slope approximation and $O(\nabla\nabla h_0)$ for the ''local'' two-scale approximation. *For these two approximations*, we can further simplify the expression for the scattering amplitude T, equation (2.14), as follows:

$$\frac{-iQ_zT}{\rho_1\omega^2}=\int d^2x[\text{ Integrand}]$$

$$\begin{aligned}\text{Integrand}=&(\rho_I-\rho_{II})\omega^2\hat{n}\cdot\hat{u}_1\hat{n}\cdot\hat{u}_2+[(\rho_I-\rho_{II})\omega^2+2\mu_{II}\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i]\vec{u}_1^{II}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{u}_2^{II}\\&-\rho_I\omega^2(\vec{u}_1^I-\vec{u}_1^{II})\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{u}_2^I-\vec{u}_2^{II})+\left(\frac{k_i^2}{\rho_I\omega^2}+\frac{1}{2\mu_{II}}\right)\tau_{nn}^1\tau_{nn}^2\\&+\frac{\lambda_{II}}{(3\lambda_{II}+2\mu_{II})^2}\left(1+\frac{\lambda_{II}}{2\mu_{II}}\right)[\text{ Tr}(\overleftrightarrow{\tau}_1^{II})\text{ Tr}(\overleftrightarrow{\tau}_2^{II})]\\&-\frac{1}{(3\lambda_{II}+2\mu_{II})}\left(1+\frac{\lambda_{II}}{2\mu_{II}}\right)[\text{ Tr}(\overleftrightarrow{\tau}_1^{II})\tau_{nn}^2+\text{ Tr}(\overleftrightarrow{\tau}_2^{II})\tau_{nn}^1].\end{aligned}\tag{3.20}$$

The derivation is given in Appendix I. We will see below that the three terms manifestly of order $1/\mu$ cancel in the limit as $\mu\to 0$ (i.e., they are associated with the elastic solid only and disappear in the limit as the solid becomes a fluid).

Note that the only quantities needed are $\vec{u}^I$, $\vec{u}^{II}$, τ_{nn}, and $\text{Tr}(\overleftrightarrow{\tau}^{II})$. *Suppressing the phase factor* $\exp(i\vec{k}_i\cdot\vec{x})$ [or $\exp(-i\vec{q}_i\cdot\vec{x})$], we have, using equations (3.15) and (3.19):

$$\text{Tr}(\overleftrightarrow{\tau}^{II})=iCk_p(3\lambda_{II}+2\mu_{II})=\frac{-b(3\lambda_{II}+2\mu_{II})}{\mu_{II}\left(1+\dfrac{\lambda_{II}}{2\mu_{II}}\right)}\frac{1}{a+1},$$

$$\tau_{nn}=-(1+B)=\frac{-2a}{a+1},\tag{3.21}$$

$$\vec{u}^I=\frac{i}{\rho_I\omega^2}[k_{in}(1-B)\hat{n}+(1+B)\mathbf{k}_\perp]=\frac{2i}{\rho_I\omega^2}\frac{1}{a+1}[k_{in}\hat{n}+a\mathbf{k}_\perp].$$

Recasting $\vec{u}^{II}$ is trickier. The result is

$$\begin{aligned}\vec{u}^{II}&=\frac{2i}{\rho_I\omega^2}\frac{1}{a+1}[k_{in}\hat{n}+\xi\mathbf{k}_\perp],\\\xi&=\frac{k_{in}}{k_{pn}k_s^2}[(k_{sn}-k_{pn})^2-k_p^2]=\frac{k_{in}}{k_{pn}}\left(1-2\frac{\vec{k}_s\cdot\vec{k}_p}{k_s^2}\right).\end{aligned}\tag{3.22}$$

The details of the derivation are given in Appendix J.

2. Key result

In Appendix K, it is shown that substituting the results (3.21) and (3.22) into equation (3.20) leads to the result

$$\begin{aligned}T(\vec{q}_i,\vec{k}_i)=\frac{i}{Q_{iz}}\int d^2x e^{i\vec{Q}_i\cdot\vec{x}}\Bigg[&\left(1-\frac{\rho_{II}}{\rho_I}\right)\frac{4k_{in}q_{in}}{(a_1+1)(a_2+1)}\\&+4\left(1-\frac{\rho_{II}}{\rho_I}\right)\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i\frac{\xi_1\xi_2}{(a_1+1)(a_2+1)}\end{aligned}$$

$$+\frac{8\rho_{II}}{\rho_I k_s^2}[\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i]^2\frac{\xi_1\xi_2}{(a_1+1)(a_2+1)}-4\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i\frac{(a_1-\xi_1)(a_2-\xi_2)}{(a_1+1)(a_2+1)}$$

$$+4k_i^2\frac{a_1a_2}{(a_1+1)(a_2+1)}+2k_s^2\frac{\rho_I}{\rho_{II}}\frac{(a_1-b_1)(a_2-b_2)}{(a_1+1)(a_2+1)}-4k_p^2\frac{\rho_I}{\rho_{II}}\frac{b_1b_2}{(a_1+1)(a_2+1)}\Bigg], \tag{3.23}$$

where a_1 and b_1 are simply a and b given in equation (3.15), and ξ_1 is similarly given by equation (3.22). For the quantities labeled by the subscript ''2'' just substitute $-\vec{q}_i$ for $\vec{k}_i$ everywhere. Recall that $\vec{k}_p$, $\vec{k}_s$, and $\mathbf{k}_\perp$ are all derived from $\vec{k}_i$ using equations (3.11), and that $-\vec{q}_p$, $-\vec{q}_s$, and $-\mathbf{q}_\perp$ are similarly defined. Since equation (3.23) directly provides the small slope ($\hat{n}=\hat{z}$) and ''local'' two-scale ($\hat{n}=\hat{n}_0$) approximations for the scattering amplitude corresponding to a fluid–solid interface, it is one of the major results of this paper.

3. Discussion

Note the following change in notation as compared with previous equations involving the scattering amplitude [such as (3.1), (3.2), and (3.20)]. We are now appending the subscript i onto the vectors $\vec{k}$, $\vec{q}$, and $\vec{Q}$ in order to bring our notation in line with that used to discuss the flat plane problem. Recall that this change was made in order to clearly distinguish these wavevectors from those related to the p- and s-waves in the solid (i.e., medium II).

Note that it is possible to make the substitution $\rho_{II}/k_s^2=\mu_{II}/\omega^2$ in the third line of equation (3.23). We will see below that the 3rd and 6th lines disappear in the limit as the solid becomes a fluid (i.e., $\mu_{II}\to 0$).

In examining (3.23), also keep in mind that $\hat{n}=\hat{z}$ for the small slope approximation and that $\hat{n}=\hat{n}_0$ for the ''local'' two-scale approximation. Recall that the error for the small slope version of the result is of order $O((\nabla h)^2,([\nabla\nabla h]/k_i)^2)$ (where $\nabla\nabla h=1/R_c$, R_c is the local radius of curvature of the interface). The error for the ''local'' two-scale version ($\hat{n}=\hat{n}_0$) of the result is $O([\nabla\nabla h_0]/k_i)$ (where $\nabla\nabla h_0=1/R_{0c}$, R_{0c} is the local radius of curvature of the reference surface).

The small slope version of result (3.23) must be equivalent to the expression for the small slope scattering amplitude (also for scattering from a fluid–solid interface) given in references 24 and 25. (To be specific, in reference 24, evaluate equation ((23) with ϕ given by equations (25) (use 1st order only) and (31); in reference 25, evaluate equation (2) with ϕ_0 given by equation (6) and ϕ_1 given by equation (7).] Note that, as remarked in reference 24, it is difficult to see reciprocity in the previously published version of this result, but reciprocity is easy to see in equation (3.23).

D. Limiting cases

Consider the limit as the 2nd Lamé constant $\mu_{II}\to 0$, while the density in the solid ρ_{II} remains non-zero. As is demonstrated in Appendix L, this leads to

$$T(\vec{q}_i,\vec{k}_i)=\frac{i}{Q_{iz}}\int d^2x e^{i\vec{Q}_i\cdot\vec{x}}\Bigg[\left(1-\frac{\rho_{II}}{\rho_I}\right)k_{in}q_{in}(2-A_{\vec{k}_i})(2-A_{-\vec{q}_i})$$

$$+\left(\frac{\rho_I}{\rho_{II}}-1\right)\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_iA_{\vec{k}_i}A_{-\vec{q}_i}+\left(k_i^2-\frac{\rho_I}{\rho_{II}}k_p^2\right)A_{\vec{k}_i}A_{-\vec{q}_i}\Bigg]+O(\mu_{II}^{1/2}), \tag{3.24}$$

where

$$A_{\vec{k}_i} \equiv \frac{2a_1}{a_1+1}; \quad A_{-\vec{q}_i} \equiv \frac{2a_2}{a_2+1}.$$

[Recall that a_1 (and analogously a_2) are given by equation (3.15).] As would be expected, this is the 2-fluid result given in equation (C12) of Appendix C in reference 3 (with the identification $k_p = k_{II}$, $k_i = k_I$, $\vec{k}_i = \vec{k}$, $\vec{q}_i = \vec{q}$, and $\vec{Q}_i = \vec{Q}$).

On the other hand, taking the limit $\mu_{II} \to \infty$, we recover

$$T(\vec{q}_i, \vec{k}_i) = \frac{i}{Q_{iz}} \int d^2x \; e^{i\vec{Q}_i \cdot \vec{x}} [-4\vec{k}_i \cdot (\vec{\mathbf{1}} - \hat{n}\hat{n}) \cdot \vec{q}_i + 4k_i^2] + O\left(\frac{1}{\mu_{II}}\right). \tag{3.25}$$

The derivation is given in Appendix M. Note that the object in parentheses can be rewritten as

$$4[k_{in} q_{in} - \vec{k}_i \cdot \vec{q}_i + k_i^2],$$

and we recover the result for Neumann boundary conditions at the interface given by equation (C11) in reference 3.

Finally, if we let $\mu_{II} \to 0$, $\rho_{II} \to 0$ simultaneously, we obtain

$$T(\vec{q}_i, \vec{k}_i) = \frac{i}{Q_{iz}} \int d^2x \; e^{i\vec{Q}_i \cdot \vec{x}} 4k_{in} q_{in} + O(\mu_{II}, \rho_{II}). \tag{3.26}$$

The derivation is sketched in Appendix N. This is the result for scattering from Dirichlet boundary conditions, equation (C10) in Ref. 3.

IV. AN IMPORTANT CAVEAT CONCERNING PERTURBATIVE SCATTERING THEORY

As several researchers have noted (see reference 9 (pp. 41,100), and reference [26]–28), perturbative approaches for calculating the scattering amplitude do not, in general, conserve energy. This phenomenon is most easily seen at very shallow grazing angles. Specifically, for the Neumann boundary conditions, the cross-section remains non-zero as the grazing angle approaches zero. For example, consider the small slope ($\hat{n} = \hat{z}$) versions of equations (3.24), (3.25), and (3.26). In equations (3.24) and (3.26), the scattering amplitude goes to zero as the angle of incidence becomes very shallow, but for equation (3.25), it does not! On the other hand, the scattered energy *must always* go to zero, because energy conservation requires that the scattered wave disappear as the grazing angle becomes very small, since all the flux associated with the incoming wave is traveling horizontally, and is thus unavailable for diffuse scattering (i.e., the energy actually incident on a patch of surface goes to zero). It is important to keep in mind that this is a particularly blatant example of what is in fact a more general problem: *that perturbative scattering theory does not conserve energy*.

This violation of energy conservation, of course, casts doubt on the validity of the perturbative approach to surface scattering. However, there are physical and mathematical grounds for concluding that this phenomenon is only important at very shallow grazing angles ($1° - 2°$).[26,28] Physically, the problem is the result of an interaction between the interface wave and the scattering process [reference 9, (p. 100) and reference 28] (i.e., the surface effectively comes out and ''grabs'' the incoming wave). A significant interaction between scattering and an interface wave would reasonably be expected to occur at very shallow grazing angles where the incoming wave can be thought of as spending a great deal of time close to the interface (without actually touching it). More specifically, use an intuitive picture taken from ray theory, and think of a given ray at shallow grazing angle as spending more time in a thin band near the surface, where it is able to interact with the interface wave. In addition, note that the purely formal mathematical argument

presented in the previous paragraph also points to the fact that the breakdown of unitarity (i.e., energy conservation) becomes most apparent as the grazing angle becomes very shallow.

In light of these insights, there is reason to believe that use of an approach based on formulas (2.12), (2.18), (2.19), and (2.20) may mitigate these problems. Note that our formulas are formally *exact* with respect to the reference solution. Therefore, provided one chooses a reference surface so that the corresponding solution includes interaction between the interface wave and the scattering, it may be possible to circumvent this problem within the context of perturbation theory. There are some tricky issues being raised here, and pursuit of such a project requires original and possibly subtle uses of the formalism. For example, note that the reference surface is typically chosen so that the perturbation δh corresponds to components of the surface wavenumber spectrum on the order of the Bragg wavenumber and larger. (See, e.g., Ref. 1 (section I) for a discussion of Bragg scattering and Bragg waves.) Such a choice for δh would not mitigate the unitarity problem, which already shows up for Bragg scattering. (To be specific, note that Bragg scattering can be extracted directly from the small slope approximation by expanding in $Q_z h$, and dropping the specular component. At lowest order, we are left with a quantity proportional to the spectral component of the surface roughness parameter evaluated at the Bragg wavevector $\widetilde{\delta h}(\mathbf{Q})$ (recalling that $\mathbf{Q}$ is the projection onto the x-y plane of $\vec{Q} \equiv \vec{k} - \vec{q}$). Consequently the average cross-section is proportional to the surface roughness spectrum $S(\mathbf{Q})$; e.g., see Ref. 1 [equation (61)] and Ref. 4 (equation (4.6)]. This approximation corresponds to the specific physical effect known as Bragg scattering (i.e., the surface scatters like a diffraction grating). The isolation of this physical effect from other physical phenomena, such as interface waves, results directly from treating the surface roughness on the order of the Bragg scale using perturbation theory. As suggested above, this decoupling is believed to be the physical reason behind the breakdown of unitarity. (Note that such decoupling is also inherent in the formal statement of the composite model when δh is chosen on the order of the Bragg scale.)

However, it *would* be legitimate to choose δh corresponding to surface spectral components having wavenumbers larger than the Bragg value (i.e., smaller scale phenomena). Essentially this strategy was successfully employed by Orris and Dashen in Ref. 29. That study examined acoustic scattering from the Dirichlet and Neumann boundary conditions. We will leave the application to scattering involving elastic solids as a possible future research direction.

For the time being, users of perturbative scattering theory in general, and results (2.12), (2.18), (2.19), and (2.20) in particular, need to be aware of this issue, and remain on the lookout for future developments.

V. CONCLUSION

A. Summary of the basic approach

The technique of constructing a physical theory from a symmetry principle has been a hallmark of modern physics. The concept was foreshadowed by the work of Fermat and Hamilton in which geometrical optics and classical mechanics, respectively, were deduced from a variational principle. More recently, the connection between symmetry principles, conservation laws, and the field equations was firmly established by Noether's theorem (see Ref. 30 for a review of this topic). The concept reached its full fruition with the subsequent development of gauge theories, which form the basis of elementary particle physics, and therefore of modern cosmology (see, e.g., Ref. 31 for an overview).

Recently a similar approach has been applied to a reexamination of a more mundane physical problem, the scattering of acoustic and electromagnetic waves from interfaces. In Refs. 1–4, a new formal approach for describing such scattering was bootstrapped from the principle of time-reversal symmetry (also called reciprocity). In this paper, the new approach has been extended to scattering problems where elastodynamic waves are involved as well.

The overall strategy employed builds upon the previously known proof for the reciprocity theorem (see, e.g., Ref. 12). The basic ingredients of this proof are the two quantities known to be associated with the energy propagation vector. In acoustics, the two field quantities involved in energy propagation are the pressure p and the displacement $\vec{u}$, for the electromagnetic field it is the electric field $\vec{E}$ and the magnetic field $\vec{H}$, and for elastodynamic waves the relevant quantities are the displacement $\vec{u}$ and the stress tensor $\vec{\tau}$. Furthermore, two independent sets of solutions to the field equations are considered (labeled here by the subscripts ''1'' and ''2''). These ingredients are combined to form a divergence-free vector. For the electromagnetic field, this result has a name, ''Lorentz's Lemma,'' but the concept also applies to acoustic and elastodynamic fields. The elastodynamic equivalent of Lorentz's Lemma is

$$\vec{\nabla}\cdot(\vec{\tau}_1\cdot\vec{u}_2-\vec{\tau}_2\cdot\vec{u}_1)=0.$$

Remarkably, this and all versions of Lorentz's Lemma involve two completely independent solutions to the field equations *in any region where both solutions are valid*. In order to prove reciprocity, the solutions are chosen to correspond to scattering from the same surface, differing only in the incoming and outgoing geometries.

Specifically, it is assumed that the problem has been decomposed so that the incoming wave is a plane wave with wavevector $\vec{k}$. The reciprocal problem concerns a plane wave incoming from the angular coordinates of the observer (i.e., with wavevector $-\vec{q}$). Reciprocity implies that the scattering amplitude is invariant under the exchange $\vec{q}\rightarrow-\vec{k}$, $\vec{k}\rightarrow-\vec{q}$. This result emerges when Lorentz's Lemma is integrated over the scattering volume, and Gauss' Law is used to convert the volume integral to a surface integral over the boundaries of the scattering region. The change in the scattering amplitude under the reciprocity exchange [i.e., $\delta T\equiv T(\vec{q},\vec{k})-T(-\vec{k},-\vec{q})$] is proportional to the contribution from the sphere at infinity, while the boundary conditions ensure that the scattering surface does not contribute to the surface integral. Thus, $\delta T=0$, so that the scattering amplitude remains unaffected by the exchange, and reciprocity is established.

In fact, this simple picture only applies to the acoustic case. The electrodynamic and elastodynamic problems are a little more complicated. For the electromagnetic field, it is additionally necessary to include the polarization of the incoming wave, and to specify the polarization to be observed. In the elastodynamic case, it is also necessary to further decompose the incoming wave into primary (p-wave) and secondary (s-wave) components, and consider the scattering of each separately (the problems legitimately separate, no information is lost). Similarly, it is necessary to specify whether the observer is viewing the p- or s-components of the scattered wave. Reciprocity is only preserved once the problem has been decomposed in this way. The key insight is the realization that the extra decompositions outlined in this paragraph are not fundamentally different from the specification of $\vec{k}$ and $\vec{q}$.

In this paper and its predecessors,[1–4] the same procedure is followed, but with a crucially important innovation. The two solutions are now chosen not only to correspond to reciprocal geometries, but to scattering from different surfaces as well (with one ultimately serving as a reference surface). The reciprocity theorem and boundary conditions are then used to obtain expressions for the change in the scattering amplitude associated with the difference between the two scattering surfaces. The results are given by equation (2.12) for the scattering of an acoustic wave from a fluid–solid interface, and by equations (2.18), (2.19), and (2.20) for the scattering of elastodynamic waves from boundaries obeying the zero-displacement, stress-free, and solid–solid boundary conditions, respectively.

In this paper, the observer and the incoming waves are always chosen to be on the same side of the scattering surface. The generalization is very straightforward, as can be seen in analogous work in Ref. 3. It will be considered in future research as it is needed for specific applications.

B. Overview of the results

Formulas (2.12), (2.18), (2.19), and (2.20) are the fundamental results of this paper. All subsequent results follow from these equations. As stated just above, the four formulas correspond to the four types of scattering problem usually cited in connection with elastodynamic fields. They each constitute a formal statement of the two-scale (i.e., composite-roughness) model, being exact with respect to the reference surface and 1st order with respect to the perturbation (i.e., the normal distance between the surfaces). Typically, since *the reference surface is usually smoother* than the true scattering surface, the solution to reference problem can be found using more conventional techniques [such as numerical techniques; e.g., see Ref. 6; Milder's operator expansion method (see, e.g., Refs. 32, 33) also turns out to be very useful]. When the new scattering formalism is used in this way, it is effectively extending the range of utility of these techniques, making them apply to rougher surfaces than would otherwise be possible. Such applications of the formalism derived above will be a topic of upcoming research.

To provide a comparatively modest illustration of the utility of these results, the formalism was first used to derive a new manifestly reciprocal expression for the scattering amplitude corresponding to scattering from a fluid–solid interface. This is given in equation (2.14). The expression is derived from the 1st order perturbative equation (2.12) by considering an *infinitesimal* translation, and it is therefore exact.

Equations (2.12) and (2.14) are then used to obtain the small slope and ''local'' two-scale approximations for the problem of scattering from a rough, but approximately planar fluid–solid interface (i.e., assume that the interface is a surface which can be parameterized as a single valued function of coordinates on a plane). The result for both approximations is given by equation (3.23), with the small slope approximation emerging when the reference surface is chosen to be a plane, while for the two-scale result, the reference surface is formally arbitrary, but its curvature must be small relative to the wavelength of the field. An examination of equation (3.23) reveals that formally, this simply implies that the normal $\hat{n}$ is taken to be a constant unit vector $\hat{z}$ for the small slope approximation, and $\hat{n}_0$, the normal to the reference surface, for the ''local'' two-scale approximation. The approximation is called ''local'' because it is of lowest order, and therefore does not include non-local effects such as shadowing or multiple scattering. From equations (3.24), (3.25), and (3.26), it is clear that in the proper limits, equation (3.23) reduces to the corresponding previously known acoustic results.

Finally, in section IV, there was a brief discussion of the issue of energy non-conservation in perturbative scattering theory and its relevance to the results presented above. The reader is reminded that all perturbative scattering results, including those in this paper, can occasionally be affected by this issue, particularly at very shallow grazing angles. On the other hand, it was also pointed out that the formalism presented here can, for some purposes, be used to circumvent this problem.

C. Significance of the results

The work presented in this paper will form the basis for a number of future research projects. The most immediate application will be a study of acoustic scattering from the ocean bottom. There is reason to believe that there are regions of the world's oceans where the sea floor can be modeled as an elastic solid. Furthermore, it is also observed that at shallow grazing angles, or moderately high frequencies (>5 kHz), scattering from the interface between the ocean and the bottom dominate the near-bottom scattering results (as opposed to, say, volume scattering in the sub-bottom). The goal of theoretical research in this area would be to provide an expression for the scattering strength in terms of the roughness spectrum for the fine structure of the bottom (i.e., features on the order of a wavelength, typically: boulders, small dunes, etc.), its material parameters (e.g., density, the Lamé constants), and large-scale location-specific features of the bathymetry (e.g., underwater mountains, ridges, etc.). Equation (2.12) would form the basis of such a

study. The fine structure would be treated as a perturbation and considered statistically. The problem of scattering from the large scale structure would be treated as a deterministic problem to be solved numerically.

It is important to understand the way in which a formula such as (2.12) becomes useful for describing scattering from a rough surface such as the sea floor. The complicated multi-scale topography of such a surface makes scattering calculations very difficult, because there is no single method suitable for calculating the scattering from both large and small scale surface features. Large scale features (i.e., those characterized by scales significantly greater than the wavelength of the field) are associated with non-local scattering effects such as diffraction, shadowing, and multiple scattering, while small scales (on the order of a wavelength) are responsible for Bragg scattering (i.e., the surface acts like a diffraction grating). The former type of effect lends itself to numerical calculation (or to an exact solution in a handful of cases). On the other hand, use of perturbation theory is greatly complicated by the fact that non-local effects are associated with higher orders, which are in general very difficult to calculate. Bragg scattering, however, already emerges from lowest order perturbation theory, which is therefore the method of choice for calculating this phenomenon. Numerical calculations of Bragg scattering would on the other hand require such fine grids that a rigorous application of this technique would be prohibitively expensive in terms of time and computing resources. This problem becomes particularly acute when the full 3-dimensional scattering problem is considered.

Equations such as (2.12) [and similarly (2.18), (2.19), and (2.20)] solve this quandary provided that the perturbation δh is chosen judiciously. Used in this context, δh should correspond to surface features on the order of the Bragg wavelength and smaller. Thus, non-local events can be calculated numerically, and Bragg scattering can be handled perturbatively. Alternately, consider equations (2.14) and especially (3.23). Since these equations are manifestly reciprocal, the most important non-local effect, shadowing, can be inserted by hand [by using ray tracing to see which points on the surface are shielded from either the source or the observer, and setting the contribution to the surface integral to zero at those points. Note that for traditional, non-reciprocal expressions for the scattering amplitude, this is only really possible for a monostatic (i.e., backscattering) geometry, while with the new formalism, this can be done for the full bistatic problem. See Ref. 2 for further discussion of this issue].

Thus, it is fair to conclude that the study of non-local effects in rough surface scattering constitutes an important application of the formalism developed here. Note that such effects are particularly important at shallow grazing angles, which is precisely where surface scattering becomes most important relative to other (e.g., volume scattering) effects. In particular, note that this observation holds for the problem of scattering from the ocean bottom, or from layers in the sub-bottom.

The issue of rough surface scattering is only one of many possible applications of the results in this paper. As mentioned in the Introduction, Dashen, Abawi, and Wandzura[7,8] have used the acoustic version of this formalism to examine the scattering from planar objects bounded by edges and corners. The scattering from such objects is usually expressed as an integral over a two-dimensional surface, but in Refs. 7, 8, it is shown that such expressions reduce to (one-dimensional) line integrals, which are naturally much easier to evaluate. Because of shadowing, the illuminated area of a finite three-dimensional scatterer consists of such planar areas bounded by edges and corners, and therefore, the results obtained for the scattering from bounded two-dimensional surfaces (embedded in three-dimensional space) can be used to develop an entirely new approach to modeling scattering from typical three-dimensional scatterers (i.e., those bounded by a *closed* two-dimensional surface).

Thus, this paper adds another building block to the structure of a new theory for the scattering of classical fields. This new approach fully incorporates the insights gained from modern field theory.

ACKNOWLEDGMENTS

This work was supported by the 6.2 NRL Bottom Interaction Project. I would also like to acknowledge the tremendous encouragement and advice I received from Professor Roger Dashen of the University of California, San Diego. This paper is dedicated to his memory. I would also like to thank Jon Wright, then of the La Jolla Institute, and now of the Institute for Non-Linear Science at the University of California, San Diego for starting me out on this problem some years ago.

APPENDIX A: DERIVATION OF EQUATION (2.6)

In this appendix, the details of the calculation leading from equation (2.5) to equation (2.6) are provided. In Figure 2 of Ref. 2, a coordinate system locally tangent to the surface S_2 is used to show that

$$\hat{n}_1 = \hat{n}_2 - (1 - \hat{n}\hat{n}) \cdot \vec{\nabla} \xi, \tag{A1}$$

where the labels ''1'' and ''2'' are dropped if the result is the same to first order in ξ. We also have

$$\vec{\tau}_1(\vec{x_2}) = \vec{\tau}_1(\vec{x_1}) - \xi(\hat{n} \cdot \vec{\nabla}) \vec{\tau}_1, \quad \vec{u}_1(\vec{x}_2) = \vec{u}_1(\vec{x}_1) - \xi(\hat{n} \cdot \vec{\nabla}) \vec{u}_1,$$

so that

$$R_\infty = \int_{S_2} dS_2 [\hat{n}_1 \cdot \vec{\tau}_1(\vec{x_1}) \cdot \vec{u}_2(\vec{x_2}) - \hat{n}_2 \cdot \vec{\tau}_2(\vec{x_2}) \cdot \vec{u}_1(\vec{x_1})] + \int dS [\vec{\nabla} \xi \cdot (1 - \hat{n}\hat{n}) \cdot \vec{\tau}_1 \cdot \vec{u}_2$$
$$- \xi \hat{n} [(\hat{n} \cdot \vec{\nabla}) \vec{\tau}_1] \cdot \vec{u}_2 + \xi \hat{n} \cdot \vec{\tau}_2 \cdot [(\hat{n} \cdot \vec{\nabla}) \vec{u}_1]]. \tag{A2}$$

Note that, on terms of $O(\xi)$, there is no need to specify whether the field is evaluated at $\vec{x}_1$ or $\vec{x}_2$. Also note that on such terms, the subscripts have been dropped from dS since to this order, dS_1, dS_2, or the area element on any intermediate surface are all the same. Therefore, when considering terms of $O(\xi)$, the surfaces are equivalent, and the label S will henceforth stand for S_1, S_2, or any surface in between. A corresponding coordinate on one of these surfaces will simply be given by $\vec{x}$; no subscript is necessary.

The term in (A2) involving $\vec{\nabla} \xi$ will now be integrated by parts. For this step, the surface S is parameterized so that $\vec{x}$ is given by the Cartesian coordinates $(\mathbf{x}, h(\mathbf{x}))$ where $\mathbf{x}$ is a two-dimensional vector. Let ∇ be the associated two-dimensional gradient vector. Then, as in Appendix B of Ref. 2, it follows that

$$\hat{n} = n_z(-\nabla h, 1), \tag{A3}$$

$$n_z \equiv \frac{1}{\sqrt{1 + (\nabla h)^2}}, \tag{A4}$$

$$dS = d^2\mathbf{x}/n_z. \tag{A5}$$

Also note that

$$(1 - \hat{n}\hat{n}) \cdot \vec{\nabla} \xi = (1 - \hat{n}\hat{n}) \cdot \nabla \xi,$$

or more generally,

$$(1-\hat{n}\hat{n})\cdot\vec{\nabla}f(\mathbf{x},y)=(1-\hat{n}\hat{n})\cdot\nabla f(\mathbf{x},h(\mathbf{x})), \tag{A6}$$

for any function f of the coordinates evaluated on the surface S [see Ref. 2, equation (B16)].

These results are substituted into the second term of equation (A2), and an integration by parts is performed. The contribution from the edge of S is zero: for a closed surface where the parameterization is broken into pieces, the edge contribution from adjacent pieces cancels, and there is no overall edge; similarly for an infinite surface, the edge is out at infinity and therefore does not contribute to the scattering amplitude. The result is

$$\int \frac{d^2\mathbf{x}}{n_z}\nabla\xi\cdot(1-\hat{n}\hat{n})\cdot\vec{\tau}_1\cdot\vec{u}_2=-\int d^2\mathbf{x}\xi\nabla\cdot\left(\frac{1-\hat{n}\hat{n}}{n_z}\right)\cdot\vec{\tau}_1\cdot\vec{u}_2 - \int d^2\mathbf{x}\xi\left(\frac{\delta^{ij}-n^in^j}{n_z}\right):\vec{\nabla}^i(\vec{\tau}_1\cdot\vec{u}_2)^j. \tag{A7}$$

Use equation (B21) in Ref. 2 to show

$$\nabla\cdot\left(\frac{1-\hat{n}\hat{n}}{n_z}\right)=\frac{\mathrm{Tr}(\vec{\varrho})}{n_z}\hat{n}, \tag{A8}$$

where

$$\vec{\varrho}\equiv-(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}\hat{n} \tag{A9}$$

is the curvature tensor, and ''Tr'' is the trace. Use this result, along with straightforward simplifications and cancellations to obtain

$$R_\infty=\int_{S_2}dS_2[\hat{n}_1\cdot\vec{\tau}_1(\vec{x_1})\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\tau}_2(\vec{x_2})\cdot\vec{u}_1(\vec{x_1})]-\int dS\xi\vec{\nabla}\cdot(\vec{\tau}_1\cdot\vec{u}_2) - \int dS\xi\,\mathrm{Tr}(\vec{\varrho})\hat{n}\cdot\vec{\tau}_1\cdot\vec{u}_2+\int dS\xi[(\hat{n}\cdot\vec{\tau}_1)\cdot[(\hat{n}\cdot\vec{\nabla})\vec{u}_2]+(\hat{n}\cdot\vec{\tau}_2)\cdot[(\hat{n}\cdot\vec{\nabla})\vec{u}_1]]. \tag{A10}$$

Note that the result is independent of the parameterization. The parameterization was only used to perform the integration by parts and it will not be used again in the derivation. As shown in Ref. 6, it is possible to perform this type of integration by parts using techniques from analytic geometry, without recourse to such a parameterization at all. Also note that on terms of $O(\xi)$ the subscripts have been dropped from S. To the order considered here, S_1, S_2 or any intermediate surface are all equivalent.

Decompose the term

$$\int dS\xi(\hat{n}\cdot\vec{\tau}_2)\cdot[(\hat{n}\cdot\vec{\nabla})\vec{u}_1] \tag{A11}$$

as follows:

$$\int dS\xi(\hat{n}\cdot\vec{\tau}_2\cdot\hat{n})(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1)+\int dS\xi(\hat{n}\cdot\vec{\tau}_2)\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot[(\hat{n}\cdot\vec{\nabla})\vec{u}_1]. \tag{A12}$$

Use the definition of $\vec{\tau}$, equation (2.1), to obtain the expressions

$$\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1=\frac{\hat{n}\cdot\vec{\vec{\tau}}_1\cdot\hat{n}}{2\mu}-\frac{\lambda}{2\mu}\vec{\nabla}\cdot\vec{u}_1,$$

$$(\vec{\vec{1}}-\hat{n}\hat{n})\cdot[(\hat{n}\cdot\vec{\nabla})\vec{u}_1]=\frac{(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\vec{\tau}}_1\cdot\hat{n}}{\mu}-n^i(\vec{\vec{1}}-\hat{n}\hat{n})\vec{\nabla}u_1^i.$$

These are substituted into (A12) above. After a little bit of algebra, and once again using the definition of $\vec{\vec{\tau}}$ [equation (2.1)], we are left with

$$\int dS\xi(\hat{n}\cdot\vec{\vec{\tau}}_2)\cdot[(\hat{n}\cdot\vec{\nabla})\vec{u}_1]=\int dS\xi\left[\frac{\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\vec{\tau}}_1\cdot\hat{n}}{\mu}-\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(1-2\hat{n}\hat{n})\cdot(\vec{\nabla}u_1^i)n^i\right]. \tag{A13}$$

Now, consider the second term on the right side of (A13) above. Use $(\vec{\nabla}u^i)n^i=\vec{\nabla}(\vec{u}\cdot\hat{n})-u^i\vec{\nabla}n^i$ and the definition of the curvature tensor $\vec{\vec{\mathcal{Q}}}$ given above to obtain

$$\begin{aligned}-\int dS\xi\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(1-2\hat{n}\hat{n})\cdot(\vec{\nabla}u_1^i)n^i&\\ =\int dS\xi[-\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\vec{u}_1\cdot\hat{n})+\hat{n}\cdot\vec{\vec{\tau}}_2\cdot\vec{\vec{\mathcal{Q}}}\cdot\vec{u}_1+\hat{n}\cdot\vec{\vec{\tau}}_2\cdot\hat{n}[\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1]],&\end{aligned} \tag{A14}$$

and we obtain the useful result

$$\begin{aligned}\int dS\xi\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(\hat{n}\cdot\vec{\nabla})\vec{u}_1=\int dS\xi\frac{\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\vec{\tau}}_1\cdot\hat{n}}{\mu}-\int dS\xi\hat{n}\cdot\vec{\vec{\tau}}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\vec{u}_1\cdot\hat{n})&\\ +\int dS\xi\hat{n}\cdot\vec{\vec{\tau}}_2\cdot\vec{\vec{\mathcal{Q}}}\cdot\vec{u}_1+\int dS\xi\hat{n}\cdot\vec{\vec{\tau}}_2\cdot\hat{n}[\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1].&\end{aligned} \tag{A15}$$

Finally, take this result and the same with the labels ''1'' and ''2'' exchanged, and substitute into (A10) to obtain equation (2.6).

APPENDIX B: THE CONTRIBUTION FROM THE SPHERE AT INFINITY FOR AN INFINITE ELASTIC MEDIUM

This is a generalization of the calculation presented in Appendix A of Ref. 2. The formal conventions presented in Ref. 12 (pp. 153–154) are used. As indicated in the reference, just as the acoustic and electromagnetic scattering problems can be decomposed so that scattering by each plane wave component of the incoming signal may be considered separately, so too can the elastodynamic scattering problem be decomposed, with the additional property that scattering by the incoming *p*-wave components and by the incoming *s*-wave components are decoupled as well. However, since incoming *p*-waves or *s*-waves scatter *into* waves of both types, when constructing a reciprocal theory, it will be convenient to consider incoming waves which consist of both *p*-waves and *s*-waves. However, it is sufficient to combine only plane waves incoming from a common direction $\hat{k}^{in}$.

Thus, an incoming plane wave is given by

$$\vec{u}^i=(k_pk_s^{-1})^{3/2}u^{ip}e^{ik_p\hat{k}^{in}\cdot\vec{r}}\hat{k}^{in}+u^{is}e^{ik_s\hat{k}^{in}\cdot\vec{r}}\hat{t}^{in}, \tag{B1}$$

$$\vec{\vec{\tau}}^i=ik_p(k_pk_s^{-1})^{3/2}[\lambda\vec{\vec{1}}+2\mu\hat{k}^{in}\hat{k}^{in}]u^{ip}e^{ik_p\hat{k}^{in}\cdot\vec{r}}+ik_s\mu[\hat{k}^{in}\hat{t}^{in}+\hat{t}^{in}\hat{k}^{in}]u^{is}e^{ik_s\hat{k}^{in}\cdot\vec{r}}, \tag{B2}$$

and the scattered wave has the form

$$\vec{u}^{sc}=(k_p k_s^{-1})^{3/2}\frac{A^p}{k_p}\frac{e^{ik_p r}}{r}\hat{r}+\frac{A^s}{k_s}\frac{e^{ik_s r}}{r}\hat{t}^{sc}, \tag{B3}$$

$$\vec{\vec{\tau}}^{sc}=i(k_p k_s^{-1})^{3/2}[\lambda\vec{\vec{1}}+2\mu\hat{r}\hat{r}]A^p\frac{e^{ik_p r}}{r}+i\mu[\hat{r}\hat{t}^{sc}+\hat{t}^{sc}\hat{r}]A^s\frac{e^{ik_s r}}{r}. \tag{B4}$$

The precise value of the unit vector $\hat{t}^{sc}$ depends on the details of the scattering process, and varies with $\hat{r}$, but it does not need to be specified for the present purposes. However, it is important to note that $\hat{k}^{in}\perp\hat{t}^{in}$ and $\hat{r}\perp\hat{t}^{sc}$. Furthermore,

- p denotes the primary wave (also known as pressure; or compressional; or longitudinal wave);
- s denotes the secondary wave (also known as shear; or equivolume wave);
- in denotes the incoming wave (in this appendix only; elsewhere in is used to denote the normal component of a vector labeled by i);
- sc denotes the scattered wave.

The wavenumbers are given by $k_p=\omega/c_p$, $k_s=\omega/c_s$, where

$$c_p=\sqrt{\frac{\lambda+2\mu}{\rho}},\quad c_s=\sqrt{\frac{\mu}{\rho}}$$

are the velocities of the two waves. Note that u^{ip} and u^{is} are completely independent.

Recall that we are calculating R_∞, the negative of the contribution from the sphere at infinity,

$$R_\infty=-\int_{S_\infty}dS(-\hat{r})\cdot[\vec{\vec{\tau}}_1\cdot\vec{u}_2-\vec{\vec{\tau}}_2\cdot\vec{u}_1], \tag{B5}$$

where

$$\int_{S_\infty}dS\Leftrightarrow\lim_{r\to\infty}r^2\int_0^{2\pi}d\phi\int_0^{\pi}\sin(\theta)d\theta\Leftrightarrow\lim_{r\to\infty}r^2\int d\Omega, \tag{B6}$$

with ϕ and θ polar angles and Ω a unit of solid angle. Use $\vec{u}=\vec{u}^{in}+\vec{u}^{sc}$ and $\vec{\vec{\tau}}=\vec{\vec{\tau}}^{in}+\vec{\vec{\tau}}^{sc}$ to obtain

$$R_\infty=\int_{S_\infty}dS[[\hat{r}\cdot(\vec{\vec{\tau}}_1^{in}\cdot\vec{u}_2^{in})+\hat{r}\cdot(\vec{\vec{\tau}}_1^{sc}\cdot\vec{u}_2^{sc})+\hat{r}\cdot(\vec{\vec{\tau}}_1^{in}\cdot\vec{u}_2^{sc})+\hat{r}\cdot(\vec{\vec{\tau}}_1^{sc}\cdot\vec{u}_2^{in})]-(1\leftrightarrow2)], \tag{B7}$$

where $(1\leftrightarrow2)$ stands for ''same as the preceding term with labels 1 and 2 exchanged.''

1. Consider $B_1=\int_{S_\infty}dS[\hat{r}\cdot(\vec{\vec{\tau}}_1^{in}\cdot\vec{u}_2^{in})-(1\leftrightarrow2)]$

The incoming plane waves are solutions to the elastodynamic equation of motion in absence of a scattering surface S_2, and, following the discussion above equation (2.4), the integrand is therefore divergence-free over all space (or the half-space as the case may be). Once again, application of Gauss's law leads us to conclude that $B_1=0$. [Another way of saying this: there is no scattering surface S_0, and equation (2.4) with S_0 being the null set remains valid with S set equal to S_∞.]

2. Consider $B_2=\int_{S_\infty} dS[\hat{r}\cdot(\vec{\vec{\tau}}_1^{sc}\cdot\vec{u}_2^{sc})-(1\leftrightarrow 2)]$

From (B3) and (B4), it follows that

$$\hat{r}\cdot(\vec{\vec{\tau}}_1^{sc}\cdot\vec{u}_2^{sc})=i\frac{(k_pk_s^{-1})^3}{k_p}(\lambda+2\mu)\frac{e^{2ik_pr}}{r^2}A_1^pA_2^p+i\mu\frac{e^{2ik_pr}}{r^2}A_1^sA_2^s(\hat{t}_1^{sc}\cdot\hat{t}_2^{sc}), \tag{B8}$$

which is completely symmetric under the exchange $(1\leftrightarrow 2)$, so that $B_2=0$.

It has thus been established that for elastodynamic waves, as for scalar and electrodynamic waves, only cross terms between incoming planar and scattered spherical waves contribute to the surface integral evaluated on the sphere at infinity.

3. Consider $B_3=\int_{S_\infty} dS[\hat{r}\cdot(\vec{\vec{\tau}}_1^{in}\cdot\vec{u}_2^{sc})-(1\leftrightarrow 2)]$

Use (B3), (B2), (B6), and the orthogonality relation $\hat{r}\perp\hat{t}^{sc}$ to obtain

$$\begin{aligned}B_3=\lim_{r\to\infty}\int d\Omega r^2\Bigg(\Bigg[&i\frac{k_p^3}{k_s^3}A_2^pu_1^{ip}(\lambda+2\mu(\hat{k}^{in}\cdot\hat{r})^2)\frac{e^{ik_pr}}{r}e^{ik_p\hat{k}^{in}\cdot\vec{r}}\\&+i\mu A_2^su_1^{is}(\hat{r}\cdot\hat{k}_1^{in}\hat{t}_1^{in}\cdot\hat{t}_2^{sc}+\hat{r}\cdot\hat{t}_1^{in}\hat{k}_1^{in}\cdot\hat{t}_2^{sc})\frac{e^{ik_sr}}{r}e^{ik_s\hat{k}^{in}\cdot\vec{r}}\\&+(\text{ a term proportional to }\hat{r}\cdot\hat{t}_1^{in})+(\text{ a term proportional to }\hat{k}_1^{in}\cdot\hat{t}_1^{sc})\Bigg]-(1\leftrightarrow 2)\Bigg).\end{aligned} \tag{B9}$$

It will shortly be shown that the terms proportional to $\hat{r}\cdot\hat{t}_1^{in}$ and $\hat{k}_1^{in}\cdot\hat{t}_1^{sc}$ do not contribute to the integral.

As in Appendix A of Ref. 2 use the stationary phase to evaluate the integral. This turns out to be exact in the limit $r\to\infty$. We use the following polar coordinates to evaluate the integral over the solid angle:

$$\hat{r}=\cos\,\phi\,\sin\,\theta\hat{x}+\sin\,\phi\,\sin\,\theta\hat{y}+\cos\,\theta\hat{z}\ .$$

Perform a change variables using $\eta\equiv\cos\,\theta$ and pick $\hat{x}=\hat{k}_a^{in}$ (where subscript a stands for 1 or 2 as needed). The axes are oriented so that $\hat{k}_a^{in}$ points in the direction of the x-axis rather than the more common choice of the z-axis so that the stationary phase points do not occur at the endpoints of an integration. Similarly, let ϕ go from $-\pi/2$ to $3\pi/2$ rather than 0 to 2π.

The result is a sum of integrals all with the basic form

$$\lim_{r\to\infty}\int_{-1}^{1}d\eta\int_{-\pi/2}^{3\pi/2}d\phi F(\hat{r})e^{ikr\sqrt{1-\eta^2}\,\cos\,\phi},$$

where $F(\hat{r})$ is slowly varying near the stationary phase points $\hat{r}=\pm\hat{k}_a^{in}$ Note that this equality combined with the orthogonality relations given above ($\hat{k}^{in}\perp\hat{t}^{in}$ and $\hat{r}\perp\hat{t}^{sc}$) implies that the terms proportional to $\hat{r}\cdot\hat{t}_1^{in}$ and $\hat{k}_1^{in}\cdot\hat{t}_1^{sc}$ do not contribute to integral (B9).

In the limit $r\to\infty$, the integrand is non-zero only within an arbitrarily small range about the stationary phase points, so we can extend the η- and ϕ-integrations to $\pm\infty$. To properly evaluate the limit, it is necessary to expand the argument of the exponential $ikr\sqrt{1-\eta^2}\,\cos\,\phi$ about the stationary phase variables. Also shift integration variables so that $\phi-\pi$ goes to ϕ where the expansion was about the point $\phi=\pi$. Now, we have

$$\lim_{r\to\infty}\int_{-1}^{1} d\eta \int_{-\pi/2}^{3\pi/2} d\phi\, rF(\hat{r})e^{ik\hat{k}_a\cdot\vec{r}}$$

$$= \lim_{r\to\infty}\sum_{+/-} e^{\pm ikr} rF(\pm\hat{k}_a)\int_{\infty}^{-\infty}\int_{\infty}^{-\infty} d\eta\, d\phi\, \exp\left[\frac{ikr}{2}(\eta \quad \phi)\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\begin{pmatrix}\eta\\ \phi\end{pmatrix}\right]$$

$$= -2\pi i \lim_{r\to\infty}\left[\left(\sum_{+/-} e^{\pm ikr}F(\pm\hat{k}_a)\right)\right]. \tag{B10}$$

Finally, using $\lambda+2\mu=\omega^2\rho/k_p^2$ and $\mu=\omega^2\rho/k_s$ we have

$$B_3=\left[\begin{matrix}+\\+\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_2^p(\pm\hat{k}_1^{in})u_1^{ip}e^{i(1\pm1)k_pr}\begin{matrix}+\\-\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_2^s(\pm\hat{k}_1^{in})u_1^{is}(\hat{t}_1^{in}\cdot\hat{t}_2^{sc})e^{i(1\pm1)k_sr}\right]-(1\leftrightarrow2). \tag{B11}$$

4. Consider $B_4=\int_{S_\infty} dS[\hat{r}\cdot(\overleftrightarrow{\tau}_1^{sc}\cdot\vec{u}_2^{in})-(1\leftrightarrow2)]$

Perform exactly the same procedure as that used in the previous section to obtain

$$B_4=\left[\begin{matrix}+\\-\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_1^p(\pm\hat{k}_2^{in})u_2^{ip}e^{i(1\pm1)k_pr}\begin{matrix}+\\+\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_1^s(\pm\hat{k}_2^{in})u_2^{is}(\hat{t}_1^{sc}\cdot\hat{t}_2^{in})e^{i(1\pm1)k_sr}\right]-(1\leftrightarrow2). \tag{B12}$$

5. Combine results

Combining $R_\infty=B_1+B_2+B_3+B_4$, we have

$$\begin{aligned}R_\infty=\Bigg[&\begin{matrix}+\\+\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_2^p(\pm\hat{k}_1^{in})u_1^{ip}e^{i(1\pm1)k_pr}\begin{matrix}+\\-\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_2^s(\pm\hat{k}_1^{in})u_1^{is}(\hat{t}_1^{in}\cdot\hat{t}_2^{sc})e^{i(1\pm1)k_sr}\\
&\begin{matrix}-\\-\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_1^p(\pm\hat{k}_2^{in})u_2^{ip}e^{i(1\pm1)k_pr}\begin{matrix}-\\+\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_1^s(\pm\hat{k}_2^{in})u_2^{is}(\hat{t}_2^{in}\cdot\hat{t}_1^{sc})e^{i(1\pm1)k_sr}\\
&\begin{matrix}+\\-\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_1^p(\pm\hat{k}_2^{in})u_2^{ip}e^{i(1\pm1)k_pr}\begin{matrix}+\\+\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_1^s(\pm\hat{k}_2^{in})u_2^{is}(\hat{t}_1^{sc}\cdot\hat{t}_2^{in})e^{i(1\pm1)k_sr}\\
&\begin{matrix}-\\+\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_2^p(\pm\hat{k}_1^{in})u_1^{ip}e^{i(1\pm1)k_pr}\begin{matrix}-\\-\end{matrix}\frac{2\pi\rho\omega^2}{k_s^3}A_2^s(\pm\hat{k}_1^{in})u_1^{is}(\hat{t}_2^{sc}\cdot\hat{t}_1^{in})e^{i(1\pm1)k_sr}\Bigg],\end{aligned} \tag{B13}$$

where there is an implicit $r\to\infty$ in this equation. When similar terms are summed together, they combine to give the equation

$$R_\infty=\frac{4\pi\rho\omega^2}{k_s^3}[A_2^p(-\hat{k}_1^{in})u_1^{ip}-A_2^s(-\hat{k}_1^{in})u_1^{is}(\hat{t}_1^{in}\cdot\hat{t}_2^{sc})-A_1^p(-\hat{k}_2^{in})u_2^{ip}+A_1^s(-\hat{k}_2^{in})u_2^{is}(\hat{t}_2^{in}\cdot\hat{t}_1^{sc})]. \tag{B14}$$

Note that terms proportional to $\exp(i2k_pr)$ have canceled. Now, define

$$\vec{u}_a^{ip}\equiv u^{ip}\hat{k}_a^{in};\quad \vec{u}_a^{is}\equiv u^{is}\hat{t}_a^{in},$$

$$\vec{A}_a^p(\hat{r})\equiv A_a^p(\hat{r})\hat{r};\quad \vec{A}_a^s(\hat{r})\equiv A_a^s(\hat{r})\hat{t}_a^{sc}, \tag{B15}$$

and so

$$R_\infty=\frac{4\pi\rho\omega^2}{k_s^3}[-\vec{u}_1^{ip}\cdot\vec{A}_2^p(-\hat{k}_1^{in})-\vec{u}_1^{is}\cdot\vec{A}_2^s(-\hat{k}_1^{in})+\vec{u}_2^{ip}\cdot\vec{A}_1^p(-\hat{k}_2^{in})+\vec{u}_2^{is}\cdot\vec{A}_1^s(-\hat{k}_2^{in})]. \quad \text{(B16)}$$

Now, following equations (2.63)–(2.64) in Ref. 12, assume that $\vec{A}^p$ and $\vec{A}^s$ depend linearly on $\vec{u}^{ip}$ and $\vec{u}^{is}$:

$$\begin{aligned}\vec{A}_a^p(-\hat{k}_b^{in})&=\vec{\vec{A}}_a^{pp}(-\hat{k}_b^{in},\hat{k}_a^{in})\cdot\vec{u}_a^{ip}+\vec{\vec{A}}_a^{ps}(-\hat{k}_b^{in},\hat{k}_a^{in})\cdot\vec{u}_a^{is},\\ \vec{A}_a^s(-\hat{k}_b^{in})&=\vec{\vec{A}}_a^{sp}(-\hat{k}_b^{in},\hat{k}_a^{in})\cdot\vec{u}_a^{ip}+\vec{\vec{A}}_a^{ss}(-\hat{k}_b^{in},\hat{k}_a^{in})\cdot\vec{u}_a^{is},\end{aligned} \quad \text{(B17)}$$

where, for now, the dependence on $\hat{t}_a$ and $\hat{t}_b$ has been suppressed. Note the dyad $\vec{\vec{A}}$ does *not* depend on the magnitudes u_a^{ip} and u_a^{is}. Now,

$$\begin{aligned}R_\infty=\frac{4\pi\rho\omega^2}{k_s^3}\{&\vec{u}_2^{ip}\cdot[-[\vec{\vec{A}}_2^{pp}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t+\vec{\vec{A}}_1^{pp}(-\hat{k}_2^{in},\hat{k}_1^{in})]\cdot\vec{u}_1^{ip}\\ &+\vec{u}_2^{ip}\cdot[-[\vec{\vec{A}}_2^{ps}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t+\vec{\vec{A}}_1^{sp}(-\hat{k}_2^{in},\hat{k}_1^{in})]\cdot\vec{u}_1^{ip}\\ &+\vec{u}_2^{ip}\cdot[-[\vec{\vec{A}}_2^{sp}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t+\vec{\vec{A}}_1^{ps}(-\hat{k}_2^{in},\hat{k}_1^{in})]\cdot\vec{u}_1^{ip}\\ &+\vec{u}_2^{ip}\cdot[-[\vec{\vec{A}}_2^{ss}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t+\vec{\vec{A}}_1^{ss}(-\hat{k}_2^{in},\hat{k}_1^{in})]\cdot\vec{u}_1^{ip}\},\end{aligned} \quad \text{(B18)}$$

where superscript t stands for ''transpose the matrix.'' Setting $S_1=S_2$, it follows that $R_\infty=0$. With u_1, u_2 properly set to 0 or 1, we recover reciprocity relations (2.66)–(2.69) or Ref. 12:

$$\begin{aligned}[\vec{\vec{A}}_2^{pp}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t&=\vec{\vec{A}}_2^{pp}(-\hat{k}_2^{in},\hat{k}_1^{in}),\\ [\vec{\vec{A}}_2^{ps}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t&=\vec{\vec{A}}_2^{sp}(-\hat{k}_2^{in},\hat{k}_1^{in}),\\ [\vec{\vec{A}}_2^{sp}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t&=\vec{\vec{A}}_2^{ps}(-\hat{k}_2^{in},\hat{k}_1^{in}),\\ [\vec{\vec{A}}_2^{ss}(-\hat{k}_1^{in},\hat{k}_2^{in})]^t&=\vec{\vec{A}}_2^{ss}(-\hat{k}_2^{in},\hat{k}_1^{in}),\end{aligned} \quad \text{(B19)}$$

where note that the subscript 2 on $\vec{\vec{A}}$ reminds us that the scattering surface is S_2.

Return to the problem $S_1 \neq S_2$. Define

$$\delta\vec{\vec{A}}\equiv\vec{\vec{A}}_1-\vec{\vec{A}}_2,$$

and let

$$\begin{aligned}-\hat{k}_2^{in}&\equiv\vec{q},\\ \hat{k}_1^{in}&\equiv\vec{k}.\end{aligned} \quad \text{(B20)}$$

This gives us the important result

$$R_\infty=\frac{4\pi\rho\omega^2}{k_s^3}[\vec{u}_2^{ip}\cdot\delta\vec{\vec{A}}^{pp}\cdot\vec{u}_1^{ip}+\vec{u}_2^{is}\cdot\delta\vec{\vec{A}}^{sp}\cdot\vec{u}_1^{ip}+\vec{u}_2^{ip}\cdot\delta\vec{\vec{A}}^{ps}\cdot\vec{u}_1^{is}+\vec{u}_2^{is}\cdot\delta\vec{\vec{A}}^{ss}\cdot\vec{u}_1^{is}]. \quad \text{(B21)}$$

Alternately, use

$$\vec{u}_2^{ip} = -u_2^{ip}\hat{q}; \quad \vec{u}_1^{ip} = u_1^{ip}\hat{k},$$

$$\vec{u}_2^{is} = u^{is}\hat{t}_{-\hat{q}} = u_2^{is}\hat{t}_{\hat{q}}^{*}; \quad \vec{u}_1^{is} = u_1^{is}\hat{t}_{\hat{k}},$$

and define

$$\begin{aligned}
T^{pp}(\hat{q};\hat{k}) &\equiv \frac{4\pi}{k_p}(-\hat{q})\cdot\vec{\vec{A}}^{pp}(\hat{q},\hat{k})\cdot\hat{k},\\
T^{sp}(\hat{q},\hat{t}_{\hat{q}};\hat{k}) &\equiv \frac{4\pi}{k_s}\hat{t}_{\hat{q}}^{*}\cdot\vec{\vec{A}}^{sp}(\hat{q},\hat{k})\cdot\hat{k},\\
T^{ps}(\hat{q};\hat{k},\hat{t}_{\hat{k}}) &\equiv \frac{4\pi}{k_p}(-\hat{q})\cdot\vec{\vec{A}}^{ps}(\hat{q},\hat{k})\cdot\hat{t}_{\hat{k}},\\
T^{ss}(\hat{q},\hat{t}_{\hat{q}};\hat{k},\hat{t}_{\hat{k}}) &\equiv \frac{4\pi}{k_s}\hat{t}_{\hat{q}}^{*}\cdot\vec{\vec{A}}^{ss}(\hat{q},\hat{k})\cdot\hat{t}_{\hat{k}}.
\end{aligned} \tag{B22}$$

Note that we have absorbed the factor 1/ outgoing wavenumber [see equation (B3)] into the definition of the scattering amplitude T, bringing it in line with the convention pursued in Ref. 2–4. Also note that the $\hat{t}$ dependence has now been inserted explicitly. It is left out in some instances since a p-wave has no polarization, and it will be shown below that (as with the reciprocity calculation outlined above and in Ref. 12) a judicious choice of u_a^{ip} and u_a^{is} completely decouples the different channels pp, ps, sp, and ss. Also note that reversing the direction of the wavevector is the same as changing the sign of the phase of the plane wave which implies taking the complex conjugate of the amplitude. We follow the convention that the phase shift of the s-wave relative to the p-wave is in the unit polarization vector $\hat{t}$, and thus $\hat{t}_{-\hat{q}} = \hat{t}_{\hat{q}}^{*}$. We now have the very important result

$$\begin{aligned}
R_\infty = \frac{\rho\omega^2}{k_s^3}[&k_p u_2^{ip}\,\delta T^{pp}(\hat{q};\hat{k})u_1^{ip} + k_s u_2^{is}\,\delta T^{sp}(\hat{q},\hat{t}_{\hat{q}};\hat{k})u_1^{ip} + k_p u_2^{ip}\,\delta T^{ps}(\hat{q};\hat{k},\hat{t}_{\hat{k}})u_1^{is}\\
&+ k_s u_2^{is}\,\delta T^{ss}(\hat{q},\hat{t}_{\hat{q}};\hat{k},\hat{t}_{\hat{k}})u_1^{is}].
\end{aligned} \tag{B23}$$

Finally, to find the four δT's, let

$$\begin{matrix}(k_p k_s^{-1})^{3/2}u_1^{ip} \\ u_1^{is}\end{matrix}\;;\;\begin{matrix}(k_p k_s^{-1})^{3/2}u_2^{ip} \\ u_2^{is}\end{matrix} = \begin{cases}1,\\ 0,\end{cases}$$

in 1,2 pairs, and solve the resulting four independent problems separately. Specifically, recall that R_∞ is an integral over the scattering surface of the solutions, *given* certain specified plane waves. Thus writing R_∞ as a function of the u^i's:

$$R_\infty = R_\infty([(k_p k_s^{-1})^{3/2}u_2^{ip}], u_2^{is}; [(k_p k_s^{-1})^{3/2}u_1^{ip}], u_1^{is}),$$

we have

$$\delta T^{pp}(\hat{q};\hat{k}) = R_\infty(1,0;1,0)\left[\frac{k_p^2}{\rho\omega^2}\right],$$

$$\delta T^{sp}(\hat{q},\hat{t}_{\hat{q}};\hat{k}) = R_\infty(0,1;1,0)\left[\frac{k_s^{1/2}k_p^{3/2}}{\rho\omega^2}\right],$$

$$\delta T^{ps}(\hat{q};\hat{k},\hat{t}_{\hat{k}}) = R_\infty(1,0;0,1)\left[\frac{k_s^{3/2}k_p^{1/2}}{\rho\omega^2}\right], \tag{B24}$$

$$\delta T^{ss}(\hat{q},\hat{t}_{\hat{q}};\hat{k},\hat{t}_{\hat{k}}) = R_\infty(0,1;0,1)\left[\frac{k_s^2}{\rho\omega^2}\right].$$

Since the right hand side cannot depend on $\hat{t}_a$ if $u_a^{is}=0$, we now see why some $\hat{t}_a$'s were left out beginning with equation (B22).

As in Ref. 2, by choosing $\xi=\hat{n}$, we obtain new manifestly reciprocal expressions for $\vec{Q}^{pp}T^{pp}$,$\vec{Q}^{sp}T^{sp}$,$\vec{Q}^{ps}T^{ps}$, and $\vec{Q}^{ss}T^{ss}$ where $\vec{Q}^{pp}\equiv k_p\hat{k}-k_p\hat{q}$, $\vec{Q}^{ps}\equiv k_s\hat{k}-k_p\hat{q}$, etc . The bottom line is that in this formulation, the different channels pp, sp, ps, and ss are treated separately. The result is a scattering matrix which solves the general problem.

Note that acoustics essentially involves finding T^{pp} (scattering from scalar wave to scalar wave) whereas the electromagnetic problem (described in Ref. 2) more or less amounts to finding T^{ss} (scattering from transverse vector wave to transverse vector wave). The elastodynamic problem differs in that it involves more than one such channel.

APPENDIX C: DETAILS IN DERIVATION OF EQUATION (2.8)

Begin with equation (2.6) with the $O(\xi^0)$ term given by (2.7). Use the boundary condition $\hat{n}\cdot\vec{\tau}\cdot(1-\hat{n}\hat{n})=0$ to drop the 3rd, 4th, and 7th rows of (2.6). It is also necessary to recall the definition of the curvature tensor (A9), and to insert $\hat{n}\hat{n}$ between $\vec{\tau}_1$ and $\vec{u}_2$ in the 2nd row of (2.6). Next, use equation (A1) to replace $\hat{n}_1$ in $\hat{n}_1\cdot\vec{u}_2(\vec{x}_2)$ and $\hat{n}_2$ in $\hat{n}_2\cdot\vec{u}_1(\vec{x}_1)$. The result is

$$R_\infty = \text{O}(\xi^0)\text{ terms which cancel at the interface } -\int dS\hat{n}\cdot\vec{\tau}_1\nabla\xi\cdot(1-\hat{n}\hat{n})\cdot\vec{u}_2$$
$$-\int dS\hat{n}\cdot\vec{\tau}_2\nabla\xi\cdot(1-\hat{n}\hat{n})\cdot\vec{u}_1 + O(\xi)\text{ terms included previously in equation (2.6).} \tag{C1}$$

Note that $I=-\int dS\hat{n}\cdot\vec{\tau}_1\cdot\nabla\xi\cdot(1-\hat{n}\hat{n})\cdot\vec{u}_2$ and the next term with labels 1 and 2 exchanged have the same sign (generally such pairs have come with opposite signs). This is no misprint; it follows from the fact that equation (A1) is not symmetric under the exchange $(1\leftrightarrow 2)$.

Consider

$$I=-\int dS\hat{n}\cdot\vec{\tau}_1\cdot\nabla\xi\cdot(1-\hat{n}\hat{n})\cdot\vec{u}_2.$$

We follow the technique outlined in Appendices B and C in Ref. 2. To integrate this result by parts, write dS as d^2x/n_z where n_z is the z-component of $\hat{n}$ for some coordinate system and d^2x is $dx\,dy$ for the same coordinate system. Perform the integration by parts. Use from Ref. 2

$$\nabla\cdot\left(\frac{\vec{\mathbf{1}}-\hat{n}\hat{n}}{n_z}\right)=\frac{\hat{n}}{n_z}\,\text{Tr}(\vec{\varrho}) \tag{C2}$$

[see the comments below equation (C11), or equation (B21) and the comment above (B23); all in Ref. 2), and also recall equation (A6). Putting these results together, we have

$$I=\int dS\xi\ \mathrm{Tr}(\vec{\vec{g}})\hat{n}\cdot\vec{u}_2\tau^1_{nn}+\int dS\xi(\vec{\vec{1}}-\hat{n}\hat{n}):\vec{\nabla}\vec{u}_2\tau^1_{nn}+\int dS\xi\vec{u}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}\tau^1_{nn}\ . \tag{C3}$$

Get the same result with labels 1 and 2 exchanged. Note that the terms involving $\hat{n}\hat{n}:\vec{\nabla}\vec{u}$ will cancel the 6th row of equation (2.6). To recapitulate, we have succeeded in eliminating the 3rd, 4th, 6th, and 7th rows of equation (2.6). Substitute into equation (2.6) the remaining results obtained so far in this appendix to obtain

$$\begin{aligned}R_\infty=&\int_{S_2}dS_2[\hat{n}_1\cdot\vec{\vec{\tau}}_1(\vec{x_1})\cdot\hat{n}_1\hat{n}_2\cdot\vec{u}_2(\vec{x_2})-\hat{n}_2\cdot\vec{\vec{\tau}}_2(\vec{x_2})\cdot\hat{n}_2\hat{n}_1\cdot\vec{u}_1(\vec{x_1})]+\int dS\xi\ \mathrm{Tr}(\vec{\vec{g}})\hat{n}\cdot\vec{u}_1\hat{n}\cdot\vec{\vec{\tau}}_2\cdot\hat{n}\\&+\int dS\xi\rho\omega^2\vec{u}_1\cdot\vec{u}_2-\int dS\xi\vec{\vec{\tau}}_1:\vec{\nabla}\vec{u}_2+\int dS\xi[(\vec{\nabla}\cdot\vec{u}_2)\tau^1_{nn}+(\vec{\nabla}\cdot\vec{u}_1)\tau^2_{nn}]\\&+\int dS\xi[\vec{u}_2\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\tau^1_{nn})+\vec{u}_1\cdot(\vec{\vec{1}}-\hat{n}\hat{n})\cdot\vec{\nabla}(\tau^2_{nn})].\end{aligned} \tag{C4}$$

Since $\vec{\vec{\tau}}$ is symmetric, we have (summing repeated indices i,j; covariance/contravariance notation is *NOT* being used here in this paper)

$$\begin{aligned}\vec{\vec{\tau}}_1:\vec{\nabla}\vec{u}_2=\frac{1}{2}\tau_1^{ij}(\nabla^i u_2^j+\nabla^j u_2^i)&=\frac{1}{2}\tau_1^{ij}\frac{\tau_2^{ij}-\lambda\vec{\nabla}\cdot\vec{u}_2\delta^{ij}}{\mu}\\&=\frac{\vec{\vec{\tau}}_1:\vec{\vec{\tau}}_2}{2\mu}-\frac{\lambda}{2\mu}\mathrm{Tr}(\vec{\vec{\tau}}_1)\vec{\nabla}\cdot\vec{u}_2\\&=\frac{\vec{\vec{\tau}}_1:\vec{\vec{\tau}}_2}{2\mu}-\frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\vec{\vec{\tau}}_1)\ \mathrm{Tr}(\vec{\vec{\tau}}_2)}{3\lambda+2\mu},\end{aligned} \tag{C5}$$

and equation (2.8) follows immediately.

APPENDIX D: DETAILS IN THE DERIVATION OF EQUATION (2.9)

Note the fact that for a standard acoustic field in a fluid,

$$\tau_{nn}=-P\Rightarrow\vec{\nabla}(\tau_{nn})=-\vec{\nabla}P=-\rho\omega^2\vec{u}.$$

Also note the following three lemmas *valid for an acoustic field in a fluid.*

Lemma 1:

$$\frac{\vec{\vec{\tau}}_1:\vec{\vec{\tau}}_2}{2\mu}=\frac{3\lambda^2}{2\mu}\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2+\frac{2k^2}{\rho\omega^2}\tau^1_{nn}\tau^2_{nn}+O(\mu). \tag{D1}$$

Lemma 2:

$$\frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\vec{\vec{\tau}}_1)\ \mathrm{Tr}(\vec{\vec{\tau}}_2)}{3\lambda+2\mu}=\frac{3\lambda^2}{2\mu}\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2+\frac{k^2}{\rho\omega^2}\tau^1_{nn}\tau^2_{nn}+O(\mu). \tag{D2}$$

Lemma 3:

$$\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1)}{3\lambda+2\mu}\tau^2_{nn}+\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_2)}{3\lambda+2\mu}\tau^1_{nn}=\frac{2k^2}{\rho\omega^2}\tau^1_{nn}\tau^2_{nn}+O(\mu). \tag{D3}$$

Given these results, (2.9) follows immediately from (2.8).

Proof of Lemma 1: Begin with

$$\overleftrightarrow{\tau}_1:\overleftrightarrow{\tau}_2=\tau^1_{nn}\tau^2_{nn}+2\hat{n}\cdot\overleftrightarrow{\tau}_1\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\tau}_2\cdot\hat{n}+\overleftrightarrow{\tau}^T_1:\overleftrightarrow{\tau}^T_2,$$

where the superscript T denotes components perpendicular to the normal $\hat{n}$ [see also equation (2.13)].

The ''cross term'' $2\hat{n}\cdot\overleftrightarrow{\tau}_1\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\tau}_2\cdot\hat{n}$ is zero on S by the slip boundary condition $\hat{n}\cdot\tau_1\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})=0$. It is also worth noting that, even away from the surface, any off-diagonal component of $\overleftrightarrow{\tau}$ is automatically $O(\mu)$ so a product of such terms must be $O(\mu^2)$.

From the definition of $\overleftrightarrow{\tau}$, equation (2.1), we have

$$\tau_{nn}=\lambda\vec{\nabla}\cdot\vec{u}+2\mu\hat{n}\hat{n}:\vec{\nabla}\vec{u}.$$

From $\vec{u}=\vec{\nabla}P/\rho\omega^2$ and the Helmholtz equation for P, we have

$$\lambda\vec{\nabla}\cdot\vec{u}=-P+O(\mu)(=\tau_{nn}+O(\mu)), \tag{D4}$$

and thus

$$\tau^1_{nn}\tau^2_{nn}=\lambda^2\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2-\frac{2\mu}{\rho\omega^2}(\hat{n}\hat{n}:\vec{\nabla}\vec{\nabla}P_2)P_1-\frac{2\mu}{\rho\omega^2}(\hat{n}\hat{n}:\vec{\nabla}\vec{\nabla}P_1)P_2+O(\mu^2). \tag{D5}$$

Now, consider

$$\overleftrightarrow{\tau}^T_1:\overleftrightarrow{\tau}^T_2=\tau^1_{t_1t_1}\tau^2_{t_1t_1}+\tau^1_{t_2t_2}\tau^2_{t_2t_2}+2\tau^1_{t_1t_2}\tau^2_{t_2t_1},$$

where the indices t_1 and t_2 label components in the ''T'' direction (i.e., $\perp\hat{n}$). Note once again that the cross term is $O(\mu^2)$. From equation (2.1), we have

$$\tau_{t_it_i}=\lambda\vec{\nabla}\cdot\vec{u}+\frac{2\mu}{\rho\omega^2}\hat{t}_i\hat{t}_i:\vec{\nabla}\vec{\nabla}P+O(\mu^2).$$

Consequently, also recalling equation (D4), we have

$$\tau^1_{t_it_i}\tau^2_{t_it_i}=\lambda^2\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2-\frac{2\mu}{\rho\omega^2}(\hat{t}_i\hat{t}_i:\vec{\nabla}\vec{\nabla}P_2)P_1-\frac{2\mu}{\rho\omega^2}(\hat{t}_i\hat{t}_i:\vec{\nabla}\vec{\nabla}P_1)P_2+O(\mu^2). \tag{D6}$$

Summing our results, and using

$$\hat{t}_1\hat{t}_1+\hat{t}_2\hat{t}_2+\hat{n}\hat{n}=1, \tag{D7}$$

as well as

$$1:\vec{\nabla}\vec{\nabla}P=\nabla^2P=-k^2P=k^2\tau_{nn},$$

to simplify the result, we have equation (D1).

Proof of Lemma 2: Note that

$$\mathrm{Tr}(\overleftrightarrow{\tau}) = (3\lambda + 2\mu)\vec{\nabla}\cdot\vec{u},$$

to obtain

$$\frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1)\,\mathrm{Tr}(\overleftrightarrow{\tau}_2)}{3\lambda+2\mu} = \frac{\lambda}{2\mu}(3\lambda+2\mu)\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2 = \frac{3\lambda^2}{2\mu}\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2 + \lambda\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2. \quad \text{(D8)}$$

Simplify using (D4) and $1/\lambda = k^2/\rho\omega^2$ to obtain equation (D2).

Proof of Lemma 3: We have

$$\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1)}{3\lambda+2\mu}\tau^2_{nn} + \frac{\mathrm{Tr}(\overleftrightarrow{\tau}_2)}{3\lambda+2\mu}\tau^1_{nn} = 2\lambda\vec{\nabla}\cdot\vec{u}_1\vec{\nabla}\cdot\vec{u}_2 = \frac{2}{\lambda}P_1P_2 + O(\mu) = \frac{2k^2}{\rho\omega^2}\tau^1_{nn}\tau^2_{nn} + O(\mu). \quad \text{(D9)}$$

APPENDIX E: DETAILS IN THE DERIVATION OF EQUATION (2.16)

Once again, begin with equation (2.6), and simplify using equation (C5) as well as the equation

$$\frac{\tau_{nn}}{2\mu} - \frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\overleftrightarrow{\tau})}{3\lambda+2\mu} = \hat{n}\hat{n}:\vec{\nabla}\vec{u},$$

obtained directly from the definition of the stress tensor, equation (2.1). Thus we have

$$\begin{aligned} R_\infty = {} & \text{terms which are zero or cancel at the boundary} + \int dS\,\xi\rho\omega^2\vec{u}_1\cdot\vec{u}_1 \\ & + \int dS\,\xi\left[-\frac{\overleftrightarrow{\tau}_1:\overleftrightarrow{\tau}_2}{2\mu} + \frac{\lambda}{2\mu}\frac{\mathrm{Tr}(\overleftrightarrow{\tau}_1)\,\mathrm{Tr}(\overleftrightarrow{\tau}_2)}{3\lambda+2\mu}\right] + \int dS\,\xi\left[\frac{\tau^1_{nn}\tau^2_{nn}}{\mu} + \frac{2}{\mu}\overleftrightarrow{\tau}_1\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\tau}_2\cdot\hat{n}\right] \\ & - \int dS\,\xi\left[\frac{\lambda}{2\mu}\frac{\tau^2_{nn}\,\mathrm{Tr}(\overleftrightarrow{\tau}_1)}{3\lambda+2\mu} + \frac{\lambda}{2\mu}\frac{\tau^1_{nn}\,\mathrm{Tr}(\overleftrightarrow{\tau}_2)}{3\lambda+2\mu}\right]. \end{aligned} \quad \text{(E1)}$$

Note that

$$\overleftrightarrow{\tau}_1:\overleftrightarrow{\tau}_2 = \overleftrightarrow{\tau}^T_1:\overleftrightarrow{\tau}^T_2 + \tau^1_{nn}\tau^2_{nn} + 2\tau^1_{nt_1}\tau^2_{t_1n} + 2\tau^1_{nt_2}\tau^2_{t_2n} = \overleftrightarrow{\tau}^T_1:\overleftrightarrow{\tau}^T_2 + \tau^1_{nn}\tau^2_{nn} + 2\hat{n}\cdot\overleftrightarrow{\tau}_2\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\tau}_1\cdot\hat{n}. \quad \text{(E2)}$$

This equality will combine the 1st term in the 3rd line with the 4th line of equation (E1). Also to combine the second term in the 3rd line with the last line of (E1), let $a=\tau_{nn}$, $b=\tau_{t_1t_1}$, $c=\tau_{t_2t_2}$, to obtain

$$\begin{aligned} & \mathrm{Tr}(\overleftrightarrow{\tau}_1)\,\mathrm{Tr}(\overleftrightarrow{\tau}_2) - \tau^1_{nn}\,\mathrm{Tr}(\overleftrightarrow{\tau}_2) - \tau^2_{nn}\,\mathrm{Tr}(\overleftrightarrow{\tau}_1) \\ & \quad = (a_1+b_1+c_1)(a_2+b_2+c_2) - a_1(a_2+b_2+c_2) - a_2(a_1+b_1+c_1) \\ & \quad = (b_1+c_1)(b_2+c_2) - a_1a_2 = \mathrm{Tr}(\overleftrightarrow{\tau}^T_1)\,\mathrm{Tr}(\overleftrightarrow{\tau}^T_2) - \tau^1_{nn}\tau^2_{nn}. \end{aligned} \quad \text{(E3)}$$

Combining these results, we are left with equation (2.16).

APPENDIX F: DETAILS OF DERIVATION OF (2.18)

Setting $\vec{u}=0$ in (2.16), we are left with the last four lines only. To evaluate these, we need to obtain two intermediate results.

1. Evaluate $\overleftrightarrow{\tau}_1^T : \overleftrightarrow{\tau}_2^T$ when $\vec{u}=0$

Expanding this quantity, we have

$$\overleftrightarrow{\tau}_1^T : \overleftrightarrow{\tau}_2^T = \tau^1_{t_1t_1}\tau^2_{t_1t_1} + \tau^1_{t_2t_2}\tau^2_{t_2t_2} + 2\tau^1_{t_2t_1}\tau^2_{t_2t_1}. \tag{F1}$$

Consider $\tau_{t_2t_1} = \mu \hat{t}_1 \hat{t}_2 : (\vec{\nabla}\vec{u} + \vec{u}\vec{\nabla}_{\hookleftarrow})$. Recall $\vec{u}=0$ implies that $\vec{\nabla}u^i \| \hat{n} \perp \hat{t}$ so that $\hat{t}\cdot\vec{\nabla}\vec{u}=0$ and $\tau_{t_2t_1}=0$.

Next, consider $\tau_{t_1t_1} = \tau_{t_2t_2} = \lambda\vec{\nabla}\cdot\vec{u}$, where again we have used $\vec{\nabla}u^i \perp \hat{t}$. Since $\vec{\nabla}u^i \| \hat{n}$ we have $(\overleftrightarrow{\mathbf{1}} - \hat{n}\hat{n}) : \vec{\nabla}\vec{u} = 0$, or $\vec{\nabla}\cdot\vec{u} = \hat{n}\hat{n} : \vec{\nabla}\vec{u}$ (note, this result is only valid for the special case $\vec{u}=0$ on S). Thus $\tau_{nn} = (\lambda + 2\mu)\vec{\nabla}\cdot\vec{u}$, and

$$\tau_{t_1t_1} = \tau_{t_2t_2} = \lambda\vec{\nabla}\cdot\vec{u} = \frac{\lambda\tau_{nn}}{\lambda+2\mu}. \tag{F2}$$

Substituting into equation (F1), it follows that

$$\overleftrightarrow{\tau}_1^T : \overleftrightarrow{\tau}_2^T = \frac{2\lambda^2}{(\lambda+2\mu)^2}\tau^1_{nn}\tau^2_{nn}. \tag{F3}$$

2. Evaluate Tr($\overleftrightarrow{\tau}^T$)

From equation (F2), it follows immediately that

$$\mathrm{Tr}(\overleftrightarrow{\tau}^T) = \frac{2\lambda}{\lambda+2\mu}\tau_{nn}.$$

3. Combine results

Substituting these results into (2.16) we find

$$R_\infty = \int dS\xi \left[\frac{\hat{n}\cdot\overleftrightarrow{\tau}_1\cdot(\overleftrightarrow{\mathbf{1}} - \hat{n}\hat{n})\cdot\overleftrightarrow{\tau}_2\cdot\hat{n}}{\mu} + \frac{\tau^1_{nn}\tau^2_{nn}}{2\mu}\left(1 - \frac{2\lambda^2}{(\lambda+2\mu)^2} + \frac{4\lambda^3}{3\lambda+2\mu}\frac{1}{(\lambda+2\mu)^2} - \frac{\lambda}{3\lambda+2\mu}\right)\right]. \tag{F4}$$

The object in parentheses on the second line of equation (F4) simplifies to $2\mu/(\lambda+2\mu)$, and equation (2.18) follows immediately. Note that this result is valid for the zero displacement ($\vec{u}=0$) boundary condition only.

APPENDIX G: THE SOLID-SOLID BOUNDARY CONDITION FOR THE OFF-DIAGONAL ELEMENT OF $\overleftrightarrow{\tau}^T$

On the interface between two elastic solids labeled I and II, the off-diagonal element of $\overleftrightarrow{\tau}^T$, $\tau_{t_1t_2}$, obeys a simple boundary condition:

$$\frac{\tau^I_{t_1t_2}}{\mu_I} - \frac{\tau^{II}_{t_1t_2}}{\mu_{II}} = 0. \tag{G1}$$

The proof is fairly simple. Note that

$$\tau_{t_1t_2}=\mu\hat{t}_1\cdot(\vec{\nabla}\vec{u})\cdot\hat{t}_2+\mu\hat{t}_2\cdot(\vec{\nabla}\vec{u})\cdot\hat{t}_1,$$

so that

$$\frac{\tau^I_{t_1t_2}}{\mu_I}-\frac{\tau^{II}_{t_1t_2}}{\mu_{II}}=\hat{t}_1\cdot[\vec{\nabla}(\vec{u}^I-\vec{u}^{II})]\cdot\hat{t}_2+(1\leftrightarrow 2)=0,$$

since $\vec{u}^I-\vec{u}^{II}=0$ on S, and therefore $\vec{\nabla}(\vec{u}^I-\vec{u}^{II})^i\|\hat{n}\perp\hat{t}$. Q.E.D.

APPENDIX H: LEMMA USEFUL FOR EXPRESSING α IN TERMS OF A_S

Note that

$$k_s^2=\frac{c_p^2}{c_s^2}k_p^2=\frac{\lambda_{II}+2\mu_{II}}{\mu_{II}},$$

so that

$$\frac{1}{1-k_s^2/2|\mathbf{k}_\perp|^2}=\frac{1}{1-(1+\lambda_{II}/2\mu_{II})(k_p^2/|\mathbf{k}_\perp|^2)}=\frac{|\mathbf{k}_\perp|^2}{-k_{pn}^2-(\lambda_{II}/2\mu_{II})k_p^2}$$
$$=\frac{|\mathbf{k}_\perp|^2 2\mu_{II}}{-k_p^2(\lambda_{II}+2\mu_{II}(k_{pn}^2/k_p^2))}=\frac{|\mathbf{k}_\perp|^2 2\mu_{II}}{k_p\alpha}. \tag{H1}$$

It follows immediately that

$$\alpha=\frac{k_s}{k_p}\frac{2\mu_{II}}{A_S}\frac{k_{pn}}{k_p}|\mathbf{k}_\perp|. \tag{H2}$$

APPENDIX I: SIMPLE FORM OF THE SCATTERING AMPLITUDE FOR SMALL SLOPE AND "LOCAL" TWO-SCALE APPROXIMATIONS

In this appendix, equation (3.20) will be derived from equation (2.14) by making the approximation that the surface is locally flat. In order to do so, it is necessary to simplify the term involving $\overleftrightarrow{\tau}_1^{II}:\overleftrightarrow{\tau}_2^{II}$. *Suppressing the label II* (i.e., inside the solid) for now, and summing repeated indices j and k, we have $\overleftrightarrow{\tau}_1^{II}:\overleftrightarrow{\tau}_2^{II}=\tau_1^{jk}\tau_2^{jk}$. Recall that $\tau^{jk}=\lambda\vec{\nabla}\cdot\vec{u}\,\delta^{jk}+\mu(\nabla^j u^k+\nabla^k u^j)$ and define $\sigma^{jk}\equiv\nabla^j u^k+\nabla^k u^j$. It follows that

$$\tau_1^{jk}\tau_2^{jk}=(3\lambda^2+4\mu\lambda)(\vec{\nabla}\cdot\vec{u}_1)(\vec{\nabla}\cdot\vec{u}_2)+\sigma_1^{jk}\sigma_2^{jk}, \tag{I1}$$

where use was made of $\delta^{jk}\delta^{jk}=3$ and $\sigma^{jk}\delta^{jk}=2\mu\vec{\nabla}\cdot\vec{u}$. Next, we consider $\overleftrightarrow{\sigma}_1:\overleftrightarrow{\sigma}_2=\sigma_1^{jk}\sigma_2^{jk}$. We can decompose $\overleftrightarrow{\sigma}$ using

$$\overleftrightarrow{\sigma}=(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\sigma}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})+\hat{n}\hat{n}\cdot\overleftrightarrow{\sigma}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})+(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\sigma}\cdot\hat{n}\hat{n}+\sigma_{nn}\hat{n}\hat{n}.$$

Recall the boundary condition

$$0=\hat{n}\hat{n}\cdot\overleftrightarrow{\tau}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})=\hat{n}\hat{n}\cdot\overleftrightarrow{\sigma}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})$$

and define

$$\overleftrightarrow{\sigma}^T\equiv(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\overleftrightarrow{\sigma}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})$$

to obtain

$$\vec{\vec{\sigma}} \equiv \vec{\vec{\sigma}}^T + \sigma_{nn}\hat{n}\hat{n}$$

and thus

$$\vec{\vec{\sigma}}^1 : \vec{\vec{\sigma}}^2 = \vec{\vec{\sigma}}^{1T} : \vec{\vec{\sigma}}^{2T} + \sigma^1_{nn}\sigma^2_{nn}. \tag{I2}$$

Now we need σ^T_{jk} evaluated for the ''locally flat'' scattering surface approximation. Using the equation for $\vec{u}^{II}$ (3.8), and recalling

$$(\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{k}_p = (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{k}_s = (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{k}_i = \mathbf{k}_\perp ,$$

we have

$$(\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{\nabla} \equiv \nabla_\perp \propto \mathbf{k}_\perp$$

(to be precise, the transverse component of the gradient brings down $i\mathbf{k}_\perp$). From equation (3.22), we also have (on the boundary)

$$\vec{u}^{II}_T \propto \mathbf{k}_\perp ,$$

so that (still suppressing the label ''*II*'')

$$\nabla^j_\perp u^k_\perp + \nabla^k_\perp u^j_T = 2\nabla^j_\perp u^k_T .$$

Thus, since $\nabla_\perp$ brings down an $i\mathbf{k}_\perp$ (or a $-i\mathbf{q}_\perp$), we have

$$\begin{aligned} \vec{\vec{\sigma}}^{1T} : \vec{\vec{\sigma}}^{2T} &= i\mathbf{k}^j_\perp u^k_{1T}(-i\mathbf{q}^j_\perp) u^k_{2T} 4\mu^2 = \mathbf{k}_\perp \cdot \mathbf{q}_\perp \vec{u}_1 \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{u}_2 4\mu^2 \\ &= 4\mu^2 \vec{k}_i \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{q}_i \vec{u}_1 \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{u}_2 . \end{aligned} \tag{I3}$$

To complete our evaluation of equation (I2), we also have the result

$$\sigma^1_{nn}\sigma^2_{nn} = 4\mu^2 (\hat{n}\hat{n} : \vec{\nabla}\vec{u}_1)(\hat{n}\hat{n} : \vec{\nabla}\vec{u}_2). \tag{I4}$$

Use (I3) and (I4) to evaluate (I2), then substitute that result into (I1), and also make the substitution

$$\vec{\nabla} \cdot \vec{u} = \frac{\vec{\vec{\tau}}}{3\lambda + 2\mu}.$$

Thus, we obtain

$$\begin{aligned} \vec{\vec{\tau}}_1 : \vec{\vec{\tau}}_2 = {} & \frac{3\lambda^2 + 4\mu\lambda}{(3\lambda + 2\mu)^2} \operatorname{Tr}(\vec{\vec{\tau}}_1) \operatorname{Tr}(\vec{\vec{\tau}}_2) + 4\mu^2 (\hat{n}\hat{n} : \vec{\nabla}\vec{u}_1)(\hat{n}\hat{n} : \vec{\nabla}\vec{u}_2) \\ & + 4\mu^2 \vec{k}_i \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{q}_i \vec{u}_1 \cdot (\vec{\vec{1}} - \hat{n}\hat{n}) \cdot \vec{u}_2 , \end{aligned} \tag{I5}$$

where the 1st and 2nd lines are universally valid, but the 3rd line ignores the curvature of the scattering surface. Now, split the 1st term using

$$\frac{3\lambda^2 + 4\mu\lambda}{(3\lambda + 2\mu)^2} = \frac{3\lambda^2 + 2\mu\lambda}{(3\lambda + 2\mu)^2} + \frac{2\mu\lambda}{(3\lambda + 2\mu)^2},$$

and also restore the label II to obtain

$$\vec{\tau}_1^{II}:\vec{\tau}_2^{II}=\frac{1}{2\mu_{II}}\frac{\lambda_{II}}{3\lambda_{II}+2\mu_{II}}\,\mathrm{Tr}(\vec{\tau}_1^{II})\,\mathrm{Tr}(\vec{\tau}_2^{II})+\frac{\lambda_{II}}{(3\lambda_{II}+2\mu_{II})^2}\,\mathrm{Tr}(\vec{\tau}_1^{II})\,\mathrm{Tr}(\vec{\tau}_2^{II})$$
$$+2\mu_{II}(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1^{II})(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_2^{II})+2\mu_{II}\vec{k}_i\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i\vec{u}_1^{II}\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{u}_2^{II}. \tag{I6}$$

Note that the 1st term on the right hand side of this equation will cancel line 6 of equation (2.14). Thus, substituting the result (I6) into equation (2.14) gives

$$\frac{-iQ_zT}{\rho_1\omega^2}=\int d^2x[\ \text{Integrand}]$$

$$\text{Integrand}=(\rho_I-\rho_{II})\omega^2\hat{n}\cdot\hat{u}_1\hat{n}\cdot\hat{u}_2+[(\rho_I-\rho_{II})\omega^2+2\mu_{II}\vec{k}_i\cdot(1-\hat{n}\hat{n})\cdot\vec{q}_i]\vec{u}_1^{II}\cdot(1-\hat{n}\hat{n})\cdot\vec{u}_2^{II}$$
$$-\rho_I\omega^2(\vec{u}_1^{I}-\vec{u}_1^{II})\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n})\cdot(\vec{u}_2^{I}-\vec{u}_2^{II})+\frac{k_i^2}{\rho_I\omega^2}\tau_{nn}^1\tau_{nn}^2$$
$$+\frac{\lambda_{II}}{(3\lambda_{II}+2\mu_{II})^2}[\ \mathrm{Tr}(\vec{\tau}_1^{II})\,\mathrm{Tr}(\vec{\tau}_2^{II})]-\frac{1}{3\lambda_{II}+2\mu_{II}}[\ \mathrm{Tr}(\vec{\tau}_1^{II})\tau_{nn}^2+\ \mathrm{Tr}(\vec{\tau}_2^{II})\tau_{nn}^1]$$
$$+2\mu_{II}(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1^{II})(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_2^{II}). \tag{I7}$$

Note that the 2nd part of line 2 (involving $\vec{k}_i$ and $\vec{q}_i$) is the only instance where the ''flat scattering surface'' approximation comes in. The remainder of the equation is exact.

Finally, simplify the term involving $\hat{n}\hat{n}:\vec{\nabla}\vec{u}$. The equation,

$$\tau_{nn}=\lambda\vec{\nabla}\cdot\vec{u}+2\mu\hat{n}\hat{n}:\vec{\nabla}\vec{u},$$

can be inverted to solve for $\hat{n}\hat{n}:\vec{\nabla}\vec{u}$. This leads to

$$2\mu_{II}(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_1^{II})(\hat{n}\hat{n}:\vec{\nabla}\vec{u}_2^{II})=\frac{1}{2\mu_{II}}\tau_{nn}^1\tau_{nn}^2+\frac{1}{2\mu_{II}}\frac{\lambda_{II}^2}{(3\lambda_{II}+2\mu_{II})^2}\,\mathrm{Tr}(\vec{\tau}_1^{II})\,\mathrm{Tr}(\vec{\tau}_2^{II})$$
$$-\frac{1}{2\mu_{II}}\frac{\lambda_{II}}{3\lambda_{II}+2\mu_{II}}[\ \mathrm{Tr}(\vec{\tau}_1^{II})\tau_{nn}^2+\ \mathrm{Tr}(\vec{\tau}_2^{II})\tau_{nn}^1].$$

Substituting this result into equation (I7), we finally obtain equation (3.20).

APPENDIX J: DETAILS OF THE DERIVATION OF EQUATION (3.22)

In this appendix, equation (3.22) is derived beginning with the 3rd part of equation (3.19):

$$\vec{u}_1^{II}=C[\hat{k}_p-A_S\hat{t}]e^{i\vec{k}_i\cdot\vec{x}}.$$

The phase factor $e^{i\vec{k}_i\cdot\vec{x}}$ will be suppressed for the rest of the discussion in this appendix.

Decompose $\vec{u}^{II}$ according to

$$\vec{u}^{II}=(\vec{u}^{II}\cdot\hat{n})\hat{n}+\vec{u}^{II}\cdot(\vec{\mathbf{1}}-\hat{n}\hat{n}), \tag{J1}$$

and note that $\vec{u}^{II}\cdot\hat{n}=\vec{u}^{I}\cdot\hat{n}$ and that $\vec{u}^{I}$ can be evaluated using equation (3.21) to give

$$\vec{u}^{II}\cdot\hat{n}=\frac{i}{\rho_I\omega^2}(1-B)k_{in}=\frac{i}{\rho_I\omega^2}\,\frac{2}{a+1}k_{in}\,. \tag{J2}$$

Using equation (3.12), it is easy to show that

$$\vec{u}^{II}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})=\frac{C\mathbf{k}_\perp}{k_p}\left[1+\frac{A_S k_p k_{sn}}{|\mathbf{k}_\perp|}k_s\right]. \tag{J3}$$

When A_S is further evaluated using equation (3.13), it follows that

$$\vec{u}_{II}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})=\frac{C\mathbf{k}_\perp}{k_p}\left[\frac{|\mathbf{k}_\perp|^2-k_s^2/2+k_{pn}k_{sn}}{|\mathbf{k}_\perp|^2-k_s^2/2}\right]. \tag{J4}$$

From equation (3.15), we have

$$C=\frac{-2b}{ik_p(\lambda_{II}+2\mu_{II})}\,\frac{1}{a+1},$$

where a and b are also given in (3.15). Substitute

$$b=\frac{\rho_{II}}{\rho_I}\,\frac{k_{in}}{k_{pn}}\left(1-\frac{2|\mathbf{k}_\perp|^2}{k_s^2}\right)$$

into C, and use equation (3.16) to make the substitution

$$\lambda_{II}+2\mu_{II}=\frac{\rho_{II}\omega^2}{k_p^2}.$$

After just a little algebra, we have

$$C=\frac{2ik_p}{\rho_I\omega^2}\,\frac{k_{in}}{k_{pn}}\,\frac{-2}{k_s^2}\left[|\mathbf{k}_\perp|^2-\frac{k_s^2}{2}\right]\frac{1}{a+1}.$$

Also, use

$$|\mathbf{k}_\perp|^2+k_{sn}^2=k_s^2\quad\text{and}\quad-|\mathbf{k}_\perp|^2=k_{pn}^2-k_p^2$$

to show that

$$|\mathbf{k}_\perp|^2-\frac{k_s^2}{2}+k_{pn}k_{sn}=-\frac{1}{2}((k_{sn}-k_{pn})^2-k_p^2).$$

Combining these results, we obtain

$$\vec{u}_{II}\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})=\mathbf{k}_\perp\,\frac{2i}{\rho_I\omega^2}\,\frac{\xi}{a+1}, \tag{J5}$$

with ξ as defined in equation (3.22). Substituting equations (J2) and (J5) back into equation (J1), we finally obtain equation (3.22).

To obtain the alternate form for ξ, note that

$$\frac{(k_{sn}-k_{pn})^2-k_p^2}{k_s^2}=\frac{k_{sn}^2+k_{pn}^2-2k_{sn}k_{pn}-k_p^2}{k_s^2}=\frac{k_s^2-|\mathbf{k}_\perp|^2+k_p^2-|\mathbf{k}_\perp|^2-2k_{sn}k_{pn}-k_p^2}{k_s^2}$$

$$=1-2\frac{|\mathbf{k}_\perp|^2+k_{sn}k_{pn}}{k_s^2}=1-2\frac{\vec{k}_s\cdot\vec{k}_p}{k_s^2}. \tag{J6}$$

APPENDIX K: DETAILS OF THE DERIVATION OF EQUATION (3.23)

We need to use the results (3.21) and (3.22) to evaluate the quantities in equation (3.20). This is absolutely straightforward, and the result is

$$\begin{aligned}
&e^{i\vec{Q}_i\cdot\vec{x}}(a_1+1)(a_2+1)[\text{ Integrand}]\\
&=\frac{(\rho_I-\rho_{II})}{\rho_I^2\omega^2}4k_{in}q_{in}+\frac{(\rho_I-\rho_{II})}{\rho_I^2\omega^2}\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i 4\xi_1\xi_2+\frac{8\mu_{II}[\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i]^2}{\rho_I^2\omega^4}\xi_1\xi_2\\
&-\frac{1}{\rho_I\omega^2}\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i 4(a_1-\xi_1)(a_2-\xi_2)+\frac{k_i^2}{\rho_I\omega^2}4a_1a_2+\frac{1}{2\mu_{II}}4a_1a_2\\
&+\frac{\lambda_{II}}{(3\lambda_{II}+2\mu_{II})^2}\left(1+\frac{\lambda_{II}}{2\mu_{II}}\right)\frac{b_1b_2(3\lambda_{II}+2\mu_{II})^2}{\mu_{II}^2(1+\lambda_{II}/(2\mu_{II}))^2}\\
&-\frac{1}{(3\lambda_{II}+2\mu_{II})}\left(1+\frac{\lambda_{II}}{2\mu_{II}}\right)\frac{2(b_1a_2+b_2a_1)(3\lambda_{II}+2\mu_{II})}{\mu_{II}(1+\lambda_{II}/(2\mu_{II}))}.
\end{aligned}\tag{K1}$$

Note the immediate cancellation of $3\lambda_{II}+2\mu_{II}$ and $1+\lambda_{II}/(2\mu_{II})$ in the last two lines of equation (K1) above. Furthermore, to evaluate the last 3 terms, note that

$$\frac{1}{\mu_{II}}=\frac{1}{\rho_{II}\omega^2}\frac{\rho_{II}\omega^2}{\mu_{II}}=\frac{k_s^2}{\rho_{II}\omega^2}=\frac{k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}},$$

so that these 3 terms become

$$\begin{aligned}
&\frac{2k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}a_1a_2+\frac{2\lambda_{II}}{\lambda_{II}+2\mu_{II}}\frac{k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}b_1b_2-\frac{2k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}(b_1a_2+b_2a_1)\\
&\quad=\frac{2(\lambda_{II}+2\mu_{II})}{\lambda_{II}+2\mu_{II}}\frac{k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}b_1b_2+\frac{2k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}a_1a_2\\
&\qquad-\frac{2(2\mu_{II})}{\lambda_{II}+2\mu_{II}}\frac{k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}b_1b_2-\frac{2k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}(b_1a_2+b_2a_1)\\
&\quad=\frac{2k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}(a_1a_2+b_1b_2-b_1a_2-b_2a_1)-\frac{4\mu_{II}}{\lambda_{II}+2\mu_{II}}\frac{k_s^2}{\rho_I\omega^2}\frac{\rho_I}{\rho_{II}}b_1b_2.
\end{aligned}$$

Simplify using

$$\frac{\mu_{II}}{\lambda_{II}+2\mu_{II}}=\frac{k_p^2}{k_s^2}\quad\text{and}\quad(a_1-b_1)(a_2-b_2)=a_1a_2+b_1b_2-b_1a_2-b_2a_1.$$

Now substitute all this into equation (K1) to obtain

$$e^{i\vec{Q}_i\cdot\vec{x}}\rho_I\omega^2(a_1+1)(a_2+1)[\text{ Integrand}]$$
$$=\left(1-\frac{\rho_I}{\rho_{II}}\right)4k_{in}q_{in}+4\left(1-\frac{\rho_I}{\rho_{II}}\right)\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i\xi_1\xi_2+\frac{8\mu_{II}}{\rho_I\omega^2}[\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i]^2\xi_1\xi_2$$
$$-4\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i(a_1-\xi_1)(a_2-\xi_2)+4k_i^2a_1a_2+2k_s^2\frac{\rho_I}{\rho_{II}}(a_1-b_1)(a_2-b_2)-4k_p^2\frac{\rho_I}{\rho_{II}}b_1b_2. \tag{K2}$$

Optionally, use $\mu_{II}/(\rho_I\omega^2)=(1/k_s^2)(\rho_{II}/\rho_I)$ in line 3. Having now evaluated the integrand in equation (3.20), equation (3.23) follows immediately.

APPENDIX L: THE LIMIT AS THE SOLID IN REGION *II* BECOMES A FLUID

In this appendix, we examine the two *(locally) flat reference surface approximations* in the limit as $\mu_{II}\to 0$. (i.e., as the solid in region *II* becomes a fluid). The result is equation (3.24).

In this limit, we have from equations (3.10) and (3.11) that

$$1/k_s^2=O(\mu_{II}),\quad k_{sn}=O(\mu_{II}^{-1/2}),$$

and further, substituting into equations (3.15) and (3.22), we find

$$a=\frac{\rho_{II}}{\rho_I}\frac{k_{in}}{k_{pn}}+O(\mu_{II}),\quad b=a+O(\mu_{II}),$$

$$\xi=\frac{k_{in}}{k_{pn}}+O(\mu_{II}^{1/2})=\frac{\rho_I}{\rho_{II}}a+O(\mu_{II}^{1/2}).$$

Note that $a-b=O(\mu_{II})$, so that

$$(a_1-b_1)(a_2-b_2)=O(\mu_{II}^2),$$

and we have

$$T(\vec{q}_i,\vec{k}_i)=\frac{i}{Q_{iz}}\int d^2x e^{i\vec{Q}_i\cdot\vec{x}}\left[\left(1-\frac{\rho_{II}}{\rho_I}\right)\frac{4k_{in}q_{in}}{(a_1+1)(a_2+1)}\right.$$
$$+4\left(\frac{\rho_I^2}{\rho_{II}^2}-\frac{\rho_I}{\rho_{II}}\right)\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i\frac{a_1a_2}{(a_1+1)(a_2+1)}$$
$$-4\vec{k}_i\cdot(\overleftrightarrow{\mathbf{1}}-\hat{n}\hat{n})\cdot\vec{q}_i\left(1-\frac{\rho_I}{\rho_{II}}\right)^2\frac{a_1a_2}{(a_1+1)(a_2+1)}$$
$$\left.+4k_i^2\frac{a_1a_2}{(a_1+1)(a_2+1)}-4k_p^2\frac{\rho_I}{\rho_{II}}\frac{a_1a_2}{(a_1+1)(a_2+1)}\right]+O(\mu_{II}^{1/2}). \tag{L1}$$

Define

$$\frac{2a}{a+1}\equiv A,$$

with the identification of the subscripts $1\leftrightarrow\vec{k}_i$, $2\leftrightarrow-\vec{q}_i$ and note that

$$\frac{\rho_I^2}{\rho_{II}^2}-\frac{\rho_I}{\rho_{II}}-\left(1-\frac{\rho_I}{\rho_{II}}\right)^2=\frac{\rho_I}{\rho_{II}}-1$$

to obtain equation (3.24).

APPENDIX M: THE LIMIT AS THE SOLID IN REGION *II* BECOMES INFINITELY STIFF

In this appendix, we examine the two *(locally) flat reference surface approximations* in the limit as $\mu_{II}\to\infty$. The result is equation (3.25)

We have

$$\begin{aligned} k_{sn}&=-\sqrt{k_s^2-|\mathbf{k}_\perp|^2}=-i|\mathbf{k}_\perp|\left(1-\frac{\rho_{II}\omega^2}{2\mu_{II}|\mathbf{k}_\perp|^2}\right)+O\left(\frac{1}{\mu_{II}^2}\right),\\ k_{pn}&=-\sqrt{k_p^2-|\mathbf{k}_\perp|^2}=-i|\mathbf{k}_\perp|\left(1-\frac{\rho_{II}\omega^2}{4\mu_{II}|\mathbf{k}_\perp|^2}\right)+O\left(\frac{1}{\mu_{II}^2}\right), \end{aligned} \tag{M1}$$

so that

$$k_{sn}-k_{pn}=\frac{ik_s^2}{4|\mathbf{k}_\perp|}. \tag{M2}$$

Thus, substituting into equation (3.15), we find

$$a_1=i|\mathbf{k}_\perp|\frac{\rho_{II}}{\rho_I}\frac{(-k_{in})}{k_s^2}+O(\mu_{II}^0)\to\infty.$$

Since $1/k_s^2\propto\mu_{II}$, we have $a_1\to\infty$ and

$$\frac{1}{a_1+1}=O\left(\frac{1}{\mu_{II}}\right)\quad\text{and}\quad\frac{a_1}{a_1+1}\to 1.$$

By also substituting the results (M1) in the equation for b in equation (3.15), we obtain

$$b_1=2a_1+O(\mu_{II}^0),$$

so that $(a_1-b_1)/(a_1+1)$ and $b_1/(a_1+1)$ are both $O(\mu_{II}^0)$ (i.e., just finite numbers).

We also have

$$k_p^2=\frac{k_s^2}{2}+O\left(\frac{1}{\mu_{II}^2}\right),$$

so that, using equations (3.22) and (M2),

$$\xi_1=-\frac{k_{in}}{i|\mathbf{k}_\perp|}\left[\frac{1}{k_s^2}\left(\frac{ik_s^2}{4|\mathbf{k}_\perp|}\right)^2-\frac{k_p^2}{k_s^2}\right]=-\frac{(-k_{in})}{2i|\mathbf{k}_\perp|}+O\left(\frac{1}{\mu_{II}}\right),$$

and consequently that

$$\frac{\xi_1}{a_1+1}=O\left(\frac{1}{\mu_{II}}\right).$$

Note that k_p^2 and k_s^2 are both $O(1/\mu_{II})$. Substituting these results, and the analogous ones with the subscript ''2'' into equation (3.23), equation (3.25) follows immediately.

APPENDIX N: THE LIMIT AS THE SOLID IN REGION *II* BECOMES A GAS

Once again, consider equation (3.23), and this time let the solid in medium II become gas-like (i.e., let both μ_{II} and ρ_{II} go to 0). In Appendix L above, it was shown that taking $\mu_{II}\to 0$ first, we recover the two-fluid result. It is well-known, and easy to verify that for a two-fluid interface, as the density of medium II approaches zero, Dirichlet boundary conditions are satisfied at the interface. Therefore, we will not reproduce a proof for that case here. Instead, let us take $\rho_{II}\to 0$ first, and only then let $\mu_{II}\to 0$ (i.e., assume the density ρ_{II} goes to zero more rapidly than the second Lamé constant μ_{II}).

If $\rho_{II}\to 0$, with μ_{II} not yet 0, we have [cf. equations (M1) and (M2)]

$$\begin{aligned} k_p^2=\frac{\rho_{II}\omega^2}{\lambda_{II}+2\mu_{II}}\Rightarrow k_{pn}=-i|\mathbf{k}_\perp|\left(1-\frac{\rho_{II}\omega^2}{2(\lambda_{II}+2\mu_{II})|\mathbf{k}_\perp|^2}\right)+O(\rho_{II}^2),\\ k_s^2=\frac{\rho_{II}\omega^2}{\mu_{II}}\Rightarrow k_{sn}=-i|\mathbf{k}_\perp|\left(1-\frac{\rho_{II}\omega^2}{2\mu_{II}|\mathbf{k}_\perp|^2}\right)+O(\rho_{II}^2), \end{aligned} \tag{N1}$$

and thus

$$k_{sn}-k_{pn}=-\frac{i\rho_{II}\omega^2}{2|\mathbf{k}_\perp|}\left(\frac{1}{\lambda_{II}+2\mu_{II}}-\frac{1}{\mu_{II}}\right)+O(\rho_{II}^2). \tag{N2}$$

Therefore, we have from equation (3.15),

$$\begin{aligned} a_1=-\frac{2ik_{in}\mu_{II}|\mathbf{k}_\perp|}{\rho_I\omega^2}\left(1-\frac{\mu_{II}}{\lambda_{II}+2\mu_{II}}\right)+O(\rho_{II}),\\ b_1=-\frac{2ik_{in}\mu_{II}|\mathbf{k}_\perp|}{\rho_I\omega^2}+O(\rho_{II}). \end{aligned} \tag{N3}$$

Furthermore, substituting results (N1) and (N2) into equation (3.22), we have

$$\xi_1=-\frac{ik_{in}}{|\mathbf{k}_\perp|}\frac{\mu_{II}}{\lambda_{II}+2\mu_{II}}+O(\rho_{II}). \tag{N4}$$

Once again, the results with the subscript ''2'' are virtually identical. Finally, letting $\mu_{II}\to 0$, we have $a,b,\xi=O(\mu_{II})\to 0$, and equation (3.24) follows immediately as these results are substituted into equation (3.23).

(Received 1 April 1996; accepted for publication 17 June 1996)

In this work the concept of entropy of a dynamical system, as given by Kolmogorov, is generalized in the sense of Tsallis. It is shown that this entropy is an isomorphism invariant, being complete for Bernoulli schemes. © *1996 American Institute of Physics.* [S0022-2488(96)03309-9]

I. INTRODUCTION

Ergodic theory not only is an important chapter of Statistical Physics but also it constitutes by itself an entire branch of Mathematics.

A basic result of ergodic theory is the isomorphism theorem for Bernoulli schemes, initially proved by Ornstein.[1] This theorem involves the concept of entropy.

Entropy was introduced by Shannon, in his mathematical theory of communications, as a measure of the amount of information[2] and generalized in the context of dynamical systems by Kolmogorov.[3] Subsequently, Sinai[4] proved Kolmogorov's entropy to be an isomorphism invariant, Meshalkin[5] demonstrated that some special Bernoulli schemes are always isomorphic whereas Ornstein's isomorphism theorem showed the isomorphism to be complete. A nice proof of this last result, which enables us to construct finitary isomorphisms, was later given by Keane and Smorodinsky based on coding-theoretical arguments.[6]

Generalizations of Shannon's entropy have been introduced by Rényi[7] and, more recently, on a multifractal basis, by Tsallis.[8] These generalized entropies have found a wide field of applications in the last few years. In particular, they enable us to explain a variety of physical phenomena such as the behavior of self-gravitating systems, the anomalous diffusion, Euler turbulence, and so on.[9–15]

In this work we generalize the concept of Tsallis entropy to abstract dynamical systems in the same spirit as Kolmogorov did for Shannon entropy and study its invariance under isomorphisms. Our main result is that the new generalized entropy we consider is also an isomorphism invariant of dynamical systems. Moreover, it is a complete invariant for Bernoulli schemes. It should be noted that very recently Zanette has studied the dynamics of multifractal generation using a generalization of the Kolmogorov entropy.[16] Zanette's generalization, however, is a particular case of the more general definition that we consider in this paper.

In the next section we give a brief review of the main concepts concerning dynamical systems, Bernoulli schemes, and isomorphisms. Section III will be devoted to introducing the new generalized entropy, whereas in Sec. IV we prove its properties we are interested in here, namely, the isomorphism invariance and the complete invariance for Bernoulli schemes.

II. DYNAMICAL SYSTEMS AND BERNOULLI SCHEMES

The idea of measure-preserving transformation,[17] mathematically generalizes the physical concept of a dynamical system. Here we understand by a physical dynamical system a collection of particles or states, the temporal evolution of which is determined by some physical law in such a way that Liouville's theorem is verified.

0022-2488/96/37(9)/4480/4/$10.00

From a mathematical point of view a dynamical system or, more precisely, a measure-preserving dynamical system, also simply called a measure-preserving transformation, is a quadruple $(X,\mathscr{A},\mu,T)$ where X is a set, $\mathscr{A}$ a σ-algebra, μ a measure on $\mathscr{A}$, and T is a mapping of the underlying set X to itself that is measurable and preserves the measure μ, i.e. *for any* $A\in\mathscr{A}$, $T^{-1}A\in\mathscr{A}$ *and* $\mu(T^{-1}A)=\mu(A)$ [$\mu(\cdot)$ denotes the measure of an element $\cdot$ of $\mathscr{A}$].

Bernoulli schemes are particular cases of measure-preserving dynamical systems of great importance in ergodic theory. Thus, a Bernoulli scheme is also a quadruple $(X,\mathscr{A},\mu,T,)$, where X is now a *sample space* associated with the possible results arising in a probabilistic experiment, say 1,2,...,n, having respective probabilities $p_1,p_2,\ldots,p_n$ (we use the notation of Ref. 17):

$$X=\{1,2,\ldots,n\}^Z=\{x=(\cdots x_{-1},x_0,x_1,\ldots):x_i\in\{1,2,\ldots,n\},\quad \text{for all } i\in Z\}. \tag{1}$$

The σ-algebra $\mathscr{A}$ on X and the measure μ are the standard ones for this kind of probabilistic experiment. Thus, $\mu=(p_1,p_2,\ldots,p_n)^Z$, assuming that the individual experiments are independent. Finally, the measure-preserving transformation T is the *shift* on X defined $Tx=x'$, where $x_i'=x_{i+1}$. As usual we denote the above Bernoulli scheme by $BS(p)$.

To finish with this brief review let us recall the concept of isomorphism between two dynamical system $S=(X,\mathscr{A},\mu,T)$ and $S'=(X',\mathscr{A}',\mu',T')$. S and S' are isomorphic if there exists a measurable mapping $f:X\to X'$, which is a bijection such that *(i) for any* $A'\in\mathscr{A}'$, $\mu(f^{-1}A')=\mu'(A')$ and *(ii) for all* x, $f(Tx)=T'(fx)$.

III. GENERALIZED ENTROPY

The Kolmogorov–Shannon entropy is constructed considering that, within Shannon's information theory, the amount of information we have if we know that a point $x\in X$ belongs to some fixed set of a partition $C=\{C_1,C_2,\ldots,C_m\}$ of X is

$$H_1(C)=-\sum_{i=1}^{m}\mu(C_i)\log\,\mu(C_i). \tag{2}$$

A generalization of this magnitude has been given, among others, by Tsallis.[8] In our context it reads as

$$H_q(C)=(q-1)^{-1}\left(1-\sum_{i=1}^{m}[\mu(C_i)]^q\right), \tag{3}$$

where q is any real number. We observe that for $q\to 1$, Shannon's expression (2) is recovered. Equation (3) enables us to give a generalized formulation of information theory in such a way that the relevant relationships of Shannon's information theory are preserved.[18]

To define our generalized entropy we follow Ref. 17. We firstly consider a finite partition $B=\{B_1,B_2,\ldots,B_k\}$ of the sample space, i.e., $\cup_{i=1}^{k}B_i=X$; $B_i\cap B_j=\phi\,\forall\, i\neq j$. Then we take n points on the orbit of X: $x,Tx,T^2x,\ldots,T^{n-1}x$. B being a partition, for each of these points there exists only one set B_i to which it belongs. We associate to each x a string $l=(l_0,l_1,\ldots,l_{n-1})$, called the name of x, where $T^ix\in B_{l_i}$. From B we construct a new partition $B^n=\{B^n(l)\colon l$ is any name of length $n\}$, where $B^n(l)$ is the set of x with name l.

Thus, we define a generalized mean entropy (Kolmogorov–Tsallis entropy) of the measure-preserving transformation T by

$$h_q(T)=(q-1)^{-1}[1-\exp(\tilde{h}_q(T))], \tag{4}$$

where

$$\widetilde{h}_q(T)=\sup_B \widetilde{h}_q(B,T) \tag{5}$$

and

$$\widetilde{h}_q(B,T)=\overline{\lim_{n\to\infty}}\frac{1}{n}\{\log[1+(1-q)H_q(B^n)]\}. \tag{6}$$

In particular, for a Bernoulli scheme $BS(p)$, we have $\mu(B^n(l)) = p_{l_0}p_{l_1}\cdots p_{l_{n-1}}$ for each name l of length n. Therefore, using for the partition B^n the generator $B_i = \{x: x_0=i\}$, $1\leqslant i\leqslant k$ we obtain

$$[\widetilde{h}_q(T)]_{BS(p)}=\log\sum_{i=1}^{n} p_i^q, \tag{7}$$

which yields Tsallis' entropy for arbitrary q,

$$[h_q(T)]_{BS(p)}=(q-1)^{-1}\left[1-\sum_{i=1}^{n} p_i^q\right], \tag{8}$$

and Shannon's expression,

$$[h_1(T)]_{BS(p)}=-\sum_{i=1}^{n} p_i\log(p_i), \tag{9}$$

for $q\to 1$.

IV. ISOMORPHISM THEOREMS FOR THE GENERALIZED ENTROPY

Let us consider two isomorphic measure-preserving dynamical systems $S=(X,\mathscr{A},\mu,T)$, $S'=(X',\mathscr{A}',\mu',T')$ [with $0<\mu,\ \mu'\leqslant 1$ and $\mu(X)=\mu'(X')=1$] and an arbitrary partition of X of size n, say $B=\{B_1,B_2,\ldots,B_n\}$. Then, if f is a bijection between X and X', the set $C=\{C_1,C_2,\ldots,C_n\}$, where $C_i=f(B_i)$ for each $i=1,2,\ldots,n$, is a partition of X' also. Let $l=(l_0,l_1,\ldots,l_{n-1})$ and $l'=(l'_0,l'_1,\ldots,l'_{n-1})$ be the names of a given point $x\in X$ with relation to B and of $y=f(x)$ with relation to C, respectively.

Since S and S' are assumed to be isomorphic, thus $T^ix\in B_{l_i}\to fT^ix=(T')^ifx\in C_{l'_i}$. On the other hand, we also know that $fT^ix\in f(B_{l_i})=C_{l_i}$ because of the form in which the partition was constructed. Therefore $l'_i=l_i$ for all $i=0,1,\ldots,n-1$ and both names l and l' are the same one. Consequently, the quantities $H_q(B^n)=(q-1)^{-1}(1-\sum_l[\mu(B^n(l))]^q)$ and $H'_q(C^n)=(q-1)^{-1}(1-\sum_l[\mu'(C^n(l))]^q)$, and hence also $\widetilde{h}_q(B,T)$ and $\widetilde{h}'_q(C,T)$, are equal because, S and S' being isomorphic, we have $\mu'(C^n(l_i))=\mu'(fB^n(l_i))=\mu(f^{-1}fB^n(l_i))=\mu(B^n(l_i))$. Then, from Eq. (5), we get $\widetilde{h}_q(T)\geqslant\widetilde{h}_q(B,T)=\widetilde{h}'_q(C,T')$ and $\widetilde{h}'_q(T')\geqslant\widetilde{h}'_q(C,T)=\widetilde{h}_q(B,T)$, which implies $\widetilde{h}_q(T)\leqslant\widetilde{h}'_q(T')$ and $\widetilde{h}'_q(T')\leqslant\widetilde{h}_q(T)$ or $\widetilde{h}_q(T)=\widetilde{h}'_q(T')$. Consequently, $h_q(T)=\widetilde{h}'_q(T')$. In this way, we have demonstrated the following theorem.

Theorem 1: *If two measure-preserving dynamical systems are isomorphic then the associated generalized (Kolmogorov–Tsallis) entropies as defined by Eqs. (4)–(6) are equal.*

The complete isomorphism is proved just for Bernoulli schemes and reads as the following.

Theorem 2: *Two Bernoulli schemes with the same generalized (Kolmogorov–Tsallis) entropies as given by Eq. (8) are finitarily isomorphic.*

Remark: we recall that an isomorphism f between two Bernoulli schemes is *finitary* if, given an element x of the sample space X [see Eq. (1)], there exist two integers $n_1\leqslant n_2$ such that for any

other $x' \in X$ that verifies $x'[n_1,n_2]=x[n_1,n_2]$, the zero coordinates $[f(x)]_0,[f(x')]_0$ and $[f^{-1}(x)]_0,[f^{-1}(x')]_0$ are, respectively, equal. Here we denote with $x[n_1,n_2]$ the word $x_{n_1}x_{n_a+1}\cdots x_{n_{2-1}}x_{n_2}$.

Proof: The demonstration is based on the following lemma, which was proved by Keane and Smorodinsky[6] in the case $q\to 1$.

Lemma: given two Bernoulli schemes $BS(p)$ and $BS(p')$, where $p=(p_0,p_1\cdots p_{a-1})$ and $p' = (p'_0,p'_1\cdots p'_{b-1})$ (with $a\geqslant 3$; $b\geqslant 3$) for which $[h_q(T)]_{BS(p)}=[h_q(T)]_{BS(p')}$, we can find a third probability vector $r=(r_0,r_1,\ldots,r_{c-1})$ with the same entropy and $r_0=p_i$ and $r_1 = p'_j$ for some i,j.

To prove it we take into account that, without loss of generality, we can assume that the vectors are ordered $p_0\geqslant p_{1\geqslant}\cdots\geqslant p_{a-1}$ and $p'_0\geqslant p'_{1\geqslant}\cdots\geqslant p'_{b-1}$ with $p_{a-1}\geqslant p'_{b-1}$. Let us consider an auxiliary triple $r' = (p_0,p'_{b-1},1-(p_0+p'_{b-1}))$ whose generalized entropy is $[h_q(T)]_{BS(r')}$. It can be shown that Tsallis entropy, Eq. (8) is a strictly decreasing function of q and that $[h_q(T)]_{BS(r')}\leqslant[h_q(T)]_{BS(p)}=[h_q(T)]_{BS(p')}$ for any q. So we can increase the entropy until we reach the entropy $[h_q(T)]_{BS(r)}=[h_q(T)]_{BS(p)}$ by successively splitting the auxiliary vector: $r'\to r''=(p_0,p'_{b-1},r_3,1-(p_0+p'_{b-1}+r_3))\to\cdots\to r$.

Remark: For $a=2$ (or $b=2$) it is still possible[6] to prove the lemma by a convenient election of the components of the vector r.

The previous lemma put us in the conditions for constructing a finitary isomorphism between the two Bernoulli schemes following the coding technic of Keane and Smorodinsky.[6] This observation proves Theorem 2.

(Received 4 December 1995; accepted for publication 29 April 1996)

The nonunitary r-matrix theory and the associated bi- and triHamiltonian schemes are considered. The language of Poisson pencils and of their formal Casimirs is applied in this framework to characterize the biHamiltonian chains of integrals of motion, pointing out the role of the Schur polynomials in these constructions. This formalism is subsequently applied to the periodic Toda lattice. Some different algebraic settings and Lax formulations proposed in the literature for this system are analyzed in detail, and their full equivalence is exploited. In particular, the equivalence between the loop algebra approach and the method of differential-difference operators is illustrated; moreover, two alternative Lax formulations are considered, and appropriate reduction algorithms are found in both cases, allowing us to derive the multiHamiltonian formalism from r-matrix theory. The systems of integrals for the periodic Toda lattice known after Flaschka and Hénon, and their functional relations, are recovered through systematic application of the previously outlined schemes.
[S0022-2488(96)01209-1]

I. INTRODUCTION

The multiHamiltonian formalism is a known geometrical tool in the theory of the integrable Hamiltonian systems; this scheme can be formulated in an elegant way using the theory of the so-called pencils of Poisson structures and of their formal Casimirs.[1] A celebrated scheme to generate a biHamiltonian structure on (the dual of) an associative algebra is provided by r-matrix theory.[2–4] Recently, the theory was extended, independently, by Oevel and Ragnisco[5] and Li and Parmentier[6] to the so-called nonunitary case, in which the r-matrix is not skew-symmetric. In the best known applications, the r-matrix is induced by a splitting of the algebra into the direct sum of two Lie subalgebras; in this case, the construction of the first Poisson structure is closely related to the earlier Adler–Kostant–Symes (AKS) scheme.[7–9]

A typical application of the nonunitary r-matrix scheme is the finite Toda lattice with fixed ends. This system is discussed in both Refs. 5 and 6; for a recent review of the fixed ends Toda-type lattices, see Ref. 10. The infinite Toda chain (and some generalizations of it) was also treated within the nonunitary scheme, see Ref. 11. Less material seems to be available on the multiHamiltonian formalism for the periodic case.

The aim of this article is to discuss some topics in the above mentioned areas, deserving in our opinion a further analysis or illustration. We are interested in the following items:

(i) to get a deeper insight into the functional relations between the Casimirs of a Poisson pencil (i.e., between the chains of integrals in involution) at three different levels: the general

[a)]Electronic mail address: Pizzoccchero@vmimat.mat.unimi.it

0022-2488/96/37(9)/4484/30/$10.00

biHamiltonian framework, the *r*-matrix scheme and the specific case of the periodic Toda lattice;

(ii) to point out the connections between the different algebraic environments proposed in the literature for the periodic Toda lattice; we refer to the loop algebra setting of Adler–van Moerbeke[12] and the differential-difference calculus of Kupershmidt;[13]

(iii) to compare two different Lax formulations proposed for the periodic lattice;

(iv) to discuss the multiHamiltonian structure as a reduction of the *r*-matrix scheme, for both the Lax formulations in item (iii).

Concerning item (i), we will point out that, for any Poisson pencil, the functional relations between different Casimirs are strictly related to the theory of Schur polynomials, or some natural generalization of it.[14] In the application we will propose to the *r*-matrix framework, the representation of the Casimirs as formal power series is particularly elegant; we think that the formal traces and the formal determinants introduced for this purpose deserve some interest by themselves.

In order to introduce items (ii) and (iii), we start from the evolution equations of the periodic Toda lattice. Using the Flaschka variables, we can describe the phase space of the lattice with n particles as a set of pairs $x=(a,b)$, where $a=(a_\alpha)$ and $b=(b_\alpha)$ are real periodic sequences of period n; the equations of motion are

$$\dot{a}=2ab-2ab_{[1]}, \quad \dot{b}=4a_{[-1]}^2-4a^2, \tag{1.1}$$

where $a_{[-1]}$ denotes the sequence $(a_{\alpha-1})$, and $b_{[1]}$ the sequence $(b_{\alpha+1})$.

To set up the Lax formulation, one must first of all choose the algebra in which the Lax operator lives. The framework of loop algebras was strongly supported by Adler and van Moerbeke;[12] these authors employ for Eq. (1.1) the Lax pair $dL/dt=[L,B_1]$, based on the $n\times n$ matrices

$$L(x):=\begin{pmatrix} b_1 & a_1 & 0 & .. & .. & 0 & \lambda^{-1}a_n \\ a_1 & b_2 & a_2 & 0 & .. & .. & 0 \\ 0 & a_2 & b_3 & a_3 & .. & .. & .. \\ .. & .. & .. & .. & .. & .. & .. \\ .. & .. & .. & .. & .. & a_{n-2} & 0 \\ 0 & .. & .. & 0 & a_{n-2} & b_{n-1} & a_{n-1} \\ \lambda a_n & 0 & .. & .. & 0 & a_{n-1} & b_n \end{pmatrix},$$

$$B_1(x):=2\begin{pmatrix} 0 & a_1 & 0 & .. & .. & .. & -\lambda^{-1}a_n \\ -a_1 & 0 & a_2 & 0 & .. & .. & 0 \\ 0 & -a_2 & 0 & .. & .. & .. & .. \\ .. & 0 & .. & .. & .. & 0 & .. \\ .. & .. & .. & .. & 0 & a_{n-2} & 0 \\ 0 & .. & .. & 0 & -a_{n-2} & 0 & a_{n-1} \\ \lambda a_n & .. & .. & .. & 0 & -a_{n-1} & 0 \end{pmatrix}. \tag{1.2}$$

Here, λ is a free parameter, and the Lax equation for the matrices in Eq. (1.2) is satisfied identically in λ. Both $L(x)$ and $B_1(x)$ are regarded in Ref. 12 as elements of the loop algebra $gl(n)(\lambda,\lambda^{-1}]$, made of formal Laurent series in λ and λ^{-1} with coefficients in the algebra $gl(n,\mathbb{R})$ of real $n\times n$ matrices.

Using the loop algebra, one can produce other Lax representations for the periodic Toda lattice, which are alternative to the scheme (1.2). In order to illustrate one of them, we remark that the evolution equations (1.1) are equivalent (up to rescaling by a common factor $\frac{1}{2}$) to

$$\dot{c}=2cb-2cb_{[1]}, \quad \dot{b}=2c_{[-1]}-2c, \tag{1.3}$$

if one stipulates that $c=a^2$. Equation (1.3) admits the Lax formulation $dV/dt=[V,C_1]$, where, at each point $y=(c,b)$,

$$V(y):=\begin{pmatrix} b_1 & 1 & 0 & .. & .. & 0 & \lambda^{-1}c_n \\ c_1 & b_2 & 1 & 0 & .. & .. & 0 \\ 0 & c_2 & b_3 & 1 & .. & .. & .. \\ .. & .. & .. & .. & .. & .. & .. \\ .. & .. & .. & .. & .. & 1 & 0 \\ 0 & .. & .. & 0 & c_{n-2} & b_{n-1} & 1 \\ \lambda & 0 & .. & .. & 0 & c_{n-1} & b_n \end{pmatrix},$$

$$C_1(y):=2\begin{pmatrix} b_1 & 1 & 0 & .. & .. & .. & 0 \\ 0 & b_2 & 1 & 0 & .. & .. & .. \\ 0 & 0 & b_3 & 1 & .. & .. & .. \\ .. & .. & .. & .. & .. & .. & .. \\ .. & .. & .. & .. & b_{n-2} & 1 & 0 \\ 0 & .. & .. & 0 & 0 & b_{n-1} & 1 \\ \lambda & .. & .. & .. & 0 & 0 & b_n \end{pmatrix}. \tag{1.4}$$

This generalizes to the periodic case a Lax scheme well known for the fixed ends lattice.[10,15]

The formulations (1.2) and (1.4) have counterparts in the environment of differential-difference calculus of Kupershmidt.[13] In the quoted reference, Kupershmidt defines a discrete analogue of the algebra of formal pseudo-differential operators, where the derivation ∂ is replaced by a shift operator Δ; the formalism can be applied, in particular, to the periodic lattices. Here, we will employ the term Kupershmidt algebra and the symbol $\mathbb{R}_n(\Delta,\Delta^{-1}]$ to denote a suitably defined algebra of (formal) differential-shift operators, obtained essentially by realizing the abstract scheme of Ref. 13 in the periodic case; we will make clear that $\mathbb{R}_n(\Delta,\Delta^{-1}]$ is algebraically isomorphic to the loop algebra $gl(n)(\lambda,\lambda^{-1}]$ of Ref. 12. Using this isomorphism, one easily constructs the equivalent of the Lax scheme (1.2); the matrices appearing in these equations correspond to the operators

$$L(x):=a\Delta+b+a_{[-1]}\Delta^{-1}, \quad B_1(x):=2a\Delta-2a_{[-1]}\Delta^{-1}. \tag{1.5}$$

More generally, one can write the Lax pairs $dL/dt_k=[L,B_k]$ ($k=1,2,3,...$) for the full hyerarchy of commuting Toda flows, recovering Eq. (1.1) for $k=1$; the operators $B_k(x)$ are constructed by translating to $\mathbb{R}_n(\Delta,\Delta^{-1}]$ the homologous prescriptions of Ref. 12 for the loop algebra setting.

The differential-difference equivalent of the Lax scheme (1.4) rests on the operators

$$V(y):=\Delta+b+c_{[-1]}\Delta^{-1}, \quad C_1(y):=2(\Delta+b), \tag{1.6}$$

which are just the Lax pair of Ref. 13 for the Toda lattice. More generally, a full hierarchy of commuting vector fields is generated in this reference prescribing the Lax equations $dV/dt_k=[V,C_k]$ ($k=1,2,3,...$), with a suitable rule to define the companion operators $C_k(y)$; the flow (1.3) is recovered for $k=1$.

Let us come to item (iv), i.e., to the triHamiltonian formulation of the periodic Toda system. As a matter of fact, the Poisson tensors of the fixed end case can be adjusted a posteriori so as to

fit the periodicity condition;[16] however, the interest in the periodic problem is not just in the final expression for the Poisson structures, but in their systematic derivation by means of appropriate reduction methods.

A construction of the first Poisson structure, based on the AKS scheme, can be found in Ref. 12. A derivation of the second Poisson tensor in the framework of loop algebras has been recently proposed in Ref. 17, but the Lax matrices employed therein are different from both $L(x)$ in Eq. (1.2) and $V(y)$ in Eq. (1.4), and require a generalization of the standard r-matrix scheme of Refs. 5 and 6. On the contrary, we show in this article that the first, the second and even the third Poisson tensors of the periodic Toda lattice can be constructed, for both the Lax schemes (1.5) and (1.6), inside the standard r-matrix theory, using appropriate splittings.

From a technical viewpoint, in our analysis we draw some advantage using the formal differential-difference calculus of Ref. 13. However, the splitting we employ for the Lax scheme (1.5) is just the correspondent in $\mathbb{R}_n(\Delta,\Delta^{-1}]$ of the one proposed in Ref. 12 in connection with the AKS scheme. The alternative splitting required for the Lax scheme (1.6) is suggested by the prescription of Ref. 13 for the companion operators $C_k(y)$ associated to the full hierarchy. This splitting is the correspondent of the one employed in Ref. 11 for the infinite Toda chain; in the periodic case, the reduction of the r-matrix structures requires some supplementary caution, yielding to replace the usual restriction schemes with a slightly more involved restriction/projection algorithm. This refinement is necessary, in particular, for the third Poisson structure.

The article is organized as follows. Section II is devoted to bi- and triHamiltonian structures and their reduction techniques, to formal Casimirs and Schur polynomials. The nonunitary r-matrix theory is reviewed in Sec. III. The isomorphism between the loop algebra $gl(n)(\lambda,\lambda^{-1}]$ and the Kupershmidt algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$ is exploited in Sec. IV. The r-matrix triHamiltonian structure in $\mathbb{R}_n(\Delta,\Delta^{-1}]$ and its restriction for the Lax scheme (1.5) are presented in Sec. V. In Sec. VI, the Flaschka and Hénon integrals of the Toda lattice are interpreted in terms of the biHamiltonian recursion and the Schur polynomials. In Sec. VII we deal with the Lax scheme (1.6) and the associated r-matrix; the reduction of the triHamiltonian structure is performed, and the relations with the Lax scheme (1.5) are illustrated in terms of gauge equivalence (as in Ref. 15 for the nonperiodic case).

II. MULTIHAMILTONIAN STRUCTURES AND RECURSION SCHEMES

A. Hamiltonian and multiHamiltonian manifolds

A wide literature is available on this topic (see, for example, Refs. 18–26 and quotations therein). If $\mathscr{V}$ is a manifold and $v\in\mathscr{V}$, we denote by $T_v\mathscr{V}$ the tangent space and by $T_v^*\mathscr{V}$ the cotangent space at v; the latter generally means a vector space in separating duality with $T_v\mathscr{V}$ through some bilinear pairing (which is a standard procedure in this framework; see, e.g., Refs. 8 and 12). Tangent vectors and covectors will often be indicated, respectively, by $\dot{v}$ and δv, and the pairing by $\langle \delta v,\dot{v}\rangle$.

A (2,0) tensor on the manifold $\mathscr{V}$ is a map $v\mapsto Q_v$ where, for each $v\in\mathscr{V}$, Q_v is a linear operator from $T_v^*\mathscr{V}$ to $T_v\mathscr{V}$. A Poisson tensor means a skew-symmetric (2,0) tensor Q such that the bracket $\{f,l\}_Q:=\langle df,Qdl\rangle$ (f,l real functions on $\mathscr{V}$) satisfies the Jacobi identity. If Q is a Poisson tensor, for each function $h:\mathscr{V}\to\mathbb{R}$, the vector field $X:=Qdh$ is called the Hamiltonian vector field corresponding to h (and it is also said that h is a Hamiltonian function for X w.r.t. Q). A function h is said to be a Casimir of Q if $Qdh=0$. The manifold $\mathscr{V}$, equipped with a Poisson tensor Q, is called a Poisson, or Hamiltonian manifold.

Two Poisson tensors Q,P are said to be compatible in the sense of Magri[21] if, for each $\xi\in\mathbb{R}$, the linear combination $Q+\xi P$ is again a Poisson tensor; similarly, three Poisson tensors Q,P,S are compatible if $Q+\xi P+\eta S$ is Poisson for each $\xi,\eta\in\mathbb{R}$. The manifold $\mathscr{V}$, equipped with a pair (resp. a triple) of compatible Poisson tensors is said to be biHamiltonian (resp. triHamiltonian).

If h_k ($k=1,2,3,\ldots$) is a sequence of real functions on the biHamiltonian manifold $\mathscr{V}$, we say that the h_k's satisfy a biHamiltonian recursion scheme if

$$Pdh_k = Qdh_{k+1} \quad (k=1,2,3,\ldots); \tag{2.1}$$

if $\mathscr{V}$ carries a third compatible Poisson tensor, and it is also

$$Sdh_{k-1} = Pdh_k \quad (k=2,3,\ldots), \tag{2.2}$$

we say that there is a triHamiltonian recursion scheme. These relations imply that the functions h_k are mutually in involution w.r.t. the Poisson brackets corresponding to both Q and P (or Q, P, S). The Hamiltonian functions h_k and the vector fields X_k are said to form a biHamiltonian (or triHamiltonian) hierarchy.

B. BiHamiltonian recursion, formal power series and Schur polynomials

Let $\mathscr{U}$ be an arbitrary real associative algebra with unit. We consider the space $\mathscr{U}[z]$ of the formal power series $U=\Sigma_{k=0}^{\infty} U_k z^k$ in one indeterminate z with coefficients $U_k \in \mathscr{U}$ (when it is convenient, we also write $U(z)$ instead of U). $\mathscr{U}[z]$ is an associative algebra with the usual Cauchy product of series.

Let $\mathscr{U}_0[z]$ be the subalgebra of $\mathscr{U}[z]$ formed by the series U without zero order term: $U_0=0$. If $\mathbb{R}[w]$ is the commutative algebra of formal series $E(w)=\Sigma_{k=0}^{\infty} e_k w^k$, with real coefficients e_k, we can define a composition law $\mathbb{R}[w]\times\mathscr{U}_0[z]\to\mathscr{U}[z]$, $(E,U)\mapsto E(U)$, where

$$E(U) := \sum_{k=0}^{\infty} e_k U^k = e_0 + e_1(U_1 z + U_2 z^2 + \ldots) + e_2(U_1 z + U_2 z^2 + \ldots)^2 + \ldots . \tag{2.3}$$

Now, let $\mathscr{V}$ be a biHamiltonian manifold with the Poisson tensors Q, P; we apply the above notions to the commutative algebra $\mathscr{U}$ of the smooth real functions on $\mathscr{V}$. Assume we are given a sequence of functions h_k on $\mathscr{V}$, and define a formal power series $h := \Sigma_{k=1}^{\infty} h_k z^k$ in the indeterminate z. Consider the condition

$$(Q - zP)dh = 0; \tag{2.4}$$

this equation is satisfied (identically in z) iff the functions h_k obey to the recursion scheme (2.1) and h_1 is a Casimir of Q, i.e., $Qdh_1=0$. The condition (2.4) can be interpreted saying that h is a (formal) Casimir for the Poisson pencil $Q-zP$; so, the biHamiltonian hierarchies starting from a Casimir of Q correspond bijectively to the Casimirs of the Poisson pencil $Q-zP$.[1]

Proposition 2.1: Let h_k ($k=1,2,3,...$) be a biHamiltonian hierarchy starting from a Casimir of Q, so that $h := \Sigma_{k=1}^{\infty} h_k z^k$ is a Casimir of the Poisson pencil $Q-zP$. Consider a formal series $E(w)=\Sigma_{k=1}^{\infty} e_k w^k$ with real coefficients e_k, and put $f := E(h) = e_1(h_1 z + h_2 z^2 + \ldots) + e_2(h_1 z + h_2 z^2 + \ldots)^2 + \ldots$. Then f is also a Casimir of $Q-zP$; so, if we write $f=\Sigma_{k=1}^{\infty} f_k z^k$, the functions f_k form a biHamiltonian hierarchy starting from a Casimir f_1 of Q.

Proof: From the definition of f it follows that $df = E'(h)dh$, where $E'(w) := e_1 + 2e_2 w + \ldots$ is the term by term derivative of E. From here and Eq. (2.4) we immediately infer $(Q-zP)df=0$. ◇

It is interesting to give explicit formulas for the functions f_k of the above Proposition in terms of the h_k's and the coefficients e_k. For each real formal series $E(w) := \Sigma_{k=1}^{\infty} e_k w^k$, define a family of polynomials $S_k(t_1,t_2,t_3,\ldots)$ in infinitely many variables t_j ($j=1,2,3,...$) stipulating that

$$E\left(\sum_{k=1}^{\infty} t_k z^k\right) = \sum_{k=1}^{\infty} S_k(t_1,t_2,t_3,\ldots) z^k. \tag{2.5}$$

Using some standard combinatorics, it can be shown that, for each k,

$$S_k(t_1,t_2,t_3,\ldots)=\sum_{k_1+2k_2+3k_3+\ldots=k} e_{k_1+k_2+k_3+\ldots}\,\frac{(k_1+k_2+k_3+\ldots)!}{k_1!k_2!k_3!\ldots}\,t_1^{k_1}t_2^{k_2}t_3^{k_3}\ldots\,. \tag{2.6}$$

In the above sum $k_1,k_2,k_3,\ldots$ are positive integers; note that S_k depends only on the first k variables $t_1,\ldots,t_k$. We will say that the S_k's are the generalized Schur polynomials generated by the formal series E.

The functions in Prop. 2.1 are related by $f_k=S_k(h_1,h_2,h_3,\ldots)$. The fact that the f_k's are functions of the Hamiltonians $h_{k'}$ implies that they are in involution (and also commute with all the $h_{k'}$) w.r.t. any Poisson bracket in which the $h_{k'}$ are themselves in involution.

The relation between the functions f_k and $h_{k'}$ can be inverted if the first coefficient e_1 in the series E is nonzero. In this case, there is a unique formal series $E^{-1}(u)=\Sigma_{k=1}^{+\infty}\tilde{e}_k u^k$ such that $E^{-1}(E(w))=w$, and we can write $h=E^{-1}(f)$; this implies $h_k=S_k(f_1,f_2,f_3,\ldots)$, where the S_k are the generalized Schur polynomials generated by E^{-1}. In Sec. III and VI, we will be interested in particular in the choice $E(w)=1-e^{-w}$, giving $e_k=(-1)^{k+1}/k!$ and

$$S_k(t_1,t_2,t_3,\ldots)=\sum_{k_1+2k_2+3k_3+\ldots.=k} \frac{(-1)^{1+k_1+k_2+k_3+\ldots.}}{k_1!k_2!k_3!\ldots}\,t_1^{k_1}t_2^{k_2}t_3^{k_3}\ldots\,. \tag{2.7}$$

Up to trivial sign changes, the S_k are the ordinary Schur polynomials.[27] The inverse of E is the formal series $E^{-1}(u)=-\ln(1-u)$, with coefficients $\tilde{e}_k=1/k$, which generates the polynomials

$$\tilde{S}_k(t_1,t_2,t_3,\ldots)=\sum_{k_1+2k_2+3k_3+\ldots=k} \frac{(k_1+k_2+k_3+\ldots-1)!}{k_1!k_2!k_3!\ldots}\,t_1^{k_1}t_2^{k_2}t_3^{k_3}\ldots\,. \tag{2.8}$$

With this choice of E, the first functions in the biHamiltonian chains of Prop. 2.1 are related by

$$\begin{gathered} f_1=h_1,\quad f_2=-\tfrac{1}{2}h_1^2+h_2,\quad f_3=\tfrac{1}{6}h_1^3-h_1h_2+h_3,\\ f_4=-\tfrac{1}{24}h_1^4-\tfrac{1}{2}h_2^2+\tfrac{1}{2}h_2h_1^2-h_1h_3+h_4,\ldots\,. \end{gathered} \tag{2.9}$$

C. Reduction schemes for Poisson structures

The schemes presented in Ref. 23 are sufficient for our purposes; for a more general formulation, see Ref. 24. Let $(\mathscr{V},Q)$ be a Poisson manifold, and $j:\mathscr{M}\to\mathscr{V}$ an embedding of another manifold $\mathscr{M}$ into $\mathscr{V}$ (i.e., a map such that $j(\mathscr{M})$ is a submanifold of $\mathscr{V}$ and j is a diffeomorphism between $\mathscr{M}$ and its image); in practical applications, $\mathscr{M}$ plays the role of a ''coordinate space'' for the submanifold $j(\mathscr{M})$. For $m\in\mathscr{M}$ and $v=j(m)$, we denote by $T_mj:T_m\mathscr{M}\to T_v\mathscr{V}$ the tangent map; its image $\mathrm{Im}T_mj\subset T_v\mathscr{V}$ is the tangent space at v of the submanifold $j(\mathscr{M})$.

Proposition 2.2: Assume that, for each $m\in\mathscr{M}$ and $v=j(m)$, it is $\mathrm{Im}Q_v\subset\mathrm{Im}T_mj$. Let $\delta v\in T_v^*\mathscr{V}$ be any covector extending a given covector $\delta m\in T_m^*\mathscr{M}$, i.e., such that

$$\langle\delta v,(T_mj)\dot{m}\rangle=\langle\delta m,\dot{m}\rangle \tag{2.10}$$

for each $\dot{m}\in T_m\mathscr{M}$; then the tangent vector $Q_v\delta v\in\mathrm{Im}T_mj$ is fully determined by δm and does not depend on the chosen extension δv. The (2,0) tensor on $\mathscr{M}$, denoted again by Q and defined by

$$Q_m\delta m:=(T_mj)^{-1}Q_v\delta v, \tag{2.11}$$

is a Poisson tensor. ◇

Another restriction scheme can be obtained by weakening the assumptions of Prop. 2.2, as explained hereafter.

Proposition 2.3: Assume that, for each $m \in \mathscr{M}$ and $\delta m \in T^*_m \mathscr{M}$, the following conditions are satisfied at the point $v = j(m)$:

(a) there is at least one covector $\delta v \in T^*_v \mathscr{V}$ extending δm in the sense of Eq. (2.10), and such that $Q_v \delta v \in \mathrm{Im} T_m j$;

(b) for δv as in (a), $Q_v \delta v$ is fully determined by δm (i.e., we have $Q_v \delta v' = Q_v \delta v$ for any other covector $\delta v'$ as in (a)).

Then a Poisson tensor is induced on $\mathscr{M}$. This tensor, denoted again by Q, is defined as in Eq. (2.11), with δv as in item (a). ◇

Definition 2.4: If the conditions of Prop. 2.2 are satisfied, we say that Q can be properly restricted from $\mathscr{V}$ to $\mathscr{M}$ along j. Under the conditions of Prop. 2.3, we say that it can be *Dirac restricted* along j. In both cases, the Poisson tensor induced on $\mathscr{M}$ is called the restriction of Q. ◇

In the case of bi- or triHamiltonian manifolds, the compatibility of the Poisson structures is preserved by both types of restriction. The restriction operation can also be applied to Hamiltonian functions and vector fields [a vector field X on $\mathscr{V}$ is restrictable to $\mathscr{M}$ along j if it is tangent to the submanifold $j(\mathscr{M})$].

We now discuss the projection of the Poisson structures.

Let $(\mathscr{V}, Q)$ be a Poisson manifold, and $\pi: \mathscr{V} \to \mathscr{W}$ a projection of the manifold $\mathscr{V}$ onto another manifold $\mathscr{W}$. For $v \in \mathscr{V}$ and $w = \pi(v)$, we consider the tangent map $T_v \pi: T_v \mathscr{V} \to T_w \mathscr{W}$ and its adjoint $T^*_v \pi: T^*_w \mathscr{W} \to T^*_v \mathscr{V}$.

Proposition 2.5: For each $w \in \mathscr{W}$ and $v \in \mathscr{V}$ such that $\pi(v) = w$, let us consider the map $T_v \pi \circ Q_v \circ T^*_v \pi: T^*_w \mathscr{W} \to T_w \mathscr{W}$. Assume that this map be completely determined by w, i.e., that it does not change if v is replaced by another point $v' \in \pi^{-1}(w)$. Then the (2,0) tensor on $\mathscr{W}$, denoted with $\tilde{Q}$ and defined by

$$\tilde{Q}_w \delta w := (T_v \pi \circ Q_v \circ T^*_v \pi)(\delta w), \tag{2.12}$$

is a Poisson tensor. ◇

Definition 2.6: We say that the Poisson tensor $\tilde{Q}$ is the projection of Q and $\mathscr{V}$ onto $\mathscr{W}$ along π. ◇

The projection operation preserves the compatibility of Poisson tensors. A function $h: \mathscr{V} \to \mathbb{R}$ is said to be projectable onto W if $h(v) = h(v')$ for each pair v, v' such that $\pi(v) = \pi(v')$; in this case, h induces in an obvious way a real function $\tilde{h}$ on $\mathscr{W}$, called the projection of h. A vector field X on $\mathscr{V}$ is said to be projectable if, for w in $\mathscr{W}$ and $v \in \pi^{-1}(w)$, the vector $(T_v \pi) X(v) \in T_w \mathscr{W}$ depends only on w; in this case, the vector field $\tilde{X}$ induced in the obvious way on $\mathscr{W}$ is called the projection of X.

III. *R*-MATRIX THEORY: A REVIEW

A. The nonunitary case (Refs. 5,6)

Let $\mathfrak{g}$ be a real associative algebra with unit 1 and typical elements $V, W, Z, \ldots$; then $\mathfrak{g}$ is a Lie algebra w.r.t. the commutator $[V, W] := VW - WV$.

Definition 3.1: An r-matrix on $\mathfrak{g}$ is a linear operator $R: \mathfrak{g} \to \mathfrak{g}$ satisfying the modified Yang-Baxter equation

$$[RV, RW] - R[V, RW] - R[RV, W] + [V, W] = 0. \tag{3.1}$$

◇

Here and in the sequel, we assume that $\mathfrak{g}$ carries a traceform, i.e., a linear functional $\mathrm{Tr}: \mathfrak{g} \to \mathbb{R}$ such that the bilinear form $\langle , \rangle: \mathfrak{g} \times \mathfrak{g} \to \mathbb{R}$, $\langle V, W \rangle := \mathrm{Tr}(VW)$ is symmetric and nondegenerate; the pairing $\langle , \rangle$ will be employed to identify $\mathfrak{g}$ with its dual space $\mathfrak{g}^*$ (in the infinite-dimensional case, the

statement $\mathfrak{g}\approx\mathfrak{g}^*$ can be viewed as the definition of $\mathfrak{g}^*$, see Ref. 2). From a geometrical viewpoint, we can regard $\mathfrak{g}$ as a manifold, with $T_V\mathfrak{g}\approx\mathfrak{g}$ and $T_V^*\mathfrak{g}\approx\mathfrak{g}$ at each point V (so, a typical element of $\mathfrak{g}$ is written as δV when it is viewed as a covector).

Let $R:\mathfrak{g}\to\mathfrak{g}$ be a linear operator with adjoint $R^*:\mathfrak{g}\to\mathfrak{g}$ (satisfying the condition $\langle R^*V,W\rangle=\langle V,RW\rangle$).

Definition 3.2: Q, P and S denote, respectively, the (2,0) tensors on the manifold $\mathfrak{g}$ defined at each point V setting Q_V, P_V, $S_V:T_V^*\mathfrak{g}\approx\mathfrak{g}\to T_V\mathfrak{g}\approx\mathfrak{g}$,

$$Q_V\delta V:=[V,R\delta V]+R^*[V,\delta V], \tag{3.2}$$

$$P_V\delta V:=[V,R(V.\delta V)]+V.R^*[V,\delta V], \tag{3.3}$$

$$S_V\delta V:=\tfrac{1}{2}[V,R(V\delta VV)]+\tfrac{1}{2}V(R^*[V,\delta V])V. \tag{3.4}$$

In Eq. (3.3), . denotes the symmetrized product, so $V.\delta V=1/2(V\delta V+\delta VV)$.

We will say that Q, P and S are, respectively, the linear, quadratic and cubic tensor induced by R (this is motivated by their dependence on the footpoint V). ◇

Proposition 3.3:[5,6] If R and its skew-symmetric part $1/2(R-R^*)$ are r-matrices, Q, P and S are compatible Poisson tensors. The functions $h_k:\mathfrak{g}\to\mathbb{R}$, $h_k(V):=1/k\mathrm{Tr}V^k$ ($k=1,2,3,....$) satisfy the triHamiltonian recursion schemes (2.1)–(2.2); the vector fields $X_k:=Pdh_k$ are given explicitly by $X_k(V)=[V,R(V^k)]$. Finally, the function h_1 is a Casimir of Q if $[V,R(1)]=0$ for each $V\in\mathfrak{g}$. ◇

B. The split case of *r*-matrix theory

Given an associative algebra $\mathfrak{g}$ with unit, assume that there is a vector space decomposition $\mathfrak{g}=\mathfrak{g}_+\oplus\mathfrak{g}_-$. If $\mathfrak{g}$ is equipped with a traceform, we can define the annihilators

$$\mathfrak{g}^\pm:=(\mathfrak{g}_\pm)^\perp=\{W\in\mathfrak{g}\,|\,\langle W,V\rangle=0\quad\text{for each}\quad V\in\mathfrak{g}_\pm\}. \tag{3.5}$$

Due to the symmetry and nondegeneracy of $\langle,\rangle$ one easily infers that $\mathfrak{g}=\mathfrak{g}^+\oplus\mathfrak{g}^-$, and that the dual of $\mathfrak{g}^\mp$ can be identified with $\mathfrak{g}_\pm:(\mathfrak{g}^\mp)^*\approx\mathfrak{g}_\pm$. For each $V\in\mathfrak{g}$, we denote with $V_\pm$ and $V^\pm$ its components according to the previous direct sum decompositions of $\mathfrak{g}$. Let $\Pi_\pm,\Pi^\mp:\mathfrak{g}\to\mathfrak{g}$ be the projections corresponding to these decompositions. Then $\Pi^\mp$ is the adjoint of $\Pi_\pm$, and $R:=\Pi_+-\Pi_-$ has adjoint $R^*=\Pi^--\Pi^+$.

It is known that, if $\mathfrak{g}_\pm$ are Lie subalgebras of $\mathfrak{g}$, R is an r-matrix. Assume that $1/2(R-R^*)$ is also an r-matrix and consider the triHamiltonian structure of Def. 3.2. Explicitating R and R^* in Eqs. (3.2)–(3.4) one finds[5] that each of the tensors Q, P and S can be written as follows, in two equivalent ways:

$$Q_V\delta V=2[V,(\delta V)_+]-2[V,\delta V]^+=-2[V,(\delta V)_-]+2[V,\delta V]^-, \tag{3.6}$$

$$P_V\delta V=2[V,(V.\delta V)_+]-2V.[V,\delta V]^+=-2[V,(V.\delta V)_-]+2V.[V,\delta V]^-, \tag{3.7}$$

$$S_V\delta V=[V,(V\delta VV)_+]-V[V,\delta V]^+V=-[V,(V\delta VV)_-]+V[V,\delta V]^-V. \tag{3.8}$$

The vector fields $X_k:=Pdh_k$ of Prop. 3.3 are given in this case by

$$X_k=2[V,(V^k)_+]=-2[V,(V^k)_-]. \tag{3.9}$$

In many applications, but not in the one considered in this article, the splitting is such that $\mathfrak{g}^\pm=\mathfrak{g}_\pm$, implying $R^*=-R$: this is the so-called unitary case.

C. Split case: The reduction to $\mathfrak{g}^+$

Let the assumptions of Prop. 3.3 be satisfied, and consider the triHamiltonian structure (3.6) –(3.8) on $\mathfrak{g}$. Let us regard $\mathfrak{g}^+$ as a manifold: at each point $L \in \mathfrak{g}^+$, $T_L\mathfrak{g}^+ \approx \mathfrak{g}^+$ and $T_L^*\mathfrak{g}^+ \approx \mathfrak{g}_-$. We consider the embedding $j: \mathfrak{g}^+ \to \mathfrak{g}$ given by the identity map, and apply Prop. 2.2.

Proposition 3.4 (Ref. 5): The Poisson tensor Q of Eq. (3.6) can be (properly) restricted to $\mathfrak{g}^+$; at any point $L \in \mathfrak{g}^+$ the restricted tensor, denoted again with Q, is given by

$$Q_L \delta L = -2[L, \delta L]^+ \tag{3.10}$$

for each $\delta L \in \mathfrak{g}_-$. The tensor P of Eq. (3.7) can be (properly) restricted to $\mathfrak{g}^+$ if this subspace is closed in the symmetrized product, i.e., $L.L' \in \mathfrak{g}^+$ for each $L, L' \in \mathfrak{g}^+$; the restricted Poisson tensor is given by

$$P_L \delta L = 2[L, (L.\delta L)_+] - 2L.[L, \delta L]^+. \tag{3.11}$$

Finally, the tensor S of Eq. (3.8) can be (properly) restricted to $\mathfrak{g}^+$ if $LL'L \in \mathfrak{g}^+$ for each, $L, L' \in \mathfrak{g}^+$, and the restricted Poisson tensor is given by

$$S_L \delta L = [L, (L\,\delta L L)_+] - L[L, \delta L]^+ L. \tag{3.12}$$

Each of the two summands in Eq. (3.11), as well as in Eq. (3.12), belongs to $\mathfrak{g}^+$. ◇

Under the assumptions of the previous Proposition, the recursion scheme (2.1),(2.2) is again satisfied on $\mathfrak{g}^+$ by the restrictions of the functions h_k; the vector fields X_k in Eq. (3.9) are tangent to this submanifold.

D. Formal Casimirs and other biHamiltonian hierarchies

Let $\mathfrak{g}$ be an algebra equipped with an abstract r-matrix, as in Sec. III A. We consider the associative algebra $\mathfrak{g}[z]$ of formal series $W = \Sigma_{k=0}^{\infty} W_k z^k$, with coefficients $W_k \in \mathfrak{g}$; let $\mathfrak{g}_0[z]$ consist of the series with $W_0 = 0$. Using the real formal series $\ln(1+w) := \Sigma_{k=1}^{\infty} (-1)^{k+1} (1/k) w^k \in \mathbb{R}[w]$, for each $W \in \mathfrak{g}_0[z]$ we define the element

$$\ln(1+W) := \sum_{k=1}^{\infty} (-1)^{k+1} \frac{1}{k} (W_1 z + W_2 z^2 + \ldots)^k \in \mathfrak{g}_0[z]. \tag{3.13}$$

Equivalently, we can consider the series $U = 1 + W$ and define $\ln U$ for each $U = \Sigma_{k=0}^{\infty} U_k z^k \in \mathfrak{g}[z]$ $U_0 = 1$.

If $W = \Sigma_{k=1}^{\infty} W_k z^k$, the exponential $e^W := 1 + \Sigma_{k=1}^{\infty} (1/k!) W^k$ is also well defined, and we have $\ln(e^W) = W$ in the sense of formal series composition. Similarly, for $U = 1 + \Sigma_{k=1}^{\infty} (1/k!) U^k z^k$ we have $e^{\ln U} = U$.

We observe that the traceform $\mathrm{Tr}: \mathfrak{g} \to \mathbb{R}$ induces a linear function $\mathrm{Tr}: \mathfrak{g}[z] \to \mathbb{R}[z]$, $\mathrm{Tr}W := \Sigma_{k=0}^{\infty} (\mathrm{Tr} W_k) z^k$. Also, if $U \in \mathfrak{g}[z]$ and $U_0 = 1$, we put $\mathrm{Det}\, U := e^{\mathrm{Trln} U}$ (here, we have a composition of the real formal series $\mathrm{Trln}\, U$ and $e^w := \Sigma_{k=0}^{\infty} (1/k!) w^k$). It is not difficult to check that $\mathrm{Trln} U = \ln \mathrm{Det}\, U$.

We now refer to the r-matrix Poisson tensors Q, P of $\mathfrak{g}$ and consider the hierarchy of Hamiltonian functions $h_k: \mathfrak{g} \to \mathbb{R}$, $h_k(V) = 1/k \mathrm{Tr} V^k$ $(k = 1,2,3,\ldots)$. We recall that h_1 is a Casimir of Q if $R(1)$ is in the center of $\mathfrak{g}$; we will assume this condition to be satisfied. On the grounds of Sec. II B, the formal series $h := \Sigma_{k=1}^{\infty} h_k z^k$ is a Casimir of the Poisson pencil $Q - zP$. From here one can generate by composition other Casimirs; in particular, composing with the series $1 - e^{-w}$ one gets the formal Casimir

$$f := 1 - e^{-h} = \sum_{k=1}^{\infty} f_k z^k. \tag{3.14}$$

The functions f_k, which can be expressed as Schur polynomials in the h_k's (see Sec. II B.), also satisfy a biHamiltonian recursion scheme w.r.t. Q and P. It is straightforward to check the following.

Proposition 3.5: At each point $V \in \mathfrak{g}$, we have

$$h(V) = -\operatorname{Tr} \ln(1 - zV) = -\ln \operatorname{Det}(1 - zV), \quad f(V) = 1 - \operatorname{Det}(1 - zV). \tag{3.15}$$

◇

Using the Hamiltonians f_k ($k = 1,2,3,...$), we can define a sequence of commuting vector fields $Y_k := P df_k = Q df_{k+1}$. Since $f_1 = h_1$, we infer that $Y_1 = X_1$ is as in Prop. 3.3. The Hamiltonians f_k and $h_{k'}$ are in mutual involution w.r.t. the Q, P (and S) Poisson brackets for each k and k'.

Definition 3.6: The formal Casimirs h and f are called, respectively, the Flaschka Casimir and the Hénon Casimir; similarly, the functions h_k and f_k are referred to as the Flaschka and Hénon integrals. ◇

We use the above names for a historical reason; the integrals of motion of the periodic Toda lattice first constructed by these authors in Refs. 28 and 29 arise by simply specializing the above formalism to a particular algebra $\mathfrak{g}$, that will be described in the next section.

IV. THE ALGEBRAIC FRAMEWORK FOR THE PERIODIC TODA LATTICE

A. The Kupershmidt algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$

Throughout the rest of the article, n is a fixed positive integer.

Definition 4.1: Let $v = (v_\alpha)_{\alpha \in \mathbb{Z}}$ be a real sequence. For each $\nu \in \mathbb{Z}$, the ν-shift of v is the sequence $v_{[\nu]} := (v_{\alpha+\nu})_{\alpha \in \mathbb{Z}}$. It is said that v is n-periodic if $v_{[n]} = v$; $\mathbb{R}_n$ denotes the (n-dimensional) vector space of these sequences. For each $v \in \mathbb{R}_n$, we put $\Sigma_0 v := \Sigma_{j=1}^n v_j$, $\langle v \rangle := 1/n \Sigma_0 v$. ◇

Definition 4.2: The Kupershmidt algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$ consists of the formal Laurent series

$$V = \sum_{\sigma \in \mathbb{Z}} v_\sigma \Delta^\sigma, \tag{4.1}$$

where Δ is an indeterminate; each v_σ is an n-periodic sequence (of elements $v_{\sigma|\alpha}$); $v_\sigma = 0$ for $\sigma \gg 0$.[30] The product of V as above with $V' = \Sigma_{\sigma \in \mathbb{Z}} v'_\sigma \Delta^\sigma$ is

$$VV' := \sum_{\sigma \in \mathbb{Z}} \left(\sum_{\mu \in \mathbb{Z}} v_\mu v'_{\sigma - \mu[\mu]} \right) \Delta^\sigma. \tag{4.2}$$

The elements of $\mathbb{R}_n(\Delta,\Delta^{-1}]$ will be called (formal) differential-shift operators. ◇

This definition is modelled on Ref. 13; note that the sum over μ on the r.h.s. of Eq. (4.2) involves only a finite number of nonzero summands, due to the assumptions $v_\mu = 0$ and $v'_\mu = 0$ for $\mu \gg 0$.

It is easily checked that the product (4.2) is associative. This product can be characterized through the multiplication rules for the elements Δ^μ ($\mu \in \mathbb{Z}$) and $v\Delta^0 := v$ (where v is an arbitrary n-periodic sequence). It is $\Delta^\mu \Delta^\nu = \Delta^{\mu+\nu}$ and $\Delta^\mu v = v_{[\mu]} \Delta^\mu$; for each pair of sequences $v, v' \in \mathbb{R}_n$, the product vv' in $\mathbb{R}_n(\Delta,\Delta^{-1}]$ is just the ordinary pointwise product. The sequence with all elements equal to 1 is the unit element of this algebra.

The composition law (4.2) and the denomination of differential-shift operators can be understood in terms of a representation of the algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$ on an appropriate space $\mathbb{R}(\infty]$ of real infinite sequences; in this representation, Δ^μ acts as the shift operator by μ, and each sequence v acts as a pointwise multiplication operator. One easily proves the following

Proposition 4.3: Let $\mathbb{R}(\infty]$ denote the vector space of sequences $\psi = (\psi_\alpha)_{\alpha\in\mathbb{Z}}$ such that $\psi_\alpha=0$ for $\alpha\ll 0$; consider the algebra $\mathscr{G}in(\mathbb{R}(\infty])$ of the linear operators on $\mathbb{R}(\infty]$. Then the map π: $\mathbb{R}_n(\Delta,\Delta^{-1}]\to\mathscr{G}in(\mathbb{R}(\infty])$ defined by

$$(\pi(V)\psi)_\alpha := \sum_{\sigma\in\mathbb{Z}} v_{\sigma|\alpha}\psi_{\alpha+\sigma} \tag{4.3}$$

is a faithful representation of the algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$. In particular, for each integer μ and each $v\in\mathbb{R}_n$, it is

$$(\pi(\Delta^\mu)\psi)_\alpha=\psi_{\alpha+\mu}, \quad (\pi(v)\psi)_\alpha=v_\alpha\psi_\alpha. \tag{4.4}$$

◇

The algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$ also carries a trace, given by

$$\mathrm{Tr}V := \sum_0 v_0 = \sum_{i=1}^n v_{0|i} \tag{4.5}$$

for V as in Eq. (4.1). The bilinear form $\langle,\rangle$: $\mathbb{R}_n(\Delta,\Delta^{-1}]\times\mathbb{R}_n(\Delta,\Delta^{-1}]\to\mathbb{R}$, $\langle V,V'\rangle := \mathrm{Tr}(VV')$ is symmetric and nondegenerate.

B. Other realizations of the Kupershmidt algebra

The algebraic setting for the periodic Toda lattice proposed by Adler and van Moerbeke is based on the loop algebra $gl(n)(\lambda,\lambda^{-1}]$ of formal Laurent series in a parameter λ, where the coefficients are $n\times n$ real matrices. In this subsection, we show that $gl(n)(\lambda,\lambda^{-1}]$ is isomorphic to $\mathbb{R}_n(\Delta,\Delta^{-1}]$; the link between the two is a third algebra $gl_n[\infty)$, consisting of infinite n-periodic matrices, already considered in Ref. 12. These facts will be illustrated using the natural linear representations possessed by the three algebras, and finally summarized through the commutative diagram (4.14).

Definition 4.4: Throughout this article, an infinite matrix means a family $M = (M_{\alpha\beta})_{\alpha,\beta\in\mathbb{Z}}$ with $M_{\alpha\beta}\in\mathbb{R}$ for each α,β and with the additional property $M_{\alpha\beta}=0$ for $\beta-\alpha\gg 0$. An infinite matrix M is said to be n-periodic if $M_{\alpha+n,\beta+n}=M_{\alpha\beta}$ for each $\alpha,\beta\in\mathbb{Z}$; $gl_n[\infty)$ denotes the set of such matrices. ◇

We observe that, for each integer σ, the matrix elements $M_{\alpha\beta}$ with $\beta-\alpha=\sigma$ form the σ-th diagonal of M. So, a matrix in $gl_n[\infty)$ has zero entries above the κ-th diagonal for some integer κ, and the elements of each one of its diagonals form an n-periodic sequence. $gl_n[\infty)$ is an associative algebra with the usual matrix product. It carries a trace, given by $\mathrm{Tr}M := \Sigma_{j=1}^n M_{jj}$.

Definition 4.5: Let $\mathbb{R}(\infty]$ be the vector space of sequences appearing in Prop. 4.3. The tautological representation of $gl_n[\infty)$ on $\mathbb{R}(\infty]$ is the map π': $gl_n[\infty)\to\mathscr{G}in(\mathbb{R}(\infty])$ given by

$$(\pi'(M)\psi)_\alpha := \sum_{\beta\in\mathbb{Z}} M_{\alpha\beta}\psi_\beta. \tag{4.6}$$

◇

Proposition 4.6: Let π be the representation of $\mathbb{R}_n(\Delta,\Delta^{-1}]$ on $\mathbb{R}(\infty]$ considered in Prop. 4.3. There is a unique algebraic isomorphism Ψ: $\mathbb{R}_n(\Delta,\Delta^{-1}]\to gl_n[\infty)$ such that $\pi(V)=\pi'(\Psi(V))$ for each $V\in\mathbb{R}_n(\Delta,\Delta^{-1}]$. The expressions in components of the relations $M=\Psi(V)$ and $V=\Psi^{-1}(M)$ are

$$M_{\alpha\beta}=v_{\beta-\alpha|\alpha}, \quad v_{\sigma|\alpha}=M_{\alpha,\alpha+\sigma}, \tag{4.7}$$

for V as in Eq. (4.1) and α,β,σ arbitrary integers. Furthermore, Ψ is trace preserving.

Proof: It amounts to simple manipulations on indices. Note that, according to Eq. (4.7), the σ-th diagonal of the matrix M is fully determined by the sequence v_σ. ◇

We finally come to the loop algebra $gl(n)(\lambda,\lambda^{-1}]$.

Definition 4.7: $gl(n)(\lambda,\lambda^{-1}]$ is the set of formal Laurent series

$$A=\sum_{\rho\in Z} A_\rho\lambda^\rho \tag{4.8}$$

in an indeterminate λ, where, for each ρ, $A_\rho=(A_{\rho|jl})_{j,l=1,\ldots,n}$ is an $n\times n$ real matrix and $A_\rho=0$ for $\rho\gg 0$. ◇

$gl(n)(\lambda,\lambda^{-1}]$ is an associative algebra w.r.t. the usual Cauchy product of series. For each $A=\Sigma_\rho A_\rho\lambda^\rho$ we put $\mathrm{Tr}\,A:=\mathrm{tr}\,A_0$, where tr is the usual trace for $n\times n$ matrices (i.e., $\mathrm{tr}A_0=\Sigma_{j=1}^n A_{0|jj}$). The bilinear form $\langle,\rangle$: $gl(n)(\lambda,\lambda^{-1}]\times gl(n)(\lambda,\lambda^{-1}]\to\mathbb{R}$, $\langle A,A'\rangle:=\mathrm{Tr}(AA')$ is symmetric and nondegenerate.

Definition 4.8: Let $\mathbb{R}^n(\lambda,\lambda^{-1}]$ be the space of formal series $x=\Sigma_{\rho\in\mathbb{Z}}x_\rho\lambda^\rho$, where, for each ρ, $x_\rho=(x_{\rho|i})_{i=1,\ldots,n}$ is in $\mathbb{R}^n$ and $x_\rho=0$ for $\rho\gg 0$. The tautological representation of $gl(n)(\lambda,\lambda^{-1}]$ on this vector space is the map $\pi'':gl(n)(\lambda,\lambda^{-1}]\to\mathcal{S}in(\mathbb{R}^n[\lambda,\lambda^{-1}))$ given by

$$\pi''(A)x:=\sum_{\rho\in\mathbb{Z}}\left(\sum_{\mu\in\mathbb{Z}}A_\mu x_{\rho-\mu}\right)\lambda^\rho. \tag{4.9}$$

◇

Now, we introduce a linear isomorphism between the vector spaces of the representations π',π''; this isomorphism is the map $\mathcal{I}:\mathbb{R}(\infty]\to\mathbb{R}^n(\lambda,\lambda^{-1}]$, $\psi\mapsto\mathcal{I}\psi=\Sigma_{\rho\in\mathbb{Z}}x_\rho\lambda^\rho$, where

$$x_{\rho|i}:=\psi_{i-n\rho}. \tag{4.10}$$

By composition with $\mathcal{I}$ and $\mathcal{I}^{-1}$, the linear operators on $\mathbb{R}(\infty]$ are applied bijectively into the linear operators on $\mathbb{R}^n(\lambda,\lambda^{-1}]$.

Proposition 4.9: There is a unique algebraic isomorphism $\Phi:gl_n[\infty)\to gl(n)(\lambda,\lambda^{-1}]$ such that

$$\pi''(\Phi(M))=\mathcal{I}\pi'(M)\mathcal{I}^{-1} \tag{4.11}$$

for each $M\in gl_n[\infty)$. For $M=(M_{\alpha\beta})$ and $A=\Sigma_\rho A_\rho\lambda^\rho\in gl(n)(\lambda,\lambda^{-1}]$, the expressions in components of the equations $A=\Phi(M)$ and $M=\Phi^{-1}(A)$ are

$$A_{\rho|jl}=M_{j,l+n\rho}, \quad M_{j+n\nu,l+n\mu}=A_{\mu-\nu|jl} \tag{4.12}$$

for each $\rho,\mu,\nu,\in\mathbb{Z}$ and $j,l=1,\ldots,n$. Finally, Φ is trace preserving.

Proof: The uniqueness of the isomorphism Φ satisfying Eq. (4.11) follows from the fact that π' and π'' are faithful. To show the existence, we define Φ to be the map that associates to each $M \in gl_n[\infty)$ the element $A \in gl(n)(\lambda,\lambda^{-1}]$ as in the first Eq. (4.12); it can be checked by direct computation that Φ is one-to-one, with inverse as in the second Eq. (4.12), and that Eq. (4.11) holds.

We note that we can write $\Phi = (\pi'')^{-1} \circ Ad_{\mathcal{J}} \circ \pi'$ where $Ad_{\mathcal{J}}: \mathcal{S}in(\mathbb{R}^n(\lambda,\lambda^{-1}]) \to \mathcal{S}in(\mathbb{R}(\infty])$ is the map given by $Ad_{\mathcal{J}}(L) := \mathcal{J} L \mathcal{J}^{-1}$. So, Φ is a composition of algebraic isomorphisms, and therefore it is itself an isomorphism. The preservation of the trace under Φ follows immediately from Eq. (4.12). ◇

The isomorphism Φ appearing in the previous Proposition was introduced in Ref. 12; here, the infinite periodic matrix $M = \Phi^{-1}(A)$ corresponding to an element $A \in gl(n)(\lambda,\lambda^{-1}]$ is described by glueing together infinitely many $n \times n$ blocks:

$$M = \begin{pmatrix} \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \cdots & A_0 & A_1 & A_2 & A_3 & \cdots \\ \cdots & A_{-1} & A_0 & A_1 & A_2 & \cdots \\ \cdots & A_{-2} & A_{-1} & A_0 & A_1 & \cdots \\ \cdots & A_{-3} & A_{-2} & A_{-1} & A_0 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix} \tag{4.13}$$

(with a fixed basepoint). So, M is organized in block diagonals, and the ρ-th block diagonal contains infinitely many copies of A_ρ for each $\rho \in \mathbb{Z}$.

Of course, Propositions 4.6 and 4.9 imply the following.

Corollary 4.10: The map $\Phi \circ \Psi: \mathbb{R}_n(\Delta,\Delta^{-1}] \to gl(n)(\lambda,\lambda^{-1}]$ is a trace preserving, algebraic isomorphism. ◇

We can summarize the above results in the following commutative diagram:

$$\begin{array}{ccccc} & & \mathcal{S}in(\mathbb{R}(\infty]) & \xrightarrow[Ad_{\mathcal{J}}]{} & \mathcal{S}in(\mathbb{R}^n(\lambda,\lambda^{-1}]) \\ & \overset{\pi}{\nearrow} & \uparrow \pi' & & \uparrow \pi'' \\ \mathbb{R}_n(\Delta,\Delta^{-1}] & \xrightarrow[\Psi]{} & gl_n[\infty) & \xrightarrow[\Phi]{} & gl(n)(\lambda,\lambda^{-1}] \end{array} \tag{4.14}$$

(with $Ad_{\mathcal{J}}$ as in the proof of Prop. 4.9).

C. Finite order elements of $\mathbb{R}_n(\Delta,\Delta^{-1}]$: Adjunction and projection on $gl(n,\mathbb{C})$

A generic element V of the Kupershmidt algebra is a formal Laurent series as in Eq. (4.1). We now consider the elements which are finite sums: $v_\sigma \neq 0$ for finitely many values of σ; these form a subalgebra of $\mathbb{R}_n(\Delta,\Delta^{-1}]$. The counterparts of this subalgebra in $gl_n[\infty)$ and $gl(n)(\lambda,\lambda^{-1}]$ are formed, respectively, by the n-periodic matrices with finitely many nonzero diagonals and by the elements A as in Eq. (4.8), with $A_\rho \neq 0$ for finitely many values of ρ.

Definition 4.11: $\mathbb{R}_n(\Delta,\Delta^{-1})$ is the subalgebra of $\mathbb{R}_n(\Delta,\Delta^{-1}]$ formed by the elements V as in Eq. (4.1) such that $v_\sigma = 0$ for $|\sigma| \gg 0$.

$gl_n(\infty)$ is the subalgebra of $gl_n[\infty)$ formed by n-periodic matrices M such that $M_{\alpha\beta} = 0$ for $|\beta - \alpha| \gg 0$.

$gl(n)(\lambda,\lambda^{-1})$ is the subalgebra of $gl(n)(\lambda,\lambda^{-1}]$ formed by the elements A as in Eq. (4.8) such that $A_\rho = 0$ for $|\rho| \gg 0$. ◇

It is easily checked that these three algebras are mapped into each other by the isomorphisms Φ and Ψ in the diagram (4.14). In each of them, we can introduce an adjunction operation, which

is preserved by the transformations Φ and Ψ; so, we have three involutive algebras, which are mutually isomorphic. Also, these adjunctions are trace invariant: each element and its adjoint have equal traces. All these statements are easily checked, on the grounds of the following.

Definition 4.12: The adjoints of the elements $V \in \mathbb{R}_n(\Delta,\Delta^{-1})$, $M \in gl_n(\infty)$ and $A \in gl(n)(\lambda,\lambda^{-1})$, denoted with the suffix *, are defined by

$$V^*:=\sum_\sigma v_{-\sigma[\sigma]}\Delta^\sigma, \quad (M^*)_{\alpha\beta}:=M_{\beta\alpha}, \quad A^*:=\sum_\rho A^*_{-\rho}\lambda^\rho. \tag{4.15}$$

In the third equation, $A^*_{-\rho}$ is the usual transpose of the $n\times n$ matrix $A_{-\rho}$. ◇

The above adjunction in $\mathbb{R}_n(\Delta,\Delta^{-1}]$ can be characterized as the only involution such that $v^*=v$ for each sequence $v \in \mathbb{R}_n$ and $\Delta^*=\Delta^{-1}$. The involution in $gl(n)(\lambda,\lambda^{-1})$ is uniquely fixed stipulating that $\lambda^*=1/\lambda$ and that * coincides with the usual transposition on the $n\times n$ real matrices.[12]

The three algebras of Def. 4.11 can be projected homomorphically onto the algebra $gl(n,\mathbb{C})$ of the complex $n\times n$ matrices; there are infinitely many projections, one for each $\xi \in \mathbb{C}$. In the case of $gl(n)(\lambda,\lambda^{-1})$, the projections are the evaluation maps

$$Ev_\xi : gl(n)(\lambda,\lambda^{-1}) \to gl(n,\mathbb{C}), \quad A=\sum_\rho A_\rho\lambda^\rho \mapsto A(\xi):=\sum_\rho A_\rho\xi^\rho. \tag{4.16}$$

For each fixed ξ, Ev_ξ is an algebraic morphism (moreover, if $\xi=\pm i$, Ev_ξ maps the adjoint A^* into the Hermitian conjugate of the matrix $A(\xi)$). The diagram

$$\mathbb{R}_n(\Delta,\Delta^{-1}) \underset{\Psi}{\to} gl_n(\infty) \underset{\Phi}{\to} gl(n)(\lambda,\lambda^{-1}) \underset{Ev_\xi}{\to} gl(n,\mathbb{C}) \tag{4.17}$$

indicates how to obtain, by composition with Φ and Ψ, the homomorphic projections of $gl_n(\infty)$ and $\mathbb{R}_n(\Delta,\Delta^{-1})$ onto $gl(n,\mathbb{C})$. In view of the application to be discussed in Sec. VI, it is interesting to observe that Ev_ξ is not trace preserving: for each $A \in gl_n(\infty)$ and $\xi \in \mathbb{C}$, it is $\mathrm{tr}A(\xi) = \mathrm{Tr}A + \Sigma_{\rho\in\mathbb{Z}\setminus\{0\}}\mathrm{tr}(A_\rho)\xi^\rho$.
On the other hand, if A is the image under $\Phi\circ\Psi$ of an operator $V \in \mathbb{R}_n(\Delta,\Delta^{-1})$, it is $\mathrm{Tr}A=\mathrm{Tr}V$ and the diagonal elements of the matrices A_ρ are $A_{\rho|jj}=v_{n\rho|j}$. So,

$$\mathrm{tr}A(\xi)=\mathrm{Tr}V+\sum_{\rho\in\mathbb{Z}\setminus\{0\}}\left(\sum_{j=1}^n v_{n\rho/j}\right)\xi^\rho=\mathrm{Tr}V+\sum_{\rho\in\mathbb{Z}\setminus\{0\}}\mathrm{Tr}(V\Delta^{-n\rho})\xi^\rho. \tag{4.18}$$

In the application to the periodic Toda lattice, this equation will be basic in proving a number of statements on the Flaschka and Hénon integrals.

V. THE TRIHAMILTONIAN STRUCTURE OF THE PERIODIC TODA LATTICE: DERIVATION FROM THE ADLER–VAN MOERBEKE SPLITTING

In this section, we apply the theoretical schemes of Secs. II and III to construct the triHamiltonian structure of the periodic Toda lattice. Here the abstract algebra $\mathfrak{g}$ of Sec. III is taken to be the Kupershmidt algebra $\mathbb{R}_n(\Delta,\Delta^{-1}]$; the traceform Tr is as in Eq. (4.5). The splitting we introduce in $\mathfrak{g}=\mathbb{R}_n(\Delta,\Delta^{-1}]$ can be as well described in terms of the other two realizations of the Kupershmidt algebra given in Sec. IV. The description in terms of the loop algebra $gl(n)(\lambda,\lambda^{-1}]$ corresponds to the original treatment of the Toda lattice given in Ref. 12, where, in place of *r*-matrix theory, the earlier AKS scheme was employed, and only the first Poisson structure was considered. The realization in terms of infinite *n*-periodic matrices strongly emphasizes the analogy with the setting proposed by Refs. 5 and 6 for the finite nonperiodic Toda lattice. In any case, working with $\mathbb{R}_n(\Delta,\Delta^{-1}]$ seems more convenient from the computational viewpoint.

A. The splitting and the *r*-matrix

We start with the following.

Definition 5.1: Let $V=\Sigma_{\sigma\in\mathbb{Z}}v_\sigma\Delta^\sigma$ be in $\mathbb{R}_n(\Delta,\Delta^{-1}]$. We say that V is
symmetric if $V\in\mathbb{R}_n(\Delta,\Delta^{-1})$ and $V^*=V$;
skew-symmetric if $V\in\mathbb{R}_n(\Delta,\Delta^{-1})$ and $V^*=-V$;
of positive (resp. negative) type if $v_\sigma=0$ for $\sigma\leqslant 0$ (resp. $\sigma\geqslant 0$);
of nonnegative (resp. nonpositive) type if $v_\sigma=0$ for $\sigma<0$ (resp. $\sigma>0$). ◇

Definition 5.2: $\mathfrak{g}_\pm$ and $\mathfrak{g}^\pm$ are the linear subspaces of $\mathfrak{g}=\mathbb{R}_n(\Delta,\Delta^{-1}]$ defined by

$$\mathfrak{g}_+ :=\{B\in\mathfrak{g}\,|\,B \text{ is skew-symmetric}\}, \tag{5.1}$$

$$\mathfrak{g}_- :=\{T\in\mathfrak{g}\,|\,T \text{ is of nonpositive type}\}, \tag{5.2}$$

$$\mathfrak{g}^+ :=\{L\in\mathfrak{g}\,|\,L \text{ is symmetric}\}, \tag{5.3}$$

$$\mathfrak{g}^- :=\{N\in\mathfrak{g}\,|\,N \text{ is of negative type}\}. \tag{5.4}$$

◇

The following statements are easily checked:

Proposition 5.3: The subspaces $\mathfrak{g}_\pm$ are Lie subalgebras of $\mathfrak{g}$, and $\mathfrak{g}=\mathfrak{g}_+\oplus\mathfrak{g}_-$ (vector space direct sum); $\mathfrak{g}^\pm$ is the orthogonal of $\mathfrak{g}_\pm$ in the pairing $\langle,\rangle$. Finally, for each $L,L'\in\mathfrak{g}^+$ one has $L\cdot L'$ and $LL'L\in\mathfrak{g}^+$. ◇

For each $V=\Sigma_{\sigma\in\mathbb{Z}}v_\sigma\Delta^\sigma$, we put $V_{>0}:=\Sigma_{\sigma>0}v_\sigma\Delta^\sigma$, $V_{\geqslant 0}:=\Sigma_{\sigma\geqslant 0}v_\sigma\Delta^\sigma$ and define $V_{<0}$, $V_{\leqslant 0}$ in a similar way. Then

$$V_+=V_{>0}-(V_{>0})^*,\quad V_-=V_{\leqslant 0}+(V_{>0})^*, \tag{5.5}$$

$$V^+=V_{\geqslant 0}+(V_{>0})^*,\quad V^-=V_{<0}-(V_{>0})^*. \tag{5.6}$$

The expressions for V_+ and V^+ can be written equivalently in terms of the symmetrizations and skew-symmetrizations $V^{\mathrm{sym}}:=1/2(V+V^*)$, $V^{\mathrm{skew}}:=1/2(V-V^*)$. For each $V=\Sigma_\sigma v_\sigma\Delta^\sigma$, it is $V_+=2(V_{>0})^{\mathrm{skew}}$, $V^+=v_0+2(V_{>0})^{\mathrm{sym}}$. From the projections corresponding to the above splitting of $\mathfrak{g}$, we construct the operator $R:=\Pi_+-\Pi_-$, whose adjoint is $R^*=\Pi^--\Pi^+$. We note that $\frac{1}{2}(R-R^*)V=V_{>0}-V_{<0}$; it can be checked by direct computation that this operator satisfies the modified Yang–Baxter equation (3.1). From here, from Prop. 5.3 and from the general *r*-matrix theory reviewed in Sec. III, we draw the following conclusions:

Proposition 5.4: R and $\frac{1}{2}(R-R^*)$ are *r*-matrices on $\mathfrak{g}$; $\mathfrak{g}$ is a triHamiltonian manifold with the Poisson tensors (3.6)–(3.8). Furthermore, each of these Poisson tensors can be (properly) restricted to the subspace $\mathfrak{g}^+$, the restrictions being as in Eqs. (3.10)–(3.12). ◇

B. Restriction to the Flaschka submanifold

Let us consider the manifold $\mathbb{R}_n\times\mathbb{R}_n$; a typical point will be written as $x=(a,b)$. Both the tangent and cotangent space at x are obviously identified with $\mathbb{R}_n\times\mathbb{R}_n$; tangent vectors and covectors will be represented as pairs $\dot{x}=(\dot{a},\dot{b})$ and $\delta x=(\delta a,\delta b)$, with the pairing $\langle\delta x,\dot{x}\rangle:=\Sigma_\circ(\delta a\dot{a}+\delta b\dot{b})$.

Definition 5.5: For each $x=(a,b)$, let us put

$$L(x):=a\Delta+b+\Delta^{-1}a=b+2(a\Delta)^{\mathrm{sym}} \tag{5.7}$$

(in agreement with Eq. (1.5)). The embedding $\mathbb{R}_n\times\mathbb{R}_n\to\mathfrak{g}^+$, $x\mapsto L(x)$ will also be denoted by j. Its image $\mathscr{F}$, i.e., the set of all the operators (5.7), will be called the Flaschka submanifold. ◇

At any point x, the tangent map $T_xj\colon \mathbb{R}_n\times\mathbb{R}_n\to\mathfrak{g}^+$ sends $\dot{x}=(\dot{a},\dot{b})$ into

$$\dot{L}=\dot{a}\Delta+\dot{b}+\Delta^{-1}\dot{a}=\dot{b}+2(\dot{a}\Delta)^{\mathrm{sym}}; \tag{5.8}$$

the set of these operators is the tangent space of the Flaschka submanifold $\mathscr{F}$. Recalling Eq. (4.13) and the diagram (4.14), the following can be checked.

Proposition 5.6: For each $x\in\mathbb{R}_n\times\mathbb{R}_n$, $L(x)$ is the image under $\Psi^{-1}.\Phi^{-1}$ of the Lax matrix in Eq. (1.2). ◇

Proposition 5.7: The linear, quadratic and cubic Poisson tensors (3.10)–(3.12) can be properly restricted from $\mathfrak{g}^+$ to $\mathbb{R}_n\times\mathbb{R}_n$ along j. The restricted Poisson tensors, denoted again with Q, P and S, have the following expressions:

$$Q_x dx=\dot{x},\quad \begin{cases}\dot{a}:=2a\,\delta b-2a\,\delta b_{[1]},\\ \dot{b}:=2a_{[-1]}\delta a_{[-1]}-2a\,\delta a\end{cases} \tag{5.9}$$

$$P_x\delta x=\dot{x},\quad \begin{cases}\dot{a}:=aa_{[-1]}\delta a_{[-1]}-aa_{[1]}\delta a_{[1]}+2ab\,\delta b-2ab_{[1]}\delta b_{[1]},\\ \dot{b}:=2a_{[-1]}b\,\delta a_{[-1]}-2ab\,\delta a+4a_{[-1]}^2\delta b_{[-1]}-4a^2\,\delta b_{[1]}\end{cases} \tag{5.10}$$

$$S_x\delta x=\dot{x},\quad \begin{cases}\dot{a}:=a_{[-1]}ab\,\delta a_{[-1]}-aa_{[1]}b_{[1]}\delta a_{[1]}+a_{[-1]}^2a\,\delta b_{[-1]}-aa_{[1]}^2\delta b_{[2]}\\ \qquad +a(a^2+b^2)\,\delta b-a(a^2+b_{[1]}^2)\,\delta b_{[1]},\\ \dot{b}:=a_{[-2]}a_{[-1]}^2\delta a_{[-2]}-a^2a_{[1]}\delta a_{[1]}+a_{[-1]}(a_{[-1]}^2+b^2)\,\delta a_{[-1]}\\ \qquad -a(a^2+b^2)\,\delta a+2a_{[-1]}^2(b_{[-1]}+b)\,\delta b_{[-1]}-2a^2(b+b_{[1]})\,\delta b_{[1]}.\end{cases} \tag{5.11}$$

Proof: We refer to Prop. 2.2 for the notion of proper restriction. Let us consider a point $x=(a,b)\in\mathbb{R}_n\times\mathbb{R}_n$ and its image $L=L(x)$ in the Flaschka submanifold $\mathscr{F}$. Our procedure is divided in the following steps:

(i)–(iii) to show that $Q_L\delta L, P_L\delta L, S_L\delta L$ are tangent to $\mathscr{F}$, for each covector $\delta L\in T_L^*\mathfrak{g}^+\approx\mathfrak{g}_-$;

(iv) to characterize the covectors δL extending a given covector $\delta x=(\delta a,\delta b)$ at x, in the sense of Eq. (2.10).

Each of the four items is treated in the sequel. If κ is an integer, we write $\mathscr{O}(\Delta^\kappa)$ to denote any element of $\mathfrak{g}$ containing only the powers of Δ of exponent $\leqslant\kappa$, i.e., of the form $\Sigma_{\sigma\leqslant\kappa}v_\sigma\Delta^\sigma$.

(i) Let us show that $Q_L\delta L=-2[L,\delta L]^+$ is tangent to the Flaschka submanifold for each $\delta L\in\mathfrak{g}_-$. An element of $\mathfrak{g}_-$ can be written as

$$\delta L=p+\Delta^{-1}q+\mathscr{O}(\Delta^{-2}), \tag{5.12}$$

where $p,q\in\mathbb{R}_n$ are arbitrary. This implies

$$[L,\delta L]=(ap_{[1]}-ap)\Delta+(aq-a_{[-1]}q_{[-1]})+\mathscr{O}(\Delta^{-1}); \tag{5.13}$$

$$[L,\delta L]^+=(aq-a_{[-1]}q_{[-1]})+2\{(ap_{[1]}-ap)\Delta\}^{sym}. \tag{5.14}$$

So, $Q_L\delta L$ has the form (5.8) (and is henceforth tangent to the Flaschka submanifold) with coefficients

$$\dot{a}=2ap-2ap_{[1]},\quad \dot{b}=2a_{[-1]}q_{[-1]}-2aq. \tag{5.15}$$

(ii) Similar computations are required to prove that $P_L\delta L$ is tangent to $\mathscr{F}$ for each $\delta L \in \mathfrak{g}_-$. We use again Eq. (5.12) and evaluate separately the two terms $2[\mathrm{L},(L.\delta L)_+]$ and $2L.[L,\delta L]^+$ giving $P_L\delta L$ according to Eq. (3.11). The results are

$$2[L,(L.\delta L)_+]=2(a_{[-1]}^2-a^2)p+2a_{[-1]}^2p_{[-1]}-2a^2p_{[1]} \\ +2\{a(bp-b_{[1]}p_{[1]}+bp_{[1]}-b_{[1]}p)\Delta+aa_{[1]}(p_{[2]}-p)\Delta^2\}^{sym}, \quad (5.16)$$

$$2L.[L,\delta L]^+=2(a_{[-1]}^2-a^2)p-2a_{[-1]}^2p_{[-1]}+2a^2p_{[1]}+2b(aq-a_{[-1]}q_{[-1]})+2\{a(a_{[1]}q_{[1]} \\ -q_{[-1]}q_{[-1]}-bp+b_{[1]}p_{[1]}+bp_{[1]}-b_{[1]}p)\Delta+aa_{[1]}(p_{[2]}-p)\Delta^2\}^{sym}. \quad (5.17)$$

Subtracting Eq. (5.17) from (5.16), we obtain that $P_L\delta L$ is tangent to the Flaschka submanifold and of the form (5.8), with coefficients

$$\dot a=aa_{[-1]}q_{[-1]}-aa_{[1]}q_{[1]}+2abp-2ab_{[1]}p_{[1]}, \\ \dot b=2a_{[-1]}bq_{[-1]}-2abq+4a_{[-1]}^2p_{[-1]}-4a^2p_{[1]}. \quad (5.18)$$

(iii) The computation of $S_L\delta L$ according to Eq. (3.12) requires the separate evaluation of the terms $[L,(L\,\delta L L)_+]$ and $L[L,\delta L]^+L$. We have

$$[L,(L\,\delta L L)_+]=k+2\{m\Delta+r\Delta^2+s\Delta^3\}^{sym}, \quad (5.19)$$

$$L[L,\delta L]^+L=u+2\{w\Delta+r\Delta^2+s\Delta^3\}^{sym}, \quad (5.20)$$

where $k,m,\ldots,w$ are given by

$$k:=2a_{[-1]}^2bp-2a^2bp+2a_{[-1]}^2b_{[-1]}p_{[-1]}-2a^2b_{[1]}p_{[1]}+2a_{[-1]}^3q_{[-1]}-2a^3q,$$

$$m:=aa_{[-1]}^2p-aa_{[1]}^2p_{[1]}+ab^2p-ab_{[1]}^2p_{[1]}+abb_{[1]}p_{[1]}-abb_{[1]}p+a^2bq-a^2b_{[1]}q,$$

$$r:=aa_{[1]}bp_{[1]}-aa_{[1]}bp+aa_{[1]}b_{[2]}p_{[2]}-aa_{[1]}b_{[2]}p_{[1]}+aa_{[1]}^2q_{[1]}-a^2a_{[1]}q,$$

$$s:=aa_{[1]}a_{[2]}p_{[2]}-aa_{[1]}a_{[2]}p_{[1]}, \quad (5.21)$$

$$u:=2a_{[-1]}^2bp-2a^2bp+2a^2bp_{[1]}-2a_{[-1]}^2bp_{[-1]}+a_{[-1]}^3q_{[-1]}-a^3q+ab^2q \\ -a_{[-1]}b^2q_{[-1]}+a^2a_{[1]}q_{[1]}-a_{[-2]}a_{[-1]}^2q_{[-2]},$$

$$w:=aa_{[-1]}^2p-aa_{[-1]}^2p_{[-1]}+a^3p_{[1]}-a^3p+abb_{[1]}p_{[1]}-abb_{[1]}p+aa_{[1]}^2p_{[2]} \\ -aa_{[1]}^2p_{[1]}+aa_{[1]}b_{[1]}q_{[1]}-aa_{[-1]}bq_{[-1]}+a^2bq-a^2b_{[1]}q.$$

Subtracting Eq. (5.20) from Eq. (5.19), we obtain that $S_L\delta L$ is as in Eq. (5.8) (and henceforth tangent to the Flaschka submanifold) with coefficients

$$\dot a=a_{[-1]}abq_{[-1]}-aa_{[1]}b_{[1]}q_{[1]}+a_{[-1]}^2ap_{[-1]}-aa_{[1]}^2p_{[2]}+a(a^2+b^2)p-a(a^2+b_{[1]}^2)p_{[1]}, \\ \dot b=a_{[-2]}a_{[-1]}^2q_{[-2]}-a^2a_{[1]}q_{[1]}+a_{[-1]}(a_{[-1]}^2+b^2)q_{[-1]}-a(a^2+b^2)q \\ +2a_{[-1]}^2(b_{[-1]}+b)p_{[-1]}-2a^2(b+b_{[1]})p_{[1]}. \quad (5.22)$$

(iv) On the grounds of the results in items (i)–(iii), the Poisson tensors Q, P and S can be properly restricted to $\mathbb{R}_n\times\mathbb{R}_n$ along j. Now, consider (at a point $L=L(x)$) a covector $\delta L\in\mathfrak{g}_-$, written as in Eq. (5.12); for each $\dot{L}$ as in (5.8), we have

$$\mathrm{Tr}(\delta L\dot{L})=\mathrm{Tr}(p\dot{a}\Delta+q_{[-1]}\dot{a}_{[-1]}+p\dot{b}+l(\Delta^{-1}))=\sum_0(q\dot{a}+p\dot{b}). \tag{5.23}$$

By definition, δL extends a covector $\delta x=(\delta a,\delta b)\in\mathbb{R}_n\times\mathbb{R}_n$ if $\langle\delta L,\dot{L}\rangle=\langle\delta x,\dot{x}\rangle=\Sigma_0(\delta a\dot{a}+\delta b\dot{b})$ for each $\dot{x}=(\dot{a},\dot{b})\in\mathbb{R}_n\times\mathbb{R}_n$. From Eq. (5.23), it is seen that this happens if $q=\delta a$, $p=\delta b$. Inserting this result in Eqs. (5.15), (5.18), and (5.22), we conclude that the restricted Poisson tensors Q, P and S are as in Eqs. (5.9)–(5.11). ◇

VI. RECURSION SCHEMES ON THE FLASCHKA SUBMANIFOLD

Throughout this section, the restrictions of Q,P,S,h_k,X_k ($k=1,2,3...$) from $\mathfrak{g}^+$ to $\mathbb{R}_n\times\mathbb{R}_n$ along j are denoted with the same symbols. At each point $x=(a,b)$, the Hamiltonians are

$$h_1(x)=\mathrm{Tr}L(x)=\sum_0 b,\quad h_2(x)=\frac{1}{2}\,\mathrm{Tr}\,L^2(x)=\sum_0\left(\frac{1}{2}\,b^2+a^2\right),$$
$$h_3(x)=\frac{1}{3}\,\mathrm{Tr}\,L^3(x)=\sum_0\left(\frac{1}{3}\,b^3+a^2b+a^2b_{[1]}\right), \tag{6.1}$$

and so on. We have $Q_xd_xh_1=0$, and

$$X_k(x)=P_xd_xh_k=Q_xd_xh_{k+1}=S_xd_xd_{k-1}. \tag{6.2}$$

$X_1(x)$ has components $\dot{a}$ and $\dot{b}$ as in Eq. (1.1). The Lax formulation (1.5) for this vector field follows from Eq. (3.9); the companion $B_1(x)$ in Eq. (1.5) is just $2(L(x))_+$, and, more generally, each vector field X_k on $\mathbb{R}_n\times\mathbb{R}_n$ admits a Lax formulation $dL/dt_k=[L,B_k]$, with $B_k(x)=2(L^k(x))_+$.

Let us choose one of the three Poisson structures, say Q. By construction, all vector fields X_k belong to $\mathrm{Im}\,Q$, so they are tangent to the symplectic leaves of the Poisson tensor;[31] on each symplectic leaf, one can discuss the Arnold–Liouville integrability of the Toda hierarchy. It is known from the literature[12] that only $n-1$ vector fields in the sequence X_k ($k=1,2,3,...$) are linearly independent at a generic point x of $\mathbb{R}_n\times\mathbb{R}_n$; the property of being generically independent is satisfied for instance by the first $n-1$ fields. On the other hand, $n-1$ is just half the dimension of a generic symplectic leaf of Q, so the complete integrability of the system is ensured. Let us consider on $\mathbb{R}_n\times\mathbb{R}_n$ the Hamiltonians h_k for the first $n+1$ values of k. To compute them, it is not even necessary to employ the operator $L(x)$; in fact, it suffices to consider a finite matrix $\Lambda(x)$ and the ordinary traces of its powers.

Proposition 6.1: At each point $x=(a,b)$, consider the $n\times n$ matrix

$$\Lambda(x):=\begin{pmatrix} b_1 & a_1 & 0 & .. & .. & 0 & -ia_n\\ a_1 & b_2 & a_2 & 0 & .. & .. & 0\\ 0 & a_2 & b_3 & a_3 & .. & .. & ..\\ .. & .. & .. & .. & .. & .. & ..\\ .. & .. & .. & .. & .. & a_{n-2} & 0\\ 0 & .. & .. & 0 & a_{n-2} & b_{n-1} & a_{n-1}\\ ia_n & 0 & .. & .. & 0 & a_{n-1} & b_n \end{pmatrix} \tag{6.3}$$

(obtained setting $\lambda = i$ in Eq. (1.2), where i is the imaginary unit). Then $h_k(x) = (1/k)\mathrm{tr}\,\Lambda^k(x)$ for $k = 1,2,\ldots,n+1$.

Proof: With the notations of Sec. IV, the matrix (6.3) is related to the operator $L(x) = a\Delta + b + a_{[-1]}\Delta^{-1}$ by the equation $\Lambda(x) = Ev_i(\Psi \circ \Phi(L(x)))$, and a similar relation holds for the powers of $\Lambda(x)$ and $L(x)$. The thesis is proved if we show that $\mathrm{tr}\,\Lambda^k(x) = \mathrm{Tr}\,L^k(x)$ for $k = 1,2,\ldots,n+1$. On the grounds of Eq. (4.18), for each positive integer k we have

$$\mathrm{tr}\,\Lambda^k(x) - \mathrm{Tr}\,L^k(x) = \sum_{\rho \in \mathbb{Z}\setminus\{0\}} i^\rho \mathrm{Tr}(L^k(x)\Delta^{-n\rho}); \tag{6.4}$$

from the explicit expression of the operator $L(x)$, one infers that the r.h.s. of this equation is zero for $k \leqslant n+1$. ◇

Remark 6.2: The finite matrix $\Lambda(x)$ is also a Lax operator for the periodic Toda lattice. Due to this fact, one might conjecture that the whole theory of the periodic Toda lattice can be developed using the finite-dimensional algebra $\mathfrak{g} = gl(n,\mathbb{C})$ of $n \times n$ complex matrices instead of the infinite-dimensional algebra $\mathfrak{g} = \mathbb{R}_n(\Delta,\Delta^{-1}]$ employed in this article. Unfortunately, it is not known how to construct an r-matrix in $gl(n,\mathbb{C})$, so as to induce the Toda multiHamiltonian structure on the submanifold described by Eq. (6.3). Working with the finite $n \times n$ matrices one introduces some ''boundary effects'' related to the presence of the element a_n in the corners of the matrix $\Lambda(x)$; the price for the elimination of such effects is the infinite dimensionality of $\mathfrak{g} = \mathbb{R}_n(\Delta,\Delta^{-1}]$.

We now recall that in Sec. III D we have considered on $\mathfrak{g}$ or $\mathfrak{g}^+$ an alternative sequence of Hamiltonian functions f_k ($k = 1,2,3,...$), in such a way that, at each point L, $\mathrm{Det}(1 - zL) = 1 - \Sigma_{k=1}^{\infty} f_k(L) z^k$. This chain also satisfies a biHamiltonian recursion scheme w.r.t. Q and P; the f_k's can be expressed as Schur polynomials in the h_k's via Eq. (2.5).

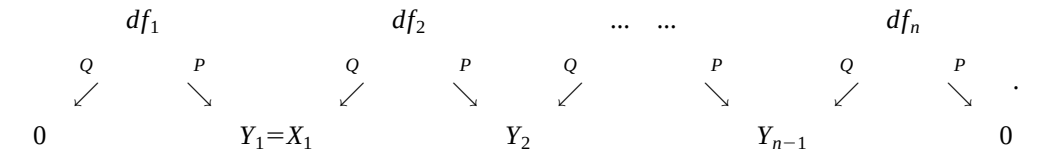
Proposition 6.3: $f_1(x),\ldots,f_n(x)$ are the coefficients of the characteristic polynomial of $\Lambda(x)$, i.e., $\det(\Lambda(x) - \zeta) = (-1)^n(\zeta^n - f_1(x)\zeta^{n-1} - f_2(x)\zeta^{n-2} - \ldots - f_n(x))$. Furthermore, it is $f_{n+1}(x) = 0$.

Proof: Let us recall that, for each k, we have $f_k(x) = S_k(h_1(x),h_2(x),h_3(x),\ldots)$, where S_k is the Schur polynomial defined as in Eq.(2.6); in particular, $f_1(x),\ldots,f_{n+1}(x)$ depend only on $h_1(x),\ldots,h_{n+1}(x)$, which can be computed from the traces of the finite matrix $\Lambda(x)$ and its powers (Prop. 6.1). The thesis follows from this and from elementary matrix theory:[32,33] in fact, if we consider any $n \times n$ matrix Λ and set $t_j := (1/j)\mathrm{tr}\Lambda^j$, then the Schur polynomials $S_k(t_1,t_2,t_3,\ldots)$ for $k \leqslant n$ are known to give the coefficients of $\det(\Lambda - \zeta)$ (this fact is related to the so-called Leverrier method for computing the characteristic polynomial[33,34]). Also, it is known that $S_k(t_1,t_2,t_3,\ldots) = 0$ for $k \geqslant n+1$, which means that the characteristic polynomial has degree n. From here we infer the thesis.[35] ◇

In Sec. III D we proposed the denomination of Flaschka and Hénon integrals for the functions h_k and f_k on an arbitrary r-matrix algebra $\mathfrak{g}$ (not necessarily the one considered here). In the present case, considering the functions h_k and f_k on the ''space of coordinates'' $\mathbb{R}_n \times \mathbb{R}_n$ of the Flaschka submanifold, we recover for $k = 1,\ldots,n$ the systems of integrals first constructed in Refs. 28 and 29 for the Toda lattice. The expression of the f_k's as polynomials in the h_k's for the first values of k was found by Hénon; our formulas (2.7)–(2.8) provide a general rule, based on the theory of the Schur polynomials.

Our framework also allows us to derive a property of the Hénon integrals, which has some interest from the biHamiltonian viewpoint. In general, for a finite dimensional system the biHamiltonian approach acquires a more elegant form if one is able to exhibit a finite hierarchy where both the initial and the final Hamiltonian are Casimirs. The chain $f_1,\ldots,f_n$ possesses this property:

Proposition 6.4: The Hénon integrals $f_1,\ldots,f_n$ and the vector fields $Y_1 = Pdf_1,\ldots,Y_{n-1} = Pdf_{n-1}$ on $\mathbb{R}_n \times \mathbb{R}_n$ form a finite biHamiltonian hierarchy, starting from a Casimir of Q and ending with a Casimir of P:



(6.5)

Proof: The recurrence relations and the property $Qdf_1=0$ hold in general on $\mathfrak{g}$ or $\mathfrak{g}^+$, so they are also satisfied by the restrictions to $\mathbb{R}_n\times\mathbb{R}_n$ along j. The statement that $Pdf_n=0$ on $\mathbb{R}_n\times\mathbb{R}_n$ follows from $Pdf_n=Qdf_{n+1}$ and the fact that $f_{n+1}=0$. ◇

Let us present explicitly the finite biHamiltonian chain for $n=3$. We have

$$f_1(x)=h_1(x)=b_1+b_2+b_3,\quad f_2(x)=a_1^2+a_2^2+a_3^2-b_1b_2-b_2b_3-b_3b_1,$$
$$f_3(x)=b_1b_2b_3-a_1^2b_3-a_2^2b_1-a_3^2b_2. \tag{6.6}$$

The vector field $Y_1=X_1$ is as in Eq. (1.1) and $Y_2(x)=(\dot{a},\dot{b})$, where

$$\dot{a}=2a(a_{[-1]}^2-a_{[1]}^2)+2ab_{[-1]}(b_{[1]}-b),$$
$$\dot{b}=4a^2b_{[-1]}-4a_{[-1]}^2b_{[1]}. \tag{6.7}$$

It turns out that Y_1 and Y_2 are independent on a generic subset of $\mathbb{R}_3\times\mathbb{R}_3$; so they can be employed to prove Liouville integrability of the system on the symplectic leaves of Q (or P), which are four-dimensional in the present case. For $n=4$, we have a chain of Hamiltonians $f_1,\ldots,f_4$ with three generically independent vector fields Y_1,Y_2,Y_3, and so on.

VII. THE TODA TRIHAMILTONIAN STRUCTURE: DERIVATION FROM THE KUPERSHMIDT LAX OPERATOR

In this section, we consider the alternative formulation of the periodic Toda lattice in which the evolution equations of the system have the form (1.3), and the associated Lax pair is given in terms of the operators (1.6); this is the setting adopted in Ref. 13. The algebra $\mathfrak{g}$ supporting this formulation is again $\mathbb{R}_n(\Delta,\Delta^{-1}]$.

A. Another splitting of $\mathbb{R}_n(\Delta,\Delta^{-1}]$

The alternative choice is suggested by the prescription of Ref. 13 for the Lax pairs $dV/dt_k=[V,C_k]$ of the Toda hierarchy, which is $C_k(y)=2(V^k(y))_{\geqslant 0}$. The same splitting was employed in Ref. 11 for the infinite Toda chain and some generalizations of it (in that paper, the reduction was performed for the first two associated Poisson structures, and not for the third one). In the sequel, the symbols $_{\geqslant 0,>0}$, etc., are intended as in Sec. V.

Definition 7.1: $\mathfrak{g}_\pm$ and $\mathfrak{g}^\pm$ are the linear subspaces of $\mathfrak{g}=\mathbb{R}_n(\Delta,\Delta^{-1}]$ defined by

$$\mathfrak{g}_+:=\{C\in\mathfrak{g}\,|\,C \text{ is of nonnegative type}\}, \tag{7.1}$$

$$\mathfrak{g}_-:=\{N\in\mathfrak{g}\,|\,N \text{ is of negative type}\}, \tag{7.2}$$

$$\mathfrak{g}^+:=\{D\in\mathfrak{g}\,|\,D \text{ is of positive type}\}, \tag{7.3}$$

$$\mathfrak{g}^-:=\{Z\in\mathfrak{g}\,|\,Z \text{ is of nonpositive type}\}. \tag{7.4}$$

◇

Proposition 7.2: The subspaces $\mathfrak{g}_{\pm}$ are Lie subalgebras of $\mathfrak{g}$, and $\mathfrak{g}=\mathfrak{g}_{+}\oplus\mathfrak{g}_{-}$ (vector space direct sum); $\mathfrak{g}^{\pm}$ is the orthogonal of $\mathfrak{g}_{\pm}$ in the pairing $\langle,\rangle$. ◇

For each $V\in\mathfrak{g}$, the components according to the splitting of Def. 7.1 are $V_{+}=V_{\geqslant 0}$, $V_{-}=V_{<0}$, $V^{+}=V_{>0}$, $V^{-}=V_{\leqslant 0}$. Of course, the operator $\mathscr{R}$ on $\mathfrak{g}$ and its adjoint $\mathscr{R}^{*}$ given by $\mathscr{R}(V):=V_{+}-V_{-}$, $\mathscr{R}^{*}(V)=V^{-}-V^{+}$ are now different from the operators R and R^{*} considered in Sec. V, but, incidentally, the skew-symmetrization $\frac{1}{2}(\mathscr{R}-\mathscr{R}^{*})$ is again as in Eq.(5.8). We have the following.

Proposition 7.3: $\mathscr{R}$ and $\frac{1}{2}(\mathscr{R}-\mathscr{R}^{*})$ are r-matrices on $\mathfrak{g}$; $\mathfrak{g}$ is a triHamiltonian manifold with the Poisson tensors (3.6)–(3.8). ◇

We will employ script letters to denote these Poisson tensors, which have the form

$$\mathscr{Q}_{v}\delta V=2[V,(\delta V)_{\geqslant 0}]-2[V,\delta V]_{>0}=-2[V,(\delta V)_{<0}]+2[V,\delta V]_{\leqslant 0}, \tag{7.5}$$

$$\mathscr{P}_{v}\delta V=2[V,(V.\delta V)_{\geqslant 0}]-2V.[V,\delta V]_{>0}=-2[V,(V.\delta V)_{<0}]+2V.[V,\delta V]_{\leqslant 0}, \tag{7.6}$$

$$\mathscr{S}_{v}\delta V=[V,(V\delta VV)_{\geqslant 0}]-V[V,\delta V]_{>0}V=-[V,(V\delta VV)_{<0}]+V[V,\delta V]_{\leqslant 0}V. \tag{7.7}$$

The functions $h_{k}(V)=(1/k)\mathrm{Tr}V^{k}$ satisfy the triHamiltonian recursion relations (2.1) and (2.2) w.r.t. $\mathscr{Q}$, $\mathscr{P}$ and $\mathscr{S}$; also, the functions f_{k} forming the Hénon Casimir give rise to a biHamiltonian recursion with $\mathscr{Q}$ and $\mathscr{P}$. Using these Hamiltonian functions, we can define infinitely many commuting vector fields $\mathscr{X}_{k}:=\mathscr{P}dh_{k}$ and $\mathscr{Y}_{k}:=\mathscr{P}df_{k}$; we have

$$\mathscr{X}_{k}(V)=2[V,(V^{k})_{\geqslant 0}]. \tag{7.8}$$

B. Restriction of the triHamiltonian structure

Let us consider the manifold $\mathbb{R}_{*}\times\mathbb{R}_{n}\times\mathbb{R}_{n}$, where $\mathbb{R}_{*}:=\mathbb{R}\backslash\{0\}$. A typical point is written as $z=(K,d,b)$; here, K is a nonzero real number, while d and b are n-periodic sequences. Both the tangent and cotangent space at z are identified with $\mathbb{R}\times\mathbb{R}_{n}\times\mathbb{R}_{n}$; tangent vectors and covectors are represented as triples $\dot{z}=(\dot{K},\dot{d},\dot{b})$ and $\delta z=(\delta K,\delta d,\delta b)$, with the pairing $\langle\delta z,\dot{z}\rangle:=\delta K\dot{K}+\Sigma_{0}(\delta d\dot{d}+\delta b\dot{b})$.

Definition 7.4: For each $z=(K,d,b)$ we put

$$V(z):=K\Delta+b+\Delta^{-1}d. \tag{7.9}$$

The embedding $\mathbb{R}_{*}\times\mathbb{R}_{n}\times\mathbb{R}_{n}\to\mathfrak{g}$, $z\mapsto V(z)$ will also be denoted by J. Its image $\mathscr{H}$, i.e., the set of all the operators (7.9), will be called the *extended Kupershmidt submanifold.* ◇

We note that, for $K=1$ and $d=c$, the operator (7.9) becomes the Kupershmidt Lax operator in Eq. (1.6).

At any point z, the tangent map $T_{z}J:\mathbb{R}\times\mathbb{R}_{n}\times\mathbb{R}_{n}\to\mathfrak{g}$ sends $\dot{z}=(\dot{K},\dot{d},\dot{b})$ into

$$\dot{V}=\dot{K}\Delta+\dot{b}+\Delta^{-1}\dot{d}; \tag{7.10}$$

the set of these operators is the tangent space of the submanifold $\mathscr{H}$ at $V(z)$.

Our aim is to restrict the r-matrix triHamiltonian structure (7.5)–(7.7) to $\mathbb{R}_{*}\times\mathbb{R}_{n}\times\mathbb{R}_{n}$ along J. As we shall see, the linear Poisson tensor fits the proper restriction scheme. This technique is not appropriate for the quadratic and the cubic ones, and the more subtle machinery of the Dirac reduction must be invoked; in a sense, this is a price one has to pay for having chosen an apparently simpler splitting than in Sec. V.

Proposition 7.5: The three Poisson tensors (7.6)–(7.8) can be restricted from $\mathfrak{g}$ to $\mathbb{R}_{*}\times\mathbb{R}_{n}\times\mathbb{R}_{n}$ along J (the first one in the proper sense, the other two in the Dirac sense). The restrictions have the following expressions:

$$\mathscr{Q}_z\delta z=\dot z,\begin{cases}\dot K:=0,\\ \dot d:=2d\,\delta b-2d\,\delta b_{[1]},\\ \dot b:=2d_{[-1]}\delta d_{[-1]}-2d\,\delta d,\end{cases}\tag{7.11}$$

$$\mathscr{P}_z\delta z=\dot z,\begin{cases}\dot K:=0,\\ \dot d:=2d(d_{[-1]}\delta d_{[-1]}-d_{[1]}\delta d_{[1]}+b\,\delta b-b_{[1]}\delta b_{[1]}),\\ \dot b:=2b(d_{[-1]}\delta d_{[-1]}-d\,\delta d)+2K(d_{[-1]}\delta b_{[-1]}-d\,\delta b_{[1]}),\end{cases}\tag{7.12}$$

$$\mathscr{S}_z\delta z=\dot z,\begin{cases}\dot K:=-K\langle(b-b_{[1]})d\,\delta d\rangle+K^2\langle d(\delta b-\delta b_{[1]})\rangle,\\ \dot d=2d(bd_{[-1]}\delta d_{[-1]}-b_{[1]}d_{[1]}\delta d_{[1]})+Kd(d_{[-1]}\delta b_{[-1]}-d_{[1]}\delta b_{[2]})\\ \quad+d(Kd+b^2)\delta b-d(Kd+b_{[1]}^2)\delta b_{[1]}+d(b_{[1]}-b)\langle d\,\delta d\rangle\\ \quad+d\langle(b-b_{[1]})d\,\delta d\rangle-Kd\langle d(\delta b-\delta b_{[1]})\rangle+1/n\;Kd(b-b_1)\delta K,\\ \dot b=K(d_{[-2]}d_{[-1]}\delta d_{[-2]}-dd_{[1]}\delta d_{[1]})+d_{[-1]}(Kd_{[-1]}+b^2)\delta d_{[-1]}\\ \quad-d(Kd+b^2)\delta d+Kd_{[-1]}(b_{[-1]}+b)\delta b_{[-1]}-Kd(b+b_{[1]})\delta b_{[1]}\\ \quad+K(d-d_{[-1]})\langle d\,\delta d\rangle-1/n\;K^2(d-d_{[-1]})\delta K.\end{cases}\tag{7.13}$$

(Recall that, for each sequence $v\in\mathbb{R}_n$, $\langle v\rangle$ denotes the average of v over a period, see Def. 4.1).

Proof: Let us consider any point $z=(K,d,b)$ and its image $V=V(z)$ in the submanifold $\mathscr{H}$. Our procedure is divided in the following steps:
(i) to compute $\mathscr{Q}_v\delta V$, $\mathscr{P}_v\delta V$ and $\mathscr{S}_v\delta V$ for an arbitrary $\delta V\in T_v^*\mathfrak{g}\approx\mathfrak{g}$;
(ii) to find the most general covector $\delta V\in\mathfrak{g}$ extending a given $\delta z=(\delta K,\delta d,\delta b)$ in the sense of Eq. (2.10);
(iii)–(v) to check restrictability, and make explicit the restrictions of $\mathscr{Q}$, $\mathscr{P}$ and $\mathscr{S}$.

In the sequel, if κ is an integer, we write $u(\Delta^\kappa)$ to denote any element of $\mathfrak{g}$ in which the powers of Δ occur with exponents $\geqslant\kappa$. We also employ the notation $\ell(\Delta^k)$ as in Sec. V, to denote the operators in which the powers of Δ have exponents $\leqslant k$.

(i) We must compute $\mathscr{Q}_v\delta V$ for an arbitrary $\delta V\in\mathfrak{g}$. Let us start from the particular case $\delta V=u(\Delta^2)$. Then $[V,\delta V]_{\leqslant 0}=0$, and from the second representation in Eq. (7.5) we infer $\mathscr{Q}_v\delta V=0$. Similarly, from the first representation in Eq. (7.5) we infer that $\mathscr{Q}_v\delta V=0$ for $\delta V=\ell(\Delta^{-1})$. A general covector in $\mathfrak{g}$ can be written as

$$\delta V=u(\Delta^2)+q\Delta+p+\ell(\Delta^{-1}),\tag{7.14}$$

with arbitrary coefficients $q,p\in\mathbb{R}_n$. Only the middle term $q\Delta+p$ gives a nonzero result on application of $\mathscr{Q}$; from the second Eq. (7.5), we conclude that

$$\mathscr{Q}_v\delta V=2[K\Delta+b+\Delta^{-1}d,q\Delta+p]_{\leqslant 0}=2(d_{[-1]}q_{[-1]}-dq)+2\Delta^{-1}(dp-dp_{[1]}).\tag{7.15}$$

This means that the vector $\mathscr{Q}_v\delta V$ is of the form (7.10), and henceforth tangent to $\mathscr{H}$, with coefficients

$$\dot K=0,\quad \dot d=2dp-2dp_{[1]},\quad \dot b=2d_{[-1]}q_{[-1]}-2dq.\tag{7.16}$$

We now compute $\mathscr{P}_v\delta V$ for an arbitrary $\delta V\in\mathfrak{g}$; the second and the first representations in Eq. (7.6) can be used to prove that $\mathscr{P}_v\delta V=0$ both for $\delta V=u(\Delta^2)$ and for $\delta V=\ell(\Delta^{-2})$. We write a general $\delta V\in\mathfrak{g}$ as

$$\delta V=u(\Delta^2)+q\Delta+p+r\Delta^{-1}+\ell(\Delta^{-2});\tag{7.17}$$

then only the middle terms in q,p,r contribute under application of $\mathscr{P}$, and the result is

$$\mathscr{P}_v \delta V = k\Delta + l + \Delta^{-1} m, \tag{7.18}$$

$$k := K(d_{[-1]}q_{[-1]} - d_{[1]}q_{[1]}) + K^2(r_{[2]} - r),$$

$$l := 2d_{[-1]}bq_{[-1]} - 2bdq + 2K(d_{[-1]}p_{[-1]} - dp_{[1]}),$$

$$m := d_{[-1]}dq_{[-1]} - dd_{[1]}q_{[1]} + 2bdp - 2b_{[1]}dp_{[1]} - Kd(r_{[2]} - r).$$

Note that this vector is not generally tangent to $\mathscr{H}$, because the coefficient k of Δ is not constant.

We finally compute $\mathscr{S}_v \delta V$. An arbitrary covector in $\mathfrak{g}$ can be written as

$$\delta V = u(\Delta^2) + q\Delta + p + r\Delta^{-1} + s\Delta^{-2} + \mathscr{O}(\Delta^{-3}); \tag{7.19}$$

only the middle terms in p,q,r,s give a nonzero result on application of $\mathscr{S}$, and it is found that

$$\mathscr{S}_v \delta V = g\Delta^2 + k\Delta + l + \Delta^{-1} m, \begin{cases} g := K^2(dq - d_{[1]}q_{[1]}) + K^3(r_{[2]} - r_{[1]}), \\ k := Kd(b_{[1]} - b)q + K(bd_{[-1]}q_{[-1]} - b_{[1]}d_{[1]}q_{[1]}) \\ \quad + K^2 d(p - p_{[1]}) + K^2(b_{[1]}r_{[2]} - br) + K^3(s_{[2]} - s_{[1]}), \\ l := K(d_{[-2]}d_{[-1]}q_{[-2]} - dd_{[1]}q_{[1]}) + d_{[-1]}b^2 q_{[-1]} \\ \quad - db^2 q + Kd_{[-1]}(b_{[-1]} + b)p_{[-1]} - Kd(b + b_{[1]})p_{[1]} \\ \quad + K^2(d_{[-1]}r - dr_{[1]}), \\ m := bdd_{[-1]}q_{[-1]} - b_{[1]}dd_{[1]}q_{[1]} + Kdd_{[-1]}p_{[-1]} \\ \quad - Kdd_{[1]}p_{[2]} + b^2 dp - b_{[1]}^2 dp_{[1]} + Kbd(r + r_{[1]}) \\ \quad - Kb_{[1]}d(r_{[1]} + r_{[2]}) - K^2 d(s_{[2]} - s_{[1]}). \end{cases} \tag{7.20}$$

The vector (7.20) is not generally tangent to $\mathscr{H}$, due to the term in Δ^2 and the fact that the coefficient k of Δ is not constant.

(ii) Let us consider (at the point $V = V(z)$) a covector $\delta V \in \mathfrak{g}$, written as in Eq. (7.14); for each $\dot{V}$ as in (7.10), we have

$$\langle \dot{V}, \delta V \rangle = \sum_0 (\dot{K}r + \dot{d}q + \dot{b}p) = \dot{K}\sum_0 r + \sum_0 (\dot{d}q + \dot{b}p). \tag{7.21}$$

By definition, δV extends a covector $\delta z = (\delta K, \delta d, \delta b) \in \mathbb{R}\times\mathbb{R}_n\times\mathbb{R}_n$ if $\langle \delta V, \dot{V}\rangle = \langle \delta z, \dot{z}\rangle = \delta K\dot{K} + \Sigma_0(\delta d\dot{d} + \delta b\dot{b})$ for each $\dot{z} = (\dot{K}, \dot{d}, \dot{b}) \in \mathbb{R}\times\mathbb{R}_n\times\mathbb{R}_n$. From Eq. (7.21), it is seen that this happens iff

$$q = \delta d, \quad p = \delta b, \quad \sum_0 r = \delta K, \tag{7.22}$$

i.e., $\langle r\rangle = (1/n)\delta K$. So, q,p and the average of r are uniquely fixed, while the remaining parts $u(\Delta^2), l(\Delta^{-2})$ of δV are arbitrary.

(iii) We have seen that $\mathscr{Q}_v \delta V$ is automatically tangent to $\mathscr{H}$, so we have a proper restriction of $\mathscr{Q}$ to $\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$ along J. Equations (7.16) and (7.22) yield the expression (7.11) for the reduced tensor.

(iv) Let us consider any extension δV of a given covector δz. The expression of $\mathscr{P}_v \delta V$ is as in Eq. (7.18), with q, p and r as in Eq. (7.22). The vector $\mathscr{P}_v \delta V$ is tangent to $\mathscr{H}$ iff the coefficient k is a constant $\dot{K}$. So, we are led to the equation

$$\dot{K} = K(d_{[-1]}\delta d_{[-1]} - d_{[1]}\delta d_{[1]}) + K^2(r_{[2]} - r). \tag{7.23}$$

The r.h.s. of this equation has zero average, so the constant $\dot{K}$ must be zero. From here, it follows $r_{[2]}-r=1/K(d_{[1]}\delta d_{[1]}-d_{[-1]}\delta d_{[-1]})$, which implies

$$r=\frac{1}{K}\,d_{[-1]}\delta d_{[-1]}+w, \tag{7.24}$$

where w is an element of $\mathbb{R}_n$ such that $w_{[2]}-w=0$. Also, w must be such that the condition $\langle r\rangle=(1/n)\,\delta\dot{K}$ be satisfied.[36] Inserting these results into Eq. (7.18), we obtain $P_v\delta V=\dot{b}+\Delta^{-1}\dot{d}$, with d and $\dot{b}$ as in Eq. (7.12). This means that P is Dirac restrictable to $\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$ along J, yielding the reduced tensor (7.12).

(v) To restrict the third Poisson tensor $\mathscr{S}$, we reconsider the most general δV extending a given covector δz. Then $\mathscr{S}_v\delta V$ is as in Eq. (7.20), with $q=\delta d$, $p=\delta b$, and we must also take into account that $\langle r\rangle=(1/n)\,\delta K$.

$\mathscr{S}_v\delta V$ is tangent to $\mathscr{H}$ iff $g=0$ and k is a constant $\dot{K}$. We regard these two constraints as equations for r and s; the equation $g=0$ and the condition on the average of r imply

$$r=\frac{1}{K}\,d_{[-1]}\delta d_{[-1]}-\frac{1}{K}\,\langle d\,\delta d\rangle+\frac{1}{n}\,\delta K. \tag{7.25}$$

Due to this outcome, the equation $k=\text{const.}=\dot{K}$ becomes

$$\dot{K}=Kd(b_{[1]}-b)\,\delta d+K^2d(\,\delta b-\delta b_{[1]})-K(b_{[1]}-b)\langle d\,\delta d\rangle+\frac{1}{n}\,K^2(b_{[1]}-b)\,\delta K+K^3(s_{[2]}-s_{[1]}). \tag{7.26}$$

Taking the average of both sides in this equation, we obtain

$$\dot{K}=K\langle d(b_{[1]}-b)\,\delta d\rangle+K^2\langle d(\,\delta b-\delta b_{[1]})\rangle; \tag{7.27}$$

Eq. (7.26) also determines the difference $s_{[2]}-s_{[1]}$. With these tangency prescriptions, $S_v\delta V$ is fully determined. These results mean that the third tensor $\mathscr{S}$ is Dirac restrictable; the explicit expression of the restriction is immediately found to be as in Eq. (7.13), and this concludes the proof. ◇

From the proper reducibility of $\mathscr{Q}$ and from the representations $\mathscr{X}_k=\mathscr{Q}dh_{k+1}$, $\mathscr{Y}_k=\mathscr{Q}df_{k+1}$, it follows that the vector fields $\mathscr{X}_k$ and $\mathscr{Y}_k$ are also restrictable from $\mathfrak{g}$ to $\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$ along J. The symbols $\mathscr{X}_k$, h_k, etc. will be maintained to denote the restrictions of the vector fields and the Hamiltonians, which satisfy the usual recursion schemes w.r.t. the restricted Poisson tensors $\mathscr{Q}$, $\mathscr{P}$ and $\mathscr{S}$. For $z=(K,d,b)$, we find

$$h_1(z)=\sum_0 b,\quad h_2(z)=\sum_0\left(\frac{1}{2}\,b^2+Kd\right),\quad h_3(z)=\sum_0\left(\frac{1}{3}\,b^3+Kdb+Kdb_{[1]}\right), \tag{7.28}$$

and so on; the components of the vector field $\mathscr{X}_1$ at z are

$$\dot{K}=0,\quad \dot{d}=2d(b-b_{[1]}),\quad \dot{b}=2K(d_{[-1]}-d). \tag{7.29}$$

C. A projection of the triHamiltonian scheme

Let us consider the product $\mathbb{R}_n\times\mathbb{R}_n$, and denote with $y=(c,b)$ a typical point. Tangent vectors and covectors at y are represented as pairs $\dot{y}=(\dot{c},\dot{b})$ and $\delta y=(\delta c,\delta b)$, respectively, with the duality $\langle\delta y,\dot{y}\rangle=\Sigma_0(\delta c\dot{c}+\delta b\dot{b})$.

Definition 7.6: π:$\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n\to\mathbb{R}_n\times\mathbb{R}_n$ is the projection given by

$$\pi(K,d,b):=(Kd,b). \tag{7.30}$$

◇

For $z=(K,d,b)$ and $y=\pi(z)$, the tangent map $T_z\pi:\mathbb{R}\times\mathbb{R}_n\times\mathbb{R}_n\to\mathbb{R}_n\times\mathbb{R}_n$ sends a vector $\dot z=(\dot K,\dot d,\dot b)$ into the vector $\dot y=(\dot c,\dot b)$, with $\dot c=\dot K d+K\dot d$. The cotangent map $T_z^*\pi:\mathbb{R}_n\times\mathbb{R}_n\to\mathbb{R}\times\mathbb{R}_n\times\mathbb{R}_n$ is defined by the condition $\langle (T_z^*\pi)\,\delta y,\dot z\rangle=\langle \delta y,(T_z\pi)\dot z\rangle$ for each δy and $\dot z$; $T_z^*\pi$ sends $\delta y=(\delta c,\delta b)$ into $\delta z=(\delta K,\delta d,\delta b)$, with $\delta K=\Sigma_0(d\,\delta c),\delta d=K\,\delta c$.

Our aim in this subsection is to project along π the triHamiltonian structure of Prop. 7.5. Before passing to this operation, we suggest a geometrical interpretation for the map (7.30), recalling that its domain $\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$ is the ''coordinate space'' of the extended Kupershmidt submanifold $\mathscr{H}$. According to this interpretation, the codomain $\mathbb{R}_n\times\mathbb{R}_n$ of π is the coordinate space for a quotient $\mathscr{H}/\!\sim$, where $\sim$ is an appropriately defined equivalence relation, and π corresponds to the quotient map. The relation $\sim$ arises from the remark that an arbitrary element $V=V(K,d,b)$ of $\mathscr{H}$ can be written as

$$V=\widetilde\Delta+b+\widetilde\Delta^{-1}c,\quad c:=Kd,\quad \widetilde\Delta:=K\Delta. \tag{7.31}$$

Some interesting conclusions can be drawn from this representation; for example, we will show that the traces $\mathrm{Tr}\,V^k(K,d,b)$ depend only on b and the product $Kd=c$.

Definition 7.7: Given the operators $V=V(K,d,b)$ and $V'=V(K',d',b')$ in $\mathscr{H}$, we write $V\sim V'$ if $b=b'$ and $Kd=K'd'$. ◇

This is clearly an equivalence relation. There is a natural diffeomorphism $I:(\mathscr{H}/\!\sim)\to\mathbb{R}_n\times\mathbb{R}_n$, which associates to any point $V(K,d,b)\,\mathrm{mod}\,\sim$ in the quotient space the pair $(c,b):=(Kd,b)$. Employing I and the diffeomorphism $J^{-1}:\mathscr{H}\to\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$, we conclude that the quotient map $\mathscr{H}\to\mathscr{H}/\!\sim$ is just the composition $I^{-1}\circ\pi\circ J^{-1}$, with π as in Eq. (7.30). By elementary computations, one can prove the following.

Proposition 7.8: The Poisson tensors (7.11)–(7.13) carried by $\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$ can be projected onto $\mathbb{R}_n\times\mathbb{R}_n$ along π, in the sense of Prop. 2.5. The projected tensors, denoted with the same letters plus a superscript $\sim$, have the following expressions:

$$\widetilde{\mathscr{Q}}_y\,\delta y=\dot y,\quad \begin{cases}\dot c:=2c\,\delta b-2c\,\delta b_{[1]},\\ \dot b:=2c_{[-1]}\delta c_{[-1]}-2c\,\delta,\end{cases} \tag{7.32}$$

$$\widetilde{\mathscr{P}}_y\,\delta y=\dot y,\quad \begin{cases}\dot c:=2c(c_{[-1]}\delta c_{[-1]}-c_{[1]}\delta c_{[1]}+b\,\delta b-b_{[1]}\delta b_{[1]}),\\ \dot b:=2b(c_{[-1]}\delta c_{[-1]}-c\,\delta c)+2(c_{[-1]}\delta b_{[-1]}-c\,\delta b_{[1]}),\end{cases} \tag{7.33}$$

$$\widetilde{\mathscr{S}}_y\,\delta y=\dot y,\quad \begin{cases}\dot c=2c(bc_{[-1]}\delta c_{[-1]}-b_{[1]}c_{[1]}\delta c_{[1]})+c(c_{[-1]}\delta b_{[-1]}-c_{[1]}\delta b_{[2]})\\ \quad +c(c+b^2)\,\delta b-c(c+b_{[1]}^2)\,\delta b_{[1]},\\ \dot b=c_{[-2]}c_{[-1]}\delta c_{[-2]}-cc_{[1]}\delta c_{[1]}+c_{[-1]}(c_{[-1]}+b^2)\,\delta c_{[-1]}\\ \quad -c(c+b^2)\,\delta c+c_{[-1]}(b_{[-1]}+b)\,\delta b_{[-1]}-c(b+b_{[1]})\,\delta b_{[1]}.\end{cases} \tag{7.34}$$

◇

Proposition 7.9: The Hamiltonian functions h_k,f_k and the vector fields $\mathscr{X}_k,\mathscr{Y}_k$ on $\mathbb{R}_*\times\mathbb{R}_n\times\mathbb{R}_n$ are projectable onto $\mathbb{R}_n\times\mathbb{R}_n$ along π.

Proof: The projectability of the vector fields follows from the previous Prop. 7.8, if one shows that the Hamiltonians can be projected. The f_k's are functions of the h_k's, so it suffices to show the projectability of each function $h_k(K,d,b)=1/k\ \mathrm{Tr}\,V^k(K,d,b)$. To this purpose, we recall that each

operator $V=V(K,d,b)\in\mathscr{H}$ can be written as in Eq. (7.31), using the rescaled shift operator $\tilde{\Delta}=K\Delta$. From Eq. (7.31), it follows that we can write $V=\Sigma_{\sigma=-1,0,1}v_\sigma\tilde{\Delta}^\sigma$, with $v_{-1}:=c_{[-1]}$, $v_0:=b$, $v_1:=1$. For each positive integer k, it is

$$V^k(K,d,b)=\sum_{\sigma=-k}^{k}v_{k,\sigma}(c,b)\tilde{\Delta}^\sigma=\sum_{\sigma=-k}^{k}K^\sigma v_{k,\sigma}(c,b)\Delta^\sigma, \tag{7.35}$$

where the coefficients $v_{k,\sigma}(c,b)\in\mathbb{R}_n$ are suitable functions of c and b. By taking the traces, we obtain $h_k(K,d,b)=(1/k)\Sigma_0 v_{k,0}(c,b)$; so, each h_k depends only on c,b and the projectability is proved. ◇.

Definition 7.10: The projections along π of the Hamiltonians and vector fields will be indicated with the same letters plus a superscript $\sim$: $\tilde{h}_k,\tilde{f}_k,\tilde{\mathscr{X}}_k,\tilde{\mathscr{Y}}_k$. ◇

At each point $y=(c,b)$, we have

$$\tilde{h}_1(y)=\sum_0 b,\quad \tilde{h}_2(y)=\sum_0\left(\frac{1}{2}b^2+c\right),\quad \tilde{h}_3(y)=\sum_0\left(\frac{1}{3}b^3+cb+cb_{[1]}\right), \tag{7.36}$$

and so on; the first vector field $\tilde{\mathscr{X}}_1$ has components $\dot{c},\dot{b}$ as in Eq. (1.3); here, it was already observed that the flow of $\tilde{\mathscr{X}}_1$ gives the time evolution of the Toda lattice, the connection with the Flaschka variables being the transformation $c=a^2$.

D. The Kupershmidt submanifold and the Lax formalism for the vector fields $\tilde{\mathscr{X}}_k$

The Lax formalism for the Toda lattice set up in Ref. 13 does not envolve directly the manifold $\mathscr{H}$ of Def. 7.4, but rather the subset of operators obtained setting $K=1$ in Eq. (7.9).

Definition 7.11: For each $y=(c,b)\in\mathbb{R}_n\times\mathbb{R}_n$, we put

$$V(y):=\Delta+b+\Delta^{-1}c. \tag{7.37}$$

The embedding $\mathbb{R}_n\times\mathbb{R}_n\to\mathfrak{g}$, $y\mapsto V(y)$ will be be denoted by Σ. Its image $\mathscr{K}\subset\mathscr{H}$ will be called the Kupershmidt submanifold. ◇

Recalling the diagram (4.14) and Eq. (4.13), one can check that, for each $y=(c,b)$, $V(y)$ is the image under the map $\Psi_\circ^{-1}\Phi^{-1}$ of the homologous element of the loop algebra $gl(n)(\lambda,\lambda^{-1}]$ in Eq. (1.4). If we think geometrically in terms of the equivalence relation $\sim$ on $\mathscr{H}$ and employ the diffeomorphism $I:(\mathscr{H}/\sim)\to\mathbb{R}_n\times\mathbb{R}_n$ (see the previous subsection), we can describe $\Sigma\circ I$ as a section of the quotient bundle $\mathscr{H}\to\mathscr{H}/\sim$.

It is straightforward to check that the Poisson tensors $\mathscr{Q},\mathscr{P}$ (Eqs. (7.6)–(7.7)) can be restricted directly from $\mathfrak{g}$ to $\mathbb{R}_n\times\mathbb{R}_n$ along Σ (the first one properly, the second in the Dirac sense). Performing the necessary computations, one finds that the restrictions coincide exactly with the tensors $\tilde{\mathscr{Q}}$ and $\tilde{\mathscr{P}}$ of Eqs. (7.32-33), previously obtained by the restriction/projection algorithm of Secs. VII B and C. Also, the vector fields $\mathscr{X}_k$ on $\mathfrak{g}$ are restrictable via Σ; the restrictions coincide with the vector fields $\tilde{\mathscr{X}}_k$, constructed previously with the restriction/projection method. The Lax formulation for these fields follows immediately from Eq. (7.8), with the Lax operator (7.37); this final result agrees with the Lax scheme of Ref. 13.

On the contrary, the third r-matrix Poisson tensor carried by $\mathfrak{g}$ (Eq. (7.7)) cannot be restricted: the tangency constraints for $\mathscr{S}_v\delta V$ appearing if one tries a Dirac reduction have no periodic solution in general.

E. A comparison with the framework of Sec. V

Let $\mathbb{R}_n^+$ denote the open subset of $\mathbb{R}_n$ formed by the periodic sequences $v=(v_\alpha)_{\alpha\in\mathbb{Z}}$ with $v_\alpha>0$ for each α.

Definition 7.12: $F:\mathbb{R}_n^+\times\mathbb{R}_n\to\mathbb{R}_n^+\times\mathbb{R}_n$ is the diffeomorphism given by

$$F(a,b):=(a^2,b). \tag{7.38}$$

◇

A point to which F is applied will be typically denoted with x or (a,b) as above; its image under F will be generally written as $y=(c,b)$. The inverse map is obviously given by $F^{-1}(c,b)=(\sqrt{c},b)$.

Proposition 7.13: Consider on $\mathbb{R}_n^+\times\mathbb{R}_n$ the Poisson structures Q, P and S given by Eqs. (5.9)–(5.11), and $\tilde{Q}$, $\tilde{P}$ and $\tilde{S}$ as in Eqs. (7.32)–(7.34). Denoting by F_* the push-forward along F, we have $F_*Q=2\tilde{Q}$, $F_*P=2\tilde{P}$, $F_*S=2\tilde{S}$.

Proof: Let us consider, for example, the tensor Q; at any point $y=(c,b)$, it is

$$(F_*Q)_y:=(T_xF\circ Q_x\circ T_x^*F)|_{x=F^{-1}(y)}, \tag{7.39}$$

where T_xF and T_x^*F denote, respectively, the tangent map of F at x and its adjoint, given by $(T_xF)(\dot{a},\dot{b})=(2a\dot{a},\dot{b})$, $(T_x^*F)(\delta c,\delta b)=(2a\delta c,\delta b)$. A straightforward computation gives $F_*Q=2\tilde{Q}$; the analogous relations for $\tilde{P}$ and $\tilde{S}$ are proved similarly. ◇

To complete the comparison with Sec. V, we point out a relevant connection between the operators $V(K,d,b)$, given by Eq. (7.9), and $L(a,b)$ in Eq. (5.7), existing if $Kd=a^2$. This relation can be illustrated in terms of the following.

Definition 7.14: Two operators $L,V\in\mathfrak{g}$ are said to be gauge equivalent if there exists an n-periodic sequence $s=(s_\alpha)_{\alpha\in\mathbb{Z}}$ such that $s_\alpha\neq 0$ for each α, and

$$sL\,\frac{1}{s}=V, \tag{7.40}$$

intending the l.h.s. of the above equation as the product in $\mathfrak{g}$ among L, the sequence s and its reciprocal $(1/s):=(1/s_\alpha)$. ◇

Proposition 7.15: For each $(a,b)\in\mathbb{R}_n^+\times\mathbb{R}_n$, there exist $K>0$, $d\in\mathbb{R}_n^+$ and a never zero sequence $s\in\mathbb{R}_n$ such that $Kd=a^2$ and

$$sL(a,b)\,\frac{1}{s}=V(K,b,d). \tag{7.41}$$

Proof: For each sequence $v\in\mathbb{R}_n$, we put $\Pi_0 v:=\Pi_{\alpha=1}^n v_\alpha$. Equation (7.41) is satisfied setting $K:=(\Pi_0 a)^{1/n}$, $d:=a^2/K$ and taking for s a periodic solution[37] of the equation $s_{[1]}=(a/K)s$. ◇

The previous result can be used to prove that the diffeomorphism F transforms the Hamiltonians $h_k(a,b)$ of Sec. V into the Hamiltonians $\tilde{h}_k(c,b)$ of Sec. VII C.

Proposition 7.16: For $(a,b)\in\mathbb{R}_n^+\times\mathbb{R}_n$ and $(c,b)=F(a,b)$, it is $\tilde{h}_k(c,b)=h_k(a,b)$.

Proof: By definition, $\tilde{h}_k(c,b):=(1/k)\mathrm{Tr}\,V^k(K,d,b)$, where $V(K,d,b)$ is any operator with $Kd=c$; also, we know that $h_k(a,b)=(1/k)\mathrm{Tr}\,L^k(a,b)$. We can choose K and d as in the previous Proposition, so as to set up a gauge equivalence; then

$$\mathrm{Tr}\,V^k(K,d,b)=\mathrm{Tr}\left(sL^k(a,b)\,\frac{1}{s}\right)=\mathrm{Tr}\left(\frac{1}{s}\,sL^k(a,b)\right)=\mathrm{Tr}\,L^k(a,b). \tag{7.42}$$

◇

Corollary 7.17: Consider on $\mathbb{R}_n^+\times\mathbb{R}_n$ the vector fields $X_k=P\,dh_k$ of Secs. V and VI and $\tilde{\mathscr{X}}_k=\tilde{\mathscr{P}}d\tilde{h}_k$ of Sec. VII C. For each k, it is $F_*X_k=2\tilde{\mathscr{X}}_k$ $(k=1,2,3,\ldots)$. ◇

Here, $F_* X_k$ stands for the push-forward, i.e., the vector field $y \mapsto (T_x F) X_k(x)|_{x=F^{-1}(y)}$; the thesis follows from Props. 7.13 and 7.16. Of course, two statements similar to Prop. 7.16 and Corollary 7.17 hold for the Hamiltonians $f_k, \tilde{f}_k$ and the associated vector fields $Y_k, \tilde{Y}_k$.

VIII. COMMENTS

This article is devoted to the periodic Toda lattice, but the r-matrix methods can be as well applied to other lattices. The system in $2N$ field variables $b, c_1, \ldots, c_{2N-1}$, described by the ''Kupershmidt-like'' Lax operator

$$V = \Delta + b + \sum_{k=1}^{2N-1} \Delta^{-k} c_k, \tag{8.1}$$

was treated in Ref. 11 in the infinite nonperiodic case; its periodic counterpart can be discussed assuming $b, c_1, \ldots, c_{2N-1}$ to be n-periodic sequences. For $N=1$, one reobtains the Toda theory in the field variables b and $c_1 := c$ [see Eq. (7.37)].

As a generalization, it is possible to analyze the theory in infinitely many field variables $b, c_k \in \mathbb{R}_n(\Delta, \Delta^{-1}]$, described by the Lax operator

$$V = \Delta + b + \sum_{k=1}^{+\infty} \Delta^{-k} c_k, \tag{8.2}$$

which can be regarded as a periodic analogue of the so-called ''full Kostant Toda lattice,'' or a discrete version of the KP theory (for the multi-Hamiltonian structure of this system, independently of r-matrix theory, see Ref. 13).

Finally, the treatment of Sec. V could be extended to the system in $2N$ field variables $b, a_1, \ldots, a_{2N-1} \in \mathbb{R}_n(\Delta, \Delta^{-1}]$, described by the symmetric Lax operator

$$L = \sum_{k=1}^{2N-1} a_k \Delta^k + b + \sum_{k=1}^{2N-1} \Delta^{-k} a_k. \tag{8.3}$$

It should be noticed that, with the exception of the Toda case $N=1$, the systems in Eqs. (8.1) and (8.3) are essentially different: in fact, their Lax operators are not gauge equivalent.

Also, it would be of interest to analyze the continuous limits of the above lattices; for example, these could be treated with the methods proposed in Ref. 38; work on this point is in progress, and it turns out that the limiting systems can be classified in terms of the Drinfeld–Sokolov scheme for KdV-type hierarchies.[39]

ACKNOWLEDGMENTS

We are grateful to the anonymous referee for some indications which led us to put this article in its present form, and for drawing our attention to the full-Kostant Toda lattice. Some of the computations in Secs. V and VII have been performed using the MATHEMATICA symbolic manipulation system.

[30] Here, and in the rest of the paper, we say that some property $\mathfrak{B}(\sigma)$, depending on an integer σ, holds for $\sigma \gg 0$ if there is $\kappa \in \mathbb{Z}$ such that $\mathfrak{B}(\sigma)$ is satisfied for each $\sigma \geqslant \kappa$; similarly, $\mathfrak{B}(\sigma)$ holds for $\sigma \ll 0$ if it is true for each σ below some κ. Other statements of a similar kind will appear in the sequel; for example, we will say that some property $\mathfrak{B}(\alpha,\beta)$, depending on two integers, holds for $\beta-\alpha \gg 0$ or for $|\beta-\alpha| \gg 0$, with an obvious meaning.
[31] The symplectic leaves are, by definition, the integral submanifolds of the distribution Im Q; as it is well known, a Poisson tensor can be properly restricted to anyone of its symplectic leaves, and the restriction is kernel free (see Ref. 20).

[35] Our arguments do not imply $f_k(x)=0$ for $k \geqslant n+2$, because the connection between the f_k's and the finite matrix $\Lambda(x)$ breaks down for $k=n+2, n+3, \ldots$. For a definite value of n, say $n=3$, one can check directly that some of the functions f_k and some of the vector fields $Y_k = P df_k$ are not zero for $k \geqslant n+2$ (even though they are not functionally independent of the first n integrals and vector fields).
[36] If n is odd, any sequence $w \in \mathbb{R}_n$ such that $w_{[2]}-w=0$ is constant: $w_\alpha = H$ for each $\alpha \in \mathbb{Z}$; the supplementary requirement on the average of r uniquely fixes H. If n is even, it is $w_{[2]}-w=0$ if there are two constants H and H' such that $w_\alpha = H$ for α even and $w_\alpha = H'$ for α odd. The condition on the average of r fixes the sum $H+H'$.
[37] Consider an equation $s_{[1]} = vs$ in the unknown s, with a prescribed $v \in \mathbb{R}_n$; this equation admits solutions in $\mathbb{R}_n$ iff $\Pi_0 v = 1$. The sequence $v = a/K$ satisfies this condition due to the choice made for K.

(Received 24 January 1995; accepted for publication 17 June 1996)

In this paper, we outline a method for symplectic integration of three degree-of-freedom Hamiltonian systems. We start by representing the Hamiltonian system as a symplectic map. This map (in general) has an infinite Taylor series. In practice, we can compute only a finite number of terms in this series. This gives rise to a truncated map approximation of the original map. This truncated map is however not symplectic and can lead to wrong stability results when iterated. In this paper, following a generalization of the approach pioneered by Irwin (SSC Report No. 228, 1989), we factorize the map as a product of special maps called ''jolt maps'' in such a manner that symplecticity is maintained. © *1996 American Institute of Physics.* [S0022-2488(96)03509-8]

I. INTRODUCTION

Consider a complicated periodic Hamiltonian system that is non-integrable. Suppose we are interested in the long-term stability of particles being transported through this system. Since the system is assumed to be nonintegrable, it is very difficult to give stability criteria in an analytic form. A possible solution is to numerically follow the trajectories of particles through the system for a large number of periods (a process that goes by the name of tracking). One could then attempt to infer the stability of motion in the system by analyzing these tracking results.

The most straightforward method that can be used to perform this long term tracking is numerical integration. However, this method is too slow for analyzing the stability of very complicated systems. Therefore, we need a method that is both fast and accurate.

Several symplectic integration methods have been discussed in the literature. Ruth,[1] Feng,[2] Channel and Scovel,[3] Yoshida,[4] Berg *et al.*[5] and others have derived symplectic integrators using generating functions. These are typically implicit methods and using these methods requires one to use Newton's method with its attendent questions of convergence, etc. Another approach is through solvable maps.[6,7] But this method has not been explored in great detail. In this paper, following Irwin,[8] we explore a more direct method of symplectic integration.

The method that we will use is the iteration of symplectic maps[9] representing the Hamiltonian system. We start by defining certain mathematical objects. Let us denote the collection of six phase space variables q_i, p_i $(i=1,2,3)$ by the symbol z:

$$z=(q_1,p_1,q_2,p_2,q_3,p_3). \tag{1.1}$$

The Lie operator corresponding to a phase space function $f(z)$ is denoted by $:f(z):$. It is defined by its action on a phase-space function $g(z)$ as shown below

$$:f(z):g(z)=[f(z),g(z)]. \tag{1.2}$$

Here $[f(z),g(z)]$ denotes the usual Poisson bracket of the functions $f(z)$ and $g(z)$. Next, we define the exponential of a Lie operator. It is called a Lie transformation and is given as follows:

[a)]Electronic mail: rangaraj@math.iisc.ernet.in

0022-2488/96/37(9)/4514/29/$10.00

$$e^{:f(z):}=\sum_{n=0}^{\infty}\frac{:f(z):^n}{n!}. \tag{1.3}$$

Powers of $:f(z):$ that appear in the above equation are defined recursively by the relation

$$:f(z):^n g(z)=:f(z):^{n-1}[f(z),g(z)], \tag{1.4}$$

with

$$:f(z):^0 g(z)=g(z). \tag{1.5}$$

For further details regarding Lie operators and Lie transformations, see Ref. 9.

The time evolution of the Hamiltonian system over one period can be represented by a symplectic map $\mathscr{M}$.[9] Symplectic maps are maps whose Jacobian matrices $M(z)$ satisfy the following symplectic condition:

$$\widetilde{M(z)}JM(z)=J, \tag{1.6}$$

where $\widetilde{M}$ is the transpose of M and J is an antisymmetric matrix defined as follows:

$$J=\begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}. \tag{1.7}$$

Matrices M satisfying Eq. (1.6) are called symplectic matrices and the corresponding maps $\mathscr{M}$ symplectic maps. It can be shown[9] that the set of all $\mathscr{M}$'s forms an infinite dimensional Lie group of symplectic maps. On the other hand, the set of all real 6×6 symplectic matrices forms the finite dimensional real symplectic group Sp(6,R).

Using the Dragt–Finn factorization theorem,[9,10] the symplectic map $\mathscr{M}$ can be factorized as shown below:

$$\mathscr{M}=\hat{M}e^{:f_3:}e^{:f_4:}\ldots e^{:f_n:}\ldots \ . \tag{1.8}$$

Here $\hat{M}$ gives the linear part of the map and hence has an equivalent representation in terms of the Jacobian matrix $M(0)$ of the map $\mathscr{M}$ at the origin:[9]

$$\hat{M}z_i=M_{ij}z_j=(Mz)_i. \tag{1.9}$$

Thus, $\hat{M}$ is said to be the Lie transformation corresponding to the 6×6 matrix M belonging to Sp(6,R). The infinite product of Lie transformations $\exp(:f_n:)$ $(n=3,4,\ldots)$ in Eq. (1.8) represents the nonlinear part of $\mathscr{M}$. Here $f_n(z)$ denotes a homogeneous polynomial (in z) of degree n uniquely determined by the factorization theorem.

The above map $\mathscr{M}$ is called the one-period map for the system. It gives the final state $z^{(1)}$ of a particle after one period as a function of its initial state $z^{(0)}$:

$$z^{(1)}=\mathscr{M}z^{(0)}. \tag{1.10}$$

To obtain the state of a particle after N periods, one has to merely iterate the above mapping N times, i.e.,

$$z^{(N)}=\mathcal{M}^N z^{(0)}. \tag{1.11}$$

It is obvious that one cannot use $\mathcal{M}$ in the form given in Eq. (1.8) for any practical computations. It involves an infinite number of Lie transformations. Therefore, we have to truncate $\mathcal{M}$ by stopping after a finite number of Lie transformations:

$$\mathcal{M}\approx\hat{M}e^{:f_3:}e^{:f_4:}\cdots e^{:f_P:}. \tag{1.12}$$

However, we are still not out of the woods. Each exponential $e^{:f_n:}$ in $\mathcal{M}$ contains an infinite number of terms in its Taylor series expansion. One possible solution is to truncate the Taylor series generated by the Lie transformations to order P. We denote this truncated map by $\mathcal{M}_P$. As a power series in the six phase space variables, it is given as follows:

$$\mathcal{M}_P z=M(1+:f_3:+\cdots)(1+:f_4:+\cdots)$$

$$\cdots(1+:f_p:+\cdots)z, \tag{1.13}$$

where we have to truncate the power series in such a way that the highest order term generated is z^{P-1}. If we did not impose this restriction, we would generate terms of order z^P and higher. Then, to be consistent, we would be forced to include in our map, $:f_n:$'s for n greater than P (since these also generate terms of order z^P and higher).

Equation (1.13) can be rewritten as follows:

$$\mathcal{M}_P z=h_1(z)+h_2(z)+\cdots+h_{P-1}(z), \tag{1.14}$$

where $h_n(z)$ denotes a polynomial of degree n in z. Since we have decided to consistently drop terms of order z^P and higher, we can define the following equivalence relation between maps of order P:

$$\mathcal{M}_P\sim\mathcal{M}'_P \quad \text{if } \mathcal{M}_P z-\mathcal{M}'_P z=h_P(z)+\text{higher order terms}. \tag{1.15}$$

This can be rephrased in terms of partial derivatives as follows. Maps $\mathcal{M}_P$ and $\mathcal{M}'_P$ are equivalent if all the partial derivatives of $\mathcal{M}_P z$ and $\mathcal{M}'_P z$ up to order $P-1$ are equal. An equivalence class with respect to this equivalence relation is called a jet of order P. Since the map $\mathcal{M}_P$ is obtained from a symplectic map $\mathcal{M}$, we call $\mathcal{M}_P$ (or more accurately, the equivalence class to which it belongs) a symplectic jet of order P. We stress that, despite its name, $\mathcal{M}_P$ is not symplectic.

We note that symplectic jets of order P have the following properties. A symplectic jet maps $\mathbb{R}^6$ into $\mathbb{R}^6$. It maps the origin of $\mathbb{R}^6$ into itself. It is invertible. And the composition of two symplectic jets $\mathcal{M}_P$ and $\mathcal{M}'_P$ is defined as follows:

$$\mathcal{M}_P\cdot\mathcal{M}'_P=(\mathcal{M}\cdot\mathcal{M}')_P. \tag{1.16}$$

This is again a symplectic jet of order P. And finally, there exists an identity given by the following equivalence class:

$$\mathcal{M}^0_P z=z+h_P(z)+\text{higher order terms}. \tag{1.17}$$

Therefore, the set of all symplectic jets of order P forms a group. It can be shown that it is actually a Lie group. This Lie group formed by the set of all symplectic jets of order P is called the symplectic jet group Spj(6;P).

However, the above solution of truncating the Taylor series has a severe shortcoming. As mentioned above, the mapping $\mathcal{M}_P$ generated by the truncated Taylor series is no longer symplectic. Therefore, repeated iterations of this mapping can lead to spurious growth (or damping) in

the amplitude of motion of the particle being tracked. Obviously, this can lead to wrong conclusions regarding the stability of the system. Therefore it is important to preserve the symplectic nature of $\mathscr{M}_P$ when using it for long term tracking. For this purpose, we need to ensure that each factor in $\mathscr{M}_P$ takes the form $e^{:g:}$. On the other hand, for the numerical tracking scheme to be practical, we need to ensure that we evaluate only a finite number of terms. In this paper, we discuss how to reconcile these two apparently contradictory objectives.

The basic goal of this paper is to refactorize $\mathscr{M}_P$ [cf. Eq. (1.13)] as a product of symplectic maps that can be evaluated exactly. Since we do not truncate the Taylor series, we preserve the symplectic nature of the map even when we evaluate it. Another attractive feature of these special maps is that their inverses can also be evaluated exactly. The process of refactorizing a map into a product of symplectic maps characterized by these nice features is called ''symplectic completion''. Since the map that is being refactorized is $\mathscr{M}_P$, a symplectic jet, this refactorization procedure is called ''symplectic completion of symplectic jets''. And this will be the subject of this paper.

We start by defining jolt maps in Section II. In Section III, we formulate the problem of symplectic completion of $\mathscr{M}_P$ in terms of these jolt maps. Here, we follow the procedure first outlined by Irwin.[8] To get a better understanding of the problem, we first solve a model problem in Section IV. In Section V, we formulate a solution to the problem of symplectic completion of symplectic jets. In Section VI, we optimize the number of jolt maps required so that an efficient numerical algorithm is obtained.

II. JOLT MAPS

Consider the symplectic map given by $e^{:g(z):}$ where $g(z)$ is a function of the phase space variables z. It is called a jolt map if $:g(z):$ is a nilpotent operator of rank 2, i.e., if the following condition is satisfied:

$$:g(z):^2 z = 0. \tag{2.1}$$

The function $g(z)$ is then called a jolt function. We note that jolt maps have only two nonzero terms in their Taylor series expansions [cf. Eq. (1.3)]. The term jolt map was first introduced in Ref. 11.

Examples of jolt maps are given by the following theorem.

Theorem 1: *The following maps are jolt maps*

$$\text{(i)}\quad \hat{R} e^{:q_1^n:} \hat{R}^{-1} = e^{:\hat{R} q_1^n:}, \tag{2.2}$$

$$\text{(ii)}\quad \hat{R} e^{:f(q_1,q_2,q_3):} \hat{R}^{-1} = e^{:\hat{R} f(q_1,q_2,q_3):}. \tag{2.3}$$

Here $f(q_1,q_2,q_3)$ is an nth degree polynomial in variables q_1, q_2, and q_3. Finally, $\hat{R}$ is the Lie transformation corresponding to a 6×6 *matrix R belonging to any subgroup of* Sp(6,R) *[including* Sp(6,R) *itself]. It is given by the following relation [cf. Eq. (1.9)]:*

$$\hat{R} z_i = R_{ij} z_j = (Rz)_i. \tag{2.4}$$

See Appendix A for a proof of this theorem. In this theorem, note that the second statement contains the first statement as a special case. However, a separate (and simpler) proof is given even for the first statement since we will be using this later in the paper.

III. FORMULATION OF THE PROBLEM OF JOLT FACTORIZATION

Our goal is to refactorize $\mathscr{M}_P$ [cf. Eq. (1.13)] in terms of a finite number of jolt maps. The first step towards achieving this goal is to formulate the problem in an appropriate form. The best way to mathematically formulate the problem appears to be as follows[8]:

Problem 1: *Given the map $\mathscr{M}_P$, find another map $\mathscr{J}$ specified by the following product of K jolt maps*:

$$\mathscr{J}=\hat{M}e^{:g_3^{(1)}+g_4^{(1)}+\cdots+g_P^{(1)}:}e^{:g_3^{(2)}+g_4^{(2)}+\cdots+g_P^{(2)}:}\cdots e^{:g_3^{(K)}+g_4^{(K)}+\cdots+g_P^{(K)}:} \tag{3.1}$$

such that this map agrees with $\mathscr{M}_P$ to order P, i.e.,

$$\mathscr{J}\cong\mathscr{M}_P \quad \text{to order } P. \tag{3.2}$$

Here $g_n^{(i)}$'s are (homogeneous) jolt polynomials of degree n given by the following relation:

$$g_n^{(i)}=\beta_n^{(i)}\hat{R}_i q_1^n, \quad i=1,2,\ldots,K, \tag{3.3}$$

where $\beta_n^{(i)}$ is a real coefficient. The matrices R_i belong to a subgroup of Sp(6,R) *[including* Sp(6,R) *itself] and $\hat{R}_i$ denotes the Lie transformation corresponding to these matrices [cf. Eq. (2.4)]*.

Before proceeding further, we note that Eq. (3.1) can be rewritten in the following form:

$$\mathscr{J}=\hat{M}e^{:g^{(1)}:}e^{:g^{(2)}:}\cdots e^{:g^{(K)}:}, \tag{3.4}$$

where

$$g^{(i)}=g_3^{(i)}+g_4^{(i)}+\cdots g_P^{(i)} \quad i=1,2,\ldots,K. \tag{3.5}$$

From Eq. (3.3) and Theorem 1 [cf. Eq. (2.2)] it is seen that $g^{(i)}$'s are jolt polynomials (a sum of jolt polynomials is easily shown to be another jolt polynomial). Consequently, $\exp(:g^{(i)}:)$'s are jolt maps.

In order to solve the above problem, we need to determine the various unknown quantities appearing in the above equations—the number of jolt maps K, the matrices R_i, and the coefficients $\beta_n^{(i)}$. It turns out that K and R_i can be determined independent of the details of the map $\mathscr{M}_P$. They depend only on the order P of the map. This will be explicitly demonstrated shortly. For the moment, we will assume that K and R_i have already been fixed. This reduces our task to merely finding the coefficients $\beta_n^{(i)}$'s such that Eq. (3.2) is satisfied. We now proceed to solve for these coefficients order by order.

Since the linear part of a symplectic map can be evaluated exactly, there is no need to refactorize it in terms of jolt maps. Hence, we have already chosen the linear parts of the maps $\mathscr{M}_P$ and $\mathscr{J}$ to be the same. Therefore, we need to refactorize only the nonlinear part of $\mathscr{M}_P$. We start by comparing terms of order 3 in $\mathscr{M}_P$ and $\mathscr{J}$ respectively. The third-order term in $\mathscr{M}_P$ is given by f_3. To obtain the third-order term in $\mathscr{J}$, we need to cast it in the standard Dragt–Finn form. This is accomplished by using the Baker–Campbell–Hausdorff (BCH) formula[10] given below:

$$\exp(t:f:)\exp(s:g:)=\exp(t:f:+s:g:+ts:[f,g]:/2+\cdots). \tag{3.6}$$

We get the following result to third order:

$$\mathscr{J}\cong\hat{M}e^{:h_3:}, \tag{3.7}$$

where

$$h_3=\sum_{i=1}^{K} g_3^{(i)}. \tag{3.8}$$

Therefore, $\mathscr{J}$ and $\mathscr{M}_P$ will be equal to order 3 if the following equality is satisfied [cf. Eq. (3.3)]:

$$\sum_{i=1}^{K} \beta_3^{(i)} \hat{R}_i q_1^3 = f_3. \tag{3.9}$$

In other words, we have to determine $\beta_3^{(i)}$'s such that the above equation is satisfied.

Next, we compare terms of order 4 in $\mathscr{M}_P$ and $\mathscr{J}$. The fourth-order term in $\mathscr{M}_P$ is given by f_4. Using the BCH formula, the Dragt–Finn factorization of $\mathscr{J}$ correct to fourth order is given by the following result:

$$\mathscr{J} \cong \hat{M} e^{:h_3:} e^{:h_4:}, \tag{3.10}$$

where

$$h_4=\sum_{i=1}^{K} g_4^{(i)} + \frac{1}{2} \sum_{j<k} [g_3^{(j)}, g_3^{(k)}]. \tag{3.11}$$

The second term on the right hand side of the above equation is a fourth-order term produced by the concatenation of third-order terms in Eq. (3.1). Equating the fourth-order terms of $\mathscr{M}_P$ and $\mathscr{J}$ we get the relation [cf. Eq. (3.3)]

$$\sum_{i=1}^{K} \beta_4^{(i)} \hat{R}_i q_1^4 = f_4 - \frac{1}{2} \sum_{j<k} \beta_3^{(j)} \beta_3^{(k)} [\hat{R}_j q_1^3, \hat{R}_k q_1^3] \equiv f_4'. \tag{3.12}$$

Here f_4' includes the fourth-order terms produced by concatenation of lower order terms. By choosing $\beta_4^{(i)}$'s such that the above equation is satisfied, we ensure that $\mathscr{J}$ and $\mathscr{M}_P$ agree to fourth order.

This process can be continued in a similar fashion to deal with the higher order terms. At the nth order, we have to choose $\beta_n^{(i)}$'s such that the following equality is satisfied:

$$\sum_{i=1}^{K} \beta_n^{(i)} \hat{R}_i q_1^n = f_n'. \tag{3.13}$$

Here f_n' includes the unwanted nth-order terms produced by $g_l^{(i)}$ $(l<n)$.

We are now in a position to determine the number of jolt maps K and the matrices R_i. We will show that they are independent of the map $\mathscr{M}_P$. We note that f_n' involves $N(n)$ independent coefficients where $N(n)$ is given by the relation[8]

$$N(n)=\binom{n+5}{n}. \tag{3.14}$$

Thus, we need at least $N(n)$ $\beta_n^{(i)}$'s to solve the above equation. Since $N(n)$ is a monotonically increasing function of n, the maximum number of $\beta_n^{(i)}$'s are required when n is equal to P (the maximum order). Thus we need $N(P)$ $\beta_n^{(i)}$'s to solve Eq. (3.13) for all n. This fixes K to be equal to $N(P)$. Moreover, $\hat{R}_i q_1^n$ $(i=1,\ldots,K)$ should be linearly independent quantities. This imposes restrictions on the matrices R_i that we can choose. Both these conditions are independent of f_n', i.e., they are independent of the map $\mathscr{M}_P$. They depend only on the maximum order P. Therefore both K and R_i's can be fixed in advance independent of the map to be represented.

Once K and the R_i's are fixed, we start by first solving Eq. (3.9) for $\beta_3^{(i)}$'s. We then proceed order by order until we reach the Pth-order equation. At the nth order, we have to solve Eq. (3.13). The right hand side involves $N(n)$ independent coefficients. Since $N(n)$ is less than K $(=N(P))$ for n less than P, we have more $\beta_n^{(i)}$'s than necessary to solve this equation, i.e., the $\beta_n^{(i)}$'s are underdetermined. The naive solution would be to set these extra $\beta_n^{(i)}$'s to zero

$$\beta_n^{(i)}=0 \quad \text{for } i>N(n). \tag{3.15}$$

But there is a better solution. We fix these extra $\beta_n^{(i)}$'s by requiring that $\Sigma_{i=1}^{K}(\beta_n^{(i)})^2$ be a minimum. The reason for this is simple. We have seen that the nth-order jolt polynomials produce higher order terms [for example, see Eq. (3.11)] upon concatenation. These higher order terms depend on the coefficients $\beta_n^{(i)}$ [for example, see Eq. (3.12)]. Therefore, by minimizing the sum of the squares of these coefficients, we reduce the magnitude of the unwanted higher order terms produced by concatenation of lower order terms.

Putting everything together, the problem of obtaining a jolt map factorization can be reduced to the following general problem:

Problem 2: *Given a nth degree homogeneous polynomial f_n and K matrices R_i, find the coefficients $\beta_n^{(i)}$'s such that the following conditions are satisfied:*

$$\text{(i)} \quad \sum_{i=1}^{K} \beta_n^{(i)} \hat{R}_i q_1^n = f_n \tag{3.16}$$

and

$$\text{(ii)} \quad \sum_{i=1}^{K} [\beta_n^{(i)}]^2 \text{ is a minimum.} \tag{3.17}$$

IV. A MODEL PROBLEM AND ITS SOLUTION

Before attempting to solve the general problem outlined above, we will first solve a model problem in this section. This model problem is deliberately designed to be quite similar to the problem of jolt factorization [cf. Eqs. (3.16) and (3.17)]. Therefore, solving this problem will enable us to get a feel for the issues involved in the solution of the jolt factorization problem.

Consider an arbitrary vector v in the two dimensional $x-y$ plane. It can be expressed as follows:

$$v=v_x e_x+v_y e_y, \tag{4.1}$$

where e_x and e_y are the usual unit vectors along the x and y axes, respectively, and v_x and v_y are the corresponding vector components. Next, we construct a new set of N basis vectors e_i (where N is an integer greater than 2) in the $x-y$ plane using the following procedure:

$$e_i=R(\theta_i)e_x, \quad i=1,2,\ldots,N, \tag{4.2}$$

where

$$R(\theta_i)e_x=\cos(\theta_i)e_x+\sin(\theta_i)e_y \tag{4.3}$$

and

$$\theta_i=(k-1)\,\frac{2\pi}{N}. \tag{4.4}$$

We are now in a position to state the problem—express v in the new basis given by the N e_i's. Of course, only two basis vectors are actually needed to express the vector v. Since we have extra basis vectors, we need to impose a constraint. Taking this into account, the problem can be formulated as follows.

Problem 3: *Given the vector v [cf. Eq. (4.1)], find coefficients* β_i *such that the following conditions are satisfied*:

$$\text{(i)} \quad v=\sum_{i=1}^{N} \beta_i e_i=\sum_{i=1}^{N} \beta_i R(\theta_i)e_x \tag{4.5}$$

and

$$\text{(ii)} \quad \sum_{i=1}^{N} \beta_i^2 \text{ is a minimum.} \tag{4.6}$$

The reader will immediately notice the striking similarity between this problem and the problem of jolt factorization [cf. Eqs. (3.16) and (3.17)].

Instead of solving this particular problem, we will solve the more general problem obtained by going to the continuum limit. Its solution will then contain the solution to the original (discrete) problem as a special case. The generalized problem is given as follows.

Generalized Problem 1: *Given the vector v [cf. Eq. (4.1)], find the function* $g(\theta)$ *such that the following conditions are satisfied:*

$$\text{(i)} \quad v=\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g(\theta)R(\theta)e_x \tag{4.7}$$

and

$$\text{(ii)} \quad \frac{1}{2\pi}\int_0^{2\pi} d\theta\, g^2(\theta) \text{ is a minimum,} \tag{4.8}$$

where

$$R(\theta)e_x=\cos(\theta)e_x+\sin(\theta)e_y\,. \tag{4.9}$$

We solve this generalized problem as follows. We first find functions $g_x(\theta)$ and $g_y(\theta)$ satisfying the following relations:

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g_x(\theta)R(\theta)e_x=e_x\,, \tag{4.10}$$

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g_y(\theta)R(\theta)e_x=e_y\,. \tag{4.11}$$

In other words, the functions $g_x(\theta)$ and $g_y(\theta)$ project out the unit vectors e_x and e_y, respectively. Substituting Eq. (4.9) in the above expressions, we obtain the relations

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g_x(\theta)[\cos(\theta)e_x+\sin(\theta)e_y]=e_x\,, \tag{4.12}$$

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g_y(\theta)[\cos(\theta)e_x+\sin(\theta)e_y]=e_y. \tag{4.13}$$

The cosine and sine functions satisfy the following orthonormality conditions:

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, \cos(m\theta)\cos(m'\theta)=\frac{1}{2}\,\delta_{mm'}+\frac{1}{2}\,\delta_{m0}\delta_{m'0}, \tag{4.14}$$

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, \sin(m\theta)\sin(m'\theta)=\frac{1}{2}\,\delta_{mm'}-\frac{1}{2}\,\delta_{m0}\delta_{m'0}, \tag{4.15}$$

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, \cos(m\theta)\sin(m'\theta)=0, \tag{4.16}$$

where m and m' are arbitrary integers. Using these orthonormality relations, we get the following solution for $g_x(\theta)$ and $g_y(\theta)$:

$$g_x(\theta)=2\cos(\theta);\quad g_y(\theta)=2\sin(\theta). \tag{4.17}$$

Consider the following function

$$g(\theta)=v_x g_x(\theta)+v_y g_y(\theta). \tag{4.18}$$

Substituting this function into the right hand side of Eq. (4.7), we get the following result:

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta[v_x g_x(\theta)+v_y g_y(\theta)]R(\theta)e_x. \tag{4.19}$$

Using Eqs. (4.10) and (4.11), we obtain the relation [cf. Eq. (4.1)]

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g(\theta)R(\theta)e_x=v_x e_x+v_y e_y=v. \tag{4.20}$$

This proves that the function $g(\theta)$ given in Eq. (4.18) is a solution satisfying Eq. (4.7).

Next, we have to show that it also satisfies Eq. (4.8). Using the standard Fourier series expansion, the most general function satisfying Eq. (4.7) is found to be

$$g(\theta)=2v_x\cos(\theta)+2v_y\sin(\theta)+b_0+\sum_{n=2}^{\infty} b_n\cos(n\theta)+\sum_{n=2}^{\infty} a_n\sin(n\theta). \tag{4.21}$$

Using the orthonormality relations [cf. Eqs. (4.14), (4.15), and (4.16)], it is easily verified that this is indeed a solution to Eq. (4.7). Substituting this result into Eq. (4.8), we get the relation

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g^2(\theta)=2(v_x^2+v_y^2)+b_0^2+\sum_{n=2}^{\infty}(a_n^2+b_n^2)/2. \tag{4.22}$$

This is a minimum only if the following condition is satisfied:

$$b_0=0;\quad a_n=b_n=0\quad n>1. \tag{4.23}$$

Imposing these conditions on the general solution [cf. Eq. (4.21)], we get back the particular solution given in Eq. (4.18). Thus, the function $g(\theta)$ displayed below is indeed the solution to the generalized problem stated in Eqs. (4.7) and (4.8):

$$g(\theta)=2v_x\cos(\theta)+2v_y\sin(\theta). \tag{4.24}$$

This solution satisfies the following relation [cf. Eqs. (4.22) and (4.23)]

$$\frac{1}{2\pi}\int_0^{2\pi} d\theta\, g^2(\theta)=2(v_x^2+v_y^2). \tag{4.25}$$

The discrete version of the generalized problem is given as follows: Given the vector v [cf. Eq. (4.1)], find values $g(\theta_i)$ $(i=1,2,\ldots,N)$ such that the following conditions are satisfied:

$$\text{(i)}\quad v=\frac{1}{N}\sum_{i=1}^{N} g(\theta_i)R(\theta_i)e_x \tag{4.26}$$

and

$$\text{(ii)}\quad \frac{1}{N}\sum_{i=1}^{N}[g(\theta_i)]^2 \text{ is a minimum.} \tag{4.27}$$

Comparing this with our original problem [cf. Eqs. (4.5) and (4.6)], we make the following identification:

$$\beta_i=g(\theta_i)/N. \tag{4.28}$$

If we choose the angles θ_i to be equally spaced over the interval $[0,2\pi]$ [as we did in the original problem, cf. Eq. (4.4)], $\cos(\theta_i)$ and $\sin(\theta_i)$ still form an othogonal set. Therefore, the solution $g(\theta)$ [cf. Eq. (4.24)] to the continuum problem is the solution even for the discrete version. The only difference is that $g(\theta)$ is now evaluated only at the discrete set of angles θ_i. Therefore, the coefficients β_i satisfying Eqs. (4.5) and (4.6) are given as follows [cf. Eqs. (4.24) and (4.28)]:

$$\beta_i=[2v_x\cos(\theta_i)+2v_y\sin(\theta_i)]/N. \tag{4.29}$$

The discrete version of Eq. (4.25) is found to be

$$\frac{1}{N}\sum_{i=1}^{N}[g(\theta_i)]^2=2(v_x^2+v_y^2). \tag{4.30}$$

Substituting Eq. (4.28) into this expression, we get the relation

$$\sum_{i=1}^{N}\beta_i^2=\frac{2}{N}(v_x^2+v_y^2). \tag{4.31}$$

We notice that the sum of the squares of the coefficients decreases as the number N of basis vectors increases. We also note that the basis vectors e_i [cf. Eq. (4.2)] form a discrete subgroup of the rotation group if the angles θ_i are equally spaced over the interval $[0,2\pi]$.

V. SOLUTION TO THE PROBLEM OF JOLT FACTORIZATION

In this section, we return to the problem of jolt factorization [cf. Eqs. (3.16) and (3.17)]. In Section II, we had concluded that the problem of obtaining a jolt factorization is equivalent to the

determination of the coefficients $\beta_n^{(i)}$ subject to the conditions given in Eqs. (3.16) and (3.17). Hence, we will achieve our goal if we determine these $\beta_n^{(i)}$'s. However, in the previous section, we had discovered that the solution to such problems is facilitated by going over to the continuum limit. Therefore, we do the same for the problem of jolt factorization and obtain the following generalized problem.

Generalized Problem 2: *Given an nth degree homogeneous polynomial f_n and a subgroup G of* Sp(6,R) *on which invariant integration is well defined, find the function $g(u)$ such that the following conditions are satisfied:*

$$\text{(i)} \quad f_n = \int_G du\ g(u)\hat{R}(u)q_1^n \tag{5.1}$$

and

$$\text{(ii)} \quad \int_G du\ g^2(u) \quad \text{is a minimum.} \tag{5.2}$$

Here u denotes a general element of the group G and $\hat{R}(u)$ denotes the Lie transformation corresponding to u. All integrations are invariant integrations performed over the group G.

First we need to choose the group G. We cannot take G to be Sp(6,R) since Sp(6,R) is a noncompact group and therefore its invariant integrals cannot be normalized. We therefore integrate over a compact subgroup of Sp(6,R). The largest compact subgroup of Sp(6,R) is the unitary group U(3). However, we prefer to use SU(3) since it is more convenient for our purposes. If needed, it is possible to generalize the invariant integrals over SU(3) to those over U(3).

Having chosen G to be SU(3), we are now in a position to solve the problem. First, we notice the strong similarity between the present problem and the model problem that was solved in the previous section. Therefore, we will closely follow the procedure used to solve the model problem.

We need to determine the function $g(u)$. For this, we expand all quantities in terms of certain basis vectors. Since we are working with SU(3), it is natural that we use SU(3) basis vectors. Appendix B defines these basis vectors in terms of phase space variables (see Ref. 7 for additional details). Further, one can show[7] that any homogeneous polynomial f_n in the phase space variables can be decomposed in terms of these vectors.

We will denote by $|j;m\rangle$ the basis vectors uniquely labeled according to their transformation properties under SU(3). Here, j denotes the collection of indices j_1 and j_2 labeling the representation and m denotes the collection of indices I, I_3, and Y labeling vectors within the representation. (These basis vectors are analogous to the basis vectors e_x and e_y of the model problem.)

We expand the given homogeneous polynomial f_n in this basis as follows

$$f_n = \sum_{j,m} \phi_m^j |j;m\rangle \quad j \leqslant n. \tag{5.3}$$

A word on the notation used here. Since j stands for a collection of indices j_1 and j_2, $j \leqslant n$ actually means that $j_1 + j_2 \leqslant n$. Here, the ϕ_m^j's are coefficients multiplying the basis vectors. [This expansion is analogous to the one given in Eq. (4.1) for v in the model problem.] Thus, the left hand side of Eq. (5.1) has been expanded in terms of $|j;m\rangle$. However the right hand side is in terms of an integral over SU(3). Therefore, we will rewrite $|j;m\rangle$ in terms of an integral over SU(3) such that a direct comparison of the two sides is possible.

We proceed as follows. Suppose we can find a function $g_m^j(u)$ satisfying the following relation:

$$\int_{\mathrm{SU}(3)} du\ g_m^j(u)\hat{R}(u)q_1^n=|j;m\rangle,\quad j\leqslant n. \tag{5.4}$$

In other words, the function $g_m^j(u)$ projects out the basis vector $|j;m\rangle$. (This function is analogous to the functions g_x and g_y in the model problem.) Substituting this equation and Eq. (5.3) in Eq. (5.1) we get

$$\sum_{j,m}\ \phi_m^j\int_{\mathrm{SU}(3)} du\ g_m^j(u)\hat{R}(u)q_1^n=\int_{\mathrm{SU}(3)} du\ g(u)\hat{R}(u)q_1^n,\quad j\leqslant n. \tag{5.5}$$

Comparing both sides, we see that

$$g(u)=\sum_{j,m}\ \phi_m^j g_m^j(u),\quad j\leqslant n. \tag{5.6}$$

All that remains to be done is to determine $g_m^j(u)$ satisfying Eq. (5.4). To do this, we rewrite $\hat{R}(u)q_1^n$ in terms of SU(3) basis vectors. As a first step, we expand q_1^n in this basis (see Appendix B for a proof of this result):

$$q_1^n=\sum_{j\leqslant n}\ \xi^j|j;m_j\rangle. \tag{5.7}$$

We note two important features of this expansion (see Appendix B for a proof). First, the coefficients ξ^j are all nonzero:

$$\xi^j\neq 0,\quad j\leqslant n. \tag{5.8}$$

Second, each representation occurs *only* once. This is indicated by the fact that there is no summation over the indices m that label vectors within a representation. In summary, each representation (labeled by $j\leqslant n$) occurs once and only once in the expansion of q_1^n. This result will play a crucial role in the discussion that follows.

To get $\hat{R}(u)q_1^n$ we act on both sides of Eq. (5.7) with $\hat{R}(u)$, obtaining the following result:

$$\hat{R}(u)q_1^n=\sum_{j\leqslant n}\ \xi^j\hat{R}(u)|j;m_j\rangle. \tag{5.9}$$

Since the basis vectors $|j;m\rangle$ form a complete set for each j, they satisfy the relation

$$\sum_m\ |j;m\rangle\langle j;m|=1\quad\forall j. \tag{5.10}$$

Inserting this result into the right hand side of Eq. (5.9), we get the following relation:

$$\hat{R}(u)q_1^n=\sum_{j,m}\ \xi^j|j;m\rangle\langle j;m|\hat{R}(u)|j;m_j\rangle,\quad j\leqslant n. \tag{5.11}$$

However, we have the following standard result from representation theory of SU(3):

$$\langle j,m|\hat{R}(u)|j;m_j\rangle=\mathscr{D}^{\,j}{}_{mm_j}(u). \tag{5.12}$$

Substituting this into Eq. (5.11), we obtain the result

$$\hat{R}(u)q_1^n=\sum_{j,m}\xi^j\mathscr{D}^j_{mm_j}(u)|j;m\rangle,\quad j\leqslant n. \tag{5.13}$$

Inserting Eq. (5.13) into Eq. (5.4), we get the result

$$\int_{\mathrm{SU}(3)}du\ g^j_m(u)\sum_{j',m'}\xi^{j'}\mathscr{D}^{j'}_{m'm_{j'}}(u)|j',m'\rangle=|j;m\rangle,\quad j\leqslant n. \tag{5.14}$$

The functions $\mathscr{D}^j(u)$ satisfy the following orthogonality relations

$$\int_{\mathrm{SU}(3)}du\overline{\mathscr{D}}^j_{ab}(u)\mathscr{D}^{j'}_{a'b'}(u)=\frac{1}{d}\ \delta_{jj'}\delta_{aa'}\delta_{bb'}. \tag{5.15}$$

Here $\overline{\mathscr{D}}^j$ is the complex conjugate of the representation $\mathscr{D}^j$ and $d=(j_1+1)(j_2+1)\times((j_1+j_2)/2+1)$ is the dimension of the SU(3) representation labeled by j. Using these orthogonality relations, it is easily verified that the expression given below for $g^j_m(u)$ satisfies Eq. (5.14)

$$g^j_m(u)=\frac{d}{\xi^j}\overline{\mathscr{D}}^j_{mm_j}(u),\quad j\leqslant n. \tag{5.16}$$

We note that this expression is well defined since ξ^j is nonzero for $j\leqslant n$ [cf. Eq. (5.8)].

Having determined $g^j_m(u)$, we immediately obtain the required solution $g(u)$ [cf. Eq. (5.6)]:

$$g(u)=\sum_{j,m}\ \frac{d\phi^j_m}{\xi^j}\overline{\mathscr{D}}^j_{mm_j}(u),\quad j\leqslant n. \tag{5.17}$$

This is a solution satisfying Eq. (5.1). We need to verify that it also satisfies Eq. (5.2).

Again, we proceed as we did in the model problem. The most general solution $g(u)$ satisfying Eq. (5.1) is of the following form:

$$g(u)=\sum_{j,m}\ \frac{d\phi^j_m}{\xi^j}\overline{\mathscr{D}}^j_{mm_j}(u)+\sum_{j',a,b}c^{j'}_{ab}\overline{\mathscr{D}}^{j'}_{ab}(u). \tag{5.18}$$

Here the indices j', a, and b are required to satisfy the condition

$$\int_{\mathrm{SU}(3)}du\overline{\mathscr{D}}^{j'}_{ab}(u)\hat{R}(u)q_1^n=0. \tag{5.19}$$

This condition ensures that the extra terms added to obtain the general solution do not contribute to the integral in Eq. (5.1). However, these extra terms do contribute to the integral in Eq. (5.2). This is easily seen by substituting the general solution given in Eq. (5.18) into Eq. (5.2). We obtain the relation

$$\int_{\mathrm{SU}(3)}du\ g^2(u)=\sum_{j,m}\ d\left|\frac{\phi^j_m}{\xi^j}\right|^2+\sum_{j',a,b}|c^{j'}_{ab}|^2. \tag{5.20}$$

The above expression is minimized only if the following conditions are satisfied:

$$c^{j'}_{ab}=0\quad\forall j',a,b. \tag{5.21}$$

Imposing these conditions on the general solution [cf. Eq. (5.18)], we get back the particular solution given in Eq. (5.17). In summary, the function $g(u)$ given in Eq. (5.17) is the solution satisfying both Eqs. (5.1) and (5.2).

Having solved the problem in the continuum limit, we now return to the discrete version. Following the analogy with the model problem, we replace the integral over SU(3) by a sum over a discrete subgroup Γ of SU(3).[7] Since the elements of the discrete subgroups satisfy the same group properties as elements of the original group, the solution for the continuum problem would still be a solution to the discrete problem. There are several discrete subgroups of SU(3) that could be used. They are listed in detail in Appendix C. One should choose a subgroup of SU(3) whose order is greater than or equal to K. The above procedure leads us to the following result:

$$f_n=\frac{1}{K}\sum_{i=1}^{K} g(u_i)\hat{R}(u_i)q_1^n, \quad u_i\in\Gamma, \tag{5.22}$$

where $g(u)$ is given by Eq. (5.17). Comparing this with Eq. (3.16), we get the following solution for the coefficients $\beta_n^{(i)}$:

$$\beta_n^{(i)}=g(u_i)/K. \tag{5.23}$$

VI. OPTIMIZATION OF THE NUMBER OF JOLT MAPS

We achieved our primary goal of finding a jolt factorization of the map $\mathscr{M}_P$ in the previous section. We now seek to optimize this solution. More specifically, we attempt to reduce the number of jolt maps to a minimum.

We start with the following result from the previous section:

$$f_n=\int_{\mathrm{SU(3)}} du\; g(u)\hat{R}(u)q_1^n, \tag{6.1}$$

where $g(u)$ is given by Eq. (5.17). Here, we take a single jolt monomial q_1^n and act on it with the group SU(3). An alternative procedure is considered below. We will show that it reduces the number of jolt maps required by a substantial amount.

First, we factor SU(3) into the orthogonal group SO(3) and SU(3)/SO(3). The group SO(3) is taken to be the rotation group in the q_1, q_2, q_3 space. We will provide the reason for employing this factorization later. For the sake of notational convenience, let us denote SU(3)/SO(3) by G'. To proceed further, we write u [belonging to the group SU(3)] as the following product of elements belonging to G' and SO(3):

$$u=c\cdot r, \quad u\in\mathrm{SU(3)}, \quad c\in G', \quad r\in\mathrm{SO(3)}. \tag{6.2}$$

Then, it can be shown[12] that the following relation holds between the measure du for SU(3) and the measures dc and dr for G' and SO(3), respectively:

$$du=dc\cdot dr. \tag{6.3}$$

Substituting these results into the expression for f_n [cf. Eq. (6.1)], we obtain the relation

$$f_n=\int_{G'} dc\int_{\mathrm{SO(3)}} dr\;\; g(c\cdot r)\hat{R}(c\cdot r)q_1^n. \tag{6.4}$$

Letting the SO(3) part of $\hat{R}(c\cdot r)$ act first on q_1^n, we get the following result:

$$\hat{R}(c\cdot r)q_1^n=\hat{R}(c)\sum_{k=1}^{N'(n)} d_k(r)P_k^{(n)}(q_1,q_2,q_3). \tag{6.5}$$

Here we have used the following relation:

$$\hat{R}(r)q_1^n=\sum_{k=1}^{N'(n)} d_k(r)P_k^{(n)}(q_1,q_2,q_3), \quad r\in \mathrm{SO}(3), \tag{6.6}$$

where $P_k^{(n)}(q_1,q_2,q_3)$ denotes a nth degree basis monomial in variables q_1, q_2, and q_3:

$$P_k^{(n)}(q_1,q_2,q_3)=q_1^{n_1}q_2^{n_2}q_3^{n_3}, \quad n_1\geqslant n_2\geqslant n_3, \ \ n_1+n_2+n_3=n. \tag{6.7}$$

The number $N'(n)$ of nth degree basis monomial in three variables is given by the following relation:[7]

$$N'(n)=\binom{n+2}{n}. \tag{6.8}$$

Substituting Eq. (6.5) into Eq. (6.4), we get the relation

$$f_n=\int_{G'} dc\hat{R}(c)\int_{\mathrm{SO}(3)} dr\ g(c\cdot r)\sum_{k=1}^{N'(n)} d_k(r)P_k^{(n)}(q_1,q_2,q_3). \tag{6.9}$$

Next, we define a function $h_k(c)$ by the following relation:

$$h_k(c)\equiv\int_{\mathrm{SO}(3)} dr\ g(c\cdot r)\sum_{k=1}^{N'(n)} d_k(r). \tag{6.10}$$

We have already calculated $g(c\cdot r)$. It is nothing but the function $g(u)$ given in Eq. (5.17). Thus, $h_k(c)$ is well defined and can be calculated. Inserting Eq. (6.10) into Eq. (6.9), we obtain the following result:

$$f_n=\int_{G'} dc\hat{R}(c)\sum_{k=1}^{N'(n)} h_k(c)P_k^{(n)}(q_1,q_2,q_3). \tag{6.11}$$

Next, we need to obtain the discrete version of the above equation. This is again done by going over to a discrete sum over SU(3)/SO(3). Starting from a discrete subgroup of SU(3), one can go over to SU(3)/SO(3) following the procedure outlined in Appendix C. We obtain the following solution:

$$f_n=\int_{G'} dc\hat{R}(c)\sum_{k=1}^{N'(n)} h_k(c)P_k^{(n)}(q_1,q_2,q_3)=\frac{1}{K(G')}\sum_{l=1}^{K(G')}\hat{R}(c_l)\sum_{k=1}^{N'(n)} h_k(c_l)P_k^{(n)}(q_1,q_2,q_3). \tag{6.12}$$

Here, $K(G')$ gives the number of jolt maps required.

We now turn to the task of determining the number of jolt maps $K(G')$. It depends on G' as indicated. We have already seen in Section V that K is determined by looking at the equation for n equal to P (the maximum order). Setting n equal to P in the above expression, we obtain the following result:

$$f_P=\frac{1}{K(G')}\sum_{l=1}^{K(G')}\hat{R}(c_l)\sum_{k=1}^{N'(P)}h_k(c_l)P_k^{(P)}(q_1,q_2,q_3). \tag{6.13}$$

Since the Pth degree homogeneous polynomial f_P on the left hand side has $N(P)$ independent coefficients [cf. Eq. (3.14)], we need $N(P)$ linearly independent vectors on the right hand side. Only then, we can express any f_P in terms of these vectors.

We are now in a position to justify our decision to factor SU(3) into SO(3) and SU(3)/SO(3). Suppose we had not factorized SU(3) as above. Then the analogue of the above equation would be

$$f_P=\frac{1}{K'}\sum_{k=1}^{K'}g(u_i)\hat{R}(u_i)q_1^P, \tag{6.14}$$

where u_i belongs to a discrete subgroup of SU(3). Since we need $N(P)$ independent coefficients to describe f_P, K' has to equal $N(P)$. On the other hand, with factorization we need only $N''(P)$ jolts in Eq. (6.13) where

$$N''(P)=N(P)/N'(P). \tag{6.15}$$

This can be seen as follows. Equation (6.13) can be rewritten to give

$$f_P=\frac{1}{K(G')}\sum_{l=1}^{K(G')}\hat{R}(c_l)H_l(q_1,q_2,q_3), \tag{6.16}$$

where

$$H_l(q_1,q_2,q_3)=\sum_{k=1}^{N'(P)}h_k(c_l)P_k^{(P)}(q_1,q_2,q_3). \tag{6.17}$$

Now, the linear combination of $N'(P)$ jolt polynomials given by $H_l(q_1,q_2,q_3)$ is again a jolt polynomial. Since the jolt polynomial $H_l(q_1,q_2,q_3)$ itself has $N'(P)$ independent coefficients, $K(G')$ needs to be equal only to $N''(P)$ [cf. Eq. (6.15)] in order to give a total of $N(P)$ independent coefficients. On the other hand, in Eq. (6.14), we only have a single jolt monomial q_1^P and hence a single coefficient. Therefore, K' has to equal $N(P)$ in this case.

The above discussion demonstrates that a fewer number of jolts are required when SU(3) is factored into G' and SO(3). We now argue that factorizing SU(3) into a different set of factors does not give an even better result. First, we note that q_1, q_2, q_3 space (or equivalently, p_1, p_2, p_3 space) gives the maximal subspace of commuting jolt polynomials. We cannot choose any group larger than SO(3) since it is shown in Appendix D that SO(3) is the largest subgroup of Sp(6,R) that leaves the q_1, q_2, q_3 space invariant. If we choose a group smaller than SO(3), we will not get all the $N'(P)$ jolt monomials. Then $K(G')$ might have to be larger to get $N(P)$ independent coefficients. Therefore, factoring SU(3) into G' and SO(3) does appear to be the best compromise.

For P equal to 6, $N''(P)$ is equal to 17 from the above procedure [cf. Eqs. (6.15), (3.14) and (6.8)]. From Appendix C, we find that starting from (a similarity transformation of) a discrete subgroup of order 108 of SU(3), one can go over to a set of 18 elements belonging to SU(3)/SO(3). Thus, the number of jolt maps $K(G')$ required for $P=6$ is 18. For this case, we have verified that we do get the required number of linearly independent vectors on the right hand side of Eq. (6.13). Irwin[8] factorizes G as U(1)×U(1)×U(1). Using this factorization, for $P=6$, one

needs 27 jolt maps. Thus, we find that the number of jolt maps required in our case is less. When using our factorization for long-term stability analysis of Hamiltonian systems, this can lead to substantial savings in computer time.

VII. SUMMARY

When a nonlinear symplectic map is used in numerical calculations, one is forced to truncate the map at a given order in phase space variables. This truncated map (also known as a symplectic jet) violates the symplectic condition and typically exhibits spurious damping or growth when used to analyze long-term behavior of particle trajectories. We therefore approximated the map by a finite product of symplectic jolt maps which constitutes a symplectic completion of the jet. The action of jolt maps on phase space functions can be evaluated exactly and this should lead to better predictions of long-term stability in complicated Hamiltonian systems. Further, our jolt factorization was optimized so that the number of jolt maps required was significantly reduced. This can result in substantial savings in computer time when used for long-term stability studies. Finally, for $P=6$, we explicitly demonstrated that a fewer number of jolt maps were required as compared to Irwin's procedure.[8] We believe this will be true even for a general P since we are using a bigger group.

ACKNOWLEDGMENTS

APPENDIX A: EXAMPLES OF JOLT MAPS

Proof of Theorem 1: (i) The equality in Eq. (2.2) follows from Eq. (2.4) and properties of Lie transformations.[9] To show that $e^{:\hat{R}q_1^n:}$ is a jolt map, we start by making the following identification:

$$\exp(:\hat{R}q_1^n:)=\exp(:(\hat{R}q_1)^n:), \tag{A1}$$

where [cf. Eq. (2.4)]

$$\hat{R}q_1=R_{11}q_1+R_{12}p_1+\cdots+R_{16}p_3. \tag{A2}$$

The action of the Lie operator $:(\hat{R}q_1)^n:$ on the phase space variables is given by the relations

$$\begin{aligned} :(\hat{R}q_1)^n:z_i&=-n(\hat{R}q_1)^{n-1}R_{1i+1}, \quad i=1,3,5,\\ :(\hat{R}q_1)^n:z_i&=n(\hat{R}q_1)^{n-1}R_{1i-1}, \quad i=2,4,6. \end{aligned} \tag{A3}$$

Now, consider the action of $:(\hat{R}q_1)^n:^2$ on the phase space variables. Using Eq. (A3) we obtain the following result:

$$\begin{aligned} :(\hat{R}q_1)^n:^2z_i&=-nR_{1i+1}[(\hat{R}q_1)^n,(\hat{R}q_1)^{n-1}], \quad i=1,3,5,\\ :(\hat{R}q_1)^n:^2z_i&=nR_{1i-1}[(\hat{R}q_1)^n,(\hat{R}q_1)^{n-1}], \quad i=2,4,6. \end{aligned} \tag{A4}$$

But[9]

$$[(\hat{R}q_1)^n,(\hat{R}q_1)^{n-1}]=\hat{R}[q_1^n,q_1^{n-1}]=0. \tag{A5}$$

This proves that $e^{:\hat{R}q_1^n:}$ is a jolt map.

(ii) We note that the equality in Eq. (2.3) follows from Eq. (2.4) and properties of Lie transformations.[9] We also note that the following equality is satisfied:[9]

$$\hat{R}f(q_1,q_2,q_3)=f(\hat{R}q_1,\hat{R}q_2,\hat{R}q_3). \tag{A6}$$

Consider

$$:\hat{R}f(q_1,q_2,q_3):z_i=[f(\hat{R}q_1,\hat{R}q_2,\hat{R}q_3),z_i]. \tag{A7}$$

Since $\hat{R}q_i$ is linear in the phase space variables, the right hand side can be a function only of $\hat{R}q_i$'s. Denote this function by h. Thus

$$:\hat{R}f(q_1,q_2,q_3):z_i=h(\hat{R}q_1,\hat{R}q_2,\hat{R}q_3)=\hat{R}h(q_1,q_2,q_3), \tag{A8}$$

where the last equality follows from standard properties of Lie transformations.[9]

Next, consider the action of $:\hat{R}f:^2$ on the phase space variables. Using Eq. (A8) we get

$$:\hat{R}f(q_1,q_2,q_3):^2z_i=[\hat{R}f(q_1,q_2,q_3),\hat{R}h(q_1,q_2,q_3)]. \tag{A9}$$

Again using properties of Lie transformations,[9] we obtain

$$:\hat{R}f(q_1,q_2,q_3):^2z_i=\hat{R}[f(q_1,q_2,q_3),h(q_1,q_2,q_3)]. \tag{A10}$$

Since q_i's commute with one another, the Poisson bracket on the right hand side is identically zero. Therefore, $e^{:\hat{R}f(q_1,q_2,q_3):}$ is indeed a jolt map. This completes the proof of the theorem.

APPENDIX B: REPRESENTATIONS OF SU(3) CARRIED BY $q_1^{(n)}$

In this appendix, we prove a theorem regarding the representations of SU(3) carried by the monomial q_1^n. The proof will be a constructive one. Therefore, as a by-product, we obtain the explicit decomposition of q_1^n in terms of the SU(3) basis vectors. We end this appendix with an example. Using the formulas derived during the course of proving the theorem, we decompose q_1^4 in terms of the SU(3) basis vectors.

Let us denote the SU(3) basis vectors by $|j_1,j_2;I,I_3,Y\rangle$. Here j_1 and j_2 label the irreducible representations of SU(3) and I, I_3 and Y label weight vectors within the irreducible representation. It can be shown[13–15] that these basis vectors are associated with harmonic functions on the 5-sphere S^5. The 5-sphere is defined by the relation

$$Z_1^*Z_1+Z_2^*Z_2+Z_3^*Z_3=r^2=1, \tag{B1}$$

where

$$Z_j\equiv\frac{1}{\sqrt{2}}(q_j+ip_j), \tag{B2}$$

$$Z_j^*\equiv\frac{1}{\sqrt{2}}(q_j-ip_j). \tag{B3}$$

Since we are interested in functions defined on the 5-space S^5, it is convenient to parametrize S^5 in terms of polar coordinates ϕ_1, ϕ_2, ϕ_3, θ and ξ. These coordinates are related to the complex phase space variables by the following relations:

$$Z_1 = re^{i\phi_1} \cos\,\theta, \tag{B4}$$

$$Z_2 = re^{i\phi_2} \sin\,\theta \cos\,\xi, \tag{B5}$$

$$Z_3 = re^{i\phi_3} \sin\,\theta \sin\,\xi, \tag{B6}$$

where

$$0 \leqslant \phi_1, \phi_2, \phi_3 \leqslant 2\pi; \quad 0 \leqslant \theta, \xi \leqslant \pi/2. \tag{B7}$$

It can be shown[15] that states within the irreducible representation (j_1, j_2) can be associated with harmonic functions defined on S^5 as shown below:

$$|j_1, j_2; I, I_3, Y\rangle = \frac{1}{\sin\,\theta}\, d^{(1/2)(j_1+j_2+1)}_{(1/6)(j_1-j_2-3Y+6I+3),(1/6)(j_1-j_2-3Y-6I-3)}(2\theta) d^{(I)}_{(1/3)(j_1-j_2)+1/2Y, I_3} \times (2\xi) e^{(1/3)i(j_1-j_2)(\phi_1+\phi_2+\phi_3)} e^{iI_3(\phi_2-\phi_3)} e^{(1/2)iY(-2\phi_1+\phi_2+\phi_3)}. \tag{B8}$$

Here $d^{(j)}_{m',m}(\beta)$ are the usual d-functions that characterize the irreducible representation (j) of SU(2). The sign convention for the d-function is taken to be that given in Edmonds,[16] i.e.,

$$d^{(j)}_{m',m}(\beta) = \langle jm' | \exp(+i\beta J_y/h) | jm \rangle. \tag{B9}$$

where $|jm\rangle$ denotes states within the representation (j) of SU(2).

The d-functions can be computed using the following formula:[17]

$$d^{(j)}_{m',m}(\beta) = [(j+m')!(j-m')!(j+m)!(j-m)!]^{1/2} \times \sum_s \frac{(-1)^s \left(\cos\frac{\beta}{2}\right)^{2j+m-m'-2s} \left(\sin\frac{\beta}{2}\right)^{m'-m+2s}}{(j+m-s)!\,s!\,(m'-m+s)!\,(j-m'-s)!}, \tag{B10}$$

where the summation index s ranges over all integral values such that the factorials in the denominator are non-negative. The d-functions can also be computed using the following recursion relation:[17]

$$d^{(j)}_{m',m}(\beta) = \left(\frac{j-m'}{j-m}\right)^{1/2} d^{(j-1/2)}_{m'+1/2,m+1/2}(\beta) \cos\frac{\beta}{2} + \left(\frac{j+m'}{j-m}\right)^{1/2} d^{(j-1/2)}_{m'-1/2,m+1/2}(\beta) \sin\frac{\beta}{2}, \quad \text{if } j \neq m. \tag{B11}$$

If j is equal to m, the following relation can be used:

$$d^{(j)}_{m',j}(\beta) = (-1)^{j-m'} \left[\frac{(2j)!}{(j+m')!(j-m')!}\right]^{1/2} \left(\cos\frac{\beta}{2}\right)^{j+m'} \left(\sin\frac{\beta}{2}\right)^{j-m'}. \tag{B12}$$

Two additional formulas which facilitate computation of the d-functions are given below

$$d^{(j)}_{m',m}(\beta) = (-1)^{m'-m} d^{(j)}_{m,m'}(\beta), \tag{B13}$$

$$d^{(j)}_{m',m}(\beta) = (-1)^{m'-m} d^{(j)}_{-m',-m}(\beta), \tag{B14}$$

We are now in a position to state and prove the theorem on the SU(3) content of q_1^n.

Theorem 2: *The monomial q_1^n contains only those representations (j_1,j_2) of* SU(3) *for which j_1+j_2 is less than or equal to n. Moreover, each such representation occurs once and only once in q_1^n.*

Proof: From Eq. (B4), we obtain the following expression for q_1^n in terms of the coordinates that parametrize the 5-sphere:

$$q_1^n=2^{n/2}(\text{Re } Z_1)^n=2^{n/2}r^n \cos^n \phi_1 \cos^n \theta. \tag{B15}$$

However, $\cos^n \phi_1$ satisfies the relation[18]

$$\cos^n \phi_1=\sum_{\substack{j_1+j_2=n \\ j_1\geqslant j_2}} a_{j_1j_2} \cos[(j_1-j_2)\phi_1], \tag{B16}$$

where

$$a_{j_1j_2}=\frac{1}{2^{n-1}}\binom{n}{j_2}, \quad j_1+j_2=n, \ j_1>j_2, \tag{B17}$$

$$a_{j_1j_2}=\frac{1}{2^n}\binom{n}{j_2}, \quad j_1+j_2=n, \ j_1=j_2. \tag{B18}$$

Notice that we have denoted the summation indices by j_1 and j_2 in anticipation of results to come. Substituting Eq. (B16) into Eq. (B15), we obtain the result

$$q_1^n=2^{n/2}r^n \sum_{\substack{j_1+j_2=n \\ j_1\geqslant j_2}} a_{j_1j_2} \cos[(j_1-j_2)\phi_1]\cos^{j_1+j_2} \theta. \tag{B19}$$

The above result has to be expressed in terms of the SU(3) state vectors given by $|j_1,j_2;I,I_3,Y\rangle$ [cf. Eq. (B8)]. However, q_1^n does not depend on the coordinates ϕ_2, ϕ_3, and ξ. Therefore, only those SU(3) state vectors that satisfy the following conditions can occur in the expansion of q_1^n:

$$I=I_3=0, \quad Y=-2(j_1-j_2)/3. \tag{B20}$$

Imposing these conditions on a general $|j_1,j_2;I,I_3,Y\rangle$ [cf. Eq. (B8)], we obtain the relation

$$|j_1,j_2;0,0,-2(j_1-j_2)/3\rangle=\frac{1}{\sin \theta} d^{(1/2)(j_1+j_2+1)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)e^{i(j_1-j_2)\phi_1}. \tag{B21}$$

As expected, these vectors do not depend on the coordinates ϕ_2, ϕ_3, and ξ. The d-function appearing in the above expression satisfies the following property [cf. Eqs. (B13) and (B14)]:

$$d^{(1/2)(j_1+j_2+1)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)=d^{(1/2)(j_2+j_1+1)}_{(1/2)(j_2-j_1+1),(1/2)(j_2-j_1-1)}(2\theta). \tag{B22}$$

That is, this function is invariant under the exchange of the indices j_1 and j_2. Using this property and Eq. (B21), we obtain the following result:

$$\begin{aligned}&\tfrac{1}{2}\left[|j_1,j_2;0,0,-2(j_1-j_2)/3\rangle+|j_2,j_1;0,0,-2(j_2-j_1)/3\rangle\right] \\ &\quad=\cos[(j_1-j_2)\phi_1]\frac{1}{\sin \theta} d^{(1/2)(j_1+j_2+1)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta), \quad j_1\geqslant j_2.\end{aligned} \tag{B23}$$

Here we have also used the standard relation

$$\tfrac{1}{2}\,[e^{i(j_1-j_2)\phi_1}+e^{-i(j_1-j_2)\phi_1}]=\cos[(j_1-j_2)\phi_1]. \tag{B24}$$

Comparing Eq. (B23) with the summand on the right hand side of Eq. (B19), we note that we somehow have to generate the function $\cos^{j_1+j_2}\theta$ out of the d-functions by taking appropriate linear combinations. In order to accomplish this, we first need explicit expressions for the d-functions. From Eq. (B10), we get the following result:

$$\frac{1}{\sin\,\theta}\,d^{(1/2)(j_1+j_2+1)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)$$
$$=[j_1!(j_1+1)!j_2!(j_2+1)!]^{1/2}\sum_{s=0}^{j_2}\frac{(-1)^s(\cos\,\theta)^{j_1+j_2-2s}(\sin\,\theta)^{2s}}{s!(s+1)!(j_1-s)!(j_2-s)!},\quad j_1\geqslant j_2. \tag{B25}$$

Using the standard binomial theorem, we obtain the relation

$$(\sin\,\theta)^{2s}=(1-\cos^2\,\theta)^s=\sum_{k=0}^{s}\binom{s}{k}(-1)^{s-k}(\cos^2\,\theta)^{s-k}. \tag{B26}$$

Substituting this relation into Eq. (B25), we get

$$\frac{1}{\sin\,\theta}\,d^{(1/2)(j_1+j_2+1)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)$$
$$=[j_1!(j_1+1)!j_2!(j_2+1)!]^{1/2}\sum_{s=0}^{j_2}\frac{1}{s!(s+1)!(j_1-s)!(j_2-s)!}$$
$$\times\sum_{k=0}^{s}\binom{s}{k}(-1)^k(\cos\,\theta)^{j_1+j_2-2k},\quad j_1\geqslant j_2. \tag{B27}$$

We had noticed earlier [cf. Eq. (B23)] that the sum of the state vectors $|j_1,j_2;0,0,-2(j_1-j_2)/3\rangle$ and $|j_2,j_1;0,0,-2(j_2-j_1)/3\rangle$ is proportional to $\cos[(j_1-j_2)\phi_1]$ [cf. Eq. (B23)]. This remains true even if we make the following substitution:

$$j_1\to j_1-i,\quad j_2\to j_2-i, \tag{B28}$$

where i is some integer. More specifically, we have the following relation:

$$\tfrac{1}{2}\,[|j_1-i,j_2-i;0,0,-2(j_1-j_2)/3\rangle+|j_2-i,j_1-i;0,0,-2(j_2-j_1)/3\rangle]$$
$$=\frac{1}{\sin\,\theta}\,d^{(1/2)(j_1+j_2+1-2i)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)\cos[(j_1-j_2)\phi_1],\quad j_1\geqslant j_2,\ \ i\leqslant j_2, \tag{B29}$$

where

$$\frac{1}{\sin\theta}\, d^{(1/2)(j_1+j_2+1-2i)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)$$
$$=[(j_1-i)!(j_1+1-i)!(j_2-i)!(j_2+1-i)!]^{1/2}$$
$$\times\sum_{s=0}^{j_2-i}\frac{1}{s!(s+1)!(j_1-s-i)!(j_2-s-i)!}\sum_{k=0}^{s}\binom{s}{k}$$
$$\times(-1)^k(\cos\theta)^{j_1+j_2-2k-2i},\quad j_1\geqslant j_2. \tag{B30}$$

Therefore, the most general combination of vectors that still gives a quantity proportional to $\cos[(j_1-j_2)\phi_1]$ is as follows:

$$2^{n/2}r^n\sum_{i=0}^{j_2}\frac{A_i^{(j_1,j_2)}}{2}\left[|j_1-i,j_2-i;0,0,-2(j_1-j_2)/3\rangle+|j_2-i,j_1-i;0,0,-2(j_2-j_1)/3\rangle\right]$$
$$=2^{n/2}r^n\cos[(j_1-j_2)\phi_1]\sum_{i=0}^{j_2}A_i^{(j_1,j_2)}\frac{1}{\sin\theta}\, d^{(1/2)(j_1+j_2+1-2i)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta),\quad j_1\geqslant j_2. \tag{B31}$$

Comparing the right hand side of the above equation with the summand in the expression for q_1^n [cf. Eq. (B19)], we obtain the condition

$$\sum_{i=0}^{j_2}A_i^{(j_1,j_2)}\frac{1}{\sin\theta}\, d^{(1/2)(j_1+j_2+1-2i)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)=\cos^{j_1+j_2}\theta. \tag{B32}$$

In other words, we need to find coefficients $A_i^{(j_1,j_2)}$ such that the above condition is satisfied. Then, we would have succeeded in decomposing q_1^n in terms of the SU(3) state vectors. We proceed as follows. First, we interchange the summations over indices s and k in Eq. (B30) to obtain the relation

$$\frac{1}{\sin\theta}\, d^{(1/2)(j_1+j_2+1-2i)}_{(1/2)(j_1-j_2+1),(1/2)(j_1-j_2-1)}(2\theta)$$
$$=B_i^{(j_1,j_2)}\sum_{k=0}^{j_2-i}(-1)^k(\cos\theta)^{j_1+j_2-2k-2i}$$
$$\times\sum_{s=k}^{j_2-i}\frac{1}{s!(s+1)!(j_1-s-i)!(j_2-s-i)!}\binom{s}{k},\quad j_1\geqslant j_2,\ \ i\leqslant j_2, \tag{B33}$$

where

$$B_i^{(j_1,j_2)}=[(j_1-i)!(j_1+1-i)!(j_2-i)!(j_2+1-i)!]^{1/2}. \tag{B34}$$

Inserting Eq. (B33) into Eq. (B32), we get the condition

$$\sum_{i=0}^{j_2}A_i^{(j_1,j_2)}B_i^{(j_1,j_2)}\sum_{k=0}^{j_2-i}(-1)^k(\cos\theta)^{j_1+j_2-2k-2i}$$
$$\times\sum_{s=k}^{j_2-i}\frac{1}{s!(s+1)!(j_1-s-i)!(j_2-s-i)!}\binom{s}{k}=\cos^{j_1+j_2}\theta,\quad j_1\geqslant j_2. \tag{B35}$$

The coefficient $C_l^{(j_1,j_2)}$ of $\cos^{j_1+j_2-2l}\theta$ on the left hand side of the above equation is given by the expression (where $l=i+k$)

$$C_l^{(j_1,j_2)}=\sum_{k=0}^{l}(-1)^k A_{l-k}^{(j_1,j_2)}B_{l-k}^{(j_1,j_2)} \times\sum_{s=k}^{j_2-l+k}\frac{1}{s!(s+1)!(j_1-s-l+k)!(j_2-s-l+k)!}\binom{s}{k},\quad j_1\geqslant j_2. \tag{B36}$$

The above expression can be simplified by using the following substitution

$$s'=s-k. \tag{B37}$$

Making this substitution in Eq. (B36), we get the relation

$$C_l^{(j_1,j_2)}=\sum_{k=0}^{l}\frac{(-1)^k}{k!}A_{l-k}^{(j_1,j_2)}B_{l-k}^{(j_1,j_2)}\sum_{s'=0}^{j_2-l}\frac{1}{s'!(s'+k+1)!(j_1-s'-l)!(j_2-s'-l)!},\quad j_1\geqslant j_2. \tag{B38}$$

In order to satisfy Eq. (B35), we need to impose the following conditions

$$C_0^{(j_1,j_2)}=1, \tag{B39}$$

$$C_l^{(j_1,j_2)}=0,\quad l=1,2,\ldots,j_2. \tag{B40}$$

Inserting the expression for $C_l^{(j_1,j_2)}$ into the above equations, we obtain the following results:

$$A_0^{(j_1,j_2)}=\frac{1}{B_0^{(j_1,j_2)}S_{00}^{(j_1,j_2)}},$$

$$A_l^{(j_1,j_2)}=\frac{1}{B_l^{(j_1,j_2)}S_{l0}^{(j_1,j_2)}}\sum_{k=1}^{l}\frac{(-1)^{k+1}}{k!}A_{l-k}^{(j_1,j_2)}B_{l-k}^{(j_1,j_2)}S_{lk}^{(j_1,j_2)},\quad 1\leqslant l\leqslant j_2, \tag{B41}$$

where

$$S_{lk}^{(j_1,j_2)}=\sum_{s'=0}^{j_2-l}\frac{1}{s'!(s'+k+1)!(j_1-s'-l)!(j_2-s'-l)!}. \tag{B42}$$

From Eqs. (B19), (B31), and (B32), we finally get the following decomposition for q_1^n:

$$q_1^n=2^{n/2}r^n\sum_{\substack{j_1+j_2=n\\ j_1\geqslant j_2}}\frac{a_{j_1j_2}}{2} \times\sum_{i=0}^{j_2}A_i^{(j_1,j_2)}[|j_1-i,j_2-i;0,0,-2(j_1-j_2)/3\rangle+|j_2-i,j_1-i;0,0,-2(j_2-j_1)/3\rangle]. \tag{B43}$$

We note that all representations (j_1,j_2) (with j_1+j_2 less than or equal to n) appear in the decomposition (since the coefficients $A_i^{(j_1,j_2)}a_{j_1j_2}$ are seen to be nonzero for all valid j_1, j_2, and i). Furthermore, from each representation (j_1,j_2), only one vector $|j_1,j_2;0,0,-2(j_1-j_2)/3\rangle$ appears in the decomposition. This proves the theorem.

As an example, we obtain the decomposition of q_1^4. Using the above formulas we get the following results:

$$a_{40}=1/8, \quad a_{31}=1/2, \quad a_{22}=3/8; \tag{B44}$$

$$A_0^{(4,0)}=1/\sqrt{5}, \quad A_0^{(3,1)}=1/5\sqrt{2}, \quad A_1^{(3,1)}=\sqrt{3}/5; \tag{B45}$$

$$A_0^{(2,2)}=1/10, \quad A_1^{(2,2)}=4/15, \quad A_2^{(2,2)}=1/6. \tag{B46}$$

Substituting these results into Eq. (B43), we obtain the following decomposition

$$\begin{aligned} q_1^4=&\frac{r^4}{4\sqrt{5}}[|4,0;0,0,-8/3\rangle+|0,4;0,0,8/3\rangle]+\frac{r^4}{5\sqrt{2}}[|3,1;0,0,-4/3\rangle+|1,3;0,0,4/3\rangle] \\ &+\frac{\sqrt{3}r^4}{5}[|2,0;0,0,-4/3\rangle+|0,2;0,0,4/3\rangle]+\frac{3}{20}r^4|2,2;0,0,0\rangle+\frac{2}{5}r^4|1,1;0,0,0\rangle \\ &+\frac{1}{4}r^4|0,0;0,0,0\rangle. \end{aligned} \tag{B47}$$

APPENDIX C: DISCRETE SUBGROUPS OF SU(3)

In this appendix, we study the discrete subgroups of SU(3) which are required in Sections V and VI. We start by defining the following matrices:

$$A(\alpha,\beta)=\begin{pmatrix} e^{i\alpha} & 0 & 0 \\ 0 & e^{i\beta} & 0 \\ 0 & 0 & e^{-i(\alpha+\beta)} \end{pmatrix}, \tag{C1}$$

$$B(\alpha,\beta)=\begin{pmatrix} e^{i\alpha} & 0 & 0 \\ 0 & 0 & e^{i\beta} \\ 0 & e^{i(\pi-\alpha-\beta)} & 0 \end{pmatrix}, \tag{C2}$$

$$E(\alpha,\beta)=\begin{pmatrix} 0 & e^{i\alpha} & 0 \\ 0 & 0 & e^{i\beta} \\ e^{-i(\alpha+\beta)} & 0 & 0 \end{pmatrix}, \tag{C3}$$

$$V=\frac{1}{\sqrt{3}i}\begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix}, \tag{C4}$$

$$V'=\frac{1}{\sqrt{3}i}\begin{pmatrix} 1 & 1 & \omega^2 \\ 1 & \omega & \omega \\ \omega & 1 & \omega \end{pmatrix}, \tag{C5}$$

$$W=\frac{1}{2}\begin{pmatrix} -1 & \mu_2 & \mu_1 \\ \mu_2 & \mu_1 & -1 \\ \mu_1 & -1 & \mu_2 \end{pmatrix}, \tag{C6}$$

$$Z=\frac{-1}{\sqrt{7}i}\begin{pmatrix} a & b & c \\ b & c & a \\ c & a & b \end{pmatrix}, \tag{C7}$$

where

$$\omega=e^{i2\pi/3}, \tag{C8}$$

$$\mu_1=\tfrac{1}{2}(-1+\sqrt{5}), \quad \mu_2=\tfrac{1}{2}(-1-\sqrt{5}), \tag{C9}$$

$$a=\xi^4-\xi^3, \quad b=\xi^2-\xi^5, \tag{C10}$$

$$c=\xi-\xi^6, \quad \xi^7=1. \tag{C11}$$

The discrete subgroups of SU(3) are listed below along with their generators.[19,20] First, we list the crystal-like subgroups. They are denoted by $\Gamma(n)$ where n denotes the order of the group:

(1) $\Gamma(60)$:$A(0,\pi)$, $E(0,0)$, and W;
(2) $\Gamma(108)$:$A(0,2\pi/3)$, $E(0,0)$, and V;
(3) $\Gamma(168)$:$A(2\pi/7,4\pi/7)$, $E(0,0)$, and Z;
(4) $\Gamma(216)$:$A(0,2\pi/3)$, $E(0,0)$, V, and V';
(5) $\Gamma(648)$:$A(0,2\pi/3)$, $E(0,0)$, V, and $A(4\pi/9,4\pi/9)$;
(6) $\Gamma(1080)$:$A(0,\pi)$, $E(0,0)$, W, and $B(\pi,5\pi/3)$.

Next, we list the dihedral-like groups and the disconnected groups. They are denoted by $\Delta(n)$ where n denotes the order of the group:

(1) $\Delta(3m^2)$:$A(j2\pi/m,k2\pi/m)$ and $E(0,0)$ where j and k are integers;
(2) $\Delta(6m^2)$:$A(j2\pi/m,k2\pi/m)$, $E(0,0)$, and $B(j2\pi/m,k2\pi/m)$ where j and k are integers;
(3) $\Delta(3\infty^2)$:$A(\alpha,\beta)$ and $E(0,0)$;
(4) $\Delta(6\infty^2)$:$A(\alpha,\beta)$, $E(0,0)$, and $B(\alpha,\beta)$.

In Section VI, we will also be interested in discrete elements of SU(3)/SO(3). We obtain discrete elements of SU(3)/SO(3) by the following procedure. We start with a discrete subgroup $\Gamma(n)$ of SU(3). Next, we identify the subgroup $\Gamma'(n')$ of $\Gamma(n)$ that belongs to SO(3) [where n' is the order of $\Gamma'(n')$]. This is easily accomplished once it is realized that an element $\Gamma_i \in \Gamma(n)$ belongs to SO(3) if and only if all its matrix elements are real. For example, it is seen that all of $\Gamma(60)$ also belongs to SO(3) since each of its elements is real. Next, we construct the $\Gamma(n)/\Gamma'(n')$ as follows. For every element Γ_i belonging to $\Gamma(n)$, we form the right coset $\Gamma'(n')\Gamma_i$. There will be n/n' distinct right cosets. From each distinct coset, we select one element to be the coset representative. These n/n' coset representatives belong to $\Gamma(n)/\Gamma'(n')$. Thus we get a collection of n/n' discrete elements of SU(3)/SO(3). Values for n' and n/n' for the various crystal groups are given below:

(1) $\Gamma(60)$:$n'=60$, $n/n'=1$;
(2) $\Gamma(108)$:$n'=6$, $n/n'=18$;
(3) $\Gamma(168)$:$n'=6$, $n/n'=28$;
(4) $\Gamma(216)$:$n'=6$, $n/n'=36$;

(5) $\Gamma(648): n' = 6,\ n/n' = 108;$
(6) $\Gamma(1080): n' = 60,\ n/n' = 18.$

Finally, we should mention that we rarely make direct use of the complex 3×3 matrices Γ_i belonging to $\Gamma(n)$. We need objects that act on the six dimensional phase space. Therefore, we first embed these complex 3×3 matrices into the compact part of Sp(6,R) following the procedure outlined in Appendix D. The real 6×6 matrices that are obtained as a result of this embedding (and the Lie transformations corresponding to these matrices) can act on phase space variables. It is these real 6×6 matrices that are used in Sections V and VI.

APPENDIX D: LARGEST SUBGROUP OF SU(3) THAT LEAVES COORDINATE SPACE INVARIANT

In this appendix, we prove a theorem satisfied by the special orthogonal group SO(3). The result of this theorem will be used in Section VI. Throughout this appendix, we will work in the rearranged basis of phase space variables given by $z=(q_1,q_2,q_3,p_1,p_2,p_3)$ for convenience. Symplectic matrices in the rearranged basis are related to those in the original basis by a simple similarity transformation.

Theorem 3: *Let $V^{(m)}$ be the vector space formed by homogeneous polynomials of degree m in variables q_1, q_2, and q_3. Then,* SO(3) *is the largest subgroup of* SU(3) *that leaves $V^{(m)}$ invariant.*

Proof: We first prove the following lemma.

Lemma 1: SO(3) *is the largest subgroup of* SU(3) *that leaves $V^{(1)}$ invariant.*

Proof: Consider a complex 3×3 matrix R belonging to SU(3). It satisfies the following conditions:

$$R^{\dagger}=R^{-1};\quad \det R=1. \tag{D1}$$

It can be decomposed into its real and imaginary parts as follows

$$R=-D+iC, \tag{D2}$$

where C and D are real 3×3 matrices.

Since the matrix R has to act on functions of phase space variables, we first need to embed it in the compact part of Sp(6,R). Following the procedure outlined in Ref. 7, the real 6×6 symplectic matrix U^s (in the rearranged basis) corresponding to the unitary matrix R is given by the relation

$$U^s=V^s\begin{pmatrix} R & 0 \\ 0 & R^* \end{pmatrix}(V^s)^{-1}, \tag{D3}$$

where V^s is given by[9]

$$V^s=\frac{1}{\sqrt{2}}\begin{pmatrix} I & iI \\ iI & I \end{pmatrix}. \tag{D4}$$

Here I is a 3×3 identity matrix. Upon evaluating this equation, we obtain the following result:

$$U^s=\begin{pmatrix} -D & C \\ -C & -D \end{pmatrix}. \tag{D5}$$

Next, consider a general 6-vector v^s belonging to $V^{(1)}$. It is given by the relation

$$v^s=(v_3^s,0_3) \tag{D6}$$

where v_3^s and 0_3 are 3-vectors defined as follows:

$$v_3^s=(a,b,c), \quad a,b,c\in\mathscr{R} \tag{D7}$$

$$0_3=(0,0,0). \tag{D8}$$

The action of U^s on v^s is given by the following relation:

$$U^s v^s=\begin{pmatrix} -Dv_3^s \\ -Cv_3^s \end{pmatrix}. \tag{D9}$$

Therefore, $U^s v^s$ belongs to $V^{(1)}$ if and only if the following condition is satisfied [cf. Eq. (D6)]

$$Cv_3^s=0. \tag{D10}$$

Since v_3^s is an arbitrary 3-vector, this implies that C is a zero matrix:

$$C=0. \tag{D11}$$

Substituting Eq. (D11) into Eq. (D5), the most general element belonging to the compact part of Sp(6,R) that leaves $V^{(1)}$ invariant is found to have the following form:

$$U_*^s=\begin{pmatrix} -D & 0 \\ 0 & -D \end{pmatrix}. \tag{D12}$$

We convert this into an element of SU(3) using the following procedure.[8] Given a 6×6 matrix U^s belonging to the compact part of Sp(6,R), one can extract the complex 3×3 matrix R belonging to SU(3) from it through the following relation:

$$(V^s)^{-1}U^sV^s=\begin{pmatrix} R & 0 \\ 0 & R^* \end{pmatrix}. \tag{D13}$$

From the above equation, we obtain the SU(3) element R_* corresponding to U_*^s as

$$R_*=-D. \tag{D14}$$

However, since this is supposed to be an element of SU(3), it has to satisfy the conditions given in Eq. (D1). Imposing these conditions on R_* and noting that R_* is real, we obtain the following restrictions on R_*:

$$\widetilde{R}_*=R_*^{-1}; \quad \det R_*=1, \tag{D15}$$

where $\widetilde{R}_*$ is the transpose of R_*. But these are precisely the conditions satisfied by an element of SO(3). This proves the lemma.

We now return to the proof of the theorem. Consider an element $P_k^{(m)}$ belonging to $V^{(m)}$:

$$P_k^{(m)}=a_1q_1^m+a_2q_1^{m-1}q_2+\cdots+a_Nq_3^m, \tag{D16}$$

where [cf. Eq. (6.8)]

$$N=\begin{pmatrix} m+2 \\ m \end{pmatrix}. \tag{D17}$$

The action of $\hat{U}^s$ (the Lie transformation corresponding to the matrix U^s) on $P_k^{(m)}$ is given as follows:

$$\hat{U}^s P_k^{(m)} = a_1(\hat{U}^s q_1)^m + a_2(\hat{U}^s q_1)^{m-1}(\hat{U}^s q_2) + \cdots + a_N(\hat{U}^s q_3)^m. \tag{D18}$$

Therefore, the condition that ''U^s leaves $V^{(1)}$ invariant'' is sufficient to ensure that $\hat{U}^s$ leaves $V^{(m)}$ invariant, i.e.,

$$\hat{U}^s V^{(1)} \subseteq V^{(1)} \Rightarrow \hat{U}^s V^{(m)} \subseteq V^{(m)}. \tag{D19}$$

To complete the proof of the theorem, we need to show that this is also a necessary condition.

Suppose that $\hat{U}^s V^{(1)} \not\subseteq V^{(1)}$. Then, there exists a vector v_*^s belonging to $V^{(1)}$ that is mapped out of $V^{(1)}$ under the action of $\hat{U}^s$, i.e.,

$$\hat{U}^s v_*^s \notin V^{(1)}. \tag{D20}$$

This can be rewritten as follows

$$\hat{U}^s (\hat{U}_1^s)^{-1} \hat{U}_1^s v_*^s \notin V^{(1)}, \tag{D21}$$

where $\hat{U}_1^s$ is chosen to satisfy the condition

$$\hat{U}_1^s v_*^s = q_1. \tag{D22}$$

This is always possible since v_*^s is effectively a vector in the three dimensional $q_1 - q_2 - q_3$ space and therefore can be rotated to orient it along the q_1 axis. Since the transformation $\hat{U}_1^s$ that brings about this rotation belongs to the subgroup SO(3), $\hat{U}^s(\hat{U}_1^s)^{-1}$ (or more accurately, the unitary matrix corresponding to this transformation) still belongs to SU(3). In summary, if $\hat{U}^s V^{(1)} \not\subseteq V^{(1)}$, there exists a transformation $\hat{U}_2^s$ [equal to $\hat{U}^s(\hat{U}_1^s)^{-1}$] that maps q_1 out of $V^{(1)}$:

$$\hat{U}_2^s q_1 \notin V^{(1)}. \tag{D23}$$

Now, consider the action of $\hat{U}_2^s$ on the vector q_1^m belonging to $V^{(m)}$:

$$\hat{U}_2^s q_1^m = (\hat{U}_2^s q_1)^m. \tag{D24}$$

Since $\hat{U}_2^s q_1$ does not belong to $V^{(1)}$, it will consist of at least one nonzero term containing p_1, p_2, or p_3. Consequently, from the above equation, even $\hat{U}_2^s q_1^m$ will contain at least one such term. Therefore, the following equation is seen to be true:

$$\hat{U}_2^s q_1^m \notin V^{(m)}. \tag{D25}$$

Since we have produced one vector which leaves $V^{(m)}$ under the action of $\hat{U}_2^s$, we have succeeded in proving the following statement:

$$\hat{U}^s V^{(1)} \not\subseteq V^{(1)} \Rightarrow \hat{U}^s V^{(m)} \not\subseteq V^{(m)}. \tag{D26}$$

Combining Eqs. (D19) and (D26), we see that the condition ''$\hat{U}^s$ leaves $V^{(1)}$ invariant'' is both necessary and sufficient to ensure that $\hat{U}^s$ leaves $V^{(m)}$ invariant. Since SO(3) is the largest subgroup of SU(3) satisfying the first condition, it is also the largest subgroup of SU(3) that leaves $V^{(m)}$ invariant. This completes the proof of the theorem.

We give a rigorous proof of the existence of solutions to the nonlinear gauge conditions on orthonormal frames introduced by Nester to prove the positive energy theorem in general relativity. The proof holds in all dimensions $n \geqslant 2$. If the second de Rham cohomology group vanishes one also proves uniqueness. © *1996 American Institute of Physics.* [S0022-2488(96)00208-3]

I. INTRODUCTION

Nester's proof of the positivity of the gravitational energy in general relativity makes use of gauge conditions which must be satisfied by a global orthonormal frame on the initial-value threefold.[1–3] These gauge conditions can be expressed in terms of a nonlinear elliptic operator acting on orthogonal automorphisms of the cotangent bundle. In Ref. 4 Nester generalizes the gauge conditions to Riemannian manifolds of any dimension $n \geqslant 2$, and gives some arguments to support an existence and uniqueness result for the linearized problem which should hold for geometries that in some suitable sense are not too far from the Euclidean geometry.

In this paper we provide a rigorous existence result for the full nonlinear problem, which holds for any parallelizable Riemannian geometry satisfying a suitable condition of asymptotic flatness (cf. Definition 2.3 below), and any $n \geqslant 2$. If the second de Rham cohomology group vanishes, one also has uniqueness.

We consider a connected parallelizable Riemannian manifold (M,g) with a fixed orientation. Let $\{e_i\}$ be a global orthonormal frame, and let $\{\theta^i\}$ be the dual coframe field. We associate with the frame $\{e_i\}$ the differential forms

$$\tilde{q} = i_{e_i} d\theta^i, \quad q = \tfrac{1}{2}\delta_{ik} d\theta^i \wedge \theta^k. \tag{1.1}$$

Nester's gauge conditions are that the forms $\tilde{q}$ and $\star q$ are closed,

$$d\tilde{q} = d\star q = 0,$$

where $\star$ is the Hodge duality operator. One therefore looks for an $SO(n)$-valued function $R^i{}_k$ on M such that the forms $\tilde{\tilde{q}}$ and $\star\overline{q}$ associated with the transformed coframe field $\theta^i = R^i{}_k \theta^k$ are closed. A straightforward computation shows that the gauge conditions amount to

$$d(\tilde{q} + R^c{}_a R^a{}_{k,c}\,\theta^k) = 0, \tag{1.2a}$$

$$d\star(q + \tfrac{1}{2}\delta_{ae} R^a{}_b dR^c{}_b \wedge \theta^e \wedge \theta^b) = 0. \tag{1.2b}$$

The existence and uniqueness result will be proved in four steps. First we prove the existence of solutions to the corresponding linearized problem; we then use Kuranishi's technique to solve the nonlinear problem when the source term in the equations (1.2) (i.e., the forms $\tilde{q}, \star q$) is small enough. The solution of the general nonlinear equation is then reduced to the solution of a finite

a)Electronic-mail: bruzzo@sissa.it

number of equations with small source term. We finally prove the uniqueness of the solutions under the assumption that the second de Rham cohomology group vanishes.

II. STATEMENT OF THE PROBLEM

In this Section we introduce some preliminary definitions and results and give a precise statement of our result.

Definition 2.1: We say that a tensor field T on $\mathbb{R}^n$ falls off as $r^{-\alpha}$ if

$$\lim_{r\to\infty} r^{\beta}T=0$$

uniformly for all $\beta<\alpha$, where r is the radial coordinate.

Definition 2.2: Let γ be a Riemannian metric on $\mathbb{R}^n$, and let γ_0 be the standard Euclidean metric. We say that γ is asymptotically Euclidean if $\gamma-\gamma_0$ falls off as $r^{-\mu}$, with $\mu\geqslant\max\{n/2-2,1\}$.

With this choice of the asymptotic behavior of the metric γ all the differential forms we shall need to consider will be square-summable on M.

We shall assume that the Riemannian manifold (M,g) is asymptotically Euclidean in the following sense (this is related to the definition adopted in Ref. 5).

Definition 2.3: A Riemannian manifold (M,g) is said to be asymptotically Euclidean if there is a compact geodesic ball $X\subset M$ such that $(M-X,g)$ is isometric to the complement of a closed ball in $\mathbb{R}^n$ endowed with an asymptotically Euclidean metric.

Note that since we assume that X is compact, the Riemannian manifold (M,g) is complete (cf. Ref. 6).

We may extend Definition 2.1 to an asymptotically Euclidean Riemannian manifold (M,g) by saying that a (say covariant) tensor field T on M falls off as $r^{-\alpha}$ if ψ^*T does so, where ψ is an isometry realizing the condition of Definition 2.3.

We denote by Ω^p_M the bundle of C^∞ differential p-forms on M, and by $\Omega^p(M)$ the space of its global sections, while $H_k(M,\Omega^p)$ will denote the Sobolev space of index k of differential p-forms on M. Moreover, if Y is a compact manifold with boundary ∂Y and interior Y°, we denote by $H_k(Y^\circ,\Omega^p)$ the space formed by the restrictions to the interior Y° of Y of the elements in $H_k(Y,\Omega^p)$ (for a careful definition of these spaces see Ref. 7, Appendix B.2).

The space V of vertical orthogonal automorphisms of T^*M may be regarded as a Banach-Lie group, modelled on the Banach space $H_2(M,\Omega^2)$. The latter space may also be identified with the Lie algebra of V. The exponential map $\exp: H_2(M,\Omega^2)\to V$ is surjective, i.e., $\phi\in V$ may be written as $\phi=\exp\mathbf{A}$ with $\mathbf{A}\in H_2(M,\Omega^2)$; if a global orthonormal frame has been fixed, this is tantamount to writing the orthogonal point-dependent matrix R representing ϕ as $R=\exp A$, where A is an antisymmetric point-dependent matrix.

Definition 2.4: We say that $\phi\in V$ is asymptotic to the identity if $\phi=\exp\mathbf{A}$, where $\mathbf{A}$ falls off as $r^{-\alpha}$, with $\alpha>n/2$.

We can now state our result. Given an orthonormal coframe θ, let $\tilde{q}$ and q be the associated forms according to (1.1), and set $p=d\tilde{q}+\delta q\in\Omega^2(M)$. The problem (1.2) may be written in the form

$$F_\theta(\phi)=-p, \tag{2.1}$$

where $\phi\in V$ and $F_\theta: V\to H_0(M,\Omega^2)$ is a second-order differential operator. Since the metric g is asymptotically Euclidean, p falls off as $r^{-\mu-2}$, so that it is square-summable [i.e., $p\in H_0(M,\Omega^2)$].

Theorem 2.5: *Let (M,g) be a connected parallelizable asymptotically Euclidean Riemannian manifold, of dimension $n\geqslant 2$, and fix a global orthonormal coframe θ. There is a $\phi\in V$ which satisfies the condition (2.1) and is asymptotic to the identity. Moreover, the automorphism ϕ is C^∞. The automorphism ϕ is unique if $H^2_{DR}(M)=0$.*

III. THE LINEARIZED PROBLEM

We linearize the problem (2.1) by fixing θ and considering an automorphism ϕ which differs ''infinitesimally'' from the identity. We obtain the conditions

$$d[\,\delta\mathbf{A}-\tfrac{1}{2}A_{ab}\delta(\theta^a\wedge\theta^b)]=d\widetilde{q}, \tag{3.1a}$$

$$d\star[d\mathbf{A}-\tfrac{1}{2}A_{ab}d(\theta^a\wedge\theta^b)]=-d\star q, \tag{3.1b}$$

where δ is the operator $\delta=(-1)^k\star d\star$, with k the rank of the form acted upon, and the unknown $\mathbf{A}=\frac{1}{2}A_{ab}\theta^a\wedge\theta^b$ is a 2-form on M.

By taking the Hodge dual of (3.1b) and summing the two equations we get a single condition,

$$\mathfrak{F}_\theta\mathbf{A}=d\widetilde{q}+\delta q; \tag{3.2}$$

here $\mathfrak{F}_\theta$ is the operator,

$$\mathfrak{F}_\theta\mathbf{A}:=\Delta\mathbf{A}-\tfrac{1}{2}d[A_{ab}\delta(\theta^a\wedge\theta^b)]-\tfrac{1}{2}\delta[A_{ab}d(\theta^a\wedge\theta^b)] \tag{3.3}$$

(cf. Ref. 4), where Δ is the Laplace-Beltrami operator $\Delta=d\delta+\delta d$. We regard $\mathfrak{F}_\theta$ as an operator $H_2(M,\Omega^2)\to H_0(M,\Omega^2)$. The problem (3.2) is equivalent to (3.1) due to the orthogonality of the two summands in $\mathfrak{F}_\theta\mathbf{A}$ and in $d\widetilde{q}+\delta q$.

We start by transferring the problem from M to the interior Y^0 of a compact manifold Y with boundary ∂Y diffeomorphic to S^{n-1}. In this way we may use available results on elliptic problems on compact manifolds with boundary (cf. Ref. 7). Let $f:Y^0\to M$ be a diffeomorphism; even though this will be understood in our notation, we shall consider for a while the problem (3.2) on Y^0 endowed with the pullback metric f^*g.

Proposition 3.1: There is a differential form $\mathbf{A}\in\overline{H_2}(Y^\circ,\Omega^2)$ *such that*

$$\mathfrak{F}_\theta\mathbf{A}=p,\quad \mathbf{A}\big|\partial Y=0.$$

Moreover, $\mathbf{A}$ *is* C^∞*, and is unique if* $H^2_{DR}(Y^\circ)=0$.

Proof: The proof of this result is given in the Appendix. □

We consider now the pullback $(f^{-1})^*\mathbf{A}$ of $\mathbf{A}$ to M; we shall denote it by the same letter.

Proposition 3.2: The differential form $\mathbf{A}$ *on* M *solves the problem (3.2) and falls off as* $r^{-\alpha}$*, with* $\alpha>n/2$*. If* $H^2_{DR}(M)=0$, $\mathbf{A}$ *is the unique form in* $H_2(M,\Omega^2)$ *which solves the problem (3.2).*

Proof: The first claim has already been proved. Since $\mathbf{A}$ is square-summable, it has the required asymptotic behavior. The uniqueness follows from the corresponding property proved in Proposition 3.1. □

IV. SOLVING THE NONLINEAR PROBLEM

Provided that the norms of the forms $\widetilde{q}$ and $\star q$ are small enough, we may use a Kuranishi technique to reduce the problem (2.1) to the corresponding linearized problem, which we have solved in Section III. We recall that V is the Banach manifold of vertical orthogonal automorphisms of T^*M. Let F_θ, p be as in Eq. (2.1). The Fréchet differential,

$$((F_\theta)_*)_{id}:T_{id}V\simeq H_2(M,\Omega^2)\to H_0(M,\Omega^2),$$

can be identified with the operator $\mathfrak{F}_\theta$ studied in Section III (id is the point in V corresponding to the identity automorphism).

As usual, by means of the inverse function theorem one shows the existence of
(i) a neighborhood U_0 of id in V;
(ii) a neighborhood U_1 of the origin in $H_2(M,\Omega^2)$;
(iii) a diffeomorphism ρ: $U_1 \to U_0$ such that

$$F_\theta \circ \rho = \mathfrak{F}_\theta \quad \text{and} \quad \rho(0) = id.$$

This, together with Proposition 3.2, implies that the equation (2.1) has a solution ϕ, provided that the L^2 norm of p is small enough, say $\|p\| < \epsilon$. (This implies the existence of solutions whenever the Riemannian metric g is close enough to the Euclidean metric, so that the norm of p is suitably small.) One should also notice that the solution ϕ so found is asymptotic to the identity due to the asymptotic behavior of p.

We may now solve the nonlinear problem by iteration. Fix an initial coframe θ, let N be an integer such that $\|p\| < N\epsilon$ (where ϵ is the same as in the foregoing discussion), and set $p_1 = (1/N)p$. We may solve the problem

$$F_\theta(\phi_1) = -p_1.$$

Let $\theta_1 = \phi_1(\theta)$; a quick computation shows that the corresponding forms q and $\tilde{q}$ are

$$q_1 = \frac{N-1}{N}\, q, \quad \tilde{q}_1 = \frac{N-1}{N}\, \tilde{q}.$$

We may now solve the problem

$$F_{\theta_1}(\phi_2) = -p_1;$$

the forms q and $\tilde{q}$ corresponding to $\theta_2 = \phi_2(\theta_1)$ are

$$q_2 = \frac{N-2}{N}\, q, \quad \tilde{q}_1 = \frac{N-2}{N}\, \tilde{q}.$$

Applying this procedure N times we obtain a coframe,

$$\theta = \phi_N \circ \cdots \circ \phi_1(\theta),$$

which solves the problem (2); since all ϕ_i's are asymptotic to the identity, $\phi = \phi_N \circ \cdots \circ \phi_1$ is asymptotic to the identity as well.

V. UNIQUENESS

Let ϕ_1, ϕ_2 be two orthogonal automorphisms which solve the problem (2) and are asymptotic to the identity, and let $\chi = \phi_2 \circ \phi_1^{-1}$. Then χ is asymptotic to the identity, and solves the problem

$$F_{\theta_1}(\chi) = 0,$$

with $\theta_1 = \phi_1(\theta)$. We may let $\chi = \rho(\mathbf{A})$, with $\mathbf{A} \in H_2(M,\Omega^2)$; $\mathbf{A}$ satisfies the equation $\mathfrak{F}_{\phi_1}\mathbf{A} = 0$. If $H^2_{DR}(M) = 0$, Proposition 3.2 gives $\mathbf{A} = 0$, so that $\chi = \mathrm{id}$.

This proves the uniqueness part of Theorem 2.5, thus concluding its proof.

APPENDIX: SOLVING THE LINEAR PROBLEM

Let Y be a compact manifold with smooth boundary ∂Y. Let g be a Riemannian metric on Y. We consider the operator $\mathfrak{F}_\theta$ defined by Eq. (3.3), and show an existence and uniqueness result for a homogeneous Dirichlet problem. We shall follow the notation and terminology of Ref. 7. Let F denote the bundle on ∂Y defined as $\Omega^2_Y|\partial Y$, and define the boundary operator,

$$B:\overline{H_2}(Y^\circ,\Omega^2)\to H_{3/2}(F), \quad B(\mathbf{A})=\mathbf{A}|\partial Y.$$

One easily shows that the pairs $\overline{\mathfrak{F}_\theta}=(\mathfrak{F}_\theta,B)$ and $\overline{\Delta}=(\Delta,B)$ define elliptic Fredholm operators (cf. Ref. 7, Chap. XX),

$$\overline{H_2}(Y^\circ,\Omega^2)\to\overline{H_0}(Y^\circ,\Omega^2)\oplus H_{3/2}(F)$$

(Δ is the Laplace-Beltrami operator).

Lemma A.1: $\ker\overline{\mathfrak{F}_\theta}=\ker\Delta$

Proof: Since $\ker\Delta$ is finite-dimensional, by the Hahn-Banach theorem there is a subspace W of $H_2(Y^\circ,\Omega^2)$ such that $H_2(Y^\circ,\Omega^2)=\ker\Delta\oplus W$. We consider the family of operators,

$$\mathfrak{F}_t:W\to\overline{H_0}(Y^\circ,\Omega^2)\oplus H_{3/2}(F)$$

$$\mathfrak{F}_t=\overline{\Delta}+t(\widetilde{\mathfrak{F}_\theta},0), \quad \text{with } t\in[0,1],$$

where

$$\widetilde{\mathfrak{F}_\theta}\mathbf{A}=-\tfrac{1}{2}\,d[A_{ab}\delta(\theta^a\wedge\theta^b)]-\tfrac{1}{2}\,\delta[A_{ab}d(\theta^a\wedge\theta^b)],$$

so that $\mathfrak{F}_1=\overline{\mathfrak{F}_\theta}$ (in this Lemma we consider all operators as defined on W). Let $\epsilon\in\mathbb{R}^+$ be such that

$$\max\left\{\frac{\|\overline{\Delta}\|}{\|\widetilde{\mathfrak{F}_\theta}\|}-2,0\right\}<\epsilon<\frac{\|\overline{\Delta}\|}{\|\widetilde{\mathfrak{F}_\theta}\|}.$$

Since $\overline{\Delta}|W$ is injective, the operator

$$H_1:=\overline{\Delta}+\left(\frac{\|\overline{\Delta}\|}{\|\widetilde{\mathfrak{F}_\theta}\|}-\epsilon\right)(\widetilde{\mathfrak{F}_\theta},0)$$

is injective as well. By iteration we obtain that the operators

$$H_k=\overline{\Delta}+2^{k-1}\left(\frac{\|\overline{\Delta}\|}{\|\widetilde{\mathfrak{F}_\theta}\|}-\epsilon\right)(\widetilde{\mathfrak{F}_\theta},0)$$

are injective for all $k\geqslant 1$. By taking k as the integer part of

$$1-\log_2\left(\frac{\|\overline{\Delta}\|}{\|\widetilde{\mathfrak{F}_\theta}\|}-\epsilon\right),$$

we obtain that $\mathfrak{F}_\theta|W$ is injective; thus $\ker\overline{\mathfrak{F}_\theta}\subset\ker\overline{\Delta}$.

By repeating the argument after exchanging the roles of the operators $\overline{\mathfrak{F}_\theta}$ and $\overline{\Delta}$ we obtain $\ker\overline{\Delta}\subset\ker\overline{\mathfrak{F}_\theta}$. □

Consider now differential forms $\widetilde{q}\in\Omega^1(Y)$ and $q\in\Omega^3(Y)$, and set $p=d\widetilde{q}+\delta q$. The pair

$$(p,0)\in\overline{H_0}(Y^\circ,\Omega^2)\oplus H_{3/2}(F)$$

is orthogonal to the cokernel of $\overline{\mathfrak{F}_\theta}$ (also in view of Lemma A.1). So there is a differential form $\mathbf{A}\in H_2(Y^\circ,\Omega^2)$ such that

$$\mathfrak{F}_\theta\mathbf{A}=p,\quad \mathbf{A}\big|\partial Y=0. \tag{A1}$$

The form $\mathbf{A}$ is actually C^∞ (cf. Ref. 7).

To prove uniqueness we note that any harmonic form $\mathbf{A}\in\overline{H_2}(Y^\circ,\Omega^2)$ which vanishes on the boundary ∂Y is d- and δ-closed. This establishes an injective map $\ker\Delta\to H^2_{DR}(Y^\circ)$.

We may now prove the following result.

Proposition A.2: There is a C^∞ differential from $\mathbf{A}\in\overline{H_2}(Y^\circ,\Omega^2)$ which solves the problem (A.1). If $H^2_{DR}(Y^\circ)=0$, the form $\mathbf{A}$ is unique.

Proof: We need only to note that if $H^2_{DR}(Y^\circ)=0$ we have $\ker\ \overline{\Delta}=0$, and by Lemma A.1 $\ker\overline{\mathfrak{F}_\theta}=0$ as well. □

The Einstein action for algebras of matrix valued functions—Toy models

Piotr M. Hajac[a)]

(Received 21 November 1995; accepted for publication 22 April 1996)

Two toy models are considered within the framework of noncommutative differential geometry. In the first one, the Einstein action of the Levi–Civita connection is computed for the algebra of matrix valued functions on a torus. It is shown that, assuming some constraints on the metric, this action splits into a classical-like, a quantum-like and a mixed term. In the second model, an analogue of the Palatini method of variation is applied to obtain critical points of the Einstein action functional for $M_4(\mathbb{R})$. It is pointed out that a solution to the Palatini variational problem is not necessarily a Levi–Civita connection. In this model, no additional assumptions regarding metrics are made. © *1996 American Institute of Physics.* [S0022-2488(96)00808-0]

I. INTRODUCTION

The goal of this paper is to analyze the behavior of a noncommutative analogue of the Einstein–Hilbert action functional on two toy models. General definitions and constructions employed to study those models are provided in the next section.

In Section III, we present some results regarding the computation of the Einstein action of the Levi–Civita connection for $C^\infty(T^m)\otimes M_n(\mathbb{R})$, the algebra of matrix valued functions on an m-tori. The approach proposed there is analogous to the ''derivation based'' approach to the calculation of the Yang–Mills (Maxwell) action for an algebra of matrix valued functions that was carried out in Ref. 1 (see Section V in Ref. 1, cf. Ref. 2 and the sections 4 and 5 of Ref. 3). We choose our manifold M to be an m-tori because it is a compact Abelian group, and we want integrals over M to be finite, and $\mathrm{Der}(C^\infty(T^m))$ to be commutative as a Lie algebra and free as a $C^\infty(T^m)$-module. We also assume that the metric, understood as a pairing of derivations, has its values in the center of an algebra. Consequently, the results presented there can be interpreted as concerning the ''commutative part'' of noncommutative geometry. [Indeed, the Levi–Civita connections for $M_n(\mathbb{R})$ can be interpreted as the torsion part of the flat connection on $SL(n,\mathbb{R})$ given by the left translations; see Remark 14.]

In Section IV, which is the main part of this work, we study a toy model that is based on the algebra $M_4(\mathbb{R})$ of 4 by 4 real matrices, and the 2-dimensional Lie subalgebra $\mathfrak{so}(2)\oplus\mathfrak{so}(2)$ of $\mathrm{Der}(M_4(\mathbb{R}))$. It is a simple but quite computable model that is presented with the aim of providing hints on how to approach more complicated situations. For this model, we derive an analogue of the Einstein vacuum field equation, and apply the Palatini method of variation to obtain critical points. We find a solution to the Palatini variational problem that is, in general, neither metric nor torsion free. Yet, this solution (a connection ∇^g determined by a metric g) turns out to be Ricci flat for all metrics. Consequently, the Einstein field equation, which depends essentially on the Ricci curvature [see (7)], is automatically satisfied, and (g,∇^g) is a critical point of the Einstein action functional for any metric g. The value of this functional at any critical point is the same (zero). Thus we obtain a result that partially reflects the classical geometric phenomenon

[a)]Present address: International Centre for Theoretical Physics, Strada Costiera 11, 34014 Trieste, Italy. On leave from the Department of Mathematical Methods in Physics, Warsaw University, ul. Hoża 74, Warsaw, 00–682 Poland. Electronic mail: pmh@ictp.trieste.it or pmh@fuw.edu.pl

that, for any Riemannian 2-manifold, the Einstein–Hilbert action computed for a metric g and its Levi–Civita connection does not depend on g (see 9.1.10 in Ref. 4). The key difference between Section IV and the preceding one is that in Section IV we no longer assume that the metric is center valued.

The proofs or calculations are rather straightforward and are often omitted here for the sake of brevity. Except for Proposition 4, the letter k will denote a field, A a unital associative k-algebra, $Z(A)$ its center, and $\Omega(A)$ a differential graded algebra $A \oplus \oplus_{n\geqslant 1}^{\infty} \mathrm{Hom}_{Z(A)}(\wedge^n \mathscr{L}, A)$ with $\mathscr{L}$ as below and the differential defined as in Proposition 4. The Einstein convention of summing over repeating indices is assumed.

II. PRELIMINARIES

Let $\mathscr{L}$ be a $Z(A)$-submodule and Lie subalgebra of $\mathrm{Der}(A)$ such that $\mathscr{L}\otimes_{Z(A)}A$ is a finitely generated projective right A-module. (Compare with the notion of a Lie–Cartan pair introduced in Ref. 5.)

Definition 1: *A linear map* $\nabla:\mathscr{L}\otimes_{Z(A)}\Omega^*(A)\to\mathscr{L}\otimes_{Z(A)}\Omega^{*+1}(A)$ *is called a connection on* $\mathscr{L}$ *iff*

$$\forall X\in\mathscr{L},\ \alpha\in\Omega(A):\ \ \nabla(X\otimes_{Z(A)}\alpha)=(\nabla X)\alpha+X\otimes_{Z(A)}d\alpha.$$

Definition 2: *The endomorphism* $\nabla^2 \in \mathrm{End}_{\Omega(A)}(\mathscr{L}\otimes_{Z(A)}\Omega(A))$ *is called the curvature of a connection* ∇.

Remark 3: The notions of connection and curvature defined above are equivalent to the usual notions of noncommutative connection and curvature on a projective module (e.g., see Section III.B of Ref. 1). In this case, the projective right A-module is $\mathscr{L}\otimes_{Z(A)}A$. ◇

Proposition 4 (cf. p. 369 in Ref. 6): *Let A be an associative unital algebra over a commutative ring k. Let $\mathscr{L}_k$ be a k-Lie subalgebra of the space of all k-derivations of A, and let $\mathscr{E}$ be any right A-module admitting a connection (see Remark 3). If $\Omega(A)$ is a differential graded subalgebra of $A \oplus \oplus_{n\geqslant 1}^{\infty} \mathrm{Hom}_k(\wedge^n\mathscr{L}_k, A)$ with the differential given by (see the first section in Ref. 2):*

$$\begin{aligned}(d\alpha)(X_0,X_1,\cdots,X_n)&\\ =\sum_{0\leqslant i\leqslant n}(-)^i X_i\,\alpha(X_0,\cdots,X_{i-1},X_{i+1},\cdots,X_n)&\\ +\sum_{0\leqslant r<s\leqslant n}(-)^{r+s}\,\alpha([X_r,X_s],X_0,\cdots,X_{r-1},X_{r+1},\cdots,X_{s-1},X_{s+1},\cdots,X_n),&\end{aligned}$$

then

$$\forall\xi\in\mathscr{E},\ \ X,Y\in\mathscr{L}_k:\ \ (\nabla^2\xi)(X,Y)=([\nabla_X,\nabla_Y]-\nabla_{[X,Y]})(\xi),$$

where, as in the classical differential geometry, $\nabla_Z\xi$ *denotes* $(\nabla\xi)(Z)$.

Definition 5: *A map* $g:(\mathscr{L}\otimes_{Z(A)}A)\times(\mathscr{L}\otimes_{Z(A)}A)\to A$ *is called a pseudo-Riemannian metric on* $\mathscr{L}$ *iff it satisfies the following conditions.*

(1) $\forall a,b\in A,\ \xi,\eta\in\mathscr{L}\otimes_{Z(A)}A$: $g(a\xi,\eta b)=ag(\xi,\eta)b$, *where the left module structure on* $\mathscr{L}\otimes_{Z(A)}A$ *is given by* $a(X_i\otimes_{Z(A)}c_i)=X_i\otimes_{Z(A)}ac_i$.

(2) $\forall X,Y\in\mathscr{L}$: $g(X,Y)=g(Y,X)$ *(symmetry condition).*

(3) The induced map $\widetilde{g}:\mathscr{L}\otimes_{Z(A)}A\ni\xi\mapsto g(.,\xi)\in\Omega^1(A)$ *is an isomorphism of right A-modules.*

Definition 6: *A connection on* $\mathscr{L}$ *is said to be compatible with g iff*

$$\forall X,Y,Z\in\mathscr{L}:\ \ Xg(Y,Z)=g(\nabla_XY,Z)+g(Y,\nabla_XZ).$$

Definition 7: The $Z(A)$*-bilinear map,*

$$T_\nabla : \mathscr{L} \times \mathscr{L} \ni (X,Y) \mapsto \nabla_X Y - \nabla_Y X - [X,Y] \otimes_{Z(A)} 1 \in \mathscr{L} \otimes_{Z(A)} A,$$

is called the torsion of ∇.

Definition 8: *Let* $\mathscr{R}_\nabla(X,Y)$ *be the Z(A)-homomorphism given by the formula*

$$\mathscr{L} \ni Z \mapsto \mathscr{R}_\nabla(X,Y)(Z) = (\nabla^2 Y)(Z,X) \in \mathscr{L} \otimes_{Z(A)} A,$$

and let $\mathscr{T}_E \in \mathrm{Hom}_A(\mathrm{Hom}_{Z(A)}(\mathscr{L}, \mathscr{L} \otimes_{Z(A)} A), A)$. *We call the Z(A)-linear map,*

$$Ric_\nabla : \mathscr{L} \ni X \mapsto \mathscr{T}_E(\mathscr{R}_\nabla(X,.)) \in \Omega^1(A),$$

the Ricci curvature of ∇.

Remark 9: When $\mathscr{L}$ or A is a finitely generated projective $Z(A)$-module,

$$\mathrm{Hom}_{Z(A)}(\mathscr{L}, \mathscr{L} \otimes_{Z(A)} A) = \mathrm{End}_{Z(A)}(\mathscr{L}) \otimes_{Z(A)} A$$

(see Proposition 2 in II.4 of Ref. 7), and we can choose $\mathscr{T}_E$ to be a trace on $\mathrm{End}_{Z(A)}(\mathscr{L})$ tensored over $Z(A)$ with id_A. ◇

Definition 10: *Let* $\mathscr{M}(\mathscr{L})$ *and* $\mathscr{C}(\mathscr{L})$ *denote the space of all pseudo-Riemannian metrics on* $\mathscr{L}$, *and the space of all connections on* $\mathscr{L}$, *respectively. The functional* $E : \mathscr{M}(\mathscr{L}) \times \mathscr{C}(\mathscr{L}) \to k$ *given by the formula*

$$E(g,\nabla) = -(\tau_g \circ \mathscr{T}_E)(\tilde{g}^{-1} \circ Ric_\nabla),$$

where $\tau_g : A \to k$ *is a metric dependent trace, is called the Einstein action functional on* $\mathscr{L}$.

Remark 11: With an appropriate choice of τ_g and $\mathscr{T}_E$ (cf. Proposition 15), the functional E coincides for $A = C^\infty(M)$ and $\mathscr{L} = \mathrm{Der}(C^\infty(M))$ with the standard Einstein–Hilbert action functional on M, for any (paracompact) manifold M admitting a (pseudo-)Riemannian metric. ◇

III. THE CASE OF Z(A) VALUED METRICS

One can apply the same reasoning as in the case of classical differential geometry to obtain the following.

Proposition 12 (cf. Section 9 in Ref. 8): *Let* $g(\mathscr{L},\mathscr{L}) \subseteq Z(A)$ *or* $\nabla_{\mathscr{L}} \mathscr{L} \subseteq \mathscr{L}$. *Then there exists at most one metric compatible connection that is torsion free. If it exists, it is given by the formula*

$$\nabla_X Y = \tfrac{1}{2} \tilde{g}^{-1} \Big(Xg(Y,.) + Yg(X,.) - dg(X,Y) + g([X,Y],.) + g([.,X],Y) + g([.,Y],X) \Big). \quad (1)$$

A connection given by (1), will be called the Levi–Civita connection of g, and denoted by ∇_g. For the rest of this section, we work under the assumption that $g(\mathscr{L},\mathscr{L}) \subseteq Z(A)$. The mathematical model considered here is practically identical with a model constructed in Refs. 9 and 10. [Compare (2) with (3.24) in Ref. 9, and Proposition 15 with (3.23), (3.21) in Ref. 9 and (3.26) in Ref. 10.] Note that there is an extra term in $(3.24)^9$ that is absent in Proposition 15 due to our assumption that the classical and the algebraic derivations are orthogonal to each other. Let us also mention that the dual point of view regarding linear connections [i.e., where the space of 1-forms rather than $\mathscr{L} \otimes_{Z(A)} A$ is taken as a starting point] was studied in Refs. 11 and 12 also in the context of ''matrix geometry'' (see Section 4.3 in Ref. 11 and Section 3 in Ref. 12; for duality issues of the aforementioned kind, see Sec. 6 in Ref. 8).

To begin with, let us consider the algebra of matrices $M_n(\mathbb{R})$ and $\mathscr{L} = \mathrm{Der}(M_n(\mathbb{R})) = \mathfrak{sl}(n,\mathbb{R})$. Since $\mathfrak{sl}(n,\mathbb{R})$ is an (n^2-1)-dimensional vector space over $\mathbb{R}$ (the

center of the algebra of matrices), the endomorphisms of this space are simply $(n^2-1)\times(n^2-1)$ matrices, and we can choose $\mathscr{T}_E$ to be the usual matrix trace tensored with $id_{M_n(\mathbb{R})}$ (see Remark 9).

Proposition 13: *Let* $A=M_n(\mathbb{R})$, $\mathscr{L}=\mathrm{Der}(M_n(\mathbb{R}))$, $\tau_g=(1/n)\,|\mathrm{det}g|^{1/2}Tr$, *and* $\mathscr{T}_E=Tr\otimes id_{M_n(\mathbb{R})}$. *Also, let* $\{E_i\}$ *be any basis of* $\mathfrak{sl}(n,\mathbb{R})$. *Then*

$$E(g,\nabla_g)=g^{jp}(K_{jp}+\tfrac{1}{2}g^{il}g_{rk}c^r_{lp}c^k_{ij})\sqrt{|\mathrm{det}g|}, \tag{2}$$

where K is the Killing metric on $SL(n,\mathbb{R})$, *and* $\{K_{jp},g_{ij},g^{kl},c^r_{lp}\}$ *are defined by the formulas* $K_{jp}=g(E_j,E_p)$, $g_{rk}=g(E_r,E_k)$, $g^{pr}g_{rk}=\delta^p_k$, $[E_l,E_p]=c^r_{lp}E_r$, *respectively.*

Proof: A direct computation using the symmetry of a metric and the anti-symmetry of the Lie algebra structure constants. □

Remark 14: Let g be a left invariant metric on $SL(n,\mathbb{R})$. Then g can be identified with a metric on $\mathrm{Der}(M_n(\mathbb{R}))$. The connection on $SL(n,\mathbb{R})$ given by the left translations is compatible with all left invariant metrics. The torsion part of this connection is given by the formula (see (44) in Ref. 13)

$$\mathfrak{T}^i_{jk}:=\tfrac{1}{2}(Q^i_{jk}+g^{il}g_{jn}Q^n_{kl}+g^{il}g_{kn}Q^n_{jl})=\tfrac{1}{2}(c^i_{kj}+g^{il}g_{jn}c^n_{lk}+g^{il}g_{kn}c^n_{lj}).$$

If the coefficients of the $M_n(\mathbb{R})$–Levi–Civita connection of g are defined by the equality $\nabla_{E_j}E_k=\Gamma^i_{kj}E_i$, then $\Gamma^i_{jk}=\mathfrak{T}^i_{jk}\in\mathbb{R}$. (Caution: One often defines the Christoffel symbols by the relation $\nabla_{E_j}E_k=\widetilde{\Gamma}^i_{jk}E_i$. In this notation, which is compatible with the notation used in Ref. 13, the aforementioned relationship between the Christoffel symbols of the noncommutative connection and the torsion part of the classical connection can be equivalently written as $\widetilde{\Gamma}^i_{jk}=\mathfrak{T}^i_{jk}+c^i_{jk}$.) In general, if $\mathrm{Der}(A)$ equals the Lie algebra of some Lie group G, then the noncommutative torsion free g-compatible connection on $\mathrm{Der}(A)$ coincides in the above sense with the torsion part of the flat connection on G given by the left translations. ◇

Our next step is to consider an algebra of matrix valued functions. The module of derivations of such an algebra splits into two direct sum components in the following way (cf. Lemma 2.1 in Ref. 1):

$$\mathrm{Der}\,(C^\infty(M)\otimes M_n(\mathbb{R})\,)=\mathrm{Der}\,(C^\infty(M)\,)\otimes\mathbb{R}\,\oplus\,C^\infty(M)\otimes\mathrm{Der}\,(M_n(\mathbb{R})\,).$$

For $M=T^m$, this module is a free $C^\infty(T^m)$-module of dimension $m+n^2-1$. Consequently, its algebra of endomorphisms is simply the algebra of matrices $M_{m+n^2-1}(C^\infty(T^m))$, and, again, we can choose $\mathscr{T}_E$ to be the usual matrix trace [with values in $C^\infty(T^m)$] tensored with $id_{M_n(\mathbb{R})}$ (see Remark 9).

Proposition 15: *Let* $A=C^\infty(T^m)\otimes M_n(\mathbb{R})$, $\mathscr{L}=\mathrm{Der}(A)$, $\tau_g=(1/n)\int_{T^m}|\mathrm{det}g|^{1/2}Tr$, *and* $\mathscr{T}_E=Tr\otimes id_{M_n(\mathbb{R})}$. *Assume also that there exists a basis* $\{E_i\}_{i\in\{1,\cdots,m\}}$ *of* $\mathrm{Der}(C^\infty(T^m))$, *and a basis* $\{E_j\}_{j\in\{m+1,\cdots m+n^2-1\}}$ *of* $\mathrm{Der}(M_n(\mathbb{R}))$ *such that*

$$g_{ij}=\begin{cases}0, & \text{for } i\leqslant m \text{ and } j>m,\\ g_c(E_i,E_j), & \text{for } i,j\leqslant m,\\ g_q(E_i,E_j), & \text{for } i,j>m,\end{cases}$$

where g_c *is a classical (pseudo-)Riemannian metric on* T^m, *and* g_q *is a function that to each point of* T^m *assigns a metric on* $\mathrm{Der}(M_n(\mathbb{R}))$. *Then*

$$E(g,\nabla_g)=\int_{T^m}R_c\sqrt{|\mathrm{det}g_c|}\sqrt{|\mathrm{det}g_q|}+\int_{T^m}R_q\sqrt{|\mathrm{det}g_q|}\sqrt{|\mathrm{det}g_c|}+\int_{T^m}R_{\,\mathrm{mixed}}\sqrt{|\mathrm{det}g|}, \tag{3}$$

where R_c is the classical scalar curvature of g_c, R_q is a (point dependent) scalar curvature of ∇_{g_q} [i.e., $R_q=\mathscr{T}_E(\tilde{g}_q^{-1}\circ Ric_{\nabla_{g_q}})$], and R_{mixed} is a function on T^m that is a sum of mixed terms of the kind

$$g^{AB}\frac{\partial}{\partial x^\mu}\left(g^{\mu\nu}\frac{\partial g_{AB}}{\partial x^\nu}\right),\quad \mu,\nu\leqslant m,\quad A,B>m.$$

Proof: Very much like the proof of Proposition 13. □

As we see from Proposition 15, the assumption that the metric g is block-diagonal allows us to split the Einstein action of the Levi–Civita connection into the following three terms.

(1) A classical-like term that differs from the usual Einstein–Hilbert action on T^m only by the ''quantum volume element'' $\sqrt{|\det g_q|}$.
(2) A quantum-like term that is equal to the integral over T^m of the (point dependent) Einstein action of the Levi–Civita connection on $M_n(\mathbb{R})$.
(3) A mixed term that involves the derivatives of g_q.

If g_q is constant over T^m, then $R_{\text{mixed}}=0$, and the expression (3) simplifies to

$$E(g,\nabla_g)=\sqrt{|\det g_q|}E(g_c)+E(g_q)\ \text{vol}(T^m,g_c),$$

where $E(g_c)$ is the usual Einstein–Hilbert action, $E(g_q)$ is the action computed in Proposition 13, and $\text{vol}(T^m,g_c)$ is the volume of T^m with respect to the metric g_c.

Finally, let us remark that the Yang–Mills (Maxwell) action calculated in Ref. 1 for a similar algebra also splits into a classical-like, a quantum-like and a mixed term.

IV. THE CASE OF *A* VALUED METRICS

Let us now lift the assumption that $g(\mathscr{S},\mathscr{S})\subseteq Z(A)$, and consider a toy model based on the following data:

$$A=M_4(\mathbb{R}),\quad \mathscr{S}=\mathfrak{so}(2)\oplus\mathfrak{so}(2),\quad \tau_g=\tfrac{1}{4}\sqrt{|\det g|}Tr_{M_4(\mathbb{R})}\ \text{and}\ \mathscr{T}_E=Tr\otimes id_{M_4(\mathbb{R})}.$$

We view $\mathscr{S}$ as a Lie subalgebra of $\text{Der}(M_4(\mathbb{R}))$ generated by $\hat{F}_1:=[F_1,.]$, $\hat{F}_2:=[F_2,.]$, where $F_1:=\left(\begin{smallmatrix}F&0\\0&0\end{smallmatrix}\right)$, $F_2:=\left(\begin{smallmatrix}0&0\\0&F\end{smallmatrix}\right)$, $F:=\left(\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right)$. A metric g is treated as an element of $GL_2(M_4(\mathbb{R}))=GL_8(\mathbb{R})$. An assumption that g is symmetric reads $g(\hat{F}_i,\hat{F}_j)=:g_{ij}=g_{ji}:=g(\hat{F}_j,\hat{F}_i)$, or equivalently $g=g^T$, where ^{T} is the transpose in the algebra of 2×2 matrices. As to the inverse of g, denoted by $g^{-1}=:\left(\begin{smallmatrix}g^{11}&g^{12}\\g^{21}&g^{22}\end{smallmatrix}\right)$, in general we do not have $g^{12}=g^{21}$. For instance, if

$$g=\begin{pmatrix}2I_2&0&I_2&I_2\\0&I_2&I_2&0\\I_2&I_2&I_2&0\\I_2&0&0&I_2\end{pmatrix},$$

where $I_2=\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$, then $g^{12}\neq g^{21}$. Very much as we did before, we define the Christoffel symbols by $\nabla_{\hat{F}_i}\hat{F}_j=\hat{F}_k\otimes\Gamma^k_{ji}$, the curvature coefficients by $(\nabla^2\hat{F}_k)(\hat{F}_i,\hat{F}_j)=\hat{F}_m\otimes R^m_{kij}$, and the Ricci curvature coefficients by $(Ric_\nabla\hat{F}_i)(\hat{F}_j)=R_{ji}$. It is straightforward to verify that $R^m_{kij}=\Gamma^m_{ni}\Gamma^n_{kj}-\Gamma^m_{nj}\Gamma^n_{ki}+[F_i,\Gamma^m_{kj}]-[F_j,\Gamma^m_{ki}]$ (see Proposition 4), $R_{kj}=R^i_{kij}$, and

$$E(g,\nabla)=-\tfrac{1}{4}\sqrt{|\det g|}Tr_{M_4(\mathbb{R})}(g^{jk}R_{kj})=-\tfrac{1}{4}\sqrt{|\det g|}tr(g^{-1}r),\tag{4}$$

where tr denotes the usual trace on $M_8(\mathbb{R})$, and $r:=\left(\begin{smallmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{smallmatrix}\right)$. In what follows, rather than look for a Levi–Civita connection, we will use an analogue of the Palatini method of variation (see 21.2 in Ref. 14, cf. 5.4–5.5 in Ref. 15) and find critical points of the Einstein action functional. First, let us determine the equation equivalent to the condition that the variation of E with respect to g vanish. At any critical point, for an arbitrary matrix $h \in M_8(\mathbb{R})$ with the coefficients satisfying $h_{12}=h_{21} \in M_4(\mathbb{R})$, we must have

$$\frac{d}{ds}E(g+sh,\nabla)|_{s=0}=0\,. \tag{5}$$

After substituting (4) into (5), and carrying out the differentiation, we obtain

$$\tfrac{1}{2}tr(g^{-1}r)tr(hg^{-1})=tr(hg^{-1}rg^{-1}). \tag{6}$$

Now, since (6) must be true for any matrix h such that $h_{12}=h_{21}$, we can conclude that

$$\forall i,j\in\{1,2\}\colon \tfrac{1}{2}tr(g^{-1}r)(g^{ij}+g^{ji})=g^{ik}R_{kl}g^{lj}+g^{jk}R_{kl}g^{li}.$$

Multiplying both sides by g_{im}, and then taking the trace, we find that

$$8tr(g^{-1}r)=2tr(g^{-1}r).$$

Hence, very much as in the classical general relativity, we have $tr(g^{-1}r)=0$. Consequently,

$$g^{-1}rg^{-1}+(g^{-1}rg^{-1})^T=0\,. \tag{7}$$

The formula (7) is an analogue of the Einstein vacuum field equation. [Observe that the implication (7)$\Rightarrow$(5) is also true.]

Our next step is to find an explicit form of the equations equivalent to the vanishing of the variation of E with respect to ∇. Let $\nabla+sA$ denote a connection on $\mathscr{L}$ whose Christoffel symbols are $\Gamma^k_{ji}+sA^k_{ji}$, where $s \in \mathbb{R}$, $A^k_{ji} \in M_4(\mathbb{R})$, $i,j,k \in \{1,2\}$. Then the condition that

$$\frac{d}{ds}E(g,\nabla+sA)|_{s=0}=0, \quad \text{for any } A,$$

is equivalent to the following 8 equations:

$$g^{11}\,\Gamma^2_{12}+\,\Gamma^1_{22}g^{22}+[\,\Gamma^1_{12}+F_2,g^{21}]=0, \tag{8}$$

$$g^{11}\,\Gamma^2_{11}+\,\Gamma^1_{21}g^{22}+[\,\Gamma^1_{11}+F_1,g^{21}]=0, \tag{9}$$

$$g^{22}\,\Gamma^1_{22}+\,\Gamma^2_{12}g^{11}+[\,\Gamma^2_{22}+F_2,g^{12}]=0, \tag{10}$$

$$g^{22}\,\Gamma^1_{21}+\,\Gamma^2_{11}g^{11}+[\,\Gamma^2_{21}+F_1,g^{12}]=0, \tag{11}$$

$$g^{22}\,\Gamma^1_{12}-\,\Gamma^2_{22}g^{22}-g^{12}\,\Gamma^2_{12}-\,\Gamma^2_{12}g^{21}-[F_2,g^{22}]=0, \tag{12}$$

$$g^{11}\,\Gamma^2_{22}-\,\Gamma^1_{12}g^{11}-g^{21}\,\Gamma^1_{22}-\,\Gamma^1_{22}g^{12}-[F_2,g^{11}]=0, \tag{13}$$

$$g^{22}\,\Gamma^1_{11}-\,\Gamma^2_{21}g^{22}-g^{12}\,\Gamma^2_{11}-\,\Gamma^2_{11}g^{21}-[F_1,g^{22}]=0, \tag{14}$$

$$g^{11}\,\Gamma^2_{21}-\,\Gamma^1_{11}g^{11}-g^{21}\,\Gamma^1_{21}-\,\Gamma^1_{21}g^{12}-[F_1,g^{11}]=0. \tag{15}$$

It is straightforward to verify that a connection ∇^g (not to be confused with the Levi–Civita connection ∇_g) whose Christoffel symbols are given by

$$\Gamma^1_{22}=\Gamma^1_{21}=-g^{11},\quad \Gamma^2_{22}=-F_2-g^{12},\quad \Gamma^1_{12}=-F_2+g^{21},$$

$$\Gamma^2_{12}=\Gamma^2_{11}=g^{22},\quad \Gamma^2_{21}=-F_1-g^{12},\quad \Gamma^1_{11}=-F_1+g^{21},$$

satisfies (8)–(15), and has vanishing Ricci curvature ($Ric_{\nabla^g}=0$). We have thus arrived at the following.

Proposition 16: *Let $A,\mathscr{S},\tau_g$ and $\mathscr{T}_E$ be as above. Then*

$$\forall g\in\mathscr{M}(\mathscr{S})\ \exists\nabla^g\in\mathscr{C}(\mathscr{S})\ \textit{such that}\ (g,\nabla^g)\ \textit{is a critical point of}\ E.$$

Furthermore, the value of E at any critical point is zero.

Remark 17: The value of the functional E calculated at noncritical points is not necessarily zero. For example, take a metric $g_0=g_0^{-1}$ with the components

$$(g_0)_{11}=(g_0)_{22}=0,\quad (g_0)_{12}=(g_0)_{21}=\begin{pmatrix} I_2 & 0\\ 0 & K\end{pmatrix},\quad K:=\begin{pmatrix}0&1\\1&0\end{pmatrix},$$

and take a connection ∇_0 whose only nonvanishing Christoffel symbol is $(\Gamma_0)^1_{11}=\left(\begin{smallmatrix}0&0\\0&J\end{smallmatrix}\right)$, where $J=\left(\begin{smallmatrix}1&0\\0&-1\end{smallmatrix}\right)$. Then $E(g_0,\nabla_0)=-1$. ◇

Remark 18: Note that for τ_g equal to $Tr_{M_4(\mathbb{R})}$ rather than to $\frac{1}{4}|\det g|^{1/2}Tr_{M_4(\mathbb{R})}$ the field equation (7) and the equations (8)–(15) are still satisfied. Also, $tr(g^{-1}r)$ still equals zero at any critical point. Consequently, Proposition 16 remains valid as well, if we replace $\frac{1}{4}|\det g|^{1/2}Tr_{M_4(\mathbb{R})}$ by the usual trace on $M_4(\mathbb{R})$. ◇

Remark 19: The fact that the functional $\widetilde{E}:\mathscr{M}(\mathscr{S})\ni g\mapsto E(g,\nabla^g)\in\mathbb{R}$ equals identically zero is a reflection of the same effect that we observe for the usual 2-torus. We might try to push this analogy even further and say that we think of a circle S^1 as a Lie group generated by $\mathfrak{so}(2)$, and replace $C^\infty(S^1)$ by $M_2(\mathbb{R})$ for which $\mathfrak{so}(2)$ is the space of all derivations satisfying $X(a^T)=(Xa)^T$. Then it is natural to replace $C^\infty(T^2)$ by $M_2(\mathbb{R})\otimes M_2(\mathbb{R})=M_4(\mathbb{R})$. ◇

Observe that although ∇^g functions as if it were a Levi–Civita connection, it is in general neither metric nor torsion free [e.g., take g to be the identity matrix of $GL_8(\mathbb{R})$]. It is perhaps worth emphasizing, however, that the metric compatibility condition, which can be equivalently written as

$$g^{pj}\Gamma^n_{ji}+\Gamma^p_{ji}g^{jn}+[F_i,g^{pn}]=0,\quad i,p,n\in\{1,2\},$$

is not very different from the formulas (8)–(15). It would be interesting to find a functional on $\mathscr{M}(\mathscr{S})\times\mathscr{C}(\mathscr{S})$ that not only would coincide with the usual Einstein–Hilbert functional (or whose equations of motion would agree with the standard ones) in the case of classical geometry, but also would yield, through its variation with respect to connection, the metric compatibility condition.

Imploding scalar fields

M. D. Roberts[a)]
Flat 5, 17 Wetherby Gardens, London SW5 OJP, United Kingdom

(Received 12 October 1995; accepted for publication 30 April 1996)

Static spherically symmetric uncoupled scalar space–times have no event horizon and a divergent Kretschmann singularity at the origin of the coordinates. The singularity is always present so that nonstatic solutions have been sought to see if the singularities can develop from an initially singular free space–time. In flat space–time the Klein–Gordon equation $\Box\varphi=0$ has the nonstatic spherically symmetric solution $\varphi=\sigma(v)/r$, where $\sigma(v)$ is a once differentiable function of the null coordinate v. In particular, the function $\sigma(v)$ can be taken to be initially zero and then grow, thus producing a singularity in the scalar field. A similar situation occurs when the scalar field is coupled to gravity via Einstein's equations; the solution also develops a divergent Kretschmann invariant singularity, but it has no overall energy. To overcome this, Bekenstein's theorems are applied to give two corresponding conformally coupled solutions. One of these has positive ADM mass and has the following properties: (i) it develops a Kretschmann invariant singularity, (ii) it has no event horizon, (iii) it has a well-defined source, (iv) it has well-defined junction condition to Minkowski space–time, and (v) it is asymptotically flat with positive overall energy. This paper presents this solution and several other nonstatic scalar solutions. The properties of these solutions which are studied are limited to the following three: (i) whether the solution can be joined to Minkowski space–time, (ii) whether the solution is asymptotically flat, (iii) and, if so, what the solutions' Bondi and ADM masses are. © *1996 American Institute of Physics.* [S0022-2488(96)02409-7]

I. INTRODUCTION

Singularities appear in many physical theories. A singularity can be defined as a domain where the description provided by the physical theory breaks down. A prime example is the infinite electromagnetic potential of a point particle in Maxwell's theory. A common approach to a theory which has singularities is to produce another theory governed by more general differential equations and then investigate whether the singularities still occur. For example, in electromagnetic theory Born and Infeld investigated a generalization of Maxwell's Lagrangian to see if the infinite potential was still present. In gravitational theory the situation is more complex: for a point particle the Kretschmann invariant $R_{abcd}R^{abcd}_{\ldots\ldots}$ diverges at the position of the particle; also on occasion the particle is surrounded by an event horizon. The event horizon is not singular in the sense defined above because a description of its effects can be made: but the effects are so bizarre that along with singularities they can be called pathological. Vacuum general relativity frequently has both pathologies, an example being the Schwarzschild solution for a point particle. It is sometimes argued that the existence of both pathologies is palatable because the event horizon makes the divergent Kretschmann invariant invisible at infinity. However, the physical description provided is still incomplete because it does not describe what happens at the divergent Kretschmann invariant. Vacuum general relativity does not furnish a good description of many astrophysical phenomena such as gravitational collapse because the pertinent space–time can

[a)]Electronic mail address: m.d.roberts@uk.ac.ic

contain many fields and fluids with nonvanishing stress. Astronomical observations purporting to be of ''black holes'' in fact do not directly observe event horizons. The models which describe the situation merely use a steeper potential than that of Newtonian theory; the Newtonian limit of most relativistic theories produces such a potential.

To find exact solutions of gravitational field equations to fit a particular physical requirement is notoriously difficult. An example is the two-body problem: since the inception of general relativity the solution for two-point particles acting only through gravity has been sought. Another example is the Yukawa problem: in the absence of gravitation a massive scalar field has a shorter range than the corresponding massless case; Yukawa's discovery of this lead to the postulation of nuclear forces. How gravitation alters the shape of the potential is unknown, and this would be of experimental interest as the Yukawa potential can be accurately measured in accelerators; also, it is unknown whether the mass of the interacting scalar field is the same as the ADM mass. Scalar fields coupled to gravity produce unusual potentials, complicated by the fact that the luminosity radial coordinate is often of the form $R=r\exp(\varphi)$, where the metric is explicitly expressed in terms of r. Perhaps the simplest modification of vacuum general relativity is to choose a stress with an uncoupled scalar field. When this is done the situation is mitigated; for the static case there is no event horizon. The problem with static space–times is that the Kretschmann invariant is always present; the space–time does not develop so as to produce it. Nonstatic spherically symmetric scalar solutions have been found, one of which is asymptotically flat.[1,2] This solution has unusual energetics; there is no overall energy, the positive energy of the scalar field and the negative energy of the gravitational field cancel out: as the space–time develops energy is just exchanged between them. To overcome this, Bekenstein's theorems are applied to uncoupled scalar field solutions to give two corresponding conformal scalar solutions. One of these is asymptotically flat and has overall positive ADM energy.

In general relativity scalar fields can implode (and explode) like the example in the abstract; the situation here is more pathological than in flat space because not only is it possible to produce a singularity in the scalar field, but in addition, there is a colocational singularity of the gravitational field as indicated by the divergence of the Kretschmann curvature invariant $R^{abcd}_{\ \ \ \ \ \ \ \ }R_{abcd}$. Einstein–scalar space–times are sometimes not covered by theorems concerned with the general global and singular structure of space–time. These often assume the space–time stress tensor is restricted to: vacuum, or electromagnetic stress, or obey energy inequalities. An example of this is the formal definition of asymptotic flat space–times which assumes that there is only an electromagnetic and gravitational field present. Numerical studies show that the rate of decay of scalar fields is between these two;[1] furthermore, many spherical symmetric perfect fluid stresses do not have (in the sense of taking a radial coordinate $r\to\infty$) asymptotically flat space–times.[3] Here a scalar solution is taken to be asymptotically flat if it reduces to Minkowski space–time as $r\to\infty$. The rate of decay of fields seems to be: most fluids and some conformal scalars are not asymptotically flat, then gravitation>uncoupled scalars>uncoupled vectors>interacting fields.

In Sec. II some Robertson–Walker scalar field solutions are given. The examples chosen have scale factors which can be expressed in terms of straightforward functions. Ordinary scalar stresses obey the energy conditions, but conformal scalar stresses sometimes do not. Violation of the energy conditions allow the possibility of a singular free Robertson–Walker space–time; this can happen for conformal scalar fields[4] and when cosmological constant is present.[5] Here the junction conditions of Robertson–Walker space–time are studied, and possible applications mentioned. In Sec. III Penny's[6] solution is presented; this can implode, but is not asymptotically flat. In Sec. IV the solution previously found by the author,[1,2] and also its two conformal scalar extensions as found by Bekenstein's theorems, are presented. These solutions are explicitly dependent on a radial coordinate so that they are more similar to the example in the abstract than the examples in Secs. II and III. The solution and one of its Bekenstein extensions are asymptotically flat, and also have well-defined junction conditions, contrary to what has been stated by Szabodos.[7] The Bondi and ADM masses of the solutions are calculated. In the first two appendices

I derive the Clarke and Dray[8] junction conditions subject to spherical symmetry. In all the specific cases looked at here if a solution has a continuous metric (and hence first fundamental form) across a junction, then its surface stress (which depends on the derivatives of the metric) vanishes and the junction is well defined. In the third appendix I derive the general expression for the ADM mass subject to spherical symmetry.

The field equations considered are Einstein's equations with scalar fields as source. Specifically the ordinary scalar–Einstein equations are

$$R_{ab}=2\varphi_a\varphi_b\,, \tag{1.1}$$

where the coupling constant is taken to be contained in the scalar field φ. On occasion a null radiation field is also taken to be present with

$$R_{ab}=\Phi^2 k_a k_b\,, \tag{1.2}$$

where k_a is a null vector and Φ is a function of x^a. Conformal scalar solutions can be obtained from ordinary scalar solutions by using Bekenstein's[9] theorems. To derive these let barred quantities denote these quantities for an ordinary scalar solution, i.e., $R_{ab}=2\varphi_a\varphi_b$. Then under a conformal transformation

$$\overline{g}_{ab}=\Omega^2 g_{ab}\,; \tag{1.3}$$

the connection is transformed,

$$\overline{\Gamma^a_{bc}}-\Gamma^a_{bc}=\Omega^{-1}(\delta^a_b\Omega_c+\delta^a_c\Omega_b-g_{bc}\Omega^a); \tag{1.4}$$

and the Ricci tensor is transformed,

$$\overline{R}_{ab}-R_{ab}=-2\Omega(\Omega^{-1})_{;ab}+\Omega^{-2}(\Omega^2)^c_{\cdot c}g_{ab}\,, \tag{1.5}$$

where the covariant derivatives ";" are taken in the unbarred system. Now take

$$\begin{aligned}\Omega=\sqrt{\pm(1-\xi^2\varphi^2)}&=\begin{cases}\text{sech}\\ \text{cosech}\end{cases}\quad \xi\varphi,\\ \xi\varphi=\sqrt{1\mp\Omega^2}&=\begin{cases}\tanh\\ \coth\end{cases}\quad \xi\varphi,\end{aligned} \tag{1.6}$$

where ξ is a constant and φ is a function. Then, substituting into the Ricci tensor (1.5), this obeys the equations for a conformal scalar field

$$(1/\xi^2-\psi^2)R_{ab}=4\psi_a\psi_b-2\psi\psi_{;ab}-(\psi\psi^c{}_{\cdot})_c g_{ab}\,. \tag{1.7}$$

Thus given an ordinary scalar field solution (1.1), Bekenstein's theorems give two conformal scalar solutions (1.6); Bekenstein refers to the upper sign conformal solution as type A and the lower sign conformal solution as type B, as no confusion with blood types should occur the ordinary scalar solution is here called type O. In the conventions used here, the coupling constant is taken to be in the scalar field and thus $\xi^2=\frac{1}{3}$. The conformal scalar solutions are traceless and also obey $\psi^a_{\cdot a}=0$. For type A the theorem generalizes for additional stress present; in the case of a null radiation field this must transform as $\Phi^2\to\Omega^{-2}\Phi^2$, c.f. Bekenstein's[9] equation 15; this generalization does not work for type B. Type B solutions are anticipated to have unusual global properties, for example as $\varphi\to 0$: $\Omega^{-1}\to 0$, $\psi\to\infty$; and also as $\varphi\to\infty$: $\Omega^{-1}\to\infty$, $\psi\to 1$; but applying Bekenstein's theorems does not *a priori* produce a maximally extended space–time so that exact

solutions have to be specified before precise pronouncements on their global properties can be made. Examples of static spherically symmetric conformal scalar fields with unusual properties can be found in Ref. 10.

Having presented some of the properties of scalar fields we can now come back to the questions: general relativity and other gravitational theories are primarily macroscopic theories which couple to stresses that have macroscopic effect; such electromagnetism and perfect fluids are natural choices—why choose scalar fields? First, it only takes an infinitesimal scalar field to change the global nature of a space–time. For example, Wyman's solution, which is the general static spherically symmetric O-scalar–Einstein solution, is a two-parameter solution (M,σ) with M the Schwarzschild mass and σ the scalar charge (an infinitesimal σ is sufficient for there to be no event horizon present). Thus microscopic fields, such as those of particle physics, can have a global effect on space–time. Second, for φ_a timelike an O-scalar field is a particular example of a perfect fluid. Perfect fluids which are well behaved and permeate the whole space–time can usually be shown to have no horizons.[3] The fluid conservation equations often allow the fluid index ω to be equated with the fluid vector and hence the metric. Typically this results in equations such as the lapse $N=1/\omega$; thus a well-behaved fluid index ω can often imply a well-behaved metric. In Appendix D an attempt is made to extend to fields the techniques that lead to this result. Third, in microscopic physics hypothetical particles, the Higgs scalars, are used to introduce ''mass'' terms while preserving gauge invariance. Although other mechanisms have been proposed, for example, by using fermion composites, or using fluids Roberts,[11,12] the resulting Lagrangians have terms similar to scalar fields. Fourth, many quantum and unified theories have gravitational actions with terms of higher order. The quadratic action can be split into two independent parts, the traceless part being the Bach tensor and the other part the Pauli tensor. Using a conformal factor solutions to these equations can be found by Barrow and Cotsakis'[13] method. The Bach tensor has several similarities to conformal scalar fields and there might be a theorem connecting their solutions. Vacuum solutions can generate O-scalar solutions by Buchdahl's trick (the analogous theorem for vector gauge theory is called the Julia–Zee correspondence) (see, for example, Ref. 11); O-scalar solutions can generate A and B scalar solutions by Bekenstien's theorems; and perhaps A and B scalar solutions can generate Bach–Einstien solutions. Fifth, O-scalar solutions obey the energy conditions. The energy conditions are inequalities designed to judge whether macroscopic fluids have reasonable energetics: they break down when considering the interacting fields necessary for particle physics (see, for example, Ref. 14, p. 95).

Apart from the above five reasons for investigating scalar fields, they can be viewed as merely a scalar function defined on a region of space, and such a requirement seems to be fairly ubiquitous in physics. Systematic discussion of them is hindered because there is no recognized way of classifying them. Some indications of their properties are given by the following. *Coupling classification*: call scalar fields coupled only to Einstein's equations type O: conformal scalar fields coupled to Einstein's equations type C, scalar fields with mass self-interaction type Y, renormalizable scalar fields with fourth-order self-interaction type L, inflationary scalar fields with potential $V(\varphi)$ type V, scalar fields that can be represented as fluids type F, symmetry breaking scalar fields coupled to vector fields type H, and so on. *Generational classification*: exact scalar field solutions can be generated from exact solutions to simpler differential equations. For a given configuration usually the generated solution is not the most general one. *Stress classification*: stress tensors can be classified by the Segre or Plebanski methods. *Energy classification*: for a space–time with Lorentz signature $(-,+,+,+)$ rather than positive definite signature $(+,+,+,+)$, vectors can be timelike, null, or spacelike. The existence of timelike vectors allows the measurement of the energy to be defined. For a given space–time ψ_a and $\psi_a T^b{}_a$ are vectors that can be timelike, null, or spacelike; the energy conditions can be investigated and on occasion the overall energy measured.

For conformal scalar fields the energy conditions can be complicated; hand calculations of them for the specific solutions presented here are too long to be practicable. Three observations are

now stated which give a rough indication of what energetics to expect. The first observation is that the general stress for conformal scalar fields contains terms of undetermined sign and this remains the case even if the conformal scalar stress has been obtained by using Bekenstein's theorems; this can been seen from (1.6) and (1.7). The second observation is for an O-scalar solution, it is possible to consider whether the vector φ_α is spacelike, timelike, or null: this just depends on the Ricci scalar because $\overset{..}{g}^{ab}\varphi_a\varphi_b=\frac{1}{2}R$; now using Bekensteins' theorems both for types A and B there is the equation $\overset{..}{g}^{ab}\Psi_a\Psi_b=\frac{1}{2}R$. Thus there is no change in the causal direction of the scalar field. The third observation is achieved by direct inspection of the scalar fields. Neglect that the equation for the stress of a conformal scalar field differs from that of the ordinary case and also that Bekenstein's theorems introduce a conformal factor into the metric. Then the energy conditions will just depend on the relative size of the scalar fields involved. The type O scalar field is a negative real scalar quantity. Bekenstein's theorems give that the type A scalar is the tanh of this and that the type B is the coth of this; thus the scalar fields take real values such that $0>A>O>B>-\infty$. Now the type O scalar field on occasion (an example being that of Sec. IV) contains the same quantity of energy but of the opposite sign as the gravitational field; the above inequalities suggest that the type A solution would have total positive energy because the scalar field is not so negative, and also that the type B solution would have total negative energy. This is found to be the case for the type A solution described in the conclusion. The above suggests that it is a reasonable guess that type A solutions have well-defined energy conditions and that type B do not: this is what would be expected from the known exact solutions where it would account for type A having mundane properties whereas those of type B solutions are bizarre.

II. ROBERTSON–WALKER SCALAR SOLUTIONS

The Robertson–Walker line element can be put in the form

$$ds^2=-N(t)^2\,dt^2+R(t)^2d\Sigma^2_{3,k}, \tag{2.1}$$

where

$$d\Sigma^2_{3,k}=d\chi^2+f(\chi)^2(d\theta^2+\sin^2\theta\,d\varphi^2)$$

and

$$f(\chi)=\sin\chi,\chi,\sinh\chi,$$

for $k=+1,0,-1$ respectively. Taking $A=R^2$, $B=R^2f^2$, $C=N^2$, and $\chi=r$ gives the line element in the spherically symmetric form (B1). Here N is called the lapse and R the scale factor. N can be absorbed into the line element; the choice $N=1$ gives the Robertson–Walker line element in proper time. For the choice $N=R$, Robertson–Walker space–time is conformal to the Einstein static universe and by convention the time coordinate is denoted by η. For $N=1$ the scale factor R can be expanded as a Taylor series around a fixed time $t=t_0$, thus

$$R=R_0[1+H_0(t-t_0)-\tfrac{1}{2}q_0H_0^2(t-t_0)^2+O(t-t_0)^3], \tag{2.2}$$

where

$$H\equiv\dot{R}/R \tag{2.3}$$

is called the Hubble parameter and

$$q\equiv-\ddot{R}.R/(\dot{R}^2) \tag{2.4}$$

is called the deceleration parameter, the subscript ''0'' indicates that the parameter is evaluated at $t=t_0$, and $\mathring{R}=\partial_t R$.

The equation of state

$$p=(\gamma-1)\mu \tag{2.5}$$

produces equations equivalent to those of an ordinary scalar field in the particular case of $\gamma=2$ (see Appendix D). Einstein's equations have been solved by Vajk[15] for the metric (2.1) and equation of state (2.5). Specializing to the $\gamma=2$ ordinary scalar field case gives

$$k=0, \quad \Xi=\alpha\eta^{1/2}, \quad \varphi=\frac{\sqrt{3}}{2}\ln\ \eta,$$

$$k=+1, \quad \Xi=\alpha(\sin\ \eta\ \cos\ \eta)^{1/2}, \quad \varphi=\frac{\sqrt{3}}{2}\ln\tan\ \eta, \tag{2.6}$$

$$k=-1, \quad \Xi=\alpha(\sinh\ \eta\ \cosh\ \eta)^{1/2}, \quad \varphi=\frac{\sqrt{3}}{2}\ln\tanh\ \eta,$$

where

$$\alpha=2R_0\sqrt{\frac{H_0^2R_0^2}{c^2}+k},$$

c is the speed of light, and Ξ is equal to both the scale factor and the lapse, i.e., $\Xi=N=R$. The $k=0$ solution is one of the few solutions known to have an exact form for the world function.[16]

Applying Bekenstein's theorems,

$$k=0, \quad \Upsilon=\frac{\alpha}{2}(\eta\pm1), \quad \frac{1}{\sqrt{3}}\psi=\frac{\eta\mp1}{\eta\pm1},$$

$$k=+1, \quad \Upsilon=\frac{\alpha}{2}(\sin\ \eta\pm\cos\ \eta), \quad \frac{1}{\sqrt{3}}\psi=\frac{\sin\ \eta\mp\cos\ \eta}{\sin\ \eta\pm\cos\ \eta}, \tag{2.7}$$

$$k=-1, \quad \Upsilon=\frac{\alpha}{2}\exp(\pm\eta), \quad \frac{1}{\sqrt{3}}\psi=-\exp(\mp\eta),$$

where $\Upsilon=\Xi\Omega^{-1}$. In the $k=0$ case the ±1 can be absorbed into the line element by defining $\eta'=\eta\pm1$, giving a single solution. Transferring the $k=+1$ solution to proper time by defining $t=(\alpha/2)(-\cos\ \eta\pm\sin\ \eta)$ gives

$$ds^2=-dt^2+\left(\frac{\alpha^2}{2}-t^2\right)d\Sigma^2_{3,+1}, \quad \frac{1}{\sqrt{3}}\psi=\left(\frac{\alpha^2}{2t^2}-1\right)^{-1/2}, \tag{2.8}$$

showing that there is only one $k=+1$ metric. In the $k=-1$ case define $t=(\alpha/2)\exp(\pm\eta)$ to give

$$ds^2=-dt^2+t^2d\Sigma^2_{3,-1}, \quad \frac{1}{\sqrt{3}}\psi=-\frac{\alpha^2}{4t^2}. \tag{2.9}$$

This is just the Milne universe, further discussed at Eq. (2.16); the field ψ is a ghost field that does not contribute to the stress. Conformal scalar stresses are traceless; this can be used to reduce the number of equations. In particular the Einstein–conformal scalar equations with Robertson–Walker metric can be quickly reduced to one equation

$$R_{,\eta\eta} = -kR. \tag{2.10}$$

This gives solutions more general than those of (2.7). However, they are particular instances of the conformal scalar and incoherent radiation solutions of Bekenstein (Ref. 9, 1973) #6. Bekenstein's theorems can then be used in reverse to give generalizations of (2.6).

The null junction conditions are studied by defining

$$v = \eta + r. \tag{2.11}$$

Robertson–Walker space–time in the conformal time coordinate η takes the single null form (A1) with $X = S = Yf^{-2} = R(v-r)^2$. The θ and φ components of the surface stress vanish identically. The v and r components are given by

$$\tau_{ab} = -f^{-2}R^{-2}[(R^2f^2)']n_a n_b, \tag{2.12}$$

which do not vanish at a junction with Minkowski space–time.

The non-null junctions are studied by calculating the second fundamental form as in Appendix B. The second fundamental form across the spacelike surface normal to (B3) is

$$K_{rr} = \frac{-R\mathring{R}}{N},$$
$$K_{\theta\theta} = \sin^{-2}\theta K_{\varphi\varphi} = -\frac{f^2R\mathring{R}}{N}, \tag{2.13}$$

which gives no junctions to Minkowski space–time. The surface normal to the radial spacelike vector (B5) has second fundamental form

$$K_{tt} = 0,$$
$$K_{\theta\theta} = \sin^{-2}\theta K_{\varphi\varphi} = ff'R. \tag{2.14}$$

Again there are no junctions to Minkowski space–time. The radial spacelike vector is not well suited to Robertson–Walker geometries. Choosing the isotropic spacelike vector (B7) gives second fundamental form

$$K_{tt} = K_{tr} = 0,$$
$$K_{r\theta} = \frac{K_{t\varphi}}{\sin\theta} = R\,\frac{K_{\theta\varphi}}{\sin\theta} = -\frac{1}{2}fK_{rr} = \frac{-f'R}{3\sqrt{3}}, \tag{2.15}$$
$$K_{\theta\theta} = \frac{K_{r\theta}}{\sin\theta} = \frac{f}{3\sqrt{3}}\{-\cot\theta + 2f'R\}.$$

Again there are no junctions to Minkowski space–time.

Consider Minkowski space–time in the form (2.1) with $k=0$ and $N=R=1$, $f=r$, and apply the coordinate transformation

$$t=\overline{t}\cosh\chi, \quad r=\overline{t}\sinh\chi. \tag{2.16}$$

This transformation gives the Milne universe which has $N=1$, $R=t$, and $f=\sinh r$. The Milne universe is flat and is identical to Minkowski space–time except that there is a point removed at the origin $t=0$. At first sight it might be expected that the Milne universe could be joined to Minkowski space–time across the surface chosen here. The reason that this does not happen is that the space and time coordinates have been ''mixed'' by (2.16) so that if there was a well defined junction it would be across a different surface from those chosen here. A general treatment of redefinitions of space and time coordinates in Robertson–Walker space–time can be found in Ref. 17.

The junction conditions of Robertson–Walker space–time have two further applications. The first is the production of a spherical Minkowski cavity which has implications for Mach's principle (see, for example, Ref. 18, p. 474). A point inside the cavity is an inertial frame if it does not rotate with respect to the reference frame of the rest of the universe, which is taken to be given by the Robertson–Walker space–time surrounding the cavity. A different approach to Mach's principle is discussed in Ref. 19. The second is to the cell universe models. The surface normal to the vectors chosen here do not allow junctions between Robertson–Walker space–time and Schwarzschild space–time. Thus for the Schwarzschild cell universe of Lindquist and Wheeler[20] to work, a different vector has to be chosen or different physical assumptions made.

III. PENNY'S SOLUTION

Penny's solution,[6] and the related solutions of Gurses[21] and Ray,[22] are conformally flat. The conformal factor generating technique used to find these solutions is also to study solutions of higher-order gravity theories, Barrow and Cotsakis (1988). Here attention is restricted to Penny's solution where the conformal factor and the ordinary scalar field are given by

$$\Xi=k_a x^a+a, \quad k_{a,b}=0, \quad \varphi=\sqrt{3}\ln\Xi, \tag{3.1}$$

respectively. Defining

$$K_a=-\Xi k_a, \tag{3.2}$$

K_a is a Killing vector which is null iff k_a is null. The conformal factor can be expressed as

$$\Xi^2=a+bt+cx+dy+ez, \tag{3.3}$$

where a,b,c,d are constants. There is no asymptotically flat solution. For $a=c=d=e=0$, $b=2R_0^2H_0$, this is the $k=0$ solution (2.6).

Using Bekenstein's theorems, conformal scalar solutions are

$$\begin{gathered}\Upsilon=\Omega^{-1}\Xi,\\ 2\Omega=2\begin{cases}\cosh\\ \sinh\end{cases}\quad \xi\varphi=\Xi\pm\Xi^{-1},\\ \xi\psi=\begin{cases}\tanh\\ \coth\end{cases}\quad \xi\varphi=\frac{\Xi^2\mp1}{\Xi^2\pm1},\end{gathered} \tag{3.4}$$

giving

$$\Upsilon=2\Xi^2/(\Xi^2\pm1).$$

Defining

$$K_a = \Upsilon^2 k_a , \tag{3.5}$$

again K_a is a Killing vector which is null iff k_a is null.

IV. THE SOLUTION PREVIOUSLY FOUND BY THE AUTHOR

The solution found in Refs. 1 and 2 is

$$ds^2 = -(1+2\alpha_{,v})dv^2 + 2dv\,dr + r(r-2\alpha)d\Sigma_2^2, \tag{4.1}$$

where $d\Sigma_2^2 = d\theta^2 + \sin^2\theta/d\varphi^2$, and α is a twice differentiable function of v. The stress is given by a scalar field and a null radiation field

$$\varphi = \frac{1}{2}\ln\left(1-\frac{2\alpha}{r}\right), \quad \Phi^2 = \frac{2\alpha\alpha_{,vv}}{r(r-2\alpha)}. \tag{4.2}$$

Defining the luminosity distance $R^2 = r(r-2\alpha)$, and taking the positive sign of the square root, the solution becomes

$$\begin{gathered} ds^2 = \left(-1+\frac{2\alpha\alpha_{,v}}{\lambda}\right)dv^2 + \frac{2R}{\lambda}\,dr\;dv + R^2 d\Sigma_2^2, \\ \varphi = \frac{1}{2}\ln\left(\frac{\lambda-\alpha}{\lambda+\alpha}\right), \quad \Phi^2 = 2\frac{\alpha\alpha_{,v}}{R^2}, \end{gathered} \tag{4.3}$$

where $\lambda^2 = \alpha^2 + R^2$. The Bondi mass $M(v)$ is half the coefficient of the R^{-1} term of g_{vv}. Expanding gives

$$M(v) = \alpha\alpha_{,v}. \tag{4.4}$$

For the null radiation field to vanish, $\alpha_{,vv} = 0$ or $\alpha = \sigma v + \beta$, where σ and β are constants. It is straightforward to show that β can be absorbed into the line element leaving $\alpha = \sigma v$; this can be substituted into (4.3) for a form of the metric using the luminosity radial coordinate; alternatively it can be substituted into (4.1), giving

$$\begin{gathered} ds^2 = -(1+2\sigma)dv^2 + 2dv\,dr + r(r-2\sigma v)d\Sigma_2^2, \\ \varphi = \frac{1}{2}\ln\left(1-\frac{2\sigma v}{r}\right). \end{gathered} \tag{4.5}$$

Defining $v' = \sqrt{1+2\sigma}v$, and $r' = r/\sqrt{1+2\sigma}$, gives

$$\begin{gathered} ds^2 = -dv'^2 + 2dv'dr' + r'((1+2\sigma)r' - 2\sigma v')d\Sigma_2^2, \\ \varphi = \frac{1}{2}\ln\left(1-\frac{2\sigma}{(1+2\sigma)}\frac{v'}{r'}\right) \end{gathered} \tag{4.6}$$

Then defining $t' = v' - r'$ gives

$$\begin{gathered} ds^2 = -dt'^2 + dr'^2 + r'(r' - 2\sigma t')d\Sigma_2^2, \\ \varphi = \ln(R/r). \end{gathered} \tag{4.7}$$

Also defining $t = t'/1+2\sigma$ the solution can be put in the form

$$ds^2=-(1+2\sigma)dt^2+\frac{dr^2}{(1+2\sigma)}+r\left(\frac{r}{(1+2\sigma)}-2\sigma t\right)d\Sigma_2^2,$$
$$\varphi=\frac{1}{2}\ln\left(\frac{1}{(1+2\sigma)}-\frac{2\sigma t}{r}\right), \tag{4.8}$$

and from this form using (C5) the ADM mass is seen to vanish identically.

Using Bekenstein's theorems to find conformal scalar solutions (4.3) gives

$$R=\overline{R}\Omega^{-1}=\overline{R}\begin{cases}\cosh\\ \sinh\end{cases}\quad \xi\varphi=\tfrac{1}{2}\overline{R}^{1-\xi}[(\lambda-\alpha)^{\xi}\pm(\lambda+\alpha)^{\xi}],$$
$$\xi\psi=\frac{(\lambda-\alpha)^{\xi}\mp(\lambda+\alpha)^{\xi}}{(\lambda-\alpha)^{\xi}\pm(\lambda+\alpha)^{\xi}}, \tag{4.9}$$

where $\lambda^2=\overline{R^2}+\alpha^2$ and $\overline{R}$ denotes the luminosity coordinate for the O-scalar solution, and R denotes it for the conformal scalar solution. For the type A solution general can be retained if the null radiation field is transformed, but for the type B solution α must equal σv. Inspecting (4.9) gives limiting behavior of the conformal scalar solution in terms of the luminosity coordinate for the ordinary solution,

$$\overline{R}\uparrow\infty,\quad \text{Type A:}\quad R\uparrow\infty,\psi\uparrow 0,\quad \text{Type B:}\quad R\downarrow-\xi,\psi\downarrow-\infty,$$
$$\overline{R}\downarrow 0,\quad \text{Type A:}\quad R\downarrow 0,\psi\downarrow-1,\quad \text{Type B:}\quad R\downarrow-0,\psi\uparrow-1. \tag{4.10}$$

The type B solution does not have an asymptotically flat region, so that attention is restricted to the type A solution. Expanding (4.9) for large R gives

$$R=\overline{R}\left(1+\frac{\xi^2\alpha^2}{2\overline{R^2}}+O\left(\frac{\alpha}{\overline{R}}\right)^3\right). \tag{4.11}$$

Solving this quadratic

$$\overline{R}=\frac{R}{2}\left(1\pm\sqrt{1-\frac{2\xi^2\alpha^2}{R^2}}\right), \tag{4.12}$$

the upper sign is taken so that $R=\overline{R}$ when $\xi=0$.

Differentiating

$$d\overline{R}=\frac{1}{2}\left(1+\frac{2}{\sqrt{1-2\xi^2\alpha^2/R^2}}\right)dR-\frac{2\xi^2\alpha\alpha_{,v}dv}{R\sqrt{1-2\xi^2\alpha^2/R^2}}, \tag{4.13}$$

inserting into the line element, and using (4.3), (4.12), (4.13) and that $\lambda^2=\alpha^2+\overline{R^2}$ gives

$$g_{vv}=-1+\frac{2(1-\xi^2)}{R}\,\alpha\alpha_{,v}+O(R^{-2}). \tag{4.14}$$

Thus the Bondi mass is given by

$$M(v)=(1-\xi^2)\alpha\alpha_{,v}, \tag{4.15}$$

which is two-thirds of (4.4). To calculate the ADM mass note that the conformal factor can be used:

$$A^t_{\cdot}=\overline{A^t_{\cdot}}+\lim_{r\to\infty}\left[-\frac{1\overline{B}}{2r}(\Omega^{-2})'\right], \tag{4.16}$$

where $\overline{B},\overline{A}$ are the values of these quantities in the O-scalar solution. Using the metric in the form (4.8) and noting that A vanishes,

$$A^t_{\cdot}=\lim_{r\to\infty}-\frac{\overline{B}\overline{\xi}}{2}\sinh(2\xi\varphi)\cdot\varphi'=\lim_{r\to\infty}-\frac{\xi\sigma}{2}\sinh(2\xi\varphi)\cdot t. \tag{4.17}$$

Expanding $\sinh(2\xi\varphi)$ for $r\to\infty$ gives

$$A^t_{\cdot}=\begin{cases}\xi^2\sigma^2 t, & \text{for } -1<2\sigma<1,\\ 2\xi^{\xi-2}\sigma^{-\xi+1}t, & \text{for } 2\sigma\geqslant 1,\end{cases} \tag{4.18}$$

for $2\sigma\leqslant -1$ the signature of the metric is not retained.

The surface stress (A6) must vanish at any null junction; this implies $[Y']$ must vanish if τ_{vv}, τ_{vr}, τ_{rv}, and τ_{rr} are to vanish, and $[(X/S)'/2S]$ must vanish if $\tau_{\theta\theta}$ and $\tau_{\varphi\varphi}$ are to vanish. For the type O solution take the line element (4.3); $[Y']$ vanishes as this line element is expressed in terms of the luminosity radial coordinate already and

$$\frac{1}{2S}\left(\frac{X}{S}\right)'=\frac{\alpha}{2R^{\xi}}(\alpha-2\lambda\alpha_{,v}). \tag{4.19}$$

Now the metric can be chosen to continuously join to Minkowski space–time by taking α to continuously increase from (or decrease to) $\alpha=0$; (4.19) shows that there is no surface stress at the join $\alpha=0$ so that the field equations are obeyed throughout the space–time. For the type A and B solutions (4.9) gives

$$Y=\tfrac{1}{4}\overline{R^{2-2\xi}}\{(\lambda-\alpha)^{\xi}\pm(\lambda+\alpha)^{\xi}\},$$

$$\begin{aligned}Y'=&\frac{1}{2}\overline{R^{1-2\xi}}\{(\lambda-\alpha)^{\xi}\pm(\lambda+\alpha)^{\xi}\}\\ &\times\left\{(1-\xi)((\lambda-\alpha)^{\xi}\pm(\lambda+\alpha)^{\xi})+\frac{\xi}{\alpha}\overline{R^2}((\lambda-\alpha)^{\xi-1}\pm(\lambda+\alpha)^{\xi-1})\right\},\end{aligned} \tag{4.20}$$

$$\frac{1}{2S}\left(\frac{X}{S}\right)'=\frac{4\alpha(\alpha-\lambda\alpha_{,v})}{\overline{R^{3-2\xi}}\{(\lambda-\alpha)^{\xi}\pm(\lambda+\alpha)^{\xi}\}}.$$

For the type B solution the metric is not continuous at $\alpha=0$ as would be anticipated from the general remarks in the Introduction. The type A solution again has a metric which can be chosen to continuously join to Minkowski space–time by taking α to behave as before.

At any junction across a timelike surface the limits (B7) of the second fundamental form either side of the junction must coincide. For the type O solution, dropping the primes on the metric (4.7) gives the second fundamental form (B6)

$$K_{\theta\theta}=\sin^{-2}\theta K_{\varphi\varphi}=r-\sigma t, \tag{4.21}$$

which gives a junction where the field equations are defined with Minkowski space–time at $t=0$. For type A and B conformal solutions the extension of the metric (4.7) has second fundamental form (B6):

$$K_{tt}=-\tfrac{1}{2}\xi\sigma t(r(r-2\sigma t))^{-\xi/2-1}\cdot\{(r-2\sigma t)^{\xi}\mp r^{\xi}\},$$
$$K_{\theta\theta}=\sin^{-2}\theta K_{\varphi\varphi}=\tfrac{1}{2}(r(r-2\sigma t))^{-\xi/2}\{(r+(\xi-1)\sigma t)(r-2\sigma t)^{\xi}\pm(r-(\xi+1)\sigma t)r^{\xi}\}. \tag{4.22}$$

Again there is a junction at $t=0$.

V. CONCLUSION

Solutions to the Einstein–scalar equations which can represent an imploding scalar field were presented. Bekenstein's theorems were used to generate the corresponding Einstein–conformal scalar solutions. The Robertson–Walker solutions presented here are examples of solutions previously found by Vajk and Bekenstein; they are not asymptotically flat and cannot be joined to Minkowski space–time by the methods used here. Penny's solution also can represent an imploding scalar field but it is not asymptotically flat, and only when it reduces to a Robertson–Walker metric is it spherically symmetric. The solution previously found by the author and its' Bekenstein type A extension are asymptotically flat and have well-defined junctions with Minkowski space–time, and therefore can represent a scalar field imploding from nothing, thus generalizing the example in the abstract. This solution has Bondi mass $\alpha\alpha_{,v}$, and zero ADM mass. The zero ADM mass is because the energy of the gravitational field is negative and equals the positive energy of the scalar field. The type A extension has Bondi mass $(1\text{-}\xi^2)\alpha\alpha_{,v}$, and ADM mass $\xi^2\sigma^2 t$, ($|2\sigma|<1$). Assuming that the null radiation field vanishes, so that there is only the conformal scalar field present, the Type A solution has $\alpha=\sigma v$, therefore

$$\text{Type O:}\quad M(v)=\sigma^2 v,\quad A^t_{\cdot}=0,$$

$$\text{Type A:}\quad M(v)=\tfrac{2}{3}\sigma^2 v,\quad A^t_{\cdot}=\tfrac{1}{3}\sigma^2 t.$$

The type A solution might violate the energy conditions, but subject to this provision it is possible to start with Minkowski space–time and join the type A solution at $t=0$ generating nonzero ADM mass. This only goes to show that you can get something (as measured by ADM mass) from nothing.

APPENDIX A: JUNCTION CONDITIONS ACROSS A NULL SURFACE

In single null coordinates a spherically symmetric line element can be written as

$$ds^2=-X\,dv^2+2S\,dv\,dr+Y(d\theta^2+\sin^2\theta\,d\varphi^2). \tag{A1}$$

A suitable null tetrad is

$$l_a=(S,0,0,0),\quad n_a=(X/2S,-1,0,0),\quad m_a=(0,0,1,i\sin\theta)\sqrt{Y/2}. \tag{A2}$$

The projection tensor is defined by $q_{ab}=g_{ab}+2l_{(a}n_{b)}$ and has nonvanishing components $q_{\theta\cdot}^{\ \theta}=q_{\varphi\cdot}^{\ \varphi}=1$. The internal second fundamental form, $\chi_{ab}=n_{d;c}q^{d}_{\ \cdot a}q^{c}_{\ \cdot b}$, involves covariant derivatives of n_a which can be calculated using the Christoffel symbols in Ref. 2, and it has nonvanishing components

$$\chi_{\theta\theta}=\sin^{-2}\theta\,\chi_{\varphi\varphi}=-(XY'/2S+Y_{,v})/2S. \tag{A3}$$

The external second fundamental form $\psi_{ab}=l_{d;c}q^{c}_{\ \cdot a}q^{d}_{\ \cdot b}$ is

$$\psi_{\theta\theta}=\sin^{-2}\theta\psi_{\varphi\varphi}=Y'/2, \tag{A4}$$

and the normal fundamental form $\eta_a=l_{d;c}q^c_{\cdot a}n^d_{\cdot}$ vanishes. The surface gravity $\omega=-l_d n^c_{\cdot} n^d_{\cdot;c}$ is

$$\omega=-(X/S)'/2S. \tag{A5}$$

The surface stress $\tau_{ab}=-[\mathrm{Tr}\ \psi]n_a n_b-2[\eta_{(a}]_{b)}-[\omega]q_{ab}$ is

$$\tau_{ab}=-[Y']n_a n_b/Y+[(X/S)'/2S]q_{ab}, \tag{A6}$$

with n_a and q_{ab} given by (A2) and where the bracket ''[ ]'' is defined by

$$[Q]|_y=\lim_{x\to y^+} Q-\lim_{x\to y^-} Q \tag{A7}$$

for a point y in the surface.

APPENDIX B: JUNCTION CONDITIONS ACROSS SPACELIKE AND TIMELIKE SURFACES

The line element can be taken in the form

$$ds^2=-C\,dt^2+A\,dr^2+B(d\theta^2+\sin^2\theta\,d\varphi^2). \tag{B1}$$

For a non-null surface, the surface stress vanishes iff the second fundamental form obeys

$$[K_{ab}]=0, \tag{B2}$$

where the bracket ''[ ]'' is defined by (A7). A suitable unit timelike vector field

$$U_\theta=(\sqrt{C},0,0,0). \tag{B3}$$

The projection tensor $h_{a\cdot}^{\ b}=g_{a\cdot}^{\ b}+U_a U^b_{\cdot}$ has three components $h_{r\cdot}^{\ r}=h_{\theta\cdot}^{\ \theta}=h_{\varphi\cdot}^{\ \varphi}=1$. The second fundamental form is $K_{ab}=U_{c;d}h^c_a h^d_{\cdot b}$. It involves covariant derivatives of U_a which can be calculated using the Christoffel symbols in Ref. 2. The nonvanishing components are

$$K_{rr}=-\mathring{A}/(2\sqrt{C}),\quad K_{\theta\theta}=\sin^{-2}\theta\,K_{\varphi\varphi}=-\mathring{B}/(2\sqrt{C}), \tag{B4}$$

where $\mathring{A}=\partial_t A$. The radial unit spacelike vector is

$$U_a=(0,\sqrt{A},0,0). \tag{B5}$$

The spacelike projection tensor $h_{a\cdot}^{\ b}=g_{a\cdot}^{\ b}-U_a U^b_{\cdot}$ has three components $h_{t\cdot}^{\ t}=h_{\theta\cdot}^{\ \theta}=h_{\varphi\cdot}^{\ \varphi}=1$. The second fundamental form for the corresponding timelike surface is

$$K_{tt}=-C'/(2\sqrt{A}),\quad K_{\theta\theta}=\sin^{-2}\theta\,K_{\varphi\varphi}=B'/(2\sqrt{A}), \tag{B6}$$

where $C'=\partial_r C$. Choosing the isotropic unit spacelike vector

$$U_a=\frac{1}{\sqrt{3}}(0,\sqrt{A},\sqrt{B},\sqrt{B}\sin\theta); \tag{B7}$$

similarly the nonvanishing components of the second fundamental form are

$$K_{tt}=-C'/(2\sqrt{3}A),$$

$$K_{tr}=-2\sqrt{\frac{A}{B}}\quad K_{t\theta}=\frac{-2}{\sin\,\theta}\sqrt{\frac{A}{B}}\quad K_{t\varphi}=\frac{-\dot{A}}{3\sqrt{3A}}+\frac{\dot{B}}{3B}\sqrt{\frac{A}{3}},$$
$$K_{r\theta}=\frac{K_{r\varphi}}{\sin\,\theta}=\frac{\sqrt{A}K_{\theta\varphi}}{\sin\,\theta}=\frac{-1}{2}\sqrt{\frac{B}{A}}\quad K_{rr}=\frac{-B'}{6\sqrt{3B}},\tag{B8}$$
$$K_{\theta\theta}=\frac{K_{r\theta}}{\sin\,\theta}=\frac{1}{3\sqrt{3A}}\{-B\,\cot\,\theta+B'\}.$$

The above three vectors (B3), (B5), and (B7) are suitable for the majority of purposes; but, for example, if there is ''Mixing'' between the space and time coordinates, like that of Eq. (2.16), then other vectors have to be used.

APPENDIX C: THE ADM ENERGY

The ADM energy for a spherically symmetric space–time is found by generalizing Weinberg's[20] derivation for the Schwarzschild solution. Define the rectilinear coordinates

$$x_1=r\,\sin\,\theta\,\cos\,\varphi,\quad x_2=r\,\sin\,\theta\,\sin\,\varphi,\quad x_3=r\,\cos\,\theta;\tag{C1}$$

the line element (B1) becomes

$$ds^2=-C\,dt^2+(A/r^2-B/r^4)(\underline{dx.x})^2+(B/r^2)\underline{dx}^2.\tag{C2}$$

Defining $h_{ij}=g_{ij}-\eta_{ij}$, and $n^i_{\cdot}=x^i_{\cdot}/r$, $i,j=1,2,3$, gives

$$h_{ij}=(A-B/r^2)n_in_j+(B/r^2-1)\,\delta_{ij}.\tag{C3}$$

The ADM mass is given by

$$A^t_{\cdot}=\oint dS^i_{\cdot}(h^j_{\cdot\,i,j}-h^j_{\cdot\,j,i}).\tag{C4}$$

Using (C3) this is

$$A^t_{\cdot}=\frac{-1}{2}\,r\left(\frac{-A}{r}+\left(\frac{B}{r^2}\right)'+\frac{B}{r^3}\right).\tag{C5}$$

The remaining components of the ADM vector are given by

$$8\pi A_j=\lim_{r\to\infty}\oint dS^i_{\cdot}(K_{ij}-\delta_{ij}K)$$

using the fundamental form (B5) gives

$$8\pi A_j=\lim_{r\to\infty}(B/(B\sqrt{C}),0,0)$$

and this vanishes in all the cases considered here.

APPENDIX D: A FIELD INDEX

A perfect fluid has Lagrangian $L_d=p$ (the pressure) (see, for example, Ref. 10) and Hamiltonian density $H_d=\mu$ (the density). Taking metric variations of the Lagrangian produces the metric stress

$$T_{ab}=(\mu+p)V_aV_b+pg_{ab}, \quad V_aV^a_{\cdot}=-1. \tag{D1}$$

The absolute derivative is defined by

$$\mathring{X}_{abc\ldots}=V_{\cdot}X_{abc\ldots}. \tag{D2}$$

The Bianchi identities give

$$-V_aT^{ab}_{\cdot\cdot;b}=\mathring{\mu}+(\mu+p)\breve{\Theta}, \quad \breve{\Theta}=V^a_{\cdot;a}$$

$$h_{ab}T^{bc}_{\cdot\cdot;c}=(\mu+p)_a+h_{a\cdot}{}^bp_b. \tag{D3}$$

The Eisenhart–Synge fluid index is

$$\omega=\ln I=\int \frac{dp}{\mu+p}, \tag{D4}$$

in the literature sometime I is called the index and sometimes ω. Assuming an equation of state

$$p=f(\mu), \quad \mu=f^{-1}(p), \tag{D5}$$

the Bianchi identities can be expressed as

$$\breve{\Theta}=\mathring{\omega}\,\frac{df^{-1}}{dp}, \quad \mathring{V}_a=-h_{a\cdot}{}^b\omega_b. \tag{D6}$$

For the equation of state (2.5) the index is $\omega=[(\gamma-1)/\gamma]\ln\mu$. An O-scalar field has this equation of state with $\gamma=2$ and $V_a=\varphi_a/\sqrt{-\varphi_c{}^2}$, $p=\mu=-\varphi_c{}^2$. Taking a timelike vector field, say

$$V_a=(N,0,0,0), \quad V^a_{\cdot}=(-1/N,0,0,0), \tag{D7}$$

it is possible to relate the behavior of the lapse N to the fluid index. For many configurations they can be equated $N=g(\omega)$, typically $N=1/\omega$. Thus if the fluid index is well behaved throughout the space, it is possible, without recourse to field equations, to discuss whether the metric is. Other choices of timelike vector field can be made; for example, for an asymptotically flat space–time there is the normal vector to the three-sphere at infinity.

There is no direct analog of the preceding for fields with infinite degrees of freedom. This is because the stress for fields does not have an explicit dependence on vector fields. It is possible to introduce vector fields into an action and vary it to produce an extreme configuration between the metric, fields, and vector field, in the following manner. Let the fields be describable by a Lagrangian

$$I_l=\int \sqrt{-g}\; d^4x\; L(\varphi,\varphi_a). \tag{D8}$$

Under infinitesimal coordinate variations this gives

$$\frac{\delta I}{\delta x^a_{\cdot}}: \int \sqrt{-g}\; d^4x \nabla_b \Theta^{ab}_c , \tag{D9}$$

where Θ^{ab}_c is the canonical stress

$$\Theta^{ab}_c = \frac{\partial \mathscr{L}}{\partial \varphi_a}\, \partial^b \varphi - g^{ab}_{\cdot\cdot} L_d . \tag{D10}$$

The Hamiltonian density is usually defined in terms of components $H_d = \Theta_{c\cdot 0}^{\;\;0}$. More generally it can be defined as

$$H_d = V_a V_b \Theta^{ab}_c , \tag{D11}$$

where V_a is a unit timelike vector field. Variations of I_l with respect to the metric produce the stress

$$T_{ab} = D_{ab} + L g_{ab} , \tag{D12}$$

where D_{ab} is given by $\delta I_d / \delta g_{ab}$. Applying the timelike vector field and using (D11) gives

$$H_d + L_d = V^a_{\cdot} V^b_{\cdot} D_{ab} . \tag{D13}$$

Variations of actions corresponding to H_d and L_d give dynamical equations. This suggests considering a new action I_n which is a sum of the Hamiltonian and Lagrangian actions

$$I_n = \int \sqrt{-g}\; d^4x (H_d + L_d) = \int \sqrt{-g}\; d^4x V^a_{\cdot} V^b_{\cdot} D_{ab} , \tag{D14}$$

which will give extremeal (maximally stable or unstable) configurations. Another possible way of producing further equations between the fields is to consider higher-order variations. For example, in Ref. 23, the second covariant variation of the point particle action gives the geodesic deviation equations.

A scalar-electrodynamic Lagrangian for a complex scalar field ψ and a vector field A_a is

$$\begin{gathered}\mathscr{L} = -\tfrac{1}{4}F^2 + \tfrac{1}{2}\mu^2 A^2 - \lambda (A^a_{\cdot a})^2 + J_a A^a_{\cdot} - \mathscr{D}_a \psi \mathscr{D}^a \overline{\psi} - V(\psi^2) + 2\beta \psi^2 R, \\ \mathscr{D}_a \psi = \partial_a \psi + ie \psi A_a , \quad \psi^2 = \psi \overline{\psi}, \\ \mathscr{D}_a \overline{\psi} = \partial_a \overline{\psi} - ie \overline{\psi} A_a .\end{gathered} \tag{D15}$$

Varying with respect to the metric gives

$$D_{ab} = F_{ac} F_{b\cdot}^{\;\;c} - \mu^2 A_a A_b - 2 J_a A_b + 4\lambda^2 A_{ab} A_{c\cdot}^{\;\;c} + 2 \mathscr{D}_{(a} \psi \mathscr{D}_{b)} \overline{\psi} - 2\beta (\psi^2)_{ab} - 2\beta \psi^2 R. \tag{D16}$$

Setting up the new action I_n and varying with respect to the fields gives

$$\begin{gathered}\frac{\delta I_n}{\delta \psi}: = -2 (V^a_{\cdot} V^a_{\cdot} \mathscr{D}_b \overline{\psi})_a + 2ie A_a V^a_{\cdot} V^a_{\cdot} \mathscr{D}_b \overline{\psi} + 2\beta \overline{\psi} [(V^a_{\cdot} V^a_{\cdot})_{ab} - R_{ab} V^a_{\cdot} V^b_{\cdot}], \\ \frac{\delta I_n}{\delta A_a}: = -2 (V_a V^b_{\cdot} F_{b\cdot}^{\;\;c} + V^c_{\cdot} V^b_{\cdot} F_{ba})_a + 2 V_a (-\mu^2 V^b_{\cdot} A_b - J_b A^b_{\cdot}) + ie V^a_{\cdot} (\psi \mathscr{D}_c \overline{\psi} - \overline{\psi} \mathscr{D}_c \psi).\end{gathered} \tag{D17}$$

It is also possible to vary with respect to $\mathring{\psi}$, $\mathring{A}_a$, g_{ab}, and V_a. Variations with respect to V_a are best done using velocity potentials (see Ref. 10). Varying with respect to g_{ab} a new ''stress'' tensor can be created. Applying the Bianchi identities to it the equations (D17) are not recovered, because the conservation equations as derived from (D9) are also changed. Choosing $D_{ab}=R_{a\mathring{b}}$ and varying with respect to g_{ab} does not reproduce Raychaudhuri's equations, but instead $\Theta = R_{ab}V^a_{\cdot}V^b_{\cdot} + \Theta^2 - \mathring{V}^a_{\cdot;a} + 1/2\Box V^2$. For the Reissner–Nordstrom solution with vector field (D7), and the null vector field l_a, (D17) becomes

$$\omega_t = -\frac{4\sqrt{2}}{r^3N^3}\, e\left[1+\frac{2m}{r}-\frac{3e^2}{r}\right],$$
$$\omega_v = 4\sqrt{2}\,\frac{e}{r^3}. \tag{D18}$$

For static O-scalar fields the field index vanishes everywhere, for nonstatic O-scalar fields using l_a gives

$$\omega = -2\left(\frac{2S'}{S}+\frac{Y'}{Y}\right)\varphi'. \tag{D19}$$

In the solution (4.5) this is

$$\omega = -\frac{4\sigma v}{Y^2}\,(r-\sigma v). \tag{D20}$$

Axially symmetric solutions for SU(2) Yang–Mills theory

D. Singleton
Department of Physics, Virginia Commonwealth University, Richmond, Virginia 23284-2000

(Recieved 29 August 1995; accepted for publication 15 April 1996)

By casting the Yang–Mills–Higgs equations of an SU(2) theory in the form of the Ernst equations of general relativity, it is shown how the known exact solutions of general relativity can be used to give similar solutions for Yang–Mills theory. Thus all the known exact solutions of general relativity with axial symmetry (e.g., the Kerr metric, the Tomimatsu–Sato metric) have Yang–Mills equivalents. In this paper we only examine in detail the Kerr-like solution. It will be seen that this solution has surfaces where the gauge and scalar fields become infinite, which correspond to the infinite redshift surfaces of the normal Kerr solution. Unlike the Kerr solution, our solution apparently does not have any intrinsic angular momentum, but rather appears to give the non-Abelian field configuration associated with concentric shells of color charge. Several possible physical consequences of these axial symmetric Yang–Mills field configurations are discussed. © *1996 American Institute of Physics.* [S0022-2488(96)00709-8]

I. INTRODUCTION

Recently, using the long known connection between general relativity and Yang–Mills theories,[1] we found exact Schwarzschild-like solutions for Yang–Mills theories.[2,3] Our results were conceptually similar to several other recent papers[4,5] which discussed related solutions. A natural question which arises from this is if there are other exact solutions of general relativity which have corresponding exact Yang–Mills solutions. Of particular interest is the Kerr solution which has an intrinsic angular momentum. In this paper we show that there are such solutions by considering an SU(2) gauge theory coupled to a scalar field in the adjoint representation. The solutions are found by first transforming the Yang–Mills field equations into the Ernst equations[6] of general relativity, and then applying the form of the general relativistic solution in terms of the gauge and scalar fields. Even though we specialize in this paper to the Kerr-like solution, it is in principle possible to use this same procedure to map over any axially symmetric solutions to Einstein's equations into an equivalent Yang–Mills solution. However, as we will show, even the Kerr-like solution has a very complex structure, which makes it difficult to deal with. In addition it may be possible to reverse the above method and use known exact solution of Yang–Mills theory (e.g., the BPS dyon solution[7,8] and multimonopole solutions[9]) to write down undiscovered solutions to Einstein's equations. One interesting feature of our previous Schwarzschild-like solution was the existence of a spherical shell surrounding the origin, on which the gauge and scalar fields became infinite, implying the presence of a spherical distribution of color charge. The Yang–Mills Kerr-like solution, in contrast, generally has two concentric shells of SU(2) charge (these shells are the equivalent of the infinite redshift surfaces of the normal Kerr solution). Just as the the Kerr solution of general relativity can permanently trap particles which carry the gravitational ''charge'' (i.e., mass-energy) behind its event horizons, so too does the Yang–Mills Kerr-like solution if it is treated as a fixed background field in which a color charged test particle is placed via minimal coupling. This gives a semi-classical type of confinement which has some similiarities with phenomenological bag models. It is not clear whether this is in any way connected with the physical confinement mechanism, which is thought to be a quantum field theoretic effect. Actually, what we call the color event horizon of our solution corresponds to the infinite redshift surfaces rather than the true event horizons of the normal Kerr metric. The reason for

0022-2488/96/37(9)/4574/10/$10.00

calling these surfaces the color event horizons is that the physical quantities of our theory (the gauge and scalar fields) develop real singularities on these surfaces. These infinite values of the fields imply, at least classically, that a particle carrying a color charge would either be strongly repelled or strongly attracted by these surfaces. For general relativity the corresponding singular surfaces are coordinate singularities which arise because of the particular coordinates that one chooses. This can best be seen for the normal Schwarzschild solution where one can eliminate the singularity in the metric at the Schwarzschild radius by transforming to Kruskal coordinates. In addition to this difference in the nature of the singularities, it is shown that while the regular Kerr solution has some angular momentum, our Yang–Mills version does not. These differences arise because the symmetries of general relativity are space-time symmetries, while the Yang–Mills symmetries are internal Lie symmetries.

II. THE KERR-LIKE SOLUTION

The theory which we consider is an SU(2) gauge field which is coupled to a scalar field in the adjoint representation, which has no self-interaction or mass terms. The Lagrangian for this theory is

$$\mathscr{L}=-\tfrac{1}{4}F^{\mu\nu a}F^{a}_{\mu\nu}+\tfrac{1}{2}D_{\mu}(\phi^{a})D^{\mu}(\phi^{a}), \tag{1}$$

where

$$F^{a}_{\mu\nu}=\partial_{\mu}W^{a}_{\nu}-\partial_{\nu}W^{a}_{\mu}+g\epsilon^{abc}W^{b}_{\mu}W^{c}_{\nu} \tag{2}$$

and

$$D_{\mu}\phi^{a}=\partial_{\mu}\phi^{a}+g\epsilon^{abc}W^{b}_{\mu}\phi^{c}. \tag{3}$$

To obtain the Bogomolny field equations associated with this theory one finds the field configuration which produces an extremum in the canonical Hamiltonian:

$$\mathscr{H}=\int d^{3}x[\tfrac{1}{4}F^{a}_{ij}F^{aij}-\tfrac{1}{2}F^{a}_{0i}F^{a0i}+\tfrac{1}{2}D_{i}\phi^{a}D^{i}\phi^{a}-\tfrac{1}{2}D_{0}\phi^{a}D^{0}\phi^{a}]. \tag{4}$$

We now introduce an explicit scale factor for the scalar field (i.e., $\phi^{a}\rightarrow A\phi^{a}$) so that we can study the special case with no scalar field by simply taking $A=0$. Next we require that all the fields are time independent and that the time components of the gauge fields are proportional to the scalar fields (i.e., $W^{a}_{0}=C\phi^{a}$, where ϕ^{a} is the rescaled field). Thus W^{a}_{0} acts like an additional Higgs field except that its kinetic term appears with the opposite sign in Eq. (4). Using all these conditions and the antisymmetry of ϵ^{abc} we find that $D_{0}\phi^{a}=0$ and $F^{a}_{0i}=C(D_{i}\phi^{a})$, so that the Hamiltonian becomes

$$\mathscr{H}=\int d^{3}x[\tfrac{1}{4}(F^{a}_{ij}-\epsilon_{ijk}\sqrt{A^{2}-C^{2}}D^{k}\phi^{a})(F^{aij}-\epsilon_{ijl}\sqrt{A^{2}-C^{2}}D^{l}\phi^{a})+\tfrac{1}{2}\epsilon_{ijk}\sqrt{A^{2}-C^{2}}F^{aij}D^{k}\phi^{a}]. \tag{5}$$

Using the relationship $\epsilon_{ijk}F^{aij}D^{k}\phi^{a}=\partial^{i}(\epsilon_{ijk}F^{ajk}\phi^{a})$ the last term in Eq. (5) can be turned into a surface integral, which in the usual development[7] is proportional to the magnetic charge carried by the fields due to the topology of the Higgs field at infinity.[10] The lower limit of the above Hamiltonian can be found be requiring

$$F_{ij}^a = \sqrt{A^2 - C^2}\,\epsilon_{ijk} D^k \phi^a,$$
$$B_k^a = \sqrt{A^2 - C^2} D_k \phi^a. \tag{6}$$

These are the usual Bogomolny field equations, with the presence of the scalar and time component of the gauge fields explicitly displayed through the constants A and C.

Several exact solutions to the field equations of this theory have been found which possess spherical symmetry: the Bogomolny–Prasad–Sommerfield dyon solution,[7,8] and more recently a Schwarzschild-like solution.[2] In this paper we are looking for an axially symmetric solution. Several authors[11,12] have already given an axially symmetric ansatz for the guage and scalar fields

$$\Phi^a = (0, \phi_1, \phi_2), \quad W_\phi^a = -(0, \eta_1, \eta_2),$$
$$W_z^a = (W_1, 0, 0), \quad W_\rho^a = -(W_2, 0, 0), \tag{7}$$

where φ, z, ρ are the usual polar coordinates and ϕ_i, η_i, W_i are functions of ρ, z only. With this ansatz the Bogomolny equations of Eq. (6) become[11]

$$\sqrt{A^2 - C^2}(\partial_\rho \phi_1 - W_2 \phi_2) = -(\partial_z \eta_1 - W_1 \eta_2)/\rho,$$
$$\sqrt{A^2 - C^2}(\partial_\rho \phi_2 + W_2 \phi_1) = -(\partial_z \eta_2 + W_1 \eta_1)/\rho,$$
$$\sqrt{A^2 - C^2}(\phi_1 \eta_2 - \phi_2 \eta_1) = \rho(\partial_\rho W_1 - \partial_z W_2), \tag{8}$$
$$\sqrt{A^2 - C^2}(\partial_z \phi_1 - W_1 \phi_2) = (\partial_\rho \eta_1 - W_2 \eta_2)/\rho,$$
$$\sqrt{A^2 - C^2}(\partial_z \phi_2 + W_1 \phi_1) = (\partial_\rho \eta_2 + W_2 \eta_1)/\rho.$$

These axially symmetric versions of the Bogomolny equations remain invariant under the following Abelian gauge transformation:

$$W_i' \to W_i + \partial_i \Lambda,$$
$$(\phi_1', \eta_1') \to (\phi_1, \eta_1)\cos(\Lambda) + (\phi_2, \eta_2)\sin(\Lambda), \tag{9}$$
$$(\phi_2', \eta_2') \to (\phi_2, \eta_2)\cos(\Lambda) - (\phi_1, \eta_1)\sin(\Lambda).$$

If one defines two new functions, $f(\rho, z)$ and $\psi(\rho, z)$, such that the fields, η_i, ϕ_i, and W_i are written as

$$\sqrt{A^2 - C^2}\,\phi_1 = -W_1 = \frac{1}{f}\frac{\partial \psi}{\partial z}, \quad \eta_1 = \rho W_2 = -\frac{\rho}{f}\frac{\partial \psi}{\partial \rho},$$
$$\sqrt{A^2 - C^2}\,\phi_2 = -\frac{1}{f}\frac{\partial f}{\partial z}, \quad \eta_2 = \frac{\rho}{f}\frac{\partial f}{\partial \rho}, \tag{10}$$

then the Bogomolny equations of Eq. (8) become[9]

$$\mathrm{Re}(\epsilon)\nabla^2 \epsilon = \boldsymbol{\nabla}\epsilon \cdot \boldsymbol{\nabla}\epsilon, \tag{11}$$

where $\epsilon = f + i\psi$, and ∇^2 and $\boldsymbol{\nabla}$ are the Laplacian and gradient in cylinderical coordinates.

Equation (11) is the Ernst equation[6] of general relativity. This form of the Bogomolny equations has been used to find exact, nonsingular, multimonopole solutions for the fields through the

use of the Bäcklund transformations of Harrison.[13] Since the axial Bogomolny equations can be written in the form of the Ernst equations, it should be possible to use the known exact solutions of general relativity to find exact solutions for SU(2) Yang–Mills–Higgs theory. That this link between the general relativistic solutions and their Yang–Mills counterparts has not been exploited before can perhaps be attributed to the singularities which exist in these solutions. Here it is conjectured that these singularities might actually be a desired feature in that they may provide a confinement mechanism for non-Abelian gauge theories. Previously,[2,3] using a different approach we have found exact Schwarzschild-like solutions for SU(2) and SU(N) Yang–Mills–Higgs theories. Here we use the well known Kerr solution, written in terms of variables of the Ernst equation, to give an equivalent solution for the Yang–Mills theory. There are actually several other exact, axially symmetric solutions in general relativity which could be mapped over into Yang–Mills theory (e.g., the Tomimatsu–Sato metric[14] and the NUT-Taub metric[15]). However, the Kerr metric is the simplest axially symmetric solution, and is of physical interest since it gives the exterior gravitational field for a central mass with angular momentum. However, our axial Yang–Mills solution apparently does not possess any angular momentum, but rather seems to represent the non-Abelian field configuration due to an axial symmetric distribution of SU(2) charge. Thus although the Kerr-like solution is found using the general relativistic solution, they appear to have some different physical characteristics.

To find the Kerr solution from the Ernst equation one first introduces the complex potential ζ such that

$$\epsilon = f + i\psi = \frac{\zeta - 1}{\zeta + 1} \tag{12}$$

so that f and ψ are the real and imaginary parts, respectively, of $(\zeta-1)/(\zeta+1)$. Substituting this expression for ϵ into Eq. (11), the Ernst equation becomes

$$(\zeta\overline{\zeta} - 1)\nabla^2\zeta = 2\overline{\zeta}\overline{\boldsymbol{\nabla}}\zeta\cdot\boldsymbol{\nabla}\zeta, \tag{13}$$

where $\overline{\zeta}$ is the complex conjugate of ζ. For this form of the equations the Kerr solution is most easily found using prolate spheroidal coordinates, which can be written in terms of the cylinderical coordinates, ρ and z, as

$$\begin{aligned} x &= \frac{1}{2k}\left[\sqrt{(z+k)^2+\rho^2} + \sqrt{(z-k)^2+\rho^2}\right], \\ y &= \frac{1}{2k}\left[\sqrt{(z+k)^2+\rho^2} - \sqrt{(z-k)^2+\rho^2}\right], \end{aligned} \tag{14}$$

where the ranges of these prolate spheroidal coordinates are $|x|\geqslant 1$ and $|y|\leqslant 1$. The inverse transformation is given by

$$\rho = k\sqrt{x^2-1}\sqrt{1-y^2}, \quad z = kxy, \tag{15}$$

with k, p, and q are arbitrary constants. In these prolate spheroidal coordinates the gradient and Laplacian become

$$\begin{aligned} \boldsymbol{\nabla} &= \frac{k}{\sqrt{x^2-y^2}}\left[\hat{\mathbf{x}}\sqrt{x^2-1}\,\frac{\partial}{\partial x} + \hat{\mathbf{y}}\sqrt{1-y^2}\,\frac{\partial}{\partial y}\right], \\ \nabla^2 &= \frac{k^2}{x^2-y^2}\left[\frac{\partial}{\partial x}(x^2-1)\,\frac{\partial}{\partial x} + \frac{\partial}{\partial y}(1-y^2)\,\frac{\partial}{\partial y}\right], \end{aligned} \tag{16}$$

where $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$ are unit vectors. Using these expressions it is easy to see that a solution to the second form of the Ernst equation, Eq. (13), is

$$\zeta = px - iqy, \tag{17}$$

where the constants p,q must satisfy the condition $p^2+q^2=1$. The above solution can be transformed into the standard form of the Kerr solution by doing a transformation from the prolate spheroidal coordinates to Boyer–Lindquist coordinates.[6] The special case when $q=0$, $p=1$, and $\zeta=x$ gives (after a transformation to Schwarzschild coordinates) the usual Schwarzschild metric for general relativity. However, using the solution $\zeta=x$ in the Yang–Mills case to write down the expressions for the gauge and scalar fields, we find that we do not recover our previous Schwarzschild-like solution for SU(2), but obtain a different solution. The reason for this lies in the fact that the ansätze we used in each case were different, and in the previous work we found our solution directly from the Euler–Lagrange field equations, while here we employed the Bogomolny formalism. A field configuration that satisfies the Bogomolny equations will also satisfy the Euler–Lagrange equations, but the reverse is not necessarily true. Nevertheless $\zeta=x$ does give a solution to the Yang–Mills–Higgs equations, which is a special case of the general solution (i.e., $p,q\neq 0$) that we are considering. In general relativity p, q, and k are related to the mass and angular momentum of the central mass which produces the gravitational field. Here p, q, and k will be related to the shape of the axially symmetric SU(2) charge configuration of our solution. In order to find expressions for the fields ϕ_i, η_i, W_i it is first necessary to determine the functions f and ψ. From Eqs. (12) and (17) we find that

$$f = \frac{p^2x^2+q^2y^2-1}{(px+1)^2+q^2y^2}, \quad \psi = \frac{-2qy}{(px+1)^2+q^2y^2}. \tag{18}$$

To get the gauge and scalar fields one simply inserts these expressions for f and ψ into Eq. (10). This is a straightforward but tedious procedure which yields very complicated expressions for the fields. The explicit expressions for the fields are

$$\begin{aligned}
\sqrt{A^2-C^2}\phi_1 = -W_1 &= \frac{-2q[x(1-y^2)((px+1)^2-q^2y^2)-2py^2(px+1)(x^2-1)]}{k[(px+1)^2+q^2y^2](p^2x^2+q^2y^2-1)(x^2-y^2)},\\
\eta_1 = \rho W_2 &= \frac{-2qy[(px+1)^2-q^2y^2+2px(px+1)](x^2-1)(1-y^2)}{(x^2-y^2)[(px+1)^2+q^2y^2](p^2x^2+q^2y^2-1)},\\
\sqrt{A^2-C^2}\phi_2 &= \frac{-2y[p(x^2-1)((px+1)^2-q^2y^2)+2q^2x(px+1)(1-y^2)]}{k(x^2-y^2)(p^2x^2+q^2y^2-1)[(px+1)^2+q^2y^2]},\\
\eta_2 &= \frac{-2(x^2-1)(1-y^2)[px(3q^2y^2-(px+1)^2)+2q^2y^2]}{(x^2-y^2)(p^2x^2+q^2y^2-1)[(px+1)^2+q^2y^2]},
\end{aligned} \tag{19}$$

where the partial derivatives like, $\partial\psi/\partial z$ were determined using the chain rule (e.g., $\partial_x\psi\partial_z x+\partial_y\psi\partial_z y$) and Eq. (14). Notice that in general relativity the physical quantities one usually deals with are the components of the metric tensor. Here the physical quantities are the gauge fields which correspond to the Christoffel symbols in general relativity. This partly explains the complexity of the expressions in Eq. (19), since even in Boyer–Lindquist coordinates, the Christoffel coefficients for the Kerr metric are somewhat involved. If one wanted to have the expressions for the fields in terms of the original coordinates, it would be necessary to use Eq. (14) to replace x,y with ρ,z, making an already complicated expression even more intractible. However, by looking at certain aspects of the expressions of the fields one can still make some interesting comments about this solution.

One feature that can be looked for are regions where the fields become singular. In analogy with Maxwell's equations, where singularities in the electromagnetic field indicate the presence of electric charge, we interpret these singularities as the location of color charge. The shape of these SU(2) charge distributions is much more involved than in electromagnetism. All of the fields from Eq. (19) have three similar terms in their denominators, so the fields can be made to approach infinity if any one of the three factors goes to zero. First, by setting $p^2x^2+q^2y^2-1=0$ it can be seen that all the fields become infinite. This factor is common to all the fields, since from Eq. (10) they all have a factor of f^{-1}. In cylinderical coordinates this condition becomes

$$|pq|(z^2+\rho^2-k^2)=\pm|q^2-p^2|\rho k. \tag{20}$$

By setting $q=\cos\theta$ and $p=\sin\theta$ we replace the two parameters p,q with one parameter, and Eq. (20) becomes

$$z^2+\rho^2-k^2=\pm 2|\cot(2\theta)|\rho k. \tag{21}$$

Solving the above condition for z as a function of ρ allows one to take a vertical slice through the two axially symmetric surfaces defined by Eq. (21). One needs only to look in the range $0°\leqslant\theta\leqslant 45°$ to cover all the possibilities. What one finds are two concentric surfaces which touch each other on the z-axis at $\pm k$. The outer surface is given by the positive solution to Eq. (21). It has a toroidal shape, without the central hole of a normal torus. The inner surface is given by the negative solution, and has an ellipsoidal shape which runs along the z axis. In the special case when $\theta=45°$ (i.e., $p=q$) the two surfaces merge into a single sphere with a radius of k. Second, the fields can become infinite if $x^2-y^2=0$. However, this condition gives two points ($\rho=0$, $z=\pm k$) which are already included in the first condition of Eq. (20). Finally some of the fields become singular when $y=0$ and $px+1=0$ (since x is positive definite this condition only has a solution when $p<0$). The condition $y=0$ implies $z=0$ so that the singularity resides in the plane perpendicular to the z axis, and then $px+1=0$ gives $\rho=k|q|/|p|=k|\cot\theta|$. This corresponds to a ring singularity of radius $k|\cot\theta|$ centered at the origin in the plane perpendicular to the z axis. However, this singularity, produced by the condition $y=0$ and $px+1=0$, duplicates that from the condition of Eq. (21). Thus the singularity produced by the third term in the denominators of the gauge fields does not produce an independent singularity. The geometrical structure of the singular surfaces is different from that of the similar Schwarzschild-like solution. For the Schwarzschild solution we obtained a spherical shell singularity surrounding a point singularity at the origin. In the present case we find concentric toroidal and ellipsoidal surfaces on which the gauge and scalar fields become infinite, with no apparent singularities in the interior of these surfaces.

One of the most interesting features of other Yang–Mills solutions, such as the 't Hooft–Polyakov monopole or the Prasad–Sommerfield dyon, was the topological nature of the magnetic charge carried by these solutions. By examining the far-field behavior of the magnetic field of a special case of the Kerr-like solution we will find that it does not carry any net topological magnetic charge, but behaves like a configuration of two opposite magnetic charge sitting on the z axis, separated by a distance $2k$ (i.e., it acts like a magnetic dipole). The special case we consider is $q=0$ and $p=1$. In this case the only non-zero fields are ϕ_2 and η_2, which become

$$\phi_2=\frac{-2y}{k(x^2-y^2)},\quad \eta_2=\frac{2x(1-y^2)}{(x^2-y^2)}. \tag{22}$$

(We are also taking $A=1$ and $C=0$ here so that the time part of the gauge field is absent.) These fields only become singular at two points $-x=\pm y$, or $\rho=0$, $z=\pm k$. They do not have the singular surfaces of the more general $q\neq 0$ case. Looking back at Eq. (8) to obtain the components of the non-Abelian magnetic field we find that $B_z=-\partial_\rho\eta_2/\rho$ and $B_\rho=\partial_z\eta_2/\rho$. Inserting the fields of Eq. (22) and applying the chain rule we find

$$B_z=\frac{2x[x^2(1-3y^2)+y^2(3-y^2)]}{k^2(x^2-y^2)^3},$$
$$B_\rho=\frac{-2y\sqrt{x^2-1}\sqrt{1-y^2}(3x^2+y^2)}{k^2(x^2-y^2)^3}, \tag{23}$$

where the group index has been dropped since the magnetic fields all point in the same direction in iso-space.[11] If one looks at these fields along the z axis (i.e., $\rho=0$) where $x\to z/k$ and $y\to 1$, then $B_z\to -4zk/(z^2-k^2)^2$ and $B_\rho\to 0$. Now the magnetic field on the z axis of two magnetic point charges $+g$ and $-g$ located at $z=-a$ and $z=+a$, respectively, is $-4agz/(z^2-a^2)^2$. Thus this special case of our solution carries no net topological magnetic charge, but behaves similar to the magnetic dipole field surrounding two point magnetic charges of opposite sign. The magnetic charges of this special case solution can be taken to be located at the two singularities on the z axis at $z=\pm k$. For the general case with $q\neq 0$ one can again take the solutions of Eq. (19) and insert them into the right-hand side of Eq. (8) to get the components of the magnetic field. After a tedious calculation, restricting ourselves to the z axis and taking the limit $z\to\infty$ one finds that all the components of the magnetic field fall off faster than $1/r^2$. Thus none of the Kerr-like solutions carry a net topological magnetic charge. One can also look at the gauge and scalar fields of Eq. (19) and see that as $\rho\to\infty$ and $z\to\infty$ that they fall off as $1/r^2$ or faster, rather than the $1/r$ falloff one would expect for a radial Coulomb field from a net charge.

Just as the Kerr and Schwarzschild solutions of general relativity confine particles behind event horizons, so one may hope that the present solutions will trap color charged particles behind the singularities in the gauge fields. If these axial Yang–Mills solutions are treated as background fields in which a test particle is placed via minimal coupling, one finds that the singular surfaces act as impenetrable barriers, and the test particle does become trapped. A similar result is obtained for the spherically symmetric Schwarzschild-like solutions considered in Refs. 4, 5, and 16. In the present solution there are in general two concentric singular surfaces so the test particle may be trapped either within the inner surface or between the inner and outer surface. The special case, $q=0$ and $p=1$, which was just considered, does not trap test particles in this manner since it only has singular points, not singular surfaces that act as barriers to the test particle. This type of semi-classical confinement is similar to the behavior of phenomenological bag models. In a fully rigorous quantum field theory approach one could argue against these solutions being connected with the physical confinement mechanism. Due to the singularities one gets an infinite action contribution from these field configurations to the path integral. This implies that these solutions are not physically important. This conclusion can be evaded if there is an infinity of neighboring solutions whose infinite entropy contribution can offset the infinite action. This occurs, for example, with the meron solutions considered by Callan, Dashen, and Gross.[17] There the logarithmic divergence of the action was compensated for by the logarithmic increase of the entropy. It is not clear whether a similar result occurs for these axial symmetric solutions, but there is an infinite set of related solutions which are obtained by varying the free parameters k and q (p is not a free parameter because of the constraint $p^2+q^2=1$). The parameter k can vary from 0 to ∞, while q can range from -1 to 1.

The exact expressions for the energy and angular momentum of the Kerr-like solution presented here are rather complicated due to the involved nature of the scalar and gauge fields [see Eq. (19)]. Still some interesting general conclusions can be made about these quantities. To find the energy and angular momentum in the fields it is necessary to calculate the energy-momentum tensor of the Lagrangian of Eq. (1):

$$T^{\mu\nu}=\frac{2}{\sqrt{-g}}\frac{\alpha(\mathscr{L}\sqrt{-g})}{\partial g_{\mu\nu}}=F^{\mu\rho a}F^{\nu a}_{\rho}+D^\mu\phi^a D^\nu\phi^a+g^{\mu\nu}\mathscr{L}. \tag{24}$$

The energy of the field configuration is then

$$E=\int d^3xT^{00}=\int d^3x\left[\frac{1}{4}F^a_{ij}F^{aij}+\frac{1}{2}F^a_{0i}F^{a0i}+\frac{A^2}{2}D_i\phi^aD^i\phi^a+\frac{A^2}{2}D_0\phi^aD^0\phi^a\right]. \quad (25)$$

This is equivalent to the Hamiltonian except the signs are all positive. Now using $D^0\phi^a=0$, $F^a_{0i}=C(D_i\phi_a)$, and $F^a_{ij}=\sqrt{A^2-C^2}\epsilon_{ijk}D^k\phi^a$, the energy becomes

$$E=A^2\int d^3xD_i\phi^aD^i\phi^a=\frac{A^2}{A^2-C^2}\int d^3xB^a_iB^{ia}, \quad (26)$$

where the Bogomolny equations ($B^a_i=\sqrt{A^2-C^2}D_i\phi^a$) were used to obtain the last expression. The constant A is the multiplicative factor that we put in front of the scalar fields in order that we could easily examine the case when there were no scalar fields by taking $A=0$. From Eq. (26) it can be seen that for this special case the energy in the fields of the Kerr-like solution is zero. In addition when $A=0$ either the time components or the space components of the gauge fields are pure imaginary. These results were the same for the Schwarzschild Yang–Mills solution, and we believe that this calls into question the physical relevance of the pure gauge case even though it is mathematically a solution. Taking this view then requires the presence of a scalar field in order to get a physically ''reasonable'' solution. The angular momentum of the field configuration is given by

$$L_i=\int d^3x\epsilon_{ijk}x^jT^{0k}. \quad (27)$$

Using the expression for $T^{\mu\nu}$ from Eq. (24), the condition $F^a_{0i}=C(D_i\phi^a)$, and the Bogomolny field equations, Eq. (6), we find

$$T^{0k}=\epsilon^{klm}C\sqrt{A^2-C^2}(D_l\phi^a)(D_m\phi^a). \quad (28)$$

The antisymmetry of ϵ^{klm} makes $T^{0k}=0$, so that there is no angular momentum in this non-Abelian field configuration. This shows that while our Yang–Mills solution is similar in many ways to its general relativistic counterpart, there are some important distinctions. Part of the reason for this stems from the fact that the symmetries of general relativity are space-time symmetries, while those of Yang–Mills theories are internal Lie symmetries. These differences showed up even in the Yang–Mills Schwarzschild-like solution where the sphere singularity was a true singularity, while for general relativity the event horizon is a coordinate singularity, as can be seen by looking at the Schwarzschild solution in Kruskal coordinates.

Finally, one may wonder if the singularities of our Kerr-like solution might not be gauge artifacts. For example, Arafune *et al.*[10] have shown that the 't Hooft–Polyakov monopole can be formulated either with singularity-free gauge fields and a ''hedgehog'' configuration scalar field, or with gauge fields with a Dirac string singularity and a scalar field in an ''Abelian'' gauge. These two formulations are connected via a singular gauge transformation. In order to show that the singularities of the Kerr-like solution are real features of the solution rather than gauge artifacts one needs to show that these singularities occur in a gauge invariant quantity. (In a certain respect it would be better if these singularities where gauge artifacts, since—leaving aside the speculation about the possible connection to the confinement phenomenon—field configurations with true singularities are often considered unphysical. Even in such cases as the Coulomb potential of electrodynamics one usually expects that the singularity is an unphysical feature.) To show that the singularities are a real feature of the Kerr-like solution one can consider the gauge invariant field energy density, which is the integrand of Eq. (26). To obtain the explicit expressions for $D_i\phi^a$ or B^a_i, which are necessary to obtain the energy density in Eq. (26), one inserts the

solutions of Eq. (19) into Eq. (8) [the left-hand side of Eq. (8) gives $D_i\phi^a$ while the right-hand side gives B_i^a]. Again considering the special case when $p=1$, $q=0$, $A=1$, and $C=0$ [where the magnetic fields are given by Eq. (23)], one finds that the field energy density in the integrand of Eq. (26) becomes

$$B_i^a B^{ia} = B_z^2 + B_\rho^2 = \frac{4(x^2 - y^2 + 3x^2y^2 + y^4)}{k^4(x^2 - y^2)^4}. \tag{29}$$

Thus the energy density develops a singularity at $x = \pm y$, and the total field energy becomes infinite if one integrates through these singularities. The general case when $p,q \neq 0$ follows in the same way, but the final expressions for the energy density are extremely long and cumbersome. In the general case one also finds singularities in the gauge invariant energy density at the locations of the gauge field singularities. A computationally simplier method of showing the gauge invariant nature of the singularities is to examine the length of the Higgs field, $\mathbf{\Phi}_a^\dagger \mathbf{\Phi}_a = \phi_1^2 + \phi_2^2$. In order to calculate this gauge invariant quantity one simply squares ϕ_1 and ϕ_2 from Eq. (19) and takes their sum. This involves much less work than is necessary to obtain the energy density, where one must not only take products of the various fields, but also compute their derivatives with respect to ρ and z. Once the general expression for $\mathbf{\Phi}_a^\dagger \mathbf{\Phi}_a$ is found, one imposes the condition $p^2x^2 + q^2y^2 - 1 = 0$, which is where the gauge and scalar fields become singular. On doing this it is seen that the denominator of $\phi_1^2 + \phi_2^2$ goes to zero while the numerator remains finite. Thus the singularities in the fields of Eq. (19) also occur in the gauge invariant quantities, $\mathbf{\Phi}_a^\dagger \mathbf{\Phi}_a$ and the energy density.

III. DISCUSSION AND CONCLUSION

Extending our previous work on the Schwarzschild-like solution for Yang–Mills–Higgs theories, we have written down the Yang–Mills equivalent of the Kerr solution. By writing the Yang–Mills field equations in the form of the Ernst equation[12] of general relativity,[6] it is straightforward to use any known axially symmetric solution of general relativity to write down similar solutions in terms of the non-Abelian gauge fields. One disadvantage of these general relativistic inspired solutions is that they contain singularities in the fields, which lead to infinite field energies at the classical level. These singularities are of the same character as the singularities which are found in other classical field theory solutions such as the singularity at the origin in the normal Schwarzschild solution, the point singularity in the Wu–Yang solution for SU(2),[18] and the singularity at $r=0$ in the Coulomb potential in electromagnetism. Since our solutions are classical field theory solutions it may be conjectured, as is the case with general relativity, that a proper quantum treatment of the problem might modify these singularities. Fortunately, unlike the case of general relativity, there do exist methods for quantizing such classical solutions.[19,20] In one sense, however, these singularities (particularly the surface singularities) could be a desirable feature in that they may yield a possible confinement mechanism for non-Abelian gauge theories, which would be analogous to the confinement mechanism of general relativistic black holes. By treating these solutions as background fields in which test particles are placed via minimal coupling, one can show that these surface singularities act as impenetrable barriers to the test particle. This procedure was outlined in Refs. 4 and 16 where color charged test particles were placed in a spherically symmetric Yang–Mills field configuration, which had some of the characteristics of the Schwarzschild solution of general relativity. It was found that the wavefunction of the test particle was confined to the region around the origin, inside the spherical singular surface. The singular surfaces of the present axially symmetric solutions should also act as barriers when treated as a background potential.

While this semi-classical type of confinement is suggestive, and shares some common features with phenomenological bag models, it does have shortcomings. First, it ignores the interaction between the color field of the test particle and the field configuration in which it is placed. Since

the field equations of Yang–Mills theories are non-linear, one is not justified in using superposition, and the color field of the test particle could significantly alter the color field of the solution. Second, from a rigorous quantum field theory point of view the existence of singularities in the solutions implies that they will give an infinite action contribution to the path integral, which means that they should have no physical effect. This line of reasoning can be circumvented if there are an infinite set of neighboring solutions in function space whose infinite entropy contribution can offset the infinite action contribution. This in fact happens for the meron solutions considered in Ref. 17. Whether a similar thing occurs for the present solutions is not clear, although there are an infinite number of neighboring solutions which are found by varying the arbitrary parameters k and q.

The very direct link, via the Ernst equations, between general relativity and Yang–Mills–Higgs theories can be used to map over any of the known axially symmetric solutions from general relativity into non-Abelian gauge theories. In this paper we examined in detail only the Kerr solution in the hope of finding a field configuration, which contained an internal angular momentum, so that quantizing this angular momentum to $\hbar/2$ one would be able to have a fermion-like object from an initial theory with only gauge and scalar fields. Explicitly carrying out the calculation of the field angular momentum showed that even though the Kerr-like solution was axially symmetric, it did not carry any angular momentum in its fields. This shows that not all the features of the general relativistic solution carry over into Yang–Mills theory. So far we have used this parallel between the two theories to find solutions for Yang–Mills theories from the known solutions of general relativity. An interesting exercise might be to see if some of the exact solutions of Yang–Mills theory (e.g., the Prasad–Sommerfield solution or the multimonopole solutions)[9] could be used to give unknown exact solutions in general relativity.

Exact solutions of the Einstein equations with sources from linearized solutions

G. F. Torres del Castillo
Departamento de Física Matemática, Instituto de Ciencias de la Universidad Autónoma de Puebla, 72000 Puebla, Pue., México

(Received 25 January 1996; accepted for publication 21 March 1996)

It is shown that if $(g_{\mu\nu},F_{\mu\nu})$ is an exact solution of the Einstein–Maxwell equations and l_μ is a principal null direction of $F_{\mu\nu}$ then $(g_{\mu\nu}+2Hl_\mu l_\nu,F_{\mu\nu})$ is also an exact solution of the Einstein–Maxwell equations if and only if $(2Hl_\mu l_\nu,0)$ satisfies the Einstein–Maxwell equations linearized about $(g_{\mu\nu},F_{\mu\nu})$. It is also shown that an analogous result applies in the case of the Einstein–Weyl equations if l_μ is parallel to the flux vector of the neutrino field. © *1996 American Institute of Physics.* [S0022-2488(96)00508-7]

I. INTRODUCTION

It is known that, despite the nonlinear nature of the Einstein field equations, there exist classes of metrics (e.g., those of the Kerr–Schild form[1]) for which the Einstein equations, written in an appropriate basis, reduce to linear differential equations (see also Refs. 2–4). A general result, obtained by Xanthopoulos,[5] states that if $g_{\mu\nu}$ is an exact solution of the Einstein vacuum field equations and l_μ is a null vector, then $g_{\mu\nu}+l_\mu l_\nu$ is also an exact vacuum solution, provided that $l_\mu l_\nu$ satisfies the Einstein vacuum field equations linearized about $g_{\mu\nu}$. The occurrence of linear equations only, simplifies the search for explicit solutions and allows the superposition of solutions.

The aim of this paper is to present a generalization of the Xanthopoulos theorem,[5] showing that if $g_{\mu\nu}$ satisfies the Einstein field equations with an electromagnetic or a neutrino field and l_μ is a principal null direction of the matter field, then $g_{\mu\nu}+l_\mu l_\nu$ is also an exact solution of the Einstein equations with the *same* matter field if and only if the metric perturbation $l_\mu l_\nu$ satisfies the Einstein field equations linearized about the background solution corresponding to $g_{\mu\nu}$. The proof consists of introducing a null tetrad for the perturbed metric related in a simple way with a null tetrad for the background metric and expressing the Einstein equations in these tetrads. We find that, with the assumed alignment of l_μ to the matter field, the Einstein equations only contain linear terms in the metric perturbation. The formulas obtained in the proof of our main result are also useful in the search for metric perturbations and a simple example is also given here. Throughout this paper we make use of the Newman–Penrose notation.[6]

II. THE FIELD EQUATIONS

We shall consider two metrics, $g_{\mu\nu}$ and $\widetilde{g}_{\mu\nu}$, related according to

$$\widetilde{g}_{\mu\nu}=g_{\mu\nu}+2Hl_\mu l_\nu, \tag{1}$$

where H is a real function and l_μ is a null vector with respect to the metric $g_{\mu\nu}$. When $g_{\mu\nu}$ is flat, $\widetilde{g}_{\mu\nu}$ is said to have a Kerr–Schild form. If l^μ, n^μ, m^μ, and $\overline{m^\mu}$ form a null tetrad for the metric $g_{\mu\nu}$, with $l^\mu:=g^{\mu\nu}l_\nu$, then it follows from Eq. (1) that

$$\widetilde{l}^\mu:=l^\mu,\quad \widetilde{n}^\mu:=n^\mu-Hl^\mu,\quad \widetilde{m}^\mu:=m^\mu,\quad \widetilde{\overline{m^\mu}}:=\overline{m^\mu}, \tag{2}$$

or, equivalently,

0022-2488/96/37(9)/4584/6/$10.00

$$\widetilde{D}:=D,\quad \widetilde{\Delta}:=\Delta-HD,\quad \widetilde{\delta}:=\delta,\quad \widetilde{\overline{\delta}}:=\overline{\delta}, \tag{3}$$

is a null tetrad for the metric $\widetilde{g}_{\mu\nu}$. (Note that l^μ is also null with respect to the metric $\widetilde{g}_{\mu\nu}$ and that $\widetilde{\overline{\delta}}=\overline{\widetilde{\delta}}$.)

The spin coefficients for the tetrad $\widetilde{D}$, $\widetilde{\Delta}$, $\widetilde{\delta}$, $\widetilde{\overline{\delta}}$ can be related with those corresponding to the tetrad D, Δ, δ, $\overline{\delta}$ by calculating the Lie brackets $[\widetilde{\Delta},\widetilde{D}]$, $[\widetilde{\delta},\widetilde{D}]$, $[\widetilde{\delta},\widetilde{\Delta}]$, and $[\widetilde{\delta},\widetilde{\overline{\delta}}]$. For instance,

$$[\widetilde{\Delta},\widetilde{D}]=[\Delta-HD,D]=[\Delta,D]+(DH)D=(\gamma+\overline{\gamma})D+(\epsilon+\overline{\epsilon})\Delta-(\overline{\tau}+\pi)\delta-(\tau+\overline{\pi})\overline{\delta}+(DH)D$$
$$=(\gamma+\overline{\gamma}+DH+(\epsilon+\overline{\epsilon})H)\widetilde{D}+(\epsilon+\overline{\epsilon})\widetilde{\Delta}-(\overline{\tau}+\pi)\widetilde{\delta}-(\tau+\overline{\pi})\widetilde{\overline{\delta}},$$

which must be equal to

$$(\widetilde{\gamma}+\overline{\widetilde{\gamma}})\widetilde{D}+(\widetilde{\epsilon}+\overline{\widetilde{\epsilon}})\widetilde{\Delta}-(\overline{\widetilde{\tau}}+\widetilde{\pi})\widetilde{\delta}-(\widetilde{\tau}+\overline{\widetilde{\pi}})\widetilde{\overline{\delta}}.$$

In this manner, one readily finds that

$$\widetilde{\kappa}=\kappa,\quad \widetilde{\sigma}=\sigma,\quad \widetilde{\rho}=\rho,\quad \widetilde{\tau}=\tau,\quad \widetilde{\epsilon}=\epsilon,\quad \widetilde{\pi}=\pi,$$
$$\widetilde{\alpha}=\alpha+\tfrac{1}{2}\overline{\kappa}H,\quad \widetilde{\beta}=\beta+\tfrac{1}{2}\kappa H,\quad \widetilde{\gamma}=\gamma+\tfrac{1}{2}(D+2\overline{\epsilon}+\rho-\overline{\rho})H, \tag{4}$$
$$\widetilde{\mu}=\mu+\rho H,\quad \widetilde{\lambda}=\lambda+\overline{\sigma}H,\quad \widetilde{\nu}=\nu+(\overline{\delta}+2\alpha+2\overline{\beta}-\pi-\overline{\tau})H+\overline{\kappa}H^2.$$

Making use of Eqs. (3) and (4), from the Ricci identities we find that the components of the curvature of the metric $\widetilde{g}_{\mu\nu}$, with respect to the null tetrad $\widetilde{D}$, $\widetilde{\Delta}$, $\widetilde{\delta}$, $\widetilde{\overline{\delta}}$, are related to the components of the curvature of $g_{\mu\nu}$, with respect to the null tetrad D, Δ, δ, $\overline{\delta}$, by

$$\widetilde{\Phi}_{00}=\Phi_{00}+2\overline{\kappa}\kappa H,$$
$$\widetilde{\Phi}_{01}=\Phi_{01}+\tfrac{1}{2}\{H\,D\kappa+\kappa(2D+\epsilon+3\overline{\epsilon}-\rho)H+\overline{\kappa}\sigma H\},$$
$$\widetilde{\Phi}_{02}=\Phi_{02}+(D-\epsilon+3\overline{\epsilon}-2\overline{\rho})\sigma H+\kappa(\delta+2\beta+2\overline{\alpha}-\tau-\overline{\pi})H+\kappa^2H^2,$$
$$2\widetilde{\Phi}_{11}=2\Phi_{11}+\tfrac{1}{2}(D+\epsilon+\overline{\epsilon}-\rho+\overline{\rho})(D+2\epsilon+2\overline{\epsilon}+\rho-\overline{\rho})H-(\rho^2-\overline{\sigma}\sigma)H \tag{5}$$
$$+(\text{linear operators acting on }\kappa\text{ or }\overline{\kappa}),$$
$$\widetilde{\Phi}_{12}=\Phi_{12}+\tfrac{1}{2}(\delta+\beta+\overline{\alpha}-\tau)(D+2\overline{\epsilon}+\rho-\overline{\rho})H+\epsilon(\delta+2\beta+2\overline{\alpha}-\tau-\overline{\pi})H+\sigma(\overline{\delta}+\alpha+2\overline{\beta}-\pi$$
$$-\overline{\tau})H+H(D-\epsilon+\overline{\epsilon}-\overline{\rho})\beta-\tau\rho H+(\text{linear operators acting on }\kappa\text{ or }\overline{\kappa}),$$
$$\widetilde{\Phi}_{22}=\Phi_{22}+\Phi_{00}H^2+(\delta+3\beta+\overline{\alpha}-\tau)(\overline{\delta}+2\alpha+2\overline{\beta}-\pi-\overline{\tau})H-(\Delta+\gamma+\overline{\gamma}+\mu)\rho H$$
$$-\mu(D+\epsilon+\overline{\epsilon}+\rho)H+HD\mu-(\lambda\sigma+\overline{\lambda\sigma})H+\pi(\delta+2\beta+2\overline{\alpha}-\tau-\overline{\pi})H$$
$$+(\text{linear operators acting on }\kappa\text{ or }\overline{\kappa}),$$

together with

$$6\widetilde{\Lambda}=6\Lambda-\tfrac{1}{2}(D+\epsilon+\overline{\epsilon}+\rho-\overline{\rho})(D+2\epsilon+2\overline{\epsilon}+\rho-\overline{\rho})H+2(D+\epsilon+\overline{\epsilon}-\overline{\rho})\rho H-(\rho^2+\overline{\sigma}\sigma)H$$
$$+(\text{linear operators acting on }\kappa\text{ or }\overline{\kappa}), \tag{6}$$

and

$$
\begin{aligned}
\widetilde{\Psi}_0 &= \Psi_0 + 2\kappa^2 H,\\
\widetilde{\Psi}_1 &= \Psi_1 + \tfrac{1}{2}\{HD\kappa + \kappa(2D + \epsilon + 3\overline{\epsilon} + 3\rho - 2\overline{\rho})H - \overline{\kappa\sigma}H\},\\
3\widetilde{\Psi}_2 &= 3\Psi_2 + \tfrac{1}{2}(D + \epsilon + \overline{\epsilon} + \rho - \overline{\rho})(D + 2\epsilon + 2\overline{\epsilon} + 3\rho - \overline{\rho})H - 2\overline{\sigma}\sigma H\\
&\quad + (\text{linear operators acting on } \kappa \text{ or } \overline{\kappa}),\\
\widetilde{\Psi}_3 &= \Psi_3 + \tfrac{1}{2}(\overline{\delta} + \alpha + \overline{\beta} - \overline{\tau})(D + 2\overline{\epsilon} + \rho - \overline{\rho})H + (\rho + \epsilon)(\overline{\delta} + 2\alpha + 2\overline{\beta} - \pi - \overline{\tau})H\\
&\quad + H(D + \epsilon - \overline{\epsilon} - \rho)\alpha - \overline{\sigma}(\beta + \tau)H + (\text{linear operators acting on } \kappa \text{ or } \overline{\kappa}),\\
\widetilde{\Psi}_4 &= \Psi_4 + (\overline{\delta} + 3\alpha + \overline{\beta} + \pi - \overline{\tau})(\overline{\delta} + 2\alpha + 2\overline{\beta} - \pi - \overline{\tau})H - (\Delta + 3\gamma - \overline{\gamma} + \mu + \overline{\mu})\overline{\sigma}H - (\lambda + \overline{\sigma}H)\\
&\quad \times (D - \epsilon + 3\overline{\epsilon} + 3\rho - \overline{\rho})H + HD(\lambda + \overline{\sigma}H) + (\text{linear operators acting on } \kappa \text{ or } \overline{\kappa}).
\end{aligned}
\tag{7}
$$

[Equations (1)–(7) are invariant under the simultaneous interchange of the tilded quantities by the untilded ones, and of H by $-H$.]

Before we consider the Einstein equations with sources, we shall give a proof of the Xanthopoulos theorem,[5] allowing the presence of a nonzero cosmological constant.

A. Vacuum case

If $g_{\mu\nu}$ and $\widetilde{g}_{\mu\nu}$ satisfy the Einstein vacuum field equations, possibly with (different) nonzero cosmological constants λ_0 and $\widetilde{\lambda}_0$, respectively, from the first equation in (5) it follows that $\kappa=0$ (excluding the trivial case $H=0$), which means that l^μ is geodetic. Then, setting $\widetilde{\Phi}_{ij}=0=\Phi_{ij}$, $6\Lambda=\lambda_0$, $6\widetilde{\Lambda}=\widetilde{\lambda}_0$, and $\kappa=0$ in Eqs. (5) and (6), the quadratic terms in H disappear, and one obtains

$$
\begin{aligned}
&\kappa = 0,\\
&(D - \epsilon + 3\overline{\epsilon} - 2\overline{\rho})\sigma H = 0,\\
&\tfrac{1}{2}(D + \epsilon + \overline{\epsilon} - \rho + \overline{\rho})(D + 2\epsilon + 2\overline{\epsilon} + \rho - \overline{\rho})H - (\rho^2 - \overline{\sigma}\sigma)H = 0,\\
&\tfrac{1}{2}(\delta + \beta + \overline{\alpha} - \tau)(D + 2\overline{\epsilon} + \rho - \overline{\rho})H + \epsilon(\delta + 2\beta + 2\overline{\alpha} - \tau - \overline{\pi})H\\
&\quad + \sigma(\overline{\delta} + \alpha + 2\overline{\beta} - \pi - \overline{\tau})H + H(D - \epsilon + \overline{\epsilon} - \overline{\rho})\beta - \tau\rho H = 0,\\
&(\delta + 3\beta + \overline{\alpha} - \tau)(\overline{\delta} + 2\alpha + 2\overline{\beta} - \pi - \overline{\tau})H - (\Delta + \gamma + \overline{\gamma} + \mu)\rho H\\
&\quad - \mu(D + \epsilon + \overline{\epsilon} + \rho)H + HD\mu + \pi(\delta + 2\beta + 2\overline{\alpha} - \tau - \overline{\pi})H - (\lambda\sigma + \overline{\lambda}\overline{\sigma})H = 0,\\
&\tfrac{1}{2}(D + \epsilon + \overline{\epsilon} + \rho - \overline{\rho})(D + 2\epsilon + 2\overline{\epsilon} + \rho - \overline{\rho})H - 2(D + \epsilon + \overline{\epsilon} - \overline{\rho})\rho H\\
&\quad + (\rho^2 + \overline{\sigma}\sigma)H = \lambda_0 - \widetilde{\lambda}_0,
\end{aligned}
\tag{8}
$$

which means that $h_{\mu\nu} := 2Hl_\mu l_\nu$ satisfies the Einstein vacuum field equations linearized about $g_{\mu\nu}$.

Conversely, if $2Hl_\mu l_\nu$ satisfies the linearized Einstein vacuum field equations, with or without cosmological constant, Eqs. (8) are fulfilled; then, assuming that $g_{\mu\nu}$ satisfies the Einstein vacuum field equations with or without a cosmological constant (i.e., $\Phi_{ij}=0$, $6\Lambda=\lambda_0$), Eqs. (5) and (6) yield $\widetilde{\Phi}_{ij}=0$, $\widetilde{\Lambda}=$const, which means that $\widetilde{g}_{\mu\nu}$ is also an exact vacuum solution.

If $g_{\mu\nu}$ and $\tilde{g}_{\mu\nu}$ are exact vacuum solutions, from Eqs. (7) it follows that l^μ is a principal null direction of the Weyl tensor of $g_{\mu\nu}$ if and only if it is a principal null direction of the Weyl tensor of $\tilde{g}_{\mu\nu}$ (compare Ref. 5), and that l^μ is a double principal null direction of the Weyl tensor of $g_{\mu\nu}$ if and only if is a double principal null direction of the Weyl tensor of $\tilde{g}_{\mu\nu}$. (Note that these conclusions apply whenever $\tilde{\Phi}_{\mu\nu}l^\mu l^\nu=\Phi_{\mu\nu}l^\mu l^\nu$.)

B. Einstein–Maxwell case

Let $F_{\mu\nu}$ be an electromagnetic field that satisfies the source-free Maxwell equations in the background metric $g_{\mu\nu}$, such that l^μ is a principal null direction of $F_{\mu\nu}$. This means that

$$\varphi_0=0, \tag{9}$$

and the remaining components of $F_{\mu\nu}$ satisfy the equations

$$\begin{gathered}(D-2\rho)\varphi_1+\kappa\varphi_2=0, \quad (\delta-2\tau)\varphi_1+\sigma\varphi_2=0,\\ (\overline{\delta}+2\pi)\varphi_1-(D+2\epsilon-\rho)\varphi_2=0,\\ (\Delta+2\mu)\varphi_1-(\delta+2\beta-\tau)\varphi_2=0.\end{gathered} \tag{10}$$

From Eqs. (2) and (9) it follows that the components of $F_{\mu\nu}$ with respect to the tetrad $\tilde{l}^\mu$, $\tilde{n}^\mu$, $\tilde{m}^\mu$, $\overline{\tilde{m}^\mu}$ are given by

$$\tilde{\varphi}_0=0, \quad \tilde{\varphi}_1=\varphi_1, \quad \tilde{\varphi}_2=\varphi_2. \tag{11}$$

Then, using Eqs. (3), (4), (10), and (11) one finds that $F_{\mu\nu}$ also satisfies the source-free Maxwell equations in the background metric $\tilde{g}_{\mu\nu}$ if and only if

$$\kappa\varphi_2=0. \tag{12}$$

(An alternative proof of this fact can be given using the connection tensor that relates the covariant derivative operators $\boldsymbol{\nabla}_\mu$ and $\tilde{\boldsymbol{\nabla}}_\mu$, as in Ref. 5.)

If $(g_{\mu\nu},F_{\mu\nu})$ and $(\tilde{g}_{\mu\nu},F_{\mu\nu})$ are exact solutions of the Einstein–Maxwell equations (possibly with nonzero cosmological constants), with l^μ being a principal null direction of $F_{\mu\nu}$, using the fact that $\Phi_{ij}=2\varphi_i\overline{\varphi_j}$ $(i,j=0,1,2)$ and Eqs. (5), (9), and (11), it follows that $\kappa=0$ and all the nonlinear terms in H contained in Eqs. (5) and (6) disappear. Hence, $(2Hl_\mu l_\nu,0)$ satisfies the Einstein–Maxwell equations linearized about $(g_{\mu\nu},F_{\mu\nu})$. It must be noticed that the equalities $\Phi_{ij}=\tilde{\Phi}_{ij}$, which follow from Eq. (11), *do not* mean that the energy-momentum tensors of the electromagnetic field $F_{\mu\nu}$ in the backgrounds $g_{\mu\nu}$ and $\tilde{g}_{\mu\nu}$ necessarily coincide. Even though $F_{\mu\nu}$ is left unchanged, the energy-momentum tensors of $F_{\mu\nu}$ in the backgrounds $g_{\mu\nu}$ and $\tilde{g}_{\mu\nu}$ may be different, owing to the presence of the metric in the expression for the energy-momentum tensor of the electromagnetic field.

Conversely, if $(g_{\mu\nu},F_{\mu\nu})$ is an exact solution of the Einstein–Maxwell equations and $(2Hl_\mu l_\nu,0)$ satisfies the Einstein–Maxwell equations linearized about $(g_{\mu\nu},F_{\mu\nu})$, with l_μ being a principal null direction of $F_{\mu\nu}$ [Eqs. (8)], then $(\tilde{g}_{\mu\nu},F_{\mu\nu})$ is an exact solution of the Einstein–Maxwell equations.

C. Einstein–Weyl case

Let η_A be a spinor field that satisfies the Weyl neutrino equation in the background metric $g_{\mu\nu}$, such that the flux vector of the neutrino field is proportional to l^μ; thus,

$$\eta_0=0 \tag{13}$$

and the Weyl equation reduces to

$$(D+\epsilon-\rho)\,\eta_1=0, \quad (\delta+\beta-\tau)\,\eta_1=0. \tag{14}$$

The components of the neutrino field with respect to the null tetrad $\tilde{l}^\mu$, $\tilde{n}^\mu$, $\tilde{m}^\mu$, $\overline{\tilde{m}^\mu}$ are given by

$$\tilde{\eta}_0=0, \quad \tilde{\eta}_1=\eta_1 \tag{15}$$

[i.e., the tensorial objects (the ''flags'') defined by the components (15) with respect to the corresponding tetrads coincide] and from Eqs. (3), (4), and (14) it follows that η_A also satisfies the Weyl equation in the background metric $\tilde{g}_{\mu\nu}$.

The tetrad components of the Einstein field equations with a neutrino field such that $\eta_0=0$, are explicitly given by

$$\begin{gathered}
\Phi_{00}=0, \quad \Phi_{01}=-ik\kappa\overline{\eta_1}\eta_1, \quad \Phi_{02}=-2ik\sigma\overline{\eta_1}\eta_1, \\
\Phi_{11}=ik[\eta_1 D\overline{\eta_1}-\overline{\eta_1}D\eta_1+(\overline{\epsilon}-\epsilon)\overline{\eta_1}\eta_1], \\
\Phi_{12}=ik[\eta_1 \delta\overline{\eta_1}-\overline{\eta_1}\delta\eta_1+(\overline{\alpha}-\beta-\tau)\overline{\eta_1}\eta_1], \\
\Phi_{22}=2ik[\eta_1 \Delta\overline{\eta_1}-\overline{\eta_1}\Delta\eta_1+(\overline{\gamma}-\gamma)\overline{\eta_1}\eta_1], \\
\Lambda=0,
\end{gathered} \tag{16}$$

where k is a real constant. Making use of Eqs. (3), (4), (14), and (15) one finds that the right-hand sides of Eqs. (16) are left unchanged by the substitution of $g_{\mu\nu}$ by $\tilde{g}_{\mu\nu}$. Therefore, if $(g_{\mu\nu},\eta_A)$ and $(\tilde{g}_{\mu\nu},\eta_A)$ are exact solutions of the Einstein–Weyl equations (possibly with nonzero cosmological constants), with l^μ being parallel to the flux vector of the neutrino field, from Eqs. (5) and (16), it follows that $\kappa=0$ and, again, the nonlinear terms in H contained in Eqs. (5) and (6) disappear, which means that $(2Hl_\mu l_\nu,0)$ satisfies the Einstein–Weyl equations linearized about $(g_{\mu\nu},\eta_A)$.

It is easy to see that, conversely, if $(g_{\mu\nu},\eta_A)$ is an exact solution of the Einstein–Weyl equations and $(2Hl_\mu l_\nu,0)$ satisfies the Einstein–Weyl equations linearized about $(g_{\mu\nu},\eta_A)$, with l_μ being parallel to the flux vector of the neutrino field, then $(g_{\mu\nu}+2Hl_\mu l_\nu,\eta_A)$ is also an exact solution of the Einstein–Weyl equations.

D. An example

The Bell–Szekeres solution represents the collision of two plane electromagnetic waves. In each region before the collision, the space-time can be described by the null tetrad,[7]

$$\begin{gathered}
D=-\frac{1}{\sqrt{2}}\,\partial_u, \quad \Delta=-\frac{1}{\sqrt{2}}\,(1-v^2)^{1/2}\partial_v, \\
\delta=(1-v^2)^{-1/2}\partial_z, \quad \overline{\delta}=(1-v^2)^{-1/2}\partial_{\overline{z}},
\end{gathered} \tag{17}$$

where u and v are real coordinates, z is a complex coordinate, and $\overline{z}$ denotes its complex conjugate. The only nonvanishing spin coefficient is

$$\mu=\frac{1}{\sqrt{2}}\,(1-v^2)^{-1/2}v, \tag{18}$$

and the only nonvanishing component of the curvature is

$$\Phi_{22}=\tfrac{1}{2}. \tag{19}$$

Therefore, the electromagnetic field can be taken as

$$\varphi_0=0=\varphi_1, \quad \varphi_2=\tfrac{1}{2}. \tag{20}$$

Since Eqs. (9) and (12) are satisfied, making use of Eqs. (17) and (18), one finds that the perturbed metric $\tilde{g}_{\mu\nu}$ with the electromagnetic field given by Eq. (20) is a solution of the Einstein–Maxwell equations, provided that the function H satisfies Eqs. (8), which reduce to

$$\partial_u^2 H=0, \quad \partial_z\,\partial_u H=0, \quad 2\partial_z\,\partial_{\bar{z}} H+v\sqrt{1-v^2}\,\partial_u H=0. \tag{21}$$

Thus,

$$H=uf(v)-\tfrac{1}{2}\,v\sqrt{1-v^2}f(v)z\overline{z}+g(z,v)+\overline{g(z,v)}, \tag{22}$$

where f is an arbitrary real function and g is an arbitrary function of two variables. Then, from Eqs. (7), it follows that $\tilde{g}_{\mu\nu}$ is of type N or conformally flat.

III. DISCUSSION

The validity of the results presented in this paper depends crucially on the insensitivity of the Maxwell and the Weyl equations to the change of the background metric $g_{\mu\nu}$ by $g_{\mu\nu}+2Hl_\mu l_\nu$ if l_μ is a principal null direction of the electromagnetic or the neutrino field, respectively, which allows us to consider metric perturbations alone (see also Ref. 4). Thus, not only it is possible to consider gravitational perturbations without perturbing the matter field, but they may correspond to exact solutions.

The results of Sec. II B can also be derived, albeit by lengthier computations, making use of the tensor formalism, as in Ref. 5. However, the null tetrad formalism employed here allows us to treat also the Einstein–Weyl equations very easily. It may be pointed out that the perturbation equations (8) possess the gauge freedom corresponding to the null tetrad rotations that preserve the direction of l^μ.

Another remarkable fact is that, owing to the invariance of Eqs. (1)–(7) under the interchange of H by $-H$ and of the tilded quantities by the untilded ones, in the perturbation equations (8), one can equivalently substitute either the tetrad and spin coefficients corresponding to $g_{\mu\nu}$ or to $\tilde{g}_{\mu\nu}$.

Irreducible tensor operators in the regular coaction formalisms of compact quantum group algebras

J. F. Cornwell
School of Physics and Astronomy, University of St. Andrews, North Haugh, St. Andrews, Fife, KY16 9SS, Scotland, United Kingdom

(Received 9 August 1995; accepted for publication 25 April 1996)

The defining conditions for the irreducible tensor operators associated with the unitary irreducible corepresentations of compact quantum group algebras are deduced first in both the right and left regular coaction formalisms. In each case it is shown that there are *two* types of irreducible tensor operator, which may be called ''ordinary'' and ''twisted.'' The consistency of the definitions is demonstrated, and various consequences are deduced, including generalizations of the Wigner–Eckart theorem for both the ordinary and twisted operators. Also included are discussions (within the regular coaction formalisms for compact quantum group algebras) of inner-products, basis functions, projection operators, Clebsch–Gordan coefficients, and two types of tensor product of corepresentations. The formulation of quantum homogeneous spaces for compact quantum group algebras is discussed, and the defining conditions for the irreducible tensor operators associated with such quantum homogeneous spaces and with the unitary irreducible corepresentations of the compact quantum group algebras are then deduced. There are two versions, which correspond to restrictions of the right and left regular coactions. In each case it is again shown that there are ordinary and twisted irreducible tensor operators. Various consequences are deduced, including the corresponding generalizations of the Wigner–Eckart theorem.

I. INTRODUCTION

It is well known that most of the applications to physics of the theories of groups and Lie algebras depend on the Wigner–Eckart theorem. It is therefore not surprising that the question of the generalization of this theorem to Hopf algebras having the structure of a deformation of a Lie algebra has also been the subject of a number of studies.[1–15] The present paper is intended to complement and extend these investigations in various important respects. Its detailed relationship to previous work will be indicated in the appropriate places.

The perspective of the present communication is best introduced by considering matters first in the very well established and familiar context of a compact Lie group $\mathscr{G}$ (cf. Refs. 16,17). Even in this context, one can distinguish *three* distinct forms of the Wigner–Eckart theorem.

1. The original form[18] involves the situation in which $\mathscr{G}$ is a group of transformations that act on an external manifold $\mathscr{M}$, the classic example being the case in which $\mathscr{M}$ is three-dimensional Euclidean space $\mathfrak{R}^3$, and $\mathscr{G}$ is the group of all rotations in this space about some fixed point, which may be taken to be the origin O of $\mathfrak{R}^3$. Associated with every such rotation T there exists a 3×3 real orthogonal matrix $\mathbf{R}(T)$, so that the effect of T is to transform each position vector $\mathbf{r}$ into another position vector $\mathbf{r}'$, where

$$\mathbf{r}' = \mathbf{R}(T)\mathbf{r}. \tag{1}$$

Also associated with every rotation T is a unitary operator $P(T)$ whose effect on any function $f(\mathbf{r})$ is defined by

0022-2488/96/37(9)/4590/45/$10.00

$$P(T)f(\mathbf{r})=f[\mathbf{R}(T)^{-1}\mathbf{r}]). \tag{2}$$

Let $\mathbf{\Gamma}^p$ be a unitary irreducible representation of dimension d_p of the group $\mathcal{G}$. If there exists a set of functions $\psi_1^p(\mathbf{r}),\psi_2^p(\mathbf{r}),\ldots,\psi_{d_p}^p(\mathbf{r})$ such that

$$P(T)\psi_n^p(\mathbf{r})=\sum_{m=1}^{d_p}\Gamma^p(T)_{mn}\psi_m^p(\mathbf{r}), \tag{3}$$

for all $T\in\mathcal{G}$ and all $n=1,2,\ldots,d_p$, then these are said to form a set of basis functions for $\mathbf{\Gamma}^p$. Similarly, if there exists a set of d_p operators $Q_1^p,Q_2^p,\ldots,Q_{d_p}^p$ that act on functions $f(\mathbf{r})$ in such a way that

$$P(T)Q_n^pP(T)^{-1}=\sum_{m=1}^{d_p}\Gamma^p(T)_{mn}Q_m^p, \tag{4}$$

for all $T\in\mathcal{G}$ and all $n=1,2,\ldots,d_p$, then these are said to form a set of irreducible tensor operators for $\mathbf{\Gamma}^p$. Finally, if the inner product for the Hilbert space of functions $f(\mathbf{r})$ is defined by

$$(f,g)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\overline{f(\mathbf{r})}\,dx\,dy\,dz, \tag{5}$$

where $\overline{f(\mathbf{r})}$ denotes the complex conjugate of $f(\mathbf{r})$, then the Wigner–Eckart theorem for this situation states that the j,k, and ℓ dependence of $[\psi_\ell^r,Q_k^q(\phi_j^p)]$ depends only on Clebsch–Gordan coefficients for the reduction of the tensor product $\mathbf{\Gamma}^p\otimes\mathbf{\Gamma}^q$ into its irreducible constituents $\mathbf{\Gamma}^r$.

2. In this form the role of the manifold $\mathcal{M}$ is played by $\mathcal{G}$ itself, so that one is concerned with the space of complex-valued continuous functions defined on $\mathcal{G}$. Let this be denoted by $C(\mathcal{G})$. The inner product of $C(\mathcal{G})$ may be taken to be

$$(f,g)=\int_{\mathcal{G}}\overline{f(T)}g(T)\,dT, \tag{6}$$

where the integral is the left and right invariant normalized Haar integral of $\mathcal{G}$, and $\overline{f(T)}$ is the complex conjugate of $f(T)$. In the *right regular formalism*, for each $T\in\mathcal{G}$ there exists an operator $\hat{R}(T)$ that is defined by $\hat{R}(T)f(T')=f(T'T)$ for all f and for all $T,T'\in\mathcal{G}$. If f is a member of $C(\mathcal{G})$ such that $\hat{R}(T)f$ spans a finite- dimensional subspace of $C(\mathcal{G})$, then f is said to be a *representative function* on $\mathcal{G}$. The subspace of $C(\mathcal{G})$ consisting of representative functions will be denoted by $R(\mathcal{G})$. If there exists a set of functions $\psi_1^p(T),\psi_2^p(T),\ldots,\psi_{d_p}^p(T)$ such that $\hat{R}(T)\psi_n^p(T')=\Sigma_{m=1}^{d_q}\Gamma^p(T)_{mn}\psi_m^p(T')$ for all $T,T'\in\mathcal{G}$ and all $n=1,2,\ldots,d_p$, then these are said to form a set of basis functions for $\mathbf{\Gamma}^p$. Similarly, if there exists a set of d_p operators $Q_1^p,Q_2^p,\ldots,Q_{d_p}^p$ that act on functions $f(T)$ in such a way that $\hat{R}(T)Q_n^p\hat{R}(T)^{-1}=\Sigma_{m=1}^{d_q}\Gamma^p(T)_{mn}Q_m^p$ for all $T\in\mathcal{G}$ and all $n=1,2,\ldots,d_p$, then this set is said to form a set of irreducible tensor operators for $\mathbf{\Gamma}^p$. The Wigner–Eckart theorem for this case states that the j,k, and ℓ dependence of $[\psi_\ell^r,Q_k^q(\phi_j^p)]$ again depends only on Clebsch–Gordan coefficients for the reduction of the tensor product $\mathbf{\Gamma}^p\otimes\mathbf{\Gamma}^q$ into its irreducible constituents $\mathbf{\Gamma}^r$. In the *left regular formalism* the situation is the same, except only that the operators $\hat{R}(T)$ are replaced by operators $\hat{L}(T)$ that are defined by $\hat{L}(T)f(T')=f(T^{-1}T')$ for all f and for all $T,T'\in\mathcal{G}$.

3. The final form involves using the abstract carrier spaces of the unitary irreducible representations of $\mathcal{G}$. Let V^p be such a carrier space for $\mathbf{\Gamma}^p$, with ortho-normal basis $\psi_1^p,\psi_2^p,\ldots,\psi_{d_p}^p$, and define for each $T\in\mathcal{G}$ a linear operator $\Phi^p(T)$ that acts on V^p by the

requirement that $\Phi^p(T)\psi_n^p=\Sigma_{m=1}^{d_p}\Gamma^p(T)_{mn}\psi_m^p$ for all $T\in\mathscr{G}$ and all $n=1,2,\ldots,d_p$. Let $\mathbf{\Gamma}^p$, $\mathbf{\Gamma}^q$, and $\mathbf{\Gamma}^r$ be any three unitary irreducible resentations of $\mathscr{G}$. Then one can consider a set of irreducible tensor operators $Q_1^q,Q_2^q,\ldots,Q_{d_q}^q$ that each map V^p into V^r and which are such that $\Phi^r(T)Q_n^q\Phi^p(T)^{-1}=\Sigma_{m=1}^{d_q}\Gamma^q(T)_{mn}Q_m^q$ for all $T\in\mathscr{G}$ and all $n=1,2,\ldots,d_q$. In this case the Wigner–Eckart theorem deals with inner products $\langle,\rangle$ defined on V^r and states that the j,k, and ℓ dependence of $\langle\psi_\ell^r,Q_k^q(\phi_j^p)\rangle$ also depends only on Clebsch–Gordan coefficients for the reduction of the tensor product $\mathbf{\Gamma}^p\otimes\mathbf{\Gamma}^q$ into its irreducible constituents $\mathbf{\Gamma}^r$. In a minor extension of this formalism, one could introduce an inner product space V that is a direct sum of carrier spaces of certain unitary irreducible representations of $\mathscr{G}$ and which contains at least $V^p\oplus V^r$ (and which, in the extreme case, may contain one carrier space for every inequivalent irreducible representation of $\mathscr{G}$). Then, for each $T\in\mathscr{G}$ an operator $\Phi(T)$ can be defined which maps elements of V into V, and which acts as $\Phi^p(T)$ on V^p, as $\Phi^r(T)$ on V^r, and so on. The irreducible tensor operators are then required to each map V into V and to be such that $\Phi(T)Q_n^q\Phi(T)^{-1}=\Sigma_{m=1}^{d_q}\Gamma^q(T)_{mn}Q_m^q$ for all $T\in\mathscr{G}$ and all $n=1,2,\ldots,d_q$. In this case the Wigner–Eckart theorem deals with inner products $\langle,\rangle$ defined on V, but is otherwise the same as above.

The developments that will be described in the present paper up to and including Section VIII are essentially within the spirit of the second of these formulations, but deal with a more general Hopf algebra structure. The generalization of the first formulation in terms of quantum homogeneous spaces then follows in Section IX. (It is intended to extend this analysis to the remaining formulation in a subsequent paper.)

One most important lesson that can be drawn from these simple group theoretical considerations concerns the *consistency* of the definitions of the basis functions (or basis vectors) *and* of the irreducible tensor operators. The essential point will be illustrated in the first of the above formulations, but similar considerations apply in the others. As $P(T)P(T')=P(TT')$ and $\mathbf{\Gamma}^p(T)\mathbf{\Gamma}^p(T')=\mathbf{\Gamma}^p(TT')$ for all $T,T'\in\mathscr{G}$, it follows that if (3) is valid for T and for T', then it is also valid for their product TT'. Similarly, and very significantly, by defining for each $T\in\mathscr{G}$ an operator $\Psi(T)$ by $\Psi(T)Q=P(T)QP(T)^{-1}$ for every operator Q that acts on functions $f(\mathbf{r})$, the definition (4) can be recast as

$$\Psi(T)(Q_n^p)=\sum_{m=1}^{d_p}\Gamma^p(T)_{mn}Q_m^p, \tag{7}$$

for all $T\in\mathscr{G}$ and all $n=1,2,\ldots,d_p$. As $\Psi(T)\Psi(T')=\Psi(TT')$ for all $T,T'\in\mathscr{G}$, it follows that if (7) is valid for T and for T', then it is also valid for their product TT'. Put another way, because of the similarity in form between (3) and (7), the *consistency* of the definition (4) of the irreducible tensor operators Q_n^p is ensured by the fact that they too form a basis for a carrier space of $\mathbf{\Gamma}^p$. In the analysis that follows (cf. Section VI), essentially this argument will be used to justify the definitions that will be given for the irreducible tensor operators of the compact quantum group algebras in the regular corepresentation formalisms, the only essential difference being that the argument has to be cast in terms of *co*representations instead of representations.

It is well known that the set of functions defined on a Lie group $\mathscr{G}$ form a Hopf algebra, $\mathscr{A}$, and that the dual $\mathscr{A}'$ of $\mathscr{A}$ is the universal enveloping algebra of the Lie algebra $\mathscr{L}$ of $\mathscr{G}$. Moreover, the structure of $\mathscr{G}$ can be encoded into the structure of $\mathscr{A}$, and, in particular, $\mathscr{A}$ is commutative. A ''deformation'' (or ''quantization'') of $\mathscr{A}'$ induces a corresponding deformation of $\mathscr{A}$, and will make $\mathscr{A}$ non-commutative as well as being non-cocommutative. Most of the previous work on irreducible tensor operators has been focused on the deformed Hopf algebras $\mathscr{A}'$, with $su_q(2)$ receiving the most attention. However, as has been demonstrated by the pioneering work of Woronowicz,[19–21] which itself has been refined and developed by Dijkhuizen and Koornwinder,[22–26] it is of very great interest to produce a self-contained and direct study of

generalizations of the Hopf algebras $\mathscr{A}$, which can be done by assuming that they have certain characteristic properties. The resulting structures have been called *compact matrix pseudogroups* by Woronowicz,[19–21] and *compact quantum group algebras* by Dijkhuizen and Koornwinder.[22–26] These provide the framework for the present paper, which is devoted to the study of the irreducible tensor operators for compact quantum group algebras. As explained above, this analysis will be given in the regular corepresentation formalisms. [The only previous investigation of irreducible tensor operators within the general compact matrix pseudogroup theory has been by Bragiel,[5] who looked at the analogue of the carrier space formalism (3) above, but with certain restrictive assumptions on multiplicities, though some of the work of Klimyk[9] involves a discussion of special cases, again in the carrier space formalism.]

The structure of the present paper is as follows. Section II contains a brief summary of the essential preliminaries, starting in Section II A with the properties of Hopf *-algebras, and continuing in Section II B with the main features of their right comodules. The definition and relevant properties of a compact quantum group algebra $\mathscr{A}$ follow in Section II C. (Of course the developments of Woronowicz and of Dijkhuizen and Koornwinder extend far beyond what is mentioned here, particularly in their invocation of quantum Tannaka–Krein duality.) This section is concluded in Section II D with some new lemmas concerning the Haar functional of $\mathscr{A}$. The right and left regular comodules of $\mathscr{A}$ are described in Section III, and these are employed in Section IV to introduce and develop the concept of basis functions for right corepresentations of $\mathscr{A}$. In Section V the tensor products (both ''ordinary'' and ''twisted'') of corepresentations of $\mathscr{A}$ are discussed, along with their associated Clebsch–Gordan coefficients. The heart of the paper is reached in Section VI, where the irreducible tensor operators are defined and some of their immediate properties are deduced. In particular, it will be shown there that in both the right and left regular coaction formulations there are *two* types of irreducible tensor operators, which will be described as being *ordinary* and *twisted*, respectively. The motivations for the definitions of Section VI are deliberately relegated to Appendix B in order to emphasize that the treatment given for the compact quantum group algebras in Sections II to IX is entirely self-contained. In Section VII it is shown that there are *two* theorems of the Wigner–Eckart type, one for ''ordinary'' and one for the ''twisted'' irreducible tensor operators. Likewise, in Section VIII, it is demonstrated that these two types of irreducible tensor operator behave differently under multiplication. Finally, in Section IX it is shown how all developments generalize when one considers operators associated with the corresponding homogeneous spaces. In particular, it emerges that there are again two formulations, one associated with the right regular representation and the other with the left regular representation. The vital algebraic quantity that appears in each version is a $\star$-subalgebra $\mathscr{B}$ of $\mathscr{A}$, which is a right coideal of $\mathscr{A}$ in the right regular formulation, but is a left coideal of $\mathscr{A}$ in the left regular formulation. In Section IX B attention is focused on the right coactions $\pi_{\mathscr{B}}^{R}$ and $\pi_{\mathscr{B}}^{L}$ of $\mathscr{A}$ that are obtained by restricting the right and left regular coactions of $\mathscr{A}$ to its subalgebra $\mathscr{B}$. As these are the *transitive* $\star$*-coactions* that correspond to the transitive action of a quantum group on a quantum homogeneous space in the sense of Dijkhuizen and Koornwinder,[23,24] they play the key role in the analysis. In particular the properties of basis functions, as defined in terms of these restricted coactions, are presented in Section IX C, and in Section IX D the irreducible tensor operators are also defined in terms of these coactions. It is shown there that, associated with both $\pi_{\mathscr{B}}^{R}$ and $\pi_{\mathscr{B}}^{L}$ there are two types of irreducible tensor operator, which are again called *ordinary* and *twisted*, and the immediate properties of all these irreducible tensor operators are described. In Section IX E it is shown that the irreducible tensor operators satisfy theorems of the Wigner–Eckart type, and the analysis is concluded in Section IX F with a demonstration that the products of these irreducible tensor operators are themselves expressible as linear combinations of irreducible tensor operators that involve the relevant Clebsch–Gordan coefficients.

Because the space of functions defined on a compact Lie group $\mathscr{G}$ is a special example of a compact quantum group algebra, all the well-known results for compact Lie groups naturally

reappear in this particular case. However, as the detailed analysis shows, the theory in the general situation is rather more subtle, and exhibits various complications.

II. PROPERTIES OF COMPACT QUANTUM GROUP ALGEBRAS

A. Hopf *-algebras

The purpose of this section is mainly to establish notations, and summarize the essential properties. For further details see, for example, Sweedler,[27] Majid,[28] and Chari and Pressley.[29]

A *Hopf algebra* $\mathscr{A}$ over the field of complex numbers $\mathbb{C}$ is a complex vector space with an identity element $1_{\mathscr{A}}$ that possesses a multiplication operator M (which maps $\mathscr{A}\otimes\mathscr{A}$ into $\mathscr{A}$), a unit operator u (which maps $\mathbb{C}$ into $\mathscr{A}$), a comultiplication operator Δ (which maps $\mathscr{A}$ into $\mathscr{A}\otimes\mathscr{A}$), a counit operator ϵ (which maps $\mathscr{A}$ into $\mathbb{C}$), and an antipode operator S (which maps $\mathscr{A}$ into $\mathscr{A}$). These are assumed to be linear in all their arguments and to have the following properties:

$$M\circ(M\otimes id)=M\circ(id\otimes M), \tag{8}$$

$$(\Delta\otimes id)\circ\Delta=(id\otimes\Delta)\circ\Delta, \tag{9}$$

$$\Delta\circ M=(M\otimes M)\circ(id\otimes\sigma\otimes id)\circ(\Delta\otimes\Delta), \tag{10}$$

$$\epsilon\circ M=M_{\mathbb{C}}\circ(\epsilon\otimes\epsilon), \tag{11}$$

$$M_{\mathbb{C},\mathscr{A}}\circ(\epsilon\otimes id)\circ\Delta=M_{\mathscr{A},\mathbb{C}}\circ(id\otimes\epsilon)\circ\Delta=id, \tag{12}$$

$$u(1_{\mathbb{C}})=1_{\mathscr{A}},\quad \epsilon(1_{\mathscr{A}})=1_{\mathbb{C}},\quad S(1_{\mathscr{A}})=1_{\mathscr{A}}, \tag{13}$$

$$M(a\otimes 1_{\mathscr{A}})=M(1_{\mathscr{A}}\otimes a)=a,\quad \text{for all}\quad a\in\mathscr{A}, \tag{14}$$

$$\Delta(1_{\mathscr{A}})=1_{\mathscr{A}}\otimes 1_{\mathscr{A}}, \tag{15}$$

$$S\circ M=M\circ\sigma\circ(S\otimes S), \tag{16}$$

$$\Delta\circ S=(S\otimes S)\circ\sigma\circ\Delta, \tag{17}$$

$$M\circ(S\otimes id)\circ\Delta=M\circ(id\otimes S)\circ\Delta=u\circ\epsilon, \tag{18}$$

$$\epsilon\circ S=\epsilon. \tag{19}$$

Here σ is the transposition operator which interchanges the order of its arguments, so that, for example, when acting on $\mathscr{A}\otimes\mathscr{A}$, $\sigma(a\otimes b)=b\otimes a$ for all $a,b\in\mathscr{A}$. Also $M_{\mathbb{C}}$, $M_{\mathscr{A},\mathbb{C}}$, and $M_{\mathbb{C},\mathscr{A}}$ are the multiplication operators defined by $M_{\mathbb{C}}(w\otimes z)=wz$ for all $w,z\in\mathbb{C}$, and $M_{\mathscr{A},\mathbb{C}}(a\otimes z)=M_{\mathbb{C},\mathscr{A}}(z\otimes a)=za$ for all $z\in\mathbb{C}$ and all $a\in\mathscr{A}$. The product $M(a\otimes b)$ will sometimes be written more concisely as ab, and the coproduct Δ will sometimes be expressed as

$$\Delta(a)=\sum_{(a)} a_{(1)}\otimes a_{(2)}. \tag{20}$$

If $\mathscr{A}$ is finite-dimensional, with basis elements $a_1,a_2,\ldots$, the structure constants m_{jk}^{ℓ}, μ_{ℓ}^{jk}, s_j^k, ϵ_j, and ϵ^j may be defined by $M(a_j\otimes a_k)=\Sigma_{\ell}m_{jk}^{\ell}a_{\ell}$, $\Delta(a_{\ell})=\Sigma_{j,k}\mu_{\ell}^{jk}a_j\otimes a_k$, $S(a_j)=\Sigma_k s_j^k a_k$, $\epsilon(a_j)=\epsilon_j$, and $1_{\mathscr{A}}=\Sigma_j\epsilon^j a_j$. Then (8) to (19) imply that

$$\sum_s m_{jk}^s m_{s\ell}^t = \sum_s m_{js}^t m_{k\ell}^s, \tag{21}$$

$$\sum_j \mu_\ell^{jk} \mu_j^{st} = \sum_j \mu_\ell^{sj} \mu_j^{tk}, \tag{22}$$

$$\sum_{p,q,s,t} \mu_j^{pq} \mu_k^{st} m_{ps}^r m_{qt}^u = \sum_p m_{jk}^p \mu_p^{ru}, \tag{23}$$

$$\sum_\ell m_{jk}^\ell \epsilon_\ell = \epsilon_j \epsilon_k, \tag{24}$$

$$\sum_j \mu_\ell^{jk} \epsilon_j = \sum_j \mu_\ell^{kj} \epsilon_j = \delta_\ell^k, \tag{25}$$

$$\sum_j \epsilon^j s_j^k = \epsilon^k, \quad \sum_j \epsilon^j \epsilon_j = 1_{\mathbb{C}}, \tag{26}$$

$$\sum_k \epsilon^k m_{jk}^\ell = \sum_k \epsilon^k m_{kj}^\ell = \delta_j^\ell, \tag{27}$$

$$\sum_j \epsilon^j \mu_j^{k\ell} = \epsilon^k \epsilon^\ell, \tag{28}$$

$$\sum_q m_{jk}^q s_q^p = \sum_{q,r} m_{rq}^p s_j^q s_k^r, \tag{29}$$

$$\sum_k \mu_k^{pq} s_j^k = \sum_{k,\ell} \mu_j^{k\ell} s_\ell^p s_k^q, \tag{30}$$

$$\sum_{k,\ell,r} \mu_j^{k\ell} s_k^r m_{r\ell}^t = \sum_{k,\ell,r} \mu_j^{k\ell} s_\ell^r m_{kr}^t = \epsilon_j \epsilon^t, \tag{31}$$

and

$$\sum_j \epsilon_j s_k^j = \epsilon_k. \tag{32}$$

A *Hopf *-algebra* $\mathscr{A}$ is defined to be a Hopf algebra that possesses an additional *-operation that maps $\mathscr{A}$ into $\mathscr{A}$. The effect of the * operation on $a \in \mathscr{A}$ will sometimes be denoted by a^*. In particular

$$1_{\mathscr{A}}^* = 1_{\mathscr{A}}. \tag{33}$$

The other properties are

$$(*\circ M_{\mathbb{C},\mathscr{A}})(z\otimes a) = M_{\mathbb{C},\mathscr{A}}(\overline{z}\otimes a^*) = (*\circ M_{\mathscr{A},\mathbb{C}})(a\otimes z) = M_{\mathscr{A},\mathbb{C}}(a^*\otimes\overline{z}) = \overline{z}a^* \tag{34}$$

(for all $z \in \mathbb{C}$ and all $a \in \mathscr{A}$, where $\overline{z}$ denotes the complex conjugate of z),

$$*\circ *=id, \tag{35}$$

$$*\circ M=M\circ(*\otimes *)\circ\sigma, \tag{36}$$

$$\Delta\circ *=(*\otimes *)\circ\Delta, \tag{37}$$

$$(\epsilon\circ *)(a)=\overline{\epsilon(a)}, \quad \text{for all} \quad a\in\mathscr{A}, \tag{38}$$

$$S\circ *\circ S\circ *=id, \tag{39}$$

which implies that S is invertible with inverse given by

$$S^{-1}=*\circ S\circ *. \tag{40}$$

If $\mathscr{A}$ is finite-dimensional, its linear dual will be denoted by $\mathscr{A}'$, the prime being used instead of the usual star to avoid any confusion with the *-operation that has just been defined. The effect of $a'\in\mathscr{A}'$ on $a\in\mathscr{A}$ will be denoted by $\langle a',a\rangle$, and the evaluation map ev (from $\mathscr{A}'\otimes\mathscr{A}$ to $\mathbb{C}$) will be defined by

$$ev(a'\otimes a)=\langle a',a\rangle, \tag{41}$$

for all $a'\in\mathscr{A}'$ and all $a\in\mathscr{A}$. In the case in which $\mathscr{A}$ is of finite dimension n, the dual basis of $\mathscr{A}'$ will be denoted by $a^1,a^2,\ldots,a^n$, and will be assumed to be such that

$$\langle a^j,a_k\rangle=\delta^j_k, \tag{42}$$

for all $j,k=1,2,\ldots,n$.

B. Right comodules of Hopf *-algebras

A *right $\mathscr{A}$-comodule* consists of a vector space V and a linear mapping π_V from V to $V\otimes\mathscr{A}$ such that

$$(\pi_V\otimes id)\circ\pi_V=(id\otimes\Delta)\circ\pi_V \tag{43}$$

and

$$M_{V,\mathbb{C}}\circ(id\otimes\epsilon)\circ\pi_V=id, \tag{44}$$

where $M_{V,\mathbb{C}}(v\otimes z)=zv$ for all $v\in V$ and all $z\in\mathbb{C}$. The operation π_V is then said to be a *right coaction* and provides a *corepresentation* of $\mathscr{A}$ with carrier space V. The present section will be devoted to a very brief account of the essential features of the corepresentations of $\mathscr{A}$. (For the intimate connection between the *corepresentation* theory of $\mathscr{A}$ and the *representation* theory of $\mathscr{A}'$, see Appendix A.)

If V is of finite dimension d, with basis $v_1,v_2,\ldots,v_d$, then there exists a uniquely determined set of elements π^V_{jk} of $\mathscr{A}$ (for $j,k=1,2,\ldots,d$), called the *matrix coefficients* of π_V, which are such that

$$\pi_V(v_j)=\sum_{k=1}^{d} v_k\otimes\pi^V_{kj}, \tag{45}$$

for all $j=1,2,\ldots,d$. (In this situation the corepresentation is said to have dimension d.) The requirements (43) and (44) then imply that

$$\Delta(\pi^V_{jk}) = \sum_{\ell=1}^{d} \pi^V_{j\ell} \otimes \pi^V_{\ell k} \tag{46}$$

and

$$\epsilon(\pi^V_{jk}) = \delta_{jk} \tag{47}$$

(for $j,k = 1,2,\ldots,d$). It is sometimes convenient to write

$$\pi_V(v) = \sum_{[v]} v_{[1]} \otimes v_{[2]}, \tag{48}$$

where $v_{[1]} \in V$ and $v_{[2]} \in \mathscr{A}$.

Two right $\mathscr{A}$-comodules, with carrier spaces V and W, coactions π_V and π_W, and matrix coefficients π^V_{jk} and π^W_{jk} are said to be *equivalent* if there exists a one-to-mapping Φ from V to W such that

$$\pi_W \circ \Phi = (\Phi \otimes id) \circ \pi_V. \tag{49}$$

If V and W have bases $v_1, v_2, \ldots, v_d$ and $w_1, w_2, \ldots, w_d$, respectively, then to the mapping Φ there corresponds a $d \times d$ non-singular matrix $\mathbf{\Phi}$ such that

$$\sum_{\ell=1}^{d} \Phi_{j\ell} \pi^V_{\ell k} = \sum_{\ell=1}^{d} \pi^W_{j\ell} \Phi_{\ell k}, \tag{50}$$

for all $j,k = 1,2,\ldots,d$.

A subspace $W \subset V$ is said to be *invariant* under π_V if $\pi_V(w) \subset W \otimes \mathscr{A}$ for all $w \in W$, and a corepresentation is described as being *irreducible* if V and 0 are the only invariant subspaces of V. If V is the direct sum of two invariant subspaces of V, then the corepresentation π_V is said to be *completely reducible*.

If V is endowed with an inner product $\langle , \rangle_V$ (such that $\langle zw, z'v \rangle_V = \overline{z}z' \langle w, v \rangle_V$ for all z, $z' \in \mathbb{C}$ and all v, $w \in V$), then π_V is said to give a *unitary* corepresentation if

$$\sum_{[v]} \langle w, v_{[1]} \rangle_V S(v_{[2]}) = \sum_{[w]} \langle w_{[1]}, v \rangle_V w^*_{[2]}, \tag{51}$$

for all $v, w \in V$. It can be shown[22–26] that if $v_1, v_2, \ldots, v_d$ is an ortho-normal basis of V then

$$S(\pi^V_{jk}) = \pi^{V*}_{kj}, \tag{52}$$

$$\sum_{\ell=1}^{d} M(\pi^{V*}_{\ell j} \otimes \pi^V_{\ell k}) = \delta_{jk} 1_{\mathscr{A}}, \tag{53}$$

and

$$\sum_{\ell=1}^{d} M(\pi^V_{j\ell} \otimes \pi^{V*}_{k\ell}) = \delta_{jk} 1_{\mathscr{A}} \tag{54}$$

(for all $j,k = 1,2,\ldots,d$).

Corresponding to a right $\mathscr{A}$-comodule with carrier space V and coaction π_V from V to $V\otimes\mathscr{A}$ there exist two other right $\mathscr{A}$-comodules formed from the same carrier space. Firstly, there is the coaction $\pi_V^{\ddagger}$ which is said to be *doubly contragredient* to π_V, and which is defined (as a mapping from V to $V\otimes\mathscr{A}$) by

$$\pi_V^{\ddagger}=(id\otimes S^2)\circ\pi_V. \tag{55}$$

With the matrix coefficients $\pi_{jk}^{V\ddagger}$ of $\pi_V^{\ddagger}$ being defined by

$$\pi_V^{\ddagger}(v_j)=\sum_{k=1}^{d} v_k\otimes\pi_{kj}^{V\ddagger}, \tag{56}$$

for all $j=1,2,\ldots,d$, it follows from (45) that

$$\pi_{jk}^{V\ddagger}=S^2(\pi_{jk}^{V}), \tag{57}$$

for all $j,k=1,2,\ldots,d$. Secondly, let $\overline{V}$ be the conjugate space to V [so that as an Abelian group V is isomorphic to V, but the scalar multiplication operator $M_{\mathbb{C},\overline{V}}$ for V is defined in terms of the corresponding operator $M_{\mathbb{C},V}$ for V by $M_{\mathbb{C},\overline{V}}(z\otimes v)=M_{\mathbb{C},V}(\overline{z}\otimes v)$]. Then the coaction $\overline{\pi_V}$, which is said to be *conjugate* to π_V, is defined (as a mapping from V to $V\otimes\mathscr{A}$) by

$$\overline{\pi_V}=(id\otimes *)\circ\pi_V, \tag{58}$$

so its matrix coefficients $\overline{\pi_{jk}^{V}}$ are given by

$$\overline{\pi_{jk}^{V}}=\pi_{jk}^{V*}, \tag{59}$$

for all $j,k=1,2,\ldots,d$.

C. Compact quantum group algebras

A *compact quantum group algebra* (or *CQG algebra* for short) may be defined[22–26] as a Hopf *-algebra that is spanned by the matrix coefficients of its non- equivalent finite-dimensional unitary irreducible corepresentations. Koornwinder and Dijkhuizen[22–26] have shown that if $\mathscr{A}$ is a CQG algebra then every finite-dimensional corepresentation of $\mathscr{A}$ is equivalent to a unitary corepresentation, and that every finite-dimensional reducible corepresentation of $\mathscr{A}$ is completely reducible. Moreover[22–26] if $\mathscr{A}$ is a CQG algebra then $\mathscr{A}$ possesses a *Haar functional*, h, which is a mapping of $\mathscr{A}$ into $\mathbb{C}$ such that

$$h(1_{\mathscr{A}})=1_{\mathbb{C}}, \tag{60}$$

$$h[M(a^*\otimes a)]>0, \tag{61}$$

$$h(a^*)=\overline{h(a)}, \tag{62}$$

$$h[S(a)]=h(a), \tag{63}$$

and

$$[M_{\mathbb{C},\mathscr{A}}\circ(h\otimes id)\circ\Delta](a)=[M_{\mathscr{A},\mathbb{C}}\circ(id\otimes h)\circ\Delta](a)=h(a)\,1_{\mathscr{A}}, \tag{64}$$

for all $a\in\mathscr{A}$.

Koornwinder and Dijkhuizen[22–26] have also shown that if π^p and π^q are two non-equivalent irreducible corepresentations of a CQG algebra $\mathscr{A}$ with dimensions d_p and d_q and matrix coefficients π^p_{jk} and π^q_{mn}, respectively, then

$$h[M(\pi^p_{jk}\otimes S(\pi^q_{mn})]=0, \quad h[M(S(\pi^p_{jk})\otimes\pi^q_{mn})]=0 \tag{65}$$

(for all $j,k=1,2,\ldots,d_p$ and for all $m,n=1,2,\ldots,d_q$). Moreover every π^p irreducible corepresentation of $\mathscr{A}$ is equivalent to its doubly contragredient partner $\pi^{p\ddagger}$, so in each such case there exists a non-singular $d_p\times d_p$ matrix $\mathbf{F}^p$ such that

$$\sum_{k=1}^{d_p} F^p_{jk}\pi^p_{k\ell}=\sum_{k=1}^{d_p}\pi^{p\ddagger}_{jk}F^p_{k\ell} \tag{66}$$

(for all $j,\ell=1,2,\ldots,d_p$). Then, if π^p is a unitary irreducible corepresentation of $\mathscr{A}$,

$$h[M(\pi^p_{jk}\otimes S(\pi^p_{mn}))]=\delta_{jn}F^p_{mk}/tr(\mathbf{F}^p) \tag{67}$$

and

$$h[M(S(\pi^p_{jk})\otimes\pi^p_{mn})]=\delta_{jn}[(\mathbf{F}^p)^{-1}]_{mk}/tr[(\mathbf{F}^p)^{-1}] \tag{68}$$

(for all $j,k,m,n=1,2,\ldots,d_p$).

Of course in the special case in which $\mathscr{A}$ is the space of functions defined on a compact group $\mathscr{G}$, $\mathscr{A}$ is commutative (i.e., $M=M\circ\sigma$), $S^2=id$, h is the Haar integral,

$$h(a)=\int_{\mathscr{G}} a(x)\,dx, \tag{69}$$

and (64) expresses the invariance properties

$$\int_{\mathscr{G}} a(yx)\,dx=\int_{\mathscr{G}} a(x)\,dx=\int_{\mathscr{G}} a(xy)\,dx \tag{70}$$

(for all $y\in\mathscr{G}$). Moreover in this case each corepresentation of $\mathscr{A}$ is *identical* to its doubly contragredient partner, and (65), (67), and (68) correspond to the orthogonality theorems for the unitary irreducible representations of $\mathscr{G}$.

D. Lemmas concerning the Haar functional

It will now be shown that

$$\sum_{(b)} h[M(a\otimes b_{(1)})]S(b_{(2)})=\sum_{(a)} h[M(a_{(1)}\otimes b)]a_{(2)}, \tag{71}$$

for all $a,b\in\mathscr{A}$.

To prove this consider the operation $u\circ h\circ M$. As the left-hand equality of (64) can be re-expressed as

$$M_{\mathbb{C},\mathscr{A}}\circ(h\otimes id)\circ\Delta=u\circ h, \tag{72}$$

it follows from (10) that

$$u\circ h\circ M=M_{\mathbb{C},\mathscr{A}}\circ(h\otimes id)\circ(M\otimes M)\circ(id\otimes\sigma\otimes id)\circ(\Delta\otimes\Delta). \tag{73}$$

However, by (12), (18), and (9), it also follows that

$$u\circ h\circ M = M_{\mathbb{C},\mathscr{A}}\circ(h\otimes M)\circ(M\otimes S\otimes id)\circ(id\otimes\Delta\otimes id)\circ(id\otimes\Delta). \tag{74}$$

Comparing (73) and (74) then gives

$$\begin{aligned} &M_{\mathbb{C},\mathscr{A}}\circ(h\otimes M)\circ(M\otimes S\otimes id)\circ(id\otimes\Delta\otimes id)\circ(id\otimes\Delta)\\ &\quad = M_{\mathbb{C},\mathscr{A}}\circ(h\otimes id)\circ(M\otimes M)\circ(id\otimes\sigma\otimes id)\circ(\Delta\otimes\Delta), \end{aligned}$$

which can be re-expressed as

$$M\circ(U\otimes id)\circ(id\otimes\Delta) = M\circ(V\otimes id)\circ(id\otimes\Delta), \tag{75}$$

where

$$U = M_{\mathbb{C},\mathscr{A}}\circ(h\otimes id)\circ(M\otimes id)\circ(id\otimes\sigma)\circ(\Delta\otimes id) \tag{76}$$

and

$$V = M_{\mathbb{C},\mathscr{A}}\circ(h\otimes S)\circ(M\otimes id)\circ(id\otimes\Delta). \tag{77}$$

However, (75) implies that

$$\begin{aligned} &M\circ(M\otimes id)\circ(U\otimes id\otimes S)\circ(id\otimes\Delta\otimes id)\circ(id\otimes\Delta)\\ &\quad = M\circ(M\otimes id)\circ(V\otimes id\otimes S)\circ(id\otimes\Delta\otimes id)\circ(id\otimes\Delta). \end{aligned} \tag{78}$$

But

$$\begin{aligned} &M\circ(M\otimes id)\circ(U\otimes id\otimes S)\circ(id\otimes\Delta\otimes id)\circ(id\otimes\Delta)\\ &\quad = M\circ(U\otimes\{M\circ(id\otimes S)\circ\Delta\})\circ(id\otimes\Delta)\\ &\quad = M\circ(U\otimes\{u\circ\epsilon\})\circ(id\otimes\Delta) = U. \end{aligned}$$

As a similar result is true with U replace by V, it follows from (78) that $U=V$, which is an equivalent way of expressing (71).

It can shown by a similar argument that

$$\sum_{(b)} h[M(b_{(2)}\otimes a)]S(b_{(1)}) = \sum_{(a)} h[M(b\otimes a_{(2)})]a_{(1)}, \tag{79}$$

for all $a,b\in\mathscr{A}$.

III. THE RIGHT AND LEFT REGULAR COMODULES

The *right regular comodule* of $\mathscr{A}$ is defined to have $\mathscr{A}$ itself as its carrier space, with Δ providing the coaction $\pi^R_{\mathscr{A}}$. That is

$$V=\mathscr{A}, \quad \pi^R_{\mathscr{A}}=\Delta. \tag{80}$$

In this case the conditions (43) and (44) for $\pi^R_{\mathscr{A}}$ to be a right coaction are immediately satisfied by virtue of the assumptions (9) and (12).

The *left regular comodule* of $\mathscr{A}$ is also defined to have $\mathscr{A}$ itself as its carrier space, but has $\sigma\circ(S\otimes id)\circ\Delta$ as its coaction $\pi^L_{\mathscr{A}}$. That is

$$V=\mathscr{A}, \quad \pi^L_{\mathscr{A}}=\sigma\circ(S\otimes id)\circ\Delta. \tag{81}$$

For this case the condition (43) for $\pi^L_{\mathscr{A}}$ to be a right coaction is satisfied by the assumptions (9) and (17), while the condition (44) is again satisfied as a result of the assumption (12). It should be noted that $\pi^R_{\mathscr{A}}$ and $\pi^L_{\mathscr{A}}$ are both *right* coactions, for, as discussed in Appendix A, the designation ''left'' of $\pi^L_{\mathscr{A}}$ comes from its relation to the left regular action of a group in the special case in which the dual $\mathscr{A}'$ is a group algebra. It is also useful to note that (81) implies that

$$\Delta=(S^{-1}\otimes id)\circ\sigma\circ\pi^L_{\mathscr{A}}. \tag{82}$$

The notation of (48) can be developed further by writing

$$\pi^X_{\mathscr{A}}(a)=\sum_{[a]} a^X_{[1]}\otimes a^X_{[2]}, \tag{83}$$

for $X=R$ and $X=L$, where $a^X_{[1]}$ and $a^X_{[1]}$ are elements of $\mathscr{A}$. Then (20) and (80) imply that

$$a^R_{[1]}=a_{(1)}, \quad a^R_{[2]}=a_{(2)}, \tag{84}$$

but (20) and (81) give

$$a^L_{[1]}=a_{(2)}, \quad a^L_{[2]}=S(a_{(1)}). \tag{85}$$

The right and left regular corepresentations are both *unitary*, provided that the inner products on the carrier space $\mathscr{A}$ are chosen in the following way.

1. For the *right* regular corepresentation take

$$\langle a,b\rangle_{\mathscr{A}}=(a,b)^R=h[M(a^*\otimes b)], \quad \text{for all} \quad a,b\in\mathscr{A}; \tag{86}$$

2. for the *left* regular corepresentation take

$$\langle a,b\rangle_{\mathscr{A}}=(a,b)^L=h\{M[b\otimes(S^2(a))^*]\}, \quad \text{for all} \quad a,b\in\mathscr{A}. \tag{87}$$

In outline the proofs of these statements are as follows. For the *right* regular corepresentation, the unitary condition (51) with the choice (86) for the inner product and with (84) becomes

$$\sum_{(v)} h[M(w^*\otimes v_{(1)})]S(v_{(2)})=\sum_{(w)} h[M(w^*_{(1)}\otimes v)]w^*_{(2)},$$

which in turn reduces to (71) with the substitutions $w=a^*$ and $v=b$. Similarly, for the *left* regular corepresentation, the unitary condition (51) with the choice (87) for inner product and with (85) becomes

$$\sum_{(v)} h\{M[v_{(2)}\otimes(S^2(w))^*]\}S^2(v_{(1)})=\sum_{(w)} h\{M[v\otimes(S^2(w_{(2)}))^*]\}[S(w_{(1)})]^*.$$

With the substitutions $w=S^{-1}(a^*)$ and $v=S^{-1}(b)$, and the application of (17), (37), and (39), this reduces again to (71).

With the choices (86) and (87), both $(a,a)^R$ and $(a,a)^L$ are real and positive for all non-zero $a\in\mathscr{A}$. For $(a,a)^R$ this is an immediate consequence of (61), while for $(a,a)^L$ the demonstration requires (63), (16), (62), and (39) as well.

The inner products (86) and (87) will be used throughout this paper. In the special case in which $\mathscr{A}$ is the space of functions defined on a compact group $\mathscr{G}$, both $(a,b)^R$ and $(a,b)^L$ reduce to the usual inner product,

$$\int_{\mathscr{G}} \overline{a(x)} b(x)\, dx.$$

It is worth noting at this stage that the invariance properties (64) imply that

$$[M_{\mathbb{C},\mathscr{A}} \circ (h \otimes id) \circ \pi^R_{\mathscr{A}}](a) = [M_{\mathscr{A},\mathbb{C}} \circ (id \otimes h) \circ \pi^R_{\mathscr{A}}](a) = h(a)\, 1_{\mathscr{A}} \tag{88}$$

and

$$[M_{\mathbb{C},\mathscr{A}} \circ (h \otimes id) \circ \pi^L_{\mathscr{A}}](a) = [M_{\mathscr{A},\mathbb{C}} \circ (id \otimes h) \circ \pi^L_{\mathscr{A}}](a) = h(a)\, 1_{\mathscr{A}}, \tag{89}$$

for all $a \in \mathscr{A}$. Acting with h again in (88) and (89), and using (60), gives

$$[M_{\mathbb{C}} \circ (h \otimes h) \circ \pi^X_{\mathscr{A}}](a) = h(a), \tag{90}$$

for both $X = R$ and L and for all $a \in \mathscr{A}$. In terms of the notation of (83), this can be re-expressed as

$$h(a) = \sum_{[a]} h(a^X_{[1]}) h(a^X_{[2]}), \tag{91}$$

for $X = R$ and L and for all $a \in \mathscr{A}$.

The effects of the right and left regular coactions on products are quite different. For the right regular coaction, (80) and (10) imply immediately that

$$\pi^R_{\mathscr{A}} \circ M = (M \otimes M) \circ (id \otimes \sigma \otimes id) \circ (\pi^R_{\mathscr{A}} \otimes \pi^R_{\mathscr{A}}), \tag{92}$$

whereas for the left regular coaction, (81), (10), and (16) show that

$$\pi^L_{\mathscr{A}} \circ M = (M \otimes M) \circ (id \otimes id \otimes \sigma) \circ (id \otimes \sigma \otimes id) \circ (\pi^L_{\mathscr{A}} \otimes \pi^L_{\mathscr{A}}), \tag{93}$$

which contains an extra twist factor σ.

IV. BASIS FUNCTIONS

A. Definitions and properties

Suppose that π^p_{jk} are the matrix coefficients of a corepresentation π^p of $\mathscr{A}$ of finite dimension d_p. Then the *basis functions* ψ^{pR}_j *of* π^p *with respect to the right regular coaction* may be defined to be a set of d_p elements of $\mathscr{A}$ that have the property that

$$\pi^R_{\mathscr{A}}(\psi^{pR}_j) = \sum_{k=1}^{d_p} \psi^{pR}_k \otimes \pi^p_{kj}, \tag{94}$$

for all $j = 1,2,\ldots,d_p$. Similarly the *basis functions* ψ^{pL}_j *of* π^p *with respect to the left regular coaction* may be defined as a set of d_p elements of $\mathscr{A}$ that have the property that

$$\pi^L_{\mathscr{A}}(\psi^{pL}_j) = \sum_{k=1}^{d_p} \psi^{pL}_k \otimes \pi^p_{kj}, \tag{95}$$

for all $j = 1,2,\ldots,d_p$.

In the right regular coaction case, an example of a set of basis functions is provided (for any fixed choice of $\ell = 1,2,\ldots$) by

$$\psi_j^{pR} = \pi^p_{\ell j}, \tag{96}$$

for all $j = 1,2,\ldots,d_p$. Likewise, in the left regular coaction case, an example is provided (for any fixed choice of $\ell = 1,2,\ldots$) by

$$\psi_j^{pL} = S^{-2}(\pi^{p*}_{j\ell}), \tag{97}$$

for all $j = 1,2,\ldots,d_p$ (provided that the corepresentation π^p is unitary).

One very useful result, which comes from applying (95), (82), (17), (37), and (39), is that

$$\pi^L_{\mathscr{A}}[(S^2(\psi_k^{qL}))^*] = \sum_{t=1}^{d_p} [S^2(\psi_t^{qL})]^* \otimes \pi^{q*}_{tk}, \tag{98}$$

for all $k = 1,2,\ldots,d_p$.

In spite of the fact that the inner products (86) and (87) for the right and left regular coactions are different, in both the cases the basis functions possess the *same* orthogonality properties, which are as follows: If ψ_k^{qX} and ϕ_j^{pX} are basis functions of the unitary irreducible corepresentations π^q and π^p of $\mathscr{A}$, then

$$(\psi_k^{qX}, \phi_j^{pX})^X = 0, \quad \text{unless} \quad p = q \quad \text{and} \quad j = k, \tag{99}$$

and

$$(\psi_j^{pX}, \phi_j^{pX})^X \text{ is independent of } j, \quad \text{for} \quad j = 1,2,\ldots,d_p. \tag{100}$$

Here X denotes both R and L, and in (100) ψ_j^{pX} and ϕ_j^{pX} need not be identical sets. Indeed, with $X = R$, if the functions ψ_j^{pR} and ϕ_j^{pR} are defined by

$$\psi_j^{pR} = \pi^p_{sj}, \quad \phi_j^{pR} = \pi^p_{tj}, \tag{101}$$

and with $X = L$, if the functions ψ_j^{pL} and ϕ_j^{pL} are similarly defined by

$$\psi_j^{pL} = S^{-2}(\pi^{p*}_{js}), \quad \phi_j^{pL} = S^{-2}(\pi^{p*}_{jt}), \tag{102}$$

then in *both* cases

$$(\psi_j^{pX}, \phi_j^{pX})^X = [(\mathbf{F}^p)^{-1}]_{ts} / tr[(\mathbf{F}^p)^{-1}], \tag{103}$$

for $j = 1,2,\ldots,d_p$.

The proofs of (99), (100), and (103) will now be outlined. Applying (92) and (88) to $M(\psi_k^{qR*} \otimes \phi_j^{pR})$ gives

$$h[M(\psi_k^{qR*} \otimes \phi_j^{pR})]1_{\mathscr{A}} = \sum_{s,t} h[M(\psi_t^{qR*} \otimes \phi_s^{pR})]M(\pi^{q*}_{tk} \otimes \pi^p_{sj}).$$

A further application of h to both sides gives

$$(\psi_k^{qX}, \phi_j^{pX})^X = \sum_{s,t} (\psi_t^{qX}, \phi_s^{pX})^X h[M(\pi^{q*}_{tk} \otimes \pi^p_{sj})], \tag{104}$$

with $X = R$, where (86) and (60) have been invoked. Similarly, applying (93) and (98) to $M[\phi_j^{pL} \otimes (S^2(\psi_k^{qL}))^*]$, and then applying (89) to the result gives

$$h\{M[\phi_j^{pL}\otimes(S^2(\psi_k^{qL}))^*]\}1_{\mathscr{A}}=\sum_{s,t} h\{M[\phi_s^{pL}\otimes(S^2(\psi_t^{qL}))^*]\}M(\pi_{tk}^{q*}\otimes\pi_{sj}^{p}).$$

A further application of h to both sides gives (104) with $X=L$, where this time (87) and (60) have been used. Thus, in both cases, it follows from (104), (52), (65), and (68) that

$$(\psi_k^{qX},\phi_j^{pX})^X=\sum_{s,t}\frac{(\psi_t^{qX},\phi_s^{pX})^X\delta^{qp}\delta_{kj}[(\mathbf{F}^p)^{-1}]_{st}}{tr[(\mathbf{F}^p)^{-1}]}. \tag{105}$$

This implies that (99) is true, and if $j=k$ and $p=q$, then (105) and (99) together give

$$(\psi_j^{pX},\phi_j^{pX})^X=\sum_{s}\frac{(\psi_s^{pX},\phi_s^{pX})^X[(\mathbf{F}^p)^{-1}]_{ss}}{tr[(\mathbf{F}^p)^{-1}]}. \tag{106}$$

As the right-hand side of (106) is independent of j, so too must be the left-hand side, which thereby establishes (100). Finally the combination of (86) and (101) and the combination of (87) and (102) both produce the result

$$(\psi_j^{pX},\phi_j^{pX})^X=h\{M[S(\pi_{js}^{p})\otimes\pi_{tj}^{p}]\},$$

for $X=R$ and for $X=L$, which gives (103) when (68) is used.

B. Projection operators

The argument in Appendix C suggests the following definition. Let π^p be a unitary irreducible corepresentation of $\mathscr{A}$ of dimension d_p with matrix coefficients π_{mn}^{p}. Then the projection operators $\mathscr{P}_{mn}^{pR}$ and $\mathscr{P}_{mn}^{pL}$ are defined by

$$\mathscr{P}_{mn}^{pX}(a)=d_p\sum_{[a]} a_{[1]}^X h[M(\pi_{mn}^{p*}\otimes a_{[2]}^X], \tag{107}$$

for $X=R$ and $X=L$, for all $m,n=1,2,\ldots,d_p$, and all $a\in\mathscr{A}$.

These projection operators have the following two useful properties: Let π^p and π^q be two unitary irreducible corepresentations of $\mathscr{A}$ of dimensions d_p and d_q with matrix coefficients π_{mn}^{p} and π_{jk}^{q}

1. Then

$$\mathscr{P}_{mn}^{pX}\mathscr{P}_{jk}^{qX}=d_p\delta^{pq}\{[(\mathbf{F}^p)^{-1}]_{nj}/tr[(\mathbf{F}^p)^{-1}]\}\mathscr{P}_{mk}^{pX}, \tag{108}$$

for $X=R$ and $X=L$, for all $m,n=1,2,\ldots,d_p$, and for all $j,k=1,2,\ldots,d_q$.

2. Also, if ψ_k^{qX} are basis functions for π^q, then

$$\mathscr{P}_{mn}^{pX}(\psi_k^{qX})=d_p\delta^{pq}\delta_{nk}\sum_{\ell=1}^{d_p}\frac{\psi_\ell^{qX}[(\mathbf{F}^p)^{-1}]_{\ell m}}{tr[(\mathbf{F}^p)^{-1}]}, \tag{109}$$

for $X=R$ and $X=L$, for all $m,n=1,2,\ldots,d_p$, and for all $k=1,2,\ldots,d_q$.

The proof of (108) is as follows. For any $f\in\mathscr{A}$, (107) and (9) imply that

$$\mathscr{P}_{mn}^{pX}[\mathscr{P}_{jk}^{qX}(f)]=d_pd_q\sum_{[f]} f_{[1]}^X h[M(\pi_{jk}^{q*}\otimes(f_{[2]}^X)_{(1)})]h[M(\pi_{mn}^{p*}\otimes(f_{[2]}^X)_{(2)})].$$

On applying (79) with $a=f_{[2]}^X$ and $b=\pi_{jk}^{q*}$ this reduces to

$$\mathscr{P}^{pX}_{mn}[\mathscr{P}^{qX}_{jk}(f)]=d_p d_q \sum_{[f]} \sum_{\ell=1}^{d_q} f^X_{[1]} h[M(\pi^{q*}_{\ell k}\otimes f^X_{[2]})]h[M(\pi^{p*}_{mn}\otimes S(\pi^{q*}_{j\ell}))],$$

so

$$\mathscr{P}^{pX}_{mn}[\mathscr{P}^{qX}_{jk}(f)]=d_p \sum_{\ell=1}^{d_q} \mathscr{P}^{qX}_{\ell k}(f)h[M(\pi^{p*}_{mn}\otimes S(\pi^{q*}_{j\ell}))],$$

which, by (52), (16), and (68) gives (108).

To prove (109) it suffices to note that (107), (94), and (87) imply that

$$\mathscr{P}^{pX}_{mn}(\psi^{qX}_k)=d_p \sum_{\ell=1}^{d_p} \psi^{qX}_\ell h[M(\pi^{p*}_{mn}\otimes \pi^{q}_{\ell k})],$$

which, by (68), leads immediately to (108).

V. TENSOR PRODUCTS AND CLEBSCH–GORDAN COEFFICIENTS

A. Ordinary and twisted tensor products

The *tensor product* of two corepresentations π_V and π_W of $\mathscr{A}$ (with carrier spaces V and W, respectively) is the mapping $\pi_V \boxtimes \pi_W$ from $V\otimes W$ to $V\otimes W\otimes \mathscr{A}$ that is defined by

$$(\pi_V\boxtimes\pi_W)(v\otimes w)=[(id\otimes id\otimes M)\circ(id\otimes\sigma\otimes id)\circ(\pi_V\otimes\pi_W)](v\otimes w), \tag{110}$$

for all $v\in V$ and all $w\in W$. It is easily checked that the conditions (43) and (44) are satisfied with π_V replaced by $\pi_V\boxtimes\pi_W$ and V replaced by $V\otimes W$, so $\pi_V\boxtimes\pi_W$ is indeed a coaction of $\mathscr{A}$ with carrier space $V\otimes W$. If V and W are of finite dimensions d_V and d_W, with bases $v_1,v_2,\ldots,v_{d_V}$, and $w_1,w_2,\ldots,w_{d_W}$, then (45) and (110) give

$$(\pi_V\boxtimes\pi_W)(v_j\otimes w_k)=\sum_{s=1}^{d_V}\sum_{t=1}^{d_W}(v_s\otimes w_t)\otimes[M(\pi^V_{sj}\otimes\pi^W_{tk})], \tag{111}$$

which implies that the matrix coefficients of $\pi_V\boxtimes\pi_W$ are given by

$$(\pi_V\boxtimes\pi_W)_{st,jk}=M(\pi^V_{sj}\otimes\pi^W_{tk}). \tag{112}$$

Henceforth it will always be assumed that in tensor product matrices such as $\pi_V\boxtimes\pi_W$ the pair of indices that specify the columns have the ordering:

$$(j,k)=(1,1),(1,2),\ldots,(1,d_W),(2,1),(2,2),\ldots, \tag{113}$$

and that the same ordering applies to the rows.

There exists a second tensor product of π_V and π_W that has the same carrier space $V\otimes W$. This will be called the *twisted tensor product*, and is defined as the mapping $\pi_V\widetilde{\boxtimes}\pi_W$ from $V\otimes W$ to $V\otimes W\otimes\mathscr{A}$ that is given by

$$(\pi_V\widetilde{\boxtimes}\pi_W)(v\otimes w)=[(id\otimes id\otimes M)\circ(id\otimes id\otimes\sigma)\circ(id\otimes\sigma\otimes id)\circ(\pi_V\otimes\pi_W)](v\otimes w), \tag{114}$$

for all $v\in V$ and all $w\in W$. It is again easily checked that the conditions (43) and (44) are satisfied with π_V replaced by $\pi_V\widetilde{\boxtimes}\pi_W$ and V replaced by $V\otimes W$, so $\pi_V\widetilde{\boxtimes}\pi_W$ is also a coaction of $\mathscr{A}$ with carrier space $V\otimes W$. Then (45) and (114) give

$$(\pi_V \widetilde{\boxtimes} \pi_W)(v_j \otimes w_k) = \sum_{s=1}^{d_V} \sum_{t=1}^{d_W} (v_s \otimes w_t) \otimes [M(\pi_{tk}^W \otimes \pi_{sj}^V)], \tag{115}$$

which implies that the matrix coefficients of $\pi_V \widetilde{\boxtimes} \pi_W$ are given by

$$(\pi_V \widetilde{\boxtimes} \pi_W)_{st,jk} = M(\pi_{tk}^W \otimes \pi_{sj}^V). \tag{116}$$

The tensor product $\pi_W \boxtimes \pi_V$, whose carrier space is $\pi_W \otimes \pi_V$, has matrix coefficients that are given [according to (112)] by

$$(\pi_W \boxtimes \pi_V)_{ts,kj} = M(\pi_{tk}^W \otimes \pi_{sj}^V). \tag{117}$$

As the matrix coefficients of (116) and (117) differ only in their ordering of the pairs of indices that label their rows (and, in the corresponding manner, their columns), it follows that $\pi_V \widetilde{\boxtimes} \pi_W$ and $\pi_W \boxtimes \pi_V$ are *equivalent* corepresentations. If $\mathscr{A}$ is *coquasitriangular* [that is, if $\mathscr{A}'$ is quasitriangular (cf. Drinfel'd[30])], then $\pi_V \boxtimes \pi_W$ and $\pi_W \boxtimes \pi_V$ are equivalent, so in this case $\pi_V \boxtimes \pi_W$ and $\pi_V \widetilde{\boxtimes} \pi_W$ are equivalent. (Of course, in the special case in which $\mathscr{A}$ is *commutative*, the corepresentations $\pi_V \widetilde{\boxtimes} \pi_W$ and $\pi_V \widetilde{\boxtimes} \pi_W$ are *identical*.)

Applying these considerations to the special case in which $\pi_V = \pi^p$ and $\pi_W = \pi^q$ are two irreducible unitary corepresentations of $\mathscr{A}$, (112) and (116) become

$$(\pi^p \boxtimes \pi^q)_{st,jk} = M(\pi_{sj}^p \otimes \pi_{tk}^q) \tag{118}$$

and

$$(\pi^p \widetilde{\boxtimes} \pi^q)_{st,jk} = M(\pi_{tk}^q \otimes \pi_{sj}^p), \tag{119}$$

respectively.

B. Characters

The *character* of a corepresentation π_V of $\mathscr{A}$ of dimension d_V is defined in terms of its matrix coefficients by

$$\chi^V = \sum_{j=1}^{d_V} \pi_{jj}^V, \tag{120}$$

so χ^V is also an element of $\mathscr{A}$. Clearly equivalent corepresentations have identical characters.

If π^p and π^q are two irreducible unitary corepresentations of $\mathscr{A}$ (assumed to be inequivalent if $p \neq q$) and if χ^p and χ^q are their corresponding characters, then (67) and (68) imply that

$$h[M(\chi^{p*} \otimes \chi^q)] = h[M(\chi^q \otimes \chi^{p*})] = \delta^{pq}. \tag{121}$$

If π_V is a (completely) reducible corepresentation of $\mathscr{A}$ that is equivalent to the direct sum $\Sigma \oplus n^p \pi^p$, then the number of times n^p that the irreducible corepresentation π^p (or a corepresentation equivalent to π^p) appears in the reduction of π_V is given by

$$\chi^V = \sum_p n^p \chi^p, \tag{122}$$

so, by (121),

$$n^p = h[M(\chi^V \otimes \chi^{p*})] = h[M(\chi^{p*} \otimes \chi^V)]. \tag{123}$$

For the tensor product $\pi^p \boxtimes \pi^q$ of two irreducible unitary corepresentations π^p and π^q the character is just $\chi^p \chi^q [= M(\chi^p \otimes \chi^q)]$, so the number of times n_{pq}^r that the irreducible corepresentation π^r (or a corepresentation equivalent to π^r) appears in the reduction of $\pi^p \boxtimes \pi^q$ is given by

$$n_{pq}^r = h(\chi^p \chi^q \chi^{r*}) = h(\chi^{r*} \chi^p \chi^q). \tag{124}$$

If $\overline{\pi^p}$ is the irreducible unitary corepresentation that is *conjugate* to π^p, then (59) and (62) show that

$$n_{pq}^r = n_{\overline{p}r}^q, \quad n_{r\overline{p}}^q = n_{qp}^r, \tag{125}$$

where $n_{\overline{p}r}^q$ is the number of times that π^q (or its equivalent) appears in the reduction of $\overline{\pi^p} \boxtimes \pi^r$, and $n_{r\overline{p}}^q$ is the number of times that π^q (or its equivalent) appears in the reduction of $\pi^r \boxtimes \overline{\pi^p}$.

C. Clebsch–Gordan coefficients

As above, suppose that the tensor product $\pi^p \boxtimes \pi^q$ of two irreducible unitary corepresentations π^p and π^q is reducible, and that n_{pq}^r is the number of times that the irreducible corepresentation π^r (or a corepresentation equivalent to it) appears in the reduction of $\pi^p \boxtimes \pi^q$. If π^p has carrier space V^p with basis elements $v_1^p, v_1^p, \ldots, v_{d_p}^p$ and π^q has carrier space V^q with basis elements $v_1^q, v_1^q, \ldots, v_{d_q}^q$, then the set of elements $v_j^p \otimes v_k^q$ form a basis for $V^p \otimes V^q$, the carrier space of $\pi^p \boxtimes \pi^q$, and consequently appropriate linear combinations form bases for all the irreducible corepresentations π^r that appear in the reduction of the tensor product. Let $w_{\ell}^{r,\alpha}$ be such a combination, so that

$$w_{\ell}^{r,\alpha} = \sum_{j=1}^{d_p} \sum_{k=1}^{d_q} \left(\begin{matrix} p & q \\ j & k \end{matrix} \middle| \begin{matrix} r & , & \alpha \\ \ell & & \end{matrix} \right) v_j^p \otimes v_k^q, \tag{126}$$

for $\ell = 1,2,\ldots,d_r$, and $\alpha = 1,2,\ldots,n_{pq}^r$, and

$$(\pi^p \boxtimes \pi^q)(w_{\ell}^{r,\alpha}) = \sum_{u=1}^{d_r} w_u^{r,\alpha} \otimes \pi_{ul}^r, \tag{127}$$

for $u = 1,2,\ldots,d_r$, and $\alpha = 1,2,\ldots,n_{pq}^r$. The inverse of (126) is

$$v_j^p \otimes v_k^q = \sum_r \sum_{\alpha=1}^{n_{pq}^r} \sum_{\ell=1}^{d_r} \left(\begin{matrix} r & , & \alpha \\ \ell & & \end{matrix} \middle| \begin{matrix} p & q \\ j & k \end{matrix} \right) w_{\ell}^{r,\alpha}, \tag{128}$$

for $j = 1,2,\ldots,d_p$ and $k = 1,2,\ldots,d_q$. The *Clebsch–Gordan coefficients* defined in (126) form the elements of a $d_p \times d_q$ matrix $\mathbf{C}$, while the inverse coefficients defined in (128) form the elements of $\mathbf{C}^{-1}$, where

$$\mathbf{C}^{-1}(\pi^p \boxtimes \pi^q)\mathbf{C} = \sum_r \oplus n_{pq}^r \pi^r. \tag{129}$$

That is,

$$\sum_{j=1}^{d_p}\sum_{t=1}^{d_q}(\pi^p\boxtimes\pi^q)_{is,jt}\left(\begin{matrix}p & q\\ j & t\end{matrix}\middle|\begin{matrix}r & , & \alpha\\ \ell & & \end{matrix}\right)=\sum_{u=1}^{d_r}\left(\begin{matrix}p & q\\ i & s\end{matrix}\middle|\begin{matrix}r & , & \alpha\\ u & & \end{matrix}\right)\pi^r_{u\ell}, \tag{130}$$

for $i=1,2,\ldots,d_p$, $s=1,2,\ldots,d_q$, $\ell=1,2,\ldots,d_r$, and $\alpha=1,2,\ldots,n^r_{pq}$.

D. Products of basis functions and Clebsch–Gordan coefficients

Consider first the *right* regular corepresentation. If ϕ^{pR}_j and ψ^{qR}_k are basis functions of the unitary irreducible corepresentations π^p and π^q of $\mathscr{A}$, then (92) and (118) imply that

$$\pi^R_{\mathscr{A}}[M(\phi^{pR}_j\otimes\psi^{qR}_k)]=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}M(\phi^{pR}_s\otimes\psi^{qR}_t)\otimes(\pi^p\boxtimes\pi^q)_{st,jk}, \tag{131}$$

so that if the set of products $M(\phi^{pR}_j\otimes\psi^{qR}_k)$ (for $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$) form a linearly independent set, then they form a basis for the tensor product corepresentation $\pi^p\boxtimes\pi^q$. Thus, by (126) and (127), there exists a set of elements $\theta^{r,\alpha R}_\ell$, all members of $\mathscr{A}$, that are defined by

$$\theta^{r,\alpha R}_\ell=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\left(\begin{matrix}p & q\\ j & k\end{matrix}\middle|\begin{matrix}r & , & \alpha\\ \ell & & \end{matrix}\right)M(\phi^{pR}_j\otimes\psi^{qR}_k), \tag{132}$$

for $\ell=1,2,\ldots,d_r$, and $\alpha=1,2,\ldots,n^r_{pq}$, and which have the property that

$$\pi^R_{\mathscr{A}}(\theta^{r,\alpha R}_\ell)=\sum_{u=1}^{d_r}\theta^{r,\alpha R}_u\otimes\pi^r_{ul}, \tag{133}$$

for $u=1,2,\ldots,d_r$, and $\alpha=1,2,\ldots,n^r_{pq}$. By (128), the inverse of (132) is then

$$M(\phi^{pR}_j\otimes\psi^{qR}_k)=\sum_r\sum_{\alpha=1}^{n^r_{pq}}\sum_{\ell=1}^{d_r}\left(\begin{matrix}r & , & \alpha\\ \ell & & \end{matrix}\middle|\begin{matrix}p & q\\ j & k\end{matrix}\right)\theta^{r,\alpha R}_\ell, \tag{134}$$

for $j=1,2,\ldots,d_p$ and $k=1,2,\ldots,d_q$. On applying the projection operator $\mathscr{P}^{rR}_{ul}$ of (107) to $M(\phi^{pR}_j\otimes\psi^{qR}_k)$, and using (109), (134), and (132), it follows that

$$\begin{aligned}&\mathscr{P}^{rR}_{ul}[M(\phi^{pR}_j\otimes\psi^{qR}_k)]\\ &\quad=\sum_{\alpha=1}^{n^r_{pq}}\sum_{v=1}^{d_r}\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\left(\begin{matrix}r & , & \alpha\\ \ell & & \end{matrix}\middle|\begin{matrix}p & q\\ j & k\end{matrix}\right)\left(\begin{matrix}p & q\\ s & t\end{matrix}\middle|\begin{matrix}r & , & \alpha\\ v & & \end{matrix}\right)\\ &\qquad\times d_r\{((\mathbf{F}^r)^{-1})_{vu}/tr[(\mathbf{F}^r)^{-1}]\}M(\phi^{pR}_s\otimes\psi^{qR}_t),\end{aligned} \tag{135}$$

for $j=1,2,\ldots,d_p$ and $k=1,2,\ldots,d_q$. However, the definition (107) taken in conjunction with (131) and (118) gives

$$\mathscr{P}^{rR}_{ul}[M(\phi^{pR}_j\otimes\psi^{qR}_k)]=d_r\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}M(\phi^{pR}_s\otimes\psi^{qR}_t)h(\pi^r_{ul}{}^*\pi^p_{sj}\pi^q_{tk}), \tag{136}$$

so equating coefficients of $M(\phi^{pR}_s\otimes\psi^{qR}_t)$ in (135) and (136) yields

$$h(\pi^r_{ul}{}^{*}\pi^p_{sj}\pi^q_{tk}) = \sum_{\alpha=1}^{n^r_{pq}}\sum_{v=1}^{d_r}\begin{pmatrix} r & , & \alpha \\ \ell & & \end{vmatrix} \begin{matrix} p & q \\ j & k \end{vmatrix} \begin{matrix} p & q \\ s & t \end{vmatrix} \begin{matrix} r & , & \alpha \\ v & & \end{pmatrix} \times\{[(\mathbf{F}^r)^{-1}]_{vu}/tr[(\mathbf{F}^r)^{-1}]\} \tag{137}$$

for all $j=1,2,\ldots,d_p$, $k=1,2,\ldots,d_q$, and $l=1,2,\ldots,d_r$. Of course, this implies that

$$h(\pi^r_{ul}{}^{*}\pi^q_{tk}\pi^p_{sj}) = \sum_{\alpha=1}^{n^r_{qp}}\sum_{v=1}^{d_r}\begin{pmatrix} r & , & \alpha \\ \ell & & \end{vmatrix} \begin{matrix} q & p \\ k & j \end{vmatrix} \begin{matrix} q & p \\ t & s \end{vmatrix} \begin{matrix} r & , & \alpha \\ v & & \end{pmatrix} \times\{[(\mathbf{F}^r)^{-1}]_{vu}/tr[(\mathbf{F}^r)^{-1}]\}, \tag{138}$$

for all $j=1,2,\ldots,d_p$, $k=1,2,\ldots,d_q$, and $l=1,2,\ldots,d_r$.

Although the conclusions (137) and (138) also follow from consideration of the *left* regular coaction, some of the intermediate results are significantly different in this case. Firstly (93) implies that

$$\pi^L_{\mathscr{A}}[M(\phi^{pL}_j\otimes\psi^{qL}_k)]=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q} M(\phi^{pL}_s\otimes\psi^{qL}_t)\otimes M(\pi^q_{tk}\otimes\pi^p_{sj}), \tag{139}$$

so, by (119),

$$\pi^L_{\mathscr{A}}[M(\phi^{pL}_j\otimes\psi^{qL}_k)]=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q} M(\phi^{pL}_s\otimes\psi^{qL}_t)\otimes(\pi^p\widetilde{\boxtimes}\pi^q)_{st,jk}, \tag{140}$$

so that if the set of products $M(\phi^{pL}_j\otimes\psi^{qL}_k)$ (for $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$) form a linearly independent set, then they form a basis for the *twisted* tensor product corepresentation $\pi^p\widetilde{\boxtimes}\pi^q$. However, on writing $\Phi^{qp}_{kj}=M(\phi^{pL}_j\otimes\psi^{qL}_k)$, (140) can be re-expressed as

$$\pi^L_{\mathscr{A}}(\Phi^{qp}_{kj})=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\Phi^{qp}_{ts}\otimes(\pi^q\boxtimes\pi^p)_{ts,kj}. \tag{141}$$

That is, the set Φ^{qp}_{kj} (for $k=1,2,\ldots,d_q$ and $j=1,2,\ldots,d_p$) form a basis for the *ordinary* tensor product corepresentation $\pi^q\boxtimes\pi^p$. Consequently, there exists a set of elements $\theta^{r,\alpha L}_{\ell}$, all members of $\mathscr{A}$, that are defined by

$$\theta^{r,\alpha L}_{\ell}=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\begin{pmatrix} q & p \\ k & j \end{vmatrix} \begin{matrix} r & , & \alpha \\ \ell & & \end{pmatrix}\Phi^{qp}_{kj}, \tag{142}$$

for $\ell=1,2,\ldots,d_r$, and $\alpha=1,2,\ldots,n^r_{qp}$, and which have the property that

$$\pi^R_{\mathscr{A}}(\theta^{r,\alpha L}_{\ell})=\sum_{u=1}^{d_r}\theta^{r,\alpha L}_u\otimes\pi^r_{ul}, \tag{143}$$

for $u=1,2,\ldots,d_r$, and $\alpha=1,2,\ldots,n^r_{qp}$. Thus

$$\theta^{r,\alpha L}_{\ell}=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\begin{pmatrix} q & p \\ k & j \end{vmatrix} \begin{matrix} r & , & \alpha \\ \ell & & \end{pmatrix} M(\phi^{pL}_j\otimes\psi^{qL}_k), \tag{144}$$

whose inverse is

$$M(\phi_j^{pL}\otimes\psi_k^{qL})=\sum_r\sum_{\alpha=1}^{n_{qp}^r}\sum_{\ell=1}^{d_r}\left(\begin{matrix} r & , & \alpha \\ \ell & & \end{matrix}\middle|\begin{matrix} q & p \\ k & j \end{matrix}\right)\theta_\ell^{r,\alpha L}, \tag{145}$$

for $j=1,2,\ldots,d_p$ and $k=1,2,\ldots,d_q$. Applying the projection operator $\mathscr{P}_{ul}^{rL}$ of (107) to $M(\phi_j^{pL}\otimes\psi_k^{qL})$, and using (109), (145), and (144), it follows that

$$\begin{aligned}&\mathscr{P}_{ul}^{rL}[M(\phi_j^{pL}\otimes\psi_k^{qL})]\\&\quad=\sum_{\alpha=1}^{n_{qp}^r}\sum_{v=1}^{d_r}\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\left(\begin{matrix} r & , & \alpha \\ \ell & & \end{matrix}\middle|\begin{matrix} q & p \\ k & j \end{matrix}\right)\left(\begin{matrix} q & p \\ t & s \end{matrix}\middle|\begin{matrix} r & , & \alpha \\ v & & \end{matrix}\right)\\&\qquad\times d_r\{[(\mathbf{F}^r)^{-1}]_{vu}/tr[(\mathbf{F}^r)^{-1}]\}M(\phi_s^{pL}\otimes\psi_t^{qL}),\end{aligned} \tag{146}$$

for $j=1,2,\ldots,d_p$ and $k=1,2,\ldots,d_q$. However, the definition (107) taken in conjunction with (139) gives

$$\mathscr{P}_{ul}^{rL}[M(\phi_j^{pL}\otimes\psi_k^{qL})]=d_r\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}M(\phi_s^{pL}\otimes\psi_t^{qL})h(\pi_{ul}^{r*}\pi_{tk}^q\pi_{sj}^p), \tag{147}$$

so equating coefficients of $M(\phi_s^{pL}\otimes\psi_t^{qL})$ in (146) and (147) yields (138) again.

It is also possible to obtain (137) [and hence (138)] *without* making any linear independence assumptions about the set of products $M(\phi_j^{pR}\otimes\psi_k^{qR})$, for by (111), (126), (127), and (128),

$$\begin{aligned}&\sum_r\sum_{\alpha=1}^{n_{pq}^r}\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{v,w=1}^{d_r}\left(\begin{matrix} r & , & \alpha \\ w & & \end{matrix}\middle|\begin{matrix} p & q \\ j & k \end{matrix}\right)\left(\begin{matrix} p & q \\ s & t \end{matrix}\middle|\begin{matrix} r & , & \alpha \\ v & & \end{matrix}\right)v_s^p\otimes v_t^q\otimes\pi_{vw}^r\\&\quad=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}v_s^p\otimes v_t^q\otimes M(\pi_{sj}^p\otimes\pi_{tk}^q),\end{aligned}$$

for all $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$. As the set $v_s^p\otimes v_t^q$ (for $s=1,2,\ldots,d_p$, and $t=1,2,\ldots,d_q$) is certainly linearly independent, it follows that

$$\sum_r\sum_{\alpha=1}^{n_{pq}^r}\sum_{v,w=1}^{d_r}\left(\begin{matrix} r & , & \alpha \\ w & & \end{matrix}\middle|\begin{matrix} p & q \\ j & k \end{matrix}\right)\left(\begin{matrix} p & q \\ s & t \end{matrix}\middle|\begin{matrix} r & , & \alpha \\ v & & \end{matrix}\right)\pi_{vw}^r=M(\pi_{sj}^p\otimes\pi_{tk}^q)$$

(for $j,s=1,2,\ldots,d_p$, and $k,t=1,2,\ldots,d_q$). On replacing r by r' in the sums of on the left-hand side, multiplying through by $\pi_{u\ell}^{r*}$ from the left, applying the Haar functional h, and using (65) and (68), one regains (137).

VI. THE IRREDUCIBLE TENSOR OPERATORS

A. Introduction

Let π^q be a unitary irreducible right coaction of $\mathscr{A}$ of dimension d_q with matrix coefficients π_{jk}^q It will be shown that within both the right and the left regular corepresentation formalisms there exist two types of irreducible tensor operators that both belong to this corepresentation π^q. These will be denoted by Q_j^{qX} and $\widetilde{Q}_j^{qX}$ (for $j=1,2,\ldots,d_q$ and for $X=R$ or L), and will be called *ordinary* and *twisted* irreducible tensor operators, respectively. Naturally the two types of irreducible tensor operators coincide in the special case in which $\mathscr{A}$ is commutative. Moreover, it should be noted that if $\mathscr{A}^{op}$ is the Hopf algebra in which the multiplication operator M and antipode S of $\mathscr{A}$ are replaced by $M\circ\sigma$ and S^{-1}, respectively, then the ''twisted'' irreducible

tensor operators for $\mathscr{A}$ are the ''ordinary'' irreducible tensor operators for $\mathscr{A}^{op}$ and the ''ordinary'' irreducible tensor operators for $\mathscr{A}$ are the ''twisted'' irreducible tensor operators for $\mathscr{A}^{op}$.

B. Definitions in the right regular corepresentation formalism

1. Definition of the ordinary irreducible tensor operators Q_j^{qR}

The *ordinary irreducible tensor operators* Q_j^{qR} belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ are *defined* to be members of $\mathscr{L}(\mathscr{A})$ that satisfy the condition

$$((id\otimes M)\circ(\Delta\otimes id)\circ(Q_j^{qR}\otimes S)\circ\Delta)(a)=\sum_{k=1}^{d_q} Q_k^{qR}(a)\otimes\pi_{kj}^q, \tag{148}$$

for all $a\in\mathscr{A}$ and all $j=1,2,\ldots,d_q$. Hereafter $\mathscr{L}(\mathscr{A})$ denotes the set of linear operators that map $\mathscr{A}$ into $\mathscr{A}$.

Clearly this definition involves *only* quantities defined on $\mathscr{A}$, for the right-hand side is a member of $\mathscr{A}\otimes\mathscr{A}$. By virtues of (80) this definition can be written equivalently in terms of the right regular coaction $\pi_{\mathscr{A}}^R$ as

$$[(id\otimes M)\circ(\pi_{\mathscr{A}}^R\otimes id)\circ(Q_j^{qR}\otimes S)\circ\pi_{\mathscr{A}}^R](a)=\sum_{k=1}^{d_q} Q_k^{qR}(a)\otimes\pi_{kj}^q, \tag{149}$$

for all $a\in\mathscr{A}$ and all $j=1,2,\ldots,d_q$. [The motivation behind the definition (148) is explained in Appendix B 2 a].

It will now be shown that (148) provides a *consistent* definition, in that it can be re-expressed by saying that the operators Q_j^{qR} (for $j=1,2,\ldots,d_q$) form the basis of a carrier space for a certain right coaction of $\mathscr{A}$. The motivation for this definition is given in Appendix B 2 b, where the special case in which $\mathscr{A}$ is finite-dimensional is considered in detail, but for the general case it is necessary to apply additional conditions to the domain of this coaction. The analysis of Appendix B 2 b implies that if $\mathscr{A}$ is *finite*-dimensional then, for *every* operator $Q\in\mathscr{L}(\mathscr{A})$, there exist operators $Q_i\in\mathscr{L}(\mathscr{A})$ and elements q_i, both indexed by the same *finite* index set I, such that

$$\sum_{i\in I} Q_i(a)\otimes q_i=[(id\otimes M)\circ(\Delta\otimes id)\circ(Q\otimes S)\circ\Delta](a), \tag{150}$$

for all $a\in\mathscr{A}$, but this is not necessarily true for every $Q\in\mathscr{L}(\mathscr{A})$ if $\mathscr{A}$ is infinite-dimensional. However, one can always define a subspace $\mathscr{T}(\mathscr{A})$ of $\mathscr{L}(\mathscr{A})$ by the requirement that $Q\in\mathscr{T}(\mathscr{A})$ if (i) $Q\in\mathscr{L}(\mathscr{A})$, (ii) Q satisfies (150) with I finite, and (iii) each Q_i appearing on the left-hand side of (150) also satisfies a condition of the same form. This subspace $\mathscr{T}(\mathscr{A})$ is certainly not empty, for the identity operator belongs to it [cf. (170)], as does every irreducible tensor operator Q_j^{qR} [cf. (148)], and, as just noted, if $\mathscr{A}$ is finite-dimensional then $\mathscr{T}(\mathscr{A})$ is identical to $\mathscr{L}(\mathscr{A})$. The *definition* of the required right coaction, which will be denoted by $\pi_{\mathscr{T}(\mathscr{A})}^R$, is then that it is the mapping of $\mathscr{T}(\mathscr{A})$ into $\mathscr{T}(\mathscr{A})\otimes\mathscr{A}$ that given by

$$\pi_{\mathscr{T}(\mathscr{A})}^R(Q)=\sum_{[Q]} Q_{[1]}\otimes Q_{[2]}, \tag{151}$$

where $Q_{[1]}\in\mathscr{T}(\mathscr{A})$ and $Q_{[1]}\in\mathscr{A}$ are such that

$$\sum_{[Q]} Q_{[1]}(a)\otimes Q_{[2]}=[(id\otimes M)\circ(\Delta\otimes id)\circ(Q\otimes S)\circ\Delta](a), \tag{152}$$

for all $Q \in \mathscr{T}(\mathscr{A})$ and all $a \in \mathscr{A}$. It is then quite easily shown [using the identities (8) to (19)] that $\pi^R_{\mathscr{T}(\mathscr{A})}$ satisfies (43) and (44) [with π_V and V replaced by $\pi^R_{\mathscr{T}(\mathscr{A})}$ and $\mathscr{T}(\mathscr{A})$, respectively, and with all operators of $\mathscr{T}(\mathscr{A})$ acting on any member of $\mathscr{A}$ according to the prescription of (152)]. That is,

$$\sum_{[Q]} \sum_{[Q_{[1]}]} (Q_{[1]})_{[1]}(a) \otimes (Q_{[1]})_{[2]} \otimes Q_{[2]} = \sum_{[Q]} Q_{[1]}(a) \otimes \Delta(Q_{[2]}) \tag{153}$$

and

$$\sum_{[Q]} (Q_{[1]})(a) \epsilon(Q_{[2]}) = Q(a),$$

for all $Q \in \mathscr{T}(\mathscr{A})$ and all $a \in \mathscr{A}$. Hence $\pi^R_{\mathscr{T}(\mathscr{A})}$ is indeed a right coaction with carrier space $\mathscr{T}(\mathscr{A})$. Thus (151) and (152) imply that the definition (148) can be written equivalently as

$$\pi^R_{\mathscr{T}(\mathscr{A})}(Q^{qR}_j) = \sum_{k=1}^{d_q} Q^{qR}_k \otimes \pi^q_{kj} \tag{154}$$

(for all $j = 1,2, \ldots$). Because (154) is similar in form to (45), and as $\pi^R_{\mathscr{T}(\mathscr{A})}$ is a right coaction with carrier space $\mathscr{T}(\mathscr{A})$, the consistency of the definition (148) is now ensured.

2. Definition of the twisted irreducible tensor operators $\tilde{Q}^{qR}_j$

The *twisted irreducible tensor operators* $\widetilde{Q}^{qR}_j$ belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ are *defined* to be members of $\mathscr{L}(\mathscr{A})$ that satisfy the condition

$$[(id \otimes M) \circ (id \otimes \sigma) \circ (\Delta \otimes id) \circ (\widetilde{Q}^{qR}_j \otimes S^{-1}) \circ \Delta](a) = \sum_{k=1}^{d_q} \widetilde{Q}^{qR}_k(a) \otimes \pi^q_{kj}, \tag{155}$$

for all $a \in \mathscr{A}$ and all $j = 1,2, \ldots, d_q$. This can be written equivalently in terms of the right regular coaction $\pi^R_{\mathscr{A}}$ as

$$[(id \otimes M) \circ (id \otimes \sigma) \circ (\pi^R_{\mathscr{A}} \otimes id) \circ (\widetilde{Q}^{qR}_j \otimes S^{-1}) \circ \pi^R_{\mathscr{A}}](a) = \sum_{k=1}^{d_q} \widetilde{Q}^{qR}_k(a) \otimes \pi^q_{kj}, \tag{156}$$

for all $a \in \mathscr{A}$ and all $j = 1,2, \ldots, d_q$. Both (155) and (156) differ from the corresponding definitions (148) and (149) only in the replacement of M by $M \circ \sigma$ *and* S by S^{-1} (neither of which have any effect in the special case in which $\mathscr{A}$ is commutative). (See Appendix B 2 a for further discussion of this pair of substitutions. It should be recorded that Rittenberg and Scheunert[8] noted previously, in the context of what was essentially the ''abstract carrier space formalism'' [form (3) of Section I] as generalized to irreducible *representations* of $\mathscr{A}'$, that these substitutions do produce another type of irreducible tensor operator, but they did not pursue this observation at all.)

The demonstration that (155) provides a *consistent* definition again involves showing that it can be re-expressed by saying that the operators $\widetilde{Q}^{qR}_j$ (for $j = 1,2, \ldots, d_q$) form the basis of a carrier space for a right coaction of $\mathscr{A}$. This right coaction $\widetilde{\pi}^R_{\mathscr{T}(\mathscr{A})}$ [and its associated space $\mathscr{T}(\mathscr{A})$] are essentially obtained from $\pi^R_{\mathscr{T}(\mathscr{A})}$ by replacing M by $M \circ \sigma$ and S by S^{-1}, so $\widetilde{\pi}^R_{\mathscr{T}(\mathscr{A})}$ is *defined* as the mapping of $\mathscr{T}(\mathscr{A})$ into $\mathscr{T}(\mathscr{A}) \otimes \mathscr{A}$ that given by

$$\widetilde{\pi}^R_{\mathscr{T}(\mathscr{A})}(Q) = \sum_{[Q]} Q_{[1]} \otimes Q_{[2]}, \tag{157}$$

where $Q_{[1]} \in \mathscr{T}(\mathscr{A})$ and $Q_{[1]} \in \mathscr{A}$ are such that

$$\sum_{[Q]} Q_{[1]}(a) \otimes Q_{[2]} = [(id \otimes (M \circ \sigma)) \circ (\Delta \otimes id) \circ (Q \otimes S^{-1}) \circ \Delta](a), \tag{158}$$

for all $Q \in \mathscr{T}(\mathscr{A})$ and all $a \in \mathscr{A}$. Then (157) and (158) imply that the definition (155) can be written equivalently as

$$\tilde{\pi}^{R}_{\mathscr{T}(\mathscr{A})}(\tilde{Q}^{qR}_{j}) = \sum_{k=1}^{d_q} \tilde{Q}^{qR}_{k} \otimes \pi^{q}_{kj} \tag{159}$$

(for all $j = 1,2, \ldots$), which then ensures the consistency of the definition (155).

C. Definitions in the left regular corepresentation formalism

1. Definition of the ordinary irreducible tensor operators Q^{qL}_j

The *ordinary irreducible tensor operators* Q^{qL}_j belonging to the unitary irreducible right coaction π^{q} of $\mathscr{A}$ are *defined* to be members of $\mathscr{L}(\mathscr{A})$ that satisfy the condition

$$[(id \otimes M) \circ (\pi^{L}_{\mathscr{A}} \otimes id) \circ (Q^{qL}_{j} \otimes S) \circ \pi^{L}_{\mathscr{A}}](a) = \sum_{k=1}^{d_q} Q^{qL}_{k}(a) \otimes \pi^{q}_{kj}, \tag{160}$$

for all $a \in \mathscr{A}$ and all $j = 1,2, \ldots, d_q$. [This is can be obtained from (149) by replacing $X = R$ by $X = L$, the justification being discussed in more detail in Appendix B 3 a.] In terms of the elementary operations of $\mathscr{A}$, (160) can be re-expressed using (81) as

$$[\sigma \circ (S \otimes id) \circ (M \otimes id) \circ (id \otimes \Delta) \circ (S \otimes Q^{qL}_{j}) \circ \Delta](a) = \sum_{k=1}^{d_q} Q^{qL}_{k}(a) \otimes \pi^{q}_{kj}, \tag{161}$$

for all $a \in \mathscr{A}$ and all $j = 1,2, \ldots, d_q$.

The demonstration that (160) provides a *consistent* definition proceeds in the same way as above. In this case the appropriate right coaction will be denoted by $\pi^{L}_{\mathscr{T}(\mathscr{A})}$, and will be *defined* as the mapping of $\mathscr{T}(\mathscr{A})$ into $\mathscr{T}(\mathscr{A}) \otimes \mathscr{A}$ that given by

$$\pi^{L}_{\mathscr{T}(\mathscr{A})}(Q) = \sum_{[Q]} Q_{[1]} \otimes Q_{[2]}, \tag{162}$$

where $Q_{[1]} \in \mathscr{T}(\mathscr{A})$ and $Q_{[1]} \in \mathscr{A}$ are such that

$$\sum_{[Q]} Q_{[1]}(a) \otimes Q_{[2]} = (\sigma \circ (S \otimes id) \circ (M \otimes id) \circ (id \otimes \Delta) \circ (S \otimes Q) \circ \Delta)(a), \tag{163}$$

for all $Q \in \mathscr{T}(\mathscr{A})$ and all $a \in \mathscr{A}$. [Here the subspace $\mathscr{T}(\mathscr{A})$ of $\mathscr{L}(\mathscr{A})$ is defined as in Section VI B 1, but with the right-hand side of (163) replacing the right-hand side of (152) in (150). The motivation for this definition is given in Appendix B 3 b.] Then the definition (160) can be written equivalently as

$$\pi^{L}_{\mathscr{T}(\mathscr{A})}(Q^{qL}_{j}) = \sum_{k=1}^{d_q} Q^{qL}_{k} \otimes \pi^{q}_{kj} \tag{164}$$

(for all $j = 1,2, \ldots$), which then guarantees its consistency.

2. Definition of the twisted irreducible tensor operators $\tilde{Q}_j^{qL}$

The *twisted irreducible tensor operators* $\tilde{Q}_j^{qL}$ belonging π^q of $\mathscr{A}$ are *defined* to be members of $\mathscr{L}(\mathscr{A})$ that satisfy the condition

$$[(id\otimes M)\circ(id\otimes\sigma)\circ(\pi^L_{\mathscr{A}}\otimes id)\circ(\tilde{Q}_j^{qL}\otimes S^{-1})\circ\pi^L_{\mathscr{A}}](a)=\sum_{k=1}^{d_q}\tilde{Q}_k^{qL}(a)\otimes\pi^q_{kj}, \tag{165}$$

for all $a\in\mathscr{A}$ and all $j=1,2,\ldots,d_q$. In terms of the elementary operations of $\mathscr{A}$, (165) can be re-expressed using (81) as

$$[(id\otimes M)\circ(\sigma\otimes S)\circ(id\otimes\sigma)\circ(id\otimes\Delta)\circ(id\otimes\tilde{Q}_j^{qL})\circ\Delta](a)=\sum_{k=1}^{d_q}\tilde{Q}_k^{qL}(a)\otimes\pi^q_{kj}, \tag{166}$$

for all $a\in\mathscr{A}$ and all $j=1,2,\ldots,d_q$. The definition (165) differs from the corresponding definition (160) only in the replacement of M by $M\circ\sigma$ *and* S by S^{-1} (neither of which have any effect in the special case in which $\mathscr{A}$ is commutative). However, because the two S factors in (161) have different origins, these substitutions do *not* convert (161) into (166). (See Appendix B 3 a for a further discussion of this point.)

The consistency of the definition (165) is again shown in the same way as above. In this case the appropriate right coaction will be denoted by $\tilde{\pi}^L_{\mathscr{T}(\mathscr{A})}$, and will be *defined* as the mapping of $\mathscr{T}(\mathscr{A})$ into $\mathscr{T}(\mathscr{A})\otimes\mathscr{A}$ that given by

$$\tilde{\pi}^L_{\mathscr{T}(\mathscr{A})}(Q)=\sum_{[Q]}Q_{[1]}\otimes Q_{[2]}, \tag{167}$$

where $Q_{[1]}\in\mathscr{T}(\mathscr{A})$ and $Q_{[1]}\in\mathscr{A}$ are such that

$$\sum_{[Q]}Q_{[1]}(a)\otimes Q_{[2]}=[(id\otimes M)\circ(\sigma\otimes S)\circ(id\otimes\sigma)\circ(id\otimes\Delta)\circ(id\otimes Q)\circ\Delta](a), \tag{168}$$

for all $Q\in\mathscr{T}(\mathscr{A})$ and all $a\in\mathscr{A}$. [Here the subspace $\mathscr{T}(\mathscr{A})$ of $\mathscr{L}(\mathscr{A})$ is defined as in Section VI B 1, but with the right-hand side of (168) replacing the right-hand side of (152) in (150). The motivation for this definition is given in Appendix B 3 b.] Then the definition (165) can be written equivalently as

$$\tilde{\pi}^L_{\mathscr{T}(\mathscr{A})}(\tilde{Q}_j^{qL})=\sum_{k=1}^{d_q}\tilde{Q}_k^{qL}\otimes\pi^q_{kj} \tag{169}$$

(for all $j=1,2,\ldots$), which then implies the consistency of (165).

D. The identity operator as an irreducible tensor operator

Suppose that Q is the *identity operator* id of $\mathscr{L}(\mathscr{A})$ [so that $Q(a)=a$ for all $a\in\mathscr{A}$]. Then, on using (9) and (18), it follows that

$$(id\otimes M)\circ(\Delta\otimes id)\circ(id\otimes S)\circ\Delta=id\otimes 1_{\mathscr{A}}, \tag{170}$$

which, by (148), leads to the agreeable conclusion that the identity operator id is an *ordinary* irreducible tensor operator in the *right* regular corepresentation formalism for the one-dimensional *identity* corepresentation whose sole matrix coefficient is $1_{\mathscr{A}}$.

It is easily checked [using (155), (161), and (166) in place of (148)], that id is also a *twisted* irreducible tensor operator for the identity corepresentation in the *right* regular corepresentation formalism , as well as being a both an *ordinary* and a *twisted* irreducible tensor operator for the identity corepresentation in the *left* regular corepresentation formalism.

In fact, if one were to adopt the view that these results concerning the identity operator are an *essential* requirement of any sensible definition of irreducible tensor operators, the fact that they are not true if M is replaced by $M \circ \sigma$ but S is left unchanged, nor if M is left unchanged but S is replaced by S^{-1}, then precludes further consideration of these possibilities.

E. Products as irreducible tensor operators

Suppose now that ψ_j^{qR} and ψ_j^{qL} are sets of basis functions for π^q [as defined in (94) and (95), respectively] and that the operators Q_j^{qX} and $\widetilde{Q}_j^{qX}$ are *defined* by

$$\begin{aligned} Q_j^{qR}(a) &= M(\psi_j^{qR} \otimes a), \\ \widetilde{Q}_j^{qR}(a) &= M(a \otimes \psi_j^{qR}), \\ Q_j^{qL}(a) &= M(a \otimes \psi_j^{qL}), \\ \widetilde{Q}_j^{qL}(a) &= M(\psi_j^{qL} \otimes a), \end{aligned} \tag{171}$$

for all $a \in \mathscr{A}$. Then the identities (21) to (32) imply that the operators Q_j^{qR}, $\widetilde{Q}_j^{qR}$, Q_j^{qL}, and $\widetilde{Q}_j^{qL}$ do indeed satisfy (148), (155), (161), and (166), respectively, and so are irreducible tensor operators belonging to π^q.

F. Two useful identities for the ordinary irreducible tensor operators Q_j^{qX} and $\tilde{Q}_j^{qX}$

If Q_k^{qX} is an *ordinary* irreducible tensor operator belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ and ψ_j^{pX} is a set of basis functions for the unitary irreducible right coaction π^p of $\mathscr{A}$, then

$$\pi_{\mathscr{A}}^X[Q_k^{qX}(\psi_j^{pX})] = \sum_{s=1}^{d_p} \sum_{t=1}^{d_q} [Q_t^{qX}(\psi_s^{pX})] \otimes [M(\pi_{tk}^q \otimes \pi_{sj}^p)], \tag{172}$$

for $X = R$ and L, for all $j = 1,2, \ldots, d_p$, and $k = 1,2, \ldots, d_q$. That is, by (118),

$$\pi_{\mathscr{A}}^X[Q_k^{qX}(\psi_j^{pX})] = \sum_{s=1}^{d_p} \sum_{t=1}^{d_q} [Q_t^{qX}(\psi_s^{pX})] \otimes (\pi^q \boxtimes \pi^p)_{ts,kj}, \tag{173}$$

for $X = R$ and L, for all $j = 1,2, \ldots, d_p$ and $k = 1,2, \ldots, d_q$.

By contrast, if $\widetilde{Q}_k^{qX}$ is a *twisted* irreducible tensor operator belonging π^q, then

$$\pi_{\mathscr{A}}^X[\widetilde{Q}_k^{qX}(\psi_j^{pX})] = \sum_{s=1}^{d_p} \sum_{t=1}^{d_q} [\widetilde{Q}_t^{qX}(\psi_s^{pX})] \otimes [M(\pi_{sj}^p \otimes \pi_{tk}^q)], \tag{174}$$

for $X = R$ and L, for all $j = 1,2, \ldots, d_p$ and $k = 1,2, \ldots, d_q$. It should be noted that the factors in the second term of the right-hand side of (174) are interchanged relative to those of (172), which implies, by (119), that

$$\pi_{\mathscr{A}}^X[\widetilde{Q}_k^{qX}(\psi_j^{pX})] = \sum_{s=1}^{d_p} \sum_{t=1}^{d_q} [\widetilde{Q}_t^{qX}(\psi_s^{pX})] \otimes (\pi^q \widetilde{\boxtimes} \pi^p)_{ts,kj}, \tag{175}$$

for $X=R$ and L, for all $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$, which involves the *twisted* tensor product.

The proof of (172) is as follows. Applying (94) or (95) to the case $a=\psi_u^{pX}$ and invoking (149) or (160) (as appropriate) gives

$$\sum_{v=1}^{d_p}(id\otimes M)[\pi^X_{\mathscr{A}}(Q_j^{qX}(\psi_v^{pX}))\otimes S(\pi^p_{vu})]=\sum_{k=1}^{d_q}[Q_k^{qX}(\psi_u^{pX})]\otimes\pi^q_{kj}. \tag{176}$$

However, for any $a\in\mathscr{A}$,

$$(id\otimes M)[\pi^X_{\mathscr{A}}(a)\otimes S(\pi^p_{vu})]=\sum_{[a]}a_{[1]}\otimes M[a_{[2]}\otimes S(\pi^p_{vu})],$$

the right-hand side of which, on multiplication from the right with $1_{\mathscr{A}}\otimes\pi^p_{ui}$, and summing over u, and using (52) and (53), reduces to $\delta_{iv}\pi^X_{\mathscr{A}}(a)$. The desired result (172) is then obtained by multiplying both sides of (176) from the right with $1_{\mathscr{A}}\otimes\pi^p_{ui}$ and summing over u. The line of proof for (174) is similar.

G. Products of operators

If Q and Q' are any two members of $\mathscr{T}(\mathscr{A})$ and $\pi^X_{\mathscr{T}(\mathscr{A})}$ is the *ordinary* right coaction defined in (151) and (152) (for $X=R$) and (162) and (163) (for $X=L$), then

$$\pi^X_{\mathscr{T}(\mathscr{A})}(QQ')=\pi^X_{\mathscr{T}(\mathscr{A})}(Q)\,\pi^X_{\mathscr{T}(\mathscr{A})}(Q'), \tag{177}$$

for $X=R$ and L. This can be re-expressed as

$$(\pi^X_{\mathscr{T}(\mathscr{A})}\circ\hat{M})(Q\otimes Q')=[(\hat{M}\otimes M)\circ(id\otimes\sigma\otimes id)\circ(\pi^X_{\mathscr{T}(\mathscr{A})}\otimes\pi^X_{\mathscr{T}(\mathscr{A})})](Q\otimes Q'), \tag{178}$$

for $X=R$ and L, where the operator multiplication operation $\hat{M}$ is defined by

$$\hat{M}(Q\otimes Q')=Q\circ Q', \tag{179}$$

for all $Q,Q'\in\mathscr{T}(\mathscr{A})$.

By contrast, if $\tilde{\pi}^X_{\mathscr{T}(\mathscr{A})}$ is the *twisted* right coaction defined in (157) and (158) (for $X=R$) and (167) and (168) (for $X=L$), then

$$\begin{aligned}&(\tilde{\pi}^X_{\mathscr{T}(\mathscr{A})}\circ\hat{M})(Q\otimes Q')\\&\quad=[(\hat{M}\otimes M)\circ(id\otimes id\otimes\sigma)\circ(id\otimes\sigma\otimes id)\circ(\tilde{\pi}^X_{\mathscr{T}(\mathscr{A})}\otimes\tilde{\pi}^X_{\mathscr{T}(\mathscr{A})})](Q\otimes Q'),\end{aligned} \tag{180}$$

for $X=R$ and L, whose righthand side involves an extra twist factor $(id\otimes id\otimes\sigma)$ relative to the corresponding result (178).

The proofs of these statements just involve a straightforward application of the identities (8) to (19).

VII. THEOREMS OF THE WIGNER–ECKART TYPE

If π^p, π^q, and π^r are unitary irreducible corepresentations of $\mathscr{A}$ of dimensions d_p, d_q, and d_r, respectively, ϕ_j^{pX} and ψ_ℓ^{rX} are basis functions belonging to π^p and π^r, and Q_k^{qX} is an *ordinary* irreducible tensor operator belonging to π^q, then

$$[\psi_{\ell}^{rX},Q_k^{qX}(\phi_j^{pX})]^X=\sum_{\alpha=1}^{n_{qp}^r}\left(\begin{array}{ccc|cc} r & , & \alpha & q & p \\ \ell & & & k & j \end{array}\right)(r|Q^{qX}|p)_\alpha, \tag{181}$$

for $X=R$ and L, all $j=1,2,\ldots,d_p$, all $k=1,2,\ldots,d_q$, and all $\ell=1,2,\ldots,d_r$. Here the *reduced matrix elements* $(r|Q^{qX}|p)_\alpha$ are given by

$$(r|Q^{qX}|p)_\alpha=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u,v=1}^{d_r}[\psi_u^{rX},Q_t^{qX}(\phi_s^{pX})]^X\left(\begin{array}{cc|ccc} q & p & r & , & \alpha \\ t & s & v & & \end{array}\right)$$
$$\times\{[(\mathbf{F}^r)^{-1}]_{vu}/tr[(\mathbf{F}^r)^{-1}]\}, \tag{182}$$

for $\alpha=1,2,\ldots,n_{qp}^r$, and the inner products $(,)^R$ and $(,)^L$ are defined in (86) and (87).

On the other hand, if $\tilde{Q}_k^{qX}$ is a *twisted* irreducible tensor operator belonging to π^q, then

$$[\psi_{\ell}^{rX},\tilde{Q}_k^{qX}(\phi_j^{pX})]^X=\sum_{\alpha=1}^{n_{pq}^r}\left(\begin{array}{ccc|cc} r & , & \alpha & p & q \\ \ell & & & j & k \end{array}\right)(r|\tilde{Q}^{qX}|p)_\alpha, \tag{183}$$

for $X=R$ and L, all $j=1,2,\ldots,d_p$, all $k=1,2,\ldots,d_q$, and all $\ell=1,2,\ldots,d_r$, where the reduced matrix elements $(r|\tilde{Q}^{qX}|p)_\alpha$ are given by

$$(r|\tilde{Q}^{qX}|p)_\alpha=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u,v=1}^{d_r}[\psi_u^{rX},\tilde{Q}_t^{qX}(\phi_s^{pX})]^X\left(\begin{array}{cc|ccc} p & q & r & , & \alpha \\ s & t & v & & \end{array}\right)$$
$$\times\{[(\mathbf{F}^r)^{-1})_{vu}/tr((\mathbf{F}^r)^{-1}]\}, \tag{184}$$

for $\alpha=1,2,\ldots,n_{pq}^r$.

The results (181) and (183) exhibit the classic Wigner–Eckart theorem behaviour, in that they show that the j, k, and ℓ dependences of the inner products $(\psi_{\ell}^{rX},Q_k^{qX}\phi_j^{pX})^X$ and $(\psi_{\ell}^{rX},\tilde{Q}_k^{qX}\phi_j^{pX})^X$ are determined only by Clebsch–Gordan coefficients, but it should be noted that in the general case in which $\mathscr{A}$ is non–commutative, the inner products for the *ordinary* and *twisted* irreducible tensor operators involve *different* sets of Clebsch–Gordan coefficients.

The proof of (181) in the case $X=R$ is as follows. By (92) and (172),

$$\pi_{\mathscr{A}}^R[\psi_{\ell}^{rR*}Q_k^{qR}(\phi_j^{pR})]=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u=1}^{d_r}[\psi_u^{rR*}Q_t^{qR}(\phi_s^{pR})]\otimes(\pi_{u\ell}^{r*}\pi_{tk}^q\pi_{sj}^p),$$

for all $j=1,2,\ldots,d_p$, $k=1,2,\ldots,d_q$, and $\ell=1,2,\ldots,d_r$. Then, by (91),

$$h[\psi_{\ell}^{rR*}Q_k^{qR}(\phi_j^{pR})]=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u=1}^{d_r}h[\psi_u^{rR*}Q_t^{qR}(\phi_s^{pR})]h(\pi_{u\ell}^{r*}\pi_{tk}^q\pi_{sj}^p),$$

for all $j=1,2,\ldots,d_p$, $k=1,2,\ldots,d_q$, and $\ell=1,2,\ldots,d_r$. Invoking (86) and (138) then immediately gives (181) and (182).

The proof of (181) in the case $X=L$ is similar. By (172), (93), and (98),

$$\pi_{\mathscr{A}}^L[Q_k^{qL}(\phi_j^{pL})(S^2(\psi_{\ell}^{rL}))^*]=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u=1}^{d_r}[Q_t^{qL}(\phi_s^{pL})(S^2(\psi_u^{rL}))^*]\otimes(\pi_{u\ell}^{r*}\pi_{tk}^q\pi_{sj}^p),$$

for all $j=1,2,\ldots,d_p$, $k=1,2,\ldots,d_q$, and $\ell=1,2,\ldots,d_r$. On applying (91), (87), and (138), the results (181) and (182) are obtained for this case as well.

The proof of (183) follows the same lines, but employs (174) and (137) in place of (172) and (138).

VIII. PRODUCTS OF IRREDUCIBLE TENSOR OPERATORS

If π^p and π^q are unitary irreducible corepresentations of $\mathscr{A}$ of dimensions d_p and d_q, respectively, and Q_j^{pX} and Q_k^{qX} are *ordinary* irreducible tensor operators belonging to π^p and π^q, then

$$\pi^X_{\mathscr{T}(\mathscr{A})}(Q_j^{pX}Q_k^{qX})=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}(Q_s^{pX}Q_t^{qX})\otimes(\pi^p\boxtimes\pi^q)_{st,jk}, \tag{185}$$

for $X=R$ and L and for all $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$. Here the coactions $\pi^R_{\mathscr{T}(\mathscr{A})}$ and $\pi^L_{\mathscr{T}(\mathscr{A})}$ are as defined in (151), (152), (162), and (163), and the matrix coefficients of the tensor product $\pi^p\boxtimes\pi^q$ are given in (118). [The proof of (185) just involves applying (178), (154), (164), and (179).]

Because of the similarity in form between (185) and (131), it follows immediately that

$$Q_\ell^{rX,\alpha}=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\left(\begin{array}{cc|ccc} p & q & r & , & \alpha \\ j & k & \ell & & \end{array}\right)Q_j^{pX}Q_k^{qX}, \tag{186}$$

for $\ell=1,2,\ldots,d_r$ and $\alpha=1,2,\ldots,n_{pq}^r$. Here $Q_\ell^{rX,\alpha}$ (for $\alpha=1,2,\ldots,n_{pq}^r$) are n_{pq}^r ordinary irreducible tensor operators belonging to π^r that are, in general, all different.

By contrast, if $\widetilde{Q}_j^{pX}$ and $\widetilde{Q}_k^{qX}$ are *twisted* irreducible tensor operators belonging to π^p and π^q, then

$$\widetilde{\pi}^X_{\mathscr{T}(\mathscr{A})}(\widetilde{Q}_j^{pX}\widetilde{Q}_k^{qX})=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}(\widetilde{Q}_s^{pX}\widetilde{Q}_t^{qX})\otimes(\pi^p\widetilde{\boxtimes}\pi^q)_{st,jk}, \tag{187}$$

for $X=R$ and L and for all $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$. Here the right coactions $\widetilde{\pi}^R_{\mathscr{T}(\mathscr{A})}$ and $\widetilde{\pi}^L_{\mathscr{T}(\mathscr{A})}$ are as defined in (157), (158), (167), and (168), and the matrix coefficients of the *twisted* tensor product $\pi^p\widetilde{\boxtimes}\pi^q$ are given in (119). [This result (187) is proved using (180), (159), (169), and (179).]

The analogue of (186) for the *twisted* case is

$$\widetilde{Q}_\ell^{rX,\alpha}=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\left(\begin{array}{cc|ccc} q & p & r & , & \alpha \\ k & j & \ell & & \end{array}\right)\widetilde{Q}_j^{pX}\widetilde{Q}_k^{qX}, \tag{188}$$

for $\ell=1,2,\ldots,d_r$ and $\alpha=1,2,\ldots,n_{qp}^r$. Here $\widetilde{Q}_\ell^{rX,\alpha}$ (for $\alpha=1,2,\ldots,n_{qp}^r$) are n_{qp}^r twisted irreducible tensor operators belonging to π^r that are, in general, all different.

IX. GENERALIZATION TO QUANTUM HOMOGENEOUS SPACES

A. Quantum homogeneous spaces

The definition and role of quantum homogeneous spaces are best introduced by considering the situation first in the very well established and familiar context of a compact Lie group $\mathscr{G}$. The homogeneous space formalism for $\mathscr{G}$ has two essential features. Firstly, it is equivalent to the theory in which $\mathscr{G}$ acts as a transformation group on an external manifold $\mathscr{M}$, and, secondly, it is closely related to the regular representation formalisms. Both of these aspects were reviewed briefly in Section I.

With $\mathscr{G}$ taken to be a group of transformations that act on an external manifold $\mathscr{M}$, select some typical point of $\mathscr{M}$. Let $\mathscr{H}$ be the *isotropy subgroup* of $\mathscr{G}$, which consists of all transformations of $\mathscr{G}$ that send this point into itself, and let $\mathscr{M}_0$ be the *orbit* of points of $\mathscr{M}$ that are obtained by acting on this typical point with every transformation of $\mathscr{G}$. In the case in which $\mathscr{G}$ is the rotation group about O and $\mathscr{M}$ is $\mathfrak{R}^3$, let $\mathbf{r}_0$ of $\mathfrak{R}^3$ be this typical point. Then $\mathscr{H}$ is the subgroup of all rotations about the axis from O to the point $\mathbf{r}_0$, and $\mathscr{M}_0$ is the sphere centered on O that contains the point $\mathbf{r}_0$. With an appropriate choice of $\mathbf{r}_0$, $\mathscr{M}_0$ can be parametrized by the spherical polar coordinates θ and ϕ. Effectively it is only the functional dependence on θ and ϕ that comes into symmetry arguments, the dependence on the radial distance r being immaterial. That is, only the subspace $\mathscr{M}_0$ is actually relevant in the group theoretical calculations. However, it is easily demonstrated that there is a one-to-one correspondence between the points of $\mathscr{M}_0$ and the set of *left* cosets $T.\mathscr{H}$ of $\mathscr{G}$ with respect to $\mathscr{H}$. Thus the quantities of interest are the subset $\mathscr{B}$ of $R(\mathscr{G})$ that consists of those members of $R(\mathscr{G})$ which are *constant* on each left coset $T.\mathscr{H}$. Then the operators acting on the members of $\mathscr{B}$ that correspond to the operators $P(T)$ of (2) may be identified with the left regular operators $\hat{L}(T)$ of (A18), as *restricted* to act *only* on $\mathscr{B}$. Moreover the only part of the integral (5) that is relevant to symmetry arguments is the part involving θ and ϕ, which is an integral over $\mathscr{M}_0$, and hence is equivalent to the Haar integral of (6) applied to the functions of $\mathscr{B}$. Finally, in the homogeneous space version, the irreducible tensor operators of (4) become mappings of $\mathscr{B}$ into $\mathscr{B}$.

Henceforth the $\star$-Hopf algebra $R(\mathscr{G})$ will be denoted by $\mathscr{A}$. Then $\mathscr{B}$ becomes a $\star$-subalgebra of $\mathscr{A}$ and a *left* coideal of $\mathscr{A}$. [The convention adopted here is that $\mathscr{B}$ is said to be a left coideal of $\mathscr{A}$ if $\Delta(f) \in \mathscr{A}\otimes\mathscr{B}$ for all $f \in \mathscr{B}$, and $\mathscr{B}$ is said to be a right coideal of $\mathscr{A}$ if $\Delta(f) \in \mathscr{B}\otimes\mathscr{A}$ for all $f \in \mathscr{B}$.] It is also trivially true that $\mathscr{B}$ is S^2-invariant.

There also exists a parallel version of this theory associated with the *right* regular representation of $\mathscr{G}$, the operators $\hat{R}(T)$ of which are defined by $\hat{R}(T)f(T') = f(T'T)$ for all f and for all $T, T' \in \mathscr{G}$. Then, for example, if $\mathscr{G}$ is the group of all rotations in this space about O and $\mathscr{M}$ is $\mathfrak{R}^3$, in place of the transformations of (1) one could define another set in which

$$(\mathbf{r}')^T = \mathbf{r}^T\mathbf{R}(T), \tag{189}$$

where $\mathbf{r}^T$ denotes the transpose of $\mathbf{r}$. Then, for a typical point $\mathbf{r}_0$, there is a one-to-one correspondence between the points of the orbit $\mathscr{M}_0$ of $\mathbf{r}_0$ and the set of *right* cosets $\mathscr{H}T$ of $\mathscr{G}$ with respect to the corresponding isotropy subgroup $\mathscr{H}$ of $\mathbf{r}_0$. In this case the quantity of interest is the set $\mathscr{B}$ of representative functions of $\mathscr{G}$ which are constant on each *right* coset $\mathscr{H}T$. Then $\mathscr{B}$ is a $\star$-subalgebra of $\mathscr{A}$ and a *right* coideal of $\mathscr{A}$, and the analogues of operators $P(T)$ of (2) are the $\hat{R}(T)$ restricted to $\mathscr{B}$. It is again trivially true that $\mathscr{B}$ is S^2-invariant.

There are various ways in which these ideas can be generalized to produce quantum homogeneous spaces,[23–26,31–36] but the present development follows the work of Dijkhuizen and Koornwinder.[23–26] In this formulation one works with a $\star$- Hopf algebra $\mathscr{A}$ (which is in general both non-commutative and non-cocommutative), and with a $\star$-subalgebra $\mathscr{B}$ of $\mathscr{A}$ that is either a right coideal of $\mathscr{A}$ or is a left coideal of $\mathscr{A}$. (The explicit discussion in Refs. 23–26 is actually given for the former situation, but clearly the formulation can also be re-expressed for the latter situation.) Dijkhuizen and Koornwinder[23–26] have discussed various other algebraic objects that are associated with $\mathscr{B}$, and have shown that in the case of the quantum SU(2) group there exists a one-parameter family of such spaces (called ''quantum 2-spheres'') which are mutually non-isomorphic, and they have related these to the work of Podleś.[31]

For the case in which $\mathscr{B}$ is a *left* coideal of $\mathscr{A}$ it will be assumed, for reasons that will become clear in due course, that $\mathscr{B}$ is S^2-invariant. However, when $\mathscr{B}$ is a *right* coideal of $\mathscr{A}$ there is no need to make this assumption when investigating the irreducible tensor operators. Whether this assumption is needed in this case for other purposes is a matter that has been discussed by Dijkhuizen and Koornwinder.[23,24]

B. The restricted right and left regular coactions

In the special case in which $\mathscr{A}$ is the dual of a group algebra, the operations of $\mathscr{A}$ corresponding to the right and left regular actions of the group algebra are the right and left regular *coactions* of $\mathscr{A}$. Consequently the restrictions of right and left regular actions of the group algebra to $\mathscr{B}$ correspond to the right and left regular coactions of $\mathscr{A}$ restricted to $\mathscr{B}$. These are not only the relevant operations of the classical homogeneous space formulation but they are also the basic operations of the *quantum* homogeneous space formulation.

Explicitly, the right regular coaction $\pi^R_{\mathscr{A}}$ and the left regular coaction $\pi^L_{\mathscr{A}}$ for a general compact quantum group algebra $\mathscr{A}$ are defined [in (43) and (81)] by

$$\pi^R_{\mathscr{A}}=\Delta, \quad \pi^L_{\mathscr{A}}=\sigma\circ(S\otimes id)\circ\Delta.$$

Both are *right* coactions of $\mathscr{A}$ with carrier space $\mathscr{A}$. The corresponding *restricted right regular coaction* $\pi^R_{\mathscr{B}}$ and *restricted left regular coaction* $\pi^L_{\mathscr{B}}$ may then be defined by

$$\pi^R_{\mathscr{B}}=\pi^R_{\mathscr{A}|\mathscr{B}}=\Delta_{|\mathscr{B}}, \quad \pi^L_{\mathscr{B}}=\pi^L_{\mathscr{A}|\mathscr{B}}=\sigma\circ(S\otimes id)\circ\Delta_{|\mathscr{B}}. \tag{190}$$

In the context of the restricted right regular coaction it is being assumed that $\mathscr{B}$ is a right coideal of $\mathscr{A}$, whereas in the restricted left regular coaction context $\mathscr{B}$ is assumed to be a left coideal of $\mathscr{A}$. Because of the extra twist factor σ in the definition of $\pi^L_{\mathscr{B}}$, it follows that *both* $\pi^R_{\mathscr{B}}$ *and* $\pi^L_{\mathscr{B}}$ are *right* coactions of $\mathscr{A}$ with carrier space $\mathscr{B}$. (The role of $\pi^R_{\mathscr{B}}$ as a transitive $\star$-coaction corresponding to the transitive action of the quantum group associated with $\mathscr{A}$ on the quantum homogeneous space associated with $\mathscr{B}$ has been described by Dijkhuizen and Koornwinder.[23,24])

The restriction of the Haar functional h of $\mathscr{A}$ to $\mathscr{B}$ provides a positive definite integral for $\mathscr{B}$ with the invariance properties

$$[M_{\mathbb{C},\mathscr{A}}\circ(h\otimes id)\circ\pi^X_{\mathscr{B}}](b)=[M_{\mathscr{A},\mathbb{C}}\circ(id\otimes h)\circ\pi^X_{\mathscr{B}}](b)=h(b)\,1_{\mathscr{A}}, \tag{191}$$

for all $b\in\mathscr{B}$ and for both $X=R$ and $X=L$ [cf. (88) and (89)].

The restricted right and left regular corepresentations are both *unitary*, provided that the inner products on the carrier space $\mathscr{B}$ are chosen in the following way.

1. for the restricted *right* regular corepresentation take

$$\langle b,b'\rangle_{\mathscr{B}}=(b,b')^R=h[M(b^\star\otimes b')], \quad \text{for all} \quad b,b'\in\mathscr{B}; \tag{192}$$

2. for the restricted *left* regular corepresentation take

$$\langle b,b'\rangle_{\mathscr{B}}=(b,b')^L=h\{M[b\otimes(S^2(b'))^\star]\} \quad \text{for all} \quad b,b'\in\mathscr{B}. \tag{193}$$

It should be noted that $(S^2(b'))^\star\in\mathscr{B}$ if $\mathscr{B}$ is S^2-invariant. [The proofs of these unitary properties are essentially the same as for the corresponding results (86) and (87) for the unrestricted regular coactions.]

The effects of the restricted right and left regular coactions on products are also essentially the same as for the unrestricted coactions [cf. (92) and (93)].

C. Basis functions for the restricted right and left regular coactions

Suppose that π^p_{jk} are the matrix coefficients of a corepresentation π^p of $\mathscr{A}$ of finite dimension d_p. Then the *basis functions* ψ^{pR}_j *of* π^p *with respect to the restricted right regular coaction* may be defined to be a set of d_p elements of $\mathscr{B}$ that have the property that

$$\pi^R_{\mathscr{B}}(\psi^{pR}_j)=\sum_{k=1}^{d_p}\psi^{pR}_k\otimes\pi^p_{kj}, \tag{194}$$

for all $j=1,2,\ldots,d_p$. Similarly the *basis functions* ψ_j^{pL} *of* π^p *with respect to the restricted left regular coaction* may be defined as a set of d_p elements of $\mathscr{B}$ that have the property that

$$\pi^L_{\mathscr{B}}(\psi_j^{pL})=\sum_{k=1}^{d_p}\psi_k^{pL}\otimes\pi^p_{kj}, \tag{195}$$

for all $j=1,2,\ldots,d_p$. In both cases the matrix coefficients π^p_{kj} are elements of $\mathscr{A}$, and need not be members of $\mathscr{B}$.

By contrast with the unrestricted coaction situation, in neither case is there any guarantee that for a given corepresentation π^p there actually exist basis functions for restricted coactions. For example, in the restricted right regular coaction case, a set of basis functions is provided (for any fixed choice of $\ell=1,2,\ldots$) by

$$\psi_j^{pR}=\pi^p_{\ell j}, \tag{196}$$

for all $j=1,2,\ldots,d_p$ *only if* $\pi^p_{\ell j}$ is an element of $\mathscr{B}$ for *some* $j=1,2,\ldots,d_p$. [Then (I.43) and the fact that $\mathscr{B}$ is assumed in this context to be a right coideal of $\mathscr{A}$ imply that $\pi^p_{\ell j}\in\mathscr{B}$ for *all* $j=1,2,\ldots,d_p$.] Similarly, in the restricted left regular coaction case, an example is provided (for any fixed choice of $\ell=1,2,\ldots$) by

$$\psi_j^{pL}=S^{-2}(\pi^{p\star}_{j\ell}), \tag{197}$$

for all $j=1,2,\ldots,d_p$ *only if* $\pi^p_{j\ell}$ is an element of $\mathscr{B}$ for *some* $j=1,2,\ldots,d_p$. [Then (I.43) and the fact that $\mathscr{B}$ is assumed in this context to be a S^2-invariant left coideal and $\star$-subalgebra of $\mathscr{A}$ imply that $S^{-2}(\pi^{p\star}_{j\ell})\in\mathscr{B}$ for *all* $j=1,2,\ldots,d_p$.]

One very useful result, proved in the same way as the corresponding unrestricted identity (98), is that if ψ_k^{qL} exists then

$$\pi^L_{\mathscr{B}}[(S^2(\psi_k^{qL}))^\star]=\sum_{t=1}^{d_p}(S^2(\psi_t^{qL}))^\star\otimes\pi^{q\star}_{tk}, \tag{198}$$

for all $k=1,2,\ldots,d_p$.

The orthogonality properties of basis functions are the essentially the same as for those for the unrestricted case that have been given in (99), (100), and (103). (The only qualification is that now it has to be assumed that the relevant matrix corepresentation coefficients are members of $\mathscr{B}$.)

If the basis functions ψ_k^{qX} and ϕ_j^{pX} are members of $\mathscr{B}$ (so that they are basis functions for the restricted coactions), then their products $M(\psi_k^{qX}\otimes\phi_j^{pX})$ are also members of $\mathscr{B}$. Consequently the analysis of Section V D goes through without modification, except that all basis functions involved (including the $\theta^{r,\alpha X}_{\ell}$) are in $\mathscr{B}$ and one can always replace the unrestricted coactions $\pi^X_{\mathscr{A}}$ by the restricted coactions $\pi^X_{\mathscr{B}}$ The rest of the discussion of Section V on tensor products and Clebsch–Gordan coefficients still applies in its entirety.

D. The irreducible tensor operators in the restricted corepresentation formalisms

1. Introduction

Let π^q be a unitary irreducible right coaction of $\mathscr{A}$ of dimension d_q with matrix coefficients π^q_{jk}. It will be shown that within both the restricted right and the restricted left regular corepresentation formalisms there exist two types of irreducible tensor operators that both belong to this corepresentation π^q. These will be denoted by $Q^{qX}_{j,\mathscr{B}}$ and $\widetilde{Q}^{qX}_{j,\mathscr{B}}$ (for $j=1,2,\ldots,d_q$ and for $X=R$ or L), and will be called *ordinary* and *twisted* irreducible tensor operators associated with $\mathscr{B}$, respectively. These operators are members of $\mathscr{L}(\mathscr{B})$, which is the set of linear operators that map

$\mathscr{B}$ into $\mathscr{B}$. Naturally the two types of irreducible tensor operators coincide in the special case in which $\mathscr{A}$ is commutative. As much of the analysis is the same as for the unrestricted case, all the proofs will be omitted.

2. Definition of the ordinary irreducible tensor operators $Q_{j,\mathscr{B}}^{qX}$ and twisted irreducible tensor operators $\tilde{Q}_{j,\mathscr{B}}^{qX}$

The *ordinary irreducible tensor operators* $Q_{j,\mathscr{B}}^{qX}$ belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ are *defined* (for $X=L,R$) to be members of $\mathscr{L}(\mathscr{B})$ that satisfy the condition

$$[(id\otimes M)\circ(\pi_{\mathscr{B}}^{X}\otimes id)\circ(Q_{j,\mathscr{B}}^{qX}\otimes S)\circ\pi_{\mathscr{B}}^{X}](b)=\sum_{k=1}^{d_q} Q_{k,\mathscr{B}}^{qX}(b)\otimes\pi_{kj}^{q}, \tag{199}$$

for all $b\in\mathscr{B}$ and all $j=1,2,\ldots,d_q$.

The *twisted irreducible tensor operators* $\tilde{Q}_{j,\mathscr{B}}^{qX}$ belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ are *defined* (for $X=L,R$) to be members of $\mathscr{L}(\mathscr{B})$ that satisfy the condition

$$[(id\otimes M)\circ(id\otimes\sigma)\circ(\pi_{\mathscr{B}}^{X}\otimes id)\circ(\tilde{Q}_{j,\mathscr{B}}^{qX}\otimes S^{-1})\circ\pi_{\mathscr{B}}^{X}](b)=\sum_{k=1}^{d_q}\tilde{Q}_{k,\mathscr{B}}^{qX}(b)\otimes\pi_{kj}^{q}, \tag{200}$$

for all $b\in\mathscr{B}$ and all $j=1,2,\ldots,d_q$. [This definition (200) differs from the corresponding definition (199) only in the replacement of M by $M\circ\sigma$ *and* S by S^{-1} (neither of which have any effect in the special case in which $\mathscr{A}$ is commutative).]

3. Properties of the irreducible tensor operators associated with quantum homogeneous spaces

(1) Suppose that Q is the *identity operator* id of $\mathscr{L}(\mathscr{B})$ [so that $Q(b)=b$ for all $b\in\mathscr{B}$]. Then id is both an *ordinary* and a *twisted* irreducible tensor operator for the one-dimensional *identity* corepresentation of $\mathscr{A}$ (whose sole matrix coefficient is $1_{\mathscr{A}}$) in the restricted *right* regular corepresentation formalism, as well as being a both an *ordinary* and a *twisted* irreducible tensor operator for this identity corepresentation in the restricted *left* regular corepresentation formalism.

(2) Suppose now that ψ_j^{qR} and ψ_j^{qL} are sets of basis functions for π^q, as defined in (194) and (195), respectively (so that they are members of $\mathscr{B}$), and suppose that the operators $Q_{j,\mathscr{B}}^{qX}$ and $\tilde{Q}_{j,\mathscr{B}}^{qX}$ are *defined* by

$$\begin{aligned} Q_{j,\mathscr{B}}^{qR}(b) &= M(\psi_j^{qR}\otimes b),\\ \tilde{Q}_{j,\mathscr{B}}^{qR}(b) &= M(b\otimes\psi_j^{qR}),\\ Q_{j,\mathscr{B}}^{qL}(b) &= M(b\otimes\psi_j^{qL}),\\ \tilde{Q}_{j,\mathscr{B}}^{qL}(b) &= M(\psi_j^{qL}\otimes b), \end{aligned} \tag{201}$$

for all $b\in\mathscr{B}$. Then $Q_{j,\mathscr{B}}^{qR}$, $\tilde{Q}_{j,\mathscr{B}}^{qR}$, $Q_{j,\mathscr{B}}^{qL}$, and $\tilde{Q}_{j,\mathscr{B}}^{qL}$ are irreducible tensor operators belonging to π^q.

E. Wigner–Eckart type theorems associated with quantum homogeneous spaces

If π^p, π^q, and π^r are unitary irreducible corepresentations of $\mathscr{A}$ of dimensions d_p, d_q, and d_r, respectively, ϕ_j^{pX} and ψ_ℓ^{rX} are basis functions belonging π^p and π^r (with ϕ_j^{pX} and ψ_ℓ^{rX} being assumed here to be members of $\mathscr{B}$), and $Q_{k,\mathscr{B}}^{qX}$ is an *ordinary* irreducible tensor operator belonging to π^q (with respect to the relevant restricted regular coaction), then

$$[\psi_{\ell}^{rX},Q_{k\mathscr{B}}^{qX}(\phi_j^{pX})]^X=\sum_{\alpha=1}^{n_{qp}^r}\begin{pmatrix} r & , & \alpha \\ \ell & & \end{vmatrix} \begin{matrix} q & p \\ k & j \end{matrix}\end{pmatrix}(r|Q_{\mathscr{B}}^{qX}|p)_\alpha, \tag{202}$$

for $X=R$ and L, all $j=1,2,\ldots,d_p$, all $k=1,2,\ldots,d_q$, and all $\ell=1,2,\ldots,d_r$. Here the *reduced matrix elements* $(r|Q_{\mathscr{B}}^{qX}|p)_\alpha$ are given by

$$(r|Q_{\mathscr{B}}^{qX}|p)_\alpha=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u,v=1}^{d_r}[\psi_u^{rX},Q_{t\mathscr{B}}^{qX}(\phi_s^{pX})]^X\begin{pmatrix} q & p & r & , & \alpha \\ t & s & v & & \end{pmatrix}$$
$$\times\{[(\mathbf{F}^r)^{-1}]_{vu}/tr[(\mathbf{F}^r)^{-1}]\}, \tag{203}$$

for $\alpha=1,2,\ldots,n_{qp}^r$, the inner products $(,)^R$ and $(,)^L$ are defined in (192) and (193), and $\mathbf{F}^r$ is defined in (66).

On the other hand, if $\widetilde{Q}_{k\mathscr{B}}^{qX}$ is a *twisted* irreducible tensor operator belonging to π^q (with respect to the relevant restricted regular coaction), then

$$[\psi_{\ell}^{rX},\widetilde{Q}_{k\mathscr{B}}^{qX}(\phi_j^{pX})]^X=\sum_{\alpha=1}^{n_{pq}^r}\begin{pmatrix} r & , & \alpha \\ \ell & & \end{vmatrix} \begin{matrix} p & q \\ j & k \end{matrix}\end{pmatrix}(r|\widetilde{Q}_{\mathscr{B}}^{qX}|p)_\alpha, \tag{204}$$

for $X=R$ and L, all $j=1,2,\ldots,d_p$, all $k=1,2,\ldots,d_q$, and all $\ell=1,2,\ldots,d_r$, where the reduced matrix elements $(r|\widetilde{Q}_{\mathscr{B}}^{qX}|p)_\alpha$ are given by

$$(r|\widetilde{Q}_{\mathscr{B}}^{qX}|p)_\alpha=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u,v=1}^{d_r}[\psi_u^{rX},\widetilde{Q}_{t\mathscr{B}}^{qX}(\phi_s^{pX})]^X\begin{pmatrix} p & q & r & , & \alpha \\ s & t & v & & \end{pmatrix}$$
$$\times\{[(\mathbf{F}^r)^{-1}]_{vu}/tr[(\mathbf{F}^r)^{-1}]\}, \tag{205}$$

for $\alpha=1,2,\ldots,n_{pq}^r$.

These results (202) and (204) demonstrate that again the j, k, and ℓ dependences of the inner products $(\psi_{\ell}^{rX},Q_{k\mathscr{B}}^{qX}\phi_j^{pX})^X$ and $(\psi_{\ell}^{rX},\widetilde{Q}_{k\mathscr{B}}^{qX}\phi_j^{pX})^X$ are determined only by Clebsch–Gordan coefficients, and so they have the same form as in the classic Wigner–Eckart theorem. (However, it should be noted that in the general case in which $\mathscr{A}$ is non–commutative, the inner products for the *ordinary* and *twisted* irreducible tensor operators involve *different* sets of Clebsch–Gordan coefficients.)

As the proofs of (202) and (204) follow the same lines as in the unrestricted case considered in Section VII, they will be omitted here.

F. Products of irreducible tensor operators associated with quantum homogeneous spaces

The arguments of Section VIII can be applied (with $\mathscr{A}$ replaced by $\mathscr{B}$) to show that

$$Q_{\ell\mathscr{B}}^{rX,\alpha}=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\begin{pmatrix} p & q & r & , & \alpha \\ j & k & \ell & & \end{pmatrix}Q_{j\mathscr{B}}^{pX}Q_{k\mathscr{B}}^{qX}, \tag{206}$$

for $\ell=1,2,\ldots,d_r$, and $\alpha=1,2,\ldots,n_{pq}^r$. Here $Q_{\ell\mathscr{B}}^{rX,\alpha}$ (for $\alpha=1,2,\ldots,n_{pq}^r$) are n_{pq}^r ordinary irreducible tensor operators belonging to π^r that are, in general, all different. Moreover,

$$\widetilde{Q}_{\ell\mathscr{B}}^{rX,\alpha}=\sum_{j=1}^{d_p}\sum_{k=1}^{d_q}\begin{pmatrix} q & p & r & , & \alpha \\ k & j & \ell & & \end{pmatrix}\widetilde{Q}_{j\mathscr{B}}^{pX}\widetilde{Q}_{k\mathscr{B}}^{qX}, \tag{207}$$

for $\ell = 1,2,\ldots,d_r$, and $\alpha = 1,2,\ldots,n_{qp}^r$, where $\tilde{Q}_{\ell\mathscr{B}}^{rX,\alpha}$ (for $\alpha = 1,2,\ldots,n_{qp}^r$) are n_{qp}^r twisted irreducible tensor operators belonging to π^r that are, in general, all different.

ACKNOWLEDGMENTS

This work was started while the author was on research leave at the Sektion Physik of the Ludwig-Maximilians-Universität, München. The author is grateful to Professor J. Wess and his colleagues for their hospitality and to the Deutscher Akademischer Austauschdienst for its financial support.

APPENDIX A: INTRODUCTION

The purpose of this appendix is to *motivate* the definitions that are given in the main body of the paper for the irreducible tensor operators and the projection operators. This will be done by considering the simple special case in which the Hopf algebra $\mathscr{A}$ is the set of functions defined on a *finite* group $\mathscr{G}$ of order g, so that the dual $\mathscr{A}'$ of $\mathscr{A}$ is the group algebra of $\mathscr{G}$. In this situation both $\mathscr{A}$ and $\mathscr{A}'$ are of finite dimension g. Of course, as $\mathscr{A}$ is commutative in this special case, the resulting expressions are to some extent ambiguous, in that in this special case M is indistinguishable from $M \circ \sigma$ and S is indistinguishable from S^{-1}. The demonstration of the correctness, consistency, and usefulness of the definitions that are actually employed for the *general* case are the subject matter of the self-contained arguments of the main body of this paper.

To proceed with this motivation, it is necessary to start with some well- known facts concerning the relationship of $\mathscr{A}$ and $\mathscr{A}'$. It is easily shown that $\mathscr{A}'$ is also a Hopf algebra, whose multiplication operation $M_{\mathscr{A}'}$, comultiplication operation $\Delta_{\mathscr{A}'}$, and antipode $S_{\mathscr{A}'}$ are related to those of $\mathscr{A}$ by

$$\langle M_{\mathscr{A}'}(a' \otimes b'), a \rangle = \langle (a' \otimes b'), \Delta(a) \rangle, \tag{A1}$$

for all $a \in \mathscr{A}$ and all $a', b' \in \mathscr{A}'$,

$$\langle \Delta_{\mathscr{A}'}(a'), (a \otimes b) \rangle = \langle a', M(a \otimes b) \rangle, \tag{A2}$$

for all $a, b \in \mathscr{A}$ and all $a' \in \mathscr{A}'$, and

$$\langle S_{\mathscr{A}'}(a'), a \rangle = \langle a', S(a) \rangle, \tag{A3}$$

for all $a \in \mathscr{A}$ and all $a' \in \mathscr{A}'$.

Now suppose that π_V is a right coaction of $\mathscr{A}$ with carrier space V. Then there exists a corresponding *left action* π_V' of $\mathscr{A}'$ with the *same* carrier space V. This is a linear mapping from $\mathscr{A}' \otimes \mathscr{V}$ to V such that

$$\pi_V' \circ (id \otimes \pi_V') = \pi_V' \circ (M_{\mathscr{A}'} \otimes id) \tag{A4}$$

and

$$\pi_V' \circ (u_{\mathscr{A}'} \otimes id) = M_{\mathbb{C},V}, \tag{A5}$$

where $u_{\mathscr{A}'}$ is the unit operator of $\mathscr{A}'$, and $M_{\mathbb{C},V}(z \otimes v) = zv$ for all $v \in V$ and all $z \in \mathbb{C}$. The relationship between π_V and π_V' can be expressed as

$$\pi_V'(a' \otimes v) = \sum_{[v]} v_{[1]} \langle a', v_{[2]} \rangle, \tag{A6}$$

for all $a' \in \mathscr{A}'$ and all $v \in V$, where the notation of (48) has been employed, or equivalently as

$$\pi'_V(a'\otimes v)=[M_{V,\mathbb{C}}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes\pi_V)](a'\otimes v), \tag{A7}$$

for all $a'\in\mathscr{A}'$ and all $v\in V$, where the evaluation map ev of (41) has been used. The inverse of these is

$$\pi_V(v)=\sum_j \pi'_V(a^j\otimes v)\otimes a_j, \tag{A8}$$

for all $v\in V$, where the basis of $\mathscr{A}$ and the dual basis of $\mathscr{A}'$ appear, and are assumed to be such that (42) holds. If V is of dimension d with basis elements $v_1,v_2,\ldots,v_d$, the matrix elements $\pi'(a')_{jk}$ of the representation are such that

$$\pi'_V(a'\otimes v_j)=\sum_{k=1}^{d}\pi'(a')_{kj}v_k, \tag{A9}$$

for all $a'\in\mathscr{A}'$ and $j=1,2,\ldots,d$. It then follows from (A8) that these representation matrix elements $\pi'(a')_{jk}$ are related to the corepresentation matrix coefficients of π^V_{jk} of (45) by

$$\pi'(a')_{jk}=\langle a',\pi^V_{jk}\rangle, \tag{A10}$$

for all $a'\in\mathscr{A}'$ and $j,k=1,2,\ldots,d$.

The *right regular action* R of $\mathscr{G}$ is defined by

$$[R(x\otimes f\,)](y)=f(yx), \tag{A11}$$

for all elements $x,y\in\mathscr{G}$ and all functions f defined on $\mathscr{G}$, where yx is evaluated using the group multiplication operation of $\mathscr{G}$. This definition (A11) can be immediately extended to all $x,y\in\mathscr{A}'$, with f being any element of $\mathscr{A}$. It is then easy to verify that R is a *left* action of $\mathscr{A}'$ with carrier space $\mathscr{A}$, and, using (A6) (or its equivalents), that it is the left action that corresponds to the right regular coaction $\pi^R_{\mathscr{A}}$ of $\mathscr{A}$ that was defined in (80). Then, by (A7),

$$R(x\otimes f\,)=[M_{\mathscr{A},\mathbb{C}}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes\Delta)](x\otimes f\,), \tag{A12}$$

for all $x\in\mathscr{A}'$ and all $f\in\mathscr{A}$, and also, by (80) and (A6),

$$\langle y,R(x\otimes f\,)\rangle=\langle y\otimes x,\Delta(\,f\,)\rangle=\langle y\otimes x,\pi^R_{\mathscr{A}}(\,f\,)\rangle, \tag{A13}$$

for all $x,y\in\mathscr{A}'$ and all $f\in\mathscr{A}$. The content of (A11) can usefully be re-expressed as

$$\hat{R}(x)f(y)=f(yx), \tag{A14}$$

by introducing an operator $\hat{R}(x)$ for each $x\in\mathscr{A}'$.

Similarly, the *left regular action* L of $\mathscr{G}$ is defined by

$$[L(x\otimes f\,)](y)=f(x^{-1}y), \tag{A15}$$

for all elements $x,y\in\mathscr{G}$ and all functions f defined on $\mathscr{G}$, which immediately extends to all $x,y\in\mathscr{A}'$ and all $f\in\mathscr{A}$. Then L is the left action of $\mathscr{A}'$ that corresponds to the left regular coaction $\pi^L_{\mathscr{A}}$ of $\mathscr{A}$ that was defined in (81). Thus, by (A7),

$$L(x\otimes f\,)=[M_{\mathscr{A},\mathbb{C}}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes\pi^L_{\mathscr{A}})](x\otimes f\,), \tag{A16}$$

for all $x\in\mathscr{A}'$ and all $f\in\mathscr{A}$, and also, by (81) and (A6),

$$\langle y, L(x\otimes f\ )\rangle = \langle y\otimes x, [\sigma\circ(S\otimes id)\circ\Delta](\ f\ )\rangle = \langle y\otimes x, \pi^{L}_{\mathscr{A}}(\ f\ )\rangle, \tag{A17}$$

for all $x,y \in \mathscr{A}'$ and all $f \in \mathscr{A}$. Moreover, (A15) can be re-written as

$$\hat{L}(x)f(y) = f[S_{\mathscr{A}'}(x)y], \tag{A18}$$

by introducing an operator $\hat{L}(x)$ for each $x \in \mathscr{A}'$.

APPENDIX B: IRREDUCIBLE TENSOR OPERATORS

1. Outline of argument

The first stage is to recall the definition of irreducible tensor operators in the group theoretical context. The next stage is to cast these considerations into the language of Hopf algebras, and the final stage is to put them into a form in which they involve quantities belonging *only* to $\mathscr{A}$. The argument will be given first for the *right* regular situation, and then for the *left* regular situation. In each case the *definitions* of irreducible tensor operators will be deduced first, and motivation for the *right coactions* that appear in the consistency arguments will follow. (The diagrammatic method that is described, for example, by Majid,[37] was employed to deduce the proofs that follow, but for typographical convenience these proofs have been transcribed here into the usual purely symbolic form.)

2. Irreducible tensor operators in the group theoretical right regular representation formalism

a. Derivations of the conditions for the Q_j^{qR} and $\tilde{Q}_j^{qR}$

Let $\mathbf{\Gamma}^q$ be a d_q dimensional representation of $\mathscr{G}$. Then the irreducible tensor operators Q_j^{qR} may be defined to act on functions defined on $\mathscr{G}$ in such a way that

$$\hat{R}(x)Q_j^{qR}\hat{R}(x^{-1}) = \sum_{k=1}^{d_q} \Gamma^q_{kj}(x)Q_k^{qR}, \tag{B1}$$

for all $x \in \mathscr{G}$ and $j = 1,2,\ldots,d_q$, or, more explicitly, such that

$$[\hat{R}(x)Q_j^{qR}\hat{R}(x^{-1})][\ f(y)] = \sum_{k=1}^{d_q} \Gamma^q_{kj}(x)[Q_k^{qR}(\ f\ )](y), \tag{B2}$$

for all $x,y \in \mathscr{G}$, for all functions f defined on $\mathscr{G}$, and $j = 1,2,\ldots,d_q$. Now define $\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)$ by

$$\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q) = \hat{R}(x)Q\hat{R}(x^{-1}), \tag{B3}$$

for all $x \in \mathscr{G}$ and for all linear operators Q that act on functions defined on $\mathscr{G}$, so that (B1) becomes

$$\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qR}) = \sum_{k=1}^{d_q} \Gamma^q_{kj}(x)Q_k^{qR}, \tag{B4}$$

for all $x \in \mathscr{G}$ and $j = 1,2,\ldots,d_q$. As discussed previously in Section I (in only a slightly different context), the consistency of the definition (B4) is consequence of the assumption that $\mathbf{\Gamma}^q$ is a representation of $\mathscr{G}$ and the fact that

$$\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(xy) = \hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)\,\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(y), \tag{B5}$$

for all $x,y \in \mathscr{G}$.

As

$$\Delta_{\mathscr{A}'}(x)=x\otimes x,\quad S_{\mathscr{A}'}(x)=x^{-1}, \tag{B6}$$

for all $x\in\mathscr{G}$, it follows from (A14) and (A11) that

$$(\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qR}))f(y)=[ev\circ(id\otimes R)\circ(id\otimes id\otimes Q_j^{qR})\circ(id\otimes id\otimes R)$$
$$\circ(id\otimes id\otimes S_{\mathscr{A}'}\otimes id)\circ(id\otimes\Delta_{\mathscr{A}'}\otimes id)](y\otimes x\otimes f), \tag{B7}$$

which is now well-defined for all $x,y\in\mathscr{A}'$, for all $f\in\mathscr{A}$, and $Q_j^{qR}\in\mathscr{L}(\mathscr{A})$. Thus, by (A12),

$$[\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qR})]f(y)=[ev\circ(id\otimes M_{\mathscr{A},\mathbb{C}})\circ(id\otimes id\otimes ev)\circ(id\otimes\sigma\otimes id)\circ(id\otimes id\otimes\Delta)$$
$$\circ(id\otimes id\otimes Q_j^{qR})\circ(id\otimes id\otimes M_{\mathscr{A},\mathbb{C}})\circ(id\otimes id\otimes id\otimes ev)\circ(id\otimes id\otimes\sigma\otimes id)$$
$$\circ(id\otimes id\otimes id\otimes\Delta)$$
$$\circ(id\otimes id\otimes S_{\mathscr{A}'}\otimes id)\circ(id\otimes\Delta_{\mathscr{A}'}\otimes id)](y\otimes x\otimes f), \tag{B8}$$

which reduces, by (A3), to

$$[\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qR})]f(y)=[M_{\mathbb{C}}\circ(ev\otimes M_{\mathbb{C}})\circ(id\otimes\sigma\otimes id)\circ(id\otimes ev\otimes id\otimes id)$$
$$\circ\{id\otimes id\otimes(\sigma\circ\Delta\circ Q_j^{qR})\otimes id\}\circ(id\otimes id\otimes\sigma)$$
$$\circ(id\otimes id\otimes ev\otimes id)\circ(id\otimes id\otimes id\otimes S\otimes id)\circ(id\otimes\Delta_{\mathscr{A}'}\otimes\sigma)$$
$$\circ(id\otimes id\otimes\Delta)](y\otimes x\otimes f), \tag{B9}$$

However, (A2) implies that

$$(ev\circ(id\otimes M)\circ(id\otimes\sigma))(x\otimes a\otimes b)=(M_{\mathbb{C}}\circ(ev\otimes ev)\circ(\Delta_{\mathscr{A}'}\otimes id\otimes id])(x\otimes a\otimes b), \tag{B10}$$

for all $a,b\in\mathscr{A}$ and all $x\in\mathscr{A}'$, so (B9) reduces to

$$(\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qR}))f(y)=[M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes M)\circ(id\otimes id\otimes\Delta\otimes id)$$
$$\circ(id\otimes id\otimes Q_j^{qR}\otimes S)\circ(id\otimes id\otimes\Delta)](y\otimes x\otimes f), \tag{B11}$$

and hence

$$(\hat{\pi}^{R\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qR}))f(y)=[M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)\circ(id\otimes id\otimes id\otimes M)$$
$$\circ(id\otimes id\otimes\Delta\otimes id)\circ(id\otimes id\otimes Q_j^{qR}\otimes S)\circ(id\otimes id\otimes\Delta)\circ(id\otimes id\otimes M_{\mathscr{A},\mathbb{C}})]$$
$$\times(y\otimes x\otimes f\otimes z), \tag{B12}$$

for all $x,y\in\mathscr{A}'$, all $f\in\mathscr{A}$, $Q_j^{qR}\in\mathscr{L}(\mathscr{A})$, and all $z\in\mathbb{C}$.

Turning to the right-hand side of (B4), by (A10),

$$\sum_{k=1}^{d_q}\Gamma^q_{kj}(x)(Q_k^{qR}(f))(y)=\sum_{k=1}^{d_q}\langle x,\pi^q_{kj}\rangle\langle y,Q_k^{qR}\rangle,$$

for all $x,y\in\mathscr{A}'$, and $j=1,2,\ldots,d_q$, and hence

$$\sum_{k=1}^{d_q} \Gamma_{kj}^{q}(x)(Q_k^{qR}(\ f\ ))(y)=\sum_{k=1}^{d_q} [M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)$$

$$\circ(id\otimes id\otimes Q_k^{qR}\otimes\pi_{kj}^{q})\circ(id\otimes id\otimes id\otimes u)](y\otimes x\otimes f\otimes z), \quad \text{(B13)}$$

for all $x,y\in\mathscr{A}'$, all $f\in\mathscr{A}$, $Q_k^{qR}\in\mathscr{L}(\mathscr{A})$, and all $z\in\mathbb{C}$.

Now (B4) implies that the expressions on the right-hand sides of (B12) and (B13) may be equated. As the first three factors of each, namely $M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)$, are the same, the equality holds with these removed. However, on both sides of this new equality, the factor $y\otimes x$ is only acted on by a succession of identity operators of the form $id\otimes id$. Consequently both $y\otimes x$ and these identity operators can be removed, leaving the result that (B1) is equivalent to the condition

$$[(id\otimes M)\circ(\Delta\otimes id)\circ(Q_j^{qR}\otimes S)\circ\Delta\circ M_{\mathscr{A},\mathbb{C}}](\ f\otimes z)$$

$$=\sum_{k=1}^{d_q} [(Q_k^{qR}\otimes\pi_{kj}^{q})\circ(id\otimes u)](\ f\otimes z), \quad \text{(B14)}$$

for all $f\in\mathscr{A}$, all $j=1,2,\ldots,d_q$, and all $z\in\mathbb{C}$. This can be rewritten as

$$((id\otimes M)\circ(\Delta\otimes id)\circ(Q_j^{qR}\otimes S)\circ\Delta)(\ f\ )=\sum_{k=1}^{d_q} Q_k^{qR}(\ f\ )\otimes\pi_{kj}^{q}, \quad \text{(B15)}$$

for all $f\in\mathscr{A}$ and all $j=1,2,\ldots,d_q$, which is the condition (148).

Because M is indistinguishable from $M\circ\sigma$ and S is indistinguishable from S^{-1} in the situation being considered here, the above arguments would equally well apply with each of the following 3 substitutions.

(1) Replace M by $M\circ\sigma$, but leave S unchanged;
(2) leave M unchanged, but replace S by S^{-1};
(3) replace M by $M\circ\sigma$ *and* replace S by S^{-1}.

However, in the general case in which $\mathscr{A}$ is non- commutative, the possibilities (1) and (2) are *excluded* because with them the identity operator would not be an irreducible tensor operator belonging to the identity corepresentation. Of course, with the substitution (3), (148) changes into (155), which is the defining condition for a *twisted* irreducible tensor operator $\widetilde{Q}_j^{qR}$.

b. Derivations of the right coactions $\pi^{R}_{\mathscr{L}(\mathscr{A})}$ and $\tilde{\pi}^{R}_{\mathscr{L}(\mathscr{A})}$

First recast (B3) as

$$\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}(x\otimes Q)=\hat{R}(x)Q\hat{R}(x^{-1}), \quad \text{(B16)}$$

for all $x\in\mathscr{G}$ and for all linear operators Q that act on functions defined on $\mathscr{G}$, where $\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}$ is a mapping from $\mathscr{A}'\otimes\mathscr{L}(\mathscr{A})$ into $\mathscr{L}(\mathscr{A})$. In Hopf algebra language, this can be re-expressed as

$$\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}(x\otimes Q)=[\hat{M}\circ(id\otimes\hat{M})\circ(\hat{R}\otimes id\otimes\hat{R})\circ(id\otimes\sigma)\circ(id\otimes S_{\mathscr{A}'}\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id)](x\otimes Q), \quad \text{(B17)}$$

where $\hat{M}$ is the operator multiplication operator defined in (179). It is then easily shown that $\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}$ is a left action of $\mathscr{A}'$ with carrier space $\mathscr{L}(\mathscr{A})$.

This expression for $\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}$ can be re- expressed in terms of the structure constants introduced in Section II with respect to the basis $a_1, a_2, \ldots$ of $\mathscr{A}$, and the basis $a^1, a^2, \ldots$ of its dual $\mathscr{A}'$. First define the operators $\mathscr{P}^k_j$ by

$$\mathscr{P}^k_j(a) = \langle a^k, a\rangle a_j \tag{B18}$$

(for all $a \in \mathscr{A}$ and all $j,k = 1,2,\ldots$), and then define the matrix elements q^k_j of Q by

$$q^k_j = \langle a^k, Q(a_j)\rangle \tag{B19}$$

(for all $j,k = 1,2,\ldots$). Clearly the operators $\mathscr{P}^k_j$ are members of $\mathscr{L}(\mathscr{A})$, and any operator Q of $\mathscr{L}(\mathscr{A})$ can be expressed as $Q = \Sigma_{j,k} Q^j_k \mathscr{P}^k_j$. Then, by (A13) and (B18),

$$\hat{R}(a^m) = \sum_{j,k=1}^{g} \mu_k^{jm} \mathscr{P}^k_j, \tag{B20}$$

for all $m = 1,2,\ldots,g$. On substituting (B20) into (B17), and using (A2) and (A3), it follows that

$$\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}(a^m \otimes Q) = \sum_{i,j,k,\ell,u,v,w=1}^{g} (m^m_{uv} s^v_w \mu_i^{ju} \mu_k^{\ell w} q^i_\ell) \mathscr{P}^k_j, \tag{B21}$$

for all $Q \in \mathscr{L}(\mathscr{A})$ and all $m = 1,2,\ldots,g$.

Using (A8), the corresponding right coaction $\pi^R_{\mathscr{L}(\mathscr{A})}$ of $\mathscr{A}$ with the same carrier space $\mathscr{L}(\mathscr{A})$ is given by

$$\pi^R_{\mathscr{L}(\mathscr{A})}(Q) = \sum_{m=1}^{g} \pi^{R\prime}_{\mathscr{L}(\mathscr{A})}(a^m \otimes Q) \otimes a_m, \tag{B22}$$

for all $Q \in \mathscr{L}(\mathscr{A})$. Thus

$$\pi^R_{\mathscr{L}(\mathscr{A})}(Q) = \sum_{i,j,k,\ell,m,u,v,w=1}^{g} (m^m_{uv} s^v_w \mu_i^{ju} \mu_k^{\ell w} q^i_\ell)(\mathscr{P}^k_j \otimes a_m),$$

for all $Q \in \mathscr{L}(\mathscr{A})$. The final stage is to re-express this in a basis free form. This can be done by writing

$$\pi^R_{\mathscr{L}(\mathscr{A})}(Q) = \sum_{[Q]} Q_{[1]} \otimes Q_{[2]},$$

where $Q_{[1]} \in \mathscr{L}(\mathscr{A})$ and $Q_{[1]} \in \mathscr{A}$ are such that

$$\sum_{[Q]} Q_{[1]}(a) \otimes Q_{[2]} = [(id \otimes M) \circ (\Delta \otimes id) \circ (Q \otimes S) \circ \Delta](a),$$

for all $Q \in \mathscr{L}(\mathscr{A})$ and all $a \in \mathscr{A}$.

The right coaction $\tilde{\pi}^R_{\mathscr{L}(\mathscr{A})}$ is obtained from $\pi^R_{\mathscr{L}(\mathscr{A})}$ by replacing M by $M \circ \sigma$ and replacing S by S^{-1}. The right coactions $\pi^R_{\mathscr{T}(\mathscr{A})}$ and $\tilde{\pi}^R_{\mathscr{T}(\mathscr{A})}$ of Sections VI B 1 and VI B 2 have essentially the same definitions as $\pi^R_{\mathscr{L}(\mathscr{A})}$ and $\tilde{\pi}^R_{\mathscr{L}(\mathscr{A})}$, except that their domains are restricted to the appropriate subspaces $\mathscr{T}(\mathscr{A})$.

3. Irreducible tensor operators in the group theoretical left regular representation formalism

a. Derivations of the conditions for the Q_j^{qL} and $\tilde{Q}_j^{qL}$

The argument for the *left* regular formalism follows exactly the same line as that for the right regular case given above up to (B7), the only differences being that the operators $\hat{R}(x)$ must be replaced by the operators $\hat{L}(x)$, the left action R must be replaced by the left action L, and the label R must be replaced by L on the irreducible tensor operators Q_j^{qR} on the left action $\pi^{R\prime}_{\mathscr{L}(\mathscr{A})}$, and on the corresponding right coaction $\pi^{R}_{\mathscr{L}(\mathscr{A})}$. Thus, by (A16), the analogue of (B8) is

$$\begin{aligned}(\hat{\pi}^{L\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qL}))f(y)(=\hat{L}(x)Q_j^{qL}\hat{L}(x^{-1}))&\\ =[ev\circ(id\otimes M_{\mathscr{A},\mathbb{C}})\circ(id\otimes id\otimes ev)&\\ \circ(id\otimes\sigma\otimes id)\circ(id\otimes id\otimes\sigma)\circ(id\otimes id\otimes S\otimes id)&\\ \circ(id\otimes id\otimes\Delta)\circ(id\otimes id\otimes Q_j^{qL})\circ(id\otimes id\otimes M_{\mathscr{A},\mathbb{C}})&\\ \circ(id\otimes id\otimes id\otimes ev)\circ(id\otimes id\otimes\sigma\otimes id)\circ(id\otimes id\otimes id\otimes\sigma)&\\ \circ(id\otimes id\otimes id\otimes S\otimes id)\circ(id\otimes id\otimes id\otimes\Delta)&\\ \circ(id\otimes id\otimes S_{\mathscr{A}'}\otimes id)\circ(id\otimes\Delta_{\mathscr{A}'}\otimes id)](y\otimes x\otimes f\ ),&\end{aligned}\tag{B23}$$

which reduces, by (A3), (B10), and (16) to

$$\begin{aligned}(\hat{\pi}^{L\prime}_{\mathscr{L}(\mathscr{A})}(x)(Q_j^{qL}))f(y)=[M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)\circ(id\otimes id\otimes\sigma)\circ(id\otimes id\otimes S\otimes id)&\\ \circ(id\otimes id\otimes M\otimes id)&\\ \circ(id\otimes id\otimes id\otimes\Delta)\circ(id\otimes id\otimes S\otimes Q_j^{qL})&\\ \circ(id\otimes id\otimes\Delta)\circ(id\otimes id\otimes M_{\mathscr{A},\mathbb{C}})](y\otimes x\otimes f\otimes z),&\end{aligned}\tag{B24}$$

for all $x,y\in\mathscr{A}'$, all $f\in\mathscr{A}$, $Q_j^{qL}\in\mathscr{L}(\mathscr{A})$, and all $z\in\mathbb{C}$.

The right-hand side of the irreducible tensor operator definition that corresponds to this is

$$\begin{aligned}\sum_{k=1}^{d_q}\Gamma^q_{kj}(x)(Q_k^{qL}(\ f\ ))(y)=\sum_{k=1}^{d_q}[M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)\circ(id\otimes id\otimes Q_k^{qL}\otimes\pi^q_{kj})&\\ \circ(id\otimes id\otimes id\otimes u)](y\otimes x\otimes f\otimes z),&\end{aligned}\tag{B25}$$

for all $x,y\in\mathscr{A}'$, all $f\in\mathscr{A}$, $Q_k^{qL}\in\mathscr{L}(\mathscr{A})$, and all $z\in\mathbb{C}$.

Equating the right-hand sides (B24) and(B25), removing the common first three factors $[M_{\mathbb{C}}\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)]$ of each, and removing the factor $y\otimes x$ and the succession of identity operators of the form $id\otimes id$ that act on $y\otimes x$, it follows that the defining condition becomes

$$\begin{aligned}[\sigma\circ(S\otimes id)\circ(M\otimes id)\circ(id\otimes\Delta)\circ(S\otimes Q_j^{qL})\circ\Delta\circ M_{\mathscr{A},\mathbb{C}}](\ f\otimes z)&\\ =\sum_{k=1}^{d_q}[(Q_k^{qL}\otimes\pi^q_{kj})\circ(id\otimes u)](\ f\otimes z),&\end{aligned}\tag{B26}$$

for all $f\in\mathscr{A}$, all $j=1,2,\ldots,d_q$, and all $z\in\mathbb{C}$. This can be rewritten as

$$[\sigma\circ(S\otimes id)\circ(M\otimes id)\circ(id\otimes\Delta)\circ(S\otimes Q_j^{qL})\circ\Delta](\ f\ )=\sum_{k=1}^{d_q}Q_k^{qL}(\ f\ )\otimes\pi^q_{kj},\tag{B27}$$

for all $f \in \mathscr{A}$ and all $j=1,2,\ldots,d_q$, which is the condition (161).

Because $\Delta_{\mathscr{A}'}$ is indistinguishable from $\sigma \circ \Delta_{\mathscr{A}'}$ and $S_{\mathscr{A}'}$ is indistinguishable from $S^{-1}_{\mathscr{A}'}$ in the situation being considered here, the above arguments would equally well apply to (B23) with each of the following 3 substitutions.

(1) Replace $\Delta_{\mathscr{A}'}$ by $\sigma \circ \Delta_{\mathscr{A}'}$, but leave $S_{\mathscr{A}'}$ unchanged;
(2) leave $\Delta_{\mathscr{A}'}$ unchanged, but replace $S_{\mathscr{A}'}$ by $S^{-1}_{\mathscr{A}'}$;
(3) (c) replace $\Delta_{\mathscr{A}'}$ by $\sigma \circ \Delta_{\mathscr{A}'}$ *and* replace $S_{\mathscr{A}'}$ by $S^{-1}_{\mathscr{A}'}$.

In each case the S factor in (B23) should be left unchanged because it comes from the definition (81) of the left regular (right) coaction. [Replacing S by S^{-1} in (81) would give another right coaction, but the original one is merely the double contragredient of this.] In the general case in which $\mathscr{A}$ is non-commutative, the possibilities (1) and (2) are again *excluded* because with them the identity operator would not be an irreducible tensor operator belonging to the identity corepresentation. However, with the substitution (3), the analogue of (161) is (166), which is the defining condition for a *twisted* irreducible tensor operator $\tilde{Q}^{qL}_j$.

b. Derivations of the right coactions $\pi^L_{\mathscr{L}(\mathscr{A})}$ and $\tilde{\pi}^L_{\mathscr{L}(\mathscr{A})}$

The *left* regular analogues of (B16) and (B17) are

$$\pi^{L\prime}_{\mathscr{L}(\mathscr{A})}(x\otimes Q)=\hat{L}(x)Q\hat{L}(x^{-1})$$

and

$$\pi^{L\prime}_{\mathscr{L}(\mathscr{A})}(x\otimes Q)=[\hat{M}\circ(id\otimes\hat{M})\circ(\hat{L}\otimes id\otimes\hat{L})\circ(id\otimes\sigma)\circ(id\otimes S_{\mathscr{A}'}\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id)](x\otimes Q), \tag{B28}$$

where $\pi^{L\prime}_{\mathscr{L}(\mathscr{A})}$ is a left action of $\mathscr{A}'$ with carrier space $\mathscr{L}(\mathscr{A})$. However, by (A17) and (B18), and with the basis of $\mathscr{A}'$ defined above,

$$\hat{L}(a^m)=\sum_{j,k,\ell=1}^{g}\mu^{\ell j}_k s^m_\ell \mathscr{P}^k_j, \tag{B29}$$

for all $m=1,2,\ldots,g$. On substituting (B29) into (B28), and using (A2) and (A3), it follows that

$$\pi^{L\prime}_{\mathscr{L}(\mathscr{A})}(a^m\otimes Q)=\sum_{i,j,k,\ell,n,u,v,w=1}^{g}(m^v_{wu}s^m_v s^w_n \mu^{uj}_i \mu^{n\ell}_k q^i_\ell)\mathscr{P}^k_j,$$

for all $Q \in \mathscr{L}(\mathscr{A})$ and all $m=1,2,\ldots,g$.

Then, using (A8), the corresponding right coaction $\pi^L_{\mathscr{L}(\mathscr{A})}$ of $\mathscr{A}$ with the same carrier space $\mathscr{L}(\mathscr{A})$ is given by

$$\pi^L_{\mathscr{L}(\mathscr{A})}(Q)=\sum_{m=1}^{g}\pi^{L\prime}_{\mathscr{L}(\mathscr{A})}(a^m\otimes Q)\otimes a_m,$$

for all $Q \in \mathscr{L}(\mathscr{A})$. Thus

$$\pi^L_{\mathscr{L}(\mathscr{A})}(Q)=\sum_{i,j,k,\ell,m,n,u,v,w=1}^{g}(m^v_{wu}s^m_v s^w_n \mu^{uj}_i \mu^{n\ell}_k q^i_\ell)(\mathscr{P}^k_j\otimes a_m),$$

for all $Q \in \mathscr{L}(\mathscr{A})$. The final stage is to re-express this in a basis free form, which can be done by writing

$$\pi^{L}_{\mathscr{L}(\mathscr{A})}(Q)=\sum_{[Q]} Q_{[1]}\otimes Q_{[2]},$$

where $Q_{[1]} \in \mathscr{L}(\mathscr{A})$ and $Q_{[1]} \in \mathscr{A}$ are such that

$$\sum_{[Q]} Q_{[1]}(a)\otimes Q_{[2]}=[\sigma\circ(S\otimes id)\circ(M\otimes id)\circ(id\otimes\Delta)\circ(S\otimes Q)\circ\Delta](a),$$

for all $Q \in \mathscr{L}(\mathscr{A})$ and all $a \in \mathscr{A}$.

For the corresponding twisted coaction $\tilde{\pi}^{L}_{\mathscr{L}(\mathscr{A})}$ the argument is similar. With the substitutions $\Delta_{\mathscr{A}'}\rightarrow\sigma\circ\Delta_{\mathscr{A}'}$ and $S_{\mathscr{A}'}\rightarrow S^{-1}_{\mathscr{A}'}$, (B28) gives

$$\tilde{\pi}^{L\prime}_{\mathscr{L}(\mathscr{A})}(x\otimes Q)=[\hat{M}\circ(id\otimes\hat{M})\circ(\hat{L}\otimes id\otimes\hat{L})\circ(id\otimes\sigma)\circ(id\otimes S^{-1}_{\mathscr{A}'}\otimes id)\circ((\sigma\otimes\Delta_{\mathscr{A}'})\otimes id)](x\otimes Q), \tag{B30}$$

where $\tilde{\pi}^{L\prime}_{\mathscr{L}(\mathscr{A})}$ is another left action of $\mathscr{A}'$ with carrier space $\mathscr{L}(\mathscr{A})$. By (B29) and (29), this gives

$$\tilde{\pi}^{L\prime}_{\mathscr{L}(\mathscr{A})}(a^{m}\otimes Q)=\sum_{i,j,k,\ell,n,u,v=1}^{g}(m^{m}_{nv}s^{v}_{u}\mu^{uj}_{i}\mu^{n\ell}_{k}q^{i}_{\ell})\mathscr{P}^{k}_{j},$$

for all $Q \in \mathscr{L}(\mathscr{A})$ and all $m=1,2,\ldots,g$. Using (A8), the corresponding right coaction $\tilde{\pi}^{L}_{\mathscr{L}(\mathscr{A})}$ of $\mathscr{A}$ with the same carrier space $\mathscr{L}(\mathscr{A})$ is given by

$$\tilde{\pi}^{L}_{\mathscr{L}(\mathscr{A})}(Q)=\sum_{m=1}^{g}\tilde{\pi}^{L\prime}_{\mathscr{L}(\mathscr{A})}(a^{m}\otimes Q)\otimes a_{m},$$

for all $Q \in \mathscr{L}(\mathscr{A})$. Thus

$$\tilde{\pi}^{L}_{\mathscr{L}(\mathscr{A})}(Q)=\sum_{i,j,k,\ell,m,n,u,v=1}^{g}(m^{m}_{nv}s^{v}_{u}\mu^{uj}_{i}\mu^{n\ell}_{k}q^{i}_{\ell})(\mathscr{P}^{k}_{j}\otimes a_{m}),$$

for all $Q \in \mathscr{L}(\mathscr{A})$. This can be re-expressed in a basis free form by writing

$$\tilde{\pi}^{L}_{\mathscr{L}(\mathscr{A})}(Q)=\sum_{[Q]} Q_{[1]}\otimes Q_{[2]},$$

where $Q_{[1]} \in \mathscr{L}(\mathscr{A})$ and $Q_{[1]} \in \mathscr{A}$ are such that

$$\sum_{[Q]} Q_{[1]}(a)\otimes Q_{[2]}=[(id\otimes M)\circ(\sigma\otimes S)\circ(id\otimes\sigma)\circ(id\otimes\Delta)\circ(id\otimes Q)\circ\Delta](a),$$

for all $Q \in \mathscr{L}(\mathscr{A})$ and all $a \in \mathscr{A}$.

The right coactions $\pi^{L}_{\mathscr{T}(\mathscr{A})}$ and $\tilde{\pi}^{L}_{\mathscr{T}(\mathscr{A})}$ of Sections VI C 1 and VI C 2 have essentially the same definitions as $\pi^{L}_{\mathscr{L}(\mathscr{A})}$ and $\tilde{\pi}^{L}_{\mathscr{L}(\mathscr{A})}$, except that their domains are restricted to the appropriate subspaces $\mathscr{T}(\mathscr{A})$.

APPENDIX C: PROJECTION OPERATORS

The *right* regular formalism will be considered first. If $\mathbf{\Gamma}^p$ is a unitary irreducible representation of dimension d_p of a finite group $\mathscr{G}$ of order g, the projection operators in the right regular formalism are defined by

$$\mathscr{P}^{pR}_{mn}=\left(\frac{d_p}{g}\right)\sum_{x\in\mathscr{G}}\Gamma^p(x)^*_{mn}\hat{R}(x),$$

for all $m,n=1,2,\ldots,d_p$. This can be re-written as

$$\mathscr{P}^{pR}_{mn}=\left(\frac{d_p}{g}\right)\sum_{x\in\mathscr{G}}\Gamma^p(x^{-1})^*_{nm}\hat{R}(x),$$

and hence, by (A10), (A14), (A11), and (B6),

$$\langle y,\mathscr{P}^{pR}_{mn}f\rangle=\left(\frac{d_p}{g}\right)\sum_{x\in\mathscr{G}}\langle S_{\mathscr{A}'}(x),\pi^p_{nm}\rangle\langle y,R(x\otimes f\ )\rangle,$$

for all $m,n=1,2,\ldots,d_p$. Here the π^p_{nm} are the matrix coefficients of the corepresentation π^p of $\mathscr{A}$ that is dual to $\mathbf{\Gamma}^p$. Then, by (A13), for all $x,y\in\mathscr{A}'$ and all $f\in\mathscr{A}$,

$$\langle y,\mathscr{P}^{pR}_{mn}f\rangle=\left(\frac{d_p}{g}\right)\sum_{x\in\mathscr{G}}\langle[(id\otimes id\otimes S_{\mathscr{A}'})\circ(id\otimes\Delta_{\mathscr{A}'})](y\otimes x),(\pi^R_{\mathscr{A}}(\ f\ )\otimes\pi^p_{nm})\rangle,$$

and so, by (52) and (72),

$$\langle y,\mathscr{P}^{pR}_{mn}f\rangle=\left(\frac{d_p}{g}\right)\sum_{x\in\mathscr{G}}\langle(y\otimes x),[(id\otimes M)\circ(id\otimes id\otimes S)](\pi^R_{\mathscr{A}}(\ f\ )\otimes\pi^p_{nm})\rangle. \tag{C1}$$

But the Haar functional is such that

$$h(a)=\left(\frac{1}{g}\right)\sum_{x\in\mathscr{G}}\langle x,a\rangle,$$

for all $a\in\mathscr{A}$, so (C1), (83), and (52) imply that

$$\mathscr{P}^{pR}_{mn}\ f=d_p\sum_{[\ f\ ]}f^R_{[1]}h[M(\ f^R_{[2]}\otimes\pi^{p*}_{mn})]. \tag{C2}$$

As multiplication is commutative in this special case, this could equally well be written as

$$\mathscr{P}^{pR}_{mn}\ f=d_p\sum_{[\ f\ ]}f^R_{[1]}h[M(\pi^{p*}_{mn}\otimes f^R_{[2]})], \tag{C3}$$

for all $m,n=1,2,\ldots,d_p$. In the general case the two formulae (C2) and (C3) are different, but the arguments given in Section IV B show that (C3) [i.e., (107)] is actually the correct choice.

The argument in the *left* regular formalism follows exactly the same line, and can be obtained by merely replacing the label R by L at each stage.

(Received 6 March 1996; accepted for publication 21 March 1996)

Properties of metrics and pairs consisting of left and right connections are studied on the bimodules of differential 1-forms. Those bimodules are obtained from the derivation based calculus of an algebra of matrix valued functions, and an $SL_q(2,\mathbb{C})$-covariant calculus of the quantum plane at a generic q and the cubic root of unity. It is shown that, in the aforementioned examples, giving up the middle-linearity of metrics significantly enlarges the space of metrics. A metric compatibility condition for the pairs of left and right connections is defined. Also, a compatibility condition between a left and right connection is discussed. Consequences entailed by reducing to the center of a bimodule the domain of those conditions are investigated in detail. Alternative ways of relating left and right connections are considered. © *1996 American Institute of Physics.* [S0022-2488(96)00408-2]

I. INTRODUCTION

Motivated to a great extent by the need to reconcile the geometric theory of gravity with the (noncommutative) operator algebraic theory of quantum physics, there is considerable interest in generalizing the formalism of General Relativity to the realm of Noncommutative Differential Geometry.[1] In this paper, we study three concepts that are apparently needed for such a generalization: metric, linear connection and metric compatibility condition.

We define a metric $g:E\times E\to A$ as a τ-symmetric A-bilinear pairing on an A-bimodule E, where τ is some generalized permutation. Then we argue that giving up the (often postulated) requirement that a metric factor to a map defined on $E\otimes_A E$ one can obtain an essentially bigger space of metrics. In particular, we provide an example with an ample supply of τ-symmetric metrics but where the requirement that a τ-symmetric metric g descend to $E\otimes_A E$ amounts to demanding that $g=0$ (see Remark 1).

Inspired by Ref. 2 on the one hand and by Ref. 3 on the other, we consider a pair of mutually compatible connections on a bimodule. The first connection of such a compatible pair is a left connection in the sense that it satisfies the Leibniz rule with respect to the left module structure. Similarly, the second connection is a right connection in the sense that it fulfills the Leibniz rule

on the right. The compatibility condition is simply a requirement that the left and the right connection agree on the center of a bimodule up to a bimodule isomorphism σ (e.g., braiding). This bimodule isomorphism is, again, a generalized permutation. Restricting the domain of the aforementioned left-right compatibility condition to the center of a bimodule permits, at least in the considered examples, a significantly bigger space of solutions to this condition. (This seems desired at least from the point of view of developing variational calculus on the space of connections.)

As to the compatibility between metrics and pairs of left and right connections, we define a 2-parameter family of compatibility conditions, but then restrict ourselves to the one that seems the most natural.

In the first section, we provide the general formalism and fix the notation. Then we proceed to the first example, where A is the algebra of matrix valued functions on a parallelizable manifold, and $E=A^1$ is the bimodule of 1-forms of the derivation based differential calculus equipped with the pullback-of-permutation automorphism. Next we pass on to the quantum plane and the differential calculus with the braiding employed in Ref. 2. First we consider the case of a generic q, and then the case of the cubic root of unity. To obtain a nonzero τ-symmetric metric on the quantum plane we have to ''rescale'' the braiding σ used in Ref. 2 by q^2. The thus obtained automorphism τ appears to be in better agreement with the theory presented in Ref. 4. (Even though in this case both automorphisms can be considered over the same domain, they are different deformations of the usual tensor product permutation.)

In what follows, Einstein's convention of summing over repeating indices is assumed, and the unadorned tensor product stands for the tensor product over a field.

II. GENERAL DEFINITIONS

Let A be a unital associative algebra over a field k, and E be a left and right projective A-bimodule. We begin with a definition of a linear pairing $g:E\times E\to A$, which, for the sake of simplicity (neglecting the nondegeneracy and reality conditions), we call a metric on E (cf. Section 8 and Section 9 in Ref. 5).

Definition 1: *Let $\tau:E\otimes E\to E\otimes E$ be a bimodule automorphism. A linear map g from $E\otimes E$ to A is called a* τ-symmetric metric *on E* (*or simply* metric, *if no confusion arises*) *iff it is*

(1) bilinear over A, i.e., $g(a\zeta,\rho b)=ag(\zeta,\rho)b$, $\forall\zeta,\rho\in E$, $a,b\in A$;

(2) τ-symmetric, i.e., $g\circ\tau=g$.

Note that if E is a central bimodule,[6,5] that is, if the left and right multiplications by the elements of $Z(A)$ coincide on any element of E (which is always the case in the examples considered in this article), then any metric g can be regarded as a map from $E\otimes_{Z(A)}E$ to A. We would like to emphasize here that, contrary to many other papers (e.g., see (10) in Ref. 7), we do not require g to be well-defined on $E\otimes_A E$. As we show in our three examples, a requirement like this (which goes under the name of middle-linearity) can be considered too restrictive (see Proposition 1, Remark 1 and Proposition 5). Giving up the middle-linearity condition allows us to get rid of those restrictions.

Another structure on a bimodule E that we wish to discuss is a pair of compatible left and right connections.

Definition 2: *Let (A^1,d) be a first order differential calculus on A, and*

$$\sigma:E\otimes_A A^1\to A^1\otimes_A E$$

be a bimodule isomorphism. Also, let ∇^L be a left connection, i.e., a linear map from E to $A^1\otimes_A E$ satisfying the left Leibniz rule,

$$\nabla^L(a\zeta)=da\otimes_A\zeta+a\nabla^L\zeta,\quad\forall a\in A,\zeta\in E,$$

and let ∇^R *be a right connection, i.e. a linear map from* E *to* $E\otimes_A A^1$ *fulfilling the right Leibniz rule,*

$$\nabla^R(\zeta a)=(\nabla^R\zeta)a+\zeta\otimes_A da,\quad \forall a\in A,\zeta\in E.$$

A pair (∇^L,∇^R) *is called* σ-compatible *iff*

$$\forall\zeta\in Z(E):\quad \nabla^L\zeta=(\sigma\circ\nabla^R)\zeta, \tag{1}$$

where $Z(E):=\{\zeta\in E\,|\,a\zeta=\zeta a,\quad \forall a\in A\}$ *is the center of* E.

Let us recall that in Section 8 of Ref. 3 a connection on a bimodule is also defined as a pair consisting of a left and right connection. There, however, instead of σ-compatibility condition (1), the condition of ∇^L being a right A-homomorphism and ∇^R being a left A-homomorphism is imposed. The latter condition, albeit it permits for an interesting algebraic theory, cannot be directly transferred to the commutative case $Z(E)=E$. On the other hand, defining a connection on a bimodule by requiring, much as in Definition 3.2 in Ref. 8, that the σ-compatibility condition is fulfilled on the whole bimodule E rather than just its center $Z(E)$, automatically yields, for the appropriate σ (i.e., the usual tensor product flip), the standard definition of a connection in the classical case, but entails essential restrictions on the space of connections in noncommutative examples (see (10), (19), (32),[9] and Theorem 5.6 in Ref. 8; cf. Lemma 1 in Ref. 5). If we demand that the equality $\nabla^L=\sigma\circ\nabla^R$be satisfied on the whole bimodule E, we can equivalently think of a pair (∇^L,∇^R) as a left connection ∇^L fulfilling an additional (right) Leibniz rule of the form

$$\nabla^L(\zeta a)=(\nabla^L\zeta)a+\sigma(\zeta\otimes_A da),\quad \forall a\in A,\zeta\in E$$

(cf. the Introduction in Ref. 10). In the classical differential geometry, with the help of the tensor product flip, any left connection uniquely determines the corresponding right connection, and vice-versa, without imposing any limitations on either of the connections. As we demonstrate in the next section, this is precisely what happens with pairs of σ-compatible connections in the noncommutative example of a ''matrix geometry'' (see Proposition 2). A very similar result (Proposition 6) is obtained for a bimodule of differential 1-forms on the quantum plane (see Proposition 2 in Ref. 11) at the cubic root of unity. (In fact, in all examples presented in this paper, we put $E=A^1$, so that the pairs of σ-compatible connections studied here can be thought of as linear connections.) When dealing with connections and metrics, it seems that in both cases we have the same mechanism at work: solving constraints over just the commutative part allows solutions to be parametrized by a whole noncommutative algebra, whereas solving them over an entire noncommutative space renders the solutions parametrized by the center of an algebra. The examples of subsequent sections allow us to explore this mechanism in some detail.

Let us now consider possible compatibility conditions between a pair of connections (∇^L,∇^R) and a metric g. In order to do so, first we must define two extensions of g:

$$\check{g}:A^1\otimes_A E\otimes E\to A^1 \text{ and } \hat{g}:E\otimes E\otimes_A A^1\to A^1.$$

It appears natural to choose

$$\check{g}(\alpha\otimes_A\zeta,\rho)=\alpha g(\zeta,\rho),\quad \forall\alpha\in A^1,\zeta,\rho\in E; \tag{2}$$

$$\hat{g}(\zeta,\rho\otimes_A\alpha)=g(\zeta,\rho)\alpha,\quad \forall\alpha\in A^1,\zeta,\rho\in E. \tag{3}$$

In principle, one can formulate the class of metric compatibility conditions by requiring the diagram

$$\begin{array}{ccccc} E\otimes E & \xrightarrow{f_L(t)\otimes id\oplus id\otimes f_R(s)} & (A^1\otimes_A E\otimes E)\oplus(E\otimes E\otimes_A A^1) & & \\ \downarrow g & & \downarrow \check{g}\oplus\hat{g}, & & \\ A & \xrightarrow{d} & A^1 & \xleftarrow{+} & A^1\oplus A^1, \end{array} \tag{4}$$

where $f_L(t):=(1-t)\nabla^L+t(\sigma\circ\nabla^R)$, $f_R(s):=s(\sigma^{-1}\circ\nabla^L)+(1-s)\nabla^R$, $t,s\in k$, to commute. Here, however, in order to ensure that $f_L(t)$ and $f_R(s)$ are connections, we settle for the particular case $t=0=s$.

Definition 3: *We say that a pair of connections* (∇^L,∇^R) is compatible with g *iff*

$$dg(\zeta,\rho)=\check{g}(\nabla^L\zeta,\rho)+\hat{g}(\zeta,\nabla^R\rho),\quad \forall\zeta,\rho\in E. \tag{5}$$

As we show in Proposition 7, formula (5) is not always sensitive to whether we consider it over E or only over $Z(E)$. Observe that, if (1) is satisfied, then on the center of a bimodule we have $f_L(t)=\nabla^L$ and $f_R(s)=\nabla^R$ for any values of $t,s\in k$, and, consequently, all metric compatibility conditions for a pair of σ-compatible connections are equivalent when considered over $Z(E)$. Finally, let us remark that the metric compatibility condition for a pair of connections related by $\nabla^L=\sigma\circ\nabla^R$ (on the whole bimodule) that is given by (1.21) and (1.26) in Ref. 2 seems inappropriate for the cases when the metric is not middle-linear.

Next, we apply the above definitions in some quantum geometric models.

III. ALGEBRAS OF MATRIX VALUED FUNCTIONS

Let us choose $A=C^\infty(M)\otimes M_n(\mathbb{C})$, $E=A^1=\mathrm{Hom}_{Z(A)}(\mathrm{Der}A,A)$,

$$\tau(\alpha\otimes\beta)(X,Y)=(\alpha\otimes\beta)(Y,X),\quad \forall X,Y\in \mathrm{Der}A,$$

and σ equal to τ factored to an automorphism of $A^1\otimes_A A^1$. Here M is a parallelizable manifold of dimension m, and the ground field of A is the field of complex numbers. Now, let $\{\theta^i\}_{i\in\{1,\ldots,m+n^2-1\}}$ be the basis of A^1 as defined in Section 3 of Ref. 10. An important property of this basis is that

$$a\,\theta^i=\theta^i a,\quad \forall a\in A,\quad i\in\{1,\ldots,m+n^2-1\}, \tag{6}$$

$$\tau(\theta^i\otimes\theta^j)=\theta^j\otimes\theta^i,\quad \forall a\in A,\quad i,j\in\{1,\ldots,m+n^2-1\}. \tag{7}$$

In this setting, one can immediately verify the following claim (cf. Section 9 in Ref. 5 and p. 5861 in Ref. 10).

Proposition 1: *Let* g^{ij} *denote* $g(\theta^i\otimes\theta^j)$, *where* $i,j\in\{1,\ldots,m+n^2-1\}$. *The map* $\psi:g\mapsto(g^{ij})$ *provides a one-to-one correspondence between the metrics (the middle-linear metrics) on* A^1 *and the symmetric matrices of* $M_{m+n^2-1}(A)$ [*the symmetric matrices of* $M_{m+n^2-1}(Z(A))$, *respectively*].

In the same basis, let us define the Christoffel symbols of ∇^L and ∇^R by

$$\nabla^L\theta^i=\theta^j\otimes_A\theta^k\Gamma^i_{jk},\quad \nabla^R\theta^i=\theta^j\otimes_A\theta^k\widetilde{\Gamma}^i_{jk}. \tag{8}$$

Taking into account (6) and (7) and noticing that $\{\theta^i\}_{i\in\{1,\ldots,m+n^2-1\}}$ is also a basis of the $Z(A)$-module $Z(A^1)$, it is straightforward to prove the following.

Proposition 2: *A pair of connections* (∇^L,∇^R) *is* σ*-compatible if and only if its Christoffel symbols satisfy the equation*

$$\widetilde{\Gamma}^i_{kj}=\Gamma^i_{jk}. \tag{9}$$

Similarly, a pair of connections is σ-compatible on the whole bimodule if and only if [*(3.9) in Ref. 10*]

$$\widetilde{\Gamma}^i_{kj}=\Gamma^i_{jk}\in C^\infty(M). \tag{10}$$

Thus the σ-compatibility condition [over $Z(E)$] allows ∇^L to uniquely determine ∇^R and vice-versa. This is not unexpected since (in this set-up)

$$A^1=AZ(A^1)=Z(A^1)A, \tag{11}$$

and ∇^L and ∇^R satisfy the left and right Leibniz rule, respectively. On the other hand, as we shall see in Section IV (Remark 3) ∇^L and ∇^R can mutually determine each other even if (11) is not satisfied.

Concerning the metric compatibility of (∇^L,∇^R), we can again take an advantage of (6) to show that (5) is equivalent to

$$dg^{ij}=(\Gamma^i_{kl}g^{lj}+g^{il}\widetilde{\Gamma}^j_{lk})\,\theta^k, \quad \forall i,j\in\{1,\ldots,m+n^2-1\}. \tag{12}$$

To end this section, let us observe that, if (∇^L,∇^R) is σ-compatible, then (12) coincides with (3.13) in Ref. 10. One should bear in mind, however, that the latter has been obtained from a different starting point [(1.9) in Ref. 10] and only for middle-linear metrics.

IV. GENERIC QUANTUM PLANE

The next example that we study regards a bimodule of differential 1-forms ($E=A^1$) on the quantum plane. We choose as our space of differential 1-forms the grade one of the differential algebra $\Omega(A)=A\oplus A^1\oplus A^2$ (e.g., see Ref. 2) that is given by the generators $1,x,y,\xi,\eta$, where $\xi=\theta^1=dx$, $\eta=\theta^2=dy$, and relations

$$\begin{gathered} xy=qyx, \quad x\xi=q^2\xi x, \quad x\eta=q\eta x+(q^2-1)\xi y, \quad y\xi=q\xi y, \quad y\eta=q^2\eta y, \\ \eta\xi+q\xi\eta=0, \quad \xi^2=0, \quad \eta^2=0. \end{gathered} \tag{13}$$

For our bimodule automorphism σ it is natural [see the paragraph between (2.11) and (2.12) in Ref. 2] to take the map defined by

$$\begin{gathered} \sigma(\xi\otimes_A\xi)=q^{-2}\xi\otimes_A\xi, \quad \sigma(\xi\otimes_A\eta)=q^{-1}\eta\otimes_A\xi, \\ \sigma(\eta\otimes_A\xi)=q^{-1}\xi\otimes_A\eta-(1-q^{-2})\eta\otimes_A\xi, \quad \sigma(\eta\otimes_A\eta)=q^{-2}\eta\otimes_A\eta. \end{gathered} \tag{14}$$

First we consider the case of a generic q. Then the center of A is $\mathbb{C}$ and, as can be checked by a direct computation, the center of A^1 is zero. If we choose τ equal to σ (modulo the tensor product over A, as was done in the previous section), we can immediately see that, unless $q=1$, there exists no nonzero metric.[2] To remedy this problem, we ''rescale'' σ by q^2. More precisely, we put

$$\begin{gathered} \tau(\xi\otimes\xi)=\xi\otimes\xi, \quad \tau(\xi\otimes\eta)=q\eta\otimes\xi, \\ \tau(\eta\otimes\xi)=q\xi\otimes\eta-(q^2-1)\eta\otimes\xi, \quad \tau(\eta\otimes\eta)=\eta\otimes\eta. \end{gathered} \tag{15}$$

It turns out that this τ is quite natural from the point of view of Ref. 4—it factors to an automorphism of $A^1\otimes_A A^1$ and preserves $\theta\otimes_A\theta$, where $\theta=x\eta-qy\xi$ is the only (up to a multiplication by a complex number) left and right $SL_q(2,\mathbb{C})$-coinvariant 1-form (see Section 2 in Ref. 2).

[Recall that if A is a Hopf algebra, then there exists a unique bimodule homomorphism τ such that $\tau(\alpha_L \otimes_A \alpha_R) = \alpha_R \otimes_A \alpha_L$ for any left coinvariant 1-form α_L and right coinvariant 1-form α_R — see Proposition 3.1 in Ref. 4.]

It is obvious that with τ specified as above, the only constraints that the coefficients of a metric g have to satisfy is

$$g(\xi,\eta) = qg(\eta,\xi). \tag{16}$$

On the other hand, it can be computed that the middle-linearity of g is equivalent to the following equations:

$$\begin{gathered}
xg(\xi,\xi) = q^4 g(\xi,\xi)x, \\
yg(\xi,\xi) = q^2 g(\xi,\xi)y, \\
xg(\xi,\eta) = q^3 g(\xi,\eta)x + q^2(q^2-1)g(\xi,\xi)y, \\
yg(\xi,\eta) = q^3 g(\xi,\eta)y, \\
xg(\eta,\xi) = q^3 g(\eta,\xi)x + q(q^2-1)g(\xi,\xi)y, \\
yg(\eta,\xi) = q^3 g(\eta,\xi)y, \\
xg(\eta,\eta) = q^2 g(\eta,\eta)x + q^2(q^2-1)g(\xi,\eta)y + q(q^2-1)g(\eta,\xi)y, \\
yg(\eta,\eta) = q^4 g(\eta,\eta)y.
\end{gathered} \tag{17}$$

Notice that, due to the commutation relation $xy = qyx$, as long as q is generic and no negative powers of x and y are allowed, there is no nonzero solution to (17) (look at the equations with y). Consequently, we obtain the following.

Remark 1: If q is not a root of unity, there is no (τ-symmetric) middle-linear metric on A^1 (see Ref. 12). ◇

Proposition 3: *If we admit negative powers of x and y, the solutions of (17) form the following three-parameter family:*

$$\begin{gathered}
g(\xi,\xi) = ax^{-2}y^4, \\
g(\xi,\eta) = qx^{-3}(by^3 + q^3 ay^5), \\
g(\eta,\xi) = x^{-3}(by^3 + q^3 ay^5), \\
g(\eta,\eta) = x^{-4}(cy^2 + q^3(q^2+1)by^4 + q^8 ay^6),
\end{gathered} \tag{18}$$

where a, b, c are complex parameters.

Since the center of A^1 is zero, we can immediately conclude that

Proposition 4: *If q is not a root of unity, any pair (∇^L, ∇^R) of σ-compatible connections on A^1 is a pair of independent and unrestricted left and right connections.*

On the other hand, there exists only a one-parameter family of solutions of the σ-compatibility condition considered over the whole A^1 (see (2.13) in Ref. 2). Defining Christoffel symbols $\{F^i_{jk}, \widetilde{F}^i_{jk}\}_{i,j,k\in\{1,2\}}$ of such a compatible pair of connections as in (8), we can write the aforementioned solutions in the following way:

$$\begin{gathered}
F^1_{11} = \nu q x y^2, \quad F^1_{12} = -\nu q^3 x^2 y, \quad F^1_{21} = -\nu q^2 x^2 y, \quad F^1_{22} = \nu q^5 x^3, \\
F^2_{11} = \nu q^3 y^3, \quad F^2_{12} = -\nu q^4 x y^2, \quad F^2_{21} = -\nu q^3 x y^2, \quad F^2_{22} = \nu q^5 x^2 y,
\end{gathered} \tag{19}$$

where ν is a complex parameter. The Christoffel symbols $\{\widetilde{F}^i_{jk}\}_{i,j,k\in\{1,2\}}$ can be expressed in a similar fashion.

As to the metric compatibility condition, formula (5) reads as

$$a_i\Big(dg(\theta^i,\theta^j)-\theta^k g(\theta^l\Gamma^i_{kl},\theta^j)-g(\theta^i,\theta^k)\theta^l\widetilde{\Gamma}^j_{kl}\Big)\widetilde{a}_j=0,\quad \forall a_i,\widetilde{a}_j\in A, i,j\in\{1,2\}. \tag{20}$$

Clearly, (20) is satisfied if and only if the expression in the large parentheses vanishes for any i and j.

V. QUANTUM PLANE AT THE CUBIC ROOT OF UNITY

The setting of this section is identical with the setting of the previous one except that now we take $q=e^{2\pi i/3}$ rather than generic q. (For the sake of simplicity, we call $e^{2\pi i/3}$ *the* cubic root of unity.) Long but rather straightforward reasoning enables one to prove the following lemma.

Lemma 1: *Let q be the cubic root of unity. Then*

$$Z(A)=\{a_{ij}x^{3i}y^{3j}|a_{ij}\in\mathbb{C}\}, \tag{21}$$

$$dZ(A)=0, \tag{22}$$

$$\forall a\in Z(A),\alpha\in A^1:\ a\alpha=\alpha a, \tag{23}$$

$$Z(A^1)=\{c_i\theta^i\in A^1|c_1=axy-bxy^3,\ c_2=bx^2y^2,\ a,b\in Z(A)\}, \tag{24}$$

$$c_i\theta^i=\theta^j\widetilde{c}_j,\ \text{where}\ c_1=axy-bxy^3,\ c_2=bx^2y^2,$$

$$\widetilde{c}_1=axy-qbxy^3,\ \widetilde{c}_2=c_2,\ a,b\in Z(A)\ [\text{see (38)}]. \tag{25}$$

Changing q from generic to $q=e^{2\pi i/3}$ entails no consequence as far as the (general τ-symmetric) metric is concerned. However, regarding middle-linear metrics, with the help of commutation formulas provided in the Appendix, one can prove the following

Proposition 5: *If q is the cubic root of unity and g is middle-linear (but not necessarily τ-symmetric), then (17) is equivalent to*

$$\begin{gathered} g(\xi,\xi)=x^3Zxy,\quad g(\xi,\eta)=qx^3Zy^2+x^3Y,\\ g(\eta,\xi)=x^3Zy^2+x^3W,\ \ g(\eta,\eta)=Ux^2y^2+(qY+W)x^2y+q^2Zx^2y^3,\end{gathered} \tag{26}$$

where Z, Y, W, U are arbitrary elements of $Z(A)$. Furthermore, g is τ-symmetric if and only if $Y=qW$.

Thus, much as in Proposition 1, the space of middle-linear metrics is three-dimensional over $Z(A)$. This is not unexpected, if one remembers that the quantum plane at the n-th root of unity is nothing but $\mathbb{C}[x,y]\otimes M_n(\mathbb{C})$ (cf. Section IV.D.15 of Ref. 13).

Our next step is to determine the space of pairs of σ-compatible connections. In order to make our reasoning more transparent, we introduce *formal* inverses of x and y. (It is simply more convenient, for instance, to write $\widetilde{\Gamma}=xy\Gamma x^{-1}y^{-1}$ as the solution of the equation $\widetilde{\Gamma}xy=xy\Gamma$ rather than consider $\widetilde{\Gamma}$ and Γ as power series in x and y and then express the complex coefficients of $\widetilde{\Gamma}$ in terms of the complex coefficients of Γ. However, we neither need nor assume the existence of x^{-1} and y^{-1} in our algebra.) Treating $\{\theta^i\otimes_A\theta^j\}_{i,j\in\{1,2\}}$ as a basis of the right A-module $A^1\otimes_A A^1$ and taking advantage of Lemma 1, one can carry out lengthy but straightforward calculations that show that the σ-compatibility condition (1) is equivalent to

$$
\begin{aligned}
\widetilde{\Gamma}^1_{11} &= q^2xy\Gamma^1_{11}y^{-1}x^{-1}+(1-q)y^2\Gamma^1_{12}y^{-1}x^{-1}+(q^2-1)y^2\Gamma^1_{21}y^{-1}x^{-1},\\
\widetilde{\Gamma}^1_{12} &= (q^2-1)xy\Gamma^1_{12}y^{-1}x^{-1}+qxy\Gamma^1_{21}y^{-1}x^{-1}+(q-q^2)y^2\Gamma^1_{22}y^{-1}x^{-1},\\
\widetilde{\Gamma}^1_{21} &= qxy\Gamma^1_{12}y^{-1}x^{-1}+(1-q)y^2\Gamma^1_{22}y^{-1}x^{-1},\\
\widetilde{\Gamma}^1_{22} &= q^2xy\Gamma^1_{22}y^{-1}x^{-1},\\
\widetilde{\Gamma}^2_{11} &= xy\Gamma^1_{11}x^{-2}-x\Gamma^1_{11}yx^{-2}+(q-1)y\Gamma^1_{12}yx^{-2}+(q-q^2)y^2\Gamma^1_{12}x^{-2}+(1-q^2)y\Gamma^1_{21}yx^{-2}\\
&\quad +(1-q)y^2\Gamma^1_{21}x^{-2}+q^2x^2y^2\Gamma^2_{11}y^{-2}x^{-2}+(q-1)x\Gamma^2_{12}yx^{-2}\\
&\quad +(1-q^2)x\Gamma^2_{21}yx^{-2}+3y\Gamma^2_{22}yx^{-2},\\
\widetilde{\Gamma}^2_{12} &= (1-q^2)x\Gamma^1_{12}yx^{-2}+(q^2-1)y^2\Gamma^1_{22}x^{-2}+(1-q)xy\Gamma^1_{12}x^{-2}+q^2xy\Gamma^1_{21}x^{-2}-qx\Gamma^1_{21}yx^{-2}\\
&\quad +(q-1)y\Gamma^1_{22}yx^{-2}+(q^2-1)x^2y^2\Gamma^2_{12}y^{-2}x^{-2}+qx^2y^2\Gamma^2_{21}y^{-2}x^{-2}+(q^2-q)x\Gamma^2_{22}yx^{-2},\\
\widetilde{\Gamma}^2_{21} &= q^2xy\Gamma^1_{12}x^{-2}-qx\Gamma^1_{12}yx^{-2}+(1-q^2)y\Gamma^1_{22}yx^{-2}+(q-q^2)y^2\Gamma^1_{22}x^{-2}+qx^2y^2\Gamma^2_{12}y^{-2}x^{-2}\\
&\quad +(q-1)x\Gamma^2_{22}yx^{-2},\\
\widetilde{\Gamma}^2_{22} &= xy\Gamma^1_{22}x^{-2}-qx\Gamma^1_{22}yx^{-2}+q^2x^2y^2\Gamma^2_{22}y^{-2}x^{-2},
\end{aligned}
\tag{27}
$$

where the Christoffel symbols are defined as in (8). The above system of equations allows one to determine uniquely ∇^R through ∇^L, but, as can be seen from the powers of x and y, it cannot be done for an arbitrary left connection ∇^L. [The total power of x and the total power of y in each term of the right hand side of (27) have to be non-negative in order for (27) to make sense.] Since only total powers of x turn negative in (27), it is convenient to think of an element of A as a polynomial in x with coefficients in polynomials in y:

$$
\Gamma^i_{jk} = x^l\Gamma^i_{jkl}, \quad i,j,k \in \{1,2\}. \tag{28}
$$

To determine the necessary and sufficient conditions that $\{\Gamma^i_{jk}\}_{i,j,k\in\{1,2\}}$ have to satisfy in order to make (27) well-defined on the quantum plane, we substitute (28) to (27) and conclude that the necessary and sufficient conditions for $\{\Gamma^i_{jk}\}_{i,j,k\in\{1,2\}}$ are fully given by

$$
\begin{aligned}
&(1-q)y^2\Gamma^1_{120}+(q^2-1)y^2\Gamma^1_{210}=0,\\
&(q-q^2)y^2\Gamma^1_{220}=0, \quad (1-q)y^2\Gamma^1_{220}=0,\\
&xy\Gamma^1_{110}-x\Gamma^1_{110}y+(q-1)y\Gamma^1_{120}y+(q-1)yx\Gamma^1_{121}y+(q-q^2)y^2\Gamma^1_{120}+(q-q^2)y^2x\Gamma^1_{121}\\
&\quad +(1-q^2)y\Gamma^1_{210}y+(1-q^2)yx\Gamma^1_{211}y+(1-q)y^2\Gamma^1_{210}+(1-q)y^2x\Gamma^1_{211}+(q-1)x\Gamma^2_{120}y\\
&\quad +(1-q^2)x\Gamma^2_{210}y+3y\Gamma^2_{220}y+3yx\Gamma^2_{221}y=0,\\
&(1-q^2)x\Gamma^1_{120}y+(q^2-1)y^2\Gamma^1_{220}+(q^2-1)y^2x\Gamma^1_{221}+(1-q)xy\Gamma^1_{120}+q^2xy\Gamma^1_{210}-qx\Gamma^1_{210}y\\
&\quad +(q-1)y\Gamma^1_{220}y+(q-1)yx\Gamma^1_{221}y+(q^2-q)x\Gamma^2_{220}y=0,\\
&q^2xy\Gamma^1_{120}-qx\Gamma^1_{120}y+(1-q^2)y\Gamma^1_{220}y+(1-q^2)yx\Gamma^1_{221}y+(q-q^2)y^2\Gamma^1_{220}\\
&\quad +(q-q^2)y^2x\Gamma^1_{221}+(q-1)x\Gamma^2_{220}y=0,\\
&xy\Gamma^1_{220}-qx\Gamma^1_{220}y=0.
\end{aligned}
\tag{29}
$$

Those equations are equivalent to

$$\Gamma^1_{210}=\Gamma^1_{120}=\Gamma^1_{220}=\Gamma^1_{221}=\Gamma^2_{220}=0$$
$$(q-1)\Gamma^2_{120}+(1-q^2)\Gamma^2_{210}+3q^2y\Gamma^2_{221}=0. \tag{30}$$

Thus we have obtained the following.

Proposition 6: *The σ-compatibility condition (1) has a solution if and only if*

$$\Gamma^1_{11}\in A,\ \ \Gamma^1_{12}\in xA,\ \ \Gamma^1_{21}\in xA,\ \ \Gamma^1_{22}\in x^2A,$$
$$\Gamma^2_{11}\in A,\ \ (q-1)\Gamma^2_{12}+(1-q^2)\Gamma^2_{21}+3q^2yx^{-1}\Gamma^2_{22}\in xA,\ \ \Gamma^2_{22}\in xA. \tag{31}$$

Moreover, if (31) is satisfied, then the general solution of (1) is given by (27).

Remark 2: Expressing $\{\Gamma^i_{jk}\}_{i,j,k\in\{1,2\}}$ in terms of $\{\tilde{\Gamma}^i_{jk}\}_{i,j,k\in\{1,2\}}$ would yield conditions for $\{\tilde{\Gamma}^i_{jk}\}_{i,j,k\in\{1,2\}}$ similar to these in Proposition 6. Only this time y would play the role of x. Let us also observe that, if we replaced σ by $q^2\sigma$ in (1), then (1) would have no solutions whatsoever as long as the negative powers of x and y are disallowed. ◇

Remark 3: As in Section II, equations (27) uniquely determine ∇^L from ∇^R, and vice-versa. Here, however, it happens despite the fact that formula (11) is not fulfilled. [It follows from (24) that $AZ(A^1)\subseteq xyA^1$.] ◇

Notice that, had we required the σ-compatibility condition to be satisfied on the whole bimodule A^1, then, in contrast with Proposition 6, we would obtain that the Christoffel symbols of a left connection have to fulfill the following equations:

$$F^1_{11}=x(y^3(-qf^1_{12}+f^1_{21})+yf^1_{11}-qy^2f^1_{22}),$$
$$F^1_{12}=x^2(yf^1_{22}+y^2f^1_{12}),\quad F^1_{21}=x^2(q^2yf^1_{22}+y^2f^1_{21}),$$
$$F^1_{22}=-q^2x^3f^1_{22},$$
$$F^2_{11}=f^2_{11}+qy^4\left(f^2_{22}-f^1_{12}-\frac{3q}{1-q}f^1_{21}\right)+qy^2(f^1_{11}-f^2_{21}-qf^2_{12}), \tag{32}$$
$$F^2_{12}=x(q^2y^3(-f^2_{22}+f^1_{12})+yf^2_{12}+qy^2f^1_{22})$$
$$F^2_{21}=x(qy^3(-f^2_{22}+qf^1_{21})+yf^2_{21}+y^2f^1_{22}),$$
$$F^2_{22}=x^2(-q^2yf^1_{22}+y^2f^2_{22}),$$

where $f^i_{jk}\in Z(A), i,j,k\in\{1,2\}$.

The metric compatibility condition (5) can again be written in the form of formula (20). This time, however, the center of A^1 is nontrivial and it makes sense to ask what would happen if we imposed the metric compatibility condition only over $Z(A^1)$. It turns out that we have the following.

Proposition 7: *Requiring that the metric compatibility condition (5) be satisfied only over $Z(A^1)$ is equivalent to demanding that it be fulfilled over the whole A^1.*

Proof. Let $\mathbf{P}^{ij}$ denote the expression in the large parentheses in (20). Furthermore, let us put $\mathbf{P}^{ij}=\theta^k\mathbf{P}_k^{ij}$, $a_1=axy-bxy^3$, $a_2=bx^2y^2$, $\tilde{a}_1=a'xy-qb'xy^3$, $\tilde{a}_2=b'x^2y^2$, where a,b,a',b' are arbitrary elements of $Z(A)$. Thanks to (24), substituting those terms to (20) yields an equation that expresses the metric compatibility condition over $Z(A^1)$:

$$(axy-bxy^3)\,\theta^k\mathbf{P}_k^{11}(a'xy-qb'xy^3)+(axy-bxy^3)\,\theta^k\mathbf{P}_k^{12}b'x^2y^2+bx^2y^2\,\theta^k\mathbf{P}_k^{21}(a'xy-qb'xy^3)$$
$$+bx^2y^2\,\theta^k\mathbf{P}_k^{21}b'x^2y^2=0. \tag{33}$$

Commuting everything to the right of $\{\theta^i\}_{i\in\{1,2\}}$ and taking advantage of the fact that $\{\theta^i\}_{i\in\{1,2\}}$ is a basis, one can reduce (33) to

$$\Big((xy\mathbf{P}_1^{11}+(q-q^2)y^2\mathbf{P}_2^{11})a \;+\; (-q^2x\mathbf{P}_1^{11}y^3-(q^2-1)y\mathbf{P}_2^{11}y^3+x^2y^2\mathbf{P}_1^{21}+(q^2-q)xy^3\mathbf{P}_2^{21})b\Big)$$
$$\times(a'xy-qb'xy^3) \;+\; \Big((xy\mathbf{P}_1^{12}+(q-q^2)y^2\mathbf{P}_2^{12})a \;+\; (-q^2x\mathbf{P}_1^{12}y^3-(q^2-1)y\mathbf{P}_2^{12}y^3$$
$$+x^2y^2\mathbf{P}_1^{22}+(q^2-q)xy^3\mathbf{P}_2^{22})b\Big)b'x^2y^2=0$$
$$\Big(xy\mathbf{P}_2^{11}a-(qx\mathbf{P}_2^{11}y^3-x^2y^2\mathbf{P}_2^{21})b\Big)a'xy-qb'xy^3$$
$$+\Big(xy\mathbf{P}_2^{12}a-(qx\mathbf{P}_2^{12}y^3-x^2y^2\mathbf{P}_2^{22})b\Big)b'x^2y^2=0. \tag{34}$$

Now, since a, b, a', b' are arbitrary elements of $Z(A)$, the above two equations boil down to

$$\begin{gathered}
xy\mathbf{P}_2^{11}xy=0,\\
xy\mathbf{P}_1^{11}xy+(q-q^2)y^2\mathbf{P}_2^{11}xy=0,\\
-qxy\mathbf{P}_2^{11}xy^3+xy\mathbf{P}_2^{12}x^2y^2=0,\\
-qxy\mathbf{P}_1^{11}xy^3+(1-q^2)y^2\mathbf{P}_2^{11}xy^3+xy\mathbf{P}_1^{12}x^2y^2+(q-q^2)y^2\mathbf{P}_2^{12}x^2y^2=0,\\
-qx\mathbf{P}_2^{11}xy^4+x^2y^2\mathbf{P}_2^{21}xy=0,\\
-q^2x\mathbf{P}_1^{11}xy^4-(q^2-1)y\mathbf{P}_2^{11}xy^4+x^2y^2\mathbf{P}_1^{21}xy+(q^2-q)xy^3\mathbf{P}_2^{21}xy=0,\\
q^2x\mathbf{P}_2^{11}xy^4-qx^2y^2\mathbf{P}_2^{21}xy^3-qx\mathbf{P}_2^{12}x^2y^5+x^2y^2\mathbf{P}_2^{22}x^2y^2=0,\\
x\mathbf{P}_1^{11}xy^6+(1-q)y\mathbf{P}_2^{11}xy^6-qx^2y^2\mathbf{P}_1^{21}xy^3-(1-q^2)xy^3\mathbf{P}_2^{21}xy^3-q^2x\mathbf{P}_1^{12}x^2y^5+(1-q^2)y\mathbf{P}_2^{12}x^2y^5\\
+x^2y^2\mathbf{P}_1^{22}x^2y^2+(q^2-q)xy^3\mathbf{P}_2^{22}x^2y^2=0.
\end{gathered} \tag{35}$$

Hence $\mathbf{P}_k^{ij}=0$ for any $i,j,k\in\{1,2\}$. Consequently, $\mathbf{P}^{ij}=0$ for any $i,j\in\{1,2\}$, and (5) follows, as claimed. □

The same effect, though in a more trivial way, occurs in the setting of Section II.

VI. CONCLUSIONS

As we have demonstrated, restricting the domain of the σ-compatibility condition $\nabla^L=\sigma\circ\nabla^R$ to $Z(A^1)$ yields a theory of noncommutative linear connections that coincides with the classical theory in the commutative case, does not discriminate against the left or right structure of a bimodule and appears to be rich in the noncommutative set-up. It is easy to check, however, that this σ-compatibility equation is not, in general, gauge covariant, either when considering it over the whole bimodule,[2] or when considering it only over the center of a bimodule. To provide a simple example, let us assume the setting of Section IV and choose our gauge

transformation to be $\theta^i \mapsto U^i_j \theta^j, U=\left(\begin{smallmatrix}1 & x\\ 0 & 1\end{smallmatrix}\right)$. Its action on ∇^L is given by the formula (cf. p. 547 and p. 559 in Ref. 1) $N \mapsto dU.U^{-1}+UNU^{-1}$, where $\nabla^L\theta^i=N^i_k\otimes_A\theta^k$, $N=(N^i_k)\in M_2(A^1)$. It is clear that, although the pure gauge connections ($\Gamma^i_{jk}=0=\tilde{\Gamma}^i_{jk}$, $i,j,k\in\{1,2\}$) satisfy $\nabla^L=\sigma\circ\nabla^R$, the Christoffel symbol Γ^1_{12} of the connection obtained by the action of U on the left pure gauge connection does not fulfill (31). More precisely, $\Gamma^1_{12}=1\notin xA$. [This can be obtained from equation $(dU.U^{-1})^i_k\otimes_A\theta^k=\theta^j\otimes_A\theta^k\Gamma^i_{jk}$, $i\in\{1,2\}$.]

A different approach to the generalized permutation σ has been suggested in Ref. 14. In the set-up of Section 5 in Ref. 14, σ is a function of the connection. Consequently, to determine the space of connections one needs to take into account all possible bimodule homomorphisms σ. Allowing σ to vary makes it possible to change it under the action of a gauge transformation. If we take as a gauge transformation a bimodule automorphism $f:E\to E$ and define its action by the formula

$$(\nabla^L,\nabla^R,\sigma)\ \mapsto\ ((id\otimes_A f^{-1})\circ\nabla^L\circ f,\ (f^{-1}\otimes_A id)\circ\nabla^R\circ f,\ (id\otimes_A f^{-1})\circ\sigma\circ(f\otimes_A id)), \quad (36)$$

then the σ-compatibility condition $\nabla^L=\sigma\circ\nabla^R$ is gauge covariant. Furthermore, since the center of a bimodule is preserved by the bimodule automorphisms, the σ-compatibility condition is also gauge covariant when considered only over $Z(E)$. (We owe noticing this point to Michel Dubois-Violette.) One should bear in mind, however, that, roughly speaking, the bimodule automorphisms correspond to the ''commutative sector'' of the space of gauge transformations.

A more radical point of view that might deserve a detailed investigation relies on employing the metric compatibility condition (5) rather than the equation $\nabla^L=\sigma\circ\nabla^R$ to relate ∇^L and ∇^R uniquely and without (undesirable) restrictions on (∇^L,∇^R). Clearly, for nondegenerate metrics, formulas (12) and (20) provide this kind of mutual dependence of ∇^L and ∇^R. [In those cases, the nondegeneracy of a metric g simply means that (g^{ij}) is an invertible matrix.]

Finally, let us remark that it is plausible that in order to obtain a satisfactory definition of a bimodule connection, one needs to use the language of quantum principal bundles, and, having understood and thoroughly worked out the left-right relationship in this context (see Theorem 4.13 and Remark 4.14 in Ref. 15 and Appendix B in Ref. 16), translate the solution(s) to bimodule terms.

APPENDIX: COMMUTATION FORMULAS

Here we provide commutation formulas for the differential algebra $\Omega(A)$ that is defined with the help of (13). Let $Q_{-1}=Q_0=0$ and, for $n>0$, let $Q_n=\Sigma_{k=1}^n q^{2(k-1)}$. For any natural $n\geqslant 0$, we have

$$x^n\xi=q^{2n}\xi x^n,\ \ x^n\eta=q^n\eta x^n+(q^2-1)Q_n\xi x^{n-1}y,\ \ y^n\xi=q^n\xi y^n,\ \ y^n\eta=q^{2n}\eta y^n;$$

$$x^n\xi\otimes_A\xi=q^{4n}\xi\otimes_A\xi x^n,$$

$$x^n\xi\otimes_A\eta=q^{3n}\xi\otimes_A\eta x^n+(q^2-1)q^{2n}Q_n\xi\otimes_A\xi x^{n-1}y,$$

$$x^n\eta\otimes_A\xi=q^{3n}\eta\otimes_A\xi x^n+(q^2-1)q^{2n-1}Q_n\xi\otimes_A\xi x^{n-1}y, \quad (A1)$$

$$x^n\eta\otimes_A\eta=q^{2n}\eta\otimes_A\eta x^n+(q^2-1)q^nQ_n\eta\otimes_A\xi x^{n-1}y+(q^2-1)q^{n+1}Q_n\xi\otimes_A\eta x^{n-1}y$$
$$+q^2(q^2-1)^2Q_nQ_{n-1}\xi\otimes_A\xi x^{n-2}y^2;$$

$$y^n\xi\otimes_A\xi=q^{2n}\xi\otimes_A\xi y^n,\quad y^n\xi\otimes_A\eta=q^{3n}\xi\otimes_A\eta y^n,$$

$$y^n\eta\otimes_A\xi=q^{3n}\eta\otimes_A\xi y^n,\quad y^n\eta\otimes_A\eta=q^{4n}\eta\otimes_A\eta y^n.$$

One also has

$$
\begin{aligned}
a\xi + b\eta &:= a_{pr}x^p y^r \xi + b_{st}x^s y^t \eta \\
&= \xi\ (q^{2p+r}a_{pr}x^p y^r + q^{2t}(q^2-1)Q_s b_{st}x^{s-1}y^{t+1}) + \eta\ (q^{2t+s}b_{st}x^s y^t) \\
&= \xi((q^{2p+r}a_{pr} + q^{2r-2}(q^2-1)Q_{p+1}b_{p+1\,r-1}\ )x^p y^r + q^{2p}a_{p0}x^p) + \eta\ (q^{2t+s}b_{st}x^s y^t) \\
&=: \xi\tilde{a} + \eta\tilde{b}, \qquad \text{(A2)}
\end{aligned}
$$

where $a_{pr}, b_{st} \in \mathbb{C}$, $p,r,s,t \in \{0,1,\dots\}$.

ACKNOWLEDGMENT

It is a pleasure to thank Michel Dubois-Violette for helpful discussions. This work was partially supported by a visiting fellowship at the International Centre for Theoretical Physics in Trieste and by the KBN Grant No. 2 P301 020 07.

A method is proposed for defining an arbitrary number of differential calculi over a given noncommutative associative algebra. As an example the generalized quantum plane is studied. It is found that there is a strong correlation, but not a one-to-one correspondence, between the module structure of the 1-forms and the metric torsion-free connections on it. In the commutative limit the connection remains as a shadow of the algebraic structure of the 1-forms. © *1996 American Institute of Physics.* [S0022-2488(96)01609-X]

I. INTRODUCTION

We propose a method of defining an arbitrary number of differential calculi over a given noncommutative associative algebra. We shall especially be interested in the generalized quantum plane, an algebra which has a commutative limit which one can identify with the algebra of rational functions on the 2-plane minus the axes. We shall see that the commutation relations between the elements of the algebra and the 1-forms determine a set of torsion-free metric connections which remain non-trivial in the commutative limit. It is to be expected that the converse is true, that every torsion-free metric connection on the 2-plane determines a set of commutation relations. This would mean that in particular the covariant calculus of Wess and Zumino[1] is determined by a geometry on the 2-plane.

The differential calculi we introduce here are based on derivations and are similar to those introduced by Dubois-Violette[2] and Dubois-Violette *et al.*[3] to construct differential calculi over matrix algebras. We refer to Madore[4,5] for a detailed description of how to use this method to construct a sequence of differential calculi over a given matrix algebra. In this previous work the set of derivations was chosen to form an irreducible representation of the Lie algebra of a special linear group SL_m. With this restriction the number of differential calculi which can be put on a matrix algebra of dimension n is equal to the number of integers m such that SL_m has an irreducible representation on a space of dimension n. There are always of course at least two, $m=2$ and $m=n$, but for large n there are in general many more.

In Section II we present a general method for constructing differential calculi, based on a set of derivations which do not necessarily close to form a Lie algebra. In Sections III and IV we present some examples using as algebra the generalized quantum plane. In Section V we investigate linear connections and show how they depend on the choice of differential calculus as well as, of course, the algebra. By $\mathscr{A}$ we designate an arbitrary associative algebra with unit element and with center $\mathscr{Z}(\mathscr{A})$.

II. GENERAL FORMALISM

Of the many differential calculi which can be constructed over an algebra $\mathscr{A}$ the largest is the differential envelope or universal differential calculus $(\Omega_u^*(\mathscr{A}), d_u)$. Every other differential calculus can be considered as a quotient of it. For the definitions we refer, for example, to the book by Connes.[6] Let $(\Omega^*(\mathscr{A}), d)$ be another differential calculus over $\mathscr{A}$. Then there exists a unique d_u-homomorphism ϕ

$$\begin{array}{ccccccc} \mathscr{A} & \overset{d_u}{\rightarrow} & \Omega_u^1(\mathscr{A}) & \overset{d_u}{\rightarrow} & \Omega_u^2(\mathscr{A}) & \overset{d_u}{\rightarrow} & \cdots \\ \| & & \phi_1\downarrow & & \phi_2\downarrow & & \\ \mathscr{A} & \overset{d}{\rightarrow} & \Omega^1(\mathscr{A}) & \overset{d}{\rightarrow} & \Omega^2(\mathscr{A}) & \overset{d}{\rightarrow} & \cdots \end{array} \tag{2.1}$$

of $\Omega_u^*(\mathscr{A})$ onto $\Omega^*(\mathscr{A})$. It is given by

$$\phi(d_u f\,) = df. \tag{2.2}$$

The restriction ϕ_p of ϕ to each Ω_u^p is defined by

$$\phi_p(f_0 d_u f_1 \cdots d_u f_p) = f_0 df_1 \cdots df_p\,.$$

Consider a given algebra $\mathscr{A}$ and suppose that we know how to construct an $\mathscr{A}$-module $\Omega^1(\mathscr{A})$ and an application

$$\mathscr{A} \overset{d}{\rightarrow} \Omega^1(\mathscr{A}). \tag{2.3}$$

Then using (2.1) there is a method of constructing $\Omega^p(\mathscr{A})$ for $p \geqslant 2$ as well as the extension of the differential. Since we know $\Omega_u^1(\mathscr{A})$ and $\Omega^1(\mathscr{A})$ we can suppose that ϕ_1 is given. We must construct $\Omega^2(\mathscr{A})$. The simplest consistent choice would be to set

$$\Omega^2(\mathscr{A}) = \Omega_u^2(\mathscr{A}) / \overline{d_u \mathrm{Ker}\phi_1}, \tag{2.4}$$

where $\overline{d_u \mathrm{Ker}\phi_1}$ is the bimodule generated by $d_u \mathrm{Ker}\phi_1$. The product of two elements ξ and η in $\Omega^1(\mathscr{A})$ is defined by choosing two inverse images ξ_u and η_u in $\Omega_u^1(\mathscr{A})$ and projecting their product onto $\Omega^2(\mathscr{A})$:

$$\xi\eta = \phi_2(\xi_u \otimes \eta_u).$$

This is well-defined because of the equality

$$\overline{d_u \mathrm{Ker}\phi_1} = d_u \mathrm{Ker}\phi_1 + (\Omega_u^1(\mathscr{A}) \otimes \mathrm{Ker}\phi_1) + (\mathrm{Ker}\phi_1 \otimes \Omega_u^1(\mathscr{A})),$$

which in turn follows from the identities

$$f d_u \xi = d_u(f\xi) - (d_u f\,)\xi, \quad (d_u \xi) f = d_u(\xi f\,) - \xi d_u f.$$

Equation (2.4) defines the largest set of 2-forms consistent with the constraints on $\Omega^1(\mathscr{A})$. The map ϕ_2 is defined to be the projection of $\Omega_u^2(\mathscr{A})$ onto $\Omega^2(\mathscr{A})$ so defined and d is defined by $d(fdg) = dfdg$. This procedure can be continued by iteration to arbitrary order in p. See, for example, Baehr *et al.*[7]

To initiate the above construction we shall define the 1-forms using a set of derivations. We shall suppose that they are interior and exclude therefore the case where $\mathscr{A}$ is commutative. For each integer n let λ_a be a set of n linearly independent elements of $\mathscr{A}$ and introduce the derivations $e_a = ad\lambda_a$. In general the e_a do not form a Lie algebra but they do however satisfy commutation relations as a consequence of the commutation relations of $\mathscr{A}$. Define the map (2.3) by

$$df(e_a) = e_a f. \tag{2.5}$$

We shall suppose that there exists a set of n elements θ^a of $\Omega^1(\mathscr{A})$ such that

$$\theta^a(e_b)=\delta^a_b. \tag{2.6}$$

In the examples which we consider we shall show that the θ^a exist by explicit construction. We shall refer to the set of θ^a as a frame or Stehbein. It commutes with the elements $f\in\mathscr{A}$,

$$f\theta^a=\theta^a f. \tag{2.7}$$

The construction of the θ^a from the derivations did not really use the fact that they were inner. For example, if the e_a are n linearly independent vector fields on a manifold V of dimension n, that is, n linearly independent outer derivations of the algebra $\mathscr{A}=\mathscr{C}(V)$ of smooth functions on V, then $\Omega^*(\mathscr{A})$ is the algebra of de Rham forms.

The $\mathscr{A}$-bimodule $\Omega^1(\mathscr{A})$ is generated by all elements of the form fdg or of the form $(df\,)g$. Because of the Leibniz rule these conditions are equivalent. Define $\theta=-\lambda_a\theta^a$. Then one sees that

$$df=-[\theta,f] \tag{2.8}$$

and it follows that as a bimodule $\Omega^1(\mathscr{A})$ is generated by one element. It follows also that the 2-form $d\theta+\theta^2$ can be written in the form

$$d\theta+\theta^2=-\frac{1}{2}K_{ab}\theta^a\theta^b \tag{2.9}$$

with coefficients K_{ab} which lie in $\mathscr{Z}(\mathscr{A})$. By definition

$$fdg(e_a)=fe_ag,\quad (dg)f(e_a)=(e_ag)f.$$

Using the frame we can write these as

$$fdg=(fe_ag)\theta^a,\quad (dg)f=(e_ag)f\theta^a. \tag{2.10}$$

The commutation relations of the algebra constrain the relations between fdg and $(dg)f$ for all f and g.

As a left or right module, $\Omega^1(\mathscr{A})$ is free of rank n. Because of the commutation relations of the algebra, or equivalently, because of the kernel of ϕ_1 in the quotient (2.4), the θ^a satisfy commutation relations. We shall suppose that they can be written in the form

$$\theta^a\theta^b+C^{ad}{}_{cb}\theta^c\theta^d=0. \tag{2.11}$$

The associativity law in $\Omega^*(\mathscr{A})$ will place constraints on the $C^{ab}{}_{cd}$ which will be satisfied in the cases which we consider in detail. If $C^{ad}{}_{cd}=\delta^a_c\delta^b_d$, then one sees that $\Omega^2(\mathscr{A})=0$. It follows from (2.11) that for an arbitrary element f of the algebra

$$[f,C^{ab}{}_{cd}]\theta^c\theta^d=0.$$

We shall suppose that

$$C^{ab}{}_{ef}C^{ef}{}_{cd}=\delta^a_c\delta^b_d$$

and that the relations (2.11) are complete in the sense that if $A_{ab}\theta^a\theta^b=0$ we can conclude that

$$A_{ab}-C^{cd}{}_{ab}A_{cd}=0. \tag{2.12}$$

This will be the case for all the differential calculi which we shall consider on the generalized quantum plane in the next sections. We can conclude then that the $C^{ab}{}_{cd}$ are elements of $\mathscr{Z}(\mathscr{A})$. In ordinary geometry one can choose

$$C^{ab}{}_{cd} = \delta^b_c \delta^a_d$$

and the relation (2.11) expresses the fact that the 1-forms anticommute. Let $\wedge^*_C$ be the twisted exterior algebra determined by the relations (2.11). Then the differential algebra $\Omega^*(\mathscr{A})$ can be factorized as the tensor product

$$\Omega^*(\mathscr{A}) = \mathscr{A} \otimes_{\mathbb{C}} \wedge^*_C .$$

Because the 2-forms are generated by products of the θ^a one has

$$d\theta^a = -\tfrac{1}{2} C^a{}_{bc} \theta^b \theta^c . \tag{2.13}$$

Without loss of generality we can suppose that the structure elements $C^a{}_{bc}$ satisfy the identities

$$C^a{}_{bc} + C^a{}_{de} C^{de}{}_{bc} = 0. \tag{2.14}$$

It is to be noticed that they do not in general lie in $\mathscr{Z}(\mathscr{A})$. In fact from the identity $d(f\theta^a) = d(\theta^a f)$ one sees that

$$(\tfrac{1}{2}[C^a{}_{bc}, f] + e_{(b} f \delta^a_{c)}) \theta^b \theta^c = 0. \tag{2.15}$$

Using the definition of the derivations one can write this in the form

$$(\tfrac{1}{2} C^a{}_{bc} + \lambda_{(b} \delta^a_{c)} - \tfrac{1}{2} F^a{}_{bc}) \theta^b \theta^c = 0 \tag{2.16}$$

with $F^a{}_{bc} \in \mathscr{Z}(\mathscr{A})$. We can suppose that the $F^a{}_{bc}$ satisfy (2.14):

$$F^a{}_{bc} + F^a{}_{de} C^{de}{}_{bc} = 0. \tag{2.17}$$

Using this and the relations (2.11) and (2.14) as well as the completeness assumption (2.12) we can conclude from (2.16) that

$$C^a{}_{bc} - F^a{}_{bc} + \lambda_{(b} \delta^a_{c)} - \lambda_{(d} \delta^a_{e)} C^{de}{}_{bc} = 0. \tag{2.18}$$

The equation (2.16) can also be written in the form

$$d\theta^a = -[\theta, \theta^a] - \tfrac{1}{2} F^a{}_{bc} \theta^b \theta^c \tag{2.19}$$

with a graded commutator. If $F^a{}_{bc} = 0$, the form (2.8) for the exterior derivative is valid for all elements of $\Omega^*(\mathscr{A})$ and the element θ plays the role of the phase of a generalized Dirac operator in the sense of Connes.[8]

From (2.19) we find that

$$d\theta = -2\theta^2 + \tfrac{1}{2} \lambda_a F^a{}_{bc} \theta^b \theta^c .$$

Comparing this with (2.9) we conclude that

$$\theta^2 = \tfrac{1}{2} (\lambda_a F^a{}_{bc} + K_{bc}) \theta^b \theta^c . \tag{2.20}$$

If we suppose that K_{bc} satisfies (2.14),

$$K_{ab} + K_{cd} C^{cd}{}_{ab} = 0,$$

then we can conclude that

$$(\lambda_b\lambda_c - C^{de}{}_{bc}\lambda_d\lambda_e - \lambda_a F^a{}_{bc} - K_{bc})\,\theta^b\theta^c = 0. \tag{2.21}$$

Using again the completeness assumption (2.12) we find

$$\lambda_b\lambda_c - C^{de}{}_{bc}\lambda_d\lambda_e = \lambda_a F^a{}_{bc} + K_{bc}\,. \tag{2.22}$$

If we introduce the twisted bracket

$$[\lambda_a,\lambda_b]_C = \lambda_a\lambda_b - C^{cd}{}_{ab}\lambda_c\lambda_d\,,$$

we can rewrite (2.22) in the form

$$[\lambda_b,\lambda_c]_C = \lambda_a F^a{}_{bc} + K_{bc}\,. \tag{2.23}$$

If we write out in detail the equation $d^2 f = 0$, using (2.12)–(2.14) we find that

$$[e_b,e_c]_C f = e_a f C^a{}_{bc}\,. \tag{2.24}$$

This is the dual relation to the 'Maurer–Cartan' equation (2.13).

The constraint (2.23) follows from the commutation relations (2.11) we have supposed for the frame as well as from the conditions we have imposed on the coefficients $C^{ab}{}_{cd}$. In the matrix case the general formalism simplifies considerably. The elements of the frame anticommute and one can choose $C^{ab}{}_{cd} = \delta^b_c\delta^a_d$. In Equation (2.19) the first term on the right-hand side vanishes and $F^a{}_{bc} = C^a{}_{bc}$. On the right-hand side of Equations (2.9) and (2.23) we have $K_{ab} = 0$.

III. CALCULI BASED ON 2 DERIVATIONS

Using the construction of the previous section one can construct an infinite sequence of differential calculi over the generalized quantum plane $\mathscr{A}$, the algebra generated by four elements (x,y,x^{-1},y^{-1}) subject to the relation $xy = qyx$ as well as the usual relations between an element and its inverse. Here q is an arbitrary complex number. The subalgebra generated by (x,y) alone with the covariant differential calculus of Wess and Zumino is called the quantum plane. In this section we shall consider the case $n = 2$. Define, for $q \neq 1$,

$$\lambda_1 = \frac{q}{q-1}\,y, \quad \lambda_2 = \frac{q}{q-1}\,x. \tag{3.1}$$

The normalization has been chosen here so that the structure elements $C^a{}_{12}$ contain no factors q. The λ_a are singular in the limit $q \to 1$ for the same reason as the limit from quantum mechanics:

$$\frac{1}{\hbar}\,\mathrm{ad}\,p \to \frac{1}{i}\,\frac{\partial}{\partial q}.$$

We find that

$$e_1 x = -xy, \quad e_1 y = 0, \quad e_2 x = 0, \quad e_2 y = xy. \tag{3.2}$$

These rather unusual derivations are extended to arbitrary polynomials in the generators by the Leibniz rule. From (3.2) we conclude that the commutation relations which follow from (2.10) are

$$\begin{aligned} xdx &= qdxx, \quad ydx = q^{-1}dxy, \\ xdy &= qdyx, \quad ydy = q^{-1}dyy. \end{aligned} \tag{3.3}$$

From these relations, if $q \neq -1$, we deduce

$$(dx)^2=0, \quad (dy)^2=0, \quad dxdy+qdydx=0. \tag{3.4}$$

Using the relations (3.2) we find

$$dx=-xy\theta^1, \quad dy=xy\theta^2, \tag{3.5}$$

and solving for the θ^a we obtain

$$\theta^1=-q^{-1}x^{-1}y^{-1}dx, \quad \theta^2=q^{-1}x^{-1}y^{-1}dy. \tag{3.6}$$

The θ^a satisfy the commutation relations

$$(\theta^1)^2=0, \quad (\theta^2)^2=0, \quad \theta^1\theta^2+q\theta^2\theta^1=0. \tag{3.7}$$

This is of the form (2.11). If we reorder the indices (11,12,21,22)=(1,2,3,4), then the matrix $C^{ab}{}_{cd}$ can be written in the form of a 4×4 matrix

$$C=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & q & 0 \\ 0 & q^{-1} & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{3.8}$$

That is, $C^{12}{}_{21}=q$ and $C^{21}{}_{12}=q^{-1}$. The structure elements $C^a{}_{bc}$ are given by

$$C^1{}_{12}=-x, \quad C^2{}_{12}=-y, \tag{3.9}$$

and the condition (2.14). Equation (2.18) is satisfied. For θ we find the expression

$$\theta=\frac{1}{q-1}(qx^{-1}dx-y^{-1}dy). \tag{3.10}$$

It is a closed form.

As a second example with $n=2$ we define, for $q^4\neq 1$,

$$\lambda_1=\frac{1}{q^4-1}x^{-2}y^2, \quad \lambda_2=\frac{1}{q^4-1}x^{-2}. \tag{3.11}$$

The normalization has been chosen here again so that the structure elements $C^a{}_{12}$ contain no factors q. We find then that for $q^2\neq -1$

$$e_1x=-\frac{1}{q^2(q^2+1)}x^{-1}y^2, \quad e_1y=-\frac{1}{q^2+1}x^{-2}y^3,$$

$$e_2x=0, \quad e_2y=-\frac{1}{q^2+1}x^{-2}y. \tag{3.12}$$

From these we conclude that the commutation relations which follow from (2.10) are

$$xdx=q^2dxx, \quad xdy=qdyx+(q^2-1)dxy,$$

$$ydx=qdxy, \quad ydy=q^2dyy. \tag{3.13}$$

We have then in this case the covariant differential calculus of Wess and Zumino. It has been encoded in the functional form of the λ_a. If $q^2 \neq -1$, from (3.13) we deduce

$$(dx)^2 = 0, \quad (dy)^2 = 0, \quad dydx + qdxdy = 0. \tag{3.14}$$

Using the relation (2.6) we find

$$dx = -\frac{1}{q^2(q^2+1)} x^{-1} y^2 \theta^1, \quad dy = -\frac{1}{q^2+1} x^{-2} y(y^2\theta^1 + \theta^2), \tag{3.15}$$

and solving for the θ^a we obtain

$$\theta^1 = -q^4(q^2+1)xy^{-2}dx, \quad \theta^2 = -q^2(q^2+1)x(xy^{-1}dy - dx). \tag{3.16}$$

The θ^a satisfy the commutation relations

$$(\theta^1)^2 = 0, \quad (\theta^2)^2 = 0, \quad q^4\theta^1\theta^2 + \theta^2\theta^1 = 0. \tag{3.17}$$

This is of the form (2.11) if the matrix $C^{ab}{}_{cd}$ is given by the 4×4 matrix

$$C = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & q^{-4} & 0 \\ 0 & q^4 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{3.18}$$

That is, $C^{12}{}_{21} = q^{-4}$ and $C^{21}{}_{12} = q^4$. The structure elements $C^a{}_{bc}$ are given by

$$C^1{}_{12} = -x^{-2}, \quad C^2{}_{12} = -x^{-2}y^2, \tag{3.19}$$

and the condition (2.14). Equation (2.18) is again satisfied.

For θ we find the expression

$$\theta = \frac{q^2}{q^2-1} y^{-1} dy. \tag{3.20}$$

It is again a closed form.

From these two examples we see that each choice of two elements λ_1 and λ_2 gives rise to a differential calculus on the generalized quantum plane and we shall see in the Section V that each choice gives rise to a linear connection.

IV. CALCULI BASED ON 3 DERIVATIONS

In this section we shall consider the case $n=3$. There is an essential difference with the previous case in that relations of the form (3.3) or (3.13) which allow one to pass from one side of the differential to the other no longer hold. The difference is given in fact in terms of the extra elements of the frame. What we do is extend the definition of dx and dy to another derivation and the extension satisfies quite naturally less relations. The left (or right) module $\Omega^1(\mathcal{A})$ is now of rank 3 instead of 2. As an example we extend the λ_a defined in (3.1) by the addition of a λ_3:

$$\lambda_1 = \frac{q}{q-1} y, \quad \lambda_2 = \frac{q}{q-1} x, \quad \lambda_3 = \frac{q}{q-1} \alpha xy. \tag{4.1}$$

The α is an arbitrary complex number. We have then $[\lambda_1,\lambda_2]=-\alpha^{-1}\lambda_3$, but of course the set of λ_a do not form a Lie algebra. To the relations (3.2) we must add two additional ones,

$$e_3x=-\alpha x^2y, \quad e_3y=\alpha xy^2, \tag{4.2}$$

and so we find

$$dx=-xy\,\theta^1-\alpha x^2y\,\theta^3, \quad dy=xy\,\theta^2+\alpha xy^2\,\theta^3 \tag{4.3}$$

instead of (3.5). Define

$$\tau=x\,dy-q\,dy\,x. \tag{4.4}$$

Then one of the commutation relations (3.3) becomes an expression for θ^3 in terms of τ:

$$\tau=\alpha q^{-1}(q-1)x^2y^2\,\theta^3. \tag{4.5}$$

We can solve then (4.3) for the θ^a and we obtain

$$\begin{aligned}
\theta^1&=-q^{-1}x^{-1}y^{-1}dx-\frac{1}{q^2(q-1)}\,x^{-1}y^{-2}\tau,\\
\theta^2&=q^{-1}x^{-1}y^{-1}dy-\frac{1}{q(q-1)}\,x^{-2}y^{-1}\tau,\\
\theta^3&=\frac{1}{\alpha q^3(q-1)}\,x^{-2}y^{-2}\tau
\end{aligned} \tag{4.6}$$

instead of (3.6). This frame is singular in the limit $q\to1$ as it must be. The differential calculus, expressed in terms of dx and dy, has however a well-defined limit which lies somewhere between the de Rham calculus and the universal one. For a discussion of this point we refer to Dimakis and Müller-Hoissen,[9] Dimakis and Tzanakis,[10] and Baehr *et al.*[7]

If $q\neq-1$, we can deduce the first two of the relations (3.4) and we can conclude that

$$\begin{aligned}
&q(\theta^1)^2+\alpha x(\theta^1\theta^3+q\,\theta^3\theta^1)+\alpha^2x^2(\theta^3)^2=0,\\
&q(\theta^2)^2+\alpha y(\theta^3\theta^2+q\,\theta^2\theta^3)+\alpha^2y^2(\theta^3)^2=0.
\end{aligned} \tag{4.7}$$

Multiply the first equation by y and the second by x and commute through. One deduces then that each of the coefficients must vanish:

$$(\theta^1)^2=0, \quad (\theta^2)^2=0, \quad (\theta^3)^2=0,$$

and

$$\theta^1\theta^3+q\,\theta^3\theta^1=0, \quad \theta^3\theta^2+q\,\theta^2\theta^3=0. \tag{4.8}$$

There is missing a relation between $\theta^1\theta^2$ and $\theta^2\theta^1$. We must therefore rather artificially complete the coefficients in (2.11) by setting $C^{12}{}_{12}=-1$ and $C^{12}{}_{21}=0$. From (2.23) we find then that $K_{ab}=0$ and the $F^a{}_{bc}$ vanish except for the values

$$F^3{}_{12}=\frac{2}{\alpha(q-1)}, \quad F^3{}_{21}=qF^3{}_{12}. \tag{4.9}$$

The form θ is given by

$$\theta = -\frac{q}{q-1}\,(y\,\theta^1 + x\,\theta^2 + \alpha xy\,\theta^3).$$

It follows then immediately from (2.19) that

$$\begin{aligned} d\theta^1 &= \frac{q}{q-1}\,x(\theta^1\theta^2 + \theta^2\theta^1) + \alpha xy\,\theta^1\theta^3, \\ d\theta^2 &= \frac{q}{q-1}\,y(\theta^1\theta^2 + \theta^2\theta^1) + \alpha xy\,\theta^3\theta^2, \\ d\theta^3 &= y\,\theta^1\theta^3 + x\,\theta^3\theta^2 - \frac{1}{\alpha(q-1)}\,(\theta^1\theta^2 + q\,\theta^2\theta^1), \end{aligned} \tag{4.10}$$

from which one can read off the expressions for the structure elements which extend (3.9). The third of the relations (3.4) becomes

$$d\tau = -x^2y^2((\theta^1\theta^2 + q\,\theta^2\theta^1) + \alpha x(\theta^2\theta^3 + \theta^3\theta^2) + \alpha y(\theta^3\theta^1 + \theta^1\theta^3)).$$

Using (4.10) one finds

$$d\tau = -x^2y^2((\theta^1\theta^2 + q\,\theta^2\theta^1) - \alpha q^{-1}(q-1)\,d\theta^3). \tag{4.11}$$

If one adds to (4.8) the supplementary relation

$$\theta^1\theta^2 + q\,\theta^2\theta^1 = 0, \tag{4.12}$$

then $\Omega^2(\mathscr{A})$ becomes a quotient of the right-hand side of (2.4). We can set $C^{12}{}_{21} = q$ and $C^{12}{}_{12} = 0$ as in (3.8). Now we have $K_{ab} = 0$ and $F^a{}_{bc} = 0$ and Equations (4.10) reduce to

$$d\theta^1 = x\,\theta^1\theta^2 + \alpha xy\,\theta^1\theta^3, \quad d\theta^2 = y\,\theta^1\theta^2 + \alpha xy\,\theta^3\theta^2, \quad d\theta^3 = y\,\theta^1\theta^3 + x\,\theta^3\theta^2.$$

Equation (4.11) simplifies to

$$d\tau = \alpha x^2y^2q^{-1}(q-1)\,d\theta^3. \tag{4.13}$$

A similar extension of the second example of the previous section can be given, again by introducing a third derivation. As before this yields an extension of the module of forms as a left (or right) module.

V. LINEAR CONNECTIONS

For each of the differential calculi defined in the previous section one can define a set of linear connections. The definition of a connection as a covariant derivative was given an algebraic form in the Tata lectures by Koszul[11] and generalized to noncommutative geometry by Karoubi[12] and Connes.[8,6] We shall often use here the expressions 'connection' and 'covariant derivative' synonymously. In fact one can distinguish three different types of connections. A 'left $\mathscr{A}$-connection' is a connection on a left $\mathscr{A}$-module; it satisfies a left Leibniz rule. A 'bimodule $\mathscr{A}$-connection' is a connection on a general bimodule $\mathscr{M}$ which satisfies a left and right Leibniz rule. In the particular case where $\mathscr{M}$ is the module of 1-forms we shall speak of a 'linear connection.' A bimodule over an algebra $\mathscr{A}$ is also a left module over the tensor product $\mathscr{A}^e = \mathscr{A}\otimes_{\mathbb{C}}\mathscr{A}^{op}$ of the

algebra with its 'opposite.' Such a bimodule can have a bimodule $\mathscr{A}$-connection as well as a left $\mathscr{A}^e$-connection.[13,14] These two definitions are compared in Dubois-Violette *et al.*[15]

Let $\mathscr{A}$ be an arbitrary algebra and $(\Omega^*(\mathscr{A}),d)$ a differential calculus over $\mathscr{A}$. One defines a left $\mathscr{A}$-connection on a left $\mathscr{A}$-module $\mathscr{H}$ as a covariant derivative

$$\mathscr{H}\overset{D}{\to}\Omega^1(\mathscr{A})\otimes_{\mathscr{A}}\mathscr{H} \tag{5.1}$$

which satisfies the left Leibniz rule

$$D(f\psi)=df\otimes\psi+fD\psi \tag{5.2}$$

for arbitrary $f\in\mathscr{A}$. This map has a natural extension

$$\Omega^*(\mathscr{A})\otimes_{\mathscr{A}}\mathscr{H}\overset{\nabla}{\to}\Omega^*(\mathscr{A})\otimes_{\mathscr{A}}\mathscr{H} \tag{5.3}$$

given, for $\psi\in\mathscr{H}$ and $\alpha\in\Omega^n(\mathscr{A})$, by $\nabla\psi=D\psi$ and

$$\nabla(\alpha\psi)=d\alpha\otimes\psi+(-1)^n\alpha\nabla\psi.$$

The operator ∇^2 is necessarily left-linear. However, when $\mathscr{H}$ is a bimodule it is not, in general, right-linear.

A covariant derivative on the module $\Omega^1(\mathscr{A})$ must satisfy (5.2). But $\Omega^1(\mathscr{A})$ has also a natural structure as a right $\mathscr{A}$-module and one must be able to write a corresponding right Leibniz rule in order to construct a bilinear curvature. Quite generally let $\mathscr{M}$ be an arbitrary bimodule. Consider a covariant derivative

$$\mathscr{M}\overset{D}{\to}\Omega^1(\mathscr{A})\otimes_{\mathscr{A}}\mathscr{M} \tag{5.4}$$

which satisfies both a left and a right Leibniz rule. In order to define a right Leibniz rule which is consistent with the left one, it was proposed by Mourad,[16] by Dubois-Violette and Michor[17] and by Dubois-Violette and Masson[18] to introduce a generalized permutation

$$\mathscr{M}\otimes_{\mathscr{A}}\Omega^1(\mathscr{A})\overset{\sigma}{\to}\Omega^1(\mathscr{A})\otimes_{\mathscr{A}}\mathscr{M}.$$

The right Leibniz rule is given then as

$$D(\xi f\ )=\sigma(\xi\otimes df\ )+(D\xi)f \tag{5.5}$$

for arbitrary $f\in\mathscr{A}$ and $\xi\in\mathscr{M}$. The purpose of the map σ is to bring the differential to the left while respecting the order of the factors. It is necessarily bilinear.[19] Let π be the product in the algebra of forms. It was argued by Mourad[16] and others[19] that a necessary as well as sufficient condition for torsion to be right-linear is that σ satisfy the consistency condition

$$\pi\circ(\sigma+1)=0. \tag{5.6}$$

We define a bimodule $\mathscr{A}$-connection to be the couple (D,σ). We shall make no mention of curvature. There is at the moment no general consensus of the correct definition of the curvature of a bimodule connection. The problem is that the operator ∇^2 is not, in general, right-linear. We refer to Dubois-Violette *et al.*[15] for a recent discussion.

This general formalism can be applied in particular to the differential calculi which we have constructed in Section II. Since $\Omega^1(\mathscr{A})$ is a free module the map σ can be defined by the action on the basis elements:

$$\sigma(\theta^a\otimes\theta^b)=S^{ab}{}_{cd}\theta^c\otimes\theta^d. \tag{5.7}$$

By the sequence of identities

$$fS^{ab}{}_{cd}\theta^c\otimes\theta^d=\sigma(f\theta^a\otimes\theta^b)=\sigma(\theta^a\otimes\theta^b f\ )=S^{ab}{}_{cd}f\theta^c\otimes\theta^d$$

we conclude that the coefficients S^{ab}_{cd} must lie in $\mathscr{Z}(\mathscr{A})$. From (2.12) we see that the condition (5.6) can be written

$$(\delta^a_e\delta^b_f+S^{ab}{}_{ef})(\delta^e_c\delta^f_d-C^{ef}{}_{cd})=0. \tag{5.8}$$

A natural, but certainly not the unique, choice of σ is given by $S^{ab}{}_{cd}=C^{ab}{}_{cd}$.

Since $\Omega^1(\mathscr{A})$ is a free module a covariant derivative can be defined by its action on the basis elements:

$$D\theta^a=-\omega^a_{bc}\theta^b\otimes\theta^c. \tag{5.9}$$

The coefficients here are elements of the algebra. Because of the identity $D(f\theta^a)=D(\theta^a f\ )$ there are very stringent compatibility conditions, which using (5.7) can be written out as

$$[\omega^a_{bc},f]=e_d f(S^{ad}{}_{bc}-\delta^d_b\delta^a_c).$$

The general solution to this equation is of the form $\omega^a{}_{bc}=\omega_{(0)}{}^a{}_{bc}+\chi^a{}_{bc}$ where

$$\omega(0)^a_{bc}=\lambda_d(S^{ad}{}_{bc}-\delta^d_b\delta^a_c) \tag{5.10}$$

and $\chi^a{}_{bc}\in\mathscr{Z}(\mathscr{A})$. One can also express $D_{(0)}$ in the form[19,20]

$$D_{(0)}\theta^a=-\theta\otimes\theta^a+\sigma(\theta^a\otimes\theta).$$

The torsion 2-form is defined as usual as

$$\Theta^a=d\theta^a-\pi\circ D\theta^a.$$

Comparing (5.10) with (2.19), we see that the torsion $\Theta^a_{(0)}$ of $D_{(0)}$ is given by

$$\Theta^a_{(0)}=-\tfrac{1}{2}F^a{}_{bc}\theta^b\theta^c. \tag{5.11}$$

In general a covariant derivative is torsion free provided the condition

$$\omega^a{}_{bc}-\omega^a{}_{de}C^{de}{}_{bc}=C^a{}_{bc}$$

is satisfied. The covariant derivative (5.9) is torsion free if and only if

$$\chi^a{}_{de}(\delta^d_b\delta^e_c-C^{de}{}_{bc})=F^a{}_{bc}.$$

On the ordinary quantum plane one can show that there is there is a unique 1-parameter family of linear connections[19] and that this connection is torsion free. We find here a different result; there is an ambiguity which depends on elements of $\mathscr{Z}(\mathscr{A})$. An interesting limit case is given by

$$S^{ab}{}_{cd}=C^{ab}{}_{cd}=\delta^b_c\delta^a_d. \tag{5.12}$$

In this case from (2.18) one sees that $F^a{}_{bc}=C^a{}_{bc}\neq 0$. From (2.22) one sees that $K_{ab}=0$ and the λ_a form a Lie algebra. The matrix case is a typical example. From (5.10) if follows that $D_{(0)}\theta^a=0$ and so $D_{(0)}$ has torsion but no curvature. The connection corresponds to the canonical flat connection on a parallelizable manifold.

One can define a metric by the condition

$$g(\theta^a\otimes\theta^b)=g^{ab}, \tag{5.13}$$

where the coefficients g^{ab} are elements of the algebra. To be well defined on all elements of the tensor product $\Omega^1(\mathscr{A})\otimes_{\mathscr{A}}\Omega^1(\mathscr{A})$ the metric must be bilinear, and by the sequence of identities

$$f^{ab}_g=g(f\theta^a\otimes\theta^b)=g(\theta^a\otimes\theta^b f\ )=g^{ab}f \tag{5.14}$$

we conclude that the coefficients must lie in $\mathscr{Z}(\mathscr{A})$. The covariant derivative (5.9) is compatible with the metric[19] if and only if

$$\omega^a{}_{bc}+\omega^f{}_{ce}S^{ae}{}_{bf}=0. \tag{5.15}$$

The condition that (5.10) be metric compatible can be written as

$$S^{ae}{}_{dh}g^{hf}S^{cb}{}_{ef}=g^{ac}\delta^b_d. \tag{5.16}$$

Consider now the first differential calculus of Section III, defined by (3.1). On the right-hand side of (2.23) we have $K_{ab}=0$ and $F^a{}_{bc}=0$. The torsion of $D_{(0)}$ vanishes. The coefficients g^{ab} are complex numbers. With the convention of (3.8) they can be written as (g^1,g^2,g^3,g^4). Using the $GL(2,\mathbb{C})$-invariance one can impose that

$$g^4=g^1,\quad g^2=-g^2.$$

If we suppose that $g^2=0$, there is no restriction in supposing that $g^1=1$; the g^{ab} are the components of the Euclidean metric in two dimensions. With the convention of (3.8) the condition (5.16) can be written in the matrix form

$$\begin{pmatrix} S^1_1 & S^1_2 & S^1_3 & S^1_4\\ S^2_1 & S^2_2 & S^2_3 & S^2_4\\ S^3_1 & S^3_2 & S^3_3 & S^3_4\\ S^4_1 & S^4_2 & S^4_3 & S^4_4 \end{pmatrix}\begin{pmatrix} S^1_1 & S^1_3 & S^3_1 & S^3_3\\ S^1_2 & S^1_4 & S^3_2 & S^3_4\\ S^2_1 & S^2_3 & S^4_1 & S^4_3\\ S^2_2 & S^2_4 & S^4_2 & S^4_4 \end{pmatrix}=1. \tag{5.17}$$

From the approximation linear in $q-1$ one sees that the solution must be of the form

$$S=\begin{pmatrix} S^1_1 & 0 & 0 & S^1_4\\ 0 & S^2_2 & S^2_3 & 0\\ 0 & S^3_2 & S^3_3 & 0\\ S^4_1 & 0 & 0 & S^4_4 \end{pmatrix}. \tag{5.18}$$

The consistency conditions (5.8) become

$$1+S^2_2=q^{-1}S^2_3,\quad 1+S^3_3=qS^3_2. \tag{5.19}$$

In general $S^{ab}{}_{cd} = C^{ab}{}_{cd}$ does not yield a metric-compatible covariant derivative. There is a solution, however, to (5.17) and (5.19) given by

$$S=\frac{1}{q^2+1}\begin{pmatrix} 2q & 0 & 0 & 1-q^2 \\ 0 & 1-q^2 & 2q & 0 \\ 0 & 2q & q^2-1 & 0 \\ q^2-1 & 0 & 0 & 2q \end{pmatrix}. \tag{5.20}$$

That is, for example,

$$S^{12}{}_{21}=S^{21}{}_{12}=\frac{2q}{q^2+1}.$$

The expression (5.20) has the same limit as (3.8) when $q\to 1$, as it must for the right-hand side of (5.10) to exist. With σ given by (5.7), the covariant derivative is compatible with the metric (5.13) and torsion free. Comparing (3.18) with (3.8) one sees that one obtains for the second example (3.11) a covariant derivative compatible with the metric (5.13) by the replacement $q\mapsto q^{-4}$ in (5.20). The dependence on q comes through the conditions (5.19). Since $S(q)=-S(-q^{-1})$ the same matrix serves two different values of the parameter q.

The metric we have chosen is not symmetric with respect to σ. That is

$$g^{ab}\neq S^{ab}{}_{cd}g^{cd}$$

in general. If one wishes to find a metric symmetric in the above sense, then one must consider (5.16) as an equation for S and the metric and add the additional equation

$$g^{ab}=S^{ab}{}_{cd}g^{cd}. \tag{5.21}$$

The system (5.16) and (5.21), without the restriction we have placed on the coefficients g^{ab}, if it has a solution, would yield a symmetric metric with a compatible connection.

Restricting one's attention to Hermitian x and y and real q, in the limit $q\to 1$ one obtains on the ordinary 2-plane a metric whose Gaussian curvature K is given by

$$K_1=x^2+y^2, \quad K_2=x^{-4}(1+y^4), \tag{5.22}$$

respectively, for the two examples of Section III. This can be calculated using the $q\to 1$ limit of (5.10). It is easy to characterize all metrics which can be obtained in this way. In the limit $q\to 1$ the commutator determines a Poisson bracket on the 2-plane, given as usual by

$$\{f,g\}=\lim_{q\to 1}\frac{1}{i(q-1)}[f,g]. \tag{5.23}$$

Define

$$p_a=\lim_{q\to 1} i(q-1)\lambda_a .$$

In the limit the differential can be written then in the form

$$df=\{p_a,f\}\theta^a. \tag{5.24}$$

If we write $\theta^a=\theta^a_b dx^b$ in terms of dx^a, from this it follows that the equation

$$\{p_c, x^a\}\theta^c_b = \delta^a_b \tag{5.25}$$

must have a solution for p_a polynomial in the variables. This is not always the case. That is, not all metrics with polynomial curvature can be obtained as were those given by (5.22). For example consider the flat metric $\theta^a_b = \delta^a_b$. The equations (5.25) become the equations $\{p_a, x^b\} = \delta^a_b$. Using the expression for the Poisson bracket for the generalized quantum plane, $\{x,y\} = xy$, one sees immediately that there is no solution for the p_a.

The generalized quantum plane has two outer derivations defined by

$$e^{(0)}_1 x = x, \quad e^{(0)}_1 y = 0, \quad \epsilon^{(0)}_2 x = 0, \quad e^{(0)}_2 y = y. \tag{5.26}$$

The corresponding θ^a are given by

$$\theta^1 = x^{-1}dx, \quad \theta^2 = y^{-1}dy. \tag{5.27}$$

Our construction yields then the ordinary flat metric. If one were to extend the algebra to the Heisenberg algebra, then these derivations would become interior. To obtain a metric which is almost flat one can add to (5.26) a 'small' inner derivation of the form given in Section II, but using λ_a which are 'small' of the order of some expansion parameter ϵ. One defines

$$e_a = e^{(0)}_a + \epsilon \mathrm{ad}\lambda_a \tag{5.28}$$

and proceeds as above but retaining only corrections of first order in ϵ. A problem closely related to this has been examined in another context by one of the authors.[5]

The equations (5.17) and (5.19) admit also the solution

$$S = \frac{1}{q^2+1}\begin{pmatrix} -2q & 0 & 0 & 1-q^2 \\ 0 & 1-q^2 & 2q & 0 \\ 0 & 2q & q^2-1 & 0 \\ q^2-1 & 0 & 0 & -2q \end{pmatrix}. \tag{5.29}$$

but the corresponding covariant derivative defined by (5.10) is singular in the limit $q \to 1$.

A complete study of the matrix case has not been made. However, for the particular case (5.12) it is easy to see that the unique torsion free covariant derivative compatible with the metric (5.13) is given by

$$D\theta^a = -\tfrac{1}{2} C^a{}_{bc}\theta^b \otimes \theta^c. \tag{5.30}$$

The ordinary quantum plane with the differential calculus given by (3.13) has no metric connection but it possesses a unique 1-parameter family of linear connections whose curvature is polynomial in the variables x and y.[19] The precise property of the curvature K_2 in (5.22) which associates the corresponding metric to the $GL_q(2)$-invariant differential calculus (3.13) is not clear. We refer to Madore and Mourad[21] for a description of the possible relevance to the theory of gravity of the relation between linear connections on the one hand and commutation relations on the other.

VI. CONCLUSIONS

We have shown that each differential calculus and set of commutation relations between the 1-forms and the elements of the algebra gives rise in the case of the generalized quantum plane to a metric connection which remains regular in the limit $q \to 1$. Not all metrics with polynomial curvature can be obtained in this way.

A non-commutative central limit theorem

T. C. Dorlas[a)]
University College Swansea, Department of Mathematics, Singleton Park, Swansea SA2 8PP, United Kingdom

(Received 2 January 1996; accepted for publication 17 June 1996)

We prove a non-commutative version of the Central Limit Theorem for spin-1/2 variables. The non-commutative spins satisfy Bose–Einstein statistics. The proof involves the Feynman–Kac formula for a hopping process and an explicit calculation of the Fourier transform of the corresponding measure. The limit process is a modification of the Ornstein–Uhlenbeck process, the Fourier transform of which was essentially already calculated by Feynman. However, his derivation is not rigorous and we therefore present an alternative derivation here. © *1996 American Institute of Physics.* [S0022-2488(96)03009-5]

I. MOTIVATION AND THE MAIN RESULTS

The usual Central Limit Theorem in the case of Bernoulli variables states that if a particle can take on two states + and − with probabilities 1/2 then the average value of the sum of n particle states has a normal distribution in the limit $n\to\infty$. To be precise:

$$\lim_{n\to\infty} \mathbb{E}\left[f\left(\frac{1}{\sqrt{n}} \sum_{k=1}^{n} x_k \right) \right] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) \exp\left[-\frac{1}{2} x^2 \right] dx \tag{1.1}$$

for any continuous bounded function f. This result can be interpreted as a result in classical statistical mechanics, giving the asymptotic distribution of the total spin of an assembly of independent classical spins x_i. One may then wonder about the behavior of quantum spins.

Quantum spins differ from classical spins in that they are described by non-commuting operators. We introduce annihilation operators a_+ and a_- and creation operators a_+^* and a_-^* which annihilate and create particles with spin + and − respectively. They obey the commutation relations

$$[a_\pm, a_\pm^*] = 1, \quad [a_\pm, a_\mp^*] = 0, \tag{1.2}$$

while creation and annihilation operators commute among themselves. The products $N_\pm = a_\pm^* a_\pm$ count the number of particles with spin + and − respectively. $a_\pm^*$ and $a_\pm$ can be represented on the Hilbert space $\mathscr{H}_\pm$ which is spanned by the eigenstates $|n\rangle_\pm$ of the number operators $N_\pm$. The total Hilbert space is the direct sum of these two: $\mathscr{H} = \mathscr{H}_+ \oplus \mathscr{H}_-$.

We now consider the operators $c_\pm$ and $c_\pm^*$ and Δ defined by

$$c_\pm = \frac{1}{\sqrt{2}} (a_+ \pm a_-) \quad \text{and} \quad \Delta = a_+^* a_+ - a_-^* a_- . \tag{1.3}$$

Notice that $c_\pm$ and $c_\pm^*$ are also annihilation and creation operators in that they satisfy commutation relations analogous to (1.2). Therefore $c_\pm^* c_\pm$ is also a number operator, giving the number of particles in the state $(1/\sqrt{2})(|+\rangle \pm |-\rangle)$. We shall write $c = c_-$ in the following. The corresponding number operator can be written as follows:

0022-2488/96/37(9)/4662/21/$10.00

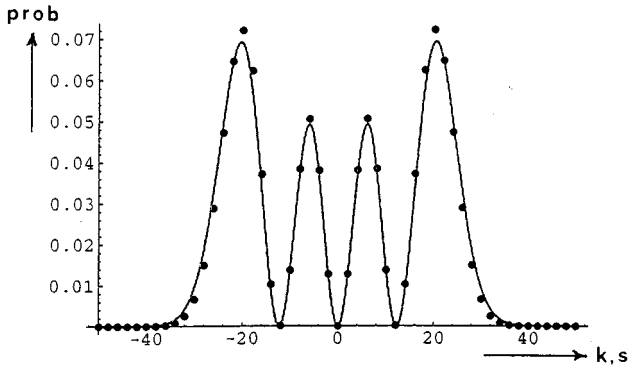

FIG. 1. The probability distribution of the eigenvalues of Δ (heavy dots) and the limiting distribution (grey curve).

$$c^*c = \tfrac{1}{2}(N_- + N_-) - \tfrac{1}{2}(a_+^* a_- + a_-^* a_+). \tag{1.4}$$

The total number operator $N = N_+ + N_-$ commutes with c^*c and also with Δ. We can therefore restrict the system to the n-particle subspace, that is, the subspace of $\mathscr{H}$ where N has the eigenvalue n. The second part of the operator c^*c is a hopping term: it annihilates a particle with one spin and creates a particle with the opposite spin. The operator Δ measures the net spin of all particles. That is similar to the expression $\Sigma_{k=1}^n x_k$ in (1.1). We now prove the following noncommutative analogue of (1.1):

Theorem 1.1: For any $n,m \in \mathbb{N}$ with $0 \leqslant m \leqslant n$, denote by $|n;m\rangle$ the eigenstate of c^*c in the n-particle subspace $\mathscr{H}_n$ with eigenvalue m. Then, for any bounded continuous function $f:\mathbb{R}\to\mathbb{R}$,

$$\lim_{n\to\infty} \langle n;m|f(\Delta/\sqrt{n})|n;m\rangle = \frac{1}{m!\sqrt{2\pi}} \int_{-\infty}^{\infty} H_m(x)^2 e^{-x^2/2} f(x)\,dx, \tag{1.5}$$

where $H_m(x)$ $(m=0,1,2,...)$ are the Hermite polynomials defined by

$$H_m(x) = (-1)^m e^{x^2/2}\left(\frac{d}{dx}\right)^m e^{-x^2/2}. \tag{1.6}$$

Before we prove this simple result, let us consider the graph of the probability distribution of the eigenvalue k of the operator Δ in the case $n=50$ and $m=3$ (see Figure 1). In the same graph the rescaled distribution function

$$\frac{1}{m!\sqrt{2\pi}} H_m\left(\frac{s}{\sqrt{n}}\right)^2 \exp[-s^2/2n]$$

is plotted as a function of the continuous variable s corresponding to k. It is clear that the graphs are already reasonably close. Notice also that the quantum nature of the system does not disappear in the limit! One could say that fluctuations of a quantum system still have a quantum nature in that interference effects remain. A similar phenomenon, but in a different setting was noted by Goderis *et al.*[1,2]

Proof: We prove that the corresponding Fourier transforms converge. This proves the theorem: see, e.g., Refs. 3, 4 or 5. We first compute the characteristic function of the limiting distribution. We use the generating function for the Hermite polynomials:

$$\sum_{m=0}^{\infty} H_m(x)\,\frac{\alpha^m}{m!} = e^{\alpha x-\alpha^2/2}. \tag{1.7}$$

This yields easily

$$\sum_{m_1=0}^{\infty} \frac{\alpha_1^m}{m_1!} \sum_{m_2=0}^{\infty} \frac{\alpha_2^{m_2}}{m_2!} \int_{-\infty}^{\infty} H_{m_1}(x)H_{m_2}(x)e^{itx}e^{-x^2/2}\,\frac{dx}{\sqrt{2\pi}} = e^{-t^2/2}e^{i(\alpha_1+\alpha_2)t+\alpha_1\alpha_2}. \tag{1.8}$$

Expanding the exponential factor we have

$$e^{i(\alpha_1+\alpha_2)t+\alpha_1\alpha_2} = \sum_{m_1=0}^{\infty}\sum_{m_2=0}^{\infty}\left(\sum_{l=0}^{m_1\wedge m_2} \frac{(it)^{m_1+m_2-2l}}{l!(m_1-l)!(m_2-l)!}\right)\alpha_1^{m_1}\alpha_2^{m_2}. \tag{1.9}$$

Extracting the terms $m_1=m_2=m$ we find that

$$\frac{1}{m!}\int_{-\infty}^{\infty} H_m(x)^2e^{itx}e^{-x^2/2}\,\frac{dx}{\sqrt{2\pi}} = \sum_{k=0}^{m}\binom{m}{k}(-1)^k\,\frac{t^{2k}}{k!}\,e^{-t^2/2}. \tag{1.10}$$

To compute the characteristic function of the discrete distribution of the eigenvalues of Δ we use the fact that

$$|n;m\rangle = \frac{1}{\sqrt{m!(n-m)!}}\,c_+^{*(n-m)}c^{*m}|0\rangle \tag{1.11}$$

and hence

$$\begin{aligned}\sum_{m=0}^{n}\binom{n}{m}^{1/2}\alpha^m|n;m\rangle &= \frac{1}{\sqrt{2^n n!}}\sum_{m=0}^{n}\binom{n}{m}\alpha^m(\alpha_+^*+a_-^*)^{n-m}(a_+^*-a_-^*)^m|0\rangle\\ &= \frac{1}{\sqrt{2^n n!}}[(1+\alpha)a_+^*+(1-\alpha)a_-^*]^n|0\rangle\\ &= 2^{-n/2}\sum_{k=0}^{n}\binom{n}{k}^{1/2}(1+\alpha)^k(1-\alpha)^{n-k}|k,n-k\rangle,\end{aligned} \tag{1.12}$$

where $|n_+,n_-\rangle$ denotes an eigenstate of the operators $N_\pm$. Inserting this identity one easily finds that

$$\begin{aligned}&\sum_{m_1=0}^{n}\binom{n}{m_1}^{1/2}\sum_{m_2=0}^{n}\binom{n}{m_2}^{1/2}\langle n;m_1|e^{it\Delta}|n;m_2\rangle\alpha_1^{m_1}\alpha_2^{m_2}\\ &\quad= 2^{-n}[(1+\alpha_1)(1+\alpha_2)e^{it}+(1-\alpha_1)(1-\alpha_2)e^{-it}]^n\\ &\quad= [(1+\alpha_1\alpha_2)\cos t + i(\alpha_1+\alpha_2)\sin t]^n.\end{aligned} \tag{1.13}$$

It follows that

$$\langle n;m|e^{it\Delta}|n;m\rangle=\binom{n}{m}^{-1}\sum_{k=0}^{[n/2]\wedge m}\binom{n}{2k}\binom{2k}{k}\binom{n-2k}{m-k}(-1)^k(\sin t)^{2k}(\cos t)^{n-2k}$$

$$=\sum_{k=0}^{[n/2]\wedge m}\frac{(-1)^k}{k!}\binom{m}{k}\frac{(n-m)!}{(n-m-k)!}(\sin t)^{2k}(\cos t)^{n-2k}. \tag{1.14}$$

Replacing t by $t/\sqrt{n}$ and taking $n\to\infty$ it is now easy to see that this tends to (1.10). Q.E.D.

The above theorem gives a way of computing expressions of the form

$$\mathrm{Trace}_n(e^{-\beta c^*c}f(\Delta/\sqrt{n}))$$

in the limit $n\to\infty$. However, in quantum statistical mechanics one is rather more interested in computing quantities of the form Trace $e^{-\beta H}$, where in our case, $H=c^*c+f(\Delta/\sqrt{n})$. This is not the same as the above because the operators c^*c and Δ do not commute. To compute the latter expression, we could try to use the Trotter product formula (Theorem 1.1 of Ref. 6):

$$e^{A+B}=\lim_{M\to\infty}(e^{A/M}e^{B/M})^M. \tag{1.15}$$

This yields:

$$\mathrm{Trace}_n\ \exp[-\beta c^*c+f(\Delta/\sqrt{n})]$$

$$=\sum_{m=0}^{n}\langle n;m|\exp[-\beta c^*c+f(\Delta/\sqrt{n})]|n;m\rangle$$

$$=\lim_{M\to\infty}\sum_{m_1,\ldots,m_M=0}^{n}\prod_{i=1}^{M}\langle n;m_{i-1}|e^{f(\Delta/\sqrt{n})/M}|n;m_i\rangle\prod_{i=1}^{M}e^{-\beta m_i/M}, \tag{1.16}$$

where $m_0=m_M$. Using a simple generalization of Theorem 1 we can now conjecture that the limit $n\to\infty$ yields

$$\lim_{n\to\infty}\mathrm{Trace}_n\ \exp[-\beta c^*c+f(\Delta/\sqrt{n})]$$

$$=\lim_{M\to\infty}\sum_{m_1,\ldots,m_M=0}^{\infty}\prod_{i=1}^{M}e^{-\beta m_i/M}\times\prod_{i=1}^{M}\left[\frac{1}{\sqrt{2\pi m_{i-1}!m_i!}}\right.$$

$$\left.\times\int_{-\infty}^{\infty}H_{m_{i-1}}(x)H_{m_i}(x)e^{f(x)/M}e^{-x^2/2}dx\right]. \tag{1.17}$$

Now,

$$\psi_m(x)=\frac{1}{\sqrt{m!}}H_m(x)\Omega_0(x) \tag{1.18}$$

is the m-th eigenfunction of the harmonic oscillator Hamiltonian

$$H_0=-\frac{d^2}{dx^2}+\frac{1}{4}x^2-\frac{1}{2}, \tag{1.19}$$

with

$$\Omega_0(x)=(2\pi)^{-1/4}e^{-x^2/4} \tag{1.20}$$

being the ground state: $H_0\Omega_0=0$ and $H_0\psi_m=m\psi_m$. Putting

$$a=\frac{1}{2}x+\frac{d}{dx} \quad \text{and} \quad a^*=\frac{1}{2}x-\frac{d}{dx} \tag{1.21}$$

as usual, we have $[a,a^*]=1$ and

$$H_0=a^*a \quad \text{and} \quad x=a+a^*. \tag{1.22}$$

This means that we can write

$$\begin{aligned}\lim_{n\to\infty}\text{Trace}_n\ \exp[-\beta c^*c+f(\Delta/\sqrt{n})]&=\lim_{M\to\infty}\sum_{m_1,\ldots,m_M=0}^{\infty}\prod_{i=1}^{M}(\psi_{m_{i-1}}|e^{-\beta H_0/M}e^{f(a+a^*)/M}\psi_{m_i})\\&=\lim_{M\to\infty}\sum_{m=0}^{\infty}(\psi_m|(e^{-\beta H_0/M}e^{f(a+a^*)/M})^M\psi_m)\\&=\text{Trace}\ \ e^{-\beta H_0+f(a+a^*)}.\end{aligned} \tag{1.23}$$

Thus we conjecture the following theorem:

Theorem 1.2. For any bounded continuous function f: $\mathbb{R}\to\mathbb{R}$,

$$\lim_{n\to\infty}\text{Trace}_n\ e^{-\beta c^*c+f(\Delta/\sqrt{n})}=\text{Trace}\ \ e^{-\beta a^*a+f(a+a^*)}. \tag{1.24}$$

It should be realized that the above derivation does not constitute a proof since the limits $n\to\infty$ and $M\to\infty$ were interchanged without justification. (Professor Zagrebnov suggested that it may in fact be possible to make the argument rigorous using trace-norm convergence proved in his paper.[7]) The remaining sections of this paper are dedicated to a proof of this last theorem using the Feynman–Kac representation.

Remark. Several versions of the non-commutative central limit theorem were also derived by Hudson.[8–10] Let us briefly comment on the main differences. In Theorem 1.1 we keep the eigenvalue m of the operator c^*c fixed while taking the number of particles n to infinity. Also, the spins are assumed to commute as opposed to anti-commute as in the case of Clifford algebra version considered in Refs. 9 and 10. Notice that we consider only two pairs of creation and annihilation operators whereas in Ref. 8 Hudson considers in effect a sequence of creation and annihilation operators. In Theorem 1.2 the eigenvalue m is not fixed as such but it is implicit in the proof that the main contribution still comes from the subspaces where m is bounded. This is a rudimentary kind of boson condensation and was in fact the main motivation for this work. In both the above theorems it is the number of particles that tends to infinity as opposed to the number of creation and annihilation operators.

II. THE FEYNMAN–KAC FORMULA

In this section we derive a Feynman-Kac formula in the spirit of Ginibre.[11] (However, the derivation is self-contained and does not assume familiarity with Ginibre's work.) We work with eigenstates of Δ instead of c^*c. Let $|x_1,\ldots,x_n\rangle$ denote the state where the k-th spin is given by $x_k(=\pm1)$. (For the moment we assume the individual spins to be distinguishable.) Then we can define individual particle creation and annihilation operators:

$$a_{k,s}|x_1,\ldots,x_n\rangle=\delta_{x_k,s}|x_1,\ldots,\hat{x}_k,\ldots,x_n\rangle,$$
$$a^*_{k,s}|x_1,\ldots,x_n\rangle=|x_1,\ldots,x_{k-1},s,x_k,\ldots,x_n\rangle. \tag{2.1}$$

(The hat above x_k in the first formula indicates that this element is to be omitted.) The states $|x_1,\ldots,x_n\rangle$ form an orthonormal basis of a 2^n-dimensional Hilbert space of distinguishable particles. We can reduce the space to one spanned by distinguishable elements given by symmetric combinations:

$$|n_+,n_-\rangle=\binom{n_++n_-}{n_+}^{-1/2}\sum_{\substack{x_1,\ldots,x_n=\pm\\ \#\{x_k=\pm\}=n_\pm}}|x_1,\ldots,x_n\rangle. \tag{2.2}$$

Let $\mathscr{F}_n$ be the space spanned by all states $|n_+,n_-\rangle$ with $n_++n_-=n$:

$$\mathscr{F}_n=[\![|n_+,n_-\rangle:n_++n_-=n]\!]. \tag{2.3}$$

It is then easy to see that the operators $a_\pm$ and $a^*_\pm$ defined previously can be represented operating on $\mathscr{F}_n$ as follows:

$$a_\pm|_{\mathscr{F}_n}=\frac{1}{\sqrt{n}}\sum_{k=1}^{n}a_{k,\pm}\Big|_{\mathscr{F}_n},\quad a^*_\pm|_{\mathscr{F}_n}=\frac{1}{\sqrt{n+1}}\sum_{k=1}^{n+1}a^*_{k,\pm}\Big|_{\mathscr{F}_n}. \tag{2.4}$$

Inserting these formulas we can now write

$$\begin{aligned}&\langle n'_+,n'_-|e^{-\beta c^*c+f(\Delta)}|n_+,n_-\rangle\\ &\quad=\binom{n}{n'_+}^{-1/2}\binom{n}{n_+}^{-1/2}\\ &\quad\times\sum_{\substack{x'_1,\ldots,x'_n\\ \#\{x'_k=\pm\}=n'_\pm}}\ \sum_{\substack{x_1,\ldots,x_n\\ \#\{x_k=\pm\}=n_\pm}}\langle x'_1,\ldots,x'_n|\exp\Bigg[-\frac{\beta}{2}\sum_{k=1}^{n}(a^*_{k,+}-a^*_{k,-})\\ &\quad\times(a_{k,+}-a_{k,-})+f\Bigg(\sum_{k=1}^{n}(a^*_{k,+}a_{k,+}-a^*_{k,-}a_{k,-})\Bigg)\Bigg]|x_1,\ldots,x_n\rangle.\end{aligned} \tag{2.5}$$

The latter scalar products can be written in terms of a stochastic process. Heuristically, we can define a simple jump process ξ with continuous time and values ±1 by the infinitesimal transition probabilities

$$\mathbb{P}_\beta[\xi(t+\delta t)=x'|\xi(t)=x]=\begin{cases}1-\dfrac{\beta}{2}\,\delta t, & \text{if } x'=x;\\[2mm] \dfrac{\beta}{2}\,\delta t, & \text{if } x'=-x.\end{cases} \tag{2.6}$$

This is the so-called *telegraph process*. It is well-known that this process can be defined rigorously as a measure $\mathbb{P}_{\beta,x}$, where $x=\pm1$ is the starting point of the process, on the space $D[0,1]$ of

functions $\xi:[0,1]\to\mathbb{R}$ which are right-continuous and have limits on the left, the so-called Cadlag space in French terminology. Thus, $\xi\in D[0,1]$ if and only if, for all $t_0\in(0,1)$,

$$\lim_{t\downarrow t_0}\xi(t)=\xi(t_0)\quad\text{and}\quad\lim_{t\uparrow t_0}\xi(t)=\xi(t_0^-)\ \text{exist},\tag{2.7}$$

and, moreover, $\xi(0)=\lim_{t\downarrow 0}\xi(t)$ and $\xi(1)=\lim_{t\uparrow 1}\xi(t)$. On this space one can introduce a metric, the Skorokhod metric, by

$$\rho(\xi,\xi')=\inf_{\lambda\in H}[\sup_{t\in\mathbb{R}}|\xi(\lambda(t))-\xi'(t)|+\sup_{t\in[0,1]}|\lambda(t)-t|].\tag{2.8}$$

Here H is the space of increasing functions $\lambda\colon[0,1]\to[0,1]$. One has the following characterization of compact subsets of $D[0,1]$:

Lemma 2.1: In order that a subset $K\subset D[0,1]$ be compact under the Skorokhod topology it is necessary and sufficient that K be bounded and closed and satisfy the condition

$$\limsup_{\delta\downarrow 0}\sup_{\xi\in K}\omega_\xi(\delta)=0,\tag{2.9}$$

where $\omega_\xi(\delta)$ is defined by

$$\begin{aligned}\omega_\xi(\delta)=&\sup_{t-\delta\le t'\le t\le t''\le t+\delta}\{|\xi(t')-\xi(t)|\wedge|\xi(t'')-\xi(t)|\}\\&+\sup_{0\le t\le\delta}|\xi(t)-\xi(0)|+\sup_{1-\delta\le t\le 1}|\xi(t)-\xi(1)|.\end{aligned}\tag{2.10}$$

(For a proof, see Ref. 12, Chapter 9, Sec. 5, Theorem 1, or Ref. 13, Chapter 7, Theorem 6.2.)

We now use Prokhorov's Theorem to extend the finite-dimensional distributions of $\mathbb{P}_{\beta,x}$ to a measure on $D[0,1]$. These finite-dimensional distributions are easily obtained by integrating the infinitesimal transition probabilities (2.6):

$$\mathbb{P}_{\beta,x}(\xi(t_1)=x_1,\ldots,\xi(t_n)=x_n)=p_{t_1}(x,x_1)p_{t_2-t_1}(x_1,x_2),\ldots,p_{t_n-t_{n-1}}(x_{n-1},x_n),\tag{2.11}$$

where the transition probabilities p_t are given by

$$p_t(x,x')=\tfrac{1}{2}(1+xx'e^{-\beta t}).\tag{2.12}$$

Lemma 2.2: There exists a unique Radon measure $\mathbb{P}_{\beta,x}$ on $D[0,1]$ (for $\beta>0$ and $x=\pm1$) with finite-dimensional distributions given by (2.11) for any finite set of points $0<t_1<\ldots<t_n\le 1$ and any corresponding set of values $x_i=\pm1$, $i=1,\ldots,n$.

Proof: According to Prokhorov's Theorem [see Ref. 14, Theorem 22 of Part I, Chapter I (p. 81)] it suffices to prove that, for all $\epsilon>0$ there exists a compact set $K\subset D[0,1]$ such that $\mu_{(t_1,\ldots,t_n)}[\pi_{(t_1,\ldots,t_n)}(K)]\geqslant 1-\epsilon$ for all finite sets $0<t_1<\ldots<t_n\le 1$, where $\mu_{(t_1,\ldots,t_n)}$ is the measure on $\mathbb{R}^n$ defined by $\mu_{(t_1,\ldots,t_n)}[A]=\mathbb{P}_{\beta,x}[(\xi(t_1),\ldots,\xi(t_n))\in A]$ and $\pi_{(t_1,\ldots,t_n)}$ is the projection given by $\pi_{(t_1,\ldots,t_n)}(\xi)=(\xi(t_1),\ldots,\xi(t_n))$.
(Indeed, it is easy to verify that the measures $\mu_{(t_1,\ldots,t_n)}$ form an exact projective system.) The uniqueness of $\mathbb{P}_{\beta,x}$ then follows from the fact that the projections $\pi_{(t_1,\ldots,t_n)}$ separate the points of $D[0,1]$.

We define the set K_N as follows:

$$K_N=\{\xi\in D[0,1]\,|\,\xi(t)=\pm 1 \text{ for all } t\in[0,1] \text{ and, for all } t_0\in(0,1):$$

$$\text{if } \xi(t_0)\neq\xi(t_0^-) \text{ then } \xi(t)=\xi(t_0)\forall t\in[t_0,t_0+1/N)$$

$$\text{and } \xi(t)=\xi(t_0^-)\forall t\in(t_0-1/N,t_0)\}.$$

The latter condition in the definition of K_N means that all jumps in ξ should be at least $1/N$ apart. It is now easy to see that

$$\mathbb{P}_{\beta,x}[K_N^c]<\frac{\beta^2}{2N}\to 0 \text{ as } N\to\infty. \tag{2.14}$$

One simply divides the interval $[0,1]$ into subintervals $[(m-1)/N,m/N]$. There must then be at least 2 jumps inside two adjacent subintervals. Since there are $N-1$ pairs of such subintervals this occurs with probability bounded by

$$(1-(1+\beta/N)e^{-\beta/N})(N-1)<\beta^2/2N.$$

(In fact this argument has to be done after projection by $\pi_{(t_1,\ldots,t_n)}$. This slightly complicates matters and will be omitted here.)

The sets K_N are obviously compact by the criterion of Lemma 2.1. Indeed, K_N is clearly bounded and it is easy to see that it is also closed (this is not essential). Moreover, $\omega_\xi(\delta)=0$ for all $\xi\in K_N$ whenever $\delta<1/2N$. Q.E.D.

We will need the following technical result:

Lemma 2.3: Given $\xi\in D[0,1]$ the step functions

$$\xi^{(n)}(t)=\sum_{i=0}^{n-2}\xi\left(\frac{i}{n}\right)1_{[(i-1)/n,i/n)}+\xi\left(\frac{n-1}{n}\right)1_{[(n-1)/n,1]}$$

tend to ξ in the ρ-topology as $n\to\infty$. Moreover, if $\xi_n\in D[0,1]$ is an arbitrary sequence tending to ξ for the ρ-topology then $\|\xi_n-\xi\|_2\to 0$, that is, the inclusion of $D[0,1]$ into $L^2[0,1]$ is continuous.

Proof: The first part of this lemma is proved in Ref. 15 (Theorem 1 of Chapter V, Sec. 3). We repeat this proof here for convenience as the second part follows the same lines. Fix $\xi\in D[0,1]$ and $\epsilon>0$. Let $\Gamma(\epsilon)$ denote the set of points τ where ξ has a jump $>\epsilon$, that is $|\xi(\tau)-\xi(\tau^-)|>\epsilon$. Then there is $\delta>0$ such that $\omega_\xi(\delta)<\epsilon/2$ by (2.9). This implies that $\Gamma(\epsilon)$ is a finite set and $\inf_{\tau,\tau'\in\Gamma(\epsilon)}|\tau-\tau'|\geqslant\delta$. Now choose $n>3/\delta$. Then, if $\tau,\tau'\in\Gamma(\epsilon)$, $\tau'\neq\tau$ and $i/n<\tau\leqslant(i+1)/n$, $(i-2)/n\geqslant\tau'$ or $(i+3)/n<\tau'$. We can thus define $\lambda_n\in H$ on the interval of length $3/n$ surrounding $\tau\in\Gamma(\epsilon)$ by

$$\lambda_n(t)=\begin{cases}\dfrac{i-1}{n}+\dfrac{n}{2}\left(t-\dfrac{i-1}{n}\right)\left(\tau-\dfrac{i-1}{n}\right) & \text{if } \dfrac{i-1}{n}\leqslant t\leqslant\dfrac{i+1}{n}\\[2ex] \tau+n\left(t-\dfrac{i-1}{n}\right)\left(\dfrac{i+2}{n}-\tau\right) & \text{if } \dfrac{i+1}{n}\leqslant t\leqslant\dfrac{i+2}{n}.\end{cases}$$

Everywhere else we define $\lambda_n(t)=t$. It is now easy to see that $|\lambda_n(t)-t|\leqslant\delta$ and $|\xi(\lambda_n(t))-\xi(t)|\leqslant 2\omega_\xi(\delta)+\epsilon<2\epsilon$. (Assuming $\omega_\xi(\delta)<\epsilon/2$.) This uses Lemma 3 of Ref. 12 (Chapter IX, Sec. 5) or Lemma 6.4 of Ref. 13 (Chapter 7), which says that if ξ has no jumps of magnitude $>\epsilon$ in an interval $[\alpha,\beta]$ then $|\xi(t')-\xi(t'')|\leqslant 2\omega_\xi(\delta)+\epsilon$ for all $t',t''\in[\alpha,\beta]$ with $|t'-t''|\leqslant\delta$. This proves the first part of the lemma.

For the second part of the lemma, let $\eta>0$ be given and choose $\epsilon>0$ such that $4\epsilon^2<\eta^2/2$. Let $\Gamma(\epsilon)$ and δ be as above and assume in addition that $8M^2\delta<\eta^2/2$, where $M=\sup_{t\in[0,1]}|\xi(t)|$. Then, if $|\lambda(t)-t|<\delta^2$ and $|t-\tau|\geq\delta^2$ for all $\tau\in\Gamma(\epsilon)$, $|\xi(\lambda(t))-\xi(t)|\leq 2\omega_\xi(\delta)+\epsilon<2\epsilon$ by the above quoted lemma, and hence

$$\begin{aligned}\|\xi\circ\lambda-\xi\|_2^2 &\leq \int_{\Gamma_{\delta^2}(\epsilon)}|\xi(\lambda(t))-\xi(t)|^2dt+\int_{\Gamma_{\delta^2}(\epsilon)^c}|\xi(\lambda(t))-\xi(t)|^2dt\\ &\leq (2M)^2\cdot 2\,\delta^2(1/\delta)+(2\epsilon)^2<\eta^2\end{aligned}$$

with $\Gamma_{\delta^2}(\epsilon)=\{t:\exists\,\tau\in\Gamma(\epsilon):|t-\tau|<\delta^2\}$, since there are at most $1/\delta$ points $\tau\in\Gamma(\epsilon)$.

Now assume $\rho(\xi_n,\xi)\to 0$. Then, given $\delta>0$, there exists n_0 such that for all $n\geq n_0$ there exists $\lambda\in H$ with $|\lambda(t)-t|\leq\delta^2$ and $|\xi(\lambda(t))-\xi_n(t)|\leq\delta^2$ for all $t\in[0,1]$. Taking δ as above, and moreover such that $\delta^2<\eta$ then

$$\|\xi_n-\xi\|_2\leq\|\xi_n-\xi\circ\lambda\|_2+\|\xi\circ\lambda-\xi\|_2\leq\delta^2+\eta<2\,\eta.$$

This proves the second part of the lemma. Q.E.D.

Having defined the measure $\mathbb{P}_{\beta,x}$ we can now formulate the Feynman-Kac formula. In the proof we need one more technical lemma, however.

Lemma 2.4: If $f:\mathbb{R}^n\to\mathbb{R}$ is a bounded continuous function then the map $\xi\mapsto\int_0^1 f(\xi(t))dt$ is continuous on $L^2([0,1],\mathbb{R}^n)$.

Proof: Suppose that $(\xi_k)_{k=1}^\infty$ is a sequence in $L^2([0,1],\mathbb{R}^n)$ tending to ξ. Then every subsequence $(\xi_k^{(1)})$ has itself a subsequence $(\xi_k^{(2)})$ converging almost everywhere to ξ. It follows that $f\circ\xi_k^{(2)}$ converges almost everywhere to $f\circ\xi$ and since it is also bounded, $\int_0^1 f(\xi_k^{(2)}(t))dt$ converges to $\int_0^1 f(\xi(t))dt$. Since the limit does not depend on the original subsequence $\xi_k^{(1)}$ chosen, this means that $\int_0^1 f(\xi_k(t))dt$ must converge to $\int_0^1 f(\xi(t))dt$. Q.E.D.

Now notice that the operator $(a_{k,+}^*-a_{k,-}^*)(a_{k,+}-a_{k,-})$ occurring in the expression (2.5) acting on the 1-particle space (at position k) acts exactly as $(1-\sigma^{(x)})$, where $\sigma^{(x)}$ is the usual Pauli matrix and, similarly, the operator $a_{k,+}^*a_{k,+}-a_{k,-}^*a_{k,-}$ acts like $\sigma^{(z)}$. We now have:

Theorem 2.1: Let $\mathbb{P}_{\beta,x}$ be the measure defined in Lemma 2.2. Then, for $x_1,\ldots,x_n$, $x_1',\ldots,x_n'\in\{-1,1\}$ and any continuous function $f:\mathbb{R}^n\to\mathbb{R}$, we have the following integral representation:

$$\langle x_1',\ldots,x_n'|\exp\left[-\frac{\beta}{2}\sum_{k=1}^n(1-\sigma_k^{(x)})+f(\sigma_1^{(z)},\ldots,\sigma_n^{(z)})\right]|x_1,\ldots,x_n\rangle$$

$$=\mathbb{E}_{\beta,x}\left[\exp\left[\int_0^1 f(\xi(t))dt\right]1_{\{\xi:\xi_k(1)=x_k'\,\forall\,k=1,\ldots,n\}}\right],\tag{2.15}$$

where $\mathbb{E}_{\beta,x}$ is the expectation w.r.t. the product measure $\Pi_{k=1}^n\mathbb{P}_{\beta,x_k}$.

Proof: We can follow the first proof of [Ref. 6 (Theorem 6.1)]. First note that

$$\langle x'|\exp\left[-\frac{\beta\delta t}{2}(1-\sigma^{(x)})\right]|x\rangle=p_{\delta t}(x,x')\tag{2.16}$$

[see (2.12)]. Now, by the Trotter product formula (1.15) we have

$$\langle x_1',\ldots,x_n'|\exp\left[-\frac{\beta}{2}\sum_{k=1}^{n}(1-\sigma_k^{(x)})+f(\sigma_1^{(z)},\ldots,\sigma_n^{(z)})\right]|x_1,\ldots,x_n\rangle$$

$$=\lim_{M\to\infty}\langle x_1',\ldots,x_n'|\left\{e^{f(\sigma_1^{(z)},\ldots,\sigma_n^{(z)})/M}\prod_{k=1}^{n}e^{-\beta(1-\sigma_k^{(z)})/2M}\right\}^M|x_1,\ldots,x_n\rangle$$

$$=\lim_{M\to\infty}\sum_{x_1^{(1)},\ldots,x_1^{(M-1)}=\pm1}\cdots\sum_{x_n^{(1)},\ldots,x_n^{(M-1)}=\pm1}\prod_{i=1}^{M}\left\{e^{f(x_1^{(i)},\ldots,x_n^{(i)})/M}\prod_{k=1}^{n}p_{1/M}(x_k^{(i-1)},x_k^{(i)})\right\}$$

$$=\lim_{M\to\infty}\mathbb{E}_{\beta,(x_1,\ldots,x_n)}\left[\exp\left[\frac{1}{M}\sum_{i=1}^{M}f\left(\xi\left(\frac{i}{M}\right)\right)\right]1_{\{\xi:\xi_k(1)=x_k'\forall k\}}\right]. \tag{2.17}$$

But

$$\frac{1}{M}\sum_{i=1}^{M}f\left(\xi\left(\frac{i}{M}\right)\right)=\int_0^1 f(\xi_1^{(M)}(t),\ldots,\xi_n^{(M)}(t))dt$$

if $\xi_k^{(M)}$ is the function defined in Lemma 2.3 and hence $\int f(\xi^{(M)}(t))dt\to\int f(\xi(t))dt$ for all $\xi\in D[0,1]$ by Lemma 2.4 since $\xi_k^{(M)}\to\xi_k$ in ρ-topology, $\xi_k^{(M)}\to\xi_k$ in L^2 by Lemma 2.3. Moreover, the integrand in (2.17) is dominated by $\exp[\sup_{|x|\leqslant\|\xi\|_\infty}|f(x)|]$, so by the dominated convergence theorem, (2.15) holds. Q.E.D.

Inserting this formula into (2.5) we obtain immediately

Corollary: Define the measure $\mathbb{K}_\beta^{(n)}$ on $D[0,1]$ by

$$\mathbb{K}_\beta^{(n)}[F]=\frac{1}{Z_n(\beta)}\sum_{k=0}^{n}\binom{n}{k}^{-1}\sum_{\substack{x_1,\ldots,x_n=\pm1\\ \#\{i:x_i=+1\}=k}}\sum_{\substack{x_1',\ldots,x_n'=\pm1\\ \#\{i:x_i'=+1\}=k}}\mathbb{E}^{(n)}_{\beta,(x_1,\ldots,x_n)}\left[F\left(\sum_{i=1}^{n}\xi_i(t)\right)\prod_{i=1}^{n}1_{\{\xi:\xi_i(1)=x_i'\}}\right] \tag{2.18}$$

for any continuous function $F:\mathbb{R}\to\mathbb{R}$, where $\mathbb{E}^{(n)}_{\beta,(x_1,\ldots,x_n)}$ is the expectation with respect to the n-fold product measure $\Pi_{i=1}^n\mathbb{P}_{\beta,x_i}(d\xi_i)$ on $D[0,1]^n$, and $Z_n(\beta)$ is a normalization factor:

$$Z_n(\beta)=\sum_{k=0}^{n}e^{-\beta n}=\frac{1-e^{-\beta(n+1)}}{1-e^{-\beta}}. \tag{2.19}$$

Then the expression in the left-hand side of (1.24), normalized to 1 for $f=0$, is given by

$$\frac{\mathrm{Trace}_n\ e^{-\beta c^*c+f(\Delta)}}{\mathrm{Trace}_n\ e^{-\beta c^*c}}=\mathbb{K}_\beta^{(n)}\left[\exp\left(\int_0^1 f(\xi(t))dt\right)\right]. \tag{2.20}$$

There is an analogous formula for the limiting expression in (1.24):

Theorem 2.2: Let $\mathbb{E}_0$ denote the expectation with respect to the Ornstein–Uhlenbeck process measure on the continuous functions $C[0,1]$ with generator given by H_0 [see (1.19)]. Then the right-hand side expression of (1.24), normalized to 1 for $f=0$ is given by

$$\frac{\mathrm{Trace}\ e^{-\beta a^*a+f(a+a^*)}}{\mathrm{Trace}\ e^{-\beta a^*a}}=\mathbb{K}_\beta\left[\exp\left(\int_0^1 f(q(\beta t))dt\right)\right], \tag{2.21}$$

where the measure $\mathbb{K}_\beta$ is defined by

$$\mathbb{K}_\beta[F]=\frac{1}{Z(\beta)}\sum_{m=0}^{\infty}\mathbb{E}_0[\psi_m(q(0))\Omega_0(q(0))^{-1}F[q(\cdot)]\psi_m(q(\beta))\Omega_0(q(\beta))^{-1}], \quad (2.22)$$

and where $Z(\beta)$ is the normalization constant given by

$$Z(\beta)=\text{Trace } e^{-\beta a^*a}=\frac{1}{1-e^{-\beta}}. \quad (2.23)$$

[The ground state function Ω_0 and the excited-state wave functions ψ_m are defined by (1.20) and (1.18) respectively.]

Proof: Since f is a bounded function, $\beta H_0 - f(a+a^*)$ is a bounded perturbation of βH_0 and therefore self-adjoint on the domain of H_0. We choose the particular representation for a and a^* given by (1.21). We can then apply the Trotter product formula and write

$$\begin{aligned}(\phi|e^{-\beta H_0+f(a+a^*)}|\psi)&=\lim_{M\to\infty}(\phi|(e^{-\beta H_0/M}e^{f(a+a^*)/M})^M|\psi)\\&=\lim_{M\to\infty}(\Omega_0|\overline{\phi}(x)\Omega_0^{-1}(x)e^{-\beta H_0/M}e^{f(x)/M}\ldots e^{f(x)/M}\psi(x)\Omega_0^{-1}(x)|\Omega_0)\\&=\lim_{M\to\infty}\mathbb{E}\left[\left[\overline{\phi}(q(0))\Omega_0^{-1}(q(0))\exp\left(\sum_{i=1}^{M}f(q(\beta i/M))/M\right)\psi(q(\beta))\Omega_0^{-1}(q(\beta))\right]\right]\\&=\mathbb{E}\left[\overline{\phi}(q(0))\Omega_0^{-1}(q(0))\exp\left(\int_0^1 f(q(\beta s))ds\right)\psi(q(\beta))\Omega_0^{-1}(q(\beta))\right].\end{aligned} \quad (2.24)$$

Here, the first identity is the Trotter product formula, the second uses the particular representation, the third uses the fact that H_0 is the generator of the Ornstein–Uhlenbeck process (see Ref. 6, Theorem 4.7 of Chapter II) and the fourth uses the fact that this process has continuous sample paths (Ref. 6 Theorem 5.2 of Chapter II) and that f is continuous and bounded.

To prove (2.21) it remains to insert the orthonormal basis $\{\psi_m\}_{m=0}^{\infty}$. Q.E.D.

We next prove that the rescaled measures $\mathbb{K}_\beta^{(n)}[d\xi/\sqrt{n}]$ converge to $\mathbb{K}_\beta$. For this we compute the respective Fourier transforms as before. This is done in the next section.

III. THE FOURIER TRANSFORMS

The Fourier transform of $\mathbb{K}_\beta$ has already been computed by Feynman [Ref. 16, Sec. 3.2, formula (3.43)]. We shall prove his formula here in a different way:

Theorem 3.1: The characteristic function of the measure $\mathbb{K}_\beta$ defined by (2.22) is given by

$$\mathbb{K}_\beta\left[\exp\left(i\int_0^1 u(t)q(\beta t)dt\right)\right]=\exp\left\{-\frac{1}{1-e^{-\beta}}\int_0^1 dt_1\int_0^1 dt_2\,\frac{1}{2}\,(e^{-\beta|t_1-t_2|}+e^{-\beta(1-|t_1-t_2|)})u(t_1)u(t_2)\right\}, \quad (3.1)$$

for any (real-valued) function $u\in L^2[0,1]$.

Proof: We first show that it suffices to prove this theorem for $u\in C[0,1]$. Indeed, both the right-hand side and the left-hand side are continuous in $L^2[0,1]$. In the case of the right-hand side this is obvious. For the left-hand side this follows from the fact that $D[0,1]\subset L^2[0,1]$ and the bounded convergence theorem. We can now write

$$\mathbb{K}_\beta\left[\exp\left(i\int_0^1 u(t)q(\beta t)dt\right)\right]=\frac{1}{Z(\beta)}\sum_{m=0}^{\infty}\frac{1}{m!}\,\mathbb{E}_0\left[H_m(q(0))\exp\left[i\int_0^1 u(t)q(\beta t)dt\right]H_m(q(\beta))\right]. \tag{3.2}$$

To compute this we use the generating function for the Hermite polynomials: formula (1.7). Using the fact that $(q(0),q(\beta t_1),\ldots,q(\beta t_{M-1}),q(\beta))$ is Gaussian with mean zero and covariance matrix $C_{i,j}=\exp[-\beta|t_i-t_j|]$ we have, for continuous functions u,

$$\begin{aligned}
&\mathbb{E}_0\left[e^{\alpha_1 q(0)}\exp\left[i\int_0^1 u(t)q(\beta t)dt\right]e^{\alpha_2 q(\beta)}\right]\\
&\quad=\lim_{M\to\infty}\mathbb{E}_0\left[e^{\alpha_1 q(0)}\prod_{i=1}^{M}e^{iu(t_i)q(\beta t_i)/M}e^{\alpha_2 q(\beta)}\right]\\
&\quad=\lim_{M\to\infty}\exp\left\{i\alpha_1\frac{1}{M}\sum_{i=1}^{M}e^{-\beta t_i}u(t_i)-\frac{1}{2M^2}\sum_{i,j=1}^{M}e^{-\beta|t_i-t_j|}u(t_i)u(t_j)\right.\\
&\qquad\left.+i\alpha_2\frac{1}{M}\sum_{i=1}^{M}e^{-\beta(1-t_i)}u(t_i)+\alpha_1\alpha_2e^{-\beta}+\frac{1}{2}(\alpha_1^2+\alpha_2^2)\right\}\\
&\quad=\exp\left\{i\alpha_1\int_0^1 e^{-\beta t}u(t)dt-\frac{1}{2}\int_0^1 dt\int_0^1 dt'e^{-\beta|t-t'|}u(t)u(t')\right.\\
&\qquad\left.+i\alpha_2\int_0^1 e^{-\beta(1-t)}u(t)dt+\alpha_1\alpha_2e^{-\beta}+\frac{1}{2}(\alpha_1^2+\alpha_2^2)\right\}.
\end{aligned}\tag{3.3}$$

Inserting (1.7) we get

$$\begin{aligned}
&\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\frac{1}{n!m!}\,\alpha_1^m\alpha_2^n\mathbb{E}_0\left[H_m(q(0))\exp\left[i\int_0^1 u(t)q(\beta t)dt\right]H_n(q(\beta))\right]\\
&\quad=\exp\left\{i\alpha_1\int_0^1 e^{-\beta t}u(t)dt-\frac{1}{2}\int_0^1 dt\int_0^1 dt'e^{-\beta|t-t'|}u(t)u(t')\right.\\
&\qquad\left.+i\alpha_2\int_0^1 e^{-\beta(1-t)}u(t)dt+\alpha_1\alpha_2e^{-\beta}\right\}.
\end{aligned}\tag{3.4}$$

Finally, we have to extract the terms $m=n$. First notice that

$$\frac{1}{1-e^{-\beta}}\exp\left\{\frac{z}{1-e^{-\beta}}\right\}=\sum_{k=0}^{\infty}\sum_{n=0}^{\infty}\binom{n+k}{k}\frac{z^n}{n!}\,e^{-\beta k}. \tag{3.5}$$

With the shorthand $u_1=\int_0^1 e^{-\beta t}u(t)dt$ and $u_2=\int_0^1 e^{-\beta(1-t)}u(t)dt$ we have

$$\begin{aligned}
\exp[i\alpha_1u_1+i\alpha_2u_2+\alpha_1\alpha_2e^{-\beta}]&=\left(\sum_{n_1=0}^{\infty}\frac{(iu_1)^{n_1}}{n_1!}\,\alpha_1^{n_1}\right)\left(\sum_{n_2=0}^{\infty}\frac{(iu_2)^{n_2}}{n_2!}\,\alpha_2^{n_2}\right)\\
&\quad\times\left(\sum_{k=0}^{\infty}\frac{(\alpha_1\alpha_2)^k}{k!}\,e^{-\beta k}\right).
\end{aligned}\tag{3.6}$$

With $A = 1/2\int_0^1 dt_1 \int_0^1 dt_2 e^{-\beta|t_1-t_2|} u(t_1)u(t_2)$ this yields

$$\sum_{m=0}^{\infty} \frac{1}{m!}\, \mathbb{E}_0\left[H_m(q(0)) \exp\left[i\int_0^1 u(t)q(\beta t)dt \right] H_m(q(\beta)) \right]$$
$$= e^{-A} \sum_{n=0}^{\infty} \sum_{k=0}^{\infty} \frac{(n+k)!}{(n!)^2 k!} (-u_1u_2)^n e^{-\beta k} = \frac{1}{1-e^{-\beta}}\, e^{-A} \exp\left[-\frac{u_1u_2}{1-e^{-\beta}} \right], \qquad (3.7)$$

which is (3.1). Q.E.D.

Next, we would like to find a formula for the characteristic function of the measure $\mathbb{K}_\beta^{(n)}$. To get an idea about the difficulty, consider the case that $u(t)=u$ is a constant. In that case we can work backward and write

$$\mathbb{K}_\beta^{(n)}\left[\exp\left[iu\int_0^1 \xi(t)dt \right] \right] = \frac{\mathrm{Trace}_n\, e^{-\beta c^*c + iu\Delta}}{\mathrm{Trace}_n\, e^{-\beta c^*c}}. \qquad (3.8)$$

The operator $-\beta c^*c + iu\Delta$ is quadratic in the creation and annihilation operators and can be diagonalised by means of a Bogoliubov transformation. The result is

$$\mathbb{K}_\beta^{(n)}\left[\exp\left[iu\int_0^1 \xi(t)dt \right] \right] = \frac{\sinh(\sqrt{(\beta/2)^2-u^2}(n+1))}{\sinh(\beta(n+1)/2)} \frac{\sinh(\beta/2)}{\sinh\sqrt{(\beta/2)^2-u^2}}. \qquad (3.9)$$

In a sense, the general case can be reduced to this case. The result is not such a nice explicit expression, but rather an expression involving series expansions:

Theorem 3.2: The characteristic function of the measures $\mathbb{K}_\beta^{(n)}$ defined by (2.18) is given by

$$\mathbb{K}_\beta^{(n)}\left[\exp\left[i\int_0^1 u(t)\xi(t)dt \right] \right] = \frac{1}{Z_n(\beta)} \frac{\lambda_+^{n+1} - \lambda_-^{n+1}}{\lambda_+ - \lambda_-}, \qquad (3.10)$$

where the $\lambda_\pm$ are the eigenvalues of a 2×2-matrix $A[u]=(A_{mm'}[u])_{m,m'=0,1}$:

$$\lambda_\pm = \frac{1}{2}\left[A_{00} + A_{11} \pm \sqrt{(A_{00}-A_{11})^2 + 4A_{01}A_{10}} \right] \qquad (3.11)$$

and where the matrix elements are given by

$$A_{00} = 1 + \sum_{k=1}^{\infty} (-1)^k \int_0^1 dt_1 \int_{t_1}^1 dt_2 \cdots \int_{t_{2k-1}}^1 dt_{2k} u(t_1)\ldots u(t_{2k}) e^{-\beta(t_{2k}-t_{2k-1}+\cdots+t_2-t_1)}, \qquad (3.12)$$

$$A_{11} = e^{-\beta} + \sum_{k=1}^{\infty} (-1)^k \int_0^1 dt_1 \int_{t_1}^1 dt_2 \cdots \int_{t_{2k-1}}^1 dt_{2k} u(t_1)\ldots u(t_{2k}) e^{-\beta(1-t_{2k}+t_{2k-1}-\cdots-t_2+t_1)}, \qquad (3.13)$$

$$A_{01} = i\sum_{k=0}^{\infty} (-1)^k \int_0^1 dt_1 \int_{t_1}^1 dt_2 \cdots \int_{t_{2k}}^1 dt_{2k+1} u(t_1)\ldots u(t_{2k+1}) e^{-\beta(1-t_{2k+1}+t_{2k}-\cdots+t_2-t_1)}, \qquad (3.14)$$

and

$$A_{10}=i\sum_{k=0}^{\infty}(-1)^k\int_0^1 dt_1\int_{t_1}^1 dt_2\cdots\int_{t_{2k}}^1 dt_{2k+1}u(t_1)\ldots u(t_{2k+1})e^{-\beta(t_{2k+1}-t_{2k}+\cdots+t_3-t_2+t_1)}. \tag{3.15}$$

Proof: With $F(\xi(\cdot))=\exp[i\int_0^1 u(t)\xi(t)dt]$ the expectation in formula (2.18) splits into single-particle expectations

$$\mathbb{E}_{\beta,x}\left[\exp\left(i\int_0^1 u(t)\xi(t)dt\right)1_{\{\xi:\xi(1)=x'\}}\right].$$

This is in fact more easily computed in the c-representation. We first write, assuming that u is continuous,

$$\begin{aligned}&\mathbb{E}_{\beta,x}\left[\exp\left(i\int_0^1 u(t)\xi(t)dt\right)1_{\{\xi:\xi(1)=x'\}}\right]\\&\quad=\lim_{M\to\infty}\sum_{x^{(1)},\ldots,x^{(M-1)}}\prod_{i=1}^{M}\langle x^{(i)}|\exp\left[-\frac{\beta}{2M}(1-\sigma^{(x)})\right]\exp\left[\frac{i}{M}u\left(\frac{i}{M}\right)\sigma^{(z)}\right]|x^{(i-1)}\rangle.\end{aligned} \tag{3.16}$$

Next we change basis in this expression from $|x\rangle$ to $|1;m\rangle$ $(m=0,1)$:

$$|x\rangle=\frac{1}{\sqrt{2}}(|1;0\rangle+x|1;1\rangle)=\frac{1}{\sqrt{2}}\sum_{m=0,1}((1-x)m+x)|1;m\rangle. \tag{3.17}$$

We therefore put

$$\begin{aligned}&\mathbb{E}_{\beta,x}\left[\exp\left(i\int_0^1 u(t)\xi(t)dt\right)1_{\{\xi:\xi(1)=x'\}}\right]\\&\quad=\langle x'|A|x\rangle=\frac{1}{2}\sum_{m,m'=0,1}((1-x)m+x)((1-x')m'+x')\langle 1;m'|A|1;m\rangle\end{aligned} \tag{3.18}$$

and compute

$$\begin{aligned}\langle 1;m'|A|1;m\rangle=\lim_{M\to\infty}\sum_{m^{(1)},\ldots,m^{(M-1)}=0,1}\prod_{i=1}^{M}&\langle 1;m^{(i)}|\exp\left[-\frac{\beta}{2M}(1-\sigma^{(x)})\right]\\&\times\exp\left[\frac{i}{M}u\left(\frac{i}{M}\right)\sigma^{(z)}\right]|1;m^{(i-1)}\rangle.\end{aligned} \tag{3.19}$$

(As usual, $m^{(0)}=m$ and $m^{(M)}=m'$.) Now,

$$\exp\left[\frac{i}{M}u_i\sigma^{(z)}\right]|1;m\rangle\approx\left(1+\frac{i}{M}u_i\sigma^{(z)}\right)|1;m\rangle=|1;m\rangle+\frac{i}{M}u_i|1;1-m\rangle. \tag{3.20}$$

First suppose $m=m'=0$. Then we must have an even number of jumps, i.e. i-values where we choose the second term in the right-hand side of (3.35). Thus,

$$A_{00}=\langle 1;0|A|1;0\rangle$$
$$=\lim_{M\to\infty}\left\{1-\frac{1}{M^2}\sum_{1\leqslant i_1<i_2\leqslant M}e^{-\beta(i_2-i_1)/M}u\left(\frac{i_1}{M}\right)u\left(\frac{i_2}{M}\right)\right.$$
$$\left.+\frac{1}{M^4}\sum_{1\leqslant i_1<i_2<i_3<i_4\leqslant M}e^{-\beta(i_4-i_3+i_2-i_1)/M}u\left(\frac{i_1}{M}\right)u\left(\frac{i_2}{M}\right)u\left(\frac{i_3}{M}\right)u\left(\frac{i_4}{M}\right)+\cdots\right\}. \quad (3.21)$$

This is just (3.12). Notice that the series converges for $u\in L^2[0,1]$ since $|A_{00}|\leqslant\Sigma_{k=0}^{\infty}[\|u\|_2^{2k}/(2k)!]=\cosh\|u\|_2$. The other expressions are derived in a similar manner.

It is easy to see, either by direct transformation or by redoing the derivation of (1.16) in the new basis, that

$$\mathbb{K}_\beta^{(n)}\left[\exp\left[i\int_0^1 u(t)\xi(t)dt\right]\right]=\frac{1}{Z_n(\beta)}\sum_{k=0}^{n}\binom{n}{k}^{-1}\sum_{\substack{m_1,\ldots,m_n=0,1\\ \Sigma m_i=k}}\sum_{\substack{m_1',\ldots,m_n'=0,1\\ \Sigma m_i'=k}}\prod_{i=1}^{n}A_{m_i,m_i'}. \quad (3.22)$$

We can transform A to Jordan normal form (see Ref. 17. Theorem 6.4.7 or Ref. 18, Sec. 7.3)

$$A=SJS^{-1},\ \text{where}\ J=\begin{pmatrix}\lambda_+ & 0\\ 1 & \lambda_-\end{pmatrix} \quad (3.23)$$

and then transform (3.22) again to obtain

$$\mathbb{K}_\beta^{(n)}\left[\exp\left[i\int_0^1 u(t)\xi(t)dt\right]\right]=\frac{1}{Z_n(\beta)}\sum_{k=0}^{n}\binom{n}{k}^{-1}\sum_{\substack{m_1,\ldots,m_n=0,1\\ \Sigma m_i=k}}\sum_{\substack{m_1',\ldots,m_n'=0,1\\ \Sigma m_i'=k}}\prod_{i=1}^{n}J_{m_i,m_i'}$$
$$=\frac{1}{Z_n(\beta)}\sum_{k=0}^{n}\lambda_+^k\lambda_-^{n-k}, \quad (3.24)$$

which is just (3.10) since $\lambda_\pm$ are the eigenvalues of the matrix A given by (3.11). Q.E.D.

Remark: This theorem gives rise to some interesting integral identities. For example, notice that by (3.18),

$$\text{Trace}\ A[u]=\sum_{x=\pm 1}\mathbb{E}_{\beta,x}\left[\exp\left(iu\int_0^1\xi(t)dt\right)1_{\{\xi;\xi(1)=x\}}\right] \quad (3.25)$$

and by (2.15),

$$\text{Trace}\ A[u]=\text{Trace}\ e^{-(\beta/2)(1-\sigma^{(x)})+iu\sigma^{(z)}}=2e^{-\beta/2}\cosh\sqrt{\left(\frac{\beta}{2}\right)^2-u^2}. \quad (3.26)$$

Inserting the expressions for A_{00} and A_{11} we obtain

$$\cosh\sqrt{\left(\frac{\beta}{2}\right)^2-u^2}=\sum_{k=0}^{\infty}(-1)^k\int_0^1 dt_1\int_{t_1}^1 dt_2\cdots\int_{t_{2k-1}}^1 dt_k$$
$$\times\cosh[\beta(\tfrac{1}{2}+t_1-t_2+\cdots+t_{2k-1}-t_{2k})]. \quad (3.27)$$

Replacing $\beta/2$ by β and taking the k-th term in the Taylor expansion in u^2 we get

$$\int_0^1 dt_1 \int_{t_1}^1 dt_2 \cdots \int_{t_{2k-1}}^1 dt_{2k} \cosh[\beta(1+2(t_1-t_2+\cdots+t_{2k-1}-t_{2k}))] = \frac{1}{k!}\left(\frac{d}{d\beta^2}\right)^k \cosh\beta. \tag{3.28}$$

[This can also be derived by means of the Dyson expansion of the second trace in (3.26).]

IV. PROOF OF THE MAIN THEOREM

To complete the proof of Theorem 1.2 we shall show that it suffices to show that the Fourier transforms of the measures $\mathbb{K}_\beta^{(n)}$ converge to those of $\mathbb{K}_\beta$ after replacing u and by $u/\sqrt{n}$. The convergence of the Fourier transforms is easy to see since, for large n,the revised matrix $\widetilde{A}[u] = A[u/\sqrt{n}]$ behaves as follows:

$$\widetilde{A}_{00} \sim 1 - \frac{1}{n}\int_0^1 dt_1 \int_{t_1}^1 dt_2 e^{-\beta(t_2-t_1)} u(t_1)u(t_2) + \mathcal{O}(n^{-2}), \tag{4.1}$$

$$\widetilde{A}_{11} \sim e^{-\beta} - \frac{1}{n}\int_0^1 dt_1 \int_{t_1}^1 dt_2 e^{-\beta+\beta(t_2-t_1)} u(t_1)u(t_2) + \mathcal{O}(n^{-2}), \tag{4.2}$$

$$\widetilde{A}_{01} \sim \frac{i}{\sqrt{n}}\int_0^1 dt e^{-\beta+\beta t} u(t) + \mathcal{O}(n^{-3/2}), \tag{4.3}$$

and

$$\widetilde{A}_{10} \sim \frac{i}{\sqrt{n}}\int_0^1 dt e^{-\beta t} u(t) + \mathcal{O}(n^{-3/2}). \tag{4.4}$$

This leads to

$$\widetilde{\lambda}_+ \sim 1 - \frac{1}{n}\frac{1}{1-e^{-\beta}}\int_0^1 dt_1 \int_{t_1}^1 dt_2 u(t_1)u(t_2)[e^{-\beta(t_2-t_1)} + e^{-\beta+\beta(t_2-t_1)}] \tag{4.5}$$

and

$$\widetilde{\lambda}_- \sim e^{-\beta}\left\{1 + \frac{1}{n}\frac{1}{1-e^{-\beta}}\int_0^1 dt_1 \int_{t_1}^1 dt_2 u(t_1)u(t_2)[e^{-\beta(t_2-t_1)} + e^{-\beta+\beta(t_2-t_1)}]\right\}. \tag{4.6}$$

If we put

$$R = \int_0^1 dt_1 \int_{t_1}^1 dt_2 u(t_1)u(t_2)[e^{-\beta(t_2-t_1)} + e^{-\beta+\beta(t_2-t_1)}], \tag{4.7}$$

then we have

$$\widetilde{\lambda}_+^{n+1} \sim \left(1 - \frac{1}{n}\frac{1}{1-e^{-\beta}}R\right)^{n+1} \to \exp\left[\frac{1}{1-e^{-\beta}}R\right],$$

$$\widetilde{\lambda}_- \sim e^{-\beta(n+1)} \to 0, \tag{4.8}$$

and $\tilde{\lambda}_+ - \tilde{\lambda}_- \to 1 - \mathrm{e}^{-\beta}$ and therefore

$$\frac{\tilde{\lambda}_+^{n+1} - \tilde{\lambda}_-^{n+1}}{\tilde{\lambda}_+ - \tilde{\lambda}_-} \to \frac{1}{1-e^{-\beta}} \exp\left[-\frac{1}{1-e^{-\beta}} R \right]. \tag{4.9}$$

As, moreover, $Z_n(\beta) \to (1-e^{-\beta})^{-1}$, this proves the convergence of the Fourier transforms.

To prove that the weak convergence of the measures follows from the convergence of the corresponding Fourier transforms we need some detailed estimates. A sufficient condition was formulated by Smolyanov and Fomin.[19] According to this condition it suffices that the Fourier transforms are equicontinuous with respect to the so-called Sazonov topology. In the present Hilbert space context this means that for all $\epsilon > 0$ there should exist a sequence $\{\lambda_k\}_{k=0}^{\infty} \in l^2$ such that

$$\sum_{k=0}^{\infty} \lambda_k^2 u_k^2 < 1 \Rightarrow \left| 1 - \mathbb{K}_\beta^{(n)} \left[\exp\left[i \int_0^1 u(t) \xi(t) dt \right] \right] \right| < \epsilon, \tag{4.10}$$

where $\{u_k\}_{k=0}^{\infty}$ are the components of u with respect to some orthonormal basis of $L^2[0,1]$. Unfortunately, this condition seems hard to check in the present case. We therefore use a more direct approach, starting from one of their main lemmas (Ref. 19, Lemma 2 of Sec. 4). We repeat the proof here for completeness:

Lemma 4.1: Suppose that μ is a Radon probability measure on $\mathbb{R}^M$ and assume that, given $\epsilon > 0$, there exists $\lambda \in \mathbb{R}^M$ such that

$$\sum_{i=1}^{M} \lambda_i^2 u_i^2 \leqslant 1 \Rightarrow |1 - \mathrm{Re}\ \tilde{\mu}[u]| \leqslant \epsilon \tag{4.11}$$

where $\tilde{\mu}$ denotes the characteristic function of μ. Then, for all $\eta > 0$ and with $c = (1-e^{-1/2})^{-1}$,

$$\mu\{\xi : \|\xi\|_2 \geqslant \eta\} \leqslant c \left(\epsilon + \frac{2}{\eta^2} \|\lambda\|_2^2 \right). \tag{4.12}$$

Proof: Notice first that if $\|\xi\| \geqslant \eta$ then $c(1 - \exp[-1/2\|\xi\|^2/\eta^2]) \geqslant 1$. It follows that if ν_η is the Gaussian measure on $\mathbb{R}^M$ with covariance $\eta^{-2}1$,

$$\begin{aligned} \mu\{\xi : \|\xi\| \geqslant \eta\} &\leqslant c \int_{\mathbb{R}^M} \left(1 - \exp\left[-\frac{1}{2} \|\xi\|^2 / \eta^2 \right] \right) \mu(d\xi) \\ &= c \int_{\mathbb{R}^M} \nu_\eta(du) \int_{\mathbb{R}^M} [1 - e^{i(\xi,u)}] \mu(d\xi) \\ &= c \int_{\mathbb{R}^M} \nu_\eta(du) [1 - \mathrm{Re}\ \tilde{\mu}[u]]. \end{aligned} \tag{4.13}$$

The latter integral can be split into one over the region where $\Sigma_{i=1}^M \lambda_i^2 u_i^2 \leqslant 1$ and one over the complementary region. The first is bounded by ϵ by the assumption (4.11). In the second we simply bound $1 - \mathrm{Re}\ \tilde{\mu}[u]$ by 2. The integral over the region where $\Sigma_{i=1}^M \lambda_i^2 u_i^2 > 1$ is thus bounded by

$$2 \nu_\eta \left\{ u \in \mathbb{R}^M : \sum_{i=1}^{M} \lambda_i^2 u_i^2 > 1 \right\} \leqslant 2 \sum_{i=1}^{M} \lambda_i^2 \int u_i^2 \nu_\eta(du) = 2 \eta^{-2} \sum_{i=1}^{M} \lambda_i^2. \tag{4.14}$$

This proves the lemma. Q.E.D.

We now use this lemma directly to prove Prokhorov's condition for the weak convergence of measures. This condition holds quite generally but is particularly easy to prove on Hilbert spaces:

Lemma 4.2: In order that the measures $\mathbb{K}_\beta^{(n)}$ converge weakly to $\mathbb{K}_\beta$ it suffices that for all $\epsilon>0$, there exists a compact set $K\subset L^2[0,1]$ such that $\mathbb{K}_\beta^{(n)}[K]>1-\epsilon$ uniformly in n.

Proof: Suppose that this condition is fulfilled. Then, given $F\in\mathscr{C}^b(L^2[0,1])$ and $\epsilon>0$, let K be compact such that $\mathbb{K}_\beta^{(n)}[K^c]\leqslant\epsilon/12\|F\|_\infty$ and the same for $\mathbb{K}_\beta$. Now, F is uniformly continuous on K so there exists $\delta>0$ such that if $\|\xi-\xi'\|_2<\delta$ then $|F(\xi)-F(\xi')|<\epsilon/6$. Moreover, a set $K\subset L^2[0,1]$ is compact if and only if it is bounded and closed and, in a given orthonormal basis $\{h_p\}_{p=0}^\infty$, for any given $\delta>0$ there exists an integer M such that $\Sigma_{r=M}^\infty|(\xi,h_p)|^2<\delta^2$ for all $\xi\in K$. Now let π_M be the projection $\pi_M:L^2[0,1]\to\mathbb{R}^M$ given by $\pi_M(\xi)=((\xi,h_0),\ldots,(\xi,h_{M-1}))$ and let $\pi_M(\mathbb{K}_\beta^{(n)})$ be the image measure. Then $\pi_M(\mathbb{K}_\beta^{(n)})\to\pi_M(\mathbb{K}_\beta)$ because the corresponding characteristic functions converge. It follows that there is n_0 such that for $n\geqslant n_0$,

$$\left|\int F\circ\pi_M d\mathbb{K}_\beta^{(n)}-\int F\circ\pi_M d\mathbb{K}_\beta\right|<\epsilon/3.$$

Also, $\|\pi_M(\xi)-\xi\|_2<\delta$ and hence $|F(\pi_M(\xi))-F(\xi)|<\epsilon/6$ for all $\xi\in K$. Thus, for $n\geqslant n_0$,

$$\begin{aligned}\left|\int Fd\mathbb{K}_\beta^{(n)}-\int Fd\mathbb{K}_\beta\right|&\leqslant\left|\int_K Fd\mathbb{K}_\beta^{(n)}-\int_K Fd\mathbb{K}_\beta\right|+\left|\int_{K^c}Fd\mathbb{K}_\beta^{(n)}\right|+\left|\int_{K^c}Fd\mathbb{K}_\beta\right|\\&\leqslant\left|\int_K F\circ\pi_M d\mathbb{K}_\beta^{(n)}-\int_K F\circ\pi_M d\mathbb{K}_\beta\right|+\frac{\epsilon}{3}+2\|F\|_\infty\frac{\epsilon}{12\|F\|_\infty}\leqslant\left|\int F\circ\pi_M d\mathbb{K}_\beta^{(n)}-\int F\circ\pi_M d\mathbb{K}_\beta\right|\\&\quad+2\|F\|_\infty\frac{\epsilon}{12\|F\|_\infty}+\frac{\epsilon}{3}+\frac{\epsilon}{6}<\epsilon.\end{aligned}\tag{4.15}$$

This proves the lemma. Q.E.D.

Theorem 4.1: The measures $\mathbb{K}_\beta^{(n)}$ converge weakly to $\mathbb{K}_\beta$ as measures on $L^2[0,1]$.

Proof: According to the previous lemma it suffices to prove that, for any $\epsilon>0$, there exists a compact set $K\subset L^2[0,1]$ such that $\mathbb{K}_\beta^{(n)}[K]>1-\epsilon$ uniformly in n. We shall define this set in terms of the Haar basis $h_p\in L^2[0,1]$ $(p=0,1,2,\ldots)$ defined by: $h_0(t)=1$ and

$$h_p(t)=\begin{cases}2^{m/2}, & \text{if } p2^{-m}-1\leqslant t<\left(p+\frac{1}{2}\right)2^{-m}-1;\\ -2^{m/2}, & \text{if } \left(p+\frac{1}{2}\right)2^{-m}-1\leqslant t\leqslant(p+1)2^{-m}-1;\\ 0, & \text{otherwise.}\end{cases}\tag{4.16}$$

We now define the set K as follows:

$$K_\delta=\left\{\xi\in L^2[0,1]\,\middle|\,\sum_{p=2^m}^{2^{m+1}-1}|(\xi,h_p)|^2\leqslant\eta_m\,\forall m\geqslant 0\quad\text{and}\quad|(\xi,h_0)|\leqslant C\right\},\tag{4.17}$$

where $\eta_m=\delta^{-3/2}2^{-m/8}$ and C is a constant depending on ϵ and where $\delta(\epsilon)$ will be determined later. It is easy to see that this set is compact in $L^2[0,1]$. To prove that the complement of this set has small measure we shall use Lemma 4.1 above for each value of m individually. We therefore need to estimate the characteristic functions of the image measures $\mu_m^{(n)}=\pi^{(m)}(\mathbb{K}_\beta^{(n)})$, where $\pi^{(m)}$ is the projection of $L^2[0,1]$ onto the span of $\{h_p;p=2^m,\ldots,2^{m+1}-1\}$. We first estimate $\widetilde{A}_{00}[u]$ with $u\in\pi^{(m)}$ $(L^2[0,1])$. Introducing new variables

$$s_i=2^{m+1}\left\{t_i-\left(p+\frac{1}{2}\right)2^{-m}-1\right\} \tag{4.18}$$

and defining $\beta_m=2^{-m-1}\beta$ we have

$$\widetilde{A}_{00}[u]=1+\sum_{k=1}^{\infty}\frac{(-1)^k}{n^k}2^{mk}2^{-2k(m+1)}\sum_{l=1}^{2k\wedge 2^m}\sum_{\substack{r_1,\dots,r_l\geqslant 1\\ \Sigma r_i=2k}}\sum_{2^m\leqslant p_1<\cdots<p_l<2^{m+1}}\prod_{i=1}^{l}\{u_{p_i}^{r_i}I_{m,r_i}^{\pm}\}, \tag{4.19}$$

where $u_p=(h_p,u)$ and

$$I_{m,r}^{\pm}=(-1)^r\int_{-1}^{1}ds_1\int_{s_1}^{1}ds_2\cdots\int_{s_{r-1}}^{1}ds_r\prod_{i=1}^{r}\operatorname{sgn}(s_i)\exp[\pm\beta_m(s_r-s_{r-1}+\cdots+(-1)^{r-1}s_1)] \tag{4.20}$$

and where the + or − sign is chosen according as to whether $\Sigma_{j=1}^{i}r_j$ is odd or even. We estimate $I_{m,r}^{\pm}$ simply as follows. First note that if $g_i, i=1,\dots,r$, are odd functions then

$$\int_{-1}^{1}ds_1\int_{s_1}^{1}ds_2\cdots\int_{s_{r-1}}^{1}ds_r\prod_{i=1}^{r}g_i(s_i)=0. \tag{4.21}$$

[This follows from the fact that if $g(s)$ is odd then $G(s)=\int_s^1 g(s')ds'$ is even.] With $g_i(s)=\operatorname{sgn}(s)$ we have that $I_{m,r}^{\pm}|_{\beta=0}=0$ and subtracting this from $I_{m,r}^{\pm}$ and using the estimates $|e^{\beta_m s}-1|<\beta_m|s|e^{\beta_m|s|}$ and $|s_r-s_{r-1}+\cdots+(-1)^{r-1}s_1|\leqslant 2$ we have

$$|I_{m,r}^{\pm}|\leqslant 2\beta_m e^{2\beta_m}\int_{-1}^{1}ds_1\int_{s_1}^{1}ds_2\cdots\int_{s_{r-1}}^{1}ds_r 1=\frac{2^{r+1}\beta_m e^{2\beta_m}}{r!}. \tag{4.22}$$

Inserting this into (4.16) we obtain

$$|\widetilde{A}_{00}[u]-1|\leqslant\sum_{k=1}^{\infty}\frac{1}{n^k}2^{-(m+2)k}\sum_{l=1}^{2k\wedge 2^m}\sum_{\substack{r_1,\dots,r_l\geqslant 1\\ \Sigma r_i=2k}}\prod_{i=1}^{l}\frac{2^{r_i+1}\beta_m e^{2\beta_m}}{r_i!}\sum_{2^m\leqslant p_1<\cdots<p_l<2^{m+1}}\prod_{i=1}^{l}|u_{p_i}|. \tag{4.23}$$

Next we use the fact that, for $r\geqslant 2$, $\Sigma_p|u_p|^r\leqslant(\Sigma_p|u_p|^2)^{r/2}=\|u\|_2^r$ and $2^{-m/2}\Sigma_p|u_p|\leqslant(\Sigma_p|u_p|^2)^{1/2}=\|u\|_2$ to bound this by

$$|\widetilde{A}_{00}[u]-1|\leqslant\sum_{k=1}^{\infty}\frac{1}{n^k}2^{-mk}e^{\beta}\beta^{2k}\sum_{l=1}^{2k\wedge 2^m}2^{-ml/2}\sum_{\substack{r_1,\dots,r_l\geqslant 1\\ \Sigma r_i=2k}}\left(\prod_{i=1}^{l}r_i!\right)^{-1}\frac{1}{l!}\|u\|^{2k}. \tag{4.24}$$

Extending the sum over l to infinity this yields

$$\begin{aligned}|\widetilde{A}_{00}[u]-1|&\leqslant e^{\beta}\sum_{k=1}^{\infty}\frac{2^{-mk}\beta^{2k}}{n^k}\sum_{l=1}^{\infty}\frac{2^{-ml/2}l^{2k}}{(2k)!l!}\|u\|_2^{2k}\leqslant e^{\beta}\sum_{l=1}^{\infty}\frac{1}{l!}\left\{\cosh\left(\frac{\beta}{\sqrt{n}}2^{-m/2}\|u\|_2 l\right)-1\right\}\\ &\leqslant\tfrac{1}{2}e^{\beta}\{\exp(e^{\beta n^{-1/2}2^{-m/2}\|u\|_2})+\exp(e^{-\beta n^{-1/2}2^{-m/2}\|u\|_2})-2e\}.\end{aligned} \tag{4.25}$$

In Lemma 4.1 we shall take λ to be the vector with components $\delta^{-1}2^{-m/4}$ with respect to the h_p with $2^m \leq p \leq 2^{m+1}-1$ and 0 with respect to the others. Thus $\|u\|_2 \leq \delta 2^{m/4}$ and hence

$$|\widetilde{A}_{00}[u]-1| \sim \mathcal{O}\left(\frac{1}{n}2^{-m}\|u\|_2^2\right) = \mathcal{O}(2^{-m/2})\,\delta^2 \tag{4.26}$$

uniformly in n. In the same way we find that

$$|\widetilde{A}_{11}[u]-e^{-\beta}| \sim \mathcal{O}\left(\frac{1}{n}2^{-m}\|u\|_2^2\right) = \mathcal{O}(2^{-m/2})\,\delta^2. \tag{4.27}$$

An analogous calculation also yields

$$\begin{aligned}|\widetilde{A}_{01}[u]| &\leq \frac{1}{2\sqrt{n}}\,e^{\beta}\{\exp(e^{\beta n^{-1/2}2^{-m/2}\|u\|_2}) - \exp(e^{-\beta n^{-1/2}2^{-m/2}\|u\|_2})\} \\ &\sim \mathcal{O}\left(\frac{1}{n}2^{-m/2}\|u\|_2\right) \leq \mathcal{O}(2^{-m/4})\,\delta\end{aligned} \tag{4.28}$$

and similarly

$$\widetilde{A}_{10}[u] \sim \mathcal{O}\left(\frac{1}{n}2^{-m/2}\|u\|_2\right) \leq \mathcal{O}(2^{-m/4})\,\delta. \tag{4.29}$$

Inserting in the expression for the eigenvalues $\widetilde{\lambda}_{\pm}$ it follows that

$$\widetilde{\lambda}_{+} \sim 1 + \mathcal{O}(\delta 2^{-m/2}) \tag{4.30}$$

and

$$\widetilde{\lambda}_{-} \sim e^{-\beta} + \mathcal{O}(\delta 2^{-m/2}) \tag{4.31}$$

and hence

$$\psi_m[u] = \pi^{(m)}(\mathbb{K}_\beta^{(n)})[\exp[i(\xi,u)]] \sim 1 + \mathcal{O}(\delta 2^{-m/2}), \tag{4.32}$$

uniformly in n.

Using Lemma 4.1 above with $\eta_m = \delta^{-3/2}2^{-m/8}$ and $\epsilon_m = \delta\mathcal{O}(2^{-m/2})$ we have

$$\mathbb{K}_\beta^{(n)}[\|\pi^{(m)}(\xi)\|_2 > \eta_m] \leq c(\delta_m + 2\eta_m^{-2}\lambda_m^2) \sim \delta\{\mathcal{O}(2^{-m/2}) + \mathcal{O}(2^{-m/4})\}. \tag{4.33}$$

Adding probabilities we now have that

$$\mathbb{K}_\beta^{(n)}[K_\delta] \leq \delta \sum_{m=0}^{\infty} \mathcal{O}(2^{-m/4}) < \epsilon \tag{4.34}$$

for δ small enough. Q.E.D.

To complete the proof of Theorem 1.2 it now suffices to remark that the weak convergence of measures means that the expectation of bounded continuous functions converges and $\int_0^1 f(\xi(t))dt$ is continuous as a function of $\xi \in L^2[0,1]$ because of Lemma 2.4. [Notice also that the denominator of (2.20) converges trivially to that of (2.21).]

ACKNOWLEDGMENTS

I would like to thank a great many people for helpful conversations about details of this work, notably, Professor John Lewis, Professor André Verbeure, Professor Oleg Smolyanov, Professor Valentin Zagrebnov, Professor Aubrey Truman, Dr. Joe Pulè, Dr. Richard London and Dr. Malcolm MacGregor. I also thank the referee for bringing to my attention the work of Hudson *et al.* on non-commutative central limit theorems.

(Received 29 August 1995; accepted for publication 28 March 1996)

The behavior of the q-Fourier transformation as $q\to 1$ is investigated. It is shown that the q-Fourier transformation converges to the classical Fourier transformation in the strong operator topology. © *1996 American Institute of Physics.* [S0022-2488(96)02608-4]

I. INTRODUCTION

The q-Fourier transformation is regarded as the q analog of the classical Fourier transformation. It arises as a special case in the context of q-hypergeometric functions and was defined in a paper by Koornwinder and Swarttouw.[1] As it can be inferred from its name, the q-Fourier transformation reduces to the usual Fourier transformation as $q\to 1$. The rigorous proof is of interest both from a mathematical as well as from a physical point of view. The physical importance of the limit transition is due to the fact that the q-Fourier transformation turns out to be the appropriate object when dealing with q-deformed quantum mechanics. In a paper of Hebecker *et al.*[2] the representations of a q-deformed Heisenberg algebra were investigated. The transition from momentum to position eigenstates and vice versa is carried out by means of the q-Fourier transformation. Thus, the analysis of the limit transition of the q-Fourier transformation is strongly related to the question of compatibility of the q-deformed theory with the classical quantum mechanics.

In the second section of this paper, the q-Fourier transformation is introduced in a slightly modified version with respect to Ref. 1. The q-Fourier transformation is defined on a particular space of functions, the space L^2_{q,π_0} of square-summable functions on the set $\{\pi_0 q^n | n\in\mathbb{Z}\}$. In the third section, a possibility of defining the q-Fourier transformation on $L^2(\mathbb{R}^+)$ is presented. This will enable a rigorous limit transition $q\to 1$, which is the subject of the fourth section.

II. DEFINITION OF THE q-FOURIER TRANSFORMATION

To start, some definitions and results of Koornwinder and Swarttouw[1] are stated. In their paper, the following q-deformed cosine and sine functions were defined:

$$\cos(z;q^2)=\sum_{k=0}^{\infty}\frac{(-1)^k q^{k(k+1)} z^{2k}}{(q;q)_{2k}},$$
$$\sin(z;q^2)=\sum_{k=0}^{\infty}\frac{(-1)^k q^{k(k+1)} z^{2k+1}}{(q;q)_{2k+1}}, \tag{2.1}$$

where $q\in\mathbb{R}^+$, $0<q<1$, is the parameter of deformation, and

$$(a;q)_k=\prod_{n=0}^{k-1}(1-aq^n),\quad (a;q)_0=1,\quad (a;q)_\infty=\prod_{n=0}^{\infty}(1-aq^n).$$

As $q\to 1$, the limits

$$\lim_{q\to 1}\cos((1-q)z;q^2)=\cos z,\quad \lim_{q\to 1}\sin((1-q)z;q^2)=\sin z, \tag{2.2}$$

hold pointwise, uniformly on compacta. In the sequel, the discussion is restricted to the cosine function, the results being analogous for the sine function. The q-deformed cosine function satisfies the orthogonality relation,

$$\sum_{n=-\infty}^{\infty} q^n \cos(q^n q^k;q^2)\cos(q^n q^l;q^2)=\frac{(q^2;q^2)_\infty^2}{(q;q^2)_\infty^2}\frac{1}{q^l}\,\delta_{kl}. \tag{2.3}$$

The goal is now to define a q-deformed Fourier transformation that formally tends to its classical analog as $q\to 1$. According to the limit transitions (2.2), the q-Fourier transformation has to be based on the function

$$\mathrm{Cos}(q^k;q^2):=\cos((1-q)q^k;q^2)=\sum_{k=0}^{\infty}\frac{(-1)^k q^{k(k+1)}(1-q)^{2k}z^{2k}}{(q;q)_{2k}}. \tag{2.4}$$

This function obeys an orthogonality relation similar to (2.3), but only if the range of the parameter q is seriously restricted.

Lemma 2.1: For $q\in\{q|(1-q)=q^j,\ j\in\mathbb{Z}\}$ the following identity holds:

$$\sum_{n=-\infty}^{\infty} q^n \,\mathrm{Cos}(q^n q^k;q^2)\mathrm{Cos}(q^n q^l;q^2)=\frac{(1-q)(q^2;q^2)_\infty^2}{(q;q^2)_\infty^2}\frac{1}{q^l}\,\delta_{kl}. \tag{2.5}$$

Proof: The relation is obtained from (2.3) by replacing $m+j$ for n. The restriction on the allowed values of q is due to the fact that the sum $\Sigma_{n=-\infty}^{\infty} q^n \cos(q^\alpha q^n;q^2)\cos(q^\alpha q^n;q^2)$ diverges for $\alpha\notin\mathbb{Z}$ (see Ref. 3). □

The q-deformed Fourier transformation will now be defined.

Definition 2.2: Let f be a function in the space L^2_{q,π_0}, with $\pi_0\in\mathbb{R}^+$ and

$$L^2_{q,\pi_0}:=\{f|\|f\|_{q,\pi_0}<\infty\},\quad \|f\|_{q,\pi_0}:=\sqrt{\sum_{n=-\infty}^{\infty} q^n|f(\pi_0 q^n)|^2}.$$

For q in $\{q|(1-q)=q^j,\ j\in\mathbb{Z}\}$, the q-Fourier transformation $\mathscr{F}_{q,\pi_0}$ is given through the transform pair

$$g(\pi_0^{-1}q^k)=(\mathscr{F}_{q,\pi_0}f)(\pi_0^{-1}q^k)=\mathscr{N}_q\sum_{n=-\infty}^{\infty}(1-q)\pi_0 q^n\,\mathrm{Cos}(q^n q^k;q^2)f(\pi_0 q^n),$$

$$f(\pi_0 q^n)=(\mathscr{F}_{q,\pi_0^{-1}}g)(\pi_0 q^n)=\mathscr{N}_q\sum_{k=-\infty}^{\infty}(1-q)\pi_0^{-1}q^k\,\mathrm{Cos}(q^n q^k;q^2)g(\pi_0^{-1}q^k),$$

where

$$\mathscr{N}_q=\frac{(q;q^2)_\infty}{\sqrt{(1-q)}(q^2;q^2)_\infty}.$$

$\mathscr{F}_{q,\pi_0}$ is an isomorphy between L^2_{q,π_0} and $L^2_{q,\pi_0^{-1}}$:

$$\sum_{k=-\infty}^{\infty} q^k|g(\pi_0^{-1}q^k)|^2=\pi_0^2\sum_{n=-\infty}^{\infty} q^n|f(\pi_0 q^n)|^2. \tag{2.6}$$

III. THE DIRECT FIBER INTEGRAL OF L^2_{q,π_0}

The problem in trying to carry out a rigorous limit transition is obvious. The metrics of L^2_{q,π_0} and $L^2(\mathbb{R}^+,dx)$ are essentially different. Furthermore, the metrics of all the spaces L^2_{q,π_0} are not equivalent for different values of q. The only way to consistently overcome this difficulty is provided by the direct fiber integral. The continuous direct sum of the spaces L^2_{q,π_0} for a fixed value of q will be seen to be the space $L^2(\mathbb{R}^+,dx)$. The q-Fourier transformation is then extended to $L^2(\mathbb{R}^+,dx)$ in a natural way.

Definition 3.1: The direct fiber integral[4,5] is defined through

$$\mathscr{H}_q := \int_{(q,1]}^{\oplus} L^2_{q,m}\, dm,$$

that is

$\mathscr{H}_q = \{f \mid f_m \in L^2_{q,m}$ f.a.e. m, f Lebesgue-meas. and $\|f\|_{\mathscr{H}_q} := (\int_q^1 \|f_m\|^2_{q,m}\, dm)^{1/2} < \infty\}$. f_m (or $\mathbf{f}$) is the restriction of f to the corresponding lattice points.

Lemma 3.2: $\mathscr{H}_q = L^2(\mathbb{R}^+,dx)$.

Proof: Let f be a function in $L^2(\mathbb{R}^+,dx)$. Then the identities

$$\|f\|^2_{L^2} = \int_0^\infty |f(x)|^2\, dx = \sum_{n=-\infty}^{+\infty} \int_{q^{n+1}}^{q^n} |f(x)|^2\, dx = \sum_{n=-\infty}^{+\infty} q^n \int_q^1 |f(mq^n)|^2\, dm$$

$$= \int_q^1 \sum_{n=-\infty}^{+\infty} q^n |f(mq^n)|^2\, dm = \int_q^1 \|\mathbf{f}\|^2_{q,m}\, dm = \|f\|^2_{\mathscr{H}_q},$$

hold and thus $f \in \mathscr{H}_q$ as well. From the second to the third line, a simple substitution is made and from the third to the fourth line Fubini's theorem applied [Σq^n is an integral with the discrete measure $\sigma(q^n) = q^n$, and for f to be Lebesgue measurable is equivalent to being measurable with respect to $(q,1]\times\{q^n \mid n \in \mathbb{Z}\}$]. If f is a function in $\mathscr{H}_q$, then all the identities can be reversed and therefore $f \in L^2(\mathbb{R}^+,dx)$. □

Definition 3.3: The q-Fourier transformation $\mathscr{F}_q$ is defined on $L^2(\mathbb{R}^+,dx)$ through the direct fiber integral of the transformations $\mathscr{F}_{q,\pi_0}$:

$$\mathscr{F}_q = \int_{(q,1]}^{\oplus} \mathscr{F}_{q,m}\, dm, \quad (\mathscr{F}_q f)_{m^{-1}} = \mathscr{F}_{q,m} f_m .$$

Lemma 3.4: $\mathscr{F}_q$ is unitary.

Proof: This is a consequence of (2.6),

$$\|\mathbf{g}\|_{q,\pi_0^{-1}} = \pi_0 \|\mathbf{f}\|_{q,\pi_0}.$$

Therefore

$$\|g_q\|^2_{\mathscr{H}_q} = \int_q^1 \|\mathbf{g_q}\|^2_{q,m}\, dm = \int_1^{q^{-1}} \frac{1}{s^2} \|\mathbf{g_q}\|^2_{q,s^{-1}}\, ds = \int_1^{q^{-1}} \|\mathbf{f}\|^2_{q,s}\, ds = \int_q^1 \frac{1}{q} \|\mathbf{f}\|^2_{q,q^{-1}t}\, dt$$

$$\overset{(*)}{=} \int_q^1 \|\mathbf{f}\|^2_{q,t}\, dt = \|f\|^2_{\mathscr{H}_q}.$$

Equation $(*)$ is due to

$$\frac{1}{q}\,\|\mathbf{f}\|^2_{q,q^{-1}t}=\sum_{k=-\infty}^{\infty} q^{k-1}|\mathbf{f}(tq^{k-1})|^2=\|\mathbf{f}\|^2_{q,t}.$$

□

IV. THE LIMIT TRANSITION $q\to 1$

Our goal is to prove the convergence of the q-Fourier transformation $\mathscr{F}_q$ to the classical Fourier transformation $\mathscr{F}$ in the strong operator topology,

$$\mathscr{F}_q \underset{s}{\to} \mathscr{F}, \tag{4.1}$$

that is for any function $f\in L^2$,

$$\|\mathscr{F}f-\mathscr{F}_q f\|\to 0, \quad \text{as } q\to 1. \tag{4.2}$$

In other words, it has to be shown that the q-deformed Fourier transform converges to the classical Fourier transform in the L^2 norm. We denote the classical Fourier transform by

$$g(\lambda):=(\mathscr{F}f)(\lambda)=\sqrt{\frac{2}{\pi}}\int \cos(\lambda x)f(x)dx,$$

and the q-deformed transform by

$$g_q(\lambda):=(\mathscr{F}_q f)(\lambda)=(\mathscr{F}_{q,m(\lambda)}\mathbf{f})(\lambda)=\mathscr{N}_q\sum_{n=-\infty}^{\infty}(1-q)m(\lambda)q^n\ \mathrm{Cos}(q^{k(\lambda)}q^n;q^2)\mathbf{f}(m(\lambda)q^n)$$

$$=g_q(m(\lambda)^{-1}q^{k(\lambda)}).$$

As enforced by the direct fiber integral, all functions are considered to be defined on $\mathbb{R}^+$, the corresponding lattice for each λ is determined through $\lambda=[1/m(\lambda)]q^{k(\lambda)}$, with $q<m(\lambda)\leqslant 1$ and $k(\lambda)\in\mathbb{Z}$. The proof is carried out in two steps. First, the uniform convergence on compacta is proven for functions in $C_c(\mathbb{R}^+)$, the set of continuous functions with compact support. This implies convergence on compacta in the L^2 norm. Second, the convergence on $\mathbb{R}^+$ for functions in $C_c(\mathbb{R}^+)$ is proven. This implies the convergence for any function in L^2, $C_c(\mathbb{R}^+)$ being dense in L^2.

A. Uniform convergence on compacta

Let f be in the sequel a function in $C_c(\mathbb{R}^+)$, the support being contained in the interval $[0,K]$. The convergence will be investigated on a compactum that is bounded by $M>1$. The series $(q_j)_{j\in\mathbb{N}}$ is fixed through the condition $(1-q)=q^j$. It is observed that

$$\lim_{j\to\infty} q_j=1.$$

It has to be proven that

$$|g(\lambda)-g_{q_j}(\lambda)|\to 0, \quad \text{for } j\to\infty, \tag{4.3}$$

uniformly for $\lambda<M$. The normalization factor $\mathscr{N}_q$ is known to converge to $\sqrt{2/\pi}$ as $q\to 1$ (see Ref. 1). Using the triangle inequality, the Jackson integral of $\cos(\lambda x)f(x)$ is inserted to obtain

$$|\mathcal{M}_{q_j}^{-1} g_{q_j}(\lambda) - \sqrt{\pi/2}\, g(\lambda)|$$

$$= \left| \int \cos(\lambda x) f(x)\, dx - \sum_{n=-\infty}^{\infty} (1--q_j) m(\lambda) q_j^n \operatorname{Cos}(q_j^n q_j^{k(\lambda)}; q_j^2) \mathbf{f}(m(\lambda) q_j^n) \right|$$

$$\leqslant \left| \int \cos(\lambda x) f(x)\, dx - m(\lambda) \int \cos(\lambda m(\lambda) x) \mathbf{f}(m(\lambda) x)\, d_{q_j} x \right|$$

$$+ \left| \sum_{n=-\infty}^{\infty} (1-q_j) m(\lambda) q_j^n \{\operatorname{Cos}(q_j^n q_j^{k(\lambda)}; q_j^2) - \cos(q_j^n q_j^{k(\lambda)})\} \mathbf{f}(m(\lambda) q_j^n) \right|. \quad (4.4)$$

Regarding the second term of the right side of (4.4), it is noted that the support of the cosine functions is bounded by $M \cdot K := K'$, since the support of f is in $[0,K]$. From (2.2) follows that for each positive number ϵ there is an integer N_ϵ, such that

$$\max_{z \leqslant K'} |\operatorname{Cos}(z; q_j^2) - \cos(z)| < \epsilon, \quad \text{for all } j > N_\epsilon,$$

and the whole term is bounded by

$$\epsilon m(\lambda) \int_{[0,K]} \mathbf{f}(m(\lambda) x)\, d_{q_j} x.$$

Because of $f \in C_c(\mathbb{R}^+)$, there is a constant C, such that $|f(x)| < C$ for all $x \in \mathbb{R}^+$, thus

$$\epsilon m(\lambda) \int_{[0,K]} \mathbf{f}(m(\lambda) x)\, d_{q_j} x \leqslant \epsilon C m(\lambda) \int_{[0,K]} d_{q_j} x = \epsilon C K.$$

ϵ was an arbitrary number and the term under consideration converges uniformly to zero as j becomes infinite.

The uniform convergence of the first term is proven, if for each $\epsilon > 0$ there is a $\delta > 0$ such that $|\int \cos(\lambda x) f(x)\, dx - m(\lambda) \int \cos(\lambda m(\lambda) x) \mathbf{f}(m(\lambda) x)\, d_q x| < \epsilon$ for $\lambda \leqslant M$ and $1 - \delta < q < 1$. The integral $\int \cos(\lambda x) f(x)\, dx$ is written as $\Sigma_{n=-\infty}^{\infty} q^n \int_{qm(\lambda)}^{m(\lambda)} \cos(\lambda s q^n) \mathbf{f}(s q^n)\, ds$. According to the mean value theorem of integration there are values $s'(n) \in (qm(\lambda), m(\lambda))$, such that

$$\int_{qm(\lambda)}^{m(\lambda)} \cos(\lambda s q^n) \mathbf{f}(s q^n)\, ds = m(\lambda)(1-q) \cos(\lambda s'(n) q^n) f(s'(n) q^n).$$

The continuous functions cos and f are uniformly continuous on the compactum $[0,K']$. Thus there is for each number $\epsilon > 0$ a number $\delta > 0$ such that $|\cos x - \cos y| < \epsilon$ and $|f(x) - f(y)| < \epsilon$ if $x, y \in [0,K']$ and $|x - y| < \delta K'$. Observe that $|\lambda s'(n) q^n - \lambda m(\lambda) q^n| < \delta K'$ and $|s'(n) q^n - m(\lambda) q^n| < \delta K'$ if $1 - \delta < q < 1$. Put $\epsilon > 0$ and find a $\delta > 0$ as described above. For $1 - \delta < q < 1$, the inequalities

$$\begin{aligned}
&\left| \int \cos(\lambda x) f(x) dx - m(\lambda) \int \cos(\lambda m(\lambda) x) \mathbf{f}(m(\lambda) x) d_q x \right| \\
&= \left| \sum_{n=-\infty}^{\infty} m(\lambda)(1-q) q^n (\cos(\lambda s'(n) q^n) f(s'(n) q^n) - \cos(\lambda m(\lambda) q^n) f(m(\lambda) q^n)) \right| \\
&\leqslant \sum_{n=-\infty}^{\infty} m(\lambda)(1-q) q^n \{ |(\cos(\lambda s'(n) q^n) - \cos(\lambda m(\lambda) q^n)) f(s'(n) q^n)| \\
&\quad + |\cos(\lambda m(\lambda) q^n)(f(s'(n) q^n) - f(m(\lambda) q^n))| \} \\
&\leqslant \sum_{n=-\infty}^{\infty} m(\lambda)(1-q) q^n \{ \epsilon |f(s'(n) q^n)| + \epsilon |\cos(\lambda m(\lambda) q^n)| \} \\
&\leqslant \epsilon K(C+1),
\end{aligned}$$

follow and the proof of uniform convergence is completed.

B. Convergence in the strong operator topology

Of course, L^2 convergence on compacta does not in general imply L^2 convergence on $\mathbb{R}^+$. In the present case, an additional condition is satisfied, namely that all the functions in the series have the same norm as the function they are converging to on compacta. This feature is due to the unitarity of both the classical and the q-deformed Fourier transformation:

$$\|g\|_{L^2} = \|f\|_{L^2} = \|g_{q_j}\|_{L^2}, \quad \forall j \in \mathbb{N}. \tag{4.5}$$

Proposition 4.1: Let $(g_n)_{n\in\mathbb{N}}$ be a series of functions in $L^2(\mathbb{R})$, such that for every compactum K $\|g - g_n\|_{L^2(K)} \to 0$ as $n\to\infty$. Let $\|g_n\|_{L^2(\mathbb{R})} = \|g\|_{L^2(\mathbb{R})}$, $\forall n \in \mathbb{N}$. Then

$$\|g - g_n\|_{L^2(\mathbb{R})} \to 0, \quad \text{as } n\to\infty. \tag{4.6}$$

Proof: Put $1>\epsilon>0$ and $\|g\|=1$. Then there is a compactum B_ϵ, such that

$$\|g\|_{L^2(B_\epsilon)} = \left(\int_{B_\epsilon} |g(p)|^2 \, dp \right)^{1/2} \geqslant 1 - \frac{\epsilon^2}{36}. \tag{4.7}$$

In addition, there is a number N_ϵ, so that

$$\|g - g_n\|_{L^2(B_\epsilon)} \leqslant \frac{\epsilon^2}{36}, \quad \forall n \geqslant N_\epsilon. \tag{4.8}$$

Because of (4.8), the norm of g_n over B_ϵ is bounded from below for each $n \geqslant N_\epsilon$:

$$\|g\|_{L^2(B_\epsilon)} \leqslant \|g - g_n\|_{L^2(B_\epsilon)} + \|g_n\|_{L^2(B_\epsilon)} \leqslant \|g_n\|_{L^2(B_\epsilon)} + \frac{\epsilon^2}{36},$$

$$\Rightarrow \|g_n\|_{L^2(B_\epsilon)} \geqslant \|g\|_{L^2(B_\epsilon)} - \frac{\epsilon^2}{36} \overset{(4.7)}{\geqslant} 1 - \frac{\epsilon^2}{18} \tag{4.9}$$

($\mathscr{C}B_\epsilon$ is the complement of B_ϵ in $\mathbb{R}^+$). Since $\|g_n\|^2_{L^2(B_\epsilon)} + \|g_n\|^2_{L^2(\mathscr{C}B_\epsilon)} = 1$, it follows that

$$\|g_n\|_{L^2(\complement B_\epsilon)} = \sqrt{1-\|g_n\|^2_{L^2(B_\epsilon)}} \leqslant \sqrt{1-\left(1-\frac{\epsilon^2}{18}\right)^2} \leqslant \frac{\epsilon}{3}. \tag{4.10}$$

From (4.7), the analogous relation for g is

$$\|g\|_{L^2(\complement B_\epsilon)} = \sqrt{1-\|g\|^2_{L^2(B_\epsilon)}} \leqslant \sqrt{1-\left(1-\frac{\epsilon^2}{36}\right)^2} \leqslant \frac{\epsilon}{3}, \tag{4.11}$$

and finally

$$\begin{aligned}\|g-g_n\|_{L^2(\mathbb{R}^+)} &\leqslant \|g-g_n\|_{L^2(B_\epsilon)} + \|g-g_n\|_{L^2(\complement B_\epsilon)} \\ &\leqslant \|g-g_n\|_{L^2(B_\epsilon)} + \|g\|_{L^2(\complement B_\epsilon)} + \|g_n\|_{L^2(\complement B_\epsilon)} \\ &\leqslant \underset{(4.8)}{\frac{\epsilon^2}{36}} + \underset{(4.11)}{\frac{\epsilon}{3}} + \underset{(4.10)}{\frac{\epsilon}{3}} \leqslant \epsilon \quad \text{for all } n \geqslant N_\epsilon. \end{aligned} \tag{4.12}$$

Since ϵ was arbitrary, the proof is completed. □

Applying the above proposition to the present case, where f is still restricted to be in $C_c(\mathbb{R}^+)$, results in

$$\|(\mathscr{F}-\mathscr{F}_{q_j})f\|_{L^2} = \|g-g_{q_j}\|_{L^2} \to 0, \quad \text{as } j\to\infty. \tag{4.13}$$

To show that the same holds for f in $L^2(\mathbb{R}^+)$, let $(f_n)_n \subset C_c(\mathbb{R}^+)$ be a series with $\|f-f_n\|_{L^2}\to 0$ as $n\to\infty$. Put $\epsilon>0$. There is an integer n, such that $\|(f-f_n)\|_{L^2} < \epsilon/3$. Due to (4.13), there is an integer N, such that $\|(\mathscr{F}-\mathscr{F}_{qN})f_n\|_{L^2} < \epsilon/3$. Therefore,

$$\begin{aligned}\|(\mathscr{F}-\mathscr{F}_{q_N})f\|_{L^2} &\leqslant \|(\mathscr{F}-\mathscr{F}_{q_N})(f-f_n)\|_{L^2} + \|(\mathscr{F}-\mathscr{F}_{q_N})f_n\|_{L^2} \\ &\leqslant \|\mathscr{F}-\mathscr{F}_{q_N}\|\|(f-f_n)\|_{L^2} + \|(\mathscr{F}-\mathscr{F}_{q_N})f_n\|_{L^2} \\ &\leqslant 2\|(f-f_n)\|_{L^2} + \|(\mathscr{F}-\mathscr{F}_{q_N})f_n\|_{L^2} \\ &< \epsilon. \end{aligned} \tag{4.14}$$

Thus, the proof of the strong convergence of the q-Fourier transformation to the classical Fourier transformation is complete. In the strong operator topology, the q-Fourier transformation emerges as a ''continuous'' deformation of the classical Fourier transformation. It is emphasized that the deformation is not continuous in the proper sense, since the allowed values of q were restricted to a discrete set.

On the inversion formula of the half-Hartley transform

Ricardo D. Gianotti,[a] Antonio E. Rodríguez, and Fernando Vericat[a),b]

The Hartley transform (HT) of a function $g(x)\in L_2[-\infty,\infty]$ is given by

$$g_{\mathrm{H}}(y)=\int_{-\infty}^{\infty} g(x)(\cos(xy)+\sin(xy))dx,\quad y\in[-\infty,\infty]. \tag{1}$$

The properties and applications of this transform can be found in Ref. 1. In particular, the inversion formula takes the form of the simple reciprocity relation,

$$g(x)=\int_{-\infty}^{\infty} g_{\mathrm{H}}(y)(\cos(xy)+\sin(xy))dy. \tag{2}$$

Actually, we are concerned about the inversion formula for the half-Hartley transform (h-HT), which is defined as

$$g_h(y)=\int_{0}^{\infty} g(x)(\cos(xy)+\sin(xy))dx,\quad y\in[0,\infty]. \tag{3}$$

The reciprocity relation, Eq. (2), is no longer satisfactory in this case, since its use requires us to know the function $g_h(y)$ in the whole interval $[-\infty,\infty]$.

Recently, Paveri-Fontana and Zweifel[2] have obtained an inversion formula for the h-HT by reducing the problem to invert the half-Hilbert transform. This last problem involves, in its turn, the solution of the homogeneous Riemann–Hilbert problem. With relation to the method of Paveri-Fontana and Zweifel, also see the work by Pagani.[3]

In this paper we solve the integral equation (3) by following a different way. Multiplying both terms of Eq. (3) by $1/\sqrt{2}$, it can be rewritten as

$$\frac{1}{\sqrt{2}}\,g_h(y)=\int_{0}^{\infty} g(x)\sin\left(xy+\frac{\pi}{4}\right)dx, \tag{4}$$

which, recalling the integral representation,[4]

$$\sin\left(xy+\frac{\pi}{4}\right)=\sqrt{\frac{y}{\pi}}\int_{x}^{\infty}\frac{\sin(uy)}{\sqrt{u-x}}\,du,\quad x,y>0, \tag{5}$$

yields

[b)]Electronic-mail: vericat@iflysi.edu.ar

0022-2488/96/37(9)/4690/3/$10.00

$$g_h(y)=\sqrt{\frac{2y}{\pi}}\int_0^\infty g(x)dx\int_x^\infty \frac{\sin(uy)}{\sqrt{u-x}}\,du \tag{6}$$

or

$$\sqrt{\frac{\pi}{2y}}g_h(y)=\int_0^\infty \sin(uy)du\int_0^u \frac{g(x)}{\sqrt{u-x}}\,dx. \tag{7}$$

By Fourier inverting this equation, we get an Abel integral equation:

$$\int_0^u \frac{g(x)}{\sqrt{u-x}}\,dx=\mathscr{F}_s\left[\frac{g_h(y)}{\sqrt{y}}\right], \tag{8}$$

where

$$\mathscr{F}_s[f(y)](u)\equiv\sqrt{\frac{2}{\pi}}\int_0^\infty f(y)\sin(uy)dy. \tag{9}$$

The solution of (8) yields (see, for example, Ref. 5):

$$g(x)=\frac{1}{\pi}\frac{d}{dx}\int_0^x \frac{\mathscr{F}_s[g_h(y)/\sqrt{y}]}{\sqrt{x-u}}\,du, \tag{10}$$

which is a formally simple expression for the inversion formula of the half-Hartley transform.

We apply formula (10) to invert a couple of functions. First we consider $g_h(y)=(2\pi/y)^{1/2}(y>0)$, which is the half-Hartley transform of $g(x)=x^{-1/2}$. In fact, we have[6] $\mathscr{F}_s[g_h(y)/\sqrt{y}]=\pi$ and hence $\int_0^x g(u)du=\int_0^x(x-u)^{-1/2}\,du=2x^{1/2}$. The second example is that given in Sec. V of Ref. 2. The function to half-Hartley invert is $g_h(y)=e^{-\alpha y}$, $\alpha>0$, $y>0$. The Fourier sine transform in the integral of Eq. (10) can be written as

$$\mathscr{F}_s\left[\frac{g_h(y)}{\sqrt{y}}\right]=-\frac{i}{\sqrt{2}}\left[\frac{1}{\sqrt{z}}-\frac{1}{\sqrt{\bar{z}}}\right], \tag{11}$$

where i is the imaginary unity, $z=\alpha-iy$, and $\bar{z}$ denotes the complex conjugate of z. Thus, the integral yields the difference between two hypergeometric functions:[7]

$$\begin{aligned}\int_0^x \frac{\mathscr{F}_s[g_h(y)/\sqrt{y}]}{\sqrt{x-u}}\,du&=-\frac{i^{1/2}}{\sqrt{2}}\,s\left\{{}_2F_1\left(\frac{1}{2},1;\frac{3}{2};s^2\right)-{}_2F_1\left(\frac{1}{2},1;\frac{3}{2};-s^2\right)\right\}\\&=-\frac{i^{1/2}}{\sqrt{2}}\left\{\ln\left[\frac{(1+s)}{(1-s)}\right]^{1/2}-\arctan(s)\right\},\end{aligned} \tag{12}$$

with $s^2=ix/\alpha$. By derivating this equation we recover the result of Ref. 2:

$$g(x)=\frac{1}{\pi}\frac{\sqrt{2\alpha x}}{\alpha^2+x^2},\quad x>0. \tag{13}$$

(Received 2 February 1996; accepted for publication 19 June 1996)

Two types of determinant representations of the rational solutions for the Painlevé II equation are discussed by using the bilinear formalism. One of them is a representation by the Devisme polynomials, and another one is Hankel determinant representation. They are derived from the determinant solutions of the KP hierarchy and Toda lattice, respectively. © *1996 American Institute of Physics.* [S0022-2488(96)04209-0]

I. INTRODUCTION

The six Painlevé transcendents are now regarded as the nonlinear version of the special functions and hence the Painlevé equations are the most fundamental integrable systems in some sense. It is known that the Painlevé transcendents cannot be expressed by the solutions of linear equations, except for two classes of solutions, namely, special function solutions and rational solutions. The Painlevé II equation (P_{II})

$$\frac{d^2}{dz^2}v = 2v^3 - 4zv + 4\alpha, \tag{1}$$

is the simplest equation that admits such solutions among the Painlevé equations. In fact, it is known that it admits one parameter family of Airy function solutions for α being half odd integers, and only one rational solutions for each integer α[1] and it has no other classical solution.[2]

It is well known that the Painlevé equations can be derived from the similarity reduction of various soliton equations.[3] In particular, P_{II} can be reduced from the modified KdV equation. A systematic study of the rational solutions was done by Airault,[4] who constructed the Bäcklund transformation of P_{II} from the similarity reduction of the modified KdV equation. On the other hand, Okamoto revealed that the Bäcklund transformations of Painlevé equations are given by the Toda lattice equation. For the KP and Toda lattice hierarchies, the solutions are described by the Wronski determinants. The Painlevé equations are deeply connected with the KP and Toda, therefore a question naturally arising is what is the structure of the solutions of Painlevé equations. Actually for the special function type solutions of Painlevé equations, it is known that they are expressed by Wronskians whose entries are given by special functions. Such Wronskians are called the τ function. Here, we note that τ functions are originally defined for arbitrary values of parameters through the Hamiltonians of the Painlevé equations.[1,5] This Wronskian structure of the solutions is quite similar to that for the soliton equations. Hence we expect that the rational solutions also have such a structure. Many studies have been done for the rational solutions, but curiously, it seems that the determinant structure of solutions itself has not been well discussed. This situation motivates us for studying the relationship of the solutions of the Painlevé equations and integrable PDE.

In this article, we present the determinant representations for the rational solutions of P_{II} and clarify how those solutions are reduced from the τ functions of the KP hierarchy and Toda lattice.

We present two types of determinant representations. One is directly derived from the Schur polynomials, namely the algebraic solutions for the KP hierarchy, by applying a reduction procedure. Entries of the determinant are expressed by the Devisme polynomials.[6,7] This reduction exactly corresponds to the derivation of P_{II} from the modified KdV equation. The bilinear form for P_{II} is nothing but the bilinear first Bäcklund transformations of the KP hierarchy. Another one is a Hankel determinant representation which is derived from the Hankel determinant solution of the B-type Toda lattice equation.[8] In this case, the Toda lattice is corresponding to the Bäcklund transformation ladder of the solutions of P_{II}.

In Sec. II, the bilinearization of P_{II} is presented. We give a brief review of the algebraic solutions for KP and KdV hierarchies in Sec. III. In Sec. IV, we give the derivation of the rational solutions for P_{II} from the Schur polynomials. In Sec. V, we briefly summarize the determinant solution for the B-type Toda lattice equation. The Hankel determinant representation of the rational solutions is presented in Sec. VI. Section VII is devoted to concluding remarks.

II. BILINEAR FORM FOR P_{II}

By using the dependent variable transformation,

$$v = \frac{d}{dz} \log \frac{g}{f}, \tag{2}$$

Eq. (1) is decomposed into the following bilinear equations:[5,9]

$$(D_z^2 - \lambda) g \cdot f = 0, \tag{3}$$

$$(D_z^3 + (4z - 3\lambda) D_z - 4\alpha) g \cdot f = 0, \tag{4}$$

where D_z^n is the Hirota bilinear differential operator and λ is an arbitrary function of z. Dividing Eqs. (3) and (4) by gf, we obtain

$$s + v^2 = \lambda,$$

$$v_{zz} + 3sv + v^3 + (4z - 3\lambda) v - 4\alpha = 0,$$

where $s = (\log gf)_{zz}$. Eliminating s from above equations, we get $P_{II}(1)$, therefore Eqs. (3) and (4) actually give the bilinear form for P_{II}.

Using the gauge transformation, we can take λ as we like. In the case of the rational solutions of P_{II}, taking λ to be 0 is convenient as is shown in the later. On the other hand, for the Airy function type solutions of P_{II}, λ is taken to be $2z$.[1] If we fix λ to be equal 0, the bilinear equations for P_{II} are

$$D_z^2 g \cdot f = 0, \tag{5}$$

$$(D_z^3 + 4z D_z - 4\alpha) q \cdot f = 0. \tag{6}$$

In this gauge, these equations allow polynomial solutions for f and g which give the rational solutions v for $P_{II}(1)$ through the variable transformation (2). In the following sections, we will show how the rational solutions are constructed from the τ functions of KP hierarchy and Toda lattice equation.

III. ALGEBRAIC SOLUTIONS FOR KP AND KdV HIERARCHIES

We first give a brief review on the algebraic solutions of KP and KdV hierarchies.[10]

Definition 3.1: Let $p_j(y)$, $j = 0,1,2,...$, be polynomials in $y = (y_1, y_2, y_3, \ldots)$ defined by

$$\sum_{k=0}^{\infty} p_k(y)\lambda^k = \exp\sum_{n=1}^{\infty} y_n\lambda^n, \quad \text{and } p_k(y)=0, \quad \text{for } k<0. \tag{7}$$

Then a set of infinitely many bilinear equations for $\tau(x)=\tau(x_1,x_2,x_3,\ldots)$ generated by

$$\left(\sum_{j=0}^{\infty} p_j(-2y)p_{j+1}(\tilde{D})\exp\left(\sum_{n=1}^{\infty} y_n D_{x_n}\right)\right)\tau\cdot\tau=0, \tag{8}$$

where

$$\tilde{D}=(D_{x_1},\tfrac{1}{2}D_{x_2},\tfrac{1}{3}D_{x_3},\ldots),$$

is called the KP hierarchy and τ is called the τ function.

The simplest bilinear equation included in this hierarchy is

$$(D_{x_1}^4-4D_{x_1}D_{x_3}+3D_{x_2}^2)\tau\cdot\tau=0, \tag{9}$$

which yields the KP equation in nonlinear form,

$$(-4u_{x_3}+6uu_{x_1}+u_{x_1x_1x_1})_{x_1}+3u_{x_2}=0, \tag{10}$$

by the dependent variable transformation,

$$u=2(\log\ \tau)_{x_1x_1}. \tag{11}$$

Proposition 3.2: The following Wronskian,

$$\tau_{N,\mathrm{KP}}=\begin{vmatrix} \partial_{x_1}^{N-1}f_1 & \cdots & \partial_{x_1}f_1 & f_1 \\ \partial_{x_1}^{N-1}f_2 & \cdots & \partial_{x_1}f_2 & f_2 \\ \vdots & \cdots & \vdots & \vdots \\ \partial_{x_1}^{N-1}f_N & \cdots & \partial_{x_1}f_N & f_N \end{vmatrix}, \tag{12}$$

solves the KP hierarchy, where f_k, $k=1,2,\ldots,N$ are arbitrary functions in infinitely many independent variables $x=(x_1,x_2,\ldots)$ satisfying

$$\partial_{x_n}f_k=\partial_{x_1}^n f_k, \quad k=1,2,\ldots,N, \quad n=1,2,\ldots\ . \tag{13}$$

The crucial point is that all the bilinear equations in the KP hierarchy for the τ function (12) are reduced to the identities of determinant which are called the Plücker relations.

Definition 3.3: A set of infinitely many bilinear equations in $\tau(x)$ and $\tau'(x)$ generated by

$$\left(\sum_{j=0}^{\infty} p_j(-2y)p_{j+2}(\tilde{D})\exp\left(\sum_{n=1}^{\infty} y_n D_{x_n}\right)\right)\tau\cdot\tau'=0, \tag{14}$$

is called the first modified KP hierarchy.

In particular, $\tau=\tau_{N+1,\mathrm{KP}}$, $\tau'=\tau_{N,\mathrm{KP}}$ solves the first modified KP hierarchy. Hence, this is regarded as the hierarchy of the first Bäcklund transformations. Moreover, the bilinear equations in this hierarchy are regarded as the identities of $(N+1)\times(N+1)$ determinant and $N\times N$ determinant, which are also the Plücker relations. First two equations of this hierarchy are given by

$$(D_{x_1}^2 - D_{x_2})\,\tau_{N+1\mathrm{KP}} \cdot \tau_{N,\mathrm{KP}} = 0, \tag{15}$$

$$(D_{x_1}^3 - 4D_{x_3} + 3D_{x_1}D_{x_2})\,\tau_{N+1,\mathrm{KP}} \cdot \tau_{N,\mathrm{KP}} = 0. \tag{16}$$

Now we discuss the algebraic solutions for the KP hierarchy. We can easily verify that the polynomials $p_k(x)$ defined by Eq. (7) satisfy

$$\partial_{x_n} p_k(x) = p_{k-n}(x), \tag{17}$$

and hence Eq. (13). Taking f_k in the τ function (12) as $p_{i_k+N-k}(x)$, we have,

Proposition 3.4: Let $Y=(i_1,i_2,\ldots,i_N)$, where $i_1 \geqslant i_2 \geqslant \ldots \geqslant i_N > 0$ are integers, be a Young diagram. Then

$$\tau_{Y,\mathrm{KP}} = \begin{vmatrix} p_{i_1}(x) & p_{i_1+1}(x) & \cdots & p_{i_1+N-1}(x) \\ p_{i_2-1}(x) & p_{i_2}(x) & \cdots & p_{i_2+N-2}(x) \\ \vdots & \vdots & \ddots & \vdots \\ p_{i_N-N+1}(x) & p_{i_N-N+2}(x) & \cdots & p_{i_N}(x) \end{vmatrix} \tag{18}$$

gives the algebraic solution for the KP hierarchy.

The polynomial $\tau_{Y,\mathrm{KP}}$ is called the Schur polynomial attached to the Young diagram Y. We note that if we define the weight of x_n as n, then $p_k(x)$ is a polynomial with homogeneous weight k and $\tau_{Y,\mathrm{KP}}$ is also homogeneous with the weight $|Y| = i_1 + i_2 + \ldots + i_N$. This τ function gives the rational solution of Eq. (10) by the dependent variable transformation (11).

Let us apply the reduction to the KdV hierarchy. This is achieved by dropping the dependence of $x_2, x_4, \ldots$, in the τ functions of KP hierarchy. In order to realize this condition, it is sufficient to choose Y as $(N, N-1, \ldots, 1)$ in the algebraic solution for the KP hierarchy (18).

Proposition 3.5:

$$\tau_{N,\mathrm{KdV}} = \begin{vmatrix} p_N(x) & p_{N+1}(x) & \cdots & p_{2N-1}(x) \\ p_{N-2}(x) & p_{N-1}(x) & \cdots & p_{2N-3}(x) \\ \vdots & \vdots & \ddots & \vdots \\ p_{-N+2}(x) & p_{-N+3}(x) & \cdots & p_1(x) \end{vmatrix}. \tag{19}$$

gives the algebraic solution of the KdV hierarchy.

Proposition 3.5 can be easily verified noticing that

$$\frac{\partial \tau_{N,\mathrm{KdV}}}{\partial x_{2j}} = 0, \quad j = 1,2,3,\ldots, \tag{20}$$

which directly follows from Eq. (17). From Eqs. (15), (16), and (20), it is clear that the τ function (19) satisfies the following bilinear equations:

$$D_{x_1}^2 \tau_{N+1,\mathrm{KdV}} \cdot \tau_{N,\mathrm{KdV}} = 0, \tag{21}$$

$$(D_{x_1}^3 - 4D_{x_3})\,\tau_{N+1,\mathrm{KdV}} \cdot \tau_{N,\mathrm{KdV}} = 0. \tag{22}$$

The modified KdV equation,

$$v_{x_3}+\tfrac{3}{2}\,v^2 v_{x_1}-\tfrac{1}{4}\,v_{x_1x_1x_1}=0, \tag{23}$$

is obtained from Eqs. (21) and (22) by the dependent variable transformation,

$$v=\frac{\partial}{\partial x_1}\log\frac{\tau_{N+1,\mathrm{KdV}}}{\tau_{N,\mathrm{KdV}}}. \tag{24}$$

IV. RATIONAL SOLUTIONS FOR P_{II}: DEVISME POLYNOMIAL REPRESENTATION

Now we give a determinant representation for the rational solutions of P_{II}. We first give the definition of the Devisme polynomials.[6,7]

Definition 4.1: The Devisme polynomials $q_k(x_1,x_2,\ldots,x_m)$, $k=0,1,2,\ldots$, are polynomials in $x_1,\ldots,x_m$ defined by

$$\sum_{k=0}^{\infty} q_k(x_1,x_2,\ldots,x_m)\lambda^k=\exp\left(x_1\lambda+x_2\lambda^2+\cdots+x_m\lambda^m+\frac{1}{m+1}\,\lambda^{m+1}\right). \tag{25}$$

Then one of our main results is stated as follows.

Theorem 4.2: Let $q_k(z,t)$, $k=0,1,2,\ldots$, be the Devisme polynomials and τ_N be an $N\times N$ determinant defined by

$$\tau_N=\begin{vmatrix} q_N(z,t) & q_{N+1}(z,t) & \cdots & q_{2N-1}(z,t)\\ q_{N-2}(z,t) & q_{N-1}(z,t) & \cdots & q_{2N-3}(z,t)\\ \vdots & \vdots & \ddots & \vdots\\ q_{-N+2}(z,t) & q_{-N+3}(z,t) & \cdots & q_1(z,t)\end{vmatrix},\quad q_k(z,t)=0\quad \text{for } k<0. \tag{26}$$

Then

$$v=\frac{d}{dz}\log\frac{\tau_{N+1}}{\tau_N}, \tag{27}$$

gives a rational solution for P_{II} (1) with $\alpha=N+1$.

Remark 4.3: (1) The τ function (26) is derived only by putting

$$x_1=z,\quad x_2=t,\quad x_3=\tfrac{1}{3},\quad x_4=x_5=\cdots=0, \tag{28}$$

in Eq. (19). Namely, the rational solutions of P_{II} are given in terms of the special case of the Schur polynomials.

(2) The τ function (26) itself does not depend on t, but we have left t dependence in the entries in order to relate the solutions with the Devisme polynomials.

Theorem 4.2 is a direct consequence of the following proposition.

Proposition 4.4: The τ function τ_N (26) satisfies the bilinear equations (5) and (6) with $\alpha=N+1$.

Proof: Putting $x_5=x_7=\cdots=0$ in the rational solutions of KdV hierarchy (19), it is readily seen that $\tau_{N,\mathrm{KdV}}$ is a homogeneous weight polynomial in x_1 and x_3 with weight $[N(N+1)]/[2]$. Hence, if we put

$$f_N=\frac{1}{x_3^{N(N+1)/6}}\,\tau_{N,\mathrm{KdV}}, \tag{29}$$

then f_N depends only on $t=(x_1)/(x_3^{1/3})$. Thus we have

$$\partial_{x_3} f_N = \frac{\partial t}{\partial x_3} \frac{d}{dt} f_N, \quad \partial_{x_1} f_N = \frac{\partial t}{\partial x_1} \frac{d}{dt} f_N, \tag{30}$$

which yield

$$\partial_{x_3} \tau_{N,\mathrm{KdV}} = \frac{1}{3x_3} \left(\frac{N(N+1)}{2} \tau_{N,\mathrm{KdV}} - x_1 \partial_{x_1} \tau_{N,\mathrm{KdV}} \right). \tag{31}$$

Substituting Eq. (31) into Eq. (22), we get

$$\left(D_{x_1}^3 + \frac{4}{3x_3} x_1 D_{x_1} - \frac{4}{3x_3} (N+1) \right) \tau_{N+1,\mathrm{KdV}} \cdot \tau_{N,\mathrm{KdV}} = 0. \tag{32}$$

Moreover, by putting $z = x_1$ and $x_3 = \frac{1}{3}$, $\tau_{N,\mathrm{KdV}}$ reduces to τ_N in Eq. (26) and Eqs. (5) and (6) with $f = \tau_N$, $g = \tau_{N+1}$ and $\alpha = N+1$ are obtained from Eqs. (21) and (32). □

V. HANKEL DETERMINANT SOLUTION FOR TODA LATTICE

Let us consider the Toda lattice equation,

$$\frac{d^2 u_N}{dz^2} = e^{u_{N-1} - u_N} - e^{u_N - u_{N+1}}, \tag{33}$$

with the symmetric lattice condition,

$$u_N = u_{-N-1}. \tag{34}$$

It is easy to see that Eq. (33) is bilinearized through the dependent variable transformation,

$$u_N = \log \frac{\tau_{N-1}}{\tau_N}, \tag{35}$$

from which we get

$$D_z^2 f_N \cdot f_N = 2(f_{N+1} f_{N-1} - f_N f_N), \quad f_N = f_{-N-1}. \tag{36}$$

Here, we call this type of symmetric lattice as B-type Toda lattice because it concerns the BKP hierarchy.[8,10] Using the gauge freedom, we can translate the above B-type Toda lattice equation in the following form:

$$(D_z^2 + 2a_0) \sigma_N \cdot \sigma_N = 2 \sigma_{N+1} \sigma_{N-1}, \tag{37}$$

where $\sigma_N = f_N / f_0$ and $a_0 = f_1 / f_0$. It is clear that σ_N satisfies

$$\sigma_N = \sigma_{-N-1}, \tag{38}$$

$$\sigma_0 = 1, \quad \sigma_1 = a_0. \tag{39}$$

It is possible to express the general solution of Eqs. (37)–(39) in determinant form.[11]

Proposition 5.1: The general solution for Eqs. (37)–(39) for an arbitrary a_0 is given in the Hankel determinant form

$$\sigma_N=\begin{vmatrix} a_0 & a_1 & \cdots & a_{N-1} \\ a_1 & a_2 & \cdots & a_N \\ \vdots & \vdots & \ddots & \vdots \\ a_{N-1} & a_N & \cdots & a_{2N-2} \end{vmatrix}, \quad N\geqslant 0, \tag{40}$$

where a_n, $n=1,2,3,...$ are recursively defined by

$$a_{n+1}=\frac{da_n}{dz}+\sum_{k=0}^{n-1} a_k a_{n-k-1}, \quad n\geqslant 0. \tag{41}$$

This contains one arbitrary function a_0, hence it gives the general solution for the B-type Toda lattice equation.

VI. RATIONAL SOLUTIONS FOR P_{II}: HANKEL DETERMINANT REPRESENTATION

The rational solutions for P_{II} are derived only by putting

$$a_0=z, \tag{42}$$

in the above σ_N.

Theorem 6.1: Let a_n, $n=0,1,2,...$, be polynomials defined by

$$a_{n+1}=\frac{da_n}{dz}+\sum_{k=0}^{n-1} a_k a_{n-k-1}, \quad n\geqslant 0, \quad a_0=z, \tag{43}$$

and let σ_N be an $N\times N$ determinant given by Eq. (40). Then

$$v=\frac{d}{dz}\log\frac{\sigma_{N+1}}{\sigma_N}, \tag{44}$$

gives a rational solution for P_{II} (1) with $\alpha=N+1$.

Similar to the previous section, Theorem 6.1 is a direct consequence of the following proposition.

Proposition 6.2: $f=\sigma_N$ and $g=\sigma_{N+1}$ satisfies the bilinear equations (5) and (6) with $\alpha=N+1$.

To prove proposition 6.2, let us first introduce the notation σ_{NY}:

Definition 6.3: Let $Y=(i_1,i_2,\ldots,i_h)$ be a Young diagram. Then we define an $N\times N$ determinant σ_{NY} by

$$\sigma_{NY}=\begin{vmatrix} a_0 & a_1 & \cdots & a_{N-h-1} & a_{N-h+i_h} & \cdots & a_{N-2+i_2} & a_{N-1+i_1} \\ a_1 & a_2 & \cdots & a_{N-h} & a_{N-h+1+i_h} & \cdots & a_{N-1+i_2} & a_{N+i_1} \\ \vdots & \vdots & \cdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ a_{N-1} & a_N & \cdots & a_{2N-h-2} & a_{2N-h-1+i_h} & \cdots & a_{2N-3+i_2} & a_{2N-2+i_1} \end{vmatrix}. \tag{45}$$

We first construct the shift operators which are differential operators generating σ_{NY} from σ_N. If entries of the determinant satisfy simple equations like Eq. (13), then construction of the shift operators is straightforward. But when we have to work on more complicated relations among the entries like Eq. (41), it is useful to apply the technique developed in Ref. 12.

We can prove the following lemma.

Lemma 6.4:

$$\sigma_{N\square}=\frac{d}{dz}\,\sigma_N. \tag{46}$$

Proof: Notice that $\sigma_{N\square}$ is expressed by

$$\sigma_{N\square}=\begin{pmatrix} a_1 & a_2 & \cdots & a_N \\ a_2 & a_3 & \cdots & a_{N+1} \\ \vdots & \vdots & \ddots & \vdots \\ a_N & a_{N+1} & \cdots & a_{2N-1} \end{pmatrix}\cdot\begin{pmatrix} \Delta_{11} & \Delta_{12} & \cdots & \Delta_{1N} \\ \Delta_{21} & \Delta_{22} & \cdots & \Delta_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ \Delta_{N1} & \Delta_{N2} & \cdots & \Delta_{NN} \end{pmatrix}, \tag{47}$$

where Δ_{ij} is the (i,j)-cofactor of σ_N and $A\cdot B$ denotes a standard scalar product for $N\times N$ matrices $A=(a_{ij})$ and $B=(b_{ij})$ which is defined as

$$A\cdot B=\sum_{i,j=1}^{N} a_{ij}b_{ij}=\text{trace } A^tB. \tag{48}$$

The first matrix of Eq. (47) is rewritten by using the recursion relation (41) as

$$\begin{pmatrix} \partial_z a_0 & \partial_z a_1 & \cdots & \partial_z a_{N-1} \\ \partial_z a_1 & \partial_z a_2 & \cdots & \partial_z a_N \\ \vdots & \vdots & \ddots & \vdots \\ \partial_z a_{N-1} & \partial_z a_N & \cdots & \partial_z a_{2N-2} \end{pmatrix}$$
$$+\begin{pmatrix} 0 & a_0^2 & \cdots & \displaystyle\sum_{k=0}^{N-2} a_k a_{N-k-2} \\ a_0^2 & a_0a_1+a_1a_0 & \cdots & \displaystyle\sum_{k=0}^{N-1} a_k a_{N-k-1} \\ \displaystyle\sum_{k=0}^{N-2} a_k a_{N-k-2} & \displaystyle\sum_{k=0}^{N-1} a_k a_{N-k-1} & \cdots & \displaystyle\sum_{k=0}^{2N-3} a_k a_{2N-k-3} \end{pmatrix}. \tag{49}$$

The above second term is separated as

$$\begin{pmatrix} 0 & a_0^2 & \cdots & \displaystyle\sum_{k=0}^{N-2} a_k N_{-k-2} \\ 0 & a_0a_1 & \cdots & \displaystyle\sum_{k=0}^{N-2} a_k a_{N-k-1} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & a_0a_{N-1} & \cdots & \displaystyle\sum_{k=0}^{N-2} a_k a_{2N-k-3} \end{pmatrix}$$
$$+\begin{pmatrix} 0 & 0 & \cdots & 0 \\ a_0^2 & a_1a_0 & \cdots & a_{N-1}a_0 \\ \vdots & \vdots & \cdots & \vdots \\ \displaystyle\sum_{k=0}^{N-2} a_k a_{N-k-2} & \displaystyle\sum_{k=1}^{N-1} a_k a_{N-k-1} & \cdots & \displaystyle\sum_{k=N-1}^{2N-3} a_k a_{2N-k-3} \end{pmatrix}. \tag{50}$$

Each of these terms gives zero contribution in Eq. (47). Hence we have proved lemma 6.4. □

Next we have:

Lemma 6.5:

$$\sigma_{N\square\square}+\sigma_{N\square}=\left(\frac{d^2}{dz^2}+z\right)\sigma_N, \tag{51}$$

$$\sigma_{N\square\square}-\sigma_{N\square}=(2N-1)z\sigma_N. \tag{52}$$

Proof: We consider

$$\sigma_{N\square\square}+\sigma_{N\square}=\begin{pmatrix} a_1 & a_2 & \cdots & a_{N-1} & a_{N+1} \\ a_2 & a_3 & \cdots & a_N & a_{N+2} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ a_N & a_{N+1} & \cdots & a_{2N-2} & a_{2N} \end{pmatrix}\cdot\begin{pmatrix} \Delta_{\square 11} & \Delta_{\square 12} & \cdots & \Delta_{\square 1N} \\ \Delta_{\square 21} & \Delta_{\square 22} & \cdots & \Delta_{\square 2N} \\ \vdots & \vdots & \ddots & \vdots \\ \Delta_{\square N1} & \Delta_{\square N2} & \cdots & \Delta_{\square NN} \end{pmatrix}, \tag{53}$$

where $\Delta_{\square ij}$ is (i,j) cofactor of $\sigma_{N\square}$. The first matrix in the right-hand side is equal to

$$\begin{pmatrix} \partial_z a_0 & \partial_z a_1 & \cdots & \partial_z a_{N-2} & \partial_z a_N \\ \partial_z a_1 & \partial_z a_2 & \cdots & \partial_z a_{N-1} & \partial_z a_{N+1} \\ \vdots & \vdots & \vdots & \vdots & \\ \partial_z a_{N-1} & \partial_z a_N & \cdots & \partial_z a_{2N-3} & \partial_z a_{2N-1} \end{pmatrix}$$
$$+\begin{pmatrix} 0 & a_0^2 & \cdots & \sum_{k=0}^{N-3} a_k a_{N-k-3} & \sum_{k=0}^{N-1} a_k a_{N-k-1} \\ 0 & a_0 a_1 & \cdots & \sum_{k=0}^{N-3} a_k a_{N-k-2} & \sum_{k=0}^{N-1} a_k a_{N-k} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & a_0 a_{N-1} & \cdots & \sum_{k=0}^{N-3} a_k a_{2N-k-4} & \sum_{k=0}^{N-1} a_k a_{2N-k-2} \end{pmatrix}$$
$$+\begin{pmatrix} 0 & 0 & \cdots & 0 & 0 \\ a_0^2 & a_1 a_0 & \cdots & a_{N-2} a_0 & a_N a_0 \\ \vdots & \vdots & \cdots & \vdots & \vdots \\ \sum_{k=0}^{N-2} a_k a_{N-k-2} & \sum_{k=1}^{N-1} a_k a_{N-k-1} & \cdots & \sum_{k=N-2}^{2N-4} a_k a_{2N-k-4} & \sum_{k=N}^{2N-2} a_k a_{2N-k-2} \end{pmatrix}. \tag{54}$$

Taking the scalar product, the first and second terms give $\partial_z \sigma_{N\square}$ and $a_0\sigma_N$, respectively, and the third term vanishes. Hence we have

$$\sigma_{N\square\square}+\sigma_{N\square}=\left(\frac{d^2}{dz^2}+z\right)\sigma_N. \tag{55}$$

Next we consider the following equality:

$$\sigma_{N\square\square}-\sigma_{N\square}=\begin{pmatrix} a_2 & a_3 & \cdots & a_{N+1} \\ a_3 & a_4 & \cdots & a_{N+2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{N+1} & a_{N+2} & \cdots & a_{2N} \end{pmatrix}\cdot\begin{pmatrix} \Delta_{11} & \Delta_{12} & \cdots & \Delta_{1N} \\ \Delta_{21} & \Delta_{22} & \cdots & \Delta_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ \Delta_{N1} & \Delta_{N2} & \cdots & \Delta_{NN} \end{pmatrix}. \tag{56}$$

The first matrix of the right-hand side of Eq. (56) is rewritten as

$$\begin{pmatrix} \partial_z a_1 & \partial_z a_2 & \cdots & \partial_z a_N \\ \partial_z a_2 & \partial_z a_3 & \cdots & \partial_z a_{N+1} \\ \vdots & \vdots & \ddots & \vdots \\ \partial_z a_N & \partial_z a_{N+1} & \cdots & \partial_z a_{2N-1} \end{pmatrix}+\begin{pmatrix} a_0^2 & a_0a_1+a_1a_0 & \cdots & \sum_{k=0}^{N-1} a_k a_{N-k-1} \\ a_0a_1 & a_0a_2+a_1a_1 & \cdots & \sum_{k=0}^{N-1} a_k a_{N-k} \\ \vdots & \vdots & \vdots & \vdots \\ a_0a_{N-1} & a_0a_N+a_1a_{N-1} & \cdots & \sum_{k=0}^{N-1} a_k a_{2N-k-2} \end{pmatrix}$$

$$+\begin{pmatrix} 0 & 0 & \cdots & 0 \\ a_1a_0 & a_2a_0 & \cdots & a_Na_0 \\ \vdots & \vdots & \cdots & \vdots \\ \sum_{k=1}^{N-1} a_k a_{N-k-1} & \sum_{k=2}^{N} a_k a_{N-k} & \cdots & \sum_{k=N}^{2N-2} a_k a_{2N-k-2} \end{pmatrix}. \tag{57}$$

Here, we note that a_n's also satisfy

$$\partial_z a_{n+1}=2na_{n-1}, \tag{58}$$

which is proved by induction from Eqs. (41) and (42). The first term of the right hand side of Eq. (57) is rewritten by using Eq. (58) as

$$\begin{pmatrix} 0 & 2a_0 & \cdots & 2(N-1)a_{N-2} \\ 0 & 2a_1 & \cdots & 2(N-1)a_{N-1} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 2a_{N-1} & \cdots & 2(N-1)a_{2N-3} \end{pmatrix}$$

$$+\begin{pmatrix} 0 & 0 & \cdots & 0 \\ 2a_0 & 2a_1 & \cdots & 2a_{N-1} \\ \vdots & \vdots & \cdots & \vdots \\ 2(N-1)a_{N-2} & 2(N-1)a_{N-1} & \cdots & 2(N-1)a_{2N-3} \end{pmatrix}. \tag{59}$$

Applying the scalar product on these terms, we obtain

$$\sigma_{N\square\square}-\sigma_{N\square}=(2N-1)z\sigma_N. \tag{60}$$

Hence we have proved lemma 6.5.

Continuing the similar argument, we get the following shift operators.

Lemma 6.6:

$$\sigma_{N\square\square\square}+2\sigma_{N\square\square}+\sigma_{N\begin{smallmatrix}\square\\\square\end{smallmatrix}}=\left(\frac{d^3}{dz^3}+3z\frac{d}{dz}+1\right)\sigma_N, \tag{61}$$

$$\sigma_{N\square\square\square}-\sigma_{N\begin{smallmatrix}\square\\\square\end{smallmatrix}}=\left((2N-1)z\frac{d}{dz}+(2N+1)\right)\sigma_N, \tag{62}$$

$$\sigma_{N\square\square\square}-\sigma_{N\square\square}+\sigma_{N\begin{smallmatrix}\square\\\square\end{smallmatrix}}=\left(2z\frac{d}{dz}+2(N^2+N-1)\right)\sigma_N. \tag{63}$$

Finally, we prove proposition 6.2. From the Plücker relations, we have

$$\sigma_{N+1\begin{smallmatrix}\square\\\square\end{smallmatrix}}\sigma_N-\sigma_{N+1\square}\sigma_{N\square}+\sigma_{N+1}\sigma_{N\square\square}=0, \tag{64}$$

$$\sigma_{N+1\square\square}\sigma_N-\sigma_{N+1\square\square}\sigma_{N\square}+\sigma_{N+1}\sigma_{N\square\square\square}=0, \tag{65}$$

which are essentially the same as the bilinear equations (15) and (16) for $\tau_{N,\mathrm{KP}}$. By using lemmas 6.4, 6.5, and 6.6, we get

$$D_z^2\sigma_{N+1}\cdot\sigma_N=0, \tag{66}$$

$$(D_z^3+4zD_z-4(N+1))\sigma_{N+1}\cdot\sigma_N=0, \tag{67}$$

which are the desired result. Thus we have proved proposition 6.2.

VII. CONCLUDING REMARKS

In this article, we have presented two types of determinant representations for the rational solutions of $\mathrm{P_{II}}$. The Devisme polynomial representation follows from the reduction procedure of modified KdV equation and the Hankel determinant representation is obtained from the Toda lattice equation, namely the Bäcklund transformation of the solution of $\mathrm{P_{II}}$. These determinant structures of the rational solutions of $\mathrm{P_{II}}$ exactly reflect the Wronskian structure of the solution of KP hierarchy and Toda lattice equation. The relationship between those two representations is not clear yet. At least, it seems that there is no simple transformation relating the two representations.

It is known that the Airy function type solutions of $\mathrm{P_{II}}$ are expressed as[1]

$$v=\frac{d}{dz}\log\frac{\rho_{N+1}}{\rho_N}, \tag{68}$$

$$\rho_N=\begin{vmatrix} \mathrm{Ai} & \frac{d}{dz}\mathrm{Ai} & \cdots & \frac{d^{N-1}}{dz^{N-1}}\mathrm{Ai} \\ \frac{d}{dz}\mathrm{Ai} & \frac{d^2}{dz^2}\mathrm{Ai} & \cdots & \frac{d^N}{dz^N}\mathrm{Ai} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{d^{N-1}}{dz^{N-1}}\mathrm{Ai} & \frac{d^N}{dz^N}\mathrm{Ai} & \cdots & \frac{d^{2N-2}}{dz^{2N-2}}\mathrm{Ai} \end{vmatrix}, \tag{69}$$

where Ai is the Airy function satisfying

$$\frac{d^2}{dz^2}\mathrm{Ai}=z\,\mathrm{Ai}. \tag{70}$$

Then v satisfies P_{II},

$$\frac{d^2v}{dz^2} = 2v^3 - 2zv + (2N+1). \tag{71}$$

In Ref. 12, it was shown that the τ function (69) can be reduced from that of the KP hierarchy (12).

In the theory of KP hierarchy, an important fact is that we can introduce the τ function which is expressed in terms of determinant. Based on this fact, we can identify the solution space, and the KP hierarchy is regarded as the dynamical system on the infinite dimensional Grassmann manifold. P_{II} is obtained from the similarity reduction of the modified KdV equation, but the parameter of the equation appears as the integration constant, which means that P_{II} has the information of various boundary conditions of the modified KdV equation. From this observation, it looks that one cannot expect such beautiful structures in the solution space of P_{II}. Nevertheless, the results in this article may imply that at least for the special function type solutions and the rational solutions, such structures in the solutions of KP hierarchy may survive through the reduction. It may be an interesting problem to investigate the determinant structures for other Painlevé equations. So far, this is completely an open problem.

Recently, discrete versions of the Painlevé equations have been proposed through the singularity confinement test.[13] As for the solutions, some of them admit discrete or q-difference analog of special function type solutions expressed by determinants.[14,15] Moreover, it was reported that the discrete Painlevé II equation admits rational solutions with determinant structure.[16] We might expect that through such determinant structures of solutions, similarity reductions[17] deriving the discrete Painlevé equations from discrete KP (or Toda) would become more transparent, as we have seen in the continuous P_{II} case.

(Received 27 March 1996; accepted for publication 10 June 1996)

The separability theorem states that, given a linear partial differential equation and special coordinates allowing to find a family of separated solutions, all solutions of physical interest of the equations can be obtained from linear combinations of the separated solutions. In developing the theory of interaction between an infinite cylinder and a Gaussian beam, it has been recently observed that the theorem may fail in terms of functions. In this paper, it is shown that the separability theorem is recovered if solutions are expressed in terms of distributions instead of in terms of functions. Relevance to light scattering theory is discussed. © *1996 American Institute of Physics.* [S0022-2488(96)02709-0]

I. INTRODUCTION

In many fields of physics and, in particular in light scattering theory, we have to deal with linear partial differential equations of the form

$$A\psi = F \tag{1}$$

in which ψ is a scalar (or a vector) field depending on coordinates and time, A is a differential operator, and F a function. The quantities A and F are known, and the field ψ is unknown.

Let us restrict our attention to homogeneous equations defined by $F=0$. Then, if we possess a set $\{\psi_i\}$, $i=1,\ldots,N$ of solutions of the equation, it appears that any linear combination ψ of the solutions is also a solution

$$\psi = \sum_{i=1}^{N} \alpha_i \psi_i . \tag{2}$$

For convenience, let us focus our attention to 3D spaces spanned by coordinates $\{x_i\}$, $i=1,2,3$. In some cases, i.e., for some equations, it is possible to find so-called separable coordinate systems in which there exists a family of separated solutions reading as

$$\psi = X_1(x_1)X_2(x_2)X_3(x_3). \tag{3}$$

Let ψ_i be a member of the family. Then the separability theorem states[1] that ''all solutions of the partial differential equation can be built up out of linear combinations of the members of the family of separated solutions,'' i.e., ''once we have computed the separated solutions, we can obtain the rest.'' Notice that no condition on the solutions is stated, so that one should not understand this statement as a theorem in the usual meaning but as a property shared by all solutions of interest in theoretical physics; this is why we may write down ''theorem'' instead of theorem.

In this paper, we deal with the theory of interaction between shaped electromagnetic beams (for example Gaussian laser beams) and regular particles (emphasizing the case of infinite cylinders). Under these circumstances, the equation to consider is the Bromwich scalar potential equation. The interaction between shaped beams and spheres (generalized Lorenz–Mie theory, GLMT, Refs. 2–3 and references therein) or stratified spheres[4] has been successfully derived by using the separability theorem in terms of functions. In developing the theory of interaction between shaped beams and infinite cylinders, it has, however, been observed that the same mathematical framework could not be used. In particular, the description of the incident Gaussian beam introduced scalar potentials which, in terms of functions, did not satisfy the separability theorem.[5] This fact induced considerable difficulties in building a complete theory, in particular when handling electromagnetic boundary conditions at the surface of the cylinder.[6] Revisiting the separability theorem, many solutions which do not satisfy the separability theorem in terms of functions have been exhibited for the Bromwich scalar potential and for the scalar wave equations, in both spherical and cylindrical coordinate systems.[7] Let us call them exotic solutions.

In this paper, it is shown that the separability theorem may, however, be recovered if the class of admissible solutions is extended from functions to distributions.[8,9] As a consequence, the theory of interaction between shaped beams and infinite cylinders has been afterward successfully developed by using this extended framework.[10–13]

The paper is organized as follows. Section II presents the Bromwich scalar potentials and their general solutions in terms of functions, relying on the separability theorem, in cylindrical coordinates. A counterexample in terms of functions is given. Section III discusses general solutions in terms of distributions and the aforementioned counterexample is shown to satisfy the separability theorem in that extended framework. Relevance to light scattering is discussed. Section IV is a conclusion.

II. THE SEPARABILITY THEOREM IN TERMS OF FUNCTIONS FOR THE BROMWICH SCALAR POTENTIAL EQUATION

A. Bromwich scalar potentials

Let us consider orthogonal curvilinear coordinates $\{x_i\}$ such as the infinitesimal Riemannian distance ds between two points $[x_i(P)]$ and $[x_i(P)+dx_i]$ reads as

$$ds^2=\sum_{n=1}^{3} e_n^2 (dx_n)^2 \tag{4}$$

in which coefficients e_n are called scale factors.

Let us furthermore assume that the scale factors satisfy the following conditions:

$$e_1=1, \tag{5}$$

$$\frac{\partial}{\partial x_1}\left(\frac{e_1}{e_3}\right)=0. \tag{6}$$

Then we may define Bromwich scalar potentials (BSP), denoted by U, which are solutions of the partial derivative equation[14–16]

$$\frac{\partial^2 U}{\partial x_1^2}+\frac{1}{e_2 e_3}\left[\frac{\partial}{\partial x_2}\left(\frac{e_3}{e_2}\frac{\partial U}{\partial x_2}\right)+\frac{\partial}{\partial x_3}\left(\frac{e_2}{e_3}\frac{\partial U}{\partial x_3}\right)\right]+k^2 U=0. \tag{7}$$

In light scattering theory, BSPs play a dominant role because, once they are known, they allow the determination of electric E_i and magnetic fields H_i by using a set of derivative operators,

here symbolically written as $\hat{d}U \rightarrow (E_i, H_i)$. Maxwell's equations are equivalent to Rel. (7) supplemented by the set $\hat{d}U$. Let us note that, within the set of 11 separable coordinate systems for the wave equation, there are only 6 coordinate systems satisfying conditions (5) and (6), including spherical and cylindrical coordinates (Ref. 1).

B. Cylindrical coordinates

In cylindrical coordinates

$$\{x_i\} = \{z, \rho, \varphi\}, \tag{8}$$

$$ds^2 = dz^2 + d\rho^2 + \rho^2 \, d\varphi^2, \tag{9}$$

the BSP equation reads as

$$\frac{\partial^2 U}{\partial z^2} + \frac{1}{\rho} \frac{\partial}{\partial \rho} \rho \frac{\partial U}{\partial \rho} + \frac{1}{\rho^2} \frac{\partial^2 U}{\partial \varphi^2} + k^2 U = 0 \tag{10}$$

which, in contrast with the case of spherical coordinates, identifies with the wave equation.[7] Separability is achieved by setting

$$U(z, \rho, \varphi) = U_1(z) U_2(\rho) U_3(\varphi). \tag{11}$$

Assuming a 2π periodicity with respect to φ, looking for solutions which are finite in whole space, and considering the description of shaped beams propagating in free space (i.e., the solutions must be defined at $\rho = 0$), it is then found that, in terms of functions, the general solution of Rel. (11) is the summation over all separated solutions reading as[5–7]

$$U = e^{ik\gamma z} \sum_{m=-\infty}^{+\infty} A_m J_m(k\rho\sqrt{1-\gamma^2}) e^{im\varphi} \tag{12}$$

in which $(k\gamma)$ pertains to the real field. Actually, the form of Rel. (12) is general enough to our purpose but is not the most general form in terms of functions. First, we may add a γ spectrum made of a combination of a discrete and of a continuous contribution. Physically, however, in studying the interaction between a Gaussian beam and an infinite cylinder, it is found that the γ spectrum contains one single peak. In particular, if the Gaussian beam is perpendicularly incident on the cylinder, we have $\gamma = 0$.[5,6] Therefore, we shall be content with Rel. (12) in this paper.

Second it is also interesting to note what would happen if we relaxed the condition that solutions should be finite in whole space. Then, we would have to accept solutions diverging exponentially or linearly with respect to z when $z \rightarrow \pm\infty$.[7]

For $\gamma = 0$, i.e., in the case of a Gaussian beam perpendicularly incident on an infinite cylinder, Rel. (12) reduces to

$$U = \sum_{m=-\infty}^{+\infty} A_m J_m(R) e^{im\varphi} \tag{13}$$

in which we use the rescaled coordinate $R = k\rho$. However, the structure given by Rel. (13) is not sufficient to describe the Gaussian beam. Instead, it is found that we may have to deal with BSPs of the form[5,6]

$$U = (Z^2 + iR \cos \varphi) e^{iR \cos \varphi} \tag{14}$$

which is equivalent to

$$U=(Z^2+iR\ \cos\ \varphi)\sum_{m=-\infty}^{+\infty} i^m J_m(R)e^{im\varphi} \tag{15}$$

in which $Z=kz$ is a rescaled coordinate. The BSP U is then equal to a Σ-separable BSP of the form given by Rel. (13) multiplied by a modulation prefactor $(Z^2+iR\ \cos\ \varphi)$. The BSP given by Rel. (15) is a non-Σ-separable solution in terms of functions. Let us note that U diverges quadratically with respect to Z when $z\to\pm\infty$. Such a behavior cannot be recovered by relaxing the condition that solutions are finite in whole space because this would lead to exponential or linear divergence when $z\to\pm\infty$ [see comments following Rel. (12)], not to quadratic divergence.

III. THE SEPARABILITY THEOREM IN TERMS OF DISTRIBUTIONS

We now show that the separability theorem is recovered if we extend the class of solutions from functions to distributions.

Let us again consider the BSP equation (10) in cylindrical coordinates and look for solutions which are temperated distributions with respect to z.

Because any temperated distribution possesses a Fourier transform which is a temperated distribution too,[8,9] we may evaluate the Fourier transform of Rel. (10). For convenience, the Fourier transform of the distribution U is here defined by

$$\hat{U}(\gamma,\rho,\varphi)=\mathscr{F}_z[U](\gamma) \tag{16}$$

in which, for a function $U(z,\rho,\varphi)$, we have

$$\mathscr{F}_z[U](\gamma)=\int U(z,\rho,\varphi)e^{-ik\gamma z}\ dz. \tag{17}$$

Then the Fourier transform $\hat{U}$ satisfies the equation

$$\frac{1}{\rho}\frac{\partial}{\partial\rho}\ \rho\ \frac{\partial\hat{U}}{\partial\rho}+\frac{1}{\rho^2}\frac{\partial^2\hat{U}}{\partial\varphi^2}+k^2(1-\gamma^2)\hat{U}=0. \tag{18}$$

Demanding that U be 2π periodic with respect to φ, we then have

$$\hat{U}(\gamma,\rho,\varphi)=\sum_m\ C_m(\gamma,\rho)e^{im\varphi} \tag{19}$$

in which $C_m(\gamma,\rho)$ is a distribution.

Inserting Rel. (19) in Rel. (18) shows that the distribution $C_m(\gamma,\rho)$ must satisfy

$$\rho^2\ \frac{\partial^2 C_m}{\partial\rho^2}+\rho\ \frac{\partial C_m}{\partial\rho}+[k^2(1-\gamma^2)\rho^2-m^2]C_m=0,\quad \forall_m \tag{20}$$

which is the Bessel equation whose solutions are taken as

$$C_m(\gamma,\rho)=a_m(\gamma)J_m(k\rho\sqrt{1-\gamma^2}) \tag{21}$$

in which $a_m(\gamma)$ is a distribution.

Therefore,

$$\hat{U}(\gamma,\rho,\varphi)=\sum_m\ a_m(\gamma)J_m(k\rho\sqrt{1-\gamma^2})e^{im\varphi} \tag{22}$$

which is Σ-separable in terms of distributions. The distribution U is, therefore, Σ-separable too and reads as

$$U(z,\rho,\varphi)=\sum_m \mathscr{F}_\gamma^{-1}[a_m(\gamma)J_m(k\rho\sqrt{1-\gamma^2})](z)e^{im\varphi}. \tag{23}$$

As an example, let us consider the BSP given by Rel. (15). The cos φ term may be rewritten as

$$U_{\cos}=\frac{1}{2}R\sum_{m=-\infty}^{+\infty} i^m e^{im\varphi}[J_{m-1}(R)-J_{m+1}(R)]=R\sum_{m=-\infty}^{+\infty} i^m e^{im\varphi}J'_m(R), \tag{24}$$

leading to

$$U=\sum_{m=-\infty}^{+\infty} i^m e^{im\varphi}[Z^2J_m(R)+RJ'_m(R)]. \tag{25}$$

On the other hand, Rel. (12) generalizes in terms of distributions to

$$U=\sum_m e^{im\varphi}\langle A_m(\gamma),J_m(R\sqrt{1-\gamma^2})e^{i\gamma Z}\rangle. \tag{26}$$

From Rels. (25) and (26), the distribution $A_m(\gamma)$ is the solution of the equation

$$\langle A_m(\gamma),J_m(R\sqrt{1-\gamma^2})e^{i\gamma Z}\rangle=i^m[Z^2J_m(R)+RJ'_m(R)]. \tag{27}$$

Now, the fact that γ is equal to 0 in terms of functions means that the γ spectrum is $\{0\}$, i.e., that the support of the distribution $A_m(\gamma)$ is $\{0\}$. However, we possess the following theorem: A distribution of support $\{0\}$ reads as

$$T=\sum_{k=0}^{N} a_k\delta^{(k)} \tag{28}$$

in which $a_k\in C$ and $\delta^{(k)}$ is the kth derivative of the Dirac distribution (the reciprocal statement is also true). It is then found that the distribution $A_m(\gamma)$ is of the form given by Rel. (28) and reads as

$$A_m(\gamma)=-i^m\delta''(\gamma). \tag{29}$$

Indeed, we check that

$$\begin{aligned}\langle A_m(\gamma),J_m(R\sqrt{1-\gamma^2})e^{i\gamma Z}\rangle&=-i^m\langle\delta''(\gamma),J_m(R\sqrt{1-\gamma^2})e^{i\gamma Z}\rangle\\&=-i^m(J_m(R\sqrt{1-\gamma^2})e^{i\gamma Z})''_{\gamma=0}\\&=i^m[Z^2J_m(R)+RJ'_m(R)].\end{aligned} \tag{30}$$

Therefore, the separability theorem is recovered in terms of distributions.

IV. CONCLUSION

We examined the Bromwich scalar equation and the wave equation in cylindrical coordinates, in which case both equations identify, and demonstrated that the separability theorem is always

satisfied if solutions are expressed in terms of distributions rather than in terms of functions. In light scattering theory, we then obtain an extended framework allowing to study the interaction between an infinite cylinder and a Gaussian beam,[10–12] more generally an arbitrary shaped beam.[13]

In Ref. 7, we also exhibited exotic solutions in spherical coordinates. The effort required to understand the nature of these solutions appears to be significantly more important than in cylindrical coordinates, an issue which is therefore not clarified at the present time. However, from the point of view of light scattering, exotic solutions in spherical coordinates are of dubious interest in so far as the theory of interaction between spheres and shaped beams can be fully developed by using only nonexotic solutions.[2–4]

ACKNOWLEDGMENT

One of us (G.G.) thanks Professor P. C. Sabatier for having pointed out the interest of the theory of distributions in this context.

Remarks on the universal central extension of sdiff(T^2)$_{loc}$

Wolé Òdúndún[a)]
International Centre for Theoretical Physics, Trieste, Italy

(Received 17 November 1995; accepted for publication 29 February 1996)

In a paper by C. N. Pope and K. S. Stelle [Phys. Lett. B **226**, 257–263 (1989)], it was shown that the algebra of local area-preserving diffeomorphisms on the torus is equivalent to su(∞). In this paper we present a few remarks on the universal central extension of this infinite dimensional Lie algebra, and construct, for this case, in analogy to the situation in which the affine Lie algebra has an underlying finite-dimensional Lie algebra, the nontrivial universal central extension. © *1996 American Institute of Physics.* [S0022-2488(96)01608-8]

I. INTRODUCTION

Let **I** be the closed unit interval [0,1], and **I**×**I** a topological space lying in the first quadrant of the $x-y$ plane so that two of its adjacent sides lie on the x and y axes of a two-dimensional coordinates system. Then the torus $S^1\times S^1=T^2$ (where $S^1=\{x\in\mathbb{R}^2 \| \|x\|=1\}$ is the one-sphere) is the quotient topological space obtained by making two identifications, i.e., by using an equivalence relation.[1] This involves first identifying the two parallel horizontal edges and subsequently the two vertical edges. We note that the first identification results in a space homeomorphic to the cylinder $S^1\times$**I**, while the second, which is the glueing of two circular edges together, results in the torus. Thus the torus is a polyhedron because of the existence of a triangulation, i.e., an ordered pair consisting of a simplicial complex (whose vertex set consists of the corners of **I**×**I**, i.e., the zero-simplices) and a homeomorphism from the underlying space of the complex to the topological space, the torus. We may note that other triangulations of **I**×**I** result in spaces of physical interest such as the real projective plane $\mathbb{R}P^2$ and the Klein bottle.

We may note that if M and N are C^∞ manifolds and f is a mapping of M into N, then f is called a diffeomorphism of M onto N if f is a one–one differentiable onto mapping and f^{-1} is also differentiable. The group of diffeomorphisms SDiff(D) on a compact Riemannian manifold D, such as the torus, has a subgroup S_0 Diff(D) consisting of volume-preserving diffeomorphisms leaving, for example, the center of mass of the torus fixed. This infinite-dimensional group, S_0 Diff(T^2) to be specific, was first studied by Arnold[2] in his research in hydrodynamics in which the aforementioned group is the configuration space of an ideal fluid filling the torus. This group corresponds to the Lie algebra on the torus of vector fields having zero divergence and such that the stream function is single valued. If one thinks of the elements of the Lie algebra as real-valued functions having zero as average value on the torus, and denotes, for simplicity, the Lie algebra of local area-preserving diffeomorphisms by sdiff(T^2)$_{\rm loc}$, such functions can be specified by their Fourier components.

Central extensions will be discussed in Sec. II. However, it was Schur[3] who first investigated the notion of a universal central extension when he was working on finite groups. After the pioneering work of Arnold, SDiff(T^2) manifested itself as the residual symmetry on relativistic two-dimensional membrane surfaces.[4] This residual symmetry of an extended object manifests itself in the light cone guage. The group has as its elements time-independent reparametrizations (with unit Jacobian) of the spatial coordinates φ^a, $a=1,2$, having the form[5,6]

$$\delta\varphi^a=\xi^a$$

[a)]Permanent address: Physics Department, Obáfémi Awólówò University, Ilé-Ifè, Nigeria.

with

$$\partial\xi^a = 0.$$

One of the two classes of solutions of the latter equation comprises local exact solutions having the form

$$\xi^a = \epsilon^{ab}\partial_b\Lambda$$

while the other class consists of global harmonic solutions which correspond to simultaneously closed and coclosed one-forms, and whose finite number is given by the first Betti number b_1 of the manifold. The term Betti number will be explained in Sec. II.

The real functions (modulo a constant), for example, $f(\underline{\varphi}), g(\underline{\varphi})$ where $\underline{\varphi} = (\varphi_1, \varphi_2)$, identified with sdiff($T^2$) on the torus have the Poisson bracket as their Lie bracket:[4,7,8]

$$[f(\underline{\varphi}),\, g(\underline{\varphi})] = \frac{\partial f}{\partial\varphi_1}\frac{\partial g}{\partial\varphi_2} - \frac{\partial f}{\partial\varphi_2}\frac{\partial g}{\partial\varphi_1}.$$

The Lie algebra also has closed forms whose properties are given in Ref. 5. The formulation of a guage theory on SDiff(T^2) involves the introduction of guage fields $A_\mu^{\varphi_1\varphi_2}$, which takes values in sdiff(T^2). If $\mathbf{m} \in \mathbb{Z}^2\backslash\{0\}$, where $\mathbb{Z}$ is the set of all integers, and we employ the basis functions, $Y_m = -i\exp(i\mathbf{m}\underline{\varphi})$, then the commutation relation above involving the Poisson bracket becomes

$$[Y_m,\, Y_n] = \mathbf{m}\times\mathbf{n}Y_{m+n},$$

where $0 \neq \mathbf{m} = (m_1, m_2)$, $\mathbf{m}\times\mathbf{n} = m_1n_2 - n_1m_2$, $Y_m^\dagger = -Y_{-m}$, and $\underline{\varphi} = (\varphi_1, \varphi_2) \in [0, 2\pi]^2$. This new form of the Lie bracket can be viewed as a representation of the unextended Lie algebra.

Since the problem of the universal central extension of the sdiff(T^2) Lie algebra, i.e., of the Lie algebra connected with the two-brane, was solved essentially about six years ago, it is appropriate to mention, albeit in a very terse manner, the direction in which membrane theory has been propagating since then. The group manifold approach to the description of supersymmetric theories pioneered by T. Regge, Y. Ne'eman, R. D'Auria, and P. Frè, among others, exploits the advantages of both the superspace and the x-component formulation to supersymmetry while endeavouring to shy away from their disadvantages.

In Ref. 9 the parallel between superstrings and higher super p-membranes in d dimensions for $d \leqslant 11$ and $p \leqslant 5$ is highlighted. Here a geometric formulation of p-membrane theories results in a manifestly covariant Wess–Zumino term because this term is $(p+1)$-th order in the supersymmetric currents. Thus it was possible to generalize Siegle's reformulation[10] of the Green–Schwartz superstring to higher super p-membranes. Consequently, a super p-membrane theory is found to be associated with every new space–time superalgebra.

In Ref. 11, which parallels the approach in Ref. 12, the consideration of super p-branes is based on a generalized action principle. This approach derives its impetus from the need to unravel the origin and the geometrical meaning of the local fermionic κ-symmetry of super p-branes in the Green–Schwartz formulation, with the ultimate aim of being able to solve the problem of the covariant quantization of superstrings. One of the attempts at finding a solution to this problem is a variant of the twistorlike approach based on a superfield formulation of super p-branes in world superspace. One may also mention that in Ref. 9 extensions are based on the same gamma matrix theories underlying super p-brane theories. In Sec. II, we construct for su(∞), in analogy to the situation in which the affine Lie algebra has an underlying finite-dimensional algebra,[13] the nontrivial universal central extension.

II. THE UNIVERSAL CENTRAL EXTENSION

Central extensions of Lie algebras are discussed in a mathematical language in which such terms as (co)chains, (co)cycles, (co)boundaries, and (co)homology groups keep on recurring. Hence, we will first discuss the concepts from the point of view of singular homology theory,[1] which provides a graphic manner of perceiving these entities. One starts by defining the standard n-simplex Δ^n as the following subset of $\mathbb{R}^{n+1}$

$$\Delta^n=\left\{(x_1,x_2,\ldots,x_{n+1})\in\mathbb{R}^{n+1}\middle|\text{each } x_i\geqslant 0 \quad \text{and } \sum x_i=1\right\}.$$

It is then clear, for example, that Δ^0 is a point, Δ^1 is a closed interval, Δ^2 is a triangle (with interior), while Δ^3 is a (solid) tetrahedron. Linearly ordering the vertices is synonymous with an orientation of $\Delta^n=[e_0,e_1,\ldots,e_n]$. Suppose X is a topological space and Δ^n is the standard n-simplex. Then a singular n-simplex in X is a continuous mapping $\sigma:\Delta^n\to X$. Since Δ^1 is a closed interval which is homeomorphic to $\mathbf{I}$, a one-simplex is essentially a path in X, while Δ^0 is a point in X.

Suppose B is a subset of an additive Abelian group F. Then F is said to be free Abelian with B as basis if the cyclic group generated by each element $b\in B$ is infinite cyclic and F is a direct sum of these infinite cyclic groups for all $b\in B$. Let X be a topological space. Then for $n\geqslant 0$, $S_n(X)$ is defined as the free Abelian group having as basis all singular n-simplices in X, with $S_{-1}(X)\equiv 0$. We call the elements of $S_n(X)$ the singular n-chains in X. For $n>0$, let $\sigma:\Delta^n\to X$ be a continuous mapping. Then its boundary is denoted by $\partial_n\sigma\in S_{n-1}(X)$. Hence, for each $n\geqslant 0$, there exists a unique homomorphism $\partial_n:S_n(X)\to S_{n-1}(X)$ called a boundary operator.

For each topological space X, the following sequence of free Abelian groups and homomorphisms,

$$\cdots\to S_n(X)\overset{\partial_n}{\to}S_{n-1}(X)\to\cdots\to S_1(X)\overset{\partial_1}{\to}S_0(X)\overset{\partial_0}{\to}0,$$

is called a singular complex of X and is denoted by $S_*(X)$. For all $n\geqslant 0$, $\partial_n\partial_{n+1}=0$. The kernel of ∂_n, $\ker\partial_n$, is called the group of all singular n-cycles in X and is denoted by $Z_n(X)$, while the image of ∂_{n+1}, $\operatorname{im}\partial_{n+1}$, is called the group of singular n-boundaries and is denoted by $B_n(X)$. For every $n\geqslant 0$,

$$B_n(X)\subset Z_n(X)\subset S_n(X).$$

By definition, for each $n\geqslant 0$, the nth singular homology group, $H_n(X)$, of a space X is the quotient of the group $Z_n(X)$ by the group $B_n(X)$, i.e.,

$$H_n(X)=Z_n(X)/B_n(X)=\ker\partial_n/\operatorname{im}\partial_{n+1}$$

In the language of categories and functors, each homology group $H_n(X)$ is, in fact, the (homology) functor from the category of all topological spaces to the category of all Abelian groups. Suppose X and Y are homeomorphic topological spaces. Then $H_n(X)$ is isomorphic to $H_n(Y)$ as groups for all $n\geqslant 0$. Since $H_n(X)$ is now an invariant of the topological space X, the rank of $H_n(X)$, i.e., the cardinality of $H_n(X)$, becomes an invariant of X for each $n\geqslant 0$, and is called the nth Betti number of X.

It was shown in Ref. 14 that there are only two inequivalent su(∞) algebras, to which the local area-preserving algebras on the sphere and on the torus were shown in Ref. 5 to correspond. The Lie algebra sdiff(T^2) corresponds to letting the Dynkin diagram of A_l, whose compact real form is su$(l+1)$, simultaneously approach infinity at both ends. The corresponding Lie algebra su(∞),

unlike $\mathrm{su}_+(\infty)$ which corresponds to sdiff(S^2) where S^2 is the two-sphere, admits a central extension. In the theory of completely integrable systems, central extensions of affine Lie algebras of infinite rank play a prominent role.

If $\mathscr{G}$ is a Lie algebra, a central extension $\mathbf{E}$ of $\mathscr{G}$ by M is the short exact sequence[13]

$$0 \to M \xrightarrow{i} \mathbf{E} \xrightarrow{\pi} \mathscr{G} \to 0$$

such that M is in the center of $\mathbf{E}$. By the definition of a short exact sequence, the image of the mapping i (which is an injection) equals the kernel of the mapping π (which is a surjection). We note that in the extension of $\mathscr{G}$ by a $\mathscr{G}$-module M given by the above short exact sequence, M becomes a $\mathscr{G}$-module by setting, for each $g \in \mathscr{G}$ and $m \in M$,

$$gm = [\tilde{g}, m],$$

which is an element of $\mathscr{G}$ such that $\pi(\tilde{g}) = g$

In defining the universal central extension of a Lie algebra $\mathscr{G}$ one first notes that if

$$0 \to M' \xrightarrow{i'} \mathbf{E}' \xrightarrow{\pi'} \mathscr{G} \to 0$$

is another central extension, then a homomorphism over $\mathscr{G}$ from $\mathbf{E}$ to this second extension is a mapping $f: \mathbf{E} \to \mathbf{E}'$ such that $\pi = \pi' f$. Then $\mathbf{E}$ is a universal central extension if a unique homomorphism $f: \mathbf{E} \to \mathbf{E}'$ exists for every central extension $\mathbf{E}'$ of $\mathscr{G}$.

A Lie algebra is said to be perfect if it is equal to its derived algebra. In the finite-dimensional situation, it is well known that the classical Lie algebras A, B, C, D are perfect in this sense. If $K[t, t^{-1}]$ is the associative algebra of finite linear combinations of integral powers of t, and $\mathscr{G}$ is a finite-dimensional Lie algebra, the space $\mathscr{G} \otimes_K K[t, t^{-1}]$ is given a Lie algebra structure by the Lie bracket

$$[x \otimes t^m, y \otimes t^n] = [x, y] \otimes t^{m+n}, \quad x, y \in \mathscr{G}, \quad m, n \in \mathbb{Z}.$$

Hence the elements of this algebra are the Laurent polynomials $\Sigma x_i t^i$ with $x_i \in \mathscr{G}$, $m, n \in \mathbb{Z}$. If $U\mathscr{G}'$ is the universal enveloping algebra of $\mathscr{G}'$ (i.e., the tensor algebra quotiented by a two-sided ideal), the Chevalley–Eilenberg complex is $V_*(\mathscr{G}' \otimes_K K[t, t^{-1}])$ and equals $V_*(\mathscr{G}') \otimes_K K[t, t^{-1}]$. In the untwisted affine Lie algebra $\mathscr{G}$ corresponding to the limit as $l \to \infty$ of $\mathrm{su}(l+1)$ that we are considering, the Chevalley–Eilenberg complex still decomposes as

$$V_*(\mathscr{G}' \otimes_K K[t, t^{-1}]) = V_*(\mathscr{G}') \otimes_K K[t, t^{-1}].$$

If the sequence of homology groups similarly decomposes, i.e., if we have $H_*(\mathscr{G}' \otimes_K K[t, t^{-1}]) = H_*(\mathscr{G}', K) \otimes_K K[t, t^{-1}]$, we will be able to prove that the affine Lie algebra is perfect.

With $\kappa: \mathscr{G}' \times \mathscr{G}' \to K$ being the Killing form on $\mathscr{G}'$, the form

$$\beta\left(\sum x_i t^i, \sum x_j t^j \right) = \sum i \kappa(x_i, y_i)$$

is bilinear and alternating and therefore a cochain. If δ is the cohomology boundary operator, we have to show that the corresponding three-cochain is mapped to zero by δ by using the invariance $\beta(x, [yz]) = \beta([xy], z)$ of the Killing form. In fact, by substituting $x = \Sigma x_i t^i$, $y = \Sigma y_j t^j$, and $z = \Sigma z_k t^k$, one finds that

$$\delta\beta(x, y, z) = -\beta([xy], z) + \beta([xz], y) - \beta([yz], x) = 0.$$

This implies that the class $[\beta]$ of all two-cocycles is an element of $H^2(\mathscr{G}'\otimes_K K[t,t^{-1}],K)$ with the following corresponding central extension:

$$0\to K\to \hat{\mathscr{G}}'\overset{\pi}{\to}\mathscr{G}'\otimes_K K[t,t^{-1}]\to 0.$$

To show that $\hat{\mathscr{G}}'$ is perfect, one starts with the exact sequence immediately above, and considers the vector space splitting σ of π corresponding to the two-cocycle β. Thus π has a Lie algebra section σ such that $\mathscr{G}'\otimes_K K[t,t^{-1}]\overset{\sigma}{\to}\hat{\mathscr{G}}'$. This vector space splitting enables us to show that $\hat{\mathscr{G}}'$ is perfect, by showing that $[\hat{\mathscr{G}}',\hat{\mathscr{G}}']$ maps onto $\hat{\mathscr{G}}'$, which itself is perfect.

If $K=\mathbb{C}$, there is an element $c\in\mathbb{C}$, such that the short exact sequence immediately above is an extension of $\mathscr{G}'\otimes_K K[t,t^{-1}]$. The universal central extension is the direct sum of $c\mathbb{C}$ and $\mathscr{G}'\otimes_K K[t,t^{-1}]$, and corresponds to the central extension which is a sum of simple coroots in Ref. 14.

ACKNOWLEDGMENTS

I have had the great priviledge of participating in the recent Summer Schools in High Energy Physics and Cosmology held at the International Centre for Theoretical Physics, and in the course of which I was introduced to some of the modern developments in High Energy Physics. I am therefore grateful to S. Randjbar-Daemi, J. Strathdee, E. Gava, K. Narain, Q. Shafi, and other organizers of the schools for this opportunity. I would like to thank both the President and the Director of ICTP, Professors Abdus Salam and M. A. Virasoro, respectively, for hospitality at the Centre, and the Swedish Agency for Research Cooperation with Developing Countries (SAREC) for financial support as an Associate Member of the Centre. Finally, I would like to thank A. R. Shastri and especially G. O. S. Ekhaguere for useful discussions.

Identifying conical singularities

(Received 16 February 1996; accepted for publication 19 June 1996)

A method based upon the concept of holonomy of a metric space–time (M,g), in order to identify the presence of conical singularities in M is proposed. The validity and usefulness of this so-called holonomy method is proven by applying it to a set of four-dimensional space–times and one three-dimensional space–time. The holonomy method predictions are confirmed by the comparison with the predictions obtained after coordinate transformations which take the metrics g, to a new basis where the global properties of conical singularities are explicitly seen. © *1996 American Institute of Physics.* [S0022-2488(96)03209-4]

I. INTRODUCTION

Conical singularities have been known to physicists for a long time.[1] During the 60's and 70's, when a great deal of work was done to understand and classify all types of singularities, the properties and geometrical nature of the conical singularities became better understood (for a review on the results in singularities see Ref. 2).

From these works, we learned that for a space–time M with a metric tensor $g(M,g)$, if there is a conical singularity in M, all scalars formed out of the Riemann tensor are bounded in M, and the presence of this singularity can only be revealed by means of a global procedure.[2] Because of the good behavior of the scalars mentioned above, the conical singularities belong to a type of singularities called quasiregular singularities.[2,3] A more recent interest in conical space–times developed after two important results; the first due to Kibble, and the second to Vilenkin.

Kibble showed in Ref. 4, that the mechanisms of symmetry breaking and symmetry restoration in gauge theories, necessarily, led to the formation of topological defects in the early universe. Among the possible types of defects are the cosmic strings. Inspired by Kibble's ideas Vilenkin demonstrated, among other things in Ref. 5, that the space–time geometry due to a static, infinite, unidimensional string, with a finite linear energy density, in the weak field approximation, is a conical space–time.

Cosmic strings have attracted greater attention than the other types of defects not only because the others have some undesirable properties,[6] but by their own observable effects.[7] Among these effects one may mention the gravitational lensing of light from distant galaxies or quasars, a significant effect on the motion of massive particles, frequency shifts of photons passing by the string and its possible role in the mechanism of galaxy formation (see Ref. 7 for a complete list of observable effects).

From the above discussion one can conclude that conical singularities are very important either on a more formal study of the space–time structure as well as in processes in the early universe leading to presently observable phenomena. One very proper question, at this stage, would be how to identify the presence of conical singularities in a given metric space–time. In fact, there is not a general method of determining whether a metric space–time (M,g), has a conical singularity or not.

[b)]Present address.

0022-2488/96/37(9)/4716/8/$10.00

What one usually does, in order to identify the conical singularity in (M,g), is determining whether one of the angular variables, in g, which by definition would vary in the range $[0,2\pi]$ has its range reduced.[8] The amount which is missing to complete 2π is called deficit angle. If a given space–time has a singular point and all the properties of a conical space–time, as described above,[2] but all the relevant angular variables have their normal range, one may try to find a coordinate transformation which reveals the presence of a deficit angle in one of these angular variables range,[9] or construct a particular demonstration of the regularity, or not, of the metric space–time under investigation.[10]

In this paper we would like to propose a method of identifying if a given metric space–time, singular in one point, and with all the properties of a conical space–time, is indeed a conical space–time. This method will use the concept of holonomy group of a space–time (therefore we shall call it holonomy method), and the global and local properties of a conical singularity.

In the next section, Sec. II, we shall introduce the holonomy method. Sec. III is devoted to the application of the holonomy method to four-dimensional space–times which are known to be conical space–times. In Sec. IV, we investigate a three-dimensional metric space–time with a conical singularity which cannot be trivially identified unless we use the holonomy method. Finally, in Sec. V, we conclude by outlining the main results of the paper and commenting on other applications of the holonomy method.

II. DESCRIPTION OF THE HOLONOMY METHOD

Our method will be based in the application of the concept of holonomy,[11] to the space–time being studied. The holonomy group of a space–time M, equipped with a metric g, (M,g) (therefore with an affine connection Γ), is defined as the linear transformations from the tangent space at the point p, T_pM, to itself, constructed by taking a fiducial vector v and parallel transporting it along all closed curves starting and finishing at p. For a space–time, the set of all linear transformations generated by the parallel transport of v along all possible closed curves from p, is called the holonomy group of M at p. In fact, we shall not be interested in computing the holonomy group of the given space–time but we shall use this concept in a related way.

Suppose that the metric g of M is apparently singular at a point s, and all scalars formed out of the Riemann curvature are well behaved in M. Then, for a fiducial vector v in M, we shall evaluate the transformation generated by the parallel transport of v around closed loops. This transformation is a matrix which we call holonomy matrix (H), its elements are functions of the coordinates. For a point p belonging to a closed loop C, both in M, the holonomy matrix at p, and around C, relates the initial value of v at T_p with the value of v, again at T_p, but now after it has completed a full loop around C. The closed loops are defined in order to converge to the apparently singular point s, of M. The convergence of the loops to s is specified by a certain limit of the coordinates describing these loops.

Now, after having computed the holonomy matrix we apply to it the same limit of the coordinates which cause the closed loops to converge to the apparently singular point s. Then, if the point s is regular, the limit of the holonomy matrix defined by the parallel transport of the fiducial vector v around closed loops must be the identity matrix. In other words, the limit of the initial and final values of the vector v at s must be the same. If this is not the case, the space–time is non-regular at s, or it has a conical singularity.

Let us now apply this method to two different types of space–times: The first is composed of space–times where one may trivially identify the presence of conical singularities; the second is a space–time with a conical singularity which cannot be trivially identified unless we use the holonomy method.

III. APPLICATION TO CONICAL SPACE–TIMES

We shall consider here a set of three four-dimensional space–times with a conical singularity. Although we shall treat them together because of their similar metric expressions, they have distinct topologies and curvature scalars **R**. The general metric expression is

$$ds^2=\eta\, dt^2+dz^2+dr^2+\mu^2F^2(r)d\theta^2, \tag{1}$$

where $-\infty<t<\infty$, $-\infty<z<\infty$, $r_{\min}<r<r_{\max}$, $0\leqslant\theta\leqslant 2\pi$; μ is a number which is in the range, $0<\mu\leqslant 1$; $F(r)$ is a function of r without numerical coefficients with the property that, $F(r=r_0)=0$ for a $r_0\in[r_{\min},r_{\max}]$; η may be either -1, which means a Lorentzian signature, or $+1$, which means an Euclidean signature; and the range of r depends on which space–time we are considering. Some remarks are now in order.

It is important to note that the angular variable must vary over the full range $[0,2\pi]$, otherwise we would identify the presence of a conical singularity by inspection. If μ was allowed to be greater than one, after a coordinate transformation of the type

$$\mu\theta\rightarrow\tilde{\theta}, \tag{2}$$

the new angular variable $\tilde{\theta}$ would vary in the range

$$0<\tilde{\theta}<2\pi\mu. \tag{3}$$

This means that we would not be able to talk about deficit angle in a natural way, besides that for this case the space changes character and the description becomes more complicated.[9]

The three distinct space–times will be characterized by different values of the function $F(r)$.[12] We shall compute for each of them the curvature scalar **R**, which for the generic form of the metric (1) is

$$\mathbf{R}=-\frac{F''(r)}{F(r)}, \tag{4}$$

where $'$ means derivation in respect to r.

For each space–time we may list the relevant properties in the following way:
Space–time (a): Topology $\Re^2\times S^2$; $F(r)=\sin r$; $0<r<2\pi$; $\mathbf{R}=1$,
Space–time (b): Topology $\Re^3\times S^1$; $F(r)=r$; $0<r<\infty$; $\mathbf{R}=0$,
Space–time (c): Topology $\Re^2\times H^2$; $F(r)=\sinh r$; $-\infty<r<\infty$; $\mathbf{R}=-1$.

One may note by the above properties of (a), (b), and (c), that they have well behaved scalar curvatures **R** (it is easy to verify that the same is true for other scalars formed out of the Riemann tensor) and an apparent singularity at $r=0$. Indeed, by means of the transformation (2) it is very easy to identify the presence of conical singularities in these space–times. By eq. (3) it is clear that, if $\mu=1$ the space–times are regular, otherwise they have conical singularities with deficit angles $2\pi(1-\mu)$. Let us see, now, how to apply the holonomy method to the above space–times (1).

We start by computing the holonomy matrix H, which can only be done when we have the parallel transport equations. The easiest way to derive them, from Eq. (1), is by working on the orthonormal basis, defined by the transformations

$$w^i=dx_i;\quad w^{\hat{\theta}}=\mu F(r)d\theta, \tag{5}$$

where $x_{0,1,2}=t,z,r$. The non-vanishing connection coefficient components in this basis are

$$-\Gamma^{\hat{r}}_{\hat{\theta}\hat{\theta}}=\frac{F'(r)}{F(r)}=\Gamma^{\hat{\theta}}_{\hat{r}\hat{\theta}}. \tag{6}$$

The general expression for the parallel transport equations of a fiducial vector v, along a given curve is[13]

$$\frac{dv^{\alpha}}{d\lambda}+v^{\beta}\Gamma^{\alpha}_{\beta\gamma}\frac{dx^{\gamma}}{d\lambda}=0, \tag{7}$$

where λ is an affine parameter describing the curve; and the Greek indices vary over all the coordinates.

We must define, now, the closed loops for these cases, as well as the limit which will make them collapsing to the apparently singular point $r=0$. Since the t and z directions do not play important roles in the present cases (the singular point is in the r axis and θ is the unique angular variable), we set them to be constants, independent of λ. For an apparently singular point in r, the simplest closed loops have constant and different values of r, and θ is a non-constant function of λ. These loops will collapse to $r=0$ when we take the limit $r\to 0$. As a matter of simplicity, we choose θ to depend linearly on λ.

Our curves may be written as

$$x_i=C_i, \quad \theta=\lambda+\lambda_0, \tag{8}$$

where λ_0 is a constant and λ varies in the range $[-\lambda_0,-\lambda_0+2\pi]$; C_i are constants and i varies as in eq. (5).

A final remark before writing down the parallel transport equations, is that the set of eqs. (7), for the non-coordinate basis, must be modified such that we may use the closed loops (8) given in the coordinate basis. Then, the new set of equations is written

$$\frac{dv^{\alpha}}{d\lambda}+v^{\beta}\Gamma^{\alpha}_{\beta\gamma}\Lambda^{\gamma}_{\delta}\frac{dx^{\delta}}{d\lambda}=0, \tag{9}$$

where Λ is the basis one-form transformation matrix, also responsible for the transformation of vector components.

We may now write the parallel transport equations (9), for the fiducial vector v, around the closed loop (8), with the aid of eq. (6). They are

$$\frac{dv^{\hat{t}}}{d\lambda}=0=\frac{dv^{\hat{z}}}{d\lambda}, \tag{10}$$

$$\frac{dv^{\hat{r}}}{d\lambda}-\mu F' v^{\hat{\theta}}=0, \tag{11}$$

$$\frac{dv^{\hat{\theta}}}{d\lambda}+\mu F' v^{\hat{r}}=0. \tag{12}$$

The general solution for the system of coupled, linear, homogeneous, first order differential equations (10)–(12), is given by

$$v^{j}(\lambda)=\widetilde{C}_j, \tag{13}$$

$$v^{\hat{r}}(\lambda)=A\ \sin(\alpha\lambda+\delta_0), \tag{14}$$

$$v^{\hat{\theta}}(\lambda)=A\ \cos(\alpha\lambda+\delta_0), \tag{15}$$

where $j=\hat{t},\hat{z}$; $\widetilde{C}_j$, A, δ_0 are constants to be determined by the initial conditions; and $\alpha\equiv\mu F'(r)$.

The initial conditions will be given by

$$v^{\alpha}(\lambda=-\lambda_0)=v_0^{\alpha}, \tag{16}$$

where α varies as in eq. (7); and v_0^{α} are constants. If one imposes these conditions (16) in the eqs. (13)–(15), after some calculations one finds

$$v^{j}(\lambda)=v_0^{j}, \tag{17}$$

$$v^{\hat{r}}(\lambda)=\cos[\alpha(\lambda+\lambda_0)]v_0^{\hat{r}}+\sin[\alpha(\lambda+\lambda_0)]v_0^{\hat{\theta}}, \tag{18}$$

$$v^{\hat{\theta}}(\lambda)=-\sin[\alpha(\lambda+\lambda_0)]v_0^{\hat{r}}+\cos[\alpha(\lambda+\lambda_0)]v_0^{\hat{\theta}}, \tag{19}$$

where j varies as in eq. (13). We may now write the holonomy matrix which relates the initial value of the fiducial vector v, with its value after a complete loop around the closed loop. It is achieved by setting $\lambda=-\lambda_0+2\pi$ in eqs. (17)–(19)

$$v(-\lambda_0+2\pi,\alpha)=H(\alpha)v_0, \tag{20}$$

where

$$H(\alpha)=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \cos(2\pi\alpha) & \sin(2\pi\alpha) \\ 0 & 0 & -\sin(2\pi\alpha) & \cos(2\pi\alpha) \end{pmatrix}. \tag{21}$$

Before we proceed, it is important to note that H is independent of η, or in other words, it is independent of the metric signature. One may use, then, this method for Lorentzian or Euclidean space–times.

It is clear from eq. (21) that $H(\alpha)$ is not, in general, the identity transformation, not even in the case of a regular space–time. This fact is only a verification that the space–time has a non-vanishing curvature. For space–times (a) and (c) one may verify this fact, for they have constant positive and negative scalars of curvature, but not for space–time (b) which is flat. The final step in our present analysis, is the evaluation of $H(\alpha)$ (21) in the limit when r goes to 0.

The relevant components of the holonomy matrix to be analyzed are

$$\cos(2\pi\alpha) \quad \text{and} \quad \sin(2\pi\alpha). \tag{22}$$

We must, now, take the limit of these quantities (22), when r goes to 0. It is not difficult because for all three space–times (a), (b) and (c), the desired limit of the first derivative of $F(r)$ is the same

$$\lim_{r\to 0} F'(r)=1. \tag{23}$$

So, once $\alpha=\mu F'(r)$, we obtain the following limit as $r\to 0$ to the relevant quantities (22):

$$\cos(2\pi\mu) \quad \text{and} \quad \sin(2\pi\mu). \tag{24}$$

We may conclude that the space–time is regular, or in other words the holonomy matrix goes to the 4×4 identity in this limit, if and only if $\mu=1$, otherwise there is a conical singularity in these space–times. This is the same result stated above and derived by a trivial coordinate transformation in the angular coordinate θ.

IV. APPLICATION TO THE DJH CONICAL SPACE–TIME

This space–time was introduced by Deser, Jackiw, and 't Hooft (DJH), as a solution of Einstein's equations for a single, massive, spinless point-particle, at rest, at the origin of the coordinate system, in three-dimensions (time+2 spatial dimensions).[9] Its metric is given by

$$ds^2=-dt^2+\frac{1}{R^{2\rho}}\,(dR^2+R^2d\Theta^2), \tag{25}$$

where $0\leqslant t\leqslant\infty$, $0\leqslant R\leqslant\infty$, $0\leqslant\Theta\leqslant2\pi$; and ρ is proportional to the mass of the particle and varies in the range $0\leqslant\rho<1$.

It is easy to see from eq. (25) that $R=0$ is an apparent singularity of this space–time, and after a brief calculation one finds that its scalar of curvature **R** is nil. Gathering together these two results we conclude that it is very likely that the apparent singularity at $R=0$ is of a conical type. How can we know beyond any doubt? In what follows we shall apply the holonomy method to this space–time (25), and compare its result with the one derived in Ref. 9 from a non-trivial coordinate transformation.

We start the application of the holonomy method by rewriting eq. (25) in a non-coordinate basis, which coordinate transformations read

$$w^{\hat{t}}=dt;\quad w^{\hat{R}}=R^{-\rho}dR;\quad w^{\hat{\theta}}=R^{1-\rho}d\Theta. \tag{26}$$

The non-vanishing connection coefficient components in this basis are

$$\Gamma^{\hat{t}}_{\hat{\phi}\hat{\phi}}=\frac{-(1-\rho)}{t^{1-\rho}}=-\Gamma^{\hat{\phi}}_{\hat{t}\hat{\phi}}. \tag{27}$$

From here onward the calculations will be a repetition of the previous case, discounting the obvious fact that we have, now, one less spatial coordinate. The closed loops will be defined by constant values of t and R and a linear function of Θ, which may be written as

$$x_i=C_i,\quad \Theta=\lambda+\lambda_0, \tag{28}$$

where $x_{0,1}=t,R$; C_i and λ_0 are constants; and λ is an affine parameter describing the closed loop, which varies in the range $[-\lambda_0,-\lambda_0+2\pi]$. These loops will collapse to the apparently singular point when we take the limit $R\to0$.

The initial conditions for the fiducial vector v, which will be parallel transported around the closed loops, are given by eq. (16) (where here $\alpha=t,R,\Theta$). With these conditions eq. (16), and the aid of eq. (28), we may write and solve the parallel transport equations for v, derived from eq. (9). After some calculations we may write the holonomy matrix $H(\rho)$, for the present case, in the following way:

$$H(\rho)=\begin{pmatrix}1 & 0 & 0\\ 0 & \cos[2\pi(1-\rho)] & \sin[2\pi(1-\rho)]\\ 0 & -\sin[2\pi(1-\rho)] & \cos[2\pi(1-\rho)]\end{pmatrix}. \tag{29}$$

Observing eq. (29) carefully, we note that it is already the final result we were looking for because $H(\rho)$ does not depend upon R. Therefore, the limit of $H(\rho)$ when R goes to zero does not modify eq. (29).

The holonomy method predicts, then, that if $\rho=0$ the space–time (25) is regular, otherwise there is a conical singularity in it. Let us compare, now, this prediction with the one derived from a non-trivial coordinate transformation.

In Ref. 9, Deser, Jackiw, and 't Hooft, proposed the following coordinate transformation for the metric (25)

$$r=\frac{R^{1-\rho}}{1-\rho}, \quad \theta=(1-\rho)\Theta. \tag{30}$$

In terms of r and θ the metric (25) becomes flat

$$ds^2=-dt^2+dr^2+r^2d\theta^2. \tag{31}$$

The ranges of the new variables may be derived by eq. (30), with the aid of the ranges of the old ones, which were given after eq. (25). They are

$$0\leqslant r\leqslant\infty, \quad 0\leqslant\theta\leqslant 2\pi(1-\rho). \tag{32}$$

V. CONCLUSIONS

In the present paper we have introduced what we have called the holonomy method. It is a systematic way, based upon the concept of holonomy, of determining the presence of conical singularities in a given metric space–time (M,g). In Sec. II, we have introduced the holonomy method. Subsequently, in Secs. III and IV, we have demonstrated the validity and usefulness of the method by means of its application in two examples.

It is important to mention that the results derived from the application of the holonomy method for a given metric space–time (M,g), may be used to analyze another metric space–time $(\widetilde{M},\widetilde{g})$. This can be done only and if only g and $\widetilde{g}$ are related by a non-singular basis one-form transformation S, because the old and new holonomy matrices (H and $\widetilde{H}$ respectively) will have the following transformation relation:

$$\widetilde{H}=SHS^{-1}. \tag{33}$$

Therefore, knowing the value of H for a given one-form basis one has only to determine the values of the transformation S, and its inverse S^{-1}, in order to derive the holonomy matrix in the new one-form basis $\widetilde{H}$.

Finally, there is yet another type of metric space–times where the use of the holonomy method greatly simplifies the identification of conical singularities. These d-dimensional space–times have the topology $\mathfrak{R}$ (time) times a flat or negatively curved, $d-1$-dimensional, compact spatial sector. The compactification of the spatial sector is done via the identification of opposite $d-2$-dimensional ''sides'' of a chosen figure.[10,12,14] It is possible that such identifications introduce a singularity of a conical, or even more complicate nature in the resulting space–time.[10,14] Therefore, applying the holonomy method to space–times constructed in this way, one may identify the presence of conical singularities there.

Quasitriangularity and enveloping algebras for inhomogeneous quantum groups

P. Podleś[a)]
Department of Mathematics, University of California, Berkeley, California 94720

(Received 7 November 1995; accepted for publication 15 April 1996)

Coquasitriangular universal $\mathscr{R}$ matrices on quantum Lorentz and quantum Poincaré groups are classified. The results are extended (under certain assumptions) to inhomogeneous quantum groups. Enveloping algebras on those objects are described. © *1996 American Institute of Physics.* [S0022-2488(96)01508-3]

I. INTRODUCTION

Possible R-matrices for the fundamental representations of inhomogeneous quantum groups were found in Proposition 3.14 of Ref. 1. In the present paper we describe universal $\mathscr{R}$ matrices for those objects (under certain assumptions which are fulfilled in the case of quantum Poincaré groups[2]). Our study will be useful in developing a simple physical model[3] of free particles on a quantum Minkowski space.[2]

In Section II we show how to construct co(quasi)triangular (*-)bialgebras and Hopf (*-)algebras whose relations are given by means of intertwiners: we simplify and extend results of Ref. 4. Next, in Section III we classify co(quasi)triangular (*-)structures $\mathscr{R}$ on quantum Lorentz groups.[5] Using the results of Sections II and III, in Section IV we classify such structures on quantum Poincaré groups[2] and also, more generally, on inhomogeneous quantum groups[1] (certain natural assumptions regarding mainly restriction of those structures to the homogeneous quantum group are made). In Section V we use $\mathscr{R}$ to define enveloping algebras for inhomogeneous quantum groups.

We sum over repeated indices (Einstein's convention). We work over the field $\mathbf{C}$. We write $a\sim b$ if $a=\lambda b$ for $\lambda\in\mathbf{C}\backslash\{0\}$. If V,W are vector spaces, then τ: $V\otimes W\to W\otimes V$ is given by $\tau(x\otimes y)=y\otimes x$, $x\in V$, $y\in W$. If $\mathscr{A}$ is an algebra, $v\in M_N(\mathscr{A})$, $w\in M_K(\mathscr{A})$, then the tensor product $v\otimes w\in M_{NK}(\mathscr{A})$ is defined by $(v\otimes w)_{ij,kl}=v_{ik}w_{jl}$, $i,k=1,\ldots,N$, $j,l=1,\ldots,K$. We set $\dim v=N$. If $\mathscr{A}$ is a *-algebra, then the conjugate of v is defined as $\overline{v}\in M_N(\mathscr{A})$ where $\overline{v}_{ij}=v_{ij}{}^*$, $i,j=1,\ldots,N$.

Throughout the paper quantum groups H are abstract objects described by the corresponding (*-)bialgebras $\mathrm{Poly}(H)=(\mathscr{A},\Delta)$. We denote by Δ,ε,S the comultiplication, counit and (if exists) coinverse of $\mathrm{Poly}(H)$. We say that v is a representation of H (i.e., $v\in\mathrm{Rep}\,H$) if $v\in M_N(\mathscr{A})$, $N\in\mathbf{N}$, and $\Delta v_{ij}=v_{ik}\otimes v_{kj}$, $\varepsilon(v_{ij})=\delta_{ij}$, $i,j=1,\ldots,N$. The conjugate of a representation and tensor product of representations are also representations. Matrix elements of representations of H span $\mathscr{A}$ as a linear space. The set of nonequivalent irreducible representations of H is denoted by $\mathrm{Irr}\,H$. If v, $w\in\mathrm{Rep}\,H$, then we say that $A\in M_{\dim w\times\dim v}(\mathbf{C})$ intertwines v with w [i.e., $A\in\mathrm{Mor}(v,w)$] if $Av=wA$. The dual vector space $\mathscr{A}'$ is an algebra wrt the convolution defined by $\rho*\rho'=(\rho\otimes\rho')\Delta$. It has a unit $I_{\mathscr{A}'}=\varepsilon$. For $\rho\in\mathscr{A}'$, $a\in\mathscr{A}$, we set $\rho*a=(id\otimes\rho)\Delta a$, $a*\rho=(\rho\otimes id)\Delta a$.

II. COQUASITRIANGULAR BIALGEBRAS

In this section we discuss bialgebras $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ defined by several fundamental representations of G and intertwiners among them. We provide necessary and sufficient conditions for

[a)]On leave from Department of Mathematical Methods in Physics, Faculty of Physics, University of Warsaw, Hoża 74, 00-682 Warszawa, Poland.

0022-2488/96/37(9)/4724/14/$10.00

the existence of coquasitriangular structure $\mathscr{R}$ for G. Hopf and $*$ structures are also investigated. The results generalize results of Theorem 1.4 of Ref. 4 (see also Theorem 1.1 of Ref. 5).

Proposition 1: Let $\mathscr{B}$ be the universal algebra generated by w^{α}_{mn}, $m,n=1,\ldots,d_{\alpha}$, $\alpha\in\mathscr{J}$, and relations ($0\in\mathscr{J}$, $d_0=1$)

$$w^{\alpha}\otimes w^{0}=w^{0}\otimes w^{\alpha}=w^{\alpha},\quad \alpha\in\mathscr{J}, \tag{II.1}$$

$$W_m(w^{\alpha_{m1}}\otimes w^{\alpha_{m2}}\otimes\cdots\otimes w^{\alpha_{ms_m}})=(w^{\beta_{m1}}\otimes\cdots\otimes w^{\beta_{mt_m}})W_m,\quad m\in K \tag{II.2}$$

(we fix sets $\mathscr{J}$, K, positive integers d_{α}, and matrices W_m of suitable dimensions).

Then $w^{0}=(I_{\mathscr{B}})$ and there exists a unique Δ such that $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ is a bialgebra and w^{α}, $\alpha\in\mathscr{J}$ are representations of G.

Proof: The proof is the same as in Theorem 1.4 of Ref. 4. □

Let us recall

Definition 1: (cf. Refs. 6–8) We say that $(\mathscr{B},\Delta,\mathscr{R})$ is a coquasitriangular (CQT) bialgebra if $(\mathscr{B},\Delta)$ is a bialgebra and $\mathscr{R}\in(\mathscr{B}\otimes\mathscr{B})'$ satisfies

$$\mathscr{R}(I\otimes x)=\mathscr{R}(x\otimes I)=\varepsilon(x), \tag{II.3}$$

$$\mathscr{R}(xy\otimes z)=\mathscr{R}(x\otimes z^{(1)})\mathscr{R}(y\otimes z^{(2)}), \tag{II.4}$$

$$\mathscr{R}(x\otimes yz)=\mathscr{R}(x^{(1)}\otimes z)\mathscr{R}(x^{(2)}\otimes y), \tag{II.5}$$

$$y^{(1)}x^{(1)}\mathscr{R}(x^{(2)}\otimes y^{(2)})=\mathscr{R}(x^{(1)}\otimes y^{(1)})x^{(2)}y^{(2)}, \tag{II.6}$$

where we have used the Sweedler's notation $\Delta(x)=x^{(1)}_i\otimes x^{(2)}_i\equiv x^{(1)}\otimes x^{(2)}$.

Remark 1: (cf. Refs. 9, 8, and Proposition 1.3 of Ref. 4) Let $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ be a bialgebra and $\mathscr{R}\in(\mathscr{B}\otimes\mathscr{B})'$. For each v, $w\in\mathrm{Rep}\,G$ one can define $R^{vw}\in\mathrm{Lin}(\mathbf{C}^{\dim v}\otimes\mathbf{C}^{\dim w},\mathbf{C}^{\dim w}\otimes\mathbf{C}^{\dim v})$ by

$$(R^{vw})_{ij,kl}=\mathscr{R}(v_{jk}\otimes w_{il}),\quad j,k=1,\ldots,\dim v,\quad i,l=1,\ldots,\dim w. \tag{II.7}$$

Then

$$(\mathbb{1}\otimes S)R^{v_1w}=R^{v_2w}(S\otimes\mathbb{1})\quad \text{if } S\in\mathrm{Mor}(v_1,v_2), \tag{II.8}$$

$$(S\otimes\mathbb{1})R^{vw_1}=R^{vw_2}(\mathbb{1}\otimes S)\quad \text{if } S\in\mathrm{Mor}(w_1,w_2), \tag{II.9}$$

v,w,v_1, $w_1\in\mathrm{Rep}\,G$. Suppose that $L\subset\mathrm{Rep}\,G$ is such that the matrix elements of representations $v\in L$ linearly span $\mathscr{B}$ (e.g., $L=\mathrm{Rep}\,G$). Consider the conditions

$$R^{0v}=R^{v0}=\mathbb{1},\quad v\in L, \tag{II.10}$$

$$R^{v_1\otimes v_2,w}=(R^{v_1w}\otimes\mathbb{1})(\mathbb{1}\otimes R^{v_2w}),\quad v_1,v_2,w\in L, \tag{II.11}$$

$$R^{v,w_1\otimes w_2}=(\mathbb{1}\otimes R^{vw_2})(R^{vw_1}\otimes\mathbb{1}),\quad v,w_1,w_2\in L, \tag{II.12}$$

$$R^{vw}\in\mathrm{Mor}(v\otimes w,w\otimes v),\quad v,w\in L. \tag{II.13}$$

Then (II.10)⇔(II.3), (II.11)⇔(II.4), (II.12)⇔(II.5), and (II.13)⇔(II.6).

Theorem 1: Let $\mathrm{Poly}\,(G)=(\mathscr{B},\Delta)$ be a bialgebra defined in Proposition 1 and $R^{\alpha\beta}\in\mathrm{Lin}(\mathbf{C}^{d_\alpha}\otimes\mathbf{C}^{d_\beta},\mathbf{C}^{d_\beta}\otimes\mathbf{C}^{d_\alpha}),\alpha,\beta\in\mathscr{J}$.

The following are equivalent:

(1) There exists $\mathscr{R}\in(\mathscr{B}\otimes\mathscr{B})'$ such that $(\mathscr{B},\Delta,\mathscr{R})$ is a CQT bialgebra and $R^{\alpha\beta}=R^{w^{\alpha}w^{\beta}}$.

(2)

$$R^{0\alpha}=R^{\alpha 0}=\mathbb{1}, \quad \alpha\in\mathscr{J}, \tag{II.14}$$

$$(\mathbb{1}\otimes W_m)R^{\alpha_{m1}\cdot\ldots\cdot\alpha_{ms_m},\gamma}=R^{\beta_{m1}\cdot\ldots\cdot\beta_{mt_m},\gamma}(W_m\otimes\mathbb{1}), \quad m\in K,\gamma\in\mathscr{J}\backslash\{0\}, \tag{II.15}$$

$$R^{\gamma,\beta_{m1}\cdot\ldots\cdot\beta_{mt_m}}(\mathbb{1}\otimes W_m)=(W_m\otimes\mathbb{1})R^{\gamma,\alpha_{m1}\cdot\ldots\cdot\alpha_{ms_m}}, \quad m\in K,\gamma\in\mathscr{J}\backslash\{0\}, \tag{II.16}$$

$$R^{\alpha\beta}\in \mathrm{Mor}(w^\alpha\otimes w^\beta, w^\beta\otimes w^\alpha), \quad \alpha,\beta\in\mathscr{J}\backslash\{0\}, \tag{II.17}$$

where $R^{\delta_1\cdot\ldots\cdot\delta_{k+1},\gamma}=(R^{\delta_1\cdot\ldots\cdot\delta_k,\gamma}\otimes\mathbb{1})(\mathbb{1}\otimes R^{\delta_{k+1}\gamma}), R^{\gamma,\delta_1\cdot\ldots\cdot\delta_{k+1}}=(\mathbb{1}\otimes R^{\gamma\delta_{k+1}})(R^{\gamma,\delta_1\cdot\ldots\cdot\delta_k}\otimes\mathbb{1}), \gamma, \delta_1,\ldots,\delta_{k+1}\in\mathscr{J}$, $k=1,2,\ldots$.

Moreover, such $\mathscr{R}$ is unique.

Remark: In special cases related statements can be found in Refs. 10, 8, 7, and Theorem 1.4 of Ref. 4 (cf. Ref. 9).

Proof: Assume condition (1). According to Remark 1, (II.10)–(II.13) follow. Thus we get (II.14) and (II.17). Using (II.8) and (II.9) for $S=W_m$ [see (II.2)] and (II.11) and (II.12), one obtains (II.15) and (II.16) and the condition (2) is proved.

Moreover, $R^{w^\alpha w^\beta}=R^{\alpha\beta}$ uniquely determine R^{vw}, where $v, w\in L_0$,

$$L_0=\{\text{tensor products of some number of copies of representations } w^\alpha, \quad \alpha\in\mathscr{J}\}.$$

Using (II.7) and the fact that the matrix elements of representations from L_0 linearly span $\mathscr{B}$, the uniqueness of $\mathscr{R}$ follows. It remains to prove

(2)⇒(1): Assume condition (2). Using (II.14), we can replace $\mathscr{J}\backslash\{0\}$ by $\mathscr{J}$ in (II.15)–(II.17). We define the homomorphisms $\mathscr{R}^\beta\colon \mathscr{B}\to M_{d_\beta}(\mathbf{C})$, $\beta\in\mathscr{J}$, by

$$[\mathscr{R}^\beta(w^\alpha_{ij})]_{kl}=R^{\alpha\beta}_{ki,jl}, \quad \alpha\in\mathscr{J} \tag{II.18}$$

[later on we will have $\mathscr{R}^\beta_{kl}=\mathscr{R}(\cdot\otimes w^\beta_{kl})$]. They preserve the relations (II.1) and (II.2) due to (II.14) and (II.15). Setting $\alpha=0$ in (II.18), we show that $\mathscr{R}^\beta$ are unital. Setting $\beta=0$ in (II.18), one gets $\mathscr{R}^0_{11}=\varepsilon$ (it is true on the generators w^α_{ij}). Hence $\mathscr{R}^0_{11}*\mathscr{R}^\beta_{kl}=\mathscr{R}^\beta_{kl}*\mathscr{R}^0_{11}=\mathscr{R}^\beta_{kl}$. Let

$$X=\{x\in\mathscr{B}\colon W_{b_1\ldots b_{t_m},a_1\ldots a_{s_m}}(\mathscr{R}^{\alpha_{ms_m}}_{a_{s_m}c_{s_m}}*\cdots*\mathscr{R}^{\alpha_{m1}}_{a_1c_1})(x)$$

$$=(\mathscr{R}^{\beta_{mt_m}}_{b_{t_m}d_{t_m}}*\cdots*\mathscr{R}^{\beta_{1t_1}}_{b_1d_1})(x)W_{d_1\ldots d_{t_m},c_1\ldots c_{s_m}}, \quad m\in K\}.$$

It is straightforward to show that X is an algebra. According to (II.16), $u^\gamma_{kl}\in X (k,l=1,\ldots,d_\gamma$, $\gamma\in\mathscr{J})$. Thus $X=\mathscr{B}$. Hence there exists a linear antihomomorphism $\theta\colon \mathscr{B}\to\mathscr{B}'$ such that $\theta(w^\beta_{kl})=\mathscr{R}^\beta_{kl}$, $k,l=1,\ldots,d_\beta$, $\beta\in\mathscr{J}$ [θ preserves (II.1) and (II.2)]. Setting $\mathscr{R}(x\otimes y)=[\theta(y)](x)$, $x,y\in\mathscr{B}$, we obtain an $\mathscr{R}\in(\mathscr{B}\otimes\mathscr{B})'$ which satisfies (II.5) and (II.3). Moreover, (II.18) yields $R^{\alpha\beta}=R^{w^\alpha w^\beta}$. Let $Y=\{z\in\mathscr{B}\colon\forall x,y\in\mathscr{B}\ \mathscr{R}(xy\otimes z)=\mathscr{R}(x\otimes z^{(1)})\mathscr{R}(y\otimes z^{(2)})\}$. Then Y is an algebra [we use (II.5)] and $w^\beta_{kl}\in Y$. Hence, $Y=\mathscr{B}$ and (II.4) follows. Thus (Remark 1) we get (II.10)–(II.12) for $L=L_0$. That and (II.13) for $v, w\in\{w^\alpha\colon\alpha\in\mathscr{J}\}$ [see (II.17)] give (II.13) for $L=L_0$, hence (Remark 1) (II.6) and the condition (1) is satisfied. □

Remark 2: The unital antihomomorphism $\theta\colon\mathscr{B}\to\mathscr{B}'$ introduced in the above proof exists for each CQT bialgebra (cf. Ref. 9) and satisfies $(\theta\otimes\theta)\Delta=\Delta'\theta$ where $\Delta'\colon\mathscr{B}'\to(\mathscr{B}\otimes\mathscr{B})'$ is defined by $\Delta'(\varphi)=\varphi\circ m$, $\varphi\in\mathscr{B}'$, cf. Appendix of Ref. 4.

Let us now pass to the Hopf algebra structure.

Proposition 2: (cf. Ref. 11 and Proof of Theorem 1.4.1 of Ref. 4) Let $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ be a bialgebra and w,w',w'' be representations of G. Suppose there exist $E\in\mathrm{Mor}(I,w\otimes w')$,

$E' \in \mathrm{Mor}(w'' \otimes w, I)$ such that E is left nondegenerate, i.e., $E_{i-} = (E_{ij})_{j=1}^{\dim w'}$, $i=1,\ldots,\dim w$, are linearly independent and E' is right nondegenerate, i.e., $E'_{-k} = (E'_{mk})_{m=1}^{\dim w''}$, $k=1,\ldots,\dim w$, are linearly independent. Then w^{-1} exists.

Proposition 3: (cf. Ref. 11 and Proof of Theorem 1.4.1 of Ref. 4) Let $(\mathscr{B},\Delta)$ be the bialgebra defined in Proposition 1. Suppose $(u^{\alpha})^{-1}$ exist, $\alpha \in \mathscr{J}$. Then $(\mathscr{B},\Delta)$ is a Hopf algebra.

A CQT bialgebra $(\mathscr{B},\Delta,\mathscr{R})$ such that $(\mathscr{B},\Delta)$ is a Hopf algebra is called CQT Hopf algebra.

Proposition 4: (cf. Proposition 1.3.1.b of Ref. 4) Let $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ and $(\mathscr{B},\Delta,\mathscr{R})$ be a CQT Hopf algebra. Then $(R^{vw})^{-1}$ exist for any $v, w \in \mathrm{Rep}\, G$. Moreover, $\mathscr{R}'=\mathscr{R}(S\otimes id)$ satisfies

$$\mathscr{R}'(x^{(1)}\otimes y^{(1)})\mathscr{R}(x^{(2)}\otimes y^{(2)})=\mathscr{R}(x^{(1)}\otimes y^{(1)})\mathscr{R}'(x^{(2)}\otimes y^{(2)})=(\varepsilon\otimes\varepsilon)(x\otimes y)$$

(i.e., $\mathscr{R}'=\mathscr{R}^{-1}$) and

$$\mathscr{R}'(v_{il}\otimes w_{jk})=(R^{vw})^{-1}_{ij,kl}, \quad i,l=1,\ldots,\dim v, \quad j,k=1,\ldots,\dim w.$$

We say that $(\mathscr{B},\Delta)$ is a *-bialgebra if $(\mathscr{B},\Delta)$ is a bialgebra, $\mathscr{B}$ is a *-algebra and

$$(*\otimes *)\Delta(x)=\Delta(x^*) \tag{II.19}$$

for $x \in \mathscr{B}$. A Hopf algebra which is a *-bialgebra is called Hopf *-algebra.

Proposition 5: Let $(\mathscr{B},\Delta)$ be the bialgebra defined in Proposition 1. Suppose there exists an involution $\sim: \mathscr{J}\to\mathscr{J}$ such that $\widetilde{0}=0$, $d_{\widetilde{\alpha}} = d_{\alpha}$ and $\widetilde{W}_m \in \mathrm{Mor}(w^{\widetilde{\alpha}_{ms_m}}\otimes\cdots\otimes w^{\widetilde{\alpha}_{m1}}, w^{\widetilde{\beta}_{mt_m}}\otimes\cdots\otimes w^{\widetilde{\beta}_{m1}})$ where $(\widetilde{W}_m)_{i_{t_m}\ldots i_1, j_{s_m}\ldots j_1} = \overline{(W_m)_{i_1\ldots i_{t_m}, j_1\ldots j_{s_m}}}$. Then there exists a unique $*: \mathscr{B}\to\mathscr{B}$ such that $(\mathscr{B},\Delta)$ is a *-bialgebra and $\overline{w^{\alpha}} = w^{\widetilde{\alpha}}$, $\alpha \in \mathscr{J}$ ($\overline{\ }$ was defined in the Introduction).

Proof: Uniqueness is trivial. Our assumptions imply that $z^{\alpha}_{ij} = w^{\widetilde{\alpha}}_{ij}$ satisfy (II.1) and (II.2) in the conjugate algebra $\mathscr{B}^j$ (conjugate vector space and opposite multiplication). Therefore the desired $*$ exists [we check $*^2=id$ and (II.19) on the generators w^{α}_{ij}]. □

Proposition 6: (cf. the proofs of Proposition 1.3.d.ii and Theorem 1.4.6 of Ref. 4) Let $(\mathscr{B},\Delta,\mathscr{R})$ be a CQT bialgebra and $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ be a *-bialgebra. Suppose $M\subset\mathrm{Rep}\, G$ is such that the matrix elements of representations from M generate $\mathscr{B}$ as unital algebra. The following are equivalent:

(1) $\overline{\mathscr{R}(y^*\otimes x^*)}=\mathscr{R}(x\otimes y), \quad x,y\in\mathscr{B}$

(2)

$$\overline{(R^{\overline{vw}})_{ji,lk}}=R^{vw}_{ij,kl}, \quad j,k=1,\ldots,\dim v, \quad i,l=1,\ldots,\dim w, \quad v,w\in M. \tag{II.20}$$

If one of the above conditions is satisfied, $(\mathscr{B},\Delta,\mathscr{R})$ is called CQT *-bialgebra. If, moreover, $(\mathscr{B},\Delta)$ is a Hopf algebra, $(\mathscr{B},\Delta,\mathscr{R})$ is called CQT Hopf *-algebra (see Definition 1.1 of Ref. 4).

Proposition 7: (cf. Ref. 9) Let $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ be a bialgebra and $\mathscr{R}\in(\mathscr{B}\otimes\mathscr{B})'$. Suppose $M\subset\mathrm{Rep}\, G$ is such that the matrix elements of representations from M generate $\mathscr{B}$ as unital algebra. The following are equivalent:

(1) $\mathscr{R}(x^{(1)}\otimes y^{(1)})\mathscr{R}(y^{(2)}\otimes x^{(2)})=(\varepsilon\otimes\varepsilon)(x\otimes y), \quad x,y\in\mathscr{B}$ (i.e., $\mathscr{R}_{21}=\mathscr{R}^{-1}$).

(2)

$$(R^{vw})^{-1}=R^{wv}, \quad v,w\in M. \tag{II.21}$$

If one of the above conditions is satisfied, we replace CQT by CT (cotriangular) in all definitions (cf. Ref. 6).

Proof: Using (II.10)–(II.12), one can assume that [in the condition (2)] matrix elements of representations from M linearly span $\mathscr{B}$. Then in (1) it is enough to consider $x=v_{ij}$, $y=w_{kl}$, $i,j=1,\ldots,\dim v$, $k,l=1,\ldots,\dim w$, $v, w\in M$. Then (1) is equivalent to (II.21). □

III. QUASITRIANGULAR STRUCTURES ON QUANTUM LORENTZ GROUPS

In this section we classify coquasitriangular (*-) structures on quantum Lorentz groups of Ref. 5. For the quantum Lorentz group of Ref. 12 examples of such structures were given in Ref. 13 and Remark 7 of Section 3 of Ref. 4. We also classify (cf. Ref. 14) coquasitriangular (*-) structures on (complex) $\mathrm{SL}_q(2)$ groups and their real forms.

We first recall the definition of Hopf *-algebra corresponding to a quantum Lorentz group[5] essentially repeating the arguments of Theorem 1.1 of Ref. 5. The bialgebra structure of $(\mathscr{A},\Delta)$ is obtained by the construction of Proposition 1 with $\{w^\alpha:\alpha\in\mathscr{I}\}=\{w^0,w,\widetilde{w}\}$. Here the relations (II.1) mean that $w^0=(I_{\mathscr{H}})$ and the relations (II.2) are given by

$$(w\otimes w)E=Ew^0, \tag{III.1}$$

$$(\widetilde{w}\otimes\widetilde{w})\widetilde{E}=\widetilde{E}w^0, \tag{III.2}$$

$$E'(w\otimes w)=w^0E', \tag{III.3}$$

$$\widetilde{E}'(\widetilde{w}\otimes\widetilde{w})=w^0\widetilde{E}', \tag{III.4}$$

$$X(w\otimes\widetilde{w})=(\widetilde{w}\otimes w)X, \tag{III.5}$$

where

$$\widetilde{E}=\tau\overline{E},\quad \widetilde{E}'=\overline{E'}\tau, \tag{III.6}$$

$E\in\mathrm{Lin}(\mathbf{C},\mathbf{C}^2\otimes\mathbf{C}^2)$, $E'\in\mathrm{Lin}(\mathbf{C}^2\otimes\mathbf{C}^2,\mathbf{C})$, $X\in\mathrm{Lin}(\mathbf{C}^2\otimes\mathbf{C}^2,\mathbf{C}^2\otimes\mathbf{C}^2)$ satisfy

$$(E'\otimes 1\!\!1)(1\!\!1\otimes E)=1\!\!1, \tag{III.7}$$

$$(X\otimes 1\!\!1)(1\!\!1\otimes X)(E\otimes 1\!\!1)=1\!\!1\otimes E, \tag{III.8}$$

$$\tau\overline{X}\tau=\beta^{-1}X, \tag{III.9}$$

$E'E\neq 0$, X is invertible, and $\beta\in\mathbf{C}\backslash\{0\}$.

Warning: Our choice of X may differ from the choice of Ref. 5 by a multiplicative nonzero constant.

Moreover, (III.7) implies that E and E' are inverse one to another as matrices,

$$(1\!\!1\otimes E')(E\otimes 1\!\!1)=1\!\!1. \tag{III.10}$$

Hence, E is left nondegenerate, E' is right nondegenerate, and w^{-1} exists (see Proposition 2). Similarly, $(1\!\!1\otimes\widetilde{E}')(\widetilde{E}\otimes 1\!\!1)=1\!\!1$, $\widetilde{E}$ is left nondegenerate, $\widetilde{E}'$ is right nondenegerate, and $\widetilde{w}^{-1}$ exists. But $(w^0)^{-1}=w^0$ and Proposition 3 implies that $(\mathscr{A},\Delta)$ is a Hopf algebra.

Setting $w^{\sim}=\widetilde{w}$, $\widetilde{w}^{\sim}=w$, $w^{0\sim}=w^0$, the assumptions of Proposition 5 are satisfied and $(\mathscr{A},\Delta)$ becomes a *-bialgebra where $*$ is defined by $\overline{w}=\widetilde{w}$. It has the same Poincaré series as the classical $\mathrm{SL}(2,\mathbf{C})$ group (Theorem 1.2 of Ref. 5). We may assume that

(1) $E=e_1\otimes e_2-qe_2\otimes e_1$, $q\in\mathbf{C}\backslash\{0,i,-i\}$, $X=\alpha\tau Q$, Q is given by (13)–(19) of Ref. 5 [$q=-1$ in (17)–(19)], $\alpha=t^{-1/2}$ for (13), $\alpha=(-t)^{-1/2}$ for (14), $\alpha=q^{1/2}$ for (15), $\alpha=(-q)^{1/2}$ for (16), $\alpha=(s^2-1)^{-1/2}$ for (17), $q=(p^2-1)^{-1/2}$ for (18), $\alpha=\frac{1}{2}$ for (19), or

(2) $E=e_1\otimes e_2-e_2\otimes e_1+e_1\otimes e_1$ (in that case we set $q=1$), $X=\tau Q$, Q is given by (20)–(21) of Ref. 5,

e_1,e_2 is the canonical basis of $\mathbf{C}^2$. Moreover, $\beta=t/|t|$ for (13) and (14), $\beta=q/|q|$ for (15), $\beta=-q/|q|$ for (16), $\beta=-i\ \mathrm{sgn}\ \mathrm{Im}(s)$ for (17), $\beta=\mathrm{sgn}(|p|-1)$ for (18), and $\beta=1$ for (19)–(21). In all cases, $\beta^4=1$.

We shall find all $\mathscr{R}\in(\mathscr{A}\otimes\mathscr{A})'$ such that $(\mathscr{A},\Delta,\mathscr{R})$ is a CQT Hopf algebra. So (cf. Theorem 1) we need to determine R^{ww}, $R^{\overline{w}\,\overline{w}}$, $R^{\overline{w}w}$, $R^{w\overline{w}}$ such that 20 relations (II.15) and (II.16) and 4 relations (II.17) are satisfied [we assume (II.14)]. We shall use them in the following. Irreducibility of $w\otimes\overline{w}$ (see Ref. 5) and (III.5) give $R^{w\overline{w}}=\varepsilon_X X$, $R^{\overline{w}w}=\varepsilon'_X X^{-1}$, where $\varepsilon_X,\varepsilon'_X\in\mathbf{C}\backslash\{0\}$ (cf. Proposition II.4). Moreover, $D=R^{ww}$ and $\widetilde{D}=\beta R^{\overline{w}\overline{w}}$ must satisfy (2.11) and (2.17)–(2.20) of Ref. 2 (with $L,\widetilde{L}$ replaced by $D,\widetilde{D}$), hence they are given by (2.21) and (2.22) of Ref. 2, i.e., $R^{ww}=L_i$, $R^{\overline{w}\,\overline{w}}=\tau\overline{L_j^{-1}}\tau$, $i,j=1,2,3,4$, $L_i=q_i(\mathbb{1}+q_i^{-2}EE')$, $q_{1,2}=\pm q^{1/2}$, and $q_{3,4}=\pm q^{-1/2}$. Using (2.1), (2.3) and (2.4) of Ref. 2, we obtain $\varepsilon_X=\pm1$, $\varepsilon'_X=\pm1$, and $\beta=\pm1$. After some calculations one gets that the 24 relations are satisfied. So we get $4\cdot4\cdot4$ $\mathscr{R}$ for $q\neq\pm1$, $\beta=\pm1$; $2\cdot2\cdot4$ $\mathscr{R}$ for $q=\pm1$, $\beta=\pm1$; and no $\mathscr{R}$ for $\beta=\pm i$.

Set $M=\{w,\overline{w}\}$. According to Proposition 6, we get a CQT Hopf *-algebra iff four relations (II.20) are satisfied iff $\beta=1$ and $q_j=q_i^{-1}$ ($4\cdot4$ $\mathscr{R}$ for $q\neq\pm1$, $\beta=1$; $2\cdot4$ $\mathscr{R}$ for $q=\pm1$, $\beta=1$; no $\mathscr{R}$ for $\beta\neq1$). According to Proposition 7, we get CT Hopf algebra iff four relations (II.21) are satisfied iff $q=1$, $\varepsilon'_X=\varepsilon_X$ ($2\cdot2\cdot2$ $\mathscr{R}$ for $q=1$, $\beta=\pm1$; no $\mathscr{R}$ otherwise). Clearly, we get CT Hopf *-algebra iff $q=\beta=1$ and $q_j=q_i^{-1}$, $\varepsilon'_X=\varepsilon_X$ ($2\cdot2$ $\mathscr{R}$ for $q=\beta=1$; no $\mathscr{R}$ otherwise).

Let us also recall $\mathrm{SL}_q(2)$ groups.[15,6] The bialgebra structure is obtained by the construction of Proposition 1 with $\{w^\alpha:\alpha\in\mathscr{J}\}=\{w^0,w\}$; the relations (II.1) mean that $w^0=(I_{\mathscr{H}})$ and those of (II.2) are given by (III.1) and (III.3), where E,E' are as above with $q\in\mathbf{C}\backslash\{0\}$ (only the case 1.). One gets that $(\mathscr{A},\Delta)$ is a Hopf algebra.

We shall describe (cf. Ref. 14) all $\mathscr{R}\in(\mathscr{A}\otimes\mathscr{A})'$ such that $(\mathscr{A},\Delta,\mathscr{R})$ is a CQT Hopf algebra. Due to Theorem 1 we should find $D=R^{ww}\in\mathrm{Mor}(w\otimes w,w\otimes w)$ satisfying four relations (II.15) and (II.16). This means $D=L_i$, $i=1,2,3,4$, so we get 4 $\mathscr{R}$ for $q\neq\pm1$, 0, and 2 $\mathscr{R}$ for $q=\pm1$. In other words, $R^{ww}=\pm L_1^{\pm1}$ where $L_1=q^{1/2}(\mathbb{1}+q^{-1}EE')$. We get CT Hopf algebras iff $L_1^2=\mathbb{1}$ (see Proposition 7 with $M=\{w\}$) iff $q=1$.

Let us pass to real forms. Then $(\mathscr{A},\Delta)$ becomes a Hopf *-algebra where * is defined by $\overline{w}=v^c$, $v=BwB^{-1}$, $B=\mathbb{1}$ for $\mathrm{SU}_q(2)$, $B=\mathrm{diag}(1,-1)$ for $\mathrm{SU}_q(1,1)$, $q\in\mathbf{R}\backslash\{0\}$ (cf. Refs. 15, 16, and 4); $\overline{w}=w$ for $\mathrm{SL}_q(2,\mathbf{R})$, $|q|=1$ (cf. Ref. 16 and Proposition 5). For $\mathrm{SU}_q(2)$, $\mathrm{SU}_q(1,1)$ we get CQT Hopf *-algebras iff L_1 is Hermitian wrt the canonical scalar product in $\mathbf{C}^2$ (see Proposition 6.2 with $M=\{w\}$ and the proof of Theorem 1.4.6 of Ref. 4) iff $q>0$. For $\mathrm{SL}_q(2,\mathbf{R})$ we get CQT Hopf*-algebras iff $\tau L_1\tau=L_1$ (see Proposition 6.2 with $M=\{w\}$) iff $q=1$. So we have CT Hopf*-algebras iff $q=1$ (for each real form).

IV. QUASITRIANGULAR STRUCTURES ON INHOMOGENEOUS QUANTUM GROUPS

For any Hopf algebra $\mathrm{Poly}(H)=(\mathscr{A},\Delta)$ satisfying certain properties one can construct[1] a Hopf algebra $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ which describes an inhomogeneous quantum group. For certain CQT Hopf algebra structures $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ we find all CQT Hopf algebra structures $(\mathscr{B},\Delta,\mathscr{R})$ such that $\mathscr{R}_{|\mathscr{A}\otimes\mathscr{A}}=\mathscr{R}_{\mathscr{A}}$. The *-structures and cotriangularity are studied as well. In particular, we find all C(Q)T Hopf (*-) algebra structures on quantum Poincaré groups.

Throughout this section $\mathrm{Poly}(H)=(\mathscr{A},\Delta)$ is any bialgebra such that

(a) each representation of H is completely reducible,
(b) Λ is an irreducible representation of H,
(c) $\mathrm{Mor}(v\otimes w,\Lambda\otimes v\otimes w)=\{0\}$ for any two irreducible representations v,w of H.

Moreover, we assume that f_{ij}, $\eta_i\in\mathscr{A}'$, $T_{ij}\in\mathbf{C}$, $i,j=1,\ldots,N=\dim\Lambda$, are given and satisfy

(1) $\mathscr{A}\ni a\to\rho(a)=\begin{pmatrix}f(a) & \eta(a)\\ 0 & \varepsilon(a)\end{pmatrix}\in M_{N+1}(\mathbf{C})$ is a unital homomorphism,
(2) $\Lambda_{st}(f_{tr}*a)=(a*f_{st})\Lambda_{tr}$ for $a\in\mathscr{A}$,
(3) $R^2=\mathbb{1}$, where $R_{ij,sm}=f_{im}(\Lambda_{js})$,
(4) $(\Lambda\otimes\Lambda)_{kl,ij}(\tau^{ij}*a)=a*\tau^{kl}$ for $a\in\mathscr{A}$ where $\tau^{jj}=(R-\mathbb{1})_{\mathrm{ij,mn}}(\eta_n*\eta_m-\eta_m(\Lambda_{ns})\eta_s+T_{mn}\varepsilon-f_{nb}*f_{ma}T_{ab})$,

(5) $A_3\widetilde{F}=0$ where $A_3=1\otimes 1\otimes 1-R\otimes 1-1\otimes R+(R\otimes 1)(1\otimes R)+(1\otimes R)(R\otimes 1)-(R\otimes 1)(1\otimes R)(R\otimes 1)$, $\widetilde{F}_{ijk,m}=\tau^{ij}(\Lambda_{km})$,
(6) $A_3(Z\otimes 1-1\otimes Z)T=0$, $RT=-T$ where $Z_{ij,k}=\eta_i(\Lambda_{jk})$.

In particular, (4) and (5) are satisfied if $\tau^{ij}=0$.

The inhomogeneous quantum group G corresponds to the bialgebra $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ defined (cf. Corollary 3.8.*a* of Ref. 1) as follows: $\mathscr{B}$ is the universal unital algebra generated by $\mathscr{A}$ and y_i, $i=1,\ldots,N$, with the relations $I_{\mathscr{B}}=I_{\mathscr{A}}$,

$$y_s a=(a*f_{st})y_t+a*\eta_s-\Lambda_{st}(\eta_t*a),\quad a\in\mathscr{A}, \tag{IV.1}$$

$$(R-1)_{kl,ij}(y_i y_j-\eta_i(\Lambda_{js})y_s+T_{ij}-\Lambda_{im}\Lambda_{jn}T_{mn})=0. \tag{IV.2}$$

Moreover, $(\mathscr{A},\Delta)$ is a subbialgebra of $(\mathscr{B},\Delta)$ and $\Delta y_i=\Lambda_{ij}\otimes y_j+y_i\otimes I$ (y_i were denoted by p_i in Ref. 1). In particular, $\mathscr{P}=\left(\begin{smallmatrix}\Lambda & y\\ 0 & 1\end{smallmatrix}\right)$ is a representation of G.

Remark 3: If H is a matrix group, Λ its fundamental representation, and $(\mathscr{A},\Delta)$ its corresponding Hopf algebra (generated by Λ_{ij}, Λ_{ij}^{-1}), then, assuming (a)–(c) above and setting $f_{ij}=\delta_{ij}\varepsilon$, $\eta_i=0$, and $T=0$, $(\mathscr{B},\Delta)$ corresponds to

$$G=H\ltimes\mathbf{R}^N=\left\{g=\begin{pmatrix}h & a\\ 0 & 1\end{pmatrix}\in M_{N+1}(\mathbf{C}):h\in H,a\in\mathbf{R}^N\right\},$$

$f(g)=f(h)$, $y_i(g)=a_i$, $f\in\mathscr{A}$, $i=1,\ldots,N$, $g\in G$.

According to Corollary 3.8.*b* and the proof of Proposition 3.12 of Ref. 1, the bialgebra $(\mathscr{B},\Delta)$ can be obtained by the construction of Proposition 1 with $\{w^\alpha:\alpha\in\mathscr{I}\}=\mathrm{Irr}\,H\cup\{\mathscr{P}\}$. Here the relations (II.1) mean that $w^0\equiv(I_{\mathscr{A}})=(I_{\mathscr{B}})$ and the relations (II.2) are given by

$$(\mathscr{P}\otimes\mathscr{P})R_P=R_P(\mathscr{P}\otimes\mathscr{P}), \tag{IV.3}$$

$$(\mathscr{P}\otimes w)N_w=N_w(w\otimes\mathscr{P}),\quad w\in\mathrm{Irr}\,H, \tag{IV.4}$$

$$(w\otimes w')S^{\alpha}_{ww'w''}=S^{\alpha}_{ww'w''}w'',\quad w,w',w''\in\mathrm{Irr}\,H,\ \ \alpha=1,\ldots,c^{w''}_{ww'}, \tag{IV.5}$$

$$\mathscr{P}i=i\Lambda, \tag{IV.6}$$

$$s\mathscr{P}=w^0 s, \tag{IV.7}$$

where

$$R_P=\begin{pmatrix}R & Z & -R\cdot Z & (R-1)T\\ 0 & 0 & 1 & 0\\ 0 & 1 & 0 & 0\\ 0 & 0 & 0 & 1\end{pmatrix},\quad N_w=\begin{pmatrix}G_w, & H_w\\ 0 & 1\end{pmatrix}, \tag{IV.8}$$

$(G_w)_{iC,Dj}=f_{ij}(w_{CD})$, $(H_w)_{iC,D}=\eta_i(w_{CD})$, $w\in\mathrm{Rep}\,H$, $R=G_\Lambda$, $Z=H_\Lambda$, $S^{\alpha}_{ww'w''}(\alpha=1,\ldots,c^{w''}_{ww'})$ form a basis of $\mathrm{Mor}(w'',w\otimes w')$, $i:\mathbf{C}^N\to\mathbf{C}^N\oplus\mathbf{C}$, $s:\mathbf{C}^N\oplus\mathbf{C}\to\mathbf{C}$ are the canonical mappings. In the following we assume that $(\mathscr{A},\Delta)$ is a Hopf algebra. Then (Proposition 3.12 of Ref. 1) $(\mathscr{B},\Delta)$ is also a Hopf algebra and G_w^{-1} exist:

$$(G_w^{-1})_{Ak,lB}=f_{kl}(w^{-1}_{AB}). \tag{IV.9}$$

If $(\mathscr{A},\Delta)$ is a Hopf*-algebra, then we also assume $\overline{\Lambda}=\Lambda$,

$$f_{ij}(S(a^*))=\overline{f_{ij}(a)},\ \eta_i(S(a^*))=\overline{\eta_i(a)},\quad i,j=1,\ldots,N,a\in\mathscr{A}, \tag{IV.10}$$

$\widetilde{T}-T\in\mathrm{Mor}(w^0,\Lambda\otimes\Lambda)$, where $\widetilde{T}_{ij}=\overline{T_{ji}}$. Then [1] $(\mathscr{B},\Delta)$ has a unique Hopf*-algebra structure such that $(\mathscr{A},\Delta)$ is its Hopf*-subalgebra and $y_i^*=y_i$.

In the following we assume $\mathrm{Mor}(I,\Lambda\otimes\Lambda)\cap\ker(R+\mathbb{1})=\{0\}$, i.e., $\mathrm{Mor}(I,\Lambda\otimes\Lambda)\subset\ker(R-\mathbb{1})$. Then [using (4.14) of Ref. 1] $\widetilde{T}=T$. The main result of the present paper is contained in the following.

Theorem 2: Let $\mathrm{Poly}(H)=(\mathscr{A},\Delta)$ and $\mathrm{Poly}(G)=(\mathscr{B},\Delta)$ be as above, $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ be a CQT Hopf algebra such that

$$R^{v\Lambda}=c_vG_v,\quad R^{\Lambda v}=c_v'G_v^{-1},\quad v\in\mathrm{Irr}\,H, \tag{IV.11}$$

$c_v,c_v'\in\mathbf{C}\setminus\{0\}$. We are interested in CQT Hopf algebra structures $(\mathscr{B},\Delta,\mathscr{R})$ such that

$$\mathscr{R}_{|\mathscr{A}\otimes\mathscr{A}}=\mathscr{R}_{\mathscr{A}}. \tag{IV.12}$$

One has the following.

(1) Such a structure exists iff

$$\tau^{ij}=0,\quad i,j=1,\ldots,N, \tag{IV.13}$$

$$R^{v\Lambda}=G_v,\quad R^{\Lambda v}=G_v^{-1},\quad v\in\mathrm{Irr}\,H. \tag{IV.14}$$

(2) Suppose (IV.13) and (IV.14). Then such structures are in one-to-one correspondence with $m\in\mathrm{Mor}(w^0,\Lambda\otimes\Lambda)$ satisfying

$$(f_{jb}*f_{ia})m_{ab}=m_{ij}\varepsilon,\quad i,j=1,\ldots,N, \tag{IV.15}$$

and are determined by

$$R^{vw}=R^{vw}\ \text{ for }\ \mathscr{R}_{\mathscr{A}},\quad v,w\in\mathrm{Irr}\,H, \tag{IV.16}$$

$$R^{v\mathscr{P}}=N_v,\quad R^{\mathscr{P}v}=N_v^{-1},\quad v\in\mathrm{Irr}\,H, \tag{IV.17}$$

$$R^{\mathscr{P}\mathscr{P}}=R_P+m_P, \tag{IV.18}$$

where

$$m_P=\begin{pmatrix}0&0&0&m\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix}. \tag{IV.19}$$

(3) Let $\mathscr{R}$ be as in (2) and let $(\mathscr{A},\Delta)$ and $(\mathscr{B},\Delta)$ be Hopf*-algebras as in the text before the Theorem. Then $(\mathscr{B},\Delta,\mathscr{R})$ is a CQT Hopf*-algebra iff $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ is a CQT Hopf*-algebra and

$$m_{ij}=\overline{m_{ji}},\quad i,j=1,\ldots,N. \tag{IV.20}$$

(4) Let $\mathscr{R}$ be as in (2). Then $(\mathscr{B},\Delta,\mathscr{R})$ is a CT Hopf algebra iff $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ is a CT Hopf algebra and $m=0$.

Proof: Ad 1 and 2: Each such structure is (see Theorem 1) uniquely determined by R^{vw}, $R^{v\mathscr{P}}$, $R^{\mathscr{P}v}$, and $R^{\mathscr{P}\mathscr{P}}$ satisfying (II.15)–(II.17) [we assume (II.14)], $v,w\in\mathrm{Irr}\,H$. Using (IV.12), we

get (IV.16). In virtue of the properties of $\mathscr{R}_{\mathscr{A}}$ the formula (II.17) for R^{vw} follows. Moreover, (II.15) and (II.16) for (IV.6) and $w^\gamma = v \in \mathrm{Irr}\, H$ mean $R^{v\mathscr{P}}(1 \otimes i) = (i \otimes 1)R^{v\Lambda}$, $R^{\mathscr{P}v}(i \otimes 1) = (1 \otimes i)R^{\Lambda v}$. That and (IV.11) give

$$R^{v\mathscr{P}} = c_v \begin{pmatrix} G_v, & ? \\ 0, & ? \end{pmatrix} = c_v N_v, \quad R^{\mathscr{P}v} = c_v' \begin{pmatrix} G_v^{-1} & ? \\ 0 & ? \end{pmatrix} = c_v' N_v^{-1},$$

where the second equalities follow from (II.17) for $R^{v\mathscr{P}}, R^{\mathscr{P}v}$, (IV.4), the independence of I, $y_i (i = 1,\ldots,N)$ over $\mathscr{A}$ [in left and also in right module, see Corollary 3.6 and (1.4) of Ref. 1] and the condition (c). Using (II.15) and (II.16) for (IV.7) and $w^\gamma = v \in \mathrm{Irr}\, H$, one obtains $c_v = c_v' = 1$; we get (IV.14), (IV.17). In virtue of (II.15) and (II.16) for (IV.6) and (IV.7) and $w^\gamma = \mathscr{P}$,

$$R^{\mathscr{P}\mathscr{P}} = \begin{pmatrix} R & Z & -R \cdot Z & ? \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} = R_P + m_P$$

for some $m \in \mathrm{Mor}(w^0, \Lambda \otimes \Lambda)$ where the second equality uses (II.17) for $R^{\mathscr{P}\mathscr{P}}$, (IV.3), and (IV.19). Thus (IV.18) follows. We set $R_Q = R_P + m_P = R^{\mathscr{P}\mathscr{P}}$ and replace (IV.3) by equivalent [assuming (IV.5)] relation

$$(\mathscr{P} \otimes \mathscr{P}) R_Q = R_Q (\mathscr{P} \otimes \mathscr{P}). \tag{IV.21}$$

The relations (II.15) and (II.16) for (IV.21), (IV.4), and any $w^\gamma \in \mathrm{Irr}\, H \cup \{\mathscr{P}\}$ are equivalent to

$$(R_Q \otimes 1)(1 \otimes R_Q)(R_Q \otimes 1) = (1 \otimes R_Q)(R_Q \otimes 1)(1 \otimes R_Q), \tag{IV.22}$$

$$(1 \otimes N_v)(N_v \otimes 1)(1 \otimes R_Q) = (R_Q \otimes 1)(1 \otimes N_v)(N_v \otimes 1), \quad v \in \mathrm{Irr}\, H, \tag{IV.23}$$

$$(1 \otimes R^{vw})(N_v \otimes 1)(1 \otimes N_w) = (N_w \otimes 1)(1 \otimes N_v)(R^{vw} \otimes 1), \quad v, w \in \mathrm{Irr}\, H. \tag{IV.24}$$

According to Proposition 3.14 of Ref. 1 and its proof, (IV.22) is equivalent to $\widetilde{F} = 0$. Let us denote the standard basis elements in $\mathbf{C}^{\dim v}$, $v \in \mathrm{Irr}\, H$, by h_i^v, $i = 1,\ldots,\dim v$, $e_i = h_i^\Lambda$, and in $\mathbf{C}$ by $f = 1$. Using (3.65) of Ref. 1 and

$$N_v(h_i^v \otimes e_j) = (G_v)_{kl,ij} e_k \otimes h_l^v,$$

$$N_v(h_i^v \otimes f) = f \otimes h_i^v + (H_v)_{kl,i} e_k \otimes h_l^v,$$

we find that (IV.23) on $h_i^v \otimes e_j \otimes e_k$ follows from the last formula before Proposition 3.14 in Ref. 1; on $h_i^v \otimes e_j \otimes f$, $h_i^v \otimes f \otimes e_j$ follows from (2.18) of Ref. 1; on $h_i^v \otimes f \otimes f$ is equivalent (using $Rm = m$) to $\tau^{ij}(v_{AB}) = 0$ and (IV.15) applied to v_{AB} for all i,j,A,B. So (IV.23) is equivalent to (IV.13) (which implies $\widetilde{F} = 0$) and (IV.15). We also get that (IV.24) on $h_i^v \otimes h_j^w \otimes e_k$ follows from $(1 \otimes R^{vw})(R^{v\Lambda} \otimes 1)(1 \otimes R^{w\Lambda}) = (R^{w\Lambda} \otimes 1)(1 \otimes R^{v\Lambda})(R^{vw} \otimes 1)$ [it can be obtained using (II.13) and (II.8) for $\mathscr{R}_{\mathscr{A}}$; cf. Refs. 6, 8, and (1.14) of Ref. 4]; on $h_i^v \otimes h_j^w \otimes f$ follows from the equality obtained by acting η_i on (II.17) for R^{vw} and using condition (1) (see the beginning of the Section).

The relations (II.15) and (II.16) for (IV.5) and $w^\gamma \in \mathrm{Irr}\, H$ follow from (II.8) and (II.11) for $\mathscr{R}_{\mathscr{A}}$ while for $w^\gamma = \mathscr{P}$ they are equivalent to

$$(N_w \otimes 1)(1 \otimes N_{w'})(S^\alpha_{ww'w''} \otimes 1) = (1 \otimes S^\alpha_{ww'w''}) N_{w''}.$$

That on $h_i^{w''} \otimes e_j$ follows from (II.8) and (II.11) for $\mathscr{R}_{\mathscr{A}}$ and on $h_i^{w''} \otimes f$ that follows from the equality obtained by acting η_i on (IV.5).

Ad 3: We need to check (II.20) for $M=\mathrm{Irr}\,H\cup\{\mathscr{P}\}$. For R^{vw}, $v,w\in\mathrm{Irr}\,H$, it is equivalent to the fact that $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ is a CQT Hopf*-algebra; for $R^{\mathscr{P}v}$ and $R^{v\mathscr{P}}$ follows from (IV.9), (IV.10), and the properties of η_i; for $R^{\mathscr{P}\mathscr{P}}$ it is equivalent [using (4.14) and the next formula of Ref. 1, $Rm=m$, $RT=-T$] to (IV.20).

Ad 4: We need to check (II.21) for $M=\mathrm{Irr}\,H\cup\{\mathscr{P}\}$. For R^{vw}, $v,w\in\mathrm{Irr}\,H$, it is equivalent to the fact that $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ is a CT Hopf algebra; for $R^{\mathscr{P}v}$ and $R^{v\mathscr{P}}$ follows from (IV.17); for $R^{\mathscr{P}\mathscr{P}}$ it is equivalent (using $R_P^2=1$) to $m=0$. □

Remark: If the first formula of the condition (6) is replaced by $0\neq A_3(Z\otimes 1-1\otimes Z)T\in\mathrm{Mor}(I,\Lambda\otimes\Lambda\otimes\Lambda)$ (this is allowed by Ref. 1), then (IV.22) is not satisfied and there is no CQT Hopf algebra structure on $(\mathscr{B},\Delta)$.

As an application we shall consider $(\mathscr{A},\Delta)=\mathrm{Poly}(L)$ where L is a quantum Lorentz group. The corresponding inhomogeneous quantum groups are called quantum Poincaré groups and are (almost) classified in Ref. 2. The classification of C(Q)T Hopf (*-) algebra structures on them is given in the following.

Theorem 3: Let $\mathrm{Poly}(P)=(\mathscr{B},\Delta)$ be the Hopf *-algebra corresponding to a quantum Poincaré group P (Ref. 2) described by an admissible choice of quantum Lorentz group [cases (1)–(7)], $s=\pm 1$, H and T.

(1) Let us consider CQT Hopf algebra structures $(\mathscr{B},\Delta,\mathscr{R})$ on P. One has:
(a)In the cases (1) (except $s=1$, $t=1$, $t_0\neq 0$, see Remark 1.8 of Ref. 2), (2), (3), (4) (except $s=1$, $b\neq 0$), (5) (except $s=\pm 1$, $t=1$, $t_0\neq 0$), (6), and (7) each such structure is uniquely determined by

$$R^{ww}=kL,\quad R^{w\overline{w}}=kX,\quad R^{\overline{w}w}=qkX^{-1},\quad R^{\overline{w}\overline{w}}=qk\widetilde{L}$$

and (IV. 17)–(IV.19), where

$$m=cm_0,\quad m_0=(V^{-1}\otimes V^{-1})(1\otimes X\otimes 1)(E\otimes\tau E),\quad L=sq^{1/2}(1+q^{-1}EE'),\quad \widetilde{L}=q\tau L\tau,$$

where $s=\pm 1$, E,E' are fixed for fixed P and given in Ref. 2, and $k=\pm 1$ (two possible $\mathscr{R}$ for each $c\in\mathbf{C}$).
(b) In the other cases there is no such structure.

(2) Let $\mathscr{R}$ be as in (1). We get CQT Hopf*-algebra iff $q=1$ [which excludes the cases (5)–(7)] and $c\in\mathbf{R}$.

(3) Let $\mathscr{R}$ be as in (1). We get CT Hopf algebra iff $q=1$ [which excludes the cases (5)–(7)] and $c=0$ (then it is also CT Hopf*-algebra).

Proof: Ad 1: We shall use Theorem 2, the results of Ref. 2, and Section III. Thus H is a quantum Lorentz group, $\Lambda=V^{-1}(w\otimes\overline{w})V$ with $V_{CD,i}=(\sigma_i)_{CD}$ ($\sigma_0=1,\sigma_1,\sigma_2,\sigma_3$ are the Pauli matrices), $q=\beta=\pm 1$, and the assumptions about H and G are satisfied. Moreover, $G_w=(V^{-1}\otimes 1)(1\otimes X)(L\otimes 1)(1\otimes V)$ and $G_{\overline{w}}=(V^{-1}\otimes 1)(1\otimes\widetilde{L})(X^{-1}\otimes 1)(1\otimes V)$, where $L=sq^{1/2}(1+q^{-1}EE')$ and $\widetilde{L}=q\tau\overline{L^{-1}}\tau=q\tau L\tau$. The possible η and T are described in Ref. 2. According to the results of Section III, each CQT Hopf algebra structure on $(\mathscr{A},\Delta)$ is uniquely characterized by $R^{ww}=\epsilon_L L$, $R^{\overline{w}\overline{w}}=\epsilon_L'\widetilde{L}$, $R^{w\overline{w}}=\epsilon_X X$, and $R^{\overline{w}w}=\epsilon_X' X^{-1}$, where $\epsilon_L^2=\epsilon_L'^2=\epsilon_X^2=\epsilon_X'^2=1$ (16 possible $\mathscr{R}_{\mathscr{A}}$). Using (II.8), (II.9), (II.11), and (II.12), one gets (IV.11) for $v=w,\overline{w}$ with $c_w=\epsilon_L\epsilon_X$, $c_{\overline{w}}=\epsilon_L'\epsilon_X'$, $c_w'=q\epsilon_L\epsilon_X'$, and $c_{\overline{w}}'=q\epsilon_X\epsilon_L'$. In virtue of Proposition 2.1 of Ref. 2 and (II.8), (II.9), (II.11) and (II.12), the condition (IV.11) is satisfied for all $v\in\mathrm{Irr}\,H$.

Due to Proposition 3.13.2 and Proposition 4.8 of Ref. 1, (IV. 13) is equivalent to $\tau^{ij}(w_{AB})=0$, $i,j=0,1,2,3$, $A,B=1,2$, which means (cf. the proof of Theorem 1.6 of Ref. 2) $\lambda=0$, which excludes the case (4), $s=1$, $b\neq 0$, the case (1), $s=1$, $t=1$, $t_0\neq 0$, and the case (5), $s=\pm 1$, $t=1$, $t_0\neq 0$, where $t_0\in\mathbf{R}$ is introduced in Remark 1.8 of Ref. 2. Moreover, (IV.14) means that $\epsilon_X'=\epsilon_L'$

$=qk$, $\epsilon_X=\epsilon_L=k$ for some $k=\pm 1$. Using Theorem 2.1–2, $\mathrm{Mor}(w^0,\Lambda\otimes\Lambda)=\mathbf{C}m_0$ and (IV.15) for $m=m_0$ (it is enough to prove it on w_{AB}, w_{AB}^* when it follows from the 20 relations considered in Section III), we get (1).

Ad 2: We use $q=\beta=1$ (which implies $q_j=q_i^{-1}$), $(m_0)_{ij}=\overline{(m_0)_{ji}}$ and Theorem 2.3.

Ad 3: We use $q=1$ (which implies $\epsilon_X'=\epsilon_X$) and Theorem 2.4. ■

V. ENVELOPING ALGEBRAS

In this section we study enveloping algebras of inhomogeneous quantum groups. We assume that $(\mathscr{A},\Delta,\mathscr{R}_{\mathscr{A}})$ and $(\mathscr{B},\Delta,\mathscr{R})$ are CQT Hopf algebras as in Theorem 2.1–2 (e.g., as in Theorem 3.1).

We essentially follow the scheme of Refs. 16 and 17, but now we do not assume $Z=T=0$. We define $l_{jl}\in\mathscr{B}'$, $j,l=1,\ldots,N,+$, by

$$l_{jl}(x)=\mathscr{R}(x\otimes\mathscr{P}_{jl}) \tag{V.1}$$

(in the CT case l corresponds to $L^{\pm}$ of Ref. 16 on the subalgebra generated by $\mathscr{P}_{ac}$). According to (II.5) and (II.13) for $v=w=\mathscr{P}$,

$$\begin{aligned}R^{\mathscr{P}\mathscr{P}}_{ab,cd}l_{df}(x^{(1)})l_{ce}(x^{(2)})&=R^{\mathscr{P}\mathscr{P}}_{ab,cd}\mathscr{R}(x^{(1)}\otimes\mathscr{P}_{df})\mathscr{R}(x^{(2)}\otimes\mathscr{P}_{ce})\\&=\mathscr{R}(x\otimes R^{\mathscr{P}\mathscr{P}}_{ab,cd}\mathscr{P}_{ce}\mathscr{P}_{df})\\&=\mathscr{R}(x\otimes\mathscr{P}_{ac}\mathscr{P}_{bd}R^{\mathscr{P}\mathscr{P}}_{cd,ef})\\&=\mathscr{R}(x^{(1)}\otimes\mathscr{P}_{bd})\mathscr{R}(x^{(2)}\otimes\mathscr{P}_{ac})R^{\mathscr{P}\mathscr{P}}_{cd,ef}\\&=l_{bd}(x^{(1)})l_{ac}(x^{(2)})R^{\mathscr{P}\mathscr{P}}_{cd,ef},\end{aligned}$$

hence

$$R^{\mathscr{P}\mathscr{P}}_{ab,cd}(l_{df}*l_{ce})=(l_{bd}*l_{ac})R^{\mathscr{P}\mathscr{P}}_{cd,ef},\quad a,b,e,f=1,\ldots,N,+. \tag{V.2}$$

Setting $l_{ab}=L_{ab}$, $l_{a+}=M_a$, and using $l_{+a}=0$, $l_{++}=\epsilon$, $a,b=1,\ldots,N$, and (IV.18), (V.2) is equivalent to

$$R_{ab,cd}(L_{df}*L_{ce})=(L_{bd}*L_{ac})R_{cd,ef}, \tag{V.3}$$

$$R_{ab,cd}(M_d*L_{ce})+Z_{ab,c}L_{ce}=(L_{bd}*L_{ac})Z_{cd,e}+L_{be}*M_a, \tag{V.4}$$

$$R_{ab,cd}(L_{df}*M_c)-(RZ)_{ab,d}L_{df}=-(L_{bd}*L_{ac})(RZ)_{cd,f}+M_b*L_{af}, \tag{V.5}$$

$$R_{ab,cd}M_d*M_c+Z_{ab,c}M_c-(RZ)_{ab,d}M_d+s_{ab}\epsilon=(L_{bd}*L_{ac})s_{cd}+M_b*M_a, \tag{V.6}$$

$a,b,e,f=1,\ldots,N$, where $s=(R-1)T+m$. Let us notice that (V.5) follows from (V.3) and (V.4). Moreover, using (II.4), (II.3), $l_{ac}(xy)=l_{ab}(x)l_{bc}(y)$, $l_{ac}(I)=\delta_{ac}$, $a,c=1,\ldots,N,+,x,y\in\mathscr{B}$. Thus $L_{ac}(I)=\delta_{ac}$, $M_a(I)=0$,

$$L_{ac}(xy)=L_{ab}(x)L_{bc}(y), \tag{V.7}$$

$$M_a(xy)=L_{ab}(x)M_b(y)+M_a(x)\epsilon(y), \tag{V.8}$$

$a,b=1,\ldots,N,x,y\in\mathscr{B}$. Also $l_{jl}(\mathscr{P}_{ab})=\mathscr{R}(\mathscr{P}_{ab}\otimes\mathscr{P}_{jl})=R^{\mathscr{P}\mathscr{P}}_{ja,bl}$, $l_{jl}(w_{AB})=\mathscr{R}(w_{AB}\otimes\mathscr{P}_{jl})=R^{w\mathscr{P}}_{jA,Bl}=(N_w)_{jA,Bl}$ [see (V.1), (II.7), (IV.17), and (IV.8)], $a,b,j,l=1,\ldots,N,+,A,B=1,\ldots,\dim w, w\in\mathrm{Rep}\,H$. Therefore

$$L_{jl}(\Lambda_{ab})=R_{ja,bl}, \tag{V.9}$$

$$L_{jl}(y_a)=-(RZ)_{ja,l}, \tag{V.10}$$

$$L_{jl}(w_{AB})=(G_w)_{jA,Bl}, \tag{V.11}$$

$$M_j(\Lambda_{ab})=Z_{ja,b}, \tag{V.12}$$

$$M_j(y_a)=s_{ja}, \tag{V.13}$$

$$M_j(w_{AB})=(H_w)_{jA,B}, \tag{V.14}$$

$a,b,j,l=1,\ldots,N, A,B=1,...,$ dim $w, w\in \mathrm{Rep}\, H$. It is clear that l_{jl} generate a unital subalgebra of $\mathscr{B}'$(wrt convolution $*$). Endowing it with Δ' of Remark 2, we get a bialgebra U with l as its corepresentation. Adding $l^{(m)}_{ij}=l_{ij}\circ S^m$, one obtains a Hopf algebra $\hat{U}$ with coinverse $S'(l^{(m)})=l^{(m+1)}$ and corepresentations $l^{(2k)}$, $(l^{(2k+1)})^T$, $k=0,1,2,\ldots$. Acting S'^m on (V.2), one obtains

$$R^{\mathscr{P}\mathscr{P}}_{ab,cd}(l^{(2k)}_{df}*l^{(2k)}_{ce})=(l^{(2k)}_{bd}*l^{(2k)}_{ac})R^{\mathscr{P}\mathscr{P}}_{cd,ef},$$

$$R^{\mathscr{P}\mathscr{P}}_{ab,cd}(l^{(2k+1)}_{ce}*l^{(2k+1)}_{df})=(l^{(2k+1)}_{ac}*l^{(2k+1)}_{bd})R^{\mathscr{P}\mathscr{P}}_{cd,ef}.$$

Here $\hat{U}$ is called enveloping algebra of $(\mathscr{B},\Delta)$. It can be sometimes too small. It happens, e.g., in the classical case (see Remark 3) with $\mathscr{R}=\epsilon\otimes\epsilon$ when $\hat{U}=\mathbf{C}\epsilon$ (cf. also Ref. 18).

Notice that $L_{jl}|_{\mathscr{A}}=f_{jl}$, $M_j|_{\mathscr{A}}=\eta_a$, $l_{|\mathscr{A}}=\rho$. According to the proof of Theorem 1, there exists antihomomorphism $\theta:\mathscr{B}\to\mathscr{B}'$ (given by $\mathscr{R}$) such that $\theta(\Lambda_{jl})=L_{jl}$, $\theta(y_j)=M_j$, $\theta(I)=\epsilon$. Therefore the formulas (3.60), (3.46), and (1.12) of Ref. 1 yield (V.4), (V.6) [with s replaced by $(R-1)T$], and (V.3) which give

$$f_{be}*\eta_a=R_{ab,cd}\eta_d*f_{ce}+Z_{ab,c}f_{ce}-(f_{bd}*f_{ac})Z_{cd,e}$$

[cf. (2.18) of Ref. 1], the condition $\tau^{jj}=0$, and the last formula before Proposition 3.14 in Ref. 1. Suppose $(\Lambda\otimes\Lambda)k=kw^0$, $n(\Lambda\otimes\Lambda)=w^0n$ $[w^0=(I_{\mathscr{B}})]$. Applying θ, we get

$$(L_{bd}*L_{ac})k_{cd}=k_{ab}\epsilon,\quad n_{ab}(L_{bd}*L_{ac})=n_{cd}\epsilon,\quad a,b,c,d=1,\ldots,N. \tag{V.15}$$

Let us set $X_{lj}=L_{jl}\circ S\in\hat{U}$, $j,l=1,\ldots,N$. Then

$$X_{ik}(xy)=X_{ij}(x)X_{jk}(y),\quad X_{ik}(I)=\delta_{ik}, x,y\in\mathscr{B}, \tag{V.16}$$

$$X_{ik}(a)=f_{ki}(S(a)),\quad a\in\mathscr{A}, i,k=1,\ldots,N. \tag{V.17}$$

Using the last equation in the proof of Proposition 3.12 of Ref. 1, (V.7), (IV.9), and (V.10), we obtain

$$X_{ik}(y_l)=Z_{lk,i}. \tag{V.18}$$

Moreover, (V.15) yields

$$k_{ab}(X_{ac}*X_{bd})=k_{cd}\epsilon,\quad (X_{ac}*X_{bd})n_{cd}=n_{ab}\epsilon. \tag{V.19}$$

As in the proof of Proposition 3.1.2 of Ref. 3, there exists a unital homomorphism $X:\mathscr{B}\to M_{N+1}(\mathbf{C})$ such that

$$X=\begin{pmatrix} (X_{jl})_{j,l=1}^{N} & (Y_j)_{j=1}^{N} \\ 0 & \epsilon \end{pmatrix}$$

for some $Y_j \in \mathscr{B}'$ satisfying $Y_j(a)=0$, $a \in \mathscr{A}$, $Y_j(y_k)=\delta_{jk}$, $j,k=1,\ldots,N$. Setting $X_{j+}=Y_j$, $X_{+j}=0$, $X_{++}=\epsilon$, $j=1,\ldots,N$, the commutation relations among X_{ij}, $i,j=1,\ldots,N,+$, are the same as in (3.7) of Ref. 3, i.e.,

$$(X_{ab}*X_{cd})K_{bd,st}=K_{ac,bd}(X_{bs}*X_{dt}), \quad a,c,s,t=1,\ldots,N,+, \tag{V.20}$$

where

$$K=\begin{pmatrix} R^T & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

[it is also possible to replace K in (V.20) by $K+n_P$, where $n \in \mathrm{Mor}(\Lambda\otimes\Lambda, w^0)$; see (IV.19) and (V.19)].

Defining $X_{ij}^{(m)}=X_{ij}\circ S^m$, $i,j=1,\ldots,N,+$, $m=0,1,2,\ldots$, one gets a Hopf algebra $\hat{V}$ generated (as a unital algebra) by $1_{ij}^{(m)}$ and $X_{ij}^{(m)}$. Clearly $S'(X^{(m)})=X^{(m+1)}$; $X^{(2k)}$, $[X^{(2k+1)}]^T$, $k=0,1,\ldots$, are corepresentations of $\hat{V}$. Letting S' act on (V.20), one obtains

$$(X_{ab}^{(2k)}*X_{cd}^{(2k)})K_{bd,st}=K_{ac,bd}(X_{bs}^{(2k)}*X_{dt}^{(2k)}),$$

$$(X_{cd}^{(2k+1)}*X_{ab}^{(2k+1)})K_{bd,st}=K_{ac,bd}(X_{dt}^{(2k+1)}*X_{bs}^{(2k+1)}).$$

Here $\hat{V}$ is called enlarged enveloping algebra of $(\mathscr{B},\Delta)$. It would be interesting to find the commutation relations between M_i and Y_j.

Integration on quantum Euclidean space and sphere

Harold Steinacker[a)]
Department of Physics, University of California and Theoretical Physics Group, Lawrence Berkeley Laboratory, Berkeley, California 94720

(Received 4 December 1995; accepted for publication 11 June 1996)

Invariant integrals of functions and forms over q-deformed Euclidean space and spheres in N dimensions are defined and shown to be positive definite, compatible with the star structure and to satisfy a cyclic property involving the D matrix of $SO_q(N)$. The definition is based on spherical and radial integration. Stokes theorem is proved with and without spherical boundary terms, as well as on the sphere. © *1996 American Institute of Physics.* [S0022-2488(96)03409-3]

I. INTRODUCTION

In recent years, there has been much interest in formulating physics and, in particular, field theory on quantized, i.e., noncommutative space–time. One of the motivations is that if there are no more ''points'' in space–time, such a theory should be well behaved in the UV. The concept of integration on such a space can certainly be expected to be an essential ingredient. In the simplest case of the quantum plane, such an integral was first introduced by Wess and Zumino;[1] also see Ref. 2. In the presumably more physical case of quantum Euclidean space,[3] the Gaussian integration method was proposed by a number of authors.[4,6] However, it is tedious to calculate, except in the simplest cases, and its properties have never been investigated thoroughly; in particular, we point out that determining the class of integrable functions is a rather subtle issue.

In this paper, we will give a different definition based on spherical integration in N dimensions and investigate its properties in detail. Although this idea has already appeared in the literature,[7] it has not been developed very far. We first show that there is a unique invariant integral over the quantum Euclidean sphere, and prove that it is positive definite and satisfies a cyclic property involving the D matrix of $SO_q(N)$. The integral over quantum Euclidean space is then defined by radial integration, both for functions and N forms. One naturally obtains a large class of integrable functions. It turns out not to be determined uniquely by rotation and translation invariance (=Stokes theorem) alone; it is unique after, e.g., imposing a general scaling law. It is positive definite as well and thus allows us to define a Hilbert space of square-integrable functions, and satisfies the same cyclic property. The cyclic property also holds for the integral of N and $N-1$-forms over spheres, which leads to a simple, truly noncommutative proof of Stokes theorem on Euclidean space with and without spherical boundary terms, as well as on the sphere. These proofs only work for $q\neq 1$, nevertheless, they reduce to the classical Stokes theorem for $q\to 1$. This shows the power of noncommutative geometry. Obviously one would like to use this integral to define actions for field theories on such noncommutative spaces; this is work in progress.

Although only the case of quantum Euclidean space is considered, the general approach is clearly applicable to, e.g., quantum Minkowski space as well.

II. INTEGRAL ON THE QUANTUM SPHERE S_q^{N-1}

To establish the notation, we briefly summarize the definitions used in this paper, following Faddeev, Reshetikhin, and Takhtadjan.[3]

The (function algebra on the) quantum orthogonal group $O_q(N)$ [which is called $SO_q(N)$ in Ref. 3] is the algebra generated by A^i_j modulo the relations

[a)]Electronic mail: hsteinac@physics.berkeley.edu

0022-2488/96/37(9)/4738/12/$10.00

$$\hat{R}^{ik}_{mn} A^m_j A^n_l = A^i_n A^k_m \hat{R}^{nm}_{jl}\,, \tag{1}$$

$$g_{ij} A^i_k A^j_l = g_{kl}\,. \tag{2}$$

$\mathrm{SO}_q(N)$ is obtained by further imposing

$$A^{i_1}_{j_1} \cdots A^{i_N}_{j_N} \epsilon^{j_1 \cdots j_N}_q = \epsilon^{i_1 \cdots i_N}_q, \tag{3}$$

using the fact that the quantum determinant is central; see, e.g., Ref. 8.

The $\hat{R}$ matrix decomposes into three projectors, $R^{ij}_{kl} = (qP^+ - q^{-1}P^- + q^{1-N}P^0)^{ij}_{kl}$. The metric is determined by $(P^0)^{ij}_{kl} = [(q^2-1)/(q^N-1)(q^{2-N}+1)]g^{ij}g_{kl}$, where $g_{ik}g^{kj} = \delta^j_i$. In this paper, we assume q is real and positive. Then there is a star structure (involution),

$$\overline{A^i_j} = g^{jm} A^l_m g_{li}\,, \tag{4}$$

so that we really have $(\mathrm{S})\mathrm{O}_q(N,\mathbb{R})$, and the antipode can be written as

$$S(A^i_j) = \overline{A^j_i}. \tag{5}$$

Quantum Euclidean space[3] is generated by x^i with commutation relations

$$(P^-)^{ij}_{kl} x^k x^l = 0, \tag{6}$$

and the center is generated by 1 and $r^2 = g_{ij}x^i x^j$. The associated differentials satisfy $(P^+)^{ij}_{kl}\, dx^k\, dx^l = 0$ and $g_{ij}\, dx^i\, dx^j = 0$, i.e.,

$$dx^i\, dx^j = -q\hat{R}^{ij}_{kl}\, dx^k\, dx^l. \tag{7}$$

The epsilon tensor is then determined by the unique top (N) form,

$$dx^{i_1} \cdots dx^{i_N} = \epsilon^{i_1 \cdots i_N}_q\, dx^1 \cdots dx^N \equiv \epsilon^{i_1 \cdots i_N}_q\, d^N x. \tag{8}$$

The above relations are preserved under the coaction of $(\mathrm{S})\mathrm{O}_q(N)$,

$$\Delta(x^i) = A^i_j \otimes x^j \equiv x^i_{(1)} \otimes x^i_{(2)}\,, \tag{9}$$

in Sweedler notation. The involution $\overline{x^i} = x^j g_{ji}$ is compatible with the left coaction of $(\mathrm{S})\mathrm{O}_q(N,\mathbb{R})$. One can also introduce derivatives that satisfy

$$(P^-)^{ij}_{kl} \partial^k \partial^l = 0, \tag{10}$$

$$\partial^i x^j = g^{ij} + q(\hat{R}^{-1})^{ij}_{kl} x^k \partial^l, \tag{11}$$

and

$$\partial^i\, dx^j = q^{-1}\hat{R}^{ij}_{kl}\, dx^k\, \partial^l, \quad x^i\, dx^j = q\hat{R}^{ij}_{kl}\, dx^k\, x^l. \tag{12}$$

This represents one possible choice. For more details, see, e.g., Ref. 9. Finally, the quantum sphere S^{N-1}_q is generated by $t^i = x^i/r$, which satisfies $g_{ij}t^i t^j = 1$.

We first define a (complex-valued) integral $\langle f(t)\rangle_t$ of a function $f(t)$ over S^{N-1}_q. It should certainly be invariant under $\mathrm{O}_q(N)$, which means

$$A^{i_1}_{j_1} \cdots A^{i_n}_{j_n} \langle t^{j_1} \cdots t^{j_n}\rangle_t = \langle t^{i_1} \cdots t^{i_n}\rangle_t\,. \tag{13}$$

Of course, it has to satisfy

$$g_{i_l i_{l+1}}\langle t^{i_1}\cdots t^{i_n}\rangle_t=\langle t^{i_1}\cdots t^{i_{l-1}}t^{i_{l+2}}\cdots t^{i_n}\rangle_t \quad \text{and} \quad (P^-)^{i_l i_{l+1}}_{j_l j_{l+1}}\langle t^{j_1}\cdots t^{j_n}\rangle_t=0. \tag{14}$$

We require one more property, namely that $I^{i_1\cdots i_n}\equiv\langle t^{i_1}\cdots t^{i_n}\rangle_t$ is analytic in $(q-1)$, i.e. its Laurent series in $(q-1)$ has no negative terms (we can then assume that the classical limit $q=1$ is nonzero). These properties, in fact, determine the spherical integral uniquely: for n odd, one should define $\langle t^{i_1}\cdots t^{i_n}\rangle_t=0$, and the following occurs.

Proposition 1: For even n, there exists (up to normalization) one and only one tensor $I^{i_1\cdots i_n}=I^{i_1\cdots i_n}(q)$ analytic in $(q-1)$ that is invariant under $\mathrm{O}_q(N)$,

$$A^{i_1}_{j_1}\cdots A^{i_n}_{j_n}I^{j_1\cdots j_n}=I^{i_1\cdots i_n}, \tag{15}$$

and symmetric,

$$(P^-)^{i_l i_{l+1}}_{j_l j_{l+1}}I^{j_1\cdots j_n}=0, \tag{16}$$

for any l. It can be normalized such that

$$g_{i_l i_{l+1}}I^{i_1\cdots i_n}=I^{i_1\cdots i_{l-1}i_{l+2}\cdots i_n}, \tag{17}$$

for any l. $I^{ij}\propto g^{ij}$.

An explicit form is, e.g., $I^{i_1\cdots i_n}=\lambda_n(\Delta^{n/2}x^{i_1}\cdots x^{i_n})$, where $\Delta=g_{ij}\partial^i\partial^j$ is the Laplacian (in either of the two possible calculi), and λ_n is analytic in $(q-1)$. For $q=1$, they reduce to the classical symmetric invariant tensors.

Proof: The proof is by induction on n. For $n=2$, g^{ij} is in fact the only invariant symmetric (and analytic) such tensor.

Assume the statement is true for n, and suppose I_{n+2} and I'_{n+2} satisfy the above conditions. Using the uniqueness of I_n, we have (in shorthand notation)

$$g_{12}I_{n+2}=f(q-1)I_n, \tag{18}$$

$$g_{12}I'_{n+2}=f'(q-1)I_n, \tag{19}$$

where the $f(q-1)$ are analytic, because the left-hand sides are invariant, symmetric, and analytic. Then $J_{n+2}=f'I_{n+2}-f'I'_{n+2}$ is symmetric, analytic, and satisfies $g_{12}\,J_{n+2}=0$. It remains to show that $J=0$.

Since J is analytic, we can write

$$J^{i_1\cdots i_n}=\sum_{k=n_0}^{\infty}(q-1)^k J^{i_1\cdots i_n}_{(k)}. \tag{20}$$

$(q-1)^{-n_0}J^{i_1\cdots i_n}$ has all the properties of J and has a well-defined, nonzero limit as $q\to 1$; so we may assume $J_{(0)}\neq 0$.

Now consider invariance,

$$J^{i_1\cdots i_n}=A^{i_1}_{j_1}\cdots A^{i_n}_{j_n}J^{j_1\cdots j_n}. \tag{21}$$

This equation is valid for all q, and we can take the limit $q\to 1$. Then A^i_j generate the commutative algebra of functions on the classical Lie group $O(N)$, and J becomes $J_{(0)}$, which is just a classical tensor. Now $(P^-)^{i_l i_{l+1}}_{j_l j_{l+1}}J^{j_1\cdots j_n}=0$ implies that $J_{(0)}$ is symmetric for neighboring indices, and

therefore it is completely symmetric. With $g_{12}J=0$, this implies that $J_{(0)}$ is totally traceless (classically!). But there exists no totally symmetric traceless invariant tensor for $O(N)$. This proves uniqueness. In particular, $I^{i_1\cdots i_n} = \lambda_n(\Delta^{n/2}x^{i_1}\cdots x^{i_n})$ obviously satisfies the assumptions of the proposition; it is analytic, because in evaluating the Laplacians, only the metric and the $\hat{R}$ matrix are involved, which are both analytic. Statement (17) now follows because x^2 is central. □

Such invariant tensors have also been considered in Ref. 4 (where they are called S), as well as the explicit form involving the Laplacian. Our contribution is a self-contained proof of their uniqueness. So $\langle t^{i_1}\cdots t^{i_n}\rangle_t \equiv I^{i_1\cdots i_n}$ for even n (and 0 for odd n) defines the unique invariant integral over S_q^{N-1}, which thus coincides with the definition given in Ref. 7.

From now on we only consider $N\geqslant 3$ since for $N=1,2$, Euclidean space is undeformed. The following lemma is the origin of the cyclic properties of invariant tensors. For quantum groups, the square of the antipode is usually not 1. For $(S)O_q(N)$, it is generated by the D matrix: $S^2A^i_j=D^i_lA^l_k(D^{-1})^k_j$, where $D^i_l=g^{ik}g_{lk}$ (note that D also defines the quantum trace). Then

Lemma 1: For any invariant tensor $J^{i_1\cdots i_n} = A^{i_1}_{j_1}\cdots A^{i_n}_{j_n}J^{j_1\cdots j_n}$, $D^{i_1}_{l_1}J^{i_2\cdots l_1}$ *is invariant too:*

$$A^{i_1}_{j_1}\cdots A^{i_n}_{j_n}D^{j_1}_{l_1}J^{j_2\cdots l_1}=D^{i_1}_{l_1}J^{i_2\cdots l_1}. \tag{22}$$

Proof: From the above, (22) amounts to

$$(S^{-2}A^{i_1}_{j_1})A^{i_2}_{j_2}\cdots A^{i_n}_{j_n}J^{j_2\cdots j_nj_1}=J^{i_2\cdots i_ni_1}. \tag{23}$$

Multiplying with $S^{-1}A^{i_0}_{i_1}$ from the left and using $S^{-1}(ab)=(S^{-1}b)(S^{-1}a)$ and $(S^{-1}A^{i_1}_{j_1})A^{i_0}_{i_1} = \delta^{i_0}_{j_1}$, this becomes

$$A^{i_2}_{j_2}\cdots A^{i_n}_{j_n}J^{j_2\cdots j_ni_0}=S^{-1}A^{i_0}_{i_1}J^{i_2\cdots i_ni_1}. \tag{24}$$

Now multiplying with $A^{l_0}_{i_0}$ from the right, we get

$$A^{i_2}_{j_2}\cdots A^{i_n}_{j_n}A^{l_0}_{i_0}J^{j_2\cdots j_ni_0}=\delta^{l_0}_{i_1}J^{i_2\cdots i_ni_1}. \tag{25}$$

But the (lhs) is just $J^{i_2\cdots i_nl_0}$ by invariance and thus equal to the (rhs). □

We can now show a number of properties of the integral over the sphere.

Theorem 1:

$$\overline{\langle f(t)\rangle_t}=\langle\overline{f(t)}\rangle_t, \tag{26}$$

$$\langle\overline{f(t)}f(t)\rangle_t\geqslant 0, \tag{27}$$

$$\langle f(t)g(t)\rangle_t=\langle g(t)f(Dt)\rangle_t, \tag{28}$$

where $(Dt)^i=D^i_jt^j$. *The last statement follows from*

$$I^{i_1\cdots i_n}=D^{i_1}_{j_1}I^{i_2\cdots i_nj_1}. \tag{29}$$

Proof: For (26), we have to show that $I^{j_n\cdots j_1}g_{j_ni_n}\cdots g_{j_1i_1} = I^{i_1\cdots i_n}$. Using the uniqueness of I, it is enough to show that $I^{j_n\cdots j_1}g_{j_ni_n}\cdots g_{j_1i_1}$ is invariant, symmetric, and normalized as I. So first,

$$A^{i_1}_{j_1}\cdots A^{i_n}_{j_n}(I^{k_n\cdots k_1}g_{k_nj_n}\cdots g_{k_1j_1})=g_{l_1i_1}\cdots g_{l_ni_n}\overline{A^{l_n}_{k_n}\cdots A^{l_1}_{k_1}}I^{k_n\cdots k_1}=\overline{A^{l_n}_{k_n}\cdots A^{l_1}_{k_1}I^{k_n\cdots k_1}}g_{l_1i_1}\cdots g_{l_ni_n}$$
$$=(I^{l_n\cdots l_1}g_{l_ni_n}\cdots g_{l_1i_1}). \tag{30}$$

We have used that I is real (since g^{ij} and $\hat{R}$ are real), and $A^{i_1}_{j_1}g_{k_1j_1}=g_{l_1i_1}\overline{A^{l_1}_{k_1}}$. The symmetry condition (16) follows from standard compatibility conditions between $\hat{R}$ and g^{ij}, and the fact that $\hat{R}$ is symmetric. The correct normalization can be seen easily using $g^{ij}=g_{ij}$ for q—Euclidean space.

To show positive definiteness (27), we use the observation made by Ref. 3 that

$$t^i\to A^i_j u^j, \tag{31}$$

with $u^j=u_1\delta^j_1+u_N\delta^j_N$ is an embedding $S^{N-1}_q\to Fun(O_q(N))$ for $u_1u_N=(q^{(N-2)/2}+q^{(2-N)/2})^{-1}$, since $(P^-)^{ij}_{kl}u^ku^l=0$ and $g_{ij}u^iu^j=1$. In fact, this embedding also respects the star structure if one chooses $u_N=u_1q^{1-N/2}$ and real. Now one can write the integral over S^{N-1}_q in terms of the Haar measure on the compact quantum group $O_q(N,\mathbb{R})$.[10,11] Namely,

$$\langle t^{i_1}\cdots t^{i_n}\rangle_t=\langle A^{i_1}_{j_1}\cdots A^{i_n}_{j_n}\rangle_A u^{j_1}\cdots u^{j_n}\equiv\langle A^i_{\underline{j}}\rangle_A u^{\underline{j}}, \tag{32}$$

(in short notation) since the Haar measure $\langle\,\rangle_A$ is left (and right) invariant $\langle A^i_{\underline{j}}\rangle_A=A^i_{\underline{k}}\langle A^k_{\underline{j}}\rangle_A=\langle A^i_{\underline{k}}\rangle_A A^k_{\underline{j}}$ and analytic, and the normalization condition is satisfied as well. Then $\langle\overline{t^{\underline{i}}}t^{\underline{j}}\rangle_t=\langle\overline{A^{\underline{i}}_{\underline{k}}}A^{\underline{j}}_{\underline{r}}\rangle_A u^{\underline{k}}u^{\underline{r}}$ and for $f(t)=\Sigma f_{\underline{i}}t^{\underline{i}}$, etc.,

$$\langle\overline{f(t)}g(t)\rangle_t=\overline{f_{\underline{i}}}g_{\underline{j}}\langle\overline{A^{\underline{i}}_{\underline{k}}}A^{\underline{j}}_{\underline{r}}\rangle_A u^{\underline{k}}u^{\underline{r}}=\langle\overline{(f_{\underline{i}}A^{\underline{i}}_{\underline{k}}u^{\underline{k}})}(g_{\underline{j}}A^{\underline{j}}_{\underline{r}}u^{\underline{r}})\rangle_A=\langle\overline{f(Au)}g(Au)\rangle_A\,. \tag{33}$$

This shows that the integral over S^{N-1}_q is positive definite, because the Haar measure over compact quantum groups is positive definite,[10] cf. Ref. 12.

Finally we show the cyclic property (29). (28) then follows immediately. For $n=2$, the statement is obvious: $g^{ij}=D^i_k g^{jk}$.

Again using a shorthand notation, define

$$J^{12\cdots n}=D_1I^{23\cdots n1}. \tag{34}$$

Using the previous proposition, we only have to show that J is symmetric, invariant, analytic, and properly normalized. Analyticity is obvious. The normalization follows immediately by induction, using the property shown in proposition (1). Invariance of J follows from the above lemma. It remains to show that J is symmetric, and the only nontrivial part of that is $(P^-)_{12}J^{12\cdots n}=0$. Define

$$\widetilde{J}^{12\cdots n}=(P^-)_{12}\,J^{12\cdots n}, \tag{35}$$

so $\widetilde{J}$ is invariant, antisymmetric, and traceless in the first two indices (12), symmetric in the remaining indices (we will say that such a tensor has the ISAT property), and analytic. It is shown below that there is no such $\widetilde{J}$ for $q=1$ (and $N\geqslant 3$). Then as in Proposition 1, the leading term of the expansion of $\widetilde{J}$ in $(q-1)$ is classical and therefore vanishes, which proves that $\widetilde{J}=0$ for any q.

So from now on $q=1$. We show by induction that $\widetilde{J}=0$. This is true for $n=2$: there is no invariant antisymmetric traceless tensor with two indices (for $N\geqslant 3$). Now assume the statement is true for n even, and that $\widetilde{J}^{12\cdots(n+2)}$ has the ISAT property. Define

$$K^{12\cdots n}=g_{(n+1),(n+2)}\widetilde{J}^{12\cdots(n+2)}. \tag{36}$$

K has the ISAT property, so by the induction assumption

$$K=0. \tag{37}$$

Define

$$M^{145\cdots(n+2)}=g_{23}\widetilde{J}^{12\cdots(n+2)}=\mathscr{S}_{14}M^{145\cdots(n+2)}+\mathscr{A}_{14}M^{145\cdots(n+2)}, \tag{38}$$

where $\mathscr{S}$ and $\mathscr{A}$ are the classical symmetrizer and antisymmetrizer. Again by the induction assumption, $\mathscr{A}_{14}M^{145\cdots(n+2)}=0$ (it satisfies the ISAT property). This shows that M is symmetric in the first two indices (1,4). Together with the definition of M, this implies that M is totally symmetric. Further, $g_{14}M^{145\cdots(n+2)}=g_{14}g_{23}\widetilde{J}^{12\cdots(n+2)}=0$ because $\widetilde{J}$ is antisymmetric in (1,2). But then M is totally traceless, and as in proposition (1) this implies $M=0$. Together with (37) and the ISAT property of $\widetilde{J}$, it follows that $\widetilde{J}$ is totally traceless. So $\widetilde{J}$ corresponds to a certain Young tableaux, describing a larger-than-one-dimensional irreducible representation of O(N). However, $\widetilde{J}$ being invariant means that it is a trivial one-dimensional representation. This is a contradiction and proves $\widetilde{J}=0$. □

Property (27) (which is also implied by results in Ref. 4, once the uniqueness of the invariant tensors is established) in particular means that one can now define the Hilbert space of square-integrable functions on S_q^{N-1}. The same will be true for the integral on the entire Quantum Euclidean space.

The cyclic property (28) is a strong constraint on $I^{i_1\cdots i_n}$ and could actually be used to calculate it recursively, besides its obvious interest in its own. An immediate consequence of (28) is $\langle f(Dt)\rangle_t=\langle f(t)\rangle_t$, which also follows from rotation invariance of the integral, because D is essentially the representation of the (exponential of the) Weyl vector of $\mathscr{U}_q(\mathrm{SO}(N))$.

Notice that although it may not look like it, (28) is consistent with conjugation: even though the D matrix is real, we have

$$\overline{\overline{f(Dt)}}=f(D^{-1}t). \tag{39}$$

To see this, take $f(t)=t^i$; then the (lhs) becomes

$$\overline{D(\overline{t^i})}=\overline{D(t^jg_{ji})}=\overline{D^j_kt^kg_{ji}} \tag{40}$$

$$=D^j_kt^lg_{lk}g_{ji}=t^lg_{jl}g_{ji}=(D^{-1})^i_lt^l, \tag{41}$$

using the cyclic property of g and $D^i_l=g_{ik}g_{lk}$, which is the (rhs) of the above.

III. INTEGRAL OVER QUANTUM EUCLIDEAN SPACE

It is now easy to define an integral over quantum Euclidean space. Since the invariant length $r^2=g_{ij}x^ix^j$ is central, we can use its square root r as well, and write any function on quantum Euclidean space in the form $f(x^i)=f(t^i,r)$. We then define its integral to be

$$\langle f(x)\rangle_x=\langle\langle f(t,r)\rangle_t(r)\cdot r^{N-1}\rangle_r, \tag{42}$$

where $\langle f(t,r)\rangle_t(r)$ is a classical, analytic function in r, and $\langle g(r)\rangle_r$ is some linear functional in r, to be determined by requiring the Stokes theorem. It is essential that this radial integral $\langle g(r)\rangle_r$ is really a functional of the *analytic continuation of* $g(r)$ to a function on the (positive) real line. Only then one obtains a large class of integrable functions, and this concept of integration over the entire space agrees with the classical one.

It will turn out that the Stokes theorem, e.g., in the form $\langle\partial_if(x)\rangle_x=0$ holds if and only if the radial integral satisfies the scaling property

$$\langle g(qr)\rangle_r = q^{-1}\langle g(r)\rangle_r . \tag{43}$$

This can be shown directly; we will instead give a more elegant proof later. This scaling property is obviously satisfied by an arbitrary superposition of Jackson sums,

$$\langle f(r)\rangle_r = \int_1^q dr_0\ \mu(r_0) \sum_{n=-\infty}^{\infty} f(q^n r_0) q^n, \tag{44}$$

with arbitrary (positive) ''weight'' function $\mu(r)>0$. The normalization can be fixed such that, e.g., $\langle e^{-r^2}\rangle_r$ the classical result. If $\mu(r)$ is a delta function, this is simply a Jackson sum; for $\mu(r)=1$, one obtains the classical radial integration,

$$\langle f(r) r^{N-1}\rangle_r = \int_1^q dr_0 \sum_{n=-\infty}^{\infty} q^n (q^n r_0)^{N-1} f(q^n r_0) = \int_0^{\infty} dr\ r^{N-1} f(r). \tag{45}$$

This is the unique choice of $\mu(r)$ for which the scaling property (43) holds for any positive real number, not just for powers of q. We define $f(x^i)$ to be integrable [with respect to $\mu(r)$] if the corresponding radial integral in (42) is finite. We therefore obtain generally inequivalent integrals for different choices of $\mu(r)$, all of which satisfy the Stokes theorem.

Let us try to compare the above definitions with the Gaussian approach. In that case, one does not resort to a classical integral, and determining the class of integrable functions seems to be rather subtle. The Gaussian integration procedure is based on the observation that the integral of functions of the type (polynomial)·(Gaussian) is uniquely determined by the Stokes theorem [and therefore agrees with our definition for any normalized $\mu(r)$]; one would then like to extend it to more general functions by a limiting process. Lacking a natural topology on the space of functions (i.e., formal power series), this limiting process is, however, quite problematic. One way to see this is because there are actually many different inequivalent integrals labeled by $\mu(r)$, such a limiting process can only be unique on the (presumably small) class of functions on which the integral is independent of $\mu(r)$. Furthermore, even classically, although one can calculate, e.g., $\int[1/(r^2+1)]e^{-r^2}$ by expanding it ''properly'' (i.e., using pointwise or L^2 convergence) in terms of Hermite functions, if one tries to expand it formally, e.g., in terms of $\{r^n e^{-r^2}\}$, one obtains a divergent sum of integrals. Thus the result may depend on the choice of basis and limiting procedure. It is not clear to the author how to properly integrate functions other than (polynomial)·(Gaussian) in the Gaussian sense, which would be very desirable, because that approach may be applied to some quantum spaces that do not have a central length element.[6]

The properties of the integral over S_q^{N-1} generalize immediately to the Euclidean case, for any positive $\mu(r)$.

Theorem 2:

$$\overline{\langle f(x)\rangle_x} = \langle \overline{f(x)}\rangle_x , \tag{46}$$

$$\langle \overline{f(x)} f(x)\rangle_x \geqslant 0, \tag{47}$$

$$\langle f(x) g(x)\rangle_x = \langle g(x) f(Dx)\rangle_x , \tag{48}$$

and

$$\langle f(qx)\rangle_x = q^{-N}\langle f(x)\rangle_x , \tag{49}$$

if and only if (43) holds.

Proof: Immediately from theorem (1), (43), and (42), using $Dr=r$ and $\mu(r_0)>0$. □

(46) and (49) were already known for the special case of the Gaussian integral.[4] It was pointed out to me by Fiore that in this case, positivity was also shown in Ref. 5.

IV. INTEGRATION OF FORMS

It turns out to be very useful to consider not only integrals over functions, but also over forms, just like classically. As was mentioned before, there exists a unique N form $dx^{i_1}\cdots dx^{i_N} = \epsilon_q^{i_1\cdots i_N} d^N x$, and we define

$$\int_x d^N x f(x) = \langle f(x)\rangle_x , \tag{50}$$

i.e., we first commute $d^N x$ to the left, and then take the integral over the function on the right. Then the two statements of the Stokes theorem $\langle \partial_i f(x)\rangle_x = 0$ and $\int_x d\omega_{N-1} = 0$ are equivalent.

The following observation by Zumino[13] will be very useful: there is a one-form,

$$\omega = \frac{q^2}{(q+1)r^2}\, d(r^2) = q\,\frac{1}{r}\,dr = dr\,\frac{1}{r}, \tag{51}$$

where $r\ dx^i = q\ dx^i\ r$, which generates the calculus on quantum Euclidean space by

$$[\omega, f]_{\pm} = (1-q)df, \tag{52}$$

for any form f with the appropriate grading. It satisfies

$$d\omega = \omega^2 = 0. \tag{53}$$

We define the integral of an N form over the sphere $r\cdot S_q^{N-1}$ with radius r by

$$\int_{r\cdot S_q^{N-1}} d^N x f(x) = \omega r^N \langle f(x)\rangle_t = dr\ r^{N-1}\langle f(x)\rangle_t , \tag{54}$$

which is a one form in r, as classically. It satisfies

$$\int_{r\cdot S_q^{N-1}} q^N\ d^N x\ f(qx) = \int_{qr\cdot S_q^{N-1}} d^N x\ f(x), \tag{55}$$

where $(drf(r))(qr) = q\ dr\ f(qr)$. Now, defining $\int_r dr\ g(r) = \langle g(r)\rangle_r$, (50) can be written as

$$\int_x d^N x\ f(x) = \int_r \left(\int_{r\cdot S_q^{N-1}} d^N x f(x) \right). \tag{56}$$

The scaling property (43), i.e. $\int_x d^N x\ f(qx) = q^{-N}\int_x d^N x\ f(x)$ holds if and only if the radial integrals satisfy

$$\int_r dr\ f(qr) = q^{-1}\int_r dr\ f(r). \tag{57}$$

We can also define the integral of an $(N-1)$-form $\alpha_{N-1}(x)$ over the sphere with radius r:

$$\int_{r\cdot S_q^{N-1}} \alpha_{N-1} = \omega^{-1}\left(\int_{r\cdot S_q^{N-1}} \omega\alpha_{N-1} \right). \tag{58}$$

The ω^{-1} simply cancels the explicit ω in (54), and it reduces to the correct classical limit for $q=1$.

The epsilon tensor satisfies the cylic property:

Proposition 2:

$$\epsilon_q^{i_1\cdots i_N}=(-1)^{N-1}D^{i_i}_{j_1}\epsilon_q^{i_2\cdots i_N j_1}. \tag{59}$$

Proof: Define

$$\kappa^{12\cdots N}=(-1)^{N-1}D^1\epsilon_q^{23\cdots N1}, \tag{60}$$

in shorthand notation again. Lemma 1 shows that κ is invariant. $\kappa^{12\cdots N}$ is traceless and (q) antisymmetric in $(23\cdots N)$. Now $g_{12}\kappa^{12\cdots N}=0$ because there exists no invariant, totally antisymmetric traceless tensor with $(N-2)$ indices for $q=1$, so by analyticity there is none for arbitrary q. Similarly from the theory of irreducible representations of $SO(N)$,[14] $P^+{}_{12}\kappa^{12\cdots N}=0$, where P^+ is the q symmetrizer, $1=P^++P^-+P^0$. Therefore $\kappa^{12\cdots N}$ is totally antisymmetric and traceless (for neighboring indices), invariant, and analytic. But there exists only one such tensor up to normalization (which can be proved similarly), so $\kappa^{12\cdots N}=f(q)\epsilon_q^{12\cdots N}$. It remains to show $f(q)=1$. By repeating the above, one gets $\epsilon_q^{12\cdots N}=(f(q))^N(\det D)\epsilon_q^{12\cdots N}$ (here $12\cdots N$ stands for the *numbers* 1,2,...,N), and since $\det D=1$, it follows $f(q)=1$ (times an Nth root of unity, which is fixed by the classical limit). □

Now consider a k form $\alpha_k(x)=dx^{i_1}\cdots dx^{i_k}f_{i_1\cdots i_k}(x)$ and an $(N-k)$ form $\beta_{N-k}(x)$. Then the following cyclic property for the integral over forms holds.

Theorem 3:

$$\int_{r\cdot S_q^{N-1}}\alpha_k(x)\beta_{N-k}(x)=(-1)^{k(N-k)}\int_{q^{-k}r\cdot S_q^{N-1}}\beta_{N-k}(x)\alpha_k(q^N\,Dx), \tag{61}$$

where $\alpha_k(q^N\,Dx)=(q^N D\,dx)^{i_1}\cdots(q^N D\,dx)^{i_k}f_{i_1\cdots i_k}(q^N\,Dx)$.

In particular, when α_k and β_{N-k} are forms on S_q^{N-1}, i.e. they involve only $dx^i(1/r)$ and t^i, then

$$\int_{S_q^{N-1}}\alpha_k(t)\beta_{N-k}(t)=(-1)^{k(N-k)}\int_{S_q^{N-1}}\beta_{N-k}(t)\alpha_k(Dt). \tag{62}$$

On Euclidean space,

$$\int_x\alpha_k(x)\beta_{N-k}(x)=(-1)^{k(N-k)}\int_x\beta_{N-k}(x)\alpha_k(q^N\,Dx), \tag{63}$$

if and only if (57) holds.

Notice that on the sphere, $d^Nxf(t)=f(t)d^Nx$.

Proof: We only have to show that

$$\int_{r\cdot S_q^{N-1}}f(x)d^Nx\;g(x)=\int_{r\cdot S_q^{N-1}}d^Nx\;g(x)f(q^N\,Dx) \tag{64}$$

and

$$\int_{r\cdot S_q^{N-1}}dx^i\;\beta_{N-1}(x)=(-1)^{N-1}\int_{q^{-1}r\cdot S_q^{N-1}}\beta_{N-1}(x)(q^N D\,dx)^i. \tag{65}$$

(64) follows immediately from (28) and $x^i\,d^Nx=d^Nx\;q^Nx^i$.

To see (65), we can assume that $\beta_{N-1}(x) = dx^{i_2}\cdots dx^{i_n} f(x)$. The commutation relations $x^i\, dx^j = q\hat{R}^{ij}_{kl}\, dx^k\, x^l$ are equivalent to

$$\begin{aligned} f(q^{-1}x)dx^j &= \mathscr{R}((dx^j)_{(a)}\otimes f_{(1)})(dx^j)_{(b)}(f(x))_{(2)} \\ &= (dx^j \triangleleft \mathscr{R}^1)(f(x)\triangleleft \mathscr{R}^2), \end{aligned} \tag{66}$$

where $\mathscr{R}=\mathscr{R}^1\otimes\mathscr{R}^2$ is the universal $\mathscr{R}$ for $SO_q(N)$, using its quasitriangular property and $\mathscr{R}(A^j_k\otimes {}^i_l) = \hat{R}^{ij}_{kl}$. $f\triangleleft Y = \langle Y, f_{(1)}\rangle f_{(2)}$ is the right action induced by the left coaction (9) of an element $Y\in \mathscr{U}_q(SO(N))$. Now invariance of the integral implies

$$(dx^j\triangleleft\mathscr{R}^1)\langle f(x)\triangleleft\mathscr{R}^2\rangle_t = dx^j\langle f(x)\rangle_t, \tag{67}$$

because $\mathscr{R}^1\otimes\epsilon(\mathscr{R}^2)=1$. Using this, (66), (55), and (54), the (rhs) of (65) becomes

$$\begin{aligned} (-1)^{N-1}\int_{q^{-1}r\cdot S^{N-1}_q}\beta_{N-1}(x)q^N D^i_j\, dx^j &= (-1)^{N-1}D^i_j\int_{r\cdot S^{N-1}_q} dx^{i_2}\cdots dx^{i_N}\, f(q^{-1}x)dx^j \\ &= (-1)^{N-1}\, D^i_j\epsilon^{i_2\cdots i_N j}\omega r^N\langle f(x)\rangle_t \\ &= \epsilon^{ii_2\cdots i_N}\omega r^N\langle f(x)\rangle_t = \int_{r\cdot S^{N-1}_q} dx^i\ \beta_{N-1}(x), \end{aligned} \tag{68}$$

using (59). This shows (65), and (62) follows immediately. (63) then follows from (57). □

Another way to show (65) following an idea of Jurco[15] is to use

$$\int_{r\cdot S^{N-1}_q}(\alpha_k\triangleleft SY)\beta_{N-k} = \int_{r\cdot S^{N-1}_q}\alpha_k(\beta_{N-k}\triangleleft Y) \tag{69}$$

to move the action of $\mathscr{R}^2$ in (66) to the left picking up $\mathscr{R}^1 S\mathscr{R}^2$, which generates the inverse square of the antipode and thus corresponds to the D^{-1} matrix. This approach, however, cannot show (28) or (48), because the commutation relations of functions are more complicated.

(61) shows in particular that the definition (58) is natural, i.e. it essentially does not matter on which side one multiplies with ω. Now we immediately obtain the Stokes theorem for the integral over quantum Euclidean space, if and only if (57) holds. Noticing that $\omega(q^N\, Dx) = \omega(x)$, (63) implies

$$\begin{aligned} \int_x d\alpha_{N-1}(x) &= \frac{1}{1-q}\int_x [\omega,\alpha_{N-1}]_\pm \\ &\propto \int_x \omega\alpha_{N-1} - (-1)^{N-1}\alpha_{N-1}\omega \\ &= \int_x (-1)^{N-1}\alpha_{N-1}\omega - (-1)^{N-1}\alpha_{N-1}\omega = 0. \end{aligned} \tag{70}$$

On the sphere, we get as easily

$$\int_{S^{N-1}_q} d\alpha_{N-2}(t) \propto \int_{S^{N-1}_q}[\omega,\alpha_{N-2}]_\pm = \omega^{-1}\int_{S^{N-1}_q}\omega(\omega\alpha_{N-2} - (-1)^{N-2}\alpha_{N-2}\omega)) = 0, \tag{71}$$

using (62) and $\omega^2=0$.

It is remarkable that these simple proofs only work for $q \neq 1$, nevertheless the statements reduce to the classical Stokes theorem for $q \to 1$. This shows the power of the q-deformation technique.

One can actually obtain a version of the Stokes theorem with spherical boundary terms. Define

$$\int_{q^k r_0}^{q^l r_0} \omega f(r) = \int_{q^k r_0}^{q^l r_0} dr \, \frac{1}{r} \, f(r) = (q-1) \sum_{n=k}^{l-1} f(r_0 q^n), \tag{72}$$

which reduces to the correct classical limit, because the (rhs) is a Riemann sum. Define

$$\int_{q^k r_0 \cdot S_q^{N-1}}^{q^l r_0 \cdot S_q^{N-1}} \alpha_N(x) = \int_{q^k r_0}^{q^l r_0} \left(\int_{r \cdot S_q^{N-1}} \alpha_N(x) \right), \tag{73}$$

For $l \to \infty$ and $k \to -\infty$, this becomes an integral over Euclidean space, as defined before. Then

$$\begin{aligned} \int_{q^k r_0 \cdot S_q^{N-1}}^{q^l r_0 \cdot S_q^{N-1}} d\alpha_{N-1} &= \frac{1}{1-q} \int_{q^k r_0}^{q^l r_0} \left(\int_{r \cdot S_q^{N-1}} \omega \alpha_{N-1} - (-1)^{N-1} \alpha_{N-1} \omega \right) \\ &= \frac{1}{1-q} \int_{q^k r_0}^{q^l r_0} \left(\int_{r \cdot S_q^{N-1}} \omega \alpha_{N-1} - \int_{qr \cdot S_q^{N-1}} \omega \alpha_{N-1} \right) \\ &= \int_{q^l r_0 \cdot S_q^{N-1}} \alpha_{N-1} - \int_{q^k r_0 \cdot S_q^{N-1}} \alpha_{N-1}. \end{aligned} \tag{74}$$

In the last line, (54), (58), and (72) were used.

ACKNOWLEDGMENTS

It is a pleasure to thank Professor Bruno Zumino for many useful discussions and encouragement. I also wish to thank Chris Chryssomalakos, Chong-Sun Chu, Pei-Ming Ho, Branislav Jurco, and Bogdan Morariu for very useful discussions, and Gaetano Fiore for pointing out his results to me.

Orbit–orbit branching rules for families of classical Lie algebra–subalgebra pairs

M. Thoma and R. T. Sharp
Physics Department, McGill University, Montreal, Quebec H3A 2T8, Canada

(Received 27 November 1995; accepted for publication 13 May 1996)

Complete orbit–orbit branching rules are derived for each classical algebra–maximal-subalgebra pair $C_{m+n}\supset C_m\oplus C_n$, $B_{m+n}\supset D_m\oplus B_n$, $D_{m+n}\supset D_m\oplus D_n$. Since each pair is equal rank, and algebra and subalgebra Weyl sectors line up, the integrity basis in each case consists of the subalgebra orbits contained in the fundamental orbits of the algebra. © *1996 American Institute of Physics.* [S0022-2488(96)00109-0]

I. INTRODUCTION

In physics it is generally useful, when possible, to reduce an object of interest to smaller ''building blocks.'' We are thinking of the reduction of irreducible representations (IRs) of a simple, or semisimple, Lie algebra to Weyl orbits (W-orbits, or simply orbits), a device which has seen little exploitation so far in applications of group theory.

A particular use of W-orbits is as an intermediate stage in finding branching rules between IRs of algebra and subalgebra. The procedure consists of three steps.

(i) Reduction of the algebra IR into algebra W-orbits; this can be done by a recursive routine[1,2] or better by a procedure described later in this paragraph under step (iii); extensive tables exist.[3]

(ii) Reduction of algebra W-orbits to subalgebra W-orbits, the subject of this paper, which treats algebra–subalgebra pairs listed in the abstract.

(iii) Assembling subalgebra orbits into subalgebra IRs; the W-orbits of the subalgebra IRs may be lifted, one IR at a time, starting with the highest, from the collection of subalgebra orbits. Alternatively, each subalgebra orbit can be written directly as a superposition of subalgebra IRs.[4] The relevant orbit–IR triangular matrix (for the algebra) can be inverted for a solution of step (i) above.

These steps have been applied to a few low-rank Kac–Moody algebras to obtain IR–IR branching rules.[5]

Usually, in representation theory, it is simplest to use a fundamental weights basis in weight space. In the present context we find it more convenient to use an orthonormal weights basis for the most part; it is easier then to recognize to which algebra W-orbit a given subalgebra W-orbit belongs.

We complete this section with some information from recent papers which give orbit–orbit branching rules for some low-rank algebras:[5,6] the three families to be considered here have the properties that algebra and subalgebra have the same rank and that Weyl sectors of algebra and subalgebra line up, that is, each subalgebra Weyl sector contains only complete algebra sectors. Then the elementary subalgebra orbits consist of the subalgebra orbits lying in the fundamental orbits of the algebra; they form the integrity basis from which all subalgebra orbits are formed by taking stretched products (orbit labels all additive). We then have only to find which pairs of elementary orbits are compatible and which are incompatible to complete the solution of the problem.

II. THE ALGEBRA–SUBALGEBRA PAIR $C_{m+n}\supset C_m\oplus C_n$

We treat this family first because it is simplest.

0022-2488/96/37(9)/4750/8/$10.00

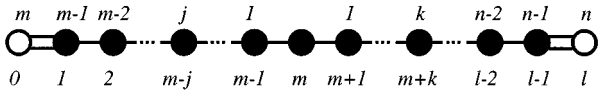

FIG. 1. The Dynkin–Coxeter diagram for $C_{m+n} \supset C_m \oplus C_n$. The numbers below the diagram label the simple roots of C_l ($l=m+n$). Those to the left above label those of C_m, and those to the right above label those of C_n.

As basis vectors in weight space we use the $l=m+n$ orthonormal vectors e_i $(i=1,\ldots l)$. Weyl reflections of C_l consist of sign reversals $e_i \rightarrow -e_i$ and interchanges $e_i \leftrightarrow e_j$.

The simple roots are $\alpha_i = e_i - e_{i+1}$ $(i=1,\ldots,l-1)$ and $\alpha_l = 2e_l$; the extended simple root is $\alpha_0 = -2e_1$ (for simplicity we have multiplied the simple roots, and the fundamental weights below, by $2^{1/2}$). The fundamental weights ω_i are given in terms of the simple roots by the inverse Cartan matrix,

$$\omega_i = \sum_{h=1}^{l} (C^{-1})_{ih} \alpha_h \quad (i=1,\ldots,l), \tag{1}$$

and thus in terms of the orthonormal basis we find

$$\omega_i = \sum_{h=1}^{i} e_h \quad (i=1,\ldots,l). \tag{2}$$

We label a W-orbit by the components λ_j of its highest weight in a fundamental weights basis. The fundamental orbit $[i]$ $[\lambda_j = \delta_{ij}$ (the Kronecker delta)] has highest weight ω_i. According to (2) the weights of the orbit $[i]$ consist of all linear combinations of i distinct e_h, each with coefficient ± 1.

The simple roots of $C_l = C_{m+n}$, C_m, and C_n are shown in Fig. 1. The simple roots α'_j of C_m and α''_k of C_n are given in terms of those of C_l by

$$\begin{aligned} \alpha'_j &= \alpha_{m-j}, \quad (j=1,\ldots,m), \\ \alpha''_k &= \alpha_{m+k}, \quad (k=1,\ldots,n). \end{aligned} \tag{3}$$

Hence the fundamental weights of C_m and C_n are, respectively,

$$\omega'_j = -\sum_{h=1}^{j} e_{m-h+1}, \quad \omega''_k = \sum_{h=1}^{k} e_{m+h}. \tag{4}$$

The elementary $C_m \oplus C_n$ W-orbits are those contained in the fundamental orbits $[i]$ of C_l. We denote one of them by $[j;k]$, the direct product of the fundamental orbits $[j]$ of C_m and $[k]$ of C_n; the ranges of j and of $k=i-j$ are specified below [in (5)]. We may write

$$[i] \supset \sum_{j=\max(i-n,0)}^{\min(i,m)} [j;i-j], \quad i=1,\ldots,l; \tag{5}$$

j is the number of e_h in a weight of $[i]$ for which $1 \leqslant h \leqslant m$ and k is the number in the range $m+1 \leqslant h \leqslant l$; for $j=0$, $[j]$ is the zero or point orbit of C_m and for $k=0$, $[k]$ is the zero orbit of C_n. The elementary orbits $[j;k]$ are shown in tabular form in Fig. 2.

The elementary orbits constitute the integrity basis for all subalgebra orbits: higher orbits are stretched (orbit labels additive) products of powers of the elementary ones.

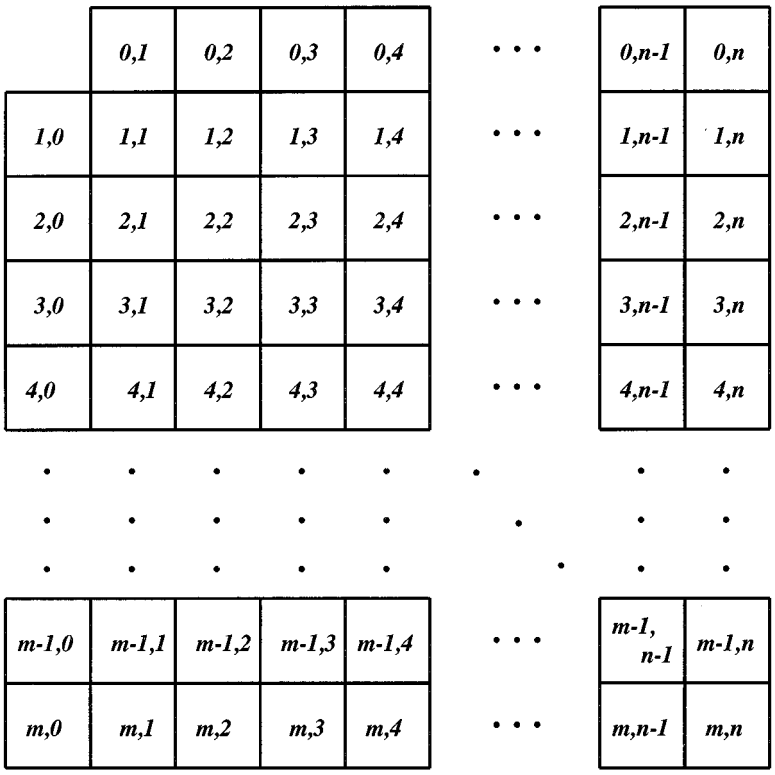

FIG. 2. The elementary $C_{m+n} \supset C_m \oplus C_n$ W-orbits. The elementary orbit $[j;k]$ belongs to the $(j+k)$th fundamental W-orbit of C_{m+n}. The elementary orbits $[j;k]$ and $[j';k']$ are compatible if $j' \geqslant j$, $k' \geqslant k$ (we suppose $j'+k' \geqslant j+k$).

It remains to find the compatibility rules, i.e., the answer to the question ''Which pairs of elementary orbits can appear together in a product yielding a higher orbit?'' Consider the stretched product of the elementary orbits $[j;k]$ and $[j';k']$ which belong respectively to the C_l orbits $[i]$ and $[i']$ with $i=j+k$ and $i'=j'+k'$. We may suppose $i'>i$ (two elementary orbits in the same fundamental orbit are known to be incompatible). Our product must belong to the C_l orbit $[i,i']$ which has labels $\lambda_h=\delta_{hi}+\delta_{hi'}$ (ith and i'th labels unity, other labels zero); each weight of $[i,i']$ has i e_h with coefficient ± 2 and $i'-i$ with coefficient ± 1; the other $l-i'$ e_h have coefficient 0. The stretched product $[j;k]\cdot[j';k']$ belongs to the $C_m \oplus C_n$ orbit $[j,j',k,k']$ with C_m labels $\lambda'_h = \delta_{hj} + \delta_{hj'}$ and C_n labels $\lambda''_h = \delta_{hk} + \delta_{hk'}$. We may suppose $j' \geqslant j$ (otherwise interchange the roles of C_m and C_n); among the first m e_hs there are then j with coefficient ± 2 and $j'-j$ with coefficient ± 1. In the last n e_hs there are thus $i-j=k$ with coefficient ± 2 and $i'-i-j'+j=k'-k$ with coefficient ± 1. It follows that $k' \geqslant k$; two elementary orbits are incompatible if one lies above and to the right of the other in Fig. 2.

Our solution for the $C_{m+n} \supset C_m \oplus C_n$ orbit–orbit branching rules is now complete. For the subalgebra orbit content of the general C_l orbit $[\lambda_1,...,\lambda_l]$ select a sequence of elementary orbits, one $[j_{i'},k_{i'}]$ from each diagonal $j_{i'}+k_{i'}=i'=\text{const}$ for which $\lambda_{i'} \neq 0$. Each one chosen must be compatible with the preceding one $[j_i;k_i]$ in the list, i.e., $j_{i'} \geqslant j_i$, $k_{i'} \geqslant k_i$. Each such sequence corresponds to one subalgebra orbit $[\lambda'_1,\ldots,\lambda'_m;\lambda''_1,\ldots,\lambda''_n]$ with $\lambda'_h = \Sigma_i \lambda_i \delta_{hj_i}$, $\lambda''_h = \Sigma_i \lambda_i \delta_{hk_i}$ (the stretched product of the chosen mutually compatible elementary orbits, the ith one used λ_i times).

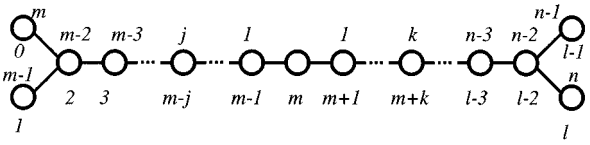

FIG. 3. The Dynkin–Coxeter diagram for $D_{m+n}\supset D_m\oplus D_n$. The numbers below the nodes label the simple roots of D_l $(l=m+n)$. Those to the left above label those of D_m, and those to the right above label those of D_n.

III. THE ALGEBRA–SUBALGEBRA PAIR $D_{m+n}\supset D_m\oplus D_n$

In this section and the next ($B_{m+n}\supset D_m\oplus B_n$), to save space, we state our results without detailed proofs; the proofs are very similar to those given in Sec. II for $C_{m+n}\supset C_m\oplus C_n$, and only slightly more complicated.

We assume here that m and n are both greater than 1. Otherwise we would have to take D_m and/or D_n to be $u(1)$ and the details would be rather different; we hope to treat $D_{m+1}\supset D_m\oplus u(1)$ in a later paper.

As basis vectors in weight space we use $l=m+n$ orthonormal vectors e_i $(i=1,\ldots,l)$. Weyl reflections for D_l consist of interchanges $e_i\leftrightarrow e_j$ and two sign reversals at a time $e_i\rightarrow -e_i$, $e_j\rightarrow -e_j$.

The simple roots are $\alpha_i=e_i-e_{i+1}$ $(i=1,\ldots,l-1)$ and $\alpha_l=e_{l-1}+e_l$. The extended simple root is $\alpha_0=-e_1-e_2$. The fundamental weights ω_i are given in terms of the simple roots by the inverse Cartan matrix [see Eq. (1)] and thus in terms of the orthonormal basis we find

$$\omega_i=\sum_{h=1}^{i} e_h, \quad i=1,\ldots,l-2,$$
$$\omega_{l-1}=\frac{1}{2}\left[\sum_{h=1}^{l-1} e_h-e_l\right], \quad \omega_l=\frac{1}{2}\sum_{h=1}^{l} e_h. \tag{6}$$

The W-orbit labels are defined as in Sec. II following Eq. (1). According to (6) the weights of the fundamental orbit $[i]$, $i=1,\ldots,l-2$, consist of all linear combinations of i distinct e_h with coefficients ± 1; the weights of $[l-1]$ and $[l]$ consist of linear combinations of all e_h, an odd number with coefficient $-\frac{1}{2}$ and the rest with coefficient $+\frac{1}{2}$ for $[l-1]$, an even number with coefficient $-\frac{1}{2}$ and the rest with coefficient $+\frac{1}{2}$ for $[l]$.

The simple roots of D_l, D_m, and D_n are shown in Fig. 3. The simple roots α'_j of D_m and α''_k of D_n are given in terms of D_l simple roots by

$$\alpha'_j=\alpha_{m-j}, \quad j=1,\ldots,m,$$
$$\alpha''_k=\alpha_{m+k}, \quad k=1,\ldots,n. \tag{7}$$

Then the fundamental weights ω'_j of D_m and ω''_k of D_n are respectively

$$\omega'_j=-\sum_{h=m-j+1}^{m} e_h, \quad j=1,\ldots,m-2,$$
$$\omega'_{m-1}=\frac{1}{2}\left[-\sum_{h=2}^{m} e_h+e_1\right], \quad \omega'_m=-\frac{1}{2}\sum_{h=1}^{m} e_h, \tag{8}$$

$$\omega_k''=\sum_{h=m+1}^{m+k} e_h\,,\quad k=1,\ldots,n-2,$$

$$\omega_{n-1}''=\frac{1}{2}\left[\sum_{h=m+1}^{l-1} e_h-e_l\right],\quad \omega_n''=\frac{1}{2}\sum_{h=m+1}^{l} e_h\,.$$

The elementary $D_m\oplus D_n$ orbits are those contained in the fundamental orbits $[i]$ of D_l. We denote one of them by $[j;k]$, the direct product of the orbit $[j]$ of D_m and $[k]$ of D_n, to be specified below. We may write

$$[i]\supset\sum_{j=\max(0,i-n)}^{\min(i,m)}[j;i-j],\quad i=1,\ldots,l-2,$$

$$[l-1]\supset[m;n']+[m';n],\tag{9}$$

$$[l]\supset[m;n]+[m';n'].$$

In the first of Eqs. (9), j is the number of e_h in a weight of $[i]$ for which $1\leqslant h\leqslant m$ and $k=i-j$ is the number in the range $m+1\leqslant h\leqslant l$; for $j=0$ $[j]$ is the zero orbit of D_m and for $j=1,\ldots,m-2$ it is jth fundamental orbit; for $j=m-1$ it is the D_m orbit for which the last two labels, the $(m-1)$th and mth, are unity and the rest zero; for $j=m$ there are two D_m orbits: $[m]$ and $[m']$. The first, $[m]$, has the mth label 2 and the rest 0, while the second, $[m']$, has the $(m-1)$th label 2 and the rest 0. The statements in the preceding sentence are all valid with the replacements $j\to k$, $m\leftrightarrow n$. For $i=l-1$ [the second of Eqs. (9)] there are two elementary orbits, $[m;n']$ and $[m';n]$; for $i=l$ [the third of Eqs. (9)] there are also two, $[m;n]$ and $[m';n']$; here $[m]$ means the mth fundamental orbit of D_m and $[m']$ is the $(m-1)$th; similarly with the replacement $m\leftrightarrow n$.

Figure 4 shows the elementary subalgebra orbits described above. Except for the four in the lower right-hand corner, those for which $j+k=i$ belong to the orbit $[i]$ of D_l. The two at the bottom of the nth column belong to $[l-1]$ while the two at the right of the mth row belong to $[l]$.

To complete the description of our solution we must now give the compatibility rules.

Consider a pair of elementary orbits in Fig. 4, of which neither is in the lower right corner, i.e., belongs to the $(l-1)$th or lth fundamental orbit of D_l and not both of which lie in the bottom row with $j=m$ or m' nor both in the right column with $k=n$ or n'. Then they are incompatible if and only if one lies above and to the right of the other. If both are in the right column and at most one in the lower right corner, they are compatible if and only if both are labeled n or both labeled n'. Similarly if both are in the bottom row and at most one in the lower right corner, they are compatible if and only if both are labeled m or both labeled m'. Those in the lower corner are compatible with all those for which $j\leqslant m-1$ and $k\leqslant n-1$. Finally both in the $(l-1)$th fundamental orbit of D_l are compatible with both in the lth fundamental orbit.

For the complete orbit–orbit branching rules, consider a D_l orbit. For each nonzero label λ_i select one elementary subalgebra orbit from the ith fundamental orbit of D_l so that all the elementary orbits chosen are mutually compatible. Then form the stretched product (orbit labels additive) of the elementary orbits chosen, the ith one used λ_i times. Each such choice of elementary orbits gives one $D_m\oplus D_n$ orbit in the D_l orbit $[\lambda_1,\ldots,\lambda_l]$.

IV. THE ALGEBRA–SUBALGEBRA PAIR $B_{m+n}\supset D_m\oplus B_n$

We suppose that $m>1$ since D_1 would be $u(1)$ and the details different. We hope to deal with $B_{m+1}\supset B_m\oplus u(1)$ in a future paper.

As basis vectors in weight space we use $l=m+n$ orthonormal vectors e_h $(h=1,\ldots,l)$. Weyl reflections for B_l consist of sign reversals $e_i\to -e_i$ and interchanges $e_i\leftrightarrow e_j$.

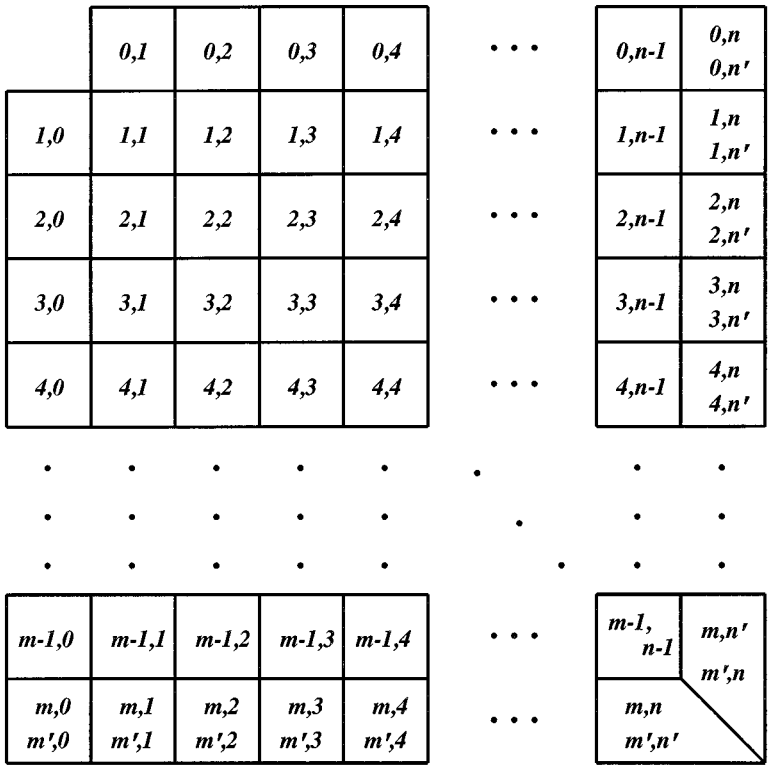

FIG. 4. The elementary $D_{m+n}\supset D_m\oplus D_n$ W-orbits. Which ones belong to a D_{m+n} orbit $[i]$ and which pairs are compatible are stated in the text.

The simple roots are $\alpha_i=e_i-e_{i+1}$ $(i=1,\ldots,l-1)$ and $\alpha_l=e_l$; the extended simple root is $\alpha_0=-e_1-e_2$. The fundamental weights are given in terms of the simple roots by means of the inverse Cartan matrix, and in terms of the orthonormal basis we have

$$\omega_i=\sum_{h=1}^{i} e_h \quad (i=1,\ldots,l-1),$$
$$\omega_l=\frac{1}{2}\sum_{h=1}^{l} e_h . \tag{10}$$

The W-orbit labels are the components λ_i of the highest weight of the orbit in a fundamental weights basis. According to (10) the weights of the fundamental orbit $[i]$, $i=1,\ldots,l-1$, consist of all linear combinations of i distinct e_h with coefficients ±1; the weights of the last fundamental orbit $[l]$ consist of linear combinations of all e_h with coefficients $\pm\frac{1}{2}$.

The simple roots of B_l, D_m, and B_n are shown in Fig. 5. The simple roots α'_j of D_m and α''_j of B_n are given in terms of the B_l simple roots by

$$\alpha'_j=\alpha_{m-j}, \quad j=1,\ldots,m,$$
$$\alpha''_k=\alpha_{m+k}, \quad k=1,\ldots,n. \tag{11}$$

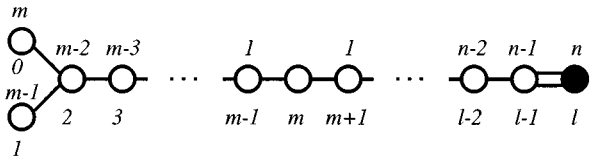

FIG. 5. The Dynkin–Coxeter diagram for $B_{m+n}\supset D_m\oplus B_n$. The numbers below the nodes label the simple roots of B_l ($l=m+n$). Those to the left above label those of D_m, and those to the right above label those of B_n.

Then the fundamental weights ω_j' of D_m and ω_j'' of B_n are respectively

$$\begin{gathered}\omega_j'=-\sum_{h=m-j+1}^{m} e_h, \quad j=1,\ldots,m-2,\\ \omega_{m-1}'=\frac{1}{2}\left(e_1-\sum_{h=2}^{m} e_h\right), \quad \omega_m'=-\frac{1}{2}\sum_{h=1}^{m} e_h,\\ \omega_k''=\sum_{h=m+1}^{m+k} e_h, \quad k=1,\ldots,n-1,\\ \omega_n''=\frac{1}{2}\sum_{h=m+1}^{l} e_h.\end{gathered} \tag{12}$$

The elementary $D_m\oplus B_n$ orbits are those contained in the fundamental orbits $[i]$ of B_l. They may be written $[j;k]$, the direct product of a D_m orbit $[j]$ and a B_n orbit $[k]$. Explicitly we have

$$\begin{gathered}[i]\supset\sum_{j=\max(0,i-n)}^{\min(i,m)}[j;i-j], \quad i=1,\ldots,l-1,\\ [l]\supset[m;n]+[m';n].\end{gathered} \tag{13}$$

Here j is the number of e_h in a weight of $[i]$ for which $1\leqslant h\leqslant m$ and $k=i-j$ is the number in the range $m+1\leqslant k\leqslant l$. For $j=0$, $[j]$ is the zero orbit of D_m and for $k=0$, $[k]$ is the zero orbit of B_n. For $j=1,\ldots,m-2$, $[j]$ is the jth fundamental orbit of D_m and for $k=1,\ldots,n-1$, $[k]$ is the kth fundamental orbit of B_n. For $j=m-1$ $[j]$ is the D_m orbit with the $(m-1)$th and mth labels unity and the rest zero; for $j=m$ there are two D_m orbits, $[m]$, which has the mth label 2 and the rest 0, and $[m']$, which has the $(m-1)$th label 2 and the rest 0. For $k=n$, the B_n orbit $[n]$ has the nth label 2 and the rest 0. For $i=l$, there are two $D_m\oplus B_n$ orbits $[m;n]$ and $[m';n]$ where $[m]$ and $[m']$ are, respectively, the mth and $(m-1)$th fundamental orbits of D_m and $[n]$ is the nth fundamental orbit of B_n.

It remains to give the compatibility rules for $B_l\supset D_m\oplus B_n$; they are very similar to those for $C_l\supset C_m\oplus C_n$ and $D_l\supset D_m\oplus D_n$.

If not more than one of a pair lies in the bottom row of Fig. 6, i.e., if $j\neq m$ for one of the pair, then they are incompatible if either lies above and to the right of the other, otherwise they are compatible. If both lie in the bottom row they are compatible if both are labelled m or both labelled m'; otherwise they are incompatible.

The instructions for finding a complete set of compatible orbits and hence the complete orbit–orbit branching rules are the same as those for $C_l\supset C_m\oplus C_n$ in Sec. II and for $D_l\supset D_m\oplus D_n$ in Sec. III.

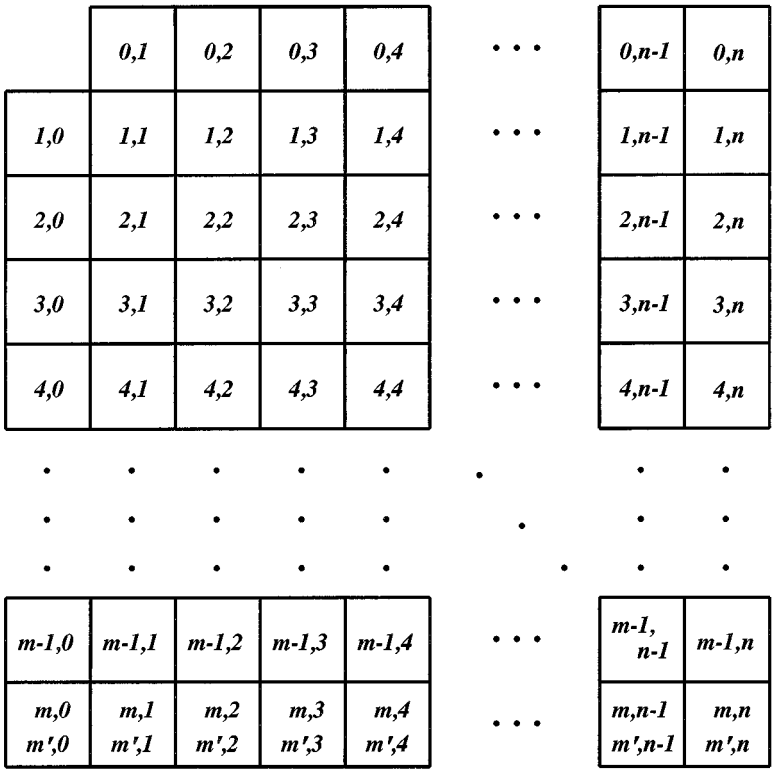

FIG. 6. The elementary $B_{m+n} \supset D_m \oplus B_n$ W-orbits. The elementary orbit $[j;k]$ belongs to the $(j+k)$th fundamental W-orbit of B_{m+n} (two of them when $k=m$).

V. CONCLUDING REMARKS

We hope in the near future to publish orbit–orbit branching rules for compact algebra–subalgebra families in which the subalgebra is reductive but not semisimple, i.e., contains a $u(1)$ factor. We are thinking of $A_{m+n+1} \supset A_m \oplus A_n \oplus u(1)$, $C_{m+1} \supset A_m \oplus u(1)$, and $D_{m+1} \supset A_m \oplus u(1)$. Then we hope to deal with families of Kac–Moody algebra–subalgebras; we had started on this problem when we noticed that the classical problem had never been solved and decided it should be dealt with first.

A group analysis approach for a nonlinear differential system arising in diffusion phenomena

M. Torrisi, R. Tracinà, and A. Valenti
Dipartimento di Matematica, Università di Catania, Viale Andrea Doria 6, 95125 Catania, Italy

(Received 19 September 1995; accepted for publication 22 May 1996)

We consider a class of second-order partial differential equations which arises in diffusion phenomena and, following a new approach, we look for a Lie invariance classification via equivalence transformations. A class of exact invariant solutions containing an arbitrary function is obtained. © *1996 American Institute of Physics.* [S0022-2488(96)00909-7]

I. INTRODUCTION

Lie point symmetries approach is a systematic way to construct exact solutions for partial differential equations (PDEs).[1–3] The looking for symmetries via the Lie infinitesimal criterion leads to the so-called ''determining system'', which is a linear PDEs system in the unknown coordinates of the invariance operator. The determining system, in general, is an overdetermined system which becomes very difficult to solve when arbitrary functions appear. In fact, quite often in these cases the general solution of the determining system is a wasteful venture. In these cases an effective way which gives a group classification is based on equivalence transformations.

In some recent papers[4–9] it was shown that it is possible to obtain subalgebras of the Lie algebra of PDEs, starting from equivalence algebra. Of course, this fact allows, quite often, only a partial classification, but this approach offers a systematic way to get solutions of the determining system.

In this framework we consider the system

$$u_t = h(u,v), \quad v_t = [g(v)v_x + f(v)u_x]_x, \tag{1.1}$$

where we assume $g' \neq 0$ and $f' \neq 0$. Moreover, we denote with $(\ )_t$ and $(\ )_x$ the partial derivatives with respect to the independent variables t and x, respectively, while the prime denotes the derivative of the functions with respect to their argument.

The equations (1.1), apart from their own theoretical interest, can describe the diffusion of a solvent into a polymer slab, which is characterized by a sharp front that moves into the medium and lasts for long time.

The stress in the polymer increases because of the intrusion of the solvent which deforms the polymer. On the contrary this stress reacts back on the penetrant and tries to push it from regions of high stress to regions of low stress.

So the model equations proposed include solvent flux due to stress gradients in the polymer in addition to the fickian flux (see, e.g., Refs. 10 and 11).

We give a group classification of system (1.1) by means of continuous equivalence transformations.

As is well known, the equivalence transformations change a system into a system belonging to the same class.[9,12] Generally speaking, the system (1.1) is mapped into a system of the same form but with different $h(u,v)$, $g(v)$, and $f(v)$.

In the classical approach for finding equivalence transformations of system (1.1) in agreement with Ref. 12, by using the Lie infinitesimal criterion, the infinitesimal equivalence generator of our system is obtained by requiring in the space of (t,x,u,v,h,f,g) the invariance of (1.1) and the invariance of the auxiliary conditions

		$X_4=\frac{\partial}{\partial u}$

$$f_t=g_t=h_t=f_x=\cdots=0, \tag{1.2}$$

which characterize the functional dependence of the functions f, g, and h.

Nevertheless, in this paper we leave the classical approach and we behave as follows:[8,9]

(a) we do not work in the space (t,x,u,v,h,f,g), but in the space (t,x,u,v,h), in order to obtain an *equivalence classification* with respect to f and g;

(b) we consider the function h at first depending on t, x, u, and v.

The plan of the paper is the following:

In Sec. II we give an *equivalence classification* of system (1.1) without taking auxiliary conditions into account (we show, at the end of Sec. III, how the auxiliary conditions restrict the equivalence algebra).

In Sec. III we obtain the Lie classification for a function $h(u,v)$ (in Tables I–IV the final results are summarized).

In Sec. IV we find a class of exact invariant solutions for the system of equations which describe the behavior of a solvent penetrating in a polymer. In this class an arbitrary function of x appears which could be determined by the initial conditions.

II. AN EQUIVALENCE CLASSIFICATION

We consider the class of second-order partial differential equation systems

$$u_t=h(t,x,u,v), \quad v_t=[g(v)v_x+f(v)u_x)]_x, \tag{2.1}$$

and look for continuous equivalence transformations which map system (2.1) into a system of the same form but with different $h(t,x,u,v)$, so we consider the function h as a dependent variable. Having in mind to apply the infinitesimal invariance criterion,[12] the infinitesimal equivalence operator Y works in the space (t,x,u,v,h), so it is chosen of the following form:

$$Y=\xi^1\frac{\partial}{\partial t}+\xi^2\frac{\partial}{\partial x}+\eta^1\frac{\partial}{\partial u}+\eta^2\frac{\partial}{\partial v}+\mu\frac{\partial}{\partial h}, \tag{2.2}$$

where the coordinates ξ^i, η^i are sought as functions of t, x, u and v, while μ may depend on t, x, u, v, and h.

The prolongation of Y, which we need, is

TABLE II. $f=f_0e^{pv}$, $g=g_0e^{qv}$, $p\neq 0$, $q\neq 0$.

f'\eta^2+f(\xi_t^1-\eta_v^2+\eta_u^1-2\xi_x^2)=0,\quad f\eta_{xx}^1+g\eta_{xx}^2-\eta_t^2=0,
\end{gathered}
\tag{2.6}
$$

for the functions

$$
\begin{gathered}
\xi^1=\xi^1(t),\quad \xi^2=\xi^2(x),\\
\eta^1=\alpha(t)u+\beta(x,t),\quad \eta^2=\gamma(x,t)v+\pi(x,t),
\end{gathered}
\tag{2.7}
$$

while μ is given from

$$\mu = h(\eta_u^1 - \xi_t^1) + \eta_t^1. \tag{2.8}$$

After some calculations we obtain the following *equivalence classification* of system (2.1):
(a) f,g arbitrary:

$$\xi^1 = 2c_3 t + c_1, \quad \xi^2 = c_3 x + c_2, \quad \eta^1 = \phi(t), \quad \eta^2 = 0, \quad \mu = \phi' - 2c_3 h, \tag{2.9}$$

where c_1, c_2, c_3 are arbitrary constants and ϕ is an arbitrary function of t.
(b) $f = f_0 e^{pv}$, $g = g_0 e^{qv}$, $p \neq 0$, $q \neq 0$:

$$\begin{gathered} \xi^1 = (2c_1 - qc_3)t + c_4, \quad \xi^2 = c_1 x + c_2, \\ \eta^1 = c_3(q-p)u + \phi(t), \quad \eta^2 = c_3, \\ \mu = \phi' + [c_3(2q-p) - 2c_1]h, \end{gathered} \tag{2.10}$$

with f_0, g_0, p, and q constitutive constants, while c_1, c_2, c_3, c_4 are arbitrary constants and ϕ is an arbitrary function of t.
(c) $f = f_0(v+\nu_0)^p$, $g = g_0(v+\nu_0)^q$, $p \neq 0,-1$; $q \neq 0,-2$:

$$\begin{gathered} \xi^1 = (2c_1 - qc_3)t + c_4, \quad \xi^2 = c_1 x + c_2, \\ \eta^1 = c_3(1+q-p)u + \phi(t), \quad \eta^2 = c_3(v+\nu_0), \\ \mu = \phi' + [c_3(1+2q-p) - 2c_1]h, \end{gathered} \tag{2.11}$$

with f_0, g_0, ν_0, p, and q constitutive constants, while c_1, c_2, c_3, c_4 are arbitrary constants and ϕ is an arbitrary function of t.
(d) $f = f_0(v+\nu_0)^{-1}$, $g = g_0(v+\nu_0)^{-2}$:

$$\begin{gathered} \xi^1 = 2c_1 t + c_2, \quad \xi^2 = \psi(x), \quad \eta^1 = \frac{g_0}{f_0}\psi' + \phi(t), \\ \eta^2 = (v+\nu_0)(c_1 - \psi'), \quad \mu = \phi' - 2c_1 h, \end{gathered} \tag{2.12}$$

with f_0, g_0, and ν_0 constitutive constants, while c_1, c_2 are arbitrary constants, ψ is an arbitrary function of x, and ϕ is an arbitrary function of t.

III. LIE SYMMETRIES VIA EQUIVALENCE TRANSFORMATIONS

In this section we will show how it is possible to obtain a symmetry classification of system (1.1), starting from the equivalence classifications obtained in Sec. II.

First of all it must be stressed that the projection of operator Y in the space (t,x,u,v), i.e.,

$$X = \xi^1 \frac{\partial}{\partial t} + \xi^2 \frac{\partial}{\partial x} + \eta^1 \frac{\partial}{\partial u} + \eta^2 \frac{\partial}{\partial v}, \tag{3.1}$$

is a symmetry operator.

Then, starting from the equivalence classification of system (2.1), we obtain some invariance algebras, applying the following theorem:[7,9,13]

Theorem 3.1: Let Y be an equivalence operator for the system (2.1). The operator X is an invariance operator for the system (2.1) where $h=\hat{h}(t,x,u,v)$ if and only if $\hat{h}$ is invariant with respect to Y.

The proof of this theorem follows immediately from the analogous theorems given in Refs. 6 and 9.

Now, we shall give some symmetry operators of systems (1.1) applying the following corollary of previous theorem:

Corollary: By choosing $\hat{h}\equiv h(u,v)$, the operator X is an invariance operator of systems (1.1).

The invariance of the function $\hat{h}$ with respect to the operator Y of the system (2.1), requested by Theorem 3.1, leads to

$$\eta^1 h_u+\eta^2 h_v=h(\eta^1_u-\xi^1_t)+\eta^1_t. \tag{3.2}$$

Specializing the form of η^1, η^2, and ξ^1 for each of the equivalence classes obtained in Sec. II, we obtain a Lie invariance classification with respect to $\hat{h}\equiv h(u,v)$.

We begin by showing the results for the equivalence class (a). With this class we have f and g as arbitrary functions and the equivalence operator Y given by

$$Y=(2c_3t+c_1)\frac{\partial}{\partial t}+(c_3x+c_2)\frac{\partial}{\partial x}+\phi(t)\frac{\partial}{\partial u}+(\phi'-2c_3h)\frac{\partial}{\partial h}. \tag{3.3}$$

So the condition (3.2) becomes

$$\phi(t)h_u=-2c_3h+\phi'. \tag{3.4}$$

This equation is the classifying equation for h in the equivalence class (a). Of course for h arbitrary, from (3.4) we obtain the principal Lie algebra $L_{\mathscr{P}}$ spanned by

$$X_1=\frac{\partial}{\partial t},\quad X_2=\frac{\partial}{\partial x}. \tag{3.5}$$

The classification of h and the corresponding extensions of $L_{\mathscr{P}}$ can be obtained solving (3.4) with respect to h, taking into account that h is independent of t and x. So by deriving with respect to t we obtain

$$\phi' h_u=\phi''. \tag{3.6}$$

From (3.6) and (3.4) three cases arise which lead, after easy calculations, to the following results:

(1) $h=\hat{h}(v)e^{au}$, $a\neq 0$, $\phi=-2c_3/a$,

$$X_3=2t\frac{\partial}{\partial t}+x\frac{\partial}{\partial x}-\frac{2}{a}\frac{\partial}{\partial u}; \tag{3.7}$$

(2) $h=h_0u+\hat{h}(v)$, $\phi=c_4e^{h_0t}$, $c_3=0$,

$$X_3=e^{h_0t}\frac{\partial}{\partial u}; \tag{3.8}$$

(3) $h=h_0$, $\phi=2c_3h_0t+c_4$,

$$X_3=2t\frac{\partial}{\partial t}+x\frac{\partial}{\partial x}+2h_0t\frac{\partial}{\partial u};\quad X_4=\frac{\partial}{\partial u}, \tag{3.9}$$

where h_0 and a are constitutive constants and $\hat{h}(v)$ is a constitutive function of v, while c_3 and c_4 are arbitrary constants.

The results concerning the other equivalence classes (b)–(d) can be obtained following a similar procedure.

The final results are summarized in Tables I–IV, which correspond to equivalence classes (a)–(d), respectively.

Remark: We have a symmetry classification of system (1.1) starting from the equivalence classifications of system (2.1). It is worthwhile remarking that the symmetry classification obtained is larger than the one which could be obtained following the procedures introduced in Ref. 6. In fact, if we look for equivalence transformations which map the system (1.1) into a system of the same form but with a function h depending only on u and v, by following the procedures introduced in Ref. 6, we must take into consideration the restrictions on the equivalence generator given from the auxiliary conditions

$$h_t = h_x = 0, \tag{3.10}$$

which characterize the functional dependence of the function h. So, the prolongation of Y, which now we need, is

$$Y^* = \widetilde{Y} + \omega_1 \frac{\partial}{\partial h_t} + \omega_2 \frac{\partial}{\partial h_x}, \tag{3.11}$$

where the coefficients ω_i, after recalling the notation introduced in (2.4), and after putting

$$\widetilde{D}_i = \frac{\partial}{\partial x^i} + h_{x^i} \frac{\partial}{\partial h}, \tag{3.12}$$

are given by

$$\omega_i = \widetilde{D}_i \mu - h_{x^k} \widetilde{D}_i \xi^k - h_{y^k} \widetilde{D}_i \eta^k. \tag{3.13}$$

Then requiring[9] the invariance of (3.10), with respect to Y^*, we obtain

$$\mu_t = \mu_x = 0, \quad \eta^1_t = \eta^1_x = 0, \quad \eta^2_t = \eta^2_x = 0. \tag{3.14}$$

After observing that the additional restrictions (3.14) are decoupled from conditions (2.6), we can obtain the equivalence transformations of systems (1.1) for the cases (a)–(d) of the previous section by substituting

$$\phi(t) = c_5, \quad \psi(x) = c_6 x + c_7, \tag{3.15}$$

where c_5, c_6, and c_7 are arbitrary constants.

It is a simple matter to verify that if we look for a symmetry classification of systems (1.1), by projection in the space (t,x,u,v), starting from the equivalence transformations of systems (1.1), some extensions of the principal Lie algebra $L_{\mathscr{P}}$ in Tables I–IV cannot be obtained because of (3.15). To ascertain this, it is enough to consider in Table IV the case Nos. 1, 2, 3, and 8 where the symmetry algebras are infinite dimensional.

IV. A CLASS OF INVARIANT SOLUTIONS

As said in Sec. I, the system of equations (1.1) can describe the diffusion of a solvent in a polymer slab. The behavior of the diffusion of the solvent in the polymer cannot be explained by the usual diffusion equation. The introduction of the stress as a dependent variable involves an evolution equation for it. A general formulation of this equation is

$$u_t = r(v)[s(v) - u], \tag{4.1}$$

which is an amalgamation of the Maxwell viscoelastic model and the Kelvin–Voigt elastic model.[10,11]

Starting from some results of previous sections, here we give a class of invariant solutions which involves an arbitrary function of the independent variable x.

After observing that in this case from (4.1) it follows that

$$h = r(v)[s(v) - u], \tag{4.2}$$

it is easy to see that such a class of solutions could be obtained from the case No. 3 in Table IV. Then the system (1.1) is specialized as follows:

$$\begin{aligned} u_t &= h_0 u + \frac{h_0 g_0}{f_0}\, lg(v+\nu_0) + h_1, \\ v_t &= [f_0 (v+\nu_0)^{-1} u_x + g_0 (v+\nu_0)^{-2} v_x]_x. \end{aligned} \tag{4.3}$$

We look for solutions invariant with respect to the generator given by a linear combination of X_1 and X_ψ, that is

$$X = c_1 \frac{\partial}{\partial t} + c_2 \left[\psi(x) \frac{\partial}{\partial x} + \frac{g_0}{f_0}\, \psi' \frac{\partial}{\partial u} - (v+\nu_0)\psi' \frac{\partial}{\partial v} \right]. \tag{4.4}$$

The invariant surface conditions lead to the following equations:

$$\begin{aligned} c_1 \frac{\partial u}{\partial t} + c_2 \psi(x) \frac{\partial u}{\partial x} &= \frac{c_2 g_0}{f_0}\, \psi', \\ c_1 \frac{\partial v}{\partial t} + c_2 \psi(x) \frac{\partial v}{\partial x} &= -c_2 (v+\nu_0)\psi', \end{aligned} \tag{4.5}$$

from which we obtain

$$u = U(\sigma) + \frac{g_0}{f_0}\, lg\, \psi(x), \quad v = V(\sigma)\psi^{-1}(x) - \nu_0, \tag{4.6}$$

where

$$\sigma := c_2 t - c_1 \Gamma(x), \quad \Gamma(x) := \int \frac{1}{\psi(x)}\, dx, \tag{4.7}$$

while U and V are solutions of the following reduced system:

$$\begin{aligned} c_2 U' &= h_0 U + \frac{h_0 g_0}{f_0}\, lgV + h_1, \\ c_2 V^3 V' &= -2 g_0 c_1^2 V'^2 + g_0 c_1^2 V V'' - f_0 c_1^2 V V' U' + f_0 c_1^2 V^2 U'', \end{aligned} \tag{4.8}$$

obtained after substituting (4.6) in (4.3). Looking for solutions of the form

$$V = e^{\mu_1 \sigma + \mu_0} \tag{4.9}$$

after some calculations from (4.8) we obtain

$$U=e^{(h_0/c_2)\sigma+2\mu_0}-\frac{h_0g_0}{2c_2f_0}\,\sigma+\gamma_0,\quad V=e^{(h_0/2c_2)\sigma+\mu_0},\tag{4.10}$$

with μ_0 arbitrary constant,

$$\gamma_0=-\frac{h_0g_0(2\mu_0+1)+2h_1f_0}{2h_0f_0},\tag{4.11}$$

and provided that

$$c_1=\frac{c_2}{\sqrt{h_0f_0}}.\tag{4.12}$$

Going back to (4.6) we obtain

$$\begin{aligned}u&=e^{(h_0/c_2)\sigma+2\mu_0}-\frac{h_0g_0}{2c_2f_0}\,\sigma+\frac{g_0}{f_0}\,lg\,\psi(x)+\gamma_0,\\ v&=\psi(x)^{-1}e^{(h_0/2c_2)\sigma+\mu_0}-\nu_0,\end{aligned}\tag{4.13}$$

where $\psi(x)$ is an arbitrary function which will determined, together with μ_0 and c_2, from suitable initial conditions.

V. CONCLUSIONS

The method proposed in this paper gives a Lie classification of the system (1.1) via equivalence transformations which is larger than that which can be obtained following the classical equivalence approach.[4–9] We showed that the auxiliary conditions restrict the equivalence algebra and then the symmetry algebras.

Moreover, it is interesting to note that, in a physical case, we get a class of invariant solutions which contain an arbitrary function of x. Often, in the nonlinear cases, the invariant solutions contain only arbitrary constants. This implies that such a type of solution cannot satisfy arbitrary initial boundary conditions. In our case, the presence of an arbitrary function of x adds more possibilities in assigning suitable initial conditions.

[S0022-2488(96)01808-7]

There are a few misprints in some of the equations in Sec. V of the paper. The following are the corrected versions of them.

1. Eq. (49b)

The expressions for $\rho(t)$ and $\zeta(t)$ given in Eqs. (49b) should read as

$$\rho(t)=\frac{\rho(0)+2n\varepsilon_2(\rho^2(0)+\zeta^2(0))t}{(1+2n\varepsilon_2\rho(0)t)^2+4n^2\varepsilon_2^2\zeta^2(0)t^2}\,, \quad \zeta(t)=\frac{\zeta(0)}{(1+2n\varepsilon_2\rho(0)t)^2+4n^2\varepsilon_2^2\zeta^2(0)t^2}\,.$$

2. Eqs. (51) and (52)

In the terms proportional to ε_1, $\lambda^2(t)t$ should be replaced by $\int_0^t\lambda^2(t')dt'$.

3. Eq. (55b)

The term $4\varepsilon_1\rho t$ must be replaced by $4\varepsilon_1\int_0^t\rho\ dt'$.

4. Eq. (55a)

The correct form of the solution given in Eq. (55a) must be read as follows.

$$\begin{aligned}S^{\pm}\equiv S^x\pm iS^y=\frac{2\zeta}{\rho^2+\zeta^2}&\left\{\rho\pm i\zeta\,\tanh\left[2\left(\frac{\zeta r^n}{n}-4\varepsilon_1\int_0^t\zeta\rho dt'\right)-\Delta_1\right]\right\}\\&\times\operatorname{sech}\left[2\zeta\left\{\frac{r^n}{n}-4\varepsilon_1\int_0^t\rho\ dt'-\Delta_1\right\}\right]\\&\times\exp\left[\pm 2i\left\{\frac{\rho r^n}{n}-2\varepsilon_1\int_0^t(\rho^2-\zeta^2)dt'+\delta_1\right\}\right].\end{aligned}$$

[S0022-2488(96)00605-0]

Corollary 2 (and therefore $2'$) is incorrect. The correct statement should read as follows: *Corollary 2:* The global coordinate transformation $\Phi: x \mapsto \xi := \Phi(x)$, $x \in \mathbb{R}^{1+n}$, transforms the Euclidean metric tensor $\delta_{\mu\nu}$ into the tensor $g^E_{\mu\nu}$ with components

$$g^E_{\mu\nu}(\xi) := \begin{cases} g_{00}(\xi), & \mu = \nu = 0, \\ 0, & \mu = 0, \nu = 1,\ldots,n; \quad \nu = 0, \mu = 1,\ldots,n, \\ g_{ij}(\xi), & \text{otherwise.} \end{cases}$$

In case $\|V\| = \text{const.}$, then $g_{00}(\xi) = f(\xi^0)$.

Corollary 3 should be understood under the assumption $g_{ij}(\xi) = \sigma_{ij}(\xi^1,\ldots,\xi^n)$.

In Sec. IV, the parameter t should be understood as belonging to a time interval $[-\Delta,\Delta]$, $\Delta \in \mathbb{R}^+$, where Δ is chosen on an appropriate scale, so that $g_{ij}(\xi^0,\xi^1,\xi^2,\xi^3) \simeq g_{ij}(\xi^0 = 0,\xi^1,\xi^2,\xi^3) \equiv \sigma_{ij}(q^1,q^2,q^3)$. Such a scale is infinite if the field V is constant.

This issue is devoted to mesoscopic physics and related topics. Mesoscopic physics is a subject whose development was led to a large extent by technology in the search of a progressive miniaturization of electronic devices. The opportunity to fabricate devices with characteristic dimensions significantly below 1 μm has stimulated the investigation of a whole range of novel physical phenomena.

It is an area of condensed matter still very young with great experimental achievements. From a conceptual point of view mesoscopic physics provides direct verifications of the fundamental laws of quantum mechanics on scales inaccessible only a few years ago. This is a leading thread that unifies the many facets of this area whose boundaries are not yet well defined.

It was clear from the beginning that this special issue could not cover all the aspects involved and choices would have to be made in view of the possible mathematical developments. It was also necessary to make guesses about the directions in which progress may be expected in the near future. After consultation with several experts I decided to take as a leitmotiv of the issue *transport properties in heterostructures*. It is a hard core of mesoscopic physics which, beside its practical importance, involves in several ways an aspect of quantum mechanics of great conceptual and mathematical interest. This is quantum chaos, a theme which appears in many articles of this issue.

The issue contains 21 original contributions and a reprint of an article by R. Landauer of considerable historical interest not easily available today. Let me describe briefly the contents of the articles and their connections.

The first article by F. Capasso, J. Faist, and C. Sirtori provides an overview on heterostructures with interesting physical properties arising from quantum confinement, tunneling and quantum coherence on a mesoscopic scale. It gives an idea of the great possibilities of quantum design.

We then have a series of six articles focused on transport in mesoscopic conductors. M. Büttiker discusses conductance and quantum noise phenomena in a unified theoretical framework. C. Presilla and J. Sjöstrand include the effect of electron–electron interaction in time-dependent transport. L. S. Levitov, H. Lee, and G. B. Lesovik consider statistical prob-lems in connection to measurements of mesoscopic currents. Ballistic transport in coupled quantum waveguides is studied in a rigorous way to P. Exner, P. Sěba, M. Tater, and D. Vaněk while S-matrix, resonances, and wave functions are exactly calculated for simple models of billiards with leads by S. Albeverio, F. Haake, P. Kurasov, M. Kus, and P. Sěba. P. W. Brouwer and C. W. J. Beenakker develop a diagrammatic method for averaging over the circular ensemble of random matrix theory and apply it to chaotic billiards and other systems.

Random matrix theory is dominant in the next group of five articles. Originally proposed in the framework of nuclear physics, this topic has become a central tool in mesoscopic physics in connection with two different aspects: complex behavior due to the presence of impurities or due to chaoticity of the corresponding classical system. Both aspects are present in the article by V. I. Fal'ko and K. B. Efetov in the study of the statistics of wave functions in the more general framework of the supersymmetric nonlinear σ model. A. V. Andreev, B. D. Simons, and B. L. Altshuler are concerned with energy level statistics in disordered systems and how these statistics deviate from the universal ones. The mathematical structures underlying the connection between random matrix theory and the supersymmetric formalism is the subject of the article by M. R. Zirnbauer. P. N. Walker, M. J. Sanchez, and M. Wilkinson discuss singularities of the energy

0022-2488/96/37(10)/4773/2/$10.00
J. Math. Phys. **37** (10), October 1996

levels of a system depending on a set of parameters and described by a random matrix model. A. M. Khorunzhy, B. A. Khoruzhenko, and L. A. Pastur develop a rigorous method for studying the normalized trace of the resolvent of large random matrices.

An alternative approach for studying the spectral statistics in disordered conductors in a regime where random matrix theory is not applicable is proposed in the article by J. T. Chalker, I. V. Lerner, and R. A. Smith.

The article by K. Richter, D. Ullmo, and R. A. Jalabert studies the response to a magnetic field of an integrable billiard in presence of disorder.

Mesoscopic physics offers, in perspective, the possibility of studying chaotic phenomena at the many-particle level when the size of heterostructures and the number of particles are such that a thermodynamic limit represents a natural first approximation. In this limit a quantum system can be chaotic in its time evolution and not simply show signatures of classical chaos as is the case with confined finite systems. One then feels the need for a systematic development of a quantum ergodic theory. The next two articles by S. Graffi and A. Martinez and by M. Lenci take an explicit step in this direction and provide, for the first time, a rigorous analytic proof of ergodicity and mixing for the infinite quantum harmonic crystal and the Volkovisky–Sinai model of an ideal gas quantized according to Boltzmann statistics, respectively.

Arrays of heterostructures represent a new challenge for experimentalists and theorists and presumably will be an important direction for development for mesoscopic physics. The articles by G. Parisi and by V. A. Geyler, B. S. Pavlov, and I. Yu. Popov provide different examples of theoretical problems arising in such a context. Parisi considers the statistical properties of arrays of Josephson junctions while Geyler, Pavlov, and Popov study the spectral properties of lattices of billiards.

Schrödinger operators with singular continuous spectrum have attracted considerable attention on the part of mathematical physicists in recent years. Mesoscopic physics with its wide possibilities of quantum design presents situations which can be modeled by such operators. The next two articles must be read in this perspective. I. Guarneri studies the relationship between quantum dynamics and fractal properties of the spectrum. C. H. Kreft and R. Seiler analyze quantum mechanical models for transport phenomena in two dimensions with fractal spectra.

The last article by F. Benatti deals with quantum information theory. He compares the concept of accessible information of quantum communication channels with the entropy of a subalgebra with respect to a quantum state. Strictly speaking it is a subject which does not belong to the main theme of the issue. It is however a topic of wide interest which in my opinion should become relevant in some applications of mesoscopic physics.

The paper by R. Landauer reprinted in the issue is put in perspective by a comment of the author.

ACKNOWLEDGMENTS

I wish to express my gratitude to all the authors who responded with great enthusiasm to the project by contributing articles of very high quality. I must acknowledge conversations with B. Altshuler, F. Capasso, and L. Levitov and correspondence with H. Baranger and L. Pastur which were useful in planning the issue. My greatest debt is with C. Presilla who collaborated with me in all phases of the realization of the project. He has been a very wise counselor and a constant source of scientific insight. Last but not least I wish to thank the editor of the *Journal of Mathematical Physics*, Roger Newton, for proposing this project. I was reluctant to accept the role of guest editor for this issue, but he insisted and I am grateful to him for involving me in a very interesting enterprise.

Mesoscopic phenomena in semiconductor nanostructures by quantum design

Federico Capasso, Jerome Faist, and Carlo Sirtori
Bell Laboratories, Lucent Technologies, Murray Hill, New Jersey 07974

(Received 13 June 1996; accepted for publication 17 June 1996)

The energy levels, wave functions, optical matrix elements, and scattering rates of electrons can be tailored at will using semiconductor nanostructures as building blocks for practically any kind of potential. This allows the design and experimental realization of new artificial materials and devices, with interesting optical and transport properties arising from quantum confinement, tunneling, and quantum coherence on a mesoscopic scale ranging typically from 1 to 100 nm. This approach is illustrated with a number of recent examples based on experiments and calculations, such as resonant tunneling through double barriers, quantum interference phenomena in transport and optical absorption, bound states in the continuum, quantum well ''pseudomolecules'' with giant nonlinear optical susceptibilities, and quantum cascade lasers. © *1996 American Institute of Physics.* [S0022-2488(96)00210-1]

I. INTRODUCTION

Quantum engineering of the electronic energy levels, wave functions and band structure, matrix elements, and scattering rates using ultrathin semiconductor layers[1,2] grown by molecular beam epitaxy (MBE)[3] allows one to design and observe quantum phenomena on a mesoscopic scale (typically 1–100 nm), much larger than the atomic one.[4–7] This approach is the basis for modifying and tailoring in unprecedented ways the electronic, transport, and optical properties, which has led in many cases to altogether new materials (materials by design) and useful device applications.[2,5–8]

Essential to the emergence of this field of research has been MBE.[3] This epitaxial growth technique allows multilayer heterojunction structures to be grown with atomically abrupt interfaces and precisely controlled material composition over distances as short as a few nanometers. Such structures include quantum wells. These potential energy wells are formed by sandwiching a material such as gallium arsenide (of thickness comparable or smaller than the carrier thermal de Broglie wavelength, which is $\sim$25 nm for electrons in gallium arsenide at room temperature) between two wider energy bandgap semiconductors (for example, aluminum gallium arsenide). The energy spacings of the discrete states of the well arising from quantum confinement depend on the well thickness and depth.

If many quantum wells are grown on top of one another and the barriers are made so thin (typically$<$5 nm) that tunneling between the coupled wells becomes important, a superlattice is formed and the energy levels broaden into energy bands called minibands separated by minigaps.[1] Superlattices are artificial materials with novel optical and transport properties introduced by the artificial periodicity.[2,6,7]

In this paper we shall review our recent work on mesoscopic quantum phenomena based on tunneling and on electronic transitions between quantized states of the same band (intersubband transitions[8]) in semiconductor nanostructures.

Several of the structures considered in this paper should also appeal to mathematicians and mathematical-physicists since this approach allows one to design, synthesize, and experimentally investigate potentials of significant mathematical interest that cannot be found in nature. We shall limit ourselves to one-dimensional potentials, i.e., structures based on quantum wells. For struc-

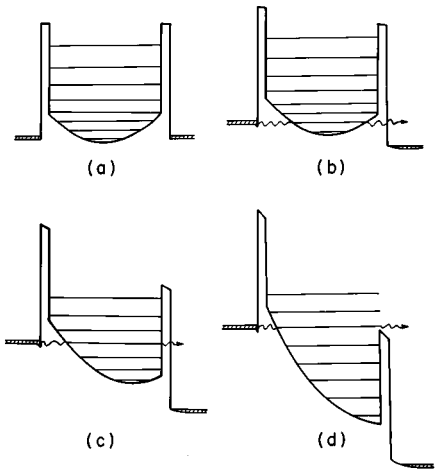

FIG. 1. Energy diagram of resonant tunneling structure under different conditions of applied electric field. (a) Zero field; (b),(c) the electric field is such that electrons resonantly tunnel through the parabolic portion of the well; (d) the applied field is high enough that electrons probe the continuum resonances. The wells are drawn to scale; however, for sake of clarity only half the number of levels in an energy interval are shown.

tures based on quantum wires and dots, i.e., relying on quantum confinement along two and three dimensions, respectively, the reader is referred to Ref. 4.

II. RESONANT TUNNELING AND QUANTUM INTERFERENCE IN ELECTRONIC TRANSPORT

The resonant tunneling double barrier consists of two potential barriers in series separated by a potential well.[9] This well can, of course, have various shapes (Fig. 1).

The kinetic energy of an electron's motion perpendicular to the layers is quantized, just as one would expect for a particle in a box. In the plane of the layers, however, the electron is free, and it behaves semiclassically. As a result, two-dimensional energy subbands $E_n(k)$ are formed:

$$E_n(k)=E_n+\frac{\hbar^2k^2}{2m^*}, \tag{1}$$

where E_n is the nth energy level given by the quantization of the perpendicular kinetic energy, and the second term is the kinetic energy of the electron's free motion parallel to the layers, with wave number k and effective mass m^*.

The energy levels E_n correspond to a half-integer number of electron de Broglie wavelengths across the width of the quantum well. The barriers are thin enough that electrons can tunnel through them into and out of the quantum well. This structure is often compared to a Fabry–Perot optical interferometer: the two barriers play the role of partially transparent mirrors through which light is coupled into and out of a resonant cavity.

As we might expect, the transmissivity for electrons through the double barrier shows resonant peaks when the perpendicular kinetic energy of the incident electrons equals E_n. At these resonant energies the transmissivity for a symmetric double barrier reaches 100%, even though the transmissivity for a single barrier might be less than 1%. This striking resonant enhancement of electron transmission is easily understood in terms of constructive interference between multiply reflected waves. But it cannot be understood within the semiclassical framework, which forbids tunneling through even a single barrier.

This description in terms of Fabry–Perot interferometry is somewhat idealized. In many realistic devices the resonant enhancement of the transmission is considerably weakened by scat-

tering processes because scattering events destroy the phase coherence of multiply reflected waves. One way to estimate the role of scattering is to compare the intrinsic energy width Γ_R of the resonance peak with the collisional broadening Γ_C of the resonance. Γ_R is determined by the degree of transmission through the individual barriers, that is, by the degree of external coupling to the cavity; it is approximately equal to $E_n T_B$, where T_B is the transmissivity of one barrier. Γ_C is determined by the scattering rate, that is, by the internal Q of the cavity. Γ_C is roughly $\hbar/\tau$, where τ is the average time between successive collisions and $\hbar$ is Planck's constant divided by 2π. If Γ_R is much larger than Γ_C, the Fabry–Perot description is appropriate. On the other hand, if Γ_C is much larger than Γ_R, the process can be viewed as sequential rather than coherent: the electrons tunnel into the well, scatter, and tunnel out the opposite side. Devices usually operate somewhere in between these extremes. The scattering reduces the peak transmissivity and broadens the resonance. The area under the transmissivity curve, however, stays constant.

A very important factor in the operation of resonant tunneling structures is the role of space-charge buildup within the well, which gives rise to an electrostatic potential that shifts the resonant energy of the well E_n relative to the energy of incident electrons in the emitter. This is analogous to the shift in the resonant frequency of a nonlinear Fabry–Perot interferometer due to light-intensity buildup, which is known to lead to optical bistability. This effect can give rise to interesting nonlinear oscillations or even chaotic behavior of the charge accumulating in the well.[10,11] Other interesting dynamical phenomena associated with charge accumulation in the well in resonant tunneling structures are discussed in the paper of Presilla and Siostrand of this issue.

In most experiments one measures the current through a resonant tunneling diode when a voltage is applied across the double barrier through the heavily doped contact layers. The applied bias voltage lowers the resonant energy of the cavity relative to the energy of the incident electrons. Once the resonant energy has fallen below the range of incident energies—below the conduction-band edge in the emitter—there is a sharp drop in the current as the applied voltage is increased further. This negative differential resistance is a useful feature for device applications such as high-frequency oscillators and multistate transistors.[5,6,12] Oscillators have operated up to frequencies in excess of 700 GHz.[12]

One can design and implement by MBE the electronic potential and the wave functions of a resonant tunneling structure in a nearly arbitrary way. This is illustrated by the energy diagram (Fig. 1) of a parabolic well between rectangular barriers under different conditions of applied electric fields.[13] This structure was grown by MBE. The 44 nm wide well is bound by 3.5 nm thick aluminum arsenide (AlAs) barriers and its chemical composition is varied from $Al_{0.30}Ga_{0.7}As$ (an alloy) at the edges and gallium arsenide (GaAs) at the center. The subscripts indicate the molar fractions of AlAs and GaAs in the alloy. This double barrier is sandwiched between two high conductivity semiconductor layers to allow application of a voltage. Figure 2 shows the measured current as a function of applied voltage for opposite polarities and the corresponding conductance (i.e., the derivative of the current with respect to voltage). The latter is plotted to enhance the features corresponding to resonant tunneling through the quantum states.

The overall features of the current voltage curve ($I-V$) can be interpreted physically by means of the energy diagrams of Fig. 1. At zero bias, [Fig. 1(a)], the first six energy levels of the well are confined by a parabolic well 225 meV deep, corresponding to the grading from $x=0$ to $x=0.30$, and their spacing is $\simeq$35 meV. When the voltage is increased from 0 to 0.3 V the first four energy levels probed by resonant tunneling [Fig. 1(b)] remain confined by the parabolic portion of the well, and their spacing is practically independent of the electric field, since it is primarily controlled by the curvature of the potential. This gives rise to the calculated and observed equal spacing of the first four resonances in the $I-V$ characteristic (Fig. 2). Consider now the higher-energy levels confined by the rectangular part of the well ($>$230 meV) at zero bias. When the voltage is raised above 0.3 V these levels become increasingly confined on the emitter side by the parabolic portion of the well and on the opposite side by a rectangular barrier, thus becoming progressively more separated, although retaining the nearly equal spacing [Fig. 1(c)].

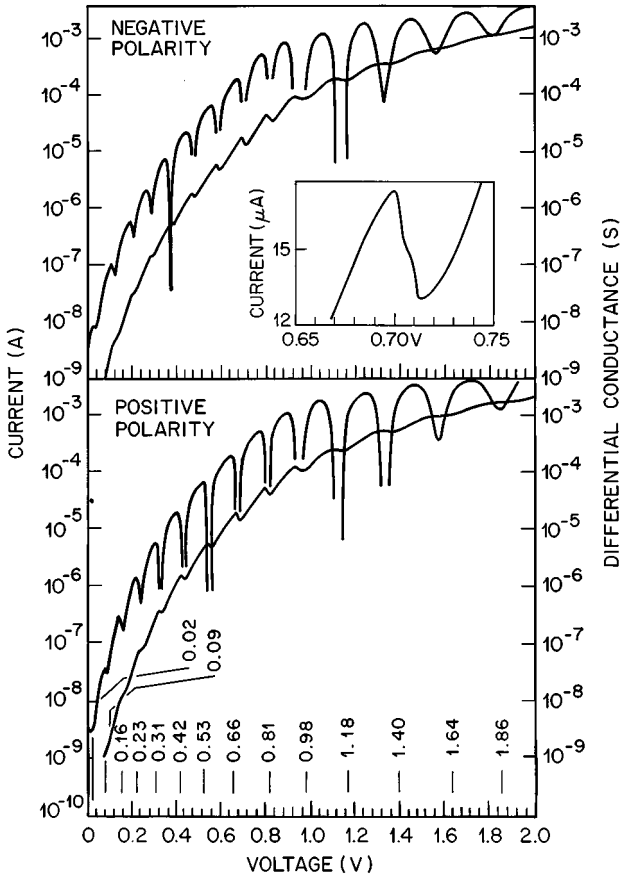

FIG. 2. Current versus applied voltage at 10 K temperature and corresponding differential conductance (dI/dV) for a double barrier structure (Fig. 1) under opposite voltage polarity conditions. The inset shows the eight resonance on a linear scale. The vertical segments near the horizontal axis indicate the calculated positions of the resonances.

This leads to the observed gradual increase in the voltage separation of the resonances as the bias is increased from 0.3 to 1.0 V. Above 1 V the electrons injected from the emitter probe the virtual levels in the quasicontinuum above the collector barrier [Fig. 1(d)]. These resonances result from electron interference effects associated with multiple quantum mechanical reflections at the well–barrier interface for energies above the barrier height. These reflections give rise to the features observed above 1 V in the current–voltage characteristic (Fig. 2), and must be clearly distinguished from the ones occurring at lower voltages, which are due to tunneling through two barriers. It should be noted that in the latter case the reflection from the second barrier is associated with an imaginary wave number in the barrier. In the case of the continuum resonances shown in Fig. 1(d) instead, the reflections from the second barrier are associated with a real wave number since the incident electron energy is greater than the barrier height.

III. QUANTUM INTERFERENCE IN OPTICAL ABSORPTION

Quantum interference effects in the absorption of atoms and molecules have been known since the classic work of Fano.[14] The development of MBE and quantum engineering of semiconductor heterostructures has made possible the observation of new optical absorption phenomena. In particular, in this section, we shall focus on intersubband absorption effects.[15] Intersubband transitions are those where the initial and final quantized states are in the same band, e.g. the

conduction band.[8] In an intersubband transition electrons in a lower state characterized by an eigenvalue (energy level) E_i with a dispersion of the type shown in Eq. (1) make a transition to a higher-energy final state (in the case of optical absorption) characterized by an eigenvalue E_f. Conservation of energy and momentum require $E_i+\hbar\omega=E_f$, where $\hbar\omega$ is the photon energy and $k_i=k_f$. The latter equality comes about because of the negligible momentum of the photon compared to that of the electron $\hbar k$. It should be noted that in such a transition the envelope function of the electron, determined by the one-dimensional heterostructure potential, changes while the rapidly oscillating Bloch function associated with the atomical level periodicity of the underlying crystal is approximately the same for the final and initial states. The latter approximation is correct under the assumptions that band nonparabolicities[15] associated with the effective mass being energy dependent are small, a condition verified in many absorption experiments.

The matrix element of the $i\rightarrow f$ transition is $\langle i|z|f\ )\rangle$, where z is the coordinate normal to the layers. In order to couple to this matrix element the incident radiation must be polarized or at least have a component of the polarization normal to the plane of the layers, i.e., along z. Electrons in the quantum well structures are introduced during crystal growth by the well-known process of doping, i.e., through impurities such as silicon atoms that release an electron. The infrared transmission spectrum can then be measured using standard techniques such as Fourier transform interferometry.

A. Suppression of optical absorption by electric-field-induced quantum interference

Recently the design and demonstration of coupled quantum well structures exhibiting a striking interference effect in the matrix element for intersubband absorption has been reported.[16] The potential and a specific optical transition (1–3) are designed [Fig. 3(a)] so that under application of an appropriate electric field the corresponding matrix element has a null [Fig. 3(b)].

The sample, grown by MBE, comprises 50 coupled quantum wells. Each period consists of two GaAs wells, respectively, 62 and 72 nm thick, separated by a 2 nm $Al_{0.33}Ga_{0.67}As$ barrier. The coupled well periods are separated by a 145 nm $Al_{0.33}Ga_{0.67}As$ spacer layer. To supply the electron charge in the wells an atomically thin layer of silicon dopant ($1\times10^{12}/cm^2$) is inserted in the spacer layers to ensure a symmetric charge transfer. Figure 3(a) shows the energy diagram of the coupled quantum well structure with no applied voltage. Indicated are the energy levels and the moduli squared of the wave functions. The energy levels and wave functions are computed by solving Schrödinger's and Poisson's equations in the envelope function formalism.[1,15]

To get a better insight into the behavior of the coupled well system as a function of the applied electric field, let us first consider the two quantum wells, denoted here as wells a and b, coupled by the barrier in a tight-binding approach.[1] In such a model, the calculated wave functions ψ_i ($i=1,...,4$) of this system are expanded in terms of the eigenfunctions $\phi_{1,2}^{a,b}$ of the first two bound states 1,2 of the two isolated wells. In the tight-binding approximation, the dipole matrix element $z_{1i}=\langle\psi_1|z|\psi_i\rangle$ ($i=3,4$) between the first and the third or fourth state of the coupled well system can now be written as the sum of the contribution from the two wells a and b,

$$z_{1i}=\langle\psi_1|\phi_1^a\rangle\langle\psi_i|\phi_2^a\rangle z_{12}^a+\langle\psi_1|\phi_1^b\rangle\langle\psi_i|\phi_2^b\rangle z_{12}^b, \tag{3}$$

where z_{12}^a and z_{12}^b are the transition matrix elements computed for the isolated wells. As ψ_1 is the ground state of the system, $\langle\psi_1|\phi_1^a\rangle$ and $\langle\psi_1|\phi_1^b\rangle$ have the same sign. On the contrary, since the second excited state ψ_3 crosses zero twice and is constructed from the antisymmetric wave functions $\phi_2^{a,b}$, $\langle\psi_3|\phi_2^a\rangle$ and $\langle\psi_3|\phi_2^b\rangle$ have opposite signs. Therefore, if we consider a transition between the first and third state of the coupled well system, the two terms of Eq. (3) have opposite signs. One thus expects large values of z_{13} for large absolute values of the electric field, where both wave functions are localized in either well a or b [the first or last term of Eq. (3) dominates] and a null for some intermediate value of the electric field. At this field the absorption will be suppressed. This behavior is clearly apparent in Fig. 3(b), where we display the calculated $|z_{13}|^2$. The absorp-

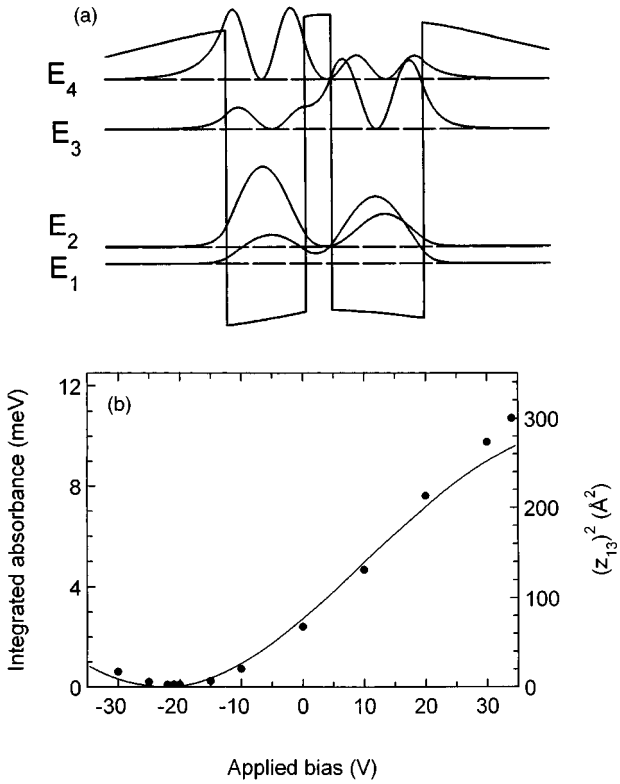

FIG. 3. (a) Energy diagram of an GaAs/$Al_{0.33}Ga_{0.67}As$ coupled-quantum-well structure used to investigate quantum interference in optical absorption. Shown are the positions of the calculated energy subbands and the corresponding modulus squared of the wave functions. We computed E_1=63 meV, E_2=80 meV, E_3=198 meV, and E_4=250 meV. (b) Square of the transition matrix element $(z_{13})^2$ (right axis), as derived experimentally from the integrated absorbance below the (1–3) absorption peak (left axis). The solid line is the calculated value.

tion spectra showed very clearly this effect as the applied electric field was varied.[16] The experimental $|z_{13}|^2$ is derived from a measurement of the area under the 1–3 absorption peak (in units of photon energy), and taking the nominal electron sheet density in the wells (5×10^{11} cm^{-2}). The experimental points in Fig. 3(b) are in good agreement with the calculation.

B. Fano quantum interference

When the excited state $|\phi\rangle$ of a quantum system is coupled to a continuum $|\psi\rangle$ at the same energy it broadens due to the finite lifetime τ introduced by the coupling to the continuum. The absorption spectrum from the ground state $|1\rangle$ to this excited state will be Lorentzian with a full width at half-maximum $\Gamma=\hbar/\tau$. However, a peculiar situation arises when the matrix element $\langle 1|z|\psi\rangle$ from the ground state to the continuum is nonvanishing: the absorption lineshape changes dramatically, becoming asymmetric, and displaying a zero within a few Γ from the absorption peak. This phenomenon, called Fano interference,[14] has been observed in many atomic, molecular, or solid-state systems.

Recently, we have reported the observation of Fano interference in a heterostructure, where all the relevant parameters, i.e., the escape rate Γ and the matrix element to the continuum $\langle 1|z|\psi\rangle$, are tailorable and controlled by design.[17]

The structures are grown by MBE and consist of ten periods. As shown in Fig. 4, each period consists of a GaAs coupled well confined by a high, 40 nm thick $Al_{0.33}Ga_{0.67}As$ barrier on the right

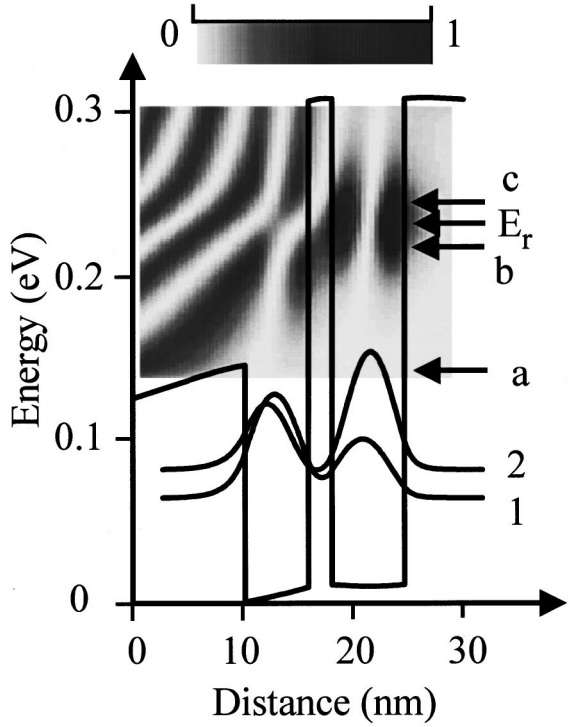

FIG. 4. Energy diagram of a portion of the structure used to study Fano quantum interference in absorption. The thicknesses and doping used in this self-consistent calculation correspond to sample A (see the text). The moduli squared of the wave functions of the $n=1$ and $n=2$ states are displayed. The modulo squared of the wave function in the continuum $|\Psi\rangle$ is represented as a gray-scale density plot. Points a, b, and c represent the final state energies corresponding to the onset of the continuum, the zero, and the maximum of the absorption spectrum (see Fig. 5). The shift between the maximum of the absorption and the position of the resonance E_r is a feature characteristic of Fano interference.

and a thick low $Al_{0.165}Ga_{0.835}As$ barrier on the left. The thickness $L=200$ nm of the $Al_{0.165}Ga_{0.835}As$ barrier is chosen such that it is much longer than the electron's coherence length $\lambda_c \sim 20-50$ nm, and therefore the states of this region behave as a continuum. Two structures with different quantum well thicknesses were grown. Sample A had the strongest coupling due to the relatively thin 2.0 nm $Al_{0.33}Ga_{0.67}As$ barrier coupling the 5.2 nm left well to the 6.4 nm right well. A doping sheet in the $Al_{0.165}Ga_{0.855}As$, separated from the quantum wells by a 25 nm spacer layer provides the 2.5×10^{11} cm^{-2} electron sheet density in the coupled well region. Sample B had a weaker coupling due to the thicker 2.5 nm barrier coupling the 5.5 nm left well to the 6.5 nm well. The electron sheet density was $n_s=5\times10^{10}$ cm^{-2} and the spacer layer 50 nm.

In these samples, the individual ground states of the two wells couple through the thin intermediate barrier to form a doublet with a splitting of about 20 meV. The same barrier also couples the excited state of the right well $|\phi\rangle$ with energy E_r to the energetically degenerate continuum that broadens the state $|\phi\rangle$ by $\Gamma\cong12$ meV for sample A and $\Gamma\cong6$ meV for sample B. In both cases, we have the condition $\Gamma \gg \Gamma_d$, where $\Gamma_d \sim 1-2$ meV is the broadening of $|\phi\rangle$ (homogenous and inhomogeneous) caused by interface roughness and optical phonon scattering. Since the ground state wave function spans both wells and therefore has a strong dipole coupling to both state $|\phi\rangle$ and the continuum state $|\psi\rangle$ above the left well, the structure fulfills the requirements for the observation of Fano interference.[14] In a tight-binding picture,[1] we are coupling a bound-to-bound transition in the right well to a bound-to-continuum in the left well. Note that one would not observe this interference in a sample having only the right well, since the matrix element $\langle 1|z|\psi\rangle \approx 0$ in this case. The features associated with Fano interference are also clearly

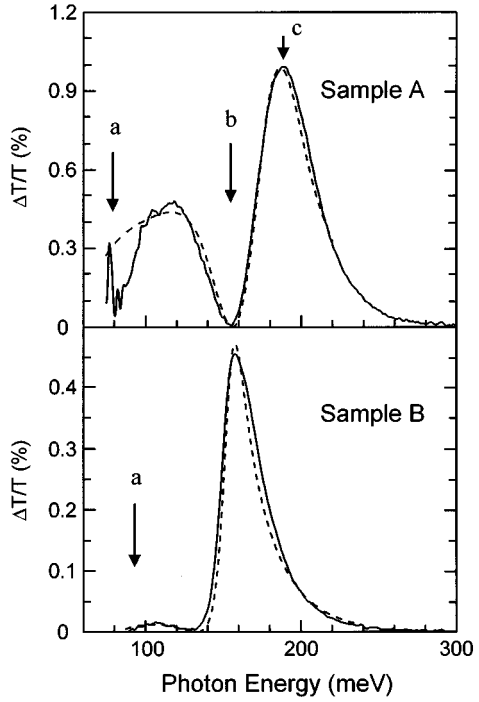

FIG. 5. Absorption spectra of structures exhibiting Fano quantum interference. (a) The solid curve is the measured absorption spectrum for sample A with strong coupling and asymmetry. Points a, b, and c refer to the onset of the continuum, the zero, and the maximum of the absorption (see Fig. 4). The dashed curve is the calculated spectrum. (b) The same for sample B. Note the shift between the absorption peak and the onset of the continuum, which is a feature specific to these samples exhibiting Fano interference.

apparent in the plot of the modulus squared of the eigenfunctions $|\psi\rangle$ of the whole system (consisting of the continuum plus the quantum wells) displayed as a gray scale plot in Fig. 4. As predicted for Fano interference, the calculated maximum and zero of the absorption (points c and b in Fig. 5) lie above and below E_r, respectively. This occurs because $\langle 1|z|\phi\rangle$ and $\langle 1|z|\psi\rangle$ interfere with *opposite phase* on the two sides of the resonance.[14] The expected energy-dependent phase shift experienced by the wave function $|\psi\rangle$ is evident in Fig. 5 as an abrupt shift of the position of the minimum of the modulus squared of the wave functions as the energy crosses the resonant energy. The absorption for both samples is reported in Fig. 5 along with the calculated spectra.[17] The Fano interference is contained in the calculated spectra automatically, since the absorption is computed using the wave function $|\psi\rangle$, which is an eigenfunction of the whole system, coupled well plus continuum. Thus the agreement between the measured and calculated spectra is the proof that these samples exhibit Fano interference. However, note that these experimental lines cannot be fitted in satisfactory fashion with the original Fano lineshape[14] because the same important assumptions used to derive that expression (invariance of both the matrix element and the coupling strength as a function of energy) do not hold in our case. Both spectra also show the qualitative features of the Fano lineshapes with a zero close to the asymmetric absorption peak. The shift ($\sim$100 meV) between the absorption peak and the onset of the continuum is another feature that is specific of these structures exhibiting Fano resonance. An absorption spectrum from a bound-to-continuum single quantum well would peak very close (20 meV) to the onset of the continuum. As expected, the main peak is broader for sample A (50 meV) than for sample B (30 meV) due to its stronger coupling to the continuum.

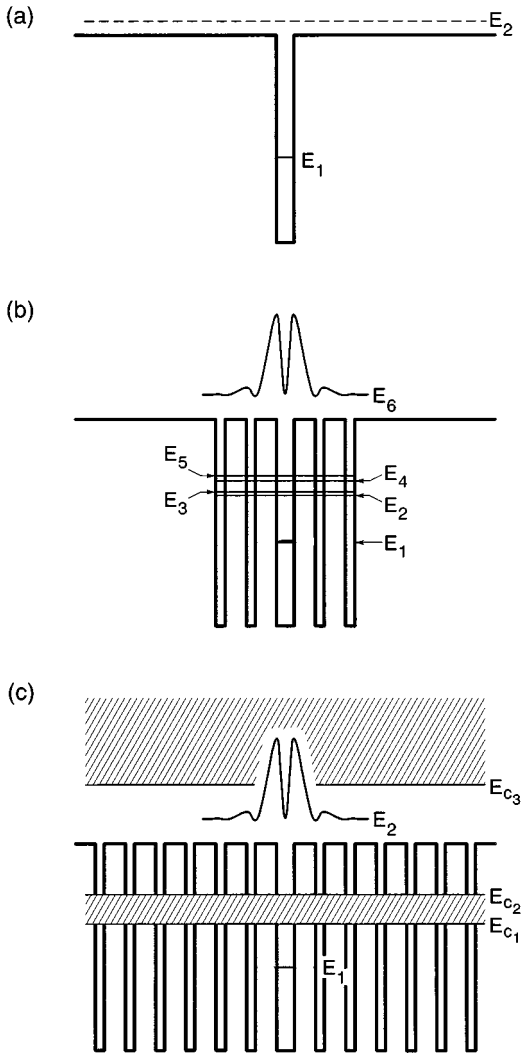

FIG. 6. Energy diagrams of potentials used to study highly localized states in the continuum. (a) Reference sample. Shown are the ground state of the well (E_1=204 meV) and the position (dashed line) of the first transmission resonance in the continuum (E_2=560 meV). (b) Quantum well cladded by two-period quarter-wave stacks. Shown is $|\Psi|^2$ of the localized quasibound state (E_6=560 meV) formed in correspondence to the transmission resonance and the positions of new states created at lower energies (E_2=320 meV, E_3=322 meV, E_4=356 meV, E_5=359 meV). (c) In the superlattice limit the $\lambda/4$ stacks behave as Bragg reflectors. The state above the well now becomes a bound state localized by the superlattice minigap (=266 meV). The low-energy miniband extends from 307 to 379 meV.

IV. CONTINUUM RESONANCES: ELECTRON WAVE INTERFERENCE AND BOUND STATES ABOVE A POTENTIAL WELL

In the previous section we have seen how confined states of quantum wells are central in a number of tunneling and optical phenomena. Highly localized states and even bound states can also be created at energies above the barrier height in a potential well using constructive interference phenomena.[18,19]

Consider first a conventional rectangular well [Fig. 6(a)]. At energies greater than the barrier height one has a continuum of scattering states. For discrete energies corresponding to a semi-integer number of electron wavelengths across the well, one finds transmission resonances. Al-

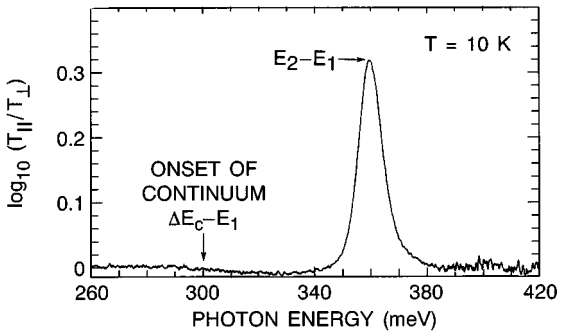

FIG. 7. Absorption spectra at cryogenic temperature for the structure with superlattice Bragg reflectors of Fig. 6(c) (bottom). The transition to the confined state above the well [E_2 in Fig. 6(c)] corresponds to the peak at 360 meV, in excellent agreement with the calculated value for E_2-E_1.

though at these energies the electron amplitude in the well layer is enhanced, the wave functions do not decay exponentially in the barrier, unlike the confined states of the well, but are plane-wave-like. These states can be localized in the well using as barriers stacks of layers of thickness $\lambda/4$ each, where λ is the de Broglie wavelength in the layer (at an energy comparable to that of the selected transmission resonance) [Figs. 6(b)–6(c)]. The net effect is that the reflection coefficient of electrons acquires a high value (near unity) for a significant range of energies (typically 0.1–0.2 eV) above the barrier height. This high value of the reflectivity is the result of interference between the waves partially reflected by the heterointerfaces of the $\lambda/4$ stacks, which leads to the formation of a quasibound state above the center well [Fig. 6(b)]. This strongly narrows the transmission resonance in analogy with a Fabry–Perot optical filter, where sharp optical resonances are produced using as high reflectivity mirrors dielectric quarter-wave stacks. The degree of localization increases with the number of periods; in the structure with just two-period stacks, the wave function is already highly confined [Fig. 6(b)]. In the superlattice limit and at low temperatures, to minimize scattering, the stacks behave as Bragg reflectors; a minigap opens up [Fig. 6(c)] and the localized state becomes a bound state at energies greater than the barrier height. The prediction that certain oscillatory potentials support bound states in the continuum, due to quantum interference, was first put forth by von Neumann and Wigner in 1929.[20]

The reference sample [Fig. 6(a)] had 20 3.2 nm InGaAs doped quantum wells separated by 15 nm undoped AlInAs barriers. In the other three structures the 3.2 nm wells, doped to the same level were cladded, respectively, by one-period, two-period [Fig. 6(b)], and six-period [Fig. 6(c)] $\lambda/4$ stacks consisting of 3.9 nm AlInAs barriers and 1.6 nm GaInAs wells, designed as discussed above. The phase coherence length in the superlattice structure of Fig. 6(c) is estimated to be $\sim$30 nm at 10 K.

The room temperature absorption spectra of the reference sample is broad with a long-wavelength cutoff determined by the height of the barrier.[18] In the structure with one $\lambda/4$ period the peak is considerably narrower and centered at an energy corresponding to the transition between the ground state of the well and the localized resonant state at the energy E_6.[18] As the number of quarter-wave stacks is doubled the absorption peak does not shift and considerably narrows, precisely the behavior expected for an interference filter. In fact, the observed narrowing (16 meV) can be quantitatively explained in terms of the reflectivity increase of the $\lambda/4$ stacks.[18] In the structure with six periods at cryogenic temperatures, the highly localized state becomes effectively a bound state confined by Bragg reflectors from the superlattice.[19] The absorption spectrum (Fig. 7) shows an isolated peak at 360 meV of width $\sim$10 meV corresponding to the transition from the state E_1 to the state E_2 in Fig. 6(c).[19] It is worth noting that the width of the transition to the confined state above the well in the two- and six-period structures is identical to that of the bound-to-bound state transition measured in a conventional 5.5 nm thick GaInAs well

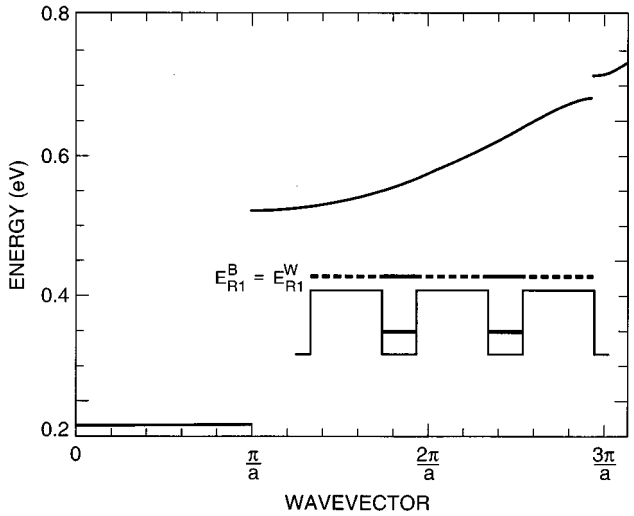

FIG. 8. Energy dispersion along the superlattice axis for a structure (inset) where the first barrier resonance E^B_{R1} is degenerate with second well resonance E^W_{R1}. The resulting mixing of these states produces a very broad miniband from π/a to $\pi/3a$ and suppression of the energy gap at $\pi/2a$. The barriers (AlInAs) and the wells (GaInAs) are, respectively, 8.8 and 3 nm thick.

with 30 nm thick barriers, thus demonstrating the highly localized nature of the state above the well.

Other intriguing phenomena arise when, for example, the first continuum resonances of quantum wells are at the same energy of the first barrier resonance.[21] This can be achieved by suitable adjustment of the layer thicknesses in a superlattice. In this case a very broad miniband is formed that extends in k space from π/a to $3\pi/a$ (where a is the superlattice period), with a minigap suppression at $2\pi/a$ (see Fig. 8). This effect has been confirmed experimentally.[21]

V. COUPLED QUANTUM WELL PSEUDOMOLECULES WITH GIANT NONLINEAR OPTICAL SUSCEPTIBILITIES

Consider an electromagnetic field at frequency ω, propagating through a material. Optical phenomena such as dispersion, absorption, and stimulated emission are described in Maxwell's equations by a linear polarization $P(\omega)=\epsilon_0\chi(\omega)E(\omega)$ proportional to the electric field of the wave $E(\omega)$ via a coefficient $\chi(\omega)$ called susceptibility, where ϵ_0 is the vacuum permittivity. More generally, the polarization contains higher-order but smaller terms at frequencies such as 2ω and 3ω. These nonlinear terms are proportional to powers of the field via nonlinear susceptibilities such as $\chi^{(2)}$ (2ω) and $\chi^{(3)}(3\omega)$, and are responsible for phenomena such as second harmonic generation (SHG) at 2ω and third harmonic generation THG 3ω. The polarizations for these two phenomena can be written as $P(2\omega)=\epsilon_0\chi^{(2)}_{(2\omega)}E^2(\omega)$ and $P(3\omega)=\epsilon_0\chi^{(3)}_{(3\omega)}E^3(\omega)$. More generally, when two beams at frequencies ω_1 and ω_2 are present, nonlinear phenomena such as sum or difference frequency generation at $\omega_1\pm\omega_2$ are possible.

The structures discussed in this section can be viewed as ''pseudomolecules'' with giant dipole matrix elements and nearly equally spaced energy levels (Fig. 9). These characteristics lead to a large enhancement of their nonlinear optical susceptibilities.[22] Physically these susceptibilities in our structures arise from the interaction of light with the quantized anharmonic oscillations of electrons in the potentials of Fig. 10. The latter are grown in the AlInAs/GaInAs system lattice matched to InP, and only the thickest well is doped n-type to provide electrons. The choice of this material system facilitates the tunnel coupling between the layers due to the low effective mass $(0.07\ m_0)$ of the barrier region and provides a large potential barrier (0.5 eV) essential for con-

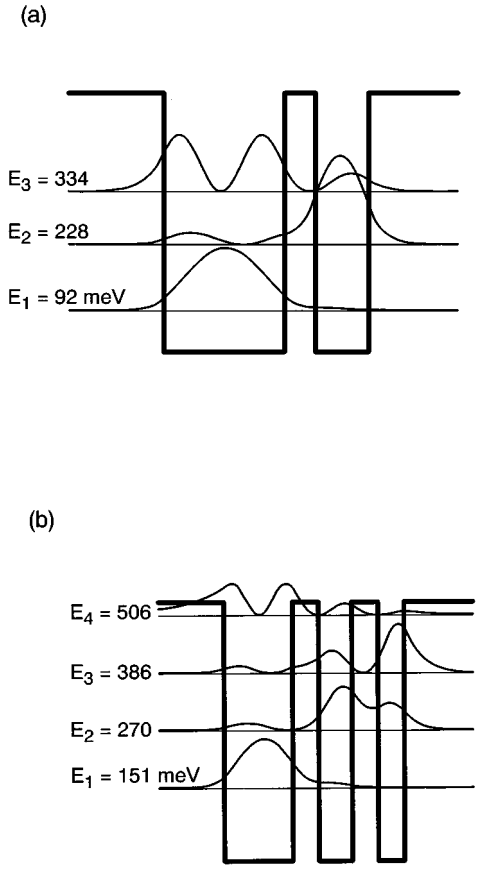

FIG. 9. Energy diagrams of the AlInAs/GaInAs coupled-quantum-well nonlinear optical structures. Shown are the positions of the calculated energy levels and the corresponding moduli squared of the wave functions. (a) The structure used for resonant second harmonic generation. The GaInAs wells have thicknesses of 6.4 and 2.8 nm and are separated by a 1.6 nm AlInAs barrier. (b) The structure used for triply resonant third harmonic generation. The GaInAs wells have thicknesses of 4.2, 2.0, and 1.8 nm, respectively, and are separated by 1.6 nm AlInAs barriers.

fining four states in the three-well structure separated by an energy corresponding to that of the photon from a carbon dioxide (CO_2) laser ($\approx$120 meV). To optically excite the quantized motion normal to the layer interfaces, one must use light with a component of the polarization normal to the layers. In our experiments this was done using linearly polarized light in a multipass waveguide structure wedged at 45°. In our SHG experiment a coherent polarization is created at double the frequency ω of the pump wave (a CO_2 laser beam) due to the lack of reflection symmetry of our two-well structure [Fig. 9(a)]. This coherent polarization radiates a wave of frequency 2ω colinear with the pump. The vicinity of the pump photon energy to E_2-E_1 and of 2ω to E_3-E_1 produces a strong resonant enhancement of the nonlinear susceptibility $\chi^{(2)}_{2\omega}$ associated with SHG.[22] The maximum susceptibility ($\chi^{(2)}_{2\omega}$) corresponds to exact matching, i.e. $\hbar\omega=E_2-E_1=E_3-E_2$. This can be achieved using the large linear Stark effect typical of this structure by applying an electric field of suitable polarity normal to the layers. In these conditions a $|\chi^{(2)}_{2\omega}|=10^{-7}$ m/V was measured, approximately 300 times the value of $|\chi^{(2)}_{2\omega}|$ in bulk GaAs at $\lambda=10$ μm.[22]

The three-well structure [Fig. 9(b)] with the near equal separation of its four energy levels is suitable for triply resonant THG. In this process a pump wave at frequency ω sets up a nonlinear polarization at 3ω that coherently radiates a wave at this frequency.[22] The nonlinear susceptibility $\chi^{(3)}_{3\omega}$ that enters the expression for the polarization is strongly enhanced when the condition

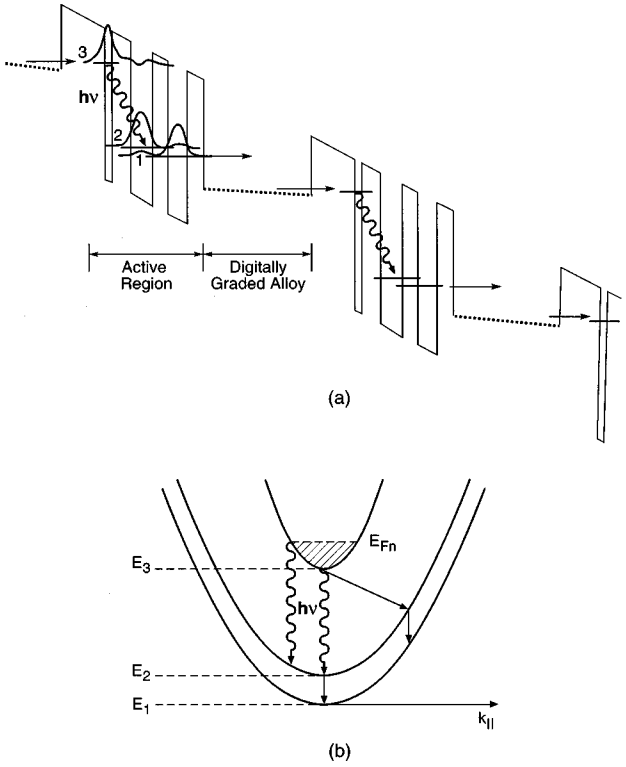

FIG. 10. (a) Energy diagram of a quantum cascade laser showing also the moduli squared of the wave functions. (b) Schematic representation of the dispersion of the $n=1$, 2, and 3 states parallel to the layers; $k_{\|}$ is the corresponding wave number. The wavy lines represent the laser transition.

$\hbar\omega \simeq E_2-E_1 \simeq E_3-E_2 \simeq E_4-E_3$ is met. It is important to note that a parabolic well (i.e., a harmonic oscillator potential) is unsuitable for this purpose, since in such a system the electron oscillations are linear (in quantum mechanical terms the transition matrix elements between nonadjacent states are zero, a property of Hermite polynomials). THG experiments in the structure of Fig. 10(b) have found a $|\chi^{(3)}_{3\omega}|=10^{-14}$ (m/V)^2 at 300 K.[22] At cryogenic temperatures $|\chi^{(3)}_{3\omega}|$ is four times larger. These are the highest third-order susceptibility of any known material system. The three-coupled well structure was also used to study multiphoton electron escape from a well under an applied electric field, the analog of multiphoton ionization of an atom.[23] In this process electrons are photoexcited into the continuum via a CO_2 laser using a three photon transition, giving rise to a photocurrent. The cross section for this process is found to be many orders of magnitude larger than in atoms and molecules.

Consider now the nonlinear optical phenomenon of difference frequency mixing in which two incident waves at frequencies ω_1 and ω_2 interact in a suitable asymmetric medium to set up a polarization at the difference frequency $\omega_1-\omega_2$.[24] This polarization is responsible for the generation of radiation at $\omega=\omega_1-\omega_2$. Quantum nanostructures can be designed to exhibit a very large $\chi^{(2)}(\omega=\omega_1-\omega_2)$ when the incident photons and their energy difference are resonant with optical transitions of the structure. The asymmetric structure of Fig. 3(a) was in fact used for infrared ($\lambda\simeq 60$ μm) difference frequency generation near the energy difference between states $n=2$ and $n=1$, i.e., $\omega_3 \simeq (E_2-E_1)/\hbar$.[24] The photons at ω_1 and ω_2 are chosen to be near resonance with the (1–3) and (3–2) transitions, respectively. As the photon energy difference $\hbar(\omega_1-\omega_2)$ of the two incident CO_2 lasers was tuned near E_2-E_1, the measured far infrared radiation (at $\lambda\sim 60$ μm) exhibited the typical resonant behavior of this process.[24]

VI. QUANTUM CASCADE LASERS

The quantum cascade (QC) laser is an excellent example of how quantum engineering can be used to design new laser materials and related light sources. It is based on intersubband transitions between excited states of coupled quantum wells and on resonant tunneling as the pumping mechanism (Fig. 10). The population inversion between the states of the laser transition is designed by tailoring the electron intersubband scattering times. This tailoring of scattering adds an important dimension to quantum engineering of mesoscopic structures. In QC lasers, unlike all other laser sources, the wavelength is determined by quantum confinement, i.e., by the layer thicknesses of the active region rather than by the chemical properties of the material. As such, it can be tailored over a very wide range using the same heterostructure material. Since the initial report of QC lasers in 1994 (Ref. 25), we have demonstrated emission wavelengths in the 4–8.5 μm range using AlInAs/GaInAs heterostructures lattice matched to InP.[26–29] Figure 10(a) illustrates the conduction band energy diagram of a portion of the 25-period (active region plus injector) section of the quantum cascade laser under an applied electric field normal to the layers $\sim 10^5$ V/cm corresponding to lasing conditions. The dashed lines are the effective conduction band edges of the digitally graded electron-injecting regions, where electrons relax their energy before being injected in the next region. These injectors are short period superlattices (Fig. 11). The population inversion between the states of the laser transition ($n=3$ and $n=2$ in Fig. 10) is obtained by ensuring, by suitable design, that the scattering time from the upper state ($n=3$) to the lower one ($n=2$) is larger than the lifetime of the latter. At the same time one must reduce as much as possible the tunneling escape rate from the $n=3$ state to the continuum, since this process in steady state tends to reduce the population of the upper level. Finally, tunneling out of the lowest state ($n=1$) should be fast enough to avoid a buildup of electrons in that subband. As described below, these requirements are met by a suitable choice of layer thicknesses, number of quantum wells, and electric field in the active region. More specifically, the latter is designed to have a laser transition that is ''diagonal in real space'' (Fig. 10) and an energy separation between the $n=2$ and $n=1$ states resonant with the optical phonon. Electrons are injected through a 4.5 nm AlInAs barrier into the $n=3$ energy level of the active region. The latter includes 0.8 and 3.5 nm thick GaInAs wells separated by a 3.5 nm AlInAs barrier. Note the reduced spatial overlap between the $n=3$ and $n=2$ states (''diagonal'' or photon-assisted tunneling transition) and the strong coupling to an adjacent 2.8 nm GaInAs well through a 3.0 nm AlInAs barrier. Electrons escape from this well through a 3.0 nm AlInAs barrier. The calculated energy differences are $E_3-E_2=295$ meV and $E_2-E_1=30$ meV. The wavy arrow indicates the laser transition. Figure 10(b) shows a schematic representation of the dispersion of the $n=1,2$, and 3 states parallel to the layers; $k_{\|}$ is the corresponding wave number. The bottom of these subbands correspond to energy levels $n=1$, 2, and 3 indicated in (a). The wavy arrows indicate that all radiative transitions originating from the electron population (shown as shaded) in the $n=3$ state have essentially the same wavelength. The quasi-Fermi energy E_{Fn} corresponding to the population inversion at threshold ($n_s=1.7\times10^{11}$ cm^{-2}) is $\sim$8 meV, measured from the bottom of the $n=3$ subband. The straight arrows represent the intersubband scattering processes by optical phonons.

The tunneling rate through the trapezoidal injection barrier is extremely fast ($\sim$0.2 ps)$^{-1}$, ensuring the efficient filling of level 3. The coupled-well region is essentially a four-level laser system, where a population inversion is achieved between the two excited states $n=3$ and $n=2$. The intersubband optical-phonon-limited relaxation time,[25] τ_{32}, between these states is estimated to be $\sim$4.3 ps at $\sim 10^5$ V/cm; this process is between states of reduced spatial overlap and accompanied by a large momentum transfer [Fig. 10(b)] associated with the large intersubband separation; as such, τ_{32} is relatively long. This ensures population inversion between the two states because the lower of the two empties with a relaxation time estimated around 0.6 ps. Strong inelastic relaxation by means of optical phonons with nearly zero momentum transfer occurs between the strongly overlapped and closely spaced $n=2$ and $n=1$ subbands [Fig. 11(b)]. Finally,

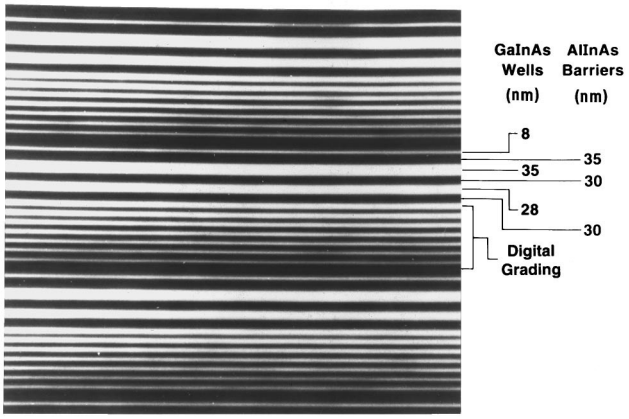

FIG. 11. Transmission electron micrograph of a portion of the cleaved cross section of the quantum cascade laser of Fig. 10. Three periods of the 25 stage structure are shown. The superlattice period of the digitally graded regions is 3 nm and the duty cycle of the AlInAs barrier layers varies from 40% to 77% top-to-bottom, creating a compositionally graded pseudoquarternary alloy in these regions. This is used for injecting electrons from top-to-bottom into the 0.8 nm GaInAs well. The wells and barriers of the digitally graded regions are doped n-type to 1.5×10^{17} cm^{-3} to avoid space-charge buildup under injection, while the other layers are undoped.

the tunneling escape time out of the $n=1$ state is extremely short ($\lesssim$0.5 ps), further facilitating population inversion. The ''diagonal'' nature of the laser transition increases the escape time into the continuum from the $n=3$ level ($\tau_{\text{escp}}\simeq$6 ps), thus enhancing the injection efficiency. Figure 11 is a transmission electron microscope photograph of a cleaved section of the QC laser, showing three periods of the active region.

The 25-period active region is sandwiched between thick AlInAs cladding layers to provide an optical waveguide parallel to the layers. The optical cavity is obtained by cleaving 0.5–3 mm long bars normal to the layers. The crystalline cleavage planes serve as mirrors. With the design of Fig. 10 laser action was obtained in pulsed mode at $\lambda=4.3$ μm with several tens of mW of peak powers and up to $\sim$100 K operating temperatures, but with relatively high thresholds. In this design, the width of the luminescence transition is relatively broad [full width at half-maximum (FWHM)=22 meV] since a diagonal transition is more sensitive to interface roughness associated with thickness fluctuations ($\sim$ one atomic layer) in the plane of the layers. As a consequence, the peak gain is reduced. To circumvent this problem we designed the structure of Fig. 12, where electrons make a vertical radiative transition essentially in the same well.[26] This reduces considerably the width of the gain spectrum (FWHM$\approx$10 meV), and therefore the laser threshold current density. To prevent electron escape in the continuum, which is greatly reduced in the case of the diagonal transition, the superlattice of the digitally graded injector is now designed as an effective Bragg reflector for electrons in the higher excited state and to simultaneously ensure swift electron escape from the lower states via a miniband facing of the latter (Fig. 12).[26] The active region consists of 4.5 mm InGaAs quantum well coupled to a 3.6 nm well by a 2.8 nm AlInAs barrier. Tunneling injection from the superlattice into the active region is through a 6.5 nm AlInAs barrier and electrons escape out of the $n=1$ state through a 3.0 nm AlInAs barrier. As in the other structure, the lower state of the laser transition is separated by an optical phonon ($\approx$30 meV) from the $n=1$ state. The calculated relaxation time is $\tau_{21}\simeq$0.6 ps, which is considerably less than that between the $n=3$ and $n=2$ state (1.8 ps), thus creating population inversion condition between these energy levels. Electrons can, in turn, tunnel out of the $n=1$ state in a subpicosecond time to prevent electron buildup.

Dramatic performance improvements have been obtained with vertical transition QC lasers.[26] The threshold current density is considerably reduced ($\sim$ a factor of 2) leading to higher operating

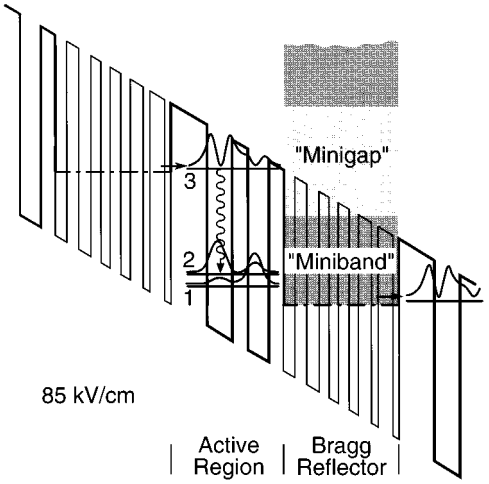

FIG. 12. The schematic energy diagram of a portion of the $Ga_{0.47}In_{0.53}As/Al_{0.48}In_{0.52}As$ quantum cascade laser with vertical transition under positive bias condition and an electric field of 8.5×10^4 V/cm. The dashed lines are the effective conduction band edges of the 20.8 nm thick superlattice electron injector. As shown, this superlattice is also designed as to create a minigap that blocks electron escape from level 3. The wavy line indicates the transition responsible for laser action. The moduli squared of the relevant wave functions are shown.

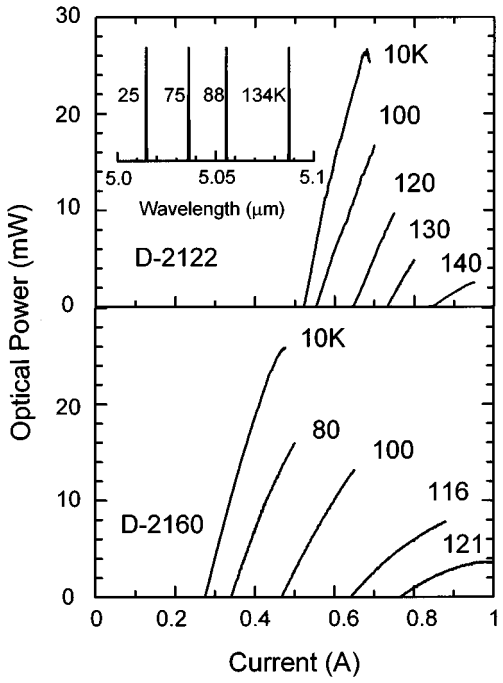

FIG. 13. Continuous optical output power from a single facet versus injection current for various temperatures of a quantum cascade laser (Ref. 30). (a) Sample D-2122, with a device 2.9 mm long and 7 μm wide. (b) Sample D-2160, with a device 3 mm long and 9 μm wide. Single mode high resolution spectra are shown in the inset at various temperatures. The lasers operated in pulsed mode up to room temperature and above (320 K).

temperatures. In addition, the peak optical power is also greatly enhanced and the lasers can operate in continuous wave.[27,28]

More recently, the design of vertical transition QC lasers has been further improved by adding a thin quantum well between the graded injector layer and the double-well active region.[29] This increases the tunneling injection efficiency. The above features, together with the substitution of the AlInAs cladding layers with InP regions of much higher thermal conductivity, has led to the room-temperature high peak power ($\sim$200 mW) pulsed operation of QC lasers at $\lambda=5.2$ μm.[30] Continuous wave single mode operation has also been achieved up to 140 K (Fig. 13). These are the first semiconductor lasers operating at room temperature in the mid-infrared. Their overall performance makes them excellent candidates for many applications such as environmental sensing and pollution monitoring in the 3–5 μm and 8–13 μm atmospheric windows.

VII. CONCLUSIONS

This review has highlighted the range of interesting transport and optical mesoscopic phenomena made possible by wave function engineering in semiconductor nanostructures grown by MBE. By controlling the phase of the electronic envelope function states and of their transition matrix elements, a number of interesting quantum interference effects have been observed in double-barrier transport and optical absorption. This quantum engineering approach has also led to the design and demonstration of new materials with giant nonlinear optical coefficients. Finally, not only the electronic states but also the scattering rates can be tailored. This adds a new dimension to quantum design and has allowed us to demonstrate new light sources (quantum cascade lasers), where the population inversion is designed rather than determined by relaxation times intrinsic to the laser material.

Dynamic conductance and quantum noise in mesoscopic conductors

M. Büttiker
Université de Genève, 24 Quai E. Ansermet CH-1211, Genève, Switzerland

(Received 29 March 1996; accepted for publication 1 July 1996)

We present results for the dc conductance, the ac conductance, and the current–current fluctuation spectra of mesoscopic, phase-coherent conductors based on a second quantization approach to scattering and a self-consistent potential approach. A second quantization approach permits an investigation of statistical effects due to the symmetry of the wave functions under exchange of particles. A self-consistent approach is needed to enforce overall charge conservation and to obtain current conserving expressions for frequency-dependent conductances and fluctuation spectra. For the particular example of a mesoscopic capacitor we present microscopic expressions for the electrochemical capacitance and the charge relaxation resistance. © *1996 American Institute of Physics.* [S0022-2488(96)00810-9]

I. INTRODUCTION

Electrical transport in conductors which are so small that carrier transport from one contact of the sample to an other contact of the sample is phase coherent is a subject of considerable interest. Much of what has been learned about samples so small that the wave nature of electrons matters has been achieved through the theoretical and experimental investigation of dc conductances.[1–3] Electrical transport can, however, not only be characterized by its steady state average behavior but also by dynamical fluctuations away from its average behavior. Therefore, it is desirable to characterize also the fluctuation, the noise, of such conductors. Moreover, the conductor can, by application of time-dependent perturbations be brought into a dynamical state and, therefore, it is useful to characterize the conductor through its ac-conductances. The growing interest in these subjects is illustrated by a series of recent clever experiments on ac conductances[4–7] and quantum shot noise.[8–11] Both noise measurements and dynamic conductance measurements can reveal properties of a conductor which cannot be tested by a dc experiment.

The purpose of this work is to show that there exists a common theoretical framework to address dc conductances, quantum noise and the ac conductance of mesoscopic conductors. We present first a scattering theory of dc-conductance[12–17] and the low frequency noise[18–24] carried out in a second quantization framework.[19,20,22,23] The derivation of the dc-conductances uses in an essential manner the coherent transmission from one electron reservoir to another and represents a rederivation of results by Büttiker[15,16] and Imry[14] and Landauer.[17] For the discussion of the noise our interest is focused on the statistical effects which arise due to the fact that an electrical conductor is made up of indistinguishable carriers. The quantum statistical effects of such a system are a property of the wave functions under exchange of two of its particles. Basically under such an exchange the wave functions must either remain invariant (Bose statistics) or the wave function changes sign (Fermi statistics). For multiprobe conductors[22,23] this gives a generalized Johnson–Nyquist formula relating the equilibrium fluctuations to transmission probabilities of the conductor. We discuss the current–current fluctuations in the presence of transport. We relate the low-frequency current fluctuations and correlations to products of four scattering matrices.[22,23] The discussions by Khlus,[18] Lesovik,[19] and Yurke and Kochanski[20] and Martin and Landauer[24] are essentially single channel discussions or assume that the scattering matrix is diagonal. The second quantization approach of Refs. 22 and 23 permits to carry out such a discussion *at every stage* in an arbitrary basis, for an arbitrary scattering matrix. To highlight the role of statistics we compare

a system subject to Fermi statistics with a system subject to Bose statistics. We extend this approach to ac transport for the case that a sample is brought into a dynamical state by application of frequency-dependent voltages to the contacts of the sample.[25,26] For this discussion the displacement of charge in response to the perturbations is central: to conserve charge the charge deviation from the equilibrium state must be of dipolar or higher order multipolar form. To achieve such a charge distribution an independent electron approach[27,28] is insufficient. As a consequence results for the ac conductance must include the effects of the long range Coulomb interaction. The leading coefficient proportional to frequency which describes the displacement currents measured at the contacts of the sample is called the emittance.[26] The emittance describes a capacitive current response if carrier transmission plays no role but describes an inductivelike, kinetic current response if transmission of carriers is important. An extension of this theory to frequency-dependent noise spectra is discussed for the case of a mesoscopic capacitor.

This work is not a review of these topics but is focused on demonstrating the unity of this approach as it is applied to these diverse but interrelated subjects. We only motivate and discuss the results and refer the reader to the original literature for detailed derivations. The conceptual points we make can be made for normal conductors: the dc conductance[29] and the zero-frequency noise[30,31] of hybrid normal and superconducting structures can be formulated in close analogy. We also emphasize only coherent transport. In the frame work presented here incoherence can be introduced by the addition of ''fictitious'' voltage probes.[32] We emphasize expressions in terms of the local density of states and the local, continuous potential. Much insight can be gained by using piecewise constant potentials[33–35,41] instead of the continuous potential distribution.

II. SECOND QUANTIZATION FORMULATION OF THE SCATTERING APPROACH

We present a brief outline of the second quantization approach to scattering theory. First, it is necessary to discuss the formulation of electron transport in the form of a scattering problem.[12,14–16]

A. Quantum channels

We envision a mesoscopic conductor (see Fig. 1) connected to an arbitrary number of contacts[15,16] labeled $\alpha=1,2,\ldots$. Each contact, far away from the connection to the conductor will be viewed as a perfect, translationally invariant conductor. For contact α, let x_α be the coordinate along the conductor and y_α and z_α the orthogonal transverse coordinates. The single-electron Hamiltonian for a carrier with effective mass m in such a lead is given by

$$H=-\frac{\hbar^2}{2m}\Delta_\alpha+eU(y_\alpha,z_\alpha), \tag{1}$$

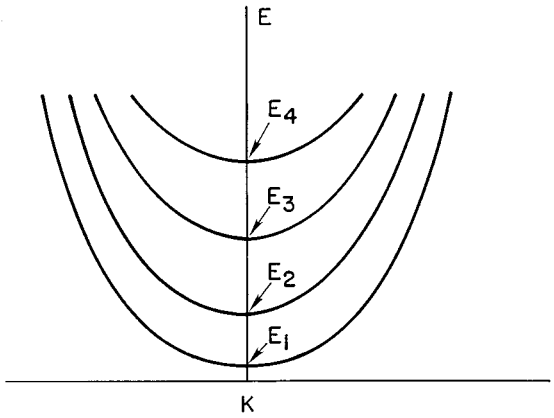

FIG. 2. Energy dispersions $E_n(k)$ of quantum channels of a perfect wire. $E_n(0)$ is the energy of the nth transverse state.

with a potential $eU(y_\alpha,z_\alpha)$ that might be an arbitrary function of the transverse coordinates but is independent of x_α. This Hamiltonian is separable. The transverse motion is described by a ladder of states with eigenfunctions[36,37] $\phi_{\alpha n}(y_\alpha,z_\alpha)$ and energies $E_{\alpha n}(0)$, labeled by the index $n=1,2,3,\ldots$. The eigenfunctions of the Hamiltonian H are of the form $\chi_{\alpha n}(k_{\alpha n},x_\alpha,y_\alpha,z_\alpha)=\exp(ik_{\alpha n}x_\alpha)\phi_{\alpha n}(y_\alpha,z_\alpha)$ with an energy

$$E_{\alpha n}(k_{\alpha n})=E_{\alpha n}(0)+\hbar^2k_{\alpha n}^2/2m \tag{2}$$

shown in Fig. 2. For a given energy E there are two solutions $k_{\pm,\alpha n}(E)$ of the equation $E=E_{\alpha n}(k_{\alpha n})$. If the energy E exceeds the channel threshold $E_{\alpha n}(0)$ the two solutions are real and describe an in-going state with velocity $v_{\alpha n}(E)$ and an out-coming state with velocity $-v_{\alpha n}(E)$. We call these two states a quantum channel. In general for a given energy E we will have N transverse states with energy $E_{\alpha n}$ below E. In this case we have $2N$ real wave vectors which characterize in and out-going states. Below such a contact is called an N channel contact. It is not necessary to have a simple dispersion of the form of Eq. (2). For a lattice Hamiltonian or in the presence of a magnetic field the transverse wave functions also depend on the longitudinal wave vector. The scattering approach to conductance is powerful because none of the results given below depends on the precise nature of the dispersion in the contacts.

B. Scattering states

The quantum channels defined above can now be used to describe in and out-going states and can thus be used to define a scattering problem. A scattering state[16] $\Psi_{\alpha n}(E,\mathbf{r})$ is a wave function with unit incident amplitude in channel n in lead α and reflected waves in typically all the other channels in the same contact and transmitted waves in typically all other contacts. The scattering states together with possible bound states form a complete set. For simplicity we assume here that all states are extended (no bound states). The amplitudes of the reflected waves and the transmitted waves are determined by the elements $s_{\beta\alpha mn}$ of the scattering matrix. The scattering matrix is the ratio of the out-going current amplitude in contact β in channel m and the incident current amplitude in contact α in channel n. An elegant description of scattering in second quantization can be given in terms of two sets of annihilation operators[22,23,38] $\hat{a}_{\alpha n}(E)$ and $\hat{b}_{\alpha n}(E)$. The operator $\hat{a}_{\alpha n}(E)$ annihilates a carrier in an incoming state in probe α in channel n with energy E. The operator $\hat{b}_{\alpha n}(E)$ annihilates a carrier in an out-going state in probe α in channel n with energy E. It is useful to group these operators for each probe together in a vector $\hat{\mathbf{a}}_\alpha(E)$ and $\hat{\mathbf{b}}_\alpha(E)$ and to

introduce the submatrice $\mathbf{s}_{\beta\alpha}$ which relates all the current amplitudes incident in probe α to the current amplitudes transmitted into probe β. The $\hat{\mathbf{a}}_\alpha(E)$ and $\hat{\mathbf{b}}_\alpha(E)$ operators are related by a unitary transformation which is given by the scattering matrix[23,38]

$$\hat{\mathbf{b}}_\beta = \sum_\alpha \mathbf{s}_{\beta\alpha}\hat{\mathbf{a}}_\alpha . \tag{3}$$

Thus the $\hat{b}_{\alpha n}$ operators obey exactly the same commutation (anticommutation) relations as the $\hat{a}_{\alpha n}$ operators.

C. Self-consistent scattering states

The scattering matrices introduced in Eq. (3) are not only a function of energy but also a functional of the electrostatic potential $U(\mathbf{r})$. The electrostatic potential depends via a Poisson equation on the charge distribution in the sample. The charge distribution in the sample depends on the voltages applied to the sample. At equilibrium when all electrochemical potentials μ_α at all contacts are identical, this potential is the equilibrium electrostatic potential $U_{\rm eq}(\mathbf{r})$. In steady-state stationary transport the charge distribution and hence the potential depends on the electrochemical potentials at the contacts. Consequently the nonequilibrium potential is also a function of the electrochemical potentials at the contacts $U([\mu_\alpha],\mathbf{r})$. Hence the scattering matrix in an electric conductor is never truly a single particle matrix but is a function both of the energy of the carriers and implicitly via the electrostatic potential a function of the electrochemical potentials,

$$\mathbf{s}_{\beta\alpha}(E, U([\mu_\alpha],\mathbf{r})). \tag{4}$$

The situation is even more complex, when we deal with quantum noise. The fluctuations in the charge density inside the conductor lead then to a potential that is also fluctuating. In the following discussion we will now present results which are correct for a fixed given potential. Later on when we discuss the ac conductance and frequency-dependent noise spectra we will also discuss the consequence of the time-dependent potential and its fluctuations.

D. The current operator

We now want to express the operator of the total current in probe α in terms of the annihilation (and creation) operators introduced above. A derivation can be found in Ref. 22 and 23. The result is simple and can be motivated as follows: Consider first the current dI incident in a fully occupied quantum channel in a small energy interval dE at energy E. In channel n in probe α this current is[37] $dI_{\alpha n} = e v_{\alpha n} dn_{\alpha n}$. Here $v_{\alpha n}$ is the velocity of this channel at energy E and $dn_{\alpha n}$ is the carrier density in this energy interval in this channel. This density is $(dn_{\alpha n}/dE)dE$. But $dn_{\alpha n}/dE = (dn_{\alpha n}/dk_{\alpha n})dk_{\alpha n}/dE_{\alpha n}$ is equal to the density of states of a uniform wire in k space which is $1/2\pi$ multiplied by $1/\hbar v_{\alpha n}$. Thus $dn_{\alpha n}/dE = 1/h v_{\alpha n}$. As a consequence the incident current $dI_{\alpha n} = (e/h)dE$ is independent of any properties of the quantum channel. This is a central result of the scattering approach to electrical conductance and is deeply connected to the fact that the conductance of quantum point contacts[39] and in Hall conductors[3] can be quantized. Now we take into account that the channel needs not always to be full. We introduce the occupation probability $n^+_{\alpha n}$ of the incoming branch of quantum channel αn. Similarly, we introduce the occupation probability $n^-_{\alpha n}$ of the outcoming branch of quantum channel αn. The net current on both the incoming and outgoing branch of quantum channel n is $dI_{\alpha n}(E) = (e/h)dE(n^+_{\alpha n}(E) - n^-_{\alpha n}(E))$. We generalize this result in two ways. First, we assume that it is valid even if the occupation probabilities are not stationary but are functions of time, $n^\pm_{\alpha n}(E,t)$. Second, we express the occupation probabilities in terms of the annihilation (creation) operators introduced above. We have $\hat{n}^+_{\alpha n}(E,t) = \int d(\hbar\omega)\hat{a}^\dagger_{\alpha n}(E)\hat{a}_{\alpha n}(E + \hbar\omega)\exp(-i\omega t)$ and

$\hat{n}^{-}_{\alpha n}(E,t) = \int d(\hbar\omega)\hat{b}^{\dagger}_{\alpha n}(E)\hat{b}_{\alpha n}(E+\hbar\omega)\exp(-i\omega t)$. Finally, to obtain the operator for the total current, we must sum over all channels in probe α and integrate the resulting expression over energy. Consequently, the operator for the total current in probe α is[23]

$$I_\alpha(t) = \frac{e}{h}\int dE dE' [\hat{\mathbf{a}}^{\dagger}_{\alpha}(E)\hat{\mathbf{a}}_{\alpha}(E') - \hat{\mathbf{b}}^{\dagger}_{\alpha n}(E)\hat{\mathbf{b}}_{\alpha}(E')]\exp(i(E-E')t/\hbar). \tag{5}$$

Clearly, this is an intuitively appealing result. Before proceeding, we remark that this expression contains no detailed spatial information on the location of the carriers but only takes into account whether a carrier is in an incoming or outgoing channel in a given reservoir. A formal derivation of Eq. (5) proceeds by constructing the Fermi field operator. This is carried out in Ref. 23 in detail. The Fourier transform of Eq. (5) is exact to first order in frequency. For larger frequencies it is an approximation to the actual space-dependent expression of the current operator (see the discussions in Refs. 40 and 41).

To proceed we use Eq. (3) to eliminate the $\hat{b}$ operators in Eq. (5) to find an expression for the current operator in terms of the $\hat{a}$ operators alone. The resulting current operator can be written in a compact form with the help of the matrix[22,23]

$$\mathbf{A}_{\beta\gamma}(\alpha,E,E+\hbar\omega) = \mathbf{1}_\alpha\delta_{\alpha\beta}\delta_{\alpha\gamma} - \mathbf{s}^{\dagger}_{\alpha\beta}(E)\mathbf{s}_{\alpha\gamma}(E+\hbar\omega). \tag{6}$$

Here $\mathbf{1}_\alpha$ is a unit matrix with dimensions N_α equal to the number of quantum channels in lead α. The elements of this matrix are the current matrix elements calculated not with the asymptotic states but with the full scattering states $\Psi_{\beta n}(E;\mathbf{r})$ and $\Psi_{\gamma n}(E;\mathbf{r})$ evaluated in lead α and divided by $(hv_{\alpha n}(E)hv_{\alpha m}(E))^{1/2}$. With the help of this matrix we obtain the desired expression for the current operator,[22]

$$I_\alpha(t) = \frac{e}{h}\sum_{\beta\gamma}\int dE dE' \hat{\mathbf{a}}^{\dagger}_{\beta}(E)\mathbf{A}_{\beta\gamma}(\alpha,E,E')\hat{\mathbf{a}}_{\gamma}(E')\exp(i(E-E')t/\hbar). \tag{7}$$

Below we will use this expression to derive the conductane coefficients, the equilibrium and transport noise of mesoscopic conductors and expressions for the ac conductance.

III. AVERAGE CURRENTS AND CONDUCTANCE

First, we now use Eq. (7) to find the average currents and conductance of an arbitrary multichannel[37,42] multilead[15,16,43] structure. The key assumption of our discussion is that the wide portion of the leads can be assumed to be reservoirs which are in an equilibrium state. Thus the $\hat{a}_\alpha$ operators which act on the incident state in reservoir α obey the equilibrium statistical mechanics of reservoir α. In principle one first finds the quantum average of $\hat{a}^{\dagger}_{\beta m}(E)\hat{a}_{\gamma n}(E')$ and then computes the statistical average. To simplify our notation we will use the symbol $\langle\ \rangle$ to denote both of these averages. With this notation we have

$$\langle \hat{a}^{\dagger}_{\beta m}(E)\hat{a}_{\gamma}(E')\rangle = \delta_{\alpha\beta}\delta_{mn}\delta(E-E')f_\alpha(E). \tag{8}$$

Here $f_\alpha(E)$ is the Fermi (Bose) function of reservoir α. Note that on the average it is only the product in which both $\hat{a}$ operators have the same reservoir and channel index and the same energy which is non-vanishing. Using Eq. (8) gives for the average currents[23]

$$\langle I_\alpha\rangle = \frac{e}{h}\sum_{\beta}\int dE\ \mathrm{Tr}[A_{\beta\beta}(\alpha,E,E)]f_\beta(E). \tag{9}$$

Here the trace Tr is over channel indices. Since $\mathrm{Tr}(\mathbf{s}^{\dagger}_{\alpha\alpha}(E)\mathbf{s}_{\alpha\alpha}(E)) = R_{\alpha\alpha}(E)$ is the total reflection probability of waves incident from lead α back into lead α and $\mathrm{Tr}(\mathbf{s}^{\dagger}_{\alpha\beta}(E)\mathbf{s}_{\alpha\beta}(E)) = T_{\alpha\beta}(E)$ is the total transmission probability of particles incident from reservoir β into reservoir α we find,[23]

$$\langle I_\alpha\rangle = \frac{e}{h}\int dE\left[(N_\alpha - R_{\alpha\alpha}(E))f_\alpha(E) - \sum_\beta T_{\alpha\beta}(E)f_\beta(E)\right]. \tag{10}$$

Equation (10) is a nonlinear result which depends on the applied voltages not only through the Fermi functions but as discussed in Sec. II C implicitly through the electrostatic potential. A more detailed discussion is given in Ref. 26 and in a work by Christen and the author.[44] Now we assume that the electrochemical potentials of the reservoirs μ_α differ only by a small amount from the equilibrium chemical potential μ_0. We can expand the Fermi functions away from this equilibrium potential, $f_\alpha(E) = f_0 - (df/dE)(\mu_\alpha - \mu_0) + \cdots$. Similarly the potential $U([\mu_\alpha],\mathbf{r})$ is expanded away from the equilibrium potential $U_{\mathrm{eq}}(\mathbf{r})$. Inserting this into Eq. (10) gives

$$\langle I_\alpha\rangle = \frac{e}{h}\int dE(-df/dE)\left[(N_\alpha - R_{\alpha\alpha}(E))\mu_\alpha - \sum_\beta T_{\alpha\beta}(E)\mu_\beta\right]. \tag{11}$$

That is the central result found in Ref. 15. In this expression the scattering matrix and the transmission and reflection probabilities are functions of the *equilibrium* electrostatic potential $U_{\mathrm{eq}}(\mathbf{r})$. The equilibrium electrochemical potential μ_0 does not appear since the unitarity of the scattering matrix gives

$$N_\alpha = R_{\alpha\alpha}(E) + \sum_\beta T_{\alpha\beta}(E) = R_{\alpha\alpha}(E) + \sum_\beta T_{\beta\alpha}(E). \tag{12}$$

From Eq. (11) we obtain the conductance coefficients at zero bias. The conductance coefficients $G_{\alpha\beta}$ are the derivatives of the current in probe α with respect to electrochemical potentials of probe β, $G_{\alpha\beta} = e d\langle I_\alpha\rangle/d\mu_\beta|_{[\mu_\alpha]=\mu_0}$. We obtain

$$G_{\alpha\alpha} = \frac{e^2}{h}\int dE(-df/dE)(N_\alpha - R_{\alpha\alpha}(E)), \tag{13}$$

and for the off-diagonal conductances obtain

$$G_{\alpha\beta} = -\frac{e^2}{h}\int dE(-df/dE)T_{\alpha\beta}(E). \tag{14}$$

Note that the unitarity of the scattering matrix (current conservation) also implies

$$\sum_\beta G_{\alpha\beta} = \sum_\beta G_{\beta\alpha} = 0. \tag{15}$$

We will later discuss what the equivalent sum rules are for ac conductances. Typically, in experiments, it is not the conductance coefficients which are measured but resistances.[45,46] In the typical setup only two probes are used to drive a current through the conductor and all other probes are connected to voltmeters. Since voltmeters have ideally an infinite impedance this implies that at a voltage probe the average current is zero. The electrochemical potential of this probe floats to a value which gives zero-current in that probe. Imposing the current on two of the probes and imposing the zero-current condition on all other probes in Eq. (11) yields rational functions for the resistances in terms of the conductance coefficients (transmission probabilities) given by Eq. (13)

and Eq. (14). It is the wide range of applicability to all possible geometries which has made Eq. (11) a very useful result. Another important aspect of these results is their symmetry under magnetic field reversal.[15,16,45,47–49]

IV. CURRENT–CURRENT FLUCTUATIONS

Electric conduction is not only characterized by its average behavior but also by its fluctuations away from the average. There are typically many sources of fluctuations. Here we are interested in the fluctuations that are fundamental in the sense that they are unavoidable. There are two such fundamental sources of fluctuations. First, at equilibrium we have Nyquist–Johnson noise. At equilibrium such thermal noise is the only unavoidable noise. As is well known, this noise is related via the fluctuation dissipation theorem to the equilibrium transport coefficients, Eqs. (13) and (14). In the presence of transport a second more interesting noise comes to the forefront: a quantum statistical partition noise.[18–20,22,50,51]

On a single particle level the origin of this noise lies in the fact that a particle can only be detected at one place and must be detected in its entirety. Consider for a moment a simple scattering problem with transmission T and reflection probability R. If we consider a series of events, each with a single particle incident from the left, the average occupation number of the transmitted beam is $\langle n_T\rangle = T$. But the actual occupation number in each event is either $n_T=1$, if the particle has been transmitted or is $n_T=0$, if the particle has been reflected. This leads to a mean square fluctuation in the occupation number which is $\langle(\Delta n_T)^2\rangle = T(1-T)$. This noise peaks when the uncertainty for the particle to arrive in this channel is maximal, i.e., when $T=1/2$. In a conductor we deal not with single particles nor with particles that arrive at the scatterer in a sequence of events that are separated in time and space. We must allow for states which carry more then one particle. As a consequence this noise depends on the symmetry of the wave function under exchange of particles. Concern with such effects in optics goes back to the midel fifties when Hanbury Brown and Twiss[50] carried out a number of experiments which revealed quantum statistical effects in beams of light from stars or man made light sources. In solid state physics, partition noise has also been discussed a long time ago, but to our knowledge only as a purely classical phenomena.[52] Text books mostly emphasize the limit of small transmission, and the resulting noise is called shot noise and given by Shottky, $\langle(\Delta I)^2\rangle = 2e\Delta\nu\langle I\rangle$. Here $\Delta\nu$ is the band width over which the noise is measured and $\langle I\rangle$ is the average current. According to this expression the noise is a consequence of carriers arriving and being transmitted with a Poisson distribution. The quantum statistical partition noise can be much smaller then the Shottky noise.

A. Spectral densities of current fluctuations

The spectral densities $S_{\alpha\beta}(\omega)$ of current fluctuations for a quantum mechanical problem are given by

$$(1/2)\langle\Delta\hat{I}_\alpha(\omega)\Delta\hat{I}_\beta(\omega')+\Delta\hat{I}_\beta(\omega')\Delta\hat{I}_\alpha(\omega)\rangle = 2\pi S_{\alpha\beta}(\omega)\,\delta(\omega-\omega'). \tag{16}$$

Here $\Delta\hat{I}_\alpha(\omega)$ stands for the Fourier transform of Eq. (7) with the average current (zero-frequency component) subtracted. Below we will use a somewhat more transparent notation. Instead of $S_{\alpha\beta}(\omega)$ we write

$$\langle\Delta I_\alpha\Delta I_\beta\rangle = 2\Delta\nu S_{\alpha\beta}(\omega) \tag{17}$$

with $\Delta\nu$ the experimental band width in which the noise is measured.

The spectral densities, Eqs. (16) or (17), are defined by expectation values of products of four operators.[53,23] These expectation values for a system at equilibrium are known and given by

$$\langle \hat{a}^{\dagger}_{\alpha m}(E_1)\hat{a}_{\beta n}(E_2)\hat{a}^{\dagger}_{\gamma k}(E_3)\hat{a}_{\delta l}(E_4)\rangle - \langle \hat{a}^{\dagger}_{\alpha m}(E_1)\hat{a}_{\beta n}(E_2)\rangle\langle a^{\dagger}_{\gamma k}(E_3)\hat{a}_{\delta l}(E_4)\rangle$$
$$= \delta_{\alpha\delta}\delta_{\beta\gamma}\delta_{ml}\delta_{nk}\delta(E_1-E_4)\,\delta(E_2-E_3)f_{\alpha}(E_1)(1-f_{\beta}(E_2)). \tag{18}$$

The statistical average of only two $\hat{a}$ operators is local in the sense that only products with the same quantum channel index and the same reservoir index are nonvanishing. However, Eq. (18) is not local: it correlates average occupation factors of different quantum channels in the same reservoir and even in different reservoirs!

Using Eq. (18) and the Fourier transform of the current operator Eq. (7) gives for the current-current correlations the expression[40,23]

$$\langle \Delta I_{\alpha}\Delta I_{\beta}\rangle = \frac{e^2}{h}\,\Delta\nu \sum_{\gamma\delta} \int dE\ \mathrm{Tr}[\mathbf{A}_{\gamma\delta}(\alpha,E,E+\hbar\omega)\mathbf{A}_{\gamma\delta}(\beta,E+\hbar\omega,E)]F_{\gamma\delta}(E,E+\hbar\omega), \tag{19}$$

where

$$F_{\gamma\delta}(E,E+\hbar\omega) = f_{\gamma}(E)(1-f_{\delta}(E+\hbar\omega)) + f_{\delta}(E+\hbar\omega)(1-f_{\gamma}(E)). \tag{20}$$

First, our interest will be in the zero-frequency limit. In this case it can be shown that Eq. (19) reduces to the following expression:[54,23]

$$\langle \Delta I_{\alpha}\Delta I_{\beta}\rangle = 2\,\frac{e^2}{h}\,\Delta\nu \sum_{\gamma\delta} \int dE\ \mathrm{Tr}[\mathbf{A}_{\gamma\delta}(\alpha,E,E)\mathbf{A}_{\gamma\delta}(\beta,E,E)]f_{\gamma}(E)(1-f_{\delta}(E)) \tag{21}$$

This is obvious for the case $\alpha=\beta$ but requires some consideration for the case that $\alpha\neq\beta$. We will discuss Eq. (21) in various limiting cases.

B. Equilibrium current fluctuations

At equilibrium our expression Eq. (21) can be simplified still further since all distribution functions f_{α} are the same and given by the distribution function f with an electrochemical potential μ_0. Only terms which are bilinear in the scattering matrices survive. Using that $f(1-f) = kT(-df/dE)$ and using $\mathrm{Tr}(\mathbf{s}_{\alpha\alpha}(E)\mathbf{s}^{\dagger}_{\alpha\alpha}(E)) = R_{\alpha\alpha}(E)$ and $\mathrm{Tr}(\mathbf{s}_{\alpha\beta}(E)\mathbf{s}^{\dagger}_{\alpha\beta}(E)) = T_{\alpha\beta}(E)$ we find for the mean square fluctuations ($\alpha=\beta$)

$$\langle (\Delta I_{\alpha})^2\rangle = 4\Delta\nu kT\,\frac{e^2}{h}\int dE(-df/dE)[N_{\alpha}-R_{\alpha\alpha}(E)] = 4\Delta\nu kT G_{\alpha\alpha} \tag{22}$$

and the correlations ($\alpha\neq\beta$)

$$\langle \Delta I_{\alpha}\Delta I_{\beta}\rangle = -2\Delta\nu kT\,\frac{e^2}{h}\int dE(-df/dE)[T_{\alpha\beta}(E)+T_{\beta\alpha}(E)] = 2\Delta\nu kT[G_{\alpha\beta}+G_{\beta\alpha}]. \tag{23}$$

Therefore, as we expect it, the equilibrium mean square fluctuations are related to the diagonal conductances and the correlations are related to the *symmetrized* off-diagonal conductances.[22,23] The equilibrium fluctuations are not without interest. They can serve to calibrate noise measurements.[10,11] The equilibrium fluctuations are also particularly interesting in the quantized Hall regime since in this case the conductances either vanish or are quantized (at least if the contacts to the sample behave ideal). If the contacts along the perimeter of the sample are labeled clock-wise only conductances between consecutive contacts $G_{\alpha+1,\alpha}$ are nonvanishing and quantized.[22] As a consequence only the correlations between currents of two next nearest neighbor

contacts are nonzero. For the voltage fluctuations this implies the absence of correlations between Hall voltage fluctuations and longitudinal voltage fluctuations. This has been observed by Kil *et al.*[55]

C. Zero temperature transport fluctuations

We have seen that at equilibrium only expressions survive which are quadratic in the scattering matrices. In fact, only transmission probabilities matter. In the presence of transport, and in the zero temperature limit, it is the products of four scattering matrices which count. In Eq. (21) all terms in the sum for which $\gamma=\delta$ vanish, since $f_\alpha(1-f_\alpha)$ is zero at zero temperature. But for the terms for which $\gamma\neq\delta$ the A matrices are of the form. $\mathbf{A}_{\gamma\delta}(\alpha)(E,E) = -\mathbf{s}^\dagger_{\alpha\gamma}(E)\mathbf{s}_{\alpha\delta}(E)$ and consequently we find from Eq. (21),

$$\langle \Delta I_\alpha \Delta I_\beta\rangle = 2\frac{e^2}{h}\Delta\nu \sum_{\gamma\delta,\,\gamma\neq\delta}\int dE\ \mathrm{Tr}[\mathbf{s}^\dagger_{\alpha\gamma}(E)\mathbf{s}_{\alpha\delta}(E)\mathbf{s}^\dagger_{\beta\delta}(E)\mathbf{s}_{\beta\gamma}(E)]f_\gamma(E)(1-f_\delta(E)), \tag{24}$$

where $f\alpha(E)=\Theta(E-\mu_\alpha(E))$ with Θ the step function.[22,24]

Let us discuss this result for the case of a two-terminal conductor. Using the notation $\mathbf{s}_{11}\equiv\mathbf{r}_{11}$, $\mathbf{s}_{22}\equiv\mathbf{r}_{22}$, $\mathbf{s}_{21}\equiv\mathbf{t}_{21}$, and $\mathbf{s}_{12}\equiv\mathbf{t}_{12}$, which more explicitly emphasizes reflection r and transmission t the conductance $G\equiv G_{11}=G_{22}=-G_{12}=-G_{21}$ is $G=(e^2/h)\mathrm{Tr}(\mathbf{t}^\dagger_{21}\mathbf{t}_{21})=(e^2/h)\mathrm{Tr}(\mathbf{t}^\dagger_{12}\mathbf{t}_{12})$. The average current driven through the sample is thus $\langle I\rangle=GV$ with $eV=\mu_1-\mu_2$. Form Eq. (24) the mean square current fluctuations are determined by a single term $\mathrm{Tr}[\mathbf{s}^\dagger_{11}\mathbf{s}_{12}\mathbf{s}^\dagger_{12}\mathbf{s}_{11}]$ $=\mathrm{Tr}[\mathbf{r}_{11}\mathbf{r}^\dagger_{11}\mathbf{t}_{12}\mathbf{t}^\dagger_{12}]$. Thus we find[22]

$$\langle(\Delta I)^2\rangle = 2\frac{e^2}{h}\Delta\nu|eV|\mathrm{Tr}[\mathbf{r}_{11}\mathbf{r}^\dagger_{11}\mathbf{t}_{12}\mathbf{t}^\dagger_{12}]. \tag{25}$$

The matrices $\mathbf{r}_{11}\mathbf{r}^\dagger_{11}$ and $\mathbf{t}_{12}\mathbf{t}^\dagger_{12}$ are hermitian and commute and can, therefore, be diagonalized simultaneously. Let us denote the eigenvalues of $\mathbf{t}_{12}\mathbf{t}^\dagger_{12}$ by T_n and the eigenvalues of $\mathbf{r}_{11}\mathbf{r}^\dagger_{11}$ by R_n. In terms of the transmission eigenvalues T_n the conductance is simply $G=(e^2/h)\Sigma_n T_n$. Our result Eq. (25) can be written in the form

$$\langle(\Delta I)^2\rangle = 2e\Delta\nu|V|\ \frac{e^2}{h}\sum_n T_n(1-T_n). \tag{26}$$

This result can now be connected with the results obtained by Khlus[18] and by Lesovik.[19] In these works it was assumed from the outset that the transmission matrix is diagonal. Thus the results given in these works are in fact general, if the diagonal elements are identified with the eigenvalues of $\mathrm{Tr}[\mathbf{tt}^\dagger]$. This result seems natural, but it is not as obvious as one might think at first! Below we illustrate this with a discussion that starts from slightly different assumptions and indeed does not lead to Eq. (25) even so for a diagonal transmission matrix it leads to the result of Khlus and Lesovik.

First, we like to discuss the interesting properties of this result. Eq. (26) leads to the standard Shottky noise formula only and only if all transmission eigenvalues T_n are small compared to 1. Then we can neglect terms quadratic in T_n in Eq. (26) and find $\langle(\Delta I)^2\rangle=2e\Delta\nu|\langle I\rangle|$. Like the partition noise Eq. (25) has the property that an eigenmode gives a maximum contribution when T_n is equal to 1/2 and gives no contribution if the channel is completely closed $T_n=0$ or completely open $T_n=1$. Conductors in which situations of completely open or completely closed eigen channels can be realized are quantum point contacts,[39] quantized Hall conductors[3] and perhaps ballistic conductors. Thus at a conductance plateau of a quantum point contact or in the quantized Hall regime in the range of a Hall plateau the noise given by Eq. (26) vanishes completely.

Initial experiments on quantum point contacts[56] and in quantized Hall conductors[57] provided only an indication of the expected noise reduction in the plateau regions. But the more recent experiments by Kumar *et al.*[10] and Reznikov *et al.*[9] provide strikingly clear data which makes even a quantitative comparison with theory possible. This advance is even more striking when one considers the often wide ranging gap of theory and experiment on noise in physical systems.[58]

We mention two results to indicate the wide range of problems to which this theory can be applied. A metallic diffusive conductor (distance between impurities small compared to the sample width and length) has transmission probabilities T_{12mn} which are very small compared to 1 when averaged over an ensemble. Thus one might expect that a mesoscopic metallic diffusive conductor exhibits full shot noise. However, the eigenvalues T_n of such an ensemble are distributed in a bi-modal manner with a concentration at $T_n=1$ and a concentration at $T_n=0$. As a consequence it is found that a mesoscopic metallic diffusive conductor exhibits a shot noise which is 1/3 of the full shot noise[59]

$$\langle(\Delta I)^2\rangle_e = \tfrac{2}{3} e \Delta\nu |V| \langle I\rangle. \tag{27}$$

Here the index e indicates not only a quantum and statistical average but also an ensemble average. A recent experimental work by Steinbach *et al.*[11] provides a more complete discussion and additional references. For a chaotic cavity connected to two leads it is found that the ensemble averaged shot noise is 1/4 of the full shot noise[60]

$$\langle(\Delta I)^2\rangle_e = \tfrac{2}{4} e \Delta\nu |V| \langle I\rangle. \tag{28}$$

It is possible to discuss not only the ensemble average but also the mean square deviations away from this average.[61]

D. Single particle versus many particle quantum shot noise

It would be deceiving if we tried to understand the result, Eq. (25) only in the special basis of eigen channels. If we write out the trace of the product of the four scattering matrices in terms of the transmission and reflection matrix elements, we find

$$\mathrm{Tr}[\mathbf{r}\mathbf{r}^\dagger\mathbf{t}\mathbf{t}^\dagger] = \sum_{klmn} r_{ml} r^*_{ml} t_{mn} t^*_{kn}. \tag{29}$$

In a general basis only a few terms in this expression are products of the transmission and reflection probabilities. Most of the terms in Eq. (29) consist of products of four scattering amplitudes which are not real valued. If we attribute a transmission probability with the transfer of one electron (a product of two hermitian conjugate) amplitudes, then we should associate a two-electron process with products of four scattering amplitudes. We should be able to demonstrate that if only one electron at the time is incident on the conductor such complex products are in fact not present. The following considerations show that this is indeed the case.

Assume for a moment that we have an electron source which injects single electrons into a definite quantum channel in events that are well separated in time and space. As above, we consider the case of vanishing temperature. First let us assume that the current source at contact η injects carriers into channel o with probability 1. For this experiment the right hand side of Eq. (18) is replaced by the quantum expectation value

$$\delta_{\alpha\delta}\delta_{\beta\gamma}\delta_{ml}\delta_{nk}\delta(E_1-E_4)\delta(E_2-E_3)n_{\alpha n}(E_1)(1-n_{\beta m}(E_2)) \tag{30}$$

with $n_{\alpha n}=\delta_{\eta\alpha}\delta_{on}$. The resulting partition noise can then be expressed in terms of the probabilities $S_{\alpha\eta o}=\Sigma_m |s_{\alpha\eta mo}|^2$. Instead of Eq. (25) we find a shot noise proportional to $S_{\alpha\eta o}[\delta_{\alpha\beta}-S_{\beta\eta o}]$. If

we now consider a series of successive experiments in which the channel o eventually can be any of the incident channels in probe η and consider the total noise, the current-current correlations are

$$\langle \Delta I_\alpha \Delta I_\beta \rangle = 2\frac{e^2}{h}\Delta\nu|eV|\sum_o S_{\alpha\eta o}[\delta_{\alpha\beta} - S_{\beta\eta o}]. \tag{31}$$

It can be shown that these expressions are current conserving, $\Sigma_\alpha \langle \Delta I_\alpha \Delta I_\beta \rangle = \Sigma_\beta \langle \Delta I_\alpha \Delta I_\beta \rangle = 0$. For the mean squared current $\langle (\Delta I)^2 \rangle$ we obtain, therefore, $\langle (\Delta I)^2 \rangle = e^2/h\Delta\nu|eV|\Sigma_o T_{21o} R_{11o}$ where $T_{21o} = S_{21o}$ and $R_{11o} = S_{11o}$. Evidently, if the transmission and reflection matrices t and r are diagonal, Eq. (31) is identical with Eq. (26). But in contrast to Eq. (25), Eq. (31) for the case of a general scattering matrix is expressed in terms of probabilities only. It contains no exchange terms.

From this exercise we can conclude that it is not possible, without ad hoc assumptions, to derive a many-channel result simply by deriving first the result in the eigen channel basis. Experimentally, it will be difficult to distinguish between Eq. (25) and Eq. (31). Thus in Ref. 54 we have proposed an experiment on a multipole conductor to directly detect the exchange terms. We will briefly restate this proposal below. But first we proceed with the discussion of noise in a two probe conductor.

E. Quantum statistical shot noise

At elevated temperatures, Eq. (21) predicts a combined thermal and shot noise, which when expressed in terms of the transmission probabilities T_n of the eigen channels is given by

$$\langle (\Delta I)^2 \rangle = 2e\Delta\nu\frac{e^2}{h}\sum_n \int dE[f_1(E)(1 \pm f_1(E))T_n + f_2(E)(1 \pm f_2(E))T_n \pm T_n(1-T_n)(f_1 - f_2)^2]. \tag{32}$$

Here we have compared a system subject to Fermi statistics (upper signs) with a system subject to Bose statistics (lower signs). The result for Fermions was obtained by Lesovik[19] and the result for Bose statistics was given in Ref. 54. Clearly, the first two terms in this expression represent thermal contributions to the noise. The last term which is quadratic in the difference of the distribution function and has an amplitude $T_n(1-T_n)$ is the quantum partition noise. This contribution to the noise is quadratic in the intensity of the incident electron (photon) flux and most significantly, changes sign as we change statistics. In comparison to the first two terms quantum statistical partition increases the overall noise for Fermions but quantum statistical partition decreases the shot noise for Bosons. The reduction of noise in the bosonic case can be understood as follows: the scattering obstacle can break up incident multiquanta states $n\hbar\omega$ and transmit a portion and reflect a portion. As a consequence the transmitted stream will on the average contain particles with fewer quanta and thus produce a reduced noise.[62]

F. Making exchange effects visible

It is illuminating to consider the following thought experiment:[23,54] Consider a conductor with four probes (see for example Fig. 1). In experiment A, contact 1 is described by a distribution function f and all other contacts by a distribution function f_0. The correlation function between the fluxes at the contacts 3 and 4 is measured and denoted by $\langle \Delta I_3 \Delta I_4 \rangle_A$. In a second experiment B, contact 2 is described by a distribution function f and all other contacts by a distribution function f_0. Again the correlation function between the fluxes at contacts 3 and 4 is measured and denoted by $\langle \Delta I_3 \Delta I_4 \rangle_B$. In a third experiment *both* contacts 1 and 2 are described by the distribution function f and only contacts 3 and 4 are determined by the distribution function f_0. The correlation function measured in the third experiment is denoted by $\langle \Delta I_3 \Delta I_4 \rangle_C$. For a classical

system, we would expect that experiment C is simply determined by the sum of the correlation functions measured in experiments A and B, $\langle \Delta I_3 \Delta I_4 \rangle_C = \langle \Delta I_3 \Delta I_4 \rangle_A + \langle \Delta I_3 \Delta I_4 \rangle_B$. The quantum mechanical result, however, is different, and is given by

$$\langle \Delta I_3 \Delta I_4 \rangle_C = \langle \Delta I_3 \Delta I_4 \rangle_A + \langle \Delta I_3 \Delta I_4 \rangle_B \pm 2\Delta\nu \frac{e^2}{h} \times \int dE (f - f_0)^2 [\mathrm{Tr}(\mathbf{s}_{31}\mathbf{s}_{32}^\dagger \mathbf{s}_{41}\mathbf{s}_{42}^\dagger) + \mathrm{Tr}(\mathbf{s}_{32}\mathbf{s}_{31}^\dagger \mathbf{s}_{42}\mathbf{s}_{41}^\dagger)]. \quad (33)$$

This contribution to the correlation function is an exchange term. It is a consequence of the fact that we deal with a quantum mechanical problem of many indistinguishable particles. Interestingly the individual terms in Eq. (33) are not real and thus have a phase associated with them. A more detailed interpretation and discussion of this phase is presented in Refs. 23 and 54.

G. Frequency-dependent noise spectra

So far we have focused only on the zero-frequency limit of the noise spectra. Let us briefly consider the equilibrium frequency-dependent spectrum. At equilibrium the function $F_{\gamma\delta}(E, E+\hbar\omega)$, given by Eq. (20), simplifies. It is independent of the indices $\gamma\delta$ and given by $F(E, E+\hbar\omega) = (f(E) - f(E+\hbar\omega))\epsilon(\hbar\omega)/\hbar\omega$, where $\epsilon(\hbar\omega)$ is the energy of a harmonic quantum oscillator with frequency ω at temperature T. As in the zero-frequency limit, it can be shown that all products of four scattering matrices vanish identically. The equilibrium frequency-dependent spectrum can be expressed as a *sum* of two **A** matrices. It is proportional to $\mathrm{Tr}[\mathbf{A}_{\beta\beta}(\alpha, E, E+\hbar\omega) + \mathbf{A}_{\alpha\alpha}(\beta, E+\hbar\omega, E)]$ and in terms of the *s* matrices the frequency-dependent equilibrium spectrum is[40]

$$\langle \Delta I_\alpha \Delta I_\beta \rangle = 2\frac{e^2}{h} \Delta\nu \int dE\ \mathrm{Tr}[2\mathbf{1}_\alpha \delta_{\alpha\beta} - \mathbf{s}_{\alpha\beta}^\dagger(E)\mathbf{s}_{\alpha\beta}(E+\hbar\omega) - \mathbf{s}_{\beta\alpha}^\dagger(E+\hbar\omega)\mathbf{s}_{\beta\alpha}(E)] \frac{(f(E) - f(E+\hbar\omega))}{\hbar\omega} \epsilon(\hbar\omega). \quad (34)$$

Now on general grounds we know that their must exist a frequency-dependent conductance $G_{\alpha\beta}(\omega)$ whose real part $G'_{\alpha\beta}(\omega) = (1/2)[G_{\alpha\beta}(\omega) + G^*_{\beta\alpha}(\omega)]$ is related to this spectrum via a fluctuation dissipation theorem,

$$\langle \Delta I_\alpha \Delta I_\beta \rangle = 4\Delta\nu\epsilon(\hbar\omega) G'_{\alpha\beta}(\omega). \quad (35)$$

The task is to find the conductance $G_{\alpha\beta}(\omega)$.

V. DYNAMIC CONDUCTANCE

The standard procedure to derive a dynamical conductance is to use linear response theory. The current density is calculated in response to an electric field. But which electric field? Most discussions use without qualification a uniform electric field. But even if we are more ambitious and calculate the dynamical conductance to a non-uniform field, we will still obtain a frequency-dependent current response that depends on the particular field configuration. In reality, the field that counts is not arbitrary but is determined by the distribution of charges inside the sample.

Against this back-ground, the immediate task we have at hand, namely deriving the $G_{\alpha\beta}(\omega)$ which belongs to the noise-spectrum Eq. (34), is puzzling. Clearly, the spectrum Eq. (34) contains *no* information on the electric field configuration. In deriving the fluctuation spectra we have made explicitly the assumption that the electric potential is fixed and given by the equilibrium potential.

To derive $G_{\alpha\beta}(\omega)$ which belongs to Eq. (34) we need thus to find perturbations (driving forces) which are not given by the frequency-dependent nonequilibrium electric field.

Of course the response to the self-consistent electric field exists and must be part of a complete answer. Therefore, we adopt a two step strategy. First, we find the conductance which belongs to Eq. (34). We call this the *external* response or the *external* conductance. In a second step we find the charges, which as a consequence of our dynamical perturbation are injected into the sample. A self-consistent scheme is then used to find the total charge (injected charge and induced charges) and the electrical-potential belonging to this charge distribution. In the next step the current response to this internal potential is calculated. The total current response is then determined by both the external conductance and an internal conductance in response to the internal electric potential.

A. External response

In collaboration with Thomas,[63] and Pretre and Thomas[25] we have found two different perturbations which give rise to the conductance which obeys the fluctuation dissipation theorem, stated in Eq. (35). The first perturbation has an energy

$$H_1^{\phi} = \sum_{\alpha} \hat{I}_{\alpha} \phi_{\alpha}. \tag{36}$$

Here $\hat{I}_{\alpha}$ is the current operator given by Eq. (5). The fluxes ϕ_{α} have the property that they act only on the carriers in reservoir α. The fluxes ϕ_{α} are linearly related to the fluxes penetrating the loops of the external circuit to which the mesoscopic sample is connected.[25] It is assumed that the mesoscopic sample itself is shielded from any effect of these fluxes. A second energy which also gives the desired response corresponds to a sample connected to an external circuit with infinite impedance. In this case each reservoir is taken to be a macroscopic entity which is closed, except for a narrow opening through which it connects to a lead of the sample. We can then define the charge $\hat{Q}_{\alpha}$ on such a reservoir. The voltage V_{α} of the reservoir can be made to oscillate by coupling capacitively to an external circuit. In this case the energy of the perturbation is

$$H_1^{V} = \sum_{\alpha} \hat{Q}_{\alpha} V_{\alpha}. \tag{37}$$

A linear response calculation using the analytic properties of the scattering matrices leads to $G_{\alpha\beta}(\omega) = \langle \delta I_{\alpha}(\omega) \rangle / \delta V_{\alpha}(\omega)$ given by[25]

$$G_{\alpha\beta}(\omega) = \frac{e^2}{h} \int dE \ \mathrm{Tr}[\mathbf{1}_{\alpha} - \mathbf{s}_{\alpha\beta}^{\dagger}(E)\mathbf{s}_{\alpha\beta}(E+\hbar\omega)] \frac{(f(E) - f(E+\hbar\omega))}{\hbar\omega}. \tag{38}$$

The real part of this conductance obeys the fluctuation dissipation theorem stated above. In the zero-frequency limit Eq. (38) leads to the dc-conductances Eqs. (13) and (14). This clearly shows that the dc-conductances are not a consequence of acceleration of carriers due to an electric field inside the sample.

Let us next discuss the low-frequency expansion of this result. To first order in frequency we find from Eq. (38)

$$G_{\alpha\beta}(\omega) = G_{\alpha\beta}(0) - i\omega e^2 \int dE (dN_{\alpha\beta}/dE)(-df/dE) \tag{39}$$

where

$$\frac{dN_{\alpha\beta}}{dE}=\frac{1}{4\pi i}\,\mathrm{Tr}\left[\mathbf{s}^{\dagger}_{\alpha\beta}(E)\,\frac{d\mathbf{s}_{\alpha\beta}(E)}{dE}-\frac{d\mathbf{s}^{\dagger}_{\alpha\beta}(E)}{dE}\,\mathbf{s}_{\alpha\beta}(E)\right] \tag{40}$$

is called a *global partial* density of states. It is called global since it relates to a density of states in an entire volume Ω that encloses the mesoscopic conductor and a large portion of the reservoirs. Later we will also introduce local densities of states. It is called a partial density of states since the total global density of states inside Ω is given by the sum of all partial densities of states, $dN/dE=\Sigma_{\alpha\beta}dN_{\alpha\beta}/dE$. The global partial density of states $dN_{\alpha\beta}/dE$ is obviously the change of charge in the sample brought about by the perturbation in contact β which contributes to the ac-current in contact α. Thus like the scattering matrix $\mathbf{s}_{\alpha\beta}$ represents a preselection of carriers (incident from β) and a post selection (exiting into contact α) so similarly the global partial density of states represent both a pre- and postselection. We should emphasize that the partial densities of states are not density of states in the usual sense. In fact $dN_{\alpha\beta}/dE$, unlike dN/dE is not necessarily a positive quantity.

The total charge injected into the volume Ω by the perturbation in probe β is $\Sigma_{\alpha}dN_{\alpha\beta}/dE$. In a metallic sample which likes to be locally charge neutral, such an addition of charge is unrealistic. Below we discuss systems with interactions, which make charge accumulation or depletion energetically costly. Before discussing such a self-consistent scheme, we discuss now the response to an oscillating electrostatic potential.

B. Internal response

Consider a time-dependent electric potential $U(\mathbf{r},t)$ which represents a small deviation away from the equilibrium electrostatic potential $U_{\mathrm{eq}}(\mathbf{r})$ of the conductor. We assume that the total potential is of the form $U(\mathbf{r},t)=U_{\mathrm{eq}}(\mathbf{r})+u(\mathbf{r})(U_{+\omega}\exp(-i\omega t)+U_{-\omega}\exp(i\omega t))$ where $u(\mathbf{r})$ is a dimensionless function which determines the spatial distribution of the potential away from its equilibrium value. Since the potential is real we have $U_{+\omega}=U^{*}_{-\omega}$. Scattering theory now leads to the following picture. Particles which are incident from a reservoir at energy E in the presence of such an oscillating potential can absorb a modulation quantum $\hbar\omega$ or emit a modulation quantum $\hbar\omega$ or can have their energy unchanged. Thus the reflected and transmitted carriers will emerge not only at the energy E but also with energies $E\pm\hbar\omega$. We cannot describe this scattering problem with the scattering matrix which we have used so far. Now we must introduce the scattering amplitudes $s_{\pm\alpha\beta mn}(E\pm\hbar\omega,E)U_{\pm\omega}$ which give the probability amplitude that a carrier incident in probe β in channel n with energy E leaves the conductor in probe α in channel m with energy $E\pm\hbar\omega$. In the next step we express the operators $\hat{b}(E)$ which annihilate outcoming carriers in terms of the $\hat{a}$ operators at energy $E,E+\hbar\omega$ and $E-\hbar\omega$ with the help of the original scattering matrix and with the help of the scattering amplitudes $s_{\pm\alpha\beta}(E\pm\hbar\omega,E)U_{\pm\omega}$. We use again the current operator Eq. (5) and use the statistical properties of the a operators valid for an equilibrium reservoir. This gives rise to a current at contact α which is given by an internal conductance $G^{i}_{\alpha}(\omega)=\langle dI_{\alpha}(\omega)\rangle/dU_{+\omega}$,

$$G^{i}_{\alpha}(\omega)=-\frac{e^2}{h}\int dE\sum_{\beta}\;\mathrm{Tr}[\mathbf{s}^{\dagger}_{\alpha\beta}(E)\mathbf{s}_{+\alpha\beta}(E+\hbar\omega,E)](f(E)-f(E+\hbar\omega)). \tag{41}$$

To proceed, we need to specify the amplitude $\mathbf{s}_{+\alpha\beta}(E+\hbar\omega,E)$. Unfortunately, little is known about this scattering matrix, except some solutions for particularly simple problems. However, in the limit of small frequencies, on which we concentrate below, the general solution is known. For small frequencies the particles see the instantaneous potential. Therefore, this amplitude can be found by replacing in the ordinary scattering matrix $\mathbf{s}_{\alpha\beta}(E,U_{\mathrm{eq}}(\mathbf{r}))$ the equilibrium potential by the actual potential $U(\mathbf{r},t)$ and by expanding the time-dependent matrix in the deviations away from the equilibrium potential. This gives

$$\lim_{\omega\to 0} \mathbf{s}_{+\,\alpha\beta}(E+\hbar\omega,E) = \int d^3r(\delta\mathbf{s}_{\alpha\beta}(E,U(\mathbf{r}))/\delta U(\mathbf{r}))u(\mathbf{r}). \tag{42}$$

Consequently, to first order in ω the low frequency response to an nonuniform potential is determined by[64]

$$G^i_\alpha(\omega) = ie^2\omega \int d^3r(dn(\alpha,\mathbf{r})/dE)u(\mathbf{r}). \tag{43}$$

Here $dn(\alpha,\mathbf{r})dE$ is a *local partial* density of states which we call the emissivity of point $\mathbf{r}$ into contact α,

$$dn(\alpha,\mathbf{r})/dE = -\frac{1}{4\pi i}\sum_\beta \mathrm{Tr}\left[\mathbf{s}^\dagger_{\alpha\beta}\frac{\delta\mathbf{s}_{\alpha\beta}}{e\,\delta U(\mathbf{r})} - \frac{\delta\mathbf{s}^\dagger_{\alpha\beta}}{e\,\delta U(\mathbf{r})}\mathbf{s}_{\alpha\beta}\right]. \tag{44}$$

Note that the emissivity is obtained by finding the variation of the scattering matrix in response to small changes of the (equilibrium) potential. Note also that the emissivity only invokes a postselection. The contact through which carriers enter is immaterial, only the contact through which the carriers leave the sample matters.

Evidently, there is a closely related local partial density of states, which we call the *injectivity* of contact β into point $\mathbf{r}$. The injectivity[26] is obtained by summing over the first index of the scattering matrices and is given by

$$dn(\mathbf{r},\beta)/dE = -\frac{1}{4\pi i}\sum_\alpha \mathrm{Tr}\left[\mathbf{s}^\dagger_{\alpha\beta}\frac{\delta\mathbf{s}_{\alpha\beta}}{e\,\delta U(\mathbf{r})} - \frac{\delta\mathbf{s}^\dagger_{\alpha\beta}}{e\,\delta U(\mathbf{r})}\mathbf{s}_{\alpha\beta}\right]. \tag{45}$$

The sum over either all the injectivities or all the emissivities is equal to the local density of states, $dn(\mathbf{r})/dE = \Sigma_\alpha dn(\mathbf{r},\alpha)/dE = \Sigma_\alpha dn(\omega,\mathbf{r})/dE$. In contrast to the partial density of states with both a pre- and post-selection the injectivities and emissivities are positive. In fact the injectivity is related to the time a carrier dwells[65] in a small region around the point $\mathbf{r}$. The dwell time $d\tau(\mathbf{r},\alpha)$ near $\mathbf{r}$ for carriers incident from contact α is given by $d\tau(\mathbf{r},\alpha) = \hbar(dn(\mathbf{r},\alpha)/dE)d^3r$. But the dwell time is directly related to the absolute square of the wave functions at point $\mathbf{r}$. Hence the injectivity can also be expressed in terms of the scattering states as[64,66]

$$dn(\mathbf{r},\alpha)/dE = \sum_{\alpha m}(1/hv_{\alpha m})|\Psi_{\alpha m}(\mathbf{r})|^2. \tag{46}$$

Using the microreversibility of the scattering matrix, we see that there is a connection between the injectivity and emissivity, $dn_{+B}(\mathbf{r},\alpha)/dE = dn_{-B}(\alpha,\mathbf{r})/dE$. The injectivity from contact α into point $\mathbf{r}$ in positive a magnetic field B is equal to the emissivity from $\mathbf{r}$ into contact α in a magnetic field pointing into the opposite direction. A detailed discussion of possible decompositions of the local density of states and their relationship to Green's functions is presented elsewhere.[66]

To complete the discussion of the ac-conductance, we must next develop a self-consistent theory of the potential $U(\mathbf{r},\omega)$. We notice that to liner order in ω it is sufficient to develop a self-consistent theory of the potential to the zero-th order in frequency for the potential $U(\mathbf{r},\omega)$ since the response given by Eq. (43) is already proportional to ω.

C. Self-consistent potentials

The electrostatic potential $U([\mu_\alpha],\mathbf{r})$ for mesoscopic conductors is a function of the electrochemical potentials $[\mu_\alpha]$ of the contacts, and a complicated function of position. Small increases in the electrochemical potentials $\delta\mu_\alpha$ bring the conductor to a new state (see Fig. 4) with an elec-

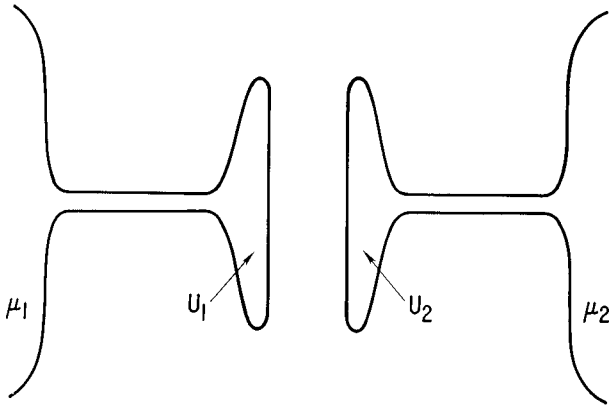

FIG. 3. Mesoscopic capacitor: Two small plates are via leads connected to electron reservoirs at electrochemical potentials μ_1 and μ_2. After Ref. 34.

trostatic potential $U([\mu_\alpha+\delta\mu_\alpha],\mathbf{r})$. The difference δU between these two potentials can be expanded in powers of the increment in the electrochemical potential. To linear order we have

$$e\,\delta U([|\mu_\alpha],\mathbf{r})=\sum_\alpha u_\alpha(\mathbf{r})\,\delta\mu_\alpha. \tag{47}$$

Here, $u_\alpha(\mathbf{r}) = e\partial U([\mu_\alpha],\mathbf{r})/\partial\mu_\alpha|_{\mu_\alpha=\mu_0}$ are the *characteristic potentials*[26] which determine the electrostatic potential inside the sample in response to a variation of an electrochemical potential μ_α at a contact. For the case of a mesoscopic capacitor [see Fig. 3] the electrochemical and the electrostatic potentials and the characteristic function u_1 are shown in Fig. 4.

Suppose for a moment that we increase all electrochemical potentials simultaneously and by the same amount, $\delta\mu_\alpha\equiv\delta\mu$. Both before and after the change the conductor is at equilibrium, hence the physical properties of the conductor remain unchanged. Consequently, the shift of the electrochemical potentials must be accompanied by a shift $e\,\delta U\equiv\delta\mu$ of the electrical potential. This implies that the sum of all characteristic potentials is equal to one at every space point,[26]

$$\sum_\alpha u_\alpha(\mathbf{r})\equiv 1. \tag{48}$$

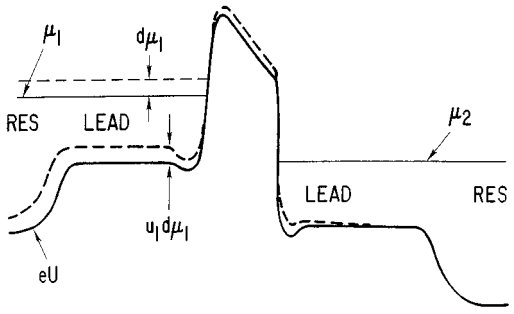

FIG. 4. Electrochemical potentials and electrostatic potentials of the mesoscopic capacitor at μ_1 and μ_2 (solid lines) and at $\mu_1+d\mu_1$ and μ_2 (broken lines). u_1 is the characteristic potential function of contact 1. After Ref. 26.

Equation (48) is a consequence of the long-range Coulomb interaction. The conservation of charge under the application of a dc or ac bias and the conservation of current are a consequence of Eq. (48).

Let us now return to our original problem and consider what happens if we increase just one electrochemical potential, say in reservoir α, by $\delta\mu_\alpha$. Obviously, the condition that the electrochemical potential and the electrostatic potential move in synchronism deep inside reservoir α implies that the characteristic function $u_\alpha(\mathbf{r})=1$ for $\mathbf{r}$ deep inside reservoir α. This implies that Eqs. (13) and (14) are valid if and only if the characteristic potentials have the property that $u_\alpha(\mathbf{r})=1$ for $\mathbf{r}$ deep in contact α and $u_\alpha(\mathbf{r})=0$ for $\mathbf{r}$ deep in any other contact.

The electrostatic potentials are determined by the charge distribution in the sample. As we increase the chemical potential of contact α *keeping the electrostatic potentials fixed*, the additional charge $\delta n(\mathbf{r})=(dn(\mathbf{r},\alpha)/dE)\,\delta\mu_\alpha$ enters the conductor. Here, $dn(\mathbf{r},\alpha)/dE$ is the *injectivity* of contact α into point $\mathbf{r}$ of the sample. The injected charges induce a change in the electrostatic potential which in turn implies an induced contribution $\delta n_{\rm ind}$ to the density. The total charge density is

$$\delta n(\mathbf{r})=(dn(\mathbf{r},\alpha)/dE)\,\delta\mu_\alpha+\delta n_{\rm ind}(\mathbf{r}). \tag{49}$$

The induced charge density is connected to the electrostatic potential via the response function $\Pi(\mathbf{r},\mathbf{r}')$ (Lindhard function or polarization function), $\delta n_{\rm ind}(\mathbf{r})=-\int d^3r'\,\Pi(\mathbf{r},\mathbf{r}')e\,\delta U(\mathbf{r}')$. The response function can be expressed in terms of the scattering states[67] (Green's function of the Schrödinger equation). For the purpose of our discussion we simply assume that this response has been calculated and is known. By inserting Eq. (49) into Poisson's equation and using $e\,\delta U(\mathbf{r})=u_\alpha(\mathbf{r})\,\delta\mu_\alpha$, we find that the characteristic potential $u_\alpha(\mathbf{r})$ is the solution of a field equation with a non-local screening kernel and a source term given by the *injectivity* of contact α,

$$-\Delta u_\alpha(\mathbf{r})+4\pi e^2\int d^3r'\,\Pi(\mathbf{r},\mathbf{r}')u_\alpha(\mathbf{r}')=4\pi e^2(dn(\mathbf{r},\alpha)/dE). \tag{50}$$

We define the Green's function $g(\mathbf{r},\mathbf{r}_0)$ as the solution of Eq. (50) with the source term $e\,dn(\mathbf{r},\alpha)/dE$ replaced by a localized test charge $e\,\delta(\mathbf{r}-\mathbf{r}_0)$ at point $\mathbf{r}_0$. The characteristic potential $u_\alpha(\mathbf{r})$ can then be written in the form

$$u_\alpha(\mathbf{r})=\int d^3r'\,g(\mathbf{r},\mathbf{r}')(dn(\mathbf{r}',\alpha)/dE). \tag{51}$$

Using Eq. (48) a summation over α implies for Green's function the property[26]

$$\int d^3r'\,g(\mathbf{r},\mathbf{r}')\sum_\alpha\,(dn(\mathbf{r}',\alpha)/dE)=\int d^3r'\,g(\mathbf{r},\mathbf{r}')(dn(\mathbf{r}')/dE)\equiv 1. \tag{52}$$

The same relationship follows from the condition that the sum of all induced charge densities plus the test charge is zero.

Now we find the condition for the electrical self-consistency of Eqs. (13) and (14). According to Eq. (52) the characteristic potential is equal to unity if the Green's function is convoluted with the total local density of states. Therefore, in order that the characteristic function $u_\alpha(\mathbf{r})$ is equal to one in reservoir α, we must have that the injectivity $dn(\mathbf{r},\alpha)/dE$ deep in contact α is equal to the local density of states $dn(\mathbf{r})/dE$. This requires that nearly all (in a thermodynamic sense) electrons approaching the contact α are reflected back into the reservoir. If the conductor and the reservoir consist of the same material then the reservoir, as emphasized by Landauer[68] must be wide compared to the mesoscopic conductor. In semiconductor samples with metallic contacts, on the other hand, the contact might be actually narrow compared to the dimensions of the semiconductor

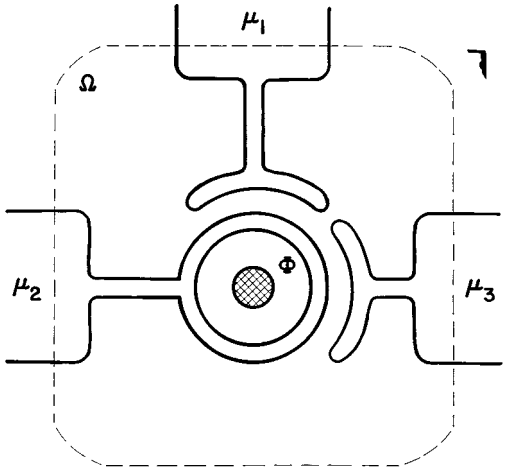

FIG. 5. Purely capacitive arrangement of conductors. The Aharonov–Bohm flux Φ threading the ring leads to oscillations in the capacitance coefficients. After Ref. 69.

since the density of states at the Fermi energy of the metal is much larger then that of the semiconductor. This is the case, for instance, in Ga/As samples used to measure the quantized Hall effect.[3] In any case, this discussion clearly implies, that one cannot attribute a conductance to a one-dimensional wire without contacts.

D. Capacitance and emittance of mesoscopic conductors

The total response is the sum of the external response Eq. (39) and the internal response Eq. (43), $G_{\alpha\beta}(\omega)=G^e_{\alpha\beta}(\omega)+G^i_{\alpha\beta}$. We express it in the form

$$G_{\alpha\beta}(\omega)=G_{\alpha\beta}(0)-i\omega E_{\alpha\beta}+O(\omega^2) \tag{53}$$

and call $E_{\alpha\beta}$ the (screened) *emittance* of the conductor. It is given by[26]

$$E_{\alpha\beta}=e^2\frac{dN_{\alpha\beta}}{dE}-e^2\int d^3r\int d^3r'\,\frac{dn(\alpha,\mathbf{r})}{dE}\,g(\mathbf{r},\mathbf{r}')\,\frac{dn(\mathbf{r}',\beta)}{dE}. \tag{54}$$

It is important to notice that Eq. (54) applies not only to one conductor but in fact also applies if there are several nearby conductors which interact via long-range Coulomb forces. The variable α then runs not only over the contacts of one conductor but over all contacts of all nearby electrical conductors. In particular it also applies if we bring two (or more) conductors near each other without any transmission between them (see Fig. 3 and Fig. 5). In this case, the scattering matrix consists only of reflection matrices $\mathbf{s}_{\alpha\alpha}$. The transmission matrices $\mathbf{s}_{\alpha\beta}$ with $\alpha\neq\beta$ vanish and all emittance coefficients are capacitive $E_{\alpha\beta}\equiv C_{\alpha\beta}$. All capacitance coefficients are even functions of the Aharonov–Bohm flux.[26,69] In contrast to the expressions for the capacitance we know from text books, the microscopic expression given here takes into account that the electric field penetrates the distance of a screening length into the two conductors. As a consequence the capacitance is not a purely geometrical quantity but depends on the physical properties of the conductors. The field penetration into the conductor gives rise to quantum corrections to the capacitance. In models in which the potential is taken to be piecewise constant[33–35,41] these corrections are determined by the density of states at the surfaces of the two conductors. This has interesting consequences: For the case were one of the plates has the form of a ring with an Aharonov–Bohm flux

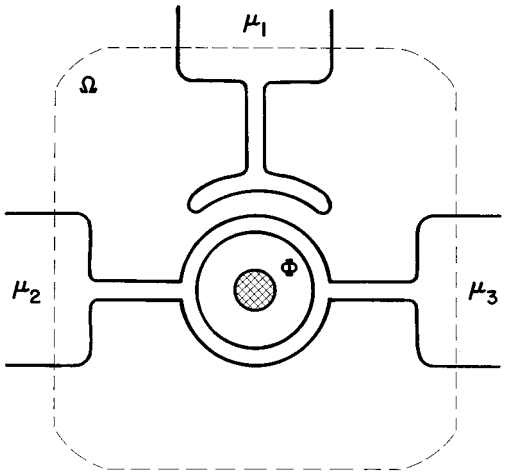

FIG. 6. An Aharonov–Bohm ring connected to two contacts, and capacitively coupled to an other nearby conductor. For a ballistic ring some emittance elements are not capacitive but inductive. After Ref. 69.

through the hole of the ring the density of states is a periodic function of flux and consequently also the capacitance is a periodic function of the Aharonov–Bohm flux.[69,70]

If one of the conductors is connected to two or more contacts (see Fig. 6) the emittance tensor is not purely capacitive. If the conductor permits good transmission, some elements of the emittance acquire a sign that is opposite to that expected for a capacitance tensor. This is reminiscent of inductive behavior. Furthermore, it can be shown[26] and has been experimentally verified[5] that for such a general arrangement the emittance tensor elements are not even functions of flux (magnetic field) but obey the reciprocity relation $E_{\alpha\beta}(\Phi)=E_{\beta\alpha}(-\Phi)$.

We emphasize that the emittance tensor is current and charge conserving. The rows and columns of the emittance matrix add up to zero. Consider the case of a conductor with two contacts. Consider the first column. If we add E_{11} and E_{21} the first terms in the emittance give the total charge $dN_{11}/dE+dN_{21}/dE$ injected from contact 1. In the second term the two emissivities add to give the local density of states. Now Eq. (52) is used. What remains is the integral over the entire volume of the injectivity which is just the total injected charge. Thus for a two terminal conductor in electrical isolation the emittance matrix satisfies $E_\mu \equiv E_{11}=-E_{12}=-E_{21}=E_{22}$. Thus the dynamical conductance matrix $G_{\alpha\beta}$ where the two indices now run over all contacts of all nearby conductors obeys the same ''sum rules,'' Eq. (15), that we found for the dc conductance. We conclude by giving two examples. Consider a uniform ballistic conductor connecting two reservoirs. Assume that contact effects can be neglected and determine the potential from a condition of local charge neutrality. It is found that the emittance is inductive (negative). The emittance is 1/4 of the density of states of the ballistic wire,[35]

$$E_\mu=-(1/4)e^2 dN/dE. \tag{55}$$

In contrast, the ensemble averaged emittance of a metallic diffusive wire is found to be capacitive and is determined by 1/6 of the total density of states,[35]

$$\langle E_\mu\rangle_e=(1/6)e^2\langle dN/dE\rangle_e. \tag{56}$$

Since the total unscreened density of states which is available to carriers from one contact is $1/2\langle dN/dE\rangle$ this corresponds (in magnitude) to a reduction factor of 1/3 similar to the reduction of the shot noise below the full Poisson result.

VI. FLUCTUATIONS OF A MESOSCOPIC CAPACITOR

In this section we derive an expression for the conductance of a mesoscopic capacitor (see Fig. 3) valid up to second order in frequency. To linear order in frequency the current response is $\langle I(\omega)\rangle = -i\omega C_\mu$, where C_μ is the electrochemical capacitance. To second order in frequency the response of a capacitor with resistances in series[34,71] is determined by the product of the capacitance and a relaxation time $R_q C_\mu$. Since we know the electrochemical capacitance the second order term determines the charge relaxation resistance R_q. With the electrochemical capacitance and the charge relaxation resistance the conductance of the capacitor is to second order in frequency

$$G(\omega) = -i\omega C_\mu + \omega^2 C_\mu^2 R_q . \tag{57}$$

We want to determine the charge relaxation resistance. One way to proceed is to generalize the discussion of the conductance. This requires us to determine the potential $U(\mathbf{r},\omega)$ to first order in frequency. Thus a dynamic screening theory is needed. An alternative way to determine this resistance is to find the current-current fluctuations to second order in frequency, and to use the fluctuation–dissipation theorem. This, as we will show, permits us to use again the (fluctuating) quasistatic potential. We chose this second approach.

The key point of our discussion is again to achieve a current and charge conserving result. A thermally induced fluctuation which leads to an increase of the charge on one capacitor plate must lead to a decrease of an equal amount of charge on the other capacitor plate. The long range Coulomb interaction completely correlates the charge fluctuations on the two plates. Consider first the charge fluctuations of the capacitor with the potential held fixed at its equilibrium value. These charge fluctuations can be found from the Fermi field operator.[23] For the local density operator we find quite generally,

$$\hat{n}(\mathbf{r},\omega) = \sum_{\alpha\beta nm} dE (h v_{\alpha n}(E))^{-1/2} (h v_{\beta m}(E+\hbar\omega))^{-1/2} \Psi^*_{\alpha n}(\mathbf{r},E)\Psi_{\beta m}(\mathbf{r},E+\hbar\omega)\hat{a}^\dagger_{\alpha n}(E) \times \hat{a}_{\beta m}(E+h\omega). \tag{58}$$

Now what counts are the deviation of this ''density'' away from the equilibrium value. Therefore, we substitute this density into the Poisson equation. The Poisson equation is now an operator equation. For each pair $\hat{a}^\dagger_{\alpha n}(E)\hat{a}_{\beta m}(E+\hbar\omega)$ there exists a potential operator $\hat{u}_{\alpha\beta nm}$. We introduce a potential operator $\hat{u}_{\alpha\beta}$ which is the sum of $\hat{u}_{\alpha\beta nm}$ over all channels in contact α and β. We can write this operator with the help of a nondiagonal density of states matrix. In the zero-frequency limit which is of interest here, this matrix is

$$d\mathbf{n}_{\gamma\delta}(\mathbf{r})/dE = -(1/4\pi i)\sum_\beta (\mathbf{s}^\dagger_{\beta\gamma}(\delta\mathbf{s}_{\beta\delta}/e\,\delta U(x)) - (\delta\mathbf{s}^\dagger_{\beta\gamma}/e\,\delta U(x))\mathbf{s}_{\beta\delta}) \tag{59}$$

with elements

$$dn_{\gamma\delta mn}(\mathbf{r})/dE = \sum_{mn} (h v_{\gamma n}(E))^{-1/2} (h v_{\delta m}(E))^{-1/2} \Psi^*_{\gamma n}(\mathbf{r},E)\Psi_{\delta m}(\mathbf{r},E). \tag{60}$$

Thus the potential operator is given by

$$\hat{u}_{\alpha\beta}(\mathbf{r}) = \int d^3r'\, g(\mathbf{r},\mathbf{r}')\hat{\mathbf{a}}^\dagger_\alpha(E)[d\mathbf{n}_{\alpha\beta}(\mathbf{r}')/dE]\hat{\mathbf{a}}_\beta(E). \tag{61}$$

So far we have been completely general. Now we consider the mesoscopic capacitor shown in Fig. 3. There is no transmission. We have only two contacts α=1,2. Thus it is only the diagonal

matrices $d\mathbf{n}_{\alpha\alpha}(\mathbf{r})/dE$ which are non-vanishing. Since the scattering matrix is unitary for each conductor separately, the expression for this matrix can be simplified, $d\mathbf{n}_{\gamma\gamma}(\mathbf{r})/dE = -(1/2\pi i)\mathbf{s}^{\dagger}_{\gamma\gamma}(\delta\mathbf{s}_{\gamma\gamma}/e\,\delta U(x))$. Next we expand the particle–current operator to first order in frequency. We find

$$\hat{I}_{\alpha}(\omega) = -ie\omega \int dE \hat{\mathbf{a}}^{\dagger}_{\alpha}(E)(d\mathbf{N}_{\alpha\alpha}(\alpha)/dE)\hat{\mathbf{a}}_{\alpha}(E), \tag{62}$$

$$d\mathbf{N}_{\alpha\alpha}(\alpha)/dE = (1/2\pi i)\mathbf{s}^{\dagger}_{\alpha\alpha}(E)(d\mathbf{s}_{\alpha\alpha}/dE). \tag{63}$$

The fluctuations in the potential give rise to an induced current. In response to a classical potential we found $I_{\alpha}(\omega) = ie^2\omega\int d^3r(dn(\alpha,\mathbf{r})/dE)u(\mathbf{r})$ [see Eq. (43)]. Now we need an operator expression. In the Hartree approach treated here we can replace the classical potential by the quantum operator potential. Thus the induced current is now

$$\hat{I}_{\alpha}(\omega) = ie^2\omega \int d^3r(dn(\alpha,\mathbf{r})/dE)\sum_{\gamma} \hat{u}_{\gamma\gamma}(\mathbf{r}). \tag{64}$$

The total current can be expressed with the help of a screened density of states matrix

$$\mathbf{D}_{\gamma\gamma}(\alpha) = \left[\delta_{\alpha\gamma}(d\mathbf{N}_{\gamma\gamma}/dE) - \int d^3r d^3r'(dn(\alpha,\mathbf{r})/dE)g(\mathbf{r},\mathbf{r}')(d\mathbf{n}_{\gamma\gamma}(\mathbf{r}')/dE)\right], \tag{65}$$

in the following simple form

$$\hat{I}_{\alpha}(\omega) = -ie\omega \int dE \sum_{\gamma} \hat{\mathbf{a}}^{\dagger}_{\gamma}(E)\mathbf{D}_{\gamma\gamma}(\alpha)\hat{\mathbf{a}}_{\gamma}(E). \tag{66}$$

It is seen immediately that we have achieved current conservation. The sum $\hat{I}_1(\omega)+\hat{I}_2(\omega)$ vanishes identically since $\int d^3r(dn(\mathbf{r})/dE)g(\mathbf{r},\mathbf{r}')$ is one at every point $\mathbf{r}'$ and since $\int d^3r'(\delta s_{\beta\delta}/e\,\delta U(x)) = -(ds_{\beta\delta}/dE)$. As a consequence we have $\mathbf{D}_{\gamma\gamma}(1)+\mathbf{D}_{\gamma\gamma}(2)=0$. Evaluating the fluctuations and writing the result in the form

$$\langle(\Delta I)^2\rangle = 2kT\Delta\nu\omega^2 C_{\mu}^2 R_q \tag{67}$$

determines the charge relaxation resistance. The electrochemical capacitance is the trace of the effective screened density of states operator,

$$C_{\mu} = e^2 \int dE(-df/dE)\mathrm{Tr}[\mathbf{D}], \tag{68}$$

where $\mathrm{Tr}[\mathbf{D}]=\mathrm{Tr}[\mathbf{D}_{11}(1)]=\mathrm{Tr}[\mathbf{D}_{22}(2)]=-\mathrm{Tr}[\mathbf{D}_{11}(2)]=-\mathrm{Tr}[\mathbf{D}_{22}(1)]$. The charge relaxation resistance is

$$R_q = \left(\frac{h}{e^2}\right)\frac{\int dE(-df/dE)\Sigma_{\gamma}\,\mathrm{Tr}[\mathbf{D}^{\dagger}_{\gamma\gamma}(\alpha)\mathbf{D}_{\gamma\gamma}(\alpha)]}{(\int dE(-df/dE)\mathrm{Tr}[\mathbf{D}])^2}. \tag{69}$$

Note that in the expression for the charge relaxation resistance α can be taken to be either 1 or 2. Equation (69) which expresses the capacitance as a trace of an effective density of states is identical to the result that one obtains from the emittance matrix Eq. (54). Equation (69) is a microscopic expression of the charge relaxation resistance given in Ref. 34 for the case of a discrete potential model. The charge relaxation resistance is inversely proportional to the number of channels which contribute to the density of states. Thus a measurement of this resistance can be carried out best by changing the number of channels for instance with the help of a magnetic field.

We can also understand the capacitance and the charge relaxation resistance in terms of the time a carrier is *dwelling* in the region of the surface over which the electric field penetrates into the conductors. For noninteracting carriers the dwell time in a volume is the integrated particle

density in this volume divided by the incident current.[65] Here we extend this consideration and take the dwell time to be the integrated charge density on a capacitor plate divided by the current at the contact of that plate. The average time a carrier dwells on either one of the plates (at $kT=0$) is $\langle\tau\rangle=h\ \mathrm{Tr}[\mathbf{D}]$. Thus the capacitance is simply $C_\mu=e^2\langle\tau\rangle/h$. Now we see that the charge relaxation resistance is related to the mean square dwell time divided by the average dwell time squared, $R_q=(e^2/h)\langle\tau^2\rangle/\langle\tau\rangle^2$. Note that these times are ultimately determined by functional derivatives (potential derivatives) of the scattering matrix rather then energy derivatives. We also note that the dwell time is the same on either plate, in contrast to the dwell times one obtains by analyzing an unscreened free electron problem. This shows clearly that one cannot apply uncritically concepts of dwell or tunneling times obtained for noninteracting particles to electrical conductors. The electrical relaxation time is the RC time. From the definition of the dwell time given above we find that the RC time is the ratio of the mean square dwell time divided by the mean dwell time, $\tau_{\mathrm{RC}}=\langle\tau^2\rangle/\langle\tau\rangle$.

VII. CONCLUSION

In this article we have discussed expressions for the dc conductance, the ac conductance and the spectral densities for the current and charge fluctuations. We have used a common mathematical framework. Starting from expressions in which the internal potential is held fixed, we have used a self-consistent scheme to obtain ac conductance and frequency-dependent noise spectra which are charge and current conserving. In fact the structure of these results suggests that a self-consistent ac-theory or frequency-dependent spectrum has exactly the same form as that found for the case of a fixed internal potential, except that the current matrix A needs to be replaced by a more complicated self-consistent expression A^{eff}. To show this with more generality then was done here, is clearly a worthwhile task.

(Received 15 April 1996; accepted for publication 19 June 1996)

An adiabatic approximation in terms of instantaneous resonances to study the steady-state and time-dependent transport properties of interacting electrons in biased resonant tunneling heterostructures is used. This approach leads, in a natural way, to a transport model of large applicability consisting of reservoirs coupled to regions where the system is described by a nonlinear Schrödinger equation. From the mathematical point of view, this work is nonrigorous but may offer some fresh and interesting problems involving semiclassical approximation, adiabatic theory, nonlinear Schrödinger equations, and dynamical systems. © *1996 American Institute of Physics.* [S0022-2488(96)00510-5]

I. INTRODUCTION

Man-tailored semiconductor heterostructures[1] offer, for the first time, the possibility to test quantum mechanics at a mesoscopic level.[2] The scenario of systems which can be investigated is so rich that the art of their realization deserves the name of quantum design.

In the simplest case, a quantum designer can grow sandwiches of different semiconductor alloys by choosing the number of atomic layers for each kind of alloy. In the resulting heterostructure, the conduction band profile along the growth direction forms steps whose height can be continuously varied by a proper choice of the alloy composition. Typical widths and heights are of the order of tens of Å and tenths of eV, respectively.

At low temperature, the mean free path of carriers for scattering from crystal impurities is of the order of 10^4 Å, and for heterostructures smaller than this size the electric transport along the growth direction is phase coherent quantum scattering from the conduction band discontinuities.[3] Due to the translational invariance in the plane orthogonal to the growth direction, the problem is one-dimensional. Moreover, the carriers are described by an effective mass which accounts for the microscopic scattering with the periodic crystal sites, and their wave function is an envelope wave function.[4]

In a homogeneous neutral conductor, the electron–electron interaction can be taken into account by a renormalization of the carrier effective masses[5] and one deals with a transport problem like in a noninteracting case. In a heterostructure, even as simple as that described above, the breaking of translational invariance in the transport direction allows the electric neutrality to be locally violated. The corresponding interaction potential, obtained, at Hartree level, by solving a proper Poisson equation, can strongly modify the transport properties. The example of a double barrier heterostructure with the exterior regions doped with donors is illuminating.[6] Due to tunneling, electrons populate the resonance(s) created by the double barrier and the region between the barriers becomes negatively charged. This generates an electric potential which decreases the

tunneling probability of electrons in the double barrier region. As a consequence, current oscillations on the picosecond scale[7,8] and chaotic behavior without classical counterpart[9] have been predicted in a ballistic configuration in which electrons are injected at some chosen energy.

Experiments with ballistic electrons are difficult, and measurements became available only recently.[10] Technologically simpler is the case of biased heterostructures where transport is due to the presence of reservoirs at thermal equilibrium with different chemical potentials. Manifestations of the electron–electron interaction are known also in this configuration. For example, hysteresis in the current–voltage characteristics of double barrier heterostructures have been observed[11] and recognized as a consequence of the accumulation of electrons in the resonance.[11–15] In this case, however, one has the theoretical problem of attaching reservoirs at thermal equilibrium to a piece of conductor where quantum coherent transport takes place.

In the recent paper[16] we proposed an approach to this problem based on a mathematical method earlier applied in the framework of ballistic transport.[17] We showed that for heterostructures with a single resonance our approach allows one (i) to obtain steady-state voltage–current characteristics having hysteresis or not in agreement with the experimental results[18] and (ii) to predict time-dependent properties analogous to those studied in optically bistable systems.[19] Here, we develop the general mathematical scheme of this approach and discuss the case with several resonances where multistability phenomena can take place as in superlattices.[20,21]

For simplicity, consider the one-dimensional double barrier heterostructure discussed above. The idea is that due to the presence of resonances the corresponding Schrödinger problem can be divided in two parts: a Schrödinger equation for the barrier region and one for the exterior space, the two being weakly coupled by tunneling. This decomposition corresponds to the schematization of the transport process as a coherent process fed by reservoirs. In the exterior space (reservoirs), homogeneous and neutral, the electron–electron interaction is neglected and thermal equilibrium is taken into account by considering a continuous set of energy eigenstates distributed according to Fermi statistics. In the barrier region (coherent conductor), the Coulomb interaction is included in a self-consistent potential obtained by solving the Poisson equation associated with the local charge density. Under the assumption that the barriers are wide enough, the corresponding nonlinear Schrödinger problem is discussed in two steps. In the first step we eliminate the potential well between the two barriers by artificially increasing the potential there, and we solve the Schrödinger equation asymptotically for the new potential by means of WKB-expansions. The resulting solution is then very small near the (filled) potential well, so we get only a small error in the Schrödinger equation when we go back to the true potential. In the second step we correct for this small error by adding a wave function concentrated near the potential well. Assuming *a priori* that the charge in the well changes slowly with time, the correcting wave function can be expected to be large only at energies close to the resonances, and be well approximated by some linear combination of the resonant states.

In most of the article we discuss the case in which only one resonance participates. The validity of this one-mode approximation has been tested numerically with excellent results in the ballistic configuration of Ref. 17. Here, the coefficient of the one-mode approximation obeys an ordinary differential equation with respect to time in the infinite-dimensional space of square integrable functions of energy. We study the stationary points of the corresponding vector field and their nature, whether they are attractive or not, and arrive at quite neat answers. For solutions of the dynamical system which have existed as bounded solutions for a long time and in a suitable asymptotic limit (of wide barriers) we derive a simplified scalar differential equation for the evolution of the sheet density of electrons trapped in the well, which gives a good global understanding of the more complete dynamical system. Using these results, we are able to discuss the phenomenon of hysteresis and we support and illustrate the discussion with several numerical results. The discussion includes the evolution of solutions away from fixed points which necessarily appears when there is hysteresis. We also discuss the case of several resonances and get analogous results.

From the mathematical point of view, the present article could be a starting point for rigorous work on some fresh problems, involving semiclassical analysis, adiabatic theory, nonlinear Schrödinger equations, and dynamical systems. A strong motivation for such an enterprise is the fact that the theory of electric transport in semiconductor devices offers many problems similar to the one we illustrate here.[22]

The plan of the article is as follows. In Sec. II we define the model. In Sec. III we review the WKB expansion for slowly varying potentials. In Secs. IV and V we determine the driving term and the ground resonant state, respectively, within the WKB approximation. The central equation of our article is derived in Sec. VI, and the general properties of the associated fixed points and linearizations are discussed in Sec. VII. In Sec. VIII we introduce an approximation valid in the limit of small resonance width and discuss the corresponding fixed-point solutions and linearizations. In Sec. IX we obtain a simplified differential equation describing the dynamics of the electron density in the well. A qualitative discussion of the hysteresis phenomenon in comparison with numerical results is given in Sec. X. In Sec. XI we finally consider the case with several resonances.

II. DEFINITION OF THE MODEL

Let us consider a heterostructure whose conduction band profile consists of two barriers of height V_0 located in $[a,b]$ and $[c,d]$,

$$V_{\mathrm{cb}}(x)=\begin{cases}0, & x<a\\ V_0, & a<x<b\\ 0, & b<x<c\\ V_0, & c<x<d\\ 0, & x>d\end{cases} \tag{2.1}$$

with $a<b<c<d$ along the growth direction x. We wish to evaluate the transport properties of this device when a bias energy ΔV is applied between the emitter ($x<a$) and collector ($x>d$) regions uniformly doped. Due to doping, the band of conduction electrons formed in the emitter and collector regions is characterized by a Fermi energy $E_F=(3\pi^2 n_D)^{2/3}$, where n_D is the net donor concentration. We will use everywhere effective atomic units $\hbar=2m^*=1$ and $e^2/\epsilon=2a_B^{-1}$, where m^* is the electron effective mass and ϵ the dielectric constant. In these units, every physical quantity is expressed in terms of the effective Bohr radius $a_B=\hbar^2\epsilon/(m^*e^2)$. Assuming an ideal heterostructure homogeneous in the plane yz parallel to the junctions (and orthogonal to the growth direction x), the single-electron momenta k_y and k_z are conserved quantities. As a consequence, the single-electron wave function at energy $E+E_\parallel$, where $E_\parallel=k_y^2+k_z^2$, can be factorized as $\phi(x,t,E)\chi(y,z,t,E_\parallel)$ with

$$\chi(y,z,t,E_\parallel)=\frac{1}{\sqrt{A}}\,e^{i(k_y y+k_z z)}e^{-iE_\parallel t}. \tag{2.2}$$

We will assume periodic boundary conditions in a two-dimensional region A so that the momenta k_y and k_z are quantized as in a real device having finite lateral area of size A. The time-dependent Schrödinger equation for the single-electron wave function at energy E along the x direction is

$$[-i\partial_t-\partial_x^2+V_{\mathrm{cb}}(x)+U(\phi,x)]\phi(x,t,E)=0, \tag{2.3}$$

where $U(\phi,x)$ takes into account the applied bias and, at Hartree level, the electron–electron interaction. Assuming ideal metallic behavior in the emitter and collector regions, i.e., neglecting the formation of accumulation and depletion layers, $U(\phi,x)$ can be obtained as the solution of the Poisson equation

$$\partial_x^2 U(\phi,x) = -8\pi a_B^{-1}\rho(\phi) \tag{2.4}$$

with Dirichlet boundary conditions $U(\phi,a)=0$ and $U(\phi,d)=-\Delta V$. The density ρ takes into account all the electrons in the occupied energy states and depends only on the wave-function component ϕ. Indeed, if the emitter and collector regions are at thermal equilibrium with temperature T we have

$$\rho = 2\int_0^\infty dE \sum_{E_\parallel} |\phi(x,t,E)\chi(y,z,t,E_\parallel)|^2 (1+e^{(E+E_\parallel-E_F)/k_BT})^{-1} = \int dE\ g(E)|\phi(x,t,E)|^2, \tag{2.5}$$

where the factor 2 takes into account the spin degeneracy. Energies are measured from the bottom of the emitter conduction band, and the lower integration bound $E=0$ in the first line of Eq. (2.5) stems from the fact that for $E_F \ll \Delta V$, as we will assume, only electrons from the emitter conduction band can penetrate the region $[a,d]$ where the electron density is of interest. In the second line of Eq. (2.5) this lower bound is absorbed in the definition of $g(E)$ by a Heaviside function $\theta(E)$. The function $g(E)$ can be explicitly evaluated by approximating the sum over the parallel degrees of freedom with an integral

$$\begin{aligned} g(E) &= \theta(E) 2\int_0^\infty dE_\parallel \frac{A}{4\pi}\left|\frac{1}{\sqrt{A}}\right|^2 (1+e^{(E+E_\parallel-E_F)/k_BT})^{-1} \\ &= \theta(E)\,\frac{1}{2\pi}\,[k_BT\,\ln(1+e^{(E-E_F)/k_BT})+E_F-E]. \end{aligned} \tag{2.6}$$

Note that the chemical potential at temperature T in the Fermi function has been approximated with its value at $T=0$, i.e., the Fermi energy determined by the net donor concentration.

In general, the solution of Eq. (2.4) cannot be handled analytically. We will suppose that, due to the accumulation of electrons in the well with sheet density

$$s(\phi) = \int dE\ g(E) \int_{(a+b)/2}^{(c+d)/2} dx |\phi(x,t,E)|^2, \tag{2.7}$$

ideal metallic behavior in the well $[b,c]$ and ideal insulating behavior in the barriers $[a,b]$ and $[c,d]$ hold. This is equivalent to approximate Eq. (2.4) with

$$\partial_x^2 U(\phi,x) = -8\pi a_B^{-1} s(\phi)[B\delta(x-b)+C\delta(x-c)], \quad B+C=1 \tag{2.8}$$

and the condition that $\partial_x U(\phi,x)=0$ for $b<x<c$. In this case $U(\phi,x)$ becomes a piecewise linear function of x with $\partial_x U(\phi,x)$ having jump discontinuities at $x=b$ and $x=c$. The total potential $V_{\rm cb}+U$ in Eq. (2.3) is better rewritten as $V+W$, where

$$V(x) = \begin{cases} 0, & x<a \\ V_0 - \Delta V(x-a)/l, & a<x<b \\ -\Delta V(b-a)/l, & b<x<c \\ V_0 - \Delta V(b-a+x-c)/l, & c<x<d \\ -\Delta V, & x>d \end{cases} \tag{2.9}$$

gives the band profile modified by the external bias and

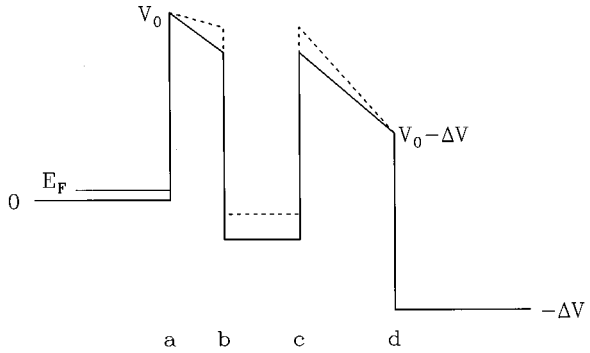

FIG. 1. Potential $V(x)$ representing the band profile modified by the external bias energy ΔV (solid line) and total potential $V(x)+W(s,x)$ including the electrostatic contribution due to electrons trapped in the well with sheet density s (dashed line).

$$W(s,x)=8\pi a_B^{-1}s(\phi)\times\begin{cases}0, & x<a\\ (x-a)(d-c)/l, & a<x<b\\ (b-a)(d-c)/l, & b<x<c\\ (b-a)(d-x)/l, & c<x<d\\ 0, & x>d\end{cases} \tag{2.10}$$

depends on the wave function ϕ through the sheet density of electrons in the well $s(\phi)$. Here $l=b-a+d-c$. The potentials $V(x)$ and $W(s,x)$ are shown in Fig. 1.

We will try to solve the nonlinear partial differential equation

$$[-i\partial_t-\partial_x^2+V(x)+W(s,x)]\phi(x,t,E)=0, \tag{2.11}$$

where $s(\phi)$ is given by Eq. (2.7), in two steps. Let $V_{\text{fill}}(x)=V(x)+V_0 1_{[b,c]}(x)$ be the potential obtained by filling the well $[b,c]$. Here $1_{[b,c]}(x)$ is the characteristic function of the interval $[b,c]$. First we solve

$$[-i\partial_t-\partial_x^2+V_{\text{fill}}(x)+W(s,x)]\tilde{\mu}(x,t,E)=0 \tag{2.12}$$

and then we look for ϕ in the form $\phi=\tilde{\mu}+\tilde{\nu}$, where $\tilde{\nu}$ should solve

$$[-i\partial_t-\partial_x^2+V(x)+W(s,x)]\tilde{\nu}(x,t,E)=V_0 1_{[b,c]}(x)\tilde{\mu}(x,t,E). \tag{2.13}$$

The wave function $\tilde{\mu}$ describes an electron at energy E which is delocalized in the emitter and collector regions and has an exponentially small probability to be found in the forbidden region $[a,d]$. The wave function $\tilde{\nu}$ describes the localization, driven by $\tilde{\mu}$, of the same electron in the well $[b,c]$. The wave function ϕ of the original problem (2.11) can be approximated by $\tilde{\nu}$ or $\tilde{\mu}$ inside or outside the two barriers, respectively, with an error which is exponentially small in the limit of wide barriers.[17]

To evaluate $\tilde{\mu}$ we will use a WKB approximation in the forbidden region $[a,d]$. Equation (2.13) will be treated with a one-mode approximation in which $\tilde{\nu}$ is assumed proportional to a resonant state corresponding to the potential $V+W$. To evaluate this resonant state and the corresponding resonance, we will again use a WKB approximation. In both cases, the justification of using a WKB approximation stems from the fact that $V_{\text{fill}}+W$ and $V+W$ are slowly varying potentials in the barriers regions if $b-a$ and $d-c$ are large while ΔV and s remain bounded.

III. WKB EXPANSION FOR SLOWLY VARYING POTENTIALS

Let $\mathscr{U}=\mathscr{U}_h(x)$ be a real valued potential on some interval, with $\partial_x\mathscr{U}=\mathscr{O}(|h|)$ and $\partial_x^2\mathscr{U}=\mathscr{O}(h^2)$, where $|h|\ll 1$ is a parameter. Let $\mathscr{E}$ be a real energy and assume that $\mathscr{U}_h(x)-\mathscr{E}$ is bounded from above and from below by some strictly positive constants that are independent of h. This means that we are in the classically forbidden region. Then

$$\begin{aligned}&[-\partial_x^2+\mathscr{U}-\mathscr{E}](\mathscr{U}-\mathscr{E})^{-1/4}\exp\left(-\int^x dx'(\mathscr{U}-\mathscr{E})^{1/2}\right)\\&\quad=\left[-\frac{5}{16}(\mathscr{U}-\mathscr{E})^{-9/4}(\partial_x\mathscr{U})^2+\frac{1}{4}(\mathscr{U}-\mathscr{E})^{-5/4}\partial_x^2\mathscr{U}\right]\exp\left(-\int^x dx'(\mathscr{U}-\mathscr{E})^{1/2}\right)\\&\quad=e^{-\int^x dx'(\mathscr{U}-\mathscr{E})^{1/2}}\mathscr{O}(h^2),\end{aligned}\tag{3.1}$$

and therefore

$$(\mathscr{U}-\mathscr{E})^{-1/4}\exp\left(-\int^x dx'(\mathscr{U}-\mathscr{E})^{1/2}\right)\tag{3.2}$$

is a good approximation to a corresponding exact eigenfunction, even over intervals of length $\mathscr{O}(|h|^{-1})$.

In the following sections, we will apply the above approximation in the barrier regions $[a,b]$ and $[c,d]$ with h equal to the x derivative of $V+W$ in these intervals.

IV. THE DRIVING TERM

Equation (2.12) can be solved by evaluating the instantaneous eigenstates of the potential $V_{\text{fill}}+W$. We set $\tilde{\mu}(x,t,E)=\exp(-iEt)\mu(x,t,E)$ and suppose that ΔV and s are slowly varying functions of time so that also $\mu(x,t,E)$ is slowly varying in time. Thus in the equation

$$[-i\partial_t-\partial_x^2+V_{\text{fill}}(x)+W(s,x)-E]\mu(x,t,E)=0,\tag{4.1}$$

we make a very small error if we neglect the term $-i\partial_t\mu$, as we shall do in the following. In the emitter region $x<a$, we take $\mu(x,t,E)$ as the sum of a left- and a right-going plane wave at energy E,

$$\mu(x,t,E)=\frac{1}{\sqrt{4\pi\sqrt{E}}}[e^{i\sqrt{E}(x-a)}+r(E)e^{-i\sqrt{E}(x-a)}],\tag{4.2}$$

where $r(E)$ is a reflection amplitude to be computed. Note that the normalization factor in Eq. (4.2) is chosen in order to have $\int dx\mu(x,t,E)\overline{\mu(x,t,E')}=\delta(E-E')$, in agreement with the expression of the electron density (2.5) in terms of an integral over the energy E. We propagate the expression (4.2) to the adjacent regions by requiring μ to be of class C^1 and applying the WKB approximation described in Sec. III. In the interval $[a,b]$ the potential is $V_{\text{fill}}+W=V_0+\alpha(x-a)$, where

$$\alpha=\frac{8\pi a_B^{-1}s(d-c)-\Delta V}{b-a+d-c}\tag{4.3}$$

plays the role of the small parameter h of Sec. III. For $a<x<b$ we can then use the WKB approximation

$$\mu(x,t,E)=\frac{1}{\sqrt{4\pi\sqrt{E}}}\frac{(V_0-E)^{1/4}}{[V_0+\alpha(x-a)-E]^{1/4}}\,t(E)\exp\left(-\int_a^x dx'[V_0+\alpha(x'-a)-E]^{1/2}\right), \tag{4.4}$$

where $t(E)$ is a transmission amplitude to be determined with $r(E)$ from the C^1 condition at $x=a$

$$1+r(E)=t(E), \tag{4.5a}$$

$$i\sqrt{E}-i\sqrt{E}r(E)=t(E)[(V_0-E)^{1/2}-\tfrac{1}{4}(V_0-E)^{-5/4}\alpha]. \tag{4.5b}$$

Neglecting the last term in the square brackets, which is $\mathcal{O}(|\alpha|)$, we get

$$r(E)=\frac{1+i(V_0/E-1)^{1/2}}{1-i(V_0/E-1)^{1/2}}, \tag{4.6a}$$

$$t(E)=\frac{2}{1-i(V_0/E-1)^{1/2}}. \tag{4.6b}$$

Note that the neglected term would give correction factors $1+\mathcal{O}(|\alpha|)$ to $r(E)$ and $t(E)$.

At $x=b$ we can set up a similar transition problem but here $V_{\text{fill}}+W$ is continuous and the corresponding transmission amplitude is $1+\mathcal{O}(|\alpha|)$. Neglecting again a factor $1+\mathcal{O}(|\alpha|)$, for $b<x<c$ we get

$$\mu(x,t,E)=\mu_0(t,E)e^{-[V_0+\alpha(b-a)-E]^{1/2}(x-b)}, \tag{4.7}$$

where

$$\mu_0(t,E)=\frac{1}{\sqrt{4\pi\sqrt{E}}}\frac{(V_0-E)^{1/4}}{(V_0+\alpha(x-a)-E)^{1/4}}\frac{2e^{\{(V_0-E)^{3/2}-[V_0+\alpha(b-a)-E]^{3/2}\}2/3\alpha}}{1+i(V_0/E-1)^{1/2}}. \tag{4.8}$$

Only this expression of μ in the region $[b,c]$ will be used in the following as driving term of Eq. (2.13).

V. RESONANCE AND RESONANT STATE

In this section we will obtain a WKB approximate expression for the ground-state resonance $\lambda(s)=E_R(s)-i\Gamma(s)/2$ and the corresponding resonant state $e(s,x)$ for the potential $V+W$. We will assume that $c-b$ is bounded from below and from above by positive constants, while $b-a$ and $d-c$ are large enough.

To start with, we recall the construction of the ground state eigenvalue E_0^w of the potential $V_w(x)=V_0[1_{]-\infty,b]}(x)+1_{[c,+\infty[}(x)]$ which coincides, up to the constant shift

$$\Delta E=\frac{8\pi a_B^{-1}s(b-a)(d-c)-\Delta V(b-a)}{b-a+d-c}, \tag{5.1}$$

with the potential $V+W$ in the well region $[b,c]$. The corresponding ground eigenstate is

$$e_0^w(x)=C_0^w\times\begin{cases}\cos[\sqrt{E_0^w}(c-b)/2]e^{-(V_0-E_0^w)^{1/2}(b-x)}, & x<b\\ \cos\{\sqrt{E_0^w}[x-(b+c)/2]\}, & b<x<c\\ \cos[\sqrt{E_0^w}(c-b)/2]e^{-(V_0-E_0^w)^{1/2}(x-c)}, & x>c\end{cases} \tag{5.2}$$

where $0<E_0^w<\min(V_0,\pi^2/(c-b)^2)$ is determined by the requirement that $e_0^w(x)$ is of class C^1,

$$\tan[\sqrt{E_0^w}(c-b)/2]=(V_0/E_0^w-1)^{1/2}, \tag{5.3}$$

and the normalization constant is

$$C_0^w=\left[\frac{E_0^w}{V_0(V_0-E_0^w)^{1/2}}+\frac{c-b}{2}+\frac{(V_0-E_0^w)^{1/2}}{V_0}\right]^{-1/2}, \tag{5.4}$$

where we used the identities $\cos^2 u=(1+\tan^2 u)^{-1}$, $(\sin 2u)/2=\sin u\cos u=\tan u(1+\tan^2 u)^{-1}$. In the following we will assume that $E_0^w+\Delta E<V_0-\Delta V$.

Next we look at the ground state of the potential

$$V_b(x)=\begin{cases} V_0+\alpha(a-b), & x<a \\ V_0+\alpha(x-b), & a<x<b \\ 0, \quad b<x<c & \\ V_0+\beta(x-c), & c<x<d \\ V_0+\beta(d-c), & x>d \end{cases} \tag{5.5}$$

which coincides, up to the constant shift ΔE, with $V+W$ on the larger region $[a,d]$ which includes the barriers. In Eq. (5.5) α is given by Eq. (4.3) and

$$\beta=\frac{-8\pi a_B^{-1}s(b-a)-\Delta V}{b-a+d-c}. \tag{5.6}$$

Note that the potential V_b has been obtained by bending the barriers of V_w in the intervals $[a,b]$ and $[c,d]$ proportionally to α and β, respectively. Let E_0^b be the ground state of V_b and $e_0^b(x)$ the corresponding eigenfunction. Since $|\alpha|$ and $|\beta|$ are small, from the same WKB considerations of Sec. III we have $E_0^b=E_0^w+\mathcal{O}(|\alpha|+|\beta|)$ and $e_0^b(x)=e_0^w(x)+\mathcal{O}(|\alpha|+|\beta|)$. To get the leading asymptotics of the resonance width, we need to determine the linear contribution to $\mathcal{O}(|\alpha|+|\beta|)$ in E_0^b. By differentiating the eigenvalue equation for the potential V_b, we have

$$\partial_\alpha E_0^b|_{\alpha=\beta=0}=\int_{-\infty}^{+\infty}dx\overline{e_0^b(x)}\partial_\alpha V_b(x)|_{\alpha=\beta=0}e_0^b(x)\simeq\int_{-\infty}^{b}dx(x-b)|e_0^w(x)|^2, \tag{5.7}$$

$$\partial_\beta E_0^b|_{\alpha=\beta=0}=\int_{-\infty}^{+\infty}dx\overline{e_0^b(x)}\partial_\beta V_b(x)|_{\alpha=\beta=0}e_0^b(x)\simeq\int_{c}^{+\infty}dx(x-c)|e_0^w(x)|^2, \tag{5.8}$$

and using Eq. (5.2) we get

$$\begin{aligned}\partial_\alpha E_0^b|_{\alpha=\beta=0}&=-\partial_\beta E_0^b|_{\alpha=\beta=0}=(C_0^w)^2\cos^2[\sqrt{E_0^w}(c-b)/2]\int_{-\infty}^{0}dx\ xe^{2(V_0-E_0^w)^{1/2}x}\\&=-\frac{(C_0^w)^2E_0^w}{4V_0(V_0-E_0^w)}.\end{aligned} \tag{5.9}$$

Observing that $\alpha-\beta=8\pi a_B^{-1}s$, we finally get

$$E_0^b=E_0^w-8\pi a_B^{-1}s\,\frac{(C_0^w)^2E_0^w}{4V_0(V_0-E_0^w)}+\mathcal{O}(\alpha^2+\beta^2). \tag{5.10}$$

The real part $E_R(s)$ of the shape resonance of $-\partial_x^2+V+W$ which is close to the ground-state eigenvalue of $-\partial_x^2+V_b+\Delta E$ is very well approximated by the above calculated $E_0^b+\Delta E$ which can be rewritten as

$$E_R(s)=E_R(0)+\eta s, \tag{5.11}$$

where

$$E_R(0)=E_0^w-\Delta V(b-a)/l \tag{5.12}$$

and

$$\eta=\frac{8\pi a_B^{-1}(b-a)(d-c)}{b-a+d-c}-\frac{8\pi a_B^{-1}(C_0^w)^2E_0^w}{4V_0(V_0-E_0^w)}. \tag{5.13}$$

Now we discuss the determination of the imaginary part $\Gamma(s)$ of the resonance. In the interval $[a,d]$ the ground state of V_b is

$$e_0^b(x)=C_0^b \times\begin{cases}\dfrac{\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\alpha(x-b)-E_0^b]^{1/4}}\exp\left(-\displaystyle\int_x^b dx'[V_0+\alpha(x'-b)-E_0^b]^{1/2}\right), & a<x<b\\ \cos\{\sqrt{E_0^b}[x-(b+c)/2]\}, & b<x<c\\ \dfrac{\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\beta(x-c)-E_0^b]^{1/4}}\exp\left(-\displaystyle\int_c^x dx'[V_0+\beta(x'-c)-E_0^b]^{1/2}\right), & c<x<d\end{cases} \tag{5.14}$$

where $C_0^b=C_0^w+\mathcal{O}(|\alpha|+|\beta|)$. In the interval $[a,d]$, the resonant state $e(s,x)$ can be approximated by adding to Eq. (5.14) terms due to reflections at $x=a$ and $x=d$. For $x\lesssim d$ we try with

$$e(s,x)=\frac{C_0^w\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\beta(x-c)-E_0^b]^{1/4}}\exp\left(-\int_c^d dx'[V_0+\beta(x'-c)-E_0^b]^{1/2}\right)$$
$$\times(e^{-[V_0+\beta(d-c)-E_0^b]^{1/2}(x-d)}+re^{[V_0+\beta(d-c)-E_0^b]^{1/2}(x-d)}), \tag{5.15}$$

where we have also replaced the exponent with its linear approximation at $x=d$. For $x\gtrsim d$ we try the right-going plane wave

$$e(s,x)=\frac{C_0^w\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\beta(d-c)-E_0^b]^{1/4}}$$
$$\times\exp\left(-\int_c^d dx'[V_0+\beta(x'-c)-E_0^b]^{1/2}\right)te^{i[E_0^b-\beta(d-c)]^{1/2}(x-d)}. \tag{5.16}$$

The C^1 condition at $x=d$ gives, up to terms $\mathcal{O}(|\beta|)$,

$$1+r=t, \tag{5.17a}$$

$$-[V_0+\beta(d-c)-E_0^b]^{1/2}+[V_0+\beta(d-c)-E_0^b]^{1/2}r=i[E_0^b-\beta(d-c)]^{1/2}t, \tag{5.17b}$$

which determines r and t so that for $x\gtrsim d$ we have

$$e(s,x)=\frac{C_0^w\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\beta(d-c)-E_0^b]^{1/4}}2\left[1-i\frac{[E_0^b-\beta(d-c)]^{1/2}}{[V_0+\beta(d-c)-E_0^b]^{1/2}}\right]^{-1}\times\exp\left\{\frac{2}{3\beta}\{(V_0-E_0^b)^{3/2}-[V_0+\beta(d-c)-E_0^b]^{3/2}\}+i[E_0^b-\beta(d-c)]^{1/2}(x-d)\right\}. \tag{5.18}$$

In these calculations we have assumed that $E_0^b-\beta(d-c)>0$, $V_0+\beta(d-c)-E_0^b>0$. The first inequality is always fulfilled in experimentally relevant situations, while the second one, equivalent to $E_R(s)<V_0-\Delta V$ may be more critical and, possibly, one should replace Eq. (5.18) by a more complicated formula.

The same calculation can be repeated for $x=a$. For $x\gtrsim a$ we try with

$$e(s,x)=\frac{C_0^w\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\alpha(x-b)-E_0^b]^{1/4}}\exp\left(-\int_a^b dx'[V_0+\alpha(x'-b)-E_0^b]^{1/2}\right)\times(e^{[V_0+\alpha(a-b)-E_0^b]^{1/2}(x-a)}+re^{-[V_0+\alpha(a-b)-E_0^b]^{1/2}(x-a)}), \tag{5.19}$$

with a new reflection amplitude r. For $x\lesssim a$ we try the left-going plane wave

$$e(s,x)=\frac{C_0^w\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0+\alpha(a-b)-E_0^b]^{1/4}}\exp\left(-\int_a^b dx'(V_0+\alpha(x'-b)-E_0^b)^{1/2}\right)\times te^{-i[E_0^b+\alpha(b-a)]^{1/2}(x-a)} \tag{5.20}$$

with a new transmission amplitude t. The C^1 condition at $x=a$ gives, up to terms $\mathcal{O}(|\alpha|)$,

$$1+r=t, \tag{5.21a}$$

$$[V_0+\alpha(a-b)-E_0^b]^{1/2}-[V_0+\alpha(a-b)-E_0^b]^{1/2}r=-i[E_0^b-\alpha(a-b)]^{1/2}t, \tag{5.21b}$$

which determines r and t so that for $x\lesssim a$ we have

$$e(s,x)=\frac{C_0^w\cos[\sqrt{E_0^b}(c-b)/2](V_0-E_0^b)^{1/4}}{[V_0-\alpha(b-a)-E_0^b]^{1/4}}2\left[1-i\frac{[E_0^b+\alpha(b-a)]^{1/2}}{[V_0-\alpha(b-a)-E_0^b]^{1/2}}\right]^{-1}\times\exp\left\{\frac{2}{3\alpha}\{[V_0-\alpha(b-a)-E_0^b]^{3/2}-(V_0-E_0^b)^{3/2}\}-i[E_0^b+\alpha(b-a)]^{1/2}(x-a)\right\}. \tag{5.22}$$

Note that for $x\lesssim a$, $e(s,x)$ is a true left-going plane wave only for ΔV not too large when $E_0^b+\alpha(b-a)>0$. If $E_0^b+\alpha(b-a)<0$, Eq. (5.22) becomes an exponentially decaying function whose corresponding probability current density vanishes. Since $E_0^b+\alpha(b-a)=E_R(s)$, this case corresponds to $E_R(s)<0$. In Eq. (5.22), we also assumed that $V_0-\alpha(b-a)-E_0^b>0$, i.e., $E_R(s)<V_0$.

The resonance width can be now computed by means of the Green formula

$$\Gamma(s)\int_{a'}^{d'}dx|e(s,x)|^2=2\,\mathrm{Im}[\overline{e(s,x)}\partial_x e(s,x)]\Big|_{a'}^{d'}, \tag{5.23}$$

where $a'<a$ and $d'>d$. The integral in the left-hand side (lhs) of Eq. (5.23) is $1+\mathcal{O}(|\alpha|+|\beta|)$ and using Eqs. (5.18) and (5.22) we get, up to such a factor,

$$\Gamma(s)=8(C_0^w)^2E_0^b(V_0-E_0^b)^{1/2}V_0^{-2}\{[V_0+\beta(d-c)-E_0^b]^{1/2}[E_0^b-\beta(d-c)]^{1/2}$$
$$\times e^{\{(V_0-E_0^b)^{3/2}-[V_0+\beta(d-c)-E_0^b]^{3/2}\}4/3\beta}+[V_0-\alpha(b-a)-E_0^b]^{1/2}$$
$$\times[E_0^b+\alpha(b-a)]_+^{1/2}e^{\{[V_0-\alpha(b-a)-E_0^b]^{3/2}-(V_0-E_0^b)^{3/2}\}4/3\alpha}\}, \tag{5.24}$$

where we used $u_+=\theta(u)\ u$.

VI. ONE-MODE APPROXIMATION

Equation (2.13) can be simplified by developing $\tilde{\nu}$ into the instantaneous eigenstates of the potential $V+W$ and keeping only the contributions from the discrete resonant states, i.e., neglecting the contributions from the continuous spectrum.[17] For the moment, we will suppose there is only one resonant state and set $\tilde{\nu}(x,t,E)=\exp(-iEt)z(t,E)e(s,x)$ where $e(s,x)$ is the (ground) resonant state of the potential $V+W$,

$$[-\lambda(s)-\partial_x^2+V(x)+W(s,x)]e(s,x)=0, \tag{6.1}$$

with complex eigenvalue $\lambda(s)=E_R(s)-i\Gamma(s)/2$. The eigenfunction $e(s,x)$ is of class L^2 on the contour $\gamma\equiv(e^{i\theta}]-\infty,0]+a)\cup[a,d]\cup(d+e^{i\theta}[0,+\infty[$ for θ conveniently chosen[23] and satisfies

$$\int_\gamma dx\ e(s,x)^2=1, \quad \int_\gamma dx\ e(s,x)\partial_s e(s,x)=0. \tag{6.2}$$

Multiplying Eq. (2.13) with $e(s,x)$ and integrating over γ, we get

$$\partial_t z(t,E)=i[E-\lambda(s)]z(t,E)+\mathscr{B}(t,s,E) \tag{6.3}$$

with the driving term given by

$$\mathscr{B}(t,s,E)=iV_0\int_b^c dx\ \mu(x,t,E)e(s,x) \tag{6.4}$$

and the sheet density (2.7) reduced, with small error, to

$$s(t)=\int dE\ g(E)|z(t,E)|^2\equiv\|z(t)\|^2. \tag{6.5}$$

VII. FIXED POINTS AND LINEARIZATIONS: GENERAL RESULTS

We consider the vector field in the lhs of Eq. (6.3),

$$\mathscr{V}(z,E)=\mathscr{A}(\|z\|^2,E)z(E)+\mathscr{B}(\|z\|^2,E), \tag{7.1}$$

where

$$\mathscr{A}(s,E)=-\Gamma(s)/2+i\{E-[E_R(0)+\eta s]\}, \tag{7.2}$$

is a nonvanishing function. For simplicity, we assume that $\mathscr{B}$ is independent of t. When $\mathscr{B}$ varies slowly with t, the discussion below should be applied to each such fixed value of t.

We first look for fixed points of $\mathscr{V}$, i.e., functions $z=z(E)$ in $L^2(g(E)dE)$ with $\mathscr{V}(z(E),E)=0$. Clearly $z=z(E)$ is a fixed point iff

$$z(E)=-\frac{\mathscr{B}(\|z\|^2,E)}{\mathscr{A}(\|z\|^2,E)}, \tag{7.3}$$

so the L^2-norm $s=\|z\|^2$ has to satisfy

$$s=\int dE\ g(E)\ \frac{|.\mathscr{B}(s,E)|^2}{|.\mathscr{A}(s,E)|^2}. \tag{7.4}$$

Conversely, if $s\geqslant 0$ is a solution of Eq. (7.4), then

$$z(E)=-\frac{\mathscr{B}(s,E)}{\mathscr{A}(s,E)} \tag{7.5}$$

gives the unique fixed point of $\mathscr{V}$ with $\|z\|^2=s$.

Assuming that we have found a fixed point $z=z(E)$, we look for the linearization of the vector field $\mathscr{V}$ at that point. By giving an infinitesimal increment $\delta z(E)$ to $z(E)$, the corresponding increment $\delta\mathscr{V}$ to $\mathscr{V}$ is

$$\delta\mathscr{V}(z,E)=\mathscr{A}(s,E)\,\delta z(E)+(\langle\delta z|z\rangle+\langle\overline{\delta z}|\overline{z}\rangle)[\partial_s.\mathscr{A}(s,E)z(E)+\partial_s.\mathscr{B}(s,E)], \tag{7.6}$$

where $s=\|z\|^2$ is the corresponding solution of Eq. (7.4) and $\langle u|v\rangle=\int dE\ g(E)u(E)\overline{v(E)}$. Hence,

$$\overline{\delta\mathscr{V}}(z,E)=\overline{\mathscr{A}}(s,E)\,\overline{\delta z}(E)+(\langle\delta z|z\rangle+\langle\overline{\delta z}|\overline{z}\rangle)[\overline{\partial_s.\mathscr{A}}(s,E)\overline{z(E)}+\overline{\partial_s.\mathscr{B}}(s,E)], \tag{7.7}$$

so with $u(E)=\delta z(E)$ and $v(E)=\overline{\delta z}(E)$, we get the complexification of the linearization,

$$\mathscr{L}\begin{pmatrix}u\\v\end{pmatrix}=\begin{pmatrix}\mathscr{A} & 0\\ 0 & \overline{\mathscr{A}}\end{pmatrix}\begin{pmatrix}u\\v\end{pmatrix}+\begin{pmatrix}(\langle u|z\rangle+\langle v|\overline{z}\rangle)(\partial_s.\mathscr{A}z+\partial_s.\mathscr{B})\\ (\langle u|z\rangle+\langle v|\overline{z}\rangle)(\partial_s.\overline{\mathscr{A}}\overline{z}+\partial_s.\overline{\mathscr{B}})\end{pmatrix}. \tag{7.8}$$

The matrix in the first term of the rhs has a continuous spectrum contained in $-\Gamma(s)/2+i\mathbf{R}$ and the second term appears as a rank one perturbation. If $\lambda\in\mathbf{C}$ is an eigenvalue of $\mathscr{L}$ with a real part different from $-\Gamma(s)/2$, we get

$$[.\mathscr{A}(s,E)-\lambda]u+(\langle u|z\rangle+\langle v|\overline{z}\rangle)[\partial_s.\mathscr{A}(s,E)z+\partial_s.\mathscr{B}(s,E)]=0, \tag{7.9a}$$

$$[.\overline{\mathscr{A}}(s,E)-\lambda]v+(\langle u|z\rangle+\langle v|\overline{z}\rangle)[\overline{\partial_s.\mathscr{A}}(s,E)\overline{z}+\overline{\partial_s.\mathscr{B}}(s,E)]=0. \tag{7.9b}$$

We must then have

$$u(E)=\kappa\,\frac{\partial_s.\mathscr{A}(s,E)z+\partial_s.\mathscr{B}(s,E)}{\mathscr{A}(s,E)-\lambda}, \tag{7.10a}$$

$$v(E)=\kappa\,\frac{\overline{\partial_s.\mathscr{A}}(s,E)\overline{z}+\overline{\partial_s.\mathscr{B}}(s,E)}{\overline{\mathscr{A}}(s,E)-\lambda}, \tag{7.10b}$$

where $\kappa=\langle u|z\rangle+\langle v|\overline{z}\rangle$. In order to have a nontrivial solution $\kappa\neq 0$, it is necessary and sufficient that

$$1+\int dE\ g(E)\ \frac{\partial_s[(\mathscr{A}-\lambda)(\overline{\mathscr{A}}-\lambda)]|.\mathscr{B}|^2-\mathscr{A}(\overline{\mathscr{A}}-\lambda).\overline{\mathscr{B}}\partial_s.\mathscr{B}-\overline{\mathscr{A}}(\mathscr{A}-\lambda).\mathscr{B}\partial_s.\overline{\mathscr{B}}}{[(\mathrm{Re}\,.\mathscr{A}-\lambda)^2+(\mathrm{Im}\,.\mathscr{A})^2]|.\mathscr{A}|^2}=0. \tag{7.11}$$

Here, the lhs is real for real λ, and tends to 1, when $\lambda \to +\infty$.

On the other hand, the s-derivative of the lhs minus the rhs of Eq. (7.4) is

$$1+\int dE\ g(E)\ \frac{|\mathscr{B}(s,E)|^2\partial_s|\mathscr{A}(s,E)|^2-|\mathscr{A}(s,E)|^2\partial_s|\mathscr{B}(s,E)|^2}{|\mathscr{A}(s,E)|^4}, \tag{7.12}$$

which coincides with the lhs of Eq. (7.11) for $\lambda=0$. So if the expression (7.12) is <0, we see that Eq. (7.11) must have a solution $\lambda>0$. Let us say that the fixed point is stable if the spectrum of the linearization $\mathscr{L}$ is contained in the open left half-plane and unstable otherwise. The discussion above then gives the following.

Proposition VII.1: Let z be a fixed point of $\mathscr{V}$ so that Eqs. (7.4) and (7.5) hold. If the s-derivative of the lhs *minus the* rhs *of Eq. (7.4) is <0, then z is an unstable fixed point. More precisely, the linearization $\mathscr{L}$ then has an eigenvalue which is >0.*

VIII. FIXED POINTS AND LINEARIZATIONS: THE SMALL-Γ LIMIT

In this section we assume that the driving term $\mathscr{B}(s,E)$ is a sufficiently smooth function of E, at least near the point $E_R(0)+\eta s$, where s solves Eq. (7.4). When the barriers are very wide, $\Gamma(s)$ will be very small and

$$\frac{1}{|\mathscr{A}(s,E)|^2}=\frac{1}{[\Gamma(s)/2]^2+[E_R(0)+\eta s-E]^2}$$

is a function of E which is sharply peaked at $E_R(s)=E_R(0)+\eta s$. In Eq. (7.4) it is therefore justified to replace $g(E)|\mathscr{B}(s,E)|^2$ by the constant value $g(E_R(0)+\eta s)|\mathscr{B}(s,E_R(0)+\eta s)|^2$. Then Eq. (7.4) is well approximated by

$$s=2\pi\,\frac{g(E_R(s))|\mathscr{B}(s,E_R(s))|^2}{\Gamma(s)}. \tag{8.1}$$

We shall next apply a similar argument to Eq. (7.11) for the eigenvalues of the linearization $\mathscr{L}$ and, for more transparency, we start with a simplified case, in which

$$\mathscr{B} \quad \text{and} \quad \Gamma \quad \text{are independent of} \quad s. \tag{8.2}$$

In this case, Eq. (7.11) reduces to

$$1-2\eta\int dE\ \frac{[E-E_R(0)-\eta s]g(E)|\mathscr{B}(E)|^2}{\{(\Gamma/2+\lambda)^2+[E-E_R(0)-\eta s]^2\}\{(\Gamma/2)^2+[E-E_R(0)-\eta s]^2\}}=0. \tag{8.3}$$

We shall use

$$\int_{-\infty}^{+\infty}dt\ \frac{t^2}{(q^2+t^2)(p^2+t^2)}=\begin{cases}\dfrac{\pi}{p+q}, & \text{Re } p>0, \quad \text{Re } q>0\\[2ex] \dfrac{\pi}{p-q}, & \text{Re } p>0, \quad \text{Re } q<0\end{cases} \tag{8.4}$$

$$\int_{-\infty}^{+\infty}dt\ \frac{1}{(q^2+t^2)(p^2+t^2)}=\begin{cases}\dfrac{\pi}{qp(p+q)}, & \text{Re } p>0, \quad \text{Re } q>0\\[2ex] \dfrac{-\pi}{qp(p-q)}, & \text{Re } p>0, \quad \text{Re } q<0.\end{cases} \tag{8.5}$$

If we replace $g(E)|\mathscr{B}(E)|^2$ in the integral in Eq. (8.3) with its value at $E=E_R(0)+\eta s$, that integral vanishes since the integrand becomes an odd function of $E-E_R(0)-\eta s$. Instead, we get an approximation of the integral in Eq. (8.3) by replacing $g(E)|\mathscr{B}(E)|^2$ with the linear term in its Taylor expansion at $E=E_R(0)+\eta s$. Using Eq. (8.4), we then get from Eq. (8.3)

$$1-2\eta\,\frac{(g|\mathscr{B}|^2)'[E_R(0)+\eta s]\pi}{\Gamma+\lambda}=0 \quad \text{when } \Gamma/2+\mathrm{Re}\,\lambda>0, \tag{8.6}$$

$$1+2\eta\,\frac{(g|\mathscr{B}|^2)'[E_R(0)+\eta s]\pi}{\lambda}=0 \quad \text{when } \Gamma/2+\mathrm{Re}\,\lambda<0, \tag{8.7}$$

where $(g|\mathscr{B}|^2)'=\partial_E(g|\mathscr{B}|^2)$. The solution of Eq. (8.6) is

$$\lambda=2\pi\eta(g|\mathscr{B}|^2)'[E_R(0)+\eta s]-\Gamma, \tag{8.8}$$

and this is an eigenvalue of the linearization $\mathscr{L}$ as long as

$$2\pi\eta(g|\mathscr{B}|^2)'[E_R(0)+\eta s]>\frac{\Gamma}{2}. \tag{8.9}$$

The solution of Eq. (8.7) is

$$\lambda=-2\pi\eta(g|\mathscr{B}|^2)'[E_R(0)+\eta s] \tag{8.10}$$

and describes an eigenvalue of $\mathscr{L}$ precisely when Eq. (8.9) is fulfilled. We then have the following conclusion under the simplifying assumption (8.2) and in the small-Γ limit.

When $2\pi\eta(g|\mathscr{B}|^2)'[E_R(0)+\eta s]\leqslant\Gamma/2$*: no eigenvalues of* $\mathscr{L}$ and hence an attractive fixed point.

When $\Gamma/2<2\pi\eta(g|\mathscr{B}|^2)'[E_R(0)+\eta s]<\Gamma$*: two eigenvalues of* $\mathscr{L}$ and still an attractive fixed point.

When $2\pi\eta(g|\mathscr{B}|^2)'[E_R(0)+\eta s]\geqslant\Gamma$*: two eigenvalues and a nonattractive fixed point.*

The main conclusion under the same assumptions is then the following.

Proposition VIII.1: We have an attractive fixed point precisely when the s-derivative of the difference of the lhs *and the* rhs *in Eq. (8.1) is* >0.

Now we drop the simplifying assumption (8.2) and see that the preceding proposition still holds in the small-Γ limit. Let z be a fixed point, so that $s=\|z\|^2$ (approximately) solves Eq. (8.1). In view of Eq. (7.2), Eq. (7.11) can be written as

$$1+\int dE\; g(E)\,\frac{\partial_s[(\mathscr{A}-\lambda)(\overline{\mathscr{A}}-\lambda)]|\mathscr{B}|^2-\mathscr{A}(\overline{\mathscr{A}}-\lambda)\partial_s\mathscr{B}\overline{\mathscr{B}}-\overline{\mathscr{A}}(\mathscr{A}-\lambda)\mathscr{B}\partial_s\overline{\mathscr{B}}}{\{[\Gamma(s)/2+\lambda]^2+[E-E_R(0)-\eta s]^2\}\{[\Gamma(s)/2]^2+[E-E_R(0)-\eta s]^2\}}=0. \tag{8.11}$$

Here, the numerator of the integrand can be simplified to

$$\begin{aligned}&[\partial_s\Gamma(\Gamma/2+\lambda)|\mathscr{B}|^2-(\Gamma/2)(\Gamma/2+\lambda)\partial_s|\mathscr{B}|^2]+\{[E-E_R(0)-\eta s][-2\eta|\mathscr{B}|^2\\&\quad+i\lambda(\partial_s\mathscr{B}\overline{\mathscr{B}}-\mathscr{B}\partial_s\overline{\mathscr{B}})]\}-\{[E-E_R(0)-\eta s]^2\partial_s|\mathscr{B}|^2\}.\end{aligned} \tag{8.12}$$

Accordingly, we split the integral into three pieces and apply the small-Γ approximation to each one. If we assume, for simplicity, that $\Gamma/2+\mathrm{Re}\,\lambda>0$ (which is necessarily the case if the eigenvalue λ is to ruin attractiveness), we get

$$1+\frac{[\partial_s\Gamma(\Gamma/2+\lambda)|.\mathscr{B}|^2-(\Gamma/2)(\Gamma/2+\lambda)\partial_s|.\mathscr{B}|^2]\pi g}{(\Gamma/2)(\Gamma/2+\lambda)(\Gamma+\lambda)}$$
$$+\frac{(\partial_E\{g[-2\eta|.\mathscr{B}|^2+i\lambda(\partial_s.\mathscr{B}.\overline{\mathscr{B}}-.\mathscr{B}\partial_s.\overline{\mathscr{B}})]\}-g\partial_s|.\mathscr{B}|^2)\pi}{\Gamma+\lambda}=0 \tag{8.13}$$

at $E=E_R(0)+\eta s$. This can be rewritten as

$$1+\frac{2\pi(\partial_s\Gamma/\Gamma)g|.\mathscr{B}|^2}{\Gamma+\lambda}-\frac{2\pi\partial_s(g|.\mathscr{B}|^2)}{\Gamma+\lambda}-\frac{2\pi\eta\partial_E(g|.\mathscr{B}|^2)}{\Gamma+\lambda}+\frac{i\lambda\pi\partial_E[g(\partial_s.\mathscr{B}.\overline{\mathscr{B}}-.\mathscr{B}\partial_s.\overline{\mathscr{B}})]}{\Gamma+\lambda}=0, \tag{8.14}$$

again at $E=E_R(0)+\eta s$. Noticing that

$$\frac{d}{ds}[(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)]=(\eta\partial_E+\partial_s)(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s),$$

and multiplying with $\Gamma+\lambda$, we get the following approximation of Eq. (7.11)

$$\lambda\{1+i\pi\partial_E[g(\partial_s.\mathscr{B}.\overline{\mathscr{B}}-.\mathscr{B}\partial_s.\overline{\mathscr{B}})]\}=-\Gamma(s)-2\pi\frac{(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)}{\Gamma(s)}\partial_s\Gamma(s)$$
$$+2\pi\frac{d}{ds}[(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)]. \tag{8.15}$$

We assume that $1+i\pi\partial_E[g(\partial_s.\mathscr{B}.\overline{\mathscr{B}}-.\mathscr{B}\partial_s.\overline{\mathscr{B}})]>0$, so that the solution λ of Eq. (8.15) is real and has the same sign as the rhs of Eq. (8.15).

On the other hand, the s-derivative of the lhs minus the rhs of Eq. (8.1) is

$$1-\frac{2\pi}{\Gamma(s)}\frac{d}{ds}[(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)]+2\pi(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)\frac{\partial_s\Gamma(s)}{\Gamma(s)^2}$$
$$=-\frac{1}{\Gamma(s)}\left(-\Gamma(s)+2\pi\frac{d}{ds}[(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)]\right.$$
$$\left.-2\pi\frac{(g|.\mathscr{B}|^2)(s,E_R(0)+\eta s)}{\Gamma(s)}\partial_s\Gamma(s)\right),$$

which is of the opposite sign to the rhs in Eq. (8.15). We then have the following.

Proposition VIII.2: Under the weaker assumptions above and in the small-Γ *limit, we still have an attractive fixed point precisely when the s-derivative of the* lhs *minus the* rhs *of Eq. (8.1) is* >0.

IX. A SIMPLIFIED DIFFERENTIAL EQUATION FOR THE SHEET DENSITY

Consider the differential equation (6.3)

$$\partial_t z(t,E)=(-\Gamma(s(t))/2+i\{E-[E_R(0)+\eta s(t)]\})z(t,E)+\mathscr{B}(s(t),E), \tag{9.1}$$

where $s(t)=\|z(t,\cdot)\|^2$, and where we could also let $\mathscr{B}$ be a slowly varying function of t through $s(t)$. Assuming $s(t)$ to be a known function, the solution of Eq. (9.1) with a prescribed initial value at time t_0 is

$$z(t,E)=\int_{t_0}^{t}dt'\ \exp\left(i[E-E_R(0)](t-t')-\int_{t'}^{t}dt''\Gamma(s(t''))/2-i\eta\int_{t'}^{t}dt''s(t'')\right).\mathscr{B}(s(t'),E)$$
$$+\exp\left(i[E-E_R(0)](t-t_0)-\int_{t_0}^{t}dt'\Gamma(s(t'))/2-i\eta\int_{t_0}^{t}dt's(t')\right)z(t_0,E).$$

Assuming that the solution has existed as a bounded solution for a very long time, say from the time $-\infty$, we can let t_0 tend to $-\infty$ in the formula above and get

$$z(t,E)=\int_{-\infty}^{t}dt'\ \exp\left(i[E-E_R(0)](t-t')-\int_{t'}^{t}dt''\Gamma(s(t''))/2-i\eta\int_{t'}^{t}dt''s(t'')\right).\mathscr{B}(s(t'),E). \tag{9.2}$$

Taking the scalar product of Eq. (9.1) and z gives the following equation for the derivative of the sheet density

$$\frac{d}{dt}s(t)=2\ \mathrm{Re}\langle z|\partial_t z\rangle=-\Gamma(s(t))s(t)+2\ \mathrm{Re}\langle z|.\mathscr{B}\rangle, \tag{9.3}$$

where

$$2\ \mathrm{Re}\langle z|.\mathscr{B}\rangle=2\ \mathrm{Re}\int dE\ g(E)\int_{-\infty}^{t}dt'\ \exp\left(i[E-E_R(0)](t-t')-\int_{t'}^{t}dt''\Gamma(s(t''))/2\right.$$
$$\left.-i\eta\int_{t'}^{t}dt''s(t'')\right).\mathscr{B}(s(t'),E).\overline{\mathscr{B}(s(t),E)}. \tag{9.4}$$

We now assume that $s(t)$ varies slowly with t and replace $\mathscr{B}(s(t'),E)$ in the above integral by $\mathscr{B}(s(t),E)$. Making the E-integration first, we get

$$2\ \mathrm{Re}\langle z|.\mathscr{B}\rangle=2\ \mathrm{Re}\int_{-\infty}^{t}dt'\ \exp\left(-iE_R(0)(t-t')-\int_{t'}^{t}dt''\Gamma(s(t''))/2-i\eta\int_{t'}^{t}dt''s(t'')\right)$$
$$\times\mathscr{F}(g|.\mathscr{B}|^2)(s(t),t'-t), \tag{9.5}$$

where $\mathscr{F}$ denotes the Fourier transform with respect to E. Assuming that $g(E)|.\mathscr{B}(s(t),E)|^2$ is sufficiently smooth as a function of E, we see that $\mathscr{F}(g|.\mathscr{B}|^2)(s(t),t'-t)$ is sufficiently rapidly decreasing as a function of $t'-t$ for the following approximations to be made: (i) since $\Gamma(s)$ is small, we may assume that $\exp\{-\int_{t'}^{t}dt''\Gamma(t'')/2\}\simeq 1$ and (ii) since $s(t'')$ varies slowly, we may replace $\int_{t'}^{t}dt''s(t'')$ by $s(t)(t-t')$. We then get

$$2\ \mathrm{Re}\langle z|.\mathscr{B}\rangle\simeq 2\ \mathrm{Re}\int_{-\infty}^{t}dt'e^{-i[E_R(0)+\eta s(t)](t-t')}\mathscr{F}(g|.\mathscr{B}|^2)(s(t),t'-t)$$
$$=2\ \mathrm{Re}\int_{-\infty}^{0}dt'e^{i[E_R(0)+\eta s(t)]t'}\mathscr{F}(g|.\mathscr{B}|^2)(s(t),t').$$

Using the property $\mathscr{F}(u)(-t)=\overline{\mathscr{F}(u)(t)}$, valid for any real valued function $u(E)$, we obtain

$$2\ \mathrm{Re}\langle s|.\mathscr{B}\rangle=\int_{-\infty}^{+\infty}dt'e^{i[E_R(0)+\eta s(t)]t'}.\mathscr{F}(g|.\mathscr{B}|^2)(s(t),t')=2\pi(g|.\mathscr{B}|^2)(s(t),E_R(0)+\eta s(t)). \tag{9.6}$$

Inserting this in Eq. (9.3), we get the approximate differential equation for the sheet density $s(t)=\|z(t,\cdot)\|^2$

$$\frac{d}{dt}\,s(t)=-\Gamma(s(t))\left[s(t)-2\pi\,\frac{(g|\mathscr{B}|^2)(s(t),E_R(0)+\eta s(t))}{\Gamma(s(t))}\right]. \tag{9.7}$$

This equation is valid for slowly varying solutions which have evolved for a time much longer than Γ^{-1}.

X. QUALITATIVE DISCUSSION AND NUMERICAL RESULTS

We start by examining the simplified fixed-point equation (8.1). For $0\leqslant E\lesssim E_F$ with $E_F\ll V_0$, we have $V_0-E\sim V_0$ (of the same order of magnitude). By evaluating the integral in Eq. (6.4) with $e(s,x)$ approximated by Eq. (5.2) and the driving term given by Eq. (4.7), we have

$$|\mathscr{B}(s,E)|^2\sim(C_0^w)^2V_0^{-1}E_0^wE^{1/2}e^{\{(V_0-E)^{3/2}-[V_0+\alpha(b-a)-E]^{3/2}\}4/3\alpha}.$$

Assuming for simplicity zero temperature, so that $g(E)=\theta(E)(E_F-E)_+/2\pi$, we get

$$g(E_R(s))|\mathscr{B}(s,E_R(s))|^2\sim(C_0^w)^2V_0^{-1}E_0^wE_R(s)_+^{1/2}[E_F-E_R(s)]_+ \times e^{\{[V_0-E_R(s)]^{3/2}-[V_0-E_R(s)+\alpha(b-a)]^{3/2}\}4/3\alpha}.$$

Recalling that $E_R(s)=E_R(0)+\eta s=E_0^b+\alpha(b-a)=E_0^b-\beta(d-c)-\Delta V$, where α and β are given by Eqs. (4.3) and (5.6), respectively, from Eq. (5.24) we get

$$\Gamma(s)\sim(C_0^w)^2E_0^bV_0^{-3/2}\{[V_0-E_R(s)]^{1/2}E_R(s)_+^{1/2}e^{\{[V_0-E_R(s)]^{3/2}-[V_0-E_R(s)+\alpha(b-a)]^{3/2}\}4/3\alpha} +[V_0-\Delta V-E_R(s)]^{1/2}[E_R(s)+\Delta V]^{1/2}e^{\{[V_0-\Delta V-E_R(s)-\beta(d-c)]^{3/2}-[V_0-\Delta V-E_R(s)]^{3/2}\}4/3\beta}\}.$$

We will consider the following two cases:

(1) The barrier $[c,d]$ is more opaque than $[a,b]$ in the sense that the exponential factor in the second term of the above expression for $\Gamma(s)$ is much smaller than the exponential factor in the first term.

(2) The barrier $[a,b]$ is more opaque than $[c,d]$.

In the intermediate case when the two barriers have opacity of the same order, the discussion of case (1) will roughly apply. Notice that opacity depends not only on the relative sizes of $b-a$ and $d-c$, but also on s and ΔV. Therefore, we may have transitions between the two cases when these parameters vary. Interesting phenomena appear when case (1) is possible and we start with that case, recalling that $E_R(s)=E_R(0)+\eta s=E_0^w-\Delta V(b-a)/l+\eta s$. In this case [and neglecting, to start with, the possibility of a transition to the case (2)] the first term in the expression for $\Gamma(s)$ dominates, except when $E_R(s)$ is negative or very small and positive. The function

$$f(s)=2\pi\,\frac{g(E_R(s))|\mathscr{B}(s,E_R(s))|^2}{\Gamma(s)} \tag{10.1}$$

vanishes for $E_R(s)\leqslant 0$ and rises very sharply [with a square root singularity at $E_R(s)=0$] from 0 to

$$f_{\max}\sim E_F \tag{10.2}$$

when $E_R(s)$ is increased from 0 to a small positive value. When $E_R(s)$ is further increased, the function $f(s)$ decreases roughly linearly and vanishes for $E_R(s)\geqslant E_F$. The values $E_R(s)=0$, $E_R(s)=E_F$ correspond to

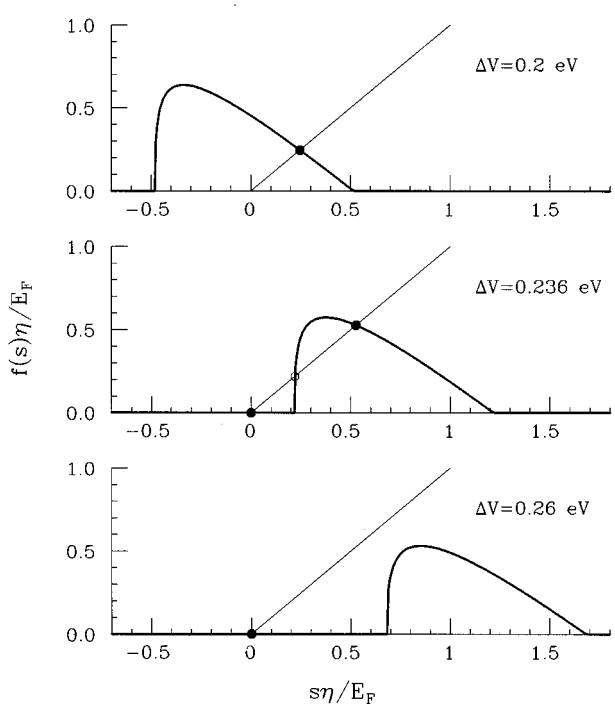

FIG. 2. Graphical solution of the equation $s=f(s)$ for different values of the bias energy ΔV. Note that the support of $f(s)$ has width $\Delta s \simeq E_F/\eta$ (equality strictly holds at zero temperature). The example shown here corresponds to a typical GaAs–AlGaAs heterostructure in which the parameters described in the text have the following values: $n_D=2\times10^{17}$ cm^{-3}, $T=1$ K, $b-a=40$ Å, $c-b=56$ Å, $d-c=70$ Å, $V_0=0.34$ eV, $\epsilon=11.44$, and $m^*=0.067m$, where m is the free electron mass.

$$s=[\Delta V(b-a)/l-E_0^w]/\eta, \quad s=[\Delta V(b-a)/l-E_0^w+E_F]/\eta, \tag{10.3}$$

and describe the boundary points of the support of the function (10.1). When ΔV is increased, these two points move to the right with the same speed as shown in the example of Fig. 2. In Fig. 2 we also see the graphical solution of Eq. (8.1), $s=f(s)$, for different values of ΔV. It is clear that Eq. (8.1) will first have only one solution when $\Delta V(b-a)/l-E_0^w \leqslant 0$, then three solutions for ΔV in some interval, until $\Delta V(b-a)/l-E_0^w \sim \eta f_{\max}$, and again only one solution for even larger values of ΔV. According to the results of Sec. VIII, we see that in the case in which Eq. (8.1) has only one solution, this solution corresponds to an attractive fixed point, and when there are three solutions, the smallest and the largest of these correspond to attractive fixed points, while the intermediate solution corresponds to an unstable fixed point.

For many experimentally relevant situations the resonance width is much smaller than the other energy scales (essentially E_F). In this case we may expect the simplified fixed-point equation (8.1) to be a very good approximation of the more correct equation (7.4), except near the boundary points of the support of the function (10.1). This is confirmed by Fig. 3 where we show the numerical solutions (stable and unstable) of both Eqs. (7.4) and (8.1) for a system having $\Gamma(0)/E_F \simeq 0.01$ at $\Delta V=0.2$ eV. In the case of Eq. (7.4), the corresponding energy integral has been evaluated on a uniform energy mesh having a density of points $\gg \Gamma(0)^{-1}$.

The solutions of the simplified differential equation (9.7) converge to one of the solutions of Eq. (8.1), associated with an attractive fixed point. The phenomenon of hysteresis then becomes clear. We let ΔV increase very slowly from some sufficiently small value up to some sufficiently large positive value and subsequently decrease it very slowly, back to its initial value. Consider a

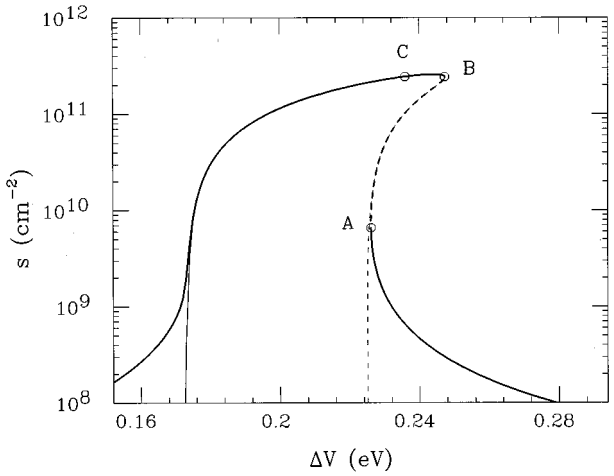

FIG. 3. Fixed point solutions of the sheet density of electrons in the well s as a function of the bias energy ΔV in the same case of Fig. 2. The thick line is the exact case (7.4) and the thin line the small-Γ approximation (8.1). Unstable solutions are represented by dashed lines (both thick and thin).

corresponding solution of the time-dependent Schrödinger equation (2.3) so that we expect the corresponding evolution of the sheet density to be well approximated by the solution of Eq. (9.7), where $\mathscr{B}$ varies slowly with time. First, there is only one (attractive) fixed point and the time-dependent solution has to stay close to that fixed point. Then we have creation of a pair of fixed points (one stable and one unstable) away from the solution, but the solution continues to stay close to the old (stable) fixed point. When ΔV reaches a sufficiently large value, the unstable fixed point runs into the old stable one and they both disappear. At this point, the time-dependent solution has no other choice than to converge to the only remaining fixed point (which is stable). When decreasing ΔV back to its initial value, we have the same behavior, in the sense that the solution stays close to the initially unique fixed point as long as it exists and converges to the new unique fixed point after the old one has collapsed with the unstable one. The bias energy ΔV at which this collapse happens depends on the value of the time-dependent solution and therefore is different when ΔV is increased or decreased.

The phenomenon of hysteresis is clearly seen in Fig. 3, where the collapse points for ΔV decreased from large values and ΔV increased from small values have been marked with A and B, respectively. We have $\Delta V_A < \Delta V_B$. We can estimate the order of magnitude of the hysteresis width $\Delta V_B - \Delta V_A$ by considering that ΔV_A is determined by the condition $E_R(s=0)=0$ and ΔV_B by the condition $E_R(s \simeq f_{\max}) \simeq 0$. We have

$$\Delta V_B - \Delta V_A \sim \eta f_{\max} l (b-a)^{-1} \sim a_B^{-1} E_F (d-c). \tag{10.4}$$

In Figs. 4 and 5 we show the time-dependent evolution of the sheet density $s(t)$ when we start from a fixed point solution corresponding to the point A or B and give an instantaneous small decrement or increment δV to ΔV_A or ΔV_B, respectively. In these figures, the thick lines are the solutions of the full equations (6.3) and (6.5) and the thin lines the solution of the simplified differential equation (9.7). In Fig. 4 the solutions corresponding to the small-Γ limit and the full Schrödinger equation start, as shown in Fig. 3, from different fixed point values, $s(0)$, and converge to the same (approximatively) values. On the other hand, when the starting point is B (Fig. 5) the small-Γ approximation is close to the solution of the full equation except for the value which $s(t)$ has to converge to, again in agreement with Fig. 3.

As a third example of time evolution of the sheet density of electrons in the well, in Fig. 6 we show the behavior of the $s(t)$ solution of the full equations (6.3) and (6.5) after an instantaneous

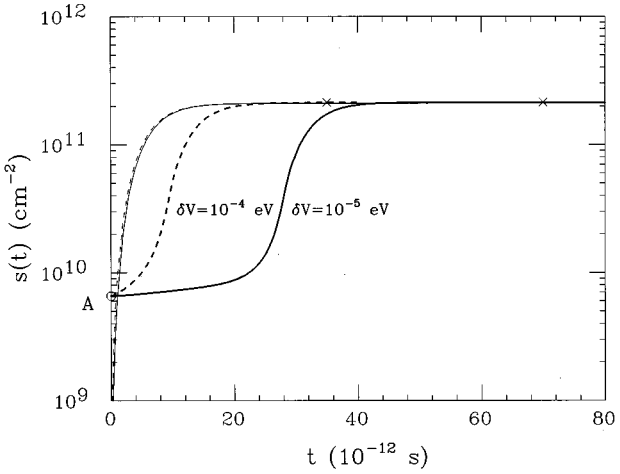

FIG. 4. Sheet density of electrons in the well $s(t)$ as a function of time after an instantaneous decrease δV of the bias energy from the point A of Fig. 3 (thick lines). The crosses are the fixed point solutions at bias $\Delta V_A - \delta V$ where $s(t)$ is expected to converge. The thin lines are the corresponding small-Γ approximation starting from $s(0)=0$.

change δV of the bias energy corresponding to the point C of Fig. 3 well inside the hysteresis region. If $|\delta V|$ is chosen sufficiently large, we observe oscillations of $s(t)$ on the picosecond time scale. Contrary to the claim of Ref. 14, these oscillations are damped since $s(t)$ has to converge to the fixed point solution corresponding the bias energy $\Delta V_C + \delta V$.

In case (2), when the barrier $[a,b]$ is more opaque than the barrier $[c,d]$, the function (10.1) is very small, and for solutions of Eq. (8.1) we can observe only a microscopical hysteresis effect, due to the square root singularity at $E_R(s)=0$, which is likely to be completely absent in the more correct equation (7.4). The absence of the hysteresis effect in this case is in agreement with the experimental results of Ref. 18 and is discussed in Ref. 16.

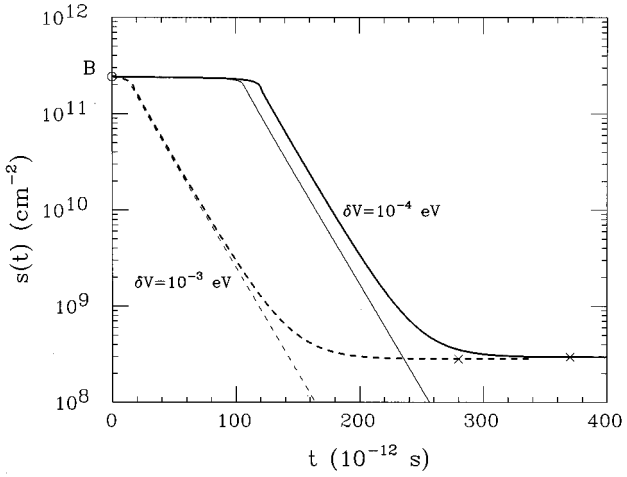

FIG. 5. Sheet density of electrons in the well $s(t)$ as a function of time after an instantaneous increase δV of the bias energy from the point B of Fig. 3 (thick lines). The crosses are the fixed point solutions at bias $\Delta V_B + \delta V$ where $s(t)$ is expected to converge. The thin lines are the corresponding small-Γ approximation. For δV not too large a ghost fixed-point solution is observed with $s(t)$ decaying linearly for $t \leq t_g$ and t_g defined by the condition $E_R(s(t_g))=0$.

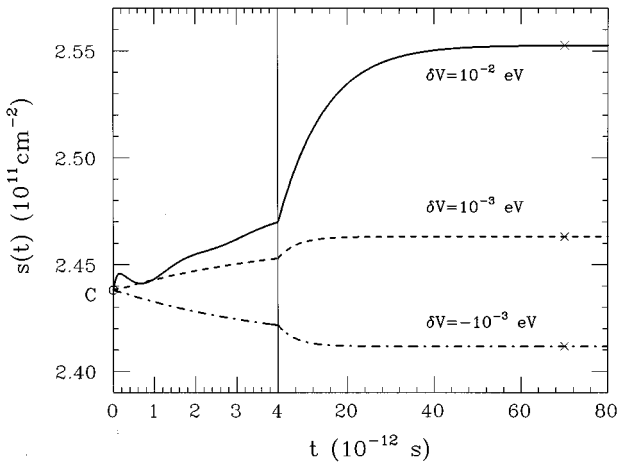

FIG. 6. Sheet density of electrons in the well $s(t)$ as a function of time after an instantaneous change δV of the bias energy from the point C of Fig. 3. The crosses are the fixed-point solutions at bias $\Delta V_C+\delta V$ where $s(t)$ is expected to converge. For $|\delta V|$ not too small damped oscillations are seen at the picosecond scale.

Let us finally consider the case of very wide barriers and see that a transition between cases (1) and (2) has to take place in the hysteresis region. Let $c-b=$const, $(b-a)/(d-c)$ $=$const<1, and $b-a\to\infty$. In this limit, $\eta\sim a_B^{-1}(b-a)$, and the values in Eq. (10.3) are the end points of a short interval of length $\sim E_F a_B/(b-a)$. Let us consider Eq. (8.1) when ΔV is increased from the initial value $(E_0^w-E_F)l/(b-a)$ for which the right end point in Eq. (10.3) is 0. If the constant $(b-a)/(d-c)$ is sufficiently small, we are in case (1). For $(E_0^w-E_F)l/(b-a)\leqslant\Delta V\leqslant E_0^w l/(b-a)$, we remain in case (1), provided that $(b-a)/(d-c)$ is sufficiently small, and Eq. (8.1) has a unique solution. At $\Delta V=E_0^w l/(b-a)$ we have the creation of two new fixed points. If we follow the old fixed point, we cannot remain in case (1) until it disappears. Indeed, if we did, the disappearance would take place when $s\sim f_{\max}$ and at a bias energy $\Delta V\sim a_B^{-1}(d-c)f_{\max}$ obtained by the condition $E_R(s\simeq f_{\max})\simeq 0$. Since $E_R(s)=E_0^b+\alpha(b-a)$ is between 0 and E_F, the inclination α of the first barrier would have to be very small, and we get a finite inclination $\beta\sim -a_B^{-1}f_{\max}$ for the barrier $[c,d]$. Therefore, when $b-a\to\infty$ only the opacity of the first barrier would diverge and, at some point, we would be no longer in case (1). What will actually happen is that when ΔV reaches some value which is bounded independently of $b-a$, we have a transition from case (1) to case (2), and $f_{\max}$ decreases to some value which is much smaller than the rhs in Eq. (10.2). This will cause the disappearance of the fixed point for a much smaller value of s. When a transition from case (1) to case (2) happens, we still observe a hysteresis phenomenon, but this is now caused not only by the *translation* of $f(s)$ as a function of ΔV but also by a *variation* of its height. This effect is already apparent in Fig. 3 where we see a decreasing height of $f(s)$ when increasing ΔV.

XI. THE CASE OF SEVERAL RESONANCES

In this section we discuss very briefly the case with several shape resonances. Much of the discussion is similar to the case of one resonance and we shall assume that we are in a parameter range where all the WKB considerations apply.

First we review the approximation for the shape resonances. We start with the potential V_w and consider its eigenstates $e_j^w(x)$, $j=0,1,\ldots,N-1$ and the corresponding eigenvalues $0<E_0^w<E_1^w<\cdots<E_{N-1}^w<V_0$. Since $e_j^w(x)$ is even as a function of $x-(b+c)/2$ for even j and odd for odd j, we have

$$e_j^w(x)=C_j^w\times\begin{cases}\sin[(j+1)\pi/2-\sqrt{E_j^w}(c-b)/2]e^{-(V_0-E_j^w)^{1/2}(b-x)}, & x<b\\ \sin\{(j+1)\pi/2+\sqrt{E_j^w}[x-(b+c)/2]\}, & b<x<c\\ \sin[(j+1)\pi/2+\sqrt{E_j^w}(c-b)/2]e^{-(V_0-E_j^w)^{1/2}(x-c)}, & x>c.\end{cases}$$

The C^1 condition at $x=b$, or equivalently at $x=c$, gives the quantization condition

$$\tan[(j+1)\pi/2+\sqrt{E_j^w}(c-b)/2]=-(V_0/E_j^w-1)^{-1/2},$$

which can also be written as

$$\tan[\sqrt{E_j^w}(c-b)/2-j\pi/2]=(V_0/E_j^w-1)^{1/2}. \tag{11.1}$$

Representing this equation graphically, we see that $N-1$ is the largest integer $\geqslant 1$ with $\sqrt{V_0}(c-b)/2>(N-1)\pi/2$. The functions $e_j^w(x)$ are normalized, if we choose

$$C_j^w=\left(\frac{E_j^w}{V_0(V_0-E_j^w)^{1/2}}+\frac{(c-b)}{2}+\frac{(V_0-E_j^w)^{1/2}}{V_0}\right)^{-1/2}. \tag{11.2}$$

The eigenvalues E_j^b associated with the potential V_b in Eq. (5.5) can be studied as before, and we get

$$E_j^b=E_j^w-8\pi a_B^{-1}s\,\frac{(C_j^w)^2E_j^w}{4V_0(V_0-E_j^w)}+\mathcal{O}(\alpha^2+\beta^2). \tag{11.3}$$

In the following, we neglect the error $\mathcal{O}(\alpha^2+\beta^2)$. The shape resonances $\lambda_j(s)=E_{R,j}(s)-i\Gamma_j(s)/2$ for the potential $V+W$ are then given by

$$E_{R,j}(s)=E_{R,j}(0)+\eta_j s, \tag{11.4}$$

where

$$E_{R,j}(0)=E_j^w-\Delta V(b-a)/l,\qquad \eta_j=\frac{8\pi a_B^{-1}(b-a)(d-c)}{b-a+d-c}-\frac{8\pi a_B^{-1}(C_j^w)^2E_j^w}{4V_0(V_0-E_j^w)}, \tag{11.5}$$

and

$$\begin{aligned}\Gamma_j(s)=8(C_j^w)^2E_j^b(V_0-E_j^b)^{1/2}V_0^{-2}\{&[V_0+\beta(d-c)-E_j^b]^{1/2}[E_j^b-\beta(d-c)]^{1/2}\\ &\times e^{\{(V_0-E_j^b)^{3/2}-[V_0+\beta(d-c)-E_j^b]^{3/2}\}4/3\beta}+[V_0-\alpha(b-a)-E_j^b]^{1/2}\\ &\times[E_j^b+\alpha(b-a)]_+^{1/2}e^{\{[V_0-\alpha(b-a)-E_j^b]^{3/2}-(V_0-E_j^b)^{3/2}\}4/3\alpha}\}.\end{aligned} \tag{11.6}$$

The corresponding resonant state $e_j(s,x)$, satisfying Eq. (6.2), can be described as in Sec. V.

We still try to solve Eq. (2.11) in two steps. Equation (2.12) is treated as before, while Eq. (2.13) is now handled by letting $\tilde{\nu}$ be a linear combination of the N resonant states $e_0(s,x),\ldots,e_{N-1}(s,x)$. More precisely, we write $\tilde{\nu}(x,t,E)=\exp(-iEt)\nu(x,t,E)$ and $\tilde{\mu}(x,t,E)=\exp(-iEt)\mu(x,t,E)$, so that Eq. (2.13) becomes

$$[-i\partial_t-\partial_x^2+V(x)+W(s,x)-E]\nu(x,t,E)=V_0 1_{[b,c]}(x)\mu(x,t,E). \tag{11.7}$$

Assume,

$$\nu(x,t,E)=\sum_{k=0}^{N-1} z_k(t,E)e_k(s,x), \tag{11.8}$$

where s is defined in Eq. (2.7) and hence will be time dependent. The functions $e_0(s,x),\ldots,e_{N-1}(s,x)$ approximately form an orthonormal family in $L^2([(a+b)/2,(c+d)/2])$, and if we assume that ν dominates over μ in $[(a+b)/2,(c+d)/2]$ then, with a small error, we have

$$s(t)=\sum_{k=0}^{N-1} \|z_k(t,\cdot)\|^2=\|z(t,\cdot)\|^2, \tag{11.9}$$

where the norms are in $L^2(g(E)dE)$ and in $L^2(g(E)dE)^N$, respectively.

Substituting Eq. (11.8) into Eq. (11.7), multiplying by $e_j(s,x)$, and integrating over the contour γ, we get

$$\sum_{k=0}^{N-1} \int_\gamma dx[-i\partial_t+\lambda_k(s)-E][z_k(t,E)e_k(s,x)]e_j(s,x)=V_0\int_b^c dx\ \mu(x,t,E)e_j(s,x). \tag{11.10}$$

From the relations $\int_\gamma dx\ e_k(s,x)e_j(s,x)=\delta_{k,j}$, we conclude that $\int_\gamma dx[\partial_s e_k(s,x)]e_j(s,x)$ is an antisymmetric matrix, and since $e_k(s,x)$ are approximately real functions near $[b,c]$, this matrix is also very close to a real one. Equation (11.10) can be written as

$$[-i\partial_t+\lambda_j(s)-E]z_j(t,E)-i\partial_t(s(t))\sum_{k=0}^{N-1}\int_\gamma dx[\partial_s e_k(s,x)]e_j(s,x)$$
$$=V_0\int_b^c dx\ \mu(x,t,E)e_j(s,x). \tag{11.11}$$

Due to the facts that (i) $\partial_t s(t)$ can be expected to be very small and (ii) $e_k(s,x)$ is roughly independent of s near $[b,c]$ so that the integral $\int_\gamma dx[\partial_s e_k(s,x)]e_j(s,x)$ can be expected to be very small, we will neglect the sum in the lhs of Eq. (11.11). In this case, we have

$$\partial_t z_j(t,E)=\{-\Gamma_j(s)/2+i[E-E_{R,j}(s)]\}z_j(t,E)+\mathscr{B}_j(t,s,E), \tag{11.12}$$

where $\mathscr{B}_j(t,s,E)=iV_0\int_b^c dx\ \mu(x,t,E)e_j(s,x)$.

We assume that $\mathscr{B}_j$ vary slowly with t, so it is meaningful to look at instantaneous fixed points of the vector field defined by the rhs of Eq. (11.12) in $L^2(g(E)dE)^N$. Assuming, for simplicity, that $\mathscr{B}_j$ are independent of t we see that $z(E)=(z_0(E),\ldots,z_{N-1}(E))$ is a fixed point precisely when

$$z_j(E)=\frac{-\mathscr{B}_j(s,E)}{-\Gamma_j(s)/2+i[E-E_{R,j}(s)]},\quad j=0,\ldots,N-1 \tag{11.13}$$

from which we get the compatibility condition for $s=\|z\|^2$:

$$s-\sum_{j=0}^{N-1}\int dE\ \frac{g(E)|\mathscr{B}_j(s,E)|^2}{[\Gamma_j(s)/2]^2+[E-E_{R,j}(s)]^2}=0. \tag{11.14}$$

Conversely, if s is a solution of Eq. (11.14), then Eq. (11.13) defines the unique fixed point with $\|z\|^2=s$.

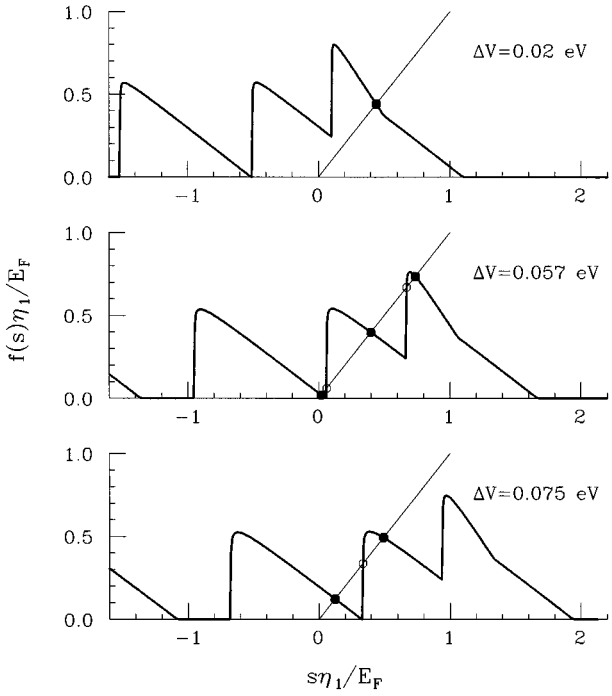

FIG. 7. Graphical solution of the equation $s=f(s)$ for different values of the bias energy ΔV in a multiple-resonance case. We used the same parameters of Fig. 2 except $b-a=20$ Å, $c-b=360$ Å, $d-c=50$ Å.

In the small-Γ limit, as in Sec. VIII we get the simplified fixed-point equation

$$s-\sum_{j=0}^{N-1} 2\pi \frac{(g|\mathscr{B}_j|^2)(s,E_{R,j}(s))}{\Gamma_j(s)}=0. \tag{11.15}$$

In view of Eq. (11.4), the term of index j in Eq. (11.15) is a function of s with support in the interval

$$[\Delta V(b-a)/l-E_j^{\mathrm{w}}]/\eta_j \leqslant s \leqslant [\Delta V(b-a)/l-E_j^{\mathrm{w}}+E_F]/\eta_j\,, \tag{11.16}$$

and when ΔV increases this interval moves to the right with speed $(b-a)/(l\eta_j)$ as shown in the example of Fig. 7.

In Fig. 8 we compare the corresponding fixed point solutions obtained by solving Eq. (11.14) with those obtained in the small-Γ limit (11.15) as a function of the bias energy ΔV. Between the points marked as A and B we observe five fixed points. Below we give some results about the nature of fixed points, which are more complicated than those in the case of a single resonance, and it is not clear that those results are applicable in the situation of Fig. 8. If we assume that they are applicable, then three fixed points are stable and two unstable. The existence of more than three fixed points, i.e., the maximum number allowed for $N=1$, is related to the possibility that the intervals (11.16) are not disjoint, as clearly understood by Fig. 7.

It is interesting to study the evolution of the sheet density $s(t)$ away from a point like B in Fig. 8 where a (presumably) stable fixed point and an unstable one collapse while two other fixed points survive. In Fig. 9 we show the behavior of $s(t)$ obtained by numerically integrating Eq. (11.12) after an instantaneous increase ΔV of the initial bias ΔV_B. If the total bias $\Delta V_B+\delta V<\Delta V_C$, where C is the next point where a new couple of fixed points collapse, $s(t)$

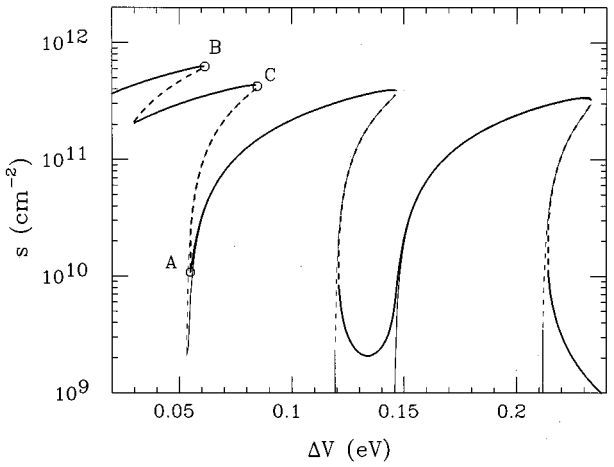

FIG. 8. Fixed-point solutions of the sheet density of electrons in the well s as a function of the bias energy ΔV in the same case of Fig. 7. The thick line is the solution of Eq. (11.14) and the thin line the small-Γ limit (11.15). Possibly unstable solutions are represented by dashed lines (both thick and thin).

converges to the fixed point closest to its initial value $s(0)$. When $\Delta V_B+\delta V>\Delta V_C$, $s(t)$ first approaches the value corresponding to the collapse point C but finally has to converge to the lower unique fixed point corresponding to the chosen bias.

Next we study the linearization of the vector field defined by the rhs of Eq. (11.12) at a fixed point under the following simplifying assumption:

$$\begin{gathered}\Gamma_j \text{ is independent of } s, \quad \mathscr{B}_j=\mathscr{B}_j(E) \text{ is independent of } t \text{ and } s,\\ \eta_j=\eta \text{ is independent of } j.\end{gathered} \tag{11.17}$$

Then Eq. (11.12) becomes,

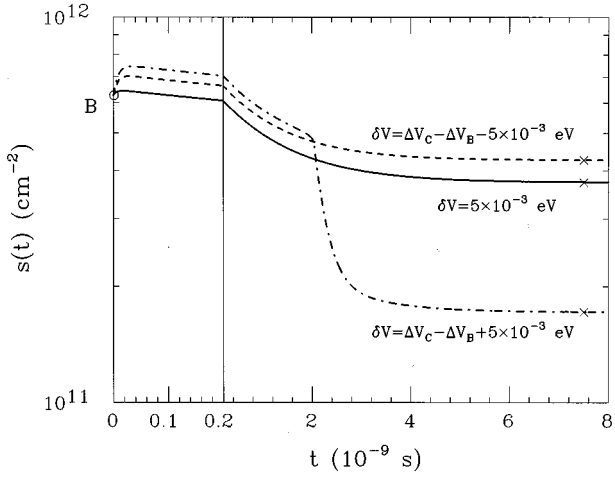

FIG. 9. Sheet density of electrons in the well $s(t)$ as a function of time after an instantaneous increase δV of the bias energy from the point B of Fig. 8. The crosses are the fixed-point solutions at bias $\Delta V_B+\delta V$ where $s(t)$ is expected to converge.

$$\partial_t z_j(t,E)=[-\Gamma_j/2+i[E-E_{R,j}(0)-\eta s]]z_j(t,E)+\mathscr{B}_j(E). \tag{11.18}$$

The same calculations as in Sec. VIII show that the complexification $\mathscr{L}$ of the linearization of the vector field defined by the rhs of Eq. (11.18) at a fixed point is given by

$$\mathscr{L}\begin{pmatrix} u_0 \\ \vdots \\ u_{N-1} \\ v_0 \\ \vdots \\ v_{N-1} \end{pmatrix} = \begin{pmatrix} \{-\Gamma_0/2+i[E-E_{R,0}(0)-\eta s]\}u_0 - i\,\eta(\langle u|z\rangle+\langle v|\overline{z}\rangle)z_0 \\ \vdots \\ \{-\Gamma_{N-1}/2+i[E-E_{R,N-1}(0)-\eta s]\}u_{N-1} - i\,\eta(\langle u|z\rangle+\langle v|\overline{z}\rangle)z_{N-1} \\ \{-\Gamma_0/2-i[E-E_{R,0}(0)-\eta s]\}v_0 + i\,\eta(\langle u|z\rangle+\langle v|\overline{z}\rangle)\overline{z_0} \\ \vdots \\ \{-\Gamma_{N-1}/2-i[E-E_{R,N-1}(0)-\eta s]\}v_{N-1} + i\,\eta(\langle u|z\rangle+\langle v|\overline{z}\rangle)\overline{z_{N-1}} \end{pmatrix}. \tag{11.19}$$

Here, $\langle u|z\rangle = \Sigma_{j=0}^{N-1}\langle u_j|z_j\rangle_{L^2(g(E)dE)}$. The operator $\mathscr{L}$ is a rank one perturbation of an operator with essential spectrum contained in $\cup_{j=0}^{N-1}(-\Gamma_j/2+i\mathbf{R})$. We look for eigenvalues $\lambda\in\mathbf{C}$ with $\mathrm{Re}\,\lambda\neq-\Gamma_j/2$ for all j. If $(u_0,\ldots,u_{N-1},v_0,\ldots,v_{N-1})$ is a corresponding eigenvector, we get as in Sec. VIII

$$u_j=\frac{\kappa z_j(E)}{-\Gamma_j/2+i[E-E_{R,j}(0)-\eta s]-\lambda}, \quad v_j=\frac{-\kappa\overline{z_j}(E)}{-\Gamma_j/2-i[E-E_{R,j}(0)-\eta s]-\lambda}, \tag{11.20}$$

where

$$\kappa=i\,\eta(\langle u|z\rangle+\langle v|\overline{z}\rangle). \tag{11.21}$$

Using Eqs. (11.13) and (11.20) in Eq. (11.21), we see that λ is an eigenvector precisely when

$$1-2\,\eta\sum_{k=0}^{N-1}\int dE\,\frac{[E-E_{R,k}(0)-\eta s]g(E)|\mathscr{B}_k(E)|^2}{\{(\Gamma_k/2+\lambda)^2+[E-E_{R,k}(0)-\eta s]^2\}\{(\Gamma_k/2)^2+[E-E_{R,k}(0)-\eta s]^2\}}=0. \tag{11.22}$$

As in the case $N=1$, we observe that the lhs of Eq. (11.22) for $\lambda=0$ is equal to the s-derivative of the lhs of Eq. (11.14). Moreover, when $\lambda\to+\infty$, the lhs of Eq. (11.22) converges to 1, so if it is <0 for $\lambda=0$, it has to vanish for some $\lambda>0$. Hence, as in the case $N=1$, we get the following:

Proposition XI.1: Let z be a fixed point of Eq. (11.18), so that $s=\|z\|^2$ solves Eq. (11.14). If the s-derivative of the lhs *of Eq. (11.14) is <0, then z is not an attractive fixed point.*

We now pass to the small-Γ limit, where Eq. (11.14) is replaced by Eq. (11.15) and we keep the simplifying assumption (11.17).

Proposition XI.2 (small-Γ limit): Assume that the intervals (11.16) are disjoint and let z be a fixed point of Eq. (11.18). Then z is attractive precisely when the s-derivative of the lhs of Eq. (11.15) is >0.

Proof: The s-derivative of the lhs of Eq. (11.15) is

$$1-\sum_{j=0}^{N-1}\frac{2\pi\eta(g|\mathscr{B}_j|^2)'[E_{R,j}(0)+\eta s]}{\Gamma_j}, \tag{11.23}$$

where $(g|\mathscr{B}_j|^2)'=\partial_E(g|\mathscr{B}_j|^2)$. On the other hand, in the small-Γ limit, Eq. (11.22) for the eigenvalues of the linearization becomes as in Sec. VIII

$$1-2\eta\sum_{k;\Gamma_k/2+\mathrm{Re}\,\lambda>0}\frac{\pi(g|\mathscr{B}_k|^2)'(E_{R,k}(0)+\eta s)}{\Gamma_k+\lambda}$$
$$+2\eta\sum_{k;\Gamma_k/2+\mathrm{Re}\,\lambda<0}\frac{\pi(g|\mathscr{B}_k|^2)'(E_{R,k}(0)+\eta s)}{\lambda}=0. \tag{11.24}$$

We are only interested in the possible existence of solutions to this equation with $\mathrm{Re}\,\lambda\geqslant 0$, and for such λ Eq. (11.24) reduces to

$$1-2\eta\sum_{k=0}^{N-1}\frac{\pi(g|\mathscr{B}_k|^2)'[E_{R,k}(0)+\eta s]}{\Gamma_k+\lambda}=0. \tag{11.25}$$

If λ is a solution, then by the condition that the intervals (11.16) are disjoint, only one term in the last sum, say for $k=m$, is $\neq 0$, so that Eq. (11.25) becomes

$$1-2\eta\,\frac{\pi(g|\mathscr{B}_m|^2)'[E_{R,m}(0)+\eta s]}{\Gamma_m+\lambda}=0, \tag{11.26}$$

while expression (11.23) becomes

$$1-2\eta\,\frac{\pi(g|\mathscr{B}_m|^2)'[E_{R,m}(0)+\eta s]}{\Gamma_m}. \tag{11.27}$$

It is then easy to see that the solution of Eq. (11.26) has a negative real part precisely when expression (11.27) is positive, and this concludes the proof of the last proposition.

When the intervals (11.16) have nonempty intersections, the situation is more complicated, and the following example is an indication that the last proposition may be false.

Example: There exist $\Gamma_1,\Gamma_2>0$, $a_1,a_2\in\mathbf{R}$, such that $1-(a_1/\Gamma_1+a_2/\Gamma_2)>0$, while $1-[a_1/(\Gamma_1+\lambda)+a_2/(\Gamma_2+\lambda)]=0$ for some positive λ. Indeed, choose $\Gamma_1=1$, $a_1=2$, $\Gamma_2=\delta>0$ very small, $a_2=-2\delta$. Then $1-a_1/\Gamma_1-a_2/\Gamma_2=1>0$. If $\delta\ll\lambda_0\ll 1$, we have

$$1-\frac{a_1}{\Gamma_1+\lambda_0}-\frac{a_2}{\Gamma_2+\lambda_0}\approx -1.$$

Hence $1-[a_1/(\Gamma_1+\lambda)+a_2/(\Gamma_2+\lambda)]$ must vanish for some λ between 0 and λ_0.

As in Sec. IX, we can derive a simplified differential equation for $(s_0(t),\ldots,s_{N-1}(t))$, where $s_j(t)=\|z_j(t,\cdot)\|^2$, so that $s(t)=\Sigma_{j=0}^{N-1}s_j(t)$. We drop the simplifying assumption (11.17), but keep, for simplicity, the assumption that $\mathscr{B}_j$ are independent of t. Assume that $z(t,E)=(z_0(t,E),\ldots,z_{N-1}(t,E))$ is a solution of Eq. (11.12) which has existed for a long time with a uniformly bounded norm. As in Sec. IX, we take the scalar product of Eq. (11.12) with z_j and get

$$\frac{d}{dt}s_j(t)=-\Gamma_j(s)+2\,\mathrm{Re}\langle z_j|\mathscr{B}_j\rangle. \tag{11.28}$$

Using

$$z_j(t,E)=\int_{-\infty}^{t}dt'\,e^{i[E-E_{R,j}(0)](t-t')-\int_{t'}^{t}dt''\Gamma_j(s(t''))/2-i\eta_j\int_{t'}^{t}dt''s(t'')}\mathscr{B}_j(s(t'),E), \tag{11.29}$$

and, under the assumption that $s(t')$ is slowly varying, we get as in Sec. IX

$$2\,\mathrm{Re}\langle z_j|\mathscr{B}_j\rangle \simeq 2\pi(g|\mathscr{B}_j|^2)(s(t),E_{R,j}(0)+\eta_j s(t)), \tag{11.30}$$

and the simplified equations

$$\frac{d}{dt}\,s_j(t) = -\Gamma_j(s(t))\left[s_j(t) - 2\pi\,\frac{(g|\mathscr{B}_j|^2)(s(t),E_{R,j}(0)+\eta_j s(t))}{\Gamma_j(s(t))}\right], \tag{11.31}$$

for $j=0,1,\ldots,N-1$, and $s=\Sigma_{j=0}^{N-1}s_j$. We notice that the region defined by $s_j\geqslant 0$ for $0\leqslant j\leqslant N-1$ is stable under the forward flow associated with the system (11.31). Moreover, if $(s_0,\ldots,s_{N-1})$ is a fixed point of this system, then we get precisely Eq. (11.15). Conversely, if s is a solution of Eq. (11.15), then

$$s_j = 2\pi\,\frac{(g|\mathscr{B}_j|^2)(s,E_{R,j}(0)+\eta_j s)}{\Gamma_j(s)} \tag{11.32}$$

defines the corresponding unique fixed point solution with $s=\Sigma_{j=0}^{N-1}s_j$.

We end this section by investigating the linearization of Eq. (11.31) at a fixed-point solution, under the simplifying assumption (11.17). An easy calculation shows that the linearization is given by

$$\mathscr{M}\begin{pmatrix} v_0 \\ \vdots \\ v_{N-1}\end{pmatrix} = \begin{pmatrix} -\Gamma_0 v_0 + 2\pi\eta s(g|\mathscr{B}_0|^2)'[E_{R,0}(0)+\eta s]\Sigma_{k=0}^{N-1}v_k \\ \vdots \\ -\Gamma_{N-1}v_{N-1} + 2\pi\eta s(g|\mathscr{B}_{N-1}|^2)'[E_{R,N-1}(0)+\eta s]\Sigma_{k=0}^{N-1}v_k\end{pmatrix}. \tag{11.33}$$

If λ is an eigenvalue of $\mathscr{M}$ with $\Gamma_j+\lambda\neq 0$ for every j, and ${}^t(v_0,\ldots,v_{N-1})$ a corresponding nontrivial eigenvector, we have

$$v_j = 2\pi\eta\,\frac{(g(|\mathscr{B}_j|^2)'[E_{R,j}(0)+\eta s]}{\Gamma_j+\lambda}\sum_{k=0}^{N-1}v_k.$$

Then necessarily the sum is $\neq 0$, and by summing these N relations, we see that λ is an eigenvalue precisely when Eq. (11.25) holds. We finally get:

Proposition XI.3: Under the simplifying assumption (11.17) and in the small-Γ limit, let z be a fixed point of Eq. (11.18) and let $(s_0,\ldots,s_{N-1})$ be the corresponding fixed-point solution of Eq. (11.31). Then the linearizations of Eqs. (11.18) and (11.31) at the corresponding fixed points have the same eigenvalues in the right half plane $\mathrm{Re}\,\lambda\geqslant 0$ *[given by Eq. (11.25)]. In particular, z is an attractive fixed point for Eq. (11.18) precisely when $(s_0,\ldots,s_{N-1})$ is an attractive fixed point for Eq. (11.31).*

(Received 1 April 1996; accepted for publication 17 June 1996)

A theory of electron counting statistics in quantum transport is presented. It involves an idealized scheme of current measurement using a spin 1/2 coupled to the current so that it precesses at the rate proportional to the current. Within such an approach, counting charge without breaking the circuit is possible. As an application, we derive the counting statistics in a single channel conductor at finite temperature and bias. For a perfectly transmitting channel the counting distribution is Gaussian, both for zero-point fluctuations and at finite temperature. At constant bias and low temperature the distribution is binomial, i.e., it arises from Bernoulli statistics. Another application considered is the noise due to short current pulses that involve few electrons. We find the time-dependence of the driving potential that produces coherent noise-minimizing current pulses, and display analogies of such current states with quantum-mechanical coherent states. © *1996 American Institute of Physics.* [S0022-2488(96)01610-6]

I. INTRODUCTION

Quantum transport in nanostructures has been a subject of many recent studies.[1] Transport properties like Ohmic conductivity can be understood in terms of the quantum scattering problem in the conductor, which provides a theory of quantum coherence of transport.[2] An interesting topic emerging from this theory is that of fluctuations of electric current due to the discreteness of electric charge, a property intrinsic to quantum transport.[3–5] It has been found that current fluctuations have properties reflecting profound aspects of underlying quantum dynamics.[6–9] For example, the quantum noise caused by a dc current is reduced below classical shot noise level.[3–9] This suppression has been understood as an effect of enhanced regularity of transmission events due to Fermi statistics.[10] Besides theoretical interest, such phenomena may lead to applications. Given the development of nano-technologies, the transmission of signals by single- or few-electron pulses will become common, and then one will see the quantum statistics of current working.

In this paper we update the theory of quantum measurement of electric current.[11] Our goal is a complete description of charge fluctuations, rather than developing measurement theory (see Secs. II, III). We shall derive a microscopic formula for electron counting distribution [see Sec. III, Eq. (11), and Sec. IV, Eq. (26)] that can be used for any system, e.g., with an interaction or with a time-dependent potential.[12] As an application, we test the method on the statistics in a single channel ideal conductor for non-equilibrium and equilibrium noise at finite temperature, and for zero-point equilibrium fluctuations (Secs. IV, V). In particular, the fluctuations of a dc current at zero temperature are found to obey binomial statistics (Sec. VI) with the probabilities of outcomes related to transmission coefficients of elastic scattering in the system, and with the number of attempts $N=eVt/h$, where V is applied voltage, and t is the time of measurement.

Another property of quantum noise that does not have a classical analog is its phase sensitivity.[13,14] For the current correlator $\langle\langle j(t_1)j(t_2)\rangle\rangle_+$ it results in a periodic sinusoidal dependence on Faraday's flux due to applied voltage, $\Phi=c\int_{t_1}^{t_2}V(t)dt$, with the period $\Phi_0=hc/e$. The

0022-2488/96/37(10)/4845/22/$10.00
J. Math. Phys. **37** (10), October 1996

phase sensitivity manifests itself in singularities of the low frequency noise power in a junction driven by ac and dc signals together.[15]

Even more remarkable is the behavior of current fluctuations induced by a short pulse of voltage.[13,16] Total charge that flows through the conductor due to a voltage pulse fluctuates in such a way that the mean square fluctuation diverges whenever the flux of the pulse is not an integer: $\varphi = e/\hbar \int_{-\infty}^{\infty} V(t)dt \neq 2\pi n$. On the other hand, for $\varphi = 2\pi n$ the fluctuation of the transmitted charge is finite (Sec. VII). This result has a simple interpretation in terms of the Anderson orthogonality catastrophe theory, since the flux φ enters the time-dependent scattering matrix of the conductor through the forward scattering amplitude.

With this, one is led to address the issue of current states that minimize the current fluctuations at fixed mean transmitted charge.[16,17] It is found in Sec. VIII that such states are produced by time-dependent voltage of the form

$$V(t) = \pm \frac{h}{\pi e} \sum_{k=1}^{n} \frac{\tau_k}{(t-t_k)^2 + \tau_k^2}, \quad \tau_k > 0, \tag{1}$$

a sum of Lorentzian pulses of unit flux each. It is remarkable that the minimal noise due to such sequence of pulses is independent of the pulse positions t_k and widths τ_k, which leads to obvious parallels with solitons in the theory of non-linear integrable systems. The noise minimizing current states can be compared to the coherent states that minimize the quantum-mechanical uncertainty. Apart from the obvious similarity, there is a difference: the coherent current states are many-body time-dependent scattering states. Their role in transport is an interesting subject of future work: one expects that representing many-body states as a superposition of these coherent states has an advantage similar to that provided by coherent states of one particle.

II. MEASURING ELECTRIC CURRENT

Instantaneous measurement is described in quantum mechanics by wavepacket reduction that involves projecting on eigenstates of an observable, represented by a Hermitian operator. A different kind of measurement, extended in the time domain, is realized in detectors and other counting devices. It is known that in such cases a certain revision of the measurement description is necessary. A famous example is the theory of photon detectors[18] in quantum optics. Due to Bose statistics, photons entering a photo-counter are correlated in time, and this makes the theory of photon detection a problem of many-particle statistics. For a single normal mode of radiation field the probability P_m to count m photons over time t is given by

$$P_m = \frac{(\eta t)^m}{m!} \langle :(a^+ a)^m e^{-\eta t a^+ a}: \rangle, \tag{2}$$

where a^+ and a are Bose operators of the mode, η is the counter efficiency parameter, and $\langle \cdots \rangle$ stands for the average over a quantum state. The normal ordering $:\cdots:$ is an important element of the formalism. Physically, it means that, after having been detected, each photon is destroyed, e.g., it is absorbed in the detector. Instead of the probabilities (2), it is more convenient to deal with the generating function

$$\chi(\lambda) = \sum_m P_m e^{i\lambda m}. \tag{3}$$

For the single normal mode Eq. (2) leads to

$$\chi(\lambda) = \langle :\exp\ \eta t (e^{i\lambda} - 1) a^+ a: \rangle. \tag{4}$$

Eqs. (2), (3), and (4) account very well for numerous experimental situations.[19] Particularly interesting is the case of a coherent state $|z\rangle$, $a|z\rangle = z|z\rangle$, where z is a complex number. It corresponds to the radiation field of an ideal laser, and with Eq. (4) one easily gets Poisson counting distribution,

$$P_m = \frac{(Jt)^m}{m!} e^{-Jt}, \quad J = \eta |z|^2, \tag{5}$$

which describes the so-called minimally bunched light source.

Similar to the photon detection, electric measurement is performed on a system containing an enormous number of particles—in this case fermions—and thus one expects the effects of Fermi statistics to be important. Also, the duration of electric measurement is typically much longer than the time it takes the system to transmit one electron by microscopic tunneling, scattering, or diffusion. Apart from these similarities, there is, however, a crucial difference from the photon counting: the number of electrons is not changed by the current measurement, since electric charge is conserved. This has to be contrasted with absorption of photons in photo-counters. Related to this, there is another important difference: at every detection of a photon, its energy $\hbar\omega$ is taken from the radiation field, which makes plain photodetectors insensitive to zero-point fluctuations of electromagnetic field. On the contrary, the measurement of current fluctuation is usually performed without changing energy of the system, which makes the zero-point noise an unavoidable component of any electric measurement.[20] (Let us emphasize that the difference has nothing to do with the type of quantum statistics, Fermi or Bose. Rather it is the difference between the two kinds of measurement, e.g., see Ref. 21, where counting of fermions was discussed using an optical-like counter that has to capture an electron in order to detect it.)

In the classical picture, the measurement gives the charge $Q(t) = \int_0^t j(t')dt'$ transmitted during the measurement time t. The probabilities P_m of counting m electrons can then be obtained by averaging $\delta(Q(t) - me)$ over the state of the system. In a quantum problem electric current is an operator, and since currents at different moments do not commute, the operator of transmitted charge $\hat{Q}(t) = \int_0^t \hat{j}(t')dt'$ generally does not make any sense. Instead, since we are interested in higher-order statistics of current fluctuations, beyond $\langle \hat{j}(t) \rangle$ and $\langle\langle j(t_1) j(t_2) \rangle\rangle_+$, in order to compute electron counting distribution, we have to include the measuring system in the quantum Hamiltonian. Our approach is motivated by the example of the quantum mechanical systems with strong coupling to macroscopic environment, introduced by Leggett, that can be treated consistently only by adding the ''measuring environment'' to the quantum problem.[22]

For that we introduce a model quantum galvanometer, a spin 1/2 that precesses in the magnetic field B of the current. For a classical system, the rate of precession is proportional to $B(t)$, and $B(t)$ is proportional to the current $I(t)$: $B(t) = \text{const}\, I(t)$. Therefore, the precession angle of the spin directly measures transmitted charge $\delta Q = \int_0^t I(t')dt'$. We adopt the same measurement procedure for the quantum circuit, i.e., we include in the electron Hamiltonian the Ampère's vector potential due to the spin:

$$\vec{A}(r) = -\mu \vec{\sigma} \times \vec{\nabla} \frac{1}{|r|}, \tag{6}$$

where $\vec{\sigma} = (\sigma_x, \sigma_y, \sigma_z)$ are Pauli matrices. Thus we obtain a Hamiltonian describing the motion of electrons, the measuring spin, and their coupling. Now, according to what has been said, we have to solve dynamics of the spin in the presence of the fluctuating current, find the distribution of precession angles, and then interpret it as a distribution of transmitted charge. Of course, a question remains about the back effect of the spin on the system, as in any other problem of quantum measurement. However, as we find below in (18) and (19), only the phase of an electron state is affected by the presence of the spin, not the amplitude. Moreover, the phase will change

only for the transmitted, but not for the reflected wave. As a result, the probabilities we obtain do not depend on the coupling constant of the spin. This justifies the assumption that the spin measures charge transfer in a non-invasive way.

It is worth remarking that our scheme resembles the ''Larmor clock'' approach[23] to the problem of traversal time for motion through a classically forbidden region. In this problem one is interested, e.g., in the time spent by a particle tunneling through a barrier. The Larmor clock approach involves an auxiliary constant magnetic field B added in the classically forbidden region, and a spin 1/2 carried by the particle that interacts with the field: $\mathscr{H}_{int}=-\hat{\sigma}_z B$. The precession angle of the spin measures traversal time. Comparing the two approaches is very tutorial: see Appendix A, where the Larmor clock is reviewed.

III. SPIN 1/2 AS A GALVANOMETER

Having clarified our motivation, we proceed semi-phenomenologically and choose a new vector potential in the spin-current interaction $-(1/c)\vec{j}\vec{A}$. We replace the Ampère's long-range form (6) by a model vector potential,

$$\hat{A}_i(r)=\frac{\lambda\Phi_0}{4\pi}\hat{\sigma}_z\nabla_i\theta(f(r)-f_0), \tag{7}$$

concentrated on some surface S defined by the equation $f(r)=f_0$. Here $\Phi_0=hc/e$, λ is a coupling constant, $f(r)$ is an arbitrary function, and, as usual, the step-function $\theta(x)=1$ for $x>0$, 0 for $x<0$. The surface S defines a section of the conductor on which the interaction is localized:

$$\mathscr{H}_{int}=\int -\frac{1}{c}\hat{\vec{j}}\vec{\hat{A}}d^3r=-\frac{\lambda\hbar}{2e}\hat{\sigma}_z\hat{I}_S, \tag{8}$$

where $\hat{I}_S=\int_S\hat{\vec{j}}\,\vec{ds}$, i.e., the spin now is coupled to the total current through the section S. With the choice (7) of the vector potential one can study current fluctuations in an arbitrary section of the conductor. Another advantage of the phenomenological Equation (7) is that it involves only one Pauli matrix, which makes the spin dynamics essentially trivial. The choice of the quantization axis of the spin is arbitrary since (8) will be the only spin-dependent part of the Hamiltonian. Finally, another advantage of the form (8) is that by switching from the smooth function (6) to the singular form (7) we enforce integer values of counted charge. To understand this, let us note that in the ''fuzzy'' case (6) the measurement can start at the moment when one of the electrons is located somewhere in the middle of the volume where $A\neq 0$, and then a fractional part of the electron charge will be counted. On the contrary, in the ''sharp'' case (7), the spin responds to the presence of an electron only when it crosses the section S. We shall see below in a microscopic calculation that integer values of charge follow automatically from gauge invariance, since the form (7) is a gradient of a scalar.

Thus we come to the Hamiltonian,

$$\hat{\mathscr{H}}_\sigma=\hat{\mathscr{H}}(\tilde{p},r),\quad \tilde{p}_i=p_i-\frac{e}{c}\hat{A}_i, \tag{9}$$

where the spin-dependent $\vec{\hat{A}}$ is taken in the form (7). An essential feature of our approach is that we treat the constant λ of coupling between the spin and the current as a *variable*, i.e., we consider the spin precession as a function of the parameter λ. The reason is that, unlike the photon counting problem, our measurement scheme directly generates the function $\chi(\lambda)$, and then the counting probabilities P_m are obtained by reading Eq. (3) backwards.

At this point we are able to formulate our main result. Let us define a new Hamiltonian,

$$\hat{\mathscr{H}}_\lambda = \hat{\mathscr{H}}(\tilde{p}, r), \quad \tilde{p}_i = p_i - \tfrac{1}{2}\lambda\hbar\nabla_i\theta(f(r) - f_0), \tag{10}$$

simply by supressing $\hat{\sigma}_z$ in Eq. (7). The Hamiltonian $\hat{\mathscr{H}}_\lambda$ involves only quantities of the electron subsystem. Below we show that by measuring precession of the spin coupled to the current, one obtains the quantity

$$\chi(\lambda) = \langle e^{i\hat{\mathscr{H}}_{-\lambda}t} e^{-i\hat{\mathscr{H}}_\lambda t}\rangle. \tag{11}$$

Here the brackets $\langle\cdots\rangle$ stand for averaging over the initial state of electrons. Note that $\chi(\lambda)$ is written in terms of a purely electron problem, not involving spin variables. We shall find that the function $\chi(\lambda)$ defines the result of any measurement of the spin polarization after the time t when the spin-current coupling is turned off. Moreover, we shall see that the function (11) has the meaning of a generating function of electron counting distribution, i.e., the Fourier transform of $\chi(\lambda)$ gives counting probabilities, entirely analogous to (3).

Our goal now will be to express evolution of the spin in terms of quantities corresponding to the electron system. The interaction is given by Eqs. (7), (9). Suppose that the measurement started at the moment 0 and stopped at the time t, i.e., the spin-current interaction is turned on during the time interval $0 < \tau < t$. Let us evaluate the density matrix $\hat{\rho}_s(t)$ of the spin, right after it is disconnected from the circuit. We have

$$\hat{\rho}_s(t) = \mathrm{tr}_e(e^{-i\hat{\mathscr{H}}_\sigma t}\hat{\rho}e^{i\hat{\mathscr{H}}_\sigma t}), \tag{12}$$

where $\hat{\rho}$ is the initial density matrix $\hat{\rho}_e \otimes \hat{\rho}_s$ at $t = 0$, $\hat{\rho}_e$ is the initial density matrix of electrons, and $\mathrm{tr}_e(\cdots)$ means the partial trace taken over electron states, the spin indices left free. In terms of the spin variables, the operator $e^{-i\hat{\mathscr{H}}_\sigma t}$ is a function only of $\hat{\sigma}_z$, and hence it is diagonal in spin: $\langle\uparrow|e^{-i\hat{\mathscr{H}}_\sigma t}|\downarrow\rangle = \langle\downarrow|e^{-i\hat{\mathscr{H}}_\sigma t}|\uparrow\rangle = 0$. In other words, if initially the spin is in a pure state, up or down, it will not precess. For $\hat{\rho}_s(t)$ this remark yields

$$\hat{\rho}_s(t) = \begin{bmatrix} \hat{\rho}_{\uparrow\uparrow}(0) & \chi(\lambda)\hat{\rho}_{\uparrow\downarrow}(0) \\ \chi(-\lambda)\hat{\rho}_{\downarrow\uparrow}(0) & \hat{\rho}_{\downarrow\downarrow}(0) \end{bmatrix}. \tag{13}$$

Here $\chi(\lambda) = \mathrm{tr}_e(e^{-i\hat{\mathscr{H}}_\lambda t}\hat{\rho}_e e^{i\hat{\mathscr{H}}_{-\lambda}t})$, where $e^{-i\hat{\mathscr{H}}_\lambda t}$ is the evolution operator for the problem (10). Now, after the spin degrees of freedom are taken care of by (13), we are left with a purely electron problem, that involves only electron degrees of freedom, but not the spin. By using the cyclic property of the trace $\mathrm{tr}_e(\cdots)$, one can show that $\chi(\lambda)$ in Eq. (13) is identical to (11).

In principle, any entry of a density matrix can be measured, and therefore the quantity $\chi(\lambda)$ is also measurable. In order to make clear the relation of $\chi(\lambda)$ with the distribution of precession angles, let us recall the transformation rule for the spin 1/2 density matrix under rotation by an angle θ around the $z-$axis:

$$\mathscr{R}_\theta(\hat{\rho}) = \begin{bmatrix} \hat{\rho}_{\uparrow\uparrow} & e^{-i\theta}\hat{\rho}_{\uparrow\downarrow} \\ e^{i\theta}\hat{\rho}_{\downarrow\uparrow} & \hat{\rho}_{\downarrow\downarrow} \end{bmatrix}. \tag{14}$$

By combining this with Eq. (3) we write $\hat{\rho}_s(t)$ as

$$\hat{\rho}_s(t) = \sum_m P_m \mathscr{R}_{\theta = m\lambda}(\hat{\rho}), \tag{15}$$

which assigns to P_m the meaning of the probability to observe precession angle $m\lambda$. Let us finally note that such an interpretation of P_m is consistent with what one expects on classical grounds,

because for a *classical* magnetic moment $\vec{\sigma}$ interacting with the current according to (7), the angle $\theta=\lambda$ corresponds to the precession due to a current pulse carrying the charge of one electron.

IV. SINGLE-CHANNEL CONDUCTOR. GENERAL FORMALISM

In order to see Eq. (11) working, let us consider an ideal single channel conductor, i.e., the Schrödinger equation,

$$i\frac{\partial\psi}{\partial t}=\left[\frac{1}{2}\left(-i\frac{\partial}{\partial x}-\frac{\lambda}{2}\delta(x)\right)^2+U(x)\right]\psi, \tag{16}$$

in one dimension, where the potential $U(x)$ represents the scattering region and the vector potential is inserted according to (7) at the $x=0$ section. In order to describe transport, we shall use scattering states, left and right. Their energy distributions $n_{L(R)}(E)$ are equilibrium Fermi functions with temperature T and chemical potentials shifted by eV, $\mu_L-\mu_R=eV$, representing a dc voltage.

For the problem (16) one can write time-dependent scattering states as

$$\begin{aligned}\psi_{L,k}(x,t)&=e^{-iE_kt}\begin{cases}e^{ikx}+B_Le^{-ikx}, & x<-a/2,\\ e^{i\lambda/2}A_Le^{ikx}, & x>a/2,\end{cases}\\ \psi_{R,k}(x,t)&=e^{-iE_kt}\begin{cases}e^{-i\lambda/2}A_Re^{-ikx}, & x<-a/2,\\ e^{-ikx}+B_Re^{ikx}, & x>a/2,\end{cases}\end{aligned} \tag{17}$$

where a is the width of the barrier, and $A_{L,R}$ and $B_{L,R}$ are the transmission and reflection amplitudes in the absence of the spin vector potential. To make expressions less heavy, we supress electron spin. The phase factors $e^{\pm i\lambda/2}$ in (17) are found immediately by observing that the vector potential in the Schrödinger equation can be eliminated by the gauge transformation $\psi(x)\to\exp(i\lambda/2\,\theta(x))\,\psi(x)$. The scattering amplitudes form a unitary matrix:

$$\hat{S}_\lambda=\begin{bmatrix}e^{i\lambda/2}A_L & B_R\\ B_L & e^{-i\lambda/2}A_R\end{bmatrix}. \tag{18}$$

We will study the range of small $T,eV\ll E_F$, when only the states close to the Fermi level are important. In this case, there is an additional simplification because the states near Fermi energy have almost linear dispersion, and thus all wavepackets travel with the speed v_F without changing shape. Then, following Landauer and Martin,[8] instead of the usual scattering states (17), it is convenient to use their Fourier transform. By ignoring the energy-dependence of $A_{L,R}$ and $B_{L,R}$, which is equivalent to saying that the scattering time is negligible, and assuming that the dispersion is strictly linear, one obtains the representation of scattering in terms of time-dependent scattering wavepackets,

$$\begin{aligned}\psi_{L,\tau}(x,t)&=\begin{cases}\delta(x_-), & t<\tau,\\ e^{i\lambda/2}A_L\,\delta(x_-)+B_L\,\delta(x_+), & t>\tau,\end{cases}\\ \psi_{R,\tau}(x,t)&=\begin{cases}\delta(x_+), & t<\tau,\\ e^{-i\lambda/2}A_R\,\delta(x_+)+B_R\,\delta(x_-), & t>\tau,\end{cases}\end{aligned} \tag{19}$$

where $x_\pm=x\pm v_F(t-\tau)$. Here τ is the packet arrival moment, at which it is scattered. It is straightforward to verify orthogonality of the states (19). Any time-dependent electron state can be written as a superposition of the states (19), with the arrival time τ serving in this representation as a label in the continuum of states, like k in (17). The assumption that the scattering amplitudes

are energy-independent (and thus the scattering takes no time) is equivalent to replacing the barrier $U(x)$ of finite width by $U_0\delta(x)$ and is consistent with the closeness of relevant energies to E_F.

Second-quantized, electron states (19) lead to $\hat{\psi}(x,t)=\hat{\psi}_L(x,t)+\hat{\psi}_R(x,t)$ with

$$\hat{\psi}_{L(R)}(x,t)=\sum_{\tau}\ \psi_{L(R),\tau}(x,t)\hat{c}_{1(2),\tau}, \tag{20}$$

where $c_{1,\tau}$ and $c_{2,\tau}$ are canonical Fermi operators corresponding to the states (19), the left and the right, respectively. One checks that fermionic commutation relations for $c_{1(2),\tau}$,

$$c^{+}_{i,\tau}c_{j,\tau'}+c_{j,\tau'}c^{+}_{i,\tau}=\delta_{ij}\delta(\tau-\tau'), \tag{21}$$

$$c_{i,\tau}c_{j,\tau'}+c_{j,\tau'}c_{i,\tau}=0,\quad c^{+}_{i,\tau}c^{+}_{j,\tau'}+c^{+}_{j,\tau'}c^{+}_{i,\tau}=0, \tag{22}$$

yield the usual commutation relations for $\psi_{L(R)}(x,t)$. From that one finds the meaning of the summation in (20): $\Sigma_{\tau}\cdots=\int_{-\infty}^{\infty}\cdots d\tau$. Mathematically, in this paragraph we defined the second-quantized $\psi(x)$ in (16).

The advantage of introducing the basis of the wavepackets (19),(20) is that now it is straightforward to write the many-particle evolution operator through the single-particle scattering matrix $\hat{S}_{\lambda}$:

$$e^{-i\hat{\mathscr{H}}_{\lambda}t}=\exp\ \int_0^t d\tau\sum_{ij}\ \ln[\hat{S}_{\lambda}]_{ij}c^{+}_{i,\tau}c_{j,\tau}, \tag{23}$$

where $\hat{S}_{\lambda}$ is given by (18). To verify (23), let us note that in the wavepacket representation (19), according to Eqs. (21), Fermi correlations occur only for the pairs of left and right states that scatter at the same instant of time. For each of such pairs the evolution operator $e^{-i\hat{\mathscr{H}}_{\lambda}t}$ is $\hat{1}$ if both states are occupied or both are empty, otherwise it is given by the single-particle scattering matrix (18).

Using similar arguments, we compute

$$e^{i\hat{\mathscr{H}}_{-\lambda}t}e^{-i\hat{\mathscr{H}}_{\lambda}t}=\exp\int_0^t d\tau\sum_{ij}\ \hat{W}_{ij}c^{+}_{i,\tau}c_{j,\tau}, \tag{24}$$

where $e^{\hat{W}}=\hat{S}^{-1}_{-\lambda}\hat{S}_{\lambda}$ is readily obtained from (18):

$$e^{\hat{W}}=\begin{bmatrix} e^{i\lambda}|A_L|^2+|B_L|^2 & 2i\ \sin\lambda\overline{A_L}B_R \\ 2i\ \sin\lambda\overline{B_R}A_L & e^{-i\lambda}|A_R|^2+|B_R|^2 \end{bmatrix}. \tag{25}$$

Using unitarity of $e^{\hat{W}}$ and commutation rules for $c_{\alpha,\tau}$ one can rewrite (24) in terms of normal ordering:

$$e^{i\hat{\mathscr{H}}_{-\lambda}t}e^{-i\hat{\mathscr{H}}_{\lambda}t}=:\exp\int_0^t d\tau\sum_{ij}\ [e^{\hat{W}}-1]_{ij}c^{+}_{i,\tau}c_{j,\tau}: \tag{26}$$

This form is ready to be plugged into Eq. (11) and averaged over the initial state. Let us note the striking similarity of two formulas obtained by different means: the fermionic Equation (26) and the bosonic Equation (4).

Also, let us mention that the periodicity of the matrix (25) in λ ensures periodicity of $\chi(\lambda)$, and thus guarantees integer values of charge.

V. EQUILIBRIUM FLUCTUATIONS

Let us start with a simple one-particle example. Consider a particle in the state $c^+_{1,\tau}|\text{vac}\rangle$, which corresponds to scattering at the moment τ. In this case, from (26) and (11) one gets

$$\chi(\lambda)=\begin{cases} e^{i\lambda}|A|^2+|B|^2, & \text{for } 0<\tau<t; \\ 1 \quad \text{otherwise;} \end{cases} \tag{27}$$

$|A|=|A_L|=|A_R|$, $|B|=|B_L|=|B_R|$. Evidently, according to Eq. (3), this simply means that for the scattering occurring during operation of the detector, the counting probabilities are identical to the one-particle scattering probabilities, as it should be expected.

Now, we consider current fluctuations in an equilibrium Fermi gas. First, let us assume perfect transmission: $B_{L(R)}=0$. Then Eq. (25) gives $\hat{W}=i\lambda\sigma_z$, and thus Eq. (24) becomes

$$e^{i\hat{\mathscr{H}}_{-\lambda}t}e^{-i\hat{\mathscr{H}}_{\lambda}t}=\exp\, i\lambda\int_0^t (c^+_{1,\tau}c_{1,\tau}-c^+_{2,\tau}c_{2,\tau})\,d\tau, \tag{28}$$

i.e., the right and the left states separate.

We observe that averaging of (28) over the Fermi ground state is identical to that performed in the orthogonality catastrophe calculation.[24,25] Hence, averaging of (28) can be done by using the bosonization method[26] that replaces the fermionic Hamiltonian by a bosonic one. (The calculation is described in Appendix B.) In the bosonized representation one has to do a simple Gaussian average, which gives

$$\chi(\lambda)=e^{-\tilde{\lambda}^2 f(t,T)}, \tag{29}$$

where $\tilde{\lambda}/2\pi+1/2=\lfloor\lambda/2\pi+1/2\rfloor$, with $\lfloor\cdots\rfloor$ being the fractional part. The function

$$f(t,T)=\left\langle\left\langle\left(\int_0^t c^+_{1,\tau}c_{1,\tau}\,d\tau\right)^2\right\rangle\right\rangle=-\text{Re}\frac{1}{4}\int_0^t\int_0^t\frac{T^2\,dt_1\,dt_2}{\sinh^2(\pi T(t_1-t_2-i\delta))} \tag{30}$$

$$=\frac{1}{2\pi^2}\ln\left(\frac{1}{\pi T\delta}\sinh\,\pi Tt\right)=\begin{cases} \dfrac{1}{2\pi^2}\ln\dfrac{t}{\delta}, & \delta\ll t\ll\dfrac{\hbar}{T}, \\ \dfrac{Tt}{h}-\dfrac{1}{2\pi^2}\ln 2\pi T\delta, & t\gg\dfrac{\hbar}{T}, \end{cases} \tag{31}$$

where δ is an ultraviolet cutoff time, of the order of $\hbar/E_F$. At long times, according to (3), this leads to Gaussian counting statistics.

As a side remark, the distribution given by Eq. (29) also gives a solution to another problem: the statistics of the number of fermions inside a segment of fixed length in one dimension. The relation is immediately obvious after one assigns to τ in Eq. (28) the meaning of a coordinate on a line. Thus, in this problem the statistics are Gaussian as well.

Now, it turns out that the general case of non-vanishing reflection, $B\neq 0$, can be reduced to (28) by a canonical Bogoliubov transformation of $c_{\alpha,\tau}$ making the quadratic form in (24) diagonal. The transformation is related in the usual way with the eigenvectors of the matrix $\hat{W}$. Thus, we come to Eqs. (28),(29) with λ replaced by λ_*:

$$\sin\frac{\lambda_*}{2}=|A|\sin\frac{\lambda}{2}. \tag{32}$$

The counting statistics in this case are non-Gaussian:

$$\chi(\lambda)=e^{-\lambda *^2 f(t,T)}. \tag{33}$$

One checks that the second moment of the distribution,

$$\langle\langle m^2\rangle\rangle=-\left.\frac{\partial^2\chi(\lambda)}{\partial\lambda^2}\right|_{\lambda=0}=2|A|^2 f(t,T), \tag{34}$$

agrees with the Johnson-Nyquist formula for the equilibrium noise.

VI. STATISTICS OF A DC CURRENT: QUANTUM SHOT NOISE

Let us consider nonequilibrium noise. In this case, due to the asymmetry in the distributions, $n_{L(R)}(E)=(\exp(E\pm\frac{1}{2}eV)/T+1)^{-1}$, generally one cannot uncouple the two channels by a canonical transformation. We calculate the statistics within an approximation that ignores the effect of switching at $\tau=0$ and $\tau=t$. Let us close the axis τ into a circle of length t, which amounts to restricting on periodic states:

$$\psi(\tau)=\psi(\tau\pm t). \tag{35}$$

For the $t-$periodic problem, by going to the Fourier space, one has

$$\chi(\lambda)=\prod_{k\in Z}\left[1+|A|^2(e^{-i\lambda}-1)n_L(E_k)(1-n_R(E_k))+|A|^2(e^{i\lambda}-1)n_R(E_k)(1-n_L(E_k))\right], \tag{36}$$

where $E_k=2\pi\hbar k/t$, k is an integer. For large t, $t\gg\hbar/T$ or $t\gg\hbar/eV$, the product is converted to an integral:

$$\ln(\chi(\lambda))=\frac{t}{2\pi\hbar}\int_{-\infty}^{+\infty}dE\ \ln(1+|A|^2(e^{-i\lambda}-1)\times n_L(1-n_R)+|A|^2(e^{i\lambda}-1)n_R(1-n_L)). \tag{37}$$

We evaluate it analytically, and get

$$\chi(\lambda)=\exp(-tTu_+u_-/h), \tag{38}$$

where

$$u_\pm=v\pm\cosh^{-1}(|A|^2\ \cosh(v+i\lambda)+|B|^2\ \cosh\ v), \tag{39}$$

$v=eV/2T$. The answer simplifies in the two limits: $T\gg eV$ and $eV\gg T$. In the first case we return to the equilibrium result (33). In the second case, corresponding to the recently discussed quantum shot noise,[3–5] we have

$$\chi(\lambda)=(e^{i\epsilon\lambda}|A|^2+|B|^2)^{e|V|t/h},\quad \epsilon=\text{sgn}\ V, \tag{40}$$

Analyzed according to Eq. (3), this $\chi(\lambda)$ leads to the binomial distribution

$$P_N(m)=p^m q^{N-m}C_N^m,$$

$p=|A|^2$, $q=|B|^2$, $N=e|V|t/h$. One checks that the moments $\langle m\rangle=pN$ and $\langle\langle m^2\rangle\rangle=pqN$ correspond directly to the Landauer formula and to the formula for the intensity of the quantum shot noise.[3–5] The correction to the statistics due to the switching effects is insignificant.[10]

VII. NOISE DUE TO A VOLTAGE PULSE: ORTHOGONALITY CATASTROPHE

Here we consider the fluctuations of current in a single-channel conductor induced by a voltage pulse. The result will be that the dependence of the fluctuations on Faraday's flux $\Phi=-c\int V(t)dt$ contains a logarithmically divergent term periodic in Φ with the period $\Phi_0=hc/e$. The fluctuation is smallest near $\Phi=n\Phi_0$. The divergence is explained by a comparison with the orthogonality catastrophe problem. The Φ_0-periodicity is related with the discreteness of ''attempts'' in the binomial statistics picture of charge fluctuations presented above.

Initially, the orthogonality catastrophe problem emerged from the observation that the ground state of a Fermi system with a localized perturbation is orthogonal to the nonperturbed ground state, no matter how weak the perturbation.[27] Originally, the discussion was focused on the purely static effect of Fermi correlations on the ground state that leads to the orthogonality, but then it shifted to dynamical effects. When a sudden localized perturbation is turned on in a Fermi gas, the number of excited particle-hole pairs detected over a large time interval t diverges as $\ln t/\tau$, where τ is the time of switching of the perturbation. This effect leads to power law singularities in transition rates involving collective response of fermions, such as x-ray absorption in metals.[28,24] In this section we present an application of the orthogonality catastrophe picture to the electric current noise.

Let us consider a single channel conductor in an external field described by the one-dimensional Schrödinger equation,

$$i\frac{\partial}{\partial t}\psi(x,t)=\hat{\mathscr{H}}\psi(x,t),$$
$$\hat{\mathscr{H}}=\frac{1}{2}\left(-i\frac{\partial}{\partial x}-\frac{e}{c}A(x,t)\right)^2+U(x), \tag{41}$$

where the potential $U(x)$ represents the scattering region and $A(x,t)$ is the vector potential corresponding to the applied pulse of electric field. Since the pulse duration τ is assumed to be much longer than the time of scattering, one can treat the vector potential as static and apply a gauge transformation in order to accumulate the flux $\varphi(t)=e/\hbar\int_{-\infty}^{t}V(t')dt'$ in the phases of the transmission amplitudes, thus making them time dependent. By going through the argument presented in Sec. IV, one obtains the scattering states (17) and (19) with time-dependent forward scattering amplitudes:

$$A_{L(R)}\rightarrow A_{L(R)}e^{\pm i\varphi(t_r)}, \tag{42}$$

where the time $t_r=t-|x|/v_F$ is taken retarded in order to account for the finite speed of motion after scattering. As before, here we assume that scattering by the potential as well as traversing the region where the voltage is applied takes negligible time compared to the duration of the voltage pulse. In this approximation the amplitudes of backward scattering $B_{L(R)}$ are time-independent constants.

To draw a relation with the orthogonality catastrophe problem, let us study the effect of the voltage pulse on the scattering phases δ_1, δ_2. They can be found by diagonalizing the scattering matrix,

$$\hat{\mathscr{S}}(t)=\begin{bmatrix} A_L e^{i\varphi(t)+i\lambda/2} & B_R \\ B_L & A_R e^{-i\varphi(t)-i\lambda/2}\end{bmatrix}, \tag{43}$$

and writing its eigenvalues as $e^{i\delta_1},e^{i\delta_2}$. The relation between the phases $\delta_{1,2}$ before and after the pulse is written conveniently through $\delta_\pm=(\delta_1\pm\delta_2)/2$. The phase δ_+ does not change at any time, and the phase δ_- changes according to

$$\cos^2\ \delta_-(t')+\cos^2\ \delta_-(t)-2\cos\ \delta_-(t')\cos\ \delta_-(t)\cos\ \Delta\varphi=|A_L|^2\ \sin^2\ \Delta\varphi, \tag{44}$$

where $\Delta\varphi=\varphi(t')-\varphi(t)$. Now, let us compare the situation to the orthogonality catastrophe in the Fermi system subjected to a time-dependent perturbation (43). Change of the flux induces the shift of the phases $\delta_\pm\to\delta'_\pm$ and makes the new ground state orthogonal to the old one:

$$\langle 0'|0\rangle=\exp\left(-2\frac{\delta_*^2}{\pi^2}\ln\frac{L}{\lambda_F}\right), \tag{45}$$

where L is the system size, λ_F is Fermi wavelength, and $e^{i\delta_*}$ is an eigenvalue of the matrix $\hat{\mathscr{S}}^{-1}(t=\infty)\hat{\mathscr{S}}(t=-\infty)$:

$$\sin\frac{\delta_*}{2}=|A_L|\sin\frac{\Delta\varphi}{2}. \tag{46}$$

In terms of dynamics, this implies that the old ground state is shaken up so that infinitely many particle-hole pairs are excited.[24] It should lead to a logarithmically diverging contribution to noise, since for each of the particle-hole pairs there is a finite probability (equal to $|A_LB_R|^2$) that the particle and the hole will go to different terminals of the conductor, thus resulting in a current fluctuation. The periodicity in Faraday's flux $\Phi=-c\int V(t)dt$ follows from the gauge invariance and is explicit in Eqs. (44),(46) for $\delta'_\pm$. The logarithmic divergence vanishes at $\Phi=n\Phi_0$, as expected, since at integer Φ there is no long-term change of the scattering.

Let us calculate the mean square fluctuation of the charge $\langle\langle Q^2\rangle\rangle$ transmitted through the system due to the pulse. For that, one can use the formula (26) with the time-dependent scattering matrix (43). To get the second cumulant $\langle\langle Q^2\rangle\rangle$ one expands the exponent (26) up to second order terms in λ, and takes an irreducible average using Wick theorem. The averages of $c_{i,\tau}$ have the usual form:

$$\begin{aligned}\langle c^+_{i,\tau}c_{j,\tau'}\rangle&=\delta_{ij}\int n(E)e^{iE(\tau-\tau')}\frac{dE}{2\pi},\\ \langle c_{i,\tau}c^+_{j,\tau'}\rangle&=\delta_{ij}\int\ (1-n(E))e^{-iE(\tau-\tau')}\frac{dE}{2\pi},\end{aligned} \tag{47}$$

where $n(E)=(e^{E/T}+1)^{-1}$ is the Fermi distribution. The result reads as

$$\langle\langle Q^2\rangle\rangle=\frac{ge^2}{2\pi}\int\left(|A|^4\left|\int_0^t e^{i\omega t'}\ dt'\right|^2+|AB|^2\times\left|\int_0^t e^{i\varphi(t')+i\omega t'}\ dt'\right|^2\right)\omega\ \coth\frac{\hbar\omega}{2T}\ \frac{d\omega}{2\pi}, \tag{48}$$

where g is spin degeneracy. The first term in (48) is a part of equilibrium noise since it does not depend on φ. To analyze the second term, let us take a step-like time-dependence of φ resulting from an abrupt voltage pulse applied at the time t_0, $0<t_0<t$, the pulse duration τ being much shorter than t. Taking the integral and keeping only the terms diverging at $t\to\infty$, we find

$$\frac{ge^2}{2\pi}\int\left|\frac{e^{i\omega t_0}-1}{i\omega}+e^{2\pi i\Phi/\Phi_0}\frac{e^{i\omega t}-e^{i\omega t_0}}{i\omega}\right|^2|\omega|\frac{d\omega}{2\pi}=\frac{ge^2}{\pi^2}\left(\ln\frac{tE_F}{\hbar}+2\sin^2\frac{\pi\Phi}{\Phi_0}\ln\frac{t}{\tau}\right), \tag{49}$$

where the ultraviolet-diveregent integrals are cut at frequency $\sim E_F/\hbar$. By subtracting the result for $\Phi=0$ as corresponding to equilibrium, one obtains a logarithmic contribution to the non-equilibrium noise:

$$\langle\langle Q^2\rangle\rangle = ge^2|AB|^2\left[\frac{2}{\pi^2}\sin^2\frac{\pi\Phi}{\Phi_0}\ln\frac{t_0}{\tau}+\frac{\Phi}{\Phi_0}\right]+\cdots+\langle\langle Q\rangle\rangle_{eq}. \tag{50}$$

The origin of the non-diverging term in Eq. (50) proportional to Φ/Φ_0 will be discussed below. The dots in Eq. (50) represent corrections higher order in Φ_0/Φ, and the equilibrium noise,

$$\langle\langle Q^2\rangle\rangle_{eq}=\frac{e^2G}{\pi^2}\ln\frac{tE_F}{\hbar}, \quad G=g\frac{e^2}{\hbar}|A|^2, \tag{51}$$

is obtained by repeating the calculation for $\Phi=0$. The expression (51) agrees with the Nyquist formula,

$$\langle\langle j_\omega j_{-\omega}\rangle\rangle = e^2G\omega\ \coth\frac{\omega}{2T}, \tag{52}$$

taken at $T=0$, Fourier transformed, and combined with the relation $Q=\int_0^t j(t')dt'$.

The term in Eq. (50) proportional to Φ/Φ_0 is obtained by rewriting the integral in the second term of (48) as

$$\int\int\int\frac{d\omega}{2\pi}|\omega|dt_1\ dt_2\ e^{i(\varphi(t_1)-\varphi(t_2)+\omega(t_1-t_2))}, \tag{53}$$

and extracting the contribution of almost coinciding times t_1 and t_2 by going to new variables $t=(t_1+t_2)/2$, $t'=t_1-t_2$, and changing the order of integrations:

$$\int dt\int\frac{d\omega}{2\pi}|\omega|\int dt'\ e^{i\varphi(t_1)-i\varphi(t_2)+i\omega t'}=\int|\dot\varphi|dt, \tag{54}$$

where we replaced $\varphi(t_1)-\varphi(t_2)=\varphi(t+t'/2)-\varphi(t-t'/2)$ by $\dot\varphi t'$. The result (54) is approximate: it does not give the log-term because the transformation (54) properly takes care of the integral (53) only in the domain $t_1\simeq t_2$, under the restriction that $\Phi(t)$ is varying sufficiently smoothly. When $\Phi(t)$ is a monotonous function, $\dot\varphi>0$, the integral in the right hand side of (54) equals $2\pi\Phi/\Phi_0$ and thus produces the term of Eq. (50) proportional to Φ/Φ_0.

It is clear from the derivation that the two terms in the brackets in Eq. (50) arise from different integration domains in the t_1-t_2 space: the first term corresponds to $|t_{1,2}|\geqslant\tau, t_1t_2<0$, while the second one is due to almost coinciding moments, $|t_1-t_2|\ll\tau$. Since these domains are almost non-overlapping, the two contributions to the noise (50) do not interfere (cross terms are small).

In order to estimate the correction to the result (50), let us derive it by another method that allows to trace out the higher order terms. For that, let us take the flux in the form $\varphi(t)=N\lambda(t)$, where $\lambda(t)$ is a smooth monotonous function, $\lambda(-\infty)=0$, $\lambda(\infty)=2\pi$. For integer $N\gg1$ the Fourier component of $e^{iN\lambda(t)}$ entering Eq. (54) in the stationary phase approximation is given by

$$\int_{-\infty}^{\infty}e^{iN\lambda(t)+i\omega t}\ dt=\sum_k\ \sqrt{\frac{2\pi i}{N\ddot\lambda(t_k)}}e^{iN\lambda(t_k)+i\omega t_k}+\cdots, \tag{55}$$

where the dots indicate terms $\sim O(N^{-3/2})$, and t_k's are real solutions of the equation $N\dot\lambda(t)+\omega=0$. Then we can write

$$\left|\int_{-\infty}^{\infty}e^{iN\lambda(t)+i\omega t}\ dt\right|^2=\sum_k\ \frac{2\pi}{N\ddot\lambda(t_k)}+O(N^{-2}), \tag{56}$$

and thus obtain

$$\langle\langle Q^2\rangle\rangle = A\int_{-\infty}^{\infty}\sum_k \frac{|\omega|d\omega}{N\ddot{\lambda}(t_k)} + \cdots, \tag{57}$$

where the dots represent higher order terms. By differentiating both sides of the equation $N\dot{\lambda}(t) = -\omega$ one finds the relation $d\omega = -N\ddot{\lambda}(t_k)dt_k$, which means that $|\omega|d\omega/\ddot{\lambda}(t_k) = -|\dot{\lambda}(t_k)|dt_k$, and therefore the integral in Eq. (57) equals $N\int_{-\infty}^{\infty}d\lambda = 2\pi N$. Since $|\omega|d\omega$ scales as N^2, the correction to Eq. (57) can be evaluated as $O(1)$, i.e., it is of the order of one for any N. This means that Eq. (77) has relative accuracy of $O(1/N)$.

The term in (50) proportional to Φ/Φ_0 is interesting in connection with the picture of binomial statistics presented in Sec. VI. In the dc bias case, the distribution of charge for a single channel situation was found to be binomial with the frequency of attempts equal to eV/h and the probabilities of outcomes $p = |A|^2$, $q = |B|^2$. Taken literally, this means that the attempts to transfer charge are repeated regularly in time, almost periodic with the period h/eV, with each attempt having two outcomes–transmission or reflection–occurring with the probabilities p and q. However, the regularity of the attempts does not lead to an ac component in the current, rather it appears just as a part of statistical description of charge fluctuations. Still, the presence of a non-zero frequency in a noninteracting system requires interpretation.

Let us suppose that the flux varies linearly with time, $\Phi(t) = -cVt$. Since the e.m.f.$= -\partial\Phi/c\,\partial t$, the linear dependence of $\Phi(t)$ is equivalent in its effect on the noise to constant voltage V. In accordance with one's expectation, the second term in the brackets in Eq. (50) for a single channel is $\langle\langle Q^2\rangle\rangle = ge^2|AB|^2\Phi/\Phi_0$, i.e., it is precisely of the form arising from the binomial distribution with probabilities of outcomes p and q, and the number of attempts $N = \Phi/\Phi_0$. (Let us recall that the second moment of the binomial distribution equals pqN.) Taking into account that the time during which the flux changes by Φ_0 is h/eV, we can interpret the number of attempts in the statistical picture as the number of flux quanta by which the flux is changed. Such a conclusion suggests an interesting generalization of the picture of binomial statistics by attributing the meaning of the number of attempts to the flux change measured in the units of Φ_0, regardless of the linear or non-linear character of the flux dependence on time.

It is appealing to put the special role of integer fluxes in connection with the binomial statistics of current, where the flux quanta are naturally interpreted as discrete attempts to transmit charge. Although this picture is yet to be confirmed by analytic treatment, it receives some support from the property of the Φ_0-periodic term in (50) to vanish at every integer Φ. One may conjecture that the statistics are close to binomial only when the flux change is an integer, and have diverging logarithmic corrections otherwise. The distinction that Eq. (50) makes between integer and non-integer values of the flux and the relation of integer flux change to the number of attempts in the binomial distribution, gives another perspective to the statistical picture of a current pulse.

To summarize, the fluctuations caused by a voltage pulse, in contrast to the average transmitted charge, distinguish between integer and non-integer flux change. As a result, the dependence of noise on the flux is non-monotonous and has minima at integer values of the flux.

VIII. COHERENT STATES OF CURRENT

The question we address in this section is about the optimal way of changing flux that minimizes induced noise. It is clear from what has been said that to achieve minimum of the noise one should change the flux by an integer amount,

$$\Delta\varphi = \varphi(t=\infty) - \varphi(t=-\infty) = 2\pi n, \tag{58}$$

in order to suppress the logarithmically divergent term. However, since for a given $\Delta\varphi$ the noise depends on the actual function $\varphi(t)$, not just on $\Delta\varphi$, we have a variational problem to solve for the noise as a functional of the time dependence of the flux. This functional was derived in Sec. VII. At zero temperature it is given by

$$\langle\langle Q^2\rangle\rangle = \frac{ge^2}{2\pi}|AB|^2 \int \left| \int e^{i\varphi(t)+i\omega t}\, dt \right|^2 |\omega| \frac{d\omega}{2\pi}, \tag{59}$$

where A and B are transmission and reflection amplitudes, and g is spin degeneracy. We shall study the variational problem (49) with the boundary condition (58) and show that its general solution has the form of a sum of soliton-like functions:

$$\Phi(t) = \pm\frac{\Phi_0}{\pi}\sum_{k=1}^{n} \tan^{-1}\left(\frac{t-t_k}{\tau_k}\right), \quad \tau_k > 0, \tag{60}$$

where t_k and τ_k are arbitrary constants. Under the condition (58), any time dependence of the form (60) gives absolute minimum to the noise:

$$\min[\langle\langle Q^2\rangle\rangle] = ge^2|AB|^2|n|. \tag{61}$$

For an optimal time dependence of the voltage $V = -\partial\Phi/c\ \partial t$, therefore, one has a sum of Lorentzian peaks:

$$V(t) = \mp\frac{\Phi_0}{c\pi}\sum_{k=1}^{n} \frac{\tau_k}{(t-t_k)^2+\tau_k^2}. \tag{62}$$

In order to compare quantum noise with conductance, let us mention that the average transmitted charge,

$$\langle\langle Q\rangle\rangle = ge|A|^2\frac{\Delta\varphi}{2\pi} = g\frac{e^2}{h}|A|^2\int V(t)dt, \tag{63}$$

simply obeys the Ohm's law, i.e., there is no particular dependence on the way the flux change $\Delta\varphi$ is realized.

The results (60),(61) have a simple interpretation in terms of the binomial statistics picture of charge fluctuations. For the binomial distribution with probabilities of outcomes p and q, $p+q=1$, and with the number of attempts N, the second moment is known to be equal to pqN. The comparison with Eq. (61) suggests that we attribute to $n=\Delta\Phi/\Phi_0$ the meaning of the *number of attempts*. This interpretation is supported by the structure of the function (60) consisting of n terms, each corresponding to a unit change of flux. A remarkable property of the function (60) is its separability, manifest both in the form of the terms and in the way the parameters t_k, τ_k enter the expression. Let us note that by making some of the t_k's close to each other one can have an overlap in time of different ''attempts.'' The overlap, however, does not change the fluctuations (61). The situation reminds us of the one with solitons in integrable non-linear systems, or with non-interacting instantons in integrable field theories. Also, the absence of interference is interesting in the context of coherent nature of transport in this system: after all, we simply have scattering by a time-dependent potential. Perhaps, proper interpretation of this effect should be sought in establishing a relation with the theory of coherent states, known to eliminate to some extent the quantum mechanical interference.

Let us now turn to the variational problem. It is convenient to do the integral over ω first and to rewrite (49) as

$$\langle\langle Q^2\rangle\rangle = -\frac{D}{\pi}\int\int \frac{e^{i\varphi(t)-i\varphi(t')}}{(t-t')^2}dt\ dt', \tag{64}$$

where $D=(ge^2/2\pi)\,|AB|^2$. In order to avoid divergence at $t=t'$ the denominator in (64) should be understood as

$$\frac{1}{2}\left[\frac{1}{(t-t'+i\delta)^2}+\frac{1}{(t-t'-i\delta)^2}\right], \quad \delta\to 0, \tag{65}$$

the condition that one obtains by introducing regularization in (49): $|\omega|\to|\omega|e^{-|\omega|\delta}$. By considering variation of the functional (64) we have the equation for an extremum:

$$\mathrm{Im}\left[e^{i\varphi(t)}\int\frac{e^{-i\varphi(t')}}{(t-t')^2}dt\right]=0. \tag{66}$$

By using the Cauchy formula one checks that the functions

$$e^{i\varphi(t)}=\prod_{k=1}^{n}\frac{t-\lambda_k}{t-\overline{\lambda}_k}, \quad \lambda_k=t_k+i\tau_k, \tag{67}$$

satisfy (66) provided that τ_k's are all of the same sign. Obviously, the functions (67) are just another form of (60).

It remains to be shown that the functional reaches its minimum on the solutions (67). To prove it we proceed in the following steps. Let us write $e^{i\varphi(t)}$ as

$$e^{i\varphi(t)}=f_+(t)+f_-(t), \tag{68}$$

where $f_+(t)$ and $f_-(t)$ are bounded analytic functions in the upper and lower complex t half-plane, respectively. Representation (68) exists for any non-singular function and defines the functions f_+ and f_- up to a constant. Then we substitute Eq. (68) in (64), and apply the Cauchy formula for the derivative,

$$\dot{f}_\pm(t)=\pm\frac{i}{2\pi}\oint\frac{f_\pm(t')dt'}{(t-t'\pm i0)^2}, \tag{69}$$

where the contour of integration is chosen in the half-plane of analyticity of f_+ or f_-, respectively. Thus one gets

$$\langle\langle Q^2\rangle\rangle=-iD\int(\overline{f_+}\dot{f}_+-\overline{f_-}\dot{f}_-)dt. \tag{70}$$

On the other hand,

$$n=\frac{1}{2\pi i}\int e^{-i\varphi(t)}\frac{d}{dt}e^{i\varphi(t)}\,dt=-\frac{i}{2\pi}\int(\overline{f_+}\dot{f}_++\overline{f_-}\dot{f}_-)dt, \tag{71}$$

where the last equality is a result of substituting (68) and using the relations

$$\int\overline{f_+}\dot{f}_-=\int\overline{f_-}\dot{f}_+=0, \tag{72}$$

which follow from the Cauchy theorem. Now, Eq. (70) can be rewritten through Fourier components of f_+ and f_- as

$$\langle\langle Q^2\rangle\rangle = D\int_0^\infty (|f_+(\omega)|^2 + |f_-(-\omega)|^2)\,\omega\,\frac{d\omega}{2\pi}, \tag{73}$$

thus demonstrating positivity of both terms in (70). [It is used that $f_+(\omega)=f_-(-\omega)=0$ for $\omega<0$.] With this, by comparing (70) and (71) we obtain

$$\langle\langle Q^2\rangle\rangle \geqslant 2\pi D|n|. \tag{74}$$

Equality in (74) is reached only when either $f_+(t)$ or $f_-(t)$ vanishes. Therefore, to obtain the minimum one has to take the functions $e^{i\varphi(t)}$ that are regular in one of the half-planes. This remark is sufficient to see that the functions (67) form a complete family of solutions.

It is worth mentioning that the method used to derive (74) copies almost entirely the procedure of derivation of the duality condition in the theory of instantons. Like in other situations where the duality condition holds, our ''solitons'' do not interact: $\langle\langle Q^2\rangle\rangle$ shows no dependence on the parameters λ_k of the solution (67). Among numerous field theories that allow for an exact solution of the instanton problem the one most similar to our case is the theory of the classical Heisenberg ferromagnet in two dimensions. For this problem the instantons were found by mapping the order parameter space (i.e., the unit sphere) on the complex plane.[29] The duality condition was shown to take the form of the constraint of analyticity or anti-analyticity of the mapped order parameter function (compare with the condition $f_+=0$ or $f_-=0$ derived above). Multi-instanton solutions were given as products of single instanton solutions [cf. Eq. (67)]. This analogy obviously deserves more attention.

At this point let us examine an interesting nonoptimal time dependence of the flux, the sum of two solitons with opposite charge:

$$\varphi(t) = 2\left[\tan^{-1}\left(\frac{t-t_1}{\tau_1}\right) - \tan^{-1}\left(\frac{t-t_2}{\tau_2}\right)\right], \tag{75}$$

$\tau_{1,2}>0$. This function corresponds to $e^{i\varphi(t)}$ of the form (67) but with the poles in both half-planes. In this case $\Delta\varphi=0$, and thus $\langle\langle Q\rangle\rangle=0$, so $\min[\langle\langle Q^2\rangle\rangle]=0$. With the function (75), however, one finds

$$\langle\langle Q^2\rangle\rangle = 4\pi D\left|\frac{\lambda_1-\lambda_2}{\lambda_1-\lambda_2}\right|^2, \tag{76}$$

where $\lambda_{1,2}=t_{1,2}+i\tau_{1,2}$. For different values of the parameters $t_{1,2}$, $\tau_{1,2}$, Eq. (76) interpolates between two trivial limiting cases: (i) $\langle\langle Q^2\rangle\rangle\to 0$, when the two flux steps in (75) have nearly the same duration and almost overlap; (ii) $\langle\langle Q^2\rangle\rangle\to 4\pi A$, when the flux steps either differ strongly in their duration or do not overlap. In the case (ii) the noise is two times bigger than the noise due to a single step, as it should be.

We see that when $\Delta\varphi/2\pi$ is of the order of one a non-optimal time dependence $\varphi(t)$ can considerably enhance the noise. It is not the case, however, for $\Delta\varphi/2\pi\gg 1$. This limit was studied in Sec. VII, where it was found that when $\varphi(t)$ is a monotonous function the result

$$\langle\langle Q^2\rangle\rangle = ge^2|AB|^2|\Delta\varphi/2\pi| \tag{77}$$

is rather accurate, even if the time dependence $\varphi(t)$ is not optimal.[13]

A more intuitive way to understand the accuracy of Eq. (77) is to note that for a given n the number of parameters in the optimal flux dependence (53) is $2n$, which means that half of them

are in some sense redundant. Because of that any smooth monotonous function with sufficiently large variation $\Delta\varphi$ can be rather accurately approximated by a function of the form (53), and therefore the noise exceeds the lower bound just slightly.

An implication of this result for the binomial statistics picture is as follows. As it was discussed above there is a (conjectured) correspondence of the terms of Eq. (60) and of the attempts. The deviation from the binomial distribution, that of course should exist for a non-optimal flux function $\varphi(t)$, will remain bounded in the case of a smooth $\varphi(t)$, as $\Delta\varphi$ increases taking integer values. More precisely, the distribution will be written as a mixture of binomial distributions with different numbers N of attempts, $P(m)=\Sigma_N \rho_N P_N(m)$, where $P_N(m)=p^m q^{N-m} C_N^m$. The estimated correction implies that the distribution of attempts ρ_N has finite variance in the limit $N=\Delta\varphi/2\pi\to\infty$.

Before closing, let us mention that in order to apply the results of Secs. VII, VIII to transport in a mesoscopic metallic conductor with disorder, described by many conducting channels with transmission constants T_n, one just needs to replace $|AB|^2$ by $\Sigma_n T_n(1-T_n)$, since different scattering channels contribute to the noise independently. The condition of validity of our treatment then is that the variation of the flux is sufficiently slow, so that $\min[\tau_k]\gg\hbar/E_c$, the time of diffusion across the sample. However, at non-zero temperature one also has to satisfy the condition $\tau_k\ll\hbar/T$, the time of phase breaking. So, the temperature interval where our estimate of the noise holds is $T\leqslant E_c$.

IX. CONCLUSIONS

We introduced a quantum-mechanical scheme that gives complete statistical description of electron transport. It involves a spin 1/2 coupled to the current so that the spin precession measures transmitted charge. The off-diagonal part of the spin density matrix, taken as a function of the coupling constant, gives the generating function for the electron counting statistics. We find the statistics in a single-channel ideal conductor for arbitrary relation between temperature and voltage. In equilibrium, the counting statistics are Gaussian, both for zero-point fluctuations and at finite temperature. At constant voltage and low temperature the statistics are Bernoullian and the distribution is binomial.

The theory leads to interesting conclusions applied to the current fluctuations produced by a voltage pulse. In this case, the noise has phase sensitivity: it oscillates as a function of Faraday's flux, $c\int V(t)dt$, reaching minimum at integer fluxes. We studied the noise as a function of the shape of the voltage pulse and found optimal time dependence that provides an absolute minimum of the noise for a given average transmitted charge. The solution displays an interesting analogy with the problem of instantons in the field theories obeying duality symmetry. Optimal time dependence is a sum of Lorentzian peaks of voltage, each corresponding to a soliton of flux. The change of flux for a soliton is equal to the flux quantum Φ_0. The solitons are interpreted in terms of the binomial statistics picture of charge fluctuations as attempts to transmit electrons, one electron per soliton.

APPENDIX A: LARMOR CLOCK MEASUREMENT OF TUNNELING TIME

How long does it take a particle to tunnel under a barrier? More precisely, suppose a particle of energy E is moving in one dimension, and is scatterred on a potential barrier:

$$i\frac{\partial}{\partial t}\psi(x,t)=\left[-\frac{1}{2}\frac{\partial^2}{\partial x^2}+U(x)\right]\psi(x,t). \tag{A1}$$

What is the probability that during the scattering the particle spends time τ within the region $a<x<b$ under the barrier? Questions of that kind arise naturally in discussion of any quantum-mechanical process that takes finite time, like nuclear or chemical reactions, resonance scattering, or tunneling.

There have been several attempts to treat such problems[23] that resulted in the formulation of a very interesting concept of a Larmor clock. It has various analogies with the spin galvanometer discussed above, and it seems useful to review the Larmor clock here using the same language. The Larmor clock uses an auxiliary spin 1/2 attached to the scattering particle, and an auxiliary constant magnetic field ω localized within the region of interest, $a<x<b$,

$$\hat{\mathscr{H}}_{int}=-\frac{1}{2}\omega\sigma_z\int_a^b \psi^+(x)\psi(x)dx. \tag{A2}$$

The choice of coupling is such that the spin precession angle is proportional to the time spent in the region $a<x<b$. The difference from our spin-galvanometer is that the spin is not stationary, but travels with the particle, and also that the spin is coupled to the particle density, rather than to the current.

To find the distribution of times one has to write down the system density matrix evolved in time, and take partial trace over the particle outgoing states. (We assume that one does not have to distinguish between different results of scattering, and is interested in the tunneling time only, regardless of whether the particle went through the barrier, or has been reflected.) Then, by following the argument of Sec. III one obtains the spin density matrix:

$$\hat{\rho}_s(t)=\begin{bmatrix} \hat{\rho}_{\uparrow\uparrow}(0) & \chi(\omega)\hat{\rho}_{\uparrow\downarrow}(0) \\ \chi(-\omega)\hat{\rho}_{\downarrow\uparrow}(0) & \hat{\rho}_{\downarrow\downarrow}(0) \end{bmatrix}. \tag{A3}$$

Here

$$\chi(\omega)=\mathrm{tr}_e(e^{-i.\hat{\mathscr{H}}_\omega t}\hat{\rho}_e e^{i.\hat{\mathscr{H}}_{-\omega}t}), \tag{A4}$$

where $e^{-i.\hat{\mathscr{H}}_\omega t}$ is the evolution operator for the one-particle problem with no spin:

$$i\frac{\partial}{\partial t}\psi(x,t)=\left[-\frac{1}{2}\frac{\partial^2}{\partial x^2}+U(x)-\frac{1}{2}\omega\theta_{ab}(x)\right]\psi(x,t), \tag{A5}$$

where $\theta_{ab}=\theta(x-a)\theta(b-x)$. The auxiliary magnetic field ω now turns into a constant potential within the region $a<x<b$, and zero outside. Here again, with the spin degrees of freedom taken care of by (A3), we are left with a single particle problem. By using cyclic property of the trace one finds

$$\chi(\omega)=\langle e^{i.\hat{\mathscr{H}}_{-\omega}t}e^{-i.\hat{\mathscr{H}}_\omega t}\rangle. \tag{A6}$$

Here the brackets $\langle\cdots\rangle$ mean averaging over the particle initial state. Note that $\chi(\omega)$ is written in terms of a purely single particle problem, not involving spin variables.

The quantity $\chi(\omega)$ obtained by measuring precession of the spin is a generating function for the distribution of times, which is clear from the Fourier transform

$$\chi(\omega)=\int P(\tau)e^{i\omega\tau}\,d\tau. \tag{A7}$$

The probabilities $P(\tau)$ of different precession angles of the spin should be interpreted as the scattering time distribution.

The probabilities $P(\tau)$ defined by (A5), (A6), and (A7) have several interesting properties: *(a)* $\int P(\tau)d\tau=1$; *(b)* $P(\tau)$ are real numbers; *(c)* $P(\tau)$ vanish at negative times $\tau<0$. The normalization property *(a)* is derived from (A6) by setting $\omega=0$. Property *(b)* (real valuedness) is derived from $\chi(-\omega)=\overline{\chi(\omega)}$ which follows from (A6). The causality property *c)* follows from considering

the evolution in the problem (A5) with ω continued to complex values. One notes that both the solution $\psi(x,t)$ of Eq. (A5) and the evolution operator $e^{-i\hat{\mathscr{H}}_\omega t}$ are regular in the upper half-plane $\mathrm{Im}\omega>0$, which means that the same is true for $\chi(\omega)$. From that, the causality property *(c)* follows by the usual argument using the Cauchy theorem in the integral

$$P(\tau)=\int_{-\infty}^{\infty}\chi(\omega)e^{-i\omega\tau}\frac{d\omega}{2\pi}, \tag{A8}$$

by closing the integration contour in the upper half-plane.

The properties *(a)*, *(b)* and *(c)* suggest that $P(\tau)$, so far defined formally as the Fourier spectrum of $\chi(\omega)$, can have a meaning of probability. However, generally the sign of $P(\tau)$ can be either positive or negative, which makes the probabilistic interpretation problematic.

For the one particle problem one can write the generating function $\chi(\omega)$ in terms of the scattering amplitudes A and B. For that, it is convenient to use the expressions (23), (24) for the evolution operator in terms of the scattering matrix $\hat{\mathscr{S}}$, written using the wavepacket scattering states (19). Specializing to one particle and taking partial trace, one finds

$$\chi(\omega)=\overline{A}_{-\omega}(E)A_\omega(E)+\overline{B}_{-\omega}(E)B_\omega(E), \tag{A9}$$

where $A(\omega)$ and $B(\omega)$ are the transmission and reflection amplitudes of the problem (A5) taken at the energy E of incident particle.

To see the Larmor clock working, let us consider an example of resonance scattering, where a particle is scattered on a potential forming a quasibound state of life-time Γ. Using the method described above one can find the distribution of times it takes the particle to scatter. For simplicity, suppose that the particle can be only reflected, but not transmitted ($A=0$). Then the reflection amplitude as function of energy is given by the Breit–Wigner formula:

$$B(E)=\frac{E-E_0-i\Gamma/2}{E-E_0+i\Gamma/2}. \tag{A10}$$

Turning on the field ω in the quasibound state region is equivalent to shifting the resonance energy: $E_0\to E_0-\omega/2$. Thus, the generating function of the time distribution is

$$\chi(\omega)=\frac{\varepsilon-\omega+i\Gamma}{\varepsilon-\omega-i\Gamma}\,\frac{\varepsilon+\omega-i\Gamma}{\varepsilon+\omega+i\Gamma}, \tag{A11}$$

where $\varepsilon=2(E-E_0)$. The distribution $P(\tau)$ is found by Fourier transform:

$$P(\tau)=\int\chi(\omega)e^{-i\omega\tau}\frac{d\omega}{2\pi}=\delta(\tau)-\frac{4\Gamma}{\varepsilon}(\Gamma\,\sin\,\varepsilon\tau-\varepsilon\,\cos\,\varepsilon\tau)e^{-\Gamma\tau}=\frac{\partial}{\partial\tau}\left(\theta(\tau)-\frac{4\Gamma}{\varepsilon}\sin\,\varepsilon\tau\,e^{-\Gamma\tau}\right). \tag{A12}$$

The δ-function term corresponds to the nonresonance scattering channel. Other terms describe dwelling in the quasi-bound state. In this example $P(\tau)$ is changing sign, which makes the probabilistic interpretation ambiguous.

The paradox arising due to negative $P(\tau)$ is only an apparent one. Really, the measurement of time performed by the Larmor clock is not the usual quantum-mechanical measurement, since the time is not an operator, and thus it cannot be measured in the same sense as other quantum-mechanical observables. This should be contrasted with the measurement of charge described above. Although the spin precession measurement scheme we use looks quite similar to the

Larmor clock, there is a difference: Electric charge is an observable in the usual quantum-mechanical sense, it takes quantized integer values, and the probabilities of those values resulting from our calculation are non-negative.

APPENDIX B: BOSONIZATION CALCULATION OF COUNTING STATISTICS

In order to find generating function of counting statistics for a single channel conductor, we have to evaluate

$$\chi(\lambda)=\langle \exp i\lambda \hat{N}_t\rangle, \tag{B1}$$

where $\hat{N}_t=\int (c^+_{1,\tau}c_{1,\tau}-c^+_{2,\tau}c_{2,\tau})d\tau$, and $c_{i,\tau}$, $c^+_{i,\tau}$ are canonical Fermi operators.

In one dimension, there is an equivalence between an ideal Fermi gas and a harmonic Bose chain, which provides a representation of the Fermi problem in terms of free bosons, known as the bosonization transformation.[24–26] This representation facilitates calculting averages like (B1), since they are being transformed to the form of a Gaussian average.[25]

According to the bosonization method, the bosonic Hamiltonian representing the fermionic problem is written as

$$\hat{\mathscr{H}}_{\text{Bose}}=\frac{\hbar v_F}{4\pi}\int :(\nabla\theta_L)^2:+:(\nabla\theta_R)^2:dx, \tag{B2}$$

where $\theta_{L(R)}(x)$ are Bose operators,

$$[\nabla\theta_{L(R)}(x),\theta_{L(R)}(y)]=\pm 2\pi i\,\delta(x-y). \tag{B3}$$

Connection to the fermionic problem is given as a relation between the densities of the left- and right-moving fermions, $\hat{\rho}_i(x)=c^+_{i,x}c_{i,x}$, $i=1,2$, and the bosonic variables $\theta_{L(R)}(x)$, written as

$$\hat{\rho}_{1(2)}(x)=\frac{1}{2\pi}\nabla\theta_{L(R)}(x). \tag{B4}$$

One notes that the operator $\hat{N}_t$ in (B1) is linear in the densities $\hat{\rho}_i$, and thus it is represented by an expression linear in the bosonic variables,

$$\hat{N}_t=\frac{1}{2\pi}(\theta_L(t)-\theta_L(0)-\theta_R(t)+\theta_R(0)), \tag{B5}$$

which turns the average in (B1) into a Gaussian type.

Therefore, the average of (28) is equal to the product of averages,

$$\chi(\lambda)=\left\langle \exp\frac{i\lambda}{2\pi}(\theta_L(t)-\theta_L(0))\right\rangle\left\langle \exp\frac{-i\lambda}{2\pi}(\theta_R(t)-\theta_R(0))\right\rangle, \tag{B6}$$

taken over the ground state of the Hamiltonian (B2). To perform the average in (B6), it is sufficient to deal with the average over θ_L's, because of the left-right symmetry of the problem.

Let us write $\theta_L(x)$ in terms of bosonic operators of plane waves:

$$\begin{aligned}\theta_L(x)&=\sum_{k>0}\left(\frac{2\pi}{k}\right)^{1/2}[e^{ikx}b_k+e^{-ikx}b^+_k];\\ \nabla\theta_L(x)&=\sum_{k>0}(2\pi k)^{1/2}i[e^{ikx}b_k-e^{-ikx}b^+_k].\end{aligned} \tag{B7}$$

One checks that the commutation relations (B3) are consistent with canonical commutation relations between b_k and $b_{k'}^+$. (The Hamiltonian of the left-moving fermions is represented by $\hat{\mathscr{H}}_L = \Sigma_{k>0} v k b_k^+ b_k$.) Then the quantity $\theta_L(t) - \theta_L(0)$ appearing in the average (B6) is written as

$$\sum_{k>0} \left(\frac{2\pi}{k}\right)^{1/2} [(e^{ikvt}-1)b_k + (e^{-ikvt}-1)b_k^+]. \tag{B8}$$

We evaluate the average

$$\begin{aligned}\langle\langle(\theta_L(t)-\theta_L(0))^2\rangle\rangle &= \sum_{k>0} \frac{2\pi}{k} |e^{ikvt}-1|^2 (2N_{\text{Bose}}(kv)+1) \\ &= 4\int_{-\infty}^{\infty} \frac{dk}{|k|} \sin^2\left(\frac{vkt}{2}\right) \coth\left(\frac{vk}{2T}\right) \\ &= 2\ln\left(\frac{1}{\pi T\delta}\sinh(\pi T t)\right),\end{aligned} \tag{B9}$$

where δ is an ultraviolet cutoff. This expression equals $(2\pi)^2$ times the function $f(t,T)$ computed in (30). From that, we find the average (B6) to be

$$\chi(\lambda) = \left\langle \exp\frac{i\lambda}{2\pi}(\theta_L(t)-\theta_L(0)) \right\rangle^2 = \exp\left[-\left(\frac{\lambda}{2\pi}\right)^2 \langle\langle(\theta_L(t)-\theta_L(0))^2\rangle\rangle\right] = \exp(-\lambda^2 f(t,T)), \tag{B10}$$

which is the desired result.

Periodicity of $\chi(\lambda)$ in λ, corresponding to the charge quantization, is recovered if one corrects the relation between $\hat{\rho}_i(x)$ and $\theta_i(x)$, in order to take into account the integer-valuedness of the particle number $\hat{N}_t$. Using the relation, $\hat{\rho}_i(x) = \Sigma_n e^{in\theta(x)}$, and performing the average, one arrives at the result (29).

(Received 26 October 1995; accepted for publication 17 June 1996)

We consider a pair of parallel straight quantum waveguides coupled laterally through a window of a width l in the common boundary. We show that such a system has at least one bound state for any $l>0$. We find the corresponding eigenvalues and eigenfunctions numerically using the mode-matching method, and discuss their behavior in several situations. We also discuss the scattering problem in this setup, in particular, the turbulent behavior of the probability flow associated with resonances. The level and phase-shift spacing statistics shows that in distinction to closed pseudo-integrable billiards, the present system is essentially nonchaotic. Finally, we illustrate time evolution of wave packets in the present model. © *1996 American Institute of Physics.* [S0022-2488(96)00310-6]

I. INTRODUCTION

Spectral and scattering properties of quantum particles whose motion is confined to nontrivial subsets of $\mathbb{R}^n$ represented until recently rather textbook examples or technical tools used in proofs. There are several reasons why these problems attracted a wave of interest in a last few years. The most mathematical among them stems from the observation that, roughly speaking, one can choose the region in such a way that the spectrum of the corresponding Neumann Laplacian coincides with a chosen set;[1,2] of course, the boundary of such a region may be in general rather complicated.

On the other hand, even regions with nice boundaries may exhibit various unexpected properties manifested, for instance, in spectra of the corresponding Dirichlet Laplacians. A prominent example is the existence of bound states, i.e., localized solutions to the free Schrödinger equation, in infinitely stretched regions such as bent, branched, or crossed tubes of a constant cross section—see, e.g., Refs. 3–7; more references are given in the review paper.[8]

A. Quantum wire systems

A strong motivation to study such bound states and related resonance effects[9–11] comes from recent developments in semiconductor physics, because they can be used as models of electron motion in so-called *quantum wires*, i.e., tiny strips of a very pure semiconductor material, and similar structures. Let us briefly recall key features of such systems; more details and a guide to the physical literature can be found in Ref. 8.

Characteristic properties of the semiconductor microstructures under consideration are of small size, typically from tens to hundreds of nanometers, high purity, which means that the electron mean free path can be a few μm or even larger, and crystalline structure. In addition,

boundaries of the microstructures consist usually of an interface between two different semiconductor materials; the electron wave functions are known to be suppressed there.

Behavior of an electron in such a ''mesoscopic'' system structure is, of course, governed by the many-body Schrödinger equation describing its interaction with the lattice atoms including the boundary, external fields, and possible impurities. The mentioned properties allow us, however, to adopt several simplifying assumptions. As we have said, the mean free path is typically two or three orders of magnitude larger than the size of the structure; hence the electron motion can be assumed in a reasonable approximation as ballistic, i.e., undisturbed by impurity scattering.

The most important simplification comes from the crystalline structure. The one-electron Hamiltonian as a Schrödinger operator with a periodic potential exhibits an absolutely continuous spectrum (see Ref. 12, Sec. XIII.16); in the solid-state physics language one says that the electron moves in the lattice as *free* with some effective mass m^*. The latter changes, of course, along the spectrum but one can regard it as a constant when we restrict our attention to the physically interesting part of the valence band; recall that its value may differ substantially from the true electron mass, for instance, one has $m^* = 0.067 m_e$ for GaAs, which is the most common semiconductor material used in mesoscopic devices.

This property together with the wave function suppression at the interfaces makes it natural to model electrons in a quantum wire system as free (spinless) particles living in the corresponding spatial region with the Dirichlet condition on its boundary; an interaction term must be added only if the whole structure is placed into an external field. This is the framework in which the mentioned curvature-induced bound states and resonances were studied. However, the physical conclusions one can draw from it are not restricted to mesoscopic devices: the results are useful for description of other ''new'' quantum systems[13] and provide fresh insights into the classical theory of electromagnetic waveguides.[14–16]

B. Motivation of the present work

Apart from these practical reasons, the curvature-induced bound states provide at the same time a warning example showing that an intuition based on semiclassical concepts may fail when dealing with quantum systems. It is well known, for instance, that low-dimensional Schrödinger operators have bound states for an arbitrarily small coupling constant as long as the potential is not repulsive in the mean and decays sufficiently fast at infinity.[17,18] A common wisdom, however, is that this is rather an exception, and that the number of bound states of a quantum system is at least *roughly* proportional to the classically allowed volume of the phase space. The waveguide systems in question illustrate that this is not true, because they can exhibit in principle *any* number of bound states, while having *no* closed classical trajectories with the exception of an obvious zero-measure set.

In this article we are going to consider another example of that kind, this time consisting of two straight parallel quantum waveguides. We suppose that they have a common boundary which has a window of a width l allowing the particle to leak from one duct to the other. This an idealized setup for several recently studied quantum-wire systems (see Refs. 19–22). Using a variational argument we shall show that such a system has always at least one bound state, i.e., an isolated eigenvalue below the threshold of the continuous spectrum. Moreover, the system can have any prescribed number of bound states provided the window width is chosen large enough. These conclusions follow from simple estimates; however, they tell us nothing about the corresponding wave functions and more detailed dependence of the bound-state energies on the parameters. To this aim, we shall formulate in Sec. IV a method to solve the problem numerically using the mode-matching technique. In particular, we shall discuss how the first eigenvalue emerges from the continuum as the window opens.

Interesting properties of the system are not exhausted by this. The coupling between the wave functions in the ''arms'' and the connecting region allows the particle to tunnel between different transverse modes, so the scattering matrix is nontrivial; one naturally expects it to have resonances

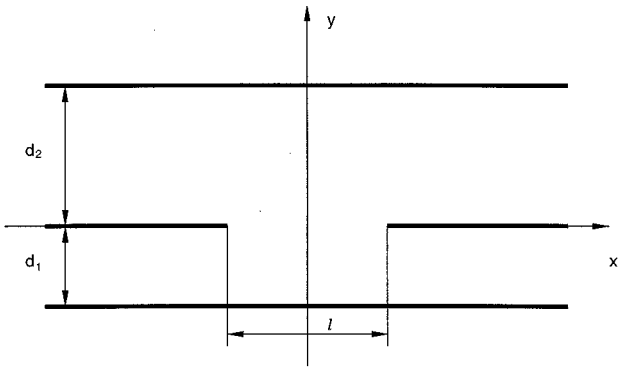

FIG. 1. Laterally coupled quantum waveguides.

with properties similar to those of the bound states below the first transverse-mode energy. It is not easy to prove the existence of such resonances, because there is no natural parameter in the problem which would make it possible to tune the intermode coupling. Neither the window width l nor the replacement of the ''empty'' window by an ''opaque'' one with a suitable point interaction as in Ref. 23 allow for a sensible perturbation theory, because in both cases the unperturbed bound state disappears as the coupling is switched out. Hence we rely again on a numerical analysis based on the mode-matching technique; the results confirm our expectation about the resonance character of the scattering and its dependence on parameters of the problem.

There is one more interesting aspect. The corresponding classical system of coupled ducts is pseudo-integrable, its phase space being of genus three. Other systems of that type have been recently studied;[24,25] it was shown that their quantum couterparts exhibit a chaotic behavior. One asks naturally whether a similar effect can be observed here. To find the level-spacing distribution of the bound states, a very wide window is needed to produce a large number of eigenvalues. At the same time, the spectrum has to be unfolded, i.e., rescaled so that the mean spacing does not change along it. The result suggests that the spacing distribution is then sharply localized around a fixed value; hence there is no chaos. This is not surprising, since all the bound-state wave functions have transversally the shape of the first mode; so effectively they correspond to a one-dimensional system. What is less trivial is that the spacing distribution of the scattering phase shifts also does not witness a fully developed chaos; this suggests that repeated reflections are an essential ingredient of the chaotic behavior of particles in bounded pseudo-integrable billiards.

The above mentioned scattering analysis relies on the stationary approach. The time evolution of wave packets deserves a separate study. In this article we limit ourselves to a single example: in the concluding section we present a numerical method to solve the corresponding time-dependent Schrödinger equation, which allows us to draw some qualitative conclusions about time delay in the scattering on the connecting window.

II. PRELIMINARIES

The system we are going to study is sketched in Fig. 1. We consider a Schrödinger particle whose motion is confined to a pair of parallel strips of widths d_1 and d_2, respectively. For definiteness we assume that they are placed to both sides of the x-axis, and they are separated by the Dirichlet boundary everywhere except in the interval $(-a,a)$; we shall denote this configuration space by Ω and $l:=2a$. Setting $\hbar^2/2m=1$, we may identify the particle Hamiltonian with the Dirichlet Laplacian,

$$H\equiv H(d_1,d_2;l):=-\Delta_D^{\Omega}, \tag{2.1}$$

on $L^2(\Omega)$ defined in the standard way (see Ref. 12, Sec. XIII.15). Since the boundary of Ω has the segment property, it acts as the usual Laplace operator with the Dirichlet condition at the boundary.

A simple bracketing argument[12] shows that H has bound states for all l large enough. Let us first introduce some notation. Set $d:=\max\{d_1,d_2\}$ and $D:=d_1+d_2$, and furthermore

$$\nu:=\frac{\min\{d_1,d_2\}}{\max\{d_1,d_2\}}.$$

We shall also use $\mu_d:=(\pi/d)^2$, with μ_D and μ_l corresponding in the same way to D and l, respectively. Cutting now Ω by the additional Neumann or Dirichlet boundaries parallel to the y-axis at $x=\pm a$, we get $H_t^{(N)}\oplus H_c^{(N)}\leqslant H\leqslant H_t^{(D)}\oplus H_c^{(D)}$, where the ''tail'' part corresponds to the four half strips and the rest to the central part with the Neumann and Dirichlet condition on the vertical boundaries, respectively.

Since $\sigma_{\rm ess}(H_t^{(j)})=[\mu_d,\infty)$, $j=N,D$, the same is by the minimax principle true for H, and possible isolated eigenvalues of H are squeezed between those of $H_c^{(j)}$, $j=N,D$. The Neumann estimate tells us that

$$\inf\,\sigma(H(d_1,d_2;l))\geqslant\mu_D=\mu_d(1+\nu)^{-2}. \tag{2.2}$$

On the other hand, H has an eigenvalue below μ_D provided $H_c^{(D)}$ does, which is true if $\mu_D+\mu_l\leqslant\mu_d$; this shows that a sufficient condition for $H(d_1,d_2;l)$ to have at least a bound state is that the length of the opening satisfies the inequality

$$l\geqslant\frac{d(1+\nu)}{\sqrt{\nu(\nu+2)}}. \tag{2.3}$$

If $\nu=1$, the coefficient on the right side is $2/\sqrt{3}\approx 1.155$; it grows as Ω becomes more asymmetric.

More generally, the number of eigenvalues of $H_c^{(D)}$ is $N_D:=[\sqrt{(\mu_d-\mu_D)/\mu_l}]$, where $[\cdot]$ denotes the entire part (recall that since $D\leqslant 2d$, the first transversally excited state is already above μ_d), while the number of ''Neumann'' eigenvalues is $N_N:=1+N_D$; this means that the number of bound states of $H(d_1,d_2;l)$ satisfies the inequality

$$\left[\frac{l}{d}\,\frac{\sqrt{\nu(\nu+2)}}{1+\nu}\right]\leqslant N\leqslant 1+\left[\frac{l}{d}\,\frac{\sqrt{\nu(\nu+2)}}{1+\nu}\right]. \tag{2.4}$$

We see that $H(d_1,d_2;l)$ has isolated eigenvalues, at least for l large enough, despite the absence of (a nonzero-measure set of) closed classical trajectories mentioned in the Introduction. In heuristic terms, this may be understood as a manifestation of the fact that the semi-infinite ''spikes'' of the open barrier between the two ducts are capable of reflecting a quantum particle due to a finite smearing of the wave packet. In the same way, one finds that the mth eigenvalue μ_m of $H(d_1,d_2;l)$ is estimated by

$$\left(\frac{m-1}{\lambda}\right)^2\leqslant\frac{\mu_m}{\mu_d}-\frac{1}{(1+\nu)^2}\leqslant\left(\frac{m}{\lambda}\right)^2, \tag{2.5}$$

where $\lambda:=l/d$, and that the critical value $\lambda_m\equiv l_m/d$ at which mth eigenvalue appears satisfies the bounds

$$\frac{(m-1)(1+\nu)}{\sqrt{\nu(\nu+2)}}\leqslant\lambda_m\leqslant\frac{m(1+\nu)}{\sqrt{\nu(\nu+2)}}. \tag{2.6}$$

To learn more about the dependence of the eigenvalues and the corresponding eigenfunctions on λ and ν, we have to use a different technique.

III. EXISTENCE OF BOUND STATES

The above existence argument giving Eq. (2.3) is a crude one; in fact, there is no lower bound on the window width as the following result shows:

Theorem: $H(d_1,d_2;l)$ has an isolated eigenvalue in $[\mu_D,\mu_d)$ for any $l>0$.

Proof: We modify for the present purpose the variational argument of Ref. 6; see also Ref. 8, Sec. 2. Without loss of generality we may assume that $d_2 \leqslant d_1 = d$. The transverse ground-state wave function is then

$$\chi_1(y) := \begin{cases} \sqrt{\dfrac{2}{d_1}} \sin(\kappa_1 y), & y \in (0,d_1), \\ 0, \quad \text{otherwise}, \end{cases}$$

where $\kappa_1 := \sqrt{\mu_d}$; similarly we define the transverse ground state in the opening,

$$\eta_1(y) := \sqrt{\frac{2}{D}} \sin[K_1(d_1-y)]$$

with $K_1 := \sqrt{\mu_D}$. For any $\Phi \in D(H)$ we set

$$q[\Phi] := \|H\Phi\|^2 - \mu_d \|\Phi\|^2$$

[if not marked explicitly, the norms always refer to $L^2(\Omega)$].

Since the essential spectrum of H starts at μ_d, we have to find a trial function Φ such that $q[\Phi]<0$; it has to belong to the form domain $Q(H)$, which means, in particular, that it must be continuous inside Ω but not necessarily smooth. Notice first that if $\Phi(x,y)=\varphi(x)\chi_1(y)$, we have

$$q[\Phi] = \|\varphi'\|^2_{L^2(\mathbb{R})}. \tag{3.1}$$

To make the longitudinal contribution to the kinetic energy small, we use an external scaling. We choose an interval $J := [-b,b]$ for a positive $b>a$ and a function $\varphi \in \mathcal{S}(\mathbb{R})$ such that $\varphi(x)=1$ if $x \in J$; then we define the family $\{\varphi_\sigma : \sigma>0\}$ by

$$\varphi_\sigma(x) := \begin{cases} \varphi(x), & |x| \leqslant b, \\ \varphi(\pm b + \sigma(x \mp b)), & |x| \geqslant b. \end{cases}$$

Finally, let us choose a localization function $j \in C_0^\infty((-a,a))$ and define

$$\Phi_{\sigma,\epsilon}(x,y) := \varphi_\sigma(x)[\chi_1(y) + \epsilon j(x)^2 \eta_1(y)] \tag{3.2}$$

for any $\sigma,\epsilon>0$. The main point of the construction is that we modify the factorized function we started with in two mutually disjoint regions, outside and inside the rectangle $J\times(-d_2,d_1)$. Hence the functions φ'_σ and j^2 have disjoint supports. Using this together with the identity

$$\|\varphi'_\sigma\|^2_{L^2(\mathbb{R})} = \sigma \|\varphi'\|^2_{L^2(\mathbb{R})}$$

and the explicit forms of the functions χ_1,η_1, we substitute Eq. (3.2) into Eq. (3.1) and find after a tedious but straightforward computation

$$q[\Phi_{\sigma,\epsilon}] = \sigma\|\varphi'\|^2_{L^2(\mathbb{R})} - 4\pi\epsilon d_1^{-3/2} D^{-1/2} \|j^2\|^2_{L^2(\mathbb{R})} \sin\left(\frac{\pi}{1+\nu}\right)$$

$$+ \epsilon^2 \{\|2jj'\|^2_{L^2(\mathbb{R})} - (\mu_d^2 - \mu_D^2)\|j^2\|^2_{L^2(\mathbb{R})}\}. \tag{3.3}$$

By construction, the last two terms on the right side of Eq. (3.3) are independent of σ. Moreover, the term linear in ϵ is negative (recall that $\nu \in (0,1]$), so choosing ϵ sufficiently small, we can make it dominate over the quadratic one. Finally, we fix this ϵ and choose a small enough σ to make the right side of Eq. (3.3) negative. ■

Remark: Though it is not the subject of the present article, we want to note that the same argument demonstrates existence of a bound state in a straight Dirichlet strip with an arbitrarily small protrusion; one has only to replace $J \times [-d_2, 0]$ by a rectangle contained in the protruded part. An alternative proof of this result has been given recently in Ref. 26; these authors also derived an asymptotic formula for the eigenvalue in terms of the protrusion volume.

IV. MODE MATCHING

To learn more about the eigenvalues and eigenfunctions in question, we shall now solve the corresponding Schrödinger equation numerically. Since Ω consists of several rectangular regions, the easiest way to do that is by the mode-matching method.

A. Symmetric case

Consider first the situation when $d_1 = d_2 = d$. The Hamiltonian (2.1) then decouples into an orthogonal sum of the even and the odd part, the spectrum of the latter being clearly trivial, i.e., the same as in the case $l = 0$. At the same time, the mirror symmetry with respect to the y-axis allows us to consider separately the symmetric and antisymmetric solutions.

We may therefore restrict ourselves to the part of Ω in the first quadrant, with the Neumann boundary condition in the segment $(0,a)$ of the x-axis, and Neumann or Dirichlet condition in the segment $(0,d)$ of the y-axis. We expand the sought solutions in terms of corresponding transverse eigenfunctions

$$\chi_j(y) := \sqrt{\frac{2}{d}} \sin(\kappa_j y), \quad j = 1,2,\ldots, \tag{4.1}$$

$$\phi_j(y) := \sqrt{2}\,\eta_{2j-1}(y) = \sqrt{\frac{2}{d}} \sin[K_{2j-1}(d-y)], \quad j = 1,2,\ldots, \tag{4.2}$$

where $\kappa_j := j\kappa_1$ and $K_{2j-1} := (2j-1)K_1$. A natural Ansatz for the solution of an energy $\epsilon\mu_d$, $\frac{1}{4} \leqslant \epsilon < 1$, is

$$\psi(x,y) = \sum_{j=1}^{\infty} b_j e^{q_j(a-x)} \chi_j(y) \tag{4.3}$$

for $x \geqslant a$, where $q_j := \kappa_1 \sqrt{j^2 - \epsilon}$, and

$$\psi_{\mathrm{s}}(x,y) = \sum_{j=1}^{\infty} a_j \frac{\cosh(p_j x)}{\cosh(p_j a)} \phi_j(y), \quad \psi_{\mathrm{as}}(x,y) = \sum_{j=1}^{\infty} a_j \frac{\sinh(p_j x)}{\sinh(p_j a)} \phi_j(y) \tag{4.4}$$

for $0 \leqslant x \leqslant a$ and the symmetric and antisymmetric cases, respectively, where the longitudinal momentum is defined by $p_j := \kappa_1 \sqrt{(j-\frac{1}{2})^2 - \epsilon}$. It is straightforward to compute the norms of the functions (4.3) and (4.4); since $j^{-1}q_j$ and $j^{-1}p_j$ tend to μ_d as $j \to \infty$, the square integrability of ψ requires the sequences $\{a_j\}$ and $\{b_j\}$ to belong to the space $l^2(j^{-1})$.

As an element of the domain of H, the function ψ should be continuous together with its normal derivative at the segment dividing the two regions, $x = a$. Let us first solve this condition formally. The continuity means $\Sigma_{k=1}^{\infty} a_k \phi_k(y) = \Sigma_{k=1}^{\infty} b_k \chi_k(y)$; using the orthonormality of $\{\chi_j\}$ we get from here

$$b_j = \sum_{k=1}^{\infty} a_k (\chi_j, \phi_k). \tag{4.5}$$

In the same way, the normal-derivative continuity at $x = a$ yields

$$q_j b_j + \sum_{k=1}^{\infty} a_k p_k \tanh(p_k a)(\chi_j, \phi_k) = 0 \tag{4.6}$$

in the Neumann case, and the analogous relation with tanh replaced by coth for Dirichlet. Substituting from Eq. (4.5) to Eq. (4.6), we can write the equation as

$$Ca = 0, \tag{4.7}$$

where

$$C_{jk} := \left(q_j + p_k \left\{ \begin{matrix} \tanh \\ \coth \end{matrix} \right\} (p_k a) \right) (\chi_j, \phi_k) \tag{4.8}$$

in the Neumann and Dirichlet case, respectively, with the two orthonormal bases related by

$$(\chi_j, \phi_k) = \frac{(-1)^{j-k}}{\pi} \frac{2j}{j^2 - (k-\frac{1}{2})^2}. \tag{4.9}$$

One has to make sure, of course, that Eq. (4.8) makes sense, and that one can solve it by a sequence of truncations. It is possible to follow the procedure formulated in Ref. 4. A more direct way, however, is to notice that if ψ is an eigenvector of H, it must belong to the domain of any integer power of this operator. It is easy to check that $\psi \in D(H^n)$ iff $\{a_j\}, \{b_j\} \in l^2(j^{2n-1})$; hence the sought sequences should belong to $l^2(j^s)$ for all $s \geqslant -1$. This fact also justifies *a posteriori* the interchange of summation and differentiation we have made in the matching procedure.

Consider now the diagonal operator S_r on $l^2(j^{-1})$, $(S_r a)_j := j^{-r} a_j$. If C has zero eigenvalue with a fast decaying eigenvector, the same is true for $C^{(s,r)} := S_s C S_r$ with arbitrary non-negative s, r. The last named operator is represented by the matrix

$$C_{jk}^{(s,r)} := [q_j + p_k \tanh(p_k a)] \frac{(-1)^{j-k}}{\pi} \frac{2 j^{1-s} k^{-r}}{j^2 - (k-\frac{1}{2})^2}$$

(for the sake of brevity, we speak about the Neumann case only), so it is Hilbert–Schmidt case for r, s large enough, and its eigenvalues can therefore be obtained from a sequence of truncated operators. Since finite matrices pose no convergence problems, the truncation procedure may be applied to the operator C directly.

Of course, $C^{(r,s)}$ may have eigenvectors to which no square-summable eigenvector of C corresponds, because S_r^{-1} is unbounded for $r>0$. Fortunately, the search for solutions may be terminated once we find the number of them which saturates the upper bound derived in Sec. II.

B. Alternative method

A natural modification of the above described procedure is to express $\{a_k\}$ from Eq. (4.5) using the orthonormality of $\{\phi_k\}$, and to substitute it into Eq. (4.6); then the spectral condition acquires the form

$$b + Kb = 0, \tag{4.10}$$

where

$$K_{jm} := \frac{1}{q_j} \sum_{k=1}^{\infty} (\chi_j, \phi_k) p_k \tanh(p_k a)(\phi_k, \chi_m), \tag{4.11}$$

and the same with $\coth(p_k a)$ in the Dirichlet case.
