(Received 26 February 1999; accepted for publication 19 May 1999)

The problem considered here is to find a function satisfying a linear elliptic differential or integral equation inside a finite simply region V and another linear first-order differential or integral equation on the ∂V boundary. The symmetries of the above problem form a point group. We show that if the homogeneous problem has only the trivial solution, then the symmetry of the solution inside V inherits the symmetry of the boundary value, given on ∂V. The boundary value is decomposed into irreducible components and the physical meaning of the irreducible components is highlighted. We then apply the results to investigate a widely utilized numerical solution technique that is based on a variational principle and utilizes two approximations. The first one approximates, the solution inside V by a polynomial, the second approximation assumes the solution on the boundary to be a low-order polynomial. By means of group representation theory, we show that the mentioned approximations may fail for certain combinations. The predicted problems have been observed in the VARIANT code, which is routinely used to solve the multigroup neutron diffusion equation. Our method is also applicable to the Schrödinger, and to heat conductance and wave equations. [S0022-2488(99)02610-9]

I. MOTIVATION

In the main fields of the authors, in neutron physics, we are looking for numerical techniques to solve the multigroup neutron diffusion equation in a large volume V of mosaic-like structure. One of the final goals is to work out real-time simulator models, where a computer program simulates a nuclear reactor. These days, the state of the art of reactor physics allows only for either a crude but real time or a fine but slow modeling of a power reactor core. Thus, acceleration methods are sought.

It is known that given a group G, the domain of which includes the solution space $\mathcal{L}$, we can split $\mathcal{L}$ into $|G|$ orthogonal subspace.[1] Since most numerical models arrive at a set of linear equations,[2] the obvious thing is to exploit the splitting offered by G. Furthermore, if G leaves the equation invariant, we can evaluate certain matrix elements easily.[3] In some cases we may hope to split the problem into independent subproblems.

In the investigations below, we focus on second-order equations (Schrödinger, heat conductance, diffusion, wave equation, etc), where the physical parameters (potential, heat conductance, diffusion constant, etc.) are regionwise constant and finite in V. In such cases[2] the solution of a boundary value problem is continuous at internal material interfaces, and the normal gradient of the solution is also continuous. The solution of the problem is unique. What is usually not unique is the solution to the associated eigenvalue problem, where we require some linear expression of the solution to become zero at the boundary. For some equations, however, the solution is unique

[a)]Electronic mail: makai@sunserv.kfki.hu
[b)]Electronic mail: YOrechwa@aol.com

up to a constant multiplication factor, and even positive inside the investigated volume.[4]

The symmetry group of the equation[5,6] can play the role of group G. In a finite volume V, the symmetries of the problem make a point group. The question is, how can we exploit that the solution space is split into orthogonal components? First, we find out, under what conditions the solution will possess the same symmetries as those of the boundary value. For a given class of operators, the solution inside V will be shown to inherit the symmetries of the boundary value on ∂V. Hence, for those operators the decomposition of the boundary value into irreducible components entails a decomposition of the solution inside V. In other words, V can be characterized by the solutions developing in response to some model boundary conditions. Those responses can be calculated beforehand and an effective iteration can be worked out in order to solve the boundary value problem.

When solving practical problems, we often resort to numerical methods.[7] A natural iteration is organized as follows. V is subdivided into smaller volumes called nodes. We sweep through the nodes one by one. Since the boundary sources determine the solution, first we collect the solution on the boundary using the continuity condition at internal boundaries and the boundary condition at an external boundary. We can approximate the solution on the boundary by low-order polynomials. The solution inside the node may again be approximated by some polynomials and, from the solution, we reevaluate the solution and its gradient at the boundaries and pass on to the next node. This procedure is often applied not to the solution, but to a linear combination of the solution and its normal gradient. This specific iterative method[8] is based on variational principles and runs into convergence problems. With the help of group theory, we can predict what kinds of approximations will lead to a convergence problem.

The structure of the paper is as follows. In Sec. II, the investigated boundary value problem is defined. The symmetries of a boundary problem[9] and their consequences are dealt with in Sec. III. A generally utilized iteration scheme is described in Sec. IV. Applications to neutron diffusion are provided in Sec. V. In Sec. VI we offer a number of concluding remarks.

II. THE PROBLEM

Throughout the present work, we consider the following boundary value problem:

$$\begin{aligned} \mathbf{A}\Psi(r) &= Q(r), \quad r \in V; \\ \mathbf{B}\Psi(x) &= q(x), \quad x \in \partial V, \end{aligned} \tag{1}$$

where V is a finite simply connected volume; its boundary is ∂V. $Q(r)$ is the external source in V, $q(x)$ is a given function on the boundary ∂V. Operator $\mathbf{A}$ is a linear, second-order differential operator in the space variable x, $\mathbf{B}$ is a linear, first-order differential operator. If $\mathbf{A}$ and $\mathbf{B}$ involve space-dependent functions, representing material properties, those functions are continuous, smooth functions of x. We assume that either $Q \neq 0$ or $q \neq 0$.

We assume, furthermore, that the homogeneous problem, with $Q=0$ and $q=0$, has no nontrivial solution. Under the stipulated conditions, the Fredholm alternative theorem ensures that the boundary value problem has a unique solution.[10] Volume V is often subdivided into parts that we call nodes, and inside a node the material properties are assumed as constant in x. In this case, the solution and its suitable normal derivative is continuous at internal material interfaces. Such problems are plentiful in mathematical physics.

Example 1: The first problem, which is mainly dealt with in this paper, is the multigroup neutron diffusion equation:[2]

$$\mathbf{A} = -\nabla^2 \underline{\Psi}(r) + S\underline{\Psi}(r), \tag{2}$$

where

$$S_{gg'} = (\Sigma_g - \chi_g \nu \Sigma_{fg'} - \Sigma_{sg'-g})/D_g. \tag{3}$$

Here subscript g refers to the neutron's energy (energy group index), D_g is the diffusion constant in energy group g, Σ_g is the removal cross section in group g, $\nu\Sigma_{fg}$ is the production cross section, Σ_{sgg} is the scattering cross section, and χ_g is the fission spectrum in energy group g. The solution $\underline{\Psi}$ is called neutron flux, it is a vector, its component Ψ_g gives the neutron flux in energy group g. The normal component of the net current is $J_g(x) = -D_g \boldsymbol{\nabla} \mathbf{n} \Psi_g(x)$, where $\mathbf{n}$ is the normal direction. The solution of problem (1) is positive provided $Q(r)$ and $q(x)$ are positive functions. Operator $\mathbf{B}$ may fix the flux, its normal gradient, or their linear combination.

Example 2: The Schrödinger equation.[11] A particle of mass m_0 moves in a potential field $V(x)$. The particle wave function is $\Psi(x)$, satisfying the Schrödinger equation:

$$\mathbf{A} = -\frac{\hbar^2}{2m_0}\nabla^2\Psi(r) + V(r)\Psi(r). \tag{4}$$

When a finite region is considered, the boundary condition may be $\Psi(x)=0$ on the boundary.

Analogous problems emerge in heat conductance, wave propagation, time-dependent diffusion, and in linear Boltzmann particle transport.[12]

Often we solve problem (1) iteratively. The solution and its normal derivatives are continuous at internal interfaces. With the help of the Green's function, the normal derivative on the boundary can be expressed by the solution on the boundary. The boundary currents can be expressed by boundary fluxes; this permits one to eliminate the gradients and to iterate only for the solution at internal boundaries. The continuity condition leads to a fix point problem; we have to find the fixed point of a set of equations.

III. SYMMETRIES OF BOUNDARY VALUE PROBLEMS

Consider a linear operator $\mathbf{A}$ acting on the function space $L_2(V)$, where V is a symmetric convex region. For a boundary condition problem, we assume linear operator $\mathbf{B}$ to form a function given on the boundary. The range of operator $\mathbf{A}$ includes V; the range of operator $\mathbf{B}$ includes the boundary ∂V. The operators commuting with $\mathbf{A}$ and $\mathbf{B}$ form the groups, G_A and G_B, respectively. Let G_V denote the symmetry group of V. The boundary value problem (BVP) is then determined by $(V, \mathbf{A}, \mathbf{B})$. We define the symmetry of the boundary value problem as follows.

Definition 1: A linear operator $\mathbf{P}$ *is said to be the symmetry of the boundary value problem* $(V, \mathbf{A}, \mathbf{B})$ *if (a)* $\mathbf{P}$ *transforms V into itself; (b)* $\mathbf{P}$ *and* $\mathbf{A}$ *commute:* $\mathbf{PA}=\mathbf{AP}$; *(c)* $\mathbf{P}$ *and* $\mathbf{B}$ *commute:* $\mathbf{PB}=\mathbf{BP}$. The symmetry group of the problem $(V, \mathbf{A}, \mathbf{B})$ is the intersection

$$G = G_V \cap G_A \cap G_B,$$

where G_V, G_A, and G_B are the symmetry groups of V, $\mathbf{A}$ and $\mathbf{B}$, respectively.

The symmetries of problem $(V, \mathbf{A}, \mathbf{B})$ form a group. This group may consist of a single element, the identity transformation, or of an infinite number of symmetries. This partly depends on operators $\mathbf{A}$ and $\mathbf{B}$. In a number of cases, it suffices to ensure that $\mathbf{P}$ commutes with $\mathbf{A}$; then it commutes with $\mathbf{B}$ as well. Often $\mathbf{B}$ is the identity transformation (Cauchy-type problem) or the normal gradient (Neumann-type problem), or a linear combination of these two operators. Most boundary value problems of reactor physics belong to one of these.

The symmetries of the boundary condition problem $(V, \mathbf{A}, \mathbf{B})$ suggest the application of point group theoretic techniques. Depending on the problem, the symmetries may form, for example, a discrete group or a Lie group. The symmetries can also be arranged into conjugacy classes[13] to which the results of group representation theory apply. Thus, by means of a projection operator (A6), any function can be decomposed into functions transforming according to the irreducible representations (irreps). First, we investigate some of the basic properties of the irreps.

According to projection operator (A6), the irrep f_i of a function f is a linear expression of f taken at different points in the range of f. Consequently, if f is n times differentiable, so is the irrep f_i. Let $f_i(\theta)$ be given in the interval $\theta \in [0, \pi/2n_F)$.

Definition 2: The $[0,\pi/2n_F)$ *interval is closed from the left and open from the right and is called the ground (where* n_F *is the number of faces of* V*).*

The direction $\theta=\pi/2n_F$ is a symmetry axis, and the character table tells us that f_i is an eigenvector of each symmetry operator, with the eigenvalue given in the ith row of the character table and in the column corresponding to the symmetry, thus, by applying a reflection through the face to f_i, we can obtain the function f_i in the range $[0,n_F)$. Here [,) denotes an interval closed from the left and open from the right. Now, applying the rotational symmetry of V, the $f_i(\theta)$ function is obtained for the entire $[0,2\pi]$ interval. When f_i is a component of a two-dimensional representation, more care is needed because the components may transform into each other. Thus, we arrive at the following statement.

Lemma 1: Let f be a given function on the boundary ∂V*. If* $f(\theta)$ *belongs to* C^n*, then its irreps* $f_i(\theta)$ *determined by (A6) also belong to* C^n*. The irrep* $f_i(\theta)$*,* $0\leqslant\theta\leqslant 2\pi$ *is uniquely given by its value in the ground* $[0,\pi/2n_F)$*.*

Thus, the ground is the quotient manifold V/G. The first question is the following: If we have a decomposition of the boundary condition, do we also have a decomposition of the solution? What can we gain by such a decomposition of the solution?

Basic Lemma. Let the problem

$$\begin{aligned} A\varphi&=0, \quad \text{in } V,\\ B\varphi&=f, \quad \text{on } \partial V, \end{aligned} \tag{5}$$

be given, and the linear operators **A** *and* **B** *be such that (a) when* $f=0$*, the only solution is* $\varphi=0$*, i.e., the homogeneous problem has only the identically zero function as the solution; (b) the null space of operator* **B** *is empty, i.e., if* $\mathbf{B}\varphi=0$ *then* $\varphi=0$*.*

Then, if f transforms according to the ith irreducible representation on the boundary, the solution transforms according to the ith irreducible representation inside V*.*

Proof: Let $f=f_i$ be a one-dimensional irreducible representation and φ_i the corresponding solution. Then, for any symmetry **P** we have $\mathbf{P}f_i=\alpha_i f_i$. Applying **P** to the second equation and making use of the commutation of **P** and **B**, we get $\mathbf{PB}\varphi_i=\mathbf{BP}\varphi_i=\alpha_i\mathbf{B}\varphi_i=\alpha_i f_i$. Applying **P** to the first equation, we get $\mathbf{PA}\varphi_i=\mathbf{AP}\varphi_i=0$. Multiplying the first equation by α_i, and because **A** is linear, we also have $\mathbf{A}(\alpha_i,\varphi_i)=0$. Thus, we have the following equations for $(\mathbf{P}\varphi_i-\alpha_i\varphi_i)$:

$$\begin{aligned} \mathbf{A}(\mathbf{P}\varphi_i-\alpha_i\varphi_i)&=0, \quad \text{in } V\\ \mathbf{B}(\mathbf{P}\varphi_i-\alpha_i\varphi_i)&=0, \quad \text{on } \partial V, \end{aligned} \tag{6}$$

but according to assumption (a), the only solution is $(\mathbf{P}\varphi_i-\alpha_i\varphi_i)=0$, which proves the statement for a one-dimensional representation. Note that the second equation above is not true unless assumption (b) is met.

Let $f=f_i$ be a component of a two- or three-dimensional representation, i.e., it transforms as

$$\mathbf{P}f_i=\sum_k P_{ik}f_k.$$

The boundary condition (BC) for each component k is given by $\mathbf{B}\varphi_k=f_k$. Multiplying that equation by P_{ik} and summing over k, **B** being linear, we have

$$\mathbf{B}\left(\sum_k P_{ik}\varphi_k\right)=\sum_k P_{ik}f_k.$$

Multiplying the second equation of the problem by **P**, and using the linearity of **B**, we have

$$\mathbf{PB}\varphi_i = \mathbf{BP}\varphi_i = \sum_k P_{ik} f_k .$$

Subtracting the last two equations, we get, by means of assumption (b),

$$\mathbf{B}\left(\mathbf{P}\varphi_i - \sum_k P_{ik}\varphi_k \right) = 0;$$

thus φ_i transforms as the ith column of a multidimensional representation on ∂V.

As to the transformation rules in V, if we multiply the first equation in (6) by P_{ik}, sum over k on one hand, and on the other we multiply the equation again by $\mathbf{P}$ and subtract the two. We have

$$\mathbf{A}\left(\mathbf{P}\varphi_i - \sum_k P_{ik}\varphi_k \right) = 0.$$

The last two equations form a BVP, the only solution of which is identically zero. This completes the proof. It should be noted that the second step of the proof also includes the first step.

Corollary: By virtue of the linearity of the problem, when a volumetric source Q is included, the solution to

$$\mathbf{A}\Phi_Q = Q, \quad in \ \ V,$$

$$\mathbf{B}\Phi_Q = f, \quad on \ \ \partial V,$$

is given by $\Phi_Q = \Phi + \Psi$, *where* Φ *is the solution of (5) and* Ψ *is the solution of*

$$\mathbf{A}\Psi = Q, \quad in \ \ V,$$

$$\mathbf{B}\Psi = 0, \quad on \ \ \partial V.$$

Applying the argument used in the proof of the Basic Lemma, we arrive at the following result. Let q_i be the ith irreducible component of Q. Then, an irreducible decomposition of the solution is $\Phi_Q = \Psi_i + \Phi_{i,}$ where

$$\begin{aligned} \mathbf{A}\Psi_i &= q_i \quad in \ \ V, \\ \mathbf{B}\Psi_i &= 0, \quad on \ \ \partial V, \end{aligned} \tag{5'}$$

and

$$\begin{aligned} \mathbf{A}\Phi_i &= 0, \quad in \ \ V, \\ \mathbf{B}\Phi_i &= f_i , \quad on \ \ \partial V. \end{aligned} \tag{5''}$$

The Basic Lemma allows one to find suitable representations for the boundary values on ∂V and for the solution in V. The general prescription is to find suitable representations with which a general function—given along the boundary—is decomposed into irreps, and then to solve the above equations for the components. To this end, projector (A6) is applied. Here we set out the following notation. A point x on the ∂V boundary of the simply connected volume V is characterized by an angle θ measured from a suitable center inside V. We assume, furthermore, that ∂V consists of n_F faces. When V is a regular triangle, square, hexagon, or pentagon, the faces are of equal length or area and there are $2n_F$ symmetry transformations leaving V invariant. Now the

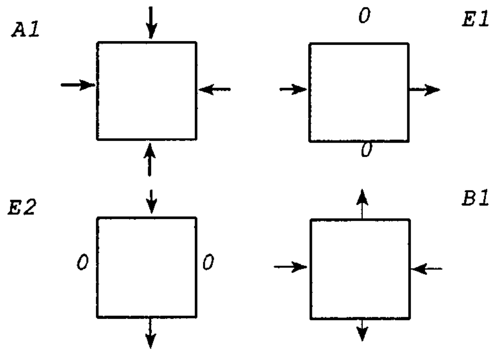

FIG. 1. Irreducible entering current patterns for a square node.

symmetries of the problem transform one point of the boundary into another boundary point. Thus, projector (A6) applied to a function $f(\theta)$ will give linear combinations of $f(\theta)$, $i=1, 2n_F$, and, the θ_i points belong to one orbit.

Lemma 2: The irreps of a boundary value $f(\theta)$ take the form

$$f_i(\theta)=m_i(\theta \bmod \pi/n_F)e_i\left(\left[\frac{\theta}{\pi}n_F\right]\right), \tag{7}$$

where [ ] denotes the entire part, and the function e_i ( ) takes only integer values, furthermore, the m_i function is not identically zero on the ground.

Proof: The irrep $f_i(\theta)$ is projected out according to Eq. (A6), therefore it is a linear combination of $P_{O_i}*f(\theta)=f(\mathbf{O}_i*\theta)$, $\mathbf{O}_i\in G$. The transformed points under the elements of group G form an orbit. The orbits crossing different points of the ground are equivalent, hence the entire ground can be treated as a single unit. $f_i(\theta)$ will transform as the ith column of an irreducible representation only when $f_i(\theta)$ takes the value in the ground multiplied by a constant for each transform of the ground. In other words, $f_i(\theta)$ is given by a nonzero distribution in the ground, and the amplitudes in each transform along the path V/G. This is precisely Eq. (7), thus, the lemma is proven. As a consequence of Lemma 2, we may characterize the irreps of a function given along the boundary by a vector e_i, which is composed of the $2n_F$ values taken by the function $e_i(\theta)$, $0\leqslant\theta\leqslant 2\pi$.

The irreps of the boundary condition have an important physical meaning: The irreps then depend on the shape of V. Since physical meaning is more transparent in a simple geometrical shape, let us consider the irreps of a square shaped V (see Fig. 1). They represent characteristic ambiances into which the volume under consideration is imbedded. The first one represents a homogeneous ambiance, the second and third one an x and a y directed gradient, respectively, and the fourth one a second derivative. To illustrate the impact of the geometrical shape of V on the irreducible boundary condition components, we introduce the irreps for a regular hexagon-shaped volume (see Fig. 2). Evidently, the six faces allow for a wider variety of ''gradients.''

We would just mention here that when we determine the energy of a charged body in the presence of an external electric potential field, we use an analogous decomposition.[14] The $\varphi(x)$ potential obeys the Poisson equation. In homogeneous space, the symmetry group of the Laplace operator is the rotation group; the irreducible basis functions are the spherical harmonics. If the charge distribution $e(x)$ and the potential $\varphi(x)$ are expanded in terms of the spherical harmonics Y_{lm}, we get

$$\varphi(x)=\sum_{l,m} a_{lm}Y_{lm}; \quad e(x)=\sum_{k,n} Q_{kn}Y_{kn},$$

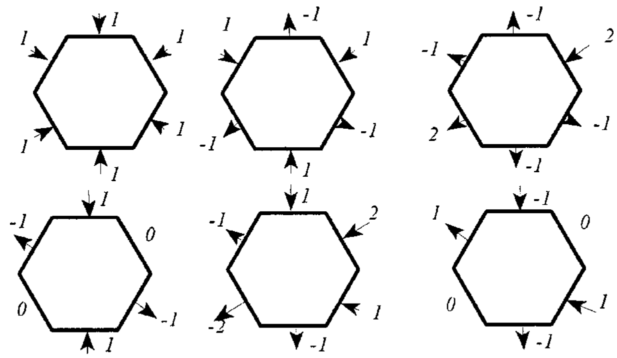

FIG. 2. Irreducible entering current patterns for a regular hexagon.

$$U=\int_V \varphi(x)e(x)dx=\sum_{l,m} a_{lm}Q_{lm}, \tag{8}$$

because the spherical harmonics form an orthonormal set. The terms in the sum correspond to the multipole (monopole, dipole, quadrupole, etc.) expansion. In Eqs. (5′) and (5″), the analogous symmetry components (irreducible representations) of the components are given. In those expressions, however, the external components (f_i and q_i) and the internal components (Ψ_i and Φ_i) are not separated explicitly.

IV. THE ITERATION

Now let us turn to the iterative solution of problem (1): more precisely, instead of problem (1), we deal with the associated eigenvalue problem, which has a distinguished role in neutron physics. Consider the following problem:

$$\begin{aligned} \mathbf{A}(k)\Phi(r)&=0, \quad r\in V,\\ \mathbf{B}\Phi(x)&=0, \quad x\in\partial V, \end{aligned} \tag{9}$$

where $\mathbf{A}(k)=\mathbf{A}^{(1)}+1/k^*\mathbf{A}^{(2)}$, and V is convex and composed of homogeneous regions:

$$V=\bigcup_{j=1}^{N} V_j,$$

where regions j and j' are disjoint except for the joint boundary $\partial V_{jj'}$. N is the number of homogeneous regions. Let ∂V_j denote the boundary of region (or node) j; then

$$V_j\cap V_{j'}=\partial V_{jj'}=(\partial V_j)\cap(\partial V_{j'}).$$

A boundary ∂V_j is called an external boundary, if

$$\partial V_j\cap\partial V=\partial V_j.$$

If ∂V_j is not external, then it is an internal boundary. $\mathbf{A}(k)$ and $\mathbf{B}$ are linear operators. Both $\mathbf{A}(k)$ and $\mathbf{B}$ may involve functions as coefficients.

In volume j, the equation to be solved is written as

$$\mathbf{A}_j(k)\Phi_j(r)=0.$$

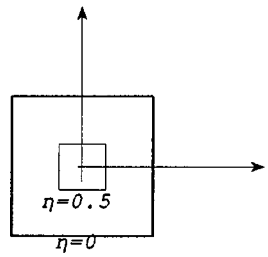

FIG. 3. Coordinate system in a node.

where subscript j refers to region j in which the coefficients associated with each $\mathbf{A}_j$ may be different. We assume, furthermore, the existence of a value of parameter k which turns the largest eigenvalue of $\mathbf{A}(k)$ into zero. The associated eigenfunction is non-negative.

On external boundaries, operator $\mathbf{B}$ involves only linear expressions:

$$\mathbf{B}\Phi = a_j \int_{\partial V_j} \Phi_j(x) dF_j + b_j \int_{\partial V_j} \partial_n \Phi_j(x) dF_j = 0.$$

Here a_j and b_j are constants. In problem (1), we have two types of approximations: the first is of the neutron distribution function inside the node, the second of the neutron distribution function on the surface of the node. Let the basis function set in node n be $[f_i(r),\ i=1,...,N_v]$ and on the surface ∂V_n $(h_j(x),\ j=1,...,N_s)$. Let us expand the solution inside a given node as

$$\Phi(r) = \sum_{i=1}^{N_v} \zeta_i f_i(r), \tag{10}$$

and on the surface of the node as

$$\Phi(x) = \sum_{i=1}^{N_s} \chi_j h_j(x). \tag{11}$$

Here the node index is suppressed; the N_v and N_s are the same for every node. The space variable inside the node is r; on the surface it is x. Thus, in general, we need a new coordinate (η) expressing how far a point is from the boundary. We use the coordinate system of Fig. 3. The boundary is given by $\eta=0$ and $\eta=1$ is the center of the node. Thus, in general, $r=(x,\eta)$ and on the boundary $\eta=0$. The $\eta=\text{const}$ lines are parallel to the volume's surface.

The two approximations [i.e., Eqs. (10) and (11)] are not independent, because when η tends to zero, the trial functions $f_i(r)$ must be expressible with the help of the trial functions $h_j(x)$:

$$f_i(x,0) = \sum_{j=1}^{N_s} b_{ij} h_j(x); \tag{12}$$

thus

$$\chi_j = \sum_{i=1}^{N_v} b_{ij} \zeta_i . \tag{13}$$

If condition (12) does not hold, the approximation is not self-consistent.

Let us express the volumetric source with the help of the basis functions as

$$S(r)=\sum_{i=1}^{N_v} f_i(r)s_i. \tag{14}$$

In this expansion and in the following we use the dot product, defined as

$$(f,g)_{V_n}=\int_{V_n} f(r)g(r)dV. \tag{15}$$

With the matrices

$$\mathbf{A}_{ij}=(f_i(r),\mathbf{A}f_j(r))_{V_n}, \tag{16}$$

and

$$\mathbf{B}_{ij}=(h_i(x),\mathbf{B}f_j(x,0))_{\partial V_n}=b_{ij}, \tag{17}$$

problem (1) is cast into the following form (see Ref. 8 for details):

$$\mathbf{A}\zeta=\mathbf{s}-\mathbf{M}\chi, \tag{18}$$

where ζ denotes the solution to the source problem,

$$\mathbf{A}\zeta=\mathbf{s}, \quad \textit{inside} \;\; V;$$

$$\mathbf{B}\zeta=0, \quad \textit{on} \;\; 2 \;\; \partial V, \tag{19}$$

and a particular solution to the nonhomogeneous problem is $\mathbf{M}_\chi$.

$$\mathbf{AM}\chi=0, \quad \mathbf{BM}\chi=\chi. \tag{20}$$

From the second line of Eq. (20), we get $\mathbf{M}=\mathbf{B}^{-1}$. This assumes that matrix b_{if} in expression (12) is invertible. In that case $\mathbf{M}_\chi$ is an interpolation: it interpolates the solution in the interior of the node from the values given on the boundary. The iteration may sweep through the nodes, starting out from a sensible initial guess. The first step in a new sweep is to solve Eq. (20) in the actual node, so we first collect χ on the boundary of the actual node using the continuity conditions. The new solution is $(\zeta+\mathbf{M}_\chi)$. From this, we determine the updated boundary values and pass on to the next node.

The iterative solution based on Eqs. (18)–(20) will be explored by symmetry considerations.[15] If there are transformations mapping the node into itself, these transformations form a group commuting with operators **A** and **B**. Such a group generates a splitting of the solution space into linearly independent subspaces. Operators **A** and **B** transform the elements of each subspace only among themselves, thus, the mentioned subspaces remain linearly independent when applying either operator to an element of the solution space. The main idea is as follows. Since the currents and fluxes are continuous at material interfaces, so is their arbitrary linear combination. We introduce the entering current $J^+=1/4(\Phi+2J)$ and the exiting current $J^-=1/4(\Phi-2J)$. We collect the fluxes, currents, and entering and exiting currents into vectors of n_F elements:

$$\underline{J}=(J_1,\ldots,J_{n_F}); \quad \underline{\Phi}=(\Phi_1,\ldots,\Phi_{n_F}),$$

$$\underline{J}^+=(J_1^+,\ldots,J_{n_F}^+); \quad \underline{J}^-=(J_1^-,\ldots,J_{n_F}^-).$$

If the iteration goes as

$$\underline{I}^{+}=\mathbf{T}\underline{I}^{-}=(1+2\mathbf{R})(1-2\mathbf{R})^{-1}\underline{I}^{-} \tag{21a}$$

or

$$\underline{J}=\mathbf{R}\underline{\Phi}, \tag{21b}$$

and there is a symmetrical matrix $\mathbf{M}$ such that $\mathbf{MR}=\mathbf{RM}$, then the eigenvectors of $\mathbf{M}$ form a suitable basis function set to expand the quantities involved in the iteration:

$$\mathbf{M}\underline{e}_i=\lambda_i\underline{e}_i,$$

$$\underline{\Phi}=\sum_i f_i\underline{e}_i; \quad \underline{J}=\sum_i g_i\underline{e}_i,$$

and on the new basis, $\mathbf{R}$ and $\mathbf{T}$ will be diagonal:

$$g_i=(\mathbf{MRM}^{-1})_i f_i.$$

The iteration proceeds as follows. From the flux on the boundary, the solution inside is determined. In the next step, the new current on the boundary is calculated from the inside solution. If there is an i such that $f_i\neq 0$ but $g_i=0$, then we get $\mathbf{R}=0$ and $\mathbf{T}=1$, indicating that in $(\underline{J}^{+},\underline{J}^{-})$ no convergence will occur.

Our purpose in the investigation is to find a relationship between two apparently independent approximations. What is the relationship between the approximation of the volumetric and surface source terms? The numerical method[16] implemented in VARIANT allows for two independent approximations for the two terms, but in certain cases the procedure did not converge. In these cases a nonvanishing, small error was observed[17] in the solution, furthermore, the phenomenon disappeared when a sufficiently high-order approximation was applied inside the node.

V. APPLICATION TO POLYNOMIAL APPROXIMATION

A. Square node

In a symmetric volume, the elements of the group G will play the role of matrix $\mathbf{M}$. The eigenvectors $\underline{e}_i$ are simultaneous eigenvectors of the elements in G. Eventually, the symmetries of the node permit one to classify the solution into different components. According to Eqs. (5′) and (5″) in Sec. II, the internal solution contains a given component only if that component is present either in the source or in the boundary condition. If a component is missing from the solution but is present in the boundary condition, it may cause numerical problems. This phenomenon is caused by solutions of the problem, which have zero average both over the node and over the entire node boundary. Such solutions do not contribute to the balance but may lead to an erroneous solution.

Before assessing the boundary value problems, a few general statements are set forth. The symmetry analysis of the solution of BVPs is given in Sec. III. We repeat briefly two things.

(i) An irreducible component is simultaneously an eigenfunction of every symmetry, and any function can be decomposed into irreducible components.

(ii) Applying the symmetries to a function, we get the same function at symmetric positions.

An irreducible component is a linear combination of the function under consideration taken at symmetric positions. Now we introduce the response matrix in order to eliminate the boundary currents and to set up an iteration for the boundary fluxes.

Definition 1: Let $\mathbf{u}=(u_1,\ldots,u_{nF})$ and $\boldsymbol{\nu}=(v_1,\ldots,v_{nF})$ be the respective values of function u and v on the n_F faces. Both functions are formed from the flux by linear operations commuting with the symmetries of the node. The matrix $\mathbf{R}$ relates $\mathbf{u}$ and $\boldsymbol{\nu}$ as

$$\mathbf{u}=\mathbf{R}\mathbf{v}, \tag{22}$$

TABLE I. Irreps of spatial polynomials in a square.

Vector	Polynomials
e_1	$1,(x^2+y^2),(x^4+y^4),x^2y^2$
e_2	(x^3y-y^3x)
e_3	$(x^2-y^2),(x^4-y^4)$
e_4	$xy,(x^3y+y^3x)$
e_5	x,x^3
e_6	xy^2
e_7	x^2y
e_8	y,y^3

and is called a response matrix.

Proposition 1: If V is a symmetric region, then any response matrix, as in Definition 1, is diagonalized by expressing both $\mathbf{u}$ and $\boldsymbol{\nu}$ by their irreducible components. If there are equivalent irreducible components, the response matrix will be block diagonal.

Below, it is shown that if a subspace is present in the approximation to the solution on the boundary, but not in the representation inside the node; the iteration scheme (18) will not converge because there is a subspace whose contribution does not decay during the iteration; its amplitude does not decrease with the number of iterations.

Proposition 2: Let us decompose the solution space $\mathcal{L}$ into irreducible subspaces as $\mathcal{L}=(\mathcal{L}^{(I)},\ldots,\mathcal{L}^{(K)})$. If there is a subspace $\mathcal{L}^{(m)}$, which is present in the boundary representation but missing from the internal representation, then the component corresponding to $\mathcal{L}^{(m)}$ represents a subspace of the entering current vector that will not decrease in the iteration (18).

Proof: The response matrix can be calculated in the following manner. The flux on the boundary is expressed in terms of the approximate polynomials as Eq. (4), and by the assumptions there is at least one nonzero coefficient in the expansion. According to the Basic Lemma, the solution inside the node will belong to the same subspace as the boundary condition. But, by the assumptions this subspace is empty inside the node, in the expansion (10) no $f_i(r)$ function belongs to this subspace. Consequently, the net current calculated from the flux inside will, according to Proposition 1, be zero. Thus, the corresponding response matrix $\mathbf{R}$ is also zero. The response matrix $\mathbf{T}$ [see Eq. (21a)] connecting entering currents to exiting currents and $\mathbf{R}$ are related as

$$\mathbf{T}=(1+2\mathbf{R})(1-2\mathbf{R})^{-1}, \tag{23}$$

so now $\|\mathbf{T}\|=1$, which means that applying n times $\mathbf{T}$ on an initial vector $\underline{I}^+$ we do not get smaller amplitudes if the initial vector has a component in the subspace m as stated.

Now we turn to the application of these observations to square-shaped nodes. The above cited statements have important consequences in the problem considered. First, a solution inside the node with given symmetry properties exists only if either the source or the boundary value has those symmetry properties. Second, the response matrix will be zero in a given irrep, if the solution has no matching component. This is because in that case the considered component of the solution is not zero on the boundary, but the solution inside V is zero. Consequently, the gradient calculated from it is also zero. Therefore, the corresponding element of the response matrix (21b) is zero, the response matrix (21a) is unity. When we determine the solution in a given subspace by means of polynomials, it should be verified whether the polynomials have at least one component in the subspace under consideration. Table I gives the symmetry components of the fourth-order polynomial in a square. There are six different subspaces; four of them are one-dimensional ones, and two, two-dimensional ones. According to Lemma 2, we can characterize their basis vectors by vectors $\underset{\sim}{e}_1,\ldots,\underset{\sim}{e}_8$. Four of them, viz. $\underset{\sim}{e}_1,\ldots,\underset{\sim}{e}_4$, are one-dimensional ones, and two, two-

TABLE II. Irreps of spatial moments on the boundary of a square.

Vector	Moment	Values at faces
e_1	0,2	(1,1,1,1)
e_2	1	(1,1,1,1)
e_3	0,2	(1,−1,1,1)
e_4	1	(1,−1,1,−1)
e_5	0,2	(0,1,0,−1)
e_6	1	(1,0,−1,0)
e_7	1	(0,1,0,−1)
e_8	0,2	(1,0,−1,0)

dimensional pairs (e_5, e_8) and $(\underline{e}_6, \underline{e}_7)$.
The irreps of the boundary conditions are given in Table II.
The response matrix will have the structure

$$I_i^- = \mathbf{R}_i I_i^+, \quad i = 1,...,4, \tag{24}$$

$$I_i^- = \mathbf{R}_5 I_i^+, \quad i = 5,...,8. \tag{25}$$

Here I_i^+ is the ith component of the entering current, proportional to vector $\underline{e}_i$. $\mathbf{R}_i$ denotes the ith block of the RM. Since $\underline{e}_5$ and $\underline{e}_6$ as well as $\underline{e}_7$ and $\underline{e}_8$ are equivalent, here the RMs are the same, according to Theorem A.6.

While the boundary condition has at least one component in each subspace when linear polynomials are used along the four faces, the linear approximation leaves four empty subspaces in Table I. In other words, to calculate the response matrix, a higher-order approximation is needed inside the node. To demonstrate the effect of an empty irrep inside, while the boundary value has that irrep, let us consider the following example.

With, at most, linear polynomials, on the boundary each subspace will have at least one component, (see Table II). At the same time inside the square, the first polynomial, where each subspace will have at least one component, is the fourth-order polynomial (see Table III).

This observation is general. A low-order approximation on the boundary is able to furnish a large number of overtones inside the node. This is because the elementary solutions to the diffusion equation are exponential functions and to fulfill the simplest boundary condition the solution will contain a number of exponential functions. Exploiting the connection between the Fourier transformation and the irreducible components, we remark here only that a polar coordinate system (r, α) can be introduced in which the irreducible component will contain $\cos(k\alpha)$ and $\sin(k\alpha)$, where k depends on the irrep and all $k(\mathrm{mod})n_F=\mathrm{const}$ modes belong to the same irrep. When the node is a circle, all modes form a separate irrep.

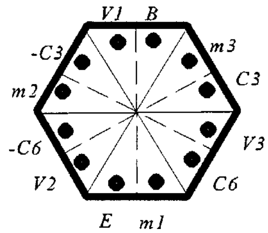

FIG. 4. Symmetries of a regular hexagon.

B. Hexagonal geometry

The hexagonal node is shown in Fig. 4. The regular representation is expressed by 12 element vectors. C_6 denotes a rotation by 60°, $-C_6$ by $-60°$. C_3 and $-C_3$ denote 120° rotations and its inverse, respectively. Let V_i denote reflections through planes connecting corners, m_i connecting midplane points. The irreps are projected out with the help of the character table. Table IV gives the irreducible vectors. Since there are two equivalent two dimensional subspaces in a regular representation, the two-dimensional representations E_1 and E_2 are associated with two subspaces distinguished by a superscript. The angular term gives the angular component of an analytical solution which transforms according to the given irrep.

Table IV has been derived with the help of the character table of group C_{6v} given in GAP.[13] The sectors belonging to subspace Γ_5 transform as coordinates (x,y), or in polar coordinates as $\cos(\alpha)$ and $\sin(\alpha)$. The subspace Γ_6 transforms as (x^2-y^2,xy), or, as $\cos(2\alpha)$ and $\sin(2\alpha)$. The vectors given in Table IV are the x and y components of the transforms of a point $(r,\ \alpha)$.

The irreps of the moments on the boundary are given in Table V. Here it is assumed that we are given a zeroth, first, or second-order power of the tangential coordinate on each face; the coefficients may be different on the six faces.

To assess the numerical method, we also need the irreps of the approximating polynomials inside the node. The irreducible components of the spatial moments are given in Table VI. It is seen that none of the interpolants contribute to the subspace Γ_2. This is because that subspace contains functions varying as $\sin(6\alpha)$ and that component appears first in sixth-order polynomials. Thus, any lower-order approximation will contain a nonvanishing subspace and cause a convergence problem.

IV. CONCLUSIONS

We investigated an iteration, Eqs. (18)–(20), which is widely used to solve the diffusion and transport equation. In the course of the iteration, the solution is iteratively improved in the nodes.

TABLE IV. Irreducible vectors of 12 elements in a regular hexagon.

If the node has symmetries, which commute with the matrices of the iteration, we are able to decompose the solution vector into linearly independent components. Those components are not mixed by the response matrices. This situation is fairly common; the response matrix commutes with the symmetries of the node. The technique presented can be described as follows. The iteration endeavors to solve a linear set of equations with matrix **A**. Let us assume that a symmetric matrix, **M** is given and **M** commutes with **A**. We may use the eigenvectors $\underset{\sim}{e}_i$ of **M** to span the solution space. The iteration does not mix the the eigenvectors $\underset{\sim}{e}_i$, so the solution goes separately for each eigenvector. If the boundary condition has a component proportional to the eigenvectors $\underset{\sim}{e}_i$ but the solution inside the node does not, the iteration does not converge.

The solution of the diffusion equation often follows this setup. We have a value on the boundary from which we derive a solution inside the node, and, from the solution, a new boundary value is obtained. The symmetries permit us to decompose the solution vector and have a closer look at a step of the iteration. When the internal solution has no component in a subspace, but the boundary condition has, the iteration will not converge because any tiny component of the initial guess in that subspace will remain the same.

It should be emphasized, however, that the component under consideration may really be tiny. In such cases, the error will decrease until that component becomes dominant. The convergence difficulties predicted in the present paper have been observed in an actual program.[17] There, the boundary term and the source term were approximated by polynomials. Low-order polynomials of the boundary term cover every subspace, whereas inside the node higher-order polynomials should be used to avoid convergence problems.

APPENDIX A: GROUP THEORY PRIMER

In this appendix we summarize the results of group theory applied throughout the present work. The results cited below are available in standard textbooks.

Definition A.1: Let us consider function $f(x)$. The transformation operator $\mathbf{P}_O$ associated with matrix O is defined by the following identity in x:

$$\mathbf{P}_o f(x) \equiv f(O^{-1}x). \tag{A1}$$

With this definition, the set of symmetry operations (symmetries) is made isomorphic with the set of matrices associated with the symmetries.

Definition A.2: $\mathbf{P}_O$ is called a symmetry of region V if $\mathbf{O}$ maps V onto itself. The symmetries of V form a group; the group operation is $\mathbf{P}^*_{O1}\mathbf{P}_{O2}=$apply first $\mathbf{P}_{O2}$ then apply $\mathbf{P}_{O1}$.

Definition A.3: An orbit is a set of points g^*x, where $x\in V$ is given, $g\in G$. There is an induced equivalence relation between the points of V, with x being equivalent to y if they are in the same orbit of G.

Definition A.4: Let V/G denote the the set of orbits of G. V/G is referred to as the quotient (region). The projection π: $V\rightarrow V/G$ associates with each x in V its equivalent class $\pi(x)$, $x\in V/G$.

Definition A.5: A set of matrices under matrix multiplication $\{O_1,O_2,\ldots,O_n\}$, which is homomorphic with the group $\{O_1,O_2,\ldots,O_n\}$, is said to be a representation of the group.

Definition A.6: A regular representation associates matrices of order h with the group G.

Definition A.7: A representation is said to be reducible if an equivalent representation[18] exists in which each matrix O_i has the form

$$\mathbf{O}_i=\begin{pmatrix} \mathbf{A}_i & \mathbf{C}_i \\ 0 & \mathbf{B}_i \end{pmatrix}, \tag{A2}$$

If no such representation exists, the representation is said to be an irreducible representation of the group.

Definition A.8: A character table is associated with every group. The character table is a square table. It contains n_c rows and columns, where n_c is the number of conjugacy classes. The first column gives the dimension of the row, sometimes also known as representation.

Theorem A.1: (FALICOV) The h-dimensional space in which the regular representation acts by h-order matrices can be split the following manner. There are n_c subspaces transforming among themselves. If the dimension of the ith subspace is l_i then there are l_i equivalent subspaces. The matrices of a regular representation do not mix the equivalent subspaces.

Definition A.9: $\mathbf{O}$ is called a symmetry of operator $\mathbf{A}$ if $\mathbf{AO}=\mathbf{OA}$.

Definition A.10: Let $\{O_i\}$ be an irreducible representation and let $\{f_i^{(1)},f_i^{(2)},\ldots,f_i^{(li)}\}$ be l_i eigenfunctions of the symmetry operations for which

$$\mathbf{O}f_i^{(k)}=\sum_{j=1}^{l_i} O_{jk}f_i^{(j)}, \tag{A3}$$

holds for $\mathbf{O}=\mathbf{O}_l,\ldots,\mathbf{O}_h$. A function $f_i^{(k)}$ is said to belong to the kth row of the irreducible representation $\mathbf{O}_i$ if there exist partner functions $\{f_i^{(1)},f_i^{(2)},\ldots,f_i^{(k-1)}f_i^{(k+1)},\ldots,f_i^{(li)}\}$ such that the above equation is satisfied.

Theorem A.2: *Let* $\mathbf{S}$ *commute with all* $\mathbf{O}_i$. *Let* $f_i^{(i)}$ *and* $g_i^{(j')}$, *belong to different irreducible representations. Then*

$$(f_i^{(j)},g_{i'}^{(j')})=\frac{1}{l_i}\delta_{ii'}\delta_{jj'}\sum_j (f_i^{(j)},g_{i'}^{(j')}) \tag{A4}$$

and

$$(f_i^{(j)}, \mathbf{S}g_{i'}^{(j')}) = \frac{1}{l_i}\delta_{ii'}\delta_{jj'}\sum_j (f_i^{(j)}, \mathbf{S}g_{i'}^{(j')}). \tag{A5}$$

Proof: Ref. 19, pp. 115, 116.

The following theorem, taken from Ref. 1, pp. 52–55, is a summary of the relationship between the eigenspace of an operator (in our case **A**) and a group commuting with **A**. The relationship is twofold. The eigenfunctions of **A** may serve as basis functions of the irreducible representations. The symmetry operators on that basis are represented by matrices and the eigenvectors of those matrices are linear combinations of the eigenfunctions of **A**, furthermore, they are basis vectors of an irreducible representation. The reverse statement is the following: If irreducible functions are used to represent operator **A** by matrices, the resulting matrix will be diagonal; the elements belonging to partner functions of a given irrep are the same.

Theorem A.3:

(1) *The eigenfunctions of operator* **A** *generate a representation of G*.
(2) *Linear transformations to new eigenfunctions generates a representation equivalent to the original*.
(3) *If the eigenfunctions are orthonormal, then operator O is merely the matrix associated with O*.
(4) *The representation so generated is unitary*.
(5) *If the degeneracy is normal, the representation is irreducible*.
(6) *An arbitrary function* Φ *in the space of* **A** *can be used to construct an invariant subspace by forming the operation* $O\Phi$ *for all O in G*.
(7) *Functions that transform in accordance with two different irreducible representations of G are orthogonal*.
(8) *Any function in the space of* **A** *can be decomposed into a linear combination of functions transforming according to irreps of G*.

The operator,

$$\mathbf{P}^{(i)} \equiv \frac{l_i}{h}\sum_O \chi^{(i)}(O)\mathbf{P}_O, \tag{A6}$$

projects out the component transforming in accordance with the ith representation of group G.

Theorem A.4: *Let* Φ_i *be irreducible,* $i=1,...,n_c$ *(the number of classes). Then the matrix,*

$$\langle \Phi_i A \Phi_j \rangle,$$

is diagonal. The elements belonging to the components of a multi- (i.e., two- or three-) dimensional representation are equal.

Proof: This statement is an immediate consequence of the Wigner–Eckart theorem; see Ref. 20, pp. 129–134.

Quasi-Hopf superalgebras and elliptic quantum supergroups

Yao-Zhong Zhang[a)] and Mark D. Gould
Department of Mathematics, University of Queensland, Brisbane, Qld 4072, Australia

(Received 6 October 1998; accepted for publication 11 February 1999)

We introduce the quasi-Hopf superalgebras which are $\mathbf{Z}_2$-graded versions of Drinfeld's quasi-Hopf algebras. We describe the realization of elliptic quantum supergroups as quasi-triangular quasi-Hopf superalgebras obtained from twisting the normal quantum supergroups by twistors which satisfy the graded shifted cocycle condition, thus generalizing the quasi-Hopf twisting procedure to the supersymmetric case. Two types of elliptic quantum supergroups are defined, that is, the face type $\mathcal{B}_{q,\lambda}(\mathcal{G})$ and the vertex type $\mathcal{A}_{q,p}[\mathrm{sl}(\widehat{n|n})]$ (and $\mathcal{A}_{q,p}[\mathrm{gl}(\widehat{n|n})]$), where $\mathcal{G}$ is any Kac–Moody superalgebra with symmetrizable generalized Cartan matrix. It appears that the vertex type twistor can be constructed only for $U_q[\mathrm{sl}(\widehat{n|n})$ in a nonstandard system of simple roots, all of which are fermionic. [S0022-2488(99)00210-8]

I. INTRODUCTION

One of the aims of this paper is to introduce $\mathbf{Z}_2$-graded versions of Drinfeld's quasi-Hopf algebras,[1] which are referred to as quasi-Hopf superalgebras. We then introduce elliptic quantum supergroups, which are defined as quasi-triangular quasi-Hopf superalgebras arising from twisting the normal quantum supergroups by twistors which satisfy the graded shifted cocycle condition, thus generalizing Drinfeld's quasi-Hopf twisting procedure[2–6] to the supersymmetric case. We adopt the approach in Ref. 4 and construct two types of twistors, i.e., the face-type twistor associated to any Kac–Moody superalgebra $\mathcal{G}$ with a symmetrizable generalized Cartan matrix and the vertex-type twistor associated to $\mathrm{sl}(\widehat{n|n})$ in a nonstandard simple root system in which all simple roots are odd (or fermionic). It should be pointed out that the face-type twistors for certain classes of *nonaffine* simple superalgebras were also constructed in Ref. 5.

The elliptic quantum groups[7,8] are believed to provide the underlying algebraic structures for integrable models based on elliptic solutions of the (dynamical) Yang–Baxter equation, such as Baxter's eight-vertex model,[9] the ABF (Andrews—Baxter–Forrester) model,[10] and their group theoretical generalizations.[11,12] The elliptic quantum supergroups described in this paper are expected to play a similar role in supersymmetric integrable models based on elliptic solutions[13,14] of the graded (dynamical) Yang–Baxter equation.

II. QUASI-HOPF SUPERALGEBRAS

Definition 1: A $\mathbf{Z}_2$-graded quasi-bialgebra is a $\mathbf{Z}_2$-graded unital associative algebra A over a field K which is equipped with algebra homomorphisms ϵ: $A\to K$ (counit), Δ: $A\to A\otimes A$ (coproduct), and an invertible homogeneous element $\Phi\in A\otimes A\otimes A$ (coassociator) satisfying

$$(1\otimes\Delta)\Delta(a)=\Phi^{-1}(\Delta\otimes 1)\Delta(a)\Phi,\quad \forall a\in A, \tag{II.1}$$

$$(\Delta\otimes 1\otimes 1)\Phi\cdot(1\otimes 1\otimes\Delta)\Phi=(\Phi\otimes 1)\cdot(1\otimes\Delta\otimes 1)\Phi\cdot(1\otimes\Phi), \tag{II.2}$$

[a)]Electronic mail: yzz@maths.uq.edu.au

$$(\epsilon\otimes 1)\Delta = 1 = (1\otimes\epsilon)\Delta, \tag{II.3}$$

$$(1\otimes\epsilon\otimes 1)\Phi = 1. \tag{II.4}$$

Equations (II.2)–(II.4) imply that Φ also obeys

$$(\epsilon\otimes 1\otimes 1)\Phi = 1 = (1\otimes 1\otimes\epsilon)\Phi. \tag{II.5}$$

The multiplication rule for the tensor products is $\mathbf{Z}_2$ graded and is defined for homogeneous elements $a,b,a',b'\in A$ by

$$(a\otimes b)(a'\otimes b') = (-1)^{[b][a']}(aa'\otimes bb'), \tag{II.6}$$

where $[a]\in\mathbf{Z}_2$ denotes the grading of the element a.

Definition 2: A quasi-Hopf superalgebra is a $\mathbf{Z}_2$*-graded quasi-bialgebra* (A,Δ,ϵ,Φ) *equipped with a* $\mathbf{Z}_2$*-graded algebra anti-homomorphism* $S: A\to A$ *(anti-pode) and canonical elements* α, $\beta\in A$ *such that*

$$m\cdot(1\otimes\alpha)(S\otimes 1)\Delta(a) = \epsilon(a)\alpha, \quad \forall a\in A, \tag{II.7}$$

$$m\cdot(1\otimes\beta)(1\otimes S)\Delta(a) = \epsilon(a)\beta, \quad \forall a\in A, \tag{II.8}$$

$$m\cdot(m\otimes 1)\cdot(1\otimes\beta\otimes\alpha)(1\otimes S\otimes 1)\Phi^{-1} = 1, \tag{II.9}$$

$$m\cdot(m\otimes 1)\cdot(S\otimes 1\otimes 1)(1\otimes\alpha\otimes\beta)(1\otimes 1\otimes S)\Phi = 1. \tag{II.10}$$

Here m denotes the usual product map on A: $m\cdot(a\otimes b) = ab$, $\forall a,b\in A$. Note that since A is associative, we have $m\cdot(m\otimes 1) = m\cdot(1\otimes m)$. For the homogeneous elements $a,b\in A$, the anti-pode satisfies

$$S(ab) = (-1)^{[a][b]}S(b)S(a), \tag{II.11}$$

which extends to inhomogeneous elements through linearity.

Applying ϵ to definitions (II.9) and (II.10) we obtain, in view of (II.4), $\epsilon(\alpha)\epsilon(\beta) = 1$. It follows that the canonical elements α and β are both even. By applying ϵ to (II.7), we have $\epsilon(S(a)) = \epsilon(a)$, $\forall a\in A$.

In the following we show that the category of quasi-Hopf superalgebras is invariant under a kind of gauge transformation. Let (A,Δ,ϵ,Φ) be a qausi-Hopf superalgebra, with α, β, and S satisfying (II.7)–(II.10), and let $F\in A\otimes A$ be an invertible homogeneous element satisfying the counit properties

$$(\epsilon\otimes 1)F = 1 = (1\otimes\epsilon)F. \tag{II.12}$$

It follows that F is even. Throughout we set

$$\Delta_F(a) = F\Delta(a)F^{-1}, \quad \forall a\in A, \tag{II.13}$$

$$\Phi_F = (F\otimes 1)(\Delta\otimes 1)F\cdot\Phi\cdot(1\otimes\Delta)F^{-1}(1\otimes F^{-1}). \tag{II.14}$$

Theorem 1: $(A,\Delta_F,\epsilon,\Phi_F)$, *defined by (II.13) and (II.14), together with* α_F,β_F, and S_F *given by*

$$S_F = S, \quad \alpha_F = m\cdot(1\otimes\alpha)(S\otimes 1)F^{-1}, \quad \beta_F = m\cdot(1\otimes\beta)(1\otimes S)F, \tag{II.15}$$

is also a quasi-Hopf superalgebra. The element F is referred to as a twistor, throughout.

The proof of this theorem is elementary. For demonstration we show in some detail the proof of the antipode properties. Care has to be taken of the gradings in tensor product multiplications and also in extending the antipode to the whole algebra. First of all let us state the following lemma.

Lemma 1: For any elements $\eta\in A\otimes A$ *and* $\xi\in A\otimes A\otimes A$,

$$m\cdot(1\otimes\alpha_F)(S\otimes 1)\eta=m\cdot(1\otimes\alpha)(S\otimes 1)(F^{-1}\eta), \tag{II.16}$$

$$m\cdot(1\otimes\beta_F)(1\otimes S)\eta=m\cdot(1\otimes\beta)(1\otimes S)(\eta F), \tag{II.17}$$

$$\begin{aligned}&m\cdot(m\otimes 1)\cdot(1\otimes\beta_F\otimes\alpha_F)(1\otimes S\otimes 1)\xi\\&\quad=m\cdot(m\otimes 1)\cdot(1\otimes\beta\otimes\alpha)(1\otimes S\otimes 1)[(1\otimes F^{-1})\cdot\xi\cdot(F\otimes 1)],\end{aligned} \tag{II.18}$$

$$\begin{aligned}&m\cdot(m\otimes 1)\cdot(S\otimes 1\otimes 1)(1\otimes\alpha_F\otimes\beta_F)(1\otimes 1\otimes S)\xi\\&\quad=m\cdot(m\otimes 1)\cdot(S\otimes 1\otimes 1)(1\otimes\alpha\otimes\beta)(1\otimes 1\otimes S)\cdot[(F^{-1}\otimes 1)\cdot\xi\cdot(1\otimes F)].\end{aligned} \tag{II.19}$$

Proof: Write $F=f_i\otimes f^i$ and $F^{-1}=\overline{f_i}\otimes\overline{f^i}$. Here and throughout, summation convention on repeated indices is assumed. Then (II.15) can be written as

$$\alpha_F=S(\overline{f_i})\alpha\overline{f^i},\quad \beta_F=f_i\beta S(f^i). \tag{II.20}$$

Further, write $\eta=\eta_k\otimes\eta^k$ and $\xi=\Sigma_i x_i\otimes y_i\otimes z_i$. Then

$$\begin{aligned}\text{lhs of (II.16)}&=m\cdot(1\otimes S(\overline{f_i})\alpha\overline{f^i})(S(\eta_k)\otimes\eta^k)\\&=m\cdot(S(\eta_k)\otimes S(\overline{f_i})\alpha\overline{f^i}\eta^k)\\&=S(\eta_k)S(\overline{f_i})\alpha\overline{f^i}\eta^k\\&=S(\overline{f_i}\eta_k)\alpha\overline{f^i}\eta^k\times(-1)^{[\eta_k][\overline{f_i}]},\end{aligned}$$

$$\begin{aligned}\text{rhs of (II.16)}&=m\cdot(1\otimes\alpha)(S\otimes 1)(\overline{f_i}\eta_k\otimes\overline{f^i}\eta^k)\times(-1)^{[\overline{f^i}][\eta_k]}\\&=S(\overline{f_i}\eta_k)\alpha\overline{f^i}\eta^k\times(-1)^{[\overline{f_i}][\eta_k]},\end{aligned}$$

thus proving (II.16). Equation (II.17) can be proved similarly. As for (II.18) we have

$$\begin{aligned}\text{lhs of (II.18)}&=\sum_i x_i\beta_F S(y_i)\alpha_F z_i\\&=\sum_i x_i f_j\beta S(f^j)S(y_i)S(\overline{f_k})\alpha\overline{f^k}z_i\\&=\sum_i x_i f_j\beta S(\overline{f_k}y_i f^j)\alpha\overline{f^k}z_i\times(-1)^{[y_i][f_j]+[\overline{f_k}])+[\overline{f_k}][f_j]},\end{aligned}$$

$$\begin{aligned}\text{rhs of (II.18)}&=m\cdot(m\otimes 1)\cdot(1\otimes\beta\otimes\alpha)(1\otimes S\otimes 1)\\&\quad\cdot\sum_i[x_i f_j\otimes\overline{f_k}y_i f^j\otimes\overline{f^k}z_i]\times(-1)^{[y_i]([f_j]+[\overline{f_k}])+[\overline{f_k}][f_j]},\end{aligned}$$

$$=\sum_i x_i f_j \beta S(\overline{f_k} y_i f^j)\alpha \overline{f^k} z_i \times(-1)^{[y_i]([f_j]+[\overline{f_k}])+[\overline{f_k}][f_j]},$$

where we have used the fact that the element F is even. Equation (II.19) is proved similarly.

Now let us prove the property (II.7) for α_F and Δ_F. We write, following Sweedler,

$$\Delta(a)=\sum_{(a)} a_{(1)}\otimes a_{(2)}. \tag{II.21}$$

Then, in view of Lemma 1,

$$\begin{aligned}
m\cdot(1\otimes\alpha_F)(S\otimes 1)\Delta_F(a) &= m\cdot(1\otimes\alpha)(S\otimes 1)(F^{-1}\Delta_F(a)\\
&= m\cdot(1\otimes\alpha)(S\otimes 1)(\Delta(a)F^{-1})\\
&= m\cdot(1\otimes\alpha)\sum_{(a)}(S(a_{(1)}\overline{f_i})\otimes a_{(2)}\overline{f^i})\times(-1)^{[\overline{f_i}][a_{(2)}]}\\
&= S(\overline{f_i})\sum_{(a)} S(a_{(1)})\alpha a_{(2)}\overline{f^i}\times(-1)^{[f_i]([a_{(1)}]+[a_{(2)}])}\\
&= S(\overline{f_i})\sum_{(a)} S(a_{(1)})\alpha a_{(2)}\overline{f^i}\times(-1)^{[f_i][a]}\\
&= (-1)^{[\overline{f_i}][a]}S(\overline{f_i})\sum_{(a)} S(a_{(1)})\alpha a_{(2)}\overline{f^i} \overset{(II.17)}{=} S(\overline{f_i})\epsilon(a)\alpha\overline{f^i}\times(-1)^{[\overline{f_i}][a]}\\
&= S(\overline{f_i})\epsilon(a)\alpha\overline{f^i} \overset{(II.20)}{=} \epsilon(a)\alpha_F,
\end{aligned} \tag{II.22}$$

where we have used the fact that

$$\epsilon(a)=0 \quad \text{if } [a]=1. \tag{II.23}$$

The property (II.8) for β_F and Δ_F is proved similarly. We then prove property (II.9), which reads in terms of the twisted objects

$$m\cdot(m\otimes 1)\cdot(1\otimes\beta_F\otimes\alpha_F)(1\otimes S\otimes 1)\Phi_F^{-1}=1. \tag{II.24}$$

Let us write

$$\Phi^{-1}=\sum_\nu \overline{X}_\nu\otimes\overline{Y}_\nu\otimes\overline{Z}_\nu. \tag{II.25}$$

Then, in view of (II.18),

$$\begin{aligned}
&\text{lhs of (II.24)}\\
&= m\cdot(m\otimes 1)\cdot(1\otimes\beta\otimes\alpha)(1\otimes S\otimes 1)[(1\otimes F^{-1})\Phi_F^{-1}(F\otimes 1)]\\
&= m\cdot(m\otimes 1)\cdot(1\otimes\beta\otimes\alpha)(1\otimes S\otimes 1)[(1\otimes\Delta)F\cdot\Phi^{-1}\cdot(\Delta\otimes 1)F^{-1}]\\
&= m\cdot(m\otimes 1)\cdot(1\otimes\beta\otimes\alpha)(1\otimes S\otimes 1)\\
&\quad\cdot\sum_{\nu,(f),(\overline{f})}[f_i\overline{X}_\nu\overline{f}_{j(1)}\otimes f^i_{(1)}\overline{Y}_\nu\overline{f}_{j(2)}\otimes f^i_{(2)}\overline{Z}_\nu\overline{f^j}]\\
&\quad\times(-1)^{([\overline{X}_\nu]+[\overline{f}_{j(1)}])([f^i_{(1)}]+[f^i_{(2)}])+[\overline{Z}_\nu]([\overline{f}_{j(1)}]+[\overline{f}_{j(2)}])+[\overline{Y}_\nu]([\overline{f}_{j(1)}]+[f^i_{(2)}])+[f^i_{(2)}][\overline{f}_{j(2)}]}
\end{aligned}$$

$$= \sum_{\nu} f_i \overline{X}_\nu \sum_{(\overline{f})} f_{j(1)} \beta S(\overline{f}_{j(2)}) S(\overline{Y}_\nu) \sum_{(f)} S(f^i_{(1)}) \alpha f^i_{(2)} \overline{Z}_\nu \overline{f^j}$$

$$\cdot (-1)^{([\overline{X}_\nu]+[\overline{Y}_\nu])([f^i_{(1)}]+[f^i_{(2)}])+([\overline{Y}_\nu]+[\overline{Z}_\nu])([\overline{f}_{j(1)}]+[\overline{f}_{j(2)}])+([f^i_{(1)}]+[f^i_{(2)}])([\overline{f}_{j(1)}]+[\overline{f}_{j(2)}])}$$

$$= \sum_{\nu} f_i \overline{X}_\nu \sum_{(f)} f_{j(1)} \beta S(\overline{f}_j(2)) S(\overline{Y}_\nu) \sum_{(f)} S(f^i_{(1)}) \alpha f^i_{(2)} \overline{Z}_\nu \overline{f^j}$$

$$\cdot (-1)^{([\overline{X}_\nu]+[Y_\nu])[f^i]+([Y_\nu]+[\overline{Z}_\nu])[\overline{f}_j]+[f^i][f_j]}$$

$$= \sum_{\nu} f_i \overline{X}_\nu \cdot (-1)^{([X_\nu]+[Y_\nu])[f^i]+([Y_\nu]+[\overline{Z}_\nu])[f_j]+[f^i][f_j]}$$

$$\cdot \sum_{(f)} f_{j(1)} \beta S(f_{j(2)}) S(\overline{Y}_\nu) \sum_{(f)} S(f^i_{(1)}) \alpha f^i_{(2)} \overline{Z}_\nu \overline{f^j}$$

$$\overset{(II.7),(II.8)}{=} \sum_{\nu} f_i \overline{X}_\nu \epsilon(\overline{f}_j) \beta S(\overline{Y}_\nu) \epsilon(f^i) \alpha Z_\nu f^j$$

$$\cdot (-1)^{([X_\nu]+[Y_\nu])[f^i]+([Y_\nu]+[Z_\nu])[f_j])+[f^i][f_j]}$$

$$\overset{(II.23)}{=} \sum_{\nu} f_i \overline{X}_\nu \epsilon(\overline{f}_j) \beta S(\overline{Y}_\nu) \epsilon(f^i) \alpha \overline{Z}_\nu \overline{f^j} = m \cdot (m \otimes 1) \cdot (1 \otimes \beta \otimes \alpha)(1 \otimes S \otimes 1)$$

$$\cdot [((1 \otimes \epsilon) F \otimes 1) \cdot \Phi^{-1} \cdot ((\epsilon \otimes 1) F^{-1} \otimes 1)]$$

$$\overset{(II.12)}{=} m \cdot (m \otimes 1) \cdot (1 \otimes \beta \otimes \alpha)(1 \otimes S \otimes 1) \Phi^{-1} \overset{(II.9)}{=} 1.$$

The property (II.10) for the twisted objects, which reads

$$m \cdot (m \otimes 1) \cdot (S \otimes 1 \otimes 1)(1 \otimes \alpha_F \otimes \beta_F)(1 \otimes 1 \otimes S) \Phi_F = 1, \tag{II.26}$$

is proved in a similar way.

Definition 3: A quasi-Hopf superalgebra (A,Δ,ϵ,Φ) *is called quasi-triangular if there exists an invertible homogeneous element* $\mathcal{R} \in A \otimes A$ *such that*

$$\Delta^T(a) \mathcal{R} = \mathcal{R} \Delta(a), \quad \forall a \in A, \tag{II.27}$$

$$(\Delta \otimes 1) \mathcal{R} = \Phi^{-1}_{231} \mathcal{R}_{13} \Phi_{132} \mathcal{R}_{23} \Phi^{-1}_{123}, \tag{II.28}$$

$$(1 \otimes \Delta) \mathcal{R} = \Phi_{312} \mathcal{R}_{13} \Phi^{-1}_{213} \mathcal{R}_{12} \Phi_{123}. \tag{II.29}$$

Throughout, $\Delta^T = T \cdot \Delta$ with T being the graded twist map which is defined, for homogeneous elements $a, b \in A$, by

$$T(a \otimes b) = (-1)^{[a][b]} b \otimes a; \tag{II.30}$$

and Φ_{132}, etc. are derived from $\Phi \equiv \Phi_{123}$ with the help of T:

$$\Phi_{132} = (1 \otimes T) \Phi_{123},$$

$$\Phi_{312} = (T \otimes 1) \Phi_{132} = (T \otimes 1)(1 \otimes T) \Phi_{123},$$

$$\Phi^{-1}_{231} = (1 \otimes T) \Phi^{-1}_{213} = (1 \otimes T)(T \otimes 1) \Phi^{-1}_{123},$$

and so on. We remark that our convention differs from the usual one which employs the inverse permutation on the positions (cf. Ref. 4).

It is easily shown that the properties (II.27)–(II.29) imply the graded Yang–Baxter-type equation,

$$\mathcal{R}_{12}\Phi_{231}^{-1}\mathcal{R}_{13}\Phi_{132}\mathcal{R}_{23}\Phi_{123}^{-1}=\Phi_{321}^{-1}\mathcal{R}_{23}\Phi_{312}\mathcal{R}_{13}\Phi_{213}^{-1}\mathcal{R}_{12}, \tag{II.31}$$

which is referred to as the graded quasi-Yang–Baxter equation, and the counit properties of $\mathcal{R}$:

$$(\epsilon\otimes 1)\mathcal{R}=1=(1\otimes\epsilon)\mathcal{R}. \tag{II.32}$$

Theorem 2: *Denoting by the set* $(A,\Delta,\epsilon,\Phi,\mathcal{R})$ *a quasi-triangular quasi-Hopf superalgebra, then* $(A,\Delta_F,\epsilon,\Phi_F,\mathcal{R}_F)$ *is also a quasi-triangular quasi-Hopf superalgebra, with the choice of* $\mathcal{R}_F$ *given by*

$$\mathcal{R}_F=F^T\mathcal{R}F^{-1}, \tag{II.33}$$

where $F^T=T\cdot F\equiv F_{21}$. *Here* Δ_F *and* Φ_F *are given by (II.13) and (II.14), respectively.*

The proof of this theorem is elementary computation. As an example, let us illustrate the proof of the property (II.28) for Δ_F, $\mathcal{R}_F$, and Φ_F. Applying the homomorphism $T\otimes 1$ to $(\Phi_F^{-1})_{123}$, one obtains

$$\begin{aligned}(\Phi_F^{-1})_{213}&=F_{13}(T\otimes 1)(1\otimes\Delta)F\cdot\Phi_{213}^{-1}\cdot(\Delta^T\otimes 1)F^{-1}\cdot(F^T)_{12}^{-1}\\&=F_{13}\sum_{(f)}(-1)^{[f^i_{(1)}][f_i]}(f^i_{(1)}\otimes f_i\otimes f^i_{(2)})\Phi_{213}^{-1}(\Delta^T\otimes 1)F^{-1}\cdot(F^T)_{12}^{-1},\end{aligned} \tag{II.34}$$

which gives rise to, by applying the homomorphism $1\otimes T$ to both sides,

$$\begin{aligned}(\Phi_F^{-1})_{231}&=F_{12}\sum_{(f)}(-1)^{([f^i_{(1)}]+[f^i_{(2)}])[f_i]}(f^i_{(1)}\otimes f^i_{(2)}\otimes f_i)\Phi_{231}^{-1}(1\otimes T)(\Delta^T\otimes 1)F^{-1}\cdot(F^T)_{13}^{-1}\\&=F_{12}(\Delta\otimes 1)F^T\cdot\Phi_{231}^{-1}(1\otimes T)(\Delta^T\otimes 1)F^{-1}\cdot(F^T)_{13}^{-1}.\end{aligned} \tag{II.35}$$

Then,

$$\begin{aligned}(\Delta_F\otimes 1)\mathcal{R}_F&=(F\otimes 1)(\Delta\otimes 1)\mathcal{R}_F\cdot(F^{-1}\otimes 1)\\&=F_{12}(\Delta\otimes 1)(F^T\mathcal{R}F^{-1})\cdot F_{12}^{-1}\\&=F_{12}(\Delta\otimes 1)F^T(\Delta\otimes 1)\mathcal{R}(\Delta\otimes 1)F^{-1}\cdot F_{12}^{-1}\\&\overset{\text{(II.28)}}{=}F_{12}(\Delta\otimes 1)F^T\cdot\Phi_{231}^{-1}\mathcal{R}_{13}\Phi_{132}\mathcal{R}_{23}\Phi_{123}^{-1}(\Delta\otimes 1)F^{-1}\cdot F_{12}^{-1}\\&\overset{\text{(II.35)}}{=}(\Phi_F^{-1})_{231}(F^T)_{13}(1\otimes T)(\Delta^T\otimes 1)F\cdot\mathcal{R}_{13}\Phi_{132}\mathcal{R}_{23}\Phi_{123}^{-1}(\Delta\otimes 1)F^{-1}\cdot F_{12}^{-1}\\&\overset{\text{(II.14)}}{=}(\Phi_F^{-1})_{231}(F^T)_{13}(1\otimes T)(\Delta^T\otimes 1)F\cdot\mathcal{R}_{13}\Phi_{132}\mathcal{R}_{23}(1\otimes\Delta)F^{-1}\cdot F_{23}^{-1}(\Phi_F^{-1})_{123}\end{aligned}$$

$$=(\Phi_F^{-1})_{231}(F^T)_{13}(1\otimes T)[(\Delta^T\otimes 1)F\cdot\mathcal{R}_{12}]\cdot\Phi_{132}\mathcal{R}_{23}(1\otimes\Delta)F^{-1}\cdot F_{23}^{-1}(\Phi_F^{-1})_{123}$$

$$\overset{\text{(II.27)}}{=}(\Phi_F^{-1})_{231}(F^T)_{13}(1\otimes T)[\mathcal{R}_{12}(\Delta\otimes 1)F]\cdot\Phi_{132}(1\otimes\Delta^T)F^{-1}\cdot\mathcal{R}_{23}F_{23}^{-1}(\Phi_F^{-1})_{123}$$

$$=(\Phi_F^{-1})_{231}(F^T)_{13}\mathcal{R}_{13}(1\otimes T)[(\Delta\otimes 1)F]\cdot\Phi_{132}(1\otimes\Delta^T)F^{-1}\cdot\mathcal{R}_{23}F_{23}^{-1}(\Phi_F^{-1})_{123}$$

$$\overset{\text{(II.33)}}{=}(\Phi_F^{-1})_{231}(\mathcal{R}_F)_{13}F_{13}^{-1}(1\otimes T)[(\Delta\otimes 1)F]\cdot\Phi_{132}(1\otimes\Delta^T)F^{-1}(F^T)_{23}^{-1}(\mathcal{R}_F)_{23}(\Phi_F^{-1})_{123}$$

$$=(\Phi_F^{-1})_{231}(\mathcal{R}_F)_{13}(1\otimes T)[F_{12}^{-1}(\Delta\otimes 1)F\Phi_{123}(1\otimes\Delta)F^{-1}\cdot F_{23}^{-1}]\cdot(\mathcal{R}_F)_{23}(\Phi_F^{-1})_{123}$$

$$\overset{\text{(II.14)}}{=}(\Phi_F^{-1})_{231}(\mathcal{R}_F)_{13}(1\otimes T)(\Phi_F)_{123}\cdot(\mathcal{R}_F)_{23}(\Phi_F^{-1})_{123}$$

$$=(\Phi_F^{-1})_{231}(\mathcal{R}_F)_{13}(\Phi_F)_{132}(\mathcal{R}_F)_{23}(\Phi_F^{-1})_{123}. \tag{II.36}$$

Let us now consider the special case that A arises from a normal quasi-triangular Hopf superalgebra via twisting with F. A quasi-triangular Hopf superalgebra is a quasi-triangular quasi-Hopf superalgebra with $\alpha=\beta=1$ and $\Phi=1\otimes 1\otimes 1$. Hence A has the following $\mathbf{Z}_2$ graded quasi-Hopf algebra structure:

$$\Delta_F(a)=F\Delta(a)F^{-1},\quad \forall a\in A,$$
$$\Phi_F=F_{12}\cdot(\Delta\otimes 1)F\cdot(1\otimes\Delta)F^{-1}\cdot F_{23}^{-1},$$
$$\alpha_F=m\cdot(S\otimes 1)F^{-1},\quad \beta_F=m\cdot(1\otimes S)F, \tag{II.37}$$
$$\mathcal{R}_F=F^T\mathcal{R}F^{-1}.$$

The twisting procedure is particularly interesting when the twistor $F\in A\otimes A$ depends on an element $\lambda\in A$, i.e., $F=F(\lambda)$, and is a shifted cocycle in the following sense. Here λ is assumed to depend on one (or possible several) parameters.

Definition 4: A twistor $F(\lambda)$ depending on $\lambda\in A$ is a shifted cocycle if it satisfies the graded shifted cocycle condition:

$$F_{12}(\lambda)\cdot(\Delta\otimes 1)F(\lambda)=F_{23}(\lambda+h^{(1)})\cdot(1\otimes\Delta)F(\lambda), \tag{II.38}$$

where $h^{(1)}=h\otimes 1\otimes 1$ and $h\in A$ is fixed.

Let $(A,\Delta_\lambda,\epsilon,\Phi(\lambda),\mathcal{R}(\lambda))$ be the quasi-triangular quasi-Hopf superalgebra obtained from twisting the quasi-triangular Hopf superalgebra by the twistor $F(\lambda)$. Then we have the following.

Proposition 1: We have

$$\Phi(\lambda)\equiv\Phi_F=F_{23}(\lambda+h^{(1)})F_{23}(\lambda)^{-1}, \tag{II.39}$$

$$\Delta_\lambda(a)^T\mathcal{R}(\lambda)=\mathcal{R}(\lambda)\Delta_\lambda(a),\quad \forall a\in A, \tag{II.40}$$

$$(\Delta_\lambda\otimes 1)\mathcal{R}(\lambda)=\Phi_{231}(\lambda)^{-1}\mathcal{R}_{13}(\lambda)\mathcal{R}_{23}(\lambda+h^{(1)}), \tag{II.41}$$

$$(1\otimes\Delta_\lambda)\mathcal{R}(\lambda)=\mathcal{R}_{13}(\lambda+h^{(2)})\mathcal{R}_{12}(\lambda)\Phi_{123}(\lambda). \tag{II.42}$$

As a corollary, $\mathcal{R}(\lambda)$ *satisfies the graded dynamical Yang–Baxter equation*

$$\mathcal{R}_{12}(\lambda+h^{(3)})\mathcal{R}_{13}(\lambda)\mathcal{R}_{23}(\lambda+h^{(1)})=\mathcal{R}_{23}(\lambda)\mathcal{R}_{13}(\lambda+h^{(2)})\mathcal{R}_{12}(\lambda). \tag{II.43}$$

III. QUANTUM SUPERGROUPS

Let $\mathcal{G}$ be a Kac–Moody superalgebra[15,16] with a symmetrizable generalized Cartan matrix $A=(a_{ij})_{i,j,\in I}$. As is well known, a given Kac–Moody superalgebra allows many inequivalent systems of simple roots. A system of simple roots is called distinguished if it has minimal odd roots. Let $\{\alpha_i, i\in I\}$ denote a chosen set of simple roots. Let (,) be a fixed invariant bilinear form on the root space of $\mathcal{G}$. Let $\mathcal{H}$ be the Cartan subalgebra and throughout we identify the dual $\mathcal{H}^*$ with $\mathcal{H}$ via (,). The generalized Cartan matrix $A=(a_{ij})_{i,j\in I}$ is defined from the simple roots by

$$a_{ij}=\begin{cases}\dfrac{2(\alpha_i,\alpha_j)}{(\alpha_i,\alpha_i)}, & \text{if } (\alpha_i,\alpha_i)\neq 0,\\ (\alpha_i,\alpha_j), & \text{if } (\alpha_i,\alpha_i)=0.\end{cases} \tag{III.1}$$

As we mentioned in the previous section, quantum Kac–Moody superalgebras are quasi-triangular quasi-Hopf superalgebras with $\alpha=\beta=1$ and $\Phi=1\otimes1\otimes1$. We shall not give the standard relations obeyed by the simple generators (or Chevalley generators) $\{h_i, e_i, f_i, i\in I\}$ of $U_q(\mathcal{G})$, but mention that for certain types of Dynkin diagrams extra q-Serre relations are needed in the defining relations. We adopt the following graded Hopf algebra structure,

$$\begin{gathered}\Delta(h)=h\otimes 1+1\otimes h,\\ \Delta(e_i)=e_i\otimes 1+t_i\otimes e_i,\quad \Delta(f_i)=f_i\otimes t_i^{-1}+1\otimes f_i,\\ \epsilon(e_i)=\epsilon(f_i)=\epsilon(h)=0,\\ S(e_i)=-t_i^{-1}e_i,\quad S(f_i)=-f_i t_i,\quad S(h)=-h,\end{gathered} \tag{III.2}$$

where $i\in I$, $t_i=q^{h_i}$ and $h\in\mathcal{H}$.

The canonical element $\mathcal{R}$ is called the universal R-matrix of $U_q(\mathcal{G})$, which satisfies the basic properties [e.g., (II.27)–(II.29) with $\Phi=1\otimes1\otimes1$ and (II.32)]

$$\begin{aligned}&\Delta^T(a)\mathcal{R}=\mathcal{R}\Delta(a),\quad \forall a\in U_q(\mathcal{G}),\\ &(\Delta\otimes 1)\mathcal{R}=\mathcal{R}_{13}\mathcal{R}_{23},\\ &(1\otimes\Delta)\mathcal{R}=\mathcal{R}_{13}\mathcal{R}_{12},\\ &(\epsilon\otimes 1)\mathcal{R}=(1\otimes\epsilon)\mathcal{R}=1,\end{aligned} \tag{III.3}$$

and the graded Yang–Baxter equation [cf. (II.31) with $\Phi=1\otimes1\otimes1$]

$$\mathcal{R}_{12}\mathcal{R}_{13}\mathcal{R}_{23}=\mathcal{R}_{23}\mathcal{R}_{13}\mathcal{R}_{12}. \tag{III.4}$$

The Hopf superalgebra $U_q(\mathcal{G})$ contains two important Hopf subalgebras U_q^+ and U_q^- which are generated by e_i and f_i, respectively. By Drinfeld's quantum double construction, the universal R-matrix $\mathcal{R}$ can be written in the form

$$\mathcal{R}=\left(1\otimes 1+\sum_t a^t\otimes a_t\right)\cdot q^{-\mathcal{T}}, \tag{III.5}$$

where $\{a^t\}\in U_q^+$ and $\{a_t\}\in U_q^-$. The element $\mathcal{T}$ is defined as follows. If the symmetrical Cartan matrix is nondegenerate, then $\mathcal{T}$ is the usual canonical element of $\mathcal{H}\otimes\mathcal{H}$. Let $\{h_l\}$ be a basis of $\mathcal{H}$ and $\{h^l\}$ be its dual basis. Then $\mathcal{T}$ can be written as

$$\mathcal{T}=\sum_l h_l\otimes h^l. \tag{III.6}$$

In the case of a degenerate symmetrical Cartan matrix, we extend the Cartan subalgebra $\mathcal{H}$ by adding some elements to it in such a way that the extended symmetrical Cartan matrix is nondegenerate.[17] Then $\mathcal{T}$ stands for the canonical element of the extended Cartan subalgebra. It still takes the form (III.6), but now $\{h_l\}$ ($\{h^l\}$) is understood to be the (dual) basis of the extended Cartan subalgebra. After such enlargement, one has $h=\Sigma_l(h^l,h)h_l=\Sigma_l(h_l,h)h^l$ for any given h in the enlarged Cartan subalgebra.

For later use, we work out the explicit form of the universal R-matrix for the simplest quantum affine superalgebra $U_q[\widehat{sl(1|1)}]$. This algebra is generated by Chevalley generators $\{e_i,f_i,h_i,d,i=0,1\}$ with e_i, f_i odd, and h_i, d even. Here and throughout d stands for the derivation operator. Let us write $h_i=\alpha_i$. Then we have $h_0=\delta-\varepsilon_1+\delta_1$ and $h_1=\varepsilon_1-\delta_1$, where $\{\varepsilon_1,\delta_1,\delta\}$ satisfy $(\varepsilon_1,\varepsilon_1)=1=-(\delta_1,\delta_1)$, $(\varepsilon_1,\delta_1)=(\delta,\delta)=(\delta,\varepsilon_1)=(\delta,\delta_1)=0$. We extend the Cartan subalgebra by adding to it the element $h_{\rm ex}=\varepsilon_1+\delta_1$. A basis for the enlarged Cartan subalgebra is thus $\{h_{\rm ex},h_0,h_1,d\}$. It is easily shown that the dual basis is $\{h^{\rm ex},h^0,h^1,c\}$, where $h^{\rm ex}=\frac{1}{2}(\varepsilon_1-\delta_1)=\frac{1}{2}h_1$, $h^0=d$, and $h^1=\varepsilon_1+d-\frac{1}{2}(\varepsilon_1-\delta_1)=d+\frac{1}{2}h_{\rm ex}$. As is well known, $U_q[\widehat{sl(1|1)}]$ can also be realized in terms of the Drinfeld generators[18] $\{X_n^\pm,H_n,H_n^{\rm ex},n\in\mathbf{Z},c,d\}$, where $X_n^\pm$ are odd and all other generators are even. The relations satisfied by the Drinfeld generators read[19]

$$\begin{gathered}
[c,a]=[H_0,a]=[d,d]=[H_n,H_m]=[H_n^{\rm ex},H_m^{\rm ex}]=0,\quad \forall a\in U_q[\widehat{sl(1|1)}],\\
q^{H_0^{\rm ex}}X_n^\pm q^{-H_0^{\rm ex}}=q^{\pm 2}X_n^\pm,\\
[d,X_n^\pm]=nX_n^\pm,\quad [d,H_n]=nH_n,\quad [d,H_n^{\rm ex}]=nH_n^{\rm ex},\\
[H_n,H_m^{\rm ex}]=\delta_{n+m,0}\frac{[2n]_q[nc]_q}{n},\\
[H_n^{\rm ex},X_m^\pm]=\pm\frac{[2n]_q}{n}X_{n+m}^\pm q^{\mp|n|c/2},\\
[H_n,X_m^\pm]=0=[X_n^\pm,X_m^\pm],\\
[X_n^+,X_m^-]=\frac{1}{q-q^{-1}}\left(q^{(c/2)(n-m)}\psi_{n+m}^+-q^{-(c/2)(n-m)}\psi_{n+m}^-\right),
\end{gathered} \tag{III.7}$$

where $[x]_q=(q^x-q^{-x})/(q-q^{-1})$, $[a,b]\equiv ab-(-1)^{[a][b]}ba$ denotes the supercommutator, and $\psi_{\pm n}^\pm$ are related to $H_{\pm n}$ by relations

$$\sum_{n\geqslant 0}\psi^{\pm}_{\pm n}z^{\mp n}=q^{\pm H_0}\exp\left(\pm(q-q^{-1})\sum_{n>0}H_{\pm n}z^{\mp n}\right). \tag{III.8}$$

The relationship between the Drinfeld generators and the Chevalley generators is

$$\begin{aligned}&e_1=X_0^+,\quad f_1=X_0^-,\quad h_1=H_0,\quad h_{\rm ex}=H_0^{\rm ex},\\&e_0=X_1^-q^{-H_0},\quad f_0=-q^{H_0}X_{-1}^+,\quad h_0=c-H_0.\end{aligned} \tag{III.9}$$

With the help of the Drinfeld generators, we find the following universal R-matrix,

$$\mathcal{R}=\mathcal{R}'\cdot q^{-\mathcal{T}}, \tag{III.10}$$

where

$$\begin{aligned}\mathcal{T}&=h_{\rm ex}\otimes h^{\rm ex}+h_0\otimes h^0+h_1\otimes h^1+d\otimes c\\&=\tfrac{1}{2}(H_0\otimes h_0^{\rm ex}+H_0^{\rm ex}\otimes H_0)+c\otimes d+d\otimes c,\end{aligned}$$

$$\mathcal{R}'=\mathcal{R}^{<}\mathcal{R}^0\mathcal{R}^{>},$$

$$\mathcal{R}^{<}=\prod_{n\geqslant 0}^{\rightarrow}\exp[(q-q^{-1})(q^{-nc/2}X_n^+\otimes q^{nc/2}X_{-n}^-)], \tag{III.11}$$

$$\mathcal{R}^0=\exp\left[-(q-q^{-1})\sum_{n=1}^{\infty}\frac{n}{[2n]_q}(H_n\otimes H_{-n}^{\rm ex}+H_n^{\rm ex}\otimes H_{-n})\right],$$

$$\mathcal{R}^{>}=\prod_{n\geqslant 0}^{\leftarrow}\exp[-(q-q^{-1})(X_{n+1}^-q^{nc/2-H_0}\otimes q^{-nc/2+H_0}X_{-n-1}^+)].$$

Here and throughout,

$$\prod_{k\geqslant 0}^{\rightarrow}A_k=A_0A_1A_2\cdots,\quad \prod_{k\geqslant 0}^{\leftarrow}A_k=\cdots A_2A_1A_0. \tag{III.12}$$

It seems to us that even for this simplest quantum affine superalgebra $U_q[\widehat{sl(1|1)}]$ the universal R-matrix has not been written down in its explicit form before.

Let us compute the image of $\mathcal{R}$ in the two-dimensional evaluation representation (π,V) of $U_q[\widehat{sl(1|1)}]$, where $V=\mathbf{C}^{1|1}=\mathbf{C}v_1\otimes\mathbf{C}v_2$ with v_1 even and v_2 odd. Let e_{ij} be the 2×2 matrix whose (i,j)-element is unity and zero otherwise. In the homogeneous gradation, the simple generators are represented by

$$\begin{aligned}&e_1=\sqrt{[\theta]_q}e_{12},\quad f_1=\sqrt{[\theta]_q}e_{21},\quad h_1=\theta(e_{11}+e_{22}),\quad h_{\rm ex}=2e_{11}+c_0(e_{11}+e_{22}),\\&e_0=z\sqrt{[\theta]_q}e_{21},\quad f_0=-z^{-1}\sqrt{[\theta]_q}e_{12},\quad h_0=-\theta(e_{11}+e_{22}),\end{aligned} \tag{III.13}$$

where θ and c_0 are arbitrary constants. Then it can be shown that the Drinfeld generators are represented by

$$\begin{aligned}&H_n=z^n\frac{[n\theta]_q}{n}(e_{11}+e_{22}),\quad H_n^{\rm ex}=z^n\frac{[2n]_q}{n}q^{n\theta}e_{11}+z^nc_n(e_{11}+e_{22}),\\&X_n^+=z^nq^{n\theta}\sqrt{[\theta]_q}e_{12},\quad X_n^-=z^nq^{n\theta}\sqrt{[\theta]_q}e_{21},\end{aligned} \tag{III.14}$$

where again c_n are arbitrary constants. In the following we set c_n to be zero. Then the image $R_{VV}(z;\theta,\theta')=(\pi_\theta\otimes\pi_{\theta'})\mathcal{R}$ depends on two extra nonadditive parameters θ, θ', and is given by

$$R_{VV}(z;\theta,\theta')=\frac{q^{-\theta-\theta'}-z}{1-zq^{-\theta-\theta'}}e_{11}\otimes e_{11}+e_{22}\otimes e_{22}+\frac{q^{-\theta'}-zq^{-\theta}}{1-zq^{-\theta-\theta'}}e_{11}\otimes e_{22}+\frac{q^{-\theta}-zq^{-\theta'}}{1-zq^{-\theta-\theta'}}e_{22}\otimes e_{11}$$
$$+\sqrt{[\theta]_q[\theta']_q}q^{-\theta}\frac{q-q^{-1}}{1-zq^{-\theta-\theta'}}e_{12}\otimes e_{21}-\sqrt{[\theta]_q[\theta']_q}q^{-\theta'}\frac{z(q-q^{-1})}{1-zq^{-\theta-\theta'}}e_{21}\otimes e_{12}. \tag{III.15}$$

Equation (III.15) is nothing but the R-matrix obtained in Ref. 20 by solving the Jimbo equation.

IV. ELLIPTIC QUANTUM SUPERGROUPS

Following Jimbo *et al.*,[4] we define elliptic quantum supergroups to be quasi-triangular quasi-Hopf superalgebras obtained from twisting the normal quantum supergroups (which are quasi-triangular quasi-Hopf superalgebras with $\alpha=\beta=1$ and $\Phi=1\otimes1\otimes1$) by twistors which satisfy the graded shifted cocycle condition.

A. Elliptic quantum supergroups of face type

Let ρ be an element in the (extended) Cartan subalgebra such that $(\rho,\alpha_i)=(\alpha_i,\alpha_i)/2$ for all $i\in I$, and

$$\phi=\mathrm{Ad}\,(q^{(1/2)\Sigma_l h_l h^l-\rho}), \tag{IV.1}$$

be an automorphism of $U_q(\mathcal{G})$. Here $\{h_l\}$ and $\{h^l\}$ are as in (III.6) and are the dual basis of the (extended) Cartan subalgebra. Namely,

$$\phi(e_i)=e_it_i,\quad \phi(f_i)=t_i^{-1}f_i,\quad \phi(q^h)=q^h. \tag{IV.2}$$

In the following we consider the special case in which the element λ introduced before belongs to the (extended) Cartan subalgebra. Let

$$\phi_\lambda=\phi^2\cdot\mathrm{Ad}\,(q^{2\lambda})=\mathrm{Ad}\,(q^{\Sigma_l h_l h^l-2\rho+2\lambda}) \tag{IV.3}$$

be an automorphism depending on the element λ and $\mathcal{R}$ be the universal R-matrix of $U_q(\mathcal{G})$. Following Jimbo *et al.*,[4] we define a twistor $F(\lambda)$ by the infinite product

$$F(\lambda)=\prod_{k\geq1}^{\leftarrow}(\phi_\lambda^k\otimes1)(q^{\mathcal{T}}\mathcal{R})^{-1}. \tag{IV.4}$$

It is easily seen that $F(\lambda)$ is a formal series in parameter(s) in λ with leading term 1. Therefore the infinite product makes sense. The twistor $F(\lambda)$ is referred to as a face-type twistor. It can be shown that $F(\lambda)$ satisfies the graded shifted cocycle condition

$$F_{12}(\lambda)(\Delta\otimes1)F(\lambda)=F_{23}(\lambda+h^{(1)})(1\otimes\Delta)F(\lambda), \tag{IV.5}$$

where, if $\lambda=\Sigma_l\lambda_l h^l$, then $\lambda+h^{(1)}=\Sigma_l(\lambda_l+h_l^{(1)})h^l$. The proof of (IV.5) is identical to the non-super case given by Jimbo *et al.*,[4] apart from the use of the graded tensor products. Moreover, it is easily seen that $F(\lambda)$ obeys the counit property

$$(\epsilon\otimes1)F(\lambda)=(1\otimes\epsilon)F(\lambda)=1. \tag{IV.6}$$

We have the following definition.

Definition 5 (Face-type elliptic quantum supergroup): We define elliptic quantum supergroup $\mathcal{B}_{q,\lambda}(\mathcal{G})$ of face type to be the quasi-triangular quasi-Hopf superalgebra $(U_q(\mathcal{G}),\Delta_\lambda,\epsilon,\Phi(\lambda),\mathcal{R}(\lambda))$ together with the graded algebra anti-homomorphism S defined by (III.2) and $\alpha_\lambda = m\cdot(S\otimes 1)F(\lambda)^{-1}$, $\beta_\lambda = m\cdot(1\otimes S)F(\lambda)$. Here ϵ is defined by (III.2), and

$$\begin{aligned}
&\Delta_\lambda(a)=F(\lambda)\Delta(a)F(\lambda)^{-1}, \quad \forall a\in U_q(\mathcal{G}),\\
&\mathcal{R}(\lambda)=F(\lambda)^T\mathcal{R}F(\lambda)^{-1},\\
&\Phi(\lambda)=F_{23}(\lambda+h^{(1)})F_{23}(\lambda)^{-1}.
\end{aligned} \tag{IV.7}$$

We now consider the particularly interesting case where $\mathcal{G}$ is of affine type. Then ρ contains two parts,

$$\rho=\bar{\rho}+gd, \tag{IV.8}$$

where $g=(\psi,\psi+2\bar{\rho})/2$, $\bar{\rho}$ is the graded half-sum of positive roots of the nonaffine part $\bar{\mathcal{G}}$, and ψ is highest root of $\mathcal{G}$; d is the derivation operator which gives the homogeneous gradation

$$[d,e_i]=\delta_{i0}e_i, \quad [d,f_i]=-\delta_{i0}f_i, \quad i\in I. \tag{IV.9}$$

We also set

$$\lambda=\bar{\lambda}+(r+g)d+s'c, \quad r,s'\in\mathbf{C}, \tag{IV.10}$$

where $\bar{\lambda}$ stands for the projection of λ onto the (extended) Cartan subalgebra of $\bar{\mathcal{G}}$. Denoting by $\{\bar{h}_j\}$ and $\{\bar{h}^j\}$ the dual basis of the (extended) Cartan subalgebra of $\bar{\mathcal{G}}$ and setting $p=q^{2r}$, we can decompose ϕ_λ into two parts,

$$\phi_\lambda=\mathrm{Ad}\,(p^dq^{2cd})\cdot\bar{\phi}_\lambda, \quad \bar{\phi}_\lambda=\mathrm{Ad}\,(q^{\Sigma_j\bar{h}_j\bar{h}^j+2(\bar{\lambda}-\bar{\rho})}). \tag{IV.11}$$

Introduce a formal parameter z (which will be identified with spectral parameter) into $\mathcal{R}$ and $F(\lambda)$ by setting

$$\begin{aligned}
&\mathcal{R}(z)=\mathrm{Ad}\,(z^d\otimes 1)\mathcal{R},\\
&F(z,\lambda)=\mathrm{Ad}\,(z^d\otimes 1)F(\lambda),\\
&\mathcal{R}(z,\lambda)=\mathrm{Ad}\,(z^d\otimes 1)\mathcal{R}(\lambda)=F(z^{-1},\lambda)^T\mathcal{R}(z)F(z,\lambda)^{-1}.
\end{aligned} \tag{IV.12}$$

Then it can be shown from the definition of $F(\lambda)$ that $F(z,\lambda)$ satisfies the difference equation

$$\begin{aligned}
&F(pq^{2c^{(1)}}z,\lambda)=(\bar{\phi}_\lambda\otimes 1)^{-1}(F(z,\lambda))\cdot q^{\mathcal{T}}\mathcal{R}(pq^{2c^{(1)}}z),\\
&F(0,\lambda)=F_{\bar{\mathcal{G}}}(\bar{\lambda}).
\end{aligned} \tag{IV.13}$$

The initial condition follows from the fact that $\mathcal{R}(z)q^{d\otimes c+c\otimes d}|_{z=0}$ reduces to the universal R-matrix of $U_q(\bar{\mathcal{G}})$.

Let us give some examples.

1. The case $\mathcal{B}q,\lambda[\mathrm{sl}(1|1)]$

In this case the universal R-matrix is given simply by

$$\begin{aligned}
&\mathcal{R}=\exp[(q-q^{-1})e\otimes f]q^{-\mathcal{T}}=[1+(q-q^{-1})e\otimes f]q^{-\mathcal{T}},\\
&\mathcal{T}=\tfrac{1}{2}(h\otimes h_{\mathrm{ex}}+h_{\mathrm{ex}}\otimes h).
\end{aligned} \tag{IV.14}$$

Let us write

$$\lambda=(s'+1)\tfrac{1}{2}h+s\tfrac{1}{2}h_{\rm ex},\quad s',s\in\mathbf{C}. \tag{IV.15}$$

Since h commutes with everything, ϕ_λ is independent of s'. Setting $w=q^{2(s+h)}$, we have

$$\phi_\lambda=\mathrm{Ad}(w^{1/2h_{\rm ex}}). \tag{IV.16}$$

The formula for the twistor becomes

$$\begin{aligned}F(w)&=\prod_{k\geqslant 1}\big(1-(q-q^{-1})w^kq^{-h}e\otimes fq^h\big)\\&=1-(q-q^{-1})\sum_{k=1}^{\infty}w^kq^{-h}e\otimes fq^h\\&=1-(q-q^{-1})\frac{w}{1-w}q^{-h}e\otimes fq^h.\end{aligned} \tag{IV.17}$$

2. The case $\mathcal{B}_{q,\lambda}[\mathrm{sl}(\hat{1}|1)$

Taking a basis $\{c,d,h,h_{\rm ex}\}$ of the enlarged Cartan subalgebra of $\mathrm{sl}(\widehat{1}|1)$, we write

$$\lambda=rd+s'c+(s''+1)\tfrac{1}{2}h+s\tfrac{1}{2}h_{\rm ex},\quad r,s',s'',s\in\mathbf{C}. \tag{IV.18}$$

Then ϕ_λ is independent of s' and s''. Set

$$p=q^{2r},\quad w=q^{2(s+h)}. \tag{IV.19}$$

Set $F(z;p,w)\equiv F(z,\lambda)$. Then (IV.13) take the form

$$F(pq^{2c^{(1)}}z;p,w)=(\overline{\phi_w}^{-1}\otimes 1)\big(F(z;p,w)\big)\cdot q^{\mathcal{T}}\mathcal{R}(pq^{2c^{(1)}}z), \tag{IV.20}$$

$$F(0;p,w)=F_{\mathrm{sl}(1|1)}(w), \tag{IV.21}$$

where $\overline{\phi_w}=\mathrm{Ad}(w^{(1/2h_{\rm ex}})$.

The image of (IV.20) in the two-dimensional representation (π,V) given by (III.13) (by setting $\theta=1$) yields a difference equation for $F_{VV}(z;p,w)=(\pi\otimes\pi)F(z;p,w)$. Noting that $\pi\cdot\overline{\phi_w}=\mathrm{Ad}\,(D_w^{-1})\cdot\pi$, where $D_w=e_{11}+we_{22}$, we find

$$F_{VV}(pz;p,w)=\mathrm{Ad}\,(D_w\otimes 1)\big(F_{VV}(z;p,w)\big)\cdot KR_{VV}(pz), \tag{IV.22}$$

where $K=(\pi\otimes\pi)q^{\mathcal{T}}=q^2e_{11}\otimes e_{11}+qe_{11}\otimes e_{22}+qe_{22}\otimes e_{11}+e_{22}\otimes e_{22}$ and $R_{VV}(pz)$ is given by (III.15) (with $\theta=\theta'=1$). Equation (IV.22) is a system of difference equations of q-KZ (Kaizhnik–Zamolodchikov) equation type,[21] and can be solved with the help of the q-hypergeometric series. The solution with the initial condition (IV.21) is given by

$$\begin{aligned}F_{VV}(z;p,w)=&{}_1\phi_0(z;p,w)e_{11}\otimes e_{11}+e_{22}\otimes e_{22}+f_{11}(z;p,w)e_{11}\otimes e_{22}+f_{22}(z;p,w)e_{22}\otimes e_{11}\\&+f_{12}(z;p,w)e_{12}\otimes e_{21}+f_{21}(z;p,w)e_{21}\otimes e_{12},\end{aligned} \tag{IV.23}$$

where

$${}_1\phi_0(z;p,w)=\frac{(pq^{-2}z;p)_\infty}{(pq^2z;p)_\infty},$$

$$f_{11}(z;p,w)={}_2\phi_1\left(\begin{matrix} wq^{-2} & q^{-2} \\ & w \end{matrix};p,pq^2z\right),$$

$$f_{12}(z;p,w)=-\frac{w(q-q^{-1})}{1-w}\,{}_2\phi_1\left(\begin{matrix} wq^{-2} & pq^{-2} \\ & pw \end{matrix};p,pq^2z\right), \tag{IV.24}$$

$$f_{21}(z;p,w)=\frac{zpw^{-1}(q-q^{-1})}{1-pw^{-1}}\,{}_2\phi_1\left(\begin{matrix} pw^{-1}q^{-2} & pq^{-2} \\ & p^2w^{-1} \end{matrix};p,pq^2z\right),$$

$$f_{22}(z;p,w)={}_2\phi_1\left(\begin{matrix} pw^{-1}q^{-2} & q^{-2} \\ & pw^{-1} \end{matrix};p,pq^2z\right).$$

Here

$$2\phi 1\left(\begin{matrix} q^a & q^b \\ & q^c \end{matrix};p,x\right)=\sum_{n=0}^{\infty}\frac{(q^a;p)_n(q^b;p)_n}{(p;p)_n(q^c;p)_n}x^n,$$
$$(a;p)_n=\prod_{k=0}^{n-1}(1-ap^k),\quad (a;p)_0=1. \tag{IV.25}$$

B. Elliptic quantum supergroups of vertex type

As we mentioned before, a given Kac–Moody superalgebras $\mathcal{G}$ allows many inequivalent simple root systems. By means of the ''extended'' Weyl transformation method introduced in Ref. 22, one can transform from one simple root system to another inequivalent one.[23] For $\mathcal{G}=\mathrm{sl}(\widehat{n|n})$, there exists a simple root system in which all simple roots are odd (or fermionic). This system can be constructed from the distinguished simple root system by using the ''extended'' Weyl operation repeatedly. We find the following simple roots, all of which are odd (or fermionic),

$$\alpha_0=\delta-\varepsilon_1+\delta_n,$$
$$\alpha_{2j}=\delta_j-\varepsilon_{j+1},\quad j=1,2,...,n-1, \tag{IV.26}$$
$$\alpha_{2i-1}=\varepsilon_i-\delta_i,\quad i=1,2,...,n$$

with δ, $\{\varepsilon_i\}_{i=1}^n$ and $\{\delta_i\}_{i=1}^n$ satisfying

$$(\delta,\delta)=(\delta,\varepsilon_i)=(\delta,\delta_i)=0,\quad (\varepsilon_i,\varepsilon_j)=\delta_{ij},$$
$$(\delta_i,\delta_j)=-\delta_{ij},\quad (\varepsilon_i,\delta_j)=0. \tag{IV.27}$$

Such a simple root system is usually called nonstandard. It seems to us that $\mathrm{sl}(\widehat{n|n})$ is the only nontwisted affine superalgebra which has a nonstandard system of simple roots, all of which are fermionic.

As will be shown below, for $\mathcal{G}=\mathrm{sl}(\widehat{n|}n)$ with the above fermionic simple roots, one can construct a different type of twistor. Following Jimbo *et al.*,[4] we say this twistor is of *vertex type*.

Let us write $h_i=\alpha_i\,(i=0,1,...,2n-1)$ with α_i given by (IV.26). We extend the Cartan subalgebra of $\mathrm{sl}(\widehat{n|}n)$ by adding to it the element $h_{\mathrm{ex}}=\Sigma_{i=1}^{n}(\varepsilon_i+\delta_i)$. A basis of the extended Cartan subalgebra is $\{h_{\mathrm{ex}},h_0,h_1,\ldots,h_{2n-1},d\}$. Denote by $\{h^{\mathrm{ex}},h^0,h^1,\ldots,h^{2n-1},c\}$ the dual basis. We have

$$h^{\mathrm{ex}}=\frac{1}{2n}\sum_{i=1}^{n}(\varepsilon_i-\delta_i),$$

$$h^{2k}=d+\sum_{i=1}^{k}(\varepsilon_i-\delta_i)-\frac{k}{n}\sum_{i=1}^{n}(\varepsilon_i-\delta_i), \tag{IV.28}$$

$$h^{2k+1}=d+\sum_{i=1}^{k+1}\varepsilon_i-\sum_{i=1}^{k}\delta_i-\frac{2k+1}{2n}\sum_{i=1}^{k}(\varepsilon_i-\delta_i),$$

where $k=0,1,...,n-1$. The canonical element $\mathcal{T}$ in the extended Cartan subalgebra reads

$$\mathcal{T}=h_{\mathrm{ex}}\otimes h^{\mathrm{ex}}+\sum_{i=0}^{2n-1}(h_i\otimes h^i)+d\otimes c. \tag{IV.29}$$

Let τ be the diagram automorphism of $U_q[\mathrm{sl}(\widehat{n|}n)]$ such that

$$\tau(e_i)=e_{i+1 \bmod 2n},\quad \tau(f_i)=f_{i+1 \bmod 2n},\quad \tau(h_i)=h_{i+1 \bmod 2n}. \tag{IV.30}$$

Obviously, the automorphism τ is nongraded since it preserves the grading of the generators and, moreover, $\tau^{2n}=1$. Then we can show

$$\tau(h_{\mathrm{ex}})=-h_{\mathrm{ex}}+\xi c,\quad \tau(c)=c,\quad \tau(h^{\mathrm{ex}})=-h^{\mathrm{ex}}+\frac{1}{2n}c,$$

$$\tau(h^{2k})=h^{2k+1 \bmod 2n}+\frac{\xi}{2n}\sum_{i=1}^{n}(\varepsilon_i-\delta_i)-\frac{\xi+n-2k-1}{2n}c, \tag{IV.31}$$

$$\tau(h^{2k+1})=h^{2k+2 \bmod 2n}+\frac{\xi}{2n}\sum_{i=1}^{n}(\varepsilon_i-\delta_i)-\frac{n-2k-1}{2n}c,$$

where $k=0,1,...,n-1$ and ξ is an arbitrary constant. Introduce element

$$\tilde{\rho}=\sum_{i=0}^{2n-1}h^i+\xi n h^{\mathrm{ex}}, \tag{IV.32}$$

which gives the principal gradation

$$[\tilde{\rho},e_i]=e_i,\quad [\tilde{\rho},f_i]=-f_i,\quad i=0,1,...,2n-1. \tag{IV.33}$$

It is easily shown that

$$\tau(\tilde{\rho})=\tilde{\rho},\quad (\tau\otimes\tau)\mathcal{T}=\mathcal{T}. \tag{IV.34}$$

Notice also that

$$(\tau\otimes\tau)\cdot\Delta=\Delta\cdot\tau, \tag{IV.35}$$

$$(\tau\otimes\tau)\mathcal{R}=\mathcal{R}.$$

Here the second relation is deduced from the uniqueness of the universal R-matrix of $U_q[sl(\widehat{n|n})]$. It can be shown that

$$\sum_{k=1}^{2n}(\tau^k\otimes 1)\mathcal{T}=\tilde{\rho}\otimes c+c\otimes\tilde{\rho}-\frac{2(n^2-1)-3\xi}{6}c\otimes c. \tag{IV.36}$$

Therefore, if we set

$$\tilde{\mathcal{T}}=\frac{1}{2n}\left(\tilde{\rho}\otimes c+c\otimes\tilde{\rho}-\frac{2(n^2-1)-3\xi}{6}c\otimes c\right), \tag{IV.37}$$

then we have

$$\sum_{k=1}^{2n}(\tau^k\otimes 1)(\mathcal{T}-\tilde{\mathcal{T}})=0. \tag{IV.38}$$

Introduce an automorphism

$$\tilde{\phi}_r=\tau\cdot \mathrm{Ad}\,(q^{[(r+c)/n]\tilde{\rho}}), \tag{IV.39}$$

which depends on a parameter $r\in\mathbf{C}$. Then the $2n$-fold product

$$\prod_{2n\geqslant k\geqslant 1}^{\leftarrow}(\tilde{\phi}_r^k\otimes 1)(q^{\tilde{\mathcal{T}}}\mathcal{R})^{-1}. \tag{IV.40}$$

is a formal power series in $p^{1/2n}$ where $p=q^{2r}$. Moreover, it has leading term 1 thanks to the relation (IV.38). Following Jimbo *et al.*,[4] we define the vertex-type twistor

$$E(r)=\lim_{N\to\infty}\prod_{2nN\geqslant k\geqslant 1}^{\leftarrow}(\tilde{\phi}_r^k\otimes 1)(q^{\tilde{\mathcal{T}}}\mathcal{R})^{-1}. \tag{IV.41}$$

Then one can show that $E(r)$ satisfies the graded shifted cocycle condition

$$E_{12}(r)(\Delta\otimes 1)E(r)=E_{23}(r+c^{(1)})(1\otimes\Delta)E(r). \tag{IV.42}$$

Moreover, $E(r)$ obeys the counit property

$$(\epsilon\otimes 1)E(r)=(1\otimes\epsilon)E(r)=1. \tag{IV.43}$$

We have the following.

Definition 6 (Vertex-type elliptic quantum supergroup): We define elliptic quantum supergroup $\mathcal{A}_{q,p}[sl(\widehat{n|n})]$ *of vertex type to be the quasi-triangular quasi-Hopf superalgebra* $(U_q[sl(\widehat{n|n})],\Delta_r,\epsilon,\Phi(r),\mathcal{R}(r))$ *together with the graded algebra anti-homomorphism S defined by (III.2) and* $\alpha_r=m\cdot(S\otimes 1)E(r)^{-1}$, $\beta_r=m\cdot(1\otimes S)E(r)$. *Here* ϵ *is defined by (III.2), and*

$$\Delta_r(a)=E(r)\Delta(a)E(r)^{-1},\quad \forall a\in U_q[sl(\widehat{n|n})],$$

$$\mathcal{R}(r)=E(r)^T\mathcal{R}E(r)^{-1}, \tag{IV.44}$$

$$\Phi(r)=E_{23}(r+c^{(1)})E_{23}(r)^{-1}.$$

Similar to the face-type case, introduce a formal parameter ζ (or spectral parameter) into $\mathcal{R}$ and $E(r)$ by the formulas

$$\tilde{\mathcal{R}}(\zeta)=\mathrm{Ad}\,(\zeta^{\tilde{\rho}}\otimes 1)\mathcal{R},$$
$$E(\zeta,r)=\mathrm{Ad}\,(\zeta^{\tilde{\rho}}\otimes 1)E(r), \tag{IV.45}$$
$$\tilde{\mathcal{R}}(\zeta,r)=\mathrm{Ad}\,(\zeta^{\tilde{\rho}}\otimes 1)\mathcal{R}(r)=E(\zeta^{-1},r)^T\tilde{\mathcal{R}}(\zeta)E(\zeta,r)^{-1}.$$

Then it can be shown from the definition of $E(r)$ that $E(\zeta,r)$ satisfies the difference equation

$$E(p^{1/2n}q^{(1/n)c^{(1)}}\zeta,r)=(\tau\otimes 1)^{-1}(E(\zeta,r))\cdot q^{\tilde{T}}\tilde{\mathcal{R}}(p^{1/2n}q^{(1/n)c^{(1)}}\zeta), \tag{IV.46}$$

$$E(0,r)=1. \tag{IV.47}$$

The initial condition follows from (IV.38) and the fact that we are working in the principal gradation. Equation (IV.46) implies that

$$E((p^{1/2n}q^{(1/n)c^{(1)}})^{2n}\zeta,r)=E(\zeta,r))\cdot\prod_{2n-1\geqslant k\geqslant 0}^{\leftarrow} q^{\tilde{T}}(\tau\otimes 1)^{2n-k}\tilde{\mathcal{R}}((p^{1/2n}q^{(1/n)c^{(1)}})^{2n-k}\zeta). \tag{IV.48}$$

Some remarks are in order. In nonsuper case,[4] π and τ are commutable in the sense that $\pi\cdot\tau=\mathrm{Ad}\,(h)\cdot\pi$ with h obeying $hv_i=v_{i+1\ \mathrm{mod}\ m}$, where $\{v_i\}$ are basis of the vector module $V=\mathbf{C}^m=\mathbf{C}v_1\oplus\cdots\oplus\mathbf{C}c_m$ of $\mathcal{A}_{q,p}(\hat{\mathrm{sl}}_m)$ and τ is the cyclic diagram automorphism of $\hat{\mathrm{sl}}_m$. In the super (or $\mathbf{Z}_2$ graded) case, however, π and τ are not ''commutable'' in the above sense. This is because τ is grading preserving while the $2n$-dimensional defining representation space $V=\mathbf{C}^{n|n}=\mathbf{C}v_1\oplus\cdots\oplus\mathbf{C}v_{2n}$ is graded. So to compute the image, one has to work out the action of τ at the universal level and then apply the representation π. Therefore, the knowledge of the universal R-matrix in its explicit form is required. This makes the image computation of the twistor more involved in the supersymmetric case.

As an example, consider the simplest case of elliptic quantum affine superalgebra $\mathcal{A}_{q,p}[\mathrm{sl}(\widehat{1|1})]$. Let us calculate the image in the two-dimensional representation (π,V), $V=\mathbf{C}^{1|1}$. As remarked above, we have to work at the universal level first and then apply the representation. We have the following.

Lemma 2: In the principal gradation, the action of τ on the Drinfeld generators is represented on V by

$$\tau(X_n^+)=(-1)^n z^{2n+1}q^{-n}e_{12},\quad \tau(X_n^-)=(-1)^{n+1}z^{2n-1}q^{-n}e_{21},$$
$$\tau(H_n)=(-1)^{n+1}z^{2n}\frac{[n]_q}{n}(e_{11}+e_{22}), \tag{IV.49}$$
$$\tau(H_n^{\mathrm{ex}})=(-1)^{n+1}z^{2n}\frac{[2n]_q}{n}\left(q^{-n}e_{11}+\frac{q-q^{-1}}{2}[n]_q(e_{11}+e_{22})\right).$$

Applying $\pi\otimes\pi$ to the both side of (IV.48) and writing $E_{VV}(\zeta;p)\equiv(\pi\otimes\pi)E(\zeta,r)$, where $p=q^{2r}$, we get

$$E_{VV}(p\zeta;p)=E_{VV}(\zeta;p)\cdot(\pi\otimes\pi)((\tau\otimes 1)\tilde{\mathcal{R}}(p^{1/2}\zeta))\cdot\tilde{\mathcal{R}}_{VV}(p\zeta), \tag{IV.50}$$

where $\tilde{R}_{VV}(\zeta)=(\pi\otimes\pi)\tilde{R}(\zeta)$. In view of (IV.49) and the explicit formula (III.11) of the universal R-matrix, (IV.50) is a system of eight difference equations.

We can also proceed directly. We have, with the help of Lemma 2,

$$(\pi\otimes\pi)(\tau^{2k}\otimes 1)(\mathrm{Ad}\,(p^k\zeta)^{\tilde\rho}\otimes 1)\mathcal{R}^{-1}q^{-\tilde{\mathcal{T}}}=K\cdot\overline{E}_{2k},$$
$$(\pi\otimes\pi)(\tau^{2k-1}\otimes 1)(\mathrm{Ad}\,(p^{k-1/2}\zeta)^{\tilde\rho}\otimes 1)\mathcal{R}^{-1}q^{-\tilde{\mathcal{T}}}=\rho_{2k-1}\cdot K^{-1}\cdot\overline{E}_{2k-1}, \tag{IV.51}$$

where $K=(\pi\otimes\pi)q^{\mathcal{T}}$ and

$$\rho_{2k-1}=\frac{(1+q^2p^{2k-1}\zeta^2)(1+q^{-2}p^{2k-1}\zeta^2)}{(1+p^{2k-1}\zeta^2)^2},$$

$$\begin{aligned}\overline{E}_{2k}=\frac{1}{1-q^2p^{2k}\zeta^2}&((1-q^{-2}p^{2k}\zeta^2)e_{11}\otimes e_{11}+(1-q^2p^{2k}\zeta^2)e_{22}\otimes e_{22}\\&+(1-p^{2k}\zeta^2)e_{11}\otimes e_{22}+(1-p^{2k}\zeta^2)e_{22}\otimes e_{11}\\&-(q-q^{-1})p^k\zeta e_{12}\otimes e_{21}+(q-q^{-1})p^k\zeta e_{21}\otimes e_{12}),\end{aligned} \tag{IV.52}$$

$$\begin{aligned}\overline{E}_{2k-1}=\frac{1}{1+q^{-2}p^{2k-1}\zeta^2}&((1+q^2p^{2k-1}\zeta^2)e_{11}\otimes e_{11}+(1+q^{-2}p^{2k-1}\zeta^2)e_{22}\otimes e_{22}\\&+(1+p^{2k-1}\zeta^2)e_{11}\otimes e_{22}+(1+p^{2k-1}\zeta^2)e_{22}\otimes e_{11}\\&+(q-q^{-1})p^{k-1/2}\zeta e_{12}\otimes e_{21}-(q-q^{-1})p^{k-1/2}\zeta e_{21}\otimes e_{12}).\end{aligned} \tag{IV.53}$$

Then

$$E_{VV}(\zeta;p)=\prod_{k\geqslant 1}^{\leftarrow}\rho_{2k-1}K\overline{E}_{2k}K^{-1}\overline{E}_{2k-1}=\rho(\zeta;p)(E_{VV}^1(\zeta;p)+E_{VV}^2(\zeta;p)), \tag{IV.54}$$

where

$$\rho(\zeta;p)=\frac{(-pq^2\zeta^2;p^2)_\infty}{(pq\zeta;p)_\infty(-pq\zeta;p)_\infty}, \tag{IV.55}$$

$$\begin{aligned}E_{VV}^1(\zeta;p)=\prod_{k\geqslant 1}^{\leftarrow}\frac{1}{(1+p^{2k-1}\zeta^2)^2}&((1-q^{-2}p^{2k}\zeta^2)(1+q^2p^{2k-1}\zeta^2)e_{11}\otimes e_{11}\\&+(1-q^2p^{2k}\zeta^2)(1+q^{-2}p^{2k-1}\zeta^2)e_{22}\otimes e_{22}\\&+(q-q^{-1})p^{k-1/2}\zeta(1-q^{-2}p^{2k}\zeta^2)e_{12}\otimes e_{12}\\&-(q-q^{-1})p^{k-1/2}\zeta(1-q^2p^{2k}\zeta^2)e_{21}\otimes e_{21}),\end{aligned} \tag{IV.56}$$

$$\begin{aligned}E_{VV}^2(\zeta;p)=\prod_{k\geqslant 1}^{\leftarrow}\frac{1}{1+p^{2k-1}\zeta^2}&((1-p^{2k}\zeta^2)e_{11}\otimes e_{22}+(1-p^{2k}\zeta^2)e_{22}\otimes e_{11}\\&-(q-q^{-1})p^k\zeta e_{12}\otimes e_{21}+(q-q^{-1})p^k\zeta e_{21}\otimes e_{12}).\end{aligned} \tag{IV.57}$$

The infinite product in $E_{VV}^2(\zeta;p)$ can be calculated directly and we find

$$E_{VV}^2(\zeta;p)=b_E(\zeta)(e_{11}\otimes e_{22}+e_{22}\otimes e_{11})+c_E(\zeta)(e_{12}\otimes e_{21}-e_{21}\otimes e_{12}), \tag{IV.58}$$

where

$$b_E(\zeta)\pm c_E(\zeta)=\frac{(pq^{\pm 1}\zeta;p)_\infty(-pq^{\mp 1}\zeta;p)_\infty}{(-p\zeta^2;p^2)_\infty}. \tag{IV.59}$$

As for $E^1_{VV}(\zeta;p)$, it can be written as

$$E^1_{VV}(\zeta;p)=X_{11}(\zeta;p)e_{11}\otimes e_{11}+X_{22}(\zeta;p)e_{22}\otimes e_{22}+X_{12}(\zeta;p)e_{12}\otimes e_{12}+X_{21}(\zeta;p)e_{21}\otimes e_{21}, \qquad \text{(IV.60)}$$

where $X_{ij}(\zeta;p)$ are the solution to the following system of four difference equations:

$$\begin{aligned}
X_{11}(p\zeta;p)&=\frac{1}{1-q^{-2}p^2\zeta^2}((1+q^{-2}p\zeta^2)X_{11}(\zeta;p)-p^{1/2}\zeta(q-q^{-1})X_{12}(\zeta;p)),\\
X_{12}(p\zeta;p)&=\frac{1}{1-q^{2}p^2\zeta^2}(-p^{1/2}\zeta(q-q^{-1})X_{11}(\zeta;p)+(1+q^{2}p\zeta^2)X_{12}(\zeta;p)),\\
X_{21}(p\zeta;p)&=\frac{1}{1-q^{-2}p^2\zeta^2}(p^{1/2}\zeta(q-q^{-1})X_{22}(\zeta;p)+(1+q^{-2}p\zeta^2)X_{21}(\zeta;p)),\\
X_{22}(p\zeta;p)&=\frac{1}{1-q^{2}p^2\zeta^2}((1+q^{2}p\zeta^2)X_{22}(\zeta;p)+p^{1/2}\zeta(q-q^{-1})X_{21}(\zeta;p)).
\end{aligned} \qquad \text{(IV.61)}$$

ACKNOWLEDGMENTS

Our interest in quasi-Hopf algebras was ignited by Bo-Yu Hou's beautiful lecture on the Jimbo *et al.* paper[4] when YZZ was visiting Northwest University, Xi'an, in December 1997. YZZ thanks Bo-Yu Hou for interesting him in the subject and for helpful discussions. The financial support from the Australian Research Council through a Queen Elizabeth II Fellowship Grant for YZZ is also gratefully acknowledged.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 10 OCTOBER 1999

Comment on ‘‘Exact periodic solutions of the complex Ginzburg–Landau equation’’ [J. Math. Phys. 40, 884 (1999)]

Robert Conte
Service de Physique de l'État Condensé, CEA Saclay, F-91191 Gif-sur-Yvette Cedex, France

Micheline Musette
Dienst Theoretische Natuurkunde, Vrije Universiteit Brussel, B-1050 Brussel, Belgium

(Received 17 March 1999; accepted for publication 17 May 1999)

[S0022-2488(99)03610-5]

In this recent paper, three solutions to the complex Ginzburg–Landau equation, numbered (18), (21), (24), were presented as new, while none of them are new, as now detailed. Solutions (18) and (21) are only defined in the case Im(p/q)=0, a case which should be listed as ‘‘degenerate’’ on page 884 since this is a confluence of the singularities of the solutions.[1,2]

The elliptic solution (18) was given earlier by Cariello and Tabor[1] [their formulas (3.7), (3.14a), and (3.14b), which in the case Im(p/q)=0 makes $|u|^2$ linear in the Weierstrass elliptic function].

Solutions (21) and (24) are neither elliptic, since the discriminant $\Delta \equiv g_2^3 - 27 g_3^2$ vanishes, nor rational, since $|u|^2$ reduces to a second degree polynomial in tanh($k\zeta$) with constant coefficients

$$|u|^2 = A_2[(k \tanh(k\zeta))^2 + c_1 k \tanh(k\zeta) + c_2], \quad A_2 k \neq 0, \quad \zeta = x - ct. \tag{1}$$

Such a class has been extensively investigated by many authors and there is no hope for any new result. Indeed, solution (21) is the front of Nozaki and Bekki,[3]

$$|u|^2 = A_2(k(\tanh(k\zeta) \pm 1))^2, \tag{2}$$

with however the constraint Im(p/q)=0. As to solution (24), it is either again the front of Nozaki and Bekki without any constraint [in the curious formula (34), the parameter S is zero], or the propagating hole of Bekki and Nozaki,[4]

$$|u|^2 = A_2[(k \tanh(k\zeta) + X)^2 + Y^2], \tag{3}$$

with however, the constraint $k^2 = X^2$ which gives to the velocity c a value only depending on (p, q, γ) while it is arbitrary in Ref. 4.

Response to ''Comment on 'Exact periodic solutions of the complex Ginzburg–Landau equation' '' [J. Math. Phys. 40, 5283 (1999)]

Alexei V. Porubov and Manuel G. Velarde
Instituto Pluridisciplinar, UCM, Paseo Juan XXIII, 28040 Madrid, Spain

(Received 20 April 1999; accepted for publication 17 May 1999)

[S0022-2488(99)03710-X]

The condition $\mathrm{Im}(p/q)=0$ is insufficient for the existence of our solution (18) because we have to assume additionally $p_i \neq 0$, $q_i \neq 0$. There is no periodic solution in Sec. 3 of Ref. 1 to the complex Ginzburg–Landau equation. Case $\mathrm{Im}(p/q)=0$ is not studied there. Even the authors of Ref. 1 conclude in the paragraph below Eqs. (3.14), p. 63, that they have not been able to find significant new solutions.

Section V of our paper is devoted to the comparison of solutions (21) and (24) with those obtained by Bekki and Nozaki. However, our solutions admit representations different from bounded tanh solutions. Indeed, using Eq. (4) of our paper we can get in the limit $k \to 1$ the relationship $\wp \sim \coth^2(\kappa\zeta)$ giving an unbounded limit of our solutions (21), (24). Hence, our solutions do not coincide with those obtained by Bekki and Nozaki.

We think that the ''curious'' formula (34) is useful because of the two possibilities for the parameter S, one of them, see (27), is not zero.

On the Schrödinger equation with steplike potentials

Tuncay Aktosun[a)]
Department of Mathematics, North Dakota State University, Fargo, North Dakota 58105

(Received 19 July 1999; accepted for publication 2 August 1999)

The one-dimensional Schrödinger equation is considered when the potential is asymptotic to a positive constant on the right half line in a certain sense. The zero-energy limits of the scattering coefficients are obtained under weaker assumptions than used elsewhere, and the continuity of the scattering coefficients from the left are established. The scattering coefficients for the potential are expressed in terms of the corresponding coefficients for the pieces of the potential on the positive and negative half lines. The number of bound states for the whole potential is related to the number of bound states for the two pieces. Finally, an improved result is given on the small-energy asymptotics of reflection coefficients for potentials supported on a half line. © *1999 American Institute of Physics.*

I. INTRODUCTION

Consider the one-dimensional Schrödinger equation

$$\psi''(k,x)+k^2\psi(k,x)=V(x)\psi(k,x),\quad x\in\mathbf{R},\tag{1.1}$$

where the potential V is real valued and may be written as $V=V_1+V_2$ such that V_1 has support in $\mathbf{R}^-$, V_2 has support in $\mathbf{R}^+$, and

$$V_1\in L_1^1(\mathbf{R}^-),\quad V_2-c^2\in L_1^1(\mathbf{R}^+),\tag{1.2}$$

for some positive c. Here the prime denotes the derivative with respect to the spatial variable x, $\mathbf{R}^-=(-\infty,0)$, $\mathbf{R}^+=(0,+\infty)$, and $L_\alpha^1(I)$ is the set of measurable functions f on an interval I such that $\int_I dx(1+|x|)^\alpha|f(x)|$ is finite. We will use $\mathbf{C}^+$ to denote the upper half complex plane and $\overline{\mathbf{C}^+}=\mathbf{C}^+\cup\mathbf{R}$.

The scattering problem for (1.1) consists of the analysis of the scattering coefficients corresponding to the potential V. Such an analysis was given by Buslaev and Fomin[1] and by Cohen and Kappeler;[2] however, in Ref. 1 only the generic case was considered, and in Ref. 2 the exceptional case was considered under the stronger assumption of L_2^1 instead of L_1^1 in (1.2). The definition of an exceptional potential is given in Sec. II; informally speaking, an exceptional potential has a ''half-bound state'' at zero energy, or equivalently it is at the boundary of changing the number of its bound states by one. The bound states of (1.1) are its square-integrable solutions.

Our primary aim is to consider the small-k asymptotics of the scattering coefficients in the exceptional case and analyze their continuity at $k=0$ by assuming only (1.2). One consequence of our analysis is that under (1.2), the number of bound states is finite. We present a Levinson theorem relating the number of bound states to the zero-energy limit of the phase of the transmission coefficient, and relate the scattering coefficients corresponding to V, V_1, and V_2 to each other.

The inverse scattering problem for (1.1) is equivalent to the recovery of the potential in terms of an appropriate set of scattering data. Such problems were analyzed in Refs. 1–3. Our result in

[a)]Electronic mail: aktosun@plains.nodak.edu

Theorem 3.4 is expected to have an impact on the inverse scattering theory for (1.1) because it was used as a hypothesis in Ref. 2 to obtain various results in the analysis of the inverse scattering problem for (1.1).

Our results are also expected to have an impact on the phase recovery problem, a version of the inverse scattering problem for (1.1) with important applications[4–6] in the recovery of material properties of thin films. Mathematically speaking, one is interested in the recovery of V_2 by using only V_1 and the reflectivity measurements, i.e., the amplitudes of reflection coefficients without their phases. In reality, the phase of the complex-valued reflection coefficient cannot be measured, even though the reflectivity is easily measured[5–8] by using a device known as the reflectometer. Our analysis of the scattering coefficients for V in terms of those for V_1 and V_2 helps us to solve the phase recovery problem by the so-called two-layer method[9,10] using 33% less data than the so-called three-layer method.[9,11–13]

Our paper is organized as follows. In Sec. II we introduce the Jost solutions and scattering coefficients for (1.1), explain the distinction between the generic and exceptional cases, and obtain the small-k asymptotics of the Jost solution from the left and of its x derivative. In Sec. III, in the exceptional case, we prove that the Wronskian defined in (2.10) vanishes linearly as $k\to 0$ in $\overline{\mathbf{C}^+}$; the proof is nontrivial, but the result is significant and it enables us to obtain the small-k asymptotics of the scattering coefficients and establish the continuity at $k=0$ of the scattering coefficients from the left. In Sec. IV we present a Levinson theorem, relating the number of bound states to the zero-energy phase of the transmission coefficient. Section V explores the relation among the scattering coefficients for V, V_1, and V_2. In Sec. VI the small-k limits of the scattering coefficients for V_1 and V_2 are given, and in Sec. VII such limits are related to the corresponding limits for V. In Sec. VII it is also shown that, except for one special case, one can derive the small-k limits of the scattering coefficients for V in terms of the corresponding limits for V_1 and V_2; in the special case, namely when both V_1 and V_2 are generic and V is exceptional, for such a derivation one needs to know that (3.52) holds for some nonzero α even though the value of α is not needed. In Sec. VII we also relate the number of bound states for V to the corresponding numbers for V_1 and V_2, and show that the former number is one less than or equal to the sum of the numbers of bound states for V_1 and V_2. Finally, in Sec. VIII, when $c=0$ in (1.2), we present an improved result on the small-k asymptotics of the reflection coefficient from the right (left) for a potential supported on the left (right) half line in the generic case; this is done by reconsidering the special case in Sec. VI and relating the value of α in (3.52) to the parameters corresponding to V_1 and V_2. The small-energy expansions of the reflection coefficients given in Sec. VIII are expected to simplify various proofs in the direct and inverse scattering theory for the Schrödinger equation with potentials belonging to $L_1^1(\mathbf{R})$.

II. PRELIMINARIES

The scattering states of (1.1) correspond to solutions behaving like $e^{\pm ikx}$ as $x\to -\infty$ and like $e^{\pm i\gamma x}$ as $x\to +\infty$, where

$$\gamma := \sqrt{k^2-c^2}, \tag{2.1}$$

and the branch of the square root function is used with $\operatorname{Im}\gamma \geqslant 0$. Thus, when $k\in(-c,c)$, γ defined in (2.1) is purely imaginary and is given by $\gamma = i\sqrt{c^2-k^2}$. The mapping $k\mapsto\gamma$ is analytic from $\mathbf{C}^+$ to itself and is continuous on $\overline{\mathbf{C}^+}$. The inverse mapping $\gamma\mapsto k$ is analytic only in $\gamma\in\mathbf{C}^+\setminus i(0,c]$ and is continuous only in $\gamma\in\overline{\mathbf{C}^+}\setminus i[0,c)$.

The Jost solution from the left, $f_l(k,x)$, associated with V is the solution of (1.1) satisfying

$$e^{-i\gamma x}f_l(k,x)=1+o(1), \quad e^{-i\gamma x}f_l'(k,x)=i\gamma+o(1), \quad x\to+\infty. \tag{2.2}$$

Similarly, $f_r(k,x)$, the Jost solution from the right, is defined as the solution of (1.1) satisfying

$$e^{ikx}f_r(k,x)=1+o(1), \quad e^{ikx}f_r'(k,x)=-ik+o(1), \quad x\to-\infty. \tag{2.3}$$

The transmission and reflection coefficients from the left, T and L, can be defined in terms of the spatial asymptotics of $f_l(k,x)$ as

$$e^{-ikx}f_l(k,x)=\frac{1}{T(k)}+\frac{L(k)}{T(k)}e^{-2ikx}+o(1),\quad x\to-\infty.$$

Similarly, the transmission and reflection coefficients from the right can be defined by using the asymptotics of $f_r(k,x)$ as $x\to+\infty$; however, these coefficients can be expressed[1,2] in terms of T and L, and they are not essential in our analysis. We will never need the transmission coefficient from the right which is equal to $\gamma T(k)/k$, and the reflection coefficient from the right is used only in Theorem 3.5 and is given in (3.53). If $c=0$ then the transmission coefficients from the left and from the right are the same, but they are different if $c\neq 0$. Further properties of these coefficients can be found in Refs. 1 and 2.

In terms of the Jost solutions, we define the Faddeev functions $m_l(k,x)$ and $m_r(k,x)$:

$$m_l(k,x):=e^{-i\gamma x}f_l(k,x),\quad m_r(k,x):=e^{ikx}f_r(k,x).\tag{2.4}$$

From (2.2), (2.3), and (2.4) it follows that

$$m_l(k,x)=1+\frac{1}{2i\gamma}\int_x^\infty dy[e^{2i\gamma(y-x)}-1][V(y)-c^2]m_l(k,y),\tag{2.5}$$

$$m_l'(k,x)=-\int_x^\infty dy\, e^{2i\gamma(y-x)}[V(y)-c^2]m_l(k,y),\tag{2.6}$$

$$m_r(k,x)=1+\frac{1}{2ik}\int_{-\infty}^x dy[e^{2ik(x-y)}-1]V(y)m_r(k,y),\tag{2.7}$$

$$m_r'(k,x)=\int_{-\infty}^x dy\, e^{2ik(x-y)}V(y)m_r(k,y).\tag{2.8}$$

Proposition 2.1: Assume (1.2) is satisfied for some $c>0$. Then, for each fixed $x\in\mathbf{R}$, the functions $f_l(k,x)$ and $f_l'(k,x)$ are analytic in $\gamma\in\mathbf{C}^+$. Consequently, as $k\to 0$ in $\overline{\mathbf{C}^+}$, we have

$$f_l(k,0)=f_l(0,0)+O(k^2),\quad f_l'(k,0)=f_l'(0,0)+O(k^2).\tag{2.9}$$

Proof: The analyticity in $\gamma\in\mathbf{C}^+$ can be proved by iterating the Volterra integrals (2.5) and (2.6) and using (2.4). By (2.1), $k=0$ corresponds to $\gamma=ic$. Expanding $f_l(k,0)$ and $f_l'(k,0)$ in γ at $\gamma=ic$, we obtain (2.9). ■

Define

$$W(k):=\frac{2ik}{T(k)}=[f_r(k,x);f_l(k,x)],\tag{2.10}$$

where $[f;g]:=fg'-f'g$ denotes the Wronskian. Recall that the Wronskian of any two solutions of (1.1) is independent of x and depends only on k. Generically, $W(0)\neq 0$, and $f_l(0,x)$ and $f_r(0,x)$ are linearly independent. In the exceptional case, $f_l(0,x)$ and $f_r(0,x)$ are linearly dependent and hence $W(0)=0$. We will say that V is a generic (exceptional) potential if the generic (exceptional) case occurs. By (2.4), (2.5), and (2.7), both $f_l(0,x)$ and $f_r(0,x)$ are real valued. In the exceptional case, there exists a real nonzero constant α such that

$$\alpha=\frac{f_l(0,x)}{f_r(0,x)},\quad x\in\mathbf{R}.\tag{2.11}$$

III. ANALYSIS OF $W(k)$ IN THE EXCEPTIONAL CASE

In this section we analyze $W(k)$ in the exceptional case and show that $W(k)/k$ has a nonzero limit as $k\to 0$. The existence of such a limit was used as a hypothesis in many theorems in Ref. 2, and it was proved there only under the stronger assumption L_2^1 instead of L_1^1 used in (1.2). Our aim is to evaluate this limit under (1.2) alone. For the proof we proceed as in the Appendix of Ref. 14, where the method was first used in Ref. 15 for the Schrödinger equation with $c=0$.

As a first step, let us define the solutions of (1.1), $s(k,x)$, and $v(k,x)$, satisfying the boundary conditions

$$s(k,0)=1,\quad s'(k,0)=0;\quad v(k,0)=0,\quad v'(k,0)=1. \tag{3.1}$$

In fact, these solutions satisfy

$$s(k,x)=\begin{cases}\cos kx+\dfrac{1}{k}\displaystyle\int_x^0 dy\,\sin k(y-x)V(y)s(k,y), & x\leqslant 0,\\[2ex] \cos\gamma x+\dfrac{1}{\gamma}\displaystyle\int_0^x dy\,\sin\gamma(x-y)[V(y)-c^2]s(k,y), & x\geqslant 0,\end{cases} \tag{3.2}$$

$$v(k,x)=\begin{cases}\dfrac{\sin kx}{k}+\dfrac{1}{k}\displaystyle\int_x^0 dy\,\sin k(y-x)V(y)v(k,y), & x\leqslant 0,\\[2ex] \dfrac{\sin\gamma x}{\gamma}+\dfrac{1}{\gamma}\displaystyle\int_0^x dy\,\sin\gamma(x-y)[V(y)-c^2]v(k,y), & x\geqslant 0.\end{cases} \tag{3.3}$$

Note also that

$$s'(k,x)=\begin{cases}-k\sin kx-\displaystyle\int_x^0 dy\,\cos k(y-x)V(y)s(k,y), & x\leqslant 0,\\[2ex] -\gamma\sin\gamma x+\displaystyle\int_0^x dy\,\cos\gamma(x-y)[V(y)-c^2]s(k,y), & x\geqslant 0,\end{cases} \tag{3.4}$$

$$v'(k,x)=\begin{cases}\cos kx-\displaystyle\int_x^0 dy\,\cos k(y-x)V(y)v(k,y), & x\leqslant 0,\\[2ex] \cos\gamma x+\displaystyle\int_0^x dy\,\cos\gamma(x-y)[V(y)-c^2]v(k,y), & x\geqslant 0.\end{cases} \tag{3.5}$$

Using (3.1) we get

$$f_l(k,0)=[f_l(k,x);v(k,x)],\quad f_l'(k,0)=-[f_l(k,x);s(k,x)], \tag{3.6}$$

$$f_r(k,0)=[f_r(k,x);v(k,x)],\quad f_r'(k,0)=-[f_r(k,x);s(k,x)]. \tag{3.7}$$

From (3.2) and (3.4), as $x\to\pm\infty$ we obtain

$$s(k,x)=\frac{e^{ikx}A_1(k)}{2ik}+\frac{e^{-ikx}A_2(k)}{2ik}+o(1),\quad x\to-\infty, \tag{3.8}$$

$$s'(k,x)=\frac{e^{ikx}A_1(k)}{2}-\frac{e^{-ikx}A_2(k)}{2}+o(1),\quad x\to-\infty, \tag{3.9}$$

$$s(k,x)=\frac{e^{i\gamma x}A_3(k)}{2i\gamma}+\frac{e^{-i\gamma x}A_4(k)}{2i\gamma}+o(1),\quad x\to+\infty, \tag{3.10}$$

$$s'(k,x)=\frac{e^{i\gamma x}A_3(k)}{2}-\frac{e^{-i\gamma x}A_4(k)}{2}+o(1),\quad x\to+\infty, \tag{3.11}$$

where we have defined

$$A_1(k):=ik-\int_{-\infty}^{0}dy\, e^{-iky}V(y)s(k,y), \tag{3.12}$$

$$A_2(k):=ik+\int_{-\infty}^{0}dy\, e^{iky}V(y)s(k,y),$$

$$A_3(k):=i\gamma+\int_{0}^{\infty}dy\, e^{-i\gamma y}[V(y)-c^2]s(k,y),$$

$$A_4(k):=i\gamma-\int_{0}^{\infty}dy\, e^{i\gamma y}[V(y)-c^2]s(k,y). \tag{3.13}$$

Similarly, from (3.3) and (3.5), as $x\to\pm\infty$ we obtain

$$v(k,x)=\frac{e^{ikx}A_5(k)}{2ik}-\frac{e^{-ikx}A_6(k)}{2ik}+o(1),\quad x\to-\infty, \tag{3.14}$$

$$v'(k,x)=\frac{e^{ikx}A_5(k)}{2}+\frac{e^{-ikx}A_6(k)}{2}+o(1),\quad x\to-\infty, \tag{3.15}$$

$$v(k,x)=\frac{e^{i\gamma x}A_7(k)}{2i\gamma}-\frac{e^{-i\gamma x}A_8(k)}{2i\gamma}+o(1),\quad x\to+\infty, \tag{3.16}$$

$$v'(k,x)=\frac{e^{i\gamma x}A_7(k)}{2}+\frac{e^{-i\gamma x}A_8(k)}{2}+o(1),\quad x\to+\infty, \tag{3.17}$$

where we have defined

$$A_5(k):=1-\int_{-\infty}^{0}dy\, e^{-iky}V(y)v(k,y), \tag{3.18}$$

$$A_6(k):=1-\int_{-\infty}^{0}dy\, e^{iky}V(y)v(k,y),$$

$$A_7(k):=1+\int_{0}^{\infty}dy\, e^{-i\gamma y}[V(y)-c^2]v(k,y),$$

$$A_8(k):=1+\int_{0}^{\infty}dy\, e^{i\gamma y}[V(y)-c^2]v(k,y). \tag{3.19}$$

Evaluating the Wronskians in (3.6) as $x\to+\infty$ and by using (2.2), (3.10), (3.11), (3.16), and (3.17), we get

$$f_l(k,0)=A_8(k), \quad f_l'(k,0)=A_4(k). \tag{3.20}$$

Similarly, evaluating the Wronskians in (3.7) as $x\to-\infty$ and by using (2.3), (3.8), (3.9), (3.14), and (3.15), we have

$$f_r(k,0)=A_5(k), \quad f_r'(k,0)=-A_1(k). \tag{3.21}$$

Now let $\phi(k,x)$ be the solution of (1.1) satisfying

$$\phi(k,0)=f_l(0,0), \quad \phi'(k,0)=f_l'(0,0). \tag{3.22}$$

For the arguments in the rest of this section, there is no loss of generality in assuming that $f_l(0,0)\neq 0$; if $f_l(0,0)=0$, the proofs can be modified as in Ref. 14 to get the results given in Theorems 3.4 and 3.5. Because $\phi(0,x)$ and $f_l(0,x)$ are solutions of the same differential equation with the same initial conditions given in (3.22), we have

$$\phi(0,x)=f_l(0,x), \quad x\in\mathbf{R}. \tag{3.23}$$

Using (2.11) and (3.23) we see that in the exceptional case $\phi(0,x)$ remains bounded as $x\to\pm\infty$; this is because $f_l(0,x)$ and $f_r(0,x)$ remain bounded as $x\to+\infty$ and $x\to-\infty$, respectively. From (3.1) and (3.22) it follows that

$$\phi(k,x)=f_l(0,0)s(k,x)+f_l'(0,0)v(k,x). \tag{3.24}$$

Our aim is to express $W(k)$ defined in (2.10) in terms of $\phi(k,x)$. Evaluating the Wronskian in (2.10) at $x=0$ and using (3.20) and (3.21), we obtain

$$f_l(0,0)W(k)=f_r(k,0)f_l(0,0)A_4(k)+f_l(k,0)f_l(0,0)A_1(k). \tag{3.25}$$

Using (3.12), (3.18), (3.21), and (3.24), we have

$$f_l(0,0)A_1(k)=ikf_l(0,0)+f_l'(0,0)-f_l'(0,0)f_r(k,0)-\int_{-\infty}^0 dy\, e^{-iky}V(y)\phi(k,y). \tag{3.26}$$

Similarly, using (3.13), (3.19), (3.20), and (3.24), we get

$$f_l(0,0)A_4(k)=i\gamma f_l(0,0)-f_l'(0,0)+f_l'(0,0)f_l(k,0)-\int_0^\infty dy\, e^{i\gamma y}[V(y)-c^2]\phi(k,y). \tag{3.27}$$

Thus, using (3.26) and (3.27) in (3.25), we obtain

$$f_l(0,0)W(k)=-f_r(k,0)M_1(k)+f_l(k,0)M_2(k). \tag{3.28}$$

where

$$M_1(k):=-i\gamma f_l(0,0)+f_l'(0,0)+\int_0^\infty dy\, e^{i\gamma y}[V(y)-c^2]\phi(k,y), \tag{3.29}$$

$$M_2(k):=ikf_l(0,0)+f_l'(0,0)-\int_{-\infty}^0 dy\, e^{-iky}V(y)\phi(k,y). \tag{3.30}$$

Proposition 3.1: Assume (1.2) is satisfied for some $c>0$. Then, $M_1(k)$ defined in (3.29) is an analytic function of $\gamma\in\mathbf{C}^+$, $M_1(0)=0$, and

$$M_1(k)=O(k^2), \quad k\to 0 \ \text{ in } \overline{\mathbf{C}^+}. \tag{3.31}$$

Proof: Using (3.20), (3.27)–(3.29), we see that $M_1(k)$ is a linear combination of $f_l(k,0)$ and $f_l'(k,0)$, and in fact

$$M_1(k) = -f_l(0,0)f_l'(k,0) + f_l'(0,0)f_l(k,0). \tag{3.32}$$

Thus, by Proposition 2.1 and (3.32), $M_1(k)$ is analytic in $\gamma \in \mathbf{C}^+$. Using its Taylor series expansion around $\gamma = ic$, which corresponds to $k=0$, we obtain (3.31) and see that $M_1(0)=0$. ■

In the following proposition and elsewhere, we will use C to denote a generic positive constant whose value is not necessarily the same in different appearances.

Proposition 3.2: Assume that we are in the exceptional case and that (1.2) holds for some $c \geqslant 0$. Then,

$$|\phi(k,x) - \phi(0,x)| \leqslant C\left(\frac{|kx|}{1+|kx|}\right)^2, \quad x \leqslant 0, \tag{3.33}$$

with $k \in [-\epsilon, \epsilon]$ for any fixed positive ϵ.

Proof: Using (3.1), (3.22), and (3.24) we obtain

$$\phi(k,x) = f_l(0,0)\cos kx + f_l'(0,0)\,\frac{\sin kx}{k} + \frac{1}{k}\int_x^0 dy\, \sin k(y-x) V(y)\phi(k,y), \quad x \leqslant 0, \tag{3.34}$$

$$\phi(0,x) = f_l(0,0) + x f_l'(0,0) + \int_x^0 dy (y-x) V(y)\phi(0,y), \quad x \leqslant 0. \tag{3.35}$$

Let us write (3.35) as

$$\phi(0,x) = B_1 + xB_2 + B_3 + B_4,$$

where

$$B_1 := f_l(0,0) + \int_{-\infty}^0 dy\, yV(y)\phi(0,y),$$

$$B_2 := f_l'(0,0) - \int_{-\infty}^0 dy\, V(y)\phi(0,y),$$

$$B_3 := x\int_{-\infty}^x dy\, V(y)\phi(0,y),$$

$$B_4 := -\int_{-\infty}^x dy\, yV(y)\phi(0,y).$$

Because $\phi(0,y)$ is bounded on $\mathbf{R}^-$ and $V \in L_1^1(\mathbf{R}^-)$, we get $B_4 = o(1)$ as $x \to -\infty$. Again using $V \in L_1^1(\mathbf{R}^-)$ and the boundedness of $\phi(0,y)$ on $\mathbf{R}^-$, with the help of

$$|B_3| \leqslant C\int_{-\infty}^x dy |x||V(y)| \leqslant C\int_{-\infty}^x dy |y||V(y)|,$$

we get $B_3 = o(1)$ as $x \to -\infty$. Since $\phi(0,x)$ remains bounded as $x \to -\infty$, the linear growth in x in (3.35) as $x \to -\infty$ cannot happen and we must have $B_2 = 0$. Hence

$$f_l'(0,0) - \int_{-\infty}^0 dy\, V(y)\phi(0,y) = 0, \tag{3.36}$$

and this leads to

$$\phi(0,x)=f_l(0,0)+\int_{-\infty}^0 dy\, yV(y)\phi(0,y)+o(1),\quad x\to-\infty. \tag{3.37}$$

From (3.34)–(3.36), we get

$$\phi(k,x)-\phi(0,x)=I_1+I_2+I_3+I_4+I_5+\frac{1}{k}\int_x^0 dy\,\sin k(y-x)V(y)[\phi(k,y)-\phi(0,y)], \tag{3.38}$$

where we have defined

$$I_1:=x\left[\frac{\sin kx}{kx}-1\right]\int_{-\infty}^x dy\, V(y)\phi(0,y), \tag{3.39}$$

$$I_2:=[\cos kx-1]f_l(0,0),\quad I_3:=\frac{\sin kx}{k}\int_x^0 dy[1-\cos ky]V(y)\phi(0,y), \tag{3.40}$$

$$I_4:=-(1-\cos kx)\int_x^0 dy\,\frac{\sin ky}{k}V(y)\phi(0,y), \tag{3.41}$$

$$I_5:=\int_x^0 dy\, y\left[\frac{\sin ky}{ky}-1\right]V(y)\phi(0,y). \tag{3.42}$$

For $z\geqslant 0$, the function $z\mapsto z/(1+z)$ is monotone increasing and we have

$$|\sin z|\leqslant\frac{Cz}{1+z},\quad \left|1-\frac{\sin z}{z}\right|\leqslant\frac{Cz^2}{(1+z)^2},\quad |1-\cos z|\leqslant\frac{Cz^2}{(1+z)^2}. \tag{3.43}$$

Hence, for $x\leqslant 0$ and $k\in[-\epsilon,\epsilon]$, from (3.39)–(3.42) we get the estimates

$$|I_j|\leqslant\frac{C|kx|^2}{(1+|kx|)^2},\quad j=1,2,3,4,5. \tag{3.44}$$

Using (3.43) and (3.44) in (3.38), we obtain

$$|\phi(k,x)-\phi(0,x)|\leqslant\frac{C|kx|^2}{(1+|kx|)^2}+\frac{C|x|}{1+|kx|}\int_x^0 dy|V(y)||\phi(k,y)-\phi(0,y)|, \tag{3.45}$$

With the help of Gronwall's lemma, from (3.45) we get (3.33). ■

Proposition 3.3: Assume V is an exceptional potential and (1.2) holds for some $c>0$, and let $M_2(k)$ be the quantity defined in (3.30). Then, as $k\to 0$ on the real axis, we have

$$f_l(k,0)M_2(k)=ik\alpha f_l(0,0)+o(k), \tag{3.46}$$

where α is the real nonzero constant given in (2.11).

Proof: Using (3.30) and (3.36) we get

$$f_l(k,0)M_2(k)=f_l(k,0)[ikf_l(0,0)+J_1+J_2], \tag{3.47}$$

where

$$J_1 := -\int_{-\infty}^{0} dy\ [e^{-iky}-1]V(y)\phi(0,y), \tag{3.48}$$

$$J_2 := -\int_{-\infty}^{0} dy\ e^{-iky}V(y)[\phi(k,y)-\phi(0,y)]. \tag{3.49}$$

Because of (3.23), in the exceptional case $\phi(0,y)$ is bounded for $y\leqslant 0$. Using the inequality

$$|e^{iz}-iz-1|\leqslant \frac{Cz^2}{1+z}, \quad z\geqslant 0,$$

from (3.48), since $V\in L_1^1(\mathbf{R}^-)$, we get

$$J_1 = ik\int_{-\infty}^{0} dy\ yV(y)\phi(0,y)+o(k). \tag{3.50}$$

Moreover, using (3.33) in (3.49) we get

$$|J_2|\leqslant C|k|\int_{-\infty}^{0} dy\ \frac{|ky|}{1+|ky|}(-y)|V(y)|,$$

which gives us $J_2=o(k)$. Hence, using (2.9) and (3.50) in (3.47), we obtain

$$f_l(k,0)M_2(k)=ikf_l(0,0)^2+ikf_l(0,0)\int_{-\infty}^{0} dy\ yV(y)\phi(0,y)+o(k). \tag{3.51}$$

Using (3.37) we can explicitly evaluate the integral on the right-hand side of (3.51). Since $f_r(0,x)=1+o(1)$ as $x\to-\infty$, with the help of (2.11), (3.23), and (3.37), we get

$$\int_{-\infty}^{0} dy\ yV(y)\phi(0,y)=\alpha-f_l(0,0),$$

and hence (3.51) reduces to (3.46). ∎

Theorem 3.4: Assume that V is an exceptional potential and that (1.2) holds for some $c>0$. Then, the Wronskian $W(k)$ defined in (2.10) satisfies $W(0)=0$ and

$$W(k)=i\alpha k+o(k), \quad k\to 0 \ \text{ in } \ \overline{\mathbf{C}^+}, \tag{3.52}$$

where α is the real nonzero constant given by (2.11).

Proof: Using (3.28), (3.31), and (3.46), we see that (3.52) holds as $k\to 0$ through real values. However, using the Phragmén–Lindelöf theorems as on p. 2927 of Ref. 14, it follows that the limit is valid also when $k\to 0$ in $\overline{\mathbf{C}^+}$. ∎

The reflection coefficient from the right for (1.1), R, is related to T and L as[1,2]

$$R(k)=-\frac{L(k)^*T(k)}{T(k)^*}, \quad k\in\mathbf{R}\setminus\{0\}, \tag{3.53}$$

where the asterisk denotes complex conjugation. The continuity of T, L, and R at $k=0$ is already known[2] in the generic case under (1.2). Next, we show that their continuity holds also in the exceptional case.

Theorem 3.5: Assume that V is an exceptional potential and that (1.2) holds for some $c>0$. Then, the scattering coefficients T, L, and R are all continuous at $k=0$, and we have

$$T(k)=\frac{2}{\alpha}+o(1), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{3.54}$$

$$L(k)=1+o(1), \quad R(k)=-1+o(1), \quad k\to 0 \text{ in } \mathbf{R}, \tag{3.55}$$

where α is the real nonzero constant given in (2.11).

Proof: From (2.10) and Theorem 3.4, we get (3.54), which also proves the continuity of T at $k=0$. Using (3.53) and the identity[1,2]

$$L(k)=\frac{T(k)}{T(k)^*}, \quad k\in[-c,c]\setminus\{0\}, \tag{3.56}$$

and the fact that α is real and nonzero, we get (3.55) and the continuity of L and R at $k=0$. ■

IV. THE LEVINSON THEOREM

In Theorem 3.5 we have proved the continuity of T and L at $k=0$ in the exceptional case. In the generic case, the continuity of these functions is already known[2] and also follows from (2.10) and (3.56), which lead to

$$T(k)=\frac{2ik}{W(0)}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{4.1}$$

$$L(k)=-1+o(1), \quad k\to 0 \text{ in } \mathbf{R}. \tag{4.2}$$

One consequence of the continuity of T at $k=0$ is the following analog of the Levinson theorem, which relates the number of bound states to the argument of T at $k=0$.

Theorem 4.1: Assume that V satisfics (1.2) for some $c\geqslant 0$. Then the number of bound states of (1.1) is finite and given by

$$N=\frac{d}{2}+\frac{1}{\pi}[\arg T(0^+)], \tag{4.3}$$

where $d=0$ in the exceptional case and $d=1$ in the generic case, and $\arg T(k)$ denotes the continuous branch of the argument of T normalized such that $\arg T(+\infty)=0$.

Proof: The continuity of T at $k=0$ is the additional assumption used in Corollary 1.5 of Ref. 2 in order to assure that $k=0$ cannot be an accumulation point for the poles of T in $\mathbf{C}^+$ and that the number of such poles is finite. It is already known[1,2] that such poles are simple and confined to the positive imaginary axis, $1/T$ is continuous in $\overline{\mathbf{C}^+}\setminus\{0\}$, and $T(k)=1+O(1/k)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$. Thus, we have all the ingredients to proceed as in the proof of Theorem 9.1 of Ref. 16. ■

Proposition 4.2: Assume that V satisfies (1.2) for some $c>0$. Then, the real nonzero constant α defined in (2.11) in the exceptional case has the same sign as that of $e^{iN\pi}$. The sign of $W(0)$ in the generic case is the same as the sign of $e^{i(N+1)\pi}$.

Proof: In the exceptional case, comparing (3.54) and (4.3) gives us the sign of α. In the generic case, comparing (4.1) and (4.3) we get the sign of $W(0)$. ■

V. FACTORIZATION

Let V_j denote V_1 and V_2 for $j=1$ and $j=2$, respectively. We will use T_j, L_j, and R_j for the transmission coefficient from the left, the reflection coefficient from the left, and the reflection coefficient from the right, respectively, for the potential V_j. Similarly, let $f_{l;j}(k,x)$ and $f_{r;j}(k,x)$ denote the Jost solutions from the left and from the right, respectively, for V_j. As in (2.10) we will use $W_j(k)$ to denote $2ik/T_j(k)$; in the exceptional case, as in (2.11) we will use α_j to denote the nonzero real constant $f_{l;j}(0,x)/f_{r;j}(0,x)$. We will also let N_j denote the number of bound states of V_j.

Proposition 5.1: Assume that V satisfies (1.2) for some $c \geqslant 0$. Then,

$$\frac{1}{T(k)} = \frac{1 - R_1(k) L_2(k)}{T_1(k) T_2(k)}, \quad k \in \mathbf{R} \setminus \{0\}, \tag{5.1}$$

$$\frac{L(k)}{T(k)} = \frac{L_2(k) - R_1(k)^*}{T_1(k)^* T_2(k)}, \quad k \in \mathbf{R} \setminus \{0\}. \tag{5.2}$$

The result stated in Proposition 5.1 holds when only L^1 is used instead of L_1^1 in (1.2); however, we will take the limit in (5.1) and (5.2) as $k \to 0$ and hence it is more convenient to have the result stated under (1.2). Proposition 5.1 is a special case of the following factorization result whose proof can be given as in Refs. 17 and 18. Let us partition the real axis $\mathbf{R}$ into p fragments as $\mathbf{R} = \cup_{j=1}^{p} (x_{j-1}, x_j)$, where $x_0 := -\infty$, $x_p := +\infty$, and $x_{j-1} < x_j$ for $j = 1,...,p$. We can then write the potential V in terms of its fragments $V_{j-1,j}$ as

$$V(x) = \sum_{j=1}^{p} V_{j-1,j}(x), \tag{5.3}$$

where we have defined

$$V_{j-1,j}(x) := \begin{cases} V(x), & x \in (x_{j-1}, x_j), \\ 0, & x \notin (x_{j-1}, x_j). \end{cases} \tag{5.4}$$

Note that $V_{j-1,j} \in L^1(\mathbf{R})$ for $j = 1,..., \ p-1$, and the rightmost fragment $V_{p-1,p}$ satisfies $V_{p-1,p} - c^2 \in L^1(\mathbf{R})$. Let $T_{j-1,j}$ and $L_{j-1,j}$ denote the transmission and reflection coefficients from the left, respectively, for $V_{j-1,j}$. Let us define the transition matrix Λ associated with V and $\Lambda_{j-1,j}$ associated with $V_{j-1,j}$ as

$$\Lambda(k) := \begin{bmatrix} \dfrac{1}{T(k)} & \dfrac{L(k)^*}{T(k)^*} \\ \dfrac{L(k)}{T(k)} & \dfrac{1}{T(k)^*} \end{bmatrix}, \quad \Lambda_{j-1,j}(k) := \begin{bmatrix} \dfrac{1}{T_{j-1,j}(k)} & \dfrac{L_{j-1,j}(k)^*}{T_{j-1,j}(k)^*} \\ \dfrac{L_{j-1,j}(k)}{T_{j-1,j}(k)} & \dfrac{1}{T_{j-1,j}(k)^*} \end{bmatrix}.$$

From (3.56) and the identity[2]

$$1 - |L(k)|^2 = \frac{\gamma}{k} |T(k)|^2, \quad k \in \mathbf{R} \setminus (-c, c),$$

it follows that the determinant of Λ is given by

$$\det \Lambda(k) = \begin{cases} \dfrac{\gamma}{k}, & k \in \mathbf{R} \setminus (-c, c) \\ 0, & 0 < |k| \leqslant c \end{cases}.$$

The two columns in each of Λ and $\Lambda_{p,p+1}$ are identical when $0 < |k| \leqslant c$.

Theorem 5.2: Assume V satisfies (1.2) for some $c \geqslant 0$, where L^1 is used instead of L_1^1. Let Λ be the transition matrix corresponding to the potential V and let $\Lambda_{j-1,j}$ correspond to the fragment $V_{j-1,j}$ defined in (5.4). Then, we have

$$\Lambda(k) = \Lambda_{0,1}(k) \Lambda_{1,2}(k) \cdots \Lambda_{p-1,p}(k), \quad k \in \mathbf{R} \setminus \{0\}. \tag{5.5}$$

The result in Proposition 5.1 corresponds to $p = 2$ in Theorem 5.2 by using the (1,1) and (2,1) entries in the matrix equality in (5.5) and that $R_1(k) = -L_1(k)^* T_1(k) / T_1(k)^*$ for $k \in \mathbf{R} \setminus \{0\}$.

VI. ASYMPTOTICS OF SCATTERING COEFFICIENTS FOR V_1 AND V_2

In considering the potential V_1, the analog of Theorem 4.1 states that

$$\arg T_1(0^+)=\left(N_1-\frac{d_1}{2}\right)\pi, \tag{6.1}$$

where $d_1=0$ if V_1 is exceptional and $d_1=1$ if V_1 is generic. Using the boundary conditions at $x=0$ based on the continuity of $f_{r;1}(k,x)$ and $f'_{r;1}(k,x)$, we have

$$\frac{1+R_1(k)}{T_1(k)}=f_{r;1}(k,0), \quad ik\frac{-1+R_1(k)}{T_1(k)}=f'_{r;1}(k,0), \tag{6.2}$$

where $f_{r;1}(k,x)$ is the Jost solution from the right for V_1. Thus, from (6.2) it follows that

$$W_1(k):=\frac{2ik}{T_1(k)}=ikf_{r;1}(k,0)-f'_{r;1}(k,0). \tag{6.3}$$

Using the general theory,[19–21] or with the help of (2.4), (2.7), and (2.8) we have

$$f_{r;1}(k,0)=f_{r;1}(0,0)+o(1), \quad f'_{r;1}(k,0)=f'_{r;1}(0,0)+o(1), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{6.4}$$

and hence (6.3) and (6.4) give us $W_1(0)=-f'_{r;1}(0,0)$. Generically $W_1(0)\neq 0$, and in the exceptional case we have $W_1(0)=0$. Thus, generically we obtain

$$W_1(k)=-f'_{r;1}(0,0)+o(1), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+},$$

and hence from (6.2) and (6.3) we get

$$T_1(k)=-\frac{2ik}{f'_{r;1}(0,0)}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{6.5}$$

$$R_1(k)=-1+T_1(k)f_{r;1}(k,0)=-1-2ik\mu_1+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{6.6}$$

where we have defined

$$\mu_1:=\frac{f_{r;1}(0,0)}{f'_{r;1}(0,0)}. \tag{6.7}$$

Note that μ_1 is well defined because $f'_{r;1}(0,0)=-W_1(0)\neq 0$ when V_1 is generic. In Sec. VIII we will improve the result in (6.6) by evaluating the next term in the expansion. Comparing (6.1) and (6.5) we see that the sign of $f'_{r;1}(0,0)$ is the same as the sign of $e^{iN_1\pi}$. Moreover, with the help of (2.3) we get

$$f_{r;1}(k,x)=f_r(k,x), \quad f'_{r;1}(k,x)=f'_r(k,x), \quad x\leqslant 0. \tag{6.8}$$

Now let us turn to the exceptional case. In this case, under $V_1\in L^1_1(\mathbf{R}^-)$, it is known that $W_1(k)$ vanishes linearly in k as $k\to 0$ in $\overline{\mathbf{C}^+}$. We have[22]

$$W_1(k)=\frac{ik(\alpha_1^2+1)}{\alpha_1}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+},$$

$$T_1(k)=\frac{2\alpha_1}{\alpha_1^2+1}+o(1), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{6.9}$$

$$R_1(k) = -\frac{\alpha_1^2-1}{\alpha_1^2+1} + o(1), \quad k \to 0 \ \text{in} \ \overline{\mathbf{C}^+}, \tag{6.10}$$

where α_1 is the real nonzero constant given by

$$\alpha_1 = \frac{f_{l;1}(0,x)}{f_{r;1}(0,x)}, \quad x \in \mathbf{R}.$$

Comparing (6.1) and (6.9) we see that the sign of α_1 is the same as the sign of $e^{iN_1\pi}$. Note that $(\alpha_1^2-1)/(\alpha_1^2+1)$ is an increasing function of α_1^2 and its values are confined to the interval $(-1,1)$. Thus, $R_1(0) \in (-1,1)$ in the exceptional case.

Let us now summarize some similar results for V_2, where (1.2) holds for some $c>0$. From Theorem 4.1 we have

$$\arg T_2(0^+) = \left(N_2 - \frac{d_2}{2} \right) \pi, \tag{6.11}$$

where $d_2=0$ for the exceptional case and $d_2=1$ in the generic case. Using the continuity of the Jost solution $f_{l;2}(k,x)$ and its derivative $f'_{l;2}(k,x)$ at $x=0$, we get

$$\frac{1+L_2(k)}{T_2(k)} = f_{l;2}(k,0), \quad ik\frac{1-L_2(k)}{T_2(k)} = f'_{l;2}(k,0). \tag{6.12}$$

As in Proposition 2.1 we have

$$f_{l;2}(k,0) = f_{l;2}(0,0) + O(k^2), \quad f'_{l;2}(k,0) = f'_{l;2}(0,0) + O(k^2), \quad k \to 0 \ \text{in} \ \overline{\mathbf{C}^+}, \tag{6.13}$$

where $f_{l;2}(0,0)$ and $f'_{l;2}(0,0)$ cannot simultaneously vanish because of (2.2). Moreover, from (2.2) we obtain

$$f_{l;2}(k,x) = f_l(k,x), \quad f'_{l;2}(k,x) = f'_l(k,x), \quad x \geqslant 0. \tag{6.14}$$

With the help of (6.12), defining

$$W_2(k) := \frac{2ik}{T_2(k)} = ikf_{l;2}(k,0) + f'_{l;2}(k,0), \tag{6.15}$$

from (6.13) we have

$$W_2(k) = f'_{l;2}(0,0) + ikf_{l;2}(0,0) + O(k^2), \quad k \to 0 \ \text{in} \ \overline{\mathbf{C}^+}. \tag{6.16}$$

The generic case occurs if $W_2(0) \neq 0$; therefore, generically we have $f'_{l;2}(0,0) \neq 0$, and in the exceptional case we have $f'_{l;2}(0,0)=0$. Thus, generically, from (6.15) and (6.16) we get

$$T_2(k) = \frac{2ik}{f'_{l;2}(0,0)} + \frac{2\mu_2 k^2}{f'_{l;2}(0,0)} + O(k^3), \quad k \to 0 \ \text{in} \ \overline{\mathbf{C}^+}, \tag{6.17}$$

where μ_2 is the real constant defined as

$$\mu_2 := \frac{f_{l;2}(0,0)}{f'_{l;2}(0,0)}. \tag{6.18}$$

Comparing (6.11) and (6.17), we conclude that the sign of $f'_{l;2}(0,0)$ is the same as the sign of $e^{i(N_2+1)\pi}$. With the help of (6.12), (6.13), and (6.17) we also get

$$L_2(k) = -1 + 2ik\mu_2 + 2k^2\mu_2^2 + O(k^3), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+}. \tag{6.19}$$

In the exceptional case we have $W_2(0)=0$, i.e., $f'_{l;2}(0,0)=0$ and $f_{l;2}(0,0)\neq 0$. In this case it follows from (6.16) that $W_2(k)$ vanishes linearly in k as $k\to 0$ in $\overline{\mathbf{C}^+}$. From (6.13) and (6.15) we get

$$W_2(k) = ikf_{l;2}(0,0) + O(k^2), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+},$$

$$T_2(k) = \frac{2}{f_{l;2}(0,0)} + O(k) = \frac{2}{\alpha_2} + O(k), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{6.20}$$

where α_2 is the real nonzero constant given by

$$\alpha_2 = \frac{f_{l;2}(0,x)}{f_{r;2}(0,x)}, \quad x \in \mathbf{R},$$

and we have used the fact that $f_{r;2}(0,x)=1$ for $x\leqslant 0$. Comparing (6.11) and (6.20), we see that the sign of α_2 is the same as the sign of $e^{iN_2\pi}$. Using (6.12) and (6.20), we obtain

$$L_2(k) = 1 + O(k), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+}. \tag{6.21}$$

VII. ASYMPTOTICS OF SCATTERING COEFFICIENTS FOR *V*

In this section, using the results in Sec. VI, with the help of (5.1) and (5.2), we will derive the small-k asymptotics of T and L and compare our results with those obtained in (4.1), (4.2), and Theorem 3.5.

With the help of (5.1), let

$$F(k) := \frac{T_1(k)T_2(k)}{T(k)} = 1 - R_1(k)L_2(k), \tag{7.1}$$

and let $\omega(k)$ denote the phase of $F(k)$ as normalized in Theorem 4.1. From (7.1) we get

$$\omega(0^+) = \arg T_1(0^+) + \arg T_2(0^+) - \arg T(0^+). \tag{7.2}$$

Using (4.3), (6.1), and (6.11) in (7.2), we obtain

$$\omega(0^+) = \left(N_1 + N_2 - N - \frac{d_1 + d_2 - d}{2} \right)\pi. \tag{7.3}$$

If both V_1 and V_2 are exceptional, from (6.10), (6.21), and (7.1) we get

$$F(k) = \frac{2\alpha_1^2}{\alpha_1^2 + 1} + o(1), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{7.4}$$

and hence $\omega(0^+)=0$. Using (6.9), (6.20), (7.1), and (7.4) we have

$$T(k) = \frac{2}{\alpha_1\alpha_2} + o(1), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+}. \tag{7.5}$$

Thus, V is exceptional, $N=N_1+N_2$, $T(0^+)$ is real and nonzero, and the sign of $T(0^+)$ is the same as that of $e^{i(N_1+N_2)\pi}$, where the latter fact is obtained by using (7.5) and the signs of α_1 and α_2 determined in Sec. VI. Using (5.2), (6.9), (6.10), (6.20), (6.21), and (7.5) we also get

$$L(k) = 1 + o(1), \quad k \to 0 \text{ in } \mathbf{R}.$$

If V_1 is exceptional and V_2 is generic, then using (6.9), (6.10), (6.17), (6.19), and (7.1), we obtain

$$F(k)=\frac{2}{\alpha_1^2+1}+o(1), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+},$$

$$T(k)=\frac{2i\alpha_1 k}{f'_{l;2}(0,0)}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}.$$

In this case, V is generic and $\omega(0^+)=0$, and hence from (7.3) we get $N=N_1+N_2$. With the help of (5.2) we also obtain

$$L(k)=-1+o(1), \quad k\to 0 \text{ in } \mathbf{R}.$$

If V_1 is generic and V_2 is exceptional, then using (6.5), (6.6), (6.20), (6.21), and (7.1) we get

$$F(k)=2+O(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+},$$

$$T(k)=-\frac{2ik}{\alpha_2 f'_{r;1}(0,0)}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+},$$

and hence V is generic, $\omega(0^+)=0$, and from (7.3) it follows that $N=N_1+N_2$. With the help of (5.2) we also obtain

$$L(k)=-1+o(1), \quad k\to 0 \text{ in } \mathbf{R}.$$

If both V_1 and V_2 are generic, using (6.6)–(6.8), (6.14), (6.18), (6.19), and (7.1) we get

$$F(k)=2ik(\mu_2-\mu_1)+o(k)=-\frac{2ikW(0)}{f'_{r;1}(0,0)f'_{l;2}(0,0)}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{7.6}$$

where $W(k)$ is the Wronskian given in (2.10) and we have used

$$W(k)=[f_r(k,x);f_l(k,x)]=f_{r;1}(k,0)f'_{l;2}(k,0)-f'_{r;1}(k,0)f_{l;2}(k,0). \tag{7.7}$$

Thus, we have two possibilities, namely $W(0)\neq 0$ and $W(0)=0$. If $W(0)\neq 0$, then V is generic, and in this case using (5.2), (6.5), (6.6), (6.17), (6.19), (7.1), and (7.6) we get

$$T(k)=\frac{2ik}{W(0)}+o(k), \quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{7.8}$$

$$L(k)=-1+o(1), \quad k\to 0 \text{ in } \mathbf{R},$$

agreeing with (4.1) and (4.2). From (4.3) and (7.8) it is seen that $W(0)$ has the same sign as the sign of $e^{i(N+1)\pi}$. From (7.6), since $W(0)\neq 0$, we get $\omega(0^+)=\pm\pi/2$. In Sec. VI we have seen that the sign of $f'_{r;1}(0,0)$ is the same as that of $e^{iN_1\pi}$ and the sign of $f'_{l;2}(0,0)$ is the same as that of $e^{i(N_2+1)\pi}$. Thus, in the subcase $\mu_2>\mu_1$ with $\omega(0^+)=\pi/2$, from (7.3) we get $N=N_1+N_2-1$. Similarly, in the subcase $\mu_2<\mu_1$ with $\omega(0^+)=-\pi/2$, we obtain $N=N_1+N_2$.

If both V_1 and V_2 are generic and $W(0)=0$, then V is exceptional. In this case, without consulting Theorem 3.4, by using (6.5), (6.6), (6.17), and (6.19) we can only conclude that $F(k)=o(k)$ as $k\to 0$. If we knew the expansion in (6.6) up to $o(k^2)$, then we would have determined $F(k)$ up to $o(k^2)$ as well. If we use Theorem 3.4, with the help of (3.52), (3.56), (6.5), (6.17), and (7.1) we get

$$F(k)=\frac{2\alpha k^2}{f'_{r;1}(0,0)f'_{l;2}(0,0)}+o(k^2),\quad T(k)=\frac{2}{\alpha}+o(1),\quad k\to 0 \text{ in } \overline{\mathbf{C}^+},$$
$$L(k)=1+o(1),\quad k\to 0 \text{ in } \mathbf{R}, \tag{7.9}$$

where, by (4.3), the sign of α is the same as that of $e^{iN\pi}$. Since $|R_1(k)L_2(k)|<1$ for $k\in\mathbf{R}\setminus\{0\}$, we must have $\omega(0^+)=0$. In this case, with the help of (7.3), we get $N=N_1+N_2-1$.

The above analysis shows that $N=N_1+N_2$ or $N=N_1+N_2-1$. As in Theorem 2.1 of Ref. 22, using induction we obtain the following general result.

Theorem 7.1: Assume V satisfying (1.2) for some $c\geq 0$ is partitioned into p fragments as in (5.3), and let $N_{j\text{-}1,j}$ denote the number of bound states corresponding to $V_{j\text{-}1,j}$. Then

$$1-p+\sum_{j=1}^{p} N_{j-1,j}\leq N\leq \sum_{j=1}^{p} N_{j-1,j},\quad p=1,2,\ldots .$$

VIII. SMALL-ENERGY ASYMPTOTICS OF $R_1(k)$

In this section, we will improve the asymptotics in (6.6). We will obtain the small-k asymptotics of the reflection coefficients for potentials supported on a half line up to $o(k^2)$.

The results given here are expected to contribute to better understanding of the scattering and inverse scattering theory for the Schrödinger equation with $c=0$.

Theorem 8.1: Assume V_1 is real valued, is supported in $\mathbf{R}^-$, and $V_1\in L_1^1(\mathbf{R}^-)$. Then, in the generic case we have

$$R_1(k)=-1-2ik\mu_1+2k^2\left[\mu_1^2+\frac{1}{f'_{r;1}(0,0)^2}\right]+o(k^2),\quad k\to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{8.1}$$

where μ_1 is the quantity defined in (6.7).

Proof: Given the generic potential V_1, let us choose V_2 satisfying (1.2) with $c>0$ such that $\mu_2=\mu_1$, where μ_2 is the quantity defined in (6.18). As seen from (7.6), this corresponds to having V_2 generic and V exceptional. In this case, using (7.7) at $k=0$, with the help of (2.11), (6.8), and (6.14), we obtain $\alpha=f'_{l;2}(0,0)/f'_{r;1}(0,0)$. Thus, (7.9) gives us

$$F(k)=\frac{2k^2}{f'_{r;1}(0,0)^2}+o(k^2),\quad k\to 0 \text{ in } \overline{\mathbf{C}^+}. \tag{8.2}$$

On the other hand, using $\mu_2=\mu_1$ in (6.19) we get

$$L_2(k)=-1+2ik\mu_1+2k^2\mu_1^2+O(k^3),\quad k\to 0 \text{ in } \overline{\mathbf{C}^+}. \tag{8.3}$$

Because of (7.1) we have

$$R_1(k)=\frac{1-F(k)}{L_2(k)}, \tag{8.4}$$

and using (8.2) and (8.3) in (8.4) we get (8.1). ■

When $c=0$, the Taylor series expansion in (6.19) is no longer valid. However, we can use the analog of Theorem 8.1 and use the transformation $x\to -x$ to obtain the following result.

Corollary 8.2: Assume V_2 is real valued, is supported in $\mathbf{R}^+$, and $V_2\in L_1^1(\mathbf{R}^+)$, i.e., assume that $c=0$ in (1.2). Then, in the generic case we have

$$L_2(k) = -1 + 2ik\mu_2 + 2k^2\left[\mu_2^2 + \frac{1}{f'_{l;2}(0,0)^2}\right] + o(k^2), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+},$$

where μ_2 is the quantity defined in (6.18).

(Received 24 May 1999; accepted for publication 9 August 1999)

By using the field–antifield formalism, we show that the method of Batalin, Fradkin, Fradkina, and Tyutin (BFFT) to convert Hamiltonian systems submitted to second class constraints introduces compensating fields which do not belong to the BRST cohomology at ghost number one. This assures that the gauge symmetries which arise from the BFFT procedure are not obstructed at quantum level. An example where massive electrodynamics is coupled to chiral fermions is considered. We solve the quantum master equation for the model and show that the respective counterterm has a decisive role in extracting anomalous expectation values associated with the divergence of the Noether chiral current. © *1999 American Institute of Physics.* [S0022-2488(99)02511-6]

I. INTRODUCTION

The seminal works of Dirac[1] on constraint Hamiltonian systems have been developed in several important research lines. One of these developments is due to Batalin, Fradkin, Fradkina, and Tyutin (BFFT),[2] where Hamiltonian systems submitted to second class constraints are conveniently considered. The method of BFFT consists in enlarging the original phase-space of the theory by adding compensating fields which permit to convert the second class constraints into first class ones. In doing so, it is possible to avoid Dirac brackets which can present severe problems when one follows the canonical approach to quantization.[3] As first class constraints are also necessarily associated with local gauge symmetries, a system converted by the BFFT procedure can be treated by using all the machinery associated with the Becchi–Rouet–Stora–Tyutin (BRST) formalism.[4]

The BRST approach for quantization of gauge theories appears with all its power in the field–antifield formalism.[5,3,6] This formalism gives an elegant and systematic way for constructing the functional generator of any general gauge theory, with possible reducible or open gauge algebras. At the same time, eventual obstructions to the gauge symmetries due to quantum effects are naturally taken in account inside the field–antifield formalism.

In this work we consider, by using some tools of the field–antifield formalism, the quantization of first order gauge theories which have been obtained from second class constrained systems by the process of conversion developed by BFFT. We show that the compensating fields introduced by the conversion procedure do not belong to the BRST cohomology[3] at ghost number one. So there is no possible term in the space of fields and antifields with ghost number one and BRST closed not being BRST exact. This means that the Wess–Zumino consistence condition[6] is solved in a trivial way; there is no gauge anomaly for such class of systems and the quantum master equation can always be solved with the inclusion of a proper counterterm in the quantum action. It is useful to observe that this counterterm, if it exists, can play a nontrivial role. We give an example where massive electrodynamics couples to chiral fermions. There we show that it is necessary to introduce a nontrivial counterterm in order to solve the quantum master equation. This counterterm permits us to extract an anomalous expectation value related to the divergence of the fermion Noether chiral current.

We would like to note that compensating fields have been largely employed directly inside Lagrangian descriptions.[7,8] There the purpose is not converting second class constraints, but to enlarge the symmetry content of a theory in such a way that the original description is recovered within some gauge choice. Under this last point of view, BFFT and Lagrangian compensating fields play similar roles. In several examples of Lagrangian descriptions it is proved that compensating fields also do not belong to the cohomology at ghost number one and can be used as well to extract anomalous expectation values of physically relevant quantities.[9]

We organized this work as follows: In Sec. II we present a brief review of the BFFT conversion of first order systems submitted to pure second class constraints. We display the local gauge invariance of the first order action which is introduced by the BFFT compensating fields. The functional quantization of such a system is described in Sec. III, by using the tools of the field–antifield formalism. We derive the BRST differential and explicitly show that the BFFT variables do not belong to the BRST cohomology at ghost number one. This assures that the quantum master equation can be solved for any system of this class. In Sec. IV the ideas presented in the first sections are applied to a model which describes massive electrodynamics coupled to chiral fermions in four space–time dimensions. By using a regularization that keeps the vector symmetry as a preferential one, the quantum master equation is solved with the introduction of an specific counterterm in the quantum action. A few different gauge fixing choices are explored and covariant actions are obtained. When the gauge freedom is fixed by identifying the compensating fields with external functions, we show that the independence of the path integral with respect to those external functions permit us to derive expectation values which are related to the anomalous divergence of the Noether chiral current. We reserve Sec. V to some general comments and concluding remarks.

II. FIRST ORDER SYSTEMS SUBMITTED TO SECOND CLASS CONSTRAINTS

In this section we will review a few topics on constrained Hamiltonian systems[3] and on the BFFT conversion procedure[2] in order to fix notations and to introduce some results that will be useful for further developments. Let us start by considering a generic first order system living in a (phase) space with discrete bosonic coordinates y^μ, $\mu=1,2,...,2N$. The extension to more general situations can be trivially done. Its action is written as

$$S_0=\int dt(B_\mu\dot{y}^\mu-\lambda^\alpha\chi_\alpha-H), \tag{2.1}$$

where B_μ, H, and χ_α are in principle arbitrary functions of the coordinates but do not depend on the velocities. The Lagrange multipliers λ^α are to be regarded as independent quantities. From the above expression one can read the symplectic form

$$f_{\mu\nu}=\frac{\partial B_\nu}{\partial y^\mu}-\frac{\partial B_\mu}{\partial y^\nu} \tag{2.2}$$

which has an inverse $f^{\mu\nu}$ if the system is well defined. With its aid, we can define the brackets between any two functions $A(y)$ and $B(y)$ as

$$\{A,B\}=\frac{\partial A}{\partial y^\mu}\,f^{\mu\nu}\frac{\partial B}{\partial y^\nu}. \tag{2.3}$$

It follows that

$$\{y^\mu,y^\nu\}=f^{\mu\nu}. \tag{2.4}$$

The brackets appearing in the above expressions can be interpreted as Poisson brackets only in a broad sense, since they take in account the primary second class constraints of the Dirac's scheme.[10] In this sense they are primary Dirac brackets. Let now H and χ_α, $\alpha=1,2,...,2n$, represent respectively, a first class Hamiltonian and a set of second class constraints. The Hamiltonian and the constraints then satisfy the structure

$$\begin{aligned}\{\chi_\alpha,\chi_\beta\}&=\Delta_{\alpha\beta},\\ \{H,\chi_\alpha\}&=V_\alpha^\beta\chi_\beta.\end{aligned}\tag{2.5}$$

As the χ's are second class, the constraint matrix $\Delta_{\alpha\beta}$ is regular.

It may be convenient to extend the phase-space by adding compensating variables ϕ^α, $\alpha=1,2,...,2n$, but at the same time converting the set of second class constraints into a first-class one. This assures that the number of degrees of freedom is not changed by the process, which also introduces local symmetries that permit one to quantize the theory by using the powerful tools of local gauge theories.

To perform this conversion through the BFFT procedure, it is assumed that the BFFT compensating variables ϕ^α satisfy fundamental brackets given by

$$\{\phi^\alpha,\phi^\beta\}=\omega^{\alpha\beta},\tag{2.6}$$

where ω is some constant, antisymmetric, and invertible matrix. In order to avoid the introduction of further second class constraints, it may be convenient to choose ω in such a way that the compensating variables form a set of canonical conjugated quantities. In any case, it follows that in the BFFT extended space, the brackets between any two quantities $A(y,\phi)$ and $B(y,\phi)$ are written as

$$\{A,B\}=\frac{\partial A}{\partial y^\mu}\,f^{\mu\nu}\frac{\partial B}{\partial y^\nu}+\frac{\partial A}{\partial\phi^\alpha}\,\omega^{\alpha\beta}\frac{\partial B}{\partial\phi^\beta}\tag{2.7}$$

as both sectors are independent.

The general idea of the BFFT algorithm is to replace the old set of second class constraints and the old Hamiltonian by a new set of first class constraints $\tilde\chi_\alpha=\tilde\chi_\alpha(y,\phi)$ and Hamiltonian $\tilde H=\tilde H(y,\phi)$ in such a way that they become involutive,

$$\begin{aligned}\{\tilde\chi_\alpha,\tilde\chi_\beta\}&=0,\\ \{\tilde H,\tilde\chi_\alpha\}&=0.\end{aligned}\tag{2.8}$$

By requiring that $\tilde A(y,0)=A(y)$ for any quantity A defined in the extended space, it is assured that the original formulation of the theory is recovered when the unitary gauge $\phi^\alpha=0$ is implemented. In Refs. 2 it is proven that Eqs. (2.8), submitted to the above condition, always have a power series solution in the compensating variables, with coefficients with only y^μ dependence. The second class constraints, for instance, can be extended to

$$\tilde\chi_\alpha(y,\phi)=\chi_\alpha(y)+X_{\alpha\beta}(y)\phi^\beta+X_{\alpha\beta\gamma}(y)\phi^\beta\phi^\gamma+\cdots.\tag{2.9}$$

Conditions (2.8) impose restrictions on the expansion coefficients. As an example, the regular matrices $X_{\alpha\beta}$ must satisfy the identity

$$X_{\alpha\beta}\omega^{\beta\gamma}X_{\delta\gamma}=-\Delta_{\alpha\delta}.\tag{2.10}$$

Even if some quantity $A(y)$ is not a second class constraint, it can also be extended to $\tilde A(y,\phi)$ in order to be involutive with the converted constraints $\tilde\chi_\alpha$. Following the BFFT procedure we can show that in this situation

$$\tilde{A}(y,\phi)=A(y)-\phi^{\alpha}\omega_{\alpha\beta}X^{\beta\gamma}\{\chi_{\gamma},A\}+\cdots, \tag{2.11}$$

where the dots represent at least second order corrections in ϕ to $A(y)$. In (2.11), the matrix X with contravariant indices is to be considered as the inverse of the corresponding covariant one. Now it is possible to prove that the first order action

$$S_0=\int dt[B_{\mu}\dot{y}^{\mu}+B_{\alpha}\dot{\phi}^{\alpha}-\lambda^{\alpha}\tilde{\chi}_{\alpha}-\tilde{H}] \tag{2.12}$$

is invariant under the gauge transformations

$$\begin{aligned}\delta y^{\mu}&=\{y^{\mu},\tilde{\chi}_{\alpha}\}\epsilon^{\alpha},\\ \delta\phi^{\alpha}&=\{\phi^{\alpha},\tilde{\chi}_{\beta}\}\epsilon^{\beta},\\ \delta\lambda^{\alpha}&=\dot{\epsilon}^{\alpha}.\end{aligned} \tag{2.13}$$

By using the Jacobi Identity and Eqs. (2.8) we see that (2.13) close in an Abelian algebra. As in (2.2), in (2.12) B_{α} is related to the inverse of $\omega^{\alpha\beta}$ through

$$\omega_{\alpha\beta}=\frac{\partial B_{\beta}}{\partial\phi^{\alpha}}-\frac{\partial B_{\alpha}}{\partial\phi^{\beta}}. \tag{2.14}$$

One can always choose $B_{\alpha}=\frac{1}{2}\omega_{\alpha\beta}\phi^{\beta}$ without loss of generality. By using some of the above equations, it is not difficult to show that

$$\delta[B_{\mu}\dot{y}^{\mu}+B_{\alpha}\dot{\phi}^{\alpha}-\lambda^{\alpha}\tilde{\chi}_{\alpha}-\tilde{H}]=\frac{d}{dt}\left\{\left[B_{\mu}f^{\mu\nu}\frac{\partial\tilde{\chi}_{\alpha}}{\partial y^{\nu}}+B_{\beta}\omega^{\beta\rho}\frac{\partial\tilde{\chi}_{\alpha}}{\partial\phi^{\rho}}-\tilde{\chi}_{\alpha}\right]\epsilon^{\alpha}\right\} \tag{2.15}$$

and consequently (2.12) is indeed invariant under the local gauge transformations (2.13), provided boundary terms can be discarded.

III. QUANTIZATION

Let us perform the quantization of the system described above along the field–antifield formalism.[5,3,6] To do so it is first necessary to introduce antifields $\Phi^*_A=(y^*_{\mu},\phi^*_{\alpha},\lambda^*_{\alpha},c^*_{\alpha})$ corresponding to the fields $\Phi^A=(y^{\mu},\phi^{\alpha},\lambda^{\alpha},c^{\alpha})$. In our case, y^{μ}, ϕ^{α}, and λ^{α} are bosonic and have ghost number zero. The ghosts c^{α} are fermionic and have ghost number one. The corresponding antifields have opposite grassmanian parity and ghost number given by minus the ghost number of the corresponding field minus one. One can verify that the field–antifield action

$$S=S_0+\int dt[y^*_{\mu}\{y^{\mu},\tilde{\chi}_{\alpha}\}c^{\alpha}+\phi^*_{\beta}\{\phi^{\beta},\tilde{\chi}_{\alpha}\}c^{\alpha}+\lambda^*_{\alpha}\dot{c}^{\alpha}] \tag{3.1}$$

satisfies then the classical master equation

$$\tfrac{1}{2}(S,S)=0, \tag{3.2}$$

where the antibracket between any two quantities $X[\Phi,\Phi^*]$ and $Y[\Phi,\Phi^*]$ is defined as

$$(X,Y)=\frac{\delta_r X}{\delta\Phi^A}\,\frac{\delta_l Y}{\delta\Phi^*_A}-\frac{\delta_r X}{\delta\Phi^*_A}\,\frac{\delta_l Y}{\delta\Phi^A}.$$

When pertinent, we are assuming the de Witt's notation of sum and integration over intermediary variables.

In the BV formalism, the BRST differential is introduced through

$$sX=(X,S) \tag{3.3}$$

for any local functional $X=X[\Phi,\Phi^*]$. As a consequence of the master equation (3.2) and Jacobi identity, s is nilpotent. So, saying that the BV action satisfies the master equation is equivalent to say that it is BRST invariant.

To fix a gauge we need to introduce trivial pairs $\overline{c}_\alpha$, $\overline{\pi}_\alpha$ as new fields. and the corresponding antifields $\overline{c}^{*\alpha}$, $\overline{\pi}^{*\alpha}$, as well as a gauge-fixing fermion Ψ. The antifields are eliminated by choosing $\Phi_A^*=\partial\Psi/\partial\Phi^A$. It is always possible to choose

$$\Psi=\overline{c}_\alpha\phi^\alpha \tag{3.4}$$

associated with the unitary gauge, but different choices can be done. It is also necessary to extend the field–antifield action to a nonminimal one,

$$S\rightarrow S_{nm}=S+\int dt\,\overline{\pi}_\alpha\overline{c}^{*\alpha} \tag{3.5}$$

in order to implement the gauge fixing introduced by Ψ. The gauge-fixed vacuum functional is then defined as

$$Z=\int [d\Phi^A][\det\omega]^{-(1/2)}[\det f]^{-(1/2)}\exp\left\{\frac{i}{\hbar}S_{nm}\left[\Phi^A,\Phi_A^*=\frac{\partial\Psi}{\partial\Phi^A}\right]\right\}. \tag{3.6}$$

In the unitary gauge, we observe that besides the identification $\overline{c}^{*\alpha}=\phi^\alpha$, $\phi_\alpha^*=\overline{c}_\alpha$, all the other antifields vanish. With this and the use of Eqs. (2.9)–(2.10), we see that formally (3.6) reduces to the Senjanovic[11] path integral

$$Z=\int [dy^\mu]|\det f|^{-(1/2)}\delta[\chi_\alpha]|\det\Delta|^{(1/2)}\exp\left\{\frac{i}{\hbar}\int dt[B_\mu\dot{y}^\mu-H]\right\}. \tag{3.7}$$

Actually this reduction can only be done if quantum effects do not obstruct the gauge symmetries. Possible obstructions are related to the dependence of the path integral with respect to redefinitions of the gauge-fixing fermion Ψ. In general, if the classical field–antifield action S can be replaced by some quantum action W expressed as a local functional of fields and antifields and satisfying the so-called quantum master equation

$$\tfrac{1}{2}(W,W)-i\hbar\Delta W=0, \tag{3.8}$$

then the gauge symmetries are not obstructed at quantum level. In expression (3.8) we have introduced the potentially singular operator $\Delta\equiv(\delta_r/\delta\Phi^A)(\delta_l/\delta\Phi_A^*)$ and it was assumed that W can be expanded in powers of $\hbar$ as

$$W[\Phi^A,\Phi_A^*]=S[\Phi^A,\Phi_A^*]+\sum_{p=1}^{\infty}\hbar^p M_p[\Phi^A,\Phi_A^*]. \tag{3.9}$$

The two first terms of the quantum master equation (3.8) are

$$(S,S)=0, \tag{3.10}$$

$$(M_1,S)=i\Delta S. \tag{3.11}$$

As expected, the tree approximation gives (3.2). Equation (3.11) is only formal, since the action of the operator Δ must be regularized. If it vanishes when applied on S, the quantum action

W can be identified with S. If ΔS gives a nontrivial result but there exists some M_1 expressed in terms of local fields such that (3.11) is satisfied, gauge symmetries are not obstructed at one loop order. Otherwise, the theory presents an anomaly

$$\mathcal{A}[\phi,\phi^*]=\Delta S+i(S,M_1)=a_\alpha c^\alpha+\cdots . \tag{3.12}$$

The nilpotency of the BRST operator implies that $s\mathcal{A}=0$, which is the Wess–Zumino consistence condition. So, looking for possible anomalies in any theory is the same as looking for local functionals with ghost number one that are BRST closed $(s\mathcal{A}=0)$ but not BRST exact $(\mathcal{A}\neq sB)$.

By using cohomological arguments, we can show that the quantum master equation, for first order systems with pure second class constraints converted with the use of the BFFT procedure, can always be solved. To prove this, let us first derive the BRST transformations of the fields and antifields for the converted system,

$$\begin{aligned}
sy^\mu&=\{y^\mu,\tilde{\chi}_\alpha\}c^\alpha,\\
s\phi^\beta&=\{\phi^\beta,\tilde{\chi}_\alpha\}c^\alpha,\\
s\lambda^\alpha&=\dot{c}^\alpha,\\
sc^\alpha&=0,\\
s\bar{c}_\alpha&=\bar{\pi}_\alpha,\\
s\bar{\pi}_\alpha&=0,\\
sy^*_\mu&=-\frac{\partial S}{\partial y^\mu},\\
s\phi^*_\alpha&=-\frac{\partial S}{\partial \phi^\alpha},\\
s\lambda^*_\alpha&=\tilde{\chi}_\alpha,\\
sc^*_\alpha&=-y^*_\mu\{y^\mu,\tilde{\chi}_\alpha\}-\phi^*_\beta\{\phi^\beta,\tilde{\chi}_\alpha\}-\dot{\lambda}^*,\\
s\bar{c}^*_\alpha&=0,\\
s\bar{\pi}^{*\alpha}&=\bar{c}^{*\alpha},
\end{aligned} \tag{3.13}$$

where S is given by (3.1). We see that $\bar{c}_\alpha$ and $\bar{\pi}_\alpha$ form BRST doublets $(sB=C,\ sC=0)$ and do not belong to the BRST cohomology.[3] The same is true for their antifields. To show that the other fields and antifields do not contribute to the cohomology at ghost number one, it is enough to study the cohomology of the linearized piece of s, which will be denoted by $s^{(1)}$.[12] If we assume that in the process of conversion of the constraints (see Eq. (2.9)), the invertible matrix $X(y)$ can be written as a power series in y (which will be the case for the example we are going to consider),

$$X(y)_{\alpha\beta}=X^{(0)}_{\alpha\beta}+X^{(1)}_{\alpha\beta\mu}y^\mu+X^{(2)}_{\alpha\beta\mu\nu}y^\mu y^\nu+\cdots \tag{3.14}$$

we see that

$$s^{(1)}\phi^{\alpha}=\omega^{\alpha\gamma}X^{(0)}_{\beta\gamma}c^{\beta},\qquad s^{(1)}c^{\alpha}=0. \tag{3.15}$$

The equations above imply that ϕ^{α} and $C^{\alpha}=\omega^{\alpha\gamma}X^{(0)}_{\beta\gamma}c^{\beta}$ form doublets under the action of $s^{(1)}$ and as a consequence they also do not belong to the cohomology. As c^{α} is trivially obtained from C^{α}, and since it is the only fundamental field (or antifield) with positive ghost number, it is not possible to construct a local functional with ghost number one that is BRST closed not being BRST exact. This means that any candidate to an anomaly can always be canceled by some counterterm M. So the situations found in Ref. 8 and later explored in Ref. 9 appear also here; enlarged symmetries due to compensating fields (here the BFFT variables) are not anomalous. This does not mean that they have a trivial role at the quantum level since the existence of a counterterm modify expectation values of relevant physical quantities.[9] In the next section we are going to show an example where all of these features are carefully taken in account in order to derive consistent quantum actions.

IV. MASSIVE VECTOR FIELDS COUPLED TO CHIRAL FERMIONS

We shall now apply the ideas discussed above to massive chiral electrodynamics. Although the fermions couple only one chirality to the connection A_{μ}, the second class system presents no gauge anomaly since it exhibits no gauge symmetry. When it is converted to a first class one, however, the fermions pass to transform in a chiral way and such a gauge transformation is known to lead to possible anomalies.[13] Accordingly to the ideas discussed in the last section, however, the BFFT variables play the role of Wess–Zumino fields and permit us to write the anomaly candidates as BRST exact functionals, solving in this way the quantum master equation at one loop order.

We start by considering the first order action

$$S_0=\int d^4x\{\dot{A}_{\mu}\pi^{\mu}+i\bar{\psi}\gamma^0\dot{\psi}-\mathcal{H}-\lambda^{\alpha}\chi_{\alpha}\}, \tag{4.1}$$

where the second class constraints

$$\chi_1=\pi^0,\qquad \chi_2=\partial_i\pi^i-m^2A^0+J^0, \tag{4.2}$$

and the first class Hamiltonian

$$H=\int d^3x\left\{\frac{1}{2}\,\pi_i^2+\frac{1}{4}F_{ij}^2+\frac{1}{2}m^2(A_0^2+A_i^2)-i\bar{\psi}\gamma^iD_i^+\psi+\partial_iA^i\chi_1-A_0\chi_2\right\} \tag{4.3}$$

have been introduced. In the above expressions we have defined the covariant derivatives D_{μ}^+ acting on the fermion ψ and the chiral projectors $P^{\pm}$, respectively, as

$$D_{\mu}^+=\partial_{\mu}-ieP^+A_{\mu},\qquad P^{\pm}=\tfrac{1}{2}(1\pm\gamma^5). \tag{4.4}$$

We have also adopted the metric convention $\eta^{\mu\nu}=\mathrm{diag}(-1,+1,+1,+1)$. Dirac matrices satisfy the usual anticommutation relation $\{\gamma^{\mu},\gamma^{\nu}\}=2\,\eta^{\mu\nu}$. As one can verify, action (4.1) is the first order version of

$$\mathcal{S}_{\mathrm{cov}}=\int d^4x\left[-\frac{1}{4}\,F_{\mu\nu}F^{\mu\nu}-\frac{1}{2}\,m^2A_{\mu}A^{\mu}+i\bar{\psi}\gamma^{\mu}D_{\mu}^+\psi\right]. \tag{4.5}$$

From (4.1) we extract the fundamental (equal time) brackets

$$\{\psi(x),\overline{\psi}(y)\}=i\gamma^0\delta^3(x-y) \tag{4.6}$$

for the fermionic sector and

$$\{A_\mu(x),\pi^\nu(y)\}=\delta_\mu^\nu\delta^3(x-y) \tag{4.7}$$

for the bosonic one. By using the above expressions, one can show, for instance, that the fermionic chiral current

$$J^\mu\equiv\overline{\psi}\gamma^\mu P^+\psi \tag{4.8}$$

has brackets between its components given by

$$\begin{aligned}\{J^\mu(x),J^\nu(y)\}&=ie^2\overline{\psi}M^{\mu\nu}P^+\psi\delta^3(x-y),\\ M^{\mu\nu}&=\gamma^\mu\gamma^0\gamma^\nu-\gamma^\nu\gamma^0\gamma^\mu.\end{aligned} \tag{4.9}$$

It is now easy to verify that the constraints and the Hamiltonian satisfy the bracket structure

$$\begin{aligned}\{\chi_1(x),\chi_2(y)\}&=-m^2\delta^3(x-y),\\ \{\chi_1(x),H\}&=\chi_2(x),\\ \{\chi_2(x),H\}&=\partial_i\partial^i\chi_1(x).\end{aligned} \tag{4.10}$$

Let us now use the BFFT algorithm for implementing the Abelian conversion of the above bracket structure. As we have two second class constraints, we introduce two BFFT variables ϕ^α, $\alpha=1,2$ and for simplicity demand that they satisfy

$$\{\phi^\alpha(x),\phi^\beta(y)\}=\epsilon^{\alpha\beta}\delta^3(x-y) \tag{4.11}$$

which gives the matrix $\omega^{\alpha\beta}$ as in Eq. (2.6). In (4.11) $\epsilon^{12}=-\epsilon^{21}=1$, $\epsilon^{11}=\epsilon^{22}=0$. A possible solution to Eqs. (2.8) via (2.9)–(2.11) is achieved with[2]

$$\begin{aligned}\tilde{\chi}_1&=\chi_1-m^2\phi^2,\\ \tilde{\chi}_2&=\chi_2+\phi^1,\\ \tilde{H}&=H+\int d^3x\left[\frac{1}{2m^2}(\phi^1)^2+\frac{1}{2}m^2(\partial_i\phi^2)^2-\frac{\phi^1}{m^2}\tilde{\chi}_2-\phi^2\nabla^2\tilde{\chi}_1\right]\\ &=\int d^3x\left[\frac{1}{2}\pi_i^2+\frac{1}{4}F_{ij}^2+\frac{1}{2}m^2(\tilde{A}_0^2+\tilde{A}_i^2)-i\overline{\psi}\gamma^iD_i^+\psi-\tilde{A}_0\tilde{\chi}_2+(\partial_i\tilde{A}^i)\tilde{\chi}_1\right],\end{aligned} \tag{4.12}$$

where we have defined the quantities

$$\begin{aligned}\tilde{A}_i&=A_i-\partial_i\phi^2,\\ \tilde{A}_0&=A_0+\frac{\phi^1}{m^2}.\end{aligned} \tag{4.13}$$

Correspondingly we have a first order action

$$S_0=\int d^4x\{\dot{A}_\mu\pi^\mu+\dot{\phi}^1\phi^2+i\bar{\psi}\gamma^0\dot{\psi}-\tilde{\mathcal{H}}-\lambda^\alpha\tilde{\chi}_\alpha\}, \tag{4.14}$$

which is invariant under the gauge transformations generated by $\tilde{\chi}_1$ and $\tilde{\chi}_2$ (see Eq. (2.13))

$$\begin{gathered}\delta\psi=-ie\epsilon^2P^+\psi,\quad \delta\bar{\psi}=ie\epsilon^2\bar{\psi}P^-,\\ \delta A_0=\epsilon^1,\quad \delta\pi^0=-m^2\epsilon^2,\\ \delta A_i=-\partial_i\epsilon^2,\quad \delta\pi^i=0,\\ \delta\phi^1=-m^2\epsilon^1,\quad \delta\phi^2=-\epsilon^2,\\ \delta\lambda^1=\dot{\epsilon}^1,\quad \delta\lambda^2=\dot{\epsilon}^2.\end{gathered} \tag{4.15}$$

In the expressions above ϵ^α are arbitrary space–time dependent parameters. We note that the variables $\tilde{A}_\mu$ are invariant under (4.15).

In order to quantize this system along the lines of the field–antifield formalism, associated with the parameters ϵ^α we introduce the ghosts c^α. We introduce also the trivial pairs $\bar{\pi}_\alpha$, $\bar{c}_\alpha$, and write down a gauge-fixed vacuum functional as in (3.6) with

$$\begin{aligned}S_{nm}=S_0+\int d^4x[&A^{0*}c^1-m^2\pi_0^*c^2-A^{i*}\partial_ic^2-m^2\phi_1^*c^1\\ &-\phi_2^*c^2+\lambda_1^*\dot{c}^1+\lambda_2^*\dot{c}^2-ie\psi^*P^+\psi c^2+ie\bar{\psi}P^-\bar{\psi}^*c^2+\bar{\pi}_\alpha\bar{c}^{\alpha*}],\end{aligned} \tag{4.16}$$

where some proper gauge-fixing fermion Ψ is assumed. Now observe that the terms in S_{nm} which involve the matter fields are

$$i\bar{\psi}[\gamma^0(\partial_0-ieP^+(\tilde{A}_0-\lambda^2))+\gamma^iD_i^+]\psi. \tag{4.17}$$

The quantities $\bar{A}_0=\tilde{A}_0-\lambda^2$ and $\bar{A}_i=A_i$ transform as $s\bar{A}_\mu=-\partial_\mu c^2$. As the fermions also transform consistently, as can be seen from (4.15), we obtain the action of the operator Δ over S_Ψ adopting canonical procedures. For instance, in a Pauli–Villars regularization scheme with a fermionic mass term with usual form, which means that the vector symmetry is taken as a preferential one, we see that

$$\Delta S_\Psi=-\frac{1}{96\pi}\int d^4x c^2\epsilon^{\mu\nu\rho\sigma}\bar{F}_{\mu\nu}\bar{F}_{\rho\sigma}, \tag{4.18}$$

where $\bar{F}_{\mu\nu}=\partial_\mu\bar{A}_\nu-\partial_\nu\bar{A}_\mu$ and possible normal parity terms in the original space of fields have been discarded. Equation (4.18) represents the essential candidate to the anomaly. It is easy to see, however, that

$$M_1=\frac{i}{96\pi}\int d^4x\phi^2\epsilon^{\mu\nu\rho\sigma}\bar{F}_{\mu\nu}\bar{F}_{\rho\sigma} \tag{4.19}$$

solves the one loop master equation, which means that we have achieved a consistent route for the quantization of the theory. The gauge fixed vacuum functional reads

$$Z=\int[d\Phi^A]\exp\left\{\frac{i}{\hbar}W\left[\Phi^A,\Phi_A^*=\frac{\partial\Psi}{\partial\Phi^A}\right]\right\} \tag{4.20}$$

with $[d\Phi^A]=(A_\mu,\pi^\mu,\phi^\alpha,\psi,\bar{\psi},\lambda^\alpha,c^\alpha,\bar{c}_\alpha,\bar{\pi}_\alpha)$, and all possible information about the system can be obtained from it. If we wish to write an effective quantum action in an explicitly covariant way we may eliminate the momenta through functional integrations in (4.20). Let us assume that the gauge fixing fermion Ψ does not depend on λ^1 or π^μ, consequently $\lambda_l^* = \pi_\mu^* = 0$. Suppose also that Ψ possibly depends on λ^2 only through an A_0 dependence. Integration in λ^1 and π^0 results in the substitution $\pi^0 \to m^2\phi^2$ in W. Under the redefinition

$$A_0 \to A_0 + \lambda^2 - \frac{\phi^1}{m^2} \tag{4.21}$$

we obtain the intermediate auxiliary quantum action

$$W_{\text{aux}} = \int d^4x \Big[(A_0 + \lambda^2)\dot{\phi} + \dot{A}_i \pi^i + i\bar{\psi}\gamma^0\dot{\psi} - \frac{1}{4}F_{ij}^2 - \frac{1}{2}\pi^{i^2} - \frac{1}{2}m^2(A_0 + \lambda_2)^2 - \frac{1}{2}m^2(A_i - \partial_i\phi)^2 + i\bar{\psi}\gamma^i D_i\psi + A_0(\partial_i\pi^i + J^0 + m^2(A_0 + \lambda^2)) \Big] + \hbar M_1 + S_{gf}, \tag{4.22}$$

where

$$S_{gf} = \int d^4x \Big[-\frac{\delta\Psi}{\delta A_\mu}\partial_\mu c^2 - m^2\frac{\delta\Psi}{\delta\phi^1}c^1 - \frac{\delta\Psi}{\delta\phi^2}c^2 - ie\frac{\delta\Psi}{\delta\psi}P^+\psi c^2 + ie\bar{\psi}P^-\frac{\delta\Psi}{\delta\psi}c^2 + \bar{\pi}_\alpha\frac{\delta\Psi}{\bar{c}_\alpha} \Big] \tag{4.23}$$

and M_1 is given by (4.19) without the bars in $F_{\mu\nu}$ because of (4.21). Further integration in λ_2 and π^i results in the effective quantum action

$$W_{\text{eff}} = \int d^4x \Big[-\frac{1}{4}F_{\mu\nu}^2 - \frac{1}{2}m^2(A_\mu - \partial_\mu\phi^2)^2 + i\bar{\psi}\gamma^\mu D_\mu^+\psi \Big] + \hbar M_1 + S_{gf}. \tag{4.24}$$

As we have already mentioned, a convenient choice of Ψ fixes all the gauge symmetry of the theory. We cite some possible choices for Ψ. The unitary gauge is achieved with $\Psi = \int d^4x \bar{c}_\alpha \phi^\alpha$ followed by functional integration on $\bar{\pi}_\alpha$ and ϕ^α. With this choice the quantum action reduces to the simple form (4.5) and the path integral presents the usual Liouville's measure for the pertinent fields. The choice

$$\Psi = \int d^4x \Big[\bar{c}_2\Big(\frac{\alpha\bar{\pi}^2}{2} + \partial_\mu A^\mu\Big) + \bar{c}_1\phi^1 \Big]$$

leads to the usual covariant Gaussian gauge fixing depending on the arbitrary parameter α. In this situation

$$S_{gf} = \int d^4x \Big[-\partial^\mu\bar{c}_2\partial_\mu c^2 + \bar{\pi}_2\Big(\frac{\alpha\bar{\pi}^2}{2} + \partial_\mu A^\mu\Big) + \bar{\pi}^1\phi^1 - m^2\bar{c}_1 c^1 \Big] \tag{4.25}$$

and the integration over c^1, $\bar{c}_1$, $\bar{\pi}_1$, ϕ^1 is trivial.

An interesting situation comes if we fix the compensating field ϕ^2 to some external value, say, $\phi^2 = \beta$. By choosing $\Psi = \bar{c}_1\phi^1 + \bar{c}_2(\phi^2 - \beta)$, we obtain, after a few trivial integrations and the absorption of some trivial normalization factors by the measure, that

$$Z[\beta] = \int [d\psi][d\bar{\psi}][dA^\mu]\exp\Big\{\frac{i}{\hbar}W_{\text{ext}}[\psi,\bar{\psi},A,\beta]\Big\}, \tag{4.26}$$

where

$$W_{\text{ext}}[\psi,\bar{\psi},A,\beta]=\int d^4x\left[-\frac{1}{4}F^{\mu\nu}F_{\mu\nu}-\frac{1}{2}m^2(A_\mu-\partial_\mu\beta)^2+i\bar{\psi}\gamma^\mu D_\mu^+\psi+\frac{i\hbar}{96\pi}\beta\epsilon^{\mu\nu\rho\sigma}F_{\mu\nu}F_{\rho\sigma}\right]. \tag{4.27}$$

The condition that the path integral cannot depend on β, which comes from the Fradkin–Vilkoviski theorem, gives, for instance, that

$$i\hbar\frac{\delta Z[\beta]}{\delta\beta}\bigg|_{\beta=0}=\left\langle m^2\partial_\mu A^\mu+\frac{i\hbar}{96\pi}\epsilon^{\mu\nu\rho\sigma}F_{\mu\nu}F_{\rho\sigma}\right\rangle\bigg|_{\beta=0}=0 \tag{4.28}$$

which is a surprising result. If we observe, however, that $\partial_\mu J^\mu=-m^2\partial_\mu A^\mu$ as a consequence of the equations of motion for the field A_μ in the unitary gauge, we can interpret Eq. (4.28) as the anomalous divergence of the Noether current (4.8) associated with the rigid chiral symmetry present in the original theory given by actions (4.1)–(4.5). This is an unexpected result derived from the quantum BFFT formalism. Similar results have recently been derived by using compensating fields at Lagrangian level.[9] In these last approaches, the compensating fields coupled directly to the chiral current in an extended QCD which presents not only vector but also chiral gauge symmetry.

V. CONCLUSIONS

In this work we have considered the BFFT quantization of first order systems submitted to pure second class constraints. We have shown that the gauge symmetries introduced by the BFFT procedure are not obstructed at the quantum level, since the compensating fields do not belong to the BRST cohomology at ghost number one. A specific example has been given, where massive electrodynamics couples to chiral fermions. The quantum master equation has been solved and the corresponding counterterm has played an essential role in extracting anomalous expectation values of physically relevant quantities. We would like to finish by commenting that a few generalizations could have been considered. We could have started from an already gauge invariant first order system with both first and second class constraints. Then it would be necessary to take care of both symmetry sectors, the original one and that introduced by the BFFT conversion procedure. Another possibility could be considering examples with more involving algebraic structure, as it occurs with some of the models cited in Ref. 2. We are now studying aspects of these subjects and results will be reported elsewhere.[14]

A path space formula for Gauss vectors in Chern–Simons quantum electrodynamics

John L. Challifour[a] and John P. Clancy
Department of Physics, Indiana University, Bloomington, Indiana 47405

(Received 1 June 1999; accepted for publication 2 July 1999)

Canonical quantization of a Chern–Simons gauge field minimally coupled to a spinor field is studied as an indefinite metric quantum field theory in the usual covariant gauges, by using a lattice cutoff. For this model, we show that positivity for the indefinite metric, Gauss' Law, gauge invariance and Osterwalder–Schrader positivity for a self-adjoint Hamiltonian are equivalent. In addition, the path-space formula for the Osterwalder–Schrader semigroup is constructed in terms of a Euclidean scalar, massive, Gaussian random field. © *1999 American Institute of Physics.* [S0022-2488(99)01011-7]

I. INTRODUCTION

Models containing Chern–Simons gauge fields have been of continuing interest in both topological and quantum field theory over the last 15 years. In particular, Chern–Simons gauge fields coupled to a Higgs field have been proposed as a microscopic framework for the quantum Hall effect.[1] Also, a lattice model of a Maxwell–Chern–Simons gauge field coupled to a Higgs field, with a modification of the Chern–Simons lattice action to provide reflection positivity, has been shown by Fröhlich and Marchetti[2] to lead to anyons[3] as the vortices for the soliton superselection sectors. This work uses a general theory of braid statistics in three-dimensional local quantum theory described in Ref. 4.

Within the framework of canonical quantization, several studies of models containing Chern–Simons terms in their action have appeared (see Ref. 5, and references therein.) In all of these papers, characterization of the physical states has been provided by means of Gauss' Law. However, there has been no attempt to connect this work with the framework of constructive quantum field theory. In this context, the primary notion must be that of Osterwalder–Schrader positivity for the Euclidean field theory.

In this work, we make explicit the indefinite metric formulation, which is implicit in the work of Haller and Lim-Lombridas,[5] for a Maxwell–Chern–Simons gauge field minimally coupled to a fermion field, hence Chern–Simons quantum electrodynamics (QED). Our cutoffs allow characterization of the physical subspace and representation of domains for the unbounded operators needed to characterize gauge invariance, Gauss' Law, and the physical Hamiltonian in terms of a Euclidean path-space formula on physical states. The Euclidean representation of the physical states provides a statement of Osterwalder–Schrader positivity for this model. Future tasks would be to implement the techniques of constructive quantum field theory so as to provide a continuum theory of a local, covariant gauge field minimally coupled to fermions in a reconstructed Hilbert space, where an indefinite metric characterizes the physical states.

The Maxwell–Chern–Simons gauge field in our model is described by the following Lagrangian:

$$\mathcal{L}_G = -\frac{1}{2}\,\partial_\mu A_\nu \partial^\mu A^\nu + \frac{\lambda}{2}\,(\partial A)^2 + \frac{m}{2}\,\epsilon^{\mu\nu\sigma}\partial_\mu A_\nu A_\sigma, \tag{1}$$

[a]Also at Department of Mathematics.

where the first term is the kinetic energy term, the second term fixes the gauge ($\lambda=0$ corresponds to the Feynman gauge and $\lambda=\infty$ corresponds to the Landau gauge), and the third part is the Chern–Simons term. Note that for these units, the parameter m must have dimensions of mass. The Euler–Lagrange equations then become

$$\Box A^{\mu}-\lambda\,\partial^{\mu}(\partial A)+m\,\epsilon^{\mu\alpha\beta}\partial_{\alpha}A_{\beta}=0 \tag{2}$$

for the field equations. Now, in terms of the electric and magnetic fields we have

$$\text{div }\mathbf{E}-mB=(\lambda-1)\,\partial_t(\partial A), \tag{3}$$

$$\text{curl }B-\partial_t\mathbf{E}+m\,\epsilon^{ij}\hat{e}_iE_j=-(\lambda-1)\,\text{grad}(\partial A), \tag{4}$$

with Faraday's Law being equivalent to the Bianchi identity. Note that in $2+1$ dimensions, the electric field lies in the plane defined by the spatial coordinates, while the magnetic field lies perpendicular to this plane. To be consistent with Ref. 5, the canonical momenta are transformed as

$$\Pi_{\mu}\rightarrow e^{-iF}\Pi_{\mu}e^{iF}, \tag{5}$$

where $F=\Sigma_{\mathbf{x}\in V}\delta^2A_0(\mathbf{x})\,\partial_lA_l(\mathbf{x})$. The effect of this transformation is a change in representation of the canonical commutation relations with

$$\Pi_0=(\lambda-1)(\partial A), \tag{6}$$

$$\Pi_l=E_l-\frac{m}{2}\,\epsilon_{ln}A_n \tag{7}$$

so that $\text{div }\mathbf{E}-mB=(m/2)\,\epsilon_{ln}\partial_lA_n-\partial_l\Pi_l$.

Deser, Jackiw, and Templeton[6] have described the electric and magnetic fields in terms of a massive scalar field ϕ having spin 1 excitations. This scalar field will become very useful in our construction of the physical subspace, so we make contact with it now. The scalar field ϕ is defined as

$$\partial_lE_l=-m\sqrt{-\Delta}\,\phi \tag{8}$$

from which E_l and B are expressed as

$$E_l=\left[\frac{m\,\partial_l}{\sqrt{-\Delta}}-\epsilon_{ln}\,\frac{\partial_n\partial_0}{\sqrt{-\Delta}}\right]\phi-\epsilon_{ln}\,\frac{\partial_n}{m}\,G, \tag{9}$$

$$B=\sqrt{-\Delta}\,\phi+\frac{\partial_0}{m}\,G, \tag{10}$$

where $G\equiv(1-\lambda)(\partial A)$ and the field equations give $\Box G=0$. From these equations, we can find particular solutions for the gauge field

$$A_0^p=-\frac{\sqrt{-\Delta}}{m}\,\phi+(1-2\xi)\,\partial_0\Box^{-1}G, \tag{11}$$

$$A_l^p=\frac{\partial_0\partial_l}{m\sqrt{-\Delta}}\,\phi-\frac{\epsilon_{ln}\partial_n}{\sqrt{-\Delta}}\,\phi+(1-2\xi)\,\partial_l\Box^{-1}G, \tag{12}$$

with $(1-2\xi)=(1-\lambda)^{-1}$, so that $\xi=0$ is the Feynman gauge and $\xi=1/2$ is the Landau gauge. As $\Box G=0$, we see that the gauge field is decomposed into a massive piece V_μ and a massless piece S_μ. As these are only particular solutions, the contribution of another massless scalar field, $R(x)$, which commutes with ϕ and satisfies the canonical commutation relations (CCR's) with G can be added to S_μ. Again, as only ϕ contributes to the physical fields, it alone should determine the physical sector of the theory.

In Sec. II, canonical quantization for Chern–Simons QED with spatial lattice cutoffs, is described in a Hilbert space with a Krein indefinite metric. The relation between the representation of the gauge field used here and that used by Haller and Lim-Lombridas[5] is given, as well as a proof that the free Hamiltonian is Krein essentially self-adjoint in all covariant gauges and essentially self-adjoint in Landau gauge. However, for the free Hamiltonian to generate a contraction semigroup, a gauge dependent shift must be implemented. In addition, it is shown that the interacting Hamiltonian is a Phillips perturbation of the free Hamiltonian, so that the full Hamiltonian generates a C_0 semigroup. Equivalence between gauge invariance, Gauss' Law, and positivity with respect to the Krein metric is demonstrated using a characterization of Gauss' Law used in Ref. 5 by means of the $\bar{\partial}$-Poincaré lemma. In Sec. III, the customary Gauss measure representation for this model is found by an extension of the Schwinger functions to coincident points which then leads to a path-space formula on the physical states for the physical self-adjoint Hamiltonian.

II. CANONCIAL QUANTIZATION

A. Indefinite metric

Ultimately, we wish to construct a gauge field A_μ (an operator valued distribution) on a Hilbert space $\mathcal{H}$, which contains a ground state, Ω_R, that is invariant under Poincaré and local gauge symmetries, and with A_μ both local and covariant. Several examples show that a modification of the usual Wightman axioms[7] is required such as suggested by Wightman and Gårding.[8] In particular, Strocchi and Wightman,[8] and Strocchi and others[9] have shown that if the gauge fields are coupled to a matter field which generates a local gauge symmetry, then an indefinite metric must be used for the existence of a nontrivial gauge field.

The indefinite metric is defined by a sesquilinear form $\{\cdot,\cdot\}$ related to the Hilbert space inner product $(\cdot,\cdot)$ by

$$\{\Phi,\Psi\}=(\Phi,\eta\Psi), \tag{13}$$

where η is required to be self-adjoint. The gauge field A_μ should be a symmetric operator with respect to the indefinite metric, i.e., $A_\mu\subset A_\mu^\dagger$, where † denotes the indefinite metric space adjoint, and * denotes the Hilbert space adjoint. In fact, the minimal closure $A_\mu^{\dagger\dagger}=A_\mu^{**}$ should be †-self-adjoint. Vacuum expectation values now satisfy

$$\{\mathcal{P}(A)\Omega_R,\mathcal{Q}(A)\Omega_R\}=(\Omega_R,\mathcal{P}(A)\mathcal{Q}(A)\Omega_R) \tag{14}$$

for polynomials in A_μ on the relativistic vacuum vector Ω_R, with $\eta\Omega_R=\Omega_R$. Physical states are defined in terms of the positive subspace

$$\mathcal{H}_+=\{\Phi\in\mathcal{H}|\{\Phi,\Phi\}\geqslant 0\} \tag{15}$$

with null vectors

$$\mathcal{H}_0=\{\Phi\in\mathcal{H}_+|\{\Phi,\Phi\}=0\} \tag{16}$$

as vectors in

$$\mathcal{H}_{\text{physical}}=\overline{\mathcal{H}_+/\mathcal{H}_0} \tag{17}$$

with the closure taken in the topology induced by the indefinite metric.

For a mathematically precise cutoff theory, we choose a spatially discrete periodic box V of side ''length'' L and lattice spacing δ. Fourier transforms are defined by

$$f_\mu(\mathbf{x}) = \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma} \hat{f}_\mu(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}}, \tag{18}$$

where Γ is the dual group to V. Our infrared cutoff is simply to restrict sums to $\mathbf{k}\in\Gamma_0 = \Gamma\backslash\{0\}$ with Γ chosen to be reflection symmetric about the origin in each variable. On this lattice, the time-zero gauge field may now be written as

$$A_\mu(\mathbf{x}) = V_\mu(\mathbf{x}) + S_\mu(\mathbf{x}), \tag{19}$$

where for $\mathbf{x}\in V$,

$$(\Omega_R, V_\mu(x)V_\nu(y)\Omega_R) = \frac{1}{V}\int_{-\infty}^{\infty} dk^0 \sum_{\mathbf{k}\in\Gamma_0} \theta(k^0)\,\delta(k^2-m^2) e^{-ik(x-y)}\left[\frac{k_\mu k_\nu}{m^2} - g_{\mu\nu} - i\epsilon_{\mu\nu\lambda}\frac{k^\lambda}{m}\right], \tag{20}$$

$$(\Omega_R, S_\mu(x)S_\nu(y)\Omega_R) = \frac{1}{V}\int_{-\infty}^{\infty} dk^0 \sum_{\mathbf{k}\in\Gamma_0} \theta(k^0) e^{-ik(x-y)}\left\{\delta(k^2)\left[\frac{-k_\mu k_\nu}{m^2} + i\epsilon_{\mu\nu\lambda}\frac{k^\lambda}{m}\right] + (1-2\xi)k_\mu k_\nu \delta'(k^2)\right\} \tag{21}$$

in which the midpoint lattice approximation

$$k_j = \frac{2\sin(k_j'\delta/2)}{\delta}, \qquad k'\in\Gamma_0 \tag{22}$$

for lattice derivatives is used. A parameterization using forward and backward approximations having a periodic Fourier transform is easily written down. Even though expression (22) is anti-periodic, it is more convenient for our purposes. The range of interest for ξ is $0\leqslant\xi\leqslant 1/2$, interpolating between the Feynman and Landau gauges.

Canonical quantization is implemented by means of the equal time commutation relations

$$[A_\mu(\mathbf{x}), \Pi_\nu(\mathbf{y})] = i g_{\mu\nu}\delta_{\mathbf{x},\mathbf{y}}. \tag{23}$$

A convenient representation for V_μ arises from the hermitian matrix appearing in (20), which has only one nonzero eigenvalue,

$$\lambda_2 = 2\left(\frac{\omega^2+m^2}{m^2}\right) \tag{24}$$

with

$$\omega^2 = 4\sum_{j=1}^{2} \frac{\sin^2(k_j\delta/2)}{\delta^2} \tag{25}$$

while the matrix for field S_μ in (21) in Landau gauge has two nonzero eigenvalues, denoted

$$\lambda_\pm = -\frac{\omega^2}{m^2} \pm \sqrt{\frac{\omega^4}{m^4} + \frac{2\omega^2}{m^2}} \tag{26}$$

and we define $\lambda_0 = -\lambda_-$ and $\lambda_1 = \lambda_+$. The presence of $\lambda_- < 0$ indicates an indefinite metric is required to recover the two point function for S_μ. The corresponding eigenvectors may readily be obtained as

$$M_2(\mathbf{k}) = \frac{1}{\sqrt{2}\omega\mu} \begin{pmatrix} \omega^2 \\ \mu k_1 - imk_2 \\ \mu k_2 + imk_1 \end{pmatrix} \tag{27}$$

and $M_0 = V_-$, $M_1 = V_+$, where

$$V_\pm(\mathbf{k}) = \frac{1}{N_\pm} \begin{pmatrix} \frac{\omega^2}{m^2}\left(\frac{\omega^2}{m^2}+1\right) \mp \frac{\omega^2}{m^2}\sqrt{\frac{\omega^2}{m^4}+\frac{2\omega^2}{m^2}} \\ \frac{\omega k_1}{m^2}\left(\frac{\omega^2}{m^2}+1\right) \mp \frac{\omega k_1}{m^2}\sqrt{\frac{\omega^4}{m^4}+\frac{2\omega^2}{m^2}} - i\frac{k_2}{m}\left(\frac{\omega^2}{m^2} \mp \sqrt{\frac{\omega^4}{m^4}+\frac{2\omega^2}{m^2}}\right) \\ \frac{\omega k_2}{m^2}\left(\frac{\omega^2}{m^2}+1\right) \mp \frac{\omega k_2}{m^2}\sqrt{\frac{\omega^4}{m^4}+\frac{2\omega^2}{m^2}} + i\frac{k_1}{m}\left(\frac{\omega^2}{m^2} \mp \sqrt{\frac{\omega^4}{m^4}+\frac{2\omega^2}{m^2}}\right) \end{pmatrix}, \tag{28}$$

$$N_\pm^2 = \left(\frac{2\omega^4}{m^4}\right)\left[2\left(\frac{\omega^2}{m^2}+1\right)\left(\frac{\omega^2}{m^2}+1 \mp \sqrt{\frac{\omega^4}{m^4}+\frac{2\omega^2}{m^2}}\right) + \left(\frac{\omega^2}{m^2} \mp \sqrt{\frac{\omega^4}{m^4}+\frac{2\omega^2}{m^2}}\right)\right]. \tag{29}$$

A representation of (23) for the time-zero gauge field may then be given by

$$A_\mu(\mathbf{x}) = \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \sum_{\alpha=0}^{2} \sqrt{\lambda_\alpha(\mathbf{k})}\left[M_{\mu\alpha}(\mathbf{k}) b_\alpha(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} + \overline{M_{\mu\alpha}(\mathbf{k}) b_\alpha^\dagger(\mathbf{k})} e^{-i\mathbf{k}\cdot\mathbf{x}}\right], \tag{30}$$

wherein

$$[\mathbf{b}_\mu(\mathbf{k}), b_\nu^\dagger(\mathbf{p})] = -g_{\mu\nu}\delta_{\mathbf{k},\mathbf{p}} \tag{31}$$

are the commutation relations with respect to the indefinite metric which make (30) formally †-symmetric. In terms of Fock space operators with

$$[c_\mu(\mathbf{k}), c_\nu^*(\mathbf{p})] = \delta_{\mathbf{k},\mathbf{p}} \tag{32}$$

place $b_\mu = c_\mu$, $b_\mu^\dagger = -g_{\mu\nu} c_\nu^*$.

The indefinite metric operator is the Gupta–Bleuler choice $\eta = -g$, where $g_{00} = 1$, $g_{ij} = -\delta_{ij}$, $j = 1,2$, and as such is a Krein metric operator, since $\eta^2 = 1$. As the eigenvectors in (27) and (28) are orthogonal to the eigenvectors for the zero eigenvalue, there is no loss of generality by working in the Landau gauge. As shown below, other gauge choices are related to each other by a Krein unitary transformation.

The massive field V_μ is given by $\alpha = 2$, while $\alpha = 0,1$ define the ghost field, S_μ. Clearly, on the Gårding domain obtained by applying polynomials in A_μ to the Fock vacuum, $A_\mu(\mathbf{x})$ is Krein symmetric and has a Krein self-adjoint closure $A_\mu(\mathbf{x})^{\dagger\dagger} = A_\mu(\mathbf{x})^{**}$. In the case of $V_\mu(\mathbf{x})$, it is readily seen that $V_\mu(\mathbf{x})$ defines an essentially self-adjoint operator on $\mathcal{H}$ and both metrics agree on the Fock space for V_μ. For the ghost piece S_μ, the situation is a bit more complicated, however we prove the following proposition.

Proposition II.1: $S_\mu = S_\mu^{(1)} + iS_\mu^{(0)}$, *where*

$$S_\mu^{(1)}(\mathbf{x}) = -\frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \sqrt{\lambda_1(\mathbf{k})}\left[M_{\mu 1}(\mathbf{k}) c_1(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} + \overline{M_{\mu 1}(\mathbf{k}) c_1^*(\mathbf{k})} e^{-i\mathbf{k}\cdot\mathbf{x}}\right], \tag{33}$$

$$S_\mu^{(0)}(\mathbf{x})=\frac{i}{\sqrt{V}}\sum_{\mathbf{k}\in\Gamma_0}\sqrt{\lambda_0(\mathbf{k})}[M_{\mu 0}(\mathbf{k})c_0(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}}-\overline{M_{\mu 0}(\mathbf{k})c_0^*(\mathbf{k})}e^{-i\mathbf{k}\cdot\mathbf{x}} \tag{34}$$

defines an essentially normal operator on $\mathcal{H}$.

Proof: First, let $N=\Sigma_{\mathbf{k}\in\Gamma_0}c_\mu^*(\mathbf{k})c_\mu(\mathbf{k})$, where μ=0, 1, or 2, denote the number operator on $\mathcal{H}$, then $S_\mu^{(j)}(N+1)^{-1/2}$ are bounded operators. Consider the following set.

Definition II.2: Let $D(N,\alpha)$ *denote the dense set*

$$D(N,\alpha)=\{\Phi|\|e^{\alpha N^2\Phi}\Phi\|\equiv\|\Phi\|_{N,2,\alpha}<\infty,\alpha>0\} \tag{35}$$

which is a common core of analytic vectors for each $S_\mu^{(j)}$, since

$$\|S_\mu^{(j)^p}\Phi\|=\|(S_\mu^{(j)})^p(N+1)^{-p/2}(N+1)^{p/2}e^{-\alpha N^2}e^{\alpha N^2}\Phi\|\leqslant C_1^p p^{p/4}\|(S_\mu^{(j)})^p(N+1)^{-p/2}\|\|\Phi\|_{N,2,\alpha}.$$

By a Glimm–Jaffe bound,[10] after writing $S_\mu^{(j)^p}$ as a sum of 2^p Wick ordered monomials, we find

$$\|S_\mu^{(j)^p}\Phi\|\leqslant C_2^p p^{p/4}\|\Phi\|_{N,2,\alpha}$$

which means that $\Sigma_{p=0}^\infty(|t|^p/p!)\|S_\mu^{(j)^p}\Phi\|<\infty$ and each $S_\mu^{(j)}$ is essentially self-adjoint on D_N. Moreover,

$$\sum_{p_1=0}^{N_1}\frac{S_\mu^{(1)p_1}}{p_1!}\sum_{p_2=0}^{N_2}\frac{S_\mu^{(0)p_2}}{p_2!}\Phi=\sum_{p_2=0}^{N_2}\frac{S_\mu^{(0)p_2}}{p_2!}\sum_{p_1=0}^{N_1}\frac{S_\mu^{(1)p_1}}{p_1!}\Phi \tag{36}$$

with a bound uniform in N_1 and N_2,

$$\sum_{p_1=0}^{N_1}\sum_{p_2=0}^{N_2}\frac{(|t_1|c_4)^{p_1}(|t_2|c_5)^{p_2}}{p_1!p_2!}(p_1+p_2)^{(p_1+p_2)/4}\|\Phi\|_N\leqslant\sum_{p=0}^{N_1+N_2}\frac{p^{p/4}}{p!}(|t_1|c_4+|t_2|c_5)^p\|\Phi\|_N<\infty,$$

so that the double series in (36) converges uniformly in t_1 and t_2 in either order. Therefore,

$$e^{it_1S_\mu^{(1)}}e^{it_2S_\mu^{(0)}}\Phi=e^{it_2S_\mu^{(0)}}e^{it_1S_\mu^{(1)}}\Phi, \tag{37}$$

so each S_μ then defines an essentially normal operator on $\mathcal{H}$. □

Note, that since S_μ is a normal operator, it follows that $D(S_\mu)=D(S_\mu^*)=D(\eta S_\mu^\dagger\eta)$ and since $D(S_\mu)\subset D(S_\mu^\dagger)$, it follows that $D(S_\mu)=D(S_\mu^\dagger)$, that is, S_μ is Krein self-adjoint.

B. Haller and Lim-Lombridas representation

Canonical quantization of Chern–Simons QED in covariant gauges has been given by Haller and Lim-Lombridas[5] by using a representation for the ghost field S_μ which does not satisfy a standard representation for the CCR's. Since we wish to use their work for our analysis, we show how to obtain their representation from (30) and (31). This also clarifies the relation between the Krein space and Hilbert space in their work.

The scalar field R and G introduced in the introduction are described by b_0 and b_1 and should satisfy

$$[G(\mathbf{x}),R(\mathbf{y})]=\delta_{\mathbf{x},\mathbf{y}} \tag{38}$$

at equal times. The combination that relates Haller and Lim-Lombridas' a_Q and a_R to the b_0 and b_1 is

$$a_Q(\mathbf{k}) = \frac{[b_1(\mathbf{k}) - b_0(\mathbf{k})]}{\sqrt{2}\sigma(\mathbf{k})}, \tag{39}$$

$$a_R(\mathbf{k}) = \frac{\sigma(\mathbf{k})[b_1(\mathbf{k}) + b_0(\mathbf{k})]}{\sqrt{2}}, \tag{40}$$

$$a(\mathbf{k}) = -b_2(\mathbf{k}) \tag{41}$$

in which the scaling factor σ needs to be

$$\sigma = \frac{8\omega^{5/2}}{m^{5/2}} \left[\frac{\sqrt{1+\lambda_0} + \sqrt{1-\lambda_1}}{\sqrt{1+\lambda_0} - \sqrt{1-\lambda_1}} \right]^{1/2} = \frac{8\omega^2(\omega^2+2m^2)^{1/4}}{m^{5/2}} \tag{42}$$

for the two representations to agree. The operators a_Q and a_R then satisfy the Haller and Lim-Lombridas algebra

$$[a_Q(\mathbf{k}), a_Q^\dagger(\mathbf{k})] = 0 = [a_R(\mathbf{k}), a_R^\dagger(\mathbf{k})], \tag{43}$$

$$[a_Q(\mathbf{k}), a_R^\dagger(\mathbf{p})] = \delta_{\mathbf{k},\mathbf{p}} = [a_R(\mathbf{k}), a_Q^\dagger(\mathbf{p})]. \tag{44}$$

Inverting (39), (40), and (41) for b_μ in terms of a, a_Q, a_R and substituting into (30) reproduces (2.24) and (2.26) of Ref. 5 in Landau gauge. Throughout the remainder of this paper we shall often use these expressions for calculations (see Appendix A). Their utility lies in providing a convenient form for Gauss Law (Sec. III, pp. 12–16, of Ref. 5) and the fact that the Fock spaces $\mathcal{H}_Q$ and $\mathcal{H}_R$ generated by $a_Q^\dagger$ and $a_R^\dagger$, respectively, form null vectors in the Krein metric.

C. The Hamiltonian

With the representation of the gauge fields and their conjugate momenta, along with our understanding of the Krein and Hilbert spaces, we can form the Hamiltonian operator. The free Hamiltonian is decomposed as

$$H_0 = H_0^V + H_0^G(\xi), \tag{45}$$

where H_0^V is formed from the V_μ field, while $H_0^G(\xi)$ is formed from the S_μ field. In terms of Krein space operators, the Hamiltonian is given by

$$H_0^V = \sum_{\mathbf{k}\in\Gamma} \sqrt{\omega^2+m^2}\, b_2^\dagger(\mathbf{k}) b_2(\mathbf{k}), \tag{46}$$

$$\begin{aligned} H_0^G(\xi) = \sum_{\mathbf{k}\in\Gamma_0} \omega[b_0^\dagger(\mathbf{k})b_0(\mathbf{k}) + b_1^\dagger(\mathbf{k})b_1(\mathbf{k})] + \frac{(1-2\xi)}{2} \sum_{\mathbf{k}\in\Gamma_0} \frac{m^2}{\sqrt{\omega^2+2m^2}} [b_0^\dagger(\mathbf{k})b_0(\mathbf{k}) \\ + b_1^\dagger(\mathbf{k})b_1(\mathbf{k}) - b_1^\dagger(\mathbf{k})b_0(\mathbf{k}) - b_0^\dagger(\mathbf{k})b_1(\mathbf{k})], \end{aligned} \tag{47}$$

and we observe that $H_0 \subset H_0^\dagger$. However, on physical grounds for uniqueness, $\overline{H_0} = H_0^\dagger$ is necessary. To this end, the Hilbert space structure is used, and the Hamiltonian becomes

$$H_0^V = \sum_{\mathbf{k}\in\Gamma} \sqrt{\omega^2+m^2}\, c_2^*(\mathbf{k}) c_2(\mathbf{k}) \tag{48}$$

$$H_0^G(\xi)=\sum_{\mathbf{k}\in\Gamma_0}\omega[c_0^*(\mathbf{k})c_0(\mathbf{k})+c_1^*(\mathbf{k})c_1(\mathbf{k})]+\frac{(1-2\xi)}{2}\sum_{\mathbf{k}\in\Gamma_0}\frac{m^2}{\sqrt{\omega^2+2m^2}}[c_0^*(\mathbf{k})c_0(\mathbf{k})-c_1^*(\mathbf{k})c_1(\mathbf{k})+c_1^*(\mathbf{k})c_0(\mathbf{k})-c_0^*(\mathbf{k})c_1(\mathbf{k})] \tag{49}$$

and we observe that in Landau gauge this expression defines an essentially self-adjoint positive operator. However, in non-Landau gauges this expression is not positive definite.

To examine the free Hamiltonian further, recall the Fock representation relations

$$[c_\mu(\mathbf{k})\Phi]^{(n)}_{\mu_1,\dots,\mu_n}(\mathbf{k}_1,\dots,\mathbf{k}_n)=\sqrt{n+1}\,\Phi^{(n+1)}_{\mu\mu_1,\dots,\mu_n}(\mathbf{k},\mathbf{k}_1,\dots,\mathbf{k}_n), \tag{50}$$

$$[c_\mu^*(\mathbf{k})\Phi]^{(n)}_{\mu_1,\dots,\mu_n}(\mathbf{k}_1,\dots,\mathbf{k}_n)=\frac{1}{\sqrt{n}}\sum_{j=1}^{n}\delta_{\mu,\mu_j}\delta_{\mathbf{k},\mathbf{k}_j}\Phi^{(n-1)}_{\mu,\dots,\hat{\mu}_j,\dots,\mu_n}(\mathbf{k}_1\dots,\hat{\mathbf{k}}_j,\dots,\mathbf{k}_n), \tag{51}$$

so that we may determine the numerical range. A calculation gives

$$(\Phi,H_0^G(\xi)\Phi)=\sum_{\mathbf{k}\in\Gamma_0}\sum_{\{\mathbf{k}\}\in\Gamma_0}\sum_{\{\mu\}}\sum_{n}\omega\left(\left[1+\frac{(1-2\xi)m^2}{2\sqrt{2m^2+\omega^2}}\right](n+1)|\Phi^{(n+1)}_{0\{\mu\}}|^2+\left[1-\frac{(1-2\xi)m^2}{2\sqrt{2m^2+\omega^2}}\right]\times(n+1)|\Phi^{(n+1)}_{1\{\mu\}}|^2+\frac{(1-2\xi)m^2}{2\sqrt{2m^2+\omega^2}}[\overline{\Phi^{(n+1)}_{1\{\mu\}}}\Phi^{(n+1)}_{0\{\mu\}}-\overline{\Phi^{(n+1)}_{0\{\mu\}}}\Phi^{(n+1)}_{1\{\mu\}}]\right), \tag{52}$$

which is complex in general when $\xi\neq 1/2$ and symmetric with respect to the real axis. On the one particle subspace, let $h_0^G(\xi)=\overline{H_0^G(\xi)}_{|_{n=1}}$. Then both h_0^G and h_0^{G*} are quasiacretive since both $\mathrm{Re}(\phi,h_0^G\phi)$ and $\mathrm{Re}(\phi,h_0^{G*}\phi)$ are bounded below by $-[(1-2\xi)m/2\sqrt{2}]\|\phi\|^2$. Then, by Lemma 2.2 of Ref. 11, h_0^G is Krein self-adjoint. As shown below it follows easily that $\overline{H_0^G(\xi)}$ is also Krein self-adjoint.

The full Hamiltonian is expressed as a sum of unbounded operators,

$$H(\xi)=H_0^V+H_0^G(\xi)+H_0^D+H_{\mathrm{int}}, \tag{53}$$

where H_0^D is the free Dirac Hamiltonian and the interaction term is

$$H_{\mathrm{int}}=\sum_{\mathbf{x}\in V}\delta^2 j^\mu(\mathbf{x})A_\mu(\mathbf{x})=\sum_{\mathbf{x}\in V}\delta^2 j^\mu(\mathbf{x})(V_\mu(\mathbf{x})+S_\mu(\mathbf{x}))=H_{\mathrm{int}}^V+H_{\mathrm{int}}^G(\xi) \tag{54}$$

with the time-zero fermion current $j^\mu(\mathbf{x})=e{:}\,\psi^\dagger(\mathbf{x})\gamma^\mu\psi(\mathbf{x}){:}$. The following proposition summarizes the Hilbert and Krein space properties of these operators:

Proposition II.3: Let $\beta=[|(1-2\xi)|m]/2\sqrt{2}$. Then:

(a) *The closure $\overline{H_0^G(\xi)}$ is Krein self-adjoint for any real value of the gauge parameter ξ and self-adjoint for $\xi=1/2$.*

(b) *The closure $\overline{H_0^G(\xi)+\beta I}$ is maximal accretive and Krein self-adjoint.*

(c) *The boson interaction H_{int}^V is symmetric and Kato tiny relative to the positive self-adjoint operator $\overline{H_0^V}$, hence, $H_0^V+H_{\mathrm{int}}^V$ is essentially self-adjoint and bounded below.*

(d) *The ghost interaction, $H_{\mathrm{int}}^G(\xi)$ is Kato tiny relative to $H_0^G(\xi)+\beta I$, hence, $H_0^G(\xi)+H_{\mathrm{int}}^G+\beta I$ has a maximal quasiaccretive and Krein self-adjoint closure.*

(e) *The Hamiltonian $H(\xi)$ defines a unique Krein self-adjoint operator which is also maximal quasiaccretive by taking closures from any suitable core, for example, the finite particle vectors. The operators $\overline{H_0^V+H_{\mathrm{int}}^V}$ and $\overline{H_0^G(\xi)+H_{\mathrm{int}}^G+\beta I}$ commute as unbounded operators.*

Proof: (a) Suppose T is a closed operator on $\mathcal{H}$, then $T^\dagger = \eta T^* \eta$, so that T is Krein self-adjoint if and only if ηT is self-adjoint. Notice that for the one-particle operator $h_0^G = h_0^{G\dagger}$ is equivalent to $\eta h_0^G = (\eta h_0^G)^*$. For for the second quantized operator[12]

$$\overline{H_0^G =} d\Gamma(h_0^G) = d\Gamma(h_0^{G\dagger}) = \eta d\Gamma(h_0^G)^* \eta = H_0^{G\dagger}$$

with $\overline{\eta H_0^G}$ self-adjoint.

Consider the semigroup generated by $h_0(\xi)$ on the one partice space and let

$$M(\omega,t) = \begin{pmatrix} 1-\rho t & \rho t \\ -\rho t & 1+\rho t \end{pmatrix}, \tag{55}$$

where $\rho = [(1-2\xi)m^2]/(2\sqrt{\omega^2 + 2m^2})$, then

$$\|e^{-th_0(\xi)}\|^2 = \sum_{\mathbf{k}\in\Gamma_0} e^{-2t\omega}\overline{\phi_\alpha(\mathbf{k})(M^*M)}_{\alpha\beta}\phi_\beta(\mathbf{k}). \tag{56}$$

The Hermitian matrix $(M^*M)_{\alpha\beta}$ has eigenvalues $(\sqrt{1+\rho^2t^2} \pm \rho^2 t^2)^2$, and setting $|\rho|t = \sinh\theta$ leads us to bound terms in the sum above as

$$e^{-2t\omega_0}e^{\beta t}\exp\left[-\frac{\beta}{|\rho|}\left(\sinh\theta - \frac{|\rho|}{\beta}\theta\right)\right] \leqslant e^{\beta t} \tag{57}$$

since $|\rho|/\beta \leqslant 1$ uniformly in $\mathbf{k}$. Consequently, $h_0(\xi) + \beta I$ defines a C_0-contraction semigroup and by the Hille–Yosida theorem the closed operator $h_0(\xi) + \beta I$ is m-accretive. Part (b) now follows from

$$e^{-t(H_0^G(\xi)+\beta I)} = e^{-td\Gamma(h_0^G(\xi)+\beta I)} = \Gamma(e^{-t(h_0^G(\xi)+\beta I)}) \tag{58}$$

as the operator Γ preserves contractions.[12]

Proceeding as in Proposition (5.1) in Ref. 13, one easily obtains bounds

$$\|a(\mathbf{k})e^{-tH_0^V}\Phi\| \leqslant \frac{\text{const}}{\sqrt{t}}\|\Phi(\mathbf{k},\cdot)\|, \tag{59}$$

$$\|c_\mu(\mathbf{k})e^{-t(H_0^G(\xi)+\beta I)}\Phi\| \leqslant \frac{\text{const}}{\sqrt{t}}\|\Phi(\mathbf{k},\cdot)\|. \tag{60}$$

On the lattice, $j^\mu(\mathbf{x})$ are bounded operators so H_{int}^V and $H_{\text{int}}^G(\xi)$ are, respectively, Phillips perturbations of H_0^V and $H_0^G(\xi) + \beta I$ and are also Kato tiny. This proves (c) and (d) while (e) follows immediately. □

The Phillips nature of the perturbation for these semigroups is used in Sec. III by means of their Duhmael expansions.

D. Gauge transformations

The expressions for A_μ and Π_μ may be expressed entirely in terms of Landau gauge fields as

$$A_0(\mathbf{x};\xi) = A_0(\mathbf{x};1/2) - \frac{(1-2\xi)}{4}(-\Delta)^{-1}\left[\partial_l \Pi_l(\mathbf{x};1/2) - \frac{m}{2}\boldsymbol{\epsilon}_{ln}\partial_l A_n(\mathbf{x};1/2)\right], \tag{61}$$

$$A_l(\mathbf{x};\xi) = A_l(\mathbf{x};1/2) - \frac{(1-2\xi)}{4}(-\Delta)^{-1}\partial_l \Pi_0(\mathbf{x};1/2), \tag{62}$$

$$\Pi_0(\mathbf{x};\xi)=\Pi_0(\mathbf{x};1/2), \tag{63}$$

$$\Pi_l(\mathbf{x};\xi)=\Pi_l(\mathbf{x};1/2)+\frac{(1-2\xi)}{4}(-\Delta)^{-1}\frac{m}{2}\epsilon_{ln}\partial_n\Pi_0(\mathbf{x};1/2). \tag{64}$$

Formally, these relations may be implemented by an operator gauge transformation,

$$A_\mu(\mathbf{x};\xi)=e^T A_\mu(\mathbf{x};1/2)e^{-T}, \tag{65}$$

$$\Pi_\mu(\mathbf{x};\xi)=e^T\Pi_\mu(\mathbf{x};1/2)e^{-T} \tag{66}$$

in which

$$\begin{aligned} T&=\frac{-i}{4}\sum_{\mathbf{x}\in V}\delta^2(-\Delta)^{-1}(\partial A)[\operatorname{div}\mathbf{E}(\mathbf{x})-mB(\mathbf{x})]\\ &=\frac{-i(1-2\xi)}{4}\sum_{\mathbf{x}\in V}\delta^2(-\Delta)^{-1}\Pi_0(\mathbf{x};1/2)\left[\partial_l\Pi_l(\mathbf{x};1/2)-\frac{m}{2}\epsilon_{ln}\partial_l A_n(\mathbf{x};1/2)\right]\\ &=(1-2\xi)\sum_{\mathbf{k}\in\Gamma_0}\frac{16\omega^3}{m^3}[a_Q^\dagger(\mathbf{k})a_Q^\dagger(-\mathbf{k})-a_Q(\mathbf{k})a_Q(-\mathbf{k})] \end{aligned} \tag{67}$$

or in terms of Hilbert space adjoints

$$\begin{aligned} T=(1-2\xi)\sum_{\mathbf{k}\in V}\frac{m^2}{8\omega\sqrt{2m^2+\omega^2}}&[c_0(\mathbf{k})c_0(-\mathbf{k})+c_0^*(\mathbf{k})c_0^*(-\mathbf{k})\\ &+c_1(\mathbf{k})c_1(-\mathbf{k})+c_1^*(\mathbf{k})c_1^*(-\mathbf{k})+2c_0(\mathbf{k})c_1(-\mathbf{k})-2c_0^*(\mathbf{k})c_1^*(-\mathbf{k})]=T_1+T_2, \end{aligned} \tag{68}$$

where $T_1\subset T_1^*$ and $T_2\subset -T_2^*$. A calculation shows that $[T_1,T_2]\neq 0$, so that $\overline{T}$ cannot be realized as a normal operator as in Sec. II A. In fact, the closure of e^T is an unbounded Krein unitary operator.

Proposition II.4: (a) The operators $e^{\pm T}$ are densely defined with a Krein unitary closure on $\mathcal{H}$.

(b) The operator gauge transformations in (65) and (66) hold for the closures of $A_\mu(\mathbf{x})$ and $\Pi_\mu(\mathbf{x})$.

Proof: Vectors in $D(N,\alpha)$ form a core for $e^{\pm T}$, since noting that as a_Q, $a_Q^\dagger$ commute amongst themselves, $T^p=:T^p:$ is a sum of 2^p Wick monomials each of which is a sum of 4^p monomials in c and c^* with kernel $m^2/(8\omega\sqrt{2m^2+\omega^2})$. Repeating the calculation from Sec. II A gives

$$\|T^p\Phi\|\leqslant C_3(C_4)^p p!\,e^{-p^2/\alpha}\|e^{\alpha N^2}\Phi\|$$

which leads to

$$\sum_{p=0}^{\infty}\frac{|z|^p\|T^p\Phi\|}{p!}\leqslant C_3\sum_{p=0}^{\infty}(C_4|z|)^p e^{-p^2/\alpha}\|e^{\alpha N^2}\Phi\|\leqslant C\|e^{\alpha N^2}\Phi\|,$$

where C is an overall constant. Vectors in $D(N,\alpha)$ are then entire vectors for T.

Next, since $e^{\pm T}\subset e^{\pm(T_1-T_2)}$, $e^{\pm T}$ are closeable. Suppose Φ is in the domain of the closure with $\{\Phi_j\}\subset D(N,\alpha)$ such that $\Phi_j\xrightarrow{s}\Phi$, $e^{\pm T}\Phi_j\xrightarrow{s}\overline{e^{\pm T}}\Phi$. Clearly,

$$\|\{\overline{e^{\pm T}}\Phi,\overline{e^{\pm T}}\Phi\}-\{e^{\pm T}\Phi_j,e^{\pm T}\Phi_j\}\|\leqslant\|\overline{e^{\pm T}}\Phi-e^{\pm T}\Phi_j\|(\|\overline{e^{\pm T}}\Phi\|+\|e^{\pm T}\Phi_j\|)$$

as $\|\eta\|=1$. Using the relation, $T\subset -T^{\dagger}$,

$$|\{e^{\pm T}\Phi_j, e^{\pm T}\Phi_j\}-\{\Phi_j,\Phi_j\}|=\left|\lim_{N\to\infty}\sum_{\substack{p_1,p_2=1\\ N+1\leq p_1+p_2}}^{N}\frac{(-1)^p}{p_1!p_2!}\{\Phi_j, T^{p_1+p_2}\Phi_j\}\right|$$

$$\leq \lim_{N\to\infty}\sum_{p=N+1}^{2N}\frac{2^p}{p!}\|\Phi_j\|\|T^p\Phi_j\|$$

$$\leq\left(\lim_{N\to\infty}\sum_{p=N+1}^{2N} C_4^p e^{-p^2/\alpha}\right)(C_3\|\Phi_j\|\|e^{\alpha N^2}\Phi_j\|)=0.$$

Now letting $j\to\infty$ establishes (a).

The argument for A_μ and Π_μ is the same. The vectors in $D(N,\alpha)$ form a core for $\overline{A_\mu(\mathbf{x};\xi)}$ so we may again suppose a sequence Φ_j, A_μ convergent to Φ, whereby a simple calculation shows $e^T A_\mu(\mathbf{x})e^{-T}\Phi_j = A_\mu(\mathbf{x};\xi)\Phi_j$ since $A_\mu(\mathbf{x})e^{-T}\Phi_j\in D(e^T)$. Taking limits gives

$$\overline{e^T A_\mu(\mathbf{x})e^{-T}\Phi = A_\mu(\mathbf{x};\xi)\Phi}$$

and $e^T A_\mu(\mathbf{x})e^{-T}$ extends to the domain of the closure. Since $\overline{A_\mu(\mathbf{x};\xi)}$ is a normal operator, so is $\overline{e^T A_\mu(\mathbf{x})e^{-T}}$, establishing (b). □

Note, that similar observations to these apply to the electric and magnetic field operators

$$\overline{e^T E_l(\mathbf{x})e^{-T}=E_l(\mathbf{x}),}$$

$$\overline{e^T B(\mathbf{x})e^{-T}=B(\mathbf{x}).} \tag{69}$$

Consider the family of commuting unbounded operators[5]

$$\Omega(\mathbf{k})=a_Q(\mathbf{k})+\frac{m^{3/2}}{16\omega^3}j_0(\mathbf{k}) \tag{70}$$

which have $D(N^{1/2})$ as a common core and $D(N,\alpha)$ as common analytic vectors. Their closures define normal operators on $\mathcal{H}$. Form the unbounded operator[5]

$$\mathcal{G}=\frac{1}{\sqrt{V}}\sum_{\mathbf{k}\in\Gamma_0}\frac{8\omega^3}{m^{3/2}}[a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}}+a_Q^{\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]+j_0(\mathbf{x}) \tag{71}$$

which is realized on $D(N^{1/2})$ as

$$\mathcal{G}(\mathbf{x})=\mathcal{G}_0(\mathbf{x})+\mathcal{G}_1(\mathbf{x})+j_0(\mathbf{x}) \tag{72}$$

and where $\mathcal{G}_0$ and j_0 are symmetric and $\mathcal{G}_1$ is skew-symmetric. These operators all commute so by the same argument as in Sec. II A, $\overline{\mathcal{G}}$ is realized as a commuting family of normal operators. One may then define a Krein unitary operator as

$$U(\lambda)=\exp\left[i\sum_{\mathbf{y}\in V}\delta^2\lambda(\mathbf{y})\mathcal{G}(\mathbf{y})\right]$$

$$=\exp\left[i\sum_{\mathbf{y}\in V}\delta^2\lambda(\mathbf{y})\mathcal{G}_0(\mathbf{y})\right]\exp\left[i\sum_{\mathbf{y}\in V}\delta^2\lambda(\mathbf{y})\mathcal{G}_1(\mathbf{y})\right]\exp\left[i\sum_{\mathbf{y}\in V}\delta^2\lambda(\mathbf{y})j_0(\mathbf{y})\right] \tag{73}$$

in which the first and third are unitary operators on $\mathcal{H}$ but the second is self-adjoint. By similar calculations to those in Proposition II.4 for λ a function in V, the transformations

$$U(\lambda)A_0(\mathbf{x})U(-\lambda)=A_0(\mathbf{x}), \tag{74}$$

$$U(\lambda)\Pi_0(\mathbf{x})U(-\lambda)=\Pi_0(\mathbf{x}), \tag{75}$$

$$U(\lambda)A_l(\mathbf{x})U(-\lambda)=A_l(\mathbf{x})-\partial_l\lambda(\mathbf{x}), \tag{76}$$

$$U(\lambda)\Pi_l(\mathbf{x})U(-\lambda)=\Pi_l(\mathbf{x})-\frac{m}{2}\,\epsilon_{ln}\partial_n\lambda(\mathbf{x}), \tag{77}$$

$$U(\lambda)\psi(\mathbf{x})U(-\lambda)=e^{-ie\lambda(\mathbf{x})}\psi(\mathbf{x}), \tag{78}$$

are valid on $D(\overline{A_\mu})$ and $D(\overline{\Pi_\mu})$ and $\mathcal{H}$, respectively. For any Gauss vector Φ_G, Ψ_G defined below one finds

$$\{\Phi_G,\mathcal{G}(\mathbf{x})\Psi_G\}=0 \tag{79}$$

as well as

$$\{U(\lambda)\Phi,U(\lambda)\Psi\}=\{\Phi,\Psi\} \tag{80}$$

on $\overline{D(U(\lambda))}\supset$Gauss vectors. The electric and magnetic fields are also invariant with respect to these c-number gauge transformations

$$\begin{aligned}\overline{U(\lambda)E_l(\mathbf{x})}U(-\lambda)&=\overline{E_l(\mathbf{x}),}\\ \overline{U(\lambda)B(\mathbf{x})}U(-\lambda)&=\overline{B(\mathbf{x})}.\end{aligned} \tag{81}$$

E. Gauss vectors

For precise statements about the domains of the unbounded operators appearing in (70), it is convenient to further exploit our choice of cutoffs by introducing harmonic oscillator coordinates (see Appendix B for definitions.) The ghost subspace is now represented as a direct sum of spaces $\mathcal{H}^{(n)}$, which are L_2 spaces. If $N=|\Gamma_0|$ is the number of nonzero momentum modes, then after elimination of redundant p's and q's, there are N-pairs of complex variables, z_1 and z_2, such that $\mathcal{H}^{(n)}$ is the nN-fold tensor product of $L_2(C^{2N},\mu_0;\mathcal{H}_V\otimes\mathcal{H}_F)$, where μ_0 is Lebesgue measure. The differential operators ∂_1, ∂_2, $\overline{\partial_1}$, $\overline{\partial_2}$ and their adjoints are defined in the distributional sense on their maximal domains. The advantage of this representation, is that it allows for a convenient characterization of the physical states, or Gauss vectors.

Definition II.5: The Gauss vectors are vectors in

$$\bigcap_{\mathbf{k}\in\Gamma_0}\text{Null}(\Omega(\mathbf{k}))=\mathcal{H}_G. \tag{82}$$

The subspace $\mathcal{H}_G$ is closed in $\mathcal{H}$ and can be related to the von Neumann algebra generated by the maximal commuting family of operators $\{\Omega(\mathbf{k})|\mathbf{k}\in\Gamma_0\}$. In terms of these harmonic oscillator coordinates, the Gauss vectors satisfy the following pair of equations:

$$[(\tfrac{1}{2}z_1+\overline{\partial_1})-i(\tfrac{1}{2}z_2+\overline{\partial_2})+\sqrt{2}\sigma\gamma j_0(\mathbf{k})]\Phi_G(\mathbf{k})=0, \tag{83}$$

$$[(\tfrac{1}{2}+\overline{\partial_1})+i(\tfrac{1}{2}z_2+\overline{\partial_2})+\sqrt{2}\sigma\gamma j_0(-\mathbf{k})]\Phi_G(\mathbf{k})=0, \tag{84}$$

where $\mathbf{k}\in\Gamma_0^+$ and $\gamma=(m^{3/2}/16\omega^3)$. As in Ref. 5, the following operator is defined:

$$D=\sum_{\mathbf{k}\in\Gamma_0}\gamma[a_R(\mathbf{k})j_0(-\mathbf{k})-a_R^\dagger(\mathbf{k})j_0(\mathbf{k})]$$
$$=\sum_{\mathbf{k}\in\Gamma_0^+}\frac{\gamma\sigma}{\sqrt{2}}[j_0(-\mathbf{k})(\overline{z_1}-i\overline{z_2})+j_0(\mathbf{k})(\overline{z_1}+i\overline{z_2})]. \tag{85}$$

A simple calculation then shows that

$$e^{-D}e^{|z|^2/2}[(\tfrac{1}{2}z_1+\overline{\partial}_1)-i(\tfrac{1}{2}z_2+\overline{\partial}_2)+\sqrt{2}\sigma\lambda j_0(\mathbf{k})]e^De^{-|z|^2/2}=\overline{\partial}_1-i\overline{\partial}_2, \tag{86}$$

$$e^{-D}e^{|z|^2/2}[(\tfrac{1}{2}z_1+\overline{\partial}_1)+i(\tfrac{1}{2}z_2+\overline{\partial}_2)+\sqrt{2}\sigma\lambda j_0(-\mathbf{k})]e^De^{-|z|^2/2}=\overline{\partial}_1+i\overline{\partial}_2, \tag{87}$$

therefore, the Gauss condition becomes a $\overline{\partial}$-equation. By applying techniques for the $L_2(C,\mu_0)-\overline{\partial}$-theory[14] one may prove the following theorem.

Theorem II.6: *The Gauss vectors have the form*

$$\Phi_G=e^De^{-|z|^2/2}F(z_1,z_2;\Phi_V,\Phi_F), \tag{88}$$

where F is analytic in z_1 and z_2 with coefficients in $\mathcal{H}_V\otimes\mathcal{H}_F$.

Corollary II.7: The operators $e^{\pm D}$ are densely defined with Krein unitary closure on $\mathcal{H}$. Moreover, for any two Gauss vectors Φ_G and Ψ_G,

$$\{\Phi_G,\Psi_G\}=(\Phi_V,\Psi_V), \tag{89}$$

where Φ_V,Ψ_V are, respectively, the projections of Φ_G, Ψ_G onto the subspace $\mathcal{H}_V\otimes\mathcal{H}_F$.

Proof: The proof follows that of Proposition II.4. From the definition of the harmonic oscillator coordinates, it follows that $D\subset -D^\dagger$, so $e^{\pm D}$ are closable operators. Suppose Φ is in the domain of closure and $\Phi_j\in C_0^\infty(\mathbb{R}^{nN},\mathcal{H}_V\otimes\mathcal{H}_F)$, such that $\Phi_j\overset{s}{\rightarrow}\Phi$, and $e^{\pm D}\Phi_j\overset{s}{\rightarrow}e^{\pm\overline{D}}\Phi$. Then, as in Proposition II.4,

$$|\{e^{\pm D}\Phi_j,e^{\pm D}\Phi_j\}-\{\Phi_j,\Phi_j\}|\leq\lim_{N\to\infty}\sum_{p=N+1}^{2N}\frac{2^p}{p!}\|\Phi_j\|\|D^p\Phi_j\|,$$

but since D is multiplication in $\overline{z_k}$, $D^p\Phi_j\in C_0^\infty$, and, due to the $p!$ in the denominator, the limit is 0.

The Gauss vector matrix elements are now of the form

$$\{\Phi_G,\Psi_G\}=\{e^{-|z|^2/2}F_\Phi,e^{-|z|^2/2}F_\Psi\}.$$

Since F is analytic, it may be expressed as a power series in z_1 and z_2. Using the definition of the harmonic oscillator coordinates, we have that

$$z_1(\mathbf{k})=\frac{\sigma}{\sqrt{2}}[a_Q^\dagger(\mathbf{k})+a_Q^\dagger(-\mathbf{k})-a_Q(\mathbf{k})-a_Q(-\mathbf{k})], \tag{90}$$

$$z_2(\mathbf{k})=\frac{i\sigma}{\sqrt{2}}[-a_Q^\dagger(\mathbf{k})+a_Q^\dagger(-\mathbf{k})-a_Q(\mathbf{k})+a_Q(-\mathbf{k})], \tag{91}$$

but, $\{a_Q e^{-|z|^2/2}, a_Q e^{-|z|^2/2}\}=0$ as well as the other combination of a_Q and $a_Q^\dagger$. Therefore, only the zeroth order term in the expansion survives, having coefficients in $\mathcal{H}_V \otimes \mathcal{H}_F$. □

A straightforward calculation shows that applying a gauge transformation to a Gauss vector does not leave the Gauss vector invariant. Rather, it produces another Gauss vector.

Proposition II.8: The Gauss subspace is an invariant subspace for the operator $e^{\pm T}$, *i.e.,* $e^{\pm T}\mathcal{H}_G \subset \mathcal{H}_G$.

The results of this section may be used to prove the following theorem.

Theorem II.9: *The following characterizations of the Gauss vectors are equivalent:*

(a) Positivity with respect to the indefinite metric;
(b) Gauge invariance;
(c) Gauss' Law.

Proof: Proposition II.8 and the remarks following (73), show that applying a gauge transformation to a Gauss vector produces another Gauss vector, so that shows that (c) implies (b). Corollary II.7 shows that the Gauss vectors are projections on $\mathcal{H}_V \otimes \mathcal{H}_F$, but, the metric η_R is positive on this subspace, so that, (c) implies (a). As gauge transformations act only on the ghost variables, it also follows from Corollary II.7 that (b) implies (a). Finally, states that are positive with respect to η are states formed from ϕ and the fermion variables, and since the ghost variables have zero norm, (a) implies (c). □

III. EUCLIDEAN FIELD

A. Two point function

The probability measure for the free Euclidean field is a complex Gauss measure and is uniquely characterized by its covariance, or two-point function. To calculate the covariance, we define the operators

$$\hat{A}_\mu(t,\mathbf{x}) = e^{-tH_0} A_\mu(0,\mathbf{x}) e^{tH_0} \quad t>0 \tag{92}$$

and their anti-time ordered product,

$$\langle \overline{T}\hat{A}_\mu(x)\hat{A}_\nu(y)\rangle = \begin{cases} (\Omega_R, \hat{A}_\mu(x)\hat{A}_\nu(y)\Omega_R) & \text{if } x_0<y_0 \\ (\Omega_R, \hat{A}_\mu(y)\hat{A}_\nu(x)\Omega_R) & \text{if } y_0<x_0 \end{cases}. \tag{93}$$

The decomposition $A_\mu = V_\mu + S_\mu$ leads to

$$\langle \overline{T}\hat{A}_\mu(x)\hat{A}_\nu(y)\rangle = \langle \overline{T}\hat{V}_\mu(x)\hat{V}_\nu(y)\rangle + \langle \overline{T}\hat{S}_\mu(x)\hat{S}_\nu(y)\rangle, \tag{94}$$

for which a short calculation shows that the anti-time ordered products for V_μ and S_μ are not continuous at equal time Schwinger points. However, the simple discontinuities for V_μ and S_μ exactly cancel, allowing the Schwinger functions for $\hat{A}_\mu$ to be extended by continuity to the Euclidean region. We shall choose this extension, whereupon

$$\langle \overline{T}(i\hat{A}_0(x))(i\hat{A}_0(y))\rangle = \langle B_0(x)B_0(y)\rangle, \tag{95}$$

$$\langle \overline{T}(i\hat{A}_0(x))(\hat{A}_l(y))\rangle = \langle B_0(x)B_l(y)\rangle, \tag{96}$$

$$\langle \overline{T}(\hat{A}_l(x))(i\hat{A}_0(y))\rangle = \langle B_l(x)B_0(y)\rangle, \tag{97}$$

$$\langle \overline{T}\hat{A}_l(x)\hat{A}_n(y)\rangle = \langle B_l(x)B_n(y)\rangle \tag{98}$$

defining the Euclidean field, B_μ, with covariance

$$\langle B_\mu(x)B_\nu(y)\rangle=\frac{1}{2\pi V}\sum_{\mathbf{k}\in\Gamma_0}\int_{-\infty}^{\infty}e^{ik(x-y)}\left[\frac{1}{k^2+m^2}\left(\delta_{\mu\nu}-\frac{k_\mu k_\nu}{k^2}-\frac{m\epsilon_{\mu\nu\lambda}k_\lambda}{k^2}\right)+(1-2\xi)\frac{k_\mu k_\nu}{(k^2)^2}\right]. \tag{99}$$

For f,g real test functions, B_μ may be realized as a real-valued Gaussian random field on a separable Hilbert space, but with a complex measure

$$\langle B(f)B(g)\rangle=\int_\Omega d\mu_{CS}(\omega)f(\omega)g(\omega) \tag{100}$$

where Ω may be chosen to be $\mathcal{S}'_R$, for example. A detailed discussion of this measure is given elsewhere.[15]

Here we deal with the semigroup representation on Gauss vectors in terms of a path-space integral. As we will show in the next section, this requires eliminating the ghost field S_μ, and defining an extension for the anti-time ordered products of V_μ to coincident Schwinger points. The extension we choose is one such that there exists a Euclidean field V_μ^E which can be expressed in terms of ϕ^E, a scalar Euclidean field, analogous to the field ϕ defined above. In this way, Osterwalder–Schrader positivity is a direct manifestation of the physical Hilbert space inner product for Gauss vectors.

The Minkowski expression for V_μ in terms of ϕ is

$$V_0(\mathbf{x})=-\frac{\sqrt{-\Delta_s}}{m}\phi(\mathbf{x}), \tag{101}$$

$$V_l(\mathbf{x})=\frac{\partial_l\pi(\mathbf{x})}{m\sqrt{-\Delta_s}}-\frac{\epsilon_{ln}\partial_n\phi(\mathbf{x})}{\sqrt{-\Delta_s}} \tag{102}$$

in which the presence of the canonical momentum $\pi(\mathbf{x})=\dot{\phi}(\mathbf{x})$ gives rise to a contact term in the anti-time ordered products through the relations

$$\langle\overline{T}(\hat{\phi}(x)\hat{\phi}(y))\rangle=\langle\phi^E(x)\phi^E(y)\rangle, \tag{103}$$

$$\langle\overline{T}(\hat{\phi}(x)\hat{\pi}(y))\rangle=\langle\phi^E(x)(-i\dot{\phi}^E(y))\rangle, \tag{104}$$

$$\langle\overline{T}(\hat{\pi}(x)\hat{\phi}(y))\rangle=\langle(-i\dot{\phi}^E(x))\phi^E(y)\rangle, \tag{105}$$

$$\langle\overline{T}(\hat{\pi}(x)\hat{\pi}(y))\rangle=\langle(-i\dot{\phi}^E(x))(-i\dot{\phi}^E(y))\rangle+\delta(x_0-y_0)\delta_{\mathbf{x},\mathbf{y}}. \tag{106}$$

In these relations, ϕ^E is the Euclidean scalar field with covariance

$$\langle\phi^E(x)\phi^E(y)\rangle=\frac{1}{2\pi V}\sum_{\mathbf{k}\in\Gamma_0}\int_{-\infty}^{\infty}dk\,\frac{e^{ik(x-y)}}{k^2+m^2} \tag{107}$$

and is valid with these cutoffs in the sense of generalized random processes. Define the Euclidean analog of (101) and (102) by

$$V_0^E(x)=i\,\frac{\sqrt{-\Delta_s}}{m}\phi^E(x), \tag{108}$$

$$V_l^E(x)=\frac{-i\partial_l\pi^E(x)}{m\sqrt{-\Delta_s}}-\frac{\epsilon_{ln}\partial_n\phi^E(x)}{\sqrt{-\Delta_s}}, \tag{109}$$

whereupon

$$\langle \overline{T}(iV_0(x))(iV_0(y))\rangle = \langle V_0^E(x)V_0^E(y)\rangle, \tag{110}$$

$$\langle \overline{T}(iV_0(x))V_l(y)\rangle = \langle V_0^E(x)V_l^E(y)\rangle, \tag{111}$$

$$\langle \overline{T}V_l(x)(iV_0(y))\rangle = \langle V_l^E(x)V_0^E(y)\rangle, \tag{112}$$

$$\langle \overline{T}V_l(x)V_n(y)\rangle = \langle V_l^E(x)V_n^E(y)\rangle + \frac{\partial_{l,x}\partial_{n,y}}{m^2(-\Delta_s)}\ \delta_{\mathbf{x},\mathbf{y}}\delta(x_0-y_0), \tag{113}$$

then up to contact terms, V_μ is given by the Euclidean field V_μ^E, constructed from ϕ^E. The expectation values for V_μ^E are to be calculated using the Gauss measure for ϕ^E and the relations (108) and (109).

B. Duhamel formula

As shown in Sec. II C, the Landau gauge Hamiltonian is the infinitesimal generator of a contraction semigroup. In addition, Theorem II.9 shows this choice of gauge to be sufficient to calculate matrix elements between Gauss states.

Proposition III.1: On the Gauss vectors we have for $t>0$,

$$\{\Phi_G, e^{-tH}\Psi_G\} = \{\Phi_V, e^{-t\tilde{H}}\Psi_V\} = (\Phi_V, e^{-t\tilde{H}}\Psi_V), \tag{114}$$

where

$$\tilde{H} = H_0^V + H_0^D + \sum_{\mathbf{x}\in V} \delta^2 j_\mu(\mathbf{x})V^\mu(\mathbf{x}) + \sum_{\mathbf{k}\in\Gamma_0} \frac{j_0^*(\mathbf{k})j_0(\mathbf{k})}{2m^2} + \sum_{\mathbf{k}\in\Gamma_0} \frac{i j_0^*(\mathbf{k})\epsilon_{ln}k_l j_n(\mathbf{k})}{m\omega^2} \tag{115}$$

and Φ_V, Ψ_V *are the projections of* Φ_G, Ψ_G *onto the physical subspace* $\mathcal{H}_V \otimes \mathcal{H}_F$.

Proof: First, we approximate the Gauss vectors with functions ϕ, $\psi \in C_0^\infty(\mathbb{R}^{nN}; \mathcal{H}_V\otimes\mathcal{H}_F)$, which are dense in L_2, but need not be Gauss vectors themselves. This approximation is necessary to handle the unbounded operators $e^{\pm D}$. Next, we approximate the exponential function as

$$e^{-tH} = s - \lim_{n\to\infty}\left(1+\frac{t}{n}H\right)^{-n} \tag{116}$$

since H is quasi m-accretive (c.f. Ref. 16, Chap. IX). Finally, we calculate

$$\{e^D\Phi_G, e^{-tH}e^D\Psi_G\} = \lim_{n\to\infty}\left\{\phi, e^{-D}\left(1+\frac{t}{n}H\right)^{-n} e^D\psi\right\} \tag{117}$$

using Corollary II.7.

Upon using the harmonic oscillator representation, the ghost part of the Hamiltonian becomes a second-order differential operator with polynomial coefficients. Therefore, $e^{-D}He^D\phi \in C_0^\infty$, and one has

$$e^{-D}\left(1+\frac{t}{n}H\right)^n e^D\phi = \left(1+\frac{t}{n}e^{-D}He^D\right)^n \phi \tag{118}$$

for Re $t>0$. The calculation of the commutators is now elementary, leading to the expression

$$e^{D}\left(1+\frac{t}{n}H\right)e^{-D}\phi=\left(1+\left[\frac{t}{n}H,D\right]+\frac{1}{2}\left[\left[\frac{t}{n}H,D\right],D\right]\right)\phi=\left(1+\frac{t}{n}[\tilde{H}+H_0^G+V_Q]\right)\phi \tag{119}$$

in which V_Q contains terms linear in a_Q and $a_Q^\dagger$, with coefficients that are bounded fermion currents (Ref. 5, Eq. (3.17)).

The arguments used for Proposition II.3 show that $\overline{\tilde{H}+H_0^G+V_Q}$ is a quasi-*m*-accretive operator, generating a C_0 semigroup, denoted $e^{-tH'}$. As a result, we have

$$e^{-D}\left(1+\frac{t}{n}H\right)^{n}e^{D}\psi=\left(1+\frac{t}{n}H'\right)^{n}\psi$$

again for $\mathrm{Re}\, t>0$. The Hille–Yosida theorem allows us to conclude that $(1+(t/n)H')^{-n}$ is a bounded operator on Fock space and agrees with $e^{-D}(1+(t/n)H)^{-n}e^{D}$ on C_0^∞, and therefore defines a unique, bounded extension for this expression. Furthermore, it follows that H' is quasi-*m*-accretive, so that

$$s-\lim_{n\to\infty} e^{-D}\left(1+\frac{t}{n}H'\right)^{-n}e^{D}=e^{-tH'}. \tag{120}$$

Therefore, the limit in (117) exists and we find

$$\{\Phi_G,e^{-tH}\Psi_G\}=\{\phi,e^{-tH'}\psi\} \tag{121}$$

for the matrix element.

The final step is to remove all the ghost terms from H' in the prior expression. This is accomplished by using the fact that V_Q is a Phillips perturbation of the free Hamiltonian, so that a norm convergent Duhamel series

$$e^{-tH'}=\sum_{n=0}^{\infty}(-1)^n\int_0^\infty du_1\cdots du_n\quad e^{-u_1(\tilde{H}+H_0^G)}V_Q e^{-u_2(\tilde{H}+H_0^G)}V_Q\cdots V_Q e^{-(t-u_n)(\tilde{H}+H_0^G)}, \tag{122}$$

where the integration variables are anti-time ordered, may be used. Operators in V_Q are of the form

$$\sum_{\mathbf{k}\in\Gamma_0}[\rho(\mathbf{k})a_Q(\mathbf{k})+\tau(\mathbf{k})a_Q^\dagger(\mathbf{k})], \tag{123}$$

where $\rho(\mathbf{k})$ and $\tau(\mathbf{k})$ are bounded fermion operators. These terms do not commute with $\tilde{H}$, but $\tilde{H}$ and H_0^G do commute. From

$$a_Q(\mathbf{k})e^{-sH_0^G}\psi=e^{-s\omega(\mathbf{k})}e^{-sH_0^G}a_Q(\mathbf{k})\psi=0,$$

where $\psi=e^{-|z|^2}/2F$, and the commutation of a_Q and $a_Q^\dagger$, successive use of this pull-through formula eliminates all a_Q terms in V_Q from (117). Only the $n=0$ term remains in (123) which produces

$$\{\phi,e^{-tH'}\psi\}=\{\phi,e^{-t\tilde{H}}e^{-tH_0^G}\psi\}.$$

The term $H_0^G(1/2)$ is given by

$$H_0^G(1/2)=\sum_{\mathbf{k}\in\Gamma_0}\omega(\mathbf{k})[a_Q^\dagger(\mathbf{k})a_R(\mathbf{k})+a_R^\dagger(\mathbf{k})a_Q(\mathbf{k})] \tag{124}$$

and one may easily show that in the sense of unbounded operators, each of the terms in the above equation commute with $\Sigma_{\mathbf{k}\in\Gamma_0}\omega(\mathbf{k})a_R^\dagger(\mathbf{k})a_Q(\mathbf{k})\psi=0$. This operator may be expressed in terms of Fock space operators as

$$\frac{1}{2}\sum_{\mathbf{k}\in\Gamma_0}\omega(\mathbf{k})[c_1(\mathbf{k})-c_0(\mathbf{k})]^*[c_1(\mathbf{k})-c_0(\mathbf{k})]$$

which defines a positive operator and generates a self-adjoint semigroup. In this manner, the two ghost parts in (124) may be separated in $e^{-tH_0^G}$, with the second term equal to one on ψ, and the first term gives one on ϕ as well, after taking Krein adjoints.

Now that all the ghost operators have been removed from the Gauss matrix elements in (117), Corollary II.7 further reduces the null vectors in ϕ and ψ to their projections onto $\mathcal{H}_V\otimes\mathcal{H}_F$. □

C. Path space formulas

Proposition III.1 showed that the Hamiltonian on the physical subspace is an essentially self-adjoint operator and that the interaction was a Phillips perturbation of the free Hamiltonian. As a result, the Hamiltonian is the infinitesimal generator of a C_0 semigroup and has a uniformly convergent Duhamel series expansion. The operator $\tilde{H}$ has additional fermion terms, but these are bounded operators, so they are also Phillips perturbations. For this operator, the Duhamel expansion is

$$\begin{aligned}(\Phi_V,e^{-t\tilde{H}}\Psi_V)&=\sum_{n=0}^{\infty}(-1)^n\int_0^\infty du_1\cdots du_n(\Phi_V,e^{-u_1H_0}\tilde{V}e^{-(u_2-u_1)H_0}\tilde{V}\cdots\tilde{V}e^{-(t-u_n)H_0})\\&=\sum_{n=0}^{\infty}(-1)^n\int_0^\infty du_1\cdots du_n(\Phi_v,\hat{\tilde{V}}(u_1)\cdots\hat{\tilde{V}}(u_n)\Psi_V),\end{aligned} \tag{125}$$

where the integration variable is anti-time ordered, $0\leqslant u_1\leqslant\cdots u_n\leqslant t$. Using a two dimensional version of Osterwalder–Schrader Euclidean fermions[17] sketched in Appendix C, the interaction terms

$$\tilde{V}=\sum_{\mathbf{x}\in V}\delta^2\left[j_\mu(\mathbf{x})V^\mu(\mathbf{x})+\frac{j_0(\mathbf{x})j_0(\mathbf{x})}{2m^2}+\frac{j_0(\mathbf{x})\epsilon_{nl}\partial_l j_n(\mathbf{x})}{m(-\Delta_s)}\right] \tag{126}$$

may be rewritten as

$$\hat{\tilde{V}}=e^{-t\tilde{H}_0}\tilde{V}e^{t\tilde{H}_0} \tag{127}$$

$$=W\sum_{\mathbf{x}\in V}\delta^2\left[j_\mu(\mathbf{x})V^\mu(\mathbf{x})+\frac{j_0(\mathbf{x})j_0(\mathbf{x})}{2m^2}+\frac{j_0(\mathbf{x})\epsilon_{nl}\partial_l j_n(\mathbf{x})}{m(-\Delta_s)}\right]. \tag{128}$$

Notice, that in the Wick expansion of the inner product in (125) when the anti-time ordered products are converted to expectations with respect to the Gauss measure for ϕ^E the extra terms on the RHS of (113) must be taken into account. It is easy to see that the net effect of this term is to add a further nonlocal interaction,

$$W\sum_{\mathbf{x}\in V}\left(\frac{\partial_l j_l^E(\mathbf{x})}{m(-\Delta)^{1/2}}\right)^2. \tag{129}$$

Consequently, removing the time ordering as all Euclidean expressions commute,

$$\begin{aligned}(\Phi_V, e^{-tH}\Psi_V) &= \left(I_0\Phi_V, W \exp\left[-\int_0^t du \sum_{\mathbf{x}\in V} \delta^2 V^E(u) \right] U(t)\Psi_V \right) \\ &= \int d\mu_0(\phi^E) \left(I_0\Phi_V, W \exp\left[-\int_0^t du \sum_{\mathbf{x}\in V} \delta^2 V^E(u) \right] I(t)\Psi_V \right), \end{aligned} \tag{130}$$

where ϕ^E is the scalar, Euclidean field defined above, and I is the corresponding Euclidean embedding map. In this way, the path-space formula on physical states satisfies Osterwalder–Schrader positivity for a Feynman–Kac–Nelson integral with a nonlocal fermion interaction density.

APPENDIX A: HALLER AND LIM-LOMBRIDAS' REPRESENTATION

$$\begin{aligned}A_0(\mathbf{x}) = &\frac{-1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{4\omega^3}{m^{7/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{(1-2\xi)}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{2\omega}{m^{3/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} \\ &+ a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{m^{3/2}}{16\omega^2} [a_R(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\ &- \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{\omega}{m\sqrt{2\mu}} [a(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}],\end{aligned} \tag{A1}$$

$$\begin{aligned}A_l(\mathbf{x}) = &\frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{8i\omega\epsilon_{ln}k_n}{m^{5/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \frac{(1-2\xi)}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{2k_l}{m^{3/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} \\ &+ a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{4\omega^2 k_l}{m^{7/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\ &+ \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{m^{3/2}k_l}{16\omega^3} [a_R(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{\sqrt{\mu}k_l}{\sqrt{2}m\omega} [a(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} \\ &+ a^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{i\epsilon_{ln}k_n}{\omega\sqrt{2\mu}} [a(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}],\end{aligned} \tag{A2}$$

$$\Pi_0(\mathbf{x}) = -\frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{8i\omega^2}{m^{3/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{A3}$$

$$\begin{aligned}\Pi_l(\mathbf{x}) = &\frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{4i\omega k_l}{m^{3/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{(1-2\xi)}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{\epsilon_{ln}k_n}{m^{1/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} \\ &+ a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{6\omega^2\epsilon_{ln}k_n}{m^{5/2}} [a_Q(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\ &- \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{m^{5/2}\epsilon_{ln}k_n}{32\omega^3} [a_R(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{imk_l}{2\omega\sqrt{2\mu}} [a(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} \\ &- a^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \frac{1}{\sqrt{V}} \sum_{\mathbf{k}\in\Gamma_0} \frac{\sqrt{\mu}\epsilon_{ln}k_n}{2^{3/2}\omega} [a(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^\dagger(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}].\end{aligned} \tag{A4}$$

APPENDIX B: HARMONIC OSCILLATOR COORDINATES

We define ghost space harmonic oscillator coordinates in the following manner:

$$
\begin{aligned}
q_{01}(\mathbf{k}) &= \tfrac{1}{2}[b_0(\mathbf{k})+b_0^\dagger(\mathbf{k})+b_0(-\mathbf{k})+b_0^\dagger(-\mathbf{k})],\\
q_{02}(\mathbf{k}) &= \frac{i}{2}[b_0(\mathbf{k})-b_0^\dagger(\mathbf{k})-b_0(-\mathbf{k})+b_0^\dagger(-\mathbf{k})],\\
p_{01}(\mathbf{k}) &= \frac{i}{2}[b_0(\mathbf{k})-b_0^\dagger(\mathbf{k})+b_0(-\mathbf{k})-b_0^\dagger(-\mathbf{k})],\\
p_{02}(\mathbf{k}) &= \tfrac{1}{2}[-b_0(\mathbf{k})-b_0^\dagger(\mathbf{k})+b_0(-\mathbf{k})+b_0^\dagger(-\mathbf{k})],
\end{aligned}
\tag{B1}
$$

$$
\begin{aligned}
q_{11}(\mathbf{k}) &= \tfrac{1}{2}[b_1(\mathbf{k})+b_1^\dagger(\mathbf{k})+b_1(-\mathbf{k})+b_1^\dagger(-\mathbf{k})],\\
q_{12}(\mathbf{k}) &= \frac{i}{2}[b_1(\mathbf{k})-b_1^\dagger(\mathbf{k})-b_1(-\mathbf{k})+b_1^\dagger(-\mathbf{k})],\\
p_{11}(\mathbf{k}) &= \frac{i}{2}[b_1(\mathbf{k})-b_1^\dagger(\mathbf{k})+b_1(-\mathbf{k})-b_1^\dagger(-\mathbf{k})],\\
p_{12}(\mathbf{k}) &= \tfrac{1}{2}[-b_1(\mathbf{k})-b_1^\dagger(\mathbf{k})+b_1(-\mathbf{k})+b_1^\dagger(-\mathbf{k})],
\end{aligned}
\tag{B2}
$$

one-half of which are redundant under $\mathbf{k}\leftrightarrow-\mathbf{k}$. One can verify that

$$[q_{\mu j}(\mathbf{k}),p_{\nu l}(\mathbf{k}')]=ig_{\mu\nu}\delta_{jl}\delta_{\mathbf{k},\mathbf{k}'} \tag{B3}$$

and that all other commutators vanish. From these definitions, suppressing the **k**-dependence, the following representation for the ghost operators arises:

$$a_Q(\mathbf{k})=\frac{1}{2\sqrt{2}\sigma}[(q_{11}-ip_{11})-(iq_{12}+p_{12})-(q_{01}-ip_{01})+(iq_{02}+p_{02})], \tag{B4}$$

$$a_Q^\dagger(\mathbf{k})=\frac{1}{2\sqrt{2}\sigma}[(q_{11}+ip_{11})+(iq_{12}-p_{12})-(q_{01}+ip_{01})+(-iq_{02}+p_{02})], \tag{B5}$$

$$a_R(\mathbf{k})=\frac{\sigma}{2\sqrt{2}}[(q_{11}-ip_{11})-(iq_{12}+p_{12})+(q_{01}-ip_{01})-(iq_{02}+p_{02})], \tag{B6}$$

$$a_R^\dagger(\mathbf{k})=\frac{\sigma}{2\sqrt{2}}[(q_{11}+ip_{11})+(iq_{12}-p_{12})+(q_{01}+ip_{01})-(-iq_{02}+p_{02})]. \tag{B7}$$

Next, we obtain a Schrödinger representation by means of von Neumann's theorem using the following:

$$q_{0j}=\frac{\partial}{\partial x_{0j}},\quad q_{1j}=-i\,\frac{\partial}{\partial x_{1j}},\quad p_{0j}=ix_{0j},\quad p_{1j}=x_{1j}. \tag{B8}$$

The following linear combinations:

$$z_1=x_{01}+ix_{11},\qquad z_2=x_{02}+ix_{12}, \tag{B9}$$

are useful and using them we can express the ghost operators as the following:

$$
\begin{aligned}
a_Q(\mathbf{k}) &= \frac{1}{\sqrt{2}\sigma}\left[-\left(\frac{1}{2}z_1+\overline{\partial_1}\right)+i\left(\frac{1}{2}z_2+\overline{\partial_2}\right)\right],\\
a_Q^\dagger(\mathbf{k}) &= \frac{1}{\sqrt{2}\sigma}\left[\left(\frac{1}{2}z_1-\overline{\partial_1}\right)+i\left(\frac{1}{2}z_2-\overline{\partial_2}\right)\right],\\
a_R(\mathbf{k}) &= \frac{\sigma}{\sqrt{2}}\left[\left(\frac{1}{2}\overline{z_1}+\partial_1\right)-i\left(\frac{1}{2}\overline{z_2}+\partial_2\right)\right],\\
a_R^\dagger(\mathbf{k}) &= \frac{\sigma}{\sqrt{2}}\left[-\left(\frac{1}{2}\overline{z_1}-\partial_1\right)-i\left(\frac{1}{2}\overline{z_2}-\partial_2\right)\right].
\end{aligned}
\tag{B10}
$$

APPENDIX C: EUCLIDEAN FERMIONS

In this appendix, the description of the two component Euclidean fermions as developed by Osterwalder and Schrader[17] is presented.

The time-zero fermion fields are defined as

$$\psi(0,\mathbf{x}) = \frac{1}{\sqrt{V}}\sum_{\mathbf{k}\in\Gamma}\sqrt{\frac{m_f}{E(\mathbf{k})}}\,[b(\mathbf{k})u(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}}+d^*(\mathbf{k})v(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}}], \tag{C1}$$

$$\psi^\dagger(0,\mathbf{x}) = \psi^*(0,\mathbf{x})\gamma_0 = \frac{1}{\sqrt{V}}\sum_{\mathbf{k}\in\Gamma}\sqrt{\frac{m_f}{E(\mathbf{k})}}\,[d(\mathbf{k})v^\dagger(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}}+b^*(\mathbf{k})u^\dagger(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}}], \tag{C2}$$

where $E(\mathbf{k}) = \sqrt{\mathbf{k}^2+m_f^2}$, and there are the standard anticommutation relations $[b(\mathbf{k}),b^*(\mathbf{p})]_+ = \delta_{\mathbf{k},\mathbf{p}} = [d(\mathbf{k}),d^*(\mathbf{p})]_+$. The two-dimensional gamma matrices that we use are

$$\gamma^0 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix},\quad \gamma^1 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},\quad \gamma^2 = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}, \tag{C3}$$

where $\gamma^\mu\gamma^\nu = g^{\mu\nu} - i\epsilon^{\mu\nu\alpha}\gamma_\alpha$ is one of the important features of the two-dimensional gamma matrices, the other being that there is no $\gamma.^5$ From this representation, the free Hamiltonian is obtained

$$H_0^D = \sum_{\mathbf{k}\in\Gamma} E(\mathbf{k})[b^*(\mathbf{k})b(\mathbf{k})+d^*(\mathbf{k})d(\mathbf{k})] \tag{C4}$$

in the usual manner.

The Dirac Hamiltonian can be used to define the following fields in the same manner as in Sec. III C, namely,

$$\hat{\psi}(t,\mathbf{x}) = e^{-tH_0^D}\psi(0,\mathbf{x})e^{tH_0^D}, \tag{C5}$$

$$\hat{\psi}^\dagger(t,\mathbf{x}) = e^{-tH_0^D}\psi^\dagger(0,\mathbf{x})e^{tH_0^D}, \tag{C6}$$

which are then used to compute the two-point function

$$(\Omega_R, \hat{\psi}(x), \hat{\psi}^\dagger(y)\Omega_R) = \frac{1}{2\pi V}\sum_{\mathbf{k}\in\Gamma}\int_{-\infty}^{\infty} dk^0 e^{ik(x-y)}\left(\frac{m_f+i\gamma^E\cdot k}{m_f^2+k^2}\right), \tag{C7}$$

where

$$\gamma_0^E=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix},\quad \gamma_1^E=\begin{pmatrix}0 & i\\ -i & 0\end{pmatrix},\quad \gamma_2^E=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix} \tag{C8}$$

are the Euclidean gamma matrices. Diagonalizing the matrix in (C7),

$$m+i\gamma^E\cdot k=S_E(k)\begin{pmatrix}m_f+i|k| & 0\\ 0 & m_f-i|k|\end{pmatrix}S_E^{-1}(k) \tag{C9}$$

allows for the definition of the vectors

$$W_\pm^1=\begin{pmatrix}\sqrt{\pm(i|k|+m_f)}\\ 0\end{pmatrix},\quad W_\pm^2=\begin{pmatrix}0\\ \sqrt{\pm(i|k|-m_f)}\end{pmatrix} \tag{C10}$$

from which the Euclidean spinors may be defined,

$$\begin{aligned}u^j(k)&=S_E(k)W_+^j(k),\quad v^j(k)=S_E(-k)W_-^j(k),\\ \hat{u}^j(k)&=(W_+^j)^T(k)S_E(k)^{-1},\quad \hat{v}^j(k)=(W_-^j)^T(k)S_E(-k)^{-1}.\end{aligned} \tag{C11}$$

Note that in these expressions, $|k|=\sqrt{k^2}=\sqrt{k_0^2+k_1^2+k_2^2}$, that is, the Euclidean length of the vector.

The Euclidean fermi fields may now be defined as

$$\Psi_\alpha^{(1)}(x)=\frac{1}{\sqrt{2\pi V}}\sum_{\mathbf{k}\in\Gamma}\sum_{j=1,2}\int_{-\infty}^{\infty}dk_0\left[\frac{B(k,j)u_\alpha^j(k)e^{ikx}+D^*(k,j)v_\alpha^j(k)e^{-ikx}}{\sqrt{k^2+m_f^2}}\right], \tag{C12}$$

$$\Psi_\alpha^{(2)}(x)=\frac{1}{\sqrt{2\pi V}}\sum_{\mathbf{k}\in\Gamma}\sum_{j=1,2}\int_{-\infty}^{\infty}dk_0\left[\frac{D(k,j)\hat{v}_\alpha^j(k)e^{ikx}+B^*(k,j)\hat{u}_\alpha^j(k)e^{-ikx}}{\sqrt{k^2+m_f^2}}\right], \tag{C13}$$

where $[B(k,j),B^*(p,l)]_+=\delta_{\mathbf{k},\mathbf{p}}\delta(k_0-p_0)\delta_{jl}=[D(k,j),D^*(p,l)]_+$ and all other terms anticommute. The Euclidean fields have the following vacuum expectation value:

$$(\Omega_E,\Psi_\alpha^{(i)}\Psi_\beta^{(j)*}\Omega_E)=\delta_{ij}\delta_{\alpha\beta}(-\Delta+m^2)^{-1/2}, \tag{C14}$$

and anticommutator,

$$\{\Psi_\alpha^{(i)},\Psi_\beta^{(j)*}\}=2\delta_{ij}\delta_{\alpha\beta}(-\Delta+m^2)^{-1/2}. \tag{C15}$$

From these definitions, the current operator is then given by

$$j_\mu^E(x)=:\Psi^{(2)}\gamma_\mu^E\Psi^{(1)}(x):. \tag{C16}$$

For this paper, the reflection operator Θ is defined as

$$\Theta\Psi_\alpha^{(1)}\Theta^{-1}=(\Psi^{(2)}\gamma_0^E)_\alpha^*(\theta x),\quad \Theta\Psi_\alpha^{(2)}\Theta^{-1}=(\Psi^{(1)}\gamma_0^E)_\alpha^*(\theta x), \tag{C17}$$

where $\theta x=(-x_0,\mathbf{x})$. Let vectors dense in $\mathcal{H}_E$ be denoted by

$$:\Psi^{(1)}(x,\alpha)\Psi^{(2)}(y,\beta):=:\Psi_{\alpha_1}^{(1)}(x_1)\cdots\Psi_{\alpha_n}^{(1)}(x_n)\Psi_{\beta_1}^{(2)}(y_1)\cdots\Psi_{\beta_n}^{(2)}(y_n): \tag{C18}$$

and vectors which are dense in $\mathcal{H}_R$ by

$$:\hat{\psi}(x,\alpha)\hat{\psi}(y,\beta):=:\hat{\psi}_{\alpha_1}(x_1)\cdots\hat{\psi}_{\alpha_n}(x_n)\hat{\psi}_{\beta_1}(y_1)\cdots\hat{\psi}_{\beta_n}(y_n):. \tag{C19}$$

The embedding map is then defined by

Definition C.1: When $x_{j0}>0$, $y_{l_0}>0$ *and for* $j,l=1,2,...,n$ *there is a subspace* $\mathcal{E}_+^0 \subset \mathcal{H}_E$ *and a map* $W: \mathcal{E}_+^0 \to \mathcal{H}_R$ *defined by*

$$W{:}\Psi^{(1)}(x,\alpha)\Psi^{(2)}(y,\beta){:}\Omega_E = {:}\hat{\psi}(x,\alpha)\hat{\psi}(y,\beta){:}\Omega_R . \tag{C20}$$

The following lemmas directly transcribe from Ref. 17.

Lemma C.2: Let $X,Y \in \mathcal{E}_+^0$, *then* $(WX,WY)=(\Theta X,Y)$.

Lemma C.3: For $t \geqslant 0$ *and* $X \in \mathcal{E}_+^0$, *let* $U(t)$ *denote time translation in* $\mathcal{H}_E$. *Then,*

$$WU(t)X = e^{-tH_0^D}WX. \tag{C21}$$

(Received 25 February 1999; accepted for publication 14 June 1999)

The Schrödinger operators with matrix rational potential, which are *D*-integrable, i.e., can be intertwined with the pure Laplacian, are investigated. Corresponding potentials are uniquely determined by their singular data which are a configuration of the hyperplanes in $\mathbf{C}^n$ with prescribed matrices. We describe some algebraic conditions (matrix locus equations) on these data, which are sufficient for *D*-integrability. As the examples some matrix generalizations of the Calogero–Moser operators are considered.
[S0022-2488(99)00911-1]

I. INTRODUCTION

Let us consider a Schrödinger operator

$$L=-\Delta+U(z),$$

where $z\in\mathbf{R}^n$ or $\mathbf{C}^n$ and $U(z)$ is a matrix-valued meromorphic function. We will call such an operator as *D-integrable* if there exists a differential operator $\mathcal{D}$ with meromorphic matrix coefficients and constant scalar highest term, such that

$$L\,\mathcal{D}=\mathcal{D}\,L_0, \tag{1}$$

where $L_0=-\Delta$ is the pure Laplacian acting on the vector-valued functions (cf. Refs. 1–3, where the scalar case $d=1$ has been considered).

In dimension $n=1$ all such operators with rational potentials can be described as the results of matrix Darboux transformations (see Ref. 4), which explains the terminology.

In dimension $n>1$ the situation is much more complicated even in the scalar case. For the review of the known results in this direction we refer to the recent paper.[5] In particular, as it has been shown in Refs. 1,2 the singularities of the potential $U(z)$ of any *D*-integrable Schrödinger operator have to be located on a union of the hyperplanes. The proof given in Refs. 1,2 works also in the matrix case under an additional assumption of the regularity (see below theorem 3), so in the rational case the potential $U(z)$ should have a form

a)Electronic mail: chalykh@mech.math.msu.su
b)Electronic mail: V.M.Gontcharenko@lboro.ac.uk
c)Electronic mail: A.P.Veselov@lboro.ac.uk

$$U(z)=\sum_{i=1}^{N}\frac{(\alpha_i,\alpha_i)A_i}{((\alpha_i,z)+c_i)^2}.$$

Such a potential is determined by a configuration of the hyperplanes Π_i in $\mathbf{C}^n$ given by the equations $(\alpha_i,z)+c_i=0$ with prescribed constant matrices A_i.

In the present paper we describe the conditions (so-called *matrix locus equations*) on these data which guarantee *D*-integrability. This generalizes to the matrix case the main result of the paper.[3] Locus equations can be interpreted as the conditions of the local trivial monodromy for the corresponding Schrödinger equations (cf. Refs. 4–6). This allows us to construct the examples of such configurations and related matrix *D*-integrable Schrödinger operators. Our proof of the existence of the intertwining operator $\mathcal{D}$ is effective; the corresponding formula is a matrix version of the Berest's formula.[7]

Some important examples of such operators were known in the theory of the generalized matrix Calogero–Moser systems (see Refs. 8–12), although the fact of their *D*-integrability seems to have not been emphasized. The corresponding operators have the form

$$L=-\Delta+\sum_{\alpha\in\mathcal{R}_+}\frac{m_\alpha(m_\alpha I-s_\alpha)(\alpha,\alpha)}{(\alpha,z)^2},$$

where $\mathcal{R}$ is a root system in $\mathbf{R}^n$ related to some Coxeter group G, m_α is an integer-valued G-invariant function on $\mathcal{R}$, s_α is the matrix of reflection with respect to the hyperplane $(\alpha,z)=0$.

We show that the operator L is *D*-integrable also for some non-Coxeter configurations $\mathcal{R}$ discovered in the scalar case in Refs. 13,14. Remarkably enough the matrix locus equations in this case turned out to coincide with the condition of the existence of the rational Baker–Akhiezer function in the so-called ''old axiomatics'' proposed in Refs. 15 and 16 (see Ref. 5 for the detailed discussion of this notion). This explains the appearance in the matrix case of the same configurations as in the scalar situation. Another interesting relation between the scalar and matrix generalizations of the Calogero–Moser system has been proposed recently by Bracken and Kamran[12] (see also Ref. 11).

We should mention that in the classical case matrix generalization of the Calogero–Moser system were introduced first by Gibbons and Hermsen in Ref. 17 (see Ref. 18 for further results in this direction). Our results show that the quantum situation is actually much richer than the classical one.

II. MONODROMY OF THE MATRIX SCHRÖDINGER EQUATIONS IN THE COMPLEX DOMAIN

Let us start with the one-dimensional case following essentially Ref. 4. Let

$$L=-D^2+U(z),\ z\in\mathbf{C},\quad D=\frac{d}{dz} \tag{2}$$

be a Schrödinger operator with meromorphic $d\times d$-matrix potential $U(z)$. Let $z=0$ be a regular singular point, i.e., a pole of the second order of $U(z)$. Consider a formal solution of the Schrödinger equation

$$L\psi=\lambda\psi \tag{3}$$

in the form

$$\psi=z^{-m}\sum_{i\geqslant 0}\psi_{-m+s}z^s. \tag{4}$$

Substituting (4) into the Schrödinger equation (3) with

$$U(z)=\frac{C_{-2}}{z^2}+\frac{C_{-1}}{z}+\sum_{r\geqslant 0}^{\infty} C_r z^r, \tag{5}$$

we obtain that ψ_{-m} is an eigenvector of C_{-2},

$$C_{-2}\psi_{-m}=m(m+1)\psi_{-m}.$$

If for any λ we can construct a basis of solutions of (3) with integer m (i.e., ψ is single-valued) then we say that the operator L has *local trivial monodromy* around $z=0$. This is equivalent to the fact that all the solutions of the corresponding matrix Schrödinger equation (3) are single-valued near $z=0$ for all λ. In this case one can prove that C_{-2} is diagonalizable with eigenvalues $\lambda_i=m_i(m_i+1)$, $i=1,2,\ldots,$ where $m_i\in\mathbf{Z}$ (see Ref. 4). Thus C_{-2} has a form

$$C_{-2}=\sum_{i=1}^{k} m_i(m_i+1)P_i, \tag{6}$$

where P_i are commuting projectors to the corresponding eigenspaces,

$$P_iP_j=\delta_{ij}P_i, \quad \sum_{i=1}^{k} P_i=I,$$

where I is identity operator. We assume that $0\leqslant m_1<m_2<\cdots<m_k=M$. The following result[4] gives the conditions on the coefficients C_j of the expansion of the potential (5) which are equivalent to the local trivial monodromy of L.

Theorem 1: *A matrix Schrödinger operator (2) with a meromorphic potential (5) has local trivial monodromy around* $z=0$ *if and only if* C_{-2} *has a form (6) and the coefficients* C_l *with* $l=-1,0,\ldots,2M-1$ *satisfy the relation*

$$P_iC_lP_j=0, \tag{7}$$

when $|m_i-m_j|\geqslant l+1$ *or* $m_i+m_j=l+1,l+3,\ldots,l+2k+1,\ldots$ *(i.e., when* m_i+m_j-l *is a positive odd number). In particular, the matrix residue* $C_{-1}=0$.

The coefficients $\psi_{-M},\psi_{-M+1},\ldots,\psi_{M-1}$ *of the corresponding expansions of the vector-eigenfunctions*

$$\psi=z^{-M}(\psi_{-M}+z\,\psi_{-M+1}+\cdots+z^k\psi_{-M+k}+\cdots)$$

satisfy the conditions

$$P_i\psi_l=0$$

if $m_i+l<0$ *or* $m_i+l=1,3,\ldots,2k+1,\ldots,2m_i-1$ *for* $m_i\geqslant 1$.

Notice that for $l=0$ conditions (7) are equivalent to the commutativity relation

$$[C_{-2},C_0]=0. \tag{8}$$

Now let us consider the multidimensional case. We will assume that the potential $U(z)$ of the Schrödinger operator

$$L=-\Delta+U(z), \tag{9}$$

where $z=(z_1,\ldots,z_n)\in\mathbf{C}^n$, $\Delta=(\partial^2/\partial z_1^2)+\cdots+(\partial^2/\partial z_n^2)$, is a meromorphic $d\times d$ matrix-valued function having a pole of the second order along the hyperplane $\Pi_\alpha:(\alpha,z)=0$, which is assumed to be nonisotropic: $(\alpha,\alpha)\neq 0$ (cf. Refs. 1,2,5). We will suppose for simplicity that $(\alpha,\alpha)=1$. The Laurent expansion of the potential in the normal direction α at the vicinity of Π_α can be written in the form

$$U(z)=\sum_{r\geqslant -2} C_r(\alpha,z)^r, \tag{10}$$

where $C_r=C_r(z^\perp)$ are some analytic $d\times d$ matrix-valued functions on the hyperplane Π_α and $z^\perp$ is orthogonal projection of z onto Π_α. Let us suppose that there exists a formal solution of the Schrödinger equation

$$L\psi=\lambda\psi \tag{11}$$

of the form

$$\psi(z)=(\alpha,z)^{-m}\sum_{s\geqslant 0} \psi_{-m+s}(\alpha,z)^s \tag{12}$$

for some m, where the coefficients $\psi_r=\psi_r(\lambda,z^\perp)$ are analytic vector-functions on Π_α. Substituting series (10) and (12) into Eq. (11) one can see that

$$C_{-2}\psi_{-m}=m(m+1)\psi_{-m},$$

i.e., ψ_{-m} is an eigenvector of C_{-2} with the eigenvalue $m(m+1)$.

Definition: We say that a Schrödinger operator (9) with the potential (10) has *local trivial monodromy around the hyperplane* Π_α if

(1) at any point of Π_α matrix C_{-2} is diagonalizable with eigenvalues having the form $m(m+1)$, $m\in\mathbf{Z}$,
(2) for any $m\in\mathbf{Z}$ such that $m(m+1)$ is an eigenvalue of C_{-2} and for any choice of the corresponding eigenvector $\psi_{-m}(z^\perp)$ there exists a formal solution (12) of Eq. (11) for any λ (notice that any such eigenvalue can be represented in the form $\mu(\mu+1)$ in two different ways: $\mu=m$ or $\mu=-m-1$).

In principle, C_{-2} might depend on the point at the hyperplane Π_α, but this is not the case.

Lemma 1: If the operator (9) has a local trivial monodromy around the hyperplane Π_α*, then* C_{-2} *is a constant matrix.*

To prove the lemma we can assume without loss of generality that $\alpha=(1,0,\ldots,0)$. Then the Schrödinger operator can be written in the form

$$L=-\frac{\partial^2}{\partial z_1^2}-\tilde{\Delta}+U(z), \tag{13}$$

where $\tilde{\Delta}=(\partial^2/\partial z_2^2)+\cdots+(\partial^n/\partial z_n^2)$. Thus we can consider (13) as a one-dimensional Schrödinger operator with the matrix operator-valued ''potential''

$$\tilde{U}(z)=-\tilde{\Delta}+U(z).$$

Applying formally theorem 1 and, in particular (8), we have

$$[C_0-\tilde{\Delta},C_{-2}]\equiv 0$$

or

$$[C_0,C_{-2}]-2\cdot\sum_{k=2}^{n}(\partial_k C_{-2})\partial_k-\tilde{\Delta}(C_{-2})\equiv 0.$$

Therefore, $\partial_k C_{-2}=0$ for all $k=2,\ldots,n$, i.e., C_{-2} is a constant. Alternative, more rigorous way to prove the lemma is to repeat the arguments of the proof of theorem 1 (see Refs. 4–6).

Now simularly to the one-dimensional case[4] (see theorem 1 above) one can prove the following:

Theorem 2: *A matrix Schrödinger operator (9) with a meromorphic potential (10) has local trivial monodromy around the hyperplane Π_α if and only if*

(1) C_{-2} is a constant diagonalizable matrix,

$$C_{-2}=\sum_{i=1}^{k} m_i(m_i+1)P_i\,,$$

where $0\leqslant m_1<m_2<\cdots<m_k=M$ are some integers, P_i are commuting projectors:

$$P_iP_j=\delta_{ij}P_i\,,\quad \sum_{i=1}^{k}P_i=I.$$

(2) The coefficients C_l with $l=-1,0,\ldots,2M-1$ satisfy the following relations:

$$P_iC_lP_j\equiv 0 \tag{14}$$

if $|m_i-m_j|\geqslant l+1$ or $m_i+m_j=l+1,l+3,\ldots,l+2k+1,\ldots$. In particular, $C_{-1}\equiv 0$ and $[C_0,C_{-2}]\equiv 0$.

The coefficients $\psi_{-M},\psi_{-M+1},\ldots,\psi_{M-1}$ of the corresponding expansions of the vector-eigenfunctions

$$\psi=(\alpha,z)^{-M}(\psi_{-M}+(\alpha,z)\psi_{-M+1}+\cdots+(\alpha,z)^k\psi_{-M+k}+\cdots)$$

satisfy the conditions

$$P_i\psi_l\equiv 0 \tag{15}$$

if $m_i+l<0$ or $m_i+l=1,3,\ldots,2k+1,\ldots,2m_i-1$ for $m_i\geqslant 1$.

III. MATRIX LOCUS EQUATIONS AND *D*-INTEGRABILITY

Let us consider a matrix Schrödinger operator (9) with a rational potential $U(z)$ decaying at infinity. We will assume that all the singularities are regular, i.e., $U(z)$ has the poles of the second order at most.

We would like to show that in this case the trivial monodromy property implies *D*-integrability, i.e., the existence of the intertwining operator (1). First of all, the potential must have the form

$$U(z)=\sum_{i=1}^{N}\frac{(\alpha_i,\alpha_i)A_i}{((\alpha_i,z)+c_i)^2} \tag{16}$$

due to the following result:

Theorem 3: *The regular singularities of the matrix potential of any D-integrable Schrödinger operator L are located on a union of nonisotropic hyperplanes. If such a potential is rational and decaying at infinity it should have a form (16).*

The proof essentially repeats the arguments of the scalar case investigated in Refs. 1,2. The coefficient (α_i,α_i) is written at the numerator of the expression (16) for the convenience, as this makes the matrices A_i independent on the choice of the equation of the corresponding hyperplane.

Let us assume now that the operator L with the potential (16) has local trivial monodromy around all the hyperplanes Π_i: $(\alpha_i,z)+c_i=0$. We will say in this case that L has *trivial monodromy*. The local trivial monodromy conditions (14) around all the hyperplanes form a highly-overdetermined algebraic system on the configuration of the hyperplanes with prescribed matrices A_i. We will call this system *matrix locus equations*.

Theorem 4: *Let L be a matrix Schrödinger operator (9) with a rational potential (16) satisfying the matrix locus equations. Then L is D-integrable.*

Proof: From the theorem 2 it follows that

$$A_s=\sum_{i=1}^{k_s} m_i^{(s)}(m_i^{(s)}+1)P_i^{(s)}, \quad 0\leqslant m_1^{(s)}<m_2^{(s)}<\cdots<m_{k_s}^{(s)}=M_s$$

with some projectors $P_i^{(s)}$: $P_i^{(s)}P_j^{(s)}=\delta_{ij}P_i^{(s)}$, $\Sigma_{i=1}^{k_s}P_i^{(s)}=I$.

Following the main idea of Ref. 3 let us introduce a linear space V consisting of the $d\times d$ matrix-valued functions $\Psi(z)$, $z\in\mathbf{C}^n$ which satisfy the conditions

(1) $\Psi(z)\Pi_{s=1}^N((\alpha_s,z)+c_s)^{M_s}$ is holomorphic in $\mathbf{C}^n$;

(2) the coefficients of the series expansion of $\Psi(z)$ at the vicinity of hyperplanes $(\alpha_s,z)+c_s=0$, $s=1,\ldots,N$ satisfy conditions (15) with $M=M_s$.

The crucial observation is that the matrix locus Eqs. (14) imply that the space V is invariant under L (cf. Refs. 3,4).

Let us consider the matrix function $\Psi_0=\Pi_{s=1}^N((\alpha_s,z)+c_s)^{M_s}e^{(k,z)}I$, where I is the identity matrix. Evidently, $\Psi_0\in V$ and, therefore, all the functions

$$\Psi_i=(L+k^2)^i\Psi_0, \quad i=1,2,\ldots$$

belong to V as well. These functions have the form

$$\Psi_i=\frac{P_i(k,z)e^{(k,z)}}{\Pi_{s=1}^N((\alpha_s,z)+c_s)^{M_s}},$$

where $P_i(k,z)$ are some matrix polynomials in k, z. Since

$$P_{i+1}=\phi\left(-\Delta-2\left(k,\frac{\partial}{\partial z}\right)+U(z)\right)\phi^{-1}P_i, \ \phi=\prod_{s=1}^N ((\alpha_s,z)+c_s)^{M_s},$$

the degrees of P_i in z are decreasing with i. So, there exists such j that $(L+k^2)\Psi_j=0$. It is easy to see that for $M=\Sigma_{s=1}^N M_s$,

$$\Psi_M=\left[(-2)^M M!\prod_{s=1}^N (\alpha_s,k)^{M_s}I+\cdots\right]e^{(k,z)}\neq 0, \tag{17}$$

where the dots mean the terms decaying while $z\to\infty$. We claim that $\Psi_{M+1}=(L+k^2)\Psi_M=0$. Indeed, assume that this is not true. Then for some $j>M$ we have

$$\Psi_{j+1}=(L+k^2)\Psi_j=0$$

with $\Psi_j\neq 0$. Since

$$P_{j+1}=\phi\left(-\Delta-2\left(k,\frac{\partial}{\partial z}\right)+U(z)\right)\phi^{-1}P_j=0$$

and P_j is polynomial in k its highest coefficient $P_j^{(0)}$ has to satisfy the condition

$$\left(k,\frac{\partial}{\partial z}\right)P_j^{(0)}=0.$$

One can show that this implies that $P_j^{(0)}$ must be polynomial in z (see Ref. 19, lemma 2.5). On the other hand one can see from (17) that Ψ_j for $j>M$ decays as $z\to\infty$. This contradiction means that $L\Psi_M=-k^2\Psi_M$. Presenting Ψ_M in the form $\Psi_M=\mathcal{D}e^{(k,z)}I$ for a proper matrix differential operator $\mathcal{D}(z,(\partial/\partial z))$ we have

$$L\Psi=L\mathcal{D}e^{(k,z)}I=-k^2\mathcal{D}e^{(k,z)}I=-\mathcal{D}k^2e^{(k,z)}I=\mathcal{D}L_0e^{(k,z)}I$$

and, therefore,

$$L\mathcal{D}=\mathcal{D}L_0.$$

The theorem is proved.

Remark: Notice that our proof gives an explicit formula for the intertwining operator

$$\mathcal{D}(e^{(k,z)}I)=(L+k^2)^M\left(\prod_{s=1}^{N}((\alpha_s,z)+c_s)^{M_s}e^{(k,z)}I\right).$$

Such a formula has been discovered in the scalar case by Berest.[7]

IV. GENERALIZED MATRIX CALOGERO–MOSER SYSTEM

Let us consider the following matrix Schrödinger operator:

$$L=-\Delta+\sum_{\alpha\in\mathcal{R}_+}\frac{m_\alpha(m_\alpha I-\hat{s}_\alpha)(\alpha,\alpha)}{(\alpha,z)^2}. \tag{18}$$

Here $\mathcal{R}$ is any Coxeter root system in $\mathbf{R}^n$, $\mathcal{R}_+$ is its positive part consisting of the normals to the reflection hyperplanes of the corresponding Coxeter group G, $m(\alpha)=m_\alpha$ is a G-invariant function on $\mathcal{A}$, $\hat{s}_\alpha$ stands for the reflection with respect to α in an arbitrary matrix representation π of the group G: $\hat{s}_\alpha=\pi(s_\alpha)$

For the trivial one-dimensional representation we have a scalar Schrödinger operator which is the well-known generalized Calogero–Moser operator related to the Coxeter group G (see Ref. 20). Thus (18) can be considered as a natural matrix generalization of these operators.

Cherednik[8] seems to be the first to consider such generalizations in the case when G is a Weyl group of any semisimple Lie algebra. He showed that the corresponding quantum system has n commuting quantum integrals and, therefore, it is integrable in a usual quantum mechanical sense.

Let us show that if all m_α are integers then the operator (18) is D-integrable. This implies the usual integrability and even more stronger property known as algebraic integrability (see theorem 7 below).

Let

$$s_\alpha(z)=z-2\frac{(\alpha,z)}{(\alpha,\alpha)}\alpha \tag{19}$$

be the orthogonal reflection with respect to the hyperplane $(\alpha,z)=0$. The matrix potential of the operator (18) has the following equivariance property for any $\alpha\in\mathcal{R}$:

$$\hat{s}_\alpha U(z)=U(s_\alpha(z))\hat{s}_\alpha. \tag{20}$$

This can be easily checked using G-invariance of m_α and the property

$$\hat{s}_\alpha \hat{s}_\beta = \hat{s}_{s_\alpha(\beta)} \hat{s}_\alpha .$$

From (20) it follows that the coefficients C_l of the Laurent expansion of the potential U near the hyperplane $(\alpha,z)=0$ satisfy the following relation:

$$\hat{s}_\alpha C_{2k} = C_{2k} \hat{s}_\alpha , \quad \hat{s}_\alpha C_{2k-1} + C_{2k-1} \hat{s}_\alpha = 0 \tag{21}$$

for any k. Comparing the formula (18) with (16) we see that the corresponding matrices A_i have two eigenvalues, $m_\alpha(m_\alpha+1)$ and $m_\alpha(m_\alpha-1)$. Using this it is easy to check that the relations (21) imply the local trivial monodromy conditions (14) and, therefore, D-integrability of the operator (18) due to the theorem 4. Thus, we have proved

Theorem 5: *The generalized matrix Calogero–Moser operator (18) with integer G-invariant* m_α *is D-integrable.*

In the scalar case the Calogero–Moser operator admits integrable deformations related to the non-Coxeter configurations of the hyperplanes.[13,14,5] It is interesting that these deformations admit a matrix generalization as well.

Let $\mathfrak{A}$ be a finite set of the hyperplanes Π_α in a complex Euclidean space $\mathbf{C}^n$ given by the equations $(\alpha,z)=0$, taken with some multiplicities $m_\alpha \in \mathbf{Z}_+$. Here $\alpha \in \mathcal{A}$, $\mathcal{A}$ is a finite set of noncollinear vectors. Consider the matrix Schrödinger operator

$$L = -\Delta + U(z)$$

with

$$U(z) = \sum_{\alpha \in \mathcal{A}} \frac{m_\alpha(m_\alpha - s_\alpha)(\alpha,\alpha)}{(\alpha,z)^2}, \tag{22}$$

where s_α is the $n\times n$ matrix of the reflection (19).

Theorem 6: *Operator L has trivial monodromy if and only if the following conditions for the configuration* $\mathcal{A}$ *hold for each* $\alpha \in \mathcal{A}$

$$A_j = \sum_{\beta \neq \alpha} \left. \frac{m_\beta(m_\beta+1)(\beta,\beta)(\alpha,\beta)^{2j-1}}{(\beta,z)^{2j+1}} \right|_{(\alpha,z)=0} \equiv 0, \quad j=1,2,\ldots,m_\alpha , \tag{23}$$

$$B_j = \sum_{\beta \neq \alpha} \left. \frac{m_\beta(\alpha,\beta)^{2j-1}}{(\beta,z)^{2j-1}} \right|_{(\alpha,z)=0} \equiv 0, \quad j=1,2,\ldots,m_\alpha . \tag{24}$$

Proof: Let us consider first the case $m_\alpha=1$. Then we have two locus conditions (see (14)) for L,

$$C_0 C_{-2} = C_{-2} C_0 \quad \text{or} \quad C_0 s_\alpha = s_\alpha C_0 \tag{25}$$

and

$$(C_1 \alpha, \alpha) = 0. \tag{26}$$

From (22) we can calculate

$$C_j = \sum_{\beta \neq \alpha} \left. \frac{m_\beta(m_\beta - s_\beta)(\beta,\beta)(\alpha,\beta)^j}{(\beta,z)^{2+j}} \right|_{(\alpha,z)=0} ,$$

and condition (25) reduces to

$$\sum_{\beta\neq\alpha}\frac{m_\beta(\beta,\beta)(s_\beta s_\alpha - s_\alpha s_\beta)}{(\beta,z)^2}\bigg|_{(\alpha,z)=0}\equiv 0. \tag{27}$$

Let us choose some $\gamma\neq\alpha$ and consider the subsum in (27) corresponding to the two-dimensional plane $\langle\alpha,\gamma\rangle$. Since s_β acts trivially on the orthogonal complement to the plane $\pi=\langle\alpha,\gamma\rangle$ for any $\beta\in\pi$ we may assume that $\alpha=(1,0),\ \beta=(\cos\phi_\beta,\sin\phi_\beta)$. Then,

$$s_\alpha=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix},\quad s_\beta=\begin{pmatrix}-\cos 2\phi_\beta & -\sin 2\phi_\beta\\ -\sin 2\phi_\beta & \cos 2\phi_\beta\end{pmatrix}$$

and

$$s_\beta s_\alpha=\begin{pmatrix}\cos 2\phi_\beta & \sin 2\phi_\beta\\ -\sin 2\phi_\beta & \cos 2\phi_\beta\end{pmatrix},\quad s_\alpha s_\beta=(s_\beta s_\alpha)^{-1}.$$

Since $(\beta,z)|_{(\alpha,z)=0}=\beta_2 z_2=z_2\sin\phi_\beta$ we have to check that

$$\sum_{\beta\in\langle\alpha,\gamma\rangle,\beta\neq\alpha}\frac{\sin 2\phi_\beta}{\sin^2\phi_\beta}=0.$$

But it easily follows from the identity (24) $B_1\equiv 0$.

The second locus condition (26) reduces to

$$\sum_{\beta\neq\alpha}\frac{m_\beta(m_\beta+\cos 2\phi_\beta)\cos\phi_\beta}{\sin^3\phi_\beta}=0.$$

This is equivalent to the combination $A_1-2B_1=0$ of the identities (23)–(24).

Now let us consider the case $m_\alpha>1$. Locus equations (14) take the form

$$C_j s_\alpha=(-1)^j s_\alpha C_j,\quad j=0,1,\dots,2m_\alpha-2, \tag{28}$$

$$(C_{2m_\alpha-1}\alpha,\alpha)=0. \tag{29}$$

As above, everything reduces to the two-dimensional case and we will use the same notations. The relations (28) reduce to

$$\sum_{\beta\neq\alpha}\frac{m_\beta\cos^j\phi_\beta\sin 2\phi_\beta}{\sin^{2+j}\phi_\beta}=0, \tag{30}$$

for $j=2l$, $l=0,1,\dots,m_\alpha-1$, and

$$\sum_{\beta\neq\alpha}\frac{2\,s_\alpha m_\beta^2\cos^j\phi_\beta-(s_\alpha s_\beta+s_\beta s_\alpha)m_\beta\cos^j\phi_\beta}{\sin^{2+j}\phi_\beta}=0, \tag{31}$$

for $j=2l-1,\ l=1,\dots,m_\alpha-1$. Relation (30) is equivalent to

$$\sum_{\beta\neq\alpha}\frac{m_\beta\cos^{2l+1}\phi_\beta}{\sin^{2l+1}\phi_\beta}=0,$$

which coincide with $B_{l+1}\equiv 0$. Condition (31) is equivalent to

$$\begin{cases} \sum_{\beta\neq\alpha} \frac{m_\beta^2 \cos^{2l-1}\phi_\beta}{\sin^{2l+1}\phi_\beta}=0, \quad l=1,\dots,m_\alpha-1 \\ \sum_{\beta\neq\alpha} \frac{m_\beta \cos^{2l-1}\phi_\beta \cos 2\phi_\beta}{\sin^{2l+1}\phi_\beta}=0, \quad l=1,\dots,m_\alpha-1. \end{cases}$$

The first part of the last equations due to the identity $A_l\equiv 0$ reduces to

$$\sum_{\beta\neq\alpha} \frac{m_\beta \cos^{2l-1}\phi_\beta}{\sin^{2l+1}\phi_\beta}=0,$$

the left-hand side of which equals B_l+B_{l+1}. The second one is equivalent to $B_{l+1}-B_l\equiv 0$ and is satisfied for $l=1,\dots,m_\alpha-1$.

Finally, the condition $(C_{2m_\alpha-1}\alpha,\alpha)=0$ is equivalent to

$$\sum_{\beta\neq\alpha} \frac{m_\beta^2 \cos^{2m_\alpha-1}\phi_\beta + m_\beta \cos 2\phi_\beta \cos^{2m_\alpha-1}\phi_\beta}{\sin^{2m_\alpha+1}\phi_\beta}=0$$

or, using $A_{m_\alpha}\equiv 0$, to

$$\sum_{\beta\neq\alpha} \frac{m_\beta \cos^{2m_\alpha-1}\phi_\beta(\cos 2\phi_\beta-1)}{\sin^{2m_\alpha+1}\phi_\beta}=0,$$

which coincides with $B_{m_\alpha}\equiv 0$. Theorem 6 is proved.

Remark: It is interesting to note that conditions (23) and (24) are equivalent to the existence of the so-called Baker–Akhiezer function in ''old axiomatics'' (see Refs. 16 and 5). Indeed, the A-conditions (23) coincide with the locus equations for the scalar case and, therefore, guarantee the existence of the Baker–Akhiezer function in ''new axiomatics.''[5] The B-conditions (24) mean that the function $\phi=\Pi_{\beta\neq\alpha}(\beta,z)^{m_\beta}$ has zero odd normal derivatives at the hyperplane Π_α,

$$\left(\frac{\partial}{\partial\alpha}\right)^{2j-1} \prod (\beta,z)^{m_\beta}\Big|_{(\alpha,z)=0}=0,$$

which together with the new axiomatics provide the old one (see Sec. 1 in Ref. 5).

In particular, conditions (23) and (24) are satisfied for the following non-Coxeter configurations $A_n(m)$ and $C_{n+1}(m,l)$ discovered in Refs. 13,14,5.

Configuration $A_n(m)$ consists of the following vectors in $\mathbf{R}^{n+1}$: e_i-e_j with multiplicity m $(1\leqslant i<j\leqslant n)$ and $e_i-\sqrt{m}e_{n+1}$ with multiplicity 1 $(i=1,\dots,n)$ (for $m=1$ we have the root system A_n). Parameter m is also allowed to be negative. Then one should consider vectors e_i-e_j with the multiplicity $-1-m$. In the last case we have a complex configuration in $\mathbf{C}^{n+1}$.

Configuration $C_{n+1}(m,l)$ consists of the following set of vectors in $\mathbf{R}^{n+1}$:

$$C_{n+1}(m,l)=\begin{cases} e_i\pm e_j \quad \text{with multiplicity } k \\ 2e_i \quad \text{with multiplicity } m \\ 2\sqrt{k}e_{n+1} \quad \text{with multiplicity } l \\ e_i\pm\sqrt{k}e_{n+1} \quad \text{with multiplicity } 1, \end{cases}$$

where l and m are integer parameters such that $k=(2m+1)/(2l+1)\in\mathbf{Z}$, $1\leqslant i<j\leqslant n$. If $l=m=k=1$ the system $C_{n+1}(m,l)$ coincides with the classical root system C_{n+1}. As before, the parameters k,m,l may be negative, in that case the corresponding multiplicities should be $-1-k$, $-1-m$ or $-1-l$, respectively.

Corollary: The matrix Schrödinger operators with potentials (22) corresponding to the configurations $A_n(m)$ and $C_{n+1}(m,l)$ are D-integrable.

Let us prove now that in the considered cases D-integrability implies usual quantum integrability and even more—so-called algebraic integrability.

We say that a matrix Schrödinger operator L in $\mathbf{R}^n$ is *integrable* if there exists n pairwise commuting matrix differential operators $L_1=L, L_2,\ldots,L_n$ having the algebraically independent constant scalar highest symbols $P_j(k),\ j=1,\ldots,n$. If there exists one more commuting matrix differential operator L_{n+1} with the highest constant scalar symbol $P_{n+1}(k)$ such that $P_{n+1}(k)$ takes different values on the solutions of the system $P_i(k)=c_i\ (i=1,\ldots,n)$ for generic $c_1,\ldots,c_n$ the operator L is called *algebraically integrable* (see Refs. 21,15,9).

Let us assume that the matrix potential U is symmetric, $U=U^*$.

Theorem 7: *Any D-integrable matrix Schrödinger operator L with a rational symmetric potential (16) is algebraically integrable.*

Proof: We follow here the idea of the paper.[22] Let A^* denote a formal conjugate to a matrix differential operator A then taking a conjugation of the relation $L\mathcal{D}=\mathcal{D}L_0$ we have $\mathcal{D}^*L^*=L_0^*\mathcal{D}^*=L_0\mathcal{D}^*$. If $U=U^*$ then $L=L^*$ and we obtain $\mathcal{D}^*L=L_0\mathcal{D}^*$. Now define the operators $L_1=L, L_{1+i}=\mathcal{D}\partial_i\mathcal{D}^*\ (i=1,\ldots,n)$. We claim that they are pairwise commuting. Indeed, $LL_{1+i}=L\mathcal{D}\partial_i\mathcal{D}^*=\mathcal{D}L_0\partial_i\mathcal{D}^*=\mathcal{D}\partial_iL_0\mathcal{D}^*=\mathcal{D}\partial_i\mathcal{D}^*L=L_{1+i}L$, so $[L_1,L_k]=0$ for all $k=2,\ldots,n+1$. Consider now the commutator $[L_l,L_k]$, $l>1$. From the previous relations and Jacobi identity it follows that $[[L_k,L_l],L]=0$. Berezin's lemma (see lemma 2.5 in Ref. 19) says that the highest symbol of $[L_k,L_l]$ has to be polynomial in z, but from the definition of L_k and the construction of $\mathcal{D}$ it follows that it decays as $z\to\infty$. This means that $[L_k,L_l]=0$ for any $k,l=1,\ldots,n+1$. One can check that the highest symbols of L_k satisfies the property demanded at the definition of algebraic integrability. The theorem is proved.

Remark: The statement of the theorem seems to be true without the assumption of the symmetry of the potential.

V. TWO-DIMENSIONAL CASE

Let us consider the matrix locus configurations on the plane in the case when all the lines pass through the origin. In the scalar case essentially all such configurations have been described by Berest and Lutsenko[23] (see Ref. 5 for details).

In the matrix case in the polar coordinates (r,ϕ) the corresponding potential U has a form

$$U(r,\phi)=\frac{1}{r^2}V(\phi), \tag{32}$$

where

$$V(\phi)=\sum_{i=1}^{k}\frac{A_i}{\sin^2(\phi-\phi_i)}. \tag{33}$$

Here A_i are some matrices, ϕ_i are the angles corresponding to the lines of configurations. Strictly speaking this is true only on the real plane $\mathbf{R}^2$ but this can be easily generalized to $\mathbf{C}^2$ (see Ref. 5).

Proposition 1: Two-dimensional matrix Schrödinger operator

$$L=-\Delta+U \tag{34}$$

with the potential (32) has trivial monodromy if and only if the same is true for the one-dimensional Schrödinger operator

$$\mathcal{L}=-\frac{d^2}{d\phi^2}+V(\phi) \tag{35}$$

with trigonometric potential (33).

The proof is a simple check that the local trivial monodromy conditions for these two operators are equivalent.

Proposition 2: If the operator (35) is D-integrable then the same is true for the two-dimensional Schrödinger operator (34).

Indeed, in the one-dimensional case D-integrability implies the trivial monodromy for the operator (35) and, therefore, for the two-dimensional operator (34). According to the theorem 4 this guarantees the D-integrability of (34).

In dimension 1 D-integrability is equivalent to the fact that the operator $\mathcal{L}$ (35) is the result of so-called matrix Darboux transformation applied to $\mathcal{L}_0 = -(d^2/d\phi^2)$ (see, e.g., Ref. 4). All such operators can be described using the notion of quasideterminants introduced by Gelfand and Retakh (see Ref. 24).

Let k be the order of the intertwining operator $\mathcal{D}$. Consider any solution Φ of the simple matrix differential equation $-(d^2/d\phi^2)\Phi = \Phi C$ where Φ is $d \times kd$ matrix, C is any diagonalizable $kd \times kd$ matrix with the eigenvalues of the form $\lambda = p^2$ with $p \in \mathbf{Z}$. Let $\Phi = (\Psi_1, \ldots, \Psi_k)$ where Ψ_i are the corresponding $d \times d$ matrices. Then the intertwining operator $\mathcal{D}$ can be written as quasideterminant

$$\mathcal{D}(\Psi) = |W(\Psi_1, \ldots, \Psi_k, \Psi)|_{k+1,k+1},$$

where

$$W(\Psi_1, \ldots, \Psi_k, \Psi) = \begin{pmatrix} \Psi_1 & \ldots & \Psi_k & \Psi \\ \vdots & \ddots & \vdots & \vdots \\ \Psi_1^{(k-1)} & \ldots & \Psi_k^{(k-1)} & \Psi^{(k-1)} \\ \Psi_1^{(k)} & \ldots & \Psi_k^{(k)} & \Psi^{(k)} \end{pmatrix},$$

(see Ref. 4 for the details). The potential V has a form

$$V = 2a_1'(\phi), \tag{36}$$

where $a_1(\phi)$ is the first matrix coefficient of $\mathcal{D}$,

$$\mathcal{D} = D^k + a_1(\phi)D^{k-1} + \cdots + a_k(\phi),\ D = \frac{d}{d\phi}.$$

Under some assumptions on Φ one can give more explicit formula for the potential (see Ref. 4).

Theorem 8: *Two-dimensional matrix Schrödinger operator (34) with the potential of the form (32) related to any result (36) of the one-dimensional matrix Darboux transformation described above has trivial monodromy and therefore D-integrable. Conversely, for any D-integrable operator (34) the corresponding one-dimensional operator (35) is related to the operator* $\mathcal{L}_0 = -d^2/d\phi^2$ *by a matrix Darboux transformation.*

The proof of the inverse statement follows from

Lemma 2: Any one-dimensional Schrödinger operator (34) with trigonometric potential (33) which satisfies local trivial monodromy conditions at all the singularities is D-integrable.

Proof of the lemma essentially combines the arguments of the matrix rational case (see Ref. 4 or theorem 3 above) and the scalar trigonometric case investigated in Ref. 3.

It is worthy to derive the explicit formula for such operators in the simplest case of three lines with prescribed 2×2 matrices with the eigenvalues 0 and 2. In this case it seems to be more suitable to use matrix locus equations rather than Darboux transformation. Thus, let $V(\phi)$ be of the form

$$V(\phi)=\frac{2P_\alpha}{\sin^2(\phi-\alpha)}+\frac{2P_\beta}{\sin^2(\phi-\beta)}+\frac{2P_\gamma}{\sin^2(\phi-\gamma)}, \tag{37}$$

where $\phi,\alpha,\beta,\gamma\in\mathbf{C}$; $P_\alpha,P_\beta,P_\gamma$ are some projector matrices of rank 1. According to theorem 1 operator (35) has trivial monodromy if its Laurent expansion at pole $\phi=\phi_0$,

$$V(\phi)=\frac{C_{-2}}{(\phi-\phi_0)^2}+\frac{C_{-1}}{(\phi-\phi_0)}+C_0+C_1(\phi-\phi_0)+\cdots$$

satisfies the conditions

$$C_{-1}=0,$$

$$[C_{-2},C_0]=0, \tag{38}$$

$$C_{-2}C_1C_{-2}=0. \tag{39}$$

Conditions $C_{-1}=0$ are, obviously, fulfilled. Expanding $V(\phi)$ near $\phi=\alpha$,

$$V(\phi)=\frac{2P_\alpha}{(\phi-\alpha)^2}+\left(\frac{2P_\beta}{\sin^2(\alpha-\beta)}+\frac{2P_\gamma}{\sin^2(\alpha-\gamma)}+\frac{2P_\alpha}{3}\right)$$
$$+\left(\frac{-4P_\beta\cos(\alpha-\beta)}{\sin^3(\alpha-\beta)}+\frac{-4P_\gamma\cos(\alpha-\gamma)}{\sin^3(\alpha-\gamma)}\right)(\phi-\alpha)+\ \ldots,$$

and then near $\phi=\beta$ and $\phi=\gamma$ we get the following system of the equations using (38):

$$\left[P_\alpha,\frac{P_\beta}{\sin^2(\alpha-\beta)}+\frac{P_\gamma}{\sin^2(\alpha-\gamma)}\right]=0, \tag{40}$$

$$\left[P_\beta,\frac{P_\alpha}{\sin^2(\beta-\alpha)}+\frac{P_\gamma}{\sin^2(\beta-\gamma)}\right]=0, \tag{41}$$

$$\left[P_\gamma,\frac{P_\alpha}{\sin^2(\gamma-\alpha)}+\frac{P_\gamma}{\sin^2(\gamma-\beta)}\right]=0. \tag{42}$$

It is easy to see that (42) follows from (40) and (41). Conditions (39) give

$$P_\alpha\left(\frac{P_\beta\cos(\alpha-\beta)}{\sin^3(\alpha-\beta)}+\frac{P_\gamma\cos(\alpha-\gamma)}{\sin^3(\alpha-\gamma)}\right)P_\alpha=0, \tag{43}$$

$$P_\beta\left(\frac{P_\alpha\cos(\beta-\alpha)}{\sin^3(\beta-\alpha)}+\frac{P_\gamma\cos(\beta-\gamma)}{\sin^3(\beta-\gamma)}\right)P_\beta=0, \tag{44}$$

$$P_\gamma\left(\frac{P_\alpha\cos(\gamma-\alpha)}{\sin^3(\gamma-\alpha)}+\frac{P_\beta\cos(\gamma-\beta)}{\sin^3(\gamma-\beta)}\right)P_\gamma=0. \tag{45}$$

Solving of system of Eqs. (40)–(45) and making a suitable transformation

$$V(\phi)\rightarrow C\,V(\phi)C^{-1} \tag{46}$$

we arrive at the formula

$$P_\alpha = \frac{1}{\sin(\alpha-\beta)\sin(\alpha-\gamma)} \cdot \xi_\alpha^t \eta_\alpha, \tag{47}$$

where

$$\xi_\alpha = (-\cos\alpha, \sin\alpha), \eta_\alpha = (s(\alpha;\beta,\gamma), c(\alpha;\beta,\gamma)),$$

$$s(\alpha;\beta,\gamma) = \sin^2\alpha \cos(\beta+\gamma-\alpha) - \cos\alpha \sin\beta \sin\gamma,$$

$$c(\alpha;\beta,\gamma) = \cos^2\alpha \sin(\beta+\gamma-\alpha) - \sin\alpha \cos\beta \cos\gamma.$$

Projectors P_β and P_γ can be obtained by corresponding permutations of α, β, and γ.

Theorem 9: *Any three lines on the plane with prescribed matrices P_α, P_β, and P_γ (47) where α, β, γ are the corresponding angles form a matrix locus configuration. Modulo (46) this describes all three lines 2×2 matrix locus configurations with prescribed matrices having the eigenvalues* 0 *and* 2.

It is interesting to note that the potential (37), (47) is symmetric if and only if $\alpha=\vartheta$, $\beta=\vartheta+(\pi/3)$ and $\gamma=\vartheta+(2\pi/3)$ for some ϑ which corresponds to the matrix Calogero–Moser system (18) related to A_2 root system.

VI. CONCLUDING REMARKS

Similarly to the scalar case[5] one can introduce the notion of the multidimensional matrix Baker–Akhiezer function. This would lead to the proof of the algebraic integrability for the corresponding Schrödinger operators. The bispectral properties of these functions and the relations to the Huygens' Principle we are planning to discuss in a separate paper.

Evaluation of multiloop diagrams via lightcone integration

Y. J. Feng[a] and C. S. Lam[b]
Department of Physics, McGill University, Montreal, Quebec H3A 2T8, Canada

(Received 27 August 1998; accepted for publication 18 December 1998)

We present a systematic method to determine the dominant regions of internal momenta contributing to any two-body high-energy near-forward scattering diagram. Such a knowledge is used to evaluate leading high-energy dependences of loop diagrams. It also gives a good idea where dominant multiparticle cross sections occur. © *1999 American Institute of Physics.* [S0022-2488(99)00811-7]

I. INTRODUCTION

It is difficult to compute high-energy ($\sqrt{s}$) scattering amplitudes at small momentum transfers ($\sqrt{-t}$), even assuming the coupling constant g^2 to be small. This is so because each loop of a Feynman diagram is capable of producing a $\ln s$ factor, thus changing the effective expansion parameter from g^2 to $g^2 \ln s$. Even though the former may be small, the latter can become quite sizable at high energies, necessitating diagrams of high orders to be included. Such is for example the case when total cross section is computed in the framework of QCD.[1]

Usually such a daunting task of computed diagrams of many loops may be contemplated only in the leading-log approximation (LLA), though there are exceptions, especially for sets of diagrams with regular structures.[2] In LLA, only terms of the highest power of $\ln s$ are kept at each perturbative order, but even so the computation is far from being simple. For low-order diagrams, or diagrams with highly regular structures, the computation has been carried out and the results are well known.[3–6] However, for complicated diagrams, a systematic procedure to find even the leading-log contribution seems to be lacking. We shall discuss a method in the present paper. The available QCD result, via the exchange of the BFKL Pomeron,[5] violates the Froissart bound and needs to be improved.[7–9] Other diagrams must be included to restore unitarity so it would be useful to have a way to find out how the other diagrams behave at high energies. This can be achieved if the regions of internal momenta dominating the Feynman amplitude can be located, for then one simply integrates around them to obtain the LLA result.

For quark–quark scattering via the exchange of gluon ladders, the dominant region is known to be the multi-Regge region,[4,5] where gluons produced in the intermediate states are strongly ordered in rapidity, and the gluons being exchanged are dominantly spacelike. What we would like to discuss in the present paper is a general way to find such dominant regions for any diagram, and its associated high-energy dependence in LLA. We shall carry out the study for Feynman diagrams and for non-Abelian cut diagrams,[10–12] both because they are more general, and because there is already a considerable body of literature on the dispersion theoretic techniques.[5,6]

Such calculations of elastic amplitudes, besides giving the energy-dependence of total cross-sections via the optical theorem,[1] also tell us the kinematical regions where the dominant inelastic cross-sections come from, for via unitarity these are intimately related to the dominant internal momenta of the elastic amplitude. This knowledge would be of direct phenomenological interest as well.

The methods developed in this paper should also be useful in the study of two-dimensional effective QCD Lagrangians at high-energies.[13,14] A prerequisite needed to arrive at a reliable effective Lagrangian is to know which are the heavy modes that can be discarded, and which of

[a]Electronic mail: feng@physics.mcgill.ca
[b]Electronic mail: lam@physics.mcgill.ca

them must be integrated out to yield a new vertex in the effective Lagrangian. In perturbative language this is equivalent to finding the important regions of internal momenta around which to integrate. All others may simply be discarded.

In the rest of this section we shall describe what our method is based on, and provide a brief summary of the results.

At high energies it is convenient to use lightcone coordinates, $k_\pm = k^0 \pm k^3$. The components of a four-vector k^μ can then be written as $(k_+, k_-, k_\perp)$, and the loop integration expressed as $d^4k = dk_+ dk_- d^2k_\perp/2$. In the center-of-mass system, the momenta of the two incoming particles, with masses neglected, can be taken to be $p_2 = (\sqrt{s},0,0)$ and $p_1 = (0,\sqrt{s},0)$. The momentum transfer $\sqrt{-t}$ as well as all other transverse momenta $k_\perp$ are taken to be of order 1 as $s\to\infty$, so it is only the dominant regions in k_+ and k_- for every loop momentum k that have to be determined.

These regions are determined in the following way. First, observe that the inverse of the internal propagators are bilinear in the ''+'' and the ''−'' components of their line momenta, so the propagators give rise to simple poles in the ''+'' (or the ''−'') momenta which enable integrations in those variables to be carried out exactly by residue calculus.[4] Once this is done the locations of the ''+'' momenta are determined by the locations of the contributing poles and the ''−'' momenta. The ''−'' momenta are then fixed to be in the regions yielding the leading-log contributions to the amplitude.

We shall be able to do this both for Feynman diagrams and ''non-Abelian cut diagrams.''[10–12] Feynman diagrams are fundamental, but they often have the undesirable property that the LLA contributions of individual diagrams get cancelled in the sum.[4] To the extent that the usual technology only allows LLA to be computed, this cancellation is disastrous because it leaves no viable means to compute the leading high-energy behavior of the sum. Non-abelian cut diagrams are designed to combat this problem. The cancellation is actually a result of the destructive interference between the virtual gluons being exchanged. The non-Abelian cut diagrams allow the destructive interferences to take place before high energy approximations are taken. In this way the LLA contribution to the non-abelian cut diagrams will reflect directly the leading contributions to the sum. No further cancellation will occur.

In Sec. II we will review the *flow diagram* method of Cheng and Wu[4] for carrying out the ''+'' component integrations by residue calculus. This method is very effective in locating the poles and the dominant integration regions for relatively simple diagrams. In complicated diagrams one encounters the problem of *flow reversal* which will be discussed in Sec. III. This problem prevents a simple reading of the contributing poles directly from the flow diagrams. Nevertheless the locations of these poles can still be computed, but the complexity of computation grows quite fast with the number of loops of the diagram. This difficulty is then overcome by a ''path'' method to be discussed in Sec. IV. With this method the contributing poles can be located and the ''+'' momenta determined. What remains is to find the dominant ''−'' momenta that give rise to the LLA contribution. The recipe for doing so will be discussed in Sec. V. Finally, in Sec. VI, a number of examples are given to illustrate the procedure.

II. FLOW DIAGRAMS

Consider a diagram with n internal lines and l loops, whose line and loop momenta are denoted by $q_i (1 \leqslant i \leqslant n)$ and $k_b (1 \leqslant b \leqslant l)$, respectively. In lightcone coordinates, the denominator of the propagator for a line with momentum q is $d(q) = (q^2 - m^2 + i\epsilon) = (q_+ q_- - q_\perp^2 - m^2 + i\epsilon) \equiv (q_+ q_- - a + i\epsilon)$. These n propagators collectively define a set of poles for the integration variables k_{b+}, thus enabling these integrations to be performed with the help of residue calculus. To carry out this program we must identify, for each k_{b+}, which are the poles in the upper-half-plane and which are the poles in the lower-half-plane, for only the poles in one half-plane will be picked up by a contour integration. Their locations in turn depends on the sign of q_{i-}, the choice of loop momenta, as well as the order the k_{b+} integrations are carried out. With so many variables the problem is very complex indeed. *Flow diagram* was invented[4] to keep track of things and to determine the location of poles. We shall review its essence[4] in this section, and point out in the next section some of the complications hitherto overlooked. This complication makes it complicated to apply it to multiloop diagrams. In Sec. IV we shall propose a ''*path method*'' to bypass these complications, and enables the evaluation of the ''+'' integration to be carried out in a simple manner.

A flow diagram is a Feynman diagram (or a non-Abelian cut diagram) with arrows attached to each of its internal lines to indicate the direction of q_{i-}. Since the signs of the q_-'s vary over the integration region, generally more than one flow diagram is present for each Feynman or nonabelian cut diagram. Nevertheless, for a diagram with n internal lines, there are far fewer than 2^n flow diagrams that one might otherwise expect, for two reasons. First, momentum conservation forbids the arrows from a common vertex to point all inwards or all outwards. Second, for reasons to be explained below, one can reject flow diagrams in which arrows around any closed loop all point in the same (clockwise or counterclockwise) direction. With these two requirements, it is easy to see that the one-loop box diagram has only one flow diagram, rather than $2^4=16$.

In a flow diagram the signs of q_{i-} along the arrows are all positive, by definition. This allows the positions of the poles be located and the ''+'' integrations to be carried out, once the independent loops and their order of integrations are chosen. We shall now proceed to see how this is accomplished for the first integration, say k_{1+}.

k_{1+} flows through the lines of this first loop either in a clockwise or a counterclockwise direction. Its coefficient in $d(q_i)$ is $\pm q_{i-}$, depending on whether this direction is the same as the arrow or opposite. The pole of $1/d(q_i)$ in k_{1+} has an imaginary part $\mp i\epsilon/q_{i-}$, with all $q_{i-}>0$ by definition. Hence the lines with arrows pointing one way (clockwise or counterclockwise) have poles all in one half-plane, and those with arrows pointing the opposite way have poles in the other half-plane. Which is which does not matter because we can always define the loop momentum by reversing its sign.

It is now easy to understand the assertion made earlier in the section, that flow diagrams containing a closed loop with flow arrows all pointing in the same direction may be rejected. Taking this loop as the first loop of integration, this would imply all poles to be in the same half-plane. By closing the integration contour in the other half-plane, we get a zero integral so such a flow diagram can be ignored.

Sometimes pole locations for *subsequent integrations* can be located in the same way, i.e., by the direction of arrows in the flow diagram. In fact the explicit examples shown in Ref. 4 all seem to be of this type.

However, it is not guaranteed that pole locations for subsequent integrations can be located this way, as we shall now see. This is the complication mentioned in the section.

To make it easier to describe things later on, we shall call two momenta pointing in the same (opposite) direction around a loop to be *parallel* (*antiparallel*) in that loop.

III. FLOW REVERSAL

Suppose there are n_1 poles picked up by the k_{1+} integration, each contributing to a term in the integral. As a result of the integration, k_{1+} acquires an imaginary part $\mp i\epsilon/q_{i-}$ from the ith pole. The sign is $-/+$ if k_{1+} and q_{i-} are parallel/antiparallel. This imaginary part in turn imparts an imaginary part on every q_{j+} of the first loop, which is why the location of poles for the second and subsequent integrations may be altered. For simplicity, we shall assume from now on that ϵ is finite and positive, and has a common value in all the propagators.

This imaginary part of k_{1+} affects the location of poles in subsequent integrations only for lines j lying in loop 1. In that case, the imaginary part of $d(q_j)$ is changed from $i\epsilon$ to $i\epsilon(\mp q_{j-}/q_{i-}+1)$, with sign $-/+$ when lines j and i are parallel/antiparallel in loop 1. Unless the sign is $-$ and $q_j>q_i$, the imaginary part of $d(q_j)$ remains positive and the location of pole j in subsequent integrations is once again determined solely by the direction of its arrow around the integration loop, viz., it can be determined directly from the flow diagram. However, if lines j and i are parallel in the first loop, and that $q_j>q_i$, then the sign of the imaginary part of $d(q_j)$ becomes negative, and the pole location (upper or lower plane) will now be opposite to naive

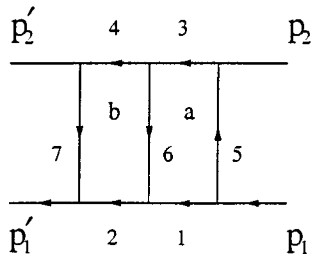

FIG. 1. A two-loop (Feynman) flow diagram.

expectations from the flow diagram. This situation can still be accommodated into the flow diagram if we simply reverse the arrow of this line by hand. This is *flow reversal*.

To summarize, here is how poles for the ''+'' integrations are computed for a given flow diagram, assuming a set of independent loops and a given order of k_{b+}-integrations have been chosen.

For the first loop, use the *naive rule* to read it off the flow diagram. This means that lines of this loop with arrows pointing in the same direction have their poles in the same half plane.

Assuming now k_{b+}-integrations have been carried out for $b=1,2,...,c$. We shall now proceed to do the $(c+1)$th integration for the term resulting from picking up poles located at line i_b for the bth loop, $b=1,2,...,c$.

First note that whatever loop $(c+1)$ is, it should not contain any of the lines $i_1,i_2,\ldots,i_c$. This is because the ''+'' momenta of these lines have been determined by previous integrations so they cannot be fixed again by the $(c+1)$th integration.

The naive rule can be used for lines j in loop $(c+1)$ if, (i) it is not in any one of the previous loops, 1,2,...,c, (ii) it is in a previous loop b but j is antiparallel to i_b in that loop, or (iii) j is parallel to i_b around loop b but $q_{j-}<q_{i_b-}$. In the remaining case, when j and i_b are parallel in loop b but $q_{j-}>q_{i_b-}$, we must reverse the arrow direction of line j before the naive rule is applied.

After all l ''+''-integrations are carried out, we obtain a number of terms, each of which is specified by a set of poles i_b for loop b. We shall call this collection of lines, $I=(i_1i_2\cdots i_l)$, a *contributing pole*.

Let us illustrate this recipe of obtaining contributing poles with two explicit examples, a two-loop diagram, and a four-loop diagram. In the process we will see how important it is to take flow reversals into account just to maintain consistency.

A. A two-loop example

Figure 1 is one of two possible flow diagrams for a two-loop Feynman diagram; the other has line 6 reversed.

Let a denote the loop with lines (1536) and b the loop with lines (2647). The big loop with lines (153472) is the union of these two loops and will be denoted by $a.b$. Only two of the three loop-momenta are independent.

There are three ways to start out the first loop integration, but the final results of their integrals must be the identical, and we must be able to pick the same contributing poles as well. We will illustrate here in detail how the latter can be achieved, iff proper flow reversals are taken into account.

Suppose we first integrate over loop a. In this loop the arrow of line 1 and the arrows of lines 5, 3, 6 are opposite, so their respective poles lie in opposite half planes of k_{a+}. We shall pick line 1 to be the relevant pole for further discussions. To simplify later descriptions we shall abbreviate this process of picking pole 1 from loop a simply by $a(1)$.

Now we are ready to tackle the second integration. Since line 1 is on $a.b$ we must not choose $a.b$ to be the second loop, so we are forced to choose it to be b. Line 6, which is in both loops b and a, is antiparallel to line 1 in loop a, so the naive rule once again applies to loop b. Lines 6 and

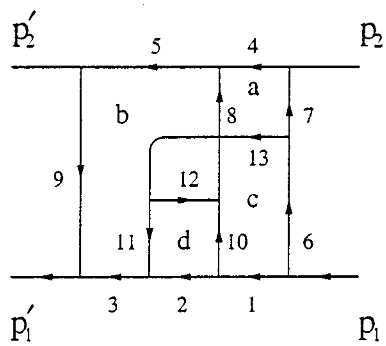

FIG. 2. A four-loop (Feynman) flow diagram.

2 are on one half-plane, and lines 4 and 7 on the other. We shall pick 2 and 6 to be the relevant poles. Consequently, we obtain two contributing poles, $I_1=(1,2)$ from $a(1)b(2)$, and $I_2=(1,6)$ from $a(1)b(6)$.

Next, let us start all over again but this time first carry out the integration around loop b to get $b(2)$ and $b(6)$. Now since line 2 lies in $a.b$, for the term $b(2)$ the second loop must be chosen to be a. In loop b line 6 is parallel to line 2, so there is a chance it might suffer a flow reversal. However, since $q_{2-}=q_{6-}+q_{1-}>q_{6-}$, flow reversal does not occur. Hence we have $b(2)a(1)$, so this contributing pole is $I_1=(1,2)$. For the term $b(6)$, since 6 is in a, the second loop must be chosen to be $a.b$. Now lines 2, 4, 7 are all in the first loop b, but 4 and 7 will not suffer flow reversal because they are antiparallel to 6. Line 2 is a different matter since $q_{2-}>q_{6-}$, so it would suffer a flow reversal. With this reversal, all lines in $a.b$ point in the same direction, with the sole exception of 1, so this yields $b(6)a.b(1)$, and the contributing pole is $I_2=(1,6)$. In this way we obtain the same set of contributing pole as before, as we should.

Finally suppose we carry out $a.b$ first, getting two terms $a.b(1)$ and $a.b(2)$. In the first case line 1 is in a so the second loop must be b. Lines 4 and 7 in b are antiparallel to 1 so they do not suffer from flow reversal. Line 2 is parallel to 1 and $q_{2-}>q_{1-}$ so it does suffer a flow reversal, thus leaving behind only line 6 of loop b in one direction. From $a.b(1)$ we therefore obtain $a.b(1)b(6)$ and the contributing pole $I_2=(1,6)$. Now consider the term $a.b(2)$. The second loop must now be a. Lines 5, 3 are antiparallel to 2 so they do not suffer flow reversal. Line 1 is parallel to 2 but $q_{1-}<q_{2-}$, so it does not suffer from flow reversal either. So no flow reversal occurs at all for lines in loop a, and this term yields $a.b(2)a(1)$, giving rise to the contributing pole $I_1=(1,2)$. The result is once again the same as the other two calculations. If flow reversals were not properly taken into account, the result would have been different and wrong.

The main lesson learned from this very simple example is that generally detailed loop-by-loop calculation must be performed, with proper flow reversals taken into account, in order to obtain the correct locations of the contributing poles. Also, the amount of calculations needed to determine the contributing poles may depend critically on the independent loops chosen and the order of integrations performed.

B. A four-loop example

The task of obtaining the contributing poles becomes more arduous for diagrams with a larger number of loops. The calculation must be carried out loop by loop, with more and more terms and flow reversals to keep track of. Besides, with multiloops there is a huge number of ways in choosing the independent loops and their order of integrations, each giving very different intermediate results though at the end they must all yield the same contributing poles. It is not known *a priori* how to make the best choice to maximally simplify the intermediate calculations.

To illustrate these points we shall work out in this subsection a four-loop example and obtain its contributing poles in two different ways.

Consider Fig. 2, with the following choice of independent loops: $a=(4,8,12,13,7)$, b

$=(5,9,3,11,12,8), c=(13,12,10,1,6)$, and $d=(10,12,11,2)$. Note that lines 8 and 13 are supposed not to intersect in the diagram. We shall carry out the integrations in the order *a,b,c,d* as much as possible.

The first integration over loop a yields $a(4)$ and $a(7)$.

We do the b integration next. The only lines common to loops a and b are 8 and 12, but since they are antiparallel to 4 and 7, no flow reversal takes place in carrying out the b integration. After the b-integration we get four terms, which for brevity shall be written together as additions: $[a(4)+a(7)][b(3)+b(11)]$.

Line 12 of loop c is also in loop a and loop b, and line 13 of loop c is in loop a. Since line 12 is antiparallel to 4 and 7 in loop a, and antiparallel to 3 and 11 in loop b, it suffers no flow reversal at loop c. Similarly line 13, being antiparallel to lines 4 and 7 in loop a, also has no flow reversal. Thus after the c integration, we get $[a(4)+a(7)][b(3)+b(1)][c(1)+c(10)]$.

The final d-integration is a bit complicated because loop d contains some of these poles from previously integrations so we are sometimes forced to take the loop *d.c* or the loop *d.b* instead of d itself. The final result contains 10 terms,

$$[a(4)+a(7)]b(3)c(1)[d(10)+d(11)]+[a(4)+a(7)]b(3)c(10)d.c(2) + [a(4)+a(7)]b(11)[c(1)d.b(2)+c(10)d.c(2)]. \tag{3.1}$$

To summarize, we have obtained ten contributing poles, (7,3,1,10), (7,3,1,11), (7,3,10,2), (7,11,2,1), (7,11,2,10), as well as another five with line 7 replaced by line 4.

Let us now illustrate another way to get the same result, by choosing this time the four independent loops to be $a=(4,8,12,13,7), b=(5,9,3,11,12,8), e=c.d=(1,6,13,11,2)$, and $d=(10,12,11,2)$, and try to carry out the integration in the order *a,b,c.d,d* as much as possible.

These loops are what we shall later call the *natural loops* for the contributing pole (7,3,1,10). They are obtained first by removing the lines 7,3,1,10 from the original diagram, and then inserting one of them back at a time to get the four loops.

The first two integrations are identical to those before, so we get $[a(4)+a(7)][b(3)+b(11)]$. Now $e=c.d$ contains the line 11 but not 3, so the next integration involving $b(3)$ gives $e(1)+e(2)$ but the next integration involving $b(11)$ gives $c(1)+c(10)$, as $c=d.(c.d)$. The last loop d contains lines 2 and 11, so for some terms the integration over d has to be changed into integration over *d.b* or $d.e=c$. The final answer is

$$[a(4)+a(7)]b(3)e(1)[d(10)+d(11)]+b(3)e(2)c(10) + b(11)c(1)d.b(2)+b(11|3)c(10)d.b(2). \tag{3.2}$$

This results in the same ten contributing poles as before, as it should.

The calculation could be even more complicated if we encounter a line j which is parallel to a pole line i of an earlier loop, but the relative magnitude of q_{j-} and q_{i-} can be either way. In that situation we must divide this flow diagram into two, one in which $q_{j-}<q_{i-}$ and line j is not reversed, and the other with $q_{j-}>q_{i-}$ where line j must be reversed.

IV. PATH METHOD FOR FINDING CONTRIBUTING POLES

In this section we propose a simple (path-) method to obtain the contributing poles. With this method there is no need to declare the independent loops and their order of integrations, so there is no need to keep track of the complicated flow reversals either. This makes the method most useful in the presence of a large number of loops.

We begin by choosing a path P in the flow diagram. By a path we mean a continuous line (no branches, no loops) running from beginning to end, with all the arrows on it pointing in the same direction. The thin solid lines in Figs. 3 and 4 are examples of such paths. By adding branches to

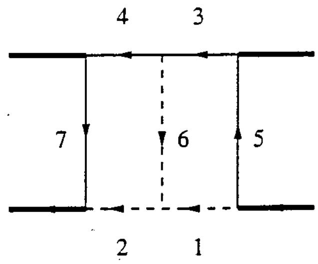

FIG. 3. The solid line is the path P used to obtain contributing poles for Fig. 1.

the path we can construct trees. A class of these trees, $T[P]$, turns out to be in one–one correspondence with the contributing poles. The path method of finding contributing poles is actually a method to construct the trees in $T[P]$.

From an l-loop diagram one can obtain trees by removing l lines. We shall refer to these removed lines as the *missing lines* for the tree. The set of all trees so obtained with path P as their common backbone will be denoted by $S[P]$. From $S[P]$ we select a subset $T[P]$ satisfying the following *directional rule*; when any one of the l missing lines is inserted into the tree, a loop is formed. If the inserted line around this loop is parallel to the lines along path P, this tree is rejected. If it is antiparallel, then this tree is retained to be a member of $T[P]$.

We assert that the missing lines of any tree in $T[P]$ is a contributing pole of the diagram, and there is actually a one–one correspondence between contributing poles and individual trees in $T[P]$. This is the essence of the *path method*.

This method does not restrict what path P one chooses, but the longer the path the fewer the number of contributing poles, and the easier the calculations. So in practice we often choose the longest path we can manage, though this is not a requirement of the method. In Sec. VII C an example will be shown in which computations based on two different paths are shown for comparison. The reason why one can get the same result by choosing different paths P, or equivalently different sets of contributing poles, is because of the freedom to choose poles from either half-plane each time we carry out any integration.

We have implicitly assumed in these discussions that a path P is chosen after we are given a flow diagram. This is not strictly necessary. We may start from a Feynman diagram or a non-Abelian cut diagram, without arrows attached, and start drawing a path on it. This can be taken as the starting point to determine possible flow diagrams consistent with this path; arrows on the path must all point in one direction, other arrows must be installed not to violate the direction rule to obtain contributing poles.

Before proceeding to prove the path method let us first see how it can be applied to obtain the contributing poles of Figs. 1 and 2 very simply.

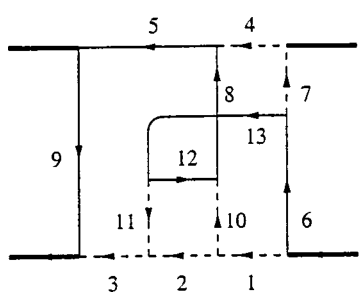

FIG. 4. The solid line is the path P used to obtain the contributing poles of Fig. 2.

A. Examples

For Fig. 1 let us choose the path P to be (5347), shown in Fig. 3 as thin solid lines. Then $S[P]=\{(P,6),(P,1),(P,2)\}$, and $T[P]=\{(P,6),(P,2)\}$. The tree $(P,1)$ violates the directional rule for the following reason so it is not in $T[P]$. When line 6 is inserted into $(P,1)$, it is parallel to P in the loop (6153), so it has to be rejected. With this $T[P]$, the contributing poles are the missing lines so they are (1,2) and (1,6), agreeing with the result obtained previously.

Let us next apply the method to obtain the contributing poles of Fig. 2, taking $P=(6,13,12,8,5,9)$ as the path (Fig. 4). Then,

$$T[P]=\{(P,7,2,11),(P,7,2,10),(P,7,1,11),(P,7,3,10),(P,7,1,3)\},$$

and five more with 7 replaced by 4. The contributing poles are therefore (7,3,1,10), (7,3,1,11), (7,3,10,2), (7,11,2,1), and (7,11,2,10), and another five with 7 replaced by 4, the same 10 terms as before. The trees in $S[P]/T[P]$ are $\{(P,7,1,2),(P,7,2,3),(P,7,10,11)\}$, and three more with 7 replaced by 4. $(P,7,1,2)$ violates the directional rule when the line 11 is inserted; $(P,7,2,4)$ violates the directional rule when line 10 is inserted; and $(P,7,10,11)$ violates the directional rule when 2 is inserted.

B. Proof

A tree $t\in S[P]$ defines a set of independent loops $\mathcal{N}[t]$ of the original diagram by filling in the missing lines one at a time. The special feature of $\mathcal{N}[t]$ is that the missing lines are never on the boundary of two loops. We shall later on refer to these loops as the *natural loops* for the missing lines.

Now we proceed to the proof of the path method. We assume we always close the integration contour in the half-plane in which poles reside on lines running in the opposite direction as those on P.

The proof makes use of the simple fact that the same set of contributing poles can be computed using any independent loops and any order of integration.

Removing the pole lines of a contributing pole from the original diagram gives rise to a tree in $S[P]$. We shall denote the set of all such tress as $T'[P]$. Our task is to show that $T[P]=T'[P]$.

Take any $t'\in T'[P]$. The removed pole lines clearly satisfy the directional rule when they are inserted back, because poles are always taken from those lines running in the opposite direction as P. Hence $t'\in T[P]$ and $T'[P]\subset T[P]$.

Conversely, take a $t\in T[P]$, and use the independent loops $\mathcal{N}[t]$ to compute the contributing poles. The missing lines of t are obviously one of the pole lines, for according to the directional rule they all run opposite to the path direction. Hence $t\in T'[P]$ and $T[P]\subset T'[P]$.

Putting the two together, we get $T[P]=T'[P]$, as desired.

V. NON-ABELIAN CUT DIAGRAMS

General methods found in the literature to compute high energy limits of Feynman diagrams[3,4] are by and large valid only in the leading-log approximation (LLA). They become virtually powerless if these leading-log contributions cancel when the Feynman diagrams are summed, a situation which unfortunately occurs quite frequently.[4] A method was developed recently to bypass this difficulty, by allowing the cancellations to occur before the high energy limit is taken. The cancellations are incorporated into the individual *non-Abelian cut diagrams*,[10,12] whose space–time amplitudes (for onshell diagrams) turn out to differ from the corresponding Feynman diagram only by having the denominators $(q_i^2-m^2+i\epsilon)^{-1}$ of certain propagators replaced by the corresponding Cutkosky propagators $-2\pi i\,\delta(q_i^2-m^2)$. The advantage of the non-Abelian cut diagrams is that the sum of Feynman diagrams is the same as the sum of non-Abelian cut diagrams, but in the latter cancellations took place before the high-energy limit is taken, so their leading-log contributions (LLA) survive the sum. For this to happen it is clearly necessary for the

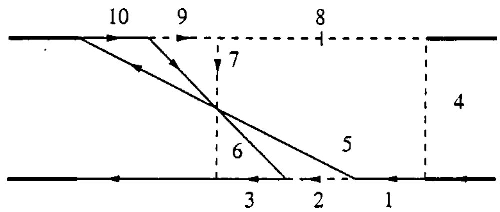

FIG. 5. A 3-loop (non-Abelian cut) flow diagram. The solid line represents the path P.

LLA of a non-Abelian cut diagram to have a smaller $\ln s$ power than the corresponding Feynman diagram, if the sum of the LLA contributions of the latter is to vanish. This is actually made possible by the presence of the Cutkosky propagators.

For high-energy two-body (e.g., *quark–quark*) scattering, the Cutkosky propagators occur only on the top quark lines. In the high energy limit, it can be shown that the combination $q_i^2 - m^2$ is actually proportional to the ''$-$'' momentum on that line, so a δ-function is that variable is a δ-function of the ''$-$'' momentum.[10,11] This has the effect of stopping the ''$-$'' momentum from flowing through this line, so as far as the flow diagram is concerned we may think of these lines as being absent. For the rest of the non-Abelian cut diagram the flows are constructed in exactly the same way as in a Feynman diagram, and contributing poles can be located the same way just as well.

As an example, consider the non-Abelian-cut (flow) diagram of Fig. 5, where the Cutkosky propagator is located at line 8, indicated there by a vertical bar ($|$). Hence the ''$-$'' momentum is absent from lines 8, and also from line 4 by continuity. We may therefore ignore these two lines in the rest of the discussions.

To obtain the contributing poles from the path method, we can choose the path to be $P=(1,5,10,6,3)$, then $T[P]=\{(P,9),(P,7)\}$, giving rise to the contributing poles (2,7) and (2,9).

VI. DOMINANT INTEGRATION REGIONS IN LLA

Contributing poles, extracted from the path method or otherwise, can be used to determine the internal momenta most important to the loop amplitude. The ''$+$'' momenta from the lines of a contributing pole $I=(i_1 i_2 \cdots i_l)$ are fixed by the pole condition to be $q_{i_k +}=(a_{i_k}-i\epsilon)/q_{i_k -}$, and those of any other line are fixed by momentum conservation. An easy way to read them out is to use the *natural loops* discussed before. These are simply the independent loops containing one and only one pole line each.

In LLA a number of simplifications emerge immediately. For quark-quark scattering in the c.m. system, quark 1 carries a ''$-$'' momentum $\sqrt{s}$ and quark 2 carries a ''$+$'' momentum $\sqrt{s}$. In LLA, where $|t|$ and squared masses are ignored compared to s, both quarks go straight through by carrying the full forward momenta with them. In other words, $q_{j-}\simeq\sqrt{s}$ for every line j of quark 1 (the ''bottom lines''), and $q_{j+}\simeq\sqrt{s}$ for every line j of quark 2 (the ''top lines''). This means that we can ignore the contributing poles with a pole line on top, for q_{j+} of a top line is $\sqrt{s}$ and not determined by the pole condition above. In other words, if we insist on taking a pole there, then this term will not contribute in the LLA.

The two-body amplitude for a flow diagram, after the ''$+$'' integration is performed, can be written as

$$M=\int\left(\prod_{b=1}^{l} d^2k_{b\perp}\right)F, \quad F=\int_R\left(\prod_{b=1}^{l} dx_b\right)G,$$
$$G\equiv\frac{N}{D}\equiv\frac{N}{\Pi_{j=1}^{n} d_j}, \tag{6.1}$$

where $x_b=k_{b-}/\sqrt{s}$ and $Q_j=q_{j-}/\sqrt{s}$ are the scaled ''$-$'' momenta. In practice x_b are chosen from the Q_j's of types (i) and (ii) below. The integration region R of x_b is determined by the n flow-diagram conditions $Q_j\geqslant 0$.

The denominator $D=\Pi_j d_j$ is derived from the denominators of the propagators $1/d(q_i)$, scaled in some convenient way as follows. (i) If line $j=i_k$ is part of the contributing pole I, then d_j is defined to be the scaled residue Q_j; (ii) if line j is a top line, then $d_j \equiv d(q_j)/s = \pm Q_j - a_j/s + i\epsilon \simeq \pm Q_j + i\epsilon$, where the sign in front of Q_j is $+/-$ if the arrow on line j is parallel/antiparallel to the ''+'' flow of quark 2; (iii) for any other line j, d_j is equal to $d(q_j)$ evaluated at the contributing pole, so

$$d_j = Q_j \sum \left(\pm \frac{a_{i_k}}{Q_{i_k}} \right) - a_j, \tag{6.2}$$

where the sum is taken over lines i_k in the same natural loops as line j, with an appropriate sign.

For convenience we will label lines of these three types by different indices; index p (for ''*p*ole'') for type (i), t (for ''*t*op'') for type (ii), and s (for ''side'') for type (iii). We shall retain the index j to denote any of them in general.

The numerator factor N consists of all the rest, including the vertex factors and factors of $\sqrt{s}$ discarded by D.

It should be noted that there are no explicit factors of ''i'' hidden in M, except those explicity contained in the vertices and those appearing as $i\epsilon$ in the propagators. An l-loop Feynman diagram has an explicit factor $(-i)^l$, and this is cancelled by the l factors of $2\pi i$ from contour integration, leaving behind no explicit factors of i. This observation is important in determining how the imaginary part of a scattering amplitude arises.

For nonabelian cut diagrams with c cuts, the Feynman propagator $1/d(q)$ at each cut line is replaced by the Cutkosky propagators $-2\pi i\delta(q^2-m^2)$,[10,11] so an explicit factor $(-i)^c$ will emerge.

From (6.1) and the rules for d_j, it would appear that the integral F diverges at the boundaries $Q_p=0$ and $Q_t=0$. Actually because of *obstructions* from the side lines s, the singularity in the Q_p variable is cancelled so there are no divergences at $Q_p=0$. This is so because as $Q_p \to 0$, the ''+'' momentum $q_{p+} \simeq a_p/Q_p$ becomes very large. At some point it will become much smaller than all the Q_s, whence $d_s \simeq (Q_s/Q_p)a_s$ for any line s in the natural loop of p. This washes out the factor Q_p in d_p, leaving behind no divergence at this boundary.

A divergence does occur at $Q_t=0$, but this divergence is an artifact of our high-energy approximation of dropping $\xi/s \equiv \mp(a_t - i\epsilon)/s$ compared Q_t, where ξ is of the order of the squared masses and the squared momentum transfer $-t$. If we restore it by installing a cutoff ξ/s at these boundaries, the divergences will be absent and they will be turned into enhancement factors of s. If the enhancement is logarithmic, the value of ξ does not matter in the LLA, and that will be the case in gauge theories. But if it is powerlike, then the coefficient of the power dependence would depend on $\xi = \mp(a_t - i\epsilon)$, and its effective value could be determined only after the transverse-momentum integrations.

The integral F, thus enhanced, receives contributions in the form

$$F \simeq \int_{(\xi/s)} \frac{dQ_1'}{Q_1'^{m_1}} F_1, \tag{6.3}$$

where Q_1' is either one of the Q_t's, or the radial variable of several of them that are linearly independent. As it will become clear shortly this will be the smallest of all the ''$-$'' variables in the dominant integration region R_0.

In the region $Q_1' \ll Q_p$, we may set the ratios $Q_1'/Q_p = 0$ in all remaining d_s. This removes obstructions from some of the side lines, so that the integrand of F_1 may now encounter singularity again in some variable Q_2', say like $1/Q_2'^{m_2}$, with $m_2 \geqslant 1$. This new singular variable Q_2' would be equal to some Q_t or Q_p, or the radial variable of several of them. Now we have

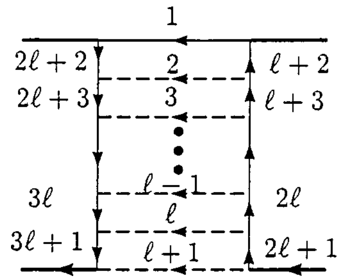

FIG. 6. Ladder diagram for scalar quarks and gluons. The path P is indicated by the light solid line and the poles indicated by the dotted lines. There is only one flow diagram and one contributing pole in this case.

$$F_1 \simeq \int_{B_1 Q_1'} \frac{dQ_2'}{Q_2'^{m_2}} F_2, \tag{6.4}$$

for some $B_1 \gg 1$. Similarly, in the region $Q_1' \ll Q_2' \ll Q_p$ for the remaining pole lines p, Q_2'/Q_p can also be set equal to zero, thus removing further obstructions from even more side lines. This enables another singular variable Q_3' to emerge, and so on. Continue this way until no further singularities are encountered, we get

$$F \simeq \int_{(\xi/s)} \frac{dQ_1'}{Q_1'^{m_1}} \int_{B_1 Q_1'} \frac{dQ_2'}{Q_2'^{m_2}} \int \cdots \int_{B_{\nu-1} Q_{\nu-1}'} \frac{dQ_\nu'}{Q_\nu'^{m_\nu}} F_{\nu+1}. \tag{6.5}$$

The integrand $F_{\nu+1}$ is assumed to be regular so its Q_i' dependencies can all be put equal to zero. All $B_i \gg 1$.

The dominant region of integration R_0 is then given by

$$R_0 = \{\xi/s \leqslant Q_1' \ll Q_2' \ll \cdots \ll Q_\nu' \ll 1\}, \tag{6.6}$$

from which we can work out where the ''+'' momenta are located as well. The transverse momenta $k_{b\perp}$ are all of the same order as the momentum transfer $\sqrt{-t}$.

In gauge theories only logarithmic enhancements occur. This means all $m_i = 1$, and

$$F \simeq \frac{F_{\nu+1}}{\nu!} (\ln s)^\nu. \tag{6.7}$$

For an l-loop Feynman diagram, the maximum enhancement is $\sim (\ln s)^l$. For an l-loop nonabelian cut diagrams with c cuts, the maximum enhancement is $\sim (\ln s)^{l-c}$. We shall refer to diagrams with these maximal enhancements as *saturated*, and these are the diagrams of most interestes to us in LLA. Diagrams with less enhancements will be called *unsaturated*. A number of saturated and unsaturated diagrams are considered in the next section as concrete examples to illustrate the procedures here. For saturated diagrams we will also work out the coefficient of the leading-log term.

VII. EXAMPLES

A. Scalar ladder diagram

Consider the ladder diagram Fig. 6 for scalar quarks and scalar gluons. There is only one nonzero flow diagram, as shown, and in it there is only one contributing pole, namely, $I = (2,3,...,l+1)$, indicated by the dotted lines. The path P from which this contributing pole is obtained is drawn as a light solid line in the diagram.

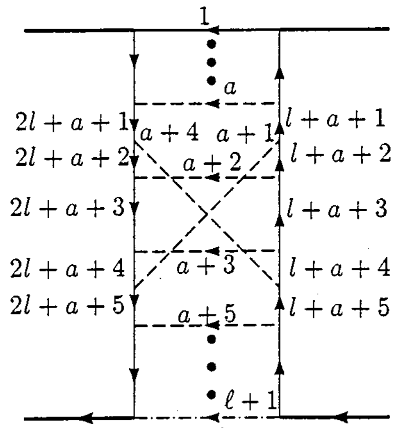

FIG. 7. A crossed ladder diagram, with path P given by the light solid line and the pole lines given by the dotted lines. The rungs above a and below $a+5$ are all uncrossed.

In the language of the last section, the pole lines are $2\leqslant p\leqslant l+1$, the top line is $t=1$, and the side lines are $l+2\leqslant s\leqslant 3l+1$.

The independent ''+'' momenta at the pole lines are given by

$$q_{p+}\sqrt{s}=(a_p-i\epsilon)/Q_p\,, \tag{7.1}$$

with $Q_{l+1}\simeq 1$ in LLA because it is a bottom line. Thus all these ''+'' momenta except q_{l+1} are capable of being large if the corresponding Q_p is small enough. The ''+'' momenta carried by the side lines can most easily be read off from the natural loops, which are rectangles bounded below by the line p and bounded above by the top line 1.

Following the discussions of last section, the top line 1 is the unique candidate for the first singular variable Q_1', and indeed it is with $m_1=1$. In the region $Q_1'\ll Q_j$ for $j>1$, obstructions from lines $l+2$ and $2l+2$ are removed, resulting in $d_{l+2}=-a_{l+2}$ and $d_{2l+2}=-a_{2l+2}$. This allows a new singular structure to emerge with $Q_2'=Q_2$ and $m_2=1$. This in turn removes the obstruction from lines $l+3$ and $2l+3$ in the region $Q_1'\ll Q_2'\ll Q_j$ for $j>2$, etc. Continuing this way, we obtain $Q_j'=Q_j$ and $m_j=1$ for $1\leqslant j\leqslant l$. Thus the diagram is saturated, and we obtain the amplitude to be

$$F=\frac{1}{l!}(\ln s)^l\prod_{i=l+2}^{3l+1}(-a_i). \tag{7.2}$$

In obtaining this expression, we have set the numerator N of the integrand to be 1.

The integration region is given by $R_0=\{\xi/s\leqslant Q_1\ll Q_2\ll\cdots\ll Q_l\ll 1\}$. According to (7.1), the ''+'' momenta are strongly ordered in the opposite way because the a_p's are all of the same order. The virtualities of the side lines s are all spacelike and of order 1, $q_s^2=-a_s=-q_{s\perp}^2$. In other words, the dominant momenta of the virtual gluons come from the multi-Regge region, the same as those used in the dispersion-relation approach.[5]

B. Crossed ladders

When the rungs of the ladders are crossed, the scalar diagram will no longer be saturated. This could be inferred from the example above and the s-channel dispersion relation, but let us see how to obtain this conclusion directly from the Feynman diagram, and how unsaturated it is.

Consider Fig. 7, which is obtained from Fig. 6 by crossing two rungs separated by $r=2$ horizontal rungs in between. The path P and the contributing pole remain unchanged. As before,

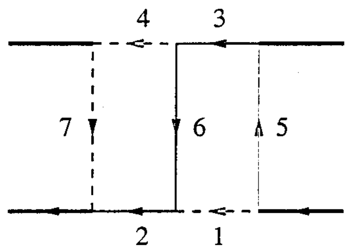

FIG. 8. The solid line is the path P' used to obtain the contributing poles from Fig. 1, indicated here by dotted lines. This is a different path than the one used in Fig. 3.

we let $Q_j'=Q_j$ for $1\leqslant j\leqslant a$, and let these Q_j''s to be strongly ordered as before. Then $m_j=1$ just as in the previous example. The question is what happens when we come to the region where the rungs are crossed.

Every ''+'' momentum $q_{i+}\sqrt{s}(1\leqslant i\leqslant 3l+1)$ is a linear combination of some $a_p/Q_p(2\leqslant p\leqslant l+1)$. We shall use the symbol $[p_1p_2\cdots p_k]$ to represent this ''+'' momentum if it receives contributions from $p=p_1,p_2,\ldots,p_k$ *in the crossed region*. Similarly, its ''−'' momenta are linear combinations of Q_1 and $Q_p(2\leqslant p\leqslant l)$, and those from the crossed region that contribute to the ''−'' momentum of a particular line will be enclosed between angular brackets $\langle\cdots\rangle$.

The ''−'' and ''+'' momenta contributions for the side line $s=l+a+k$ on the right $(1\leqslant k\leqslant 5)$ are $\langle a,\ldots,a+k-1\rangle[a+k,\ldots,a+5]$. For the side lines $s=2l+a+k$ on the left, they are $\langle a\rangle[a+4,a+2,a+3,a+1,a+5]$ for $k=1$, $\langle a,a+4\rangle[a+2,a+3,a+1,a+5]$ for $k=2$, $\langle a,a+4,a+2\rangle[a+3,a+1,a+5]$ for $k=3$, $\langle a,a+4,a+2,a+3\rangle[a+1,a+5]$ for $k=4$, and finally $\langle a,a+4,a+2,a+3,a+1\rangle[a+5]$ for $k=5$. There is no way to strongly order the variables $Q_{a+1},Q_{a+2},Q_{a+3},Q_{a+4}$ in the crossed region to get rid of all the obstructions. Whatever that works on the right-hand side will fail on the left-hand side, and vice versa. The only way out is to have these four to be of the same order, for then the ratio of any two of these four would be of order 1, and all the obstructions from the side lines would disappear. Their common radial variable $Q_{a+1}'=(\Sigma_{i=1}^4 Q_{a+i}^2)^{1/2}$ is singular, with $m_{a+1}=1$, because $Q_{a+1}'^3 dQ_{a+1}'/Q_{a+1}'^4=dQ_{a+1}'/Q_{a+1}'$. From there on, everything looks like the uncrossed ladder again, so $Q_j'=Q_{j+3}$ for $a+2\leqslant j\leqslant p=l-3$. The final integral F is proportional to $(\ln s)^{l-3}$, hence unsaturated. More generally, the same argument shows that if there are r uncrossed rungs between the two crossed rungs, then $F\sim(\ln s)^{l-r-1}$.

C. Two-loop QED diagram

Consider now the two-loop diagram Fig. 1 for electron–electron scattering by exchanging 3 photons.

We shall compute this in two ways. First, using the path P and the contributing poles of Fig. 3, we will obtain saturated contributions from each of these two contributing poles, but their sum vanishes so this diagram turns out to be unsaturated. To see this unsaturation directly, we will use another path P' shown in Fig. 8. This path has only one contributing pole so there can be no chance of a cancellation, and it gives rise to an unsaturated LLA amplitude. In this latter approach we would also be able to compute the coefficient of the leading log term by LLA calculation if we should want to.

The numerator N of (6.1) in this case comes from the vertices, and is proportional to s. For simplicity we will assume it to be simply s.

The path P from Fig. 3 gives two contributing poles, $I_1=(1,2)$ and $I_2=(1,6)$. First consider $I_1=(1,2)$. Since both poles lie on the bottom line, $Q_1\simeq Q_2\simeq 1$, there are no obstructions on the side lines. Since $Q_3>Q_4$, the integral is

$$F \simeq -\frac{s}{a_5 a_6 a_7}\int_{(\xi/s}\frac{dQ_4}{Q_4}\int_{Q_4}\frac{dQ_3}{Q_3} \simeq \frac{s}{(-)^3 a_5 a_6 a_7}\int_{\xi/s}\frac{dQ_4}{Q_4}\int_{Q_4}\frac{dQ_3}{Q_3} \simeq -\frac{s}{2a_5 a_5 a_6 a_7}(\ln s)^2. \tag{7.3}$$

Next consider $I_2=(1,6)$. The pole on 6 causes an obstruction from lines 2 and 7. By choosing $Q_1'=Q_4 \ll Q_2'=Q_6$, the obstruction from line 7 is removed but the obstruction from line 2 remains because $Q_2 \simeq 1$. However, since $Q_3 \simeq Q_6 = Q_2'$, the contribution from I_2 is

$$F \simeq \frac{s}{(-)^2 a_5 a_7}\int_{\xi/s}\frac{dQ_1'}{dQ_1'}\int_{B_1 Q_1'}\frac{dQ_2'}{Q_2'^2 (a_6/Q_2')} \simeq +\frac{s}{2a_5 a_6 a_7}(\ln s)^2. \tag{7.4}$$

The sum of the contributions from I_1 and I_2 vanishes in order $(\ln s)^2$ so the diagram is unsaturated.

To see this unsaturation directly, choose another path P' as shown in Fig. 8. The contributing pole is now $I'=(1,7)$. The obstruction induced by line 7 on lines 2 and 6 block out the factor $d_4 d_7 = Q_4 Q_7$, so to get a singular integrand for F we must enlist the help of Q_3. If Q_1' is the radial variable of Q_7 and Q_3, then the integrand of F is proportional to $Q_1' dQ_1'/Q_3 Q_4 Q_7 d_2 \sim dQ_1'/Q_1'$, so the leading contribution to this diagram is of the order $\ln s$.

D. Four-loop diagram

If the path P for the four-loop diagram Fig. 2 is chosen as in Fig. 4, then as we have seen there are 10 contributing poles. For illustration we will look at the contribution from a single one, (7,3,10,2). We shall see that there will be no $\ln s$ enhancement if the diagram is scalar, but if it is a QCD diagram then there will be a linear $\ln s$ enhancement from this contributing pole.

There are two top lines in this diagram, lines 4 and 5. Since $Q_5 > Q_4 = Q_7$, the only single-variable candidate for Q_1' is $Q_4 = Q_7$. However, the pole in 7 produces an obstruction on all the other lines in its natural loop, lines 8, 12, and 13. With three obstructing lines and only two singular factors, the resulting Q_1' dependence cannot be singular for a scalar diagram. One could go on and try to find a singular Q_1' among the radial variables of several Q_j's, and one would not succeed either. Consequently as a scalar diagram it has no $\ln s$ enhancement.

As a QCD diagram we must incorporate the vertex factors into the numerator N of the integrand of F. The vertex factor for a gluon connected to the top line is $2p_2$, and to the bottom line is $2p_1$. There are however also three triple-gluon vertices, at the junctions of lines (6,7,13) $=A$, $(11,12,13)=B$, and $(8,10,12)=C$. Each of them contains three terms, but one of the three terms of each is dotted into $2p_1$ and therefore produces an appropriate combination of $q_{i+j} g_{7,13}(q_{7+} - q_{13+})$ for A, $g_{12,13}(q_{12+} + q_{13+})$ for B, and $g_{8,12}(q_{8+} + q_{12+})$ for C. Since every line in the natural loop of 7 contains $\pm q_{7+}$, and hence a factor $1/Q_1'$, these three vertex factors can make the Q_1' variable much more singular. However, we may use only two out of the three, for otherwise the $g_{\alpha\beta}$ factors will lead to a dot product of the (7,4) vertex and the (4,5,8) vertex, thus producing an extra factor $2p_2 \cdot 2p_2 = 0$. With the help of two triple-gluon vertices, we get $m_1 = 1$ and a $\ln s$ enhancement from the Q_1' variable.

The remaining singular factors for the integrand come from lines 5 and 10. Since $Q_5 > Q_{10}$, if Q_2' comes from a single variable Q_j we must have $j=10$. This pole at 10 may produce obstructions on lines of its natural loop (10,12,13,6,1). Those on lines 12 and 13 have already been removed by Q_1', so this leaves obstructions from lines 1 and 6. The one on 1 is particularly troublesome because it is a bottom line, so $Q_1 \simeq 1$ and the obstruction can never be removed. For that reason Q_{10} is not a singular variable, and it can be checked that the radial variable of Q_{10} and one or two other Q_j's cannot be a singular variable either. The enhancement of the QCD diagram is therefore just $\ln s$.

E. Non-Abelian cut diagram

As a last example we consider the non-Abelian cut diagram, Fig. 5, treated as a scalar diagram with numerator factor $N=1$. The path is $P=(1,5,10,6,3)$ and the contributing poles are (2, 7) and (2, 9). Since in the LLA we would never have to consider any contributing pole on the top line, we can drop (2, 9) and consider only (2, 7).

In either case there is actually a hidden contributing pole at line 1. This does not show up explicitly in the path method because the cut line 8 reduces the flow diagram into a two-loop diagram, hence only two of the three poles show up explicitly. In any case, since $Q_4=Q_8=0$, we have $Q_1=1$, so the pole at 1 produces $q_{1+}=a_1$. This together with the q_{p+} obtained from the other two pole lines uniquely determine all the ''+'' momenta of all the lines. However, the contribution from q_{1+} is finite, it will never lead to an obstruction, so in some sense we can just forget about it.

Of the two uncut top lines, $Q_{10}>Q_9=Q_7$, so if Q_1' is given by a single Q_j, it would have to be $j=9$. The second singular variable is $Q_2'=Q_6=Q_{10}\gg Q_1'$, and the integral is

$$F=\int_{\xi/s}\frac{dQ_1'}{Q_1'^2(-a_7/Q_1')(-a_6)}\int_{m_1Q_1'}\frac{dQ_2'}{Q_2'(-a_5)(-a_4)}\int dQ_8(-2\pi i)\delta(Q_8)$$

$$\simeq-\frac{\pi i}{a_4a_5a_6a_7}(\ln s)^2. \tag{7.5}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 11 NOVEMBER 1999

Quasispin graded-fermion formalism and $gl(m|n)\downarrow osp(m|n)$ branching rules

Mark D. Gould and Yao-Zhong Zhang[a)]
Department of Mathematics, University of Queensland, Brisbane, Queensland Qld 4072, Australia

(Received 11 May 1999; accepted for publication 13 July 1999)

The graded-fermion algebra and quasispin formalism are introduced and applied to obtain the $gl(m|n)\downarrow osp(m|n)$ branching rules for the ''two-column'' tensor irreducible representations of $gl(m|n)$, for the case $m\leqslant n(n>2)$. In the case $m<n$, all such irreducible representations of $gl(m|n)$ are shown to be completely reducible as representations of $osp(m|n)$. This is also shown to be true for the case $m=n$, except for the ''spin-singlet'' representations, which contain an indecomposable representation of $osp(m|n)$ with composition length 3. These branching rules are given in fully explicit form.
[S0022-2488(99)04410-2]

I. INTRODUCTION

It is well known that branching rules are of great importance in the study of representation theory. They also play an essential role in the determination of the parities for the components appearing in the twisted tensor product graphs and the construction of corresponding *R* matrices.[1,2]

There appear to be virtually no results in the literature on the branching rules for Lie superalgebras. The only exception is Ref. 3, in which the branching rules are determined for all typical and atypical irreducible representations of $osp(2|2n)$ with respect to its subalgebra $osp(1|2n)$. It is very interesting (and important) to investigate the branching rules for other Lie superalgebras.

In this paper we investigate the antisymmetric tensor irreducible representations of $gl(m|n)$. This class of representations is of interest since they are also irreducible under the fixed point subalgebra $osp(m|n)$. Moreover, their quantized versions can be shown to be affinizable to provide irreducible representations of the twisted quantum affine superalgebra $U_q[gl(m|n)^{(2)}]$ from which trigonometric *R* matrices with $U_q[osp(m|n)]$ invariance may be constructed.[4]

These *R* matrices determine new integrable models that have generated remarkable interest in physics recently,[5–7] particularly in condensed matter physics, where they give rise to new integrable models of strongly correlated electrons.

To explicitly construct such *R* matrices it is necessary to determine the reduction of the tensor product of two antisymmetric tensor irreducible representations into ''two column'' irreducible representations of $gl(m|n)$ which are then decomposed into irreducible representations of its fixed point subalgebra $osp(m|n)$.

We determine the $gl(m|n)\downarrow osp(m|n)$ branching rules for these two column irreducible tensor representations of $gl(m|n)$, for the case $m\leqslant n$, $n>2$. A natural framework for solving this problem is provided by the graded-fermion algebra and the quasispin formalism, which we introduce and develop in this paper. The Fock space for this graded-fermion algebra affords a convenient realization of the class of irreducible representations of $gl(m|n)$ concerned. The reduction to $osp(m|n)$, and thus the $gl(m|n)\downarrow osp(m|n)$ branching rules, can be achieved using the quasispin formalism.

II. $osp(m|n=2k)$ AS A SUBALGEBRA OF $gl(m|n)$

Throughout this paper, we assume $n=2k$ is even and set $h=[m/2]$ so that $m=2h$ for even m and $m=2h+1$ for odd m. For homogeneous operators A, B we use the notation $[A,B]=AB-(-1)^{[A][B]}BA$ to denote the usual graded commutator. Let E^a_b be the standard generators of $gl(m|n)$ obeying the graded commutation relations,

$$[E^a_b,E^c_d]=\delta^c_b E^a_d-(-1)^{([a]+[b])([c]+[d])}\delta^a_d E^c_b. \tag{II.1}$$

In order to introduce the subalgebra $osp(m|n)$, we first need a graded symmetric metric tensor $g_{ab}=(-1)^{[a][b]}g_{ba}$, which is assumed to be even. We shall make the convenient choice

$$g_{ab}=\xi_a\delta_{a\bar{b}}, \tag{II.2}$$

where

$$\bar{a}=\begin{cases} m+1-i, & a=i, \\ n+1-\mu, & a=\mu, \end{cases} \quad \xi_a=\begin{cases} 1, & a=1 \\ (-1)^{\mu}, & a=\mu \end{cases}. \tag{II.3}$$

In the above equations, $i=1,2,...,m$ and $\mu=1,2,...,n$. Note that

$$\xi_a^2=1, \quad \xi_a\xi_{\bar{a}}=(-1)^{[a]}, \quad g^{ab}=\xi_b\delta_{a\bar{b}}. \tag{II.4}$$

As generators of the subalgebra $osp(m|n=2k)$, we take

$$\sigma_{ab}=g_{ac}E^c_b-(-1)^{[a][b]}g_{ac}E^c_a=-(-1)^{[a][b]}\sigma_{ba}, \tag{II.5}$$

which satisfy the graded commutation relations,

$$[\sigma_{ab},\sigma_{cd}]=g_{cb}\sigma_{ad}-(-1)^{([a]+[b])([c]+[d])}g_{ad}\sigma_{cb}-(-1)^{[c][d]}(g_{bd}\sigma_{ac} \\ -(-1)^{([a]+[b])([c]+[d])}g_{ac}\sigma_{db}). \tag{II.6}$$

We have an $osp(m|n)$-module decomposition,

$$gl(m|n)=osp(m|n)+T, \quad [T,T]\subset osp(m|n), \tag{II.7}$$

where T is spanned by operators

$$T_{ab}=g_{ac}E^c_b+(-1)^{[a][b]}g_{bc}E^c_a=(-1)^{[a][b]}T_{ba}. \tag{II.8}$$

It is convenient to introduce the Cartan–Weyl generators,

$$\sigma^a_b=g^{ac}\sigma_{cb}=-(-1)^{[a]([a]+[b])}\xi_a\xi_b\sigma^{\bar{b}}_{\bar{a}}. \tag{II.9}$$

As a Cartan subalgebra we take the diagonal operators,

$$\sigma^a_a=E^a_a-E^{\bar{a}}_{\bar{a}}=-\sigma^{\bar{a}}_{\bar{a}}. \tag{II.10}$$

Note that for odd $m=2h+1$ we have $\overline{h+1}=h+1$, and thus $\sigma^{h+1}_{h+1}=E^{h+1}_{h+1}-E^{h+1}_{h+1}=0$.

The positive roots of $osp(m|n)$ are given by the even positive roots [usual positive roots for $o(m)\oplus sp(n)$] together with the odd positive roots $\delta_\mu+\epsilon_i$, $1\leqslant i\leqslant m$, $1\leqslant\mu\leqslant k=n/2$, where we have adopted the useful convention $\epsilon_{\bar{i}}=-\epsilon_i$, $i\leqslant h=[m/2]$ so that $\epsilon_{h+1}=0$ for odd $m=2h+1$. This is consistent with the **Z** gradation,

$$osp(m|n)=L_{-2}\oplus L_{-1}\oplus L_0\oplus L_1\oplus L_2. \tag{II.11}$$

Here $L_0=o(m)\oplus gl(k)$; the $gl(k)$ generators are given by

$$\sigma^{\mu}_{\nu}=E^{\mu}_{\nu}-(-1)^{\mu+\nu}E^{\bar{\nu}}_{\bar{\mu}},\quad 1\leqslant\mu,\nu\leqslant k, \tag{II.12}$$

and $L_{-2}\oplus L_0\oplus L_2=o(m)\oplus sp(n)$, where L_2 gives rise to an irreducible representation of L_0 with highest weight $(\dot{0}|2,\dot{0})$ spanned by the generators

$$\sigma^{\mu}_{\bar{\nu}}=E^{\mu}_{\bar{\nu}}-\xi_{\mu}\xi_{\bar{\nu}}E^{\nu}_{\bar{\mu}}=E^{\mu}_{\bar{\nu}}+(-1)^{\mu+\nu}E^{\nu}_{\bar{\mu}},\quad 1\leqslant\mu,\nu\leqslant k. \tag{II.13}$$

Finally, L_1 is spanned by odd root space generators,

$$\sigma^{\mu}_{i}=E^{\mu}_{i}+\xi_{\mu}E^{\bar{i}}_{\bar{\mu}}=E^{\mu}_{i}+(-1)^{\mu}E^{\bar{i}}_{\bar{\mu}},\quad 1\leqslant\mu\leqslant k,\quad 1\leqslant i\leqslant m, \tag{II.14}$$

and gives rise to an irreducible representation of L_0 with highest weight $(1,\dot{0}|1,\dot{0})$. L_{-1}, L_{-2} give rise to irreducible representations of L_0 dual to L_1, L_2, respectively.

The simple roots of $osp(m|n=2k)$ are thus given by the usual (even) simple roots of L_0 together with the odd simple root $\alpha_s=\delta_k-\epsilon_1$, which is the lowest weight of L_0-module L_1. Note that the simple roots of $o(m)$ depend on whether m is odd or even, and are given here for convenience: For $m=2h$, $\alpha_i=\epsilon_i-\epsilon_{i+1}$, $1\leqslant i<h$, $\alpha_h=\epsilon_{h-1}+\epsilon_h$. For $m=2h+1$, $\alpha_i=\epsilon_i-\epsilon_{i+1}$, $1\leqslant i<h$, $\alpha_h=\epsilon_h$. The simple roots of $gl(k)$ are given by

$$\alpha_{h+\mu}=\delta_{gm}-\delta_{\mu+1},\quad 1\leqslant\mu<k. \tag{II.15}$$

The graded half-sum of the positive roots of $osp(m|n=2k)$ is given by

$$\rho=\frac{1}{2}\sum_{i=1}^{h}(m-2i)\epsilon_i+\frac{1}{2}\sum_{\mu=1}^{k}(n-m+2-2\mu)\delta_{\mu}. \tag{II.16}$$

III. GRADED-FERMION REALIZATIONS

We introduce the graded anticommutator:

$$\{A,B\}\equiv AB+(-1)^{[A][B]}BA. \tag{III.1}$$

Note that $\{A,B\}\neq\{B,A\}$. To realize the antisymmetric tensor irreducible representations of $gl(m|n)$, we introduce graded fermions c_a and their adjoints $c_a^{\dagger}$ obeying the graded anticommutation relations,

$$\{c_a,c_b\}=\{c_a^{\dagger},c_b^{\dagger}\}=0,\quad \{c_a,c_b^{\dagger}\}=\delta_{ab}. \tag{III.2}$$

Thus, when $a=i$ is even c_i are fermions while for $a=\mu$ odd, c_{μ} are bosons that anticommute with the fermions.

To get a graded fermion realization of $gl(m|n)$, we set

$$E^a_b=c_a^{\dagger}c_b, \tag{III.3}$$

and note the graded commutation relations:

$$[E^a_b,c_d^{\dagger}]=\delta_{bd}c_a^{\dagger},\quad [E^a_b,c_d]=(-1)^{([a]+[b])[d]}\delta^a_d c_b. \tag{III.4}$$

Using these relations, it is easy to verify that the operators E^a_b given above indeed satisfy the $gl(m|n)$ graded commutation relations.

Thus, we obtain representations of $gl(m|n)$ on the graded fermion Fock space, which include the antisymmetric tensor representations. The Fock space can be shown to be completely reducible into type I unitary irreducible representations of $gl(m|n)$ according to

$$F=\bigoplus_{a=0}^{m}\hat{V}(\dot{1}_a,\dot{0}|\dot{0})\bigoplus_{b=1}^{\infty}\hat{V}(\dot{1}|b,\dot{0}). \tag{III.5}$$

Thus, for $N\leqslant m$, the space of N-particle states comprises the antisymmetric tensor representation of $gl(m|n)$ with highest weight $\Lambda_N=(\dot{1}_N,\dot{0}|\dot{0})$. For $N>m$ the space of N-particle states comprises the irreducible representations of $gl(m|n)$ with highest weights $\Lambda_N=(\dot{1}|N-m,\dot{0})$.

We introduce an extra ''spin'' index α and consider the family of graded fermions $c_{a\alpha}$ and their adjoints $c^\dagger_{a\alpha}$ obeying the graded anticommutation relations,

$$\{c_{a\alpha},c_{b\beta}\}=\{c^\dagger_{a\alpha},c^\dagger_{b\beta}\}=0,\quad \{c_{a\alpha},c^\dagger_{b\beta}\}=\delta_{ab}\delta_{\alpha\beta}. \tag{III.6}$$

Here all spin indices are understood to be even (so that the grading only depends on the orbital labels a, b, c, etc.).

We take, for our $gl(m|n)$ generators,

$$E^a_b=\sum_\alpha c^\dagger_{a\alpha}c_{b\alpha}, \tag{III.7}$$

which can be shown, as before, to satisfy the graded commutation relations

$$[E^a_b,c^\dagger_{d\alpha}]=\delta_{bd}c^\dagger_{a\alpha},\quad [E^a_b,c_{d\alpha}]=(-1)^{([a]+[b])[d]}\delta^a_d c_{b\alpha}, \tag{III.8}$$

from which we deduce that the E^a_b indeed obey the $gl(m|n)$ graded commutation relations. Thus, we may now construct more general irreducible representations of $gl(m|n)$ in the graded-fermion Fock space. In particular, for ''two-column'' irreducible representations, only two spin labels $\alpha=\pm$ are required.

IV. QUASISPIN (TWO SPIN LABELS)

We employ the above graded-fermion algebra with two spin labels $\alpha=\pm$. We set

$$Q_+=g_{dd'}c^\dagger_{d,+}c^\dagger_{d',-}=\sum_d \xi_d c^\dagger_{d,+}c^{\dagger}_{\overline{d},-},$$
$$Q_-=g^{dd'}c^\dagger_{d,-}c^\dagger_{d',+}=\sum_d \xi_d c_{d,-}c_{\overline{d},+}. \tag{IV.1}$$

Let $Q_0=\frac{1}{2}(\hat{N}-m+n)$, where $\hat{N}=\Sigma_{a=1}^{m+n}E^a_a$ is the first-order invariant of $gl(m|n)$ (i.e., the number operator). By straightforward computation, the following can be shown.

Proposition 1: *$Q_\pm$, Q_0 generate an $sl(2)$ Lie algebra, called the quasispin Lie algebra,*

$$[Q_+,Q_-]=2Q_0,\quad [Q_0,Q_\pm]=\pm Q_\pm. \tag{IV.2}$$

Moreover, $Q_\pm$, Q_0 commute with the generators of $osp(m|n=2k)$.

To see the significance of the graded fermion algebra for the construction of irreducible representations, we set

$$E^{a\alpha}_{b\beta}=c^\dagger_{a\alpha}c_{b\beta}, \tag{IV.3}$$

and note the graded commutation relations,

$$[E^{a\alpha}_{b\beta},c^\dagger_{c\gamma}]=\delta_{bc}\delta_{\beta\gamma}c^\dagger_{a\alpha},\quad [E^{a\alpha}_{b\beta},c_{c\gamma}]=-(-1)^{[c]([a]+[b])}\delta^a_c\delta^\alpha_\gamma c_{b\beta}, \tag{IV.4}$$

from which we deduce

$$[E^{a\alpha}_{b\beta}, E^{c\gamma}_{d\delta}] = \delta^c_b \delta^\gamma_\beta E^{a\alpha}_{d\delta} - (-1)^{([a]+[b])([c]+[d])} \delta^a_d \delta^\alpha_\delta E^{c\gamma}_{b\beta}, \tag{IV.5}$$

which are the defining relations of $gl(2m|2n)$. That is, $E^{a\alpha}_{b\beta}$ are the generators of $gl(2m|2n)$.

As we have seen, the spin-averaged operators,

$$E^a_b = \sum_{\alpha=\pm} E^{a\alpha}_{b\alpha}, \tag{IV.6}$$

form the generators of $gl(m|n)$. Similarly, the orbital averaged operators,

$$E^\alpha_\beta = \sum_\alpha E^{a\alpha}_{a\beta}, \quad \alpha,\beta = \pm, \tag{IV.7}$$

form the generators of the spin Lie algebra $gl(2)$, which commute with the $gl(m|n)$ generators. It is worth noting that the spin $sl(2)$ algebra with generators,

$$S_+ = E^+_-, \quad S_- = E^-_+, \quad S_0 = \tfrac{1}{2}(E^+_+ - E^-_-), \tag{IV.8}$$

also commute with the quasispin Lie algebra. Throughout, we denote the spin Lie algebra (IV.8) by $sl_S(2)$ and the quasispin Lie algebra by $sl_Q(2)$.

Then, the space of N-particle states gives rise to an irreducible representation of $gl(2m|2n)$ [and $osp(2m|2n)$] with highest weight,

$$\begin{cases} (\dot{1}_N, \overline{0}|\dot{0}), & N \leqslant 2m \\ (\dot{1}|N-2m, \dot{0}), & N > 2m. \end{cases} \tag{IV.9}$$

This N-particle space decomposes into a multiplicity-free direct sum of irreducible $gl(m|n) \oplus sl_S(2)$ modules,

$$\hat{V}(a,b) \otimes V_s, \tag{IV.10}$$

where V_s denotes the $(2s+1)$-dimensional irreducible representation of $sl_S(2)$, $b=2s$, $N=2a+b$ and $\hat{V}(a,b)$ denotes the irreducible representation of $gl(m|n)$ with highest weight,

$$\Lambda_{a,b} = \begin{cases} (\dot{2}_a, \dot{1}_b, \dot{0}|\dot{0}), & a+b \leqslant m, \\ (\dot{2}_a, \dot{1}|a+b-m, \dot{0}), & a \leqslant m, a+b > m, \\ (\dot{2}|a+b-m, a-m, \dot{0}), & a > m. \end{cases} \tag{IV.11}$$

In this way we may realize all required "two-column" irreducible representations of $gl(m|n)$, inside a given antisymmetric tensor irreducible representation of $gl(2m|2n)$ utilizing the graded-fermion calculus.

V. CASIMIR INVARIANTS AND CONNECTION WITH QUASISPIN

From now on we shall use the notation

$$\hat{L} \equiv gl(m|n), \quad L \equiv osp(m|n), \quad \hat{L}_0 \equiv gl(m) \oplus gl(n), \quad L_o \equiv o(m) \oplus sp(n). \tag{V.1}$$

Let $C_{\hat{L}}$, C_L denote the universal Casimir invariants of $\hat{L}$, L, respectively. Then for the two-column irreducible representations of $\hat{L}$ we are considering, a straightforward but tedious calculation shows that

$$C_{\hat{L}} - C_L = (m-n+2-\tfrac{1}{2}\hat{N})\hat{N} - \tfrac{1}{2}(n-m)(n-m-2) + 2Q^2, \tag{V.2}$$

where

$$Q^2=\mathbf{Q}\cdot\mathbf{Q}=Q_0(Q_0+1)+Q_-Q_+=Q_0(Q_0-1)+Q_+Q_- \tag{V.3}$$

is the square of the quasispin. Equation (V2) shows that Q^2 is expressible in terms of $C_{\hat{L}}$, C_L, and $\hat{N}$. It follows that Q^2, Q_-Q_+, Q_+Q_- must leave invariant (in fact, reduce to a scalar multiple of the identity on) a given irreducible representation of L inside a given (two-column) representation of $\hat{L}$. Given the highest weight of such an L module we may determine its quasispin $\overline{Q}$ [the lowest weight of the relevant $sl_Q(2)$ module] using (V2) and $Q^2=\overline{Q}(\overline{Q}-1)$.

It is worth noting that we may write, for our quasispin generators,

$$\mathbf{Q}=\mathbf{Q}^{(0)}+\mathbf{Q}^{(1)}, \tag{V.4}$$

where

$$Q_-^{(0)}=\sum_{i=1}^{m} c_{i,-}c_{\bar{i},+}, \quad Q_-^{(1)}=\sum_{\mu=1}^{n}(-1)^{\mu}c_{\mu,-}c_{\bar{\mu},+}, \tag{V.5}$$

and, similarly, for Q_+, while

$$Q_0^{(0)}=\tfrac{1}{2}(\hat{N}_0-m), \quad Q_0^{(1)}=\tfrac{1}{2}(\hat{N}_1+n), \tag{V.6}$$

with $\hat{N}_0=\Sigma_{i=1}^m E_i^i$ and $\hat{N}_1=\Sigma_{\mu=1}^n E_\mu^\mu$ being the number operators for even fermions and odd bosons, respectively. Then it can be shown that $\mathbf{Q}^{(0)}$, $\mathbf{Q}^{(1)}$ both determine $sl(2)$ algebra that commute, so that the quasispin $\mathbf{Q}$ may be interpreted as the total quasispin obtained by coupling the quasispins of the even and odd components, respectively.

Similar remarks apply to the total spin algebra. The total spin vector is a sum of even and odd components,

$$\mathbf{S}=\mathbf{S}^{(0)}+\mathbf{S}^{(1)}, \tag{V.7}$$

whose corresponding $sl(2)$ algebras [cf. (IV.8)] are generated by

$$E^{(0)\alpha}{}_{\beta}=\sum_{i=1}^{m} E^{i\alpha}_{i\beta}, \quad E^{(1)\alpha}{}_{\beta}=\sum_{\mu=1}^{n} E^{\mu\alpha}_{\mu\beta}, \tag{V.8}$$

respectively. We note that the quasispin and spin algebras $sl_Q^{(0)}(2)$, $sl_Q^{(1)}(2)$, $sl_S^{(0)}(2)$, $sl_S^{(1)}(2)$ all commute with each other.

We remark that the quasispin algebras $sl_Q^{(0)}(2)$, $sl_Q^{(1)}(2)$ play an important role in decomposing irreducible representations of $\hat{L}_0$ into irreducible representations of $L_{\bar{0}}$. They commute with the even subalgebra $L_{\bar{0}}$ of L, but not with L itself.

VI. QUASISPIN EIGENVALUES

Throughout, $\hat{V}(a,b)$ denotes the irreducible representation of $\hat{L}$ with highest weight $\Lambda_{a,b}$ given by (IV.11). Let $\hat{V}_{\bar{0}}(a,b)=\hat{V}_0(\dot{0}|a+b,a,\dot{0})$ be its minimal $\mathbf{Z}$-graded component. Note that $\hat{V}_{\bar{0}}(a,b)$ is an irreducible $gl(n)$ module and thus an irreducible $\hat{L}_0$ module. We have the following.

Proposition 2: $\hat{V}_{\bar{0}}(a,b)$ cyclically generates $\hat{V}(a,b)$ as an L module: viz.,

$$\hat{V}(a,b)=U(L)\hat{V}_{\bar{0}}(a,b). \tag{VI.1}$$

Proof: Set

$$W = U(L)\hat{V}_0^-(a,b) \subset \hat{V}(a,b), \tag{VI.2}$$

i.e., W is an L submodule. We show that equality holds. Obviously, $\hat{V}_0^-(a,b)$ is an L_0^- module (since $L_0^- = L_{-2} \oplus L_0 \oplus L_2 \subset \hat{L}_0$). Now, since $\hat{V}_0^-(a,b)$ is the minimal **Z**-graded component of $\hat{V}(a,b)$, we have, by the PBW theorem,

$$\hat{V}(a,b) = U(\hat{L}_+)\hat{V}_0^-(a,b). \tag{VI.3}$$

Using

$$\sigma^i_\mu = E^i_\mu - (-1)^\mu E^{\bar{\mu}}_i \in L_1^- \equiv L_1 \oplus L_{-1}, \tag{VI.4}$$

we have

$$E^i_\mu \hat{V}_0^-(a,b) = \sigma^i_\mu \hat{V}_0^-(a,b) + (-1)^\mu E^{\bar{\mu}}_i \hat{V}_0^-(a,b) = \sigma^i_\mu \hat{V}_0^-(a,b) \subset W, \tag{VI.5}$$

since $E^{\bar{\mu}}_i \hat{V}_0^-(a,b) \subset \hat{L}_- \hat{V}_0^-(a,b) = (0)$. It follows that

$$\hat{L}_+ \hat{V}_0^-(a,b) \subset W. \tag{VI.6}$$

Proceeding recursively, let us assume that

$$(\hat{L}_+)^i \hat{V}_0^-(a,b) \subset W, \quad \forall i \leqslant r. \tag{VI.7}$$

Then

$$\begin{aligned} E^i_\mu \hat{L}^r_+ \hat{V}_0^-(a,b) &= \sigma^i_\mu \hat{L}^r_+ \hat{V}_0^-(a,b) + (-1)^\mu E^{\bar{\mu}}_i \hat{V}_0^-(a,b) \\ &\subset L\hat{L}^r_+ \hat{V}_0^-(a,b) + \hat{L}_- \hat{L}^r_+ \hat{V}_0^-(a,b) \\ &\subset L\hat{L}^r_+ \hat{V}_0^-(a,b) + \hat{L}^{r-1}_+ \hat{V}_0^-(a,b) \subset W, \end{aligned} \tag{VI.8}$$

since $\hat{L}_- \hat{V}_0^-(a,b) = (0)$ and $\hat{L}^r_+ \hat{V}_0^-(a,b) \subset W$, $\hat{L}^{r-1}_+ \hat{V}_0^-(a,b) \subset W$ by the recursion hypothesis. Thus $\hat{L}^{r+1}_+ \hat{V}_0^-(a,b) \subset W$ so that, by induction, $\hat{L}^r_+ \hat{V}_0^-(a,b) \subset W$, $\forall r$. It follows that

$$\hat{V}(a,b) = U(\hat{L}_+)\hat{V}_0(a,b) \subset W. \tag{VI.9}$$

Thus, we must have $W = \hat{V}(a,b)$.

From the traditional quasispin formalism for $gl(n) \supset sp(n)$, we have a decomposition of L_0^- modules,

$$\hat{V}_0^-(a,b) = V_0(a,b) \oplus Q_+^{(1)} \hat{V}_0^-(a-1,b), \tag{VI.10}$$

where $V_0(a,b)$ is an irreducible L_0^- module with highest weight $(\dot{0}|a+b,a,\dot{0})$ and comprises quasispin minimal states with respect to quasispin algebra $\mathbf{Q}^{(1)}$ (and thus also $\mathbf{Q}$), so

$$Q_-^{(1)} V_0(a,b) = Q_- V_0(a,b) = 0. \tag{VI.11}$$

Note that for $n=2$, $\hat{V}_0^-(a,b) = V_0(a,b)$ is an irreducible L_0^- module, but not quasispin minimal. Thus, the case $n=2$ requires a separate treatment. However, for this case, $\hat{V}_0^-(a,b) = V_0(a,b)$ still has well-defined quasispin $\overline{Q}$ (the minimal weight of the quasispin algebra): in fact, $\overline{Q} = \frac{1}{2}(b-m+n)$ for this case.

Proceeding recursively, we arrive at the irreducible $sp(n)$ (and hence L_0^-) module decomposition,

$$\hat{V}_0^-(a,b)=\bigoplus_{c=0}^{a} Q^{(1)a-c}_{+}V_0(c,b), \tag{VI.12}$$

where

$$Q^{(1)a-c}_{+}V_0(c,b)\cong V_0(c,b)\subset \hat{V}_0^-(c,b) \tag{VI.13}$$

is the irreducible L_0^- module with highest weight $(\dot{0}|c+b,c,\dot{0})$. From the above remarks $V_0(c,b)$ in the decomposition (VI.13) is quasispin minimal with respect to $\mathbf{Q}^{(1)}$ (and $\mathbf{Q}$) so $Q_-^{a-c+1}Q^{(1)a-c}_{+}V_0(c,b)=(0)$. It follows that $Q_-^{a+1}\hat{V}_0^-(a,b)=(0)$. Thus, if $q_N=\frac{1}{2}(N-m+n)$ is the eigenvalue of Q_0 on $\hat{V}(a,b)$, $N=2a+b$, then we have the following.

Theorem 1: *The quasispin eigenvalues (i.e., quasispin minimal weights) occurring in $\hat{V}(a,b)$ lie in the range*

$$\overline{Q}=q_N,\ \ q_N-1,...,\ \ q_N-a, \tag{VI.14}$$

or $q_N\geqslant\overline{Q}\geqslant q_N-a$ (in integer steps).

In view of (V.2) and (V.3), the operator Q_-Q_+ must leave invariant an L submodule of $\hat{V}(a,b)$. In view of the above theorem, the (generalized) eigenvalues of Q_-Q_+ on $\hat{V}(a,b)$ must be of the form

$$Q_-Q_+\equiv\overline{Q}(\overline{Q}-1)-q_N(q_N+1)=(\overline{Q}+q_N)(\overline{Q}-q_N-1). \tag{VI.15}$$

This eigenvalue can only vanish if $\overline{Q}+q_N=0$, which would imply, from the above theorem, $q_N-k=-q_N$ for some $0\leqslant k\leqslant a$. Thus, $k=2q_N=N-m+n$ or, equivalently, $a\geqslant N-m+n\Leftrightarrow a\geqslant 2a+b-m+n\Leftrightarrow m-n\geqslant a+b$.

Thus, if $m\leqslant n$, the (generalized) eigenvalues of Q_-Q_+ are all nonzero, except for the trivial module $(a=b=0)$, which we ignore below. Thus, we have proved the following lemma.

Lemma 1: For $m\leqslant n$, Q_-Q_+ determines a nonsingular operator on $\hat{V}(a,b)$, except possibly for the trivial module corresponding to $m=n$, $a=b=0$.

Remarks: The above result is crucial in what follows and will not generally hold for $m>n$. Hence, throughout the remainder we assume $m\leqslant n$, $n>2$. Note that Q_-Q_+ is nonsingular even on the trivial module, except when $m=n$.

VII. INDUCED FORMS AND AN ORTHOGONAL DECOMPOSITION

We recall that the graded fermion calculus admits a grade-$*$ operation, defined by

$$(c^{\dagger}_{a,\alpha})^*=(-1)^{[a]}c_{a,\alpha},\quad c^*_{a,\alpha}=c^{\dagger}_{a,\alpha}, \tag{VII.1}$$

which we extend in the usual way with $(AB)^*=(-1)^{[A][B]}B^*A^*$. This induces a grade-$*$ operation on $\hat{L}$ and L. Explicitly,

$$(E^a_b)^*=(-1)^{[a]([a]+[b])}E^b_a,\quad (\sigma^a_b)^*=(-1)^{[a]([a]+[b])}\sigma^b_a. \tag{VII.2}$$

Moreover, the quasispin generators satisfy $Q_+^*=Q_-$, $Q_-^*=Q_+$, and $Q_0^*=Q_0$.

With this convention, the graded fermion Fock space admits a nondegenerate graded sesquilinear form $\langle,\rangle$. In particular, $\hat{V}(a,b)$ is equipped with such a form and is nondegenerate. Note that

$$\langle v,E^a_bw\rangle=(-1)^{[v]([a]+[b])}\langle(E^a_b)^*v,w\rangle, \tag{VII.3}$$

which is the invariance condition of the form. It is the unique (up to scalar multiples) invariant graded form on $\hat{V}(a,b)$.

We now note that $Q_+\hat{V}(a-1,b)$ is an L submodule of $\hat{V}(a,b)$. In view of Lemma 1 and Eqs. (V.2) and (V.3), we have the following.

Lemma 2: The form $\langle\, , \rangle$ *restricted to* $Q_+\hat{V}(a-1,b)\subset\hat{V}(a,b)$ *is nondegenerate, except for the case* $a=1$, $b=m-n=0$.

Proof: Under the above conditions, Q_-Q_+ is nonsingular on $\hat{V}(a-1,b)$, so $Q_-Q_+\hat{V}(a-1,b)=\hat{V}(a-1,b)$. Hence, for $v\in\hat{V}(a-1,b)$, we have $0=\langle Q_+\hat{V}(a-1,b),Q_+v\rangle\Rightarrow 0=\langle Q_-Q_+\hat{V}(a-1,b),v\rangle=\langle\hat{V}(a-1,b),v\rangle\Rightarrow v=0$ since $\langle\, , \rangle$ on $\hat{V}(a-1,b)$ is nondegenerate. This shows that the form $\langle\, , \rangle$ restricted to $Q_+\hat{V}(a-1,b)$ is nondegenerate, as required.

In view of Proposition 2, we have the following.

Proposition 3: $Q_-\hat{V}(a,b)=\hat{V}(a-1,b)$.

Proof: From Proposition 2, we have

$$Q_-\hat{V}(a,b)=Q_-U(L)\hat{V}_0^-(a,b)=U(L)Q_-\hat{V}_0^-(a,b)=U(L)Q_-^{(1)}\hat{V}_0^-(a,b)=U(L)\hat{V}_0^-(a-1,b), \tag{VII.4}$$

where the last step follows from a classical Lie algebra result. Again, utilizing Proposition 2, we have $U(L)\hat{V}_0^-(a-1,b)=\hat{V}(a-1,b)$, from which the result follows.

We are now in a position to prove the following.

Proposition 4: We have an L-module orthogonal decomposition;

$$\hat{V}(a,b)=\mathcal{K}\oplus Q_+\hat{V}(a-1,b), \tag{VII.5}$$

where $\mathcal{K}=\mathrm{Ker}\, Q_-\cap\hat{V}(a,b)$, *except for the case* $a=1$, $b=m-n=0$.

Proof: For $v\in\hat{V}(a,b)$, $\langle v,Q_+\hat{V}(a-1,b)\rangle=0\Leftrightarrow\langle Q_-v,\hat{V}(a-1,b)\rangle=0\Leftrightarrow Q_-v=0$ (by Proposition 3) $\Leftrightarrow v\in\mathcal{K}$. Since $\langle\, , \rangle$ restricted to $Q_+\hat{V}(a-1,b)$ is nondegenerate, the result follows.

Finally, in view of Theorem 1 we have Proposition 5.

Proposition 5: $\hat{V}(a=0,b)$ *is an irreducible L module.*

Proof: In such a case, $\hat{V}_0^-(0,b)=V_0(0,b)$ is an irreducible L_0^- module cyclically generated by an L maximal state. Thus, $\hat{V}(0,b)=U(L)V_0(0,b)$ must be an indecomposable L module. Since the form $\langle\, , \rangle$ on $\hat{V}(0,b)$ is nondegenerate, this forces $\hat{V}(0,b)$ to be an irreducible L module.

The result above shows that the minimal $\hat{L}$ irreducible representations are indeed irreducible under L.

VIII. PRELIMINARIES TO BRANCHING RULES

It is our aim below to prove, barring the exceptional case of Lemma 2, that $\mathcal{K}$ is an irreducible L module. Note that the maximal state of the L_0^- module $V_0(a,b)$ occurring in the decomposition (VI.10), in fact, coincides with the $\hat{L}_0$ maximal vector v_+^Λ of $\hat{V}_0^-(a,b)$: For $n>2$ it can be seen directly that

$$Q_-v_+^\Lambda=Q_-^{(1)}v_+^\Lambda=0, \tag{VIII.1}$$

for this maximal vector. Moreover, for $n>2$ we have

$$E_{\bar{\mu}}^{i}v_+^\Lambda=0, \quad 1\leqslant i\leqslant m, \quad 1\leqslant\mu\leqslant k; \tag{VIII.2}$$

otherwise, this vector would have weight $(\dot{0}|a+b,a,\dot{0})+\epsilon_i-\delta_{\bar{\mu}}$ $(\overline{\mu}>k=n/2)$, which is impossible since all $\hat{L}$ weight components are positive. Also, since v_+^Λ belongs to the $\hat{L}$ minimal **Z**-graded component, we must have

$$E_i^{\mu} v_+^{\Lambda} = 0, \quad \forall i, \mu. \tag{VIII.3}$$

Thus, for $\sigma_i^{\mu} \in L_1$, we have

$$\sigma_i^{\mu} v_+^{\Lambda} = (E_i^{\mu} + (-1)^{\mu} E_{\overline{\mu}}^{\overline{i}}) v_+^{\Lambda} = 0, \quad \forall i, 1 \leq \mu \leq k \Rightarrow L_1 v_+^{\Lambda} = (0). \tag{VIII.4}$$

It follows that the L_0^- module $V_0(a,b)$ must cyclically generate an indecomposable module over L:

$$V(a,b) = U(L) V_0(a,b), \tag{VIII.5}$$

with highest weight

$$\lambda_{a,b} \equiv (\dot{0} | a+b, a, \dot{0}). \tag{VIII.6}$$

Since

$$Q_- V_0(a,b) = Q_-^{(1)} V_0(a,b) = (0), \tag{VIII.7}$$

we have

$$Q_- V(a,b) = Q_- U(L) V_0(a,b) = U(L) Q_- V_0(a,b) = (0). \tag{VIII.8}$$

It follows that $V(a,b) \subset \mathcal{K}$.

We now show that $V(a,b) = \mathcal{K}$ is irreducible. First, in view of Proposition 3, we have the following lemma.

Lemma 3: $v \in \mathcal{K} \Leftrightarrow Q_+ Q_- v = 0$.

Proof: Obviously $v \in \mathcal{K} \Rightarrow Q_- v = 0 \Rightarrow Q_+ Q_- v = 0$. Conversely, $Q_+ Q_- v = 0 \Rightarrow$

$$0 = \langle Q_+ Q_- v, \hat{V}(a,b) \rangle = \langle Q_- v, Q_- \hat{V}(a,b) \rangle = \langle Q_- v, \hat{V}(a-1,b) \rangle \tag{VIII.9}$$

$\Rightarrow Q_- v = 0 \Rightarrow v \in \mathcal{K}$.

It follows that $\mathcal{K}$ consists of eigenstates of $Q_+ Q_-$ with a zero eigenvalue. Also, since $Q_- \mathcal{K} = (0)$ and $\mathcal{K} \subset \hat{V}(a,b)$, it follows that all states in $\mathcal{K}$ are eigenvectors of Q_0 with eigenvalue $q_N = \frac{1}{2}(N - m + n)$ and are, moreover, quasispin minimal states, and so have quasispin $\overline{Q} = q_N$. Thus, Q^2 reduces to a scalar multiple $\overline{Q}(\overline{Q} - 1) = q_N(q_N - 1)$ on $\mathcal{K}$. It then follows from (V.2) that the universal Casimir element C_L of L must reduce to a scalar multiple of the identity on $\mathcal{K}$. Since $V(a,b) \subset \mathcal{K}$ has highest weight $\lambda_{a,b}$, this eigenvalue can be shown to be given by

$$\chi_{\lambda_{a,b}}(C_L) = (\lambda_{a,b}, \lambda_{a,b} + 2\rho) = -(a+b)(a+b+n-m) - a(a+n-m-2). \tag{VIII.10}$$

Hence we have proved the following.

Lemma 4: C_L reduces to a scalar multiple of the identity on $\mathcal{K}$ with an eigenvalue given by (VIII.10).

Now $\mathcal{K}$ is a completely reducible L_0^- module. Hence we have the following.

Lemma 5: Suppose for any irreducible L_0^- module $V_0(\lambda)$ contained in an irreducible $\hat{L}_0$ module $\hat{V}_0(\Lambda) \subset \hat{V}(a,b)$ that $\chi_\lambda(C_L) = \chi_{\lambda_{a,b}}(C_L) \Leftrightarrow \Lambda = \Lambda_{a,b}$ and $\lambda = \lambda_{a,b}$. Then $\mathcal{K} = V(a,b)$ is irreducible.

Proof: Indeed, in such a case it follows from Lemma 4 that the highest weight vector of $V(a,b)$ must be the unique primitive vector in $\mathcal{K}$. This is enough to prove that $\mathcal{K}$ is irreducible.

Finally, we recall that $\hat{V}(a,b)$ comprises states with total spin $s = b/2$ and with particle number $N = 2a + b$. Then the possible irreducible representations of $\hat{L}_0$ occurring in $\hat{V}(a,b)$ must have highest weights of the form

$$\Lambda=(\dot{2}_{a'},\dot{1}_{b'},\dot{0}|c',d',\dot{0}). \tag{VIII.11}$$

Then we must have

$$2a'+b'+c'+d'=N=2a+b. \tag{VIII.12}$$

Moreover, the total spins for the even and odd components of this irreducible representation are $s_0=b'/2$ and $s_1=(c'-d')/2$, respectively. So, using the triangular rule for angular momenta, we have

$$s\leqslant s_0+s_1,\quad s_0\leqslant s+s_1,\quad s_1\leqslant s+s_0, \tag{VIII.13}$$

or

$$b\leqslant b'+c'-d',\quad b'\leqslant b+c'-d',\quad c'-d'\leqslant b+b'. \tag{VIII.14}$$

These inequalities turn out to be important below.

IX. $\hat{L}\downarrow L$ BRANCHING RULES

We start this section with some facts concerning $\hat{L}_0\downarrow L_0^-$. The possible $\hat{L}_0$ highest weights Λ occurring in $\hat{V}(a,b)$ are of the form of (VIII.11). The possible L_0^- highest weights λ in $\hat{V}(a,b)$ are obtained from such Λ by a classical contraction procedure and have the form

$$\lambda=(\dot{2}_c,\dot{1}_d,\dot{0}|e,f,\dot{0}),\quad c+d\leqslant h, \tag{IX.1}$$

where $d=b'\wedge(m-2c-b')$, $e-f=c'-d'$ [here and below $x\wedge y\equiv\min(x,y)$] and

$$c\leqslant a',\quad e+f\leqslant c'+d'=2a+b-2a'-2b'. \tag{IX.2}$$

Note that for $n>4$, there are additional restrictions on the allowed L_0^- dominant weights in order that they give rise to highest weights of L.[8] In the interests of a unified treatment of all cases, including $n=4$, we do not impose these supplementary conditions here.

Since $e-f=c'-d'$, the inequalities (VIII.14) lead to

$$b'\leqslant b+e-f,\quad b\leqslant b'+e-f,\quad e-f\leqslant b+b'. \tag{IX.3}$$

Hence, we have the following inequalities.

Lemma 6: $e\leqslant a+b-c$, $f\leqslant a-c$.

Proof: We have

$$e+f\leqslant 2a+b-2a'-b',\quad e-f\leqslant b+b'.$$

Adding these two inequalities gives $e\leqslant a+b-a'$. Thus, $e\leqslant a-c$ since $c\leqslant a'$. Similarly, adding

$$e+f\leqslant 2a+b-2a'-b',\quad f-e\leqslant b'-b$$

leads to $f\leqslant a-a'\leqslant a-c$.

We are now in a position to compute the eigenvalue $\chi_\lambda(C_L)$ compared with that of (VIII.10). By direct computation we have

$$\chi_\lambda(C_L)=(\lambda,\lambda+2\rho)=m(2c+d)-c(c+1)-(c+d)(c+d+1)$$
$$-(n-m)(e+f)+4c+d+2f-e^2-f^2, \tag{IX.4}$$

where we have used

$$\lambda=\sum_{i=1}^{c} 2\epsilon_i+\sum_{i=c+1}^{d+c}\epsilon_i+e\delta_1+f\delta_2, \tag{IX.5}$$

together with the expression for ρ of L. By a straightforward but tedious calculation, using (VIII.10) and (IX.4), we obtain

$$\chi_\lambda(C_L)-\chi_{\lambda_{a,b}}(C_L)=2cn+d(m-d)+2c(2a+b-2c-d)+(a+b-c-e)\times(a+b-c+e+n-m)+(a-c-f)(a-c+f+n-m-2) \tag{IX.6}$$

$$=[2c(n+1)+2f-2a]+d(m-d)+2c(2a+b-2c-d)+(a+b-c-e)(a+b-c+e+n-m)+(a-c-f)(a-c+f+n-m). \tag{IX.7}$$

All terms on the rhs of (IX.6) are positive, in view of the inequalities given above, except possibly the last due to the term $(a-c+f+n-m-2)$. Similarly, in (IX.7) all terms on the rhs are positive, except possibly the first.

We proceed stepwise.

(i) $c\geqslant 1$: Then the first term on the rhs of (IX.7) gives

$$2c(n+1)+2f-2a\geqslant 2(n+1+f-a).$$

This leads to two subclasses.

(i.1) $a\leqslant n+1$: The rhs terms are all non-negative, so (IX.7) can only vanish if $a=n+1$, $f=0=d$, $2a+b=2c+d$. But then, since $d=0$ this would imply $2c=2a+b\Rightarrow c>a=n+1$, which is impossible since $c\leqslant h\leqslant m\leqslant n$. Thus we conclude that the rhs must be strictly positive in this case.

(i.2) $a\geqslant n+2$: In this case all terms on the rhs of (IX.6) are non-negative, including the last term, since, for the case at hand,

$$a-c+f+n-m-2\geqslant n+2-c+f+n-m-2\geqslant n-c+f+n-m\geqslant 0,$$

since $n\geqslant m\geqslant h\geqslant c$. Since $c\geqslant 1$, the rhs of (IX.6) must be strictly positive in this case.

We thus conclude, for $c\geqslant 1$, that $\chi_\lambda(C_L)-\chi_{\lambda_{a,b}}(C_L)>0$. It remains then to consider the case $c=0$, in which case we have

$$\chi_\lambda(C_L)-\chi_{\lambda_{a,b}}(C_L)=d(m-d)+(a+b-e)(a+b+e+n-m)+(a-f)(a+f+n-m-2). \tag{IX.8}$$

Note that for the case $c=0$, the inequalities of Lemma 6 reduce to $e\leqslant a+b$, $f\leqslant a$ and for the case at hand we have

$$e-f=c'-d', \quad d=b'\wedge(m-b').$$

It is convenient to treat the cases $m=n$ and $m<n$ separately.

(ii) $c=0$, $n>m$: Here we assume $a\geqslant 1$, since when $a=0$, $\hat{V}(a=0,b)$ is already known to be an irreducible L module, so the branching rule is trivial.

Under these assumptions all terms on the rhs of (IX.8) are non-negative, including the last, since

$$a+f+n-m-2\geqslant f+n-m-1\geqslant 0.$$

Note that this factor can only vanish when $a=1$, $f=0$, $n=m+1$. There are thus two possibilities to consider for vanishing of the rhs of (IX.8):

(ii.1) $d=0$, $e=a+b$, $f=a$: Since $c'+d'=2a+b-2a'-b'\geqslant e+f=2a+b$ and $c'-d'=e-f=b$, this implies that $a'=b'=0$, $c'=a+b$, $d'=a$, and $\lambda=\lambda_{a,b}$. So in this case $\Lambda=(\dot{0}|a+b,a,\dot{0})=\Lambda_{a,b}$ and $\lambda=\lambda_{a,b}$.

(ii.2) $d=0$, $e=a+b$, $f=0$, $a=1$, $n=m+1$: Then $c'+d'\geqslant e+f=a+b$. Since $a=1$, we thus have

$$2+b=N=2a'+b'+c'+d'\geqslant 2a'+b'+a+b=2a'+b'+1+b$$

$\Rightarrow 1\geqslant 2a'+b'\Rightarrow a'=0$ and $b'\leqslant 1$. In such a case we must have $d=b'\wedge(m-b')$ and since $d=0\Rightarrow b'=0$, or $m=b'=1\Rightarrow n=2$, which we ignore. Then $\Lambda=(\dot{0}|c',b',\dot{0})$ with $c'-b'=e-f=a+b=1+b$, which corresponds to states with spin $(1+b)/2$, which is impossible since all states in $\hat{V}(a,b)$ have spin $b/2$. Thus, this latter case cannot occur.

Thus we have shown, for all cases, that when $n>m$, $\mathcal{K}=V(a,b)$ must be an irreducible module with highest weight $\lambda_{a,b}$, using Lemma 4.

In view of Proposition 3 we thus have the L module decomposition,

$$\hat{V}(a,b)=V(a,b)\oplus Q_+\hat{V}(a-1,b). \tag{IX.9}$$

Since Q_-Q_+ is nonsingular, $Q_+\hat{V}(a-1,b)\cong\hat{V}(a-1,b)$. By repeated application of (IX.9), we arrive at the irreducible L module decomposition,

$$\hat{V}(a,b)=\bigoplus_{c=0}^{a} Q_+^{a-c}V(c,b). \tag{IX.10}$$

Hence we have proved the following theorem.

Theorem 2: $(n>m,n>2)$**:** *We have the irreducible L-module decomposition,*

$$\hat{V}(a,b)=\bigoplus_{c=0}^{a} V(c,b). \tag{IX.11}$$

We emphasize that throughout $V(a,b)$ denotes the L module with highest weight $\lambda_{a,b}=(\dot{0}|a+b,a,\dot{0})$. It remains now to consider the case $m=n$, which is somewhat more interesting.

(iii) $c=0$, $m=n>2$: Again, we assume $a\geqslant 1$ since $\hat{V}(a=0,b)$ is an irreducible L module, as we have seen. We recall for the case at hand $e\leqslant a+b$, $f\leqslant a$, $a\geqslant 1$, $m=n>2$, $e-f=c'-d'$, $d=b'\wedge(m-b')$ and

$$\chi_\lambda(C_L)-\chi_{\lambda_{a,b}}(C_L)=d(m-d)+(a+b-e)(a+b+e)+(a-f)(a+f-2). \tag{IX.12}$$

There are now several cases to consider for the vanishing of (IX.12).

(iii.1) $a=f$: Then (IX.12) vanishes when $d=0$, $e=a+b$. Thus

$$c'+d'\geqslant e+f=2a+b=2a'+b'+c'+d'$$

$\Rightarrow a'=b'=0$, $c'+d'=2a+b$, and $c'-d'=e-f=b$. This corresponds to $\Lambda=\Lambda_{a,b}$ and $\lambda=\lambda_{a,b}$.

(iii.2) $f=2-a$: Then (IX.12) vanishes when $d=0$, $e=a+b$. Since $a\geqslant 1$ there are two cases.

(iii.2.1) $f=0$, $a=2$: This is only possible when $c'+d'\geqslant e+f=a+b\Rightarrow$

$$2a+b\geqslant 2a'+b'+c'+d'\geqslant 2a'+b'+a+b$$

$\Rightarrow a\geqslant 2a'+b'$ or $2\geqslant 2a'+b'$. This leads to two further cases.

(iii.2.1a) $f=0$, $a=2$, $a'=0$, $b'\leqslant 2$: In view of the contraction procedure, this is only consistent with $d=0$ if $b'=0$ (so $c'=a+b$, $d'=a$) or if $b=2$ and $m=n=2$. The latter case is being ignored and the former case cannot occur since then $c'-d'=e-f=a+b>b$ in contradiction to the fact that all states in $\hat{V}(a,b)$ have spin $b/2$.

(iii.2.1b) $f=0$, $a=2$, $a'=1$, $b'=d=0$: Then $c'-d'=e-f=a+b>b$, which again is impossible since all states have spin $b/2$.

(iii.2.2) $f=a=1$: Then $c'-d'=a+b-a=b$, $c'+b'\geqslant e+f=2a+b \Rightarrow a'=b'=0$, $c'=a+b$, $d'=a \Rightarrow \Lambda=\Lambda_{a,b}$, $\lambda=\lambda_{a,b}$.

(iii.3) $a+f-2<0$, $a>f$: This can only occur when $a=1$, $f=0$, in which case the rhs of (IX.12) becomes

$$d(m-d)+(a+b+e)(a+b-e)-1.$$

There are two cases for the vanishing of this.

(iii.3.1) $e=a+b$, $d=1$, $m=2$, which can occur, but we are ignoring since $n=m>2$.

(iii.3.2) $d=f=e=b=0$: Then $c'-d'=e-f=0$ and

$$N=2=2a+b=2a'+b'+c'+d'=2(a'+c')+b',$$

which can occur in the following cases:

$$a'=b'=0, \quad c'=d'=1 \Rightarrow \lambda=(\dot{0}|\dot{0}), \quad \Lambda=(\dot{0}|1,1,\dot{0});$$

$$b'=c'=d'=0, \quad a'=1 \Rightarrow \lambda=(\dot{0}|\dot{0}), \quad \Lambda=(2,\dot{0}|\dot{0}).$$

This exhausts all possibilities. It follows from the above that for $n=m>2$ the rhs of (IX.12) is always strictly positive and can only vanish in the last case, corresponding to $a=1$ and $b=0$. This is the irreducible representation $\hat{V}(2,\dot{0}|\dot{0})$ of $gl(n|n)$, which is known to give rise to an indecomposable $osp(n|n)$ module with a composition series of length 3 whose factors are isomorphic to the $osp(n|n)$ modules $V(1,0)$ and $V(0,0)$ (see Appendix).

Thus we have proved the decomposition

$$\hat{V}(a,b)=V(a,b)\oplus Q_+\hat{V}(a-1,b) \tag{IX.13}$$

with $V(a,b)$ an irreducible L-module of highest weight $\lambda_{a,b}$, provided $(a,b)\neq(1,0)$. Proceeding recursively we have the following theorem.

Theorem 3 (n=m>2): For $b>0$ we have the irreducible L-module decomposition,

$$\hat{V}(a,b)=\bigoplus_{c=0}^{a} V(c,b). \tag{IX.14}$$

For $b=0$ we have the L-module decomposition,

$$\hat{V}(a,0)=\bigoplus_{c=1}^{a} V(c,0), \tag{IX.15}$$

where $V(c,0)$ is irreducible for $c>1$ but $V(1,0)$ is indecomposable with a composition series of length 3 with composition factors isomorphic to irreducible L modules $V(1,0)$ and $V(0,0)$, the latter occurring twice.

Theorems 2 and 3 are our main results in this section concerning the $\hat{L}\downarrow L$ branching rules for the two-column tensor representations of $\hat{L}$. We remark that for the special case $n-m=0=b$, $a=1$, $\hat{V}(a-1,b)=\hat{V}(0,0)$ coincides with the identity module, which is the exceptional case of Lemma 2. For this case the form $\langle , \rangle$ on $\hat{V}(a,b)=\hat{V}(1,0)$ is degenerate on $Q_+\hat{V}(a-1,b)$

$=Q_+\hat{V}(0,0)$. Thus, Proposition 4 fails in this case (and only this case). This, of course, agrees with the result that $\hat{V}(a,b)=\hat{V}(1,0)\equiv\hat{V}(2,\dot{0}|\dot{0})$ is indecomposable for $m=n$.

APPENDIX: STRUCTURE OF $\hat{V}(z,\dot{0}|\dot{0})$ AS A $osp(n|n)$-MODULE

Here for completeness we determine the structure of the irreducible $\hat{L}=gl(n|n=2k)$ module $\hat{V}(2,\dot{0}|\dot{0})$ as a module over $L=osp(n|n)$, in fully explicit form.

First $\hat{V}(2,\dot{0}|\dot{0})$ admits the following **Z**-graded decomposition into irreducible $\hat{L}_0$ modules with highest weights shown:

$$\hat{V}(2,\dot{0}|\dot{0})=\hat{V}_0(2,\dot{0}|\hat{0})\oplus\hat{V}_1(1,\dot{0}|1,\dot{0})\oplus\hat{V}_2(\dot{0}|1,1,\dot{0}).$$

In the notation of the paper, the last space corresponds to the irreducible $\hat{L}_0$ module $\hat{V}_0^-(a=1,b=0)$. In terms of the graded fermion formalism, we have the following basis states:

$$\begin{aligned}
&\hat{V}_0(2,\dot{0}|\dot{0}):\ (c_{i,+}^\dagger c_{j,-}^\dagger+c_{j,+}^\dagger c_{i,-}^\dagger)|0\rangle,\quad 1\leqslant i,j\leqslant n,\\
&\hat{V}_1(1,\dot{0}|1,\dot{0}):\ (c_{i,+}^\dagger c_{\mu,-}^\dagger+c_{\mu,+}^\dagger c_{i,-}^\dagger)|0\rangle,\quad 1\leqslant i,\mu\leqslant n,\\
&\hat{V}_2(\dot{0}|1,1\dot{0}):\ (c_{\mu,+}^\dagger c_{\nu,-}^\dagger-c_{\nu,+}^\dagger c_{\mu,-}^\dagger)|0\rangle,\quad 1\leqslant\mu,\nu\leqslant n,
\end{aligned}\tag{A1}$$

where $|0\rangle$ is the vacuum state. The latter space decomposes into L_0^- modules according to

$$\hat{V}_2(\dot{0}|1,1,\dot{0})=V_0(\dot{0}|1,1\dot{0})\oplus V_0(\dot{0}|\dot{0}),$$

where $V_0(\dot{0}|\dot{0})$ is spanned by $Q_+^{(1)}|0\rangle$ (the trivial L_0^- module) and $V_0(\dot{0}|1,1,\dot{0})$ is an irreducible L_0^- module with the highest weight indicated and the following basis vectors:

$$(c_{\mu,+}^\dagger c_{\nu,-}^\dagger-c_{\nu,+}^\dagger c_{\mu,-}^\dagger)|0\rangle,\quad 1\leqslant\nu\neq\overline{\mu}\leqslant n,\tag{A2}$$

$$(\Omega_\mu^\dagger-\Omega_{\mu+1}^\dagger)|0\rangle,\quad 1\leqslant\mu<k,\tag{A3}$$

where

$$\Omega_\mu^\dagger\equiv c_{\mu,+}^\dagger c_{\overline{\mu},-}^\dagger-c_{\overline{\mu},+}^\dagger c_{\mu,-}^\dagger\,.$$

Note that this irreducible L_0^- module cyclically generates an indecomposable L module $\tilde{V}(\delta_1+\delta_2)$ with highest weight $\delta_1+\delta_2$ and highest weight vector given by (A2) with $\mu=1$, $\nu=2$.

Now $\hat{V}_1(1,\dot{0}|1,\dot{0})$ is also irreducible as an L_0^- module that is contained in $\tilde{V}(\delta_1+\delta_2)$. Then by applying the odd lowering generators $\sigma_\mu^i=E_\mu^i-(-1)^\mu E_i^{\overline{\mu}}(1\leqslant\mu\leqslant k,1\leqslant i\leqslant n)$ of L to the states (A1), the following states in $\hat{V}_0(2,\dot{0}|\dot{0})$ are easily seen to be in $\tilde{V}(\delta_1+\delta_2)$:

$$(c_{i,+}^\dagger c_{j,-}^\dagger+c_{j,+}^\dagger c_{i,-}^\dagger)|0\rangle,\quad 1\leqslant j\neq\overline{i}\leqslant n,\tag{A4}$$

$$(\Omega_i^\dagger-\Omega_{i+1}^\dagger)|0\rangle,\quad 1\leqslant i<k,\tag{A5}$$

where

$$\Omega_i^\dagger \equiv c_{i,+}^\dagger c_{,-}^\dagger + c_{\overline{i,+}}^\dagger c_{i,-}^\dagger .$$

Further, the following states are also seen to be in $\tilde{V}(\delta_1+\delta_2)$:

$$(\Omega_i^\dagger + (-1)^\mu \Omega_\mu^\dagger)|0\rangle, \quad 1 \leqslant i, \mu < k, \tag{A6}$$

which follows by applying $\sigma_i^{\overline{\mu}}$ to the states (A1) with $1 \leqslant \mu \leqslant k$. Summing (A6) on $\mu = i$ from 1 to k, we thus obtain

$$\left(\sum_{i=1}^{k} \Omega_i^\dagger + \sum_{\mu=1}^{k} (-1)^\mu \Omega_\mu^\dagger \right) |0\rangle = Q_+|0\rangle \in \tilde{V}(\delta_1+\delta_2). \tag{A7}$$

It is worth noting that the states (A6) are expressible in terms of the states (A3), (A5), and (A7).

The states (A1)–(A7) form a basis for the standard cyclic L module $\tilde{V}(\delta_1+\delta_2)$. We note that $\dim \tilde{V}(\delta_1+\delta_2) = \dim \hat{V}(2,\dot{0}|\dot{0}) - 1$ and $\tilde{V}(\delta_1+\delta_2)$ is the unique maximal L submodule of $\hat{V}(2,\dot{0}|\dot{0})$. In view of (A7), this module is not irreducible since it contains the trivial one-dimensional L module $V(\dot{0}|\dot{0})$ as a unique submodule.

The remaining state in $\hat{V}(2,\dot{0}|\dot{0})$, not in $\tilde{V}(\delta_1+\delta_2)$, is $Q_+^{(1)}|0\rangle$ (or $Q_+^{(0)}|0\rangle$), which thus generates the basis vector for the L factor module $\hat{V}(2,\dot{0}|\dot{0})/\tilde{V}(\delta_1+\delta_2)$, which is obviously isomorphic to the trivial L module $V(\dot{0}|\dot{0})$. We thus arrive at the L-module composition series $\hat{V}(2,\dot{0}|\dot{0}) \supset \tilde{V}(\delta_1+\delta_2) \supset V(\dot{0}|\dot{0}) \supset (0)$ with corresponding factors isomorphic to the irreducible L modules with highest weights $(\dot{0}|\dot{0})$, $\delta_1+\delta_2$, and $(\dot{0}|\dot{0})$, respectively.

This result is of importance to the explicit construction of new R matrices.[4] In particular, it gives rise to an L-invariant nilpotent contribution to the R matrices, a new effect not seen in the untwisted or nonsuper cases.

(Received 9 February 1999; accepted for publication 6 May 1999)

We construct a class of Euclidean invariant distributions Φ_H indexed by a function H holomorphic at zero. These generalized functions can be considered as generalized densities w.r.t. the white noise measure, and their moments fulfill all Osterwalder–Schrader axioms, except for reflection positivity. The case where $F(s)=-(H(is)+\frac{1}{2}s^2)$, $s\in\mathbb{R}$, is a Lévy characteristic is considered in Rev. Math. Phys. **8**, 763 (1996). Under this assumption the moments of the Euclidean invariant distributions Φ_H can be represented as moments of a generalized white noise measure P_H. Here we enlarge this class by convolution with kernels G coming from Euclidean invariant operators $\mathcal{G}$. The moments of the resulting Euclidean invariant distributions Φ_H^G also fulfill all Osterwalder–Schrader axioms except for reflection positivity. For no nontrivial case we succeeded in proving reflection positivity. Nevertheless, an analytic extension to Wightman functions can be performed. These functions fulfill all Wightman axioms except for the positivity condition. Moreover, we can show that they fulfill the Hilbert space structure condition and therefore the modified Wightman axioms of indefinite metric quantum field theory [*Dynamics of Complex and Irregular Systems* (World Scientific, Singapore, 1993)].

I. INTRODUCTION

This paper is motivated by the Euclidean strategy for constructing interacting field theories; see, e.g., Refs. 1 and 2 and the references therein. Formally, the interacting field theory with interaction V lives on the same measure space as the Euclidean free field μ_0 but has measure

$$d\mu_V=\frac{\exp(-\int_{\mathbb{R}^d}V(\phi(x))d^d(x))d\mu_0}{\int \exp(-\int_{\mathbb{R}^d}V(\phi(x))d^d(x))d\mu_0},\tag{1}$$

where $\phi(x)$ is a Gaussian random process at the point $x\in\mathbb{R}^d$, $d\in\mathbb{N}$. Since $\phi(x)$ in general is not an integrable function but rather a generalized function the question of how to define $V(\phi(x))$ leads to the problem of defining powers of $\phi(x)$. Furthermore, (1) is only formal if $\mu_V\neq\mu_0$, since the only probability measure absolutely continuous w.r.t. μ_0 and invariant under Euclidean translations is μ_0 itself.

A first step in the direction of giving sense to (1) is to construct Wick powers: $\phi(x)^m$: $m\in\mathbb{N}$, of the Gaussian random process ϕ at the point $x\in\mathbb{R}^d$. For $d\geqslant 2$ the Wick powers: $\phi(x)^m$: still are not integrable functions. Additionally, a so-called space cutoff is necessary, i.e., the integration in (1) is performed only over a bounded subset of $\mathbb{R}^d$, and sometimes also an ultraviolet cutoff, i.e., the Wick powers: $\phi(x)^m$: are smeared out with delta sequences. For certain

[a)]Electronic mail: grothaus@wiener.iam.uni.bonn.de

classes of interactions by these renormalizations integrable densities w.r.t. μ_0 have been constructed, and then some kind of limit that removes the cutoffs has been taken; a limit that does not require the output to be absolutely continuous. Examples are the following: the $P(\phi)_2$ model (the 2 stands for $d=2$), where the interaction is given by a Wick ordered polynomial $V=:P:$, semibounded from below, see, e.g., Ref. 1 and the references therein; the Høegh–Krohn model[3] in $d=2$ space–time dimensions, where the interaction is given by

$$V(s)=\int :\exp(as):d\nu(a),$$

where ν is a finite measure with compact support in the interval $(\sqrt{2\pi},\sqrt{2\pi})$; and the Albeverio Høegh–Krohn model[4] in d space–time dimensions, where the interaction is given by the Fourier transform of a measure ν with bounded support on the real line [and $d\nu(s)=\overline{d\nu(-s)}$], i.e.,

$$V(s)=\int \exp(ias)d\nu(a).$$

The Schwinger functions associated to the interacting field theory with interaction V are the moments of the measure ν_V. But moments one can also obtain from generalized functions considered as generalized densities w.r.t. a Gaussian measure μ, they only have to have the property that monomials are test functions. This is the basic idea of our approach. Motivated by the Euclidean strategy we consider the following generalized white noise functional:

$$\Phi_H=\exp^{\diamond}\left(-\int_{\mathbb{R}^d}H^{\diamond}(\phi(x))d^dx\right). \tag{2}$$

We assume that the function H is holomorphic at zero and $H(0)=0$. The Wick analytic function $H^{\diamond}(\phi(x))$ of the Gaussian process ϕ at the point $x\in\mathbb{R}^d$ coincides with the usual Wick ordered function $:H(\phi(x)):$. It turns out that $H^{\diamond}(\phi(x))$ is a generalized function from the Kondratiev space $(S)^{-1}$; see Sec. II B, and therefore also its integral, if it exists, is in $(S)^{-1}$. Thus, in general, we cannot take its exponential. But in the white noise distribution space $(S)^{-1}$ there exists the so-called Wick calculus; see Sec. II B; hence we can take its Wick exponential. In the case where H is linear and if we integrate only over $K\subset\mathbb{R}^2$, K compact (space cutoff), the function Φ_H is square integrable and we have a direct correspondence between (1) and (2), i.e.,

$$\Phi_H=\frac{\exp(-\int_K H(\phi(x))d^2(x))}{\int\exp(-\int_K H(\phi(x))d^2(x))d\mu},$$

where μ is the Gaussian white noise measure. In general, however, there is no need for the distribution Φ_H to be positive and for a large class of functions H there exists no measure that is representing Φ_H. It turns out that Φ_H can be represented by a measure if and only if the function $F(s)=-H(is)+\frac{1}{2}s^2$, $s\in\mathbb{R}$, is a Lévy characteristic; see Remark III.7 (ii). The associated measures are called generalized white noise measures.

Generalized white noise measures have been considered in Ref. 5. There are authors constructed Euclidean random fields over $\mathbb{R}^d$ by convoluting generalized white noise with integral kernels G coming from Euclidean invariant operators. The corresponding moments satisfy all Osterwalder–Schrader axioms[6] except for reflection positivity.

For all convoluted generalized white noise measures such that the Lévy characteristic of the generalized white noise measure has a holomorphic extension at zero, we can give an explicit formula for the generalized density w.r.t. the white noise measure; see Theorem III.9 below. Furthermore, there exists a large class of generalized functions Φ_H as in (2) that do not have an associated measure; see Remark III.16. In Theorem III.9 and Theorem III.15 we prove that the Schwinger functions corresponding to the convoluted generalized functions Φ_H^G also fulfill all Osterwalder–Schrader axioms except for reflection positivity.

For no nontrivial case we succeeded in proving reflection positivity. In Ref. 5 the authors present a partial negative result on reflection positivity for the Schwinger functions corresponding to moments of convoluted generalized white noise. We quote more details about their results in Sec. IV A.

Without reflection positivity we cannot perform the analytic continuation to Wightman functions via the reconstruction theorem.[6] Nevertheless, an analytic continuation can be performed. Using results from the theory of Laplace transforms in Ref. 5, the authors analytically continued the Schwinger functions, which are given as moments of convoluted generalized white noise to Wightman functions. In general, these functions only fulfill a part of the Wightman axioms, i.e., positivity (positive definiteness of the set of Wightman functions[7–9]) is missing. We generalized their idea to our case and in Theorem IV.1 we prove that the Schwinger functions corresponding to convoluted generalized functions Φ_H^G also have an analytic extension to Wightman functions. These Wightman functions fulfill all Wightman axioms, except for the positivity property. Furthermore, they fulfill the strong spectral condition with mass gap $m_0 > 0$, and their two-point functions admit a Källen–Lehmann representation. For the Fourier transform of the truncated Wightman functions in Ref. 5, the authors found explicit formulas. Using these formulas and the Jost–Schroer theorem, in Theorem IV.2 we prove a negative result concerning the positivity property; see also Remark IV.3.

Since the appearance of gauge theories, it has become natural to consider (local) quantum field theories (QFT) in which not all Wightman axioms are satisfied. Such a consideration has, in particular, been natural and also necessary for the study of ‘‘charged’’ fields interacting with gauge fields, because their description conflicts either with locality or with positivity. The physical reason for this is that in such theories one must use observables of the charged type that obey a Gaussian law; see, e.g., Morchio and Strocchi,[10] instead of using the usual local observables. Actually, from the study of fields such as, e.g., α-gauge-type Higgs models that do not satisfy positivity; see, e.g., Ref. 11 and references therein, it turns out that it is preferable to keep the locality condition and to give up the positivity condition. This leads to the so-called modified Wightman axioms of indefinite metric QFT.[12] The difference between indefinite metric QFT and standard QFT is that the axiom of positivity in the latter is replaced by the so-called Hilbert space structure condition in the former that permits the construction of a Hilbert space and a quantum field associated to a given collection of functions fulfilling the modified Wightman axioms.

In Ref. 13 the authors proved that the Wightman functions that are analytic continuations of the moments of convoluted generalized white noise fulfill the Hilbert space structure condition, and therefore the modified Wightman axioms. Again it was possible to generalize their proof to our case, and in Theorem IV.5 we prove that the Wightman functions that are analytic continuations of the moments of convoluted generalized functions Φ_H^G also fulfill the modified Wightman axioms.

The article is organized as follows. In Sec. II we introduce the concepts of Gaussian and white noise analysis[14–19] as far as necessary for our considerations. In the framework of white noise analysis, various aspects of QFT have been discussed.[20–23,16] Section III of this paper is intended to represent Euclidean QFT in the framework of white noise analysis. In Sec. III A we show how to check the Osterwalder–Schrader axioms (OS axioms) in terms of the T transform (the T transform is an infinite-dimensional generalization of the Fourier transform). The T transform of a generalized function is the generating functional of the corresponding Schwinger functions. Properties of generating functionals have also been discussed in Refs. 24 and 25. Having this tool in hands in Sec. III B, we construct the Euclidean invariant distributions Φ_H^G. In Sec. IV we discuss the reflection positivity, analytic continuation, and QFT with an indefinite metric.

II. GAUSSIAN ANALYSIS

A. Gaussian spaces

We start by considering the Gel’fand triple,

$$S(\mathbb{R}^d) \subset \mathcal{H} \subset S'(\mathbb{R}^d),$$

where $S(\mathbb{R}^d)$ is the space of rapidly decreasing, smooth test functions on $\mathbb{R}^d$. We assume $S(\mathbb{R}^d)$ to be equipped with its standard locally convex topology such that it is a nuclear space. $\mathcal{H}$ is a real separable Hilbert space containing $S(\mathbb{R}^d)$ as a dense and topological subspace. For instance, $\mathcal{H}$ can be chosen as the space of real-valued square integrable functions w.r.t. the Lebesgue measure on $\mathbb{R}^d$ or as a Sobolev space on $\mathbb{R}^d$. As is well known[26,27] $S=S(\mathbb{R}^d)$ is the projective limit of a family of Hilbert spaces $(\mathcal{H}_p)_{p\in\mathbb{N}_0}$, $\mathcal{H}_0=\mathcal{H}$, such that for all $p_1,p_2\in\mathbb{N}$ there exists $p\in\mathbb{N}$, such that $\mathcal{H}_p\subset\mathcal{H}_{p_1}$ and $\mathcal{H}_p\subset\mathcal{H}_{p_2}$ and the embeddings are of the Hilbert–Schmidt class. That is, S is a countably Hilbert space in the sense of Ref. 28. The dual space space S' is the space of tempered distributions. It is given as the inductive limit of the spaces $(\mathcal{H}_{-p})_{p\in\mathbb{N}_0}$ that are dual to the spaces $(\mathcal{H}_p)_{p\in\mathbb{N}}$ w.r.t. $\mathcal{H}$. We denote by $\langle\cdot,\cdot\rangle$ the dual pairings between $\mathcal{H}_p$ and $\mathcal{H}_{-p}$ and between S and S' given by the extension of the inner product $(\cdot,\cdot)$ on $\mathcal{H}$. Furthermore, $|\cdot|_p$ denote the norms on $\mathcal{H}_p$ and $\mathcal{H}_{-p}$, respectively, and we preserve this notation for the norms on the complexifications $\mathcal{H}_{p,\mathbb{C}}$ and $\mathcal{H}_{-p,\mathbb{C}}$ and tensor powers of these spaces.

Additionally, we introduce the notion of symmetric tensor power of the nuclear space S. The simplest way to do this is to start from usual symmetric tensor powers $\mathcal{H}_p^{\hat{\otimes}n}, n\in\mathbb{N}$, of Hilbert spaces. Using the definition

$$S^{\hat{\otimes}n}:=\underset{p\in\mathbb{N}}{\mathrm{prlim}}\ \mathcal{H}_p^{\hat{\otimes}n},$$

one can prove[26,27] that $S^{\hat{\otimes}n}$ is a nuclear space that is called the nth symmetric tensor power of S. The dual space $S'^{\hat{\otimes}n}$ can be written as

$$S'^{\hat{\otimes}n}=\underset{p\in\mathbb{N}}{\mathrm{indlim}}\ \mathcal{H}_{-p}^{\hat{\otimes}n}.$$

The space $S'(\mathbb{R}^d)^{\hat{\otimes}n}$ is canonically isomorphic to $S'(\mathbb{R}^{nd})$, the space of symmetric tempered distributions on $\mathbb{R}^{nd}$. All the results quoted above also hold for complex spaces.

In order to introduce a probability measure on the vector space S', we consider the σ-algebra $\mathcal{C}_\sigma(S')$ generated by cylinder sets. The canonical Gaussian measure μ on $(S',\mathcal{C}_\sigma(S'))$ is given by its characteristic function

$$\int_{S'}\exp(i\langle\omega,f\rangle)\,d\mu(\omega)=\exp\left(-\frac{1}{2}|f|^2\right),\quad f\in S,$$

via Minlos' theorem.[14–16] If we chose $\mathcal{H}=L^2(\mathbb{R}^d)$, the space of real-valued square-integrable functions w.r.t. the Lebesgue measure on $\mathbb{R}^d$, this is the Gaussian white noise measure. For $\mathcal{H}=H^{-1,2}(\mathbb{R}^d)$, the Sobolev space of order $(-1,\,2)$, this is the measure corresponding to the Euclidean free field with mass 1 in d dimensions.

The central space in our setup is the space of complex-valued functions that are square integrable w.r.t. this measure $L^2(\mu)=L^2(S',\mathcal{C}_\sigma(S'),\mu)$. An element of this space is the Wick exponential,

$$\begin{aligned}:\exp(\langle\omega,f\rangle):&:=\frac{\exp(\langle\omega,f\rangle)}{\mathbb{E}_\mu(\exp(\langle\cdot,f\rangle))},\quad \omega\in S',\ f\in S,\\ &=\sum_{n=0}^{\infty}\frac{1}{n!}\langle:\omega^{\otimes n}:,f^{\otimes n}\rangle.\end{aligned}\tag{3}$$

$\mathbb{E}_\mu$ denotes the expectation w.r.t. μ and the map $S'\ni\omega\mapsto:\omega^{\otimes n}:\in S'^{\hat{\otimes}n}$, $n\in\mathbb{N}$, is called the nth Wick power of $\omega\in S'$ $(\langle:\omega^{\otimes 0}:,f^{\otimes 0}\rangle:=f^{\otimes 0}:=1)$.[15,16] For any $\varphi^{(n)}\in S_{\mathbb{C}}^{\hat{\otimes}n}$, $n\in\mathbb{N}$, $\varphi^{(0)}\in\mathbb{C}$, we define the smooth Wick monomial of order n corresponding to the kernel $\varphi^{(n)}$ as follows:

$$I(\varphi^{(n)})(\omega) := \langle :\omega^{\otimes n}:, \varphi^{(n)} \rangle, \quad \omega \in S', n \in \mathbb{N}_0 .$$

Smooth Wick monomials of different order are orthogonal w.r.t. the standard inner product in $L^2(\mu)$. Furthermore, we can construct Wick monomials $I(f^{(n)})$ with kernels $f^{(n)} \in \mathcal{H}_{\mathbb{C}}^{\hat{\otimes} n}$ in the sense of measurable functions by using an approximation. More precisely, for any sequence $(\varphi_j^{(n)})_{j \in \mathbb{N}} \subset S_{\mathbb{C}}^{\hat{\otimes} n}$ that converges to $f^{(n)}$ in $\mathcal{H}_{\mathbb{C}}^{\hat{\otimes} n}$ we have the convergence of $I(\varphi^{(n)})$ to $I(f^{(n)})$ in any $L^p(\mu), p \geqslant 1$.[15] We use $I(f^{(n)}) = \langle :\omega^{\otimes n}:, f^{(n)} \rangle$ as a formal notation for the monomial introduced above. For Wick monomials associated to the kernels $f^{(n)} \in \mathcal{H}_{\mathbb{C}}^{\hat{\otimes} n}$ and $h^{(m)} \in \mathcal{H}_{\mathbb{C}}^{\hat{\otimes} m}$, $n,m \in \mathbb{N}_0$, we have the following orthogonality property:

$$(I(f^{(n)}), I(h^{(m)}))_{L^2(\mu)} = \int_{S'} \overline{\langle :\omega^{\otimes n}:, f^{(n)} \rangle} \langle :\omega^{\otimes m}:, h^{(m)} \rangle d\mu(\omega) = \delta_{n,m} n! (\overline{f^{(n)}}, h^{(n)}) \tag{4}$$

($\delta_{n,m}$ is the Kronecker delta).

Consider the space $\mathcal{P}(S')$ of smooth Wick polynomial on S':

$$\mathcal{P}(S') = \left\{ \varphi \,\middle|\, \varphi(\omega) = \sum_{n=0}^{N} \langle :\omega^{\otimes n}:, \varphi^{(n)} \rangle, \varphi^{(n)} \in S_{\mathbb{C}}^{\hat{\otimes} n}, \, \omega \in S', \, N \in \mathbb{N}_0 \right\}.$$

This space is dense in $L^2(\mu)$ and, as a consequence, for any $f \in L^2(\mu)$ we have the Itô–Segal–Wiener chaos decomposition,

$$f = \sum_{n=0}^{\infty} I(f^{(n)}), \quad f^{(n)} \in \mathcal{H}_{\mathbb{C}}^{\hat{\otimes} n}.$$

B. Generalized functions

For our considerations the space $L^2(\mu)$ is too small. A convenient way to solve this problem is to introduce a subspace of test functions in $L^2(\mu)$ and to use its larger dual space. In Gaussian analysis there exist various triples of test and generalized functions with $L^2(\mu)$ as a central space, here we choose the Kondratiev triple[29]

$$(S)^1 \subset L^2(\mu) \subset (S)^{-1}.$$

In order to construct these spaces of test and generalized functions, we define for any given $p,q \in \mathbb{Z}$ the following Hilbertian norm for the smooth Wick polynomials $\varphi(\omega) = \sum_{n=0}^{N} \langle :\omega^{\otimes n}:, \varphi^{(n)} \rangle$, $\omega \in S'$:

$$\|\varphi\|_{p,q,1}^2 := \sum_{n=0}^{\infty} (n!)^2 2^{nq} |\varphi^{(n)}|_p^2.$$

Then, for $p,q \in \mathbb{N}_0$, we define the Hilbert space $(\mathcal{H}_p)_q^1$ as the completion of $\mathcal{P}(S')$ w.r.t. $\|\cdot\|_{p,q,1}$. Or, equivalently,

$$(\mathcal{H}_p)_q^1 = \left\{ f \in L^2(\mu) \,\middle|\, f(\omega) = \sum_{n=0}^{\infty} \langle :\omega^{\otimes n}:, f^{(n)} \rangle, \, \|f\|_{p,q,1}^2 < \infty \right\}.$$

Finally, the space of test functions $(S)^1$ is defined as the projective limit of the spaces $(\mathcal{H}_p)_q^1$,

$$(S)^1 = \bigcap_{p,q \geqslant 0} (\mathcal{H}_p)_q^1.$$

Let $(\mathcal{H}_{-p})_{-q}^{-1}$ be the dual w.r.t. $L^2(\mu)$ of $(\mathcal{H}_p)_q^1$ and let $(S)^{-1}$ be the dual w.r.t. $L^2(\mu)$ of $(S)^1$. We know from general duality theory that[15]

$$(S)^{-1}=\bigcup_{p,q\geqslant 0}(\mathcal{H}_{-p})_{-q}^{-1}.$$

The bilinear dual pairing $\langle\langle\cdot,\cdot\rangle\rangle$ between $(S)^1$ and $(S)^{-1}$ is connected to the sesquilinear inner product on $L^2(\mu)$ by

$$\langle\langle f,\varphi\rangle\rangle=(\overline{f},\varphi)_{L^2(\mu)},\quad f\in L^2(\mu),\quad \varphi\in(S)^1. \tag{5}$$

Since the constant function 1 is in $(S)^1$, we may extend the notion of expectation from integrable functions to distributions $\Phi\in(S)^{-1}$:

$$\mathbb{E}_\mu(\Phi):=\langle\langle\Phi,1\rangle\rangle.$$

The chaos decomposition introduces the following natural decomposition of $\Phi\in(S)^{-1}$. Let $\Phi^{(n)}\in S_{\mathbb{C}}'^{\hat{\otimes}n}$ be given. Then there exists a distribution $I(\Phi^{(n)})$ acting on test functions $\varphi\in(S)^1$ as

$$\langle\langle I(\Phi^{(n)}),\varphi\rangle\rangle=n!\langle\Phi^{(n)},\varphi^{(n)}\rangle.$$

We use $I(\Phi^{(n)})=\langle:\omega^{\otimes n}:,\Phi^{(n)}\rangle$, as a formal notation for the distribution introduced above. Any $\Phi\in(S)^{-1}$ then has the unique decomposition

$$\Phi=\sum_{n=0}^{\infty}\langle:\omega^{\otimes n}:,\Phi^{(n)}\rangle, \tag{6}$$

where the sum converges in $(S)^{-1}$, and we have[29]

$$\langle\langle\Phi,\varphi\rangle\rangle=\sum_{n=0}^{\infty}n!\langle\Phi^{(n)},\varphi^{(n)}\rangle,\quad \varphi\in(S)^1.$$

Now it is not hard to see that $(\mathcal{H}_{-p})_{-q}^{-1}$ is a Hilbert space that can be described as follows:

$$(\mathcal{H}_{-p})_{-q}^{-1}=\{\Phi\in(S)^{-1}|\Phi^{(n)}\in S_{\mathbb{C}}'^{\hat{\otimes}n},\|\Phi\|_{-p,-q,-1}<\infty\}.$$

A useful tool in order to characterize $(S)^{-1}$ is the S transform. The S transform of elements from $(S)^{-1}$ is defined as the dual paring with the Wick exponential; see (3). Since the Wick exponential is not an element of $(S)^1$ the S transform of an element Φ from $(S)^{-1}$ is defined only locally, i.e.,

$$S\Phi(g):=\langle\langle\Phi,:\exp(\langle\cdot,g\rangle):\rangle\rangle,\quad g\in\mathcal{U}\subset S_{\mathbb{C}},$$

where $\mathcal{U}$ is an open neighborhood of zero depending on $\Phi\in(S)^{-1}$.

In order to characterize $(S)^{-1}$ we need to define holomorphic functions.

Definition II.1: Let $\mathcal{U}\subset S_{\mathbb{C}}$ be an open neighborhood of zero in $S_{\mathbb{C}}$. The map

$$F:\mathcal{U}\to\mathbb{C}$$

is holomorphic in $\mathcal{U}$ if it satisfies the following two properties.

(i) For each $g_0\in\mathcal{U}$, $g\in S_{\mathbb{C}}$, there exists a neighborhood $V_{g_0,g}$ around zero in $\mathbb{C}$, such that the map

$$z\mapsto F(g_0+zg)$$

is holomorphic in $V_{g_0,g}$.

(ii) For each $g\in\mathcal{U}$ *there exists an open set* $\mathcal{V}\subset\mathcal{U}$ *containing g such that* $F(\mathcal{V})$ *is bounded.*

Furthermore, if we identify two functions F_1 and F_2 coinciding on a neighborhood of zero, we can define $\mathrm{Hol}_0(S_{\mathbb{C}})$ as the space of germs of functions with the above properties.

The proof of the following characterization theorem is given in Ref. 29.

Theorem II.2: *(i) If* $\Phi\in(S)^{-1}$, *then* $S\Phi\in\mathrm{Hol}_0(S_{\mathbb{C}})$.

(ii) For any $F\in\mathrm{Hol}_0(S_{\mathbb{C}})$ *there exists a unique* $\Phi\in(S)^{-1}$ *such that* $S\Phi=F$.

As a consequence of this characterization we have the following corollary; for a proof we again refer to Ref. 29.

Corollary II.3: Let $(\Lambda, \mathcal{A}, \nu)$ *be a measure space and* $\lambda\mapsto\Phi_\lambda$ *a mapping from* Λ *to* $(S)^{-1}$. *Assume there exists an open neighborhood* $\mathcal{U}\subset S_{\mathbb{C}}$ *of zero such that (i)* $S\Phi_\lambda$, $\lambda\in\Lambda$, *is holomorphic on* $\mathcal{U}$; *(ii) the mapping* $\lambda\mapsto S\Phi_\lambda(g)$ *is measurable for every* $g\in\mathcal{U}$; *and (iii) there exists* $C\in L^1(\Lambda,\nu)$ *such that* $|S\Phi_\lambda(g)|\leqslant C(\lambda)$ *for all* $g\in\mathcal{U}$ *and for* ν*—almost all* $\lambda\in\Lambda$.

Then there are $p,q\in\mathbb{N}_0$ *such that* Φ *is Bochner integrable on* $(\mathcal{H}_{-p})^{-1}_{-q}$. *In particular,*

$$\int_\Lambda \Phi_\lambda\, d\nu(\lambda)\in(S)^{-1}.$$

Later on we also use the T transform of generalized functions, which is defined as

$$T\Phi(g):=\exp(-\tfrac{1}{2}|g|^2)\cdot S\Phi(ig),\quad \Phi\in(S)^{-1},\quad g\in\mathcal{U}. \tag{7}$$

An elementary calculation shows that the T transform is also given by

$$T\Phi(g)=\langle\langle\Phi,i\exp(\langle\cdot,g\rangle)\rangle\rangle,\quad g\in\mathcal{U}. \tag{8}$$

The characterization theorem and its corollary are also valid for the T transform.

For elements from $(S)^{-1}$ we can define the Wick product.

Definition II.4: Let $\Phi,\Psi\in(S)^{-1}$. *Then we define the Wick product by*

$$\Phi\diamond\Psi:=S^{-1}(S\Phi\cdot S\Psi).$$

This is well defined because $\mathrm{Hol}_0(S_{\mathbb{C}})$ is an algebra and thus by the characterization theorem in $(S)^{-1}$ there exists a unique element $\Phi\diamond\Psi$ such that $S(\Phi\diamond\Psi)=S\Phi\cdot S\Psi$. Clearly, this multiplication is associative.

By induction, we can define Wick powers,

$$\Phi^{\diamond n}=S^{-1}((S\Phi)^n)$$

in $(S)^{-1}$, and by taking finite linear combinations of them also Wick polynomials of finite order $\Sigma_{n=1}^N a_n\Phi^{\diamond n}$ can be defined in $(S)^{-1}$. Moreover, it is even possible to define Wick analytic functions in $(S)^{-1}$ under very general assumptions.

Theorem II.5: *Let F be analytic in a neighborhood of the point* $z_0=\mathbb{E}_\mu(\Phi)$ *in* $\mathbb{C}$, $\Phi\in(S)^{-1}$. *Then* $F^\diamond(\Phi)$ *defined as* $F^\diamond(\Phi):=S^{-1}(F(S\Phi))$ *exists in* $(S)^{-1}$.

For a proof we refer to Ref. 29.

Remark II.6: Let F be analytic at $z_0=\mathbb{E}_\mu(\Phi)$, $\Phi\in(S)^{-1}$, *i.e., F has the power series representation* $F(z)=\Sigma_n a_n(z-z_0)^n$, $z,a_n\in\mathbb{C}$. *Then the Wick series* $\Sigma_n a_n(\Phi-z_0)^{\diamond n}$ *converges in* S^{-1} *and*

$$F^\diamond(\Phi)=\sum_{n=1}^\infty a_n(\Phi-z_0)^{\diamond n}.$$

III. EUCLIDEAN QFT IN THE FRAMEWORK OF WHITE NOISE ANALYSIS

A. OS axioms in terms of the *T* transform

In 1973, Nelson[30] showed how to construct a relativistic QFT from a Euclidean Markov field. Inspired by this, Osterwalder and Schrader[6,31–34] gave a set of axioms, where Schwinger functions $(\mathcal{S}_n)_{n\in\mathbb{N}_0}$ defined on the Euclidean space–time can be analytically continued to Wightman distributions, i.e., to vacuum expectation values of a relativistic QFT. The OS axioms for a single, scalar field are the following.

OS1 (temperedness)**:** The sequence $(\mathcal{S}_n)_{n\in\mathbb{N}_0}$ is a sequence of tempered distributions, where $\mathcal{S}_n\in S'_{\mathbb{C}}(\mathbb{R}^{dn})$ and $S_0=1$. There exists $p\in\mathbb{N}$ and a sequence $(\sigma_n)_{n\in\mathbb{N}}$ of factorial growth such that for all $n\in\mathbb{N}$ the Schwinger functions fulfill the growth condition of the form

$$|\mathcal{S}_n(f_1\otimes\cdots\otimes f_n)|\leq\sigma_n\prod_{i=1}^{n}|f_i|_p,$$

where $f_1,\ldots,f_n\in S_{\mathbb{C}}(\mathbb{R}^d)$. A sequence $(\sigma_n)_{n\in\mathbb{N}}$ of positive numbers is said to be of factorial growth if the existent constants $\alpha,\beta\in\mathbb{R}^+$ such that

$$\sigma_n\leq\alpha(n!)^\beta,\quad\forall n\in\mathbb{N}.$$

OS2 (Euclidean invariance)**:** Each $\mathcal{S}_n$ is Euclidean invariant, i.e.,

$$\mathcal{S}_n(E_{(a,\Lambda)}f)=\mathcal{S}_n(f),\quad\forall f\in S_{\mathbb{C}}(\mathbb{R}^{dn}),$$

for all $(a,\Lambda)\in E^+(\mathbb{R}^d)$, the proper Euclidean group, where

$$E_{(a,\Lambda)}f(x_1,\ldots,x_n)=f(\Lambda^{-1}(x_1-a),\ldots,\Lambda^{-1}(x_n-a)),$$

for $a\in\mathbb{R}$, $\Lambda\in SO(d)$.

OS3 (reflection positivity)**:** For each sequence $(f_n)_{n\in\mathbb{N}_0}$, where $f_n\in S_{\mathbb{C}}(\mathbb{R}^{dn}_<)$, $f_0\in\mathbb{C}$, and for each $k\in\mathbb{N}_0$,

$$\sum_{n,m=0}^{k}S_{n+m}((\theta f_n)^*\otimes f_m)\geq0,$$

where $(\theta f_n)(t_1,\vec{x}_1;\ldots;t_n,\vec{x}_n)=f_n(-t_1,\vec{x}_1;\ldots;-t_n,\vec{x}_n)$, $t_i\in\mathbb{R}$, $\vec{x}_i\in\mathbb{R}^{d-1}$ (time reflection), $f_n^*(x_1,\ldots,x_n):=\overline{f_n(x_n,\ldots,x_1)}$, and the overbar denotes complex conjugation. The space $S_{\mathbb{C}}(\mathbb{R}^{dn}_<)$ is the space of Schwartz test functions having support in $\mathbb{R}^{dn}_<:=\{(t_1,\vec{x}_1;\ldots;t_n,\vec{x}_n)\in\mathbb{R}^{dn}|0<t_1<\cdots<t_n\}$.

OS4 (symmetry)**:** For $n\geq2$ and all $\pi\in\Sigma_n$, the permutation group,

$$\mathcal{S}_n(f_1\otimes\cdots\otimes f_n)=\mathcal{S}_n(f_{\pi(1)}\otimes\cdots\otimes f_{\pi(n)}),$$

where $f_1,\ldots,f_n\in S_{\mathbb{C}}(\mathbb{R}^d)$.

OS5 (cluster property)**:** For all $a\in\mathbb{R}$, $a\neq0$, and $m,n\geq1$,

$$\lim_{\lambda\to\infty}(\mathcal{S}_{m+n}(f_1\otimes\ldots\otimes f_m\otimes E_{(\lambda a,0)}(f_{m+1}\otimes\ldots\otimes f_{m+n}))-\mathcal{S}_m(f_1\otimes\ldots\otimes f_m)\mathcal{S}_n(f_{m+1}\otimes\ldots\otimes f_{m+n}))=0,$$

where $f_1,\ldots,f_{m+n}\in S_{\mathbb{C}}(\mathbb{R}^d)$.

Remark III.1 The assumptions in axiom (OS1) can be slightly weakened.[31] For technical reasons, by using this formulation it is convenient for us, and since the sequences of generalized functions we consider fulfill (OS1), we do not lose anything by this slightly stronger formulation.

In the case of Euclidean Markov fields, and also in the more general case of Euclidean reflection positivity fields,[35] Schwinger functions fulfilling (OS1)–(OS5) are obtained as the moments of the Euclidean field. In this section we construct Schwinger functions $(\mathcal{S}_n^{\Phi})_{n\in\mathbb{N}_0}$ that are moments of generalized functions $\Phi\in(S)^{-1}$ with $\mathbb{E}_{\mu}(\Phi)=1$. The moments $(\mathcal{S}_n^{\Phi})_{n\in\mathbb{N}_0}$, in general, do not satisfy all axioms (OS1)–(OS5). Nevertheless, we call them Schwinger functions because our aim is to work out a class of generalized functions $\Phi\in(S)^{-1}$ such that their moments fulfill all or a part of the OS axioms.

Definition III.2: Let $f_1,\dots,f_n\in S(\mathbb{R}^d)$, $n\in\mathbb{N}$. *The* nth *Schwinger function corresponding to* $\Phi\in(S)^{-1}$, $\mathbb{E}_{\mu}(\Phi)=1$, *is given as*

$$\mathcal{S}_n^{\Phi}(f_1\otimes\cdots\otimes f_n)=\langle\langle\Phi,\langle\omega,f_1\rangle\cdot\ \cdots\ \cdot\langle\omega,f_n\rangle\rangle\rangle,$$

and $\mathcal{S}_0^{\Phi}=\mathbb{E}_{\mu}(\Phi)=1$.

Since $\mathcal{P}(S')\subset(S)^1$, the dual paring in the above definition is well defined.

The Schwinger functions corresponding to $\Phi\in(S)^{-1}$ can be calculated via their T transform; see (8).

Proposition III.3 (Wick theorem)*:* Let $f_1,\dots,f_n\in S(\mathbb{R}^d)$, $n\in\mathbb{N}$. *Then the* nth *Schwinger functions corresponding to* $\Phi\in(S)^{-1}$ *is given by*

$$\mathcal{S}_n^{\Phi}(f_1\otimes\cdots\otimes f_n)=(-i)^n\frac{\partial^n}{\partial t_1\cdots\partial t_n}T\Phi(t_1f_1+\cdots+t_nf_n)\bigg|_{t_1=\cdots t_n=0}.$$

Proof: By construction, every distribution $\Phi\in(S)^{-1}$ is of finite order, i.e., for each $\Phi\in(S)^{-1}$ there exist $p,q\in\mathbb{N}_0$, such that $\Phi\in(\mathcal{H}_{-p})_{-q}^{-1}$. Furthermore, a straightforward calculation shows that for each $f\in S(\mathbb{R}^d)$ there exists $t_0>0$ such that $\exp(it\langle\cdot,f\rangle)\in(\mathcal{H}_p)_q^1$ for all $0\leqslant t<t_0$, and

$$-i\frac{d}{dt}\exp(it\langle\cdot,f\rangle)\bigg|_{t=0}=\langle\cdot,f\rangle,$$

w.r.t. the Hilbert space norm in $(\mathcal{H}_p)_q^1$. From this we can conclude that

$$\mathcal{S}_1^{\Phi}(f)=-i\frac{d}{dt}T\Phi(tf)\bigg|_{t=0}=-i\frac{d}{dt}\langle\langle\Phi,\exp(it\langle\cdot,f\rangle)\rangle\rangle\bigg|_{t=0}.$$

Since $(S)^1$ is an algebra under multiplication and this multiplication is continuous, we can define the pointwise product $\Phi\cdot\varphi\in(S)^{-1}$ of a distribution $\Phi\in(S)^{-1}$ with a test function $\varphi\in(S)^1$ via the dual paring. Utilizing this product, the proposition follows by an induction argument. ∎

Proposition III.4: For each generalized function $\Phi\in(S)^{-1}$ *with* $\mathbb{E}_{\mu}(\Phi)=1$, *the Schwinger functions* $(\mathcal{S}_n^{\Phi})_{n\in\mathbb{N}^0}$ *fulfill the axioms (OS1) and (OS4). Furthermore, (OS2) is fulfilled if* $T\Phi$ *is Euclidean invariant.*

Proof: The Schwinger functions $(\mathcal{S}_n^{\Phi})_{n\in\mathbb{N}_0}$ are symmetric by definition. Temperedness and factorial growth follows immediately from the fact that $\Phi\in(S)^{-1}$. Thus, (OS1) and (OS4) are fulfilled.

Assume that $T\Phi$ is Euclidean invariant. Then we apply Proposition III.3 to calculate the nth Schwinger function corresponding to Φ; of course, it is also Euclidean invariant. ∎

B. Euclidean-invariant distributions

In this section we construct a class of Euclidean-invariant generalized functions. We call generalized functions from $(S)^{-1}$ Euclidean invariant if their T transform is Euclidean invariant. Our construction is motivated by the Euclidean strategy for constructing interacting field theories; see, e.g., Refs. 1 and 2 and the references therein. In the framework of a white noise analysis, we can define the Gaussian random process indexed by $\mathcal{H}=L^2(\mathbb{R}^d)$ as

$$\phi(h):=\langle\cdot,h\rangle,\quad h\in L^2(\mathbb{R}^d).$$

As discussed in Sec. II A, $\phi(h)$ is an element of $L^2(\mu)$ for all $h\in L^2(\mathbb{R}^d)$. We are interested in the Gaussian random process ϕ at time that $t\in\mathbb{R}$ and at the point $\vec{x}\in\mathbb{R}^{d-1}$, where we write $x\in\mathbb{R}^d$ as $x=(t,\vec{x})$. $\phi(t,\vec{x})$ does not exist as a square-integrable function, but we can define

$$\phi(t,\vec{x}):=\langle\cdot,\delta_{t,\vec{x}}\rangle,\qquad \in(S)^{-1},$$

see (6) where $\delta_{t,\vec{x}}\in S'(\mathbb{R}^d)$ is the Dirac delta function at point $(t,\vec{x})\in\mathbb{R}^d$.

Assume that $H(z)=\Sigma_{k=0}^{\infty}(1/k!)H_k z^k$, $z\in U\subset\mathbb{C}$, is a holomorphic function in U, where U is an open neighborhood of $\mathbb{E}_\mu(\phi(t,\vec{x}))=0$. Then by using Theorem II.5, we can define

$$H^\diamond(\phi(t,\vec{x}))=\sum_{k=0}^{\infty}\frac{1}{k!}H_k\phi(t,\vec{x})^{\diamond k}\in(S)^{-1}=\sum_{k=0}^{\infty}\frac{1}{k!}H_k\langle:\omega^{\otimes k}:,\delta_{t,\vec{x}}^{\otimes k}\rangle;$$

also see Remark II.6.

Next, we want to define the integral

$$\int_{\mathbb{R}^d}H^\diamond(\phi(x))d^dx. \tag{9}$$

This can only be possible if we assume that $H_0=0$.

Theorem III.5: *Let H be holomorphic at zero such that* $H(0)=0$, *then (9) exists as a Bochner integral in a suitable subspace of* $(S)^{-1}$.

Proof: Our aim is to apply Corollary II.3. Let $r>0$ be in the radius of convergence of the Taylor expansion of H at the origin. We define

$$\mathcal{U}=\{g\in S_{\mathbb{C}}|\sup_{x\in\mathbb{R}^d}\{(1+|x|^2)^d|g(x)|\}<r\}.$$

It is easy to check that $\mathcal{U}$ is an open neighborhood of zero. For $g\in\mathcal{U}$ we have

$$\begin{aligned}S(H^\diamond(\phi(x)))(g)&=\sum_{k=1}^{\infty}\frac{1}{k!}H_k\langle g^{\otimes k},\delta_x^{\otimes k}\rangle=\sum_{k=1}^{\infty}\frac{1}{k!}H_k g(x)^k\leqslant\sum_{k=1}^{\infty}|r^{-1}g(x)|^k|H_k|\frac{r^k}{k!}\\&\leqslant\frac{1}{(1+|x|^2)^d}(1+|x|^2)^d|g(x)|r^{-1}\sum_{k=1}^{\infty}|H_k|\frac{r^k}{k!}\leqslant\frac{1}{(1+|x|^2)^d}\sum_{k=1}^{\infty}|H_k|\frac{r^k}{k!}.\end{aligned}\tag{10}$$

Obviously, $S(H^\diamond(\phi(\cdot)))(g)$ is measurable for all $g\in\mathcal{U}$. With the estimate (10) the holomorphy of $S(H^\diamond(\phi(x)))$ is clear. Since $(1+|x|^2)^{-d}\in L^1(\mathbb{R}^d)$, all assumption required in Corollary II.3 are fulfilled and the theorem is proved. ■

Corollary III.6: Let the function H be as in Theorem III.5. Then the generalized function,

$$\Phi_H:=\exp^\diamond\left(-\int_{\mathbb{R}^d}H^\diamond(\phi(x))d^dx\right),$$

is an elements of $(S)^{-1}$. *Its T transform is given by*

$$T\Phi_H(g)=\exp\left(-\int_{\mathbb{R}^d}H(ig(x))+\frac{1}{2}g(x)^2\,d^dx\right),$$

for all g in a neighborhood $\mathcal{U}\subset S_{\mathbb{C}}$ *of zero. In particular*, $\mathbb{E}_\mu(\Phi_H)=1$.

Proof: This corollary is an immediate consequence of Theorem II.5. For the calculation of the T transform, we used (7). Observe that $\mathbb{E}_\mu(\Phi_H)=T\Phi_H(0)$. ■

Remark III.7: (i) Since the Lebesgue measure on $\mathbb{R}^d$ *is Euclidean-invariant* $T\Phi_H$ *is Euclidean invariant.*

(ii) Consider the case in which the function $F(s) := -(H(is)+\frac{1}{2}s^2)$, $s\in\mathbb{R}$, *is a Lévy characteristic, i.e.,*

$$F(s)=ias-\frac{\sigma^2 s^2}{2}+\int_{\mathbb{R}\setminus\{0\}}\left(\exp(irs)-1-\frac{irs}{1+r^2}\right)d\nu(r),\quad s\in\mathbb{R},$$

where $a\in\mathbb{R}$, $\sigma\geqslant 0$, *and the measure* ν *satisfies the following condition:*

$$\int_{\mathbb{R}\setminus\{0\}}\min\{1,r^2\}d\nu(r)<\infty.$$

Then by the Lévy–Khinchine theorem[36] *we know that there exists a probability measure* P_H *on* $S'(\mathbb{R}^d)$ *such that*

$$T\Phi_H(f)=\int_{S'(\mathbb{R}^d)}\exp(i\langle\omega,f\rangle)dP_H(\omega),\quad f\in S(\mathbb{R}^d).$$

This implies that the Schwinger functions $(\mathcal{S}_n^{\Phi_H})_{n\in\mathbb{N}_0}$ *are the moments of the measure* P_H*. These measures are called generalized white noise measures.*

Next, we enlarge the class of Euclidean-invariant distributions. We do this by convolution with kernels associated to Euclidean-invariant operators. This idea is inspired by the method used in Ref. 5. There the authors started with Euclidean-invariant measures from the Lévy–Khinchine class and then they constructed image measures by convoluting the corresponding generalized white noise with kernels associated to Euclidean-invariant operators. These image measures are called convoluted generalized white noise measures.

Let $\mathcal{G}:S(\mathbb{R}^d)\to S(\mathbb{R}^d)$ be a linear continuous mapping. Then by the well-known kernels theorem there exists a distribution $K\in S'(\mathbb{R}^{2d})$, hereafter called the kernel of $\mathcal{G}$, such that

$$\mathcal{G}f(x)=\int_{\mathbb{R}^d}K(x,y)f(y)dy,\quad f\in S(\mathbb{R}^d),\quad x\in\mathbb{R}^d,$$

in the distributional sense. It is clear that the adjoint operator $\mathcal{G}^*:S'(\mathbb{R}^d)\to S'(\mathbb{R}^d)$ is a measurable transformation from $(S'(\mathbb{R}^d),\mathcal{C}_\sigma(S'(\mathbb{R}^d)))$ into itself. Furthermore, we assume that $\mathcal{G}$ is Euclidean invariant, i.e., $\mathcal{G}E_{(a,\wedge)}=E_{(a,\wedge)}\mathcal{G}$ for all $E_{(a,\wedge)}\in E^+(\mathbb{R}^d)$. This implies that $\mathcal{G}$ is translation invariant, thus, its kernel K has the form $K(x,y)=G(x-y)$.[7] The action of $\mathcal{G}$ on test functions from $S(\mathbb{R}^d)$ [and by duality on $S'(\mathbb{R}^d)$] is, by convolution,

$$\mathcal{G}f(x)=\int_{\mathbb{R}^d}G(x-y)f(y)dy,\quad f\in S(\mathbb{R}^d),\quad x\in\mathbb{R}^d.$$

We can also write $\mathcal{G}f$ as $G*f$. From now on we assume $\mathcal{G}$ to be essentially self-adjoint in $L^2(\mathbb{R}^d)$, with $S(\mathbb{R}^d)$ as a core. Then the convolution of the Gaussian random process ϕ with G is defined as

$$(G*\phi)(h)(\omega):=\langle G*\omega,f\rangle=\langle\omega,G*f\rangle,\quad \omega\in S'(\mathbb{R}^d),\quad f\in S(\mathbb{R}^d).$$

This definition can also be generalized from test functions f to tempered distributions. Then the process is in $(S)^{-1}$.

Example III.8: Let Δ *be the Laplace operator on* $\mathbb{R}^d$*. Let* $K(x,y)=G_\alpha(x-y)$ *be the Green's function of the pseudodifferential operator* $\mathcal{G}_\alpha=(-\Delta+m_0^2)^{-\alpha}$ *for some arbitrary* $m_0>0$ *and* $0<\alpha$*. It is given by*

$$G_\alpha(x)=\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\frac{\exp(ikx)}{(|k|^2+m_0^2)^\alpha}dk,\quad x\in\mathbb{R}^d,$$

where the integral has to be understood in the sense of a Fourier transform of a tempered distribution. One easily proves that $\mathcal{G}_\alpha:S(\mathbb{R}^d)\to S(\mathbb{R}^d)$ is continuous, essentially self-adjoint in $L^2(\mathbb{R}^d)$ with $S(\mathbb{R}^d)$ as a core, and Euclidean invariant.

Let $\Phi\in(S)^{-1}$ be a generalized function. We define its convolution with a Euclidean invariant kernel G by

$$T\Phi^G(g):=T\Phi(G*g),\quad g\in\mathcal{U}\subset S_{\mathbb{C}}(\mathbb{R}^d),$$

where $\mathcal{U}$ is an open neighborhood of zero. Since the operator $\mathcal{G}$ is linear and continuous, the characterization, Theorem II.2, implies that Φ^G is a well-defined and unique element in $(S)^{-1}$.

Theorem III.9: *Let H be as in Theorem III.5 and let the operator $\mathcal{G}$ be continuous in $S(\mathbb{R}^d)$, essentially self-adjoint in $L^2(\mathbb{R}^d)$ with $S(\mathbb{R}^d)$ as a core, and Euclidean invariant. Then the generalized function $\Phi_H^G\in(S)^{-1}$ is Euclidean invariant and can be written as*

$$\Phi_H^G=\exp^\diamond\left(-\int_{\mathbb{R}^d}H^\diamond(G*\phi(x))d^dx+\frac{1}{2}\langle :\cdot^{\otimes 2}:,(\mathcal{G}^{\otimes 2}-1)\mathrm{Tr}\rangle\right);\tag{11}$$

here $Tr\in S'(\mathbb{R}^d)^{\hat{\otimes}2}$ denotes the trace kernel defined by $\langle Tr,f\otimes g\rangle=(f,g)$, $f,g\in S(\mathbb{R}^d)$. The Schwinger functions $(\mathcal{S}_n^{H,G})_{n\in\mathbb{N}_0}$ (with the abbreviation $\mathcal{S}^{H,G}=\mathcal{S}^{\Phi_H^G}$) fulfill the axioms $(OS1)$, $(OS2)$, and $(OS4)$.

Remark III.10: In the case where F is a Lévy characteristic, see Remark III.7(ii), the measure P_H^G corresponding to the distribution Φ_H^G is an image measures of the measure P_H, more concretely, $P_H^G(A)=P_H(\mathcal{G}^{-1}A)$, $A\in\mathcal{C}_\sigma(S'(\mathbb{R}^d))$

Proof of Theorem III.9: Formula (11) is clear by taking its T transform. Euclidean invariance follows from the Euclidean invariance of $\mathcal{G}$ and Φ_H. Obviously, $\mathbb{E}_\mu(\Phi_H)=1$, thus the theorem follows by an application of Proposition III.3. ■

Example III.11: The choice $H\equiv 0$ and $\mathcal{G}_{1/2}=(-\Delta+m_0^2)^{-1/2}$ gives the free Euclidean field with mass $m_0>0$; see Example III.8. Theorem III.9 implies that the corresponding measure $P_0^{G_{1/2}}$ has the generalized density

$$\Phi_0^{G_{1/2}}=\exp^\diamond\left(\tfrac{1}{2}\langle :\cdot^{\otimes 2}:,(\mathcal{G}_{1/2}^{\otimes 2}-1)Tr\rangle\right),$$

w.r.t. the Gaussian white noise measure.

Remark III.12: Consider the Hilbert space N_{m_0}, which is defined as the closure of $S(\mathbb{R}^d)$ w.r.t. the Hilbert space norm $|\cdot|_{m_0}$ given by the scalar product

$$(f,g)_{m_0}:=\int_{\mathbb{R}^d}f(x)(-\Delta+m_0^2)^{-1}g(x)dx,\quad f,g\in S(\mathbb{R}^d),\quad m_0>0.$$

The random process indexed by $\mathcal{H}=N_{m_0}$:

$$\phi(h):=\langle\cdot,h\rangle_{m_0},\quad h\in N_{m_0},$$

is the free Euclidean field with mass m_0. Since N_{m_0} fulfills the assumptions on the Hilbert space $\mathcal{H}$ required in Sec. II A, it is also possible to take the measure corresponding to the free Euclidean field as a reference measure for the Euclidean-invariant distributions constructed above (this is the usual choice in constructive Euclidean QFT). Here we have chosen the white noise measure because it has the identity operator as a covariance operator. This is a reasonable choice for our approach, which involves a convolution with the operator kernel G.

In Ref. 5 the authors studied Schwinger functions $(\mathcal{S}_n^{H,G})_{n\in\mathbb{N}_0}$ that are moments of the measures P_H^G corresponding to the generalized functions Φ_H^G, where $F(s)=-(H(is)+\frac{1}{2}s^2)$, $s\in\mathbb{R}$, is a Lévy characteristic; see Remark III.7 (ii) and Remark III.10 For the truncated Schwinger functions the authors worked out explicit formulas. Before we give them let us recall the definition of truncated Schwinger functions.

A partition of the ordered set $\{1,...,n\}$ is a family of ordered subsets $I_1=\{i_1,\dots,i_{k(1)}\},\dots,I_l=\{i'_1,\dots,i'_{k(l)}\}$, so that $i_1<\cdots<i_{k(1)},\dots,i'_1<\cdots<i'_{k(l)}$ and so that $\cup_{1\leqslant j\leqslant l}I_j=\{1,...,n\}$ and $I_j\cap I_q=\emptyset$, $j\neq q$. The set of all partitions of $\{1,...,n\}$ we denote as $P^{(n)}$.

Definition III. 13: The truncated Schwinger functions $(\mathcal{S}_{n,T})_{n\in\mathbb{N}_0}$ corresponding to a given sequence of Schwinger functions $(\mathcal{S}_n)_{n\in\mathbb{N}_0}$ are defined recursively by the relation

$$\mathcal{S}_n(f_1\otimes\cdots\otimes f_n)=\sum_{P^{(n)}}\mathcal{S}_{k(1),T}(f_{i_1}\otimes\cdots\otimes f_{i_{k(1)}})\cdot\ \cdots\ \cdot\mathcal{S}_{k(l),T}(f_{i'_1}\otimes\cdots\otimes f_{i'_{k(l)}}),$$

where $f_1,\dots,f_n\in S(\mathbb{R}^d)$, $n\geqslant1$.

Proposition III.14: Let $H(z)=\Sigma_{n=0}^{\infty}(1/n!)H_nz^n$, $z\in U\subset\mathbb{C}$, and $\mathcal{G}$ be as in Theorem III.9 and $f_1,\dots,f_n\in S(\mathbb{R}^d)$, $n\geqslant1$. Then the truncated Schwinger functions $(\mathcal{S}_{n,T}^{H,G})_{n\in\mathbb{N}}$ are given by

$$\mathcal{S}_{n,T}^{H,G}(f_1\otimes\cdots\otimes f_n)=-H_n\int_{\mathbb{R}d}G*f_1(x)\cdot\ \cdots\ \cdot G*f_n(x)d^dx,\quad n\neq2,$$

$$\mathcal{S}_{2,T}^{H,G}(f_1\otimes f_2)=(-H_2+1)\int_{\mathbb{R}d}G*f_1(x)\cdot G*f_2(x)d^dx. \tag{12}$$

Proof: In the case where $F(s)=-(H(is)+\frac{1}{2}s^2)$, $s\in\mathbb{R}$ is a Lévy characteristic, this follows from Proposition 3.9 in Ref. 5 and the uniqueness of the truncated Schwinger functions. The coefficients in front of the integrals corresponding to the nth truncated Schwinger function in (12) are just the nth derivatives of the Lévy characteristic divided by i^n. Hence, for a general H as in Theorem III.9 these coefficients are given by the nth derivative of $-(H(iz)+\frac{1}{2}z^2)$, $z\in U$. ■

In Corollary 4.7. of Ref. 5, the authors have proved the cluster property of the Schwinger functions $(\mathcal{S}_n^{H,G})_{n\in\mathbb{N}_0}$ arising from measures. The proof given there easily generalizes to our case.

Theorem III.15: Let $\Phi_H^G\in(S)^{-1}$ *be as in Theorem III.9. Then the corresponding Schwinger functions $(\mathcal{S}_n^{H,G})_{n\in\mathbb{N}_0}$ fulfill the cluster property (OS5), i.e., for all $a\in\mathbb{R}$, $a\neq0$, and $m,n\geqslant1$,*

$$\lim_{\lambda\to\infty}(\mathcal{S}_{m+n}^{H,G}(f_1\otimes\cdots\otimes f_m\otimes E_{(\lambda a,0)}(f_{m+1}\otimes\cdots\otimes f_{m+n}))-\mathcal{S}_m^{H,G}(f_1\otimes\cdots\otimes f_m)$$
$$\times\mathcal{S}_n^{H,G}(f_{m+1}\otimes\cdots\otimes f_{m+n}))=0,$$

where $f_1,\dots,f_{m+n}\in S(\mathbb{R}^d)$.

Proof: See the proof of Corollary 4.7 in Ref. 5. There the authors proved the cluster property in the case where $F(s)=-(H(is)+\frac{1}{2}s^2)$, $s\in\mathbb{R}$ is a Lévy characteristic. The idea is to express the cluster property of the Schwinger functions as an equivalent property of the truncated Schwinger functions. Since their proof works independently of the choice of the coefficients in front of the integrals corresponding to the nth truncated Schwinger function, see (12), it easy generalizes to our case. ■

Remark III.16: The class of Schwinger functions $(\mathcal{S}_n^{H,G})_{n\in\mathbb{N}_0}$ corresponding to the distributions $\Phi_H^G\in(S)^{-1}$ as in Theorem III.9 differs from the class of Schwinger functions corresponding to the convoluted generalized white noise measures in Ref. 5. Let us compare the properties of the Lévy characteristics F that have been used in Ref. 5 with the properties of the functions H we employ, where $F(s)=-(H(is)+\frac{1}{2}s^2)$, $s\in\mathcal{O}\subset\mathbb{R}$.

We need that the function H is holomorphic at zero and $H(0)=0$. *This is our restriction in choosing the coefficients in front of the integrals corresponding to the* nth *truncated Schwinger function; see (12).*

In Ref. 5 the authors needed the condition that the measure ν *in the representation of the Lévy characteristic, see Remark III.7(ii), has finite moments to all orders. This implies that* $F \in C^{\infty}(\mathbb{R})$, *but F does not have to have a holomorphic extension. Furthermore, also* $F(0)=0$ *and F cannot be a polynomial of order larger than 2. That is, if only finite many* $H_n, n \in \mathbb{N}$, *are different from zero then all* H_n, $n \geqslant 3$, *have to be zero. Furthermore, the constant* $-H_n$ *is the* nth *moment of the measure* ν *for* $n \geqslant 3$.

IV. ON REFLECTION POSITIVITY, ANALYTIC CONTINUATION, AND QFT WITH INDEFINITE METRIC

A. Reflection positivity

In Sec. III B, we proved all OS axioms for Schwinger functions $(\mathcal{S}_n^{H,G})_{n \in \mathbb{N}_0}$ corresponding to the distributions $\Phi_H^G \in (S)^{-1}$, H,G as in Theorem III.9, except for reflection positivity.

In Ref. 5 the authors present a partial negative result on reflection positivity of Schwinger functions $(\mathcal{S}_n^{H,G})_{n \in \mathbb{N}_0}$, which are moments of convoluted generalized white noise P_H^G. Consider a Lévy characteristic represented as in Remark III 7(ii). The part arising from the measure ν is called the Poisson part and the other part is called the Gaussian part (the reason for these names and decomposition lies in the properties of the corresponding measures). For the Schwinger functions $(\mathcal{S}_n^{H,G})_{n \in \mathbb{N}_0}$ that are moments of convoluted generalized white noises P_H^G with the nonzero Poisson in part in Ref. 5, some examples have been constructed that do not have the reflection positivity property. Roughly speaking, the Schwinger functions $(\mathcal{S}_n^{H,G})_{n \in \mathbb{N}_0}$ do not have the reflection positivity property, if the terms in $\mathcal{S}_n^{H,G}$ emerging from the ''interaction'' (Poisson part) are large in comparison with the ''free'' terms (the Gaussian part). More details on this considerations can be found in Ref. 5, Remark 5.12.

We discuss the question of whether reflection positivity holds or does not hold in the next section in terms of the Wightman functions; see Theorem IV.2 and Remark IV.3.

B. Analytic continuation to Wightman functions

If a sequence of Schwinger functions fulfills all OS axioms one can perform the analytic continuation to Wightman functions via the reconstruction theorem.[6] These Wightman functions fulfill the Wightman axioms

W1 (temperedness)**:** The sequence $(W_n)_{n \in \mathbb{N}_0}$ is a sequence of tempered distributions, where $W_n \in S'_{\mathbb{C}}(\mathbb{R}^{dn})$ and $W_0=1$. These functions fulfill the Hermiticity condition

$$\overline{W_n(f)} = W_n(f^{\star}).$$

W2 (Poincaré invariance)**:** Each W_n is Poincaré invariant, i.e.,

$$W_n(P_{(a,\Lambda)}f) = W_n(f), \quad \forall f \in S_{\mathbb{C}}(\mathbb{R}^{dn}),$$

for all $(a,\Lambda) \in P_+^{\uparrow}(\mathbb{R}^d)$, where $P_+^{\uparrow}(\mathbb{R}^d)$ is the proper, orthochronous Poincaré group. The definition of $P_{(a,\Lambda)}f$ is analog to the definition of Euclidean transformations in $S_{\mathbb{C}}(\mathbb{R}^{dn})$; see (OS2).

W3 (positivity)**:** For each sequence $(f_n)_{n \in \mathbb{N}_0}$, where $f_n \in S_{\mathbb{C}}(\mathbb{R}^{dn})$, $f_0 \in \mathbb{C}$, and each $k \in \mathbb{N}_0$,

$$\sum_{n,m=0}^{k} W_{n+m}(f_n^{\star} \otimes f_m) \geqslant 0.$$

W4 (locality)**:** If for $n \geqslant 2$ for some $1 \leqslant j \leqslant n-1$: $\langle x_{j+1}-x_j, x_{j+1}-x_j \rangle_M < 0$, then

$$W_n(x_1,\ldots,x_j,x_{j+1},\ldots,x_n) = W_n(x_1,\ldots,x_{j+1},x_j,\ldots,x_n),$$

where $\langle x,x\rangle_M = t^2 - |\vec{x}|^2$, $x=(t,\vec{x})\in\mathbb{R}^d$, is the Minkowski inner product.

We remark that by (W2) every W_n is actually a distribution in the difference variables, i.e., there is a tempered distribution $w_n \in S'_{\mathbb{C}}(\mathbb{R}^{d(n-1)})$, defined as

$$w_n(x_1-x_2,\dots,x_{n-1}-x_n) := W_n(x_1,\dots,x_n).$$

The Fourier transform on $S_{\mathbb{C}}(\mathbb{R}^{dn})$ and $S'_{\mathbb{C}}(\mathbb{R}^{dn})$, respectively, we denote by $\mathcal{F}$ or $\hat{}$ and is taken w.r.t. the Euclidean inner product. The forward mass cone of mass m_0 is defined as

$$V^+_{m_0} := \{p\in\mathbb{R}^d | p^2 > m_0^2, \quad p^0 = \langle p, e_0\rangle_M > 0\}, \quad m_0 \geqslant 0,$$

where $e_0=(1,0,0,0)$. By $V^{\star,+}_{m_0}$ we denote its closure and V^+_0 is called a forward light cone. The backward mass cone is defined by $V^-_{m_0} := \theta V^+_{m_0}$ where θ again denotes the time reflection.

W5 (spectral condition)**:** For any $n\geqslant 2$ the Fourier transform $\hat{w}_n$ has support in the $(n+1)$-fold product of the forward light cone $(V^{\star +}_0)^{n-1}$.

W6 (cluster property)**:** For any $n,m\in\mathbb{N}$ and any space like $a\in\mathbb{R}^d$, i.e., $\langle a,a\rangle_M<0$,

$$\lim_{\lambda\to\infty} \big(W_{m+n}(f_1\otimes\cdots\otimes f_m\otimes T_{\lambda a}(f_{m+1}\otimes\cdots\otimes f_{m+n})) - W_m(f_1\otimes\cdots\otimes f_m)W_n(f_{m+1}\otimes\cdots\otimes f_{m+n})\big) = 0,$$

for $f_1,\dots,f_{m+n}\in S_{\mathbb{C}}(\mathbb{R}^d)$, where $T_{\lambda a}$ denotes the translation by λa.

Without reflection positivity we cannot perform the analytic continuation to Wightman functions via the standard reconstruction theorem. Nevertheless, an analytic continuation can be done. Using the results from the theory of Laplace transforms in Ref. 5, the authors analytically continued the truncated Schwinger functions $(\mathcal{S}^{H,G_\alpha}_{n,T})_{n\in\mathbb{N}_0}$, which are moments of convoluted generalized white noise, to truncated Wightman functions $(W^{H,G_\alpha}_{n,T})_{n\in\mathbb{N}_0}$ for $\alpha\in(0,\frac{1}{2}]$; see Example III 8. The truncated Wightman functions are related to the Wightman functions in the same way as truncated Schwinger functions are related to Schwinger functions; see Definition III.13. In particular, the authors found an explicit formula for $\hat{W}^{H,G_\alpha}_{n,T}$, the Fourier transform of the nth truncated Wightman function. In order to give these formulas we introduce the notations

$$\mu^+_\alpha(p) = (2\pi)^{-d/2}\sin(\pi\alpha)\mathbf{1}_{\{p^2>m_0^2, p^0>0\}}(p)\frac{1}{(p^2-m_0^2)^\alpha}, \quad p\in\mathbb{R}^d, \quad m_0>0,$$

$$\mu^-_\alpha(p) = (2\pi)^{-d/2}\sin(\pi\alpha)\mathbf{1}_{\{p^2>m_0^2, p^0<0\}}(p)\frac{1}{(p^2-m_0^2)^\alpha}, \quad \alpha\in(0,\tfrac{1}{2}],$$

$$\mu_\alpha(p) = (2\pi)^{-d/2}(\cos(\pi\alpha)\mathbf{1}_{\{p^2>m_0^2\}}(p) + \mathbf{1}_{\{p^2<m_0^2\}}(p))\frac{1}{|p^2-m_0^2|^\alpha},$$

where $\mathbf{1}_A$ is the indicator function of the subset $A\subset R^d$. In Proposition 7.12. and Corollary 7.13 in Ref. 5, it is proved that in the case when $F(s) = -(H(is)+\frac{1}{2}s^2)$, $s\in\mathbb{R}$ is a Lévy characteristic and $\alpha\in(0,\frac{1}{2}]$, the Fourier transform of the nth truncated Wightman function for $n\geqslant 3$ is given by

$$\hat{W}^{H,G_\alpha}_{n,T} = -H_n(2\pi)^d 2^{(n-1)}\left(\sum_{j=1}^n \prod_{l=1}^{j-1}\mu^+_\alpha(p_l)\mu_\alpha(p_j)\prod_{l=j+1}^n \mu^-_\alpha(p_l)\right)\delta\left(\sum_{l=1}^n p_l\right). \tag{13}$$

In the case $n=2$ one has to distinguish between the two cases $\alpha\in(0,\frac{1}{2})$ and $\alpha=\frac{1}{2}$. For $\alpha\in(0,\frac{1}{2})$ the two-point function is given by

$$\hat{W}_{2,T}^{H,G_\alpha}=(-H_2+1)(2\pi)^d 2(\mu_\alpha(p_1)\mu_\alpha^-(p_2)+\mu_\alpha^+(p_1)\mu_\alpha(p_2))\delta(p_1+p_2) \tag{14}$$

and

$$\hat{W}_{2,T}^{H,G_{1/2}}=(-H_2+1)(2\pi)^{d+1}\mathbf{1}_{\{p_1^0>0\}}(p_1)\,\delta(p_1^2-m_0^2)\,\delta(p_1+p_2) \tag{15}$$

is the Fourier transform of the well-known two-point function of the relativistic free field.

The truncated Wightman function $W_{n,T}^{H,G_\alpha}$ is an analytic continuation of the truncated Schwinger function $\mathcal{S}_{n,T}^{H,G_\alpha}$ in the sense that

$$\mathcal{S}_{n,T}^{H,G_\alpha}(\mathfrak{I}(z_1^0,\mathfrak{R}(\vec{z_1}),\dots,\mathfrak{I}(z_n^0),\mathfrak{R}(\vec{z_n}))=\mathcal{F}\hat{W}_{n,T}^{H,G_\alpha}(z), \quad z\in\mathbb{C}_<^{dn}, \tag{16}$$

where

$$\mathbb{C}_<^{dn}:=\{(z_1^0,\vec{z_1};\dots;z_n^0,\vec{z_n})\in\mathbb{C}^{dn}|\mathfrak{I}(z_{j+1}^0-z_j^0)>0, j=1,...,n-1, \mathfrak{I}(\vec{z_j})=0, \mathfrak{R}(z_j^0)=0, j=1,...,n\}$$

[$\mathfrak{R}(z)$ is the real part and $\mathfrak{I}(z)$ is the imaginary part of a (vector-valued) complex variable z]. The function $\hat{W}_{n,T}^{H,G_\alpha}$ is determined uniquely by this requirement. Furthermore, $W_{n,T}^{H,G_\alpha}(\mathfrak{R}(z))$ is the boundary value of $\mathcal{F}\hat{W}_{n,T}^{H,G_\alpha}(z)$ for $\mathfrak{I}(z_{j+1}-z_j)\to 0$ inside T^n, i.e., the relation

$$\lim_{\Gamma\ni\mathfrak{I}(z_{j+1}-z_j)\to 0}\mathcal{F}\hat{W}_{n,T}^{H,G_\alpha}(z)=W_{n,T}^{H,G_\alpha}(\mathfrak{R}(z)), \tag{17}$$

holds in the sense of tempered distributions in the argument $\mathfrak{R}(z)\in\mathbb{R}^d$. Here T^n is the tubular domain in $\mathbb{C}^{dn}$ with base V_0^+, i.e.,

$$T^n:=\{(z_1,\dots,z_n)\in\mathbb{C}^{dn}|z_{j+1}-z_j\in\mathbb{R}^d+iV_0^+, j=1,...,n-1\},$$

and $\Gamma\subset V_0^+$ is a subcone of V_0^+ such that $\Gamma\cup\{0\}$ is closed in $\mathbb{R}^d$.

Theorem IV.1: *Let H be as in Theorem III.5 and $\mathcal{G}_\alpha$ as in Example III.8, $\alpha\in(0,\frac{1}{2}]$.*

(i) The Schwinger functions $(\mathcal{S}_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$ can be analytically extended to Wightman functions $(W_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$ in the sense of (16) and (17).

(ii) The sequence $(W_n^{H,G\alpha})_{n\in\mathbb{N}_0}$ satisfies the axioms (W1), (W2), and (W4)–(W6).

(iii) The Fourier transform of the truncated Wightman functions are given by the formulas (13), (14), and (15), respectively.

(iv) For $0<\alpha<\frac{1}{2}$, $H_1=0$, $H_2<1$, $\hat{W}_2^{H,G_\alpha}=\hat{W}_{2,T}^{H,G_\alpha}$ admits a Källen–Lehmann representation. Therefore, the corresponding Gaussian Euclidean field with covariance function $\mathcal{S}_2^{H_\alpha}$ is reflection positive but not Markov. For $\alpha=\frac{1}{2}$ the corresponding Gaussian Euclidean field is the Markov free field of mass m_0.

(v) The sequence $(W_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$ fulfills the strong spectral condition with mass gap m_0, i.e., $\hat{w}_{n,T}^{H,G_\alpha}$ is supported in the forward mass cones $(V_{m_0}^{\star+})^{n-1}$ for any $n\geq 2$.

Proof: (i) Let us consider the Fourier transformed truncated Wightman functions in (13), (14), and (15). If we now chose coefficients H_n corresponding to a general function H as assumed in the theorem, then the corresponding truncated Wightman functions $W_{n,T}^{H,G_\alpha}$ are analytic continuations of the truncated Schwinger functions $\mathcal{S}_{n,T}^{H,G_\alpha}$ in the sense of (16) and (17). Of course, the corresponding Wightman functions W_n^{H,G_α} are analytic continuations of the truncated Schwinger functions $\mathcal{S}_n^{H,G_\alpha}$ in the same sense.

(ii)–(v) In the case where the Wightman functions correspond to Schwinger functions obtained from convoluted generalized white noise this was proved in Ref. 5, Sec. 7.5. Since in our case we only have a different coefficient H_n, the same is true for a general function H as assumed in the theorem. ■

Now let us return to the question of whether positivity holds or not. In terms of the Schwinger functions, this question has been discussed in Ref. 5, see Sec. IV A. The following theorem is an immediate consequence of the Jost–Schroer theorem.[37–40]

Theorem IV.2: *Let H be as in Theorem III.5,* $H_1=0$, $H_2<1$. *Then the following statements are equivalent*

(i) The sequence of Wightman functions $(W_n^{H,G_{1/2}})_{n\in\mathbb{N}_0}$ *fulfills the positivity condition (W3).*

(ii) For $n\geqslant 3$ *vanish the truncated Wightman functions, i.e.,*

$$W_{n,T}^{H,G_{1/2}}=0, \quad n\geqslant 3.$$

Proof: Since the two-point function $W_2^{H,G_{1/2}}$ is the two-point function of the relativistic free field with mass m_0 and the sequence of Wightman functions $(W_n^{H,G_{1/2}})_{n\in\mathbb{N}_0}$ fulfills (W1), (W2), and (W4)–(W6), see Theorem IV.1, the statement of Theorem IV.2 is just the statement of the Jost–Schroer theorem. ■

Remark IV.3: (i) Theorem IV.2 implies together with the explicit formulas for the Fourier transform of the truncated Wightman functions, see (13), that in the case $\alpha=\frac{1}{2}$ *positivity holds if and only if* $H_n=0$, $n\geqslant 3$.

(ii) For $\alpha=\frac{1}{2}$, Theorem IV.2 implies the negative result on reflection positivity of the Schwinger functions derived in Ref. 5, see Sec. II A.

(iii) Under certain assumptions on the measure in the Källen–Lehmann representation, one can also prove a Jost–Schroer theorem for generalized free fields. It is still an open question, whether this generalization of the Jost–Schroer theorem can be applied to the sequence of Wightman functions $(W_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$, $\alpha\in(0,\frac{1}{2})$; see Theorem IV.1. One has to check whether one can prove a Jost–Schroer theorem for generalized free fields having a Källen–Lehmann representation as the two-point functions $\hat{W}_{2,T}^{H,G_\alpha}$, $\alpha\in(0,\frac{1}{2})$; see Theorem IV.1 (iv).

C. QFT with indefinite metric

In Sec. IV B we performed the analytic continuation from Schwinger functions to Wightman functions. The main interesting object, however, is the underlying quantum field theory. Given a family $(W_n)_{n\in\mathbb{N}}$ obeying (W1)–(W6) by the Wightman reconstruction theorem,[41] there exists an essentially unique field theory obeying the Gårding–Wightman axioms for a single Hermitian scalar field. Since for no nontrivial cases we proved positivity of the sequence of tempered distributions $(W_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$ as in Theorem IV.1, we cannot reconstruct the field theory by the Wightman reconstruction theorem. The positivity conditions is used in order to construct a physical Hilbert space as the closure of the Borchers algebra. This is not possible without the positivity condition.

Morchio and Strocchi[10,12] considered quantum field theories in which not all Wightman axioms are satisfied. For Wightman functions not fulfilling the positivity condition Morchio and Strocchi introduced the so-called modified Wightman axioms of indefinite metric QFT. In their set of axioms, the positivity condition is substituted by the weaker Hilbert space structure condition (HSSC):

W′3 (HSSC): There exists a sequence $(p_n)_{n\in\mathbb{N}}$, where for all $n\in\mathbb{N}, p_n: S(\mathbb{R}^{nd})\to[0,\infty)$ is a Hilbert seminorm, such that

$$|W_{m+n}(f^\star\otimes g)|\leqslant p_m(f)p_n(g),$$

for all $f\in S_{\mathbb{C}}(\mathbb{R}^{dm})$ and $g\in S_{\mathbb{C}}(\mathbb{R}^{dn}), n,m\in\mathbb{N}$.

The HSSC permits the construction of a Hilbert space $\mathcal{K}$ and a scalar, local quantum field ϕ associated to a given collection of tempered distributions $(W_n)_{n\in\mathbb{N}_0}$ fulfilling the modified Wightman axioms (W1), (W2), (W′3), (W4), and (W5). Moreover, in Ref. 10, the following theorem is proved.

Theorem IV.4: *Let* $(W_n)_{n\in\mathbb{N}_0}$ *be a sequence of Wightman functions that fulfill (W1), (W2),* $(W'3)$*, (W4), and (W5). Then there exists:*

(i) a Hilbert space $\mathcal{K}$ *with scalar product* $(\cdot,\cdot)_{\mathcal{K}}$*, a distinguished vacuum vector* $\Omega\in\mathcal{K}$*, and an indefinite inner product* $(\cdot,\cdot)_T$*, which differs from* $(\cdot,\cdot)_{\mathcal{K}}$ *only by a self-adjoint metric operator T with* $T^2=1$*, i.e.,* $(\cdot,\cdot)_T=(\cdot,T\cdot)_{\mathcal{K}}$*;*

(ii) a T-symmetric and local quantum field ϕ*, which is a distribution valued field operator* $\phi(x)$ *acting on a dense core* $\mathcal{D}\subset\mathcal{K}$ *with adjoint* $\phi^{\star}(x)=T\phi(x)T$ *and the commutator*

$$[\phi(x),\phi(y)]=0,$$

for x and y space-like separated. Furthermore, ϕ *is connected with the Wightman functions of the theory by*

$$W_n(x_1,\ldots,x_n)=(\Omega,\phi(x_1)\cdots\phi(x_n)\Omega)_T;\quad \text{and}$$

(iii) a T unitary representation $\mathcal{U}$ *of the orthochonous Poincaré group on* $\mathcal{K}$*, i.e., a representation with* $T\mathcal{U}^{\star}T=\mathcal{U}^{-1}$*, such that* Ω *is invariant under* $\mathcal{U}$ *and* $\phi(x)$ *transforms covariantly,*

$$\mathcal{U}(a,\Lambda)\phi(x)\mathcal{U}(a,\Lambda)^{-1}=\phi(\Lambda^{-1}(x-a)),\quad (a,\Lambda)\in P_+^{\uparrow}(\mathbb{R}^d).$$

Furthermore, $\mathcal{U}$ *fulfills the following spectral condition:*

$$\int_{\mathbb{R}^d}(\Psi_1,\mathcal{U}(a,1)\Psi_2)_T\exp(-iqa)\,da=0,\quad \forall\Psi_1,\Psi_2\in\mathcal{D},$$

if $q\notin V_0^{\star +}$.

A quadruple $((\mathcal{K},(\cdot,\cdot)_{\mathcal{K}},\Omega),T,\phi,\mathcal{U})$ is called a QFT with indefinite metric.

Theorem IV.5: *The Wightman functions* $(W_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$ *as obtained in Theorem IV.1 fulfill the modified Wightman axioms (W1), (W2),* $(W'3)$*, (W4), and (W5) (of Morchio and Strocchi).*

Proof: In Ref. 13, Theorem 4.1, this is proved for the Wightman functions corresponding to the moments of convoluted generalized white noise. The proof is done under the use of explicit formulas for the Fourier transform of the truncated Wightman functions and works for an arbitrary sequence of coefficients $(H_n)_{n\in\mathbb{N}}$; see (13), (14), and (15). Thus, also in our case. ■

In general the seminorms in the HSSC are not invariant under transformations of the orthochonous Poincaré group. Hence, in general, the metric operator T does not commute with $\mathcal{U}(a,\Lambda),(a,\Lambda)\in P_+^{\uparrow}(\mathbb{R}^d)$, and the representation of the orthochonous Poincaré group on $\mathcal{H}$ is not unitary. In our case, however, the seminorms in the HSSC at least can be chosen translations invariant.

Theorem IV.6: For the sequence of Wightman functions $(W_n^{H,G_\alpha})_{n\in\mathbb{N}_0}$ *as in Theorem IV.5, the Hilbert seminorms in the HSSC can be chosen translations invariant. Thus, there exists a Hilbert space structure such that* $[\mathcal{U}(a,1),T]=0$*,* $a\in\mathbb{R}^d$*, and the representation of the translation group* $\mathcal{U}(a,1)$ *is unitary. If P denotes the generator of* $\mathcal{U}(a,1)$*, then spec*$(P)\subset V_0^{\star +}$*.*

Proof: In Ref. 42, Theorem 4.3, this is proved for the Wightman functions corresponding to the moments of convoluted generalized white noise. By the same arguments as in the proof of Theorem IV.5, their proof generalizes to our case. ■

Remark IV.7: (i) We remark that the cluster property of Wightman functions is not an item of the modified Wightman axioms, since, in general, it does not imply the uniqueness of the vacuum and irreducibility of the field algebra as it does in the standard QFT.

(ii) The uniqueness of the vacuum cannot hold if T commutes with $\mathcal{U}(a,1),a\in\mathbb{R}^d$*, and* $T\Omega\notin\mathbb{C}\Omega$*, since in this case* $T\Omega$ *is translations invariant.*

(iii) We observe that there exist sequences of Wightman functions associated to sequences of Schwinger functions that are not moments of measures, fulfilling the modified Wightman axioms of Morchio and Strocchi.

(Received 10 May 1999; accepted for publication 1 July 1999)

The derivative expansion of the one-loop effective action in QED_3 and QED_4 (quantum electrodynamics) is considered. The first term in such an expansion is the effective action for a constant electromagnetic field. An explicit expression for the next term containing two derivatives of the field strength $F_{\mu\nu}$, but exact in the magnitude of the field strength, is obtained. The general results for both fermion and scalar electrodynamics are presented. The cases of pure electric and pure magnetic external fields are considered in detail. The Feynman technique for the perturbative expansion of the one-loop effective action in the number of derivatives is developed. © *1999 American Institute of Physics.* [S0022-2488(99)00711-2]

I. INTRODUCTION

Quantum electrodynamics (QED) is known to be the best studied example of quantum field theory. Mainly, this is due to the weakness of the fine structure (coupling) constant, $\alpha \approx 1/137$, which allows us to perform many perturbative calculations as power series in α with an incredibly high accuracy. Despite the smallness of α, even in the realm of quantum electrodynamics, there are some questions that theory has not answered yet. In this paper, in particular, we address the problem of derivation of the low-energy effective action which at present is solved only partially for QED.

The low-energy effective action in quantum electrodynamics describes the dynamics of the electromagnetic field, assuming that the production of the on shell fermions is absent or negligible. Apparently, such a description is self-consistent only if the fermions are massive and the characteristic photon energies are sufficiently small. The mentioned two conditions, as is clear, are necessary to suppress the process of the particle–antiparticle pair creation (on-shell).

Intuitively, the low-energy effective theory is obtained from quantum electrodymanics by ''integrating out'' the fermion field. After doing so, one arrives at a nonlinear theory that involves only the electromagnetic field degrees of freedom. In terms of the S-matrix language, one considers just those processes in QED which contain only photons among the asymptotic scattering states. The fermions, on the other hand, appear only through the internal loops by producing all kinds of photon vertices.

The problem of deriving the effective action is an old one. Its roots go back to the well known papers of Heisenberg and Euler,[1] and Weisskopf.[2] There, for the first time, the effective action in QED (for the case of a constant electromagnetic field) was derived. From the viewpoint of application, the derived effective action contains, for example, the information on the photon–photon scattering at the tree level. It was this scattering process, in fact, that motivated consideration of the problem in Refs. 1,2, in the first place. Later, some further progress was achieved by Schwinger[3] who, by using the proper time technique, rederived the result of Refs. 1,2 and, in

[a)]On leave of absence from Bogolyubov Institute for Theoretical Physics, 252143 Kiev, Ukraine.

addition, gave a nice interpretation to the imaginary part of the effective action in the case of a constant electric field.

Obviously, the next most natural step in deriving the low-energy effective action in QED would be to take into account the effect of small deviations from the constant configuration of the field. In other words, the problem is to obtain the effective action as an expansion in powers of derivatives of the field strength. It turns out, however, that the latter is very difficult to accomplish (see Refs. 4,5 for some early attempts in this direction) unless the weak field approximation is used. In this connection it is appropriate to mention that, in the weak field limit, the expansion is known up to four derivatives with respect to the field strength.[6] Our approach, on the other hand, does not involve any assumptions about the weakness of the background field.

A real progress in solving the problem started with the result of Ref. 7, where an elaborated method, which, in principle, leads to a general result for the derivative expansion in QED, was presented. Because of the complicated character of the method, however, the explicit expression applicable to the most general case of the electromagnetic field background was not presented there. Recently, the derivative expansion of the effective action was obtained in the case of (2+1)-dimensional QED.[8] This latter is a quite general result, containing all the terms quadratic in derivatives of the field strength with respect to the space–time coordinates. Finally, in our previous paper,[9] we obtained a similar result for the effective action but in (3+1)-dimensional QED. As in the (2+1)-dimensional case, it was given in a covariant form valid for the most general constant component of the electromagnetic field background what, as we will see later, is a much more complicated problem than that in 2+1 dimensions.

For completeness, we mention that some related interesting results were obtained in Ref. 10 for QED and in Refs. 11,12 for non-Abelian gauge theories.

In this paper we extend our method, which was originally presented for the case of (3+1)-dimensional QED,[9] to QED in 2+1 dimensions. In particular, we obtain the derivative expansion of the effective action which includes up to two space–time derivatives of the electromagnetic field and, further, we formulate the Feynman rules for the perturbative expansion of the one-loop effective action in the number of derivatives. We also derive the explicit expressions for the derivative corrections to the imaginary part of the effective action in an external electric field. And finally, as a by-product, we resolve the controversy posed in Ref. 13 where a result different from that of Ref. 8 was presented.

The paper is organized as follows. In Sec. II we outline the general method developed in our previous paper.[9] Section III is devoted to solving some technical problems in dealing with functions of the matrix argument $F_{\mu\nu}$. Then, in Secs. IV and VII, we present the main results of our paper, namely, the derivative expansions for spinor and scalar QED, respectively. In Secs. V–VI and Secs. VIII–IX we calculate the derivative expansions for two particular cases of the external electromagnetic field, the purely magnetic and purely electric backgrounds, in both 2+1 and 3+1 dimensions. Finally, in Sec. X, we develop the Feynman diagram technique for generating the perturbative expansion in the number of derivatives. Four appendices contain different formulas used throughout the main text.

II. DERIVATIVE EXPANSION OF THE ONE-LOOP EFFECTIVE ACTION IN QED

Let us start from the general formalism which was originally developed in Ref. 9 for (3+1)-dimensional quantum electrodynamics. While doing so, we will notice that, to a great extent, the method does not depend on the dimension of the space–time. We will pay special attention to all those places where it does depend.

In this paper we restrict ourselves to the one-loop effective action. This is the same approximation which was used by Schwinger[3] in the case of a constant external electromagnetic field.

As is known, the one-loop effective action in QED reduces to computing the fermion determinant

$$W^{(1)}(A)\equiv\int d^n x\mathcal{L}^{(1)}=-i\ln\det(i\hat{\mathcal{D}}-m)=-\frac{i}{2}\ln\det\left(\mathcal{D}_\mu^2+\frac{e}{2}\sigma_{\mu\nu}F^{\mu\nu}+m^2\right)$$
$$=-\frac{i}{2}\int d^n x\langle x|tr\ln\left(\mathcal{D}_\mu^2+\frac{e}{2}\sigma_{\mu\nu}F^{\mu\nu}+m^2\right)|x\rangle. \tag{1}$$

Here $\hat{\mathcal{D}}=\gamma^\mu\mathcal{D}_\mu$ and the covariant derivative is $\mathcal{D}_\mu=\partial_\mu+ieA_\mu$. By definition, $\sigma_{\mu\nu}=i[\gamma_\mu,\gamma_\nu]/2$ and tr refers to the spinor indices of the Dirac matrices γ_μ. States $|x\rangle$ are the eigenstates of a self-conjugate coordinate operator x_μ. Throughout the paper we use the Minkowski metric, i.e., $\eta_{\mu\nu}=(1,-1,-1)$ or $\eta_{\mu\nu}=(1,-1,-1,-1)$, depending on the actual space-time dimension. And in both 2+1 and 3+1 dimensions, we work with the 4×4 representation of the Dirac γ-matrices.

For calculating the effective action in Eq. (1), we employ a version of the so-called worldline (or string-inspired) formalism developed in Refs. 14–16. Such an approach to an ordinary field theory, based on the path integral over one-dimensional world lines, was extended to the evaluation of Feynman diagrams for Green functions in higher loop orders.[17–19] It has demonstrated its power reproducing known theoretical results in QED while allowing one to invoke new technique to study the theory's behavior in strong coupling regime.[20] For some recent applications of the worldline formalism as well as for an extensive list of references, see Refs. 21 and 22. Note, however, that our method differs from the one commonly used in the literature by a choice of the worldline propagators, and is closer in spirit to the method used in Refs. 17 and 23.

With use of the formal identity $\ln(H+m^2)=-\int_0^\infty\exp[-i\tau(H+m^2)]d\tau/\tau$ for introducing the proper-time coordinate τ, the effective Lagrangian can be represented through the diagonal matrix elements of the operator $U(\tau)=\exp(-i\tau H)$,

$$\mathcal{L}^{(1)}(A)=\frac{i}{2}\int_0^\infty\frac{d\tau}{\tau}e^{-im^2\tau}tr\langle x|\exp(-i\tau H)|x\rangle, \tag{2}$$

where the second order differential operator H is given by

$$H=-\Pi_\mu\Pi^\mu+\frac{e}{2}\sigma_{\mu\nu}F^{\mu\nu}(x),\quad \Pi_\mu=-i\mathcal{D}_\mu. \tag{3}$$

The matrix elements $\langle x|\exp(-i\tau H)|x\rangle$ entering the right-hand side of Eq. (2) may be interpreted as the matrix elements of the evolution operator of a spinning particle with τ and H being the proper time and the Hamiltonian of the particle. The corresponding canonical momenta are P_μ's which obey the commutation relations $[x_\mu,P^\nu]=i\delta_\mu^\nu$ and are defined by $\langle x|P_\mu|y\rangle=-i\partial_\mu\delta(x-y)$ in coordinate representation. Following the standard approach,[24] we represent the transition amplitude $\langle z|U(\tau)|y\rangle$ between points $x(0)=y$ and $x(\tau)=z$ in terms of a path integral over the real and Grassmann coordinates, $x_\mu(t)$ and $\psi_\mu(t)$, as

$$tr\langle z|U(\tau)|y\rangle=N^{-1}\int\mathcal{D}[x(t),\psi(t)]\exp\left\{i\int_0^\tau dt[L_{\rm bos}(x(t))+L_{\rm fer}(\psi(t),x(t))]\right\}, \tag{4}$$

where N is a normalization factor, and

$$L_{\rm bos}(x)=-\frac{1}{4}\frac{dx_\nu}{dt}\frac{dx^\nu}{dt}-eA_\nu(x)\frac{dx^\nu}{dt}, \tag{5}$$

$$L_{\rm fer}(\psi,x)=\frac{i}{2}\psi_\nu\frac{d\psi^\nu}{dt}-ie\psi^\nu\psi^\lambda F_{\nu\lambda}(x). \tag{6}$$

The integration in Eq. (4) goes over trajectories $x^{\mu}(t)$ and $\psi^{\mu}(t)$ parameterized by $t\in[0,\tau]$. The definition of the integration measure assumes the following boundary conditions:

$$x(0)=y,\quad x(\tau)=z,\quad \psi(0)=-\psi(\tau). \tag{7}$$

We choose a special gauge condition for the vector potential $A_{\mu}(x)$, namely, the Fock–Schwinger gauge[25]

$$(x^{\nu}-y^{\nu})A_{\nu}(x)=0, \tag{8}$$

which leads to the series

$$\begin{aligned}A_{\nu}(x)&=\tfrac{1}{2}(x^{\lambda}-y^{\lambda})F_{\lambda\nu}(y)+\tfrac{1}{3}(x^{\lambda}-y^{\lambda})(x^{\sigma}-y^{\sigma})\partial_{\sigma}F_{\lambda\nu}(y)\\&\quad+\tfrac{1}{8}(x^{\lambda}-y^{\lambda})(x^{\sigma}-y^{\sigma})(x^{\mu}-y^{\mu})\partial_{\sigma}\partial_{\mu}F_{\lambda\nu}(y)+\cdots\\&=\sum_{n=0}^{\infty}\frac{(x^{\lambda}-y^{\lambda})(x^{\nu_1}-y^{\nu_1})\cdots(x^{\nu_n}-y^{\nu_n})}{n!(n+2)}\partial_{\nu_1}\partial_{\nu_2}\cdots\partial_{\nu_n}F_{\lambda\nu}(y).\end{aligned} \tag{9}$$

This choice of the gauge for the vector potential turns out to be very convenient for developing a perturbative theory in the number of the derivatives of the electromagnetic field with respect to the space–time coordinates.

Carrying out the change of the variable $x(t)$ for $x'(t)=x(t)-y$ in the path integral in Eq. (4) (henceforth we omit the prime) and substituting Eq. (9) into Eq. (4), we obtain

$$\begin{aligned}tr\langle z|U(\tau)|y\rangle&=N^{-1}\int D[x(t),\psi(t)]\exp\left[i\int_0^{\tau}dt\left(-\frac{1}{4}\frac{dx_{\nu}}{dt}\frac{dx^{\nu}}{dt}-\frac{e}{2}x^{\lambda}F_{\lambda\nu}(y)\frac{dx^{\nu}}{dt}+L_{\text{bos}}^{\text{int}}(x)\right)\right]\\&\quad\times\exp\left[i\int_0^{\tau}dt\left(\frac{i}{2}\psi_{\nu}\frac{d\psi^{\nu}}{dt}-ie\psi^{\nu}\psi^{\lambda}F_{\nu\lambda}(y)+L_{\text{fer}}^{\text{int}}(x,\psi)\right)\right].\end{aligned} \tag{10}$$

The new boundary conditions for $x(t)$ are $x(0)=0$ and $x(\tau)=z-y$. Notice, that $F_{\mu\nu}$ in Eq. (10) does not depend on $x(t)$. As follows from Eqs. (5), (6), and (9), the expressions for the interacting terms, $L_{\text{bos}}^{\text{int}}(x)$ and $L_{\text{fer}}^{\text{int}}(x,\psi)$, containing derivatives of $F_{\mu\nu}$ with respect to coordinates, take the form

$$\begin{aligned}L_{\text{bos}}^{\text{int}}(x)&=\sum_{n=1}^{\infty}\frac{eF_{\nu_0\nu_1,\nu_2\cdots\nu_{n+1}}}{n!(n+2)}\frac{dx^{\nu_0}}{dt}x^{\nu_1}(t)\cdots x^{\nu_{n+1}}(t)\\&=\frac{e}{3}F_{\nu\lambda,\sigma}\frac{dx^{\nu}}{dt}x^{\lambda}x^{\sigma}+\frac{e}{8}F_{\nu\lambda,\sigma\kappa}\frac{dx^{\nu}}{dt}x^{\lambda}x^{\sigma}x^{\kappa}+\cdots,\end{aligned} \tag{11}$$

$$\begin{aligned}L_{\text{fer}}^{\text{int}}(x,\psi)&=-\sum_{n=1}^{\infty}\frac{i}{n!}eF_{\lambda\mu,\nu_1\cdots\nu_n}\psi^{\lambda}(t)\psi^{\mu}(t)x^{\nu_1}(t)\cdots x^{\nu_n}(t)\\&=-ieF_{\nu\lambda,\sigma}\psi^{\nu}\psi^{\lambda}x^{\sigma}-\frac{ie}{2}F_{\nu\lambda,\sigma\kappa}\psi^{\nu}\psi^{\lambda}x^{\sigma}x^{\kappa}+\cdots.\end{aligned} \tag{12}$$

Here we use the conventional notation for the partial derivatives

$$F_{\lambda\mu,\nu_1\nu_2\cdots\nu_n}(x)=\partial_{\nu_1}\partial_{\nu_2}\cdots\partial_{\nu_n}F_{\lambda\mu}(x). \tag{13}$$

Now we see that the problem of obtaining the derivative expansion reduces to the evaluation of the path integral in Eq. (10) in the framework of the perturbative theory with an infinite number of interacting terms given in Eqs. (11) and (12). Fortunately, for computing the effective action that includes only a finite number of the derivatives, it is sufficient to consider only a finite number of the interacting terms. Later, we shall restrict ourselves to obtaining only the two-derivative terms in the action. So far, we continue developing the scheme for the most general case.

As usual, introducing real and Grassmann external sources, the matrix elements of the evolution operator can be represented as follows:

$$tr\langle z|U(\tau)|y\rangle=\exp\left\{ i\int_0^\tau dt\left[L_{\rm bos}^{\rm int}\left(\frac{1}{i}\,\frac{\delta}{\delta\eta(t)}\right)+L_{\rm fer}^{\rm int}\left(\frac{1}{i}\,\frac{\delta}{\delta\eta(t)},-\frac{\delta}{\delta\xi(t)}\right)\right]\right\} \times Z_\tau[\eta,\xi](z;y)\Big|_{\eta=0,\xi=0}, \tag{14}$$

where the generating functional is just the Gaussian path integral,

$$Z_\tau[\eta,\xi](z;y)=N^{-1}\int D[x(t),\psi(t)]\exp\left[\frac{i}{2}\int_0^\tau dt\left(-\frac{1}{2}\,\frac{dx_\nu}{dt}\,\frac{dx^\nu}{dt}-ex^\lambda F_{\lambda\nu}(y)\,\frac{dx^\nu}{dt}+2\,\eta_\nu x^\nu\right)\right] \times\exp\left[-\frac{1}{2}\int_0^\tau dt\left(\psi_\nu\frac{d\psi^\nu}{dt}-2e\,\psi^\nu\psi^\lambda F_{\nu\lambda}(y)+2\,\xi_\nu\psi^\nu\right)\right]. \tag{15}$$

The calculation of this generating functional reduces to obtaining the ''classical'' trajectories for $x_\nu(t)$ and $\psi_\nu(t)$, satisfying the appropriate boundary conditions, and to computing the determinants of the one-dimensional differential operators,

$$O_1=\frac{\eta_{\mu\nu}}{2}\,\frac{d^2}{dt^2}-eF_{\mu\nu}\frac{d}{dt},\quad \text{and}\ \ O_2=i\,\eta_{\mu\nu}\frac{d}{dt}-2ieF_{\mu\nu}, \tag{16}$$

defined on the interval $[0,\tau]$ with the periodic and antiperiodic boundary conditions for their eigenstates, respectively.

The ''classical'' trajectories are easily obtained by solving the equations of motion that the bosonic and Grassmanian worldline actions in Eq. (15) require. So, we arrive at

$$x_{\rm cl}^\mu(t)=\left(\frac{e^{2eFt}-1}{e^{2eF\tau}-1}\right)^{\mu\nu}(z-y)_\nu +\int_0^\tau dt'\left(\frac{e^{2eFt}-1}{e^{2eF\tau}-1}\,\frac{(e^{2eF(\tau-t')}-1)}{eF}-\theta(t-t')\,\frac{(e^{2eF(t-t')}-1)}{eF}\right)^{\mu\nu}\eta_\nu(t'), \tag{17}$$

and

$$\psi_{\rm cl}^\mu(t)=\int_0^\tau dt'\left(e^{2eF(t-t')}\left(\theta(t-t')-\frac{1}{1+e^{-2eF\tau}}\right)\right)^{\mu\nu}\xi_\nu(t'). \tag{18}$$

Then, the result of the path integration in Eq. (15) for the case of the coincident arguments $z=y=x$ reads

$$Z_\tau[\eta,\xi](x;x)=C_0\sqrt{\frac{\det(O_2)}{\det'(O_1)}}\exp\left(\frac{i}{2}S_{\rm cl}^{\rm bos}[\eta]-\frac{1}{2}S_{\rm cl}^{\rm fer}[\xi]\right), \tag{19}$$

where the normalization constant C_0 should be determined by comparing the result with the Schwinger's one, or by satisfying the normalization condition

$$Z_{r=0}[\eta,\xi](z;y)=\delta(z-y), \tag{20}$$

which is equivalent to the operator equality $U(0)=1$. The prime in Eq. (19) denotes skipping a zero mode in the definition of the determinant. With our normalization convention for the determinants (see the next section), it is easy to check that the overall factor $C_0=-i/(2\pi\tau)^2$ in 3+1 dimensions and $C_0=\exp[-i\pi/4]/[2(\pi\tau)^{3/2}]$ in 2+1 dimensions.

The expressions for $S_{\rm cl}^{\rm bos}$ and $S_{\rm cl}^{\rm fer}$ are quadratic forms in the external sources

$$S_{\rm cl}^{\rm bos}[\eta]=\int_0^\tau dt_1\int_0^\tau dt_2\,\eta_\nu(t_1)D_\lambda^\nu(t_1,t_2)\,\eta^\lambda(t_2), \tag{21}$$

$$S_{\rm cl}^{\rm fer}[\xi]=\int_0^\tau dt_1\int_0^\tau dt_2\,\xi_\nu(t_1)S_\lambda^\nu(t_1,t_2)\,\xi^\lambda(t_2), \tag{22}$$

where the Green functions are given in terms of functions of the matrix argument $F_{\mu\nu}$,

$$D(t_1,t_2)=\frac{1}{2eF}\left[\epsilon(t_1-t_2)(1-e^{2eF(t_1-t_2)})+\coth(eF\tau)(1+e^{2eF(t_1-t_2)})-\frac{e^{eF(\tau-2t_2)}+e^{eF(2t_1-\tau)}}{\sinh(eF\tau)}\right], \tag{23}$$

$$S(t_1,t_2)=\tfrac{1}{2}[\epsilon(t_1-t_2)-\tanh(eF\tau)]e^{2eF(t_1-t_2)}. \tag{24}$$

Substitution of Eqs. (19), (23), and (24) into Eq. (14) leads to the expression for $tr\langle x|U|x\rangle$. After expanding the exponent in powers of the operator valued interacting terms, $L_{\rm bos}^{\rm int}$ and $L_{\rm fer}^{\rm int}$ (containing functional derivatives with respect to the sources $\eta_\mu(t)$ and $\xi_\mu(t)$), one has to calculate the result of the derivative action on the generating functional. Starting from this point, we have to restrict ourselves to a specific finite number of the derivatives in the effective action. As we mentioned before, in this paper we are interested in the two-derivative terms (see Sec. X for some discussions on computing the higher order approximations). Therefore, we obtain

$$tr\langle x|U(\tau)|x\rangle=\left(1+i\int_0^\tau dt[V_2(t)+W_2(t)]-\frac{1}{2}\int_0^\tau\int_0^\tau dt_1dt_2[V_1(t_1)V_1(t_2)+W_1(t_1)W_1(t_2)]-\int_0^\tau\int_0^\tau dt_1dt_2V_1(t_1)W_1(t_2)\right)Z_\tau[\eta,\xi](x,x)\Big|_{\eta=0,\xi=0}, \tag{25}$$

where, as follows from Eqs. (11), (12), and (14), the vertex generating operators are

$$\begin{aligned}
V_1(t)&=\frac{i}{3}eF_{\nu\lambda,\mu}\lim_{t_0\to t}\frac{d}{dt_0}\,\frac{\delta^3}{\delta\eta_\nu(t_0)\,\delta\eta_\lambda(t)\,\delta\eta_\mu(t)},\\
V_2(t)&=\frac{1}{8}eF_{\nu\lambda,\mu\kappa}\lim_{t_0\to t}\frac{d}{dt_0}\,\frac{\delta^4}{\delta\eta_\nu(t_0)\,\delta\eta_\lambda(t)\,\delta\eta_\mu(t)\,\delta\eta_\kappa(t)},\\
W_1(t)&=-eF_{\nu\lambda,\mu}\frac{\delta^2}{\delta\xi_\nu(t)\,\delta\xi_\lambda(t)}\,\frac{\delta}{\delta\eta_\mu(t)},\\
W_2(t)&=\frac{i}{2}eF_{\nu\lambda,\mu\kappa}\frac{\delta^2}{\delta\xi_\nu(t)\,\delta\xi_\lambda(t)}\,\frac{\delta^2}{\delta\eta_\mu(t)\,\delta\eta_\kappa(t)}.
\end{aligned} \tag{26}$$

Substituting the generating functional (19) which depends on the Green functions (23) and (24), we rewrite Eq. (25) in the form

$$
\begin{aligned}
tr\langle x|U(\tau)|x\rangle = C_0\sqrt{\frac{\det(O_2)}{\det'(O_1)}}\Bigg\{ 1-\frac{i}{8}eF_{\nu\lambda,\mu\kappa}\int_0^\tau dt[\dot{D}^{\nu\lambda}(t,t)D^{\mu\kappa}(t,t)+\dot{D}^{\nu\mu}(t,t)D^{\lambda\kappa}(t,t) \\
+\dot{D}^{\nu\kappa}(t,t)D^{\lambda\mu}(t,t)+4S^{\nu\lambda}(t,t)D^{\mu\kappa}(t,t)] \\
-\frac{i}{18}e^2F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\int_0^\tau\int_0^\tau dt_1dt_2[9D^{\mu\rho}(1,2)(S^{\kappa\sigma}(2,2)S^{\lambda\nu}(1,1) \\
-2S^{\kappa\lambda}(2,1)S^{\sigma\nu}(2,1))+6S^{\sigma\kappa}(2,2)(\dot{D}^{\nu\lambda}(1,1)D^{\mu\rho}(1,2)+\dot{D}^{\nu\mu}(1,1)D^{\lambda\rho}(1,2) \\
+\dot{D}^{\nu\rho}(1,2)D^{\lambda\mu}(1,1))+\dot{D}^{\nu\lambda}(1,1)\dot{D}^{\sigma\kappa}(2,2)D^{\mu\rho}(1,2)+2\dot{D}^{\nu\lambda}(1,1) \\
\times(\dot{D}^{\sigma\rho}(2,2)D^{\mu\kappa}(1,2)+\dot{D}^{\sigma\mu}(2,1)D^{\kappa\rho}(2,2))+\dot{D}^{\nu\mu}(1,1)\dot{D}^{\sigma\rho}(2,2)D^{\lambda\kappa}(1,2) \\
+2\dot{D}^{\nu\kappa}(1,2)(\dot{D}^{\sigma\rho}(2,2)D^{\lambda\mu}(1,1)+\dot{D}^{\sigma\mu}(2,1)D^{\lambda\rho}(1,2)) \\
+\dot{D}^{\nu\kappa}(1,2)\dot{D}^{\sigma\lambda}(2,1)D^{\mu\rho}(1,2)+\dot{D}^{\nu\rho}(1,2)\dot{D}^{\sigma\mu}(2,1)D^{\lambda\kappa}(1,2) \\
+\ddot{D}^{\nu\sigma}(1,2)(D^{\lambda\mu}(1,1)D^{\kappa\rho}(2,2)+D^{\lambda\kappa}(1,2)D^{\mu\rho}(1,2)+D^{\lambda\rho}(1,2)D^{\mu\kappa}(1,2))]\Bigg\}.
\end{aligned}
\tag{27}
$$

Here the dotted functions are defined by the expressions

$$\dot{D}^{\mu\nu}(1,2)\stackrel{\text{def}}{=}\frac{\partial}{\partial t_1}D^{\mu\nu}(t_1,t_2), \tag{28}$$

$$\ddot{D}^{\mu\nu}(1,2)\stackrel{\text{def}}{=}\frac{\partial^2}{\partial t_1\partial t_2}D^{\mu\nu}(t_1,t_2), \tag{29}$$

$$\dot{D}^{\mu\nu}(t,t)\stackrel{\text{def}}{=}\lim_{t_0\to t}\frac{\partial}{\partial t_0}D^{\mu\nu}(t_0,t). \tag{30}$$

Having the representation (27) together with the Green functions (23) and (24), one is left with a need to perform the integrations over the proper time. This latter, however, may look like a rather complicated problem due to the necessity to disentangle the Lorentz indices while doing the integration. In the next section, we show how this problem can be solved.

III. HOW TO DEAL WITH FUNCTIONS OF THE MATRIX ARGUMENT $F_{\mu\nu}$

In the previous section we developed the general method for calculation the derivative expansion in QED. However, there was not given an explicit final expression, since we needed a technique dealing with functions of the matrix argument $F_{\mu\nu}$. Below we show, following the method of Ref. 26, how to deal with those functions as well as how to calculate the determinants of the differential operators in Eq. (16).

Let us begin by introducing notations that we are going to use below. When working with the electromagnetic field strength tensor, it is usually very convenient to introduce the invariants built of the field strength. In (3+1)-dimensional theory, the standard choice of the two independent invariants reads

$$\mathcal{F}=-\tfrac{1}{4}F^{\mu\nu}F_{\mu\nu}, \quad \mathcal{G}=\tfrac{1}{8}\epsilon^{\mu\nu\lambda\kappa}F_{\lambda\kappa}F_{\mu\nu}. \tag{31}$$

In our calculations, though, it will be more convenient to work with the following couple of invariants

$$K_+ = \sqrt{\sqrt{\mathcal{F}^2+\mathcal{G}^2}+\mathcal{F}}, \quad K_- = \sqrt{\sqrt{\mathcal{F}^2+\mathcal{G}^2}-\mathcal{F}}. \tag{32}$$

As for the (2+1)-dimensional theory, there exists only one independent invariant built of the electromagnetic field strength, and it is given by the expression analogous to $\mathcal{F}$ in Eq. (31).

Now we proceed to the case of (3+1)-dimensional QED. It is this case that was considered in Ref. 26. The authors of that paper introduced the set of matrices $A^{\nu\lambda}_{(j)}$ with $j \in \{1,2,3,4\}$,

$$A_{(j)\mu\nu} = \frac{-\overline{f}_j^2 \eta_{\mu\nu} + f_j F_{\mu\nu} + F^2_{\mu\nu} - i \overline{f}_j \overset{*}{F}_{\mu\nu}}{2(f_j^2 - \overline{f}_j^2)}, \tag{33}$$

where

$$f_{1,2} = \pm i K_-, \quad f_{3,4} = \pm K_+; \tag{34}$$

$$\overline{f}_{1,2} = \mp K_+, \quad \overline{f}_{3,4} = \mp i K_-. \tag{35}$$

The main property of the matrices (33) that we are interested in are their (left and right) contractions with the field strength tensor,

$$F^{\nu\lambda} A_{(i)\lambda\mu} = A^{\nu\kappa}_{(i)} F_{\kappa\mu} = f_i A^{\nu}_{(i)\mu}. \tag{36}$$

Other useful properties of these matrices that will be used below are

$$\sum_j A^{\mu\nu}_{(j)} = \eta^{\mu\nu}, \quad A^{\mu}_{(j)\mu} = 1, \quad A^{\mu\nu}_{(k)} A_{(j)\nu\lambda} = \delta_{kj} A^{\mu}_{(j)\lambda}. \tag{37}$$

As follows from the property in Eq. (36), for any function $\Phi(F)$ of the tensor argument $F_{\mu\nu}$, we get

$$\Phi(F)_{\mu\nu} = \sum_j A_{(j)\mu\nu} \Phi(f_{(j)}). \tag{38}$$

Matrices with similar properties can also be introduced for (2+1)-dimensional tensor $F_{\mu\nu}$ as well. Indeed, the following set of matrices:

$$A^{\mu\nu}_{(\pm 1)} = \frac{1}{2}\left(\frac{(F^2)^{\mu\nu}}{2\mathcal{F}} \pm \frac{F^{\mu\nu}}{\sqrt{2\mathcal{F}}} \right), \quad A^{\mu\nu}_{(0)} = \eta^{\mu\nu} - \frac{(F^2)^{\mu\nu}}{2\mathcal{F}} \tag{39}$$

in the (2+1)-dimensional case have properties similar to those in Eqs. (36) and (37). As is easy to check directly, their eigenvalues are

$$f_{\pm 1} = \pm \sqrt{2\mathcal{F}}, \quad f_0 = 0. \tag{40}$$

In particular, for the Green functions (23) and (24), which are functions of the tensor argument $F_{\mu\nu}$, we obtain the following representations:

$$D^{\nu\lambda}(t_1,t_2)=\sum_j A^{\nu\lambda}_{(j)}\frac{1}{2ef_j}\Bigg[\epsilon(t_1-t_2)(1-e^{2ef_j(t_1-t_2)})+\coth(ef_j\tau)(1+e^{2ef_j(t_1-t_2)}) -\frac{e^{ef_j(\tau-2t_2)}+e^{ef_j(2t_1-\tau)}}{\sinh(ef_j\tau)}\Bigg], \tag{41}$$

$$S^{\nu\lambda}(t_1,t_2)=\sum_j A^{\nu\lambda}_{(j)}\frac{1}{2}(\epsilon(t_1-t_2)-\tanh(ef_j\tau))\exp[2ef_j(t_1-t_2)]. \tag{42}$$

As is seen, in the case of vanishing field, the propagators $D^{\nu\lambda}(t_1,t_2)$ and $S^{\nu\lambda}(t_1,t_2)$ coincide with those used in Refs. 17 and 23.

Another problem is related to calculating the determinants of the operators (16). The latter are nothing else but products of all eigenvalues of the operators. Once again, making use of the matrices in Eq. (33) or in Eq. (39) for (3+1)- or (2+1)-dimensional cases, respectively, we look for the eigenvectors of the operators O_1 and O_2 in the form

$$x^{\nu}_{(j)}(t)=A^{\nu}_{(j)\lambda}a^{\lambda}\phi(t), \tag{43}$$

$$\psi^{\nu}_{(j)}(t)=A^{\nu}_{(j)\lambda}\xi^{\lambda}\eta(t), \tag{44}$$

where a^{λ} and ξ^{λ} are constant nonzero vectors, ϕ and η are scalar functions of t. As a result, the problem of obtaining eigenvalues reduces to solving ordinary differential equations for the scalar functions ϕ and η with appropriate boundary conditions.

Now, it is easy to check that, up to an unimportant constant, the corresponding determinants read (note that we skip a zero mode of the operator O_1),

$$\det{}'^{(3+1)}(O_1)=\frac{\sinh^2(e\tau K_+)}{(e\tau K_+)^2}\frac{\sin^2(e\tau K_-)}{(e\tau K_-)^2}, \tag{45}$$

$$\det{}^{(3+1)}(O_2)=\cosh^2(e\tau K_+)\cos^2(e\tau K_-), \tag{46}$$

in the case of QED in 3+1 dimensions, and

$$\det{}'^{(2+1)}(O_1)=\frac{\sinh^2(e\tau\sqrt{2\mathcal{F}})}{(e\tau\sqrt{2\mathcal{F}})^2}, \tag{47}$$

$$\det{}^{(2+1)}(O_2)=\cosh^2(e\tau\sqrt{2\mathcal{F}}), \tag{48}$$

in the case of QED in 2+1 dimensions. To obtain these results we used the following formulas for infinite products:[27]

$$\prod_{n=1}^{\infty}\left(1+\frac{x^2}{\pi^2n^2}\right)=\frac{\sinh x}{x},\quad \prod_{n=1}^{\infty}\left(1+\frac{4x^2}{\pi^2(2n+1)^2}\right)=\cosh x, \tag{49}$$

and similar ones with replacement $x\to iy$.

IV. GENERAL RESULTS IN THE SPINOR QED

By making use of the results from the previous section, we can proceed with the calculation of (27).

After substituting the Green functions (41) and (42), as well as the explicit expressions for the determinants of the operators O_1 and O_2, a straightforward, though tedious computation gives the result for the diagonal matrix element of the $U(\tau)$,

$$
\begin{aligned}
tr\langle x|U(\tau)|x\rangle = tr\langle x|U(\tau)|x\rangle_0 \\
\times\Bigg[1 - \frac{i}{8} eF_{\nu\lambda,\mu\kappa} \sum_{j,l} \big(C^V(f_j,f_l)(A_{(j)}^{\nu\lambda}A_{(l)}^{\mu\kappa} + 2A_{(j)}^{\nu\mu}A_{(l)}^{\lambda\kappa}) + 2C^W(f_j,f_l)A_{(j)}^{\lambda\nu}A_{(l)}^{\mu\kappa} \big) \\
- \frac{i}{18} e^2 F_{\nu\lambda,\mu} F_{\sigma\kappa,\rho} \sum_{j,l,k} \big(9C_1^{WW}(f_j,f_l,f_k)A_{(j)}^{\kappa\sigma}A_{(l)}^{\lambda\nu}A_{(k)}^{\mu\rho} \\
+ 9C_2^{WW}(f_j,f_l,f_k)A_{(j)}^{\kappa\lambda}A_{(l)}^{\sigma\nu}A_{(k)}^{\mu\rho} + 6C_1^{VW}(f_j,f_l,f_k)A_{(j)}^{\sigma\kappa}(A_{(l)}^{\nu\lambda}A_{(k)}^{\mu\rho} + A_{(l)}^{\nu\mu}A_{(k)}^{\lambda\rho}) \\
+ 6C_2^{VW}(f_j,f_l,f_k)A_{(j)}^{\sigma\kappa}A_{(l)}^{\nu\rho}A_{(k)}^{\lambda\mu} - C_1^{VV}(f_j,f_l,f_k)(A_{(j)}^{\nu\lambda}A_{(l)}^{\kappa\sigma}A_{(k)}^{\mu\rho} + A_{(j)}^{\nu\mu}A_{(l)}^{\kappa\rho}A_{(k)}^{\lambda\sigma} \\
+ 2A_{(j)}^{\nu\lambda}A_{(l)}^{\kappa\rho}A_{(k)}^{\mu\sigma}) - C_2^{VV}(f_j,f_l,f_k)(A_{(j)}^{\nu\sigma}A_{(l)}^{\kappa\lambda}A_{(k)}^{\mu\rho} + A_{(j)}^{\nu\rho}A_{(l)}^{\kappa\mu}A_{(k)}^{\lambda\sigma} + 2A_{(j)}^{\nu\sigma}A_{(l)}^{\kappa\mu}A_{(k)}^{\lambda\rho}) \\
- 2C_3^{VV}(f_j,f_l,f_k)(A_{(j)}^{\nu\lambda}A_{(l)}^{\kappa\mu}A_{(k)}^{\sigma\rho} + A_{(j)}^{\kappa\rho}A_{(l)}^{\nu\sigma}A_{(k)}^{\lambda\mu}) - C_4^{VV}(f_j,f_l,f_k)A_{(j)}^{\nu\kappa}A_{(l)}^{\lambda\mu}A_{(k)}^{\sigma\rho} \\
- C_5^{VV}(f_j,f_l,f_k)A_{(j)}^{\nu\kappa}(A_{(l)}^{\lambda\sigma}A_{(k)}^{\mu\rho} + A_{(l)}^{\lambda\rho}A_{(k)}^{\mu\sigma}) \big) \Bigg],
\end{aligned}
\tag{50}
$$

where the explicit expressions for the coefficients $C_i^{XY}(\alpha,\beta,\gamma)$ (with $X,Y \in \{V,W\}$) are given in Appendix A and the diagonal matrix elements $tr\langle x|U(\tau)|x\rangle_0$ correspond to the nonderivative case,

$$tr\langle x|U(\tau)|x\rangle_0^{(3+1)} = -\frac{i}{4\pi^2\tau^2}(e\tau K_-)(e\tau K_+)\cot(e\tau K_-)\coth(e\tau K_+) \tag{51}$$

in 3+1 dimensions, and

$$tr\langle x|U_0(\tau)|x\rangle_0^{(2+1)} = \frac{\exp(-i\pi/4)}{2(\pi\tau)^{3/2}}(e\tau\sqrt{2\mathcal{F}})\coth(e\tau\sqrt{2\mathcal{F}}) \tag{52}$$

in 2+1 dimensions.

Equation (50) (along with a similar one for scalar QED) is the main result of our paper. Note that the renormalization of the effective action (2) formally reduces to (i) performing a subtraction (precisely the same as in the original Schwinger's paper[3]) of a term containing no derivatives of field strength with respect to coordinates, and (ii) changing all bare quantities for the renormalized ones, $e \to e_R$ and $A_\mu \to A_\mu^R$, defined as follows:

$$e_R = Z_3^{1/2} e, \quad A_\mu^R = Z_3^{-1/2} A_\mu, \quad Z_3^{-1} = 1 + \mathbf{C} e^2, \tag{53}$$

where

$$\mathbf{C}^{(3+1)} = \frac{1}{12\pi^2}\int_{1/\Lambda^2}^{\infty}\frac{ds}{s}\exp(-sm^2), \tag{54}$$

$$\mathbf{C}^{(2+1)} = \frac{1}{6\pi^{3/2}}\int_0^{\infty}\frac{ds}{\sqrt{s}}\exp(-sm^2) = \frac{1}{6\pi m}, \tag{55}$$

and Λ is an ultraviolet cutoff in (3+1)-dimensional QED.

After subtraction and conversion to the renormalized quantities the effective action becomes finite in the limit $\Lambda \to \infty$. Since the derivative part of the effective action depends on e and A_μ only through the product $eA_\mu = e_R A_\mu^R$ it does not change its form and no further renormalization is required to make the derivative part well defined (below we use only renormalized quantities, although we always omit the script ''R'' in their notation).

By using the asymptotic behavior of the coefficient functions (given in Appendix A), one easily finds the following expansion of $tr\langle x|U(\tau)|x\rangle$ in powers of τ:

$$tr\langle x|U(\tau)|x\rangle = tr\langle x|U(\tau)|x\rangle_0 \left[1 + \frac{ie^2\tau^3}{20} F^{\nu\lambda} F_{\nu\lambda,\mu}{}^{\mu} + \frac{ie^2\tau^3}{180} \left(\frac{7}{2} F^{\nu\lambda,\mu} F_{\nu\lambda,\mu} - F^{\nu\lambda,}{}_{\lambda} F_{\nu\mu,}{}^{\mu} \right) + \cdots \right]. \tag{56}$$

As is clear, this is the weak field limit of our general result in spinor QED. In the effective action, the given order in τ results in the two-derivative corrections of the order $1/m^2$,

$$\mathcal{L}_{1/m^2}^{(3+1)\mathrm{spin}} = \frac{\alpha}{720\pi m^2} [18F^{\nu\lambda} F_{\nu\lambda,\mu}{}^{\mu} + 7F^{\nu\lambda,\mu} F_{\nu\lambda,\mu} - 2F^{\nu\lambda,}{}_{\lambda} F_{\nu\mu,}{}^{\mu}], \tag{57}$$

in 3+1 dimensions, and of the order $1/m^3$,

$$\mathcal{L}_{1/m^3}^{(2+1)\mathrm{spin}} = \frac{\alpha}{720 m^3} [18F^{\nu\lambda} F_{\nu\lambda,\mu}{}^{\mu} + 7F^{\nu\lambda,\mu} F_{\nu\lambda,\mu} - 2F^{\nu\lambda,}{}_{\lambda} F_{\nu\mu,}{}^{\mu}], \tag{58}$$

in 2+1 dimensions.

The expansion in Eq. (56) was obtained earlier in the heat kernel approach.[4] While the latter is a perfect tool for deriving the effective action in the weak field limit, it is not very useful when the field becomes strong. Our approach here, on the other hand, is free from such a limitation and the general result in Eq. (50) contains all the two derivative terms like $\partial F \partial F (F/m^2)^n$, where n is an arbitrary positive integer and the Lorentz indices (not shown) are contracted in all possible ways. To substantiate this claim, we present the next to leading terms of the weak field expansion in Eq. (B1) in Appendix B.

As we saw above, the formal expansion in τ corresponds to an expansion of the effective action in the inverse powers of the mass parameter. This means that, while making use of such an expansion, one cannot get any reliable results in the limit of the vanishing fermion mass. This, in particular, is the main reason why the authors of Ref. 13, who used an expression like (56), came to a wrong conclusion about the absence of corrections to the one-loop effective action coming from inhomogeneities of a static magnetic field when $m \to 0$. Such a conclusion ''contradicts'' the result of Ref. 8. The latter, as we will see, completely agrees with our result for the derivative expansion.

V. SPINOR QED IN 2+1 DIMENSIONS

Let us consider the case of the purely magnetic field background to which a special attention was paid in Ref. 8. To proceed with analyzing this case, note that the electromagnetic field strength tensor takes the following form:

$$F^{\mu\nu}(x) = B(x) \mathbf{F}^{\mu\nu}, \tag{59}$$

where $B(x)$ is a pseudoscalar function coinciding with the magnetic field strength and $\mathbf{F}^{\mu\nu}$ is a constant matrix with the only nonzero components $\mathbf{F}^{12} = -\mathbf{F}^{21} = 1$. As is seen it satisfies the following normalization condition: $\mathbf{F}^{\mu\nu}\mathbf{F}_{\mu\nu} = 2$.

To reduce the general result presented in Eq. (50) for the particular choice of the field given in Eq. (59), we have to use the properties of $A_{(j)}^{\mu\nu}$'s presented in Sec. III. Just to get a feeling of how they work, let us consider an example,

$$F_{\nu\lambda,\mu\kappa}\sum_{j,l} C^W(f_j,f_l)A^{\lambda\nu}_{(j)}A^{\mu\kappa}_{(l)}=\frac{\partial_\mu\partial_\kappa B}{B}\sum_{j,l} C^W(f_j,f_l)f_{(j)}A^{\mu\kappa}_{(l)}$$
$$=2\frac{\partial_\mu\partial_\kappa B}{B}\sqrt{2\mathcal{F}}[C^W(\sqrt{2\mathcal{F}},0)A^{\mu\kappa}_{(0)}$$
$$+C^W(\sqrt{2\mathcal{F}},\sqrt{2\mathcal{F}})(A^{\mu\kappa}_{(-1)}+A^{\mu\kappa}_{(+1)})]$$
$$=-2iC^W(\sqrt{2\mathcal{F}},\sqrt{2\mathcal{F}})(\mathbf{F}^2)^{\mu\kappa}\partial_\mu\partial_\kappa B$$
$$=-2iC^W(\sqrt{2\mathcal{F}},\sqrt{2\mathcal{F}})\sum_{i=1}^{2}\partial_i\partial_i B. \tag{60}$$

In this derivation, we made use of the Bianchi identity. We recall that the latter should be satisfied since the electromagnetic field was introduced in the theory through the vector potential by minimal coupling. The identity itself reads $A^{\mu\nu}_{(0)}\partial_\nu B\equiv 0$. The direct consequence of it is the independence of the magnetic field, for the particular choice (59), on the time coordinate. By noticing that the matrix $A^{\mu\nu}_{(0)}$, as well as any other from the set, does not depend on $B(x)$ we obtain the secondary identity, $A^{\mu\nu}_{(0)}\partial_\mu\partial_\nu B\equiv 0$, by differentiating the original one. It is this last form of the Bianchi identity that was actually used in our derivation in Eq. (60).

The other expressions, similar to that in Eq. (60), along with the functions like $C^W(\sqrt{2\mathcal{F}},\sqrt{2\mathcal{F}})$ are listed in Appendix C.

The final result for the derivative part of the diagonal matrix element (50), for the particular choice of the field configuration in Eq. (59), reads

$$tr\langle x|U(\tau)|x\rangle^{(2+1)}_{\rm der}=-\frac{ie^2(\partial_i B)^2}{(4\pi|eB|)^{3/2}}\frac{1}{\sqrt{\omega}}(3\omega^2Y^4-3\omega Y^3-4\omega^2Y^2+3\omega Y+\omega^2)$$
$$=\frac{ie^2(\partial_i B)^2}{(4\pi|eB|)^{3/2}}\frac{\sqrt{\omega}}{2}\frac{d^3}{d\omega^3}(\omega\coth\omega), \tag{61}$$

where $\omega=i\tau|eB|$, $Y=\coth\omega$, and $(\partial_i B)^2\equiv\Sigma_{i=1}^2\partial_i B\partial_i B$. Substituting the last expression into Eq. (2), we come to the integral representation for the derivative part of the effective Lagrangian (we perform the change of the integration variable τ for $\omega=i\tau|eB|$),

$$\mathcal{L}^{(2+1)\rm spin}_{\rm der}(B)=-\frac{e^2(\partial_i B)^2}{4(4\pi|eB|)^{3/2}}\int_0^\infty\frac{d\omega}{\sqrt{\omega}}\exp\left(-\frac{m^2}{|eB|}\omega\right)\frac{d^3}{d\omega^3}(\omega\coth\omega). \tag{62}$$

The last expression coincides with the result presented in Ref. 8 (note that in notation of Ref. 8, $\partial_i B\partial_i B=4\partial B\bar{\partial}B$). One can be convinced that the integrand in (62) is a negative function that means that inhomogeneities of the magnetic field background, in approximation under consideration (one-loop and two derivatives), lead to the reduction of vacuum energy density for any value of the ratio $m^2/|eB|$. The latter situation does not, however, prove that a spontaneous generation of a nonhomogeneous magnetic field happens in QED since the sign of the two derivative term in the expansion of the effective action is not a sufficient argument for making a conclusion of that kind.[28]

We would like also to give another representation for the derivative part of the Lagrangian in terms of special functions. To get it, we need to perform the integration in (62) by parts (see Eq. (D5) in Appendix D). Here is such a representation,

$$\mathcal{L}_{\rm der}^{(2+1){\rm spin}}(B) = -\frac{e^2(\partial_i B)^2}{\sqrt{2}\pi(4|eB|)^{3/2}}\left[5\zeta\left(-\frac{3}{2},1+\frac{m^2}{2|eB|}\right) - 9\frac{m^2}{2|eB|}\zeta\left(-\frac{1}{2},1+\frac{m^2}{2|eB|}\right) + 3\left(\frac{m^2}{2|eB|}\right)^2\zeta\left(\frac{1}{2},1+\frac{m^2}{2|eB|}\right) + \left(\frac{m^2}{2|eB|}\right)^3\zeta\left(\frac{3}{2},1+\frac{m^2}{2|eB|}\right)\right]. \tag{63}$$

Often, in the limit of large or small values of the external field, it is more convenient to work with the asymptotic expansions of the effective action rather than the exact expression as in Eq. (63). First, let us consider the case $m^2 \ll |eB|$. Then, using the last representation, we easily derive the following asymptotic expansion:

$$\mathcal{L}_{\rm der}^{(2+1){\rm spin}}(B) \simeq -\frac{e^2(\partial_i B)^2}{\sqrt{2}(4\pi|eB|)^{3/2}}\sum_{k=0}^{\infty}\frac{5-2k}{k!}\Gamma\left(k+\frac{1}{2}\right)\zeta\left(k-\frac{3}{2}\right)\left(-\frac{m^2}{2|eB|}\right)^k. \tag{64}$$

In order to get the asymptotic expansion for $m^2 \gg |eB|$, we make use of the integral representation in Eq. (62) and obtain

$$\mathcal{L}_{\rm der}^{(2+1){\rm spin}}(B) \simeq -\frac{e^2(\partial_i B)^2}{2\pi^{3/2}m^3}\sum_{k=0}^{\infty}\frac{B_{2k+4}}{(2k+1)!}\Gamma\left(2k+\frac{3}{2}\right)\left(\frac{2|eB|}{m^2}\right)^{2k}, \tag{65}$$

where B_k are the Bernoulli numbers.

Now, let us consider the case of the purely electric field background. Without losing the generality, we assume that the field is directed along the first axis of the two-dimensional space. Again the field strength tensor is factored similar to (59),

$$F^{\mu\nu}(x) = E(x)\mathbf{F}^{\mu\nu}, \tag{66}$$

where $E(x)$ is the magnitude of the electric field. Now the constant matrix $\mathbf{F}^{\mu\nu}$ has nonzero components $\mathbf{F}^{10} = -\mathbf{F}^{01} = 1$, and satisfies the normalization condition, $\mathbf{F}^{\mu\nu}\mathbf{F}_{\mu\nu} = -2$. The general expression (50) simplifies considerably for our choice of the background field. And the derivative part of that expression now reads

$$tr\langle x|U(\tau)|x\rangle_{\rm der}^{(2+1)}(E) = \frac{i\exp(-i\pi/4)}{(4\pi|eE|)^{3/2}}\frac{e^2(\partial_\parallel E)^2}{\sqrt{\omega}}(3\omega^2Y^4 - 3\omega Y^3 - 4\omega^2Y^2 + 3\omega Y + \omega^2)$$
$$= -\frac{i\exp(-i\pi/4)}{(4\pi|eE|)^{3/2}}\frac{e^2(\partial_\parallel E)^2}{2}\sqrt{\omega}\frac{d^3}{d\omega^3}(\omega\coth\omega), \tag{67}$$

where now $\omega = \tau|eE|$, $Y = \coth\omega$, and $(\partial_\parallel E)^2 \equiv (\partial_0 E\partial_0 E - \partial_1 E\partial_1 E)$. Here we used the Bianchi identity again to show that the electric field does not depend on the second spatial coordinate. Substituting this expression into Eq. (2), we come to the integral representation for the derivative part of the effective Lagrangian,

$$\mathcal{L}_{\rm der}^{(2+1){\rm spin}}(E) = \frac{\exp(-i\pi/4)e^2(\partial_\parallel E)^2}{4(4\pi|eE|)^{3/2}}\int_0^\infty\frac{d\omega}{\sqrt{\omega}}\exp\left(-i\frac{m^2}{|eE|}\omega\right)\frac{d^3}{d\omega^3}(\omega\coth\omega). \tag{68}$$

As expected in the case of an electric field background, this derivative correction to the effective action contains a nonzero imaginary contribution. A convenient representation of the latter can be obtained in the following way. First, in Eq. (68), we switch to a new variable, $z = i\omega$, so that the integration runs along the imaginary axis of z from zero to $i\infty$. Then, we move the integration contour to the real axis of z. As is easy to check, the integrand has poles at $z = \pi n$ $(n = 1,2,...)$. As a result, the real and the imaginary contributions get naturally separated. Indeed, the real part of $\mathcal{L}_{\rm der}^{(2+1){\rm spin}}$ is given by the principal value of the integral along the Re(z) axis, while the imaginary part appears due to the integration along the infinite set of the vanishingly small semi-circles above the poles, $z=\pi n+\epsilon\exp[i(\pi-\phi)]$ (where $0<\phi<\pi$ and $\epsilon\to 0$ at the end). In this way, we easily obtain the imaginary part of the right-hand side in Eq. (68),

$$\mathrm{Im}\,\mathcal{L}_{\mathrm{der}}^{(2+1)\mathrm{spin}}(E)=-\frac{e^2(\partial_\parallel E)^2}{2^8\pi^3|eE|^{3/2}}\sum_{n=1}^{\infty}\frac{1}{n^{5/2}}\exp\left(-\frac{\pi m^2 n}{|eE|}\right)\times\left[15+18\frac{\pi m^2 n}{|eE|}+12\left(\frac{\pi m^2 n}{|eE|}\right)^2+8\left(\frac{\pi m^2 n}{|eE|}\right)^3\right]. \tag{69}$$

We note that the result of the summation in the last expression (as well as in similar formulas later on) can be given in terms of the polylogarithmic function $\mathrm{Li}_\nu(x)$.[29] Equation (69) determines the correction to the probability of the particle-antiparticle pair creation (by definition, the probability density is $\mathcal{W}=2\,\mathrm{Im}\,\mathcal{L}$) in an external electric field due to small inhomogeneities in space–time. We emphasize that the correction due to a time derivative of the field has the ''wrong'' sign, i.e., it works against the particle creation. The gradient in the space direction parallel to the field strength, on the other hand, amplifies the process.

As is known, in the case of constant electric field, the imaginary part of the effective Lagrangian is given by

$$\mathrm{Im}\,\mathcal{L}^{(2+1)\mathrm{spin}}(E)=\frac{|eE|^{3/2}}{4\pi^2}\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}\exp\left(-\frac{\pi m^2}{|eE|}n\right)=\frac{|eE|^{3/2}}{4\pi^2}\mathrm{Li}_{3/2}\left[\exp\left(-\frac{\pi m^2}{|eE|}\right)\right]. \tag{70}$$

This as well as the first correction due to the derivatives remain finite even in the limit of zero fermion mass. Despite of this fact, we still expect that the derivative expansion (with the electric field background) may fail in the limit of vanishingly small mass due to higher orders in the number of derivatives. Below we shall see that the same is true in the spinor QED in 3+1 dimensions as well.

VI. SPINOR QED IN 3+1 DIMENSIONS

As was mentioned at the beginning of the paper, the derivative expansion in QED_4 was also studied in Ref. 7. The result of that paper was presented in an explicit form for the special class of the electromagnetic field configurations,

$$\mathcal{G}=0,\quad F^{\mu\nu}(x)=\Phi(x)\mathbf{F}^{\mu\nu}, \tag{71}$$

where $\Phi(x)$ is a slowly varying function that defines the magnitude of the field, and $\mathbf{F}^{\mu\nu}$ is a constant matrix. For convenience, let us normalize the matrix $\mathbf{F}^{\mu\nu}$ by the condition $\mathbf{F}^{\mu\nu}\mathbf{F}_{\mu\nu}=2$. Then the scalar function $\Phi(x)$ is nothing else but $\sqrt{(-2\mathcal{F})}$. As was shown in our previous paper,[9] the general result for the diagonal matrix element (50) in the case of field (71) reduces to the same result as was presented in Ref. 7,

$$\begin{aligned} tr\langle x|U(\tau)|x\rangle_{\mathrm{der}}^{(3+1)}(\Phi)&=\frac{1}{(4\pi)^2\tau}\frac{\partial_\mu\Phi\,\partial^\mu\Phi}{\Phi^2}(3\omega^2Y^4-3\omega Y^3-4\omega^2Y^2+3\omega Y+\omega^2),\\ &=-\frac{1}{(4\pi)^2\tau}\frac{\partial_\mu\Phi\,\partial^\mu\Phi}{\Phi^2}\frac{\omega}{2}\frac{d^3}{d\omega^3}(\omega\coth\omega),\end{aligned} \tag{72}$$

where $\omega=\tau e\Phi$, $Y=\coth\omega$. As in the (2+1)-dimensional theory, here we used the Bianchi identity, which this time reads

$$(\eta^{\mu\nu}+(\mathbf{F}^2)^{\mu\nu})\partial_\nu\Phi\equiv 0. \tag{73}$$

In the case of magnetic field along the third axis, for example, this condition means that the specified field cannot depend on the time and the third spatial coordinates, while in the case of electric field along the first axis, it cannot depend on the second and third spatial coordinates.

Now, let us consider two particular cases of external field that we studied in 2+1 dimensions; purely magnetic and purely electric field backgrounds. Both of them are just different possibilities of that given in Eq. (71).

Thus, in the case of magnetic field (along the third axis in space) we come to the following integral representation for the derivative part of the effective Lagrangian:

$$\mathcal{L}_{\rm der}^{(3+1)\rm spin}(B) = -\frac{e^2(\partial_i B)^2}{(8\pi)^2|eB|}\int_0^\infty \frac{d\omega}{\omega}\exp\left(-\frac{m^2}{|eB|}\omega\right)\frac{d^3}{d\omega^3}(\omega\coth\omega). \tag{74}$$

Resembling the situation in 2+1 dimensions, inhomogeneities of the external magnetic field tend to reduce vacuum energy density for any value of the ratio $m^2/|eB|$.

Performing integration in the right-hand side of Eq. (74) by parts (see Eq. (D6) in Appendix D), we find the following representation (for the representation of the part of the effective action without derivatives in terms of special functions, see Ref. 30):

$$\begin{aligned}\mathcal{L}_{\rm der}^{(3+1)\rm spin}(B) = &-\frac{e^2(\partial_i B)^2}{(8\pi)^2|eB|}\left[\frac{11}{6}\left(\frac{m^2}{|eB|}\right)^3 + \left(\frac{m^2}{|eB|}\right)^2 - \frac{1}{3}\frac{m^2}{|eB|} - \left(\frac{m^2}{|eB|}\right)^3\psi\left(1+\frac{m^2}{2|eB|}\right)\right.\\ &+24\zeta'\left(-2,1+\frac{m^2}{2|eB|}\right) - 24\frac{m^2}{|eB|}\zeta'\left(-1,1+\frac{m^2}{2|eB|}\right)\\ &\left.+6\left(\frac{m^2}{|eB|}\right)^2\left[\ln\Gamma\left(1+\frac{m^2}{2|eB|}\right)-\ln\sqrt{2\pi}\right]\right].\end{aligned} \tag{75}$$

As $m^2 \ll |eB|$, this expression allows the following asymptotic expansion:

$$\begin{aligned}\mathcal{L}_{\rm der}^{(3+1)\rm spin}(B) \simeq &-\frac{e^2(\partial_i B)^2}{(8\pi)^2|eB|}\left[24\zeta'(-2) + \frac{2m^2}{3|eB|} - \frac{m^4}{2|eB|^2} + \frac{m^6}{3|eB|^3}\right.\\ &\left.-\frac{m^8}{2|eB|^4}\sum_{k=0}^{\infty}\frac{k+1}{k+4}\zeta(k+2)\left(-\frac{m^2}{2|eB|}\right)^k\right],\end{aligned} \tag{76}$$

where $\zeta'(-2) \approx -0.030$. As $m^2 \gg |eB|$, on the other hand, we obtain

$$\mathcal{L}_{\rm der}^{(3+1)\rm spin}(B) \simeq -\frac{e^2(\partial_i B)^2}{(2\pi)^2 m^2}\sum_{k=0}^{\infty}\frac{B_{2k+4}}{2k+1}\left(\frac{2|eB|}{m^2}\right)^{2k}. \tag{77}$$

In case of the electric field along the first axis, on the other hand, we obtain the following expression for the derivative part of the effective action:

$$\mathcal{L}_{\rm der}^{(3+1)\rm spin}(E) = -\frac{ie^2(\partial_\parallel E)^2}{(8\pi)^2|eE|}\int_0^\infty \frac{d\omega}{\omega}\exp\left(-i\frac{m^2}{|eE|}\omega\right)\frac{d^3}{d\omega^3}(\omega\coth\omega). \tag{78}$$

This expression has both real and imaginary part, as always happens in the case of an external electric field. Another representation for it is obtained by analytical continuation of (75) according to the rule $|eB| \to -i|eE|$. The imaginary part though is easily extracted from (78) in a standard way,

$$\mathrm{Im}\,\mathcal{L}^{(3+1)\mathrm{spin}}_{\mathrm{der}}(E)=\frac{e^2(\partial_\parallel E)^2}{2^6\pi^4|eE|}\sum_{n=1}^{\infty}\frac{1}{n^3}\exp\left(-\frac{\pi m^2 n}{|eE|}\right)\left[6+6\frac{\pi m^2 n}{|eE|}+3\left(\frac{\pi m^2 n}{|eE|}\right)^2+\left(\frac{\pi m^2 n}{|eE|}\right)^3\right], \tag{79}$$

which determines a correction to the Schwinger result[3] for the imaginary part of the effective action in a constant electric field,

$$\mathrm{Im}\,\mathcal{L}^{(3+1)\mathrm{spin}}(E)=\frac{(eE)^2}{8\pi^3}\sum_{n=1}^{\infty}\frac{1}{n^2}\exp\left(-\frac{\pi m^2}{|eE|}n\right)=\frac{(eE)^2}{8\pi^3}\mathrm{Li}_2\left[\exp\left(-\frac{\pi m^2}{|eE|}\right)\right]. \tag{80}$$

The result in Eq. (79) is in agreement with that of Ref. 10.

As is easy to establish, both the Schwinger result for a constant field and the first correction due to derivatives are finite in the limit of the vanishing fermion mass. As we argued in the case of the (2+1)-dimensional spinor QED, this may not be the case in higher orders of the perturbative expansion in the number of derivatives.

VII. GENERAL RESULT IN THE SCALAR QED

Now turning to the calculation of the derivative expansion for the scalar electrodynamics, one does not need to repeat all the calculations similar to those done in Sec. IV. In order to see this, we recall that the effective one-loop Lagrangian in this case reads

$$L^{(1)\mathrm{scal}}(x)=-i\int_0^\infty\frac{d\tau}{\tau}\langle x|U_{\mathrm{bos}}(\tau)|x\rangle e^{-im^2\tau}. \tag{81}$$

The evolution connected with the transition amplitude, $\langle z|U_{\mathrm{bos}}(\tau)|y\rangle$, is described now by the Hamiltonian (compare with Eqs. (2) and (3)),

$$H_{\mathrm{bos}}=-\Pi_\mu\Pi^\mu,\quad \Pi_\mu=-i\partial_\mu+eA_\mu(x). \tag{82}$$

Thus, omitting all terms originating from the fermion part in the expression (4), i.e., putting $L^{\mathrm{int}}_{\mathrm{fer}}=0$ in Eqs. (10), (14) and $S^{\mathrm{fer}}_{\mathrm{cl}}=0$ in Eq. (19), we come to the following expression:

$$\begin{aligned}\langle x|U_{\mathrm{bos}}(\tau)|x\rangle=&\langle x|U_{\mathrm{bos}}(\tau)|x\rangle_0\\&\times\Bigg[1-\frac{i}{8}eF_{\nu\lambda,\mu\kappa}\sum_{j,l}C^V(f_j,f_l)(A^{\nu\lambda}_{(j)}A^{\mu\kappa}_{(l)}+2A^{\nu\mu}_{(j)}A^{\lambda\kappa}_{(l)})+\frac{i}{18}e^2F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\\&\times\sum_{j,l,k}(C^{VV}_1(f_j,f_l,f_k)(A^{\nu\lambda}_{(j)}A^{\kappa\sigma}_{(l)}A^{\mu\rho}_{(k)}+A^{\nu\mu}_{(j)}A^{\kappa\rho}_{(l)}A^{\lambda\sigma}_{(k)}+2A^{\nu\lambda}_{(j)}A^{\kappa\rho}_{(l)}A^{\mu\sigma}_{(k)})\\&+C^{VV}_2(f_j,f_l,f_k)(A^{\nu\sigma}_{(j)}A^{\kappa\lambda}_{(l)}A^{\mu\rho}_{(k)}+A^{\nu\rho}_{(j)}A^{\kappa\mu}_{(l)}A^{\lambda\sigma}_{(k)}+2A^{\nu\sigma}_{(j)}A^{\kappa\mu}_{(l)}A^{\lambda\rho}_{(k)})\\&+2C^{VV}_3(f_j,f_l,f_k)(A^{\nu\lambda}_{(j)}A^{\kappa\mu}_{(l)}A^{\sigma\rho}_{(k)}+A^{\kappa\rho}_{(j)}A^{\nu\sigma}_{(l)}A^{\lambda\mu}_{(k)})+C^{VV}_4(f_j,f_l,f_k)A^{\nu\kappa}_{(j)}A^{\lambda\mu}_{(l)}A^{\sigma\rho}_{(k)}\\&+C^{VV}_5(f_j,f_l,f_k)A^{\nu\kappa}_{(j)}(A^{\lambda\sigma}_{(l)}A^{\mu\rho}_{(k)}+A^{\lambda\rho}_{(l)}A^{\mu\sigma}_{(k)})\Bigg].\end{aligned} \tag{83}$$

The coefficients used here are the same as in Eq. (50). As for the nonderivative factors, they have the standard form,

$$\langle x|U_{\mathrm{bos}}(\tau)|x\rangle_0^{(3+1)}=-\frac{i}{(4\pi\tau)^2}\frac{(e\tau K_-)(e\tau K_+)}{\sin(e\tau K_-)\sinh(e\tau K_+)} \tag{84}$$

in 3+1 dimensions, and

$$\langle x|U_{\rm bos}(\tau)|x\rangle_0^{(2+1)} = -\frac{\exp(-i\pi/4)}{(4\pi\tau)^{3/2}} \frac{(e\tau\sqrt{2\mathcal{F}})}{\sinh(e\tau\sqrt{2\mathcal{F}})} \tag{85}$$

in 2+1 dimensions, as can be easily checked by using the expressions for the determinants given in Sec. III and by taking into account the fact that, because of spin degrees of freedom, we had the additional factor 4 for fermions.

In the case of scalar theory, the renormalization of the electromagnetic field and charge is given by the same formulas (53) but this time the corresponding constants read

$$\mathbf{C}^{(3+1)} = \frac{1}{48\pi^2}\int_{1/\Lambda^2}^{\infty} \frac{ds}{s}\exp(-sm^2), \tag{86}$$

$$\mathbf{C}^{(2+1)} = \frac{1}{24\pi^{3/2}}\int_0^{\infty} \frac{ds}{\sqrt{s}}\exp(-sm^2) = \frac{1}{24\pi m}. \tag{87}$$

To get a result of the type as in Ref. 4, one has to expand the coefficient functions in powers of proper time. Thus the expansion for $\langle x|U_{\rm bos}(\tau)|x\rangle$ (weak field limit) reads

$$\langle x|U_{\rm bos}(\tau)|x\rangle = \langle x|U_{\rm bos}(\tau)|x\rangle_0\left[1 - \frac{ie^2\tau^3}{30}F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu} - \frac{ie^2\tau^3}{180}(4F^{\nu\lambda,\mu}F_{\nu\lambda,\mu} + F^{\nu\lambda,}{}_{\lambda}F_{\nu\mu,}{}^{\mu}) + \cdots\right]. \tag{88}$$

This expansion up to the order τ^5 is given in Eq. (B26) in Appendix B. As in the spinor QED, it is useful only in the case of heavy scalar particles (weak fields), when the mass scale is much larger than all other scales in the theory.

In the effective action of scalar QED, the expansion in Eq. (88) corresponds to the following leading two derivative terms

$$\mathcal{L}_{1/m^2}^{(3+1)\rm scal} = \frac{\alpha}{720\pi m^2}[6F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu} + 4F^{\nu\lambda,\mu}F_{\nu\lambda,\mu} + F^{\nu\lambda,}{}_{\lambda}F_{\nu\mu,}{}^{\mu}], \tag{89}$$

in 3+1 dimensions, and

$$\mathcal{L}_{1/m^3}^{(2+1)\rm scal} = -\frac{\alpha}{720m^3}[6F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu} + 4F^{\nu\lambda,\mu}F_{\nu\lambda,\mu} + F^{\nu\lambda,}{}_{\lambda}F_{\nu\mu,}{}^{\mu}], \tag{90}$$

in 2+1 dimensions.

VIII. SCALAR QED IN 2+1 DIMENSIONS

Let us start by considering the case of an external magnetic field as in Eq. (59). This time the derivative part of the general expression (83) reduces to

$$\begin{aligned}\langle x|U_{\rm bos}(\tau)|x\rangle_{\rm der}^{(2+1)} &= -\frac{ie^2(\partial_i B)^2}{4(4\pi|eB|)^{3/2}}\frac{\sqrt{\omega}}{\sinh\omega}(3\omega Y^3 - 3Y^2 - 2\omega Y + 1)\\ &= \frac{ie^2(\partial_i B)^2}{4(4\pi|eB|)^{3/2}}\frac{\sqrt{\omega}}{2}\left(\frac{d^3}{d\omega^3} + \frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right),\end{aligned} \tag{91}$$

where $\omega = i\tau|eB|$, $Y = \coth\omega$. After substituting the last expression into Eq. (81), we come to the integral representation for the derivative part of the effective Lagrangian (after performing the change of integration variable $\tau\to\omega = i\tau|eB|$),

$$\mathcal{L}_{\rm der}^{(2+1){\rm scal}}(B)=\frac{e^2(\partial_i B)^2}{(16\pi|eB|)^{3/2}}\int_0^\infty \frac{d\omega}{\sqrt{\omega}}\exp\left(-\frac{m^2}{|eB|}\omega\right)\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right), \tag{92}$$

which coincides with the result presented in Ref. 8. As in the case of spinor QED, there exists another representation of (92) given in terms of special functions (see Eq. (D11) in Appendix D),

$$\mathcal{L}_{\rm der}^{(2+1){\rm scal}}(B)=\frac{e^2(\partial_i B)^2}{\sqrt{2}\pi(16|eB|)^{3/2}}\left[20\zeta\left(-\frac{3}{2},\frac{1}{2}+\frac{m^2}{2|eB|}\right)-18\frac{m^2}{|eB|}\zeta\left(-\frac{1}{2},\frac{1}{2}+\frac{m^2}{2|eB|}\right)\right.$$
$$\left.+\left(1+3\left(\frac{m^2}{|eB|}\right)^2\right)\zeta\left(\frac{1}{2},\frac{1}{2}+\frac{m^2}{2|eB|}\right)+\frac{1}{2}\left(\frac{m^2}{|eB|}+\left(\frac{m^2}{|eB|}\right)^3\right)\zeta\left(\frac{3}{2},\frac{1}{2}+\frac{m^2}{2|eB|}\right)\right]. \tag{93}$$

Numerical study of the integral in (92) shows that inhomogeneities of magnetic field background, in approximation under consideration (one-loop and two derivatives), lead to decreasing the vacuum energy density for $m^2/|eB|\gtrsim 0.927$ and to increasing that density for $m^2/|eB|\lesssim 0.927$, in accordance with Ref. 8.

Analytically, we can obtain only the limiting cases as we did in spinor electrodynamics. In particular, for $m^2\ll|eB|$, the effective action takes the following asymptotic form:

$$\mathcal{L}_{\rm der}^{(2+1){\rm scal}}(B)\simeq\frac{e^2(\partial_i B)^2}{(16\pi|eB|)^{3/2}}\sum_{k=0}^{\infty}\frac{1}{k!}\left[(2^k-2\sqrt{2})(5-2k)\zeta\left(k-\frac{3}{2}\right)\right.$$
$$\left.+\left(2^k-\frac{1}{\sqrt{2}}\right)(1-2k)\zeta\left(k+\frac{1}{2}\right)\right]\Gamma\left(k+\frac{1}{2}\right)\left(-\frac{m^2}{2|eB|}\right)^k, \tag{94}$$

while for $m^2\gg|eB|$, the expansion reads

$$\mathcal{L}_{\rm der}^{(2+1){\rm scal}}(B)\simeq-\frac{e^2(\partial_i B)^2}{32\pi^{3/2}m^3}\sum_{k=0}^{\infty}\frac{(2^{2k+3}-1)B_{2k+4}+(2^{2k+1}-1)B_{2k+2}}{(2k+1)!}\Gamma\left(2k+\frac{3}{2}\right)\left(\frac{|eB|}{m^2}\right)^{2k}. \tag{95}$$

Now, let us consider the case of electric field background. Without losing the generality, we assume that the field is directed along the first axis of space. We obtain

$$\langle x|U_{\rm bos}(\tau)|x\rangle_{\rm der}^{(2+1)}(E)=\frac{i\exp(-i\pi/4)}{4(4\pi|eE|)^{3/2}}\frac{e^2(\partial_\parallel E)^2\sqrt{\omega}}{\sinh\omega}(3\omega Y^3-3Y^2-2\omega Y+1)$$
$$=-\frac{i\exp(-i\pi/4)}{(16\pi|eE|)^{3/2}}e^2(\partial_\parallel E)^2\sqrt{\omega}\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right), \tag{96}$$

where now $\omega=\tau|eE|$ and $Y=\coth\omega$. Substituting this expression into (81), we come to the integral representation for the derivative part of the effective Lagrangian,

$$\mathcal{L}_{\rm der}^{(2+1){\rm scal}}(E)=-\frac{\exp(-i\pi/4)e^2(\partial_\parallel E)^2}{(16\pi|eE|)^{3/2}}\int_0^\infty\frac{d\omega}{\sqrt{\omega}}\exp\left(-i\frac{m^2}{|eE|}\omega\right)\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right). \tag{97}$$

And we easily find the imaginary part of the expression,

$$\mathrm{Im}\,\mathcal{L}_{\mathrm{der}}^{(2+1)\mathrm{scal}}(E)=\frac{e^2(\partial_{\parallel}E)^2}{2^9\pi^3|eE|^{3/2}}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n^{5/2}}\exp\left(-\frac{\pi m^2 n}{|eE|}\right)$$
$$\times\left[15+18\frac{\pi m^2 n}{|eE|}+4\pi^2n^2\left(3\frac{m^4}{|eE|^2}-1\right)+8\frac{m^2\pi^3n^3}{|eE|}\left(\frac{m^4}{|eE|^2}-1\right)\right], \quad (98)$$

which determines the correction to the corresponding result for case of constant electric field,

$$\mathrm{Im}\,\mathcal{L}^{(2+1)\mathrm{scal}}(E)=\frac{|eE|^{3/2}}{8\pi^2}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n^{3/2}}\exp\left(-\frac{\pi m^2}{|eE|}n\right)=-\frac{|eE|^{3/2}}{8\pi^2}\mathrm{Li}_{3/2}\left[-\exp\left(-\frac{\pi m^2}{|eE|}\right)\right]. \quad (99)$$

A simple numerical analysis of the derivative correction in Eq. (98) shows that the sum in the right-hand side, being positive for large values of the mass (or small values of the electric field), changes its sign at $m^2\approx 0.721|eE|$. Therefore, unlike the case of spinor QED, the time derivative of the field increases (while the gradient in space decreases) the probability of particle–antiparticle pair creation only for $m^2 \gtrsim 0.721|eE|$.

As in spinor QED, the two-derivative correction to the process of the pair production in scalar QED is convergent even in the limit of the vanishing mass. This observation, of course, is not enough to prove that the derivative expansion is well defined to all orders in the massless theory.

IX. SCALAR QED IN 3+1 DIMENSIONS

The derivative expansion for the electromagnetic field of the form (71) was presented in our previous paper[9] (we just rewrite it in different form),

$$\langle x|U_{\mathrm{bos}}(\tau)|x\rangle_{\mathrm{der}}^{(3+1)}=\frac{1}{(8\pi)^2\tau}\frac{\partial_\mu\Phi\partial^\mu\Phi}{\Phi^2}\frac{\omega}{\sinh\omega}(3\omega Y^3-3Y^2-2\omega Y+1)$$
$$=-\frac{1}{(8\pi)^2\tau}\frac{\partial_\mu\Phi\partial^\mu\Phi}{\Phi^2}\frac{\omega}{2}\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right), \quad (100)$$

with $\omega=\tau e\Phi$, $Y=\coth\omega$.

Now, let us consider the two most interesting particular cases as before. As in the case of the fermion theory presented in Sec. VI, in the case of scalar QED, the derivative part of the effective Lagrangian is easily obtained by using (100) with $\Phi=iB$,

$$\mathcal{L}_{\mathrm{der}}^{(3+1)\mathrm{scal}}(B)=\frac{e^2(\partial_i B)^2}{2(8\pi)^2|eB|}\int_0^\infty\frac{d\omega}{\omega}\exp\left(-\frac{m^2}{|eB|}\omega\right)\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right). \quad (101)$$

And again, as is easy to check, the situation with (101) resembles that in (2+1)-dimensional scalar QED; inhomogeneities of the external magnetic field lead to decreasing the vacuum energy density for large values of the ratio $m^2/|eB|$ $(m^2/|eB|\gtrsim 0.41)$ and to increasing for small values $(m^2/|eB|\lesssim 0.41)$.

In addition to the representation (101), we find the following one (see Eq. (D12) in Appendix D):

$$\mathcal{L}_{\rm der}^{(3+1){\rm scal}}(B)=\frac{e^2(\partial_i B)^2}{2(8\pi)^2|eB|}\left[\frac{11}{6}\left(\frac{m^2}{|eB|}\right)^3-\frac{m^2}{|eB|}\left(1+\left(\frac{m^2}{|eB|}\right)^2\right)\psi\left(\frac{1}{2}+\frac{m^2}{2|eB|}\right)\right.$$
$$+\frac{7}{6}\frac{m^2}{|eB|}+2\left(1+3\left(\frac{m^2}{|eB|}\right)^2\right)\left[\ln\Gamma\left(\frac{1}{2}+\frac{m^2}{2|eB|}\right)-\ln\sqrt{2\pi}\right]$$
$$\left.+24\zeta'\left(-2,\frac{1}{2}+\frac{m^2}{2|eB|}\right)-24\frac{m^2}{|eB|}\zeta'\left(-1,\frac{1}{2}+\frac{m^2}{2|eB|}\right)\right]. \tag{102}$$

In the limit $m^2 \ll |eB|$, this expression allows the following asymptotic expansion:

$$\mathcal{L}_{\rm der}^{(3+1){\rm scal}}(B)\simeq\frac{e^2(\partial_i B)^2}{2(8\pi)^2|eB|}\left[-18\zeta'(-2)-\ln 2+\frac{2m^2}{3|eB|}+\frac{m^6}{3|eB|^3}\right.$$
$$-\frac{m^4}{2|eB|^2}\sum_{k=0}^{\infty}\frac{k+1}{k+2}(2^{k+2}-1)\zeta(k+2)\left(-\frac{m^2}{2|eB|}\right)^k$$
$$\left.-\frac{m^8}{2|eB|^4}\sum_{k=0}^{\infty}\frac{k+1}{k+4}(2^{k+2}-1)\zeta(k+2)\left(-\frac{m^2}{2|eB|}\right)^k\right]. \tag{103}$$

In the limit $m^2 \gg |eB|$, on the other hand, we obtain

$$\mathcal{L}_{\rm der}^{(3+1){\rm scal}}(B)\simeq\frac{e^2(\partial_i B)^2}{(8\pi)^2 m^2}\sum_{k=0}^{\infty}\frac{(2^{2k+3}-1)B_{2k+4}+(2^{2k+1}-1)B_{2k+2}}{2k+1}\left(\frac{|eB|}{m^2}\right)^{2k}. \tag{104}$$

In the case of the electric field directed along the first axis, we obtain

$$\mathcal{L}_{\rm der}^{(3+1){\rm scal}}(E)=\frac{ie^2(\partial_{\|}E)^2}{2(8\pi)^2|eE|}\int_0^{\infty}\frac{d\omega}{\omega}\exp\left(-i\frac{m^2}{|eE|}\omega\right)\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\left(\frac{\omega}{\sinh\omega}\right). \tag{105}$$

Thus, the imaginary part of derivative part of the Lagrangian reads

$$\operatorname{Im}\mathcal{L}_{\rm der}^{(3+1){\rm scal}}(E)=\frac{e^2(\partial_{\|}E)^2}{2^7\pi^4|eE|}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n^3}\exp\left(-\frac{\pi m^2 n}{|eE|}\right)$$
$$\times\left[6+6\frac{\pi m^2 n}{|eE|}+\pi^2 n^2\left(3\frac{m^4}{|eE|^2}-1\right)+\frac{m^2\pi^3 n^3}{|eE|}\left(\frac{m^4}{|eE|^2}-1\right)\right], \tag{106}$$

which determines the correction to the probability of particle-antiparticle creation in a constant electric field expressed through

$$\operatorname{Im}\mathcal{L}^{(3+1){\rm scal}}(E)=\frac{(eE)^2}{16\pi^3}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n^2}\exp\left(-\frac{\pi m^2}{|eE|}n\right)=-\frac{(eE)^2}{16\pi^3}\operatorname{Li}_2\left[-\exp\left(-\frac{\pi m^2}{|eE|}\right)\right]. \tag{107}$$

As in (2+1)-dimensional case, we observe that the sum in the right-hand side of Eq. (106) is positive only for the large enough values of the mass ($m^2 \gtrsim 0.388|eE|$).

The expression (106) concludes the list of our results describing the influence of slowly varying external electromagnetic fields on the spinor and scalar QED vacuum in the two-derivative approximation.

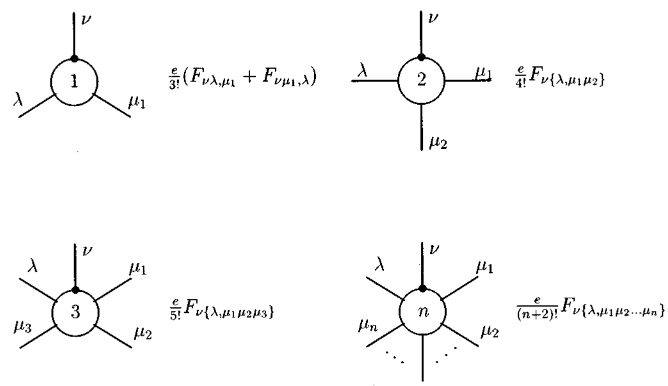

FIG. 1. Diagrammatic notations for the boson interaction vertices. The curly brackets denote symmetrization of the type, $F_{\nu\{\lambda,\mu_1,\ldots,\mu_n\}}=F_{\nu\lambda,\mu_1,\ldots,\mu_n}+F_{\nu\mu_1,\lambda,\ldots,\mu_n}+\cdots+F_{\nu\mu_n,\mu_1,\ldots,\lambda}$.

X. HOW TO GET HIGHER DERIVATIVE TERMS

Obviously, the method of the present paper can be applied for calculating the higher derivative terms (with their total number equal to four or higher) of the low energy effective action in QED. However, the computational work with increasing the total number of derivatives is getting so hard that obtaining already all the four derivative terms seems to be impossible without use of a computer. Just to get feeling how difficult this problem is, let us consider the classification of all the relevant Feynman diagrams in four derivative approximation.

To facilitate the calculation of the perturbative expansion in number of derivatives in the problem at hand, it is appropriate to develop the Feynman diagram technique. Our starting point will be the system of Eqs. (14) and (19). Then, as is seen, the derivative expansion results from all (connected as well as disconnected) vacuum diagrams produced by (14). A somewhat disappointing feature of our Lagrangian is an infinite number of local interactions. Nevertheless, as will become clear in a moment, while working at any finite order of the perturbative theory, one requires only a finite number of those interactions.

We observe that there are two different types of local interactions in (14). The first (bosonic) type contains only the bosonic fields, $x_\mu(t)$. The corresponding vertices are shown in Fig. 1. The other interactions involve both the boson, $x_\mu(t)$, and the spinor fields, $\psi_\mu(t)$. These latter produce the vertices given in Fig. 2. The integers in the vertices denote the number of derivatives (later called the weights of vertices) of the electromagnetic field with respect to space–time. Some legs in the diagrams are marked by circles and bullets. The circles correspond to legs related to the first Lorentz index (ν) of the tensor weight, $F_{\nu\lambda,\mu_1,\ldots,\mu_n}$, assigned to the vertex, while the bullets, on the other hand, mark legs which contain the derivatives with respect to the proper time. The latter act on the (bosonic) propagators attached to the marked legs.

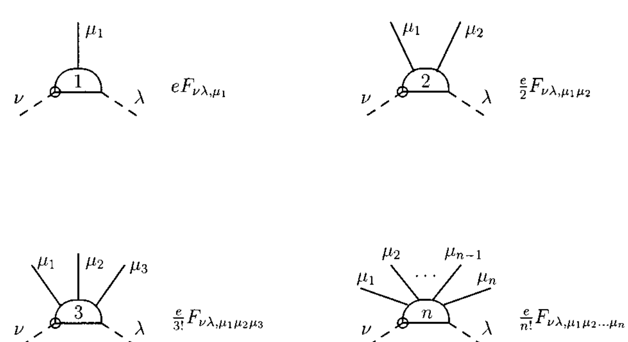

FIG. 2. Diagrammatic notations for the fermion–boson interaction vertices.

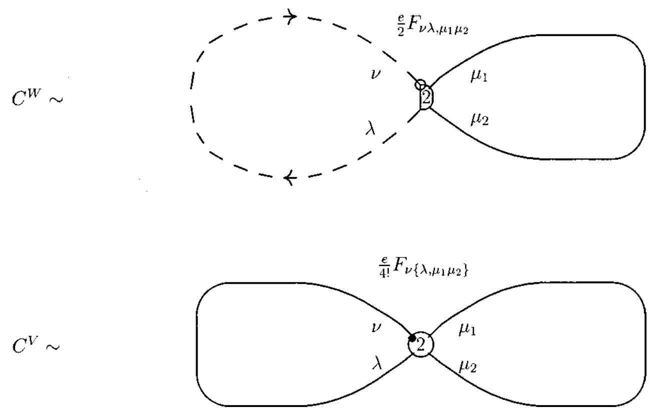

FIG. 3. Two simplest examples of diagrams related to the two-derivative terms C^W and C^V in our general expression for spinor QED.

The Feynman rules for writing expressions corresponding to Feynman diagrams are more or less standard. One has to use the propagators given in (41) and (42) for connecting the bosonic (solid) and the fermion (dashed) legs, respectively. The combinatoric factors can be straightforwardly derived. Two simplest diagrams giving a nonzero contribution to two-derivative terms in the effective action are represented in Fig. 3.

Let us mention the most general rules. To start with, we classify all diagrams leading to terms with a given finite number (called the weight of the corresponding diagrams from now on) of derivatives in the expansion. First of all, we see that diagrams with weight N may contain different number of vertices. We denote by der(N) the set of all diagrams of a given weight N. By marking the bosonic (Fig. 1) and the fermion (Fig. 2) vertices with n derivatives just by $[n]$ and $\overline{[n]}$, respectively, we see that the set der(N) contains a finite number of elements: der(N) $=\{\overline{[N]},[N],\overline{[N-1]}\oplus\overline{[1]},\overline{[N-1]}\oplus[1],[N-1]\oplus\overline{[1]},[N-1]\oplus[1],\ldots\}$. Each of the elements in der(N) produces in its turn a (finite) number of Feynman diagrams differing from one another by all possible connections (by means of propagators) between all legs of the vertices. Thus, the diagrams of weight two in Fig. 3, related to C^W and C^V in the general expression (50), correspond to elements $\overline{[2]}$ and $[2]$ in the set der(2), respectively.

Any element of der(N) specifies the number of different vertices as well as their separate weights. If the number of different vertices in a diagram is given by integers $\{V_1,V_2,\ldots,V_k\}$ then the overall factor in front of the corresponding expression is $1/(V_1!V_2!\ldots V_k!)$. Next, let the total number of bosonic and the fermion vertices be k_B and k_F (so that $k_B+k_F=k$), respectively. Then the total number of bosonic legs of all the vertices in such a diagram is $2k_B+N)$, while the number of the fermion legs is $2k_F$. Since, we are interested in vacuum diagrams (with all legs being connected) only, the diagrams of an odd weight N are not relevant for our derivative expansion. So, we put $N=2n$. As is easy to count, the total number of all possible connections (by means of k_B+n bosonic and k_F the fermion propagators) between these vertices is $(N+2k_B-1)!!(2k_F-1)!!$, where we assume that $(-1)!!\equiv 1$. This is an upper bound for the number of different diagrams with the given vertex set corresponding to the given element $\overline{[V_1]}\oplus\cdots\oplus\overline{[V_{k_F}]}\oplus[V_{k_F+1}]\oplus\cdots\oplus[V_k]\in\text{der}(N)$. However, due to the symmetry of the vertices with respect to permutations of their nonmarked legs as well as with respect to permutations of identical vertices, some of the diagrams are in fact equivalent. For example, the naive number of all relevant diagrams for the two-derivative terms in the expansion of the effective action is 25. On the other hand, as is seen from our general result (50), the actual number of nonequivalent terms is 11.

Now let us say several words about the sign factors of diagrams. First, all diagrams of weight $N=2n$ have an overall factor $(-i)^n$. To get the right sign resulting from the fermion loops, one preliminary has to assign the direction of the fermion flow in the diagram by adding arrows on the fermion (dashed) lines. Then the overall sign factor is obtained by multiplying sign factors for each the fermion loop of the diagram. Each of the loop factors is defined by the formula, $(-1)^{N_0+1}$, where N_0 is the number of arrows running into circles of loop vertices. This rule takes into account the fact that the fermion propagators are antisymmetric with respect to the simultaneous permutation of their Lorentz indices and proper time coordinates as well as the fact that tensor weight at the fermion vertices feels the order of first two indices.

Concluding this section, we would like to express a hope that the brief description of the Feynman technique given here would be enough for writing a code in some of the languages used for analytical computations if such a need appears.

XI. CONCLUSIONS

In conclusion, here we further develop the method of our previous paper[9] and generalize it to quantum electrodynamics in $2+1$ dimensions. The distinctive feature of our approach is the use of a special matrix basis (in Lorentz indices) in order to deal with functions of antisymmetric tensors such as the (background) field strength tensor in QED. In Sec. III, we give the explicit representation for these matrices as well as demonstrate how they facilitate the calculation. It is also the use of these matrices that allowed us to obtain the derivative expansion in the fully covariant form.

Then, in this paper, we derived explicit expression of the two-derivative term in the derivative expansion of the effective action in QED in both fermion and scalar QED in $2+1$ and $3+1$ dimensions. In addition, we also calculated the leading order corrections to the probability of the particle–antiparticle creation rate produced by space–time gradients of the electric field background. The latter gives a nontrivial generalization of the famous Schwinger result in a constant electric field.[3]

Among other results, here we derived the Feynman rules for generating the perturbative expansion of the effective action in the number of derivatives. This means that, in principle, an arbitrary finite order of the derivative expansion is calculable in our approach. For obvious reasons, the complexity of calculation explodes at higher orders and, in the case of the four-derivative approximation, the computational work already becomes so hard that it is almost impossible to get a result in the closed form without using a computer. By making use of the Feynman rules, derived in this paper, one can write a computer code in order to calculate higher order approximations.

At the end, let us also make a few remarks about possible tests and applications of derivative expansion obtained in this paper.

As in the case of the Euler–Heisenberg action, the derivative corrections will affect, among other things, the photon–photon scattering amplitude. For a vanishing background field, the latter is discussed in detail in Ref. 6. Obviously, when the background field is nonzero the corresponding amplitude and the energy dependence of the cross section are going to change. As for the explicit form of the result, it will be given elsewhere.

Besides that, it is likely that the explicit dependence of the photon–photon cross section would be of great interest in studies of some real systems which exist under extremely large magnetic fields. The vicinity of the neutron stars and the early Universe[31] are the most natural candidates of such systems.

The formal derivative expansion might also be useful in other problems, such as the generalization of the theory of magnetic catalysis of chiral symmetry breaking in QED_4 (Ref. 32) and QED_3 (Ref. 33) to the case of inhomogeneous external fields.

ACKNOWLEDGMENTS

We would like to thank Theodore Hall for pointing out mistakes in the expressions for the imaginary part of the effective action in the first version of the paper. V.P.G. is grateful to the members of the Institute for Theoretical Physics, University of Bern, Switzerland, for hospitality during his stay there. The work of V.P.G. was supported by Grant No. INTAS-93-2058-ext ''East–West network in constrained dynamical systems,'' by the Swiss National Science Foundation Grant No. CEEC/NIS/96-98/7 IP 051219 and by the Foundation of Fundamental Researches of Ministry of Sciences of Ukraine under Grant No. 2.5.1/003. APPENDIX A: COEFFICIENT FUNCTIONS WHICH APPEAR IN THE DERIVATIVE EXPANSION

Here we give the functions used in Eqs. (50) and (83). [Here we corrected the typos which appeared in Ref. 9, namely we (i) omitted an extra term in the expression for C_4^{VV} that was mistakenly present; (ii) replaced the wrong factor $H(\tau\beta)$ in the last term of C_4^{VV} by $H(\tau\gamma)$, and (iii) added the third term in C_5^{VV} which was originally missing. In addition, we rewrote C_5^{VV} in a slightly different form.]

$$C^W(\overline{\alpha},\overline{\beta})=\tau^2\tanh(\alpha\tau)H(\beta\tau), \tag{A1}$$

$$C^V(\overline{\alpha},\overline{\beta})=\alpha\tau^3H(\alpha\tau)H(\beta\tau)-\frac{\alpha\tau}{\beta^2-\alpha^2}[H(\beta\tau)-H(\alpha\tau)], \tag{A2}$$

$$C_1^{WW}(\overline{\alpha},\overline{\beta},\overline{\gamma})=\frac{\tau^3}{8}\tanh(\alpha\tau)\tanh(\beta\tau)H(\gamma\tau), \tag{A3}$$

$$C_2^{WW}(\overline{\alpha},\overline{\beta},\overline{\gamma})=\frac{\tau^2}{4}[\tanh(\alpha\tau)+\tanh(\beta\tau)]\left(\frac{H(\alpha\tau+\beta\tau)-H(\gamma\tau)}{\alpha+\beta-\gamma}-\frac{H(\gamma\tau)}{\alpha+\beta}\right), \tag{A4}$$

$$C_1^{VW}(\overline{\alpha},\overline{\beta},\gamma)=-\frac{\tau^3}{4}\tanh(\alpha\tau)\left(\beta\tau H(\beta\tau)H(\gamma\tau)-\frac{H(\beta\tau)-H(\gamma\tau)}{\tau(\beta+\gamma)}\right), \tag{A5}$$

$$C_2^{VW}(\overline{\alpha},\overline{\beta},\overline{\gamma})=\frac{\tau^2\beta\tanh(\alpha\tau)}{2(\beta^2-\gamma^2)}[H(\beta\tau)-H(\gamma\tau)], \tag{A6}$$

$$\begin{aligned}C_1^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})=&\frac{\tau^5\alpha\beta}{2}H(\alpha\tau)H(\beta\tau)H(\gamma\tau)-\frac{\tau^3\alpha H(\alpha\tau)}{2(\beta-\gamma)}(H(\beta\tau)-H(\gamma\tau))\\&-\frac{\tau^3\beta H(\beta\tau)}{2(\alpha+\gamma)}(H(\alpha\tau)-H(\gamma\tau))-\frac{\tau}{2}\frac{H(\alpha\tau)}{(\alpha+\gamma)(\alpha+\beta)}\\&-\frac{\tau}{2}\frac{H(\beta\tau)}{(\alpha+\beta)(\beta-\gamma)}+\frac{\tau}{2}\frac{H(\gamma\tau)}{(\alpha+\gamma)(\beta-\gamma)},\end{aligned} \tag{A7}$$

$$\begin{aligned}C_2^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})=&-\frac{\tau^3\alpha\beta H(\alpha\tau)H(\beta\tau)}{2(\alpha-\beta)(\alpha-\beta+\gamma)}+\frac{\tau^3[2(\alpha-\beta)+\gamma]H(\gamma\tau)[\beta H(\beta\tau)-\alpha H(\alpha\tau)]}{2(\alpha-\beta)(\alpha-\beta+\gamma)}\\&+\frac{\alpha\tau}{2}H(\alpha\tau)\left(\frac{2(\beta+\gamma)}{(\alpha^2-\beta^2)(\alpha^2-\gamma^2)}-\frac{2\alpha-\beta+\gamma}{(\alpha-\beta)^2(\alpha+\gamma)(\alpha-\beta+\gamma)}\right)\\&+\frac{\beta\tau}{2}H(\beta\tau)\left(\frac{2(\gamma-\alpha)}{(\alpha^2-\beta^2)(\beta^2-\gamma^2)}+\frac{2\beta-\alpha-\gamma}{(\alpha-\beta)^2(\beta-\gamma)(\alpha-\beta+\gamma)}\right)\\&+\frac{\tau}{2}H(\gamma\tau)\left(\frac{2(\alpha\beta+\gamma^2)}{(\alpha^2-\gamma^2)(\beta^2-\gamma^2)}-\frac{\gamma}{(\alpha+\gamma)(\beta-\gamma)(\alpha-\beta+\gamma)}\right)\\&+\frac{\tau}{2(\alpha-\beta)(\alpha-\beta+\gamma)},\end{aligned} \tag{A8}$$

$$C_3^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})=-\frac{\tau^3\alpha\beta H(\alpha\tau)}{\beta^2-\gamma^2}[H(\beta\tau)-H(\gamma\tau)]+\frac{\alpha\tau H(\alpha\tau)}{(\alpha-\beta)(\alpha^2-\gamma^2)}-\frac{\tau}{\beta^2-\gamma^2}\left(\frac{\beta}{\alpha-\beta}H(\beta\tau)-\frac{\alpha\beta+\gamma^2}{\alpha^2-\gamma^2}H(\gamma\tau)\right), \tag{A9}$$

$$C_4^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})=-\frac{2\tau\alpha^2H(\alpha\tau)}{(\alpha^2-\beta^2)(\alpha^2-\gamma^2)}+\frac{2\tau\beta^2H(\beta\tau)}{(\alpha^2-\beta^2)(\beta^2-\gamma^2)}+\frac{2\tau\gamma^2H(\gamma\tau)}{(\alpha^2-\gamma^2)(\gamma^2-\beta^2)}, \tag{A10}$$

$$\begin{aligned}C_5^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})=&\frac{\tau^3\alpha}{2}\left(\frac{\alpha}{(\alpha+\beta)(\alpha+\beta+\gamma)}+\frac{1}{\alpha+\gamma}\right)H(\alpha\tau)H(\beta\tau)\\&+\frac{\tau^3\alpha}{2}\left(\frac{\alpha}{(\alpha+\gamma)(\alpha+\beta+\gamma)}+\frac{1}{\alpha+\beta}\right)H(\alpha\tau)H(\gamma\tau)+\tau^3H(\beta\tau)H(\gamma\tau)\\&+\frac{\tau^3}{2}\left(\frac{\beta\gamma(\beta+\gamma)}{\alpha+\beta+\gamma}-2\alpha^2\right)\frac{H(\beta\tau)H(\gamma\tau)}{(\alpha+\beta)(\alpha+\gamma)}+\frac{\alpha\tau H(\alpha\tau)\left(2+\frac{\alpha+\beta}{\alpha+\gamma}+\frac{\alpha+\gamma}{\alpha+\beta}\right)}{2(\alpha+\beta)(\alpha+\gamma)(\alpha+\beta+\gamma)}\\&+\frac{\tau}{2}\left(\frac{2H(\gamma\tau)}{(\alpha+\gamma)(\beta-\gamma)}-\frac{2H(\beta\tau)}{(\alpha+\beta)(\beta-\gamma)}+\frac{\gamma H(\gamma\tau)}{(\alpha+\gamma)^2(\alpha+\beta+\gamma)}\right.\\&\left.+\frac{\beta H(\beta\tau)}{(\alpha+\beta)^2(\alpha+\beta+\gamma)}-\frac{1}{(\alpha+\beta)(\alpha+\beta+\gamma)}-\frac{1}{(\alpha+\gamma)(\alpha+\beta+\gamma)}\right).\end{aligned} \tag{A11}$$

Here we used the following notation:

$$H(x)=\frac{x\coth x-1}{x^2}, \tag{A12}$$

and the letters with bars differ from the letters without those only in a factor of the electric charge, $\alpha=e\overline{\alpha}$. Note that in Ref. 9 we ignored this difference.

As $\tau\rightarrow 0$, these coefficient functions have the following asymptotic behavior:

$$C^W(\overline{\alpha},\overline{\beta})\simeq\frac{\alpha\tau^3}{3}-\frac{\alpha\tau^5}{45}(5\alpha^2+\beta^2)+O(\tau^7), \tag{A13}$$

$$C^V(\overline{\alpha},\overline{\beta})\simeq\frac{2\alpha\tau^3}{15}-\frac{\alpha\tau^5}{105}(\alpha^2+\beta^2)+O(\tau^7), \tag{A14}$$

$$C_1^{WW}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq\frac{\alpha\beta\tau^5}{24}+O(\tau^7), \tag{A15}$$

$$C_2^{WW}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq-\frac{\tau^3}{12}+\frac{\tau^5}{180}(4\alpha^2+4\beta^2+\gamma^2-7\alpha\beta-\alpha\gamma-\beta\gamma)+O(\tau^7), \tag{A16}$$

$$C_1^{VW}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq\frac{\alpha\tau^5}{180}(\gamma-6\beta)+O(\tau^7), \tag{A17}$$

$$C_2^{VW}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq\frac{\alpha\beta\tau^5}{90}+O(\tau^7), \tag{A18}$$

$$C_1^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq\frac{\tau^3}{90}-\frac{\tau^5}{1890}(2\alpha^2+2\beta^2+2\gamma^2-51\alpha\beta-9\alpha\gamma+9\beta\gamma)+O(\tau^7), \tag{A19}$$

$$C_2^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq-\frac{4\tau^3}{45}+\frac{\tau^5}{1890}(10\alpha^2+10\beta^2+13\gamma^2+15\alpha\beta+3\alpha\gamma-3\beta\gamma)+O(\tau^7), \tag{A20}$$

$$C_3^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq-\frac{\tau^3}{45}+\frac{\tau^5}{945}(2\alpha^2+2\beta^2+2\gamma^2+9\alpha\beta)+O(\tau^7), \tag{A21}$$

$$C_4^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq\frac{2\tau^3}{45}-\frac{4\tau^5}{945}(\alpha^2+\beta^2+\gamma^2)+O(\tau^7), \tag{A22}$$

$$C_5^{VV}(\overline{\alpha},\overline{\beta},\overline{\gamma})\simeq\frac{8\tau^3}{45}-\frac{\tau^5}{1890}(20\alpha^2+23\beta^2+23\gamma^2-12\alpha\beta-12\alpha\gamma+6\beta\gamma)+O(\tau^7). \tag{A23}$$

APPENDIX B: EXPANSION OF THE DERIVATIVE TERMS IN POWERS OF THE PROPER TIME

In this Appendix we give the proper time expansion of the derivative terms, as in Eqs. (56) and (88), up to the order τ^5.

In case of spinor QED, from Eq. (50) we derive the expansion

$$\begin{aligned}tr\langle x|U(\tau)|x\rangle\simeq tr\langle x|U(\tau)|x\rangle_0\Bigg[&1+\frac{ie^2\tau^3}{20}F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu}\\&+\frac{ie^2\tau^3}{180}\left(\frac{7}{2}F^{\nu\lambda,\mu}F_{\nu\lambda,\mu}-F^{\nu\lambda,}{}_{\lambda}F_{\nu\mu,}{}^{\mu}\right)-\frac{ie^4\tau^5}{315}F_{\nu\lambda,\mu\kappa}(16\mathcal{F}\eta^{\mu\kappa}F^{\nu\lambda}+F^{\nu\lambda}(F^2)^{\mu\kappa})\\&+\frac{ie^4\tau^5}{1890}(2F_{\nu\lambda,\mu}F^{\nu\rho,}{}_{\rho}(F^2)^{\lambda\mu}-2F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)^{\mu}{}_{\rho}-37F_{\nu\lambda,\mu}F^{\nu\sigma,\mu}(F^2)^{\lambda}{}_{\sigma}\\&+F_{\nu\mu,}{}^{\mu}F_{\sigma\rho,}{}^{\rho}(F^2)^{\nu\sigma})-\frac{ie^4\tau^5}{2520}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}(38\eta^{\mu\rho}F^{\lambda\sigma}F^{\nu\kappa}-12\eta^{\nu\kappa}F^{\lambda\rho}F^{\mu\sigma}\\&+47\eta^{\mu\rho}F^{\nu\lambda}F^{\sigma\kappa}+16\eta^{\kappa\rho}F^{\lambda\sigma}F^{\nu\mu})\Bigg].\end{aligned} \tag{B1}$$

Notice that despite the difference between the two sets of matrices $A_{(j)}^{\mu\nu}$ in 2+1 and 3+1 dimensions, the expression in square brackets is independent of the dimension up to this order in the expansion. In calculation, we took into account the Bianchi identity to show that many seemingly different terms appearing in the expansion reduce to the same structures. In particular, the following relations are the identities that we needed:

$$F_{\nu\lambda,\mu\kappa}\eta^{\lambda\kappa}F^{\nu\mu}=\tfrac{1}{2}F_{\nu\lambda,\mu\kappa}\eta^{\mu\kappa}F^{\nu\lambda}, \tag{B2}$$

$$F_{\nu\lambda,\mu\kappa}F^{\nu\mu}(F^2)^{\lambda\kappa}=\tfrac{1}{2}F_{\nu\lambda,\mu\kappa}F^{\nu\lambda}(F^2)^{\mu\kappa}, \tag{B3}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\nu\rho}F^{\lambda\sigma}F^{\mu\kappa}=\tfrac{1}{2}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\rho}F^{\lambda\sigma}F^{\nu\kappa}, \tag{B4}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\nu\kappa}F^{\lambda\sigma}F^{\mu\rho}=F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\nu\kappa}F^{\lambda\rho}F^{\mu\sigma}+\tfrac{1}{2}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\rho}F^{\lambda\sigma}F^{\nu\kappa}, \tag{B5}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\sigma}F^{\kappa\rho}F^{\nu\lambda}=-\tfrac{1}{2}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\rho}F^{\nu\lambda}F^{\sigma\kappa}, \tag{B6}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\sigma\rho}F^{\mu\kappa}F^{\nu\lambda}=-2F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\kappa\rho}F^{\lambda\sigma}F^{\nu\mu}, \tag{B7}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\lambda\sigma}F^{\kappa\rho}F^{\nu\mu}=-\tfrac{1}{4}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\rho}F^{\nu\lambda}F^{\sigma\kappa}, \tag{B8}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\nu\kappa}\eta^{\sigma\rho}(F^2)^{\lambda\mu}=-F_{\nu\lambda,\mu}F_{\rho}{}^{\nu\rho,}(F^2)^{\lambda\mu}, \tag{B9}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\sigma}\eta^{\nu\kappa}(F^2)^{\lambda\rho}=-\tfrac{1}{2}F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)_{\rho}{}^{\mu}, \tag{B10}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\rho}\eta^{\nu\kappa}(F^2)^{\lambda\sigma}=-F_{\nu\lambda,\mu}F^{\nu\sigma,\mu}(F^2)_{\sigma}{}^{\lambda}, \tag{B11}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\mu\kappa}\eta^{\nu\rho}(F^2)^{\lambda\sigma}=-F_{\nu\lambda,\mu}F^{\nu\sigma,\mu}(F^2)^{\lambda}{}_{\sigma}+\tfrac{1}{2}F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)^{\mu}{}_{\rho}, \tag{B12}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\nu\sigma}\eta^{\lambda\kappa}(F^2)^{\mu\rho}=F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)^{\mu}{}_{\rho}, \tag{B13}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\eta^{\nu\mu}\eta^{\kappa\rho}(F^2)^{\lambda\sigma}=-F_{\nu\mu,}{}^{\mu}F_{\sigma\rho,}{}^{\rho}(F^2)^{\nu\sigma}. \tag{B14}$$

After expanding $tr\langle x|U(\tau)|x\rangle_0$ in Eq. (B1) in powers of τ up to the terms of order τ^3 and substituting the obtained expression in the definition of the effective action, we arrive at the following two-derivative correction of the order $1/m^6$:

$$\begin{aligned}\mathcal{L}_{1/m^6}^{(3+1)\mathrm{spin}}=&-\frac{11\alpha^2}{630m^6}F^{\beta\gamma}F_{\beta\gamma}F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu}+\frac{4\alpha^2}{315m^6}(F^2)^{\mu\kappa}F^{\nu\lambda}F_{\nu\lambda,\mu\kappa}\\&+\frac{\alpha^2}{270m^6}F^{\beta\gamma}F_{\beta\gamma}\left(\frac{7}{2}F^{\nu\lambda,\mu}F_{\nu\lambda,\mu}-F^{\nu\lambda}{}_{\lambda}F_{\nu\mu,}{}^{\mu}\right)\\&-\frac{2\alpha^2}{945m^6}(2F_{\nu\lambda,\mu}F^{\nu\rho,}{}_{\rho}(F^2)^{\lambda\mu}-2F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)^{\mu}{}_{\rho}-37F_{\nu\lambda,\mu}F^{\nu\sigma,\mu}(F^2)^{\lambda}{}_{\sigma}\\&+F_{\nu\mu,}{}^{\mu}F_{\sigma\rho,}{}^{\rho}(F^2)^{\nu\sigma})+\frac{\alpha^2}{630m^6}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}(38\eta^{\mu\rho}F^{\lambda\sigma}F^{\nu\kappa}-12\eta^{\nu\kappa}F^{\lambda\rho}F^{\mu\sigma}\\&+47\eta^{\mu\rho}F^{\nu\lambda}F^{\sigma\kappa}+16\eta^{\kappa\rho}F^{\lambda\sigma}F^{\nu\mu}),\end{aligned} \tag{B15}$$

to the one-loop effective action in spinor QED in 3+1 dimensions, and the correction of the order $1/m^7$,

$$\begin{aligned}\mathcal{L}_{1/m^7}^{(2+1)\mathrm{spin}}=&-\frac{11\alpha^2\pi}{336m^7}F^{\beta\gamma}F_{\beta\gamma}F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu}+\frac{\alpha^2\pi}{42m^7}(F^2)^{\mu\kappa}F^{\nu\lambda}F_{\nu\lambda,\mu\kappa}\\&+\frac{\alpha^2\pi}{144m^7}F^{\beta\gamma}F_{\beta\gamma}\left(\frac{7}{2}F^{\nu\lambda,\mu}F_{\nu\lambda,\mu}-F^{\lambda}{}_{\nu\lambda,}F_{\nu\mu,}{}^{\mu}\right)\\&-\frac{\alpha^2\pi}{252m^7}(2F_{\nu\lambda,\mu}F^{\nu\rho,}{}_{\rho}(F^2)^{\lambda\mu}-2F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)^{\mu}{}_{\rho}-37F_{\nu\lambda,\mu}F^{\nu\sigma,\mu}(F^2)^{\lambda}{}_{\sigma}\\&+F_{\nu\mu,}{}^{\mu}F_{\sigma\rho,}{}^{\rho}(F^2)^{\nu\sigma})+\frac{\alpha^2\pi}{336m^7}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}(38\eta^{\mu\rho}F^{\lambda\sigma}F^{\nu\kappa}-12\eta^{\nu\kappa}F^{\lambda\rho}F^{\mu\sigma}\\&+47\eta^{\mu\rho}F^{\nu\lambda}F^{\sigma\kappa}+16\eta^{\kappa\rho}F^{\lambda\sigma}F^{\nu\mu}),\end{aligned} \tag{B16}$$

to the effective action in 2+1 dimensions. It turns out that these latter can be further simplified. Indeed, after integrating by parts, the results can be expressed through the following seven Lorentz scalars,

$$L_1=F^{\beta\gamma}F_{\beta\gamma}F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu}, \tag{B17}$$

$$L_2 = F^{\beta\gamma} F_{\beta\gamma} F^{\nu\lambda,\mu} F_{\nu\lambda,\mu}, \tag{B18}$$

$$L_3 = F^{\beta\gamma} F_{\beta\gamma} F^{\nu\lambda,}{}_{\lambda} F_{\nu\mu}{}^{\mu}, \tag{B19}$$

$$L_4 = F_{\nu\lambda,\mu\kappa} F^{\nu\lambda} (F^2)^{\mu\kappa}, \tag{B20}$$

$$L_5 = F^{\kappa\nu} F_{\nu\lambda,\mu} F^{\lambda\sigma} F_{\sigma\kappa}{}^{\mu}, \tag{B21}$$

$$L_6 = F_{\nu\lambda,\mu}{}^{\mu} (F^3)^{\nu\lambda} \tag{B22}$$

$$L_7 = F_{\nu\mu,}{}^{\mu} F_{\lambda\rho,}{}^{\rho} (F^2)^{\nu\lambda}. \tag{B23}$$

Thus, the final results in 3+1 and in 2+1 dimensions read

$$\mathcal{L}^{(3+1)\mathrm{spin}}_{1/m^6} = -\frac{16\alpha^2}{315 m^6} L_1 - \frac{8\alpha^2}{315 m^6} L_2 + \frac{2\alpha^2}{315 m^6} L_3 - \frac{\alpha^2}{945 m^6} L_4 - \frac{11\alpha^2}{945 m^6} L_5 - \frac{26\alpha^2}{945 m^6} L_6 + \frac{4\alpha^2}{189 m^6} L_7, \tag{B24}$$

$$\mathcal{L}^{(2+1)\mathrm{spin}}_{1/m^7} = -\frac{2\alpha^2\pi}{21 m^6} L_1 - \frac{\alpha^2\pi}{21 m^6} L_2 + \frac{\alpha^2\pi}{84 m^6} L_3 - \frac{\alpha^2\pi}{504 m^6} L_4 - \frac{11\alpha^2\pi}{504 m^6} L_5 - \frac{13\alpha^2\pi}{252 m^6} L_6 + \frac{5\alpha^2\pi}{126 m^6} L_7, \tag{B25}$$

respectively. This should be compared with the result of Ref. 6 (see Eq. (14) there). Notice that the photon field in Ref. 6 desribes on-shell quanta, and, as a result, the terms containing L_1, L_3, L_6, and L_7 do not appear (they are proportional to $k^2=0$).

In a similar way, in the case of scalar QED we obtain the following expression for the expansion of Eq. (83):

$$\begin{aligned}\langle x|U_{\mathrm{bos}}(\tau)|x\rangle \simeq \langle x|U_{\mathrm{bos}}(\tau)|x\rangle_0 \Big[1 &- \frac{ie^2\tau^3}{30} F^{\nu\lambda} F_{\nu\lambda,\mu}{}^{\mu} - \frac{ie^2\tau^3}{180} (4F^{\nu\lambda,\mu} F_{\nu\lambda,\mu} + F^{\nu\lambda,}{}_{\lambda} F_{\nu\mu,}{}^{\mu}) \\ &+ \frac{ie^4\tau^5}{840} F_{\nu\lambda,\mu\kappa} (4\mathcal{F}\eta^{\mu\kappa} F^{\nu\lambda} + 2F^{\nu\lambda}(F^2)^{\mu\kappa}) + \frac{ie^4\tau^5}{7560} (8F_{\nu\lambda,\mu} F^{\nu\rho,}{}_{\rho} (F^2)^{\lambda\mu} \\ &+ 13F_{\nu\lambda,\mu} F^{\nu\lambda,\rho} (F^2)^{\mu}{}_{\rho} + 20F_{\nu\lambda,\mu} F^{\nu\sigma,\mu} (F^2)^{\lambda}{}_{\sigma} + 4F_{\nu\mu,}{}^{\mu} F_{\sigma\rho,}{}^{\rho} (F^2)^{\nu\sigma}) \\ &+ \frac{ie^4\tau^5}{5040} F_{\nu\lambda,\mu} F_{\sigma\kappa,\rho} (8\eta^{\mu\rho} F^{\lambda\sigma} F^{\nu\kappa} - 4\eta^{\nu\kappa} F^{\lambda\rho} F^{\mu\sigma} - 17\eta^{\mu\rho} F^{\nu\lambda} F^{\sigma\kappa} \\ &+ 24\eta^{\kappa\rho} F^{\lambda\sigma} F^{\nu\mu}) \Big],\end{aligned} \tag{B26}$$

leading to the $1/m^6$ correction to the effective Lagrangian density,

$$\begin{aligned}\mathcal{L}^{(3+1)\mathrm{scal}}_{1/m^6} = &-\frac{\alpha^2}{126 m^6} F^{\beta\gamma} F_{\beta\gamma} F^{\nu\lambda} F_{\nu\lambda,\mu}{}^{\mu} + \frac{\alpha^2}{210 m^6} (F^2)^{\mu\kappa} F^{\nu\lambda} F_{\nu\lambda,\mu\kappa} \\ &- \frac{\alpha^2}{1080 m^6} F^{\beta\gamma} F_{\beta\gamma} \left(4F^{\nu\lambda,\mu} F_{\nu\lambda,\mu} + F^{\nu\lambda,}{}_{\lambda} F_{\nu\mu,}{}^{\mu} \right. \\ &+ \frac{\alpha^2}{3780 m^6} \left(8F_{\nu\lambda,\mu} F^{\nu\rho,}{}_{\rho} (F^2)^{\lambda\mu} + 13F_{\nu\lambda,\mu} F^{\nu\lambda,\rho} (F^2)^{\mu}{}_{\rho} + 20F_{\nu\lambda,\mu} F^{\nu\sigma,\mu} (F^2)^{\lambda}{}_{\sigma} \right. \\ &+ 4F_{\nu\mu,}{}^{\mu} F_{\sigma\rho,}{}^{\rho} (F^2)^{\nu\sigma} + \frac{\alpha^2}{2520 m^6} F_{\nu\lambda,\mu} F_{\sigma\kappa,\rho} (8\eta^{\mu\rho} F^{\lambda\sigma} F^{\nu\kappa} - 4\eta^{\nu\kappa} F^{\lambda\rho} F^{\mu\sigma} \\ &- 17\eta^{\mu\rho} F^{\nu\lambda} F^{\sigma\kappa} + 24\eta^{\kappa\rho} F^{\lambda\sigma} F^{\nu\mu}),\end{aligned} \tag{B27}$$

in 3+1 dimensions, and the $1/m^7$ correction,

$$\mathcal{L}^{(2+1)\mathrm{scal}}_{1/m^7}=\frac{5\alpha^2\pi}{336m^7}F^{\beta\gamma}F_{\beta\gamma}F^{\nu\lambda}F_{\nu\lambda,\mu}{}^{\mu}-\frac{\alpha^2\pi}{112m^7}(F^2)^{\mu\kappa}F^{\nu\lambda}F_{\nu\lambda,\mu\kappa}$$
$$+\frac{\alpha^2\pi}{576m^7}F^{\beta\gamma}F_{\beta\gamma}\left(4F^{\nu\lambda,\mu}F_{\nu\lambda,\mu}+F^{\nu\lambda,}{}_{\lambda}F_{\nu\mu,}{}^{\mu}-\frac{\alpha^2\pi}{2016m^7}\left(8F_{\nu\lambda,\mu}F^{\nu\rho,}{}_{\rho}(F^2)^{\lambda\mu}\right.\right.$$
$$+13F_{\nu\lambda,\mu}F^{\nu\lambda,\rho}(F^2)^{\mu}{}_{\rho}+20F_{\nu\lambda,\mu}F^{\nu\sigma,\mu}(F^2)^{\lambda}{}_{\sigma}+4F_{\nu\mu,}{}^{\mu}F_{\sigma\rho,}{}^{\rho}(F^2)^{\nu\sigma}$$
$$-\frac{\alpha^2\pi}{1344m^7}F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}(8\eta^{\mu\rho}F^{\lambda\sigma}F^{\nu\kappa}-4\eta^{\nu\kappa}F^{\lambda\rho}F^{\mu\sigma}-17\eta^{\mu\rho}F^{\nu\lambda}F^{\sigma\kappa}$$
$$+24\eta^{\kappa\rho}F^{\lambda\sigma}F^{\nu\mu}), \tag{B28}$$

in 2+1 dimensions.

Up to a divergence, the derived corrections to the effective action are equivalent to

$$\mathcal{L}^{(3+1)\mathrm{scal}}_{1/m^6}=-\frac{13\alpha^2}{2520m^6}L_1-\frac{\alpha^2}{840m^6}L_2-\frac{\alpha^2}{2520m^6}L_3+\frac{\alpha^2}{1890m^6}L_4$$
$$+\frac{\alpha^2}{3780m^6}L_5-\frac{11\alpha^2}{3780m^6}L_6+\frac{\alpha^2}{1890m^6}L_7, \tag{B29}$$

$$\mathcal{L}^{(2+1)\mathrm{scal}}_{1/m^7}=\frac{13\alpha^2}{1344m^6}L_1+\frac{\alpha^2}{448m^6}L_2+\frac{\alpha^2}{1344m^6}L_3-\frac{\alpha^2}{1008m^6}L_4$$
$$-\frac{\alpha^2}{2016m^6}L_5+\frac{11\alpha^2}{2016m^6}L_6-\frac{\alpha^2}{1008m^6}L_7, \tag{B30}$$

in 3+1 and 2+1 dimensions, respectively. Here we used the same seven scalars as in the case of spinor QED above.

APPENDIX C: COEFFICIENT FUNCTIONS WHICH APPEAR IN PURELY ELECTRIC AND PURELY MAGNETIC CASES

In this Appendix we list the formulas, similar to that in Eq. (60), which appear in the course of reduction the general expression for the derivative contribution to the case of a pure magnetic (electric) field background. These are

$$F_{\nu\lambda,\mu\kappa}\sum_{j,l}C^W(f_j,f_l)A^{\lambda\nu}_{(j)}A^{\mu\kappa}_{(l)}=-2iC^W(\overline{\alpha},\overline{\alpha})\sum_{i=1}^{2}\partial_i\partial_iB, \tag{C1}$$

$$F_{\nu\lambda,\mu\kappa}\sum_{j,l}C^V(f_j,f_l)(A^{\nu\lambda}_{(j)}A^{\mu\kappa}_{(l)}+2A^{\nu\mu}_{(j)}A^{\lambda\kappa}_{(l)})=4iC^V(\overline{\alpha},\overline{\alpha})\sum_{i=1}^{2}\partial_i\partial_iB, \tag{C2}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k}C_1^{WW}(f_j,f_l,f_k)A^{\kappa\sigma}_{(j)}A^{\lambda\nu}_{(l)}A^{\mu\rho}_{(k)}=4C_1^{WW}(\overline{\alpha},\overline{\alpha},\overline{\alpha})\sum_{i=1}^{2}(\partial_iB)^2, \tag{C3}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k} C_2^{WW}(f_j,f_l,f_k)A^{\kappa\lambda}_{(j)}A^{\sigma\nu}_{(l)}A^{\mu\rho}_{(k)}=-2C_2^{WW}(\bar{\alpha},-\bar{\alpha},\bar{\alpha})\sum_{i=1}^{2}(\partial_i B)^2, \tag{C4}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k} C_1^{VW}(f_j,f_l,f_k)A^{\sigma\kappa}_{(j)}(A^{\nu\lambda}_{(l)}A^{\mu\rho}_{(k)}+A^{\nu\mu}_{(l)}A^{\lambda\rho}_{(k)})$$
$$=2(C_1^{VW}(\bar{\alpha},\bar{\alpha},\bar{\alpha})+2C_1^{VW}(\bar{\alpha},\bar{\alpha},-\bar{\alpha}))\sum_{i=1}^{2}(\partial_i B)^2, \tag{C5}$$

$$F_{\nu\lambda,\mu}F_{\sigma k,\rho}\sum_{j,l,k} C_2^{VW}(f_j,f_l,f_k)A^{\sigma\kappa}_{(j)}A^{\nu\rho}_{(l)}A^{\lambda\mu}_{(k)}=2C_2^{VW}(\bar{\alpha},\bar{\alpha},\bar{\alpha})\sum_{i=1}^{2}(\partial_i B)^2, \tag{C6}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k} C_1^{VV}(f_j,f_l,f_k)(A^{\nu\lambda}_{(j)}A^{\kappa\sigma}_{(l)}A^{\mu\rho}_{(k)}+A^{\nu\mu}_{(j)}A^{\kappa\rho}_{(l)}A^{\lambda\sigma}_{(k)}+2A^{\nu\lambda}_{(j)}A^{\kappa\rho}_{(l)}A^{\mu\sigma}_{(k)})$$
$$=(4C_1^{VV}(\bar{\alpha},\bar{\alpha},\bar{\alpha})-4C_1^{VV}(-\bar{\alpha},\bar{\alpha},\bar{\alpha})-C_1^{VV}(\bar{\alpha},-\bar{\alpha},\bar{\alpha}))\sum_{i=1}^{2}(\partial_i B)^2, \tag{C7}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k} C_2^{VV}(f_j,f_l,f_k)(A^{\nu\sigma}_{(j)}A^{\kappa\lambda}_{(l)}A^{\mu\rho}_{(k)}+A^{\nu\rho}_{(j)}A^{\kappa\mu}_{(l)}A^{\lambda\sigma}_{(k)}+2A^{\nu\sigma}_{(j)}A^{\kappa\mu}_{(l)}A^{\lambda\rho}_{(k)})$$
$$=-(4C_2^{VV}(\bar{\alpha},\bar{\alpha},\bar{\alpha})-C_2^{VV}(-\bar{\alpha},\bar{\alpha},\bar{\alpha}))\sum_{i=1}^{2}(\partial_i B)^2, \tag{C8}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k} C_3^{VV}(f_j,f_l,f_k)(A^{\nu\lambda}_{(j)}A^{\kappa\mu}_{(l)}A^{\sigma\rho}_{(k)}+A^{\kappa\rho}_{(j)}A^{\nu\sigma}_{(l)}A^{\lambda\mu}_{(k)})$$
$$=-(4C_3^{VV}(\bar{\alpha},\bar{\alpha},\bar{\alpha})-C_3^{VV}(\bar{\alpha},-\bar{\alpha},\bar{\alpha}))\sum_{i=1}^{2}(\partial_i B)^2, \tag{C9}$$

$$C_4^{VV}(f_j,f_l,f_k)A^{\nu\kappa}_{(j)}A^{\lambda\mu}_{(l)}A^{\sigma\rho}_{(k)}=C_4^{VV}(\bar{\alpha},\bar{\alpha},\bar{\alpha})\sum_{i=1}^{2}(\partial_i B)^2, \tag{C10}$$

$$F_{\nu\lambda,\mu}F_{\sigma\kappa,\rho}\sum_{j,l,k} C_5^{VV}(f_j,f_l,f_k)A^{\nu\kappa}_{(j)}(A^{\lambda\sigma}_{(l)}A^{\mu\rho}_{(k)}+A^{\lambda\rho}_{(l)}A^{\mu\sigma}_{(k)})$$
$$=(C_5^{VV}(\bar{\alpha},-\bar{\alpha},\bar{\alpha})+2C_5^{VV}(-\bar{\alpha},\bar{\alpha},\bar{\alpha}))\sum_{i=1}^{2}(\partial_i B)^2, \tag{C11}$$

where $\bar{\alpha}=\sqrt{2\mathcal{F}}$.

The latter expressions contain the coefficient functions from Appendix A calculated for a particular value of their arguments. The convenient representation for them reads

$$C^V(\bar{\alpha},\bar{\alpha})=\frac{\tau^2}{2\omega}(3\omega^2H^2+3H-1), \tag{C12}$$

$$C^W(\bar{\alpha},\bar{\alpha})=\tau^2\tanh(\omega)H, \tag{C13}$$

$$C_1^{WW}(\bar{\alpha},\bar{\alpha},\bar{\alpha})=\frac{\tau^3}{8}\tanh^2(\omega)H, \tag{C14}$$

$$C_2^{WW}(\overline{\alpha},-\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4}(1-\tanh^2(\omega))H, \tag{C15}$$

$$C_1^{VW}(\overline{\alpha},\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4}\tanh(\omega)\omega H^2, \tag{C16}$$

$$C_1^{VW}(\overline{\alpha},\overline{\alpha},-\overline{\alpha}) = -\frac{\tau^3}{4\omega}\tanh(\omega)(2\omega^2H^2+3H-1), \tag{C17}$$

$$C_2^{VW}(\overline{\alpha},\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4\omega}\tanh(\omega)(\omega^2H^2+3H-1), \tag{C18}$$

$$C_1^{VV}(\overline{\alpha},\overline{\alpha},\overline{\alpha}) = \frac{\tau^3}{4\omega^2}(4\omega^4H^3+7\omega^2H^2-2\omega^2H+3H-1), \tag{C19}$$

$$C_1^{VV}(-\overline{\alpha},\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{2\omega^2}(4\omega^4H^3+10\omega^2H^2-3\omega^2H+6H-2), \tag{C20}$$

$$C_1^{VV}(\overline{\alpha},-\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4\omega^2}(2\omega^4H^3-\omega^2H^2-3H+1), \tag{C21}$$

$$C_2^{VV}(\overline{\alpha},\overline{\alpha},\overline{\alpha}) = \frac{\tau^3}{2\omega^2}(2\omega^4H^3+5\omega^2H^2-2\omega^2H+3H-1), \tag{C22}$$

$$C_2^{VV}(-\overline{\alpha},\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4\omega^2}(2\omega^4H^3+11\omega^2H^2-2\omega^2H+9H-3), \tag{C23}$$

$$C_3^{VV}(\overline{\alpha},\overline{\alpha},\overline{\alpha}) = \frac{\tau^3}{4\omega^2}(4\omega^4H^3+13\omega^2H^2-4\omega^2H+9H-3), \tag{C24}$$

$$C_3^{VV}(\overline{\alpha},-\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{2\omega^2}(\omega^4H^3+4\omega^2H^2-\omega^2H+3H-1), \tag{C25}$$

$$C_4^{VV}(\overline{\alpha},\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4\omega^2}(2\omega^4H^3+5\omega^2H^2-2\omega^2H+3H-1), \tag{C26}$$

$$C_5^{VV}(\overline{\alpha},-\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{4\omega^2}(2\omega^4H^3-\omega^2H^2-2\omega^2H-3H+1), \tag{C27}$$

$$C_5^{VV}(-\overline{\alpha},\overline{\alpha},\overline{\alpha}) = -\frac{\tau^3}{\omega^2}(2\omega^4H^3+5\omega^2H^2-2\omega^2H+3H-1), \tag{C28}$$

where, by definition, $\omega = e\overline{\alpha}\tau$ and $H = H(\omega)$.

APPENDIX D: SPECIAL FUNCTION REPRESENTATION FOR THE INTEGRALS WHICH APPEAR IN THE PURELY ELECTRIC AND PURELY MAGNETIC CASES

In the main text, we saw that the calculation of the effective action for spinor QED in an external magnetic field reduces to evaluating the following integral (with $\mu=1/2$ in 2+1 dimensions, and $\mu=0$ in 3+1 dimensions):

$$I^{(\mathrm{spin})}(\sigma;\mu)=\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\frac{d^3}{d\omega^3}(\omega\coth\omega)=\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\frac{d^3}{d\omega^3}\left(\omega\coth\omega-1-\frac{\omega^2}{3}\right)$$
$$=-\int_0^\infty d\omega\left(\omega\coth\omega-1-\frac{\omega^2}{3}\right)\frac{d^3}{d\omega^3}(\omega^{\mu-1}e^{-\sigma\omega})$$
$$=\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\left(\coth\omega-\frac{1}{\omega}-\frac{\omega}{3}\right)\left(\frac{(3-\mu)(2-\mu)(1-\mu)}{\omega^2}+\frac{3\sigma(2-\mu)(1-\mu)}{\omega}+3\sigma^2(1-\mu)+\sigma^3\omega\right),\tag{D1}$$

where we integrated by parts (to avoid divergences as $\omega\to 0$ we subtracted the first two terms of the hyperbolic cotangent asymptotes). For large enough values of the parameter μ, one can apply the following table integrals:[27]

$$\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\coth\omega=\Gamma(\mu)\left[2^{1-\mu}\xi\left(\mu,1+\frac{\sigma}{2}\right)+\sigma^{-\mu}\right],\tag{D2}$$

$$\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}=\sigma^{-\mu}\Gamma(\mu).\tag{D3}$$

Thus, the integral in Eq. (D1) yields

$$I^{(\mathrm{spin})}(\sigma;\mu)=2^{-\mu}\Gamma(\mu+1)\left[\sigma^3\zeta\left(\mu+1,1+\frac{\sigma}{2}\right)+6\sigma^2\frac{1-\mu}{\mu}\zeta\left(\mu,1+\frac{\sigma}{2}\right)-12\sigma\frac{2-\mu}{\mu}\zeta\left(\mu-1,1+\frac{\sigma}{2}\right)+8\frac{3-\mu}{\mu}\zeta\left(\mu-2,1+\frac{\sigma}{2}\right)\right].\tag{D4}$$

As one can easily check, the original integral in Eq. (D1) is well defined for $\mu>-1$. Therefore, the last expression should allow a well defined analytical continuation to the whole that range of values of μ. Notice that this should be true even despite the fact that the intermediate integrals, as in Eqs. (D2) and (D3), may not be well defined for all values $\mu>-1$. In particular, by an analytical continuation, we obtain the results for the values of μ which are of interest,

$$I^{(\mathrm{spin})}\left(\sigma;\frac{1}{2}\right)=2\sqrt{2\pi}\left[5\zeta\left(-\frac{3}{2},1+\frac{\sigma}{2}\right)-9\frac{\sigma}{2}\zeta\left(-\frac{1}{2},1+\frac{\sigma}{2}\right)+3\left(\frac{\sigma}{2}\right)^2\zeta\left(\frac{1}{2},1+\frac{\sigma}{2}\right)+\left(\frac{\sigma}{2}\right)^3\zeta\left(\frac{3}{2},1+\frac{\sigma}{2}\right)\right],\tag{D5}$$

$$I^{(\mathrm{spin})}(\sigma;0)=\frac{11}{6}\sigma^3+\sigma^2-\frac{1}{3}\sigma-\sigma^3\psi\left(1+\frac{\sigma}{2}\right)+6\sigma^2\left[\ln\Gamma\left(1+\frac{\sigma}{2}\right)-\ln\sqrt{2\pi}\right]-24\sigma\zeta'\left(-1,1+\frac{\sigma}{2}\right)+24\zeta'\left(-2,1+\frac{\sigma}{2}\right),\tag{D6}$$

where the prime denotes the derivative of zeta function with respect to its first argument. In derivation of the second expression we used the following identities:[27]

$$\zeta(-1,q)=-\frac{q^2}{2}+\frac{q}{2}-\frac{1}{12},\qquad \zeta(0,q)=\frac{1}{2}-q,$$

$$\zeta(-2,q)=-\frac{q^3}{3}+\frac{q^2}{2}-\frac{q}{6}, \quad \zeta'(0,q)\equiv \left.\frac{\partial\zeta(z,q)}{\partial z}\right|_{z=0}=\ln\Gamma(q)-\ln\sqrt{2\pi}, \tag{D7}$$

$$\lim_{z\to 1}\left(\zeta(z,q)-\frac{1}{z-1}\right)=-\psi(q).$$

In the case of scalar QED, we come to the integral (again, with $\mu=1/2$ in 2+1 dimensions, and $\mu=0$ in 3+1 dimensions),

$$\begin{aligned}
I^{(\mathrm{scal})}(\sigma;\mu)&=\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\left(\frac{d^3}{d\omega^3}+\frac{d}{d\omega}\right)\frac{\omega}{\sinh\omega}\\
&=\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\left[\frac{d^3}{d\omega^3}\left(\frac{\omega}{\sinh\omega}-1+\frac{\omega^2}{6}\right)+\frac{d}{d\omega}\left(\frac{\omega}{\sinh\omega}-1\right)\right]\\
&=-\int_0^\infty d\omega\left[\left(\frac{\omega}{\sinh\omega}-1+\frac{\omega^2}{6}\right)\frac{d^3}{d\omega^3}+\left(\frac{\omega}{\sinh\omega}-1\right)\frac{d}{d\omega}\right](\omega^{\mu-1}e^{-\sigma\omega})\\
&=\int_0^\infty d\omega\,\omega^{\mu-1}e^{-\sigma\omega}\left[\left(\frac{1}{\sinh\omega}-\frac{1}{\omega}+\frac{\omega}{6}\right)\left(\frac{(3-\mu)(2-\mu)(1-\mu)}{\omega^2}+\frac{3\sigma(2-\mu)(1-\mu)}{\omega}\right.\right.\\
&\quad\left.\left.+3\sigma^2(1-\mu)+\sigma^3\omega\right)+\left(\frac{1}{\sinh\omega}-\frac{1}{\omega}\right)(1-\mu+\sigma\omega)\right],
\end{aligned}\tag{D8}$$

where we integrated by parts as in the spinor case. In addition to the table integral in (D3), we need also the following one:

$$\int_0^\infty \frac{d\omega\,\omega^{\mu-1}e^{-\sigma\omega}}{\sinh\omega}=2^{1-\mu}\Gamma(\mu)\zeta\left(\mu,\frac{1+\sigma}{2}\right). \tag{D9}$$

Thus, we obtain

$$\begin{aligned}
I^{(\mathrm{scal})}(\sigma;\mu)&=2^{-\mu}\Gamma(\mu+1)\left[\sigma(1+\sigma^2)\zeta\left(\mu+1,\frac{1+\sigma}{2}\right)+2(1+3\sigma^2)\frac{1-\mu}{\mu}\zeta\left(\mu,\frac{1+\sigma}{2}\right)\right.\\
&\quad\left.-12\sigma\frac{2-\mu}{\mu}\zeta\left(\mu-1,\frac{1+\sigma}{2}\right)+8\frac{3-\mu}{\mu}\zeta\left(\mu-2,\frac{1+\sigma}{2}\right)\right].
\end{aligned}\tag{D10}$$

And, finally, by analytical continuation, we obtain the results for two values of μ that are of interest,

$$\begin{aligned}
I^{(\mathrm{scal})}\left(\sigma;\frac{1}{2}\right)&=\sqrt{\frac{\pi}{2}}\left[20\zeta\left(-\frac{3}{2},\frac{1+\sigma}{2}\right)-18\sigma\zeta\left(-\frac{1}{2},\frac{1+\sigma}{2}\right)\right.\\
&\quad\left.+(1+3\sigma^2)\zeta\left(\frac{1}{2},\frac{1+\sigma}{2}\right)+\frac{\sigma}{2}(1+\sigma^2)\zeta\left(\frac{3}{2},\frac{1+\sigma}{2}\right)\right],
\end{aligned}\tag{D11}$$

$$\begin{aligned}
I^{(\mathrm{scal})}(\sigma;0)&=\frac{11}{6}\sigma^3+\frac{7}{6}\sigma-\sigma(1+\sigma^2)\psi\left(\frac{1+\sigma}{2}\right)+2(1+3\sigma^2)\left[\ln\Gamma\left(\frac{1+\sigma}{2}\right)-\ln\sqrt{2\pi}\right]\\
&\quad-24\sigma\zeta'\left(-1,\frac{1+\sigma}{2}\right)+24\zeta'\left(-2,\frac{1+\sigma}{2}\right).
\end{aligned}\tag{D12}$$

Monopoles and harmonic maps

Theodora Ioannidou and Paul M. Sutcliffe
Institute of Mathematics, University of Kent at Canterbury, Canterbury, CT2 7NZ, United Kingdom

(Received 1 March 1999; accepted for publication 16 June 1999)

Recently Jarvis has proved a correspondence between SU(N) monopoles and rational maps of the Riemann sphere into flag manifolds. Furthermore, he has outlined a construction to obtain the monopole fields from the rational map. In this paper we examine this construction in some detail and provide explicit examples for spherically symmetric SU(N) monopoles with various symmetry breakings. In particular we show how to obtain these monopoles from harmonic maps into complex projective spaces. The approach extends in a natural way to monopoles in hyperbolic space and we use it to construct new spherically symmetric SU(N) hyperbolic monopoles. © *1999 American Institute of Physics.* [S0022-2488(99)03009-1]

I. INTRODUCTION

This paper is concerned with static SU(N) BPS monopoles, which are topological solitons in a Yang–Mills–Higgs gauge theory. The Bogomolny equation, which describes all static monopoles, is integrable and so a variety of techniques are available for studying monopoles, including twistor methods. Despite this fact there are still only a limited number of known explicit monopole solutions, though the integrability of the Bogomolny equation allows many features of monopoles, such as the dimensions of their moduli spaces, to be determined.

An example where the integrability of the Bogomolny equation can be used to prove results on monopoles is the correspondence proved by Jarvis,[1] between monopoles and rational maps from the Riemann sphere into flag manifolds. The rational map arises as the scattering data, along half-lines from the origin, of a linear operator constructed from the monopole fields. Furthermore, in proving the correspondence Jarvis outlines an ''inverse scattering'' procedure whereby the monopole fields can be reconstructed from the rational map. It is this construction which is the focus of this paper. The construction involves solving a nonlinear partial differential equation which is equivalent to the Bogomolny equation, but for which the boundary conditions are given in terms of the rational map. This is the main point of the construction, since for the original Bogomolny equation it is not at all clear how to specify boundary conditions on the fields so as to obtain a unique monopole solution. We perform the construction explicitly for several examples of SU(N) monopoles with spherical symmetry and a variety of symmetry breakings. The solutions are obtained from harmonic maps of the plane into $\mathbb{CP}^{N-1}$, with the degrees of the harmonic maps related to the topological charges of the monopoles.

Perhaps we should make it clear at this point that there are several approaches to studying spherically symmetric monopoles[2–5] and the main aim of this paper is not the construction of new monopole solutions, but rather to gain a better understanding of the correspondence between monopoles and rational maps. In particular we study the construction of monopole solutions from the rational map data, and SU(N) monopoles with spherical symmetry are a good vehicle for this.

The construction of monopoles from rational maps has a natural generalization to monopoles in hyperbolic space. Using this approach we construct explicit solutions for spherically symmetric SU(N) hyperbolic monopoles. As far as we are aware these multimonopole solutions are new. As we shall see, the construction of hyperbolic monopoles has a simplifying feature in comparison to the Euclidean case, and therefore a useful way to obtain the Euclidean solutions is as the zero curvature limit of the hyperbolic ones.

II. SU(N) MONOPOLES

BPS monopoles are finite energy solutions to the Bogomolny equation

$$D_i\Phi=-\tfrac{1}{2}\epsilon_{ijk}F^{jk}, \tag{1}$$

where $D_i=\partial_i+[A_i,]$ is the covariant derivative with A_i, for $i=1,2,3$, an su(N)-valued gauge potential with gauge field $F_{jk}=\partial_j A_k-\partial_k A_j+[A_j,A_k]$. The Higgs field Φ, is an su(N)-valued scalar field for which nontrivial asymptotic boundary conditions are imposed so that topological solitons exist. More precisely, there is a choice of gauge such that in a given direction the Higgs field for large radius r is given by

$$\Phi=i\Phi_0-\frac{i}{r}\Phi_1+O\left(\frac{1}{r^2}\right), \tag{2}$$

where $\Phi_0=\text{diag}(\lambda_1,\lambda_2,...,\lambda_N)$, with the trace-free condition requiring that $\lambda_1+\lambda_2+\cdots+\lambda_N=0$, and we choose the ordering such that $\lambda_1\geqslant\lambda_2\geqslant\cdots\geqslant\lambda_N$. Φ_1 is another diagonal matrix, $\Phi_1=\frac{1}{2}\text{diag}(n_1,n_2-n_1,...,n_{N-1}-n_{N-2},-n_{N-1})$, and it can be shown that the numbers $n_1,n_2,\dots,n_{N-1}$ are always integers.

Φ_0 is the vacuum expectation value of Φ and it breaks the symmetry group from SU(N) to a residual symmetry group J, given by the isotropy group of Φ_0. The Higgs field on the two-sphere at infinity defines a map from S^2 to the coset space of vacua SU(N)/J, so that when $\pi_2(\text{SU}(N)/J)$ is nontrivial then all solutions have a topological characterization.

If the λ_i are all distinct then the residual symmetry group is the maximal torus, that is, $J=\text{U}(1)^{N-1}$, and this is known as maximal symmetry breaking. In this case

$$\pi_2\left(\frac{\text{SU}(N)}{\text{U}(1)^{N-1}}\right)=\pi_1(\text{U}(1)^{N-1})=\mathbb{Z}^{N-1} \tag{3}$$

so the monopoles are associated with $N-1$ integers, which are called the topological charges, and are precisely the integers $n_1,n_2,\dots,n_{N-1}$ appearing in Φ_1.

In contrast the case of minimal symmetry breaking is when all but one of the λ_i coincide, so the residual symmetry group is U($N-1$). Since

$$\pi_2\left(\frac{\text{SU}(N)}{\text{U}(N-1)}\right)=\mathbb{Z} \tag{4}$$

there is only one topological charge in this case and the remaining integers are called magnetic weights. The simplest way to distinguish the topological charges from the magnetic weights is to examine the expression for the energy of the monopole.

The condition (2) guarantees that the configuration has finite energy

$$E=\frac{1}{4\pi}\int-\text{tr}\left(\frac{1}{2}F_{ij}^2+(D_i\Phi)^2\right)d^3x. \tag{5}$$

The energy depends only on the topological charges and the asymptotic eigenvalues of Φ, in fact

$$E=(\lambda_1-\lambda_2)n_1+(\lambda_2-\lambda_3)n_2+\cdots+(\lambda_{N-1}-\lambda_N)n_{N-1}. \tag{6}$$

From this expression it can be seen that the difference $\lambda_j-\lambda_{j+1}$ determines the mass of the monopole of type j, of which there are n_j in the given solution. In the minimal symmetry breaking case, where $\lambda_2=\lambda_3=\cdots=\lambda_N$, then all but the first type of monopole becomes massless, so that n_1 remains a topological charge but the remaining integers become magnetic weights and do not contribute to the value of the energy. Note that we cannot distinguish in a gauge invariant way between $n_2 - n_1, \ldots, n_{N-1} - n_{N-2}$ and $-n_{N-1}$, and so when we refer to values of magnetic weights it is understood that this equivalence should be applied.

For intermediate cases of symmetry breaking the residual symmetry group is $J = \mathrm{U}(1)^r \times K$, where K is a rank $N - r - 1$ semisimple Lie group, the exact form of which depends on how the λ_i coincide with each other. Such monopoles have r topological charges.

III. RATIONAL MAPS

In this section we briefly review the recent correspondence proved by Jarvis,[1] between SU(N) monopoles and rational maps from the Riemann sphere into flag manifolds. Actually the correspondence proved in Ref. 1 is more general than this and is valid for all compact semisimple gauge groups G, but in this paper we shall only be concerned with the simplest case of $G = \mathrm{SU}(N)$.

The first step is to introduce polar coordinates, so that a point of $\mathbb{R}^3$ is given by a distance r from the origin and a direction determined by a point z on the Riemann sphere around the origin. In terms of the usual angular coordinates θ, φ this is simply $z = e^{i\varphi} \tan(\theta/2)$.

The Jarvis map is obtained by considering Hitchin's equation

$$(D_r - i\Phi)s = 0 \tag{7}$$

for the complex N-vector s, along each radial half-line from the origin out to infinity, with the direction of the half-line determined by the value of z.

For the moment we shall assume that we are dealing with maximal symmetry breaking. From the boundary conditions (2) we see that since at spatial infinity Φ is in the gauge orbit of Φ_0 then in the N-dimensional solution space there is a one-dimensional subspace generated by the solution which decays at the fastest rate as $r \to \infty$. Now evaluate this solution at $r = 0$. This procedure has thus determined a line in $\mathbb{C}^N$ for each value of z. The next step is to consider how this line varies with the direction z, and the analysis shows that it varies holomorphically. The crucial ingredient here is that the Bogomolny equation (1) implies that $[D_r - i\Phi, D_{\bar{z}}] = 0$, so that the operator in Eq. (7) commutes with the covariant derivative in the angular direction $D_{\bar{z}}$. It can be shown that the degree of this holomorphic map into $\mathbb{CP}^{N-1}$ is precisely the topological charge n_1, and hence the map is rational. Note that if we apply a gauge transformation then the map will be transformed by multiplication by a constant element of SU(N), corresponding to the gauge transformation evaluated at the origin, so that we consider only the equivalence classes of such maps.

Now we repeat the above process but this time we consider the two-dimensional solution space generated by the solution which decays fastest and the solution which decays the next fastest. In the same way as above this will now define a holomorphic plane in $\mathbb{C}^N$ (i.e., a space spanned by two holomorphic lines), which of course will contain the holomorphic line we have already described. The degree of this plane is equal to the topological charge n_2, and so again the map is rational. Proceeding in this way we finally arrive at the rational map $R: \mathbb{CP}^1 \mapsto F(\mathbb{C}^N)$, where $F(\mathbb{C}^N)$ denotes the space of total flags in $\mathbb{C}^N$. This is a series of vector subspaces $0 \subset V_1 \subset V_2 \subset \cdots \subset V_{N-1} \subset \mathbb{C}^N$, where V_i has dimension i, which is clearly the structure we have just described.

In the above discussion the degrees refer to the elements of the homotopy group $\pi_2(F(\mathbb{C}^N)) = \mathbb{Z}^{N-1}$, and are given by the highest powers which occur in some holomorphic polynomials, as described later. For a detailed discussion of rational maps into flag manifolds and their relationship to monopoles the interested reader may find it useful to consult Refs. 6 and 7.

For symmetry breaking which is not maximal the picture is similar, except that now the rational map will not be into the space of total flags, since the exponential decay of some of the solutions will be the same and hence some of the subspaces V_i will be missing from the flag. This of course corresponds to the fact that there will now be fewer topological charges, and these correspond to the degrees of the maps into the vector spaces which remain in the flag.

Because the construction of the rational map from the monopole does not break the rotational symmetry of $\mathbb{R}^3$ it is a very useful approach for studying monopoles with symmetries. For the case of SU(2) there is only one vector subspace; the space of lines in $\mathbb{C}^2$. Thus the rational map is $R:\mathbb{CP}^1 \mapsto \mathbb{CP}^1$, that is, a rational map between Riemann spheres, and its degree is the sole topological charge. By explicit construction of some symmetric maps the existence of various SU(2) monopoles with special symmetries has been proved.[8]

IV. CONSTRUCTING THE MONOPOLE

The proof of the correspondence between monopoles and rational maps[1] involves constructing the monopole from the rational map. The starting point is to write the Bogomolny equation (1) in terms of the coordinates $r,z,\bar{z}$ and observe that a (complex) gauge can always be chosen so that

$$\Phi = -iA_r = -\frac{i}{2}H^{-1}\partial_r H, \quad A_z = H^{-1}\partial_z H, \quad A_{\bar{z}} = 0, \tag{8}$$

where $H \in SL(N,\mathbb{C})$ is a Hermitian matrix.

The Bogomolny equation is then equivalent to the single equation for H

$$\partial_r(H^{-1}\partial_r H) + \frac{(1+|z|^2)^2}{r^2}\partial_{\bar{z}}(H^{-1}\partial_z H) = 0 \tag{9}$$

which we shall refer to as the Jarvis equation. Jarvis[1] then proves that solutions of this equation are determined by the rational map, which specifies the asymptotic boundary conditions on H for large r. The analysis presented in Ref. 1 is complicated and is not very suitable for attempting to implement the construction explicitly, so in this section we shall present a more explicit prescription for determining the boundary conditions on H in terms of the rational map.

For simplicity in this section we shall restrict to the case of SU(2) monopoles. With a choice of normalization for the Higgs field we have the boundary conditions on the monopole as

$$\Phi = \Phi_\infty\left[1 - \frac{n}{2r} + O\left(\frac{1}{r^2}\right)\right] \tag{10}$$

where Φ_∞ is in the gauge orbit of $i\sigma_3 = \text{diag}(i,-i)$, and n is the topological charge.

Any 2×2 Hermitian matrix H, which has unit determinant, can always be written in the form

$$H = \exp\{g(P - \tfrac{1}{2})\} \tag{11}$$

where g is a real function and P is a 2×2 Hermitian projector, that is, $P^\dagger = P = P^2$. A motivation for introducing projectors is that it is a useful formulation for dealing with similar equations that arise in the context of Skyrmions.[9] Examining the asymptotic boundary condition (10) for large r we see that the magnitude of the Higgs field at infinity is a constant and moreover the direction of the Higgs field in the SU(2) algebra is independent of the radius to leading order in $1/r$. Comparing this behavior with Eq. (8) for the Higgs field in terms of H, we find that the leading order behavior for large r is that the profile function g is independent of the angular coordinates $z,\bar{z}$ and the projector P is a function only of the angular coordinates. We are now going to examine the large r behavior of the solution, so we use the above leading order result and set $g(r)$ and $P(z,\bar{z})$.

Computing the Higgs field we obtain

$$\Phi = -\frac{i}{2}H^{-1}\partial_r H = -\frac{i}{2}g'\left(P - \frac{1}{2}\right) \tag{12}$$

with magnitude

$$\|\Phi\|^2=-\tfrac{1}{2}\,\mathrm{tr}(\Phi^2)=\frac{g'^2}{16}=1-\frac{n}{r}+O\left(\frac{1}{r^2}\right). \tag{13}$$

Integrating this equation for g we obtain (there is a choice of sign here that we shall discuss below)

$$g=-4r+2n\log r+O(1). \tag{14}$$

On substituting the form (11) into Eq. (9) and using the asymptotic expression (14) we obtain the result that

$$e^{4r}r^{-2(n+1)}(1+|z|^2)^2[PP_{z\bar{z}}+P_{\bar{z}}P_z]+O\left(\frac{1}{r^2}\right)=0, \tag{15}$$

where subscripts denote partial differentiation. The coefficient of the growing term in (15) must therefore vanish and we find the equation satisfied by P is

$$(PP_z)_{\bar{z}}=0. \tag{16}$$

The equation $PP_z=0$ gives the instanton solutions of the $\mathbb{CP}^1$ σ-model in the plane (see e.g., Ref. 10) and clearly these will satisfy Eq. (16). Furthermore, as we prove in the Appendix, this gives all solutions of Eq. (16).

All instanton solutions of the $\mathbb{CP}^1$ σ-model are given by

$$P=\frac{ff^\dagger}{|f|^2}, \tag{17}$$

where f is a 2-component column vector whose entries are holomorphic functions of z. Note that the multiplication of f by an overall factor does not change the projector P, so that f is an element of $\mathbb{CP}^1$.

Substituting the asymptotic behavior (14) into equation (12) we obtain the expression for the Higgs field on the two-sphere at infinity

$$\Phi_\infty=i(2P-1). \tag{18}$$

The topological charge, n, is the winding number of this map, which is equal to the degree of the holomorphic vector $f(z)$ which is used to construct the projector via (17). Thus we conclude that the boundary condition on H is determined in this simple and explicit way in terms of the degree n rational map $f(z)\colon\mathbb{CP}^1\mapsto\mathbb{CP}^1$.

Note that (17) and (18) give us an explicit expression for the Higgs field at infinity in terms of the rational map. Naively one may think that this does not contain very much information, since for example it is always possible to choose a (singular) gauge in which the Higgs field at infinity is diagonal and constant. However, the important point is that our expression is given in an explicit *known* gauge, and therefore we have removed the gauge freedom and are left with the physical information in the Higgs field: the fact that it is rational.

To be precise, we have not yet proved an equivalence between the rational map f and the one introduced by Jarvis.[1] To prove this equivalence we shall now show that f is indeed the map obtained as the scattering data. (We thank Nick Manton for suggesting this analysis.)

In a unitary gauge there is a basis of solutions to Hitchin's equation (7) which have the leading order large r behavior

$$s\sim e^{-\lambda_j r}v_j,$$

where λ_j is an eigenvalue of $-i\Phi_\infty$ and v_j is the corresponding eigenvector. In the SU(2) case, where $\lambda_1=-\lambda_2=1$, the scattering map is determined by the decaying solution or more fundamentally by the solution associated with the $\lambda_1=1$ eigenspace. Recall that the scattering map is obtained by evaluating this solution at the origin $r=0$. Now, the gauge (8) Hitchin's equation is trivialized to $\partial_r s=0$, so the solutions are r independent and hence the scattering map is the eigenvector of $-i\Phi_\infty$ with eigenvalue one. Thus all that remains to be shown is that f is the eigenvector of $-i\Phi_\infty$ with eigenvalue one. Using the explicit expression (18) and the definition of the projector (17) this is elementary as

$$-i\Phi_\infty f=(2P-1)f=\left(\frac{2ff^\dagger}{|f|^2}-1\right)f=f.$$

At this point it is worth while making a comment about the choice of sign made in Eq. (14) when taking the square root and integrating Eq. (13). If the opposite choice of sign is made then following through the analysis we find that the boundary condition is determined by an antiholomorphic map. Thus this choice of sign is merely an orientation and determines whether we wish monopoles to correspond to holomorphic or antiholomorphic rational maps.

The construction of a monopole from its rational map is now clear. Choose a rational map $f(z)$ and calculate the associated projector (17). Then compute the solution of the Jarvis equation (9) satisfying the boundary condition that for large r

$$H\sim\exp(r(2-4P)). \tag{19}$$

Obviously this construction is not easy to implement explicitly in practice, since it still requires the solution of a nonlinear partial differential equation. In this sense it is not as powerful as say the ADHMN construction,[11] which reduces the problem to solving a set of nonlinear matrix ordinary differential equations plus a further linear system of ordinary differential equations. The advantage is that for the construction discussed here the data is free, in that any rational map is allowed, whereas in the ADHMN construction the Nahm data must satisfy complicated constraints (including the aforementioned set of nonlinear ordinary differential equations). Thus even using the ADHMN construction very few explicit examples of monopole solutions are known. There is always an inherent difficulty associated with solving the monopole equations and the difference between these two alternative constructions is whether the main difficulty resides in performing the construction or specifying the data upon which the construction is performed.

There are simplifying special cases for which we are able to perform the construction explicitly, the easiest example being the rational map $f=(1,z)^t$, which corresponds to the spherically symmetric SU(2) 1-monopole. In this case the asymptotic behavior, $g(r)$ and $P(z,\overline{z})$, is valid for all r and substituting (11) into the Jarvis equation gives the following ordinary differential equation for the profile function

$$g''+\frac{2}{r^2}(1-e^g)=0. \tag{20}$$

The large r boundary condition $g\sim-4r$, together with the condition $g(0)=0$, which is required for H to be well defined at the origin, determines the unique solution of (20) as

$$g=2\log(2r/\sinh 2r). \tag{21}$$

This gives the well-known 1-monopole solution and comparing the asymptotic expansion of (21) with Eq. (14) we verify that $n=1$, so we see explicitly that the topological charge is determined as the degree of the rational map and there is no freedom in the profile function once the map has been specified.

In the following section we provide some explicit examples of solutions to the Jarvis equation, corresponding to spherically symmetric SU(N) monopoles with various symmetry breakings. We present the rational maps and describe how the solutions of the Jarvis equation are obtained from these in terms of harmonic maps into $\mathbb{CP}^{N-1}$.

V. HARMONIC MAPS AND SPHERICAL MONOPOLES

In the first part of this section we briefly review some facts that we shall need about harmonic maps of the $\mathbb{CP}^{N-1}$ σ-model in the plane. These results can be found in, for example, Ref. 10.

A. Harmonic maps

The harmonic map (or σ-model) equations for the $\mathbb{CP}^{N-1}$ model are given by

$$[P_{z\bar{z}},P]=0, \tag{22}$$

where P is an $N\times N$ Hermitian projector.

As stated earlier, one set of solutions to these equations are the instantons given by

$$P(f)=\frac{ff^{\dagger}}{|f|^2} \tag{23}$$

where $f(z)$ is an N-component column vector which is a holomorphic function of z and whose degree is equal to the topological charge of the σ-model. Another set of solutions are the anti-instantons, which have the same form but this time f is an antiholomorphic function, and then the σ-model topological charge is minus the degree of f.

For $N=2$ these are all the finite action solutions, but for $N>2$ there are other noninstanton solutions. These can be described by introducing the operator Δ defined by its action on any vector $f\in\mathbb{C}^N$ as

$$\Delta f=\partial_z f-\frac{f(f^{\dagger}\partial_z f)}{|f|^2} \tag{24}$$

and then define further vectors $\Delta^k f$ by induction: $\Delta^k f=\Delta(\Delta^{k-1}f)$.

To proceed further we note the following useful properties of $\Delta^k f$ when f is holomorphic:

$$(\Delta^k f)^{\dagger}\Delta^l f=0, \quad k\neq l \tag{25}$$

$$\partial_{\bar{z}}(\Delta^k f)=-\Delta^{k-1}f\frac{|\Delta^k f|^2}{|\Delta^{k-1}f|^2}, \quad \partial_z\left(\frac{\Delta^{k-1}f}{|\Delta^{k-1}f|^2}\right)=\frac{\Delta^k f}{|\Delta^{k-1}f|^2}. \tag{26}$$

These properties either follow directly from the definition of Δ or are easy to prove.[10] It is also convenient to define projectors P_k corresponding to the family of vectors $\Delta^k f$ as

$$P_k=P(\Delta^k f), \quad k=0,...,N-1. \tag{27}$$

Applying Δ a total of $N-1$ times to a holomorphic vector gives an antiholomorphic vector, so that a further application of Δ gives the zero vector and hence no corresponding projector.

The projectors P_k are solutions of the harmonic map equations (22) and all solutions can be found in this way by starting with an appropriate holomorphic vector f. In the $\mathbb{CP}^1$ case the operator Δ converts a holomorphic vector to an antiholomorphic vector, that is, instantons to anti-instantons and these are all the solutions in this case.

Note that the projectors obtained from this sequence always satisfy the relation $\Sigma_{k=0}^{N-1}P_k=1$.

For connecting harmonic maps with monopoles it is useful to recall the following interpretation of the noninstanton solutions.[10] From a holomorphic vector f form the exterior product of f and its derivatives as

$$h^k=f\wedge\partial_z f\wedge\cdots\wedge\partial_z^k f, \quad k=0,...,N-1. \tag{28}$$

Thus h^k is holomorphic, though it is an element of a larger dimensional space; it may be represented as a totally antisymmetric tensor with $k+1$ indices. With this notation it may then be shown that

$$\overline{h^{k-1}}\cdot h^k \simeq \Delta^k f \tag{29}$$

where $\cdot$ denotes the summation over all the indices of h^{k-1} and all but the first index of h^k. Here $\simeq$ denotes that two vectors are equal up to an overall factor, which is the important equivalence since we are dealing with elements of projective spaces. Equation (29) leads to the relation

$$\deg(\Delta^k f) = \deg(h^k) - \deg(h^{k-1}) \tag{30}$$

where the left-hand side is defined as the σ-model topological charge of the projector $P_k = P(\Delta^k f)$, and $\deg(h^k)$ is the highest power of z which occurs in the holomorphic tensor h^k. Thus the noninstanton solutions may be interpreted as special mixtures of instantons and anti-instantons.

B. Spherical monopoles

In Sec. IV we saw that the rational map for the spherically symmetric SU(2) 1-monopole is given by $f(z) = (1,z)^t$. This map is spherically symmetric in the sense that a rotation in $\mathbb{R}^3$, which is realized as an SU(2) Möbius transformation

$$z \mapsto \tilde{z} = \frac{\alpha z + \beta}{-\bar{\beta} z + \bar{\alpha}} \quad \text{with } |\alpha|^2 + |\beta|^2 = 1 \tag{31}$$

can be compensated by a constant SU(2) gauge transformation. Explicitly

$$f(\tilde{z}) \simeq \begin{pmatrix} \bar{\alpha} & -\bar{\beta} \\ \beta & \alpha \end{pmatrix} f(z). \tag{32}$$

This is the only spherically symmetric map into $\mathbb{CP}^1$ which has positive degree and hence there are no more spherically symmetric SU(2) monopoles. For SU(N) we first require spherically symmetric maps into $\mathbb{CP}^{N-1}$ and these are given by

$$f = (f_0, \ldots, f_j, \ldots, f_{N-1})^t, \quad \text{where } f_j = z^j \sqrt{\binom{N-1}{j}} \tag{33}$$

and $\binom{N-1}{j}$ denote the binomial coefficients. It can be shown that these maps are spherically symmetric by an explicit presentation of the compensating transformation as in (32). Of course there are other spherically symmetric maps which are obtained by embedding the above maps and setting all other entries to be zero.

For a spherically symmetric SU(N) monopole we require a rational map into the space of total flags $F(\mathbb{C}^N)$, which has spherical symmetry. Thus we need an explicit representation of the holomorphic line, the holomorphic plane (which contains the line), etc. As we shall see in more detail below, we take each k-dimensional subspace to be the space spanned by the vectors $f, \partial_z f, \ldots, \partial_z^{k-1} f$, where f is the spherical map (33). Note that these are precisely the spaces h^{k-1} defined in (28). Thus the topological charges of the monopole, n_k, are given by

$$n_k = \deg(h^{k-1}), \quad k = 1,\ldots,N-1. \tag{34}$$

Hence from (30) it is clear that the monopole topological charges are therefore not equal to the σ-model topological charges of the harmonic maps from which we shall create them. The exception to this statement is the case $N=2$, where all the harmonic maps are instantons and then the only degree is $\deg(h^0)$ which in this case is equal to the σ-model topological charge.

The degree of the map (33) is $N-1$ and hence it is easy to calculate the degree of h^k from (28) which, after taking into account the antisymmetry, gives

$$n_k = \deg(h^{k-1}) = k(N-k), \quad k = 1,\ldots,N-1. \tag{35}$$

Thus we have computed the monopole topological charges and now it remains to construct the corresponding solution of the Jarvis equation. The SU(N) generalization of the SU(2) form given in (11) is to take a sum of the $N-1$ projectors

$$H=\exp\left[g_0\left(P_0-\frac{1}{N}\right)+g_1\left(P_1-\frac{1}{N}\right)+\cdots+g_{N-2}\left(P_{N-2}-\frac{1}{N}\right)\right], \tag{36}$$

where $g_k(r)$ for $k=0,\ldots,N-2$, are profile functions. Recall that the projector P_{N-1} is a linear combination of the other projectors plus the identity matrix, which is why it is not included in the above formula. The profile functions satisfy the regularity condition $g_k(0)=0$, and have a linear growth in r for large r, the coefficients of which determine the symmetry breaking pattern. Once the symmetry breaking is specified the profile functions are, of course, uniquely determined; since there is a one-to-one correspondence between monopoles and rational maps. We shall illustrate this explicitly in the following with some examples.

C. SU(3) examples

For $N=3$, with symmetry breaking to $U(1)\times U(1)$, the charges (35) are $(n_1,n_2)=(2,2)$. From (33) the holomorphic line is given by $f=(1,\sqrt{2}z,z^2)^t$ and the plane is spanned by f and f_z. The SU(3) case has a simplifying feature, in that the holomorphic plane in $\mathbb{C}^3$ can be specified by giving a line orthogonal to the plane; which will then be antiholomorphic. This line is given by

$$f_\perp=\overline{f\times f_z}=\sqrt{2}(\bar{z}^2,-\sqrt{2}\bar{z},1)^t \tag{37}$$

which is clearly antiholomorphic and by construction is orthogonal to the holomorphic plane, that is, $f_\perp^+ f=f_\perp^+ f_z=0$. By inspection of (37) the plane has degree two and clearly has spherical symmetry (compare the structure of $f_\perp$ and f). Hence in this case it is simple to see that the charge is (2, 2). However, as an illustration of the general formalism we shall also present this example in terms of the notation described above. Thus we find

$$h^0=\begin{pmatrix}1\\ \sqrt{2}z\\ z^2\end{pmatrix},\quad h^1=\begin{pmatrix}0 & \sqrt{2} & 2z\\ -\sqrt{2} & 0 & \sqrt{2}z^2\\ -2z & -\sqrt{2}z^2 & 0\end{pmatrix} \tag{38}$$

giving $(n_1,n_2)=(\deg(h^0),\ \deg(h^1))=(2,2)$.

Taking the h^k from (38) we construct the associated projectors, using (29), and insert these into the form for H given in (36). This gives a solution of the Jarvis equation provided the profile functions satisfy the ordinary differential equations

$$-g_0''+\frac{2}{r^2}(e^{g_0-g_1}-1)+\frac{2}{r^2}(e^{g_1}-1)=0,$$

$$-g_1''-\frac{2}{r^2}(e^{g_0-g_1}-1)+\frac{4}{r^2}(e^{g_1}-1)=0. \tag{39}$$

The Higgs field is given in terms of the solution of the Jarvis equation by (8) and the eigenvalues and topological charges can simply be read off by restricting to a given radial line, say $z=0$, which gives

$$\Phi=\frac{i}{6}\,\mathrm{diag}(g_1'-2g_0',g_0'-2g_1',g_0'+g_1').$$

Each profile function has an asymptotic expansion of the form

$$g_k = -\alpha_k r + \beta_k \log r + \log \gamma_k + O\left(\frac{1}{r}\right) \tag{40}$$

with the α_k determined by the vacuum expectation value of the Higgs field. Comparing with (2) for this case we have that

$$\lambda_1 = \frac{2\alpha_0 - \alpha_1}{6}, \quad \lambda_2 = \frac{2\alpha_1 - \alpha_0}{6}, \quad \lambda_3 = -\frac{\alpha_0 + \alpha_1}{6}, \quad n_1 = \frac{2\beta_0 - \beta_1}{3}, \quad n_2 = \frac{\beta_0 + \beta_1}{3}. \tag{41}$$

It is simple to verify that the topological charge is (2, 2) without resorting to an explicit solution of the profile function equations (39). Maximal symmetry breaking implies that $\alpha_0 > \alpha_1 > 0$, so that the terms in (39) which contain exponentials of profile functions do not contribute to the leading order behavior which is $O(1/r^2)$. The coefficients of this leading order term then simply give that $\beta_0 = 4$, $\beta_1 = 2$, which when substituted into (41) confirms that $(n_1, n_2) = (2,2)$.

The explicit solutions for the profile functions can be obtained, for example, if we choose $\Phi_0 = \mathrm{diag}(2,0,-2)$, then the solution is $g_0 = 2g_1 = 2g$, where g is the 1-monopole profile function defined in (21).

If we now consider the case of minimal symmetry breaking then the topological charges which survive will be unchanged, but the magnetic weights will not be given by the topological charges which do not survive. As an example consider the symmetry breaking to U(1)×SU(2) given by $\Phi_0 = \mathrm{diag}(1, -\frac{1}{2}, -\frac{1}{2})$. From (41) this corresponds to setting $\alpha_0 = 3$, $\alpha_1 = 0$. The previous analysis of the profile function equations must now be modified to take into account the fact that exponentials of profile functions may now contribute to leading order (this happens whenever any of the α_k coincide or are zero, and corresponds to changing the symmetry breaking pattern). In this case it is easy to see that (39) requires that $\beta_0 = 3$, $\beta_1 = 0$, $\gamma_1 = \frac{1}{2}$ which gives the values $(n_1, [n_2]) = (2,[1])$, where we have used the notation that square brackets denote magnetic weights rather than topological charges.

The profile function equations that we obtain are related to those derived from the ansatz based approach of Bais *et al.*[3,2] and the methods employed there can be adapted to solve for the profile functions explicitly. This method requires a careful limiting procedure to be taken to deal with nonmaximal symmetry breaking. In Sec. VI we shall see that the solutions for monopoles in hyperbolic space are obtained without the need for this limiting procedure and the Euclidean case can then be obtained from the natural limit in which the curvature of hyperbolic space tends to zero.

For this example the solution is (see Sec. VI)

$$g_0 = \log \frac{81 r^4}{4[(-3r-1)e^{-r} + e^{2r}][(3r-1)e^{r} + e^{-2r}]},$$

$$g_1 = \log \frac{9r^2[(-3r-1)e^{-r} + e^{2r}]}{2[(3r-1)e^{r} + e^{-2r}]^2} \tag{42}$$

and it can be checked that the asymptotic properties are as stated above.

Spherically symmetric monopoles of lower charge, such as the (1, 1) monopole, can be obtained in a similar way by embedding the spherically symmetric maps (33) of lower degree.

D. SU(4) examples

For maximally broken SU(4) the charge, from (35), is (3, 4, 3) and the associated profile function equations are

$$-g_0'' + \frac{3}{r^2}(e^{g_0 - g_1} - 1) + \frac{3}{r^2}(e^{g_2} - 1) = 0,$$

$$-g_1''-\frac{3}{r^2}(e^{g_0-g_1}-1)+\frac{4}{r^2}(e^{g_1-g_2}-1)+\frac{3}{r^2}(e^{g_2}-1)=0,$$

$$-g_2''-\frac{4}{r^2}(e^{g_1-g_2}-1)+\frac{6}{r^2}(e^{g_2}-1)=0. \tag{43}$$

As for the SU(3) case it is a simple task to confirm the topological charge by a leading order analysis of this set of equations. For the choice $\Phi_0=\mathrm{diag}(3,1,-1,-3)$, corresponding to equal monopole masses, the explicit solution is $g_0/3=g_1/2=g_2=g$, where g is given by (21).

There are several possible symmetry breakings and in each case it is a simple matter to determine both the topological charges and magnetic weights by an analysis of equations (43).

For $\Phi_0=\mathrm{diag}(1,\frac{1}{2},\frac{1}{2},-2)$ the symmetry breaking is U(1)×SU(2)×U(1) and the charge is (3, [3], 3). The corresponding explicit solution is

$$g_0=\log\frac{625r^6}{[-25e^{-2r}-(30r-24)e^{-r}+e^{4r}][25e^{2r}-(30r+24)e^{r}-e^{-4r}]},$$

$$g_1=\log\frac{25r^4[25e^{2r}-(30r+24)e^{r}-e^{-4r}]}{2[-25e^{-2r}-(30r-24)e^{-r}+e^{4r}][6e^{-2r}+(5r-6)e^{3r}-(5r+6)e^{-3r}+6e^{2r}]},$$

$$g_2=\log\frac{50r^2[6e^{-2r}+(5r-6)e^{3r}-(5r+6)e^{-3r}+6e^{2r}]}{[-25e^{-2r}-(30r-24)e^{-r}+e^{4r}]^2}. \tag{44}$$

Choosing $\Phi_0=\mathrm{diag}(\frac{3}{4},\frac{3}{4},-\frac{1}{4},-\frac{5}{4})$ gives the symmetry breaking SU(2)×U(1)×U(1) with charge ([2], 4, 3) and solution

$$g_0=\log\frac{256r^6}{9[(4r+3)e^{-3r/2}+e^{5r/2}-4e^{r/2}][(4r-3)e^{3r/2}-e^{-5r/2}+4e^{-r/2}]},$$

$$g_1=\log\frac{16r^4[(4r-3)e^{3r/2}-e^{-5r/2}+4e^{-r/2}]}{3[(4r+3)e^{-3r/2}+e^{5r/2}-4e^{r/2}][(-4r-1)e^{r}+(4r-1)e^{-r}+e^{-3r}+e^{3r}]},$$

$$g_2=\log\frac{16r^2[(-4r-1)e^{r}+(4r-1)e^{-r}+e^{-3r}+e^{3r}]}{3[(4r+3)e^{-3r/2}+e^{5r/2}-4e^{r/2}]^2}. \tag{45}$$

By taking two pairs of eigenvalues to be equal, for example $\Phi_0=\mathrm{diag}(\frac{1}{2},\frac{1}{2},-\frac{1}{2},-\frac{1}{2})$, the symmetry is broken to SU(2)×U(1)×SU(2). In this case the charge is ([2], 4, [2]) and the profile functions are given by

$$g_0=\log\frac{r^6}{9(r\cosh r-\sinh r)^2},\quad g_1=\log\frac{r^4}{3(\sinh^2 r-r^2)},\quad g_2=\log\frac{r^2(\sinh^2 r-r^2)}{3(r\cosh r-\sinh r)^2}. \tag{46}$$

Finally, minimal symmetry breaking to U(1)×SU(3) occurs when three eigenvalues coincide, say $\Phi_0=\mathrm{diag}(3,-1,-1,-1)$ and this gives a charge (3, [2], [1]) with solution

$$g_0=\log\frac{1024r^6}{9[e^{r}(8r^2-4r+1)-e^{-3r}][e^{3r}-e^{-r}(8r^2+4r+1)]},$$

$$g_1=\log\frac{16r^4[e^{3r}-e^{-r}(8r^2+4r+1)]}{3[e^{r}(8r^2-4r+1)-e^{-3r}][e^{2r}(2r^2-r)+e^{-2r}(2r^2+r)]},$$

$$g_2 = \log \frac{64r^2[e^{2r}(2r^2-r)+e^{-2r}(2r^2+r)]}{3[e^r(8r^2-4r+1)-e^{-3r}]^2}. \tag{47}$$

VI. HYPERBOLIC MONOPOLES

Hyperbolic monopoles are solutions of the Bogomolny equation (1) in which Euclidean space $\mathbb{R}^3$ is replaced by hyperbolic 3-space, which we denote by $\mathbb{H}^3_\kappa$, where $-\kappa^2$ is the curvature of hyperbolic space. They were first studied by Atiyah,[12] who observed that S^1 invariant instantons can be interpreted as hyperbolic monopoles. Often hyperbolic monopoles turn out to be easier to study than the Euclidean case and we shall see this explicitly in the following. It has long been expected that in the limit as the curvature of hyperbolic space tends to zero then Euclidean monopoles are recovered, but only recently has this been rigorously established.[13] In this section we shall adapt the methods of Sec. V to the hyperbolic case to obtain spherically symmetric SU(N) monopoles. The SU(2) 1-monopole solution has been obtained before,[14] as a circle invariant instanton, but we believe that all our multi-monopole solutions are new. By explicitly taking the zero curvature limit we recover the Euclidean monopole solutions and explain why this is a simpler way to obtain these solutions than to consider the Euclidean case from the beginning.

Perhaps the most familiar description of $\mathbb{H}^3_\kappa$ is as the interior of the unit ball. In terms of angular coordinates $z,\bar{z}$ and radial coordinate $\rho \in [0,1)$ the metric is

$$ds^2 = \frac{4}{\kappa^2(1-\rho^2)^2}\left(d\rho^2 + \rho^2 \frac{4dzd\bar{z}}{(1+|z|^2)^2}\right) = dr^2 + \frac{\sinh^2(\kappa r)}{\kappa^2}\frac{4\,dz\,d\bar{z}}{(1+|z|^2)^2}, \tag{48}$$

where we have introduced r, the hyperbolic distance from the origin, through the relation $\rho = \tanh(\kappa r/2)$.

The radial scattering analysis proceeds as in the Euclidean case with the upshot that the Jarvis equation (9) in hyperbolic space becomes[13,1]

$$\partial_r(H^{-1}\partial_r H) + \frac{\kappa^2(1+|z|^2)^2}{\sinh^2(\kappa r)}\partial_{\bar{z}}(H^{-1}\partial_z H) = 0. \tag{49}$$

Note that in the zero curvature limit, $\kappa \to 0$, the Euclidean equation (9) is recovered.

Solutions of (49) can be obtained using the form (36), with the same harmonic maps, but leading to modified equations for the profile functions. The equations for the monopole fields in terms of H are still given by (8), but with r now being hyperbolic distance. Hence the asymptotic boundary conditions remain the same as in the Euclidean case and together with the requirement that the profile functions vanish at the origin this determines a unique solution for any given choice of vacuum expectation value Φ_0.

For the SU(2) 1-monopole there is just one profile function, which must satisfy the equation

$$g'' + \frac{2\kappa^2}{\sinh^2(\kappa r)}(1-e^g) = 0. \tag{50}$$

If we again normalize the Higgs field to have unit magnitude then the boundary conditions on the profile function are $g(0)=0$ and $g(r) \sim -4r$ for large r. The solution is

$$g = 2\log \frac{(2+\kappa)\sinh(\kappa r)}{\kappa \sinh((2+\kappa)r)} \tag{51}$$

which gives the known SU(2) hyperbolic 1-monopole.[14]

A. SU(3) examples

The profile function equations for the SU(3) charge (2, 2) hyperbolic monopole are

$$-g_0''\frac{\sinh^2(\kappa r)}{\kappa^2}+2(e^{g_0-g_1}-1)+2(e^{g_1}-1)=0,$$

$$-g_1''\frac{\sinh^2(\kappa r)}{\kappa^2}-2(e^{g_0-g_1}-1)+4(e^{g_1}-1)=0. \tag{52}$$

For equal monopole masses, with $\Phi_0=\mathrm{diag}(2,0,-2)$, the solution is $g_0=2g_1=2g$, with g given by (51). For general Φ_0, including minimal symmetry breaking, we now describe how the solution to (52) can be obtained using Hirota's method.

Introducing the tau-functions τ_0,τ_1 via the transformation

$$g_0=\log\frac{\sinh^4(\kappa r)}{\tau_0\tau_1\kappa^4},\quad g_1=\log\frac{\tau_0\sinh^2(\kappa r)}{\tau_1^2\kappa^2} \tag{53}$$

converts Eq. (52) into Hirota bilinear form

$$\mathcal{D}^2\tau_i\cdot\tau_i+4\tau_{i+1}\tau_{i-1}=0,\quad i=0,1 \tag{54}$$

where we have defined $\tau_{-1}=\tau_2=1$, and $\mathcal{D}$ is the Hirota derivative defined by[15]

$$\mathcal{D}^m\alpha\cdot\beta=(\partial_r-\partial_{\tilde{r}})^m\alpha(r)\beta(\tilde{r})|_{\tilde{r}=r}. \tag{55}$$

The Hirota derivative has many special properties which make the construction of solutions to bilinear equations such as (54) an elegant procedure. In particular from (55) it is clear that its action on exponential functions takes the simple form

$$\mathcal{D}^m e^{\alpha_1 r}\cdot e^{\alpha_2 r}=(\alpha_1-\alpha_2)^m e^{(\alpha_1+\alpha_2)r}. \tag{56}$$

Using this property, together with the bilinear form of the equation, means that it is a simple task to find solutions which are finite sums of exponential functions; in the context of integrable soliton equations, such as the KdV equation, solutions of bilinear equations which are a finite sum of exponentials correspond to multi-solitons.[15]

Note that the bilinear equations (54) are independent of the curvature, $-\kappa^2$, so in particular these equations are the ones which also arise for Euclidean monopoles. However, the transformation (53) involves κ which means that the boundary conditions on the tau-functions are κ dependent, and this is of crucial importance. For hyperbolic monopoles, i.e., $\kappa\neq 0$, the solutions satisfying the required boundary conditions are always given as a simple sum of exponentials, whereas for Euclidean monopoles the boundary conditions (except for the case of maximal symmetry breaking) mean that the solutions are not so simple and involve a sum of products of exponentials and polynomials. By taking the limit $\kappa\to 0$ of a hyperbolic solution the more complicated Euclidean solutions are obtained and this is perhaps the most natural method to construct Euclidean monopoles.

As an example, consider the minimal symmetry breaking of SU(3) obtained from $\Phi_0=\mathrm{diag}(1,-\frac{1}{2},-\frac{1}{2})$. As discussed in Sec. V this choice of Φ_0 corresponds to the large r boundary conditions $g_i\sim-\alpha_i r$, with $\alpha_0=3$, $\alpha_1=0$. Comparing this with the transformation (53) gives the large r boundary conditions

$$\tau_0\sim A_0 e^{(2+2\kappa)r},\quad \tau_1\sim A_1 e^{(1+2\kappa)r} \tag{57}$$

for some constants A_i. The requirement that $g_i(0)=0$ gives the conditions at the origin that $\tau_0=r^2+\cdots$, $\tau_1=r^2+\cdots$ as $r\to 0$. Using the leading order behavior (57) together with the properties of the Hirota derivative it is a simple task to find the following explicit solution

$$\tau_0=\frac{2\kappa e^{(2+2\kappa)r}-(3+4\kappa)e^{-r}+(3+2\kappa)e^{-(1+2\kappa)r}}{(3+2\kappa)(3+4\kappa)\kappa},$$

$$\tau_1=\frac{(3+2\kappa)e^{(1+2\kappa)r}-(3+4\kappa)e^{r}+2\kappa e^{-(2+2\kappa)r}}{(3+2\kappa)(3+4\kappa)\kappa}. \tag{58}$$

As claimed above, we see that there is only an exponential dependence on r; this corresponds to the fact that hyperbolic monopoles approach the vacuum value exponentially, rather than algebraically like Euclidean monopoles.

Taking the limit $\kappa\to 0$ this solution becomes

$$\tau_0=\tfrac{2}{9}(e^{2r}-(3r+1)e^{-r}),\qquad \tau_1=\tfrac{2}{9}((3r-1)e^{r}+e^{-2r}) \tag{59}$$

so we see the emergence of the algebraic factors. Substituting (59) into (53) we obtain the Euclidean monopole solution given by (42).

B. SU(4) examples

The SU(4) equations are

$$-g_0''\frac{\sinh^2(\kappa r)}{\kappa^2}+3(e^{g_0-g_1}-1)+3(e^{g_2}-1)=0,$$

$$-g_1''\frac{\sinh^2(\kappa r)}{\kappa^2}-3(e^{g_0-g_1}-1)+4(e^{g_1-g_2}-1)+3(e^{g_2}-1)=0,$$

$$-g_2''\frac{\sinh^2(\kappa r)}{\kappa^2}-4(e^{g_1-g_2}-1)+6(e^{g_2}-1)=0. \tag{60}$$

The solution $g_0/3=g_1/2=g_2=g$, with g given by (51), corresponds to maximal symmetry breaking with $\Phi_0=\mathrm{diag}(3,1,-1,-3)$.

To obtain the solution for arbitrary Φ_0 we introduce the tau-functions as

$$g_0=\log\frac{\sinh^6(\kappa r)}{\tau_0\tau_2\kappa^6},\quad g_1=\log\frac{\tau_0\sinh^4(\kappa r)}{\tau_1\tau_2\kappa^4},\quad g_2=\log\frac{\tau_1\sinh^2(\kappa r)}{\tau_2^2\kappa^2} \tag{61}$$

which transforms the equation into the Hirota form

$$\mathcal{D}^2\tau_i\cdot\tau_i+2(1+i)(3-i)\tau_{i+1}\tau_{i-1}=0,\quad i=0,1,2 \tag{62}$$

where $\tau_{-1}=\tau_3=1$.

As an example we give the solution for minimal symmetry breaking with $\Phi_0=\mathrm{diag}(3,-1,-1,-1)$, which is

$$\tau_0=3\,\frac{\kappa^2e^{(3+3\kappa)r}-(3\kappa^2+5\kappa+2)e^{(-1+\kappa)r}+(3\kappa^2+8\kappa+4)e^{(-1-\kappa)r}-(\kappa^2+3\kappa+2)e^{(-1-3\kappa)r}}{8(1+\kappa)(2+\kappa)(2+3\kappa)\kappa^2},$$

$$\tau_1=3\,\frac{(2+\kappa)\cosh((2+4\kappa)r)-(4+4\kappa)\cosh((2+2\kappa)r)+(2+3\kappa)\cosh(2r)}{8(1+\kappa)(2+\kappa)(2+3\kappa)\kappa^2},$$

$$\tau_2=3\,\frac{(\kappa^2+3\kappa+2)e^{(1+3\kappa)r}-(3\kappa^2+8\kappa+4)e^{(1+\kappa)r}+(3\kappa^2+5\kappa+2)e^{(1-\kappa)r}-\kappa^2e^{-(3+3\kappa)r}}{8(1+\kappa)(2+\kappa)(2+3\kappa)\kappa^2}.$$

Taking the zero curvature limit results in

$$\tau_0=\frac{3}{32}(e^{3r}-(8r^2+4r+1)e^{-r}),$$

$$\tau_1=\frac{3r}{16}((2r-1)e^{2r}+(2r+1)e^{-2r}), \tag{63}$$

$$\tau_2=\frac{3}{32}((8r^2-4r+1)e^{r}-e^{-3r}),$$

which is the Euclidean monopole solution given in (47).

VII. CONCLUSION

We have studied in some detail the construction of SU(N) monopoles from scattering data which consists of a rational map of the Riemann sphere into a flag manifold. Explicit solutions have been obtained in the case of spherical symmetry and we have shown how these solutions involve harmonic maps of the plane into $\mathbb{CP}^{N-1}$. This approach was generalized to the case of hyperbolic monopoles and new spherically symmetric solutions found, whose zero curvature limit was investigated explicitly.

The Jarvis equation is integrable, but in this paper we have made no use of the Lax pair. The precise description of the boundary conditions in terms of the rational map makes this a very convenient formulation of the Bogomolny equation and it may prove useful to undertake a classical inverse scattering study. An alternative, which is currently under investigation, is the numerical solution of the Jarvis equation, which is more promising than a numerical solution of the Bogomolny equation since the boundary conditions can be specified in a simple manner to ensure the existence of a unique solution.

APPENDIX

Let $P(z,\overline{z})$ be a 2×2 Hermitian projector. In this appendix we prove that the only solutions of the equation

$$(PP_z)_{\overline{z}}=0 \tag{A1}$$

are the σ-model instantons given by

$$PP_z=0. \tag{A2}$$

Let $F=PP_z$, then using the fact that P is a projector, which is a solution of (A1), it is clear that F satisfies the following properties:

$$F_{\overline{z}}=0, \tag{A3}$$

$$PF=F, \tag{A4}$$

$$FP=0. \tag{A5}$$

Taking (A4) with (A5) gives that $F^2=0$, so that it has at most rank one and can be written as

$$F=uw^{\dagger}, \tag{A6}$$

where u and w are two orthogonal column vectors, that is $w^{\dagger}u=0$. Substituting this expression for F into (A3) and multiplying both sides by w leads to the result that $w^{\dagger}u_{\bar{z}}=0$, that is, $u_{\bar{z}}$ is orthogonal to w. But since we already know that u is orthogonal to w and they are elements of a two-dimensional vector space then this implies that u and $u_{\bar{z}}$ are parallel. Thus u must have the form $u(z,\overline{z})=g(z,\overline{z})\tilde{u}(z)$, where $\tilde{u}$ is a holomorphic vector and g is some function.

P is a Hermitian projector so it may be written as

$$P=\frac{vv^{\dagger}}{v^{\dagger}v} \tag{A7}$$

for some 2-component column vector v. Substituting the expressions (A6) and (A7) into property (A4) shows that u and v are parallel, that is, $v=\lambda u$ for some function λ. Now using the earlier factorization of u we obtain $v=\lambda g\tilde{u}$, so that finally we arrive at the result that

$$P=\frac{\tilde{u}\tilde{u}^{\dagger}}{\tilde{u}^{\dagger}\tilde{u}}. \tag{A8}$$

As we have already shown that $\tilde{u}$ is a holomorphic vector then this is an instanton solution of Eq. (A2) (see, for example, Ref. 10) and the required result is proved.

(Received 31 December 1998; accepted for publication 22 July 1999)

We formulate an adiabatic theorem adapted to models that present an instantaneous eigenvalue experiencing an infinite number of crossings with the rest of the spectrum. We give an upper bound on the leading correction terms with respect to the adiabatic limit. The result requires only differentiability of the considered projector, and some geometric hypothesis on the local behavior of the eigenvalues at the crossings. © *1999 American Institute of Physics.* [S0022-2488(99)00511-3]

I. INTRODUCTION

The availability of intense pulsed laser sources has opened a large field of possibilities to control atomic and molecular dynamical processes. One of the main theoretical tools to analyze these processes is adiabatic Floquet theory[1] and references therein. The general setup can be described as follows. One considers a molecule described by a Hamiltonian H_0 acting on a Hilbert space $\mathcal{H}$, in interaction with one radiation mode of frequency ω. (The description of the interaction with several modes of different frequencies can be formulated along similar lines.) Since the intensity of the field is quite large, the field is treated as a classical field. The Hamiltonian of the molecule perturbed by the electromagnetic field can be written, for example, as

$$H=H_0+EMF(\omega t+\theta_0), \tag{1}$$

where M is the dipole moment operator of the molecule, $E\in\mathbb{R}$ is a parameter representing the amplitude of the radiation field, F is a real valued 2π-periodic function and θ_0 the initial phase. We assume that H_0 has a discrete spectrum. In order to describe a laser pulse the amplitude is taken as a slowly varying time dependent function $E(\epsilon t)$, where one takes, e.g., $\epsilon=1/T_p$ with T_p the duration of the pulse. A new technique that provides an efficient method for complete transfer of population is based on frequency chirping: within the pulse duration the frequency is also slowly modulated $\omega=\omega(\epsilon t)$.

This model has thus two kinds of time dependencies in the Hamiltonian: one that is periodic and another one that is slowly varying. The periodic part can be treated by Floquet methods, and the slowly varying part by adiabatic theory. Adiabatic Floquet theory is based on the following statement: Assume that in the Hamiltonian (1) the parameter E and the frequency ω are made time dependent, $E(t)$, $\omega(t)$, and M stays time independent. Consider the propagator $U(t,t_0;\theta_0)$, solution of the Schrödinger equation

$$i\frac{\partial}{\partial t}U(t,t_0;\theta_0)=H(\omega t+\theta_0)U(t,t_0;\theta_0),\quad U(t,t;\theta_0)=\mathbb{1} \tag{2}$$

acting on the Hilbert space $\mathcal{H}$. We consider an enlarged Hilbert space by tensoring $\mathcal{H}$ with the space of square integrable functions on the unit circle: $L^2(\mathbb{S}^1,\mathcal{H})$. The operator $U(t,t_0;\theta)$ can be lifted into the enlarged space, interpreting the θ-dependence as a multiplication operator. We can then define

$$U_K(t,t_0)=e^{-t\omega(t)\partial}U(t,t_0;\theta)e^{t_0\omega(t_0)\partial}$$

where $\partial=\partial/\partial\theta$. The statement is that Eq. (2) is equivalent to

$$i\frac{\partial}{\partial t}U_K(t,t_0)=K(t)U_K(t,t_0) \tag{3}$$

with

$$K(t)=-i\varpi(t)\frac{\partial}{\partial\theta}+H_0+E(t)MF(\theta)$$

and $\varpi(t)$ denotes an effective instantaneous frequency defined by $\varpi(t)=\omega(t)+t\,d\omega(t)/dt$. Assuming that the time dependence of $E(t)$, $\omega(t)$ is slow one can develop adiabatic techniques for the evolution of (3). When K has pure point spectrum, the first ingredients are the instantaneous eigenvalues and eigenvectors. They always can be written and labeled in the form

$$\begin{aligned}\lambda_{j,k}&=\lambda_{j,0}+k\varpi,\quad k\in\mathbb{Z}\\ \psi_{j,k}(\theta)&=\psi_{j,0}(\theta)e^{ik\theta}.\end{aligned} \tag{4}$$

The index j has the same cardinality as the dimension of the Hilbert space $\mathcal{H}$. Thus, even if we take simple models with finite dimensional $\mathcal{H}$, the Floquet spectrum has infinitely many eigenvalues. As functions of E and ϖ, these eigenvalues may exhibit crossings, which the adiabatic approximation can accommodate in case there is a finite number of them, see Refs. 2 and 3. The structure (4) of the eigenvalues is such that if we consider a slowly varying *effective* frequency $\varpi(t)$ that goes through 0 at some time t_0, the nature of the spectrum becomes quite different. One can encounter situations in which a branch of instantaneous eigenvalues undergoes an infinite number of crossings with other branches, or the spectrum may become suddenly continuous. Hence it becomes necessary to investigate the validity of the adiabatic theorem in such situations. Let us stress that a strictly positive time dependent frequency $\omega(t)$ may give rise quite naturally to an effective frequency $\varpi(t)$ that goes to zero.[4] Indeed, consider a linear variation of ω of the form

$$\omega(t)=\omega_0-at,$$

with ω_0, $a>0$ on the time interval $[0,\omega_0/a)$, which is far from exotic. Then

$$\varpi(t)=\omega_0-2at$$

goes through zero at $t_0=\omega_0/(2a)\in[0,\omega_0/a)$. As it has been shown in Refs. 4 and 5, the possibility to vary the frequency is a powerful method to enhance the control of molecular processes driven by laser.

We will confine ourselves to the case where a branch of eigenvalue undergoes an infinity of crossings with other branches. As this situation is not generic, as actual crossings are more the exception than the rule, we give below a whole class of systems for which this situation is true. Moreover, it is probably the only case in which we get enough regularity to prove an adiabatic theorem. Note also that in case $\varpi(t)$ passes through 0, the domain of $K(t)$ becomes time dependent, so that technical issues regarding regularity of the evolution operator have to be addressed. This is done in the Appendix A.

The goal of the present paper is to formulate an adiabatic theorem that can be applied to such situations with an estimate on the corrections to the adiabatic limit. Adiabatic Theorems without gap conditions are known to be true, see Ref. 6, however, in general, no estimates on the error terms are available.

While this work was motivated by the physical situation described above and discussed below in the examples, our analysis of the adiabatic approximation is model independent and can be applied to more general situations.

II. ADIABATIC THEOREM

A. Context

The adiabatic approximation in quantum mechanics has a long history which we will not attempt to retrace here. We refer the reader to the recent surveys[7,8] and references therein. Let us simply recall here that the works following that of Born and Fock[2] by Kato,[9] Nenciu,[10] and Avron, Seiler, and Yaffe[11] have led to a formulation of the adiabatic theorem under the usual gap assumption that is general and where the error term is well controlled and of order ϵ. In case the gap assumption is modified, the situation is less explicit. In this section, we switch back to the notation $H(\epsilon t)$ for the slowly varying time-dependent Hamiltonian. Assume $H(s)$ is smooth in $s\in[0,1]$ and there exists a spectral projector $P(s)$ of $H(s)$ which is strongly C^2 on $[0,1]$. Avron and Elgart have shown in Ref. 6 that the adiabatic theorem holds under these conditions, provided $P(s)$ is of finite rank, independently of any spectral considerations. A similar result was proven by Bornemann[18] for discrete hamiltonians in case the set of eigenvalue crossings is of measure zero in time. The limitation of these approaches is that, in general, no estimate can be made on the rate at which the adiabatic regime is attained. In certain specific situations, an estimate on this rate is available. In the case where the spectral measure μ_φ is α-Hölder continuous, with $\varphi=P'(s)\psi(s)$, ψ such that $P=|\psi\rangle\langle\psi|$, the rate of convergence was shown in Ref. 6 to be of order $\epsilon^{\alpha/(2+\alpha)}$. A case where the spectrum of $H(s)$ is assumed to be dense pure point is dealt with in Ref. 12. Another situation, considered in Ref. 13, where the gap hypothesis is not necessarily fulfilled occurs when $H(s)=H_0(s)+\epsilon H_1(s)$, where the domain of $H_1(s)$ is smaller than that of $H_0(s)$. In both cases, the error term remains of order ϵ. In the present article, we consider another situation in which the usual gap assumption is modified and the error made in the adiabatic approximation can be estimated. We make the hypothesis that the projector $P(s)$ is associated with an eigenvalue $\lambda(s)$, in the sense that $H(s)P(s)=\lambda(s)P(s)$, for all $s\in[0,1]$. We assume that $\lambda(s)$ is isolated in the spectrum except at a series of times $\{o_k\}_{k\in\mathbb{N}}$ accumulating at $a\in(0,1)$ where it experiences crossings with the rest of the spectrum. Requiring some conditions on the local behavior of the gap between $\lambda(s)$ and the rest of the spectrum near the crossing points o_k, we estimate the error term in the theorem without *a priori* knowledge on the nature of the rest of the spectrum. Note that for $s=o_k$ such that $\lambda(o_k)$ is not isolated in the spectrum, $P(o_k)$ does not represent the entire spectral projector associated with the eigenvalue $\lambda(o_k)$.

B. One crossing

Let us make more precise the regularity hypotheses under which we shall work. In order to deal with the application described above, we will assume the Hamiltonian is unbounded. This causes technical difficulties motivating the part (ii) of the hypothesis below which justifies our manipulations. We show in the appendix that this assumption is verified for our models. In case $H(s)$ is bounded, this part of the assumption is automatically verified.

$(H0)$ (i) We assume that for all $s\in[0,1]\setminus\{a\}$, $H(s)$ is a strongly C^1 self-adjoint operator defined on a dense domain $\mathcal{D}$ independent of s in a separable Hilbert space $\mathcal{K}$, where $0<a<1$.

Whereas $H(a)$ is bounded self-adjoint on $\mathcal{K}$. We also assume the existence of a projector $P(s)$ of $H(s)$ which is strongly C^2 on $[0,1]$ and such that $H(s)P(s)=P(s)H(s)=\lambda(s)P(s)$, for all $s \in [0,1]$.

(ii) Further assume that the unitary evolution operators $U(s)=U(s,0)$ and $A(s)=A(s,0)$ generated by $H(s)$, respectively $H(s)+\epsilon i[P'(s),P(s)]$ (see (5), (6)) are well defined for all $s \in [0,1]$ and possess the properties (i) to (v) listed in Theorem A.1. Note that $P(s)$ needs not be finite dimensional and λ is continuous.

We start by considering one crossing of λ with the rest of the spectrum by revisiting the strategy proposed in Ref. 2, making use of the general analysis presented in Ref. 11.

Let $g(s)$ be the gap between $\lambda(s)$ and the rest of the spectrum of $H(s)$: $g(s) = \mathrm{dist}(\lambda(s),\sigma(s)\setminus\{\lambda(s)\})\geq 0$, $s\in[0,1]$. We also introduce the bounded, strongly C^1 operator $L(s)=i[P'(s),P(s)]$. We assume that $g^{-1}\{0\}=\{o\}$ and consider the strong differential equations on $\mathcal{D}$

$$i\epsilon U'(s)=H(s)U(s), \quad U(0)=\mathbb{1}, \tag{5}$$

$$i\epsilon A'(s)=(H(s)+\epsilon L(s))A(s), \quad A(0)=\mathbb{1}. \tag{6}$$

The unitary A is the so called *adiabatic evolution* which possesses the well known intertwining relation $A(s)P(0)=P(s)A(s)$.[9,14] Finally, let $W(s)$ be defined by $W(s)=A^{-1}(s)U(s)$. We have on $\mathcal{D}$

$$iW'(s)=-A^{-1}(s)L(s)A(s)W(s), \quad W(0)=\mathbb{1}, \tag{7}$$

in the strong sense. To compare the adiabatic and actual evolutions, we need to compute the size of the difference of the unitary $W(s)$ at two times surrounding the crossing. This is the aim of the next result.

Lemma 2.1: Under the above assumptions, we have for any $0\leq u_0\leq t<o<s\leq u_1\leq 1$,

$$\|W(u_0)-W(u_1)\|\leq C(\epsilon|u_0-t|/g_t^2+\epsilon|u_1-s|/g_s^2+\epsilon/g_t+\epsilon/g_s+|s-t|) \tag{8}$$

where $g_t=\inf_{u\in[u_0,t]}g(u)$, $g_s=\inf_{u\in[s,u_1]g(u)}$ and the constant C is uniform in u_0, u_1, s, and t (see Fig. 1).

Remark: On the basis of the classical paper by Born and Fock,[2] and the detailed analysis of crossings by Hagedorn,[3] one would expect the corresponding estimate without the first two terms.

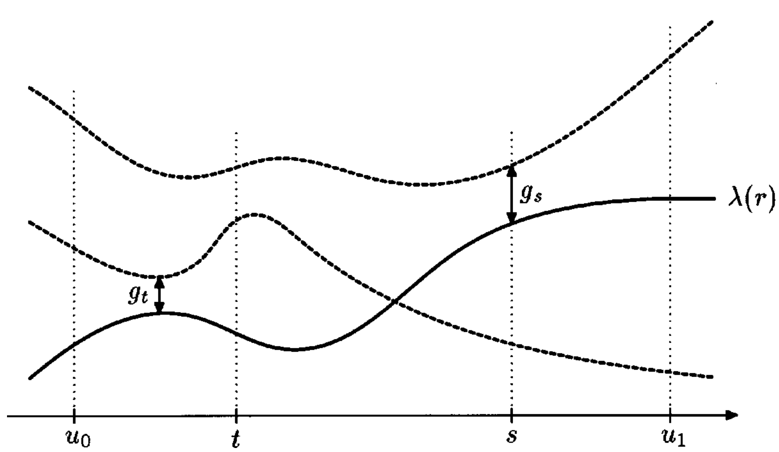

FIG. 1. The various quantities defined in Lemma 2.1.

However, such an estimate requires more detailed knowledge of the structure of spectrum, e.g., that the gap is given by the distance between two eigenvalues, than what we assume in our general setting.

The proof of Lemma 2.1 is presented in Appendix B. The idea of the proof is to integrate Eq. (7) over the interval $[u_0,u_1]$ and then to get estimates of the sizes on each subintervals $[u_0,t]$, $[t,s]$, and $[s,u_1]$ which involves only the gaps.

Lemma 2.1 can be used to treat two standard situations:

(1) If there is a gap G between $\lambda(s)$ and the rest of the spectrum, this lemma implies that the adiabatic approximation holds with an error term bounded by $C\epsilon/G^2$.

(2) If one starts the evolution on a crossing point which splits like s^α near 0, we can use this lemma to show that the adiabatic approximation is valid with an error bounded by

$$\|U(1)-A(1)\|\leqslant C\epsilon^{1/(1+2\alpha)}$$

if ϵ is small enough. This is precisely the situation encountered at the beginning of the interaction of a laser pulse with frequency that is in resonance with the difference between two energy levels of the molecule.[15,16]

To get this estimate, we can consider only half of the problem by letting aside all the terms containing a t and setting $u_1=1$:

$$\|W(1)-W(0)\|\leqslant C(\epsilon|1-s|/g_s^2+\epsilon/g_s+s). \tag{9}$$

This is indeed fully justified by the proof of the lemma (see Appendix B). Next, we have by hypothesis that $g(s)\geqslant g_s=Gs^\alpha$ if s is small. Introducing this behavior in Eq. (9), we obtain $\|W(1)-W(0)\|\leqslant C(\epsilon/s^{2\alpha}+s)$. The result follows now by balancing the two contributions by choosing $s=s(\epsilon)=\epsilon^{1/(1+2\alpha)}$. Again, with more information on the spectrum, as in Refs. 2 and 3, one should be able to improve the above estimate to order $\epsilon^{1/(1+\alpha)}$.

C. Infinite number of crossings

We now have all the information required to proceed to the case of an infinite number of crossings. We make the following hypotheses describing what happens in the neighborhood of each crossing (see Fig. 2).

Spectral hypotheses: There exist two partitions $\{u_k^\pm\}_{k\in\mathbb{N}}$ of $[0,a)$ and $(a,1]$ respectively:

$$0=u_0^-<\cdots<u_{k-1}^-<u_k^-\cdots\to u_\infty^-=a=u_\infty^+\leftarrow\cdots u_k^+<u_{k-1}^+<\cdots<u_0^+=1$$

such that for each $k\in\mathbb{N}^*$,

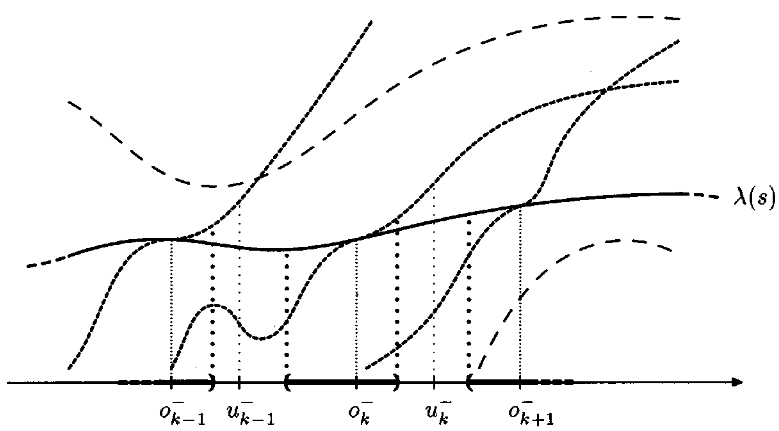

FIG. 2. Illustration of the spectral hypotheses $H1-H2$ on the interval $(0,a)$. The intervals V_l^- are represented by (——).

$(H1)$ one can find non empty open intervals $V_k^{\pm}$, which satisfy $V_k^- \subset [u_{k-1}^-, u_k^-]$, $V_k^+ \subset [u_k^+, u_{k-1}^+]$ and

$$\sup_{s \in V_k^{\pm}} g(s) \leq \inf_{t \in I_k^{\pm}} g(t), \tag{10}$$

where $I_k^- = [u_{k-1}^-, u_k^-] \setminus V_k^-$ and $I_k^+ = [u_k^+, u_{k-1}^+] \setminus V_k^+$.

$(H2)$ there are constants $G_{\pm}(k) > 0$ and a k-independent positive constant α such that for all $s \in V_k^{\pm}$:

$$G_{\pm}(k)|s - o_k^{\pm}|^{\alpha} \leq g(s), \tag{11}$$

for some points $o_k^{\pm} \in V_k^{\pm}$.

Comments: (1) These Spectral Hypotheses mean that the crossings are well separated and that they behave as power of order at most α. Hypothesis $(H1)$ tells us that outside the crossing regions $(V_k^{\pm})$ the gaps are relatively ''large.'' This means that the only accumulation point of small gaps is a.

(2) The choice of a constant exponent α is not as restrictive as it might look at first. Indeed, we are interested in an upper bound, so it is the greatest α that will determine the global behavior.

(3) In the applications, we will consider examples where $g^{-1}\{0\} = \{o_k^{\pm}\}$: the set of crossing points of $\lambda(s)$ with the rest of the spectrum. This implies $\alpha > 0$. But, the case of an infinite number of avoided crossings can be treated by taking $\alpha = 0$ in Hypothesis $(H2)$.

To obtain an estimate for the difference between the real evolution $U(1)$ and the adiabatic one $A(1)$, the idea is to apply Lemma 2.1 on a finite number of crossings and to take a simple integral bound [as in (B2)] over the rest of the interval surrounding a. The choice of the number of crossings will be optimized with respect to ϵ in order to get a simple form for the bound of the remainder term. To state the corresponding result, we need to introduce some notations. Let $\Delta_{\pm}(k) = \max\{|u_k^{\pm} - o_k^{\pm}|, |u_{k-1}^{\pm} - o_k^{\pm}|\}$ and $\tau_{\pm}(k) = \max\{\Delta_{\pm}(k)/G_{\pm}^2(k), \Delta_{\pm}^{\alpha}(k)/G_{\pm}(k)\}$. The functions $K \mapsto |u_K^{\pm} - a| / \sum_{k=1}^{K} \tau_{\pm}(k)^{1/(1+2\alpha)}$ are monotonically decreasing to zero, so, if ϵ is small enough, we define $K_{\pm}(\epsilon) \in \mathbb{N}^*$ as the greatest integer satisfying

$$\frac{|u_K^{\pm} - a|}{\sum_{k=1}^{K} \tau_{\pm}(k)^{1/(1+2\alpha)}} \geq \epsilon^{1/(1+2\alpha)}. \tag{12}$$

This integer always exists if ϵ is sufficiently small and, by construction, $K_{\pm}(\epsilon) \to \infty$ as $\epsilon \to 0$.

Theorem 2.1: For ϵ small enough, under $(H0)$ and the spectral hypotheses $(H1)$, $(H2)$ and provided that

$$\varsigma(\epsilon \tau_{\pm}(k))^{1/(1+2\alpha)} \leq |V_k^{\pm}|/2 \quad \text{for all} \quad 1 \leq k \leq K_{\pm}(\epsilon), \tag{13}$$

for some constant $\varsigma > 0$, we have that

$$U(1) = A(1) + O(\max\{|u_{K_-(\epsilon)}^- - a|, |u_{K_+(\epsilon)}^+ - a|\}).$$

Hence, as $\lim_{\epsilon \to 0} K_{\pm}(\epsilon) = \infty$, $\|U(1) - A(1)\|$ goes to zero for $\epsilon \to 0$ as fast as $\max\{|u_{K_-(\epsilon)}^- - a|, |u_{K_+(\epsilon)}^+ - a|\}$.

Remarks: (1) The theorem states that the error can be estimated provided we can compute the critical value $K_{\pm}(\epsilon)$. Further considerations on the practical aspects of this computation are given in the next section.

(2) Condition (13) implies that the size of the intervals $V_k^{\pm}$ cannot be too small with respect to $\epsilon \tau_{\pm}(k)$.

(3) While we shall apply the theorem in a situation where the spectrum is simple and pure point, the theorem remains valid under the sole existence of an eigenvalue separated from the rest of the spectrum by gaps with the properties stated in $(H1)-(H2)$, without any knowledge on the rest of the spectrum or restriction on the dimension of $P(s)$.

(4) The introduction of an adjustable constant ς is necessary in the following application to satisfy the hypothesis of the theorem.

III. APPLICATION

We can obtain more explicit estimates on the rest by considering some specific behavior at the crossings.

Let us introduce the following notation: $F_k \sim f(k)$ means that there exist two constants $0<c_1<c_2<\infty$ such that $c_1 f(k) \leqslant F_k \leqslant c_2 f(k)$ for $k\in\mathbb{N}^*$ large enough. We have the

Proposition 3.1: Assume the hypothesis of Theorem 2.1 and the following behavior for the relevant quantities:

$$|u_k^{\pm}-a| = C_1/k^{\beta}+C_2/k^{\beta+1}+o(1/k^{\beta+1}), \quad \beta>0,\ C_1\neq 0$$

$$G_{\pm}(k)\sim k^{\gamma},$$

$$|V_k^{\pm}|\sim 1/k^{\delta}, \quad \delta>0.$$

We set $\mu=\min\{\beta+1+2\gamma,\alpha(\beta+1)+\gamma\}$. Then $\|U(1)-A(1)\|=O(\epsilon^p)$ where the exponent p is given by

$$p=\begin{cases} \dfrac{1}{1+2\alpha} & \text{if } \mu>(1+2\alpha) \\ \dfrac{1}{1+2\alpha}-\nu \quad \forall \nu>0 & \text{if } \mu=(1+2\alpha) \\ \dfrac{\beta}{(\beta+1)(1+2\alpha)-\mu} & \text{if } \mu<(1+2\alpha) \end{cases}$$

provided that δ satisfy the following constraints: $\beta+1\leqslant\delta\leqslant\beta+\max\{1,\mu/(1+2\alpha)\}$.

Remark: Let us mention that it can be shown that in case $\alpha=\beta=\gamma=1$ and $\delta=2$, we can take $p=1/3$, instead of $p=1/3-\nu$, for all $\nu>0$. Now, if in Lemma 2.1, the right member were missing the terms $\epsilon|u_0-t|/g_t^2+\epsilon|u_1-s|/g_s^2$, as one would expect with a little more information on the spectrum, an analysis similar to the one provided above leads to an error term of order $\epsilon^{1/3}$. This makes it reasonable to expect that in such a situation the error actually is of that order, as it was the case in the corresponding analysis of one crossing performed in Ref. 2, see Ref. 3. Finally, it is shown in the examples below that the values $\alpha=\beta=\gamma=1$ and $\delta=2$ are generic in some sense.

IV. EXAMPLES

We now consider a family of models for which the situation just described takes place as the effective frequency ϖ takes the value zero. We start by considering the most general model for a two level system driven by a periodic field. The model can be characterized by choosing freely the eigenvalues $\lambda_{+,m}=\lambda_+ + m\omega$ and $\lambda_{-,k}=\lambda_- + k\omega$ and the corresponding eigenfunctions of the form:

$$\psi_{+,m}(\theta)=\begin{pmatrix} e^{ix(\theta)}\cos z(\theta) \\ e^{iy(\theta)}\sin z(\theta)\end{pmatrix} e^{im\theta} \quad \text{and} \quad \psi_{-,k}(\theta)=\begin{pmatrix} -e^{-iy(\theta)}\sin z(\theta) \\ e^{-ix(\theta)}\cos z(\theta)\end{pmatrix} e^{ik\theta}, \tag{14}$$

in which the functions x, y, and z are periodic modulo an integer multiple of θ.

Defining the unitary matrix

$$\Upsilon(\theta)=\begin{pmatrix} e^{ix(\theta)}\cos z(\theta) & -e^{iy(\theta)}\sin z(\theta) \\ e^{iy(\theta)}\sin z(\theta) & e^{-ix(\theta)}\cos z(\theta) \end{pmatrix}$$

the corresponding Floquet Hamiltonian can be written as (dropping the θ dependence in the notation)

$$K=-i\varpi\partial-i\varpi\Upsilon(\partial\Upsilon^{-1})+\Upsilon D\Upsilon^{-1},$$

where $D=\mathrm{diag}(\lambda_+,\lambda_-)$. Using the notation $2\wp=x+y$, $2\vartheta=y-x$ and choosing, without loss of generality, $\lambda_+=-\lambda_-=\lambda$, the Floquet Hamiltonian can be expressed as

$$K=-i\varpi\partial+\begin{pmatrix} \varpi\partial\vartheta+(\lambda-\varpi\partial\wp)\cos(2z) & (-i\varpi\partial z+(\lambda-\varpi\partial\wp)\sin(2z))e^{-2i\vartheta} \\ (i\varpi\partial z+(\lambda-\varpi\partial\wp)\sin(2z))e^{2i\vartheta} & -\varpi\partial\vartheta-(\lambda-\varpi\partial\wp)\cos(2z) \end{pmatrix} \tag{15}$$

where ∂f denotes the derivative with respect to θ. Note that when $\varpi=0$ the operator K reduces to the (matrix) multiplication operator by $\Upsilon(\theta)D\Upsilon^{-1}(\theta)$ on $L^2(\mathbb{S}^1,\mathbb{C}^2)$, whose spectrum consists of two eigenvalues $\pm\lambda$ which are infinitely degenerate. This is to be compared with the general situation where K for $\varpi=0$ becomes a multiplication operator by an arbitrary 2π periodic 2×2 matrix $H(\theta)$. In that case, the spectrum of K is continuous and given by two band functions which are the instantaneous (in θ) eigenvalues of $H(\theta)$.

We will consider two different models with the same eigenvalues but with different eigenfunctions. We remark that since the validity of the adiabatic theorem depends only on the properties of the eigenvalues (and regularity properties of the projectors), it gives the same upper bound for the correction for all the models (15) with equal spectrum. However, it is clear that the theorem is useful if the couplings between considered levels are nonzero. With this regard, we discuss below two examples that have the same spectrum, with an infinite number of crossings. For the first one, which is the widely used RWA (rotating wave approximation) model of quantum optics, the couplings are all equal to zero, except one (see below). The second model is a perturbation of the first one that yields nonzero couplings between the levels.

We choose, for example, the following eigenvalues:

$$\lambda_{\pm,k}(\varpi)=k\varpi\pm(\eta(\varpi)+\varpi)/2, \quad \text{where} \quad \eta(\varpi)=\sqrt{(\varpi-\omega_0)^2+\Omega^2} \tag{16}$$

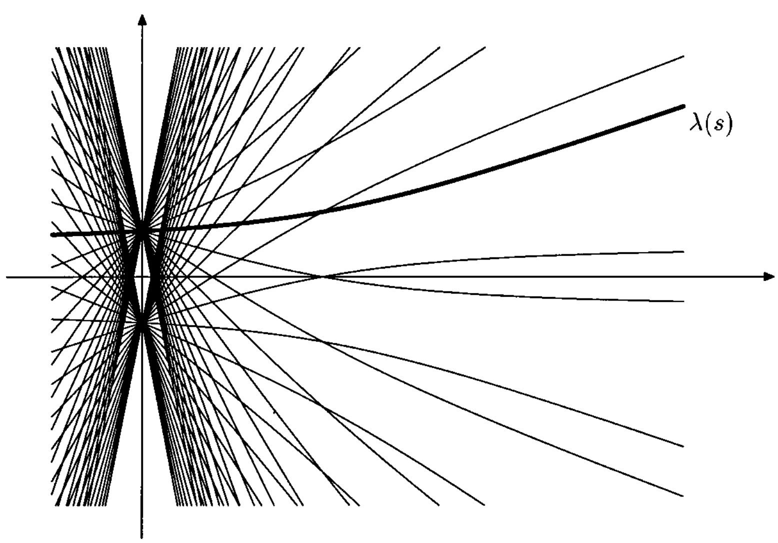

FIG. 3. The first eigenvalues of the RWA and modified RWA models.

and ω_0, Ω are constants. The first model is defined by choosing $x(\theta)=0$, $y(\theta)=\theta$, i.e., $2\vartheta(\theta)=2\wp(\theta)=\theta$ and $\cos(2z)=-(\varpi-\omega_0)/\eta(\varpi)$, $\sin(2z)=\Omega/\eta(\varpi)$, hence z is independent of θ. The corresponding Floquet Hamiltonian is given by

$$K_{\mathrm{RWA}}(\theta)=-i\varpi\frac{\partial}{\partial\theta}+\frac{1}{2}\begin{pmatrix}\omega_0 & \Omega e^{-i\theta}\\ \Omega e^{i\theta} & -\omega_0\end{pmatrix}.$$

The second model is defined by the choice $x(\theta)=-\varrho(\theta)/2$, $y(\theta)=\theta-\varrho(\theta)/2$, i.e., $2\vartheta(\theta)=\theta$, $2\wp(\theta)=\theta-\varrho(\theta)$ and the same z as for the RWA case. This leads to

$$K_M(\theta)=K_{\mathrm{RWA}}(\theta)+\frac{\varpi}{2\eta}\partial\varrho\begin{pmatrix}\omega_0-\varpi & \Omega e^{-i\theta}\\ \Omega e^{i\theta} & \varpi-\omega_0\end{pmatrix}.$$

We consider now a supplementary smooth slow time dependence in the parameter $\varpi=\varpi(s)$ and in $\varrho=\varrho(\theta,s)$. This implies that the eigenvalues, the eigenvectors and the corresponding eigenprojectors are smooth functions of s, so that the regularity Hypothesis $(H0)$(i) is satisfied. We show in appendix that $(H0)$(ii) is satisfied as well for any choice of smooth functions x, y, z, and λ.

We assume, for simplicity, that $\varpi(s)=s$ (but any other smooth monotonic function of s would equally do). This choice corresponds to the chirping that is most often realized in experiments. We select the eigenvalue $\lambda(s)=\lambda_{+,0}(s)=(\eta(s)+s)/2$ and denote by ψ the associated eigenvector (see Fig. 3). The only crossings that λ experiences are with the $\lambda_{-,k+1}$'s and they take place at times s such that

$$\eta(s)=ks, \quad k\in\mathbb{Z}^*. \tag{17}$$

We remark however that these crossings can lead to corrections to adiabaticity, or not, depending on whether the corresponding eigenvectors are coupled. The nonadiabatic coupling among the branches is measured by the following scalar product:

$$\begin{aligned}\langle\psi(s)|\partial_s\psi_{-,k+1}(s)\rangle&=-\frac{1}{2\pi}\int_0^{2\pi}e^{i(k+1)\theta-2i\wp(\theta,s)}(z'(s)-i\sin(2z(s))\vartheta'(\theta,s))d\theta\\&=-\frac{z'(s)}{2\pi}\int_0^{2\pi}e^{ik\theta+i\varrho(\theta,s)}d\theta,\end{aligned}$$

where the $'$ denotes the derivative with respect to s.

Recall that the couplings between the eigenstate $\psi(s)$ associated with the level $\lambda(s)$ and its orthogonal complement in the Hilbert space is given by the operator $L(s)=i[P'(s),P(s)]$, see (7), since the adiabatic evolution $A(s)$ follows the instantaneous eigenspaces. A direct computation of the matrix elements $\langle\psi_{-,k+1}(s)|L(s)\psi(s)\rangle$ with $P'(s)=|\psi'(s)\rangle\langle\psi(s)|+|\psi(s)\rangle\langle\psi'(s)|$ shows that the above scalar product is proportional to the couplings responsible for the nonadiabatic transitions.

For the RWA model, as $\varrho=0$ the nonadiabatic couplings are given by

$$\langle\psi(s)|\partial_s\psi_{-,k+1}(s)\rangle=-z'(s)\,\delta_{k,0}.$$

Thus, the level $\lambda(s)$ is *not* coupled to the infinitely many other levels it crosses. Hence we are led in this case to an effective problem displaying no crossing, so that the error is of order ϵ in this case.

For the other model, we will obtain nonzero couplings at all the crossings, if we choose $\varrho(\theta,s)$ such that $\exp(i\varrho(\theta,s))$ has infinitely many nonzero Fourier components. For example, one can take $\varrho(\theta,s)=\rho(s)\sin(\theta)$ (in particular ρ can be chosen constant). This coupling is then given by

$$\langle \psi(s)|\partial_s \psi_{-,k+1}(s)\rangle = (-1)^{k+1} z'(s) J_k(\rho(s)),$$

where J_k is a Bessel function.

We will now verify that the assumptions of Proposition 3.1 are satisfied. Let us focus on the interval $(0,S]$, for S small enough. The interval $[-S,0)$ can be treated similarly. Again to simplify the notations we will not explicit the $+$ sub/superscripts.

Remark: The preceding two examples have been chosen for their simplicity and explicit complete analytical solvability. However, we emphasize that the following analysis is valid for all the models (15) under the sole assumption that the eigenvalues can be written as $\lambda_{\pm,m}(s) = ms \pm \aleph(s)/2$, where $\aleph$ is a C^2 function with bounded derivatives such that $\aleph(0) > 0$. In particular they are satisfied for the eigenvalues given in (16). The hypotheses imply that the function $f_\zeta(s) = \aleph(s) - \zeta s$ is strictly decreasing for any ζ greater than, say, some ζ_0. Under these conditions the following assertion shows that the crossings that $\lambda(s) = \aleph(s)/2$ experiences with the rest of the spectrum take place at times such that $\aleph(s) = ks$, $k \in \mathbb{N}$ large enough. Again, the actual corrections to adiabaticity will depend on the particular properties of the associated eigenvectors which are measured by the scalar product $\langle \psi(s)|\partial_s \psi_{-,k+1}(s)\rangle$, which generically will not be zero for an infinite number of crossings.

Assertion 1: For $\zeta \geqslant \zeta_0$, the function $f_\zeta(s) = \aleph(s) - \zeta s$ has a unique positive zero o_ζ and if $\zeta < \xi$ we have $o_\zeta > o_\xi$.

From the expansion

$$f_\zeta(s) = \aleph(0) + (\aleph'(0) - \zeta)s + O(s^2),$$

we obtain the behavior of o_ζ:

$$o_\zeta = \frac{\aleph(0)}{\zeta - \aleph'(0)} + O(1/\zeta^3). \tag{18}$$

We define the sequence $u_k > 0$ by the equation:

$$\aleph(u_k) - k u_k = (k+1)u_k - \aleph(u_k), \quad \text{i.e.,} \quad \aleph(u_k) = (k+1/2)u_k. \tag{19}$$

Assertion 1 implies that $u_k < o_k < u_{k-1}$ and, from Eq. (18) and the fact that $u_k = o_{k+1/2}$, we obtain

$$u_k = \frac{\aleph(0)}{k + 1/2 - \aleph'(0)} + O(1/k^3). \tag{20}$$

Next, we have

Assertion 2: On the interval $[u_k, u_{k-1}]$, the spectral gap is given by

$$g(s) = \text{dist}(\lambda(s), \sigma(s) \backslash \{\lambda(s)\}) = |\aleph(s) - ks| \leqslant u_{k-1}/2.$$

More precisely, for $u_k \leqslant s \leqslant o_k$ we have that $g(s) = \aleph(s) - ks \leqslant u_k/2$ and for $o_k \leqslant s \leqslant u_{k-1}$ we have that $g(s) = ks - \aleph(s) \leqslant u_{k-1}/2$.

This assertion is easily proven by considering the different cases.

We now prove that the spectral hypothesis $(H1)$–$(H2)$ are verified. Assertion 1 and Equation (20) show that the sequence $\{u_k\}$ is (for k large enough) monotonically decreasing to $a = 0$. To define the intervals V_k, we choose any point r_k in (o_k, u_{k-1}) such that $g(r_k) = kr_k - \aleph(r_k) \leqslant u_k/2$ and set $V_k = (u_k, r_k)$. The V_k's are disjoint and $I_k = \{u_k\} \cup [r_k, u_{k-1}]$. By definition of V_k, we have that $g(s) \leqslant u_k/2 = g(u_k)$ and for $r_k \leqslant s \leqslant u_{k-1}$ the gap is given by $g(s) = ks - \aleph(s) \geqslant u_k/2$. Whence, hypothesis $(H1)$ is satisfied. Finally to prove that $(H2)$ holds, we need to estimate the behavior of $g(s)$ on V_k: the mean value theorem implies that for each $s \in V_k \backslash \{o_k\}$, there is a q_s, in the interval joining s and o_k, such that

$$g(s) = |\aleph(s) - ks| = |k - \aleph'(q_s)||s - o_k| \sim k|s - o_k|,$$

which shows that $(H2)$ is satisfied with $\alpha=1$ and $G(k)\sim k$.

It remains to check the conditions given in the statement of Proposition 3.1. We have

$$|u_k-0|=u_k=\aleph(0)/k+\aleph(0)(\aleph'(0)-1/2)/k^2+O(1/k^3),\quad \text{i.e.,}\quad \beta=1$$

$$G(k)\sim k \quad \text{i.e.,}\quad \gamma=1, \tag{21}$$

$$|V_k|\sim 1/k^2 \quad \text{i.e.,}\quad \delta=2.$$

To get the estimate for $|V_k|$, we have used that $(u_k,o_k]\subset V_k\subset(u_k,u_{k-1}]$ and the expressions for o_k, and u_k in Eqs. (18) and (20). This implies that, $\mu=\alpha(\beta+1)+\gamma=1+2\alpha$ and $\delta=\beta+1$. So, we can use the second case of Proposition 3.1 to prove that the adiabatic approximation holds for the models:

$$\|U(1)-A(1)\|\leqslant c\epsilon^p,\quad \text{for any}\quad p<\tfrac{1}{3}. \tag{22}$$

In keeping with the first remark of Sec. III, we recall that a more careful analysis yields $p=1/3$.

APPENDIX A: TECHNICALITIES

In this appendix, we show that an operator on $L^2(S^1,\mathcal{H})$ of the form

$$K(s,\theta)=-i\varpi(s)\frac{\partial}{\partial\theta}+H(s,\theta), \tag{A1}$$

where $H(s,\theta)$ is a bounded operator in $\mathcal{H}$ such that $s\mapsto H(s,\theta)$ and $s\mapsto\partial/\partial\theta H(s,\theta)$ are norm continuous and $s\mapsto\varpi(s)$ is continuous, admits a strongly continuous unitary propagator $U(s)=U(s,0)$ with all expected regularity properties, even if there is a value a for which $\varpi(a)=0$. Notice that the assumptions on H will be satisfied if, for example, $(s,\theta)\mapsto H(s,\theta)$ is strongly C^1.

The proof relies on a theorem of Kato,[17] which we will restate in a more suitable form for our purpose.

Theorem A.1 (Kato). Let $\mathcal{K}$ and $\mathcal{D}$ be Hilbert spaces such that $\mathcal{D}$ is densely and continuously embedded in $\mathcal{K}$ and let $K(t)$, $0\leqslant t\leqslant T$, be a family of self-adjoint operators in $\mathcal{K}$. Suppose that

(1) $\mathcal{D}\subset\operatorname{dom}K(t)$ for all $0\leqslant t\leqslant T$, whence the $K(t)$ are bounded operators from $\mathcal{D}$ to $\mathcal{K}$, and the application $t\mapsto K(t)$ is norm continuous from $\mathcal{D}$ to $\mathcal{K}$;

(2) there exists a family of isomorphisms $S(t)$ from $\mathcal{D}$ to $\mathcal{K}$ which is strongly continuously differentiable and such that

$$S(t)K(t)S(t)^{-1}=K(t)+B(t)$$

where $B(t)$ is a strongly continuous bounded operator on $\mathcal{K}$.

Under those conditions, there exists a unique family of unitary operators $U(t,s)$ on $\mathcal{K}$ defined for $0\leqslant s,t\leqslant T$ with the following properties:

(i) $U(t,s)$ is strongly continuous on $\mathcal{K}$ in s,t with $U(s,s)=\mathbb{1}$;

(ii) $U(t,r)=U(t,s)U(s,r)$;

(iii) $U(t,s)\mathcal{D}\subset\mathcal{D}$, $\|U(t,s)\|_{\mathcal{D}}\leqslant Ne^{c|t-s|}$ and is strongly continuous on $\mathcal{D}$ in s,t simultaneously;

(iv) $(d/ds)\,U(t,s)\psi=iU(t,s)K(s)\psi$ for any $\psi\in\mathcal{D}$, for $0\leqslant s,t\leqslant T$;

(v) for each $\psi\in\mathcal{D}$ and fixed s, $(d/dt)\,U(t,s)\psi$ exists and is equal to $-iK(t)U(t,s)\psi$ and strongly continuous in $\mathcal{K}$ in t.

To prove this theorem, we apply Theorem 6.1 in Ref. 17 to the operator $A(t)=iK(t)$, which is stable with constants of stability $c=0$ and $N=1$ (see Definition 3.1 and Theorem 4.1 therein). The fact that $U(t,s)$ is unitary follows from the self-adjointness of $K(t)$, the construction of $U(t,s)$ by unitary approximants given in the proofs of Theorem 4.1 and 6.1 in Ref. 17 and the invertibility of $U(t,s)$, which is a consequence of the fact that $A^o(t)=-iK(T-t)$ satifies also the hypothesis of Theorem 6.1 in Ref. 17. See also Remark 5.3 therein.

We now prove that the family of self-adjoint operators defined by Eq. (A1) satisfies the hypothesis of Theorem A.1. To simplify the notation, we will not explicit the θ-dependence and write ∂ for $\partial/\partial\theta$.

Proof: For $\mathcal{D}$, we choose $\mathrm{dom}(-iw_*\partial)$ for some $w_*>0$, and we notice that for any t such that $\varpi(t)\neq 0$, we have that $\mathrm{dom}\,K(t)=\mathcal{D}$ and if $\varpi(t)=0$, then $\mathrm{dom}\,K(t)=\mathcal{K}$. For the norm on $\mathcal{D}$, we choose the graph norm associated to $-iw_*\partial$:

$$\|\psi\|_{\mathcal{D}}^2=\|\psi\|^2+\|-iw_*\partial\psi\|^2\geq\|\psi\|^2.$$

Whence, $\mathcal{D}$ is a dense continuously embedded subspace of $\mathcal{K}$. For any s,t and any $\psi\in\mathcal{D}$, we have

$$\|(K(t)-K(s))\psi\|^2\leq 2\,\frac{|\varpi(t)-\varpi(s)|^2}{w_*^2}\|-iw_*\partial\psi\|^2+2\|H(t)-H(s))\psi\|^2$$
$$\leq 2\,\max\left\{\frac{|\varpi(t)-\varpi(s)|^2}{w_*^2};\left\|H(t)-H(s)\right\|^2\right\}\|\psi\|_{\mathcal{D}}^2.$$

which shows the norm continuity of $K(t)$.

We set $S(t)=S=-iw_*\partial+i$. S is an isomorphism between $\mathcal{D}$ and $\mathcal{K}$ which is strongly differentiable (by t independence). It remains to show that S satisfies Hypothesis (2) of Theorem A.1. For this, we first notice that for any $\psi\in\mathrm{dom}\,K(t)$, we have that $S^{-1}\psi\in\mathcal{D}\subset\mathrm{dom}\,K(t)$ and

$$K(t)S^{-1}\psi=S^{-1}K(t)\psi+H(t)S^{-1}\psi-S^{-1}H(t)\psi=S^{-1}K(t)\psi+S^{-1}SH(t)S^{-1}\psi-S^{-1}H(t)\psi$$
$$=S^{-1}(K(t)-iw_*\partial H(t)S^{-1})\psi. \tag{A2}$$

Whence, for any $\psi\in\mathrm{dom}\,K(t)$, we have that the left-hand side of Eq. (A2) belongs to $\mathcal{D}$. So we can write,

$$SK(t)S^{-1}\psi=K(t)\psi-iw_*\partial H(t)S^{-1}\psi,\quad \text{for all}\quad \psi\epsilon\mathrm{dom}\,K(t).$$

Setting $B(t)=-iw_*\partial H(t)S^{-1}$, we have a strongly continuous bounded operator (by the assumptions on H) which satisfies $SK(t)S^{-1}\supset K(t)+B(t)$. To show the reverse inclusion, we can consider any $b\geq 2\,\sup_t\|B(t)\|$ which implies that ib belongs to the resolvent set of both $K(t)+B(t)$ and $SK(t)S^{-1}$. It follows that $(K(t)+B(t)+ib)^{-1}\subset S(K(t)+ib)^{-1}S^{-1}$. But since the left hand side has domain $\mathcal{K}$, we must have equality between $K(t)+B(t)$ and $SK(t)S^{-1}$ instead of inclusion. □

In the examples of Sec. IV, both $H(s,\theta)$ defined through (15) by means of smooth functions x,y,z,λ of (s,θ), and $H(s,\theta)+\epsilon i[P'(s,\theta),P(s,\theta)]$ where $P(s,\theta)=|\psi(s,\theta)\rangle\langle\psi(s,\theta)|$ with $\psi(s,\theta)$ given by one of the vectors (14) satisfy the hypotheses of the theorem. Hence assumption $(H0)$ (ii) is satisfied for these models.

APPENDIX B: PROOF OF LEMMA 2.1, THEOREM 2.1, AND PROPOSITION 3.1

Proof of Lemma 2.1: The idea of the proof is to integrate Eq. (7) over the interval $[u_0,u_1]$ and then to get ''nice'' estimates of the sizes on each subintervals $[u_0,t]$, $[t,s]$, and $[s,u_1]$. By integrating Eq. (7), we get

$$i(W(u_1)-W(u_0))=-\int_{u_0}^{t}A^{-1}(u)L(u)A(u)W(u)du-\int_{t}^{s}A^{-1}(u)L(u)A(u)W(u)du$$
$$-\int_{s}^{u_1}A^{-1}(u)L(u)A(u)W(u)du. \tag{B1}$$

For the middle term, we simply use the properties of the operator norm and the fact that $A(u)$ and $W(u)$ are unitary to obtain

$$\|W(s)-W(t)\|\leqslant\int_{t}^{s}\|L(u)\|du\leqslant\sup_{u\in[0,1]}\|L(u)\||s-t|, \tag{B2}$$

i.e., we do not care about the behavior of $g(u)$ inside the subinterval $[t,s]$. To estimate the first integral, let $Q(u)=\mathbb{1}-P(u)$. A simple computation, using $P(s)P'(s)P(s)\equiv 0$, shows that

$$P(u)L(u)P(u)=Q(u)L(u)Q(u)=0, \tag{B3}$$

and due to the intertwining property of $A(u)$, we can write

$$W(t)-W(u_0)=i\int_{u_0}^{t}(P(0)A^{-1}(u)L(u)A(u)Q(0)+Q(0)A^{-1}(u)L(u)A(u)P(0))W(u)du. \tag{B4}$$

Now, we need to extract an explicit ϵ dependence from this equality in order to obtain the estimates stated in the lemma. To do this, we follow Ref. 11 and introduce the bounded operator $\mathcal{R}_L(u)$ defined by

$$\mathcal{R}_L(u)=\frac{1}{2i\pi}\oint_{\Gamma(u)}R(u,\lambda)L(u)R(u,\lambda)d\lambda,$$

where $R(u,\lambda)=(H(u)-\lambda)^{-1}$ is the resolvent of $H(u)$ at λ and where the loop $\Gamma(u)$ is a circle centered at $\lambda(u)$ of radius $g(u)/2$. It has the properties (see Refs. 11 and 13)

$$[\mathcal{R}_L(u),H(u)]=[L(u),P(u)], \tag{B5}$$

$$P(u)\mathcal{R}_L(u)P(u)=Q(u)\mathcal{R}_L(u)Q(u)=0. \tag{B6}$$

Standard arguments show that $\mathcal{R}_L(u)$ is strongly C^1 and that

$$\mathcal{R}_L'(u)=\frac{1}{2i\pi}\oint_{\Gamma(u)}(R(u,\lambda)L'(u)R(u,\lambda)-R(u,\lambda)H'(u)R(u,\lambda)L(u)R(u,\lambda)$$
$$-R(u,\lambda)L(u)R(u,\lambda)H'(u)R(u,\lambda))d\lambda, \tag{B7}$$

where $H'(u)R(u,\lambda)$ is to be understood as the bounded operator

$$H'(u)R(u,\lambda)=H'(u)R(u,i)(\mathbb{1}+(\lambda-i)R(u,\lambda)). \tag{B8}$$

Hence, we get the following estimates:

$$\|\mathcal{R}_L(u)\| \leq \frac{|\Gamma(u)|}{2\pi}\|L(u)\|(g(u)/2)^{-2} = 2\|L(u)\|/g(u), \tag{B9}$$

$$\|\mathcal{R}_L'(u)\| \leq c \max\{\|H'(u)R(u,i)\|\|L(u)\|,\|L'(u)\|\}/g^2(u). \tag{B10}$$

The main property of $\mathcal{R}_L(u)$ (see Ref. 11) is that it satisfies for any $\psi\in\mathcal{D}$ the following equalities, as verified by means of (B5):

$$P(0)A^{-1}(u)L(u)A(u)Q(0)\psi = -i\epsilon\frac{d}{du}(P(0)A^{-1}(u)\mathcal{R}_L(u)A(u)Q(0)\psi) + i\epsilon P(0)A^{-1}(u)\mathcal{R}_L'(u)A(u)Q(0)\psi \tag{B11}$$

and

$$Q(0)A^{-1}(u)L(u)A(u)P(0)\psi = i\epsilon\frac{d}{du}(Q(0)A^{-1}(u)\mathcal{R}_L(u)A(u)P(0)\psi) - i\epsilon Q(0)A^{-1}(u)\mathcal{R}_L'(u)A(u)P(0)\psi. \tag{B12}$$

These equations imply that $\int_{u_0}^{t}A^{-1}(u)L(u)A(u)W(u)du$ is proportional to ϵ. Indeed, Equalities (B3) and the intertwining property of $A(u)$ show that the diagonal blocks are 0.

Introducing Equalities (B11) and (B12) in Eq. (B4), we get

$$\begin{aligned} W(t)-W(u_0) = &-\epsilon\int_{u_0}^{t}\frac{d}{du}(Q(0)A^{-1}(u)\mathcal{R}_L(u)A(u)P(0) \\ &- P(0)A^{-1}(u)\mathcal{R}_L(u)A(u)Q(0))W(u)du - \epsilon\int_{u_0}^{t}(P(0)A^{-1}(u)\mathcal{R}_L'(u)A(u)Q(0) \\ &- Q(0)A^{-1}(u)\mathcal{R}_L'(u)A(u)P(0))W(u)du. \end{aligned} \tag{B13}$$

Performing an integration by part in the first integral, using the differential equation (7) for $W(u)$ and taking into account that $A(u)$, $W(u)$ are unitary and $P(0)$, $Q(0)$ are projectors, gives us the following bound for the norm of the difference $W(t)-W(u_0)$:

$$\begin{aligned} \|W(t)-W(u_0)\| \leq 2\epsilon(&\|\mathcal{R}_L(t)\| + \|\mathcal{R}_L(u_0)\| + \sup_{u\in[u_0,t]}\|\mathcal{R}_L(u)\|\|L(u)\|(t-u_0) \\ &+ \sup_{u\in[u_0,t]}\|\mathcal{R}_L'(u)\|(t-u_0)). \end{aligned} \tag{B14}$$

Next, we use first Estimates (B9) and (B10) and then the fact that $0\leq u_0<t\leq 1$ to obtain the desired bound:

$$\begin{aligned} \|W(t)-W(u_0)\| &\leq \frac{8\epsilon}{g_t}\sup_{u\in[u_0,t]}\|L(u)\| + \frac{4\epsilon}{g_t}\sup_{u\in[u_0,t]}\|L(u)\|^2(t-u_0) + c\,\frac{2\epsilon}{g_t^2} \\ &\quad\times\sup_{u\in[u_0,t]}\{\|H'(u)R(u,i)\|\|L(u)\|,\|L'(u)\|\}(t-u_0) \\ &\leq 12\frac{\epsilon}{g_t}\sup_{u\in[0,1]}\{\|L(u)\|,\|L(u)\|^2\} + 2\,\frac{\epsilon|t-u_0|}{g_t^2} \\ &\quad\times\sup_{u\in[0,1]}\{\|H'(u)R(u,i)\|\|L(u)\|,\|L'(u)\|\} \\ &\leq c_2\left(\frac{\epsilon}{g_t} + \frac{\epsilon|t-u_0|}{g_t^2}\right). \end{aligned} \tag{B15}$$

Using the same kind of arguments, shows that on the subinterval $[s,u_1]$, we have

$$\|W(u_1)-W(s)\|\leq c_2\left(\frac{\epsilon|s-u_1|}{g_s^2}+\frac{\epsilon}{g_s}\right). \tag{B16}$$

Combining estimates (B2), (B15), and (B16) gives the announced bound for $\|W(u_1)-W(u_0)\|$.□

Proof of Theorem 2.1: In the sequel, we will denote by the same symbol c all inessential constants. Let us consider the interval $[0;a)$. In order to simplify the notations, we will not write the subscripts/superscripts $-$. Picking some $t,s\in V_k$ such that $t<o_k<s$ and $|t-o_k|=|s-o_k|$, we get

$$\begin{aligned}\|W(u_k)-W(u_{k-1})\|&\leq c(\epsilon|t-u_{k-1}|/g_t^2+\epsilon|s-u_k|/g_s^2+\epsilon/g_t+\epsilon/g_s+|t-s|)\\&\leq c\left(\epsilon\frac{\Delta(k)}{G(k)^2}|t-o_k|^{-2\alpha}+\epsilon\frac{1}{G(k)}|t-o_k|^{-\alpha}+|t-o_k|\right)\\&\leq c\left(\epsilon\frac{\Delta(k)}{G(k)^2}|t-o_k|^{-2\alpha}+\epsilon\frac{\Delta^{\alpha}(k)}{G(k)}|t-o_k|^{-2\alpha}+|t-o_k|\right) \qquad (B17)\\&\leq c(\epsilon\tau(k)|t-o_k|^{-2\alpha}+|t-o_k|) \qquad (B18)\end{aligned}$$

by the preceding section. Indeed, we have that $g_t=\inf_{u\in[u_{k-1},t]}g(u)=g(r_t)$ for some $r_t\in[u_{k-1},t]$. Now, by Hypothesis $(H1)$, $r_t\in V_k$. Whence, we have that

$$g_t=g(r_t)\geq G(k)|r_t-o_k|^{\alpha}\geq G(k)|t-o_k|^{\alpha}$$

as $r_t\leq t\leq o_k$. Using the same kind of arguments, we can show that $g_s=\inf_{u\in[s,u_k]}g(u)\geq G(k)|s-o_k|^{\alpha}$. Finally to obtain the bound (B17), it remains to notice that $|s-t|=|t-o_k|+|s-o_k|=2|t-o_k|$ together with $|t-o_k|$, $|t-u_{k-1}|\leq\Delta(k)$ and $|s-o_k|$, $|s-u_k|\leq\Delta(k)$.

We now get an estimate by choosing $t=t(\epsilon,k)$ in order to balance the two contributions appearing in the last term of Eq. (B17) above: for some constant $\varsigma>0$, we set

$$\frac{\varsigma^{1+2\alpha}\epsilon\tau(k)}{|t(\epsilon,k)-o_k|^{2\alpha}}=|t(\epsilon,k)-o_k|, \tag{B19}$$

i.e.,

$$|t(\epsilon,k)-o_k|=\varsigma(\epsilon\tau(k))^{1/(1+2\alpha)}. \tag{B20}$$

By definition, $t(\epsilon,k)\in V_k$, hence, as k will eventually be bounded from above by $K(\epsilon)$, this imposes Condition (13) in the statement of the theorem. Replacing t by $t(\epsilon,k)$ in (B17) and summing over k, we get for any $K\leq K(\epsilon)$,

$$\|W(0)-W(u_K)\|\leq c(\varsigma+\varsigma^{-2\alpha})\sum_{k=1}^{K}(\epsilon\tau(k))^{1/(1+2\alpha)}. \tag{B21}$$

On the other hand, using the differential Eq. (7), we obtain

$$\|W(u_K)-W(a)\|\leq\int_{u_K}^{a}\|L(u)\|du\leq c|u_K-a|. \tag{B22}$$

Again, we balance the two right-hand sides in (B21) and (B22) by setting the integer $K=K(\epsilon)$, which has been defined in Eq. (12). Consequently,

$$\|W(0)-W(a)\| \leqslant c\left((\varsigma+\varsigma^{-2\alpha})\epsilon^{1/(1+2\alpha)}\sum_{k=1}^{K(\epsilon)} \tau(k)^{1/(1+2\alpha)}+|u_{K(\epsilon)}-a|\right)$$
$$\leqslant c(\varsigma+\varsigma^{-2\alpha}+1)|u_{K(\epsilon)}-a| \equiv C(\varsigma)|u_{K(\epsilon)}-a|, \tag{B23}$$

where $C(\varsigma)$ is independent of ϵ. Proceeding similarly on $(a,1]$ completes the proof. □

Remark: In the step (B17) we deliberately lost a little in the estimate by using $|t-o_k|^{-\alpha} \leqslant \Delta_k^{\alpha}|t-o_k|^{-2\alpha}$ in order to simplify the subsequent arguments. It is nevertheless possible to get slightly sharper results by not adopting this simplification, however the analysis gets more involved and less transparent. We simply note here that in the examples discussed in this paper, this more careful analysis yields, for the generic situation, an error term of order ϵ^p with an exponent $p=1/3$, instead of the value $p=1/3-\nu$, for any $\nu>0$ obtained there.

Proof of Proposition 3.1: The idea of the proof is to explicit conditions on the different exponents ensuring the validity of Theorem 2.1. We will only consider the interval $[0,a)$, the same kind of arguments will apply on $(a,1]$. Again, in order to simplify the notations we will let aside the subscripts/superscripts $-$.

First, we have that $2\Delta(k)=u_k-u_{k-1}=C_1\beta/k^{\beta+1}+o(1/k^{\beta+1})\sim 1/k^{\beta+1}$, which implies that

$$\delta \geqslant \beta+1>0, \tag{B24}$$

since $2\Delta(k)\geqslant |V_k|\sim 1/k^{\delta}$. Notice that the length of the V_k can be rescaled by a uniform constant if $\delta=\beta+1$.

Next, $\Delta(k)/G^2(k)\sim 1/k^{\beta+1+2\gamma}$ and $\Delta^{\alpha}(k)/G(k)\sim 1/k^{\alpha(\beta+1)+\gamma}$. So, if we denote by $\mu=\min\{\beta+1+2\gamma,\alpha(\beta+1)+\gamma\}$ then $\tau(k)=\max\{\Delta(k)/G^2(k), \Delta^{\alpha}(k)/G(k)\}\sim 1/k^{\mu}$ by increasing the overall constant in Theorem 2.1 if necessary. Whence,

$$\sum_{k=1}^{K}\tau(k)^{1/(1+2\alpha)}\sim\sum_{k=1}^{K}k^{-\mu/(1+2\alpha)}\sim\begin{cases}K^0 & \text{if } \mu>1+2\alpha\\ \log K & \text{if } \mu=1+2\alpha\\ K^{1-\mu/(1+2\alpha)} & \text{if } \mu<1+2\alpha\end{cases} \tag{B25}$$

and considering the definition of $K(\epsilon)$ [see Eq. (12)], we obtain

$$\epsilon^{1/(1+2\alpha)}\sim\frac{|u_{K(\epsilon)}-a|}{\sum_{k=1}^{K(\epsilon)}\tau(k)^{1/(1+2\alpha)}}\sim\begin{cases}K(\epsilon)^{-\beta} & \text{if } \mu>1+2\alpha\\ K(\epsilon)^{-\beta}/\log K(\epsilon) & \text{if } \mu=1+2\alpha\\ K(\epsilon)^{-\beta-1+\mu/(1+2\alpha)} & \text{if } \mu<1+2\alpha\end{cases}. \tag{B26}$$

Condition (13) stated in Theorem 2.1 reads

$$\varsigma(\epsilon\tau(k))^{1/(1+2\alpha)}\leqslant |V_k|/2 \tag{B27}$$

for all $1\leqslant k\leqslant K(\epsilon)$. Notice that this condition is automatically satisfied if $\delta<\mu/(1+2\alpha)$. In general, it will be satisfied for a sufficiently small ς, if

$$F(\epsilon)\equiv\epsilon^{1/(1+2\alpha)}K(\epsilon)^{\delta-\mu/(1+2\alpha)} \tag{B28}$$

remains bounded as $\epsilon\to 0$. Using (B26), we have

$$F(\epsilon)\sim\begin{cases}K(\epsilon)^{\delta-\beta-\mu/(1+2\alpha)} & \text{if } \mu>1+2\alpha,\\ K(\epsilon)^{\delta-1-\beta}/\log K(\epsilon) & \text{if } \mu=1+2\alpha,\\ K(\epsilon)^{\delta-\beta-1} & \text{if } \mu<1+2\alpha.\end{cases} \tag{B29}$$

As $K(\epsilon)\to\infty$ for $\epsilon\to 0$, Eq. (B29) implies that $F(\epsilon)$ will remain bounded if $\delta\leqslant\beta+\max\{1;\mu/(1+2\alpha)\}$.

Hence, using (B23) and (B26), we get that the adiabatic theorem (2.1) holds with a remainder term on $[0,a)$,

$$O(|u_{K_-(\epsilon)}-\alpha|)=O(K(\epsilon)^{-\beta})=O(\epsilon^p)$$

where the exponent p is given by

$$p=\begin{cases}\dfrac{1}{1+2\alpha} & \text{if } \mu>(1+2\alpha)\\[2mm] \dfrac{1}{1+2\alpha}-\nu\ \forall\nu>0 & \text{if } \mu=(1+2\alpha)\\[2mm] \dfrac{\beta}{(\beta+1)(1+2\alpha)-\mu} & \text{if } \mu<(1+2\alpha)\end{cases}$$

provided that $\beta+1\leqslant\delta\leqslant\beta+\max\{1;\mu/(1+2\alpha)\}$. To determine p in case $\mu=1+2\alpha$ and $\delta=\beta+1$, we have used the estimate $\epsilon^{-1/(1+2\alpha)}\sim K(\epsilon)^{\beta}\log K(\epsilon)<K(\epsilon)^{\beta+\nu'}$ for all $\nu'>0$. This ends the proof of the proposition. □

(Received 22 July 1999; accepted for publication 11 August 1999)

Using the formalism of supersymmetric quantum mechanics, we obtain a large number of new analytically solvable one-dimensional periodic potentials and study their properties. More specifically, the supersymmetric partners of the Lamé potentials $ma(a+1)\,\mathrm{sn}^2(x,m)$ are computed for integer values $a=1,2,3,\ldots$. For all cases (except $a=1$), we show that the partner potential is distinctly different from the original Lamé potential, even though they both have the same energy band structure. We also derive and discuss the energy band edges of the associated Lamé potentials $pm\,\mathrm{sn}^2(x,m)+qm\,\mathrm{cn}^2(x,m)/\mathrm{dn}^2(x,m)$, which constitute a much richer class of periodic problems. Computation of their supersymmetric partners yields many additional new solvable and quasiexactly solvable periodic potentials. © *1999 American Institute of Physics.* [S0022-2488(99)03511-2]

I. INTRODUCTION

The energy spectrum of electrons on a lattice is of central importance in condensed matter physics. In particular, knowledge of the existence and locations of band edges and band gaps determines many physical properties. Unfortunately, even in one dimension, there are very few analytically solvable periodic potential problems in quantum mechanics. The aim of this paper is to extend the small currently known set of analytically solvable periodic potentials.

For a potential with period L, one is seeking solutions of the Schrödinger equation subject to the Bloch condition

$$\psi(x)=e^{ikL}\psi(x+L), \tag{1}$$

where k denotes the crystal momentum. The spectrum shows energy bands whose edges correspond to $kL=0,\ \pi$, that is the wave functions at the band edges satisfy $\psi(x)=\pm\psi(x+L)$. For periodic potentials, the band edge energies and wave functions are often called eigenvalues and eigenfunctions, and we will also use this terminology. The classic textbook example which is used to demonstrate band structure is the Kronig–Penney model,

$$V(x)=\sum_{n=-\infty}^{\infty} V_0\,\delta(x-nL).$$

It should be noted that the band edges for the Kronig–Penney model can only be computed by solving a transcendental equation. Another well-studied class of periodic potentials is

$$V(x)=pm\,\mathrm{sn}^2(x,m), \quad p\equiv a(a+1). \tag{2}$$

[a)]Electronic mail: khare@iopb.res.in
[b)]Electronic mail: sukhatme@uic.edu

Here $\mathrm{sn}(x,m)$ is a Jacobi elliptic function of real elliptic modulus parameter $m(0\leqslant m\leqslant 1)$ with period $4K(m)$. For simplicity, from now on, we will not explicitly display the modulus parameter m as an argument of Jacobi elliptic functions.[1] The elliptic function potentials of Eq. (2) have a period $L=2K(m)$, and will be referred to as Lamé potentials, since the corresponding Schrödinger equation is called Lamé's equation.[2,3] It is well known that for any integer value $a=1,2,3,...$, the corresponding Lamé potential (2) has a bound bands followed by a continuum band.[2,3] All band edge energies and wave functions are analytically known.

At this point it is worth recalling that supersymmetric quantum mechanics (SUSYQM) has proved useful in discovering many, new, analytically solvable potentials on both the full as well as the half line.[4] It is then natural to enquire if one can also use similar techniques to discover new solvable periodic potentials. In this paper, we demonstrate that this is indeed possible.

Our work is inspired by several recent papers,[5–8] which discuss various general aspects of SUSYQM for periodic potentials. In particular, Dunne and Feinberg[5] defined and developed the concept of ''self-isospectral'' periodic potentials in detail. A one-dimensional potential $V_-(x)$ of period L is said to be self-isospectral if its supersymmetric partner potential $V_+(x)$ is just the original potential up to a discrete transformation—a translation by any constant amount, a reflection, or both. A common example is translation by half a period, in which case the condition for self-isospectrality is

$$V_+(x)=V_-(x-L/2). \tag{3}$$

It is easily checked that if the superpotential W satisfies

$$W(x)=-W(x-L/2), \tag{4}$$

then condition (3) immediately follows. In this sense, any self-isospectral potential is rather uninteresting, since application of the SUSYQM formalism[4] to it just yields a discrete transformation and basically nothing new. We have recently pointed out[9] that the Lamé potentials given in Eq. (2) are not self-isospectral for $a\geqslant 2$, and hence SUSYQM generates new exactly solvable periodic problems. This point is further developed in detail in this paper.

We expand our discussion to the band edges and wave functions of a much richer class of periodic potentials given by

$$V(x)=pm\,\mathrm{sn}^2(x)+qm\frac{\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)},\quad p\equiv a(a+1),\quad q\equiv b(b+1), \tag{5}$$

where, like $\mathrm{sn}(x)$, the Jacobi elliptic functions $\mathrm{cn}(x)$ and $\mathrm{dn}(x)$ also have a modulus parameter m which, for notational convenience, is not explicitly displayed. The potentials of Eq. (5) are called associated Lamé potentials, since the corresponding Schrödinger equation is called the associated Lamé equation.[3] More precisely, we often refer to the associated Lamé potential of Eq. (5) as the (p,q) potential and note that $(p,0)$ potentials are just the ordinary Lamé potentials. Although some results for (p,q) potentials are available in scattered form in the mathematical literature, many of our results are new. In particular, we obtain all band edge energies and wave functions for the special case $p=q=a(a+1)$ for $a=1,2,3,...$. We study many (p,q) potentials and check whether they are self-isospectral by constructing and examining the supersymmetric partner potentials. In most cases, $V_-(x)$ is not self-isospectral, and consequently $V_+(x)$ is a new, exactly, or quasiexactly solvable periodic potential.

The associated Lamé potentials given by Eq. (5) can also be rewritten in the alternative form

$$V(x)=pm\,\mathrm{sn}^2(x)+qm\,\mathrm{sn}^2(x+K(m)), \tag{6}$$

since[1]

$$\mathrm{sn}(x+K)=\mathrm{cn}(x)/\mathrm{dn}(x),\quad \mathrm{cn}(x+K)=-\sqrt{1-m}\,\mathrm{sn}(x)/\mathrm{dn}(x),\quad \mathrm{dn}(x+K)=\sqrt{1-m}/\mathrm{dn}(x).$$

It is clear from (6) that potentials (p,q) and (q,p) have the same energy spectra with wave functions shifted by $K(m)$. Therefore, it is sufficient to restrict our attention to $p \geqslant q$.

Before actually solving the Schrödinger equation for the associated Lamé potential (5), let us make a few general comments. Throughout this paper, we have chosen units with $\hbar = 1$, and taken the particle mass in the Schrödinger equation to be 1/2. Note that in the limit when the elliptic modulus parameter $m = 0$, the potential vanishes and one has a rigid rotator problem of period $2K(0) = \pi$, whose energy eigenvalues are at $E = 0,1,4,9,...$, with all the nonzero values being twofold degenerate. On the other hand, the limit $m \rightarrow 1$ is much trickier since $K(m)$ tends to infinity and the periodic nature of the potential is obscured. The Schrödinger equation for finding the eigenstates for an arbitrary periodic potential is called Hill's equation in the mathematics literature.[3] A general property of Hill's equation is the oscillation theorem which states that for a potential with period L, the band edge wave functions arranged in order of increasing energy $E_0 \leqslant E_1 \leqslant E_2 \leqslant E_3 \leqslant E_4 \leqslant E_5 \leqslant E_6 \leqslant \cdots$ are of period $L,2L,2L,L,L,2L,2L,\ldots$. The corresponding number of wave function nodes in the interval L are 0,1,1,2,2,3,3,..., and the energy band gaps are given by $\Delta_1 \equiv E_2 - E_1$, $\Delta_2 \equiv E_4 - E_3$, $\Delta_3 \equiv E_6 - E_5, \ldots$. We shall see that the expected $m = 0$ limit and the oscillation theorem are very useful in identifying if all band edge eigenstates have been properly determined or if some have been missed.

The plan of the paper is as follows. In Sec. II, we briefly review the basic ideas of SUSYQM. A detailed discussion of Lamé potentials and their supersymmetric partners is given in Sec. III. Solutions of the Schrödinger equation for the associated Lamé potentials are presented in Sec. IV. Many key new results are summarized in Table III. It is shown that the locus of quasiexactly solvable problems[10,11] in the (p,q) plane are parabolas about the line $p = q$. Our solutions are valid for any real choice of the parameters a, b [recall $p = a(a+1)$, $q = b(b+1)$]. Integer and half-integer values of a, b, including the very interesting special case $a = b =$ integer, are treated in detail in Sec. V. In most cases, the application of SUSYQM gives new solvable periodic potentials, many of which are illustrated in the figures. Finally, Sec. VI contains some concluding remarks.

II. SUPERSYMMETRIC QUANTUM MECHANICS FORMALISM

The supersymmetric partner potentials $V_{\pm}(x)$ are defined in terms of the superpotential $W(x)$ by

$$V_{\pm}(x) = W^2(x) \pm W'(x). \tag{7}$$

The corresponding Hamiltonians $H_{\pm}$ can be factorized as

$$H_{-} = A^{+}A, \quad H_{+} = AA^{+}, \tag{8}$$

where

$$A = \frac{d}{dx} + W(x), \quad A^{+} = -\frac{d}{dx} + W(x), \tag{9}$$

so that the spectra of $H_{\pm}$ are non-negative. It is also clear that on the full line, both $H_{\pm}$ cannot have zero energy modes since both $\psi_0^{(\pm)}$ given by

$$\psi_0^{(\pm)}(x) = \exp\left(\pm \int^x W(y)\, dy \right), \tag{10}$$

cannot be simultaneously normalized.

On the other hand, when the superpotential $W(x)$ is periodic $[W(x+L) = W(x)]$ then the potentials $V_{-}(x)$ and $V_{+}(x)$ are isospectral—their spectra match completely, including the zero modes, and SUSY is unbroken provided

TABLE I. The eigenvalues and eigenfunctions for the five band edges coresponding to the $a=2$ Lamé potential V_- which gives $(p,q)=(6,0)$ and its SUSY partner V_+. Here $B\equiv 1+m+\delta$ and $\delta\equiv\sqrt{1-m+m^2}$. The potentials $V_\pm$ have period $L=2K(m)$ and their analytic forms are given by Eqs. (14) and (17), respectively. The periods of various eigenfunctions and the number of nodes in the interval L are tabulated.

E	$\psi^{(-)}$	$(B-3m\,\mathrm{sn}^2(x))\psi^{(+)}$	Period	Nodes
0	$m+1+\delta-3m\,\mathrm{sn}^2(x)$	1	$2K$	0
$2\delta-1-m$	$\mathrm{cn}(x)\mathrm{dn}(x)$	$\mathrm{sn}(x)[6m-(m+1)B+m\,\mathrm{sn}^2(x)(2B-3-3m)]$	$4K$	1
$2\delta-1+2m$	$\mathrm{sn}(x)\mathrm{dn}(x)$	$\mathrm{cn}(x)[B+m\,\mathrm{sn}^2(x)(3-2B)]$	$4K$	1
$2\delta+2-m$	$\mathrm{sn}(x)\mathrm{cn}(x)$	$\mathrm{dn}(x)[B+\mathrm{sn}^2(x)(3m-2B)]$	$2K$	2
4δ	$m+1-\delta-3m\,\mathrm{sn}^2(x)$	$\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}(x)$	$2K$	2

$$\int_0^L W(y)\,dy=0. \tag{11}$$

It is worth noting that in this case both $\psi_0^{(\pm)}$ belong to the Hilbert space. Thus in this case even though SUSY is unbroken, the Witten index is zero.[5] The condition (11) is trivially satisfied in case $W(x)$ is an odd function of x and throughout this paper we shall only consider superpotentials W which are odd function of x. Further, using the known eigenfunctions $\psi_n^{(-)}(x)$ of $V_-(x)$ one can immediately write down the corresponding un-normalized eigenfunctions $\psi_n^{(+)}(x)$ of $V_+(x)$. In particular, from Eq. (10) it follows that the ground state of $V_+(x)$ is given by

$$\psi_0^{(+)}(x)=\frac{1}{\psi_0^{(-)}(x)}, \tag{12}$$

while the excited states $\psi_n^{(+)}(x)$ are obtained from $\psi_n^{(-)}(x)$ by using the relation

$$\psi_n^{(+)}(x)=\left[\frac{d}{dx}+W(x)\right]\psi_n^{(-)}(x) \quad (n\geqslant 1). \tag{13}$$

Thus by starting from an exactly solvable periodic potential $V_-(x)$, one gets another isospectral periodic potential $V_+(x)$. As emphasized previously, if $V_-(x)$ is not self-isospectral, then $V_+(x)$ is a new solvable periodic potential!

III. LAMÉ POTENTIALS $(p,0)$ AND THEIR SUPERSYMMETRIC PARTNERS

The supersymmetric quantum mechanics formalism of Sec. II will now be applied to the Lamé potentials $ma(a+1)\mathrm{sn}^2(x,m)$. Analytic solutions are known for integer values of a,[2] and the supersymmetric partner potentials can be readily computed. We first discuss the results for small integer values of a, and then present some eigenstate results for arbitrary integer values of a.

A. Lamé potentials with $a=1,2,3$

1. $a=1$

The $a=1$ Lamé potential $V_-=2m\,\mathrm{sn}^2(x)-m$ is known to be self-isospectral[5] since its SUSY partner satisfies $V_+(x)=V_-(x-K(m))$. Both $V_+(x)$ and $V_-(x)$ have one energy band ranging from energy 0 to energy $1-m$, with a continuum starting at energy 1.[2] Note that at $m=0$ one has energy eigenvalues at 0, 1 as expected for a rigid rotator and as $m\to 1$, one gets $V_-(x)\to 1-2\,\mathrm{sech}^2 x$, the bandwidth $1-m$ vanishes as expected, and one has an energy level at $E=0$.

2. $a=2$

For the $a=2$ case, the Lamé potential (2) has two bound bands and a continuum band. The energies and wave functions of the five band edges are well known.[2,3] The lowest energy band ranges from $2+2m-2\delta$ to $1+m$, the second energy band ranges from $1+4m$ to $4+m$, and the continuum starts at energy $2+2m+2\delta$, where $\delta=\sqrt{1-m+m^2}$. The wave functions of all the band edges are given in Table I. Note that in the interval $2K(m)$ corresponding to the period of the Lamé potential, the number of nodes increases with energy. In order to use the SUSYQM formalism, we must shift the Lamé potential by a constant to ensure that the ground state, i.e., the lower edge of the lowest band, has energy $E=0$. As a result, the potential

$$V_-(x)=-2-2m+2\delta+6m\,\mathrm{sn}^2(x) \tag{14}$$

has its ground state energy at zero with a corresponding un-normalized wave function[2]

$$\psi_0^{(-)}(x)=1+m+\delta-3m\,\mathrm{sn}^2(x). \tag{15}$$

The corresponding superpotential is

$$W=-\frac{d}{dx}\log\psi_0^{(-)}(x)=\frac{6m\,\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}(x)}{\psi_0^{(-)}(x)}, \tag{16}$$

and hence the partner potential $V_+(x)$ for the potential $V_-(x)$ given in Eq. (14) is

$$V_+(x)=-V_-(x)+\frac{72m^2\,\mathrm{sn}^2(x)\mathrm{cn}^2(x)\mathrm{dn}^2(x)}{[1+m+\delta-3m\,\mathrm{sn}^2(x)]^2}. \tag{17}$$

Although the SUSYQM formalism guarantees that the potentials $V_\pm$ are isospectral, they are not self-isospectral, since they do not satisfy Eq. (3).[9] Therefore, $V_+(x)$ as given by Eq. (17) is a new periodic potential which is strictly isospectral to the potential (14) and hence it also has two bound bands and a continuum band. In Fig. 1 we have plotted the potentials $V_\pm(x)$ corresponding to $a=2$ for three different values of the parameter m. The values are $m=0.5$, 0.8, 0.998. The difference in shape between $V_-(x)$ and $V_+(x)$ is manifest from the figures, especially for large m. Using Eqs. (12) and (13) and the known eigenstates of $V_-(x)$, we can immediately compute all the band-edge Bloch wave functions for $V_+(x)$. In Table I we have given the energy eigenvalues and wave functions for the isospectral partner potentials $V_\pm(x)$. At $m=0$ one has energy eigenvalues 0, 1, 4 as expected for a rigid rotator. As $m\to 1$, one gets $V_-(x)\to 4-6\,\mathrm{sech}^2 x$, the bandwidths vanish as expected, and one has two energy levels at $E=0$, 3, with a continuum above $E=4$.

3. $a=3$

For the $a=3$ Lamé potential, the ground state wave function is

$$\psi_0^{(-)}(x)=\mathrm{dn}(x)[2m+\delta_1+1-5m\,\mathrm{sn}^2(x)],$$

the corresponding superpotential is[9]

$$W=\frac{m\,\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)}\,\frac{[2m+\delta_1+11-15m\,\mathrm{sn}^2(x)]}{[2m+\delta_1+1-5m\,\mathrm{sn}^2(x)]}, \tag{18}$$

and the partner potentials $V_\pm(x)$ are[9]

$$V_-(x)=-2-5m+2\delta_1+12m\,\mathrm{sn}^2(x),\qquad \delta_1\equiv\sqrt{1-m+4m^2}, \tag{19}$$

and

$$V_+(x)=-V_-(x)+\frac{2m^2\,\mathrm{sn}^2(x)\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)}\,\frac{[2m+\delta_1+11-15m\,\mathrm{sn}^2(x)]^2}{[2m+\delta_1+1-5m\,\mathrm{sn}^2(x)]^2}. \tag{20}$$

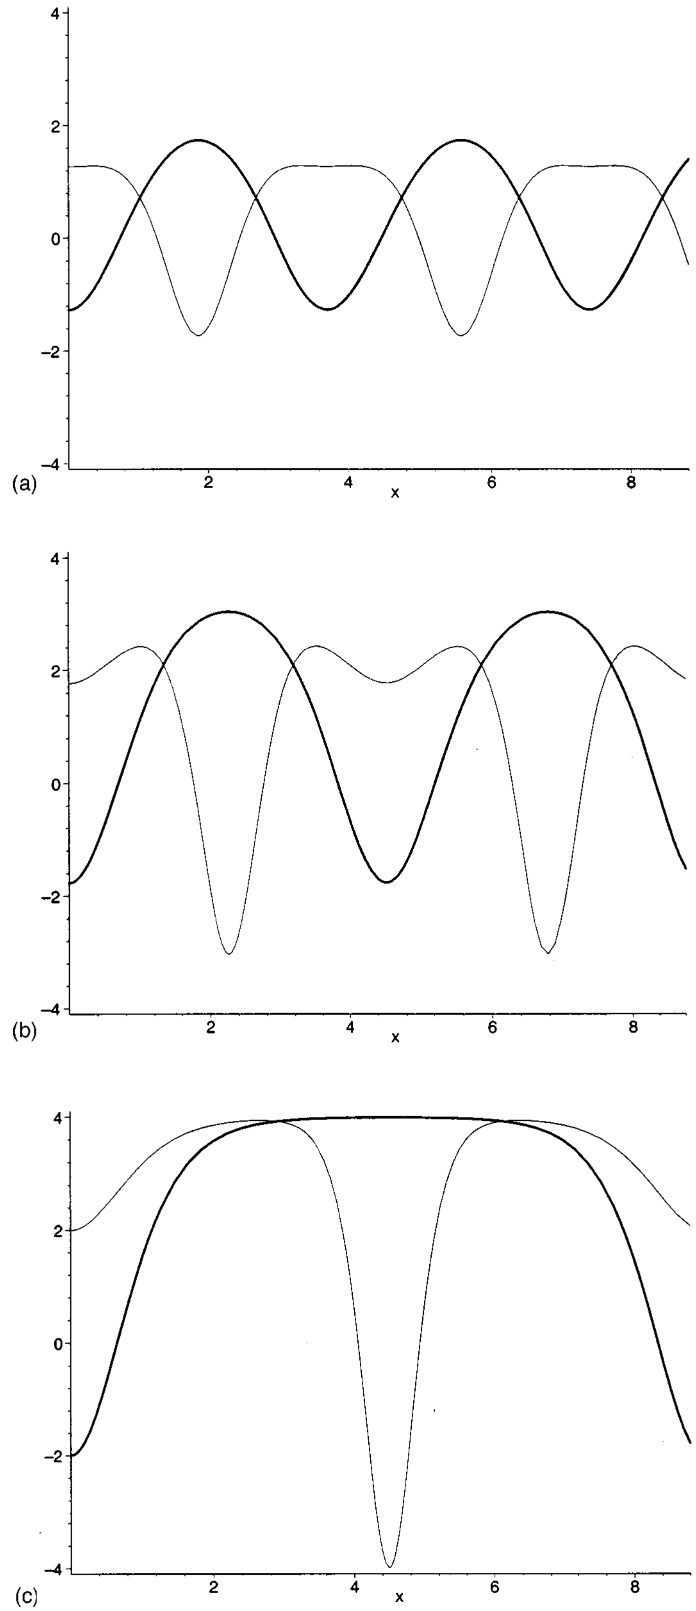

FIG. 1. The (6,0) Lamé potential $V_-(x)$ corresponding to $a=2$ (the thick line) as given by Eq. (14) and its supersymmetric partner potential $V_+(x)$ (the thin line) as given by Eq. (17) for three choices of m: (a) 0.5, (b) 0.8, (c) 0.998.

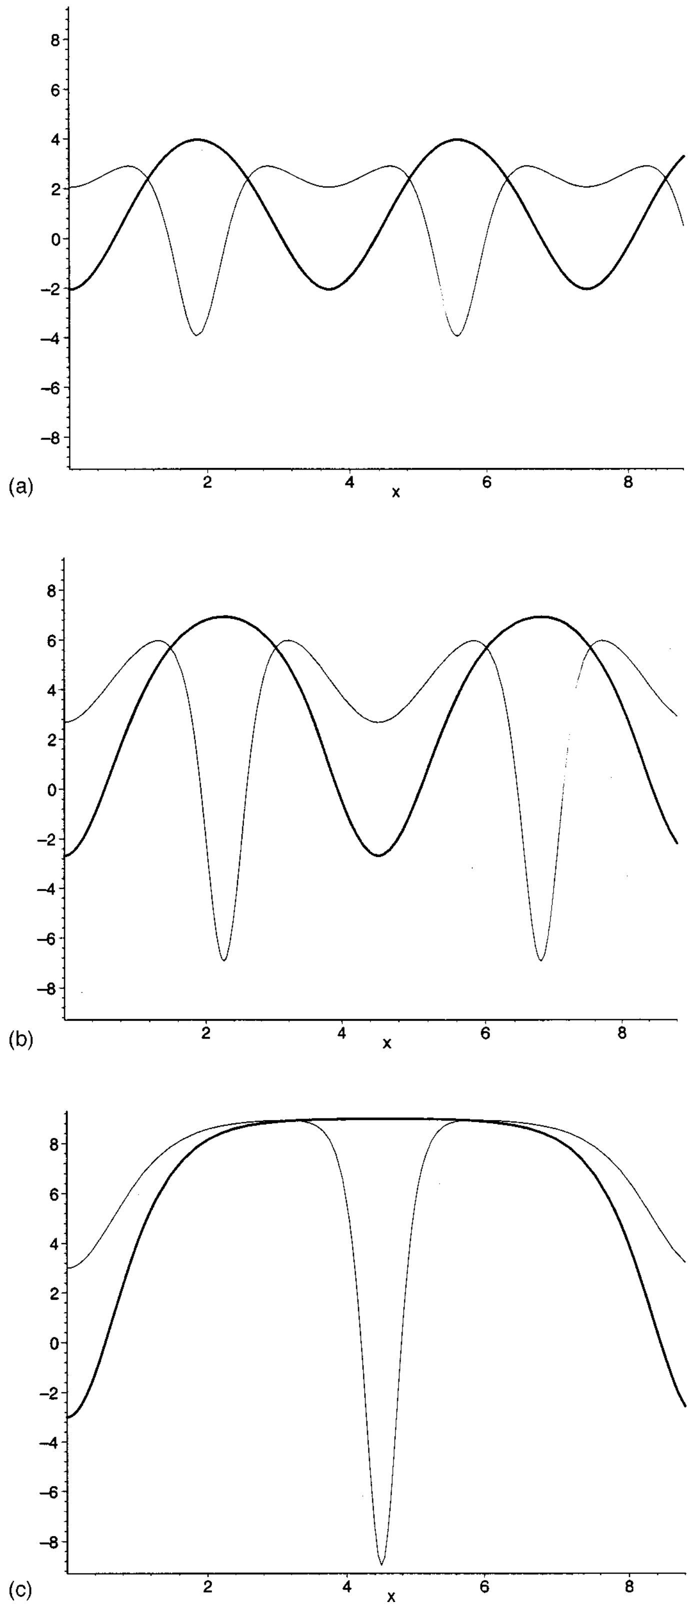

FIG. 2. The (12, 0) Lamé potential $V_{-}(x)$ corresponding to $a=3$ (the thick line) as given by Eq. (19) and its supersymmetric partner potential $V_{+}(x)$ (the thin line) as given by Eq. (20) for three choices of m: (a) 0.5, (b) 0.8, (c) 0.998.

TABLE II. The eigenvalues and eigenfunctions for the seven band edges corresponding to the $a=3$ Lamé potential V_- which gives $(p,q)=(12,0)$ and its SUSY partner V_+. Here $\delta_1 \equiv \sqrt{1-m+4m^2}$; $\delta_2 \equiv \sqrt{4-m+m^2}$; $\delta_3 \equiv \sqrt{4-7m+4m^2}$. The potentials $V_\pm$ have period $L=2K(m)$ and their analytic forms are given by Eqs. (19) and (20), respectively. The periods of various eigenfunctions and the number of nodes in the interval L are tabulated.

E	$\psi^{(-)}$	$\psi_0^- \psi^{(+)}$	Period	Nodes
0	$\mathrm{dn}(x)[1+2m+\delta_1-5m\,\mathrm{sn}^2(x)]$	1	$2K$	0
$3-3m+2\delta_1-2\delta_2$	$\mathrm{cn}(x)[2+m+\delta_2-5m\,\mathrm{sn}^2(x)]$	$10m(1-m+\delta_2-\delta_1)\mathrm{sn}(x)\mathrm{cn}^2(x) \times \mathrm{dn}^2(x)-(1-m)\dfrac{\mathrm{sn}(x)\psi_0^-\psi^-}{\mathrm{cn}(x)\mathrm{dn}(x)}$	$4K$	1
$3+2\delta_1-2\delta_3$	$\mathrm{sn}(x)[2+2m+\delta_3-5m\,\mathrm{sn}^2(x)]$	$10m(1+\delta_3-\delta_1)\mathrm{cn}(x)\mathrm{sn}^2(x)\mathrm{dn}^2(x) -(1-2m\,\mathrm{sn}^2(x))\dfrac{\mathrm{cn}(x)\psi_0^-\psi^-}{\mathrm{sn}(x)\mathrm{dn}(x)}$	$4K$	1
$2-m+2\delta_1$	$\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}(x)$	$\mathrm{dn}^3(x)[1+2m+\delta_1+(m-2-2\delta_1) \times \mathrm{sn}^2(x)]$	$2K$	2
$4\delta_1$	$\mathrm{dn}(x)[1+2m-\delta_1-5m\,\mathrm{sn}^2(x)]$	$\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}^3(x)$	$2K$	2
$3-3m+2\delta_1+2\delta_2$	$\mathrm{cn}(x)[2+m-\delta_2-5m\,\mathrm{sn}^2(x)]$	$10m(1-m-\delta_2-\delta_1)\mathrm{sn}(x)\mathrm{cn}^2(x) \times \mathrm{dn}^2(x)-(1-m)\dfrac{\mathrm{sn}(x)\psi_0^-\psi^-}{\mathrm{cn}(x)\mathrm{dn}(x)}$	$4K$	3
$3+2\delta_1+2\delta_3$	$\mathrm{sn}(x)[2+2m-\delta_3-5m\,\mathrm{sn}^2(x)]$	$10m(1-\delta_3-\delta_1)\mathrm{cn}(x)\mathrm{sn}^2(x) \times \mathrm{dn}^2(x)-(1-2m\,\mathrm{sn}^2(x))\dfrac{\mathrm{cn}(x)\psi_0^-\psi^-}{\mathrm{sn}(x)\mathrm{dn}(x)}$	$4K$	3

Clearly, the potential $V_-(x)$ is not self-isospectral. In fact, $V_-(x)$ and $V_+(x)$ are distinctly different periodic potentials which have the same seven band edges corresponding to three bound bands and a continuum band.[2] In Fig. 2 we have plotted the potentials $V_\pm(x)$ corresponding to $a=3$ for several different values of the parameter m. The values of m are 0.5, 0.8, 0.998. It is clear from Fig. 2 that the potentials $V_+(x)$ and $V_-(x)$ have different shapes and are far from being self-isospectral. Using Eqs. (12) and (13) and the known eigenstates of $V_-(x)$, we can immediately compute all seven band edges corresponding to the known three bound bands and a continuum band.[2,3] For example, the ground state $\psi_0^{(+)}$ is given by

$$\psi_0^{(+)}(x)=\frac{1}{\psi_0^{(-)}(x)}=\frac{1}{\mathrm{dn}(x)[1+2m+\delta_1-5m\,\mathrm{sn}^2(x)]}. \tag{21}$$

The wave functions for the remaining six states are similarly written down by using Eq. (13). These are shown in Table II. The band edge energies for the $a=3$ Lamé potential (12,0) as a function of the elliptic modulus parameter m are plotted in Fig. 3. Note that at $m=0$ one has energy eigenvalues at 0,1,4,9 as expected for a rigid rotator and as $m\to 1$, one gets $V_-(x)\to 9 - 12\,\mathrm{sech}^2 x$, the bandwidths vanish as expected, and one has three energy levels at $E=0$, 5, 8 with a continuum above $E=9$.

B. Results for general integer values of *a*

The extension to higher values of a is straightforward. It is possible to make several general comments about the form of the band edge wave functions for the partner potentials $V_+(x)$. This is most conveniently done by separately discussing the cases of even and odd values of a.

1. a=even integer

For a even, say $a=2N$, it is known[2] that there are $N+1$ solutions of the form $F_N(\mathrm{sn}^2 x)$, and N solutions each of the three forms

$$\mathrm{sn}\,x\,\mathrm{cn}\,x\,F_{N-1}(\mathrm{sn}^2 x), \quad \mathrm{sn}\,x\,\mathrm{dn}\,x\,F_{N-1}(\mathrm{sn}^2 x), \quad \mathrm{cn}\,x\,\mathrm{dn}\,x\,F_{N-1}(\mathrm{sn}^2 x).$$

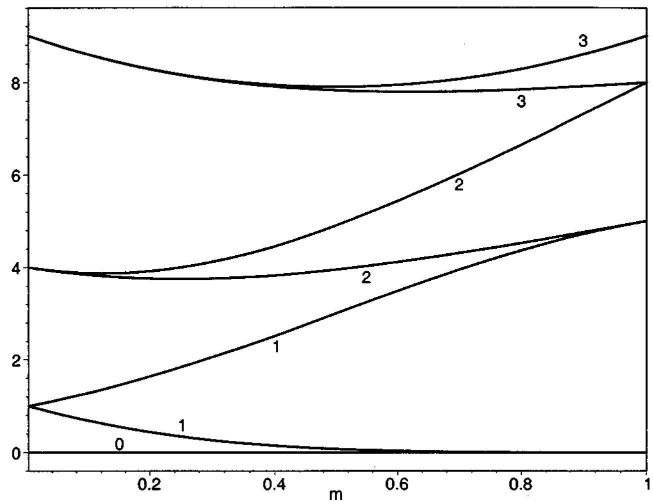

FIG. 3. Band edge energies for the (12,0) Lamé potential corresponding to $a=3$ as a function of the elliptic modulus parameter m. This figure is drawn using the eigenvalues given in Table II. The band edges are labeled by the number of wave function nodes in the interval $2K(m)$.

Here F_r denotes a polynomial of degree r in its argument. The ground state $\psi_0^-(x)$ (which is the lower edge of the lowest band) is of the form $F_N(\mathrm{sn}^2 x)$. It is easily checked using Eq. (13) that the corresponding partner potential $V_+(x)$ has N solutions each of the four forms

$$\frac{\mathrm{dn}\,x\,G_N(\mathrm{sn}^2 x)}{\psi_0^-(x)},\quad \frac{\mathrm{sn}\,x\,G_N(\mathrm{sn}^2 x)}{\psi_0^-(x)},\quad \frac{\mathrm{cn}\,x\,G_N(\mathrm{sn}^2 x)}{\psi_0^-(x)},\quad \frac{\mathrm{sn}\,x\,\mathrm{cn}\,x\,\mathrm{dn}\,x\,G_{N-1}(\mathrm{sn}^2 x)}{\psi_0^-(x)},$$

while the ground state is given by $\psi_0^+(x)=1/\psi_0^-(x)$.

2. a=odd integer

For a odd, say $a=2N+1$, it is known[2] that the Lamé potentials have $N+1$ solutions each of the three forms

$$\mathrm{sn}\,x\,F_N(\mathrm{sn}^2 x),\quad \mathrm{cn}\,x\,F_N(\mathrm{sn}^2 x),\quad \mathrm{dn}\,x\,F_N(\mathrm{sn}^2 x)$$

and N solutions of the form

$$\mathrm{sn}\,x\,\mathrm{cn}\,x\,\mathrm{dn}\,x\,F_{N-1}(\mathrm{sn}^2 x).$$

The ground state $\psi_0^-(x)$ is of the form $\mathrm{dn}\,x\,F_N(\mathrm{sn}^2 x)$. We can then easily deduce that the corresponding partner potentials $V_+(x)$ will have $N+1$ solutions each of the two forms

$$\frac{\mathrm{sn}\,x\,G_{N+1}(\mathrm{sn}^2 x)}{\psi_0^-(x)},\quad \frac{\mathrm{cn}\,x\,G_{N+1}(\mathrm{sn}^2 x)}{\psi_0^-(x)},$$

and N solutions each of the two forms

$$\frac{\mathrm{dn}\,x\,G_{N+1}(\mathrm{sn}^2 x)}{\psi_0^-(x)},\quad \frac{\mathrm{sn}\,x\,\mathrm{cn}\,x\,\mathrm{dn}\,x\,G_N(\mathrm{sn}^2 x)}{\psi_0^-(x)},$$

while as usual, the ground state is given by $\psi_0^+(x)=1/\psi_0^-(x)$.

In summary, for integral a, Lamé potentials with $a \geqslant 2$ are not self-isospectral. They have distinct supersymmetric partner potentials even though both potentials have the same $(2a+1)$ band edge eigenvalues.

IV. ASSOCIATED LAMÉ POTENTIALS (p,q) AND THEIR SUPERSYMMETRIC PARTNERS

In contrast to the Lamé potentials discussed previously, there seems to be no systematic treatment of associated Lamé potentials in the literature. Therefore, we will first devote some time to discussing the properties of associated Lamé potentials, show that they are quasiexactly solvable, and then proceed to construct and study their isospectral supersymmetric partner potentials.

A. Description of associated Lamé potentials

As mentioned before, we will refer to the associated Lamé potentials given by Eq. (5) or equivalently Eq. (6) as the (p,q) potential. The special cases $q=0$, as well as $p=0$, correspond to ordinary Lamé potentials.

In general, for any value of p and q, the associated Lamé potentials have a period $2K(m)$ since

$$\mathrm{sn}(x+2K) = -\mathrm{sn}(x), \quad \mathrm{cn}(x+2K) = -\mathrm{cn}(x), \quad \mathrm{dn}(x+2K) = \mathrm{dn}(x).$$

However, for the special case $p=q$, Eq. (6) shows that the period is $K(m)$. From a physical viewpoint, if one thinks of a Lamé potential $(p,0)$ as due to a one-dimensional regular array of atoms with spacing $2K(m)$, and ''strength'' p, then the associated Lamé potential (p,q) results from two alternating types of atoms spaced by $K(m)$ with ''strengths'' p and q, respectively. If the two types of atoms are identical [which makes $p=q$], one expects a potential of period $K(m)$.

Extrema (defined for this discussion as either local or global maxima and minima) of associated Lamé potentials are easily found by setting $dV(x)/dx=0$. This gives

$$\mathrm{sn}(x)\mathrm{cn}(x)[p\,\mathrm{dn}^4(x) - q(1-m)] = 0.$$

Extrema occur when (i) $\mathrm{sn}(x)=0$, that is $x=0, \pm 2K(m), \pm 4K(m), \ldots$; (ii) $\mathrm{cn}(x)=0$, that is $x=\pm K(m), \pm 3K(m), \ldots$; (iii) $\mathrm{dn}^4(x)=(1-m)q/p$. At the points specified by (i) and (ii), one always has extrema and $V(x)$ has values pm and qm. In addition, since $\mathrm{dn}^4(x)$ has a minimum value $(1-m)^2$ and a maximum value unity,[1] condition (iii) also yields extrema provided

$$(1-m)^2 \leqslant (1-m)q/p \leqslant 1.$$

For given fixed values of q and m, this condition has a solution provided p lies in the critical range

$$q(1-m) \leqslant p \leqslant q/(1-m).$$

Alternatively, for given fixed values of p and q with $p \geqslant q$, condition (iii) has a solution provided m is greater than the critical value $1-q/p$.

The associated Lamé potentials for $q=2$, $m=0.5$, and several values of p are plotted in Fig. 4(a). In the critical range of p values $1 \leqslant p \leqslant 4$, one expects extrema coming from condition (iii), and these are clearly seen in Fig. 4(a). In general the period is $2K(0.5)=3.708$, but for $p=q=2$, the period $K(0.5)$ is evident. Note that as p increases, any given extremum changes character. For example, at $x=0$, as p increases, one goes from a maximum to a local minimum to an absolute minimum. In Fig. 4(b) we have plotted associated Lamé potentials for $p=4$, $q=2$, and several values of m. As expected from the previous discussion, one always sees extrema at the points specified by conditions (i) and (ii), and additional extrema coming from condition (iii) are evident for $m \geqslant 1/2$.

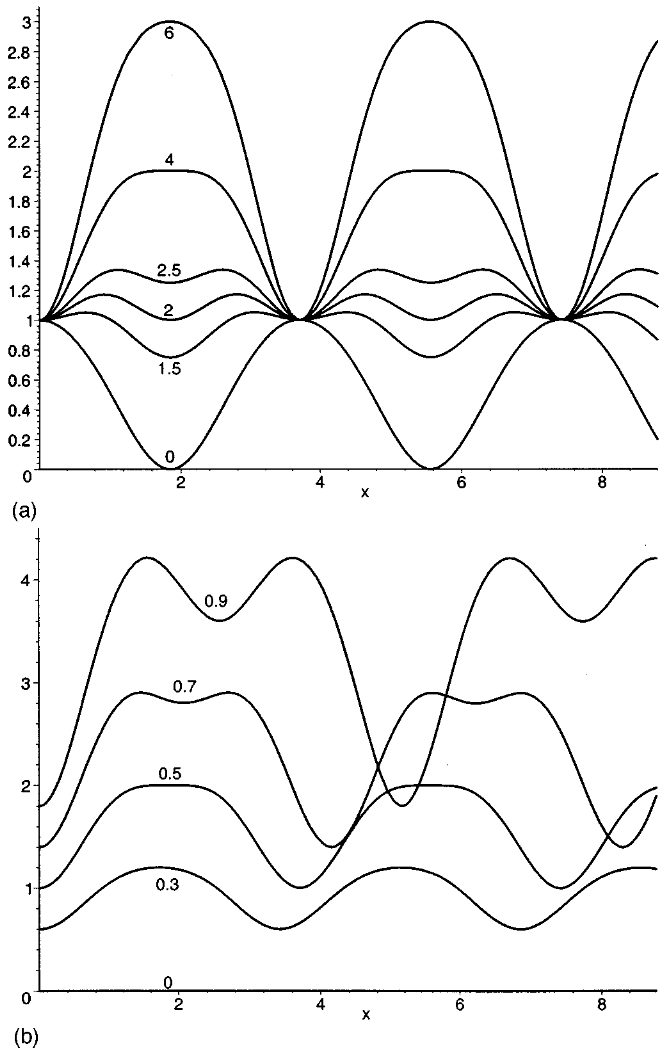

FIG. 4. (a) Plots of the (p,q) associated Lamé potentials for $q=2$, $m=0.5$, and several values of p. The curves are labeled by the value of p. (b) Plots of the (p,q) associated Lamé potentials for $p=4$, $q=2$, and several values of m. The curves are labeled by the value of m.

B. Solutions of the associated Lamé equation: Parabolas of solvability

The associated Lamé equation is just the Schrödinger equation for the potential in Eq. (5),

$$-\frac{d^2\psi}{dx^2}+\left[pm\,\mathrm{sn}^2(x)+qm\,\frac{\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)}-E\right]\psi=0. \tag{22}$$

On substituting

$$\psi(x)=[\mathrm{dn}(x)]^{-b}y(x), \tag{23}$$

it is easily shown that $y(x)$ satisfies the Hermite elliptic equation[3]

$$y''(x)+2bm\,\frac{\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)}\,y'(x)+[\lambda-(a+1-b)(a+b)m\,\mathrm{sn}^2(x)]y(x)=0, \tag{24}$$

where

TABLE III. Eigenvalues and eigenfunctions for various associated Lamé potentials (p,q) with $p=a(a+1)$ and $q=(a-n+1)(a-n)$ for $n=1,2,3,\ldots$. The periods of various eigenfunctions and the number of nodes in the interval $2K(m)$ are tabulated. Here $\delta_4 \equiv \sqrt{1-m+m^2(a-1)^2}$; $\delta_5 \equiv \sqrt{4-7m+2ma+m^2(a-2)^2}$; $\delta_6 \equiv \sqrt{4-m-2ma+m^2(a-1)^2}$; $\delta_7 \equiv \sqrt{9-9m+m^2(a-2)^2}$.

q	E	$\mathrm{dn}^{-a}(x)\psi$	Period	Nodes
$a(a-1)$	ma^2	1	$2K$	0
$(a-1)(a-2)$	$1+m(a-1)^2$	$\dfrac{\mathrm{cn}(x)}{\mathrm{dn}(x)}$	$4K$	1
$(a-1)(a-2)$	$1+ma^2$	$\dfrac{\mathrm{sn}(x)}{\mathrm{dn}(x)}$	$4K$	1
$(a-2)(a-3)$	$2+m(a^2-2a+2)\pm 2\delta_4$	$\dfrac{[m(2a-1)\mathrm{sn}^2(x)-1+m-ma\pm\delta_4]}{\mathrm{dn}^2(x)}$	$2K$	2,0
$(a-2)(a-3)$	$4+m(a-1)^2$	$\dfrac{\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}^2(x)}$	$2K$	2
$(a-3)(a-4)$	$5+m(a^2-4a+5)\pm 2\delta_5$	$\dfrac{\mathrm{cn}(x)[m(2a-1)\mathrm{sn}^2(x)-2+2m-ma\pm\delta_5]}{\mathrm{dn}^3(x)}$	$4K$	3,1
$(a-3)(a-4)$	$5+m(a^2-2a+2)\pm 2\delta_6$	$\dfrac{\mathrm{sn}(x)[m(2a-1)\mathrm{sn}^2(x)-2+m-ma\pm\delta_6]}{\mathrm{dn}^3(x)}$	$4K$	3,1
$(a-4)(a-5)$	$10+m(a^2-4a+5)\pm 2\delta_7$	$\dfrac{\mathrm{sn}(x)\mathrm{cn}(x)[m(2a-1)\mathrm{sn}^2(x)-3+2m-ma\pm\delta_7]}{\mathrm{dn}^4(x)}$	$2K$	4,2

$$p=a(a+1), \quad q=b(b+1), \quad E=\lambda+mb^2. \tag{25}$$

On further substituting $\mathrm{sn}(x)=\sin t$, $y(x)\equiv z(t)$, one obtains Ince's equation,

$$(1-m\sin^2 t)z''(t)+(2b-1)m\sin t\cos t\, z'(t)+[\lambda-(a+1-b)(a+b)m\sin^2 t]z(t)=0, \tag{26}$$

which is a well-known quasiexactly solvable (QES) equation.[3] In particular, on substituting

$$\cos t=u, \quad z(t)\equiv w(u)=\sum_{n=0}^{\infty}\frac{u^n R_n}{n!}, \tag{27}$$

it is easily shown that R_n satisfies a three-term recursion relation. In particular, if $a+b+1=n$ $(n=1,2,3,\ldots)$, then one obtains n QES solutions. Actually n QES solutions are also obtained in case $b-a=-n(n=1,2,3,\ldots)$, but since q is unchanged under $b\to-b-1$, no really new solutions are obtained in this case. The QES solutions for $n=1,2,3,4,5$ are given in Table III. In particular, for any given choice of $p=a(a+1)$, Table III lists the eigenstates of the associated Lamé equation for various values of q.

For $q=a(a-1)$, there is just one eigenstate with energy ma^2 and wave function $\psi=\mathrm{dn}^a(x)$. Since the wave function has period $2K(m)$ and is nodeless, this is clearly the ground state wave function of the $(a(a+1),a(a-1))$ potential for any real choice of the parameter a. The equations $p=a(a+1)$ and $q=a(a-1)$ are the parametric forms of the equation of the parabola $(p-q)^2=2(p+q)$, which is plotted in Fig. 5 and labeled $P1$. For any point on the parabola, one knows the ground state wave function and energy $E_0=ma^2$. The parabola $P1$ includes the points (2,0) and (6,2).

For $q=(a-1)(a-2)$, we see from Table III that two eigenstates with energies $1+m(a-1)^2$ and $1+ma^2$ are known. Since they have period $4K(m)$ and just one node in the interval $L=2K(m)$, they must correspond to the first and second band edge energies E_1 and E_2 of the $(a(a+1),(a-1)(a-2))$ potential. Eliminating a from the equations $p=a(a+1)$ and $q=(a-1)(a-2)$ gives the ''parabola of solvability'' $(p-q)^2=8(p+q)-12$, which is plotted in Fig. 5 and labeled $P2$. This parabola includes the points (2,0) and (6,0), which correspond to Lamé

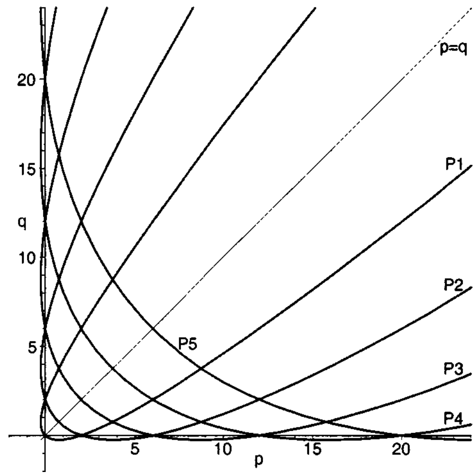

FIG. 5. Parabolas of solvability. All associated Lamé potentials (p,q) which are quasisolvable are illustrated. Each parabola corresponds to a choice of q in Table III. Parabola Pn is for $p=a(a+1)$, $q=(a-n+1)(a-n)$ for $n=1,2,3,...$, and one knows n eigenstates for any point on it from Table III.

potentials. Similarly, the parabolas of solvability Pn $(n=0,1,2,...)$ corresponding to $q=(a-n+1)(a-n)$ in Table III are plotted. n eigenstates are known for any point on the parabola of solvability Pn.

C. Supersymmetric partner potentials

It is easily checked from Table III that the solution corresponding to $q=a(a-1)$ as well as one of the $q=(a-2)(a-3)$ solutions are nodeless and correspond to the ground state. Hence, for these cases, one can obtain the superpotential and hence the partner potential V_+ and enquire if V_- is self-isospectral. For example, consider the case of $p=a(a+1), q=a(a-1)$ in which case W is given by

$$W \equiv -\frac{\psi_0'(x)}{\psi_0(x)} = am\,\frac{\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)}, \tag{28}$$

so that the corresponding partner potentials are

$$\begin{aligned} V_- &= (a-1)am\,\frac{\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)} + ma(a+1)\mathrm{sn}^2(x) - ma^2, \\ V_+ &= a(a+1)m\,\frac{\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)} + m(a-1)a\,\mathrm{sn}^2(x) - ma^2. \end{aligned} \tag{29}$$

It is easily seen that these partner potentials satisfy Eq. (3), are consequently self-isospectral, and SUSY gives nothing new in this case. It is amusing to note that the superpotential W obtained here was in fact discussed in Ref. 5 [see their Eq. (32)].

Let us now consider the SUSY partner potential computed from the ground state for the $p=a(a+1), q=(a-2)(a-3)$ case. It is given by (see Table III)

$$\psi_0(x) = [m(a-1) - 1 - \delta_1 + m(2a-1)\mathrm{sn}^2(x)](\mathrm{dn}(x))^{a-2}, \tag{30}$$

where $\delta_1 = \sqrt{1-m+m^2(a-1)^2}$. The corresponding superpotential W turns out to be

TABLE IV. The five eigenvalues and eigenfunctions for the self-isospectral associated Lamé potential corresponding to $a=2$, $b=1$ which gives $(p,q)=(6,2)$. The potential is $V_-(x)=6m\,\mathrm{sn}^2(x)+2m\,\mathrm{cn}^2(x)/\mathrm{dn}^2(x)-4m$, and has period $2K(m)$. The number of nodes in the interval $2K(m)$ is tabulated.

E	$\psi^{(-)}$	Period	Nodes
0	$\mathrm{dn}^2(x)$	$2K$	0
$5-3m-2\sqrt{4-3m}$	$\frac{\mathrm{cn}(x)}{\mathrm{dn}(x)}[3m\,\mathrm{sn}^2(x)-2-\sqrt{4-3m}]$	$4K$	1
$5-2m-2\sqrt{4-5m+m^2}$	$\frac{\mathrm{sn}(x)}{\mathrm{dn}(x)}[3m\,\mathrm{sn}^2(x)-2-m-\sqrt{4-5m+m^2}]$	$4K$	1
$5-2m+2\sqrt{4-5m+m^2}$	$\frac{\mathrm{sn}(x)}{\mathrm{dn}(x)}[3m\,\mathrm{sn}^2(x)-2-m+\sqrt{4-5m+m^2}]$	$4K$	3
$5-3m+2\sqrt{4-3m}$	$\frac{\mathrm{cn}(x)}{\mathrm{dn}(x)}[3m\,\mathrm{sn}^2(x)-2+\sqrt{4-3m}]$	$4K$	3

$$W=\frac{m(a-2)\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)}-\frac{2m(2a-1)\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}(x)}{[m(1-a)-1-\delta_1+m(2a-1)\mathrm{sn}^2(x)]}. \tag{31}$$

Hence the corresponding partner potentials are

$$V_-(x)=ma(a+1)\mathrm{sn}^2(x)+m(a-3)(a-2)\frac{\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)}-2-m(a^2-2a+2)+2\delta_1, \tag{32}$$

$$V_+(x)=-V_-(x)+2W^2(x). \tag{33}$$

It is easily checked that these potentials are not self-isospectral since they do not satisfy the condition (3). Thus one has discovered a whole class of new elliptic periodic potentials $V_+(x)$ as given by Eq. (33) for which three states are analytically known no matter what a is. In particular, the energy eigenfunctions for V_+ of these three states are easily obtained by using the corresponding energy eigenstates of V_- as given in Table III and using Eqs. (12) and (13).

V. ASSOCIATED LAMÉ POTENTIALS WITH SPECIAL VALUES OF *p* AND *q*

We shall now discuss associated Lamé potentials $(a(a+1),b(b+1))$, where a and b are either both positive integers or half-integers. These values are of special interest since they correspond to intersections of two parabolas of solvability. Consequently, one has greater knowledge about the eigenstates, especially if states of period $2K$ are known for one parabola and states of period $4K$ are known for the other. In most cases, we show that although several band edge energies are exactly known from Table III, one usually does not know all the band edge energies, that is one has a quasiexactly solvable problem. However, in the special case of $p=q$ $(a=b=\text{integer})$, we show that all the band edge eigenstates can be obtained and one has an exactly solvable periodic problem.

A. $a,b=$ integer, $a\neq b$

First, let us note that the Lamé potentials $(a(a+1),0)$ are in this category when $a=$ integer and $b=0$. For example, when $a=3$, one has the (12,0) potential. We see from Fig. 5 that two parabolas of solvability pass through the point (12,0). From Table III it follows that three band edges of period $2K(m)$ are obtained from $q=(a-2)(a-3)$ and four band edges of period $4K(m)$ are obtained from $q=(a-3)(a-4)$. Altogether, arranging in order of increasing nodes, one has seven band edges with periods $2K$, $4K$, $4K$, $2K$, $2K$, $4K$, $4K$ with 0, 1, 1, 2, 2, 3, 3 nodes, respectively. There are no missing states, and as discussed in Sec. III A, this gives three bound bands and a continuum band.

TABLE V. The three eigenvalues and eigenfunctions for the associated Lamé potential corresponding to $a=b=1$ which gives $(p,q)=(2,2)$. The potential has period $K(m)$ and the number of nodes in the interval $K(m)$ is tabulated.

E	$\text{dn}(x)\psi^{(-)}$	Period	Nodes
0	$\text{dn}^2(x)+\sqrt{1-m}$	K	0
$4\sqrt{1-m}$	$\text{dn}^2(x)-\sqrt{1-m}$	$2K$	1
$2-m+2\sqrt{1-m}$	$\text{sn}(x)\text{cn}(x)$	$2K$	1

As a second example with $q\neq 0$, consider the (6,2) associated Lamé potential, that is $p=6$, $q=2$. In this case, taking $a=2$, one can get five band edges from Table III—one solution of period $2K$ is obtained from $q=a(a-1)$, while the remaining four solutions of period $4K$ are obtained from $q=(a-3)(a-4)$. The eigenvalues and eigenfunctions are given in Table IV along with the number of nodes in one period $2K$. It is clear that there are two solutions of period $2K$ with two nodes in the interval $2K$ which have to be present but have not been obtained. This is also clear from the $m=0$ limit, since the energies from Table V are 0,1,1,9,9 and the states at 4,4 are missing. Thus, this is a QES problem. Figure 6 illustrates the (6,2) associated Lamé potential and its supersymmetric partner for three choices of m. The self-isospectral nature of the (6,2) potential is evident from Fig. 6—it also follows from Eq. (29) with $a=2$. The band edge energies for the (6,2) associated Lamé potential as a function of the elliptic modulus parameter m are shown in Fig. 7. The two unobtained band edges of period $2K$ will have energies $E=4$ at $m=0$.

Let us now discuss the general associated Lamé potential $(a(a+1),b(b+1))$, with $a>b$. Using Table III, we obtain $(a-b)$ states of period $2K(4K)$ for $q=[a-(a-b)][a-(a-b-1)]$ for $(a-b)$ odd (even), and $(a+b+1)$ states of period $4K(2K)$ for $q=[a-(a+b+1)]\times[a-(a+b)]$ for $(a-b)$ odd (even). It can be established that some states are missing by looking at the node structure as well as the $m=0$ limit. Hence, we again have a QES problem.

B. $a=b=$ integer

Let us now discuss the special case of $p=q=a(a+1)$, $a=1,2,\ldots$. In this case the associated Lamé potential (5) has period K, rather than $2K$. It then follows from the oscillation theorem that with increasing energy, the band edges must have periods $K,2K,2K,K,K,\ldots$ and in the $m=0$ limit the eigenvalues must go to $E=0,4,16,36,\ldots$, with all nonzero eigenvalues being doubly degenerate. It is easy to check from Table V that one case for which we already have exact results is when $p=q=2$. In particular, consider the special case $a=1$, for which $V_-(x)$ of Eq. (32) takes the form

$$V_-(x)=2m\,\text{sn}^2(x)+2m\frac{\text{cn}^2(x)}{\text{dn}^2(x)}-2-m+2\sqrt{1-m}. \tag{34}$$

Using Table V, we can calculate three energy eigenvalues and eigenfunctions of V_- taking $a=1$ in $q=(a-2)(a-3)$. These are given in Table V. Whereas the ground state is of period K, the next two states in Table V indeed have period $2K$. Using $a=1$ in Eqs. (30)–(33), we find that the corresponding SUSY partner potential is

$$V_+(x)=2-m-2\sqrt{1-m}-\frac{8\sqrt{1-m}m^2\,\text{sn}^2(x)\text{cn}^2(x)}{[\text{dn}^2(x)+\sqrt{1-m}]^2}. \tag{35}$$

Are the potentials $V_\pm(x)$ self-isospectral? Using the relations

$$\text{sn}(x+K(m)/2)=(1+\sqrt{1-m})^{1/2}\left[\frac{\sqrt{1-m}\,\text{sn}(x)+\text{cn}(x)\text{dn}(x)}{\text{dn}^2(x)+\sqrt{1-m}}\right], \tag{36}$$

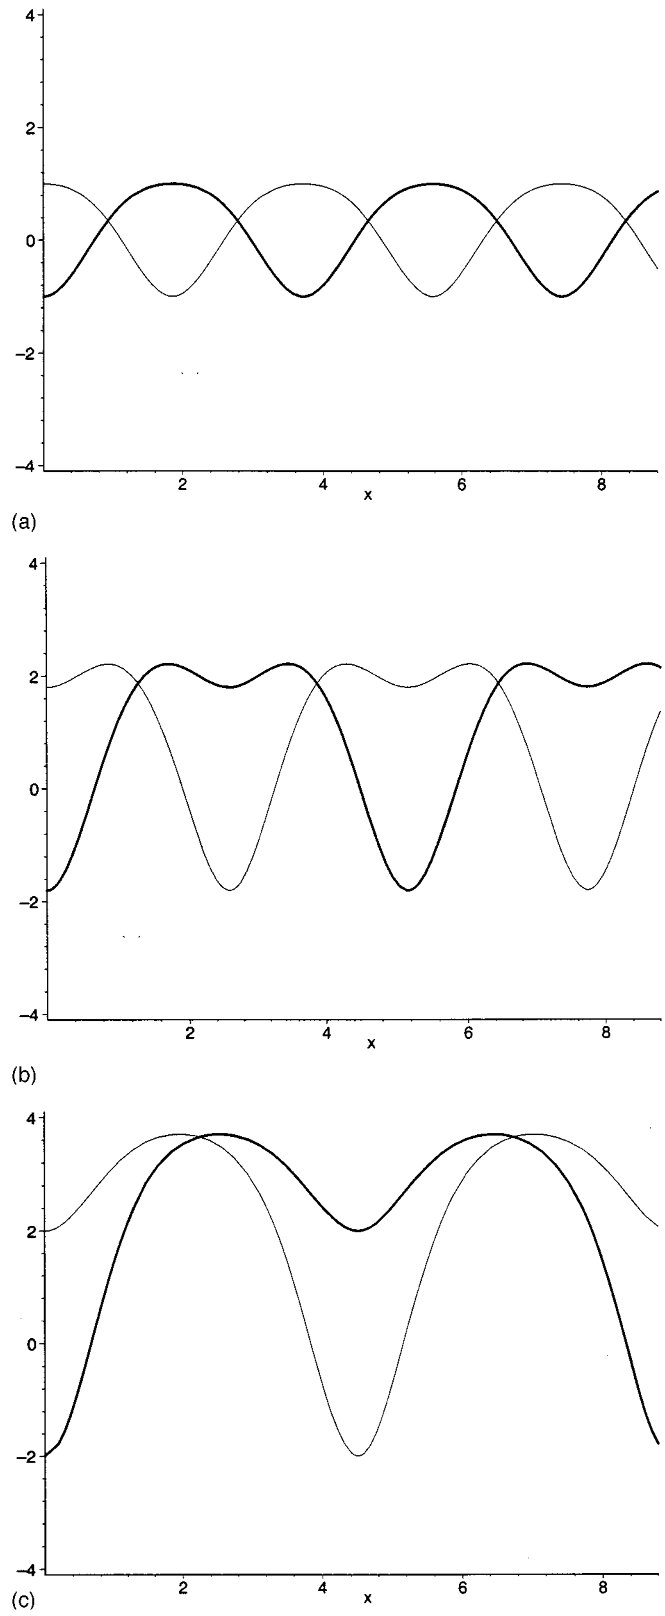

FIG. 6. The (6, 2) associated Lamé potential $V_-(x)$ (the thick line) and its supersymmetric partner potential $V_+(x)$ (the thin line) for three choices of m: (a) 0.5, (b) 0.9, (c) 0.998.

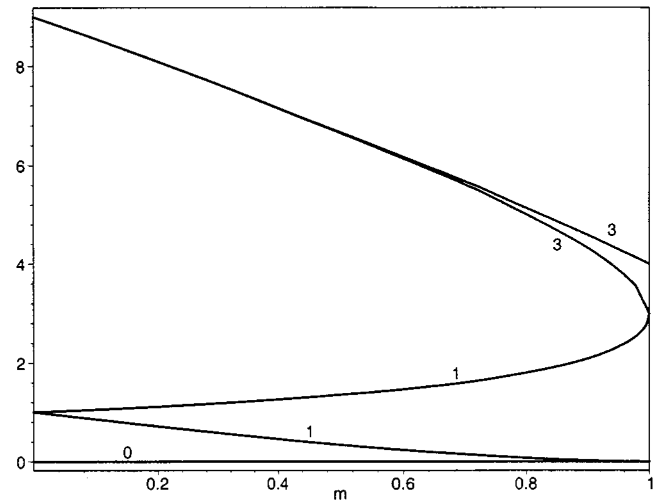

FIG. 7. Band edge energies for the associated Lamé potential (6, 2) as a function of the elliptic modulus parameter m. This figure corresponds to Table IV. The band edges are labeled by the number of wave function nodes in the interval $2K(m)$.

$$\mathrm{cn}(x+K(m)/2)=(1+\sqrt{1-m})^{1/2}(1-m)^{1/4}\left[\frac{(1+\sqrt{1-m})^{1/2}\,\mathrm{cn}(x)-\mathrm{sn}(x)\mathrm{dn}(x)}{\mathrm{dn}^2(x)+\sqrt{1-m}}\right], \quad (37)$$

$$\mathrm{dn}(x+K(m)/2)=(1-m)^{1/4}\left[\frac{(1+\sqrt{1-m})\mathrm{dn}(x)-m\,\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}^2(x)+\sqrt{1-m}}\right], \quad (38)$$

a little algebra reveals that indeed $V_\pm$ are self-isospectral and satisfy Eq. (3).

Are the higher members of the $p=q$ family (i.e., $p=q=6,12,20,...$) also self-isospectral? If our experience with the Lamé case is any guide then we would doubt it. Indeed, we will now show that the (6,6) associated Lamé potential is not self-isospectral. We get five band edges analytically from Table III. In particular, take $a=2$ and consider the case of $q=(a-4)(a-5)$, for which we know two eigenstates as given in Table III. In fact, in this case three more eigenstates can be analytically obtained but the corresponding eigenvalues and eigenfunctions have not been given in Table III since the energy eigenvalues are solutions of a cubic equation whose exact solution for arbitrary a cannot be written in a compact form. However, for $a=2$, we are able to solve the cubic equation and obtain the three eigenvalues in a closed simple form. In particular consider an ansatz of the form

$$y=A+B\,\mathrm{sn}^2 x+D\,\mathrm{sn}^4 x. \quad (39)$$

On substituting this ansatz in Eq. (24) it is easy to show that the energy eigenvalue $\lambda(=E-m(a-4)^2)$ must obey the cubic equation

TABLE VI. The five eigenvalues and eigenfunctions for the associated Lamé potential corresponding to $a=b=2$ which gives $(p,q)=(6,6)$. Here $\delta_8\equiv\sqrt{16-16m+m^2}$. The number of nodes in one period $K(m)$ of the potential is tabulated.

E	$\mathrm{dn}^2(x)\psi^{(-)}$	Period	Nodes
0	$1-(4-m-\delta_8)\mathrm{sn}^2(x)+(4-2m-\delta_8)\mathrm{sn}^4(x)$	K	0
$-4+2m+2\delta_8$	$1-2\,\mathrm{sn}^2(x)+m\,\mathrm{sn}^4(x)$	$2K$	1
$2-m-6\sqrt{1-m}+2\delta_8$	$\mathrm{sn}(x)\mathrm{cn}(x)[1-(1-\sqrt{1-m})\mathrm{sn}^2(x)]$	$2K$	1
$2-m+6\sqrt{1-m}+2\delta_8$	$\mathrm{sn}(x)\mathrm{cn}(x)[1-(1+\sqrt{1-m})\mathrm{sn}^2(x)]$	K	2
$4\delta_8$	$1-(4-m+\delta_8)\mathrm{sn}^2(x)+(4-2m+\delta_8)\mathrm{sn}^4(x)$	K	2

$$\lambda^3+[28m-20-12am]\lambda^2+[64-304m+160ma+32m^2(a-2)(a-3)]\lambda$$
$$-64m(2a-3)(2-2m+ma)=0. \tag{40}$$

The solution of Eq. (40) is in general quite lengthy but in the special case of $a=2$ this cubic equation is easily solved yielding three eigenvalues in a compact form. On combining them with the two levels given in Table III, we obtain the eigenvalues and eigenfunctions of all the five band edges for the case $p=q=6$. These are given in Table VI. We have also verified that these five eigenstates in ascending order of energy indeed have periods K, $2K$, $2K$, K, K, respectively, and that the energy eigenvalues have expected limits at $m=0$. In particular the associated Lamé potential $V_-(x)$ is

$$V_-(x)=6m\,\mathrm{sn}^2(x)+6m\,\frac{\mathrm{cn}^2(x)}{\mathrm{dn}^2(x)}-8-2m+2\delta_8, \tag{41}$$

whose ground state energy is zero while the corresponding eigenfunction ψ_0^- is

$$\psi_0^-(x)=\frac{[1-(4-m-\delta_8)\mathrm{sn}^2(x)+(4-2m-\delta_8)\mathrm{sn}^4(x)]}{\mathrm{dn}^2(x)},\qquad \delta_8=\sqrt{16-16m+m^2}. \tag{42}$$

Hence the corresponding superpotential is

$$W(x)=\frac{-2m\,\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)}+\frac{2\,\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)\psi_0^-(x)}[(4-m-\delta_8)-2(4-2m-\delta_8)\mathrm{sn}^2(x)], \tag{43}$$

and the partner potential $V_+(x)$ which is isospectral to $V_-(x)$ is

$$V_+(x)=-V_-(x)+2W^2(x). \tag{44}$$

It is not difficult to see that the W as given by Eq. (43) does not satisfy the self-isospectral condition (4) and hence unlike the $p=q=2$ case, the $p=q=6$ potential is *not* self-isospectral. In Fig. 8, we have plotted the potentials $V_\pm(x)$ corresponding to $p=q=6$ for several different values of the parameter m. The figures confirm that the potentials are far from being self-isospectral. Thus we have obtained a new exactly solvable periodic potential (44) which has two bound bands and a continuum band, with five band edges and the corresponding eigenfunctions being exactly known using Table VI and Eqs. (12) and (13). In Fig. 9, we plot the band edge energies for the (6,6) potential as a function of the elliptic modulus parameter m.

It is also clear from here that even the higher associated Lamé potentials with $p=q=12$, 20,..., which have 7, 9,...band edges are also exactly solvable in principle and none of them will be self-isospectral, so that in each case one obtains a new exactly solvable periodic potential. In particular, for $p=q=n(n+1)$ there will be $(2n+1)$ band edges in both $V_\pm(x)$ whose energy eigenvalues can be obtained from Table III when q has the form $[n-2n][n-(2n+1)]$. Out of the $(2n+1)$ band edges in $V_-(x),(n+1)$ solutions (including the ground state) have the form $F_n(\mathrm{sn}^2 x)/[\mathrm{dn}^n x]$ while n solutions have the form $F_{n-1}(\mathrm{sn}^2 x)\mathrm{sn}\,x\,\mathrm{cn}\,x/[\mathrm{dn}^n x]$. On the other hand, as far as the $(2n+1)$ solutions of the partner potential V_+ are concerned, there are n states each of the two forms

$$\frac{\mathrm{sn}\,x\,\mathrm{cn}\,x\,G_n(\mathrm{sn}^2 x)}{\mathrm{dn}^{2n-1}x\,\psi_0^-(x)},\ \frac{G_{n+1}(\mathrm{sn}^2 x)}{\mathrm{dn}^{2n-1}x\,\psi_0^-(x)},$$

while the ground state (i.e., the lower edge of the lowest band) is given by $\psi_0^+(x)=1/\psi_0^-(x)$.

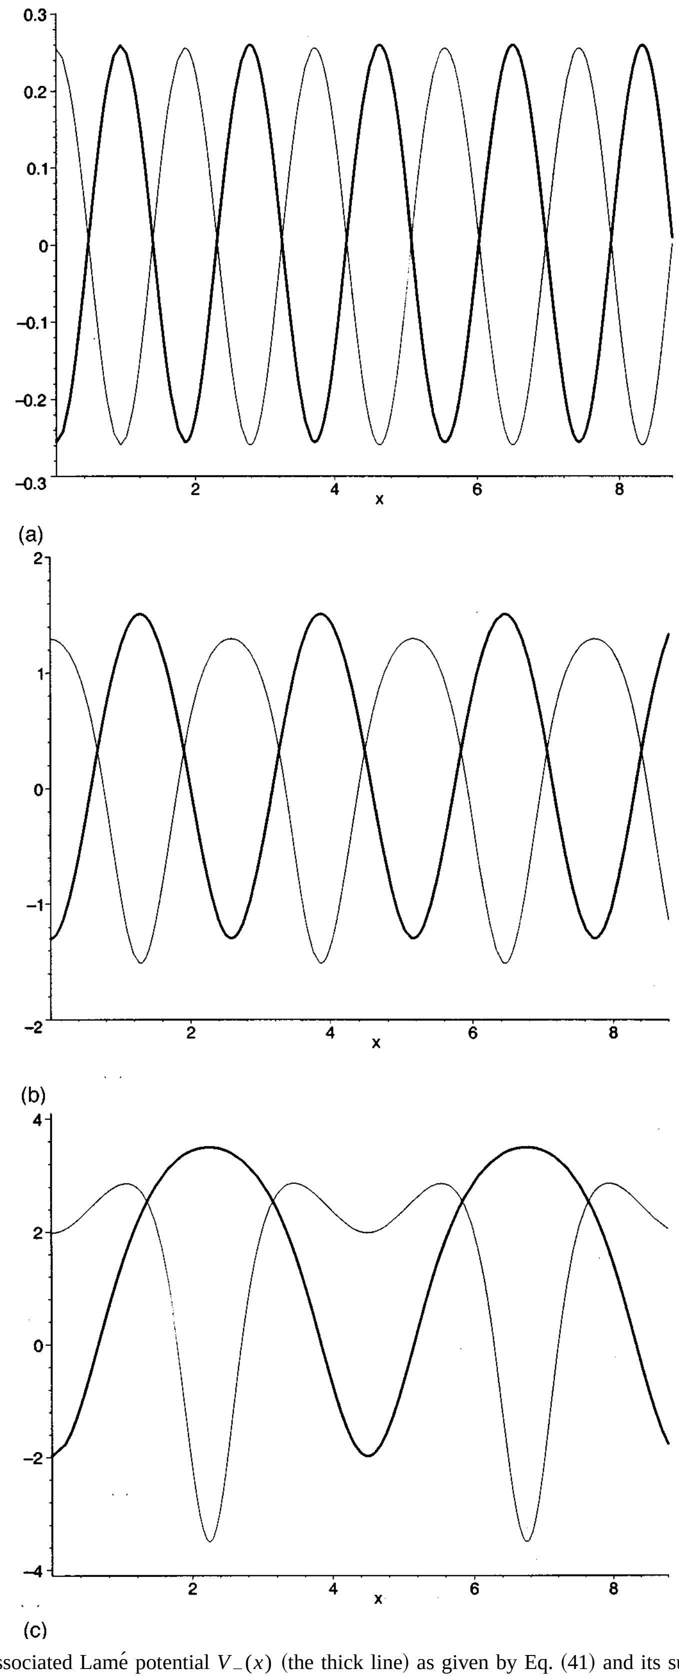

FIG. 8. The (6, 6) associated Lamé potential $V_{-}(x)$ (the thick line) as given by Eq. (41) and its supersymmetric partner potential $V_{+}(x)$ (the thin line) as given by Eq. (44) for three choices of m: (a) 0.5, (b) 0.9, (c) 0.998.

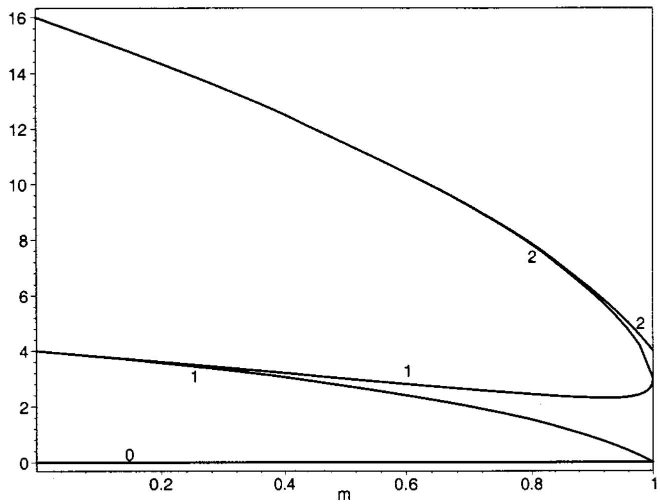

FIG. 9. Band edge energies for the associated Lamé potential (6, 6) as a function of the elliptic modulus parameter m. This figure corresponds to Table VI. The band edges are labeled by the number of wave function nodes in the interval $K(m)$.

C. a,b = half-integer

Let us now specialize to the case when both a, b are half-integral with $a>b$. As an illustration, let us first consider the case of $a=3/2$, $b=1/2$ so that $p=15/4$, $q=3/4$. In this case, the oscillation theorem requires band edges with periods $2K,4K,4K,2K,2K,\ldots$. Using Table III and Fig. 5, we see one gets three eigenstates when $q=(a-2)(a-3)$ with $a=3/2$, all with period $2K$. The ground state is at $E_0=9m/4$ while there are two degenerate levels at $E_3=E_4=4+m/4$. To understand this degeneracy better, let us go along the parabola of solvability P2 given by $q=(a-2)(a-3)$. The band gap is given by $\Delta_2\equiv|-2+m+2\sqrt{1-m+m^2(a-1)^2}|$ and is plotted in Fig. 10. It vanishes at $a=3/2$ (15/4, 3/4) potential, and has the correct values $\Delta_2=2\sqrt{1-m+m^2}-2+m$ for $a=2$ and $\Delta_2=2\sqrt{1-m+4m^2}-2+m$ for $a=3$, which correspond to the (6,0) and (12,0) Lamé potentials. The vanishing of Δ_2 at $a=3/2$ occurs because the eigenfunctions corresponding to E_3 and E_4 cross over as one goes along the parabola P2.

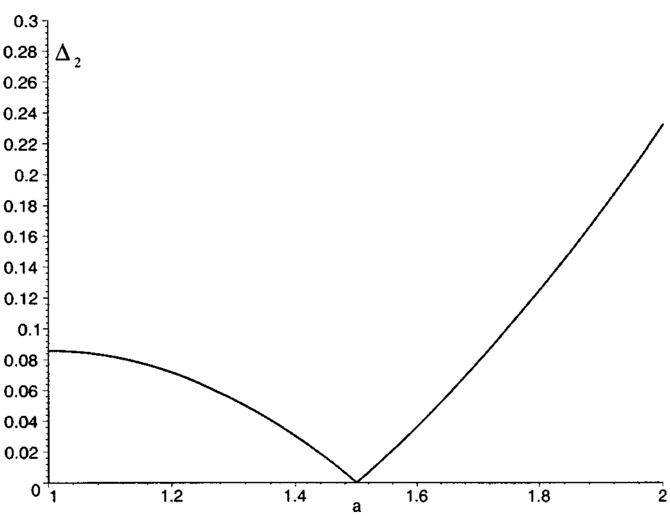

FIG. 10. Energy gap $\Delta_2\equiv|E_4-E_3|$ as one moves along the parabola of solvability $P2$ corresponding to $q=(a-2)\times(a-3)$ and $p=a(a+1)$.

TABLE VII. Energy eigenvalues and eigenfunctions for the associated Lamé potential corresponding to $a=7/2$, $b=1/2$ which gives $(p,q)=(63/4,3/4)$. Here $\delta_9 \equiv \sqrt{4-4m+25m^2}$; $V_-(x)=\frac{63}{4}m\,\mathrm{sn}^2(x)+\frac{3}{4}m\,\mathrm{cn}^2(x)/\mathrm{dn}^2(x)-2-29m/4+\delta_9$. The last column gives the number of eigenfunction nodes in one period $2K(m)$ of the potential.

E	$\mathrm{dn}^{1/2}(x)\psi^{(-)}$	Period	Nodes
0	$[12m\,\mathrm{sn}^2(x)-2-5m-\delta_9]\mathrm{dn}^2(x)$	$2K$	0
$2-m+\delta_9$	$\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}^2(x)$	$2K$	2
$2\delta_9$	$[12m\,\mathrm{sn}^2(x)-2-5m+\delta_9]\mathrm{dn}^2(x)$	$2K$	2
$14-7m+\delta_9$	$\mathrm{sn}(x)\mathrm{cn}(x)[1-2\,\mathrm{sn}^2(x)]$	$2K$	4
$14-7m+\delta_9$	$[1-8\,\mathrm{sn}^2(x)\mathrm{cn}^2(x)]$	$2K$	4

These arguments are easily generalized in case $p=(n+1/2)(n+3/2)$, $q=(k+1/2)(k+3/2)$ with $n>k$. The energy eigenvalues of $(n-k)$ states can be obtained by using Table III in case q is of the form $q=[n+1/2-(n-k)][n+1/2-(n-k-1)]$ and the corresponding eigenstates have period $2K(4K)$ depending on whether $(n-k)$ is odd (even). On the other hand, the energy of $(n+k+2)$ states is obtained when q is of the form $q=[n+1/2-(n+k+2)][n+1/2-(n+k+1)]$ and these states have the same period $2K(4K)$ as the $n-k$ states when $n-k$ is odd (even). It turns out that the $n-k$ solutions are in fact common in both and so we only obtain the energy of the $n+k+2$ band edges and all of them have the same period $2K(4K)$ depending on whether $n-k$ is odd (even), so that it is only a QES problem and not an exactly solvable problem since one is unable to obtain a single eigenstate with period $4K(2K)$ in case $n-k$ is odd (even).

We would like to point out some of the pecularities of the spectrum in these cases. For example, in case $(p,q)=(35/4,3/4),(63/4,3/4),(99/4,3/4)\ldots$ then one finds that several QES energy levels of period $4K,2K,4K,\ldots$, respectively, are analytically known of which the two at the highest energy are doubly degenerate. As an illustration, in Table VII we have given several QES energy eigenstates all of period $2K$ for the (63/4, 3/4) potential. The interesting point about this case is that the partner potentials $V_\pm(x)$ are not self-isospectral and hence one has discovered a new QES potential where several band edges of period $2K$ and the corresponding eigenfunctions are explicitly known. Of these, the band edges with four nodes are doubly degenerate, again due to crossover of energy levels. Using the ground state wave function, the superpotential is computed to be

$$W=\frac{3m}{2}\frac{\mathrm{sn}(x)\mathrm{cn}(x)}{\mathrm{dn}(x)}-\frac{24m\,\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}(x)}{[12m\,\mathrm{sn}^2(x)-2-5m-\sqrt{4-4m+25m^2}]}. \tag{45}$$

Using Eqs. (12) and (13) the eigenstates of the SUSY partner potential V_+ are then determined.

VI. COMMENTS AND CONCLUSIONS

In this paper, we have discussed solutions of the type given in Table III, which correspond to the parabolas of solvability shown in Fig. 5. Lamé potentials $(p,0)$ with $p=a(a+1)$ and integer a, always have two parabolas of solvability passing through—one parabola gives all states of period $2K$ and the other gives all states of period $4K$. This provides a deeper understanding of why such Lamé potentials are fully solvable.[12] Similarly, we have obtained eigenstates for a large class of associated Lamé potentials (p,q). Further, using the formalism of supersymmetric quantum mechanics, we have been able to discover many new exactly solvable and quasiexactly solvable periodic potentials involving Jacobi elliptic functions. This is a very substantial improvement over the currently known small number of exactly solvable periodic problems.

Random Schrödinger operators arising from lattice gauge fields. I. Existence and examples

Oliver Knill[a)]
Department of Mathematics, University of Texas, Austin, Texas 78712

(Received 3 August 1998; accepted for publication 19 July 1999)

We consider new models of ergodic Schrödinger operators whose existence relies on a cohomological theorem of Feldman and Moore in ergodic theory. These operators generalize the Harper operator which describes the case of a constant magnetic field. An example is the case when the magnetic field is given by independent random variables attached to the lattice plaquettes. A generalization of the Feldman–Moore theorem by Lind to non-Abelian groups also allows us to consider Schrödinger operators obtained from non-Abelian lattice gauge fields. The existence result extends to more general graphs like to operators on tilings and to higher dimensions. We compute some moment expansions for the density of states. For example, for independent, identically and uniformly distributed magnetic fields, a model which has been studied at least since 1970, and whose existence can also be seen without involving the above-mentioned existence theorem, we show that the *n*th moment is the number of closed paths in the two-dimensional lattice starting at the origin for which the winding number vanishes at each plaquette point. This goes beyond the Brinkman–Rice self-retracing path approximation. Other examples are a higher dimensional example, a one-dimensional Anderson model which can be treated in this framework, as well as the Hofstadter model with constant magnetic field, where one averages over all possible magnetic fields. We also reprove a result of Jitomirskaya–Mandelshtam stating that the deterministic Aharonov–Bohm model is a compact perturbation of the free Laplacian. © *1999 American Institute of Physics.* [S0022-2488(99)03911-0]

I. INTRODUCTION

In this article, we consider a class of ergodic discrete Schrödinger operators which we call discrete random electromagnetic Laplacians. An example in two dimensions is the bounded ergodic self-adjoint operator $L=A+A^*$ on $l^2(\mathbf{Z}^2,\mathbf{C}^N)$, where

$$(Au)_n=A_1(n)u_{n+e_1}+A_2(n)u_{n+e_2}$$

and where the unitary matrices $A_i(n)\in \mathrm{U}(N)$ have the property that the magnetic fields

$$B(n)=A_2(n)^*A_1(n+e_2)^*A_2(n+e_1)A_1(n)$$

on different plaquettes are identically distributed $\mathrm{U}(N)$-valued random variables with law μ (Fig. 1).

The question arises: Given a magnetic field B determined by an arbitrary stochastic process, can we find A such that $B=dA$? If the $B(n)$ are invariant under translation in one direction, the answer is no in general: For a measurable circle-valued map B, there is in general no measurable circle-valued map A such that $B=dA=A(T)A^{-1}$. In a probabilistic or ergodic theoretical setup, nontrivial cohomological constraints appear. Feldman and Moore noticed, however, in Ref. 1 that in dimensions $d=2$, these constraints are absent. This stays true even if the Abelian group $\mathrm{U}(1)$ is

[a)]Electronic mail: knill@math.utexas.edu

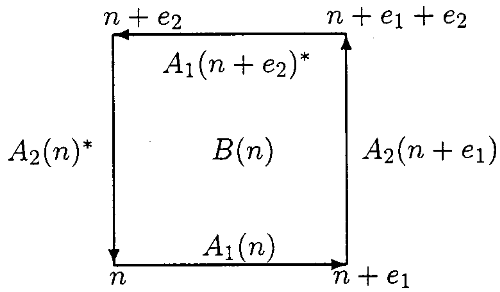

FIG. 1. The magnetic field $B=dA$ at a plaquette n is obtained by integrating up A along the boundary $B(n) = A_2(n)^* A_1(n+e_2)^* A_2(n+e_1) A_1(n)$.

replaced by a non-Abelian group like $U(N)$.[2] For Abelian groups, we generalized this theorem in Ref. 3 to higher dimensions. The existence theorem furthermore extends to discrete ergodic Laplacians on more general graphs like graphs defined by aperiodic tilings.

While in special cases the independent magnetic fields can be obtained directly by choosing the random variables $A_i(n)$ to be independent, this is not true in general. Already in the case of independent identically distributed magnetic fields, there are counterexamples: independent identically distributed random variables $A_i(n)$ lead in general to correlations between the magnetic field variables $B(n)$: If, for example, $A_i(n)$ take randomly the two values 1 and $e^{i\pi/4}$, then two adjacent plaquettes P_n, P_m cannot have magnetic fields $B(n)=1$ and $B(m)=-1$. In other words, vector potentials A, which give independent identically distributed magnetic fields B, are not independent in general.

There are several motivations to study such operators.

(1) Discrete magnetic Laplacians in two dimensions are tight binding approximations for the quantum mechanical model of an electron in the plane exposed to an ergodic magnetic field. This generalizes the Harper operator for which the magnetic field is constant in the plane. Independent identically distributed magnetic fields are models for which the spectral type[4–6] is still unclear. One of the questions is whether such models have eigenvalues.[7] Another problem is to describe the density of states for which approximations have been known since Ref. 8 and for which numerical investigations[9–12] have been done.

(2) Each random operator is an element of a C^* algebra $(\mathcal{X},\mathrm{tr})$ which is determined entirely by the field F. This generalizes the case when $B=F_{12}=e^{2\pi i\alpha}$ is constant and where $\mathcal{X}$ is the rotation algebra.[13,14] The relatively abstract Feldman–Moore theorem in ergodic theory allows us to so define subalgebras in the crossed products of $L^\infty(X)$ with a $\mathbf{Z}^2$ action which is generated by two unitaries U,V which have a prescribed commutator $UVU^{-1}V^{-1}$ in $L^\infty(X)$.

(3) In the partition function of one matrix models appears a van der Monde determinant (see, e.g., Ref. 15). Using the potential theoretical energy $I(L)=-\int\int \log|E-E'|dk(E)dk(E')$ of the density of states dk of an ergodic Schrödinger operator L one can define an infinite-dimensional van der Monde determinant $e^{-I(L)}$. This leads to the variational problem $L \mapsto e^{-I(L)}$ which is the topic of Ref. 16.

We now give an overview over the results of this paper. We first define electromagnetic Laplacians and observe that the Feldman–Moore–Lind results imply that ergodic magnetic Laplacians exist. The formalism can be considered as an ergodic version of differential forms. To a field $F=dA$ is attached a current $j=d^*F$ which is divergence-free $d^*j=0$. In two dimensions, not every current is given by a field. The equivalence classes of currents j, modulo currents of the form d^*F is the cohomology group $\mathcal{H}^1(U)$, a group with the cardinality of the continuum.[3] However, in dimensions $d>2$, it is again a consequence of the triviality of higher dimensional cohomology groups that every one-form j is of the form $j=d^*F$.

In Sec. II, we compute moments of the density of states for independent identically distributed magnetic Laplacians in two dimensions. If the law of the magnetic field B is the Haar measure μ_{Haar} on $U(1)$, then the density of states is determined by a random walk in $\mathbf{Z}^2$ having the following global geometrical constraints: the nth moment of the density of states, $\mathrm{tr}(L^n)$ is the number of closed paths in $\mathbf{Z}^2$ which have length n and give zero winding number to every plaquette. The combinatorial problem to compute the moments of the density of states was considered first in Ref. 8, where the approximation was used that the paths should have no loops. This is now called the ''Brinkman–Rice approximation.'' The exact expression which we give in this paper for the number of paths is new and was not mentioned in Ref. 8 or in subsequent works on the problem that we are aware of. We show also that random magnetic fields with law μ_{Haar} can be generated by taking μ_{Haar}-distributed vector potentials, so that in this special case, Feldman–Moore's existence theorem is not needed. We notice then that all the spectral properties of the operators in the Abelian as well as non-Abelian case depend only on the field $F=dA$ and not on the specific realization of the vector potential A. The explicit calculation of the moments of the density of states for independent identically distributed fields leads to an Aubry duality for the deformed operators $L_\lambda = A_1 + A_1^* + \lambda(A_2 + A_2^*)$: the density of states of L_λ is related to the density of states of $L_{1/\lambda}$ in the same way as for the Harper case.[17]

Some other examples follow in Sec. III. We review a result of Jitomirskaya and Mandelshtam[18] stating that a change of the field on a finite set of cells is a compact perturbation of the operator. A special case is the magnetic Aharonov–Bohm operator with magnetic flux $B \in \mathrm{U}(1)$ different from 1 only in one cell. This result stays true for aperiodic lattices like the Penrose lattice. It seems to be unknown, whether the Aharonov–Bohm perturbation from the free operator is trace class. Also the existence result generalizes to other periodic graphs or aperiodic tilings. We notice for example that to any measure μ on U(1), there exists a measurable vector potential on a Penrose lattice such that the magnetic fields in the plaquettes are independent, identically distributed U(1)-valued random variables with law μ. Because a Penrose graph is not a Cayley graph of a group, the more abstract setup of countable ergodic equivalence relations developed in Ref. 1 is needed.

II. NOTATION AND EXISTENCE

We consider first the two-dimensional case. Let $(X,\mathcal{F},m)$ be a probability space. Two commuting measure-preserving invertible transformations T_1, T_2 on X define a dynamical system with time $\mathbf{Z}^2$. Let U be a Polish (=complete separable metrisable) group. Examples are subgroups of Lie groups like the unitary groups U(N) or the special linear group SL(N,**C**). A two-form $B\tau_{12}$ is defined by a measurable map $B \in \mathcal{U} = \mathcal{L}(X,U) = \{B | X \to U, \text{measurable}\}$. Two measurable U-valued maps $A_1, A_2 \in \mathcal{U}$ define a one-form or vector potential $A = A_1\tau_1 + A_2\tau_2$. Define the curvature of A as the two-form $dA\tau_{12}$ with

$$dA(x) = A_2^{-1}(x) A_1^{-1}(T_2 x) A_2(T_1 x) A_1(x).$$

Not every two-form B can be written as $B = dA$ with a one-form A. For example, if T_1 is the identity map and $T_2 = T$ is ergodic, then not every measurable map $B \in \mathcal{U} = \mathcal{L}(X,U)$ can be written as $B = A^{-1}A(T)$ with $A \in \mathcal{U}$ because the cohomology group

$$\mathcal{H}^1(U) = \mathcal{U} / \{A \in \mathcal{U} | B = A^{-1}A(T)\}$$

of cocycles modulo coboundaries is nontrivial. We know that this group has the cardinality of the continuum.[3] The following result of Feldman and Moore[1] was extended by Lind[2] to non-Abelian groups. A dynamical system given by a group T^g of automorphisms on $(X,\mathcal{F},m)$ is called free, if $m(\{T^g(x) = x\}) > 0$ implies $g = 0$.

Theorem II.1 (Feldman–Moore–Lind): *Assume that the $\mathbf{Z}^2$-dynamical system is free. Let U be a not necessarily Abelian Polish group. For any magnetic field distribution $B\tau_{12}$ with $B \in \mathcal{U}$, there is a vector potential $A = A_1\tau_1 + A_2\tau_2$, which satisfies $dA = B$.*

Example. A magnetic field B taking values in $\{1,-1\}$ is determined by the measurable set $Y = B^{-1}(-1) = \{x | B(x) = -1\}$. Feldman–Moore's result implies that there exist two measurable sets Z_1, Z_2 such that

$$Y=Z_1+T_1(Z_1)+Z_2+T_2(Z_2),$$

where $+$ is the symmetric difference, the addition in the group $\mathcal{F}$.

Assume now that U is a subgroup of the unitary group $U(N)$ of $n\times n$ matrices. Given a one-form $A=A_1\tau_1+A_2\tau_2$, we define a discrete self-adjoint random Schrödinger operator $L=A+A^*$ as follows: For almost all $x\in X$, consider the operator $L(x)$ on $l^2(\mathbf{Z}^2,\mathbf{C}^N)$ given by $(L(x)u)=(A(x)+A(x)^*)u$, where

$$(A(x)u)_n=A_1(x)u_{n+e_1}+A_2(x)u_{n+e_2}$$

and where $e_1=(1,0),e_2=(0,1)$ are the basis vectors in $\mathbf{Z}^2$. We call $L=A+A^*$ a discrete random magnetic Laplacian. Such operators are discrete versions of the continuous operators $L=(\nabla-iA)^2$ (see, e.g., Ref. 5). We also call them ''random magnetic Laplacians'' if $U=U(1)$ or ''random Yang–Mills Laplacians'' if $U=U(N)$. Associated with L is a one-parameter family of operators $L=A_1+A_1^*+\lambda(A_2+A_2^*)$, $\lambda\in\mathbf{R}$ in which we will mainly concentrate on the case $\lambda=1$. The field of a random Laplacian $L=A+A^*$ is defined for $d\geqslant 2$ as $F_{ij}=dA_{ij}=A_j^{-1}A_i(T_j)^{-1}A_j(T_i)A_i$. If $U=U(1)$, one says that the magnetic field $B=A_2^{-1}A_1(T_2)^{-1}A_2(T_1)A_1$ has the magnetic flux $\arg(B)$. The phases of L are the functions $\arg(A_i)$.

The operator L is not uniquely defined by the field B. With a zero-form $C\in\mathcal{U}$, the gauge transformed operator CLC^{-1} is also a discrete random Laplacian with the same magnetic field B but the gauge potential A has changed to $CAC^*\tau=\Sigma_i C_iA_iC_i(T_i)^*\tau_i$. The choice of the gauge is not the only source of nonuniqueness. The nontrivial nonuniqueness is measured by the moduli space of flat fields $\{(A_1,A_2)|dA=0\}/\{A=dC\}$ which is for Abelian U as a group isomorphic to the first cohomology group $\mathcal{H}^1(U)$.

The above-mentioned definitions generalize to the higher dimensional case. Take d automorphisms $T_1,\ldots,T_d$ on a probability space $(X,\mathcal{F},m)$. A one-form $A=\Sigma_{i=1}^d A_i\tau_i$ is given by d functions $A_i\in\mathcal{U}=\mathcal{L}(X,U(N))$ and defines a field

$$dA=F=\sum_{i<j}F_{ij}\tau_{ij},$$

where $F_{ij}=A_iA_j(T_i)A_j(T_i)^{-1}A_j^{-1}$. This gives random self-adjoint operator $L=A+A^*$ where each $L(x)$ acts on the Hilbert space $l^2(\mathbf{Z}^d,\mathbf{C}^N)$ by

$$(L(x)u)=\sum_{i=1}^{d}A_i(x)u+A_i^*u.$$

Theorem II.2 (Triviality of cohomology groups in higher dimensions): *If U is Abelian and* $\mathbf{Z}^d$ *acts freely, then* $dF=0$ *implies that there exists A such that* $dA=F$.

The proof of this theorem which was included in Ref. 19 is now the subject of a separate article.[3] We call a random operator $L=A+A^*$ determined by F a random discrete electromagnetic Laplacian with field F. Examples are given in the following.

(1) A Harper operator is obtained when the field B takes a constant value in $U(N)$. Diagonalization reduces all questions to the case $N=1$. For reviews see Refs. 20–22.

(2) An example of a quasiperiodic magnetic Laplacian is defined by the dynamical system $(U(1),T_1:\theta\mapsto\theta+\alpha,T_2:\theta\mapsto\theta+\beta,d\theta)$ and the magnetic field $B(n)(\theta)=\exp(i(\theta+n_1\alpha+n_2\beta))\in U(1)$. The spectrum of the Laplacian is determined by the two real numbers α,β. Non-Abelian versions, where T_i are translations on the unitary group $U(N)$ are defined similarly. Note however that the vector potential (A_1,A_2) is only measurable and we cannot expect it to be almost periodic.

(3) An example of a limit periodic magnetic field is $B(n)=\Sigma_{j=0}^{\infty} b_j \cos(2\pi(n_1 2^{-j}+n_2 3^{-j}))$ with $\Sigma_j |b_j|<\infty$. As in the previous example, the operator L is not limit periodic and only the physically relevant field B is.

(4) Given a probability measure μ on U(1) and independent, identically distributed random variables $B(n)$, $n\in\mathbf{Z}^2$ with law μ. Even so $B(n)$ are independent, the vector potential A is in general not given by independent identically distributed random variables.

(5) An example of an aperiodic, strictly ergodic field taking only finitely many values is $B(n)=1-2\cdot 1_{[0,\gamma)}(\theta+n_1\alpha+n_2\beta)\in\{-1,1\}$, where γ,α,β are rationally independent.

(6) In all these examples, one obtains one-parameter families of deformed operators $L=A_1+A_1^*+\lambda(A_2+A_2^*)$ with $\lambda\in\mathbf{R}$. In the stationary independent magnetic field case the almost sure spectral properties of L depend only on λ and the field $B=dA$.

Higher dimensional cohomology groups[23–25] are defined as follows (see Refs. 23–25).

Let $I=\{1,\ldots,d\}$ and let $\mathcal{I}_p$ be the set of sets $J=\{j_1<j_2<\ldots<j_p\}\subset I$. Let $\mathcal{C}^p$ be the set of maps $A:\mathcal{I}_p\to\mathcal{U}$ which becomes a group by pointwise addition. Extend this map to the set of all p-tuples $J=(j_1,j_2\ldots,j_p)$ with $j_k\in I$ by requiring $A_{\pi(J)}=\mathrm{sign}(\pi)A_J$ for any permutation π of J. We write $A=\Sigma_J A_J\tau_J$. Define $d_p:\mathcal{C}^p\to\mathcal{C}^{p+1}$ by

$$d_pA=\sum_{i,J}(A_J(T_i)-A_J)\tau_{iJ}.$$

The kernel of d_p contains cocycles of degree p, whereas the image of d_{p-1} consists of coboundaries of degree p. Because for $A=\Sigma_J A_J\tau_J$,

$$d_p\circ d_{p-1}A=\sum_{i,j,J}[A_J(T_iT_j)-A_J(T_i)-A_J(T_j)+A_J]\tau_{ijJ}$$

is both symmetric and antisymmetric in i,j, it must vanish and $d_p\circ d_{p-1}=0$ gives rise to geometric cohomology groups $\mathcal{H}^p_{\mathrm{geom}}(G,\mathcal{U})=\ker(d_p)/\mathrm{im}(d_{p-1})$.

Cohomology of currents. Given a $\mathbf{Z}^d$ action on the group $\mathcal{U}=\mathcal{L}(X,U)$. A one-form $A=\Sigma_i A_i\tau_i\in\mathcal{C}^1$ defines an electromagnetic field $F=dA\in\mathcal{C}^2$ and so a current $j=d^*F=*d*F\in\mathcal{C}^1$, where an asterisk $(*)$ is the Hodge operation $*:\mathcal{C}^n\to\mathcal{C}^{d-n},A_I\mapsto(-1)^{n(d-n)}A_{I*}$, where $I^*=\{1,\ldots,n\}\setminus I\}$. A current is defined even if the group $\mathcal{U}$ is non-Abelian.

Proposition II.3: Assume $N\geq 1,d=2$ *or* $N=1,d\geq 2$. *Every current* $d^*F=j$ *is divergence free:* $d^*j=0$.

Proof: If $d=2$, the Hodge involution for one-forms is given by $A_1\tau_1+A_2\tau_2=(A_1,A_2)\mapsto(A_2,A_1^{-1})$. The divergence of j is given by

$$d^*j=*d*(j_1,j_2)=(*d)(j_2,j_1^*)=j_1j_2(T_2)^*j_1^*(T_1)j_2.$$

If we plug in $j=(j_1,j_2)=d^*F=(F^*F(T_2),F(T_1)^*F)$, we get

$$d^*j=F^*F(T_2)F(T_2)^*F(T_1T_2)F(T_2T_1)^*F(T_1)F(T_1)^*F=1.$$

In the Abelian case, $d^*j=0$ follows in any dimension from $d^*d^*=0$. □

One can ask whether every current j which is divergence free $d^*j=0$ does come from a field F satisfying $d^*F=j$ (Fig. 2). The answer is ''no'' in two dimensions and ''yes'' in dimensions three or higher. There are uncountably many equivalence classes of currents in two dimensions because of the following Proposition.

Proposition II.4: Assume $d=2$, *let* U *be a Polish group and let* G *be a free* $\mathbf{Z}^2$ *action. The moduli space of all divergence free currents* j *modulo currents* j *coming from fields* $j=d^*F$ *is isomorphic to the first cohomology group* $\mathcal{H}^1(U)$. *On the other hand, for* $d\geq 3$ *and Abelian* U, *every divergence free current* j *is of the form* d^*F.

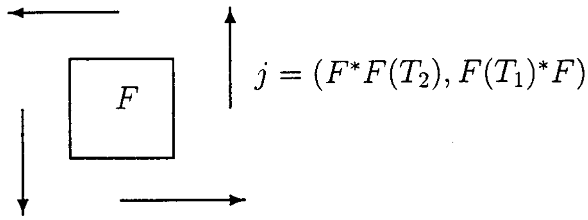

FIG. 2. Illustration of the current of a not necessarily Abelian Aharonov–Bohm field, where the field F is constant different from 1 on one plaquette only.

Proof: Assume first $d=2$. j is a cocycle if $j_2 j_1^*(T_1)=j_1^* j_2(T_2)$ and a coboundary if there exists a solution F of $j_1=F(T_2)F^*$, $j_2=FF(T_1)^*$. If j is a cocycle, then the Hodge dual $\tilde{j}=*j$ satisfies a zero curvature equation. Also, $d^*F=j$ if and only if $\tilde{j}$ is a gradient $d(*F)=\tilde{j}$. The moduli space of zero curvature fields modulo gradient fields is $\mathcal{H}^1(U)$.

Assume now $d\geq 3$ and that U is Abelian. Given the one-form j, define the $(d-1)$-form $\tilde{j}=*j$. Since $\mathcal{H}^{d-1}(U)$ is trivial for $d\geq 3$, there exists a $(d-2)$-form $\tilde{F}$ satisfying $d\tilde{F}=\tilde{j}$. Let $F=*\tilde{F}$. Then $d^*F=j$. □

Question. We do not know whether in dimensions $d\geq 3$, every current j can be written as d^*F with a field F satisfying additionally $dF=0$. If this were true and F were unique, an interesting class of higher dimensional operators $L=A+A^*$ were defined by taking independent identically distributed random variables j and taking A satisfying $d^*dA=j$.

III. GENERAL REMARKS ON THE SPECTRUM

If U is a subgroup of the unitary group $\mathrm{U}(N)$, the Laplacian L is an element of a von Neumann algebra $\mathcal{X}$ which is the crossed product of $\mathcal{A}=L^\infty(X,M(N,\mathbf{C}))$ with the $\mathbf{Z}^d$-action generated by automorphisms $f\mapsto f(T^n)$, where $f(T^n)(x)=f(T^n x)$. The algebra $\mathcal{X}$ is obtained by completing the algebra of all polynomials in the variables $\tau_1,\ldots,\tau_d$ with coefficients in $\mathcal{A}$,

$$K=\sum_{n\in F\subset\mathbf{Z}^d} K_n\tau^n,\quad (KL)_n=\sum_{l+m=n} K_l L_m(T^l)\tau^n$$

with respect to the norm $|||K|||=|\ ||K(x)||\ |_\infty$. Here, $K(x)$ is the bounded linear operator on $l^2(\mathbf{Z}^d,\mathbf{C}^N)$ defined by $(K(x)u)(n)=\Sigma_m K_m(x)u(n+m)$ and $||\cdot||$ is the operator norm on $\mathcal{B}(l^2(\mathbf{Z}^d))$ and $|\cdot|_\infty$ the essential supremum norm. The involution in $\mathcal{X}$ is $(\Sigma_n K_n\tau^n)^*=\Sigma_n K_n^*(T^{-n})\tau^{-n}$ and the *trace* is $\mathrm{tr}(K)=\int_X \mathrm{Tr}(L_0(x))d\mu(x)$, where Tr denotes the usual trace on the finite dimensional matrix algebra $M(N,\mathbf{C})$. This construction of Murray and von Neumann works in the same way, when $\mathbf{Z}^d$ is replaced by a more general discrete group.

For any self-adjoint $L\in\mathcal{X}$, and if f is a continuous, bounded function on $\mathbf{R}$, the element $f(L)\in\mathcal{X}$ is defined through the functional calculus. The functional $f\mapsto\mathrm{tr}(f(L))$ on $C(R)$ defines a measure on $\mathbf{R}$, called the density of states of L. If the $\mathbf{Z}^2$ action is ergodic, then the spectrum of $L(x)$ is constant almost everywhere and coincides with the support of the density of states.

The magnetic field does not determine L because of gauge ambiguity. However, all the information about the spectrum is determined from B only:

Proposition III.1: Assume $N\geq 1, d=2$ *or* $N=1, d\geq 2$. *Given two one-forms* $A,\tilde{A}$ *which satisfy* $d\tilde{A}=dA=B$. *Define* $L=A+A^*, \tilde{L}=\tilde{A}+\tilde{A}^*$. *There exists for every x a unitary operator* $\mathrm{U}(x)$ *on* $l^2(\mathbf{Z}^d,\mathbf{C}^N)$ *such that* $\mathrm{U}^*(x)L(x)\mathrm{U}(x)=\tilde{L}$. *Especially, the density of states, the (in the ergodic case almost everywhere constant) spectral types and the spectrum depend only on the field B.*

Proof: We consider first a setup, where measurability is discarded. Let $\mathcal{U}=\mathrm{U}(N)^{\mathbf{Z}^2}$ be the set of possible fields $n\mapsto B(n)$. For every $B\in\mathcal{U}$, we can find a bounded self-adjoint operator $L=A+A^*$ on $l^2(\mathbf{Z}^2,\mathbf{C}^N)$ which has the field $B=dA$. The special gauge $A_2(n,m)=A_1(0,m)=1$ for

$n,m \in \mathbf{Z}$, determines A and makes $L = L_B$ unique. For $N=1$, a canonical gauge can also be defined for $d \geqslant 2$: let $E_i \subset \mathbf{Z}^d$ be the vector space spanned by $(e_1, e_2, \ldots, e_i)$. Put $A_i = 1$ on E_1, then on all lines orthogonal to E_1 in E_2 and inductively on all lines orthogonal to E_j in E_{j+1}. This determines A as can be seen by induction: first construct A on E_2 then on edges orthogonal to E_2 in E_3, etc., always using $dA = B$. The condition $dB = 0$ assures that the definition is consistent. The map $B \mapsto L_B$ is continuous if $\mathcal{U}$ has the product topology and $\mathcal{B}(l^2(\mathbf{Z}^d))$ has the strong operator topology. However a change of the magnetic field of one single plaquette changes L_B globally.

Take the diagonal operator $U_{n,m} = G(n) \delta_{n,m}$, where $\overline{G(n)} A_i(n) G(n-e_i) = \tilde{A}_i$. This function $n \mapsto G(n)$ exists since any vector potential can be gauged to the canonical gauge.

For ergodic operators L, the density of states of L and $\tilde{L}$ exists. We do not need the measurability of the conjugating operator $\mathrm{U}(x)$ to get $L^n(x)_{00} = \tilde{L}^n(x)_{00}$. It follows that $\mathrm{tr}(L^n) = \int_X \mathrm{Tr}(L^n(x)_{00}) dm(x) = \int_X \mathrm{Tr}(\tilde{L}^n(x)_{00}) dm(x) = \mathrm{tr}(\tilde{L}^n)$.

Similarly, $(\phi, L^n(x), \phi) = (U(x)\phi, \tilde{L}^n(x), U(x)\phi)$ for every $\phi \in l^2(\mathbf{Z}^d, \mathbf{C}^N)$, so that also the spectral types are the same. □

Remark: The map $x \mapsto \mathrm{U}(x)$ is not measurable in general. Examples with $T_1 = \mathrm{Id}$ show this. In other words, while the operators $L(x)$ and $\tilde{L}(x)$ are conjugated in $\mathcal{B}(l^2(\mathbf{Z}^d, \mathbf{C}^N))$, the conjugation is in general not possible in the algebra $\mathcal{X}$.

Corollary III.2: Given a sequence of operators $L^{(n)} = A^{(n)} + (A^{(n)})^*$ and an operator $L = A + A^*$ defined over the same $\mathbf{Z}^d$ action. Assume that the fields $B^{(n)} = dA^{(n)}$ converge to $B = dA$ in $L^\infty(X,U)^d$. If there exists an interval $I \subset \mathbf{R}$ such that $\sigma(L^{(n)}) \cap I = \emptyset, \forall n \in \mathbf{N}$ then also $\sigma(L) \cap I = \emptyset$.

Proof: In the canonical gauge, the operators converge pointwise in the strong operator topology and so in the resolvent sense. The claim follows from general principles (Ref. 26 Theorem VIII.24). □

IV. INDEPENDENT IDENTICALLY DISTRIBUTED MAGNETIC FIELDS

We concentrate in this paragraph on the case of magnetic Laplacians, where the magnetic fields $\{B(n)\}_{n \in \mathbf{Z}^2}$ are independent, identically distributed U(1)-valued random variables B with law μ. This means that the probability that B takes a value in some interval $I \subset \mathbf{T}$ is $\mu(I)$. Denote by $\hat{\mu}_n = \int_{\mathrm{U}(1)} z^n \, d\mu$ the nth moment of μ. The sequence $\{\hat{\mu}\}_n$ is the Fourier transform of the measure μ. Denote by Γ_n the set of oriented closed paths in $\mathbf{Z}^2$ of length n. Let $n(\gamma,P)$ be the winding number of the path γ with respect to the plaquette P. The moments of the density of states can be computed with a random walk expansion as it is used in statistical physics (see, e.g., Ref. 27).

Proposition IV.1: Let μ be a Borel measure on the circle $\mathrm{U}(1)$. *The* nth *moment of the density of states* $\mathrm{tr}(L^n)$ *of an independent identically distributed magnetic Laplacian with law μ is*

$$\sum_{\gamma \in \Gamma_n} \prod_P \left(\int_{\mathrm{U}(1)} z^{n(\gamma,P)} \, d\mu(z) \right) = \sum_{\gamma \in \Gamma_n} \prod_P \hat{\mu}_{n(\gamma,P)} .$$

Proof: Given A satisfying $dA = B$. Write $\int_\gamma A$ for the product of the A_i along the path γ. The path γ encloses a region $\Omega(\gamma)$ which is a collection $\{P\}$ of plaquettes. We use the discrete Green formula $\int_\gamma A = \prod_P B^{n(\gamma,P)}$ to compute

$$\begin{aligned}
\mathrm{tr}(L^n) &= \sum_{\gamma \in \Gamma_n} \int_X \int_\gamma A(x) \, dm(x) \\
&= \sum_{\gamma \in \Gamma_n} \int_X \prod_P B_P(x)^{n(\gamma,P)} \, dm(x) \\
&= \sum_{\gamma \in \Gamma_n} \prod_P \int_X B_P(x)^{n(\gamma,P)} \, dm(x)
\end{aligned}$$

$$= \sum_{\gamma \in \Gamma_n} \prod_P \left(\int_{U(1)} z^{n(\gamma,P)} \, d\mu(z) \right).$$

In this calculation, we used that the expectation of a product of independent random variables is the product of the expectation and that X^n is independent of Y^n if X is independent of Y. □

Remarks: (1) The random walk expansion breaks down if the group U(1) is replaced by a non-Abelian group U. While it is then still true that $\mathrm{tr}(L^n) = \Sigma_{\gamma \in \Gamma_n} \int_X \int_\gamma A(x)\, dm(x)$, where $\int_\gamma A(x)$ is an ordered product, the Green formula $\int_\gamma A = \Pi_P B^{n(\gamma,P)}$ no longer makes sense.

(2) The moments of the spectral measures of the unit vectors δ_k, $k \in \mathbf{Z}^2$ can also be computed with a random walk expansion $(\delta_k, L^n(x)\delta_k) = \Sigma_{\gamma \in \Gamma_n} \Pi_\gamma A(T^k x) = \Sigma_{\gamma \in \Gamma_n} \Pi_P B_P(T^k x)^{n(\gamma,P)}$.

(3) It follows from Proposition IV.1 that the density of states dk depends continuously on the law μ.

Also for the deformed operators $L_\lambda = A_1 + A_1^* + \lambda(A_2 + A_2^*)$, there is a similar formula for the density of states. Let $y(\gamma) \in 2\mathbf{N}$ be the number of steps a path makes in the y direction.

Corollary IV.2 (Aubry duality): The moments of the density of states of L_λ depend only on μ and λ:

$$\mathrm{tr}(L_\lambda^n) = \sum_{\gamma \in \Gamma_n} \lambda^{y(\gamma)} \prod_P \hat{\mu}_{n(\gamma,P)}.$$

Furthermore, the duality $dk(\mu,\lambda,E) = dk(\mu,1/\lambda,E/\lambda)$ holds.

Proof: The random walk expansion is proven in the same way as in Proposition IV.1. It follows that $L_\lambda^{(1)} = A_1 + A_1^* + \lambda(A_2 + A_2^*)$ and that $L_\lambda^{(2)} = \lambda(A_1 + A_1^*) + A_2 + A_2^*$ have the same density of states. The duality follows from $L_\lambda^{(1)}/\lambda = L_{1/\lambda}^{(2)}$. □

It follows that the ''Lyapunov exponent'' $\lambda(\mu,\lambda,E) := \int \log|E-E'| dk(\mu,\lambda,E')$ satisfies $\lambda(\mu,\lambda,E) \geq \log(\lambda/2)$.

Remark: If μ is the Haar measure and $\{A_1(n), A_2(n)\}_{n \in \mathbf{Z}^2}$ are independent Haar distributed random variables, the duality is stronger: The obvious symmetry $A_1 \leftrightarrow A_2$ implies that the operators $L_\lambda^{(1)} = A_1 + A_1^* + \lambda(A_2 + A_2^*)$ and $L_\lambda^{(2)} = \lambda(A_1 + A_1^*) + A_2 + A_2^*$ are isospectral. Especially, L_λ and $\lambda L_{1/\lambda}$ are isospectral.

The formula for the moments of the density of states becomes especially simple if μ is the Haar measure on $\mathbf{T}$.

Corollary IV.3: Let μ be the Haar measure on U(1). *Then* $\mathrm{tr}(L^n)$ *is the number of closed paths of length n starting at* $0 \in \mathbf{Z}^2$ *for which every plaquette has zero winding number.*

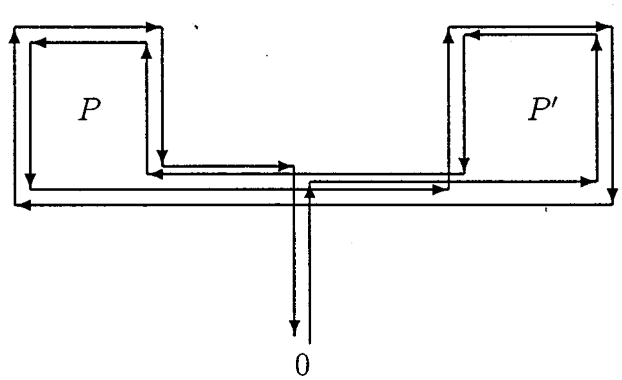

FIG. 3. A noncontractible path in the two-dimensional lattice which gives zero winding number to all plaquettes. These paths are neglected in the Brinkman–Rice ''self-retracting path approximation.''

Proof: In this case, $\hat{\mu}_k = \delta_{k,0}, \forall k \in \mathbf{Z}$. This implies $\Pi_P(\int_{\mathrm{U}(1)} z^{n(\gamma,P)}\, d\mu(z)) = 0$ if there exists a plaquette P for which the path γ has positive winding number $n(\gamma,P)$. If the winding number is zero for all P, then $\Pi_P(\int_{\mathrm{U}(1)} 1\, d\mu(z)) = 1$. □

Remarks: (1) The number of closed paths γ of length n in $\mathbf{Z}^2$ for which $n(\gamma,P)=0$ for all plaquettes P is in general strictly larger than the number of closed contractible paths of length n. A path can visit different plaquettes at different times without being contractible. See Fig. 3.

The additional paths not treated in the Brinkman–Rice approximation are so numerous that the radius of convergence for the Green function changes. Random walks with the stronger topological constraint of being contractible were investigated in Ref. 28.

(2) For the deformed operator $L = A_1 + A_1^* + \lambda(A_2 + A_2^*)$ with independent Haar distributed functions A_i, we get

$$\mathrm{tr}(L^n) = \sum_{\gamma \in \Gamma_n^{(0)}} \lambda^{y(\gamma)},$$

where $\Gamma_n^{(0)}$ is the set of paths in Γ_n which give zero winding number to every plaquette and $y(\gamma)$ is the number of steps the path γ makes in the y direction.

Corollary IV.4: Let μ be the Haar measure on a finite cyclic subgroup $\mathbf{Z}_p$ of U(1). *Then* $\mathrm{tr}(L^n)$ *is the number of closed paths of length n beginning at $0 \in \mathbf{Z}^2$ for which the winding numbers satisfy $n(\gamma,P) = 0 (\mathrm{mod}\, p)$ for all plaquettes P.*

Proof: $\Pi_P(\int_{\mathrm{U}(1)} z^{n(\gamma,P)}\, d\mu(z)) = 0$, if there exists a plaquette P which has a winding number $n(\gamma,P)$ which is not zero modulo p. □

Remarks: (1) The independence of the magnetic fields is essential in Proposition IV.1 and its Corollaries. Independent vector potentials would not be enough in general.

(2) The random walk expansion in Proposition IV.1 shows that $\mathrm{tr}(L^n)$ is a polynomial in the infinite set of variables $\hat{\mu}_k, \hat{\mu}_k^{-1}$ with integer coefficients.

Let us illustrate the random walk expansion in the almost Mathieu–Harper case, where μ is a point measure so that the magnetic field is constant:

Corollary IV.5: If μ is the Dirac measure on $e^{2\pi i\alpha} \in$ U(1), *then*

$$\mathrm{tr}(L^n) = \sum_{\gamma \in \Gamma_n} \prod_P e^{2\pi i \alpha n(\gamma,P)}.$$

(Especially, if μ is the Dirac measure on $1 \in$ U(1), *then* $\mathrm{tr}(L^n) = ((2n)!)^2 (n!)^{-2}$ *is the number of closed paths of length n beginning at $0 \in \mathbf{Z}^2$.) For the Harper magnetic Laplacian $L = A_1 + A_1^* + \lambda(A_2 + A_2^*)$,*

$$\mathrm{tr}(L^n) = \sum_{\gamma \in \Gamma_n} \lambda^{y(\gamma)} \prod_P e^{2\pi i \alpha n(\gamma,P)},$$

where $y(\gamma) \in 2\mathbf{N}$ is the number of steps of γ in the y direction.

For another illustration, let L be the Harper operator over the (nonergodic) integrable ''twist map'' $T:(x,y) \mapsto (x+y,y)$ on the two-dimensional torus $\mathbf{T}^2$ with invariant Lebesgue measure. We consider the potential $V(x,y) = 2\cos(x)$. Call the random (now nonergodic) operator the ''Hofstadter operator.'' The density of states has zero Lebesgue measure.[29] The following illustration should be compared with the case of a random magnetic field:

Corollary IV.6: If L is the Hofstadter operator, then $\mathrm{tr}(L^n)$ *is the number of closed paths of length n beginning at $0 \in \mathbf{Z}^2$ for which the sum of all winding numbers $\Sigma_P n(\gamma,P)$ over all plaquettes P vanishes.*

Proof: $\int_{\mathbf{T}} \exp(\Sigma_P 2\pi i y n(\gamma,P)) dy = 1$ if and only if $\Sigma_P n(\gamma,P) = 0$. □

Remarks: (1) Random walk expansions would work on any planar graph generalizing $\mathbf{Z}^2$ (see also Sec. VI). A solvable case is the Bethe lattice $\mathbf{B}_{2h}$ with degree $2h$, where Kesten determined the number of closed paths of length n.[30] His calculation leads to $\mathrm{tr}(L-E)^{-1} = (2h-1)/(E(h$

$-1)+h\sqrt{E^2-4(2h-1)})$. The imaginary part of this divided by π is the density of states which has support on $[-2\sqrt{2h-1},2\sqrt{2h-1}]$. (For a modern calculation see Ref. 31). Since there are no closed loops on the Bethe lattice, there is no magnetic field and the density of states of any magnetic Laplacian on the Bethe lattice is the same.

(2) Corollary IV.5 shows that $\mathrm{tr}(L^4)=8+4(\hat{\mu}_0+\hat{\mu}_0^{-1})$, so that discrete random magnetic Laplacians with different values of $\mathrm{Re}(\hat{\mu}_0)$ have different density of states. Especially, almost Mathieu operators with different $\cos(\alpha)$ cannot be isospectral (see also Ref. 32).

(3) By changing the orientation of the plaquettes, it becomes obvious that the laws μ and $\overline{\mu}(A)=\mu(\overline{A})$ give isospectral Laplacians.

In some cases, the theorem of Feldman–Moore is not needed for constructing the Laplacian.

Proposition IV.7: Let U be a compact subgroup of U(1). *If the law μ of the independent identically distributed U*-valued random variables $\{A_i(n)\}_{n\in\mathbf{Z},i=1,2}$ *of the vector potential* $A_1\tau_1+A_2\tau_2$ *is the Haar measure on U, then $B(n)=dA(n)$ are independent identically distributed U-valued random variables with law μ.*

Proof: Given measurable subsets $Y_n\subset U$, $n\in\mathbf{Z}^2$ of positive measure, define $Z_n=B(n)^{-1}(Y_n)\subset X=U^{(\mathbf{Z}^2)}$. Let $m=\mu^{(\mathbf{Z}^2)}$ be the product measure on X. The claim is that

$$m\Big(\bigcap_{n\in F} Z_n\Big)=m(Z_k)\cdot m\Big(\bigcap_{n\in F\setminus\{k\}} Z_n\Big) \tag{1}$$

for any finite set $F\subset\mathbf{Z}^2$ and that the law of $B(n)$ is the Haar measure μ.

(i) $m(Z_n)=\mu(Y_n)$, for all $n\in\mathbf{Z}^2$.

Proof: A product of Haar distributed U-valued random variables is again Haar distributed because it must be U invariant. It follows that the law of $B(n)=A_2^*(n)A_1^*(n+1)A_2(n+1)A_1(n)$ is the Haar measure μ and therefore $m(Z_n)=\mu(Y_n)$.

(ii) For any finite set F of sets $\{Y_n\}_{n\in F}\subset U$ with $m(Y_n)>0$, one has $m(\cap_{n\in F}B(n)^{-1}(Y_n))>0$.

Proof: We can realize one element in $\cap_{n\in F}B(n)^{-1}(Y_n)$ using the canonical gauge. There exists then an open neighborhood of this point in $U^{(\mathbf{Z}^2)}$ which is in $\cap_{n\in F}B(n)^{-1}(Y_n)$. An open set has positive measure.

(iii) For $k\in F$, the measure $\tilde{\mu}(Y_k)=m(B(k)^{-1}(Y_k)|\cap_{n\in F\setminus\{k\}}Z_n)$ is equal to $\mu(Y_k)=m(Z_k)=m(B(k)^{-1}(Y_k))$.

Proof: By the uniqueness of the Haar measure, we have only to show that $\tilde{\mu}$ is translational invariant. By multiplying $A_1(k+l\cdot e_i),l=1,\ldots,|F|$ with some constant $C=e^{2\pi\alpha}\in U$, we change the field $B(k)\mapsto B(k)C$ without affecting $\{B(n)\}_{n\in F\setminus\{k\}}$. Therefore $\tilde{\mu}(Y_k)=\tilde{\mu}(Y_k+\alpha)$ and $\tilde{\mu}=\mu$.

Proof of the claim. By (ii), Eq. (1) can be written as

$$m\Big(Z_k\Big|\bigcap_{n\in F\setminus\{k\}} Z_n\Big)=m(Z_k).$$

The left-hand side of this is by (iii) equal to $\tilde{\mu}(Y_k)=\mu(Y_k)$ and the right-hand side is by (i) also equal to $\mu(Y_k)$. □

Remarks: (1) There are other ways to get independent magnetic fields, if μ is the Haar measure: Define $A_2(n)=1$ for all $n\in\mathbf{Z}^2$ and a family $\{A_1(n)\}_{n\in\mathbf{Z}^2}$ of independent Haar distributed random variables. An argument similar to the proof of Proposition IV.7 shows that $\{dA(n)=B(n)\}_{n\in\mathbf{Z}^2}$ are independent Haar distributed random variables.

(2) We do not know whether a generalization of Proposition IV.7 holds when U is non-Abelian.

(3) In dimensions $d>2$, there is no hope to get a result analogous to Proposition IV.7, because there are then more plaquettes than bonds so that a single bond influences several plaquettes and prevents independent, identically distributed fields.

(4) Another open question is whether one has some or even pure point spectrum almost everywhere in the case of magnetic Laplacians with Haar distributed magnetic vector potentials. One would at least expect to have pure point spectrum for L_λ with λ large or small enough. For numerical calculations see Ref. 7.

(5) Proposition IV.7 shows that for those specific operators, there is more symmetry as in the Mathieu case. Aubry-duality goes deeper: the operators L_λ and $L_{1/\lambda}$ have the same spectral type because a multiplication of L_λ with $1/\lambda$ gives $L_{1/\lambda}$.

V. OTHER EXAMPLES

A. Laplacians in higher dimensions

We turn now to independent identically distributed magnetic Laplacians in higher dimensions. We restrict the discussion to the case $d=3$. As indicated already, we cannot realize independent, identically distributed electromagnetic fields F by a vector potential, since such fields do not satisfy the Maxwell equation $dF=0$, which is required if $F=dA$. Consider now time-dependent magnetic fields in the plane together with an electric field changing in time. Given a vector potential $A=(A_1,A_2,A_3)\in\mathcal{C}^1$, we think of A_1 as the electrostatic potential and of (A_2,A_3) as the magnetic vector potential. Then $dA=F$ is a three-dimensional field. $E_1=F_{12}$ and $E_2=F_{13}$ are the coordinates of an ''electric'' vector field in the plane and $B=F_{23}$ is a ''magnetic'' field in the plane. For fixed $k\in\mathbf{Z}$, denote by $L^{(k)}$ the magnetic Laplacian in the plane, given by the vector potential $(n,m)\mapsto(A_2(k,n,m),A_3(k,n,m))$. The operator $L^{(k)}$ is a two-dimensional magnetic Laplacian at time k.

The existence theorem in Ref. 3 assures that a field F satisfying $dF=0$ defines an electromagnetic Laplacian L determined by a one-form A satisfying $F=dA$. By prescribing the electric fields E_1,E_2 and the magnetic field $B^{(k_0)}$ at some time k_0, the Maxwell equation $dF=0$ determines the whole field F.

The next proposition which follows from the central limit theorem for circle-valued random variables, emphases why IID magnetic distributed operators with Haar distribution are natural.

Proposition V.1: Let F be determined by the electric fields and the magnetic field at some time k_0. *Assume that the electric fields* $\{E_1(n),E_2(n)\}_{n\in\mathbf{Z}^3}$ *are independent identically distributed random variables with the same distribution* μ *which is not a Haar distribution of a subgroup of* U(1). *Let* $B(k_0,n)$, $n\in\mathbf{Z}^2$ *be any set of random variables. Then the distribution of the magnetic field of the two-dimensional operators* $L^{(k)}$ *converges in law to the uniform Haar distribution of* U(1) *for* $|k|\to\infty$.

Proof: The Maxwell equation $dF=0$ (which follows from $F=dA$), *implies that*

$$B^{(k+1)}(n)^*=B^{(k)}(n)E_1^{(k)}(n+e_1)E_1^{(k)}(n)^*E_2^{(k)}(n)E_2^{(k)}(n+e_1)^*.$$

The proof of Proposition IV.7 shows that the random variables

$$\{C(n)=E_2^{(k_0)}(n+e_2)^*E_2^{(k_0)}(n)E_1^{(k_0)}(n)^*E_1^{(k_0)}(n+e_1)\}_{n\in\mathbf{Z}^2}$$

are all independent so that also $\{B^{(k_0\pm l)}(n)\}_{n\in\mathbf{Z}^2}$ is obtained from $\{B^{(k)}(n)\}_{n\in\mathbf{Z}^2}$ by multiplying it with independent identically distributed random variables. The claim follows now from the central limit theorem for independent identically distributed U(1)-valued random variables.[33] (On compact topological groups, the Haar measure plays the role of the Gaussian measure in $\mathbf{R}$) (Fig. 4). □

Proposition V.1 has the following interpretation: a time-dependent random electric field [which might be arbitrarily small but which does not take values in a subgroup of U(1)] turns an initially arbitrary magnetic field for time $|k|\to\infty$ into an independent identically distributed Haar distributed magnetic field.

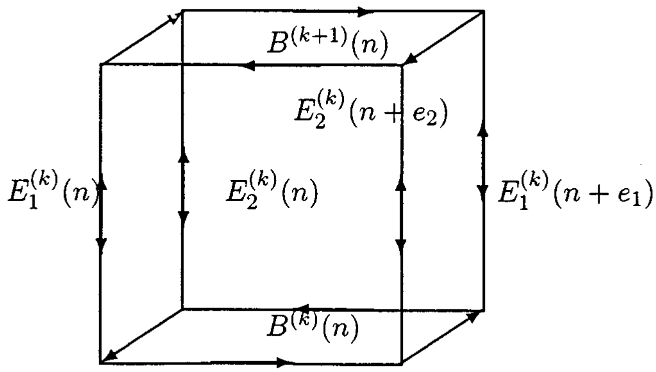

FIG. 4. The Maxwell equation $dF=0$ determines the magnetic field $B^{(k+1)}(n)^*=B^{(k)}(n)E_1^{(k)}(n+e_1)E_1^{(k)}(n)^*E_2^{(k)}(n)E_2^{(k)}(n+e_1)^*$ at time $(k+1)$ from the magnetic field $B^{(k)}$ and the electric field $(E_1^{(k)},E_2^{(k)})$ at time k.

B. One-dimensional operators

Take an electromagnetic Laplacian $L=A+A^*$ in d dimensions, where the electromagnetic field $dA=F$ has only electric components $F_{1k}(n)=E_k(n)$ which are constant in space ($\mathbf{Z}^d=\mathbf{Z}\oplus\mathbf{Z}^{d-1}=$space$\oplus$time) and depend therefore only on the first (=time) coordinate $n=n_1$. The restriction of L to the invariant Hilbert space of functions which are constant in space gives a one-dimensional operator $(Hu)_n=u_{n+1}+u_{n-1}+V(n)u_n$, where

$$V(n)=\sum_{k=1}^{d} E_k(n)+E_k(n)^*=\sum_{k=1}^{d} 2\cos(\arg(E_k(n))).$$

Every one-dimensional operator can be written like this. The number of dimensions which are needed depends on the norm. Since $dF=0$, Feldman–Moore's existence theorem shows that if V is an ergodic potential, then the equation $F=dA$ can be solved with a measurable vector potential A leading to an ergodic electromagnetic Laplacian. The one-dimensional potential $\Sigma_{k=1}^{d} 2\cos(\arg(E_k(n)))$ is ergodic, if T_1 was ergodic.

Some Anderson models can be treated as random magnetic Laplacians and allow a combinatorial calculation of the density of states: given independent identically distributed random variables $V(n)$ $n\in\mathbf{Z}^d$ with law μ, define the $\mathcal{B}(l^2(\mathbf{Z}^d))$-valued random variable $(Lu)_n=\Sigma_{|m-n|=1}u_m+V(n)u_n$ which is an Anderson model. By adding to each vertex of $\mathbf{Z}^d$ an oriented loop, one obtains a new lattice $\mathbf{L}^d$. Denote by Γ_n the set of paths γ in $\mathbf{L}^d$ which have length n. (Each loop has length 1 and we distinguish paths which pass in different directions through the loop) (Fig. 5).

Corollary V.2: (a) Given the discrete d-dimensional Anderson Schrödinger operator with independent identically distributed potential $V(n)=2\cos(\alpha(n))$, *where* $\alpha(n)$ *are uniformly distributed in* $[0,2\pi]$. *The* n'th *moment of the density of states is the number of closed paths of length n in* $\mathbf{L}^d$, *for which every loop has vanishing winding number.*

(b) If $V(n)=\pm 2$, *where* $V(n)$ *are uniformly distributed in* $\{0,2\}$, *the* n'th *moment of the density of states is the number of closed paths of length n* in $\mathbf{L}^d$ *for which every loop has an even winding number.*

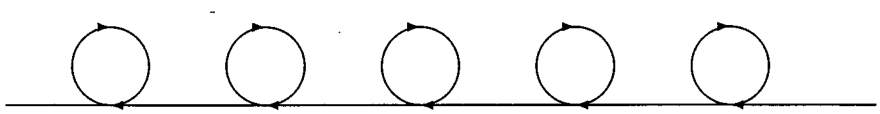

FIG. 5. The graph $\mathbf{L}$ in the case $d=1$. At each vertex is attached an oriented loop.

Proof: Write $L=A+A^*$ as a $(d+1)$-dimensional magnetic Laplacian, where $A_i=1,i=1,\ldots,d$ and $A_{d+1}(n)=\exp(i\alpha(n))$ are independent identically distributed U(1)-valued random variables with uniform Haar distribution μ. This is equivalent to taking real-valued random variables $\alpha(n)$ with uniform distribution on $[0,1]$ and to form the independent identically distributed potential $V(n)=2\cos(2\pi\alpha(n))$ which has an absolutely continuous law $4(2\pi)^{-1}\sqrt{1-x^2}$. As before, we compute with the random walk expansion

$$\mathrm{tr}(L^n)=\sum_{\gamma\in\Gamma_n}\prod_P \hat{\mu}_{n(\gamma,P)}.$$

Since all nonzero moments of ν are zero, $\mathrm{tr}(L^n)$ is the number of closed paths in the lattice $\mathbf{L}^d$ which give in case (a) zero and in case (b) zero $(\mathrm{mod}\,2)$ winding number to every loop. □

Remark: Relations between two- and one-dimensional operators are prototyped by the Harper–Mathieu case $A_1=\tau$, $A_2=e^{2\pi i\alpha}$ which give the one-dimensional operator $\tau+\tau^*+2\cos(2\pi\alpha)$. For more examples with constant magnetic field, see Ref. 34. Other, not constant magnetic fields can be obtained as follows: let $A_1\tau_1=\tau$ be the unitary Koopman operator for a transformation T on a probability space Ω and let $A_2(x)=e^{2\pi f(x)}$, where f is a su(N)-valued random variable. Then $UV=VUe^{2\pi i(f(Tx)-f(x))}$ and we get a one-dimensional operator $L=\tau+\tau^*+2\cos(f(x))$ on $l^2(\mathbf{Z},\mathbf{C}^N)$.

C. Deterministic Aharonov–Bohm Laplacians

It is illustrative to see what deterministic perturbations of the magnetic field does on the operator. We denote by L_F the d-dimensional Laplacian with field F in the special gauge.

Proposition V.3 (Jitomirskaya–Mandelshtam Ref. 18): Assume U is Abelian. A change of $F\in U^{\mathbf{Z}^d}$ *on a finite set of plaquettes leads to a compact perturbation* L_F *of the free Laplacian* L_1.

Proof: Assume first $d=2$. If B is multiplied by $C\in U^{\mathbf{Z}^2}$ such that $C_n\neq 1$ only for finitely many n and $\Pi_n C_n=1$, we call $\tilde{B}=BC$ a zero flux perturbation of 1. It is enough to show the claim for a perturbation of the field B of one single plaquette. By construction, if $\tilde{B}$ is a zero flux perturbation of B, then $L_{\tilde{B}}$ is a finite rank perturbation of L_B.

Let $L=L_B$ be the original operator and let $\tilde{L}=L_{\tilde{B}}$ be the operator belonging to $\tilde{B}$ satisfying $\tilde{B}(n)=B(n)$ for all $n\in\mathbf{Z}^2$ except one n_0, where $\tilde{B}(n_0)=B(n_0)C$ with $C=e^{i\alpha}\in U$. Define for each $k\in\mathbf{N}$ a zero flux perturbation B_k of B by changing $\tilde{B}$ on k^2 plaquettes in a box of size $k\times k$ to $\tilde{B}_kC_k^{-1}$ with $C_k=e^{-i\alpha/n^2}$. Then, $L_{B_k}\to L_{\tilde{B}}$ in norm so that $L_{\tilde{B}}$ is a limit of finite rank operators L_{B_k}.

For general d, we can build any perturbation by composing finitely many perturbations lying in two-dimensional planes and for which the previous argument applies. □

Remarks: (1) The Aharonov–Bohm operator [the situation when the field $B(n)$ is different from 1 exactly at one plaquette] shows that one has never a finite rank perturbation $L_B\mapsto L_{\tilde{B}}$, if $B\tilde{B}^{-1}$ has compact support and nonzero flux. It would be interesting to know if the Aharonov–Bohm operator is a trace class perturbation of the free Laplacian.

(2) There is the following formula for the Fourier transform of the spectral measure $dk_l=dk_{e_l}$, where $e_l(n)=\delta_{ln}$ is a unit vector in $l^2(\mathbf{Z}^2)$:

$$\widehat{dk}_{ln}=\sum_{\gamma\in\Gamma_n} B^{n(\gamma)},$$

where $n(\gamma)$ is the winding number of the path with respect to a point in the plaquette, where B is different from 1.

(3) A similar argument shows that the Jitomirskaya–Mandelstam result is also true for some aperiodic tilings like the Penrose tiling.

(4) Beside the Abelian or non-Abelian Aharonov–Bohm operators (for which a complete spectral analysis is not yet done), other deterministic operators would be interesting to study. An example is a discrete version of the Iwatsuka operator L in $d=2$ (see Ref. 5), where the magnetic field B is translational invariant in one direction and asymptotically constant in the other direction. Then, L is a direct product of one-dimensional operators $(Lu)_n = u_{n+1} + u_{n-1} + \cos(n\alpha(n))u(n)$, where $\alpha(n) \to \alpha^{\pm}$ for constants $\alpha^{\pm}$. If α^- or α^+ is rational, then also L has some absolutely continuous spectrum. If both $\alpha^{\pm}$ are irrational, Last's results[29] allow us to prove that L has no absolutely continuous spectrum. This is different from the continuous case, where the corresponding operator has purely absolutely continuous spectrum.

VI. MAGNETIC LAPLACIANS ON TILINGS AND OTHER LATTICES

A. Magnetic Laplacians on the triangular lattice

The triangular lattice is the Cayley graph of the group $G=\mathbf{Z}^2$ with the three generators e_1, e_2, e_1+e_2. A situation with two different fluxes has been considered in Ref. 35 (see also Ref. 14). A magnetic field is a cocycle which assigns to each triangle $\Delta(g_1, g_2, g_3)$, $g_i \in \mathbf{Z}^2$ a group element in U. This cocycle is determined by the value of $B_d(n)$ on $\Delta(n, n+e_1, n+e_2)$ and $B_u(n)$ on $\Delta(n+e_1, n+e_1+e_2, n+e_2)$ for each $n \in \mathbf{Z}^2$. The two measurable maps $B_d, B_u \in L^{\infty}(X,U)$ and an ergodic $\mathbf{Z}^2$ action so determine the magnetic field.

Proposition VI.1: Every stationary $\mathrm{U}(N)$*-valued field B on a triangular lattice in* $\mathbf{Z}^2$ *is given by a vector potential A so that* $B=dA$. *The spectral properties of L depend only on B. If* $\{B(n)\}_{n \in \mathbf{Z}^2}$ *are independent identically distributed random variables with Haar distribution on* $U=\mathrm{U}(1)$, *then* $\mathrm{tr}(L^n)$ *is the number of closed paths in the triangular lattice which give zero winding number to all triangles.*

Proof: In order to get the vector potential A, we form $B(x)=B_u(x)B_d(x)$, which is the field on the quadratic plaquette $P(x)$. Feldman–Moore–Lind's theorem gives the existence of the first two coordinates (A_1, A_2) of the vector potential. We define then A_3 through $A_3A_2(T_1)A_1=B_d$.

In the Abelian case, a second proof is obtained directly from the algebraic group cohomology for the group $G=\mathbf{Z}^2$ acting on $\mathcal{U}=\mathcal{L}(X,U)$: the magnetic field B with law μ is an algebraic 2-cocycle. Since the second cohomology group is trivial, it is of the form dA, where A is a one-form.

For Abelian U, the random walk expansion is done in the same way as for the square lattice by putting A_2 identically zero.

In order to see that all the spectral properties depend only on the field B, we take the same special gauge as in the square lattice case. □

Remarks: (1) Discrete magnetic Laplacians on more general graphs with uniform magnetic field with values in U(1) have been considered by Sunada.[36]

(2) If the graph G is the Cayley graph of an infinite Abelian group with finitely many generators and $U \subset \mathrm{U}(1)$, the magnetic Laplacians are elements in a hyperfinite von Neumann algebra $\mathcal{X}$. The second group cohomology vanishes and every algebraic cocycle B is of the form $B=dA$.

B. Magnetic Laplacians on aperiodic tilings

Aperiodic tilings in $\mathbf{R}^2$ define a plane graph and one can ask if it is possible to assign to the edges of the graph U(1) random variables in such a way that the magnetic fields in the pieces of the tiling are independent identically distributed U(1)-valued random variables. For simplicity, we consider only the case of the Penrose tiling with plaquettes built by Robinson triangles. The case when the plaquettes are Penrose rhombs can be reduced to that by multiplying the field values of the triangles building the rhomb.

Proposition VI.2: Given a measurable $U=\mathrm{U}(1)$*-valued field distribution B on the Penrose lattice. There exists a vector potential A such that* $dA=B$.

For a proof see Ref. 3. One can deduce from this:

Corollary VI.3: Given an independent identically distributed U(1)*-valued field B on the Robinson triangles of a Penrose tiling. There exists a measurable vector potential A on the edges of the Penrose graph such that* $dA=B$.

Remarks: (1) For more general tilings, where all pieces of the tiling are composed of the same number k of triangles (which is the case in the Penrose tiling where each Penrose rhomb is a union of two Robinson triangles) we can also realize independent identically distributed magnetic field configurations, where the law $\mu=\nu\oplus\cdots\oplus\nu$ is the kth convolution of a measure ν. This is for example the case if μ is the Haar measure on a closed subgroup of U(1).

(2) The existence of the density of states of a magnetic Laplacian L on the tiling follows from the fact L in a finite type von Neumann algebra. Hof[37] has given a direct proof of the existence and proven that the density of states and spectrum is constant on the space of tilings.

(3) For independent identically distributed magnetic fields with Haar measure of U(1), we get that $\mathrm{tr}(L^n)$ is the number of closed paths in the tiling graph such that the winding number is zero for each tile. The computation of the density of states is already nontrivial for the free Laplacian with zero magnetic field. There are some numerical results about the random walk on Penrose lattice.[38]

ACKNOWLEDGMENTS

This paper with a cohomological part was written at Caltech and was posted in *mp_arc* in 1995.[19] The present version is reorganized, updated and the proofs of the cohomological results are subject to a separate paper.[3] I owe valuable remarks or literature information to Y. Avron, A. Barrelli, J.Bellisard, J.-P. Conze, J. Feldman, G. Hjorth, A. Hof, S. Jitomirskaya, Y. Last, D. Lind, Y. Peres, and B. Simon. Nonstandard Feynman path integral for the harmonic oscillator

Ken Loo[a)]
PO Box 9160, Portland, Oregon 97207

(Received 8 April 1998; accepted for publication 13 July 1999)

Using Nonstandard Analysis, we will provide a rigorous computation for the harmonic oscillator Feynman path integral. The computation will be done without having prior knowledge of the classical path. We will see that properties of classical physics falls out naturally from a purely quantum mechanical point of view. We will assume that the reader is familiar with Nonstandard Analysis. © *1999 American Institute of Physics.* [S0022-2488(99)01711-9]

I. INTRODUCTION

In quantum mechanics, we are interested in finding the wave function that satisfies Schrodinger's equation. Equivalently, we can find the propagator or integral kernel $K(q,q_0,t)$ which satisfies

$$i\hbar\frac{\partial K(q,q_0,t)}{\partial t}=\left[\frac{-\hbar^2}{2m}\Delta_q+V(q)\right]K(q,q_0,t),$$
$$K(q,q_0,0)=\delta(q-q_o),\quad q,q_0\in\mathbb{R}^d. \tag{1.1}$$

Formally, the wave function is related to the propagator via

$$\varphi(q,t)=\int_{-\infty}^{+\infty}K(q,q_0,t)\phi(q_0)dq_0=\langle K(q,q_0,t),\phi(q_0)\rangle, \tag{1.2}$$

with boundary condition $\varphi(q,0)=\phi(q)$. In Feynman's formulation of quantum mechanics, he proposed that the propagator is given by a functional integral, also referred to as Feynman path integral or just path integral in physics literature,

$$K(q,q_0,t)=\int_{x(0)=q_0}^{x(t)=q}\exp\left\{\frac{iS[x(s)]}{\hbar}\right\}dx(s)=\lim_{n\to\infty}\int_{R^{dn}}w_{d,n}\exp\left[\frac{i\epsilon}{\hbar}S\{\mathbf{x}_{n+1}\ldots,\mathbf{x}_0\}\right]d\mathbf{x}_1\cdots d\mathbf{x}_n, \tag{1.3}$$

where

$$x_0=q_0,x_{n+1}=q,\epsilon=\frac{t}{n},$$

$$w_{d,n}=\left(\frac{m}{2i\pi\hbar\epsilon}\right)^{d(n+1)/2},$$

$$S\{\mathbf{x}_{n+1}\cdots\mathbf{x}_0\}=\sum_{j=1}^{n+1}\left[\frac{m}{2}\left(\frac{\mathbf{x}_j-\mathbf{x}_{j-1}}{\epsilon}\right)^2-V(\mathbf{x}_j)\right].$$

[a)]Electronic mail: look@sdf.lonestar.org

The integrals in the second line of (1.3) are d-dimensional improper Riemann integrals. The integral in the first equality is the purely formal path integral that integrates over all paths $x(s)$, $0\leqslant s\leqslant t$, with $x(0)=q_0$, and $x(t)=q$. The quantity $S[x(s)]$ is the action integral,

$$S[x(s)]=\int_0^t L(x,\dot{x})ds, \quad L(x,\dot{x})=\frac{m}{2}\dot{x}-V(x). \tag{1.4}$$

The motivation for the notation of the formal path integral is that as n goes to infinity, the sum in the exponent becomes the action integral. In this manner, Feynman was able to deduce classical mechanics from quantum mechanics through the action integral and $\hbar\to 0$. In this paper, we will compute the harmonic oscillator path integral without prior knowledge of classical physics. It turns out that properties of classical physics naturally falls out of the computation without taking $\hbar\to 0$. The computation shows that the path integral separates into the product of two quantities: one independent of $\hbar$, the other dependent on $\hbar$. The quantity that is independent of $\hbar$ contains properties of classical physics. Thus, in some sense we are deviating from the standard interpretation of the path integral being a bridge between quantum mechanics and classical mechanics via the action integral and $\hbar$. We are considering quantum mechanics as purely quantum mechanics and extracting properties of classical mechanics without prior knowledge of classical physics.

Mathematically, the formal integration over paths can not be a rigorously well-defined measure theoretic integration because of the oscillatory nature of the integrand (see Refs. 1 and 2). A popular technique to make sense of the (1.3) is to replace t by $-it$ and use the Wiener integral (see Refs. 3 and 4).

In nonstandard analysis, we have that $\lim_{n\to\infty} a_n=a$ iff ${}^*a_\omega\approx a$ for any infinite natural number $\omega\in{}^*\mathbb{N}-\mathbb{N}$ with $\{{}^*a_m\}_{m\in{}^*\mathbb{N}}$ being the $*$ extension of $\{a_n\}_{n\in\mathbb{N}}$, and $\approx$ means that $a_\omega+h_\omega=a$ where h_ω an infinitesimal. We can use nonstandard analysis to define the path integral; the standard part can replace the limit in (1.3). Using nonstandard analysis to replace the limit in (1.3) is not a new concept (see Refs. 5, 6 and references within), doing so partially solves the problems of the Feynman path integral on the propagator.

We can redefine (1.3) in the following manner: let $\omega\in{}^*\mathbb{N}, m,t\in\mathbb{R}^+$, $\epsilon=t/\omega$, ${}^*V(x):{}^*\mathbb{R}^d\to{}^*\mathbb{R}$ be an internal function, and $x_0=q_0$, $x_{\omega+1}=q$ be fixed points in $\mathbb{R}^d$. We call the expression

$$\int_{{}^*\mathbb{R}^{d\omega}}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{(d/2)(\omega+1)}\exp\left[\frac{i\epsilon}{\hbar}\sum_{j=1}^{\omega+1}\left[\frac{m}{2}\left(\frac{x_j-x_{j-1}}{\epsilon}\right)^2-{}^*V(x_j)\right]\right]dx_1\cdots dx_\omega, \tag{1.5}$$

an internal functional integral. In (1.5), all integrals are $*$-transformed improper Riemann integrals. In particular, if for all $\omega\in{}^*\mathbb{N}-\mathbb{N}$, the standard part of the internal functional integral exists and it is independent of the choice of ω, we call the standard part a standard functional integral or Feynman path integral and denote it by

$$st\int_{{}^*\mathbb{R}^{d\omega}}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{(d/2)(\omega+1)}\exp\left[\frac{i\epsilon}{\hbar}\sum_{j=1}^{\omega+1}\left[\frac{m}{2}\left(\frac{x_j-x_{j-1}}{\epsilon}\right)^2-{}^*V(x_j)\right]\right]dx_1\cdots dx_\omega. \tag{1.6}$$

Equation (1.6) is just a nonstandard analysis way of saying that the limit in (1.3) exists. There still remain the problem of for which class of potentials V the expression (1.5) exists and whether (1.6) actually produces the propagator.

We will demonstrate the usage of (1.5) and (1.6) on the d-dimensional harmonic oscillator path integral. The harmonic oscillator plays a major role in quantum field theory and the recent advances due to Duru and Kleinert in the Coulomb potential path integral (see Ref. 7 and references within). The harmonic oscillator carries the potential $V(x)=m\lambda^2/2x^2$, its internal functional integral is:

$$\int_{{}^*\mathbb{R}^{d\omega}}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{(d/2)(\omega+1)}\exp\left[\frac{i\epsilon}{\hbar}\sum_{j=1}^{\omega+1}\left[\frac{m}{2}\left(\frac{x_j-x_{j-1}}{\epsilon}\right)^2-\frac{m}{2}\lambda^2x_j^2\right]\right]dx_1\ldots dx_\omega. \tag{1.7}$$

Notice that each *d*-dimensional integral factors into *d* products of one-dimensional integrals, thous we shall compute the one-dimensional harmonic oscillator internal functional integral.

II. THE HARMONIC OSCILLATOR

There are many ways to compute the harmonic oscillator path integral (see Refs. 7–9 and references within), we will use a method of computation similar to that of Ref. 8. We differ from the popular techniques in that we will do the computation without prior knowledge of the classical path of the harmonic oscillator and we will rigorously do the computation with nonstandard analysis. As pointed out earlier, it turns out that properties of classical physics falls out naturally from a purely quantum mechanical derivation.

It is well known that for $0<t<\pi/\lambda$, the propagator for the one-dimensional harmonic oscillator is

$$K(q,q_0,t)=\left(\frac{m}{2\pi i\hbar}\right)^{1/2}\sqrt{\frac{\lambda}{\sin\lambda t}}\exp\left\{\frac{im}{\hbar}\frac{\lambda}{\sin\lambda t}[(q_0^2+q^2)\cos\lambda t-2qq_0]\right\}. \tag{2.1}$$

Equation (2.1) carries a singularity at $t=\pi/\lambda$. A singularity like that of (2.1) can, in fact, be given rigorous mathematical meaning if $K(q,q_0,t)$ is interpreted as a distribution (see Ref. 10). Due to the form of (2.1), we would not expect the standard functional integral to exist at $t=\pi/\lambda$ as a function.

The popular method to compute the one-dimensional harmonic oscillator Feynman path integral is by writing $S[x(s)]=S[x^{\mathrm{cl}}(s)+\delta x(s)]$, where $x^{\mathrm{cl}}(s)$ is the classical path of the harmonic oscillator that satisfies the equation of motions $\ddot{x}^{\mathrm{cl}}(s)=-\lambda^2x^{\mathrm{cl}}(s)$, with the boundary condition $x^{\mathrm{cl}}(0)=q_0$, $x^{\mathrm{cl}}(t)=q$. Namely, $x^{\mathrm{cl}}(s)=[q\sin\lambda s+q_0\sin\lambda(t-s)]/\sin\lambda t$. The action integral becomes

$$\int_0^t\frac{m}{2}[(\dot{x}^{\mathrm{cl}})^2-\lambda^2(x^{\mathrm{cl}})^2]ds+\int_0^t\frac{m}{2}[(\delta\dot{x})^2-\lambda^2(\delta x)^2]ds+\int_0^t m(\dot{x}^{\mathrm{cl}}\,\delta\dot{x}-\lambda^2x^{\mathrm{cl}}\,\delta x)ds. \tag{2.2}$$

Using $\delta x(0)=0=\delta x(t)$ and the equation of motions of x^{cl}, the last integral is 0 after an integration by parts. Integrating by parts on the first integral and using the equation of motions of x^{cl}, the first integral becomes $(m/2)x^{\mathrm{cl}}\dot{x}^{\mathrm{cl}}|_0^t=(m\lambda/2\sin\lambda t)[(q^2+q_0^2)\cos t-2qq_0]$. Without much concern on the existence and meaning of the path integral, we can write

$$\begin{aligned}&\int_{x(0)=q_0}^{x(t)=q}\exp\left\{\frac{iS[x(s)]}{\hbar}\right\}dx(s)\\&\quad=\exp\left\{\frac{im\lambda}{2\hbar\sin\lambda t}[(q^2+q_0^2)\cos t-2qq_0]\right\}\int_{\delta x(0)=0}^{\delta x(t)=0}\exp\left\{\frac{iS[\delta x(s)]}{\hbar}\right\}d\,\delta x(s).\end{aligned} \tag{2.3}$$

The path integral on the right-hand side is the quantum fluctuation; the integral is over all paths, which starts from 0 at $s=0$, and ends at 0 at $s=t$. We leave it to the reader to look up the computation of the quantum fluctuation in the literature.

We will give a rigorous treatment of (2.3) by using the time-sliced internal path integral in (1.5) and (1.6). In our work, we do not start with having knowledge of the classical path. We will start with an arbitrary bounded path $w(s)$ which satisfies $w(0)=q_0$, $w(t)=q$, and separate the propagator into a product of classical and quantum amplitudes. In this approach, we will see that the classical contribution actually comes from quantum mechanics without prior knowledge of classical mechanics.

To shorten the notation, we write

$$
\begin{aligned}
&\frac{i\epsilon}{\hbar}\sum_{j=1}^{n+1}\left[\frac{m}{2}\left(\frac{x_j-x_{j-1}}{\epsilon}\right)^2-\frac{m}{2}\lambda^2x_j^2\right]\\
&=\left(\frac{im}{2\hbar\epsilon}\right)\left[x_0^2-2x_0x_1+x_{n+1}^2-2x_nx_{n+1}+\sum_{j=1}^{n}2x_j^2-\sum_{j=1}^{n}2x_jx_{j-1}-\epsilon^2\lambda^2\sum_{j=1}^{n+1}x_j^2\right]\\
&=\left(\frac{im}{2\hbar\epsilon}\right)x^t\left\{\begin{pmatrix}
1 & -1 & 0 & \cdots & 0\\
-1 & & & & \vdots\\
0 & & 0 & & 0\\
\vdots & & & & -1\\
0 & \cdots & & -1 & 1
\end{pmatrix}\right.\\
&\quad-\epsilon^2\lambda^2\begin{pmatrix}
0 & \cdots & & & & \cdots & \cdots & 0\\
0 & 1 & 0 & \cdots & & & \cdots & 0\\
\vdots & \ddots & \ddots & \ddots & \ddots & & & \vdots\\
 & & \ddots & \ddots & \ddots & & & \\
 & & & \ddots & \ddots & \ddots & & \\
\vdots & & & & \ddots & \ddots & & \vdots\\
0 & \cdots & & & \cdots & 0 & 1 & 0\\
0 & \cdots & & & & \cdots & 0 & 1
\end{pmatrix}\\
&\quad\left.+\begin{pmatrix}
0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0\\
0 & 2 & -1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0\\
\vdots & -1 & 2 & -1 & 0 & \cdots & \cdots & \cdots & \cdots & 0\\
\vdots & 0 & -1 & 2 & -1 & 0 & \cdots & \cdots & \cdots & 0\\
\vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & & \vdots\\
\vdots & \vdots & & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots\\
0 & & & \ddots & \ddots & \ddots & \ddots & \ddots & & \\
0 & \cdots & \cdots & \cdots & \cdots & 0 & -1 & 2 & -1 & 0\\
0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & -1 & 2 & 0\\
0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0
\end{pmatrix}\right\}x=\left(\frac{im}{2\hbar\epsilon}\right)(x^tT_nx),
\end{aligned}
\tag{2.4}
$$

where T_n is the $(n+2)$ by $(n+2)$ symmetric matrix,

$$
T_n=\begin{pmatrix}
1 & -1 & 0 & \cdots & 0\\
-1 & & & & \vdots\\
0 & & S_n & & 0\\
\vdots & & & & -1\\
0 & \cdots & & -1 & 1-\epsilon^2\lambda^2
\end{pmatrix},
\tag{2.5}
$$

with S_n being the n by n symmetric matrix $S_n = A_n - \epsilon^2 \lambda^2 B_n$, where

$$A_n = \begin{pmatrix} 2 & -1 & 0 & \cdots & \cdots & \cdots & \cdots & 0 \\ -1 & 2 & -1 & 0 & \cdots & \cdots & \cdots & 0 \\ 0 & -1 & 2 & -1 & \cdots & \cdots & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & & & \ddots & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & \cdots & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & \cdots & \cdots & \cdots & 0 & -1 & 2 \end{pmatrix},$$

$$B_n = \begin{pmatrix} 1 & 0 & \cdots & & & & \cdots & 0 \\ 0 & 1 & 0 & \cdots & & & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & & & & \vdots \\ & & \ddots & \ddots & \ddots & & & \\ & & & \ddots & \ddots & \ddots & & \\ \vdots & & & & \ddots & \ddots & & \vdots \\ 0 & \cdots & & & \cdots & 0 & 1 & 0 \\ 0 & \cdots & & & & \cdots & 0 & 1 \end{pmatrix}, \tag{2.6}$$

and x is the column vector,

$$x = \begin{pmatrix} x_0 \\ x_1 \\ \vdots \\ x_n \\ x_{n+1} \end{pmatrix}. \tag{2.7}$$

For notation convenience, we will use a bar instead of $*$ to indicate the $*$ transforms of matrices, determinate of matrices, and vectors.

We are interested in knowing when the internal functional integral of the harmonic oscillator exists. From (2.1), it would be reasonable to postulate the existence of the functional integral for $t < \pi/\lambda$. Indeed, this turns out to be the case. For $t < \pi/\lambda$, $\overline{S_\omega}$ (the $*$ transform of S_n with $n = \omega \in {}^*\mathbb{N} - \mathbb{N}$) turns out to be $*$-positive definite, which allows us to actually compute the integrals.

Proposition 2.1: For $0 < t < \sqrt{[n^2\pi^2/\lambda^2(n+1)^2][1-\pi^2/12(n+1)^2]}$, S_n *is positive definite.*

Proof: An elementary computation shows that for $k = 1,2,...,n$,

$$A_n \begin{pmatrix} \sin\frac{k\pi}{n+1} \\ \sin\frac{2k\pi}{n+1} \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \sin\frac{nk\pi}{n+1} \end{pmatrix} = \left(2 - 2\cos\frac{k\pi}{n+1}\right) \begin{pmatrix} \sin\frac{k\pi}{n+1} \\ \sin\frac{2k\pi}{n+1} \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \sin\frac{nk\pi}{n+1} \end{pmatrix}. \tag{2.8}$$

Hence, the n distinct eigenvalues of S_n are $2-2\cos(k\pi/(n+1))-\lambda^2(t/n)^2$. To show that S_n is positive definite, it is enough to find the values of t for which the eigenvalues are positive, or $\cos(k\pi/(n+1))<1-\lambda^2t^2/2n^2$. Since $\cos(k\pi/(n+1))\leqslant\cos(\pi/(n+1))$ for $k=1,2,...,n$, it is enough to find t for which $\cos(\pi/(n+1))<1-\lambda^2t^2/2n^2$. By Taylor expanding $\cos(\pi/(n+1))$ to about 0 for the first three nonzero terms, we have

$$\cos\left(\frac{\pi}{n+1}\right)<1-\frac{\lambda^2t^2}{2n^2}\Leftrightarrow 1-\frac{\pi^2}{2(n+1)^2}+\frac{\pi^4\cos\eta}{4!(n+1)^4}$$
$$<1-\frac{\lambda^2t^2}{2n^2}\Leftrightarrow t^2<\frac{\pi^2n^2}{\lambda^2(n+1)^2}\left[1-\frac{\pi^2\cos\eta}{12(n+1)^2}\right], \tag{2.9}$$

where $0<\eta\leqslant\pi/(n+1)$. When $t<\sqrt{[n^2\pi^2/\lambda^2(n+1)^2][1-\pi^2/12(n+1)^2]}$, we have $t^2<[\pi^2n^2/\lambda^2(n+1)^2][1-\pi^2\cos\eta/12(n+1)^2]$. □

Theorem 2.2: *Let $t\in\mathbb{R}$ and $0<t<\pi/\lambda$. For any $\omega\in{}^*\mathbb{N}-\mathbb{N}$, $\overline{S_\omega}$ is positive definite in the $*$ transformed sense.*

Proof: $*$ transforming Proposition 2.1 and setting $n=\omega$, we have that $\overline{S_\omega}$ is positive definite when

$$0<t<\sqrt{\frac{\omega^2\pi^2}{\lambda^2(\omega+1)^2}\left[1-\frac{\pi}{12(\omega+1)^2}\right]}=\frac{\pi}{\lambda}+h, \tag{2.10}$$

where h is infinitesimal. When t is standard and $0<t<\pi/\lambda$, (2.10) holds. □

From here on, let us take $0<t<\pi/\lambda$. We will now proceed to separate the functional integral into a classical part and a quantum fluctuation part. Suppose $w(s)$ is an arbitrary path with $|w(s)|<\infty$ for $0\leqslant s\leqslant t$. Furthermore, let $w(0)=q_0$, and $w(t)=q$. We make the substitution $x_j=w(jt/(n+1))+y_j=w_j+y_j$ [notice that $y_0=0=y_{n+1}$ since $w(0)=x_0=q_0$ and $w(t)=x_{n+1}=q$]. Using the fact that T_n is symmetric, we have

$$\begin{aligned}x^tT_nx&=(y+w)^tT_n(y+w)\\&=w^tT_nw+y^tT_ny+w^tT_ny+y^tT_nw\\&=w^tT_nw+y^tT_ny+(T_nw)^ty+(w^tT_ny)^t\\&=w^tT_nw+y^tT_ny+(T_nw)^ty+w^tT_ny\\&=w^tT_nw+y^tT_ny+2(T_nw)^ty.\end{aligned} \tag{2.11}$$

By using $y_0=0=y_{n+1}$ and writing T_n as

$$T_n=\begin{pmatrix}0&0&0&\cdots&0\\0&&&&\vdots\\0&&S_n&&0\\\vdots&&&&0\\0&\cdots&&0&0\end{pmatrix}+\begin{pmatrix}1&-1&0&\cdots&&0\\-1&&&&&\vdots\\0&&0&&&0\\\vdots&&&&&-1\\0&\cdots&&&-1&1-\epsilon^2\lambda^2\end{pmatrix}, \tag{2.12}$$

we obtain

$$x^tT_nx=w^tT_nw+y^tT_ny+2(T_nw)^ty=w^tT_nw+\hat{y}^tS_n\hat{y}+2\rho^t\hat{y}, \tag{2.13}$$

where

$$y=\begin{pmatrix}0\\ y_1\\ \vdots\\ y_n\\ 0\end{pmatrix},\quad \hat{y}=\begin{pmatrix}y_1\\ \vdots\\ y_n\end{pmatrix},\quad w=\begin{pmatrix}w_0\\ w_1\\ \vdots\\ w_n\\ w_{n+1}\end{pmatrix},\tag{2.14}$$

and

$$\rho=S_n\begin{pmatrix}w_1\\ w_2\\ \vdots\\ w_{n-1}\\ w_n\end{pmatrix}-\begin{pmatrix}w_0\\ 0\\ \vdots\\ 0\\ w_{n+1}\end{pmatrix}=S_n\hat{w}-\hat{\hat{w}}.$$

We then have the following.

Lemma 2.3: Under the assumption on t, let $\epsilon=t/n$, *then*

$$\int_{\mathbb{R}^n}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{(1/2)(n+1)}\exp\left[\frac{i\epsilon}{\hbar}\sum_{j=1}^{n+1}\left[\frac{m}{2}\left(\frac{x_j-x_{j-1}}{\epsilon}\right)^2-\frac{m}{2}\lambda^2x_j^2\right]\right]dx_1\cdots dx_n$$
$$=\exp\left[\frac{im}{\hbar\epsilon}(w^tT_nw-\rho^tS_n^{-1}\rho)\right]\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{1/2}\sqrt{\frac{1}{\det S_n}}.\tag{2.15}$$

Proof: Since S_n is positive definite, it is invertible. Since S_n is symmetric, the following holds:

$$\hat{y}^tS_n\hat{y}+2\rho^t\hat{y}=(\hat{y}+S_n^{-1}\rho)^tS_n(\hat{y}+S_n^{-1}\rho)-\rho^tS^{-1}\rho.\tag{2.16}$$

Using our shortened notation in (2.13) and (2.16), the integrals in (2.15) is equivalent to

$$\exp\left[\frac{im}{\hbar\epsilon}(w^tT_nw-\rho^tS_n^{-1}\rho)\right]\int_{\mathbb{R}^n}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{(1/2)(n+1)}\exp\left(\frac{im}{2\hbar\epsilon}z^tS_nz\right)dz_1\cdots dz_n.\tag{2.17}$$

In obtaining (2.17), we performed the change of variables $x_j=w_j+y_j$, and then from $y_j+(S_n^{-1}\rho)_j=z_j$. We get (2.15) after diagonalizing S_n and doing the decoupled integrals. □

Corollary 2.4: Under the previous definition of $w(s)$, *The one-dimensional harmonic oscillator internal functional integral is well defined, and it is equal to*

$$\exp\left[\frac{im}{\hbar\epsilon}(\overline{w}^t\overline{T}_\omega\overline{w}-\overline{\rho}^t\overline{S}_\omega^{-1}\overline{\rho})\right]\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{1/2}\sqrt{\frac{1}{\det S_\omega}}.\tag{2.18}$$

where the bars denote a $*$ *transform.*

Proof: This is just the $*$ transform, Lemma 2.3. □

Remark 2.1: There is no restriction on the choice of the path w except that it starts at q_0 and ends at q. We will show that the exponential part of (2.18) turns out to be the classical amplitude of the previous formal calculation of the propagator and the other factor is the quantum fluctuation. If we choose $\overline{w}$ to be the $*$ transform of the classical path, it can be shown that each entry in $\overline{\rho}$ is infinitesimal, and $\overline{w}^t\overline{T}_\omega\overline{w}/\epsilon$ is infinitesimally close to $\lambda/\sin\lambda t[(q_0^2+q^2)\cos\lambda t-2qq_0]$.

There are many techniques to compute the quantum fluctuation $\lim_{n\to\infty}\sqrt{1/\epsilon\det S_n}$ in the literature; we present a rigorous method to compute the limit with Nonstandard Analysis by computing $\mathrm{st}\sqrt{1/\epsilon\det S_\omega}$, for $\omega\epsilon{}^*\mathbb{N}-\mathbb{N}$.

Proposition 2.5: Let $\epsilon=t/n$. *Denote* $A_{j,n}$ *and* $C_{j,n}$ *with* $0<j\leqslant n$ *to be the j by j matrices given by*

$$A_{j,n}=\begin{pmatrix} 2 & -1 & 0 & \cdots & \cdots & \cdots & \cdots & 0 \\ -1 & 2 & -1 & 0 & \cdots & \cdots & \cdots & 0 \\ 0 & -1 & 2 & -1 & \cdots & \cdots & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & & & \ddots & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & \cdots & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & \cdots & \cdots & \cdots & 0 & -1 & 1 \end{pmatrix}, \tag{2.19}$$

and

$$C_{j,n}=\begin{pmatrix} 1 & 0 & \cdots & & & & \cdots & 0 \\ 0 & 1 & 0 & \cdots & & & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & & & & \vdots \\ & & \ddots & \ddots & \ddots & & & \\ & & & \ddots & \ddots & \ddots & & \\ \vdots & & & & \ddots & \ddots & & \vdots \\ 0 & \cdots & & & \cdots & 0 & 1 & 0 \\ 0 & \cdots & & & & \cdots & 0 & 0 \end{pmatrix}.$$

Define $D_{j,n}=\det\|A_{j,n}-\epsilon^2\lambda^2 C_n\|$. *After* $*$ *transforming, we have that for* $\omega\in{}^*\mathbb{N}-\mathbb{N}$, $\overline{D}_{k,\omega}\approx{}^*\cos(kt\lambda/\omega)={}^*\cos(k\epsilon\lambda)$.

Proof: For $k=1$, $A_{1,\omega}=(1)$, $C_{1,\omega}=(0)$, and $D_{1,\omega}=1$. For $k=2$,

$$\overline{A}_{2,\omega}=\begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix}, \quad \overline{C}_{2,\omega}=\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \tag{2.20}$$

and $\overline{D}_{2,\omega}=1-\epsilon^2\lambda^2$. Hence, the claim is true for $k=1,2$. We expand $D_{j,n}$ on the top row, and get the recursion relation

$$D_{j,n}=(2-\epsilon^2\lambda^2)D_{j-1,n}-D_{j-2,n}, \quad 2<j\leqslant n. \tag{2.21}$$

Since we are interested in $\omega\in{}^*\mathbb{N}-\mathbb{N}$, we will consider the cases for which $4-(2-\lambda^2\epsilon^2)^2>0$. To solve the difference equation, we substitute $D_{j,n}=Aa^{j-1}$ into (2.21) and get $a^2-(2-\lambda^2\epsilon^2)a+1=0$ with solutions

$$a_{\pm}=\frac{(2-\lambda^2\epsilon^2)\pm i\sqrt{4-(2-\lambda^2\epsilon^2)^2}}{2}. \tag{2.22}$$

Both solutions $a_{\pm}$ have norm 1. Thus, we can denote $a_{\pm}=e^{i\pm\theta}$, where $\theta=\arg(a_+)>0$. Hence,

$$D_{j,n}=A^+\exp\{i(j-1)\theta\}+A^-\exp\{-i(j-1)\theta\}. \tag{2.23}$$

Solving for the initial conditions,

$$D_1=1=A^++A^-, \quad D_2=1-\epsilon^2\lambda^2=A^+a_++A^-a_-, \tag{2.24}$$

we get

$$A^{\pm}=\frac{1}{2}\pm i\left(\frac{\lambda\epsilon}{2\sqrt{4-\lambda^2\epsilon^2}}\right). \tag{2.25}$$

We now proceed to get an estimate for θ. By definition of θ, $\cos\theta=1-\lambda^2\epsilon^2/2$. After expanding the left-hand side about 0, we get $1-(\theta^2/2)\cos\eta=1-\lambda^2\epsilon^2/2$, $0<\eta\leq\theta$. To estimate θ by $\lambda\epsilon$, we write $\theta=\lambda\epsilon+\phi$, and obtain

$$1-\frac{(\lambda\epsilon+\phi)^2}{2}\cos\eta=1-\frac{\lambda^2\epsilon^2}{2},\quad \Rightarrow\phi=-\lambda\epsilon\pm\frac{\lambda\epsilon}{\sqrt{\cos\eta}},\Rightarrow\phi=-\lambda\epsilon+\frac{\lambda\epsilon}{\sqrt{\cos\eta}}, \tag{2.26}$$

where the last implication is due to $\theta>0$. Thus, $\theta=\lambda\epsilon-\lambda\epsilon(1-1/\sqrt{\cos\eta})$.

By $*$ transforming the above and setting $j=k$, $n=\omega$, $2<k\leq\omega$, $\omega\in{}^*\mathbb{N}-\mathbb{N}$, we get

$$\epsilon=\frac{t}{\omega}\approx 0,\quad \theta,\eta\approx 0,\quad 1-\frac{1}{\sqrt{{}^*\cos\eta}}\approx 0,\quad A^{+}\approx A^{-}\approx\frac{1}{2}. \tag{2.27}$$

Equations (2.27) and (2.23) imply that

$$\overline{D}_{k,\omega}\approx{}^*\cos\{(k-1)\theta\}={}^*\cos\left\{\left(k\lambda\epsilon-\theta-k\lambda\epsilon\left(1-\frac{1}{\sqrt{{}^*\cos\eta}}\right)\right)\right\}\approx{}^*\cos(k\lambda\epsilon). \tag{2.28}$$

In the last $\approx$ in (2.28), we used the fact that the cosine function is uniformly continuous, which translates into $*\cos x\approx{}^*\cos y$ whenever $x\approx y$ in the language of Nonstandard Analysis. □

With the aid of Proposition 2.5, we can show the following.

Theorem 2.6: $\epsilon\det\overline{S_\omega}$ *is infinitesimally close to* $\sin(\lambda t)/\lambda$.

Proof: As before, we will use bars to denote the $*$ transform of the determinant of matrices. Let $S_{j,n}=\det\|A_{j,n}-\epsilon^2\lambda^2B_{j,n}\|$, where $A_{j,n}$ is a j by j matrix as defined in (2.19), $B_{j,n}$ is the j by j identity matrix, $\epsilon=t/n$, and $1\leq j\leq n$. Notice that $S_{n,n}=\det\|S_n\|$. Expanding $S_{j,n}$ and $D_{j,n}$ on the bottom row, we get the recursion relation $S_{j,n}=D_{j,n}+(1-\epsilon^2\lambda^2)S_{j-1,n}$, or, equivalently, $S_{j,n}-S_{j-1,n}=D_{j,n}-\epsilon^2\lambda^2S_{j-1,n}$. Summing the last equality gives

$$S_{n,n}-S_{1,n}=\sum_{j=2}^{n}D_{j,n}-\epsilon^2\lambda^2\sum_{j=2}^{n}S_{j-1,n},$$

$$\Rightarrow\epsilon S_{n,n}=\epsilon S_{1,n}+\sum_{j=2}^{n}\epsilon D_{j,n}-\epsilon^2\lambda^2\sum_{j=2}^{n}\epsilon S_{j-1,n}. \tag{2.29}$$

From the recursion relation, we also get that for $j\geq 3$, $|S_{j-1,n}|\leq(\Sigma_{k=2}^{j-1}|D_{k,n}|)+|S_{1,n}|$.

We now $*$ transform the second equation in (2.29) and write from Proposition (2.5) $\overline{D}_{m,\omega}={}^*\cos(m\epsilon\lambda)+h_m$, where h_m is infinitesimal. We get

$$\epsilon\det\overline{S}_\omega=\epsilon\overline{S}_{1,\omega}+\sum_{m=1}^{\omega}\epsilon\,{}^*\cos\left(\frac{mt\lambda}{\omega}\right)-\epsilon\,{}^*\cos(\epsilon\lambda)+\epsilon\sum_{m=2}^{\omega}h_m-\epsilon^2\lambda^2\sum_{m=2}^{\omega}\epsilon\overline{S}_{m-1,\omega}. \tag{2.30}$$

The set $\{h_m|1\leq m\leq\omega\}$ is an internal set, so $\max_{1\leq m\leq\omega}h_m\in\{h_m|1\leq m\leq\omega\}$, and it is an infinitesimal. Thus, $\epsilon\Sigma_{m=2}^{\omega}h_m\leq(t/\omega)\omega\max_{1\leq m\leq\omega}h_m\approx 0$. From the bound on $|S_{j-1,n}|$, we get

$$\left|\epsilon^2\lambda^2\sum_{m=2}^{\omega}\epsilon\overline{S}_{m-1,\omega}\right|\leqslant\epsilon^3\lambda^2|\overline{S}_{1,\omega}|+\epsilon^2\lambda^2\left\{\sum_{m=3}^{\omega}\epsilon\left[\left(\sum_{k=2}^{m-1}|\overline{D}_{k,\omega}|\right)+|\overline{S}_{1,\omega}|\right]\right\}$$
$$<\epsilon^3\lambda^2|\overline{S}_{1,\omega}|+\epsilon^2\lambda^2\left[\left(\sum_{m=2}^{\omega}2t\right)+t|\overline{S}_{1,\omega}|\right]\approx 0. \tag{2.31}$$

Finally, using the limit of Riemann sums in the language of nonstandard analysis, we have $\Sigma_{m=1}^{\omega}\epsilon*\cos(mt\lambda/\omega)\approx\int_0^t\cos(\lambda s)ds=\sin(\lambda t)/\lambda$. Since the other two terms in (2.30) are also infinitesimals, the result follows. □

We are now ready to derive the classical amplitude from the exponential in (2.18) by using results from Theorem 2.6.

Proposition 2.7: The exponential in (2.18) satisfies the following:

$$\exp\left[\frac{im}{\hbar\epsilon}(\overline{\omega}^t\overline{T}_\omega\overline{\omega}-\overline{\rho}^t\overline{S}_\omega^{-1}\overline{\rho})\right]\approx\exp\left\{\frac{im}{\hbar}\frac{\lambda}{\sin\lambda t}[(q_0^2+q^2)\cos\lambda t-2qq_0]\right\}, \tag{2.32}$$

where $q_0=x_0$, *and* $q=x_{\omega+1}$.

Proof: From the definition of ρ, w, T_n, and S_n^{-1} in (2.12)–(2.14), we multiply out $\rho^tS_n^{-1}\rho$ and express it in terms of w^tT_nw,

$$\begin{aligned}\rho^tS_n^{-1}\rho&=(\hat{w}^tS_n-\hat{\hat{w}}^t)S_n^{-1}(S_n\hat{w}-\hat{\hat{w}})\\&=(\hat{w}^t-\hat{\hat{w}}^tS_n^{-1})(S_n\hat{w}-\hat{\hat{w}})\\&=\hat{w}^tS_n\hat{w}-\hat{w}^t\hat{\hat{w}}-\hat{\hat{w}}^t\hat{w}+\hat{\hat{w}}^tS_n^{-1}\hat{\hat{w}}\\&=w^tT_nw-w_0^2-(1-\epsilon^2\lambda^2)w_{n+1}^2\\&\quad+w_0^2(\overline{S_n^{-1}})_{11}+w_0w_{n+1}(\overline{S_n^{-1}})_{1n}\\&\quad+w_0w_{n+1}(\overline{S_n^{-1}})_{n1}+w_{n+1}^2(\overline{S_n^{-1}})_{nn}.\end{aligned} \tag{2.33}$$

After $*$ transforming (2.33), we get

$$\begin{aligned}\frac{1}{\epsilon}(\overline{w}^t\overline{T}_\omega\overline{w}-\overline{\rho}^t\overline{S}_\omega^{-1}\overline{\rho})&=\frac{1}{\epsilon}[\overline{w}_0^2+(1-\epsilon^2\lambda^2)\overline{w}_{\omega+1}^2-\overline{w}_0^2(\overline{S_\omega^{-1}})_{11}\\&\quad-\overline{w}_{\omega+1}^2(\overline{S_\omega^{-1}})_{\omega\omega}-\overline{w}_0\overline{w}_{\omega+1}(\overline{S_\omega^{-1}})_{1\omega}-\overline{w}_0\overline{w}_{\omega+1}(\overline{S_\omega^{-1}})_{\omega1}]\\&=\frac{1}{\epsilon}\left[q_0^2\left(1-\frac{\overline{S}_{\omega-1,\omega}}{\overline{S}_{\omega,\omega}}\right)+q^2\left(1-\frac{\overline{S}_{\omega-1,\omega}}{\overline{S}_{\omega,\omega}}\right)\right.\\&\quad\left.-2qq_0\frac{(-1)^{\omega+1}(-1)^{\omega-1}}{\overline{S}_{\omega,\omega}}-\epsilon^2\lambda^2q^2\right]\\&=\frac{1}{\epsilon\det\overline{S}_\omega}[q_0^2(\overline{S}_{\omega,\omega}-\overline{S}_{\omega-1,\omega})+q^2(\overline{S}_{\omega,\omega}-\overline{S}_{\omega-1,\omega})-2qq_0]-\epsilon\lambda^2q^2\\&\approx\frac{\lambda}{\sin\lambda t}[(q_0^2+q^2)\cos\lambda t-2qq_0].\end{aligned} \tag{2.34}$$

In the third line above, we used $*$-Cramer's rule and our previous definition of $\overline{S}_{k,\omega}$. The factor $(-1)^{\omega+1}$ comes from a cofactor expansion in the numerator of Cramer's rule for $(S_\omega^{-1})_{1\omega}$ and $(S_\omega^{-1})_{\omega1}$; the factor $(-1)^{\omega-1}$ comes from the determinant of a triangular matrix with -1's along the diagonal after the latter expansion. In the fourth line, we used results from Theorem 2; namely, $\overline{S}_{\omega,\omega}=\det\overline{S}_{\omega}$, $\epsilon\det\overline{S}_{\omega}\approx\sin\lambda t/\lambda$, and $\overline{S}_{\omega,\omega}-\overline{S}_{\omega-1,\omega}\approx\overline{D}_{\omega,\omega}\approx\cos\lambda t$. □

Notice that in (2.34), the end result depends only on the end points of the path w. It does not matter which path is chosen as long as it starts at q and ends at q_0. Hence, it is not necessary to use the classical path x^{cl} to do the computation.

Theorem 2.8: *For $t<\pi/\lambda$, the one-dimensional harmonic oscillator standard functional integral is given by*

$$\left(\frac{m}{2\pi i\hbar}\right)^{1/2}\sqrt{\frac{\lambda}{\sin\lambda t}}\exp\left\{\frac{im}{\hbar}\,\frac{\lambda}{\sin\lambda t}\left[(q_0^2+q^2)\cos\lambda t-2qq_0\right]\right\}. \tag{2.35}$$

Proof: This follows from Corollary 2.4, Theorem 2.6, and Proposition 2.7. □

Corollary 2.9: For the d-dimensional harmonic oscillator standard functional integral, we have

$$st\left\{\int_{*\mathbb{R}^{d\omega}}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{(d/2)(\omega+1)}*\exp\left[\frac{i\epsilon}{\hbar}\sum_{j=1}^{\omega+1}\left[\frac{m}{2}\left(\frac{x_j-x_{j-1}}{\epsilon}\right)^2-\frac{m}{2}\lambda^2x_j^2\right]\right]dx_1\cdots dx_\omega\right\}$$

$$=\left(\frac{m}{2\pi i\hbar}\right)^{d/2}\left(\frac{\lambda}{\sin\lambda t}\right)^{d/2}\exp\left\{\frac{im}{\hbar}\,\frac{\lambda}{\sin\lambda t}\left[(\mathbf{q}_0^2+\mathbf{q}^{-2})\cos\lambda t-2\mathbf{q}\mathbf{q}_0\right]\right\}. \tag{2.36}$$

Proof: Follows from factoring (2.36) into products of one-dimensional harmonic oscillator standard functional integrals and Theorem 2.8. □

Bose–Einstein condensation in an external potential at zero temperature: Solitary-wave theory

Dionisios Margetis[a)]
Gordon McKay Laboratory, Harvard University, Cambridge, Massachusetts 02138-2901

(Received 28 June 1999; accepted for publication 26 July 1999)

For a trapped, dilute atomic gas of short-range, repulsive interactions at extremely low temperatures, when Bose–Einstein condensation is nearly complete, some special forms of the time-dependent condensate wave function and the pair-excitation function, the latter being responsible for phonon creation, are investigated. Specifically, (i) a class of external potentials $V_e(\mathbf{r},t)$ that allow for localized, shape-preserving solutions to the nonlinear Schrödinger equation for the condensate wave function, each recognized as a solitary wave moving along an arbitrary trajectory, is derived and analyzed in any number of space dimensions; and (ii) for any such external potential and condensate wave function, the nonlinear integro-differential equation for the pair-excitation function is shown to admit solutions of the same nature. Approximate analytical results are presented for a sufficiently slowly varying trapping potential. Numerical results are obtained for the condensate wave function when V_e is a time-independent, spherically symmetric harmonic potential. © *1999 American Institute of Physics.* [S0022-2488(99)03211-9]

I. INTRODUCTION

The first successful experiments on Bose–Einstein condensation in dilute atomic gases were reported recently by the groups at JILA,[1] Rice University,[2] and MIT.[3] In their respective experiments, vapors of ^{87}Rb, ^{7}Li, and ^{23}Na atoms were confined by traps of inhomogeneous magnetic fields acting on the spin of the unpaired electron of each atom. A combination of laser and evaporative cooling techniques were employed to cool each gas below the phase transition point. Many similar experiments followed soon after these pioneering works. These experimental observations have, in turn, stimulated theoretical interest, with emphasis on the study of the effect on condensation of parameters that can be controlled externally, aiming at new predictions or designs of future experiments. Major problems related to Bose–Einstein condensation in a trap include equilibrium and nonequilibrium properties of the boson gas, such as collective excitations and vortices, and description of time evolution under the influence of time-dependent trapping potentials.

An entirely quantum mechanical treatment of Bose–Einstein condensation in dilute systems of hard spheres lacking translational symmetry at extremely low temperatures, when condensation into a single-particle state is nearly complete, was given in 1961 by Wu.[4] In his approach, the two crucial quantities for the minimal description of the Bose system are: (i) the condensate wave function $\Phi(\mathbf{r},t)$, which, to the lowest approximation in the particle density, satisfies a Schrödinger equation with a self-coupling term of third order, also derived by Gross[5] and Pitaevskii[6] by other methods, and (ii) the pair-excitation function $K_0(\mathbf{r},\mathbf{r}';t)$, which describes the scattering of two atoms from the condensate to other states at positions $\mathbf{r}$ and $\mathbf{r}'$, offers a systematic treatment of physical effects such as sound vibrations, and provides corrections to higher orders in the particle density; $K_0(\mathbf{r},\mathbf{r}';t)$ was shown to satisfy a nonlinear integro-differential equation. To the lowest approximation, this analysis has recently been extended both for zero and finite temperatures to incorporate the effect of a sufficiently smooth external potential that increases rapidly at large

[a)]Electronic mail: dmarget@fas.harvard.edu

distances.[7–9] Of particular significance is the underlying ansatz for the many-body Schrödinger state vector at zero temperature:[4,7,8]

$$\mathbf{\Psi}(t)=\mathcal{N}(t)e^{\mathcal{P}(t)}(N!)^{-1/2}a_0^*(t)^N|\mathrm{vac}\rangle, \tag{1.1}$$

where $\mathcal{P}(t)$ describes the creation of pairs from the condensate

$$\mathcal{P}(t)=(2N)^{-1}\int d\mathbf{r}\,d\mathbf{r}'\,\psi_1^*(\mathbf{r},t)\psi_1^*(\mathbf{r}',t)K_0(\mathbf{r},\mathbf{r}';t)a_0(t)^2, \tag{1.2}$$

$\mathcal{N}(t)$ is the normalization constant, which is immaterial for present purposes, N is the total number of atoms, $a_0^*(t)$ and $a_0(t)$ are the creation and annihilation operators for the condensate, respectively, and $\psi_1^*(\mathbf{r},t)$ is the boson creation field operator corresponding to the space orthogonal to the condensate wave function. Formula (1.1), being combined with a consistent approximation for the N-body Hamiltonian, is a nontrivial generalization of the many-body wave function of Lee, Huang, and Yang[10] for the case with translational invariance and periodic boundary conditions, where the main effect of particle interactions is the creation and annihilation of pairs of opposite momenta. The inclusion of pair excitation according to Eq. (1.1) necessarily modifies the equation of motion for $\Phi(\mathbf{r},t)$. Some physically interesting implications of this second-order approximation without any external potential, such as the difference between a compressional wave and a phonon, are discussed in Ref. 4.

Recent numerical or analytical studies of properties of nonuniform atomic gases undergoing Bose–Einstein condensation at extremely low temperatures have focused on the nonlinear Schrödinger equation for the condensate wave function either in its time-independent[8,11–14] or its time-dependent form.[15] A different approach by Benjamin, Quiroga, and Johnson[16] deals with the relative motion of the atoms in a hyperspherical coordinate system, with application to two-dimensional harmonic traps. In other contexts, several types of nonlinear Schrödinger equations are examined in the light of soliton theory,[17] often with emphasis on the description and conditions of existence of a pulselike solution—from now on referred to as a solitary wave—whose main feature is the preservation of its shape during propagation. A summary and discussion of some of these approaches can be found in the very recent comprehensive paper by Morgan *et al.*,[18] whose terminology is mainly adopted here.

Soliton theory usually describes nonlinear waves that interact like classical elastic particles, in the sense that the initial shape and velocity of the waves are regained asymptotically, yet possibly with a phase shift. Studies of such a behavior are believed to have been motivated from some unusual findings in a computation by Fermi, Pasta, and Ulam in 1955.[19,20] Significant advances toward the understanding of solutions to the underlying Korteweg–deVries (or KdV) equation were made ten years later by Zabusky and Kruskal,[21] followed by systematic investigations of Gardner *et al.*[22] A good list of references and exposition of methods or concepts germane to widely known types of evolution equations are given in Ref. 23. It has been realized that a central role in soliton theory is played by the ''Bäcklund transformations,'' which have provided a test for solitonic behavior and led to higher soliton solutions to some equations. (For a review of the mathematically advanced theory, see Ref. 19 and the references therein.)

It is well-known that the Schrödinger equation with a self-coupling term of third order and zero external potential admits soliton solutions in the sense of Ref. 24. In general, the inclusion of a term accounting for an external potential modifies the nature of the associated solutions, as is pointed out in Ref. 18. Specifically, Morgan *et al.*[18] examine conditions on nonlinear terms and accompanying external potentials that allow for localized solitary-wave solutions, and provide a physical interpretation of their results. They justifiably conclude that (i) such nonlinearities should not explicitly depend on the space variable x in $(1+1)$ dimensions, and (ii) the change in the potential experienced by the wave must be linear in x. They subsequently attempt to extend their results to higher dimensions, with restriction to motion along fixed axes in space. This in turn imposes conditions on the external potential, which they briefly describe. Notably, one-dimensional motion of shape-preserving pulses of the condensate wave function is also studied in

Refs. 25 and 26 for positive and negative scattering lengths, respectively, with restriction to time-independent parabolic potentials of weak confinement along one specified axis (cigar-shaped traps).

It should be emphasized, however, that, although it simplifies the treatment, the assumption of rectilinear motion in a space of dimensions higher than one is not necessary for the existence of solitary-wave solutions: motion of the solitary wave along an arbitrary trajectory in any number of space dimensions is possible, provided the external potential is consistently chosen. Furthermore, in Refs. 18, 25, and 26 the effects of scattering processes due to atomic interactions are ignored. Such a simplified approach, though adequate for some cases of experimental relevance, is certainly physically incomplete and needs improvement. It has been argued by others, for instance, that predictions based on the usual nonlinear Schrödinger equation become, in general, questionable for time-dependent systems, when the number of noncondensed particles may grow in time.[27] In the present paper, scattering processes are minimally taken into account through the *joint* consideration of the condensate wave function and the pair-excitation function.[4,7–9] The purpose of this work is to study solitary-wave motion by addressing the aforementioned issues in some detail, complementing, therefore, the analysis in Ref. 18, as a step toward an understanding of more complicated nonequilibrium properties of the trapped Bose gas. An outline of the paper is provided below.

In Sec. II, external potentials $V_e(\mathbf{r},t)$ in $(d+1)$ dimensions $(d\geqslant 1)$ are analyzed under the assumption that they sustain a condensate wave function identified with a single pulse that preserves its shape while moving along an arbitrarily prescribed trajectory in the d-dimensional Euclidean space. Focus is on the Schrödinger equation containing a cubic self-coupling term and positive scattering length a. The analysis starts with $d=1$, but with a perspective different from Ref. 18, and proceeds to generalizing to $d\geqslant 2$. Given a consistent V_e, the initial condition for the condensate wave function, when the nonlinearity plays an important role, is discussed. An argument is sketched to verify that, as a consequence of the requisite decomposition for the potential, the harmonic potentials constitute the sole class of admissible time-independent potentials that allow for solitary-wave solutions.[28] Furthermore, the assumption of nonuniqueness of the derived decomposition for the potential furnishes a class of time-dependent harmonic potentials. In Sec. III, it is demonstrated that the corresponding lowest-order nonlinear integro-differential equation for the pair-excitation function admits solitary waves in $(2d+1)$ dimensions. Section IV proceeds to determine approximately the initial amplitudes for the condensate wave function and the pair-excitation function corresponding to the lowest state of the condensate in a case of experimental interest, namely, when the trapping potential is slowly varying in space. In Sec. V, both analytical and numerical results are obtained for the lowest-energy condensate wave function under a three-dimensional, spherically symmetric harmonic potential.

II. THE CONDENSATE WAVE FUNCTION

The time-dependent nonlinear Schrödinger equation for the condensate wave function $\Phi(\mathbf{r},t)$ in an external potential $V_e(\mathbf{r},t)$ is $(\hbar=2m=1)$[7,8]

$$i(\partial/\partial t)\Phi(\mathbf{r},t)=[-\nabla^2+V_e(\mathbf{r},t)+8\pi aN\Omega^{-1}|\Phi(\mathbf{r},t)|^2-4\pi aN\Omega^{-1}\zeta(t)]\Phi(\mathbf{r},t), \tag{2.1}$$

where

$$\Omega^{-1}\int d\mathbf{r}|\Phi(\mathbf{r},t)|^2=1, \tag{2.2}$$

$$\zeta(t)=\Omega^{-1}\int d\mathbf{r}|\Phi(\mathbf{r},t)|^4, \tag{2.3}$$

a is the scattering length, assumed to be positive, N is the number of particles, and Ω is the volume of the system.

For mathematical convenience, Eq. (2.1) is cast in the form

$$i(\partial/\partial t)F(\mathbf{r},t)=[-\nabla^2+V_e(\mathbf{r},t)+|F(\mathbf{r},t)|^2]F(\mathbf{r},t), \tag{2.4}$$

where

$$F(\mathbf{r},t)=(8\pi a\rho_0)^{1/2}e^{-i4\pi\alpha\rho_0\sigma(t)}\Phi(\mathbf{r},t), \quad \rho_0=N/\Omega, \tag{2.5}$$

provided that

$$\sigma(t)=\int^t dt\,\zeta(t)+\text{const}, \tag{2.6}$$

where $\int^t$ denotes an indefinite integral. The normalization condition (2.2) now reads

$$\int d\mathbf{r}|F(\mathbf{r},t)|^2=8\pi aN. \tag{2.7}$$

A. The one-dimensional nonlinear Schrödinger equation

In the one-dimensional case, both the external potential and the condensate wave function depend on one space variable, say x. Equation (2.4) then becomes

$$i\,\frac{\partial F(x,t)}{\partial t}=\left[-\frac{\partial^2}{\partial x^2}+V_e(x,t)+|F(x,t)|^2\right]F(x,t). \tag{2.8}$$

For $V_e=0$, this reduces to the more or less standard form of the nonlinear Schrödinger equation.[24] Solitary-wave solutions of this equation are assumed to be of the form (see the Appendix):

$$F(x,t)=f(x-\alpha(t))e^{-i\theta(x,t)}, \tag{2.9}$$

where $f(x)$ and $\theta(x,t)$ are real functions, sufficiently smooth in x and t, and $\alpha(t)$ is a continuously differentiable function of time. Under the assumption of a potential $V_e(x,t)$ increasing sufficiently rapidly for $x\to\pm\infty$, it is necessary to require that

$$f(x)\to 0 \ \text{ rapidly } \quad \text{as } |x|\to\infty. \tag{2.10}$$

The example of the one-dimensional harmonic oscillator (briefly reviewed in the Appendix) suggests that f should decrease faster than exponentially in $|x|$ for large values of $|x|$. The same conclusion can be reached by employing the Wentzel–Kramers–Brillouin method.

The substitution of Eq. (2.9) into Eq. (2.8), and separation of real and imaginary parts, yield a system of coupled differential equations for f and θ:

$$f(x-\alpha(t))\,\frac{\partial^2\theta}{\partial x^2}+2f'(x-\alpha(t))\,\frac{\partial\theta}{\partial x}=-\alpha'(t)f'(x-\alpha(t)), \tag{2.11}$$

$$-f''(x-\alpha(t))+\left(\frac{\partial\theta}{\partial x}\right)^2 f(x-\alpha(t))+[V_e(x,t)+f(x-\alpha(t))^2]f(x-\alpha(t))=\frac{\partial\theta}{\partial t}f(x-\alpha(t)), \tag{2.12}$$

where the prime denotes differentiation with respect to argument. Equation (2.11) can be rewritten as

$$\frac{\partial}{\partial x}\left[f(x-\alpha(t))^2\frac{\partial\theta}{\partial x}\right]=-\alpha'(t)f'(x-\alpha(t))f(x-\alpha(t)). \tag{2.13}$$

This is explicitly integrated to give

$$\frac{\partial\theta}{\partial x}=-\frac{1}{2}\alpha'(t)+\frac{A_1(t)}{f(x-\alpha(t))^2}, \tag{2.14}$$

except at points $x=x(t)$ where $f(x-\alpha(t))$ vanishes. It immediately follows that

$$\theta(x,t)=\int^x dx\,\frac{\partial\theta}{\partial x}+A(t)=-\frac{1}{2}\alpha'(t)x+\int^x dx\,\frac{A_1(t)}{f(x-\alpha(t))^2}+A(t), \tag{2.15}$$

where x lies between consecutive zeros of $f(x-\alpha(t))$, calling for the possible use of different corresponding A_1's and A's. Consider the simplest case where f has no zeros. According to the preceding formula, for nonzero $A_1(t)$, the limiting behavior of f at large distances x and fixed time t gives rise to increasingly rapid oscillations in x of the real and imaginary parts of the condensate wave function. This in turn implies an infinite expectation value of the kinetic energy term $-\partial^2/\partial x^2$ in the Hamiltonian of the system. To eliminate this unphysical possibility, it is necessary to set $A_1(t)$ equal to zero:

$$A_1(t)\equiv 0. \tag{2.16}$$

To put this argument on a firm foundation, it is expedient to invoke the following conditions.

(i) Normalizability of $F(x,t)$ from Eq. (2.7), viz.

$$\int dx|F(x,t)|^2=\int dx\, f(x-\alpha(t))^2<\infty. \tag{2.17}$$

(ii) Finite kinetic energy of the condensate, viz.

$$\int dx\,F^*(x,t)\left(-\frac{\partial^2}{\partial x^2}\right)F(x,t)=\int dx\left|\frac{\partial F}{\partial x}\right|^2<\infty. \tag{2.18}$$

The last condition entails

$$\int dx\, f'(x-\alpha(t))^2<\infty, \tag{2.19a}$$

$$\int dx\left(\frac{\partial\theta}{\partial x}\right)^2 f(x-\alpha(t))^2<\infty. \tag{2.19b}$$

The use of Eqs. (2.14) and (2.17) in Eq. (2.19b) gives

$$\int dx\,A_1(t)\left[-\alpha'(t)+\frac{A_1(t)}{f(x-\alpha(t))^2}\right]<\infty, \tag{2.20}$$

which is impossible unless identity (2.16) holds. A similar argument can be applied to the case where f has any number of zeros.

For smooth real f, the resulting phase $\theta(x,t)$ is

$$\theta(x,t)=-\tfrac{1}{2}\alpha'(t)x+A(t), \tag{2.21}$$

in agreement with Eq. (9) of Ref. 18. The substitution of Eq. (2.21) into Eq. (2.12) yields a consistency equation for $V_e(x,t)$:

$$f''(x-\alpha(t))=[V_e(x,t)+f(x-\alpha(t))^2+\tfrac{1}{2}\alpha''(t)x+\tfrac{1}{4}\alpha'(t)^2-A'(t)]f(x-\alpha(t)). \tag{2.22}$$

It is inferred that $V_e(x,t)$ must be expressed as

$$V_e(x,t)=\mathcal{V}_1(x-\alpha(t))+x\mathcal{V}_2(t)+\mathcal{V}_3(t), \tag{2.23}$$

where

$$\mathcal{V}_1(x)=\frac{f''(x)}{f(x)}-f(x)^2, \tag{2.24}$$

$$\mathcal{V}_2(t)=-\tfrac{1}{2}\alpha''(t), \tag{2.25}$$

$$\mathcal{V}_3(t)=-\tfrac{1}{4}\alpha'(t)^2+A'(t). \tag{2.26}$$

Equation (2.23) gives the requisite form of potentials for given $f(x)$, $\alpha(t)$, and $A(t)$. Note that some of the inflection points of $f(x)$ need to coincide with its zeros. By close examination of Eqs. (2.23)–(2.26), the following should be pointed out.

(1) Given a $\mathcal{V}_1(x)$, the differential equation (2.24) suggests, in some sense, an eigenvalue problem. More particularly, when $|x|$ is sufficiently large, condition (2.10) becomes effective, indicating that $f^2 \ll |f''/f|$. Under this approximation, Eq. (2.24) becomes

$$f''(x)\sim\mathcal{V}_1(x)f(x), \tag{2.27a}$$

which is a linear equation. Hence, only discrete shifts ϵ_m of $\mathcal{V}_1(x)=\mathcal{V}_{1m}(x)$ are permissible, corresponding to ''eigenfunctions'' $f=f_m$ (m=non-negative integer). These shifts in turn induce discrete amounts of shift in $A'(t)$ through Eqs. (2.23) and (2.26). Accordingly, $F(x,t)$ exhibits a behavior of the form $e^{-i\epsilon_m t}f_m(x-\alpha(t))$ in the fixed trapping potential

$$\mathcal{V}_e(x)=\mathcal{V}_{1m}(x)+\sum_{l\leqslant m-1}\epsilon_l+C_0 \tag{2.27b}$$

experienced by the pulse, where C_0 is a constant.[29]

(2) For $\alpha(t)$ different from a constant, the only class of time-independent potentials $V_e(x,t)=V_e(x)$ of the form (2.23) consists of the harmonic potentials. Indeed, differentiation in x of both sides of Eq. (2.23) twice yields

$$V_e''(x)=\mathcal{V}_l''(x-\alpha(t))=K=\text{const}>0. \tag{2.28}$$

Hence,

$$V_e(x)=\tfrac{1}{2}Kx^2+\overline{K}x+\mathcal{C}. \tag{2.29}$$

(3) If $V_e(x,t)$ admits a second decomposition

$$V_e(x,t)=\mathcal{U}_1(x-\beta(t))+x\mathcal{U}_2(t)+\mathcal{U}_3(t), \tag{2.30}$$

where

$$\mathcal{U}_1(x)=\frac{\breve{f}''(x)}{\breve{f}(x)}-\breve{f}(x)^2, \tag{2.31}$$

$$\mathcal{U}_2(t)=-\tfrac{1}{2}\beta''(t), \tag{2.32}$$

$$\mathcal{U}_3(t)=-\tfrac{1}{4}\beta'(t)^2+B'(t), \tag{2.33}$$

and $\mathcal{U}_1(x)\neq\mathcal{V}_1(x)$, $\mathcal{U}_3(t)\neq\mathcal{V}_3(t)$, two cases for $\alpha(t)$ and $\beta(t)$ need to be distinguished.

(i) $\alpha(t)-\beta(t)\neq\text{const}$. Differentiation of Eqs. (2.23) and (2.30) with respect to x twice yields

$$\mathcal{V}_1''(x-\alpha(t))=\mathcal{U}_1''(x-\beta(t))=K. \tag{2.34}$$

Therefore,

$$V_e(x,t)=\tfrac{1}{2}K[x-\alpha(t)]^2+K_1[x-\alpha(t)]+K_2+x\mathcal{V}_2(t)+\mathcal{V}_3(t) \tag{2.35a}$$

$$=\tfrac{1}{2}K[x-\beta(t)]^2+M_1[x-\beta(t)]+M_2+x\mathcal{U}_2(t)+\mathcal{U}_3(t), \tag{2.35b}$$

i.e., $V_e(x,t)$ is the *time-dependent* harmonic potential

$$V_e(x,t)=\tfrac{1}{2}Kx^2+\overline{K}(t)x+\mathcal{C}(t) \quad (K>0). \tag{2.36}$$

A comparison of Eqs. (2.35a) and (2.35b) furnishes the consistency equations

$$-K\alpha(t)+K_1+\mathcal{V}_2(t)=-K\beta(t)+M_1+\mathcal{U}_2(t), \tag{2.37a}$$

$$\tfrac{1}{2}K\alpha(t)^2-K_1\alpha(t)+K_2+\mathcal{V}_3(t)=\tfrac{1}{2}K\beta(t)^2-M_1\beta(t)+M_2+\mathcal{U}_3(t). \tag{2.37b}$$

(ii) $\alpha(t)-\beta(t)=\mathcal{C}_1=\text{const}$. From Eqs. (2.25) and (2.32),

$$\mathcal{V}_2(t)=\mathcal{U}_2(t). \tag{2.38}$$

Equations (2.23) and (2.30) combined give

$$\mathcal{V}_3(t)-\mathcal{U}_3(t)=\mathcal{U}_1(x-\mathcal{C}_1)-\mathcal{V}_1(x)=\epsilon=\text{const}. \tag{2.39}$$

In view of (2.26) and (2.33),

$$A(t)=B(t)+\epsilon t+\text{const}. \tag{2.40}$$

The meaning of this ϵ becomes apparent from Eqs. (2.27): it is the discrete amount of shift in $\mathcal{V}_1(x)$ corresponding to a shift from the ''eigenfunction'' $f(x)$ to another ''eigenfunction'' $\breve{f}(x)$ under the same trapping potential $\mathcal{V}_e$ experienced by the solitary wave.

B. The nonlinear Schrödinger equation in d space dimensions, $d\geqslant 2$

The foregoing analysis in one dimension can be extended to higher dimensions. For definiteness, consider $d=3$. In accord with the conditions in the recent experiments,[1–3] it is assumed that

$$V_e(\mathbf{r},t)\to+\infty, \quad \text{uniformly in } \hat{\mathbf{r}}=\mathbf{r}/|\mathbf{r}| \quad \text{as } r=|\mathbf{r}|\to\infty. \tag{2.41}$$

Instead of assuming motion of the solitary wave along a fixed axis, as is the case in Ref. 18, let

$$F(\mathbf{r},t)=f(\mathbf{r}-\boldsymbol{\alpha}(t))e^{-i\theta(\mathbf{r},t)}, \tag{2.42}$$

where $\boldsymbol{\alpha}(t)$ is a twice differentiable vector function of time, $f(\mathbf{r})$ and $\theta(\mathbf{r},t)$ are real and sufficiently smooth, and from Eq. (2.7),

$$\int d\mathbf{r}\, f(r-\boldsymbol{\alpha}(t))^2=8\pi aN. \tag{2.43}$$

In view of condition (2.41), it is reasonable to assume that

$$f\to 0 \quad \text{rapidly}, \quad \text{uniformly in } \hat{\mathbf{r}}=\mathbf{r}/|\mathbf{r}| \quad \text{as } r\to\infty, \tag{2.44}$$

ensuring that the condensate is localized and has a finite kinetic energy, as indicated in the Appendix. The substitution of Eq. (2.42) in Eq. (2.4) gives

$$-i\boldsymbol{\alpha}'(t)\cdot\nabla f(\mathbf{r}-\boldsymbol{\alpha}(t))+f(\mathbf{r}-\boldsymbol{\alpha}(t))\frac{\partial\theta(\mathbf{r},t)}{\partial t}=-\nabla^2 f(\mathbf{r}-\boldsymbol{\alpha}(t))+2i\nabla f(\mathbf{r}-\boldsymbol{\alpha}(t))\cdot\nabla\theta(\mathbf{r},t)$$
$$+if(\mathbf{r}-\boldsymbol{\alpha}(t))\nabla^2\theta(\mathbf{r},t)+f(\mathbf{r}-\boldsymbol{\alpha}(t))|\nabla\theta(\mathbf{r},t)|^2$$
$$+[V_e(\mathbf{r},t)+f(\mathbf{r}-\boldsymbol{\alpha}(t))^2]f(\mathbf{r}-\boldsymbol{\alpha}(t)). \tag{2.45}$$

Upon separation of real and imaginary parts, the preceding equation decomposes into

$$-\boldsymbol{\alpha}'(t)\cdot\nabla f(\mathbf{r}-\boldsymbol{\alpha}(t))=2\nabla f(\mathbf{r}-\boldsymbol{\alpha}(t))\cdot\nabla\theta(\mathbf{r},t)+f(\mathbf{r}-\boldsymbol{\alpha}(t))\nabla^2\theta(\mathbf{r},t), \tag{2.46}$$

$$f(\mathbf{r}-\boldsymbol{\alpha}(t))\frac{\partial\theta(\mathbf{r},t)}{\partial t}=-\nabla^2 f(\mathbf{r}-\boldsymbol{\alpha}(t))+|\nabla\theta(\mathbf{r},t)|^2 f(\mathbf{r}-\boldsymbol{\alpha}(t))$$
$$+[V_e(\mathbf{r},t)+f(\mathbf{r}-\boldsymbol{\alpha}(t))^2]f(\mathbf{r}-\boldsymbol{\alpha}(t)). \tag{2.47}$$

Equation (2.46) is recast in the form

$$\nabla\cdot(f^2\nabla\theta)=-f\boldsymbol{\alpha}'(t)\cdot\nabla f, \quad f=f(\mathbf{r}-\boldsymbol{\alpha}(t)), \tag{2.48}$$

which holds regardless of the specific form for the shape $f=f(\mathbf{r},t)$ of $F(\mathbf{r},t)$. A particular solution to this equation is

$$\theta_p(\mathbf{r},t)=-\tfrac{1}{2}\boldsymbol{\alpha}'(t)\cdot\mathbf{r}+A(t). \tag{2.49}$$

With $\theta=\theta_p+\theta_1$, $\theta_1(\mathbf{r},t)$ satisfies the homogeneous equation

$$\nabla\cdot(f^2\nabla\theta_1)=0. \tag{2.50}$$

Integration by parts over a finite region $\mathcal{R}$ bounded by a surface $\mathcal{S}$ yields

$$0=\int d\mathbf{r}\,\theta_1\nabla\cdot(f^2\nabla\theta_1)=\oint_{\mathcal{S}}d\mathcal{S}\,f^2\theta_1\hat{\mathbf{n}}\cdot\nabla\theta_1-\int d\mathbf{r}\,f^2|\nabla\theta_1|^2, \tag{2.51}$$

where $\hat{\mathbf{n}}$ is the unit vector normal to $\mathcal{S}$ pointing outward. When $\mathcal{R}$ extends to infinity, the surface integral becomes arbitrarily small because of the condition (2.44), in analogy with the one-dimensional case. Consequently,

$$f^2|\nabla\theta_1|^2=0 \quad \text{almost everywhere}, \tag{2.52}$$

i.e., except for a set of points of measure zero. When $f\neq 0$, this in turn entails

$$\theta_1(\mathbf{r},t)=C_1(t) \quad \text{almost everywhere}. \tag{2.53}$$

At the zeros of f, $|\nabla\theta_1|$ seems to be indeterminate, calling for the use of different C_1's in Eq. (2.53). However, for a sufficiently smooth $\theta(\mathbf{r},t)$, $C_1(t)$ can be taken to be zero everywhere without loss of generality. Accordingly, $\theta(\mathbf{r},t)$ reads

$$\theta(\mathbf{r},t)=\theta_p(\mathbf{r},t)=-\tfrac{1}{2}\boldsymbol{\alpha}'(t)\cdot\mathbf{r}+A(t), \tag{2.54}$$

which is a generalization of Eq. (2.21).

The external potential consistent with Eqs. (2.47) and (2.54) is

$$V_e(\mathbf{r},t)=\mathcal{V}_1(\mathbf{r}-\boldsymbol{\alpha}(t))+\boldsymbol{\mathcal{V}}_2(t)\cdot\mathbf{r}+\mathcal{V}_3(t), \tag{2.55}$$

where

$$\mathcal{V}_1(\mathbf{r})=\frac{\nabla^2 f(\mathbf{r})}{f(\mathbf{r})}-f(\mathbf{r})^2, \tag{2.56}$$

$$\boldsymbol{\mathcal{V}}_2(t)=-\tfrac{1}{2}\boldsymbol{\alpha}''(t), \tag{2.57}$$

$$\mathcal{V}_3(t)=-\tfrac{1}{4}|\boldsymbol{\alpha}'(t)|^2+A'(t). \tag{2.58}$$

Notably, $\nabla^2 f(\mathbf{r})$ needs to vanish at any surface where $f(\mathbf{r})$ vanishes.

A few important remarks are in order.

(1) For an external potential increasing in $|\mathbf{r}|$, Eq. (2.56) bears the features of an eigenvalue problem. Specifically, for $|\mathbf{r}|\to\infty$, a linear equation is recovered approximately:

$$\nabla^2 f(\mathbf{r})\sim\mathcal{V}_1(\mathbf{r})f(\mathbf{r}). \tag{2.59}$$

Analogies with the one-dimensional case are easily drawn from this equation.

(2) When $\boldsymbol{\alpha}(t)$ is not a constant, the only time-independent potential of the form (2.55) that satisfies condition (2.41) is the d-dimensional harmonic potential. The justification for this is somewhat more demanding than for the one-dimensional case. With $V_e(\mathbf{r},t)=V_e(\mathbf{r})$, the application of the Laplacian to both sides of Eq. (2.55) gives

$$\nabla^2 V_e(\mathbf{r})=\nabla^2\mathcal{V}_1(\mathbf{r}-\boldsymbol{\alpha}(t))=K=\text{const}>0. \tag{2.60}$$

In three dimensions, a solution to Eq. (2.60) for $V_e(\mathbf{r})$ is:

$$V_p(\mathbf{r})=\frac{1}{2}\sum_{i,j=1,2,3}K_{ij}x_i x_j+\sum_{j=1,2,3}\overline{K}_j x_j+\mathcal{C}, \tag{2.61}$$

where $(x_1,x_2,x_3)=\mathbf{r}=(x,y,z)$,

$$\text{Tr}[K_{ij}]=K, \tag{2.62}$$

and the matrix $[K_{ij}]$ is symmetric and positive definite. Every admissible solution to Eq. (2.60) can be written as

$$V_e(\mathbf{r})=V_p(\mathbf{r})+V_1(\mathbf{r}), \tag{2.63}$$

where $V_1(\mathbf{r})$ is a smooth function satisfying Laplace's equation:

$$\nabla^2 V_1(\mathbf{r})=0 \quad \text{everywhere}. \tag{2.64}$$

If $\mathcal{S}$ is now a spherical surface with center $\mathbf{r}$ and radius R, then according to Gauss' mean value theorem[30]

$$V_1(\mathbf{r})=\frac{1}{4\pi R^2}\oint_{\mathcal{S}}dS'\,V_1(\mathbf{r}'). \tag{2.65}$$

Since R can be taken to be arbitrarily large, it follows that V_1 cannot be forced to comply with condition (2.41). Consequently, $V_1(\mathbf{r})$ is equal to a constant. Without loss of generality,

$$V_1(\mathbf{r})\equiv 0. \tag{2.66}$$

(3) Let $V_e(\mathbf{r},t)$ admit an alternative decomposition,

$$V_e(\mathbf{r},t)=\mathcal{U}_1(\mathbf{r}-\boldsymbol{\beta}(t))+\mathbf{r}\cdot\boldsymbol{\mathcal{U}}_2(t)+\mathcal{U}_3(t), \tag{2.67}$$

where

$$\mathcal{U}_1(\mathbf{r}) = \frac{\nabla^2 \breve{f}(\mathbf{r})}{\breve{f}(\mathbf{r})} - \breve{f}(\mathbf{r})^2, \tag{2.68}$$

$$\boldsymbol{\mathcal{U}}_2(t) = -\tfrac{1}{2}\boldsymbol{\beta}''(t), \tag{2.69}$$

$$\mathcal{U}_3(t) = -\tfrac{1}{4}|\boldsymbol{\beta}'(t)|^2 + B'(t), \tag{2.70}$$

and $\mathcal{U}_1(\mathbf{r}) \neq \mathcal{V}_1(\mathbf{r})$, $\mathcal{U}_3(t) \neq \mathcal{V}_3(t)$. In analogy with the one-dimensional case, there are two distinct possibilities.

(i) $\boldsymbol{\alpha}(t) - \boldsymbol{\beta}(t) \neq \text{const}$. Then,

$$\nabla^2 \mathcal{V}_1(\mathbf{r} - \boldsymbol{\alpha}(t)) = \nabla^2 \mathcal{U}_1(\mathbf{r} - \boldsymbol{\beta}(t)) = K, \tag{2.71}$$

which in turn implies that

$$\begin{aligned} V_e(\mathbf{r},t) &= \frac{1}{2} \sum_{i,j=1,2,3} K_{ij}[x_i - \alpha_i(t)][x_j - \alpha_j(t)] + [\mathbf{r} - \boldsymbol{\alpha}(t)] \cdot \mathbf{K}_1 + K_2 + \mathbf{r} \cdot \boldsymbol{\mathcal{V}}_2(t) + \mathcal{V}_3(t) \\ &= \frac{1}{2} \sum_{i,j=1,2,3} M_{ij}[x_i - \beta_i(t)][x_j - \beta_j(t)] + [\mathbf{r} - \boldsymbol{\beta}(t)] \cdot \mathbf{M}_1 + M_2 + \mathbf{r} \cdot \boldsymbol{\mathcal{U}}_2(t) + \mathcal{U}_3(t), \end{aligned} \tag{2.72}$$

where

$$\mathrm{Tr}[K_{ij}] = \mathrm{Tr}[M_{ij}] = K, \tag{2.73}$$

and K_2, M_2 are immaterial constants. Therefore, $V_e(\mathbf{r},t)$ is the time-dependent harmonic potential

$$V_e(\mathbf{r},t) = \frac{1}{2} \sum_{i,j=1,2,3} K_{ij} x_i x_j + \mathbf{r} \cdot \overline{\mathbf{K}}(t) + \mathcal{C}(t). \tag{2.74}$$

(ii) $\boldsymbol{\alpha}(t) - \boldsymbol{\beta}(t) = \mathbf{C}_1 = \text{const}$. Without loss of generality, $\mathbf{C}_1 = 0$. It is easily found that

$$\boldsymbol{\mathcal{V}}_2(t) = \boldsymbol{\mathcal{U}}_2(t), \tag{2.75}$$

$$\mathcal{V}_3(t) - \mathcal{U}_3(t) = \mathcal{U}_1(\mathbf{r}) - \mathcal{V}_1(\mathbf{r}) = \epsilon = \text{const}. \tag{2.76}$$

Equation (2.76) implies that

$$A(t) = B(t) + \epsilon t + \text{const}. \tag{2.77}$$

Therefore, $\breve{f}(\mathbf{r})$ is just another ''eigenfunction'' of Eq. (2.56) under the same trapping potential $\mathcal{V}_e$ seen by the pulse.

III. THE PAIR-EXCITATION FUNCTION

The pair-excitation function $K_0(\mathbf{r},\mathbf{r}';t)$ satisfies the integro-differential equation[8]

$$\left[i\frac{\partial}{\partial t}-2E(t)\right]K_0(\mathbf{r},\mathbf{r}';t)=-\nabla^2K_0(\mathbf{r},\mathbf{r}';t)-\nabla'^2K_0(\mathbf{r},\mathbf{r}';t)+8\pi a\rho_0\Phi(\mathbf{r},t)^2\delta(\mathbf{r}-\mathbf{r}')$$
$$+\{-2\overline{\zeta}(t)-16\pi a\rho_0\zeta(t)-2\zeta_e(t)+V_e(\mathbf{r},t)+V_e(\mathbf{r}',t)$$
$$+16\pi a\rho_0[|\Phi(\mathbf{r},t)|^2+|\Phi(\mathbf{r}',t)|^2]\}K_0(\mathbf{r},\mathbf{r}';t)$$
$$+8\pi a\rho_0\int d\mathbf{r}''\,\Phi^*(\mathbf{r}'',t)^2K_0(\mathbf{r},\mathbf{r}'';t)K_0(\mathbf{r}',\mathbf{r}'';t)$$
$$-8\pi a\rho_0\Omega^{-1}\Big\{\Phi(\mathbf{r},t)\Phi(\mathbf{r}',t)[|\Phi(\mathbf{r},t)|^2+|\Phi(\mathbf{r}',t)|^2-\zeta(t)]$$
$$+\Phi(\mathbf{r},t)\int d\mathbf{r}''\,K_0(\mathbf{r}',\mathbf{r}'';t)|\Phi(\mathbf{r}'',t)|^2\Phi^*(\mathbf{r}'',t)$$
$$+\Phi(\mathbf{r}',t)\int d\mathbf{r}''\,K_0(\mathbf{r},\mathbf{r}'';t)|\Phi(\mathbf{r}'',t)|^2\Phi^*(\mathbf{r}'',t)\Big\}, \tag{3.1}$$

where

$$E(t)=i\Omega^{-1}\int d\mathbf{r}\,\frac{\partial\Phi(\mathbf{r},t)}{\partial t}\Phi^*(\mathbf{r},t), \tag{3.2}$$

$$\overline{\zeta}(t)=\Omega^{-1}\int d\mathbf{r}|\nabla\Phi(\mathbf{r},t)|^2,\quad \zeta_e(t)=\Omega^{-1}\int d\mathbf{r}\,V_e(\mathbf{r},t)|\Phi(\mathbf{r},t)|^2, \tag{3.3}$$

and $\nabla\equiv\nabla_{\mathbf{r}}$, $\nabla'\equiv\nabla_{\mathbf{r}'}$. Without loss of generality, $K_0(\mathbf{r},\mathbf{r}';t)$ has been chosen to satisfy

$$K_0(\mathbf{r},\mathbf{r}';t)=K_0(\mathbf{r}',\mathbf{r};t), \tag{3.4}$$

$$\int d\mathbf{r}\,\Phi^*(\mathbf{r},t)K_0(\mathbf{r},\mathbf{r}';t)=0. \tag{3.5}$$

In order to investigate the possibility for solitary-wave solutions to Eq. (3.1), the following preliminary steps are taken:

(i) By virtue of Eq. (2.5), $\Phi(\mathbf{r},t)$ is replaced by $(8\pi a\rho_0)^{-1/2}e^{i4\pi a\rho_0\sigma(t)}F(\mathbf{r},t)$.
(ii) To balance out the exponential factor introduced above, $K_0(\mathbf{r},\mathbf{r}';t)$ is written as

$$K_0(\mathbf{r},\mathbf{r}';t)=e^{i8\pi a\rho_0\sigma(t)}\mathcal{K}_0(\mathbf{r},\mathbf{r}';t). \tag{3.6}$$

The resulting equation for this $\mathcal{K}_0(\mathbf{r},\mathbf{r}';t)$ is

$$i\frac{\partial\mathcal{K}_0(\mathbf{r},\mathbf{r}';t)}{\partial t}=-\nabla^2\mathcal{K}_0(\mathbf{r},\mathbf{r}';t)-\nabla'^2\mathcal{K}_0(\mathbf{r},\mathbf{r}';t)+F(\mathbf{r},t)^2\delta(\mathbf{r}-\mathbf{r}')+\{V_e(\mathbf{r},t)+V_e(\mathbf{r}',t)$$
$$+2[|F(\mathbf{r},t)|^2+|F(\mathbf{r}',t)|^2]\}\mathcal{K}_0(\mathbf{r},\mathbf{r}';t)+\int d\mathbf{r}''\,F^*(\mathbf{r}'',t)^2\mathcal{K}_0(\mathbf{r},\mathbf{r}'';t)\mathcal{K}_0(\mathbf{r}',\mathbf{r}'';t)$$
$$-(8\pi aN)^{-1}\Big\{F(\mathbf{r},t)F(\mathbf{r}',t)[|F(\mathbf{r},t)|^2+|F(\mathbf{r}',t)|^2-\hat{\zeta}(t)]$$
$$+F(\mathbf{r},t)\int d\mathbf{r}''\,\mathcal{K}_0(\mathbf{r}',\mathbf{r}'';t)|F(\mathbf{r}'',t)|^2F^*(\mathbf{r}'',t)$$
$$+F(\mathbf{r}',t)\int d\mathbf{r}''\,\mathcal{K}_0(\mathbf{r},\mathbf{r}'';t)|F(\mathbf{r}'',t)|^2F^*(\mathbf{r}'',t)\Big\}, \tag{3.7}$$

where

$$\hat{\zeta}(t)=8\pi a\rho_0\zeta(t), \tag{3.8}$$

and $E(t)$ was replaced by

$$E(t)=\overline{\zeta(t)}+\zeta_e(t)+4\pi a\rho_0\zeta(t), \tag{3.9}$$

by employing Eq. (2.1).

Given Eqs. (2.42) and (3.4), solitary-wave solutions are sought in the form

$$\mathcal{K}_0(\mathbf{r},\mathbf{r}';t)=\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))e^{-i\chi(\mathbf{r},\mathbf{r}';t)}, \tag{3.10}$$

where $\kappa_0(\mathbf{r},\mathbf{r}')$, $\chi(\mathbf{r},\mathbf{r}';t)$, and $\boldsymbol{\gamma}(t)$ are sufficiently smooth real functions satisfying

$$\kappa_0(\mathbf{r},\mathbf{r}')=\kappa_0(\mathbf{r}',\mathbf{r}),\qquad \chi(\mathbf{r},\mathbf{r}';t)=\chi(\mathbf{r}',\mathbf{r};t), \tag{3.11}$$

$$\int d\mathbf{r}\, f(\mathbf{r}-\boldsymbol{\alpha}(t))\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))e^{i[\theta(\mathbf{r},t)-\chi(\mathbf{r},\mathbf{r}';t)]}=0. \tag{3.12}$$

The substitution of Eq. (3.10) into Eq. (3.7) by virtue of Eqs. (2.42) and (2.55) yields

$$\begin{aligned}
&-i\boldsymbol{\gamma}'(t)\cdot(\nabla\kappa_0+\nabla'\kappa_0)+\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))\frac{\partial\chi(\mathbf{r},\mathbf{r}';t)}{\partial t}\\
&\quad=-\nabla^2\kappa_0-\nabla'^2\kappa_0+2i(\nabla\kappa_0\cdot\nabla\chi+\nabla'\kappa_0\cdot\nabla'\chi)+i\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))(\nabla^2\chi+\nabla'^2\chi)\\
&\qquad+\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))(|\nabla\chi|^2+|\nabla'\chi|^2)+f(\mathbf{r}-\boldsymbol{\alpha}(t))^2\delta(\mathbf{r}-\mathbf{r}')e^{i\chi(\mathbf{r},\mathbf{r}';t)-i2\theta(\mathbf{r},t)}\\
&\qquad+\{\mathcal{V}_1(\mathbf{r}-\boldsymbol{\alpha}(t))+\mathcal{V}_1(\mathbf{r}'-\boldsymbol{\alpha}(t))+(\mathbf{r}+\mathbf{r}')\cdot\boldsymbol{\mathcal{V}}_2(t)+2\mathcal{V}_3(t)\\
&\qquad+2[f(\mathbf{r}-\boldsymbol{\alpha}(t))^2+f(\mathbf{r}'-\boldsymbol{\alpha}(t))^2]\}\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))\\
&\qquad+\int d\mathbf{r}''\, f(\mathbf{r}''-\boldsymbol{\alpha}(t))^2\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}''-\boldsymbol{\gamma}(t))\kappa_0(\mathbf{r}'-\boldsymbol{\gamma}(t),\mathbf{r}''-\boldsymbol{\gamma}(t))\\
&\qquad\times\exp\{2i\theta(\mathbf{r}'',t)-i[\chi(\mathbf{r},\mathbf{r}'';t)+\chi(\mathbf{r}',\mathbf{r}'';t)-\chi(\mathbf{r},\mathbf{r}';t)]\}\\
&\qquad-(8\pi aN)^{-1}\Big\{f(\mathbf{r}-\boldsymbol{\alpha}(t))f(\mathbf{r}'-\boldsymbol{\alpha}(t))[f(\mathbf{r}-\boldsymbol{\alpha}(t))^2+f(\mathbf{r}'-\boldsymbol{\alpha}(t))^2-\hat{\zeta}]\\
&\qquad\times\exp\{i\chi(\mathbf{r},\mathbf{r}';t)-i[\theta(\mathbf{r},t)+\theta(\mathbf{r}',t)]\}\\
&\qquad+f(\mathbf{r}-\boldsymbol{\alpha}(t))\int d\mathbf{r}''\,\kappa_0(\mathbf{r}'-\boldsymbol{\gamma}(t),\mathbf{r}''-\boldsymbol{\gamma}(t))f(\mathbf{r}''-\boldsymbol{\alpha}(t))^3\\
&\qquad\times\exp\{i[\theta(\mathbf{r}'',t)-\theta(\mathbf{r},t)]+i[\chi(\mathbf{r},\mathbf{r}';t)-\chi(\mathbf{r}',\mathbf{r}'';t)]\}\\
&\qquad+f(\mathbf{r}'-\boldsymbol{\alpha}(t))\int d\mathbf{r}''\,\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t)),\mathbf{r}''-\boldsymbol{\gamma}(t))f(\mathbf{r}''-\boldsymbol{\alpha}(t))^3\\
&\qquad\times\exp\{i[\theta(\mathbf{r}'',t)-\theta(\mathbf{r}',t)]+i[\chi(\mathbf{r},\mathbf{r}';t)-\chi(\mathbf{r},\mathbf{r}'';t)]\}\Big\},
\end{aligned} \tag{3.13}$$

where it is understood that $\kappa_0=\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))$ and $\chi=\chi(\mathbf{r},\mathbf{r}';t)$, and $\hat{\zeta}$ is now time independent. Elimination of the above phase factors succeeds if χ is taken equal to

$$\chi(\mathbf{r},\mathbf{r}';t)=\theta(\mathbf{r},t)+\theta(\mathbf{r}',t)=-\tfrac{1}{2}\boldsymbol{\alpha}'(t)\cdot(\mathbf{r}+\mathbf{r}')+2A(t). \tag{3.14}$$

In view of Eq. (3.14), separation of the real and imaginary parts in Eq. (3.13) leads to

$$-\boldsymbol{\gamma}'(t)\cdot(\nabla\kappa_0+\nabla'\kappa_0)=2(\nabla\kappa_0\cdot\nabla\chi+\nabla'\kappa_0\cdot\nabla'\chi)+\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))(\nabla^2\chi+\nabla'^2\chi), \tag{3.15}$$

$$\begin{aligned}
&-\tfrac{1}{2}\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))\boldsymbol{\alpha}''(t)\cdot(\mathbf{r}+\mathbf{r}')+2\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))A'(t)\\
&\quad=-\nabla^2\kappa_0-\nabla'^2\kappa_0+\tfrac{1}{2}\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))|\boldsymbol{\alpha}'(t)|^2+f(\mathbf{r}-\boldsymbol{\alpha}(t))^2\delta(\mathbf{r}-\mathbf{r}')\\
&\qquad+\{\mathcal{V}_1(\mathbf{r}-\boldsymbol{\alpha}(t))+\mathcal{V}_1(\mathbf{r}'-\boldsymbol{\alpha}(t))+(\mathbf{r}+\mathbf{r}')\cdot\boldsymbol{\mathcal{V}}_2(t)+2\mathcal{V}_3(t)\\
&\qquad+2[f(\mathbf{r}-\boldsymbol{\alpha}(t))^2+f(\mathbf{r}'-\boldsymbol{\alpha}(t))^2]\}\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}'-\boldsymbol{\gamma}(t))\\
&\qquad+\int d\mathbf{r}''\,f(\mathbf{r}''-\boldsymbol{\alpha}(t))^2\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t)),\mathbf{r}''-\boldsymbol{\gamma}(t))\kappa_0(\mathbf{r}'-\boldsymbol{\gamma}(t),\mathbf{r}''-\boldsymbol{\gamma}(t))\\
&\qquad-(8\pi aN)^{-1}\Big\{f(\mathbf{r}-\boldsymbol{\alpha}(t))f(\mathbf{r}'-\boldsymbol{\alpha}(t))[f(\mathbf{r}-\boldsymbol{\alpha}(t))^2+f(\mathbf{r}'-\boldsymbol{\alpha}(t))^2-\hat{\zeta}]\\
&\qquad+f(\mathbf{r}-\boldsymbol{\alpha}(t))\int d\mathbf{r}''\,\kappa_0(\mathbf{r}'-\boldsymbol{\gamma}(t),\mathbf{r}''-\boldsymbol{\gamma}(t))f(\mathbf{r}''-\boldsymbol{\alpha}(t))^3\\
&\qquad+f(\mathbf{r}'-\boldsymbol{\alpha}(t))\int d\mathbf{r}''\,\kappa_0(\mathbf{r}-\boldsymbol{\gamma}(t),\mathbf{r}''-\boldsymbol{\gamma}(t))f(\mathbf{r}''-\boldsymbol{\alpha}(t))^3\Big\},
\end{aligned} \tag{3.16}$$

of which the first one is satisfied if

$$\boldsymbol{\gamma}(t)=\boldsymbol{\alpha}(t)+\boldsymbol{\alpha}_0, \tag{3.17}$$

where $\boldsymbol{\alpha}_0$ is a vector constant. Without loss of generality, this $\boldsymbol{\alpha}_0$ is set equal to zero.

In Eq. (3.16), $\boldsymbol{\mathcal{V}}_2(t)$ and $\mathcal{V}_3(t)$ are replaced by $-\frac{1}{2}\boldsymbol{\alpha}''(t)$ and $-\frac{1}{4}|\boldsymbol{\alpha}'(t)|^2+A'(t)$ from Eqs. (2.57) and (2.58), respectively. With a subsequent shift both of $\mathbf{r}$ and $\mathbf{r}'$ by $\boldsymbol{\alpha}(t)$, all time dependencies are eliminated and an equation for $\kappa_0(\mathbf{r},\mathbf{r}')$ is obtained:

$$\begin{aligned}
&-\nabla^2\kappa_0(\mathbf{r},\mathbf{r}')-\nabla'^2\kappa_0(\mathbf{r},\mathbf{r}')+f(\mathbf{r})^2\delta(\mathbf{r}-\mathbf{r}')+\{\mathcal{V}_1(\mathbf{r})+\mathcal{V}_1(\mathbf{r}')+2[f(\mathbf{r})^2+f(\mathbf{r}')^2]\}\kappa_0(\mathbf{r},\mathbf{r}')\\
&\quad+\int d\mathbf{r}''\,f(\mathbf{r}'')^2\kappa_0(\mathbf{r},\mathbf{r}'')\kappa_0(\mathbf{r}',\mathbf{r}'')-(8\pi aN)^{-1}\Big\{f(\mathbf{r})f(\mathbf{r}')[f(\mathbf{r})^2+f(\mathbf{r}')^2-\hat{\zeta}]\\
&\quad+f(\mathbf{r})\int d\mathbf{r}''\,\kappa_0(\mathbf{r}',\mathbf{r}'')f(\mathbf{r}'')^3+f(\mathbf{r}')\int d\mathbf{r}''\,\kappa_0(\mathbf{r},\mathbf{r}'')f(\mathbf{r}'')^3\Big\}=0,
\end{aligned} \tag{3.18}$$

where

$$\int d\mathbf{r}\,f(\mathbf{r})\kappa_0(\mathbf{r},\mathbf{r}')=0. \tag{3.19}$$

When the number of particles, N, is sufficiently large, Eq. (3.18) is approximated by

$$\begin{aligned}
&-\nabla^2\kappa_0(\mathbf{r},\mathbf{r}')-\nabla'^2\kappa_0(\mathbf{r},\mathbf{r}')+f(\mathbf{r})^2\delta(\mathbf{r}-\mathbf{r}')+\{\mathcal{V}_1(\mathbf{r})+\mathcal{V}_1(\mathbf{r}')+2[f(\mathbf{r})^2+f(\mathbf{r}')^2]\}\kappa_0(\mathbf{r},\mathbf{r}')\\
&\quad+\int d\mathbf{r}''\,f(\mathbf{r}'')^2\kappa_0(\mathbf{r},\mathbf{r}'')\kappa_0(\mathbf{r}',\mathbf{r}'')=0.
\end{aligned} \tag{3.20}$$

IV. SLOWLY VARYING TRAPPING POTENTIAL

In order to elucidate the dependence on the physical parameters of the problem, let

$$\tilde{\Phi}(\mathbf{r},t)=\sqrt{\rho_0}\Phi(\mathbf{r},t), \quad \rho_0=N/\Omega. \tag{4.1}$$

$\tilde{\Phi}(\mathbf{r},t)$ satisfies

$$i(\partial/\partial t)\tilde{\Phi}(\mathbf{r},t)=[-\nabla^2+V_e(\mathbf{r},t)+8\pi a|\tilde{\Phi}(\mathbf{r},t)|^2-4\pi a\tilde{\zeta}(t)]\tilde{\Phi}(\mathbf{r},t), \tag{4.2}$$

and the normalization condition

$$N^{-1}\int d\mathbf{r}|\tilde{\Phi}(\mathbf{r},t)|^2=1. \tag{4.3}$$

In the above,

$$\tilde{\zeta}(t)=N^{-1}\int d\mathbf{r}|\tilde{\Phi}(\mathbf{r},t)|^4. \tag{4.4}$$

Equation (2.42) reads

$$\tilde{\Phi}(\mathbf{r},t)=\tilde{f}(\mathbf{r}-\boldsymbol{\alpha}(t))\exp\{i\tfrac{1}{2}\boldsymbol{\alpha}'(t)\cdot\mathbf{r}-iA(t)\}, \tag{4.5}$$

where

$$N^{-1}\int d\mathbf{r}\,\tilde{f}(\mathbf{r})^2=1. \tag{4.6}$$

The external potential is

$$V_e(\mathbf{r},t)=\tilde{\mathcal{V}}_1(\mathbf{r}-\boldsymbol{\alpha}(t))+\mathbf{r}\cdot\tilde{\boldsymbol{\mathcal{V}}}_2(t)+\tilde{\mathcal{V}}_3(t), \tag{4.7}$$

where

$$\tilde{\mathcal{V}}_1(\mathbf{r})=\frac{\nabla^2\tilde{f}(\mathbf{r})}{\tilde{f}(\mathbf{r})}-8\pi a\tilde{f}(\mathbf{r})^2+4\pi a\tilde{\zeta}, \quad \tilde{\zeta}=N^{-1}\int d\mathbf{r}\,\tilde{f}(\mathbf{r})^4, \tag{4.8a}$$

and $\tilde{\boldsymbol{\mathcal{V}}}_2(t)$, $\tilde{\mathcal{V}}_3(t)$ are given by equations similar to Eqs. (2.57) and (2.58). Therefore, $\tilde{f}(\mathbf{r})=\tilde{f}_m(\mathbf{r})(m=0,1,...,)$ correspond to states of the condensate with energies $\mathcal{E}_m$ under the external potential

$$\mathcal{V}_e=\tilde{\mathcal{V}}_{1m}+\mathcal{E}_m \quad (\tilde{\mathcal{V}}_1=\tilde{\mathcal{V}}_{1m}). \tag{4.8b}$$

Given a $\mathcal{V}_e(\mathbf{r})$, Eq. (4.2) can be solved approximately for the lowest state of the condensate when $\mathcal{V}_e(\mathbf{r})$ is sufficiently slowly varying. This is the case in the recent experiments on Bose–Einstein condensation, where the trap is of macroscopic dimensions. By applying the procedure of Refs. 8 and 13, neglect of the Laplacian furnishes

$$[\mathcal{V}_e(\mathbf{r})+8\pi a\tilde{f}(\mathbf{r})^2-4\pi a\tilde{\zeta}-\mathcal{E}]\tilde{f}(\mathbf{r})=0, \tag{4.9}$$

where $\mathcal{E}=\mathcal{E}_0$, or,

$$\tilde{f}(\mathbf{r})\sim\begin{cases}(8\pi a)^{-1/2}[\mathcal{E}+4\pi a\tilde{\zeta}-\mathcal{V}_e(\mathbf{r})]^{1/2}, & \mathbf{r}\text{ inside }\mathcal{R}_0\\ 0, & \mathbf{r}\text{ outside }\mathcal{R}_0\end{cases}, \tag{4.10}$$

since $\tilde{f}(\mathbf{r})$ can be chosen to be non-negative. The region $\mathcal{R}_0$ is determined by

$$\mathcal{V}_e(\mathbf{r})<\mathcal{E}+4\pi a\tilde{\zeta}, \quad \mathbf{r}\in\mathcal{R}_0. \tag{4.11}$$

At the boundary $\partial\mathcal{R}_0$ of $\mathcal{R}_0$,

$$\mathcal{E}+4\pi a\tilde{\zeta}=\mathcal{V}_e(\mathbf{r}), \quad \mathbf{r}\in\partial\mathcal{R}_0. \tag{4.12}$$

Under this approximation, an expression for $\mathcal{E}$ is obtained via multiplication of Eq. (4.9) by $\tilde{f}(\mathbf{r})$ and integration over $\mathbf{r}$:

$$\mathcal{E}\sim 4\pi a\tilde{\zeta}+\tilde{\zeta}_e, \tag{4.13}$$

where

$$\tilde{\zeta}_e=N^{-1}\int d\mathbf{r}\,\mathcal{V}_e(\mathbf{r})|\tilde{f}(\mathbf{r})|^2. \tag{4.14}$$

Formula (4.10) breaks down in the vicinity of $\partial\mathcal{R}_0$. A remedy to this problem is provided in Refs. 8 and 13.

It remains to discuss the pair-excitation function $K_0(\mathbf{r},\mathbf{r}';t)$. With

$$K_0(\mathbf{r},\mathbf{r}';t)=\tilde{\kappa}_0(\mathbf{r}-\boldsymbol{\alpha}(t),\mathbf{r}'-\boldsymbol{\alpha}(t))e^{-i\chi(\mathbf{r},\mathbf{r}';t)}, \tag{4.15}$$

and use of Eq. (3.14), $\tilde{\kappa}_0(\mathbf{r},\mathbf{r}')$ should satisfy

$$\begin{aligned}&-\nabla^2\tilde{\kappa}_0(\mathbf{r},\mathbf{r}')-\nabla'^2\tilde{\kappa}_0(\mathbf{r},\mathbf{r}')+8\pi a\tilde{f}(\mathbf{r})^2\delta(\mathbf{r}-\mathbf{r}')+\{-2\check{\zeta}-16\pi a\tilde{\zeta}-2\tilde{\zeta}_e+\mathcal{V}_e(\mathbf{r})+\mathcal{V}_e(\mathbf{r}')\\&\quad+16\pi a[\tilde{f}(\mathbf{r})^2+\tilde{f}(\mathbf{r}')^2]\}\tilde{\kappa}_0(\mathbf{r},\mathbf{r}')+8\pi a\int d\mathbf{r}''\,\tilde{f}(\mathbf{r}'')^2\tilde{\kappa}_0(\mathbf{r},\mathbf{r}'')\tilde{\kappa}_0(\mathbf{r}',\mathbf{r}'')=0,\end{aligned} \tag{4.16}$$

where

$$\check{\zeta}=N^{-1}\int d\mathbf{r}|\nabla\tilde{f}(\mathbf{r})|^2. \tag{4.17}$$

Note that shifting $\mathcal{V}_e$ by a constant does not affect the equation of motion.

Following Ref. 8, let

$$p_0(\mathbf{R},\mathbf{r})=\tilde{\kappa}_0(\mathbf{r}_1,\mathbf{r}_2), \tag{4.18}$$

where

$$\mathbf{R}=\tfrac{1}{2}(\mathbf{r}_1+\mathbf{r}_2), \quad \mathbf{r}=\mathbf{r}_1-\mathbf{r}_2. \tag{4.19}$$

Hence,

$$p_0(\mathbf{R},-\mathbf{r})=p_0(\mathbf{R},\mathbf{r}). \tag{4.20}$$

The integro-differential equation for $p_0(\mathbf{R},\mathbf{r})$ reads

$$\begin{aligned}&-\tfrac{1}{2}\nabla_{\mathbf{R}}^2p_0(\mathbf{R},\mathbf{r})-2\nabla_{\mathbf{r}}^2p_0(\mathbf{R},\mathbf{r})+8\pi a\tilde{f}(\mathbf{R})^2\delta(\mathbf{r})+\{-2\check{\zeta}-16\pi a\tilde{\zeta}-2\tilde{\zeta}_e+\mathcal{V}_e(\mathbf{R}+\tfrac{1}{2}\mathbf{r})\\&\quad+\mathcal{V}_e(\mathbf{R}-\tfrac{1}{2}\mathbf{r})+16\pi a[\tilde{f}(\mathbf{R}+\tfrac{1}{2}\mathbf{r})^2+\tilde{f}(\mathbf{R}-\tfrac{1}{2}\mathbf{r})^2]\}p_0(\mathbf{R},\mathbf{r})\\&\quad+8\pi a\int d\mathbf{r}'\,\tilde{f}(\mathbf{R}+\mathbf{r}')^2p_0(\mathbf{R}+\tfrac{1}{4}\mathbf{r}+\tfrac{1}{2}\mathbf{r}',\tfrac{1}{2}\mathbf{r}-\mathbf{r}')p_0(\mathbf{R}-\tfrac{1}{4}\mathbf{r}+\tfrac{1}{2}\mathbf{r}',-\tfrac{1}{2}\mathbf{r}-\mathbf{r}')=0.\end{aligned} \tag{4.21}$$

In the spirit of Eq. (4.9), $\nabla_{\mathbf{R}}^2$ is neglected, while

$$\mathcal{V}_e(\mathbf{R}+\tfrac{1}{2}\mathbf{r})\sim\mathcal{V}_e(\mathbf{R})\sim\mathcal{V}_e(\mathbf{R}-\tfrac{1}{2}\mathbf{r}), \tag{4.22}$$

$$\tilde{f}(\mathbf{R}+\tfrac{1}{2}\mathbf{r})\sim\tilde{f}(\mathbf{R})\sim\tilde{f}(\mathbf{R}-\tfrac{1}{2}\mathbf{r}), \tag{4.23}$$

$$p_0(\mathbf{R}+\tfrac{1}{4}\mathbf{r}+\tfrac{1}{2}\mathbf{r}',\tfrac{1}{2}\mathbf{r}-\mathbf{r}')\sim p_0(\mathbf{R},\tfrac{1}{2}\mathbf{r}-\mathbf{r}'), \tag{4.24a}$$

$$p_0(\mathbf{R}-\tfrac{1}{4}\mathbf{r}+\tfrac{1}{2}\mathbf{r}',-\tfrac{1}{2}\mathbf{r}-\mathbf{r}')\sim p_0(\mathbf{R},-\tfrac{1}{2}\mathbf{r}-\mathbf{r}'). \tag{4.24b}$$

Equation (4.21) then reduces to

$$-\nabla_{\mathbf{r}}^2 p_0(\mathbf{R},\mathbf{r})+4\pi a\tilde{f}(\mathbf{R})^2\delta(\mathbf{r})+\{-\check{\zeta}-8\pi a\tilde{\zeta}-\tilde{\zeta}_e+\mathcal{V}_e(\mathbf{R})+16\pi a\tilde{f}(\mathbf{R})^2\}p_0(\mathbf{R},\mathbf{r})$$
$$+4\pi a\tilde{f}(\mathbf{R})^2\int d\mathbf{r}'\, p_0(\mathbf{R},\mathbf{r}')p_0(\mathbf{R},\mathbf{r}-\mathbf{r}')=0. \tag{4.25}$$

Because the nonlinear term is a convolution integral, the equation of motion can be solved *exactly* with recourse to the Fourier transform in $\mathbf{r}$ of $p_0(\mathbf{R},\mathbf{r})$:

$$\overline{p_0}(\mathbf{R},\mathbf{k})=\int d\mathbf{r}e^{i\mathbf{k}\cdot\mathbf{r}}p_0(\mathbf{R},\mathbf{r}), \tag{4.26}$$

which transforms Eq. (4.25) into

$$4\pi a\tilde{f}(\mathbf{R})^2\overline{p_0}(\mathbf{R},\mathbf{k})^2+[k^2+k_0(\mathbf{R})^2]\overline{p_0}(\mathbf{R},\mathbf{k})+4\pi a\tilde{f}(\mathbf{R})^2=0, \tag{4.27}$$

where

$$k_0(\mathbf{R})^2=-\check{\zeta}-8\pi a\tilde{\zeta}-\tilde{\zeta}_e+\mathcal{V}_e(\mathbf{R})+16\pi a\tilde{f}(\mathbf{R})^2. \tag{4.28}$$

Equation (4.27) is solved explicitly to give

$$\overline{p_0}(\mathbf{R},\mathbf{k})=[8\pi a\tilde{f}(\mathbf{R})^2]^{-1}\{-k^2-k_0(\mathbf{R})^2+\sqrt{[k^2+k_0(\mathbf{R})^2]^2-(8\pi a)^2\tilde{f}(\mathbf{R})^4}\}. \tag{4.29}$$

In view of formula (4.10),

$$\overline{p_0}(\mathbf{R},\mathbf{k})\sim\begin{cases}-k_0(\mathbf{R})^{-2}\{k^2+k_0(\mathbf{R})^2-k[k^2+2k_0(\mathbf{R})^2]^{1/2}\}, & \mathbf{R}\ \text{inside}\ \mathcal{R}_0\\ 0, & \mathbf{R}\ \text{outside}\ \mathcal{R}_0\end{cases}, \tag{4.30}$$

by neglecting $\check{\zeta}$ since $|\nabla\tilde{f}(\mathbf{r})|\simeq 0$ unless $\mathbf{r}$ is sufficiently close to $\partial\mathcal{R}_0$, so that

$$k_0(\mathbf{R})^2=8\pi a\tilde{f}(\mathbf{R})^2. \tag{4.31}$$

Inversion of $\overline{p_0}(\mathbf{R},\mathbf{k})$ is carried out as follows. For $\mathbf{R}$ outside $\mathcal{R}_0$,

$$p_0(\mathbf{R},\mathbf{r})=0. \tag{4.32}$$

If $\mathbf{R}$ lies inside $\mathcal{R}_0$,

$$
\begin{aligned}
p_0(\mathbf{R},\mathbf{r}) &= \frac{1}{(2\pi)^3} \lim_{\delta\to 0^+} \int d\mathbf{k}\, e^{-i\mathbf{k}\cdot\mathbf{r}} e^{-\delta k} \overline{p_0}(\mathbf{R},\mathbf{k}) \\
&= -\frac{1}{k_0^2} \frac{1}{(2\pi)^3} \lim_{\delta\to 0^+} \int_0^{2\pi} d\phi \int_0^{\pi} d\theta \sin\theta \int_0^{\infty} dk\, k^2 e^{-ik|\mathbf{r}|\cos\theta} e^{-\delta k} \\
&\quad \times [k^2 + k_0^2 - k(k^2 + 2k_0^2)^{1/2}] \\
&= \frac{2}{k_0^2|\mathbf{r}|} \frac{1}{(2\pi)^2} \lim_{\delta\to 0^+} \mathrm{Im} \int_0^{\infty} dk\, e^{ik|\mathbf{r}|} e^{-\delta k} k^2 (k^2 + 2k_0^2)^{1/2} \quad (k = \sqrt{2} k_0 \sinh t) \\
&= \frac{k_0^2}{2\pi^2|\mathbf{r}|} \lim_{\delta\to 0^+} \mathrm{Im} \int_0^{\infty} dt\, e^{i\sqrt{2}k_0|\mathbf{r}|\sinh t} e^{-\delta\sqrt{2}k_0 \sinh t} (\sinh 2t)^2 \\
&= \pi^{-2}(4\pi a)^{3/2} \tilde{f}(\mathbf{R})^3 \frac{\mathrm{Im}\{S_{0,4}(iw) - S_{0,0}(iw)\}}{w},
\end{aligned}
\tag{4.33}
$$

where $k_0 = k_0(\mathbf{R})$ and

$$
w = (16\pi a)^{1/2} \tilde{f}(\mathbf{R}) |\mathbf{r}|, \tag{4.34}
$$

and $S_{0,4}$ and $S_{0,0}$ are Lommel's functions.[31]

V. $\tilde{f}(\mathbf{r})$ IN A THREE-DIMENSIONAL SPHERICALLY SYMMETRIC HARMONIC POTENTIAL

In the actual experiments on Bose–Einstein condensation, the trapping potential is of complicated form. This is usually modeled as an anisotropic harmonic potential. In this section, $\tilde{f}(\mathbf{r})$ for the lowest state of the condensate is examined in some detail in the simplifying case of a spherically symmetric harmonic potential. A similar task is undertaken in Ref. 12, where the nonlinear Schrödinger equation is given in terms of the chemical potential.

With an external potential $V_e(\mathbf{r},t) = \frac{1}{4}\omega_0^2 r^2$, $\tilde{\mathcal{V}}_1(\mathbf{r})$ is taken to be

$$
\tilde{\mathcal{V}}_1(\mathbf{r}) = \tfrac{1}{4}\omega_0^2 r^2 - \mathcal{E}, \tag{5.1}
$$

as is suggested by the eigenvalue problem associated with Eq. (2.56). Terms linear in x, y, and z are omitted. It follows that

$$
\tilde{\boldsymbol{\mathcal{V}}}_2(t) = \tfrac{1}{2}\omega_0^2 \boldsymbol{\alpha}(t), \quad \tilde{\mathcal{V}}_3(t) = \mathcal{E} - \tfrac{1}{4}\omega_0^2 |\boldsymbol{\alpha}(t)|^2, \tag{5.2}
$$

yielding

$$
\boldsymbol{\alpha}(t) = \mathbf{r}_0 \cos\omega_0 t + \frac{\mathbf{v}_0}{\omega_0} \sin\omega_0 t, \tag{5.3}
$$

$$
A(t) = \mathcal{E}t + \frac{1}{8}\left(\frac{|\mathbf{v}_0|^2 - \omega_0^2|\mathbf{r}_0|^2}{\omega_0} \sin 2\omega_0 t + 2\mathbf{v}_0\cdot\mathbf{r}_0 \cos 2\omega_0 t \right) + \text{const}, \tag{5.4}
$$

where $\mathbf{r}_0$ and $\mathbf{v}_0$ are determined by the initial conditions and the constant is real.

For the state of lowest energy $\mathcal{E} = \mathcal{E}_0$, $\tilde{f}(\mathbf{r}) = \tilde{f}_0(r)$ is spherically symmetric.[32] Let

$$
q(\xi) = (4\pi)^{1/2} (N^2\omega_0/2)^{-1/4} r \tilde{f}_0(r), \quad \xi = (\omega_0/2)^{1/2} r. \tag{5.5}
$$

From Eq. (4.8a), this $q(\xi)$ satisfies

$$-\frac{d^2q(\xi)}{d\xi^2}+\xi^2q(\xi)+\Lambda^2\frac{q(\xi)^3}{\xi^2}=\lambda^2q(\xi)\quad(\xi>0),\tag{5.6}$$

supplemented with the boundary conditions

$$q(0)=0,\tag{5.7}$$

$$\lim_{\xi\to\infty}q(\xi)=0,\tag{5.8}$$

and the normalization condition

$$\int_0^\infty d\xi\, q(\xi)^2=1.\tag{5.9}$$

In the above,

$$\Lambda=(2a^2N^2\omega_0)^{1/4},\tag{5.10}$$

$$\lambda^2=\frac{2\mathcal{E}}{\omega_0}+\frac{1}{2}\Lambda^2\int_0^\infty\frac{d\xi}{\xi^2}q(\xi)^4,\quad \lambda>0.\tag{5.11}$$

Note that, for $\xi\to\infty$, the nonlinear term in Eq. (5.6) can be neglected, and the asymptotic behavior of $q(\xi)$ is found via the direct application of the Wentzel–Kramers–Brillouin method:

$$q(\xi)\sim C(\xi^2-\lambda^2)^{-1/4}\exp\{-(\lambda^2/2)[(\xi/\lambda)\sqrt{(\xi/\lambda)^2-1}-\cosh^{-1}(\xi/\lambda)]\},\tag{5.12}$$

where C is independent of ξ. Compare with Ref. 12. For a discussion on the determination of this C see Ref. 33.

Some insight into the solution to Eqs. (5.6)–(5.9) can be obtained by considering the following cases.

(i) $\Lambda\gg1$. To leading order in Λ, neglect of the second derivative of $q(\xi)$ results in

$$q(\xi)\sim q^{(0)}(\xi)=\begin{cases}(\xi/\Lambda)\sqrt{\lambda^2-\xi^2}, & 0\leqslant\xi<\lambda\\ 0, & \xi>\lambda,\end{cases}\tag{5.13}$$

which trivially satisfies Eqs. (5.7) and (5.8). $q^{(0)}(\xi)$ satisfies Eq. (5.9) provided that λ is

$$\lambda\sim\lambda^{(0)}=(\tfrac{15}{2}\Lambda^2)^{1/5}.\tag{5.14}$$

A similar calculation for an anisotropic potential can be found in Ref. 14, where the chemical potential is employed. From Eq. (5.11),

$$\mathcal{E}^{(0)}=\tfrac{5}{14}(\tfrac{15}{2})^{2/5}(2a^2N^2\omega_0)^{1/5}\omega_0=\tfrac{5}{21}(\tfrac{15}{2})^{2/5}\Lambda^{4/5}\epsilon_0^{\text{ho}},\tag{5.15}$$

where $\epsilon_0^{\text{ho}}=\frac{3}{2}\omega_0$ is the ground-state energy of the three-dimensional harmonic oscillator. Approximation (5.13) starts to break down at a distance of the order of $\Lambda^{-2/15}$ from inside the ''boundary'' $\xi=\lambda$, and then needs to be modified according to the procedure in Refs. 8 and 13. This procedure provides a smooth connection to asymptotic formula (5.12) when $0<\xi-\lambda\ll1$ while $\xi-\lambda\gg O(\Lambda^{-2/15})$.[33]

(ii) $\Lambda\ll1$. To zeroth order in Λ, the known solution for the ground-state wave function of the three-dimensional harmonic oscillator is obtained:

$$q^{(0)}(\xi)=2\pi^{-1/4}\xi e^{-\xi^2/2},\tag{5.16}$$

with energy $\mathcal{E}^{(0)}=(\omega_0/2)\lambda^{(0)^2}=\epsilon_0^{\text{ho}}$. The first-order energy correction $\mathcal{E}^{(1)}$ can be obtained

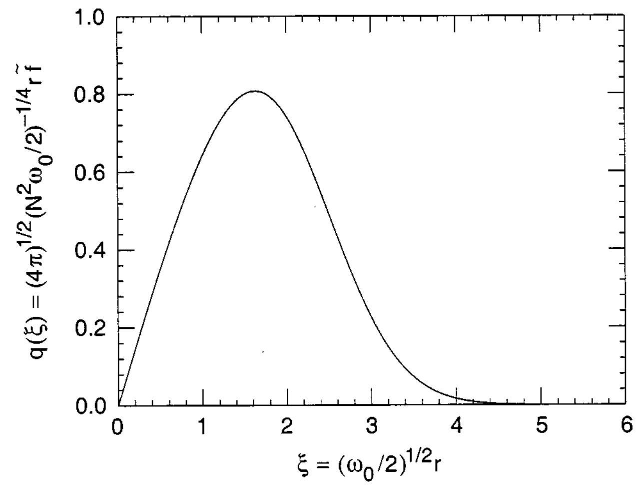

FIG. 1. Solution to Eqs. (5.6)–(5.9) for $\Lambda^2=12.1$ (^{87}Rb atoms, $a\simeq 110a_0$, $N=10^3$, and $\omega_0=(2\pi\times 120)/\sqrt{8}$ rad/s). Numerically computed eigenvalue is $\lambda^2=6.8$.

through the standard perturbation methods, by treating $V^{(0)}(\xi)=\Lambda^2\xi^{-2}q^{(0)}(\xi)^2$ as the perturbing potential. Therefore, $\lambda^{(1)^2}$ equals the matrix element

$$\lambda^{(1)^2}=\int_0^\infty d\xi\, q^{(0)}(\xi)V^{(0)}(\xi)q^{(0)}(\xi). \tag{5.17}$$

By virtue of Eq. (5.11),

$$\mathcal{E}^{(1)}=\frac{\omega_0\Lambda^2}{4}\int_0^\infty \frac{d\xi}{\xi^2}q^{(0)}(\xi)^4=\sqrt{\frac{2}{\pi}}\frac{\omega_0\Lambda^2}{4},\quad \Lambda\ll 1, \tag{5.18}$$

or

$$\mathcal{E}\sim\mathcal{E}^{(0)}+\mathcal{E}^{(1)}=\frac{3}{2}\omega_0+\sqrt{\frac{2}{\pi}}\frac{\omega_0\Lambda^2}{4}. \tag{5.19}$$

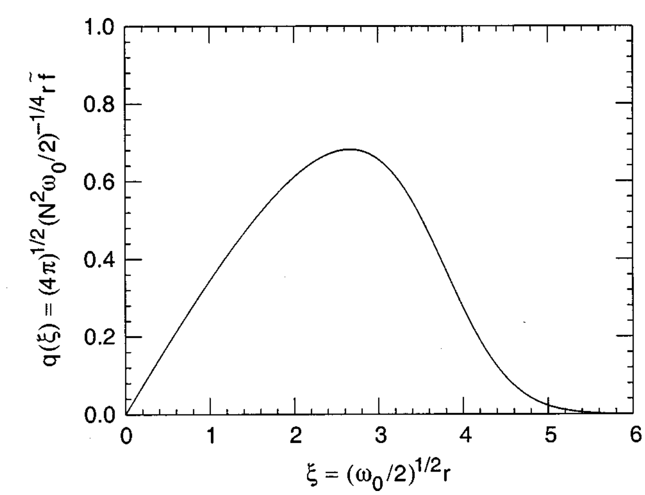

FIG. 2. Solution to Eqs. (5.6)–(5.9) for $\Lambda^2=121$ (^{87}Rb atoms, $N=10^4$, and $\omega_0=(2\pi\times 120)/\sqrt{8}$ rad/s). Eigenvalue is $\lambda^2=15.6$.

Numerical results. In order to make some contact with recent experimental situations, plots of $q(\xi)$ are presented in Figs. 1 and 2 for two different values of Λ, in close relation to the JILA experiments, where ^{87}Rb atoms were used ($a=110a_0$, a_0: the Bohr radius).[1] Specifically, in Fig. 1, $\Lambda^2=12.1$, corresponding, for instance, to $N=10^3$ and $\omega_0=(2\pi\times 120)/\sqrt{8}$ rad/s. The numerically computed eigenvalue there is $\lambda^2=6.8$, giving $\mathcal{E}=1.8\epsilon_0^{\text{ho}}$. Compare with $\mathcal{E}^{(0)}=1.45\epsilon_0^{\text{ho}}$ provided by Eq. (5.15). In Fig. 2, $\Lambda^2=121$. The corresponding eigenvalue is found to be $\lambda^2=15.6$, giving $\mathcal{E}=3.8\epsilon_0^{\text{ho}}$. Compare with $\mathcal{E}^{(0)}=3.63\epsilon_0^{\text{ho}}$ from Eq. (5.15).

VI. CONCLUSIONS AND DISCUSSION

In the theoretical treatment of Bose–Einstein condensation in dilute atomic gases with repulsive interactions, the trap is replaced by a sufficiently smooth external potential $V_e(\mathbf{r},t)$ that acts simultaneously on each atom and increases sufficiently rapidly at large distances. As a consequence, the boson system is no longer translationally invariant. Work carried out 38 years ago[4] turns out to be a suitable starting point. An important element introduced there was the systematic consideration of scattering processes, such as pair creation, with a study of some of their physical consequences. In the presence of a trapping potential, pair creation plays a significant role, being described mathematically by the pair-excitation function $K_0(\mathbf{r},\mathbf{r}';t)$. On the basis of the ansatz (1.1), a nonlinear integro-differential equation is satisfied by $K_0(\mathbf{r},\mathbf{r}';t)$.

Solitary-wave solutions to the nonlinear evolution equations for the condensate wave function $\Phi(\mathbf{r},t)$ and the pair-excitation function are uncovered in any number of space dimensions, if $V_e(\mathbf{r},t)$ can properly be decomposed into (i) a trapping potential $\mathcal{V}_e$ translated by the position vector $\mathbf{r}(t)=\boldsymbol{\alpha}(t)$ of the pulse ''center of mass,'' and (ii) a potential linear in the space coordinates, according to (2.55)–(2.58). It is somewhat tempting to put these statements in the language of classical mechanics, recognizing, for instance, the second term mentioned above as the potential associated with a uniform force. The conclusions here are the natural generalization of results obtained for the one-dimensional case, without any restriction to motion along fixed axes in space.[18] Given an external potential that meets the aforementioned conditions, the initial amplitudes are obtained by solving a nonlinear ''eigenvalue problem'' for $\Phi(\mathbf{r},t=0)$ under $\mathcal{V}_e$, and a nonlinear integro-differential equation for $K_0(\mathbf{r},\mathbf{r}';t=0)$. The motion of the solitary wave in space, i.e., the vector $\boldsymbol{\alpha}(t)$, is determined by the uniform force. In this sense, the solitary wave is expected to behave like a classical particle. Conversely, given an admissible $\Phi(\mathbf{r},t=0)$, i.e., sufficiently smooth and rapidly decreasing to zero as $\mathbf{r}\rightarrow\infty$, it is possible to construct an external potential that permits solitary-wave behavior for both $\Phi(\mathbf{r},t>0)$ and $K_0(\mathbf{r},\mathbf{r}';t>0)$. Of course, in real experimental situations, the form of the external potential may deviate from the one given by Eq. (2.55). The question of the stability of the solitary-wave solutions under variations of $V_e(\mathbf{r},t)$ is not addressed in this paper.

As is also pointed out in Ref. 8, the approximate Hamiltonian that furnishes the equation of motion for K_0 does not include, for instance, the scattering of phonons and the decay of a single phonon into two or three phonons. In other words, under the present approximation, the phonons have infinite lifetimes and remain stable. This in turn implies that the ansatz (1.1) and the existing equations of motion are of rather special forms, being valid only over some moderate time scale. The problem of shorter or longer time scales is not touched upon in this paper; this time limitation may depend on the higher-order terms in the Hamiltonian or the initial condition for the condensate wave function. It is believed that the ansatz for the many-body wave function can be generalized. A challenging open problem is to obtain such generalizations, which must satisfy many consistency conditions.

ACKNOWLEDGMENTS

The author is greatly indebted to Professor Tai Tsun Wu for his unwavering guidance and encouragement. He also wishes to thank Professor Wolfgang Ketterle and Professor Bertrand

Halperin for useful discussions, and Margaret Owens for her valuable assistance throughout the preparation of the manuscript. This work was supported in part by the United States Department of Energy under Grant No. DE-FG02-84ER40158.

APPENDIX

Consider the one-dimensional linear Schrödinger equation in a harmonic-oscillator potential ($\hbar=2m=1,\ \omega_0=2$):

$$i\,\frac{\partial\varphi(x,t)}{\partial t}=\left(-\frac{\partial^2}{\partial x^2}+x^2\right)\varphi(x,t). \tag{A1}$$

It is well known[34] that an initial displacement of the ground-state wave function $\varphi_0(x)=\pi^{-1/4}e^{-x^2/2}$ at $t=0$ by $x=x_0$ produces the wave packet

$$\varphi(x,t)=\varphi_0(x-x_0e^{-2it})e^{-i\nu(t)},\quad t>0, \tag{A2}$$

where, for definiteness, $\nu(t=0)=0$. Substitution into Eq. (A1) furnishes

$$\nu(t)=t+\frac{ix_0^2}{4}e^{-i4t}-\frac{ix_0^2}{4}. \tag{A3}$$

$\varphi(x,t)$ is subsequently recast in a form where magnitude and phase are separated:

$$\begin{aligned}\varphi(x,t)&=\pi^{-1/4}\exp\left\{-\frac{1}{2}(x-x_0e^{-2it})^2-it+\frac{x_0^2}{4}e^{-i4t}-\frac{x_0^2}{4}\right\}\\&=\pi^{-1/4}\exp\left[-\frac{1}{2}(x-x_0\cos 2t)^2\right]\exp\left[-i\left(t+x_0x\sin 2t-\frac{x_0^2}{4}\sin 4t\right)\right],\end{aligned} \tag{A4}$$

which is a one-dimensional solitary wave. Note that with the units of Eq. (A1) the eigenvalue corresponding to $\varphi_0(x)$ is equal to 1.

The preceding analysis can be extended to the d-dimensional Schrödinger equation

$$i\,\frac{\partial\varphi(\mathbf{r},t)}{\partial t}=\left(-\nabla^2+\sum_{j=1}^{d}x_j^2\right)\varphi(\mathbf{r},t), \tag{A5}$$

where $\mathbf{r}=(x_1,\ldots,x_d)$, $d\geqslant 2$. With an initial displacement of the ground-state wave function $\varphi_0(\mathbf{r})=\pi^{-d/4}e^{-\mathbf{r}\cdot\mathbf{r}/2}$ by $\mathbf{r}=\mathbf{r}_0$, at later times $\varphi(\mathbf{r},t)$ becomes

$$\varphi(\mathbf{r},t)=\varphi_0(\mathbf{r}-\mathbf{r}_0e^{-2it})e^{-i\nu(t)},\quad t>0. \tag{A6}$$

After some straightforward algebra,

$$\nu(t)=d\cdot t+\frac{i|\mathbf{r}_0|^2}{4}e^{-i4t}-\frac{i|\mathbf{r}_0|^2}{4}, \tag{A7}$$

$$\begin{aligned}\varphi(\mathbf{r},t)&=\pi^{-d/4}\left(\prod_{j=1}^{d}\exp\left[-\frac{1}{2}(x_j-x_{j0}\cos 2t)^2\right]\right)\exp\left[-i\left(d\cdot t+\mathbf{r}_0\cdot\mathbf{r}\sin 2t-\frac{|\mathbf{r}_0|^2}{4}\sin 4t\right)\right]\\&=\varphi_0(\mathbf{r}-\mathbf{r}_0\cos 2t)\exp\left[-i\left(d\cdot t+\mathbf{r}_0\cdot\mathbf{r}\sin 2t-\frac{|\mathbf{r}_0|^2}{4}\sin 4t\right)\right].\end{aligned} \tag{A8}$$

This is a solitary wave in d space dimensions.

A generalization of Wigner's unitary–antiunitary theorem to Hilbert modules

Lajos Molnár
Institute of Mathematics and Informatics, Lajos Kossuth University, 4010 Debrecen, P.O. Box 12, Hungary

(Received 4 May 1999; accepted for publication 30 June 1999)

Let $\mathcal{H}$ be a Hilbert C^*-module over a matrix algebra A. It is proved that any function $T:\mathcal{H}\to\mathcal{H}$ which preserves the absolute value of the (generalized) inner product is of the form $Tf=\varphi(f)Uf$ $(f\in\mathcal{H})$, where φ is a phase-function and U is an A-linear isometry. The result gives a natural extension of Wigner's classical unitary–antiunitary theorem for Hilbert modules. © *1999 American Institute of Physics.* [S0022-2488(99)01611-4]

I. INTRODUCTION AND STATEMENT OF THE RESULT

Wigner's unitary–antiunitary theorem reads as follows. Let H be a complex Hilbert space and let $T:H\to H$ be a bijective function (linearity or continuity is not assumed) with the property that

$$|\langle Tx,Ty\rangle|=|\langle x,y\rangle| \quad (x,y\in H).$$

Then T is of the form

$$Tx=\varphi(x)Ux \quad (x\in H),$$

where $U:H\to H$ is either a unitary or an antiunitary operator and $\varphi:H\to\mathbb{C}$ is a so-called phase-function which means that its values are of modulus 1. This celebrated result plays a very important role in quantum mechanics and in representation theory in physics.

In our recent paper[1] we presented a new, algebraic approach to this theorem. Our idea turned out to be strong enough to give a natural generalization of Wigner's theorem for Hilbert C^*-modules over matrix algebras. However, in the main result [Ref. 1, Theorem 1] we supposed that our map is surjective and, in addition, a condition was imposed on the underlying module which was proved to be equivalent to that its so-called modular dimension is high enough. In the present paper, refining and modifying our argument quite significantly, we obtain our Wigner-type result in full generality, that is, neither the surjectivity of the transformation in question nor the high dimensionality of the Hilbert module is assumed.

First, we clarify the concepts and notation that we are going to use throughout. For a bit more detailed discussion we refer to the introduction of Ref. 1. Let A be a C^*-algebra. Let $\mathcal{H}$ be a left A-module with a map $[.,.]:\mathcal{H}\times\mathcal{H}\to A$ satisfying

(i) $[f+g,h]=[f,h]+[g,h]$;
(ii) $[af,g]=a[f,g]$;
(iii) $[g,f]=[f,g]^*$;
(iv) $[f,f]\geqslant 0$ and $[f,f]=0$ if and only if $f=0$

for every $f,g,h\in\mathcal{H}$ and $a\in A$. If $\mathcal{H}$ is complete with respect to the norm $f\mapsto\|[f,f]\|^{1/2}$, then we say that $\mathcal{H}$ is a Hilbert A-module or a Hilbert C^*-module over A with generalized inner product [.,.]. Nowadays, Hilbert modules over C^*-algebras play a very important role in many parts of functional analysis such as, for example, in the K-theory of C^*-algebras. There is another concept of Hilbert modules due to Saworotnow.[2] These are modules over H^*-algebras. The only formal difference in the definition is that in the case of Saworotnow's modules, the generalized inner product takes its values in the trace-class of the underlying H^*-algebra and the norm with respect to which we require completeness is $f \mapsto (\mathrm{tr}[f,f])^{1/2}$. Saworotnow's modules appear naturally when dealing with multivariate stochastic processes and they have applications in Clifford analysis and hence in some parts of mathematical physics.

If the underlying C^*-algebra A is the algebra $M_d(\mathbb{C})$ of all $d \times d$ complex matrices, then, A being finite dimensional, the norms on A are all equivalent. Therefore, the Hilbert C^*-modules over the C^*-algebra $M_d(\mathbb{C})$ are the same as Saworotnow's Hilbert modules over the H^*-algebra $M_d(\mathbb{C})$. We emphasize this fact since, in general, the behavior of Saworotnow's Hilbert modules is much nicer and we shall use several results concerning them. Finally, we note that it seems to be more common to use right modules instead of left ones. Of course, this is not a real difference, only a question of taste.

Now we are in a position to formulate the main result of the paper. Recall that in any C^*-algebra A, the element $|a|$ denotes the square root of a^*a $(a \in A)$.

Theorem: *Let $\mathcal{H}$ be a Hilbert C^*-module over the matrix algebra $A = M_d(\mathbb{C})$, $d > 1$. Let $T:\mathcal{H} \to \mathcal{H}$ be a function with the property that*

$$|[Tf,Tf']| = |[f,f']| \quad (f,f' \in \mathcal{H}). \tag{1}$$

Then there exists an A-isometry $U:\mathcal{H} \to \mathcal{H}$ and a phase-function $\varphi:\mathcal{H} \to \mathbb{C}$ such that

$$Tf = \varphi(f)Uf \quad (f \in \mathcal{H}).$$

Here, A-isometry means that $U:\mathcal{H} \to \mathcal{H}$ is a linear map with $U(af) = aUf$ and $[Uf,Uf'] = [f,f']$ $(a \in A,\ f,\ f' \in \mathcal{H})$.

The corresponding result for the case $d = 1$, that is, when $\mathcal{H}$ is a Hilbert space, can be found in Refs. 3 and 4 (for a recent paper also see Ref. 5). As we shall see in the proof, the nonappearance of A-anti-isometries in the above result is the consequence of the noncommutativity of the underlying algebra A.

Hilbert spaces over algebras different from $\mathbb{R}$ and $\mathbb{C}$ do appear in mathematical physics (see, for example, Ref. 6 for a Wigner-type theorem concerning Hilbert spaces over the skew-field of quaternions). We believe that our present result may also have physical interpretation.

II. PROOF

We give some additional definitions and notation that we shall use in the proof of our theorem. As mentioned in the introduction, Saworotnow's modules have many convenient properties which are familiar in the theory of Hilbert spaces (we refer to Ref. 2). First of all, if $\mathcal{H}$ is a Hilbert module over an H^*-algebra, then $\mathcal{H}$ is a Hilbert space with the inner product $\langle .,. \rangle = \mathrm{tr}[.,.]$. If $\mathcal{M} \subset \mathcal{H}$ is a closed submodule, then its orthogonal complement with respect to $\langle .,. \rangle$ and $[.,.]$ are the same. A linear operator T on $\mathcal{H}$ which is bounded with respect to the Hilbert space norm defined above is called an A-linear operator if $T(af) = aTf$ holds true for every $f \in \mathcal{H}$ and $a \in A$. Every A-linear operator T is adjointable, namely, the adjoint T^* of T in the Hilbert space sense is A-linear and we have $[Tf,g] = [f,T^*g]$ $(f,g \in \mathcal{H})$. Consequently, the collection of all A-linear operators forms a C^*-subalgebra in the full operator algebra on the Hilbert space $\mathcal{H}$. This will be denoted by $\mathcal{B}(\mathcal{H})$ while the notation of the full operator algebra over a Hilbert space H is $B(H)$.

In the case of a Hilbert module $\mathcal{H}$ over an H^*-algebra, the natural equivalent of the Hilbert basis is the so-called modular basis.[7] An element $f \in \mathcal{H}$ is called a modular unit vector, if $[f,f]$ is a nonzero minimal projection in A. A family $\{f_\alpha\}_\alpha \subset \mathcal{H}$ is said to be modular orthonormal if

(a) $[f_\alpha, f_\beta] = 0$ if $\alpha \neq \beta$,
(b) f_α is a modular unit vector for every α.

A maximal modular orthonormal family of vectors in $\mathcal{H}$ is called a modular basis. The common cardinality of modular bases in $\mathcal{H}$ is called the modular dimension of $\mathcal{H}$ (see Ref. 7, Theorem 2).

Now, we define operators which are the natural equivalent of the finite rank operators in the case of Hilbert spaces. If $f,g \in \mathcal{H}$, then let $f \odot g$ denote the A-linear operator defined by

$$(f \odot g)h = [h,g]f \quad (h \in \mathcal{H}).$$

It is easy to see that for every A-linear operator S we have

$$S(f \odot g) = (Sf) \odot g, \quad (f \odot g)S = f \odot (S^* g)$$

and

$$(f \odot g)(f' \odot g') = ([f',g]f) \odot g' = f \odot ([g,f']g').$$

Define

$$\mathcal{F}(\mathcal{H}) = \left\{ \sum_{k=1}^{n} f_k \odot g_k : f_k, g_k \in \mathcal{H} (k=1,...,n), n \in \mathbb{N} \right\}$$

which is a *-ideal in the C^*-algebra of all A-linear operators. Observe that if $\mathcal{H}$ is a Hilbert module over $M_d(\mathbb{C})$, then the range of every element of $\mathcal{F}(\mathcal{H})$ has finite linear dimension, but there can be finite rank operators on the Hilbert space $\mathcal{H}$ which do not belong to $\mathcal{F}(\mathcal{H})$. In general, if the underlying H^*-algebra is infinite dimensional, then these two classes of operators have nothing to do with each other.

We begin with some auxiliary results that we shall need in the proof of our theorem.

Lemma 1: Let $A = M_d(\mathbb{C})$, $d \in \mathbb{N}$. If $\mathcal{H}$ is a Hilbert A-module, then every projection in $\mathcal{B}(\mathcal{H})$ is of the form $P = \Sigma_\alpha f_\alpha \odot f_\alpha$, where $\{f_\alpha\}_\alpha \subset \mathcal{H}$ is a modular orthonormal basis in the range of P (the range of an A-linear projection is a closed submodule).

If $\{f_\alpha\}_\alpha \subset \mathcal{H}$ is a modular orthonormal set, then for the orthogonal projection onto the closed submodule generated by $\{f_\alpha\}_\alpha$ (which is an A-linear projection) we have $P = \Sigma_\alpha f_\alpha \odot f_\alpha$.

Proof: Let first $P \in \mathcal{B}(\mathcal{H})$ be a projection and let $\{f_\alpha\}_\alpha$ denote a modular orthonormal basis in the closed submodule $\operatorname{rng} P$. By Ref. 7 Theorem 1, we have

$$f = \sum_\alpha [f,f_\alpha] f_\alpha \quad (f \in \operatorname{rng} P).$$

Since $Pf = 0$ and $[f,f_\alpha] = 0$ for $f \in \operatorname{rng} P^\perp$, we obtain $P = \Sigma_\alpha f_\alpha \odot f_\alpha$.

Now, let $\{f_\alpha\}_\alpha \subset \mathcal{H}$ be a modular orthonormal set and denote $\mathcal{M}$ the closed submodule generated by this set. We show that $\{f_\alpha\}_\alpha$ is a modular basis in $\mathcal{M}$. Since this collection is a modular orthonormal family, if this was not maximal, then we could find a nonzero element $f \in \mathcal{M}$ which is modular orthogonal to $\{f_\alpha\}_\alpha$, that is, $[f,f_\alpha] = 0$ for every α. But this is a contradiction, since every element of $\mathcal{M}$ can be approximated by finite sums of the form $a_1 f_{\alpha_1} + \cdots + a_n f_{\alpha_n}$ $(a_i \in A)$ and hence we would obtain that f is modular orthogonal to itself. By the first part of the proof we obtain that the orthogonal projection onto $\mathcal{M}$ is equal to $\Sigma_\alpha f_\alpha \odot f_\alpha$, so this operator is an A-linear projection. □

Lemma 2: Let $A = M_d(\mathbb{C})$, $d \in \mathbb{N}$ and let $\mathcal{H}$ be a Hilbert A-module. Suppose that $\mathcal{M} \subset \mathcal{H}$ is a closed submodule and $\{f_\alpha\}_\alpha$ is a modular orthonormal system generating $\mathcal{M}$. Then for every $g,h \in \mathcal{M}$ we have

(i) $g = \Sigma_\alpha [g,f_\alpha] f_\alpha$,
(ii) $[g,h] = \Sigma_\alpha [g,f_\alpha][f_\alpha,h]$.

Moreover, the vector $k \in \mathcal{H}$ belongs to $\mathcal{M}$ if and only if

$$[k,k]=\sum_{\alpha}[k,f_\alpha][f_\alpha,k].$$

Proof: See Ref. 7, Theorem 2, and its proof. □

Proposition 3: Let $A=M_d(\mathbb{C})$, $d\in\mathbb{N}$. If $\mathcal{H}$ is a Hilbert A-module, then $\mathcal{B}(\mathcal{H})$ is a type I von Neumann factor. If the modular dimension of $\mathcal{H}$ is greater than 2, then $\mathcal{B}(\mathcal{H})$ is not isomorphic to $M_2(\mathbb{C})$.

Proof: It is clear that $\mathcal{B}(\mathcal{H})$ is a von Neumann algebra since it is the commutant of the set $\{L_a : L_a f=af(f\in\mathcal{H},a\in A)\}$ in the full operator algebra over $\mathcal{H}$ as a Hilbert space. To show that $\mathcal{B}(\mathcal{H})$ is a factor, it is sufficient to verify that the central projections in $\mathcal{B}(\mathcal{H})$ are all trivial. Let $P\in\mathcal{B}(\mathcal{H})$ be a nonzero central projection. Let f be a modular unit vector in rng P. For any $a,b\in A$ we have

$$P\cdot g\odot(af)=g\odot(af)\cdot P=g\odot P(af)=g\odot(af).$$

This implies that

$$P(b[f,f]a^*g)=P((g\odot(af))bf)=(g\odot(af))bf=b[f,f]a^*g.$$

The element $[f,f]$ is a rank-one projection. Hence, every element of A is the sum of $b[f,f]a^*$-type elements and hence we obtain that $Pg=g$ for every $g\in\mathcal{H}$. Thus $P=I$. So, $\mathcal{B}(\mathcal{H})$ is a factor. We next prove that $\mathcal{B}(\mathcal{H})$ is type I. Let $f\in\mathcal{H}$ be a modular unit vector. Since $[f,f]f=f$ (see Ref. 7, Lemma 1), for any $A\in\mathcal{B}(\mathcal{H})$ we compute

$$f\odot f\cdot A\cdot f\odot f=([Af,f]f)\odot f=([A([f,f]f),[f,f]f]f\odot f)=([f,f][Af,f][f,f]f)\odot f=\lambda(f\odot f),$$

where λ is scalar such that $[f,f][Af,f][f,f]f=\lambda f$ (the existence of such a scalar follows from the fact that $[f,f]$ is a rank-one matrix). This shows that the projection $f\odot f$ is Abelian. So, every nonzero central projection in $\mathcal{B}(\mathcal{H})$ contains a nonzero Abelian projection which means that $\mathcal{B}(\mathcal{H})$ is type I.

Suppose that the modular dimension of $\mathcal{H}$ is greater than 2. To see that $\mathcal{B}(\mathcal{H})$ is not isomorphic to $M_2(\mathbb{C})$ it is now enough to show that the linear dimension of $\mathcal{B}(\mathcal{H})$ is greater then 4. Let $\{f_1,f_2,f_3\}$ be a modular orthonormal set in $\mathcal{H}$. Denote $[f_i,f_i]=e_i$. If $d\geqslant 2$, then there are elements $a_i,b_i\in A$ such that $\{e_ia_i,e_ib_i\}$ is independent for every $i=1,2,3$. It is easy to check that $\{(a_if_i)\odot f_i,(b_if_i)\odot f_i : i=1,2,3\}$ is linearly independent. Therefore, the algebraic dimension of $\mathcal{B}(\mathcal{H})$ is at least 6. If $d=1$, then the statement is trivial. □

Let H be a Hilbert space. Recall that if $x,y\in H$, then $x\otimes y$ stands for the operator defined by $(x\otimes y)(z)=\langle z,y\rangle x(z\in H)$. The ideal of all finite rank operators in $B(H)$ is denoted by $F(H)$.

*Lemma 4: Let H be a Hilbert space. If $\phi:F(H)\to B(H)$ is a *-homomorphism which preserves the rank-one projections, then there is an isometry $U\in B(H)$ such that ϕ is of the form*

$$\phi(A)=UAU^*\quad (A\in F(H)).$$

*Similarly, if $\psi:F(H)\to B(H)$ is a *-antihomomorphism preserving the rank-one projections, then ψ is of the form*

$$\psi(A)=VA^{\mathrm{tr}}V^*\quad (A\in F(H)),$$

where V is an isometry and tr *denotes the transpose with respect to a fixed orthonormal basis in H.*

Proof: Let $y,z\in H$ be such that $\langle\phi(y\otimes y)z,z\rangle=1$. Define

$$Ux=\phi(x\otimes y)z\quad (x\in H).$$

It is easy to see that U is an isometry and $UA=\phi(A)U(A\in F(H))$. Let $x\in H$ be an arbitrary unit vector. Then $\phi(x\otimes x)$ is a rank-one projection, so it is of the form $\phi(x\otimes x)=x'\otimes x'$ with some unit vector $x'\in H$. Since

$$Ux\otimes x=\phi(x\otimes x)U=x'\otimes U^*x',$$

we obtain that x' is equal to Ux multiplied by a scalar of modulus 1. Therefore, $\phi(x\otimes x)=Ux\otimes Ux=U\cdot x\otimes x\cdot U^*$. Since this holds true for every unit vector $x\in H$, by linearity we have the first assertion of the lemma.

As for the second statement, we can apply a similar argument. Choosing $y,z\in H$ such that $\langle\psi(y\otimes y)z,z\rangle=1$, define

$$\tilde{V}x=\psi(y\otimes x)z \quad (x\in H).$$

One can verify that $\tilde{V}$ is an anti-isometry (that is, a conjugate-linear isometry), and then prove that $\psi(A)=\tilde{V}A^*\tilde{V}^*(A\in F(H))$. Considering an antiunitary operator J for which $JA^*J^*=A^{\mathrm{tr}}$ and defining $V=\tilde{V}J$, we conclude the proof. □

Lemma 5: Let (a_n) *be a sequence in the Hilbert space H and let* $b\in H$ *be such that* $\Sigma_n a_n\otimes a_n=b\otimes b$ *in the trace norm. Then for every n there exists a scalar* λ_n *such that* $a_n=\lambda_n b$.

Proof: Clearly, we may assume that $\|b\|=1$. Taking traces on both sides of the equality $\Sigma_n a_n\otimes a_n=b\otimes b$, we obtain $\Sigma_n\|a_n\|^2=1$. On the other hand, we also have

$$\sum_n |\langle b,a_n\rangle|^2=\left\langle\left(\sum_n a_n\otimes a_n\right)b,b\right\rangle=1.$$

By the Schwarz inequality,

$$1=\sum_n |\langle b,a_n\rangle|^2\leqslant\sum_n \|a_n\|^2=1.$$

So, there are equalities in the Schwarz inequalities $|\langle b,a_n\rangle|\leqslant\|a_n\|$. This implies the assertion. □

Proof of Theorem: We define an orthoadditive projection-valued measure μ on the lattice $\mathcal{P}(\mathcal{H})$ of all A-linear projections as follows. If $\{f_\alpha\}_\alpha$ is a modular orthonormal set, then let

$$\mu\left(\sum_\alpha f_\alpha\odot f_\alpha\right)=\sum_\alpha Tf_\alpha\odot Tf_\alpha.$$

Observe that by (1), $\{Tf_\alpha\}_\alpha$ is also modular orthonormal and, hence, by Lemma 1 $\Sigma_\alpha Tf_\alpha\odot Tf_\alpha$ belongs to $\mathcal{P}(\mathcal{H})$. We show that μ is well-defined. Let $\{f_\alpha\}_\alpha$ and $\{g_\beta\}_\beta$ generate the same closed submodule $\mathcal{M}$. We claim that the same holds true for $\{Tf_\alpha\}_\alpha$ and $\{Tg_\beta\}_\beta$. Indeed, if $g\in\mathcal{M}$, then due to the fact that $\{f_\alpha\}_\alpha$ is a modular basis in $\mathcal{M}$ we see that $g=\Sigma_\alpha[g,f_\alpha]f_\alpha$. This implies that

$$[Tg,Tg]=[g,g]=\sum_\alpha [g,f_\alpha][f_\alpha,g]=\sum_\alpha [Tg,Tf_\alpha][Tf_\alpha,Tg],$$

which, by Lemma 2, gives us that Tg belongs to the closed submodule generated by $\{Tf_\alpha\}_\alpha$. It is now obvious that μ is an orthoadditive $\mathcal{P}(\mathcal{H})$-valued measure on $\mathcal{P}(\mathcal{H})$.

Let us suppose that the modular dimension of $\mathcal{H}$ is greater than 2. By Proposition 3 we can apply a deep result of Bunce and Wright [Ref. 8, Theorem A]. It states that every bounded finitely orthoadditive, Banach space valued measure on the set of all projections in a von Neumann algebra without a summand isomorphic to $M_2(\mathbb{C})$ can be uniquely extended to a bounded linear transformation defined on the whole algebra. Let $\phi:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H})$ denote the transformation corresponding to μ. Since it sends projections to projections, it is a standard argument to verify that ϕ is a Jordan *-endomorphism of $\mathcal{B}(\mathcal{H})$, that is, we have $\phi(T)^2=\phi(T^2)$, $\phi(T)^*=\phi(T^*)(T\in\mathcal{B}(\mathcal{H}))$ (see, for example, the proof of Ref. 9, Theorem 2).

We prove that $\phi(f\odot f)=Tf\odot Tf$ for every $f\in\mathcal{H}$. Let $[f,f]=\Sigma_i\lambda_i^2 e_i$, where λ_i's are non-negative real numbers and e_i's are pairwise orthogonal rank-one projections. Define $f_i=(1/\lambda_i)e_i f$. We have $[f_i,f_i]=e_i$ and $[f_i,f_j]=0$ if $i\neq j$, that is, $\{f_i\}_i$ is modular orthonormal. Then $f=\Sigma_i\lambda_i f_i=\Sigma_i e_i f$ since

$$\sum_i [f,f_i][f_i,f]=\sum_i \lambda_i^2 e_i=[f,f]$$

implies that $f=\Sigma_i[f,f_i]f_i=\Sigma_i e_i f$ (see Lemma 2). So, we have

$$\phi(f\odot f)=\sum_{i,j} \phi(e_i f\odot e_j f).$$

But $(e_i f)\odot(e_j f)=0$ if $i\neq j$. Indeed, we compute $[g,e_j f]e_i f=[g,f]e_j e_i f=0$ for every $g\in\mathcal{H}$. Hence,

$$\phi(f\odot f)=\sum_i \phi(e_i f\odot e_i f)=\sum_i \lambda_i^2\phi(f_i\odot f_i)=\sum_i \lambda_i^2\mu(f_i\odot f_i)=\sum_i \lambda_i^2 Tf_i\odot Tf_i.$$

So, the question is that whether the equality $Tf\odot Tf=\Sigma_i\lambda_i^2 Tf_i\odot Tf_i$ holds true. Clearly, $\{Tf_i\}$ is modular orthonormal. We compute

$$[Tf,Tf]=[f,f]=\sum_i [f,f_i][f_i,f]=\sum_i [Tf,Tf_i][Tf_i,Tf]$$

which, by Lemma 2, implies that $Tf=\Sigma_i[Tf,Tf_i]Tf_i$. We know that $|[Tf,Tf_i]|=|[f,f_i]|=\lambda_i e_i$. Similarly, $|[Tf_i,Tf]|=|[f_i,f]|=\lambda_i e_i$. Since e_i is a rank-one projection, we obtain that $[Tf,Tf_i]$ is also rank-one. Furthermore, as $|[Tf,Tf_i]|=|[Tf_i,Tf]|$ is a scalar multiple of e_i we can infer that $[Tf,Tf_i]=\mu_i\lambda_i e_i$, where μ_i is a scalar of modulus 1. Therefore, we have

$$Tf\odot Tf=\sum_{i,j} \mu_i\overline{\mu_j}(\lambda_i e_i Tf_i\odot\lambda_j e_j Tf_j).$$

But similarly as above, for $i\neq j$ we have

$$(e_i Tf_i\odot e_j Tf_j)g=[g,e_j Tf_j]e_i Tf_i=[g,Tf_j]e_j e_i Tf_i=0.$$

Therefore

$$\begin{aligned}Tf\odot Tf&=\sum_{i,j} \mu_i\overline{\mu_j}(\lambda_i e_i Tf_i\odot\lambda_j e_j Tf_j)\\&=\sum_i \mu_i\overline{\mu_i}(\lambda_i e_i Tf_i\odot\lambda_i e_i Tf_i)=\sum_i \lambda_i e_i Tf_i\odot\lambda_i e_i Tf_i=\sum_i \lambda_i^2(e_i Tf_i\odot e_i Tf_i).\end{aligned}$$

But $(e_i Tf_i\odot e_i Tf_i)=Tf_i\odot Tf_i$. Indeed, since Tf_i is a modular unit vector, we have $e_i Tf_i=[f_i,f_i]Tf_i=[Tf_i,Tf_i]Tf_i=Tf_i$ (see Ref. 7, Lemma 1). Consequently, we obtain $Tf\odot Tf=\Sigma_i\lambda_i^2 Tf_i\odot Tf_i$ and this was to be proved. So, we get $\phi(f\odot f)=Tf\odot Tf$ for every $f\in\mathcal{H}$.

We assert that ϕ is either a *-homomorphism or a *-antihomomorphism. By Lemma 1 the minimal projections in $\mathcal{H}$ are exactly the operators of the form $f\odot f$, where $f\in\mathcal{H}$ is a modular unit vector. Clearly, ϕ sends minimal projections to minimal projections. By Ref. 1, Lemma 2, the linear space generated by the minimal projections in $\mathcal{B}(\mathcal{H})$ is $\mathcal{F}(\mathcal{H})$. Since $\mathcal{B}(\mathcal{H})$ is a type I factor, it is isomorphic to the full operator algebra $B(H)$ on a Hilbert space H. Since *-isomorphisms preserve the minimal projections, $\mathcal{F}(\mathcal{H})$ corresponds to the ideal $F(H)$ of all finite rank operators in $B(H)$. Under this identification, we obtain a Jordan *-homomorphism $\tilde{\phi}$ on $F(H)$ corresponding to $\phi_{|\mathcal{F}(\mathcal{H})}$ which sends rank-one projections to rank-one projections. Since $F(H)$ is a local matrix algebra, by Ref. 10, Theorem 8, we obtain that $\tilde{\phi}$ is the sum of a *-homomorphism and a *-antihomomorphism. As $\tilde{\phi}$ preserves the rank-one projections, from the simplicity of the ring $F(H)$ it follows that $\tilde{\phi}$ is either a *-homomorphism or a *-antihomomorphism. Obviously, the same holds for $\phi_{|\mathcal{F}(\mathcal{H})}$.

Let us suppose that the modular dimension of $\mathcal{H}$ is greater than d. By Ref. 1, Remark 2, there are vectors $g,h\in\mathcal{H}$ such that $[g,h]=I$. The map $\phi_{|\mathcal{F}(\mathcal{H})}$ is either a *-homomorphism or a *-antihomomorphism. First consider this latter case. Referring to Lemma 4 we have an operator $U\in\mathcal{B}(\mathcal{H})$ with $U^*U=I$ and a *-antiautomorphism ψ of $\mathcal{F}(\mathcal{H})$ such that $\phi(A)=U\psi(A)U^*(A\in\mathcal{F}(\mathcal{H}))$.

We define

$$Vf=\psi(g\odot f)U^*Th \quad (f\in\mathcal{H}),$$

where $g,h\in\mathcal{H}$ are fixed and such that $[g,h]=I$. Clearly, V is a conjugate-linear operator. We have

$$VAf=\psi(g\odot(Af))U^*Th=\psi(g\odot fA^*)U^*Th=\psi(A)^*\psi(g\odot f)U^*Th=\psi(A)^*Vf,$$

that is, $VA=\psi(A)^*V(A\in\mathcal{F}(\mathcal{H}))$. We compute

$$\begin{aligned}[Vf,Vf]&=[\psi(g\odot f)U^*Th,\psi(g\odot f)U^*Th]\\&=[\psi(g\odot f\cdot f\odot g)U^*Th,U^*Th]\\&=[U\psi(g\odot f\cdot f\odot g)U^*Th,Th]\\&=[\phi(g\odot f\cdot f\odot g)Th,Th]\\&=[\phi(\sqrt{[f,f]}g\odot\sqrt{[f,f]}g)Th,Th]\\&=[(T(\sqrt{[f,f]}g)\odot T(\sqrt{[f,f]}g))Th,Th]\\&=[Th,T(\sqrt{[f,f]}g)][T(\sqrt{[f,f]}g),Th]\\&=[h,\sqrt{[f,f]}g][\sqrt{[f,f]}g,h]=[h,g][f,f][g,h]=[f,f].\end{aligned}$$

Since V is conjugate-linear, by polarization we obtain

$$[Vf,Vf']=[f',f] \quad (f,f'\in\mathcal{H}).$$

We show that $\operatorname{rng}T\subset\operatorname{rng}U$ which will imply $UU^*T=T$ (UU^* is the projection onto the range of U). Let $f\in\mathcal{H}$. In the previous part of the proof we have learned that $Tf\odot Tf$ is a linear combination of operators of the form $Tf_b\odot Tf_b$, where f_b's are modular unit vectors. We have

$$Tf_b\odot Tf_b=\phi(f_b\odot f_b)=U\psi(f_b\odot f_b)U^*$$

and, ψ being a *-antiautomorphism, $\psi(f_b\odot f_b)$ is a minimal projection. Therefore, $\psi(f_b\odot f_b)=f'_b\odot f'_b$ with some modular unit vector f'_b and hence $Tf_b\odot Tf_b=Uf'_b\odot Uf'_b$. Now let $Tf=g'+g''$, where $g'\in\operatorname{rng}U$ and $g''\in\operatorname{rng}U^\perp$. We have

$$[g'',g'']^2=[g'',Tf][Tf,g'']=[(Tf\odot Tf)g'',g'']=0.$$

This gives us that $g''=0$ which shows that $Tf\in \operatorname{rng} U$.

We next prove that V is surjective. Let $f\in\mathcal{H}$ be arbitrary. Since ψ is a *-antiautomorphism of $\mathcal{F}(\mathcal{H})$, we can find an operator $R\in\mathcal{F}(\mathcal{H})$ such that $\psi(R)^*=f\odot U^*Th$. We compute

$$\begin{aligned}VRg&=\psi(R)^*Vg\\&=\psi(R)^*\psi(g\odot g)U^*Th\\&=\psi(R)^*U^*\phi(g\odot g)Th\\&=\psi(R)^*U^*(Tg\odot Tg)Th\\&=[Th,Tg]\psi(R)^*U^*Tg\\&=[Th,Tg][U^*Tg,U^*Th]f\\&=[Th,Tg][UU^*Tg,Th]f\\&=[Th,Tg][Tg,Th]f=[h,g][g,h]f=f.\end{aligned}$$

Since f was arbitrary, we have the surjectivity of V.

We compute

$$\begin{aligned}[][UVf',Tf][Tf,UVf']&=[(Tf\odot Tf)UVf',UVf']\\&=[U^*(Tf\odot Tf)UVf',Vf']\\&=[U^*\phi(f\odot f)UVf',Vf']\\&=[\psi(f\odot f)Vf',Vf']\\&=[(V\cdot f\odot f)f',Vf']=[f',(f\odot f)f']=[f',f][f,f'].\end{aligned}$$

This gives us that

$$\begin{aligned}[][V^{-1}U^*Tf',f][f,V^{-1}U^*Tf']&=[UVV^{-1}U^*Tf',Tf][Tf,UVV^{-1}U^*Tf']\\&=[UU^*Tf',Tf][Tf,UU^*Tf']\\&=[Tf',Tf][Tf,Tf']=[f',f][f,f'].\end{aligned}$$

Replacing f by $xf(x\in A)$, we obtain

$$[V^{-1}U^*Tf',f]x^*x[f,V^{-1}U^*Tf']=[f',f]x^*x[f,f'].$$

Since every element of A is a linear combination of elements of the form x^*x, it follows that

$$[V^{-1}U^*Tf',f]y[f,V^{-1}U^*Tf']=[f',f]y[f,f']$$

holds for every $y\in A$. This implies that for every $f\in\mathcal{H}$, the matrices $[f,V^{-1}U^*Tf']$ and $[f,f']$ are linearly dependent. It requires only elementary linear algebra to verify the following assertion. If X,Y are vector spaces and $A,B:X\to Y$ are linear operators such that for every $x\in X$, the set $\{Ax,Bx\}$ is linearly dependent, then either A and B have rank at most one or $\{A,B\}$ is linearly dependent. Since the rank of the linear operator $f\mapsto[f,f']$ is clearly greater than 1 if $f'\neq 0$, we have a scalar $\lambda_{f'}$ (depending only on f') such that $[f,V^{-1}U^*Tf']=\lambda_{f'}[f,f'](f,f'\in\mathcal{H})$. This gives us that there is a function $\varphi:\mathcal{H}\to\mathbb{C}$ such that $V^{-1}U^*Tf'=\varphi(f')f'$ which results in $Tf'=\varphi(f')UVf'$. It follows from the properties of T,U,V that φ is of modulus 1. Finally, we have

$$|[f,f']|=|[Tf,Tf']|=|[UVf,UVf']|=|[Vf,Vf']|=|[f',f]|.$$

Since this must hold true for every $f,f' \in \mathcal{H}$, it follows that for every rank-one matrix $a \in A$ we have $|a| = |a^*|$. But this is an obvious contradiction. Since we have started with assuming that $\phi_{|\mathcal{F}(\mathcal{H})}$ is a *-antihomomorphism, we thus obtain that it is in fact a *-homomorphism.

Pushing the problem from $\mathcal{B}(\mathcal{H})$ to the full operator algebra $B(H)(\cong \mathcal{B}(\mathcal{H}))$, we see that there is an A-isometry $U \in \mathcal{B}(\mathcal{H})$ such that $\phi(A) = UAU^*(A \in \mathcal{F}(\mathcal{H}))$. This gives us that $Tf \odot Tf = Uf \odot Uf$ for every $f \in \mathcal{H}$. Similarly as before, this implies that $\operatorname{rng} T \subset \operatorname{rng} U$ which yields $UU^*Tf = Tf(f \in \mathcal{H})$. We next compute

$$[Uf',Tf][Tf,Uf'] = [(Tf \odot Tf)Uf',Uf'] \\ = [(Uf \odot Uf)Uf',Uf'] = [Uf',Uf][Uf,Uf'] = [f',f][f,f'],$$

which gives us that

$$[U^*Tf',f][f,U^*Tf'] = [UU^*Tf',Tf][Tf,UU^*Tf'] = [Tf',Tf][Tf,Tf'] = [f',f][f,f'].$$

Just as above, it follows that U^*Tf' is a scalar multiple of f'. Therefore, there exists an A-isometry U and a phase-function $\varphi:\mathcal{H} \to \mathbb{C}$ such that

$$Tf = \varphi(f)Uf \quad (f \in \mathcal{H}).$$

This completes the proof in the case when the modular dimension n of $\mathcal{H}$ is greater than d.

We now treat the low dimensional cases, that is, when $n \leqslant d$. Let H_d denote the d-dimensional complex Euclidean space. Then H_d can be considered as a Hilbert A-module. Here, the module operation is $(a,\xi) \mapsto a(\xi)$ and the generalized inner product is defined by $[\xi,\zeta] = \xi \otimes \zeta$. Clearly, the modular dimension of this module is 1. It now follows from the structure of our Hilbert A-modules (see, for example, Ref. 11) that $\mathcal{H}$ is isomorphic to the n-fold direct sum of H_d with itself. So, we may assume that $\mathcal{H} = \Sigma_{i=1}^n \oplus H_d$. The definition of the module operation and that of the inner product on this direct sum is defined as follows:

$$a[\xi_i]_i = [a\xi_i]_i, \quad [[\xi_i]_i,[\zeta_i]_i] = \sum_i \xi_i \otimes \zeta_i .$$

Let us describe the elements of $\mathcal{B}(\mathcal{H})$. Since every element of $\mathcal{B}(\mathcal{H})$ is a linear operator on the direct sum of vector spaces, it can represented by a matrix

$$\begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{bmatrix},$$

where a_{ij}'s are linear operators acting on H_d. Now, A-linearity means that

$$\begin{bmatrix} a_{11}a\xi_1 + \cdots + a_{1n}a\xi_n \\ \vdots \\ a_{n1}a\xi_1 + \cdots + a_{nn}a\xi_n \end{bmatrix} = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} a\xi_1 \\ \vdots \\ a\xi_n \end{bmatrix} = \begin{bmatrix} a(a_{11}\xi_1 + \cdots + a_{1n}\xi_n) \\ \vdots \\ a(a_{n1}\xi_1 + \cdots + a_{nn}\xi_n) \end{bmatrix}$$

holds for every $a \in A$ and $\xi_i \in H_d$. It is easy to see that this is equivalent to $a_{ij}a = aa_{ij}(a \in A)$ which means that a_{ij}'s are scalars. Consequently, $\mathcal{B}(\mathcal{H})$ is isomorphic to $M_n(\mathbb{C})$.

Suppose that $n > 1$. If ζ is any vector in H_d, then let ζ^k denote the element of $\mathcal{H}$ whose coordinates are all 0 except for the kth one which is ζ. Fix a unit vector $\xi \in H_d$. We have

$$\sum_i (T\xi^k)_i \otimes (T\xi^k)_i = [T\xi^k, T\xi^k] = [\xi^k, \xi^k] = \xi \otimes \xi.$$

From Lemma 5 we infer that for every $i=1,...,n$, there is a scalar α_{ik} such that $(T\xi^k)_i=\alpha_{ik}\xi$. Clearly, the columns of the matrix (α_{ik}) are unit vectors. Since $[T\xi^k,T\xi^l]=0$ for $k\neq l$, it follows that the columns of our matrix are pairwise orthogonal as well. So (α_{ik}) is a unitary matrix and hence it defines an A-unitary operator U on $\mathcal{H}$. Considering U^*T instead of T, we can assume that $T\xi^k$ is equal to ξ^k for every $k=1,...,n$. If f is any vector in $\mathcal{H}$, then considering the equality

$$|\xi\otimes(Tf)_k|=|[T\xi^k,Tf]|=|[\xi^k,f]|=|\xi\otimes f_k|,$$

we obtain

$$(Tf)_k=\mu_k f_k \quad (k=1,...,n) \tag{2}$$

with some scalars μ_k of modulus 1. We claim that all the μ_k's are equal. Fix a $g\in\mathcal{H}$ whose coordinates are pairwise orthogonal unit vectors in H_d (recall that $n\leqslant d$). It is apparent that if we multiply T from the left by an A-unitary operator whose matrix is diagonal, then the so obtained transformation still has the property (2). So we may assume that $Tg=g$. Let $f\in\mathcal{H}$ be arbitrary. We have

$$\left|\sum_i \mu_i f_i\otimes g_i\right|=|[Tf,Tg]|=|[f,g]|=\left|\sum_i f_i\otimes g_i\right|.$$

This implies that

$$\sum_{i,j}\langle\mu_j f_j,\mu_i f_i\rangle g_i\otimes g_j=\sum_{i,j}\langle f_j,f_i\rangle g_i\otimes g_j$$

which gives that

$$\langle\mu_j f_j,\mu_i f_i\rangle=\langle f_j,f_i\rangle.$$

So, if $\langle f_i,f_j\rangle\neq 0$, then we have $\mu_i=\mu_j$. Suppose now that $\langle f_i,f_j\rangle=0$ but $f_i,f_j\neq 0$. Let $\zeta\in H_d$ be any nonzero vector and consider $\zeta^i+\zeta^j$. By what we have just proved, it follows that $T(\zeta^i+\zeta^j)$ is a scalar multiple of $\zeta^i+\zeta^j$. We compute

$$|\zeta\otimes(\mu_i f_i+\mu_j f_j)|=|[\zeta^i+\zeta^j,Tf]|=|[T(\zeta^i+\zeta^j),Tf]|=|[\zeta^i+\zeta^j,f]|=|\zeta\otimes(f_i+f_j)|$$

which clearly gives us that $\mu_i=\mu_j$. Therefore, we obtain that for any vector $f\in\mathcal{H}$, Tf is equal to f multiplied by a complex number of modulus 1. The assertion of the theorem now follows for the case $1<n\leqslant d$.

Finally, suppose that $n=1$, which means that $\mathcal{H}=H_d$. Our problem is to describe those maps $T:H_d\rightarrow H_d$ for which $|T\xi\otimes T\zeta|=|\xi\otimes\zeta|(\xi,\zeta\in H_d)$. But this equality clearly implies that $T\zeta$ is equal to ζ multiplied by a scalar of modulus 1.

The proof of the theorem is now complete. □

Two new potentials for the free particle model

J. Morales[a)] and J. J. Peña
Universidad Autónoma Metropolitana, Azcapotzalco, CBI-Area de Física, Av. San Pablo 180, 02200 México, D.F., Mexico

(Received 18 January 1999; accepted for publication 11 August 1999)

In this work, is proposed a very simple method for obtaining the generalized potential associated with a known standard potential. The procedure is straightforward because it only uses two Ricatti-type relationships as enough condition to find a generalized potential; one particular equation is needed to identify the specific potential under study and one general Ricatti relationship is used to find the corresponding generalized potential. Moreover, the method is completely general due to the fact that an arbitrary potential has been considered in its development for which the procedure can also be used to find new potentials which could be needed in the modeling of important quantum interactions. The usefulness of the proposed approach, is shown with the treatment of the three- and one-dimensional potential for the free particle model. This work example leads to two new potentials whose Hamiltonians are isospectral when they are compared with the former Hamiltonian.

I. INTRODUCTION

At the origin of the quantum theory, the proposition of interaction models to explain different experimental data has played a role of extraordinary importance in the theoretical treatment of atoms and molecules. In this regard, in search of solutions for the second order differential equation involved, the factorization of the Schrödinger relationship is a powerful operational method which has its roots in the Dirac's second quantization treatment of the one-dimensional harmonic oscillator potential.[1] Today, for obtaining the algebraic representation of any other standard potential, the following procedures are available: Infeld and Hull's (IH) factorization method,[2] quantizing classical dynamical variables,[3] using the algebraic representation of the orthogonal polynomials directly involved[4] and by an alternative approach[5] to the IH procedure. However, the above procedures do not allow extending the scope of the so-called isospectral potentials,[6,7] generalized or modified, whose treatment has been considered only for some particular cases.[8–10] In the present work we consider a general formalism for obtaining any modified and generalized potential associated with a known or unknown specific potential. The proposed approach is based on a procedure that instead of factoring the Schrödinger equation uses the equivalent of supersymmetry techniques applied to quantum mechanics.[11] As it can be seen later, as a result of the factorization of the Hamiltonian, which incorporates an arbitrary potential, we propose a general method to find isospectral potentials by means of the use of two Ricatti-type relationships: a specific one to identify the potential under study and a general one to obtain the isospectral potentials. Finally, in spite that the proposed approach is totally general, due to the fact that it considers know and unknown potentials, in Sec. III we show the usefulness of the proposed algorithm by obtaining the generalized potential associated with the free particle model.

II. GENERAL PROCEDURE FOR ANY $V(r)$ POTENTIAL

As mentioned in the previous section, the principal idea behind this work is concerned with the factorization of a general Hamiltonian H, with an arbitrary potential $V(r)$, instead of the factorization of the corresponding Schrödinger relationship. That is, when one consider the first order operational equations

[a)]Electronic mail: jmr@hp9000a1.uam.mx

$$a^{\pm}=\frac{\hbar}{\sqrt{2m}}\left(\beta(r)-\frac{l}{r}\mp\frac{d}{dr}\right), \tag{2.1}$$

where $\beta(r)$ is any function, it becomes evident that

$$a^{\mp}a^{\pm}=H^{\pm}-V^{\pm}(r)+\frac{\hbar^2}{2m}\left(\beta^2(r)\pm\beta'(r)-\frac{2l\beta(r)}{r}-\frac{(l\mp l)}{r^2}\right), \tag{2.2}$$

where

$$H^{\pm}=-\frac{\hbar^2}{2m}\left(\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}\right)+V^{\pm}(r). \tag{2.3}$$

That is, there are two Hamiltonians (named $H^{\pm}$) related with two potentials (named $V^{\pm}(r)$), which can be exactly factorized by means of

$$a^{\mp}a^{\pm}=H^{\pm}+C^{\pm} \tag{2.4}$$

with the condition to fulfill the relationship

$$C^{\pm}=-V^{\pm}(r)+\frac{\hbar^2}{2m}\left(\beta^2(r)\pm\beta'(r)-\frac{2l\beta(r)}{r}-\frac{(l\mp l)}{r^2}\right), \tag{2.5}$$

where $C^{\pm}$ is a constant parameter. Without loss of generality, one can always choose $C^{\pm}=C$ in order to obtain

$$V^{\pm}(r)-V^{\mp}(r)=\pm\frac{\hbar^2}{m}\left(\beta'(r)+\frac{l}{r^2}\right) \tag{2.6}$$

which is equivalent to

$$V^{+}(r)-V^{-}(r)=\frac{\hbar^2}{m}\left(\beta'(r)+\frac{l}{r^2}\right), \tag{2.7}$$

where, from Eq. (2.5),

$$V^{+}(r)=\frac{\hbar^2}{2m}\left(\beta^2(r)+\beta'(r)-\frac{2l\beta(r)}{r}\right)-C. \tag{2.8}$$

Consequently, this last equation can be arranged in order to have the form of the Ricatti relationship,

$$\beta'(r)=-\beta^2(r)+\frac{2l}{r}\beta(r)+\frac{2m}{\hbar^2}(V^{+}(r)+C). \tag{2.9}$$

In fact, the identification of $\beta(r)=y$, $Q(r)=-1$, $P(r)=2l/r$, and $R(r)=(2m/\hbar^2)(V^{+}(r)+C)$, allows us to obtain

$$y'=Q(r)y^2+P(r)y+R(r), \tag{2.10}$$

which has as general solution

$$y=y_p+\frac{b}{\mu}, \tag{2.11}$$

where y_p is a particular solution,

$$\mu=e^{-\int^r[2Q(r)y_p+P(r)]dr}\left(\gamma-b\int^r e^{\int^r[2Q(r)y_p+P(r)]dr}Q(r)dr\right), \tag{2.12}$$

and where γ and b are constant. In other words, if we consider a specific $\beta_p(r)$ as a particular solution of the specific Ricatti relationship,

$$\beta_p'(r)=-\beta_p^2(r)+\frac{2l}{r}\beta_p(r)+\frac{2m}{\hbar^2}(V_p^+(r)+C), \tag{2.13}$$

two events take place; first, the choice of an $\beta_p(r)$ ansatz lets us identify the $V_p^+(r)$ particular potential under study and, second, it is always possible to construct $\beta_g(r)$, the general solution of Eq. (2.9), by means of

$$\beta(r)=\beta_g(r)=\beta_p(r)+\frac{b}{\rho(r)}, \tag{2.14}$$

where the subindex g is used to denote the general solution and

$$\rho(r)=\frac{1}{r^{2l}}e^{2\int^r\beta_p(r)dr}\left(\gamma+b\int^r r^{2l}e^{-2\int^r\beta_p(r)dr}dr\right). \tag{2.15}$$

Thus, according to Eq. (2.7), the identification of the corresponding $V_p^-(r)$ particular potential under study occurs by means of

$$V_p^-(r)=V_p^+(r)-\frac{\hbar^2}{m}\left(\beta_p'(r)+\frac{l}{r^2}\right) \tag{2.16}$$

in such a way that using Eq. (2.8) and Eqs. (2.13)–(2.15) one finds that the generalized potential $V_g^+(x)$ is given by

$$V_g^+(r)=V_p^+(r)+\frac{\hbar^2 b}{m}\left(\frac{b}{\rho^2(r)}-\frac{\rho'(r)}{\rho^2(r)}+\frac{2\beta_p(r)}{\rho(r)}-\frac{2l}{r\rho(r)}\right). \tag{2.17}$$

At this point, it should be noticed that

$$\rho'(r)=2\beta_p(r)\rho(r)+b-\frac{2l\rho(r)}{r}, \tag{2.18}$$

thereby reducing Eq. (2.17) to

$$V_g^+(r)=V_p^+(r) \tag{2.19}$$

as well as

$$H_g^+=H_p^+=-\frac{\hbar^2}{2m}\left(\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}\right)+V_p^+(r) \tag{2.20}$$

which means that there does not exist a special $V_g^+(r)$ potential. This important result indicates that the generalized operators

$$a_g^{\pm}=A^{\pm}=\frac{\hbar}{\sqrt{2m}}\left(\beta_p(r)+\frac{b}{\rho(r)}-\frac{l}{r}\mp\frac{d}{dr}\right) \tag{2.21}$$

factorize, both, the particular Hamiltonian H_p^+ or H_g^+ according to

$$A^-A^+=H_{p,g}^+ +C. \tag{2.22}$$

Similarly, the generalized Hamiltonian H_g^- is factorized by means of

$$A^+A^-=H_g^- +C, \tag{2.23}$$

where H_g^- is associated with the generalized potential $V_g^-(r)$ which is given, after using Eq. (2.7), Eq. (2.14), and Eq. (2.16), by

$$V_g^-(r)=V_p^-(r)-\frac{\hbar^2}{m}\frac{d}{dr}\left(\frac{b}{\rho(r)}\right). \tag{2.24}$$

Finally, the existence of this new potential, which is generalized, is particularly important due to the fact that Eq. (2.22) and Eq. (2.23) lead to

$$H_g^-A^+=A^+H_{p,g}^+ \tag{2.25}$$

or

$$H_g^-A^+\psi=E_nA^+\psi, \tag{2.26}$$

where E_n and ψ are, respectively, the energy and eigenfunctions of $H_{p,g}^+$. Therefore, from the above equation it becomes evident that the Hamiltonian H_g^- has eigenfunctions $\phi=A^+\psi$ with the same energy spectra of $H_{p,g}^+$ and consequently the corresponding $V_g^-(r)$ generalized potential has the energy spectra of the particular potential $V_p^+(r)$. This result clearly justifies why the new potential $V_g^-(r)$ is called isospectral, which is in good agreement with already published results on certain particular Hamiltonians.[6–8,12–14] Evidently, the same occurs with the modified potential $V_p^-(r)$ given in Eq. (2.16) because the Hamiltonians H_p^+ or H_g^+ are related to H_p^- through the operators $a^{\pm}$ by means of

$$H_{p,g}^+a^-=a^-H_p^- \quad \text{and} \quad H_p^-a^+=a^+H_{p,g}^+, \tag{2.27}$$

which lead to

$$H_p^-(a^+\psi)=E_p^+(a^+\psi), \tag{2.28}$$

where $E_p^+=E_n$, proving that the modified Hamiltonian H_p^- is also isospectral.

III. TWO NEW POTENTIALS FOR THE FREE PARTICLE MODEL

The previously described procedure for obtaining generalized potentials, is straightforward and reduces to the use of three relationships; the master Eq. (2.8) with a specific solution $\beta_p(r)$, which can be taken *ad hoc* to match with the $V_p^+(r)$ particular potential under study, Eq. (2.16) used to find the $V_p^-(r)$ modified partner potential and finally the use of Eq. (2.24) to get the corresponding $V_g^-(r)$ generalized potential. In this section, we will consider the case of the well known free particle model in order to generalize it as well as to find the corresponding associated potential and its reduction to the particular one-dimensional situation.

A. A new three-dimensional potential for the free particle model $(0<r<\infty)$

According to Eq. (2.8), any particular potential is given by

$$V_p^+(r)=\frac{\hbar^2}{2m}\left(\beta_p^2(r)+\beta_p'(r)-\frac{2l\beta_p(r)}{r}\right)-C_p. \tag{3.1}$$

Thus, with the purpose of identifying the three-dimensional potential for the free-particle interaction model we use in the previous equation the ansatz $\beta_p(r)=0$ which gives rise to

$$V_p^+(r)=C_p=0. \tag{3.2}$$

Consequently, according to Eq. (2.16), the corresponding modified potential is then

$$V_p^-(r)=-\frac{\hbar^2 l}{mr^2}. \tag{3.3}$$

That is, the Hamiltonians $H_p^\pm$ associated with these potentials are

$$H_p^\pm=-\frac{\hbar^2}{2m}\left(\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}\right)-\frac{\hbar^2(l\mp l)}{2mr^2}, \tag{3.4}$$

and they are factorized by means of $a^\mp a^\pm=H_p^\pm$, where $a^\pm$ are the first order differential operators

$$a^\pm=\frac{\hbar}{\sqrt{2m}}\left(-\frac{l}{r}\mp\frac{d}{dr}\right). \tag{3.5}$$

On the other hand, from Eq. (2.15) and by considering the fact that $\beta_p(r)=0$ one gets

$$\rho(r)=\frac{\gamma}{r^{2l}}+\frac{br}{2l+1}. \tag{3.6}$$

Finally, according to Eq. (2.24), the generalized potential that corresponds to this case is given by

$$V_g^-(r)=-\frac{\hbar^2 l}{mr^2}-\frac{\hbar^2 b(2l(\gamma+R(r))r^{2l-1}-br^{4l})}{m(\gamma+R(r))^2}, \tag{3.7}$$

where $R(r)=(br^{2l+1}/2l+1)$. Consequently, the Hamiltonian H_g^- associated with this generalized potential becomes

$$H_g^-=-\frac{\hbar^2}{2m}\left(\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}\right)-\frac{\hbar^2 l}{mr^2}-\frac{\hbar^2 b(2l(\gamma+R(r))r^{2l-1}-br^{4l})}{m(\gamma+R(r))^2} \tag{3.8}$$

in such a way that it is factorized by means of $A^+A^-=H_g^-$, where $A^\pm$ are given by

$$A^\pm=\frac{\hbar}{\sqrt{2m}}\left(\frac{br^{2l}}{\gamma+R(r)}-\frac{l}{r}\mp\frac{d}{dr}\right). \tag{3.9}$$

On the other hand, due to the fact that wave functions for this case of the free particle model are given, according to Buckingham,[15] by $\psi_p(l,r)=krj_l(kr)$, where $j_l(kr)$ are the spherical Bessel functions, it becomes that normalized eigenfunctions of the corresponding generalized H_g^- Hamiltonian are given, from Eq. (2.26), by

$$\phi_g(l,z)=\phi_g(z)=A^+\psi_p(l,z)=\frac{\hbar k}{\sqrt{2m}}\left(\frac{bz^{2l+1}j_l(z)}{\gamma_k+R(z)}-(l+1)j_l(z)-zj_l'(z)\right), \tag{3.10}$$

where $z=kr$, $\gamma_k=k^{2l+1}\gamma$, and $\psi_p(l,z)=zj_l(z)$. Thus, the normalized Hamiltonian $H_g^-(z)$ of Eq. (3.8) becomes

$$H_g^-(z)=-\frac{\hbar^2k^2}{2m}\left(\frac{d^2}{dz^2}-\frac{l(l-1)}{z^2}+\frac{4blz^{2l-1}}{\gamma_k+R(z)}-\frac{2b^2z^{4l}}{(\gamma_k+R(z))^2}\right) \tag{3.11}$$

for which it follows that

$$H_g^-(z)\phi_g(z)=-\frac{\hbar^3k^3}{(2m)^{3/2}}\left(\frac{bz^{2l+1}j_l''(z)}{\gamma_k+R(z)}+\frac{2bz^{2l}j_l'(z)}{\gamma_k+R(z)}-\frac{l(l+1)bz^{2l-1}j_l(z)}{\gamma_k+R(z)}\right.$$
$$\left.-(l+3)j_l''(z)-zj_l'''(z)+\frac{l(l+1)(l-1)j_l(z)}{z^2}+\frac{l(l-1)j_l'(z)}{z}\right). \tag{3.12}$$

Finally, with the aim of simplifying the third and second order derivatives of the spherical Bessel functions that appeared in the above relationship, we use repeatedly the differential equation[16]

$$j_l''(z)+\frac{2j_l'(z)}{z}+\left(1-\frac{l(l+1)}{z^2}\right)j_l(z)=0 \tag{3.13}$$

in order to get

$$H_g^-(z)\phi_g(z)=-\frac{\hbar^2k^2}{2m}\left(\frac{\hbar k}{\sqrt{2m}}\right)\left\{zj_l'(z)-\frac{bz^{2l+1}j_l(z)}{\gamma_k+R(z)}+(l+1)j_l(z)\right\}. \tag{3.14}$$

That is, by identifying the terms inside the two parentheses with the wave function $\phi_g(z)$ of Eq. (3.10) it becomes that

$$H_g^-(z)\phi_g(z)=E_g\phi_g(z), \tag{3.15}$$

where $E_g=E_p=(\hbar^2k^2/2m)$, which proves that the generalized Hamiltonian $H_g^-(z)$ is isospectral with respect to the particular Hamiltonians $H_p^{\pm}(z)$ as expected for the free particle interaction model.

Due to fact that we are involved with a scattering potential, it is important to find the phase shift existing between the generalized potential and the specific one of the free particle model. In this case, according to Eq. (3.10) the asymptotic wave functions of the generalized potential are given by

$$\phi_g(z)\rightarrow\sin\left(z-\frac{\pi(l+1)}{2}\right), \tag{3.16}$$

$$z\rightarrow\infty$$

which indicates that these wave functions are displaced in one unit in the angular momentum l with respect to the corresponding free particle wave functions given by[17]

$$\phi_g(z)\rightarrow \sin\left(z-\frac{\pi l}{2}\right), \tag{3.17}$$

$$z\rightarrow\infty.$$

Finally, concerning the specific case of the free particle one-dimensional potential, it is important to notice that $l=0$ in Eq. (3.3) leads to the modified potential $V_p^-=0$ in such a way that the use of Eq. (3.7) gives origin to the corresponding generalized potential

$$V_g^-(x)=\frac{\hbar^2}{m}\left(\frac{b}{\gamma+bx}\right)^2 \tag{3.18}$$

in good agreement with already published results.[14] At this point, it is important to notice that there is the possibility of finding another, different from the above, one-dimensional potential for the same free particle model if, instead of using the mentioned reductions in the general solutions, one can consider an alternative ansatz in the corresponding Ricatti relationship for $l=0$ as shown in the following section.

B. A new one-dimensional potential for the free particle model

As mentioned in the last paragraph, when considering the Ricatti relationship given in Eq. (2.9) for the one-dimensional potential situation, $r=x, -\infty<x<\infty$ and $l=0$, one have

$$\beta'(x)=-\beta^2(x)+\frac{2m}{\hbar^2}(V^+(x)+C) \tag{3.19}$$

which it has as its general solution, Eq. (2.11). It should be pointed out, that in this new situation the μ that appears in Eq. (2.12) is given by

$$\mu=e^{-\int^x 2Q(x)y_p dx}\left(\gamma-b\int^x e^{\int^x 2Q(x)y_p dx}Q(x)dx\right), \tag{3.20}$$

where γ and b are constant. Similarly to the three-dimensional case, we can consider $\beta_p(x)$ as a particular solution of the specific Ricatti relationship

$$V_p^+(x)=\frac{\hbar^2}{2m}(\beta_p^2(x)+\beta_p'(x))-C_p \tag{3.21}$$

in such a way that the corresponding solution of Eq. (3.19) is

$$\beta(x)=\beta_g(x)=\beta_p(x)+\frac{b}{\rho(x)}, \tag{3.22}$$

where the subindex g is used to denote the general solution and

$$\rho(x)=e^{2\int\beta_p(x)dx}\left(\gamma+b\int e^{-2\int\beta_p(x)dx}dx\right). \tag{3.23}$$

Thus, according to Eq. (2.16) and Eq. (2.24), the one-dimensional modified potential is given by

$$V_p^-(x) = V_p^+(x) - \frac{\hbar^2}{m}\beta_p'(x) \tag{3.24}$$

and

$$V_g^-(x) = V_p^-(x) - \frac{\hbar^2}{m}\frac{d}{dx}\left(\frac{b}{\rho(x)}\right) \tag{3.25}$$

is the corresponding generalized potential.

In consequence, if in Eq. (3.21) we choose the ansatz $\beta_p(x) = B$, where B is any constant, it obtained the specific potential

$$V_p^+(x) = \frac{\hbar^2 B^2}{2m} - C_p\,. \tag{3.26}$$

Clearly, without loss of generality we can put in the previous equation $C_p = (\hbar^2 B^2/2m)$ in order to shown that $V_p^+(x)$ and the corresponding modified $V_p^-(x)$ potentials are null which means that both are the well known one-dimensional potential for the free particle model. In that case, the first order operational equations

$$a_p^{\pm} = \frac{\hbar}{\sqrt{2m}}\left(B \mp \frac{d}{dx}\right) \tag{3.27}$$

factorize the corresponding Hamiltonians $H_p^{\pm}$ by means of

$$a_p^{\mp} a_p^{\pm} = H_p^{\pm} + C_p\,, \tag{3.28}$$

where $H_p^- = H_p^+ = -(\hbar^2/2m)(d^2/dx^2)$.

Finally, with the purpose of identifying the generalized potential that corresponds to this new situation of $\beta_p(x) = B$, it is necessary to consider Eq. (3.23) in order to find

$$\rho(x) = \gamma e^{2Bx} - \frac{b}{2B}. \tag{3.29}$$

In consequence, putting $b = 1$ in the above relationship and using Eq. (3.25), we found that the new generalized or partner potential associated with the one-dimensional free particle system is given by

$$V_g^-(x) = \frac{(2B)^3 \hbar^2 \gamma e^{2Bx}}{m(2B\gamma e^{2Bx} - 1)^2} \tag{3.30}$$

in such a way that the respective generalized Hamiltonian

$$H_g^- = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{(2B)^3 \hbar^2 \gamma e^{2Bx}}{m(2B\gamma e^{2Bx} - 1)^2}, \tag{3.31}$$

as well as $H_p^{\pm}$, are factorized according to the rule

$$A^+ A^- = H_g^- + C \text{ and } A^- A^+ = H_p^{\pm} + C, \tag{3.32}$$

where $C = C_p$ and

$$A^{\pm}=\frac{\hbar}{\sqrt{2m}}\left(B+\frac{2B}{2B\gamma e^{2Bx}-1}\mp\frac{d}{dx}\right). \tag{3.33}$$

Concerning the generalized wave functions, if we consider the most simple form $\psi_p=\sin(kx)$ for the eigenfunctions of the particular one-dimensional free particle Hamiltonian, it becomes that the ϕ_g eigenfunctions of the corresponding generalized Hamiltonian are given, according to Eq. (2.26), by

$$\phi_g=A^{+}\psi_p=\frac{\hbar}{\sqrt{2m}}\left(k\sin(kx)+\frac{2k\sin(kx)}{2k\gamma e^{2kx}-1}-k\cos(kx)\right), \tag{3.34}$$

where, without loss of generality, we have used $B=k$ in order to normalize the exponential function.

This means that, in a similar way to the three-dimensional case, we have

$$H_g^{-}\phi_g=\frac{\hbar^3k^3}{(2m)^{3/2}}\left(\sin(kx)+\frac{2\sin(kx)}{2k\gamma e^{2kx}-1}-\cos(kx)\right). \tag{3.35}$$

Thus, by identifying in the previous equation those terms defining the wave function ϕ_g, it obtained the eigenvalue relationship

$$H_g^{-}\phi_g=E_g\phi_g=\frac{\hbar^2k^2}{2m}\phi_g, \tag{3.36}$$

which means that $E_g=E_p$, as should be fulfilled in order to have a generalized Hamiltonian H_g^{-} which should be isospectral when compared with the particular Hamiltonians $H_p^{\pm}$.

Before closing this work, with the Concluding Remarks, it is important to point out that in the above development it was considered a one-dimensional free particle Hamiltonian which does not have any negative energy eigenvalue. In fact, the positive energy spectrum results from the selection of $\psi_p=\sin(kx)$ as eigenfunctions of $H_p^{\pm}$. That means that the existence of negative energy eigenvalues for the same Hamiltonian occurs only on the condition of having an appropriate wave function. That is, for $V(x)=0$ exists a spectrum with negative energy E_{p-} when $\psi_{p-}=\sinh(kx)$ is taken as an eigenfunction of the one-dimensional free particle Hamiltonian although it is well known that this form of the wave function is unnormalizable. In spite of the above, in this new situation it becomes that the eigenfunctions for the generalized Hamiltonian H_g^{-} are given by

$$\phi_{g-}=A^{+}\psi_{p-}=\frac{\hbar k}{\sqrt{2m}}\left(\sinh(kx)+\frac{2\sinh(kx)}{2k\gamma e^{2kx}-1}-\cosh(kx)\right), \tag{3.37}$$

where the down sign minus in the wave functions is used to denote negative energy eigenvalues, for which

$$H_g^{-}\phi_{g-}=-\frac{\hbar^2k^2}{2m}\left(\frac{\hbar k}{\sqrt{2m}}\right)\left(\sinh(kx)+\frac{2\sinh(kx)}{2k\gamma e^{2kx}-1}-\cosh(kx)\right). \tag{3.38}$$

Clearly, this last relationship is rewritten as

$$H_g^{-}\phi_{g-}=E_{g-}\phi_{g-}=-\frac{\hbar^2k^2}{2m}\phi_{g-}, \tag{3.39}$$

which means, as before in the case of unbounded states, that the generalized Hamiltonian is also isospectral with negative energy spectrum $E_{g-}=-(\hbar^2k^2/2m)=E_{p-}$ in good agreement with Sukumar.[8]

IV. CONCLUDING REMARKS

This work is concerned with the fact that quantum mechanical problems can be solved from the factorization of the Hamiltonian instead of, as usual, the factorization of the Schrödinger equation for any arbitrary potential. For that, in this paper we have shown how two Ricatti-type relationships can be used in order to identify standard potentials as well as to find the corresponding modified and generalized potentials which, as far as we know, are so-called isospectral potentials. It is important to emphasize that the proposed procedure is general, due to the fact that in its development the potential involved is always considered anyone. For that reason, it becomes evident that the displayed method can be used to obtain new potentials that can be incorporated in the treatment of different quantum mechanical applications. This new potentials come from a simple proposition of an ansatz which is necessary to start the procedure for obtaining the corresponding generalized potential. In order to show the usefulness of the proposed approach, we have obtained the generalized three-dimensional potential associated with the free particle model when an ansatz null was used. In this respect, it is important to point out that the generalized potential that corresponds to the one-dimensional case it is not necessarily unique. For example, we have shown that a generalized potential for the one-dimensional free particle model is derived from the use of the three-dimensional treatment for the particular case $l=0$. However, another different generalized potential for the same situation results as a consequence of the use of the one-dimensional version of the proposed approach with a different ansatz. In any case, as expected, we explicitly prove that in all cases the new Hamiltonians are isospectral due to the fact that they lead to the same energy spectra which is obtained when using specific or standard Hamiltonians.

ACKNOWLEDGMENTS

We want to acknowledge the referee for having pointed out to us the convenience of including the treatment of a bounded state which has improved the results presented here. This work was supported by CONACYT-México, under Scientific Project No. 5-4840E.

(Received 20 January 1999; accepted 25 February 1999)

The von Neumann collapse of the quantum mechanical wave function after a position measurement is derived by a purely probabilistic mechanism in the context of Nelson's stochastic mechanics. © *1999 American Institute of Physics.* [S0022-2488(99)01109-3]

I. INTRODUCTION

Nelson's stochastic mechanics[1–5] is a quantization procedure for classical dynamical systems based on stochastic processes of the diffusion type. This theory leads to predictions that agree with those of standard quantum mechanics and are confirmed by experiment. The fundamental assumption is that interaction with a background field causes the system to undergo a diffusion process with diffusion coefficient $\hbar/m$. A fascinating hypothesis concerning the origin of the underlying Brownian motion has been recently advanced by Calogero in Ref. 6. Namely, that this ''tremor'' may be caused by the interaction of every particle with the gravitational force due to all other particles of the Universe. Following this idea, he obtains a formula for Planck's action constant h. The latter yields the correct order of magnitude for h when current cosmological data are employed.

It is hardly surprising that the most controversial issue in stochastic mechanics is the measurement problem. Indeed, in Ref. 7, Francesco Guerra writes: ''Therefore, we see that the basic problem in the interpretation of stochastic mechanics is related to the basic problem in the interpretation of quantum mechanics: To evaluate the effects of the measurement and explain the mechanism of the wave packet reduction.''

Our purpose in this paper is to show that, in the frame of Nelson's stochastic mechanics, *the wave function reduction after a position measurement may be obtained through a purely probabilistic mechanism*, namely a stochastic variational principle. The latter has the appealing interpretation of changing the pair of forward and backward drifts of the reference process as little as possible given the result of the measurement. This variational principle is quite similar to the one that yields the new stochastic model after measurement for nonequilibrium thermodynamical systems, see Sec. V, the only difference being that, in view of the time reversibility of stochastic mechanics, a time-symmetric kinematics has to be employed. As we have shown elsewhere,[8–10] this kinematics also permits us to develop in a natural way a Lagrangian and a Hamiltonian formalism in stochastic mechanics. In particular, it permits us to define a *momentum process* having the same first and second moment of the corresponding quantum momentum operator. It is then possible to derive a stochastic counterpart of Hamilton's canonical equations, and to obtain a simple probabilistic interpretation of the uncertainty principle[9] along the lines of Refs. 1, 11–13.

II. KINEMATICS OF FINITE-ENERGY DIFFUSIONS

In this section, we review some essential concepts and results of the kinematics of the diffusion processes. We refer the reader to Refs. 2–5 and 14–18 for a thorough account. Let

[a)]Electronic mail: pavon@dei.unipd.it

$(\Omega,\mathcal{E},\mathbf{P})$ be a probability space, and let I_n denote the $n\times n$ identity matrix. A stochastic process $\{\xi(t);t_0\leqslant t\leqslant t_1\}$ mapping $[t_0,t_1]$ into $L_n^2(\Omega,\mathcal{E},\mathbf{P})$ is called a *finite-energy diffusion* with constant diffusion coefficient $I_n\sigma^2$ if the increments admit the representation

$$\xi(t)-\xi(s)=\int_s^t\beta(\tau)d\tau+\sigma[w_+(t)-w_+(s)],\quad t_0\leqslant s<t\leqslant t_1, \tag{II.1}$$

where the *forward drift* $\beta(t)$ is at each time t a measurable function of the past $\{\xi(\tau);0\leqslant\tau\leqslant t\}$, and $w_+(\cdot)$ is a standard, n-dimensional *Wiener process* with the property that $w_+(t)-w_+(s)$ is independent of $\{\xi(\tau);0\leqslant\tau\leqslant s\}$. Moreover, β must satisfy the finite-energy condition

$$E\left\{\int_{t_0}^{t_1}\beta(t)\cdot\beta(t)dt\right\}<\infty. \tag{II.2}$$

In Ref. 16, Föllmer has shown that a finite-energy diffusion also admits a reverse-time differential. Namely, there exists a measurable function $\gamma(t)$ of the future $\{\xi(\tau);t\leqslant\tau\leqslant t_1\}$ called *backward drift*, and another Wiener process w_- such that

$$\xi(t)-\xi(s)=\int_s^t\gamma(\tau)d\tau+\sigma[w_-(t)-w_-(s)],\quad t_0\leqslant s<t\leqslant t_1. \tag{II.3}$$

Moreover, γ satisfies

$$E\left\{\int_{t_0}^{t_1}\gamma(t)\cdot\gamma(t)dt\right\}<\infty, \tag{II.4}$$

and $w_-(t)-w_-(s)$ is independent of $\{\xi(\tau);t\leqslant\tau\leqslant t_1\}$. Let us agree that dt always indicates a strictly positive variable. For any function f defined on $[t_0,t_1]$, let

$$d_+f(t):=f(t+dt)-f(t)$$

be the *forward increment* at time t, and

$$d_-f(t)=f(t)-f(t-dt)$$

be the *backward increment* at time t. For a finite-energy diffusion, Föllmer has also shown in Ref. 16 that the forward and backward drifts may be obtained as Nelson's conditional derivatives, namely

$$\beta(t)=\lim_{dt\searrow 0}E\left\{\frac{d_+\xi(t)}{dt}\middle|\xi(\tau),t_0\leqslant\tau\leqslant t\right\}, \tag{II.5}$$

and

$$\gamma(t)=\lim_{dt\searrow 0}E\left\{\frac{d_-\xi(t)}{dt}\middle|\xi(\tau),t\leqslant\tau\leqslant t_1\right\}, \tag{II.6}$$

the limits being taken in $L_n^2(\Omega,\mathcal{B},P)$. It was finally shown in Ref. 16 that the one-time probability density $\rho(\cdot,t)$ of $\xi(t)$ (which exists for every $t>t_0$) is absolutely continuous on $\mathbb{R}^n$ and the following relation holds a.s. $\forall t>0$

$$E\{\beta(t)-\gamma(t)|\xi(t)\}=\sigma^2\nabla\log\rho(\xi(t),t). \tag{II.7}$$

Let ξ be a finite-energy diffusion satisfying (II.1) and (II.3). Let $f:\mathbb{R}^n\times[t_0,t_1]\to\mathbb{R}$ be twice continuously differentiable with respect to the spatial variable and once with respect to time. Then, we have the following change of variables formulas:

$$f(\xi(t),t)-f(\xi(s),s)=\int_s^t\left(\frac{\partial}{\partial\tau}+\beta(\tau)\cdot\nabla+\frac{\sigma^2}{2}\Delta\right)f(\xi(\tau),\tau)d\tau \tag{II.8}$$

$$+\int_s^t\sigma\nabla f(\xi(\tau),\tau)\cdot d_+w_+(\tau), \tag{II.9}$$

$$f(\xi(t),t)-f(\xi(s),s)=\int_s^t\left(\frac{\partial}{\partial\tau}+\gamma(\tau)\cdot\nabla-\frac{\sigma^2}{2}\Delta\right)f(\xi(\tau),\tau)d\tau \tag{II.10}$$

$$+\int_s^t\sigma\nabla f(\xi(\tau),\tau)\cdot d_-w_-(\tau). \tag{II.11}$$

The stochastic integrals appearing in (II.9) and (II.11) are a (forward) Ito integral and a backward Ito integral, respectively; see Ref. 15 for details. Let us introduce the *current drift* $v(t):=(\beta(t)+\gamma(t))/2$ and the *osmotic drift* $u(t):=(\beta(t)-\gamma(t))/2$. Notice that, when σ tends to zero, v tends to $\dot{\xi}$, and u tends to zero. The semisum and the semidifference of (II.9) and (II.11) give two more useful formulas:

$$f(\xi(t),t)-f(\xi(s),s)=\int_s^t\left(\frac{\partial}{\partial\tau}+v(\tau)\cdot\nabla\right)f(\xi(\tau),\tau)d\tau$$

$$+\frac{\sigma}{2}\left[\int_s^t\nabla f(\xi(\tau),\tau)\cdot d_+w_++\int_s^t\nabla f(\xi(\tau),\tau)\cdot d_-w_-\right], \tag{II.12}$$

$$0=\int_s^t\left(u(\tau)\cdot\nabla+\frac{\sigma^2}{2}\Delta\right)f(\xi(\tau),\tau)d\tau+\frac{\sigma}{2}\left[\int_s^t\nabla f(\xi(\tau),\tau)\cdot d_+w_+-\int_s^t\nabla f(\xi(\tau),\tau)\cdot d_-w_-\right]. \tag{II.13}$$

Specializing (II.12) and (II.13) to $f(x,t)=x$, we get

$$\xi(t)-\xi(s)=\int_s^t v(\tau)d\tau+\frac{\sigma}{2}[w_+(t)-w_+(s)+w_-(t)-w_-(s)], \tag{II.14}$$

$$0=\int_s^t u(\tau)d\tau+\frac{\sigma}{2}[w_+(t)-w_+(s)-w_-(t)+w_-(s)]. \tag{II.15}$$

The finite-energy diffusion $\xi(\cdot)$ is called *Markovian* if there exist two measurable functions $b_+(\cdot,\cdot)$, and $b_-(\cdot,\cdot)$, such that $\beta(t)=b_+(\xi(t),t)$ a.s. and $\gamma(t)=b_-(\xi(t),t)$ a.s., for all t in $[t_0,t_1]$. The duality relation (II.7) now reads as

$$b_+(\xi(t),t)-b_-(\xi(t),t)=\sigma^2\nabla\log\rho(\xi(t),t). \tag{II.16}$$

This immediately gives the *osmotic equation*,

$$u(x,t)=\frac{\sigma^2}{2}\nabla\log\rho(x,t), \tag{II.17}$$

where $u(x,t):=(b_+(x,t)-b_-(x,t))/2$. The probability density $\rho(\cdot,\cdot)$ of $\xi(t)$ satisfies (at least weakly) the *Fokker–Planck equation*,

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(b_+\rho)=\frac{\sigma^2}{2}\Delta\rho.$$

The latter can also be rewritten, in view of (II.16), as the *equation of continuity* of hydrodynamics,

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(v\rho)=0, \tag{II.18}$$

where $v(x,t):=(b_+(x,t)+b_-(x,t))/2$.

III. A TIME-SYMMETRIC KINEMATICS FOR DIFFUSION PROCESSES

We recall here the basic facts from the time-symmetric kinematics developed in Refs. 8, 19. Let us multiply (II.15) by $-i$, and add it to (II.14). We get

$$\xi(t)-\xi(s)=\int_s^t[v(\tau)-iu(\tau)]d\tau+\frac{\sigma}{2}[(1-i)(w_+(t)-w_+(s))+(1+i)(w_-(t)-w_-(s))]. \tag{III.19}$$

We call $v_q(t):=v(t)-iu(t)$ the *quantum drift*, and

$$w_q(t):=\frac{1-i}{2}w_+(t)+\frac{1+i}{2}w_-(t) \tag{III.20}$$

the *quantum noise*. Hence, we can rewrite (III.19) as

$$\xi(t)-\xi(s)=\int_s^t v_q(\tau)d\tau+\sigma[w_q(t)-w_q(s)]. \tag{III.21}$$

At first sight, this decomposition of the *real-valued* increments of ξ into the sum of two *complex* quantities might look somewhat odd. Nevertheless, this representation enjoys several important properties:

(1) When σ^2 tends to zero, $v-iu$ tends to $\dot{\xi}$.

(2) The quantum drift $v_q(t)$ contains at each time t precisely the same information as the pair $(v(t),u(t))$ [or, equivalently, the pair $(\beta(t),\gamma(t))$].

(3) The representation (III.21), differently from (II.1) and (II.3), enjoys an important symmetry with respect to time. Indeed, under time reversal, (III.21) transforms into

$$\xi(t)-\xi(s)=\int_s^t\overline{v_q(\tau)}d\tau+\sigma[\overline{w_q(t)-w_q(s)}], \tag{III.22}$$

where an overbar indicates conjugation; see Ref. 9, p. 145.

The representation (III.21) has proven to be crucial in order to develop a Lagrangian and Hamiltonian dynamics formalism in the context of Nelson's stochastic mechanics; see Refs. 8–10. In particular, to develop the second form of Hamilton's principle, the key tool has been a change of variables formula related to representation (III.21). In order to recall such a formula, we need first to define stochastic integrals with respect to the quantum noise w_q. Let us denote by $d_bf(t):=[(1-i)/2]\,d_+f(t)+[(1+i)/2]\,d_-f(t)$ the *bilateral increment* of f at time t. Then, from (III.20) and (II.15), we get

$$d_+w_q(t)=\frac{1+i}{\sigma}u(x(t),t)dt+d_+w_++o(dt),$$

$$d_- w_q(t) = \frac{-1+i}{\sigma} u(x(t),t)dt + d_+ w_- + o(dt).$$

These, in turn, give immediately

$$d_b w_q(t) := \frac{1-i}{2} d_+ w_+(t) + \frac{1+i}{2} d_- w_-(t) + o(dt). \tag{III.23}$$

Let $f(x,t)$ be a measurable, $\mathbb{C}^n$-valued function, such that

$$P\left\{ \omega: \int_0^T f(\xi(t),t) \cdot \overline{f(\xi(t),t)} dt < \infty \right\} = 1.$$

In view of (III.23), we define

$$\int_s^t f(\xi(\tau),\tau) \cdot d_b w_q(\tau) := \frac{1-i}{2} \int_s^t f(\xi(\tau),\tau) \cdot d_+ w_+(\tau) + \frac{1+i}{2} \int_s^t f(\xi(\tau),\tau) \cdot d_- w_-(\tau).$$

Thus, integration with respect to the bilateral increments of w_q is defined through a linear combination with complex coefficients of a forward and a backward Ito integral. Let $f(x,t)$ be a complex-valued function with real and imaginary parts of class $C^{2,1}$. Then, multiplying (II.13) by $-i$, and then adding it to (II.12), we get the change of variables formula

$$f(\xi(t),t) - f(\xi(s),s) = \int_s^t \left(\frac{\partial}{\partial \tau} + v_q(\tau) \cdot \nabla - \frac{i\sigma^2}{2} \Delta \right) f(\xi(\tau),\tau) d\tau + \int_s^t \sigma \nabla f(\xi(\tau),\tau) \cdot d_b w_q(\tau). \tag{III.24}$$

It is important to understand that this formula, and, in particular, the coefficient of the Laplacian term, follows from basic probabilistic arguments.

IV. THE QUANTUM HAMILTON PRINCIPLE

Stochastic mechanics may be based, since the fundamental paper by Guerra and Morato,[20] on stochastic variational principles of a hydrodynamic type. Other versions of the variational principle have been proposed in Refs. 4, 14, and in Ref. 8. We outline here the quantum Hamilton principle of Ref. 8, since it employs the time-symmetric kinematics of Sec. III that we shall need to derive the wave function collapse.

Let $\mathcal{X}_{\rho_1}$ denote the family of all finite-energy, $\mathbb{R}^n$-valued diffusions on $[t_0,t_1]$ with diffusion coefficient $I_n(\hbar/m)$, and having marginal probability density ρ_1 at time t_1. Let $\mathcal{V}$ denote the family of finite-energy, C^n-valued stochastic processes on $[t_0,t_1]$. Let $L(x,v) := \frac{1}{2} m v \cdot v - V(x)$ be defined on $R^n \times C^n$. Also, let S_0 be a complex-valued function on R^n. Consider the problem of extremizing on $(x,v_q) \in (\mathcal{X}_{\rho_1} \times \mathcal{V})$,

$$E\left\{ \int_{t_0}^{t_1} L(x(t),v_q(t))dt + S_0(x(t_0)) \right\}, \tag{IV.25}$$

subject to the constraint that

$$x \text{ has quantum drift (velocity) } v_q. \tag{IV.26}$$

Notice that the quadratic term in the Lagrangian may be rewritten in terms of the forward and backward drifts as follows:

$$\frac{m}{2}v_q(t)\cdot v_q(t)=\frac{m}{2}\left[\frac{1-i}{2}\beta(t)+\frac{1+i}{2}\gamma(t)\right]\cdot\left[\frac{1-i}{2}\beta(t)+\frac{1+i}{2}\gamma(t)\right]$$

$$=\frac{-im}{4}[\beta(t)\cdot\beta(t)+2i\beta(t)\cdot\gamma(t)-\gamma(t)\cdot\gamma(t)]$$

$$=\frac{-im}{4}[(\beta(t)+i\gamma(t))\cdot(\beta(t)+i\gamma(t))] \tag{IV.27}$$

In Ref. 8, Sec. VIII, the following result was established.

Theorem IV.1: *Suppose that $S_q(x,t)$ of class $C^{2,1}$ solves on $[t_0,t_1]$ the initial value problem,*

$$\frac{\partial S_q}{\partial t}+\frac{1}{2m}\nabla S_q\cdot\nabla S_q+V(x)-\frac{i\hbar}{2m}\Delta S_q=0, \tag{IV.28}$$

$$S_q(x,t_0)=S_0(x), \tag{IV.29}$$

and satisfies the technical condition

$$E\left\{\int_{t_0}^{t_1}\nabla S_q(x(t),t)\cdot\overline{\nabla S_q(x(t),t)}dt\right\}<\infty,\quad \forall x\in\mathcal{X}_{\rho_1}. \tag{IV.30}$$

Then, any $x\in\mathcal{X}_{\rho_1}$ having quantum drift $(1/m)\nabla S(x(t),t)$ solves the extremization problem.

A crucial role in the proof is played by the change of variables formula (III.24) that here reads as

$$f(\xi(t),t)-f(\xi(s),s)=\int_s^t\left(\frac{\partial}{\partial\tau}+v_q(\tau)\cdot\nabla-\frac{i\hbar}{2m}\Delta\right)f(\xi(\tau),\tau)d\tau+\int_s^t\sqrt{\frac{\hbar}{m}}\nabla f(\xi(\tau),\tau)\cdot d_b w_q(\tau). \tag{IV.31}$$

The existence of a solution for the apparently complicated nonlinear, complex Cauchy problem (IV.28)–(IV.29) is dealt with as follows. Let $\{\psi(x,t);t_0\leq t\leq t_1\}$ be the solution of the *Schrödinger equation*,

$$\frac{\partial\psi}{\partial t}=\frac{i\hbar}{2m}\Delta\psi-\frac{i}{\hbar}V(x)\psi, \tag{IV.32}$$

with initial condition $\psi_0(x):=\exp(i/\hbar)S_0(x)$. If $\psi(x,t)$ never vanishes on $\mathbb{R}^n\times[t_0,t_1]$, and satisfies the condition

$$E\left\{\int_{t_0}^{t_1}\nabla\log\psi(x(t),t)\cdot\overline{\nabla\log\psi(x(t),t)}dt\right\}<\infty,\quad\forall x\in\mathcal{X}_{\rho_1}; \tag{IV.33}$$

then $S_q(x,t):=(\hbar/i)\log\psi(x,t)$ satisfies (IV.28)–(IV.29) and (IV.30). If, moreover, $\psi_0(x)$ has L^2 norm 1, and the terminal density satisfies $\rho_1(x,t)=|\psi(x,t_1)|^2$, then there does exist a Markov diffusion having the required quantum drift, namely, the *Nelson process* associated to $\{\psi(x,t);t_0\leq t\leq t_1\}$, and Born's relation $\rho(x,t)=|\psi(x,t)|^2$ holds; see Ref. 8 for the details. The construction of the Nelson process corresponding to $\psi(x,t)$ in the case where $\psi(x,t)$ vanishes requires considerable care. It is discussed in Ref. 21 and Ref. 5, Chap. IV, and references therein.

V. MEASUREMENT IN NONEQUILIBRIUM THERMODYNAMICS

In this section, we discuss the measurement for nonequilibrium thermodynamical systems. This serves as an introduction to measurement in stochastic mechanics to be discussed in the following section. Consider an open thermodynamical system whose macroscopic evolution is modeled by an n-dimensional Markov diffusion process $\{x(t);t_0 \leqslant t\}$ with a forward Ito differential,

$$d_+ x(t) = b_+(x(t))dt + \sigma\, d_+ w_+ .$$

Let $\rho(x,t)$ denote the probability density of $x(t)$ satisfying the Fokker–Planck equation,

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (b_+ \rho) = \frac{\sigma^2}{2} \Delta \rho. \tag{V.34}$$

The *equilibrium state* is given by the Maxwell–Boltzmann distribution law,

$$\overline{\rho}(x) = C \exp\left[-\frac{H(x)}{kT} \right],$$

where H is the Hamiltonian function, and we have the relation

$$b_+(x) = -\frac{\sigma^2}{2kT} \nabla H(x),$$

where k is Boltzmann's constant and T is the absolute temperature. Suppose that at time t_1 a measurement is made that yields the new probability density $\tilde{\rho}(x,t_1)$. Let $\mathcal{X}_{\tilde{\rho}(t_1)}$ denote the class of finite-energy diffusions on $[t_1,t_2]$ with diffusion coefficient σ^2 and having marginal $\tilde{\rho}(x,t_1)$ at time t_1. Let us pose the following question: Among all processes in $\mathcal{X}_{\tilde{\rho}(t_1)}$, which one should we use to model the macroscopic evolution of the system from t_1 up to t_2? Everybody agrees that we should employ the stochastic process $\{\tilde{x}(t);t_1 \leqslant t \leqslant t_2\}$ that has the same forward drift field $b_+(x)$ of the ''reference'' process x. This is supported by the observation that the new process must have the same equilibrium distribution of the previous one. Let us show that the new process $\{\tilde{x}(t);t_1 \leqslant t \leqslant t_2\}$ may be obtained as the solution of a variational problem. Assume that the Kullback–Leibler pseudodistance between $\tilde{\rho}(t_1)$ and $\rho(t_1)$ is finite, namely,

$$H(\tilde{\rho}(t_1),\rho(t_1)) := E\left\{ \log \frac{\tilde{\rho}(\tilde{x}(t_1),t_1)}{\rho(\tilde{x}(t_1),t_1)} \right\} = \int_{\mathbb{R}^n} \log \frac{\tilde{\rho}(\tilde{x},t_1)}{\rho(\tilde{x},t_1)} \tilde{\rho}(x,t_1)dx < \infty.$$

Let $\mathbb{D}_{\tilde{\rho}(t_1)}$ denote the class of probability measures on $\Omega = C([t_1,t_2])$ that are equivalent to the measure P induced by the reference process $\{x(t);t_1 \leqslant t \leqslant t_2\}$. For $Q \in \mathbb{D}_{\tilde{\rho}(t_1)}$, let

$$H(Q,P) = E_Q\left[\log \frac{dQ}{dP} \right]$$

denote the *relative entropy* of Q with respect to P. It then follows from Girsanov's theorem that[16,17]

$$H(Q,P) = H(\tilde{\rho}(t_1),\rho(t_1)) + E_Q\left[\int_{t_1}^{t_2} \frac{1}{2\sigma^2} [b_+(\tilde{x}(t)) - \beta^Q(t)] \cdot [b_+(\tilde{x}(t)) - \beta^Q(t)] dt \right].$$

Since $H(\tilde{\rho}(t_1),\rho(t_1))$ is constant over $\mathbb{D}_{\tilde{\rho}(t_1)}$, it trivially follows that the probability measure $\tilde{Q}$ corresponding to the process $\tilde{x}$ having forward drift b_+ minimizes $H(Q,P)$ over $\mathbb{D}_{\tilde{\rho}(t_1)}$. This problem may be interpreted as a problem of large deviation of the empirical distribution according to Schrödinger's original motivation.[22,17] We consider now an apparently different variational problem that has the same solution as the previous one. We do so because it is this second form, which, in a suitably modified form, applies to the quantum case. Let $\mathcal{X}_{\tilde{\rho}_2}$ denote the family of finite-energy diffusions on $[t_1,t_2]$ with diffusion coefficient σ^2 and having marginal density $\tilde{\rho}_2$ at time t_2. Consider the problem of minimizing with respect to the pair $(\tilde{x},\gamma)$ the functional

$$E\left\{\int_{t_1}^{t_2}\frac{1}{2\sigma^2}[b_-(\tilde{x}(t))-\gamma(t)]\cdot[b_-(\tilde{x}(t))-\gamma(t)]dt-\log\frac{\tilde{\rho}(\tilde{x}(t_1),t_1)}{\rho(\tilde{x}(t_1),t_1)}\right\},$$

subject to the constraint that γ be the backward drift of $\tilde{x}$ on $[t_1,t_2]$. This problem is a variant of the one first considered and solved in Ref. 23, Theorem 2. The connection between the two variational problems, and their relation to the theory of Schrödinger processes and bridges, has been thoroughly investigated in Ref. 24. In order to solve this problem, rather than reproducing the arguments in Refs. 23, 24, we take the opportunity to introduce the variational method based on nonlinear Lagrange functionals.[25] This method permits us to solve also the more complicated quantum case. Suppose that we wish to minimize $J:Y\to\overline{\mathbb{R}}$, where $\overline{\mathbb{R}}$ denotes the extended reals, over the nonempty subset S of Y.

Lemma V.1: (Lagrange Lemma): *Let* $\Lambda:Y\to\overline{\mathbb{R}}$ *and let* $y_0\in S$ *minimize* $J+\Lambda$ *over* Y. *Assume that* $\Lambda(\cdot)$ *is* finite *and* constant *over* S. *Then* y_0 *minimizes* J *over* S.

Proof: For any $y\in S$, we have $J(y_0)+\Lambda(y_0)\leqslant J(y)+\Lambda(y)=J(y)+\Lambda(y_0)$. Hence $J(y_0)\leqslant J(y)$. □

A functional Λ that is constant and finite on S is called a *Lagrange functional*. Obviously, a similar result holds if the problem is an extremization problem. Let us apply this simple idea to the above problem. Let $\varphi(x,t)$ be a real-valued function of class $C^{2,1}$ defined on $\mathbb{R}^n\times[t_1,t_2]$, and satisfying the technical condition

$$E\left\{\int_{t_1}^{t_2}\nabla\varphi(x(t),t)\cdot\nabla\varphi(x(t),t)dt\right\}<\infty,\quad \forall x\in\mathcal{X}_{\tilde{\rho}_2}. \tag{V.35}$$

Corresponding to such a φ, we introduce the functional,

$$\Lambda^{\varphi}(\tilde{x},\gamma):=E\Bigg\{\varphi(\tilde{x}(t_2),t_2)-\varphi(\tilde{x}(t_1),t_1) + \int_{t_1}^{t_2}\left[-\frac{\partial\varphi}{\partial t}(\tilde{x}(t),t)-\gamma(t)\cdot\nabla\varphi(\tilde{x}(t),t)+\frac{\sigma^2}{2}\Delta\varphi(\tilde{x}(t),t)\right]dt\Bigg\}.$$

In view of (II.11) and (V.35), we have that $\Lambda^{\varphi}(\tilde{x},\gamma)=0$ whenever the pair $(\tilde{x},\gamma)$ satisfies the constraint, since the stochastic integral has zero expectation. Thus, it is a *Lagrange functional* for the problem. Consider next the *unconstrained* minimization of the functional $J+\Lambda^{\varphi}$. For a fixed $\tilde{x}\in\mathcal{X}_{\tilde{\rho}_2}$, and a fixed time $t\in[t_1,t_2]$, we consider the *pointwise* minimization of the integrand of $J+\Lambda^{\varphi}$ with respect to γ,

$$\text{minimize}_{\gamma\in R^n}\left\{\frac{1}{2\sigma^2}(b_-(\tilde{x}(t),t)-\gamma)\cdot(b_-(\tilde{x}(t),t)-\gamma)-\gamma\cdot\nabla\varphi(\tilde{x}(t),t)\right\}.$$

We get

$$\gamma^o(\tilde{x})(t)=b_-(\tilde{x}(t),t)+\sigma^2\,\nabla\varphi(\tilde{x}(t),t). \tag{V.36}$$

Substituting back expression (V.36) into $J+\Lambda^{\varphi}$, we get the following functional of $\tilde{x}$:

$$(J+\Lambda^{\varphi})(\tilde{x},\gamma^{o}(\tilde{x})):=E\left\{\varphi(\tilde{x}(t_2),t_2)-\varphi(\tilde{x}(t_1),t_1)-\log\frac{\tilde{\rho}(\tilde{x}(t_1),t_1)}{\rho(\tilde{x}(t_1),t_1)}\right.$$
$$+\int_{t_1}^{t_2}\left[-\frac{\sigma^2}{2}\nabla\varphi(\tilde{x}(t),t)\cdot\nabla\varphi(\tilde{x}(t),t)-\frac{\partial\varphi}{\partial t}(\tilde{x}(t),t)\right.$$
$$\left.\left.-b_-(\tilde{x}(t),t)\cdot\nabla\varphi(\tilde{x}(t),t)+\frac{\sigma^2}{2}\Delta\varphi(\tilde{x}(t),t)\right]dt\right\}. \tag{V.37}$$

Next, we seek to find a function φ such that the functional $(J+\Lambda^{\varphi})(\tilde{x},\gamma^{o}(\tilde{x}))$ becomes constant over $\mathcal{X}_{\tilde{\rho}_2}$. Suppose φ solves on $[t_1,t_2]$ the initial value problem,

$$\frac{\partial\varphi}{\partial t}+b_-(x,t)\cdot\nabla\varphi(x,t)-\frac{\sigma^2}{2}\Delta\varphi(x,t)=-\frac{\sigma^2}{2}\nabla\varphi(x,t)\cdot\nabla\varphi(x,t), \tag{V.38}$$

$$\varphi(x,t_1)=-\log\frac{\tilde{\rho}(x,t_1)}{\rho(x,t_1)}. \tag{V.39}$$

Then $(J+\Lambda^{\varphi})(\tilde{x},\gamma^{o}(x))=E\{\varphi(\tilde{x}(t_2),t_2)\}$ is constant over $\mathcal{X}_{\tilde{\rho}_2}$ since such processes have the same marginal density at time t_2. Hence, any $x\in\mathcal{X}_{\tilde{\rho}_2}$ solves the unconstrained minimization of $J+\Lambda^{\varphi}$. To solve the original constrained problem, we need to find $\tilde{x}\in\mathcal{X}_{\tilde{\rho}_2}$ that has backward drift given by (V.36). In order to do that, we first proceed to find the solution of (V.38)–(V.39). Define $\tilde{\rho}(x,t):=\exp[-\varphi(x,t)]\rho(x,t)$. Then, if φ satisfies (V.38), using the Fokker–Planck equation satisfied by ρ, we get

$$\frac{\partial\tilde{\rho}}{\partial t}=\exp[-\varphi]\left(-\frac{\partial\varphi}{\partial t}\rho+\frac{\partial\rho}{\partial t}\right)$$
$$=\left(b_-\cdot\nabla\varphi-\frac{\sigma^2}{2}\Delta\varphi+\frac{\sigma^2}{2}\nabla\varphi\cdot\nabla\varphi\right)\tilde{\rho}-\exp[-\varphi]\nabla\cdot(b_+\rho)+\exp[-\varphi]\frac{\sigma^2}{2}\Delta\rho$$
$$=\frac{\sigma^2}{2}\Delta\tilde{\rho}+b_+\cdot\nabla\varphi\tilde{\rho}-\exp[-\varphi]\nabla\rho\cdot b_+-\exp[-\varphi]\rho\nabla\cdot b_+=-\nabla\cdot(\tilde{\rho}b_+)+\frac{\sigma^2}{2}\Delta\tilde{\rho}.$$

We conclude that if $\tilde{\rho}$ is the solution of the Fokker–Planck equation (V.34) on $[t_1,t_2]$ with an initial condition at time t_1 given by $\tilde{\rho}(x,t_1)$, then $\varphi:=-\log(\tilde{\rho}/\rho)$ solves the initial value problem (V.38)–(V.39). Thus, we have the following result.

Theorem V.2: *Let $\tilde{\rho}$ be the solution of the Fokker–Planck equation (V.34) on $[t_1,t_2]$ with initial condition given by $\tilde{\rho}(x,t_1)$. Then $\varphi:=-\log(\tilde{\rho}/\rho)$ solves the initial value problem (V.38)–(V.39). Suppose that φ satisfies (V.35), and that $\tilde{\rho}_2(x)=\tilde{\rho}(x,t_2)$. Then the stochastic process $\tilde{x}\in\mathcal{X}_{\tilde{\rho}_2}$ having backward drift field $\tilde{b}_-(x,t)=b_-(x,t)-\sigma^2\nabla\log(\tilde{\rho}/\rho)(x,t)=b_+-\sigma^2\nabla\log\tilde{\rho}(x,t)$ solves the constrained minimization problem.*

In view of (II.16), we see that the solution process has forward drift $b_+(\cdot)$, and therefore coincides with the solution of the previous variational problem. Consider the same problem on the interval $[t_1,t_3]$, where $t_3>t_2$. If we impose the density $\tilde{\rho}(x,t_3)$ at the final time, the solution process coincides with the previous solution process up to time t_2. This may be viewed as a form of coherence with respect to the terminal time. It is also important to observe that the new process $\{\tilde{x}(t);t_1\leq t\leq t_2\}$ has the same forward drift of the reference process $\{x(t);t_1\leq t\leq t_2\}$, but a *different backward drift*. Hence, while the forward transition probabilities have been preserved, *the reverse-time transition probabilities have changed*. Thus, we see that it is impossible, even in principle, to estimate the reverse-time transition probabilities by repeated measurement. In Refs. 14, 7, Nelson and Guerra regard as a serious drawback of stochastic mechanics the fact that transition probabilities of the Nelson process are not open to experimental verification if we accept that transition probabilities are associated to a definite quantum state. We shall come back to this crucial point in the next section.

VI. A STOCHASTIC DERIVATION OF WAVE FUNCTION COLLAPSE

In Sec. IV, we have seen that the Schrödinger equation is obtained through a simple exponential transformation from the Hamilton–Jacobi equation (IV.28) of an appropriate stochastic variational principle. Suppose now that a position measurement of the quantum system is made at time t_1, and we ask the following: What should be the new stochastic process on $[t_1,t_2]$? First of all, we consider the situation without measurement up to time t_2. In this case, the variational principle of Sec. IV would have as a solution the Nelson process $\{x(t);t_0\leqslant t\leqslant t_2\}$ extended up to time t_2 with quantum drift $v_q(t)=(\hbar/im)\,\nabla\log\psi(x(t),t)$, where $\{\psi(x,t):t_0\leqslant t\leqslant t_2\}$ is the solution of the Schrödinger equation (IV.32). The Nelson process $\{x(t);t_1\leqslant t\leqslant t_2\}$ will play the role of a ''reference process.'' Suppose that the measurement at time t_1 yields the new probability density $\tilde{\rho}(x,t_1)$. For instance, if we assume that the measurement at time t_1 only gives the information that x lies in a certain subset D of the configuration space of the system, the density $\tilde{\rho}(x,t_1)$ just after the measurement is given, according to Bayes' theorem, by

$$\tilde{\rho}(x,t_1)=\frac{\chi_D(x)\rho(x,t_1)}{\int_D\rho(x',t_1)dx'},$$

where $\rho(x,t_1)$ is the probability density of the Nelson reference process right before the measurement is made. We need now to find an appropriate variational mechanism that, employing the Nelson reference process and the probability density $\tilde{\rho}(x,t_1)$, produces the new process $\{\tilde{x}(t);t_1\leqslant t\leqslant t_2\}$. It is apparent that the variational mechanism of the previous section is not suitable here. Indeed, as observed before, that mechanism preserves completely the *forward* drift and transition probabilities, but changes, possibly in a dramatic way, the backward drift and transition probabilities. This is not acceptable in stochastic mechanics, were forward and backward drifts and transition probabilities *must always be granted the same status*. In other words, the time reversibility of the theory must be reflected also by the theory of measurement. On the other hand, preserving both drifts, or equivalently both transition probabilities, amounts to preserving the process $\{x(t);t_0\leqslant t\leqslant t_2\}$, which is impossible since the probability density at time t_1 has changed. Thus, we need to find a variational mechanism that *changes both drifts as little as possible, given the new density at time* t_1. It should be apparent that, at this point, the time-symmetric kinematics of Sec. III is called for. Given that kinematics, and by analogy with the variational principle of the previous section, we are then led to the following formulation.

In the notation of Sec. IV, we consider the problem of extremizing on $(\tilde{x},\tilde{v}_q)\in(\mathcal{X}_{\tilde{\rho}_2}\times\mathcal{V})$ the functional

$$J(\tilde{x},\tilde{v}_q):=E\left\{\int_{t_1}^{t_2}\frac{mi}{2\hbar}(v_q(\tilde{x}(t),t)-\tilde{v}_q(t))\cdot(v_q(\tilde{x}(t),t)-\tilde{v}_q(t))\,dt+\frac{1}{2}\log\frac{\tilde{\rho}(\tilde{x}(t_1),t_1)}{\rho(\tilde{x}(t_1),t_1)}\right\},\tag{VI.40}$$

subject to the constraint that

$$\tilde{x}\ \text{ has quantum drift (velocity) }\ \tilde{v}_q.\tag{VI.41}$$

Here $v_q(x,t)=(\hbar/im)\,\nabla\log\psi(x,t)$ is the quantum drift field of the Nelson reference process, and $\mathcal{X}_{\tilde{\rho}_2}$ is the family of all finite-energy, $\mathbb{R}^n$-valued diffusions on $[t_1,t_2]$ with diffusion coefficient

$I_n(\hbar/m)$, and having probability density $\tilde{\rho}_2$ at time t_2. The structure of the functional is quite similar to the one of the previous section. Here, $\hbar/mi$ replaces σ^2 in view of formula (IV.31). The $\frac{1}{2}$ in the boundary term is justified by the following relation; see (IV.27),

$$\frac{mi}{2\hbar}(v_q(x,t)-\tilde{v}_q(t))\cdot(v_q(x,t)-\tilde{v}_q(t))$$
$$=\frac{m}{4\hbar}[(b_+(x,t)-\tilde{b}_+(t))+i(b_-(x,t)-\tilde{b}_-(t))]\cdot[(b_+(x,t)-\tilde{b}_+(t))+i(b_-(x,t)-\tilde{b}_-(t))],$$

which shows that a $\frac{1}{4}$ appears on the right-hand side. To solve this variational problem, we employ the same strategy as in the previous section. Let $\varphi(x,t)$ be a complex-valued function of class $C^{2,1}$ defined on $\mathbb{R}^n\times[t_1,t_2]$, and satisfying the technical condition

$$E\left\{\int_{t_1}^{t_2}\nabla\varphi(x(t),t)\cdot\overline{\nabla\varphi(x(t),t)}dt\right\}<\infty,\quad \forall x\in\mathcal{X}_{\rho_2}. \tag{VI.42}$$

Corresponding to such a φ, we introduce the functional

$$\Lambda^{\varphi}(\tilde{x},\tilde{v}_q):=E\left\{\varphi(\tilde{x}(t_2),t_2)-\varphi(\tilde{x}(t_1),t_1)\right.$$
$$\left.+\int_{t_1}^{t_2}\left[-\frac{\partial\varphi}{\partial t}(\tilde{x}(t),t)-\tilde{v}_q(t)\cdot\nabla\varphi(\tilde{x}(t),t)+\frac{i\hbar}{2m}\Delta\varphi(\tilde{x}(t),t)\right]dt\right\}.$$

In view of (III.24), and of property (VI.42), we see that $\Lambda^{\varphi}(\tilde{x},\tilde{v}_q)=0$ whenever the pair $(\tilde{x},\tilde{v}_q)$ satisfies the constraint. Thus, it is a *Lagrange functional* for the problem. Consider next the *unconstrained* extremization of the functional $J+\Lambda^{\varphi}$. For a fixed $\tilde{x}\in\mathcal{X}_{\tilde{\rho}_2}$, and a fixed time $t\in[t_1,t_2]$, we consider the *pointwise* extremization of the integrand of $J+\Lambda^{\varphi}$ with respect to $\tilde{v}_q$,

$$\text{extremize}_{\tilde{v}\in C^n}\left\{\frac{mi}{2\hbar}(v_q(\tilde{x}(t),t)-\tilde{v})\cdot(v_q(\tilde{x}(t),t)-\tilde{v})-\tilde{v}\cdot\nabla\varphi(\tilde{x}(t),t)\right\}.$$

We get

$$\tilde{v}_q^o(\tilde{x})(t)=v_q(\tilde{x}(t),t)+\frac{\hbar}{mi}\nabla\varphi(\tilde{x}(t),t). \tag{VI.43}$$

Substituting back expression (VI.43) into $J+\Lambda^{\varphi}$, we get the following functional of $\tilde{x}$:

$$(J+\Lambda^{\varphi})(\tilde{x},\tilde{v}_q^o(x)):=E\left\{\varphi(\tilde{x}(t_2),t_2)-\varphi(\tilde{x}(t_1),t_1)+\int_{t_1}^{t_2}\left[\frac{i\hbar}{2m}\nabla\varphi(\tilde{x}(t),t)\cdot\nabla\varphi(\tilde{x}(t),t)-\frac{\partial\varphi}{\partial t}(\tilde{x}(t),t)\right.\right.$$
$$\left.\left.-v_q(\tilde{x}(t),t)\cdot\nabla\varphi(\tilde{x}(t),t)+\frac{i\hbar}{2m}\Delta\varphi(\tilde{x}(t),t)\right]dt\right\}. \tag{VI.44}$$

We seek next to choose the function φ so that the functional $(J+\Lambda^{\varphi})(\tilde{x},\tilde{v}_q^o(x))$ becomes constant over $\mathcal{X}_{\tilde{\rho}_2}$. Suppose φ solves on $[t_1,t_2]$ the initial value problem,

$$\frac{\partial\varphi}{\partial t}+v_q(x,t)\cdot\nabla\varphi(x,t)-\frac{i\hbar}{2m}\Delta\varphi(x,t)=\frac{i\hbar}{2m}\nabla\varphi(x,t)\cdot\nabla\varphi(x,t), \tag{VI.45}$$

$$\varphi(x,t_1)=\frac{1}{2}\log\frac{\tilde{\rho}(x,t_1)}{\rho(x,t_1)}. \tag{VI.46}$$

Then $(J+\Lambda^{\varphi})(\tilde{x},\tilde{v}_q^o(x))=E\{\varphi(\tilde{x}(t_2),t_2)\}$ is constant over $\mathcal{X}_{\tilde{\rho}_2}$ since such processes have the same marginal density at time t_2. Hence, any $x\in\mathcal{X}_{\tilde{\rho}_2}$ solves the unconstrained extremization of $J+\Lambda^{\varphi}$. To solve the original constrained extremization problem, we need to find the $\tilde{x}\in\mathcal{X}_{\tilde{\rho}_2}$ that has quantum drift given by (VI.43). In order to do that, we first proceed to find the solution of (VI.45)–(VI.46). Write $\psi(x,t_1)=\rho(x,t_1)^{1/2}\exp[(i/\hbar)S(x,t_1)]$, and define $\tilde{\psi}(x,t):=\exp[\varphi(x,t)]\psi(x,t)$. Then, if φ satisfies (VI.45), using the Schrödinger equation (IV.32) satisfied by ψ, we get

$$\frac{\partial\tilde{\psi}}{\partial t}=\exp[\varphi]\left(\frac{\partial\varphi}{\partial t}\psi+\frac{\partial\psi}{\partial t}\right)$$
$$=\frac{i}{\hbar}V(x)\tilde{\psi}+\frac{i\hbar}{2m}\exp\varphi(\Delta\psi+2\nabla\psi\cdot\nabla\varphi+\nabla\varphi\cdot\nabla\varphi\psi+\Delta\varphi\psi)=\frac{i\hbar}{2m}\Delta\tilde{\psi}-\frac{i}{\hbar}V(x)\tilde{\psi}.$$

Observing that $\tilde{\psi}(x,t_1)=\tilde{\rho}(x,t_1)^{1/2}\exp[(i/\hbar)S(x,t_1)]$, we conclude that if $\tilde{\psi}$ is the solution of the Schrödinger equation (IV.32) on $[t_1,t_2]$ with initial condition at time t_1 given by $\tilde{\rho}(x,t_1)^{1/2}\exp[(i/\hbar)S(x,t_1)]$; then $\varphi:=\log(\tilde{\psi}/\psi)$ solves the initial value problem (VI.45)–(VI.46). Thus, we get the following result.

Theorem VI.1: *Suppose that $\tilde{\psi}$ is the solution of the Schrödinger equation (IV.32) on $[t_1,t_2]$ with initial condition at time t_1 given by $\tilde{\rho}(x,t_1)^{1/2}\exp[(i/\hbar)S(x,t_1)]$. Then $\varphi:=\log(\tilde{\psi}/\psi)$ solves the initial value problem (VI.45)–(VI.46). Suppose that φ satisfies (VI.42), and that $\tilde{\rho}_2(x)=|\tilde{\psi}(x,t_2)|^2$. Then the stochastic process $\tilde{x}\in\mathcal{X}_{\tilde{\rho}_2}$ having quantum drift $(\hbar/mi)\nabla\log\tilde{\psi}(\tilde{x}(t),t)$ solves the constrained extremization problem.*

Thus, by a purely probabilistic argument, we have shown that the new process after the measurement at time t_1 is associated to another solution $\tilde{\psi}$ of the same Schrödinger equation (IV.32). The association is precisely as before, namely, the quantum drift is proportional to the gradient of the logarithm of $\tilde{\psi}$. In other words, the new process is just the Nelson process associated to the solution $\{\tilde{\psi}(x,t);t_1\leq t\leq t_2\}$. It is important to observe that the new wave function has the same phase at time t_1 as the old one before measurement. This agrees with standard quantum mechanics when it is assumed that immediate repetition of the measurement yields the same result and does not change the wave function except for an arbitrary phase factor; see, e.g., Refs. 26, 27. Here, however, no further assumption is needed: *The invariance of the phase follows from the variational principle*. This is a crucial point. Indeed, if we assume the invariance of the phase after a position measurement in stochastic mechanics, then the variational principle of Sec. IV suffices to produce the new Nelson process (associated to the solution $\{\tilde{\psi}(x,t)\}$ of the Schrödinger equation). Also notice that the solution process possesses the same coherence property with respect to the time interval as the solution process of the previous section.

VII. DISCUSSION

In this paper we have shown that, in the frame of Nelson's stochastic mechanics, the wave function reduction does not need to be *postulated*, but may be *derived* from the standard rules of probability (Bayes' theorem) and a stochastic variational principle of transparent significance. It seems to us that this result lends support to the point of view of Blanchard, Golin, and Serva in Ref. 28, where it was shown that some apparent paradoxes of stochastic mechanics related to repeated measurements could be removed by introducing an appropriate new process after each measurement. The new process, indeed, is the Nelson process associated to the new solution $\tilde{\psi}$ of the Schrödinger equation. A general comparison between standard quantum mechanics and stochastic mechanics is beyond the aims of this paper, and anyway beyond the knowledge and the understanding of the present author. We refer the reader to Refs. 4, 14, as well as to a series of recent papers by Guerra,[7,29] for a thorough and deep analysis on the possibility of regarding Nelson's stochastic mechanics as a complete physical theory.

Nevertheless, it seems legitimate to us to stress that stochastic mechanics, including the elements of a theory of measurement outlined in Ref. 28 and here, can simply be based on the hypothesis of universal Brownian motion and on stochastic variational principles. Thus, stochastic mechanics appears as a generalization of classical mechanics whose foundations are completely independent from standard quantum mechanics. Moreover, this theory is now capable of providing a transparent probabilistic derivation of the two most mysterious features of standard quantum mechanics, namely the uncertainty principle and the wave function collapse.

ACKNOWLEDGMENTS

We wish to thank all the participants in the Fall 98 seminar on''Control of quantum systems,'' and expecially P. Marchetti for stimulating me through very lively discussions to (hopefully) improve my understanding on the measurement problem in stochastic mechanics.

Estimates for the spectral shift function of the polyharmonic operator

Alexander Pushnitski[a)]
Department of Mathematical Sciences, Loughborough University, Loughborough, Leicestershire LE11 3TU, United Kingdom

(Received 19 May 1999; accepted for publication 10 August 1999)

The Lifshits–Krein spectral shift function is considered for the pair of operators $H_0=(-\Delta)^l$, $l>0$ and $H=H_0+V$ in $L_2(\mathbb{R}^d)$, $d\geqslant 1$; here V is a multiplication operator. The estimates for this spectral shift function $\xi(\lambda;H,H_0)$ are obtained in terms of the spectral parameter $\lambda>0$ and the integral norms of V. These estimates are in a good agreement with the ones predicted by the classical phase space volume considerations.
[S0022-2488(99)02311-7]

I. INTRODUCTION

The main object of study of this paper is the Lifshits–Krein *spectral shift function* (SSF). For an exposition of the SSF theory, see, e.g., Ref. 1 or 2. For a general pair of self-adjoint operators H_1, H_2 in a Hilbert space $\mathcal{H}$, satisfying some trace class condition (see Sec. II C), the SSF $\xi(\lambda;H_2,H_1)$ appears in connection with the *trace formula:*

$$\mathrm{Tr}(\psi(H_2)-\psi(H_1))=\int_{-\infty}^{\infty}\xi(\lambda;H_2,H_1)\psi'(\lambda)d\lambda,\quad \psi\in C_0^\infty(\mathbb{R}). \tag{1.1}$$

Besides, the SSF is related to the scattering matrix $S(\lambda)$ for the pair H_1, H_2 by the *Birman–Krein formula*:

$$\det S(\lambda)=e^{-2\pi i\xi(\lambda;H_2,H_1)},$$

for almost every λ on the absolutely continuous spectrum of H_1. This formula allows one to interpret the SSF as the scattering phase. Moreover, sometimes it is treated as the definition of the SSF. See Ref. 1 for references and a discussion.

Let $H_0=(-\Delta)^l$, $l>0$ in $L_2(\mathbb{R}^d)$, $d\geqslant 1$, and let $V=V(x)$, $x\in\mathbb{R}^d$, be a (real-valued) perturbation potential, which decays sufficiently fast as $|x|\to\infty$. In this paper we obtain bounds on $\xi(\lambda;H_0+V,H_0)$ in terms of λ and integral norms of V. The most interesting case is $l=1$ (Schrödinger operator). Nevertheless, the technique of this paper allows us to obtain bounds on the SSF in a uniform way for all $l\in(0,\infty)$ (and all dimensions d), and thus we consider the problem in its natural generality. The main result of this paper (Theorem 2.2) is formulated in Sec. II and its corollaries—in Sec. III. Our estimates are very close to the ones predicted by the semiclassical intuition—see the discussion in Sec. III. Our results extend the estimates of Ref. 3 and are closely related to the results of Ref. 4—see the discussion at the end of Sec. III. Our technique is based on the new representation for the SSF obtained in Ref. 5.

II. PRELIMINARIES: STATEMENT OF THE MAIN RESULT

A. Notation

For a closable linear operator T in a Hilbert space $\mathcal{H}$, by $\overline{T}$ we denote the closure of T. For a self-adjoint operator A, the symbols $\sigma(A)$, $\rho(A)$ denote its spectrum and resolvent set; $R(z,A) = (A-zI)^{-1}$ [for $z\in\rho(A)$] and $E_A(\delta)$ is the spectral projection associated to a Borel set $\delta\subset\mathbb{R}$. By $\mathbf{S}_\infty(\mathcal{H})$ we denote the space of all compact operators in $\mathcal{H}$. For $T=T^*\in\mathbf{S}_\infty(\mathcal{H})$ we introduce the counting functions of the spectrum by $n_\pm(s,T) := \operatorname{rank} E_{\pm T}((s,+\infty))$, $s>0$. Note that (see, e.g., Ref. 6)

$$n_\pm(s_1+s_2,T_1+T_2)\leqslant n_\pm(s_1,T_1)+n_\pm(s_2,T_2), \quad s_1,s_2>0. \tag{2.1}$$

For $p\geqslant 1$ the Neumann–Schatten classes $\mathbf{S}_p$ are defined in a usual way:

$$T\in\mathbf{S}_p \quad \text{if } \|T\|_{\mathbf{S}_p}^p := \sum_n s_n^p(T)<\infty,$$

where $\{s_n(T)\}$ is the sequence of singular numbers of T.

An integral without the domain of integration explicitly specified implies integration over $\mathbb{R}^d$. Formulas and statements with double indices ($\pm$ and $\mp$) should be read as pairs of statements, in one of which all the indices take upper values and in another—the lower ones. By $C(d), C(l)$, etc. (possibly with sub- and superscripts) we denote various constants that depend only on d, l, etc. and whose particular values are of no importance. A constant that first appears in formula $(i.j)$ is denoted by $C_{i.j}$.

We remind the reader of the definition of the lattice space $l_1(L_r)\subset L_r(\mathbb{R}^d), r\geqslant 1$:

$$u\in l_1(L_r) \quad \text{if } \|u\|_{l_1(L_r)} := \sum_{j\in\mathbb{Z}^d}\left(\int_{\mathbf{Q}^d+j}|u|^r\,dx\right)^{1/r}<\infty, \quad \mathbf{Q}^d=(0,1)^d\subset\mathbb{R}^d.$$

Everywhere $\mathcal{H}=L_2(\mathbb{R}^d)$, $d\geqslant 1$ and $H_0=(-\Delta)^l$, $l>0$; $\varkappa = d/(2l)$. We shall need a notation for a logarithmic weight function. Namely, for $x\in\mathbb{R}^d$ and $\gamma>0$ let

$$F_\gamma(x)=1+(\log_+|x|)^\gamma. \tag{2.2}$$

B. Assumptions on *V*

Below by V we denote both a function $V:\mathbb{R}^d\to\mathbb{R}$ and the (self-adjoint) operator of multiplication by $V(x)$ in $L_2(\mathbb{R}^d)$. In various places we shall use some of the following assumptions on V:

$$V \text{ is } H_0\text{-form compact;} \tag{2.3}$$

$$V\in L_1(\mathbb{R}^d); \tag{2.4}$$

$$V\in L_\varkappa(\mathbb{R}^d); \tag{2.5}$$

$$\int |V(x)|F_\gamma(x)\,dx<\infty, \quad \gamma>2. \tag{2.6}$$

Note that for $\varkappa<1$ (2.3) follows from (2.4), and for $\varkappa>1$—from (2.5). Clearly, under the assumption (2.3) the operators H_0+V, H_0+V_+, H_0-V_- are well defined via the corresponding quadratic forms.

The following assumption will appear only for $\varkappa\geqslant 2$:

$$\text{if } \varkappa\geqslant 2, \quad \text{then } V\in l_1(L_2). \tag{2.7}$$

C. Existence of the SSF

Let $H_1,\ H_2$ be a pair of self-adjoint operators in a Hilbert space $\mathcal{H}$, such that

$$H_2 - H_1 \in \mathbf{S}_1(\mathcal{H}). \tag{2.8}$$

Then the SSF $\xi(\lambda;H_2,H_1)$ exists and is given by the *Krein formula*,[7]

$$\xi(\lambda;H_2,H_1) = \frac{1}{\pi} \lim_{\epsilon\to+0} \arg \Delta_{H_2/H_1}(\lambda + i\epsilon), \quad \text{a.e. } \lambda \in \mathbb{R}, \tag{2.9}$$

where $\Delta_{H_2/H_1}(z) = \det(H_2 - zI)(H_1 - zI)^{-1}$ and the branch of the argument is fixed by

$$\arg \Delta_{H_2/H_1}(z) \to 0 \quad \text{as } \operatorname{Im} z \to +\infty.$$

The SSF obeys the monotonicity property:[7]

$$\pm((H_2 - H_1)\chi,\chi) \geqslant 0 \quad \forall \chi \in \mathcal{H} \Rightarrow \pm \xi(\lambda;H_2,H_1) \geqslant 0. \tag{2.10}$$

For a triple $H_0,\ H_1,\ H_2$ of operators, such that $H_1 - H_0 \in \mathbf{S}_1$ and $H_2 - H_0 \in \mathbf{S}_1$, one has

$$\xi(\lambda;H_2,H_0) = \xi(\lambda;H_2;H_1) + \xi(\lambda;H_1,H_0). \tag{2.11}$$

In applications, instead of (2.8), it is usually possible to check the inclusion $f(H_2) - f(H_1) \in \mathbf{S}_1$, where f is some monotone smooth enough function. In this case one can first take $\tilde{H}_1 = f(H_1),\ \tilde{H}_2 = f(H_2)$ and define $\xi(\lambda;\tilde{H}_2,\tilde{H}_1)$ according to (2.9), and then put

$$\xi(\lambda;H_2,H_1) := \operatorname{sign} f' \cdot \xi(f(\lambda);f(H_2),f(H_1)). \tag{2.12}$$

Thus defined, $\xi(\lambda;H_2,H_1)$ still obeys the trace formula (1.1). See Refs. 1 and 2 for details.

Proposition 2.1: (i) *Let $\varkappa < 2$ and let V obey (2.3), (2.4). Then, for any $\lambda_0 < \inf(\sigma(H_0) \cup \sigma(H_0 + V))$, the relation*

$$R(\lambda_0,H_0) - R(\lambda_0,H_0 + V) \in \mathbf{S}_1 \tag{2.13}$$

holds. Thus, the spectral shift functions $\xi(\lambda;H_0 + V,H_0)$, $\xi(\lambda;H_0 + V_+,H_0)$, $\xi(\lambda;H_0 - V_-,H_0)$ are well defined by (2.12) with $f(\lambda) = (\lambda - \lambda_0)^{-1}$. The following inequalities hold:

$$\xi(\lambda;H_0 - V_-,H_0) \leqslant 0 \leqslant \xi(\lambda;H_0 + V_+,H_0), \tag{2.14}$$

$$\xi(\lambda;H_0 - V_-,H_0) \leqslant \xi(\lambda;H_0 + V,H_0) \leqslant \xi(\lambda;H_0 + V_+,H_0). \tag{2.15}$$

(ii) *Let $\varkappa \geqslant 2$ and let V obey (2.3), (2.7). Then, for any $\lambda_0 < \inf(\sigma(H_0) \cup \sigma(H_0 + V))$ with a large enough absolute value, and for any integer $k > \varkappa - \frac{1}{2}$, the relation*

$$R^k(\lambda_0,H_0) - R^k(\lambda_0,H_0 + V) \in \mathbf{S}_1 \tag{2.16}$$

holds. Thus, the spectral shift functions $\xi(\lambda;H_0 + V,H_0)$, $\xi(\lambda;H_0 + V_+,H_0)$, $\xi(\lambda;H_0 - V_-,H_0)$ are well defined by (2.12) with $f(\lambda) = (\lambda - \lambda_0)^{-k}$. The inequalities (2.14), (2.15) hold.

Similar statements appeared in the literature in many different versions in connection with the trace class scattering theory. Nevertheless, for the sake of completeness, we give the proof of Proposition 2.1 at the end of this section.

The inequalities (2.15) reduce the problem of estimating the SSF to the case of perturbations of a definite sign. Thus, below we shall always assume that $V \geqslant 0$ and consider the pair of functions $\xi(\lambda;H_0 \pm V,H_0)$.

Finally, note that, since $\sigma(H_0) = [0,\infty)$, one has

$$\xi(-\lambda;H_0-V,H_0)=-\operatorname{rank} E_{H_0-V}((-\infty,-\lambda)),\quad \lambda>0. \tag{2.17}$$

D. Estimates for the SSF

The main result of this paper is the following.

Theorem 2.2: *Let $V>0$. Under the assumptions (2.3), (2.6), (2.7), the following estimates hold for $\lambda>0$ and $\gamma>2$:*

$$\xi(\lambda;H_0+V,H_0)\leqslant C(d,l,\gamma)\lambda^{\varkappa-1}\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d,l)\lambda^{\varkappa-1}(\log_+\lambda)\|V\|_{L_1}, \tag{2.18}$$

$$|\xi(\lambda;H_0-V,H_0)|\leqslant C(d,l,\gamma)\lambda^{\varkappa-1}\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d,l)\lambda^{\varkappa-1}(\log_+\lambda)\|V\|_{L_1}$$
$$+|\xi(-\lambda;H_0-6V,H_0)|. \tag{2.19}$$

The proof is given in Secs. IV–VIII. The factor 6 in (2.19) is chosen this way in order to simplify the constants appearing in the proof. Actually, this factor can be replaced by any number greater than 1; at the same time, the constants $C(d,l,\gamma)$ and $C(d,l)$ may have to be increased. Using bounds for $|\xi(-\lambda;H_0-6V,H_0)|$ [which, by (2.17), reduce to the bounds on the number of eigenvalues of H_0-6V], one can estimate the SSF $\xi(\lambda;H_0-V,H_0)$ entirely in terms of λ and integral norms of V. This will be done in Sec. III. In Sec. III we also discuss Theorem 2.2 and related results.

E. Proof of Proposition 2.1

(i) By (2.4), one has $\sqrt{|V|}R(\lambda_0,H_0)\in\mathbf{S}_2$. Therefore, (2.13) follows from the identity

$$R(\lambda_0,H_0+V)=R(\lambda_0,H_0)-(\operatorname{sign}V\sqrt{|V|}R(\lambda_0,H_0))^*(I+\sqrt{|V|}R(\lambda_0,H_0)\sqrt{|V|}\operatorname{sign}V)^{-1}$$
$$\times(\sqrt{|V|}R_0(\lambda_0,H_0)).$$

Clearly,

$$H_0-V_-\leqslant H_0\leqslant H_0+V_+,\quad H_0-V_-\leqslant H_0+V\leqslant H_0+V_+,$$

in the quadratic form sense. Therefore,

$$R(\lambda_0,H_0-V_-)\geqslant R(\lambda_0,H_0)\geqslant R(\lambda_0,H_0+V_+), \tag{2.20}$$

$$R(\lambda_0,H_0-V_-)\geqslant R(\lambda_0,H_0+V)\geqslant R(\lambda_0,H_0+V_+). \tag{2.21}$$

From here, by (2.10) and (2.11), we get

$$\xi((\lambda-\lambda_0)^{-1};R(\lambda_0,H_0-V_-),R(\lambda_0,H_0))\geqslant 0\geqslant\xi((\lambda-\lambda_0)^{-1};R(\lambda_0,H_0+V_+),R(\lambda_0,H_0)),$$

$$\xi((\lambda-\lambda_0)^{-1};R(\lambda_0,H_0-V_-),R(\lambda_0,H_0))\geqslant\xi((\lambda-\lambda_0)^{-1};R(\lambda_0,H_0+V),R(\lambda_0,H_0))$$
$$\geqslant\xi((\lambda-\lambda_0)^{-1};R(\lambda_0,H_0+V_+),R(\lambda_0,H_0)).$$

From here, by the definition (2.12), the relations (2.14), (2.15) follow.

(ii) By (2.7), one has

$$VR^{k+1/2}(\lambda_0,H_0)\in\mathbf{S}_1,\quad k>\varkappa-\tfrac{1}{2}$$

(see, e.g., Ref. 8, Theorem 11.1). Therefore, by Ref. 9, Theorem XI.12, the inclusion (2.16) holds. Due to the results of Ref. 10 (see also Ref. 2, Sec. 8.10), the inequalities (2.20), (2.21) together with (2.16), (2.11) imply

$$\xi((\lambda-\lambda_0)^{-k};R^k(\lambda_0,H_0-V_-),R^k(\lambda_0,H_0))\geqslant 0\geqslant \xi((\lambda-\lambda_0)^{-k};R^k(\lambda_0,H_0+V_+),R^k(\lambda_0,H_0)),$$

$$\xi((\lambda-\lambda_0)^{-k};R^k(\lambda_0,H_0-V_-),R^k(\lambda_0,H_0))\geqslant \xi((\lambda-\lambda_0)^{-k};R^k(\lambda_0,H_0+V),R^k(\lambda_0,H_0))$$
$$\geqslant \xi((\lambda-\lambda_0)^{-k};R^k(\lambda_0,H_0+V_+),R^k(\lambda_0,H_0)).$$

From here, by the definition (2.12), the relations (2.14), (2.15) follow. ■

III. COROLLARIES AND DISCUSSION

A. Semiclassical considerations

Let us consider a ''classical analog'' of the SSF, expressed in terms of the phase space volumes, corresponding to the systems with the Hamiltonians $h_0(p,x)=p^{2l}$ and $h_\pm(p,x)=p^{2l}\pm V(x)$, where $V\geqslant 0$. Let ω_d be the volume of a unit ball in $\mathbb{R}^d$; define

$$\xi^{\mathrm{cl}}(\lambda;H_0+V,H_0)=(2\pi)^{-d}\,\mathrm{vol}\{(p,x)\in\mathbb{R}^{2d}|h_0(p,x)<\lambda<h_+(p,x)\}$$
$$=(2\pi)^{-d}\omega_d\int_{\mathbb{R}^d}(\lambda^{\varkappa}-(\lambda-V(x))_+^{\varkappa})dx,\quad \lambda>0, \tag{3.1}$$

$$\xi^{\mathrm{cl}}(\lambda;H_0-V,H_0)=-(2\pi)^{-d}\,\mathrm{vol}\{(p,x)\in\mathbb{R}^{2d}|h_-(p,x)<\lambda<h_0(p,x)\}$$
$$=-(2\pi)^{-d}\omega_d\int_{\mathbb{R}^d}((\lambda+V(x))^{\varkappa}-\lambda^{\varkappa})dx,\quad \lambda>0. \tag{3.2}$$

It is well known that $\xi^{\mathrm{cl}}(\lambda;H_0\pm V,H_0)$ behaves in many respects like $\xi(\lambda;H_0\pm V,H_0)$; for example, it has the same asymptotics in most asymptotical regimes—see the review in Ref. 11 and references therein. The integrands in (3.1), (3.2) admit the following elementary bounds:

$$\lambda^{\varkappa}-(\lambda-V)_+^{\varkappa}\leqslant\max\{\varkappa,1\}\lambda^{\varkappa-1}V,\quad \varkappa>0; \tag{3.3}$$

$$(\lambda+V)^{\varkappa}-\lambda^{\varkappa}\leqslant\varkappa\lambda^{\varkappa-1}V,\quad \varkappa\leqslant 1; \tag{3.4}$$

$$(\lambda+V)^{\varkappa}-\lambda^{\varkappa}\leqslant C_1V^{\varkappa}+C_2\lambda^{\varkappa-1}V,\quad \varkappa>1. \tag{3.5}$$

It is easy to give concrete explicit values for C_1, C_2 in (3.5); for example, $C_1=2^{\varkappa}$, $C_2=2^{\varkappa}-1$. Substituting (3.3)–(3.5) into (3.1), (3.2), we get the following bounds for ξ^{cl}:

$$\xi^{\mathrm{cl}}(\lambda;H_0+V,H_0)\leqslant(2\pi)^{-d}\omega_d\max\{\varkappa,1\}\lambda^{\varkappa-1}\|V\|_{L_1},\quad \varkappa>0; \tag{3.6}$$

$$|\xi^{\mathrm{cl}}(\lambda;H_0-V,H_0)|\leqslant(2\pi)^{-d}\omega_d\varkappa\lambda^{\varkappa-1}\|V\|_{L_1},\quad \varkappa\leqslant 1; \tag{3.7}$$

$$|\xi^{\mathrm{cl}}(\lambda;H_0-V,H_0)|\leqslant C_1(2\pi)^{-d}\omega_d\|V\|_{L_\varkappa}^{\varkappa}+C_2(2\pi)^{-d}\omega_d\lambda^{\varkappa-1}\|V\|_{L_1},\quad \varkappa>1. \tag{3.8}$$

Estimates (3.6)–(3.8) are in good agreement with the asymptotics of ξ^{cl} for high energy and a large coupling constant:

$$\xi^{\mathrm{cl}}(\lambda;H_0\pm V,H_0)\sim\pm(2\pi)^{-d}\omega_d\varkappa\lambda^{\varkappa-1}\int V(x)dx,\quad \lambda\to\infty, \tag{3.9}$$

$$\xi^{\mathrm{cl}}(\lambda;H_0-gV,H_0)\sim-(2\pi)^{-d}\omega_d g^{\varkappa}\int V^{\varkappa}(x)dx,\quad g\to\infty. \tag{3.10}$$

We consider (3.6)–(3.8) as the model estimates. Clearly, (2.18) is in agreement with (3.6) up to the constants, the logarithmic weight F_γ and the term $\log_+ \lambda$. In order to compare (2.19) with (3.7), (3.8), one has to estimate the term $|\xi(-\lambda;H_0-6V,H_0)|$. This will be done below differently for $\varkappa>1$, $\varkappa<1$ and $\varkappa=1$.

B. The case $\varkappa>1$

In this case, we use the Cwikel–Lieb–Rozenblum bound:[12–14]

$$|\xi(-\lambda;H_0-V,H_0)|\leqslant C(d,l)\|V\|_{L_\varkappa}^{\varkappa}. \tag{3.11}$$

Substituting (3.11) into (2.19), we get the following.

Corollary 3.1: Let $\varkappa>1$. Assume the hypothesis of Theorem 2.2 and the inclusion (2.5); then, for any $\lambda>0$ and $\gamma>2$,

$$|\xi(\lambda;H_0-V,H_0)|\leqslant C(d,l,\gamma)\lambda^{\varkappa-1}\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d,l)\lambda^{\varkappa-1}(\log_+\lambda)\|V\|_{L_1}+C(d,l)\|V\|_{L_\varkappa}^{\varkappa}. \tag{3.12}$$

C. The case $\varkappa<1$

For $\varkappa<1$ let us use the Birman–Schwinger principle and estimate $|\xi(-\lambda;H_0-V,H_0)|$ (for $V\geqslant 0$) in the following way:

$$|\xi(-\lambda;H_0-V,H_0)|\leqslant \mathrm{Tr}(\sqrt{V}R(-\lambda,H_0)\sqrt{V})=C(d,l)\lambda^{\varkappa-1}\|V\|_{L_1}. \tag{3.13}$$

Substituting (3.13) into (2.19) and taking into account the obvious estimate $\|V\|_{L_1}\leqslant\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}$, we get the following corollary.

Corollary 3.2: Let $V\geqslant 0$ and $\varkappa<1$; assume (2.6). Then, for any $\lambda>0$ and $\gamma>2$,

$$|\xi(\lambda;H_0-V,H_0)|\leqslant C(d,l,\gamma)\lambda^{\varkappa-1}\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d,l)\lambda^{\varkappa-1}(\log_+\lambda)\|V\|_{L_1}. \tag{3.14}$$

D. The case $\varkappa=1$

Now

$$\xi^{\mathrm{cl}}(-\lambda;H_0-V,H_0)=-(2\pi)^{-d}\omega_d\int V(x)dx,\quad \forall\lambda\in\mathbb{R}.$$

Nevertheless, as it is well known, the ''naive'' estimate,

$$|\xi(-\lambda;H_0-V,H_0)|\leqslant C\|V\|_{L_1},\quad \lambda>0, \tag{3.15}$$

is wrong; see, e.g., Ref. 15 for the discussion. Instead, there are numerous estimates of $\xi(-\lambda;H_0-V,H_0)$, which are worse than (3.15) by a logarithmic term of some kind; see Refs. 16 and 17. Such estimates are a bit cumbersome as compared to (3.11), (3.13). Instead of discussing them, we consider two rough but simple estimates. The first one is (see, e.g., Ref. 18, Proposition 5.5)

$$|\xi(-\lambda;H_0-V,H_0)|\leqslant\|\sqrt{V}R(-\lambda,H_0)\sqrt{V}\|_{\mathbf{S}_q}^q\leqslant C(d,q)\lambda^{1-q}\|V\|_{L_q}^q,\quad q>1; \tag{3.16}$$

it is of an ''almost correct'' order in V and λ. Substituting (3.16) into (2.19), we get the following corollary.

Corollary 3.3: Let $\varkappa=1$; assume (2.3), (2.6) and let $V\in L_q(\mathbb{R}^d)$ for some $q>1$. Then, for any $\lambda>0$ and $\gamma>2$,

$$|\xi(\lambda;H_0-V,H_0)|\leqslant C(d,\gamma)\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d)(\log_+\lambda)\|V\|_{L_1}+C(d,q)\lambda^{1-q}\|V\|_{L_q}^q. \tag{3.17}$$

Another simple estimate is valid (see, e.g., Ref. 18, Proposition 5.4) for λ bounded away from zero:

$$|\xi(-\lambda;H_0-V,H_0)|\leqslant C(d,r)\|V\|_{l_1(L_r)},\quad r>1,\quad \lambda\geqslant 1. \tag{3.18}$$

Note that $V\in l_1(L_r)$, $r>1$, implies (2.3). Thus, substituting (3.18) into (2.19), we obtain the following.

Corollary 3.4: Let $\varkappa=1$; *assume (2.6) and let* $V\in l_1(L_r)$ *for some* $r>1$. *Then, for any* $\lambda\geqslant 1$ *and* $\gamma>2$,

$$|\xi(\lambda;H_0-V,H_0)|\leqslant C(d,\gamma)\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d)(\log_+\lambda)\|V\|_{L_1}+C(d,r)\|V\|_{l_1(L_r)}. \tag{3.19}$$

Substituting the estimates of Refs. 16, 17 into (2.19), one can obtain more precise statements.

E. A comparison with the results of Ref. 3

In Ref. 3, the following result has been obtained. Let $d\geqslant 2$, $l=1$ and let $V=V(x)\geqslant 0$ satisfy the estimate

$$V(x)\leqslant C_{3.20}(1+|x|)^{-\rho},\quad \rho>d. \tag{3.20}$$

For all $\lambda\geqslant C>0$ and all coupling constants $g>0$ the following bounds have been established (See Ref. 3, Theorem 4.2):

$$\xi(\lambda;H_0+gV,H_0)\leqslant C_{3.21}g\lambda^{\varkappa-1}(|\log\lambda|+1), \tag{3.21}$$

$$|\xi(\lambda;H_0-gV,H_0)|\leqslant C_{3.22}(g\lambda^{\varkappa-1}(|\log\lambda|+1)+g^{\varkappa}). \tag{3.22}$$

The constants $C_{3.21},C_{3.22}$ may depend on d and $C_{3.20}$. Clearly, (3.21) follows from (2.18) and (3.22)—from (3.12), (3.19). The basic difference between our results and the ones of Ref. 3 is in the fact that the dependence on V is explicit in (2.18), (3.12), (3.19) but not in (3.21), (3.22). Besides, Theorem 2.2 and Corollaries 3.1–3.4 extend the results of Ref. 3 in some other respects.

(1) Theorem 2.2 and Corollary 3.2 deal with the case $\varkappa<1$, which has not been considered in Ref. 3.
(2) The class of potentials V in Theorem 2.2 and Corollaries 3.1–3.4 is broader than the one given by (3.20).
(3) Theorem 2.2 and Corollaries 3.1–3.3 concern all $\lambda>0$, whereas in Ref. 3 λ is assumed to be bounded away from zero.

F. Integral estimates for the SSF

In Ref. 4, the *integral* estimates for the SSF $\xi(\lambda,H_0\pm V,H_0)$ have been obtained (for the same operators $H_0,V\geqslant 0$ as in the present paper). Before discussing them, let us write down the estimates for ξ^{cl}, which easily follow from the definition (3.1), (3.2):

$$\int_0^R\xi^{\mathrm{cl}}(\lambda;H_0+V,H_0)d\lambda\leqslant(2\pi)^{-d}\omega_dR^{\varkappa}\|V\|_{L_1}\quad R>0,\quad \varkappa>0, \tag{3.23}$$

$$\int_0^R|\xi^{\mathrm{cl}}(\lambda;H_0-V,H_0)|d\lambda\leqslant(2\pi)^{-d}\omega_dR^{\varkappa}\|V\|_{L_1}\quad R>0,\quad \varkappa\leqslant 1, \tag{3.24}$$

$$\int_0^R |\xi^{\mathrm{cl}}(\lambda;H_0-V,H_0)|d\lambda \leqslant C_1(d,l)R^{\varkappa}\|V\|_{L_1}+C_2(d,l)R\|V\|_{L_\varkappa}^{\varkappa}, \quad R>0, \ \ \varkappa>1. \tag{3.25}$$

It appears that the estimates (3.23), (3.25) can be carried over to the ''real'' SSF (see estimates (6.2) and (6.10), respectively, in Ref. 4); it is interesting that even the constant in [Ref. 4, Eq. (6.2)] coincides with the classical one, given by (3.23). For $\varkappa<1$, the estimate

$$\int_0^R |\xi(\lambda;H_0-V,H_0)|d\lambda \leqslant C(d,l)R^{\varkappa}\|V\|_{L_1} \quad R>0, \quad \varkappa<1$$

[with the constant $C(d,l)$ different from the classical one, given by (3.24)] follows from [Ref. 4, Eq. (6.7)] and (3.13). For $\varkappa=1$ the estimate [Ref. 4, Eq. (6.7)] together with (3.16) implies

$$\int_0^R |\xi(\lambda;H_0-V,H_0)|d\lambda \leqslant C(d)R\|V\|_{L_1}+C(d,q)R^{2-q}\|V\|_{L_q}^{q}, \quad R>0, \quad \varkappa=1,$$

for any $q>1$, and together with (3.18) it implies

$$\int_0^R |\xi(\lambda;H_0-V,H_0)|d\lambda \leqslant C(d)R\|V\|_{L_1}+C(d,r)R\|V\|_{l_1(L_r)}, \quad R>1, \quad \varkappa=1,$$

for any $r>1$.

G. Remarks

(1) Note that in Ref. 3 some estimates for the SSF have been found that have better order in λ and g, than (3.21), (3.22), depending on the exponent ρ in (3.20). These estimates, however, are of a conditional character, since they depend on some hypothesis on the boundary values of the resolvent of H_0, which has not been proved yet.

(2) The proof of Theorem 2.2 borrows some elements of Ref. 3. But the operator theoretic part of our approach (Propositions 4.2, 4.3) is completely different.

(3) It is natural to compare the estimates for the SSF with its asymptotics. Note that formula (3.9) for the ''real'' SSF and its various extensions is well known (see, e.g., Ref. 11 and references therein). The relation (3.10) for the ''real'' SSF is a well-known fact for $\lambda<0$ (see, e.g., Ref. 18) and has been proved in Ref. 19 for $\lambda>0$ and $l=1$. Comparing the estimates (2.18), (3.12), (3.14), (3.19) with the asymptotics (3.9), (3.10), we see that the estimates are of a correct order in the coupling constant g (as $g\to\infty$) and of an almost correct (up to the logarithmic terms) order in λ as $\lambda\to\infty$.

(4) In the case $d=l=1$, a pointwise estimate on the SSF, which is somewhat different from (3.14), has been obtained in Ref. 20. See the end of Sec. VIII for the discussion of this estimate.

IV. REPRESENTATION FOR THE SSF

Assume (2.3), (2.4) and denote $W:=\sqrt{V}$. Assumption (2.3) means that

$$W(H_0+I)^{-1/2}\in \mathbf{S}_\infty. \tag{4.1}$$

For $\operatorname{Im} z>0$ consider the ''sandwiched resolvent,''

$$T(z):=(W(H_0+I)^{-1/2})(H_0+I)R_0(z)(W(H_0+I)^{-1/2})^*=\overline{WR_0(z)W};$$

by (4.1), $T(z)\in\mathbf{S}_\infty$. Denote

$$A(z)=\operatorname{Re} T(z), \quad K(z)=\operatorname{Im} T(z).$$

By (2.4), for any bounded interval $\delta\subset\mathbb{R}$, one has

$$WE_{H_0}(\delta)\in\mathbf{S}_2. \tag{4.2}$$

From here we get the following statement.

Proposition 4.1: Assume (2.3), (2.4). For a.e. $\lambda\in\mathbb{R}$,

$$\exists\lim_{\epsilon\to 0+} T(\lambda+i\epsilon)=:T(\lambda+i0)\in\mathbf{S}_\infty \quad\text{and}\quad K(\lambda+i0)\in\mathbf{S}_1. \tag{4.3}$$

Proof: For any $\delta\subset\mathbb{R}$, denote

$$T_\delta(z):=(W(H_0+I)^{-1/2}E_{H_0}(\delta))(H_0+I)R_0(z)(W(H_0+I)^{-1/2}E_{H_0}(\delta))^*,$$

$$A_\delta(z)=\operatorname{Re}T_\delta(z),\quad K_\delta(z)=\operatorname{Im}T_\delta(z). \tag{4.4}$$

Now let $\delta\subset\mathbb{R}$ be some open *bounded* interval. It is one of the fundamental results of the trace class scattering theory (see Ref. 21 or 2) that (4.2) implies

$$\exists T_\delta(\lambda+i0)\in\mathbf{S}_2 \quad\text{and}\quad K_\delta(\lambda+i0)\in\mathbf{S}_1,\quad a.e.\ \lambda\in\mathbb{R}. \tag{4.5}$$

On the other hand, the operator $T_{\mathbb{R}\setminus\delta}(z)$ is analytically extendable through δ; obviously,

$$T_{\mathbb{R}\setminus\delta}(\lambda)\in\mathbf{S}_\infty \quad\text{and}\quad K_{\mathbb{R}\setminus\delta}(\lambda)=0,\quad \lambda\in\delta. \tag{4.6}$$

Finally, writing $T(z)=T_\delta(z)+T_{\mathbb{R}\setminus\delta}(z)$ and taking into account (4.5), (4.6), we get (4.3) for *a.e.* $\lambda\in\delta$. Since $\delta\subset\mathbb{R}$ is arbitrary, this implies the required statement. ■

It will follow from the reasoning of Sec. VII that under the additional assumption (2.6), the condition (4.3) actually holds for all $\lambda\neq 0$ and $T(\lambda+i0)$ depends continuously on λ in the operator norm and $K(\lambda+i0)$—in the trace norm.

Let λ be such that (4.3) holds; denote

$$\mathcal{N}_\pm(\lambda):=\frac{1}{\pi}\int_{-\infty}^{\infty}\frac{dt}{1+t^2}n_\pm(1,A(\lambda+i0)+tK(\lambda+i0)). \tag{4.7}$$

One easily checks that (4.3) implies convergence of the integral in (4.7).

Proposition 4.2 (Refs. 5 and 4): Assume (2.3), (2.4), (2.7); then for a.e. $\lambda\in\mathbb{R}$,

$$\xi(\lambda;H_0\pm V,H_0)=\pm\mathcal{N}_\mp(\lambda). \tag{4.8}$$

Representation (4.7), (4.8) for the SSF has been established in Ref. 4 (see also Ref. 22 for a generalization) as an abstract operator theoretic fact; application to the polyharmonic operator was considered in Ref. 4, Theorems 6.2, 6.3. Formula (4.8) can be considered as the *Birman–Schwinger principle on the continuous spectrum*; see Ref. 5 for the discussion.

A straightforward analysis of the r.h.s. of (4.7) gives the following.

Proposition 4.3 (Ref. 5): Let, for some $\lambda>0$, *the condition (4.3) hold. Then for any* $\theta\in(0,1)$ *the following estimate holds:*

$$\mathcal{N}_\pm(\lambda)\leq n_\pm(1-\theta,A(\lambda+i0))+\theta^{-1}\pi^{-1}\|K(\lambda+i0)\|_{\mathbf{S}_1}. \tag{4.9}$$

In the proof of Theorem 2.2, we shall use (4.9) together with the following decomposition:

$$A(\lambda+i0)=A_\delta(\lambda+i0)+A_{\mathbb{R}\setminus\delta}(\lambda),\quad \lambda>0,\quad \delta=(0,2\lambda), \tag{4.10}$$

where the operators on the r.h.s. are defined by (4.4). Substituting (4.10) into (4.9), fixing $\theta=1/4$, and using (2.1), we get the following inequality:

$$\mathcal{N}_\pm(\lambda)\leqslant n_\pm(\tfrac{1}{2},A_{\mathbb{R}\setminus\delta}(\lambda))+n_\pm(\tfrac{1}{4},A_\delta(\lambda+i0))+4\pi^{-1}\|K(\lambda+i0)\|_{\mathbf{S}_1}. \tag{4.11}$$

The relation (4.11) plays the key role in the proof of Theorem 2.2. In what follows we estimate each of the three terms on the r.h.s. of (4.11). Note that $A_{\mathbb{R}\setminus\delta}(\lambda)\geqslant 0$; thus, $n_-(\tfrac{1}{2},A_{\mathbb{R}\setminus\delta}(\lambda))=0$. Certainly, there is much freedom in choosing the constants θ in (4.9) and $s_{1,2}$ in (2.1), but this choice affects only the constants in the resulting formulas (2.18), (3.12), (3.14), (3.17), (3.19).

V. ESTIMATE FOR $A_{\mathbb{R}\setminus\delta}$

Assume (2.3); as in the end of the previous section, let us fix some $\lambda>0$, denote $\delta=(0,2\lambda)$, and define the operator $A_{\mathbb{R}\setminus\delta}$ according to (4.4).

Proposition 5.1: Under the above assumptions, for any $s>0$,

$$n_+(s,A_{\mathbb{R}\setminus\delta}(\lambda+i0))\leqslant|\xi(-\lambda;H_0-3s^{-1}V,H_0)|. \tag{5.1}$$

Proof: A straightforward calculation shows that

$$R(\lambda,H_0)E_{H_0}(\mathbb{R}\setminus\delta)\leqslant 3R(-\lambda,H_0),$$

in the quadratic form sense. It follows that $A_{\mathbb{R}\setminus\delta}(\lambda+i0)\leqslant 3T(-\lambda)$. From here, using the Birman–Schwinger principle, we get

$$\begin{aligned} n_+(s,A_{\mathbb{R}\setminus\delta}(\lambda+i0))&\leqslant n_+(s,3T(-\lambda))\\ &=\operatorname{rank}E_{H_0-3s^{-1}V}((-\infty,-\lambda))\\ &=|\xi(-\lambda;H_0-3s^{-1}V,H_0)|. \end{aligned}$$

■

VI. ESTIMATE FOR K

Assume (2.3), (2.4). For $\lambda>0$ consider the operator

$$(WE((0,\lambda)))(WE((0,\lambda)))^*. \tag{6.1}$$

By (4.2), the operator (6.1) belongs to the trace class. We will need a well-known representation for the derivative of (6.1) with respect to λ. In order to write down this representation, for every $t>0$ define the operator $J(t):L_2(\mathbb{R}^d)\to L_2(\mathbb{S}^{d-1})$, which acts according to the formula

$$J(t):\ \ f(x)\mapsto(2\pi)^{-d/2}\int_{\mathbb{R}^d}e^{it\langle x,\nu\rangle}W(x)f(x)dx,\quad \nu\in\mathbb{S}^{d-1}.$$

For $d=1$ by $\mathbb{S}^{d-1}$ we mean the set $\{-1,\ 1\}$. Clearly, $J(t)\in\mathbf{S}_2$ and

$$\|J(t)\|^2_{\mathbf{S}_2}=d\omega_d(2\pi)^{-d}\|V\|_{L_1}. \tag{6.2}$$

A straightforward calculation shows that the operator-valued function (6.1) is differentiable in λ in the trace class and

$$\mathcal{F}(\lambda):=\frac{d}{d\lambda}(WE((0,\lambda)))(WE((0,\lambda)))^*=(2l)^{-1}\lambda^{\varkappa-1}J^*(\lambda^{1/(2l)})J(\lambda^{1/(2l)})\geqslant 0. \tag{6.3}$$

If for some $\lambda>0$ the limit $T(\lambda+i0)$ exists, then, clearly,

$$K(\lambda+i0)=\pi\mathcal{F}(\lambda). \tag{6.4}$$

Thus,

$$\|K(\lambda+i0)\|_{\mathbf{s}_1}=\pi\,\mathrm{Tr}\,\mathcal{F}(\lambda)=\pi(2l)^{-1}\lambda^{\varkappa-1}\|J(\lambda^{1/(2l)})\|_{\mathbf{s}_2}^2=\pi\varkappa\omega_d(2\pi)^{-d}\lambda^{\varkappa-1}\|V\|_{L_1}. \quad (6.5)$$

VII. ESTIMATE FOR A_δ

A. Preliminary estimates

Define the function $\varphi(t)$, $t>0$, by

$$\varphi(t)=\begin{cases}|e^{it}-1|^2, & t\leqslant\pi,\\ 4, & t\geqslant\pi.\end{cases} \quad (7.1)$$

Proposition 7.1: Assume (2.4). For any $t_1>0$, $t_2>0$ *the following estimate holds:*

$$\|J(t_1)-J(t_2)\|_{\mathbf{s}_2}^2\leqslant d\,\omega_d(2\pi)^{-d}\int_{\mathbb{R}^d}V(x)\varphi(|x||t_1-t_2|)dx. \quad (7.2)$$

Proof:

$$\|J(t_1)-J(t_2)\|_{\mathbf{s}_2}^2\leqslant(2\pi)^{-d}\int_{\mathbb{R}^d}V(x)\int_{\mathbb{S}^{d-1}}|e^{it_1\langle\nu,x\rangle}-e^{it_2\langle\nu,x\rangle}|^2\,d\nu\,dx$$

$$\leqslant(2\pi)^{-d}\int_{\mathbb{R}^d}V(x)\int_{\mathbb{S}^{d-1}}\varphi(|x||t_1-t_2|)d\nu\,dx$$

$$=(2\pi)^{-d}\,d\,\omega_d\int_{\mathbb{R}^d}V(x)\varphi(|x||t_1-t_2|)dx.$$

■

We are reminded that $\mathcal{F}(\lambda)$ is defined by (6.3).

Proposition 7.2: Assume (2.4). For any $\lambda_1>0$, $\lambda_2>0$*:*

$$\|\mathcal{F}(\lambda_1)-\mathcal{F}(\lambda_2)\|_{\mathbf{s}_1}\leqslant\varkappa\omega_d(2\pi)^{-d}|\lambda_1^{\varkappa-1}-\lambda_2^{\varkappa-1}|\|V\|_{L_1}+2\varkappa\omega_d(2\pi)^{-d}\lambda_2^{\varkappa-1}\|V\|_{L_1}^{1/2}$$

$$\times\left(\int V(x)\varphi(|x||\lambda_1^{1/(2l)}-\lambda_2^{1/(2l)}|)dx\right)^{1/2}. \quad (7.3)$$

Proof: By (6.3),

$$\|\mathcal{F}(\lambda_1)-\mathcal{F}(\lambda_2)\|_{\mathbf{s}_1}=(2l)^{-1}\|\lambda_1^{\varkappa-1}J^*(\lambda_1^{1/(2l)})J(\lambda_1^{1/(2l)})-\lambda_2^{\varkappa-1}J^*(\lambda_2^{1/(2l)})J(\lambda_2^{1/(2l)})\|_{\mathbf{s}_1}$$

$$\leqslant(2l)^{-1}|\lambda_1^{\varkappa-1}-\lambda_2^{\varkappa-1}|\|J^*(\lambda_1^{1/(2l)})J(\lambda_1^{1/(2l)})\|_{\mathbf{s}_1}$$

$$+(2l)^{-1}\lambda_2^{\varkappa-1}\|(J^*(\lambda_1^{1/(2l)})-J^*(\lambda_2^{1/(2l)}))J(\lambda_1^{1/(2l)})\|_{\mathbf{s}_1}$$

$$+(2l)^{-1}\lambda_2^{\varkappa-1}\|J^*(\lambda_2^{1/(2l)})(J(\lambda_1^{1/(2l)})-J(\lambda_2^{1/(2l)}))\|_{\mathbf{s}_1}.$$

Substituting (6.2) and (7.2) onto the r.h.s. of the last estimate, we arrive at (7.3). ■

Proposition 7.3: Assume (2.6); then there exist such constants $0<C_{7.4}^{(1)}(\gamma)$ *and* $0<C_{7.4}^{(2)}(\gamma)<1$, *that*

$$\int V(x)\varphi(|x|s)dx\leqslant C_{7.4}^{(1)}(\gamma)|\log s|^{-\gamma}\|VF_\gamma\|_{L_1},\quad \forall s\in(0,C_{7.4}^{(2)}(\gamma)). \quad (7.4)$$

Proof: One has

$$\int V(x)\varphi(|x|s)dx \le \sup_{x\in\mathbb{R}^d}\frac{\varphi(|x|s)}{F_\gamma(x)}\int V(x)F_\gamma(x)dx.$$

It is a straightforward calculation to check that

$$\sup_{x\in\mathbb{R}^d}\frac{\varphi(|x|s)}{F_\gamma(x)} \le C_{7.4}^{(1)}(\gamma)|\log s|^{-\gamma},$$

for some constant $C_{7.4}^{(1)}(\gamma)$ and for all small enough $s>0$. ∎

B. Existence of $A_\delta(\lambda+i0)$

Proposition 7.4: Assume (2.6), fix $\lambda>0$ and let $\delta=(0,2\lambda)$. Then the limit $A_\delta(\lambda+i0)$ exists in the trace norm and

$$A_\delta(\lambda+i0)=\int_0^{2\lambda}\frac{\mathcal{F}(t)-\mathcal{F}(\lambda)}{t-\lambda}dt; \tag{7.5}$$

the last integral is absolutely convergent in the trace norm.

Proof: We start from the obvious formula, which is a consequence of the spectral theorem:

$$A_\delta(\lambda+i\epsilon)=\int_0^{2\lambda}\frac{t-\lambda}{(t-\lambda)^2+\epsilon^2}\mathcal{F}(t)dt, \quad \epsilon>0.$$

Clearly,

$$\int_0^{2\lambda}\frac{t-\lambda}{(t-\lambda)^2+\epsilon^2}\mathcal{F}(t)dt=\int_0^{2\lambda}\frac{t-\lambda}{(t-\lambda)^2+\epsilon^2}(\mathcal{F}(t)-\mathcal{F}(\lambda))dt. \tag{7.6}$$

From Propositions 7.2, 7.3, it follows that

$$\|\mathcal{F}(\lambda+s)-\mathcal{F}(\lambda)\|_{\mathbf{S}_1}\le C(\lambda,V)|\log|s\|^{-\gamma/2}, \tag{7.7}$$

for all small enough $s\in\mathbb{R}$. Thus, the integrands both in (7.6) and in (7.5) are dominated (in the trace norm) by an integrable function $C(\lambda,V)|t-\lambda|^{-1}|\log|t-\lambda\|^{-\gamma/2}$ in the neighborhood of $t=\lambda$. It follows that the r.h.s. of (7.6) converges to the r.h.s. of (7.5) as $\epsilon\to+0$. ∎

Remark 7.5: Note that it follows from the estimate (7.7) that under the assumptions (2.3), (2.6) the condition (4.3) holds for all $\lambda>0$ and the operator $A_\delta(\lambda+i0)$ is continuous in $\lambda>0$ in the trace norm. Thus, $T(\lambda+i0)$ is continuous in $\lambda>0$ in the operator norm. Next, if instead of (2.6) one assumes a stronger condition,

$$\int V(x)(1+|x|)^\gamma dx<\infty, \quad \gamma\in(0,2),$$

then the same reasoning leads to the estimate

$$\|\mathcal{F}(\lambda+s)-\mathcal{F}(\lambda)\|_{\mathbf{S}_1}\le C(\lambda,V)|s|^{\gamma/2},$$

for all small enough $s\in\mathbb{R}$. This estimate implies a Hölder continuity of $A_\delta(\lambda+i0)$ in the trace norm with the exponent $\gamma/2$ and thus the Hölder continuity of $T(\lambda+i0)$ in the operator norm. However, in what follows we shall not need these facts.

C. Estimates for $A_\delta(\lambda+i0)$

First we consider the case $\lambda=1$.

Proposition 7.6: Assume (2.6); let $\delta=(0,2)$. *One has*

$$\|A_\delta(1+i0)\|_{\mathbf{s}_1}\leqslant C(d,l)\|V\|_{L_1}+C(d,l)\|V\|_{L_1}^{1/2}\int_0^1\frac{ds}{s}\left(\int V(x)\varphi(|x|s)dx\right)^{1/2}. \tag{7.8}$$

Proof: Let us use (7.5) and (7.3):

$$\begin{aligned}\|A_\delta(1+i0)\|_{\mathbf{s}_1}&\leqslant\int_0^2\frac{\|\mathcal{F}(\lambda)-\mathcal{F}(1)\|_{\mathbf{s}_1}}{|\lambda-1|}d\lambda\\&\leqslant\varkappa\omega_d(2\pi)^{-d}\|V\|_{L_1}\int_0^2\frac{|\lambda^{\varkappa-1}-1|}{|\lambda-1|}d\lambda\\&\quad+2\varkappa\omega_d(2\pi)^{-d}\|V\|_{L_1}^{1/2}\int_0^2\frac{d\lambda}{|\lambda-1|}\left(\int V(x)\varphi(|x||\lambda^{1/(2l)}-1|)dx\right)^{1/2}.\end{aligned} \tag{7.9}$$

Changing the variable in the last integral, we obtain

$$\begin{aligned}&\int_0^2\frac{1}{|\lambda-1|}\left(\int V(x)\varphi(|x||\lambda^{1/(2l)}-1|)dx\right)^{1/2}d\lambda\\&=\int_{-1}^{2^{1/(2l)}-1}\frac{2l(s+1)^{2l-1}}{|(s+1)^{2l}-1|}\left(\int V(x)\varphi(|x|s)dx\right)^{1/2}ds\\&\leqslant C(l)\int_{-1}^1\frac{ds}{|s|}\left(\int V(x)\varphi(|x|s)dx\right)^{1/2}+\int_1^{2^{1/(2l)}-1}\frac{2l(s+1)^{2l-1}}{|(s+1)^{2l}-1|}\left(\int V(x)\varphi(|x|s)dx\right)^{1/2}ds\\&\leqslant C(l)\int_0^1\frac{ds}{s}\left(\int V(x)\varphi(|x|s)dx\right)^{1/2}+C(l)\|V\|_{L_1}^{1/2}.\end{aligned} \tag{7.10}$$

Note that the integral over $(1,2^{1/(2l)}-1)$ enters the last calculation only if $2^{1/(2l)}-1>1$, i.e., if $l<\frac{1}{2}$. In order to estimate this integral, we use the bound $\varphi(t)\leqslant 4$. The estimates (7.9) and (7.10) together give (7.8). ■

Proposition 7.7: Assume (2.6), fix $\lambda>0$ *and let* $\delta=(0,2\lambda)$. *The following estimate holds:*

$$\|A_\delta(\lambda+i0)\|_{\mathbf{s}_1}\leqslant C(d,l,\gamma)\lambda^{\varkappa-1}\|V\|_{L_1}^{1/2}\|VF_\gamma\|_{L_1}^{1/2}+C(d,l)\lambda^{\varkappa-1}(\log_+\lambda)\|V\|_{L_1}. \tag{7.11}$$

Proof: We start from the standard dilatation argument. Namely, let U_r, $r>0$ be the unitary dilatation operator in $L_2(\mathbb{R}^d)$: $(U_rf)(x)=r^{d/2}f(rx)$. Then

$$U_rA(z)U_r^*=r^{2l}A^{(r)}(r^{2l}z),$$

where $A^{(r)}$ corresponds to the perturbation potential $V^{(r)}(x)=V(xr)$. Thus, taking $r=\lambda^{-1/(2l)}$, using (7.8), and changing variable in the resulting integrals, we obtain

$$\begin{aligned}\|A(\lambda+i0)\|_{\mathbf{s}_1}&=\|U_rA(\lambda+i0)U_r^*\|_{\mathbf{s}_1}\\&=\lambda^{-1}\|A^{(r)}(1+i0)\|_{\mathbf{s}_1}\\&\leqslant\lambda^{\varkappa-1}C(d,l)\|V\|_{L_1}+C(d,l)\lambda^{\varkappa-1}\|V\|_{L_1}^{1/2}\int_0^{\lambda^{1/(2l)}}\frac{ds}{s}\left(\int V(x)\varphi(|x|s)dx\right)^{1/2}.\end{aligned}$$

It remains to estimate the last integral. First let $\lambda \geqslant 1$. Using (7.4) and the bound $\varphi(t) \leqslant 4$, we get

$$\int_0^{\lambda^{1/(2l)}} \frac{ds}{s} \left(\int V(x)\varphi(|x|s)dx \right)^{1/2} \leqslant (C_{7.4}^{(1)}(\gamma))^{1/2} \|VF_\gamma\|_{L_1}^{1/2} \int_0^{C_{7.4}^{(2)}} \frac{ds}{s} |\log s|^{-\gamma/2} + 2\|V\|_{L_1}^{1/2} \int_{C_{7.4}^{(2)}}^{\lambda^{1/(2l)}} \frac{ds}{s}$$
$$\leqslant C(\gamma)\|VF_\gamma\|_{L_1}^{1/2} + \|V\|_{L_1}^{1/2} l^{-1} \log_+ \lambda - 2\|V\|_{L_1}^{1/2} \log C_{7.4}^{(2)}$$
$$\leqslant (C(\gamma) - 2\log C_{7.4}^{(2)})\|VF_\gamma\|_{L_1}^{1/2} + \|V\|_{L_1}^{1/2} l^{-1} \log_+ \lambda$$
$$\leqslant C(\gamma)\|VF_\gamma\|_{L_1}^{1/2} + \|V\|_{L_1}^{1/2} l^{-1} \log_+ \lambda.$$

Finally, if $\lambda < 1$, we merely replace the integration interval $(0,\lambda^{1/(2l)})$ by (0, 1), thus getting the upper bound. ■

VIII. PROOF OF THEOREM 2.2. CONCLUDING REMARKS

A. Proof of Theorem 2.2

Obviously,

$$n_\pm(\tfrac{1}{4}, A_\delta(\lambda + i0)) \leqslant 4\|A_\delta(\lambda + i0)\|_{\mathbf{s}_1}.$$

It remains to substitute the last estimate together with (5.1), (6.5), (7.11) into (4.11) and take into account Proposition 4.2. ■

B. Remarks

(1) Our Proposition 7.4 is fairly close to the ''limiting absorption principle in the trace class'' of Ref. 3, though these two statements are proved by using a very different technique.

(2) One can exploit (4.11) by using some other (different from ours) estimates for $K(\lambda + i0)$, $A_\delta(\lambda + i0)$, $A_{\mathbb{R}\setminus\delta}(\lambda + i0)$, thus obtaining new estimates for the SSF. Let us give an example.

In Ref. 23, the following estimate has been proved for $l = 1$, $d \geqslant 2$:

$$\|A_\delta(\lambda + i0)\|_{\mathbf{s}_2}^2 \leqslant C(d)\lambda^{d-2-(q/2)} \int\int \frac{V(x)V(x')}{|x-x'|^q} dx\, dx', \quad q \in [0, d-1]. \tag{8.1}$$

For $d = 1$ this estimate is also true (which follows from the explicit formula for the integral kernel of the resolvent of H_0). Observing that

$$n_\pm(s, A_\delta(\lambda + i0)) \leqslant \tfrac{1}{2} s^{-2} \|A_\delta(\lambda + i0)\|_{\mathbf{s}_2}^2, \tag{8.2}$$

and substituting (8.1), (8.2) into (4.11), one obtains the following estimates for $l = 1$, $\lambda > 0$, $q \in [0, d-1]$:

$$\xi(\lambda; H_0 + V, H_0) \leqslant C(d)\lambda^{d-2-(q/2)} \int\int \frac{V(x)V(x')}{|x-x'|^q} dx\, dx' + C(d)\lambda^{(d/2)-1}\|V\|_{L_1},$$

$$|\xi(\lambda; H_0 - V, H_0)| \leqslant C(d)\lambda^{d-2-(q/2)} \int\int \frac{V(x)V(x')}{|x-x'|^q} dx\, dx' + C(d)\lambda^{(d/2)-1}\|V\|_{L_1}$$
$$+ |\xi(-\lambda; H_0 - 6V, H_0)|.$$

One can combine the last estimate with (3.11), (3.13), (3.16), (3.18) or similar bounds in an obvious way. Note that the estimate (2.10) of Ref. 20 is contained in this series of estimates (for $d=1$).

Symplectic Dirac–Kähler fields

M. Reuter[a)]
Institut für Physik, Universität Mainz, Staudingerweg 7, D-55099 Mainz, Germany

(Received 26 March 1999; accepted for publication 12 July 1999)

For the description of space–time fermions, Dirac–Kähler fields (inhomogeneous differential forms) provide an interesting alternative to the Dirac spinor fields. In this paper we develop a similar concept within the symplectic geometry of phase spaces. Rather than on space–time, symplectic Dirac–Kähler fields can be defined on the classical phase space of any Hamiltonian system. They are equivalent to an infinite family of metaplectic spinor fields, i.e., spinors of $\mathrm{Sp}(2N)$, in the same way an ordinary Dirac–Kähler field is equivalent to a (finite) multiplet of Dirac spinors. The results are interpreted in the framework of the gauge theory formulation of quantum mechanics which was proposed recently. An intriguing analogy is found between the lattice fermion problem (species doubling) and the problem of quantization in general.
[S0022-2488(99)01411-5]

I. INTRODUCTION

In a classic paper[1] Kähler proposed a description of fermions in terms of inhomogeneous differential forms. Rather than by spinor fields, the fermions are represented by a set of antisymmetric tensors in this approach. The role of the Dirac equation is taken over by the so-called Dirac–Kähler equation which involves only tensor manipulations. It imitates the γ-matrix algebra with the help of the Clifford product for forms.

At first sight it seems puzzling how a family of tensor fields carrying integer spin can describe a particle of half-integer spin. This paradox is resolved if one notes that (in 4 space–time dimensions) a single Dirac–Kähler field actually corresponds to a multiplet of 4 ordinary Dirac spinors which mix under Lorentz transformations in a nontrivial way (''flavor mixing'').

The Dirac–Kähler fermions have attracted a lot of attention both from the physics[2–9] and the mathematics[10,11] point of view. In particular they have made their appearance in lattice field theory.[12] It is a well-known problem that a straightforward lattice discretization of the ordinary Dirac action does not describe one but rather 16 fermions in the continuum limit. The reason for this replication of fermionic states (usually referred to as the species ''doubling'' problem) is that the lattice propagator in momentum space has poles at all 16 corners of the Brillouin zone. The Kogut–Susskind[13] or staggered lattice fermions were proposed as an attempt to solve this problem. They are based on a more sophisticated lattice action which reduces the number of fermion species from 16 to 4. Later on it turned out[2,3] that the Kogut–Susskind fermions are nothing but Dirac–Kähler fields discretized on a hypercubic lattice. As it deals with differential forms only, Dirac–Kähler theory on the lattice can take advantage of all the mathematical tools provided by the algebraic topology of cell complexes. In particular, by a standard procedure, the differential forms of the continuum formulation can be replaced by appropriate cochains on the lattice. These cochains are functions defined on the lattice points, links, plaquettes, cubes, and hypercubes of the underlying lattice. In this manner it becomes obvious that the extra fermion species implied by the Kogut–Susskind lattice action and the fact that a Dirac–Kähler field contains 4 ordinary Dirac fermions have a common origin.

We only mention that the species doublers on the lattice can be avoided completely by using

[a)]Electronic mail: reuter@thep.physik.uni-mainz.de

Wilson fermions or the nonlocal ''SLAC derivative,''[12] for instance. Alternatively one can regard the 4 Dirac fermions contained in one Kogut–Susskind field as 4 different physical ''flavors.'' As we are interested in Dirac–Kähler fermions here we shall adopt this latter point of view in the following.

Dirac–Kähler (DK) fields can be defined on any Riemannian manifold $(\mathcal{M}_n, g)$, i.e., on any smooth n-dimensional manifold equipped with a metric g. [The pseudo-Riemannian case (Lorentzian space–times) can be dealt with in a completely analogous fashion.] From the physics point of view this manifold represents *space–time*.

The main purpose of the present paper is to propose an analog of the DK fields which ''live'' on symplectic rather than Riemannian manifolds. This means that we are going to study DK fields not over space–time but rather over a *phase space*.

A symplectic manifold $(\mathcal{M}_{2N}, \omega)$ is a smooth $2N$-dimensional manifold which is endowed with a closed, nondegenerate 2-form $\omega = \frac{1}{2}\omega_{ab} d\phi^a \wedge d\phi^b$. (The ϕ^a, $a=1,...,2N$, are local coordinates on $\mathcal{M}_{2N}$.) This manifold should be thought of as the phase space of a Hamiltonian system with N degrees of freedom. The corresponding Poisson bracket is given by $\{\phi^a, \phi^b\} = \omega^{ab}$ where the matrix (ω^{ab}) is the inverse of (ω_{ab}). Using local Darboux coordinates $\phi^a \equiv (p^i, q^i)$, $i = 1,...,N$, this matrix is independent of ϕ^a, $\omega^{qp} = -\omega^{pq} = I$, and the only nonvanishing brackets are $\{q^i, p^j\} = \delta^{ij}$. If ϕ^a and $\tilde{\phi}^a$ are local coordinates belonging to two overlapping charts of an atlas covering $\mathcal{M}_{2N}$ then, by the very definition of a symplectic manifold, the coordinate transformation $\phi \to \tilde{\phi}$ is symplectic, i.e., the Jacobian matrix $(\partial \tilde{\phi}^a / \partial \phi^b)$ is an element of Sp$(2N)$ at every point of the overlap region. Sp$(2N)$, the group of linear canonical transformations, plays the same role for phase space which the Lorentz group plays for space–time. In particular, it is the structure group of the frame bundle over $\mathcal{M}_{2N}$.

As for introducing DK fields on symplectic manifolds the first question which we must answer is what kind of spinor field should be used in place of the ordinary Dirac spinors of relativistic field theory. The only natural choice here is to employ the so-called metaplectic spinors,[14] i.e., the spinors of the metaplectic group Mp$(2N)$. Basically Mp$(2N)$ is related to Sp$(2N)$ in the same way Spin(n) is related to SO(n). In particular, there exists a two-to-one homomorphism between the two groups, i.e., Mp$(2N)$ covers Sp$(2N)$ twice. The construction of metaplectic spin bundles and spinor fields over a symplectic manifold proceeds almost literally along the same lines as in the case of space–time spinors, the main difference being that it is Mp$(2N)$ now which serves as the structure group. For a detailed exposition we must refer to the literature.[14,15]

Metaplectic spinors have been used in many different contexts including geometric quantization,[15] semiclassical approximations,[16] Parisi–Sourlas supersymmetry,[17] string theory,[18,19] and anyon superconductivity.[20] Most recently they played an important role in an approach to quantization[21] which is based upon a Yang–Mills theory on phase space with metaplectic ''matter'' fields. This new formulation of quantum mechanics is one of the main motivations for the present work. We shall come back to it later on.

Let us briefly describe how one can construct representations of Mp$(2N)$.[22] One has to associate an operator $M(S)$ to every matrix $S \equiv (S^a{}_b) \in \text{Sp}(2N)$ in such a way that $M(S_1)M(S_2) = \pm M(S_1 S_2)$. These operators can be built up from a kind of ''γ matrices'' which constitute a symplectic Clifford algebra:

$$\gamma^a \gamma^b - \gamma^b \gamma^a = 2i\omega^{ab}. \tag{1.1}$$

We require $M(S)$ to satisfy the usual compatibility condition between the vector and the spinor representation:

$$M(S)^{-1} \gamma^a M(S) = S^a{}_b \gamma^b. \tag{1.2}$$

Every infinitesimal Sp$(2N)$ transformation is of the form $S^a{}_b = \delta^a_b + \omega^{ac}\kappa_{cb}$ with symmetric coefficients κ_{ab}. Inserting this together with the ansatz $M(S) = 1 - (i/2)\kappa_{ab}\Sigma^{ab}_{\text{meta}}$ into the compatibility condition it is easy to show that the latter is solved by

$$\Sigma^{ab}_{\text{meta}} = \tfrac{1}{4}(\gamma^a\gamma^b + \gamma^b\gamma^a) \tag{1.3}$$

and that these generators satisfy the $\text{Sp}(2N)$ commutator relations.[22] Thus every representation of the symplectic Clifford algebra gives rise to a representation of $\text{Mp}(2N)$.

The most obvious difference between the metaplectic and the space–time spinors is that the symplectic Clifford algebra involves a commutator rather than an anticommutator. As an immediate consequence, this algebra has no finite dimensional matrix representations, and metaplectic spinors are necessarily infinite component objects. What is meant by a ''metaplectic representation'' is a representation in which γ^a is a Hermitian operator on an infinite dimensional Hilbert space $\mathcal{V}$. Hence the operators M obtained by exponentiating the generators (1.3) give rise to a unitary representation. (See Refs. 22 and 23 for further details.)

The symplectic Clifford algebra (1.1) admits a rather intriguing reinterpretation which is also at the heart of the new approach to quantization[21] mentioned above. Assume we are given a quantum mechanical system with a Hilbert space $\mathcal{V}$ along with N position and momentum operators $\hat{x}^i$ and $\hat{\pi}^i$ acting on it. They satisfy the canonical commutator relations $[\hat{x}^i,\hat{\pi}^j] = i\hbar\,\delta^{ij}$. By virtue of the identification $\gamma^i = \kappa\hat{\pi}^i$, $\gamma^{N+i} = \kappa\hat{x}^i$ for $i=1,...,N$ and with the constant $\kappa \equiv \sqrt{2/\hbar}$ it is obvious that the ''symplectic Clifford algebra'' (1.1) is actually nothing but the canonical commutation relations for the $\hat{x}-\hat{\pi}$ auxiliary quantum system. We call it an ''auxiliary'' system because it should not be confused with the actual physical system under consideration, the one whose (curved) phase space is $\mathcal{M}_{2N}$. (The classical phase space pertaining to the auxiliary system is simply $\mathbf{R}^{2N}$ equipped with the standard symplectic structure.)

The metaplectic spin bundles are bundles over $\mathcal{M}_{2N}$ with the typical fiber $\mathcal{V}$ and the structure group $\text{Mp}(2N)$.[14] At each point ϕ of $\mathcal{M}_{2N}$ a local copy of $\mathcal{V}$, denoted $\mathcal{V}_\phi$, is attached. Metaplectic spinor fields are sections through these bundles. Locally they are simply functions which assume values in $\mathcal{V}$:

$$\psi: \quad \mathcal{M}_{2N} \to \mathcal{V}, \quad \phi \mapsto |\psi\rangle_\phi \in \mathcal{V}_\phi. \tag{1.4}$$

The notation $|\psi\rangle_\phi$ means that the spinor $|\psi\rangle \in \mathcal{V}$, ''lives'' in the local Hilbert space at ϕ. Upon introducing a basis $\{|\alpha\rangle\}$ in $\mathcal{V}$ we write $\psi^\alpha(\phi) \equiv \langle\dot{\alpha}|\psi\rangle_\phi$ for its components. Here α is an infinite dimensional generalization of a spinor index. If we take $\{|\alpha\rangle\}$ to be the $\hat{x}$ eigenbasis, for instance, then $\alpha \equiv (\alpha^1,\dots,\alpha^N) \in \mathbf{R}^N$. (See Refs. 22 and 23 for details.)

In the present paper we shall focus on the local aspects of the bundles involved. We only mention that on certain manifolds there are topological obstructions which prevent them from carrying globally well-defined metaplectic spinor fields.[14] In Ref. 23 we characterized these obstructions using methods from quantum field theory.

Let us come back to the main question which we are trying to answer in this paper: *Do there exist ''symplectic Dirac-Kähler fields'' which are related to the metaplectic spinors in the same way the ordinary Dirac-Kähler fields are related to Dirac spinors*?

Apart from being interesting in its own right, this question is of obvious physical relevance. The fascinating property of metaplectic spinor fields is that, *on a purely group theoretical basis*, they introduce aspects of quantum mechanics into the geometry of classical phase spaces. By pure representation theory one is led to the auxiliary quantum system in the local Hilbert spaces $\mathcal{V}_\phi$. In Ref. 21 we explained in detail how these auxiliary systems relate to the actual physical quantum system with the classical phase space $\mathcal{M}_{2N}$. Using this as our starting point, we showed that it is possible to replace conventional canonical quantization by two new rules with a more transparent physical and geometrical meaning.

Classical mechanics and classical statistical mechanics are geometric theories which are conveniently described in the language of symplectic geometry. Only tensor fields are needed to formulate them. Quantum mechanics, on the other hand, has a natural interpretation in terms of spinor fields on phase space. Thus, in a sense, the very process of quantization is tantamount to a transition from tensors to spinors. But this is precisely what Dirac–Kähler theory is about: its basic fields are tensors which, however, are equivalent to a multiplet of spinors.

Before embarking on the detailed constructions let us briefly outline the strategy for finding the ''symplectic DK fields'' which we shall follow in this paper.

Our main tools are two types of auxiliary quantum systems with Hilbert spaces $\mathcal{V}$ and $\mathcal{V}^F$, respectively. We mentioned already the (bosonic) $\hat{x}-\hat{\pi}$ system on $\mathcal{V}$ whose canonical operators realize the metaplectic γ-matrices γ^a. We also need a similar fermionic system with a (finite-dimensional) Hilbert space $\mathcal{V}^F$ and a set of operators $\hat{\chi}^\mu$, $\mu=1,...,n$, satisfying the canonical anticommutator relations $\hat{\chi}^\mu\hat{\chi}^\nu+\hat{\chi}^\nu\hat{\chi}^\mu=\hbar\,\delta^{\mu\nu}$. The SO($n$)-Dirac matrices γ^μ are treated as a special realization of this algebra.

An important technical ingredient is the Weyl symbol calculus.[24–28] Let $\mathcal{L}(\mathcal{V})$ and $\mathcal{L}(\mathcal{V}^F)$ be the spaces of linear operators on $\mathcal{V}$ and $\mathcal{V}^F$, respectively. It is possible to uniquely characterize every operator $\hat{b}\in\mathcal{L}(\mathcal{V})$ and $\hat{f}\in\mathcal{L}(\mathcal{V}^F)$ in terms of classical phase functions (symbols) $b(y)$ and $f(\theta)$. Here y and θ are coordinates on the (flat) classical phase spaces which belong to the auxiliary systems. In the bosonic case, $y\equiv(y^a)\in\mathbf{R}^{2N}$ is a vector with commuting entries, while $\theta\equiv(\theta^\mu)$ is a set of n anticommuting Grassmann numbers. The space of all bosonic (fermionic) symbol functions, equipped with certain algebraic structures, is referred to as the bosonic (fermionic) Weyl algebra $\mathcal{W}(\mathcal{W}^F)$.

Given a space–time manifold $\mathcal{M}_n$, we consider fields on this manifold which assume values in $\mathcal{V}^F$, $\mathcal{L}(\mathcal{V}^F)$ and $\mathcal{W}^F$, respectively. In an obvious notation, we denote them $\psi^\alpha(x)$, $\hat{F}(x)$, and $F(x,\theta)$.

Similarly, given a phase-space manifold $\mathcal{M}_{2N}$, we define fields $\psi^\alpha(\phi)$, $\hat{B}(\phi)$, and $B(\phi,y)$ which assume values in $\mathcal{V}$, $\mathcal{L}(\mathcal{V})$ and $\mathcal{W}$, respectively.

In the first part of this paper we shall reformulate standard Dirac–Kähler theory in terms of the fermionic Weyl symbol calculus. We shall see that $\psi^\alpha(x)$ is an ordinary Dirac spinor and that $F(x,\theta)$ can be identified with a DK field. The Grassmann variables θ^μ will play the role of the basis differentials dx^μ.

This first part of the investigation is quite interesting in its own right. For instance, we shall discover that the Clifford product which is at the heart of DK theory is basically the same thing as the star product of the fermionic Weyl symbol calculus. As a consequence, $\mathcal{W}^F$ turns out to be an Atiyah–Kähler algebra.[10,11]

In the second part of this paper we investigate in detail what happens to the standard DK theory, reformulated in terms of fermionic Weyl symbols, when we replace fermionic symbols by bosonic ones everywhere. This means that we switch from the $\hat{\chi}^\mu$ to the $\hat{x}-\hat{\pi}$ system. Then $\psi^\alpha(\phi)$ is a metaplectic spinor field, and by analogy with the fermionic setting we shall argue that $B(\phi,y)$ is the ''symplectic DK field'' which we are looking for. Schematically our approach can be summarized as follows:

$$\begin{array}{ccc} \text{DK fields} & \Leftrightarrow & \text{fermionic symbols} \\ & & \downarrow \\ \text{symplectic DK fields} & \Leftrightarrow & \text{bosonic symbols} \end{array} \tag{1.5}$$

The rest of this paper is organized as follows: In the second half of this introduction we discuss some aspects of standard DK theory which will be important later on. Then, in Sec. II, we reformulate this theory in terms of fermionic Weyl symbols. Particular attention is paid to the decomposition of DK fields as a set of Dirac spinors. The construction of the symplectic DK fields is performed in Sec. III. We investigate in detail which properties of SO(n) DK fields can be translated to the Sp($2N$) case and which cannot. Section IV contains a summary and various remarks on the quantization problem in the light of the present work. Some material needed as a background for Sec. II is relegated to the Appendix.

As for its mathematical rigor, the style of this paper is informal. Occasionally the language of fiber bundles is used as a convenient tool but we are mostly interested in the local properties of the bundles involved and no pretense is made as for a rigorous and complete discussion of the global aspects.

DK fields on space–time

Let us start with an arbitrary (curved) n-dimensional Riemannian manifold $(\mathcal{M}_n,g)$. Upon introducing local coordinates x^μ, the tangent space $T_x\mathcal{M}_n$ and the cotangent space $T_x^*\mathcal{M}_n$ at the point x of $\mathcal{M}_n$ are spanned by the basis vectors $\partial_\mu\equiv\partial/\partial x^\mu$ and dx^μ, $\mu=1,...,n$, respectively. These spaces constitute the fibers of the (co-)tangent bundle over $\mathcal{M}_n$. Replacing $T^*\mathcal{M}_n$ by its p-fold tensor power we obtain the bundle of (covariant) tensors of rank p. Restricting ourselves to completely antisymmetric tensors we are led to the exterior algebra $\bigwedge(T_x^*\mathcal{M}_n)=\oplus_{p=0}^n \bigwedge^p(T_x^*\mathcal{M}_n)$. Its elements are the inhomogeneous differential forms

$$\Phi(x)=\sum_{p=0}^{n}\Phi^{(p)}(x),\quad \Phi^{(p)}(x)\in\bigwedge^p(T_x^*\mathcal{M}_n),$$
$$\Phi^{(p)}(x)=\frac{1}{p!}F^{(p)}_{\mu_1\cdots\mu_p}(x)dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_p} \tag{1.6}$$

where $F^{(p)}_{\mu_1\cdots\mu_p}$ are completely antisymmetric coefficients. The corresponding algebra multiplication is the wedge product ''$\wedge$.''

Since we have a metric $g=g_{\mu\nu}(x)dx^\mu\otimes dx^\nu$ at our disposal which gives rise to an analogous bilinear form $g'=g^{\mu\nu}(x)\partial_\mu\otimes\partial_\nu$ for the cotangent bundle we can promote the fibers $\bigwedge(T_x^*\mathcal{M}_n)$ of the exterior algebra bundle to an Atiyah–Kähler algebra $\mathbf{AK}(T_x^*\mathcal{M}_n,g')$.[1,10,11]

Quite generally, the Atiyah–Kähler algebra $\mathbf{AK}(V,Q)$ corresponding to an arbitrary vector space V equipped with a quadratic form Q consists of the elements of the exterior algebra over V, $\bigwedge(V)=\oplus_p\bigwedge^p(V)$, for which the following three products are defined:

(1) the exterior product ''$\wedge$,''
(2) the inner product $(\cdot,\cdot)$ induced by Q,
(3) the Clifford product ''$\vee$.''

The three products are required to be distributive with respect to the addition and to satisfy the relation

$$a\vee b=a\wedge b+(a,b) \tag{1.7}$$

for all $a,b\in\bigwedge^1(V)$. The Clifford product is associative by definition. Hence the basic rule (1.7) is sufficient in order to work out the $\vee$ product of two arbitrary elements in $\bigwedge(V)$. Below we shall give a closed formula for this product.

The Atiyah–Kähler algebra combines the notions of an exterior algebra, a Grassmann algebra, and a Clifford algebra in an consistent manner. If we omit the Clifford product it reduces to the Grassmann algebra $\bigwedge(V,Q)$, while omitting both $\vee$ and $(\cdot,\cdot)$ yields the exterior algebra $\bigwedge(V)$. Without the structure of the $\wedge$ product it becomes a Clifford algebra because (1.7) entails $a\vee b+b\vee a=2(a,b)$.[11]

In the case at hand, $V=\bigwedge(T_x^*\mathcal{M}_n)$ and $Q=g'$. This means that for two basis one-forms the inner product is given by $(dx^\mu,dx^\nu)=g'(dx^\mu,dx^\nu)=g^{\mu\nu}$ and similarly for higher forms; for instance, $(dx^\mu\wedge dx^\nu,dx^\rho\wedge dx^\sigma)=g^{\mu\rho}g^{\nu\sigma}-g^{\mu\sigma}g^{\nu\rho}$.

A bundle over $\mathcal{M}_n$ with typical fiber $\mathbf{AK}(T_x^*\mathcal{M}_n,g')$ is called an Atiyah–Kähler bundle and sections through such bundles are referred to as Dirac–Kähler fields. Locally they are described by a collection of antisymmetric tensor fields $\{F^{(p)}_{\mu_1\cdots\mu_p},\ p=0,...,n\}$. The three products defined in the fiber give rise to analogous products on the space of sections, for instance $(\Phi_1\vee\Phi_2)(x)\equiv\Phi_1(x)\vee\Phi_2(x)$. Of course, also all the other operations of the conventional exterior calculus can be applied to Dirac–Kähler fields: the exterior derivative d, the coderivative $d^\dagger$, or the contraction with a vector field v, $\mathbf{i}(v)$, to mention just a few.

In our case the relations defining the Clifford product assume the following form when expressed in terms of the generating elements:

$$1 \vee 1 = 1, \quad 1 \vee dx^\mu = dx^\mu \vee 1 = dx^\mu,$$
$$dx^\mu \vee dx^\nu = dx^\mu \wedge dx^\nu + g^{\mu\nu}. \tag{1.8}$$

By virtue of the postulated associativity of the $\vee$ product, these relations are sufficient in order to determine the Clifford product of two arbitrary differential forms. One finds[1,3]

$$\Phi_1 \vee \Phi_2 = \sum_{p=0}^{n} \frac{(-1)^{p(p-1)/2}}{p!} (\mathcal{A}^p e_{\mu_1} \neg \cdots e_{\mu_p} \neg \Phi_1) \wedge (e^{\mu_1} \neg \cdots e^{\mu_p} \neg \Phi_2) \tag{1.9}$$

with $e_\mu \neg \equiv \mathbf{i}(\partial_\mu)$, $e^\mu \neg \equiv g^{\mu\nu} \mathbf{i}(\partial_\nu)$ where $\mathbf{i}(\partial_\mu)$ denotes the contraction with the basis vector ∂_μ. It is an antiderivation with the properties

$$\mathbf{i}(\partial_\mu) 1 = 0, \quad \mathbf{i}(\partial_\mu) dx^\nu = \delta_\mu^\nu,$$
$$\mathbf{i}(\partial_\mu)(\Phi_1 \wedge \Phi_2) = (\mathbf{i}(\partial_\mu)\Phi_1) \wedge \Phi_2 + (\mathcal{A}\Phi_1) \wedge \mathbf{i}(\partial_\mu)\Phi_2.$$

In writing down Eqs. (1.9) and (1.10) we used the ''main automorphism'' $\mathcal{A}$, a linear map whose action on the DK-field (1.6) is defined as

$$\mathcal{A}\Phi = \sum_{p=0}^{n} (-1)^p \Phi^{(p)}. \tag{1.10}$$

Later on we shall also need the ''main antiautomorphism'' $\mathcal{B}$ which acts according to

$$\mathcal{B}\Phi = \sum_{p=0}^{n} (-1)^{p(p-1)/2} \Phi^{(p)}. \tag{1.11}$$

Obviously, $\mathcal{A}^2 = \mathcal{B}^2 = 1$, $\mathcal{AB} = \mathcal{BA}$, and also

$$\mathcal{A}(\Phi_1 \wedge \Phi_2) = (\mathcal{A}\Phi_1) \wedge (\mathcal{A}\Phi_2),$$
$$\mathcal{B}(\Phi_1 \wedge \Phi_2) = (\mathcal{B}\Phi_2) \wedge (\mathcal{B}\Phi_1), \tag{1.12}$$

for any pair of DK fields.

As an important special case of (1.9) we note for later use that

$$dx^\mu \vee \Phi = dx^\mu \wedge \Phi + e^\mu \neg \Phi. \tag{1.13}$$

Let us look at the physical interpretation of the DK fields now. From now on we shall specialize the discussion to a flat space–time $\mathcal{M}_n = \mathbf{R}^n$ with the metric $g_{\mu\nu} = \delta_{\mu\nu}$. The generalization of a curved manifold and/or a manifold with Lorentzian signature would be straightforward, but we shall avoid these technical complications here since they are not important for the point we would like to make.

The interpretation of a DK field as a multiplet of Dirac spinors is based upon the following two logically independent observations.

(i) From (1.8) we obtain for the antisymmetrized Clifford product of two basis differentials

$$dx^\mu \vee dx^\nu + dx^\nu \vee dx^\mu = 2\delta^{\mu\nu}. \tag{1.14}$$

This relation should be compared to the one satisfied by the Euclidean Dirac matrices γ^μ:

$$\gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2\delta^{\mu\nu}. \tag{1.15}$$

We conclude that the Clifford left multiplication with dx^μ defines a representation of the algebra of γ matrices in the space of (complex) inhomogeneous differential forms: $\gamma^\mu \triangleq dx^\mu \vee$. This representation is reducible though. Assuming n even from now on, a Dirac spinor has $2^{n/2}$ complex components, and an irreducible representation of the algebra (1.15) is in terms of $2^{n/2} \times 2^{n/2}$ matrices. On the other hand, the dimension of the exterior algebra is 2^n, i.e., a DK field Φ has 2^n independent complex component fields. We shall see in a moment that the space $\mathcal{K}$ of all DK fields Φ can be decomposed into $2^{n/2}$ subspaces $\mathcal{K}^{(\alpha)}$ which are invariant under Clifford left multiplication, $\mathcal{K} = \oplus_{\alpha=1}^{k} \mathcal{K}^{(\alpha)}$, $k \equiv 2^{n/2}$. On $\mathcal{K}^{(\alpha)}$, $dx^\mu \vee$ gives rise to an irreducible representation of the algebra (1.15).

(ii) From the exterior derivative d and its adjoint, the coderivative $d^\dagger$, we can form the so-called Dirac–Kähler operator $d-d^\dagger$ which has the property that it squares to the Laplacian:

$$(d-d^\dagger)^2 = -(dd^\dagger + d^\dagger d) = \partial_\mu \partial^\mu. \tag{1.16}$$

It shares this property with the Dirac operator $\gamma^\mu \partial_\mu$ and hence some relationship among the two might be expected. In fact, it turns out that the Dirac–Kähler operator can be expressed in terms of a Clifford multiplication from the left:

$$(d-d^\dagger)\Phi(x) = dx^\mu \vee \partial_\mu \Phi(x). \tag{1.17}$$

Since we know already that $dx^\mu \vee$ corresponds to a γ matrix and leaves the spaces $\mathcal{K}^{(\alpha)}$ invariant, we see that the Dirac–Kähler equation

$$(d-d^\dagger + m)\Phi = 0 \tag{1.18}$$

decomposes to a set of equations $(d-d^\dagger+m)\Phi^{(\alpha)}=0$, $\Phi^{(\alpha)} \in \mathcal{K}^{(\alpha)}$, each of which is equivalent to an ordinary Dirac equation $(\gamma^\mu \partial_\mu + m)\psi = 0$.

Following Becher and Joos[3] we can construct the invariant subspaces $\mathcal{K}^{(\alpha)}$ as follows. We introduce a new basis $\{Z_{\alpha\beta}\}$ in $\mathcal{K}$ whose elements are labeled by a pair of indices $\alpha,\beta = 1,...,2^{n/2}$ and which are required to satisfy

$$dx^\mu \vee Z_{\alpha\beta} = \sum_{\gamma=1}^{2^{n/2}} (\gamma^{\mu T})_{\alpha\gamma} Z_{\gamma\beta} \tag{1.19}$$

where the Euclidean Dirac matrices γ^μ are in the irreducible $2^{n/2}$-dimensional representation. (We use the notation $\mu,\nu,\ldots = 1,...,n$ for Lorentz indices and $\alpha,\beta,\gamma,\ldots = 1,...,2^{n/2}$ for spinor indices.) They satisfy (1.15) and are assumed to be Hermitian, $\gamma_\mu = \gamma_\mu^\dagger$. Frequently we shall regard $Z \equiv (Z_{\alpha\beta})$ as a matrix or, more precisely, as an inhomogeneous differential form which assumes values in the space of spinor matrices. Then (1.19) reads

$$dx^\mu \vee Z = \gamma^{\mu T} Z. \tag{1.20}$$

This equation is satisfied by

$$Z = \sum_{p=0}^{n} \frac{1}{p!} \gamma_{\mu_1}^T \cdots \gamma_{\mu_p}^T \, dx^{\mu_1} \wedge \cdots \wedge dx^{\mu_p}. \tag{1.21}$$

Every DK field Φ can be expanded in the basis $\{Z_{\alpha\beta}\}$:

$$\Phi(x) = \sum_{\alpha,\beta} \psi_\alpha^{(\beta)}(x) Z_{\alpha\beta}. \tag{1.22}$$

Hence it follows immediately from (1.19) that the invariant subspaces $\mathcal{K}^{(\alpha)}$ are spanned by

$$\Phi^{(\beta)} \equiv \sum_\alpha \psi_\alpha^{(\beta)} Z_{\alpha\beta} \in \mathcal{K}^{(\beta)}, \quad \beta \text{ fixed.} \tag{1.23}$$

In fact, one has

$$dx^\mu \vee \Phi^{(\beta)} = \sum_\alpha \left(\sum_\delta \gamma^\mu_{\alpha\delta} \psi_\delta^{(\beta)} \right) Z_{\alpha\beta}, \tag{1.24}$$

which shows that on $\mathcal{K}^{(\beta)}$ Clifford left-multiplication with dx^μ is equivalent to acting with the Dirac matrix γ^μ on the spinor $\psi^{(\beta)} \equiv \{\psi_\alpha^{(\beta)}; \alpha = 1,...,2^{n/2}\}$. For every fixed value of β, $\psi^{(\beta)}$ is an ordinary $2^{n/2}$-component Dirac field. By virtue of the orthogonal decomposition $\Phi = \Sigma_\beta \Phi^{(\beta)}$, a DK field describes a multiplet of $2^{n/2}$ Dirac fields.

It is convenient to combine the expansion coefficients $\psi_\alpha^{(\beta)}$ into a spinor matrix $\hat{\psi}$,

$$(\hat{\psi})_{\alpha\beta} \equiv \psi_\alpha^{(\beta)}, \tag{1.25}$$

so that (1.22) reads

$$\Phi(x) = \mathrm{Tr}[\hat{\psi}(x) Z^T]. \tag{1.26}$$

Writing $\hat{\psi}[\Phi]$ for the matrix related to a given DK field Φ, Eq. (1.24) amounts to

$$\hat{\psi}[dx^\mu \vee \Phi] = \gamma^\mu \hat{\psi}[\Phi]. \tag{1.27}$$

Occasionally one finds a slightly different approach in the literature.[2] One assumes that the inhomogeneous form (1.6) is given and one uses its coefficient functions $F^{(p)}_{\mu_1 \cdots \mu_p}$ in order to construct a spinor matrix $\hat{F}$ by simply replacing $dx^\mu \to \gamma^\mu$ everywhere:

$$\hat{F} \equiv \hat{F}[\Phi] \equiv \sum_{p=0}^{n} \frac{1}{p!} F^{(p)}_{\mu_1 \cdots \mu_p} \gamma^{\mu_1} \cdots \gamma^{\mu_p}. \tag{1.28}$$

Then one verifies that the map $\Phi \mapsto \hat{F}[\Phi]$ satisfies

$$\hat{F}[dx^\mu \vee \Phi] = \gamma^\mu \hat{F}[\Phi], \tag{1.29}$$

a property it has in common with $\hat{\psi}$. Hence we might expect that these two matrix-valued fields are related. Indeed, it turns out that they coincide up to a constant factor. To see this, one inserts the expansions (1.6) and (1.21) into (1.26) and obtains the following formula for the coefficients of Φ, $F^{(p)}_{\mu_1 \cdots \mu_p}$, as a function of $\hat{\psi}$:

$$F^{(p)}_{\mu_1 \cdots \mu_p}(x) = (-1)^{p(p-1)/2} \mathrm{Tr}[\hat{\psi}(x) \gamma_{[\mu_1} \cdots \gamma_{\mu_p]}]. \tag{1.30}$$

Because of the orthogonality and completeness relations enjoyed by the Dirac matrices, Eq. (1.30) has a unique solution for $\hat{\psi}$ as a function of the coefficients $F^{(p)}_{\mu_1 \cdots \mu_p}$ which define Φ. One finds that $\hat{\psi}$ and $\hat{F}$ are essentially the same thing:

$$\hat{\psi}(x) = 2^{-n/2} \sum_{p=0}^{n} \frac{1}{p!} F^{(p)}_{\mu_1 \cdots \mu_p}(x) \gamma^{\mu_1} \cdots \gamma^{\mu_p} \tag{1.31}$$

$$= 2^{-n/2} \hat{F}(x). \tag{1.32}$$

This formula together with (1.25) gives us a practical tool to compute the projection of Φ on the invariant subspaces $\mathcal{K}^{(\alpha)}$.

In standard discussions of Dirac–Kähler theory, because of the simple proportionality of $\hat{\psi}$ and $\hat{F}$, there is no need for a conceptual distinction between the two matrices. In order to establish their equivalence only familiar identities involving γ matrices such as

$$\mathrm{Tr}[\gamma^{[\mu_1}\cdots\gamma^{\mu_p]}(\gamma_{[\nu_1}\cdots\gamma_{\nu_q]})^\dagger]=2^{n/2}p!\,\delta^{pq}\delta^{\mu_1}_{[\nu_1}\cdots\delta^{\mu_p}_{\nu_q]} \tag{1.33}$$

are needed. In the symplectic case, the situation will be more complicated and we have to distinguish more carefully $\hat{\psi}$ which arises from the construction of left-invariant subspaces and $\hat{F}$ which obtains by replacing $dx^\mu\to\gamma^\mu$ in Φ. *A priori* it is not clear that the two objects can easily be related to each other since the metaplectic γ ''matrices'' are infinite dimensional. Hence the question whether there are trace identities analogous to (1.33) is a nontrivial issue.

II. DIRAC–KÄHLER FIELDS AND FERMIONIC WEYL SYMBOLS

In this section we describe the relation between the conventional Dirac–Kähler fermions and the Weyl symbol calculus. In Sec. II A we summarize various properties of the fermionic Weyl symbol calculus and discuss a number of special aspects and applications which will be relevant. In Sec. II B we show that the fermionic Weyl algebra $\mathcal{W}^F$ is an Atiyah–Kähler algebra, and in Sec. II C we introduce $\mathcal{W}^F$-valued fields over space–time. In Sec. II D we demonstrate that they can be identified with Dirac–Kähler fields. They carry a reducible representation of the Clifford algebra. The decomposition of $\mathcal{W}^F$ into invariant subspaces which carry an irreducible representation is performed in Sec. II E.

A. The fermionic Weyl algebra

We consider a set of operators $\hat{\chi}^\mu$, $\mu=1,...,n$, which satisfy the canonical anticommutation relations

$$\hat{\chi}^\mu\hat{\chi}^\nu+\hat{\chi}^\nu\hat{\chi}^\mu=\hbar\,\delta^{\mu\nu}. \tag{2.1}$$

We could think of the $\hat{\chi}$'s as world line fermions which represent the spin of a relativistic particle, for instance.[17,26] The most general operator we can construct by forming linear combinations of products of $\hat{\chi}$'s has the structure

$$\hat{f}=\sum_{p=0}^{n}\frac{1}{p!}f^{(p)}_{\mu_1\cdots\mu_p}\hat{\chi}^{\mu_1}\hat{\chi}^{\mu_2}\cdots\hat{\chi}^{\mu_p} \tag{2.2}$$

with arbitrary (complex-valued) constants $f^{(p)}_{\mu_1\cdots\mu_p}$.

We would like to establish a linear one-to-one correspondence between the operators (2.2) and functions f depending on Grassmann numbers $\theta^1,\theta^2,\ldots,\theta^n$ with $\theta^\mu\theta^\nu+\theta^\nu\theta^\mu=0$. The function $f(\theta)$ which characterizes the operator $\hat{f}$ is called the symbol of $\hat{f}$: $f=\mathrm{symb}(\hat{f})$. There are many ''symbol maps'' which relate operators to classical functions. Here we are interested in the Weyl symbol which is defined as follows. Given the operator (2.2) we define

$$f(\theta)=[\mathrm{symb}(\hat{f})](\theta)=\sum_{p=0}^{n}\frac{1}{p!}f^{(p)}_{\mu_1\cdots\mu_p}\theta^{\mu_1}\theta^{\mu_2}\cdots\theta^{\mu_p} \tag{2.3}$$

which for a given ordering is a well-defined map from operators to functions. In particular, $\mathrm{symb}(\hat{\chi}^\mu)=\theta^\mu$ and $\mathrm{symb}(I)=1$ where I is the unit operator. The inverse mapping is not well defined yet, because in (2.3) we can add to $f^{(p)}_{\mu_1\cdots\mu_p}$ arbitrary tensors which are symmetric in at least one index pair. This does not change $f(\theta)$, but it does change $\hat{f}$. Specifying a unique operator $\hat{f}$ for a given $f(\theta)$ amounts to picking a particular operator ordering prescription. In fact,

$f(\theta)$ can be regarded as a classical phase function of a mechanical system with Grassmann-odd phase-space coordinates θ^μ, and the $\hat{\chi}^\mu$'s are the corresponding quantum operators. We shall employ the Weyl correspondence rule which means that $\hat{f}$ follows from $f(\theta)$ by substituting $\theta^\mu \to \hat{\chi}^\mu$ in (2.3) and writing all operator products in Weyl ordered, i.e., completely antisymmetrized form. For instance, the product $\theta^\mu \theta^\nu$ yields the operator $[\hat{\chi}^\mu \hat{\chi}^\nu]_{\text{Weyl}} = \frac{1}{2}(\hat{\chi}^\mu \hat{\chi}^\nu - \hat{\chi}^\nu \hat{\chi}^\mu) \equiv \hat{\chi}^{[\mu} \hat{\chi}^{\mu]}$. For an arbitrary monomial,

$$\text{symb}^{-1}(\theta^{\mu_1} \cdots \theta^{\mu_p}) = \hat{\chi}^{[\mu_1} \cdots \hat{\chi}^{\mu_p]} \tag{2.4}$$

where the square brackets indicate complete antisymmetrization.

From now on we shall require the constants $f^{(p)}_{\mu_1 \cdots \mu_p}$ appearing in the series expansion of the symbol $f(\theta)$ to be completely antisymmetric tensors. Then the operator $\hat{f}$ associated with the series (2.3) is obtained by simply replacing $\theta^\mu \to \hat{\chi}^\mu$ in this series, and this leads us back to the operator (2.2).

If n is odd, the inverse symbol map is still not uniquely defined, because in this case the operator $\hat{\chi}^1 \hat{\chi}^2 \cdots \hat{\chi}^n$ commutes with all operators and is proportional to the identity therefore. By multiplying any operator by $\hat{\chi}^1 \hat{\chi}^2 \cdots \hat{\chi}^\nu$ if necessary one can represent all operators by even symbols. This prescription makes the correspondence between operators and symbols bijective. (See Refs. 26 and 27 for further details.)

If a string of operators is not contracted with an antisymmetric tensor we must reorder it before we can use

$$\text{symb}(\hat{\chi}^{[\mu_1} \cdots \hat{\chi}^{\mu_p]}) = \theta^{\mu_1} \cdots \theta^{\mu_p} \tag{2.5}$$

in order to read off its symbol. For instance,

$$\text{symb}(\hat{\chi}^\mu \hat{\chi}^\nu) = \text{symb}\left[\hat{\chi}^{[\mu} \hat{\chi}^{\nu]} + \frac{\hbar}{2} \delta^{\mu\nu} \right] = \theta^\mu \theta^\nu + \frac{\hbar}{2} \delta^{\mu\nu}. \tag{2.6}$$

The symbols $f(\theta)$ are functions of the same type as those considered in Appendix A, to which the reader might turn at this point. Among other things, various linear operations on such functions are discussed there which are particularly useful in the context of the symbol calculus. This includes the ''main automorphism'' $\mathcal{A}$, the ''main antiautomorphism'' $\mathcal{B}$, the Hodge operator $*$, and the modified Hodge operator $\star$.

While we allow for complex coefficients $f^{(p)}_{\mu_1 \cdots \mu_p}$, we assume that the operators $\hat{\chi}^\mu$ are Hermitian, $\hat{\chi}^\mu = (\hat{\chi}^\mu)^\dagger$, and that θ^μ is real, $\overline{\theta^\mu} = \theta^\mu$. Hence it follows that

$$\text{symb}(\hat{f}^\dagger) = \overline{\text{symb}(\hat{f})}, \tag{2.7}$$

where the overbar means complex conjugation.

There is a simple integral formula for the operator $\hat{f}$ associated with a given Weyl symbol $f(\theta)$:

$$\hat{f} = \int \hat{\Omega}(\rho) \tilde{f}(\rho) d^n \rho. \tag{2.8}$$

Here $\tilde{f}(\rho)$ is the Fourier transform of $f(\theta)$ as defined in Eq. (A22) of the Appendix, and

$$\hat{\Omega}(\rho) \equiv \exp(-i \hat{\chi}^\mu \rho_\mu) \tag{2.9}$$

is the fermionic analogue of the Weyl operators which implement translations on phase space. Using the identities of Appendix A one can verify that Eqs. (2.4) and (2.8) are indeed equivalent.

An important concept is the ''star product''[3] or ''twisted product'' which mimics the multiplication of operators at the level of symbols. [Both in the fermionic and the bosonic case we keep using the traditional name ''star product'' even though we write ''$\circ$'' instead of the usual symbol ''$*$.'' Following Refs. 29, 30, and 21 this notation indicates that we are dealing with a *fiberwise* twisted product which should not be confused with the $*\equiv *_{\mathcal{M}}$ product which would refer to the *base* of the Weyl algebra bundles we are going to construct in Sec. II B. It is the $*_{\mathcal{M}}$ product rather than the $\circ$ product which is needed for the deformation quantization[24] of physical systems on the phase-space $\mathcal{M}$. In the present paper, the $*_{\mathcal{M}}$ product plays no role, however. (Note also that ''$*$'' stands for the Hodge operator in our case.)] It satisfies

$$\mathrm{symb}(\hat{f}\hat{g})=\mathrm{symb}(\hat{f})\circ\mathrm{symb}(\hat{g}) \tag{2.10}$$

for all operators $\hat{f}$ and $\hat{g}$. As a consequence, the $\circ$ product is associative, distributive with respect to $+$, but not commutative. It is a deformation of the pointwise product of functions to which it reduces in the limit $\hbar\to 0$. From

$$\mathrm{symb}(I)=1, \quad \mathrm{symb}(\hat{\chi}^\mu)=\theta^\mu \tag{2.11}$$

and Eq. (2.6) it follows that

$$\begin{aligned} 1\circ 1=1, \quad 1\circ\theta^\mu=\theta^\mu\circ 1=\theta^\mu, \\ \theta^\mu\circ\theta^\nu=\theta^\mu\theta^\nu+\frac{\hbar}{2}\delta^{\mu\nu}. \end{aligned} \tag{2.12}$$

By virtue of its postulated distributivity and associativity, the relations (2.12) characterize the $\circ$ product uniquely. They are sufficient to work out the product $f\circ g$ of arbitrary functions f and g.

Equation (2.7) implies that complex conjugation changes the order of the factors in a star product:

$$\overline{f_1\circ f_2}=\overline{f_2}\circ\overline{f_1}. \tag{2.13}$$

The space of functions $f(\theta)$ equipped with the $\circ$ product will be referred to as the *fermionic Weyl algebra* $\mathcal{W}^F$.

In the literature[26,27] one finds the following integral representation for the $\circ$ product of two arbitrary functions:

$$(f_1\circ f_2)(\theta)=\epsilon_n\left(\frac{\hbar}{2i}\right)^n\int \exp\left[-\frac{2}{\hbar}(\theta_1\theta+\theta\theta_2+\theta_2\theta_1)\right]f_1(\theta_1)f_2(\theta_2)d^n\theta_1 d^n\theta_2, \tag{2.14}$$

where (indices are raised and lowered with $g_{\mu\nu}=\delta_{\mu\nu}$) $\theta_1\theta\equiv\theta_1^\mu\theta_\mu$, etc., and with ϵ_n defined as in Eq. (A23). For our purposes, various alternative representations of the star product are needed. They are derived in appendix B. The first one reads

$$(f_1\circ f_2)(\theta)=\sum_{p=0}^{n}\left(\frac{\hbar}{2}\right)^p\frac{(-1)^{p(p-1)/2}}{p!}\left[\mathcal{A}^p\frac{\partial}{\partial\theta^{\mu_1}}\frac{\partial}{\partial\theta^{\mu_2}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}f_1(\theta)\right]\left[\frac{\partial}{\partial\theta_{\mu_1}}\frac{\partial}{\partial\theta_{\mu_2}}\cdots\frac{\partial}{\partial\theta_{\mu_p}}f_2(\theta)\right] \tag{2.15}$$

with the automorphism $\mathcal{A}:\mathcal{W}^F\to\mathcal{W}^F$ defined in Appendix A. An equivalent form involving both left and right derivatives is

$$(f_1\circ f_2)(\theta)=\sum_{p=0}^{n}\left(\frac{\hbar}{2}\right)^p\frac{1}{p!}f_1(\theta)\frac{\overleftarrow{\partial}}{\partial\theta^{\mu_p}}\frac{\overleftarrow{\partial}}{\partial\theta^{\mu_{p-1}}}\cdots\frac{\overleftarrow{\partial}}{\partial\theta^{\mu_1}}\frac{\partial}{\partial\theta_{\mu_1}}\frac{\partial}{\partial\theta_{\mu_2}}\cdots\frac{\partial}{\partial\theta_{\mu_p}}f_2(\theta). \tag{2.16}$$

The most compact representation reads

$$(f_1 \circ f_2)(\theta) = f_1(\theta) \exp\left[\frac{\hbar}{2} \frac{\overleftarrow{\partial}}{\partial\theta^\mu} \frac{\vec{\partial}}{\partial\theta_\mu}\right] f_2(\theta), \tag{2.17}$$

where $\overleftarrow{\partial}/\partial\theta^\mu$ is a right derivative acting on f_1 and $\vec{\partial}/\partial\theta^\mu$ a left derivative acting on f_2. The result (2.17) looks surprisingly simple and is completely analogous to its bosonic counterpart. All the complicated sign factors which appeared during the calculation, either explicitly or hidden in the $\mathcal{A}$ automorphism, conspired to disappear from the final result.

Depending on the problem at hand one or another of the above representations is the most convenient one. Equation (2.15) we shall relate to Kähler's formula for the Clifford product shortly. From Eq. (2.16) one immediately reads off the important special cases

$$\theta^\mu \circ f(\theta) = \theta^\mu f(\theta) + \frac{\hbar}{2} \frac{\partial}{\partial\theta_\mu} f(\theta), \tag{2.18}$$

$$f(\theta) \circ \theta^\mu = f(\theta)\theta^\mu + \frac{\hbar}{2} f(\theta) \frac{\overleftarrow{\partial}}{\partial\theta_\mu}. \tag{2.19}$$

In order to calculate the product of two δ functions, which we shall need later on, Eq. (2.14) is most suitable:

$$(\delta \circ \delta)(\theta) = (-1)^{n(n-1)/2} \left(\frac{\hbar}{2}\right)^n. \tag{2.20}$$

Up to now we regarded the $\hat{\chi}^\mu$'s as abstract operators. Let us look at concrete representations on some finite dimensional vector space $\mathcal{V}^F$. If Γ_μ is a set of Hermitian matrices which satisfy the Clifford algebra relations

$$\Gamma^\mu \Gamma^\nu + \Gamma^\nu \Gamma^\mu = 2\delta^{\mu\nu}, \tag{2.21}$$

then

$$\hat{\chi}^\mu = \sqrt{\frac{\hbar}{2}} \Gamma^\mu \tag{2.22}$$

satisfies the canonical anticommutation relations (2.1). Here Γ^μ denotes the Dirac matrices in an arbitrary, possibly reducible representation. The notation γ^μ is reserved for the (essentially unique) irreducible representation on $\mathcal{V}^F = \mathbf{C}^k$, $k \equiv 2^{n/2}$, if n is even. The operators $\hat{f}: \mathcal{W}^F \to \mathcal{W}^F$ of Eq. (2.2) are $k \times k$ matrices then. The space of these operators will be denoted by $\mathcal{L}(\mathcal{W}^F)$.

The identification (2.22) must be interpreted with some care. In setting up the symbol calculus one adopts the rule that the operators $\hat{\chi}^\mu$ anticommute with numbers of odd Grassmann parity. On the other hand, the entries of the matrices Γ^μ are ordinary complex numbers, so Γ^μ commutes with all elements of the Grassmann algebra.

Next we list a few properties of the operators $\hat{\Omega}$ which we shall need shortly. These operators are reminiscent of the (bosonic) Weyl operators. However, as they stand, they are not unitary but rather Hermitian, $\Omega(\rho) = \Omega(\rho)^\dagger$. This is due to the fact that $\hat{\chi}^\mu$ anticommutes with the Grassmann-odd ρ_μ's. Actually it is the operators $\hat{\Omega}(i\rho/\hbar) = \exp(\hat{\chi}^\mu \rho_\mu/\hbar)$ which play the role of the Weyl operators on a fermionic phase space. They are unitary, $\hat{\Omega}(i\rho/\hbar)^\dagger = \hat{\Omega}(i\rho/\hbar)^{-1}$, and they shift $\hat{\chi}^\mu$ by ρ^μ times the unit operator:

$$\hat{\Omega}(i\rho/\hbar)^\dagger \hat{\chi}^\mu \hat{\Omega}(i\rho/\hbar) = \hat{\chi}^\mu + \rho^\mu. \tag{2.23}$$

This leads to a projective representation of the translation group since

$$\hat{\Omega}(\rho_1)\hat{\Omega}(\rho_2)=\exp\left(\frac{\hbar}{2}\rho_1^\mu\rho_{2\mu}\right)\hat{\Omega}(\rho_1+\rho_2). \tag{2.24}$$

The derivative of $\hat{\Omega}(\rho)$ can be written in either of the two forms

$$\frac{\partial}{\partial\rho_\mu}\hat{\Omega}(\rho)=\hat{\Omega}(\rho)\left[i\hat{\chi}^\mu+\frac{\hbar}{2}\rho^\mu\right] \tag{2.25}$$

$$=\left[i\hat{\chi}^\mu-\frac{\hbar}{2}\rho^\mu\right]\hat{\Omega}(\rho). \tag{2.26}$$

When we replace in $\hat{\Omega}$ the operators $\hat{\chi}^\mu$ by the Dirac matrices via (2.22) we are led to

$$\check{\Omega}(\rho)=\exp(-i\sqrt{\hbar/2}\Gamma^\mu\rho_\mu). \tag{2.27}$$

The properties of $\check{\Omega}$ are slightly different from those of $\hat{\Omega}$ because Γ^μ commutes with ρ_μ. The $\check{\Omega}$'s are unitary matrices,

$$\check{\Omega}(\rho)^\dagger=\check{\Omega}(-\rho)=\check{\Omega}(\rho)^{-1} \tag{2.28}$$

with the composition law

$$\check{\Omega}(\rho_1)\check{\Omega}(\rho_2)=\exp\left(-\frac{\hbar}{2}\rho_1^\mu\rho_{2\mu}\right)\check{\Omega}(\rho_1+\rho_2). \tag{2.29}$$

The expressions for their derivative are

$$\frac{\partial}{\partial\rho_\mu}\check{\Omega}(\rho)=\check{\Omega}(-\rho)\left[-i\sqrt{\frac{\hbar}{2}}\Gamma^\mu-\frac{\hbar}{2}\rho^\mu\right] \tag{2.30}$$

$$=\left[-i\sqrt{\frac{\hbar}{2}}\Gamma^\mu+\frac{\hbar}{2}\rho^\mu\right]\check{\Omega}(\rho). \tag{2.31}$$

We shall need these relations when we decompose the reducible Dirac–Kähler representation.

An interesting example where one can see the symbol calculus at work is the generalization of the chirality matrix γ_5 in four dimensions. We assume that n is even in the remainder of this section and employ the Dirac matrices γ^μ in the $2^{n/2}$-dimensional representation. From (1.15) and $(\gamma^\mu)^\dagger=\gamma^\mu$ it follows that the matrix

$$\gamma_{n+1}\equiv-i^{n(n-1)/2}\gamma^1\gamma^2\cdots\gamma^n \tag{2.32}$$

satisfies $\gamma^\mu\gamma_{n+1}=-\gamma_{n+1}\gamma^\mu$,

$$\gamma_{n+1}^2=1,\quad \gamma_{n+1}^\dagger=\gamma_{n+1} \tag{2.33}$$

in all even dimensions. The sign of (2.32) is chosen such that for $n=4$

$$\gamma_5=\gamma^1\gamma^2\gamma^3\gamma^4. \tag{2.34}$$

We identify

$$\gamma^\mu=\kappa\hat{\chi}^\mu, \tag{2.35}$$

where

$$\kappa \equiv \sqrt{\frac{2}{\hbar}} \tag{2.36}$$

and interpret γ_{n+1} as the matrix representation of the abstract operator

$$\hat{G}_{n+1} = -i^{n(n-1)/2} \kappa^n \hat{\chi}^1 \hat{\chi}^2 \cdots \hat{\chi}^n. \tag{2.37}$$

Its symbol $\text{symb}(\hat{G}_{n+1}) \equiv G_{n+1}$ follows directly from (2.5) if we note that $\hat{\chi}^1 \cdots \hat{\chi}^n = \epsilon_{\mu_1 \cdots \mu_n} \hat{\chi}^{[\mu_1} \cdots \hat{\chi}^{\mu_n]}/(n!)$:

$$\begin{aligned} G_{n+1}(\theta) &= -i^{n(n-1)/2} \kappa^n \theta^1 \theta^2 \cdots \theta^n \\ &= -(-i)^{n(n-1)/2} \kappa^n \theta^n \theta^{n-1} \cdots \theta^1. \end{aligned} \tag{2.38}$$

Hence, up to a constant, γ_{n+1} is represented by the δ function:

$$G_{n+1}(\theta) = -(-i)^{n(n-1)/2} \kappa^n \delta(\theta). \tag{2.39}$$

As a consequence of Eqs. (2.20) and (A21), this function satisfies

$$G_{n+1} \circ G_{n+1} = 1, \quad \overline{G_{n+1}} = G_{n+1}, \tag{2.40}$$

which reflects the properties (2.33) of γ_{n+1}. By virtue of (A26) the Fourier transform of G_{n+1} is the constant function

$$\tilde{G}_{n+1}(\rho) = -(-i)^{n(n-1)/2} \kappa^n. \tag{2.41}$$

In Appendix A we defined the modified Hodge operator $\star$ for a general Grassmann algebra and we showed that it is related to the Fourier transformation via Eq. (A41). Using the latter equation together with the integral representation (2.14) for the star product it is not difficult to see that the application of $\star$ to some $f \in \mathcal{W}^F$ is essentially equivalent to a star-multiplication with G_{n+1} from the right. For a homogeneous function of degree p,

$$\star f^{(p)}(\theta) = -(-i)^{n(n-1)/2} \kappa^{2p-n} (f^{(p)} \circ G_{n+1})(\theta). \tag{2.42}$$

If we rescale θ we can write down a similar equation for inhomogeneous functions even:

$$\star f(\theta/\kappa) = -(-i)^{n(n-1)/2} (f \circ G_{n+1})(\theta/\kappa). \tag{2.43}$$

Finally we remark that the chirality operator $\hat{G}_{n+1}$ can be expressed as an integral over the Weyl operators:

$$\hat{G}_{n+1} = -(-i)^{n(n-1)/2} \kappa^n \int d^n\rho\, \hat{\Omega}(\rho). \tag{2.44}$$

This is a remarkable relation because contrary to the original definition of γ_{n+1} as the product of all Dirac matrices it carries over to the symplectic case almost literally.

B. $\mathcal{W}^F$ as an Atiyah–Kähler algebra

Let us come back to the abstract Atiyah–Kähler algebra $\mathbf{AK}(V,Q)$ discussed in Sec. I. It is important to observe that the Weyl algebra $\mathcal{W}^F$ which we reviewed in the previous section contains all the ingredients which make up an Atiyah–Kähler algebra.

(i) The vector space V is spanned by the basis elements $\theta^1, \ldots, \theta^n$ and the exterior algebra over this space, $\bigwedge(V) = \oplus_{p=0}^n \bigwedge^p(V)$, consists of monomials $\theta^{\mu_1} \cdots \theta^{\mu_p} \in \bigwedge^p(V)$. The exterior product "$\wedge$" on $\bigwedge(V)$ is the pointwise product of (inhomogeneous) functions $f(\theta) \in \bigwedge(V)$.

(ii) By starting from the canonical anticommutation relations (2.1) we have tacitly decided for an inner product $(\cdot|\cdot)$ on $\bigwedge(V)$. The quadratic form Q is induced by $g_{\mu\nu}\equiv\delta_{\mu\nu}$, regarded as an inner product of V. On $\bigwedge^1(V)$ we have

$$(\theta^\mu|\theta^\nu)=\kappa^{-2}\delta^{\mu\nu} \tag{2.45}$$

and similarly for $p>1$ (see below).

(iii) The star product on $\mathcal{W}^F$ provides a concrete realization of the abstract Clifford product. The Clifford product is associative and distributive over "+," and so is the star product. Moreover, $\vee$, $\wedge$, and $(\cdot,\cdot)$ have to satisfy the consistency condition (1.7). From Eq. (2.12) it follows that this relation is indeed satisfied by the star multiplication together with the pointwise multiplication and the inner product $(\cdot|\cdot)$:

$$\theta^\mu\circ\theta^\nu=\theta^\mu\theta^\nu+(\theta^\mu|\theta^\nu). \tag{2.46}$$

In particular, upon symmetrization, $\theta^\mu\circ\theta^\nu+\theta^\nu\circ\theta^\mu=2(\theta^\mu|\theta^\nu)$.

Thus we may conclude that the *fermionic Weyl algebra* $\mathcal{W}^F$ *is a concrete realization of an Atiyah–Kähler algebra*.

Let us be more explicit about the inner product on $\bigwedge(V)$. Within the symbol calculus, the standard inner product of DK theory[11] admits a very natural representation in terms of the star product:

$$(f_1|f_2)=[\overline{f_1}\circ f_2](\theta=0). \tag{2.47}$$

Here f_1 and f_2 are two arbitrary inhomogeneous functions. We allow their expansion coefficients $f^{(p)}_{\mu_1\cdots\mu_p}$ to become complex. Note, however, that the complex conjugation in (2.47) is necessary even if the coefficients are taken to be real, see Eq. (A10). Using the integral representation

$$(f_1|f_2)=(i\kappa^2)^{-n}\epsilon_n\int\overline{f_1(\theta_1)}\exp(\kappa^2\theta_1^\mu\theta_{2\mu})f_2(\theta_2)d^n\theta_1d^n\theta_2 \tag{2.48}$$

and expanding f_1 and f_2 according to

$$f(\theta)=\sum_{p=0}^{n}\frac{1}{p!}\kappa^p f^{(p)}_{\mu_1\cdots\mu_p}\theta^{\mu_1}\cdots\theta^{\mu_p} \tag{2.49}$$

with appropriate powers of κ separated off from the expansion coefficients, it is easy to derive that

$$(f_1|f_2)=\sum_{p=0}^{n}\frac{1}{p!}\overline{f^{(p)}_{1\mu_1\cdots\mu_p}}f_2^{(p)\mu_1\cdots\mu_p}. \tag{2.50}$$

The inner products among the basis elements of $\bigwedge^p(V)$ (homogeneous functions of degree p) can be written down similarly. For $p=1$ one recovers (2.45), and for $p=2$ one has, for instance

$$(\theta^\mu\theta^\nu|\theta^\rho\theta^\sigma)=\kappa^{-4}(\delta^{\mu\rho}\delta^{\nu\sigma}-\delta^{\mu\sigma}\delta^{\nu\rho}). \tag{2.51}$$

We note that $(\cdot|\cdot)$ has the important property of making the star multiplication with θ^μ a self-adjoint operator. If we define

$$C^\mu:\mathcal{W}^F\rightarrow\mathcal{W}^F,\quad (C^\mu f)(\theta)=\kappa\theta^\mu\circ f(\theta) \tag{2.52}$$

then Eq. (2.18) tells us that C^μ is given by the first-order differential operator

$$C^\mu=\kappa\theta^\mu+\frac{1}{\kappa}\frac{\partial}{\partial\theta_\mu}. \tag{2.53}$$

If one writes the inner product as in (2.47), the self-adjointness of C^μ is obvious:

$$(C^\mu f_1|f_2)=\kappa[\overline{(\theta^\mu\circ f_1)}\circ f_2](0)=\kappa[(\overline{f_1}\circ\theta^\mu)\circ f_2](0)=\kappa[\overline{f_1}\circ(\theta^\mu\circ f_2)](0)=(f_1|C^\mu f_2). \tag{2.54}$$

Here we exploited (2.13) and the associativity of the star product.

C. Symbol-valued fields on space–time

The most familiar application of the above symbol calculus is the deformation theory approach[24,26] to the quantization of fermionic systems. In this context, the variables θ^μ are coordinates on the *phase space* of the physical system under consideration. If there are additional bosonic degrees of freedom (such as the position of a spinning particle, say) this fermionic phase space is embedded in a larger graded phase space, a supermanifold with both commuting and anticommuting coordinates.[17]

In the present paper we are investigating a different setting. Rather than phase space, the physical arena here is *space–time*, an ordinary Riemannian manifold $(\mathcal{M}_n,g)$, not a supermanifold. The fermionic Weyl algebra $\mathcal{W}^F$ enters the construction as the fiber of certain bundles over space–time which we shall refer to as ''Weyl algebra bundles.''[30]

By definition, the base of a Weyl algebra bundle is $(\mathcal{M}_n,g)$ and the typical fiber is $\mathcal{W}^F$, i.e., at each space–time point x we attach a local copy $\mathcal{W}_x^F$ of $\mathcal{W}^F$. The quadratic form Q on $\mathcal{W}_x^F$ is provided by the metric g evaluated at the point x. Local coordinates on the total space are pairs (x,f) where $x\equiv(x^\mu)$ are coordinates referring to some chart of $\mathcal{M}_n$, and f is a function of the Grassmann variables $\theta^1,\ldots,\theta^n$. The transition functions are defined in close analogy with the exterior algebra bundle. A coordinate transformation $x\to\tilde{x}(x)$ on $\mathcal{M}_n$ is accompanied by $f\to\tilde{f}$ with $\tilde{f}$ such that $\tilde{f}(\tilde{\theta})=f(\theta)$ where $\tilde{\theta}^\mu\equiv(\partial\tilde{x}^\mu/\partial x^\nu)\theta^\nu$, i.e., θ^μ transforms in the same manner as dx^μ.

Sections through a Weyl algebra bundle are locally represented by functions

$$x\mapsto F(x,\cdot)\in\mathcal{W}_x^F, \tag{2.55}$$

where

$$F(x,\cdot):\theta\mapsto F(x,\theta) \tag{2.56}$$

is a function of n commuting and n anticommuting variables. We define a fiberwise star product of two such sections by

$$(F_1\circ F_2)(x,\theta)=(F_1(x,\cdot)\circ F_2(x,\cdot))(\theta) \tag{2.57}$$

for each point x.

We can apply the inverse symbol map to $F(x,\cdot)$ and thus obtain a family of operators labeled by the space–time points x:

$$\hat{F}(x)\equiv\mathrm{symb}^{-1}F(x,\cdot). \tag{2.58}$$

If we fix a concrete matrix representation of the fermionic operators on some representation space $\mathcal{V}^F$, then $\hat{F}(x)$ acts on a local copy $\mathcal{V}_x^F$ of $\mathcal{V}^F$, i.e., $\hat{F}(x)\in\mathcal{L}(\mathcal{V}_x^F)$. We are particularly interested in the case where $\mathcal{V}^F$ carries the irreducible $2^{n/2}$-dimensional representation of the Clifford algebra (for n even). Then $\mathcal{V}_x^F$ is a fiber of the usual spin bundle over $\mathcal{M}_n$ whose sections are the familiar Dirac spinor fields.

In the present paper we shall not be concerned with the global properties of Weyl algebra bundles. Our main interest is in the metaplectic analog of the Dirac–Kähler construction, and for this purpose it is sufficient to compare to the topologically trivial bundles over the flat space–time $\mathcal{M}_n=\mathbf{R}^n$. An analogous discussion could be given for arbitrary curved space–times as well, but we shall avoid the necessary technical complications here. Thus, in our case, sections can be represented globally by functions $F(x,\theta)$. We remark that there exists a natural inner product on the space of these functions:

$$\langle F_1|F_2\rangle = \int d^n x (F_1(x,\cdot)|F_2(x,\cdot)). \tag{2.59}$$

D. Dirac–Kähler fields and symbol calculus

Let us assume we are given an arbitrary DK field Φ on flat Euclidean space–time $\mathbf{R}^n$. It possesses an expansion

$$\Phi(x) = \sum_{p=0}^{n} \frac{1}{p!} F^{(p)}_{\mu_1\cdots\mu_p}(x) dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_p}. \tag{2.60}$$

The (complex) coefficient functions are taken to be completely antisymmetric in all p indices so that there is a bijective correspondence between forms Φ and sets $\{F^{(p)}_{\mu_1\cdots\mu_p}\}$ of antisymmetric tensors. Given these tensors, we form the following matrix-valued field:

$$\hat{F}(x) = \sum_{p=0}^{n} \frac{1}{p!} F^{(p)}_{\mu_1\cdots\mu_p}(x) \gamma^{\mu_1}\gamma^{\mu_2}\cdots\gamma^{\mu_p}. \tag{2.61}$$

From now on we assume that n is even and that the Dirac matrices are in their irreducible representation. Hence $\hat{F}(x)$ acts on a local copy $\mathcal{V}^F_x$ of the representation space $\mathcal{V}^F = \mathbf{C}^k$, $k = 2^{n/2}$. By virtue of (2.35) we may regard $\hat{F}(x)$ as a matrix realization of the abstract operator

$$\hat{F}(x) = \sum_{p=0}^{n} \frac{\kappa^p}{p!} F^{(p)}_{\mu_1\cdots\mu_p}(x) \hat{\chi}^{\mu_1}\hat{\chi}^{\mu_2}\cdots\hat{\chi}^{\mu_p}. \tag{2.62}$$

For every point x, the symbol of this operator is $F(x,\theta) = [\mathrm{symb}\,\hat{F}(x)](\theta)$, or

$$F(x,\theta) = \sum_{p=0}^{n} \frac{\kappa^p}{p!} F^{(p)}_{\mu_1\cdots\mu_p}(x) \theta^{\mu_1}\theta^{\mu_2}\cdots\theta^{\mu_p}. \tag{2.63}$$

Thus we have set up a linear one-to-one correspondence between differential forms $\Phi(x)$ and symbol functions $F(x,\theta)$. Schematically,

$$\Phi(x) \in \bigwedge(T^*_x\mathcal{M}_n) \leftrightarrows \hat{F}(x) \in \mathcal{L}(\mathcal{V}^F_x) \leftrightarrows F(x,\cdot) \in \mathcal{W}^F_x. \tag{2.64}$$

The first one of the two bijections in (2.64) is the usual ''Dirac–Kähler correspondence'' $dx^\mu \leftrightarrows \gamma^\mu$ which we mentioned already in Sec. I, while the second one is the Weyl symbol map. Taken in conjunction, these maps relate DK fields to symbols. In particular,

$$dx^\mu \leftrightarrows \kappa\theta^\mu. \tag{2.65}$$

We shall use the notation $\Phi: F \mapsto \Phi[F]$ for the linear map which yields the differential form belonging to a given symbol. For instance,

$$\Phi[\kappa\theta^\mu] = dx^\mu. \tag{2.66}$$

What makes the above construction particularly useful is that under the map Φ many of the familiar linear and bilinear operations involving differential forms naturally pass over to the symbol functions and vice versa. This is immediately obvious for the automorphism $\mathcal{A}$, the antiautomorphism $\mathcal{B}$, the Hodge operator $*$, and the modified Hodge operator $\star$. Comparing their definition for symbols in Appendix A to their standard definition in terms of differential forms one sees that

$$\mathcal{A}\Phi[F]=\Phi[\mathcal{A}F], \quad \mathcal{B}\Phi[F]=\Phi[\mathcal{B}F],$$
$$*\Phi[F]=\Phi[*F], \quad \star\Phi[F]=\Phi[\star F]. \tag{2.67}$$

The exterior derivative $d=dx^\mu\partial_\mu$ translates into $\kappa\theta^\mu\partial_\mu$,

$$d\Phi[F]=\Phi[\kappa\theta^\mu\partial_\mu F] \tag{2.68}$$

while the contraction $\mathbf{i}(v)$ with a vector field $v=v^\mu\partial_\mu$ becomes a derivative with respect to θ:

$$\mathbf{i}(v)\Phi[F]=\Phi\left[\kappa^{-1}v^\mu\frac{\partial}{\partial\theta^\mu}F\right]. \tag{2.69}$$

In particular,

$$e_\mu\neg\Phi[F]=\Phi\left[\kappa^{-1}\frac{\partial}{\partial\theta^\mu}F\right]. \tag{2.70}$$

The natural inner product on the space of DK fields is[5]

$$\langle\Phi_1,\Phi_2\rangle=\int\tilde{\Phi}_1\wedge*\Phi_2. \tag{2.71}$$

[All terms which are not of degree n are supposed to be discarded from the integrand in (2.71).] Its counterpart at the symbol level is (2.59) with (2.47):

$$\langle\Phi[F_1],\Phi[F_2]\rangle=\langle F_1|F_2\rangle. \tag{2.72}$$

The coderivative $d^\dagger$ is the formal adjoint of d with respect to $\langle\cdot,\cdot\rangle$. On flat space one has

$$d^\dagger\Phi=-e^\mu\neg\partial_\mu\Phi \tag{2.73}$$

whence

$$d^\dagger\Phi[F]=\Phi\left[-\kappa^{-1}\partial_\mu\frac{\partial}{\partial\theta_\mu}F\right]. \tag{2.74}$$

The wedge product of differential forms is mapped onto the pointwise product of symbol functions:

$$\Phi[F_1]\wedge\Phi[F_2]=\Phi[F_1F_2]. \tag{2.75}$$

The most important aspect of the form/symbol correspondence is that the image of the Clifford product is precisely the fiberwise star product (2.57):

$$\Phi[F_1]\vee\Phi[F_2]=\Phi[F_1\circ F_2]. \tag{2.76}$$

This can be seen for instance by mapping Kähler's formula (1.9) for the Clifford product on our representation (2.15) of the fermionic Weyl star product:

$$\begin{aligned}\Phi[F_1]\vee\Phi[F_2]&=\sum_{p=0}^{n}\frac{(-1)^{p(p-1)/2}}{p!}(\mathcal{A}^p e_{\mu_1}\neg\cdots e_{\mu_p}\neg\Phi[F_1])\wedge(e^{\mu_1}\neg\cdots e^{\mu_p}\neg\Phi[F_2])\\&=\sum_{p=0}^{n}\frac{(-1)^{p(p-1)/2}}{p!}\Phi\left[\kappa^{-p}\mathcal{A}^p\frac{\partial}{\partial\theta^{\mu_1}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}F_1\right]\wedge\Phi\left[\kappa^{-p}\frac{\partial}{\partial\theta_{\mu_1}}\cdots\frac{\partial}{\partial\theta_{\mu_p}}F_2\right]\\&=\Phi\left[\sum_{p=0}^{n}\kappa^{-2p}\frac{(-1)^{p(p-1)/2}}{p!}\left(\mathcal{A}^p\frac{\partial}{\theta^{\mu_1}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}F_1\right)\left(\frac{\partial}{\partial\theta_{\mu_1}}\cdots\frac{\partial}{\partial\theta_{\mu_p}}F_2\right)\right]\\&=\Phi[F_1\circ F_2].\end{aligned}\tag{2.77}$$

Here we used (2.67), (2.70), and (2.75).

One also could prove Eq. (2.76) inductively. If we replace dx^μ by $\kappa\theta^\mu$ and ''$\vee$'' by the star product in the relations (1.8) which define the Clifford product we obtain exactly Eq. (2.12) for the star product. Therefore Eq. (2.76) is correct for zero- and one-forms. Its generalization for arbitrary p forms makes essential use of the associativity of both the Clifford and the star product.

By virtue of our rules for the form/symbol correspondence also Eqs. (1.13) and (2.18) are now seen to be completely equivalent.

In the DK equation we need the Clifford product of dx^μ with an arbitrary form:

$$dx^\mu\vee\Phi[F]=\Phi[\kappa\theta^\mu]\vee\Phi[F]=\Phi[\kappa\theta^\mu\circ F]=\Phi[C^\mu F].\tag{2.78}$$

Here C^μ is the first-order differential operator (2.53). In Sec. I we discussed already that $dx^\mu\vee$, regarded as an operator on the space of DK fields, gives rise to the Clifford algebra (1.14). For consistency the same should be true for the star multiplication with $\kappa\theta^\mu$ and for C^μ on the space of symbols. In fact, it is easy to see that

$$(\kappa\theta^\mu\circ)(\kappa\theta^\nu\circ)+(\kappa\theta^\nu\circ)(\kappa\theta^\mu\circ)=2\,\delta^{\mu\nu}\tag{2.79}$$

and

$$C^\mu C^\nu+C^\nu C^\mu=2\,\delta^{\mu\nu}.\tag{2.80}$$

The DK operator acting on forms reads

$$(d-d^\dagger)\Phi=dx^\mu\wedge\partial_\mu\Phi+e^\mu\neg\partial_\mu\Phi=dx^\mu\vee\partial_\mu\Phi,\tag{2.81}$$

where the second equality follows from (1.13). Therefore $d-d^\dagger$ becomes $\kappa\theta^\mu\circ\partial_\mu$ or $C^\mu\partial_\mu$ at the symbol level:

$$(d-d^\dagger)\Phi[F]=\Phi[\kappa\theta^\mu\circ\partial_\mu F]=\Phi[C^\mu\partial_\mu F].\tag{2.82}$$

This converts the DK equation to

$$\left[\left(\frac{1}{\kappa}\frac{\partial}{\partial\theta_\mu}+\kappa\theta^\mu\right)\partial_\mu+m\right]F(x,\theta)=0.\tag{2.83}$$

In closing we return to the chirality operator γ_{n+1}. Under the map Φ, the image of the delta function is essentially the volume form $\mathrm{Vol}\equiv dx^1\wedge dx^2\wedge\cdots\wedge dx^n$:

$$\Phi[\kappa^n\delta(\cdot)]=(-1)^{n(n-1)/2}\,\mathrm{Vol}.\tag{2.84}$$

For the chirality operator this means that

$$\Phi[G_{n+1}\circ F]=-i^{n(n-1)/2}\,\mathrm{Vol}\vee\Phi[F]\tag{2.85}$$

which, at the operator level, corresponds to

$$\widehat{G_{n+1}\circ F}=\gamma_{n+1}\hat{F}. \tag{2.86}$$

Thus we see that (up to unimportant constants) the fermionic δ function, the volume form, and the chirality matrix γ_{n+1} are simply different variants of the same object. Furthermore, by Eq. (2.43), star multiplication of F by G_{n+1} *from the right* amounts to applying the modified Hodge operator $\star$.

E. Invariant subspaces of $\mathcal{W}^F$

The differential operators C^μ or the star left-multiplication by $\kappa\theta^\mu$ define a representation of the Clifford algebra (2.21) in the space of symbols $f(\theta)$. As $f(\theta)$ has 2^n independent (complex) components, this representation is reducible. It can be decomposed into $2^{n/2}$ representations each of which is isomorphic to the $2^{n/2}$-dimensional irreducible representation provided by the matrices γ^μ. (We assume n even in this section.) As a consequence, a symbol-valued field $F(x,\theta)$ describes $2^{n/2}$ ordinary Dirac spinor fields.

In the light of the form/symbol correspondence which we developed in Sec. II D it is clear that the representation carried by $\mathcal{W}^F$ could be decomposed simply by invoking the standard discussion at the level of differential forms. However, as our main motivation for studying the symbol formulation of DK fields is to get some understanding of their symplectic analogs we shall reformulate the method of Becher and Joos[3] in symbol language and use this as a guide in the symplectic case. As a by-product we shall find a very elegant derivation of their matrix-valued form Z which puts it in a more general perspective.

We have to decompose the Weyl algebra in orthogonal subspaces,

$$\mathcal{W}^F=\bigoplus_{\alpha=1}^{k}\mathcal{W}^F_{(\alpha)},\quad k=2^{n/2} \tag{2.87}$$

such that $\mathcal{W}^F_{(\alpha)}$ is invariant under star left-multiplication by θ^μ. Following a strategy similar to the one described in Sec. I we look for a $k\times k$-matrix valued function $Z(\theta)$ with the property

$$\kappa\theta^\mu\circ Z_{\alpha\beta}(\theta)=\sum_{\gamma=1}^{k}(\gamma^{\mu T})_{\alpha\gamma}Z_{\gamma\beta}(\theta). \tag{2.88}$$

The function Z is readily found in our formalism. Since the star product with θ^μ involves first derivatives at most, Eq. (2.88) is reminiscent of the formulas for the derivative of the Weyl operators $\hat{\Omega}$ and $\check{\Omega}$ which we displayed in Sec. II A. In fact, using those formulas together with (2.18) it is easy to show that there exists a rescaling of the arguments of $\hat{\Omega}$ and $\check{\Omega}$ in such a way that the star multiplication by θ^μ corresponds to an operator multiplication by $\hat{\chi}^\mu$ or Γ^μ:

$$\theta^\mu\circ\hat{\Omega}(\pm i\kappa^2\theta)=\mp\hat{\Omega}(\pm i\kappa^2\theta)\hat{\chi}^\mu, \tag{2.89}$$

$$\theta^\mu\circ\hat{\Omega}(\pm\kappa^2\theta)=\pm i\hat{\chi}^\mu\hat{\Omega}(\pm\kappa^2\theta), \tag{2.90}$$

$$\kappa\theta^\mu\circ\check{\Omega}(\pm i\kappa^2\theta)=\pm\Gamma^\mu\check{\Omega}(\pm i\kappa^2\theta). \tag{2.91}$$

For the problem at hand, Eq. (2.91) is precisely what we need. If Γ_μ constitutes a Clifford algebra, so does Γ_μ^T. Hence we may set $Z(\theta)=\check{\Omega}(i\kappa^2\theta)$ with $\Gamma_\mu=\gamma_\mu^T$. Thus

$$Z(\theta)=\exp[\kappa\theta^\mu\gamma_\mu^T] \tag{2.92}$$

or in expanded form

$$Z(\theta)=\sum_{p=0}^{n}\frac{\kappa^p}{p!}\gamma_{\mu_1}^T\cdots\gamma_{\mu_p}^T\theta^{\mu_1}\cdots\theta^{\mu_p}. \tag{2.93}$$

Clearly (2.93) is precisely the symbol corresponding to the form (1.21) which was found by Becher and Joos[3] using different techniques. In the context of the present investigation it is important to keep in mind that Z is nothing but a rescaled fermionic Weyl operator since the latter has a well-known bosonic analog.

Because of the completeness properties of the γ matrices, $\{Z_{\alpha\beta};\quad \alpha,\beta=1,...,k\}$ is a basis for $\mathcal{W}^F$ and we may expand any symbol as

$$F(x,\theta)=\sum_{\beta=1}^{k}\sum_{\alpha=1}^{k}\psi_\alpha^{(\beta)}(x)Z_{\alpha\beta}(\theta)=\sum_{\beta=1}^{k}F^{(\beta)}(x,\theta). \tag{2.94}$$

(Here we use already the notation appropriate for the role of $\mathcal{W}^F$ as a fiber at the point x.) The rest of the argument parallels our discussion in Sec. I. We obtain $k\equiv 2^{n/2}$ invariant subspaces $\mathcal{W}_{(\alpha)}^F$ (left ideals) which are spanned by

$$F^{(\beta)}(x,\cdot)=\sum_{\alpha=1}^{k}\psi_\alpha^{(\beta)}(x)Z_{\alpha\beta}(\cdot)\in\mathcal{W}_{x(\beta)}^F. \tag{2.95}$$

For every fixed value of β, the expansion coefficients $\psi^{(\beta)}\equiv\{\psi_\alpha^{(\beta)};\alpha=1,...,k\}$ can be interpreted as an ordinary Dirac spinor. Equation (2.88) shows that acting with $\kappa\theta^\mu\circ$ on $F^{(\beta)}$ is equivalent to applying γ^μ on $\psi^{(\beta)}$:

$$\kappa\theta^\mu\circ F^{(\beta)}=\sum_\alpha\left(\sum_\delta\gamma^\mu_{\alpha\delta}\psi_\delta^{(\beta)}\right)Z_{\alpha\beta}=\sum_\alpha[\gamma^\mu\psi^{(\beta)}]_\alpha Z_{\alpha\beta}. \tag{2.96}$$

Let us arrange the expansion coefficients $\psi_\alpha^{(\beta)}$ as a $k\times k$-matrix: $(\hat{\psi})_{\alpha\beta}\equiv\psi_\alpha^{(\beta)}$. Then,

$$F(x,\theta)=\mathrm{Tr}[\hat{\psi}(x)Z(\theta)^T]. \tag{2.97}$$

Denoting the $\hat{\psi}$ matrix which belongs to a given section F by $\hat{\psi}[F]$ we obtain from (2.96)

$$\hat{\psi}[\kappa\theta^\mu\circ F]=\gamma^\mu\hat{\psi}[F], \tag{2.98}$$

which mirrors (1.27) at the symbol level.

Given a symbol-valued field $F(x,\theta)$ we can immediately construct the associated spinor matrix-valued field $\hat{F}(x)$ of (2.61) by replacing $\theta^\mu\rightarrow\kappa^{-1}\gamma^\mu$ in its series expansion (2.63). In the process of decomposing the reducible representation carried by F we discovered a second spinor-matrix, $\hat{\psi}$, which is related to F in a canonical way, too. By essentially the same argument as in Sec. I it follows that the two matrices are equal up to a constant:

$$\hat{\psi}[F](x)=2^{-n/2}\hat{F}(x). \tag{2.99}$$

If we insert the expansions (2.63) and (2.93) for $F(x,\theta)$ and $Z(\theta)$, respectively, into Eq. (2.97), we obtain Eq. (1.30) for the set $\{F^{(p)}_{\mu_1\cdots\mu_p}\}$ expressed in terms of $\hat{\psi}$. Making an ansatz for $\hat{\psi}$ in terms of antisymmetrized products of γ matrices and using the trace identity (1.33), one finds that the expansion coefficients of $\hat{\psi}$ and $\hat{F}$ differ by an overall constant only.

While this last step was straightforward for the SO(n) spinors, it will be much less trivial for metaplectic spinors where the representation space is infinite-dimensional and trace identities such as (1.33) are not likely to exist. It will be interesting to see how (2.99) is modified then.

III. SYMPLECTIC DIRAC–KÄHLER FIELDS

In Sec. II we reformulated the theory of standard DK fermions over space–time in terms of fields F which assume values in the fermionic Weyl algebra $\mathcal{W}^F$. Now we are going to ask what happens if we replace $\mathcal{W}^F$ by its (actually much more familiar) bosonic counterpart, the bosonic Weyl algebra $\mathcal{W}$. Rather than space–time it is now a phase-space $(\mathcal{M}_{2N},\omega)$ which plays the role of the base manifold. As we shall argue, replacing the Riemannian structure by a symplectic one, the structure group SO(n) by Sp$(2N)$, and, most importantly, fermionic Weyl symbols by bosonic ones, we are led to the notion of a ''symplectic DK field'' in a very natural way.

In Sec. III A we begin by working out some special properties of bosonic Weyl symbols which will become important in our construction. In this context, we are basically discussing the conventional quantum mechanics of the auxiliary quantum system with canonical operators $\hat{x}^i$ and $\hat{\pi}^i$ which results from quantizing the flat ''auxiliary phase-space'' $\mathbf{R}^{2N}$. [Later on the auxiliary phase space will be identified with the tangent space to the true (physical) phase-space $\mathcal{M}_{2N}$.] The operators $\hat{x}^i$ and $\hat{\pi}^i$ take over the role previously played by $\hat{\chi}^\mu$.

Section III B is devoted to the metaplectic γ matrices. In particular, we propose a symplectic analog of the chirality matrix γ_5 there. The actual construction of the symplectic DK fields is performed in Sec. III C, and in Sec. III D it is shown how they relate to the metaplectic spinor fields.

A. Bosonic Weyl symbols

We consider a Hamiltonian system with N degrees of freedom whose classical phase space is the symplectic plane $(\mathbf{R}^{2N},\omega)$. The associated quantum mechanical Hilbert space is $\mathcal{V}$ and $\mathcal{L}(\mathcal{V})$ denotes the space of linear operators on $\mathcal{V}$. The Hilbert space $\mathcal{V}$ carries a representation of the canonical commutation relations

$$[\hat{\varphi}^a,\hat{\varphi}^b]=i\hbar\,\omega^{ab},\quad a,b=1,...,2N. \tag{3.1}$$

In a canonical operator basis we split $\hat{\varphi}^a\equiv(\hat{\pi}^i,\hat{x}^i)$, $i=1,...,N$, so that the only nonvanishing commutator is between the momenta $\hat{\pi}^i$ and the positions $\hat{x}^i$:$[\hat{\pi}^i,\hat{x}^j]=-i\hbar\,\delta^{ij}$. The matrix (ω^{ab}) is the inverse of the constant matrix (ω_{ab}) formed from the coefficients of the symplectic two-form ω: $\omega_{ab}\omega^{bc}=\delta_a^c$. On $(\mathbf{R}^{2N},\omega)$ we use canonical coordinates $y^a\equiv(y_p^i,y_q^i)$ such that

$$(\omega_{ab})=\begin{pmatrix}0 & +I\\ -I & 0\end{pmatrix},\quad (\omega^{ab})=\begin{pmatrix}0 & -I\\ +I & 0\end{pmatrix}.$$

For the natural skew-symmetric inner product on the symplectic plane we write

$$\omega(y_1,y_2)\equiv y_1^a\omega_{ab}y_2^b. \tag{3.2}$$

The Weyl (or Heisenberg) operators[16]

$$\hat{T}(y)=\exp\left(\frac{i}{\hbar}y^a\omega_{ab}\hat{\varphi}^b\right) \tag{3.3}$$

implement the translations on phase space in the Hilbert space $\mathcal{V}$:

$$\hat{T}(y)^\dagger\hat{\varphi}^a\hat{T}(y)=\hat{\varphi}^a+y^a. \tag{3.4}$$

This is a projective representation of the translation group since

$$\hat{T}(y_1)\hat{T}(y_2)=\exp\left[\frac{i}{2\hbar}\,\omega(y_1,y_2)\right]\hat{T}(y_1+y_2). \tag{3.5}$$

The Weyl operators are orthogonal and complete in the sense that

$$\mathrm{Tr}[\hat{T}(y_1)^\dagger \hat{T}(y_2)] = (2\pi\hbar)^N \delta^{(2N)}(y_1 - y_2) \tag{3.6}$$

$$\int d^{2N}y \langle \alpha | \hat{T}(y)^\dagger | \alpha' \rangle \langle \beta | \hat{T}(y) | \beta' \rangle = (2\pi\hbar)^N \delta^{(N)}(\alpha - \beta') \delta^{(N)}(\beta - \alpha'). \tag{3.7}$$

Here $\{|\alpha\rangle\}$ is the basis which diagonalizes the position operators:

$$\hat{x}^i |\alpha\rangle = \alpha^i |\alpha\rangle, \quad \alpha \equiv (\alpha^1, \dots, \alpha^N). \tag{3.8}$$

Sometimes it will be more suggestive to use a tensor notation instead of the bra-ket formalism; for instance, one writes $\hat{b}^\alpha{}_\beta \equiv \langle \alpha | \hat{b} | \beta \rangle$ for the matrix elements of some arbitrary $\hat{b} \in \mathcal{L}(\mathcal{V})$ or $\delta^\alpha{}_\beta \equiv \delta^{(N)}(\alpha - \beta)$ for the identity operator. The eigenvalues $\alpha \in \mathbb{R}^N$ should be thought of as a continuous analog of a spinor index. In the $\hat{x}$ eigenbasis, the Weyl operators are given by

$$\hat{T}(y)^\alpha{}_\beta = \exp\left[\frac{i}{\hbar} \left(y_p \alpha - \frac{1}{2} y_p y_q \right) \right] \delta^{(N)}(\alpha - \beta - y_q) \tag{3.9}$$

with $y_p \alpha \equiv y_p^i \alpha^i$, etc., where the summation over $i = 1,...,N$ is understood.

From the completeness relation (3.7) it follows that every operator $\hat{b}$ can be represented as

$$\hat{b} = (2\pi\hbar)^{-N} \int d^{2N}y \, \tilde{b}(y) \hat{T}(y) \tag{3.10}$$

with the complex-valued function $\tilde{b}$ given by

$$\tilde{b}(y) = \mathrm{Tr}[\hat{T}(y)^\dagger \hat{b}]. \tag{3.11}$$

The function $\tilde{b}$ (referred to as the *alternative* Weyl symbol[16]) is closely related to the Weyl symbol of $\hat{b}$. In fact, $b(y) \equiv [\mathrm{symb}(\hat{b})](y)$ is the Fourier transform of $\tilde{b}$:

$$b(y) = (2\pi\hbar)^{-N} \int d^{2N}y_0 \, \tilde{b}(y_0) \exp\left[\frac{i}{\hbar} \omega(y_0, y) \right] \tag{3.12}$$

The inverse transformation reads

$$\tilde{b}(y) = (2\pi\hbar)^{-N} \int d^{2N}y_0 \, b(y_0) \exp\left[\frac{i}{\hbar} \omega(y_0, y) \right], \tag{3.13}$$

i.e., the symplectic Fourier transformation is an exact involution, $\tilde{\tilde{b}}(y) = b(y)$ (and not only an involution up to a reflection of the argument).

Equations (3.10)–(3.12) define the (bosonic) Weyl symbol map ''symb'' from $\mathcal{L}(\mathcal{V})$ to the space of (generalized) functions over the symplectic plane, as well as its inverse. The classical phase function $b(y)$ uniquely represents an operator $\hat{b}$ which is Weyl ordered. In particular, the monomial $y^{a_1} y^{a_2} \cdots y^{a_p}$ stands for the completely symmetrized operator product $\hat{\varphi}^{(a_1} \hat{\varphi}^{a_2} \cdots \hat{\varphi}^{a_p)}$. Conversely,

$$[\mathrm{symb}\{\hat{\varphi}^{(a_1} \cdots \hat{\varphi}^{a_p)}\}](y) = y^{a_1} y^{a_2} \cdots y^{a_p}. \tag{3.14}$$

The symmetrization in (3.14) is crucial, otherwise commutator terms would occur. For instance,

$$[\mathrm{symb}\{\hat{\varphi}^a \hat{\varphi}^b\}](y) = y^a y^b + i \frac{\hbar}{2} \omega^{ab}. \tag{3.15}$$

An important special class of symbols are those which admit a power series expansion

$$b(y)=\sum_{p=0}^{\infty}\frac{\kappa^p}{p!}b^{(p)}_{a_1\cdots a_p}y^{a_1}y^{a_2}\cdots y^{a_p}. \tag{3.16}$$

By the symbol map, they are bijectively related to the operators

$$\hat{b}=\sum_{p=0}^{\infty}\frac{\kappa^p}{p!}b^{(p)}_{a_1\cdots a_p}\hat{\varphi}^{a_1}\cdots\hat{\varphi}^{a_p} \tag{3.17}$$

provided the tensors $b^{(p)}_{a_1\cdots a_p}$ are completely symmetric. If b is a power series, the ''alternative Weyl symbol'' $\tilde{b}$ is a sum of derivatives of δ functions:

$$\tilde{b}(y)=(2\pi\hbar)^N b\left(i\hbar\,\omega^{ac}\frac{\partial}{\partial y^c}\right)\delta^{(2N)}(y). \tag{3.18}$$

As in every symbol calculus, the pertinent star product is required to satisfy symb$(\hat{b}_1\hat{b}_2)=b_1\circ b_2$ where b_1 and b_2 are the symbols of $\hat{b}_1$ and $\hat{b}_2$, respectively. At least for power series, the bosonic Weyl star product is uniquely determined by its associativity, the distributivity over ''+,'' and the basic relations

$$\begin{gathered}1\circ 1=1,\quad 1\circ y^a=y^a\circ 1=y^a,\\ y^a\circ y^b=y^a y^b+i\frac{\hbar}{2}\omega^{ab},\end{gathered} \tag{3.19}$$

which follow from (3.14), (3.15) and symb$(I)=1$. Explicit formulas for the star product[25,28] of arbitrary symbols include

$$(b_1\circ b_2)(y)=b_1(y)\exp\left[i\frac{\hbar}{2}\frac{\overleftarrow{\partial}}{\partial y^a}\omega^{ac}\frac{\overrightarrow{\partial}}{\partial y^c}\right]b_2(y) \tag{3.20}$$

and

$$\begin{aligned}(b_1\circ b_2)(y)=(\pi\hbar)^{-2N}\int d^{2N}y_1 d^{2N}y_2\exp[-2i\{\omega(y,y_1)+\omega(y_1,y_2)\\ +\omega(y_2,y)\}/\hbar]b_1(y_1)b_2(y_2).\end{aligned} \tag{3.21}$$

The differential operators which effect the star left-multiplication with κy^a,

$$(C^a b)(y)=\kappa y^a\circ b(y), \tag{3.22}$$

are easily read off from Eq. (3.20):

$$C^a=\kappa y^a+\frac{i}{\kappa}\omega^{ab}\frac{\partial}{\partial y^b}. \tag{3.23}$$

On the space of symbols with an appropriate fall-off behavior we would like to introduce a sesquilinear inner product $(\cdot|\cdot)$ with respect to which C^a is self-adjoint,

$$(C^a b_1|b_2)=(b_1|C^a b_2). \tag{3.24}$$

It is clear from our earlier discussion that the choice

$$(b_1|b_2)=[\overline{b_1}\circ b_2](y=0) \tag{3.25}$$

meets this requirement. Since $\overline{b_1 \circ b_2} = \overline{b_2} \circ \overline{b_1}$ also here, the proof is the same as in (2.54). If b_1 and b_2 are power series of the type (3.16), Eq. (3.25) boils down to

$$(b_1|b_2) = \sum_{p=0}^{\infty} \frac{i^p}{p!} \overline{b_{1,a_1 \cdots a_p}^{(p)}} \omega^{a_1 c_1} \cdots \omega^{a_p c_p} b_{2,c_1 \cdots c_p}^{(p)}. \tag{3.26}$$

It is instructive to look at various alternative ways of representing this inner product. There exists the integral representation

$$(b_1|b_2) = (2\pi)^{-2N} \int d^{2N}y_1 d^{2N}y_2 \overline{b_1}(y_1/\kappa) e^{-i\omega(y_1,y_2)} b_2(y_2/\kappa), \tag{3.27}$$

which can be reexpressed in terms of a symplectic Fourier transform:

$$(b_1|b_2) = (2\pi\hbar)^{-N} \int d^{2N}y \overline{b_1}(\tfrac{1}{2}y) \tilde{b}_2(y). \tag{3.28}$$

Furthermore, if (3.18) can be applied,

$$(b_1|b_2) = b_2\left(-i\kappa^{-2}\omega^{ac} \frac{\partial}{\partial y^c} \right) \overline{b_1}(y)|_{y=0}. \tag{3.29}$$

The above formulas should be compared to their counterparts in the fermionic symbol calculus. Bosonic symbols admitting a power series expansion are characterized by sets $\{b_{a_1 \cdots a_p}^{(p)}, p = 0,1,2,...\}$ consisting of infinitely many *symmetric* tensors. Fermionic symbol functions are equivalent to a finite set $\{f_{\mu_1 \cdots \mu_p}^{(p)}, p = 0,1,...,n\}$ of *antisymmetric* tensors instead.

We saw that the (modified) Hodge operator is essentially the same operation as the Grassmannian Fourier transformation. Omitting all sign factors (which anyhow have no bosonic analog) we have, schematically,

$$*f(\theta) \propto \star f(\theta) \propto \tilde{f}(\theta) \propto f\left(\frac{\partial}{\partial\theta} \right) \delta(\theta). \tag{3.30}$$

Thus one is tempted to define a bosonic version of the Hodge operator simply by setting $(*b)(y) = \tilde{b}(y)$ so that $** = 1$ on any b. If b is a power series, Eq. (3.18) is indeed formally analogous to (A24) for the fermionic Fourier transformation. However, the difference is that the derivative of the fermionic delta function, $f(\partial/\partial\theta)\delta(\theta)$, again is a powers series in the θ's, while this is of course not true for the derivatives of the bosonic delta function, $\delta^{(2N)}(y)$. In the former case, the monomials $\theta^{\mu_1} \cdots \theta^{\mu_p}$ are mapped onto monomials of the same type. Therefore one set of antisymmetric tensors $\{f_{a_1 \cdots a_p}^{(p)}\}$ is mapped onto another set of such tensors. In the latter case, the space of symmetric tensors $b_{a_1 \cdots a_p}^{(p)}$ is not mapped onto itself. The image of $y^{a_1} y^{a_2} \cdots y^{a_p}$ is a singular symbol $\propto \partial_y^{a_1} \cdots \partial_y^{a_p} \delta^{(2N)}(y)$, $\partial_y^a \equiv \omega^{ab} \partial/\partial y^b$.

Nevertheless it will be helpful to think of the symplectic Fourier transformation as the bosonic (symmetric tensor) analog of the Hodge operator. For instance, by (2.48) with (A22) and (A40) the fermionic inner product has the same general structure as (3.28):

$$(f_1|f_2) \propto \int \overline{f_1}(\theta) \tilde{f}_2(\theta) d^n\theta \propto \int \overline{f_1}(\theta)(*f_2)(\theta) d^n\theta. \tag{3.31}$$

In the language of differential forms this is nothing but the familiar inner product $*(\overline{\Phi_1} \wedge *\Phi_2)$ in disguise. The product $(b_1|b_2)$ introduced above is analogous to it, but refers to symmetric rather than antisymmetric tensors.

The space of symbols $b(y)$ equipped with the pointwise product of functions, the star product, and the inner product constitutes the bosonic Weyl algebra $\mathcal{W}$. It is the counterpart of the algebra $\mathcal{W}^{\mathrm{F}}$ which, endowed with analogous structures, had turned out to be an Atiyah–Kähler algebra. Because $(y^a|y^b)=i\hbar\omega^{ab}/2$ we see that the three product structures on $\mathcal{W}$ satisfy the consistency condition

$$y^a\circ y^b=y^a y^b+(y^a|y^b). \tag{3.32}$$

This relation is completely analogous to Eq. (2.46) which had been identified with the defining property of an Atiyah–Kähler algebra, Eq. (1.7). This supports our point of view that *the bosonic Weyl algebra is the natural analog of an Atiyah–Kähler algebra if one works in a symplectic rather than a Riemannian setting*.

B. γ matrices for Mp$(2N)$ and the analog of γ_5

The generators of Mp$(2N)$ in the spinor representation are obtained as symmetrized bilinears $\Sigma^{ab}_{\mathrm{meta}}=(\gamma^a\gamma^b+\gamma^b\gamma^a)/4$ built from $2N$ ''γ matrices'' satisfying

$$\gamma^a\gamma^b-\gamma^b\gamma^a=2i\omega^{ab}. \tag{3.33}$$

Upon identifying

$$\gamma^a=\kappa\hat{\varphi}^a \tag{3.34}$$

it is clear that the relations (3.33) coincide precisely with (3.1). Hence, what in the language of group theory is called a ''symplectic Clifford algebra'' is nothing but the canonical commutation relations of a bosonic quantum system with the canonical operators $\hat{\varphi}^a=(\hat{\pi}^j,\hat{x}^j)$. For N finite, all irreducible representations of the canonical commutation relations are unitarily equivalent, so the same is true for the symplectic Clifford algebra. All these representations are infinite dimensional.

We consider representations where γ^a is a Hermitian operator on the Hilbert space $\mathcal{V}$. Frequently $\mathcal{V}$ is taken to be the Fock space of N independent harmonic oscillators.[17,31] Then the γ^a's are linear combinations of the corresponding creation and annihilation operators. Here we shall employ another representation which is particularly natural in the gauge theory approach to quantum mechanics.[21] We pick the $\hat{x}$-eigenbasis (3.8) with respect to which $\langle\alpha|\hat{x}^j|\beta\rangle=\alpha^j\delta^{(N)}(\alpha-\beta)$ and $\langle\alpha|\hat{\pi}^j|\beta\rangle=-i\hbar\partial_j\delta^{(N)}(\alpha-\beta)$. Therefore, in a symbolic matrix notation with $\langle\alpha|\gamma^a|\beta\rangle\equiv(\gamma^a)^\alpha{}_\beta$,

$$\begin{aligned}(\gamma^j)^\alpha{}_\beta&=-(2i/\kappa)\partial^j\delta^{(N)}(\alpha-\beta),\\ (\gamma^{N+j})^\alpha{}_\beta&=\kappa\alpha^j\delta^{(N)}(\alpha-\beta),\quad j=1,...,N.\end{aligned} \tag{3.35}$$

The Hilbert space $\mathcal{V}$ is the space of square integrable functions $\psi(\alpha)\equiv\langle\alpha|\psi\rangle\equiv\psi^\alpha$ with its usual inner product. The generators $\Sigma^{ab}_{\mathrm{meta}}$ act on $\mathcal{V}$ as second-order differential operators (Schrödinger Hamiltonians with a quadratic potential; see Refs. 22 and 23 for further details).

Any attempt at putting metaplectic spinors on a similar footing as the SO(n) spinors faces the problem that $\mathcal{V}$ is infinite dimensional and that a metaplectic spinor formally is an object $\psi^\alpha\equiv\psi(\alpha)$ with infinitely many components. As an immediate consequence, trace identities such as (1.33) have no direct counterpart for the metaplectic γ ''matrices''. In the $\hat{x}$ basis, for instance, the trace of an operator $\hat{b}\in\mathcal{L}(\mathcal{V})$ reads $\mathrm{Tr}(\hat{b})=\int d^N\alpha\langle\alpha|\hat{b}|\alpha\rangle$, and it is clear that monomials such as $\gamma^{a_1}\cdots\gamma^{a_p}$ do not possess a trace. Remarkably enough, it turns out that there exist identities similar to (1.33) even in the infinite dimensional case which, however, involve the Sp$(2N)$ analog of γ_{n+1}.

We are familiar with the fact that when we are dealing with spinors on an even-dimensional space–time there exists a chirality matrix γ_{n+1}, a generalization of γ_5 in four dimension, which anticommutes with any γ^μ. Its eigenvalues are -1 and $+1$, and the corresponding eigenspaces are the left- and right-handed Weyl spinors, respectively. It is quite interesting that we can introduce an analogous concept for metaplectic spinors and that the pertinent ''chirality operator'' has a very natural interpretation even. Let us try to find an operator $\gamma_P \in \mathcal{L}(\mathcal{V})$ which anticommutes with all γ^a's,

$$\gamma_P \gamma^a + \gamma^a \gamma_P = 0 \tag{3.36}$$

and satisfies

$$\gamma_P^\dagger = \gamma_P^{-1} = \gamma_P . \tag{3.37}$$

Thus γ_P has the same algebraic properties as γ_5, its eigenvalues are ± 1 and, provided it actually exists, we can use it to form the ''chiral'' projections

$$\psi_\pm = \Pi_\pm \psi, \quad \Pi_\pm \equiv \tfrac{1}{2}(1 \pm \gamma_P) \tag{3.38}$$

of any $\psi \in \mathcal{V}$. Since $\Sigma^{ab}_{\rm meta}$ commutes with γ_P, the M$p(2N)$ transformations leave the subspaces with $\gamma_P = +1$ and $\gamma_P = -1$ invariant, so that the representation of Mp$(2N)$ implied by the γ matrices (3.35) decomposes accordingly.

Looking at the ''metaplectic γ_5 matrix'' from the point of view of the auxiliary quantum mechanics with the $\hat{\varphi}$ degrees of freedom it becomes clear that we may identify γ_P with the standard parity operator P in this context. By definition, P changes the sign of both the positions $\hat{x}^i$ and the momenta $\hat{\pi}^i$: $P\hat{x}^i P = -\hat{x}^i$, $P\hat{\pi}^i P = -\hat{\pi}^i$. Hence $P\gamma^a P = -\gamma^a$ for $\gamma^a = \kappa(\hat{\pi}^i, \hat{x}^i)$, which is exactly (3.36) with $\gamma_P \equiv P$. The operator P acts on the wave functions $\psi \in \mathcal{V}$ as $(P\psi)(\alpha) \equiv (\gamma_P \psi)(\alpha) = \psi(-\alpha)$. This means that in the $\hat{x}$ representation

$$\gamma_P |\alpha\rangle = |-\alpha\rangle \tag{3.39}$$

so that the matrix elements of γ_P are given by

$$(\gamma_P)^\alpha{}_\beta \equiv \langle \alpha | \gamma_P | \beta \rangle = \delta^{(N)}(\alpha + \beta). \tag{3.40}$$

Thus, ''metaplectic chirality'' is nothing but ''fiberwise parity,'' and the projections $\Pi_\pm \mathcal{V}$ are simply the subspaces of even and odd wave functions, respectively.

The operator γ_P can be written in a manifestly basis independent way:

$$\gamma_P = (4\pi\hbar)^{-N} \int d^{2N} y \, \hat{T}(y). \tag{3.41}$$

[Equation (3.41) shows that γ_P belongs to the family of parity-type operators discussed by Grossmann[32] and Royer.[33]] The general properties of the Weyl operators imply that (3.41) has the desired properties (3.36), (3.37) and using the matrix elements (3.9) one finds that (3.41) coincides with (3.40). Equation (3.41) is strikingly similar to Eq. (2.44) for $\hat{G}_{n+1}$ which confirms our interpretation that the *fiberwise parity transformation is the analog of* γ_5.

The operator γ_P has a well-defined finite trace:

$$\mathrm{Tr}[\gamma_P] = 2^{-N}. \tag{3.42}$$

This follows from (3.41) with (3.6) or simply by noting that

$$\mathrm{Tr}[\gamma_P] = \int d^N \alpha (\gamma_P)^\alpha{}_\alpha = \int d^N \alpha \, \delta^{(N)}(2\alpha) = 2^{-N}. \tag{3.43}$$

While the very existence of this trace is remarkable, we see the first major difference between the bosonic and the fermionic case here. Both γ_5 and γ_P have eigenvalues ± 1, but the pairing of positive and negative eigenvalues which leads to $\mathrm{Tr}(\gamma_5) = 0$ does not happen for γ_P.

Finite products of γ^a matrices and in particular the unit operator do not possess a well-defined trace. On the other hand, traces with a γ_P insertion,

$$\mathrm{Tr}[\hat{b}\,\gamma_P]=\int d^N\alpha\langle\alpha|\hat{b}|-\alpha\rangle \tag{3.44}$$

are much better behaved because the reflection $\alpha\mapsto-\alpha$ removes possible ''short distance singularities'' (reminiscent of ultraviolet divergences in field theory) which would plague $\langle\alpha|\hat{b}|\alpha\rangle$.

This situation is quite similar to what one encounters in quantum field theory in the computation of chiral anomalies or, from a mathematical point of view, of the analytical index of the Dirac operator.[34,35] There one considers $\mathrm{Tr}(I)$ and $\mathrm{Tr}(\gamma_5)$ where the trace is over the infinite dimensional Hilbert space of Dirac spinor fields. While $\mathrm{Tr}(I)$ does not exist, $\mathrm{Tr}(\gamma_5)$ can be interpreted as the index of the Dirac operator.

An important trace of the type (3.44) is

$$\mathrm{Tr}[\gamma^{(a_1}\cdots\gamma^{a_p)}\gamma_P\gamma_{(b_1}\cdots\gamma_{b_q)}]=i^p2^{-N}p!\,\delta^{pq}\delta^{a_1}_{(b_1}\delta^{a_2}_{b_2}\cdots\delta^{a_p}_{b_p)} \tag{3.45}$$

with the convenient abbreviation $\gamma_a\equiv\omega_{ab}\gamma^b$, $\omega^{ab}\gamma_b=\gamma^a$. Equation (3.45) is similar to (1.33) for the $\mathrm{SO}(n)$ γ matrices, but contains an additional factor of γ_P without which the trace would not exist. Equation (3.45) follows from the properties for the $\hat{T}$ operators. First one uses (3.41) with (3.6) to show that

$$\mathrm{Tr}[\hat{T}(y)\gamma_p]=2^{-N} \tag{3.46}$$

is independent of y. Next one writes

$$\begin{aligned}\mathrm{Tr}[\hat{T}(y_1)\gamma_P\hat{T}(y_2)]&=\mathrm{Tr}[\hat{T}(y_1)\hat{T}(-y_2)\gamma_P]\\&=\exp\left[\frac{i}{2\hbar}\,\omega(y_1,-y_2)\right]\mathrm{Tr}[\hat{T}(y_1-y_2)\gamma_P]=2^{-N}\exp\left[-\frac{i}{2\hbar}y_1^a\omega_{ab}y_2^b\right].\end{aligned} \tag{3.47}$$

If one now expands the first and the last expression of (3.47) in powers of y_1 and y_2 and equates equal powers, the result is precisely Eq. (3.45).

Some important special cases of (3.45) include

$$\begin{aligned}\mathrm{Tr}[\gamma^a\gamma_P]&=0,\\\mathrm{Tr}[\gamma^{(a_1}\cdots\gamma^{a_p)}\gamma_P]&=0,\\\mathrm{Tr}[\gamma^a\gamma^b\gamma_P]&=2^{-N}i\,\omega^{ab}.\end{aligned} \tag{3.48}$$

The reader is invited to check some of these relations by using the matrix elements of γ^a in the $|\alpha\rangle$ basis. It is instructive to see that these calculations involve only well-defined manipulations of distributions and that no additional ad hoc regularization is needed. This is different from the derivation of the closely related dimension-counting formulas for the spinors of $\mathrm{OSp}(n|2N)$ which appear in certain approaches to the covariant quantization of superstrings,[18] for instance.

C. The Dirac–Kähler construction on phase space

Let $(\mathcal{M}_{2N},\omega)$ denote an arbitrary $2N$-dimensional symplectic manifold which serves as the phase space of some Hamiltonian system. Let us consider the Weyl algebra bundle[30,31] over $\mathcal{M}_{2N}$. Its typical fiber is the bosonic Weyl algebra $\mathcal{W}$, i.e., the space of symbols $b(\cdot)$ equipped with the pointwise product of functions, the star product, and the inner product $(\cdot|\cdot)$. At each point ϕ of

$\mathcal{M}_{2N}$ we attach a local copy $\mathcal{W}_\phi$ of $\mathcal{W}$. The matrix (ω_{ab}) which enters the definition of the Weyl algebra $\mathcal{W}_\phi$ are the coefficients of the symplectic two-form ω evaluated at the point ϕ. By virtue of Darboux's theorem, there exist local coordinates (ϕ^a) such that those coefficients assume their canonical form on the entire (ϕ^a) chart. Local coordinates on the total space are pairs (ϕ,b) with b a function $b:\mathbf{R}^{2N}\to\mathbf{C}$, $y\mapsto b(y)$. The transition functions of the bundle are defined in such a way that the variables $(y^1,\ldots,y^{2N})$ on which b depends are the components of a vector $y \in T_\phi\mathcal{M}_{2N}$, i.e., $y^a=d\phi^a(y)$. A symplectic change of coordinates $\phi^a\to\tilde{\phi}^a(\phi)$ (canonical transformation) is to be combined with a transformation in the fiber, $b\to\tilde{b}$, such that $\tilde{b}(\tilde{y})=b(y)$ with $\tilde{y}^a=(\partial\tilde{\phi}^a/\partial\phi^b)y^b$.

Along with the Weyl algebra bundle we also consider the metaplectic spinor bundle over $(\mathcal{M}_{2N},\omega)$ which we described in Sec. I. Its fiber at ϕ, $\mathcal{V}_\phi$, is a copy of the Hilbert space $\mathcal{V}$ on which we already constructed a representation of the metaplectic Clifford algebra and, as a consequence, of the structure group $\mathrm{Mp}(2N)$.

Let us look at sections through the Weyl algebra bundle. Locally they are specified by functions $\phi\mapsto B(\phi,\cdot)\in\mathcal{W}_\phi$ where $B(\phi,\cdot):\mathbf{R}^{2N}\to\mathbf{C}$, $y\mapsto B(\phi,y)$ is a Weyl symbol ''living'' in the fiber at ϕ. In this context, the flat ''auxiliary phase-space'' $\mathbf{R}^{2N}$ is identified with the tangent space $T_\phi\mathcal{M}_{2N}$. Hence the function $B(\cdot,\cdot)$ is a map from (a part of) the total space of the tangent bundle into $\mathbf{C}$.

Many of the concepts which we developed in Sec. III A for symbols $b\in\mathcal{W}$ naturally pass over to the sections B. At every point ϕ of $\mathcal{M}_{2N}$ we can apply the inverse symbol map to $B(\phi,\cdot)\in\mathcal{W}_\phi$ and obtain a unique operator $\hat{B}(\phi)=\mathrm{symb}^{-1}B(\phi,\cdot)$ which acts on the local copy $\mathcal{V}_\phi$ of the Hilbert space $\mathcal{V}$. Thus a section B gives rise to a family of operators $\hat{B}(\phi)\in\mathcal{L}(\mathcal{V}_\phi)$ labeled by the points of phase space. Its matrix elements with respect to a given basis in $\mathcal{V}$ will be denoted $\hat{B}(\phi)^\alpha{}_\beta\equiv\langle\alpha|\hat{B}(\phi)|\beta\rangle$. Globally speaking, $\hat{B}$ is a section through the bundle of (1,1) multispinors.[22,21]

The fiberwise star product of two sections is defined by

$$(B_1\circ B_2)(\phi,y)=B_1(\phi,y)\exp\left[\frac{i\hbar}{2}\frac{\overleftarrow{\partial}}{\partial y^a}\omega^{ab}\frac{\overrightarrow{\partial}}{\partial y^b}\right]B_2(\phi,y). \tag{3.49}$$

This star product has to be carefully distinguished from the $*_\mathcal{M}$ product whose associated Moyal bracket $\{f,g\}_M=(f*_\mathcal{M}g-g*_\mathcal{M}f)/i\hbar$ replaces the classical Poisson bracket in the deformation quantization approach,[24,36] and which involves derivatives with respect to ϕ^a rather than y^a. In general, the $*_\mathcal{M}$ product is much more complicated than the $\circ$ product. It can be constructed iteratively by Fedosov's method,[29,37–40] but we shall not need it in the present context.

The fiberwise inner product of two sections is given by $(B_1|B_2)(\phi)=(\overline{B_1}\circ B_2)(\phi,0)$. The natural sesquilinear form on the space of sections is $\langle B_1|B_2\rangle=\int d\mu_L(B_1|B_2)$ where $d\mu_L$ is the Liouville measure.

After these preparations we are now able to construct an analog of the Dirac–Kähler fields on phase spaces.

Let $\bigotimes^p_{\mathrm{sym}}(T^*\mathcal{M}2N)$ denote the p-fold symmetrized tensor power of the cotangent bundle. A section $\mathbf{\Sigma}^{(p)}$ through this bundle is a symmetric tensor field of rank p. We shall also consider the direct sum

$$\bigotimes_{\mathrm{sym}}(T^*\mathcal{M}_{2N})=\bigoplus_{p=0}^{\infty}\bigotimes^p_{\mathrm{sym}}(T^*\mathcal{M}_{2N}). \tag{3.50}$$

Its sections $\mathbf{\Sigma}=\Sigma_{p=0}^\infty\mathbf{\Sigma}^{(p)}$ are analogous to the inhomogeneous differential forms, but with symmetric rather than antisymmetric tensor fields. In local (Darboux) coordinates ϕ^a, $\mathbf{\Sigma}$ can be expanded as

$$\boldsymbol{\Sigma}(\phi)=\sum_{p=0}^{\infty}\frac{1}{p!}B^{(p)}_{a_1\cdots a_1}(\phi)d\phi^{a_1}\otimes_{\text{sym}}d\phi^{a_2}\otimes_{\text{sym}}\cdots\otimes_{\text{sym}}d\phi^{a_p} \tag{3.51}$$

with $\otimes_{\text{sym}}$ denoting the symmetric counterpart of the wedge product; for instance, $d\phi^a\otimes_{\text{sym}}d\phi^b = d\phi^a\otimes d\phi^b+d\phi^b\otimes d\phi^a$. The complex-valued coefficients $B^{(p)}_{a_1\cdots a_p}$ are taken to be completely symmetric in all p indices. We shall refer to $\boldsymbol{\Sigma}$ as an ''inhomogeneous symmetric tensor'' (IST).

Guided by the corresponding construction in the fermionic case we shall now associate an operator $\hat{B}(\phi)\in\mathcal{L}(\mathcal{V}_\phi)$ to $\boldsymbol{\Sigma}(\phi)$ by replacing in Eq. (3.51) the differentials $d\phi^a$ with the Gamma matrices γ^a:

$$\hat{B}(\phi)=\sum_{p=0}^{\infty}\frac{1}{p!}B^{(p)}_{a_1\cdots a_p}(\phi)\gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_p}=\sum_{p=0}^{\infty}\frac{\kappa^p}{p!}B^{(p)}_{a_1\cdots a_p}(\phi)\hat{\varphi}^{a_1}\hat{\varphi}^{a_2}\cdots\hat{\varphi}^{a_p}. \tag{3.52}$$

(As discussed earlier, we interpret the γ matrices as κ times the canonical operators $\hat{\varphi}^a$ of the auxiliary quantum system in the fiber.) Conversely, every Weyl ordered operator on $\mathcal{V}_\phi$ which admits a power series expansion gives rise to a unique IST. The operator can be expanded in the symmetrized monomials $\hat{\varphi}^{(a_1}\ldots\hat{\varphi}^{a_p}$ with coefficients which are symmetric tensors and define an IST therefore.

Now we form the symbol of $\hat{B}$: $B(\phi,y)=[\text{symb}\,\hat{B}(\phi)](y)$, i.e.,

$$B(\phi,y)=\sum_{p=0}^{\infty}\frac{\kappa^p}{p!}B^{(p)}_{a_1\cdots a_p}(\phi)y^{a_1}y^{a_2}\cdots y^{a_p}. \tag{3.53}$$

Taking both steps together we arrive at a one-to-one correspondence between ISTs and symbols with a power series expansion in y:

$$\boldsymbol{\Sigma}(\phi)\in\otimes_{\text{sym}}(T^*_\phi\mathcal{M}_{2N})\leftrightarrows\hat{B}(\phi)\in\tilde{\mathcal{L}}(\mathcal{V}_\phi)\leftrightarrows B(\phi,\cdot)\in\tilde{\mathcal{W}}_\phi. \tag{3.54}$$

This chain of bijections is similar to (2.64). However, the difference is that in the fermionic setting every symbol or every Weyl ordered operator gives rise to an inhomogeneous tensor field. This is not true in the bosonic case. We have to explicitly restrict the symbols and operators to those which allow for a power series expansion in y^a or $\hat{\varphi}^a$, respectively. [This is indicated by the notation $\tilde{\mathcal{L}}(\mathcal{V}_\phi)$ and $\tilde{\mathcal{W}}_\phi$.] Nevertheless we shall continue to consider also symbols B which are not analytic in y because they will play a central role in the reduction of symplectic DK fields.

Now let us look at the rules of the symbol/tensor correspondence in the bosonic case. Clearly the differentials $d\phi^a$ correspond to κy^a: $d\phi^a\leftrightarrows\kappa y^a$. Hence, if we write the (linear, invertible) map from the symbols to the ISTs as $B\mapsto\boldsymbol{\Sigma}[B]$, we have $\boldsymbol{\Sigma}[\kappa y^a]=d\phi^a$ or more generally

$$\boldsymbol{\Sigma}[\kappa^p y^{a_1}\cdots y^{a_1}]=d\phi^{a_1}\otimes_{\text{sym}}\cdots\otimes_{\text{sym}}d\phi^{a_p}. \tag{3.55}$$

Up to this point the situation is the same as in Sec. II D with the commuting y's replacing the anticommuting θ's. This converts the wedge product to the symmetric tensor product. Differences become manifest when we look at the list of natural operations for ISTs and their realization at the symbol level.

The automorphism $\mathcal{A}$ and the antiautomorphism $\mathcal{B}$, while important for dealing with the ubiquitous sign factors in exterior algebra computations, are unnecessary for symmetric tensors. As we argued already, the Hodge operator has a natural bosonic translation, the symplectic Fourier transformation. However it does not leave the space $\tilde{\mathcal{W}}$ invariant and, as a consequence, does not induce a map of one IST onto another. Furthermore, the exterior derivative is a derivation on the exterior algebra which does not require a connection for its definition. Also this concept has no analog on the bosonic side.

However, every vector field $v=v^a(\phi)\partial_a$ on $\mathcal{M}_{2N}$ gives rise to a contraction operator $\mathbf{i}(v)$. By definition, it is a linear operator on the space of ISTs, depending linearly on v, and satisfying $\mathbf{i}(\partial_a)1=0$, $\mathbf{i}(\partial_a)d\phi^b=\delta_a^b$ as well as

$$\mathbf{i}(v)[\boldsymbol{\Sigma}_1\otimes_{\text{sym}}\boldsymbol{\Sigma}_2]=[\mathbf{i}(v)\boldsymbol{\Sigma}_1]\otimes_{\text{sym}}\boldsymbol{\Sigma}_2+\boldsymbol{\Sigma}_1\otimes_{\text{sym}}[\mathbf{i}(v)\boldsymbol{\Sigma}_2]. \tag{3.56}$$

Its realization on $\tilde{\mathcal{W}}$ reads

$$\mathbf{i}(v)\boldsymbol{\Sigma}[B]=\boldsymbol{\Sigma}\left[\kappa^{-1}v^a\frac{\partial}{\partial y^a}B\right]. \tag{3.57}$$

We also define the operators

$$e_a\neg\equiv\mathbf{i}(\partial_a),\quad e^a\neg\equiv\omega^{ab}\mathbf{i}(\partial_b) \tag{3.58}$$

with the basis vectors $\partial_a\equiv\partial/\partial\phi^a$ referring to a system of Darboux local coordinates.

The most important properties of the fermionic Weyl algebra $\mathcal{W}^F$ were the three different product structures with which it is endowed and which make it an Atiyah–Kähler algebra. The bosonic Weyl algebra $\mathcal{W}$ is equipped with three analogous products (pointwise multiplication, star product, inner product) which satisfy the basic consistency condition (3.32). At the end of Sec. III A this led us to the conclusion that $\mathcal{W}$ is the symplectic counterpart of an Atiyah–Kähler algebra. In the same sense the ISTs $\boldsymbol{\Sigma}$ are analogous to the Dirac–Kähler fields Φ.

The product structures on $\mathcal{W}_\phi$ give rise to related products on the space of symmetric tensor fields. One easily verifies that the pointwise product of bosonic symbols is tantamount to the symmetric tensor product:

$$\boldsymbol{\Sigma}[B_1]\otimes_{\text{sym}}\boldsymbol{\Sigma}[B_2]=\boldsymbol{\Sigma}[B_1B_2]. \tag{3.59}$$

Furthermore, guided by our experience with the fermionic case, we now *define* the Clifford product for symmetric tensor field as the image of the bosonic star product under the symbol/tensor correspondence (3.54):

$$\boldsymbol{\Sigma}[B_1]\vee\boldsymbol{\Sigma}[B_2]=\boldsymbol{\Sigma}[B_1\circ B_2]. \tag{3.60}$$

By construction, the ''symplectic Clifford product,'' also denoted ''$\vee$,'' is associative and distributive (but not commutative). From Eqs. (3.49), (3.57), and (3.58) one obtains the following explicit representation for the product of two ISTs:

$$\boldsymbol{\Sigma}_1\vee\boldsymbol{\Sigma}_2=\sum_{p=0}^{\infty}\frac{i^p}{p!}[e_{a_1}\neg e_{a_2}\neg\cdots e_{a_p}\neg\boldsymbol{\Sigma}_1]\otimes_{\text{sym}}[e^{a_1}\neg e^{a_2}\neg\cdots e^{a_p}\neg\boldsymbol{\Sigma}_2]. \tag{3.61}$$

This equation is strikingly similar to Kähler's formula (1.9) for the ordinary Clifford product. We emphasize that while Eq. (3.61) might look complicated it is uniquely determined by the fundamental relations

$$\begin{gathered}1\vee 1=1,\quad 1\vee d\phi^a=d\phi^a\vee 1=d\phi^a,\\ d\phi^a\vee d\phi^b=d\phi^a\otimes_{\text{sym}}d\phi^b+i\omega^{ab}\end{gathered} \tag{3.62}$$

if associativity and distributivity are imposed.

Turning to the last product structure on $\mathcal{W}$, there is an obvious choice for a fiberwise inner product $(\cdot,\cdot)$ of symmetric tensor fields: $(\boldsymbol{\Sigma}_1,\boldsymbol{\Sigma}_2)=(B_1|B_2)$ where $\boldsymbol{\Sigma}_{1,2}$ is related to $B_{1,2}$ via (3.54). Thus it is clear that the ISTs may be regarded as sections through a ''symplectic Atiyah–Kähler bundle.''

The left-multiplication by the basis element $d\phi^a$ reads explicitly

$$d\phi^a \vee \mathbf{\Sigma} = d\phi^a \otimes_{\rm sym} \mathbf{\Sigma} + i e^a \neg \mathbf{\Sigma}. \tag{3.63}$$

It defines a representation of the symplectic Clifford algebra in the space of inhomogeneous symmetric tensor fields:

$$d\phi^a \vee d\phi^b - d\phi^b \vee d\phi^a = 2i\omega^{ab}. \tag{3.64}$$

Comparing (3.64) to (3.33), $d\phi^a \vee$ takes the place of the metaplectic Dirac matrix γ^a. Since $d\phi^a = \mathbf{\Sigma}[\kappa y^a]$, $d\phi^a \vee$ applied to tensors is the same as $\kappa y^a \circ$ applied to symbols:

$$d\phi^a \vee \mathbf{\Sigma}[B] = \mathbf{\Sigma}[\kappa y^a \circ B] = \mathbf{\Sigma}[C^a B]. \tag{3.65}$$

The differential operators C^a were introduced in Eq. (3.23). They are formally self-adjoint with respect to the inner product $(\cdot|\cdot)$. They constitute a representation of the symplectic Clifford algebra in space of bosonic Weyl symbols:

$$C^a C^b - C^b C^a = 2i\omega^{ab}. \tag{3.66}$$

Since κy^a is the symbol of $\kappa \hat{\varphi}^a = \gamma^a$, the operator associated to $C^a B$ is $\gamma^a \hat{B}$ with $\hat{B} = \mathrm{symb}^{-1}(B)$. In summary, we have the chain of correspondences

$$d\phi^a \vee \mathbf{\Sigma} \leftrightarrows \gamma^a \hat{B} \leftrightarrows C^a B. \tag{3.67}$$

Thus we managed to implement the essence of the Dirac–Kähler idea in a symplectic rather than a Riemannian setting. We constructed a representation of the corresponding Clifford algebra on the space of symmetric tensor fields over a phase-space manifold rather than on the exterior algebra over space–time.

Up to this point our considerations focused on the kinematic aspects of the theory. We have not yet found an analog of the DK equation. Since d and $d^\dagger$ do not exist for symmetric tensors, the DK operator $d - d^\dagger$ has no direct counterpart. Still it is possible to write down a ''symplectic DK equation'' with the necessary covariance properties:

$$[d\phi^a \vee \nabla_\alpha + m]\mathbf{\Sigma} = 0. \tag{3.68}$$

(Here ∇ is a symplectic connection.) Equation (3.68) could be rewritten as a set of ''metaplectic Dirac equations'' in the same way as the ordinary DK equation can be decomposed into a set of ordinary Dirac equations. Metaplectic Dirac operators have been investigated in the mathematical literature recently[41] but no physical application has emerged so far. In Sec. IV we shall see that from a kinematical and representation theory point of view the symplectic DK fields indeed do play an important role in the gauge theory approach to quantization. The interpretation of field equations such as Eq. (3.68), if any, will remain an open problem though.

We close this section with a few comments on the ''metaplectic γ_5 matrix'' in relation to the DK fields. In the SO(n) case we saw that γ_{n+1}, the volume form, and the δ function are different guises of the same object. Some properties of γ_{n+1} are similar in the symplectic case, others are quite different. The symbol of γ_P, too, is proportional to a δ function,

$$G_P \equiv \mathrm{symb}(\gamma_P), \quad G_P(y) = (\pi\hbar)^N \delta^{(2N)}(y). \tag{3.69}$$

This symbol is completely unrelated to the volume form, however. In the SO(n) case we know that the Clifford right multiplication by G_{n+1} is equivalent to the modified Hodge operator ($\star f \propto f \circ G_{n+1} \propto f \circ \delta^{(n)}$). This property has a partial analog since by virtue of (3.21) the symplectic Fourier transformation which corresponds to $\star$ is essentially the same operation as the star multiplication by G_P from the right:

$$\tilde{b}(y) = 2^{-N}(b \circ G_P)(y/2). \tag{3.70}$$

However, this statement on the space of symbol functions (including distributions) does not imply a corresponding relation for symmetric tensors. The symbol G_P has no IST associated to it.

The matrix γ_P makes its appearance also in the natural inner product on $\mathcal{L}(\mathcal{V}_\phi)$. By virtue of the identity

$$(B_1|B_2)=2^N \operatorname{Tr}[\hat{B}_1^\dagger \hat{B}_2 \gamma_P] \tag{3.71}$$

the inner product on $\mathcal{W}_\phi$ induces a corresponding product for the operators. The latter differs form the familiar Hilbert–Schmidt inner product by the additional γ_P matrix which tends to improve the regularity properties of the trace. Equation (3.71) is most easily proven as follows:

$$\begin{aligned}(B_1|B_2)&=(\overline{B_1}\circ B_2)(y=0)\\ &=(\pi\hbar)^{-N}\int d^{2N}y(\overline{B_1}\circ B_2)(y)G_P(y)\\ &=(\pi\hbar)^{-N}\int d^{2N}y(\overline{B_1}\circ B_2\circ G_P)(y)\\ &=(\pi\hbar)^{-N}\int d^{2N}y[\operatorname{symb}\{\hat{B}_1^\dagger\hat{B}_2\gamma_P\}](y)=2^N\operatorname{Tr}[\hat{B}_1^\dagger\hat{B}_2\gamma_P].\end{aligned} \tag{3.72}$$

Here (3.69) was used along with the standard results[24] $\int d^{2N}y\, b_1(y) b_2(y)=\int d^{2N}y(b_1\circ b_2)(y)$ and $\operatorname{Tr}(\hat{b})=(2\pi\hbar)^{-N}\int d^{2N}y\, b(y)$.

D. Decomposition of the symplectic DK representation

We have seen that $d\phi^a\vee$ and $\kappa y^a\circ$ induce a representation of the symplectic Clifford algebra on the space of symmetric tensors and their symbols, respectively. We also saw that the corresponding representations in the SO(n) case are reducible, so it is natural to ask if the same is true in the symplectic setting. We shall demonstrate that *at the level of the symbols* the representation is indeed reducible. However, in contradistinction to the SO(n) case, the decomposition of $\mathcal{W}$ does not induce a concomitant decomposition of the (symmetric) tensor algebra.

We shall see that the representation of the symplectic Clifford algebra carried by the symbol-valued fields $B(\phi,y)$ can be decomposed into infinitely many irreducible representations each of which is equivalent to the one defined by the metaplectic γ matrices (3.35). (We recall that this is the representation of the Heisenberg algebra used in conventional canonical quantization.) As a consequence, every field $B(\phi,y)$ amounts to a collection of infinitely many metaplectic spinor fields $\psi^\alpha(\phi)$. Now we discuss the question of the (ir)reducibility for the symbols B, the operators $\hat{B}$ and the tensors Σ separately.

1. Symbols

We are going to show that the bosonic Weyl algebra $\mathcal{W}$ admits an orthogonal decomposition

$$\mathcal{W}=\bigoplus_{\alpha\in\mathbf{R}^N}\mathcal{W}_{(\alpha)} \tag{3.73}$$

such that the subspaces $\mathcal{W}_{(\alpha)}$ are invariant under star-left multiplication by y^a, i.e., $y^a\circ b\in\mathcal{W}_{(\alpha)}$ if $b\in\mathcal{W}_{(\alpha)}$. To this end we use an infinite dimensional generalization of the Becher–Joos method.[3] We look for a $2N$-parameter family of operators $\hat{Z}(y)$, $y\in\mathbf{R}^{2N}$, with the property

$$y^a\circ\hat{Z}(y)=\hat{Z}(y)\hat{\varphi}^a. \tag{3.74}$$

One should think of $\hat{Z}(\cdot)$ as an operator-valued symbol, i.e., the ''$y^a \circ$'' in (3.74) is given by $\kappa^{-1}C^a$ as if $\hat{Z}$ was an ordinary symbol. With our experience from the fermionic case we suspect that $\hat{Z}$ should be closely related to the Weyl operators. It turns out that this is indeed the case. The derivative of the Weyl operators reads

$$\frac{\partial}{\partial y^a}\hat{T}(y)=\frac{i}{\hbar}\,\omega_{ab}\left[\hat{\varphi}^b-\frac{1}{2}y^b\right]\hat{T}(y)=\frac{i}{\hbar}\,\omega_{ab}\hat{T}(y)\left[\hat{\varphi}^b+\frac{1}{2}y^b\right]. \tag{3.75}$$

Equation (3.75) entails that the argument of $\hat{T}$ can be rescaled in such a way that left multiplication with y^a is equivalent to the operator multiplication by $\hat{\varphi}^a$, either from the left or from the right:

$$\begin{aligned} y^a\circ\hat{T}(\pm 2iy)&=\mp i\hat{\varphi}^a\hat{T}(\pm 2iy),\\ y^a\circ\hat{T}(\pm 2y)&=\mp\hat{T}(\pm 2y)\hat{\varphi}^a. \end{aligned} \tag{3.76}$$

Hence

$$\hat{Z}(y)=\hat{T}(-2y)=\exp(-i\kappa y^a\omega_{ab}\gamma^b) \tag{3.77}$$

is a solution to our problem. In the $\hat{x}$ eigenbasis the matrix elements $\hat{Z}(y)^\alpha{}_\beta=\langle\alpha|\hat{Z}|\beta\rangle$ are given by

$$\hat{Z}(y)^\alpha{}_\beta=\exp\left[-\frac{i}{\hbar}y_p(\alpha+\beta)\right]\delta^{(N)}(\alpha-\beta+2y_q). \tag{3.78}$$

They can be used in order to verify that

$$\begin{aligned} \langle\alpha|y_q\circ\hat{Z}(y)|\beta\rangle&=\beta\langle\alpha|\hat{Z}(y)|\beta\rangle,\\ \langle\alpha|y_p\circ\hat{Z}(y)|\beta\rangle&=i\hbar\frac{\partial}{\partial\beta}\langle\alpha|\hat{Z}(y)|\beta\rangle, \end{aligned} \tag{3.79}$$

which is (3.74) in the ''position representation.''

We shall need the star product of two different $\hat{Z}$ matrix elements. After some algebra one finds the remarkably simple result

$$\hat{Z}(y)^\alpha{}_\beta\circ\hat{Z}(y)^{\bar{\alpha}}{}_{\bar{\beta}}=2^{-N}(\gamma_P)^{\alpha}{}_{\bar{\beta}}\hat{Z}(y)^{\bar{\alpha}}{}_\beta. \tag{3.80}$$

When combined with the identity $\hat{Z}^\dagger=\gamma_P\hat{Z}\gamma_P$ Eq. (3.80) at $y=0$ gives rise to the inner product

$$(\hat{Z}^\alpha{}_\beta|\hat{Z}^{\bar{\alpha}}{}_{\bar{\beta}})=2^{-N}(\gamma_p)^{\alpha\bar{\alpha}}\delta_{\beta\bar{\beta}}. \tag{3.81}$$

The orthogonality and completeness relations (3.6) and (3.7) for $\hat{T}(y)$ imply similar relations for $\hat{Z}(y)$. As a consequence, $\{\hat{Z}(\cdot)^\alpha{}_\beta|\alpha,\beta\in\mathbf{R}^N\}$ is a basis in the space of symbol functions $b(\cdot)$. Every $b\in\mathcal{W}$ has an expansion of the form $b(y)=\int d^N\alpha d^N\beta\psi^\alpha_{(\beta)}\hat{Z}(y)^\beta{}_\alpha$ where the ''coefficients'' $\psi^\alpha_{(\beta)}$ are actually functions $\mathbf{R}^N\times\mathbf{R}^N\to\mathbf{C}$.

We continue the discussion directly for the case when $\mathcal{W}$ is the fiber $\mathcal{W}_\phi$ and the symbols $b(\cdot)$ are the $\mathcal{W}$-valued fields $B(\cdot,\phi)$ evaluated at a given point ϕ. Equations (3.6) and (3.7) imply that B can be expanded as

$$B(\phi,y)=\int d^N\alpha\int d^N\beta\psi^\alpha_{(\beta)}(\phi)\hat{Z}(y)^\beta{}_\alpha \tag{3.82}$$

and that the expansion coefficients are given by

$$\psi^{\alpha}_{(\beta)}(\phi)=(\pi\hbar/2)^{-N}\int d^{2N}y B(\phi,y)\hat{Z}^{\dagger}(y)^{\alpha}{}_{\beta}. \tag{3.83}$$

In a sense which we shall make precise later on, $\psi_{(\beta)}\equiv\{\psi^{\alpha}_{(\beta)};\alpha\in\mathbf{R}^N\}$ are the components of infinitely many metaplectic spinors labeled by the ''index'' β. If we define

$$B_{(\beta)}(\phi,y)\equiv\int d^N\alpha\,\psi^{\alpha}_{(\beta)}(\phi)\hat{Z}(y)^{\beta}{}_{\alpha} \tag{3.84}$$

so that $B(\phi,y)=\int d^N\beta B_{(\beta)}(\phi,y)$ then Eq. (3.74) implies that the invariant subspace $\mathcal{W}_{(\beta)}$ is spanned by precisely the symbols of the type (3.84):

$$y^a\circ B_{(\beta)}=\int d^N\alpha\int d^N\overline{\alpha}\psi^{\alpha}_{(\beta)}\hat{Z}^{\beta}{}_{\overline{\alpha}}(\hat{\varphi}^a)^{\overline{\alpha}}{}_{\alpha}=\int d^N\overline{\alpha}(\hat{\varphi}^a\psi_{(\beta)})^{\overline{\alpha}}\hat{Z}^{\beta}{}_{\overline{\alpha}}. \tag{3.85}$$

Here $(\hat{\varphi}^a\psi_{(\beta)})^{\overline{\alpha}}\equiv\int d^N\alpha(\hat{\varphi}^a)^{\overline{\alpha}}{}_{\alpha}\psi^{\alpha}_{(\beta)}$. We see that if the symbol $B_{(\beta)}$ is related to the spinor $\psi_{(\beta)}$ by (3.84) then $y^a\circ B_{(\beta)}$ and $\hat{\varphi}^a\psi_{(\beta)}$ are related in the same way. Likewise $\kappa y^a\circ$ corresponds to a multiplication by γ^a.

Given an arbitrary symbol in $\mathcal{W}$ we can project it on any of the subspaces $\mathcal{W}_{(\beta)}$. We introduce projection operators $\mathcal{P}_{(\beta)}$ by $B_{(\beta)}=\mathcal{P}_{(\beta)}B$. If we combine Eqs. (3.83) and (3.84) it follows that

$$B_{(\beta)}(\phi,y)=\int d^{2N}y'\,\mathcal{P}_{(\beta)}(y,y')B(\phi,y'), \tag{3.86}$$

where the integral kernel of the projector is given by

$$\mathcal{P}_{(\beta)}(y,y')=(\pi\hbar/2)^{-N}\langle\beta|\hat{Z}(y)\hat{Z}^{\dagger}(y')|\beta\rangle. \tag{3.87}$$

Upon using (3.77), (3.5), and (3.9) we obtain explicitly

$$\mathcal{P}_{(\beta)}(y,y')=(\pi\hbar)^{-N}\exp\left[-\frac{2i}{\hbar}(\beta+y_q)(y_p-y'_p)\right]\delta^{(N)}(y_q-y'_q). \tag{3.88}$$

The projectors $\{\mathcal{P}_{(\beta)};\beta\in\mathbf{R}^N\}$ are orthogonal and complete in the sense that

$$\begin{gathered}\int d^{2N}y'\,\mathcal{P}_{(\beta)}(y,y')\mathcal{P}_{(\overline{\beta})}(y',y'')=\delta^{(N)}(\beta-\overline{\beta})\mathcal{P}_{(\beta)}(y,y''),\\ \int d^N\beta\,\mathcal{P}_{(\beta)}(y,y')=\delta^{(2N)}(y-y').\end{gathered} \tag{3.89}$$

Furthermore, as a consequence of Eq. (3.80), the inner product of two different projections reads

$$(B_{(-\beta_1)}|B_{(\beta_2)})=2^{-N}\delta^{(N)}(\beta_1-\beta_2)\int d^N\alpha\,\overline{\psi}^{\alpha}_{(\beta_1)}\psi^{\alpha}_{(\beta_2)}. \tag{3.90}$$

Note the sign flip on the left-hand side of Eq. (3.90). Obviously $B_{(-\beta)}$ is the natural dual of $B_{(\beta)}$ (similar to a spinor adjoint).

To summarize: Every symbol-valued field $B(\phi,y)$ gives rise to infinitely many projections $B_{(\beta)}(\phi,y)$ each of which is equivalent to a metaplectic spinor field $\psi_{(\beta)}(\phi)$ with components $\psi^{\alpha}_{(\beta)}(\phi)$ given by (3.83). This is to mean that the fields $\psi_{(\beta)}$ carry an irreducible representation of the Clifford algebra: $\kappa y^a\circ B_{(\beta)}$ corresponds to the spinor multiplied by a γ matrix, $\gamma^a\psi_{(\beta)}$.

Up to this point the situation is similar to the SO(n) case, but differences will show up shortly.

2. Operators

As in the fermionic case, it proves advantageous to combine the expansion coefficients $\psi^{\alpha}_{(\beta)}$ as a matrix $\hat{\psi}$:

$$\hat{\psi}^{\alpha}{}_{\beta} \equiv \psi^{\alpha}_{(\beta)} \equiv \langle \alpha | \hat{\psi} | \beta \rangle. \tag{3.91}$$

(We suppress the argument ϕ for the time being.) We shall need some properties of the linear, invertible map $B \mapsto \hat{\psi}[B]$ which relates the symbols to the new operator $\hat{\psi}$.

By definition, $B(y)$ is the *ordinary* Weyl symbol of the operator $\hat{B}$ introduced earlier. Remarkably enough, this symbol plays a dual role: the same function but with its argument rescaled, $B(\frac{1}{2}y)$, turns out to be the *alternative* Weyl symbol of the new operator $\hat{\psi}$. This is most easily seen if one uses $\hat{Z}^{\dagger}(y) = \hat{T}(2y)$ in

$$\hat{\psi} = (\pi\hbar/2)^{-N} \int d^{2N}y B(y) \hat{Z}^{\dagger}(y), \tag{3.92}$$

$$B(y) = \mathrm{Tr}[\hat{Z}(y)\hat{\psi}], \tag{3.93}$$

which follows from the equations in Sec. III D 1, and then compares (3.92), (3.93) to Eqs. (3.10) and (3.11). Thus,

$$[\mathrm{symb}\{\hat{B}\}](y) = B(y) \Leftrightarrow [\text{alt-symb}\{\hat{\psi}\}](y) = B(\tfrac{1}{2}y). \tag{3.94}$$

This dual role played by B is another hint at the very natural relationship between the Dirac–Kähler idea and the Weyl symbol calculus.

Regarding $\hat{\psi}$ as a functional of B it is not difficult to establish that

$$\hat{\psi}[1] = 2^N \gamma_P, \tag{3.95}$$

$$\hat{\psi}[\kappa y^a] = 2^N \gamma^a \gamma_P, \tag{3.96}$$

$$\hat{\psi}[\kappa y^a \circ B] = \gamma^a \hat{\psi}[B], \tag{3.97}$$

$$\hat{\psi}[B_1 \circ B_2] = 2^{-N} \hat{\psi}[B_1] \gamma_P \hat{\psi}[B_2], \tag{3.98}$$

$$\hat{\psi}[\kappa^p y^{a_1} \circ y^{a_2} \circ \cdots y^{a_p}] = 2^N \gamma^{a_1} \gamma^{a_2} \cdots \gamma^{a_p} \gamma_P, \tag{3.99}$$

$$\hat{\psi}[\kappa^2 y^a y^b] = 2^N \gamma^a \gamma^b \gamma_P - 2^N i \omega^{ab} \gamma_P. \tag{3.100}$$

Equation (3.95) follows directly from the definition of γ_P and Eq. (3.97) is our earlier result (3.85), Eq. (3.96) being a special case. The most important relation is (3.98). It can be proven by using (3.80) and (3.93) in order to show that $B_1 \circ B_2 = 2^{-N} \mathrm{Tr}\{\hat{Z}\hat{\psi}[B_1]\gamma_P \hat{\psi}[B_2]\}$. When compared to Eq. (3.93), this equation implies (3.98).

Above we had introduced the projectors $\mathcal{P}_{(\beta)}$ which project any symbol on the invariant subspaces $\mathcal{W}_{(\beta)}$. The map $B \mapsto \hat{\psi}[B]$ given by (3.92) induces a corresponding projection on the space of operators $\hat{\psi}$. In the language of our auxiliary quantum mechanical system this projection has a very natural interpretation: it is simply the projection on the position eigenstate $|\beta\rangle$. From Eq. (3.84) we can read off that $B_{(\beta)}$ has the structure of an expectation value in the state $|\beta\rangle$,

$$B_{(\beta)}(y)=\langle\beta|\hat{Z}(y)\hat{\psi}[B]|\beta\rangle=\mathrm{Tr}[\hat{Z}(y)\hat{\psi}[B]\hat{P}_{(\beta)}]. \tag{3.101}$$

Here $\hat{P}_{(\beta)}\equiv|\beta\rangle\langle\beta|$ is the corresponding projector on the Hilbert space. It follows from (3.101) that symbols $B\in\mathcal{W}_{(\beta)}$ are associated to operators of the form $\hat{\psi}P_{(\beta)}$:

$$\hat{\psi}[\mathcal{P}_{(\beta)}B]=\hat{\psi}[B]\hat{P}_{(\beta)}. \tag{3.102}$$

Finally we have to address the important question of how the operator $\hat{\psi}$ is related to the operator $\hat{B}$ which was the central building block in the Dirac–Kähler construction. Imitating the SO(n) case, we had obtained $\hat{B}$ in Eq. (3.52) by replacing $d\phi^a\rightarrow\gamma^a$ in the tensor field $\mathbf{\Sigma}$. In Sec. II we have seen that for ordinary DK fields $\hat{\psi}$ and $\hat{F}$ coincide up to a constant factor. It is quite remarkable that, with a minor modification, the same identification is possible in the symplectic situation where $\mathcal{V}$ is infinite dimensional. It turns out that

$$\hat{\psi}[B]=2^N\hat{B}\gamma_P$$

or

$$\hat{B}=2^{-N}\hat{\psi}[B]\gamma_P. \tag{3.103}$$

This relationship can be proven in a variety of ways. For instance, we can take advantage of the following very compact representation of operators $\hat{b}$ in terms of their symbols b:[32]

$$\hat{b}=2^{-N}(2\pi\hbar)^{-N}\int d^{2N}y\,b(\tfrac{1}{2}y)\hat{T}(y)\gamma_P. \tag{3.104}$$

The advantage of (3.104) as compared to the old representation (3.10) is that no Fourier transformation is involved any longer. Equation (3.104) is easily established by inserting the integral representation for γ_P on its right-hand side and then combining the two Weyl operators with the help of (3.5). From Eq. (3.104) we infer that if $B(y)$ is the ordinary symbol of $\hat{B}$ then $B(\tfrac{1}{2}y)$ is the alternative Weyl symbol of $2^N\hat{B}\gamma_P$. Moreover, we saw already that $B(\tfrac{1}{2}y)$ is the alternative Weyl symbol of $\hat{\psi}$. As a consequence, $\hat{\psi}$ must coincide with $2^N\hat{B}\gamma_P$.

It is instructive to give a different proof when $B(y)$ is a power series. This is the case for instance when the symbol originates from an IST via the DK construction. For $\hat{B}$ or $B(y)$ given, the task is to solve $B(y)=\mathrm{Tr}[\hat{Z}(y)\hat{\psi}]$ for the unknown operator $\hat{\psi}$. Using the expansion (3.53) for B and the (expanded) exponential (3.77) for $\hat{Z}$, Eq. (3.104) turns into

$$B^{(p)}_{a_1\cdots a_p}=i^{-p}\,\mathrm{Tr}[\gamma_{(a_1}\cdots\gamma_{a_p)}\hat{\psi}]. \tag{3.105}$$

In the corresponding calculation for the SO(n) case we made an ansatz for $\hat{\psi}$ as a power series in γ^μ and used the γ^μ-trace identities in order to project on its coefficients. Because of the additional matrix γ_P in the analogous identities (3.45) for the metaplectic γ matrices the appropriate ansatz for the symplectic $\hat{\psi}$ is a power series in γ^a (with coefficients $\psi^{(p)}_{a_1\cdots a_p}$) times an explicit factor of γ_P. With this ansatz in (3.105), the trace identities imply $\psi^{(p)}_{a_1\cdots a_p}=2^NB^{(p)}_{a_1\cdots a_p}$ which proves (3.103). In this manner we see that the factor of γ_P connecting $\hat{\psi}$ to $\hat{B}$ is simply a reflection of the corresponding factor in the trace identities. We discussed already that in the infinite dimensional situation the γ_P under the traces is crucial in order to make them well defined.

The γ_P matrix in (3.103) has the consequence that $\hat{\psi}$ does not admit a power series expansion even if $\hat{B}$ does so. This has important implications for the Dirac–Kähler program. As we are going to discuss next it means that the decomposition of $\mathcal{W}$ into subspaces $\mathcal{W}_{(\alpha)}$ which are invariant under star left multiplication does *not* translate into a corresponding decomposition of the symmetric tensor algebra into subspaces invariant under (symplectic) Clifford left multiplication. In this respect the SO(n) and the Sp($2N$) cases are quite different.

Let us first look at how the space of operators $\hat{B}$ decomposes under $\mathcal{W}=\oplus\mathcal{W}_{(\beta)}$. Equations (3.102) and (3.103) imply that

$$\widehat{\mathcal{P}_{(\beta)}B}=\hat{B}\,\gamma_P\hat{P}_{(\beta)}\gamma_P=\hat{B}\hat{P}_{(-\beta)}\,. \tag{3.106}$$

Hence, at the level of the $\hat{B}$ operators, the projection $\mathcal{P}_{(\beta)}$ amounts to a right multiplication by $\hat{P}_{(-\beta)}$.

From Eq. (3.106) we can obtain a very useful by-product. If we take the symbol on both sides of this equation and abbreviate $P_{(\alpha)}\equiv\mathrm{symb}[\hat{P}_{(\alpha)}]$ then the result is the following compact formula for the projection $B_{(\beta)}$:

$$\mathcal{P}_{(\beta)}B\equiv B_{(\beta)}=B\circ P_{(-\beta)}\,. \tag{3.107}$$

More explicitly, because $P_{(\alpha)}(y)=\delta^{(N)}(y_q-\alpha)$, this means that

$$B_{(\beta)}(y)=B(y)\circ\delta^{(N)}(y_q+\beta). \tag{3.108}$$

By virtue of (3.21) the latter equation can be brought to the following form which is the most convenient one for practical calculations:

$$B_{(\beta)}(y_p,y_q)=B\left(y_p-\frac{i\hbar}{2}\frac{\partial}{\partial\overline{y_q}},y_q\right)\delta^{(N)}(\overline{y_q}+\beta)\bigg|_{\overline{y_q}=y_q}. \tag{3.109}$$

As usual, $y\equiv(y_p,y_q)$ consists of N-component momentum- and position-type variables y_p and y_q.

The structure of $B_{(\beta)}$ is particularly transparent if $B(y)\equiv B(y_q)$ does not depend on the momenta. Then its projection on $\mathcal{W}_{(\beta)}$ reads

$$B_{(\beta)}(y)=B(y_q)\,\delta^{(N)}(y_q+\beta), \tag{3.110}$$

i.e., it is sharply localized at $y_q=-\beta$. If B depends also on y_p there are additional terms involving derivatives of $\delta^{(N)}(y_q+\beta)$. Nevertheless, *as long as B depends on y polynomially, the projected symbol* $B_{(\beta)}$ *has support only on the hyperplane* $y_q=-\beta$. This localization of the symbols makes it very easy to visualize the β subspace of $\mathcal{W}$. In fact, this intuitive interpretation of $\mathcal{W}_{(\beta)}$ is the reason why we are using the $\hat{x}$ eigenbasis on $\mathcal{V}$ rather than the harmonic oscillator (Fock space) basis which yields the traditional representation of the γ^a matrices.

3. Inhomogeneous symmetric tensors

We know that every symbol-valued field $B(\phi,y)$ gives rise to infinitely many projections $B_{(\beta)}\in\mathcal{W}_{(\beta)}$ each of which is equivalent to a spinor $\psi_{(\beta)}$. On $\mathcal{W}_{(\beta)}$, $\kappa y^a\circ B_{(\beta)}$ corresponds to $\gamma^a\psi_{(\beta)}$ and it represents the Clifford algebra irreducibly. On the other hand, in Sec. III C we defined the symplectic Clifford product as the image of the star product under the symbol/tensor-correspondence (3.54). It is a natural question therefore whether the representation of the Clifford algebra provided by ''$d\phi^a\vee$'' on the space of symmetric tensors is reducible as well.

At this point we have to recall that the symbol/tensor-correspondence (3.54) is a bijection between tensors $\mathbf{\Sigma}(\phi)$ and symbols $B(\phi,y)$ which are *analytic in y*. Only if B allows for a power series expansion in y the substitution $\kappa y^a\to d\phi^a$ yields a tensor field. As for the question of the reducibility, the crucial observation is that *even if* $B(\phi,y)$ *is analytic in y, the projections* $B_{(\beta)}(\phi,y)$ *are not in general*. This is obvious from Eq. (3.109) which shows that $B_{(\beta)}$ is typically a distribution with a sharp localization (in the auxiliary phase space) on the plane $y_q=-\beta$.

Therefore we must conclude that the decomposition of the bosonic Weyl algebra $\mathcal{W} = \oplus \mathcal{W}_{(\beta)}$ does not imply a corresponding decomposition of the space of ISTs. This was different in the fermionic case where the analyticity of $F(x,\theta)$ comes for free and where ''symbol-valued fields'' and ''inhomogeneous differential forms'' are two completely equivalent concepts.

From these observations we can learn what the correct notion of a ''symplectic Dirac–Kähler field'' actually is. Traditionally, in the SO(N) case, a DK field meant a set of (antisymmetric) tensor fields. This is a historic accident, however, and one could have talked equally well about $\mathcal{W}^F$-valued fields over space–time. When we go from space–time to phase space and from SO(n) to Sp($2N$) we see that the notion which generalizes is not that of a collection (of now symmetric) tensor fields but rather the idea of Weyl symbol-valued fields. On phase space the fields $B(\phi,y)$, with a not necessarily analytic dependence on y, play a role which is completely analogous to that of $F(x,\theta)$ on space–time. The former is equivalent to a set of Mp($2N$) spinors in very much the same way as the latter gives rise to a multiplet of Spin(n) spinors.

IV. SUMMARY AND DISCUSSION

In the first part of this paper we have shown that the theory of space–time DK fermions allows for a remarkably simple and natural reinterpretation in the framework of the symbol calculus. More precisely, it is the fermionic Weyl symbol which is to be used here. This symbol was employed in the context of first quantized particle and string theory occasionally, but so far it has not reached the popularity of the Wick symbol which is commonly chosen for fermionic systems.

We have set up a one-to-one correspondence between DK fields $\Phi(x)$ and symbol-valued fields $F(x,\theta)$ by associating a family of auxiliary quantum systems, with canonical operators $\hat{\chi}^\mu$ and anticommuting phase-space coordinates θ^μ, to each point x of space–time. The fermionic operators $\hat{\chi}^\mu$ and Grassmann variables θ^μ replace the Dirac matrices γ^μ and the differentials dx^μ, respectively. The nontrivial aspect of this correspondence is that it maps all the natural operations which we know for differential forms onto equally natural and well-known operations for symbols. For instance, the star product which is at the heart of every symbol calculus turned out to be related to the Clifford product, a pivotal concept in standard DK theory, in precisely this manner. More generally, we were able to identify all the defining structures of an Atiyah–Kähler algebra on the space of fermionic Weyl symbols.

Our approach provides some new computational tools for calculations involving DK fields, an integral representation of the Clifford product, for example. More important, it sheds new light on the geometrical meaning of various constructions in the standard approach. For instance, the matrix-valued form Z has turned out to be nothing but a fermionic Weyl operator.

In the second part of this paper we developed a symplectic analog of DK theory. We replaced space–time by phase space, the ''Lorentz group'' SO(n) by Sp($2N$), Dirac fields by metaplectic spinors, and we then asked if there exists a corresponding notion of a DK field. The answer turned out to be in the affirmative, but with some qualifications. The crucial step in our construction was switching from the fermionic auxiliary quantum system to a bosonic one whose basic operators $\hat{\varphi}^a$ satisfy canonical commutation relations and thus realize the symplectic Clifford algebra. Using the Riemannian situation as a guideline we formulated the auxiliary quantum theory in terms of (now bosonic) Weyl symbols. We argued that it is the symbol-valued fields $B(\phi,y)$ which deserve the name of a ''symplectic Dirac–Kähler field.'' The fields with an analytic dependence on y are equivalent to a set of symmetric tensor fields, the symplectic counterpart of an inhomogeneous differential form. We described in detail which properties of the standard DK fields pass over to the symplectic case and which do not. We discovered for example that all the defining structures of an Atiyah–Kähler algebra have analogs in the symplectic setting. In particular, the bosonic Weyl star product gives rise to a ''Clifford product.''

It is an interesting feature of this method that both the ordinary and the symplectic Clifford product arise as a quantum deformation (in the sense of Ref. 24) of the corresponding tensor product (wedge product and $\otimes_{\text{sym}}$), the deformation parameter being $\hbar$ or κ^{-2}. (In order to make this explicit at the tensor level one should refrain from the convenient rescaling of the tensor components by factors of κ.)

The most important differences between the Riemannian and the symplectic case occur when it comes to decomposing the representation of the Clifford algebra carried by the symbol-valued fields. While the decomposition of the bosonic Weyl algebra into left invariant subspaces can be carried out along the same lines as for the fermionic algebra, it does not induce a corresponding decomposition of the space of inhomogeneous symmetric tensor fields. The reason is that the projection on the invariant subspaces does not respect the analyticity of $B(\phi,y)$ which is necessary for a tensor interpretation. We take this as a hint that it is actually the concept of a Weyl-algebra-valued field which is at the heart of DK theory, both on space–time and on phase space, rather than the idea of inhomogeneous (anti)symmetric tensors. The fields $B(\phi,y)$ are equivalent to a multiplet of metaplectic spinors in the same way an ordinary DK field is equivalent to a multiplet of Dirac spinors.

Let us close with a few additional comments.

We begin with a remark on what it precisely means that a DK field is ''equivalent'' to a set of spinor fields. This remark applies to SO(n) and Sp($2N$) DK fields alike. Strictly speaking, a metaplectic spinor is defined by its transformation properties under local Sp($2N$) transformations, the phase-space analog of the local Lorentz transformations. (See Ref. 21 for a detailed discussion of those transformation properties and of the vielbein formalism for phase spaces.) Let us fix some point ϕ of $\mathcal{M}_{2N}$ and let us change the basis in its tangent space $T_\phi\mathcal{M}_{2N}$ by means of a symplectic matrix $S(\phi)\equiv[S(\phi)^a{}_b]$. This induces a corresponding unitary transformation $M(S)\in \mathrm{Mp}(2N)$ in the local Hilbert space $\mathcal{V}_\phi$. The components of a vector and a spinor transform as $y^a \to (S^{-1})^a{}_b y^b$ and $\psi^\alpha \to M(S)^\alpha{}_\beta \psi^\beta$, respectively. It is important to observe that the spinors contained in a DK field $B(\phi,y)$ do not individually transform in this manner. In fact, as a direct consequence of (1.2) the $\hat{Z}$ operator transforms according to

$$M(S)^\dagger \hat{Z}(y) M(S) = \hat{Z}(S^{-1}y). \tag{4.1}$$

Therefore Eq. (3.93) reads in the rotated basis

$$B(\phi,S^{-1}y) = \mathrm{Tr}[\hat{Z}(y) M(S) \hat{\psi}(\phi) M(S)^\dagger]. \tag{4.2}$$

This means that $\hat{\psi}\equiv(\psi^\alpha_{(\beta)})$ does not transform as a set of independent spinors labeled by the index β. The index β, too, is acted upon by a spin matrix:

$$\psi^\alpha_{(\beta)} \to M(S)^\alpha{}_\gamma \psi^\gamma_{(\delta)} M^\dagger(S)^\delta{}_\beta. \tag{4.3}$$

For space–time DK fields this is a well-known phenomenon which is referred to as ''flavor mixing.''[3] Among other things it implies that DK fermions have a nonstandard coupling to gravity.[2,42,6] The curved-space Dirac equation for a massless DK field reads

$$\gamma^\mu(\partial_\mu \hat{\psi} - i\omega_\mu^{IJ}[\sigma_{IJ},\hat{\psi}]) = 0. \tag{4.4}$$

If $\hat{\psi}$ was a set of independent spinors the spin connection $\omega_\mu^{IJ}\sigma_{IJ}$ multiplied $\hat{\psi}$ from the left only. The flavor mixing caused by the commutator is weak in the Newtonian limit of gravity and most probably cannot be excluded on experimental grounds.[42]

Finally let us comment on the relation of the symplectic DK fields to the gauge theory formulation of quantum mechanics[21] which was proposed recently. Its basic ingredient is a family of local Hilbert spaces $\mathcal{V}_\phi$ attached to the points of phase space. (For different formulations of quantum (field) theory using local Hilbert spaces see Refs. 43, 31, and 44.) This theory resulted from an attempt at understanding the principles of canonical quantization at a perhaps deeper or at least physically and geometrically more natural level.

The theory is a Yang–Mills-type gauge theory on phase space. Its ''matter fields'' are metaplectic spinors $\psi^\alpha(\phi)$. Canonical quantization is replaced by two new rules. The first one is that in order to go from classical mechanics to semiclassical quantum mechanics we must switch from the vector representation of $\mathrm{Sp}(2N)$ to its spinor representation. The second rule is a consistency condition which tells us how to sew together local semiclassical expansions so as to recover exact quantum mechanics. It is formulated as symmetry principle: the Yang–Mills theory must be invariant under a new type of background-quantum split symmetry. As it turns out, this implies that the gauge field is a universal, nondynamical Abelian connection $\tilde{\Gamma}$. (The gauge group is the group of all unitary transformations on $\mathcal{V}$ and the connection components $\tilde{\Gamma}_a$ are Hermitian operators. Being Abelian means that the curvature of $\tilde{\Gamma}$ is proportional to the unit operator on $\mathcal{V}$.)

The upshot of this construction is the following two-step procedure for the quantization of physical systems on arbitrary curved phase spaces $\mathcal{M}_{2N}$

(1) Find an Abelian spin connection $\tilde{\Gamma}$ on $\mathcal{M}_{2N}$. It is guaranteed to exist on any symplectic manifold and can be constructed iteratively by Fedosov's method.[29,30,38]

(2) Construct (multi) spinor fields which are covariantly constant (possibly up to a phase) with respect to the connection $\tilde{\Gamma}$. They are local generalizations of states and observables.

In particular, states are represented by a covariantly constant spinor field $\psi^\alpha(\phi)$. If the value of this field is known at a fixed reference point ϕ_0 it is known everywhere in phase space (up to a physically irrelevant phase). The wave function $\mathbf{\Psi}$ of conventional quantum mechanics is identified with $\psi^\alpha(\phi_0)\equiv\mathbf{\Psi}(\alpha)$. For further details we refer to Ref. 21.

This approach reveals that, in a sense, classical mechanics is related to quantum mechanics in the same way tensor fields (integer spin) relate to spinor fields (half-integer spin) or space–time bosons relate to fermions. What is at the heart of the quantization process is changing the representation of $\mathrm{Sp}(2N)$, the ''Lorentz group'' of phase space.

According to the proposal of Ref. 21 this change of representation, while very natural from a particle physics point of view, still has to be done ''by hand'' in the same sense as in the standard approach the canonical commutation relations are imposed ''by hand.'' One might wonder if there is a more natural way of describing this change of representation, and it is here that Dirac–Kähler theory comes into play. DK theory certainly cannot *explain* why nature has decided to pick the spinor representation of $\mathrm{Sp}(2N)$ but it can put this question into a novel and perhaps somewhat unexpected perspective.

The symplectic DK fields give a precise meaning to the idea that classical mechanics ''contains'' the basic building blocks of quantum mechanics, namely the metaplectic spinor fields. On the one hand, the DK fields $B(\phi,y)$ belong to the realm of classical mechanics in the sense that they are c-number functions on the classical tangent bundle. On the other hand, $B(\phi,y)$ is equivalent to a family of spinor fields $\psi_{(\beta)}=(\psi^\alpha_{(\beta)})$ whose members are labeled by the ''flavor index'' β. Quantum mechanics is a theory whose basic ingredient is a *single* metaplectic spinor field. This leads us to conclude *that the process of quantization can be understood as the elimination of all but one flavor of metaplectic spinors, i.e., as a projection on a fixed* β*-subspace*. [Note, however, that covariantly constant DK fields do not amount to covariantly constant projected spinor fields. The reason is the flavor mixing: the condition $\nabla(\tilde{\Gamma})B=0$ involves a commutator of $\tilde{\Gamma}$ with B, while $\nabla(\tilde{\Gamma})\psi=0$ contains only a left-multiplication by $\tilde{\Gamma}$.]

In the same sense as above, this projection has to be done ''by hand.'' [1] (We mention that also the approach of Ref. 45 constructs quantum mechanics from functions on the classical tangent bundle by imposing certain constraints. This approach does not involve metaplectic spinors, however, and the DK construction seems not to answer the questions raised there.) However, with this interpretation, there is an almost perfect analogy between the following two problems which are usually thought of as belonging to rather different branches of physics: the construction of a lattice theory which describes a single species of fermions, and the quantization of physical systems in general. On the Riemannian (or space–time) side, the question is how to avoid the fermion replication which results from the Kogut–Susskind action, and the corresponding symplectic (or phase-space) problem is how to obtain a quantum theory from classical structures. At a heuristic level, the solution to both problems is exactly the same: one must project out a single spinor from a Dirac–Kähler field. Whether this is merely a formal similarity or whether space-time fermions can teach us something about the general structure of quantum mechanics remains to be seen.

ACKNOWLEDGMENTS

It is a pleasure to thank Professor H. Joos for introducing me to the Dirac–Kähler equation long ago and for many interesting discussions ever since. I am also grateful to E. Gozzi for numerous helpful conversations and for the hospitality at the Department of Theoretical Physics, University of Trieste, while this work was in progress. This project was supported in part by a NATO traveling grant.

APPENDIX A: GRASSMANN ALGEBRAS

In this appendix we collect a number of definitions and identities related to Grassmann algebras which are needed in the main body of the paper. In particular, the main automorphism $\mathcal{A}$, the main antiautomorphism $\mathcal{B}$, the Hodge operator $*$, and the modified Hodge operator $\star$ are discussed and our conventions are specified.

We consider a Grassmann algebra with the real generators $\theta^1,\dots,\theta^n$, i.e., $\theta^\mu\theta^\nu+\theta^\nu\theta^\mu=0$ for all $\mu,\nu=1,...,n$, and introduce functions

$$f(\theta)\equiv f(\theta^1,\dots,\theta^n)=\sum_{p=0}^{n} f^{(p)}(\theta), \tag{A1}$$

where $f^{(p)}$ is homogeneous of degree p:

$$f^{(p)}(\theta)=\frac{1}{p!}f^{(p)}_{\mu_1\cdots\mu_p}\theta^{\mu_1}\cdots\theta^{\mu_p}. \tag{A2}$$

The complex-valued constants $f_{\mu_1\cdots\mu_p}$ are completely antisymmetric in all indices. By definition, the main automorphism $\mathcal{A}$ and the main antiautomorphism $\mathcal{B}$ act on these functions according to

$$(\mathcal{A}f)(\theta)=\sum_{p=0}^{n}(-1)^p f^{(p)}(\theta), \tag{A3}$$

$$(\mathcal{B}f)(\theta)=\sum_{p=0}^{n}(-1)^{p(p-1)/2} f^{(p)}(\theta). \tag{A4}$$

Their main properties are

$$\begin{gathered}\mathcal{A}^2=\mathcal{B}^2=1,\quad \mathcal{A}\mathcal{B}=\mathcal{B}\mathcal{A},\\ \mathcal{A}(fg)=(\mathcal{A}f)(\mathcal{A}g),\\ \mathcal{B}(fg)=(\mathcal{B}g)(\mathcal{B}f),\end{gathered} \tag{A5}$$

where $(fg)(\theta)\equiv f(\theta)g(\theta)$ is the pointwise product. Some useful identities involving $\mathcal{A}$ and $\mathcal{B}$ include

$$\theta^\mu f(\theta)=(\mathcal{A}f)(\theta)\,\theta^\mu, \tag{A6}$$

$$\theta^{\mu_1}\cdots\theta^{\mu_p}f(\theta)=(\mathcal{A}^p f)(\theta)\,\theta^{\mu_1}\cdots\theta^{\mu_p}, \tag{A7}$$

$$\theta^{\mu_p}\theta^{\mu_{p-1}}\cdots\theta^{\mu_1}=(-1)^{p(p-1)/2}\theta^{\mu_1}\theta^{\mu_2}\cdots\theta^{\mu_p}=\mathcal{B}\theta^{\mu_1}\theta^{\mu_2}\cdots\theta^{\mu_p}. \tag{A8}$$

Denoting complex conjugation by an overbar we assume $\overline{\theta^\mu}=\theta^\mu$ and set

$$\overline{fg}=\overline{g}\,\overline{f} \tag{A9}$$

for any two functions f and g. If one makes the additional assumption that the coefficients $f^{(p)}_{\mu_1\cdots\mu_p}$ are real, then Eq. (A8) shows that

$$\overline{f(\theta)}=(\mathcal{B}f)(\theta). \tag{A10}$$

Usually we shall allow the coefficients to be complex though. The automorphism $\mathcal{A}$ can be used in order to convert right-derivatives $\overleftarrow{\partial}/\partial\theta^\mu$ to left-derivatives $\overrightarrow{\partial}/\partial\theta^\mu\equiv\partial/\partial\theta^\mu$:

$$f(\theta)\frac{\overleftarrow{\partial}}{\partial\theta^\mu}=\mathcal{A}\frac{\partial}{\partial\theta^\mu}f(\theta). \tag{A11}$$

More generally, one has

$$f(\theta)\frac{\overleftarrow{\partial}}{\partial\theta^{\mu_p}}\cdots\frac{\overleftarrow{\partial}}{\partial\theta^{\mu_1}}=\mathcal{A}^p\frac{\partial}{\partial\theta^{\mu_p}}\cdots\frac{\partial}{\partial\theta^{\mu_1}}f(\theta), \tag{A12}$$

which is easily proven by induction. Since $\mathcal{A}$ anticommutes with $\partial/\partial\theta^\mu$, it follows that ($p,q=0,1,2,...$)

$$\mathcal{A}^q\frac{\partial}{\partial\theta^{\mu_1}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}f(\theta)=(-1)^{pq}\frac{\partial}{\partial\theta^{\mu_1}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}\mathcal{A}^qf(\theta). \tag{A13}$$

In particular,

$$\mathcal{A}^p\frac{\partial}{\partial\theta^{\mu_1}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}f(\theta)=(-1)^{p}\frac{\partial}{\partial\theta^{\mu_1}}\cdots\frac{\partial}{\partial\theta^{\mu_p}}\mathcal{A}^pf(\theta). \tag{A14}$$

These identities will be needed in order to establish the equivalence of the Clifford product and the fermionic star product.

Our conventions for the integration are $\int d\theta^\mu=0$ and $\int\theta^\mu\,d\theta^\mu=1$ (μ not summed). We define

$$d^n\theta\equiv d\theta^1 d\theta^2\cdots d\theta^n \tag{A15}$$

so that

$$\int\theta^{\mu_n}\theta^{\mu_{n-1}}\cdots\theta^{\mu_1}d^n\theta=\epsilon^{\mu_1\mu_2\cdots\mu_n} \tag{A16}$$

with $\epsilon^{12\cdots n}=+1$. Using (A11) one can show that

$$\int f(\theta)\frac{\partial}{\partial\theta^\mu}g(\theta)d^n\theta=\int f(\theta)\frac{\overleftarrow{\partial}}{\partial\theta^\mu}g(\theta)d^n\theta \tag{A17}$$

for arbitrary inhomogeneous functions f and g.

In our conventions, the delta function is defined to satisfy

$$\int f(\theta)\delta(\theta-\xi)d^n\theta=f(\xi). \tag{A18}$$

(Note the order of the factors.) It is given by

$$\delta(\theta-\xi)=(\theta^n-\xi^n)(\theta^{n-1}-\xi^{n-1})\cdots(\theta^1-\xi^1) \tag{A19}$$

or by the Fourier representation

$$\delta(\theta-\xi)=(-1)^{n(n-1)/2}\int e^{(\theta^\mu-\xi^\mu)\rho_\mu}d^n\rho. \tag{A20}$$

Here $\{\xi^1,\ldots,\xi^n\}$ and $\{\rho_1,\ldots,\rho_n\}$ are two additional sets of real Grassmann variables which anticommute among themselves and with the θ's. (Indices are raised and lowered with the flat metric $g_{\mu\nu}=\delta_{\mu\nu}$.) Depending on the value of n, δ is either Grassmann real or purely imaginary:

$$\overline{\delta(\theta)}=(-1)^{n(n-1)/2}\delta(\theta). \tag{A21}$$

The Fourier transform $\tilde{f}$ is defined according to

$$\tilde{f}(\rho)=\epsilon_n^{-1}\int e^{i\theta^\mu\rho_\mu}f(\theta)d^n\theta \tag{A22}$$

with (all formulas given in this appendix are valid for both n even and n odd)

$$\epsilon_n\equiv\begin{cases}1: & \text{for } n \text{ even}\\ -i: & \text{for } n \text{ odd.}\end{cases} \tag{A23}$$

The advantage of our conventions is that they give rise to a simple formula for $\tilde{f}$ in terms of multiple derivatives of the δ function which is free from explicit sign factors and powers of i. One obtains

$$\tilde{f}(\rho)=f\left(i\frac{\partial}{\partial\rho}\right)\delta(\rho) \tag{A24}$$

because with (A20)

$$\tilde{f}(\rho)=\epsilon_n^{-1}\int f\left(i\frac{\partial}{\partial\rho}\right)e^{i\theta^\mu\rho_\mu}d^n\theta=f\left(i\frac{\partial}{\partial\rho}\right)\epsilon_n^{-1}(-1)^{n(n-1)/2}\delta(-i\rho)=f\left(i\frac{\partial}{\partial\rho}\right)\delta(\rho). \tag{A25}$$

In particular,

$$f(\theta)=1\Rightarrow\tilde{f}(\rho)=\delta(\rho). \tag{A26}$$

The inverse transformation reads

$$f(\theta)=\int e^{-i\theta^\mu\rho_\mu}\tilde{f}(\rho)d^n\rho. \tag{A27}$$

The Grassmann Fourier transformation has the involutive property

$$\tilde{\tilde{f}}(\theta)=\epsilon_n^{-1}f(\theta), \tag{A28}$$

i.e., for n even it is an exact involution. Derivative and multiplication operators are conjugate in the sense that

$$[\widetilde{\theta^\mu f(\theta)}](\rho)=i\frac{\partial}{\partial\rho_\mu}\tilde{f}(\rho), \tag{A29}$$

$$\left[i \widetilde{\frac{\partial}{\partial \theta^\mu} f(\theta)} \right](\rho) = \rho_\mu \tilde{f}(\rho). \tag{A30}$$

Using either (A22) or (A24) one can work out the Fourier transform of a product of θ's. The result is

$$[\theta^{\mu_1} \widetilde{\theta^{\mu_2} \cdots} \theta^{\mu_p}](\rho) = \frac{C_{np}}{(n-p)!} \epsilon^{\mu_1 \cdots \mu_p \nu_1 \cdots \nu_{n-p}} \rho_{\nu_1} \rho_{\nu_2} \cdots \rho_{\nu_{n-p}} \tag{A31}$$

with the constants

$$C_{np} \equiv i^p (-1)^{p(p-1)/2} (-1)^{n(n-1)/2}. \tag{A32}$$

Identifying $dx^\mu \equiv \theta^\mu$, the exterior algebra $\bigwedge(T_x^* \mathbf{R}^n)$ endowed with the inner product coming from $g_{\mu\nu} = \delta_{\mu\nu}$ provides a special example of a Grassmann algebra. In this context we are familiar with the notion of a Hodge star operator which maps p forms onto $(n-p)$ forms. In the case at hand we introduce a corresponding linear map $*: f(\theta) \mapsto (*f)(\theta)$ which generalizes this concept. On the basis elements, the Hodge operator acts according to

$$*(\theta^{\mu_1} \cdots \theta^{\mu_p}) = \frac{1}{(n-p)!} \epsilon^{\mu_1 \cdots \mu_p}{}_{\nu_1 \cdots \nu_{n-p}} \theta^{\nu_1} \cdots \theta^{\nu_{n-p}} \tag{A33}$$

and it is extended to arbitrary functions $f(\theta)$ by linearity. Writing $(*f)(\theta) = \Sigma_{p=0}^n (1/p!) \times [*f]^{(p)}_{\mu_1 \cdots \mu_p} \theta^{\mu_1} \cdots \theta^{\mu_p}$ one finds for the components

$$[*f]^{(n-p)}_{\mu_1 \cdots \mu_{n-p}} = \frac{1}{p!} f^{(p)}_{\nu_1 \cdots \nu_p} \epsilon^{\nu_1 \cdots \nu_p}{}_{\mu_1 \cdots \mu_{n-p}}. \tag{A34}$$

(Note that in parts of the literature a different definition of $*$ is used which amounts to interchanging the transformation laws of the basis vectors and the components, respectively.) Acting twice with $*$ on a homogeneous function of degree p the result is

$$** f^{(p)} = (-1)^{p(n-p)} f^{(p)}. \tag{A35}$$

Because of the p-dependent sign factor on the right-hand side of (A35) the star operator does not give rise to an involution on the space of all (i.e., inhomogeneous) functions. This motivates us to introduce the operator

$$\star \equiv * \mathcal{B}, \tag{A36}$$

which we shall refer to as the ''modified Hodge operator.'' For homogeneous functions,

$$\star f^{(p)} = (-1)^{p(p-1)/2} * f^{(p)}, \tag{A37}$$

which implies

$$\star\star f^{(p)} = (-1)^{n(n-1)/2} f^{(p)} \tag{A38}$$

with a sign factor independent of p. Hence, for any inhomogeneous function f,

$$\star\star f = (-1)^{n(n-1)/2} f. \tag{A39}$$

For $n=4$, say, $\star\star = 1$ so that $\star$ is an exact involution.

The (modified) Hodge operator is closely related to the Grassmann Fourier transformation. Comparing (A31) to (A33) shows that for homogeneous functions

$$*f^{(p)}=(-i)^{p}(-1)^{p(p-1)/2}(-1)^{n(n-1)/2}\widetilde{f^{(p)}},\tag{A40}$$

$$\star f^{(p)}=(-i)^{p}(-1)^{n(n-1)/2}\widetilde{f^{(p)}}.\tag{A41}$$

Using (A24) we may express the Fourier transform by the derivative of a δ function:

$$*f^{(p)}(\theta)=(-1)^{p(p-1)/2}(-1)^{n(n-1)/2}f^{(p)}\left(\frac{\partial}{\partial\theta}\right)\delta(\theta),\tag{A42}$$

$$\star f^{(p)}(\theta)=(-1)^{n(n-1)/2}f^{(p)}\left(\frac{\partial}{\partial\theta}\right)\delta(\theta).\tag{A43}$$

Note that the sign factor on the right-hand side of (A43) is independent of p. Hence it follows that for arbitrary inhomogeneous functions

$$\star f(\theta)=(-1)^{n(n-1)/2}f\left(\frac{\partial}{\partial\theta}\right)\delta(\theta).\tag{A44}$$

This is an interesting representation of the Hodge operator, because in contrast to (A33), Eq. (A44) continues to be meaningful if we regard θ^{μ} as a *commuting* variable. This fact will become important in the construction of the metaplectic DK fields.

APPENDIX B: REPRESENTATIONS OF THE FERMIONIC WEHL STAR PRODUCT

In this appendix we derive several important representations of the fermionic star product, Eqs. (2.15), (2.16), and (2.17), from the integral representation (2.14).

We start by shifting θ_1 and θ_2 in Eq. (2.14):

$$(f_1\circ f_2)(\theta)=\epsilon_n\left(\frac{\hbar}{2i}\right)^n\int\exp\left(\frac{2}{\hbar}\theta_1\theta_2\right)f_1(\theta_1+\theta)f_2(\theta_2+\theta)d^n\theta_1 d^n\theta_2.\tag{B1}$$

Next we Taylor-expand f_1 and f_2 with respect to θ_1 and θ_2. Because the exponential produces only terms with equal numbers of θ_1's and θ_2's, only those terms in the product of the two Taylor series survive the integration which contain equal numbers as well:

$$\begin{aligned}(f_1\circ f_2)(\theta)=\epsilon_n\left(\frac{\hbar}{2i}\right)^n\sum_{p=0}^{n}\left(\frac{1}{p!}\right)^2\int\exp\left(\frac{2}{\hbar}\theta_1\theta_2\right)[\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}\tilde{\partial}_{\mu_1}\cdots\tilde{\partial}_{\mu_p}f_1(\theta)]\\ \times[\theta_2^{\nu_1}\cdots\theta_2^{\nu_p}\tilde{\partial}_{\nu_1}\cdots\tilde{\partial}_{\nu_p}f_2(\theta)]d^n\theta_1 d^n\theta_2.\end{aligned}\tag{B2}$$

Here $\tilde{\partial}_\mu\equiv\partial/\partial\theta^\mu$. Because

$$(\theta^1\theta^2\cdots\theta^p)(\xi^1\xi^2\cdots\xi^p)=(-1)^p(\xi^1\xi^2\cdots\xi^p)(\theta^1\theta^2\cdots\theta^p)\tag{B3}$$

for two arbitrary sets of mutually anticommuting Grassmann-odd objects, we may use Eqs. (A7) and (A14) to write

$$\begin{aligned}\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}\tilde{\partial}_{\mu_1}\cdots\tilde{\partial}_{\mu_p}f_1(\theta)&=(-1)^p\tilde{\partial}_{\mu_1}\cdots\tilde{\partial}_{\mu_p}\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}f_1(\theta)\\ &=(-1)^p\tilde{\partial}_{\mu_1}\cdots\tilde{\partial}_{\mu_p}(\mathcal{A}^pf_1)(\theta)\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}\\ &=[\mathcal{A}^p\tilde{\partial}_{\mu_1}\cdots\tilde{\partial}_{\mu_p}f_1(\theta)]\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}.\end{aligned}\tag{B4}$$

Thus we arrive at

$$(f_1\circ f_2)(\theta)=\epsilon_n\left(\frac{\hbar}{2i}\right)^n\sum_{p=0}^{n}\left(\frac{1}{p!}\right)^2[\mathcal{A}^p\tilde{\partial}_{\mu_1}\cdots\tilde{\partial}_{\mu_p}f_1(\theta)]I^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}[\tilde{\partial}^{\nu_1}\cdots\tilde{\partial}^{\nu_p}f_2(\theta)] \tag{B5}$$

with

$$I^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}=\int\exp\left(\frac{2}{\hbar}\theta_1\theta_2\right)\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}\theta_{2\nu_1}\cdots\theta_{2\nu_p}d^n\theta_1 d^n\theta_2. \tag{B6}$$

Upon expanding the exponential, only the term of order $n-p$ can contribute to the integral:

$$I^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}=\frac{1}{(n-p)!}\left(\frac{2}{\hbar}\right)^{n-p}J^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}, \tag{B7}$$

$$J^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}\equiv\int(\theta_1^\alpha\theta_{2\alpha})^{n-p}\theta_1^{\mu_1}\cdots\theta_1^{\mu_p}\theta_{2\nu_1}\cdots\theta_{2\nu_p}d^n\theta_1 d^n\theta_2. \tag{B8}$$

For symmetry reasons the tensor J must have the structure

$$J^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}=\lambda(n,p)\delta^{[\mu_1}_{\nu_1}\cdots\delta^{\mu_p]}_{\nu_p}=\frac{\lambda(n,p)}{p!}\sum_{\pi\in\mathcal{S}_p}\mathrm{sign}(\pi)\delta^{\pi(\mu_1)}_{\nu_1}\delta^{\pi(\mu_2)}_{\nu_2}\cdots\delta^{\pi(\mu_p)}_{\nu_p}, \tag{B9}$$

where $\mathcal{S}_p$ is the symmetric group of p objects. The constants $\lambda(n,p)$ are most easily determined by choosing the special index combination $J^{12\cdots p}_{12\cdots p}$ for which only the identical permutation contributes in (B9). Furthermore, the summation over α in (B8) is restricted to $\alpha>p$ then:

$$\begin{aligned}\lambda(n,p)&=p!\int[\theta_1^{p+1}\theta_2^{p+1}+\cdots+\theta_1^n\theta_2^n]^{n-p}(\theta_1^1\theta_1^2\cdots\theta_1^p)(\theta_2^1\theta_2^2\cdots\theta_2^p)d^n\theta_1 d^n\theta_2\\&=p!(n-p)!\int(\theta_1^1\theta_1^2\cdots\theta_1^p)[\theta_1^{p+1}\theta_2^{p+1}\theta_1^{p+2}\theta_2^{p+2}\cdots\theta_1^n\theta_2^n](\theta_2^1\theta_2^2\cdots\theta_2^p)d^n\theta_1 d^n\theta_2.\end{aligned} \tag{B10}$$

Commuting the θ's next to the corresponding $d\theta$'s produces various sign factors so that finally

$$\lambda(n,p)=(-1)^n(-1)^{n(n-1)/2}(-1)^{p(p-1)/2}p!(n-p)! \tag{B11}$$

If we note that $\epsilon_n i^n(-1)^{n(n-1)/2}=1$ both for n even and n odd, we see that

$$\epsilon_n\left(\frac{\hbar}{2i}\right)^n\frac{1}{p!}I^{\mu_1\cdots\mu_p}_{\nu_1\cdots\nu_p}=(-1)^{p(p-1)/2}\left(\frac{\hbar}{2}\right)^p\delta^{[\mu_1}_{\nu_1}\cdots\delta^{\mu_p]}_{\nu_p}. \tag{B12}$$

Inserting (B12) into (B5) we obtain precisely the final result given in Eq. (2.15) of the main text.

The representation (2.16) follows from (2.15) by using (A12) in order to convert the left derivatives which act on f_1 to right derivatives. One also needs (A8) to switch from the index sequence $(\mu_1,\mu_2,\ldots,\mu_p)$ to $(\mu_p,\mu_{p-1},\ldots,\mu_1)$.

The last representation, Eq. (2.17), follows from (2.16) by commuting left and right derivatives with the same index next to each other. No sign factor is picked up during this reshuffling.

World-line Green functions with momentum and source conservations

Haru-Tada Sato[a)]
Institut für Theoretische Physik, Universität Heidelberg, Philosophenweg 16, D-69120 Heidelberg, Germany

(Received 11 May 1999; accepted for publication 4 August 1999)

Based on the generating functional method with an external source function, a useful constraint on the source function is proposed for analyzing the one- and two-loop world-line Green functions. The constraint plays the same role as the momentum conservation law of a certain nontrivial form, and transforms ambiguous Green functions into the uniquely defined Green functions. We also argue reparametrizations of the Green functions defined on differently parameterized world-line diagrams. © *1999 American Institute of Physics.*

I. INTRODUCTION

String theory organizes the scattering amplitudes in a very compact form (in the infinite string tension limit), and this fact makes the investigation of field theory scattering amplitudes very nontrivial and potentially useful.[1–5] In this spirit, multiloop scattering amplitudes have also been studied both from the string theory viewpoint[6–9] and the field theory based on the first quantization formalism (world-line formalism).[10–14] The general structure of field theory amplitudes (with N external momenta $p_1, p_2, \ldots, p_N$) at the one-loop order is described as[1,2]

$$\Gamma_N = \int_0^\infty \frac{dT}{T}\left(\frac{1}{4\pi T}\right)^{D/2}\left(\prod_{n=1}^{N}\int_0^T d\tau_n\right)K(\tau_1,\tau_2,\ldots,\tau_n;T)\exp\left[\frac{1}{2}\sum_{j,k=1}^{N} p_j\cdot p_k G_B(\tau_j,\tau_k)\right], \tag{1.1}$$

where K is a certain function which depends on the detail of theory in question (it can be determined systematically). The exponent including the function G_B is sometimes called the generating kinematical factor, and is a theory independent object. G_B is the (world-line) Green function between two points on a loop of length T. One can similarly write down the generalized formulas for certain multiloop cases[9,13] with using multiloop Green functions.[8,11] In this sense, determinations of multiloop Green functions are important factors in the world-line formalism.

On the whole, there are three kinds of computation methods to obtain the world-line Green functions: (i) invert kinematic terms (solve differential equations); (ii) define as Gaussian determinants or compute two-point correlators in the path integral method; (iii) similar as the second method, but reducing the path integrals into ordinary integrals (thus no appearance of determinants). Depending on the computation methods, different forms for Green functions have been obtained (we show several examples in the main text), and a natural question raised from this observation is whether or not they all describe the same amplitudes when applied to the amplitude formulas such as (1.1). The answer should be yes if the formalism is self-consistent. We call this problem the ambiguity problem of Green functions, and there must be a reason why we are allowed to have a variety of Green functions for a unique amplitude. Once we find a prescription for this problem, we shall be able to ignore the existence of various ambiguous Green functions, and rather understand them all as a family of Green functions.

[a)]Electronic mail: sato@thphys.uni-heidelberg.de

In this paper, we focus on the ambiguity problem of the multiloop Green functions. This is an important problem from the above viewpoint: All of ambiguous Green functions should be reduced to the uniquely defined ones under the constraint of a vanishing identity, without changing the value of a kinematical factor. The problem is trivial in the one-loop case, and summarized as follows. In the original definition

$$\frac{1}{2}\partial^2 G_B(\tau)=\delta(\tau)-\frac{1}{T} \tag{1.2}$$

with imposing rotational invariance and periodicity, G_B is uniquely determined as the rotational symmetric form

$$G_B(\tau_1,\tau_2)=G_B(\tau_1-\tau_2)=|\tau_1-\tau_2|-\frac{(\tau_1-\tau_2)^2}{T}. \tag{1.3}$$

However, we do not necessarily use this functional form as concerns the kinematical factor itself, which actually does not change if we add a polynomial in τ_j to the $G_B(\tau_j,\tau_k)$ in (1.1) because of the conservation law $\Sigma_k p_k=0$. This ambiguity is very easy to verify in the one-loop case, where the defining equation of G_B is simple and its rotational invariance should be clear. On the other hand, in multiloop cases, the situation is much too complicated to identify the ambiguity which can be canceled by a certain condition such as conservation law, because the definitions and calculations of multiloop Green functions are in general complicated—in addition that the rotational invariance is unclear in certain cases.

As the simplest nontrivial example, we discuss the two-loop Green functions.[11,12] We refer to the Green functions containing the ambiguity as the *wide sense* Green functions. As suggested above, the value of a kinematical factor should be invariant for any set of wide sense Green functions. Various wide sense Green functions can be obtained depending on how to define and evaluate, and we shall verify that all of them can be identified with each other in the sense of keeping the kinematical factor invariant by way of examples. To this end, we obviously need a constraint such as the total momentum conservation law. However, in the generic multiloop cases, a useful form of the conservation law is in practice not a simple summation (along the single loop as mentioned in the one-loop case), because of the presence of additional internal lines. We generalize the conservation law into a more suitable form to our purpose. In addition to the momentum conservation law, we also present a continuous analog of the conservation law; that is a constraint on the integrals of external source functions along the two-loop world-line vacuum diagram. This continuous version is very simple and useful to apply practical computations, and is nontrivial since such a constraint does not exist in the source term of the usual formulation of field theory.

In Sec. II, for notational conveniences, we briefly review the two-loop kinematical factor and the Green functions in ϕ^3 theory. In Sec. III, we present a useful two-loop momentum conservation formula, and demonstrate how to apply the formula to the identification of different wide sense Green functions. In Sec. IV, employing the generating functional method with external source functions,[14] we consider another derivation of the Green functions. In this case, we show that there also exists a similar constraint formula on the source functions, and verify that it plays the same role as the momentum conservation method of Sec. III. In Sec. V, we further confirm the validity and usefulness of the source constraint in more specific cases (one-loop QED). Section VI is a short note on the previous work,[12] concerning new reparametrization transformations of the two-loop Green functions. Section VII contains conclusions.

II. NOTATIONS

For the purpose of setting our notations, we briefly review the world-line Green functions and the master amplitude formulas corresponding to Eq. (1.1) in the two-loop ϕ^3 theory.[9,11,13] The (two-loop) master formula is a fundamental quantity which contains all necessary Feynman diagrams belonging to a certain class of diagrams. The classes are labeled by two or three integers (N',N_3) or (N_1,N_2,N_3), and amplitudes are certain combinations of these classes.[13] We call the first labeling the loop type, and the latter the symmetric type. The general form of the master formula is as follows:

$$\Gamma_M^{\text{2-loop}}=\frac{1}{12}(-g)^{N+2}\int dM(4\pi)^{-D}\Delta^{D/2}\exp[E_G]. \tag{2.1}$$

For the loop type parameterization $(N=N'+N_3)$, the integration measure dM is

$$dM=\frac{dT}{T}dT_3 d\tau_\alpha d\tau_\beta \prod_{n=1}^{N'} d\tau_n \prod_{l=1}^{N_3} d\tau_l^{(3)}, \tag{2.2}$$

and Δ is the determinant factor

$$\Delta=(TT_3+TG_B(\tau_\alpha,\tau_\beta))^{-1}. \tag{2.3}$$

The exponential part E_G, the generating kinematical factor, takes the following bilinear form in N external momenta $(p_j, p_k^{(3)};\ j=1,...,N';\ k=1,...,N_3)$:

$$E_G=\frac{1}{2}\sum_{j,k=1}^{N'} p_j p_k G_{00}^{(1)}(\tau_j,\tau_k)+\frac{1}{2}\sum_{j,k=1}^{N_3} p_j^{(3)} p_k^{(3)} G_{33}^{(1)}(\tau_j^{(3)},\tau_k^{(3)})+\sum_{j=1}^{N'}\sum_{k=1}^{N_3} p_j p_k^{(3)} G_{03}^{(1)}(\tau_j,\tau_k^{(3)}), \tag{2.4}$$

where the bilinear momenta should be understood as Lorentz contracted forms (hereafter as well). The explicit forms of these Green functions are[12]

$$G_{00}^{(1)}(\tau,\tau')=G_B(\tau,\tau')-\frac{1}{4}\frac{(G_B(\tau,\tau_\alpha)-G_B(\tau,\tau_\beta)-G_B(\tau',\tau_\alpha)+G_B(\tau',\tau_\beta))^2}{T_3+G_B(\tau_\alpha,\tau_\beta)}, \tag{2.5}$$

$$G_{33}^{(1)}(z_1,z_2)=G_{33}^{(1)}(z_1-z_2)==|z_1-z_2|-\frac{(z_1-z_2)^2}{T_3+G_B(\tau_\alpha,\tau_\beta)}, \tag{2.6}$$

$$G_{03}^{(1)}(\tau,z)=\begin{cases} G_{00}^{(1)}(\tau,\tau_\alpha)+\dfrac{1}{T_3+G_B(\tau_\alpha,\tau_\beta)}(T_3 z-z^2+z[G_B(\tau,\tau_\beta)-G_B(\tau,\tau_\alpha)]) & \text{for } \tau_\beta<\tau_\alpha \\ G_{00}^{(1)}(\tau,\tau_\beta)+\dfrac{1}{T_3+G_B(\tau_\alpha,\tau_\beta)}(T_3 z-z^2+z[G_B(\tau,\tau_\alpha)-G_B(\tau,\tau_\beta)]) & \text{for } \tau_\alpha<\tau_\beta. \end{cases} \tag{2.7}$$

The τ parameters $\{\tau_\alpha,\tau_\beta,\tau_n|n=1,...,N'\}$ run from zero to T, which stands for the length of a loop (fundamental loop), and $\tau_n^{(3)}$, $n=1,...,N_3$ run from zero to T_3, the length of the internal line (the rest part of the vacuum diagram). T and T_3 are to be integrated from zero to infinity. In Ref. 9, we pointed out that one may fix and eliminate one of the parameters $\{\tau_\alpha,\tau_\beta,\tau_n|n=1,...,N'\}$ because of the rotational symmetry of the fundamental loop. This means that we can set one of these parameters to be zero which corresponds to the origin of world-line coordinate along the fundamental loop. Obviously, $G_{00}^{(1)}$ is invariant under this rotation, and does not receive any serious change, however $G_{03}^{(1)}$ does not even possess any translational symmetry such as seen in $G_{33}^{(1)}$. Hence the explicit form of $G_{03}^{(1)}$ depends on which parameter will be set zero. For example, if we choose τ_β as such origin, $G_{03}^{(1)}$ should follow the form for $\tau_\beta<\tau_\alpha$. Similarly, if τ_α, then take for $\tau_\alpha<\tau_\beta$. There is also a different Green function[11] from Eq. (2.5). However, both coincide under the same momentum conservation constraint (for $N_3=0$) as the one-loop type.

Using the transformation obtained in Ref. 12, we can transform the above quantities to the other version (symmetric parameterization). It is done by dividing the fundamental loop into two pieces $T=T_1+T_2$ with $N'=N_1+N_2$ and $\{\tau_n\}\rightarrow\{\tau_n^{(1)},\tau_n^{(2)}\}$. In this case, we have[11]

$$dM=dT_1dT_2dT_3\prod_{i=1}^{3}\prod_{n=1}^{N_i}d\tau_n^{(i)}, \tag{2.8}$$

$$\Delta=(T_1T_2+T_2T_3+T_3T_1)^{-1}, \tag{2.9}$$

and

$$E_G=\frac{1}{2}\sum_{a=1}^{3}\sum_{j,k}^{N_a}p_j^{(a)}G_{aa}^{\text{sym}}(\tau_j^{(a)},\tau_k^{(a)})+\sum_{a=1}^{3}\sum_{j}^{N_a}\sum_{k}^{N_{a+1}}p_j^{(a)}p_k^{(a+1)}G_{aa+1}^{\text{sym}}(\tau_j^{(a)},\tau_k^{(a+1)}), \tag{2.10}$$

where we set $\tau^{(4)}=\tau^{(1)}$ and $N_4=N_1$, etc. in accord with the cyclic expression. The Green functions are[11]

$$G_{aa}^{\text{sym}}(\tau,\tau')=G_{aa}^{\text{sym}}(\tau-\tau')=|\tau-\tau'|-\frac{T_{a+1}+T_{a+2}}{T_1T_2+T_2T_3+T_3T_1}(\tau-\tau')^2, \tag{2.11}$$

$$G_{aa+1}^{\text{sym}}(\tau,\tau')=\tau+\tau'-\frac{\tau^2T_{a+1}+\tau'^2T_a+(\tau+\tau')^2T_{a+2}}{T_1T_2+T_2T_3+T_3T_1}. \tag{2.12}$$

All the formulas in this section are reproduced from string theory,[8,9] and in this sense, we refer to these Green functions (2.5)–(2.7), (2.11), and (2.12) as the standard forms.

III. MOMENTUM CONSERVATION CONSTRAINT

In this section, we encounter the (wide sense) Green functions of different forms, depending on calculation methods (in the symmetric parameterization). However, the value of E_G should be shown to be invariant under the constraint of total momentum conservation. In the one-loop case, as mentioned in the introduction, the constraint is expressed by the identity

$$\sum_{j=1}^{N}\sum_{k=1}^{N}p_j\cdot p_k\tau_k^m=0. \tag{3.1}$$

The single summation over all momenta p_j is nothing but the summation over the fundamental loop. However, the same structure cannot be seen in (2.4) or (2.10) for the $N_3\neq 0$ case. Hence, we shall derive a suitable two-loop generalization of this identity, and explain how it works. To illustrate the idea clearly, we need a couple of examples of different Green functions in the first place.

As explained in Ref. 13, Eq. (2.1) is obtained from the path integral

$$\Gamma_M^{\text{2-loop}}=\frac{(-g)^{N+2}}{2\cdot 3!}\int d^Dx_1d^Dx_2\prod_{a=1}^{3}\int_0^\infty dT_ae^{-m^2T_a}\int_{y_a(T_a)=x_1}^{y_a(0)=x_2}\mathcal{D}y_a(\tau)$$
$$\times\exp\left[-\int_0^{T_a}\frac{1}{4}\dot{y}_a^2d\tau^{(a)}\right]\prod_{n=1}^{N_a}\int_0^{T_a}d\tau_n^{(a)}e^{ip_n^{(a)}y(\tau_n^{(a)})} \tag{3.2}$$

by using the mode expansion

$$y_a(\tau)=x_1+\frac{\tau}{T_a}(x_2-x_1)+\sum_{m=1}^{\infty}y_m\sin\left(\frac{m\pi\tau}{T_a}\right). \tag{3.3}$$

A straightforward computation in this case shows that the E_G part is composed of the following Green functions instead of $G_{ab}^{\rm sym}$:

$$G_{aa}^M(\tau,\tau')=|\tau-\tau'|-(\tau+\tau')+2\,\frac{\tau\tau'}{T_a}\left(1-\Delta\,\frac{T_1T_2T_3}{T_a}\right), \tag{3.4}$$

$$G_{aa+1}^M(\tau,\tau')=-2\Delta T_1T_2T_3\;\frac{\tau\tau'}{T_aT_{a+1}}. \tag{3.5}$$

Note that the x_1 integration generates the total momentum conservation factor

$$(2\pi)^D\delta\left(\sum_a\sum_n^{N_a}p_n^{(a)}\right). \tag{3.6}$$

A second example is from Ref. 14. The world-line Green function should also be derived as a two-point function in the sense of ordinary field theory,

$$\mathcal{G}_{\mu\nu}(\tau_1^{(a)},\tau_2^{(b)})=\langle x_\mu(\tau_1^{(a)})x_\nu(\tau_2^{(b)})\rangle=\frac{\delta}{\delta J_a^\mu(\tau_1^{(a)})}\,\frac{\delta}{\delta J_c^\nu(\tau_2^{(b)})}\ln Z[J]\bigg|_{J=0}, \tag{3.7}$$

where the generating functional is given by

$$Z[J]\equiv\int d^Dy_1d^Dy_2\left(\prod_{a=1}^3\int_{x_a(0)=y_1}^{x_a(T_a)=y_2}\mathcal{D}x_a\right)\exp\left[-\frac{1}{4}\sum_a\int_0^{T_a}\dot{x}_a^2(\tau)d\tau+\sum_a\int_0^{T_a}J_a^\mu(\tau)x_a^\mu(\tau)d\tau\right]. \tag{3.8}$$

For later convenience, we here write the intermediate expression (putting $w=(y_1+y_2)/2$, $z=y_2-y_1$)

$$Z[J]=(\Pi_{a=1}^3(4\pi T_a)^{-D/2})\exp\left[-\frac{1}{2}\sum_{a=1}^3\int_0^{T_a}\int_0^{T_a}J_\mu^a(\tau)\tilde{G}_{\mu\nu}^{(a)}(\tau,\tau')J_\nu^a(\tau')d\tau d\tau'\right]$$
$$\times\int dzdw\prod_{a=1}^3\;\exp\left[w\int_0^{T_a}J^a(\tau)d\tau-\frac{1}{4}z^\mu A_{\mu\nu}^a z^\nu+z^\nu\int_0^{T_a}J_\mu^aR_{\mu\nu}^a\right] \tag{3.9}$$

as well as the final expression

$$Z[J]=i\,\delta^D\left(\sum_{a=1}^3\int_0^{T_a}J_a^\mu(\tau)d\tau\right)(4\pi)^{(D/2)}\left(\prod_{a=1}^3(4\pi T_a)^{(-D/2)}\right)\det\nolimits_L^{-(1/2)}\left(\sum_a A^a\right)$$
$$\times\exp\left[-\frac{1}{2}\sum_a\int_0^{T_a}\int_0^{T_a}J_\mu^a(\tau)\tilde{G}_{\mu\nu}^{(a)}(\tau,\tau')J_\nu^a(\tau')d\tau d\tau'\right]$$
$$\times\exp\left[\left(\sum_a A^a\right)_{\rho\sigma}^{-1}\left(\sum_a\int_0^{T_a}R_{\rho\mu}^aJ_\mu^a(\tau)d\tau\right)\left(\sum_c\int_0^{T_c}R_{\sigma\nu}^cJ_\nu^c(\tau)d\tau\right)\right], \tag{3.10}$$

where we take

$$A_{\mu\nu}^a=\delta_{\mu\nu}T_a^{-1},\quad R_{\mu\nu}^a=\left(\frac{\tau^{(a)}}{T_a}-\frac{1}{2}\right)\delta_{\mu\nu}, \tag{3.11}$$

and

$$\tilde{G}^{(a)}_{\mu\nu}(\tau_1,\tau_2)=\delta_{\mu\nu}\left(|\tau_1-\tau_2|-(\tau_1+\tau_2)+2\,\frac{\tau_1\tau_2}{T_a}\right). \tag{3.12}$$

A main difference from the first example is the existence of nonconstant source terms, where further τ integrations are formally impossible. This is the reason for having a different form of the Green function. Further decoupling the metric factor ($g_{\mu\nu}=-\delta_{\mu\nu}$),

$$\mathcal{G}_{\mu\nu}(\tau^{(a)},\tau^{(b)})=-g_{\mu\nu}G^J_{ab}(\tau^{(a)},\tau^{(b)}), \tag{3.13}$$

we actually derive the second different form

$$G^J_{ab}(\tau_1^{(a)},\tau_2^{(b)})=\delta_{ab}\left(|\tau_1^{(a)}-\tau_2^{(b)}|-(\tau_1^{(a)}+\tau_2^{(b)})+2\,\frac{\tau_1^{(a)}\tau_2^{(b)}}{T_a}\right)$$
$$-\frac{1}{2}(2\tau_1^{(a)}-T_a)(2\tau_2^{(b)}-T_b)\,\frac{T_1T_2T_3}{T_aT_b}\,\Delta. \tag{3.14}$$

Now, let us derive the two-loop version of the constraint (3.1). It can be derived by combining the trivial identities

$$\left(\sum_{a=1}^{3}\sum_{j=1}^{N_a}p_j^{(a)}\right)\sum_{k=1}^{N_b}p_k^{(b)}(\tau_k^{(b)})^m=0;\quad b=1,2,3 \tag{3.15}$$

with multiplying weight coefficients $C_m^{(b)}$. The result is arranged in the form suitable to E_G,

$$0=\sum_{a=1}^{3}\sum_{j,k}^{N_a}p_j^{(a)}p_k^{(a)}C_m^{(a)}(\tau_j^{(a)})^m+\sum_{a=1}^{3}\sum_{j}^{N_a}\sum_{k}^{N_{a+1}}p_j^{(a)}p_k^{(a+1)}(C_m^{(a)}(\tau_j^{(a)})^m+C_m^{(a+1)}(\tau_k^{(a+1)})^m), \tag{3.16}$$

where m is an arbitrary integer and the mth coefficient $C_m^{(a)}$ may depend only on T_a. One can add an arbitrary number of copies of this identity to E_G with different choices of $C_m^{(a)}$. Consider the E_G where G^M_{ab} is substituted for $G^{\rm sym}$ in (2.10), and add the identity (3.16) to the E_G. Then a new set of Green functions can be read from the modified E_G as

$$G'_{aa}(\tau_1^{(a)},\tau_2^{(a)})=G^M_{aa}(\tau_1^{(a)},\tau_2^{(a)})+2C_m^{(a)}(\tau_1^{(a)})^m+\cdots, \tag{3.17}$$

$$G'_{aa+1}(\tau_1^{(a)},\tau_2^{(a+1)})=G^M_{aa+1}(\tau_1^{(a)},\tau_2^{(a+2)})+C_m^{(a)}(\tau_1^{(a)})^m+C_m^{(a+1)}(\tau_2^{(a+1)})^m+\cdots, \tag{3.18}$$

where $\cdots$ means the additions of further different copies mentioned above. These relations suggest that a variety of Green function's representations can be derived starting from G^M_{ab}. In practice, the three representations listed here ($G^{\rm sym}$,$G^M G^J$) are connected to the following choices of the $C_m^{(a)}$ coefficients. We obtain $G'_{ab}=G^J_{ab}$, if we choose

$$C_0^{(a)}=-\frac{1}{2}\Delta T_1T_2T_3,\quad C_1^{(a)}=\Delta\,\frac{T_1T_2T_3}{T_a},\ \text{ others}=0, \tag{3.19}$$

and we obtain $G'_{ab}=G^{\rm sym}_{ab}$, if we choose

$$C_1^{(a)}=1,\ \ C_2^{(a)}=-\frac{1}{T_a}\left(1-\Delta\,\frac{T_1T_2T_3}{T_a}\right),\ \text{ others}=0. \tag{3.20}$$

In this way, every possible form is related to the standard form by the transformation rules (3.17) and (3.18), or in other words, by the two-loop momentum constraint formula (3.16).

IV. SOURCE CONSTRAINT

In this section, we discuss what identity in the generating functional method should play the same role as the momentum conservation constraint (3.16).

Let us first recall the computation process from (3.9) to (3.10). The w integration in (3.9) gives rise to the similar δ-function divergence as before (cf. Eq. (3.6)) in the sense of the Minkowski formulation, and we then have

$$Z[J]=i\delta\left(\sum_{a=1}^{3}\int_0^{T_a}J^a_\mu(\tau)d\tau\right)\prod_{a=1}^{3}(4\pi T_a)^{-D/2}$$
$$\times\exp\left[-\frac{1}{2}\sum_{a=1}^{3}\int_0^{T_a}\int_0^{T_a}J^a_\mu(\tau)\tilde{G}^{(a)}_{\mu\nu}(\tau,\tau')J^a_\nu(\tau)d\tau d\tau'\right]I[J] \tag{4.1}$$

with

$$I[J]=\int dz\prod_{a=1}^{3}\exp\left[-\frac{1}{4}z^\mu A^a_{\mu\nu}z^\nu+z^\nu\int_0^{T_a}J^a_\mu(\tau)R^a_{\mu\nu}(\tau)d\tau\right]. \tag{4.2}$$

Here, the $R^a_{\mu\nu}$ given in (3.11) is a symmetric tensor, however it is not a general property. Rather, the following reflection antisymmetry is general and important,

$$R^a_{\mu\nu}(\tau)=-R^a_{\mu\nu}(T^a-\tau). \tag{4.3}$$

Suppose that J^a_μ behaves as an even or odd function with respect to the center point $T^a/2$ for the interval $0\leqslant\tau^{(a)}\leqslant T_a$; i.e.,

$$J^a_\mu(\tau^{(a)})=\pm J^a_\mu(T_a-\tau^{(a)}). \tag{4.4}$$

Using these properties, we have

$$z^\nu\int_0^{T_a}J^a_\mu(\tau)R^a_{\mu\nu}(\tau)d\tau=\mp z^\nu\int_0^{T_a}R^a_{\nu\mu}(\tau)J^a_\mu(\tau)d\tau. \tag{4.5}$$

By this formula, we perform the Gaussian integral in (4.2),

$$I[J]=(4\pi)^{(D/2)}\det{}_L^{-(1/2)}\left(\sum_a A^a\right)$$
$$\times\exp\left[\mp\left(\sum_a\int_0^{T_a}J^a_\mu R^a_{\mu\rho}d\tau\right)\left(\sum_a A^a\right)^{-1}_{\rho\sigma}\left(\sum_a\int_0^{T_a}R^a_{\sigma\nu}J^a_\nu d\tau\right)\right]. \tag{4.6}$$

Again using (4.5), we can eliminate the complex signature symbol

$$I[J]=(4\pi)^{(D/2)}\det{}_L^{-(1/2)}\left(\sum_a A^a\right)$$
$$\times\exp\left[\left(\sum_a\int_0^{T_a}R^a_{\rho\mu}J^a_\mu d\tau\right)\left(\sum_a A^a\right)^{-1}_{\rho\sigma}\left(\sum_a\int_0^{T_a}R^a_{\sigma\nu}J^a_\nu d\tau\right)\right]. \tag{4.7}$$

This result (4.7) holds for any linear combination of even and odd J^a_μ functions. It should be noted that the odd source case implies

$$\int_0^{T_a} J_\mu^a(\tau^{(a)})d\tau^{(a)}=0 \quad (a=1,2,3). \tag{4.8}$$

It means a strong sense ''momentum'' conservation which is subjected to only one of three internal lines, and trivially satisfies

$$\sum_{a=1}^{3}\int_0^{T_a} J_\mu^a(\tau^{(a)})d\tau^{(a)}=0. \tag{4.9}$$

Mimicking this property, we in general impose this identity as the total ''momentum'' conservation (sum of three lines), as advocated by the δ-function in (4.1).

Now, let us compare the roles of discrete and continuous constraints (3.16) and (4.9) in an example. We notice the following term in G_{ab}^J (q.v. (3.14)):

$$-\frac{1}{2}(2\tau_1^{(a)}-T_a)(2\tau_2^{(b)}-T_b)\frac{T_1T_2T_3}{T_aT_b}\Delta \tag{4.10}$$

and its corresponding term in the generating functional (4.7),

$$\ln I[J]=\delta_{\mu\nu}T_1T_2T_3\Delta\sum_a\sum_b\int_0^{T_a}\left(\frac{\tau^{(a)}}{T_a}-\frac{1}{2}\right)J_\mu^a d\tau^{(a)}\int_0^{T_b}\left(\frac{\tau^{(b)}}{T_b}-\frac{1}{2}\right)J_\nu^b d\tau^{(b)}+\cdots. \tag{4.11}$$

If we subtract the $C_m^{(a)}$ terms from (4.10) with the choice (3.19), we obtain G^M as understood from (3.17) and (3.18). On the other hand, using the source constraint (4.9), we can remove from (4.11) the linear terms in $\tau^{(a)}$ and $\tau^{(b)}$ as well as the constant term,

$$\ln I[J]\approx\delta_{\mu\nu}T_1T_2T_3\Delta\sum_a\sum_b\int_0^{T_a}\int_0^{T_b}\frac{\tau^{(a)}\tau^{(b)}}{T_aT_b}J_\mu^a(\tau^{(a)})J_\nu^b(\tau^{(a)})d\tau^{(a)}d\tau^{(b)}+\cdots. \tag{4.12}$$

This manipulation leads to the Green function G_{ab}^M as expected; i.e., the removal of the $\tau^{(a)}$ and $\tau^{(b)}$ linear terms corresponds to the subtraction of $C_1^{(a)}$ given in (3.19), and the constant term removal to $C_0^{(a)}$. In this way, the source constraint (4.9) plays the same role as the actual momentum conservation constraint (3.16) on the kinematical factor E_G, thus on the wide sense world-line Green functions. It is worth noting that the constraint (4.9) is simpler than (3.16).

V. EXAMPLES IN QED

The idea of the source constraint gives a family of equivalent world-line Green functions as seen in the previous section. This property is useful for identifying different (wide sense) Green functions obtained by various computations. In this section, we verify its usefulness in more specific cases. The examples discussed here is the one-loop photon scatterings in the scalar and spinor QED cases. First, we discuss the scalar case, and then the spinor case.

The N-point function for a complex boson loop is known to be given[2] by the closed path integral of one-dimensional bosonic field $x^\mu(\tau)$,

$$\Gamma_N(p_1,\ldots,p_N)\equiv\int_0^\infty\frac{dT}{T}\oint\mathcal{D}x\left(\int_0^T\prod_{j=1}^N d\tau_j d\theta_j\overline{\theta_j}\right)\exp\left[\int_0^T\left(-\frac{1}{4}\dot{x}^2+J\cdot x\right)d\tau\right], \tag{5.1}$$

with the following specific source function;

$$J^\mu(\tau)=\sum_{j=1}^N\delta(\tau-\tau_j)\left(\overline{\theta_j}\theta_j\epsilon_j^\mu\frac{\partial}{\partial\tau_j}+ip_j^\mu\right), \tag{5.2}$$

where ϵ_j^μ are photon polarization vectors, and θ_j and $\overline{\theta_j}$ are the Grassmann variables. This source is neither an even function nor an odd one in τ, and we assume the one-loop version of the constraint (4.9) to be

$$\int_0^T J^\mu(\tau)d\tau=0. \tag{5.3}$$

This leads to the constraint similar to the momentum conservation law

$$\sum_{j=1}^{N} J_j^\mu=0; \quad J_j^\mu=\overline{\theta_j}\theta_j\epsilon_j^\mu\frac{\partial}{\partial\tau_j}+ip_j^\mu. \tag{5.4}$$

The second term in J_j exactly corresponds to the momentum conservation law, while the first term does not vanish in the sum at all. In this sense, the present constraint (5.4) assumes a nontrivial conservation law. Let us see how our idea works in the following. We perform the path integral (5.1) as the mode integrations with expanding

$$x^\mu(\tau)=x_0^\mu+\sum_{n>0} x_n^\mu \sin\left(\frac{n\pi\tau}{T}\right) \quad (-\infty\leqslant x_n\leqslant\infty). \tag{5.5}$$

Note that x_0 integration diverges as the δ-function corresponding to the constraint (5.3). (This is similar to the δ-function in Eq. (4.1)). Remember that this kind of divergence is usually removed by hand (so-called zero mode divergence). The resulting expression is then

$$\Gamma_N(p_1,\ldots,p_N)=\int \frac{dT}{T}\left(\frac{1}{4\pi T}\right)^{D/2}\left(\prod_{j=1}^{N} d\tau_j d\theta_j d\overline{\theta_j}\right)\exp\left[\frac{1}{2}g_{\mu\nu}\sum_{j,l=1}^{N} J_j^\mu J_l^\nu \widetilde{G}_B(\tau_j,\tau_l)\right], \tag{5.6}$$

where we formally put $g_{\mu\nu}=-\delta_{\mu\nu}$ and

$$\widetilde{G}_B(\tau_i,\tau_j)=\sum_{m=1}^{\infty}\frac{4T}{m^2\pi^2}\sin\left(\frac{\pi m\tau_i}{T}\right)\sin\left(\frac{\pi m\tau_j}{T}\right) \tag{5.7}$$

$$=|\tau_i-\tau_j|-(\tau_i+\tau_j)+2\frac{\tau_i\tau_j}{T}. \tag{5.8}$$

Here we have used the following formula at the second line of the above,

$$\sum_{m=1}^{\infty}\frac{\cos(mx)}{m^2}=\frac{1}{4}(|x|-\pi)^2-\frac{\pi^2}{12}. \tag{5.9}$$

Under the constraint (5.4), we realize that $\widetilde{G}_B$ in the exponent (the generating kinematical factor) in Eq. (5.6) behaves as the one-loop Green function (1.3) exactly, and we thus rederive the same result[2]

$$\Gamma_N(p_1,\ldots,p_N)=\int \frac{dT}{T}\left(\frac{1}{4\pi T}\right)^{D/2}\left(\prod_{j=1}^{N} d\tau_j d\theta_j d\overline{\theta_j}\right)\exp\left[-\frac{1}{2}\sum_{j,l=1}^{N} J_j\cdot J_l G_B(\tau_j,\tau_l)\right]. \tag{5.10}$$

In this example, it is clear that the source constraint helps us obtain a correct kinematical factor even if a different (wide sense) Green function appears in an intermediate step.

The similar argument applies to the fermion loop case as well. For simplicity, we discuss only the spin part (world-line fermion $\psi^\mu(\tau)$), since the bosonic part is essentially the same as the above case. The world-line fermion part of the N-point amplitude is given by[2]

$$\tilde{\Gamma}_N \equiv \oint \mathcal{D}\psi \left(\prod_{j=1}^{N} \int_0^T d\tau_j d\theta_j d\overline{\theta_j} \right) \exp\left[\int_0^T \left(-\frac{1}{2} \psi^\mu \partial_\tau \psi_\mu + \eta^\mu \psi_\mu \right) d\tau \right] \tag{5.11}$$

with the source function

$$\eta^\mu(\tau) = \sum_{j=1}^{N} \sqrt{2}(\theta_j \epsilon_j^\mu + i\overline{\theta}_j p_j^\mu)\delta(\tau - \tau_j). \tag{5.12}$$

Assuming the source constraint

$$\int_0^T \eta^\mu(\tau) d\tau = 0 \tag{5.13}$$

or equivalently

$$\sum_{j=1}^{N} K_j = 0, \quad K_j^\mu = \sqrt{2}(\theta_j \epsilon_j^\mu + i\overline{\theta}_j p_j^\mu), \tag{5.14}$$

and performing the path integral with the mode expansion

$$\psi^\mu(\tau) = \sum_{r \in \mathbf{Z} + \frac{1}{2}} b_r^\mu \cos\left(\frac{2\pi r \tau}{T} \right), \tag{5.15}$$

we obtain (the detail is in Appendix A),

$$\overline{\Gamma}_N = \prod_{j=1}^{N} \int d\tau_j d\theta_j d\overline{\theta_j} \exp\left[\frac{1}{4} \sum_{j,l=1}^{N} K_j \cdot K_l \tilde{G}_F(\tau_j, \tau_l) \right] \tag{5.16}$$

with

$$\tilde{G}_F(\tau_i, \tau_j) = \mathrm{sign}(\tau_j - \tau_i) + \frac{2}{T}(\tau_i - \tau_j). \tag{5.17}$$

Under the constraint (5.14), $\tilde{G}_F$ in the exponent plays the same role as the standard fermion Green function

$$G_F(\tau_i, \tau_j) = \mathrm{sign}(\tau_j - \tau_i), \tag{5.18}$$

and we reproduce the correct answer[2]

$$\tilde{\Gamma}_N = \prod_{j=1}^{N} \int d\tau_j d\theta_j d\overline{\theta_j} \exp\left[\frac{1}{4} \sum_{j,l=1}^{N} K_j \cdot K_l G_F(\tau_j, \tau_l) \right]. \tag{5.19}$$

VI. REPARAMETRIZATION-TYPE TRANSFORMATION

This section is independent of the previous sections. In this section, we consider reparametrizations and transformations between the standard two-loop Green functions. As mentioned in Sec. II, it is known that G^{sym} and $G^{(1)}$ are connected by a certain transformation.[12] Here, we point out another transformation between them, using periodicities of the Green functions, and also discuss reparametrizations of $G^{(1)}$ through exchanging two of internal lines.

The symmetric Green functions G^{sym} and also $G_{33}^{(1)}$ satisfy the following properties of periodicity:

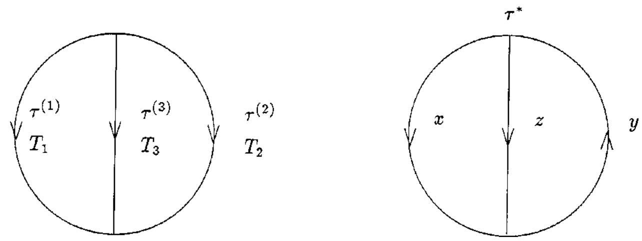

FIG. 1. The directions of τ parameters.

$$G_{ab}^{\rm sym}(T_a-\tau^{(a)},T_b-\tau^{(b)})=G_{ab}^{\rm sym}(\tau^{(a)},\tau^{(b)})\quad (a,b=1,2,3), \tag{6.1}$$

$$G_{aa}^{\rm sym}(\tau-P_a)=G_{aa}^{\rm sym}(\tau),\quad G_{33}^{(1)}(\tau-P_{11})=G_{33}^{(1)}(\tau), \tag{6.2}$$

where

$$P_a=T_a+\frac{T_{a+1}T_{a+2}}{T_{a+1}+T_{a+2}},\quad P_{11}=T_3+G_B(\tau_\alpha,\tau_\beta)=\frac{1}{T\Delta}. \tag{6.3}$$

Putting $P_3=P_{11}$ with identifying $T_1=T(1-u)$ and $T_2=Tu$, we easily find

$$u=\frac{|\tau_\alpha-\tau_\beta|}{T}, \tag{6.4}$$

and the necessary relations for the transformation between $G^{\rm sym}$ and $G^{(1)}$,[12]

$$T_1=T-|\tau_\alpha-\tau_\beta|,\quad T_2=|\tau_\alpha-\tau_\beta|. \tag{6.5}$$

For later convenience, we assign more concrete notations to τ_n in $G^{(1)}$ on the loop-type parameterization:

$$\tau_n=\begin{cases} x_n & (\tau^*<\tau_n)\\ y_n & (\tau_n<\tau^*)\\ z_n & \text{on the internal line } T_3,\end{cases} \tag{6.6}$$

where τ^* is given below (see Eq. (6.8) and Fig. 1).

With these relations, the transformation rule between $G^{\rm sym}$ and $G^{(1)}$ is allowed to be expressed as

$$\begin{cases} \tau_n^{(1)}=x_n-\tau^*,\\ \tau_n^{(2)}=\tau^*-y_n,\\ \tau_n^{(3)}=z_n,\end{cases} \tag{6.7}$$

where

$$\tau^*=\tau_\alpha\theta(\tau_\alpha-\tau_\beta)+\tau_\beta\theta(\tau_\beta-\tau_\alpha), \tag{6.8}$$

$$\tau^*-T_2\leqslant y_n\leqslant \tau^*\leqslant x_n\leqslant T_1+\tau^*. \tag{6.9}$$

We can obtain another transformation by combining the property (6.1) with (6.7); i.e., replacing $\tau^{(a)}\to T_a-\tau^{(a)}$ on the right-hand side in (6.7),

$$\begin{cases} \tau_n^{(1)}=T_1-x_n+\tau^*, \\ \tau_n^{(2)}=T_2+y_n-\tau^*, \\ \tau_n^{(3)}=T_3-z_n. \end{cases} \tag{6.10}$$

From these (two-loop) transformations, we can generate an infinite number of transformations for the *one-loop* case, since τ^* is reduced to an arbitrary number when the both edges of the z line approach each other along the fundamental loop (of course, with vanishing T_3); for example,

$$\text{for} \quad \tau^*=0: \quad \begin{cases} \tau^{(1)}=x \\ \tau^{(2)}=-y \end{cases}, \quad \text{or} \quad \begin{cases} \tau^{(1)}=T_1-x \\ \tau^{(2)}=T_2+y \end{cases}, \tag{6.11}$$

$$\text{for} \quad \tau^*=T_2: \quad \begin{cases} \tau^{(1)}=x-T_2 \\ \tau^{(2)}=T_2-y \end{cases}, \quad \text{or} \quad \begin{cases} \tau^{(1)}=T-x \\ \tau^{(2)}=y \end{cases}. \tag{6.12}$$

Although these one-loop transformations are certainly trivial by themselves, an interesting deduction is that one can generate a set of transformations of h-loop Green functions from $(h+1)$-loop transformations by setting one of h copies of τ^* to be an arbitrary value.

As a second application of (6.7), let us consider some reparametrizations of $G_{ab}^{(1)}$; $a,b=0,3$. We show that the transformation of the Green functions $G_{ab}^{(1)}(\tau_1,\tau_2)$ living on the zx-loop (loop made of internal lines where the z and x variables are defined) into $G_{00}^{(1)}(\tau_1',\tau_2')$ on the xy-loop can be found through the cyclic permutation symmetry of G^{sym} (exchanging z-line and y-line). Namely, transforming $G^{(1)}\to G^{\mathrm{sym}}\to G^{(1)}$ successively, we can read how to transform like

$$G_{00}^{(1)}(x_1,x_2)\to G_{00}^{(1)}(x_1',x_2'), \tag{6.13}$$

$$G_{03}^{(1)}(x,z)\to G_{00}^{(1)}(x',y'), \tag{6.14}$$

$$G_{33}^{(1)}(z_1,z_2)\to G_{00}^{(1)}(y_1',y_2'). \tag{6.15}$$

Suppose that each of $G_{ab}^{(1)}$ on the xz-loop is related to $G_{ij}^{\mathrm{sym}}(\tau^{(i)},\tau^{(j)})$ by the rule (6.7), and that each of $G_{00}^{(1)}$ on the xy-loop is related to $G_{ij}^{\mathrm{sym}}(\tau^{(i)},\tau'^{(j)})$ by the same rule as (6.7), $\tau'^{(1)}=x'-\tau^*$, $\tau'^{(2)}=\tau^*-y'$, $\tau'^{(3)}=z'$. Putting $\tau'^{(2)}=\tau^{(3)}$ and $\tau'^{(3)}=\tau^{(2)}$ (corresponding to the exchange of z- and y-lines), and eliminating $\tau^{(a)}$ and $\tau'^{(a)}$ from these transformation rules, we find the following transformation rule attributed from the exchange between z- and y-lines:

$$\begin{cases} x'=x \\ y'=\tau^*-z \quad \text{and} \quad T_3\leftrightarrow T_2 \\ z'=\tau^*-y. \end{cases} \tag{6.16}$$

Remember that Δ^{-1} is invariant in any exchange of T_a. The simplest check of this rule is the following case:

$$\begin{aligned} G_{33}^{(1)}(z_1,z_2)&=|y_1'-y_2'|-\frac{(y_1'-y_2')^2}{(T_3+G_B(\tau_\alpha,\tau_\beta))T}(T_1+T_2)|_{T_2\leftrightarrow T_3} \\ &=|y_1'-y_2'|-\frac{(y_1'-y_2')^2}{(T_3+G_B(\tau_\alpha,\tau_\beta))T}(T_3+T(1-u))=G_{00}^{(1)}(y_1',y_2'). \end{aligned} \tag{6.17}$$

Similarly, we derive another transformation rule from the yz-loop to the xy-loop (exchange of z-line and x-line),

$$\begin{cases} x' = \tau^* + z \\ y' = y \quad \text{and} \quad T_3 \leftrightarrow T_1 \\ z' = x - \tau^* . \end{cases} \tag{6.18}$$

One can organize these two sets of transformations in a unified way: Let us express the untransforming (identical) variables in (6.16) and (6.18) as

$$\tau = x\,\theta(\tau - \tau^*) + y\,\theta(\tau^* - \tau), \tag{6.19}$$

and assign $\tilde{\tau}$ to be the parameter transforming to the z' variable,

$$\tilde{\tau} = y\,\Theta(\tau - \tau^*) + x\,\theta(\tau^* - \tau), \tag{6.20}$$

while considering the transformation

$$G_{00}^{(1)}(\tau_1, \tau_2) \to G_{00}^{(1)}(\tau_1', \tau_2'), \tag{6.21}$$

$$G_{03}^{(1)}(\tau, z) \to G_{00}^{(1)}(\tau', \tilde{\tau}'), \tag{6.22}$$

$$G_{33}^{(1)}(z_1, z_2) \to G_{00}^{(1)}(\tilde{\tau}_1', \tilde{\tau}_2'). \tag{6.23}$$

The above two sets of rules (6.16) and (6.18) are now expressed in the compact form

$$\begin{cases} \tau' = \tau \\ \tilde{\tau}' = \tau^* - z\,\text{sign}(\tau - \tau^*) \quad \text{and} \quad T_3 \leftrightarrow T^* \\ z' = (\tau^* - \tilde{\tau})\text{sign}(\tau - \tau^*) , \end{cases} \tag{6.24}$$

where

$$T^* = T_2\,\theta(\tau - \tau^*) + T_1\,\theta(\tau^* - \tau). \tag{6.25}$$

In order to verify these relations, one should note that TP_{11} $(=\Delta^{-1})$ is invariant under this transformation rule, and also that T transforms as

$$T = T^* + \tilde{T}^* \to T_3 + \tilde{T}^*, \tag{6.26}$$

where

$$\tilde{T}^* = T - T^* = T_1\,\theta(\tau - \tau^*) + T_2\,\theta(\tau^* - \tau). \tag{6.27}$$

It is rather convenient to rewrite the Green function (2.7) as

$$G_{03}^{(1)}(\tau, z) = z + |\tau - \tau^*| - \frac{1}{TP_{11}}[z^2 T + 2z|\tau - \tau^*|T^* + (\tau - \tau^*)^2 (T_3 + T^*)], \tag{6.28}$$

than considering the original form

$$G_{03}^{(1)}(\tau, z) = G_B^{(1)}(\tau, \tau^*) + \frac{1}{P_{11}}\{T_3 z - z^2 - \text{sign}(\tau_\alpha - \tau_\beta)[G_B(\tau, \tau_\alpha) - G_B(\tau, \tau_\beta)]\}. \tag{6.29}$$

Applying the transformation (6.24) to Eqs. (6.21), (6.28), and (6.23), we obtain

$$G_{00}^{(1)}(\tau_1, \tau_2) = G_B(\tau_1, \tau_2) - \frac{\Delta}{T} T^{*2} (\tau_1 - \tau_2)^2, \tag{6.30}$$

$$G_{00}^{(1)}(\tau,\tilde{\tau}) = G_B(\tau,\tilde{\tau}) - \frac{\Delta}{T}[T(\tau^* - \tilde{\tau}) - T^*(\tau - \tilde{\tau})]^2, \tag{6.31}$$

$$G_{00}^{(1)}(\tilde{\tau}_1,\tilde{\tau}_2) = G_B(\tilde{\tau}_1,\tilde{\tau}_2) - \frac{\Delta}{T}\tilde{T}^{*2}(\tilde{\tau}_1 - \tilde{\tau}_2)^2. \tag{6.32}$$

These representations are independent of the choice of either $\tau^* = \tau_\alpha$ or τ_β, and reproduce Eq. (23) of Ref. 12 for the particular choice $\tau^* = \tau_\beta$ (correcting an error in the literature).

VII. CONCLUSIONS

In this paper, we have investigated two types of the constraints on the two-loop kinematical factor and the world-line Green functions. One is nothing but the momentum conservation law on external legs, and the other is the vanishing constraint on the source term integrals along the whole of world-line. Although there is no direct connection between two of them, the latter can be regarded as a continuous version of the former. Because of the ambiguity raised by the constraints, an infinite number of wide sense Green functions are in fact possible to take part in the kinematical factor exponent. However, we have verified that all these Green functions can be identified with the standard (restricted) Green functions, all of which are reduced from a world-sheet Green function,[8] and some of which are related to actual solutions of defining differential equations with possessing the rotational invariance along the fundamental loop.[11] Conversely, this fact means that the conservation constraints loosen some imposed restrictions on the standard Green functions, and eventually make various evaluations and approaches possible. Since this ambiguity is a reflection of the conservation laws, it is easy to infer that the ignorance of it can lead to the breaking of unitarity and gauge invariance. Therefore we always have to take account of either of two versions of the constraints when dealing with the world-line formalism.

Once having the constraints, one can ignore the differences among different Green functions when applying the Green functions to amplitude formulas. In this sense, these constraints will be useful for analyzing higher loop's world-line Green functions. Especially it is clear that the source constraint is much easier to apply than the momentum conservation constraint in the multiloop cases. In two-loop Yang–Mills theory, there arises a different Green function in the calculation in a constant background field,[14] and the source constraint is actually useful to identify the Green function with the standard one in the vanishing limit of constant background field (as demonstrated in Secs. III and IV). Obviously, the similar thing is expected to occur in the multiloop cases. Since expressions of multiloop Green functions are complicated, these constraints will be useful for simplifying and transforming the expressions into convenient forms together with the transformation property (suggested below (6.12). It might be interesting to speculate a usefulness of our techniques in the thermal world-line cases.[15]

In the final part of the paper, we have considered the transformations among the Green functions of standard forms, associated with the reparametrizations of the two-loop world-line diagram. On the one hand, the form of world-sheet Green function is independent of the orderings of two vertices, which join the internal line and the fundamental loop. On the other hand, the crossing type Green functions (2.7) and (2.12), which belong to the type of a correlation between the fundamental loop and the internal line, are neither translational invariant nor ordering independent. It might be that this gap will be filled in some way around by taking account of the discussed transformations into the loop-type Green function $G_{00}^{(1)}$. The crossing-type Green functions are necessary in non-Abelian gauge theory, and a complexity in the combinatorics problem will be caused by this type (similarly to the ϕ^3 theory case[14]). We hope for a useful parameterization or a transformation to overcome these problems.

APPENDIX: FERMION MODE INTEGRATION

We show the derivation of (5.16) in this Appendix. The fermion field (5.15) is an expansion which satisfies $\psi(0) = -\psi(T) \neq 0$ and $\int_0^T \psi^\mu(\tau)d\tau = 0$. First, we rewrite

$$H\equiv\int_0^T\left(-\frac{1}{2}\psi^\mu\partial_\tau\psi_\mu+\eta^\mu\psi_\mu\right)d\tau=I-J, \tag{A1}$$

where

$$I\equiv\int_0^T d\tau_1 d\tau_2 d\tau d\tau'\left(\psi(\tau_1)-\frac{1}{2}\eta(\tau)G_I(\tau-\tau_1)\right)\left(\delta(\tau_1-\tau_2)\frac{-1}{2}\frac{\partial}{\partial\tau_2}\right)\times\left(\psi(\tau_2)-\frac{1}{2}\eta(\tau')G_I(\tau'-\tau_2)\right), \tag{A2}$$

$$J\equiv-\left(\frac{1}{2}\right)^3\int_0^T d\tau_1 d\tau_2 d\tau d\tau'\,\eta(\tau)\eta(\tau')G_I(\tau-\tau_1)\delta(\tau_1-\tau_2)\frac{\partial}{\partial\tau_2}G_I(\tau'-\tau_2), \tag{A3}$$

with introducing the function

$$G_I(\tau)=\frac{2}{\pi}\sum_{m\geqslant 1}\frac{1}{m}\sin\left(\frac{2\pi m\tau}{T}\right), \tag{A4}$$

which satisfies

$$\frac{1}{2}\partial_\tau G_I(\tau)=\delta(\tau)-\frac{1}{T}, \tag{A5}$$

and

$$G_I(\tau_1-\tau_2)=\frac{\partial}{\partial\tau_1}G_B(\tau_1,\tau_2). \tag{A6}$$

Putting (5.12) and (A4) into (A3), and performing the integrals, we obtain

$$J=-\left(\frac{1}{2}\right)^3\sum_{j,l}K_jK_l\left(-\frac{\partial}{\partial\tau_j}\right)\sum_{m\geqslant 1}\frac{2T}{\pi^2m^2}\cos\left(\frac{2\pi m(\tau_i-\tau_j)}{T}\right). \tag{A7}$$

Using the summation formula (5.9), we have

$$J=-\left(\frac{1}{2}\right)^2\sum_{j,l}K_jK_l\left(\frac{2}{T}(\tau_j-\tau_l)-\mathrm{sign}(\tau_j-\tau_l)\right). \tag{A8}$$

Shifting $\psi\to\psi+\frac{1}{2}\eta G_I$ in the path integral (5.11), the quantity I is reduced to the free integral

$$I\to-\frac{1}{2}\int_0^T\psi\cdot\dot\psi, \tag{A9}$$

and this yields nothing but the path integral normalization

$$\oint\mathcal{D}\psi e^{-(1/2)\int_0^T\psi\cdot\dot\psi d\tau}=1. \tag{A10}$$

This can be checked by integrating the modes (5.15). Therefore we derive (5.16) owing to (A8) and (A10),

$$\tilde{\Gamma}_N = \oint \mathcal{D}\psi\left(\prod_{j=1}^{N}\int d\tau_j d\theta_j d\overline{\theta_j}\right)e^H = \prod_{j=1}^{N}\int d\tau_j d\theta_j d\overline{\theta_j} e^J. \tag{A11}$$

The action operator for continuous-time histories

K. Savvidou[a)]
Theoretical Physics Group, Blackett Laboratory, Imperial College of Science, Technology & Medicine, London SW7 2BZ, United Kingdom

(Received 12 March 1999; accepted for publication 29 March 1999)

We define the action operator for the consistent histories formalism, as the quantum analog of the classical action functional, for the simple harmonic oscillator case. We conclude that the action operator is the generator of time transformations, and is associated with the two types of time evolution of the standard quantum theory: the wave-packet reduction and the unitary time evolution. We construct the corresponding classical histories and demonstrate the relevance with the quantum histories. Finally, we show the relation of the action operator to the decoherence functional. © *1999 American Institute of Physics.* [S0022-2488(99)02510-4]

I. INTRODUCTION

One of the basic elements in the consistent histories formalism is the idea of a ''homogeneous history.'' This is a time-ordered sequence of propositions about the system and, in the original approaches to the formalism, is represented by a class operator $\widetilde{C}$,

$$\widetilde{C} := U(t_0,t_1)\alpha_{t_1}U(t_1,t_2)\alpha_{t_2}\cdots U(t_{n-1},t_n)\alpha_{t_n}U(t_n,t_0), \tag{I.1}$$

where α_{t_i} is a single-time projection operator representing a property of the system at time t_i, and $U(t,t')=e^{-(i/h)H(t-t')}$ is the unitary time evolution operator.[1–4]

In the ''History Projection Operator'' (HPO) approach developed by Isham and collaborators,[5–8] a homogeneous history ''α_{t_1} is true at time t_1 and α_{t_2} is true at time $t_2\dots$ and α_{t_n} is true at time t_n'' is represented by a *projection operator* α, defined as the tensor product of projection operators $\alpha := \alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ on the n-fold tensor product of copies of the standard Hilbert space $\mathcal{V}_n := \mathcal{H}_{t_1}\otimes\mathcal{H}_{t_2}\otimes\cdots\otimes\mathcal{H}_{t_n}$. This approach reestablishes the logical nature of propositions about a physical system since these projection operators (and their disjunctions) represent a type of *temporal* quantum logic.

Most discussions of the consistent-histories formalism have involved histories defined at a finite set of time points. However, it is important to extend this to include a continuous-time variable (especially for potential applications to quantum field theory), and in order to construct continuous-time histories on the continuous tensor product of copies of the Hilbert space $\mathcal{V}_{\rm cts} := \otimes\mathcal{H}_t$, Isham and Linden defined the History Group[6] as an analog of the canonical group of normal quantum theory. This group plays a crucial role in the physical interpretation of the theory: the spectral projectors of the generators of its Lie algebra represent history propositions about the system.

For the example of a nonrelativistic point particle moving on a line, the history group was defined as a generalized Weyl group with Lie algebra,

$$[x_t,x_{t'}]=0, \tag{I.2}$$

$$[p_t,p_{t'}]=0, \tag{I.3}$$

[a)]Electronic mail: k.savvidou@ic.ac.uk

$$[x_t, p_{t'}] = i\hbar\tau\delta(t-t'), \tag{I.4}$$

where $-\infty < t, t' < +\infty$, and τ is a constant with dimensions of time. It is important to emphasize that the generators of the history algebra x_t and p_t, $t \in \mathbf{R}$, are Schrödinger-picture operators. After being properly smeared, they correspond (actually, their spectral projectors), to propositions about the time-averaged values of the position and the momentum of the system, respectively. The evident resemblance of the history algebra to the algebra of a quantum field theory meant that the one-dimensional quantum mechanics history theory could be treated mathematically in some respects as a $1+1$ dimension quantum *field* theory.

In a previous paper,[5] the requirement of the existence of the Hamiltonian operator H that represents propositions about the time-averaged values of the energy of the system—in particular, for the example of a simple harmonic oscillator in one dimension—together with the explicit relation between the Hamiltonian and the creation and annihilation operators, selected uniquely a Fock space as the representation space of the history algebra (1.2–1.4) on the history space $\mathcal{V}_n$. We shall return to this representation in more detail shortly.

The history algebra generators x_t and p_t can be seen heuristically as operators (actually they are operator-valued distributions on $\mathcal{V}_n$), that for each time label t, are defined on the Hilbert space $\mathcal{H}_t$. The question then arises if, and how, these Schrödinger-picture objects with different time labels are related: in particular, is there a transformation law ''from one Hilbert space to another?'' One anticipates that the analog of this question in the context of a histories treatment of a relativistic quantum field theory would be crucial to showing the Poincaré invariance of the system.

In the Hamilton–Jacobi formulation of Classical Mechanics, it is the *action functional* that plays the role of the generator of a canonical transformation of the system from one time to another.[9] Indeed, the Hamilton–Jacobi functional S, evaluated for the realized path of the system—i.e., for a solution of the classical equations of motion, under some initial conditions—is the generating function of a canonical transformation, which transforms the system variables position x and momentum p from an initial time $t=0$ to another time t. It is therefore natural to investigate whether a quantum analog of the action functional exists for the HPO theory.

Indeed, in Ref. 5, where we explored the quantum field theory case for the continuous-time histories, we were not able to show the manifest covariance of the theory under the ''external'' Poincaré group. However, we did not consider the action as an operator, our main goal in the present paper is to enhance the theory in this direction so as to have a clearer view of the time-transformation issue. This will ultimately allow us to readdress the problem of the Poincaré covariance of the quantum field theory.[10]

In what follows, we first prove the existence of the action operator S_κ, using the same type of quantum field theory methods that were used to prove the existence of the Hamiltonian operator H_κ.[5] We will show that, constructed as a quantum analog of the classical action functional, S_κ does indeed act as a generator of time transformations in the HPO theory. Furthermore—and more speculatively—this is arguably related to the two laws of time-evolution in standard quantum theory: namely, wave-packet reduction and the unitary time evolution between measurements.

A comparison with the classical theory case seems appropriate at this point, and thus, in Secs. III and IV, we present a classical analog of the HPO, where the continuous-time classical histories can be seen to be an analog of the continuous-time quantum histories.

In Sec. V, we further exploit the classical analogy to discuss the ''classical'' behavior of the history quantum scheme. In particular, we expect the action operator to be involved in some way with the dynamics of the theory. To this end, we show how it appears in the expression for the decoherence functional expression, with operators acting on coherent states, as used earlier by Isham and Linden.[6]

II. THE ACTION OPERATOR DEFINED

In the generalized consistent histories theory by Gell-Mann and Hartle[1,2] and others, a homogeneous history α is a time-ordered sequence of propositions about the system, and is represented by a class operator $\tilde{C}$,

$$\tilde{C} := U(t_0,t_1)\alpha_{t_1} U(t_1,t_2)\alpha_{t_2} \cdots U(t_{n-1},t_n)\alpha_{t_n} U(t_n,t_0), \tag{II.1}$$

where α_t, is a single-time projection operator representing a proposition about the system at time t_i. If a particular history α belongs to a consistent set, then the probability for the history to be realized is

$$\mathrm{Prob}(\alpha) = \mathrm{tr}_H \tilde{C}^\dagger_\alpha \rho_{t_0} \tilde{C}_\alpha, \tag{II.2}$$

where ρ_{t_0} is the density matrix of the initial state. Deciding whether or not a particular set of histories is consistent involves evaluating the decoherence functional,

$$d(\alpha,\beta) := \mathrm{tr}_H \tilde{C}^\dagger_\alpha \rho_{t_0} \tilde{C}_\beta, \tag{II.3}$$

which is a complex-valued function of a pair of histories α and β. In particular, if α and β are disjoint propositions belonging to a consistent set, then they satisfy the ''decoherence'' condition,

$$d(\alpha,\beta) = 0. \tag{II.4}$$

We note that, as a product of projectors, the class operator $\tilde{C}_\alpha$ is generally not itself a projector, and hence the temporal logic structure of quantum mechanics is lost. This is remedied in the HPO theory, in which the history proposition ''α_{t_1} is true at time t_1 and α_{t_2} is true at time t_2... and α_{t_n} is true at time t_n'' is represented by the tensor product $\alpha := \alpha_{t_1} \otimes \alpha_{t_2} \otimes \cdots \otimes \alpha_{t_n}$.[8] This is a genuine projection operator on the n-fold tensor product $\mathcal{V}_n := \mathcal{H}_{t_1} \otimes \mathcal{H}_{t_2} \otimes \cdots \otimes \mathcal{H}_{t_n}$. Each constituent proposition α_t, labeled by the time parameter t, is defined on a copy of the standard quantum theory Hilbert space, with the same t-label $\mathcal{H}_t$.

This is a straightforward idea for a discrete set of times $(t_1,t_2,\ldots,t_n)$, but, for reasons given in the Introduction, it is important to extend these ideas to continuous-time histories that are to be defined on some sort of continuous tensor product of copies of the Hilbert space $\mathcal{V}_{\mathrm{cts}} := \otimes \mathcal{H}_t$.

A key technical tool is the history group, constructed as an analog of the canonical group[3] of normal quantum theory. For a particle moving in one dimension, the standard canonical commutation relation,

$$[x,p] = i\hbar, \tag{II.5}$$

is replaced by the ''history algebra,''

$$[x_t, x_{t'}] = 0, \tag{II.6}$$

$$[p_t, p_{t'}] = 0, \tag{II.7}$$

$$[x_t, p_{t'}] = i\hbar\tau\delta(t-t'), \tag{II.8}$$

where $-\infty < t,t' < +\infty$. The constant τ has dimensions of time[11] and, in what follows, for convenience we shall choose units in which $\tau=1$. These operators are written in the Schrödinger picture: t labels the Hilbert space—it is *not* the time parameter that appears in the Heisenberg picture for normal quantum theory.

To be mathematically precise, Eqs. (II.6)–(II.7) must be smeared,

$$[x_f, x_g] = 0, \tag{II.9}$$

$$[p_f, p_g] = 0, \tag{II.10}$$

$$[x_f,p_g]=i\hbar\int_{-\infty}^{+\infty}f(t)g(t)dt, \tag{II.11}$$

where f and g belong to some appropriate subset of the space $\mathcal{L}^2(\mathbf{R},dt)$ of square integrable functions on $\mathbf{R}$.

The evident resemblance of the above with the canonical commutation algebra of a quantum field theory in 1+1 dimensions leads to the treatment of the history algebra using mathematical ideas drawn from the former. In particular, a unique representation of the history algebra can be selected by the requirement that a representation of the (analog of the) Hamiltonian operator exists:[12] physically, this operator represents history propositions about the time-averaged values of the energy.

In previous work,[5] we explored the familiar example of a simple harmonic oscillator in one dimension. In this case, the history algebra is extended to include the commutators,

$$[H_\kappa,x_f]=-\frac{i\hbar}{m}p_{\kappa f}, \tag{II.12}$$

$$[H_\kappa,p_f]=i\hbar\omega^2x_{\kappa f}, \tag{II.13}$$

$$[H_\kappa,H_{\kappa'}]=0, \tag{II.14}$$

where H_κ is the time-averaged history energy operator $H_\kappa:=\int_{-\infty}^{\infty}\kappa(t)H_t\,dt$. The smearing function $\kappa(t)$ belongs to some subset of the space $\mathcal{L}^2(\mathbf{R},dt)$, in general, not the same as the subset on which the test functions of the x_t and p_t are defined. The specific choice of test functions is partly determined by the physical situations to which the formalism is to be applied.

The Fock representation of the history algebra is based on the definition of the ''annihilation'' operator,

$$b_t:=\sqrt{\frac{m\omega}{2\hbar}}x_t+i\sqrt{\frac{1}{2m\omega\hbar}}p_t, \tag{II.15}$$

with commutation relations

$$[b_t,b_{t'}]=0, \tag{II.16}$$

$$[b_t,b_{t'}^\dagger]=\delta(t-t'), \tag{II.17}$$

and is uniquely selected by the requirement that the time-averaged Hamiltonian operator exists in this representation; heuristically, H_t is connected with the operator $b^\dagger$ by the expression $H_t=\hbar\omega b_t^\dagger b_t$.

In the Hamiltonian formalism for a classical system, the action functional is defined as

$$S_{\rm cl}:=\int_{-\infty}^{+\infty}(p\dot{q}-H)dt, \tag{II.18}$$

where q is the position, p is the momentum, and H the Hamiltonian of the system. Following the same line of thought as for the definition of the Hamiltonian algebra, we want to find a representation of the history algebra in which their exists a one-parameter family of operators S_t—or better their smeared form $S_{\lambda,\kappa}$. Heuristically, we have

$$S_t:=(p_t\dot{x}_t-H_t), \tag{II.19}$$

$$S_{\lambda,\kappa}:=\int_{-\infty}^{+\infty}(\lambda(t)p_t\dot{x}_t-\kappa(t)H_t)dt, \tag{II.20}$$

where $S_{\lambda,\kappa}$ is the smeared action operator with smearing functions $\lambda(t),\kappa(t)$. In order to discuss the existence of an operator $S_{\lambda,\kappa}$, we note that, if this operator exists, the Hamiltonian algebra, Eqs. (II.12)–(II.14), would be augmented in the form

$$[S_{\lambda,\kappa},x_f]=i\hbar\left(x_{(d/dt)(\lambda f)}+\frac{p_{\kappa f}}{m}\right), \tag{II.21}$$

$$[S_{\lambda,\kappa},p_f]=i\hbar(p_{\lambda f}+m\omega x_{\kappa f}), \tag{II.22}$$

$$[S_{\lambda,\kappa},H_{\kappa'}]=i\hbar H_{(d/dt)(\lambda\kappa')}-\frac{i\hbar}{m}\int_{-\infty}^{\infty}(\kappa'(t)\dot{\lambda}(t)\dot{p}_t^2)dt, \tag{II.23}$$

$$[S_{\lambda,\kappa},S'_{\lambda,\kappa}]=i\hbar H_{(d/dt)(\lambda'\kappa)}-i\hbar H_{(d/dt)(\lambda\kappa')}-i\hbar\int_{-\infty}^{\infty}\left([(\kappa(t)\dot{\lambda}'(t))-(\kappa'(t)\dot{\lambda}(t))]\frac{\dot{p}_t^2}{m}\right)dt. \tag{II.24}$$

Although we have defined the action operator in a general smeared form, in what follows we will mainly employ only the case $\lambda(t)=1$ and $\kappa(t)=1$ that accords with the expression for the classical action functional. This choice of smearing functions poses no technical problems restrictions, provided we keep to the requirement that the smearing functions for the position and momentum operators are square-integrable functions. In particular, the products of the smearing functions f and g in Eqs (II.21)–(II.24) with the test functions $\lambda(t)=1$ and $\kappa(t)=1$, are still square integrable.

The existence of the action operator in HPO. We now examine whether the action operator actually exists in the Fock representation of the history algebra employed in our earlier work.[5] Henceforward we choose $\lambda(t)=1$. Then the formal commutation relations are

$$S_\kappa:=\int_{-\infty}^{+\infty}(p_t\dot{x}_t-\kappa(t)H_t)dt, \tag{II.25}$$

$$[S_\kappa,x_f]=i\hbar\left(x_{\dot{f}}+\frac{p_{\kappa f}}{m}\right), \tag{II.26}$$

$$[S_\kappa,p_f]=i\hbar(p_{\dot{f}}+m\omega x_{\kappa f}), \tag{II.27}$$

$$[S_\kappa,H_{\kappa'}]=i\hbar H_{\dot{\kappa}'}, \tag{II.28}$$

$$[S_\kappa,S_{\kappa'}]=i\hbar H_{\dot{\kappa}}-i\hbar H_{\dot{\kappa}'}. \tag{II.29}$$

A key observation is that *if* the operators $e^{(i/\hbar)S_\kappa}$ existed, they would produce the history algebra automorphism,

$$e^{(i/\hbar)sS_\kappa}b_te^{-(i/\hbar)sS_\kappa}=e^{-i\omega\int_t^{t+s}\kappa(t+s')ds'+s(d/dt)}b_t, \tag{II.30}$$

or, in the more rigorous smeared form,

$$e^{(i/\hbar)sS_\kappa}b_fe^{-(i/\hbar)sS_\kappa}=b_{\Sigma_s f}, \tag{II.31}$$

where the unitary operator Σ_s is defined on $\mathcal{L}^2(\mathbf{R})$ by

$$(\Sigma_s\psi)(t):=e^{-i\omega\int_t^{t+s}\kappa(t+s')ds'}\psi(t+s). \tag{II.32}$$

However, an important property of the Fock construction states that when there exists a unitary operator e^{isA} acting on $\mathcal{L}^2(\mathbf{R})$, there exists a unitary operator $\Gamma(e^{isA})$ that acts on the exponential Fock space [a general expression for a Fock space is $e^{\mathcal{H}}=\oplus_{n=0}^{\infty}(\otimes_n \mathcal{H})$, where $\mathcal{H}$ is called the base Hilbert space of the Fock space $e^{\mathcal{H}}$] $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ in such a way that

$$\Gamma(e^{isA})b_f^\dagger\Gamma(e^{isA})^{-1}=b^\dagger_{e^{isA}f}, \tag{II.33}$$

then the operator $d\Gamma(A)$ on $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ can also be defined as

$$\Gamma(e^{isA})=e^{is\,d\Gamma(A)}, \tag{II.34}$$

in terms of A, a self-adjoint operator that acts on $\mathcal{L}^2(\mathbf{R})$. In particular, it follows that the representation of the history algebra on the Fock space $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ carries a (weakly continuous) representation of the one-parameter family of unitary operators $s\mapsto e^{(i/\hbar)sS_\kappa}=\Gamma(\Sigma_s)$. Therefore, the generator S_κ also exists on $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ and $S=d\Gamma(-\hbar\sigma_\kappa)$, where σ_κ is a self-adjoint operator that acts on $\mathcal{L}^2(\mathbf{R})$ and is defined as

$$\sigma_\kappa\psi(t):=\left(-\omega\kappa(t)-i\frac{d}{dt}\right)\psi(t). \tag{II.35}$$

In what follows, we will restrict our attention to the particular case $\kappa(t)=1$ for the simple harmonic oscillator action operator S,

$$S:=\int_{-\infty}^{+\infty}\langle p_t\dot{x}_t-H_t\rangle dt. \tag{II.36}$$

The Liouville operator definition. The first term of the action operator, Eq. (II.36), is identical to the kinematical part of the classical action functional, Eq. (II.18). For reasons that will become apparent later, we write S_κ as the difference between two operators: the Liouville operator and the Hamiltonian operator. The Liouville operator is formally written as

$$V:=\int_{-\infty}^{\infty}(p_t\dot{q}_t)dt, \tag{II.37}$$

where

$$S_\kappa=V-H_\kappa. \tag{II.38}$$

We prove the existence of V on $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ using the same technique as before. Namely, we can see at once that the history algebra automorphism,

$$e^{(i/\hbar)sV}b_f e^{-(i/\hbar)sV}=b_{B_s f}, \tag{II.39}$$

is unitarily implementable. Here, the unitary operator B_s, $s\in\mathbf{R}$, acting on $\mathcal{L}^2(\mathbf{R})$ is defined by

$$(B_s f)(t):=e^{s(d/dt)}f(t)=e^{isD}f(t)=f(t+s), \tag{II.40}$$

where $D:=-i(d/dt)$. The Liouville operator V has some interesting commutation relations with the generators of the history algebra:

$$[V,x_f]=-i\hbar x_{\dot{f}}, \tag{II.41}$$

$$[V,p_f]=-i\hbar p_{\dot{f}}, \tag{II.42}$$

$$[V,H_\kappa]=-i\hbar H_{\dot{\kappa}}, \tag{II.43}$$

$$[V,S_k]=i\hbar H_{\dot\kappa}, \tag{II.44}$$

$$[V,H]=0, \tag{II.45}$$

$$[V,S]=0, \tag{II.46}$$

where we have defined $H:=\int_{-\infty}^{\infty}H_t\,dt$.

We notice that V transforms, for example, b_t from one time t—that refers to the Hilbert space $\mathcal{H}_t$—to another time $t+s$, that refers to $\mathcal{H}_{t+s}$. More precisely, V transforms the support of the operator-valued distribution b_t from t to $t+s$:

$$e^{(i/\hbar)sV}b_f e^{-(i/\hbar)sV}=b_{f_s}, \tag{II.47}$$

where $f_s(t):=f(s+t)$. We shall return to the significance of this later.

The Fourier-transformed ''n-particle'' history propositions. An interesting family of history propositions emerges from the representation space $\mathcal{F}[\mathcal{L}^2(\mathbf{R},dt)]$, acting on the δ-function normalized basis of states $|0\rangle$, $|t_1\rangle:=b^\dagger_{t_1}|0\rangle$, $|t_1,t_2\rangle:=b^\dagger_{t_1}b^\dagger_{t_2}|0\rangle$, etc.; or, in smeared form, $|\phi\rangle:=b^\dagger_\phi|0\rangle$, etc. The projection operator $|t\rangle\langle t|$ corresponds to the history proposition ''there is a unit energy $\hbar\omega$ concentrated at the time point t.'' The physical interpretation for this family of propositions, was deduced from the action of the Hamiltonian operator on the family of $|t\rangle$ states:

$$H_t|0\rangle=0, \tag{II.48}$$

$$H_t|t_1\rangle=\hbar\omega\,\delta(t-t_1)|t_1\rangle, \tag{II.49}$$

$$H_t|t_1,t_2\rangle=\hbar\omega[\delta(t-t_1)+\delta(t-t_2)]|t_1,t_2\rangle.$$
$$\vdots \tag{II.50}$$

To study the behavior of the S operator, a particularly useful basis for $\mathcal{F}[\mathcal{L}^2(\mathbf{R},dt)]$ is the Fourier transforms of the $|t\rangle$ states. Indeed, if we consider the Fourier transformations,

$$|\nu\rangle=\int_{-\infty}^{+\infty}e^{i\nu t}b_t^\dagger|0\rangle dt, \tag{II.51}$$

$$|\nu_1,\nu_2\rangle=\int_{-\infty}^{+\infty}e^{i\nu_1t_1}e^{i\nu_2t_2}b^\dagger_{t_1}b^\dagger_{t_2}|0\rangle dt_1\,dt_2, \tag{II.52}$$

$$b_\nu=\int_{-\infty}^{+\infty}e^{i\nu t}b_t\,dt, \tag{II.53}$$

$$b_\nu^\dagger=\int_{-\infty}^{+\infty}e^{-i\nu t}b_t^\dagger\,dt, \tag{II.54}$$

the Fourier transformed $|\nu\rangle$ states are defined by $|\nu\rangle:=b^\dagger_\nu|0\rangle$, $|\nu_1,\nu_2\rangle:=b^\dagger_{\nu_1}b^\dagger_{\nu_2}|0\rangle$, etc. The eigenvectors of the operator S are calculated to be

$$S|0\rangle=0, \tag{II.55}$$

$$S|\nu\rangle=\hbar(\nu-\omega)|\nu\rangle, \tag{II.56}$$

$$S|\nu_1,\nu_2\rangle=\hbar[(\nu_1-\omega)+(\nu_2-\omega)]|\nu_1,\nu_2\rangle, \tag{II.57}$$

and we note, in particular, that $e^{(i/\hbar)sS}|0\rangle=|0\rangle$.

The $|\nu\rangle$ states are also eigenstates of the Hamiltonian operator:

$$H|0\rangle=0, \tag{II.58}$$

$$H|\nu\rangle=\hbar\omega|\nu\rangle, \tag{II.59}$$

$$H|\nu_1,\nu_2\rangle=2\hbar\omega|\nu_1,\nu_2\rangle. \\ \vdots \tag{II.60}$$

Again, as for the case of the $|t\rangle$ states, for the special case of $H:=\int_{-\infty}^{\infty}H_t\,dt$, and for the simple harmonic oscillator example, we see how the integer-spaced spectrum of the standard quantum field theory appears in the HPO theory. The $|\nu\rangle\langle\nu|$ history propositions give the spectrum of the action operator and they have an interesting connection with the $|t\rangle\langle t|$ propositions.

A. The velocity operator

In Ref. 5, we emphasized the existence of the operator $\dot{x}_t:=(d/dt)x_t$, that corresponds to history propositions about the velocity of the system. The velocity operator is better defined in its smeared form using the familiar quantum field theory procedure,

$$\dot{x}_f=-x_{\dot{f}}. \tag{II.61}$$

In analogy with quantum field theory, this requires the function f to be differentiable and to ''vanish at infinity'' so that the implicit integration by parts in Eq. (II.61) is valid. We note that, in this HPO theory, the velocity operator commutes with the position

$$[x_t,\dot{x}_{t'}]=0, \tag{II.62}$$

and therefore there exist history propositions about the position and the velocity at the same time.

Furthermore, the existence of the Liouville operator in the HPO scheme, allows an interesting comparison between the velocity $\dot{x}_f$ and the momentum p_f operators: namely, the momentum operator is defined by the history commutation relation of the position with the Hamiltonian, while we can define the velocity operator from the history commutation relation of the position with the Liouville operator:

$$[x_f,H]=i\hbar\frac{p_f}{m}, \tag{II.63}$$

$$[x_f,V]=i\hbar\dot{x}_f. \tag{II.64}$$

These relations signify the different nature of the momentum p_f from the velocity $\dot{x}_f$ concerning the dynamical behavior of the momentum (related to the Hamiltonian operator), as opposed to the kinematical behavior of the velocity (related to the Liouville operator).

B. The Heisenberg picture

In standard quantum theory, a Heisenberg-picture operator $A(s)$ is defined as

$$A_{\mathrm{H}}(s):=e^{(i/\hbar)sH}Ae^{-(i/\hbar)sH}. \tag{II.65}$$

In particular, for the case of a simple harmonic oscillator, the equation of motion is

$$\frac{d^2}{ds^2}x(s)+\omega^2x(s)=0, \tag{II.66}$$

from which we obtain the solution

$$x(s)=\cos(s\omega)x+\frac{1}{m\omega}\sin(s\omega)p, \tag{II.67}$$

$$p(s) = -m\omega \sin(s\omega)x + \cos(s\omega)p, \tag{II.68}$$

where we have used the classical equation,

$$p := m \left.\frac{dx(s)}{ds}\right|_{s=0}. \tag{II.69}$$

The commutation relations between these operators is

$$[x(s_1), x(s_2)] = \frac{i\hbar}{m\omega} \sin[\omega(s_1 - s_2)]. \tag{II.70}$$

In formulating a history analog of the Heisenberg picture,[5] we adopted a ''time-averaged'' Heisenberg picture defined by

$$x_{\kappa,t} := e^{i/\hbar H_\kappa} x_t e^{-i/\hbar H_\kappa} = \cos[\omega\kappa(t)]x_t + \frac{1}{m\omega}\sin[\omega\kappa(t)]p_t, \tag{II.71}$$

for suitable test functions κ. The analog of the equations of motion is the functional differential equation,

$$\frac{\delta^2 x_{\kappa,t}}{\delta\kappa(s_1)\,\delta\kappa(s_2)} + \delta(t - s_1)\,\delta(t - s_2)\,\omega^2 x_{\kappa,t} = 0 \tag{II.72}$$

and

$$\delta(t - s)p_t = m \left.\frac{\delta x_{\kappa,t}}{\delta\kappa(s)}\right|_{\kappa=0} \tag{II.73}$$

is the history analog of the classical equation, $p := m[dx(s)/ds]|_{s=0}$.

We noted then that the Heisenberg-picture in a HPO theory involves two time labels: an ''external'' label t—that specifies the time the proposition is asserted—and an ''internal'' label s that, for a fixed time t, is the time parameter of the Heisenberg picture associated with the copy $\mathcal{H}_t$ of the standard Hilbert space. Using our new results, the two labels appear naturally in a new version of the Heisenberg picture: they are related to the groups that produce the two types of time transformations. In addition, the analogy with the classical expressions is regained.

To see this explicitly, we define a Heisenberg picture analog of x_t as

$$x_{\kappa,t,s} := e^{(i/\hbar)sH_\kappa} x_t e^{-(i/\hbar)sH_\kappa} = \cos[\omega s\kappa(t)]x_t + \frac{1}{m\omega}\sin[\omega s\kappa(t)]p_t \tag{II.74}$$

$$p_{\kappa,t,s} := e^{(i/\hbar)sH_\kappa} p_t e^{-(i/\hbar)sH_\kappa} = -m\omega \sin[\omega s\kappa(t)]x_t + \cos[\omega s\kappa(t)]p_t. \tag{II.75}$$

The commutation relations for these operators are

$$[x_{\kappa,t}(s), x_{\kappa',t'}(s')] = \frac{i\hbar}{m\omega}\sin[\omega\kappa(s' - s)]\,\delta(t - t'), \tag{II.76}$$

$$[x_{\kappa,t}(s), S_{\kappa'}] = i\hbar\left[\cos[s\omega\kappa(t)]\dot{x}_t + \frac{1}{m\omega}\sin[s\omega\kappa(t)]\dot{p}_t - \frac{\kappa'}{m}p_{\kappa,t,s}\right], \tag{II.77}$$

$$[p_{\kappa,t}(s), S_{\kappa'}] = i\hbar\left[\cos[s\omega\kappa(t)]\dot{p}_t - m\omega\sin[s\omega\kappa(t)]\dot{x}_t + \kappa'(t)x_{\kappa,t,s}\right], \tag{II.78}$$

and from these commutators we obtain the HPO analog of the equations of motion,

$$\frac{d^2}{ds^2}x_{\kappa,t,s}+\omega^2\kappa(t)^2 x_{\kappa,t,s}=0. \tag{II.79}$$

We notice the strong resemblance with standard quantum theory; for the case $\kappa(t)=1$, the classical expressions are fully recovered.

In the HPO formalism, the Heisenberg picture objects appear time averaged with respect to the "external" time label t. On the other hand, the "internal" time label s is the time-evolution parameter of the standard Heisenberg picture, as viewed in the Hilbert space $\mathcal{H}_t$. In what follows, we will show how the Heisenberg picture operators evolve in time under the action of the groups of time transformations.

III. TIME TRANSFORMATION IN THE HPO FORMALISM

In classical theory, the Hamiltonian H is the generator of time transformations. In terms of Poisson brackets, the generalized equation of motion for an arbitrary function u is given by

$$\frac{du}{dt}=\{u,H\}+\frac{\partial u}{\partial t}. \tag{III.1}$$

In a HPO theory, the Hamiltonian operator H_t produces phase changes in time, preserving the time label t of the Hilbert space on which, at least formally, H_t is defined. On the other, it is the Liouville operator V that assigns, analogous to the classical case, history commutation relations, and produces time transformations "from one Hilbert space to another." The action operator generates a combination of these two types of time transformation. If we use the notation $x_f(s)$ for the *history* Heisenberg-picture operators smeared with respect to the time label t, we observe that they behave as standard Heisenberg-picture operators, with time parameter s. Furthermore, their history commutation relations strongly resemble the classical expressions:

$$[x_f(s),V]=i\hbar\dot{x}_f(s), \tag{III.2}$$

$$[x_f(s),H]=\frac{i\hbar}{m}p_f(s), \tag{III.3}$$

$$[x_f(s),S]=i\hbar\left(\dot{x}_f(s)-\frac{1}{m}p_f(s)\right). \tag{III.4}$$

We define a one-parameter group of transformations $T_V(\tau)$, with elements $e^{(i/\hbar)\tau V}$, $\tau\in\mathbf{R}$, where V is the Liouville operator and we consider its action on the b_t operator; for simplicity, we write the unsmeared expressions

$$e^{(i/\hbar)\tau V}b_{t,s}e^{-(i/\hbar)\tau V}=b_{t+\tau,s}. \tag{III.5}$$

The Liouville operator is the generator of transformations of the time parameter t labeling the Hilbert spaces $\mathcal{H}_t$.

Then, we define a one-parameter group of transformations T_{H}, with elements $e^{(i/\hbar)\tau H}$, where H is the time-averaged Hamiltonian operator,

$$e^{(i/\hbar)\tau H}b_{t,s}e^{-(i/\hbar)\tau H}=b_{t,s+\tau}. \tag{III.6}$$

The Hamiltonian operator is the generator of phase changes of the time parameter s, produced only on one Hilbert space $\mathcal{H}_t$, for a fixed value of the t parameter.

Finally, we define the one-parameter group of transformations T_S, with elements $e^{(i/\hbar)\tau S}$, where S is the action operator,

$$e^{(i/\hbar)\tau S}b_{t,s}e^{-(i/\hbar)\tau S}=b_{t+\tau,s+\tau}. \tag{III.7}$$

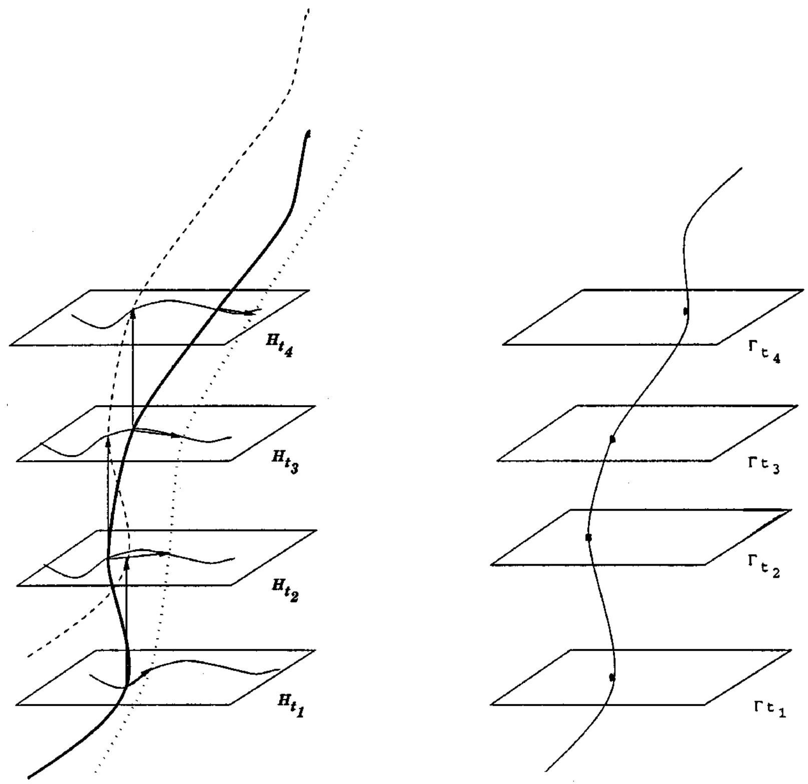

FIG. 1. Quantum and classical history curves. In (a) the transformation of the history curves generated by V is represented by the dashed line, while the transformation generated by H are represented by the dotted line. The curves drawn on each ''Hilbert plane'' correspond to the Hamiltonian transformations, as affected on the corresponding Hilbert space. In (b) the classical history remains invariant under the corresponding time transformations.

The action operator generates both types of time transformations—a feature that appears only in the HPO scheme.

In Fig. 1(a) and 1(b), we denote a quantum continuous-time history as a curve and the tensor product of Hilbert spaces as a sequence of planes, each one representing a copy of the standard Hilbert space. Each plane is labeled by the time label t that the corresponding Hilbert space H_t carries. We depict then a history, as a curve along an n-fold sequence of ''Hilbert planes'' $\mathcal{H}_{t_i}$. In analogy to this, we symbolize a classical history, as a curve along an n-fold sequence of planes corresponding to copies of the standard phase space Γ_{t_i}, as we will explain later. The time transformations generated by the Liouville operator shift the path in the direction of the ''Hilbert planes.'' On the other hand, the Hamiltonian operator generates time transformations that move the history curve in the direction of the path, as represented on one ''Hilbert plane.''

The duality in time evolution. In standard quantum theory, time evolution is described by two different laws: the wave-packet reduction that occurs at a measurement, and the unitary time evolution that takes place between measurements. Thus, according to von Neumann, one has to augment the Schrödinger equation with the collapse of the wave function associated with a measurement.[13]

It seems that the two types of time transformations observed in the HPO theory correspond to the two dynamical processes in standard quantum theory: the time transformations generated by the Liouville operator V are (argueably) related to the wave-packet reduction (the time ordering implied by the wave-packet reduction to be precise), while the time transformations produced by the Hamiltonian operator H are related to the unitary time evolution between measurements.

The argument in support of this assertion is as follows. Keeping in mind the description of the History space as a tensor product of single-time Hilbert spaces $\mathcal{H}_t$, the V operator acts on the

Schrödinger-picture projection operators, translating them in time from one Hilbert space to another. These time-ordered projectors appear in the expression for the decoherence functional that defines probabilities. In history theory, the expression for probabilities in a consistent set is the same as that derived in standard quantum theory using the projection postulate on a time-ordered sequence of measurements.[1,2] It is this that suggests a relation of the Liouville operator to ''wave-packet reduction.'' To strengthen this claim, in what follows we will show the analogy of V with the S_{cts} operator (an approximation of the derivative operator), that appears in the decoherence function and is implicitly related to the wave-packet reduction by specifying the time ordering of the action of the single-time projectors. The action of V as a generator of time translations depends on the partial (in fact, total) ordering of the time parameter treated as the causal structure in the underlying spacetime. Hence, the V-time translations illustrate the purely kinematical function of the Liouville operator.

The Hamiltonian operator producing transformations, with an evident reference to the Heisenberg time evolution, appears as the ''clock'' of the theory. As such, it depends on the particular physical system that the Hamiltonian describes. Indeed, we would expect the definition of a ''clock'' for the evolution in time of a physical system to be connected with the dynamics of the system concerned. We note that the idea of reparametrizing time depends on the smearing function $\kappa(t)$ used in the definition of the Hamiltonian operator; $\kappa(t)$ is kept fixed for a particular physical system.

The coexistence of the two types of time evolution, as reflected in the action operator identified as the generator of such time transformations, is a striking result. In particular, its definition is in accord with its classical analog, namely, the Hamilton action functional. In classical theory, a distinction between a kinematical and a dynamical part of the action functional also arises, in the sense that the first part corresponds to the symplectic structure and the second to the Hamiltonian.

IV. THE CLASSICAL SIGNATURE OF THE HPO FORMALISM

Let us now consider more closely the relation of the classical and the quantum histories. We have shown above how the action operator generates time translations from one Hilbert space to another through the Liouville operator; and on each labeled Hilbert space $\mathcal{H}_t$, through the Hamiltonian operator. We now wish to discuss in more detail the analog of these transformations in the classical case.

We recall that a history is a time-ordered sequence of propositions about the system. The continuous-time quantum history in the HPO system makes assertions about the values of the position or the momentum of the system, or a linear combination of them, at each moment of time, and is represented by a projection operator on the continuous tensor product of copies of the standard Hilbert space.

One expects that a continuous-time classical history should reflect the underlying temporal logic of the situation. Thus, the assertions about the position and the momentum of the system at each moment of time should be represented on an analogous history space: this can be achieved by using the Cartesian product of a continuous family (labeled by the time t) of copies of the standard classical state space.

In classical mechanics, a (fine-grained) classical history is represented by a path in the state space. Indeed, a path γ is defined as a map on the standard phase space,

$$\gamma:\mathbf{R}\rightarrow\Gamma,$$

$$t\mapsto(q(\gamma(t)),p(\gamma(t))), \tag{IV.1}$$

where $q(\gamma(t))$ and $p(\gamma(t))$ are the position and momentum coordinates of the path γ, at the time t. For our purposes, we shall consider the path $t\mapsto\gamma(t)$ to defined for t in some finite time interval $[t_1,t_2]$. We shall denote the set of such paths by Π.

The key idea of this new approach to classical histories is contained in the symplectic structure of the theory: the choice of the Poisson bracket must be such that it includes entries at different moments of time. Thus, we suppose that the space of functions on Π is equipped with the ''history Poisson bracket'' defined by

$$\{q_t, p_{t'}\} = \delta(t - t'), \tag{IV.2}$$

where we defined the functions q_t on Π as

$$q_t : \Pi \rightarrow \mathbf{R}$$

$$\gamma \mapsto q_t(\gamma) := q(\gamma(t)),$$

and similarly for p_t.

We now define the history action functional $S_h(\gamma)$ on Π as

$$S_h(\gamma) := \int_{t_1}^{t_2} [p_t \dot{q}_t - H_t(p_t, q_t)](\gamma) dt, \tag{IV.3}$$

where $q_t(\gamma)$ is the position coordinate q at the time point $t \in [t_1, t_2]$ of the path γ, and $\dot{q}_t(\gamma)$ is the velocity coordinate at the time point $t \in [t_1, t_2]$ of the path γ.

We also define the history classical analogs for the Liouville and time-averaged Hamiltonian operators as

$$V_h(\gamma) := \int_{t_1}^{t_2} [p_t \dot{q}_t](\gamma) dt, \tag{IV.4}$$

$$H_h(\gamma) := \int_{t_1}^{t_2} [H_t(p_t, q_t)](\gamma) dt, \tag{IV.5}$$

$$S_h(\gamma) = V_h(\gamma) - H_h(\gamma). \tag{IV.6}$$

In classical mechanics, the least action principle states that there exists a functional $S(\gamma) = \int_{t_1}^{t_2} [p\dot{q} - H(p,q)](\gamma) dt$ such that the physically realized path is the curve in state space, γ_0, with respect to which the condition $\delta S(\gamma_0) = 0$ holds, when we consider variations around this curve. From this, the Hamilton equations are deduced to be

$$\dot{q} = \{q, H\}, \tag{IV.7}$$

$$\dot{p} = \{p, H\}, \tag{IV.8}$$

where q and p—the coordinates of the realized path γ_0—are the solutions of the classical equations of motion. For any function $F(q,p)$ of the classical solutions, it is also true that

$$\{F, H\} = \dot{F}. \tag{IV.9}$$

In the case of the classical continuous-time histories, one can formulate the above variational principal in terms of the Hamilton equations with the statement: A classical history $\gamma_{\rm cl}$ is the realized path of the system—i.e., a solution of the equations of motion of the system—if it satisfies the equations

$$\{q_t, V_h\}(\gamma_{\rm cl}) = \{q_t, H_h\}(\gamma_{\rm cl}), \tag{IV.10}$$

$$\{p_t, V_h\}(\gamma_{\rm cl}) = \{p_t, H_h\}(\gamma_{\rm cl}), \tag{IV.11}$$

where $\gamma_{\rm cl}=(q_t(\gamma_{\rm cl}),p_t(\gamma_{\rm cl}))$, and $q_t(\gamma_{\rm cl})$ is the position coordinate of the realized path $\gamma_{\rm cl}$ at the time point t. The equations (IV.10)–(IV.11) are the history equivalent of the Hamilton equations of motion. Indeed, for the case of the simple harmonic oscillator in one dimension, Eqs. (IV.10)–(IV.11) become

$$\dot{q}_t(\gamma_{\rm cl})=\frac{p_t}{m}(\gamma_{\rm cl}), \tag{IV.12}$$

$$\dot{p}_t(\gamma_{\rm cl})=-m\omega^2 q_t(\gamma_{\rm cl}), \tag{IV.13}$$

where $\dot{q}_t(\gamma_{\rm cl})=\dot{q}(\gamma_{\rm cl}(t))|$ is the value of the velocity of the system at time t. One would have expected the result in Eqs. (IV.10)–(IV.11) for the classical analog of the histories formalism, as it shows that the classical analog of the two types of time transformation in the quantum theory coincide.

From Eqs. (IV.10)–(IV.11), we also conclude that the canonical transformation generated by the history action functional $S_h(\gamma_{\rm cl})$ leaves invariant the paths that are classical solutions of the system:

$$\{q_t,S_h\}(\gamma_{\rm cl})=0, \tag{IV.14}$$

$$\{p_t,S_h\}(\gamma_{\rm cl})=0. \tag{IV.15}$$

It also holds that any function F on Π satisfies the equation

$$\{F,S_h\}(\gamma_{\rm cl})=0. \tag{IV.16}$$

Some of these statements are implicit in a previous work by Anastopoulos;[14] an interesting application of a similar extended Poisson bracket using a different formulation has been done by Kouletsis.[15]

''Classical'' coherent states for the simple harmonic oscillator. The relation between the classical and the quantum theories can be further exemplified by using coherent states. This special class of states was used in Ref. 6 to represent certain continuous-time history propositions in the history space. Coherent states are particularly useful for this purpose since they form a natural (overcomplete) base for the Fock space representation of the history algebra.

A class of coherent states in the relevant Fock space is generated by unitary transformations on the cyclic vacuum state:

$$|f,h\rangle := U[f,h]|0\rangle, \tag{IV.17}$$

where $U[f,h]$ is the Weyl operator defined as

$$U[f,h]:=e^{(i/\hbar)(x_f-p_h)}, \tag{IV.18}$$

where f and h are test functions in $L^2(\mathbf{R})$. The Weyl generator,

$$\alpha(f,h):=x(f)-p(h), \tag{IV.19}$$

can alternatively be written as

$$\alpha(f,h)=\frac{\hbar}{i}(b^\dagger(w)-b(w^*)), \tag{IV.20}$$

where $w:=f+ih$.

Suppose now that, for a pair of functions (f,h), the operator $\alpha(f,h)$ commutes with the action operator S,

$$[S,\alpha(f,h)]=0. \tag{IV.21}$$

Then any pair (*f*,*h*) satisfying this equation is necessarily a solution of the system of differential equations obtained from Eq. (IV.21):

$$\dot{f}+m\omega^2 h=0, \tag{IV.22}$$

$$\dot{h}-\frac{f}{m}=0. \tag{IV.23}$$

We see that if we identify f with the classical momentum $p_{\rm cl}$ and h with the classical position $x_{\rm cl}$, then Eqs. (IV.22)–(IV.23) are precisely the classical equations of motion for the simple harmonic oscillator:

$$\ddot{x}_{\rm cl}+\omega^2 x_{\rm cl}=0. \tag{IV.24}$$

The classical solutions (*f*,*h*) distinguish a special class of Weyl operators $\alpha_{\rm cl}(f,h)$, and, hence, a special class of coherent states:

$$|\exp z_{\rm cl}\rangle := U_{\alpha_{\rm cl}(f,h)}|0\rangle, \tag{IV.25}$$

where $z_{\rm cl}:=f+ih$.

These classical-like features stem from the following relation with S:

$$[S,U_{\alpha_{\rm cl}}]=0, \tag{IV.26}$$

$$[S,P_{|\exp z_{\rm cl}\rangle}]=0, \tag{IV.27}$$

where $P_{|\exp z_{\rm cl}\rangle}$ is the projection operator onto the (non-normalized) coherent state $|\exp z_{\rm cl}\rangle$:

$$P_{|\exp z_{\rm cl}\rangle} := \frac{|\exp z_{\rm cl}\rangle\langle \exp z_{\rm cl}|}{\langle \exp z_{\rm cl}|\exp z_{\rm cl}\rangle}. \tag{IV.28}$$

We note that there exists an analogy between Eqs. (IV.14)–(IV.15) and Eq. (IV.27), if we consider (*f*,*h*) to be the classical solution: $t\mapsto(q_t,p_t)(\gamma_{\rm cl})$. In classical histories, the canonical transformation, Eqs. (IV.14)–(IV.15), generated by the history action functional, vanishes on a solution to the equations of motion. On the other hand, when we deal with quantum histories, the action operator produces the classical equations of motion, Eqs. (IV.23)–(IV.22), when we require that it commutes with the projector [as in Eq. (IV.28)], which corresponds to a classical solution (*f*,*h*) of the system. However, we do not imply from this appearance of the classical limit: to make any such physical predictions, we must involve the decoherence functional and the coarse graining operation.

Notice that the construction above holds for a generic potential, as long as there exists a representation on $\mathcal{V}_{\rm cts}$ of the history algebra on which the action operator is defined.

V. THE DECOHERENCE FUNCTIONAL ARGUMENT

In the consistent histories quantum theory, the dynamics of a system is described by the decoherence functional. In a classical theory it is the action functional that plays a similar role in regard to the dynamics of the system. It is only natural, then, to seek for the appearance of the action operator in the decoherence functional. The aim is to write the HPO expression for the decoherence functional, with respect to an operator that includes S, and to compare this operator (i.e., its matrix elements), with the operator $\mathcal{S}_{\rm cts}\mathcal{U}$ that appears in the decoherence functional.[6]

In the HPO formalism, the decoherence functional d has been constructed for the special case of continuous-time projection operators corresponding to coherent states.[6] To this end, a continuous product of projectors $\otimes_t P_{|\exp \lambda(t)\rangle}$ is identified with $P_{\otimes_t|\exp \lambda(\cdot)\rangle}$: the projector onto the (non-normalized) coherent states $\otimes_t|\exp \lambda(t)\rangle$ in the continuous tensor product $\otimes_t L^2_t(\mathcal{R})$. More precisely, this continuous tensor product is isomorphic to Fock space:

$$\mathcal{V}_{\mathrm{cts}} := \otimes_{t\in \mathbf{R}} \mathcal{L}^2{}_t(\mathbf{R}) \approx \exp(\mathcal{L}^2(\mathbf{R}, dt)), \tag{V.1}$$

and we can identify a projector on the Hilbert space $\mathcal{V}_{\mathrm{cts}}$ as

$$\otimes_{t\in \mathbf{R}} P_{|\exp(\lambda(t))\rangle} = P_{|\exp \lambda(\cdot)\rangle}, \tag{V.2}$$

with $P_{|\exp \lambda(\cdot)\rangle} = e^{-\langle \lambda,\lambda\rangle}|\exp \lambda(\cdot)\rangle\langle \exp \lambda(\cdot)|$. The action of the continuous-time histories projectors on the non-normalized coherent states $|\exp(\lambda(\cdot))\rangle$ is denoted by

$$P_{|\exp \lambda(\cdot)\rangle}|\exp(\mu(\cdot))\rangle = e^{-(\lambda,\mu-\lambda)}|\exp \lambda(\cdot)\rangle. \tag{V.3}$$

The decoherence functional $d(\mu,\nu)$ for two continuous-time histories is denoted by

$$d(\mu,\nu) = \mathrm{tr}_{\mathcal{V}_{\mathrm{cts}}\otimes \mathcal{V}_{\mathrm{cts}}}(P_{|\exp \mu(\cdot)\rangle} \otimes P_{|\exp(\nu(\cdot))\rangle} X), \tag{V.4}$$

where

$$X := \langle 0|\rho_{-\infty}|0\rangle (\mathcal{S}_{\mathrm{cts}}\mathcal{U})^{\dagger} \otimes (\mathcal{S}_{\mathrm{cts}}\mathcal{U}). \tag{V.5}$$

The operator $\mathcal{S}_{\mathrm{cts}}$ that appears in this expression for the $d(\mu,\nu)$ was defined as an approximation of the derivative operator, in the sense that

$$\mathcal{S}_{\mathrm{cts}}|\exp \nu(\cdot)\rangle = |\exp(\nu(\cdot) + \dot{\nu}(\cdot))\rangle, \tag{V.6}$$

while the dynamics was introduced by the operator $\mathcal{U}$, defined in such a way that the notion of time evolution is encoded,

$$e^{\langle \lambda,\dot{\lambda}\rangle} e^{(i/\hbar)H[\lambda]} = \mathrm{tr}_{\mathcal{V}_{\mathrm{cts}}}(\mathcal{S}_{\mathrm{cts}}\mathcal{U}\mathcal{P}_{|\exp \lambda(\cdot)\rangle}). \tag{V.7}$$

We expect V and H to play a similar role to that of $\mathcal{S}_{\mathrm{cts}}$ and $\mathcal{U}$, respectively, inside an expression for the decoherence functional. To demonstrate this, we will use the type of Fock space construction given in Eqs. (II.33)–(II.34). In particular, we use the property

$$\Gamma(A)|\exp \nu(\cdot)\rangle = |\exp(A\nu(\cdot))\rangle, \tag{V.8}$$

where A is an operator that acts on the elements $\nu(\cdot)$ of the base Hilbert space $\mathcal{H}$, while the operator $\Gamma(A)$, defined by Eq. (II.33), acts on the coherent states $|\exp \nu(\cdot)\rangle$ of the Fock space $e^{\mathcal{H}}$.

We notice that $\mathcal{U}$ is related to the unitary time evolution, Eq. (V.7), in a similar way to that of the Hamiltonian operator H,

$$e^{isH}|\exp \nu(\cdot)\rangle = \Gamma(e^{is\omega I})|\exp \nu(\cdot)\rangle = |\exp(e^{is\omega}\nu(\cdot))\rangle, \tag{V.9}$$

where I is the unit operator. We also notice that the action of the operator e^{isH} produces phase changes, as reflected on the right-hand side of Eq. (V.9) (which has been calculated for the special case of the simple harmonic oscillator). Furthermore, when the operator $\mathcal{S}_{\mathrm{cts}}$ acts on a coherent state, Eq. (V.6), it transforms it to another coherent state, which involves the addition to the defining function $\nu(\cdot)$ in a way that involves the time derivative of ν; and it is noteworthy that the Liouville operator V acts in a similar way:

$$e^{isV}|\exp \nu(\cdot)\rangle = \Gamma(e^{isD})|\exp \nu(\cdot)\rangle = |\exp(e^{isD}\nu(\cdot))\rangle, \tag{IV.10}$$

where

$$(e^{isD}\nu)(t)=\nu(t+s), \tag{V.11}$$

where $D:=-i(d/dt)$. The operator e^{isD} acts on the base Hilbert space, and corresponds to the operator e^{isV} under the Γ construction on the Fock space; that is, it acts on the vector $\nu(t)$ and transforms it to another one $\nu(t+s)$, which, for each time t, is translation by the time interval s.

This suggests that we define the operator $\mathcal{A}_s:=e^{isS}$, where $\mathcal{S}:=\int_{-\infty}^{+\infty}(p_t\dot{x}_t-H_t)dt$ is the action operator for the simple harmonic oscillator, which one expects to be related to the operator $\mathcal{S}_{\rm cts}\mathcal{U}$. For this reason, we write the matrix elements of both operators and compare them.

The general formula for the matrix elements of an arbitrary operator $\mathcal{T}$ with respect to the coherent states basis in the history space that was used in Ref. 6 is

$$\langle \exp \mu(\cdot)|\mathcal{T}|\exp \nu(\cdot)\rangle = e^{(\langle \mu,\delta/\delta\overline{\lambda}\rangle+\langle \delta/\delta\lambda,\nu\rangle)}\langle \exp \lambda(\cdot)|\mathcal{T}|\exp \lambda(\cdot)\rangle|_{\lambda=\overline{\lambda}=0}, \tag{V.12}$$

hence we need only compare the diagonal matrix elements of the two operators $\mathcal{S}_{\rm cts}\mathcal{U}$ and $\mathcal{A}_s$. Thus, we have

$$\langle \exp(\lambda(\cdot)|\mathcal{S}_{\rm cts}\mathcal{U}|\exp(\lambda(\cdot)\rangle = e^{\langle \lambda,\lambda+\dot{\lambda}\rangle}e^{(i/\hbar)H[\lambda]}, \tag{V.13}$$

where $H[\lambda]:=\int_{-\infty}^{\infty}H(\lambda(t))dt$ and $H(\lambda):=H(\lambda,\lambda)=\langle\lambda|H|\lambda\rangle/\langle\lambda|\lambda\rangle$; and

$$\langle \exp \lambda(\cdot)|\mathcal{A}_s|\exp \lambda(\cdot)\rangle = e^{\langle \lambda, e^{is(\omega I+D)}\lambda\rangle}, \tag{V.14}$$

with

$$(e^{is(\omega I+D)}\lambda)(t)=e^{is\omega}\lambda(t+s). \tag{V.15}$$

We can also write both of the above operators on the history space $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ using their corresponding operators on the Hilbert space $\mathcal{L}^2(\mathbf{R})$. The Γ construction shows that

$$\mathcal{S}_{\rm cts}\mathcal{U}=\Gamma(1+i\sigma), \tag{V.16}$$

$$\mathcal{A}_s=\Gamma(e^{is\sigma})=e^{is\, d\Gamma(\sigma)}, \tag{V.17}$$

where $\sigma=\omega I+iD$, and I is the unit operator. As expressions of the same function σ, the operators $\mathcal{S}_{\rm cts}\mathcal{U}$ and $\mathcal{A}_s$ commute. However, we cannot readily compute their common spectrum because the operator $\mathcal{S}_{\rm cts}\mathcal{U}$ is not self-adjoint.

We might speculate that the value of the decoherence functional is maximized for a continuous-time projector that corresponds to a coarse graining around the classical path. Indeed, if we take such a generic projection operator P, we expect that it should commute with the operator $\mathcal{S}_{\rm cts}\mathcal{U}$. In this context, we noticed earlier that the projection operator that corresponds to a classical solution (f,h) commutes with the action operator

$$[\mathcal{S}_{\rm cts}\mathcal{U},P_{(f,h)}]=0. \tag{V.18}$$

Finally, this argument should be compared with the similar condition for classical histories:

$$\{S_h,F_C\}(\gamma_{\rm cl})=0. \tag{V.19}$$

VI. CONCLUSIONS

We have examined the example of the simple harmonic oscillator, in one dimension, within the History Projection Operator formulation of the consistent-histories scheme. We defined the action operator as the quantum analog of the classical Hamilton action functional and we have proved its existence by finding a representation on the $\mathcal{F}(\mathcal{L}^2(\mathbf{R}))$ space of the history algebra. We have shown that the action operator is the generator of two types of time transformations: translations in time from one Hilbert space $\mathcal{H}_t$, labeled by the time parameter t, to another Hilbert space with a different label t, and phase changes in time with respect to the time parameter s of the standard Heisenberg-time evolution that acts in each individual Hilbert space $\mathcal{H}_t$. We have expressed the action operator in terms of the Liouville and Hamiltonian operators—which are the generators of the two types of time transformation— and that correspond to the kinematics and the dynamics of the theory, respectively.

We have constructed continuous-time classical histories defined on the continuous Cartesian product of copies of the phase space and demonstrated an analogous expression to the classical Hamilton's equations.

Finally, we have shown that the action operator commutes with the defining operator of the decoherence functional, thus appearing in the expression for the dynamics of the theory, as would have been expected.

One of the major reasons for undertaking this study was to provide new tools for tackling the recalcitrant problem of constructing a manifestly covariant quantum field theory in the consistent histories formalism. Work on this problem is now in progress, with the expectation that the Hamiltonian and Liouville operators will play a central role in the proof of explicit Poincaré invariance of the theory.

(Received 24 March 1999; accepted for publication 22 July 1999)

The information entropy of a single particle in a quantum-mechanical *D*-dimensional central potential is separated in two parts. One depends only on the specific form of the potential (radial entropy) and the other depends on the angular distribution (spatial entropy). The latter is given by an entropic-like integral of the hyperspherical harmonics, which is expressed in terms of the entropy of the Gegenbauer polynomials. This entropy is expressed in terms of the values of the quadratic logarithmic potential of Gegenbauer polynomials $C_n^\lambda(t)$ at the zeros of these polynomials. Then this potential for integer λ is given as a finite expansion of Chebyshev polynomials of even order, whose coefficients are shown to be Wilson polynomials. [S0022-2488(99)00111-5]

I. INTRODUCTION

The Boltzmann–Shannon information entropy[1,2] of a many particle system cannot have a closed form, although tight rigorous bounds in terms of radial expectation values have been derived.[3] Even for single-particle systems with prototypic central potentials (e.g., Coulomb and harmonic oscillator) this quantity, which measures the spread or extent of the associated quantum-mechanical probability density, has been fully determined in an analytical way only recently for quantum-mechanical states located at the two extremes of the energy spectrum.[4–9] That is, for the ground state and the first few lowest-lying excited states (where the wave function has a very simple form) and for high-lying (Rydberg) excited states (where the physical entropies are controlled by the asymptotics of L^p-like norms of the classical orthogonal polynomials[4,6,7,8,10,11])

Let us consider the information entropy of a *D*-dimensional single-particle system in a central potential $V(r)$, defined by

$$S_\rho = -\int \rho(\mathbf{r}) \log \rho(\mathbf{r}) d\mathbf{r}, \tag{1}$$

where $\mathbf{r}=(x_1,\ldots,x_D)$ and $\rho(\mathbf{r})=|\Psi(\mathbf{r})|^2$. The wave function Ψ is given by the Schrödinger equation of the system which in atomic units is

$$[-\tfrac{1}{2}\nabla^2+V(r)]\Psi(\mathbf{r})=E\Psi(\mathbf{r}).$$

Here, the information entropy S_ρ is shown to decompose into two parts; the radial entropy, which depends on the specific form of the potential $V(r)$, and the angular or ''spatial'' entropy $S(Y,D)$, which is an integral involving hyperspherical harmonics $Y_{l,\{\mu\}}(\Omega_D)$, as it is shown later on in this section. The rest of the paper is devoted to the determination of the spatial entropy, what is carried out in three steps. First, in Sec. II, this entity is explicitly expressed in terms of the entropy of the orthonormal Gegenbauer or ultraspherical polynomials $\{\hat{C}_n^\lambda(x);\ n=0,1,...\}$. Then, in Sec. III, this Gegenbauer entropy $E_n^\lambda \equiv E_n(\hat{C}_n^\lambda)$ is given in terms of the logarithmic potential of the squares of Gegenbauer polynomials; and, finally, this quadratic logarithmic potential with integer parameter λ is expressed in the form of a finite Chebyshev expansion, whose coefficients turn out to be Wilson polynomials.

To show the entropy decomposition we start writing the kinetic energy operator $-\frac{1}{2}\boldsymbol{\nabla}$ in hyperspherical coordinates,[12] this equation is transformed in

$$\left[-\frac{1}{2}\left(\frac{d^2}{dr^2}+\frac{D-1}{r}\frac{d}{dr}-\frac{\Lambda^2}{r^2}\right)+V(r)\right]\Psi(\mathbf{r})=E\Psi(\mathbf{r}).$$

The solution of this equation takes the form

$$\Psi(\mathbf{r})=R_{nl}(r)Y_{l,\{\mu\}}(\Omega_D), \tag{2}$$

where $R_{nl}(r)$ is the radial eigenfunction, i.e., solution of the radial Schrödinger equation

$$\left[-\frac{1}{2}\left(\frac{d^2}{dr^2}+\frac{D-1}{r}\frac{d}{dr}+\frac{l(l+D-2)}{r^2}\right)+V(r)\right]R_{nl}(r)=E_{nl}R_{nl}(r) \tag{3}$$

and $Y_{l,\{\mu\}}(\Omega_D)$ are the eigenfunctions of the nonradial part of the Hamiltonian, Λ^2, i.e.,[12]

$$\Lambda^2 Y_{l,\{\mu\}}(\Omega_D)=l(l+D-2)Y_{l,\{\mu\}}(\Omega_D), \tag{4}$$

where the orbital quantum number l and the magnetic quantum numbers $\{\mu\}$, are integers verifying

$$l=\mu_1\geqslant\mu_2\geqslant\cdots\geqslant\mu_{D-1},$$

with $\mu_{D-1}=|m|$. The functions $Y_{l,\{\mu\}}(\Omega_D)$ are the hyperspherical harmonics, given by[12–14]

$$Y_{l,\{\mu\}}(\Omega_D)=N_{l,\{\mu\}}e^{im\varphi}\prod_{j=1}^{D-2} C_{\mu_j-\mu_{j+1}}^{\alpha_j+\mu_{j+1}}(\cos\theta_j)(\sin\theta_j)^{\mu_{j+1}}, \tag{5a}$$

with the normalizing constant

$$N_{l,\{\mu\}}^2=\frac{1}{2\pi}\prod_{j=1}^{D-2}\frac{(\alpha_j+\mu_j)(\mu_j-\mu_{j+1})![\Gamma(\alpha_j+\mu_{j+1})]^2}{\pi 2^{1-2\alpha_j-2\mu_{j+1}}\Gamma(2\alpha_j+\mu_j+\mu_{j+1})}=\frac{1}{2\pi}\prod_{j=1}^{D-2}N_{l,\{\mu\}}^{(j)}. \tag{5b}$$

Here $2\alpha_j=D-j-1$, $C_n^\lambda(t)$ is a Gegenbauer polynomial of degree n and parameter λ, and the angles $\theta_1,\theta_2,\ldots,\theta_{D-2}$, ϕ are defined by

$$x_1=r\sin\theta_1\sin\theta_2\cdots\sin\theta_{D-2}\cos\varphi,$$

$$x_2=r\sin\theta_1\sin\theta_2\cdots\sin\theta_{D-2}\sin\varphi,$$

$$x_3=r\sin\theta_1\sin\theta_2\cdots\cos\theta_{D-2},$$

$$\vdots\ \vdots$$

$$x_{D-1}=r\sin\theta_1\cos\theta_2,$$

$$x_D=r\cos\theta_1,$$

with $0\leqslant\theta_j\leqslant\pi$, $j=1,...,D-2$, and $0\leqslant\varphi<2\pi$.

As a particular case, in two dimensions, we have

$$Y_m(\Omega_2)=\frac{e^{im\varphi}}{2\pi} \tag{6a}$$

with $|m|=0,1...$, and in the three-dimensional case ($D=3$),

$$Y_{l,m}(\Omega_3)=\left(\frac{(l+\frac{1}{2})(l-|m|)![\Gamma(|m|+\frac{1}{2})]^2}{2^{1-2|m|}\pi^2(l+|m|)!}\right)^{1/2} e^{im\varphi}(\sin\theta)^{|m|}C_{l-|m|}^{|m|+1/2}(\cos\theta), \tag{6b}$$

with $l=0,1,...y$ $|m|=0,1,...,l$. The expression (6b) can be written in terms of Legendre functions using the relationship between these functions and the Gegenbauer polynomials[15]

$$C_{l-m}^{m+1/2}(t)=(-1)^m\frac{(1-t^2)^{-m/2}m!2^m}{(2m)!}P_l^m(t). \tag{7}$$

Then, taking into account (2) and that the volume element in a D-dimensional space is

$$d\mathbf{r}=r^{D-1}drd\Omega_D, \quad d\Omega_D=\left(\prod_{j=1}^{D-2}\sin^{2\alpha_j}\theta_j d\theta_j\right)d\phi,$$

we have from (1) that the Boltzmann–Shannon entropy of a D-dimensional particle in a central potential $V(r)$ can be decomposed into two parts,

$$S_\rho=S(R;D)+S(Y;D), \tag{8}$$

where

$$S(R;D)=-\int r^{D-1}R_{nl}^2(r)\log R_{nl}^2(r)dr \tag{9}$$

is the contribution from the radial part of the wave function to the entropy (to be called radial entropy heretoforth), and

$$S(Y;D)=-\int |Y_{l,\{\mu\}}(\Omega_D)|^2\log|Y_{l,\{\mu\}}(\Omega_D)|^2 d\Omega_D \tag{10}$$

is the contribution from the angular part of the density, to be called spatial entropy heretoforth.

The radial entropy $S(R;D)$ cannot be calculated without knowing the specific form of the potential $V(r)$. Moreover, even when this form is known such as for Coulomb and harmonic oscillator potentials, its closed form has not yet been derived; despite it, its asymptotic behavior has been rigorously found as said before.

On the contrary, the spatial entropy $S(Y;D)$, also called entropy of the hyperspherical harmonic $Y_{l,\{\mu\}}(\Omega_D)$, does not depend on the potential so that it can be evaluated independently of it. This is done in the following sections.

II. SPATIAL ENTROPY AND GEGENBAUER ENTROPY

Taking into account expression (5a) of the hyperspherical harmonics, we find that the spatial entropy of a D-dimensional particle is

$$S(Y;D) = -\int |Y_{l,\{\mu\}}(\Omega_D)|^2 \log|Y_{l,\{\mu\}}(\Omega_D)|^2 d\Omega_D$$

$$= -\log N^2_{l,\{\mu\}} + \sum_{j=1}^{D-2} N^{(j)}_{l,\{\mu\}} (S(C^{\alpha_j+\mu_j+1}_{\mu_j-\mu_{j+1}}) - \mu_{j+1} I^{(j)}_{\{\mu\}}), \tag{11a}$$

where

$$S(C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}) \equiv -\int_{-1}^{+1} (1-t^2)^{\alpha_j+\mu_{j+1}-(1/2)} [C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(t)]^2 \log[C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(t)]^2 dt, \tag{11b}$$

and

$$I^{(j)}_{\{\mu\}} = \int_{-1}^{+1} (1-t^2)^{\alpha_j+\mu_{j+1}-(1/2)} [C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(t)]^2 \log(1-t^2) dt, \tag{11c}$$

where $S(C^\alpha_n)$ is the entropy of the Gegenbauer polynomials of degree n and parameter α. The integral $I^{(j)}_{\{\mu\}}$ can be calculated by use of the following result:[16]

$$\int_{-1}^{1} (1-x^2)^{\lambda-1/2} [C^\lambda_n(x)]^2 \log(1-x^2) dx$$

$$= \frac{\Gamma(2\lambda+n) 2^{1-2\lambda}}{n! \Gamma^2(\lambda)} \frac{\pi}{\lambda+n} \left[2\psi(2\lambda+n) - 2\psi(\lambda+n) - 2\log 2 - \frac{1}{\lambda+n} \right],$$

where $\psi(x)$ is the digamma or psi function, i.e., $\psi(x) = \Gamma'(x)/\Gamma(x)$. This value can also be obtained by differentiation of the Gegenbauer orthogonality relation

$$\int_{-1}^{+1} (1-x^2)^{\lambda-1/2} [C^\lambda_n(x)/(\lambda)_n]^2 dx = \frac{\pi 2^{1-2\lambda} \Gamma(n+2\lambda)}{n! [\Gamma(n+\lambda+1)]^2}$$

with respect to λ and noting that $(\partial/\partial\lambda)[C^\lambda_n(x)/(\lambda)_n]$ is a polynomial of degree $n-1$.

Taking into account this value and substituting it into (11a), one has

$$S(Y;D) = \log 2\pi - \sum_{j=1}^{D-2} \log N^{(j)}_{l,\{\mu\}} + \sum_{j=1}^{D-2} N^{(j)}_{l,\{\mu\}} S(C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}})$$

$$-\sum_{j=1}^{D-2} \mu_{j+1} \left[2\psi(2\alpha_j+\mu_j+\mu_{j+1}) - 2\psi(\alpha_j+\mu_j) - 2\log 2 - \frac{1}{\alpha_j+\mu_j} \right]. \tag{12}$$

Finally, since the orthonormal Gegenbauer polynomial $\hat{C}^\lambda_n(x) = h_n^{-1} C^\lambda_n(x)$, with

$$h_n^2 = \pi \frac{2^{1-2\lambda} \Gamma(n+2\lambda)}{[\Gamma(\lambda)]^2 (n+\lambda) n!},$$

one has from (11b),

$$S(Y;D) = \log 2\pi + \sum_{j=1}^{D-2} E(\hat{C}^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}})$$

$$-\sum_{j=1}^{D-2} \mu_{j+1} \left[2\psi(2\alpha_j+\mu_j+\mu_{j+1}) - 2\psi(\alpha_j+\mu_j) - 2\log 2 - \frac{1}{\alpha_j+\mu_j} \right], \tag{13a}$$

where

$$E(\hat{C}^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}})=-\int_{-1}^{+1}(1-t^2)^{\alpha_j+\mu_{j+1}-(1/2)}[\hat{C}^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(t)]^2\log[\hat{C}^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(t)]^2dt \tag{13b}$$

is the entropy of orthonormal Gegenbauer polynomials of degree $\mu_j-\mu_{j+1}$ and parameter $\alpha_j+\mu_{j+1}$, or simply, Gegenbauer entropy.

So, it is observed that the calculation of the angular entropy of a particle under an arbitrary central potential gets reduced to the computation of the entropy of Gegenbauer polynomials. In particular, we have

(i) For $D=2$, the entropy $S(Y;2)$ is

$$S(Y;2)=\log 2\pi, \tag{14}$$

which does not depend on the magnetic quantum number m.

(ii) For $D=3$, Eq. (12) reduces to

$$\begin{aligned}S(Y;3)=&-\int|Y_{lm}(\Omega_3)|^2\log|Y_{lm}(\Omega_3)|^2d\Omega_3\\ &=\log 2\pi-\log\left[\frac{(l+\frac{1}{2})(l-|m|)![\Gamma(|m|+\frac{1}{2})]^2}{\pi 2^{-2|m|}(l+|m|)!}\right]+\frac{(l+\frac{1}{2})(l-|m|)![\Gamma(|m|+\frac{1}{2})]^2}{\pi 2^{-2|m|}(l+|m|)!}S(C^{|m|+(1/2)}_{l-|m|})\\ &-|m|\left[2\psi(l+|m|+1)-2\psi\left(l+\frac{1}{2}\right)-2\log 2-\frac{1}{l+\frac{1}{2}}\right].\end{aligned} \tag{15}$$

Also, from Eq. (13b) one has

$$S(Y;3)=\log 2\pi+E(\hat{C}^{|m|+(1/2)}_{l-|m|})-|m|\left[2\psi(l+|m|+1)-2\psi\left(l+\frac{1}{2}\right)-2\log 2-\frac{1}{l+\frac{1}{2}}\right]. \tag{16}$$

It is interesting to note that, using the relations (7) and (15), we have the alternative expression

$$S(Y;3)=-\log\left(\frac{(2l+1)(l-m)!}{4\pi(l+m)!}\right)+\left(\frac{(2l+1)(l-m)!}{2(l+m)!}\right)S(P_l^m), \tag{17a}$$

where

$$S(P_l^m)=-\int_{-1}^{+1}[P_l^m(t)]^2\log[P_l^m(t)]^2dt \tag{17b}$$

denotes the entropy of the Legendre function $P_l^m(t)$.

III. ENTROPY AND LOGARITHMIC POTENTIAL OF GEGENBAUER POLYNOMIALS

Aptekarev *et al.*[4] have recently shown that the asymptotic behavior of the entropy of the Gegenbauer polynomials $E_n^\lambda=E(\hat{C}_n^\lambda)$ defined by

$$E_n^\lambda:=-\int_{-1}^{+1}\omega_\lambda(t)[\hat{C}_n^\lambda(t)]^2\log[\hat{C}_n^\lambda(t)]^2dt \tag{18}$$

is given by

$$E_n^\lambda\approx E_\infty^\lambda=-1+\log 2-I(\rho_0,\omega_\lambda)=-1+(1-2\lambda)\log 2+\log\pi+o(1),$$

where the relative entropy between the equilibrium measure

$$\rho_0(x)=(1/\pi)(1/\sqrt{1-x^2})$$

and the weight function $\omega_\lambda(x)=(1-x^2)^{\lambda-(1/2)}$ is

$$I(\rho_0,\omega_\lambda)=\int_{-1}^{+1}\rho_0(t)\log\frac{\rho_0(t)}{\omega_\lambda(t)}\,dt=2\lambda\log 2-\log\pi.$$

Also, they observed[4] that the rate of convergence of E_n^λ is

$$E_n^\lambda=E_\infty^\lambda+\frac{k_\lambda}{n}+o\left(\frac{1}{n}\right) \tag{19}$$

and studied the numerical dependence of k_λ on λ. Moreover, they conjectured a similar rate of convergence for the entropy of general orthogonal polynomials with a constant k depending only on the weight function of the polynomials.

Moreover, the consideration of the probability weight function

$$\rho_\lambda(x)=\frac{\lambda\Gamma^2(\lambda)}{2^{1-2\lambda}\Gamma(2\lambda)\pi}(1-x^2)^{\lambda-(1/2)}$$

and its corresponding orthonormal polynomials

$$p_n^\lambda(x)=\left[\frac{\Gamma(2\lambda)(n+\lambda)n!}{\lambda\Gamma(n+2\lambda)}\right]^{1/2}\qquad C_n^\lambda(x)=\frac{2^{1-2\lambda}\Gamma(2\lambda)\pi}{\lambda\Gamma^2(\lambda)}\hat{C}_n^\lambda(x)$$

has led to the authors[5] to obtain the following asymptotic expression:

$$\begin{aligned}\mathcal{E}_n^\lambda&=-\int_{-1}^{+1}\rho_\lambda(x)[p_n^\lambda(x)]^2\log[p_n^\lambda(x)]^2dx\\&=-\frac{n}{n+\lambda}-2\log\frac{\Gamma(n+\lambda)}{\Gamma(\lambda)n!}[1+o(1)]-\log\frac{\Gamma(2\lambda)(n+\lambda)n!}{\lambda\Gamma(n+2\lambda)}.\end{aligned}$$

Here we will use a two-step method which allow us to calculate the exact value of the Gegenbauer entropy $\mathcal{E}_n^\lambda$ for any n. First, we use the expression[7]

$$\mathcal{E}_n^\lambda=2\log\gamma_n-2\sum_{j=1}^{n}V_n^\lambda(x_{j,n};\nu_n), \tag{20}$$

where $x_{j,n}$ $(j=1,2,...,n)$ and γ_n are the zeros and the leading coefficient of the orthonormal Gegenbauer polynomial $p_n^\lambda(x)$, respectively, ν_n is the probability measure given by

$$d\nu_n(t)=(1-t^2)^{\lambda-(1/2)}[p_n^\lambda(t)]^2,$$

and the logarithmic potential $\hat{V}_n^\lambda(x,\nu_n)$ of the measure ν_n is given by

$$\hat{V}_n^\lambda=\hat{V}_n^\lambda(z,\nu_n)=\int_{-1}^{+1}(1-t^2)^{\lambda-(1/2)}[p_n^\lambda(t)]^2\log\frac{1}{|z-t|}\,dt,$$

which is related to the logarithmic potential of the Gegenbauer polynomial C_n^λ defined as

$$V_n^\lambda(z,\nu_n)=\int_{-1}^{+1}(1-t^2)^{\lambda-1/2}[C_n^\lambda(t)]^2\log\frac{1}{|z-t|}\,dt$$

by the relationship

$$\hat{V}_n^{\lambda}(z)=\frac{n+\lambda}{n}\frac{\Gamma(2\lambda)}{\Gamma(n+2\lambda)}\frac{n!\Gamma(\lambda+1)}{\sqrt{\pi}\Gamma(\lambda+\frac{1}{2})}V_n^{\lambda}(z).$$

Taking into account that

$$\gamma_n=\frac{2^n\Gamma(\lambda+n+1)\Gamma(2\lambda)}{\Gamma(\lambda+1)\Gamma(n+2\lambda)},$$

we remark from (20) that the Gegenbauer entropy $\mathcal{E}_n^{\lambda}$ can be computed once we will have a precise knowledge of the logarithmic potential V_n^{λ} at the zeros of C_n^{λ}. The use of the recursive approach recently developed by the authors[7] to determine this logarithmic potential does not allow to find an explicit closed expression for the Gegenbauer entropy $\mathcal{E}_n^{\lambda}$ in a simple way save for the first two integers values $\lambda=0,1,$[5,7]

$$\mathcal{E}_n^0=\log 2-1,\quad \mathcal{E}_n^1=-\frac{n}{n+1}.$$

To go further we need a procedure to calculate the logarithmic potential other than the aforementioned recursive approach.[7] This is done in the following by expanding it in terms of Chebyshev polynomials of the first kind $T_k(x)$; this is the second step of our method.

If P_n $(n=0,1,2,...)$ are orthogonal polynomials with respect to the measure μ on $[-1,1]$, then we can use that[7]

$$\log|z-t|=\log\frac{1}{2}-2\sum_{k=1}^{\infty}\frac{1}{k}T_k(z)T_k(t)$$

to find

$$-\int_{-1}^{1}\log|x-t|P_n^2(x)d\mu(x)=\log 2\int_{-1}^{1}P_n^2(x)d\mu(x)+2\sum_{k=1}^{\infty}\frac{T_k(t)}{k}\int_{-1}^{1}T_k(x)P_n^2(x)d\mu(x),$$

which gives an expansion in terms of Chebyshev polynomials of the first kind, with expansion coefficients in terms of

$$\int_{-1}^{1}T_k(x)P_n^2(x)d\mu(x),$$

and these integrals still need to be computed explicitly. Let us apply this idea for Gegenbauer polynomials $P_n(x)=C_n^{\lambda}(x)$. The use of Clausen's formula[17]

$$[C_n^{\lambda}(x)]^2=\left[\frac{(2\lambda)_n}{n!}\right]^2{}_3F_2\left(\begin{matrix}-n,n+2\lambda,\lambda\\2\lambda,\lambda+\frac{1}{2}\end{matrix};1-x^2\right),$$

allows us to find

$$\int_{-1}^{1}T_k(x)[C_n^{\lambda}(x)]^2(1-x^2)^{\lambda-(1/2)}dx$$
$$=\left[\frac{(2\lambda)_n}{n!}\right]^2\sum_{j=0}^{n}\frac{(-n)_j(n+2\lambda)_j(\lambda)_j}{(2\lambda)_j(\lambda+\frac{1}{2})_j j!}\int_{-1}^{1}(1-x^2)^{j+\lambda-(1/2)}T_k(x)dx.$$

If λ is an integer, then $[C_n^\lambda(x)]^2(1-x^2)^\lambda$ is a polynomial of degree $2n+2\lambda$, and by the orthogonality of the Chebyshev polynomials the integral will vanish for $k>2n+2\lambda$. Therefore we only need to consider $k\leqslant 2n+2\lambda$. By symmetry the integral for k odd vanishes and for even indices we have[18]

$$\int_{-1}^{1}(1-x^2)^{\lambda+j-(1/2)}T_{2k}(x)dx=(-1)^k\frac{\pi\Gamma(2j+2\lambda+1)}{2^{2j+2\lambda}\Gamma(j+k+\lambda+1)\Gamma(j+\lambda+1-k)}.$$

Using Legendre's duplication formula for the gamma function gives $\Gamma(2j+2\lambda+1)=2^{2j+2\lambda}\pi^{-1/2}\Gamma(j+\lambda+\frac{1}{2})\Gamma(j+\lambda+1)$ so that

$$\int_{-1}^{1}[C_n^\lambda(x)]^2(1-x^2)^{\lambda-(1/2)}T_{2k}(x)dx$$
$$=\left[\frac{(2\lambda)_n}{n!}\right]^2\frac{(-1)^k\sqrt{\pi}\Gamma(\lambda+\frac{1}{2})\Gamma(\lambda+1)}{\Gamma(k+\lambda+1)\Gamma(\lambda+1-k)}\,{}_4F_3\left(\begin{matrix}-n,n+2\lambda,\lambda,\lambda+1\\2\lambda,\lambda+1+k,\lambda+1-k\end{matrix};1\right). \quad (21)$$

Hence, we have

$$V_n^\lambda(t)=\left[\frac{(2\lambda)_n}{n!}\right]^2\sqrt{\pi}\left[\log 2\,\frac{\Gamma(\lambda+\frac{1}{2})}{\Gamma(\lambda+1)}\,{}_3F_2\left(\begin{matrix}-n,n+2\lambda,\lambda\\2\lambda,\lambda+1\end{matrix};1\right)+\Gamma\left(\lambda+\frac{1}{2}\right)\Gamma(\lambda+1)\right.$$
$$\left.\times\sum_{k=1}^{n+\lambda}(-1)^kT_{2k}(t)\frac{1}{k\Gamma(k+\lambda+1)\Gamma(\lambda+1-k)}\,{}_4F_3\left(\begin{matrix}-n,n+2\lambda,\lambda,\lambda+1\\2\lambda,\lambda+1+k,\lambda+1-k\end{matrix};1\right)\right]. \quad (22)$$

Observe that this shows that on the interval $[-1,1]$ the logarithmic potential V_n^λ is a polynomial of degree $2n+2\lambda$ when λ is an integer, which is indeed compatible with the explicit formulas

$$\hat{V}_n^{(0)}(t)=\log 2+\frac{T_{2n}(t)}{2n};\quad n\geqslant 1$$

$$\hat{V}_n^{1}(t)=\log 2-\frac{T_{2n+2}(t)}{2n+2};\quad n\geqslant 0$$

$$\hat{V}_n^{2}(t)=\log 2+\frac{n+1}{n+3}\,\frac{T_{2n+4}(t)}{2n+4}-\frac{U_{2n+2}(t)}{(n+1)(n+3)}+\frac{1}{(n+1)(n+3)},$$

already found by us.[7]

The ${}_3F_2$ series is terminating and balanced, hence Saalschütz' theorem[19] gives

$${}_3F_2\left(\begin{matrix}-n,n+2\lambda,\lambda\\2\lambda,\lambda+1\end{matrix};1\right)=\frac{\lambda\Gamma(2\lambda)n!}{(n+\lambda)\Gamma(2\lambda+n)}.$$

Also the ${}_4F_3$ series is balanced, but its evaluation is more complicated. A balanced and terminating ${}_4F_3$ at unit argument is however a Wilson polynomial or a Racah polynomial taken at some point. The Wilson polynomial W_n is given by

$$\frac{W_n(x^2;a,b,c,d)}{(a+b)_n(a+c)_n(a+d)_n}={}_4F_3\left(\begin{matrix}-n,n+a+b+c+d-1,a+ix,a-ix\\a+b,a+c,a+d\end{matrix};1\right)$$

(see, e.g., Koekoek and Swarttouw[20] or Wilson[21,22]). Identifying parameters shows that

$$ {}_4F_3\left(\begin{matrix} -n,n+2\lambda,\lambda,\lambda+1 \\ 2\lambda,\lambda+1+k,\lambda+1-k \end{matrix};1\right) = \frac{W_n(-\frac{1}{4};\lambda+\frac{1}{2},\lambda-\frac{1}{2},k+\frac{1}{2},-k+\frac{1}{2})}{(2\lambda)_n(\lambda+1+k)_n(\lambda+1-k)_n}. $$

Using this and the normalization

$$ \frac{n+\lambda}{\lambda}\frac{\Gamma(2\lambda)}{\Gamma(n+2\lambda)}\frac{n!\Gamma(\lambda+1)}{\sqrt{\pi}\Gamma(\lambda+\frac{1}{2})}V_n^\lambda(t)=\hat{V}_n^\lambda(t), $$

this gives

$$ \hat{V}_n^\lambda(t)=\log 2+\frac{2(n+\lambda)\Gamma^2(\lambda+1)}{\lambda n!}\sum_{k=1}^{n+\lambda}(-1)^k\frac{T_{2k}(t)}{2k}\frac{W_n(-\frac{1}{4};\lambda+\frac{1}{2},\lambda-\frac{1}{2},k+\frac{1}{2},-k+\frac{1}{2})}{\Gamma(\lambda+k+n+1)\Gamma(\lambda-k+n+1)}. \tag{23} $$

A few comments about Wilson polynomials, which are pertinent to illustrate the effectiveness of Eq. (23), are contained in the Appendix. Expression (23) for the logarithmic potential with integer λ generalizes our expressions for $\lambda=0$, 1, and 2 already mentioned.

For completeness and comparison, it is worth to mention here that recently Buyarov *et al.*[23] have developed an alternative, fully different method to work out a formula for the logarithmic potential (with integer λ) evaluated at the zeros of the polynomial $C_n^\lambda(x)$. This formula, which does not use Wilson polynomials, together with Eq. (20) has allowed them to obtain an explicit expression for the entropy $\mathcal{E}_n^\lambda$ for λ, $n\in\mathbb{N}$, $\lambda\geqslant 2$. In doing so, they corrected and extended the value obtained previously by one of them[24] for $\mathcal{E}_n^2$, which is given by

$$ \begin{aligned} \mathcal{E}_n^2&=\log\frac{n+3}{3(n+1)}-\frac{n(n^2+2n-1)}{(n+1)(n+2)(n+3)}-\frac{2}{\sqrt{(n+1)^3(n+3)^3}}\frac{T'''_{n+2}(z_n)}{T''_{n+2}(z_n)} \\ &=\log\frac{n+3}{3(n+1)}-\frac{n^3-5n^2-29n-27}{(n+1)(n+2)(n+3)}-\frac{1}{n+2}\left(\frac{n+3}{n+1}\right)^{n+2}, \end{aligned} $$

where $z_n=n+2/\sqrt{(n+1)(n+3)}$. Also, they were able to obtain analytically[23] that the rate of convergence of $\mathcal{E}_n^\lambda$, $\lambda\in\mathbb{N}$, $\lambda\geqslant 2$, is given by

$$ \mathcal{E}_n^\lambda=\mathcal{E}_\infty^\lambda+\frac{\gamma_\lambda}{n}+O(n^{-2}), $$

where the dominant term is

$$ \mathcal{E}_\infty^\lambda=1+\log\frac{\Gamma(2\lambda)}{\Gamma(\lambda)\Gamma(\lambda+1)} $$

and the second term is controlled by the constant

$$ \gamma_\lambda=-2\lambda^2+\lambda-2\sum_{j=1}^{\lambda-1}\sqrt{\xi_j}\,\frac{R}{S'}\,\frac{J_{\lambda+\frac{1}{2}}}{J_{\lambda-\frac{1}{2}}}(\xi_j). $$

Here, $J_\lambda(x)$ denotes the Bessel function of order λ and ξ_j, $j=1,...,\lambda-1$ are the zeros of the polynomial $S\equiv S_{2\lambda-2}(x)$. The polynomials $\{S_{-1}=0,\ S_0=1,...,S_{2\lambda-2}\}$ are generated by the recurrence relation

$$ S_{j+1}(x)=(2\lambda-2j-3)S_j(x)-xS_{j-1}(x), $$

and the polynomial $R(x)$ is given by

$$R(x)=\sum_{j=0}^{2\lambda-2}(-1)^{j}S_{j-1}(x)S_{2\lambda-j-3}(x).$$

Finally, let us mention that there exists another alternative to be explored which replaces the second step of our method for the following procedure. Instead of expanding the quadratic Gegenbauer potential V_n^λ in Chebyshev polynomials, one can express it as a sum of linear Gegenbauer potentials by the linearization formula of $[C_n^\lambda(t)]^2$ in terms of $C_n^\lambda(t)$; this can be done by use of the Dougall's linearization formula of products of two $C_n^\lambda(x)$ as a sum involving $C_k^\lambda(x)$. Then, the linear Gegenbauer potential, which is a definite integral of $(1-z^2)^{\lambda-1/2}Q_n^\lambda(z)$, can be evaluated by use of the explicit hypergeometric representation for the Gegenbauer function of the second kind $Q_n^\lambda(z)$.

IV. SUMMARY AND CONCLUSIONS

The spread of the quantum-mechanical probability density $\rho(\mathbf{r})$ for a D-dimensional single-particle system moving in a potential $V(\mathbf{r})$ is controlled by the Boltzmann–Shannon information entropy S_ρ. For central potentials, this quantity can be decomposed in two parts: the radial entropy and the angular or spatial entropy. The former is given by Eq. (9) and it depends on the analytic form of the potential. The latter, denoted by $S(Y;D)$ and associated to the physical form of the system, is described in Eq. (10) by the entropic integral or just the ''entropy'' of the known hyperspherical harmonics $Y_{l,\{\mu\}}(\Omega_D)$. Moreover, the entropy $S(Y;D)$ is explicitly expressed by Eq. (13b) in terms of the entropic integral of the orthonormal Gegenbauer polynomial $\hat{C}_n^\lambda$, where n and λ depends on D and the quantum numbers $l,\{\mu\}$. This mathematical notion $E_n^\lambda \equiv E(\hat{C}_n^\lambda)$, defined by Eq. (18) and called Gegenbauer entropy, was naturally encountered in the study of the position and momentum information entropies of two specific physical systems: the harmonic oscillator and the hydrogen atom.[5,7] Its asymptotic ($n\to\infty$) behavior has been thoroughly investigated specifically[4,23] and in the more general context of entropic integrals for general orthogonal polynomials.[10]

Finally, this paper and Ref. 23 describe methods to calculate the Gegenbauer entropy for arbitrary integer values of λ and n. However we have not been able yet to extend our results to real or, at least, half-integer values of the parameter λ, what is necessary [see, e.g., Eq. (16)] for a complete description of the entropy of an arbitrary (hyper)spherical harmonic, which describes the spatial entropy of single-particle systems in arbitrary quantum-mechanical states of any (D-dimensional) central potential. This would require a generalization of our methods or the design of a new mathematical strategy to evaluate the Gegenbauer entropy E_n^λ and/or $\mathcal{E}_n^\lambda$ for real λ.

APPENDIX: SOME NOTES ABOUT WILSON POLYNOMIALS

Wilson polynomials are invariant under a permutation of the parameters. They are orthogonal on $[0,\infty)$ when all the parameters a,b,c,d are such that $\Re(a,b,c,d)>0$ and non-real parameters occur in conjugate pairs. In our case, one of the parameters $-k+\frac{1}{2}$ may be negative (also $\lambda-\frac{1}{2}$ when $\lambda<1/2$). If some of the parameters are negative, then Wilson polynomials can still be orthogonal on $[0,\infty)\cup E$, where E contains mass points of the orthogonality measure on $(-\infty,0]$. The first mass point in this case turns out to be $-1/4$, which is exactly the point where we evaluate the Wilson polynomial.

We will use a generating function for the Wilson polynomials

$$ {}_2F_1\left(\begin{matrix} a+ix, b+ix \\ a+b \end{matrix}; t\right) {}_2F_1\left(\begin{matrix} c-ix, d-ix \\ c+d \end{matrix}; t\right) = \sum_{n=0}^{\infty} \frac{W_n(x^2;a,b,c,d)}{(a+b)^n(c+d)^n} \frac{t^n}{n!}, $$

(see Refs. 20 or 21). In our case the parameters are $a=\lambda+\frac{1}{2}$, $b=\lambda-\frac{1}{2}$, $c=k+\frac{1}{2}$, $d=-k+\frac{1}{2}$, and the variable is $x^2=-\frac{1}{4}$. The generating function then becomes

$$ {}_2F_1\left(\begin{matrix} \lambda, \lambda-1 \\ 2\lambda \end{matrix}; t\right) {}_2F_1\left(\begin{matrix} 1-k, k+1 \\ 1 \end{matrix}; t\right) = \sum_{n=0}^{\infty} W_n\left(-\frac{1}{4};\lambda+\frac{1}{2},\lambda-\frac{1}{2},k+\frac{1}{2},-k+\frac{1}{2}\right) \frac{t^n}{(2\lambda)_n(n!)^2}. \tag{A1} $$

Observe that one of the hypergeometric functions on the left is a polynomial of degree $k-1$. From this generating function we can now obtain the coefficient of t^n as the convolution of the coefficients of the two hypergeometric series on the left, giving

$$ W_n\left(-\frac{1}{4};\lambda+\frac{1}{2},\lambda-\frac{1}{2},k+\frac{1}{2},-k+\frac{1}{2}\right) = (2\lambda)_n(n!)^2 \sum_{j=0}^{k-1} \frac{(1-k)_j(k+1)_j}{(j!)^2} \frac{(\lambda)_{n-j}(\lambda-1)_{n-j}}{(2\lambda)_{n-j}(n-j)!}, \quad n \geqslant k-1. \tag{A2} $$

(Received 20 October 1998; accepted for publication 26 May 1999)

We have constructed a one-dimensional exactly solvable model, which is based on the $t-J$ model of strongly correlated electrons, but which has additional quantum group symmetry, ensuring the degeneration of states. We use Bethe Ansatz technique to investigate this model. The thermodynamic limit of the model is considered and equations for different density functions written down. These equations demonstrate that the additional color degrees of freedom of the model behave as in a gauge theory, namely, an arbitrary distribution of color indices over particles leave invariant the energy of the ground state and the excitations. The *S*-matrix of the model is shown to be the product of the ordinary $t-J$ model *S*-matrix and the unity matrix in the color space.
[S0022-2488(99)02411-1]

I. INTRODUCTION

Since the discovery of high-T_c cuprate superconductivity the one-dimensional physics of strongly correlated electrons has been in focus in many publications.[1] The Hubbard[2] and $t-J$ models[3] are such examples, motivated in part by the fact that high-T_c compounds display antiferromagnetism in the absence of doping. The $t-J$ model was proposed by Zhang and Rice[3] and describes strongly correlated electrons with anntiferromagnetic exchange interaction.

The interest in one-dimensional physics grew after Andersons claim[4] that two-dimensional systems may have features in common with one-dimensional systems. In addition it should be mentioned that powerful methods in 1D such as bosonization, 2D conformal field theory, and in particular the Bethe Ansatz technique allow the detailed study of such systems.

The $t-J$ model may be used as well for the heavy fermion system.[5,6]

At the supersymmetric point $J=2t$ the $t-J$ model becomes exactly integrable[5,7–12] because the Hamiltonian can be represented as a graded permutation in a superalgebra of two fermions and one boson.

In Refs. 13–15 we developed the technique for construction of a family of spin chain Hamiltonians and their fermionic representations, which have the same energy levels as some basic model (XXZ, Hubbard, $t-J$ or others) but with huge degeneracy as a result of an affine quantum symmetry added to the basic model. We called this procedure an affinization of the model.

The first example of this type of model was constructed in Ref. 16, giving rise to the Hubbard Hamiltonian in the infinite repulsion limit.

In Ref. 14 we have fermionized the simplest examples of this newly defined family of models and have shown that it leads to extensions of one-band Hubbard Hamiltonians. The η-pairing mechanism introduced by Yang[17,18] was found in one of examples in addition to other exactly solvable Hubbard models with the superconducting ground state.[19–23] The essential property of this extensions is the fact that, besides the ordinary electron hopping and Hubbard interaction terms, they contain also bond-charge interaction, pair-hopping, and nearest-neighbor interaction terms. In Ref. 15 the SU(N) affinization of the $t-J$ model was carried out, giving rise to a model where the spin–spin coupling term consists of interaction between the total spins (i.e., the sum of the spins of all band) at nearest-neighbor sites. The presence of the affine symmetry, which ensures the degeneracy of levels exponentially proportional to the length (area) of the space, might lead to a new type of string theory.

In this article we define an extension of $t-J$ model such that an affine quantum group symmetry is present, and we use the Bethe Ansatz technique to solve the model. We find the *S*-matrix excitations on empty background, the ground state and construct the thermodynamic limit of the model. As one might expect, the *S*-matrix of the excitations on empty background consists of the *S*-matrix of the ordinary $t-J$ model multiplied by the unity matrix in the additional space of ''colors.'' Therefore the Bethe equations are not different from ones for the $t-J$ model, but the rapidities presented in equations correspond to particles with the arbitrary colors. The degeneracy of the corresponding n-particle states come from arbitrary partitions of the color indices over particles. The same is true for the ground state. The situation is exactly as in gauge theories if we distinguish the states which differ by pure gauge transformations. All these results are presented in Sec. V.

The thermodynamic limit of the model with corresponding equations are represented in Sec. VI, where we also shown that the *S*-matrix of our model in an arbitrary background is equal to ordinary $t-J$ model *S*-matrix multiplied by the Kronecker symbols over the additional color indices.

II. QUANTUM GROUP INVARIANT HAMILTONIANS FOR REDUCIBLE REPRESENTATIONS

Let $\mathbf{V}=\oplus_{i=1}^{N}\mathbf{V}_{\lambda_i}$ be a direct sum of finite dimensional irreducible representations $\mathbf{V}_{\lambda_i}$ of quantum group $U_q g$.[24–26] We denote by $\mathbf{V}(x_1,\ldots,x_N)$ the representation with spectral parameters x_i of the corresponding affine quantum group $U_q\hat{g}$,[26]

$$\mathbf{V}(x_1,\ldots,x_N)=\bigoplus_{i=1}^{M}\mathbf{N}_{\lambda_i}\hat{\otimes}\mathbf{V}_{\lambda_i}(x_i), \tag{1}$$

where all the $\mathbf{V}_{\lambda_i}(x_i)$ are M nonequivalent irreps and $\mathbf{N}_{\lambda_i}\simeq\mathbf{C}^{N_i}$ have dimensions equal to the multiplicity of $\mathbf{V}_{\lambda_i}(x_i)$ in $\mathbf{V}(x_1,\ldots,x_N)$. Note that $\Sigma_{i=1}^{M}N_i=N$. The $\hat{}$ over the tensor product signifies that $U_q\hat{g}$ does not act on $\mathbf{N}_{\lambda_i}\hat{\otimes}\mathbf{V}_{\lambda_i}(x_i)$ by means of comultiplication Δ but instead acts as $\mathrm{id}\otimes g$.

In Ref. 14 the general matrix form of the intertwining operator

$$H(x_1,\ldots,x_N):$$

$$\mathbf{V}(x_1,\ldots,x_N)\otimes\mathbf{V}(x_1,\ldots,x_N)\rightarrow\mathbf{V}(x_1,\ldots,x_N)\otimes\mathbf{V}(x_1,\ldots,x_N), \tag{2}$$

$$[H(x_1,\ldots,x_N),\ \Delta(a)]=0,\quad \forall a\in U_q\hat{g}$$

had been written using the projection operators

$$X_b^a=|a\rangle\langle b|. \tag{3}$$

Here the vectors $|a\rangle$ span the space $\mathbf{V}$. In accordance with the decomposition (1) we will use the double index $a=(n_i,a_i)$, $i=1,...,M$ where the first index $n_i=1,...,N_i$ characterizes the multiplicity of $\mathbf{V}_{\lambda_i}$ and the second one $a_i=1,...,\dim \mathbf{V}_{\lambda_i}$ is the vector index of $\mathbf{V}_{\lambda_i}$. Then the intertwining operator (2) is

$$H(A,B)=\sum_{i,j=1}^{M}\left(\sum_{n_i,n_j,m_i,m_j} A_{ij}{}^{m_i m_j}_{n_i n_j}\sum_{a_i,a_j} X^{(n_i,a_i)}_{(m_i,a_i)}\otimes X^{(n_j,a_j)}_{(m_j,a_j)}\right.$$
$$\left.+\sum_{n_i,n_j,m_i,m_j} B_{ij}{}^{m_i m_j}_{n_i n_j}\sum_{a_i,a_j,a_i',a_j'} R_{ij}{}^{a_i a_j}_{a_i' a_j'}(x_i/x_j) X^{(n_j,a_j')}_{(m_i,a_i)}\otimes X^{(n_i,a_i')}_{(m_j,a_j)}\right), \tag{4}$$

where the R-matrix

$$R_{\mathbf{V}_{\lambda_i}\otimes \mathbf{V}_{\lambda_j}}(x_i/x_j)|a_i\rangle\otimes|a_j\rangle=\sum_{a_i',a_j'} R_{ij}{}^{a_i a_j}_{a_i' a_j'}(x_i/x_j)|a_i'\rangle\otimes|a_j'\rangle$$

is the intertwining operator between two actions of affine quantum group $U_q\hat{g}$ on $\mathbf{V}_{\lambda_i}\otimes\mathbf{V}_{\lambda_j}$, which are induced correspondingly by comultiplication Δ and opposite comultiplication $\bar{\Delta}$,[24–26]

$$R_{\mathbf{V}_{\lambda_i}\otimes \mathbf{V}_{\lambda_j}}(x_i/x_j)\Delta(g)=\bar{\Delta}(g)R_{\mathbf{V}_{\lambda_i}\otimes \mathbf{V}_{\lambda_j}}(x_i/x_j).$$

A_{ij} and B_{ij}, $B_{ii}=0$ in (4) are arbitrary matrices. In general, $H(A,B)$ depends on deformation parameter q of quantum group, which is included in the R-matrix. Note that $R_{\mathbf{V}_{\lambda_i}\otimes \mathbf{V}_{\lambda_j}}(x_i/x_j)$ does not depend on q and is identity only if λ_i or λ_j are trivial one-dimensional representations. So, in the special case, when the only nontrivial R-matrixes in (4) are between representations, one of which is trivial representation, the expression of $H(A,B)$ does not depend on q. Then $H(A,B)$ commutes with the quantum group action for all values of deformation parameter. In the following we consider only this case.

Following Refs. 13 and 16 we can from the operator H construct the following Hamiltonian acting on $\mathbf{W}=\mathbf{V}^{\otimes L}$ (here and in the following we omit the dependence on x_i)

$$\mathcal{H}=\sum_{i=1}^{L-1} H_{ii+1}, \tag{5}$$

where the indices i and $i+1$ denote the sites where H acts nontrivially. By the construction, $\mathcal{H}$ is quantum group invariant,

$$[\mathcal{H},\Delta^{L-1}(g)]=0, \quad \forall g\in U_q\hat{g}.$$

Let us define the projection operators $\mathcal{Q}^i$ on $\mathbf{V}$ for each class of equivalent irreps (λ_i,x_i), $i=1,...,M$,

$$\mathcal{Q}^i v_j=\delta_{ij}v_j, \quad \forall v_j\in V_{\lambda_j}(x_j),$$

$$\sum_{i=1}^{M}\mathcal{Q}^i=\mathrm{id}, \quad (\mathcal{Q}^i)^2=\mathcal{Q}^i.$$

Their action on $\mathbf{W}$ is given by

$$\mathcal{Q}^i=\sum_{l=1}^{L}\mathcal{Q}^i_l.$$

It is easy to see that these projections commute with Hamiltonian $\mathcal{H}$ and quantum group $U_q\hat{g}$,

$$[\mathcal{Q}^i,\mathcal{H}]=0,\ \ [\mathcal{Q}^i,U_q\hat{g}]=0. \tag{6}$$

Denoted by $\mathbf{W}_{p_1\cdots p_M}$ the subspace of $\mathbf{W}$ with values p_i of $\mathcal{Q}^i$ on it. Then we have the decomposition

$$\mathbf{W}=\bigoplus_{\substack{p_1,\ldots,p_M\\ p_1+\cdots+p_M=L}}\mathbf{W}_{p_1\cdots p_M}. \tag{7}$$

Let $\mathbf{V}^0$ be the linear space, spanned by the highest weight vectors in V,

$$\mathbf{V}^0:=\oplus_{i=1}^N v^0_{\lambda_i},$$

where $v^0_{\lambda_i}\in\mathbf{V}_{\lambda_i}$ is a highest weight vector. We also define $\mathbf{W}^0:=\mathbf{V}^{0\otimes L}$. The space $\mathbf{W}^0$ is $\mathcal{H}$-invariant. For general q the action of $U_q\hat{g}$ on $\mathbf{W}^0$ generate the whole space $\mathbf{W}$. Indeed, the $U_q\hat{g}$-action on each state of type $v^0_{\lambda_{i_1}}\otimes\cdots\otimes v^0_{\lambda_{i_L}}$ generates the space $\mathbf{V}_{\lambda_{i_1}}\otimes\cdots\otimes\mathbf{V}_{\lambda_{i_L}}$, because the tensor product of finite dimensional irreducible representations of an affine quantum group is irreducible.[27]

Consider now the subspace $\mathbf{W}^0_{p_1\cdots p_M}=\mathbf{W}^0\cap\mathbf{W}_{p_1\cdots p_M}$. According to (7) we have the decomposition

$$\mathbf{W}^0=\bigoplus_{\substack{p_1,\ldots,p_M\\ p_1+\cdots+p_M=L}}\mathbf{W}^0_{p_1\cdots p_M}. \tag{8}$$

Note that

$$d_{p_1\cdots p_M}:=\dim\mathbf{W}^0_{p_1\cdots p_M}=\binom{L}{p_1\cdots p_M}N_1^{p_1}\cdots N_M^{p_M}.$$

Let us define by $\mathcal{H}_0$ the restriction of $\mathcal{H}$ on $\mathbf{W}_0$: $\mathcal{H}_0:=\mathcal{H}|_{\mathbf{W}_0}$. It follows from (6) that Hamiltonians $\mathcal{H}$ and $\mathcal{H}_0$ have block diagonal form with respect to the decompositions (7) and (8), respectively. Every eigenvector $w^0_{\alpha_{p_1\cdots p_M}}\in\mathbf{W}^0_{p_1\cdots p_M}$ with energy value $E_{\alpha_{p_1\cdots p_M}}$ gives rise to an irreducible $U_q\hat{g}$-multiplet $\mathbf{W}_{\alpha_{p_1\cdots p_M}}$ of dimension

$$\dim\mathbf{W}_{\alpha_{p_1\cdots p_M}}=\prod_{k=1}^{M}(\dim\mathbf{V}_{\lambda_k})^{p_k}. \tag{9}$$

On $\mathbf{W}_{\alpha_{p_1\cdots p_M}}$ the Hamiltonian $\mathcal{H}$ is diagonal with eigenvalue $E_{\alpha_{p_1\cdots p_M}}$. In particular, in the case when all $\mathbf{V}_{\lambda_i}$ are equivalent, the degeneracy levels are the same for all $E_{\alpha_{p_1\cdots p_M}}$ and are equal to $(\dim\mathbf{V}_\lambda)^L$.

Now, let us assume we know the energy spectrum $E_{\alpha_{p_1\cdots p_M}}$ for $\mathcal{H}_0$. Then the statistical sum is given by

$$Z_{\mathcal{H}_0}(\beta)=\sum_{\substack{p_1,\ldots,p_M\\ p_1+\cdots+p_M=L}}\ \sum_{\alpha_{p_1\cdots p_M}=1}^{d_{p_1\cdots p_M}}\exp(-\beta E_{\alpha_{p_1\cdots p_M}}), \tag{10}$$

and it follows that the statistical sum of $\mathcal{H}$ has the following form:

$$Z_{\mathcal{H}}(\beta)=\sum_{\substack{p_1,\ldots,p_M\\ p_1+\cdots+p_M=L}}\prod_{k=1}^{M}(\dim \mathbf{V}_{\lambda_k})^{p_k}\sum_{\alpha_{p_1\cdots p_M}=1}^{d_{p_1\cdots p_M}}\exp(-\beta E_{\alpha_{p_1\cdots p_M}}). \tag{11}$$

So, if the underlying Hamiltonian $\mathcal{H}_0$ is integrable and its eigenvectors and eigenvalues can be found, then we know these for $\mathcal{H}$ too. Acting with the quantum group on all eigenvectors of an energy level of $\mathcal{H}_0$ one obtains the whole eigenspace of $\mathcal{H}$ for this level.

III. MULTIBAND $t-J$ MODEL WITH VANISHING SPIN–SPIN COUPLING $J=0$

Let us consider here the quantum group $U_q\widehat{sl}_2$. We choose $\mathbf{V}=\mathbf{V}_0\oplus\mathbf{V}_j$ for decomposition (1) i.e., we take a direct sum of the trivial spin-0 and the $2j+1$-dimensional spin-j representation of $U_q sl_2$. The R-matrix in the second term in (4) does not depend on q and spectral parameters x_i and coincides with the identity, as it was mentioned above. So, using (4) and (5), we obtain the following Hamiltonian:

$$\mathcal{H}(t,V_1,V_2)=\sum_{i=1}^{L-1}\left[-t\sum_{p=1}^{2j+1}(X_{i0}^{\,p}X_{i+1p}^{\,0}+X_{i+10}^{\,p}X_{ip}^{\,0})+V_1X_{i0}^{\,0}X_{i+10}^{\,0}+V_2\sum_{p,p'=1}^{2j+1}X_{ip}^{\,p}X_{i+1p'}^{\,p'}\right]. \tag{12}$$

The Hamiltonian $\mathcal{H}=\Sigma_i H_{ii+1}$ was constructed from the operator $H=H_{ii+1}$, where H can be written in the matrix form

$$H=\begin{pmatrix} V_1 & 0 & 0 & 0\\ 0 & 0 & -t\cdot\mathrm{id} & 0\\ 0 & -t\cdot\mathrm{id} & 0 & 0\\ 0 & 0 & 0 & V_2\cdot\mathrm{id}\end{pmatrix}. \tag{13}$$

The projection on the highest weight space coincides with the constructing block of the XXZ Hamiltonian in an external magnetic field. This implies that the restriction of (12) to the space $\mathbf{W}^0$ is

$$\mathcal{H}_0(t,W_1,W_2)=\mathcal{H}_{XXZ}(t,\Delta,B)=-\frac{t}{2}\sum_{i=1}^{L-1}\left(\sigma_i^x\sigma_{i+1}^x+\sigma_i^y\sigma_{i+1}^y+\Delta\sigma_i^z\sigma_{i+1}^z+\frac{B}{2}\sigma_i^z\right), \tag{14}$$

where

$$\Delta=-\frac{V_1+V_2}{2t},\qquad B=\frac{2}{t}(V_1-V_2). \tag{15}$$

For the special case $V_1+V_2=0$ $\mathcal{H}_0$ gives rise to the free fermionic (or equivalently XY) Hamiltonian ($\Delta=0$).

The projection operators X_b^a are expressed through the fermionic creation-annihilation operators as follows:

$$\begin{gathered} X_{i0}^{\,p}=\mathcal{P}c_{i,p}^{+},\qquad X_{ip}^{\,0}=c_{i,p}\mathcal{P},\\ X_{ip}^{\,p}=n_{i,p}\mathcal{P}=\mathcal{P}n_{i,p},\qquad X_{i0}^{\,0}=(1-n_i)\mathcal{P}=\mathcal{P}(1-n_i). \end{gathered} \tag{16}$$

Here we introduced the projection operator which forbids double occupation on all sites

$$\mathcal{P}=\prod_{i=1}^{L}\mathcal{P}_i,\qquad \mathcal{P}_i=\prod_{p\neq p'}(1-n_{i,p}n_{i,p'})$$

and the total particle number $n_i=\Sigma_p n_{i,p}$ at site i.

After the substitution of the fermionic representation (16) into (12) we obtain

$$\mathcal{H}(t,V_1,V_2)=\mathcal{P}\sum_{i=1}^{L-1}\left[-t\sum_{p=1}^{2j+1}(c_{i,p}^{+}c_{i+1,p}+c_{i+1,p}^{+}c_{i,p})+Vn_in_{i+1}-V_1(n_i+n_{i+1})+V_1\right]\mathcal{P}, \tag{17}$$

where $V=V_1+V_2$. The chemical potential term $-V_1\Sigma_{i=1}^{L-1}(n_i+n_{i+1})$ commutes with $\mathcal{H}$ and can be omitted. So, up to unessential boundary and constant terms (17) is a multicomponent $t-J$ model with vanishing spin–spin coupling $(J=0)$,

$$\mathcal{H}(t,V)=\sum_{i=1}^{L-1}\left[-t\sum_{p=1}^{2j+1}(c_{i,p}^{+}c_{i+1,p}+c_{i+1,p}^{+}c_{i,p})+Vn_in_{i+1}\right]+\sum_{i=1}^{L}\sum_{\substack{p\neq p',\\ p,p'=1}}^{2j+1}U_{p,p'}n_{i,p}n_{i,p'}, \tag{18}$$

where the infinite Hubbard interaction amplitude $U_{p,p'}=+\infty$ between p and p' bands excludes sites with double and more occupations. It follows from the above considerations that this model has energy levels which coincide with the levels of XXZ Heisenberg model, but that the degeneracy of the levels is different.

For vanishing density–density interaction $V=0$ the Hamiltonian (18) describes the infinite repulsion limit of the multiband Hubbard model. Thus, according to (15) $\Delta=0$ and it has the energy levels of the free fermionic model.

IV. MULTIBAND EXTENSION OF THE $t-J$ MODEL WITH AFFINE QUANTUM GROUP SYMMETRY

In this section we consider Hamiltonians which have the same energy levels as the $t-J$ model but have affine quantum group symmetry. Because each site in the ordinary $t-J$ model has three states, one should for this purpose take the direct sum of three spaces. Let

$$\mathbf{V}=\mathbf{V}_0\oplus\mathbf{V}_j\oplus\mathbf{V}_j. \tag{19}$$

Recall that the $t-J$ model is given by

$$\mathcal{H}_{t-J}(t,J,V)-\mathcal{P}\sum_{i=1}^{L-1}\left[-t\sum_{\sigma=\pm\frac{1}{2}}(c_{i,\sigma}^{+}c_{i+1,\sigma}+c_{i+1,\sigma}^{+}c_{i,\sigma})+J\mathbf{S}_i\mathbf{S}_{i+1}+Vn_in_{i+1}\right]\mathcal{P}, \tag{20}$$

where c_σ^+, c_σ are creation–annihilation operators of spin-$\frac{1}{2}$ fermion, $\mathbf{S}=\Sigma_{\sigma,\sigma'}c_\sigma^+\sigma_{\sigma\sigma'}c_{\sigma'}$ is the fermionic spin operator and $\mathcal{P}=\Pi_{i=1}^{L}(1-n_{i,\uparrow}n_{i,\downarrow})$ forbids double occupation of sites.

We rewrite it in terms of Hubbard operators X_b^a, where $a,b=0,\pm\frac{1}{2}$,

$$\mathcal{H}(t,J,V)=\sum_{i=1}^{L-1}\left[\sum_{\sigma=\pm\frac{1}{2}}\left(-t(X_{i0}^{\ \sigma}X_{i+1\sigma}^{\ 0}+X_{i+10}^{\ \sigma}X_{i\sigma}^{\ 0})+\frac{1}{2}J\cdot X_{i-\sigma}^{\ \sigma}X_{i+1\sigma}^{\ -\sigma}\right)\right.$$
$$\left.+\sum_{\sigma,\sigma'=\pm\frac{1}{2}}(\sigma\sigma' J+V)X_{i\sigma}^{\ \sigma}X_{i+1\sigma'}^{\ \sigma'}\right]. \tag{21}$$

Let us now look at the general expression (4) of intertwining operators H_{ij} acting on the space (19). For convenience we make index change in the following way. The two spin-j representations we use are denoted by $\sigma=\pm\frac{1}{2}$. The intrinsic index in each $V_j^{(\sigma)}$ is denoted by $k,k=1,...,2j+1$. So, instead of (n_i,a_i) in (4) we have (σ,k), if i corresponds to the spin-j multiplet. Because the spin-0 singlet is one dimensional and single, we just use for it the index 0. The nonequivalent irreps in

(19) are $V_j^{(\sigma)}$ and V_0 and, as mentioned above, the R-matrix for two such representations is the identity. After performing the first sum in (4) over nonequivalent multiplets we obtain

$$H(A,a,b_1,b_2)=\sum_{\sigma_1,\sigma_2,\sigma_1',\sigma_2'}\left(A_{\sigma_1\sigma_1'}^{\sigma_2\sigma_2'}\sum_{k,k'}X_{(\sigma_2,k)}^{(\sigma_1,k)}\otimes X_{(\sigma_2',k')}^{(\sigma_1',k')}\right)+a\cdot X_0^0\otimes X_0^0$$
$$+\sum_{k,\sigma}(b_1\cdot X_0^{(\sigma,k)}\otimes X_{(\sigma,k)}^0+b_2\cdot X_{(\sigma,k)}^0\otimes X_0^{(\sigma,k)}). \tag{22}$$

To implement the restriction $H_0(A,a,b_1,b_2)$ of this operator on the highest weight space one just should eliminate the sum over k,k' and put $k=k'=0$. Comparing (22) and (21) it follows that the expressions coincide if one chooses

$$a=0,\quad b_1=b_2=-t,\quad A_{\sigma-\sigma}^{-\sigma\sigma}=J/2,\quad A_{\sigma\sigma}^{\sigma'\sigma'}=(\sigma\sigma')\cdot J+V,$$

and choose the other values of $A_{\sigma_1\sigma_2}^{\sigma_1'\sigma_2'}$ equal to zero.

So, the Hamiltonian $\mathcal{H}(A,a,b_1,b_2)$ corresponding to (22) with these values of parameters gives rise to a $t-J$ model (20) on the highest weight space. According to the previous considerations it will have the same energy levels as the $t-J$ model, but with different degeneracy. Recall that for $J=2t$ the $t-J$ model is ''supersymmetric'' and integrable.

We express the Hubbard operators in terms of multiband fermionic creation–annihilation operators as follows:

$$X_{i0}^{(\sigma,k)}=\mathcal{P}c_{i,\sigma}^{k+},\quad X_{i(\sigma,k)}^{0}=c_{i,\sigma}^{k}\mathcal{P},$$
$$X_{i(-\sigma,k)}^{(\sigma,k)}=c_{i,\sigma}^{k+}c_{i,-\sigma}^{k}\mathcal{P}=\mathcal{P}c_{i,\sigma}^{k+}c_{i,-\sigma}^{k},\quad X_{i(\sigma,k)}^{(\sigma,k)}=n_{i,\sigma}^{k}\mathcal{P}=\mathcal{P}n_{i,\sigma}^{k}. \tag{23}$$

Here as before we used the projection operator, which forbids double occupation on all sites

$$\mathcal{P}=\prod_{i=1}^{L}\mathcal{P}_i,\quad \mathcal{P}_i=\prod_{(\sigma,k)\neq(\sigma',k')}(1-n_{i,\sigma}^{k}n_{i,\sigma'}^{k'}).$$

Now, we can write down the Hamiltonian (5) in terms of multiband fermions, substituting (23) into (22). We obtain in this way the multiband generalization of (20),

$$\mathcal{H}(t,J,V)=\mathcal{P}\sum_{i=1}^{L-1}\left[-t\sum_{k=1}^{2j+1}\sum_{\sigma=\pm\frac{1}{2}}(c_{i,\sigma}^{k+}c_{i+1,\sigma}^{k}+c_{i+1,\sigma}^{k+}c_{i,\sigma}^{k})+J\mathbf{S}_i\mathbf{S}_{i+1}+Vn_in_{i+1}\right]\mathcal{P}. \tag{24}$$

Here k is the band index, and $\mathbf{S}=\Sigma_k\mathbf{S}^k$, $n=\Sigma_k n^k$ are total spin and total particle number operators. It is easy to see that we have conservation of the particle number operators $\Sigma_{i,\sigma}^{k}=n^k$ for the all colors k.

V. BETHE ANSATZ FOR THE $t-J$ MODEL WITH AFFINE QUANTUM GROUP SYMMETRY

The goal of this section is to apply the Bethe Ansatz technique to our model and derive the corresponding Bethe equations for the excitations.

After making some trivial Pauli matrix calculations one can represent Hamiltonian (24) as

$$\mathcal{H}(t,J,V)=\mathcal{P}\sum_{i=1}^{L-1}\left[-t\sum_{k=1}^{2j+1}\sum_{\sigma=\pm\frac{1}{2}}(c_{i,\sigma}^{k+}c_{i+1,\sigma}^{k}+c_{i+1,\sigma}^{k+}c_{i,\sigma}^{k})\right.$$

$$\left.+2J\sum_{k,k',\sigma\neq\tau}c_{i,\sigma}^{k+}c_{i,\tau}^{k}c_{i+1,\tau}^{k'+}c_{i+1,\sigma}^{k'}+(V-J)n_in_{i+1}\right]\mathcal{P}. \tag{25}$$

Due to the conservation of the particle number operator n^k, and according to the coordinate Bethe Ansatz we look for eigenvectors of (25), corresponding to N fermions of $2j+1$ bands in the following form:

$$|\Psi\rangle=\sum_{k_1\cdots k_N=1}^{2j+1}\sum_{x_1\sigma_1}\cdots\sum_{x_N\sigma_N}\psi^{k_1\cdots k_N}(x_1\sigma_1,\ldots,x_N\sigma_N)c_{x_1\sigma_1}^{k_1+}\cdots c_{x_N\sigma_N}^{k_N+}|0\rangle, \tag{26}$$

where $|0\rangle$ is the empty vacuum state.

The eigenvalue equation $H|\Psi\rangle=E|\Psi\rangle$ in the one particle sector

$$-t(\Psi^k(x-1,\sigma)+\Psi^k(x,\sigma))=E\Psi^k(x,\sigma) \tag{27}$$

gives us

$$E=-2t\cos p \tag{28}$$

after substituting of the plane wave function with momentum p into (27).

The eigenvalue equations in the two particle sector allows us to fix the energy of the state as a sum of two one particle energies, as well as the two two particle scattering matrix $S_{\sigma_1\sigma_2,k_1k_2}^{\sigma_1'\sigma_2',k_1'k_2'}(p_1,p_2)$. We choose the antisymmetric wave function $\Psi^{k_1k_2}(x_1\sigma_1,x_2\sigma_2)$ as

$$\psi^{k_1,k_2}(x_1\sigma_1,x_2\sigma_2)=A^{k_1k_2}(p_1\sigma_1,p_2\sigma_2)e^{i(p_1x_1+p_2x_2)}-A^{k_2k_1}(p_2\sigma_1,p_1\sigma_2)e^{i(p_2x_1+p_1x_2)} \tag{29}$$

for $x_2\leqslant x_1$ and

$$\psi^{k_1,k_2}(x_1\sigma_1,x_2\sigma_2)=A^{k_2k_1}(p_2\sigma_2,p_1\sigma_1)e^{i(p_1x_1+p_2x_2)}-A^{k_1k_2}(p_1\sigma_2,p_2\sigma_1)e^{i(p_2x_1+p_1x_2)} \tag{30}$$

for $x_1\leqslant x_2$.

The continuity condition at $x_1\approx x_2$ should be imposed,

$$A^{k_1k_2}(p_1\sigma_1,p_2\sigma_2)-A^{k_1k_2}(p_2\sigma_1,p_1\sigma_2)=A^{k_2k_1}(p_2\sigma_2,p_1\sigma_1)-A^{k_2k_1}(p_1\sigma_2,p_2\sigma_1). \tag{31}$$

Use of the Hamiltonian (24) and the most general form (26) of the eigenfunctions ψ, the eigenvalue equations can be written as

$$\begin{aligned}-t[\psi^{k_1k_2}&(x_1+1\sigma_1,x_2\sigma_2)(1-\delta_{x_1+1,x_2})+\psi^{k_1k_2}(x_1-1\sigma_1,x_2\sigma_2)(1-\delta_{x_1,x_2+1})\\&+\psi^{k_1k_2}(x_1\sigma_1,x_2+1\sigma_2)(1-\delta_{x_1,x_2-1})+t+\psi^{k_1k_2}(x_1\sigma_1,x_2-1\sigma_2)(1-\delta_{x_1-1,x_2})]\\&+2J\delta_{|x_1,x_2|,1}\psi^{k_1k_2}(x_1\sigma_2,x_2\sigma_1)++(V-J)\delta_{|x_1-x_2|,1}\psi^{k_1k_2}(x_1\sigma_1,x_2\sigma_2)\\&=E\psi^{k_1k_2}(x_1\sigma_1,x_2\sigma_2).\end{aligned} \tag{32}$$

The terms $(1-\delta)$ appeared near the hopping terms as a result of projective operator $\mathcal{P}$, preventing double occupancy of the sites.

Two different cases can be considered:

(i) $|x_1-x_2|>1$. In this case eigenvalue Eq. (32) is reduced to

$$-t[\psi^{k_1k_2}(x_1+1\sigma_1,x_2\sigma_2)+\psi^{k_1k_2}(x_1-1\sigma_1,x_2\sigma_2)+\psi^{k_1k_2}(x_1\sigma_1,x_2+1\sigma_2)$$
$$+\psi^{k_1k_2}(x_1\sigma_1,x_2-1\sigma_2)]=E\psi^{k_1k_2}(x_1\sigma_1,x_2\sigma_2). \tag{33}$$

After substitution of expressions (29)–(30) for the plane waves into (33) and some simple calculations, the spectrum of two particle state can be found,

$$E=-2t(\cos p_1+\cos p_2). \tag{34}$$

(ii) $|x_1-x_2|=1$. Without loss of generality one can take $x_2=x_1+1$. Then the eigenvalue equation reduces to

$$-t[\psi^{k_1k_2}(x_1-1\sigma_1,x_2\sigma_2)+\psi^{k_1k_2}(x_1\sigma_1,x_2+1\sigma_2)+2J\psi^{k_1k_2}(x_1\sigma_2,x_2\sigma_1)$$
$$+(V-J)\psi^{k_1k_2}(x_1\sigma_1,x_2\sigma_2)=E\psi^{k_1k_2}(x_1\sigma_1,x_2\sigma_2). \tag{35}$$

By substitution of (29) and use of continuity conditions (31) one can express the amplitude $A^{k_2k_1}(p_2\sigma_1,p_1\sigma_2)$ after scattering through $A^{k_1k_2}(p_1\sigma_1,p_2\sigma_2)$ and $A^{k_1k_2}(p_1\sigma_2,p_2\sigma_1)$ before, and, therefore get the R-matrix of the model,

$$A^{k_2k_1}(p_2\sigma_1,p_1\sigma_2)=R^{\sigma_1'\sigma_2',k_2k_1}_{\sigma_1\sigma_2,k_1'k_2'}A^{k_1'k_2'}(p_1\sigma_1',p_2\sigma_2'), \tag{36}$$

where the R-matrix is the product of the ordinary $t-J$ model R-matrix multiplied by the permutation operator in the k-index space,

$$R^{\sigma_1'\sigma_2',k_2k_1}_{\sigma_1\sigma_2,k_1'k_2'}=R^{\sigma_1'\sigma_2'}_{\sigma_1\sigma_2}(t-J)\cdot\delta^{k_2}_{k_1'}\cdot\delta^{k_1}_{k_2'}. \tag{37}$$

At the supersymmetric point $2J=t,\ V=-J/4$,

$$R^{\sigma_1'\sigma_2'}_{\sigma_1\sigma_2}(t-J)=\frac{(\lambda_1-\lambda_2)\hat{P}+i\hat{I}}{\lambda_1-\lambda_2+i}. \tag{38}$$

In (38) $\lambda=\frac{1}{2}\cot(p/2)$ is the rapidity, $\hat{I}=\delta^{\sigma_1'}_{\sigma_1}\delta^{\sigma_2'}_{\sigma_2}$, and $\hat{P}=\delta^{\sigma_2'}_{\sigma_1}\delta^{\sigma_1'}_{\sigma_2}$.

The scattering matrix $S^{\sigma_1'\sigma_2',k_1'k_2'}_{\sigma_1\sigma_2,k_1k_2}$ will be defined multiplying the R-matrix by permutation operator $\hat{P}$ in the spin (σ) and color (k) spaces.

The exact integrability of the model is connected with the fact that the S-matrix should fulfill the Yang–Baxter triangular relations

$$S^{\sigma_1'\sigma_2',k_1'k_2'}_{\sigma_1\sigma_2,k_1k_2}(\lambda_1-\lambda_2)\cdot S^{\sigma_1''\sigma_3',k_1''k_3'}_{\sigma_1'\sigma_3,k_1'k_3}(\lambda_1-\lambda_3)\cdot S^{\sigma_2''\sigma_3'',k_2''k_3''}_{\sigma_2'\sigma_3',k_2'k_3'}(\lambda_2-\lambda_3)$$
$$=S^{\sigma_2'\sigma_3',k_2'k_3'}_{\sigma_2\sigma_3,k_2k_3}(\lambda_2-\lambda_3)\cdot S^{\sigma_1'\sigma_3'',k_1'k_3''}_{\sigma_1\sigma_3',k_1k_3'}(\lambda_1-\lambda_3)\cdot S^{\sigma_1''\sigma_3'',k_1''k_2''}_{\sigma_1'\sigma_2',k_1'k_2'}(\lambda_1-\lambda_2) \tag{39}$$

and constraints on t,J,V are imposed just by these equations.

Consider now N itinerant electrons in a box of L sites with periodic boundary conditions. If we successively make a change of position of an electron and its neighboring electron in a chain, each interchange produces a scattering matrix and when the particle comes back to its starting position from the other side, we will have the cyclic product of S-matrices, which is called the transfer matrix,

$$\hat{T}_j(\lambda_j)=\hat{S}_{j,j+1}(\lambda_j-\lambda_{j+1})\cdots\hat{S}_{j,N}(\lambda_j-\lambda_N)\cdot\hat{S}_{j,1}(\lambda_j-\lambda_1)\cdots\hat{S}_{j,j-1}(\lambda_j-\lambda_{j-1}). \tag{40}$$

Here we skip the matrix indexes σ and k while the hat on S means the operator in that space. The periodicity means that the transfer matrix has to be diagonal for all $j=1,...,N$ with the eigenvalues $\exp(ip_jN)$, or, on terms of rapidity λ_j,

$$e^{ip_jN}=\left(\frac{\lambda_j+i/2}{\lambda_j-i/2}\right)^L. \tag{41}$$

The matrix (40) is the trace of the so-called monodromy matrix, which by definition is the product of the S-matrices without taking trace. Hence, the monodromy matrix can be considered as a $(2\times 2)\otimes((2j+1)\times(2j+1))$ matrix in the spin σ and color k spaces. Let us remember now that this operator is a unity operator in the color space. We will not describe here the details of the algebraic Bethe Ansatz (see, e.g., Ref. 28), but already now it is clear, that because the monodromy matrix of our model is the monodromy matrix of the ordinary $t-J$ model multiplied by the unity matrix in the k-space, the generalization of the algebraic Bethe Ansatz to the present model gives rise to the same equations as the ordinary $t-J$ model.

Specifically we get

$$\left(\frac{\lambda_j+i/2}{\lambda_j-i/2}\right)^L=\prod_{\beta=1}^{M}\frac{\lambda_j-\Lambda_\beta+i/2}{\lambda_j-\Lambda_\beta-i/2},\quad j=1,...,N, \tag{42}$$

$$\prod_{j=1}^{N}\frac{\Lambda_\alpha-\lambda_j+i/2}{\Lambda_\alpha-\lambda_j-i/2}=-\prod_{\beta=1}^{M}\frac{\Lambda_\alpha-\Lambda_\beta+i}{\Lambda_\alpha-\Lambda_\beta-i},\quad \alpha=1,...,M, \tag{43}$$

where L is the number of lattice sites, N is the number of electrons, and M is the number of spin down electrons.

We see that color disappeared from the equations, which means that we can make an arbitrary partition of color charges on the state of N particles in a chain and all wave vectors will become eigenvalues of the Hamiltonian, provided that their λ's fulfill the Bethe equations.

Equations (42)–(43) are Lai's[8] form of Bethe equations, written on a basis of empty background.

The total energy is given by

$$E=-2N+2\sum_{j=1}^{N}\frac{1/2}{\lambda_j^2+1/4}. \tag{44}$$

However for the construction of the thermodynamic limit of our model it is more convenient to use the Sutherland's form [7] of the Bethe equations, which is equivalent to Lai's equations.[11,29] In Sutherland's representation one start with a ferromagnetic pseudovacuum state with all spins up and consider excitations as N_h-holes(empty sites) and M spin down electrons.

In Sutherland's representation we have

$$\begin{aligned}\left(\frac{\lambda_j+i/2}{\lambda_j-i/2}\right)^L&=\prod_{\beta=1}^{M}\frac{\lambda_j-\Lambda_\beta+i/2}{\lambda_j-\Lambda_\beta-i/2},\quad j=1,...,M+N_h,\\ 1&=\prod_{j=1}^{M+N_h}\frac{\lambda_j-\Lambda_\beta+i/2}{\lambda_j-\Lambda_\beta-i/2},\quad \beta=1,...,M.\end{aligned} \tag{45}$$

Equations (45) have real and complex solutions. The complex solutions are in a form known as strings, which may be found by fixing N_h and M (they are conserved quantities) and letting the lattice size $L\to\infty$. Following Refs. 11 and 30 one finds complex solutions in the form

$$\lambda_j=\lambda+i(n+1-2j),\quad j=1,...,n,$$
$$\Lambda_\tau=\lambda+i(n-2\tau),\quad \tau=1,...,n-1, \tag{46}$$

for arbitrary n. In a finite box these string solutions are not exact but as in Refs. 8, 31, and 32, we will assume that the corrections are small in the power of L and hence vanish in the thermodynamic limit.

We would like to write the equation for the centrum of the strings of length n, λ_α^n (which are the real variables), let their number is M' and rapidities Λ_β of spin down electrons.

Substituting (45) into Lai's form of Bethe equations and taking the logarithms from the left- and right-hand sides, one can get

$$L\theta\left(\frac{\lambda_\alpha^n}{n}\right)=2\pi I_\alpha^n+\sum_{m=1}^{\infty}\sum_{\gamma}^{N_m}\Theta_{nm}(\lambda_\alpha^n-\lambda_\gamma^m)+\sum_{\beta=1}^{M}\theta\left(\frac{\lambda_\alpha^n-\Lambda_\beta}{n}\right) \tag{47}$$

and

$$\sum_{n=1}^{\infty}\sum_{\alpha=1}^{N_n}\theta\left(\frac{\Lambda_\beta-\lambda_{pha}^n}{n}\right)=2\pi J_\beta, \tag{48}$$

where N_m is the number of strings of length m, $\theta(x)=2\tan^{-1}(x)$, and

$$\Theta_{mn}=\begin{cases}\theta\left(\frac{x}{|n-m|}\right)+2\theta\left(\frac{x}{|n-m|+2}\right)+\cdots+2\theta\left(\frac{x}{n+m-2}\right) & \text{if } n\neq m\\ 2\theta\left(\frac{x}{2}\right)+2\theta\left(\frac{x}{4}\right)+\cdots+2\theta\left(\frac{x}{n+m-2}\right) & \text{if } n=m\end{cases}. \tag{49}$$

I_α^n and J_β are integers (half-integers) appearing after the choice of the branch of the logarithm.

The integers M, N_m, and M' satisfy the relation

$$M'=M+\sum_{m=1}^{\infty}mN_m. \tag{50}$$

Any solution is defined by a set of I_α^n and J_β. All possible integer (half-integer) values define the states called vacancies. The vacancies may be occupied by particles of color k or not occupied at all. In a case of occupied vacancies one can mark the corresponding I_α^n and J_β by the color index k as for particles, $I_\alpha^{n,k}$ and J_β^k. When the state is empty, the corresponding integer will be mentioned as $\underline{I}_\alpha^n$ and $\underline{J}_\beta$.

One may calculate the number of string states (46) taking account also color degrees of freedom and will get $(2j+1)^L$.

VI. THE THERMODYNAMIC LIMIT OF THE BETHE ANSATZ EQUATIONS

In the thermodynamic limit $L\to\infty$ the solution becomes densely packed (the difference of two neighbor solutions is of order $1/L$, $\lambda_{j+1}^n-\lambda_j^n=O(1/L)$) and one can introduce density functions of the states and pass from sums to integrals in Eqs. (47)–(48).

Let us define the particle and hole densities as follows:

$$\rho_p^{n,k}(\lambda)=\lim_{L\to\infty}\frac{1}{L(\lambda_{I_{j+1}^{n,k}}-\lambda_{I_j^{n,k}})},\quad \rho_h^n(\lambda)=\lim_{L\to\infty}\frac{1}{L(\lambda_{\bar{I}_{j+1}^n}-\lambda_{\bar{I}_j^n})},$$
$$\sigma_p^k(\lambda)=\lim_{L\to\infty}\frac{1}{L(\Lambda_{J_{j+1}^k}-\Lambda_{J_j^k})},\quad \sigma_h(\lambda)=\lim_{L\to\infty}\frac{1}{L(\Lambda_{\bar{J}_{j+1}}-\Lambda_{\bar{J}_j})}, \tag{51}$$

and the sum of the hole and particle densities defines the density functions of vacancies,

$$\rho_t^n=\sum_{k=1}^{2j+1}\rho_p^{n,k}+\rho_h^n,\quad \sigma_t=\sum_{k=1}^{2j+1}\sigma_p^k+\sigma_h. \tag{52}$$

The passage from sum to integral is straightforward and in the thermodynamic limit the Bethe equations (47)–(48) become integral equations,

$$\rho_t^n(\lambda)=f_n(\lambda)-\sum_{m=1}^{\infty}\int_{-\infty}^{\infty}d\lambda' A_{n,m}(\lambda-\lambda')\rho_p^m(\lambda')-\int_{-\infty}^{\infty}d\Lambda f_n(\lambda-\Lambda)\sigma_p(\Lambda) \tag{53}$$

and

$$\sigma_t(\Lambda)=\sum_{n=1}^{\infty}\int_{-\infty}^{\infty}d\lambda f_n(\Lambda-\lambda)\rho_p^n(\lambda). \tag{54}$$

$f_n(\lambda)$ and $A_{n,m}(\lambda)$ in Eqs. (53)–(54) are defined by

$$f_n(\lambda)=\frac{1}{2\pi}\frac{d\theta(\lambda)}{d\lambda}=\frac{1}{\pi}\frac{n}{\lambda^2+n^2} \tag{55}$$

and

$$A_{n,m}=\begin{cases} f_{|n-m|}(\lambda)+2f_{|n-m|+2}(\lambda)+\cdots+2f_{n+m-2}(\lambda), & \text{if } n\neq m\\ 2f_2(\lambda)+2f_4(\lambda)+\cdots+2f_{2n-2}(\lambda), & \text{if } n=m\end{cases}. \tag{56}$$

Following Yang and Yang,[33] Takahashi,[31] and Gaudin,[32] we can write down the thermodynamic equilibrium equations. For the ordinary $t-J$ model it was done in Refs. 5,30, and 34.

The conserved quantities of our model are the following:

(1) *The energy* (the expression in ferromagnetic background slightly differs from Lai's expression (44)),

$$E=L\left(1-4\pi\sum_{n=1}^{\infty}\sum_{k=1}^{2j+1}\int d\lambda f_n(\lambda)\rho_p^{n,k}(\lambda)\right); \tag{57}$$

(2) *The number of different particles*,

$$N^k=L\left(1-\int d\lambda\sum_{n=1}^{\infty}\rho_p^{n,k}(\lambda)+\int d\Lambda\sigma_p^k(\Lambda)\right); \tag{58}$$

(3) *And the magnetization*,

$$S_z=\frac{L}{2}\left(1-\sum_{n=1}^{\infty}\sum_{k=1}^{2j+1}(2n-1)\int d\lambda\rho_p^{n,k}(\lambda)-\sum_{k=1}^{2j+1}\int d\Lambda\sigma_p^k(\Lambda)\right). \tag{59}$$

Correspondingly, for the free energy F one can write

$$F=E-\sum_{k=1}^{2j+1}\mu_k N^k - BS_z - TS, \tag{60}$$

where μ_k are the chemical potentials of particles, B is the external magnetic field, and T is the temperature. We will calculate the entropy S in a standard way, as the logarithm of the number of possible states of the model in the interval $d\lambda$,

$$N(\lambda,d\lambda)=e^{S(\lambda)d\lambda}=\frac{L(\Sigma_{k=1}^{2j+1}\rho_p^k d\lambda)!}{\Pi_{k=1}^{2j+1}(L\rho_p^k d\lambda)!(L\rho_h d\lambda)!}. \tag{61}$$

By Stirling's formula one finds from (61),

$$S=L\left\{\int d\lambda \sum_{m=1}^{\infty}\left[\rho_t^n \log \rho_t^n - \sum_{k=1}^{2j+1}\rho_p^{n,k}\log \rho_p^{n,k} - p_h^n \log \rho_h^n\right]\right.$$
$$\left.+\int d\Lambda\left[\sigma_t \log \sigma_t - \sum_{k=1}^{2j+1}\sigma_p^k \log \sigma_p^k - \sigma_h \log \sigma_h\right]\right\}. \tag{62}$$

To obtain the equilibrium equations one should minimize the free energy over density functions of the particles and holes. Puting $\delta F=0$ for variations of the density functions $\rho_p^{n,k}$, ρ_h^n, σ_p^k, σ_h one gets after some algebraic transformations an infinite set of integral equations for the densities. If one defines the excited energies as usual

$$\frac{\rho_p^{n,k}}{\rho_t^n-\rho_p^{n,k}}=e^{-(\epsilon^{n,k}/T)}, \qquad \frac{\sigma_p^k}{\sigma_t-\sigma_p^k}=e^{-(\epsilon_\Lambda^k/T)} \tag{63}$$

and

$$\epsilon_0^{n,k}=-4\pi f_n(\lambda)-(2n-1)B+\mu_k, \tag{64}$$

we obtain

$$\epsilon^{n,k}(\lambda)=\epsilon_0^{n,k}+T\sum_{m=1}^{\infty}\int d\lambda' A_{n,m}(\lambda-\lambda')\log(1+e^{[-\epsilon^{m,k}(\lambda')]/T})$$
$$-T\int d\Lambda f_n(\lambda-\Lambda)\log(1+e^{[-\epsilon_\Lambda^k(\Lambda)]/T}) \tag{65}$$

for $n=1,...,\infty$, and

$$\epsilon_\Lambda^k=-\mu_k-B+T\sum_{n=1}^{\infty}\int d\lambda f_n(\lambda-\Lambda)\log(1+e^{[-e^{n,k}(\lambda)]/T}). \tag{66}$$

It is seen from these equations for densities and excitation energies that if all particles have the same chemical potential $\mu=\mu_k$, the solutions will be independent of k. Correspondingly, for minimum value of the free energy one can has

$$\frac{F}{L}=(1+B-\mu)-T\sum_{m=1}^{\infty}\int d\lambda f_m(\lambda)\log(1+e^{[-\epsilon^m(\lambda)]/T})=(1-2\mu)-\epsilon_\Lambda(\Lambda=0) \tag{67}$$

in correspondence with Refs. 5 and 30.

In order to analyze the ground state further one should take the limit $T\to 0$ Eqs. (65)–(66) and then put the solution obtained into the expression for the energy (57). If we suppose that $\epsilon^n>0$ for

$n > 1$ (which can be checked after all by analysing the corresponding equations for the ϵ^n's) in the sum of the integral Eqs. (65)–(66), only one term will contribute in the limit $T \to 0$, and we have

$$\epsilon^{1,k}(\lambda) = \epsilon_0^{1,k} + \int d\Lambda f_1(\lambda - \Lambda) \overline{\epsilon_\Lambda^k}(\Lambda),$$
$$\epsilon_\Lambda^k(\Lambda) = -(\mu_k + B) - \int d\lambda f_1(\Lambda - \lambda) \overline{\epsilon^{1,k}}(\lambda), \tag{68}$$

where

$$\overline{\epsilon_\Lambda^k}(\Lambda) = \begin{cases} \epsilon_\Lambda^k(\Lambda), & \text{if } \epsilon_\Lambda^k(\Lambda) < 0 \\ 0, & \text{if } \epsilon_\Lambda^k(\Lambda) > 0 \end{cases}, \quad \overline{\epsilon^{1,k}}(\lambda) = \begin{cases} \epsilon^{1,k}(\lambda), & \text{if } \epsilon^{1,k}(\lambda) < 0 \\ 0, & \text{if } \epsilon_\Lambda^k(\Lambda) > 0 \end{cases}. \tag{69}$$

Hence, in Sutherland's approach we are lead to the concept of two seas; one for real(nonstring) solutions, another for rapidity Λ (spin-down electrons).

Suppose that $\epsilon^{1,k}(\lambda) = 0$ at some point $\lambda = Q$ and $\epsilon_\Lambda^k = 0$ at $\Lambda = Q_\Lambda$, which are the Fermi rapidities. Then we can write the equations for the ground state energy as

$$\frac{E_0}{L} = 1 - 4\pi \sum_{k=1}^{2j+1} \int_{-Q}^{Q} d\lambda f_1(\lambda) \rho_p^{1,k}(\lambda). \tag{70}$$

The equations for the density functions also simplify

$$\sum_{k=1}^{2j+1} \rho_p^{1,k}(\lambda) = f_1(\lambda) - \sum_{k=1}^{2j+1} \left(\int_{-\infty}^{-Q_\Lambda} + \int_{Q_\Lambda}^{\infty} \right) d\Lambda f_1(\lambda - \Lambda) \sigma_p^k(\Lambda) \tag{71}$$

and

$$\sum_{k=1}^{2j+1} \sigma_p(\Lambda) = \sum_{k=1}^{2j+1} \int_{-Q}^{Q} d\lambda f_1(\Lambda - \lambda) \rho_p^{1,k}(\lambda). \tag{72}$$

The Fermi boundaries Q and Q_Λ are determined from the particle number and magnetization equations

$$\frac{N}{L} = 1 - \sum_{k=1}^{2j+1} \left[\int_{-Q}^{Q} d\lambda \rho_p^{1,k}(\lambda) + \left(\int_{-\infty}^{-Q_\Lambda} + \int_{Q_\Lambda}^{\infty} \right) d\Lambda \sigma_p^k(\Lambda) \right],$$
$$\frac{2S_z}{L} = 1 - \sum_{k=1}^{2j+1} \left[\int_{-Q}^{Q} d\lambda \rho_p^{1,k}(\lambda) + \left(\int_{-\infty}^{-Q_\Lambda} - \int_{Q_\Lambda}^{\infty} \right) d\Lambda \sigma_p^k(\Lambda) \right]. \tag{73}$$

Due to a theorem by Lieb and Mattis,[35] in zero magnetic field S_z should be zero, which means that spin-down electrons constitute half of all electrons $M = N/2$ and there is no string state in the ground state.

We see that the equations for the ground state are invariant under transformation of the index k, which means that we can arbitrarily distribute the color over the particles. They are as gauge modes in the vacuum of gauge theories.

In the half-filled case $Q_\Lambda = 0$ and $Q = \infty$ (as easy to see in Lai's form of equations[5]) and following Refs. 5 and 9, one can obtain $E_0 = 1 - 2 \log 2$.

It is also possible, following Ref. 30, to consider the excitations of the model, introduce the so-called shift functions, and write down equations for them. After that, following Ref. 36, one can find the S-matrix for the excitations of the model. It follows as above, that the S-matrix of our model is equal to the S-matrix of ordinary $t-J$ model multiplied by unity operators in an additional color space.

VII. CONCLUSIONS

We have constructed a one-dimensional model which is based on the $t-J$ model of strongly correlated electrons, but which has an additional quantum group symmetry, ensuring the degeneration of the states. We use the Bethe Ansatz technique to investigate this model. The equations for density functions, written in the thermodynamic limit, demonstrate that the additional degrees of freedom of the model behave as gauge modes. The presence of these modes, in our opinion, gives rise to the possibility of constructing a new type of integrable models, if one has an interaction between two models of this kind. Also, different topological properties, usually appearing in gauge theories, could be present in our model, and would be interesting to investigate.

(Received 22 February 1999; accepted for publication 24 May 1999)

We use the relative modular operator to define a generalized relative entropy for any convex operator function g on $(0,\infty)$ satisfying $g(1)=0$. We show that these convex operator functions can be partitioned into convex subsets, each of which defines a unique symmetrized relative entropy, a unique family (parametrized by density matrices) of continuous monotone Riemannian metrics, a unique geodesic distance on the space of density matrices, and a unique monotone operator function satisfying certain symmetry and normalization conditions. We describe these objects explicitly in several important special cases, including $g(w)=-\log w$, which yields the familiar logarithmic relative entropy. The relative entropies, Riemannian metrics, and geodesic distances obtained by our procedure all contract under completely positive, trace-preserving maps. We then define and study the maximal contraction associated with these quantities. © *1999 American Institute of Physics.* [S0022-2488(99)01410-3]

I. INTRODUCTION

For quantum systems, a state is described by a density matrix P, i.e., a positive semidefinite operator with trace one. We will let $\overline{\mathcal{D}}$ denote the set of *density matrices*. For classical discrete or commutative systems we can identify the states with the subset of diagonal density matrices, each of which defines a probability vector $p\in\mathbf{R}^n$. For commutative systems the usual logarithmic relative entropy,

$$H_{\log}(p,q)=\sum_k p_k\log(p_k/q_k), \tag{1}$$

can be generalized to

$$h_g(p,q)=\sum_k p_k g(q_k/p_k), \tag{2}$$

where g is a convex function on $(0,\infty)$ with $g(1)=0$. It is well known that any such H_g contracts under stochastic mappings, i.e., $H_g(Ap,Aq)\leqslant H_g(p,q)$ when A is a column stochastic matrix. Cohen *et al.*[1] defined the entropy contraction coefficient as

$$\eta_g(A)=\sup_{p\neq q}\frac{H_g(Ap,Aq)}{H_g(p,q)}. \tag{3}$$

[a)]Electronic mail: bruskai@cs.uml.edu

In the pair of papers,[1,2] it was shown that for each fixed A all the contraction coefficients associated with those g that are also *operator* convex are equivalent, more precisely the following.

Theorem I.1: *If g is operator convex, then*

$$\eta_g(A)=\eta_{\log}(A)=\eta_{(w-1)^2}(A)\leqslant\eta_{|w-1|}(A). \tag{4}$$

A summary of these results is given in Ref. 3. It suffices to mention here that the observation,

$$\frac{d^2}{dt^2}H_g(p,p+tv)\bigg|_{t=0}=g''(0)\sum_k (v_k)^2/p_k=H_{(w-1)^2}(p,p+v), \tag{5}$$

plays a critical role. The quantity $\Sigma_k(v_k)^2/p_k$ can also be written as $M_p(v,v)$, where

$$M_p(u,v)=-\frac{\partial^2}{\partial\alpha\,\partial\beta}H_g(p+\alpha u,p+\beta v)\bigg|_{\alpha=\beta=0} \tag{6}$$

is the Riemannian metric corresponding to the Fisher information. Čencov[4,5] showed that, for commutative systems, this is the *only* Riemannian metric that satisfies the monotonicity condition $M_{Ap}(Av,Av)\leqslant M_p(v,v)$. Thus, we can regard Theorem I.1 as stating that for operator convex g the maximal contraction of the relative entropy and its associated Riemannian metric are the same. Since there is only one Riemannian metric, all the contraction coefficients must be equal.

For quantum systems, the usual logarithmic relative entropy is given by

$$H_{\log}(P,Q)=\operatorname{Tr}P(\log P-\log Q) \tag{7}$$

$$=\int_0^\infty \operatorname{Tr}P\left[\frac{1}{Q+tI}(P-Q)\frac{1}{P+tI}\right]dt, \tag{8}$$

with P,Q in $\mathcal{D}$, the set of invertible density matrices. The integral representation (8) can be used to show that

$$M_P^{\log}(A,B)\equiv-\frac{\partial^2}{\partial\alpha\,\partial\beta}H_{\log}(P+\alpha A,Q+\beta B)\bigg|_{\alpha=\beta=0}$$

$$=\int_0^\infty \operatorname{Tr}A\left[\frac{1}{P+tI}B\frac{1}{P+tI}\right]dt. \tag{9}$$

Although $M_P^{\log}(A,B)$ is a monotone Riemannian metric, it is not the only possibility; $M_P(A,B)=\operatorname{Tr}A^*P^{-1}B$ is also monotone under completely positive, trace-preserving maps. The study of monotone Riemannian metrics on noncommutative probability spaces was initiated by Morozova and Čencov,[6] who did not, however, provide any explicit examples. A complete characterization of monotone Riemannian metrics (which includes the examples above) was given recently by Petz.[7–10] The quantum structure is much richer because left and right multiplications by P^{-1} are not equivalent. We will see that $M_P(A,B)$ can always be written in the form $\operatorname{Tr}A^*\Omega_P(B)$, where Ω_P reduces to multiplication by P^{-1} when P and B commute. Thus, for example, (9) above gives $\Omega_P(B)=\int_0^\infty[1/(P+tI)]B[1/(P+tI)]dt$, which becomes $P^{-1}B$ when P and B commute.

Earlier, Ruskai[3] tried to extend the entropy contraction coefficient results of Cohen *et al.* to noncommutative situations, but obtained only a few preliminary results. Although one can formally define $H_g(P,Q)=\operatorname{Tr}Pg(Q/P)$ the expression Q/P is ambiguous in the quantum case. Using the nonstandard definition $Q/P=P^{-1/2}QP^{-1/2}$ [which yields $H_g(P,Q)=\operatorname{Tr}P\log P^{-1/2}QP^{-1/2}$ rather than (7) when $g(w)=-\log w$] Ruskai and Petz[11] were able to prove an analog of Theorem I.1, using the fact that

$$\frac{d^2}{dt^2} H_g(P,P+tA)\bigg|_{t=0} = g''(0)\,\mathrm{Tr}\,AP^{-1}A, \tag{10}$$

for all g. In essence, their convention for Q/P always yields the Riemannian metric $M_P(A,B) = \mathrm{Tr}\,A^*P^{-1}B$.

A better alternative is to use the relative modular operator introduced by Araki[12–16,7] to define Q/P. This yields the usual logarithmic entropy (7) and a rich family of generalized relative entropies. Moreover, differentiation then yields the entire family of monotone Riemannian metrics found by Petz.[7–10]

In this paper we use the relative modular operator to study both the relative entropies and Riemannian metrics associated with convex operator functions. For simplicity, we restrict ourselves to the matrix algebras associated with finite dimension systems. Although we do not believe this restriction is essential, it avoids many technical complications. [The most serious arises when the condition $\mathrm{Tr}\,P=1$ is not compatible with the requirement that P be invertible (in the sense of having a bounded inverse in the relevant operator algebra). In that case, one must restrict the domain of $H_g(P,Q)$ to those pairs P,Q that have comparable approximate null spaces in some suitable sense.] We show that each convex operator function defines a convex family of relative entropies, a unique symmetrized relative entropy, a unique family (parametrized by density matrices) of continuous monotone Riemannian metrics, a unique geodesic distance on the space of density matrices, and a unique monotone operator function. We describe these objects explicitly in several important special cases, including $g(w) = -\log w$. We then define and study the contraction coefficient associated with the relative entropy, Riemannian metrics, and metrics. Finally, we present examples showing that these contraction coefficients can have any value in [0,1] for a suitable stochastic map.

The paper is organized as follows. In Sec. II, we give some basic definitions and results for relative entropy and Riemannian metrics. In Sec. III, we define the corresponding geodesic distance, including the Bures metric as a special case. Finally, in Sec. IV we study the contraction of all the quantities under stochastic maps and give bounds on the maximal contraction.

II. RELATIVE ENTROPY AND RIEMANNIAN METRICS

A. Definitions

We begin by describing the relative modular operator that was originally introduced by Araki to generalize the logarithmic relative entropy to type III von Neumann algebras.[12–16,7] Later, Petz[16] used it to generalize relative entropy itself. Let $\mathcal{D}$ denote the subset of invertible operators in $\mathcal{D}$. Let $P,Q \in \mathcal{D}$, i.e., P and Q are positive definite matrices with $\mathrm{Tr}(P) = \mathrm{Tr}(Q) = 1$. For matrix algebras, the relative modular operator associated with the pair of states $\rho_P(A) = \mathrm{Tr}(AP)$ and $\rho_Q(A) = \mathrm{Tr}(AQ)$ reduces to

$$\Delta_{Q,P} = L_Q R_P^{-1}, \tag{11}$$

where L_Q and R_P are the left and right multiplication operators, respectively. Thus, $\Delta_{Q,P}(A) = QAP^{-1}$. It is easy to verify directly that $\Delta_{Q,P}$ is a positive Hermitian operator with respect to the Hilbert–Schmidt inner product.

Definition II.1: Let g be an operator convex function defined on (0,∞) such that $g(1) = 0$. *The relative g entropy of P and Q is*

$$H_g(P,Q) = \mathrm{Tr}(P^{1/2} g(\Delta_{Q,P}) P^{1/2}). \tag{12}$$

We will let $\mathcal{G}$ denote the set of functions satisfying these conditions. Note, however, that the argument of g, as defined here, is shifted from that (which we here denote g_C) in Refs. 1 and 2 so that $g_C(w) = g(w+1)$. Using standard results from the theory of monotone and convex operator functions, one can show that $\mathcal{G}$ is the class of functions that can be written in the form

$$g(w)=a(w-1)+b(w-1)^2+c\,\frac{(w-1)^2}{w}+\int_0^\infty \frac{(w-1)^2}{w+s}\,d\nu(s), \tag{13}$$

where $b,c>0$ and ν is a positive measure on $(0,\infty)$ with finite mass $\int_0^\infty d\nu(s)$. The term $(w-1)^2/w$ may seem unfamiliar, as it is usually included implicitly in the integral. However, writing it separately will be convenient later and is necessary to ensure that the measure has finite mass. The function $g(w)=-\log w$ yields the usual logarithmic relative entropy (7), which we continue to denote as $H_{\log}(P,Q)$. The function $g(w)=(w-1)^2$ yields

$$H_{(w-1)^2}=\mathrm{Tr}(P-Q)P^{-1}(P-Q), \tag{14}$$

which we call the ''quadratic relative entropy;'' it plays an extremely important role in our development. The function $g(w)=(w-1)^2/(w+1)$ yields the equally important, but less familiar, $H_{\mathrm{Bures}}(P,Q)=\mathrm{Tr}(P-Q)[L_Q+R_P]^{-1}(P-Q)$, where we use the subscript Bures because (as will be explained in Sec. III) it eventually leads to a geodesic on $\mathcal{D}$ referred to as the ''metric of Bures.''

We will study the properties of relative entropy and related quantities under a class of maps referred to as ''stochastic'' based on the concept of a completely positive, trace-preserving map $\phi:\mathcal{A}_1\to\mathcal{A}_2$ from one operator algebra to another. Such maps are linear and positivity preserving, not only on the original algebra, but when lifted to tensors products. A precise definition and useful representation theorems can be found in Stinespring,[17] Arveson,[18] Choi,[19] Kraus,[20] and Lindblad.[21] In particular, ϕ is a completely positive map if and only if there exist operators $\{V_k\}$ with $V_k:\mathcal{A}_1\to\mathcal{A}_2$, such that

$$\phi(A)=\sum_{k=1}^{N} V_k A V_k^* . \tag{15}$$

It then follows that ϕ is trace preserving if and only if $\Sigma_k V_k^* V_k=I$; whereas ϕ is unital [i.e., $\phi(I_1)=I_2$] if and only if $\Sigma_k V_k V_k^*=I$. For von Neumann algebras with finite trace (as is the case here) one can use the Hilbert–Schmidt inner product $\langle A,B\rangle=\mathrm{Tr}\,A^*B$ to define the adjoint $\hat{\phi}$ of any completely positive map so that $\mathrm{Tr}\,A^*\phi(B)=\mathrm{Tr}\,\hat{\phi}(A)^*B$. It is then easy to see that $\hat{\phi}(A)=\Sigma_k V_k^* A V_k$ and that ϕ is trace preserving if and only if $\hat{\phi}$ is unital. Then, for the finite-dimensional algebras considered here, we can use the following.

Definition II.2: A stochastic map $\phi:\mathcal{A}_1\to\mathcal{A}_2$ *is a completely positive, trace-preserving map.*

(For general von Neumann algebras, a stochastic map should be defined as the dual of a unital completely positive map.) For commutative systems, a stochastic map always corresponds to a column stochastic matrix, as discussed in the Introduction above and in Refs. 1–3. For noncommutative systems, a partial trace (see Sec. IV D or, e.g., Refs. 22, 21) is an example of a stochastic map.

B. Relative entropy

We begin by defining a relative entropy distance as a bilinear function on $\mathcal{D}$ with the properties we expect of the relative g entropy $H_g(P,Q)$. It is sometimes convenient to extend our definition from $\mathcal{D}\times\mathcal{D}$ to the somewhat larger set of pairs P,Q of positive definite matrices with $\mathrm{Tr}\,P=\mathrm{Tr}\,Q$.

Definition II.3: By a relative entropy distance *we mean a function* $H(P,Q)$ *satisfying the following.*

(a) $H(P,Q)\geq 0$ *with* $H(P,Q)=0\Leftrightarrow P=Q$.
(b) $H(\lambda P,\lambda Q)=\lambda H(P,Q)$ *for* $\lambda>0$.
(c) $H(P,Q)$ *is jointly convex in* P *and* Q.

In addition, we say that the relative entropy is monotone *if*

(d) *$H(P,Q)$ decreases under stochastic maps ϕ,*
that it is symmetric *if*
(e) *$H(P,Q)=H(Q,P)$,*
and that it is differentiable *if*
(f) *the function $g(x,y)=H(P+xA,Q+yB)$ is differentiable.*

Conditions (b), (c), and (d) are not independent. It is well known that by embedding $\mathbf{C}^{n\times n}$ in $\mathbf{C}^{n\times n}\otimes\mathbf{C}^{2\times 2}$ and choosing ϕ to correspond to the partial trace over $\mathbf{C}^2$, one can show that (d) implies the subadditivity relation,

$$H(P_1+P_2,Q_1+Q_2)\leq H(P_1,Q_1)+H(P_2,Q_2). \tag{16}$$

But for functions satisfying the homogeneity condition (b) this is equivalent to joint convexity. Because any stochastic map can be represented as a partial trace,[21] it follows that when (a) and (b) hold, then $(c)\Leftrightarrow(d)$. Nevertheless, the properties of convexity and monotonicity are each of sufficient importance to justify explicitly stating them separately.

A relative entropy distance (even if symmetric) is not a metric in the usual sense, because it need not satisfy the triangle inequality. Nevertheless, such quantities have been widely used[23–25] to measure the difference between P and Q. Later, we shall show that every relative g entropy defines a relative entropy distance that then defines a Riemannian metric and an associated geodesic distance.

Theorem II.4: *Every relative g entropy of the form given in Definition II.1 is a differentiable monotone relative entropy distance in the sense of Definition II.3.*

Proof: Properties (a), (b), and (f) are straightforward; (d) is due to Petz[16] and implies (c) by the above remarks. A simple new proof of (d) is given in Sec. II F.

Theorem II.5: *For each operator convex function $g\in\mathcal{G}$,*

$$H_g(P,Q)=\mathrm{Tr}(Q-P)[b_gP^{-1}+c_gQ^{-1}](Q-P), \tag{17}$$

$$\int_0^\infty \mathrm{Tr}\left((Q-P)\frac{1}{L_Q+sR_P}(Q-P)\right)d\nu_g(s)$$

$$=\mathrm{Tr}[(Q-P)R_P^{-1}g(\Delta_{QP})(Q-P)], \tag{18}$$

where b_g, c_g, and ν_g are as in (13).

Proof: We first observe that

$$(\Delta_{Q,P}-I)(P^{1/2})=(Q-P)P^{-1/2}=R_{P^{-1/2}}(Q-P), \tag{19}$$

so that

$$H_{w-1}(P,Q)=\mathrm{Tr}[P^{1/2}(Q-P)P^{-1/2}]=0, \tag{20}$$

and the linear term in (13) does not contribute. We also find using (19) again,

$$\begin{aligned}H_g(P,Q)&=\langle(\Omega_{Q,P}-I)(P^{1/2}),(\Delta_{Q,P}+sI)^{-1}(\Delta_{Q,P}-I)(P^{1/2})\rangle\\&=\mathrm{Tr}[(Q-P)(\Delta_{Q,P}+sI)^{-1}R_{P^{-1}}(Q-P)]\\&=\mathrm{Tr}(Q-P)\frac{1}{L_Q+sR_p}(Q-P).\end{aligned} \tag{21}$$

Letting $s=0$ yields

$$H_{(w-1)^2/w}(P,Q)=\mathrm{Tr}[(Q-P)Q^{-1}(Q-P)]=H_{(w-1)^2}(Q,P), \tag{22}$$

and one easily verifies that

$$H_{(w-1)^2}(P,Q)=\mathrm{Tr}((Q-P)P^{-1}(Q-P)). \tag{23}$$

Using these results in (13) gives the desired result (17).

It is worth pointing out that the cyclicity of the trace implies that

$$\mathrm{Tr}(Q-P)\frac{1}{R_P+sL_Q}(Q-P)=\mathrm{Tr}(Q-P)\frac{1}{L_P+sR_Q}(Q-P), \tag{24}$$

although

$$\mathrm{Tr}(Q-P)\frac{1}{R_P+sL_Q}(Q-P)\neq\mathrm{Tr}(Q-P)\frac{1}{R_Q+sL_P}(Q-P),$$

in general.

One can also use the heat kernel representation,

$$(\Delta_{Q,P}+sI)^{-1}=\int_0^\infty e^{-u(\Delta_{Q,P}+sI)}\,du, \tag{25}$$

to obtain another integral representation of $H_g(P,Q)$.

Theorem II.6: *Let $m_g(u)=\int_0^\infty e^{-us}d\nu(s)$ denote the Laplace transform of the measure ν_g. Then*

$$H_g(P,Q)=b_gH_{(w-1)^2}(P,Q)+c_gH_{(w-1)^2}(Q,P)+\int_0^\infty H_{(w-1)^2e^{-uw}}(P,Q)m_g(u)du,$$

where we formally extend our definition of $H_g(P,Q)$ to the nonconvex function $g(w)=(w-1)^2e^{-uw}$.

Proof: We use (25) in (13) to get

$$\begin{aligned}&\int_0^\infty\langle(\Delta_{Q,P}-I)(P^{1/2}),(\Delta_{Q,P}+sI)^{-1}(\Delta_{Q,P}-I)(P^{1/2})\rangle d\nu_g(s)\\&=\int_0^\infty\langle(\Delta_{Q,P}-I)(P^{1/2}),e^{-u\Delta_{Q,P}}(\Delta_{Q,P}-I)(P^{1/2})\rangle m_g(u)du\\&=\int_0^\infty\mathrm{Tr}((Q-P)(R_{P^{-1}}e^{-u\Delta_{Q,P}})(Q-P))m_g(u)du\\&=\int_0^\infty H_{(w-1)^2e^{-uw}}(P,Q)m_g(u)du,\end{aligned}$$

where we have interchanged the order of integration and then used (19) again.

C. Monotone Riemannian metrics

We now consider the relation between relative g entropy and Riemannian metrics. Note that the set of density matrices $\mathcal{D}$ has a natural structure as a smooth manifold, so that we can define a Riemannian metric on its tangent bundle $T_*\mathcal{D}$, whose fibers consist of traceless, self-adjoint matrices or

$$T_P\mathcal{D}=\{A=A^*:\mathrm{Tr}\,A=0\}. \tag{26}$$

Definition II.7: By a Riemannian metric on $\mathcal{D}$, we mean a positive definite bilinear form $M_P(A,B)$ on $T_P\mathcal{D}$ such that the map $P\rightarrow M_P(A,A)$ is smooth for each fixed $A\in T_*\mathcal{D}$. The metric is monotone if it contracts under stochastic maps in the sense

$$m_{\phi(P)}[\phi(A),\phi(B)]\leqslant M_P(A,B), \tag{27}$$

when ϕ is a stochastic map.

Note that this definition of monotone requires that the stochastic map ϕ act on the base point (i.e., the indexing density matrix P) as well as the arguments of the bilinear form.

Theorem II.8: *For each $g\in\mathcal{G}$ and density matrix $P\in\mathcal{D}$,*

$$M_P^g(A,B)=-\frac{\partial^2}{\partial\alpha\,\partial\beta}H_g(P+\alpha A,P+\beta B)\bigg|_{\alpha=\beta=0}, \tag{28}$$

$$=\langle A,\Omega_P^g(B)\rangle=\mathrm{Tr}\,A_P^g(B), \tag{29}$$

defines a Riemannian metric on $T_P\mathcal{D}$, and a positive linear operator Ω_P^g on $T_P\mathcal{D}$.

The theorem follows easily from the fact that R_P,L_P and their inverses are positive semidefinite operators with respect to the Hilbert–Schmidt inner product, e.g., $\mathrm{Tr}\,A^*R_PA>0$, and the integral representation in Theorem II.5. We find

$$\begin{aligned}\langle A,\Omega_P^g(B)\rangle&=(b_g+c_g)\mathrm{Tr}[AL_P^{-1}(B)+BL_P^{-1}(A)]\\&\quad+\int_0^\infty \mathrm{Tr}[A(L_P+sR_P)^{-1}(B)+B(L_P+sR_P)^{-1}(A)]d\nu_g(s)\\&=(b_g+c_g)\mathrm{Tr}\,A[L_P^{-1}+R_P^{-1}](B)\\&\quad+\int_0^\infty \mathrm{Tr}\,A[(L_P+sR_P)^{-1}+(R_P+sL_P)^{-1}](B)d\nu_g(s)\\&=\int_0^\infty \mathrm{Tr}\,A[(L_P+sR_P)^{-1}+(R_P+sL_P)^{-1}](B)N_g(s)ds\\&=\left\langle A,\int_0^\infty[(L_P+sR_P)^{-1}+(R_P+sL_P)^{-1}](B)N_g(s)ds\right\rangle,\end{aligned} \tag{30}$$

where, for simplicity, we temporarily subsume the quadratic terms into the integral by defining N_g so that $N_g(s)ds=(b_g+c_g)\delta(s)ds+d\nu_g(s)$. It is critical that A and B are self-adjoint so that we can interchange A and B by replacing L_P by R_P as in

$$\mathrm{Tr}\,BL_P^{-1}(A)=\mathrm{Tr}\,BP^{-1}A=\mathrm{Tr}\,ABP^{-1}=\mathrm{Tr}\,AR_P^{-1}(B). \tag{31}$$

This result would not hold if we did not require the perturbations of P and Q to be self-adjoint. Given that requirement, the result is necessarily symmetric in the sense that we get the same result from both $H_g(P,Q)$ and $H_g(Q,P)$. This is already evident in the quadratic term, whose coefficient depends only on the sum $b+c$, and will be discussed further below.

We can now use (30) to obtain several explicit formulas for Ω_P^g:

$$\Omega_P^g=\int_0^\infty\left(\frac{1}{sR_P+L_P}+\frac{1}{sL_P+R_P}\right)N_g(s)ds \tag{32}$$

$$=\int_0^\infty\frac{1}{sR_P+L_P}(N_g(s)+s^{-1}N_g(s^{-1}))ds \tag{33}$$

$$=R_P^{-1}\int_0^{\infty}\frac{1}{s+\Delta_{P,P}}\,\sigma_g(s)ds \tag{34}$$

$$=\int_0^1\left(\frac{1}{sR_P+L_P}+\frac{1}{sL_P+R_P}\right)\sigma_g(s)ds, \tag{35}$$

where we have used the change of variable $s\to s^{-1}$ and

$$\sigma_g(s)=N_g(s)+s^{-1}N_g(s^{-1}).$$

Note that $\sigma_g(s^{-1})=s\sigma_g(s)$. Then, if we define

$$k(\lambda)=\int_0^{\infty}\frac{1}{s+\lambda}\,\sigma_g(s)ds=\int_0^1\left[\frac{1}{s+\lambda}+\frac{1}{s\lambda+1}\right]\sigma_g(s)ds, \tag{36}$$

we find that $k(\lambda^{-1})=\lambda k(\lambda)$, $\Omega_P^g=R_P^{-1}k(\Delta_{P,P})$, and that k can be expressed in terms of g as

$$k(w)=\frac{g(w)+wg(w^{-1})}{(w-1)^2}. \tag{37}$$

We will let $\mathcal{K}$ denote this set of functions, i.e.,

$$\mathcal{K}=\{k:-k \text{ is operator monotone, } k(w^{-1})=wk(w), \quad\text{and}\quad k(1)=1\}. \tag{38}$$

We have recovered half of Petz's result[7–10] that there is a one-to-one correspondence between symmetric Riemannian metrics and functions of the form (36) that satisfy the normalization condition $k(1)=1$. (But note that our k corresponds to $1/f$ in Petz's notation.) Our approach also easily yields an explicit expression for both Ω_P^g and its inverse.

Theorem II.9: *For each $g\in\mathcal{G}$ and $P\in\mathcal{D}$, the operator Ω_P^g as defined in Theorem II.8 satisfies $\Omega_P^g=R_P^{-1}k(L_PR_P^{-1})$ and $[\Omega_P^g]^{-1}=R_Pf(L_PR_P^{-1})$, where $k(w)$ is given by (37) and $f(w)=1/k(w)$.*

Although Ω_P^g is initially defined only on $T_*\mathcal{D}$, it can easily be extended to all traceless matrices using the natural complexification $\mathrm{Tr}\,A=0\Rightarrow A=A_1+iA_2$ with $A_1,A_2\in T_P\mathcal{D}$ and then to all of $\mathbf{C}^{n\times n}$ using linearity and $\Omega_P^g(I)=P^{-1}I$. The result is equivalent to using any of the formulas for Ω_P^g above together with the obvious extension of L_P and R_P to all of $\mathbf{C}^{n\times n}$. We can summarize this discussion as follows.

Theorem II.10: *For each $g\in\mathcal{G}$ and $P\in\mathcal{D}$, the operator Ω_P^g as defined in Theorem II.8 can be extended to a positive linear operator on $\mathbf{C}^{n\times n}$ so that $M_P^g(A,B)=\mathrm{Tr}\,A^*\Omega_P^g(B)$ defines an inner product on $\mathbf{C}^{n\times n}$. On the other hand, for each $g\in\mathcal{G}$ and $P\in\mathcal{D}$, Eq. (34) defines a positive linear operator Ω_P^g on all of $\mathbf{C}^{n\times n}$, and the bilinear form $M_P^g(A,B)=\mathrm{Tr}\,A^*\Omega_P^g(B)$ extends to a monotone Riemannian metric satisfying the symmetry condition $M_P^g(A,B)=M_P^g(B^*,A^*)$.*

This result is essentially due to Petz,[7–10] who also showed the converse result that every symmetric monotone Riemannian metric is of this form. We give an independent proof of monotonicity at the end of this section. That the metric is symmetric is a consequence of the cyclicity of the trace.

The following result is essentially due to Kubo and Ando,[26] who developed a theory of operator means.

Theorem II.11: *If k given by (36) satisfies $k(1)=1$, then for all $P,Q\in\mathcal{D}$,*

$$R_P^{-1}+L_Q^{-1}\geqslant R_P^{-1}k(\Delta_{Q,P})\geqslant(R_P+L_Q)^{-1}. \tag{39}$$

Proof: This follows easily from (36), the elementary inequality,

$$\frac{w+1}{2w} \geqslant \frac{1+t}{2}\left[\frac{1}{t+w}+\frac{1}{tw+1}\right] \geqslant \frac{2}{w+1}, \tag{40}$$

and the fact that the normalization $k(1)=1$ implies that $2\sigma_g(t)/(t+1)$ is a probability measure on $[0,1]$.

As immediate corollaries, we find

$$\Omega_P^{(w-1)^2} = L_P^{-1} + R_P^{-1} \geqslant \Omega_P^{\sigma} \geqslant (R_P + L_P)^{-1} = \Omega_p^{\text{Bures}}, \tag{41}$$

$$M_P^{(w-1)^2}(A,A) \geqslant M_P^g(A,A) \geqslant M_P^{\text{Bures}}(A,A), \tag{42}$$

$$H_{(w-1)^2}^{\text{sym}}(P,Q) \geqslant H_g^{\text{sym}}(P,Q) \geqslant H_{\text{Bures}}(P,Q), \tag{43}$$

where the superscript indicates the symmetric relative entropy associated with g. Thus $k(w)=2/(w+1)$ corresponds to the minimum symmetric relative entropy and minimum Riemannian metric among the class studied here. By contrast, we will see that $g(w)=(w-1)^2$ corresponds to $k(w)=(w+1)/(2w)$ so that the quadratic relative entropy is maximal.

The operators Ω_P^g and $[\Omega_P^g]^{-1}$ are noncommutative versions of multiplication by P^{-1} and P, respectively. Hence, in view of the cyclicity of the trace, the following result is not surprising.

Theorem II.12: *The operator* Ω_P^g *given by (34) satisfies* $\mathrm{Tr}\,\Omega_P^g(A) = \mathrm{Tr}\,AP^{-1}$ *and* $\mathrm{Tr}[\Omega_P^g]^{-1}(A) = \mathrm{Tr}\,AP$.

Proof: We first observe that in a basis in which P is diagonal with eigenvalues p_k,

$$\left[R_P^{-1}\frac{1}{s+\Delta_{P,P}}(A)\right]_{jk} = \left[\frac{1}{sR_P+L_P}(A)\right]_{jk} = \frac{1}{sp_k+p_j}a_{jk}, \tag{44}$$

so that

$$[\Omega_P^g(A)]_{jk} = \int_0^\infty \frac{a_{jk}}{sp_k+p_j}\sigma_g(s)ds. \tag{45}$$

Then for every $g\in\mathcal{G}$, $P\in\mathcal{D}$, and $A\in T_P\mathcal{D}$,

$$\begin{aligned}\mathrm{Tr}\,\Omega_P^g(A) &= \sum_j \int_0^\infty \frac{a_{jj}}{sp_j+p_j}\sigma_g(s)ds\\ &= \sum_j p_j^{-1}a_{jj}\int_0^\infty \frac{1}{s+1}\sigma_g(s)ds = k(1)\,\mathrm{Tr}\,P^{-1}A = \mathrm{Tr}\,P^{-1}A.\end{aligned}$$

The proof for the inverse is similar. Since $1/k$ is also operator monotone, we can use Theorem II.9 to conclude that $[\Omega_P^g]^{-1}$ can be written in the form

$$[\Omega_P^g]^{-1} = aR_P + bL_P - \int_0^\infty \frac{R_P^2}{sR_P+L_P}d_\mu(s),$$

for some positive measure μ.

D. Correspondence between defining functions

We now make some remarks on the relation between $g(w)$, $wg(w^{-1})$, and $k(w)$. It should be clear from the development above that every function $g\in\mathcal{G}$ defines a Riemannian metric and a function k as in (36) or (37). If we now consider $\hat{g}(w)=wg(w^{-1})$, it is easy to verify that $\hat{g}(w)\in\mathcal{G}$ as well and that $H_{\hat{g}}(P,Q)=H_g(Q,P)$. Thus, the map $g(w)\to wg(w^{-1})$ has the effect of switching the arguments of the relative entropy and the function $g(w)+wg(w^{-1})$ yields the symmetrized relative entropy $H_g(P,Q)+H_g(Q,P)$. Now, if we begin with a function g and relative entropy $H_g(P,Q)$, the differentiation in (28) automatically yields a symmetric result. Thus, all convex combinations $ag(w)+(1-a)\hat{g}(w)$ of g and $\hat{g}(w)$ yield the same Riemannian metric and the same function $k\in\mathcal{K}$.

Conversely, every $k\in\mathcal{K}$ defines a unique *symmetric* relative entropy via the function $g^{\rm sym}(w)=(w-1)^2k(w)$. It follows immediately from the integral representation (37) and (13) that $g^{\rm sym}(w)$ is also in $\mathcal{G}$ and that $wg^{\rm sym}(w^{-1})=g^{\rm sym}(w)$. Thus, k selects from the convex set of relative entropies associated with a given $g\in\mathcal{G}$, the symmetric one. If we observe that the integral representation (36) is equivalent to $-k$ being an operator monotone function, we can summarize the discussion above as follows.

Theorem II.13: *There is a one-to-one correspondence between each of the following.*

(a) *Monotone Riemannian metrics extended to bilinear forms via the symmetry condition* $M_P^g(A,B)=M_P^g(B^*,A^*)$.
(b) *Monotone (decreasing) operator functions satisfying* $k(w^{-1})=wk(w)$ *with the normalization* $k(1)=1$.
(c) *Convex operator functions in* $\mathcal{G}$ *that satisfy the symmetry relation* $wg(w^{-1})=g(w)$.

The relations between these are given by (34), (36), and (37). In view of this theorem, it would be appropriate to identify a given operator Ω_P^g by using the (unique) symmetric function $g^{\rm sym}$. However, we will continue to use the asymmetric g for such familiar cases as the logarithm. One might expect the one-to-one correspondence to extend to twice-differentiable symmetric monotone relative entropies. However, Petz and Ruskai[11] consider relative entropies of the form $\tilde{H}_g(P,Q)=\mathrm{Tr}\,Pg(P^{-1/2}QP^{-1/2})$. This class of monotone relative entropies can be symmetrized, however, differentiation of H_g yields the Riemannian metric $M_P^{(w-1)^2}(A,B)=\mathrm{Tr}\,A^*[P^{-1}B+BP^{-1}]$ for all $g\in\mathcal{G}$. Thus, in particular $\tilde{H}_{\log}(P,Q)=\mathrm{Tr}\,P\log(P^{-1/2}QP^{-1/2})$ is an example of a relative entropy distance (in the sense of Definition II.3) that is *not* a relative g entropy. Another class of distinct relative entropy distances is given by squares of the geodesic distances introduced in Sec. III. Thus, the properties in Definition 1.3 are *not* sufficient to completely characterize the relative g entropy and allow us to extend the one-to-one correspondence in Theorem 2.4 to a class of relative entropies. Although we believe that such an additional condition must exist, we have not found it.

E. Examples

We now give explicit expressions for the relative entropy, Ω_P^g and related quantities in several important special cases. These examples will also illustrate the relation between the functions g, $\hat{g}$, $g^{\rm sym}$, and k discussed above.

Example 1: Take $g(w)=-\log w$. Then $\hat{g}(w)=w\log w$, $g^{\rm sym}=(w-1)\log w$, $k(w)=(w-1)^{-1}\log w$, $N_g(s)=(s+1)^{-2}$ and $\sigma_g(s)=1/(s+1)$. Then, $H_{\log}(P,Q)$ is given by (7), and

$$H_{\log}^{\rm sym}=H_{(w-1)\log w}=\mathrm{Tr}(P-Q)[\log P-\log Q] \tag{46}$$

$$=\int_0^\infty \mathrm{Tr}(P-Q)\,\frac{1}{Q+xI}\,(P-Q)\,\frac{1}{P+xI}\,dx \tag{47}$$

and

$$\Omega_P^{\log}=\int_0^\infty\left(\frac{1}{sR_P+L_P}+\frac{1}{sL_P+R_P}\right)\frac{1}{(s+1)^2}\,ds=\int_0^\infty\frac{1}{s+1}\,\frac{1}{L_P+sR_P}\,ds.$$

Making the change of variables $s\to sR_P$ in the last integral yields

$$\Omega_P^{\log}=\int_0^\infty \frac{1}{s+L_P}\,\frac{1}{s+R_P}\,ds, \tag{48}$$

so that

$$\langle A,\Omega_P^{\log}(B)\rangle=\mathrm{Tr}\int_0^\infty A^*\frac{1}{sI+P}\,B\,\frac{1}{sI+P}\,ds, \tag{49}$$

a result that we obtained earlier (9) using the integral representation (8), or

$$\log P-\log Q=\int_0^\infty\left[\frac{1}{Q+xI}-\frac{1}{P+xI}\right]dx. \tag{50}$$

In this case, it is also well known[27,15] that the inverse operator can be written as

$$[\Omega_P^{\log}]^{-1}(B)=\int_0^1 P^tBP^{1-t}\,dt. \tag{51}$$

Example 2: Take $g(w)=(w-1)^2$. Then $\hat{g}(w)=(w-1)^2/w$, $g^{\mathrm{sym}}(w)=(w-1)^2(w+1)/w$ and $k(w)=(w+1)/(2w)$. Then $H_{(w-1)^2}(P,Q)$ is given by (14),

$$H^{\mathrm{sym}}_{(w-1)^2}(P,Q)=\mathrm{Tr}(Q-P)[P^{-1}+Q^{-1}](Q-P),$$

$$\Omega_P^{(w-1)^2}=R_P^{-1}+L_P^{-1},$$

and

$$\langle A,\Omega_P^{(w-1)^2}(A)\rangle=H_{(w-1)^2}(P,P+A)=\mathrm{Tr}\,AP^{-1}A.$$

The associated function is the maximal function satisfying the prescribed conditions. The operator $\Omega_P^{(w-1)^2}(B)=P^{-1}B+BP^{-1}$, so that

$$\Omega_P^{(w-1)^2}=R_P^{-1}+L_P^{-1}=R_P^{-1}[R_P+L_P]L_P^{-1}. \tag{52}$$

Example 3: For $s_0>0$ take $g_{s_0}(w)=(w-1)^2/(w+s_0)$. Then $\hat{g}_{s_0}(w)=(w-1)^2/(1+ws_0)$, $g^{\mathrm{sym}}(w)=(w-1)^2(w+1)(1+s_0)/(1+ws_0)(w+s_0)$, $k(w)=(w+1)(1+s_0)/(1+ws_0)(w+s_0)$, and $N_g(s)=\delta(s-s_0)$. Thus

$$\Omega_P^{g_{s_0}}=\frac{1}{s_0R_P+L_P}+\frac{1}{s_0L_P+R_P}=(s_0+1)[s_0R_P+L_P]^{-1}[R_P+L_P][R_P+s_0L_P]^{-1}. \tag{53}$$

When no confusion will result, it will be convenient to employ a slight abuse of notation and write $\Omega_P^{s_0}$ for $\Omega_P^{g_{s_0}}$. The case $s_0=1$ is particularly important; we have already seen that it yields the minimal $k\in\mathcal{K}$. Then $k(w)=2/(1+w)$, $g(w)=g^{\mathrm{sym}}(w)=(w-1)^2/(w+2)$, and $\Omega_P^{g_{s_0=1}}\equiv\Omega_P^{\mathrm{Bures}}=[R_P+L_P]^{-1}$. The corresponding Riemannian metric is $\langle A,\Omega_P^{\mathrm{Bures}}(B)\rangle=\mathrm{Tr}\,A^*[R_P+L_P]^{-1}(B)$ and the corresponding relative entropy,

$$H_{\mathrm{Bures}}(P,Q)=\mathrm{Tr}(Q-P)[R_P+L_Q]^{-1}(Q-P)=\mathrm{Tr}\,QXPX, \tag{54}$$

where $X=[R_P+L_Q]^{-1}(Q-P)$. Because of the cyclicity of the trace, $H_{\mathrm{Bures}}(P,Q)$ is already symmetric and $[R_Q+L_P]^{-1}$ would have given the same result.

Example 4: Take $g(w)=1-w^\alpha$. Then $k(w)=(1-w^\alpha)(1-w^{1-\alpha})/\alpha(1-\alpha)(1-w)^2$ and $N_g(s)=(\sin\pi s/\pi)(1+s)^{\alpha-2}$. Thus

$$H_{1-w^\alpha}(P,Q)=1-\mathrm{Tr}\,Q^\alpha P^{1-\alpha},$$

$$\Omega_P^g=R_P^{-1}\int_0^\infty \frac{1}{sI+\Delta_{P,P}}\,\frac{\sin \pi s}{\pi}\,(1+s)^{\alpha-2}\,ds.$$

After the change of variables $s\rightarrow sR_P$, this becomes

$$\Omega_P^g=\frac{\sin \pi s}{\pi}\int_0^\infty \frac{1}{L_P+s}\,\frac{R_P^{1-\alpha}+s^{1-\alpha}}{(R_P+s)^{2-\alpha}}\,ds. \tag{55}$$

F. Monotonicity proof

We now present a new proof of the monotonicity of the relative entropies and Riemannian metrics associated with convex operator functions.

Theorem II.14: *For every convex operator function g of the type considered here, both the relative entropy $H_g(P,Q)$ and the corresponding Riemannian metric are monotone, i.e.,*

$$H_g(P,Q)\geqslant H_g[\phi(P),\phi(Q)], \tag{56}$$

$$\langle A\Omega_P^g A\rangle \geqslant \langle \phi(A)\Omega_{\phi(P)}^g\phi(A)\rangle. \tag{57}$$

This result is essentially due to Petz.[16] We given an independent proof as an immediate corollary of the following theorem and the integral representations (17) and (34).

Theorem II.15: If ϕ is stochastic,

$$\mathrm{Tr}\,A^*\frac{1}{R_P+sL_Q}A=\mathrm{Tr}\,\phi\left(A^*\frac{1}{R_P+sL_Q}A\right)\geqslant \mathrm{Tr}\,\phi(A^*)\,\frac{1}{R_{\phi(P)}+sL_{\phi(Q)}}\,\phi(A). \tag{58}$$

Proof: If $P>0$, then $\mathrm{Tr}\,A^*PA\geqslant 0$, and $\mathrm{Tr}\,A^*AP\geqslant 0$, so that both L_P and R_P are positive as operators on the Hilbert–Schmidt space. Thus, for $Q>0$, the operator R_P+sL_Q is also positive. Let $X=[R_P+sL_Q]^{-1/2}(A)-[R_P+sL_Q]^{1/2}\hat{\phi}(B)$ with $B=[R_{\phi(P)}+sL_{\phi(Q)}]^{-1}\phi(A)$. Then $\mathrm{Tr}\,X^*X\geqslant 0$, so that

$$\mathrm{Tr}\,A^*\frac{1}{R_P+sL_Q}A-\mathrm{Tr}\,A^*\hat{\phi}(B)-\mathrm{Tr}\,\hat{\phi}(B^*)A+\mathrm{Tr}\,\hat{\phi}(B^*)[R_P+sL_Q]\hat{\phi}(B)\geqslant 0. \tag{59}$$

Since it is easy to see that

$$-\mathrm{Tr}\,A^*\hat{\phi}(B)-\mathrm{Tr}\,\phi(B^*)A=-2\,\mathrm{Tr}\,\phi(A^*)\,\frac{1}{R_{\phi(P)}+sL_{\phi(Q)}}\,\phi(A),$$

the desired result will follow if we can show that the last term in (59) is bounded above by the right side of (58). We find

$$\begin{aligned}\mathrm{Tr}\,\hat{\phi}(B^*)[R_P+sL_Q]\hat{\phi}(B)&=\mathrm{Tr}\,\hat{\phi}(B^*)\hat{\phi}(B)P+\hat{\phi}(B^*)sQ\hat{\phi}(B)\\&=\mathrm{Tr}\,\hat{\phi}(B^*)\hat{\phi}(B)P+\hat{\phi}(B)\hat{\phi}(B^*)sQ\\&\leqslant \mathrm{Tr}\,\hat{\phi}(B^*B)P+\hat{\phi}(BB^*)sQ,\end{aligned}$$

where the inequality follows from the positivity of P and Q and the operator inequality:

$$\hat{\phi}(B^*)\hat{\phi}(B)\leqslant \hat{\phi}(B^*B), \tag{60}$$

which holds for any B because the trace-preserving condition on ϕ gives $\hat{\phi}(I_2)=I_1$. Then using, e.g., $\mathrm{Tr}\,\hat{\phi}(B^*B)P=\mathrm{Tr}\,B^*B\phi(P)$, we find

$$\begin{aligned}\mathrm{Tr}\,\hat{\phi}(B^*)[R_P+sL_Q]\hat{\phi}(B) &\leqslant \mathrm{Tr}\,B^*B\phi(P)+BB^*s\phi(Q)\\ &=\mathrm{Tr}\,B^*[B\phi(P)+s\phi(Q)B]\\ &=\mathrm{Tr}\,B^*[R_{\phi(P)}+sL_{\phi(Q)}]B=\mathrm{Tr}\,B^*\phi(A)\\ &=\mathrm{Tr}\,\phi(A^*)\frac{1}{R_{\phi(P)}+sL_{\phi(Q)}}\phi(A).\end{aligned}$$

It is interesting to observe that the strategy used here is very similar to that used by Lieb and Ruskai[22] to prove a Schwarz inequality for completely positive mappings and, as a special case, the monotonicity of the quadratic relative entropy. At that time, Lieb and Ruskai could use these Schwarz inequalities to prove many special cases of the strong subadditivity of the logarithmic relative entropy, but not the general case. A complete proof of strong subadditivity[28] (see also Refs. 3, 29) seemed to require one of the convex trace function theorems of Lieb.[27] It is therefore curious that now, some 25 years later, we have finally found a way to recover strong subadditivity directly from the Schwarz strategy of Lieb and Ruskai.[22]

It should also be noted that Uhlmann had earlier[30] used a very different approach (based on interpolation theory) to show the logarithmic relative entropy was monotone under a related class of mappings that are Schwarz in the sense $\phi(A^*A)\geqslant\phi(A^*)\phi(A)$ and Petz[16] extended this to other relative entropies.

III. GEODESIC DISTANCE

We now wish to consider the contraction of the relative entropy and corresponding Riemannian metric under stochastic mappings. Before doing so, it will be useful to consider the geodesic distance that arises from the Riemannian metrics considered here.

Definition III.1: Associated with every Riemannian metric $\langle A,\Omega_P^g(B)\rangle$ *of the form (28) is a geodesic distance* $D_g(P,Q)$, *which is defined as*

$$D_g(P,Q)\equiv\inf\int_0^1\sqrt{\langle\dot{S}(t),\Omega_{S(t)}^g\dot{S}(t)\rangle dt},$$

where the infimum is taken over all smooth paths $S(t)$ *with* $S(0)=P$ *and* $S(1)=Q$.

Theorem III.2: *The square* $[D_g(P,Q)]^2$ *of every geodesic distance of the form given in Definition III.1 is a differentiable monotone relative entropy distance in the sense of Definition II.3. In addition,* $D_g(P,Q)$ *satisfies the triangle inequality* $D_g(P,R)\leqslant D_g(P,Q)+D_g(Q,R)$.

Proof: Properties (a), (b), and (e) of Definition II.3 are readily verified. Property (d), i.e., the monotonicity $D_g[\phi(P),\phi(Q)[\leqslant D_g(P,Q)$, can be proven directly, but also follows easily as a corollary to Theorem IV.2 below. The triangle inequality is standard. That $D_g(P+xA,Q+yB)$ is differentiable in the sense of Definition II.3(f) follows from standard results (see, e.g., Theorem 3.6, part (2) of Ref. 31. Q.E.D.

It is well known (see, e.g., Refs. 32–36) that the metric associated with the minimal function $k(w)=2/(1+w)$, discussed in Example 3, is (except for normalization) the metric of Bures, i.e., $D_{2(w-1)^2/(1+w)}(P,Q)=4D^{\mathrm{Bures}}(P,Q)$, where

$$\begin{aligned}[D^{\mathrm{Bures}}(P,Q)]^2&=\inf\{\mathrm{Tr}(W-X)(W-X)^*:WW^*=P,XX^*=Q\}\\ &=2[1-\mathrm{Tr}(\sqrt{P}Q\sqrt{P})^{1/2}] \qquad (61)\\ &\leqslant\mathrm{Tr}[\sqrt{P}-\sqrt{Q}]^2=2[1-\mathrm{Tr}\sqrt{P}\sqrt{Q}]=H_{1-\sqrt{w}}(P,Q). \qquad (62)\end{aligned}$$

It follows immediately from (41) that

$$D^{\mathrm{sym}}_{(w-1)^2}(P,Q) \geq D_g(P,Q) \geq 4D^{\mathrm{Bures}}(P,Q), \tag{63}$$

so that $4D^{\mathrm{Bures}}(P,Q)$ gives the minimal geodesic distance of this type.

IV. CONTRACTION UNDER STOCHASTIC MAPS

A. Contraction coefficients

Because the relative entropies, Riemannian metrics, and geodesic distances all contract under stochastic maps, their maximal contraction is a well-defined quantity in the following sense.

Definition IV.1: For each fixed convex operator function g of the form given in Def. II.1 and stochastic map ϕ, *we define three entropy contraction coefficients:*

$$\eta_g^{\mathrm{RelEnt}}(\phi) = \sup_{P\neq Q} \frac{H_g[\phi(P),\phi(Q)]}{H_g[P,Q]}, \tag{64}$$

$$\eta_g^{\mathrm{Riem}}(\phi) = \sup_{P} \sup_{A\in T_P\mathcal{D}} \frac{\langle \phi(A), \Omega^g_{\phi(P)}[\phi(A)]\rangle}{\langle A, \Omega^g_P[A]\rangle}, \tag{65}$$

$$\eta_g^{\mathrm{geod}}(\phi) = \sup_{P\neq Q} \frac{[D_g(\phi(P),\phi(Q))]^2}{[D_g(P,Q)]^2}. \tag{66}$$

In Refs. 1, 2 it was shown that for commutative systems, $\eta_g^{\mathrm{RelEnt}}(\phi) = \eta_g^{\mathrm{Riem}}(\phi) = \eta_{(w-1)^2}(\phi)$. Here, we will prove some relations between these various η.

Theorem IV.2: *The three contraction coefficients defined above satisfy*

$$1 \geq \eta_g^{\mathrm{RelEnt}}(\phi) \geq \eta_g^{\mathrm{Riem}}(\phi) \geq \eta_g^{\mathrm{geod}}(\phi). \tag{67}$$

The intuition behind the second inequality can be seen by letting $A=B=Q-P$ in the integral representations of Theorems 2.2 and 2.3. Then the only difference between the ratios in (64) and (65) is that the modular operator in the former is $\Delta_{Q,P}$ while that in the latter is $\Delta_{P,P}$. This would seem to indicate that the first supremum is taken over a larger set. However, the two are not directly comparable because the condition $P\neq Q$ in the first case precludes the choice $\Delta_{P,P}$. Hence, we consider $Q=P+\epsilon A$.

Proof: The upper bound of 1 follows immediately from Theorem II.14. To prove the second inequality $\eta_g^{\mathrm{RelEnt}}(\phi) \geq \eta_g^{\mathrm{Riem}}(\phi)$, we consider, as suggested above, $H_g(P,P+\epsilon A) = \mathrm{Tr}\, P^{1/2} g(\Delta_{P,P+\epsilon A})(P^{1/2})$. Proceeding as in the proof of Theorem II.5, but with the shorthand $dN_g(s) = (b_g + c_g)\delta(s)ds + d\nu_g(s)$, we obtain

$$\begin{aligned} H_g(P,P+\epsilon A) &= \epsilon^2 \int_0^\infty \mathrm{Tr}\left[A \frac{1}{L_{P+\epsilon A} + sR_P}(A)\right] dN_g(s) \\ &= \epsilon^2 \int_0^\infty \mathrm{Tr}\left[A \frac{1}{L_P + sR_P}(A)\right] dN_g(s) + O(\epsilon^2) \\ &= \epsilon^2 \langle \phi(A), \Omega^g_{\phi(P)}(A))\rangle + O(\epsilon^3). \end{aligned}$$

Thus

$$\eta_g^{\mathrm{RelEnt}}(\phi) = \sup_{P\neq Q} \frac{H_g[\phi(P),\phi(Q)]}{H_g[P,Q]} \geq \sup_{P} \sup_{A\in T_*\mathcal{D}} \frac{H_g[\phi(P),\phi(P+\epsilon A)]}{H_g(P,P+\epsilon A)}.$$

However,

$$\frac{H_g[\phi(P),\phi(P+\epsilon A)]}{H_g(P,P+\epsilon A)}=\frac{\langle\phi(A),\Omega^g_{\phi(P)}[\phi(A)]\rangle+O(\epsilon)}{\langle A,\Omega^g_P[A]\rangle+O(\epsilon)}.$$

Since the quantity on the right can be made arbitrarily close to $\eta_g^{\rm Riem}(\phi)$, we conclude that $\eta_g^{\rm RelEnt}(\phi)\geq\eta_g^{\rm Riem}(\phi)$. Finally, to prove the third inequality we first choose $S_0(t)$ to be a minimizing path for $D_g(P,Q)$, i.e.,

$$D_g(P,Q)=\int_0^1\sqrt{\langle\dot{S}_0(t),\Omega^g_{S_0(t)}\dot{S}_0(t)\rangle}dt.$$

Then, $\phi\circ S_0$ is a smooth path from $\phi(P)$ to $\phi(Q)$. Moreover, the linearity of ϕ implies that $(d/dt)\phi\circ S_0(t)=\phi\circ\dot{S}_0(t)$. Thus

$$\begin{aligned}D_g[\phi(Q),\phi(Q)]&\leq\int_0^1\sqrt{\langle\phi\circ\dot{S}_0(t),\Omega^g_{\phi\circ S_0(t)}\phi\circ\dot{S}_0(t)\rangle}dt\\&\leq[\eta_g^{\rm Riem}(\phi)]^{1/2}\int_0^1\sqrt{\langle\dot{S}_0(t),\Omega^g_{S_0(t)}\dot{S}_0(t)\rangle}dt\\&=[\eta_g^{\rm Riem}(\phi)]^{1/2}D_g(P,Q).\end{aligned}$$

Dividing both sides by $D_g(P,Q)$ and taking the supremum of the left-hand side, gives the desired result. Q.E.D.

In this case of the first inequality $\eta_g^{\rm RelEnt}(\phi)\geq\eta_g^{\rm Riem}(\phi)$, we proved slightly more, namely, that either equality holds or the supremum in $\eta_g^{\rm RelEnt}(\phi)$ is actually attained for some non-negative (but not necessarily strictly positive) density matrices P,Q, i.e., strict inequality implies that there exists $P\neq Q\in\overline{\mathcal{D}}$ such that

$$H_g[\phi(P),\phi(Q)]=\eta_g^{\rm RelEnt}(\phi)H_g(P,Q). \tag{68}$$

This follows from the fact that we can always find a maximizing sequence (P_k,Q_k) such that

$$\lim_{k\to\infty}\frac{H_g[\phi(P_k),\phi(Q)_k]}{H_g(P_k,Q_k)}=\eta_g^{\rm RelEnt}(\phi).$$

Since we are in a finite-dimensional space, the space of non-negative density matrices is compact so that we can find a convergent subsequence $(P_{k_j},Q_{k_j})\rightarrow(P,Q)$. Then either $P=Q$, in which case we necessarily have $\eta_g^{\rm RelEnt}(\phi)=\eta_g^{\rm Riem}(\phi)$, or (68) holds. (Strictly speaking, we must also exclude the possibility that both $H_g(P_k,Q_k)$ and $H_g[\phi(P_k),\phi(Q_k)]$ diverge to ∞.) We expect that for most choices of g, Eq. (68) holds only in very special cases [see, e.g., the partial trace example in Sec. IV D, which yield $\eta_g^{\rm RelEnt}(\phi)=1=\eta_g^{\rm Riem}(\phi)$.] Indeed, even for commutative systems, early proofs[37,1] that equality holds for $\eta_{\log}(A)=\eta_{(w-1)^2}(A)$ depended on a demonstration that (68) could not hold in general.

Another special situation occurs for the minimal g, which yields the Bures metric. If P,Q commute, then

$$\begin{aligned}H_{\rm Bures}(P,Q)&\equiv{\rm Tr}(P-Q)([L_P+R_Q]^{-1}+[L_Q+R_P]^{-1})(P-Q)\\&=2\,{\rm Tr}(P-Q)(P+Q)^{-1}(P-Q)=2\langle(P-Q),\Omega^{\rm Bures}_{P+Q}[(P-Q)]\rangle.\end{aligned}$$

Thus, if the supremum for $\eta^{\rm Riem}_{\rm Bures}(\phi)$ happens to be attained for a commuting pair R,A (with $R\in\mathcal{D}$ and $A\in T_P\mathcal{D}$) whose images $\phi(R),\phi(A)$ also commute, then

$$H_{\text{Bures}}[\phi(R+A),\phi(R-A)]=\eta_{\text{Bures}}^{\text{Riem}}(\phi)H_{\text{Bures}}(R+A,R-A). \tag{69}$$

If $\eta_{\text{Bures}}^{\text{RelEnt}}(\phi)=\eta_{\text{Bures}}^{\text{Riem}}(\phi)$, then this also yields equality in (68); however, it does *not* give a strict inequality for $\eta_{\text{Bures}}^{\text{RelEnt}}(\phi)\geqslant\eta_{\text{Bures}}^{\text{Riem}}(\phi)$. On the contrary, it seems to offer some heuristic support for equality.

We expect that in those exceptional situations in which the supremum $\eta_g^{\text{RelEnt}}(\phi)$ is attained the result is equal to $\eta_g^{\text{Riem}}(\phi)$ so that equality always holds, at least for the first inequality in Theorem IV.2.

Recall that many common choices for g [e.g., $g(w)=(w-1)^2$ or $g(w)=-\log w$] do not yield a symmetric relative entropy, i.e., $H_g(P,Q)\neq H_g(Q,P)$. This raises the question of whether or not the entropy contraction coefficient [which we denote $\eta_g^{\text{sym}}(\phi)\equiv\eta_{g(w)+wg(w^{-1})}^{\text{RelEnt}}(\phi)$] for the symmetrized relative entropy,

$$H_g^{\text{sym}}(P,Q)=H_g(P,Q)+H_g(Q,P)=H_{g(w)+wg(w^{-1})}(P,Q), \tag{70}$$

is the same as $\eta_g^{\text{RelEnt}}(\phi)$. Although we believe equality holds, we can only prove that

$$\eta_g^{\text{sym}}(\phi)\leqslant\eta_g^{\text{RelEnt}}(\phi). \tag{71}$$

Nevertheless, Theorem IV.2 holds for any g. In fact, since there is a unique Riemannian metric associated with all g, which yield the same symmetrized relative entropy, we have $\eta_g^{\text{RelEnt}}(\phi)\geqslant\eta_g^{\text{sym}}(\phi)\geqslant\eta_g^{\text{Riem}}(\phi)$. To prove (71) it suffices to observe that

$$H_{g(w)+wg(w^{-1})}(P,Q)=H_g^{\text{sym}}(P,Q)=H_g(P,Q)+H_g(Q,P),$$

so that

$$\begin{aligned}H_g^{\text{sym}}[\phi(P),\phi(Q)]&=H_g[\phi(P),\phi(Q)]+H_g[\phi(Q),\phi(P)]\\&\leqslant\eta_g^{\text{RelEnt}}(\phi)H_g(P,Q)+\eta_g^{\text{RelEnt}}(\phi)H_g(Q,P)\\&=\eta_g^{\text{RelEnt}}(\phi)H_g^{\text{sym}}(P,Q).\end{aligned}$$

In the case of the quadratic entropy, it easily follows that $\eta_{(w-1)^2}^{\text{Riem}}(\phi)=\eta_{(w-1)^2}^{\text{RelEnt}}(\phi)=\eta_{(w-1)^2}^{\text{sym}}(\phi)$.

Finally, we note that the joint convexity of relative entropy, Riemannian metrics, and $[D_g(P,Q)]^2$ imply that the corresponding contraction coefficients are convex in ϕ. [Although we did not explicitly state the joint convexity for $M_P(A,A)$ it is an easy consequence of homogeneity and contraction under partial traces.]

Theorem IV.3: *For each fixed $g\in\mathcal{G}$, each of the contraction coefficients $\eta_g^{\text{RelEnt}}(\phi)$, $\eta_g^{\text{Riem}}(\phi)$, and $\eta_g^{\text{geod}(\phi)}$ is convex in ϕ.*

Proof: Since the argument is straightforward, we give details only for the relative entropy. Let $\phi=x\phi_1+(1-x)\phi_2$:

$$\begin{aligned}H_g[\phi(P),\phi(Q)]&=H_g[x\phi_1(P)+(1-x)\phi_2(P),x\phi_1(Q)+(1-x)\phi_2(Q)]\\&\leqslant xH_g[\phi_1(P),\phi_1(Q)]+(1-x)H_g[\phi_2(P),\phi_2(Q)]\\&\leqslant x\eta_g^{\text{RelEnt}}(\phi_1)H_g(P,Q)+(1-x)\eta_g^{\text{RelEnt}}(\phi_2)H_g(P,Q)\\&=[x\eta_g^{\text{RelEnt}}(\phi_1)+(1-x)\eta_g^{\text{RelEnt}}(\phi_2)]H_g(P,Q).\end{aligned}$$

Dividing both sides by $H_g(P,Q)$ implies

$$\eta_g^{\text{RelEnt}}(\phi)\leqslant x\eta_g^{\text{RelEnt}}(\phi_1)+(1-x)\eta_g^{\text{RelEnt}}(\phi_2).$$ Q.E.D.

B. Eigenvalue formulation of $\eta_g^{\text{Riem}}(\phi)$

We now show how $\eta_g^{\text{Riem}}(\phi)$ is related to the following set of eigenvalue problems:

$$[\hat{\phi}\circ\Omega_{\phi(P)}^g\circ\phi](A)=\lambda\,\Omega_P^g(A). \tag{72}$$

In view of Theorem II.10, this is a well-defined linear eigenvalue problem on $\mathbf{C}^{n\times n}$ for each fixed pair ϕ and P. The following remarks are easily verified.

(a) The eigenvalue problem (72) can be rewritten as $\Phi_P^g\circ\phi(B)=\lambda B$, where

$$\Phi_P^g\equiv(\Omega_P^g)^{-1}\circ\hat{\phi}\circ\Omega_{\phi(P)}^g. \tag{73}$$

Furthermore, Φ_P^g is trace preserving. This follows from Theorem II.12 and

$$\begin{aligned}\operatorname{Tr}\Phi_P^g(B)&=\operatorname{Tr}P\,\hat{\phi}\circ\Omega_{\phi(P)}^g(B)=\langle P,\hat{\phi}\circ\Omega_{\phi(P)}^g(B)\rangle\\&=\langle\phi(P),\Omega_{\phi(P)}^g(B)\rangle=\langle\Omega_{\phi(P)}^g[\phi(P)],B\rangle\\&=\langle I,B\rangle=\operatorname{Tr}B.\end{aligned}$$

(b) We can assume without loss of generality that the matrices that are eigenvectors in (72) are self-adjoint, i.e., that $A=A^*$. Indeed, it is easy to check that the operator $\Omega_P^{g_{s_0}}(A)=(sR_P+L_P)\times[R_P+L_P]^{-1}(R_P+sL_P)(A)$ satisfies $[\Omega_P^{g_{s_0}}(A)]^*=\Omega_P^{g_{s_0}}(A^*)$. Therefore, the operators Ω_P^g, $\Omega_{\phi(P)}^g$, ϕ, $\hat{\phi}$ and Φ_P^g all map adjoints to adjoints.

(c) For each fixed P, the eigenvalue equation is satisfied with $A=P$ and eigenvalue $\lambda=1$, which is the largest eigenvalue. The operators on both sides of (72) are self-adjoint (in fact, positive definite) with respect to the Hilbert–Schmidt inner product and the corresponding orthogonality condition for the other eigenvectors reduces to $\operatorname{Tr}A=0$.

In view of these observations, it is easy to conclude from the max–min principle that the second-largest eigenvalue $\lambda_2^g(\phi,P)$ satisfies

$$\lambda_2^g(\phi,P)=\sup_{A\in T_P\mathcal{D}}\frac{\langle\phi(A),\Omega_{\phi(P)}^g[\phi(A)]\rangle}{\langle A,\Omega_P^g[A]\rangle}, \tag{74}$$

for each fixed P. Then taking the supremum over $\mathcal{D}$ yields

Theorem IV.4: *For each $g\in\mathcal{G}$ and stochastic map ϕ,*

$$\eta_g^{\text{Riem}}(\phi)=\sup_{P\in\mathcal{D}}\lambda_2^g(\phi,P). \tag{75}$$

We have already observed that every Ω_P^g can be regarded as a noncommutative variant of multiplication by P^{-1}. Indeed, if both pairs of operators P,A and $\phi(P),\phi(A)$ associated with a particular eigenvalue commute for some g, then $\Omega_P^g(A)=R_{P^{-1}}(A)=L_{P^{-1}}(A)$ for *all* g and the corresponding eigenvalue equations are the same. It may be tempting to conjecture that the eigenvalue equations for different g are related by a similarity transform, which would then imply that all $\lambda_2(\phi,P)$ are equal so that all $\eta_g^{\text{Riem}}(\phi)$ are identical. However, for a given fixed P, R_P, and L_P commute, which implies that Ω_P^g and Ω_P^h commute for any pair of functions g and h. Since commuting operators are simultaneously diagonalizable and similar operators have the same eigenvalues, this would imply that all of the eigenvalue operators $B\to[(\Omega_P^g)^{-1}\circ\hat{\phi}\circ\Omega_{\phi(P)}^g\circ\phi](B)$ are identical. This is easily seen to be false in specific examples. Moreover, as discussed at the end of Sec. IV D, one can find examples of nonunital ϕ for which different $\eta_g^{Riem}(\phi)$ are *not* identical.

Theorem IV.5: *We can rewrite the eigenvalue problem (72) so that*

$$\lambda_2^g(\phi,P)=\sup_\alpha \frac{\langle \hat{\phi}(\alpha),(\Omega_P^g)^{-1}[\hat{\phi}(\alpha)]\rangle}{\langle \alpha,(\Omega_{\phi(P)}^g)^{-1}[\alpha]\rangle},$$

where the supremum is now taken over $\{\alpha\in \mathrm{Range}(\phi):\mathrm{Tr}[\Omega_{\phi(P)}^g]^{-1}(\alpha)=0\}$.

Proof:

$$\lambda_2^g(\phi,P)=\sup_{A:\mathrm{Tr}(A)=0} \frac{\langle \phi(A),\Omega_{\phi(P)}^g[\phi(A)]\rangle}{\langle A,\Omega_P^g[A]\rangle}$$

$$=\sup_{B:\mathrm{Tr}[\Omega_P^g]^{-1/2}(B)=0} \frac{\langle B[\Omega_P^g]^{-1/2}\circ\hat{\phi}\circ\Omega_{\phi(P)}^g\circ\phi\circ[\Omega_P^g]^{-1/2}B]\rangle}{\langle B,B\rangle}.$$

If we now write $\Gamma=[\Omega_{\phi(P)}^g]^{1/2}\circ\phi\circ[\Omega_P^g]^{-1/2}$, we see that $\lambda_2^g(\phi,P)$ is the largest eigenvalue of $\Gamma^*\Gamma$, where Γ maps

$$\{B:\mathrm{Tr}[\Omega_P^g]^{-1/2}(B)=0\}\to\{\beta\in\mathrm{Range}(\phi):\mathrm{Tr}[\Omega_{\phi(P)}^g]^{-1/2}(\beta)=0\}.$$

Since $\Gamma\Gamma^*$ and $\Gamma^*\Gamma$ have the same nonzero eigenvalues,

$$\lambda_2^g(\phi,P)=\sup_{\beta:\mathrm{Tr}[\Omega_{\phi(P)}^g]^{-1/2}(\beta)=0} \frac{\langle \beta[\Omega_{\phi(P)}^g]^{1/2}\circ\phi\circ[\Omega_P^g]^{-1}\circ\hat{\phi}\circ[\Omega_{\phi(P)}^g]^{1/2}]\beta\rangle}{\langle \beta,\beta\rangle}$$

$$=\sup_{\alpha:\mathrm{Tr}[\Omega_{\phi(P)}^g]^{-1}(\alpha)=0} \frac{\langle \hat{\phi}(\alpha)[\Omega_P^g]^{-1}\hat{\phi}(\alpha)\rangle}{\langle \alpha,[\Omega_{\phi(P)}^g]^{-1}\alpha\rangle}.$$

If we apply this result with $\Omega_P^{\mathrm{Bures}}=[R_P+L_p]^{-1}$, it follows easily from the theorem above that

$$\lambda_2^{\mathrm{Bures}}(\phi,P)=\sup_{\alpha:\mathrm{Tr}\ \phi(P)\alpha=0} \frac{\mathrm{Tr}\ \phi(\alpha)P\hat{\phi}(\alpha)}{\mathrm{Tr}\ \alpha\phi(P)\alpha}. \tag{76}$$

It is tempting to write $\phi(P)\alpha=\beta=\phi(B)$ and replace the constraint $\mathrm{Tr}\ \phi(P)\alpha=0$ by $\mathrm{Tr}\,B=0$. The denominator would then become $\langle \phi(B)[\phi(P)]^{-1}\phi(B)\rangle$, which has the same form as the numerator in (65) when $k(w)=(w+1)/2w$ [corresponding to $g=(w-1)^2$]. However, there is no guarantee that $\phi(\alpha)=\hat{\phi}([\phi(P)]^{-1}]B)$. On the contrary, this cannot possibly hold because we would then have that the λ (and hence η) for the two extremal functions $k(w)=2/(1+w)$ and $k(w)=(w+1)/2w$ are inverses, which is inconsistent with $\lambda^g(\phi,P)\leqslant\eta_g^{\mathrm{Riem}}(\phi)\leqslant 1$ (except in the case $\lambda=1$, which is not generic). There is, however, a sense in which the operators associated with these two extremal functions are inverses since $\Omega_P^{(w-1)^2}=R_P^{-1}+L_P^{-1}=R_P^{-1}[R_P+L_P]L_P^{-1}=R_P^{-1}[\Omega_P^{\mathrm{Bures}}]^{-1}L_P^{-1}$. It seems likely that if the η_g^{Riem} for these two extremal functions are equal, then all of them are.

Unlike the case of $\eta_g^{\mathrm{RelEnt}}(\phi)$, we do expect that the supremum for $\eta_g^{\mathrm{Riem}}(\phi)$ is actually attained. Indeed, we know that for each fixed P the supremum in (74) is attained for some $A\neq 0$, which satisfies the eigenvalue problem (72). As before, we can find a maximizing sequence of density matrices P_k for (75) so that $\eta_g^{\mathrm{Riem}}(\phi)=\lim_{k\to\infty}\lambda_2^g(\phi,P_k)$. For each P_k, let A_k be the solution to the eigenvalue problem (72) for $\lambda_2^g(\phi,P_k)$ normalized so that $\mathrm{Tr}|A_k|=1$. Then we can find a convergent subsequence for which $P_k\to P\in\mathcal{D}$ and $A_k\to A\neq 0$, since $\mathrm{Tr}|A|\neq 0$. It then follows that (72) holds for this P,A with $\lambda=\eta_g^{\mathrm{Riem}}(\phi)$ (although P is only non-negative), which implies that

$$\langle \phi(A),\Omega^{g}_{\phi(P)}[\phi(A)]\rangle = \eta^{\mathrm{Riem}}_{g}(\phi)\langle A,\Omega^{g}_{P}(A)\rangle .$$

C. Bounds on contraction coefficients

We first give an upper bound for $\eta^{\mathrm{Riem}}_{\log}$ using

$$\eta^{\mathrm{Dobrushin}}(\phi)\equiv \sup_{A\in T_{*}\mathcal{D}} \frac{\mathrm{Tr}|\phi(A)|}{\mathrm{Tr}|A|}. \tag{77}$$

This can be interpreted as the norm of ϕ regarded as an operator on the Banach space of traceless matrices with norm $\mathrm{Tr}|A|$. Although the function $g(w)=|w-1|$ is *not* operator convex, $\eta^{\mathrm{Dobrushin}}(\phi)$ is analogous to the contraction coefficient of the (nondifferentiable) symmetric relative g entropy $H_{|w-1|}(P,Q)=\mathrm{Tr}|P-Q|$, which, however, is *not* the relative g entropy obtained by using $g(w)=|w-1|$ in Definition II.1. Nevertheless, $\eta^{\mathrm{Dobrushin}}(\phi)$ is a natural and useful object to consider. It was shown in Ref. 3 (see Theorem 2) that

$$\eta^{\mathrm{Dobrushin}}(\phi)=\tfrac{1}{2}\sup\{\mathrm{Tr}|\phi(E-F)|:E,F \text{ 1-dim proj s};EF=0\}, \tag{78}$$

where ''1-dim projs'' means that E,F are one-dimensional projections in $\overline{\mathcal{D}}$. The expression on the right in (78) shows that we are justified in interpreting $\eta^{\mathrm{Dobrushin}}(\phi)$ as a noncommutative analog of Dobrushin's coefficient of ergodicity.

Theorem IV.6: *If ϕ is stochastic,*

$$\eta^{\mathrm{Riem}}_{\log}(\phi)\le \eta^{\mathrm{Dobrushin}}(\phi)\equiv \sup_{A\in T_{*}\mathcal{D}} \frac{\mathrm{Tr}|\phi(A)|}{\mathrm{Tr}|A|}. \tag{79}$$

Proof: The map $B\to(\Omega^{\log}_{P})^{-1}\circ\hat{\phi}\circ\Omega^{\log}_{\phi(P)}(B)\equiv\Phi_{\log}(B)$ is positivity preserving, as well as trace preserving. The former follows from the integral representations (49) and (51) for $\Omega^{\log}_{P}$ and its inverse, together with the fact that the composition of positivity-preserving maps is positive preserving. Then, taking the trace of the absolute value of both sides of the eigenvalue problem $\Phi[\phi(A)]=\lambda A$ and using Theorem 1 of Ref. 3 yields

$$\lambda\,\mathrm{Tr}|A|=\mathrm{Tr}|\Phi[\phi(A)]|\le \mathrm{Tr}|\phi(A)|. \quad \text{Q.E.D.} \tag{80}$$

Although we believe that this result holds for any g, we do not have a proof except for the log. Our proof depended on the observation that in the case of the log the map $\Phi_{g}(B)=(\Omega^{g}_{P})^{-1}\circ\hat{\phi}\circ\Omega^{g}_{\phi(P)}(B)$ is positivity preserving. However, explicit examples can be found to show that Φ_{g} is *not* positivity preserving in general. Indeed, although both $\Omega^{\mathrm{Bures}}_{P}=[R_{P}+L_{P}]^{-1}$ and $\Omega^{(w-1)^{2}}_{P}=R_{P}^{-1}+L_{P}^{-1}$ are positive semidefinite with respect to the Hilbert–Schmidt inner product, they are not positivity preserving in the sense of mapping positive operators to positive operators. The difference is analogous to the difference between an ordinary matrix being positive semidefinite and having positive elements.

We now consider lower bounds on $\eta^{\mathrm{Riem}}_{g}(\phi)$. In Ref. 3 it was shown that

$$\eta^{\mathrm{Dobrushin}}(\phi)\le\sqrt{\eta^{\mathrm{Riem}}_{(w-1)^{2}}(\phi)}. \tag{81}$$

We now give a lower bound that holds for all $\eta^{\mathrm{Riem}}_{g}(\phi)$ when the map ϕ is unital, i.e., $\phi(I)=I$.

Theorem IV.7: *If ϕ is unital,*

$$\eta^{\mathrm{Riem}}_{g}(\phi)\ge \sup_{\mathrm{Tr}\,A=0}\frac{\mathrm{Tr}|\phi(A)|^{2}}{\mathrm{Tr}|A|^{2}}. \tag{82}$$

This is an immediate consequence of the definition (65); it also follows from Theorem IV.4 and the fact that the right side of (82) is just $\lambda_2(\phi,I)$ when ϕ is unital. The right side of (82) can also be interpreted as the square of the norm of ϕ regarded as an operator on the Banach space of traceless matrices with Hilbert–Schmidt norm $\sqrt{\operatorname{Tr} A^*A}$. When ϕ is self-adjoint in the sense $\hat{\phi}=\phi$, every trace-preserving map is unital.

If ϕ maps $\mathbf{C}^{n\times n}$ to itself, then the results of this section can be restated in terms of the eigenvalues and singular values of ϕ. Since ϕ is trace preserving, $\phi(B)=\Lambda B$ implies that either $\Lambda=1$ or $\operatorname{Tr} B=0$. If we restrict ϕ to the matrices with trace zero, then $\eta^{\text{Dobrushin}}(\phi)$ is the largest magnitude of an eigenvalue and for unital ϕ, $\lambda_2(\phi,I)$ is the largest eigenvalue of $\hat{\phi}\phi$. Thus, for unital stochastic maps, $\lambda_2(\phi,I)=\Lambda_2(\hat{\phi}\phi)$, where we have continued our convention of using the subscript 2 for eigenvalues of maps restricted to $T_*\overline{\mathcal{D}}$. If ϕ is self-adjoint, the two lower bounds (81) and (82) coincide and $\lambda_2(\phi,I)=\Lambda_2(\hat{\phi}\phi)=[\Lambda_2(\phi)]^2$ in the usual sense of second largest eigenvalue of. For general unital ϕ, (82) is stronger since

$$\eta^{\text{Riem}}_{(w-1)^2}(\phi)\geqslant\lambda_2(\phi,I)=\Lambda_2(\hat{\phi}\phi)\geqslant[\eta^{\text{Dobrushin}}(\phi)]^2. \tag{83}$$

We now explicitly state some conjectures that have already been discussed.

Conjecture IV.8: For each fixed $g\in\mathcal{G}$,

$$\eta_g^{\text{RelEnt}}(\phi)=\eta_g^{\text{Riem}}(\phi)=\eta_g^{\text{geod}}(\phi)\leqslant\eta_g^{\text{Dobrushin}}(\phi). \tag{84}$$

Conjecture IV.9: If ϕ *is unital, then*

$$\eta_g^{\text{Riem}}=\Lambda_2(\hat{\phi}\phi)\equiv\sup_{\operatorname{Tr} A=0}\frac{\operatorname{Tr}|\phi(A)|^2}{\operatorname{Tr}|A|^2}, \tag{85}$$

for all $g\in\mathcal{G}$.

If this conjecture holds, then for unital ϕ the contraction coefficient η_g^{Riem} is independent of g. Theorem IV.13 at the end of the next section contains an explicit example of a nonunital stochastic map for which η_g^{Riem} depends nontrivially on g; therefore, the hypothesis that ϕ be unital is essential. In view of (82) it would suffice to show that $\eta_g^{\text{Riem}}\leqslant\Lambda_2(\hat{\phi}\phi)$.

D. Examples

We now consider some special classes of stochastic maps $\phi:\mathcal{A}_1\to\mathcal{A}_2$. We begin by looking at some maps for which all contraction coefficients are easily seen to be zero or one. We then consider maps from $\mathbf{C}^{2\times2}$ to $\mathbf{C}^{2\times2}$ that provide support for the conjectures above.

We first consider the case in which $\mathcal{A}_2$ is one dimensional, e.g., ϕ projects onto a one-dimensional subalgebra (which need not have an identity) of $\mathcal{A}_1$. Then, since ϕ is trace preserving and maps density matrices to density matrices, we must have $\phi(P)=\phi(Q)$, $\forall P,Q$ with $\operatorname{Tr}\varphi(P)=1$ so that $\phi(P)\neq0$. Thus, $H_g[\phi(P),\phi(Q)]=D_g[\phi(P),\phi(Q)]=0$, $\forall P,Q$, which implies $\eta_g^{\text{RelEnt}}(\phi)=\eta_g^{\text{geod}}(\phi)=0$. If $\operatorname{Tr} B=0$, then $\phi(B)=0$. [To see this note that one can find a,b such that $P=(aI+bB)$ is a density matrix.] Thus, $\langle\phi(B)\Omega^g_{\phi(P)}\phi(B)\rangle=0$ and $\operatorname{Tr}|\phi(B)|=0$ for all B in $T_*\overline{\mathcal{D}}$, which implies that $\eta_g^{\text{Riem}}(\phi)=\eta^{\text{Dobrushin}}(\phi)=0$. We can summarize this as the following.

Theorem IV.10: *If the image of the stochastic map* ϕ *is one dimensional, then* $\eta_g^{\text{RelEnt}}(\phi)=\eta_g^{\text{Riem}}(\phi)=\eta_g^{\text{geod}}(\phi)=\eta^{\text{Dobrushin}}(\phi)=0$ *for all* $g\in\mathcal{G}$.

We next consider the important special case in which ϕ is a partial trace τ. In the simplest case, let $\tau:\mathbf{C}^{2n\times2n}\to\mathbf{C}^{n\times n}$ be the map that takes

$$\mathbf{M}=\begin{pmatrix}A & B\\ C & D\end{pmatrix}\to\tau(\mathbf{M})=A+D, \tag{86}$$

where $\mathbf{M}\in\mathbf{C}^{2n\times 2n}$ has been written in block form and $A,B,C,D\in\mathbf{C}^{n\times n}$. Then the homogeneity of relative entropy (see Definition II.3b) implies that for

$$\mathbf{P}=\begin{pmatrix} P & 0 \\ 0 & P \end{pmatrix} \quad \text{and} \quad \mathbf{Q}=\begin{pmatrix} Q & 0 \\ 0 & Q \end{pmatrix},$$

$$H_g(\mathbf{P},\mathbf{Q})=H_g(2P,2Q)=H_g(\tau(\mathbf{P}),\tau(\mathbf{Q})),$$

for any g, and, similarly,

$$\langle \mathbf{A},\Omega_P^g(\mathbf{A})\rangle=\langle 2A,\Omega_{2P}^g(2A)\rangle=\langle \tau(\mathbf{A}),\Omega_{\tau(P)}^g(\tau(\mathbf{A}))\rangle,$$

when

$$\mathbf{A}=\begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix}.$$

From this, we easily see that

$$\eta_g^{\text{RelEnt}}(\phi)=\eta_g^{\text{Riem}}(\phi)=\eta_g^{\text{geod}}(\phi)=\eta^{\text{Dobrushin}}(\phi)=1, \tag{87}$$

where we have assumed implicitly that τ acts on the full algebra of all $2n\times 2n$ matrices.

The partial trace described above is similar to a conditional expectation, i.e., a map for which $\mathcal{A}_2$ is a subalgebra (with identity) of $\mathcal{A}_1$ and $\phi(A)=A$, $\forall A\in\mathcal{A}_2$. Both partial traces and conditional expectations are included in the following.

Theorem IV.11: *If the stochastic map ϕ is also an isomorphism from a nontrivial subalgebra (with identity) of $\mathcal{A}_1$ to $\mathcal{A}_2$, then $\eta_g^{\text{RelEnt}}(\phi)=\eta_g^{\text{Riem}}(\phi)=\eta_g^{\text{geod}}(\phi)=\eta^{\text{Dobrushin}}(\phi)=1$ for all $g\in\mathcal{G}$.*

Since every completely positive map can be represented as a partial trace,[21] this might seem to suggest that $\eta=1$ always holds. However, these representations involve multiple copies of the algebra, so that the partial trace is not acting on the full algebra in the higher-dimensional space. Thus, the representation of $\mathcal{A}_1$ need necessarily not contain a subalgebra with the desired isomorphism property. Examples of maps with $\eta<1$ were already found in Ref. 1 for commutative algebras, and two different noncommutative examples are given below.

We now state two results for maps $\phi:\mathbf{C}^{2\times 2}\to\mathbf{C}^{2\times 2}$. The proofs are postponed to a subsequent paper.[38] Recall that any density matrix in $\mathbf{C}^{2\times 2}$ can be written in the form $\frac{1}{2}[I+\mathbf{w}\cdot\sigma]$, where $\mathbf{w}\in\mathbf{R}^3$ and σ denotes the vector of Pauli matrices. The first theorem provides evidence for the two conjectures at the end of the previous section.

Theorem IV.12: *For the unital map $\phi_T:I+\mathbf{w}\cdot\sigma\to I+T\mathbf{w}\cdot\sigma$,*

$$\eta_g^{\text{RelEnt}}(\phi_T)=\eta_g^{\text{Riem}}(\phi_T)=\eta_g^{\text{geod}}(\phi_T)=\|T\|^2, \quad \forall g\in\mathcal{G},$$

and $\eta^{\text{Dobrushin}}(\phi_T)=\|T\|$.

The next example gives a nonunital stochastic map for which $\eta_g^{\text{Riem}}(\phi)$ varies with g. For $\alpha,\tau>0$ with $\alpha+\tau\leq 1$, define

$$\phi_{\alpha,\tau}[I+\mathbf{w}\cdot\sigma]=I+\alpha w_1\sigma_1+\tau\sigma_2. \tag{88}$$

It is easily seen to be stochastic because the condition $\alpha+\tau\leq 1$ ensures that it is a convex combination of stochastic maps. For $g_{s_0}(w)=(w-1)^2/(w+s_0)$ as in Example 3 of Sec. II E,

$$\eta_{g_{s_0}}^{\text{Riem}}(\phi)=\sup_{0\leqslant\omega\leqslant1}\frac{[(1-\tau^2+(\rho-\alpha^2)\omega^2][1-\omega^2]}{[1-\tau^2-\alpha^2\omega^2][1-\tau^2(1-\rho)-(1-\rho)\alpha^2\omega^2]}$$

$$\geqslant\frac{\alpha^2}{1-\left(\frac{1-s_0}{1+s_0}\right)^2\tau^2},$$

where $1-\rho=(1-s_0)/(1+s_0)$ and equality holds for $s_0\approx0$. In particular, we can conclude the following.

Theorem IV.13: *For the nonunital stochastic map ϕ given by (88), there is an $S>0$ such that for $s_0\in[0,S)$,*

$$\eta_{s_0}^{\text{Riem}}(\phi)=\frac{\alpha^2}{1-\left(\frac{1-s_0}{1+s_0}\right)^2\tau^2}.$$

Furthermore,

$$\eta_{(w-1)^2}^{\text{Riem}}(\phi)=\frac{\alpha^2}{1-\tau^2}<\alpha=\eta^{\text{Dobrushin}}(\phi).$$

If $s_1\in(0,S)$, we have $\eta_{s_1}^{\text{Riem}}(\phi)>\eta_{s_0}^{\text{Riem}}(\phi)=\alpha^2/1-\tau^2$.

(Received 12 February 1999; accepted for publication 21 July 1999)

The theory of separability of one-Casimir bi-Hamiltonian chains is extended onto unsplit multi-Casimir bi-Hamiltonian chains. Multi-Casimir extensions of the known one-Casimir chains are constructed. © *1999 American Institute of Physics.* [S0022-2488(99)01811-3]

I. INTRODUCTION

In the last decade considerable progress has been made in construction of new integrable finite dimensional dynamical systems showing bi-Hamiltonian property. The majority of them originate from stationary flows, restricted flows or nonlinearization of Lax equations of underlying soliton systems (see Ref. 1 and the literature quoted there). Quite recently a fundamental property of such systems has been discovered, i.e., their separability. It was proved[1,2,3] that most bi-Hamiltonian finite dimensional chains, which start with a Casimir of the first Poisson structure and terminate with a Casimir of the second Poisson structure, are integrable by quadratures, through the solutions of the appropriate Hamilton–Jacobi equation. In this paper we develop a theory generalizing them into multi-Hamiltonian systems with more than one Casimir variable. The results are illustrated by several examples of the known and new multi-Hamiltonian systems whose integrability by quadratures is demonstrated.

II. PRELIMINARY CONSIDERATIONS

Let us reexamine some facts about bi-Hamiltonian systems, both finite and infinite dimensional. We recall some definitions. Let M be a differentiable manifold, TM and T^*M its tangent and cotangent bundle. At any point $u \in M$, the tangent and cotangent spaces are denoted by T_uM and T_u^*M, respectively. The pairing between them is given by the map $\langle \cdot , \cdot \rangle : T_u^*M \times T_uM \to R$. For each smooth function $F \in C^\infty(M)$, dF denotes the differential of F (gradient ∇F for finite systems and variation δF for field systems). M is said to be a Poisson manifold if it is endowed with a Poisson bracket $\{\cdot,\cdot\}: C^\infty(M) \times C^\infty(M) \to C^\infty(M)$, in general degenerated. The related Poisson tensor π is defined by $\{F,G\}_\pi(u) := \langle dG, \pi \circ dF \rangle(u) = \langle dG(u), \pi(u) dF(u) \rangle$. So, at each point u, $\pi(u)$ is a linear map $\pi(u)$: $T_u^*M \to T_uM$ which is skew-symmetric and fulfills the Jacobi identity. Any function $c \in C^\infty(M)$, such that $dc \in \ker \pi$, is called a Casimir of π. Let π_0, π_1: $T^*M \to TM$ be two Poisson tensors on M. A vector field K is said to be a bi-Hamiltonian with respect to π_0 and π_1 if there exist two smooth functions $H, F \in C^\infty(M)$ such that

$$K = \pi_0 \circ dH = \pi_1 \circ dF. \tag{1}$$

Poisson tensors π_0 and π_1 are said to be compatible if the associated pencil $\pi_\lambda = \pi_1 - \epsilon \pi_0$ is itself a Poisson tensor for any λ. Moreover, if π_0 is invertible, the tensor $N = \pi_1 \circ \pi_0^{-1}$, called a recursion operator, is a Nijenhuis (hereditary) tensor of such a property that when it acts on a given bi-Hamiltonian vector field K, it produces another bi-Hamiltonian vector field being a symmetry generator of K. Hence, having the invariant Nijenhuis tensor, one can construct a hierarchy of Hamiltonian symmetries and related hierarchy of constants of motion for underlying system, so important for its integrability.

Unfortunately, for majority of bi-Hamiltonian finite dimensional systems, both Poisson structures are degenerated, so one cannot construct the recursion Nijenhuis tensor inverting one of the Poisson structures. Nevertheless, due to the nonuniqueness of Hamiltonian functions, determined up to an appropriate Casimir function, it is always possible to construct a finite bi-Hamiltonian chain starting and terminating with Casimirs of π_0 and π_1, respectively. Actually, as was first shown by Gel'fand and Zakharevich,[4] having Poisson manifold M of $\dim M = 2n+1$ with a linear Poisson pencil $\pi_\lambda = \pi_1 - \lambda \pi_0$ of maximal rank, a Casimir of the pencil is a polynomial in λ of order n

$$h_\lambda = h_0 \lambda^n + h_1 \lambda^{n-1} + \cdots + h_n \tag{2}$$

and generates a bi-Hamiltonian chain

$$\pi_\lambda \nabla h_\lambda = 0 \Leftrightarrow \begin{array}{c} \pi_0 \circ \nabla h_0 = 0 \\ \pi_0 \circ \nabla h_1 = K_1 = \pi_1 \circ \nabla h_0 \\ \pi_0 \circ \nabla h_2 = K_2 = \pi_1 \circ \nabla h_1 \\ \vdots \\ \pi_0 \circ \nabla h_n = K_n = \pi_1 \circ \nabla h_{n-1} \\ 0 = \pi_1 \circ \nabla h_n, \end{array} \tag{3}$$

where $K \equiv K_1$, $H \equiv h_1$, $F \equiv h_0$, and $d \equiv \nabla$. References 1–3 demonstrate that in canonical coordinates (q,p,c), where $q = (q_1,\ldots,q_n)^T$ and $p = (p_1,\ldots,p_n)^T$ are generalized coordinates and c is a Casimir coordinate, a canonical π_0 and noncanonical π_1 Poisson structure (both degenerated) take the general form

$$\pi_0 = \begin{pmatrix} \theta_0 & 0 \\ 0 & 0 \end{pmatrix}, \quad \pi_1 \begin{pmatrix} \theta_1 & \overline{K} \\ -\overline{K}^T & 0 \end{pmatrix}, \tag{4}$$

where

$$\theta_0 = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad \theta_1 = \begin{pmatrix} D & A \\ -A^T & B \end{pmatrix} \tag{5}$$

are nondegenerated Poisson matrices from the space $\overline{M} \ni (q,p)$, $\overline{K} = \overline{K}(q,p,c)$ is related to K_1 vector field from the hierarchy (5) in the following way: $K_1 = (\overline{K},0)^T$ and A,B,D are entries depending on the generalized coordinates (q,p). Moreover, the operator

$$N = \theta_1 \circ \theta_0^{-1} = \begin{pmatrix} A & -D \\ B & A^T \end{pmatrix} \tag{6}$$

is a Nijenhuis tensor on $\overline{M}$ but not a recursion operator for the projected vector fields $\overline{K}_r \in T\overline{M}$.

Then, it was shown that each hierarchy (3), where θ_1 takes the form

$$\theta_1 = \begin{pmatrix} 0 & A(q) \\ -A^T(q) & B(q,p) \end{pmatrix}, \tag{7}$$

or can be transformed into the form (7) by an appropriate canonical transformation, with Hamiltonian functions

$$h_k(q,p,c) = h_k(q,p) + c b_k(q), \tag{8}$$

is separable. The expression for θ_1 given by (7) is the most general form of the second Poisson tensor when the change from natural coordinates to separation coordinates is given by a point transformation. Actually, first one has to pass to the so-called Darboux–Nijenhuis coordinates (λ_i,μ_i) via a canonical transformation $\phi:(\lambda,\mu)\rightarrow(q,p)$. The transformation ϕ is constructed by a generating function $S=\Sigma_{i=1}^{n}p_i\sigma_i(\lambda)$ from the equations

$$q_i=\frac{\partial S}{\partial p_i},\quad \mu_i=\frac{\partial S}{\partial \lambda_i}, \tag{9}$$

where $q_k=\sigma_k(\lambda)$ are calculated from

$$b_k(q)=(-1)^k\sum_{\substack{j_1,\ldots,j_k\\ j_1<..<j_k}}\lambda_{j_1}\cdot\cdots\cdot\lambda_{j_k}:=\rho_k(\lambda),\quad k=1,\ldots,n, \tag{10}$$

and $b_0(q)=1:=\rho_0(\lambda)$, where $\rho_k(\lambda)$ are the so-called Viete polynomials (symmetric polynomials). In Darboux–Nijenhuis coordinates the chain (3) transforms into a bi-Hamiltonian Nijenhuis chain (3) where now

$$\pi_0=\begin{pmatrix}0 & I & 0\\ -I & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\quad \pi_1=\begin{pmatrix}0 & \Lambda & \dfrac{\partial h_1}{\partial \mu}\\ -\Lambda & 0 & -\dfrac{\partial h_1}{\partial \lambda}\\ -\left(\dfrac{\partial h_1}{\partial \mu}\right)^T & \left(\dfrac{\partial h_1}{\partial \lambda}\right)^T & 0\end{pmatrix},\quad \Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_n),$$
$$h_k(\lambda,\mu,c)=-\sum_{i=1}^{n}\frac{\partial\rho_k(\lambda)}{\partial\lambda_i}\frac{f_i(\lambda_i,\mu_i)}{\Delta_i(\lambda)}+c\rho_k(\lambda)=h_k(q,p,c)\cdot\phi, \tag{11}$$

$\rho_k(\lambda)$ are given by (10),

$$\Delta_i(\lambda):=\prod_{j\neq i}(\lambda_i-\lambda_j) \tag{12}$$

and $f_i(\lambda_i,\mu_i)$ are arbitrary smooth functions.

Then, it was demonstrated that for each $h_k(\lambda,\mu,c)$ there exists a canonical transformation $(\lambda,\mu)\rightarrow(b,a)$ in the form $b_i=\partial W/\partial a_i$, $\mu_i=\partial W/\partial\lambda_i$, where $W(\lambda,a)$ is the generating function, such that the related Hamilton–Jacobi equations

$$h_r\left(\lambda,\frac{\partial W}{\partial\lambda},c\right)=\mathrm{const} \tag{13}$$

can be solved and hence, the implicit solutions for the trajectories $\lambda_i(t_r)$, with respect to the evolution parameter t_r, can be constructed.

In the next section we extend the formalism onto unsplit multi-Casimir chains, i.e., the case with more then one Casimir variable, when each bi-Hamiltonian chain conserves the form (3) and does not split into two or more sub-chains. So, the theory presented does not cover such examples as stationary Boussinesq flows.[5] The following properties of Viete $\rho_r(\lambda)$ and $\Delta_i(\lambda)$ polynomials will be useful[1,2]

$$\frac{\partial\rho_r}{\partial\lambda_i}:=-\rho_{r-1}^{i},\quad \lambda_i\frac{\partial\rho_r}{\partial\lambda_i}=\rho_r-\rho_r^{i},\quad \lambda_i\rho_{r-1}^{i}=-\rho_r+\rho_r^{i}, \tag{14}$$

$$\frac{\partial\rho_r^k}{\partial\lambda_i}:=-\rho_{r-1}^{ki}, \quad \lambda_i\frac{\partial\rho_r^k}{\partial\lambda_i}=\rho_r^k-\rho_r^{ki}, \quad \lambda_i\rho_{r-1}^{ki}=-\rho_r^k+\rho_r^{ki},$$
$$\frac{\partial}{\partial\lambda_i}\frac{1}{\Delta_i}=-\frac{1}{\Delta_i}\sum_{\alpha\neq i}\frac{1}{\lambda_{i\alpha}}, \quad \frac{\partial}{\partial\lambda_\beta}\frac{1}{\Delta_i}=\frac{1}{\Delta_i}\frac{1}{\lambda_{i\beta}}, \quad \beta\neq i. \tag{15}$$

III. MULTI-HAMILTONIAN NIJENHUIS CHAINS AND THEIR INTEGRABILITY BY QUADRATURES

Consider the set of Hamiltonian functions

$$h_r(\lambda,\mu,c)=-\sum_{i=1}^n\frac{\partial\rho_r}{\partial\lambda_i}\frac{f_i(\lambda_i,\mu_i)}{\Delta_i}+\sum_{j=1}^n c_j\beta_{j,r}(\lambda), \quad r=1,...,n, \tag{16}$$

where $\beta_{1,r}(\lambda)\equiv\rho_r(\lambda)$ and $\beta_{m,r}$, $m=2,...,n$, are defined by the recursive formula

$$\beta_{m,r}=\beta_{m-1,r+1}-\beta_{m-1,1}\cdot\beta_{1,r}. \tag{17}$$

The explicit forms of $\beta_{j,r}$ functions for $n=2,3$ are given in Appendix A.

In this section we prove that functions (16) form $\binom{n+1}{2}$ bi-Hamiltonian chains with respect to $(n+1)$ appropriate Poisson matrices, and then we solve the related Hamilton–Jacobi equations, confirming the separability of dynamical systems generated by Hamiltonians (16). We start with proofs of some properties of h_r functions and their components.

Lemma 1: (i) The following representation of $\beta_{k,r}$ is valid:

$$\beta_{k,r}(\lambda)=\sum_{i=1}^n\frac{\partial\rho_r}{\partial\lambda_i}\frac{\lambda_i^{n+k-1}}{\Delta_i}=-\sum_{i=1}^n\rho_{r-1}^i\frac{\lambda_i^{n+k-1}}{\Delta_i}. \tag{18}$$

(ii) The following property of $\beta_{k,r}$ is fulfilled:

$$\frac{\partial\beta_{r,k+1}}{\partial\lambda_i}=-\frac{\partial\rho_{k+1}}{\partial\lambda_i}\frac{\partial\beta_{r,1}}{\partial\lambda_i}=\rho_k^i\frac{\partial\beta_{r,1}}{\partial\lambda_i}. \tag{19}$$

The proof is given in Appendix B.

Lemma 2: Let $R=\Sigma_{j=1}^n[\lambda_j^2(\partial/\partial\lambda_j)+\lambda_j]$, then the following relations hold for functions $\beta_{k,1}$: (i)

$$R\cdot\beta_{k-1,1}=k\beta_{k,1}\Rightarrow\frac{1}{k!}R^k\cdot\beta_{0,1}=\beta_{k,1}, \quad \beta_{0,1}=1, \tag{20}$$

(ii)

$$\beta_{k,1}(\lambda)=-\sum_{\substack{i_1,...,i_k\\ i_1\leq...\leq i_k}}\lambda_{i_1}\lambda_{i_2}\dots\lambda_{i_k}, \quad k\leq n. \tag{21}$$

The proof is inductive, using the results of Lemma 1.

Notice that according to Lemma 1 (i), functions h_r can be put into the form

$$h_r(\lambda,\mu,c)=-\sum_{j=1}^n\frac{\partial\rho_r}{\partial\lambda_j}\frac{\overline{f}_j(\mu_j,\lambda_j,c)}{\Delta_j}, \quad \overline{f}_j(\mu_j,\lambda_j,c)=f_j(\mu_j,\lambda_j)-\sum_{l=1}^n c_l\lambda_j^{n-1+l}. \tag{22}$$

Lemma 3: The respective derivatives of h_r read

$$
\frac{\partial h_r}{\partial \mu_i} = -\frac{\partial \rho_r}{\partial \lambda_i}\frac{\partial h_1}{\partial \mu_i} = \rho^i_{r-1}\frac{\partial h_1}{\partial \mu_i},
$$

$$
\frac{\partial h_r}{\partial \lambda_i} = -\frac{\partial \rho_r}{\partial \lambda_i}\frac{\partial h_1}{\partial \lambda_i} = \rho^i_{r-1}\frac{\partial h_1}{\partial \lambda_i}, \tag{23}
$$

$$
\frac{\partial^2 h_r}{\partial \lambda_i \partial \lambda_j} = -\frac{1}{\lambda_i-\lambda_j}\frac{\partial \rho_r}{\partial \lambda_j}\frac{\partial h_1}{\partial \lambda_i} - \frac{1}{\lambda_j-\lambda_i}\frac{\partial \rho_r}{\partial \lambda_i}\frac{\partial h_1}{\partial \lambda_j} = \frac{\rho^j_{r-1}}{\lambda_i-\lambda_j}\frac{\partial h_1}{\partial \lambda_i} + \frac{\rho^i_{r-1}}{\lambda_j-\lambda_i}\frac{\partial h_1}{\partial \lambda_j}.
$$

The proof is given in Appendix C.

Now, let us consider $n+1$ matrices $3n\times 3n$ of rank $2n$ in the following form:

$$
\pi_0 = \left(\begin{array}{c|c}
\begin{array}{cc} 0 & I \\ -I & 0 \end{array} & \begin{array}{c|c|c} 0 & \cdots & 0 \end{array} \\
\hline
\begin{array}{c} 0 \\ \hline \vdots \\ \hline 0 \end{array} & 0
\end{array}\right),
$$

$$
\pi_1 = \left(\begin{array}{c|c}
\begin{array}{cc} 0 & \Lambda \\ -\Lambda & 0 \end{array} & \begin{array}{c|c|c|c} K_1 & 0 & \cdots & 0 \end{array} \\
\hline
\begin{array}{c} -K_1^T \\ \hline 0 \\ \hline \vdots \\ \hline 0 \end{array} & 0
\end{array}\right)
$$

$$
\pi_2 = \left(\begin{array}{c|c}
\begin{array}{cc} 0 & \Lambda^2 \\ -\Lambda^2 & 0 \end{array} & \begin{array}{c|c|c|c|c} K_2 & K_1 & 0 & \cdots & 0 \end{array} \\
\hline
\begin{array}{c} -K_2^T \\ \hline -K_1^T \\ \hline 0 \\ \hline \vdots \\ \hline 0 \end{array} & 0
\end{array}\right)
$$

$$
\vdots \tag{24}
$$

$$
\pi_n = \left(\begin{array}{c|c}
\begin{array}{cc} 0 & \Lambda^n \\ -\Lambda^n & 0 \end{array} & \begin{array}{c|c|c|c} K_n & K_{n-1} & \cdots & K_1 \end{array} \\
\hline
\begin{array}{c} -K_n^T \\ \hline -K_{n-1}^T \\ \hline \vdots \\ \hline -K_1^T \end{array} & 0
\end{array}\right),
$$

where I is $n\times n$ unit matrix, $\Lambda^m=\operatorname{diag}(\lambda_1^m,\lambda_2^m,...,\lambda_n^m)$ where all λ_i are different and $K_m=(\partial h_m/\partial\mu_1,\ldots,\partial h_m/\partial\mu_n,-\partial h_m/\partial\lambda_1,\ldots,-\partial h_m/\partial\lambda_n)^T$ are Hamiltonian vector fields with Hamiltonians h_r (16).

Lemma 4: All functions $h_r(\lambda,\mu,c)$ are in involution with respect to canonical Poisson tensor π_0.

Proof: According to Lemma 1, for a given r, all terms $c_j\beta_{j,r}(\lambda)$ $j=1,...,n$ can be absorbed by f_i $i=1,...,n$ terms of h_r. However, according to the results from Refs. 1 and 2, functions of the form (22) are in involution with respect to π_0. □

Theorem 1: (i) Consider two Poisson tensors $3n\times 3n$ of rank $2n$

$$\pi_0=\left(\begin{array}{cc|c|c|c} 0 & I & 0 & \cdots & 0 \\ -I & 0 & & & \\ \hline \multicolumn{2}{c|}{0} & & & \\ \multicolumn{2}{c|}{\vdots} & & 0 & \\ \multicolumn{2}{c|}{0} & & & \end{array}\right), \tag{25}$$

$$\pi_m=\left(\begin{array}{cc|c|c|c|c|c|c} 0 & \Lambda^m & X_m & \cdots & X_1 & 0 & \cdots & 0 \\ -\Lambda^m & 0 & Y_m & & Y_1 & & & \\ \hline -X_m^T & -Y_m^T & & & & & & \\ \multicolumn{2}{c|}{\vdots} & & & & & & \\ -X_1^T & -Y_1^T & & & 0 & & & \\ \multicolumn{2}{c|}{0} & & & & & & \\ \multicolumn{2}{c|}{\vdots} & & & & & & \\ \multicolumn{2}{c|}{0} & & & & & & \end{array}\right).$$

The compatibility condition between π_0 and π_m is given by

$$\frac{\partial Y_{rj}}{\partial\mu_i}+\frac{\partial X_{ri}}{\partial\lambda_j}=0,\quad i,j=1,...,n,\quad r=1,...,m \tag{26}$$

with admissible solution

$$X_{ri}=\frac{\partial f_r}{\partial\mu_i},\quad Y_{ri}=-\frac{\partial f_r}{\partial\lambda_i},\quad f_r=f_r(\lambda,\mu,c). \tag{27}$$

(ii) Conditions for f_r functions to make π_m Poissonian follow from Jacobi identity and read

$$0=\{\{\lambda_i,\lambda_j\}_{\pi_m},c_k\}_{\pi_m}+\text{c.p.}$$

$$\Updownarrow \tag{28}$$

$$0=(\lambda_j^m-\lambda_i^m)\frac{\partial^2 f_{m+1-k}}{\partial\mu_i\partial\mu_j}+\sum_{r=1}^m\left(\frac{\partial^2 f_{m+1-k}}{\partial\mu_i\partial c_r}\frac{\partial f_{m+1-r}}{\partial\mu_j}-\frac{\partial^2 f_{m+1-k}}{\partial\mu_j\partial c_r}\frac{\partial f_{m+1-r}}{\partial\mu_i}\right),$$

$$0=\{\{\mu_i,\mu_j\}_{\pi_m},c_k\}_{\pi_m}+\text{c.p.}$$

$$\Updownarrow \tag{29}$$

$$0=(\lambda_j^m-\lambda_i^m)\frac{\partial^2 f_{m+1-k}}{\partial\lambda_i\partial\lambda_j}+\sum_{r=1}^{m}\left(\frac{\partial^2 f_{m+1-k}}{\partial\lambda_i\partial c_r}\frac{\partial f_{m+1-r}}{\partial\lambda_j}-\frac{\partial^2 f_{m+1-k}}{\partial\lambda_j\partial c_r}\frac{\partial f_{m+1-r}}{\partial\lambda_i}\right),$$

$$0=\{\{\lambda_i,\mu_j\}_{\pi_m},c_k\}_{\pi_m}+\text{c.p.}$$

$$\Updownarrow \tag{30}$$

$$0=(\lambda_j^m-\lambda_i^m)\frac{\partial^2 f_{m+1-k}}{\partial\mu_i\partial\lambda_j}-m\lambda_j^{m-1}\delta_{ij}\frac{\partial f_{m+1-k}}{\partial\mu_i}$$

$$+\sum_{r=1}^{m}\left(\frac{\partial^2 f_{m+1-k}}{\partial\mu_i\partial c_r}\frac{\partial f_{m+1-r}}{\partial\lambda_j}-\frac{\partial^2 f_{m+1-k}}{\partial\lambda_j\partial c_r}\frac{\partial f_{m+1-r}}{\partial\mu_i}\right),$$

$$0=\{\{c_i,c_j\}_{\pi_m},\lambda_k(\mu_k)\}_{\pi_m}+\text{c.p.}$$

$$\Updownarrow$$

$$0=\frac{\partial}{\partial\mu_k(\lambda_k)}\sum_{l=1}^{m}\left(\frac{\partial f_{m+1-i}}{\partial\lambda_l}\frac{\partial f_{m+1-j}}{\partial\mu_l}-\frac{\partial f_{m+1-i}}{\partial\mu_l}\frac{\partial f_{m+1-j}}{\partial\lambda_l}\right),$$

$$\Updownarrow \tag{31}$$

$$0=\{f_i,f_j\}_{\pi_m},\quad i,j=1,...,m.$$

Lemma 5: Functions $f_r=h_r(\lambda,\mu,c)$ (16) fulfill the conditions of Theorem 1. The proof is given in Appendix D.

Consequently, all matrices (24) are Poissonian and compatible with the canonical one.

Theorem 2: On the extended phase space $M\ni(\lambda_1,\ldots,\lambda_n,\mu_1,\ldots,\mu_n,c_1,\ldots,c_n)$, the functions

$$h_r(\lambda,\mu,c)=-\sum_{i=1}^{n}\frac{\partial\rho_r}{\partial\lambda_i}\frac{f_i(\lambda_i,\mu_i)}{\Delta_i}+\sum_{j=1}^{n}c_j\beta_{j,r}(\lambda),$$

$$h_{1-r}=c_r,\quad r=1,...,n, \tag{32}$$

form $\binom{n+1}{2}$ bi-Hamiltonian chains

$$\begin{array}{l}\pi_i\nabla h_{-i}=0\\ \pi_i\nabla h_{-i+1}=K_1=\pi_k\nabla h_{-k+1}\\ \pi_i\nabla h_{-i+2}=K_2=\pi_k\nabla h_{-k+2}\\ \qquad\vdots\\ \pi_i\nabla h_{-i+j}=K_j=\pi_k\nabla h_{-k+j}\\ \qquad\vdots\\ \pi_i\nabla h_{-i+n}=K_n=\pi_k\nabla h_{-k+n}\\ \qquad 0=\pi_k\nabla h_{-k+n+1}\end{array}\qquad 0\leqslant i<k\leqslant n, \tag{33}$$

with respect to $(n+1)$ Poisson tensors (24).

The proof is given in Appendix E.

From the fact that $h_{n+1}=0$ and the validity of the chain (33) we find that the Poisson structure π_m has the following Casimir functions: $c_{m+1}, c_{m+2}, \ldots, c_n, h_n, \ldots, h_{n-m+1}$.

Lemma 6: Functions $h_r(\lambda,\mu,c)$, $r=1,\ldots,n$ are in involution with respect to an arbitrary Poisson tensor π_k, $k=1,\ldots,n$.

Proof: As all h_r are in involution with respect to π_0 and belong to chains (33), hence

$$\{h_i,h_j\}_{\pi_k}=\langle\nabla h_j,\pi_k\nabla h_i\rangle=\langle\nabla h_j,\pi_0\nabla h_{i+k}\rangle=\{h_{i+k},h_j\}_{\pi_0}=0. \tag{34}$$

□

Now, we integrate equations of motion from the hierarchy (33) solving the Hamilton–Jacobi equation for Hamiltonians (16). According to the Hamilton–Jacobi theory, we look for a canonical transformation $(\lambda,\mu)\rightarrow(b,a)$ in the form $b_i=\partial W/\partial a_i$, $\mu_i=\partial W/\partial\lambda_i$, where $W(\lambda,a)$ is the generating function, satisfying the Hamilton–Jacobi equation

$$h_r\left(\lambda,\frac{\partial W}{\partial\lambda},c\right)=\sum_{k=1}^{n}\frac{\rho_{r-1}^k(\lambda)f_k(\lambda_k,\partial W/\partial\lambda_k)}{\Delta_k}+\sum_{i=1}^{n}c_i\beta_{i,r}(\lambda)=\text{const}_r. \tag{35}$$

Now we demonstrate the separability of Eq. (35). Take the generating $W(\lambda,a)$ function in the form

$$W(\lambda,a)=\sum_{i=1}^{n}W_i(\lambda_i,a), \tag{36}$$

apply the result of Lemma 1 and hence, Eq. (35) turns into the form

$$\sum_{k=1}^{n}\frac{\rho_{r-1}^k(\lambda)[f_k(\lambda_k,\partial W_k/\partial\lambda_k)-\Sigma_{i=1}^n c_i\lambda_k^{n-1+i}]}{\Delta_k}=\text{const}_r. \tag{37}$$

Applying the relation

$$-\sum_{i=1}^{n}\frac{\partial\rho_r}{\partial\lambda_i}\frac{\lambda_i^m}{\Delta_i}=\sum_{i=1}^{n}\frac{\rho_{r-1}^i(\lambda)\lambda_i^m}{\Delta_i}=\begin{Bmatrix}1, & m=n-r\\ 0, & m\neq n-r\end{Bmatrix},\quad r=1,\ldots,n, \tag{38}$$

the solution of Eq. (37) reads

$$f_k(\lambda_k,\partial W_k/\partial\lambda_k)=g(\lambda_k),\quad \text{const}_r=a_{n+1-r}, \tag{39}$$

where

$$g(\xi)=a_1+a_2\xi+\cdots+a_n\xi^{n-1}+c_1\xi^n+\cdots+c_n\xi^{2n-1}. \tag{40}$$

Hence, $W(\lambda,a)$ can be obtained by solving n decouples first-order ODE (39). For example, if

$$f_i(\lambda_i,\mu_i)=\varphi(\lambda_i)f(\mu_i)+\psi(\lambda_i), \tag{41}$$

then we obtain

$$W(\lambda,a)=\sum_{k=1}^{n}\int^{\lambda_k}f^{-1}\left(\frac{g(\xi)-\psi(\xi)}{\varphi(\xi)}\right)d\xi. \tag{42}$$

In new canonical variables a_i, $b_i=\partial W/\partial a_i$, the Hamiltonians $h_r(\lambda,\mu,c)$ become

$$h_r = a_{n+1-r} \tag{43}$$

with

$$b_i = \frac{\partial W}{\partial a_i} = \sum_{k=1}^{n} \int^{\lambda_k} (f^{-1})' \frac{\xi^{i-1}}{\varphi(\xi)} d\xi, \tag{44}$$

where $(f^{-1})'$ means derivative of f^{-1}. As in the new coordinates each h_r generates a trivial flow

$$(a_j)_{t_r} = -\frac{\partial h_r}{\partial b_j} = 0, \quad (b_j)_{t_r} = \frac{\partial h_r}{\partial a_j} = \delta_{j,n+1-r}, \quad (c_j)_{t_r} = 0, \tag{45}$$

hence

$$b_i = t_{n+1-i} + \text{const.} \tag{46}$$

Combining (44) with (46) we arrive at implicit solutions for the trajectories $\lambda_i(t_k)$, with respect to the evolution parameter t_k in the form

$$\sum_{k=1}^{n} \int^{\lambda_k} (f^{-1})' \frac{\xi^{i}}{\varphi(\xi)} d\xi = \delta_{i,n-k} t_k + \text{const}, \quad i = 0,...,n-1. \tag{47}$$

IV. MULTI-HAMILTONIAN CHAINS IN ARBITRARY CANONICAL COORDINATES AND THEIR TRANSFORMATION TO DARBOUX–NIJENHUIS REPRESENTATION

Let us introduce arbitrary coordinates (q,p,c) related to the Darboux–Nijenhuis coordinates (λ,μ,c) by a point transformation

$$q_k = \zeta_k(\lambda), \quad k = 1,...,n, \tag{48}$$

which is canonical, i.e., coming from the generating function $S = \Sigma_{i=1}^{n} p_i \zeta_k(\lambda)$. Then

$$q_i = \frac{\partial S}{\partial p_i}, \quad \mu_i = \frac{\partial S}{\partial \lambda_i}, \tag{49}$$

so the first equation reconstructs $q_i = \zeta_k(\lambda)$ and solving the second one with respect to p_k we get the missing part of the canonical transformation

$$p_k = \eta_k(\lambda,\mu). \tag{50}$$

Applying the inverse of the transformation (48), (50) to Hamiltonian functions (16) and Poisson matrices (24) one finds that

$$h_r(q,p,c) = h_r(q,p) + \sum_{i=1}^{n} c_i b_{i,r}(q) \tag{51}$$

and the nondegenerated part θ_m of rank $2n$ of each π_m (also implectic)

$$\theta_m = N^m \circ \theta_0 = \begin{pmatrix} 0 & \Lambda^m \\ -\Lambda^m & 0 \end{pmatrix} \tag{52}$$

takes now the form

$$\theta_m = N^m \circ \theta_0 = \begin{pmatrix} 0 & A_m(q) \\ -A_m^T(q) & B_m(q,p) \end{pmatrix}, \quad m=1,...,n, \tag{53}$$

where matrix elements $(B_m)_{ij}$ are at most linear in p coordinates.

Conversely, if we have a multi-Hamiltonian chain in (q,p,c) coordinates, and the set of equations

$$\beta_{1,r}(\lambda) \equiv \rho_r(\lambda) = b_{1,r}(q), \quad r=1,...,n \tag{54}$$

has the solution $\lambda_i = \lambda_i(q)$, $\quad i=1,...,n$ such that $\lambda_i(q) \neq \lambda_j(q)$ for $i \neq j$, which is equivalent to the statement that the Nijenhuis (but not recursion) tensor

$$N(q,p) = \begin{pmatrix} 0 & A_1(q) \\ -A_1^T(q) & B_1(q,p) \end{pmatrix} \cdot \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}^{-1} = \begin{pmatrix} A_1(q) & 0 \\ B_1(q,p) & A_1^T(q) \end{pmatrix} \tag{55}$$

is nondegenerated and has n distinct eigenvalues λ_i each with multiplicity 2, then the canonical transformation (48)–(50) transforms a given chain to the one considered in the preceding section.

The admissible reductions of the number of Casimir variables are the following. For arbitrary $1 \leqslant m < n$, let $c_i \neq 0$, $1 \leqslant i \leqslant m$ and $c_i = 0$ for $m < i \leqslant n$. The first m Poisson structures π_i, $i \leqslant m$ survey the projection $(\lambda,\mu,c_1,\ldots,c_n) \in M \to \bar{M} \ni (\lambda,\mu,c_1,\ldots,c_m)$ and we have still $\binom{m+1}{2}$ bi-Hamiltonian chains (33).

Remark: In the limit $c_1 = \cdots = c_n = 0$, the systems considered lose the bi-Hamiltonian property, turning into the so-called quasi-bi-Hamiltonian systems[1–3,6,7] on a symplectic manifold $M \ni (q,p)$, being still separable and integrable by quadratures. Moreover, because of the property (22), each of the multi-Hamiltonian systems considered on a Poisson manifold $M \ni (q,p,c)$ has a quasi-bi-Hamiltonian representation on a symplectic manifold $M \ni (q,p)$.

V. EXAMPLES

The theory developed in the preceding sections will be illustrated by several representative examples of already known as well as new multi-Hamiltonian systems.

Example 1: Stationary t_2—flow of dispersive water waves.[8]

The Hamiltonian functions and Poisson structures in Ostrogradsky variables are as follows:

$$h_1(q,p,c) = -4p_1p_2 + 5q_2p_1^2 - \tfrac{5}{8}q_1q_2^3 - \tfrac{3}{4}q_1^2q_2 - \tfrac{7}{64}q_2^5 + \tfrac{1}{2}q_2c_1 + (\tfrac{1}{2}q_1 + \tfrac{1}{8}q_2^2)c_2,$$

$$h_2(q,p,c) = q_1p_1^2 + 4q_2p_1p_2 - \tfrac{5}{4}q_2^2p_1^2 - 2p_2^2 + \tfrac{5}{64}q_1q_2^4 - \tfrac{3}{16}q_1^2q_2^2 - \tfrac{1}{4}q_1^3 + \frac{45}{6\times 128}q_2^6$$
$$+ (\tfrac{1}{2}q_1 + \tfrac{3}{8}q_2^2)c_1 - (\tfrac{1}{4}q_1q_2 - \tfrac{3}{16}q_2^3)c_2,$$

$$\pi_0 = \left(\begin{array}{cccc|cc} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$\pi_1=\left(\begin{array}{cccc|cc} 0 & 0 & -\frac{3}{2}q_2 & -\frac{1}{2}q_1-\frac{15}{8}q_2^2 & \frac{\partial h_1}{\partial p_1} & 0 \\ 0 & 0 & 1 & q_2 & \frac{\partial h_1}{\partial p_2} & 0 \\ \frac{3}{2}q_2 & -1 & 0 & -p_1 & -\frac{\partial h_1}{\partial q_1} & 0 \\ \frac{1}{2}q_1+\frac{15}{8}q_2^2 & -q_2 & p_1 & 0 & -\frac{\partial h_1}{\partial q_2} & 0 \\ \hline -\frac{\partial h_1}{\partial p_1} & -\frac{\partial h_1}{\partial p_2} & \frac{\partial h_1}{\partial q_1} & \frac{\partial h_1}{\partial q_2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$\pi_2=\left(\begin{array}{cccc|cc} 0 & 0 & \frac{3}{8}q_2^2-\frac{1}{2}q_1 & -\frac{1}{4}q_1q_2-\frac{15}{16}q_2^3 & \frac{\partial h_2}{\partial p_1} & \frac{\partial h_1}{\partial p_1} \\ 0 & 0 & -\frac{1}{2}q_2 & -\frac{1}{2}q_1-\frac{7}{8}q_2^2 & \frac{\partial h_2}{\partial p_2} & \frac{\partial h_1}{\partial p_2} \\ -\frac{3}{8}q_2^2+\frac{1}{2}q_1 & \frac{1}{2}q_2 & 0 & \frac{1}{2}q_2p_1 & -\frac{\partial h_2}{\partial q_1} & -\frac{\partial h_1}{\partial q_1} \\ \frac{1}{4}q_1q_2+\frac{15}{16}q_2^3 & \frac{1}{2}q_1+\frac{7}{8}q_2^2 & -\frac{1}{2}q_2p_1 & 0 & -\frac{\partial h_2}{\partial q_2} & -\frac{\partial h_1}{\partial q_2} \\ \hline -\frac{\partial h_2}{\partial p_1} & -\frac{\partial h_2}{\partial p_2} & \frac{\partial h_2}{\partial q_1} & \frac{\partial h_2}{\partial q_2} & 0 & 0 \\ -\frac{\partial h_1}{\partial p_1} & -\frac{\partial h_1}{\partial p_2} & \frac{\partial h_1}{\partial q_1} & \frac{\partial h_1}{\partial q_2} & 0 & 0 \end{array}\right).$$

Hence, we have three bi-Hamiltonian chains (33)

$$\pi_0\nabla c_1=0 \qquad \pi_0\nabla c_1=0$$

$$\pi_0\nabla h_1=K_1=\pi_1\nabla c_1 \qquad \pi_0\nabla h_1=K_1=\pi_2\nabla c_2$$

$$\pi_0\nabla h_2=K_2=\pi_1\nabla h_1\pi_0 \qquad \nabla h_2=K_2=\pi_2\nabla c_1$$

$$0=\pi_1\nabla h_2, \qquad\qquad 0=\pi_2\nabla h_1,$$

$$\pi_1\nabla c_2=0$$

$$\pi_1\nabla c_1=K_1=\pi_2\nabla c_2$$

$$\pi_1\nabla h_1=K_2=\pi_2\nabla c_1$$

$$0=\pi_2\nabla h_1.$$

The canonical transformation to the Darboux–Nijenhuis coordinates reads

$$q_1=-(3\lambda_1^2+3\lambda_2^2+4\lambda_1\lambda_2),$$

$$q_2=-2(\lambda_1+\lambda_2),$$

$$p_1=\frac{1}{2}\,\frac{\mu_2-\mu_1}{\lambda_1-\lambda_2},$$

$$p_2=-\frac{1}{2}\,\frac{\lambda_1(3\mu_2-2\mu_1)-\lambda_2(3\mu_1-2\mu_2)}{\lambda_1-\lambda_2},$$

where now h_r, $r=1,2$ take the form (16) with

$$f_i(\lambda_i,\mu_i)=2\lambda_i^6-\tfrac{1}{2}\mu_i^2.$$

Example 2: The first two-Casimir extension of the Henon–Heiles system.

In Ref. 1 the first one-Casimir extension of the Henon–Heiles system was considered in the form

$$(q_1)_{tt}=-3q_1^2-\tfrac{1}{2}q_2^2+c,\quad (q_2)_{tt}=-q_1q_2,$$

with two constants of the motion

$$h_1=H=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+q_1^3+\tfrac{1}{2}q_1q_2^2-cq_1,$$

$$h_2=\tfrac{1}{2}q_2p_1p_2-\tfrac{1}{2}q_1p_2^2+\tfrac{1}{16}q_2^4+\tfrac{1}{4}q_1^2q_2^2-\tfrac{1}{4}q_2^2c.$$

The transformation to Darboux–Nijenhuis coordinates was found in the form

$$q_1=\lambda_1+\lambda_2,\quad p_1=\frac{\lambda_1\mu_1}{\lambda_1-\lambda_2}+\frac{\lambda_2\mu_2}{\lambda_2-\lambda_1},$$

$$q_2=2\sqrt{-\lambda_1\lambda_2},\quad p_2=\sqrt{-\lambda_1\lambda_2}\left(\frac{\mu_1}{\lambda_1-\lambda_2}+\frac{\mu_2}{\lambda_2-\lambda_1}\right),$$

$$f_i(\lambda_i,\mu_i)=\lambda_i^4+\tfrac{1}{2}\lambda_i\mu_i^2. \tag{56}$$

For a two-Casimir extension we get immediately

$$\beta_{2,1}=-[(\lambda_1+\lambda_2)^2-\lambda_1\lambda_2]=-(q_1^2+\tfrac{1}{4}q_2^2),$$

$$\beta_{2,2}=\lambda_1\lambda_2(\lambda_1+\lambda_2)=-\tfrac{1}{4}q_1q_2^2,$$

hence, new constants of the motion read

$$h_1=H=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+q_1^3+\tfrac{1}{2}q_1q_2^2-c_1q_1-(q_1^2+\tfrac{1}{4}q_2^2)c_2,$$

$$h_2=\tfrac{1}{2}q_2p_1p_2-\tfrac{1}{2}q_1p_2^2+\tfrac{1}{16}q_2^4+\tfrac{1}{4}q_1^2q_2^2-\tfrac{1}{4}q_2^2c_1-\tfrac{1}{4}q_1qc_2,$$

where the Newton equations related to the energy H are

$$(q_1)_{tt}=-3q_1^2-\tfrac{1}{2}q_2^2+c_1+2q_1c_2,\quad (q_2)_{tt}=-q_1q_2+\tfrac{1}{2}q_2c_2.$$

This is tri-Hamiltonian system with the following Poisson structures

$$\pi_0=\left(\begin{array}{cccc|cc} 0 & 0 & 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0 & 0\\ -1 & 0 & 0 & 0 & 0 & 0\\ 0 & -1 & 0 & 0 & 0 & 0\\ \hline 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$\pi_1=\left(\begin{array}{cccc|cc} 0 & 0 & q_1 & \frac{1}{2}q_2 & \frac{\partial h_1}{\partial p_1} & 0\\ 0 & 0 & \frac{1}{2}q_2 & 0 & \frac{\partial h_1}{\partial p_2} & 0\\ -q_1 & -\frac{1}{2}q_2 & 0 & \frac{1}{2}p_2 & -\frac{\partial h_1}{\partial q_1} & 0\\ -\frac{1}{2}q_2 & 0 & -\frac{1}{2}p_2 & 0 & -\frac{\partial h_1}{\partial q_2} & 0\\ \hline -\frac{\partial h_1}{\partial p_1} & -\frac{\partial h_1}{\partial p_2} & \frac{\partial h_1}{\partial q_1} & \frac{\partial h_1}{\partial q_2} & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$\pi_2=\left(\begin{array}{cccc|cc} 0 & 0 & q_1^2+\frac{1}{4}q_2^2 & \frac{1}{2}q_1q_2 & \frac{\partial h_2}{\partial p_1} & \frac{\partial h_1}{\partial p_1}\\ 0 & 0 & \frac{1}{2}q_1q_2 & \frac{1}{4}q_2^2 & \frac{\partial h_2}{\partial p_2} & \frac{\partial h_1}{\partial p_2}\\ -q_1^2-\frac{1}{4}q_2^2 & -\frac{1}{2}q_1q_2 & 0 & \frac{1}{2}q_1p_2 & -\frac{\partial h_2}{\partial q_1} & -\frac{\partial h_1}{\partial q_1}\\ -\frac{1}{2}q_1q_2 & -\frac{1}{4}q_2^2 & -\frac{1}{2}q_1p_2 & 0 & -\frac{\partial h_2}{\partial q_2} & -\frac{\partial h_1}{\partial q_2}\\ \hline -\frac{\partial h_2}{\partial p_1} & -\frac{\partial h_2}{\partial p_2} & \frac{\partial h_2}{\partial q_1} & \frac{\partial h_2}{\partial q_2} & 0 & 0\\ -\frac{\partial h_1}{\partial p_1} & -\frac{\partial h_1}{\partial p_2} & \frac{\partial h_1}{\partial q_1} & \frac{\partial h_1}{\partial q_2} & 0 & 0 \end{array}\right).$$

The first two of them come from one-Casimir extension and the last one was constructed according to formula (53). Notice that again we have three bi-Hamiltonian chains (33).

Example 3: The second two-Casimir extension of the Henon–Heiles system.

In Ref. 1 the second one-Casimir extension of the Henon–Heiles system was considered in the form

$$(q_1)_{tt}=-3q_1^2-\frac{1}{2}q_2^2,\quad (q_2)_{tt}=-q_1q_2+\frac{c}{q_2^3},$$

with two constants of motion

$$\overline{h_1}=-2q_2p_1p_2+2q_1p_2^2-\frac{1}{4}q_2^4-q_1^2q_2^2+\frac{2q_1}{q_2^2}c,$$

$$\overline{h_2}=-2H=-p_1^2-p_2^2-2q_1^3-q_1q_2^2-\frac{1}{q_2^2}c.$$

Moreover, a transformation to the inverse Darboux–Nijenhuis coordinates was found. Nevertheless, according to the result of Ref. 3, the admissible transformation to the Darboux–Nijenhuis coordinates reads

$$q_1=\frac{1}{2}\left(\frac{1}{\lambda_1}+\frac{1}{\lambda_2}\right),\quad p_1=2\lambda_1\lambda_2\left(\frac{\lambda_1\mu_1}{\lambda_1-\lambda_2}+\frac{\lambda_2\mu_2}{\lambda_2-\lambda_1}\right),$$

$$q_2=\frac{1}{\sqrt{-\lambda_1\lambda_2}},\quad p_2=-2\sqrt{-\lambda_1\lambda_2}\left(\frac{\lambda_1^2\mu_1}{\lambda_1-\lambda_2}+\frac{\lambda_2^2\mu_2}{\lambda_2-\lambda_1}\right),$$

$$f_i(\lambda_i,\mu_i)=\frac{1}{4}\lambda_i^{-3}+4\lambda_i^4\mu_i^2.$$

The two-Casimir extension we get by adding new terms to the constants of motion

$$h_1(q,p,c_1,c_2)=\overline{h_1}(q,p,c=c_1)+b_{2,1}(q)c_2=\overline{h_1}(q,p,c_1)-\left(\frac{4q_1^2}{q_2^4}+\frac{1}{q_2^2}\right)c_2,$$

$$h_2(q,p,c_1,c_2)=\overline{h_2}(q,p,c=c_1)+b_{2,2}(q)c_2=\overline{h_2}(q,p,c_1)+\frac{2q_1}{q_2^4}c_2,$$

where the Newton equations related to the energy $H=-1/2h_2$ are

$$(q_1)_{tt}=-3q_1^2-\frac{1}{2}q_2^2-\frac{1}{q_2^4}c_2,\quad (q_2)_{tt}=-q_1q_2+\frac{c_1}{q_2^3}-\frac{4q_1}{q_2^5}c_2.$$

Again this is tri-Hamiltonian system, where the first two Poisson structures are given in Ref. 1 (with additional last row and column with zeros), while the new third Poisson structure reads

$$\pi_2=\left(\begin{array}{cccc|cc}
0 & 0 & \frac{1}{q_2^2} & -\frac{2q_1}{q_2^3} & \frac{\partial h_2}{\partial p_1} & \frac{\partial h_1}{\partial p_1}\\
0 & 0 & -\frac{2q_1}{q_2^3} & \frac{4q_1^2+q_2^2}{q_2^4} & \frac{\partial h_2}{\partial p_2} & \frac{\partial h_1}{\partial p_2}\\
-\frac{1}{q_2^2} & \frac{2q_1}{q_2^3} & 0 & -\frac{2q_1p_2}{q_2^4} & -\frac{\partial h_2}{\partial q_1} & -\frac{\partial h_1}{\partial q_1}\\
\frac{2q_1}{q_2^3} & -\frac{4q_1^2+q_2^2}{q_2^4} & \frac{2q_1p_2}{q_2^4} & 0 & -\frac{\partial h_2}{\partial q_2} & -\frac{\partial h_1}{\partial q_2}\\
\hline
-\frac{\partial h_2}{\partial p_1} & -\frac{\partial h_2}{\partial p_2} & \frac{\partial h_2}{\partial q_1} & \frac{\partial h_2}{\partial q_2} & 0 & 0\\
-\frac{\partial h_1}{\partial p_1} & -\frac{\partial h_1}{\partial p_2} & \frac{\partial h_1}{\partial q_1} & \frac{\partial h_1}{\partial q_2} & 0 & 0

Example 4: m-Casimir extension of the relativistic *n*-body problem.

Consider the Hamiltonian dynamical system with the Hamiltonian given by

$$H=\sum_{i=1}^{n}\frac{\varphi_i(\lambda_i)}{\Delta_i}e^{a\mu_i}, \tag{57}$$

where φ_i are arbitrary smooth functions and a is an arbitrary constant. The corresponding dynamical system takes the Newtonian form

$$(\lambda_i)_{tt}=2\sum_{k\neq i}\frac{(\lambda_i)_t(\lambda_k)_t}{\lambda_i-\lambda_k}, \quad i=1,...,n, \tag{58}$$

which depends explicitly on velocities. The derivative of the formula (58) is given in Appendix F. Notice that Eqs. (58) do not depend on φ_i functions, hence the dynamics is not influenced by φ_i terms.

Newtonian dynamics (58) is a special case of the integrable relativistic n-body problems introduced by Ruijsenaars and Schneider.[9] Now, comparing (57) with (22) one immediately concludes that (λ,μ) is a Darboux–Nijenhuis chart for the Hamiltonian H, and as a consequence, system (58) is quasi-bi-Hamiltonian and separable, with solution given by the implicit formulas (47)

$$\frac{1}{a}\sum_{k=1}^{n}\int^{\lambda_k}\frac{\xi^i}{g(\xi)}d\xi=\delta_{i,n-1}t+\text{const}, \quad i=0,...,n-1, \tag{59}$$

where $g(\xi)=a_1+a_2\xi+\cdots+a_n\xi^{n-1}$. This fact was noticed for the first time by Morosi and Tondo.[10] Notice, that trajectories $\lambda_i(t)$ do not depend on the $\varphi_i(\lambda_i)$ factors, as expected, so without a loss of generality one can put $\varphi_i(\lambda_i)=1$.

The system (58) can be naturally extended to an m-Casimir one with the Hamiltonian

$$H=\sum_{i=1}^{n}\frac{\varphi_i(\lambda_i)}{\Delta_i}e^{a\mu_i}+\sum_{j=1}^{m}c_j\beta_{j,1}(\lambda), \quad 1\leqslant m\leqslant n \tag{60}$$

and the related Newton equations of motion

$$(\lambda_i)_{tt}=2\sum_{k\neq i}\frac{(\lambda_i)_t(\lambda_k)_t}{\lambda_i-\lambda_k}-a\sum_{j=1}^{m}c_j\frac{\partial\beta_{j,1}}{\partial\lambda_i}(\lambda_i)_t. \tag{61}$$

The dynamical system (61) has n constants of motion

$$h_r(\lambda,\mu,c)=-\sum_{i=1}^{n}\frac{\partial\rho_r(\lambda)}{\partial\lambda_i}\frac{e^{a\mu_i}}{\Delta_i}+\sum_{j=1}^{m}c_j\beta_{j,r}(\lambda), \quad r=1,...,n,$$

$(m+1)$ Poisson structures (24) and the solution given by implicit formula (59), where now

$$g(\xi)=a_1+a_2\xi+\cdots+a_n\xi^{n-1}+c_1\xi^n+\cdots+c_m\xi^{n+m-1}.$$

The one-Casimir extension, which is bi-Hamiltonian, has the following Newton equations of motion:

$$(\lambda_i)_{tt}=2\sum_{k\neq i}\frac{(\lambda_i)_t(\lambda_k)_t}{\lambda_i-\lambda_k}+ac(\lambda_i)_t, \quad i=1,...,n.$$

The two-Casimir extension, which is tri-Hamiltonian, has the Newton equations in the form

$$(\lambda_i)_{tt}=2\sum_{k\neq i}\frac{(\lambda_i)_t(\lambda_k)_t}{\lambda_i-\lambda_k}+ac_1(\lambda_i)_t+ac_2\left(\lambda_i+\sum_{k=1}^{n}\lambda_k\right)(\lambda_i)_t, \quad i=1,...,n.$$

Example 5: $(m+1)$-Hamiltonian formulation for elliptic separable potentials.

In Ref. 11 a theorem has been proved which says that every natural Hamiltonian system

$$H(q,p,c)=\tfrac{1}{2}(p,p)+V(q)+\tfrac{1}{2}c(q,q) \tag{62}$$

separable in generalized elliptic coordinates, in the extended phase space of variables (q,p,c), where $p=(q_1,\dots,q_n)^T$, $p=(p_1,\dots,p_n)^T$ and c is additional Casimir variable, admits the bi-Hamiltonian formulation

$$\begin{pmatrix} q \\ p \\ c \end{pmatrix}_t = \pi_0 \nabla h_1 = \pi_1 \nabla h_0,$$

where

$$\pi_0 = \left(\begin{array}{cc|c} 0 & I & 0 \\ -I & 0 & 0 \\ \hline 0 & 0 & 0 \end{array}\right), \tag{63}$$

$$\pi_1 = \left(\begin{array}{cc|c} 0 & A-\tfrac{1}{2}q\otimes q & \partial h_1/\partial p \\ -A+\tfrac{1}{2}q\otimes q & \tfrac{1}{2}p\otimes q - \tfrac{1}{2}q\otimes p & -\partial h_1/\partial q \\ \hline -(\partial h_1/\partial p)^T & (\partial h_1/\partial q)^T & 0 \end{array}\right),$$

$A=\mathrm{diag}(\alpha_1,\dots,\alpha_n)$, α_i are different positive constants, $h_0=c$, $h_1=H-c\Sigma_i\alpha_i$, $(.,.)$ stands for the scalar product and $\otimes-$ the respective tensor product. The potential $V(q)$ satisfies the equations

$$0=(\alpha_i-\alpha_k)\frac{\partial^2 V}{\partial q_i \partial q_k}+\frac{3}{2}\left(q_k\frac{\partial V}{\partial q_i}-q_i\frac{\partial V}{\partial q_k}\right)+\frac{1}{2}\sum_{j=1}^{n}\left(q_j q_k\frac{\partial^2 V}{\partial q_i\partial q_j}-q_i q_j\frac{\partial^2 V}{\partial q_j \partial q_k}\right), \tag{64}$$

$i,k=1,\dots,n$, which are the iff conditions for π_1 to fulfill the Jacobi identity. This bi-Hamiltonian formulation generates the chain of commuting bi-Hamiltonian vector fields

$$\pi_0\nabla h_0=0, \quad \pi_0\nabla h_1=\pi_1\nabla h_0,\dots, \quad \pi_0\nabla h_n=\pi_1\nabla h_{n-1}, \quad 0=\pi_1\nabla h_n, \tag{65}$$

starting with the Casimir h_0 of π_0 and terminating with the Casimir h_n of π_1, where

$$h_r=\sum_{k=0}^{r}\rho_k(\alpha)\overline{h}_{r-k}, \quad \overline{h}_r=\frac{1}{2}\sum_{i=1}^{n}\alpha_i^{r-1}K_i+\frac{1}{2}c(q,A^{r-1}q),$$

$$K_i=\sum_{j\neq i}\frac{q_i p_j-q_j p_i}{\alpha_i-\alpha_j}+p_i^2+V_i(q), \tag{66}$$

$\rho_k(\alpha)$ are Viete polynomials of α_i, $V_i(q)$ are functions of q such that $\Sigma_i V_i(q)=V(q)$ and the Poisson brackets $\{H,K_i\}_{\pi_0}=0$, $i=1,\dots,n$.

Then, in Refs. 1 and 3 the inverse statement was proved, i.e., every natural Hamiltonian system (62) admitting the bi-Hamiltonian formulation (63)–(66) is separable in the generalized elliptic coordinates, which are just the Darboux–Nijenhuis coordinates $\lambda_1,\dots,\lambda_n$.

Now, according to the theory presented, let us generalize the Hamiltonian system (62) to the form

$$H(q,p,c)=\frac{1}{2}(p,p)+V(q)+\sum_{k=1}^{m}c_k b_{k,1}(q), \quad m=1,\dots,n \tag{67}$$

being multi-Hamiltonian and separable. The few first $b_{k,1}(q)$ functions are the following:

$$b_{1,1}(q)=\tfrac{1}{2}(q,q),$$

$$b_{2,1}(q)=\tfrac{1}{2}(q,Aq)-\tfrac{1}{4}(q,q)^2,$$

$$b_{3,1}(q)=\tfrac{1}{2}(q,q)(q,Aq)-\tfrac{1}{2}(q,A^2q)-\tfrac{1}{8}(q,q)^3,\ldots \tag{68}$$

being particular solutions of Eq. (64).

For example, the three Poisson structures of the system (67) with two Casimirs read

$$\pi_0=\left(\begin{array}{cc|cc} 0 & I & 0 & 0\\ -I & 0 & 0 & 0\\ \hline 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\end{array}\right),$$

$$\pi_1=\left(\begin{array}{cc|cc} 0 & A-\tfrac{1}{2}q\otimes q & \partial h_1/\partial p & 0\\ -A+\tfrac{1}{2}q\otimes q & \tfrac{1}{2}p\otimes q-\tfrac{1}{2}q\otimes p & -\partial h_1/\partial q & 0\\ \hline -(\partial h_1/\partial p)^T & (\partial h_1/\partial q)^T & 0 & 0\\ 0 & 0 & 0 & 0\end{array}\right),$$

$$\pi_2=\left(\begin{array}{cc|cc} 0 & (A-\tfrac{1}{2}q\otimes q)^2 & \partial h_2/\partial p & \partial h_1/\partial p\\ -(A-\tfrac{1}{2}q\otimes q)^2 & \begin{array}{c}(A-\tfrac{1}{2}q\otimes q)(\tfrac{1}{2}p\otimes q-\tfrac{1}{2}q\otimes p)\\ +(\tfrac{1}{2}p\otimes q-\tfrac{1}{2}q\otimes p)(A-\tfrac{1}{2}q\otimes q)\end{array} & -\partial h_2/\partial q & -\partial h_1/\partial q\\ \hline -(\partial h_2/\partial p)^T & (\partial h_2/\partial q)^T & 0 & 0\\ -(\partial h_1/\partial p)^T & (\partial h_1/\partial q)^T & 0 & 0\end{array}\right).$$

The functions $h_r(q,p,c)$, forming three admissible bi-Hamiltonian chains, are given by formulas (66), where now

$$\overline{h_r}=\frac{1}{2}\sum_{i=1}^{n}\alpha_i^{r-1}K_i+c_1b_{1,r}(q)+c_2b_{2,r}(q).$$

VI. SUMMARY AND FINAL COMMENTS

In this paper we have discussed the separability theory of multi-Hamiltonian systems in the case when each Poisson structure has more then one Casimir. In fact, we started from the system written in separated coordinates $(\mu_i,\lambda_i)_{i=1}^n$. Such a system can be represented by n-point dynamics on some curve. Actually, let us consider a curve in (λ,μ) plane, in the particular form

$$f(\lambda,\mu)=h_\lambda,\quad h_\lambda=c\lambda^n+h_1\lambda^{n-1}+\cdots+h_n, \tag{69}$$

where $f(\lambda,\mu)$ is an arbitrary smooth function. Then, let us take n different points (μ_i,λ_i) from the curve:

$$f(\lambda_i,\mu_i)=c\lambda_i^n+h_1\lambda_i^{n-1}+\cdots+h_n,\quad i=1,\ldots,n, \tag{70}$$

which will define our separated coordinates. The explicit dependence of h_k on $(\mu_i,\lambda_i,c)_{i=1}^n$ is given by the solution of n linear equations (70), while for fixed values of $h_k=a_{n+1-k}$ and $\mu_i=\partial W_i/\partial\lambda_i$ the system (70) allows us to solve the appropriate Hamilton–Jacobi equations.

In previous papers[1–3] the bi-Hamiltonian chain was constructed for a *separation curve* in the form (69). In this paper multi-Hamiltonian chains was constructed for a separation curve in the form

$$f(\lambda,\mu)=c_n\lambda^{2n-1}+\cdots+c_1\lambda^n+h_1\lambda^{n-1}+\cdots+h_n. \tag{71}$$

Here we have to mension that the idea to relate of multi-Hamiltonian property with an m-parameter family of curves comes from Vanhaecke.[12]

While in the case of one Casimir the admissible form of a separation curve for which one can construct a Poisson pencil is rather restrictive, in multi-Casimir case the freedom of the choice is much bigger. Here we consider the simplest multi-Casimir extension leading to unsplit chains, like in the one-Casimir case. Choosing other admissible forms of the separation curve with more then one Casimir, one can construct split bi(multi)-Hamiltonian chain, i.e., the chain which splits onto few bi(multi)-Hamiltonian sub-chains, each starting and terminating with some Casimir of the appropriate Poisson structure. The work is still in progress and the results will be published in a separate paper.

The structure of degenerated Poisson pencils π_λ expressed in separated coordinates $(\mu_i,\lambda_i)_{i=1}^n$ is particularly clear, i.e., rows and columns related with Casimir variables are appropriate vector fields from the chain. Hence, the reduction of the pencil onto a symplectic leaf of π_0 (fixing the values of all c_i) is immediate as obviously $\theta_\lambda=\theta_1-\lambda\theta_0$, where

$$\theta_0=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad \theta_1=\begin{pmatrix} 0 & \Lambda \\ -\Lambda & 0 \end{pmatrix}, \tag{72}$$

is a nondegenerated Poisson pencil. Hence, the Marsden–Ratiu bi-Hamiltonian reduction[13,14] of the pair π_0, π_1 is trivial in separated coordinates.

Now, let us consider an arbitrary canonical transformation

$$(q,p)\to(\lambda,\mu)$$

independent of Casimir coordinates. The advantage of staying inside such class of transformations is that the clear structure of the pencil is preserved and the Marsden–Ratiu reduction of the Poisson pencil is still trivial. Of course the most general case of multi-Hamiltonian separability theory takes place when one goes beyond the set of canonical coordinates. But then the simple structure of degenerated Poisson pencil is lost and the nontrivial problem of the Marsden–Ratiu reduction for such pencil appears.

Although for all examples from previous section the related Nijenhuis tensor N takes the form (55), i.e., is diagonalizable by an appropriate point transformation, nevertheless, also the more general case, when a diagonalizing transformation is of nonpoint nature, is also admissible. One of the systematic method of construction of separated coordinates in such a case leads through the so-called Hankel–Fröbenius coordinates. Some details the reader can find in Ref. 5.

Concluding, it seems that the developing nowadays multi-Hamiltonian separability theory, which bases on a Poisson pencil and separation curve, is enough general and efficient to be considered as an alternative to the well-known Sklyanin one,[15] bases on Lax operator and a spectral curve.

APPENDIX A

$$n=2$$

$$\beta_{1,1}=-\lambda_1-\lambda_2, \quad \beta_{2,1}=-\lambda_1^2-\lambda_2^2-\lambda_1\lambda_2,$$

$$\beta_{1,2}=\lambda_1\lambda_2, \quad \beta_{2,2}=\lambda_1\lambda_2(\lambda_1+\lambda_2),$$

$$n=3$$

$$\beta_{1,1}=-\lambda_1-\lambda_2-\lambda_3,$$

$$\beta_{1,2}=\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3,$$

$$\beta_{1,3}=-\lambda_1\lambda_2\lambda_3,$$

$$\beta_{2,1}=-\lambda_1^2-\lambda_2^2-\lambda_3^2-\lambda_1\lambda_2-\lambda_1\lambda_3-\lambda_2\lambda_3,$$

$$\beta_{2,2}=2\lambda_1\lambda_2\lambda_3+\lambda_1\lambda_2(\lambda_1+\lambda_2)+\lambda_1\lambda_3(\lambda_1+\lambda_3)+\lambda_2\lambda_3(\lambda_2+\lambda_3),$$

$$\beta_{2,3}=-\lambda_1\lambda_2\lambda_3(\lambda_1+\lambda_2+\lambda_3),$$

$$\beta_{3,1}=-\lambda_1^3-\lambda_2^3-\lambda_3^3-\lambda_1\lambda_2(\lambda_1+\lambda_2)-\lambda_1\lambda_3(\lambda_1+\lambda_3)-\lambda_2\lambda_3(\lambda_2+\lambda_3)-\lambda_1\lambda_2\lambda_3,$$

$$\beta_{3,2}=\lambda_1\lambda_2(\lambda_1^2+\lambda_1\lambda_2+\lambda_2^2)+\lambda_1\lambda_3(\lambda_1^2+\lambda_1\lambda_3+\lambda_3^2)$$
$$+\lambda_2\lambda_3(\lambda_2^2+\lambda_2\lambda_3+\lambda_3^2)+2\lambda_1\lambda_2\lambda_3(\lambda_1+\lambda_2+\lambda_3),$$

$$\beta_{3,3}=-\lambda_1\lambda_2\lambda_3(\lambda_1^2+\lambda_2^2+\lambda_3^2+\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3).$$

APPENDIX B: THE PROOF OF LEMMA 1

(i) The proof is inductive. As

$$\beta_{1,r}(\lambda)\equiv\rho_r(\lambda)=-\sum_{i=1}^{n}\frac{\rho_{r-1}^i\lambda_i^n}{\Delta_i},$$

then

$$\begin{aligned}\beta_{k+1,r}(\lambda)&=\beta_{k,r+1}-\beta_{k,1}\cdot\beta_{1,r}\\&=-\sum_{i=1}^{n}\left[\frac{\rho_r^i\lambda_i^{n+k-1}}{\Delta_i}-\frac{\rho_r\lambda_i^{n+k-1}}{\Delta_i}\right]\\&=-\sum_{i=1}^{n}\left[\frac{(\rho_r+\lambda_i\rho_{r-1}^i)\lambda_i^{n+k-1}}{\Delta_i}-\frac{\rho_r\lambda_i^{n+k-1}}{\Delta_i}\right]\\&=-\sum_{i=1}^{n}\frac{\rho_{r-1}^i\lambda_i^{n+k}}{\Delta_i},\end{aligned}$$

where we used the relation $\lambda_i\rho_{r-1}^i=-\rho_r+\rho_r^i$. □

(ii)

$$\begin{aligned}\frac{\partial\beta_{r,k+1}}{\partial\lambda_i}&=-\frac{\partial}{\partial\lambda_i}\sum_{l=1}^{n}\frac{\rho_k^l\lambda_l^{n+r-1}}{\Delta_l}\\&=-\rho_k^i\frac{\partial}{\partial\lambda_i}\frac{\lambda_i^{n+r-1}}{\Delta_i}-\sum_{l\neq i}\lambda_l^{n+r-1}\frac{\partial}{\partial\lambda_i}\frac{\rho_k^l}{\Delta_l}\\&=-\rho_k^i(n+r-1)\frac{\lambda_i^{n+r-2}}{\Delta_i}+\rho_k^i\frac{\lambda_i^{n+r-1}}{\Delta_i}\sum_{l\neq i}\frac{1}{\lambda_i-\lambda_l}+\sum_{l\neq i}\rho_{k-1}^{il}\frac{\lambda_l^{n+r-1}}{\Delta_l}\\&\quad-\sum_{l\neq i}\rho_k^l\frac{\lambda_l^{n+r-1}}{\Delta_l}\frac{1}{\lambda_l-\lambda_i}.\end{aligned}$$

Applying formulas (14), (15), the last two terms can be transformed into the form

$$\sum_{l\neq i}\left(\rho_{k-1}^{il}-\frac{\rho_k^l}{\lambda_l-\lambda_i}\right)\frac{\lambda_l^{n+r-1}}{\Delta_l}=-\sum_{l\neq i}\frac{\rho_k^i}{\lambda_l-\lambda_i}\frac{\lambda_l^{n+r-1}}{\Delta_l}$$

$$=-\rho_k^i\sum_{l\neq i}\frac{\lambda_l^{n+r-1}}{\Delta_l}\frac{1}{\lambda_l-\lambda_i},$$

hence

$$\frac{\partial\beta_{r,k+1}}{\partial\lambda_i}=-\rho_k^i(n+r-1)\frac{\lambda_i^{n+r-2}}{\Delta_i}+\rho_k^i\left(\frac{\lambda_i^{n+r-1}}{\Delta_i}\sum_{l\neq i}\frac{1}{\lambda_i-\lambda_l}+\sum_{l\neq i}\frac{\lambda_l^{n+r-1}}{\Delta_l}\frac{1}{\lambda_i-\lambda_l}\right)$$

$$=-\rho_k^i\frac{\partial}{\partial\lambda_i}\sum_{l=1}^{n}\frac{\lambda_l^{n+r-1}}{\Delta_l}=\rho_k^i\frac{\partial\beta_{r,1}}{\partial\lambda_i}.$$

□

APPENDIX C: THE PROOF OF LEMMA 3

Applying relations (14), (15) and representation (22) we have

$$\frac{\partial h_r}{\partial\mu_i}=\rho_{r-1}^i\left(\frac{\partial}{\partial\mu_i}\frac{\overline{f_i}}{\Delta_i}\right)$$

$$=\rho_{r-1}^i\frac{\partial h_1}{\partial\mu_i},$$

$$\frac{\partial h_r}{\partial\lambda_i}=\sum_{j=1}^{n}\left(\frac{\partial\rho_{r-1}^j}{\partial\lambda_i}\frac{\overline{f_j}}{\Delta_j}+\rho_{r-1}^j\frac{\partial}{\partial\lambda_i}\frac{\overline{f_j}}{\Delta_j}\right)$$

$$=\rho_{r-1}^i\left(\frac{\partial}{\partial\lambda_i}\frac{\overline{f_i}}{\Delta_i}\right)+\sum_{j\neq i}\left(\frac{\partial\rho_{r-1}^j}{\partial\lambda_i}\frac{\overline{f_j}}{\Delta_j}+\rho_{r-1}^j\overline{f_j}\frac{\partial}{\partial\lambda_i}\frac{1}{\Delta_j}\right)$$

$$=\rho_{r-1}^i\left(\frac{\partial}{\partial\lambda_i}\frac{\overline{f_i}}{\Delta_i}\right)+\sum_{j\neq i}\left(-\rho_{r-2}^{ji}+\frac{\rho_{r-1}^j}{\lambda_j-\lambda_i}\right)\frac{\overline{f_j}}{\Delta_j}$$

$$=\rho_{r-1}^i\left(\frac{\partial}{\partial\lambda_i}\frac{\overline{f_i}}{\Delta_i}\right)+\sum_{j\neq i}\frac{\rho_{r-1}^i}{\lambda_j-\lambda_i}\frac{\overline{f_j}}{\Delta_j}$$

$$=\rho_{r-1}^i\left(\frac{\partial}{\partial\lambda_i}\frac{\overline{f_i}}{\Delta_i}+\sum_{j\neq i}\frac{1}{\lambda_j-\lambda_i}\frac{\overline{f_j}}{\Delta_j}\right)=\rho_{r-1}^i\frac{\partial h_1}{\partial\lambda_i}.$$

□

Analogously one can prove the last derivative.

APPENDIX D: THE PROOF OF LEMMA 5

Vector fields $K_r=(X_r,Y_r)^T$ are Hamiltonian, i.e., $K_r=\pi_0\nabla H_r$. Conditions (28) are fulfilled as

$$\frac{\partial}{\partial p_i}\frac{\partial}{\partial p_j}h_r=\frac{\partial}{\partial p_k}\frac{\partial}{\partial c_l}h_r=0,\quad i\neq j.$$

Conditions (31) follow from involutivity of h_r with respect to π_0. Taking into account the results of Lemma 1 (ii) and Lemma 3, conditions (29) and (30) reduce to the following three:

$$m\lambda_i^{m-1}+\sum_{k=1}^{m}\frac{\partial\beta_{k,1}}{\partial\lambda_i}\rho_{m-k}^i=0,\quad j=i, \tag{D1}$$

$$(\lambda_j^m-\lambda_i^m)\frac{1}{\lambda_i-\lambda_j}+\sum_{k=1}^{m}\frac{\partial\beta_{k,1}}{\partial\lambda_j}\rho_{m-k}^i=0,\quad j\neq i, \tag{D2}$$

$$(\lambda_j^m-\lambda_i^m)\frac{1}{\lambda_i-\lambda_j}+\sum_{k=1}^{m}\frac{\partial\beta_{k,1}}{\partial\lambda_i}\rho_{m-k}^j=0,\quad j\neq i. \tag{D3}$$

First we prove the relation (D1). From $\pi_0\nabla h_r=\pi_m\nabla h_{r-m}$ we get

$$\frac{\partial h_r}{\partial\lambda_i}=\lambda_i^m\frac{\partial h_{r-m}}{\partial\lambda_i}+\sum_{k=1}^{m}\frac{\partial h_{r-m-k}}{\partial\lambda_i}\beta_{k,r-m}$$

$$\Downarrow$$

$$\frac{\partial\beta_{l,r}}{\partial\lambda_i}=\lambda_i^m\frac{\partial\beta_{l,r-m}}{\partial\lambda_i}+\sum_{k=1}^{m}\frac{\partial\beta_{l,r-m-k}}{\partial\lambda_i}\beta_{k,r-m}$$

$$\Downarrow \text{ Lemma1(ii)}$$

$$\rho_{r-1}^i\frac{\partial\beta_{l,1}}{\partial\lambda_i}=\lambda_i^m\rho_{r-m-1}^i\frac{\partial\beta_{l,1}}{\partial\lambda_i}+\sum_{k=1}^{m}\rho_{m-k}^i\frac{\partial\beta_{l,1}}{\partial\lambda_i}\beta_{k,r-m}$$

$$\Downarrow$$

$$\rho_{r-1}^i=\lambda_i^m\rho_{r-m-1}^i+\sum_{k=1}^{m}\rho_{m-k}^i\beta_{k,r-m} \tag{D4}$$

$$\Downarrow\frac{\partial}{\partial\lambda_i}$$

$$0=m\lambda_i^{m-1}\rho_{r-m-1}^i+\sum_{k=1}^{m}\frac{\partial\beta_{k,r-m}}{\partial\lambda_i}\rho_{m-k}^i$$

$$\Downarrow \text{ Lemma1(i)}$$

$$0=m\lambda_i^{m-1}\rho_{r-m-1}^i+\sum_{k=1}^{m}\frac{\partial\beta_{k,1}}{\partial\lambda_i}\rho_{r-m-1}^i\rho_{m-k}^i$$

$$\Downarrow$$

$$0=m\lambda_i^{m-1}+\sum_{k=1}^{m}\frac{\partial\beta_{k,1}}{\partial\lambda_i}\rho_{m-k}^{i}.$$

□

To prove relations (D2) and (D3) substitute (D4) to equality

$$\frac{\partial}{\partial\lambda_j}\rho_{2m-l}^{i}-\frac{\partial}{\partial\lambda_i}\rho_{2m-l}^{j}=0,$$

hence we get

$$0=(\lambda_j^m-\lambda_i^m)\rho_{m-l-1}^{ij}+\sum_{k=1}^{m}\left(\rho_{m-k}^{i}\rho_{m-l}^{j}\frac{\partial\beta_{k,1}}{\partial\lambda_j}-\rho_{m-k}^{j}\rho_{m-l}^{i}\frac{\partial\beta_{k,1}}{\partial\lambda_i}\right).$$

Applying the relation $\rho_r^i-\rho_r^j=(\lambda_i-\lambda_j)\rho_{r-1}^{ij}$ we have

$$0=\left[(\lambda_j^m-\lambda_i^m)\frac{1}{\lambda_j-\lambda_i}+\sum_{k=1}^{m}\rho_{m-k}^{i}\frac{\partial\beta_{k,1}}{\partial\lambda_j}\right]\rho_{m-l}^{j}+\left[(\lambda_j^m-\lambda_i^m)\frac{1}{\lambda_i-\lambda_j}+\sum_{k=1}^{m}\rho_{m-k}^{j}\frac{\partial\beta_{k,1}}{\partial\lambda_i}\right]\rho_{m-l}^{i}.$$

From arbitrariness of l one gets equalities (D2) and (D3). □

APPENDIX E: THE PROOF OF THEOREM 2

The basic bi-Hamiltonian chains read

$$\pi_{m-1}\nabla h_{r+1}=\pi_m\nabla h_r,\quad m=1,...,n. \tag{E1}$$

All the remaining chains can be constructed from (E1) ones. The validity of (E1) can be proved by induction. For $m=1$ we get

$$\pi_0\nabla h_{r+1}=\pi_1\nabla h_r$$

$$\Updownarrow$$

$$\frac{\partial h_{r+1}}{\partial\mu_i}=\lambda_i\frac{\partial h_r}{\partial\mu_i}+\beta_{1,r}\frac{\partial h_1}{\partial\mu_i}, \tag{E2}$$

$$\frac{\partial h_{r+1}}{\partial\lambda_i}=\lambda_i\frac{\partial h_r}{\partial\lambda_i}+\beta_{1,r}\frac{\partial h_1}{\partial\lambda_i},\quad i=1,...,n, \tag{E3}$$

$$\left(\frac{\partial h_1}{\partial\lambda}\right)^T\frac{\partial h_r}{\partial\mu}-\left(\frac{\partial h_1}{\partial\mu}\right)^T\frac{\partial h_r}{\partial\lambda}=0. \tag{E4}$$

This was proved for $c_1\neq 0$ in Ref. 2. Additional terms with $c_j\neq 0$, $j>1$ do not influence (E2) and from (E3) have to fulfill the conditions

$$\frac{\partial\beta_{j,r+1}}{\partial\lambda_i}=\lambda_i\frac{\partial\beta_{j,r}}{\partial\lambda_i}+\beta_{1,r}\frac{\partial\beta_{j,1}}{\partial\lambda_i},\quad j=2,...,n. \tag{E5}$$

Equations (E5) are true according to Lemma 1 (i) and the relation $\rho_r^i=\lambda_i\rho_{r-1}^i+\rho_r$. Assuming the validity of the chain

$$\pi_{m-2}\nabla h_{r+1}=\pi_{m-1}\nabla h_r \tag{E6}$$

we prove the validity of

$$\pi_{m-1}\nabla h_{r+1}=\pi_m\nabla h_r \tag{E7}$$

$$\Updownarrow$$

$$\lambda_i^{m-1}\frac{\partial h_{r+1}}{\partial\mu_i(\lambda_i)}-\lambda_i^m\frac{\partial h_r}{\partial\mu_i(\lambda_i)}=(\beta_{m,r}-\beta_{m-1,r+1})\frac{\partial h_1}{\partial\mu_i(\lambda_i)}+(\beta_{m-1,r}-\beta_{m-2,r+1})\frac{\partial h_2}{\partial\mu_i(\lambda_i)}+\cdots$$
$$+(\beta_{m+1-j,r}-\beta_{m-j,r+1})\frac{\partial h_j}{\partial\mu_i(\lambda_i)}+\cdots+(\beta_{2,r}-\beta_{1,r+1})\frac{\partial h_{m-1}}{\partial\mu_i(\lambda_i)}$$
$$+\beta_{1,r}\frac{\partial h_m}{\partial\mu_i(\lambda_i)},\quad i=1,...,n, \tag{E8}$$

$$\sum_{i=1}^{m-1}\left[\left(\frac{\partial h_i}{\partial\lambda}\right)^T\frac{\partial h_{r+1}}{\partial\mu}-\left(\frac{\partial h_i}{\partial\mu}\right)^T\frac{\partial h_{r+1}}{\partial\lambda}\right]=\sum_{j=1}^{m}\left[\left(\frac{\partial h_j}{\partial\lambda}\right)^T\frac{\partial h_r}{\partial\mu}-\left(\frac{\partial h_j}{\partial\mu}\right)^T\frac{\partial h_r}{\partial\lambda}\right]$$
$$\Leftrightarrow\sum_{i=1}^{m-1}\{h_i,h_{r+1}\}_{\pi_0}$$
$$=\sum_{j=1}^{m}\{h_j,h_r\}_{\pi_0}. \tag{E9}$$

Equality (E9) is fulfilled according to involutivity of h_r with respect to π_0. Now, let us consider (E8) with respect to $\mu_i(\lambda_i)$ derivatives. From the analogous ith component of the chain (E6), multiplied by λ_i we get

$$\lambda_i^{m-1}\frac{\partial h_{r+1}}{\partial\mu_i(\lambda_i)}-\lambda_i^m\frac{\partial h_r}{\partial\mu_i(\lambda_i)}=(\beta_{m-1,r}-\beta_{m-2,r+1})\lambda_i\frac{\partial h_1}{\partial\mu_i(\lambda_i)}+\cdots$$
$$+(\beta_{m-j,r}-\beta_{m-1-j,r+1})\lambda_i\frac{\partial h_j}{\partial\mu_i(\lambda_i)}+\cdots+\beta_{1,r}\lambda_i\frac{\partial h_{m-1}}{\partial\mu_i(\lambda_i)}. \tag{E10}$$

Comparing (E8) with (E10) and using relations from Lemma 3 we get

$$0=(\beta_{m,r}-\beta_{m-1,r+1})+(\beta_{m-1,r}-\beta_{m-2,r+1})(\rho_1^i-\lambda_i\rho_0^i)+\cdots$$
$$+(\beta_{m-j,r}-\beta_{m-1-j,r+1})(\rho_j^i-\lambda_i\rho_{j-1}^i)+\cdots+\beta_{1,r}(\rho_{m-1}^i-\lambda_i\rho_{m-2}^i). \tag{E11}$$

Taking into account the relation $\rho_j^i-\lambda_i\rho_{j-1}^i=\rho_j\equiv\beta_{1,j}$, (E11) turns into

$$0=(\beta_{m,r}-\beta_{m-1,r+1})+(\beta_{m-1,r}-\beta_{m-2,r+1})\beta_{1,1}+\cdots+(\beta_{m-j,r}-\beta_{m-1-j,r+1})\beta_{1,j}+\cdots$$
$$+(\beta_{2,r}-\beta_{1,r+1})\beta_{1,m-2}+\beta_{1,r}\beta_{1,m-1}. \tag{E12}$$

To verify the equality (E12) we apply the relations

$$\beta_{m-j,r}-\beta_{m-1-j,r+1}=-\beta_{m-1-j,1}\cdot\beta_{1,r},$$

$$\beta_{m,1}=\beta_{1,m}-\beta_{m-1,1}\cdot\beta_{1,1}-\beta_{m-2,1}\cdot\beta_{1,2}-\cdots-\beta_{2,1}\cdot\beta_{1,m-2}-\beta_{1,1}\cdot\beta_{1,m-1},$$

following from (17). □

APPENDIX F: THE DERIVATION OF EQUATION OF MOTION (58)

$$(\lambda_i)_t=\frac{\partial H}{\partial \mu_i}=\frac{a\varphi_i(\lambda_i)}{\Delta_i}e^{a\mu_i},$$

$$(\mu_i)_t=-\frac{\partial H}{\partial \lambda_i}=-\frac{\partial \varphi_i}{\partial \lambda_i}\frac{1}{\Delta_i}e^{a\mu_i}+\frac{\varphi_i}{\lambda_i}e^{a\mu_i}\sum_{k\neq i}\frac{1}{\lambda_i-\lambda_k}-\sum_{k\neq i}\frac{\varphi_k}{\lambda_k}e^{a\mu_k}\frac{1}{\lambda_k-\lambda_i}$$

$$=-\frac{\partial \varphi_i}{\partial \lambda_i}\frac{1}{\varphi_i}\frac{1}{a}(\lambda_i)_t+\frac{1}{a}(\lambda_i)_t\sum_{k\neq i}\frac{1}{\lambda_i-\lambda_k}-\frac{1}{a}\sum_{k\neq 1}(\lambda_k)_t\frac{1}{\lambda_k-\lambda_i},$$

$$\ln(\lambda_i)_t=\ln a+\ln \varphi_i+a\mu_i-\ln \Delta_i\,,$$

$$\frac{(\lambda_i)_{tt}}{(\lambda_i)_t}=[\ln(\lambda_i)_t]_t=\frac{(\varphi_i)_t}{\varphi_i}+a(\mu_i)_t-\frac{(\Delta_i)_t}{\Delta_i}$$

$$=\frac{\partial \varphi_i}{\partial \lambda_i}\frac{1}{\varphi_i}(\lambda_i)_t+a(\mu_i)_t-\sum_{k\neq i}\frac{(\lambda_k)_t}{\lambda_k-\lambda_i}-(\lambda_i)_t\sum_{k\neq i}\frac{1}{\lambda_i\lambda_k}$$

$$=-2\sum_{k\neq i}\frac{(\lambda_k)_t}{\lambda_k-\lambda_i},$$

as

$$\frac{\partial}{\partial \lambda_k}\Delta_i=\frac{\Delta_i}{\lambda_k-\lambda_i},\quad k\neq i,\quad \frac{\partial}{\partial \lambda_i}\Delta_i=\sum_{k\neq i}\frac{\Delta_i}{\lambda_i-\lambda_k}.$$

Nonisospectral scattering problems: A key to integrable hierarchies

Pilar R. Gordoa and Andrew Pickering
Area de Fisica Teórica, Facultad de Ciencias, Edificio de Fisica, Universidad de Salamanca, 37008 Salamanca, Spain

(Received 12 February 1999; accepted for publication 19 July 1999)

We show that certain partial differential equations associated to nonisospectral scattering problems in $2+1$ dimensions provide a key to associated integrable hierarchies of both ordinary and partial differential equations. This is illustrated using (an extension of) a known second-order and two new third-order nonisospectral scattering problems. These scattering problems allow us to derive new hierarchies of integrable partial differential equations, in both $1+1$ and $2+1$ dimensions, together with their underlying linear problems (isospectral and nonisospectral); and also new hierarchies of integrable ordinary differential equations, again with their underlying linear problems. [S0022-2488(99)04210-3]

I. INTRODUCTION

The introduction of the inverse scattering transform (IST) for the Korteweg–de Vries (KdV) equation[1] and the nonlinear Schrödinger equation[2] marked the birth of a whole new area of mathematics. Since then, a great deal of effort has been spent on finding new completely integrable systems, i.e., similarly solvable through an underlying linear problem. The extension of these ideas to partial differential equations (PDEs) in multidimensions[3,4] and, through the development of the inverse monodromy transform (IMT), to ordinary differential equations (ODEs),[5] has led to the huge variety of completely integrable systems that we know today.

In this paper we will be concerned with a particular class of PDEs in multidimensions, namely those arising as the compatibility condition of a *nonisospectral* scattering problem. The first example of such a PDE is in fact due to Calogero,[6] and has as a subcase the equation

$$u_{xt}=u_{xxxy}+4u_xu_{xy}+2u_{xx}u_y\,. \tag{1.1}$$

This equation arises as the compatibility condition of the Lax pair,

$$\psi_{xx}+(u_x-\lambda)\psi=0,\quad \psi_t=4\lambda\psi_y+2u_y\psi_x-u_{xy}\psi, \tag{1.2}$$

where the spectral parameter $\lambda=\lambda(y,t)$ satisfies the constraint[7,8]

$$\lambda_t=4\lambda\lambda_y\,. \tag{1.3}$$

Such a construction can be carried out with any number of additional spatial variables, i.e., y could be taken to be a vector $y=(y_1,y_2,\ldots,y_n)$. For the purposes of the present work we will, however, be taking y to be a scalar.

The application of the inverse scattering transform to Eq. (1.1) has been discussed by Calogero and Degasperis.[6,7] More recently, Bogoyavlenskii has shown that this equation admits ''breaking soliton'' solutions.[8] Other examples of PDEs associated with nonisospectral scattering problems in $2+1$ dimensions can be found in Refs. 9, 10, 11. The $2+1$-dimensional extension of the nonlinear Schrödinger equation given in Ref. 9 has also been discussed in Refs. 12 and 13. It is related to the $2+1$-dimensional extension of the classical Boussinesq system given in Ref. 10

in the same way as the $1+1$-dimensional systems.[14] The systems constructed in Ref. 11 are multicomponent generalizations of Eq. (1.1) above; more recently we have looked at modifications of such systems.

The aim of the present paper is to show that PDEs such as (1.1) above, or in fact generalizations thereof, play a key role in the construction of hierarchies of integrable equations and their associated linear problems. This is one of the reasons why we believe that the study of PDEs having nonisospectral scattering problems is of importance. Another is the connection that exists between nonisospectral scattering problems and linear problems for ODEs,[15] which we exploit (and generalize) below. Other reasons include the information they give about the Painlevé analysis (including truncation) of whole hierarchies of differential equations, and also the new nontrivial deformations of well-known PDEs that can arise from such scattering problems.[16]

In what follows we derive a wide variety of new integrable PDEs and ODEs. In their most general formulation these include nonlocal terms. We also obtain a wide variety of corresponding linear problems; nonisospectral scattering problems for hierarchies of PDEs in $2+1$ dimensions; nonisospectral and isospectral scattering problems for hierarchies of PDEs in $1+1$ dimensions; and also monodromy problems for hierarchies of ODEs.

The layout of the paper is as follows. In Sec. II we introduce the main ideas underlying our approach within the context of the KdV and nonisospectral KdV hierarchies. We show how these hierarchies can be characterized using a single equation. These ideas are then further developed in Sec. III, again within the context of KdV-type scattering problems. We use a single PDE in $2+1$ dimensions, and its associated nonisospectral scattering problem, to construct whole hierarchies of both PDEs and ODEs, together with their corresponding hierarchies of underlying linear problems. The extension of our ideas to third-order scattering problems is made in Secs. IV and V, which deal, respectively, with linear problems based on those for the Kaup–Kupershmidt (KK) (Refs. 17, 18), and Sawada–Kotera (SK) (Refs. 19, 20) hierarchies. In these sections we introduce new hierarchies of PDEs in $2+1$ and $1+1$ dimensions, together with their underlying linear problems, and also new hierarchies of ODEs, again with their underlying linear problems. That is, in addition to new hierarchies of PDEs, and the known hierarchies of ODEs which arise directly as similarity reductions of the KK and SK hierarchies,[21,22] we also obtain four new hierarchies of ODEs. These hierarchies of ODEs govern special integrals of similarity reductions of the modified KK/SK hierarchy, and we believe them to be analagous to the hierarchy of the first Painlevé equation P_I.[22] The third order linear problems given here for these hierarchies of ODEs are all new. Our final section is devoted to conclusions.

II. HIERARCHIES FROM NONISOSPECTRAL SCATTERING

In this section we describe our main ideas within the context of the KdV hierarchy. Our claim is that instead of considering Eq. (1.1) as simply an extension of the KdV equation to two spatial dimensions, that in fact this equation embodies information about the entire KdV hierarchy, and also about the entire nonisospectral KdV hierarchy. This is done by considering the extra variable not as a spatial variable, but as a temporal variable, say τ, and recalling that (1.1) can be written as

$$U_t = \mathcal{R} U_\tau, \tag{2.1}$$

where

$$\mathcal{R} = \partial_x^2 + 4U + 2U_x \partial_x^{-1} \tag{2.2}$$

is the recursion operator of the KdV hierarchy.[6,23] [Equation (1.1) is then recovered by the change of variables $U = u_x$, and relabeling τ as y.] In (2.2) $\partial_x \equiv \partial/\partial x$. We use such partial differential operators in what follows, and without further comment, also in the case of ODEs; similarly for the notation U_x.

Given Eq. (2.1) together with its Lax pair, we can then write down the Lax pair of any member of the KdV or nonisospectral KdV hierarchies simply by specifying t and τ to be appropriate flow times. Equation (2.1) gives both the iteration required and also our base equation (the starting point for our iteration). Thus, taking $t=t_5$ and $\tau=t_3$, the fifth order flow of each of these hierarchies can be written as $U_{t_5}=\mathcal{R}U_{t_3}$, for which we have the Lax pair,

$$\psi_{xx}+(U-\lambda)\psi=0,\quad \psi_{t_5}=4\lambda\psi_{t_3}+2[\partial_x^{-1}U_{t_3}]\psi_x-U_{t_3}\psi, \tag{2.3}$$

where

$$\lambda_{t_5}=4\lambda\lambda_{t_3}. \tag{2.4}$$

This gives the iteration between the fifth order flow and the third order flow. It is this third order flow which is our base equation, and which then gives the evolution of U and ψ with respect to t_3 (we could also specify an evolution with respect to t_1 as our base equation). For the nonisospectral KdV hierarchy we take $t=t_3$ and $\tau=y$ in (2.1), which then gives $U_{t_3}=\mathcal{R}U_y$, $\psi_{t_3}=4\lambda\psi_y+2[\partial_x^{-1}U_y]\psi_x-U_y\psi$, and $\lambda_{t_3}=4\lambda\lambda_y$. Combining these last with Eqs. (2.3), (2.4) then gives the fifth order nonisospectral flow $U_{t_5}=\mathcal{R}^2U_y$ and its Lax pair

$$\psi_{xx}+(U-\lambda)\psi=0,\quad \psi_{t_5}=(4\lambda)^2\psi_y+2[\partial_x^{-1}(4\lambda U_y+\mathcal{R}U_y)]\psi_x-[4\lambda U_y+\mathcal{R}U_y]\psi, \tag{2.5}$$

where λ now satisfies the constraint $\lambda_{t_5}=(4\lambda)^2\lambda_y$. For the isospectral KdV hierarchy we set $t=t_3$ in (2.1) and take the reduction $\partial_\tau=\partial_x$. This then gives $U_{t_3}=\mathcal{R}U_x$, $\psi_{t_3}=(4\lambda+2U)\psi_x-U_x\psi$, and $\lambda_{t_3}=0$. Thus we obtain the well known fifth order KdV flow, $U_{t_5}=\mathcal{R}^2U_x$, together with its Lax pair (isospectral since $\lambda_{t_5}=0$).

Now, it is a basic technique within the theory of integrable systems to specify a spectral problem of a certain type, and to expand the coefficients as polynomials in the spectral parameter, thus generating hierarchies of PDEs. This was first done by Ablowitz, Kaup, Newell, and Segur in their seminal paper of 1974,[24] and was in fact the technique we used in Ref. 11 to generate multicomponent hierarchies of PDEs in $2+1$ dimensions associated with nonisospectral scattering problems. Here we have essentially reversed this process; given a recursion operator $\mathcal{R}$, we characterize the corresponding hierarchy using a single equation of the form (2.1), and in this way generate the corresponding hierarchy of linear problems. It is interesting that this connection between relations of the form $U_{t_5}=\mathcal{R}U_{t_3}$, implicit whenever we write down higher order members of a hierarchy, and PDEs of the form $U_t=\mathcal{R}U_\tau$, having nonisospectral scattering problems, has not been exploited before.

In fact the equations we will be using are more general than (2.1), since we are interested not only in obtaining new hierarchies of PDEs, but also in their reductions to ODEs. The advantage of our approach is that it gives immediately a recursion relation between the coefficients of scattering problems corresponding to successive members of a hierarchy; this makes itself felt when dealing with scattering problems of order three or higher. In what follows we do not take different choices of base equation as we did above, but rather we take one base equation in $2+1$ dimensions. We then look at reductions or special cases of the resulting hierarchy.

III. THE KORTEWEG–de VRIES CASE

In this section we illustrate our approach using a generalization of the scattering problem for Eq. (2.1) above. That is, instead of (2.1) we consider the equation

$$U_t=\mathcal{R}U_\tau+g, \tag{3.1}$$

where $g=g(\tau,t)$, i.e., g is a function of all possible times and y, but not of x. This PDE has the Lax pair,

$$\psi_{xx}+(U-\lambda)\psi=0, \quad \psi_t=4\lambda\psi_\tau+[2\partial_x^{-1}U_\tau]\psi_x-U_\tau\psi, \tag{3.2}$$

where the spectral parameter $\lambda=\lambda(\tau,t)$, again to be thought of as a function of all possible times and y, but not of x, satisfies

$$\lambda_t=4\lambda\lambda_\tau+g. \tag{3.3}$$

We also note that this PDE admits the Darboux transformation (DT),

$$\tilde{U}=U+2(\ln\psi)_{xx} \tag{3.4}$$

between two solutions U and $\tilde{U}$. Given this DT and the Lax pair, it is a simple matter to write down a Bäcklund transformation (BT) for (3.1).

We now consider the form taken by higher members of a hierarchy, and their corresponding linear problems, if we use (3.1) both as a starting point and also to iterate between successive flows. The reasons why we are interested in the particular sequence generated by (3.1) will become clear shortly.

We label the times of our hierarchy as t_{2n+1}, and write a generic member of the hierarchy as

$$U_{t_{2n+1}}=Q_n, \tag{3.5}$$

for some (in general nonlocal) functional Q_n of U, and we write corresponding generic evolutions of ψ and λ as

$$\psi_{t_{2n+1}}=\Gamma_n\psi_y+2P_n\psi_x-P_{n,x}\psi, \quad \lambda_{t_{2n+1}}=\Lambda_n. \tag{3.6}$$

It is then easy to see that (3.1), (3.2), and (3.3) yield the recursion relations

$$Q_n=\mathcal{R}Q_{n-1}+g_n, \tag{3.7}$$

$$\Gamma_n=4\lambda\Gamma_{n-1}, \tag{3.8}$$

$$P_n=4\lambda P_{n-1}+\partial_x^{-1}Q_{n-1}, \tag{3.9}$$

$$\Lambda_n=4\lambda\Lambda_{n-1}+g_n \tag{3.10}$$

(note that we also iterate on the function g in (3.1)).

These are the recursion relations between successive flows of the hierarchy and the coefficients of their corresponding linear problems. Since we take as our starting point the PDE,

$$U_{t_3}=\mathcal{R}U_y+g_1, \tag{3.11}$$

along with its corresponding scattering problem (which gives the evolution of ψ and λ with t_3), we obtain in this way the hierarchy of evolution equations

$$U_{t_{2n+1}}=Q_n=\mathcal{R}^nU_y+\sum_{i=1}^{n}g_i\mathcal{R}^{n-i}1. \tag{3.12}$$

This has the corresponding hierarchy of nonisospectral scattering problems

$$\psi_{xx}+(U-\lambda)\psi=0, \quad \psi_{t_{2n+1}}=(4\lambda)^n\psi_y+2P_n\psi_x-P_{n,x}\psi, \tag{3.13}$$

with

$$P_n = \partial_x^{-1} \sum_{i=0}^{n-1} (4\lambda)^{n-1-i} Q_i, \tag{3.14}$$

where we have set $Q_0 = U_y$, and where λ satisfies

$$\lambda_{t_{2n+1}} = (4\lambda)^n \lambda_y + \sum_{i=1}^{n} (4\lambda)^{n-i} g_i. \tag{3.15}$$

The flows of the hierarchy (3.12) are nonlocal, because of the action of powers of $\mathcal{R}$ on U_y and also on 1. This last yields nonautonomous terms, whose inclusion here is new. These flows can be made local by introducing suitable auxiliary dependent variables. The DT (3.4) holds, of course, for every member of this hierarchy, and thus we can easily write down a BT. Allowing τ in (3.1) to be a vector would allow the construction of a hierarchy consisting of linear combinations of the above flows.

In the special case where all $g_i \equiv 0$, the above hierarchy is the one-component breaking soliton hierarchy. The DT (3.4) had previously been shown to hold for this special case in Ref. 25. Making the reduction $\partial_y = \partial_x$ in this special case just obtains the KdV hierarchy, for which the hierarchy of linear problems and DT is of course well-known. We now consider other subcases and reductions.

In addition to nonisospectral scattering problems, our interest here is in obtaining hierarchies of ODEs and their linear problems. From (3.12) we consider two alternative routes to a hierarchy of ODEs, via two different hierarchies of PDEs in $1+1$ dimensions. Our first reduction is via $\partial_y = \partial_x$, which requires $g_{i,y} = \lambda_y = 0$, and which leads to a nonisospectral deformation of the KdV hierarchy,

$$U_{t_{2n+1}} = \mathcal{R}^n U_x + \sum_{i=1}^{n} g_i \mathcal{R}^{n-i} 1. \tag{3.16}$$

This hierarchy could have been obtained immediately through a suitable choice of base equation (in $1+1$ dimensions) and corresponding nonisospectral Lax pair, i.e., $U_{t_3} = \mathcal{R} U_x + g_1$, $\psi_{xx} + (U - \lambda)\psi = 0$, $\psi_{t_3} = (4\lambda + 2U)\psi_x - U_x \psi$, and $\lambda_{t_3} = g_1$. We note that this hierarchy of evolution equations in $1+1$ dimensions can also be found in Ref. 26.

Our second reduction is via $\partial_{t_{2n+1}} = 0$, which then requires $g_{i,t_{2n+1}} = \lambda_{t_{2n+1}} = 0$, and leads to a nonisospectral deformation of inverse KdV flows,

$$\mathcal{R}^n U_y + \sum_{i=1}^{n} g_i \mathcal{R}^{n-i} 1 = 0. \tag{3.17}$$

The Lax pairs of (3.16) and (3.17) follow immediately from those for our $2+1$ hierarchy.

We now consider reductions to ODEs. For the case where an ODE arises as a stationary reduction of an evolution equation having a nonisospectral scattering problem, the connection between the linear problem for that ODE and the nonisospectral scattering problem was discussed in Ref. 15 (e.g., for the case $n=1$ of (3.16)). However in this paper we will be interested in more than just stationary reductions, and in more than just reductions of evolution equations. In Secs. IV and V we deal with hierarchies of ODEs that apparently do not arise simply as the (integrated) stationary flows of completely integrable evolution equations. The simplest examples of such ODEs are fourth order.

For the PDEs (3.16) and (3.17) we consider respectively the reductions $\partial_{t_{2n+1}} = 0$ and $\partial_y = \partial_x$. All g_i are now of course just constant parameters. Each of these reductions obtains the sequence of ODEs,

$$\mathcal{R}^n U_x + \sum_{i=1}^{n} g_i \mathcal{R}^{n-i} 1 = 0. \tag{3.18}$$

A corresponding sequence of linear problems for these ODEs is obtained from the Lax pairs for (3.16) and (3.17); the reduction from (3.17) requires a generalization of the approach in Ref. 15. This sequence of linear problems is

$$\psi_{xx} + (U-\lambda)\psi = 0, \quad \left(\sum_{i=1}^{n} (4\lambda)^{n-i} g_i \right) \psi_\lambda = [(4\lambda)^n + 2P_n]\psi_x - P_{n,x}\psi, \tag{3.19}$$

where we must assume of course that not all g_i are zero, and where

$$P_n = \partial_x^{-1} \left(\sum_{i=0}^{n-1} (4\lambda)^{n-1-i} \left[\mathcal{R}^i U_x + \sum_{j=1}^{i} g_j \mathcal{R}^{i-j} 1 \right] \right). \tag{3.20}$$

It is then straightforward to write down corresponding matrix linear problems for the hierarchy (3.18).

The first of these ODEs and associated linear problems is equivalent, under a simple change of variables, to the first Painlevé equation and its (scalar or matrix) linear problem, so we do not consider this case further here. For $n>1$, the ODEs (3.18) represent an extension of those discussed in Refs. 27, 28, 21, 29 (for $n=2$ simply by an additive constant).

We note that for $n>1$ the ODEs (3.18) are in the general case nonautonomous, and that for $n>2$ they are nonlocal. This last means that for $n>2$ these ODEs could not be obtained using a standard Painlevé classification at that order. All of these ODEs can of course be written locally by introducing suitable auxiliary dependent variables.

Let us now consider the case where the ODEs (3.18), for $n>1$, are local, i.e., where $g_i=0$ for $i=1,2,...,n-2$. In this case the hierarchy of ODEs becomes

$$\mathcal{R}^n U_x + g_{n-1}(4U + 2xU_x) + g_n = 0. \tag{3.21}$$

For $g_{n-1} \neq 0$ this hierarchy has the first integral

$$F_n F_{n,xx} - \frac{1}{2}(F_{n,x})^2 + \left(2U + \frac{g_n}{2g_{n-1}} \right) F_n^2 = -\frac{1}{2}\left(\frac{1}{2} - \alpha_n \right)^2, \tag{3.22}$$

where the right-hand side is the constant of integration, and where

$$F_n = (\partial_x^{-1}\mathcal{R}^{n-1}U_x) + g_{n-1}x + \left(\sum_{i=0}^{n-2} \left(-\frac{g_n}{g_{n-1}} \right)^{n-i-1} \partial_x^{-1}\mathcal{R}^i U_x \right) + \frac{1}{2}\left(-\frac{g_n}{g_{n-1}} \right)^n. \tag{3.23}$$

The hierarchy (3.22), (3.23) is equivalent under the Bäcklund transformation,

$$U = V_x - V^2 - \frac{1}{4}\left(\frac{g_n}{g_{n-1}} \right), \tag{3.24}$$

$$V = -\frac{1}{2}\left(\frac{F_{n,x} + (1/2) - \alpha_n}{F_n} \right), \tag{3.25}$$

to the generalized P_{II} hierarchy

$$(\partial_x + 2V)F_n \Big|_{U=V_x - V^2 - (g_n/(4g_{n-1}))} + (1/2) - \alpha_n = 0. \tag{3.26}$$

For $g_n=0$ the hierarchy (3.22), (3.23) is the P_{34} hierarchy as defined in Ref. 29, (3.24), (3.25) is the Bäcklund transformation[21,29] onto the corresponding P_{II} hierarchy,[27,5,28] and the hierarchy (3.21) is a similarity reduction of the standard KdV hierarchy $U_{t_{2n+1}}=\mathcal{R}^n U_x$ (Refs. 28, 21, 29) (for which in the case $n=2$ a matrix linear problem is known to the author of Ref. 21). Thus for $g_n\neq 0$ the above results give a generalization of this P_{34} hierarchy, Bäcklund transformation, corresponding P_{II} hierarchy, and KdV similarity reduction. For the special case $n=2$ these results can be found in Ref. 30. Further generalizations are possible (e.g., see Remark One below).

When $g_{n-1}=0$ we can integrate (3.21) immediately to obtain the hierarchy of the first Painlevé equation as defined by Kudryashov,[28] i.e.,

$$(\partial_x^{-1}\mathcal{R}^n U_x)+g_n x=0, \tag{3.27}$$

where our requirement now that $g_n\neq 0$ allows us to set any constant of integration to zero. Again it is straightforward to also give matrix linear problems for this hierarchy (with compatibility condition (3.27) rather than its derivative). We note that matrix linear problems for the first three members of this hierarchy have been obtained in Ref. 31.

Remark one: It is possible to generalize the above results if we allow functions of integration to be introduced under the application of the recursion operator. A simple way to do this is to include an extra term in (3.1) which explicitly represents such an integration, i.e., we consider $U_t=\mathcal{R}U_\tau+aU_x+g$, where $a=a(\tau,t)$. The corresponding nonisospectral Lax pair is $\psi_{xx}+(U-\lambda)\psi=0$, $\psi_t=4\lambda\psi_\tau+[(2\partial_x^{-1}U_\tau)+a]\psi_x-U_\tau\psi$, where λ satisfies the same equation (3.3). The DT (3.4) also holds for this PDE.

Iterating also on a, we obtain corresponding to (3.12) above the hierarchy of PDEs,

$$U_{t_{2n+1}}=\mathcal{R}^n U_y+\sum_{i=1}^{n} a_i\mathcal{R}^{n-i}U_x+\sum_{i=1}^{n} g_i\mathcal{R}^{n-i}1. \tag{3.28}$$

The extra terms correspond of course to the addition of lower order KdV flows. Taking reductions as before, we obtain corresponding generalizations of our hierarchies of PDEs in $1+1$ dimensions, and also of our hierarchy of ODEs. In the local case this generalized hierarchy of ODEs reads

$$\mathcal{R}^n U_x+\sum_{i=2}^{n} a_i\mathcal{R}^{n-i}U_x+g_{n-1}(4U+2xU_x)+g_n=0, \tag{3.29}$$

where g_{n-1}, g_n (not both zero) and all a_i are now constant, and where without loss of generality we have taken $a_1=0$. For $g_n=0$ these ODEs are just similarity reductions of sums of KdV flows. The above results on first integrals of (3.21) are easily generalized to (3.29). The case $n=2$ of (3.29) has recently been obtained by Cosgrove,[30] and is known to have hyperelliptic asymptotics.[32] Linear problems for the hierarchy (3.29) are obtained in the same way as described above.

Remark two: So far we have insisted that not all g_i are zero. If we allow all g_i to vanish, in which case the hierarchy of ODEs (3.29) is autonomous, then, following the approach in Ref. 33, we can use the linear problems to obtain constants of motion. Equivalently, we could also use the corresponding matrix linear problem. For Eq. (3.29) with $g_{n-1}=g_n=0$, this approach then yields $n+1$ constants of integration. These are easily identified as the fluxes corresponding to conserved densities consisting of appropriate linear combinations of the Hamiltonian densities of the KdV hierarchy. We note that in the case $n=2$ our third constant of motion vanishes when rewritten in the coordinates of the corresponding Hénon–Heiles system, which then leaves the two constants of motion obtained in Ref. 33.

IV. THE KAUP–KUPERSHMIDT CASE

In this section we consider a PDE associated with a nonisospectral scattering problem based on a member of the KK hierarchy. We write this PDE as the system

$$U_t = \theta[U]W, \tag{4.1}$$

$$W = K[U]U_\tau - qx, \tag{4.2}$$

where $q = q(\tau,t)$ is a function of all possible times and y, but not of x, and where the operators $\theta[U]$ and $K[U]$ are defined by[34,35,36]

$$\theta[U] = \partial_x^3 + (U\partial_x + \partial_x U), \tag{4.3}$$

$$K[U] = \partial_x^{-1}[\partial_x^5 + 3(\partial_x U\partial_x^2 + \partial_x^2 U\partial_x) + 2(\partial_x^3 U + U\partial_x^3) + 8(\partial_x U^2 + U^2\partial_x)]\partial_x^{-1}. \tag{4.4}$$

The recursion operator of the KK hierarchy is given by $\mathcal{R} = \theta[U]K[U]$, so the above system can be written

$$U_t = \mathcal{R}U_\tau - q(2U + xU_x). \tag{4.5}$$

The Lax pair for the system (4.1), (4.2) is

$$\psi_{xxx} = -2U\psi_x - (U_x - \lambda)\psi, \tag{4.6}$$

$$\psi_t = -27\lambda^2\psi_\tau - 9\lambda[2(\partial_x^{-1}U_\tau)]\psi_{xx} + [9\lambda U_\tau + W]\psi_x - [3\lambda U_{x\tau} + 24\lambda U(\partial_x^{-1}U_\tau) + W_x]\psi, \tag{4.7}$$

where $\lambda = \lambda(\tau,t)$ is a function of all possible times and y, but not of x, and satisfies the equation

$$\lambda_t = -27\lambda^2\lambda_\tau - 3\lambda q. \tag{4.8}$$

The compatibility condition of this Lax pair reads

$$(\psi_{xxx})_t - (\psi_t)_{xxx} \equiv X_1\psi_x + X_0\psi = 0, \tag{4.9}$$

where

$$X_1 \equiv 2(-U_t + \theta[U]W) = 0, \tag{4.10}$$

$$X_0 \equiv (-U_t + \theta[U]W)_x + 3\lambda(-W_x + \partial_x K[U]U_\tau - q) = 0. \tag{4.11}$$

This nonisospectral scattering problem, and the corresponding system of PDEs (4.1), (4.2), appear to be new. This system admits the Darboux transformation

$$\tilde{U} = U + \tfrac{3}{2}[\log(\psi\psi_{xx} - \tfrac{1}{2}\psi_x^2 + U\psi^2)]_{xx}, \tag{4.12}$$

where we also have a corresponding mapping on W, too long to be included here. This DT is of course the same as that which holds for the $1+1$ KK hierarchy.[26]

In this section we will construct a new hierarchy of PDEs in $2+1$ dimensions having nonisospectral scattering problems. By taking various reductions to $1+1$ dimensions we will obtain new hierarchies of PDEs having isospectral or nonisospectral scattering problems. By taking further reductions we will obtain new hierarchies of integrable ODEs, together with their underlying linear problems. Explicit examples are given in the case $n=1$ and also in Appendix C for $n=2$.

It is the system (4.1), (4.2) which provides the iteration we use in order to construct our hierarchy of PDEs in $2+1$ dimensions. However we should remember that the KK hierarchy is a double sequence of PDEs, defined as[34,35,36]

$$U_{\tau_m}=\theta[U]H_m[U], \quad H_{m+2}[U]=K[U]\theta[U]H_m[U], \tag{4.13}$$

where the two starting points

$$H_0[U]=1 \quad \text{and} \quad H_1[U]=U_{xx}+4U^2 \tag{4.14}$$

give one sequence beginning with the trivial flow $U_{\tau_0}=U_x$, and another beginning with the fifth order KK equation itself, respectively. However if we use (4.1), (4.2) also as our base equation we will obtain a hierarchy which when we take reductions to $1+1$ dimensions will allow the recovery of only one of the KK sequences (the first mentioned above, i.e., that which includes the first and seventh order flows). This problem can be overcome by making a shift in the system (4.1), (4.2). To do this locally we set $U=u_x$; we then send $u\to u+\frac{1}{2}\partial_y^{-1}a$, where a is a function of all possible times and y, but not of x. This means that as base equation we take the more general $2+1$ system,

$$U_{t_1}=\theta[U]W_1, \tag{4.15}$$

$$W_1=K[U]U_y+a(U_{xx}+4U^2)-q_1x. \tag{4.16}$$

This PDE has the Lax pair,

$$\psi_{xxx}=-2U\psi_x-(U_x-\lambda)\psi, \tag{4.17}$$

$$\begin{aligned}\psi_{t_1}=&-27\lambda^2\psi_y-9\lambda[2(\partial_x^{-1}U_y)+a]\psi_{xx}+[9\lambda U_y+W_1]\psi_x\\&-[3\lambda U_{xy}+24\lambda U(\partial_x^{-1}U_y)+12a\lambda U+W_{1,x}]\psi,\end{aligned} \tag{4.18}$$

where λ satisfies the equation

$$\lambda_{t_1}=-27\lambda^2\lambda_y-3\lambda q_1. \tag{4.19}$$

The extra term included in (4.16) is of course just a copy of $H_1[U]$. This means that reductions to $1+1$ dimensions of this t_1 flow will include both the τ_2 and τ_1 (seventh and fifth order) flows of the standard KK hierarchy (4.13), (4.14). Similarly, the t_n flow of the $2+1$ nonisospectral hierarchy that we now construct will include amongst its reductions to $1+1$ dimensions both the τ_{2n} and τ_{2n-1} flows of the standard KK hierarchy. The DT (4.12) holds also for the system (4.15), (4.16).

Following the approach developed in the last section, we consider a generic member of this $2+1$ hierarchy,

$$U_{t_n}=\theta[U]W_n, \tag{4.20}$$

and write corresponding generic evolutions of ψ and λ as

$$\psi_{t_n}=\Gamma_n\psi_y+A_n\psi_{xx}+B_n\psi_x+C_n\psi, \tag{4.21}$$

$$\lambda_{t_n}=\Lambda_n \tag{4.22}$$

where the compatibility condition of (4.21) with (4.6) tells us that we may take

$$C_n=\tfrac{1}{3}(4UA_n-A_{n,xx}-3B_{n,x}). \tag{4.23}$$

We then obtain from (4.1), (4.2), (4.7), and (4.8) the recursion relations

$$W_n = K[U]\theta[U]W_{n-1} - q_n x, \tag{4.24}$$

$$\Gamma_n = -27\lambda^2\Gamma_{n-1}, \tag{4.25}$$

$$A_n = -27\lambda^2 A_{n-1} - 18\lambda\,\partial_x^{-1}\theta[U]W_{n-1}, \tag{4.26}$$

$$B_n = -27\lambda^2 B_{n-1} + 9\lambda\,\theta[U]W_{n-1} + W_n, \tag{4.27}$$

$$\Lambda_n = -27\lambda^2\Lambda_{n-1} - 3\lambda q_n \tag{4.28}$$

(where we have also iterated on the function q in (4.2)). These recursion relations, together with the base Eq. (4.15), (4.16), and its scattering problem, then yield a hierarchy of evolution equations, which for future convenience we note can be written as

$$U_{t_n} = \theta[U]W_n, \tag{4.29}$$

$$W_n = (K[U]\theta[U])^{n-1}K[U]U_y + a(K[U]\theta[U])^{n-1}H_1[U] - \sum_{i=1}^{n} q_i (K[U]\theta[U])^{n-i}x, \tag{4.30}$$

or equivalently as

$$U_{t_n} = Q_n = \theta[U]W_n = \mathcal{R}^n U_y + a\mathcal{R}^{n-1}\theta[U]H_1[U] - \sum_{i=1}^{n} q_i \mathcal{R}^{n-i}\theta[U]x. \tag{4.31}$$

This hierarchy has the scattering problem

$$\psi_{xxx} = -2U\psi_x - (U_x - \lambda)\psi, \tag{4.32}$$

$$\psi_{t_n} = (-27\lambda^2)^n\psi_y + A_n\psi_{xx} + B_n\psi_x + \tfrac{1}{3}(4UA_n - A_{n,xx} - 3B_{n,x})\psi, \tag{4.33}$$

where

$$A_n = -9a\lambda(-27\lambda^2)^{n-1} - 18\lambda\,\partial_x^{-1}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i, \tag{4.34}$$

$$B_n = 9\lambda\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i + \sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i, \tag{4.35}$$

where Q_i is as given by (4.31) and we have set $Q_0 = U_y$. The spectral parameter λ satisfies

$$\lambda_{t_n} = (-27\lambda^2)^n\lambda_y - 3\lambda\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i. \tag{4.36}$$

Note that in the above

$$B_n = -\frac{1}{2}A_{n,x} + \sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i. \tag{4.37}$$

The first term on the right-hand side of (4.31) represents a nonisospectral extension to $2+1$ dimensions of the standard KK sequence which includes the seventh order flow. The second term is the standard $1+1$-dimensional KK sequence based on the fifth order flow. The last term represents a nonisospectral deformation which gives rise to nonautonomous terms; for $n>1$, these are in the general case nonlocal. This $2+1$ hierarchy can be written locally using suitable auxiliary dependent variables. The DT (4.12) holds, of course, for every member of this hierarchy. Allowing τ in (4.1), (4.2) to be a vector would allow us to construct a hierarchy consisting of linear combinations of the above flows.

This hierarchy of PDEs in $2+1$ dimensions is new. We now consider reductions of this hierarchy to $1+1$ dimensions and also to ODEs. In both cases we again obtain new hierarchies of equations together with their underlying linear problems.

A. Reductions to hierarchies of PDEs in 1+1 dimensions

In this subsection we discuss reductions to $1+1$ dimensions of our $2+1$ hierarchy. We begin by looking at reductions which give nonisospectral deformations of the standard KK hierarchy (4.13), (4.14).

Our first reduction is via $\partial_y=\partial_x$ and $a=0$. This then requires $q_{i,y}=\lambda_y=0$ and leads to the sequence of equations

$$U_{t_n}=\theta[U]W_n, \tag{4.38}$$

$$W_n=H_{2n}[U]-\sum_{i=1}^{n} q_i(K[U]\theta[U])^{n-i}x, \tag{4.39}$$

which we can also write as

$$U_{t_n}=\mathcal{R}^n U_x-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x. \tag{4.40}$$

This is a nonisospectral deformation of the standard KK sequence which includes the trivial and seventh order flows ($n=0$ and $n=1$, respectively). The Lax pair follows easily from that for our $2+1$ system.

Our second reduction is via $\partial_y=0$ and $a=1$. This requires $q_{i,y}=\lambda_y=0$ and leads to

$$U_{t_n}=\theta[U]W_n, \tag{4.41}$$

$$W_n=H_{2n-1}[U]-\sum_{i=1}^{n} q_i(K[U]\theta[U])^{n-i}x, \tag{4.42}$$

which we can also write as

$$U_{t_n}=\mathcal{R}^{n-1}\theta[U]H_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x. \tag{4.43}$$

This is a nonisospectral deformation of the standard KK sequence which includes fifth order KK itself $(n=1)$. Again the Lax pair follows easily from that for our $2+1$ system.

We see from the above that the t_n flow has as reductions nonisospectral deformations of both the τ_{2n} and τ_{2n-1} flows of the KK hierarchy. For $n>1$ the additional nonautonomous terms are in the general case nonlocal. In the special case where all $q_i=0$ we just recover the standard $1+1$-dimensional KK hierarchy.

We now look at alternative reductions of our $2+1$ system to hierarchies in $1+1$ dimensions. We begin by taking the reduction $\partial_{t_n}=0$, which requires $a_{t_n}=q_{i,t_n}=\lambda_{t_n}=0$, and which leads to the system,

$$0=\theta[U]W_n\,, \tag{4.44}$$

$$W_n=(K[U]\theta[U])^{n-1}K[U]U_y+a(K[U]\theta[U])^{n-1}H_1[U]-\sum_{i=1}^{n} q_i(K[U]\theta[U])^{n-i}x. \tag{4.45}$$

This corresponds to a nonisospectral deformation of inverse KK flows,

$$\mathcal{R}^nU_y+a\mathcal{R}^{n-1}\theta[U]H_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x=0. \tag{4.46}$$

If we make the further reduction $W_n=0$ in (4.44), (4.45) then we obtain the hierarchy

$$(K[U]\theta[U])^{n-1}K[U]U_y+a(K[U]\theta[U])^{n-1}H_1[U]-\sum_{i=1}^{n} q_i(K[U]\theta[U])^{n-i}x=0, \tag{4.47}$$

which again in the general case is nonisospectral. The Lax pairs for Eqs. (4.46) and (4.47) follow from the Lax pairs for our $2+1$-dimensional system. In the special case where all $q_i=0$ these Lax pairs are isospectral.

B. Reductions to hierarchies of ODEs

We now consider reductions from the $1+1$-dimensional systems given in the previous section to hierarchies of integrable ODEs. In what follows we consider reductions to four different hierarchies of ODEs. The local cases of two of these just correspond to similarity reductions of the two sequences of the KK hierarchy, and are known.[21,22] The local cases of the other two hierarchies appear to be analogous to the P_{I} hierarchy and are new. Only the first member of each of these, which are P_{I} and a fourth order equation found by Cosgrove,[30] was known previously. The results presented here for this fourth order ODE, namely, integrable PDEs from which it can be obtained as a reduction, and the underlying linear problems for those PDEs and also for the ODE, are all new. Similarly for every member of these two new sequences of ODEs (except of course for P_{I}).

We begin by considering the reduction $\partial_{t_n}=0$ of the hierarchies (4.40) and (4.43), which gives

$$\mathcal{R}^nU_x-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x=0 \tag{4.48}$$

and

$$\mathcal{R}^{n-1}\theta[U]H_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x=0, \tag{4.49}$$

respectively. All q_i are now of course just constant parameters. The inclusion of the nonlocal terms in the above two hierarchies is new. The same two sequences of ODEs can also be obtained from the reductions $\partial_y=\partial_x$ and $a=0$, and $\partial_y=0$ and $a=1$, respectively, of (4.46). Both of these reductions constitute a generalization of the approach in Ref. 15.

The linear problem for (4.48) is given by

$$\psi_{xxx}=-2U\psi_x-(U_x-\lambda)\psi, \tag{4.50}$$

$$-3\lambda\left(\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i\right)\psi_\lambda=A_n\psi_{xx}+[(-27\lambda^2)^n+B_n]\psi_x+\frac{1}{3}(4UA_n-A_{n,xx}-3B_{n,x})\psi, \tag{4.51}$$

where we must assume of course that not all q_i are zero, and where

$$A_n=-18\lambda\,\partial_x^{-1}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i\,, \tag{4.52}$$

$$B_n=9\lambda\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i+\sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i\,, \tag{4.53}$$

W_i is as given by (4.39) and $Q_i=\theta[U]W_i$ $(Q_0=U_x)$.

The linear problem for (4.49) is given by

$$\psi_{xxx}=-2U\psi_x-(U_x-\lambda)\psi, \tag{4.54}$$

$$-3\lambda\left(\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i\right)\psi_\lambda=A_n\psi_{xx}+B_n\psi_x+\frac{1}{3}(4UA_n-A_{n,xx}-3B_{n,x})\psi, \tag{4.55}$$

where again we must assume that not all q_i are zero, and where

$$A_n=-9\lambda(-27\lambda^2)^{n-1}-18\lambda\,\partial_x^{-1}\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}Q_i\,, \tag{4.56}$$

$$B_n=9\lambda\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}Q_i+\sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i\,, \tag{4.57}$$

W_i is as given by (4.42) and $Q_i=\theta[U]W_i$ (and we have used the fact that $Q_0=0$). It is then straightforward to give corresponding matrix linear problems for the hierarchies (4.48) and (4.49).

In the local case $q_i=0$, $i=1,...,n-1$, the sequences of ODEs (4.48) and (4.49) become

$$\mathcal{R}^nU_x-q_n(2U+xU_x)=0, \tag{4.58}$$

and

$$\mathcal{R}^{n-1}\theta[U]H_1[U]-q_n(2U+xU_x)=0, \tag{4.59}$$

where our requirement now is that $q_n\neq 0$. These ODEs are just similarity reductions of the KK hierarchy.[21,22] First integrals for every member of these hierarchies are given in Refs. 21, 22, and also in Ref. 30 for the case $n=1$ of (4.59). This case $n=1$ of (4.59) was derived in Ref. 30 using Painlevé classification.

Let us now consider reductions to what are arguably more interesting sequences of ODEs. Instead of simply taking the reduction $\partial_{t_n}=0$ in (4.38), (4.39) and (4.41), (4.42), we take $\partial_{t_n}=0$ and also $W_n=0$ to obtain

$$H_{2n}[U]-\sum_{i=1}^{n}q_i(K[U]\theta[U])^{n-i}x=0 \tag{4.60}$$

and

$$H_{2n-1}[U]-\sum_{i=1}^{n} q_i(K[U]\theta[U])^{n-i}x=0, \tag{4.61}$$

respectively, where again all q_i are just constant parameters. The sequences (4.60) and (4.61) can also be obtained from the reductions $\partial_y=\partial_x$ and $a=0$, and $\partial_y=0$ and $a=1$, respectively, of (4.47). These sequences of ODEs, except for the case $n=1$ of (4.61) which is just the first Painlevé equation P_I, apparently do not arise simply as the (integrated) stationary flow of hierarchies of completely integrable evolution equations. The derivation of the corresponding linear problems is therefore nontrivial, and requires a generalization of the approach in Ref. 15.

The linear problem for (4.60) is given by that for (4.48) but with $W_n=0$. This we can write in the form (here A_n and B_n have been divided by -3λ, and so are different from those defined above)

$$\psi_{xxx}=-2U\psi_x-(U_x-\lambda)\psi, \tag{4.62}$$

$$\left(\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i\right)\psi_\lambda=A_n\psi_{xx}+[9\lambda(-27\lambda^2)^{n-1}+B_n]\psi_x+\frac{1}{3}(4UA_n-A_{n,xx}-3B_{n,x})\psi, \tag{4.63}$$

where we assume that not all q_i are zero, and where

$$A_n=6\partial_x^{-1}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i\,, \tag{4.64}$$

$$B_n=-3\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i+9\lambda\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}W_i\,, \tag{4.65}$$

W_i is as given by (4.39) and $Q_i=\theta[U]W_i$ (and $Q_0=U_x$).

The linear problem for (4.61) is given by that for (4.49) but again with $W_n=0$. This we rewrite as (again A_n and B_n have been divided by -3λ)

$$\psi_{xxx}=-2U\psi_x-(U_x-\lambda)\psi, \tag{4.66}$$

$$\left(\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i\right)\psi_\lambda=A_n\psi_{xx}+B_n\psi_x+\frac{1}{3}(4UA_n-A_{n,xx}-3B_{n,x})\psi, \tag{4.67}$$

where again we must assume that not all q_i are zero, and where

$$A_n=3(-27\lambda^2)^{n-1}+6\partial_x^{-1}\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}Q_i\,, \tag{4.68}$$

$$B_n=-3\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}Q_i+9\lambda\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}W_i\,, \tag{4.69}$$

W_i is as given by (4.42) and $Q_i=\theta[U]W_i$ (and $Q_0=0$).

In the local case $q_i=0$, $i=1,...,n-1$, the sequences of ODEs (4.60) and (4.61) become

$$H_{2n}[U]-q_nx=0, \tag{4.70}$$

and

$$H_{2n-1}[U]-q_nx=0, \tag{4.71}$$

where our requirement now is that $q_n \neq 0$. Corresponding to the above linear problems we can give matrix linear problems with compatibility conditions Eqs. (4.70) and (4.71), rather than their derivatives. For example, that for the case $n=1$ of (4.70) is given in Appendix A. These hierarchies of ODEs (and of course the nonlocal extensions given above) are new. They govern special integrals of similarity reductions of the modified KK/SK hierarchy, and we believe them to be analogous to the P_{I} hierarchy.[22] A further two such sequences can be derived from the SK hierarchy (see Sec. V). Only two of the above ODEs, namely, the case $n=1$ of each sequence, are known. The case $n=1$ of (4.70) is a special case of an ODE obtained by Cosgrove using Painlevé classification.[30] The linear problem given above is new. The case $n=1$ of (4.71) is just the first Painlevé equation P_{I}. This ODE does of course have a second order linear problem. However here it appears as the first member of a sequence of ODEs for which we can give third order linear problems.

Remark one: It is possible to generalize the above results if we allow functions of integration to be included under the application of the recursion operator. This can be done by including extra terms in (4.1), (4.2) which explicitly represent the two integrations in the operator $K[U]$ in $\mathcal{R}$. Thus instead of (4.1), (4.2) we could consider the system

$$U_t = \theta[U]W + bU_x, \tag{4.72}$$

$$W = K[U]U_\tau + a(U_{xx} + 4U^2) - qx, \tag{4.73}$$

where $a=a(\tau,t)$ and $b=b(\tau,t)$ are functions of all possible times and y, but not of x. This system has the Lax pair

$$\psi_{xxx} = -2U\psi_x - (U_x - \lambda)\psi, \tag{4.74}$$

$$\begin{aligned}\psi_t = &-27\lambda^2\psi_\tau - 9\lambda[2(\partial_x^{-1}U_\tau) + a]\psi_{xx} + [9\lambda U_\tau + W + b]\psi_x \\ &- [3\lambda U_{x\tau} + 24\lambda U(\partial_x^{-1}U_\tau) + 12a\lambda U + W_x]\psi,\end{aligned} \tag{4.75}$$

where λ satisfies the same Eq. (4.8). The DT (4.12) also holds for this system.

Iterating also on a and b we obtain corresponding to (4.29), (4.30) the hierarchy

$$U_{t_n} = \theta[U]W_n + b_n U_x, \tag{4.76}$$

$$\begin{aligned}W_n = &(K[U]\theta[U])^{n-1}K[U]U_y + \sum_{i=1}^{n} a_i H_{2n-2i+1}[U] \\ &+ \sum_{i=1}^{n-1} b_i H_{2n-2i}[U] - \sum_{i=1}^{n} q_i (K[U]\theta[U])^{n-i}x,\end{aligned} \tag{4.77}$$

and so we see that a_1 here is just the function a appearing in (4.29), (4.30). Corresponding to (4.31) we obtain

$$U_{t_n} = \mathcal{R}^n U_y + \sum_{i=1}^{n} b_i \mathcal{R}^{n-i} U_x + \sum_{i=1}^{n} a_i \mathcal{R}^{n-i}\theta[U]H_1[U] - \sum_{i=1}^{n} q_i \mathcal{R}^{n-i}\theta[U]x, \tag{4.78}$$

and so we see that the extra terms correspond of course to the addition of lower order KK flows. Taking reductions as before we obtain corresponding generalizations of our hierarchies of PDEs in $1+1$ dimensions and also of our hierarchies of ODEs, together with their associated linear problems. In the local case (corresponding, respectively, to (4.58), (4.59), (4.70), (4.71)) these generalized hierarchies of ODEs are

$$\mathcal{R}^n U_x + \sum_{i=1}^{n} a_i \mathcal{R}^{n-i}\theta[U]H_1[U] + \sum_{i=1}^{n} b_i \mathcal{R}^{n-i}U_x - q_n(2U + xU_x) = 0, \tag{4.79}$$

$$\mathcal{R}^{n-1}\theta[U]H_1[U] + \sum_{i=2}^{n} a_i \mathcal{R}^{n-i}\theta[U]H_1[U] + \sum_{i=1}^{n} b_i \mathcal{R}^{n-i}U_x - q_n(2U + xU_x) = 0, \tag{4.80}$$

$$H_{2n}[U] + \sum_{i=1}^{n} a_i H_{2n-2i+1}[U] + \sum_{i=1}^{n} b_i H_{2n-2i}[U] - q_n x = 0, \tag{4.81}$$

$$H_{2n-1}[U] + \sum_{i=2}^{n} a_i H_{2n-2i+1}[U] + \sum_{i=1}^{n} b_i H_{2n-2i}[U] - q_n x = 0, \tag{4.82}$$

where in the last two equations we have taken the reduction $W_n = -b_n$ instead of $W_n = 0$. (In fact our requirement that $q_n \neq 0$ allows us to take $b_n = 0$ in all of the above.) The hierarchies (4.79) and (4.80) are just similarity reductions of sums of KK flows; the results of Refs. 21, 22 on first integrals of (4.58) and (4.59) are easily generalized to this case. For $n=1$ (4.81) is equivalent to Cosgrove's equation,[30] including nondominant terms (see Appendix A). Linear problems for the above four hierarchies follow in the same way as described above.

Remark two: So far we have insisted that not all q_i are zero. If we allow all q_i to vanish, in which case the hierarchies of ODEs (4.79), (4.80), (4.81), and (4.82) are autonomous, then, following the approach in Ref. 33, we can use the linear problems to obtain constants of motion. Equivalently, we could also use the corresponding matrix linear problems. For the case $n=1$ of (4.79) and (4.80) with $q_n = 0$ (ODEs of orders 7 and 5 respectively), we obtain in this way two constants of motion; for (4.80) these are as obtained in Ref. 33 for the corresponding Hénon–Heiles system, the first being just the trivial first integral of (4.80), which corresponds to the energy. For the case $n=1$ of (4.81) with $q_n = 0$ (an ODE of order 4) this approach yields one constant of motion, which in addition to a simple first integral then leads to two constants of motion. These are as found in Ref. 30. For (4.82) with $q_n = 0$, the case $n=1$ is trivial. However the case $n=2$ (an ODE of order eight) is less so, and we are able to obtain three constants of motion.

C. Examples: $n=1$

In the case $n=1$ we can set $U = u_x$, and write the system (4.29), (4.30) locally as

$$u_{xt_1} = W_{1,xxx} + 2u_x W_{1,x} + u_{xx} W_1, \tag{4.83}$$

$$W_{1,x} = u_{xxxxxy} + 10u_{xxxy}u_x + 2u_{xxxx}u_y + 15u_{xxy}u_{xx} + 9u_{xxx}u_{xy} + 16u_{xy}u_x^2 + 16u_{xx}u_x u_y + a(u_{xxxx} + 8u_x u_{xx}) - q_1, \tag{4.84}$$

where $a = a(y,t)$ and $q_1 = q_1(y,t)$. This system is of course just our base equation (4.15), (4.16), which has Lax pair (4.17), (4.18) with $\lambda = \lambda(y,t)$ satisfying (4.19). We now consider reductions of this system to PDEs in $1+1$ dimensions, and also to ODEs.

Our first two reductions are to the PDEs,

$$U_{t_1} = W_{1,xxx} + 2UW_{1,x} + U_x W_1, \tag{4.85}$$

$$W_1 = H_2[U] - q_1 x = U_{xxxx} + 12UU_{xx} + 6U_x^2 + \tfrac{32}{3}U^3 - q_1 x, \tag{4.86}$$

and

$$U_{t_1} = W_{1,xxx} + 2UW_{1,x} + U_x W_1, \tag{4.87}$$

$$W_1 = H_1[U] - q_1 x = U_{xx} + 4U^2 - q_1 x, \tag{4.88}$$

where in each case q_1 is a function of t_1 only. These have temporal part of the Lax pair given, respectively, by

$$\psi_{t_1} = -18\lambda U \psi_{xx} + [-27\lambda^2 + 9\lambda U_x + W_1]\psi_x - [3\lambda U_{xx} + 24\lambda U^2 + W_{1,x}]\psi, \tag{4.89}$$

and

$$\psi_{t_1} = -9\lambda \psi_{xx} + W_1 \psi_x - [12\lambda U + W_{1,x}]\psi, \tag{4.90}$$

where in each case λ is a function of t_1 only and $\lambda_{t_1} = -3\lambda q_1$. This last means that for $q_1 \neq 0$ the above Lax pairs are nonisospectral. When $q_1 = 0$ they become isospectral, in which case (4.85), (4.86) and (4.87), (4.88) reduce to seventh and fifth order KK, respectively.

Our second two reductions to PDEs in $1+1$ dimensions are to

$$0 = W_{1,xxx} + 2u_x W_{1,x} + u_{xx} W_1, \tag{4.91}$$

$$\begin{aligned} W_{1,x} = {} & u_{xxxxxy} + 10u_{xxxy}u_x + 2u_{xxxx}u_y + 15u_{xxy}u_{xx} + 9u_{xxx}u_{xy} \\ & + 16u_{xy}u_x^2 + 16u_{xx}u_x u_y + a(u_{xxxx} + 8u_x u_{xx}) - q_1, \end{aligned} \tag{4.92}$$

and to its further reduction

$$\begin{aligned} 0 = {} & u_{xxxxxy} + 10u_{xxxy}u_x + 2u_{xxxx}u_y + 15u_{xxy}u_{xx} + 9u_{xxx}u_{xy} \\ & + 16u_{xy}u_x^2 + 16u_{xx}u_x u_y + a(u_{xxxx} + 8u_x u_{xx}) - q_1, \end{aligned} \tag{4.93}$$

where in each case a and q_1 are functions of y only. The temporal (now y) part of the Lax pair for (4.91), (4.92) is

$$27\lambda^2 \psi_y = -9\lambda[2u_y + a]\psi_{xx} + [9\lambda u_{xy} + W_1]\psi_x - [3\lambda u_{xxy} + 24\lambda u_x u_y + 12a\lambda u_x + W_{1,x}]\psi, \tag{4.94}$$

and that for (4.93) is

$$9\lambda \psi_y = -3[2u_y + a]\psi_{xx} + 3u_{xy}\psi_x - [u_{xxy} + 8u_x u_y + 4au_x]\psi, \tag{4.95}$$

where in each case λ is a function of y only and $\lambda_y = -q_1/(9\lambda)$. For $q_1 \neq 0$ (4.91), (4.92) is a nonisospectral deformation of an inverse KK flow $\mathcal{R}U_y + a\theta[U]H_1[U] - q_1(2U + xU_x) = 0$ and appears to be new. The case $q_1 = 0$ has isospectral Lax pair. Equation (4.93) also appears to be new and again has isospectral or nonisospectral Lax pair according as to whether $q_1 = 0$ or $q_1 \neq 0$, respectively. Details of the Painlevé analysis of (4.93), and also of the system (4.83), (4.84), can be found in Appendix B.

Our first two reductions to ODEs are to $\mathcal{R}U_x - q_1\theta[U]x = 0$, i.e.,

$$\left(U_{xxxxxx} + 14UU_{xxxx} + 35U_x U_{xxx} + \tfrac{49}{2}U_{xx}^2 + 56U^2 U_{xx} + 70UU_x^2 + \tfrac{56}{3}U^4 \right)_x - q_1(2U + xU_x) = 0, \tag{4.96}$$

and to $\theta[U]H_1[U] - q_1\theta[U]x = 0$, i.e.,

$$(U_{xxxx} + 10UU_{xx} + \tfrac{15}{2}U_x^2 + \tfrac{20}{3}U^3)_x - q_1(2U + xU_x) = 0. \tag{4.97}$$

These ODEs are similarity reductions of seventh and fifth order KK, respectively. They have linear problems with ψ_λ given, respectively, by

$$3\lambda q_1 \psi_\lambda = 18\lambda U \psi_{xx} + [27\lambda^2 - 9\lambda U_x - W_1]\psi_x + [3\lambda(U_{xx} + 8U^2) + W_{1,x}]\psi, \tag{4.98}$$

where W_1 is given by (4.86), and

$$3\lambda q_1\psi_\lambda=9\lambda\psi_{xx}-W_1\psi_x+[12\lambda U+W_{1,x}]\psi, \tag{4.99}$$

where W_1 is given by (4.88), and where in each case $q_1\neq 0$. We note that a matrix linear problem for the ODE (4.97) is known to the author of Ref. 21.

Our second two reductions to ODEs are to $H_2[U]-q_1x=0$, i.e.,

$$U_{xxxx}+12UU_{xx}+6U_x^2+\tfrac{32}{3}U^3-q_1x=0, \tag{4.100}$$

and to $H_1[U]-q_1x=0$, i.e.,

$$U_{xx}+4U^2-q_1x=0. \tag{4.101}$$

These ODEs have linear problems with ψ_λ given by

$$q_1\psi_\lambda=6U\psi_{xx}+[9\lambda-3U_x]\psi_x+[U_{xx}+8U^2]\psi, \tag{4.102}$$

and

$$q_1\psi_\lambda=3\psi_{xx}+4U\psi, \tag{4.103}$$

respectively, where in each case $q_1\neq 0$. Equation (4.101) is of course just P_{I}, which has a well-known second order linear problem. Equation (4.100) is a special case of an ODE found by Cosgrove using Painlevé classification,[30] although the dominant terms are in fact due to Harada and Oishi[37] (see also Ito[38]). The full equation is (4.82) with $n=1$; a matrix linear problem for this ODE is given in Appendix A.

V. THE SAWADA–KOTERA CASE

In this Section we consider a PDE associated with a nonisospectral scattering problem based on a member of the SK hierarchy. We note that the structure of the SK hierarchy bears a close resemblence to that of the KK hierarchy. Moreover, these two hierarchies have the same modified hierarchy, and so are related by a Bäcklund transformation.[18,34]

We write our $2+1$-dimensional member of the SK hierarchy as the system

$$U_t=\theta[U]W, \tag{5.1}$$

$$W=J[U]U_\tau-qx, \tag{5.2}$$

where $q=q(\tau,t)$ is a function of all possible times and y, but not of x, and where the operators $\theta[U]$ and $J[U]$ are defined by[34,35,36]

$$\theta[U]=\partial_x^3+(U\partial_x+\partial_xU), \tag{5.3}$$

$$J[U]=\partial_x^{-1}[\partial_x^5+\tfrac{1}{2}(\partial_x^3U+U\partial_x^3)+\tfrac{1}{8}(\partial_xU^2+U^2\partial_x)]\partial_x^{-1}. \tag{5.4}$$

The recursion operator of the SK hierarchy is given by $\mathcal{R}=\theta[U]J[U]$, so the above system can be written

$$U_t=\mathcal{R}U_\tau-q(2U+xU_x). \tag{5.5}$$

The Lax pair for the system (5.1), (5.2) is

$$\psi_{xxx}=-\tfrac{1}{2}U\psi_x+\lambda\psi, \tag{5.6}$$

$$\psi_t = -27\lambda^2\psi_\tau - \tfrac{3}{4}[6\lambda(\partial_x^{-1}U_\tau) - UU_\tau - U_x(\partial_x^{-1}U_\tau) - 2U_{xx\tau}]\psi_{xx}$$
$$+[\tfrac{3}{4}(6\lambda U_\tau - 2U_xU_\tau - UU_{x\tau} - U_{xx}(\partial_x^{-1}U_\tau) - 2U_{xxx\tau}) + W]\psi_x$$
$$-\tfrac{3}{2}\lambda[2U_{x\tau} + U(\partial_x^{-1}U_\tau)]\psi, \tag{5.7}$$

where the spectral parameter λ, again a function of all possible times and y, but not of x, satisfies the equation

$$\lambda_t = -27\lambda^2\lambda_\tau - 3\lambda q. \tag{5.8}$$

The compatibility condition of this Lax pair reads

$$(\psi_{xxx})_t - (\psi_t)_{xxx} \equiv X_2\psi_{xx} + X_1\psi_x + X_0\psi = 0, \tag{5.9}$$

where

$$X_2 \equiv 3(-W_x + \partial_x J[U]U_\tau - q)_x = 0, \tag{5.10}$$

$$X_1 \equiv \tfrac{3}{2}(-W_x + \partial_x J[U]U_\tau - q)_{xx} + \tfrac{1}{2}(-U_t + \theta[U]W) = 0, \tag{5.11}$$

$$X_0 \equiv 3\lambda(-W_x + \partial_x J[U]U_\tau - q) = 0. \tag{5.12}$$

We note that the spatial part of the above Lax pair and that of the KK hierarchy are related as arising from different scalar representations of the scattering problem for the aforementioned common modified hierarchy.[34]

The above nonisospectral scattering problem, and the corresponding system of PDEs (5.1), (5.2), appear to be new. This system admits the Darboux transformation

$$\tilde{U} = U + 12(\log\psi)_{xx}, \tag{5.13}$$

where we also have a corresponding mapping on W, too long to be included here. This DT is of course the same as that which holds for the $1+1$ SK hierarchy.[26]

As in the previous section, we construct a new hierarchy of PDEs in $2+1$ dimensions having nonisospectral scattering problems; by taking various reductions we obtain new hierarchies of PDEs and ODEs together with their underlying linear problems. Once again we give explicit examples in the cases $n=1$ and $n=2$ (these last can be found in Appendix D).

It is the system (5.1), (5.2) which provides the iteration we use in order to construct our hierarchy of PDEs in $2+1$ dimensions. However the SK hierarchy, just like the KK hierarchy, is a double sequence of PDEs. This double sequence is defined as[34,35,36]

$$U_{\tau_m} = \theta[U]G_m[U], \quad G_{m+2}[U] = J[U]\theta[U]G_m[U], \tag{5.14}$$

where the two starting points

$$G_0[U] = 1 \quad \text{and} \quad G_1[U] = U_{xx} + \tfrac{1}{4}U^2 \tag{5.15}$$

give one sequence beginning with the trivial flow $U_{\tau_0} = U_x$, and another beginning with the fifth order SK equation itself, respectively. In order to include reductions to each of the above sequences in our $2+1$ hierarchy, we make, in the same way as we did in the KK case, a shift in the system (5.1), (5.2). This then leads to the more general base equation,

$$U_{t_1} = \theta[U]W_1, \tag{5.16}$$

$$W_1 = J[U]U_y + a(U_{xx} + \tfrac{1}{4}U^2) - q_1 x, \tag{5.17}$$

where a is a function of all possible times and y, but not of x. This PDE has the Lax pair,

$$\psi_{xxx}=-\tfrac{1}{2}U\psi_x+\lambda\psi, \tag{5.18}$$

$$\begin{aligned}\psi_{t_1}=&-27\lambda^2\psi_y\\&-\tfrac{3}{4}[6\lambda(\partial_x^{-1}U_y)-UU_y-U_x(\partial_x^{-1}U_y)-2U_{xxy}+2a(6\lambda-U_x)]\psi_{xx}\\&+[\tfrac{3}{4}(6\lambda U_y-2U_xU_y-UU_{xy}-U_{xx}(\partial_x^{-1}U_y)-2U_{xxxy}-2aU_{xx})\\&+W_1]\psi_x-\tfrac{3}{2}\lambda[2U_{xy}+U(\partial_x^{-1}U_y)+2aU]\psi,\end{aligned} \tag{5.19}$$

where λ satisfies the equation

$$\lambda_{t_1}=-27\lambda^2\lambda_y-3\lambda q_1. \tag{5.20}$$

The extra term included in (5.17) is just a copy of $G_1[U]$. This means that the $2+1$ nonisospectral hierarchy that we now construct will include amongst its reductions to $1+1$ dimensions both the τ_{2n} and τ_{2n-1} flows of the standard SK hierarchy. We also note that the DT (5.13) holds also for the system (5.16), (5.17).

Following the approach developed in Sec. III, we consider a generic member of this $2+1$ hierarchy,

$$U_{t_n}=\theta[U]W_n, \tag{5.21}$$

and write corresponding generic evolutions of ψ and λ as

$$\psi_{t_n}=\Gamma_n\psi_y+A_n\psi_{xx}+B_n\psi_x+C_n\psi, \tag{5.22}$$

$$\lambda_{t_n}=\Lambda_n, \tag{5.23}$$

where the compatibility condition of (5.22) with (5.6) tells us that we may take

$$C_n=\tfrac{1}{3}(UA_n-A_{n,xx}-3B_{n,x}). \tag{5.24}$$

We then obtain from (5.1), (5.2), (5.7), and (5.8) the recursion relations

$$W_n=J[U]\theta[U]W_{n-1}-q_nx, \tag{5.25}$$

$$\Gamma_n=-27\lambda^2\Gamma_{n-1}, \tag{5.26}$$

$$A_n=-27\lambda^2A_{n-1}-\tfrac{9}{2}\lambda\partial_x^{-1}\theta[U]W_{n-1}+\tfrac{3}{4}[U\theta[U]W_{n-1}+U_x\partial_x^{-1}\theta[U]W_{n-1}+2\partial_x^2\theta[U]W_{n-1}], \tag{5.27}$$

$$\begin{aligned}B_n=&-27\lambda^2B_{n-1}+\tfrac{9}{2}\lambda\theta[U]W_{n-1}\\&-\tfrac{3}{4}\partial_x[U\theta[U]W_{n-1}+U_x\partial_x^{-1}\theta[U]W_{n-1}+2\partial_x^2\theta[U]W_{n-1}]+W_n,\end{aligned} \tag{5.28}$$

$$\Lambda_n=-27\lambda^2\Lambda_{n-1}-3\lambda q_n \tag{5.29}$$

(where we have also iterated on the function q in (5.2)). These recursion relations, together with the base Eq. (5.16), (5.17) and its scattering problem, then yield a hierarchy of evolution equations, which for future convenience we note can be written as

$$U_{t_n}=\theta[U]W_n, \tag{5.30}$$

$$W_n=(J[U]\theta[U])^{n-1}J[U]U_y+a(J[U]\theta[U])^{n-1}G_1[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x, \tag{5.31}$$

or equivalently as

$$U_{t_n}=Q_n=\theta[U]W_n=\mathcal{R}^nU_y+a\mathcal{R}^{n-1}\theta[U]G_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x. \tag{5.32}$$

This hierarchy has the scattering problem

$$\psi_{xxx}=-\tfrac{1}{2}U\psi_x+\lambda\psi, \tag{5.33}$$

$$\psi_{t_n}=(-27\lambda^2)^n\psi_y+A_n\psi_{xx}+B_n\psi_x+C_n\psi, \tag{5.34}$$

where

$$A_n=-\frac{3}{2}a(-27\lambda^2)^{n-1}(6\lambda-U_x)-\frac{9}{2}\lambda\partial_x^{-1}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i + \frac{3}{4}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}[UQ_i+U_x\partial_x^{-1}Q_i+2\partial_x^2Q_i], \tag{5.35}$$

$$B_n=-\frac{3}{2}a(-27\lambda^2)^{n-1}U_{xx}+\frac{9}{2}\lambda\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i -\frac{3}{4}\partial_x\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}[UQ_i+U_x\partial_x^{-1}Q_i+2\partial_x^2Q_i] +\sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i, \tag{5.36}$$

$$C_n=-3a\lambda(-27\lambda^2)^{n-1}U-\frac{3}{2}\lambda\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}[U\partial_x^{-1}Q_i+2Q_{i,x}], \tag{5.37}$$

C_n being calculated either directly (by iteration) or from (5.24) modulo equations (5.17) and (5.25) and any additive functions of *y* and *t*, and where Q_i is as given by (5.32), and we have set $Q_0=U_y$. The spectral parameter λ satisfies

$$\lambda_{t_n}=(-27\lambda^2)^n\lambda_y-3\lambda\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i. \tag{5.38}$$

Note that in the above

$$B_n=-A_{n,x}+\sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i. \tag{5.39}$$

The first term on the right-hand side of (5.32) represents a nonisospectral extension to $2+1$ dimensions of the standard SK sequence which includes the seventh order flow. The second term is the standard $1+1$-dimensional SK sequence based on the fifth order flow. The last term represents a nonisospectral deformation which gives rise to nonautonomous terms; for $n>1$, these are in the general case nonlocal. This $2+1$ hierarchy can be written locally using suitable auxiliary dependent variables. The DT (5.13) holds, of course, for every member of this hierarchy. Allowing τ in (5.1), (5.2) to be a vector would allow us to construct a hierarchy consisting of linear combinations of the above flows.

This hierarchy of PDEs in $2+1$ dimensions is new. We now consider reductions of this hierarchy to $1+1$ dimensions and also to ODEs. In both cases we again obtain new hierarchies of equations together with their underlying linear problems.

A. Reductions to hierarchies of PDEs in 1+1 dimensions

As we did above in the KK case, we now discuss reductions to $1+1$ dimensions of our $2+1$ hierarchy. Once again, we begin by looking at reductions which give nonisospectral deformations of the standard flows in $1+1$ dimensions (5.14), (5.15).

Our first reduction is via $\partial_y=\partial_x$ and $a=0$. This then requires $q_{i,y}=\lambda_y=0$ and leads to the sequence of equations

$$U_{t_n}=\theta[U]W_n\,, \tag{5.40}$$

$$W_n=G_{2n}[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x, \tag{5.41}$$

which we can also write as

$$U_{t_n}=\mathcal{R}^n U_x-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x. \tag{5.42}$$

This is a nonisospectral deformation of the standard SK sequence which includes the trivial and seventh order flows ($n=0$ and $n=1$, respectively). The Lax pair follows easily from that for our $2+1$ system.

Our second reduction is via $\partial_y=0$ and $a=1$. This requires $q_{i,y}=\lambda_y=0$ and leads to

$$U_{t_n}=\theta[U]W_n\,, \tag{5.43}$$

$$W_n=G_{2n-1}[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x, \tag{5.44}$$

which we can also write as

$$U_{t_n}=\mathcal{R}^{n-1}\theta[U]G_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x. \tag{5.45}$$

This is a nonisospectral deformation of the standard SK sequence which includes fifth order SK itself $(n=1)$. Again the Lax pair follows easily from that for our $2+1$ system.

We see from the above that the t_n flow has as reductions nonisospectral deformations of both the τ_{2n} and τ_{2n-1} flows of the SK hierarchy. For $n>1$ the additional nonautonomous terms are in the general case nonlocal. In the special case where all $q_i=0$ we just recover the standard $1+1$-dimensional SK hierarchy.

We now look at alternative reductions of our $2+1$ system to hierarchies in $1+1$ dimensions. We begin by taking the reduction $\partial_{t_n}=0$, which requires $a_{t_n}=q_{i,t_n}=\lambda_{t_n}=0$, and which leads to the system,

$$0=\theta[U]W_n\,, \tag{5.46}$$

$$W_n=(J[U]\theta[U])^{n-1}J[U]U_y+a(J[U]\theta[U])^{n-1}G_1[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x. \tag{5.47}$$

This corresponds to a nonisospectral deformation of inverse SK flows,

$$\mathcal{R}^nU_y+a\mathcal{R}^{n-1}\theta[U]G_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x=0. \tag{5.48}$$

If we make the further reduction $W_n=0$ in (5.46), (5.47) then we obtain the hierarchy

$$(J[U]\theta[U])^{n-1}J[U]U_y+a(J[U]\theta[U])^{n-1}G_1[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x=0, \tag{5.49}$$

which again in the general case is nonisospectral. The Lax pairs for Eqs. (5.48) and (5.49) follow from the Lax pairs for our $2+1$-dimensional system. In the special case where all $q_i=0$ these Lax pairs are isospectral.

B. Reductions to hierarchies of ODEs

We now consider reductions from the $1+1$-dimensional systems given in the previous section to hierarchies of integrable ODEs. In what follows we consider reductions to four different hierarchies of ODEs. The local cases of two of these just correspond to similarity reductions of the two sequences of the SK hierarchy, and are known.[21,22] The local cases of the other two hierarchies again appear to be analogous to the P_{I} hierarchy, and are new. The first member of each of these is in fact equivalent under a simple rescaling to the corresponding first member of each of the two new hierarchies of ODEs obtained in Sec. IV. The linear problems and other results given here for these two hierarchies are new (except again for P_{I}).

We begin by considering the reduction $\partial_{t_n}=0$ of the hierarchies (5.42) and (5.45), which gives

$$\mathcal{R}^nU_x-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x=0 \tag{5.50}$$

and

$$\mathcal{R}^{n-1}\theta[U]G_1[U]-\sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x=0, \tag{5.51}$$

respectively, where all q_i are now just constant parameters. The inclusion of the nonlocal terms in the above two hierarchies is new. The same two sequences of ODEs can also be obtained from the reductions $\partial_y=\partial_x$ and $a=0$, and $\partial_y=0$ and $a=1$, respectively, of (5.48). Again these last two reductions constitute a generalization of the approach in Ref. 15.

The linear problem for (5.50) is given by

$$\psi_{xxx}=-\tfrac{1}{2}U\psi_x+\lambda\psi, \tag{5.52}$$

$$-3\lambda\left(\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i\right)\psi_\lambda=A_n\psi_{xx}+[(-27\lambda^2)^n+B_n]\psi_x+C_n\psi, \tag{5.53}$$

where we must assume of course that not all q_i are zero, and where

$$A_n=-\frac{9}{2}\lambda\partial_x^{-1}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i+\frac{3}{4}\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}[UQ_i+U_x\partial_x^{-1}Q_i+2\partial_x^2Q_i], \tag{5.54}$$

$$B_n=-A_{n,x}+\sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i, \tag{5.55}$$

$$C_n=-\frac{3}{2}\lambda\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}[U\partial_x^{-1}Q_i+2Q_{i,x}], \tag{5.56}$$

W_i is as given by (5.41) and $Q_i=\theta[U]W_i$ ($Q_0=U_x$).

The linear problem for (5.51) is given by

$$\psi_{xxx}=-\tfrac{1}{2}U\psi_x+\lambda\psi, \tag{5.57}$$

$$-3\lambda\left(\sum_{i=1}^{n}(-27\lambda^2)^{n-i}q_i\right)\psi_\lambda=A_n\psi_{xx}+B_n\psi_x+C_n\psi, \tag{5.58}$$

where again we must assume that not all q_i are zero, and where

$$A_n=-\frac{3}{2}(-27\lambda^2)^{n-1}(6\lambda-U_x)-\frac{9}{2}\lambda\partial_x^{-1}\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}Q_i$$
$$+\frac{3}{4}\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}[UQ_i+U_x\partial_x^{-1}Q_i+2\partial_x^2Q_i], \tag{5.59}$$

$$B_n=-A_{n,x}+\sum_{i=1}^{n}(-27\lambda^2)^{n-i}W_i, \tag{5.60}$$

$$C_n=-3\lambda(-27\lambda^2)^{n-1}U-\frac{3}{2}\lambda\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}[U\partial_x^{-1}Q_i+2Q_{i,x}], \tag{5.61}$$

W_i is as given by (5.44) and $Q_i=\theta[U]W_i$ (and we have used the fact that $Q_0=0$). Again it is straightforward to give corresponding matrix linear problems for the hierarchies (5.50) and (5.51).

In the local case $q_i=0$, $i=1,...,n-1$, the sequences of ODEs (5.50) and (5.51) become

$$\mathcal{R}^nU_x-q_n(2U+xU_x)=0, \tag{5.62}$$

and

$$\mathcal{R}^{n-1}\theta[U]G_1[U]-q_n(2U+xU_x)=0, \tag{5.63}$$

where our requirement now is that $q_n\neq 0$. These ODEs are similarity reductions of the SK hierarchy.[21,22] First integrals for every member of these hierarchies are given in Refs. 21, 22, and also in Ref. 30 for the case $n=1$ of (5.63). These first integrals of the above hierarchies are related by a Bäcklund transformation to those of the hierarchies (4.58) and (4.59).[22] The case $n=1$ of (5.63) was derived in Ref. 30 using Painlevé classification.

We now consider further reductions, as we did in Sec. IV, to what we again consider to be perhaps more interesting sequences of ODEs. Thus, instead of simply taking the reduction $\partial_{t_n}=0$ in (5.40), (5.41) and (5.43), (5.44), we take $\partial_{t_n}=0$ and also $W_n=0$ to obtain

$$G_{2n}[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x=0 \tag{5.64}$$

and

$$G_{2n-1}[U]-\sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x=0, \tag{5.65}$$

respectively, where again all q_i are constant parameters. The sequences (5.64) and (5.65) can also be obtained from the reductions $\partial_y=\partial_x$, and $a=0$, and $\partial_y=0$ and $a=1$, respectively, of (5.49). As with the two sequences (4.60) and (4.61), it seems that except for the case $n=1$ of (5.65) which is again just the first Painlevé equation P_{I}, these two sequences do not arise as the (integrated) stationary flow of hierarchies of completely integrable evolution equations.

The linear problem for (5.64) is given by that for (5.50) but with $W_n=0$. That is, it is (5.52), (5.53) (where we assume that not all q_i are zero) with A_n given by (5.54), $B_n=-A_{n,x}+\Sigma_{i=1}^{n-1}(-27\lambda^2)^{n-i}W_i$, i.e.,

$$B_n=\frac{9}{2}\lambda\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}Q_i$$
$$-\frac{3}{4}\partial_x\sum_{i=0}^{n-1}(-27\lambda^2)^{n-i-1}[UQ_i+U_x\partial_x^{-1}Q_i+2\partial_x^2Q_i]+\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i}W_i, \tag{5.66}$$

and C_n by (5.56), and where W_i is as given by (5.41) and $Q_i=\theta[U]W_i$ (and $Q_0=U_x$).

The linear problem for (5.65) is given by that for (5.51) but again with $W_n=0$. That is, it is (5.57), (5.58) (where we assume that not all q_i are zero) with A_n given by (5.59), $B_n=-A_{n,x}+\Sigma_{i=1}^{n-1}(-27\lambda^2)^{n-i}W_i$, i.e.,

$$B_n=-\frac{3}{2}(-27\lambda^2)^{n-1}U_{xx}+\frac{9}{2}\lambda\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}Q_i$$
$$-\frac{3}{4}\partial_x\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i-1}[UQ_i+U_x\partial_x^{-1}Q_i+2\partial_x^2Q_i]+\sum_{i=1}^{n-1}(-27\lambda^2)^{n-i}W_i, \tag{5.67}$$

and C_n by (5.61), and where W_i is as given by (5.44) and $Q_i=\theta[U]W_i$ (and $Q_0=0$).

Note that the order of the highest derivative of U appearing in the above two expressions for B_n (in the term $\partial_x^3Q_{n-1}$) is the same as the order of the corresponding ODE ((5.64) or (5.65), respectively), and so this derivative of U can be replaced. In general, the coefficients of W_n and of the highest derivative of U appearing in B_n are inherited from our $2+1$-dimensional scattering problem. In certain of our reductions to PDEs in $1+1$ dimensions and to ODEs, where we can express W_n locally, we can then eliminate either W_n or this highest derivative of U, one in favor of the other, if we so wish. Of the reductions dealt with in the current paper, it is only in the case of those to the ODEs (5.64) and (5.65) that the linear problem contains derivatives of U of the same order as the ODE, which can then be replaced (see our examples later). Doing so then gives a scalar linear problem with compatibility condition (5.64) or (5.65), rather than their derivatives.

In the local case $q_i=0$, $i=1,...,n-1$, the sequences of ODEs (5.64) and (5.65) become

$$G_{2n}[U]-q_nx=0, \tag{5.68}$$

and

$$G_{2n-1}[U]-q_nx=0, \tag{5.69}$$

where our requirement now is that $q_n \neq 0$. Corresponding to the above linear problems we can give matrix linear problems with compatibility conditions (5.68) and (5.69). These hierarchies of ODEs are new, as also are the nonlocal extensions given above. They govern special integrals of similarity reductions of the modified KK/SK hierarchy, and we believe them to be analogous to the P_{I} hierarchy.[22] The first member of each of the above hierarchies is equivalent under a simple rescaling to the corresponding first member of (4.70) and (4.71).

Remark one: Again we can generalize the above results if we allow functions of integration to be included under the application of the recursion operator. Thus instead of (5.1), (5.2) we could consider the system

$$U_t = \theta[U]W + bU_x, \tag{5.70}$$

$$W = J[U]U_\tau + a(U_{xx} + \tfrac{1}{4}U^2) - qx, \tag{5.71}$$

where $a = a(\tau,t)$ and $b = b(\tau,t)$ are functions of all possible times and y, but not of x. This system has the Lax pair

$$\psi_{xxx} = -\tfrac{1}{2}U\psi_x + \lambda\psi, \tag{5.72}$$

$$\begin{aligned}\psi_t = &-27\lambda^2\psi_\tau \\ &- \tfrac{3}{4}[6\lambda(\partial_x^{-1}U_\tau) - UU_\tau - U_x(\partial_x^{-1}U_\tau) - 2U_{xx\tau} + 2a(6\lambda - U_x)]\psi_{xx} \\ &+ [\tfrac{3}{4}(6\lambda U_\tau - 2U_xU_\tau - UU_{x\tau} - U_{xx}(\partial_x^{-1}U_\tau) - 2U_{xxx\tau} - 2aU_{xx}) \\ &+ W + b]\psi_x - \tfrac{3}{2}\lambda[2U_{x\tau} + U(\partial_x^{-1}U_\tau) + 2aU]\psi,\end{aligned} \tag{5.73}$$

where λ satisfies the same equation (5.8). The DT (5.13) also holds for this system.

Iterating also on a and b we obtain corresponding to (5.30), (5.31) the hierarchy

$$U_{t_n} = \theta[U]W_n + b_nU_x, \tag{5.74}$$

$$\begin{aligned}W_n = &(J[U]\theta[U])^{n-1}J[U]U_y + \sum_{i=1}^{n} a_iG_{2n-2i+1}[U] \\ &+ \sum_{i=1}^{n-1} b_iG_{2n-2i}[U] - \sum_{i=1}^{n} q_i(J[U]\theta[U])^{n-i}x,\end{aligned} \tag{5.75}$$

and so we see that a_1 here is the function a appearing in (5.30), (5.31). Corresponding to (5.32) we obtain

$$U_{t_n} = \mathcal{R}^nU_y + \sum_{i=1}^{n} b_i\mathcal{R}^{n-i}U_x + \sum_{i=1}^{n} a_i\mathcal{R}^{n-i}\theta[U]G_1[U] - \sum_{i=1}^{n} q_i\mathcal{R}^{n-i}\theta[U]x, \tag{5.76}$$

and so we see that the extra terms correspond to the addition of lower order SK flows. Taking reductions as before we obtain corresponding generalizations of our hierarchies of PDEs in 1 + 1 dimensions and also of our hierarchies of ODEs, together with their associated linear problems. In the local case (corresponding, respectively, to (5.62), (5.63), (5.68), (5.69)) these generalized hierarchies of ODEs read

$$\mathcal{R}^nU_x + \sum_{i=1}^{n} a_i\mathcal{R}^{n-i}\theta[U]G_1[U] + \sum_{i=1}^{n} b_i\mathcal{R}^{n-i}U_x - q_n(2U + xU_x) = 0, \tag{5.77}$$

$$\mathcal{R}^{n-1}\theta[U]G_1[U]+\sum_{i=2}^{n} a_i\mathcal{R}^{n-i}\theta[U]G_1[U]+\sum_{i=1}^{n} b_i\mathcal{R}^{n-i}U_x-q_n(2U+xU_x)=0, \quad (5.78)$$

$$G_{2n}[U]+\sum_{i=1}^{n} a_iG_{2n-2i+1}[U]+\sum_{i=1}^{n} b_iG_{2n-2i}[U]-q_nx=0, \quad (5.79)$$

$$G_{2n-1}[U]+\sum_{i=2}^{n} a_iG_{2n-2i+1}[U]+\sum_{i=1}^{n} b_iG_{2n-2i}[U]-q_nx=0, \quad (5.80)$$

where in the last two equations we have taken the reduction $W_n=-b_n$ instead of $W_n=0$. (Again, our requirement that $q_n\neq 0$ allows us to take $b_n=0$ in all of the above.) The hierarchies (5.77) and (5.78) are just similarity reductions of sums of SK flows. It is straightforward to give first integrals for these two hierarchies and thus generalize the results of Refs. 21,22 for (5.62) and (5.63). For $n=1$ (5.79) is equivalent to (4.81) (see Appendix A). Linear problems for the above four hierarchies follow in the same way as described above.

Remark two: Once again, we have so far asked that not all q_i are zero. If we allow all q_i to vanish, in which case the hierarchies of ODEs (5.77), (5.78), (5.79), and (5.80) are autonomous, then we are able to use the linear problems to obtain constants of motion. For the case $n=1$ of (5.77) and (5.78) with $q_n=0$, we obtain two constants of motion; for (5.78) these are as obtained in Ref. 33 for the corresponding Hénon–Heiles system, the first being just the trivial first integral of (5.78), which corresponds to the energy. The case $n=1$ of (5.79) with $q_n=0$ is equivalent to the corresponding case of (4.81), and the first integral obtained here is equivalent (modulo the additional simple first integral) to the first integral obtained earlier for the latter. The case $n=1$ of (5.80) with $q_n=0$ is trivial; for the case $n=2$ we obtain three constants of motion.

C. Examples: $n=1$

In the case $n=1$ we can set $U=u_x$, and write the system (5.30), (5.31) locally as

$$u_{xt_1}=W_{1,xxx}+2u_xW_{1,x}+u_{xx}W_1, \quad (5.81)$$

$$W_{1,x}=u_{xxxxxy}+u_{xxxy}u_x+\tfrac{1}{2}u_{xxxx}u_y+\tfrac{3}{2}(u_{xxy}u_{xx}+u_{xxx}u_{xy})$$
$$+\tfrac{1}{4}(u_{xy}u_x^2+u_{xx}u_xu_y)+a(u_{xxxx}+\tfrac{1}{2}u_xu_{xx})-q_1, \quad (5.82)$$

where $a=a(y,t)$ and $q_1=q_1(y,t)$. This system is just our base equation (5.16), (5.17), which has Lax pair (5.18), (5.19) with $\lambda=\lambda(y,t)$ satisfying (5.20). We now consider reductions of this system to PDEs in $1+1$ dimensions, and also to ODEs.

Our first two reductions are to the PDEs,

$$U_{t_1}=W_{1,xxx}+2UW_{1,x}+U_xW_1, \quad (5.83)$$

$$W_1=G_2[U]-q_1x=U_{xxxx}+\tfrac{3}{2}UU_{xx}+\tfrac{3}{4}U_x^2+\tfrac{1}{6}U^3-q_1x \quad (5.84)$$

and

$$U_{t_1}=W_{1,xxx}+2UW_{1,x}+U_xW_1, \quad (5.85)$$

$$W_1=G_1[U]-q_1x=U_{xx}+\tfrac{1}{4}U^2-q_1x, \quad (5.86)$$

where in each case q_1 is a function of t_1 only. These have temporal part of the Lax pair given, respectively, by

$$\psi_{t_1} = -\tfrac{3}{2}[3\lambda U - UU_x - U_{xxx}]\psi_{xx} + [-27\lambda^2 + \tfrac{3}{2}(3\lambda U_x - U_x^2 - UU_{xx} - U_{xxxx}) + W_1]\psi_x - \tfrac{3}{2}\lambda[2U_{xx} + U^2]\psi \tag{5.87}$$

and

$$\psi_{t_1} = -\tfrac{3}{2}(6\lambda - U_x)\psi_{xx} + (W_1 - \tfrac{3}{2}U_{xx})\psi_x - 3\lambda U\psi, \tag{5.88}$$

where in each case λ is a function of t_1 only and $\lambda_{t_1} = -3\lambda q_1$. This last means that for $q_1 \neq 0$ the above Lax pairs are nonisospectral. When $q_1 = 0$ they become isospectral, in which case (5.83), (5.84) and (5.85), (5.86) reduce to seventh and fifth order SK, respectively.

Our second two reductions to PDEs in $1+1$ dimensions are to

$$0 = W_{1,xxx} + 2u_x W_{1,x} + u_{xx} W_1, \tag{5.89}$$

$$W_{1,x} = u_{xxxxxy} + u_{xxxy}u_x + \tfrac{1}{2}u_{xxxx}u_y + \tfrac{3}{2}(u_{xxy}u_{xx} + u_{xxx}u_{xy}) + \tfrac{1}{4}(u_{xy}u_x^2 + u_{xx}u_x u_y) + a(u_{xxxx} + \tfrac{1}{2}u_x u_{xx}) - q_1 \tag{5.90}$$

and to its further reduction

$$0 = u_{xxxxxy} + u_{xxxy}u_x + \tfrac{1}{2}u_{xxxx}u_y + \tfrac{3}{2}(u_{xxy}u_{xx} + u_{xxx}u_{xy}) + \tfrac{1}{4}(u_{xy}u_x^2 + u_{xx}u_x u_y) + a(u_{xxxx} + \tfrac{1}{2}u_x u_{xx}) - q_1, \tag{5.91}$$

where in each case a and q_1 are functions of y only. The temporal (now y) part of the Lax pair for (5.89), (5.90) is

$$27\lambda^2\psi_y = -\tfrac{3}{4}[6\lambda u_y - u_x u_{xy} - u_{xx}u_y - 2u_{xxxy} + 2a(6\lambda - u_{xx})]\psi_{xx} + [\tfrac{3}{4}(6\lambda u_{xy} - 2u_{xx}u_{xy} - u_x u_{xxy} - u_{xxx}u_y - 2u_{xxxxy} - 2au_{xxx}) + W_1] \times \psi_x - \tfrac{3}{2}\lambda[2u_{xxy} + u_x u_y + 2au_x]\psi, \tag{5.92}$$

and that for (5.91) is

$$27\lambda^2\psi_y = -\tfrac{3}{4}[6\lambda u_y - u_x u_{xy} - u_{xx}u_y - 2u_{xxxy} + 2a(6\lambda - u_{xx})]\psi_{xx} + [\tfrac{3}{4}(6\lambda u_{xy} - 2u_{xx}u_{xy} - u_x u_{xxy} - u_{xxx}u_y - 2u_{xxxxy} - 2au_{xxx})]\psi_x - \tfrac{3}{2}\lambda[2u_{xxy} + u_x u_y + 2au_x]\psi, \tag{5.93}$$

where in each case λ is a function of y only and $\lambda_y = -q_1/(9\lambda)$. For $q_1 \neq 0$ (5.89), (5.90) is a nonisospectral deformation of an inverse SK flow $\mathcal{R}U_y + a\theta[U]G_1[U] - q_1(2U + xU_x) = 0$ and appears to be new. The case $q_1 = 0$ has isospectral Lax pair. Equation (5.91) also appears to be new and again has isospectral or nonisospectral Lax pair according as to whether $q_1 = 0$ or $q_1 \neq 0$, respectively. In Appendix B we give details of the Painlevé analysis of (5.91), and also of (5.81), (5.82).

Our first two reductions to ODEs are to $\mathcal{R}U_x - q_1\theta[U]x = 0$, i.e.,

$$(U_{xxxxxx} + \tfrac{7}{2}UU_{xxxx} + \tfrac{7}{2}U_x U_{xxx} + \tfrac{7}{2}U_{xx}^2 + \tfrac{7}{2}U^2 U_{xx} + \tfrac{7}{4}UU_x^2 + \tfrac{7}{24}U^4)_x - q_1(2U + xU_x) = 0, \tag{5.94}$$

and to $\theta[U]G_1[U] - q_1\theta[U]x = 0$, i.e.,

$$(U_{xxxx} + \tfrac{5}{2}UU_{xx} + \tfrac{5}{12}U^3)_x - q_1(2U + xU_x) = 0. \tag{5.95}$$

These ODEs are similarity reductions of seventh and fifth order SK, respectively. They have linear problems with ψ_λ given, respectively, by

$$\begin{aligned}3\lambda q_1\psi_\lambda=&\tfrac{3}{2}[3\lambda U-UU_x-U_{xxx}]\psi_{xx}\\&+[27\lambda^2-\tfrac{3}{2}(3\lambda U_x-U_x^2-UU_{xx}-U_{xxxx})-W_1]\psi_x\\&+\tfrac{3}{2}\lambda[2U_{xx}+U^2]\psi,\end{aligned}\tag{5.96}$$

where W_1 is given by (5.84), and

$$3\lambda q_1\psi_\lambda=\tfrac{3}{2}(6\lambda-U_x)\psi_{xx}+(\tfrac{3}{2}U_{xx}-W_1)\psi_x+3\lambda U\psi,\tag{5.97}$$

where W_1 is given by (5.86), and where in each case $q_1\neq0$. We note that a matrix linear problem for the ODE (5.95) is known to the author of Ref. 21.

Our second two reductions to ODEs are to $G_2[U]-q_1x=0$, i.e.,

$$U_{xxxx}+\tfrac{3}{2}UU_{xx}+\tfrac{3}{4}U_x^2+\tfrac{1}{6}U^3-q_1x=0,\tag{5.98}$$

and to $G_1[U]-q_1x=0$, i.e.,

$$U_{xx}+\tfrac{1}{4}U^2-q_1x=0.\tag{5.99}$$

These ODEs have linear problems with ψ_λ given by

$$\begin{aligned}\lambda q_1\psi_\lambda=&\tfrac{1}{2}[3\lambda U-UU_x-U_{xxx}]\psi_{xx}\\&+[9\lambda^2-\tfrac{1}{2}(3\lambda U_x-\tfrac{1}{4}U_x^2+\tfrac{1}{2}UU_{xx}+\tfrac{1}{6}U^3-q_1x)]\psi_x+\tfrac{1}{2}\lambda[2U_{xx}+U^2]\psi\end{aligned}\tag{5.100}$$

and

$$\lambda q_1\psi_\lambda=\tfrac{1}{2}(6\lambda-U_x)\psi_{xx}+\tfrac{1}{2}(q_1x-\tfrac{1}{4}U^2)\psi_x+\lambda U\psi,\tag{5.101}$$

respectively, where we have used the ODEs (5.98) and (5.99) to replace the highest order derivatives of U, and where in each case $q_1\neq0$. Equation (5.99) is just P_{I}, which again we have placed at the base of a hierarchy of ODEs having third order linear problems. Equation (5.98) can be rescaled onto (4.100) (see Appendix A).

VI. CONCLUSIONS

We have shown that certain PDEs associated with nonisospectral scattering problems in $2+1$ dimensions play an important role in the construction of hierarchies of integrable PDEs and ODEs, together with their underlying linear problems. This approach makes use of a characterization of hierarchies using a single equation. We have thus obtained a wide variety of new hierarchies of integrable PDEs and ODEs. These include new PDEs in $2+1$ dimensions having nonisospectral scattering problems, new PDEs in $1+1$ dimensions having nonisospectral or isospectral scattering problems, and also new ODEs and their corresponding monodromy problems. Certain examples of these last appear to be of particular interest. In addition, we have considered the use of linear problems to derive constants of motion. The examples in this paper are based on KdV, KK, and SK type scattering problems. Further extensions and examples can be found in Ref. 39.

ACKNOWLEDGMENTS

A.P. is grateful to Professor J. M. Cervero for his invitation to visit the University of Salamanca in June 1998, where the main part of this work was completed. A.P. thanks the Ministry of

Education and Culture of Spain for a postdoctoral fellowship. The research in this paper was supported in part by the DGICYT under Contract No. PB95-0947. A.P. and P.R.G. thank Chris Cosgrove for providing them with a copy of Ref. 30.

APPENDIX A: SCALAR AND MATRIX LINEAR PROBLEMS FOR COSGROVE'S EQUATION

Here we give scalar and matrix spectral problems for the fourth order ODEs corresponding to the case $n=1$ of (4.81) and (5.79), that is, for

$$U_{xxxx}+12UU_{xx}+6U_x^2+\tfrac{32}{3}U^3+a_1(U_{xx}+4U^2)-q_1x=0, \tag{A1}$$

and

$$V_{yyyy}+\tfrac{3}{2}VV_{yy}+\tfrac{3}{4}V_y^2+\tfrac{1}{6}V^3+\tilde{a}_1(V_{yy}+\tfrac{1}{4}V^2)-\tilde{q}_1y=0, \tag{A2}$$

where in each case we have used the fact that $q_n\neq 0$ and $\tilde{q}_n\neq 0$ to set the additional additive constant equal to zero. The question of how to find the linear problem for such ODEs would appear to be nontrivial since they apparently do not arise, for example, as the (integrated) stationary flow of an integrable evolution equation. The two PDEs which perhaps most naturally give (A1) and (A2) as reductions, and from which we can most easily obtain the corresponding linear problems, are (4.93) and (5.91), respectively.

The ODEs (A1) and (A2) are related by the transformation

$$U(x)=(V(y)+\tilde{a}_1)/8,\quad x=y-(\tilde{a}_1^3/(12\tilde{q}_1)),\quad a_1=-\tilde{a}_1/2,\quad q_1=\tilde{q}_1/8, \tag{A3}$$

and in turn to the equation found by Cosgrove using Painlevé classification[30] (see also Ref. 37),

$$W_{zzzz}-18WW_{zz}-9W_z^2+24W^3-\alpha W^2-(\alpha^2/9)W-\beta z=0, \tag{A4}$$

by the transformation

$$U(x)=-(3W(z)/2)-(\alpha/24),\quad x=z-(7\alpha^3)/(3888\beta),\quad a_1=\alpha/2,\quad q_1=-3\beta/2. \tag{A5}$$

Here we assume $\beta\neq 0$ and so again set the additive constant to zero. Note that in the gauge chosen by Cosgrove, which removes the W_{zz} term, the coefficient α appears nonlinearly, whereas in our corresponding generalized hierarchies such constants appear linearly (since these consist of a linear combination of such equations).

Our scalar linear problem for (A1) is

$$\psi_{xxx}=-2U\psi_x-(U_x-\lambda)\psi, \tag{A6}$$

$$q_1\psi_\lambda=(6U+3a_1)\psi_{xx}+(9\lambda-3U_x)\psi_x+(U_{xx}+8U^2+4a_1U)\psi, \tag{A7}$$

and that for (A2) is

$$\psi_{yyy}=-\tfrac{1}{2}V\psi_y+\lambda\psi, \tag{A8}$$

$$\begin{aligned}\lambda\tilde{q}_1\psi_\lambda=&\tfrac{1}{2}[3\lambda V-VV_y-V_{yyy}+\tilde{\alpha}_1(6\lambda-V_y)]\psi_{yy}\\&+[9\lambda^2-\tfrac{1}{2}(3\lambda V_y-\tfrac{1}{4}V_y^2+\tfrac{1}{2}VV_{yy}+\tfrac{1}{6}V^3+\tfrac{1}{4}\tilde{a}_1V^2-\tilde{q}_1y)]\psi_y\\&+\tfrac{1}{2}\lambda[2V_{yy}+V^2+2\tilde{a}_1V]\psi.\end{aligned} \tag{A9}$$

We recall that there is a well-known relationship between the two third order operators (A.6) and (A.8).[34]

The compatibility condition of the linear problem (A6), (A7) gives the derivative of (A1). That for (A8), (A9) gives (A2). Corresponding to each of these scalar linear problems we have matrix linear problems with compatibility conditions (A1) and (A2), respectively. The simplest of these is that corresponding to (A6), (A7), i.e.,

$$\mathbf{\Psi}_x=\begin{pmatrix} 0 & 1 & 0\\ -U & 0 & 1\\ -\lambda & -U & 0\end{pmatrix}\mathbf{\Psi}, \tag{A10}$$

$$q_1\mathbf{\Psi}_\lambda=\begin{pmatrix} -(U_{xx}+2U^2+a_1U) & 3(U_x+3\lambda) & -3(2U+a_1)\\ \begin{matrix}-U_{xxx}-7UU_x\\ -3\lambda(U-a_1)-a_1U_x\end{matrix} & 2(U_{xx}+2U^2+a_1U) & 3(3\lambda-U_x)\\ \begin{matrix}2UU_{xx}-U_x^2+\frac{14}{3}U^3\\ +a_1U^2-9\lambda^2-q_1x\end{matrix} & \begin{matrix}U_{xxx}+7UU_x+a_1U_x\\ +3\lambda(a_1-U)\end{matrix} & \begin{matrix}-U_{xx}-2U^2\\ -a_1U\end{matrix}\end{pmatrix}\mathbf{\Psi}. \tag{A11}$$

Corresponding to (A8), (A9) we have a matrix linear problem with

$$\mathbf{\Psi}_y=\begin{pmatrix} 0 & 1 & 0\\ -V/4 & 0 & 1\\ -\lambda-(V_y/4) & -V/4 & 0\end{pmatrix}\mathbf{\Psi}. \tag{A12}$$

The second half of this matrix linear problem is too long to reproduce here.

APPENDIX B: PAINLEVÉ ANALYSIS

In this Appendix we give brief details of the WTC Painlevé test[40] for some of the more fundamental equations presented in this paper. Thus for example for the $2+1$-dimensional system (4.83), (4.84) we seek expansions about a noncharacteristic movable singular manifold $\varphi=0$, assuming a leading order behavior $u\sim u_0\varphi^\alpha$, $W\sim W_0\varphi^\beta$. Without loss of generality we use Kruskal's "reduced ansatz" and take $\varphi=x+\xi(y,t)$ and all coefficients in the expansion to be functions of y and t only. For the system (4.83), (4.84) we thus obtain the families

$$\alpha=-1\quad u_0=3/2\quad \beta=-1\quad W_0\ \text{arbitrary}\quad \{-1,0,1,2,3,4,4,6,8\} \tag{B1}$$

$$\alpha=-1\quad u_0=15/2\quad \beta=-3\quad W_0\ \text{arbitrary}\quad \{-5,-1,0,1,4,6,8,8,12\} \tag{B2}$$

$$\alpha=-1\quad u_0=24\quad \beta=-6\quad W_0=-95040\xi_y\quad \{-11,-5,-1,1,6,8,12,14,18\}, \tag{B3}$$

where for each leading order behavior the set of numbers in braces is the set of indices or "resonances" where arbitrary data is to be introduced into the expansion. The PDE (4.83), (4.84) is then found to pass the WTC Painlevé test.

The system (4.83), (4.84) has as a subequation the $1+1$-dimensional PDE (4.93). This has the families

$$\alpha=-1\quad u_0=3/2\quad \{-1,1,3,4,6,8\}, \tag{B4}$$

$$\alpha=-1\quad u_0=15/2\quad \{-5-1,1,6,8,12\}, \tag{B5}$$

whose leading orders and indices are easily seen to be subsets of those of the above families of (4.83), (4.84) (and so to be consistent under an appropriate reduction). The PDE (4.93) is again found to pass the WTC Painlevé test.

The system (5.81), (5.82) also passes the WTC Painlevé test, with families

$$\alpha=-1 \quad u_0=12 \quad \beta=-4 \quad W_0 \text{ arbitrary} \quad \{-1,0,1,3,4,5,6,8,10\}, \tag{B6}$$

$$\alpha=-1 \quad u_0=60 \quad \beta=1 \quad W_0 \text{ arbitrary} \quad \{-11,-5,-1,0,1,6,8,11,12\}, \tag{B7}$$

$$\alpha=-1 \quad u_0=24 \quad \beta=-6 \quad W_0=1728\xi_y \quad \{-2,-1,1,3,4,6,8,9,14\}. \tag{B8}$$

Again this system has a $1+1$-dimensional subequation, namely, (5.91). This has the families

$$\alpha=-1 \quad u_0=12 \quad \{-1,1,3,4,6,8\}, \tag{B9}$$

$$\alpha=-1 \quad u_0=60 \quad \{-5,-1,1,6,8,12\}, \tag{B10}$$

whose leading orders and indices are clearly subsets of those of the families of (5.81), (5.82). Equation (5.91) also passes the WTC Painlevé test.

The families of (4.83), (4.84) and (5.81), (5.82) correspond to those of seventh order KK and seventh order SK, respectively. Here we have two additional indices (1 and 6) which correspond to having taken a potential and an extra derivative, and the remaining seven indices are then identified with those of the corresponding families of seventh order KK and seventh order SK if we also take account of any shift on the leading order behavior of W (any such shift affects three of the remaining indices). We also note that the actual expansion for W for the family (B7) is $W\sim\xi_t+W_0\varphi$, where the extra lower order term ξ_t restores the dominance in (5.81) (see Ref. 41).

The families of the ODE (A1) (equivalently (A2) or (A4)) correspond in exactly the same way to those of the PDEs (4.93) or (5.91); again we have the two additional indices 1 and 6. Details of the Painlevé analysis of this ODE can be found in Ref. 30 (the dominant terms and corresponding families were first given in Ref. 37).

APPENDIX C: THE KAUP–KUPERSHMIDT CASE: $n=2$

Here we consider reductions of our $2+1$ system (4.29), (4.30) in the special case $n=2$. As described in Sec. IV, we have reductions to PDEs in $1+1$ dimensions, with isospectral and nonisospectral Lax pairs. However here, for reasons of brevity, we restrict ourselves to giving explicitly only the further reductions of these PDEs down to ODEs.

Our first two reductions are to the ODEs $\mathcal{R}^2U_x-q_1\mathcal{R}\theta[U]x-q_2\theta[U]x=0$ and $\mathcal{R}\theta[U]H_1[U]-q_1\mathcal{R}\theta[U]x-q_2\theta[U]x=0$, which we write (here $U_{(4x)}$ means U_{xxxx} and $U^2_{(4x)}$ means $(U_{xxxx})^2$, etc.) as

$$\begin{aligned}
&(U_{(12x)}+26UU_{(10x)}+143U_xU_{(9x)}+494U_{xx}U_{(8x)}+260U^2U_{(8x)}\\
&\quad+1144U_{xxx}U_{(7x)}+2288UU_xU_{(7x)}+1872U_{(4x)}U_{(6x)}+6292UU_{xx}U_{(6x)}\\
&\quad+4459U_x^2U_{(6x)}+\tfrac{3848}{3}U^3U_{(6x)}+\tfrac{2197}{2}U^2_{(5x)}+11102UU_{xxx}U_{(5x)}\\
&\quad+20787U_xU_{xx}U_{(5x)}+12636U^2U_xU_{(5x)}+6374UU^2_{(4x)}+31200U_xU_{xxx}U_{(4x)}\\
&\quad+20618U_{xx}^2U_{(4x)}+26312U^2U_{xx}U_{(4x)}+36634UU_x^2U_{(4x)}+\tfrac{10192}{3}U^4U_{(4x)}\\
&\quad+25480U_{xx}U_{xxx}^2+16146U^2U_{xxx}^2+122694UU_xU_{xx}U_{xxx}+30225U_x^3U_{xxx}\\
&\quad+\tfrac{88816}{3}U^3U_xU_{xxx}+\tfrac{83876}{3}UU_{xx}^3+\tfrac{120315}{2}U_x^2U_{xx}^2+\tfrac{64792}{3}U^3U_{xx}^2\\
&\quad+85176U^2U_x^2U_{xx}+\tfrac{14560}{3}U^5U_{xx}+21021UU_x^4+\tfrac{40040}{3}U^4U_x^2\\
&\quad+\tfrac{4160}{9}U^7)_x-q_1(g_{xxx}+2Ug_x+U_xg)-q_2(2U+xU_x)=0
\end{aligned} \tag{C1}$$

and

$$
\begin{aligned}
&(U_{(10x)}+22U_{(8x)}+99U_xU_{(7x)}+275U_{xx}U_{(6x)}+176U^2U_{(6x)}\\
&\quad+495U_{xxx}U_{(5x)}+1188UU_xU_{(5x)}+\tfrac{605}{2}U_{(4x)}^2+2464UU_{xx}U_{(4x)}\\
&\quad+1716U_x^2U_{(4x)}+\tfrac{1936}{3}U^3U_{(4x)}+1518UU_{xxx}^2+5566U_xU_{xx}U_{xxx}\\
&\quad+4312U^2U_xU_{xxx}+\tfrac{3674}{3}U_{xx}^3+3124U^2U_{xx}^2+8360UU_x^2U_{xx}\\
&\quad+\tfrac{3520}{3}U^4U_{xx}+1089U_x^4+2640U^3U_x^2+\tfrac{1408}{9}U^6)_x\\
&\quad-q_1(g_{xxx}+2Ug_x+U_xg)-q_2(2U+xU_x)=0,
\end{aligned}
\tag{C2}
$$

respectively, where in order to write these ODEs and their corresponding linear problems locally we have defined

$$
g=K[U]f_x \quad \text{and} \quad f_x=\theta[U]x=(2U+xU_x). \tag{C3}
$$

Equation (C1) has linear problem with ψ_λ given by

$$
-3\lambda(q_2-27\lambda^2q_1)\psi_\lambda=A_2\psi_{xx}+[(-27\lambda^2)^2+B_2]\psi_x+\tfrac{1}{3}[4UA_2-A_{2,xx}-3B_{2,x}]\psi, \tag{C4}
$$

where

$$
A_2=-18\lambda\partial_x^{-1}(Q_1-27\lambda^2Q_0), \tag{C5}
$$

$$
B_2=9\lambda(Q_1-27\lambda^2Q_0)+(W_2-27\lambda^2W_1), \tag{C6}
$$

$\partial_x^{-1}Q_0=U,$ W_1 is given by (4.86),

$$
\begin{aligned}
\partial_x^{-1}Q_1&=\partial_x^{-1}\theta[U]W_1\\
&=U_{xxxxxx}+14UU_{xxxx}+35U_xU_{xxx}+\tfrac{49}{2}U_{xx}^2\\
&\quad+56U^2U_{xx}+70UU_x^2+\tfrac{56}{3}U^4-q_1f
\end{aligned}
\tag{C7}
$$

and

$$
\begin{aligned}
W_2&=H_4[U]-(q_1K[U]\theta[U]x+q_2x)\\
&=U_{(10x)}+24UU_{(8x)}+96U_xU_{(7x)}+277U_{xx}U_{(6x)}+212U^2U_{(6x)}\\
&\quad+495U_{xxx}U_{(5x)}+1272UU_xU_{(5x)}+302U_{(4x)}^2+2746UU_{xx}U_{(4x)}\\
&\quad+1563U_x^2U_{(4x)}+\tfrac{2576}{3}U^3U_{(4x)}+1686UU_{xxx}^2+5384U_xU_{xx}U_{xxx}\\
&\quad+5152U^2U_xU_{xxx}+\tfrac{3821}{3}U_{xx}^3+3864U^2U_{xx}^2+8596UU_x^2U_{xx}\\
&\quad+1680U^4U_{xx}+861U_x^4+3360U^3U_x^2+\tfrac{2240}{9}U^6-(q_1g+q_2x).
\end{aligned}
\tag{C8}
$$

Equation (C2) has a linear problem with ψ_λ given by

$$
-3\lambda(q_2-27\lambda^2q_1)\psi_\lambda=A_2\psi_{xx}+B_2\psi_x+\tfrac{1}{3}[4UA_2-A_{2,xx}-3B_{2,x}]\psi, \tag{C9}
$$

where

$$
A_2=-9\lambda(-27\lambda^2)-18\lambda\partial_x^{-1}Q_1, \tag{C10}
$$

$$
B_2=9\lambda Q_1+(W_2-27\lambda^2W_1), \tag{C11}
$$

W_1 is given by (4.88),

$$\partial_x^{-1}Q_1=\partial_x^{-1}\theta[U]W_1=U_{xxxx}+10UU_{xx}+\tfrac{15}{2}U_x^2+\tfrac{20}{3}U^3-q_1f, \tag{C12}$$

and

$$\begin{aligned}W_2&=H_3[U]-(q_1K[U]\theta[U]x+q_2x)\\&=U_{(8x)}+20UU_{(6x)}+60U_xU_{(5x)}+134U_{xx}U_{(4x)}+136U^2U_{(4x)}\\&\quad+84U_{xxx}^2+544UU_xU_{xxx}+408UU_{xx}^2+396U_x^2U_{xx}+\tfrac{1120}{3}U^3U_{xx}\\&\quad+560U^2U_x^2+\tfrac{256}{3}U^5-(q_1g+q_2x).\end{aligned} \tag{C13}$$

In each of the above examples q_1 and q_2 are not both zero. The nonlocal terms included in the above ODEs are new. When $q_1=0$, Eqs. (C1) and (C2) are similarity reductions of thirteenth and eleventh order KK, respectively.

Our second two reductions to ODEs are to $H_4[U]-q_1K[U]\theta[U]x-q_2x=0$ and $H_3[U]-q_1K[U]\theta[U]x-q_2x=0$, which we can write as

$$\begin{aligned}&U_{(10x)}+24UU_{(8x)}+96U_xU_{(7x)}+277U_{xx}U_{(6x)}+212U^2U_{(6x)}\\&\quad+495U_{xxx}U_{(5x)}+1272UU_xU_{(5x)}+302U_{(4x)}^2+2746UU_{xx}U_{(4x)}\\&\quad+1563U_x^2U_{(4x)}+\tfrac{2576}{3}U^3U_{(4x)}+1686UU_{xxx}^2+5384U_xU_{xx}U_{xxx}\\&\quad+5152U^2U_xU_{xxx}+\tfrac{3821}{3}U_{xx}^3+3864U^2U_{xx}^2+8596UU_x^2U_{xx}\\&\quad+1680U^4U_{xx}+861U_x^4+3360U^3U_x^2+\tfrac{2240}{9}U^6-(q_1g+q_2x)=0\end{aligned} \tag{C14}$$

and

$$\begin{aligned}&U_{(8x)}+20UU_{(6x)}+60U_xU_{(5x)}+134U_{xx}U_{(4x)}+136U^2U_{(4x)}\\&\quad+84U_{xxx}^2+544UU_xU_{xxx}+408UU_{xx}^2+396U_x^2U_{xx}+\tfrac{1120}{3}U^3U_{xx}\\&\quad+560U^2U_x^2+\tfrac{256}{3}U^5-(q_1g+q_2x)=0,\end{aligned} \tag{C15}$$

where f and g are as defined in (C3). Both of these ODEs are new.

Equation (C14) has a linear problem with ψ_λ given by (C4) with $W_2=0$, i.e.,

$$(q_2-27\lambda^2q_1)\psi_\lambda=A_2\psi_{xx}+[9\lambda(-27\lambda^2)+B_2]\psi_x+\tfrac{1}{3}[4UA_2-A_{2,xx}-3B_{2,x}]\psi, \tag{C16}$$

where now

$$A_2=6\partial_x^{-1}(Q_1-27\lambda^2Q_0), \tag{C17}$$

$$B_2=-3(Q_1-27\lambda^2Q_0)+9\lambda W_1, \tag{C18}$$

$\partial_x^{-1}Q_0=U$, and W_1 and $\partial_x^{-1}Q_1$ are given by (4.86) and (C7), respectively.

Equation (C15) has a linear problem with ψ_λ given by (C9) with $W_2=0$, i.e.,

$$(q_2-27\lambda^2q_1)\psi_\lambda=A_2\psi_{xx}+B_2\psi_x+\tfrac{1}{3}[4UA_2-A_{2,xx}-3B_{2,x}]\psi, \tag{C19}$$

where now

$$A_2=3(-27\lambda^2)+6\partial_x^{-1}Q_1, \tag{C20}$$

$$B_2=-3Q_1+9\lambda W_1, \tag{C21}$$

and W_1 and $\partial_x^{-1}Q_1$ are given by (4.88) and (C12), respectively.

Once again in each of the above examples q_1 and q_2 are not both zero.

APPENDIX D: THE SAWADA–KOTERA CASE: $n=2$

Here we consider reductions of our $2+1$ system (5.30), (5.31) in the special case $n=2$. As described in Sec. V, we have reductions to PDEs in $1+1$ dimensions, with isospectral and nonisospectral Lax pairs. However as in Appendix C, for reasons of brevity, we restrict ourselves here to giving explicitly only the further reductions of these PDEs down to ODEs.

Our first two reductions are to the ODEs $\mathcal{R}^2U_x-q_1\mathcal{R}\theta[U]x-q_2\theta[U]x=0$ and $\mathcal{R}\theta[U]G_1[U]-q_1\mathcal{R}\theta[U]x-q_2\theta[U]x=0$, which we write as

$$\begin{aligned}(U_{(12x)}&+\tfrac{13}{2}UU_{(10x)}+26U_xU_{(9x)}+\tfrac{169}{2}U_{xx}U_{(8x)}+\tfrac{65}{4}U^2U_{(8x)}\\&+169U_{xxx}U_{(7x)}+104UU_xU_{(7x)}+\tfrac{507}{2}U_{(4x)}U_{(6x)}+\tfrac{1105}{4}UU_{xx}U_{(6x)}\\&+\tfrac{299}{2}U_x^2U_{(6x)}+\tfrac{481}{24}U^3U_{(6x)}+143U_{(5x)}^2+\tfrac{871}{2}UU_{xxx}U_{(5x)}\\&+\tfrac{1443}{2}U_xU_{xx}U_{(5x)}+\tfrac{585}{4}U^2U_xU_{(5x)}+260UU_{(4x)}^2+\tfrac{2067}{2}U_xU_{xxx}U_{(4x)}\\&+\tfrac{3029}{4}U_{xx}^2U_{(4x)}+\tfrac{1235}{4}U^2U_{xx}U_{(4x)}+325UU_x^2U_{(4x)}+\tfrac{637}{48}U^4U_{(4x)}\\&+910U_{xx}U_{xxx}^2+\tfrac{351}{2}U^2U_{xxx}^2+\tfrac{4563}{4}UU_xU_{xx}U_{xxx}+195U_x^3U_{xxx}\\&+\tfrac{2093}{24}U^3U_xU_{xxx}+\tfrac{6799}{24}UU_{xx}^3+\tfrac{1755}{4}U_x^2U_{xx}^2+\tfrac{3367}{48}U^3U_{xx}^2\\&+\tfrac{819}{4}U^2U_x^2U_{xx}+\tfrac{455}{96}U^5U_{xx}+\tfrac{273}{8}UU_x^4+\tfrac{455}{48}U^4U_x^2\\&+\tfrac{65}{576}U^7)_x-q_1(g_{xxx}+2Ug_x+U_xg)-q_2(2U+xU_x)=0\end{aligned}\tag{D1}$$

and

$$\begin{aligned}(U_{(10x)}&+\tfrac{11}{2}UU_{(8x)}+\tfrac{33}{2}U_xU_{(7x)}+44U_{xx}U_{(6x)}+11U^2U_{(6x)}\\&+66U_{xxx}U_{(5x)}+\tfrac{99}{2}UU_xU_{(5x)}+\tfrac{77}{2}U_{(4x)}^2+\tfrac{209}{2}UU_{xx}U_{(4x)}\\&+\tfrac{99}{2}U_x^2U_{(4x)}+\tfrac{121}{12}U^3U_{(4x)}+\tfrac{231}{4}UU_{xxx}^2+187U_xU_{xx}U_{xxx}\\&+\tfrac{187}{4}U^2U_xU_{xxx}+\tfrac{143}{3}U_{xx}^3+\tfrac{77}{2}U^2U_{xx}^2+\tfrac{275}{4}UU_x^2U_{xx}\\&+\tfrac{55}{12}U^4U_{xx}+\tfrac{33}{8}U_x^4+\tfrac{55}{8}U^3U_x^2+\tfrac{11}{72}U^6)_x\\&-q_1(q_{xxx}+2Ug_x+U_xg)-q_2(2U+xU_x)=0,\end{aligned}\tag{D2}$$

respectively, where in order to write these ODEs and their corresponding linear problems locally we have defined

$$g=J[U]f_x\quad\text{and}\quad f_x=\theta[U]x=(2U+xU_x).\tag{D3}$$

Equation (D1) has a linear problem with ψ_λ given by

$$-3\lambda(q_2-27\lambda^2q_1)\psi_\lambda=A_2\psi_{xx}+[(-27\lambda^2)^2+B_2]\psi_x+C_2\psi,\tag{D4}$$

where

$$\begin{aligned}A_2=&-\tfrac{9}{2}\lambda\partial_x^{-1}(Q_1-27\lambda^2Q_0)+\tfrac{3}{4}[(UQ_1+U_x\partial_x^{-1}Q_1+2Q_{1,xx})\\&-27\lambda^2(UQ_0+U_x\partial_x^{-1}Q_0+2Q_{0,xx})],\end{aligned}\tag{D5}$$

$$B_2=-A_{2,x}+(W_2-27\lambda^2W_1),\tag{D6}$$

$$C_2=-\tfrac{3}{2}\lambda[(U\partial_x^{-1}Q_1+2Q_{1,x})-27\lambda^2(U\partial_x^{-1}Q_0+2Q_{0,x})], \tag{D7}$$

$\partial_x^{-1}Q_0=U, W_1$ is given by (5.84),

$$\begin{aligned}\partial_x^{-1}Q_1&=\partial_x^{-1}\theta[U]W_1\\&=U_{xxxxxx}+\tfrac{7}{2}UU_{xxxx}+\tfrac{7}{2}U_xU_{xxx}\\&\quad+\tfrac{7}{2}U_{xx}^2+\tfrac{7}{2}U^2U_{xx}+\tfrac{7}{4}UU_x^2+\tfrac{7}{24}U^4-q_1f\end{aligned} \tag{D8}$$

and

$$\begin{aligned}W_2&=G_4[U]-(q_1J[U]\theta[U]x+q_2x)\\&=U_{(10x)}+\tfrac{9}{2}UU_{(8x)}+18U_xU_{(7x)}+43U_{xx}U_{(6x)}+\tfrac{29}{4}U^2U_{(6x)}\\&\quad+66U_{xxx}U_{(5x)}+\tfrac{87}{2}UU_xU_{(5x)}+\tfrac{155}{4}U_{(4x)}^2+\tfrac{337}{4}UU_{xx}U_{(4x)}\\&\quad+\tfrac{123}{2}U_x^2U_{(4x)}+\tfrac{133}{24}U^3U_{(4x)}+48UU_{xxx}^2+197U_xU_{xx}U_{xxx}\\&\quad+\tfrac{133}{4}U^2U_xU_{xxx}+\tfrac{271}{6}U_{xx}^3+\tfrac{399}{16}U^2U_{xx}^2+\tfrac{259}{4}UU_x^2U_{xx}+\tfrac{35}{16}U^4U_{xx}+\tfrac{63}{8}U_x^4\\&\quad+\tfrac{35}{8}U^3U_x^2+\tfrac{35}{576}U^6-(q_1g+q_2x).\end{aligned} \tag{D9}$$

Equation (D2) has a linear problem with ψ_λ given by

$$-3\lambda(q_2-27\lambda^2q_1)\psi_\lambda=A_2\psi_{xx}+B_2\psi_x+C_2\psi, \tag{D10}$$

where

$$A_2=-\tfrac{3}{2}(-27\lambda^2)(6\lambda-U_x)-\tfrac{9}{2}\lambda\partial_x^{-1}Q_1+\tfrac{3}{4}(UQ_1+U_x\partial_x^{-1}Q_1+2Q_{1,xx}), \tag{D11}$$

$$B_2=-A_{2,x}+(W_2-27\lambda^2W_1), \tag{D12}$$

$$C_2=-3\lambda(-27\lambda^2)U-\tfrac{3}{2}\lambda[U\partial_x^{-1}Q_1+2Q_{1,x}], \tag{D13}$$

W_1 is given by (5.86),

$$\partial_x^{-1}Q_1=\partial_x^{-1}\theta[U]W_1=U_{xxxx}+\tfrac{5}{2}UU_{xx}+\tfrac{5}{12}U^3-q_1f \tag{D14}$$

and

$$\begin{aligned}W_2&=G_3[U]-(q_1J[U]\theta[U]x+q_2x)\\&=U_{(8x)}+\tfrac{7}{2}UU_{(6x)}+\tfrac{21}{2}U_xU_{(5x)}+\tfrac{37}{2}U_{xx}U_{(4x)}+4U^2U_{(4x)}\\&\quad+\tfrac{39}{4}U_{xxx}^2+16UU_xU_{xxx}+12UU_{xx}^2+\tfrac{33}{2}U_x^2U_{xx}+\tfrac{25}{12}U^3U_{xx}\\&\quad+\tfrac{25}{8}U^2U_x^2+\tfrac{1}{12}U^5-(q_1g+q_2x).\end{aligned} \tag{D15}$$

In each of the above examples q_1 and q_2 are not both zero. The nonlocal terms included in the above ODEs are new. In the case $q_1=0$, Eqs. (D1) and (D2) are similarity reductions of thirteenth and eleventh order SK, respectively.

Our second two reductions to ODEs are to $G_4[U]-q_1J[U]\theta[U]x-q_2x=0$ and $G_3[U]-q_1J[U]\theta[U]x-q_2x=0$, which we can write as

$$
\begin{aligned}
&U_{(10x)}+\tfrac{9}{2}UU_{(8x)}+18U_xU_{(7x)}+43U_{xx}U_{(6x)}+\tfrac{29}{4}U^2U_{(6x)}\\
&\quad+66U_{xxx}U_{(5x)}+\tfrac{87}{2}UU_xU_{(5x)}+\tfrac{155}{4}U_{(4x)}^2+\tfrac{337}{4}UU_{xx}U_{(4x)}\\
&\quad+\tfrac{123}{2}U_x^2U_{(4x)}+\tfrac{133}{24}U^3U_{(4x)}+48UU_{xxx}^2+197U_xU_{xx}U_{xxx}\\
&\quad+\tfrac{133}{4}U^2U_xU_{xxx}+\tfrac{271}{6}U_{xx}^3+\tfrac{399}{16}U^2U_{xx}^2+\tfrac{259}{4}UU_x^2U_{xx}\\
&\quad+\tfrac{35}{16}U^4U_{xx}+\tfrac{63}{8}U_x^4+\tfrac{35}{8}U^3U_x^2+\tfrac{35}{576}U^6-(q_1g+q_2x)=0
\end{aligned}
\tag{D16}
$$

and

$$
\begin{aligned}
&U_{(8x)}+\tfrac{7}{2}UU_{(6x)}+\tfrac{21}{2}U_xU_{(5x)}+\tfrac{37}{2}U_{xx}U_{(4x)}+4U^2U_{(4x)}\\
&\quad+\tfrac{39}{4}U_{xxx}^2+16UU_xU_{xxx}+12UU_{xx}^2+\tfrac{33}{2}U_x^2U_{xx}+\tfrac{25}{12}U^3U_{xx}\\
&\quad+\tfrac{25}{8}U^2U_x^2+\tfrac{1}{12}U^5-(q_1g+q_2x)=0,
\end{aligned}
\tag{D17}
$$

where f and g are as defined in (D3). Both of these ODEs are new.

Equation (D16) has a linear problem with ψ_λ given by (D4) with $W_2=0$, i.e., A_2 is as given by (D5), $B_2=-A_{2,x}-27\lambda^2W_1$, and C_2 is as given by (D7). In these expressions for A_2, B_2, and C_2, $\partial_x^{-1}Q_0=U$, W_1 and $\partial_x^{-1}Q_1$ are given by (5.84) and (D8), respectively, and the tenth order derivative of U appearing in B_2 can be replaced using Eq. (D16).

Equation (D17) has a linear problem with ψ_λ given by (D10) with $W_2=0$, i.e., A_2 is as given by (D11), $B_2=-A_{2,x}-27\lambda^2W_1$, and C_2 is as given by (D13). In these expressions for A_2, B_2, and C_2, W_1 and $\partial_x^{-1}Q_1$ are given by (5.86) and (D14), respectively, and the eighth order derivative of U appearing in B_2 can be replaced using Eq. (D17).

Once again in each of the above examples q_1 and q_2 are not both zero.

Elliptic Calogero–Moser systems and isomonodromic deformations

Kanehisa Takasaki[a)]
Department of Fundamental Sciences, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606-8501, Japan

(Received 27 May 1999; accepted for publication 21 July 1999)

We show that various models of the elliptic Calogero–Moser systems are accompanied with an isomonodromic system on a torus. The isomonodromic partner is a nonautonomous Hamiltonian system defined by the same Hamiltonian. The role of the time variable is played by the modulus of the base torus. A suitably chosen Lax pair (with an elliptic spectral parameter) of the elliptic Calogero–Moser system turns out to give a Lax representation of the nonautonomous system as well. This Lax representation ensures that the nonautonomous system describes isomonodromic deformations of a linear ordinary differential equation on the torus on which the spectral parameter of the Lax pair is defined. A particularly interesting example is the ''extended twisted BC_l model'' recently introduced along with some other models by Bordner and Sasaki, who remarked that this system is equivalent to Inozemtsev's generalized elliptic Calogero–Moser system. We use the ''root-type'' Lax pair developed by Bordner *et al.* to formulate the associated isomonodromic system on the torus.
[S0022-2488(99)02911-4]

I. INTRODUCTION

In 1996, Manin[1] proposed a new expression of the sixth Painlevé equation. This is a differential equation of the form

$$(2\pi i)^2 \frac{d^2 q}{d\tau^2} = \sum_{a=0}^{3} \alpha_a \wp'(q+\omega_a), \tag{1}$$

where $\wp'(u)$ is the derivative of the Weierstrass $\wp$ function with primitive periods 1 and τ,

$$\wp(u) = \wp(u|1,\tau) = \frac{1}{u^2} + \sum_{(m,n)\neq(0,0)} \left(\frac{1}{(u+m+n\tau)^2} - \frac{1}{(m+n\tau)^2} \right), \tag{2}$$

ω_a $(a=0,1,2,3)$ are the origin and the three half-periods of the torus $E_\tau = \mathbb{C}/(\mathbb{Z}+\tau\mathbb{Z})$,

$$\omega_0 = 0, \quad \omega_1 = \frac{1}{2}, \quad \omega_2 = \frac{1}{2} + \frac{\tau}{2}, \quad \omega_3 = \frac{\tau}{2}, \tag{3}$$

and α_a $(a=0,1,2,3)$ are the simple linear combinations $(\alpha_0,\alpha_1,\alpha_2,\alpha_3) = (\alpha, -\beta, \gamma, 1/2-\delta)$ of the four parameters α, β, γ, and δ of the sixth Painlevé equation

a)Electronic mail: takasaki@yukawa.kyoto-u.ac.jp

$$\frac{dy^2}{dx^2}=\frac{1}{2}\left(\frac{1}{y}+\frac{1}{y-1}+\frac{1}{y-x}\right)\left(\frac{dy}{dx}\right)^2-\left(\frac{1}{x}+\frac{1}{x-1}+\frac{1}{y-x}\right)\frac{dy}{dx}$$
$$+\frac{y(y-1)(y-x)}{x^2(x-1)^2}\left(\alpha+\beta\frac{x}{y^2}+\gamma\frac{x-1}{(y-1)^2}+\delta\frac{x(x-1)}{(y-x)^2}\right). \tag{4}$$

Manin's equation can be written in the Hamiltonian form

$$2\pi i\frac{dq}{d\tau}=p,\quad 2\pi i\frac{dp}{d\tau}=-\frac{\partial\mathcal{H}}{\partial q}, \tag{5}$$

with the Hamiltonian

$$\mathcal{H}=\frac{1}{2}p^2-\sum_{a=0}^{3}\alpha_a\wp(q+\omega_a). \tag{6}$$

Since the Hamiltonian depends on the modulus τ explicitly, this is a nonautonomous Hamiltonian system. In this new framework, Manin reconsidered the affine Weyl group symmetries of the sixth Painlevé equation discovered by Okamoto,[2] solutions for special values of α, β, γ, and δ constructed by Hitchin,[3] etc.

Manin's equation reveals an unexpected link between the Painlevé equation and the elliptic Calogero–Moser systems, i.e., the Calogero–Moser systems[4] with elliptic potentials. In order to see this relation, we introduce a new variable t and formally replace $2\pi i d/d\tau\to d/dt$ in the aforementioned equations. The outcome is the autonomous equation

$$\frac{d^2q}{dt^2}=\sum_{a=0}^{3}\alpha_a\wp'(q+\omega_a) \tag{7}$$

and its Hamiltonian form

$$\frac{dq}{dt}=p,\quad \frac{dp}{dt}=-\frac{\partial\mathcal{H}}{\partial q}. \tag{8}$$

If all α_n's take the same value $-g^2/8$, one can use an identity of the $\wp$ function to rewrite the above equation as

$$\frac{d^2q}{dt^2}=-\frac{g^2}{8}\sum_{a=0}^{3}\wp'(q+\omega_a)=-g^2\wp'(2q). \tag{9}$$

This is exactly the two-body elliptic Calogero–Moser system; the l-body elliptic Calogero–Moser system (A_{l-1} model) is defined by the Hamiltonian

$$\mathcal{H}=\frac{1}{2}\sum_{j=1}^{l}p_j^2+\frac{g^2}{2}\sum_{j\neq h}\wp(q_j-q_k). \tag{10}$$

As Krichever[5] demonstrated, this elliptic Calogero–Moser system is an isospectral integrable system with a Lax representation

$$\frac{\partial L(z)}{\partial t}=[L(z),M(z)], \tag{11}$$

where the Lax pair $L(z)$ and $M(z)$ are matrix-valued functions of a spectral parameter z on the torus E_τ. Furthermore, the general case falls into Inozemtsev's generalization of the elliptic Calogero–Moser system[6] defined by the Hamiltonian

$$\mathcal{H}=\frac{1}{2}\sum_{j=1}^{l} p_j^2+\frac{g_m^2}{2}\sum_{\epsilon,\epsilon'=\pm 1}\sum_{j\neq k}\wp(\epsilon q_j+\epsilon' q_k)+\frac{1}{2}\sum_{j=1}^{l}\sum_{a=0}^{3} g_a^2\wp(q_j+\omega_a). \tag{12}$$

Levin and Olshanetsky[7] developed a geometric formulation of isomonodromic systems on a general Riemann surface, and characterized Manin's equation as an isomonodromic system on the torus E_τ. Their interpretation of isomonodromic deformations is based on the notion of the Hitchin systems.[8] According to this interpretation, the coordinates q_j of Calogero–Moser particles are identified with the moduli of an SU(l) flat bundle on the torus E_τ, and the L-matrix $L(z)$ is nothing but the Higgs field on this bundle. (Such a link between the elliptic Calogero–Moser systems and the Hitchin systems was already pointed out before their work by Nekrasov[9] and Enriquez and Rubtsov.[10]) Isomonodromic deformations are special deformations of these geometric data as the complex structure of the base torus (or, equivalently, the modulus τ) varies. This geometric picture suggests a wide range of generalizations of isomonodromic deformations (see, e.g., the recent work of Levin and Olshanetsky[11]).

Unfortunately, however, it is only the special case with $\alpha_0=\alpha_1=\alpha_2=\alpha_3$ that was successfully treated in the formulation of Levin and Olshanetsky. This is simply because no suitable Lax representation was available for the Inozemtsev system. Inozemtsev[6] presented a Lax representation, but it is not suited for that purpose.

Recently, a new type of Lax pair—the root type Lax pair—was proposed by Bordner *et al.*[12,13,14] for various models of the elliptic Calogero–Moser systems including the Inozemtsev system. This is a Lax pair constructed on the basis of an underlying root system (e.g., the A_{l-1} root system for the aforementioned elliptic Calogero–Moser system, and the BC_l root system for the Inozemtsev system). The construction covers not only the ordinary elliptic Calogero–Moser systems (the ''untwisted models'') but also the ''twisted models'' introduced by D'Hoker and Phong[15] and their generalizations (the ''extended twisted models''). The Inozemtsev system coincides with the extended twisted BC_l model in the classification of Bordner and Sasaki.[14] In particular, the root type Lax pair for the extended twisted BC_l model gives a Lax representation to the aforementioned isospectral analogue of Manin's equation.

One of the goals of this paper is to show, using the root type Lax pair, that each of these elliptic Calogero–Moser systems are accompanied with an isomonodromic system on a torus. The first step of the construction is simply to replace the equations of motions

$$\frac{dq}{dt}=\{q,\mathcal{H}\},\quad \frac{dp}{dt}=\{p,\mathcal{H}\} \tag{13}$$

of the elliptic Calogero–Moser system by the nonautonomous system

$$2\pi i\frac{dq}{d\tau}=\{q,\mathcal{H}\},\quad 2\pi i\frac{dp}{d\tau}=\{p,\mathcal{H}\} \tag{14}$$

with the same Hamiltonian $\mathcal{H}$. We then rewrite this nonautonomous system into a Lax equation of the form

$$2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}=[L(z),M(z)] \tag{15}$$

using a root type Lax pair $L(z)$ and $M(z)$. This Lax equation implies the Frobenius integrability of the linear system

$$\frac{\partial Y(z)}{\partial z}=L(z)Y(z),\quad 2\pi i\frac{\partial L(z)}{\partial \tau}+M(z)Y(z)=0, \tag{16}$$

from which one can deduce that the non-autonomous system is an isomonodromic system on the torus E_τ.

Actually, we shall use the root type Lax pair made of slightly different building blocks. The root type Lax pairs, like the previously known Lax pairs, contain complex analytic functions $x(u,z)$, $y(u,z)$, etc. that satisfy special functional equations (called the ''Calogero functional equations''[16]). Bordner *et al.* use the Weierstrass sigma function to construct those functions. We use the Jacobi theta function θ_1 instead. This is inspired by the work of Levin and Olshanetsky, who used substantially the same function to construct the *L*-matrix (i.e., the Higgs field in their framework) for isomonodromic systems on a torus. This minuscule difference is rather crucial for deriving an isomonodromic Lax equation as above.

The functions $x(u,z)$ and $y(u,z)$ that we use are, in fact, identical to the functions that Felder and Wieczerkowski[17] used in their study on the Knizhnik–Zamolodchikov–Bernard (KZB) equation.[18] This is by no means a coincidence. As Levin and Olshanetsky stressed, the KZB equation and the Hitchin system (or, rather, its isomonodromic version) are closely related.

In order to illustrate that our method also works for some other cases, we show a construction of an isomonodromic analogue for the ''spin generalization''[19] of the elliptic Calogero–Moser system. Actually, a multispin generalization of this construction is also possible, which is nothing but the genus-one case of Levin and Olshanetsky's framework.

This paper is organized as follows: In Sec. II, we illustrate our construction of isomonodromic systems in the case of the most classical A_{l-1} model. This will serve as a prototype of the subsequent discussion. Section III is devoted to the models treated by the root type Lax pairs, and Sec. IV to the spin generalization. Section V is for concluding remarks. Technically complicated calculations are collected in the Appendices.

II. ISOMONODROMIC SYSTEMS ON THE TORUS: A PROTOTYPE

We start with illustrating our construction for the most fundamental case—the A_{l-1} model and its Lax pair in the vector representation of $\mathrm{SU}(l)$.

A. A_{l-1} model of elliptic Calogero–Moser systems

The A_{l-1} model is defined by the Hamiltonian

$$\mathcal{H}=\frac{1}{2}\sum_{j=1}^{l} p_j^2+\frac{g^2}{2}\sum_{j\neq k}\wp(q_j-q_k). \tag{17}$$

Here q_j and p_j $(j=1,...,l)$ are the coordinates and momenta of the particles with the canonical Poisson brackets

$$\{q_j,p_k\}=\delta_{jk},\quad \{q_j,q_k\}=\{p_j,p_k\}=0. \tag{18}$$

Following Manin's equation, we normalize the primitive periods as

$$2\omega_1=1,\quad 2\omega_3=\tau. \tag{19}$$

The equations of motion are give by the canonical equations

$$\begin{aligned}\frac{dq_j}{dt}&=\{q_j,\mathcal{H}\}=p_j,\\ \frac{dp_j}{dt}&=\{p_j,\mathcal{H}\}=-g^2\sum_{k\neq j}\wp'(q_j-q_k).\end{aligned} \tag{20}$$

This elliptic Calogero–Moser system has a Lax pair of the form

$$L(z)=\sum_{j=1}^{l} p_j E_{jj}+ig\sum_{j\neq k} x(q_j-q_k,z)E_{jk},$$
$$M(z)=\sum_{j=1}^{l} D_j E_{jj}+ig\sum_{j\neq k} y(q_j-q_k,z)E_{jk}, \tag{21}$$

where E_{jk} is the matrix unit, $(E_{jk})_{mn}=\delta_{mj}\delta_{nk}$. The diagonal elements D_j of $M(z)$ are given by

$$D_j=ig\sum_{k\neq j}\wp(q_j-q_k), \tag{22}$$

and $x(u,z)$ is a function that satisfies, along with its u-derivative

$$y(u,z)=\frac{\partial x(u,z)}{\partial u}, \tag{23}$$

the functional equations,

$$x(u,z)y(v,z)-y(u,z)x(v,z)=x(u+v,z)(\wp(u)-\wp(v)), \tag{24}$$

$$x(u,z)y(-u,z)-y(u,z)x(-u,z)=\wp'(u), \tag{25}$$

$$x(u,z)x(-u,z)=\wp(z)-\wp(u). \tag{26}$$

Using these functional equations, one can easily prove the following well known result:[5]

Proposition 1: The matrices L(z) and M(z) satisfy the Lax equation

$$\frac{\partial L(u)}{\partial t}=[L(z),M(z)]. \tag{27}$$

As far as the elliptic Calogero–Moser system is concerned, the choice of $x(u,z)$ and $y(u,y)$ is rather irrelevant. A standard choice is the function

$$x(u,z)=\frac{\sigma(z-u)}{\sigma(z)\sigma(u)}, \tag{28}$$

where $\sigma(u)=\sigma(u|1,\tau)$ is the Weierstrass sigma function with primitive periods 1 and τ.

Thus, the elliptic Calogero–Moser system is an isospectral integrable system. An involutive set of conserved quantities can be extracted from the traces $\mathrm{Tr}\,L(z)^k$, $k=2,3,...$ of powers of the L-matrix. The quadratic trace is substantially the Hamiltonian itself,

$$\mathrm{Tr}\frac{L(z)^2}{2}=\mathcal{H}+(\text{independent of } p \text{ and } q). \tag{29}$$

The functions $x(u,z)$ and $y(u,z)$ based on the sigma function, however, are not very suited for constructing an isomonodromic system. We shall show an alternative in the next subsection.

B. Our choice of $x(u,z)$ and $y(u,z)$

Inspired by the work of Levin and Olshanetsky,[7] we take the following function $x(u,z)$ and its u-derivative $y(u,z)$ for constructing an isomonodromic Lax pair:

$$x(u,z)=\frac{\theta_1(z-u)\theta_1'(0)}{\theta_1(z)\theta_1(u)}. \tag{30}$$

Here $\theta_1(u)$ is one of Jacobi's elliptic theta functions,

$$\theta_1(u)=\theta_1(u|\tau)=-\sum_{n=-\infty}^{\infty}\exp\left(\pi i\tau\left(n+\frac{1}{2}\right)^2+2\pi i\left(n+\frac{1}{2}\right)\left(u+\frac{1}{2}\right)\right), \tag{31}$$

and $\theta_1'(u)$ its derivative. Accordingly, the partner $y(u,z)$ can be written

$$y(u,z)=-x(u,z)(\rho(u)+\rho(z-u)), \tag{32}$$

where $\rho(u)$ denotes the logarithmic derivative of $\theta_1(u)$,

$$\rho(u)=\frac{\theta_1'(u)}{\theta_1(u)}. \tag{33}$$

The function $\rho(u)$, too, plays an important role throughout this paper.

Proposition 2: These functions x(u,z) and y(u,z) satisfy the functional equations (24)–(26) and the differential equation

$$2\pi i\frac{\partial x(u,z)}{\partial\tau}+\frac{\partial^2 x(u,z)}{\partial u\partial z}=0. \tag{34}$$

The last differential equation (a kind of 1+2-dimensional ''heat equation'') is a characteristic of our (x,y) pair, and plays a key role in our construction of isomonodromic systems.

We give a proof of these properties in Appendix A. The following are supplementary remarks on these functions:

(a) The proof of (24–26) is based on the following analytical properties of $x(u,z)$:
(1) $x(u,z)$ is a meromorphic function of u and z. The poles on the u plane and the z plane are both located at the lattice points $u=m+n\tau$ and $z=m+n\tau(m,n\in\mathbb{Z})$.
(2) $x(u,z)$ has the following quasiperiodicity:

$$\begin{gathered}x(u+1,z)=x(u,z),\ \ x(u+\tau,z)=e^{2\pi iz}x(u,z),\\ x(u,z+1)=x(u,z),\ \ x(u,z+\tau)=e^{2\pi iu}x(u,z).\end{gathered} \tag{35}$$

(3) At the origin of the u and z planes, $x(u,z)$ exhibits the following singular behavior:

$$\begin{gathered}x(u,z)=\frac{1}{u}-\rho(z)+O(u)\ \ (u\to 0),\\ x(u,z)=-\frac{1}{z}+\rho(u)+O(z)\ \ (z\to 0).\end{gathered} \tag{36}$$

(b) These properties are an immediate consequence of the following well known facts:
(1) $\theta_1(u)$ is an entire function with simple zeros at the lattice points $u=m+n\tau(m,n\in\mathbb{Z})$.
(2) $\theta_1(u)$ is an odd and quasiperiodic function,

$$\begin{gathered}\theta_1(-u)=\theta_1(u+1)=-\theta_1(u),\\ \theta_1(u+\tau)=-e^{-\pi i\tau-2\pi iu}\theta_1(u).\end{gathered} \tag{37}$$

(c) One can similarly see the following analytical properties of $\rho(u)$:
(1) $\rho(u)$ is a meromorphic function with poles at the lattice points $u=m+n\tau(m,n\in\mathbb{Z})$.
(2) $\rho(u)$ is an odd function with additive quasiperiodicity,

$$\rho(-u)=-\rho(u),\ \ \rho(u+1)=\rho(u),\ \ \rho(u+\tau)=\rho(u)-2\pi i. \tag{38}$$

(3) At the origin $u=0$, $\rho(u)$ exhibits the following singular behavior:

$$\rho(u)=\frac{1}{u}+\frac{\theta_1'''(0)}{3\theta_1'(0)}u+O(u^3)\ \ (u\to 0). \tag{39}$$

(d) The proof of (34) is based on the well known ‘‘heat equation’’

$$4\pi i\frac{\partial\theta_1(u)}{\partial\tau}=\frac{\partial^2\theta_1(u)}{\partial u^2} \tag{40}$$

of the Jacobi theta function.

C. Isomonodromic deformations

Replacing $d/dt\to 2\pi i d/d\tau$, one obtains a nonautonomous Hamiltonian system,

$$\begin{aligned} 2\pi i\frac{dq_j}{d\tau}&=\{q_j,\mathcal{H}\}=p_j,\\ 2\pi i\frac{dp_j}{d\tau}&=\{p_j,\mathcal{H}\}=-g^2\sum_{k\neq j}\wp'(q_j-q_k). \end{aligned} \tag{41}$$

We now demonstrate that this gives an isomonodromic system on the torus E_τ. A key is the following Lax equation:

Proposition 3: L(z) and M(z) satisfy the Lax equation

$$2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}=[L(z),M(z)]. \tag{42}$$

Proof: Let us notice that the right-hand side of the isospectral Lax equation is in fact the Poisson bracket of $L(z)$ and the Hamiltonian,

$$[L(z),M(z)]=\frac{\partial L(z)}{\partial t}=\{L(z),\mathcal{H}\}. \tag{43}$$

Since the phase space and the Hamiltonian are the same as those of the original system, the relation $[L(z),M(z)]=\{L(z),\mathcal{H}\}$ persists in the present setup. Thus the right-hand side of the Lax equation can be written

$$[L(z),M(z)]=\{L(z),\mathcal{H}\}=\sum_{j=1}^{l}\{p_j,\mathcal{H}\}E_{jj}+ig\sum_{j\neq k}\{q_j-q_k,\mathcal{H}\}y(q_j-q_k,z)E_{jk}. \tag{44}$$

On the other hand,

$$\begin{aligned} 2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}&=\sum_{j=1}^{l}2\pi i\frac{dp_j}{d\tau}E_{jj}+ig\sum_{j\neq k}2\pi i\left(\frac{dq_j}{d\tau}-\frac{dq_k}{d\tau}\right)y(q_j-q_k,z)E_{jk}\\ &\quad+ig\sum_{j\neq k}\left(2\pi i\frac{\partial x(u,z)}{\partial\tau}+\frac{\partial y(u,z)}{\partial z}\right)_{u=q_j-q_k}E_{jk}. \end{aligned} \tag{45}$$

The last sum vanishes because of the ‘‘heat equation’’ (34). The other part coincides, term-by-term, with the above expression of the commutator $[L(z),M(z)]$. Q.E.D.

This Lax equation enables us to interpret the nonautonomous Hamiltonian system as an isomonodromic system on the torus E_τ. The Lax equation is nothing but the Frobenius integrability condition of a linear system of the form

$$\frac{\partial Y(z)}{\partial z}=L(z)Y(z),\quad 2\pi i\frac{\partial Y(z)}{\partial \tau}+M(z)Y(z)=0. \tag{46}$$

The first equation is an ordinary differential equation on the torus E_τ, and has a regular singular point at $z=0$. Analytic continuation of the solution along this singular point yields a monodromy matrix Γ_0. Besides this local monodromy matrix, there are global monodromy matrices Γ_α and Γ_β that arise in analytic continuation along the $\alpha(z\to z+1)$ and $\beta(z\to z+\tau)$ cycles. The second equation of the above linear system implies that these monodromy matrices are left invariant as τ varies.

Let us specify this observation in more detail. The situation is more complicated than isomonodromic systems on the Riemann sphere. The monodromy of $L(z)$ and $M(z)$ themselves are nontrivial,

$$L(z+1)=L(z),\quad M(z+1)=M(z),$$
$$L(z+\tau)=e^{2\pi iQ}L(z)e^{-2\pi iQ}, \tag{47}$$
$$M(z+\tau)=e^{2\pi iQ}(M(z)+2\pi iL(z))e^{-2\pi iQ}-2\pi iP,$$

where $Q=\Sigma_{j=1}^{l}q_jE_{jj}$ and $P=\Sigma_{j=1}^{l}p_jE_{jj}$. These relations are a consequence of the quasi-periodicity of $x(u,z)$, $y(u,z)$, and $\rho(z)$. The monodromy of $L(z)$ implies that $Y(z)$ has to be treated as a section of a nontrivial $GL(l,\mathbb{C})$-bundle (or $SL(l,\mathbb{C})$-bundle, if we take the center of mass frame with $\Sigma_{j=1}^{l}p_j=0$) on the torus E_τ. The monodromy matrices Γ_0, Γ_α, and Γ_β thus arise as follows:

$$Y(ze^{2\pi i})=Y(z)\Gamma_0,\quad Y(z+1)=Y(z)\Gamma_\alpha,\quad Y(z+\tau)=e^{2\pi iQ}Y(z)\Gamma_\beta. \tag{48}$$

Note that the exponential factor in the last relation reflects the nontrivial monodromy of $L(z)$ along the β-cycle. Having this monodromy structure of $Y(z)$, one can deduce the following fundamental observation:

Proposition 4: The monodromy matrices do not depend on τ, *i.e.,*

$$\frac{d\Gamma_0}{d\tau}=\frac{d\Gamma_\alpha}{d\tau}=\frac{d\Gamma_\beta}{d\tau}=0. \tag{49}$$

Proof: Let us rewrite the second equation of the linear system as

$$M(z)=-2\pi i\frac{\partial Y(z)}{\partial \tau}Y(z)^{-1}, \tag{50}$$

and examine the implication of the monodromy structure of $Y(z)$ noted above. This leads to the following relations:

$$M(ze^{2\pi i}) = M(z) - 2\pi i Y(z)\frac{\partial \Gamma_0}{\partial \tau}\Gamma_0^{-1}Y(z)^{-1},$$

$$M(z+1) = M(z) - 2\pi i Y(z)\frac{\partial \Gamma_\alpha}{\partial \tau}\Gamma_\alpha^{-1}Y(z)^{-1}, \tag{51}$$

$$M(z+\tau) = e^{2\pi i Q}(M(z)+2\pi i L(z))e^{-2\pi i Q} - 2\pi i P - 2\pi i Y(z)\frac{\partial \Gamma_\beta}{\partial \tau}\Gamma_\beta^{-1}Y(z)^{-1}.$$

(We have used the relation $2\pi i dQ/d\tau = P$.) These relations are consistent with the aforementioned monodromy structure of $M(z)$ if and only if the monodromy matrices of $Y(z)$ are independent of τ. Q.E.D.

III. ELLIPTIC CALOGERO–MOSER SYSTEMS BASED ON ROOT SYSTEMS

Here we consider the elliptic Calogero–Moser systems associated with a general irreducible (but not necessary reduced) root system Δ.

In the following, the root system Δ is assumed to be realized in an l-dimensional Euclidean space $M = \mathbb{R}^l$. Let $x \cdot y$ denote the inner product of two vectors in M and its bilinear extension to the complexification $M^{\mathbb{C}} = M \otimes_{\mathbb{R}} \mathbb{C}$. The dual space $M^* = \mathrm{Hom}(M, \mathbb{R})$ of M is identified with M by this inner product. Each element $\alpha \in \Delta$ induces a reflection (the Weyl reflection) $s_\alpha(x) = x - (2\alpha \cdot x/\alpha \cdot \alpha)\alpha$. This gives a representation of the Weyl group $W(\Delta)$ on M. The root system Δ is invariant under the action of this Weyl group.

The elliptic Calogero–Moser system associated with the root system Δ is a Hamiltonian system on $M \times M$ (or its complexification $M^{\mathbb{C}} \times M^{\mathbb{C}}$). The orthogonal coordinates $(q,p) = (q_1,\ldots,q_l,p_1,\ldots,p_l)$ of $M \times M$ give canonical coordinates and momenta with the Poisson brackets

$$\{q_j,p_k\} = \delta_{jk}, \quad \{p_j,p_k\} = \{q_j,q_k\} = 0. \tag{52}$$

A. Simply laced models

We first consider the case of simply laced (A_{l-1}, D_l, and E_l) root systems. The associated elliptic Calogero–Moser system is defined by the Hamiltonian

$$\mathcal{H} = \frac{1}{2}p \cdot p + \frac{g^2}{2}\sum_{\alpha \in \Delta} \wp(\alpha \cdot q). \tag{53}$$

Here g is a coupling constant, and $\wp(u)$ the Weierstrass $\wp$ function with primitive periods 1 and τ. The equations of motion can be written

$$\frac{dq}{dt} = p, \quad \frac{dp}{dt} = -\frac{g^2}{2}\sum_{\alpha \in \Delta} \wp'(\alpha \cdot q)\alpha. \tag{54}$$

We first review the "root type" Lax pair of Bordner *et al.* for these models,[12] then explain how to convert these isospectral systems to isomonodromic systems.

1. Root-type Lax pair

The "root-type" Lax pair for these simply laced models are $\Delta \times \Delta$ matrices, i.e., matrices whose rows and columns are indexed by the root system Δ. They are made of three parts,

$$L(z) = P + X_1(z) + X_2(z), \quad M(z) = D + Y_1(z) + Y_2(z). \tag{55}$$

P and D are diagonal matrices,

$$P_{\beta\gamma} = p \cdot \beta \delta_{\beta\gamma}, \quad D_{\beta\gamma} = D_\beta \delta_{\beta\gamma} \quad (\beta, \gamma \in \Delta), \tag{56}$$

and the diagonal elements D_β of D are given by

$$D_\beta = ig\wp(\beta\cdot q) + ig\sum_{\gamma\in\Delta,\beta\cdot\gamma=1}\wp(\gamma\cdot q). \tag{57}$$

$X_1(z)$, etc. are diagonal-free matrices of the form

$$\begin{aligned}
X_1(z) &= ig\sum_{\alpha\in\Delta} x(\alpha\cdot q,z)E(\alpha),\\
X_2(z) &= 2ig\sum_{\alpha\in\Delta} x(\alpha\cdot q,2z)E(2\alpha),\\
Y_1(z) &= ig\sum_{\alpha\in\Delta} y(\alpha\cdot q,z)E(\alpha),\\
Y_2(z) &= ig\sum_{\alpha\in\Delta} y(\alpha\cdot q,2z)E(2\alpha),
\end{aligned} \tag{58}$$

where $x(u,z)$ and $y(u,z)$ are the same as the functions used in the previous section, and $E(\alpha)$ and $E(2\alpha)$ are $\Delta\times\Delta$ matrices of the form

$$E(\alpha)_{\beta\gamma} = \delta_{\alpha,\beta-\gamma},\quad E(2\alpha)_{\beta\gamma} = \delta_{2\alpha,\beta-\gamma}\quad (\beta,\gamma\in\Delta). \tag{59}$$

(We have slightly modified the notation of Bordner *et al.*; $x(u,2z)$, $y(u,2z)$, and $E(2\alpha)$ amount to $x_d(u,z)$, $y_d(u,z)$, and $E_d(\alpha)$ in their notation.)

These matrices satisfy the Lax equation

$$\frac{\partial L(z)}{\partial t} = [L(z),M(z)] \tag{60}$$

under the equations of motions. The traces $\mathrm{Tr}\,L(z)^k$, $k=2,3,\ldots$, of powers of $L(z)$ are conserved, and an involutive set of conserved quantities can be extracted from these traces. The Hamiltonian itself can be reproduced from the quadratic trace $\mathrm{Tr}\,L(z)^2$. We refer the details of these results to the paper of Bordner *et al.*[12] The choice of $x(u,z)$ and $y(u,z)$ is irrelevant in this case, too.

Thus, in particular, the A_{l-1} model turns out to have at least two distinct Lax pairs—the Lax pair of $l\times l$ matrices realized in the vector representation of $sl(l)$, and the Lax pair of $l(l-1)\times l(l-1)$ matrices based on the A_{l-1} root system. This is also the case for the other simply laced root systems. Bordner *et al.* call the Lax pairs of the first type the ''minimal type,'' because they are realized in a minimal representation of the associated (not necessary simply laced) Lie algebra. It should be noted that the ''root type'' Lax pairs do not possess a Lie algebraic structure; unlike the usual root basis of simple Lie algebras, the matrices $E(\alpha)$ and $E(2\alpha)$ are not closed under the Lie bracket.

2. Isomonodromic system

The prescription for constructing an isomonodromic analogue is the same as the previous case, namely, to replace $d/dt\to 2\pi i d/d\tau$. This converts the equations of motion of the elliptic Calogero–Moser system to the nonantonomous system

$$2\pi i\frac{dq}{dt} = p,\quad 2\pi i\frac{dp}{dt} = -\frac{g^2}{2}\sum_{\alpha\in\Delta}\wp'(\alpha\cdot q)\alpha. \tag{61}$$

Let $x(u,z)$ be the function defined in (30), and $y(u,z)$ its u-derivative. The following are the keys to an isomonodromic interpretation.

Proposition 5: 1. L(z) and K(z) satisfy the Lax equation

$$2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}=[L(z),M(z)]. \tag{62}$$

2. L(z) and M(z) have the following monodromy properties:

$$\begin{gathered}L(z+1)=L(z),\ \ M(z+1)=M(z),\\ L(z+\tau)=e^{2\pi iQ}L(z)e^{-2\pi iQ},\\ M(z+\tau)=e^{2\pi iQ}(M(z)+2\pi iL(z))e^{-2\pi iQ}-2\pi iP,\end{gathered} \tag{63}$$

where Q is the diagonal matrix with matrix elements $Q_{\beta\gamma}=q\cdot\beta\delta_{\beta\gamma}$.

Proof: The proof is almost the same as the proof for the isomonodromic Lax pair of the A_{l-1} model in the vector representation. Let us first verify the Lax equation. The right-hand side of the Lax equation can be written

$$[L(z),M(z)]=\{P,\mathcal{H}\}+ig\sum_{\alpha\in\Delta}\{\alpha\cdot q,\mathcal{H}\}y(\alpha\cdot q,z)E(\alpha)+2ig\sum_{\alpha\in\Delta}\{\alpha\cdot q,\mathcal{H}\}y(\alpha\cdot q,2z)E(2\alpha). \tag{64}$$

On the other hand,

$$\begin{aligned}2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}=&\,2\pi i\frac{\partial P}{\partial\tau}+ig\sum_{\alpha\in\Delta}2\pi i\frac{\partial\alpha\cdot q}{\partial\tau}y(\alpha\cdot q,z)E(\alpha)\\ &+2ig\sum_{\alpha\in\Delta}2\pi i\frac{\partial\alpha\cdot q}{\partial\tau}y(\alpha\cdot q,2z)E(2\alpha)\\ &+ig\sum_{\alpha\in\Delta}\left(2\pi i\frac{\partial x(u,z)}{\partial\tau}+\frac{\partial y(u,z)}{\partial z}\right)_{u=\alpha\cdot q}E(\alpha)\\ &+2ig\sum_{\alpha\in\Delta}\left(4\pi i\frac{\partial x(u,2z)}{\partial\tau}+\frac{\partial y(u,2z)}{\partial z}\right)_{u=\alpha\cdot q}E(2\alpha).\end{aligned} \tag{65}$$

The last two sums vanish because of (34). The other part coincides by the equations of motion. Thus we obtain the Lax equation. Let us next consider the monodromy of $L(z)$ and $M(z)$. Note the commutation relations

$$[Q,E(\alpha)]=q\cdot\alpha E(\alpha),\ \ [Q,E(2\alpha)]=2q\cdot\alpha E(2\alpha), \tag{66}$$

which can be exponentiated as follows:

$$e^{2\pi iQ}E(\alpha)e^{-2\pi iQ}=e^{2\pi iq\cdot\alpha}E(\alpha),\ \ e^{2\pi iQ}E(2\alpha)e^{-2\pi iQ}=e^{4\pi iq\cdot\alpha}E(2\alpha). \tag{67}$$

The monodromy property of $L(z)$ and $M(z)$ can be derived from these relations and the quasiperiodicity of $x(u,z)$ and $y(u,z)$. Q.E.D.

The rest is parallel to the case in the previous section. The only difference is that the ordinary differential equation

$$\frac{dY(z)}{dz}=L(z)Y(z) \tag{68}$$

on the torus E_τ has *four* regular singular points at $z=0,\omega_1,\omega_2,\omega_3$. The latter three singular points originates in $X_2(z)$. Let Γ_a $(a=0,1,2,3)$ denote the monodromy matrices in analytic continuation of $Y(z)$ around these four points. The Lax equation implies that these local monodromy matrices and the two global ones Γ_α and Γ_β are independent of τ,

$$\frac{\partial\Gamma_0}{\partial\tau}=\cdots=\frac{\partial\Gamma_3}{\partial\tau}=\frac{\partial\Gamma_\alpha}{\partial\tau}=\frac{\partial\Gamma_\beta}{\partial\tau}=0. \tag{69}$$

B. Nonsimply laced models

The elliptic Calogero–Moser system associated with a nonsimply laced (B_l, C_l, F_4, G_2, and BC_l) root systems can have several independent coupling constants, one for each Weyl group orbit in the root system. The root type Lax pairs are extended to the nonsimply laced cases by Bordner *et al.*[13] As they pointed out, one can construct a different root type Lax pair for each Weyl group orbit of the root system. Thus the B_l, C_l, F_4, and G_2 models have, respectively, two distinct Lax pairs based on the orbits of long and short roots, whereas the BC_l model has three based on the orbits of long, middle, and short roots. Note that each Weyl group orbit consists of roots of the same length.

Although all the nonsimply laced models can be treated in the same way, let us illustrate our construction of isomonodromic systems for the BC_l model. This is also intended to be a prototype of the case that we shall consider in the next subsection.

1. BC_l model

The BC_l root system can be realized in $M=\mathbb{R}^l$,

$$\begin{aligned}
&\Delta(BC_l)=\Delta_l\cup\Delta_m\cup\Delta_s,\\
&\Delta_l=\{\pm 2e_j|1\leq j\leq l\}\quad(\text{long roots}),\\
&\Delta_m=\{\pm e_j\pm e_k|j\neq k\}\quad(\text{middle roots}),\\
&\Delta_s=\{\pm e_j|1\leq j\leq l\}\quad(\text{short roots}),
\end{aligned} \tag{70}$$

where $e_1,\ldots,e_l$ are the standard orthonormal basis of $\mathbb{R}^l$. Δ_l, Δ_m, and Δ_s give the three Weyl group orbits.

The Hamiltonian of the BC_l model takes the form

$$\mathcal{H}=\frac{1}{2}p\cdot p+\frac{g_m^2}{2}\sum_{\alpha\in\Delta_m}\wp(\alpha\cdot q)+\frac{g_l^2}{4}\sum_{\alpha\in\Delta_l}\wp(\alpha\cdot q)+\tilde{g}_s^2\sum_{\alpha\in\Delta_s}\wp(\alpha\cdot q). \tag{71}$$

The equations of motion can be written

$$\begin{aligned}
&\frac{dq}{d\tau}=p,\\
&\frac{dp}{d\tau}=-\frac{g_m^2}{2}\sum_{\alpha\in\Delta_m}\wp'(\alpha\cdot q)\alpha-\frac{g_l^2}{4}\sum_{\alpha\in\Delta_l}\wp'(\alpha\cdot q)\alpha-\tilde{g}_s^2\sum_{\alpha\in\Delta_s}\wp'(\alpha\cdot q)\alpha.
\end{aligned} \tag{72}$$

g_m, g_l, and $\tilde{g}_s$ are three independent coupling constants. $\tilde{g}_s$ is a modified (''renormalized'' in the terminology of Bordner *et al.*) coupling constant connected with a more fundamental (''bare,'' so to speak) coupling constant g_s as

$$\tilde{g}_s^2 = g_s^2 + \frac{g_s g_l}{2}. \tag{73}$$

The ''bare'' coupling constant appears in the construction of a Lax pair.

2. Root-type Lax pair for the BC_l model

As mentioned above, there are at least three root type Lax pairs based on the three Weyl group orbits Δ_m, Δ_l, and Δ_s. Bordner *et al.* constructed only one of them, namely, a Lax pair based on Δ_m. Here we present a Lax pair based on Δ_s. This is a $2l \times 2l$ system, much smaller than the Lax pair based on Δ_m, and presumably more suitable for studying the associated isomonodromic deformations.

The Lax pair are indexed by Δ_s and take the following form:

$$\begin{aligned} L(z) &= P + X_1(z) + X_2(z) + X_3(z), \\ M(z) &= D + Y_1(z) + Y_2(z) + Y_3(z). \end{aligned} \tag{74}$$

P and D are diagonal matrices,

$$P_{\beta\gamma} = p \cdot \beta \delta_{\beta\gamma}, \quad D_{\beta\gamma} = D_\beta \delta_{\beta\gamma} \quad (\beta, \gamma \in \Delta_s), \tag{75}$$

and the diagonal elements of D are given by

$$D_\beta = i g_m \sum_{\gamma \in \Delta_s, \beta \cdot \gamma = 1} \wp(\gamma \cdot q) + i g_l \wp(2\beta \cdot q) + i g_s \wp(\beta \cdot q). \tag{76}$$

$X_1(z)$, etc. are diagonal-free matrices of the form

$$\begin{aligned} X_1(z) &= i g_m \sum_{\alpha \in \Delta_m} x(\alpha \cdot q, z) E(\alpha), \quad X_2(z) = i g_l \sum_{\alpha \in \Delta_l} x(\alpha \cdot q, z) E(\alpha), \\ X_3(z) &= 2 i g_s \sum_{\alpha \in \Delta_s} x(\alpha \cdot q, 2z) E(2\alpha), \quad Y_1(z) = i g_m \sum_{\alpha \in \Delta_m} y(\alpha \cdot q, z) E(\alpha), \\ Y_2(z) &= i g_l \sum_{\alpha \in \Delta_l} y(\alpha \cdot q, z) E(\alpha), \quad Y_3(z) = i g_s \sum_{\alpha \in \Delta_s} y(\alpha \cdot q, 2z) E(2\alpha), \end{aligned} \tag{77}$$

where

$$E(\alpha)_{\beta\gamma} = \delta_{\alpha, \beta - \gamma}, \quad E(2\alpha)_{\beta\gamma} = \delta_{2\alpha, \beta - \gamma} \quad (\beta, \gamma \in \Delta_s). \tag{78}$$

This Lax pair is a specialization of the Lax pair for the extended twisted model that we shall present in the next subsection.

3. Isomonodromic system

This system, too, can be converted to an isomonodromic system by replacing $d/dt \to 2\pi i d/d\tau$. The equations of motion are a nonautonomous system of the form

$$\begin{aligned} 2\pi i \frac{dq}{d\tau} &= p, \\ 2\pi i \frac{dp}{d\tau} &= -\frac{g_m^2}{2} \sum_{\alpha \in \Delta_m} \wp'(\alpha \cdot q)\alpha - \frac{g_l^2}{4} \sum_{\alpha \in \Delta_l} \wp'(\alpha \cdot q)\alpha - \tilde{g}_s^2 \sum_{\alpha \in \Delta_s} \wp'(\alpha \cdot q)\alpha. \end{aligned} \tag{79}$$

The following can be verified just as in the case of simply lased models:

(1) $L(z)$ and $M(z)$ satisfy the Lax equation

$$2\pi i \frac{\partial L(z)}{\partial \tau} + \frac{\partial M(z)}{\partial z} = [L(z),M(z)]. \tag{80}$$

(2) $L(z)$ and $M(z)$ have the following monodromy property:

$$L(z+1)=L(z), \quad M(z+1)=M(z),$$

$$L(z+\tau)=\epsilon^{2\pi iQ}L(z)e^{-2\pi iQ}, \tag{81}$$

$$M(z+\tau)=e^{2\pi iQ}(M(z)+2\pi iL(z))e^{-2\pi iQ}-2\pi iP.$$

The interpretation of this Lax equation, too, is parallel to the simply laced models. The ordinary differential equation

$$\frac{dY(z)}{dz}=L(z)Y(z) \tag{82}$$

on the torus E_τ has four regular singular points at $z=0,\omega_1,\omega_2,\omega_3$. The local monodromy matrices Γ_a $(a=0,1,2,3)$ at these points and the global monodromy matrices Γ_α and Γ_β are invariant as τ varies.

C. Twisted and extended twisted models

We now proceed to the ''twisted'' and ''extended twisted'' models. The Hamiltonian of the untwisted models can be generally written

$$\mathcal{H}=\frac{1}{2}p\cdot p+\frac{1}{2}\sum_{\alpha\in\Delta} g_{|\alpha|}^2\wp(\alpha\cdot q). \tag{83}$$

The twisted models, introduced by D'Hoker and Phong[15] for nonsimply laced root systems, are defined by a Hamiltonian of the form

$$\mathcal{H}=\frac{1}{2}p\cdot p+\frac{1}{2}\sum_{\alpha\in\Delta} g_{|\alpha|}^2\wp_{\nu(\alpha)}(\alpha\cdot q), \tag{84}$$

where $\wp_{\nu(\alpha)}(u)$ are the $\wp$-functions with suitably rescaled primitive periods. D'Hoker and Phong proved the integrability of those twisted models by constructing a Lax pair in a representation of the associated Lie algebra. Bordner and Sasaki[14] proposed an alternative approach based on root systems rather than Lie algebras, and pointed out that the twisted model of the B_l, C_l, and BC_l types can be further extended. The extended twisted models have one (for the B_l and C_l models) or two (for the BC_l model) extra types of elliptic potentials.

Our construction of isomonodromic systems can be extended to the twisted and extended twisted models. We illustrate this result, just as in the previous subsection, for the BC_l model. As Bordner and Sasaki noted, the extended twisted BC_l model is made of five different types of elliptic potentials, and coincides with the Inozemtsev system.[6]

1. Extended twisted BC_l model

The extended twisted BC_l model is defined by the Hamiltonian

$$\mathcal{H}=\frac{1}{2}p\cdot p+\frac{g_m^2}{2}\sum_{\alpha\in\Delta_m}\wp(\alpha\cdot q)+\frac{g_{l1}^2}{4}\sum_{\alpha\in\Delta_l}\wp(\alpha\cdot q)+\frac{\tilde{g}_{l2}^2}{4}\sum_{\alpha\in\Delta_l}\wp^{(2)}(\alpha\cdot q)$$
$$+\tilde{g}_{s1}^2\sum_{\alpha\in\Delta_s}\wp(\alpha\cdot q)+\tilde{g}_{s2}^2\sum_{\alpha\in\Delta_s}\wp^{(1/2)}(\alpha\cdot q). \tag{85}$$

$\tilde{g}_{l2}$, $\tilde{g}_{s1}$, and $\tilde{g}_{s2}$ are ''renormalized'' coupling constants, which are related to unrenormalized coupling constants g_{l2}, g_{s1}, and g_{s2} as follows:

$$\tilde{g}_{l2}^2=g_{l2}^2+2g_{l1}g_{l2},$$
$$\tilde{g}_{s1}^2=g_{s1}^2+2g_{s1}g_{s2}+\tfrac{1}{2}(g_{s1}g_{l1}+g_{s1}g_{l2}+g_{s2}g_{l2}), \tag{86}$$
$$\tilde{g}_{s2}^2=g_{s2}^2+\frac{g_{s2}g_{l1}}{2}.$$

$\wp^{(1/2)}$ and $\wp^{(2)}$ are the $\wp$ functions with rescaled primitive periods

$$\wp^{(1/2)}(u)=\wp(u|\tfrac{1}{2},\tau),\quad \wp^{(2)}(u)=\wp(u|2,\tau). \tag{87}$$

(This Hamiltonian is slightly different from the Hamiltonian of Bordner and Sasaki, though the contents are essentially the same. With this modification, this model reduces to the untwisted BC_l model as $g_{l2}\rightarrow 0$ and $g_{s2}\rightarrow 0$.)

2. Root-type Lax pair for the extended twisted BC_l model

One can construct, like the untwisted model, three different root type Lax pairs can be constructed based on the three Weyl group orbits Δ_m, Δ_l, and Δ_s. The Lax pair based on Δ_m is presented by Bordner and Sasaki. The Lax pair based on Δ_s can be obtained by modifying the Lax pair for the untwisted BC_l model as follows.

The Lax pair $L(z)$ and $M(z)$ are indexed by Δ_s and made of four parts,

$$L(z)=P+X_1(z)+X_2(z)+X_3(z),$$
$$M(z)=D+Y_1(z)+Y_2(z)+Y_3(z). \tag{88}$$

The diagonal matrix P is the same as the P in the untwisted model. The diagonal matrices of D are given by

$$D_\beta=ig_m\sum_{\gamma\in\Delta_m,\beta\cdot\gamma=1}\wp(\gamma\cdot q)+ig_{l1}\wp(2\beta\cdot q)+ig_{l2}\wp^{(2)}(2\beta\cdot q)+ig_{s1}\wp(\beta\cdot q)+ig_{s2}\wp^{(1/2)}(\beta\cdot q). \tag{89}$$

$X_1(z)$ and $Y_1(z)$ are the same as those for the untwisted model. The other matrices take the following form:

$$
\begin{aligned}
X_2(z) &= \sum_{\alpha\in\Delta_l} (ig_{l1}x(\alpha\cdot q,z)+ig_{l2}x^{(2)}(\alpha\cdot q,z))E(\alpha),\\
X_3(z) &= \sum_{\alpha\in\Delta_s} (2ig_{s1}x(\alpha\cdot q,2z)+2ig_{s2}x^{(1/2)}(\alpha\cdot q,2z))E(2\alpha),\\
Y_2(z) &= \sum_{\alpha\in\Delta_l} (ig_{l1}y(\alpha\cdot q,z)+ig_{l2}y^{(2)}(\alpha\cdot q,z))E(\alpha),\\
Y_3(z) &= \sum_{\alpha\in\Delta_s} (ig_{s1}y(\alpha\cdot q,2z)+ig_{s2}y^{(1/2)}(\alpha\cdot q,2z))E(2\alpha).
\end{aligned}
\tag{90}
$$

This Lax pair reduces to the Lax pair of the untwisted model if $g_{l2}=0$ and $g_{s2}=0$.

The new objects arising here are the functions $x^{(1/2)}(u,z)$, $x^{(2)}(u,z)$ and their u-derivatives

$$
y^{(1/2)}(u,z)=\frac{\partial x^{(1/2)}(u,z)}{\partial u},\quad y^{(2)}(u,z)=\frac{\partial x^{(2)}(u,z)}{\partial u}.
\tag{91}
$$

For the consistency of the Lax equation

$$
\frac{\partial L(z)}{\partial t}=[L(z),M(z)],
\tag{92}
$$

these functions have to satisfy several functional equations. D'Hoker and Phong[15] and Bordner and Sasaki[14] use a set of functions based on the Weierstrass sigma functions. We use the function $x(u,z)=x(u,z|\tau)$ defined in (30) and its modifications

$$
\begin{aligned}
x^{(1/2)}(u,z) &= 2x(2u,z|2\tau)=\frac{2\theta_1(z-2u|2\tau)\theta_1'(0|2\tau)}{\theta_1(z|2\tau)\theta_1(2u|2\tau)},\\
x^{(2)}(u,z) &= \frac{1}{2}x\left(\frac{u}{2},z\,\middle|\,\frac{\tau}{2}\right)=\frac{\theta_1\left(z-\frac{u}{2}\,\middle|\,\frac{\tau}{2}\right)\theta_1'\left(0\,\middle|\,\frac{\tau}{2}\right)}{2\theta_1\left(z\,\middle|\,\frac{\tau}{2}\right)\theta_1\left(\frac{u}{2}\,\middle|\,\frac{\tau}{2}\right)}.
\end{aligned}
\tag{93}
$$

These functions $x^{(1/2)}(u,z)$ and $x^{(2)}(u,z)$, too, satisfy 1+2-dimensional ''heat equations'' of the form

$$
\begin{aligned}
2\pi i\frac{\partial x^{(1/2)}(u,z)}{\partial\tau}+\frac{\partial^2 x^{(1/2)}(u,z)}{\partial u\,\partial z} &= 0,\\
2\pi i\frac{\partial x^{(2)}(u,z)}{\partial\tau}+\frac{\partial^2 x^{(2)}(u,z)}{\partial u\,\partial z} &= 0.
\end{aligned}
\tag{94}
$$

The functional identities for these functions and the proof of the Lax equation are presented in Appendices B and C.

3. Isomonodromic system

Replacing $d/dt\to 2\pi i d/d\tau$, we obtain a nonautonomous Hamiltonian system with the same Hamiltonian. The isomonodromic interpretation of this nonautonomous system is again based on the following two observations:

(1) $L(z)$ and $M(z)$ satisfy the Lax equation

$$2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}=[L(z),M(z)]. \tag{95}$$

(2) The monodromy of $L(z)$ and $M(z)$ is the same as the monodromy of the Lax pair for the untwisted model,

$$\begin{aligned}L(z+1)&=L(z),\quad M(z+1)=M(z),\\ L(z+\tau)&=e^{2\pi iQ}L(z)e^{-2\pi iQ},\\ M(z+\tau)&=e^{2\pi iQ}(M(z)+2\pi iL(z))e^{-2\pi iQ}-2\pi iP.\end{aligned} \tag{96}$$

The ordinary differential equation defined on the torus E_τ by the matrix $L(z)$ has four regular singular points at $u=0,\omega_1,\omega_2,\omega_3$. The Lax equation and the monodromy of $L(z)$ and $M(z)$ ensure that the local monodromy matrices Γ_α $(a=0,1,2,3)$ and the global monodromy matrices Γ_α and Γ_β are independent of τ.

4. Relation to the Inozemtsev system

The final task is to clarify the relation to the Inozemtsev system. In terms of the orthogonal coordinates $q_j=q\cdot e_j$ and $p_j=p\cdot e_j$ $(j=1,...,l)$, the aforementioned Hamiltonian can be written

$$\begin{aligned}\mathcal{H}=&\frac{1}{2}\sum_{j=1}^{l}p_j^2+\frac{g_m^2}{2}\sum_{\epsilon,\epsilon'=\pm1}\sum_{j\neq k}\wp(\epsilon q_j+\epsilon' q_k)+\frac{g_{l1}^2}{2}\sum_{j=1}^{l}\wp(2q_j)\\ &+\frac{\tilde g_{l2}^2}{2}\sum_{j=1}^{l}\wp^{(2)}(2q_j)+2\tilde g_{s1}^2\sum_{j=1}^{l}\wp(q_j)+2\tilde g_{s2}^2\sum_{j=1}^{l}\wp^{(1/2)}(q_j).\end{aligned} \tag{97}$$

One can rewrite this Hamiltonian using the identities

$$\begin{aligned}\wp(2u)&=\tfrac{1}{4}\wp(u)+\tfrac{1}{4}\wp(u+\omega_1)+\tfrac{1}{4}\wp(u+\omega_2)+\tfrac{1}{4}\wp(u+\omega_3),\\ \wp^{(1/2)}(u)&=\wp(u)+\wp(u+\omega_1)-\wp(\omega_1),\\ \wp^{(2)}(2u)&=\tfrac{1}{4}\wp(u)+\tfrac{1}{4}\wp(u+\omega_3)-\tfrac{1}{4}\wp(\omega_3).\end{aligned} \tag{98}$$

The outcome is, up to a term $h(\tau)$ depending on τ only, the Inozemtsev Hamiltonian

$$\mathcal{H}=\frac{1}{2}\sum_{j=1}^{l}p_j^2+\frac{g_m^2}{2}\sum_{\epsilon,\epsilon'=\pm1}\sum_{j\neq k}\wp(\epsilon q_j+\epsilon' q_k)+\sum_{j=1}^{l}\sum_{a=0}^{3}g_a^2\wp(q_j+\omega_a)+h(\tau). \tag{99}$$

The coupling constants g_a $(a=0,1,2,3)$ are given by

$$g_0^2=\frac{1}{8}(g_{l1}^2+\tilde g_{l2}^2)+2(\tilde g_{s1}^2+\tilde g_{s2}^2),\quad g_1^2=\frac{g_{l1}^2}{8}+2\tilde g_{s2}^2,\quad g_2^2=\frac{g_{l1}^2}{8},\quad g_3^2=\frac{1}{8}(g_{l1}^2+\tilde g_{l2}^2). \tag{100}$$

IV. SPIN GENERALIZATION OF ELLIPTIC CALOGERO–MOSER SYSTEMS

''Spin generalization'' is a generalization of the elliptic Calogero–Moser systems coupled to spin degrees of freedom. Such a spin generalization is characterized by a simple Lie algebra rather than a root system. The (classical) spin variables take values in the dual space $\mathfrak{g}^*$, or a coadjoint orbit therein, of the Lie algebra $\mathfrak{g}$. We shall first examine the $sl(l)$ model as a prototype, then proceed to the models based on a general simple Lie algebra.

A. Spin generalization for $sl(l)$

The $sl(l)$ spin generalization was first introduced by Krichever *et al.*[19] They obtained the spin generalization, just like the spinless case,[5] via the pole dynamics of the matrix KP hierarchy.

1. Hamiltonian formalism

This model is a constrained Hamiltonian system. The Hamiltonian is given by

$$\mathcal{H}=\frac{1}{2}\sum_{j=1}^{l} p_j^2-\frac{1}{2}\sum_{j\neq k}\wp(q_j-q_k)F_{jk}F_{kj}. \tag{101}$$

Here q_j and p_j $(j=1,...,l)$ are the canonical coordinates and momenta of the Calogero–Moser particles, and F_{jk} $(j,k=1,...,l)$ a set of classical $sl(l)$ spin variables, whose Poisson brackets are determined by the Kostant–Kirillov Poisson structure on the dual space of $sl(l)$,

$$\{F_{jk},F_{mn}\}=\delta_{mk}F_{jn}-\delta_{jn}F_{mk}. \tag{102}$$

The equations of motion can be written

$$\begin{gathered}\frac{dq_j}{dt}=p_j,\quad \frac{dp_j}{dt}=\sum_{k\neq j}\wp'(q_j-q_k)F_{jk}F_{kj},\\ \frac{dF_{jk}}{dt}=-\sum_{m\neq j}\wp(q_j-q_m)F_{jm}+\sum_{m\neq k}\wp(q_m-q_k)F_{mk}-\wp(q_j-q_k)(F_{jj}-F_{kk}).\end{gathered} \tag{103}$$

In particular, the diagonal elements F_{jj} of the spin variables are conserved quantities, $dF_{jj}/dt=0$. Although the Hamiltonian does not contain the diagonal elements explicitly, they do appear in the equations of motion. We now put the constraints

$$F_{jj}=0\quad (j=1,...,l). \tag{104}$$

These constraints ensure the integrability. (Actually, the integrability is retained if the constraints are replaced by $F_{jj}=c$, $j=1,...,l$, where c is a constant.)

2. Lax pair in vector representation

The Lax pair of the spinless A_{l-1} model in the vector representation of $sl(l)$ can be readily extended to the spin generalization as follows:

$$\begin{gathered}L(z)=\sum_{j=1}^{l} p_jE_{jj}+\sum_{j\neq k}\sigma(q_j-q_k,z)F_{kj}E_{jk},\\ M(z)=-\sum_{j\neq k}\sigma(q_j-q_k,z)(\rho(q_j-q_k)+\rho(z-q_j+w_k))F_{kj}E_{jk},\end{gathered} \tag{105}$$

where

$$\rho(u)=\frac{\theta_1'(u)}{\theta_1(u)},\quad \sigma(u,z)=\frac{\theta_1(u-z)\,\theta_1'(0)}{\theta_1(z)\,\theta_1(u)}. \tag{106}$$

It is these functions that Felder and Wieczerkowski used in the KZB equation.[17] The function $\rho(u)$ is already familiar to us. The function $\sigma(u,z)$ is also just a disguise of the function $x(u,z)$ that we have used in the preceding sections,

$$\sigma(u,z)=-x(u,z). \tag{107}$$

We however dare to retain the notation of Felder and Wieczerkowski so as to stress the similarity with their work. In these notations, the aforementioned functional identities of $x(u,z)$ and $y(u,z)$ can be rewritten

$$\sigma(u,z)\sigma(v,z)(\rho(v)+\rho(z-v)-\rho(u)-\rho(z-u))=\sigma(u+v,z)(\wp(u)-\wp(v)), \tag{108}$$

$$2\sigma(u,z)\sigma(-u,z)(\rho(u)+\rho(z-u))=-\wp'(u), \tag{109}$$

$$\sigma(u,z)\sigma(-u,z)=\wp(z)-\wp(u). \tag{110}$$

Using these functional identities, one can derive the Lax equation

$$\frac{\partial L(z)}{\partial t}=[L(z),M(z)]. \tag{111}$$

Note that the constraints (104) are always assumed when we consider the Lax equation. Thus the spin generalization, too, is an isospectral integrable system. An involutive set of conserved quantities obtained from the traces $\mathrm{Tr}\,L(z)^k$, $k=2,3,\ldots$. The Hamiltonian itself can be reproduced from the quadratic trace.

The matrix $F=\Sigma_{j\neq k}F_{kj}E_{jk}$, which is the residue of $L(z)$ at $z=0$, stays on a coadjoint orbit of $sl(l)$ as t varies. The phase space of the spin generalization can be thereby restricted to the direct product of the phase space of Calogero–Moser particles and a coadjoint orbit of various dimensions in the dual space of $sl(l)$. The lowest dimensional non-trivial coadjoint orbit can be parametrized by $2l$ variables a_j, b_j $(j=1,\ldots,l)$ as

$$F_{jk}=igb_ja_k \quad (j\neq k), \tag{112}$$

where g is a constant. These reduced spin degrees of freedom, however, can be eliminated by a diagonal gauge transformation of the Lax equations. (This does not mean that a_j and b_j are nondynamical. The elimination procedure is done by partially solving the equations of motion for those variables.) This gauge transformation in turn gives rise to non-zero diagonal elements in $M(z)$, and the outcome is nothing but the Lax equation of the spinless elliptic Calogero–Moser system with coupling constant g. The spinless system is thus embedded in the spin generalization.

3. Isomonodromic system

There is no substantial difference in the construction of an isomonodromic system. The equations of motion are given by

$$\begin{gathered}2\pi i\frac{dq_j}{d\tau}=p_j, \quad 2\pi i\frac{dp_j}{d\tau}=\sum_{k\neq j}\wp'(q_j-q_k)F_{jk}F_{kj}, \\ 2\pi i\frac{dF_{jk}}{d\tau}=\sum_{m\neq j}\wp(q_j-q_m)F_{jm}-\sum_{m\neq k}\wp(q_m-q_k)F_{mk}.\end{gathered} \tag{113}$$

(Terms including F_{jj}'s have been eliminated by the constraints.) The Lax equation, too, can be written in the same form

$$2\pi i\frac{\partial L(z)}{\partial\tau}+\frac{\partial M(z)}{\partial z}=[L(z),M(z)]. \tag{114}$$

Behind this Lax equation is the ‘‘heat equation’’

$$2\pi i\frac{\partial\sigma(u,z)}{\partial\tau}+\frac{\partial^2\sigma(u,z)}{\partial u\,\partial z}=0 \tag{115}$$

satisfied by $\sigma(u,z)$. The final piece of the ring is the monodromy of $L(z)$ and $M(z)$,

$$L(z+1)=L(z), \quad M(z+1)=M(z),$$
$$L(z+\tau)=e^{2\pi iQ}L(z)e^{-2\pi iQ}, \tag{116}$$
$$M(z+\tau)=e^{2\pi iQ}(M(z)+2\pi iL(z))e^{-2\pi iQ}-2\pi iP.$$

As opposed to the root type Lax pairs, the ordinary differential equation

$$\frac{dY(z)}{dz}=L(z)Y(z) \tag{117}$$

on the torus E_τ has only one regular singularity at $z=0$. Thus the local monodromy matrix Γ_0 and the global monodromy matrices Γ_α and Γ_β are all that are invariant under the deformations.

B. Preliminaries for the general simple Lie algebra

Let $\mathfrak{g}$ be a (complex) simple Lie algebra of rank l, $\mathfrak{h}$ a Cartan subalgebra, and Δ the associated root system. The Cartan subalgebra induces a root space decomposition of $\mathfrak{g}$,

$$\mathfrak{g}=\mathfrak{h}\oplus\bigoplus_{\alpha\in\Delta}\mathfrak{g}_\alpha. \tag{118}$$

We choose a basis $\{e_\alpha,h_\mu|\alpha\in\Delta,\mu=1,...,l\}$ of $\mathfrak{g}$ as follows:

(1) h_μ, $\mu=1,...,l$, are an orthonormal basis of $\mathfrak{h}$ with respect to the Killing form $B:\mathfrak{h}\times\mathfrak{h}\to\mathbb{C}$, i.e.,

$$B(h_\mu,h_\nu)=\delta_{\mu\nu}. \tag{119}$$

(2) The Killing form induces an isomorphism $\mathfrak{h}^*=\mathrm{Hom}(\mathfrak{h},\mathbb{C})\simeq\mathfrak{h}$, which determines an element h_α for each $\alpha\in\mathfrak{h}^*$. In terms of the basis h_μ of $\mathfrak{h}$, this map can be written explicitly,

$$\alpha\mapsto h_\alpha=\sum_{\mu=1}^{l}\alpha(h_\mu)h_\mu, \tag{120}$$

The root subspace $\mathfrak{g}_\alpha$ is one dimensional. e_α is a basis of $\mathfrak{g}_\alpha$ such that

$$[e_\alpha,e_{-\alpha}]=h_\alpha. \tag{121}$$

This choice of e_α amounts to the normalization

$$B(e_\alpha,\epsilon_{-\alpha})=1. \tag{122}$$

The Lie brackets of the basis elements other than $[e_\alpha,e_{-\alpha}]$ now takes the form

$$[e_\alpha,e_\beta]=N_{\alpha,\beta}e_{\alpha+\beta} \quad (\alpha+\beta\neq 0),$$
$$[h_\mu,e_\alpha]=\alpha(h_\mu)e_\alpha, \tag{123}$$
$$[h_\mu,h_\nu]=0.$$

The structure constants $N_{\alpha,\beta}$ are antisymmetric with respect to the indices, and vanish if $\alpha+\beta\notin\Delta$. The following general relation among the structure constants will be used in the course of the proof of a Lax equation.

Lemma 1:

$$N_{-\beta,\alpha+\beta}=N_{-\alpha,-\beta}=N_{\alpha+\beta,-\alpha}. \tag{124}$$

Proof: If $\alpha=\beta$, this relation is trivially satisfied, because all the structure constants vanish. Let us consider the case where $\alpha\neq\beta$. By the Jacobi identity, we have

$$[e_{\alpha+\beta},[e_{-\alpha},e_{-\beta}]]=[[e_{\alpha+\beta},e_{-\alpha}],e_{-\beta}]+[e_{-\alpha},[e_{\alpha+\beta},e_{-\beta}]].$$

This implies the identity

$$N_{-\alpha,-\beta}h_{\alpha+\beta}=N_{\alpha+\beta,-\alpha}h_{\beta}-N_{\alpha+\beta,-\beta}h_{\alpha},$$

which, by the relation $h_{\alpha+\beta}=h_\alpha+h_\beta$, can be rewritten

$$(N_{-\alpha,-\beta}+N_{\alpha+\beta,-\beta})h_\alpha+(N_{-\alpha,-\beta}-N_{\alpha+\beta,-\alpha})h_\beta=0.$$

Since we have assumed that $\alpha\neq\beta$, h_α and h_β are linearly independent, so that the two coefficients in this linear retion are equal to zero. Q.E.D.

We can now specify the classical spin variables for a general simple Lie algebra. Those spin variables, by definition, are coordinates of the dual space $\mathfrak{g}^*=\mathrm{Hom}(\mathfrak{g},\mathbb{C})$. Let F_α and G_μ be the coordinates dual to the above basis e_α and h_μ. In other words, they are the coefficients of e_α and h_μ in the linear combination

$$\sum_{\alpha\in\Delta}F_{-\alpha}e_\alpha+\sum_{\mu=1}^{l}G_\mu h_\mu \tag{125}$$

that realizes the isomorphism $\mathfrak{g}^*\simeq\mathfrak{g}$ induced by the Killing form. The Kostant–Kirillov Poisson structure on $\mathfrak{g}^*$ determine the Poisson brackets of these spin variables, which take the same form as the Lie brackets of the Lie algebra basis,

$$\begin{gathered}\{F_\alpha,F_{-\alpha}\}=G_\alpha=\sum_{\mu=1}^{l}\alpha(h_\mu)G_\mu,\\ \{F_\alpha,F_\beta\}=N_{\alpha,\beta}F_{\alpha+\beta}\quad(\alpha+\beta\neq0),\\ \{G_\mu,F_\alpha\}=\alpha(h_\mu)F_\alpha,\\ \{G_\mu,G_\nu\}=0.\end{gathered}\tag{126}$$

C. Spin generalization for the general simple Lie algebra

1. Hamiltonian formalism

The spin generalization based on $\mathfrak{g}$, too, is a constrained Hamiltonian system defined on $\mathfrak{h}\times\mathfrak{h}\times\mathfrak{g}^*$ by the Hamiltonian

$$\mathcal{H}=\frac{1}{2}B(p,p)-\frac{1}{2}\sum_{\alpha\in\Delta}\wp(\alpha(q))F_{-\alpha}F_\alpha \tag{127}$$

and the constraints

$$G_\mu=0\quad(\mu=1,...,l). \tag{128}$$

Here q and p are understood to take values in $\mathfrak{h}$. $B(p,q)$ and $\alpha(q)$ amount to $p\cdot p$ and $\alpha\cdot q$ in the models based on root systems. Let us use the same ''dot notation'' for the Killing form $\mathfrak{h}\times\mathfrak{h}\to\mathbb{C}$ and the pairing $\mathfrak{h}^*\times\mathfrak{h}\to\mathbb{C}$. The Hamiltonian then takes a more familiar form

$$\mathcal{H}=\frac{1}{2}p\cdot p-\frac{1}{2}\sum_{\alpha\in\Delta}\wp(\alpha\cdot q)F_{-\alpha}F_\alpha. \tag{129}$$

The equations of motion can be readily written down in the language of the coordinates $q_\mu = q\cdot h_\mu$ and momenta $p_\mu = p\cdot h_\mu$ of Calogero–Moser particles and the spin variables F_α and G_μ on $\mathfrak{g}^*$,

$$\frac{dq_\mu}{dt} = p_\mu,$$
$$\frac{dp_\mu}{dt} = -\frac{1}{2}\sum_{\alpha\in\Delta} \alpha\cdot h_\mu \wp'(\alpha\cdot q)F_{-\alpha}F_\alpha,$$
$$\frac{dF_\alpha}{dt} = -\sum_{\beta\in\Delta,\alpha-\beta\in\Delta} \wp(\beta\cdot q)F_{\alpha-\beta}F_\beta N_{\alpha,-\beta} - \wp(\alpha\cdot q)G_\alpha F_\alpha, \tag{130}$$
$$\frac{dG_\mu}{dt} = 0.$$

In particular, the diagonal elements G_μ of the spin variables are conserved quantities. One can thereby safely put the aforementioned constraints.

2. Lax pair

The integrability of our spin generalization is ensured by the existence of a Lax pair as follows:

Proposition 6: Let V be any finite dimensional representation of $\mathfrak{g}$, *and* E_α *and* H_μ *the endomorphisms on V that represent* e_α *and* h_μ. *Then the endomorphisms*

$$L(z) = P + \sum_{\alpha\in\Delta} \sigma(\alpha\cdot q,z)F_{-\alpha}E_\alpha \quad P = \sum_{\mu=1}^{l} p_\mu H_\mu,$$
$$M(z) = -\sum_{\alpha\in\Delta} \sigma(\alpha\cdot q,z)(\rho(\alpha\cdot q)+\rho(z-\alpha\cdot q))F_{-\alpha}E_\alpha \tag{131}$$

on V satisfy the Lax equation

$$\frac{\partial L(z)}{\partial t} = [L(z),M(z)]. \tag{132}$$

Proof: Using the equations of motion and the constraints, one can express the t-derivative of the L-matrix as

$$\frac{\partial L(z)}{\partial t} = \mathrm{I}+\mathrm{II}+\mathrm{III}, \tag{133}$$

where

$$\mathrm{I} = \sum_{\mu=1}^{l} \frac{dp_\mu}{dt} H_\mu = -\frac{1}{2}\sum_{\alpha\in\Delta} \wp'(\alpha\cdot q)F_{-\alpha}F_\alpha H_\alpha,$$
$$\mathrm{II} = \sum_{\alpha\in\Delta}\sum_{\mu=1}^{l} \frac{d\alpha\cdot q}{dt} \left.\frac{\partial\sigma(u,z)}{\partial u}\right|_{u=\alpha\cdot q} F_{-\alpha}E_\alpha$$
$$= -\sum_{\alpha\in\Delta} \alpha\cdot\alpha\sigma(\alpha\cdot q,z)(\rho(\alpha\cdot q)+\rho(z-\alpha\cdot q))F_{-\alpha}E_\alpha,$$

$$\mathrm{III}=\sum_{\alpha\in\Delta}\sigma(\alpha\cdot q,z)\frac{dF_{-\alpha}}{dt}E_{\alpha}=-\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma(\alpha\cdot q,z)\wp(\beta\cdot q)F_{-\alpha-\beta}F_{\beta}N_{-\alpha,-\beta}E_{\alpha}.$$

Similarly, the commutator of the Lax pair can be written

$$[L(z),M(z)]=\mathrm{IV}+\mathrm{V}+\mathrm{VI}, \tag{134}$$

where VI stands for terms from the commutator $[P,M(z)]$,

$$\mathrm{IV}=-\sum_{\alpha\in\Delta}\sigma(\alpha\cdot q,z)(\rho(\alpha\cdot q)+\rho(z-\alpha\cdot q))F_{-\alpha}[P,E_{\alpha}]$$

$$=-\sum_{\alpha\in\Delta}\sigma(\alpha\cdot q,z)(\rho(\alpha\cdot q)+\rho(z-\alpha\cdot q))\alpha\cdot pF_{-\alpha}E_{\alpha},$$

and V+VI are the the other terms grouped into the Cartan part (V) and the off-Cartan part (VI),

$$\mathrm{V}=-\sum_{\alpha\in\Delta}\sigma(-\alpha\cdot q,z)\sigma(\alpha\cdot q,z)(\rho(\alpha\cdot q)+\rho(z-\alpha\cdot q))F_{-\alpha}F_{\alpha}[E_{\alpha},E_{-\alpha}]$$

$$=-\sum_{\alpha\in\Delta}\sigma(-\alpha\cdot q,z)\sigma(\alpha\cdot q,z)(\rho(\alpha\cdot q)+\rho(z-\alpha\cdot q))F_{-\alpha}F_{\alpha}H_{\alpha},$$

$$\mathrm{VI}=-\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma(\alpha\cdot q,q)\sigma(\beta\cdot q,z)(\rho(\beta\cdot q)+\rho(z-\beta\cdot q))F_{-\alpha}F_{\alpha}[E_{\alpha},E_{\beta}]$$

$$=-\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma(\alpha\cdot q,z)\sigma(\beta\cdot q,z)(\rho(\beta\cdot q)+\rho(z-\beta\cdot q))F_{-\alpha}F_{-\beta}N_{\alpha,\beta}E_{\alpha+\beta}.$$

It is obvious that IV=II. Using (109), we can readily see that V=I. Thus it remains to prove that VI=III. This is achieved as follows:

$$\mathrm{VI}=-\frac{1}{2}\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma(\alpha\cdot q,z)\sigma(\beta\cdot q,z)(\rho(\beta\cdot q)+\rho(z-\beta\cdot q)-\rho(z-\alpha\cdot q)$$
$$-\rho(\alpha\cdot q))F_{-\alpha}F_{-\beta}N_{\alpha,\beta}E_{\alpha+\beta}\ \text{[symmetrized with respect to } \alpha \text{ and } \beta\text{]},$$
$$=-\frac{1}{2}\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma((\alpha+\beta)\cdot q,z)(\wp(\alpha\cdot q)-\wp(\beta\cdot q))F_{-\alpha}F_{-\beta}N_{\alpha,\beta}E_{\alpha+\beta}\cdot\text{[(108) is used]},$$
$$=\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma((\alpha+\beta)\cdot q,z)\wp(\beta\cdot q)F_{-\alpha}F_{-\beta}N_{\alpha,\beta}E_{\alpha+\beta}$$
$$\text{[asymmetrized with respect to } \alpha \text{ and } \beta\text{]},$$
$$=\sum_{\alpha,\beta\in\Delta,\alpha+\beta\neq 0}\sigma(\alpha\cdot q,z)\wp(\beta\cdot q)F_{-\alpha,-\beta}F_{\beta}N_{\alpha+\beta-\beta}E_{\alpha}.$$
$$\text{[substituting } \beta\rightarrow-\beta \text{ and } \alpha\rightarrow\alpha+\beta\text{]}.$$

Finally using the identity $N_{\alpha+\beta,-\beta}=-N_{-\alpha,-\beta}$, cf. (124), we find that the last sum is equal to III. Q.E.D.

Note that the above proof persists to be meaningful if E_{α} and H_{μ} are replaced by the Lie algebra elements e_{α} and h_{μ}. In other words, the Lax equation actually lives in the Lie algebra $\mathfrak{g}$ itself rather than its representations. This resembles the case of the Toda systems.

3. Isomonodromic system

The passage to an isomonodromic analog is straightforward. Replacing $d/dt \to 2\pi i d/d\tau$, one obtains the nonautonomous system,

$$2\pi i \frac{dq_\mu}{d\tau} = p_\mu ,$$

$$2\pi i \frac{dp_\mu}{d\tau} = -\frac{1}{2} \sum_{\alpha \in \Delta} \alpha \cdot h_\mu \wp'(\alpha \cdot q) F_{-\alpha} F_\alpha , \tag{135}$$

$$2\pi i \frac{dF_\alpha}{d\tau} = -\sum_{\beta \in \Delta, \alpha - \beta \in \Delta} \wp(\beta \cdot q) F_{\alpha - \beta} F_\beta N_{\alpha, -\beta} .$$

(Terms including G_μ's have been eliminated by the constraints.) These equations can be converted to the Lax equation

$$2\pi i \frac{\partial L(z)}{\partial \tau} + \frac{\partial M(z)}{\partial z} = [L(z), M(z)]. \tag{136}$$

The monodromy of $L(z)$ and $M(z)$, too, takes the same form,

$$L(z+1) - L(z), \quad M(z+1) = M(z),$$

$$L(z+\tau) = e^{2\pi i Q} L(z) e^{-2\pi i Q}, \tag{137}$$

$$M(z+\tau) = e^{2\pi i Q}(M(z) + 2\pi i L(z)) e^{-2\pi i Q} - 2\pi i P,$$

where $Q = \Sigma_{\mu=1}^{l} q_\mu H_\mu$. The Lax equation implies that the monodromy data of the ordinary differential equation

$$\frac{dY(z)}{dz} = L(z) Y(z) \tag{138}$$

on the torus E_τ is invariant as τ varies. $Y(z)$ now take values in the representation space V; the monodromy around a singular point or of a cycle of E_τ is represented by a linear transformation on V. The ordinary differential equation has a regular singularity at $z=0$ only. The local monodromy around this singular point is a linear transformation $\Gamma_0 \in GL(V)$. Similarly, the global monodromy along the α and β cycles give Γ_α, $\Gamma_\beta \in GL(V)$. These linear transformations Γ_0, Γ_α, and Γ_β are the monodromy data that are left invariant.

V. CONCLUSION

We have thus demonstrated that various models of the elliptic Calogero–Moser systems are accompanied with an isomonodromic partner. A technical clue is the choice of fundamental functions $x(u,z)$, $y(u,z)$, etc. in the Lax pair $L(z)$ and $M(z)$. For $L(z)$ and $M(z)$ to give an isomonodromic Lax pair, these functions are required to satisfy a kind of ''heat equation'' besides the functional equations. We have illustrated the construction of the isomonodromic Lax pair for several typical cases—the Lax pair of the A_{l-1} mode in the vector representation, the root type Lax pair for various untwisted and twisted models, and the Lax pair of the spin generalizations.

The most interesting case in the context of Manin's equation is the root type Lax pair for the extended twisted BC_l model (or, equivalently, the Inozemtsev system). The root type Lax pair based on short roots of the BC_l root system consists of $2l \times 2l$ matrices.

The construction of a Lax pair, however, is merely the first step towards a full understanding of Manin's equation and its possible generalizations. The next issue is to elucidate the meaning of the affine Weyl group symmetries, various special solutions, etc. in this framework. Recent works by Noumi and Yamada,[20] Deift, Its, Kapaev, and Zhou[21] and Kitaev and Korotkin[22] are very suggestive in this respect.

The spin generalization that we have discussed is a special case of a more general multispin system, i.e., the elliptic Calogero–Moser systems coupled to ''Gaudin spins'' sitting at the punctures of a punctured torus.[9,10] This is the Hitchin system on a punctured torus; we have considered the case with only one puncture located at $z=0$. It is rather straightforward, though more complicated, to generalize our Lax pair to the multispin generalization. This gives a generalization, to other simple Lie groups, of the SU(2) isomonodromic system of Korotkin and Samtleben.[23] The dynamical r-matrix in the work of Felder and Wieczerkowski[17] plays a central role here. We shall report this result elsewhere.

ACKNOWLEDGMENTS

I am indebted to Ryu Sasaki for a number of crucial ideas on the elliptic Calogero–Moser systems. I am also grateful to Shingo Kawai and Kazuo Okamoto for valuable comments on isomonodromic systems on the torus. Finally, I would like to thank Koji Hasegawa, Gen Kuroki, Takashi Takebe, and Yasuhiko Yamada for discussions on many aspects of isospectral and isomonodromic systems. This work is partly supported by the Grant-in-Aid for Scientific Research (No. 10640165) from the Ministry of Education, Science, and Culture.

APPENDIX A: PROOF OF FUNCTIONAL IDENTITIES AND HEAT EQUATION FOR UNTWISTED MODELS

1. Proof of (24)

Let $f(u,v,z)$ denote the difference of both hand sides of (24),

$$f(u,v,z)=x(u,z)y(v,z)-y(u,z)x(v,z)-x(u+v,z)(\wp(u)-\wp(v)). \tag{A1}$$

This function turns out to have the following analytical properties:

(1) $f(u,v,z)$ has the same quasiperiodicity as $x(u,z)$ on the u plane, i.e.,

$$f(u+1,v,z)=f(u,v,z),\quad f(u+\tau,v,z)=e^{2\pi i z}f(u,v,z). \tag{A2}$$

(2) $f(u,v,z)$ is an entire function on the u plane.

The first property is obvious from the quasiperiodicity of $x(u,z)$ and the periodicity of $\wp(u)$. Furthermore, poles of $f(u,v,z)$ can appear only at the lattice points $u=m+n\tau\,(m,n\in\mathbb{Z})$ on the u plane. Therefore, in order to verify the second property, we have only to show that $f(u,v,z)$ is nonsingular at these points. Actually, because of the quasiperiodicity, it is sufficient to consider the point $u=0$ only. As $u\to 0$, the singular terms $x(u,z)$, $y(u,z)$, and $\wp(u)$ in $f(u,v,z)$ behave as

$$x(u,z)=\frac{1}{u}+O(1),\quad y(u,z)=-\frac{1}{u^2}+O(1),\quad \wp(u)=\frac{1}{u^2}+O(u^2) \tag{A3}$$

so that

$$\begin{aligned} f(u,v,z)&=\left(\frac{1}{u}+O(1)\right)y(v,z)-\left(-\frac{1}{u^2}+O(1)\right)x(v,z)\\ &\quad-(x(u,z)+y(u,z)u+O(u^2))\left(\frac{1}{u^2}-\wp(v)+O(u^2)\right)\\ &=O(1). \end{aligned} \tag{A4}$$

We can thus verify the above two properties of $f(u,v,x)$.

Actually, any function with these two properties should vanish identically. This can be seen in several different ways. The shortest will be to resort to algebraic geometry of line bundles on the torus E_τ. A more elementary proof is to consider the quotient $f(u,v,z)/x(u,z)$. This quotient is a doubly-periodic meromorphic function, and all possible poles are located at the lattice points $u=m+n\tau\,(m,n\in\mathbb{Z})$, and at most of first order. In other words, $f(u,v,z)/x(u,z)$ is a meromorphic function on the torus with the only possible pole at $u=0$, but the order of pole cannot be greater than one. Such a function has to be a constant. On the other hand, because of the pole of $x(u,z)$ at $u=0$, $f(u,v,z)/x(u,z)$ has a zero at $u=0$. Therefore the constant should be equal to zero.

2. Proof of (25) and (26)

(25) can be readily derived from (24) by letting $v\to -u$. Let us consider (26). By (25),

$$\frac{\partial}{\partial u}(x(u,z)x(-u,z)) = -x(u,z)y(-u,z)+y(u,z)x(-u,z) = -\wp'(u). \tag{A5}$$

Consequently,

$$x(u,z)x(-u,z) = -\wp(u)+(\text{independent of } u). \tag{A6}$$

Since $x(u,z)=-x(z,u)=-x(-u,-z)$, the left-hand side of the last relation is in fact an anti-symmetric function of u and z. Therefore,

$$x(u,z)x(-u,z) = \wp(z)-\wp(u)+\text{const}. \tag{A7}$$

Now consider the limit as $u\to z$. Both $x(u,z)x(-u,z)$ and $\wp(z)-\wp(u)$ tend to zero in this limit. Thus the constant on the right-hand side has to be zero.

3. Proof of (34)

Let us rewrite the both hand sides of (34) into a more accessible form. Differentiating $x(u,z)$ by τ gives

$$\frac{\partial x(u,z)}{\partial \tau} = x(u,z)\frac{\partial}{\partial \tau}(\log\theta_1(z-u)+\log\theta_1'(0)-\log\theta_1(z)-\log\theta_1(u)). \tag{A8}$$

By the heat equation (40) of the Jacobi theta function,

$$4\pi i\frac{\partial}{\partial\tau}\theta_1(u) = \frac{\theta_1''(u)}{\theta_1(u)} = \frac{\partial}{\partial u}\left(\frac{\theta_1'(u)}{\theta_1(u)}\right)+\left(\frac{\theta_1'(u)}{\theta_1(u)}\right)^2 = \rho'(u)+\rho(u)^2. \tag{A9}$$

Letting $u\to 0$ and recalling the singular behavior of $\rho(u)$ at $u=0$, we obtain

$$4\pi i\frac{\partial}{\partial\tau}\log\theta_1'(0) = \lim_{u\to 0}(\rho'(u)+\rho(u)) = \frac{\theta_1'''(0)}{\theta_1'(0)}. \tag{A10}$$

Plugging these formulas into the above expression of $\partial x(u,z)/\tau$ gives

$$4\pi i\frac{\partial x(u,z)}{\partial\tau} = x(u,z)f(u,z), \tag{A11}$$

where

$$f(u,z)=\rho'(z-u)+\rho(z-u)^2+\frac{\theta_1'''(0)}{\theta_1'(0)}-\rho'(z)-\rho(z)^2-\rho'(u)-\rho(u)^2. \tag{A12}$$

On the other hand, we have

$$\frac{\partial x(u,z)}{\partial u\partial z}=-\frac{\partial}{\partial z}(x(u,z)(\rho(u)+\rho(z-u)))=-x(u,z)g(u,z), \tag{A13}$$

where

$$g(u,z)=(\rho(z-u)-\rho(z))(\rho(u)+\rho(z-u))+\rho'(z-u). \tag{A14}$$

The goal is to verify that $f(u,z)=2g(u,z)$. It is sufficient to prove the following two properties of $f(u,z)-2g(u,z)$, because such a function has to be identically zero.

(1) $f(u,z)-2g(u,z)$ is a doubly-periodic function on the u plane with primitive periods 1 and τ.
(2) $f(u,z)-2g(u,z)$ is an entire function, and has a zero at $u=0$.

The first property is obvious if one notices the following quasiperiodicity of $f(u,z)$ and $g(u,z)$:

$$\begin{aligned} f(u+1,z)&=f(u,z), \quad f(u+\tau,z)=f(u,z)+4\pi i(\rho(u)+\rho(z-u)),\\ g(u+1,z)&=g(u,z), \quad g(u+\tau,z)=g(u,z)+2\pi i(\rho(u)+\rho(z-u)). \end{aligned} \tag{A15}$$

Let us check the second property. Possible poles of $f(u,z)$ and $g(u,z)$ are located at the two points $u=0$ and $u=z$ of the fundamental domain of the period lattice $\mathbb{Z}+\tau\mathbb{Z}$. Again recalling the singular behavior of $\rho(u)$ at $u=0$, one can confirm by straightforward calculations that

$$f(u,z)=O(u), \quad g(u,z)=O(u) \quad (u\to 0). \tag{A16}$$

Thus $f(u,z)-2g(u,z)$ turns out to be nonsingular and have a zero at $u=0$. Similarly, one can see that $f(u,z)-2g(u,z)$ is nonsingular at $u=z$.

APPENDIX B: VERIFICATION OF THE LAX PAIR FOR EXTENDED TWISTED BC_l MODEL

To prove the Lax equation, it is sufficient to derive the following three equations:

$$\frac{\partial X_a(z)}{\partial t}=[P,X_a(z)] \quad (a=1,2,3), \tag{B1}$$

$$\frac{dp\cdot\mu}{dt}=[X_1(z)+X_2(z)+X_3(z),Y_1(z)+Y_2(z)+Y_3(z)]_{\mu\mu}, \tag{B2}$$

$$0=[X_1(z)+X_2(z)+X_3(z),D+Y_1(z)+Y_2(z)+Y_3(z)]_{\mu\nu} \quad (\mu\neq\nu). \tag{B3}$$

μ and ν run over the set Δ_s of short roots.

The proof of (B1) is quite easy. Let us consider the case of $a=1$. The t-derivative of $X_1(z)$ can be written

$$\frac{\partial X_1(z)}{\partial t}=ig_m\sum_{\alpha\in\Delta_m}\alpha\cdot py(\alpha\cdot q,z)E(\alpha). \tag{B4}$$

Using the commutation relation $[P,E(\alpha)]=\alpha\cdot pE(\alpha)$, one can readily see that the right-hand side is equal to $[P,X_1(z)]$. The other two in (B1) can be similarly derived.

The rest of this Appendix is devoted to the other two equations (B2) and (B3).

1. Proof of (B2)

We calculate the diagonal elements

$$[X_a(z),Y_b(z)]_{\mu\mu}=\sum_{\nu\in\Delta_s}(X_{a,\mu\nu}(z)Y_{b,\nu\mu}(z)-Y_{b,\mu\nu}(z)X_{a,\nu\mu}(z)) \tag{B5}$$

of the nine commutators one-by-one.

a. Vanishing terms

Some part of the matrix elements of $X_a(z)$ and $Y_b(z)$ turn out to vanish by the nature of the BC_l root system,

$$X_{1,\mu,-\mu}(z)=Y_{1,\mu,-\mu}(z)=0, \tag{B6}$$

$$X_{2,\mu\nu}(z)=Y_{2,\mu\nu}(z)=0 \quad (\mu\neq-\nu), \tag{B7}$$

$$X_{3,\mu\nu}(z)=Y_{3,\mu\nu}(z)=0 \quad (\mu\neq-\nu). \tag{B8}$$

The first relation is due to the fact that $\mu-(-\mu)=2\mu$ can never be a middle root. The second and third relations are obvious if one notices that $\mu-\nu$ is a long root (or, equivalently, twice a short root) if and only if $\mu=-\nu$.

In particular,

$$[X_1(z),Y_2(z)]_{\mu\mu}=[X_1(z),Y_3(z)]_{\mu\mu}=[X_2(z),Y_1(z)]_{\mu\mu}=[X_3(z),Y_1(z)]_{\mu\mu}=0. \tag{B9}$$

b. Calculation of $[X_1(z),Y_1(z)]_{\mu\mu}$

By definition,

$$[X_1(z),Y_1(z)]_{\mu\mu}=-g_m^2\sum_{\nu\in\Delta_s,\mu-\nu\in\Delta_m}(x((\mu-\nu)\cdot q,z)y((\nu-\mu)\cdot q,z)$$
$$-y((\mu-\nu)\cdot q,z)x((\nu-\mu)\cdot q,z)). \tag{B10}$$

We rewrite this sum to a sum over the middle root $\alpha=\mu-\nu$. Since the middle roots α of this form are characterized by the condition that $\alpha\cdot\mu=1$, the right-hand side can be rewritten

$$-g_m^2\sum_{\alpha\in\Delta_m,\alpha\cdot\mu=1}(x(\alpha\cdot q,z)y(-\alpha\cdot q,z)-y(\alpha\cdot q,z)x(-\alpha\cdot q,z)).$$

Actually, the possible values of $\alpha\cdot\mu$ are limited to 0 and ±1 only. Therefore this sum is equal to

$$-\frac{g_m^2}{2}\sum_{\alpha\in\Delta_m}\alpha\cdot\mu(x(\alpha\cdot q,z)y(-\alpha\cdot q,z)-y(\alpha\cdot q,z)x(-\alpha\cdot q,z)).$$

(The factor 1/2 compensates the contributions from $\alpha\cdot\mu=1$ and $\alpha\cdot\mu=-1$.) Noting that $\alpha\cdot\mu=\{p\cdot\mu,\alpha\cdot q\}$, we can express $[X_1(z),Y_1(z)]$ as a Poisson bracket of the form

$$[X_1(z),Y_1(z)]_{\mu\mu}=\{p\cdot\mu,V_{11}\}, \tag{B11}$$

where

$$V_{11}=\frac{g_m^2}{2}\sum_{\alpha\in\Delta_m}x(\alpha\cdot q,z)x(-\alpha\cdot q,z). \tag{B12}$$

c. Contributions of other commutators

By (B7) and (B8), the diagonal elements of the other commutators are a sum of just two terms,

$$[X_a(z),Y_b(z)]_{\mu\mu}=X_{a,\mu,-\mu}Y_{b,-\mu,\mu}-Y_{b,\mu,-\mu}X_{a,-\mu,\mu}. \tag{B13}$$

Let us consider the case of $a=2$ and $b=2$ in some detail. By definition,

$$\begin{aligned}[X_2(z),Y_2(z)]_{\mu\mu}=&-(g_{l1}x(2\mu\cdot q,z)+g_{l2}x^{(2)}(2\mu\cdot q,z))(g_{l1}y(-2\mu\cdot q,z)+g_{l2}y^{(2)}(-2\mu\cdot q,z))\\ &+(g_{l1}y(2\mu\cdot q,z)+g_{l2}y^{(2)}(2\mu\cdot q,z))(g_{l1}x(-2\mu\cdot q,z)+g_{l2}x^{(2)}(-2\mu\cdot q,z)).\end{aligned}$$

Since $\alpha=2\mu$ is a long root, and long roots with nonvanishing inner product with μ are 2μ and -2μ only, the right-hand side can be rewritten

$$\begin{aligned}&-\frac{1}{4}\sum_{\alpha\in\Delta_l}\alpha\cdot\mu(g_{l1}x(\alpha\cdot q,z)+g_{l2}x^{(2)}(\alpha\cdot q,z))(g_{l1}y(-\alpha\cdot q,z)+g_{l2}y^{(2)}(-\alpha\cdot q,z))\\ &+\frac{1}{4}\sum_{\alpha\in\Delta_l}\alpha\cdot\mu(g_{l1}y(\alpha\cdot q,z)+g_{l2}y^{(2)}(\alpha\cdot q,z))(g_{l1}x(-\alpha\cdot q,z)+g_{l2}x^{(2)}(-\alpha\cdot q,z)).\end{aligned}$$

(The factor 1/4 compensates the contributions from $\alpha\cdot\mu=2$ and $\alpha\cdot\mu=-2$.) We can again cast this into a Poisson bracket,

$$[X_2(z),Y_2(z)]_{\mu\mu}=\{p\cdot\mu,V_{22}\}, \tag{B14}$$

where

$$V_{22}=\frac{1}{4}\sum_{\alpha\in\Delta_l}(g_{l1}x(\alpha\cdot q,z)+g_{l2}x^{(2)}(\alpha\cdot q,z))(g_{l1}x(-\alpha\cdot q,z)+g_{l2}x^{(2)}(-\alpha\cdot q,z)). \tag{B15}$$

Similarly, one can obtain

$$\begin{gathered}[X_2(z),Y_3(z)]_{\mu\mu}=\{p\cdot\mu,V_{23}\},\quad [X_3(z),Y_2(z)]_{\mu\mu}=\{p\cdot\mu,V_{32}\},\\ [X_3(z),Y_3(z)]_{\mu\mu}=\{p\cdot\mu,V_{33}\},\end{gathered} \tag{B16}$$

where

$$\begin{aligned}V_{23}&=\frac{1}{2}\sum_{\alpha\in\Delta_s}(g_{l1}x(2\alpha\cdot q,z)+g_{l2}x^{(2)}(2\alpha\cdot q,z))(g_{s1}x(-\alpha\cdot q,2z)+g_{s2}x^{(1/2)}(-\alpha\cdot q,2z)),\\ V_{32}&=\frac{1}{2}\sum_{\alpha\in\Delta_s}(g_{s1}x(\alpha\cdot q,2z)+g_{s2}x^{(1/2)}(\alpha\cdot q,2z))(g_{l1}x(-2\alpha\cdot q,z)+g_{l2}x^{(2)}(-2\alpha\cdot q,z)),\\ V_{33}&=\sum_{\alpha\in\Delta_s}(g_{s1}x(\alpha\cdot q,2z)+g_{s2}x^{(1/2)}(\alpha\cdot q,2z))(g_{s1}x(-\alpha\cdot q,2z)+g_{s2}x^{(1/2)}(-\alpha\cdot q,2z)).\end{aligned} \tag{B17}$$

Collecting the results of these calculations, we find that the right-hand side of (B2) takes the form of the Poisson bracket $\{p\cdot\mu,V\}$, where

$$V=V_{11}+V_{22}+V_{23}+V_{32}+V_{33}. \tag{B18}$$

d. Writing V in terms of $\wp$ functions

The final step is to rewrite V in terms of the Weierstrass $\wp$ functions. For V_{11}, this can be done by use of (26). The other parts are due to the following functional identities:

$$x^{(1/2)}(u,z)x^{(1/2)}(-u,z) = -\wp^{(1/2)}(u) + \wp^{(1/2)}\left(\frac{z}{2}\right), \tag{B19}$$

$$x^{(2)}(u,z)x^{(2)}(-u,z) = -\wp^{(2)}(u) + \wp^{(2)}(2z), \tag{B20}$$

$$x(u,2z)x^{(1/2)}(-u,2z) + x^{(1/2)}(u,2z)x(-u,2z) = -2\wp(u) + \text{const.}, \tag{B21}$$

$$x(u,2z)x(-2u,z) + x(2u,z)x(-u,2z) = -\wp(u) + \text{const.}, \tag{B22}$$

$$x(u,2z)x^{(2)}(-2\mu,z) + x^{(2)}(2u,z)x(-u,2z) = -\wp(u) + \text{const.}, \tag{B23}$$

$$x^{(1/2)}(u,2z)x(-2u,z) + x(2u,z)x^{(1/2)}(-u,2z) = -\wp^{(1/2)}(u) + \text{const.}, \tag{B24}$$

$$x^{(1/2)}(u,2z)x^{(2)}(-2u,z) + x^{(2)}(2u,z)x^{(1/2)}(-u,2z) = -\wp(u) + \text{const.}, \tag{B25}$$

$$x(u,z)x^{(2)}(-u,z) + x^{(2)}(u,z)x(-u,z) = -2\wp^{(2)}(u) + \text{const.} \tag{B26}$$

The first two are substantially the same as (26) except that the variables and the primitive periods are rescaled. ''const.'' in the other identities stand for terms that are independent of u, thereby negligible in the Poisson bracket with $p\cdot\mu$; remember that they are not absolute constants, but functions of z and τ. We shall prove these identities in Appendix C. Using these functional identities, one can see that V is equal to the potential part of the Hamiltonian $\mathcal{H}$, up to nondynamical terms independent of p and q.

To summarize, we have shown that the sum of the (μ,μ) elements of the nine commutators coincides with the Poisson bracket $\{p\cdot\mu,V\}$, which is equal to $dp\cdot\mu/dt$ by the equations of motion of the model.

2. Proof of (B3)

The proof can be separated into the cases where $\nu=-\mu$ and $\nu\neq\pm\mu$.

a. $\nu=-\mu$

The vanishing of the $(\mu,-\mu)$ elements of the commutators other than $[X_a(z),D]$ $(a=1,2,3)$ and $[X_1(z),D]$ is immediate from (B7) and (B8). $[X_a(z),D]_{\mu,-\mu}$ vanishes because of the symmetry $D_{-\mu}=D_\mu$. As for $[X_1(z),Y_1(z)]_{\mu,-\mu}$, we have

$$[X_1(z),Y_1(z)]_{\mu,-\mu} = -g_m^2 \sum_{\nu\in\Delta_s\setminus\{\pm\mu\}} x((\mu-\nu)\cdot q,z)y((\nu+\mu)\cdot q,z) + g_m^2 \sum_{\nu\in\Delta_s\setminus\{\pm\mu\}} y((\mu-\nu)\cdot q,z)x((\nu+\mu)\cdot q,z). \tag{B27}$$

By substituting $\nu\to-\nu$, the second sum on the right-hand side turns out to be identical to the first sum. The two sums thus cancel with each other.

b. $\nu\neq\pm\mu$

The following can be readily seen by using (B7) and (B8):

$$\begin{gathered}[X_2(z),D]_{\mu\nu} = [X_3(z),D]_{\mu\nu} = 0,\\ [X_2(z),Y_2(z)]_{\mu\nu} = [X_2(z),Y_3(z)]_{\mu\nu} = [X_3(z),Y_3(z)]_{\mu\nu} = 0.\end{gathered} \tag{B28}$$

The (μ,ν) elements of other commutators can be calculated as follows:

$$\begin{aligned}[X_1(z),D]_{\mu\nu} &= -X_{1,\mu\mu}(z)(D_\mu - D_\nu)\\ &= g_m x((\mu-\nu)\cdot q,z)\\ &\quad\times\Big(g_{s1}\wp(\mu\cdot q)+g_{s2}\wp^{(1/2)}(\mu\cdot q)+g_{l1}\wp(2\mu\cdot q)+g_{l2}\wp^{(2)}(2\mu\cdot q)\\ &\quad -g_{s1}\wp(\nu\cdot q)-g_{s2}\wp^{(1/2)}(\nu\cdot q)-g_{l1}\wp(2\nu\cdot q)-g_{l2}\wp^{(2)}(2\nu\cdot q)\\ &\quad +\sum_{\lambda\in\Delta_m,\alpha\cdot\mu=1}\wp(\alpha\cdot q)-\sum_{\alpha\in\Delta_m,\alpha\cdot\nu=1}\wp(\alpha\cdot q)\Big),\end{aligned} \tag{B29}$$

$$\begin{aligned}[X_1(z),Y_1(z)]_{\mu\nu} &= \sum_{\lambda\in\Delta_s}(X_{1,\mu\lambda}(z)Y_{1,\lambda\nu}(z)-Y_{1,\mu\lambda}(z)X_{1,\lambda\nu}(z))\\ &= -g_m^2\sum_{\lambda\in\Delta_s\setminus\{\mu,\nu\}}(x((\mu-\lambda)\cdot q,z)y((\lambda-\nu)\cdot q,z)\\ &\quad -y((\mu-\lambda)\cdot q,z)x((\lambda-\nu)\cdot q,z)),\end{aligned} \tag{B30}$$

$$\begin{aligned}[X_1(z),Y_2(z)]_{\mu\nu} &= X_{1,\mu,-\nu}(z)Y_{2,-\nu,\nu}(z)-Y_{2,\mu,-\mu}(z)X_{1,-\mu,\nu}(z)\\ &= -g_m x((\mu+\nu)\cdot q,z)(g_{l1}y(-2\nu\cdot q,z)+g_{l2}y^{(2)}(-2\nu\cdot q,z))\\ &\quad +(g_{l1}y(2\mu\cdot q,z)+g_{l2}y^{(2)}(2\mu\cdot q,z))g_m x(-(\mu+\nu)\cdot q,z),\end{aligned} \tag{B31}$$

$$\begin{aligned}[X_1(z),Y_3(z)]_{\mu\nu} &= X_{1,\mu,-\nu}(z)Y_{3,-\nu,\nu}(z)-Y_{3,\mu,-\mu}(z)X_{1,-\mu,\nu}(z)\\ &= -g_m x((\mu+\nu)\cdot q,z)(g_{s1}y(-\nu\cdot q,2z)+g_{s2}y^{(1/2)}(-\nu\cdot q,2z))\\ &\quad +(g_{s1}y(\mu\cdot q,2z)+g_{s2}y^{(1/2)}(\mu\cdot q,2z))g_m x(-(\mu+\nu)\cdot q,z),\end{aligned} \tag{B32}$$

$$\begin{aligned}[X_2(z),Y_1(z)]_{\mu\nu} &= X_{2,\mu,-\mu}(z)Y_{1,-\mu,\nu}(z)-Y_{1,\mu,-\nu}(z)X_{2,-\nu,\nu}(z)\\ &= -(g_{l1}x(2\mu\cdot q,z)+g_{l2}x^{(2)}(2\mu\cdot q,z))g_m y(-(\mu+\nu)\cdot q,z)\\ &\quad +g_m y((\mu+\nu)\cdot q,z)(g_{l1}x(-2\nu\cdot q,z)+g_{l2}x^{(2)}(-2\nu\cdot q,z)),\end{aligned} \tag{B33}$$

$$\begin{aligned}[X_3(z),Y_1(z)]_{\mu\nu} &= X_{3,\mu,-\nu}(z)Y_{1,-\nu,\nu}(z)-Y_{1,\nu,-\nu}(z)X_{3,-\nu,\nu}(z)\\ &= -2(g_{s1}x(\mu\cdot q,2z)+g_{s2}x^{(1/2)}(\mu\cdot q,2z))g_m y(-(\mu+\nu)\cdot q,z)\\ &\quad +2g_m y((\mu+\nu)\cdot q,z)(g_{s1}x(-\nu\cdot q,2z)+g_{s2}x^{(1/2)}(-\nu\cdot q,2z)).\end{aligned} \tag{B34}$$

We now sum up all these quantities, regroup terms into those multiplied by the same monomial of coupling constants, and show the cancellation in each partial sum. There are six monomials of coupling constants that can occur, i.e., g_m^2, $g_m g_{l1}$, $g_m g_{l2}$, $g_m g_{s1}$, and $g_m g_{s2}$.

Let us consider the terms multiplied by g_m^2. This is a sum of the following two quantities:

$$\mathrm{I}=x((\mu-\nu)\cdot q,z)\Big(\sum_{\alpha\in\Delta_m,\alpha\cdot\mu=1}\wp(\alpha\cdot q)-\sum_{\alpha\in\Delta_m,\alpha\cdot\nu=1}\wp(\alpha\cdot q)\Big)$$

$$\mathrm{II}=-\sum_{\lambda\in\Delta_s\setminus\{\mu,\nu\}}(x((\mu-\lambda)\cdot q,z)y((\lambda-\nu)\cdot q,z)-y((\mu-\lambda)\cdot q,z)x((\lambda-\nu)\cdot q,z)).$$

By the functional identity (24), we can rewrite II into a sum over middle roots,

$$\mathrm{II}=-\sum_{\lambda\in\Delta_s\setminus\{\mu,\nu\}} x((\mu-\nu)\cdot q,z)(\wp((\mu-\lambda)\cdot q)-\wp((\nu-\lambda)\cdot q))$$

$$=-x((\mu-\nu)\cdot q,z)\left(\sum_{\alpha\in\Delta_m,\alpha\cdot\mu=1}\wp(\alpha\cdot q)-\sum_{\alpha\in\Delta_m,\alpha\cdot\nu=1}\wp(\alpha\cdot q)\right).$$

Here the sum over λ has been converted to a sum over α by putting $\alpha=\mu-\lambda$ and $\alpha=\nu-\lambda$ in the two $\wp$ function in the first line. Note that μ, ν, and λ are all orthogonal to each other. We thus find that $\mathrm{I}+\mathrm{II}=0$.

For the other partial sums, we use the following functional identities, which we shall prove in Appendix C:

$$x(2u,z)y(-u-v,z)-y(2u,z)x(-u-v,z)+x(u+v,z)y(-2v,z)$$
$$-y(u+v,z)x(-2v,z)-x(u-v,z)(\wp(2u)-\wp(2v))=0, \tag{B35}$$

$$x^{(2)}(2u,z)y(-u-v,z)-y^{(2)}(2u,z)x(-u-v,z)+x(u+v,z)y^{(2)}(-2v,z)$$
$$-y(u+v,z)x^{(2)}(-2v,z)-x(u-v,z)(\wp^{(2)}(2u)-\wp^{(2)}(2v))=0, \tag{B36}$$

$$2x(u,2z)y(-u-v,z)-y(u,2z)x(-u-v,z)+x(u+v,z)y(-v,2z)$$
$$-2y(u+v,z)x(-v,2z)-x(u-v,z)(\wp(u)-\wp(v))=0, \tag{B37}$$

$$2x^{(1/2)}(u,2z)y(-u-v,z)-y^{(1/2)}(u,2z)x(-u-v,z)+x(u+v,z)y^{(1/2)}(-v,2z)$$
$$-2y(u+v,z)x^{(1/2)}(-v,2z)-x(u-v,z)(\wp^{(1/2)}(u)-\wp^{(1/2)}(v))=0. \tag{B38}$$

By these functional identities, we can confirm that all the partial sums regrouped by $g_m g_{l1}$, $g_m g_{l2}$, $g_m g_{s1}$, and $g_m g_{s2}$, respectively, cancel out.

APPENDIX C: PROOF OF FUNCTIONAL IDENTITIES FOR TWISTED MODELS

We here prove the functional identities that we have encountered in Appendix B. Although the proof is optimized to our choice of $x(u,z)$, $x^{(1/2)}(u,z)$, and $x^{(2)}(u,z)$, the same method can in principle apply to other solutions of the functional equations, such as the functions used by D'Hoker and Phong[15] and Bordner and Sasaki.[14]

1. Analytical properties of $x^{(1/2)}(u,z)$ and $x^{(2)}(u,z)$

The proof of the identities including $x^{(1/2)}(u,z)$ and $x^{(2)}(u,z)$, like the proof in Appendix A, is based on the analytical properties of those functions.

(a) $x^{(1/2)}(u,z)$ has the following analytical properties:

(1) $x^{(1/2)}(u,z)$ is a meromorphic function of u and z. The poles on the u plane and the z plane are located at the lattice points $u=m/2+n\tau$ and $z=m+2n\tau\,(m,n\in\mathbb{Z})$.

(2) $x^{(1/2)}(u,z)$ has the following quasiperiodicity:

$$x^{(1/2)}(u+\tfrac{1}{2},z)=x^{(1/2)}(u,z),\quad x^{(1/2)}(u+\tau,z)=e^{2\pi iz}x^{(1/2)}(u,z),$$
$$x^{(1/2)}(u,z+1)=x^{(1/2)}(u,z),\quad x^{(1/2)}(u,z+2\tau)=e^{4\pi iz}x^{(1/2)}(u,z). \tag{C1}$$

(3) At the origin of the u and z planes, this function exhibits the following singular behavior:

$$x^{(1/2)}(u,z)=\frac{1}{u}-2\rho(z|2\tau)+O(u)\quad(u\rightarrow 0),$$
$$x^{(1/2)}(u,z)=-\frac{2}{z}+2\rho(2u|2\tau)+O(z)\quad(z\rightarrow 0).\tag{C2}$$

(b) $x^{(2)}(u,z)$ has the following analytical properties:

(1) $x^{(2)}(u,z)$ is a meromorphic function of u and z. The poles on the u plane and the z plane are located at the lattice points $u=2m+n\tau$ and $z=m+n\tau/2\,(m,n\in\mathbb{Z})$.

(2) $x^{(2)}(u,z)$ has the following quasiperiodicity:

$$x^{(2)}(u+2,z)=x^{(2)}(u,z),\quad x^{(2)}(u+\tau,z)=e^{2\pi iz}x^{(2)}(u,z),$$
$$x^{(2)}(u,z+1)=x^{(2)}(u,z),\quad x^{(2)}\left(u,z+\frac{\tau}{2}\right)=e^{\pi iu}x^{(2)}(u,z).\tag{C3}$$

(3) At the origin of the u and z planes, this function exhibits the following singular behavior:

$$x^{(2)}(u,z)=\frac{1}{u}-\frac{1}{2}\rho\left(z\,\middle|\,\frac{\tau}{2}\right)+O(u)\quad(u\rightarrow 0),$$
$$x^{(2)}(u,z)=-\frac{1}{2z}+\frac{1}{2}\rho\left(\frac{u}{2}\,\middle|\,\frac{\tau}{2}\right)+O(z)\quad(z\rightarrow 0).\tag{C4}$$

2. Proof of (B35)–(B38)

These four identities can be treated in much the same way. Let us illustrate the proof for (B35) only. Since the line of the proof is almost the same as the proof of (24), we show an outline of the proof and leave the details to the reader.

Let $f(u,v,z)$ denote the left-hand side of (B35),

$$f(u,v,z)=x(2u,z)y(-u-v,z)-y(2u,z)x(-u-v,z)+x(u+v,z)y(-2v,z)$$
$$-y(u+v,z)x(-2v,z)-x(u-v,z)(\wp(2u)-\wp(2v)).\tag{C5}$$

Our task is to show the following analytic properties of $f(u,v,z)$, which imply that this function is identically zero:

(1) $f(u,v,z)$ has the quasiperiodicity as follows:

$$f(u+1,v,z)=f(u,v,z),\quad f(u+\tau,v,z)=e^{2\pi iz}f(u,v,z).\tag{C6}$$

(2) $f(u,v,z)$ is an entire function on the u plane.

The first property is immediate from the quasiperiodicity of $x(u,z)$, etc. Furthermore, it is obvious from the definition that all possible poles of $f(u,v,z)$ on the u plane are limited to the lattice points $u=m/2+n\tau/2$ and $u=-v+m+n\tau\,(m,n\in\mathbb{Z})$. In view of the quasiperiodicity, therefore, we have only to verify that $f(u,v,z)$ is nonsingular at $u=0,1/2,\tau/2,1/2+\tau/2$, and $-v$.

The absence of poles at $u=0,1/2$ and $-v$ can be verified by straightforward calculations on the basis of the singular behavior of $x(u,z)$, $x^{(1/2)}(u,z)$, and $x^{(2)}(u,z)$ as $u\rightarrow 0$.

In order to examine the points $u=\tau/2$ and $u=1/2+\tau/2$, one has to examine the singular behavior of $x(2u,z)$ and $y(2u,z)$ as $u\rightarrow\tau/2,1/2+\tau/2$. This can be worked out by combining the quasiperiodicity of $x(u,z)$ and $y(u,z)$ and their singular behavior as $u\rightarrow 0$,

(1) As $u\rightarrow\tau/2$,

$$x(2u,z)=e^{2\pi iz}x(2u-\tau,z)=e^{2\pi iz}\left(\frac{1}{2u-\tau}+O(1)\right),$$
$$y(2u,z)=2^{2\pi iz}y(2u-\tau,z)=e^{2\pi iz}\left(-\frac{1}{(2u-\tau)^2}+O(1)\right). \tag{C7}$$

(2) As $u\to 1/2+\tau/2$,

$$x(2u,z)=e^{2\pi iz}x(2u-1-\tau,z)=e^{2\pi iz}\left(\frac{1}{2u-1-\tau}+O(1)\right),$$
$$y(2u,z)=e^{2\pi iz}y(2u-1-\tau,z)=e^{2\pi iz}\left(-\frac{1}{(2u-1-\tau)^2}+O(1)\right). \tag{C8}$$

Using these observations, one can confirm the absence of poles of $f(u,v,z)$ at $u=\tau/2$ and $1/2+\tau/2$ by direct calculations.

We can thus verify that $f(u,v,z)$ is indeed an entire function on the u plane.

3. Proof of (B21)–(B26)

Rather than directly proving these identities, let us prove them in a differentiated form. For illustration, we consider the first identity (B21). Differentiating this identity by u gives

$$x(u,2z)y^{(1/2)}(-u,2z)-y(u,2z)z^{(1/2)}(-u,2z)+x^{(1/2)}(u,2z)y(-u,2z)-y^{(1/2)}(u,2z)x(-u,2z)$$
$$=2\wp'(u). \tag{C9}$$

One can prove it directly, repeating the complex analytic reasoning that we have presented in other cases. An alternative way is to take the limit, as $v\to u$, of the functional identity

$$x(2u,2z)y^{(1/2)}(-u-v,2z)-y(2u,2z)x^{(1/2)}(-u-v,2z)+x^{(1/2)}(u+v,2z)y(-2v,2z)$$
$$-y^{(1/2)}(u+v,2z)x(-2v,2z)-x(u-v,z)(\wp(2u)-\wp(2v))=0. \tag{C10}$$

(This yields the above identity upon substituting $u\to u/2$ and $v\to v/2$.) This functional identity can be derived by the same method as the proof of (B35)–(B38).

Similarly, the third and fifth of (B21)–(B26) are obtained from the following functional identities:

$$2x(u,2z)y^{(2)}(-u-v,z)-y(u,2z)x^{(2)}(-u-v,z)+x^{(2)}(u+v,z)y(-2v,2z)$$
$$-2y^{(2)}(u+v,z)x(-2v,2z)-x(u-v,z)(\wp(u)-\wp(v))=0, \tag{C11}$$

$$2x^{(1/2)}(u,2z)y^{(2)}(-u-v,z)-y^{(1/2)}(u,2z)x^{(2)}(-u-v,z)+x^{(2)}(u+v,z)y^{(1/2)}(-2v,2z)$$
$$-2y^{(2)}(u+v,z)x^{(1/2)}(-2v,z)-x(u-v,z)(\wp(u)-\wp(v))=0. \tag{C12}$$

The second, fourth, and sixth of (B21)–(B26) can be similarly derived from the last three of (B35)–(B38). This completes the proof of the functional identities.

We conclude this Appendix with a comment on the ''const.'' terms of these identities. In principle, these terms can be determined by examining the identities at a special point of the u plane. Let us consider, e.g., (B21). At $u=z$, the first term on the left-hand side vanishes. Evaluating the other terms at this point, therefore, one finds that

$$\text{const.}=2\wp(z)-x^{(1/2)}(z,2z)x(-z,2z). \tag{C13}$$

The same formula can be reproduced by substituting $u=-z$. One can similarly derive an explicit expression for the other identities.

A Sato formula for reflectionless finite difference operators

J. F. van Diejen
Universidad de Chile, Departamento de Matemáticas, Facultad de Ciencias, Casilla 653, Santiago 1, Chile

(Received 29 March 1999; accepted for publication 1 June 1999)

An explicit parametrization of the Jost functions of the reflectionless Jacobi operators in terms of their spectral data is presented. Interpolation produces a Sato formula for the eigenfunctions of a class of reflectionless finite difference operators on the line. © *1999 American Institute of Physics.* [S0022-2488(99)00311-4]

I. INTRODUCTION

The works on the underlying algebraic structure of infinite-dimensional integrable systems, first initiated by Sato and then further developed (mainly) by the Kyoto school, stand out as one of the highlights of soliton theory.[1–8] Central in Sato's scheme is the idea that a large class of integrable nonlinear evolution equations, among which, e.g., archetype equations as the Korteweg–de Vries (KdV) and the Kadomtsev–Petviashvili (KP) equations, may be understood from a conceptual point of view within the framework of the geometry of infinite-dimensional Grassmann manifolds and the representation theory of Kac–Moody algebras. An important practical feature of the Sato construction is that it produces a closed formula for the eigenfunctions of the Lax operator of the associated linear problem. For instance, in the case of the (soliton regime of the) KdV equation one ends up with an explicit formula for the eigenfunctions of the one-dimensional Schrödinger operators with reflectionless rapidly decreasing potentials.[1–6,8,9] (The potentials of interest are also commonly referred to as soliton potentials or Bargmann potentials.)

The present paper aims at exhibiting an analogous Sato formula for the eigenfunctions of the reflectionless Jacobi operators. To this end we employ inverse-scattering techniques for these operators that have their origin in the work of Flaschka on the soliton dynamics of the infinite Toda chain.[10–14] (The Jacobi operator in turn arises as the Lax operator in the linear problem associated to the infinite Toda chain.)

The structure of the paper is as follows. Sections II and III serve to prepare the grounds by recalling briefly some preliminaries regarding the scattering and inverse scattering theory of Jacobi operators. The inverse scattering theory is then applied in Sec. IV so as to produce a determinantal formula for the *Jost function* of the reflectionless Jacobi operator. The method followed here is based on Flaschka's approach towards corresponding determinantal formulas for the *coefficients* of this Jacobi operator.[10–12] In Sec. V we evaluate our determinantal representation for the reflectionless Jost function with the aid of the Cauchy determinant formula; this entails an explicit Sato type formula for the Jost function under consideration. The transition from the determinantal formula for the Jost function to the Sato type formula is to be compared with the passage from Flaschka's determinantal expressions for the coefficients of the reflectionless Jacobi operator to their explicit representation in terms of tau functions due to Hirota (who, incidentally, used direct methods rather than inverse scattering theory).[15,16,12] Next, in Sec. VI, our Sato formula is interpolated from $\mathbb{Z}$ to $\mathbb{R}$. The result is a Sato formula for reflectionless finite difference operators living on the whole line rather than just on the integer lattice. (In other words, we pass from discrete difference operators acting on functions over $\mathbb{Z}$ to analytic difference operators acting on functions over $\mathbb{R}$.) Finally, the paper is concluded with a list of miscellaneous remarks in Sec. VII.

II. SCATTERING

We will start out by recalling some standard notions from the scattering theory for Jacobi operators (see, e.g., Refs. 10–12). Let

$$D=a_n T+a_{n-1} T^{-1}+b_n \quad (n\in\mathbb{Z}) \tag{II.1}$$

be a Jacobi operator with $a_n>0$ and $b_n\in\mathbb{R}$ for $n\in\mathbb{Z}$. Here T represents a shift operator that acts on lattice functions $\psi:\mathbb{Z}\to\mathbb{C}$ via $(T\psi)(n)=\psi(n+1)$. For the purpose of scattering we are interested in the situation of a Jacobi operator that tends asymptotically to a discrete Laplacian when $|n|$ becomes large. More precisely, from now on it will be assumed that for $|n|\to\infty$ the coefficients a_n and b_n converge rapidly (say exponentially) to 1 and 0, respectively. We then have that our Jacobi operator constitutes a self-adjoint operator in the Hilbert space $l^2(\mathbb{Z})$ of square-summable functions over the integer lattice $\mathbb{Z}$.

The spectral problem associated to D (II.1) is governed by a discrete difference equation of the form

$$a_n\psi(n+1,z)+b_n\psi(n,z)+a_{n-1}\psi(n-1,z)=(z+z^{-1})\psi(n,z), \quad n\in\mathbb{Z}. \tag{II.2}$$

Here z denotes a (possibly complex) spectral parameter. The conditions on the coefficients guarantee that asymptotically (for $|n|\to\infty$) the solutions of the difference equation in Eq. (II.2) decompose into a linear combination of the plane waves z^n and z^{-n}. The Jost function (of the first kind) $\psi_{\text{jost}}(n,z)$ is the solution to Eq. (II.2) that is characterized by an asymptotics of the form z^n for $n\to\infty$. More precisely, one has that

$$\psi_{\text{jost}}(n,z)\to\begin{cases} z^n & \text{for } n\to+\infty \\ \alpha(z)z^n+\beta(z)z^{-n} & \text{for } n\to-\infty, \end{cases} \tag{II.3}$$

where $\alpha(z)$ and $\beta(z)$ represent two z-dependent coefficients that describe the asymptotics of the Jost function at minus infinity. For generic z, the solution $\psi_{\text{jost}}(n,z)$ is obtained from a fundamental system consisting of two independent solutions to the second-order difference Eq. (II.2) by taking an appropriate linear combination. The coefficients $\alpha(z)$ and $\beta(z)$ contain important information regarding the spectrum of the Jacobi operator under consideration. Specifically, the zeros of $\alpha(z)$—which with our conditions on the coefficients a_n and b_n are simple, finite in number, and lie inside the punctured interval $]-1,1[\setminus\{0\}$—determine the discrete spectrum. (Notice in this connection that at such spectral values the Jost function decays exponentially for $|n|\to\infty$.) Let us denote the zeros in question by $1>z_1>z_2>\cdots>z_N>-1$ (with $z_j\neq 0$) and let the numbers $\nu_1,\ldots,\nu_N>0$ be the corresponding normalization constants,

$$\nu_j=\left(\sum_{n\in\mathbb{Z}}\psi^2_{\text{jost}}(n,z_j)\right)^{-1}, \quad j=1,\ldots,N. \tag{II.4}$$

The discrete spectral values $z_1,\ldots,z_N$ and normalization constants $\nu_1,\ldots,\nu_N$, together with the *reflection coefficient* $r(z):=-\beta(z^{-1})/\alpha(z)$, are referred to as the *spectral data* of the Jacobi operator. (Our definition of $\beta(z)$ differs from the standard conventions (cf. e.g., Refs. 10–12) by the change $\beta(z)\to-\beta(z^{-1})$.) When $r(z)=\beta(z)\equiv 0$ (identically in z) the Jacobi operator is said to be *reflectionless*.

III. INVERSE SCATTERING

It is known from the inverse scattering theory for Jacobi operators (with $a_n>0$, $b_n\in\mathbb{R}$ and $a_n\to 1$, $b_n\to 0$ rapidly for $|n|\to\infty$) that both the coefficients a_n, b_n and the Jost function $\psi_{\text{jost}}(n,z)$ can be completely recovered from the spectral data.[10–12] Specifically, one has that

$$a_n=\frac{K(n+1,n+1)}{K(n,n)}, \tag{III.1a}$$

$$b_n=\frac{K(n,n+1)}{K(n,n)}-\frac{K(n-1,n)}{K(n-1,n-1)}, \tag{III.1b}$$

and

$$\psi_{\text{jost}}(n,z)=\sum_{m=n}^{\infty} K(n,m)z^m, \quad 0<|z|\leqslant 1 \tag{III.2}$$

$(n\in\mathbb{Z})$, where $K(n,m)$ is a kernel of the form

$$K(n,m)=\begin{cases}\left(1+F(2n)+\sum_{l=n+1}^{\infty} k(n,l)F(l+n)\right)^{-1/2} & \text{for } m=n,\\ K(n,n)\,k(n,m) & \text{for } m>n.\end{cases} \tag{III.3}$$

Here the kernel $F(l+n)$, which is determined by the function

$$F(m)=\frac{1}{2\pi i}\oint r(z)z^{m-1}\mathrm{d}z+\sum_{j=1}^{N} \nu_j z_j^m \tag{III.4}$$

(where the integration is along the unit circle in the positive direction), encodes the dependence on the spectral data, and the kernel $k(n,m)$, $m>n$ is obtained from $F(m)$ (III.4) as the (unique) solution of the *discrete Gelfand–Levitan–Marchenko equation*

$$k(n,m)+F(n+m)+\sum_{l=n+1}^{\infty} k(n,l)F(l+m)=0, \;\; m>n. \tag{III.5}$$

IV. THE REFLECTIONLESS CASE: DETERMINANTAL REPRESENTATIONS

In the reflectionless situation, i.e., with $r(z)\equiv 0$, the kernel associated to $F(m)$ (III.4) becomes seperable and of finite rank,

$$F(m)=\sum_{j=1}^{N} \nu_j z_j^m. \tag{IV.1}$$

It is known from the work of Flaschka that the question of solving the discrete Gelfand–Levitan–Marchenko equation (III.5) reduces in this situation to a finite-dimensional problem that can be solved explicitly in closed form.[10–12] In this section we will use the exact solution in question to arrive at a determinantal formula for the reflectionless Jost function.

To this end we first recall Flaschka's solution of the Gelfand–Levitan–Marchenko equation with $r(z)\equiv 0$. The key step lies in the substitution of the separable ansatz,

$$k(n,m)=\sum_{j=1}^{N} k_j(n)z_j^m \tag{IV.2}$$

for the unknown kernel $k(n,m)$. The discrete Gelfand–Levitan–Marchenko equation of Eq. (III.5)—with the function $F(m)$ is taken from Eq. (IV.1)—produces the relation

$$\sum_{j=1}^{N} (\nu_j z_j^n+k_j(n))z_j^m+\sum_{i,j=1}^{N} \left(k_i(n)\,\nu_j z_j^m \sum_{l=n+1}^{\infty} (z_i z_j)^l\right)=0. \tag{IV.3}$$

Summation of the geometric series gives rise to the following N-dimensional linear system for the quantities $k_1(n),\ldots,k_N(n)$,

$$k_j(n)+\nu_j\sum_{i=1}^{N} k_i(n)\frac{z_i^{n+1}z_j^{n+1}}{1-z_iz_j}=-\nu_j z_j^n,\quad j=1,\ldots,N. \tag{IV.4}$$

The linear system is subsequently solved in the standard way by means of Cramer's Rule,

$$k_j(n)=\frac{\det \mathbf{A}^{(j)}(n)}{\det \mathbf{A}(n)},\quad j=1,\ldots,N, \tag{IV.5}$$

where

$$\mathbf{A}(n)=\begin{bmatrix} 1+\nu_1\frac{z_1^{2n+2}}{1-z_1^2} & \cdots & \nu_1\frac{z_1^{n+1}z_j^{n+1}}{1-z_1z_j} & \cdots & \nu_1\frac{z_1^{n+1}z_N^{n+1}}{1-z_1z_N} \\ \vdots & \ddots & \vdots & & \vdots \\ \nu_j\frac{z_j^{n+1}z_1^{n+1}}{1-z_jz_1} & \cdots & 1+\nu_j\frac{z_j^{2n+2}}{1-z_j^2} & \cdots & \nu_j\frac{z_j^{n+1}z_N^{n+1}}{1-z_jz_N} \\ \vdots & & \vdots & \ddots & \vdots \\ \nu_N\frac{z_N^{n+1}z_1^{n+1}}{1-z_Nz_1} & \cdots & \nu_N\frac{z_N^{n+1}z_j^{n+1}}{1-z_Nz_j} & \cdots & 1+\nu_N\frac{z_N^{2n+2}}{1-z_N^2} \end{bmatrix} \tag{IV.6}$$

and

$$\mathbf{A}^{(j)}(n)=\begin{bmatrix} 1+\nu_1\frac{z_1^{2n+2}}{1-z_1^2} & \cdots & -\nu_1 z_1^n & \cdots & \nu_1\frac{z_1^{n+1}z_N^{n+1}}{1-z_1z_N} \\ \vdots & \ddots & \vdots & & \vdots \\ \nu_j\frac{z_j^{n+1}z_1^{n+1}}{1-z_jz_1} & \cdots & -\nu_j z_j^n & \cdots & \nu_j\frac{z_j^{n+1}z_N^{n+1}}{1-z_jz_N} \\ \vdots & & \vdots & \ddots & \vdots \\ \nu_N\frac{z_N^{n+1}z_1^{n+1}}{1-z_Nz_1} & \cdots & -\nu_N z_N^n & \cdots & 1+\nu_N\frac{z_N^{2n+2}}{1-z_N^2} \end{bmatrix}. \tag{IV.7}$$

$\uparrow$
(jth column)

(The matrix $\mathbf{A}^{(j)}(n)$ is obtained from $\mathbf{A}(n)$ (IV.6) by replacing its jth column by the transpose of the vector $(-\nu_1 z_1^n,\ldots,-\nu_N z_N^n)$.) The (inverse square of the) diagonal of the kernel $K(n,m)$ (III.3) is now computed as

$$K^{-2}(n,n)\overset{\text{Eqs. (IV.1),(IV.2)}}{=}1+\sum_{j=1}^{N}\nu_j z_j^{2n}+\sum_{i,j=1}^{N}k_i(n)\nu_j\frac{z_i^{n+1}z_j^{2n+1}}{1-z_iz_j}$$

$$\overset{\text{Eq. (IV.4)}}{=}1-\sum_{j=1}^{N}k_j(n)z_j^n$$

$$\stackrel{\text{Eq. (IV.5)}}{=} \frac{\det \mathbf{A}(n) - \Sigma_{j=1}^{N} z_j^n \det \mathbf{A}^{(j)}(n)}{\det \mathbf{A}(n)}$$

$$= \det \mathbf{A}(n-1)/\det \mathbf{A}(n). \tag{IV.8}$$

(In the last step one uses that the difference $\mathbf{A}(n-1)-\mathbf{A}(n)$ is a rank-one matrix of the form $[\nu_i z_i^n z_j^n]_{1\leqslant i,j\leqslant N}$, whence $\det \mathbf{A}(n-1) - \det \mathbf{A}(n) = -\Sigma_{j=1}^{N} z_j^n \det \mathbf{A}^{(j)}(n)$.)

One thus ends up with the following determinantal representation for the coefficients a_n (III.1a):

$$a_n = \frac{\sqrt{\det \mathbf{A}(n+1)\det \mathbf{A}(n-1)}}{\det \mathbf{A}(n)}, \quad n\in\mathbb{Z}. \tag{IV.9}$$

In a similar way one arrives at a determinantal formula for the coefficients b_n (III.1b),

$$\begin{aligned} b_n &\stackrel{\text{Eqs. (III.1b),(III.3)}}{=} k(n,n+1) - k(n-1,n) \\ &\stackrel{\text{Eq. (IV.2)}}{=} \sum_{j=1}^{N} (k_j(n) z_j^{n+1} - k_j(n-1) z_j^n) \\ &\stackrel{\text{Eq. (IV.5)}}{=} \sum_{j=1}^{N} \left(\frac{\det \mathbf{A}^{(j)}(n)}{\det \mathbf{A}(n)} z_j^{n+1} - \frac{\det \mathbf{A}^{(j)}(n-1)}{\det \mathbf{A}(n-1)} z_j^n \right) \\ &= \sum_{j=1}^{N} \left(\frac{\det \mathbf{B}^{(j)}(n)}{\det \mathbf{A}(n)} - \frac{\det \mathbf{B}^{(j)}(n-1)}{\det \mathbf{A}(n-1)} \right), \end{aligned} \tag{IV.10}$$

where

$$\mathbf{B}^{(j)}(n) = \begin{bmatrix} 1+\nu_1 \frac{z_1^{2n+2}}{1-z_1^2} & \cdots & \nu_1(z_1-z_1^{-1})\frac{z_1^{n+1}z_j^{n+1}}{1-z_1 z_j} & \cdots & \nu_1 \frac{z_1^{n+1} z_N^{n+1}}{1-z_1 z_N} \\ \vdots & \ddots & \vdots & & \vdots \\ \nu_j \frac{z_j^{n+1} z_1^{n+1}}{1-z_j z_1} & \cdots & \nu_j(z_j - z_j^{-1}) \frac{z_j^{2n+2}}{1-z_j^2} & \cdots & \nu_j \frac{z_j^{n+1} z_N^{n+1}}{1-z_j z_N} \\ \vdots & & \vdots & \ddots & \vdots \\ \nu_N \frac{z_N^{n+1} z_1^{n+1}}{1-z_N z_1} & \cdots & \nu_N(z_N - z_N^{-1}) \frac{z_N^{n+1} z_j^{n+1}}{1-z_N z_j} & \cdots & 1+\nu_N \frac{z_N^{2n+2}}{1-z_N^2} \end{bmatrix}. \tag{IV.11}$$

↑
(jth column)

(So the matrix $\mathbf{B}^{(j)}(n)$ is obtained from $\mathbf{A}(n)$ (IV.6) by replacing the jth column by the transpose of the vector $(\nu_1(z_1-z_1^{-1})z_1^n z_j^n/(1-z_1z_j), \ldots, \nu_N(z_N-z_N^{-1})z_N^n z_j^n/(1-z_N z_j))$.) In passing from the third to the fourth line of Eq. (IV.10) it was used that

$$\sum_{j=1}^{N} \left(\det \mathbf{A}^{(j)}(n) z_j^{n+1} - \det \mathbf{B}^{(j)}(n) \right)$$

$$= \sum_{j=1}^{N} \det \begin{bmatrix} 1+\nu_1 \frac{z_1^{2n+2}}{1-z_1^2} & \cdots & \nu_1 \frac{z_1^{n+1} z_j^{n+1}}{1-z_1 z_j}(z_j - z_1) & \cdots & \nu_1 \frac{z_1^{n+1} z_N^{n+1}}{1-z_1 z_N} \\ \vdots & \ddots & \vdots & & \vdots \\ \nu_j \frac{z_j^{n+1} z_1^{n+1}}{1-z_j z_1} & \cdots & 0 & \cdots & \nu_j \frac{z_j^{n+1} z_N^{n+1}}{1-z_j z_N} \\ \vdots & & \vdots & \ddots & \vdots \\ \nu_N \frac{z_N^{n+1} z_1^{n+1}}{1-z_N z_1} & \cdots & \nu_N \frac{z_N^{n+1} z_j^{n+1}}{1-z_N z_j}(z_j - z_N) & \cdots & 1+\nu_N \frac{z_N^{2n+2}}{1-z_N^2} \end{bmatrix} = 0.$$

$$\uparrow$$
$$(j\text{th column})$$

(To see that the determinants on the second line of the above formula indeed sum up to yield zero, one develops the determinant of jth term to the jth column; this way it is not difficult to see that the subdeterminant in the jth term originating from the minor corresponding to the ith row cancels against the subdeterminant in the ith term originating from the minor corresponding to the jth row.) It is immediate from the last line of Eq. (IV.10) that we may write

$$b_n = \partial_t \log\left(\frac{\det \mathbf{A}(n,t)}{\det \mathbf{A}(n-1,t)} \right) \bigg|_{t=0}, \quad n \in \mathbb{Z}, \tag{IV.12}$$

where $\mathbf{A}(n,t)$ denotes the matrix of the form in Eq. (IV.6) with $\nu_j \to \nu_j e^{t(z_j - z_j^{-1})}$, $j = 1, \ldots, N$.

The above method for computing the coefficients of the reflectionless Jacobi operator is due to Flaschka,[10] who used it to arrive at the determinantal representation for a_n given by Eq. (IV.9). The determinantal representation for b_n in Eq. (IV.12) can moreover be found e.g., in the book by Toda[12] (who provides a somewhat different proof). More recently an alternative approach towards the derivation of the determinantal formulas for the coefficients a_n and b_n was presented in Ref. 17 (see also Refs. 13,14).

After these preparations we are now finally in the position to present the corresponding determinantal formula for the Jost function $\psi_{\text{jost}}(n,z)$. Indeed, starting from Eq. (III.2) we get by successive manipulations,

$$\begin{aligned} \psi_{\text{jost}}(n,z) &\overset{\text{Eqs. (III.3),(IV.2)}}{=} K(n,n)\left(z^n + \sum_{j=1}^{N} k_j(n) \sum_{l=n+1}^{\infty} (z_j z)^l \right) \\ &= K(n,n)\left(z^n + \sum_{j=1}^{N} k_j(n) \frac{(z_j z)^{n+1}}{1-z_j z} \right) \\ &\overset{\text{Eqs. (IV.5),(IV.8)}}{=} \frac{z^n \left(\det \mathbf{A}(n) + \sum_{j=1}^{N} z_j^n \det \mathbf{A}^{(j)}(n) \frac{z_j z}{1-z_j z} \right)}{\sqrt{\det \mathbf{A}(n) \det \mathbf{A}(n-1)}} \\ &= \frac{z^n \det \mathbf{C}(n,z)}{\sqrt{\det \mathbf{A}(n) \det \mathbf{A}(n-1)}}, \end{aligned} \tag{IV.13}$$

where $\mathbf{C}(n,z)$ denotes the matrix obtained from $\mathbf{A}(n)$ (IV.6) by the substitution $\nu_j \to \nu_j(1-zz_j^{-1})/(1-zz_j)$, $j=1,\ldots,N$. More explicitly, the matrix $\mathbf{C}(n,z)$ is given by

$$\mathbf{C}(n,z)=\begin{bmatrix} 1+\nu_1\frac{z_1^{2n+2}}{1-z_1^2}\left(\frac{1-zz_1^{-1}}{1-zz_1}\right) & \cdots & \nu_1\frac{z_1^{n+1}z_N^{n+1}}{1-z_1z_N}\left(\frac{1-zz_1^{-1}}{1-zz_1}\right) \\ \vdots & \ddots & \vdots \\ \nu_N\frac{z_N^{n+1}z_1^{n+1}}{1-z_Nz_1}\left(\frac{1-zz_N^{-1}}{1-zz_N}\right) & \cdots & 1+\nu_N\frac{z_N^{2n+2}}{1-z_N^2}\left(\frac{1-zz_N^{-1}}{1-zz_N}\right) \end{bmatrix}. \quad \text{(IV.14)}$$

In order to verify that the expressions on the third and fourth line of Eq. (IV.13) are indeed equivalent, we employ the following pole expansion for the determinant of the matrix $\mathbf{C}(n,z)$ (IV.14):

$$\det \mathbf{C}(n,z)=\det \mathbf{C}_0(n)+\sum_{j=1}^{N} \det \mathbf{C}_j(n)\,\frac{zz_j}{1-zz_j}, \quad \text{(IV.15)}$$

where $\mathbf{C}_0(n)=\lim_{z\to 0}\mathbf{C}(n,z)=\mathbf{A}(n)$ and $\mathbf{C}_j(n)$ is the matrix obtained from $\mathbf{C}(n,z)$ via the substitution $z=z_j^{-1}$ after having multiplied the jth row by a factor $1-zz_j$ to compensate the singularity. Subtraction of z_k^{n+1}/z_j^{n+1} times the jth column of $\mathbf{C}_j(n)$ from its kth column (for $k=1,\ldots,N,\ k\neq j$) and multiplication of the resulting matrix from the left by $\mathrm{diag}(1-z_1/z_j,\ldots,1,\ldots,1-z_N/z_j)$ and from the right by $\mathrm{diag}(1/(1-z_1/z_j),\ldots,1,\ldots,1/(1-z_N/z_j))$ (where the units are in the jth slot), leads one to a matrix that is equal to the matrix $\mathbf{A}^{(j)}(n)$ with its jth column multiplied by z_j^n. Hence, we conclude that the expressions on the third and fourth line of Eq. (IV.13) are equal.

V. THE DISCRETE SATO FORMULA

We will now evaluate the determinantal representations of the previous section with the aid of the Cauchy determinant formula [see, e.g., Macdonald (Ref. 18, p. 67)],

$$\det\left[\frac{1}{1-x_jy_k}\right]_{1\leq j,k\leq N}=\frac{\prod_{1\leq j<k\leq N}(x_j-x_k)(y_j-y_k)}{\prod_{1\leq j,k\leq N}(1-x_jy_k)}. \quad \text{(V.1)}$$

This leads us to an explicit parametrization of the Jost function for the reflectionless Jacobi operator in terms of the spectral data. To describe the result some notation is needed,

$$\tau(n)=\sum_{J\in\{1,\ldots,N\}}\prod_{j\in J}\frac{\nu_jz_j^{2n+2}}{1-z_j^2}\prod_{\substack{j,k\in J\\ j<k}}\left(\frac{z_j-z_k}{1-z_jz_k}\right)^2, \quad \text{(V.2a)}$$

$$\sigma(n)=\sum_{J\in\{1,\ldots,N\}}\sum_{j\in J}(z_j-z_j^{-1})\prod_{j\in J}\frac{\nu_jz_j^{2n+2}}{1-z_j^2}\prod_{\substack{j,k\in J\\ j<k}}\left(\frac{z_j-z_k}{1-z_jz_k}\right)^2, \quad \text{(V.2b)}$$

$$\chi(n,z)=\sum_{J\in\{1,\ldots,N\}}\prod_{j\in J}\frac{\nu_jz_j^{2n+2}}{1-z_j^2}\left(\frac{1-zz_j^{-1}}{1-zz_j}\right)\prod_{\substack{j,k\in J\\ j<k}}\left(\frac{z_j-z_k}{1-z_jz_k}\right)^2. \quad \text{(V.2c)}$$

The following theorem provides the parametrization of the reflectionless Jost function in terms of the spectral data.

Theorem 1 (Spectral Parametrization): *Let $D=a_nT+a_{n-1}T^{-1}+b_n$ be a (self-adjoint) Jacobi operator in $l^2(\mathbb{Z})$ with $a_n>0$, $b_n\in\mathbb{R}$ such that $a_n\to 1$, $b_n\to 0$ rapidly (say exponentially)* *for* $|n|\to\infty$. *Furthermore, let D be reflectionless* $(r(z)\equiv 0)$ *and characterized by spectral data of the form* $1>z_1>\cdots>z_N>-1$, $z_j\neq 0$ *(corresponding to the discrete spectrum (more precisely, the discrete spectrum consists of N eigenvalues of the form* $(z_j+z_j^{-1})$, $j=1,\ldots,N$.*)) and* $\nu_1,\ldots,\nu_N>0$ *(corresponding to the associated normalization constants, cf. Eq. (II.4)).*

Then the coefficients of D may be written as

$$a_n=\frac{\sqrt{\tau(n+1)\,\tau(n-1)}}{\tau(n)},\qquad b_n=\frac{\sigma(n)}{\tau(n)}-\frac{\sigma(n-1)}{\tau(n-1)},$$

and the Jost solution $\psi_{\mathrm{jost}}(n,z)$ *of the eigenvalue equation* $D\psi=(z+z^{-1})\psi$ *with asymptotics of the form* $\psi_{\mathrm{jost}}(n,z)\to z^n$ *for* $n\to+\infty$ *takes the form*

$$\psi_{\mathrm{jost}}(n,z)=\frac{z^n\,\chi(n,z)}{\sqrt{\tau(n)\,\tau(n-1)}}.$$

Here the functions $\tau(n)$, $\sigma(n)$, *and* $\chi(n,z)$ *are defined by Eqs. (V.2a), (V.2b) and (V.2c), respectively. Moreover, the spatial variable n lives on the integer lattice* $\mathbb{Z}$ *and the spectral variable z is assumed to take values in the punctured unit disk* $0<|z|\leqslant 1$.

Proof: The reconstruction from the spectral data given in Sec. IV provides us with determinantal representations for the coefficients and Jost function of the reflectionless Jacobi operator (cf. Eqs. (IV.9), (IV.12), and (IV.13).

It is not very difficult to infer—with the aid of the Cauchy determinant formula (V.1)—that the determinant of the matrix $\mathbf{A}(n)$ (IV.6) is given by $\tau(n)$ (V.2a). Indeed, the matrix $\mathbf{A}(n)$ (IV.6) has the structure of an identity matrix plus a matrix of the form **NDCD**, where $\mathbf{N}=\mathrm{diag}(\nu_1,\ldots,\nu_N)$, $\mathbf{D}=\mathrm{diag}(z_1^{n+1},\ldots,z_N^{n+1})$, and $\mathbf{C}=[(1-z_jz_k)^{-1}]_{1\leqslant j,k\leqslant N}$. We thus have that the determinant of $\mathbf{A}(n)$ amounts to the sum of all principal minors of the matrix **NDCD**, which are readily evaluated by means of the Cauchy determinant formula (with $x_j=y_j=z_j$, $j=1,\ldots,N$) so as to produce $\det\mathbf{A}(n)=\tau(n)$. The stated expressions for a_n, b_n, and $\psi_{\mathrm{jost}}(n,z)$ then follow from Eqs. (IV.9), (IV.12), and (IV.13). In this connection it is helpful to recall that the matrices $\mathbf{A}(n,t)$ and $\mathbf{C}(n,z)$, appearing in Eqs. (IV.12) and (IV.13), are obtained from the matrix $\mathbf{A}(n)$ (IV.6) via the substitutions $\nu_j\to\nu_j e^{t(z_j-z_j^{-1})}$ and $\nu_j\to\nu_j(1-zz_j^{-1})/(1-zz_j)$, respectively. (Thus one has that $\partial_t\log(\det\mathbf{A}(n,t))|_{t=0}=\sigma(n)/\tau(n)$ and $\det\mathbf{C}(n,z)=\chi(n,z)$.) □

Theorem V immediately implies the following Sato-type formula for (the wave functions of) the reflectionless discrete difference operators of Jacobi-type.

Corollary 1. (Discrete Sato Formula): Let $0<|z|\leqslant 1$, $1>z_1>\cdots>z_N>-1$ *with* $z_j\neq 0$, $\nu_1,\ldots,\nu_N>0$, *and let* $\tau(n)$, $\sigma(n)$, *and* $\chi(n,z)$ *be given by Eqs. (V.2a), (V.2b), and (V.2c). Then we have that the discrete Sato function of the form*

$$\psi_{\mathrm{jost}}(n,z)=\frac{z^n\,\chi(n,z)}{\sqrt{\tau(n)\,\tau(n-1)}}$$

solves the discrete difference equation,

$$a_n\,\psi(n+1,z)+b_n\,\psi(n,z)+a_{n-1}\,\psi(n-1,z)=(z+z^{-1})\,\psi(n,z),\quad n\in\mathbb{Z},$$

with coefficients given by

$$a_n=\frac{\sqrt{\tau(n+1)\,\tau(n-1)}}{\tau(n)},\qquad b_n=\frac{\sigma(n)}{\tau(n)}-\frac{\sigma(n-1)}{\tau(n-1)}.$$

VI. INTERPOLATION: FROM $\mathbb{Z}$ TO $\mathbb{R}$

Next we interpolate the discrete Sato formula of Corollary V so as to arrive at a corresponding Sato formula for certain reflectionless finite difference operators living on the whole line instead of merely on the integer lattice. For this purpose it is convenient to perform a trigonometric change of variables/parameters,

$$z=e^{y},\quad n=x,\ z_j=e^{-\kappa_j}\quad (j=1,\ldots,N). \tag{VI.1}$$

The functions τ, σ, and χ of Eqs. (V.2a), (V.2b), and (V.2c) pass with these substitutions over into

$$\tau(x)=\sum_{J\in\{1,\ldots,N\}}\prod_{j\in J}\frac{\nu_j e^{-\kappa_j}}{2\sinh(\kappa_j)}\prod_{\substack{j,k\in J\\ j<k}}\left(\frac{\sinh\frac{1}{2}(\kappa_j-\kappa_k)}{\sinh\frac{1}{2}(\kappa_j+\kappa_k)}\right)^2\exp\left(-2x\sum_{j\in J}\kappa_j\right), \tag{VI.2a}$$

$$\sigma(x)=-2\sum_{J\in\{1,\ldots,N\}}\left[\sum_{j\in J}\sinh(\kappa_j)\prod_{j\in J}\frac{\nu_j e^{-\kappa_j}}{2\sinh(\kappa_j)}\prod_{\substack{j,k\in J\\ j<k}}\left(\frac{\sinh\frac{1}{2}(\kappa_j-\kappa_k)}{\sinh\frac{1}{2}(\kappa_j+\kappa_k)}\right)^2\right.$$
$$\left.\times\exp\left(-2x\sum_{j\in J}\kappa_j\right)\right], \tag{VI.2b}$$

$$\chi(x,y)=\sum_{J\in\{1,\ldots,N\}}\left[\prod_{j\in J}\frac{\nu_j}{2\sinh(\kappa_j)}\frac{\sinh\frac{1}{2}(y+\kappa_j)}{\sinh\frac{1}{2}(y-\kappa_j)}\prod_{\substack{j,k\in J\\ j<k}}\left(\frac{\sinh\frac{1}{2}(\kappa_j-\kappa_k)}{\sinh\frac{1}{2}(\kappa_j+\kappa_k)}\right)^2\exp\left(-2x\sum_{j\in J}\kappa_j\right)\right]. \tag{VI.2c}$$

The following theorem provides a Sato formula for the wave functions of analytic difference operators of the form $\mathcal{D}=a(x)\,T+a(x-1)\,T^{-1}+b(x)$ acting on functions $\psi:\mathbb{R}\to\mathbb{C}$. Here $(T\psi)(x)=\psi(x+1)$ and the coefficients $a(x)$, $b(x)$ are obtained from the coefficients a_n, b_n of Theorem 1/Corollary 2 via the substitutions in Eq. (VI.1).

Theorem 3. (Difference Sato Formula): *Let* $0<\kappa_1<\cdots<\kappa_N$, $\nu_1,\ldots,\nu_N>0$, *and let* $\tau(x)$, $\sigma(x)$. *and* $\chi(x,z)$ *be given by Eqs. (VI.2a), (VI.2b), and (VI.2c). Then we have that the difference Sato function of the form,*

$$\psi(x,y)=\frac{\exp(xy)\ \chi(x,y)}{\sqrt{\tau(x)\ \tau(x-1)}},$$

solves the analytic difference equation

$$a(x)\ \psi(x+1,y)+b(x)\ \psi(x,y)+a(x-1)\ \psi(x-1,y)=2\cosh(y)\ \psi(x,y),\quad x\in\mathbb{R},$$

with coefficients given by

$$a(x)=\frac{\sqrt{\tau(x+1)\ \tau(x-1)}}{\tau(x)},\quad b(x)=\frac{\sigma(x)}{\tau(x)}-\frac{\sigma(x-1)}{\tau(x-1)}.$$

Here it is assumed that the spectral parameter $y\in\mathbb{C}$ *is not equal to* $\kappa_j \bmod 2\pi i$ *for* $j=1,\ldots,N$.

Proof: It is clear that, with the stated restrictions on the parameters, the coefficients $a(x)$, $b(x)$, and the wave function $\psi(x,y)$ are well-defined and regular for $x\in\mathbb{R}$. Indeed, the tau functions in the denominators stay away from zero for $x\in\mathbb{R}$, since $\tau(x)$ is positive on the real line as a sum of positive terms. For $x\in\mathbb{Z}$ and $\mathrm{Re}(y)\leqslant 0$, the statement of the theorem is immediate from Corollary V. Hence, we have that at such integer values for x the difference equation with Sato wave function holds as an identity in the parameters $\kappa_1,\ldots,\kappa_N$ and $\nu_1,\ldots,\nu_N$. The generalization to general $x\in\mathbb{R}$ then follows from the observation that a translation $x\to x+\Delta$, $\Delta\in\mathbb{R}$ is equivalent to a reparametrization of the form $\nu_j\to\nu_j e^{2\Delta}$, $j=1,\ldots,N$, together with a multiplication of the wave function by the (x-independent) overall factor $e^{\Delta y}$. The passage from y in the left half-plane to general complex $y\neq\kappa_j \bmod 2\pi i$, $j=1,\ldots,N$ is clear by analyticity. □

VII. MISCELLANEOUS REMARKS

A. Asymptotics

From the formula of Theorem 1/Corollary 2 we read-off that our Jost function $\psi_{\mathrm{jost}}(n,z)$ has an asymptotics at infinity of the form

$$\psi_{\mathrm{jost}}(n,z)\to\begin{cases} z^n & \text{for } n\to+\infty \\ z^n\prod_{j=1}^{N}\left(\frac{z_j-z}{1-z_jz}\right) & \text{for } n\to-\infty. \end{cases} \tag{VII.1}$$

This asymptotics is thus of the general form given by Eq. (II.3) with $\alpha(z)=\Pi_{j=1}^{N}[(z_j-z/1-z_jz)]$ and $\beta(z)=0$. The vanishing of $\beta(z)$ is in agreement with the fact that our Jacobi operator is reflectionless. The formulas moreover confirm that the zeros of $\alpha(z)$ do indeed correspond to the values $z=z_j$, $j=1,\ldots,N$. For the wave function of Theorem 3 the asymptotics at infinity becomes ($n\to x$, $z\to e^y$ and $z_j\to e^{-\kappa_j}$),

$$\psi(x,y)\to\begin{cases} \exp(xy) & \text{for } x\to+\infty \\ \exp(xy)\prod_{j=1}^{N}\frac{\sinh\frac{1}{2}(y+\kappa_j)}{\sinh\frac{1}{2}(y-\kappa_j)} & \text{for } x\to-\infty. \end{cases} \tag{VII.2}$$

B. Summation and integration formulas

It is clear from the explicit formula of Theorem 1/Corollary 2 that the reflectionless Jost function $\psi_{\mathrm{jost}}(n,z)$ decays exponentially for $|n|\to\infty$ at the discrete spectral values $z=z_j$, $j=1,\ldots,N$. Hence, the wave function is indeed square-summable at these spectral values. (As it should be, because the spectral values $z_1,\ldots,z_N$ constitute the discrete spectrum.) The interpretation of the parameters $\nu_1,\ldots,\nu_N$ as the corresponding normalization constants (cf. Eq. (II.4)) moreover implies that the wave function of Theorem 1/Corollary 2 satisfies the following summation identity;

$$\sum_{n\in\mathbb{Z}}\psi_{\mathrm{jost}}^2(n,z_j)=1/\nu_j,\quad j=1,\ldots,N. \tag{VII.3}$$

For the wave function of Theorem 3 this translates into the summation formula

$$\sum_{n\in\mathbb{Z}}\psi^2(n+x,-\kappa_j)=1/\nu_j,\quad j=1,\ldots,N \tag{VII.4a}$$

($x\in\mathbb{R}$). Here it was again used (cf. the proof of Theorem 3) that the shifted function $\psi(n+x,-\kappa_j)$ differs from $\psi(n,-\kappa_j)$ by a factor $e^{-\kappa_j x}$ combined with a reparametrization of the form $\nu_k\to\nu_k e^{-2\kappa_k x}$, $k=1,\ldots,N$. Multiplication of Eq. (VII.4a) by $e^{2\pi i m x}$ ($m\in\mathbb{Z}$), and integration in x over a unit interval, entails upon interchanging the summation and integration on the left-hand side,

$$\int_{-\infty}^{\infty} \psi^2(x,-\kappa_j)\, e^{2\pi i m x} \mathrm{d}x = \begin{cases} 1/\nu_j & \text{for } m=0 \\ 0 & \text{for } m\in\mathbb{Z}\setminus\{0\}, \end{cases} \tag{VII.4b}$$

$j=1,\ldots,N$. The integration formula of Eq. (VII.4b) not only follows from the summation formula of Eq. (VII.4a) but is in fact *equivalent* to it in view of the Poisson summation formula.

C. Analyticity

The restrictions on the domains of the variables and the parameters in Theorem 3 are not very essential. In fact, we have that for the given wave function $\psi(x,y)$ our difference equation holds as an identity between analytic expressions (with singularities) in the variables x, y and the parameters $\kappa_1,\ldots,\kappa_N$, $\nu_1,\ldots,\nu_N$. Within the parameter and variable regimes stated by the theorem, however, both our wave function and the coefficients of the difference equation are regular.

D. Relation to the infinite Toda chain

The expressions for the coefficients a_n, b_n in the case of a reflectionless Jacobi operator, given by Eqs. (IV.9), (IV.12) (determinantal representations) or by Theorem 1/Corollary 2 (explicit representations in terms of the tau function), induce formulas for the N-soliton solutions of the inifinite Toda chain that are due to Flaschka[10] and Hirota,[15] respectively.

It is well-known that the Jacobi operator $D=a_nT+a_{n-1}T^{-1}+b_n$ may serve as a Lax operator for the infinite Toda chain. In fact, this observation formed the starting point for Flaschka's solution of the equations of motion for this dynamical particle system by means of the *Inverse Scattering Transform*.[10–12] In a nutshell, the state of affairs is the following. Let us assume that the Jacobi operator D is characterized by the spectral data $1>z_1>\cdots>z_N>-1$ $(z_j\neq 0)$, $\nu_1,\ldots,\nu_n>0$ and $r(z)$. Furthermore, let us denote by $a_n(t)$, $b_n(t)$ the coefficients of the Jacobi operator characterized by the time-dependent spectral data $z_j(t)=z_j$, $\nu_j(t)=\nu_j e^{(z_j-z_j^{-1})t}$ ($j=1,\ldots,N$) and $r(z;t)=r(z)e^{(z-z^{-1})t}$, with $t\in\mathbb{R}$. Then the quantities $a_n(t)$, $b_n(t)$ satisfy (Flaschka's version of) the equations of motion for the infinite Toda chain,

$$\dot{a}_n(t)=a_n(t)(b_{n+1}(t)-b_n(t))/2,\quad \dot{b}_n(t)=a_n^2(t)-a_{n-1}^2(t), \tag{VII.5}$$

with initial conditions given by $a_n(0)=a_n$, $b_n(0)=b_n$ $(n\in\mathbb{Z})$.[10–12] In other words, the complicated nonlinear Toda dynamics for the coefficients $a_n(t)$, $b_n(t)$ is related via the (inverse) scattering transform to a simple linear evolution of the corresponding spectral data $z_j(t)$, $\nu_j(t)$, and $r(z;t)$. The fact that the discrete spectral values $z_1,\ldots,z_N$ actually turn out to be time-independent is by no means a coincidence. It is a reflection of a more general phenomenon referred to as *iso-spectrality*, which says that the whole spectrum of the Jacobi operator with coefficients evolving in accordance with the Toda flow (VII.5) does not depend on t.

In the above picture *reflectionless* Jacobi operators correspond to *soliton* solutions of the infinite Toda chain. The formulas for the coefficients a_n, b_n in Eqs. (IV.9), (IV.12) thus give rise—upon plugging in the time-dependence for the normalization constants $\nu_j\to\nu_j e^{(z_j-z_j^{-1})t}$—to a determinantal representation for the N-soliton solution of the Toda chain. These are the well-known solutions found by Flaschka.[10–12] (To be precise, Flaschka actually wrote down only the determinantal formula for $a_n(t)$; the formula for $b_n(t)$ may be found in Ref. 12.) In exactly the same way the closed expressions for the coefficients a_n, b_n in terms of the tau function $\tau(n)$ (V.2a) (cf. Theorem 1 and Corollary 2) are converted into completely explicit formulas for the N-soliton solutions of the infinite Toda chain. The explicit soliton formulas of this type are also well-known and were in fact first introduced by Hirota using direct methods rather than inverse scattering theory.[15,16,12] For more recent developments pertaining to the integration of the Toda equations of motion via inverse scattering techniques we refer, e.g., to Refs. 17,14, and references therein.

In the present paper we concentrated on the solution of the eigenvalue problem for the reflectionless Jacobi operator by means of inverse scattering theory rather than on the solution of the equations of motion for the Toda system. One could nevertheless plug in the time dependence $\nu_j \to \nu_j e^{(z_j - z_j^{-1})t}$ also in the Sato formula for the Jost function of Theorem 1/Corollary 2. This way one arrives at a closed expression for the so-called *Baker function* (see, e.g., Ref. 5) of (the linear problem associated to) the infinite Toda chain. Our original Jost function (i.e., with time-independent spectral data) is in this context often referred to as the *stationary Baker function*. From the point of view of integrable sytems the main result of this paper therefore amounts to an explicit (Sato type) formula for the soliton Baker function of the infinite Toda chain.

E. Bidiagonal reduction: $b_n = 0$

For the special case of a Jacobi operator with zeros on the main diagonal, i.e., with $b_n = 0$ for all $n \in \mathbb{Z}$, the inverse scattering theory leading up to the discrete Gelfand–Levitan–Marchenko equation (cf. Eq. (III.5)) was developed by Case and Chui.[19,20] From the point of view of integrable systems (cf. the previous remark), the specialization to $b_n = 0$ amounts to a reduction from the Toda chain to the Kac–van Moerbeke chain.[21,12,17,14]

It is not difficult to see that the Jost function for the relevant bidiagonal Jacobi operator of the type $D = a_n T + a_{n-1} T^{-1}$ enjoys the symmetry property $\psi_{\text{jost}}(n,-z) = (-1)^n \psi_{\text{jost}}(n,z)$. (This is immediate from the definition of the Jost function, cf. Sec. II.) As a consequence, the spectrum of the Jacobi operator is now evenly distributed around the origin. In particular, the discrete eigenvalues always occur in even pairs. More precisely, in the bidiagonal situation the spectral data possess the following symmetry properties: (i) $r(-z) = r(z)$, (ii) the discrete spectral values are of the form $1 > z_1 > \cdots > z_M > 0 > z_{M+1} > \cdots > z_{2M} > -1$ with $z_{2M+1-j} = -z_j$, and (iii) the associated normalization constants $\nu_1, \ldots, \nu_{2M} > 0$ satisfy the symmetry property $\nu_{2M+1-j} = \nu_j$.

Reversely, if we assume that the spectral data of a reflectionless Jacobi operator $D = a_n T + a_{n-1} T^{-1} + b_n$ possess the above symmetry properties (ii) and (iii) (the first property is now of course trivial since $r(z) \equiv 0$ by assumption), then it follows that the main diagonal vanishes: $b_n = 0$ for all $n \in \mathbb{Z}$. To see this it is convenient to employ the representation for b_n in the second line of Eq. (IV.10) (with $N = 2M$). Indeed, we have from (ii) and (iii) that $k_{2M+1-j}(n) = (-1)^n k_j(n)$, whence the sums on the second line of Eq. (IV.10) vanish (since the jth term cancels against the $(2M+1-j)$th term). A simple way to deduce the symmetry property of the kernel functions $k_j(n)$, is to convince oneself that the original linear system for $k_1(n), \ldots, k_{2M}(n)$ in Eq. (IV.4) $(N = 2M)$ admits a solution with the symmetry property $k_{2M+1-j}(n) = (-1)^n k_j(n)$ when the spectral data meet conditions (ii) and (iii). Indeed, substitution of a solution of the type $(k_1(n), \ldots, k_M(n), (-1)^n k_M(n), \ldots, (-1)^n k_1(n))$ into Eq. (IV.4) reduces the linear system of $2M$ equations in $2M$ unknowns (viz., $k_1(n), \ldots, k_{2M}(n)$) to (two copies of) a linear system of M equations in M unknowns (viz., $k_1(n), \ldots, k_M(n)$).

The upshot is that for the case of a Jacobi operator with zero diagonal the dimension of the determinantal formulas for the coefficients a_n and the Jost function $\psi_{\text{jost}}(n,z)$ given by Eqs. (IV.9) and (IV.13) may be reduced from $2M$ to M. Furthermore, the explicit expressions for the coefficients a_n and the Jost function $\psi_{\text{jost}}(n,z)$ from Theorem 1/Corollary 2 admit in this bidiagonal situation a corresponding simplification. (Specifically, the sums in the relevant tau and chi functions become over subsets of $\{1, \ldots, M\}$ rather than $\{1, \ldots, 2M\}$ (cf. Eqs. (V.2a)–(V.2c)) and the spectral parameters z and $z_1, \ldots, z_M, -z_M, \ldots, -z_1$ enter the formulas via their squares z^2 and $z_1^2, \ldots, z_M^2$). This gives rise to a corresponding reduction of the Sato formula of Theorem 3 for reflectionless difference operators of the form $\mathcal{D} = a(x)\, T + a(x-1)\, T^{-1}$.

For the precise details regarding the resulting parametrization of the coefficients and Jost function for the bidiagonal reflectionless Jacobi operators, as well as the associated Sato formula for reflectionless analytic difference operators, the reader is referred to Ref. 22.

(Received 8 March 1999; accepted for publication 14 April 1999)

In an open time-convex region Λ of a strongly causal Lorentzian manifold $(\mathcal{M},g)$, we consider an event p and a timelike, injective curve γ. We look for geodesics connecting p and γ in Λ and satisfying the conservation law $g(z)[\dot{z},\dot{z}]=-E$ for a fixed $E>0$. It is already known that such geodesics are the stationary points of the arrival time functional τ. Our main result is to prove the existence of a decreasing flow for τ, by means of a shortening procedure. This makes possible to apply to τ global variational methods obtaining existence and multiplicity results (using the Ljusternik–Schnirelmann category theory) and also to develop a Morse theory. [S0022-2488(99)03210-7]

I. INTRODUCTION AND STATEMENT OF THE RESULTS

This paper deals with the study of timelike geodesics, having a prescribed parameterization proportional to the arc length, on a noncomplete, strongly causal Lorentzian manifold representing a universe with boundary.

In recent years variational methods have been applied to the study of Lorentzian geodesics. In particular, a large number of papers concerns variational principles which allow us to get existence and multiplicity results for geodesics connecting a point with a curve (see, e.g., Refs. 1, 2 and 3).

In Ref. 4, Kovner stated a variational principle for timelike and lightlike geodesics joining a source with a receiver in a space–time $(\mathcal{M},g)$. The source is represented by a timelike curve γ and the observer by an event p of $\mathcal{M}$. The principle states that among the future pointing curves $z:[0,1]\rightarrow\mathcal{M}$ joining p and γ and satisfying

$$g(z)[\dot{z},\dot{z}]=-E \tag{1}$$

for some $E\geqslant 0$, geodesics are the critical points of the *arrival time* functional τ defined (assuming that γ is injective) in the following way:

$$\tau(z)=\gamma^{-1}(z(1)). \tag{2}$$

A rigorous mathematical proof of this principle can be found in Ref. 3 for the lightlike case and in Ref. 2 for the timelike case. In Ref. 5, assuming that $\mathcal{M}$ admits a time function T the authors develop a Ljusternik–Schnirelmann theory for light rays (namely they take $E=0$) obtaining some multiplicity results depending on the topology of the space of the lightlike curves joining p and γ in a manifold with boundary. They look for the critical points of the functional

[a)]Electronic mail: germinar@pascal.dm.uniba.it
[b)]Electronic mail: giannoni@campus.unicam.it

$$Q(z)=\int_0^1 \langle \dot{z},\nabla T(z)\rangle^2 ds$$

that are lightlike pregeodesics and they assume that $\mathcal{M}$ is not complete which is equivalent to search geodesics lying in some open subset Λ of a complete manifold. Moreover in Ref. 6 a Morse theory has been developed for the same problem. In Ref. 2 the variational principle for timelike curves involving the functional τ is examined. Assuming that $\mathcal{M}$ is a manifold without boundary, existence and multiplicity results are obtained. This is done after proving that the critical points of τ on the space of the future pointing curves satisfying (1) are timelike geodesics.

The approach based on the use of the functional τ has some advantages; for example, the critical points of Q have not a clear physical meaning and their Euler–Lagrange equation is rather complicated. This makes the proof of the Morse theory in Ref. 6 quite involved. For this reason in Ref. 7, using τ, the Morse relations are stated for timelike geodesics and, with a limit process, also for lightlike geodesics.

Our aim in this paper is to prove the existence and the multiplicity (using Ljusternik–Schnirelmann category theory and Morse theory) of timelike geodesics z joining a point p and a curve γ, satisfying (1) for some $E>0$, when the space–time has a boundary. More precisely, we look for geodesics z lying in an open subset Λ of $\mathcal{M}$ with topological boundary $\partial\Lambda$. We are motivated in this study by the fact that some relevant physical examples of space–times have a boundary (e.g., Schwarzchild, Reissner–Nordström, Kerr space–times).

We point out that, as it will be clear in the sequel, the presence of $\partial\Lambda$ makes the problem more difficult. Indeed in Refs. 2 and 7, where the case of manifolds without boundary is studied, the functional τ is defined on a manifold of curves of class $H^{1,1}$, in order to prove that it satisfies the Palais–Smale condition. On the other hand, when Λ has a boundary, the manifold of the curves joining p and γ is not complete and τ does not satisfy the Palais–Smale condition because of the existence of sequences of curves approaching $\partial\Lambda$. A technique based on a penalization argument (used, for example, in Refs. 5 and 6 with curves of class $H^{1,2}$) fails with curves of class $H^{1,1}$. More precisely, if f is a functional defined on a set of curves of a manifold with boundary, we can add to f a term (depending on a parameter δ) which goes to infinity on each sequence of curves approaching $\partial\Lambda$ (see, e.g., Ref. 5, Lemma 7.2). Then a limit process allows us to get the critical points of f.

Unfortunately, this approach works when we deal with curves of class $H^{1,m}$ with $m>1$. When, as in our case, the natural space for the problem is $H^{1,1}$, it is not possible to prove that the penalized functionals satisfy useful completeness and compactness properties because we are not able to prove that the penalization term goes to infinity near the boundary.

In this paper we shall use a completely different approach to the problem. Indeed, in critical point theorems and in the Ljusternik–Schnirelmann theory for a functional f, the Palais–Smale condition is used for the construction of a flow along which f is strictly decreasing. Here we shall directly prove the existence of a decreasing flow for the functional τ, by means of a shortening method.

This procedure has been firstly introduced for studying Riemannian geodesics connecting two fixed points (see, e.g., Ref. 8). Recently, in Ref. 9, the authors have used a similar technique in stating a Morse theory for lightlike geodesics connecting a point with a curve. Here we shall deal with the timelike case. The main difference with respect to Ref. 9 is a different way to prove the existence of minimizers between a point and an integral curve of the vector field giving the time orientation on $\mathcal{M}$.

We wish to point out that the shortening method has a further advantage; it allows us to work in a very general context. Indeed, (a) the Lorentzian manifold is not assumed to be stably causal but only time orientable; (b) the boundary $\partial\Lambda$ of the open region Λ where we search timelike geodesics is not assumed neither smooth nor having a spacelike normal vector at any point; (c) the curve γ is not assumed to be a closed embedding of $\mathbf{R}$. Moreover, the shortening method (far from the critical points) makes simpler the proof of the Morse relations (see Ref. 7 for the case without boundary).

We consider a Lorentzian manifold $(\mathcal{M},g)$ whose metric tensor g will be denoted by

$$g(z)[\cdot,\cdot]=\langle \cdot,\cdot \rangle$$

for any $z\in\mathcal{M}$. It is not restrictive to assume that there exists a time orientation W on $\mathcal{M}$ namely a smooth timelike vector field W on $\mathcal{M}$. We recall that a vector $v\in T_p\mathcal{M}$, $p\in\mathcal{M}$ is said *future pointing* if

$$\langle W(z),v\rangle<0,$$

it is called *causal* if

$$\langle W(z),v\rangle\leq 0.$$

A smooth curve $y:I\rightarrow\mathcal{M}$ is *future pointing* (respectively *causal*) if $\dot{y}(s)$ is future pointing (respectively causal) for any $s\in I$. (We refer to Refs. 10 and 11 for the basic notions of Lorentzian geometry.)

The main results of this paper will be stated assuming that $\mathcal{M}$ is *strongly causal*. This means that, for any $q\in\mathcal{M}$, each future pointing causal curve starting arbitrarily close to q and leaving some fixed neighborhood of q, can not return arbitrarily close to q (for more details see Refs. 10 and 11).

Let Λ be an open, connected subset of $\mathcal{M}$, $p\in\Lambda$, $\gamma:\mathbf{R}\rightarrow\Lambda$ a smooth, timelike curve such that $p\notin\gamma(\mathbf{R})$. With respect to the orientation W, we assume that

$$\gamma \text{ is future pointing.} \tag{3}$$

From now on, we fix $E>0$. To prove the existence of future pointing, timelike curves joining p and γ we need the following assumption:

$$\begin{gathered}\text{there exists a } C^1\text{-piecewise, future pointing, curve } z:[0,1]\rightarrow\Lambda\\ \text{joining } p \text{ and } \gamma \text{ and satisfying } \langle\dot{z},\dot{z}\rangle=-E\\ \text{on any interval where } z \text{ is } C^1.\end{gathered} \tag{4}$$

Moreover we need a time-convexity assumption on the closure $\overline{\Lambda}$ of Λ. We assume that

$$\begin{gathered}\overline{\Lambda} \text{ is time-convex, i.e., all the timelike geodesics in } \Lambda\cup\partial\Lambda,\\ \text{whose end points are in } \Lambda, \text{ are entirely contained in } \Lambda.\end{gathered} \tag{5}$$

Here $\partial\Lambda$ denotes the topological boundary of Λ. To be sure that the arrival time functional τ defined in (2) is well defined we need that

$$\gamma \text{ is injective.} \tag{6}$$

In the following, for any $q\in\Lambda$ we shall denote by $\gamma_q:I\rightarrow\mathcal{M}$, (where $I\subset\mathbf{R}$ is an interval) the maximal integral curve of W starting at q, i.e., the maximal solution of the Cauchy problem

$$\begin{cases}\dot{\eta}=W(\eta)\\ \eta(0)=q.\end{cases}$$

In order to get a decreasing flow for the functional τ, we shall prove the existence of minimizers in Λ between events and timelike curves. The following hypothesis will be necessary:

$$\gamma \text{ is an integral curve of } W, \tag{7}$$

$$\forall q \in \Lambda, \quad \gamma_q(s) \in \Lambda, \quad \forall s \leqslant 0. \tag{8}$$

We introduce now a space of broken timelike geodesics which will be used as a space of trial curves. We set

$$\mathcal{B}^+_{p,\gamma,E}(\Lambda) = \{z:[0,1] \to \Lambda\} | z \text{ is a } C^2\text{-piecewise curve, such that}$$

$$z(0)=p, \ z(1) \in \gamma(\mathbf{R}) \text{ and, on any interval } I \text{ where } z \text{ is } C^2, \ z \text{ is}$$

$$\text{a future pointing geodesic satisfying } \langle \dot{z}, \dot{z} \rangle = -E\}.$$

We want to relate the number of future pointing timelike geodesics satisfying (1) with the Ljusternik–Schnirelmann category of $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$. In next sections we shall prove the homotopy equivalence between $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ (endowed with the uniform topology) and the Sobolev space of future pointing geodesics satisfying (1) and joining p and γ. Moreover a timelike extention of the Fermat principle holds (see Ref. 2).

Now we can state our last assumption which is equivalent to the ones formulated in Refs. 2 and 7 (as shown in Sec. II). For any $c \in \mathbf{R}$ we set

$$\tau^c = \{z \in \mathcal{B}^+_{p,\gamma,E}(\Lambda) | \tau(z) \leqslant c\}.$$

Definition I.1: Let c be a real number. We say that $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ *is c-precompact if any sequence* $(z_n)_{n \in \mathbf{N}} \subset \tau^c$ *has a uniformly convergent subsequence in* Λ*, up to reparameterization. The functional* τ *is said pseudocoercive on* $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ *if* $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ *is c-precompact for any* $c \in \mathbf{R}$.

We note that, if τ is pseudocoercive on $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ and if γ is an integral curve of W, then τ is bounded from below on $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$.

We shall prove the following existence result:

Theorem I.2: *Let* $(\mathcal{M},g)$ *be a strongly causal Lorentzian manifold. Let* $E>0,p,\gamma,\Lambda$ *satisfy assumptions (3)–(8) and* τ *be pseudocoercive on* $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$*. Then there exists at least one future pointing, timelike geodesic z joining p and* γ *in* Λ*, satisfying (1) and minimizing* τ *on the set of the future pointing curves joining p and* γ *and satisfying (1).*

We shall also prove a multiplicity result by using the Ljusternik–Schnirelmann theory. We refer to Ref. 12 for its main properties. Here we only recall that, if X is a topological space and Y is a subspace of X, the *Ljusternik–Schnirelmann category* of Y in X, denoted by $\mathrm{cat}(Y,X)$, is the minimal integer number (possibly infinite) of closed, contractible subsets of X covering Y. We shall denote by $\mathrm{cat}(X)$ the category of X in itself.

Theorem I.3: *Let* $\mathcal{M},E>0,p,\gamma,\Lambda$ *as in Theorem I.2. Assume that* τ *is pseudocoercive on* $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$*. Then there exists at least* $\mathrm{cat}(\mathcal{B}^+_{p,\gamma,E}(\Lambda))$ *future pointing, timelike geodesics z joining p and* γ *in* Λ *and satisfying (1).*

The shortening method allows us to state also a Morse theory for this problem. To this aim, we recall some definitions.

Definition I.4: Let $(\mathcal{M},g)$ *be a Lorentzian manifold, and z:* $[0,1] \to \mathcal{M}$ *be a geodesic. A smooth vector field* ζ *along z is called Jacobi field if it satisfies the equation*

$$D_s^2 \zeta + R(\zeta,\dot{z})\dot{z} = 0,$$

where R is the curvature tensor of the metric g. A point $z(s)$*,* $s \in]0,1]$ *is said to be conjugate to* $z(0)$ *along z if there exists a nonvanishing Jacobi field* ζ *along* $z_{|[0,s]}$ *such that*

$$\zeta(0) = \zeta(s) = 0. \tag{9}$$

The multiplicity of the conjugate point $z(s)$ *is the maximal number of linearly independent Jacobi fields satisfying (9).*

Definition I.5: Let $z:[0,1]\to\mathcal{M}$ *be a geodesic. The index* $\mu(z)$ *of* z *is the number of conjugate points* $z(s)$, $s\in]0,1]$ *to* $z(0)$, *counted with their multiplicity.*

Let X be a topological space and $\mathcal{K}$ a field. For any $l\in\mathbf{N}$ let $H_l(X;\mathcal{K})$ be the lth homology group of X with coefficients in $\mathcal{K}$. Since $\mathcal{K}$ is a field, then $H_l(X;\mathcal{K})$ is a vector space whose dimension $\beta_l(X;\mathcal{K})$ (eventually $+\infty$) is called the lth *Betti number of* X (with coefficients in $\mathcal{K}$). The *Poincaré polynomial* $\mathcal{P}(X;\mathcal{K})$ is defined as the following formal series:

$$\mathcal{P}(X;\mathcal{K})(\kappa)=\sum_{l\in\mathbf{N}}\beta_l(X;\mathcal{K})\kappa^l.$$

Let $\mathcal{G}^+_{p,\gamma,E}(\Lambda)$ be the set of the future pointing geodesics satisfying (1), joining p and γ and whose image is contained in Λ.

Theorem I.6: *Let* $(\mathcal{M},g)$ *be a strongly causal Lorentzian manifold. Let* $E>0,p,\gamma,\Lambda$ *satisfy (3)–(8). Moreover, assume that*

(1) *for any geodesic* $z\in\mathcal{L}^+_{p,\gamma,E}$, $z(1)$ *is nonconjugate to* $z(0)=p$;
(2) τ *is pseudocoercive on* $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$.

Then, for any field $\mathcal{K}$, *there exists a formal series* $S(\kappa)$ *with coefficients in* $\mathbf{N}\cup\{+\infty\}$, *such that*

$$\sum_{z\in\mathcal{G}^+_{p,\gamma,E}(\Lambda)}\kappa^{\mu(z)}=\mathcal{P}(\mathcal{B}^+_{p,\gamma}(\Lambda);\mathcal{K})(\kappa)+(1+\kappa)S(\kappa). \tag{10}$$

We point out that Theorem I.6 has been proved in Ref. 7 when $\mathcal{M}$ is a manifold without boundary. Moreover, we refer to Ref. 9 for a discussion and some consequences of the previous theorem, which, up to obvious changes hold also for the timelike case. Here we point out that relations (10) link the number card $(\mathcal{G}^+_{p,\gamma,E}(\Lambda))$ of geodesics in $\mathcal{G}^+_{p,\gamma,E}(\Lambda)$ to the topology of the space $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$. Indeed, setting $\kappa=1$ in (10) we get

$$\text{card}(\mathcal{G}^+_{p,\gamma,E}(\Lambda))=\sum_{l=0}^{\infty}\beta_l(\mathcal{B}^+_{p,\gamma,E}(\Lambda);\mathcal{K})+2S(1). \tag{11}$$

As $S(1)$ is non-negative, by (11) we can deduce the classical Morse inequalities (see Ref. 8) and information about the oddity of card$(\mathcal{G}^+_{p,\gamma,E}(\Lambda))$.

In Sec. II we shall discuss the existence of minimizers between a point and a future pointing timelike curve in $\mathcal{M}$. In Sec. III we shall describe the shortening procedure and prove the main theorems.

II. MINIMIZERS FOR THE ARRIVAL TIME

Let W be the smooth vector field giving an orientation on $\mathcal{M}$. Then, we can equip $\mathcal{M}$ with the Riemannian structure, given by

$$\langle\zeta,\zeta\rangle_R=\langle\zeta,\zeta\rangle-2\,\frac{\langle\zeta,W(z)\rangle^2}{\langle W(z),W(z)\rangle} \tag{12}$$

for any $z\in\mathcal{M}$ and $\zeta\in T_z\mathcal{M}$. It is not difficult to prove that (12) defines a bilinear form on $\mathcal{M}$ whose positivity follows from the wrong way Schwartz inequality (see Ref. 11). In the sequel we shall denote by d_R the distance induced by (12). The metric (12) allows us to define in an intrinsic way the Sobolev space,

$$H^{1,2}([0,1],\Lambda)=\left\{z\in\text{Ac}([0,1],\Lambda)\,\middle|\,\int_0^1\langle\dot z,\dot z\rangle_R ds<+\infty\right\},$$

where Ac([0,1],Λ) is the set of absolutely continuous curves from [0,1] to Λ (with respect to d_R). It is well known that $H^{1,2}([0,1],\Lambda)$ is a smooth Hilbert manifold. Now we set

$$\Omega^{1,2}_{p,\gamma}=\Omega^{1,2}_{p,\gamma}(\Lambda)=\{z\in H^{1,2}([0,1],\Lambda)\,|\,z(0)=p\quad z(1)\in\gamma(\mathbf{R})\}.$$

It is not difficult to see that $\Omega^{1,2}_{p,\gamma}$ is a smooth manifold. For any $z\in\Omega^{1,2}_{p,\gamma}$ the tangent space at z can be identified with

$$T_z\Omega^{1,2}_{p,\gamma}=\{\zeta\in H^{1,2}([0,1],T\Lambda)\,|\,\zeta(s)\in T_{z(s)}\mathcal{M}\quad \zeta(0)=0\quad \zeta(1)\parallel\dot\gamma(\tau(z))\}.$$

As we look for future pointing timelike geodesics satisfying (1), we set

$$\mathcal{L}^+_{p,\gamma,E}=\{z\in\Omega^{1,2}_{p,\gamma}\,|\,\langle\dot z,\dot z\rangle=-E,\quad \langle W(z),\dot z\rangle<0\ \text{ a.e.}\}.$$

By (4)

$$\mathcal{L}^+_{p,\gamma,E}\neq\emptyset$$

and following the results of Refs. 2 and 7, it can be proved that, for any $E>0$, $\mathcal{L}^+_{p,\gamma,E}$ is a C^1 Hilbert manifold whose tangent space at $z\in\mathcal{L}^+_{p,\gamma,E}$ can be identified with

$$T_z\mathcal{L}^+_{p,\gamma,E}=\{\zeta\in T_z\Omega^{1,2}_{p,\gamma}\,|\,\langle\dot z,D_s\zeta\rangle=0\ \text{ a.e.}\}.$$

The natural scalar product on $\mathcal{L}^+_{p,\gamma,E}$ is

$$\langle\zeta,\zeta\rangle_1=\int_0^1\langle D^R_s\zeta,D^R_s\zeta\rangle_R ds+\int_0^1\langle\zeta,\zeta\rangle_R ds \tag{13}$$

for any $z\in\mathcal{L}^+_{p,\gamma,E}$ and $\zeta\in T_z\mathcal{L}^+_{p,\gamma,E}$, where D^R_s denotes the covariant derivative with respect to (12) evaluated along $\dot z$.

It has been proven in Refs. 2 and 7 the following timelike extension of the Fermat principle.

Proposition II.1: Let τ *be as in (2),* $E>0$ *and* $z\in\mathcal{L}^+_{p,\gamma,E}$*. Then z is a critical point for* τ *in* $\mathcal{L}^+_{p,\gamma,E}$ *if and only if z is a geodesic.*

In the sequel, for any $p_*\in\mathcal{M}$ and any future pointing, injective, timelike curve $\gamma_*:]\alpha_*,\beta_*[\to\Lambda$ we shall use the following notation:

$$\mathcal{L}^+_{p_*,\gamma_*,E}([a_1,a_2],\Lambda)=\{z\in\Omega^1_{p_*,\gamma_*}([a_1,a_2],\Lambda)\,|\,\langle\dot z,\dot z\rangle=-E,\ \langle W(z),\dot z\rangle<0\ \text{ a.e.}\}.$$

We shall again denote by τ the functional defined by

$$\gamma_*^{-1}(z(a_2))$$

on $\mathcal{L}^+_{p_*,\gamma_*,E}([a_1,a_2],\Lambda)$.

Remark II.2: For any $z\in\mathcal{M}$ there exists a neighborhood $\mathcal{U}_z$ of z and a coordinate system $\varphi=(x_1,\dots,x_{N-1},t)$ ($N=\dim\mathcal{M}$) on $\mathcal{U}_z$ such that

$$W=\frac{\partial}{\partial t},\quad \mathcal{U}_z=\Sigma\times]a_1,a_2[,$$

where Σ is a spacelike hypersurface parameterized by $x_1,\dots,x_{N-1}$. Moreover in the coordinate $x=(x_1,\dots,x_{N-1})$ and $t\in]a_1,a_2[$ the metric g is given by

$$g(x,t)[(\xi,\theta)(\xi,\theta)]=\langle\alpha(x,t)\xi,\xi\rangle_0+2\langle\delta(x,t),\xi\rangle_0\theta-\beta(x,t)\theta^2, \tag{14}$$

where $(\xi,\theta)\in T_{(x,(a_1+a_2)/2)}\Sigma\times\mathbf{R}$, $\langle\cdot,\cdot\rangle_0$ is the (positive definite) restriction of g to Σ, α is a smooth, symmetric positive definite operator, δ is a smooth vector field on Σ and β is a smooth positive real function such that

$$\beta(x,t)=-g(x,t)[W,W] \tag{15}$$

(see Ref. 9 for further details).

Remark II.3: From now on, unless it is to normalize the vector field W and to take a reparameterization of γ we can assume that

$$\langle W(z),W(z)\rangle=-1 \quad \forall z\in\mathcal{M}, \tag{16}$$

so that by (7)

$$\langle\dot\gamma,\dot\gamma\rangle=-1 \quad \forall s\in\mathbf{R}.$$

Therefore in the coordinate systems $(x_1,\ldots,x_{N-1},t)$ (see Remark II.2), a curve $z=(x,t)\in\mathcal{L}^+_{p,\gamma,E}$ if and only if

$$\dot t=\langle\delta(x,t),\dot x\rangle_0+\sqrt{\langle\delta(x,t),\dot x\rangle_0^2+\langle\alpha(x,t)\dot x,\dot x\rangle_0+E} \tag{17}$$

as (15) becomes

$$\beta(x,t)=1. \tag{18}$$

Moreover, in such a coordinate system, any integral curve of W can be written as

$$s\mapsto(\overline{x},s+\overline{t})$$

for some $(\overline{x},\overline{t})$.

Proposition II.4: Let $q\in\mathcal{M}$. For any sufficiently small compact neighborhood U of q there exists $\rho=\rho(q,U)>0$ and $l=l(q,U)>0$ such that, for any integral curve γ_* of W such that

$$0<d_R(q,\mathrm{Im}\,\gamma_*)\leq\rho$$

and for any interval $[a_1,a_2]$ such that

$$a_2-a_1<l,$$

there exists a future pointing geodesic $z:[a_1,a_2]\to U$ joining q and γ_* and minimizing τ on $\mathcal{L}^+_{q,\gamma_*,E}([a_1,a_2],\mathcal{M})$.

Proof: Let U be a compact neighborhood of q where the metric g can be written as in (14) of Remark II.2. Assume that

$$U=V\times]b_1,b_2[,\quad q=(x_1,0)\in U$$

for some $x_1\in V$. By Remark II.3, there exists $\alpha_*,\beta_*\in\mathbf{R}$ such that

$$\gamma_*(s)=(x_2,t_2+s)\in U \quad s\in]\alpha_*,\beta_*[$$

for some $(x_2,t_2)\in U$. By Proposition II.1, we have to minimize the functional

$$F(x)=\int_{a_1}^{a_2}[\langle\delta(x,t_x),\dot x\rangle_0+\sqrt{\langle\delta(x,t_x),\dot x\rangle_0^2+\langle\alpha(x,t)\dot x,\dot x\rangle_0+E}]ds$$

on the manifold $\Omega^{1,2}([a_1,a_2],V)$ of the curves of class $H^{1,2}([a_1,a_2],V)$ joining x_1 and x_2, where t_x is the solution of the Cauchy problem

$$\begin{cases} \dot{t}=\langle \delta(x,t),\dot{x}\rangle_0+\sqrt{\langle \delta(x,t),\dot{x}\rangle_0^2+\langle \alpha(x,t)\dot{x},\dot{x}\rangle_0+E} \\ t(0)=0. \end{cases} \tag{19}$$

As the support of any curve $z=(x,t_x)$ is contained in the compact subset U, thanks to the Schwartz inequality

$$\frac{|\langle \delta(x,t_x),\dot{x}\rangle_0|}{\sqrt{\langle \alpha(x,t_x)\dot{x},\dot{x}\rangle_0}}\leqslant c_1$$

for some $c_1>0$, so that it is not difficult to show that there exists $c_2,c_3>0$ such that

$$c_2\int_{a_1}^{a_2}\sqrt{\langle \dot{x},\dot{x}\rangle_0}ds\leqslant F(x)\leqslant c_3\int_{a_1}^{a_2}\sqrt{\langle \dot{x},\dot{x}\rangle_0}ds+\sqrt{E}(a_2-a_1) \tag{20}$$

for any curve $x\in\Omega^{1,2}([a_1,a_2],V)$. Then, by the first inequality of (20), F is bounded from below.

Now let $(x_n)_{n\in\mathbf{N}}$ be a minimizing sequence for F. We prove that there exists $M>0$ such that for any $n\in\mathbf{N}$,

$$d_0(x_n(s_n),\partial V)\geqslant M, \tag{21}$$

where s_n is defined by

$$d_0(x_n(s_n),\partial V)=\min_{s\in[a_1,a_2]} d_0(x_n(s),\partial V)$$

and d_0 denotes the distance induced by $\langle\cdot,\cdot\rangle_0$. Indeed if (21) were not true, up to a subsequence,

$$\lim_{n\to+\infty} d_0(x_n(s_n),\partial V)=0. \tag{22}$$

By the first inequality of (20), there results

$$F(x_n)\geqslant c_2\int_{a_1}^{a_2}\sqrt{\langle \dot{x}_n,\dot{x}_n\rangle_0}ds\geqslant c_2 d_0(x_1,x_n(s_n)). \tag{23}$$

By (22), for n sufficiently large,

$$d_0(x_1,x_n(s_n))\geqslant\frac{d_0(x_1,\partial V)}{2}.$$

Then in (23) we get

$$\inf F\geqslant c_2\frac{d_0(x_1,\partial V)}{2}. \tag{24}$$

On the other hand, let $y:[a_1,a_2]\to V$ the geodesic chord joining x_1 and x_2 with respect to $\langle\cdot,\cdot\rangle_0$. By the second inequality of (20), there results

$$F(y)\leqslant c_3\int_{a_1}^{a_2}\sqrt{\langle \dot{y},\dot{y}\rangle_0}+\sqrt{E}(a_2-a_1)=c_3 d_0(x_1,x_2)+\sqrt{E}(a_2-a_1). \tag{25}$$

By opportunely choosing ρ and l we get by (25)

$$\inf F \leqslant c_2 \frac{d_0(x_1, \partial V)}{4}$$

in contradiction with (24). This proves that each minimizing sequence is uniformly far from ∂V and, by the Ekeland variational principle (see Ref. 13), the existence of a minimizing Palais–Smale sequence (with respect to the $H^{1,1}$-norm). Since F satisfies the Palais–Smale condition with respect to the $H^{1,1,}$-norm (see Ref. 2), we get the existence of a minimum point of F whose support is contained in V. □

As a first consequence of Proposition II.4 we can prove the equivalence of Definition I.1 with the corresponding ones of Refs. 2 and 7 (where the pseudocoercivity is assumed on $\mathcal{L}^+_{p,\gamma,E}$). Indeed any curve $z \in \mathcal{L}^+_{p,\gamma,E}$ can by uniformly approximated by a sequence $(z_n)_{n\in\mathbf{N}} \subset \mathcal{B}^+_{p,\gamma,E}(\Lambda)$ (see Ref. 9). Then it is not difficult to prove the following Proposition.

Proposition II.5: The functional τ is pseudocoercive on $\mathcal{L}^+_{p,\gamma,E}$ if and only if it is pseudocoercive on $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$.

The following proposition has already been proven in Ref. 7. However, we give here a sketch of the proof. We shall denote by $l(z)$ the length of z with respect to the Riemann structure (12) for any $z \in H^{1,2}([0,1],\Lambda)$.

Proposition II.6: Let $\mathcal{M}$ be strongly causal and τ be pseudocoercive on $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$. Then for any $c \in \mathbf{R}$ there exists $D(c)>0$ such that for any $z \in \mathcal{L}^+_{p,\gamma,E}$,

$$\tau(z) \leqslant c \Rightarrow l(z) \leqslant D(c).$$

Proof: Assume by contradiction the existence of a sequence $(z_m)_{m\in\mathbf{N}}$ in $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ such that

$$\tau(z_m) \leqslant c$$

and

$$\lim_{m\to+\infty} l(z_m) = +\infty. \tag{26}$$

As τ is pseudocoercive, there exists a curve $z:[0,1]\to\mathcal{M}$ such that

$$\lim_{m\to+\infty} \hat{z}_m = z \quad \text{uniformly in } [0,1], \tag{27}$$

where $\hat{z}_m$ is a reparameterization of z_m. Since $\mathcal{M}$ is strongly causal and z is the uniform limit of a sequence of causal curves, z is injective or constant. As $p \notin \gamma(\mathbf{R})$, z is nonconstant so it is injective. Moreover $z([0,1])$ is compact, then it can be covered by a finite number of local charts where the metric can be written as in (14). This makes it possible, to construct a smooth map T on a relatively compact neighborhood $\mathcal{U}$ of $z([0,1])$ such that for any $q \in \mathcal{U}$,

$$\langle \nabla T(q), \nabla T(q)\rangle < 0, \quad \langle \nabla T(q), W(q)\rangle < 0,$$

and, for m sufficiently large and $s \in [0,1]$,

$$\langle \nabla T(z_m), \dot{z}_m\rangle > 0.$$

By (27),

$$T(z_m(1)) \quad \text{is bounded.} \tag{28}$$

Moreover,

$$T(z_m(1)) - T(p) = \int_0^1 \langle \nabla T(z_m), \dot{z}_m\rangle ds, \tag{29}$$

and, by the choice of the orientation of ∇T, there exists $\nu_0 > 0$ such that

$$\langle \nabla T(z_m), \dot{z}_m \rangle \geq \nu_0 \sqrt{\langle \dot{z}_m, \dot{z}_m \rangle_R} \tag{30}$$

for any $s \in [0,1]$. Then, by (28), (29), (30), there results that $l(z_m)$ is bounded, in contradiction with (26). □

Proposition II.7: Let $E, W, \Lambda, p, \gamma: \mathbf{R} \to \Lambda$ satisfy assumptions (3)–(8), τ be pseudocoercive on $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ and fix $c \in \mathbf{R}$. Then there exists $\rho^* = \rho^*(c) > 0$ and $l^* = l^*(c) > 0$ satisfying the following property: for any $z \in \tau^c \cap \mathcal{L}^+_{p,\gamma,E}(\Lambda)$, $[a_1, a_2] \subset [0,1]$ with $a_2 - a_1 \leq l^*$, $z_1 = z(a_1)$, $z_2 = z(a_2) \in z([0,1])$ with $d_R(z_1, z_2) \leq \rho^*$ and for any $\hat{z}_1 \in \gamma_1(]\alpha_1, 0])$ with $d_R(\hat{z}_1, z_1) \leq \rho^*$, there exists a unique future pointing geodesic w satisfying (1) and such that

(1) $w(a_1) = \hat{z}_1$;
(2) $w(a_2) \in \gamma_2(]\alpha_2, \beta_2[)$;
(3) $w(s) \in \Lambda$ *for any* $s \in [a_1, a_2]$;
(4) $\tau(w) = \inf\{\tau(y) | y \in \mathcal{L}^+_{\hat{z}_1, \gamma_2, E}([a_1, a_2], \Lambda)\}$;

where $\gamma_i :]\alpha_i, \beta_i[\to \Lambda$, $i = 1,2$, denotes the maximal integral curve W in Λ starting at z_i.

Proof: As τ is pseudocoercive, there exists a compact subset K of $\bar{\Lambda}$ such that

$$z([0,1]) \subset K \quad \forall z \in \tau^c \cup \mathcal{L}^+_{p,\gamma,E}(\Lambda).$$

We can consider a finite number of open subsets $U_1, \ldots, U_m$ of $\mathcal{M}$ covering K, such that $\bar{U}_i$ is compact and each $\bar{U}_i$ satisfies the properties of Remarks II.2 and II.3. If ρ_* is sufficiently small, $z_1, z_2, \hat{z}_1 \in U_i \cap \Lambda$ for some $i = 1,...,m$. Then, by Proposition II.4 there exists a minimizer w in $\mathcal{L}^+_{\hat{z}_1, \gamma_2, E}([a_1, a_2], U_i)$. Since $\cup_{i=1}^m \bar{U}_i$ is compact, as the exponential map is locally invertible and as w is the minimum point of τ, the minimizing geodesic is unique provided that ρ^* is sufficiently small. It remains to be proved that the minimizer w is included in Λ. Note that, by Remarks II.2, II.3, setting $z(s) = (x(s), t(s))$ in $[a_1, a_2]$, it is possible to prove the existence of a curve $\hat{z} \in \mathcal{L}^+_{\hat{z}_1, \gamma_2, E}([a_1, a_2], U_i)$ having the same spatial component x of z and such that (using comparison theorems in ordinary differential equations) $\tau(\hat{z}) \leq \tau(z) = 0$. Then as w is the minimum point of τ, also $\tau(w) \leq 0$, so that by (8), $w(a_2) \in \Lambda$. Moreover there exists two continuous maps $\theta_1, \theta_2 : [0,1] \to U_i \cap \Lambda$ such that

(a) for any $\lambda \in [0,1]$, $\theta_2(\lambda)$ is in the future of $\theta_1(\lambda)$;
(b) $\theta_1(0) = \hat{z}_1$, $\theta_2(0) = w(a_2)$;
(c) $\theta_1(\lambda) \neq \theta_2(\lambda)$ for any $\lambda \neq 1$;
(d) $\theta_1(1) = \theta_2(1)$;
(e) for any $\lambda \in [0,1]$, denoting by $\gamma_2(\lambda)$ the maximal integral curve of W starting at $\theta_2(\lambda)$, there exists a unique minimizer of τ on $\mathcal{L}^+_{\theta_1(\lambda), \gamma_2(\lambda), E}([a_1, a_2], U_i)$.

We set

$$A = \{\lambda \in [0,1] \,|\, \text{the geodesic minimizing } \tau \text{ on } \mathcal{L}^+_{\theta_1(\lambda), \gamma_2(\lambda), E}([a_1, a_2], U_i) \text{ does not intersect } \partial\Lambda\}.$$

If we choose ρ^* and l^* sufficiently small, by Proposition II.4, $1 \in A$ so A is not empty. Then we consider

$$\lambda_0 = \inf A \geq 0.$$

It is sufficient to prove that $\lambda_0 \in A$ and $\lambda_0 = 0$. Consider a sequence $(\lambda_n)_{n \in \mathbf{N}} \subset A$ such that

$$\lim_{n\to\infty} \lambda_n = \lambda_0$$

and let $(w_n)_{n\in\mathbf{N}}$ be the corresponding sequence of geodesics such that, for any $n\in\mathbf{N}, w_n$ is the minimum point of τ on $\mathcal{L}^+_{\theta_1(\lambda_n),\gamma_2(\lambda_n),E}([a_1,a_2],U_i)$ and

$$w_n([a_1,a_2])\subset\Lambda \quad \forall n\in\mathbf{N}.$$

Up to a subsequence, there exists a geodesic $\overline{w}$ satisfying (1) such that

$$\lim_{n\to\infty} w_n = \overline{w}$$

with respect to the C^2-norm and

$$\overline{w}(a_1)=\theta_1(\lambda_0),\;\; \overline{w}(a_2)\in\Lambda,\;\; \overline{w}([a_1,a_2])\subset\overline{\Lambda}.$$

By the time-convexity of $\overline{\Lambda}$, we get

$$\overline{w}([a_1,a_2])\subset\Lambda,$$

then $\lambda_0\in A$ and by continuity, $\lambda_0=0$. □

III. DEFORMATION RESULTS

Here we shall state the existence of a shortening flow for τ, adapting to our case the ideas of Ref. 8. This is the crucial step for developing a Ljusternik–Schnirelmann category theory and a Morse theory.

Fix $c>\inf\{\tau(z)|z\in\mathcal{L}^+_{p,\gamma,E}\}$. Let $K=K(c)$ be the compact subset of $\overline{\Lambda}$ such that

$$z([0,1])\subset K(c) \quad \forall z\in\tau^c\cup\mathcal{L}^+_{p,\gamma,E}$$

whose existence is assured by the pseudocoercivity. We can cover $K(c)$ by a finite number of U_i, open subsets of $\mathcal{M}$, where the metric can be written as in Remarks II.2 and II.3. Consider $D(c)$ as in Proposition II.6, $\rho^*(c)$ and $l^*(c)$ as in Proposition II.7, and choose $N=N(c)$ such that

$$\frac{D(c)}{N}<\rho^*, \quad \frac{1}{N}<l^*.$$

Choose a partition

$$0=s_0<s_1<\cdots<s_{N-1}<s_N=1$$

of [0,1], such that for any $i=1,...,N$,

$$s_i-s_{i-1}=\frac{1}{N}.$$

Consider a curve $z\in\tau^c\cap\mathcal{L}^+_{p,\gamma,E}$ and choose $N+1$ points $z_0,\ldots,z_N$ on $z([0,1])$ such that for any $i=1,...,N$,

$$z_0=z(0)=p,\;\; z_N=z(1),\;\; d_R(z_i,z_{i-1})=\frac{l(z)}{N}.$$

Denote by $\gamma_i (i=1,...,N)$ the maximal integral curve of W such that $\gamma_i(0)=z_i$. Note that $\gamma_N=\gamma(s+\tau(z))$ for any s. By Proposition II.7, let w_1 be the future pointing geodesic minimizing τ

on $\mathcal{L}^+_{p,\gamma_1,E}([s_0,s_1],\Lambda)$ and, for any $i=2,...,N$, let w_i be the future pointing geodesic minimizing τ on $\mathcal{L}^+_{w_{i-1}(s_{i-1}),\gamma_i,E}([s_{i-1},s_i],\Lambda)$. Note that, if ρ^* is opportunely chosen and N is large enough

$$d_R(w_i(s_i),z_i)\leqslant\rho^* \quad i=1,...,N.$$

We define a curve $\eta_1\in\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ by setting

$$\eta_1([s_{i-1},s_i])=w_i \quad i=1,...,N.$$

By elementary comparison theorems for ordinary differential equations,

$$\tau(\eta_1)\leqslant\tau(z)\leqslant c,$$

then

$$\eta_1([0,1])\subset K(c).$$

Starting from η_1, a second curve η_2 can be constructed. On any minimizer $w_i(i=1,...,N)$ consider the point m_i such that

$$d_R(w_i(s_{i-1}),m_i)=d_R(m_i,w_i(s_i)).$$

Denote by λ_i the maximal integral curve of w starting at m_i for any $i=1,...,N$ and denote by $\lambda_{N+1}(s)=\gamma(s+\tau(\eta_1))$. Consider the partition of $[0,1]$ given by

$$\sigma_0=0,\ \ \sigma_i=\frac{2i-1}{2N} \quad \forall i=1,...,N,\ \ \sigma_{N+1}=1.$$

Denote by u_1 the minimizer of τ on $\mathcal{L}^+_{p,\lambda_1,E}([\sigma_0,\sigma_1],\Lambda)$ and, by induction, for any $i=1,2,...,N+1$ let u_i be the minimizer of τ on $\mathcal{L}^+_{u_{i-1}(\sigma_{i-1}),\lambda_i,E}([\sigma_{i-1},\sigma_i],\Lambda)$. The curve $\eta_2\in\mathcal{B}^+_{p,\gamma,E}(\Lambda)$ is such that

$$\eta_2([\sigma_{i-1},\sigma_i])=u_i\,.$$

Again by using comparison theorems in ordinary differential equations, it is possible to prove that

$$\tau(\eta_2)\leqslant\tau(\eta_1).$$

We can prove now that

$$\tau(\eta_2)<\tau(\eta_1). \tag{31}$$

Indeed, if $\tau(\eta_2)=\tau(\eta_1)$, by comparison theorems in ordinary differential equations, there results that η_1 is a minimizer on an interval $[\sigma_i,\sigma_{i+1}]$. By the above construction, η_1 consists of two timelike geodesics satisfying (1). If it is not a geodesic, $\dot{\eta}_1$ has a discontinuity at $s_{i+1}=(\sigma_{i+1}+\sigma_i)/2$. Denote by U_{η_1} the parallel transport of $\dot{\gamma}(\tau(\eta_1))$ along η_1. Since η_1 is a minimizer, it satisfies (see Ref. 2)

$$\int_{\sigma_i}^{\sigma_{i+1}}\frac{\langle\dot{\eta}_1,D_s\zeta\rangle}{\langle U_{\eta_1},\dot{\eta}_1\rangle}ds=0 \tag{32}$$

for any C^∞-vector field ζ along η_1 such that $\zeta(\sigma_i)=0=\zeta(\sigma_{i+1})$. By (32),

$$g=\frac{\dot{\eta}_1}{\langle U_{\eta_1},\dot{\eta}_1\rangle}\in C^1([\sigma_i,\sigma_{i+1}],T\mathcal{M}), \tag{33}$$

then also

$$-\frac{E}{\langle U_{\eta_1}\dot{\eta}_1\rangle^2}=\langle g,g\rangle\in C^1([\sigma_i,\sigma_{i+1}],\mathbf{R}).$$

As $\langle U_{\eta_1},\dot{\eta}_1\rangle^2$ is strictly positive,

$$\langle U_{\eta_1},\dot{\eta}_1\rangle\in C^1([\sigma_i,\sigma_{i+1}],\mathbf{R}),$$

then, by (33), $\dot{\eta}_1$ is of class C^1. Then, whenever we are far from timelike geodesics satisfying (1), (31) holds.

Now we can construct a continuous flow $\eta(\sigma,z)$ for any $\sigma\in[0,1]$, $z\in\tau^c$. For any $\sigma\in[0,1]$ we can define $\eta(\sigma,z)$ on the interval $[s_0,s_1]$ as follows. Assume that $z([s_0,s_1])$ is contained in U_i. Thanks to Remarks II.2, II.3, we set $p=(x_0,0)$, $\gamma_1=(x_1,t_1+s)$ and $z(s)=(x(s),t(s))$ in $[s_0,s_1]$, where x is a curve joining x_0 and x_1 and t satisfies the Cauchy problem (19). Let α_i and δ_i be the coefficients of the metric g in U_i. Let $y(\sigma)$ be the minimizer of the functional

$$F_\sigma(y)=\int_{s_0}^{\sigma s_1}\langle\delta_i(y,t_y),\dot{y}\rangle_0 ds+\int_{s_0}^{\sigma s_1}\sqrt{\langle\alpha_i(y,t_y)\dot{y},\dot{y}\rangle_0^2+\langle\delta_i(y,t_y),\dot{y}\rangle_0+E}\,ds \tag{34}$$

with boundary conditions $y(0)=x_0$, $y(\sigma s_1)=x(\sigma s_1)$, where t_y is the solution of (19) in $[0,\sigma s_1]$. Denote by $\hat{y}(\sigma)$ the extention of $y(\sigma)$ to $[s_0,s_1]$ obtained taking $\hat{y}(\sigma)(s)=x(s)$ for any $s\in[\sigma s_1,s_1]$. Finally denote by $\hat{t}_y(\sigma)$ the corresponding solution of (19) in $[s_0,s_1]$. We define

$$\eta(\sigma,z)_{|[s_0,s_1]}=(\hat{y}(\sigma),\hat{t}_y(\sigma)).$$

In the same way, η can be defined on the other intervals $[s_{i-1},s_i]$. Note that

$$\eta(1,z)=\eta_1.$$

Similarly, we can extend the flow η to a map on $[0,2]\times\tau^c$ in such a way that

$$\eta(2,z)=\eta_2.$$

Iterating the previous arguments, replacing the original curve z by η_2, we obtain a flow $\eta(\sigma,z)$ defined on $\mathbf{R}^+\times\tau^c$.

As a first consequence of the existence of the flow η, since

$$\tau(\eta(\sigma,z))\leqslant\tau(z)$$

for any σ and for any z, we immediately deduce the following proposition.

Proposition III.1: $\mathcal{L}^+_{p,\gamma,E}\cap\tau^c$ is homotopically equivalent to $\mathcal{B}^+_{p,\gamma,E}(\Lambda)\cap\tau^c$, for any $c\in\mathbf{R}$. Moreover, choosing a suitable continuous map $\rho^*(c)$ and arguing as in Sec. IX of Ref. 5, we also obtain

Proposition III.2: $\mathcal{L}^+_{p,\gamma,E}$ is homotopically equivalent to $\mathcal{B}^+_{p,\gamma,E}(\Lambda)$.

Classical deformation results (see, e.g., Ref. 12) can be reproved for the functional τ on $\mathcal{L}^+_{p,\gamma,E}$ by using compactness arguments close to the ones used for the shortening method for Riemannian geodesics. More precisely the following propositions hold.

Proposition III.3: Let c be a regular value for τ on $\mathcal{L}^+_{p,\gamma,E}$ *(namely $\tau^{-1}(c)$ does not contain geodesics). Then, there exists a positive number $\delta=\delta(c)$ and a continuous map $H\in C^0([0,1]\times\tau^{c+\delta},\tau^{c+\delta})$, such that*

(1) *$H(0,z)=z$, for every $z\in\tau^{c+\delta}$;*

(2) $\mathrm{H}(1,\tau^{c+\delta})\subset\tau^{c-\delta}$;
(3) *$H(\sigma,z)\in\tau^{c-\delta}$, for any $\sigma\in[0,1]$ and $z\in\tau^{c-\delta}$.*

Proposition III.4: Let K_c be the set of the geodesics in $\tau^{-1}(c)\cap\mathcal{L}^+_{p,\gamma,E}$. Then for any open neighborhood U of K_c, there exists a positive number $\delta=\delta(U,c)$ and a homotopy $H\in C^0([0,1]\times\tau^{c+\delta},\tau^{c+\delta})$, such that

(1) *$H(0,z)=z$, for any $z\in\tau^{c+\delta}$.*
(2) *$H(1,\tau^{c+\delta}\setminus U)\subset\tau^{c-\delta}$;*
(3) *$H(\sigma,z)\in\tau^{c-\delta}$, for any $\sigma\in[0,1]$ and $z\in\tau^{c-\delta}$.*

Proof of Theorem I.2: As, by Proposition II.5, τ is pseudocoercive on $\mathcal{L}^+_{p,\gamma,E}$ and γ is an integral curve of W, it is not difficult to show that τ is bounded from below on $\mathcal{L}^+_{p,\gamma,E}$. Then, if

$$d=\inf_{z\in\mathcal{L}^+_{p,\gamma,E}}\tau(z)\in\mathbf{R}$$

were not a critical value for τ, by Proposition III.3, there should exist $\delta>0$ and a homotopy between $\tau^{d+\delta}$ and $\tau^{d-\delta}$. But this is a contradiction, as $\tau^{d+\delta}\neq\emptyset$ and $\tau^{d-\delta}=\emptyset$. □

Proof of Theorem I.3: As $\mathcal{L}^+_{p,\gamma,E}$ is not empty, $\mathrm{cat}(\mathcal{L}^+_{p,\gamma,E})\geqslant 1$. Then, for any $k\in\mathbf{N}$, $0<k\leqslant\mathrm{cat}(\mathcal{L}^+_{p,\gamma,E})$ we can define

$$\Gamma_k=\{B\subset\mathcal{L}^+_{p,\gamma,E}|\mathrm{cat}(B,\mathcal{L}^+_{p,\gamma,E})\geqslant k\},\qquad c_k=\inf_{B\in\Gamma_k}\sup_{z\in B}\tau(z).$$

By using Propositions III.3 and III.4 and by classical arguments in critical point theory (see, e.g., Ref. 12), each c_k is well defined and it is a critical value of τ. Moreover if for some k, $c_k=c_{k+1}$ there are infinitely many critical points of τ at the level c_k, so, by Proposition III.2, the proof is complete. □

Proof of Theorem I.6: Far from geodesics of $\mathcal{L}^+_{p,\gamma,E}$, we can use the shortening flow described in this section for studying the homotopy type of the sublevels of τ. Near geodesics we can proceed as in Ref. 7. This makes it possible to write the classical Morse relations using, for any geodesic $z\in\mathcal{L}^+_{p,\gamma,E}$, the Morse index $m(z,\tau)$ of z as a critical point of τ. As in Ref. 7 and using the nondegeneracy assumption 1., it can be proved that

$$m(z,\tau)=\mu(z)$$

giving the proof of (10). □

(Received 10 June 1999; accepted for publication 22 July 1999)

The system of Einstein–Maxwell equations for fields mentioned in the title is simplified. Known pure radiation solutions are systematized and new solutions are given by separating the variables. © *1999 American Institute of Physics.* [S0022-2488(99)00611-8]

I. INTRODUCTION

There exists many papers dealing with algebraically special, expanding and twisting vacuum, pure radiation or Einstein–Maxwell fields. An extensive bibliography up to 1980 exists in Ref. 1. Further results on Einstein–Maxwell fields may be found in Ref. 2. Pure radiation fields have been studied extensively in Refs. 3–8. Petrov type II fields are characterized by the nonvanishing of the second Weyl scalar Ψ_2,

$$\Psi_2=(m+iM)\rho^3. \tag{1}$$

Here m is the mass parameter, M is the Newman–Unit–Tamburino (NUT) parameter, and ρ is given by

$$\rho=-\frac{1}{r+i\Sigma}, \tag{2}$$

where r is the coordinate along the null congruence of geodesics and Σ is the twist.[1]

It has been noticed in different contexts that the condition $M=0$ simplifies the equations.[2,4,5,7,9] In the present paper we explore this condition with the help of the method proposed in Ref. 3, putting the emphasis on intrinsically time-dependent solutions. We clarify the general structure of the solutions obtained by separation of the traditional variables r, u, ζ, $\bar{\zeta}$, where u is the retarded time and ζ, $\bar{\zeta}$ span a two-dimensional surface. Known solutions are systematized and new solutions are given.

Twisting gravitational fields with $M=0$ generalize the classes of Robinson–Trautman (RT) (Ref. 10) and Kerr–Schild (KS) fields[11] and are physically realistic, their simplest representatives being the Schwarzschild, Kerr, and Vaidya solutions.

In Sec. II the method of Stephani is applied to simplify the Einstein–Maxwell equations. In Sec. III the main field equation is reduced to a linear second order equation. Its general solution with separated variables is found and studied in Sec. IV. Section V is devoted to solutions linear in u, while in Sec. VI solutions with exponential behavior are discussed. Section VII contains some conclusions.

II. THE METRIC AND FIELD EQUATIONS

The standard form of the metric for expanding and twisting fields is[1]

$$ds^2=\frac{2d\zeta d\bar{\zeta}}{\rho\bar{\rho}P^2}-2\Omega[dr+Wd\zeta+\bar{W}d\bar{\zeta}+H\Omega], \tag{3}$$

$$\Omega = du + L d\zeta + \overline{L} d\overline{\zeta}.$$

It is determined by the r-independent real functions P, m, M and the complex function L,

$$2i\Sigma = P^2(\overline{\partial} L - \partial \overline{L}), \tag{4}$$

$$W = \rho^{-1} L_u + i\partial\Sigma, \tag{5}$$

$$H = -r(\ln P)_u - (mr + M\Sigma - \kappa \Phi_1^0 \overline{\Phi}_1^0)\rho\overline{\rho} + \frac{K}{2}, \tag{6}$$

$$K = 2P^2 Re[\partial(\overline{\partial} \ln P - \overline{L}_u)], \tag{7}$$

where $\partial = \partial_\zeta - L\partial_u$ and κ is the Newton constant. The basic functions satisfy the following system of equations:

$$(\partial - 3L_u)(m + iM) = -2\kappa P^{-1} \Phi_1^0 \overline{\Phi}_2^0, \tag{8}$$

$$P^{-3} M = \mathrm{Im}\, \partial\partial\overline{\partial\partial} V, \tag{9}$$

$$\frac{n^2}{2P^2} = -P[P^{-3}(m + iM)]_u + P(\partial\partial\overline{\partial\partial} V)_u - (\partial\partial V)_u (\overline{\partial\partial} V)_u, \tag{10}$$

$$(\partial - 2L_u)\Phi_1^0 = 0, \tag{11}$$

$$(\partial - L_u)(P^{-1}\Phi_2^0) + (P^{-2}\Phi_1^0)_u = 0, \tag{12}$$

where $V_u = P$, Φ_1^0, and Φ_2^0 are the essential parts of the Maxwell scalars

$$\Phi_1 = \rho^2 \Phi_1^0, \tag{13}$$

$$\Phi_2 = \rho\Phi_2^0 + \rho^2 P(2\overline{L}_u - \overline{\partial})\Phi_1^0 + 2i\rho^3 P(\Sigma \overline{L}_u - \overline{\partial}\Sigma)\Phi_1^0, \tag{14}$$

and n is either the energy density of pure radiation (then $\Phi_1 = \Phi_2 = 0$) or is given in the Einstein–Maxwell case by

$$n^2 = 2\kappa \Phi_2^0 \overline{\Phi}_2^0. \tag{15}$$

Vacuum solutions have $\Phi_1 = \Phi_2 = n = 0$.

The form of the metric is preserved by certain coordinate transformations, one of which is the change of the retarded time

$$u' = F(u, \zeta, \overline{\zeta}), \tag{16}$$

$$P' = F_u^{-1} P, \tag{17}$$

$$L' = F_u L - F_\zeta, \tag{18}$$

$$\Sigma' = F_u^{-1}\Sigma, \tag{19}$$

$$(m + iM)' = F_u^{-3}(m + iM). \tag{20}$$

Let us apply now to the system (8)–(12) the method of Stephani.[3] It works when either Φ_1^0 or Φ_2^0 vanishes. Then Eq. (8) is solved by

$$m+iM=\phi_u^3. \tag{21}$$

The complex field ϕ is invariant under Eq. (16). It satisfies $\partial\phi=0$, which stated differently gives

$$L=\frac{\phi_\zeta}{\phi_u}. \tag{22}$$

When $M=0$ we can use Eq. (16) to transform m to a positive or negative constant m_0 so that

$$\phi=m_0^{1/3}[u+iq(\zeta,\bar{\zeta})], \tag{23}$$

$$L=iq_\zeta. \tag{24}$$

Obviously $L_u=0$. This gauge differs from the most popular Kerr's gauge when $P_u=0$, but is very suitable when the NUT parameter vanishes. Equations (9) and (10) become

$$\partial\partial\overline{\partial\partial}V=\overline{\partial\partial}\partial\partial V, \tag{25}$$

$$\frac{n^2}{2P^2}=3m_0P^{-3}P_u+P\partial\partial\overline{\partial\partial}P-\partial\partial P\overline{\partial\partial}P, \tag{26}$$

with $\partial=\partial_\zeta-iq_\zeta\partial_u$. When $P_u\neq 0$, n^2 can be made positive by the choice of m_0 at least for some region of space–time.[1,4,9]

If $\Phi_1^0=0$, Eq. (12) gives

$$\Phi_2^0=PG(\phi,\bar{\zeta}), \tag{27}$$

where G is an arbitrary function. If $\Phi_2^0=0$, Eqs. (11) and (12) give

$$\Phi_1^0=\overline{C}(\bar{\zeta})\exp\left[2i\int(\ln P)_u q_\zeta d\zeta\right], \tag{28}$$

with $C(\zeta)$ being an arbitrary analytic function. This is a particular case of Theorem 26.2 from Ref. 1. The expressions for the other functions in the metric simplify

$$\Sigma=P^2Q, \tag{29}$$

$$W=i\partial(P^2Q), \tag{30}$$

$$K=P^2(\bar{\partial}\partial+\partial\bar{\partial})\ln P, \tag{31}$$

$$H=-r(\ln P)_u-(m_0r-\kappa\Phi_1^0\overline{\Phi}_1^0)\rho\bar{\rho}+\frac{K}{2}. \tag{32}$$

We have introduced the real, invariant under (16), function

$$Q(\zeta,\bar{\zeta})=q_{\zeta\bar{\zeta}}. \tag{33}$$

The Weyl scalars[12] contain a lot of terms with L_u and also simplify in the gauge $L_u=0$. We quote only the leading terms:

$$\Psi_2=m_0\rho^3, \tag{34}$$

$$\Psi_3=-\rho^2P^3\partial I+O(\rho^3), \tag{35}$$

$$\Psi_4 = \rho P^2 I_u + O(\rho^2), \tag{36}$$

$$I = P^{-1}\overline{\partial\partial P}. \tag{37}$$

What remains to be solved is the couple of Eqs. (25) and (26) for P and q. For pure radiation Eq. (26) is just an inequality.

When $m+iM=0$ (Petrov types III and N) Eq. (8) holds identically, but still a potential ϕ may be introduced with the property $\partial\phi=0$ and we can study the subclass of solutions satisfying Eq. (23) (with $m_0=1$). Then in all other equations we can set $m_0=0$.

III. THE FIELD EQUATION (25)

Equation (25) is a linear equation of fourth order with respect to V. However, in the gauge $L_u=0$ it becomes a linear equation of second order for P. This can be established with the help of the commutator

$$[\partial,\overline{\partial}] = 2iQ\partial_u. \tag{38}$$

Then Eq. (25) becomes

$$Q_{\zeta\bar\zeta}P + 2Q_{\bar\zeta}P_\zeta + 2Q_\zeta P_{\bar\zeta} + 4QP_{\zeta\bar\zeta} + 2i(q_{\bar\zeta}Q_\zeta - q_\zeta Q_{\bar\zeta})P_u + 4iQ(q_{\bar\zeta}P_{\zeta u} - q_\zeta P_{\bar\zeta u}) + 4Qq_\zeta q_{\bar\zeta}P_{uu} = 0. \tag{39}$$

This equation characterizes the twisting solutions because when $\Sigma=0$ it is trivial. It is nonlinear in q except for time-independent solutions when only the first four terms remain. In this case Eq. (26) turns into the equation for type III RT solutions, containing only P. It is logical to solve first Eq. (26) for P and plug the result in Eq. (39) to find q. In the present paper time-dependent solutions will be discussed mainly. In this case Eq. (39) should be solved for P when q is given and the result placed in Eq. (26) to find n^2 for pure radiation solutions.

Similar equations have been derived for time-independent fields in Ref. 1 [see Eq. (25.46)] and 2 [Eq. (5.12)]. For time-dependent fields and concrete expressions for q such equations can be found in Refs. 7 and 9. A linear equation of second order for $(-2\Sigma)^{1/2}$ is found in Ref. 5 in terms of Cauchy–Riemann structures admitting Lie groups of symmetries and used in Refs. 4–6 to obtain pure radiation solutions.

If P and q depend on ζ and $\bar\zeta$ via a single function $\alpha(\zeta,\bar\zeta)$ the terms in brackets in Eq. (39) cancel and it yields

$$(Q_{\alpha\alpha}\alpha_\zeta\alpha_{\bar\zeta} + Q_\alpha\alpha_{\zeta\bar\zeta})P + 4(Q_\alpha\alpha_\zeta\alpha_{\bar\zeta} + Q\alpha_{\zeta\bar\zeta})P_\alpha + 4Q\alpha_\zeta\alpha_{\bar\zeta}(P_{\alpha\alpha} + q_\alpha^2 P_{uu}) = 0. \tag{40}$$

Let $\zeta=(1/\sqrt{2})(x+iy)$. Suppose that $\alpha=x$ and ∂_y is a Killing vector. Then Eq. (40) becomes

$$q_x^2 QP_{uu} + QP_{xx} + Q_xP_x + \tfrac{1}{4}Q_{xx}P = 0 \tag{41}$$

and $Q=\frac{1}{2}q_{xx}$. In the case of axial symmetry $\alpha=\sigma=\zeta\bar\zeta$ and Eq. (40) reads

$$q_\sigma^2 P_{uu} + P_{\sigma\sigma} + \frac{(\sigma Q)_\sigma}{\sigma Q}P_\sigma + \frac{(\sigma Q_\sigma)_\sigma}{4\sigma Q}P = 0, \tag{42}$$

$$Q = (\sigma q_\sigma)_\sigma. \tag{43}$$

The introduction of $z=\ln\sigma$ as a variable greatly simplifies Eqs. (42) and (43) making them an analog of Eq. (41),

$$q_z^2 QP_{uu} + QP_{zz} + Q_zP_z + \tfrac{1}{4}Q_{zz}P = 0, \tag{44}$$

$$Q=e^{-z}q_{zz}. \tag{45}$$

Thus every solution with y-symmetry has an axisymmetric mirror with the same P and Q but as functions of z.

IV. SEPARATION OF VARIABLES

Let us search for twisting solutions by separating the variables $P=p(\zeta,\bar{\zeta})f(u)$. Equation (39) transforms into

$$f_{uu}+Af_u+Cf=0, \tag{46}$$

$$A=\frac{i}{2}\left[\frac{Q_\zeta}{q_\zeta Q}-\frac{Q_{\bar{\zeta}}}{q_{\bar{\zeta}}Q}+2\left(\frac{p_\zeta}{q_\zeta p}-\frac{p_{\bar{\zeta}}}{q_{\bar{\zeta}}p}\right)\right], \tag{47}$$

$$C=(4q_\zeta q_{\bar{\zeta}}Qp)^{-1}(Q_{\zeta\bar{\zeta}}p+2Q_{\bar{\zeta}}p_\zeta+2Q_\zeta p_{\bar{\zeta}}+4Qp_{\zeta\bar{\zeta}}). \tag{48}$$

Equation (46) is a well-known linear equation. It requires that A and C must be constant and possesses three types of solutions according to the sign of $\lambda^2=4C-A^2$,

$$f=e^{-(Au/2)}(C_1e^{(\beta u/2)}+C_2e^{-(\beta u/2)}), \tag{49}$$

$$f=e^{-(Au/2)}\left(C_1\sin\frac{\lambda u}{2}+C_2\cos\frac{\lambda u}{2}\right), \tag{50}$$

$$f=e^{-(Au/2)}(C_1u+C_2), \tag{51}$$

where $\beta^2\equiv-\lambda^2>0$, $\lambda^2>0$ and $\lambda=0$, respectively. Notice the common exponential factor if $A\neq0$. It is quite interesting that damping exponential behavior is generic for RT solutions, but it stems from the analog of Eq. (26) in the nontwisting case.[13,14] When Eq. (40) holds, A vanishes. There are still three types of solutions, one of them with exponential behavior. When there is y-symmetry Eqs. (46) and (41) become

$$f_{uu}+Cf=0, \tag{52}$$

$$Qp_{xx}+Q_xp_x+(\tfrac{1}{4}Q_{xx}-Cq_x^2Q)p=0. \tag{53}$$

In the case of axial symmetry Eq. (52) still holds, but Eq. (53) is replaced either by the same equation with x changed to $z=\ln\sigma$ or by

$$p_{\sigma\sigma}+(\ln\sigma Q)_\sigma p_\sigma+\left[\frac{(\sigma Q_\sigma)_\sigma}{4\sigma Q}-Cq_\sigma^2\right]p=0. \tag{54}$$

Let us discuss next Eq. (26) for two of the types of u-behavior allowed by Eq. (39). Suppose first that $P=pe^{cu}$. Introduce the function $B=pe^{icq}$. Then Eq. (26) reads

$$n^2=6m_0c+2p^2(\psi e^{-4icq})_\zeta e^{2icq+4cu}, \tag{55}$$

$$\psi=BB_{\zeta\bar{\zeta}\bar{\zeta}}-B_\zeta B_{\bar{\zeta}\bar{\zeta}}. \tag{56}$$

When $m_0=0$ the solution is of type III only when $\psi\neq0$ because $\partial I=\psi/B^2$. When $m_0\neq0$ and $\psi=0$ the solution is of KS type because $\partial I=I_{\bar{\zeta}}=0$ and I can be nullified by a coordinate transformation $\bar{\zeta}'=\bar{g}(\bar{\zeta})$. This means $\partial\partial P=0$ [see Eq. (37)], which can be lifted to $\partial\partial V=0$. The latter is exactly the Kerr–Schild condition.[1,3]

Suppose next that $P=pu$. When there is y-symmetry Eq. (26) yields

$$n^2=\frac{6m_0}{u}+\frac{1}{2}p^2(pp_{xxxx}-p_{xx}^2)u^4-2p^2(q_xp_x+Qp)^2u^2. \tag{57}$$

When there is axial symmetry Eq. (26) changes into

$$n^2=\frac{6m_0}{u}+2p^2[2pp_{\sigma\sigma}+4\sigma pp_{\sigma\sigma\sigma}+\sigma^2(pp_{\sigma\sigma\sigma\sigma}-p_{\sigma\sigma}^2)]u^4-2\sigma^2[(q_\sigma p^2)_\sigma]^2u^2. \tag{58}$$

Finally, let us perform the separation of variables in the Maxwell equations. Equation (28) simplifies

$$\Phi_1^0=\overline{C(\zeta)}\exp[2iq(\ln f)_u]. \tag{59}$$

When $f=u$ and $f=e^{cu}$ this becomes, respectively,

$$\Phi_1^0=\overline{C(\zeta)}e^{(2iq/u)}, \tag{60}$$

$$\Phi_1^0=\overline{C(\zeta)}e^{2icq}. \tag{61}$$

Equation (12) or (27) separates as follows:

$$P^{-1}\Phi_2^0=\overline{N(\zeta)}e^{a(u+iq)}, \tag{62}$$

$N(\zeta)$ being another arbitrary analytic function and a is a constant different from c in general. The energy density of a null Maxwell field (15) becomes

$$\frac{n^2}{2P^2}=\kappa|N(\zeta)|^2e^{2au}. \tag{63}$$

Obviously polynomial dependence of P in Eq. (26) is not allowed by (63). Consequently, null Maxwell fields cannot induce solutions with $P=pu$. It is seen also from Eqs. (55), (57), and (58) that vacuum solutions of type II are not possible because the different terms cannot cancel each other.

V. SOLUTIONS LINEAR IN *U*

These are solutions with $C=0$ in Eq. (46) or Eqs. (52), (53), and (54). Then these equations are identical to the equations for a u-independent P. Therefore we can use any time-independent solution of Eqs. (25) and (26) found in the literature which has $L_u=0$ and axial or y-symmetry. We can also use time-independent solutions of Eq. (53) or Eq. (54) which are not solutions of Eq. (26).

For example, let us find polynomial solutions with y-symmetry which capitalize on the only known vacuum RT solution for type III fields.[1,10] If we take $L=ix^{b-1}$, $b\neq 1$ then Eq. (53) becomes the Euler equation

$$x^2p_{xx}+(b-2)xp_x+\tfrac{1}{4}(b-2)(b-3)p=0 \tag{64}$$

and its solutions are

$$p=|x|^a, \tag{65}$$

$$p=\ln|x|, \tag{66}$$

$$p=|x|^{(3-b)/2}[C_1\sin(\mu\ln|x|)+C_2\cos(\mu\ln|x|)], \tag{67}$$

when $b<3$, $b=3$, and $b>3$, respectively. Here $a=\frac{1}{2}(3-b\pm\sqrt{3-b})$ and $\mu=\frac{1}{2}\sqrt{b-3}$. The first of these solutions has been obtained essentially in Ref. 4 by a rather intricate procedure. Plugging Eq. (65) and $q_x=x^{b-1}$ into Eq. (57) yields the inequality to be satisfied,

$$\frac{12m_0}{u}|x|^{2(b-1\pm\sqrt{3-b})}+2a(a-1)(3-2a)u^4-(2-\sqrt{3-b})^2|x|^{2b}u^2\geqslant 0. \tag{68}$$

Throughout the paper we consider $u>0$. The first term is always positive (we accept that $m_0>0$ unless stated otherwise), the third is always negative, while the second changes sign and is positive for $a<0$ and $1<a<3/2$. The third term has negative poles in x for any $b\neq 0$ and $b\neq -1$ which cannot be compensated by the second term. Hence, pure radiation solutions of type III are not allowed and the first term should be present to compensate the negative poles with positive ones. This is achieved when $b<2$. The plus sign in the formula for a must be taken in both cases. For growing u, however, the first term diminishes to zero. Thus the energy density is positive for $b<2$ and small enough u. When $b=0$ the third term is x-independent but the second is negative, excluding again a type III solution. Type II solution still exists. Finally, when $b=-1$ the third term vanishes but the second is still nonpositive because $a=1$ or $a=3$. When $a=1$ only the first term remains and n is x-independent, positive and bounded. This is a KS solution because $\partial\bar{\partial}V=-xq_x^2/2$ and can be turned into zero by a u-independent transformation of V.

The second solution, given by Eq. (66), has no free parameters and leads to incurable negative poles and logarithmic singularities in n and is therefore unphysical. As a last comment, we may start with $p=x^{b-1}$ in Eq. (53) and obtain a Euler equation for Q with the corresponding three types of solutions.

The simplest solution of Eq. (53) is probably when P is u-dependent only, i.e., $p=p_0=\text{const}$. Then $Q_{xx}=0$ and $P=p_0u$, $L=(i/\sqrt{2})x(c_1x+2c_2)$, where c_i are arbitrary constants and

$$n^2=\frac{6m_0}{u}-2p_0^4(c_1x+c_2)^2u^6. \tag{69}$$

The energy density is positive for any x when $c_1=0$ and u is small enough. This is not a KS field.

Another simple solution is obtained when $p=e^{ax}$, a being some constant. Then Eq. (53) has constant coefficients and one of the solutions is $q_x=\exp(-2ax)$. The energy density is positive, $n^2=6m_0/u$ and $I=a^2/2$. Consequently the solution is of type II and is equivalent to a KS solution.

Let us investigate next the axisymmetric solutions. As has been mentioned in the previous sections, Eq. (53) has a counterpart for axisymmetric fields with the same Q and P but with x replaced by z. However, q and n are different, being given by Eqs. (45) and (58) instead of $q_{xx}=2Q$ and Eq. (57). The solution with $p=p_0$ has a mirror solution

$$L=i\bar{\zeta}(c_3\ln\sigma+c_4), \tag{70}$$

$$n^2=\frac{6m_0}{u}-2c_3^2p_0^4u^6. \tag{71}$$

The energy density is positive for small u. When $c_3=0$ it is positive everywhere and the solution is a KS field.

Another solution has $q=\sigma$, $L=i\bar{\zeta}$, $Q=1$. Then Eq. (54) yields

$$p_{\sigma\sigma}+\frac{1}{\sigma}p_\sigma=0 \tag{72}$$

and $p=c_5\ln\sigma+c_6$. It was found by a different method in Ref. 9. When $c_5=0$ it coincides with the previous solution with $c_3=0$.

A well-known solution is given by $p=1+\sigma/2$. Equation (54) becomes linear with respect to Q,

$$(2+\sigma)\sigma Q_{\sigma\sigma}+(2+5\sigma)Q_{\sigma}+4Q=0 \tag{73}$$

and its solution is the hypergeometric function $F(2,2,1,-\sigma/2)$. It degenerates into a rational function for these values of its parameters and we have

$$Q=\frac{4k(2-\sigma)}{(2+\sigma)^3}, \tag{74}$$

$$L=-\frac{ik\bar{\zeta}}{(1+\sigma/2)^2}, \tag{75}$$

where k is an arbitrary constant, characterizing the magnitude of the twist (rotation). This is the Kramer solution[1,7,8,9] which is of KS type and has $n^2=6m_0/u$. It represents a radiating Kerr metric. This is seen best in the gauge $P_u=0$.

It must be stressed that any solution of the type $P=pu$ can be transformed from the $L_u=0$ gauge to the $P_u=0$ gauge by choosing $F=u^2/2$ in Eq. (16). Then $P'=p$, $L'=(2u)^{1/2}L$, $m'=(2u)^{-3/2}m$ which transfers the u-dependence to the mass parameter and the twist.

A generalization of the Kramer solution was undertaken in Ref. 7 for the same L and the ansatz $P=A(\sigma,u)(1+\sigma/2)$. It was shown that A satisfies a second order linear equation. The results of this paper guarantee that P also satisfies a second order linear equation.

The mirror of the solution with $p=e^{ax}$ described above is $p=e^{az}$ and $Q=k(1-2a)e^{-2az}$, $a\neq 1/2$. Hence,

$$P=\sigma^a u, \tag{76}$$

$$L=ik\bar{\zeta}\sigma^{-2a}. \tag{77}$$

It is very similar to the Kramer solution for $a=1$. For $a=1/2$, P is still given by Eq. (76) while $L=ik\bar{\zeta}\sigma^{-1}\ln\sigma$. The energy density is

$$n^2=\frac{6m_0}{u}-2\delta_{1,2a}u^2. \tag{78}$$

VI. SOLUTIONS WITH EXPONENTIAL BEHAVIOR

These are solutions with $P=pe^{cu}$ and $C=-c^2$ in Eq. (46) or Eqs. (52), (53), and (54). We shall give two solutions with y-symmetry. First we take $q_x=2(1-b)x^{b-1}$, where the constant $b\neq 1$ and put this expression in Eq. (53),

$$x^2p_{xx}+(b-2)xp_x+[\tfrac{1}{4}(b-2)(b-3)+4c^2(1-b)^2x^{2b}]p=0. \tag{79}$$

When $b=0$ this is the Euler equation, similar to Eq. (64) and has three types of solutions. The first two of them read

$$p=|x|^{(3/2)\pm\gamma}, \tag{80}$$

$$p=|x|^{(3/2)}\ln|x|, \tag{81}$$

when $c^2<3/16$ or $c^2=3/16$, respectively. Here $\gamma=\frac{1}{2}(3-16c^2)^{1/2}$. When $b\neq 0$ the solution is given by Bessel functions,

$$p=x^{(3-b)/2}[C_1J_\nu(\epsilon x^b)+C_2Y_\nu(\epsilon x^b)], \tag{82}$$

where $\nu = \sqrt{3-b}/2b$, $\epsilon = 2|b-1|c/b$. In all cases

$$L = i\sqrt{2}(1-b)x^{b-1}. \tag{83}$$

These are essentially the solutions found in Ref. 4, where x-symmetry was used instead together with a special transformation between a u-independent and a u-dependent solution.

The second solution to be presented is an analog of Eq. (69), i.e., $P = e^{cu}$ depends only on u. Then Eq. (53) may be integrated to

$$Q = \tfrac{1}{2}(b^2 - \tfrac{2}{3}c^2 q_x^4 + 2dq_x)^{1/2}, \tag{84}$$

where $b > 0$ and d are constants. When $d = 0$, Eq. (84) is solved by elliptic functions,

$$L = i\frac{b}{\lambda} cn(\lambda x), \tag{85}$$

where $\lambda = (\frac{8}{3}b^2c^2)^{1/4}$ and the modulus of cn is 1/2. It is clear from Eq. (84) that $Q \leqslant b/2$. Equation (55) yields

$$n^2 = 6cm_0 - 4c^2Q^2e^{4cu}. \tag{86}$$

The second term is definitely negative and if $m_0 > 0$, $c > 0$ dominates for large u, no matter how big m_0 is. However, if $m_0 < 0$, $c < 0$ the first term remains positive while the second is damped exponentially for large retarded times. Choosing $|m_0|$ big enough we can arrange for $n^2 > 0$.

Let us give next an example of an axisymmetric solution. Let us substitute in Eq. (54) $q_\sigma = Q = a = \text{const}$ to obtain the generalization of Eq. (72),

$$p_{\sigma\sigma} + \frac{1}{\sigma}p_\sigma + a^2c^2p = 0. \tag{87}$$

It is solved by Bessel functions, e.g.,

$$P = e^{cu}J_0(ac\sigma), \tag{88}$$

$$L = ia\bar{\zeta}. \tag{89}$$

This solution was found and discussed in Ref. 9.

Finally, we give an example of a solution without y-symmetry or axial symmetry. We shall obtain the most general KS pure radiation field with $P = pe^{cu}$. The results of Sec. IV and Eq. (56) show that

$$q = \frac{1}{2ic}\ln\frac{B}{\bar{B}}, \tag{90}$$

$$P = (B\bar{B})^{1/2}e^{cu}, \tag{91}$$

where B satisfies $\psi = 0$, namely,

$$B^2(\ln B)_{\zeta\bar{\zeta}} = S(\zeta). \tag{92}$$

S is an arbitrary analytic function. If $S \neq 0$ we introduce the new variable $\omega = \int^\zeta S(\zeta')d\zeta'$ and Eq. (92) transforms into the Liouville equation,

$$B^2(\ln B)_{\omega\bar{\zeta}} = 1. \tag{93}$$

Returning to the original variables, its general solution reads

$$B = S(\zeta)^{1/2} \frac{f(\zeta) + g(\bar{\zeta})}{\sqrt{f(\zeta)_\zeta g(\bar{\zeta})_{\bar{\zeta}}}}. \tag{94}$$

The functions f and g are arbitrary. When $S=0$ the solution of Eq. (92) is

$$B = f(\zeta) g(\bar{\zeta}). \tag{95}$$

It has zero twist, i.e., it is a RT solution. Then we may set $L=q=0$ which means $f(\bar{\zeta}) \equiv g(\zeta)$ and $P = f\bar{f}e^{cu}$. A coordinate transformation sets $f=1$. Therefore solution (95) is equivalent to $B=1$.

In Refs. 3 and 15 the general axisymmetric pure radiation KS fields were found. Interestingly enough, their u-dependence covers the three types (49), (50), and (51) with $A=0$. The exponential solution was generalized in Ref. 3 to a nonsymmetric one with

$$B = G(\zeta) + \bar{\zeta} K(\zeta), \tag{96}$$

G and K being arbitrary. Equation (96) may be obtained from the general formula (94) by specializing to $g(\bar{\zeta}) = \bar{\zeta}$,

$$B = f(\zeta) \left[\frac{S(\zeta)}{f(\zeta)_\zeta} \right]^{1/2} + \bar{\zeta} \left[\frac{S(\zeta)}{f(\zeta)_\zeta} \right]^{1/2}. \tag{97}$$

The general KS field with nonradiative Maxwell field has been given in Ref. 11. It was remarked in Ref. 1 that no solution with a null Maxwell field has been found. Formulas (94) and (95) allow the study of this question in the context of solutions with separated variables. The energy density (63) tolerates exponential dependence. Equation (55) reads in this case,

$$3 m_0 c = \kappa N(\zeta) \bar{N}(\bar{\zeta}) B \bar{B}. \tag{98}$$

Obviously B cannot be given by Eq. (94) but a nontwisting solution with $B=1$ is possible. Then $P = e^{cu}$ and $\Phi_2^0 = (3 m_0 c/\kappa)^{1/2}$. The mass parameter is constant, as usual, $m = m_0$. This is nothing but a special case of the Einstein–Maxwell solution of Robinson and Trautman[10] in disguise [see also Eq. (24.41) in Ref. 1]. The conclusion is that there is no twisting KS solution with a null Maxwell field and separated variables.

VII. CONCLUSIONS

In this paper we have carried out the idea of Stephani based on the introduction of an invariant potential for algebraically special, twisting and expanding gravitational fields. It works best in the important subclass of fields with vanishing NUT parameter. The system of Einstein–Maxwell equations is reduced to the couple of Eqs. (25) and (26) for P and L where L is represented by a real function of two variables $q(\zeta,\bar{\zeta})$ (the $L_u = 0$ gauge). We have studied mainly pure radiational solutions for which Eq. (26) is an inequality. The main equation (25), originally of fourth order, becomes a linear second order equation for P (39), which further simplifies for the most common symmetries. In some cases it is linear for q_x, too. Of course, it is not possible to enumerate all solutions of Eq. (39). The method of separation of variables was used to systematize most of the known solutions obtained in the past by a variety of different approaches. We have also investigated the region where the energy density of pure radiation is positive. Samples of new solutions were given to illustrate the application of Eqs. (39), (53), (54), and (55). Three types of behavior with respect to the retarded time have been found; exponential, trigonometric, and linear. Among the new solutions is the most general KS pure radiation field with exponential time behavior. It was shown that the radiation field cannot be a null Maxwell field unless the twist vanishes. Finally, it should be mentioned that the case $m=0,\ M\neq 0$ is much more difficult because Eq. (9) remains nonlinear in P.

Noncanonical quantization of gravity. I. Foundations of affine quantum gravity

John R. Klauder[a)]
Departments of Physics and Mathematics, University of Florida, Gainesville, Florida 32611

(Received 11 June 1999; accepted for publication 14 July 1999)

The nature of the classical canonical phase-space variables for gravity suggests that the associated quantum field operators should obey affine commutation relations rather than canonical commutation relations. Prior to the introduction of constraints, a primary kinematical representation is derived in the form of a reproducing kernel and its associated reproducing kernel Hilbert space. Constraints are introduced following the projection operator method, which involves no gauge fixing, no complicated moduli space, nor any auxiliary fields. The result, which is only qualitatively sketched in the present paper, involves another reproducing kernel with which inner products are defined for the physical Hilbert space and which is obtained through a reduction of the original reproducing kernel. Several of the steps involved in this general analysis are illustrated by means of analogous steps applied to one-dimensional quantum mechanical models. These toy models help in motivating and understanding the analysis in the case of gravity. © *1999 American Institute of Physics.* [S0022-2488(99)02011-3]

I. INTRODUCTION

General relativity is, in certain ways, fundamentally different than most other physically relevant classical field theories, and the same remark applies to attempts to provide associated quantum formulations. The space–time metric $g_{\mu\nu}(x)$, $x\in\mathbb{R}^4$, $\mu,\nu=0,1,2,3$, possesses a signature requirement that is incompatible with the space of metrics being a linear vector space. (Although we assume a $3+1$ theory of gravity for illustrative purposes, it is straightforward to generalize to an $s+1$ theory as well, $s\geqslant 1$.) The inverse metric $g^{\sigma\mu}(x)$, defined so that $g^{\sigma\mu}(x)g_{\mu\nu}(x)=\delta^\sigma_\nu$, is classically trivial but it is quantum mechanically challenged since the left-hand side involves the product of two operator-valued distributions. Moreover, the spatial and temporal constraints that hold at each space–time point classically close algebraically, but they exhibit an anomaly (more commonly called a factor-ordering problem) when quantized. In effect, this fact changes the constraints from first class (classically) to second class (quantum mechanically). And, of course, there is the well-known fact that unlike other theories that take place on a fixed space–time stage, the theory of gravity involves the dynamics of the space–time stage itself. Our purpose in this article is to discuss some basic issues surrounding quantum gravity from a viewpoint different than traditional ones. (*Remark*: The closest work in spirit to that discussed in this paper is that of the author,[1] Isham and Kakas,[2] and especially Pilati.[3] See Sec. V for an extensive discussion. We do not directly comment on current schemes for quantizing gravity.)

Let us outline the general approach we shall adopt. First, we focus on basic kinematics and the quantum theory of positive definite, 3×3 matrix-valued field variables and associated noncanonical "conjugate" field variables, designed to offer an initial class of coherent states and coherent-state induced Hilbert space representations. In this step it is noteworthy that, besides the signature issue for the metric, the existence of an operator $g^{jk}(x)$, $j,k=1,2,3$, inverse to $g_{kl}(x)$ is shown, such that, when suitably defined, the equation $g^{jk}(x)g_{kl}(x)=\delta^j_k$ is fulfilled. Second, we introduce

[a)]Electronic mail: klauder@phys.ufl.edu

the spatial and temporal constraints in the projection operator approach recently developed by the author and others.[4–7] This procedure has the advantage of working entirely with the classical degrees of freedom, including the *c*-number Lagrange multipliers—specifically, the lapse and shift functions. It is not necessary to introduce additional fields (e.g., ghosts with false statistics), nor choose gauges, nor pass to moduli spaces, etc. Initially, the constraints are imposed in a regularized fashion. Subsequently, the removal of the regularization is analyzed, a process that often involves an automatic change of Hilbert-space representation. Assuming that the limit removing the regularization exists, the physical Hilbert space that arises is then, generally speaking, best described as a reproducing kernel Hilbert space that emerges from the reduction of the original reproducing kernel.

Before we undertake any discussion of gravity, however, we sketch in Sec. II the key concepts as applied to some simple, few degree-of-freedom systems. In Sec. III we construct a suitable kinematical framework for quantum gravity, while in Sec. IV we analyze the introduction of constraints. Section V contains a general discussion about operator representations and constraints in relation to reparametrization invariance. In Part II of this work, the analysis of gravitational constraints is discussed in detail. In addition, the classical limit of the affine gravitational quantum theory developed in Secs. III–IV will be discussed and compared with classical gravity.

II. ELEMENTARY ILLUSTRATION OF KEY CONCEPTS

As is generally well known, there is only one irreducible representation up to unitary equivalence of the canonical, self-adjoint operators P and Q satisfying the Weyl form of the canonical commutation relations. This representation, equivalent to the Schrödinger representation, implies that the spectrum of both P and Q cover the whole real line. Such operator degrees of freedom are appropriate for many systems with a finite or an infinite number of degrees of freedom, but they are inappropriate for gravity. The reason for this is that the classical 3×3 metric is strictly positive definite and the associated quantum field operator cannot be represented by an operator whose spectrum is unbounded above and below. Instead of the usual relation $[Q,P]=i$, with $\hbar=1$, one is led to consider an *affine commutation relation*,[8] which for a single degree of freedom takes the form

$$[Q,D]=iQ. \tag{1}$$

Here $D\equiv(PQ+QP)/2$ denotes the dilation operator, and it follows[9,10] that solutions of the affine commutation relations exist with irreducible, self-adjoint operators D and Q for which—and this is the important part—$Q>0$. (There are two other inequivalent self-adjoint solutions: one where $Q<0$, which is rather like the representation of interest, and another for which $Q=0$.[9] Neither of these representations will be of interest in this article.) Even though the operator P is only a symmetric operator that has no self-adjoint extension, the introduction of the self-adjoint operator D provides the substitute commutation relation given above. These two commutation relations are not in conflict since the affine commutation relation follows directly from the Heisenberg commutation relation simply by multiplication of the latter by Q. We note that an analog of the affine variables will be used in the case of the gravitational field to maintain the positivity of the local quantum field operator for the 3×3 spatial metric.

Continuing with the one-dimensional example, and based on self-adjoint operators that satisfy the affine commutation relation, let us introduce *affine coherent states*,[11] $|p,q\rangle\in\mathfrak{H}$, defined by the expression

$$|p,q\rangle\equiv e^{ipQ}e^{-i\ln(q)D}|\eta\rangle, \quad -\infty<p<\infty, \quad 0<q<\infty. \tag{2}$$

Here, the fiducial vector $|\eta\rangle$ is chosen to satisfy several conditions, which, using the shorthand $\langle(\cdot)\rangle\equiv\langle\eta|(\cdot)|\eta\rangle$, are specifically given by

$$\langle Q^{-1}\rangle\equiv C<\infty, \quad \langle\mathbf{1}\rangle=1, \quad \langle Q\rangle=1, \quad \langle D\rangle=0, \quad \langle P\rangle=0. \tag{3}$$

The first condition is required, while the remaining conditions are chosen for convenience. The coherent states also admit a resolution of unity[11] expressed in the form

$$\mathbf{1}=\int |p,q\rangle\langle p,q|\,d\tau(p,q), \quad d\tau(p,q)=dp\,dq/2\pi C, \tag{4}$$

integrated over the half-plane $\mathbb{R}\times\mathbb{R}^+$.

In particular, diagonalizing the self-adjoint operator $Q=\int_0^\infty x|x\rangle\langle x|\,dx$ in terms of standard Dirac-normalized eigenvectors, leads to a representation for the coherent-state overlap given by

$$\begin{aligned}\langle p,q|r,s\rangle &\equiv \langle \eta|e^{i\ln(q)D}e^{-ipQ}\,e^{irQ}e^{-i\ln(s)D}|\eta\rangle\\ &=(qs)^{-1/2}\int_0^\infty \eta(x/q)^* e^{-ix(p-r)}\eta(x/s)\,dx,\end{aligned} \tag{5}$$

where the fiducial function $\eta(x)=\langle x|\eta\rangle$ denotes the Schrödinger representation of the fiducial vector $|\eta\rangle$. It is important to observe, for some suitable function F, that

$$\langle p,q|r,s\rangle=F(q,p-r,s), \tag{6}$$

namely, that p and r universally enter in the form $p-r$. It is also clear that $\langle p,q|r,s\rangle$ defines a *continuous, positive-definite function*, which, apart from the continuity, means that

$$\sum_{n,m=1}^{N} \alpha_n^*\alpha_m\,\langle p_n,q_n|p_m,q_m\rangle \geqslant 0, \tag{7}$$

for arbitrary complex $\{\alpha_n\}_{n=1}^N$ and real $\{p_n,q_n\}_{n=1}^N$ sequences, with $N<\infty$. The function (5) may be taken as the *reproducing kernel for a reproducing kernel Hilbert space*.[12] Note that the information in $\langle p,q|r,s\rangle$ is enough to recover $\eta(x)$ apart from an overall constant phase factor. Thus, different fiducial functions (not related by a constant phase factor) generate distinct reproducing kernels. Since each reproducing kernel Hilbert space has one and only one reproducing kernel,[12] it follows for different $\eta(x)$ that the Hilbert space functional realizations are completely disjoint, except for the zero element. Basic elements of a dense set of vectors in each such Hilbert space are given by continuous functions of the form

$$\psi(p,q)\equiv\sum_{n=1}^{N} \alpha_n\langle p,q|p_n,q_n\rangle, \tag{8}$$

defined for arbitrary complex $\{\alpha_n\}_{n=1}^N$ and real $\{p_n,q_n\}_{n=1}^N$ sequences, with $N<\infty$. Let a second such function be given by

$$\phi(p,q)\equiv\sum_{j=1}^{J} \beta_j\langle p,q|\overline{p_j},\overline{q_j}\rangle, \tag{9}$$

defined for arbitrary complex $\{\beta_j\}_{j=1}^J$ and real $\{\overline{p_j},\overline{q_j}\}_{j=1}^J$ sequences, with $J<\infty$. The inner product of two such vectors is then *defined*[12] to be

$$\langle\psi|\phi\rangle\equiv(\psi(\cdot,\cdot)_J\,\phi(\cdot,\cdot))\equiv\sum_{n=1}^{N}\sum_{j=1}^{J} \alpha_n^*\beta_j\langle p_n,q_n|\overline{p_j},\overline{q_j}\rangle, \tag{10}$$

which when $|\phi\rangle=|\psi\rangle$ is, by definition, non-negative. The resultant pre-Hilbert space is completed to a (reproducing kernel) Hilbert space $\mathcal{C}$ by including all Cauchy sequences in the norm $\||\psi\rangle\| \equiv\sqrt{\langle\psi|\psi\rangle}$ as N tends to infinity. Finally, we note that the space of functions appropriate to one reproducing kernel is *identical* to the space of functions appropriate to a second reproducing kernel that is just a constant multiple of the first reproducing kernel. This fact does not contradict the uniqueness of the reproducing kernel for each Hilbert space because strictly different inner products are assigned in the two cases. Of course, the foregoing discussion applies quite generally and is not limited to any one sort of reproducing kernel.

When the states $|p,q\rangle$ form a set of coherent states—as we assume in the present case—the inner product has an *alternative representation* given by a local integral of the form

$$\langle\psi|\phi\rangle=\int \psi(p,q)^*\phi(p,q)\,d\tau(p,q), \tag{11}$$

expressed in terms of $\psi(p,q)\equiv\langle p,q|\psi\rangle$ and $\phi(p,q)\equiv\langle p,q|\phi\rangle$. It follows that this formula holds for all elements of the completed Hilbert space $\mathcal{C}$, and, moreover, every element of the so-completed space is a *bounded and continuous function*, the collection of which forms a rather special closed subspace of $L^2(\mathbb{R}^2,d\tau)$.

Thanks to the coherent-state resolution of unity, it follows that the coherent state overlap function satisfies the integral equation

$$\langle p'',q''|p',q'\rangle=\int \langle p'',q''|p,q\rangle\langle p,q|p',q'\rangle\,d\tau(p,q), \tag{12}$$

a basic relation, which, if it was established as a first step for the continuous function $\langle p'',q''|p',q'\rangle$ $[=\langle p',q'|p'',q''\rangle^*]$, guarantees the existence of a local integral representation for the inner product of two arbitrary elements in the associated reproducing kernel Hilbert space. Several useful properties follow from this reproducing property. For example, repeated use of the resolution of unity leads to the fact that

$$\langle p'',q''|p',q'\rangle=\lim_{L\to\infty}\int\cdots\int\prod_{l=0}^{L}\langle p_{l+1},q_{l+1}|p_l,q_l\rangle\prod_{l=1}^{L}\,d\tau(p_l,q_l), \tag{13}$$

in which we have identified $p'',q''=p_{L+1},q_{L+1}$ and $p',q'=p_0,q_0$. In turn, making an (unjustified!) interchange of the (continuum) limit with the integrations, and writing for the integrand the form it would assume for continuous and differentiable paths, gives rise to the suggestive but strictly formal expression[13]

$$\langle p'',q''|p',q'\rangle=\int e^{-i\int_0^T q(t)\,\dot p(t)\,dt}\,\mathcal{D}\tau(p,q), \tag{14}$$

which determines a formal path integral representation for the kinematics that applies for any $T>0$. Thus, the existence of a coherent state resolution of unity is the necessary and sufficient condition to introduce a traditional coherent state phase-space path integral representation for the kinematics, which specifically leads to the reproducing kernel. A path integral for the kinematics is a necessary prerequisite to obtain a path integral for the dynamics. While less than ideal, the formal path integral itself may be used as a starting point for quantization. Even though the formal nature of the path integral renders it basically undefined, one may always (re)introduce a regularization by a lattice-limit formulation (as above), using suitable ingenuity to choose an acceptable integrand. This procedure is more or less standard by now.

However, it must be appreciated that reproducing kernels for reproducing kernel Hilbert spaces are *not required* to fulfill a (positive) local integral representation for the inner product. In cases where the integral for the resolution of unity does not exist, one must accept the inner product that is given directly by the reproducing kernel, which means that the integral relation (12) is replaced by

$$(\langle\cdot,\cdot|p'',q''\rangle_J\langle\cdot,\cdot|p',q'\rangle)\equiv\langle p'',q''|p',q'\rangle. \tag{15}$$

When this is the case, we say that $\{|p,q\rangle\}$ forms a set of *weak coherent states*,[14] i.e., the elements of $\{|p,q\rangle\}$ span the Hilbert space $\mathfrak{H}$, but do not admit a local integral representation for the inner product of elements in the associated reproducing kernel Hilbert space.

A simple example of a reproducing kernel Hilbert space without a local integral representation for the inner product is determined, for $u'',u'\in\mathbb{R}$, by the reproducing kernel $\langle u''|u'\rangle \equiv\exp[-(u''-u')^2]$; here, one must use $(\langle\cdot|u''\rangle_J\langle\cdot|u'\rangle)\equiv\langle u''|u'\rangle$, which is then extended by linearity and continuity to all Hilbert space vectors.

A more relevant set of examples is given by the following discussion applied to our simple model. Let $\alpha>-\frac{1}{2}$, and choose $\eta(x)\equiv N\,x^{\alpha}\exp(-\beta x)$. Here the factor N is fixed by requiring $\int_0^\infty|\eta(x)|^2\,dx=1$. The two conditions $\langle Q\rangle=1$ and $\langle Q^{-1}\rangle=C<\infty$, lead to $\beta-\frac{1}{2}=\alpha>0$; in this case $C=1-1/(2\beta)$. In turn, the reproducing kernel is given explicitly[15] by

$$\langle p,q|r,s\rangle=\left[\frac{(qs)^{-1/2}}{\frac{1}{2}(q^{-1}+s^{-1})+i\frac{1}{2}\beta^{-1}(p-r)}\right]^{2\beta}$$

$$=\exp(-2\beta\ln\{[\tfrac{1}{2}(q^{-1}+s^{-1})+i\tfrac{1}{2}\beta^{-1}(p-r)]/(qs)^{-1/2}\}); \tag{16}$$

the second form is given for comparison purposes to the gravitational case. As long as $\beta>\frac{1}{2}$, it follows that the states $|p,q\rangle$ form a set of coherent states with a proper resolution of unity, and therefore a local integral representation for the inner product exists. In this case, path integrals exist as lattice limits, and the whole situation seems familiar. On the other hand, if $0<\beta\leqslant\frac{1}{2}$, the overlap function $\langle p,q|r,s\rangle$ defined above is still a positive-definite function and, therefore, it is a valid reproducing kernel that leads to an associated reproducing kernel Hilbert space; however, *such a Hilbert space does not admit a local integral representation for the inner product in terms of the given representatives*. Therefore, there is *no* conventional coherent state path integral for the kinematics, and thus also for the dynamics, in a reproducing kernel Hilbert space representation when $0<\beta\leqslant\frac{1}{2}$. This lack of a conventional coherent state path integral representation may appear to be detrimental to any program to introduce quantization, dynamics, etc.—but there is hope.

There is another way to generate the reproducing kernel for the given family of fiducial vectors that may be applied for all $\beta>0$. Let us first focus on $\beta>\frac{1}{2}$. In that case, observe, by construction and using $\partial_p\equiv\partial/\partial p$, etc., that for every $|\psi\rangle\in\mathfrak{H}$,

$$B\,\psi(p,q)\equiv\{-iq^{-1}\partial_p+1+\beta^{-1}q\,\partial_q\}\,\psi(p,q)=0, \tag{17}$$

an equation that represents a (complex) *polarization*[16] of $L^2(\mathbb{R}^2,d\tau)$. It follows that the second-order differential operator $A\equiv\frac{1}{2}\beta B^\dagger B\geqslant 0$, and therefore A can be used to generate a semigroup. In particular, for any $T>0$ and as $\nu\rightarrow\infty$, the expression $e^{-\nu TA}$ becomes a *projection operator* onto the subspace $\mathcal{C}$ of solutions to the polarization equation.[17] In a two degree of freedom Schrödinger representation—symbolized by $|p,q)$, where $(p,q)\in\mathbb{R}\times\mathbb{R}^+$ and $(p,q|r,s)=\delta(p-r)\delta(q-s)$—it follows, from a two-variable Feynman–Kac–Stratonovich path integral formula,[18] that

$$\langle p'',q''|p',q'\rangle\equiv\lim_{\nu\to\infty}(p'',q''|e^{-\nu TA}|p',q')$$

$$=\lim_{\nu\to\infty}\mathcal{N}\int e^{-i\int_0^T q(t)\,\dot p(t)\,dt-(1/2\nu)\int_0^T[\beta^{-1}q(t)^2\dot p(t)^2+\beta q(t)^{-2}\dot q(t)^2]\,dt}\,\mathcal{D}p\,\mathcal{D}q$$

$$\equiv\lim_{\nu\to\infty}e^{\nu T/2}\int e^{-i\int_0^T q(t)\,dp(t)}\,dW^{\nu}(p,q), \tag{18}$$

where W^ν denotes a two-dimensional Wiener measure with diffusion constant ν, pinned at $t=0$ to p',q' and at time $t=T$ to p'',q'', which is supported on a space of constant negative curvature $R=-2/\beta$. It is noteworthy in (18) that the variable $p(t)$ enters only in the form $\dot p(t)$, a fact which leads to the result depending only on the difference, $p''-p'$. For every $\nu<\infty$, and with probability one, all Wiener paths in the given path integral are *continuous*, and, for purposes of coordinate transformations, it is convenient to adopt the (midpoint) Stratonovich rule to define the stochastic integral $-\int q(t)\,dp(t)$ since, in that case, the rules of the ordinary calculus hold. Such a representation is said to involve a *continuous-time regularization*.[19]

Now we consider the case where $0<\beta\leqslant\frac{1}{2}$. The solutions to (17) are, up to a factor, analytic functions, but they are no longer square integrable, as is clear from the fact that the large q behavior of (16) is controlled only by the factor $q^{-\beta}$. As a consequence, the operator $A\geqslant 0$ has only a continuous spectrum. The family of operators $e^{-\nu TA}$ is still a semigroup, and the expression $(p'',q'|e^{-\nu TA}|p',q')$ still has the formal path integral representation given in the middle line of (18). However, as $\nu\to\infty$, $e^{-\nu TA}$ does not lead to a projection operator; instead we need to extract the germ of that semigroup as $\nu\to\infty$. If we let $E\geqslant 0$ denote continuum eigenvalues for the operator $\frac{1}{2}B^{\dagger}B$, we can write

$$(p'',q''|e^{-\nu TA}|p',q')=\int (p'',q''|E,v)\,e^{-\nu T\beta E}(E,v|p',q')\,\rho(E,v)\,dE\,dv, \tag{19}$$

for some density of states $\rho(E,v)$. Here, the variable v labels degeneracy for $\frac{1}{2}B^{\dagger}B$. For the sake of illustration, let us assume that $\rho(E,v)\simeq\overline{C}E^{w}\,\overline{\rho}(v)$, $w>-1$, for $E\ll 1$. We base this assumption on the fact that there is no reason for an E-dependent degeneracy for very tiny E. Thus, we consider the expression $J(\nu)\equiv(\nu\beta T)^{w+1}/\overline{C}\,\Gamma(w+1)$, and are led to the fact that

$$\begin{aligned}\lim_{\nu\to\infty} J(\nu)\,(p'',q''|e^{-\nu TA}|p',q')\\ &=\lim_{\nu\to\infty}\int (p'',q''|E,v)\,e^{-\nu T\beta E}(E,v|p',q')\,J(\nu)\,\rho(E,v)\,dE\\ &=\int (p'',q''|0,v)(0,v|p',q')\,\overline{\rho}(v)\,dv.\end{aligned} \tag{20}$$

In effect, this procedure has enabled us to pass to the germ of the semigroup. Observe that the rescaling factor is independent of the coherent state labels, and thus we are only making a ν-dependent rescaling before the limit $\nu\to\infty$ is taken. If necessary, we can rescale our expression by letting $J(\nu)\to\overline{J}(\nu)=M(p'',q'')\,M(p',q')\,J(\nu)$ to achieve normalization without affecting its positive-definite character. In summary, for $0<\beta\leqslant\frac{1}{2}$, we claim that instead of (18) we can write

$$\begin{aligned}\langle p'',q''|p',q'\rangle&\equiv\lim_{\nu\to\infty}\overline{J}(\nu)(p'',q''|e^{-\nu TA}|p',q')\\ &=\lim_{\nu\to\infty}\overline{\mathcal{N}}\int e^{-i\int_0^T q(t)\,\dot{p}(t)\,dt-(1/2\nu)\int_0^T[\beta^{-1}q(t)^2\dot{p}(t)^2+\beta q(t)^{-2}\dot{q}(t)^2]\,dt}\,\mathcal{D}p\,\mathcal{D}q\\ &\equiv\lim_{\nu\to\infty}\overline{J}(\nu)\,e^{\nu T/2}\int e^{-i\int_0^T q(t)\,dp(t)}\,dW^{\nu}(p,q).\end{aligned} \tag{21}$$

Convergence in this case is initially regarded in the sense of distributions. To lead to the desired result, we appeal to analyticity (up to a specific factor) of the result in $q^{-1}+i\beta^{-1}p$, analyticity (up to another factor) in the variable $s^{-1}-i\beta^{-1}r$, and dependence on $p-r$ [cf. (16)].Note that $\overline{J}(\nu)$ can always be determined self-consistently by insisting that $\langle p,q|p,q\rangle=1$ for all (p,q). In simpler terms, we can always regard $\overline{J}(\nu)$ as part of the needed normalization coded into $\overline{\mathcal{N}}$ in the formal path integral expression.

As will become evident later, various features of reproducing kernels, reproducing kernel Hilbert spaces, and associated rules for defining inner products illustrated above will carry over into the quantum gravity case as well.

A. Operators and symbols

In addition to the properties of the reproducing kernel Hilbert space, certain *symbols* associated with operators are important. Let us introduce the upper symbol $H(p,q)$ associated to the operator $\mathcal{H}(P,Q)$ and defined, modulo suitable domain conditions, by the expression

$$H(p,q)\equiv\langle p,q|\mathcal{H}(P,Q)|p,q\rangle=\langle\mathcal{H}(p+P/q,qQ)\rangle. \tag{22}$$

For example, if $\mathcal{H}(P,Q)=P^2-Q^{-1}$ denotes a quantum Hamiltonian, then $H(p,q)=p^2+\langle P^2\rangle/q^2-C/q$. Since $C=O(1)$ (e.g., for large β) and $\langle Q\rangle=1$, it follows that $\langle P^2\rangle=O(\hbar^2)$. Observe that H basically agrees with the expected classical Hamiltonian in the limit that $\hbar\rightarrow 0$, but prior to that limit H includes a quantum-induced barrier to singularities in solutions of the usual classical equations of motion. We adopt the expression $H(p,q)$ as the ($\hbar$-augmented) classical Hamiltonian and refer to the connection between the quantum generator $\mathcal{H}$ and the classical generator H as the *weak correspondence principle*.[20] In this way, the classical and quantum theories may both *coexist*, as they do in Nature.

There is also another set of symbols that are important. We introduce the lower symbol $h(p,q)$ that is related to the operator $\mathcal{H}(P,Q)$ by the expression

$$\mathcal{H}(P,Q)=\int h(p,q)\,|p,q\rangle\langle p,q|\,d\tau(p,q). \tag{23}$$

For the one-parameter class of fiducial vectors leading to (16), it follows that a dense set of operators admit such a symbol for a reasonable set of functions.

In the quantum gravity case, there are twin goals: (i) to ensure that the field operators of interest are well defined and locally self-adjoint in the given field operator representation; and (ii) to choose locally self-adjoint constraint operators that have a weak correspondence principle which connects them with the desired form of the classical constraint generators (possibly $\hbar$ augmented).

B. Imposition of constraints

We adopt the projection operator approach to the quantization of systems with constraints.[4–7] Let $\{\Phi_\alpha(P,Q)\}_{\alpha=1}^{A}$, $A<\infty$, denote a set of constraints, each element given by a self-adjoint operator. Further, assume that $\Phi\cdot\Phi\equiv\Sigma_{\alpha=1}^{A}(\Phi_\alpha)^2$ is also self adjoint. We define the (provisional) physical Hilbert space $\mathfrak{H}_{\text{phys}}\equiv\mathbb{E}\mathfrak{H}$, where $\mathbb{E}=\mathbb{E}^\dagger=\mathbb{E}^2$ is a uniquely defined projection operator, and in turn choose

$$\mathbb{E}\equiv\mathbb{E}(\Phi\cdot\Phi\leqslant\delta(\hbar)^2), \tag{24}$$

where $\delta(\hbar)$ is *not* a δ-function but a small, positive, possibly $\hbar$-dependent, *regularization parameter* for the set of constraints. As shown below, $\delta(\hbar)$ is chosen so that $\mathbb{E}$ is the desired projection operator. This choice may entail a specific representation of the Hilbert space and a suitable limit as $\delta\rightarrow 0$ to extract the germ of the projection operator.

We may illustrate this latter situation for the constraint $\Phi\equiv\mathrm{Q}-1$, assuming initially that $\delta<1$. In this case

$$\langle\psi|\mathbb{E}((Q-1)^2\leqslant\delta^2)|\phi\rangle=\int_{1-\delta}^{1+\delta}dx\int d\sigma(y)\,\psi(x,y)^*\phi(x,y), \tag{25}$$

where σ accounts for any degeneracy that may be present. When restricted to functions ψ_0 and ϕ_0 in the dense set $\mathfrak{D}$, where (say)

$$\mathfrak{D}\equiv\{\text{ polynomial }(x,y)\,e^{-x^2-y^2}\}, \tag{26}$$

and rescaled by a suitable factor, the projection operator matrix elements lead to the expression

$$(2\delta)^{-1}\langle\psi_0|\mathbb{E}((Q-1)^2\leq\delta^2)|\phi_0\rangle=(2\delta)^{-1}\int_{1-\delta}^{1+\delta}dx\int d\sigma(y)\ \psi_0(x,y)^*\phi_0(x,y). \tag{27}$$

Now, as $\delta\to 0$, this expression becomes

$$\int \psi_0(1,y)^*\phi_0(1,y)\,d\sigma(y)\equiv((\psi_0,\phi_0)). \tag{28}$$

Interpreting this final expression as a sequilinear form, one completes the desired Hilbert space by adding all Cauchy sequences in the associated norm $\||\psi_0))\|\equiv\sqrt{((\psi_0,\psi_0))}$. The result is the true physical Hilbert space in which the constraint $Q-1=0$ is fulfilled, and this example illustrates how constraints are to be treated when $\Phi\cdot\Phi$ has its zero in the continuous spectrum.

A second example of an imposition of constraints is given by $\Phi_1=Q-1$, as before, along with $\Phi_2=D$. This situation corresponds to second class constraints, and serves as a simple qualitative model of what occurs in the gravitational case. In this case

$$\mathbb{E}=\mathbb{E}(D^2+(Q-1)^2\leq\delta(\hbar)^2). \tag{29}$$

Here, the left-hand side of the argument can be regarded as a ''Hamiltonian,'' and the ground state $|0'\rangle$ for such a system (nondegenerate, in the present example) can be sought. In particular, there are two positive parameters, δ' and δ'', such that, for all δ with $\delta'\leq\delta<\delta''$, then

$$\mathbb{E}=\mathbb{E}(D^2+(Q-1)^2\leq\delta(\hbar)^2)\equiv|0'\rangle\langle 0'|. \tag{30}$$

This is the desired choice to make for $\mathbb{E}$ in the case where $\Phi\cdot\Phi$ has a discrete spectrum near zero that does not include zero.

For completeness, if $\Phi\cdot\Phi$ has a discrete spectrum including zero, then it suffices to choose

$$\mathbb{E}=\mathbb{E}(\Phi\cdot\Phi=0)=\mathbb{E}(\Phi\cdot\Phi\leq\delta(\hbar)^2), \tag{31}$$

where in the present case $\delta(\hbar)>0$ is chosen small enough to include only the subspace for which $\Phi\cdot\Phi=0$. This simple case does not seem to arise in quantum gravity. See Refs. 4,7 for a discussion of gauge invariance.

When the number of constraints is infinite, $A=\infty$, as will be the case for a field theory, then a slightly different approach is appropriate. One form this takes is dealt with in Sec. IV.

C. Appearance of time

In a reparametrization-invariant problem in quantum mechanics it is typical that dynamics is cast in the guise of kinematics at the expense of introducing an additional degree of freedom plus a first-class constraint; see, e.g., Ref. 21. Let the resultant kinematical reproducing kernel with the extra degree of freedom be given by $\langle p'',q'',s'',t''|\mathbb{E}|p',q',s',t'\rangle$, where $\mathbb{E}$ is the projection operator enforcing the constraint. Next, reduce this expression, for example, as in the procedure

$$\langle p'',q'',t''|p',q',t'\rangle\equiv\int\int\langle p'',q'',s'',t''|\mathbb{E}|p',q',s',t'\rangle\,ds''\,ds'. \tag{32}$$

The result is a new positive-definite function that can be used to define a reproducing kernel Hilbert space. However, it may well happen that the following identity holds:

$$\begin{aligned}\langle p'',q'',t''|p',q',t'\rangle&=(\langle\cdot,\cdot,\cdot|p'',q'',t''\rangle_J\langle\cdot,\cdot,\cdot|p',q',t'\rangle)\\&=(\langle\cdot,\cdot,t|p'',q'',t''\rangle_J\langle\cdot,\cdot,t|p',q',t'\rangle).\end{aligned} \tag{33}$$

This equation means that the space spanned by the states $|p,q,t\rangle$ by varying p, q, *and t* is the *same space* spanned, by the same states, by varying p and q but with t held *fixed* at some value (e.g.,

$t=0$). This situation implies that the states $|p,q,t\rangle$ are *extended coherent states* in the sense of Ref. 22, and, in particular, thanks to using canonical group coordinates in the coherent-state parametrization, that $|p,q,t\rangle=\exp(-i\mathcal{H}t)|p,q,0\rangle$ for some self-adjoint ''Hamiltonian'' $\mathcal{H}$. The parameter t is then recognized as the ''time'' t. For an explicit example of how this procedure works in detail, see Ref. 23.

It is expected that a suitable time parameter will emerge in the extension of these ideas to the gravitational case.

D. Matrix generalization

Our preceding analysis has been confined to a single p and q and the associated affine quantum operators. In any generalization to the gravitational case, it will first be necessary to generalize the preceding discussion to 3×3 (or more generally to $s\times s$) matrix degrees of freedom and repeat an analysis similar to that of the present section. We do not include this discussion here since that is the subject of a separate work.[24] It is safe to say, apart from some technical details, that there are no special surprises in this generalization, and the basic concepts that we shall need are already present in the simplest case on which we have concentrated.

III. GRAVITATIONAL KINEMATICS

A. Preliminaries

Let us start with the introduction of a three-dimensional topological space $\mathcal{S}$ that is locally isomorphic to a subset of $\mathbb{R}^3$. Locally, we generally use three ''spatial'' coordinates, say x^j, $j=1,2,3$, to label a point in $\mathcal{S}$. This labeling is nonsingular and thus one-to-one. Whether a single coordinate chart covers $\mathcal{S}$ depends on the global topological structure of $\mathcal{S}$. Let us fix this global topological structure from the outset—for example, topologically equivalent to $\mathbb{R}^3$, S^3, T^3, etc. The theory of quantum gravity developed here does not engender topological changes of the underlying topological space $\mathcal{S}$. Note this lack of topological change applies only to the space $\mathcal{S}$. It is unrelated to any presumed ''space'' and/or ''topology'' associated with any quantum metric tensor, which, after all, is typically distributional in character.

If the space $\mathcal{S}$ is such that more than one coordinate patch is required we arrange for the necessary matching conditions and rename the coordinates within each patch by x^j, $j=1,2,3$, for some domain. We can also consider alternative coordinates, say $\overline{x^j}$, $j=1,2,3$, which are also nonsingular. We admit only differentiable coordinate transformations such that the Jacobian $[\partial x/\partial\overline{x}]\equiv\det(\partial x^j/\partial\overline{x^k})\neq0$ everywhere. The group composed of such invertible coordinate transformations is the *diffeomorphism group*.

We can also introduce functions on the space $\mathcal{S}$ which in coordinate form may be denoted by $f(x)$. A scalar function is one for which $\overline{f}(\overline{x})=f(x)$, while a scalar density of weight one satisfies $\overline{b}(\overline{x})=[\partial x/\partial\overline{x}]\,b(x)$, or stated as a volume form, $dV=\overline{b}(\overline{x})\,d^3\overline{x}=b(x)\,d^3x$. Observe that it is not necessary to have a metric in order to have a volume form. Whether $\mathcal{S}$ is compact or noncompact, we assume that $0<b(x)<\infty$ for all x and therefore $0<b(x)^{-1}<\infty$ for all x as well. These properties are still valid after a nonsingular coordinate change. Integrals of a scalar function take the form $\int f\,dV=\int f(x)\,b(x)\,d^3x$ and are invariant under any coordinate transformation in the diffeomorphism group.

In the ADM (Arnowitt, Deser, Misner)[25] canonical formulation of classical gravity there are two fundamental fields $g_{kl}(x)$ $[=g_{lk}(x)]$ and $\pi^{kl}(x)$ $[=\pi^{lk}(x)]$. The metric $g_{kl}(x)$ transforms as a (two-valent covariant) tensor, while the momentum $\pi^{kl}(x)$ transforms as a (two-valent contravariant) tensor density of weight one. Thus $\int g_{kl}(x)\,\pi^{kl}(x)\,d^3x$ [or even $\int g_{kl}(x,t)\,\dot{\pi}^{kl}(x,t)\,d^3x\,dt$] is an invariant under diffeomorphism group transformations (on the spatial hyperspace, of course). Note well: The latter example pertains to a generalization of the former one, including an additional independent variable t that possibly could be identified with (coordinate) ''time.''

A metric is not an arbitrary tensor but is restricted to be positive definite. Specifically, for any real α^j, $j=1,2,3$, where $\Sigma_{j=1}^{3}(\alpha^j)^2>0$, it follows that $\alpha^k g_{kl}(x)\,\alpha^l>0$ for all x. As a consequence, the positive-definite (two-valent contravariant) tensor $g^{kl}(x)$ exists at each point and is defined so that $g^{kl}(x)\,g_{lm}(x)=\delta^k_m$. In addition, $\sqrt{g(x)}\equiv\sqrt{\det[g_{kl}(x)]}>0$ transforms as a scalar density of weight one. Thus, as is well known, $\sqrt{g(x)}\,d^3x$ characterizes a volume form, but this choice ties the volume form to a specific metric, or at least to a specific class of metrics. This close association to specific metrics is something we would like to avoid, and it leads us to choose $b(x)\,d^3x$ as the preferred volume form. Of course, if $b(x)=\sqrt{g(x)}$ everywhere in any coordinate system, then the volume form $b(x)\,d^3x$ is identical to the one based on a metric space and given by $\sqrt{g(x)}\,d^3x$.

B. Reproducing kernel—Original Hilbert space

A study of canonical quantum gravity begins with the introduction of metric and momentum local quantum field operators, which we denote by $\sigma_{kl}(x)$ $[=\sigma_{lk}(x)]$ and $\mu^{kl}(x)$ $[=\mu^{lk}(x)]$, respectively. For such fields one postulates the canonical commutation relations,

$$[\sigma_{kl}(x),\,\mu^{rs}(y)]=i\,\delta^{rs}_{kl}\,\delta(x,y),$$
$$[\sigma_{kl}(x),\,\sigma_{rs}(y)]=0, \tag{34}$$
$$[\mu^{kl}(x),\,\mu^{rs}(y)]=0,$$

with $\delta^{rs}_{kl}\equiv(\delta^r_k\delta^s_l+\delta^r_l\delta^s_k)/2$. Since the right-hand side of the first equation is a tensor density of weight one, it is consistent that we define $\sigma_{kl}(x)$ to be a tensor and $\mu^{rs}(x)$ to be a tensor density of weight one. However, just as its one-dimensional counterpart, there are no local self-adjoint field and momentum operators that satisfy the canonical commutation relations as well as the requirement that $\{\sigma_{kl}(x)\}>0$. To arrive at a suitable substitute set of commutation relations, we introduce, along with the local metric field operator $\sigma_{kl}(x)$, the local ''scale'' field operator $\kappa^r_k(x)$, which together obey the *affine commutation relations*[1–3]

$$[\kappa^r_k(x),\,\kappa^s_l(y)]=i\,\tfrac{1}{2}[\delta^s_k\,\kappa^r_l(x)-\delta^r_l\,\kappa^s_k(x)]\,\delta(x,y),$$
$$[\sigma_{kl}(x),\,\kappa^r_s(y)]=i\,\tfrac{1}{2}[\delta^r_k\,\sigma_{ls}(x)+\delta^r_l\,\sigma_{ks}(x)]\,\delta(x,y), \tag{35}$$
$$[\sigma_{kl}(x),\,\sigma_{rs}(y)]=0.$$

In these relations, $\sigma_{kl}(x)$ remains a tensor, while $\kappa^r_s(x)$ is a tensor density of weight one under coordinate transformations. The local operators $\kappa^r_s(x)$ are generators of the $GL(3,R)^\infty$ group,[2,3] while the local operators $\sigma_{kl}(x)$ are commuting ''translations'' coupled with the $GL(3,R)^\infty$ group by a semidirect product. The given affine commutation relations are the natural generalization of the one-dimensional affine commutation relation presented in (1). In the case of one degree of freedom, the affine commutation relations follow from the canonical ones, while in the case of fields this is, strictly speaking, incorrect. It is true that

$$\kappa^r_k(x)=\tfrac{1}{2}[\sigma_{kl}(x)\,\mu^{lr}(x)+\mu^{rl}(x)\sigma_{lk}(x)]_R, \tag{36}$$

where the subscript R denotes an infinite multiplicative renormalized product to be defined later. However, the presence of an infinite rescaling means that either the canonical or the affine set of commutation relations can hold, but not both at the same time. Since it is the affine commutation relations that are consistent with local self-adjoint operator solutions enjoying metric positivity, we shall adopt the noncanonical affine commutation relations. The choice of the affine commutation relations means that the canonical commutation relations do *not* hold, and therefore we are dealing with a *non*canonical quantization of the gravitational field.

Accepting the affine field operators as generators, we introduce a primary set of normalized affine coherent states each of which—in a deliberate abuse of notation—is defined by

$$|\pi,g\rangle \equiv e^{i\int \pi^{kl}(x)\,\sigma_{kl}(x)\,d^3x}\,e^{-i\int \gamma^r_s(x)\,\kappa^s_r(x)\,d^3x}\,|\eta\rangle, \tag{37}$$

for a suitable fiducial vector $|\eta\rangle$ characterized below. In $|\pi,g\rangle$ the argument ''π'' denotes the momentum matrix field π^{ab} while ''g'' denotes the metric matrix field g_{ab}. By all rights, the states in question should have been called $|\pi,\gamma\rangle$, but as we shall see, the overlap of two such states, *for the featured choice of* $|\eta\rangle$ [cf. (70)], depends only on the matrix (for each point x) $g \equiv \exp(\gamma^T/2)\exp(\gamma/2)\equiv\{g_{ab}\}$, where T means ''transpose.'' [Observe by this parametrization that $g>0$, as opposed to a traditional triad for which $g\geqslant 0$. To see that this distinction may possibly make a real difference, see Ref. 15. We remark that the nonsymmetric matrix $\exp(\gamma/2)$ would have relevance for spinor fields.] If the space $\mathcal{S}$ is noncompact, then, as smooth c-number fields, both π and γ should go to zero sufficiently fast so that the indicated smeared field operators are indeed self-adjoint operators and generate unitary transformations as required. On the other hand, as we shall shortly see, this asymptotic behavior can, effectively, be significantly relaxed.

The overlap of two such coherent states leads to an expression of the form

$$\langle \pi'',g''|\pi',g'\rangle = F(g'',\pi''-\pi',g'), \tag{38}$$

for some continuous functional F that depends only on the difference of the fields, $\pi''(x)-\pi'(x)$, an analog of which already occurred for the one-dimensional example. Whatever choice is made for the fiducial vector $|\eta\rangle$, the coherent state overlap function defines a continuous, positive-definite functional, which, therefore, defines a reproducing kernel and its associated (separable) reproducing kernel Hilbert space $\mathcal{C}$. By construction, therefore, the set of coherent states $\{|\pi,g\rangle\}$ span the Hilbert space $\mathfrak{H}$. As such they form a basis (overcomplete to be sure!) for $\mathfrak{H}$. Based on arguments to follow, we are led to the proposal [cf., (16)] that

$$\langle \pi'',g''|\pi',g'\rangle = \exp\left(-2\int b(x)\,d^3x\,\ln \left\{\frac{\det\{\tfrac{1}{2}[g''^{kl}(x)+g'^{kl}(x)]+i\tfrac{1}{2}b(x)^{-1}[\pi''^{kl}(x)-\pi'^{kl}(x)]\}}{(\det[g''^{kl}(x)])^{1/2}(\det[g'^{kl}(x)])^{1/2}}\right\}\right). \tag{39}$$

This equation is central to our analysis of quantum gravity.

The coherent-state overlap (39) may be read in two qualitatively different ways. Although arrived at on the basis that $\pi''(x),\pi'(x)\to 0$ and $\gamma''(x),\gamma'(x)\to 0$ as $|x|\to\infty$, the given expression exists for a far wider limiting behavior. In particular, suppose there is a *fixed asymptotic behavior* such that for both $\pi=\pi''$ and $\pi=\pi'$, $\pi^{ab}(x)-\tilde{\pi}^{ab}(x)\to 0$ and for both $g=g''$ and $g=g'$, $g_{ab}(x)-\tilde{g}_{ab}(x)\to 0$, all terms vanishing sufficiently fast as $|x|\to\infty$. In this case $g\equiv \exp(\gamma^T/2)\tilde{g}\exp(\gamma/2)$. Note that the asymptotic fields can depend on x. In this case the coherent-state overlap still holds in the form given. This kind of asymptotic behavior reflects a change of the fiducial vector $|\eta\rangle$, which now depends on the explicitly chosen asymptotic form for the momentum and metric—or, equivalently, as we effectively do, one can hold $|\eta\rangle$ fixed and change the representations of the operator [cf. (71)]. By choosing a suitable asymptotic momentum and metric one can, in effect, redefine the topology of the underlying space $\mathcal{S}$. However, for simplicity, we shall assume simple Euclidean-like asymptotic behavior of the momentum and metric [$\tilde{\pi}^{ab}(x)\equiv 0$ and $\tilde{\gamma}^r_s(x)\equiv 0$, i.e., $\tilde{g}_{ab}(x)\equiv\delta_{ab}$].

A second way to study the coherent-state overlap is under coordinate transformations. Observe that $\langle \pi'',g''|\pi',g'\rangle$ is *invariant* if, everywhere, we make the replacements

(i) $b(x)\,d^3x$, by $\overline{b(\overline{x})}\,d^3\overline{x} = b(x)\,d^3x$,

(ii) $g^{kl}(x)$, by $\overline{g}^{kl}(\overline{x}) = M^k_r(x)\,g^{rs}(x)\,M^l_s(x)$,

(iii) $b(x)^{-1}\pi^{kl}(x)$, by $\overline{b(\overline{x})}^{-1}\overline{\pi}^{kl}(\overline{x})=b(x)^{-1}M_r^k(x)\pi^{rs}(x)M_s^l(x)$,

all for an arbitrary nonsingular matrix $M\equiv\{M_r^k\}$, $M_r^k(x)\equiv(\partial\overline{x}^k/\partial x^r)(x)$, which arises from a nonsingular coordinate transformation $x\rightarrow\overline{x}=\overline{x}(x)$. It suffices to restrict attention to those coordinate transformations continuously connected to the identity. When $\mathcal{S}$ is compact, a wide class of M is allowed; when $\mathcal{S}$ is noncompact, the allowed elements M must also map coherent states into coherent states for the same fiducial vector. This restriction excludes any connection by coordinate transformations of two field sets with fundamentally different asymptotic behavior; such fields live in disjoint sets. The invariance under admissible coordinate transformations is symbolized by the statement that

$$\langle\overline{\pi''},\overline{g''}|\overline{\pi'},\overline{g'}\rangle=\langle\pi'',g''|\pi',g'\rangle, \tag{40}$$

for all suitable M. Since the allowed M form a representation of the connected component of the diffeomorphism group, it follows from this identity, and suitable continuity, that for sufficiently restricted M, the transformation $|\pi,g\rangle\rightarrow|\overline{\pi},\overline{g}\rangle$ is induced by a *unitary transformation*, specifically that

$$|\overline{\pi},\overline{g}\rangle\equiv U(M)|\pi,g\rangle, \tag{41}$$

$$U(M)\equiv\exp\left[-i\int N^j(x)\mathcal{H}_j(x)d^3x\right]. \tag{42}$$

Here $\mathcal{H}_j(x)$ denotes a local operator tensor density of weight one while $N^j(x)$ denotes a *c*-number tensor with sufficiently rapid decay at spatial infinity. Furthermore, using the shorthand that $\int N^jH_j\equiv\int N^j(y)H_j(y)d^3y$, the connection between M and N^j is implicitly given by

$$M_r^a g^{rs} M_s^b=g^{ab}-\left\{\int N^jH_j,g^{ab}\right\}+\frac{1}{2!}\left\{\int N^kH_k,\left\{\int N^jH_j,g^{ab}\right\}\right\}+\ldots\equiv e^{-\{\int N^jH_j,\cdot\}}g^{ab}, \tag{43}$$

where $\{\cdot,\cdot\}$ denotes the classical Poisson brackets, and specifically, e.g., $\{g_{ab}(x),\pi^{rs}(y)\}=\delta_{ab}^{rs}\delta(x,y)$. In this expression, $H_j(x)=-2g_{jk}(x)\pi^{kl}_{|l}(x)$, $j=1,2,3$, where $(\ )_{|l}$ is the covariant derivative with respect to the 3×3 metric, denotes the classical generators of the diffeomorphism group.[26] The relationship of $H_j(y)$ and $\mathcal{H}_j(y)$ may be determined as follows. Expansion of the relation

$$\langle\pi'',g''|e^{-i\int N^j(x)\mathcal{H}_j(x)d^3x}|\pi',g'\rangle=\langle\pi'',g''|\overline{\pi'},\overline{g'}\rangle, \tag{44}$$

to first order in N^j, leads to

$$\begin{aligned}\langle\pi'',g''|&\int N^j(x)\mathcal{H}_j(x)d^3x|\pi',g'\rangle/\langle\pi'',g''|\pi',g'\rangle\\&=-i2\int b(x)d^3x([g''^{kl}(x)+g'^{kl}(x)]+ib(x)^{-1}[\pi''^{kl}(x)-\pi'^{kl}(x)])^{-1}\\&\quad\times[\delta g'^{kl}(x)-ib(x)^{-1}\delta\pi'^{kl}(x)]+i\int b(x)d^3x\ g'_{kl}(x)\delta g'^{kl}(x),\end{aligned} \tag{45}$$

where

$$\delta g'^{kl}(x)\equiv g'^{kl}_{,j}(x)N^j(x)-g'^{jl}(x)N^k_{,j}(x)-g'^{kj}(x)\,N^l_{,j}(x), \tag{46}$$

and likewise for $\delta\pi'^{kl}(x)$. This relation determines the coherent state matrix elements of $\mathcal{H}_j(x)$. Finally, observe that the diagonal coherent state matrix elements read as

$$\langle \pi,g|\mathcal{H}_j(x)|\pi,g\rangle = -2g_{jk}(x)\pi^{kl}_{|l}(x), \tag{47}$$

in conformity with the weak correspondence principle.

C. Path integral construction

If the given coherent states $|\pi,g\rangle$ possessed a resolution of unity, namely a non-negative measure $\rho(\pi,g)$ (countably or even finitely additive), such that

$$\int \langle \pi'',g''|\pi,g\rangle\langle \pi,g|\pi',g'\rangle d\rho(\pi,g) = \langle \pi'',g''|\pi',g'\rangle, \tag{48}$$

then the construction of a path integral for the reproducing kernel would be straightforward and would follow the pattern illustrated in Sec. II for a single degree of freedom. However, for the proposed reproducing kernel $\langle \pi'',g''|\pi',g'\rangle$ given in (39), no such measure exists and thus the traditional resolution of unity is unavailable. Consequently, as defined, $\{|\pi,g\rangle\}$ is a set of weak coherent states.

A similar kind of problem arose in the simple model discussed in Sec. II (when $0<\beta\leqslant\frac{1}{2}$). In that case, the construction of a path integral representation proceeded in an alternative manner, beginning first with a polarization. We assert that each of the given Hilbert space representatives,

$$\psi(\pi,g) \equiv \langle \pi,g|\psi\rangle = \sum_{n=1}^{N} \alpha_n \langle \pi,g|\pi_n,g_n\rangle \in \mathcal{C}, \tag{49}$$

satisfies the functional differential equation [cf. (17)],

$$B^r_s(x)\psi(\pi,g) \equiv \left[-ig^{rt}(x)\frac{\delta}{\delta\pi^{ts}(x)} + \delta^r_s + b(x)^{-1}g_{st}(x)\frac{\delta}{\delta g_{tr}(x)}\right]\psi(\pi,g) = 0, \tag{50}$$

for all spatial points x. Next, let us introduce the operator

$$\mathcal{A} \equiv \tfrac{1}{2}\int B^s_r(x)^\dagger B^r_s(x) b(x) d^3x, \tag{51}$$

and observe that $\mathcal{A}\geqslant 0$. Thus, with $T>0$ and as $\nu\to\infty$, it follows that $\overline{\mathcal{J}}(\nu)e^{-\nu T\mathcal{A}}$, for some $\overline{\mathcal{J}}(\nu)$, serves to select out the subspace where (50) is fulfilled. Just as in the toy model of Sec. II, the operator $\mathcal{A}$ is a second-order (functional) differential operator, and, as a consequence, a Feynman–Kac–Stratonovich path (i.e., functional) integral representation may be introduced. In particular, we obtain the formal expression [cf. (21)],

$$\langle \pi'',g''|\pi',g'\rangle = \lim_{\nu\to\infty}\overline{\mathcal{N}}\int \exp\left[-i\int g_{ab}\dot{\pi}^{ab}\,d^3x\,dt\right]\exp\left\{-(1/2\nu)\int [b(x)^{-1}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}\right.$$
$$\left. + b(x)g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]d^3x\,dt\right\}\prod_{x,t}\prod_{a\leqslant b} d\pi^{ab}(x,t)dg_{ab}(x,t). \tag{52}$$

Here, let us interpret t, $0\leqslant t\leqslant T$, as coordinate ''time.'' On the right-hand side the canonical fields are functions of space and time, that is,

$$g_{ab} = g_{ab}(x,t), \quad \pi^{ab} = \pi^{ab}(x,t); \tag{53}$$

the overdot ($\dot{}$) denotes a partial derivative with respect to t, and the integration is subject to the boundary conditions that $\pi(x,0),g(x,0)=\pi'(x),g'(x)$ and $\pi(x,T),g(x,T)=\pi''(x),g''(x)$. Observe that the field π enters this path integral expression only in the form $\dot{\pi}$; this fact is responsible for the result of the path integral depending only on $\pi''-\pi'$. It is important to note, for any $\nu<\infty$, that underlying the formal measure given above, there is a genuine, countably additive measure on (generalized) functions g_{kl} and π^{rs}. Loosely speaking, such functions have Wiener-like behavior with respect to time and δ-correlated, generalized Poisson-like behavior with respect to space.

While (52) is invariant under spatial diffeomorphisms, it is less evident that it is also invariant under transformations of the time coordinate (by itself). (The author thanks A. Ashtekar for raising the question of temporal transformation properties.) Formally speaking, the role of the limit $\nu\to\infty$ is to remove the effects of the continuous-time regularization. It is clear, however, that there is no need that removing those effects must be done in a *uniform* way independent of x. Thus, we may replace ν by $\nu N(x)$—now under the integral sign—where $N(x)$, $0<N(x)<\infty$, is smooth and reflects the relative rate at which the regularization is removed at different spatial points. The end result is invariant under such a change. Moreover, at each point x we can run the process with different ''clock'' rates, i.e., $N(x)dt\to N(x,t)dt$ as long as the elapsed time is qualitatively unchanged. This remark means that we can choose any smooth *lapse function* $N(x,t)$, $0<N(x,t)<\infty$, with the consequence that

$$\langle \pi'',g''|\pi',g'\rangle=\lim_{\nu\to\infty}\mathcal{N}\int \exp\left[-i\int g_{ab}\dot{\pi}^{ab}\,d^3x\,dt\right]\exp\left\{-(1/2\nu)\int [b(x)^{-1}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}\right.$$

$$\left.+b(x)g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]N(x,t)^{-1}\,d^3x\,dt\right\}\prod_{x,t}\prod_{a\leq b}d\pi^{ab}(x,t)dg_{ab}(x,t). \tag{54}$$

The necessary conditions for this more general expression to hold are, for all T, $0<T<\infty$, and at all x, that

$$\int_0^T N(x,t)dt<\infty, \tag{55}$$

$$\int_0^\infty N(x,t)dt=\infty. \tag{56}$$

In this sense we observe that our formal path integral representation (52) for the coherent-state overlap is actually *invariant* under transformations of the time coordinate.

D. Metrical quantization

The formal, ν-dependent, weighting factor in the path integral expression (52) involves a *metric* $d\Sigma^2$ on the classical phase space, which may be read out of the expression

$$d\Sigma^2/dt^2=\int [b^{-1}g_{kl}g_{rs}\dot{\pi}^{lr}\dot{\pi}^{sk}+bg^{kl}g^{rs}\dot{g}_{lr}\dot{g}_{sk}]d^3x. \tag{57}$$

As presented, this expression for $d\Sigma^2$ is a *derived* quantity. Alternatively, it is clear that one could *start* the analysis by *postulating* a specific functional form for $d\Sigma^2$ to be used in a continuous-time regularization in the path integral construction of the reproducing kernel, and, finally, by appealing to the GNS (Gel'fand, Naimark, Segal) Theorem,[27] to recover the representation of the local field operators $\sigma_{kl}(x)$ and $\kappa^r_s(x)$. Adopting a metric on the classical phase space as the first step in a quantization procedure is called *metrical quantization*.[28] To carry out such a scheme for gravity, it is necessary that any postulated $d\Sigma^2$ satisfy several properties. First, it must be diffeomorphism *invariant* and, second, on physical grounds, it should only depend on $d\pi^{kl}$ (or $\dot{\pi}^{kl}$ for $d\Sigma^2/dt^2$) and not on π^{kl} itself. Hence, we are initially led to consider

$$d\Sigma^2/dt^2=\int [b^{-2}L_{abcd}\dot{\pi}^{bc}\dot{\pi}^{da}+M^{abcd}\dot{g}_{bc}\dot{g}_{da}]b(x)d^3x, \tag{58}$$

for suitable, positive-definite tensors L and M constructed just from g_{kl}. The given choice for L and M, i.e., $L_{abcd}=\frac{1}{2}[g_{ab}g_{cd}+g_{ac}g_{bd}]$ and $M^{abcd}=\frac{1}{2}[g^{ab}g^{cd}+g^{ac}g^{bd}]$ satisfy $M=L^{-1}$ as matrices. This choice is very natural and moreover is identical to the form suggested by the study of certain GL(3,R) coherent states for a 3×3 positive-definite matrix degree of freedom.[24]

Nevertheless, in a metric-first quantization scheme, it is appropriate to examine other choices as well. For example, a term such as $b(x)^{-1}\dot{g}_{ab}(x)\dot{\pi}^{ab}(x)$ might be included, but this term may be eliminated by a translation of the momentum. Additionally, one may consider nonlocal contributions involving, for example, the term $\dot{g}_{bc}(x)\dot{g}_{da}(y)$, together with a kernel $K(x,y)$ specifying the interrelationship of the field at y to the field at x. However, no satisfactory solution for $K(x,y)$ other than one proportional to $\delta(x,y)$ will lead to an expression for $d\Sigma^2$ that is *invariant* under all diffeomorphisms. In point of fact, the possible choices for L and M are rather limited, especially when one requires that the (formal) integration measure at each point is canonical and thus has the form $\Pi_{a\leqslant b}\, d\pi^{ab}\, dg_{ab}$. For example, for $\lambda>0$, let us consider the proposal that

$$L_{abcd}(\lambda)\equiv\tfrac{1}{2}[g_{ab}g_{cd}+g_{ac}g_{bd}+(\lambda-1)g_{bc}g_{da}]. \tag{59}$$

Then in order to lead to a canonical integration measure, it would be necessary that

$$M^{abcd}(\lambda)\equiv\tfrac{1}{2}[g^{ab}g^{cd}+g^{ac}g^{bd}+(\lambda^{-1}-1)g^{bc}g^{da}]. \tag{60}$$

Only for $\lambda=1$ is $M=L^{-1}$, which is just the choice we have made. (The form for the DeWitt metric,[29] where $\lambda=-1$, is excluded because we require that L and M be positive definite.)

The preceeding discussion has rather convincingly suggested the specifically chosen functional form for $d\Sigma^2$—apart from one issue. It may seem even more natural to choose[30]

$$d\Sigma^2/dt^2=\int [g^{-1/2}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}+g^{1/2}g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]d^3x, \tag{61}$$

rather than the choice we have made. This is a natural choice from a classical point of view, but it is less satisfactory from a quantum point of view. In either case, observe that a path integral such as (52) involves fields with $3+1$ independent variables; however, there are no *space derivatives* involved, only *time derivatives*. Such a model is known as an *ultralocal quantum field theory*, and by now there is much that is known about the rigorous construction and evaluation of such nontrivial (i.e., non-Gaussian) functional integrals through the study, for example, of ultralocal scalar quantum fields.[31] It is through the analysis of the gravitational models as ultralocal quantum field theories that the metric (61) is ruled out; for a simple reason, see Sec. V.

E. Operator realization

In order to realize the metric and scale fields as quantum operators in a Hilbert space, $\mathfrak{H}$, it is expedient to introduce a set of conventional local *annihilation and creation operators*, $A(x,k)$ and $A(x,k)^\dagger$, respectively, with the only nonvanishing commutator given by

$$[A(x,k),A(x',k')^\dagger]=\delta(x,x')\,\delta(k,k')\mathbf{1}, \tag{62}$$

where $\mathbf{1}$ denotes the unit operator. Here, $x\in\mathbb{R}^3$, while $k\equiv\{k_{rs}\}$ denotes a positive-definite, 3×3 matrix degree of freedom confined to the domain where $\{k_{rs}\}>0$. We introduce a ''no-particle'' state $|0\rangle$ such that $A(x,k)|0\rangle=0$ for all arguments. Additional states are determined by suitably smeared linear combinations of

$$A(x_1,k_1)^\dagger A(x_2,k_2)^\dagger\cdots A(x_p,k_p)^\dagger|0\rangle, \tag{63}$$

for all $p \geqslant 1$, and the span of all such states is $\mathfrak{H}$ provided, apart from constant multiples, that $|0\rangle$ is the only state annihilated by all the A operators. Thus, we are led to a conventional Fock representation for the A and $A^\dagger$ operators. Note that the Fock operators are irreducible, and thus all operators acting in $\mathfrak{H}$ are given as suitable functions of them.

Next, let $c(x,k)$ be a possibly complex, c-number function and introduce the translated Fock operators,

$$B(x,k) \equiv A(x,k) + c(x,k)\mathbf{1}, \tag{64}$$

$$B(x,k)^\dagger \equiv A(x.k)^\dagger + c(x,k)^* \mathbf{1}. \tag{65}$$

Evidently, the only nonvanishing commutator of the B and $B^\dagger$ operators is

$$[B(x,k), B(x',k')^\dagger] = \delta(x,x')\,\delta(k,k')\mathbf{1}, \tag{66}$$

the same as the A and $A^\dagger$ operators. With regard to transformations of the coordinate x, it is clear that $c(x,k)$ (just like the local operators A and B) should transform as a scalar density of weight one-half. Thus, we set

$$c(x,k) \equiv b(x)^{1/2} d(x,k), \tag{67}$$

where $d(x,k)$ transforms as a scalar. The criteria for acceptable $d(x,k)$ are, for each x, that

$$\int_+ |\, d(x,k)|^2\, dk = \infty, \tag{68}$$

$$\int_+ k_{rs} |d(x,k)|^2 dk = 2\,\delta_{rs}, \tag{69}$$

the latter assuming [cf. the discussion following (39)] that $\tilde{g}_{kl}(x) = \delta_{kl}$. In (68) and (69) we have introduced $dk \equiv \Pi_{a \leqslant b}\, dk_{ab}$, and the symbol ''+'' signifies an integration over only those k values for which $\{k_{ab}\} > 0$.

We shall focus on only one particular choice for d, specifically,

$$d(x,k) \equiv \frac{K e^{-\operatorname{tr}(k)}}{\det(k)}, \tag{70}$$

which is everywhere independent of x; K denotes a positive constant to be fixed later. The given choice for d corresponds to the case where the asymptotic fields $\tilde{\pi}^{kl}(x) \equiv 0$ and $\tilde{g}_{kl}(x) \equiv \delta_{kl}$. [*Remark:* For different choices of asymptotic fields it suffices to choose

$$d(x,k) \rightarrow \tilde{d}(x,k) \equiv \frac{K\, e^{-ib(x)^{-1}\tilde{\pi}^{ab}(x)k_{ab}}\, e^{-\tilde{g}^{ab}(x)k_{ab}}}{\det(k)}. \tag{71}$$

We shall not explicitly discuss this case further.]

In terms of these quantities, the local metric operator is defined by

$$\sigma_{ab}(x) \equiv b(x)^{-1} \int_+ B(x,k)^\dagger k_{ab} B(x,k)\, dk, \tag{72}$$

and the local scale operator is defined by

$$\kappa_s^r(x) \equiv -i\,\frac{1}{2}\int_+ B(x,k)^\dagger (k_{st}\vec{\partial}^{tr} - \overleftarrow{\partial}^{rt} k_{ts}) B(x,k)\, dk. \tag{73}$$

Here $\vec{\partial}^{st} \equiv \partial/\partial k_{st}$, $\overleftarrow{\partial}^{rt} \equiv \partial/\partial k_{rt}$ *acting to the left*, and $\sigma_{ab}(x)$ transforms as a tensor while $\kappa_s^r(x)$ transforms as a tensor density of weight one. It is straightforward to show that these operators satisfy the required affine commutation relations, and, moreover, that[31,32]

$$\langle 0| e^{i\int \pi^{ab}(x)\sigma_{ab}(x)d^3x} e^{-i\int \gamma_r^s(x)\kappa_s^r(x)d^3x}|0\rangle$$
$$= \exp\left\{ -K^2 \int b(x)d^3x \int [e^{-2\delta^{ab}k_{ab}} - e^{-i\pi^{ab}(x)k_{ab}/b(x)} e^{-[(\delta^{ab}+g^{ab}(x))k_{ab}]}]dk/(\det k)^2 \right\}$$
$$= \exp\left[-2\int b(x)d^3x \ln\left([\det(g_{ab}(x))]^{1/2} \det\left\{ \frac{1}{2}[\delta^{ab}+g^{ab}(x)] - i\frac{1}{2} b(x)^{-1}\pi^{ab}(x) \right\} \right) \right], \tag{74}$$

where K has been chosen so that

$$K^2 \int_+ k_{rs} e^{-2\,\mathrm{tr}(k)}\, dk/(\det k)^2 = 2\,\delta_{rs}\,. \tag{75}$$

An obvious extension of this calculation leads to (39).

F. Local operator products

Basically, local products for the gravitational field operators follow the pattern for other ultralocal quantum field theories.[31,32] As motivation, consider the product

$$\sigma_{ab}(x)\sigma_{cd}(y) = b(x)^{-2} \int_+ \int_+ B(x,k)^\dagger k_{ab}[B(x,k),B(y,k')^\dagger]k'_{cd}B(y,k')\,dk\,dk' + :\sigma_{ab}(x)\sigma_{cd}(y):$$
$$= b(x)^{-2}\delta(x,y)\int_+ B(x,k)^\dagger k_{ab}k_{cd}B(x,k)\,dk + :\sigma_{ab}(x)\sigma_{cd}(y):, \tag{76}$$

where : : denotes normal ordering with respect to A and $A^\dagger$. When $y=x$, this relation formally becomes

$$\sigma_{ab}(x)\sigma_{cd}(x) = b(x)^{-2}\delta(x,x)\int_+ B(x,k)^\dagger k_{ab}k_{cd}B(x,k)\,dk + :\sigma_{ab}(x)\sigma_{cd}(x):. \tag{77}$$

We define the renormalized (subscript ''R'') local product,

$$[\sigma_{ab}(x)\sigma_{cd}(x)]_R \equiv b(x)^{-1}\int_+ B(x,k)^\dagger\, k_{ab}\, k_{cd}\, B(x,k)\, dk, \tag{78}$$

after formally dividing both sides by the divergent dimensionless ''scalar'' $b(x)^{-1}\delta(x,x)$. [*Remark*: For scalar ultralocal theories, the formal dividing factor is the divergent dimensionless ''number'' $b^{-1}\delta(0)$, where $b>0$ is an arbitrary factor with suitable dimensions. For gravity, $b \to b(x)$, our scalar density of weight one. Note that limits involving test functions offer a rigorous definition of the renormalized product.[31,32]] Higher-order local products exist as well, for example,

$$[\sigma_{a_1b_1}(x)\sigma^{a_2b_2}(x)\sigma_{a_3b_3}(x)\cdots\sigma_{a_pb_p}(x)]_R$$
$$\equiv b(x)^{-1}\int_+ B(x,k)^\dagger\,(k_{a_1b_1}k^{a_2b_2}k_{a_3b_3}\cdots k_{a_pb_p})\,B(x,k)\,dk\,, \tag{79}$$

which, after contracting on b_1 and b_2, implies that

$$[\sigma_{a_1b}(x)\sigma^{a_2b}(x)\sigma_{a_3b_3}(x)\cdots\sigma_{a_pb_p}(x)]_R=\delta^{a_2}_{a_1}[\sigma_{a_3b_3}(x)\cdots\sigma_{a_pb_p}(x)]_R\,. \tag{80}$$

It is in this sense that $[\sigma_{ab}(x)\sigma^{bc}(x)]_R=\delta^c_a$.

We take up only one further point regarding local products. It is rather natural[31,32] to try to define the local momentum ''operator'' by

$$\mu^{rs}(y)=-i\frac{1}{2}\int_+ B(y,k)^\dagger\,(\vec{\partial}^{rs}-\overleftarrow{\partial}^{rs})\,B(y,k)\,dk, \tag{81}$$

but this expression only leads to a form and not a local operator. Furthermore, the putative canonical commutation relation becomes

$$\begin{aligned}[\sigma_{ab}(x),\,\mu^{rs}(y)]&=i\,\delta^{rs}_{ab}\,\delta(x,y)\,b(x)^{-1}\int_+ B(x,k)\,B(x,k)\,dk\\ &=i\,\delta^{rs}_{ab}\,\delta(x,y)\,[\textstyle\int_+|d(x,k)|^2\,dk+\cdots],\end{aligned} \tag{82}$$

which has a divergent multiplier and is, therefore, not even a form. On the other hand, it is true that

$$\begin{aligned}\tfrac{1}{2}[\sigma_{rl}(x)\mu^{ls}(x)+\mu^{sl}(x)\sigma_{lr}(x)]_R&=-i\tfrac{1}{2}\int_+ B(x,k)\,(k_{rl}\vec{\partial}^{ls}-\overleftarrow{\partial}^{sl}k_{lr})\,B(x,k)\,dk\\ &=\kappa^s_r(x),\end{aligned} \tag{83}$$

as claimed.

IV. IMPOSITION OF CONSTRAINTS

Gravity has four constraints at every point $x\in\mathcal{S}$, and, when expressed in suitable units, they are the familiar spatial and temporal constraints, all densities of weight one, given by[26]

$$H_a(x)=-2g_{ab}(x)\pi^{bc}{}_{|c}(x), \tag{84}$$

$$\begin{aligned}H(x)=\tfrac{1}{2}g(x)^{-1/2}&[g_{ab}(x)g_{cd}(x)+g_{ad}(x)g_{cb}(x)-2g_{ac}(x)g_{bd}(x)]\\ &\times\pi^{ac}(x)\pi^{bd}(x)+g(x)^{1/2}\;\;{}^{(3)}R(x).\end{aligned} \tag{85}$$

The spatial constraints are comparatively easy to incorporate since their generators serve as generators of the diffeomorphism group acting on functions of the canonical variables. Stated otherwise, finite spatial diffeomorphism transformations map any coherent state onto another coherent state as in (41) and (42). However, this is decidely not the case for the temporal constraint. What follows is an account of what to do about these constraints *in principle*; in Part II on this subject, we will discuss how to accomplish these goals.

One satisfactory procedure to incorporate all the necessary constraints is as follows. Let $\{h_p(x)\}_{p=1}^\infty$ denote a complete, orthonormal set of real functions on $\mathcal{S}$ relative to the weight $b(x)$. In particular, we suppose that

$$\int\;h_p(x)\,h_n(x)\,b(x)\,d^3x=\delta_{pn}\,, \tag{86}$$

$$b(x)\,\Sigma_{p=1}^\infty\,h_p(x)\,h_p(y)=\delta(x,y). \tag{87}$$

Based on this orthonormal set of functions, we next introduce four infinite sequences of constraints,

$$H_{(p)\,a} \equiv \int h_p(x)\, H_a(x)\, d^3x, \tag{88}$$

$$H_{(p)} \equiv \int h_p(x)\, H(x)\, d^3x, \tag{89}$$

$1 \leq p < \infty$, all of which vanish in the classical theory.

For the quantum theory let us assume, for each p, that $\mathcal{H}_{(p)\,a}$ and $\mathcal{H}_{(p)}$ are selfadjoint, and even stronger that

$$X_P^2 \equiv \Sigma_{p=1}^{P}\, 2^{-p}\, [\Sigma_{a=1}^{3} (\mathcal{H}_{(p)\,a})^2 + (\mathcal{H}_{(p)})^2], \tag{90}$$

is selfadjoint for all $P < \infty$. Note well, as one potential example, the factor 2^{-p} introduced as part of a regulator as $P \rightarrow \infty$; we comment on this regulator in the next section. For each $\delta \equiv \delta(\hbar) > 0$, let

$$\mathbb{E}_P \equiv \mathbb{E}(X_P^2 \leq \delta^2) \tag{91}$$

denote a projection operator depending on X_P and δ, as indicated. How such projection operators may be constructed is discussed in Ref. 7 and will be dealt with in Part II. Let

$$S_P \equiv \limsup_{\pi,\, g}\, \langle \pi, g | \mathbb{E}_P | \pi, g \rangle, \tag{92}$$

which satisfies $S_P > 0$ since $\mathbb{E}_P \not\equiv 0$ when restricted to sufficiently large δ. Finally, we define

$$\langle\langle \pi'', g'' | \pi', g' \rangle\rangle \equiv \limsup_{P \rightarrow \infty} S_P^{-1}\, \langle \pi'', g'' | \mathbb{E}_P | \pi', g' \rangle, \tag{93}$$

as a reduction of the original reproducing kernel. The result is either trivial, say if δ is too small, or it leads to a continuous, positive-definite functional on the original phase space variables. We focus on the latter case.

To obtain the final physical Hilbert space, one must study $\langle\langle \pi'', g'' | \pi', g' \rangle\rangle$ as a function of the regularization parameter δ. Since gravity has an anomaly,[33] there should be a minimum value of δ, which is still positive, that defines the proper theory, rather like the example in (30). Assuming we can find and then use that value, $\langle\langle \pi'', g'' | \pi', g' \rangle\rangle$ becomes the reproducing kernel for the physical Hilbert space $\mathfrak{H}_{\rm phys}$. Attaining this goal would then permit the real work of extracting the physics to begin.

Our discussion regarding constraints in this paper has indeed been brief. Although the program we have in mind is not simple, it has the virtue of being realizable, at least in principle. After all, before any calculational scheme is developed it is always wise to ensure that the object under study has a good chance of existing!

V. DISCUSSION

In the preceding sections we have outlined an approach to quantum gravity that it is somewhat different than currently considered. As a background to our philosophy, let us briefly review some of the common weak points in the standard ways of quantizing gravity, and use these comments as motivation for our approach.

A. Traditional viewpoints and commentary

(i) Viewed by way of conventional perturbation theory, quantum gravity has two main difficulties of principle. On the one hand, the perturbative split of the metric in the form $g_{\mu\nu}(x) = \eta_{\mu\nu} + h_{\mu\nu}(x)$ (or any other background metric), with canonical quantization of the ''small'' deviation $h_{\mu\nu}(x)$ violates signature properties, since in that case the spectrum of $h_{\mu\nu}(x)$ is unbounded above and below. On the other hand, as an asymptotically nonfree theory, gravity is nonrenormalizable and poorly described by a perturbation theory that needs an unending addition of distinct counterterms with divergent coefficients.

To address these obstacles, we first note that the affine approach guarantees a proper metric signature from the very beginning, and, second, we remind the reader that certain asymptotically nonfree, nonrenormalizable models have indeed been solved,[31] and their solution procedures form the core of the present approach to quantize gravity.

(ii) While the constraints of classical gravity are first class, there is an anomaly in the quantum constraints and thus they are effectively second class. Usual views toward second-class constraints involve solving and eliminating them, introducing and then quantizing Dirac brackets, or the conversion of second-class constraints into first-class constraints. Each of these methods is often complicated and not all are guaranteed to be valid beyond a semiclassical treatment if the classical constraint hypersurface has a non-Euclidean geometry.[34] These difficulties have stimulated searches to get around the second-class character altogether, either by introducing non-Hermitian constraint operators that may close algebraically,[35] or by introducing additional fields and space–time dimensions until the anomaly cancels.

Regarding these comments, we accept the anomaly and the second-class constraints that it implies. Giving up a classical symmetry is not so heretical as it may seem. For example, Hamiltonian classical mechanics enjoys a full covariance under general canonical coordinate transformations, but that invariance is *not* preserved *in its classical form* when we go to the quantum theory. For example, consider the classical Poisson brackets for a set of generator elements,

$$\{e^{ap+bq}, e^{cp+dq}\} = (bc-ad)\, e^{(a+c)p+(b+d)q}, \tag{94}$$

where a,b,c, and d are parameters, while in canonical quantum mechanics we have the corresponding commutator algebra,

$$[e^{aP+bQ}, e^{cP+dQ}] = (2i)\sin[(bc-ad)/2]\, e^{(a+c)P+(b+d)Q}. \tag{95}$$

These expressions agree in their algebraic structure for selected elements, but not for the whole algebra. Equivalence begins to break down at the quadratic level, which is exactly the case for the temporal constraint in gravity. In particle mechanics there are sound physical reasons[36] for this ‘‘breakdown’’ of symmetry, and attempts to restore the symmetry—as in geometric quantization[37]—go counter to such sound physical principles. There is no reason that a similar scenario does not hold for gravity. The breakdown of the classical symmetry and the appearance of a quantum ‘‘anomaly’’ (better called a ‘‘quantum mechanical symmetry breaking’’[38]) could, just as in the quantum mechanics case, carry real physics.

Accepting the second-class nature of (part of) the constraints of quantum gravity means a different approach must be taken. As already noted, earlier approaches required solving for and eliminating the unphysical variables, the introduction of Dirac brackets, etc., all of which are rather technical and may be extremely complicated. In the present view, afforded by the projection operator approach to constraints—*second-class constraints included*—none of these particular complications arise. Instead, one projects onto the state (or, with degeneracy, states) for which the sum of the square of the constraints is bounded. Why the square and not the fourth power? Using the fourth power would not be wrong; the only change would involve a unitary transformation of the original result, which maps one set of ‘‘ground’’ states onto another set of ‘‘ground’’ states. The square is chosen for simplicity, not for any reasons of exclusivity.

B. Relation to earlier work

Pilati, in a series of papers[3] (see also Ref. 2), analyzed a strong coupling model of quantum gravity in which the temporal constraint given in (85) was modified to read as

$$H'(x) = \tfrac{1}{2} g(x)^{-1/2} [g_{ab}(x) g_{cd}(x) + g_{ad}(x) g_{cb}(x) - 2 g_{ac}(x) g_{bd}(x)]\, \pi^{ac}(x) \pi^{bd}(x), \tag{96}$$

namely, the second term involving the scalar curvature ${}^{(3)}R(x)$ based on the metric $g_{ab}(x)$ was dropped. The reason for doing so was to achieve a theory in which the temporal constraint $H'(x)$ itself was patterned after the Hamiltonian density of an ultralocal theory. This modification was thought to be advantageous because then all the machinery developed for ultralocal quantum field theory could be used for the strong coupling gravitational model. Once that model was under control, it was the hope to reintroduce the dropped term by a perturbation theory analysis. Unfortunately, the reintroduction of dropped terms involving spatial gradients has never been successfully accomplished by a perturbation analysis about a non-Gaussian ultralocal model. This failure is most likely because such ''interaction terms'' generally amount to nonrenormalizable perturbations of the unperturbed (ultralocal) models.

The program advanced in the present paper takes a different view toward these issues.

First, we focus on kinematics with the knowledge that for pure gravity the Hamiltonian operator vanishes, as it does in any situation that is reparametrization invariant. In its place we find constraints, and the real physical content of the theory lies in the particular constraints. However, before the constraints can be introduced, there must be a ''primary container'' to receive them. In our case, this primary container is the Hilbert space and set of relevant operators prior to the introduction of *any* form of the constraints, and which is based on the fundamental physical nature of the variables, i.e., positive-definite, 3×3 matrix-valued, local field operators, etc. This is the preferred procedure: *Quantization before the introduction of any constraints*. At this primary level, there is no coupling of one degree of freedom with another—any coupling comes through the enforcement of specific constraints. Hence, in the primary container the degrees of freedom are mutually independent of each other. For finitely many kinematical degrees of freedom this means that the Hilbert space is a product over spaces for each of the separate degrees of freedom; in a field theory, this independence means that the kinematical operators enter as ultralocal field operators. Consequently, even though the several constraint operators waiting to be introduced may themselves *not* be ultralocal in nature, the primary container itself, which has been prepared to receive them, is ultralocal.

At this point the reader may wish to reexamine (39)—in essence our ''primary container''—to recall the appearance of an ultralocal state on a set of field operators. Apart from the 3×3 matrix character, the functional form of (39) emerges from (i) the product of N expressions of the form (16) for independent arguments p_n, q_n, r_n, s_n, $1\leq n\leq N$; (ii) the replacement of β by $b_n\Delta$ and (p_n-r_n) by $(p_n-r_n)\Delta$; and (iii) the limit as $N\rightarrow\infty$, $\Delta\rightarrow0$ such that $\Sigma(\cdot)\, b_n\,\Delta\rightarrow\int(\cdot)\, b(x)\, dx$. In this way we have created, from a collection of independent single affine degrees of freedom, the reproducing kernel for affine gravity in $1+1$-dimensional space. In a similar manner, a set of independent 3×3 affine degrees of freedom can be (and were) used to build an ultralocal representation for 3×3 metric and momentum fields in (39); moreover, this type of construction does not favor the ''natural'' phase-space metric (61). In summary, we emphasize that whenever the ''dynamics'' appears through constraints, the primary container should be ultralocal in character. We next turn our attention to the introduction of the constraints.

In the projection operator approach it is recognized from the outset that the physical Hilbert space—or better the *regularized* physical Hilbert space—is a *subspace* of the original Hilbert space that is uniquely determined by an associated projection operator $\mathbb{E}$. Whatever form the constraints may take, they are ''encoded'' into the projection operator $\mathbb{E}$, and a regularization means that the constraints are satisfied to a certain level of precision determined by a regularization parameter δ. How to turn constraint operators into projection operators in general has been discussed in Ref. 7; as regards the gravitational case, that project will be discussed in Part II .

Continuing still in a general framework, let us consider an expression that may be used either to generate dynamics or to enforce constraints. From a classical point of view, and especially from a path integral point of view, it may seem that quantities used in either of these ways may be rather similar. However, it is important to already understand that there is a fundamental distinction between the use of a quantum operator either (i) to generate unitary transformations or (ii) to serve as a constraint operator in a given system. In the first case, the operator must be self-adjoint and thus densely defined, while in the second case the operator may be defined on only the zero vector!

This fact has profound consequences. In particular, to have a self-adjoint generator requires that the operator representation in the primary container must already be finely ''tuned'' to ensure that the generator that will be introduced is self-adjoint (as in Haag's Theorem[39]). For constraint operator imposition this need not be the case, and the reason this is so is because we allow for changes, i.e., adaptions, of the primary container representations through the process of reduction of the reproducing kernel. As an example, let us consider only the local temporal operator $\mathcal{H}(x)$ for gravity. On the one hand, to generate unitary time evolutions it may be necessary that $\int\mathcal{H}(x)\,d^3x$ be self-adjoint. On the other hand, to enforce constraints, it is only necessary that $\mathcal{H}_{(p)}$ [cf. (89)] be ''small,'' but there is no requirement that these operators must be *uniformly* ''small.'' Instead they can be ''small'' in the sense that $X^2 \equiv \Sigma_{p=1}^{\infty} s_p(\mathcal{H}_{(p)})^2$ is ''small,'' where the set of positive constants $\{s_p\}$ serve as regulators to control convergence of the series. The example chosen was that $s_p = 2^{-p}$, but there is nothing special about that choice. Any reasonable choice that leads to a self-adjoint operator X should lead to the same reproducing kernel in the final analysis when the regularization parameter δ attains its final value for the problem at hand.

A rather simple example of the general procedure discussed above can be seen in studies involving product representations.[40] Additionally, it is instructive to reanalyze the relativistic free field by this procedure to see how ultralocal representations turn into nonultralocal representations.

Suffice it to say, it is this vast difference between the required nature of constraint operators and unitary generators that permits us to start with ultralocal field operator representations and emerge with *non*ultralocal operators in the physical Hilbert space.

K slicing the Schwarzschild and the Reissner–Nordstrom spacetimes

Asghar Qadir[a)] and Azad A. Siddiqui[b)]
Department of Mathematics, Quaid-i-Azam University, Islamabad, Pakistan

(Received 17 August 1998; accepted for publication 20 May 1999)

A K slicing of the Reissner–Nordstrom (RN) spacetime is shown to provide a complete foliation of the region up to the inner horizon, and the horizon to correspond to the limit as $K\rightarrow\pm\infty$. The implications of this foliation in the context of York time are discussed.
[S0022-2488(99)00909-3]

I. INTRODUCTION

In an earlier paper[1] we had followed up the proposal of Brill *et al.*[2] (hereafter referred to as BCI) for foliating the Schwarzschild spacetime by a sequence of spacelike hypersurfaces of constant mean extrinsic curvature, K. They used a variational principle for minimizing the (3−) area of the hypersurface for a given (4−) volume of the world tube traced out by it. The corresponding Lagrange multiplier turns out to be K. Using Kruskal–Szekres (KS) coordinates (v,u),[3] BCI obtained the K-slicing equation,

$$\frac{dv}{du}=\frac{Av+Eu}{Au+Ev}, \tag{1}$$

$$E=H-Kr^3/3, \quad A=[E^2+r^3(r-r_s)]^{1/2}, \tag{2}$$

where r_s is the Schwarzschild radius ($2m$ in gravitational units) and H is an arbitrary parameter that measures how much the intrinsic and extrinsic curvatures vary on the K surface. We converted to the compactified KS coordinates (ψ,ξ), given by[4]

$$\begin{aligned}\psi&=\tan^{-1}(v+u)+\tan^{-1}(v-u),\\ \xi&=\tan^{-1}(v+u)-\tan^{-1}(v-u),\end{aligned} \tag{3}$$

so as to be able to see the foliation in a Penrose diagram. In these coordinates, Eq. (1) becomes

$$\frac{d\psi}{d\xi}=\frac{A\sin\psi\cos\xi+E\sin\xi\cos\psi}{A\sin\xi\cos\psi+E\sin\psi\cos\xi}. \tag{4}$$

Our procedure was to take a trial value of the initial r for a given K, r_i, and put

$$H=Kr_i^3/3\pm\sqrt{r_i^3(r_s-r_i)}. \tag{5}$$

We found that the hypersurfaces would rise, very slowly at first. Taking r_i such that it rose least allowed r_f (the final value of r) to come at $I°$ ($\psi=0$, $\xi=\pi$). Thus, our ansatz required that the hypersurfaces have $d\psi/d\xi|_{\xi=0}=0$ and that they end at $I°$. The procedure worked but we had

[a)]Senior Associate Member of the International Center for Theoretical Physics, Trieste, Italy. Electronic mail: qadirs@isb.pol.com.pk
[b)]Present address: College of Electrical and Mechanical Engineering, National University of Sciences and Technology, Rawalpindi, Pakistan.

provided no proof that we had a complete foliation. In this paper we provide a proof that a complete foliation was achieved by the ansatz for the Schwarzschild spacetime and extend it to the Reissner–Nördstrom geometry. It is shown that a complete K foliation of the spacetime up to the inner horizon is achieved, but it does not proceed beyond it.

II. PROOF OF COMPLETENESS OF THE SCHWARZSCHILD FOLIATION

To prove completeness we need to verify that no region of the spacetime is left out from the foliation and that the foliating hypersurfaces do not intersect anywhere. We first discuss the hypersurfaces for limiting values of K. $K=0$ corresponds to the hypersurface, $\psi=0$. For this hypersurface the value of r at $\xi=0$, r_i, is r_s. We now consider the limit as $|K|\to\infty$. It had been seen that as we increased $|K|$ we had to choose smaller values for r_i. Let us suppose that for some very large $|K|$, $r_i=\epsilon r_s>0$ is such that $\epsilon\ll 1$. Then, from Eq. (5),

$$H=Kr_s^3\epsilon^3/3\pm r_s^2\epsilon^{3/2}(1-\epsilon)^{1/2}. \tag{6}$$

Now E and A cannot remain small for sufficiently large $|K|$ unless $r=r_i$ throughout. Thus, considering Eqs. (6) and (4), we require that as $|K|\to\infty$, either: (i) $\epsilon\to 0$ and hence $r-\epsilon r_s\to 0$; or (ii) $\epsilon\nrightarrow 0$ and hence r, A, $|E|\to\infty$. In fact, for case (i) $\epsilon\sim|K|^{-1/3}$ so that H, E, and A remain constant. Hence, the limit $|K|\to\infty$ corresponds to the limiting hypersurface $r=0$, which is $v=\infty (u\neq\infty)$ or $\psi=\pi/2$, $|\xi|<\pi/2$. In case (ii) $A\sim\pm E$. In that case Eq. (4) gives $d\psi/d\xi=\pm 1$. Thus, the rest of the hypersurface is at $\psi=\pm\xi+\pi$ and $\psi=\pm\xi-\pi$ with r at infinity. Hence the complete hypersurfaces are $\mathscr{I}_L^-\cup\{r=0\}\cup\mathscr{I}_R^-$ for $K=-\infty$ and $\mathscr{I}_L^+\cup\{r=0\}\cup\mathscr{I}_R^+$ for $K=+\infty$, where the subscript L refers to the left and R to the right side of the Penrose diagram. Notice that these hypersurfaces are not spacelike in themselves ($\mathscr{I}^\pm$ being null). This does not reflect a problem with the foliation as that consists of spacelike hypersurfaces that tend to these null hypersurfaces as $|K|\to\infty$. Also notice that the family of hypersurfaces is symmetric under ψ reflection, with $K\leftrightarrow -K$.

It remains to verify that the hypersurfaces before the limit do cover the whole space and do not intersect. The key point is the existence and uniqueness of the solution of differential equation (4). It can be written in (t,r) coordinates as

$$\frac{dt}{dr}=f(r)=\frac{rE}{(r-r_s)A}, \tag{7}$$

which is a function of r only. It is continuous and $\lim_{r\to\infty}f(r)=1$ while $\lim_{r\to 0}f(r)=0$. The boundedness of the function at $r=r_s$, which is the Schwarzschild coordinate singularity, can be seen in (ψ,ξ) coordinates from Eq. (4), $\lim_{r\to r_s}f(r)=\lim_{\psi\to\pm\xi}f(\psi,\xi)=\pm 1$. Further, writing $f(r)$ as $f(t,r)$, it clearly satisfies the Lipshitz condition:

$$|f(t_1,r)-f(t_2,r)|=|f(r)-f(r)|=0\leqslant N|t_1-t_2|, \tag{8}$$

where N is a $+ve$ constant. Therefore $\exists!$ solution of Eq. (4) for the given conditions. There are two free parameters H and K in Eq. (4). These two parameters are fixed by our requirements $d\psi/d\xi|_{\xi=0}=0$ and $\psi(\pi)=0$. Let us consider two different hypersurfaces: $\psi_1(\xi)$ and $\psi_2(\xi)$, for two different values of the curvature $K_1\neq K_2$ satisfying the requirements. Suppose that these hypersurfaces intersect at some point $\xi=\xi_0$. Considering $\xi=\xi_0$ as our starting point, $\psi_1(\xi_0)=\psi_2(\xi_0)$ fixes one of the parameters, say H. Now, by the uniqueness of the solution of Eq. (4) two different values of K, K_1 and K_2, cannot give the same end point $\psi_1(\pi)=0=\psi_2(\pi)$. Hence, our assumption that the two hypersurfaces intersect must be wrong. This proves that the hypersurfaces do not intersect.

To show that the hypersurfaces cover the whole space, we write Eq. (4) as the integral equation,

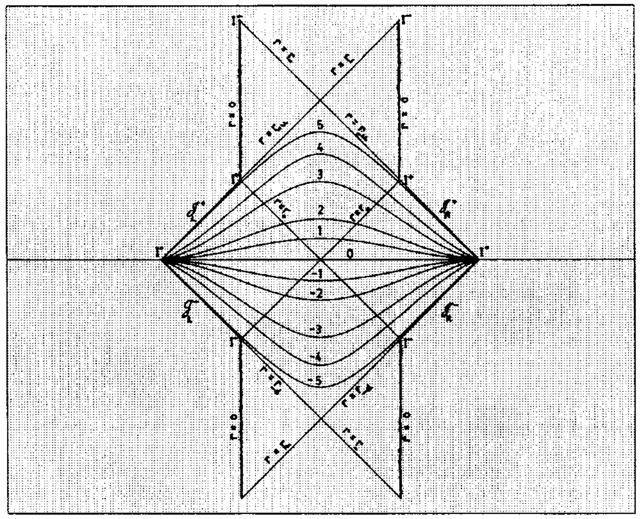

FIG. 1. Foliation of the compactified RN spacetime, with $Q/m=0.8$, by spacelike K slices. The hypersurfaces are labeled according to their serial numbers in Table I. Notice that only the region $r_-<r<\infty$ is covered by them. In the limit of $K\rightarrow+\infty$ we get the upper boundary of the central block, $\mathscr{T}_L^+\cup\{r=r_{-u}\}\cup\mathscr{T}_R^+$ and in the limit of $K\rightarrow-\infty$ we get the lower boundary, $\mathscr{T}_L^-\cup\{r=r_{-d}\}\cup\mathscr{T}_R^-$.

$$\psi(\xi)=\int_{z=0}^{\xi} f(\psi(z),z,K,H)dz+C. \tag{9}$$

Using the requirement $d\psi/d\xi|_{\xi=0}=0$, in principle, we can eliminate H from Eq. (9).

Now, requiring that (ψ_0,ξ_0) lies on the hypersurface, and that $\psi(\pi)=0$, gives

$$\psi(\xi)=-\int_{\xi}^{\pi} f(\psi(z),z,K)dz. \tag{10}$$

This proves the existence of hypersurfaces passing through every pair (ψ_0,ξ_0). Hence, the hypersurfaces cover the whole space. Note that for a given (ψ_0,ξ_0) there will be a specific K that satisfies Eq. (10).

III. FOLIATION OF THE REISSNER–NÖRDSTROM SPACETIME

We now turn our attention to the RN geometry. Following the BCI procedure again leads to Eq. (4) with v and u in Eq. (3) being the generalized KS (GKS) coordinates,[5]

TABLE I. Eleven K slices for different values of the mean extrinsic curvature, K, for an RN black hole with $Q/m=0.8$, are described by the corresponding values for the initial value of r, r_i, the constant H, and the initial value of ψ in the Penrose diagram, ψ_i. The maximum (minimum for $K<0$) value, ψ^*, in these cases is identical to ψ_i.

± 8	± 0.1	4/5	± 2.078
± 9		4.75/5	± 2.353

$$
\begin{aligned}
v &= \alpha \exp(r/\beta_+)\left|\frac{r}{r_+}-1\right|^{r_+^2/\beta_+(r_+-r_-)}\left|\frac{r}{r_-}-1\right|^{-r_-^2/\beta_+(r_+-r_-)}\cosh(t/\beta_+),\\
u &= \alpha \exp(r/\beta_+)\left|\frac{r}{r_+}-1\right|^{r_+^2/\beta_+(r_+-r_-)}\left|\frac{r}{r_-}-1\right|^{-r_-^2/\beta_+(r_+-r_-)}\sinh(t/\beta_+),
\end{aligned}
\tag{11}
$$

for $r_+<r<\infty$ and v, u interchanged for $r_-<r<r_+$, where

$$r_\pm = m \pm \sqrt{m^2-Q^2}, \tag{12}$$

are the outer and inner horizons (Q being the RN black hole charge) and α, β_+ are the constants

$$\alpha = \frac{16 r_+ r_-}{r_+ - r_-}, \quad \beta_+ = \frac{2r_+^2}{r_+ - r_i}. \tag{13}$$

The entire spacetime cannot be covered simply by these coordinates. For $0<r<r_-$ they are not applicable. There we must replace β_+ by β_- with the obvious change in Eq. (13). The two patches together are adequate for the entire spacetime, the latter being valid for $0<r<r_+$. In the region $r_-<r<r_+$ we can patch the coordinate systems together by providing a coordinate transformation.

We now follow the rest of the procedure as before. Now A of Eq. (2) is modified to

$$A = [E^2 + r^2(r-r_+)(r-r_-)]^{1/2}, \tag{14}$$

while E is unaltered. For the ansatz, Eq. (5) is altered to

$$H = K r_i^3/3 \pm r_i \sqrt{(r_+-r_i)(r_i-r_-)}, \tag{15}$$

in the region $r_-<r<r_+$. Note that $r_i \leqslant r_+$ always, as is obvious from the Penrose diagram (since we take $\xi_i=0$). We again require that the hypersurfaces have $d\psi/d\xi|_{\xi=0}=0$ and ask that the hypersurfaces extend to $I°$.

The foliation proceeds smoothly for medium values of $|K|$ (about 0.01–0.8) but runs into problems of numerical instability at very high or very low values of $|K|$. By using more computer time one can extend the range of stability. As such, there is no inherent problem with the numerics but merely a matter of economizing the use of the computer. Typical hypersurfaces are given for six values of $|K|$ for an RN black hole with $Q/m=0.8$, in the Penrose diagram given in Fig. 1.

Table I gives the values of K with r_i and the corresponding ψ_i. We note that it is only the region $r_-<r<\infty$ that is covered by this foliation. This is not surprising as the requirements, that the hypersurfaces be spacelike and reach $I°$, could not be met by hypersurfaces that enter the region $r<r_-$. We will consider the physical implications of this observation shortly. At present we need to verify that our ansatz provides a complete foliation of the central block of the Penrose diagram, shown in Fig. 1.

IV. PROOF OF COMPLETENESS OF THE REISSNER–NÖRDSTROM FOLIATION

To see this we note that Eqs. (2) and (5) as modified by Eqs. (14) and (15) allow two possible solutions as $|K|\rightarrow\infty$: (i) either $r\rightarrow r_i$ throughout, A, $E\rightarrow 0$ and $d\psi/d\xi\rightarrow\pm 1$ or $|\psi|=-\pi\pm\xi$; or (ii) r, A, $|E|\rightarrow\infty$ and again $d\psi/d\xi\rightarrow\pm 1$ or $|\psi|=\pi\pm\xi$. Thus, the hypersurfaces $K=\pm\infty$ correspond to $\mathscr{T}_L^+\cup\{r=r_{-u}\}\cup\mathscr{T}_R^+$ and $\mathscr{T}_L^-\cup\{r=r_{-d}\}\cup\mathscr{T}_R^-$ in Fig. 1. Thus, our ansatz works and gives the boundary of the central block as the limit as $K\rightarrow\pm\infty$. Again the differential equation (4) with E unaltered and A now given by Eq. (14), satisfies all the conditions for the existence of the unique solution. The same argument that is used for the Schwarzschild case can be applied here to prove that the hypersurfaces do not intersect and cover the whole space *up to the inner horizon*.

V. DISCUSSION OF THE RESULTS

We now turn to the discussion of the implications of our foliation. It had been argued[6] that there is a special significance of the York time in a cosmological context. Namely, in terms of such a time parameter the formation of a black hole singularity is simultaneous with the ‘‘big crunch’’ singularity of a closed universe containing the black hole. In the sense of a compactified (‘Schwarzschild universe’) the same point was noted in our foliation of the Schwarzschild spacetime by K surfaces.[1] Of course, our foliation procedure is not the only one for obtaining K slices. Since the singularity, $r=0$, is timelike, here it does not appear to be possible to obtain spacelike K slices in the region $0<r<r_-$. In this foliation it appears that we should regard the inner horizon as simultaneous with the end of the ‘‘compactified RN universe.’’ This is, of course, consistent with the fact that $r=r_-$ is a blue-shift horizon and the barrier that forms at this place due to backreaction that was noticed by Matzner *et al.*[7] and the infinitely blue-shifted radiation from the outside universe pointed out by Penrose and Simpson.[8] We conjecture that there may be a physical barrier at $r=r_-$. This would remove the enormous difference between the topology of the Schwarzschild and RN–Penrose diagrams. This argument would be stronger if the above foliation could be proved to be unique, but we have not been able to prove it so far.

It is now necessary to investigate how a variation of Q/m changes the behavior of the hypersurfaces. In the case $Q/m=0$ we have the Schwarzschild spacetime[1] and some hypersurfaces first rise then fall to I° (for $K>0$). For the RN spacetime with $Q/m=0.8$, we found that the hypersurfaces started flat (i.e., $d\psi/d\xi=0$) at the highest point and then dropped to I° (again for $K>0$). For comparison we considered hypersurfaces for $|K|=0.01$, 0.02 and 0.1 with $Q/m=0.6$, 0.8, and 0.95 in Fig. 2. It is seen that for a given K the ψ_i is raised or lowered by raising or lowering Q/m.

Finally, it is worthwhile to comment on wider applications of the BCI procedure to obtain K-slice foliations. It is natural to limit the attempt to static spacetimes, where there can be greater expectations of achieving the foliation. However, one could try to look for stationary but nonstatic solutions of the Einstein equations, such as the Kerr metric. We find that the procedure is implementable to the extent of providing the K-slicing equation. Work is in progress to check if our ansatz can be appropriately modified for the purpose. Other such investigations would be valuable in view of the importance of K slicing.[6]

Exact solutions in Einstein–Yang–Mills–Dirac systems

Gerd Rudolph and Torsten Tok
Institute of Theoretical Physics, University Leipzig, 04109 Leipzig, Augustusplatz 10, Germany

Igor Volobuev[a)]
Institute of Nuclear Physics, Moscow State University, 119899 Moscow, Russia

(Received 11 June 1998; accepted for publication 13 July 1999)

For the first time, exact solutions for the full self-consistent Einstein–Yang–Mills–Dirac systems with gauge groups $SU(2)$ and $SU(4)$ in Robertson–Walker space–time $R\times S^3$ are presented, which are symmetric under the action of the group $SO(4)$ of spatial rotations. The approach is based on the dimensional reduction method for gauge, spinor, and gravitational fields and relates symmetric solutions in EYMD theory to certain solutions of an effective dynamic system. The solutions are interpreted as solutions of the cosmological type with an oscillating Yang–Mills field, which exchanges energy with a spinor field. The explicit form of the solution for the spinor field shows that its energy changes the sign in the process of the evolution of the Yang–Mills field from one vacuum to another. © *1999 American Institute of Physics.* [S0022-2488(99)04710-6]

I. INTRODUCTION

Exact solutions in gravity coupled to fields of different types have always attracted much attention. In particular, the last few years witnessed a great interest in solutions to EYM systems. There were found both numerical[1] and exact solutions with $SO(3)$ and $SO(4)$ groups of spatial symmetry.[2,3] The exact $SO(3)$-symmetric solutions turn out to be static and singular and are, in fact, a generalization of Reissner–Nordström solutions to non-Abelian gauge theories. The $SO(4)$-symmetric solutions correspond to the Robertson–Walker ansatz for the metric and are interpreted either as wormhole solutions in the Euclidean domain[4] or as cosmological solutions for the radiation dominated universe.[5]

The study of exact solutions in Einstein–Dirac systems also attracted attention.[6,7] It was found that the Robertson-Walker ansatz in such a system leads to the so-called ''ghost solutions'' in ED systems, for which the Dirac field has a vanishing energy–momentum tensor.

In the present paper we consider a self-consistent EYMD system and find exact solutions for the case of the gauge groups $SU(2)$ and $SU(4)$. The group $SU(4)$ is the simplest gauge group, which gives qualitatively new results in comparison with the group $SU(2)$. We would like to note that the obtained solutions are interesting in their own right as the first example of exact self-consistent solutions in the Einstein–Yang–Mills–Dirac system. Our solutions are of the radiation-dominated type and describe an exchange of energy between the YM and Dirac fields. They can be considered as a first step toward finding cosmological solutions with the energy–momentum tensors derived from the fundamental Lagrangians of particle physics, rather than with phenomenological ones, which is important for treating the dynamics of the early Universe. We also show that our solutions explain the phenomenon of the ''ghost solutions'' in ED systems.

To find these solutions we employ the dimensional reduction method for gravitational, gauge, and spinor fields,[8,9] which enables us to relate symmetric solutions in EYMD system to certain solutions of an effective dynamic system and essentially simplifies the problem of finding symmetric solutions.

[a)]Electronic mail: volobuev@theory.npi.msu.su

II. THE EFFECTIVE ACTION

We consider an $SO(4)$-symmetric Einstein–Yang–Mills–Dirac system with the standard action in space–time $M=R\times S^3$:

$$S=S_{\rm E}+S_{\rm YM}+S_{\rm D}, \tag{1}$$

where

$$S_{\rm E}=\frac{1}{16\pi\kappa}\int_M (R-\Lambda)\mathrm{d}v, \tag{2}$$

$$S_{\rm YM}=\frac{1}{8g^2}\int_M \mathrm{tr}(F_{\alpha\beta}F^{\alpha\beta})\mathrm{d}v, \tag{3}$$

$$S_{\rm D}=\int_M \frac{i}{2}\bar{\psi}\gamma^\alpha E_\alpha{}^\mu\left(\frac{\partial}{\partial x^\mu}-\frac{1}{8}\,\omega_{\mu\alpha\beta}[\gamma^\alpha,\gamma^\beta]+\delta'(A_\mu)\right)\psi\,\mathrm{d}v+\mathrm{h.c.} \tag{4}$$

Here Λ denotes the cosmological constant (which is assumed to be positive and very small, in accordance with the existing experimental data), R is the scalar curvature, and $dv=\sqrt{|\det(\mathbf{g})|}\mathrm{d}^4x$ is the canonical volume form corresponding to a metric $\mathbf{g}$ on $M=R\times S^3$. F and A are the Yang–Mills field strength and potential, respectively, and the trace is taken in the adjoint representation of the Lie algebra of the gauge group. In the Dirac action, ψ denotes the spinor field, $\{E_\alpha=E_\alpha{}^\mu\partial_\mu\}$ is an orthonormal frame on $M=R\times S^3$, $\omega_{\mu\alpha\beta}=\omega_{\alpha\beta}(\partial_\mu)=\mathbf{g}(E_\alpha,\boldsymbol{\nabla}_\mu E_\beta)$ is the spin connection, $\{\gamma^\alpha\}$ are the gamma matrices, δ is the representation of the gauge group in the spinor space, and δ' denotes the induced representation of its Lie algebra. Finally, h.c. stands for Hermitian conjugate.

We identify S^3 with the group manifold of $SU(2)$. Then the action σ of the symmetry group, $K=SO(4)\equiv(SU(2)\times SU(2))/\{\mathbf{1},-\mathbf{1}\}$ on $SU(2)$, is given by

$$\sigma((k_1,k_2),x)=k_1xk_2{}^{-1},\quad (k_1,k_2)\in SU(2)\times SU(2),\quad x\in SU(2). \tag{5}$$

The isotropy subgroup H at $x=\mathbf{1}_{SU(2)}$ is isomorphic to $SU(2)$, and is given by

$$H=\{(k,k)\in K,\ \ k\in SU(2)\}. \tag{6}$$

Further, we have the reductive decomposition $\mathfrak{K}=\mathfrak{H}\oplus\mathfrak{M}$ of the Lie algebra $\mathfrak{K}$ of K, where

$$\mathfrak{H}=\{(X,X);\quad X\in su(2)\}, \tag{7}$$

$$\mathfrak{M}=\{(X,-X);\quad X\in su(2)\}. \tag{8}$$

Obviously $S^3=(SU(2)\times SU(2))/H$ is a symmetric space, and $SO(4)$ invariance is equivalent to invariance under $SU(2)\times SU(2)$. The isotropy representation of $H=SU(2)$ in $\mathfrak{M}$ is $\underset{\sim}{3}$, i.e., it is equivalent to the adjoint representation.

Now we have to reduce the action of the original theory due to the $SO(4)$ symmetry. We begin with the action of the gravitational field.

The most general form of an $SO(4)$-invariant metric $\mathbf{g}$ on M is

$$\mathbf{g}=-N^2(t)\mathrm{d}t^2+a^2(t)\mathrm{d}\Omega^2_{S^3}, \tag{9}$$

where $\mathrm{d}\Omega^2_{S^3}$ is the standard line element on a 3-sphere of radius 2 corresponding to the Killing metric on $SU(2)\equiv S^3$ multiplied by $-\frac{1}{2}$, and $N(t),a(t)$ are arbitrary functions of time. For the sake of the future convenience, we assume $N(t)$ and $a(t)$ to have the dimension of length and t and $\mathrm{d}\Omega^2_{S^3}$ to be dimensionless. Though the metric (9) can be brought to the conformal form with

$N(t)=a(t)$ by an appropriate reparametrization of time, in the Lagrangian formalism $N(t)$ must be kept arbitrary, until the equations of motion are obtained with the help of the variational principle, because it plays the role of a Lagrange multiplier in the gravitational action (2).

An orthonormal coframe $\{\theta^\mu\}$ on M is given by

$$\theta^0=N\,\mathrm{d}t, \quad \theta^i=a\,\vartheta^i, \quad i=1,2,3, \tag{10}$$

where $\vartheta^i\sigma_i/(2i)\equiv\vartheta$ is the canonical left-invariant 1-form on $SU(2)$, σ_i being the Pauli matrices. In what follows we put $\tau_k=\sigma_k/(2i)$ and denote by $\eta_{\alpha\beta}$ the Minkowski metric $\eta_{\alpha\beta}=\mathrm{diag}(-1,1,1,1)$. It is a matter of simple calculations to find the components of the spin connection on M:

$$\begin{aligned}\omega_{0i}&=-\omega_{i0}=-\dot{a}\frac{1}{aN}\,\delta_{il}\theta^l,\\ \omega_{ik}&=-\frac{1}{2a}\,\epsilon_{ikl}\theta^l, \quad i=1,2,3.\end{aligned} \tag{11}$$

Using the standard formulas for the curvature, substituting it into (2), and integrating over S^3, one easily finds the reduced gravitational action,

$$S_{\mathrm{E}}=\frac{16\pi^2}{16\pi\kappa}\int_R a^3N\left(\frac{3}{2a^2}+6\left(\dot{a}\frac{1}{aN}\right)^2-\dot{a}\dot{N}\frac{6}{aN^3}+\ddot{a}\frac{6}{aN^2}-\Lambda\right)\mathrm{d}t, \tag{12}$$

where $16\pi^2$ is the volume of $SU(2)=S^3$ with the standard metric $\mathrm{d}\Omega^2_{S^3}$.

In accordance with the principle of the least action, to obtain the corresponding equations of motion we have to vary this action, keeping all the variations equal to zero at the boundaries. Therefore, it is possible to omit a complete divergence in this action without altering the equations of motion (Ref. 10, Sec. 93). Doing so, we get the effective action

$$S_{\mathrm{E}}^{\mathrm{eff}}=\frac{16\pi^2}{16\pi\kappa}\int_R\left(\frac{3}{2}aN-\Lambda a^3N-6\,\frac{1}{N}a\dot{a}^2\right)\mathrm{d}t, \tag{13}$$

which we consider as the reduced action of the gravitational field.

Next, we turn to the gauge field action (3). It is common knowledge that symmetric gauge fields are pull-backs to the base manifold of the invariant connections in the corresponding principal fiber bundles. The classification of invariant connections for the case of fiber-transitive group action is given by Wang's theorem (Ref. 11, Chap. 2, Sec. 11). A generalization to the case of nontransitive symmetry group action was given in Ref. 12, and the problem of lifting the symmetry group action to the bundle was considered in Ref. 13. Using the results of these papers, we get that an $SO(4)$-symmetric gauge potential A on $R\times S^3$ is in one-to-one correspondence with a triplet $\{\tau, \mathcal{A}, \Phi\}$, where τ is a homomorphism from the isotropy group H into the gauge group G, defined up to conjugacy,

$$\tau: H\to G, \tag{14}$$

$\mathcal{A}$ is a gauge potential on R with values in the centralizer $\mathfrak{C}_{\mathfrak{G}}(\tau'(\mathfrak{H}))$ of $\tau'(\mathfrak{H})$ in $\mathfrak{G}=\mathrm{Lie}(G)$ and Φ is a linear mapping,

$$\Phi: R\to\mathfrak{M}^*\otimes\mathfrak{G}, \tag{15}$$

satisfying

$$\Phi\circ\mathrm{Ad}(h)=\mathrm{Ad}(\tau(h))\circ\Phi, \quad \forall h\in H. \tag{16}$$

Here $\mathrm{Ad}(h)$ is the restriction to H of the adjoint representation of K applied to $\mathfrak{M}$ and $\mathrm{Ad}(\tau(h))$ is the restriction to $\tau(H)$ of the adjoint representation of G in $\mathfrak{G}$. In fact, Eq. (16) means that the mapping Φ intertwines these representations.

As we have already mentioned, we will consider gauge groups $SU(2)$ and $SU(4)$. It turns out that the corresponding principal bundles are trivial, because they are classified by the second Chern number, which is equal to zero due to $H^4(R\times S^3)=0$. Therefore, the gauge potential A is defined on $R\times S^3$ globally for both gauge groups.

Further, since the isotropy subgroup is simple, the homomorphism τ can be either injective or trivial. In the latter case the intertwining operator $\Phi=0$, and it is easy to see that the spinor field decouples from the EYM system, which leads to the known ''ghost solutions'' for this field. The same is valid, when the representation δ is trivial. Therefore, we discard these possibilities in the sequel.

If the homomorphism τ is injective, the intertwining operator Φ is nontrivial for any gauge group G, because the isotropy representation in the case under consideration is equivalent to the adjoint one and the restriction to $\tau(H)$ of the adjoint representation of G always contains at least one adjoint representation of H. Thus, we see that the gauge fields on $R\times S^3$ always possess symmetric degrees of freedom for injective homomorphisms τ.

As for the spinor field, the situation is more complicated: it is quite possible that there are no symmetric spinor fields on $R\times S^3$ for some injective homomorphisms τ and some representations δ of the gauge group carried by the spinor field. A sufficient condition for the existence of symmetric spinor fields on $R\times S^3$ is that the restriction of δ to $\tau(H)$ contains a representation $\underline{2}$ of $H=SU(2)$ (see, for example, Ref. 9). If we restrict ourselves to gauge groups of the $SU(n)$ series and to the fundamental representations δ, this condition is fulfilled, in particular, for regular embeddings of $SU(2)$ into $SU(n)$, but it turns out that the resulting effective dynamic systems are the same, as for the gauge group $SU(2)$. The first qualitatively new case is that of the gauge group $SU(4)$ with the nonregular embedding $SU(2)\rightarrow SU(4)$ defined by the decomposition of the fundamental representation of $SU(4)$, $\underline{4}\rightarrow\underline{2}\oplus\underline{2}$. Effective dynamic systems for other gauge groups and similar nontrivial embedding look very much like this one. It is for these reasons that in the present paper we restrict ourselves to the consideration of the gauge groups $SU(2)$ and $SU(4)$.

It is easy to see that in the case of the gauge group $SU(2)$ the centralizer is trivial, and there is no reduced gauge potential $\mathcal{A}$, whereas in the second case there can be a nontrivial centralizer. Therefore, the case of the group $SU(4)$ is more general, and we will carry out all the calculations for this case and then explain the difference from the case of $SU(2)$.

Thus, we take the gauge group $G=SU(4)$ and define the homomorphism $\tau:H\rightarrow G$ by the decomposition of the fundamental representation $\underline{4}$ of $SU(4)$:

$$\underline{4}\rightarrow(\underline{2},\underline{2}), \tag{17}$$

i.e., we represent the space C^4 as the tensor product $C^2\otimes C^2$ and let the fundamental representation of $\tau(H)$ act on the first factor and the fundamental representation of the centralizer $C_G(\tau(H))=SU(2)$ act on the second factor.

It is known that the adjoint representation of $sl(n)$ can be expressed in terms of its fundamental representation by[14]

$$\mathrm{ad}\, sl(n)=\underline{n}^*\tilde{\otimes}\,\underline{n}, \tag{18}$$

where an overtilde means dropping a one-dimensional trivial representation and $\underline{n}^*$ denotes the contragradient representation, $t(x)^*=-t(x)^T$. Therefore, we get

$$\mathrm{ad}\, su(4)\rightarrow(\underline{2},\underline{2})^*\tilde{\otimes}(\underline{2},\underline{2})=(\underline{3},\underline{1})\oplus(\underline{3},\underline{3})\oplus(\underline{1},\underline{3}). \tag{19}$$

A basis in $su(4)$ adapted to this decomposition is

$$H_k = \tau_k \otimes \mathbf{1} = \begin{pmatrix} \tau_k & 0 \\ 0 & \tau_k \end{pmatrix}, \tag{20}$$

$$P_{kA} = \tau_k \otimes \sigma_A, \tag{21}$$

$$H_A = \mathbf{1} \otimes \tau_A, \tag{22}$$

where Eq. (20) explains our rule for evaluating the tensor product of matrices. It is easy to calculate the commutators of these generators, for instance,

$$[P_{kA}, P_{lB}] = \epsilon_{klm} H_m \delta_{AB} + \epsilon_{ABC} H_C \delta_{kl}. \tag{23}$$

The constraint (16) means that the mapping Φ is an intertwining operator, which intertwines the isotropy representation $\underline{3}$ of $H = SU(2)$ in $\mathfrak{M}$ with the representation (19). We introduce basic intertwining operators from $\mathfrak{M}$ into $\mathfrak{G}$ defined by the relations

$$I((\tau_k, -\tau_k)) = H_k, \tag{24}$$

$$I_A((\tau_k, -\tau_k)) = P_{kA}. \tag{25}$$

Then for any $X = (X^k \tau_k) \in su(2)$, we have

$$\Phi((X, -X)) = \xi I(X, -X) + \xi^A I_A(X, -X), \tag{26}$$

$$= X^k(\xi H_k + \xi^A P_{kA}) = X \otimes (\xi \mathbf{1} + \xi^A \sigma_A), \tag{27}$$

where ξ and ξ^A, $A = 1,2,3$, are real-valued functions on R. In what follows we denote the vector (ξ^1, ξ^2, ξ^3) by $\vec{\xi}$ and put $\hat{\xi} = \xi \mathbf{1} + \xi^A \sigma_A$ and $\tilde{\xi} = \xi^A \sigma_A$. The centralizer $\mathfrak{C}_{su(4)}(\tau'(su(2)))$ of $\tau'(su(2))$ in $\mathfrak{G} = su(4)$ is $su(2)$ and is spanned by the Lie algebra elements H_A, $A = 1,2,3$. The matrix $\hat{\xi}$ is in the representation $(\underline{1} + \underline{3})$ of the centralizer $\mathfrak{C}$ and $i\hat{\xi} \in u(2)$.

The symmetric gauge potential A on $R \times S^3$ can be easily expressed in terms of the matrix $\hat{\xi}$ and the canonical left-invariant 1-form $\vartheta = \vartheta^i \tau_i$ on $SU(2) \equiv S^3$:

$$A = \frac{\xi + 1}{2} H_i \vartheta^i + \frac{1}{2} \xi^A P_{kA} \vartheta^k + A_0^A H_A \, dt = \frac{1}{2} \vartheta \otimes (\hat{\xi} + \mathbf{1}) + \mathbf{1} \otimes A_0 \, dt. \tag{28}$$

Here A_0 is a function on R with values in $su(2)$, i.e., $A_0 = A_0^A \tau_A$. The term $\mathbf{1} \otimes A_0 \, dt$ is the reduced gauge potential on R, which can be gauged out, but we keep it for the moment, because it is necessary for deriving the equations of motion. It is not difficult to calculate the corresponding field strength F and to obtain the reduced Yang–Mills action, which takes the simple form

$$S_{\mathrm{YM}} = \frac{16\pi^2}{8g^2} \int_R 24 \left(\frac{a}{2N} \dot{\xi}^2 + \frac{a}{2N} (\dot{\vec{\xi}} + \vec{A}_0 \times \vec{\xi})^2 - \frac{N}{8a} ((\xi^2 + (\vec{\xi})^2 - 1)^2 + 4\xi^2 (\vec{\xi})^2) \right) dt, \tag{29}$$

where $\vec{A}_0$ is the vector (A_0^1, A_0^2, A_0^3) and $\vec{A}_0 \times \vec{\xi}$ is the vector product of $\vec{A}_0$ and $\vec{\xi}$.

If the gauge group is $G = SU(2)$, the unique (up to conjugacy) nontrivial homomorphism $\tau: H \to G$ can be defined by the identity mapping, i.e.,

$$\tau((k,k)) = k, \quad k \in SU(2). \tag{30}$$

In this case, the centralizer $\mathfrak{C}_{\mathfrak{G}}(\tau'(\mathfrak{H}))$ is trivial, and the intertwining operator is

$$\Phi((X, -X)) = \xi(t) X, \quad X \in su(2), \quad \xi(t) \in R. \tag{31}$$

It is clear that the gauge potential A on $R\times S^3$ still has the form (28) with $\vec{\xi}=0$, $A_0=0$. The reduced Yang–Mills action is also given by (29), provided one puts $\vec{\xi}=0$ and rescales the coupling constant $g\rightarrow 2g$.

Next we have to reduce the action (4) for a symmetric spinor field. We choose δ to be the fundamental representation, i.e., we can write the spinor ψ as a 4×4, resp., 4×2 matrix on which an element g of $SU(4)$, resp., $SU(2)$ acts via right multiplication by g^{-1}.

In accordance with our choice of the metric signature (9), we have

$$\{\gamma^\mu,\gamma^\nu\}=-2\,\eta^{\mu\nu},\quad \eta^{\mu\nu}=\mathrm{diag}(-1,1,1,1),\quad \gamma^5=i\gamma^0\gamma^1\gamma^2\gamma^3, \tag{32}$$

$$\gamma^0=\begin{pmatrix}0 & \mathbf{1}\\ \mathbf{1} & 0\end{pmatrix},\quad \gamma^i=\begin{pmatrix}0 & -\sigma^i\\ \sigma^i & 0\end{pmatrix},\quad i=1,2,3,\quad \gamma^5=\begin{pmatrix}\mathbf{1} & 0\\ 0 & -\mathbf{1}\end{pmatrix}. \tag{33}$$

The bispinor representation $\Delta(s)$ is defined by

$$\Delta(s)^{-1}\gamma^\mu\Delta(s)=\Lambda(s)^\mu{}_\rho\gamma^\rho, \tag{34}$$

where s is an element of the group Spin(1,3) and Λ is the covering homomorphism from Spin(1,3) onto $SO(1,3)$. On the Lie algebra level we get

$$[\Delta'(A),\gamma^\mu]=-A^\mu{}_\nu\gamma^\nu,\quad \Delta'(A)=-\tfrac{1}{8}A^\mu{}_\nu[\gamma_\mu,\gamma^\nu], \tag{35}$$

where $A_{\mu\nu}=-A_{\nu\mu}$ is an element of $so(1,3)\equiv\mathrm{spin}(1,3)\equiv sl(2,C)$.

An $SO(4)$-symmetric spinor field ψ on $R\times S^3$ is in one-to-one correspondence with a matrix-valued function ρ on R, which satisfies the condition[9]

$$(\delta'(\tau'(h))+\Delta'(\lambda'(h)))\rho=0,\quad \forall h\in\mathfrak{H}. \tag{36}$$

Here $\lambda':\mathfrak{H}\rightarrow so(1,3)$ is the homomorphism induced by the isotropy representation, which can be calculated explicitly: $\lambda'(\tau_a)^b_c=-\epsilon^b_{ac}$. Therefore, if the gauge group G is $SU(4)$, Eq. (36) reads as

$$(\tfrac{1}{4}\gamma^i\gamma^j\epsilon_{ijk}+\delta'(H_k))\rho=((\tau_k\otimes\mathbf{1})\rho-\rho(\tau_k\otimes\mathbf{1}))=0. \tag{37}$$

The general solution of this constraint equation is

$$\rho=\begin{pmatrix}u_1\mathbf{1} & u_2\mathbf{1}\\ v_1\mathbf{1} & v_2\mathbf{1}\end{pmatrix}=\mathbf{1}\otimes\begin{pmatrix}u_1 & u_2\\ v_1 & v_2\end{pmatrix},\quad u_1,u_2,v_1,v_2\in C^\infty(R), \tag{38}$$

i.e., a symmetric spinor on $R\times S^3$ is parametrized by two complex doublets $u=(u_1,u_2)^T$ and $v=(v_1,v_2)^T$, one for each chirality. We see from (38) that the reduced gauge group $C=SU(2)$ acts on both doublets by the fundamental representation. Taking into account Eqs. (11) and (28), it is a matter of simple calculations to get the reduced action,

$$S_{\mathrm{D}}=16\pi^2\int_R a^3N\left(\frac{i}{N}(\bar{u}\dot{u}-\dot{\bar{u}}u+\bar{v}\dot{v}-\dot{\bar{v}}v)+\frac{1}{N}A_0^B(\bar{u}\sigma_Bu+\bar{v}\sigma_Bv)-\frac{3}{2a}(\bar{u}\hat{\xi}u-\bar{v}\hat{\xi}v)\right)\mathrm{d}t. \tag{39}$$

If the gauge group G is $SU(2)$, Eq. (36) reads as

$$((\tau_k\otimes\mathbf{1})\rho-\rho\tau_k)=0, \tag{40}$$

and we get

$$\rho = \begin{pmatrix} u\mathbf{1} \\ v\mathbf{1} \end{pmatrix} = \mathbf{1} \otimes \begin{pmatrix} u \\ v \end{pmatrix}, \quad u,v \in C^{\infty}(R), \tag{41}$$

i.e., a symmetric spinor on $R \times S^3$ for $G = SU(2)$ depends on two arbitrary complex functions u and v, one for each chirality. The reduced action has the same form (39), if we put there $\vec{\xi} = 0$, $A_0 = 0$.

Now we can write down the reduced action of the coupled EYMD system. In the case of the gauge group $SU(4)$ it has the form

$$S = S_E^{\text{eff}} + S_{\text{YM}} + S_{\text{D}} = 16\pi^2 \int_R \Bigg\{ \frac{1}{16\pi\kappa} \left(\frac{3}{2} aN - \Lambda a^3 N - 6 \frac{a}{N} \dot{a}^2 \right)$$
$$+ \frac{24}{8g^2} \left(\frac{a}{2N} \dot{\xi}^2 + \frac{a}{2N} (\dot{\vec{\xi}} + \vec{A}_0 \times \vec{\xi})^2 - \frac{N}{8a} ((\xi^2 + (\vec{\xi})^2 - 1)^2 + 4\xi^2 (\vec{\xi})^2) \right)$$
$$+ \left(i a^3 (\bar{u}\dot{u} - \dot{\bar{u}} u + \bar{v}\dot{v} - \dot{\bar{v}} v) + a^3 A_0^B (\bar{u}\sigma_B u + \bar{v}\sigma_B v) - \frac{3a^2 N}{2} (\bar{u}\hat{\xi} u - \bar{v}\hat{\xi} v) \right) \Bigg\} \mathrm{d}t. \tag{42}$$

If we choose the gauge group to be $SU(2)$, we have to put $\vec{\xi} = 0$, $A_0 = 0$ in this action, to rescale the coupling constant $g \to 2g$, and to take into account that the variables u and v are no longer isospinors, but ordinary functions.

At this point, we have to comment on the meaning of our classical spinor field. It is clear that it can describe the symmetric energy levels of the Dirac field in the EYM background: either the lowest one with the positive energy, or the highest one with the negative energy. Therefore, we have to assume that the spinor field of our solutions is a one-particle Dirac wave function and should be normalized to unity, which, in the case of symmetric fields, amounts to

$$16\pi^2 a^3 (\bar{u}u + \bar{v}v) = 1. \tag{43}$$

It turns out that this constraint is compatible with the equations of motion derived from the action (42).

III. THE FIELD EQUATIONS AND SOLUTIONS

Variation of this action with respect to a, N, ξ, $\vec{\xi}$, u, v and $\bar{u}$, $\bar{v}$ gives us the field equations. When taken in the special gauge $A_0 = 0$ and in the conformal time [the latter condition means that now $N(t) = a(t)$], they have the form

$$a \frac{\delta}{\delta a} S = \frac{1}{16\pi\kappa} \left(\frac{3}{2} a^2 - 3\Lambda a^4 - 6\dot{a}^2 + 12 a\ddot{a} \right) + \frac{3}{2g^2} \left(\dot{\xi}^2 + (\dot{\vec{\xi}})^2 + \frac{1}{4} ((\xi^2 + (\vec{\xi})^2 - 1)^2 + 4\xi^2 (\vec{\xi})^2) \right)$$
$$+ 3a^3 (i(\bar{u}\dot{u} - \dot{\bar{u}} u + \bar{v}\dot{v} - \dot{\bar{v}} v) - (\bar{u}\hat{\xi} u - \bar{v}\hat{\xi} v)) = 0, \tag{44}$$

$$a \frac{\delta}{\delta N} S = \frac{1}{16\pi\kappa} \left(\frac{3}{2} a^2 - \Lambda a^4 + 6\dot{a}^2 \right) - \frac{3}{2g^2} \left(\dot{\xi}^2 + (\dot{\vec{\xi}})^2 + \frac{1}{4} ((\xi^2 + (\vec{\xi})^2 - 1)^2 + 4\xi^2 (\vec{\xi})^2) \right)$$
$$- \frac{3}{2} a^3 (\bar{u}\hat{\xi} u - \bar{v}\hat{\xi} v) = 0, \tag{45}$$

$$\frac{\delta}{\delta \xi} S = -\frac{3}{2g^2} (2\ddot{\xi} + (\xi(\xi^2 + (\vec{\xi})^2 - 1) + 2\xi(\vec{\xi})^2)) - \frac{3}{2} a^3 (\bar{u}u - \bar{v}v) = 0, \tag{46}$$

$$\frac{\delta}{\delta \xi^A} S = -\frac{3}{g^2} \left(\ddot{\xi}^A + \frac{1}{2} (\xi^A (\xi^2 + (\vec{\xi})^2 - 1) + 2\xi^2 \xi^A) \right) - \frac{3}{2} a^3 (\bar{u}\sigma^A u - \bar{v}\sigma^A v) = 0, \tag{47}$$

$$\frac{1}{2}a^{-3/2}\frac{\delta}{\delta\overline{u}}S=i\frac{d}{dt}a^{3/2}u-\frac{3}{4}\hat{\xi}a^{3/2}u=0,$$
$$\frac{1}{2}a^{-3/2}\frac{\delta}{\delta u}S=i\frac{d}{dt}a^{3/2}\overline{u}+\frac{3}{4}a^{3/2}\overline{u}\hat{\xi}=0, \tag{48}$$

$$\frac{1}{2}a^{-3/2}\frac{\delta}{\delta\overline{v}}S=i\frac{d}{dt}a^{3/2}v+\frac{3}{4}\hat{\xi}a^{3/2}v=0,$$
$$\frac{1}{2}a^{-3/2}\frac{\delta}{\delta v}S=i\frac{d}{dt}a^{3/2}\overline{v}-\frac{3}{4}a^{3/2}\overline{v}\hat{\xi}=0. \tag{49}$$

Variation with respect to A_0 gives a constraint,

$$\frac{\delta S}{\delta A_0^B}=\frac{3}{g^2}(\epsilon_{BCD}\xi^C\dot{\xi}^D)+a^3(\overline{u}\sigma_B u+\overline{v}\sigma_B v)=0, \tag{50}$$

which means that the total isospin of the gauge and the spinor fields equals zero.

Now we will show that it is possible to find exact solutions to this system of equations. We begin with the simpler case of the gauge group $SU(2)$. There is no constraint (50) in this case, and we also have to drop the equation (47), to put $\vec{\xi}=0$ in the others and to rescale $g\to 2g$.

The Dirac equations (48) and (49) give

$$\overline{u}u=\frac{C_u}{a^3},\quad \overline{v}v=\frac{C_v}{a^3} \tag{51}$$

and

$$\overline{u}\dot{u}-\dot{\overline{u}}u=-\frac{3i}{2}\xi\overline{u}u, \tag{52}$$

$$\overline{v}\dot{v}-\dot{\overline{v}}v=\frac{3i}{2}\xi\overline{v}v, \tag{53}$$

where, in accordance with (43), the positive constants C_u and C_v fulfill the normalization condition

$$16\pi^2(C_u+C_v)=1. \tag{54}$$

We will discuss the explicit choice of these constants later.

Now Eqs. (44) and (45) simplify considerably. Their sum gives

$$\frac{1}{16\pi\kappa}(3a^2-4\Lambda a^4+12a\ddot{a})=0. \tag{55}$$

Multiplying this equation by $\dot{a}/a$ and integrating, we see that

$$\tfrac{3}{2}a^2-\Lambda a^4+6\dot{a}^2=E, \tag{56}$$

where E is an arbitrary constant, which has the meaning of the total energy of the system. Equation (56) is the standard Friedman equation for the radiation-dominated universe and has a simple analog in mechanics. We can consider a as the coordinate of a particle with unit mass and energy $E/12$, which moves in an inverted double-well potential (recall that $\Lambda>0$),

$$W(a)=\tfrac{1}{8}a^2-\tfrac{1}{12}\Lambda a^4. \tag{57}$$

If $\Lambda<\Lambda_E=9/16E$, then the motion will be periodic. This means that our solution describes a universe that first expands and then contracts, where $a=0$ corresponds to a singular metric in the beginning and the end. If $\Lambda\geqslant\Lambda_E$, then the solution can be either static or can describe an expanding or contracting universe, but such solutions are of no interest from the physical point of view, and we will not discuss them in more detail.

Next we turn to the YM equation (46) (we recall that we have rescaled $g\to 2g$ in the case under consideration). Due to Eq. (51), it decouples from the equations for u and v:

$$\frac{3}{8g^2}(2\ddot{\xi}+(\xi(\xi^2-1)))+\frac{3}{2}(C_u-C_v)=0. \tag{58}$$

The first integral of this equation is

$$\frac{3}{8g^2}\left(\dot{\xi}^2+\frac{1}{4}(\xi^2-1)^2\right)+\frac{3}{2}\xi(C_u-C_v)=\frac{E}{16\pi k}, \tag{59}$$

where the integration constant is due to Eqs. (45) and (56).

Equation (59) also has an analog in mechanics. A point particle with unit mass, energy $g^2E/(12\pi\kappa)$ and coordinate ξ, moves in a double-well potential,

$$V(\xi)=\tfrac{1}{8}(\xi^2-1)^2+2g^2\xi(C_u-C_v). \tag{60}$$

We can interpret the first term in (59) as the energy of the Yang–Mills field and the second term as the energy of the Dirac field due to the interaction with the gauge field, the equation describing an exchange of energy between the two fields. The exact solution of Eq. (59) is possible in terms of elliptic functions of the first kind.[15]

It is not difficult to see that for sufficiently small values of the coupling constant, for example, $g^2/4\pi<1$, potential (60) always has three extrema: the absolute minimum, a local minimum, and a local maximum. We consider, for instance, the case where $C_u-C_v<0$ and the energy of the system $g^2E/(12\pi\kappa)$ lies between the local minimum and the local maximum of the potential $V(\xi)$. Then the system will move between the turning points defined by the real zeros of the polynomial,

$$\frac{g^2E}{12\pi\kappa}-V(\xi). \tag{61}$$

In the case under consideration we have four real zeros $d<c<b<a$, i.e.,

$$\frac{1}{2}\dot{\xi}^2=\frac{g^2E}{12\pi\kappa}-V(\xi)=\frac{1}{8}(a-\xi)(b-\xi)(c-\xi)(\xi-d). \tag{62}$$

Moreover, the form of the potential (60) stipulates that in the case $C_u-C_v<0$ we have $d<c<0$.

The equations of motion have two solutions with either $b\leqslant\xi\leqslant a$ or $d\leqslant\xi\leqslant c$. The solution for the latter case is given by the integral

$$t(\xi)=\int_d^\xi\frac{dx}{\sqrt{\dfrac{g^2E}{6\pi\kappa}-\dfrac{1}{4}(x^2-1)^2-4g^2x(C_u-C_v)}}, \tag{63}$$

which can be solved explicitly,[15]

$$t(\xi)=\frac{2}{\sqrt{(a-a)(b-d)}}F\left(\arcsin\sqrt{\frac{(a-c)(\xi-d)}{(c-d)(a-\xi)}},\sqrt{\frac{(a-b)(c-d)}{(a-c)(b-d)}}\right), \tag{64}$$

where F is the elliptic integral of the first kind. This function can be inverted, and we can get $\xi(t)$ expressed in terms of the Jacobi elliptic function *sinus amplitudinis*. Solutions for other values of E and C_u-C_v can be written out in a similar way with the help of the formulas available in Ref. 15.

With a given solution ξ we can solve the Dirac equations (48) and (49),

$$u=\sqrt{\frac{C_u}{a^3}}\exp\left\{-i\int\frac{3}{4}\xi\,\mathrm{d}t\right\}, \tag{65}$$

$$v=\sqrt{\frac{C_v}{a^3}}\exp\left\{i\int\frac{3}{4}\xi\mathrm{d}t\right\}. \tag{66}$$

One easily checks that our solution fulfills the whole system of field equations.

Now we consider the case of gauge group $SU(4)$. The Dirac equations (48) and (49) again lead to (51), but instead of (52) and (53) we now have

$$\bar{u}\dot{u}-\dot{\bar{u}}u=-\frac{3i}{2}\bar{u}\hat{\xi}u, \tag{67}$$

$$\bar{v}\dot{v}-\dot{\bar{v}}v=\frac{3i}{2}\bar{v}\hat{\xi}v. \tag{68}$$

These equations are also sufficient to decouple the Friedman equation from the Yang–Mills–Dirac equations, and we get again the equation (56) for the scale factor a.

Now we have to solve the Yang–Mills equations (46) and (47). We start with the discussion of the constraint (50). In what follows we restrict ourselves to the case where

$$\epsilon_{BCD}\xi^C\dot{\xi}^D=0,\quad \text{for } B=1,2,3, \tag{69}$$

i.e., the isospins of the gauge field and the Dirac field vanish separately. This equation means that the angular momentum of the motion in the $\vec{\xi}$ space equals zero, that is, the motion goes along a straight line passing through the origin, and the vector $\vec{\xi}$ is always proportional to a fixed vector $\vec{\xi}_0$. We use the remaining gauge freedom to choose $\vec{\xi}_0=(0,0,1)$, i.e., $\tilde{\xi}=\zeta\sigma_3$, $\zeta\in R$. In this gauge we obtain from the Yang–Mills equations (47),

$$\bar{u}\sigma_A u-\bar{v}\sigma_A v=0,\quad \text{for } A=1,2. \tag{70}$$

Further, we get from Eqs. (50) and (69),

$$\bar{u}\sigma_B u+\bar{v}\sigma_B v=0,\quad B=1,2,3. \tag{71}$$

Hence, we have $\bar{u}\sigma_1 u=\bar{u}\sigma_2 u=0$. These equations have two solutions:

$$\text{1st case:}\quad u=a^{-3/2}\alpha_1 w_+,\quad v=a^{-3/2}\beta_1 w_- \tag{72}$$

$$\text{2nd case:}\quad u=a^{-3/2}\alpha_2 w_-,\quad v=a^{-3/2}\beta_2 w_+, \tag{73}$$

where

$$w_+ = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad w_- = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{74}$$

and $\alpha_i, \beta_i \in C$, $|\alpha_i| = |\beta_i|$, $i = 1,2$. In particular, we obtain $C_u = C_v = |\alpha_i|^2 = 1/(32\pi^2)$ in the ith case, because the constants also must fulfill the normalization condition (54).

If we put $\tilde{\xi} = \zeta\sigma_3 \equiv 0$, then the Yang–Mills equations (47) demand $u = v = 0$. Therefore, we consider only the nontrivial case, when $\tilde{\xi} \not\equiv 0$. Hence, we have two Yang–Mills equations (46) and (47), which now take the form

$$\frac{3}{2g^2}(2\ddot{\xi} + (\xi(\xi^2 + \zeta^2 - 1) + 2\xi\zeta^2)) = 0, \tag{75}$$

$$\frac{3}{2g^2}(2\ddot{\zeta} + (\zeta(\xi^2 + \zeta^2 - 1) + 2\xi^2\zeta)) + 3S = 0, \tag{76}$$

with $S := C_u = 1/(32\pi^2)$ in the first and $S := -C_u = -1/(32\pi^2)$ in the second case.

To solve Eqs. (75) and (76), we pass to new variables, in accordance with

$$\begin{aligned} \xi &= \tfrac{1}{2}(x + y), \\ \zeta &= \tfrac{1}{2}(x - y). \end{aligned} \tag{77}$$

It is easy to check that the equations for x and y decouple and take the form

$$\frac{3}{2g^2}(2\ddot{x} + x(x^2 - 1)) + 3S = 0, \tag{78}$$

$$\frac{3}{2g^2}(2\ddot{y} + y(y^2 - 1)) - 3S = 0. \tag{79}$$

The first integrals of these equations are

$$\frac{3}{2g^2}\left(\dot{x}^2 + \frac{1}{4}(x^2 - 1)^2\right) + 3Sx = \frac{E_1}{8\pi\kappa}, \tag{80}$$

$$\frac{3}{2g^2}\left(\dot{y}^2 + \frac{1}{4}(y^2 - 1)^2\right) - 3Sy = \frac{E_2}{8\pi\kappa}, \tag{81}$$

where due to (45) and (56) the constants E_1 and E_2 fulfill

$$E_1 + E_2 = E. \tag{82}$$

These equations can also be solved exactly in terms of Jacobi elliptic functions, but unlike the case of the group $SU(2)$, there will be two different periods of motion in x and y.

We would like to note here that equations of the type (75), (76) with $S = 0$ for the Euclidean EYM system were first found in Ref. 4, but they were solved there only for the case of either $\xi = 0$ or $\zeta = 0$. It is likely that the existence of two periods can modify the equations for the energy quantization of the wormholes.[4,16]

Substituting the solutions for ξ and ζ into Eq. (28), we get

$$A=\frac{1}{2}\,\theta\otimes(\hat{\xi}+\mathbf{1})=\begin{pmatrix}\frac{1+x}{2}\,\theta & 0\\ 0 & \frac{1+y}{2}\,\theta\end{pmatrix}, \tag{83}$$

i.e., the gauge potential A takes values only in the $su(2)\oplus su(2)$ subalgebra of $su(4)$, each $su(2)$ part of the gauge potential being coupled to only one of the spinor fields u, resp., v.

If we have a solution to the system of equations (80) and (81), it is easy to integrate the Dirac equations (48) and (49). With given solutions ξ and ζ we obtain

$$u=w+\sqrt{\frac{C_u}{a^3}}\exp\left\{-i\int\frac{3}{4}x\,\mathrm{d}t\right\}, \tag{84}$$

$$v=w_-\sqrt{\frac{C_u}{a^3}}\exp\left\{i\int\frac{3}{4}y\,\mathrm{d}t+i\varphi_1\right\} \tag{85}$$

in the first and

$$u=w_-\sqrt{\frac{C_u}{a^3}}\exp\left\{-i\int\frac{3}{4}y\,\mathrm{d}t\right\}, \tag{86}$$

$$v=w+\sqrt{\frac{C_u}{a^3}}\exp\left\{i\int\frac{3}{4}x\mathrm{d}t+i\varphi_2\right\}, \tag{87}$$

in the second case, φ_1 and φ_2 being arbitrary constant phases.

IV. DISCUSSION

In studying the self-consistent EYMD system we have found that the evolution of the metric decouples from the remaining system and is described by the Friedman equation for the radiation-dominated universe. The same result for the case of EYM systems was obtained earlier in Refs. 4, 5, and solutions for the spinor field in this background were studied in Ref. 17. Unlike the latter solutions, our solutions take into account the back-reaction of the spinor field on the YM and gravitational fields.

As we have already mentioned, our solutions describe just one energy level of the Dirac field in the EYM background, which is the symmetric one and therefore exactly the lowest one. It is easy to see from the Dirac equations (48), (49) that the symmetric lowest level has a nonzero energy, when $\xi\neq 0$ in the case $G=SU(2)$ and $\det\hat{\xi}=\xi^2-\tilde{\xi}^2\neq 0$ in the case $G=SU(4)$. It makes clear that, in the absence of gauge fields, the symmetric level of the Dirac field always has zero energy. Therefore, the corresponding energy–momentum tensor vanishes, and the $SO(4)$-invariant solution for the Dirac field becomes a ''ghost solution.''

Now we will discuss our solutions in more detail. We start with the simpler case of the gauge group $SU(2)$. In this case the Yang–Mills equations admit three static solutions: two minima and one local maximum of the potential,

$$V(\xi)=\tfrac{1}{8}(\xi^2-1)^2+2g^2\xi(C_u-C_v). \tag{88}$$

Of course, these are solutions of the whole system only if the constant E is equal to the value of $V(\xi)$ in these extrema. In the absence of the spinor field, these extrema are two vacua $\xi=-1$, $\xi=+1$ of the YM field with Chern–Simons numbers $q=0$ and $q=1$ and a sphaleronlike solution $\xi=0$ with Chern–Simons number $q=\frac{1}{2}$ lying on top of the potential barrier between the vacua, where the Chern–Simons number is defined for any t as

$$q(t)=\frac{1}{8\pi^2}\int_{\{t\}\times S^3}\mathrm{tr}_\delta\left(A\wedge \mathrm{d}A+\frac{1}{3}A\wedge[A,A]\right),$$

the trace being taken in the representation δ of the gauge group in the spinor space. In the case of symmetric gauge fields this number can be calculated explicitly to be $q(t)=(\frac{1}{4})(2+3\xi(t)-(\xi(t))^3)$. Chiral spinor field configuration shifts the position of the extrema and the Chern–Simons index of the corresponding gauge field configurations, which is quite natural in the presence of matter fields.[18–22]

By fine tuning the cosmological constant Λ and the energy E, we can get a static sphaleronlike solution of the whole system. This solution corresponds to the local maxima of $V(\xi)$ (60) and $W(a)$ (57). Obviously, this solution has two unstable modes—one in the gravitational and one in the gauge field sector. This is another indication that the static solution is a ''cosmological'' analog of the first Bartnik–McKinnon solution.[23]

Next, we observe that Eq. (45) is the (0,0) component of the Einstein equations, and therefore we can interpret the constant E, see Eq. (56), as the total energy of the YMD system. Then Eq. (59) describes, in particular, the exchange of energy between Yang–Mills and spinor fields. This interpretation is in agreement with the solutions (65) and (66) for the spinor field in the case of the gauge group $SU(2)$: the momentary frequency, resp., energy of the spinor field is given by the integrand in the exponent of the solutions, and this is up to a factor ξ.

At this point we encounter the problem of positive definiteness of the energy, which is well known in classical Dirac theory. We see that the left-handed and the right-handed spinors make contributions of opposite sign to the energy of the system (59). Therefore, a physically meaningful solution in our case can only be a solution with either left-handed or right-handed spinors and the Yang–Mills field ξ taking values in the interval, where the energy of the corresponding spinor field is positive. Thus, the solution (64) with $C_u=0$, $C_v=1/(16\pi^2)$ is physically meaningful, because $\xi<0$ for this solution and the energy of the left-handed spinor field v is positive definite, which is also seen from Eq. (59).

If the total energy of the YMD system is larger than the local maximum of the potential $V(\xi)$, the motion in the variable ξ, stemming from the YM field, will go over an interval, including both minima of the potential $V(\xi)$. When ξ crosses zero, the energy of the spinor field also changes its sign. This is in accordance with the observations in Refs. 17 and 24, where it was shown that the spinor field has zero modes in the sphaleron background and that moving between neighboring vacua of the gauge field results in a shift of the energy levels of the spinor field. We also obtain from our solution that the effect is opposite for the spinor fields with opposite chirality.

However, when ξ crosses zero, our solution describes spinor matter with negative energy, which is unphysical. Furthermore, because we are dealing with a one-particle system, we cannot consistently describe the process of creation and annihilation of fermions. This is also easily seen from the fact that the classical axial current of the Dirac field, given in the case under consideration by

$$j=\overline{\psi}\gamma_\alpha\gamma^5\psi\theta^a=-\overline{\psi}\gamma_a\psi\theta^\alpha=-\frac{C_v}{a^3}\theta^0, \tag{89}$$

is classically conserved, i.e., $d(*j)=0$, whereas the anomaly equation,[18,19,25,22]

$$d(*j)=-(1/8\pi^2)\mathrm{tr}_\delta(F\wedge F), \tag{90}$$

implies that the evolution of the YM field between topologically distinct vacua must result in a change of the fermion number,

$$N_L(t)=-\int_{\{t\}\times S^3}*j. \tag{91}$$

Thus, within our interpretation of the solutions, only the motion in the vicinity of a certain vacuum is allowed.

Finally, we comment on the case of gauge group $SU(4)$. Under assumption (69), we can completely solve the field equations. Equation (83) means that the Yang–Mills potential takes values only in an $su(2)\oplus su(2)$ subalgebra of $su(4)$ and, therefore, splits into two parts. Each part is coupled to one spinor field of a definite chirality. Thus, in some sense, we simply have a doubling of the solution for $SU(2)$.

Similar to (59), Eqs. (80) and (81) describe the exchange of energy between the spinor and gauge field. In the absence of the spinor field, the YM field has the following extrema:
a local maximum,

$$\xi=0, \quad \zeta=0, \quad q=1;$$

four minima,

$$\xi=1, \quad \zeta=0, \quad q=2,$$

$$\xi=0, \quad \zeta=\pm 1, \quad q=1,$$

$$\xi=-1, \quad \zeta=0, \quad q=0;$$

and four saddle points,

$$\xi=\tfrac{1}{2}, \quad \zeta=\pm\tfrac{1}{2}, \quad q=\tfrac{3}{2},$$

$$\xi=-\tfrac{1}{2}, \quad \zeta=\pm\tfrac{1}{2}, \quad q=\tfrac{1}{2},$$

the Chern–Simons number now being given by $q(t)=(\frac{1}{2})(2+3\xi(t)-(\xi(t))^3-3\xi(t)(\zeta(t))^2)$.

For sufficiently small values of the coupling constant [approximately, $g^2/(16\pi)<1$], the inclusion of the spinor field lifts the degeneracy so that three of the four absolute minima become local minima. Again, by fine tuning the constants E_1 and E_2 and the cosmological constant Λ we can obtain the corresponding static solutions, some of them being stable and some unstable.

If the constants E_1 and E_2 are such that the variables x and y describe a motion in the vicinity of the local minimum, where the energy of both left-handed and right-handed spinors is positive, the corresponding solutions are physically meaningful. Such solutions exist for any sign of the constant S (76), but, in contrast to the $SU(2)$ case, we have no chiral solutions.

If the energies E_1 and E_2 are large enough, in the case of gauge group $SU(4)$ we also have the phenomenon of energy level crossing in the evolution of the spinor field. But similar to the case of the gauge group $SU(2)$, these solutions become unphysical, because of negative energy of the Dirac field. Therefore, they are unable to describe transitions between the topologically distinct vacua, which the system has in this case.

In the end we would like to emphasize once again that the obtained solutions are interesting in their own right as the first example of exact self-consistent solutions in the Einstein–Yang–Mills–Dirac system. They can be of use for constructing cosmological solutions in EYMD theories, which would take into account the excited levels of the Dirac field as well. Their physical interpretation is not clear yet. For example, they can be considered as describing baby universes,[26] but it is quite possible that there can exist other interpretations of these solutions, which differ from the one proposed here.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 11 NOVEMBER 1999

The identities of the algebraic invariants of the four-dimensional Riemann tensor. III

G. E. Sneddon[a)]
School of Computer Science, Mathematics, and Physics, James Cook University, Townsville, 4811, Australia

(Received 6 March 1998; accepted for publication 13 July 1999)

This paper extends the investigation of the invariants of the Riemann tensor to include the invariants that are of odd degree in the trace-free Ricci tensor. It is shown that these invariants can be expressed in terms of 15 such invariants that are irreducible. As a consequence, it is possible to write down a complete set of invariants of the Riemann tensor. Several syzygies for these invariants have been found and examples of these are given. These syzygies suggest there may be several new syzygies of invariants with even degree in the trace-free Ricci tensor. A large number of these have also been found and are discussed in the paper.
 [S0022-2488(99)04110-9]

I. INTRODUCTION

As the title suggests, the aim of this paper is to extend the recent work of the author[1,2] on the invariants of the Riemann tensor. The main result is to include those invariants that are of odd degree in the trace-free Ricci tensor and thereby find a complete set of Riemann invariants.

An *invariant* of a set of tensors in n dimensions is a polynomial function of the components of those tensors that is invariant under some group of transformations of the tensors. It is known[3] that any invariant of a set of tensors can be expressed as a linear combination of complete contractions of products of those tensors (together with the metric or $\epsilon_{i_1 \cdots i_n}$ as appropriate). In our case, the components of the Riemann tensor transform under the proper Lorentz group. A *complete* set of invariants, $\{I_1,\ldots,I_m\}$, is one for which any other invariant I can be written as a polynomial function of $\{I_1,\ldots,I_m\}$, but no element of the set can be written as a polynomial function of the others. An *independent* set of invariants, $\{I_1,\ldots,I_m\}$, is one for which $f(I_1,\ldots,I_m)=0$ implies that f is the trivial function, $f\equiv 0$. An invariant, T, is *reducible* if it can be written as a polynomial whose arguments are invariants of lower degree than T. This shall be written as $T\approx 0$. Two invariants will be said to be *equivalent* if their difference is reducible.

In the past 50 years there have been several attempts to understand the invariants of the Riemann tensor and the relations between them. Initial attempts were directed towards finding a suitable set of independent invariants[4–8] and, more recently, the physical interpretation of some of the invariants.[9,10] Carminati and McLenaghan[9] pointed out that in many cases an independent set is not sufficient, and that it is important to have a complete set of invariants. Such a set can be used to find all other invariants in any algebraically special case, as well as in the general case. In this sense, a complete set will contain all possible information about the invariants.

However, a complete set of invariants typically will contain more elements than an independent set, and so there must be relationships (syzygies) between them. Carminati and McLenaghan, McIntosh and Zachary,[11] and Zachary and McIntosh[12] have made some preliminary investigations into these relationships in algebraically special cases. Sneddon[1,2] showed how the complex bivector representation, together with some results from invariant theory, could be used to obtain a large number of the identities connecting the invariants of the Riemann tensor. These papers shall be referred to as I and II, respectively. The bivector formalism used is that of Buchdahl.[13] (A

a)Electronic mail: Graeme.Sneddon@jcu.edu.au

summary is given in I.) In this formalism, the Riemann tensor is represented by two complex 3×3 matrices together with the Ricci scalar, R. The matrix, Ψ, that corresponds to the Weyl tensor, is symmetric and trace-free. The other matrix, Γ, corresponds to the trace-free part of the Ricci tensor and is Hermitian. Under a proper Lorentz transformation, the bivectors undergo a complex orthogonal transformation.[13]

It was observed in II that there are two subsets of the invariants for which the problem of finding a complete set simplifies somewhat. The first subset is the set of invariants in which Γ appears only in the combination $K=\Gamma\bar{\Gamma}$. The second is the set of invariants of even degree in Γ. For simplicity, it is convenient to refer to invariants that are of even degree in the trace-free Ricci tensor as ''even'' invariants, and those with odd degree as ''odd'' invariants.

Since the product of any two odd invariants will be an even invariant, the view was expressed in II that, in most cases, it may be sufficient to consider the even invariants only. However, there are a number of reasons why the odd invariants should also be investigated. First, various odd invariants have been used previously. The invariant $S^i{}_j S^j{}_k S^k{}_i$, where $S^i{}_j$ is the trace-free Ricci tensor, is the most elementary of these. This is proportional to the invariant r_2 of Carminati and McLenaghan. There is also the invariant, D^-D^+S, of Géhéniau and Debever[5] (as expressed by Campbell and Wainwright[14]). This is proportional to the odd invariant m_4 introduced by Carminati and McLenaghan. It is important to understand how these quantities relate to the even invariants described in II. Second, there is the hope that it may be possible to simplify the rather large set of invariants found in II if the odd invariants are included. Third, it may be possible to simplify the syzygies of the even invariants if they can be written in terms of the odd invariants. At the very least, it may be possible to gain further insight into the nature of these syzygies. Unfortunately, these hopes are realized to a limited extent only. While the inclusion of the odd invariants means that some even invariants are no longer needed in a complete set, there is a greater number of odd invariants that need to be added to the set. Also, there does not seem to be any great simplification of the syzygies of even invariants beyond the observation that some can be obtained from corresponding syzygies of odd invariants. However, one consequence of this work is that several more syzygies of even invariants have been found. Some of these have total degree that is less than the total degree of those in II and so, in this sense, are more fundamental.

The initial goal is to find a set, $\mathcal{K}_0$, of odd invariants which are irreducible and for which any other odd invariant can be expressed as a polynomial function of the elements of $\mathcal{K}_0$ together with the even invariants. Section II summarizes the existing results for even invariants. In Sec. III, the nature of the odd invariants is discussed and some preliminary results are obtained. It is shown that any odd invariant can be written as a linear function of a small number of odd invariants with the coefficients of these terms being even invariants. In Sec. IV, a suitable set of odd invariants is obtained. Since these invariants are irreducible, they will form the set $\mathcal{K}_0$. A complete set, $\mathcal{K}$, of invariants of Ψ and Γ can then be given. Section V describes some of the syzygies of the odd invariants. Many of these syzygies are obtained by the method of skew-symmetrizing over $n+1$ indices that was discussed in II. Others are obtained by a ''method of undetermined coefficients,'' a numerical procedure developed by Ouchterlony[15] for finding syzygies. In Sec. VI, it is noted that several of these syzygies can be used to obtain syzygies of even invariants. The method of undetermined coefficients is then used to find those syzygies of even invariants that have the lowest possible degree. Examples of some of the new syzygies are given in the appendices. They are also available in an electronic form from http://www.jcu.edu.au/~mages/.

Throughout, the notation used is that of I and II. Indices $i,j,\ldots$ will range from 1 to 4, while bivector indices $A,B,\ldots$ will range from 1 to 3. Square brackets will be used to denote the trace of a matrix. Thus $[AB]$ is the trace of the matrix AB. Details of the symbols used are in Appendix D.

II. THE EVEN INVARIANTS

For those invariants where Γ appears only in the combination $\Gamma\bar{\Gamma}$, the invariants are best expressed in terms of the matrices $A=\Psi$ and $B=\Gamma\bar{\Gamma}$. It was demonstrated in I that a complete set for these invariants is the set, $\mathcal{I}$, given by

TABLE I. This is the set $\mathcal{J}$. Any invariant of Ψ and Γ that is of even degree in Γ can be written as a polynomial function of these invariants.

Real invariants	Complex invariants
$[B]=[K]$	
$[B^2]=[K^2]$	$[A^2]=[\Psi^2]$
$\det B=\det K$	$\det A=\det \Psi$
	$[AB]=[\Psi K]=\overline{[C]}$
	$[AB^2]=[\Psi K^2]=\overline{[BC]}$

$[AB^2C]=[\Psi K^2\Gamma\bar{\Psi}\bar{\Gamma}]$	$[ABD]=[\Psi K\Gamma\bar{\Psi}^2\bar{\Gamma}]=\overline{[A^2BC]}$
$[A^2D]=[\Psi^2\Gamma\bar{\Psi}^2\bar{\Gamma}]$	
$[A^2BD]=[\Psi^2 K\Gamma\bar{\Psi}^2\bar{\Gamma}]$	$[AB^2D]=[\Psi K^2\Gamma\bar{\Psi}^2\bar{\Gamma}]=\overline{[A^2B^2C]}$
$[A^2B^2D]=[\Psi^2K^2\Gamma\bar{\Psi}^2\bar{\Gamma}]$	
$[A^2BACD]=[\Psi^2K\Psi\Gamma\bar{\Psi}\bar{K}\bar{\Psi}^2\bar{\Gamma}]$	

$$\begin{array}{cccc} & & [A^2] & [A^3] \\ [B] & [AB] & [A^2B] & \\ [B^2] & [AB^2] & [A^2B^2] & \\ [B^3]. & & & \end{array} \tag{1}$$

Since there will be 15 real invariants in $\mathcal{I}$, and there can only be 13 independent invariants of Ψ and Γ, there must be two identities connecting these invariants. In fact, $[A^2B^2]$ satisfies a cubic equation whose coefficients are functions of the other invariants in (1). This equation was given in I and II, but in an incorrect form.[16] The corrected version is given in Appendix A.
