Next we show that $\ker P'=\{0\}$. Let $\mathfrak{f}\in\ker P'$. Since $P'\lceil\mathcal{D}_1$ is essentially self-adjoint by (iii), there exists a sequence $\{\mathfrak{f}_n\}$ of vectors $\mathfrak{f}_n\in\mathcal{D}_1$ such that $\mathfrak{f}_n\to\mathfrak{f}$ and $P'\mathfrak{f}_n\to P'\mathfrak{f}=0$ in $\mathcal{H}$. Since $X'P'\mathfrak{f}_n=\mathrm{i}(q^{1/2}U'^*+q^{1/2}U')\mathfrak{f}_n$ by (ii) and the operators U' and U'^* are bounded, we obtain $(q^{-1/2}U'^*+q^{1/2}U')\mathfrak{f}=0$ in the limit. This in turn yields that $q\|\mathfrak{f}\|=\|\mathfrak{f}\|$ and so $\mathfrak{f}=0$.

By (ii), we have $U'P'\mathfrak{f}=qP'U'\mathfrak{f}$ for all $\mathfrak{f}\in\mathcal{D}_1$. Since $p'\lceil\mathcal{D}_1$ is essentially self-adjoint, this remains valid for $\mathfrak{f}\in\mathcal{D}(P')$, so that $P'\subseteq qU'^*P'U'$. Since P' is self-adjoint, we conclude that $P'=qU'^*P'U'$. Hence we have $U'^nE(\mathfrak{N})=E(q^{-n}\mathfrak{N})$ for any Borel subset $\mathfrak{N}$ of $\mathbb{R}$ and arbitrary $n\in\mathbb{Z}$. Let $\mu^{j,+}$ be the extension of the measure $\mu_1^{j,+}$ to $\mathbb{R}_+$ as in Sec. II (1). From the preceding considerations it follows that $E(\mathbb{R}_+)\mathcal{H}=\oplus_j L^2(\mathbb{R}_+,\mu^{j,+})\equiv\mathcal{H}_+$ and that U' acts in each component by formula (i) in Sec. II (1). Proceeding in a similar manner, we obtain a family $\{\mu_1^{j,-};j\in I_-\}$ of measures on $[q,1]$ such that $\mu_1^{j,-}(\{1\})=0$ for $j\in I_-,E(\mathbb{R}_-)\mathcal{H}=\oplus_j L^2(\mathbb{R}_-,\mu^{j,-})\equiv\mathcal{H}_-$ in the notation of Sec. II and U' acts componentwise as given by formula (i) in Sec. II (1). Since $E(\{0\})\mathcal{H}=\ker P'=\{0\}$ as proved in the preceding paragraph, we conclude that $\mathcal{H}=\mathcal{H}_+\oplus\mathcal{H}_-$.

From the construction it is clear that P' and U' are the operators P and U, respectively, as in Sec. II. Let us finally turn to the operator X'. Recall that we have $X'P'\mathfrak{f}=\mathrm{i}(q^{-1/2}U'^*+q^{1/2}U')\mathfrak{f}$ for $\mathfrak{f}\in\mathcal{D}_1$. By arguing as in the paragraph before last, this relation remains valid for all $\mathfrak{f}\in\mathcal{D}(P')$. If f denotes a component of the vector $\mathfrak{f}$, then the preceding equation yields that $g:=tf\in\mathcal{H}$, $t^{-1}g=f\in\mathcal{H}$ and $(X'g)(t)=\mathrm{i}(q^{-1}f(q^{-1}t)-qf(qt))=\mathrm{i}t^{-1}(g(q^{-1}t)-g(qt))=(Xg)\times(t)$. Hence $X'\mathfrak{f}=X\mathfrak{f}$ for all $\mathfrak{f}\in\mathcal{D}(P')$. Since $X'\lceil\mathcal{D}_1$ is essentially self-adjoint, the relation $U'X'\mathfrak{f}=q^{-1}X'U'\mathfrak{f}$ for $\mathfrak{f}\in\mathcal{D}_1$ by (ii) extends to vectors $\mathfrak{f}\in\mathcal{D}(X')$, so that $U'X'U'^*=q^{-1}X'$. Thus, X' is a self-adjoint extension of the operator X such that $U\mathcal{D}(X')=\mathcal{D}(X')$. By Proposition 1, X' is of the form $X_{V,W}$. ■

VI. ∗-REPRESENTATIONS OF THE *q*-HEISENBERG ALGEBRA

(1) We have considered so far only operator triples and operator relations rather than representations of the algebra $\mathcal{A}(q)$. However, any operator triple $\{P,X_{V,W},U\}$ gives rise to a self-adjoint representation of the ∗-algebra as follows. Indeed, let $\mathcal{D}_1$ be the domain defined at the beginning of Sec. IV. For vectors in $\mathcal{D}_1$ the operators $P,X_{V,W},U$ satisfy the defining relations (1) and (2) of the algebra $\mathcal{A}(q)$. Hence there exists a unique ∗-representation π_1 of the ∗-algebra $\mathcal{A}(q)$ on the domain $\mathcal{D}_1$ such that

$$\pi_1(p)=P\lceil\mathcal{D}_1,\pi_1(x)=X_{V,W}\lceil\mathcal{D}_1,\pi_1(u)=U\lceil\mathcal{D}_1.$$

(For the notions on unbounded ∗-representations used in what follows we refer to Ref. 13. Recall that the symbol $T\lceil\mathcal{D}_1$ means the restriction of T to $\mathcal{D}_1$.)

The ∗-representation π_1 is not yet self-adjoint (see Ref. 13, Definition 8.1.10), because, roughly speaking, $\mathcal{D}_1$ is not the largest possible domain. However, since the operators $\pi_1(p)$ and $\pi_1(x)$ are essentially self-adjoint, it follows at once from Proposition 8.1.12(v) in Ref. 13 that the adjoint representation $\pi:=(\pi_1)^*$ is self-adjoint. It is not difficult to verify that the domain $\mathcal{D}$ of the ∗-representation π is just the intersection of domains of all possible products of the operators $P,X_{V,W},U$ (see Ref. 13, Proposition 8.1.17). From these facts it follows that the operator triple $\{P,X_{V,W},U\}$ is irreducible if and only if the ∗-representation π is so and that two triples are unitarily equivalent if and only if the corresponding ∗-representations are so. That is, Propositions 2 and 3 provide also the conditions for the irreducibility and the unitary equivalence of these ∗-representations of the ∗-algebra $\mathcal{A}(q)$.

(2) Finally, we briefly discuss how operator representations of the q-deformed Heisenberg algebra $\mathcal{A}(q)$ can be constructed by means of the Schrödinger representation $\mathcal{P}:=-\mathrm{i}(d/dt)$ and $\mathcal{Q}:=t$ of the ‘‘ordinary’’ momentum and position operators.

Let us write $q=e^{-\alpha}$ with $\alpha\in\mathbb{R}$. We define three operators U, P, and X on the Hilbert space $\mathcal{H}=L^2(\mathbb{R})$:

$$U=e^{\mathrm{i}\,Q},\quad P=e^{\alpha\mathcal{P}},\quad X=\mathrm{i}(q^{-1/2}e^{-\mathrm{i}\,Q}-q^{1/2}e^{\mathrm{i}\,Q})e^{-\alpha\mathcal{P}}. \tag{19}$$

The vector space $\mathcal{D}:=\mathrm{Lin}\{e^{\gamma t-t^2};\gamma\in\mathbb{C}\}$ is a dense linear subspace of $\mathcal{H}$. Since the operator $e^{\beta\mathcal{P}},\beta\in\mathbb{R}$, acts as $(e^{\beta\mathcal{P}}f)(t)=f(t-\beta\,\mathrm{i})$ on functions $f\in\mathbb{C}$ (see, for instance, Ref. 14 for a rigorous proof), the operators U, P, and X satisfy the relations (1) and (2)$'$ and the restrictions of these operators to the invariant dense domain $\mathcal{D}$ define a $*$-representation of the $*$-algebra $\mathcal{A}(q)$. This operator representation (19) appears already somewhat hidden in Ref. 1. Indeed, if we change the variable t to e^t, then the operator triple $\{U\oplus U,(-P)\oplus P,(-X)\oplus X\}$ on the direct sum Hilbert space $\mathcal{H}\oplus\mathcal{H}$ is easily seen to be unitarily equivalent to the triple in formula (2.2) in Ref. 1.

The operator representation (19) is irreducible on $\mathcal{H}$. Obviously, U is unitary and P is self-adjoint. However, an essential disadvantage of the representation (19) is that the operator X is only symmetric, but not essentially self-adjoint. The latter can be shown by the argument used in the proof of Proposition A.2 in Ref. 14. The reason for this failure is the fact the holomorphic function $h(z)=q^{-1/2}e^{\mathrm{i}\,z}-q^{1/2}e^{-\mathrm{i}\,z}$ admits the zero $z_o=i(\alpha/2)$ in the strip $\{z\in\mathbb{C}:\ 0<\mathrm{Im}\,z<\alpha\}$.

We obtain an extended gauge theory by imposing that the matter field Lagrangian is invariant under a local gauge transformation that also contains a vector parameter besides the usual scalar one.
[S0022-2488(99)03810-4]

I. INTRODUCTION

It is well-known that usual gauge theories, described by vector fields, may arise from matter field Lagrangians by imposing their invariance under local phase transformation. In this procedure, the vector gauge field naturally appears as that one that compensates an extra term given by the derivative of the phase function.

Nowadays, there has been a great deal of interest in tensor gauge fields,[1] but these are never introduced as fields that compensate gauge transformations of matter fields. We mention that they are antisymmetric and their gauge transformations are taken as a direct extension of the vector case. Up to some multiplicative factor, these gauge transformations are given by (we concentrate on the Abelian case only)

$$\delta B_{\mu\nu}=\partial_\mu\xi_\nu-\partial_\nu\xi_\mu . \tag{1.1}$$

As we observe, if the vector gauge parameter ξ_μ is taken as the gradient of some scalar quantity, we obtain that $\delta B_{\mu\nu}=0$. This property gives us an interesting structure of constraints for gauge theories involving tensor fields. It means that their first-class constraints are not all independent (reducibility condition) and their quantization deserve some additional care comparing with the usual case of rank one gauge theories.[1,2] We also mention that antisymmetric tensor fields appear as massless solutions of modern string theories among other fields such as photons, gravitons, etc.[3]

When one takes into account the coupling between matter and tensor gauge fields, there are some discordances and inconsistencies in literature. For example, in the study of chiral anomaly, tensor gauge fields can be coupled to a tensor current $\bar\psi\Sigma^{\mu\nu}\psi$ (up to some coupling factor).[4] {We use the following convention and notation throughout this paper: $\{\gamma^\mu,\gamma^\nu\}=2\eta^{\mu\nu}$, $\eta^{\mu\nu}=\text{diag.}(+,-,-,-)$, $\gamma^0\gamma^{\mu\dagger}\gamma^0=\gamma^\mu$, $\epsilon^{0123}=1$, $\gamma_5=i\gamma_0\gamma_1\gamma_2\gamma_3$ and $\Sigma^{\mu\nu}=(i/4)[\gamma^\mu,\gamma^\nu]$.} In this situation, the gauge transformation for the matter field is considered to be the usual one, i.e., by means of a local phase exponential factor, what is compensated by the presence of a vector gauge field. The gauge transformation for the tensor gauge field, however, is not the same one as (1.1). In fact, it is taken as zero (Abelian case).

Another kind of coupling between matter and tensor gauge fields, compatible with the gauge transformation (1.1), has already been considered.[5] It has a topological nature, but the coupling is with a vector current, i.e., the interaction Lagrangian density is given by $(i/2m)\epsilon_{\mu\nu\lambda\rho}\partial^\nu B^{\lambda\rho}\bar\psi\gamma^\mu\psi$, where m is a mass parameter.[5] It is opportune to mention that topological interactions are also used

[b)]Electronic mail: barcelos@if.ufrj.br

to couple vector and tensor gauge fields[6] with the purpose to obtain an alternative mechanism of mass generation for gauge fields (vector or tensor), also compatible with the Salam–Weinberg theory when applied to the non-Abelian case.[7]

The purpose of the present paper is to show that tensor gauge fields can also be introduced as fields that may compensate extended gauge transformations for the matter field. In this case, we shall see that the transformation (1.1) is just part of a more general gauge transformation satisfying a non-Abelian algebra even though all fields are here taken as Abelian. Concerning the kinetical gauge sector, the problem appears to be more subtle, because we do not know how to write the gauge curvature tensor when fields of different ranks are put together. We also address our attention to this part and try to circumvent this problem by adopting an iterative process of looking for an invariant Lagrangian step by step. Our conclusion is that the Lagrangian we are able to obtain in this way is a trivial one, expressed in terms of collective fields.[8]

Our paper is organized as follows: In Sec. II we discuss the extended gauge transformation we are going to use for the matter field. We shall see that it is necessary to add a Lorentz-type gauge transformation in order to close the gauge algebra (which is also non-Abelian). Section III is devoted to the obtainment of the matter field Lagrangian that is invariant under this extended gauge transformation. In Sec. IV we discuss the problem of obtaining the Lagrangian for the gauge sector. We left Sec. V for some concluding remarks and introduce an Appendix where some details of the calculations are presented.

II. EXTENSION OF THE GAUGE TRANSFORMATION

Let us try an extension of the usual gauge transformation for the matter field by introducing a vector parameter. A natural way of doing this is to take

$$\delta\psi = i(\alpha(x) + \xi^\mu(x)\gamma_\mu)\psi. \tag{2.1}$$

Contrarily to the gauge transformations involving γ_5, the mass term $m\bar{\psi}\psi$ is invariant under the transformation (2.1),

$$\delta(\bar{\psi}\psi) = (i\xi_\mu\gamma^\mu\psi)^\dagger\gamma^0\psi + \bar{\psi}(i\xi_\mu\gamma^\mu\psi) = i\xi_\mu(-\psi^\dagger\gamma^{\mu\dagger}\gamma^0\psi + \bar{\psi}\gamma^\mu\psi) = i\xi_\mu(-\bar{\psi}\gamma^\mu\psi + \bar{\psi}\gamma^\mu\psi) = 0. \tag{2.2}$$

However, the kinetic term is not. Before trying to see what we have to do in order to get an invariant kinetic term, there is a problem that ought to be solved first. The transformation (2.1) does not close in an algebra. In fact,

$$[\delta_1, \delta_2]\psi = 4i\xi_1^\mu\xi_2^\nu\Sigma_{\mu\nu}\psi. \tag{2.3}$$

We observe that to close the algebra, what is an essential condition to have the theory consistently quantized, the transformation of the matter field must also include a Lorentz-type term,

$$\delta\psi = i(\alpha(x) + \xi^\mu(x)\gamma_\mu - \tfrac{1}{2}\omega(x)^{\mu\nu}\Sigma_{\mu\nu})\psi, \tag{2.4}$$

where the parameter $\omega^{\mu\nu}$ was generically taken as local. Now the transformation (2.4) closes in an algebra, whose general form reads

$$[\delta_1, \delta_2]\psi = i(\alpha_3 + \xi_3^\mu\gamma_\mu + \omega_3^{\mu\nu}\Sigma_{\mu\nu})\psi, \tag{2.5}$$

where

$$\alpha_3=0,$$

$$\xi_3^\mu=\xi_{1\nu}\omega_2^{\nu\mu}-\xi_{2\nu}\omega_1^{\nu\mu}, \tag{2.6}$$

$$\omega_3^{\mu\nu}=2(\xi_1^\mu\xi_2^\nu-\xi_2^\mu\xi_1^\nu)-\tfrac{1}{2}(\omega_1^{\mu\lambda}\omega_{2\lambda}{}^{\nu}-\omega_2^{\mu\lambda}\omega_{1\lambda}{}^{\nu}).$$

We observe that the tensor parameter $\omega_{\mu\nu}$ has actually to be local. So, to have a closed algebra, it is also necessary to include a local Lorentz-type gauge transformation. The presence of this term means that gravitation might be naturally embodied in the theory.

III. INVARIANT MATTER FIELD LAGRANGIAN

It is just a question of algebraic work to show that the transformation of the kinetic matter field Lagrangian $\mathcal{L}_0=i\bar{\psi}\partial\!\!\!/\psi$ under (2.4) is given by

$$\delta\mathcal{L}_0=i\,\delta\bar{\psi}\partial\!\!\!/\psi+i\bar{\psi}\partial\!\!\!/\delta\psi=-\bar{\psi}\gamma^\mu\psi\partial_\mu\alpha-4i\xi_\mu\bar{\psi}\Sigma^{\mu\nu}\partial_\nu\psi+i\omega_{\mu\nu}\bar{\psi}\gamma^\nu\partial^\mu\psi-\bar{\psi}\gamma^\mu\gamma^\nu\psi\partial_\mu\xi_\nu$$
$$+\tfrac{1}{2}\bar{\psi}\gamma^\lambda\Sigma^{\mu\nu}\psi\partial_\lambda\omega_{\mu\nu}. \tag{3.1}$$

We see that to implement the gauge invariance by means of gauge fields is not a simple task for the tensor sector. In order to have a general view of the problem and avoid the presence of big equations, it is convenient to use a compact notation by redefining some terms. For example, for the general transformation (2.4), we simply take

$$\delta\psi=i\Gamma\psi, \tag{3.2}$$

where

$$\Gamma=\alpha(x)+\xi^\mu(x)\gamma_\mu-\tfrac{1}{2}\omega(x)^{\mu\nu}\Sigma_{\mu\nu}. \tag{3.3}$$

Instead of expression (3.1), we now just have

$$\delta\mathcal{L}_0=\bar{\psi}[\Gamma,\gamma^\mu]\partial_\mu\psi-\bar{\psi}\partial\!\!\!/\Gamma\psi. \tag{3.4}$$

If one introduces a general compensating field A that interacts with the fermionic one as

$$\mathcal{L}_1=\bar{\psi}A\psi, \tag{3.5}$$

we obtain

$$\delta(\mathcal{L}_0+\mathcal{L}_1)=\bar{\psi}[\Gamma,\gamma^\mu]\partial_\mu\psi+\bar{\psi}(\delta A-i[\Gamma,A]-\partial\!\!\!/\Gamma)\psi. \tag{3.6}$$

We note that if one takes $\delta A=i[\Gamma,A]+\partial\!\!\!/\Gamma$, the last term of (3.6) cancels, but the invariance is only attained when $[\Gamma,\gamma^\mu]=0$. This occurs of course for the particular case of the electromagnetic field where Γ is just the parameter $\alpha(x)$. Further, with a convenient change of coordinates, this equation is also solved for a constant $\omega^{\mu\nu}$ associated with global Poincaré transformations.

To obtain the invariance for the general case, let us consider that instead of $\mathcal{L}_0$ we have a more general kind of Lagrangian like

$$\mathcal{L}_2=i\bar{\psi}K^\mu\partial_\mu\psi, \tag{3.7}$$

where K^μ is some vectorial function of auxiliary fields in a suitable combination of gamma matrices (containing of course the particular case given by $\mathcal{L}_0$). For the resulting Lagrangian $\mathcal{L}_1+\mathcal{L}_2$, we have

$$\delta(\mathcal{L}_1+\mathcal{L}_2)=\bar{\psi}([\Gamma,K^\mu]+i\,\delta K^\mu)\partial_\mu\psi+\bar{\psi}(\delta A-i[\Gamma,A]-K^\mu\partial_\mu\Gamma)\psi. \tag{3.8}$$

The invariance is finally attained if

$$\delta K^{\mu}=i[\Gamma,K^{\mu}], \tag{3.9}$$

$$\delta A=i[\Gamma,A]+K^{\mu}\partial_{\mu}\Gamma. \tag{3.10}$$

One important point to be emphasized is that, for Γ given by (3.3), the transformations (3.9) and (3.10) close in an algebra, independently of the form of K^{μ} and A (see Appendix).

To obtain a solution for Eqs. (3.9) and (3.10), we have to use some identities expressing products of gamma matrices in terms of the sixteen independent terms I, γ^{μ}, $\Sigma^{\mu\nu}$, γ_5, and $\gamma_5\gamma^{\mu}$. Let us list them below,

$$\begin{aligned}
\gamma^{\mu}\gamma^{\nu}&=\eta^{\mu\nu}-2i\Sigma^{\mu\nu},\\
\gamma_5\gamma^{\mu}\gamma^{\nu}&=\eta^{\mu\nu}\gamma_5+\epsilon^{\mu\nu\lambda\rho}\Sigma_{\lambda\rho},\\
\gamma^{\mu}\gamma^{\nu}\gamma^{\lambda}&=\eta^{\mu\nu}\gamma^{\lambda}-\eta^{\mu\lambda}\gamma^{\nu}+\eta^{\nu\lambda}\gamma^{\mu}-i\epsilon^{\mu\nu\lambda\rho}\gamma_5\gamma_{\rho},
\end{aligned} \tag{3.11}$$

$$\Sigma^{\mu\nu}\Sigma^{\lambda\rho}=\frac{1}{4}(\eta^{\mu\lambda}\eta^{\nu\rho}-\eta^{\mu\rho}\eta^{\nu\lambda})+\frac{i}{4}\epsilon^{\mu\nu\lambda\rho}\gamma_5$$
$$-\frac{i}{2}(\eta^{\mu\lambda}\eta^{\nu\alpha}\eta^{\rho\beta}+\eta^{\nu\rho}\eta^{\mu\alpha}\eta^{\lambda\beta}-\eta^{\mu\rho}\eta^{\nu\alpha}\eta^{\lambda\beta}-\eta^{\nu\lambda}\eta^{\mu\alpha}\eta^{\rho\beta})\Sigma_{\alpha\beta}.$$

To solve Eq. (3.9), we conclude that K^{μ} should be expressed by

$$K^{\mu}=H^{\mu\nu}\gamma_{\nu}+I^{\mu\nu\lambda}\Sigma_{\nu\lambda}, \tag{3.12}$$

where the fields $H^{\mu\nu}$ and $I^{\mu\nu\lambda}$ play the role of a kind of Stuckelberg fields. It is opportune to say that if we had written a simpler expression for K^{μ} as, for example, $H\gamma^{\mu}+I_{\nu}\Sigma^{\nu\mu}$, it would not work because Eq. (3.9) would lead to an expression with different symmetries on left and right sides.

Using K^{μ} given by expression (3.12), as well as the expression of Γ given by (3.3), into (3.9), we obtain that the auxiliary fields $H^{\mu\nu}$ and $I^{\mu\nu\lambda}$ must transform as

$$\delta H^{\mu\nu}=2I^{\mu\nu\lambda}\xi_{\lambda}-\omega^{\mu\nu}-H^{\mu}{}_{\lambda}\omega^{\lambda\nu}, \tag{3.13}$$

$$\delta I^{\mu\nu\lambda}=2(\eta^{\mu\lambda}\xi^{\nu}-\eta^{\mu\nu}\xi^{\lambda})+2(H^{\mu\lambda}\xi^{\nu}-H^{\mu\nu}\xi^{\lambda})+I^{\mu\rho\nu}\omega_{\rho}{}^{\lambda}-I^{\mu\rho\lambda}\omega_{\rho}{}^{\nu}. \tag{3.14}$$

Concerning the solution of (3.10), we see that it is attained by using (3.3) and (3.12) and we may conclude that the general expression for A should be

$$A=S-A_{\mu}\gamma^{\mu}+\tfrac{1}{2}B_{\mu\nu}\Sigma^{\mu\nu}+P\gamma_5+V_{\mu}\gamma_5\gamma^{\mu}. \tag{3.15}$$

It is interesting to notice the presence of chiral fields, P and V_{μ} in the gauge sector even though there is no chiral gauge transformation in the matter Lagrangian.

The transformations for the fields contained in A are obtained after a long algebraic work. The result is

$$\delta S=\partial_{\mu}\xi^{\mu}+H^{\mu\nu}\partial_{\mu}\xi_{\nu}-\tfrac{1}{4}I^{\mu\nu\lambda}\partial_{\mu}\omega_{\nu\lambda}, \tag{3.16}$$

$$\delta A_{\mu}=-\partial_{\mu}\alpha+iB_{\mu\nu}\xi^{\nu}-i\omega_{\mu\nu}A^{\nu}+H_{\mu\nu}\partial^{\nu}\alpha \tag{3.17}$$
$$+\frac{i}{2}\partial^{\nu}\omega_{\nu\mu}+\frac{i}{2}H^{\lambda\nu}\partial_{\lambda}\omega_{\nu\mu}-iI_{\lambda\mu\nu}\partial^{\lambda}\xi^{\nu},$$

$$\delta B_{\mu\nu}=-2i(\partial_\mu\xi_\nu-\partial_\nu\xi_\mu)+4i(\xi_\mu A_\nu-\xi_\nu A_\mu)$$
$$+i(\omega^\lambda{}_\mu B_{\lambda\nu}-\omega^\lambda{}_\nu B_{\lambda\mu})-2i(H_{\lambda\mu}\partial^\lambda\xi_\nu-H_{\lambda\nu}\partial^\lambda\xi_\mu)$$
$$+2I_{\lambda\mu\nu}\partial^\lambda\alpha+i(I_{\lambda\rho\mu}\partial^\lambda\omega^\rho{}_\nu-I_{\lambda\rho\nu}\partial^\lambda\omega^\rho{}_\mu), \tag{3.18}$$

$$\delta P=-2\xi_\mu V^\mu-\frac{i}{8}\epsilon_{\mu\nu\lambda\rho}I^{\alpha\mu\nu}\partial_\alpha\omega^{\lambda\rho}, \tag{3.19}$$

$$\delta V_\mu=-2P\xi_\mu-i\omega_{\mu\nu}V^\nu+\tfrac{1}{4}\epsilon_{\mu\nu\lambda\rho}\partial^\nu\omega^{\lambda\rho}$$
$$+\tfrac{1}{4}\epsilon_{\mu\nu\lambda\rho}H^{\alpha\nu}\partial_\alpha\omega^{\lambda\rho}-\tfrac{1}{2}\epsilon_{\mu\nu\lambda\rho}I^{\alpha\nu\lambda}\partial_\alpha\xi^\rho. \tag{3.20}$$

The transformations of A_μ and $B_{\mu\nu}$ contain the usual terms, that is to say, $\partial_\mu\alpha$ and $\partial_\mu\xi_\nu-\partial_\nu\xi_\mu$, respectively, but also contain some other terms in order to render the gauge invariant condition to the kinetic Lagrangian. It is interesting to notice, in these transformations, the presence of the terms $iB_{\mu\nu}\xi^\nu$ and $4i(\xi_\mu A_\nu-\xi_\nu A_\mu)$ (terms involving the same initial gauge fields coupled with the vector parameter ξ_μ).

IV. ON THE INVARIANT LAGRANGIAN FOR THE KINETICAL GAUGE SECTOR

In the usual case of invariant gauge theories just involving vector fields, the corresponding Lagrangian for the kinetical sector can be directly obtained by introducing the curvature gauge tensor, i.e.,

$$F_{\mu\nu}=i[D_\mu,D_\nu]=\partial_\mu A_\nu-\partial_\nu A_\mu, \tag{4.1}$$

where $D_\mu=\partial_\mu-iA_\mu$ is the covariant derivative. In the case of theories involving gauge fields of rank higher than one, the concept of covariant derivative is here meaningless. However, the stress tensor for these theories can be introduced as a direct extension of the vector case. For example, for a tensor gauge potential $B_{\mu\nu}$, we have

$$H_{\mu\nu\rho}=\partial_\mu B_{\nu\rho}+\partial_\rho B_{\mu\nu}+\partial_\nu B_{\rho\mu}. \tag{4.2}$$

We mention that the non-Abelian extension of this problem is much more subtle and the obtainment of the invariant Lagrangian is, in some sense, still controversial.[9] A similar problem appears to occur here, since the gauge transformations given by (3.16)–(3.20) have a non-Abelian nature. Let us try to circumvent this problem by following an iterative process. We then start from the simplest gauge invariant Lagrangian involving vector and tensor gauge fields, i.e.,

$$\mathcal{L}_g=-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}+\tfrac{1}{12}H_{\mu\nu\lambda}H^{\mu\nu\lambda}. \tag{4.3}$$

This Lagrangian is invariant under the well-known gauge transformations,

$$\delta A_\mu=-\partial_\mu\alpha,$$
$$\delta B_{\mu\nu}=-2i(\partial_\mu\xi_\nu-\partial_\nu\xi_\mu), \tag{4.4}$$

that are just part of the full gauge transformations given by (3.17) and (3.18).

The iterative process consists in increasing step-by-step these gauge transformations and looking for the corrections we have to do in the previous corresponding Lagrangian, in order to get invariance under these partial transformations. So, instead of the simplest gauge transformations (4.4), we look at (3.17) and (3.18) and take

$$\delta A_\mu = -\partial_\mu \alpha + i B_{\mu\nu} \xi^\nu,$$
$$\delta B_{\mu\nu} = -2i(\partial_\mu \xi_\nu - \partial_\nu \xi_\mu) + 4i(\xi_\mu A_\nu - \xi_\nu A_\mu). \tag{4.5}$$

Now, the Lagrangian (4.3) is not invariant under the transformations above. Actually,

$$\delta \mathcal{L}_g = i\partial^\mu F_{\mu\nu} B^{\nu\lambda} \xi_\lambda - 4i\partial^\mu H_{\mu\nu\lambda} \xi^\nu A^\lambda. \tag{4.6}$$

We try to obtain a gauge invariant Lagrangian by adding to $\mathcal{L}_g$ two new terms involving two auxiliary fields, X^μ and $Y^{\mu\nu}$ (antisymmetric in μ and ν). After some attempts, we conclude that these terms are

$$\mathcal{L}_X = X^\nu \partial^\mu F_{\mu\nu} + \tfrac{1}{2}\partial_\mu X^\mu \partial_\nu X^\nu - \tfrac{1}{2}\partial_\mu X^\nu \partial^\mu X_\nu,$$
$$\mathcal{L}_Y = -\tfrac{1}{2} Y^{\nu\lambda} \partial^\mu H_{\mu\nu\lambda} + 2\partial_\mu Y^{\mu\lambda} \partial^\nu Y_{\nu\lambda} - \tfrac{1}{2}\partial_\mu Y^{\nu\lambda} \partial^\mu Y_{\nu\lambda}. \tag{4.7}$$

The Lagrangian $\mathcal{L}_g + \mathcal{L}_X + \mathcal{L}_Y$ is invariant under the transformations (4.5) since

$$\delta X^\mu = -iB^{\mu\lambda} \xi_\lambda, \quad \delta Y^{\mu\nu} = -4i(\xi^\mu A^\nu - \xi^\nu A^\mu). \tag{4.8}$$

We then easily observe that X^μ and $Y^{\mu\nu}$ are an example of collective fields.[8] This means that the Lagrangian $\mathcal{L}_g + \mathcal{L}_X + \mathcal{L}_Y$ can be trivially rewritten as

$$\mathcal{L}_g + \mathcal{L}_X + \mathcal{L}_Y = -\tfrac{1}{4}\tilde{F}_{\mu\nu}\tilde{F}^{\mu\nu} + \tfrac{1}{12}\tilde{H}_{\mu\nu\lambda}\tilde{H}^{\mu\nu\lambda}, \tag{4.9}$$

where

$$\tilde{F}_{\mu\nu} = \partial_\mu (A_\nu - X_\nu) - \partial_\nu (A_\mu - X_\mu),$$
$$\tilde{H}_{\mu\nu\rho} = \partial_\mu (B_{\nu\rho} - Y_{\nu\rho}) + \partial_\rho (B_{\mu\nu} - Y_{\mu\nu}) + \partial_\nu (B_{\rho\mu} Y_{\rho\mu}). \tag{4.10}$$

We observe that this kind of procedure lead always to the introduction of collective fields. Although they can play important roles in the derivation of Ward identities[8] or in the implementation of quantization procedures such as the field antifield formalism,[8,10] they do not modify the physical content displayed by the original theory without using collective fields.

V. CONCLUSION

In this paper, we have extended the gauge transformation of the matter field Lagrangian by first introducing a vector gauge parameter, besides de scalar one. We have seen that the gauge transformation with these two parameters does not close in an algebra. This is only achieved if a local Lorentz-type gauge transformation is also included. We have seen that a tensor gauge field naturally arises in this procedure to compensate the extra terms that appear in the transformation of the kinetic Lagrangian. In addition, it also arises scalar, pseudo scalar and axial fields, besides the usual vector one. We have also show that the Lagrangians for the gauge sector are only obtained by means of collective fields that, even though may be useful for writing auxiliary Lagrangians in the quantization procedure due to Batalin–Vilkovisky,[10] they lead to a trivial result in the case of kinetic Lagrangians. This problem continue under study. We are trying to find out some alternative mechanism of getting invariant Lagrangians without using collective fields and also avoiding to define a curvature tensor for the theory. Possible results shall be reported elsewhere.[11]

APPENDIX: DEMONSTRATION THAT GAUGE TRANSFORMATION (3.9) AND (3.10) CLOSE IN AN ALGEBRA

In this Appendix, we are going to show that the transformations (3.9) and (3.10) close in an algebra, consistently with (2.5), independently of the form of K^μ and A, since Γ is given by (3.3).

We have already seen that the transformation (3.2) satisfies the following algebra

$$[\delta_2,\delta_1]\psi=i\Gamma_3\psi, \tag{A1}$$

where

$$\Gamma_3=i[\Gamma_1,\Gamma_2]=\alpha_3(x)+\xi_3^\mu(x)\gamma_\mu-\tfrac{1}{2}\omega(x)_3^{\mu\nu}\Sigma_{\mu\nu}, \tag{A2}$$

with α_3, ξ_3^μ, and $\omega_3^{\mu\nu}$ being given by (2.6).

For the transformation (3.9), we have

$$[\delta_2,\delta_1]K^\mu=-[\Gamma_2,[\Gamma_1,K^\mu]]+[\Gamma_1,[\Gamma_2,K^\mu]]=[K^\mu,[\Gamma_2,\Gamma_1]]=i[\Gamma_3,K^\mu], \tag{A3}$$

where we have used the Jacobi identity and the expression (A2). We actually see that the algebra closes independently of the form we have for K^μ.

For the next relation, we have

$$\begin{aligned}\delta_2\delta_1A&=i[\Gamma_2,\delta_1,A]+\delta_1K^\mu\partial_\mu\Gamma_2\\&=-[\Gamma_2,[\Gamma_1,A]]+i[\Gamma_2,K^\mu\partial_\mu\Gamma_1]+\delta_1K^\mu\partial_\mu\Gamma_2\\&=-[\Gamma_2,[\Gamma_1,A]]+\delta_2K^\mu\partial_\mu\Gamma_1+iK^\mu[\Gamma_2,\partial_\mu\Gamma_1]+\delta_1K^\mu\partial_\mu\Gamma_2.\end{aligned} \tag{A4}$$

Hence,

$$\begin{aligned}[\delta_2,\delta_1]A&=-[\Gamma_2,[\Gamma_1,A]]-[\Gamma_1,[A,\Gamma_2]]+iK^\mu[\Gamma_2,\partial_\mu\Gamma_1]+iK^\mu[\Gamma_1,\partial_\mu\Gamma_2]\\&=[A,[\Gamma_2,\Gamma_1]]+iK^\mu\partial_\mu\Gamma_3=i[\Gamma_3,A]+K^\mu\partial_\mu\Gamma_3,\end{aligned} \tag{A5}$$

where we have used again the Jacobi identity and (A2).

(Received 30 November 1998; accepted for publication 21 June 1999)

A precise calculation of the ground-state energy of the complex $\mathcal{PT}$-symmetric Hamiltonian $H=p^2+\frac{1}{4}x^2+i\lambda x^3$, is performed using high-order Rayleigh–Schrödinger perturbation theory. The energy spectrum of this Hamiltonian has recently been shown to be real using numerical methods. Here we present convincing numerical evidence that the Rayleigh–Schrödinger perturbation series is Borel summable, and show that Padé summation provides excellent agreement with the real energy spectrum. Padé analysis provides strong numerical evidence that the once-subtracted ground-state energy considered as a function of λ^2 is a Stieltjes function. The analyticity properties of this Stieltjes function lead to a dispersion relation that can be used to compute the imaginary part of the energy for the related real but unstable Hamiltonian $H=p^2+\frac{1}{4}x^2-\epsilon x^3$. *© 1999 American Institute of Physics.* [S0022-2488(99)01810-1]

It has been conjectured[1] that the spectrum of the complex Hamiltonian,

$$H=p^2+\frac{1}{4}x^2+i\lambda x^3, \tag{1}$$

is real and positive. Although there is no rigorous proof of this conjecture, it has been argued[2] that the reality and positivity of the spectrum is a consequence of the $\mathcal{PT}$ symmetry of H. (Recall that the parity operation acts as $\mathcal{P}: p\to -p$ and $\mathcal{P}: x\to -x$ and that the antiunitary time reversal operation acts as $\mathcal{T}: p\to -p$, $\mathcal{T}: x\to -x$, and $\mathcal{T}: i\to -i$.) The notion that $\mathcal{PT}$ symmetry can replace the much more restrictive condition of hermiticity has been studied in the context of quasiexactly solvable quantum theories,[3] new kinds of symmetry breaking in quantum field theory,[4,5] and complex periodic potentials.[6] There have been many other instances of non-Hermitian $\mathcal{PT}$-invariant Hamiltonians in physics. Energies of solitons in Toda theories with imaginary coupling have been found to be real.[7] Hamiltonians rendered non-Hermitian by an imaginary external field have been used to study population biology[8] and to study delocalization transitions, such as vortex flux-line depinning in type-II superconductors.[9]

In this paper we study the large-order behavior of Rayleigh–Schrödinger perturbation theory for the ground-state energy of the complex $\mathcal{PT}$-symmetric Hamiltonian (1). Note that this Hamiltonian describes a $0+1$-dimensional ϕ^3 field theory, and recall that ϕ^3 theories were the first quantum field theories in which the divergences of perturbation theory were studied.[10] For the Hamiltonian (1) the perturbation series for the ground-state energy is divergent, and we give strong numerical evidence that it is Borel summable. Furthermore, by studying the numerical properties of the Padé approximants we infer that the (once-subtracted) ground-state energy considered as a function of λ^2 is a Stieltjes function. This is a very strong result because it implies analyticity in the cut-λ^2 plane and other properties. [It is surprising that this Stieltjes condition holds for a complex Hamiltonian such as (1); the proof that the once-subtracted ground-state

energy of the conventional λx^{2N} anharmonic oscillator is a Stieltjes function of λ makes use of hermiticity.] We then use these analyticity properties to establish a dispersion relation that yields the precise large-order behavior of the perturbation series.

Let us consider the conventional Rayleigh–Schrödinger perturbation series about the ground state ($E_0=\frac{1}{2}$) of the harmonic oscillator $H_0=p^2+\frac{1}{4}x^2$. The perturbed energy has an asymptotic series representation in powers of λ^2 because the perturbation x^3 is an odd function of x:

$$E(\lambda)-\frac{1}{2}\sim\sum_{n=1}^{\infty} b_n\lambda^{2n}. \tag{2}$$

[We have chosen the form of H_0 so that the perturbative expansion coefficients b_n in (2) are integers.]

Using recursion formulas, we can easily generate as many terms as desired in this expansion. The coefficients b_n alternate in sign, and their magnitude grows rapidly with n. The first 20 values are listed in Table I. We have computed enough of the coefficients b_n so that we can fit the leading large-n behavior as

$$b_n\sim(-1)^{n+1}\frac{60^{n+1/2}}{(2\pi)^{3/2}}\Gamma\left(n+\frac{1}{2}\right)\left[1-O\left(\frac{1}{n}\right)\right]. \tag{3}$$

Therefore, although divergent, the series in (2) is potentially Borel summable.[11,12] Observe that if the factor of i were absent from the Hamiltonian (1), then the perturbation coefficients b_n would not alternate in sign and the perturbation series would not be Borel summable.

We have performed a Padé analysis[11,12] on the divergent series for the once-subtracted ground-state energy $[E(\lambda)-\frac{1}{2}]/\lambda^2$. Using the first 46 perturbation coefficients b_n, we find that for all real positive λ^2 the diagonal Padé sequence $P_N^N(\lambda^2)$ is monotone decreasing with increasing N, and the off-diagonal Padé sequence $P_{M+1}^M(\lambda^2)$ is monotone increasing with increasing M:

$$P_1^0<P_2^1<P_3^2<\cdots<P_{M+1}^M<\cdots<P_N^N<\cdots<P_2^2<P_1^1<P_0^0. \tag{4}$$

TABLE II. The diagonal and off-diagonal Padé sequences $P_N^N(\lambda^2)$ and $P_{N+1}^N(\lambda^2)$ evaluated at $\lambda=0.125$. Observe the rapid convergence and note that the inequalities in (4) are satisfied.

21	6.074 575 882	6.074 573 036
22	6.074 575 311	6.074 573 460

The results for $\lambda=0.125$ are shown in Table II. If the inequalities in (4) hold for all N and M and for all real positive λ^2, then it is rigorously true that $[E(\lambda)-\frac{1}{2}]/\lambda^2$ is a Stieltjes function of λ^2.[12] This means that $[E(\lambda)-\frac{1}{2}]/\lambda^2$ is analytic in the cut-λ^2 plane, vanishes as $|\lambda^2|\to\infty$, and is a Herglotz function of λ^2. [A function $f(z)$ is said to be Herglotz if $\mathrm{Im}\, f(z)$ is positive (negative) when z is in the upper (lower) plane.] The fact that (4) holds for $0\leqslant M,\ N\leqslant 23$ provide strong numerical evidence that $[E(\lambda)-\frac{1}{2}]/\lambda^2$ is a Stieltjes function. We stress that this is a much stronger result than merely saying that the divergent series (2) is Borel summable.

Furthermore, in addition to the inequality in (4), the limits of the two Padé sequences appear to be identical. Therefore, we can extract values for the Padé summed energy from the two Padé sequences. The best estimate for the ground-state energy is obtained by averaging the last diagonal and off-diagonal Padé approximants. (To obtain an estimate of the ground-state energy from this average we multiply the average by λ^2 and add $\frac{1}{2}$.) The results are shown in Table III for various values of the coupling λ. Previous numerical calculations of the ground-state energy were obtained by direct numerical integration of the Schrödinger equation (see Ref. 2); this technique gave a typical accuracy of about five decimal places. The agreement between the method of numerical integration and the Padé summation is excellent. Moreover, for $\lambda<\frac{1}{10}$ the Padé technique provides an accuracy of more than ten decimal places. The agreement is better for smaller values of λ, as is expected, because of a faster convergence rate of the Padé sequence.

The above Padé analysis provides strong evidence that the once-subtracted ground-state energy is analytic in the cut-λ^2 plane. Thus, we can derive a dispersion relation in the expansion parameter λ^2 to deduce the leading behavior of the imaginary part of the energy for negative λ^2. Physically, this means that we can compute the imaginary part of the energy (and hence the decay width) of the unstable ground state of the *real* Hamiltonian,

$$H=p^2+\frac{1}{4}x^2-\epsilon x^3. \tag{5}$$

TABLE III. The ground-state energy for the Hamiltonian (1) for various values of the coupling λ; the ground-state energy was computed by Padé summation and by direct numerical integration. The Padé sequences were computed for the once-subtracted energy $[E(\lambda)-\frac{1}{2}]/\lambda^2$. The diagonal Padé energy refers to the energy extracted from the diagonal Padé sequence $P_N^N(\lambda^2)$, and the off-diagonal Padé energy refers to the energy extracted from the off-diagonal Padé sequence $P_{N+1}^N(\lambda^2)$. The best estimate for Padé energy is the average of the diagonal and off-diagonal values.

λ	Diagonal Padé energy	Off-diagonal Padé energy	Padé energy	Numerical energy
0.015 625	0.502 63	0.502 63	0.502 63	0.502 63
0.031 25	0.509 98	0.509 98	0.509 98	0.509 98
0.0625	0.533 93	0.533 93	0.533 93	0.533 93
0.125	0.594 92	0.594 92	0.594 92	0.594 92
0.25	0.713 05	0.712 84	0.712 95	0.712 94
0.5	0.914 45	0.890 35	0.902 40	0.900 26
1.0	1.400 07	1.058 17	1.229 12	1.167 46
2.0	3.160 75	1.140 32	2.150 53	1.530 78

Note that the ambiguity in the choice of the sign of the coupling ϵ corresponds to choosing the sign of i in (1). This has no effect on the decay width; the sign simply distinguishes the direction (left or right) in which the potential in (5) is unstable.

In the $t=\lambda^2$ plane there is a cut along the negative t axis, and in the standard way the[13–15] b_n coefficients are related to the discontinuity across the cut by the exact formula

$$b_n=\frac{1}{\pi}\int_0^\infty \frac{dt}{t}\,\frac{D(-t)}{t^n}, \tag{6}$$

where $D(-t)(t>0)$ is the imaginary part of $E(\lambda)-\frac{1}{2}$, evaluated with λ^2 negative. From the growth estimate (3) we deduce that

$$D(-t)\sim-\frac{e^{-1/(60t)}}{2\sqrt{2\pi t}}[1+O(t)] \quad (t\to 0^+). \tag{7}$$

Thus, the leading contribution (for small ϵ) to the imaginary part of the energy for the unstable ground state of the Hamiltonian (5) is

$$\mathrm{Im}[E(\epsilon)]\sim\frac{\exp\left(-\frac{1}{60\epsilon^2}\right)}{(2\pi)^{3/2}\epsilon} \quad (\epsilon\to 0^+). \tag{8}$$

There are several ways to check this result. First, it agrees with a direct leading-order WKB calculation[16] of the imaginary part of the energy of the unstable ground state of the real Hamiltonian (5). Second, applying the ''bounce'' method[17] to the real unstable Hamiltonian (5), we find that

$$\mathrm{Im}[E(\epsilon)]_{\mathrm{bounce}}\sim cS_0^{1/2}\exp(-S_0) \quad (\epsilon\to 0^+), \tag{9}$$

where the action S_0 of the bounce solution is given by

$$S_0=2\int_0^{1/4\epsilon} dx\,\sqrt{\frac{1}{4}x^2-\epsilon x^3}=\frac{1}{60\epsilon^2}, \tag{10}$$

and c is a constant (whose determination requires the computation of a fluctuation determinant).

Finally, the answer in (8) is in agreement with the variational perturbation theory analysis in Ref. 18. In fact, Ref. 18 contains a higher-order WKB expression for $\mathrm{Im}[E(\epsilon)]$. Inserting this higher-order WKB result into the dispersion relation (6), we obtain a WKB-based prediction for the corrections to the leading-order growth of the b_n coefficients given in (3):

$$b_n^{\mathrm{WKB}} \sim (-1)^{n+1} \frac{60^{n+1/2}}{(2\pi)^{3/2}} \Gamma\left(n+\frac{1}{2}\right)\left[1-\frac{169}{120(n-\frac{1}{2})}-\frac{44\,507}{28\,800(n-\frac{1}{2})(p-\frac{3}{2})}\right.$$
$$-\frac{9\,563\,539}{1\,920\,000(n-\frac{1}{2})(n-\frac{3}{2})(n-\frac{5}{2})}-\frac{189\,244\,716\,209}{8\,294\,400\,000(n-\frac{1}{2})(n-\frac{3}{2})(n-\frac{5}{2})(n-\frac{7}{2})}$$
$$-\frac{42\,943\,442\,679\,817}{331\,776\,000\,000(n-\frac{1}{2})(n-\frac{3}{2})(n-\frac{5}{2})(n-\frac{7}{2})(n-\frac{9}{2})}$$
$$-\frac{342\,541\,916\,236\,654\,541}{398\,131\,200\,000\,000(n-\frac{1}{2})(n-\frac{3}{2})(n-\frac{5}{2})(n-\frac{7}{2})(n-\frac{9}{2})(n-\frac{11}{2})}$$
$$\left.-\frac{933\,142\,404\,651\,555\,165\,943}{143\,327\,232\,000\,000\,000(n-\frac{1}{2})(n-\frac{3}{2})(n-\frac{5}{2})(n-\frac{7}{2})(n-\frac{9}{2})(n-\frac{11}{2})(n-\frac{13}{2})}-\cdots\right]. \tag{11}$$

With these higher-order corrections, this growth estimate of the b_n coefficients is spectacularly accurate. For example,

$$\frac{b_{46}^{\mathrm{WKB}}}{b_{46}} = 1.000\,000\,008\,07. \tag{12}$$

To conclude, we note that the strategy employed here to relate the large-order Rayleigh–Schrödinger perturbation theory coefficients of a stable (and Borel-summable) problem to the imaginary part of the energy of an unstable (and Borel-nonsummable) problem is familiar from the quartic double-well potential $H=p^2+\frac{1}{4}x^2+gx^4$, which is stable when $g>0$ and unstable when $g<0$.[19,13,15] The novelty in this paper is that we begin with a *complex* Hamiltonian $H=p^2+\frac{1}{4}x^2+i\lambda x^3$, which, despite being non-Hermitian, nevertheless appears to be stable in the sense that it has a real and positive (and discrete) energy spectrum and a Borel-summable perturbation expansion for the ground-state energy. We can then relate the large-order perturbation coefficients to the imaginary part of the energy of an unstable state of the real but unstable Hamiltonian $H=p^2+\frac{1}{4}x^2-\epsilon x^3$. It is interesting to note that the quartic case is relevant to the physics of instantons[20,17] while the cubic case is relevant to ''bounces'' in scalar field theories[17] and to string perturbation theory.[21]

(Received 30 July 1998; accepted for publication 22 April 1999)

Using the self-adjoint character of the operators governing the field perturbations in the Einstein–Yang–Mills-dilaton–axion theory, we demonstrate that a covariantly (both gauge covariant and space–time covariant) conserved current associated with the coupled field perturbations arises, by contrast to other approaches, in a natural way. Our results cover, in particular, the bosonic low-energy limit of the string theory. We discuss how the present results can serve as a starting point for future investigations. © *1999 American Institute of Physics.* [S0022-2488(99)01409-7]

I. INTRODUCTION

The concepts of energy and momentum have been under investigation for a long time in the context of field theories involving gravity, in the general relativity itself, and in the modern unified theories. The main problem is to find a local expression that is physically meaningful and related to some form of continuity equation, which yields a conserved quantity. In the scheme of the unified theories such as supergravity and (super)string theory, the problem may become more complicated since they predict that gravity is mediated by one or several long-range scalar fields in addition to the ordinary tensor field of the Einstein theory, being the main feature of these scalar fields that they appear nonminimally coupled to the gravity and matter fields. However, although such conservation laws have not been established in the exact theories, some conservations laws are known in the context of perturbation theory, for example, in the frameworks of the ordinary Einstein–Maxwell theory,[1] Yang–Mills theory, and general relativity.[2,3] On the other hand, although the approach of Refs. 1, 2 may provide a general method for constructing a conserved current for the field perturbations—called the symplectic current—in various gravity theories, the main novelty that arises in the present approach is that the symplectic current does not need to be defined *a priori* (and subsequently it will have the wanted properties), but that it emerges naturally as a consequence of the self-adjointness of the equations for the field perturbations. The self-adjointness is, as will be seen below, an intrinsic property of the operators governing the field perturbations in the Einstein–Yang–Mills-dilaton–axion (EYMDA) theory.

We start with the (bosonic) four-dimensional effective action,

$$S=\int \sqrt{-g}d^4x\left\{R-2(\partial_\mu\phi)\partial^\mu\phi-\frac{1}{2}\zeta(\phi)(\partial_\mu\eta)\partial^\mu\eta+\xi(\phi)\mathrm{Tr}(F_{\mu\nu}F^{\mu\nu})\right.$$
$$\left.+\omega(\eta)\mathrm{Tr}(F_{\mu\nu}\tilde{F}^{\mu\nu})+V(\phi,\eta)\right\}, \tag{1}$$

where R is the Ricci scalar, $F_{\mu\nu}$ is the Yang–Mills field given by the matrix-valued two-form $F_{\mu\nu}=2\nabla_{[\mu}A_{\nu]}+2A_{[\mu}A_{\nu]}$. Here we consider non-Abelian gauge fields with an arbitrary gauge group [then, the electromagnetic case is, of course, just that one corresponding to the gauge group $U(1)$]. $\tilde{F}^{\mu\nu}=(1/2\sqrt{-g})\,\epsilon^{\mu\nu\lambda\rho}F_{\lambda\rho}$ is the dual matrix of $F_{\mu\nu}$. Tr denotes, as usual, the trace.

[a)]Electronic mail: rcartas@sirio.ifuap.buap.mx

Furthermore, ϕ and η correspond to the dilaton and axion fields, respectively. The arbitrary coupling functions $\zeta(\phi)$, $\xi(\phi)$, and $\omega(\eta)$ depend only on ϕ and η and contain no derivatives of these fields. By suitable choice of these coupling functions, the low-energy effective action in string theory is covered. The peculiar nature of the dilaton and axion couplings to tensor fields is due to the presence of these functions. On the other hand, $V(\phi,\eta)$ is known as the dilaton–axion potential, and also depends on ϕ and η alone. V may be a Liouville-type dilaton potential (a cosmological constant term with dilaton coupling); V also may contain the possible mass terms for dilaton and axion fields, i.e., it can take the form $V=m_D\phi^2+m_A\eta^2$, where m_D and m_A are the masses of the dilaton and axion fields respectively, etc.

Variations of S with respect to the axion field, dilaton field, gauge field A_μ, and metric tensor $g_{\mu\nu}$ give, respectively, the following equations of motion:

$$\nabla_\mu(\zeta\ \partial^\mu\eta)+\frac{d\omega}{d\eta}\mathrm{Tr}(F_{\mu\nu}\tilde{F}^{\mu\nu})+\frac{\partial V}{\partial\eta}=0, \tag{2}$$

$$\boldsymbol{\nabla}_\mu\ \boldsymbol{\nabla}^\mu\phi+\frac{1}{4}\left[\frac{d\xi}{d\phi}\mathrm{Tr}(F_{\mu\nu}F^{\mu\nu})-\frac{1}{2}\frac{d\zeta}{d\phi}(\partial_\mu\eta)\partial^\mu\eta+\frac{\partial V}{\partial\phi}\right]=0, \tag{3}$$

$$\mathbb{V}_\mu(\omega\tilde{F}^{\mu\nu}+\xi F^{\mu\nu})=0,\quad \mathbb{V}_\mu\tilde{F}^{\mu\nu}=0, \tag{4}$$

where $\mathbb{V}_\mu=\nabla_\mu+[A_\mu,\ ]$; and the Einstein field equations read as

$$R_{\mu\nu}-\tfrac{1}{2}g_{\mu\nu}R=T_{\mu\nu}, \tag{5}$$

with the energy–momentum tensor of matter given by

$$\begin{aligned}T_{\mu\nu}=&2(\partial_\mu\phi)\partial_\nu\phi+\tfrac{1}{2}\zeta(\partial_\mu\eta)\partial_\nu\eta-g_{\mu\nu}[(\partial^\alpha\phi)\partial_\alpha\phi+\tfrac{1}{4}\zeta(\partial^\alpha\eta)\partial_\alpha\eta]\\&-2\xi\mathrm{Tr}(F_{\mu\alpha}F_{\nu\beta}g^{\alpha\beta}-\tfrac{1}{4}g_{\mu\nu}F_{\rho\lambda}F^{\rho\lambda})+\tfrac{1}{2}g_{\mu\nu}V.\end{aligned} \tag{6}$$

The remainder of the paper is organized as follows. Section II is devoted to the linearization of the equations of motion (2)–(6) around a general curved background. In Sec. III we establish the general relationship between adjoint operators and conserved currents, which allows us in Sec. IV to find the corresponding symplectic current for the perturbed EYMDA theory. Finally, in Sec. V we conclude and discuss future directions that this research will take.

II. LINEARIZATION OF EYMDA THEORY

In the following expressions and what follows the superscript B denotes the corresponding linear perturbations. In particular, the metric, gauge potential, dilaton, and axion perturbations are represented by $h_{\mu\nu}$, b_μ, ϕ^{B}, and η^{B}, respectively.

Furthermore, we can find that

$$(g^{\mu\nu})^{\mathrm{B}}=-h^{\mu\nu},\quad g^{\mathrm{B}}=gg_{\mu\nu}h^{\mu\nu},\quad F^{\mathrm{B}}_{\mu\nu}=\mathbb{V}_\mu b_\nu-\mathbb{V}_\nu b_\mu,$$

$$(\tilde{F}^{\mu\nu})^{\mathrm{B}}=\frac{2}{\sqrt{-g}}\epsilon^{\mu\nu\alpha\beta}\mathbb{V}_\alpha b_\beta-\frac{1}{2}\tilde{F}^{\mu\nu}g_{\alpha\beta}h^{\alpha\beta},$$

$$\xi^{\mathrm{B}}=\frac{d\xi}{d\phi}\phi^{\mathrm{B}},\quad\left[\left(\frac{d\xi}{d\phi}\right)^{\mathrm{B}}=\frac{d^2\xi}{d\phi^2}\phi^{\mathrm{B}}\right],$$

$$\zeta^{\mathrm{B}}=\frac{d\zeta}{d\phi}\phi^{\mathrm{B}},\quad\omega^{\mathrm{B}}=\frac{d\omega}{d\eta}\eta^{\mathrm{B}},$$

$$
\begin{aligned}
V^{\mathrm{B}} &= \frac{\partial V}{\partial \phi}\phi^{\mathrm{B}} + \frac{\partial V}{\partial \eta}\eta^{\mathrm{B}},\\
\left(\frac{\partial V}{\partial \phi}\right)^{\mathrm{B}} &= \frac{\partial^2 V}{\partial \phi^2}\phi^{\mathrm{B}} + \frac{\partial^2 V}{\partial \eta \partial \phi}\eta^{\mathrm{B}},\\
\left(\frac{\partial V}{\partial \eta}\right)^{\mathrm{B}} &= \frac{\partial^2 V}{\partial \phi \partial \eta}\phi^{\mathrm{B}} + \frac{\partial^2 V}{\partial \eta^2}\eta^{\mathrm{B}},\\
(\Gamma^{\lambda}_{\mu\nu})^{\mathrm{B}} &= \tfrac{1}{2} g^{\lambda\rho}[\nabla_\mu h_{\nu\rho} + \nabla_\nu h_{\mu\rho} - \nabla_\rho h_{\mu\nu}],
\end{aligned}
\tag{7}
$$

in the above expressions and throughout, the covariant derivative ∇_μ is with respect to the background metric $g_{\mu\nu}$, and similarly $\not{\nabla}_\mu$ is with respect to both background metric and background gauge field A_μ. The indices are raised and lowered by means of the background metric, for example, $h^{\mu\nu} = g^{\mu\alpha} g^{\nu\beta} h_{\alpha\beta}$, that will be used implicitly below.

In addition, using the expressions (7), one easily finds that

$$
\begin{aligned}
[\mathrm{Tr}(F_{\mu\nu}F^{\mu\nu})]^{\mathrm{B}} &= \mathrm{Tr}[4F^{\mu\nu}\not{\nabla}_\mu b_\nu + 2g_{\rho\nu}F^{\nu\alpha}F^{\mu\rho}h_{\mu\alpha}],\\
[\mathrm{Tr}(F_{\mu\nu}\tilde{F}^{\mu\nu})]^{\mathrm{B}} &= \mathrm{Tr}[4\tilde{F}^{\mu\nu}\not{\nabla}_\mu b_\nu - \tfrac{1}{2}F_{\rho\gamma}\tilde{F}^{\rho\gamma}g^{\mu\nu}h_{\mu\nu}].
\end{aligned}
\tag{8}
$$

In this manner, using the expressions (7) and (8) we can find that the linearized versions of the equations of motion (2)–(4) are given, respectively, by (after some arrangements)

$$
\begin{aligned}
&-\left\{\zeta\nabla_\mu\partial^\mu + (\partial^\mu\zeta)\partial_\mu + \frac{d^2\omega}{d\eta^2}\mathrm{Tr}(F_{\mu\nu}\tilde{F}^{\mu\nu}) + \frac{\partial^2 V}{\partial\eta^2}\right\}\eta^{\mathrm{B}} - \left\{\left[\nabla_\mu\left(\frac{d\zeta}{d\phi}\partial^\mu\eta\right)\right] + \frac{d\zeta}{d\phi}(\partial^\alpha\eta)\partial_\alpha\right.\\
&\left.+\frac{\partial^2 V}{\partial\eta\partial\phi}\right\}\phi^{\mathrm{B}} - 4\frac{d\omega}{d\eta}\mathrm{Tr}(\tilde{F}^{\mu\nu}\not{\nabla}_\mu b_\nu) + \{\zeta[(\nabla^\alpha\partial^\mu\eta) + (\partial^\alpha\eta)\nabla^\mu - \tfrac{1}{2}g^{\mu\alpha}(\partial^\rho\eta)\nabla_\rho]\\
&+(\partial^\mu\zeta)(\partial^\alpha\eta)\}h_{\mu\alpha} + \frac{1}{2}\frac{d\omega}{d\eta}\mathrm{Tr}(F_{\rho\lambda}\tilde{F}^{\rho\gamma}g^{\mu\alpha}h_{\mu\alpha}) = 0,
\end{aligned}
\tag{9}
$$

$$
\begin{aligned}
&\left\{\frac{d\zeta}{d\phi}(\partial^\mu\eta)\partial_\mu - \frac{\partial^2 V}{\partial\phi\,\partial\eta}\right\}\eta^{\mathrm{B}} - 4\left\{\frac{1}{4}\left[\mathrm{Tr}(F_{\mu\nu}F^{\mu\nu})\frac{d^2\xi}{d\phi^2} - \frac{1}{2}\frac{d^2\zeta}{d\phi^2}(\partial^\mu\eta)(\partial_\mu\eta) + \frac{\partial^2 V}{\partial\phi^2}\right] + \nabla^\mu\nabla_\mu\right\}\phi^{\mathrm{B}}\\
&-4\frac{d\xi}{d\phi}\mathrm{Tr}(F^{\mu\nu}\not{\nabla}_\mu b_\nu) - 4\left\{-(\nabla^\alpha\nabla^\mu\phi) + \frac{1}{8}\frac{d\zeta}{d\phi}(\partial^\mu\eta)(\partial^\alpha\eta) - (\nabla^\alpha\phi)\nabla^\mu\right.\\
&\left.+\frac{1}{2}g^{\mu\alpha}(\nabla^\rho\phi)\nabla_\rho\right\}h_{\mu\alpha} - 2\frac{d\xi}{d\phi}\mathrm{Tr}(F^{\lambda\mu}F^{\alpha}{}_{\lambda}h_{\mu\alpha}) = 0,
\end{aligned}
\tag{10}
$$

$$
\begin{aligned}
&4g^{\lambda\mu}\tilde{F}_{\lambda\nu}\partial_\mu\left(\frac{d\omega}{d\eta}\eta^{\mathrm{B}}\right) + 4\not{\nabla}^\mu\left(\frac{d\xi}{d\phi}F_{\mu\nu}\phi^{\mathrm{B}}\right) + 4\left\{g_\nu{}^\mu\not{\nabla}^\rho(\xi\not{\nabla}_\rho) - \not{\nabla}^\mu(\xi\not{\nabla}_\nu)\right.\\
&\left.+\frac{1}{\sqrt{-g}}g_{\alpha\nu}\epsilon^{\rho\alpha\lambda\mu}(\partial_\rho\omega)\partial_\lambda\right\}b_\mu + 4\left\{\frac{1}{2}g^{\mu\alpha}[\xi F^\rho{}_\nu\nabla_\rho - (\partial_\rho\omega)\tilde{F}^\rho{}_\mu]\right.\\
&\left.-g^\mu{}_\nu[\xi F^{\rho\alpha}\nabla_\rho - (\partial_\rho\omega)\tilde{F}^{\rho\mu}]\right\}h_{\mu\alpha} - 4\not{\nabla}^\alpha(\xi F^\mu{}_\nu h_{\mu\alpha}) = 0,
\end{aligned}
\tag{11}
$$

where we have multiplied Eqs. (9)–(11) by the factors -1, -4, 4, respectively, for future convenience.[4] In order to linearize the Einstein equations (5) and (6), it is suitable to write the left-hand side of Eqs. (5) as $R^{\mathrm{B}}_{\mu\nu}-\frac{1}{2}g_{\mu\nu}R^{\mathrm{B}}-\frac{1}{2}Rh_{\mu\nu}$, where

$$R^{\mathrm{B}}_{\mu\nu}-\tfrac{1}{2}g_{\mu\nu}R^{\mathrm{B}}=[\mathcal{E}_V(h_{\alpha\beta})]_{\mu\nu}=-\nabla_\mu\nabla_\nu g_{\alpha\beta}h^{\alpha\beta}-\nabla^\alpha\nabla_\alpha h_{\mu\nu}+\nabla^\rho\nabla_\nu h_{\rho\mu}+\nabla^\rho\nabla_\mu h_{\rho\nu}$$
$$+g_{\mu\nu}(\nabla^\rho\nabla_\rho g_{\alpha\beta}h^{\alpha\beta}-\nabla^\alpha\nabla^\beta h_{\alpha\beta}), \tag{12}$$

i.e., $\mathcal{E}_V$ is the operator describing gravitational perturbations of vacuum space–times.[4] The perturbed term $-\frac{1}{2}Rh_{\mu\nu}$ will be absorbed in the operator $\mathcal{E}_S$ in the next equation. In this manner, using Eqs. (7) and (8), the perturbed version of Einstein equations takes the form

$$-\left\{\zeta(\partial_{(\mu}\eta)\partial_{\alpha)}-\frac{1}{2}\zeta g_{\mu\alpha}(\partial^\rho\eta)\partial_\rho+\frac{1}{2}g_{\mu\alpha}\frac{\partial V}{\partial\eta}\right\}\eta^{\mathrm{B}}-\left\{4(\partial_{(\mu}\phi)\partial_{\alpha)}\right.$$
$$\left.-2g_{\mu\alpha}(\partial^\rho\phi)\partial_\rho+\frac{1}{2}\frac{d\zeta}{d\phi}\left[(\partial_\mu\eta)(\partial_\alpha\eta)-\frac{1}{2}g_{\mu\alpha}(\partial^\rho\eta)(\partial_\rho\eta)\right]+\frac{1}{2}g_{\mu\alpha}\frac{\partial V}{\partial\phi}-\frac{d\xi}{d\phi}\mathrm{Tr}(T^{\mathrm{YM}}_{\mu\alpha})\right\}\phi^{\mathrm{B}}$$
$$-2\xi\ \mathrm{Tr}(\{g_{\mu\alpha}F^{\lambda\gamma}\nabla_\lambda+2[F^\gamma{}_{(\mu}\nabla_{\alpha)}+g^\gamma{}_{(\mu}F_{\alpha)}{}^\lambda\nabla_\lambda]\}b_\gamma)+[(\mathcal{E}_V+\mathcal{E}_S)h_{\rho\gamma}]_{\alpha\mu}=0, \tag{13}$$

where

$$T^{\mathrm{YM}}_{\mu\nu}=2[F_{\mu\alpha}F_{\nu\beta}g^{\alpha\beta}-\tfrac{1}{4}g_{\mu\nu}F_{\rho\lambda}F^{\rho\lambda}],$$

is the usual energy–momentum tensor of the background Yang–Mills field; in addition, $\mathcal{E}_S$ represents the operator acting on the metric perturbations associated with the perturbed tensor of matter and only corresponds to a function, without containing differential operators.

The coupled equations for the field perturbations (9)–(11) and (13) can be identified with the first, second, third, and fourth rows, respectively, of the following matrix:

$$\begin{bmatrix} \mathcal{E}_A & \mathcal{E}_{AD} & \mathcal{E}_{A(\mathrm{YM})} & \mathcal{E}_{AG} \\ \mathcal{E}_{DA} & \mathcal{E}_D & \mathcal{E}_{D(\mathrm{YM})} & \mathcal{E}_{DG} \\ \mathcal{E}_{(\mathrm{YM})A} & \mathcal{E}_{(\mathrm{YM})D} & \mathcal{E}_{\mathrm{YM}} & \mathcal{E}_{(\mathrm{YM})G} \\ \mathcal{E}_{GA} & \mathcal{E}_{GD} & \mathcal{E}_{G(\mathrm{YM})} & \mathcal{E}_G \end{bmatrix}\begin{bmatrix}\eta^{\mathrm{B}} \\ \phi^{\mathrm{B}} \\ (b_\mu) \\ (h_{\mu\nu})\end{bmatrix}=0. \tag{14}$$

From Eqs. (9)–(11) and (13) we can note that the $\mathcal{E}$'s are linear partial differential operators involving only the background fields, which satisfy Eqs. (2)–(6); furthermore, the presence of the coupling functions and of the dilaton–axion potential makes that all field perturbations be present in each of the perturbation equations.

At first sight it might appear that, due to the very complicated appearance of Eqs. (9)–(11) and (13), they have not any special property; however, as will be seen in the next section, they have an intrinsic property, the self-adjointness, which will guarantee automatically the existence of a conserved current for the field perturbations.

III. ADJOINT OPERATORS AND CONSERVED CURRENTS

According to the definition introduced in Ref. 5, if $\mathcal{P}$ is a linear partial differential operator, which takes matrix-valued tensor fields into themselves, then, the adjoint operator of $\mathcal{P}$, is that operator $\mathcal{P}^\dagger$, such that

$$\mathrm{Tr}\{f^{\rho\sigma\cdots}[\mathcal{P}(g_{\mu\nu\ldots})]_{\rho\sigma\ldots}-[\mathcal{P}^\dagger(f^{\rho\sigma\cdots})]^{\mu\nu\cdots}g_{\mu\nu\ldots}\}=\nabla_\mu J^\mu, \tag{15}$$

where Tr denotes again the trace and J^μ is some vector field (this definition generalizes that given by Wald in Ref. 4). From this definition, if $\mathcal{Q}$ and $\mathcal{R}$ are any two linear operators, one easily finds that

$$(\mathcal{Q}\mathcal{R})^{\dagger}=\mathcal{R}^{\dagger}\mathcal{Q}^{\dagger},\quad (\mathcal{Q}+\mathcal{R})^{\dagger}=\mathcal{Q}^{\dagger}+\mathcal{R}^{\dagger}. \tag{16}$$

In the case of a function F, such as the operator $\mathcal{E}_S$ of Eq. (13),

$$F^{\dagger}=F. \tag{17}$$

Furthermore, from the definition (15) we can easily see that if f and g are two independent solutions admitted by any linear system $\mathcal{P}(f)=0=\mathcal{P}(g)$ and the operator $\mathcal{P}$ is self-adjoint, it means that $\mathcal{P}^{\dagger}=\mathcal{P}$ (or antiself-adjoint, $\mathcal{P}^{\dagger}=-\mathcal{P}$), then J^{μ} appearing on the right-hand side is a covariantly conserved quantity depending on the fields f and g.[6]

In this manner, the above discussion yields a completely general result, the existence of a conserved current for a self-adjoint system of the differential equations. The important point of this fact is the adjoint character of the system under study, and as we will see, this is effectively the case for the system of equations (14). For this purpose let us consider the element $\mathcal{E}_{A(\mathrm{YM})}$, which is taking the matrix-valued field b_{ν} into a scalar field in Eq. (9); using the properties of the Tr and the background equation $\nabla_{\mu}\tilde{F}^{\mu\nu}=0$ [see Eq. (2)], it is easy to demonstrate that

$$\mathrm{Tr}[\psi_1(\mathcal{E}_{A(\mathrm{YM})}B_{\nu})]=\mathrm{Tr}[B^{\nu}(\mathcal{E}_{(\mathrm{YM})A}\psi_1)_{\nu}]+\nabla_{\mu}\ \mathrm{Tr}\left[4\frac{d\omega}{d\eta}\tilde{F}^{\nu\mu}B_{\nu}\psi_1\right],$$

where ψ_1 is any scalar field, B_{μ} is any matrix-valued field, and $\mathcal{E}_{(\mathrm{YM})A}$ is that operator taking η^{B} (a scalar field) into a matrix-valued field in Eq. (11). The above expression has the form (15) and allows us to identify that

$$\mathcal{E}^{\dagger}_{A(\mathrm{YM})}=\mathcal{E}_{(\mathrm{YM})A}. \tag{18}$$

Similarly, using the definition (15), the properties (16) and (17), and assuming that the background fields satisfy Eqs. (2)–(6), we can demonstrate the following relations:

$$\psi_2\mathcal{E}_A\psi_1=\psi_1\mathcal{E}_A\psi_2+\nabla_{\mu}\zeta(\psi_1\ \partial^{\mu}\psi_2-\psi_2\ \partial^{\mu}\psi_1)(\mathcal{E}^{\dagger}_A=\mathcal{E}_A),$$

$$\psi_2\mathcal{E}_{DA}\psi_1=\psi_1\mathcal{E}_{AD}\psi_2+\nabla_{\mu}\left[\frac{d\zeta}{d\phi}\psi_1\psi_2\ \partial^{\mu}\eta\right](\mathcal{E}^{\dagger}_{DA}=\mathcal{E}_{AD}),$$

$$A^{\mu\alpha}(\mathcal{E}_{GA}\psi_1)_{\mu\alpha}=\psi_1(\mathcal{E}_{AG}A_{\mu\alpha})+\nabla_{\mu}\zeta\psi_1[\tfrac{1}{2}A_{\alpha}{}^{\alpha}\ \partial^{\mu}\eta-A^{\mu\nu}\ \partial_{\nu}\eta](\mathcal{E}^{\dagger}_{AG}=\mathcal{E}_{GA}),$$

$$\psi_2\mathcal{E}_D\psi_1=\psi_1\mathcal{E}_D\psi_2+\nabla_{\mu}4(\psi_1\ \partial^{\mu}\psi_2-\psi_2\ \partial^{\mu}\psi_1)(\mathcal{E}^{\dagger}_D=\mathcal{E}_D),$$

$$\mathrm{Tr}[\psi_1(\mathcal{E}_{D(\mathrm{YM})}B_{\nu})]=\mathrm{Tr}[B^{\nu}(\mathcal{E}_{(\mathrm{YM})D}\psi_1)_{\nu}]+\nabla_{\mu}\mathrm{Tr}\left(4\frac{d\xi}{d\phi}F^{\nu\mu}B_{\nu}\psi_1\right)(\mathcal{E}^{\dagger}_{D(\mathrm{YM})}=\mathcal{E}_{(\mathrm{YM})D}),$$

$$\psi_1(\mathcal{E}_{DG}A_{\mu\alpha})=A^{\mu\alpha}(\mathcal{E}_{GD}\psi_1)_{\mu\alpha}+\nabla_{\mu}2\psi_1[2A^{\mu}{}_{\alpha}\partial^{\alpha}\phi-A_{\alpha}{}^{\alpha}\partial^{\mu}\phi](\mathcal{E}^{\dagger}_{DG}=\mathcal{E}_{GD}),$$

$$\mathrm{Tr}[A^{\nu}(\mathcal{E}_{\mathrm{YM}}B_{\mu})_{\nu}]=\mathrm{Tr}(B^{\nu}(\mathcal{E}_{\mathrm{YM}}A_{\mu})_{\nu})+\nabla_{\mu}8\mathrm{Tr}\left\{\xi[A_{\rho}\nabla^{[\mu}B^{\rho]}+B_{\rho}\nabla^{[\rho}A^{\mu]}]\right.$$

$$\left.+\frac{1}{2\sqrt{-g}}\epsilon^{\rho\alpha\mu\lambda}A_{\alpha}B_{\lambda}\partial_{\rho}\eta\right\}(\mathcal{E}^{\dagger}_{\mathrm{YM}}=\mathcal{E}_{\mathrm{YM}}),$$

$$\mathrm{Tr}[A^{\mu\alpha}(\mathcal{E}_{G(\mathrm{YM})}B_{\nu})_{\mu\alpha}]=\mathrm{Tr}[B^{\nu}(\mathcal{E}_{(\mathrm{YM})G}A_{\mu\alpha})_{\nu}]+\nabla_{\mu}2\xi\ \mathrm{Tr}\{4B_{\nu}F_{\alpha}{}^{[\nu}A^{\mu]\alpha}-A_{\alpha}{}^{\alpha}B_{\nu}F^{\mu\nu}\}(\mathcal{E}^{\dagger}_{G(\mathrm{YM})}$$

$$=\mathcal{E}_{(\mathrm{YM})G}), \tag{19}$$

where ψ_2 is another scalar field, A_μ and B_μ are any two matrix fields, and $A_{\mu\nu}$ any 2-index (symmetric) tensor field (such as $h_{\mu\nu}$). On the other hand, since $\mathcal{E}_G=\mathcal{E}_V+\mathcal{E}_S$, using the expression for $\mathcal{E}_V$ given in Eq. (12), the property (17), we can find that

$$A^{\mu\nu}(\mathcal{E}_G B_{\alpha\rho})_{\mu\nu}=B^{\alpha\rho}(\mathcal{E}_G A_{\mu\nu})_{\alpha\rho}+\nabla_\mu S^{\mu\alpha\beta\lambda\rho\gamma}(A_{\alpha\beta}\nabla_\lambda B_{\rho\gamma}-B_{\alpha\beta}\nabla_\lambda A_{\rho\gamma}) \quad (\mathcal{E}_G^\dagger=\mathcal{E}_G), \tag{20}$$

where $B_{\mu\nu}$ is another 2-index (symmetric) tensor field and[1]

$$S^{\mu\alpha\beta\lambda\rho\gamma}=g^{\mu(\rho}g^{\gamma)(\alpha}g^{\beta)\lambda}-\tfrac{1}{2}g^{\mu\lambda}g^{\alpha(\rho}g^{\gamma)\beta}-\tfrac{1}{2}g^{\mu(\alpha}g^{\beta)\lambda}g^{\rho\gamma}-\tfrac{1}{2}g^{\alpha\beta}g^{\mu(\rho}g^{\gamma)\lambda}+\tfrac{1}{2}g^{\alpha\beta}g^{\mu\lambda}g^{\rho\gamma}. \tag{21}$$

We thereby have found from Eqs. (18)–(20) that the matrix operator in Eq. (14) governing the linear field perturbations for the EYMDA theory, is self-adjoint, that is[7]

$$\begin{bmatrix} \mathcal{E}_A & \mathcal{E}_{AD} & \mathcal{E}_{A(\mathrm{YM})} & \mathcal{E}_{AG} \\ \mathcal{E}_{DA} & \mathcal{E}_D & \mathcal{E}_{D(\mathrm{YM})} & \mathcal{E}_{DG} \\ \mathcal{E}_{(\mathrm{YM})A} & \mathcal{E}_{(\mathrm{YM})D} & \mathcal{E}_{\mathrm{YM}} & \mathcal{E}_{(\mathrm{YM})G} \\ \mathcal{E}_{GA} & \mathcal{E}_{GD} & \mathcal{E}_{G(\mathrm{YM})} & \mathcal{E}_G \end{bmatrix}^\dagger = \begin{bmatrix} \mathcal{E}_A & \mathcal{E}_{AD} & \mathcal{E}_{A(\mathrm{YM})} & \mathcal{E}_{AG} \\ \mathcal{E}_{DA} & \mathcal{E}_D & \mathcal{E}_{D(\mathrm{YM})} & \mathcal{E}_{DG} \\ \mathcal{E}_{(\mathrm{YM})A} & \mathcal{E}_{(\mathrm{YM})D} & \mathcal{E}_{\mathrm{YM}} & \mathcal{E}_{(\mathrm{YM})G} \\ \mathcal{E}_{GA} & \mathcal{E}_{GD} & \mathcal{E}_{G(\mathrm{YM})} & \mathcal{E}_G \end{bmatrix}. \tag{22}$$

It is important to remark that the only assumption that we have made in order to establish the intrinsic property (22) is that the background fields satisfy Eqs. (2)–(7); moreover, we would like point out that any operator appearing in physics is not necessarily self-adjoint.[8]

With the end of obtaining the explicit form of the symplectic current for the EYMDA field perturbations, let S_1 and S_2 be any two independent solutions admitted by the system (14), given by

$$(S_1)=\begin{pmatrix} \eta_1^{\mathrm{B}} \\ \phi_1^{\mathrm{B}} \\ (b_\mu) \\ (h_{\mu\nu}) \end{pmatrix}, \quad (S_2)=\begin{pmatrix} \eta_2^{\mathrm{B}} \\ \phi_2^{\mathrm{B}} \\ (B_\mu) \\ (H_{\mu\nu}) \end{pmatrix}, \tag{23}$$

and from definition (14),

$$S_2(\mathcal{E}S_1)-S_1(\mathcal{E}^\dagger S_2)=\nabla_\mu J^\mu, \tag{24}$$

where $\mathcal{E}$ is the matrix operator (22), and using Eqs. (19) we easily find that

$$J^\mu=J_A{}^\mu+J_{AD}{}^\mu+J_{A(\mathrm{YM})}{}^\mu+J_{AG}{}^\mu+J_D{}^\mu+J_{D(\mathrm{YM})}{}^\mu+J_{DG}{}^\mu+J_{\mathrm{YM}}{}^\mu+J_{(\mathrm{YM})G}{}^\mu+J_G{}^\mu, \tag{25}$$

where

$$J_A{}^\mu=\zeta(\eta_1^B\,\partial^\mu\eta_2^B-\eta_2^B\,\partial^\mu\eta_1^B), \quad J_{AD}{}^\mu=\frac{d\zeta}{d\phi}(\partial^\mu\eta)[\eta_1^B\phi_2^B-\phi_1^B\eta_2^B],$$

$$J_{A(\mathrm{YM})}{}^\mu=4\frac{d\omega}{d\eta}\mathrm{Tr}[\tilde{F}^{\mu\rho}[B_\rho\eta_1^B-b_\rho\eta_2^B]],$$

$$J_{\mathrm{AG}}{}^\mu=\zeta[(\partial_\rho\eta)[h^{\mu\rho}\eta_2^B-H^{\mu\rho}\eta_1^B]+\tfrac{1}{2}(\partial^\mu\eta)[H\eta_1^B-h\eta_2^B]],$$

$$J_D{}^\mu=4[\phi_1^B\partial^\mu\phi_2^B-\phi_2^B\,\partial^\mu\phi_1^B],$$

$$J_{D(\mathrm{YM})}{}^{\mu}=4\frac{d\xi}{d\phi}\mathrm{Tr}[F^{\mu\rho}[B_\rho\phi_1^B-b_\rho\phi_2^B]], \tag{26}$$

$$J_{DG}{}^{\mu}=2[2(\partial^\rho\phi)[h^\mu{}_\rho\phi_2^B-H^\mu{}_\rho\phi_1^B]+(\partial^\mu\phi)[H\phi_1^B-h\phi_2^B]],$$

$$J_{\mathrm{YM}}{}^{\mu}=8\,\mathrm{Tr}\left\{\xi[B_\rho\,\nabla^{[\mu}b^{\rho]}-b_\rho\,\nabla^{[\mu}B^{\rho]}]+\frac{1}{2\sqrt{-g}}\epsilon^{\rho\alpha\mu\lambda}(\partial_\rho\eta)B_\alpha b_\lambda\right\},$$

$$J_{(\mathrm{YM})G}{}^{\mu}=2\xi\ \mathrm{Tr}\{2F_\rho{}^\mu[h^{\rho\lambda}B_\lambda-H^{\rho\lambda}b_\lambda]+2F_{\rho\lambda}[H^{\mu\rho}b^\lambda-h^{\mu\rho}B^\lambda]+F^{\mu\rho}(hB_\rho-Hb_\rho)\},$$

$$J_G{}^{\mu}=S^{\mu\alpha\beta\lambda\rho\gamma}(H_{\alpha\beta}\,\nabla_\lambda h_{\rho\gamma}-h_{\alpha\beta}\,\nabla_\lambda H_{\rho\gamma}),$$

where $H=g^{\mu\nu}H_{\mu\nu}$, $h=g^{\mu\nu}h_{\mu\nu}$ and the subscripts only denote the types of field perturbations involved; for example, $J_{A(\mathrm{YM})}{}^{\mu}$ involves axion and Yang–Mills perturbations. Note that J^μ is, just like the symplectic currents constructed by means of the approach of Refs. 1, 2, a function of an unperturbed set of fields and is bilinear and antisymmetric in pairs of field perturbations. Moreover, the dilaton–axion potential does not contribute to the symplectic current (those possible mass terms, etc.).

Our expression for J^μ is not gauge invariant with respect to either ordinary gauge transformations $B_\mu\to B_\mu+\partial_\mu\chi+[A_\mu,\chi]$ and $b_\mu\to b_\mu+\partial_\mu\chi+[A_\mu,\chi]$ or infinitesimal diffeomorphisms. However, the integral of J^μ over a compact Cauchy surface is gauge invariant.[1,2] On the other hand, since the dilaton and axion are fundamental physical fields (i.e., their zero modes are physically meaningful), there are no gauge invariances associated with these fields.

We can compare the expression for $J_{\mathrm{YM}}{}^{\mu}$ in Eq. (26) with that for the symplectic current introduced in 3, and note that they have the same form in terms of the gauge field perturbations. Moreover, if we set $\phi=\eta=\omega=V=0$ and $\xi=-k$ (gravitational constant) without imposing any restriction on the remaining gauge field in the background according to Eqs. (2), (3), it is not difficult to show that the sum [in the case when the gauge group corresponds to $U(1)$] $J_{\mathrm{YM}}{}^{\mu}+J_{(\mathrm{YM})G}{}^{\mu}+J_G{}^{\mu}$ reduces exactly to the expression (3.12) in Ref. 1 for the symplectic current in the Einstein–Maxwell theory.

IV. CONCLUDING REMARKS

In conclusion, we have applied to a system of perturbation equations derived from a string-inspired action, a general result that connects the self-adjointness of any linear system of differential equations with the existence of a conserved current. The applicability of the present approach depends on the fact that the self-adjoint character of the system under study is established. However, if a given system is not self-adjoint, one can still be able to find a conserved current, which will be associated, formally, to a solution of the original system and to a solution of the adjoint system, in accordance with the definition (15); but, at present, we do not know in general what one must understand physically by ‘‘a solution of the adjoint system.’’ In this sense, the present approach can be, in principle, a general method to generate a conserved current for any gravity theory, such as the approaches of Refs. 1, 2.

In addition to that, our approach is a more direct procedure of obtaining the symplectic current than that employed in Refs. 1, 2, it has another advantage: the self-adjointness allows the generation of solutions for perturbation equations by means of potentials, provided the corresponding decoupled equations are obtained (originally, with this idea the concept of adjoint operators was introduced by Wald[4] and Torres del Castillo[5]); that will permit, in its turn, a detailed study of the corresponding symplectic current, since we do not have yet a general physical interpretation for such a current (however, a connection with the conservation of energy has been shown in a particular case in Ref. 1; see also Ref. 3). Reference 8 shows how our approach applies when the string fields are involved, and references cited therein correspond to some particular cases whose perturbation study may be very interesting.

On the other hand, the action considered in the present work contains only the (truncated) bosonic sector of a generic low-energy string effective theory; the question of whether the presence of the additional terms in the generic action yields a self-adjoint perturbation equation remains to be worked out. Moreover, the inclusion of fermionic fields (superstrings theory) is possible, since the fundamental definition of Ref. 5, which has been our starting point, extends for spinor fields. All these questions will be the subject of a future investigation.

(Received 9 February 1998; accepted for publication 8 April 1999)

We discuss the discrete spectrum of N particles in a curved planar waveguide. If they are neutral fermions, the maximum number of particles that the waveguide can bind is given by a one-particle Birman–Schwinger bound in combination with the Pauli principle. On the other hand, if they are charged, e.g., electrons in a bent quantum wire, the Coulomb repulsion plays a crucial role. We prove a sufficient condition under which the discrete spectrum of such a system is empty. © *1999 American Institute of Physics.* [S0022-2488(99)01309-2]

I. INTRODUCTION

A rapid progress of mesoscopic physics brought, in particular, interesting new problems concerning relations between geometry and spectral properties of quantum Hamiltonians. They involve models of quantum wires, dots, and similar systems. While in reality these are rather complicated systems composed of different semiconductor materials, experience tells us that their basic features can be explained using simple models in which electrons (regarded as free particles with an effective mass) are supposed to be confined to an appropriate spatial region, either by a potential or by a hard wall. A brief description of this approximation with a guide to further reading is given in Ref. 1. In addition, such models apply not only to electrons in semiconductor microstructures; a different example is represented by atoms trapped in hollow optical fibers.[2]

It is natural that most theoretical results up to date refer to the case of a single particle in the confinement. On the other hand, from the practical point of view it is rather an exception than a rule that an experimentalist is able to isolate a single electron or atom, and therefore many-body problems in this setting are of interest. For instance, two-dimensional quantum dots that can be regarded as artificial atoms have been studied recently, usually in the presence of a magnetic field, either for a pair of electrons or in the semiclassical situation when a Thomas–Fermi-type approach is applicable—cf. Refs. 3–6 and references therein.

In these studies, however, geometry of the dot played a little role, because the confinement was realized by a harmonic potential or a circular hard wall. This is not the case for open systems modeling quantum wires where a deformation of a straight channel is needed to produce nontrivial spectral properties. In particular, a quantum waveguide exhibit bound states if it is bent,[1,7,8] protruded,[9–11] or allowing a leak to another duct,[12–14] and the discrete spectrum depends substantially on the shape of the channel. With few exceptions such as Ref. 15, however, the known results refer to the one-particle case.

It is our aim in the present paper to initiate a rigorous investigation of many-particle effects in quantum waveguides. We are going to discuss here a system of N particles in a bent planar Dirichlet tube, i.e., a hard-wall channel, and ask whether N-particle bound states exist for a given

geometry. After collecting the necessary preliminaries in the next section, we shall derive first in Sec. III a simple bound for the neutral case that follows from the Birman–Schwinger estimate of the one-particle Hamiltonian in combination with the Pauli principle.

The main result of the paper is formulated and proved in Sec. IV. It concerns the physically interesting case of charged particles; the example we have in mind is, of course, electrons in a bent semiconductor quantum wire. The electrostatic repulsion makes spectral analysis of the corresponding Hamiltonian considerably more complicated. Using a variational technique borrowed from atomic physics, we derive here a sufficient condition under which the discrete spectrum is empty. The condition is satisfied for N large enough and represents an implicit equation for the maximum number of charged particles that a waveguide of a given curvature and width can bind. Some other aspects of the result and open questions are discussed briefly in the concluding section.

II. PRELIMINARIES

The waveguide in question will be modeled by a curved planar strip Σ in $\mathbb{R}^2$, of a constant width $d=2a$. It can be obtained by transporting the perpendicular interval $[-a,a]$ along the curve Γ, which is the axis of Σ. Up to Euclidean transformations, the strip is uniquely characterized by its halfwidth a and the (signed) curvature $s\mapsto\gamma(s)$ of Γ, where s denotes the arclength. We adopt the regularity assumptions of Refs. 1,7: (i) Ω is not self-intersecting, (ii) $a\|\gamma\|_\infty<1$, (iii) γ is piecewise C^2 with γ', γ'' bounded, and restrict our attention to the case when the tube is curved in a bounded region only: and (iv) there is $b>0$ such that $\gamma(s)=0$ for $|s|>b$; without loss of generality we may assume that $2b>a$.

As usual, we put $\hbar=2m=1$; then the one-particle Hamiltonian of such a waveguide is the Dirichlet Laplacian $-\Delta_{\mathrm{D}}^{\Sigma}$ defined in the conventional way—cf. Ref. 16, Sec. XIII.15. Using the natural locally orthogonal curvilinear coordinates s,u in Σ one can map $-\Delta_{\mathrm{D}}^{\Sigma}$ unitarily onto the operator,

$$H_1=-\partial_s(1+u\gamma)^{-2}\partial_s-\partial_u^2+V(s,u) \tag{2.1}$$

on $L^2(\mathbb{R}\times(-a,a))$ with the effective curvature–induced potential,

$$V(s,u):=-\frac{\gamma(s)^2}{4(1+u\gamma(s))^2}+\frac{u\gamma''(s)}{2(1+u\gamma(s))^3}-\frac{5}{4}\,\frac{u\gamma''(s)^2}{(1+u\gamma(s))^4}, \tag{2.2}$$

which is e.s.a. on the core $D(H)=\{\psi:\psi\in C^\infty,\ \ \psi(s,\pm a)=0,\ H\psi\in L^2\}$—cf. Refs. 1,7 for more details.

If the waveguide contains N particles, the state Hilbert space is $L^2((\Sigma))^N$; the Pauli principle will be taken into account later. We assume that each particle has the charge e; using the same ‘‘straightening’’ transformation we are then able to rewrite the Hamiltonian as

$$H_N\equiv H_N(\gamma,a,e)=\sum_{j=1}^{N}\{-\partial_{s_j}(1+u_j\gamma(s_j))^{-2}\partial_{s_j}-\partial_{u_j}^2+V(s_j,u_j)\}+e^2\sum_{1\le j<l\le N}|\mathbf{r}_j-\mathbf{r}_l|^{-1}, \tag{2.3}$$

with the domain $(\mathcal{H}^2(\mathbb{R})\otimes\mathcal{H}_0^2(-a,a))^N$, where $\mathbf{r}_j=\mathbf{r}_j(s_j,u_j)$ are the Cartesian coordinates of the Nth particle.

As we have said our main aim in this paper is to estimate the maximum number of particles that a curved waveguide with given γ,a can bind, i.e., to find conditions under which the discrete spectrum of H_N is empty. To this end, one has to determine first the bottom of the essential spectrum. In complete analogy with the usual HVZ theorem,[16] we find

$$\sigma_{\mathrm{ess}}(H_N)=\left[\mu_{N-1}+\left(\frac{\pi}{2a}\right)^2,\infty\right), \tag{2.4}$$

where $\mu_{N-1}:=\inf\sigma(H_{N-1})$. Obviously,

$$\inf\sigma_{\mathrm{ess}}(H_N)\le\mu_{N-k}+k\left(\frac{\pi}{2a}\right)^2$$

holds for $k=1,\dots,N-1$, so

$$\inf\sigma_{\mathrm{ess}}(H_N)\le N\left(\frac{\pi}{2a}\right)^2. \tag{2.5}$$

In a straight tube the two expressions equal each other, while for $\gamma\neq 0$ we have a sharp inequality because $\mu_1<(\pi/2a)^2$ holds in this case.

III. NEUTRAL FERMIONS

If the particles in question are neutral fermions, one can get a simple upper bound on the number of bound states using the one-particle Hamiltonian (2.1); it is sufficient to estimate the dimension of $\sigma_{\mathrm{disc}}(H_1)$ and to employ the Pauli principle. To this aim, one has to estimate H_1 from above by an operator with the transverse and longitudinal variables decoupled; its projections to transverse modes are then one-dimensional Schrödinger operators to which the modified Birman–Schwinger bound may be applied.[17–19] In Ref. 1 we used this argument in the situation where a is small so that only the lowest transverse mode and the leading term in (2.2) may be taken into account.

A modification to the more general case is straightforward. We introduce the function

$$\tilde{W}(s):=\frac{\gamma(s)^2}{4\delta_-^2}+\frac{a|\gamma''(s)|}{2\delta_-^3}+\frac{5a^2\gamma'(s)^2}{4\delta_-^4}, \tag{3.1}$$

where

$$\delta_\pm:=1\pm a\|\gamma\|_\infty, \tag{3.2}$$

which majorizes the effective potential, $V(s,u)\le\tilde{W}(s)$. Furthermore, we set

$$\tilde{W}_j(s):=\max\left\{0,\left(\frac{\pi}{2a}\right)^2(1-j^2)\right\}, \tag{3.3}$$

for $j=2,3,\dots$; in view of the assumptions (ii), (iii) only a finite number of them is different from zero.

Replacing V by $\tilde{W}$, and $(1+u\gamma)^{-2}$ by δ_+^{-2}, we get an estimating operator with separating variables, or, in other words, a family of shifted one-dimensional Schrödinger operators; we are looking for the number of their eigenvalues below $\inf\sigma_{\mathrm{ess}}(H_1)=(\pi/2a)^2$. The mentioned modification of the Birman–Schwinger bound is based on splitting the rank–one operator corresponding to the singularity of the resolvent kernel $(1/2\kappa)e^{-\kappa|s-s'|}$ at $\kappa=0$ and applying a Hilbert–Schmidt estimate to the rest. In analogy with Refs. 17–19 we employ this trick for the lowest–mode component of the estimating operator, while for the higher modes we use the full resolvent at the values $\kappa_j:=(\pi/2a)\sqrt{j^2-1}$. In this way we arrive at the following conclusion.

Proposition III.1: The number N of neutral particles of half-integer spin S that a curved quantum waveguide can bind satisfies the inequality

$$N\le(2S+1)\left\{1+\delta_+^2\frac{\int_{\mathbb{R}^2}\tilde{W}(s)|s-t|\tilde{W}(t)\,ds\,dt}{\int_{\mathbb{R}}\tilde{W}(s)\,ds}+\sum_{j=2}^{\infty}\frac{a\delta_+^2}{\pi\sqrt{j^2-1}}\int_{\mathbb{R}}\tilde{W}_j(s)\,ds\right\}. \tag{3.4}$$

Remarks III.2: (a) As we have said, the number of nonzero terms in the last sum is finite. More exactly, the index j runs up to the entire part of $\sqrt{1+(2a/\pi)^2\|\tilde{W}\|_\infty}$; hence if a is small enough this term is missing at all.

(b) The assumption (iv) is not needed here. It is sufficient, e.g., that the functions γ,γ', and $|\gamma''|^{1/2}$ decay as $|s|^{-1-\varepsilon}$ as $|s|\to\infty$.

IV. MAIN RESULT: *N* CHARGED PARTICLES

We have said in the Introduction that the present study is motivated mainly by the need to describe electrons in curved quantum wires. Unfortunately, the above simple estimate have no straightforward consequences for the situation when the particles are charged. While the electrostatic repulsion adds a positive term to the Hamiltonian (2.3), it may move at the same time the bottom of the essential spectrum since the energies of the bound ''clusters'' are, of course, sensitive to the interaction change.

We need therefore another approach that would allow us to take the repulsion term in (2.3) into account. An inspiration can be found in an analysis of atomic N-body Hamiltonians. To formulate the result we need some notation. Given a positive β we denote by $\{\lambda_m\}_{m=1}^\infty$ the ordered sequence of eigenvalues of a Dirichlet Laplacian at the rectangle,

$$R_\beta:=[-\tfrac{3}{2}\beta\delta_+,\tfrac{3}{2}\beta\delta_+]\times[-a,a], \tag{4.1}$$

and set

$$T_\beta(N):=\begin{cases} 2\sum_{m=1}^{n}\lambda_m & \dots\quad N=2n,\\ 2\sum_{m=1}^{n}\lambda_m+\lambda_{n+1} & \dots\quad N=2n+1.\end{cases} \tag{4.2}$$

We have in mind here electrons and assume that the spin is $\frac{1}{2}$, otherwise $T_\beta(N)$ has to be replaced by the sum of the first N eigenvalues of $2S+1$ identical copies of the Laplacian. Now we are able state our main result.

Theorem IV.1: Assume (i)–(iv). $\sigma_{\rm disc}(H_N(\gamma,a,e))=\emptyset$ for $N\geq 2$ if the condition

$$T_\beta(N)+\frac{e^2}{2\beta\sqrt{7}}N(N-1)\geq\|\tilde{W}\|_\infty N+\left(\frac{\pi}{2a}\right)^2 N+\frac{e^2}{18\beta\sqrt{2}} \tag{4.3}$$

is valid for some $\beta\geq\max\{2b,596e^{-2}\}$.

Proof: We use a variational argument that relies on a suitable decomposition of the configuration space. Consider a pair of smooth functions v,g from $\mathbb{R}_+$ to $[0,1]$ such that

$$v(t)=\begin{cases}0 & \dots\quad t\leq 1,\\ 1 & \dots\quad t\geq\frac{3}{2},\end{cases} \tag{4.4}$$

and

$$v(t)^2+g(t)^2=1. \tag{4.5}$$

Elements of the configuration space are (s,u) with $s=\{s_1,\dots,s_N\}$ and $u=\{u_1,\dots,u_N\}$. We denote $\|s\|_\infty:=\max\{s_1,\dots,s_N\}$ and employ the functions

$$s\mapsto v(\|s\|_\infty\beta^{-1}),\quad g(\|s\|_\infty\beta^{-1}),$$

where $\beta > 2b > a$ is a parameter to be specified later. By an abuse of notation, we use the symbols v, g again both for these functions and the corresponding operators of multiplication. It is straightforward to evaluate $([H_N, v]\psi, v\psi)$ and the analogous expression with v replaced by g for a vector $\psi \in D(H_N)$; in both cases it is only the longitudinal kinetic part in (2.3) that contributes. This yields the identity

$$(H_N\psi,\psi) = (H_N v\psi, v\psi) + (H_N g\psi, g\psi) + \sum_{j=1}^{N} \{\|(1+u_j\gamma_j)^{-1} v_j\psi\|^2 + \|(1+u_j\gamma_j)^{-1} g_j\psi\|^2\},$$

where we have used the shorthand $v_j := \partial v/\partial s_j$, $g_j := \partial g/\partial s_j$, and $\gamma_j := \gamma(s_j)$. Notice further that the factors $(1+u_j\gamma_j)^{-1}$ may be neglected, because $v_j g_j$ are nonzero only if $s_j \geqslant \beta > 2b$, in which case $\gamma_j = 0$. Furthermore, with the exception of the hyperplanes where two or more coordinates coincide (which is a zero measure set) the norm $\|s\|_\infty$ coincides with just one of the coordinates $s_1, \dots, s_n$, and therefore

$$\sum_{j=1}^{N} \{\|v_j\psi\|^2 + \|g_j\psi\|^2\} \leqslant \|\psi\|^2 \max_{1\leqslant j\leqslant N} \{\|v_j\|_\infty^2 + \|g_j\|_\infty^2\} \leqslant \beta^{-2} C_0 \|\psi\|^2, \tag{4.6}$$

where $C_0 := \|v'\|_\infty^2 + \|g'\|_\infty^2$. We arrive at the estimate

$$(H_N\psi,\psi) \geqslant L_1[v\psi] + L_1[g\psi] \tag{4.7}$$

with

$$L_1[\phi] := (H_N\phi,\phi) - \frac{C_0}{\beta^2}\|\phi\|^2_{\mathcal{N}_\beta}, \tag{4.8}$$

where the last index symbolizes the norm of the vector ϕ restricted to the subset $\mathcal{N}_\beta := \{s : \beta \leqslant \|s\|_\infty \leqslant 3\beta/2\}$ of the configuration space.

Next, one has to estimate separately the contributions from the inner and outer parts. Let us begin with the exterior. We introduce the following functions:

$$f_1(s) = v(2s_1\|s\|_\infty^{-1}),$$

$$f_j(s) = v(2s_j\|s\|_\infty^{-1}) \prod_{n=1}^{j-1} g(2s_n\|s\|_\infty^{-1}), \quad j = 2, \dots, N-1,$$

$$f_N(s) = \prod_{n=1}^{N-1} g(2s_n\|s\|_\infty^{-1}).$$

It is clear from the construction that

$$\sum_{j=1}^{N} f_j(s)^2 = 1. \tag{4.9}$$

Moreover, the functions

$$s_j \mapsto v(2s_j\|s\|_\infty), g(2s_j\|s\|_\infty)$$

have a nonzero derivative only if $|s_j| \geqslant \frac{1}{2}\|s\|_\infty^{-1}$. Hence, on the support of $s \mapsto v(\|s\|_\infty\beta^{-1})$ the derivative is nonzero if $|s_j| \geqslant \frac{1}{2}\beta > b$. In other words, the function $s \mapsto f_j(s)^2 v(\|s\|_\infty\beta^{-1})$ has a zero derivative in all the parts of the configuration space, where at least one of the electrons dwells in the curved part of the waveguide. Commuting the (longitudinal kinetic part of) H_N with f_j, we get in the same way as above the identity

$$L_1[v\psi]=\sum_{j=1}^{N}\{L_1[f_j v\psi]-\|(\nabla_s f_j)v\psi\|^2\}, \tag{4.10}$$

where $\nabla_s:=(\partial_{s_1},\dots,\partial_{s_1})$. Next, we need a pointwise upper bound on $\Sigma_{j=1}^N(\nabla_s f_j)^2$: denoting $\sigma_j:=2s_j\|s\|_\infty$, we can write

$$\sum_{j=1}^{N}|(\nabla_s f_j)(s)|^2=\frac{4}{\|s\|_\infty^2}\{v'(\sigma_1)^2+g'(\sigma_1)^2v(\sigma_2)^2+g(\sigma_1)^2v'(\sigma_2)^2+\cdots$$
$$+g'(\sigma_1)^2g(\sigma_2)^2\cdots g(\sigma_N)^2+\cdots+g(\sigma_1)^2\dots g(\sigma_{N-1})^2g'(\sigma_N)^2\},$$

which gives after a partial resummation,

$$=\frac{4}{\|s\|_\infty^2}\{v'(\sigma_1)^2+g'(\sigma_1)^2+g(\sigma_1)^2g'(\sigma_2)^2+\cdots+g(\sigma_1)^2\cdots g(\sigma_{N-1})^2g'(\sigma_N)^2\}$$
$$\leqslant\frac{4}{\|s\|_\infty^2}\left\{v'(\sigma_1)^2+\sum_{j=1}^{N}g'(\sigma_j)^2\right\}\leqslant\frac{4NC_0}{\|s\|_\infty^2};$$

recall that $C_0:=\|v'\|_\infty^2+\|g'\|_\infty^2$. Consequently,

$$L_1[v\psi]\geqslant\sum_{j=1}^{N}L_1[f_j v\psi]-4NC_0\|v\psi\|s\|_\infty^{-1}\|^2$$
$$=\sum_{j=1}^{N}\{L_1[f_j v\psi]-4NC_0\|f_j v\psi\|s\|_\infty^{-1}\|^2\}=\sum_{j=1}^{N}L_2[f_j v\psi], \tag{4.11}$$

where

$$L_2[\phi]:=L_1[\phi]-4NC_0\|\phi\|s\|_\infty^{-1}\|^2. \tag{4.12}$$

Hence, we have to find a lower bound to $L_2(\psi_j)$ with $\psi_j:=f_j v\psi)$. Since $s_j\geqslant\frac{1}{2}\|s\|_\infty\geqslant\frac{1}{2}\beta>b$ holds on the support of ψ_j, we have $V(s_j,u_j)=0$ there. This allows us to write

$$(H_N\psi_j,\psi_j)=(H_{N-1}\psi_j,\psi_j)+\|\partial_{s_j}\psi_j\|^2+\|\partial_{u_j}\psi_j\|^2+e^2\sum_{j\neq l=1}^{N}(|\mathbf{r}_j-\mathbf{r}_l|^{-1}\psi_j,\psi_j),$$

where H_{N-1} refers to the system with the jth electron excluded, and therefore

$$(H_N\psi_j,\psi_j)\geqslant\left(\mu_{N-1}+\left(\frac{\pi}{2a}\right)^2\right)\|\psi_j\|^2+e^2\sum_{j\neq l=1}^{N}(|\mathbf{r}_j-\mathbf{r}_l|^{-1}\psi_j,\psi_j).$$

Since $|\mathbf{r}_j-\mathbf{r}_l|\leqslant\sqrt{(s_j-s_l)^2+4a^2}\leqslant2\sqrt{\|s\|_\infty^2+a^2}$, we have

$$(H_N\psi_j,\psi_j)\geqslant\left(\mu_{N-1}+\left(\frac{\pi}{2a}\right)^2\right)\|\psi_j\|^2+\frac{e^2(N-1)}{2}((\|s\|^2+a^2)^{-1/2}\psi_j,\psi_j).$$

The sought lower bound then follows from (4.12) and (4.8):

$$L_2[\psi_j] \geqslant \left(\mu_{N-1}+\left(\frac{\pi}{2a}\right)^2\right)\|\psi_j\|^2 - 4NC_0\|\psi_j\|s\|_\infty^{-1}\|^2$$

$$-C_0\beta^{-2}\|\psi_j\|^2_{\mathcal{N}_\beta}+\frac{e^2(N-1)}{2}((\|s\|^2+a^2)^{-1/2}\psi_j,\psi_j);$$

recall that $\mathcal{N}_\beta := \{s:\ \ \beta \leqslant \|s\|_\infty \leqslant 3\beta/2\}$. The second and the third term at the rhs can be combined, using

$$4NC_0\|\psi_j\|s\|_\infty^{-1}\|^2 + C_0\beta^{-2}\|\psi_j\|^2_{\mathcal{N}_\beta} \leqslant (4N+1)C_0\|\psi_j\|s\|_\infty^{-1}\|^2.$$

Furthermore, $\|s\|_\infty \geqslant \beta > 2b > a$ yields $(\|s\|^2+a^2)^{1/2} \leqslant \sqrt{2}\|s\|_\infty$ and

$$L_2[\psi_j] \geqslant \left(\mu_{N-1}+\left(\frac{\pi}{2a}\right)^2\right)\|\psi_j\|^2 + \left(\frac{e^2(N-1)}{2\sqrt{2}} - \frac{C_0(4N+1)}{\beta}\right)\|\psi_j\|s\|_\infty^{-1}\|^2. \tag{4.13}$$

We are interested in the situation when the second term at the rhs is positive. This is achieved if

$$\frac{e^2(N-1)}{2\sqrt{2}} > \frac{C_0(4N+1)}{\beta},$$

which is ensured if we choose β in such a way that

$$\beta > \frac{18\sqrt{2}C_0}{e^2}; \tag{4.14}$$

recall that $N \geqslant 2$. Owing to the identity (4.11) we then have

$$L_1[v\psi] \geqslant \left(\mu_{N-1}+\left(\frac{\pi}{2a}\right)^2\right)\|v\psi\|^2, \tag{4.15}$$

which means in view of (2.4) that the external part of ψ does not contribute to the discrete spectrum.

Let us turn now to the inner part. The corresponding quadratic form in the decomposition (4.7) can be estimated with the help of (2.3) and (4.8) by

$$L_1[g\psi] \geqslant \delta_+^{-2}\|\nabla_s g\ \psi\|^2 + \|\nabla_u g\ \psi\|^2 + \sum_{j=1}^{N} (V(s_j,u_j)g\psi, g\psi)$$

$$+e^2 \sum_{1\leqslant < k \leqslant N} (\|\mathbf{r}_j - \mathbf{r}_k\|^{-1} g\psi, g\psi) - \frac{C_0}{\beta^2}\|g\psi\|^2; \tag{4.16}$$

recall that $\delta_+ := 1 + a\|\gamma\|_\infty$. Using the function $\tilde{W}$ defined by (3.1) we find $|V(s_j,u_j)| \leqslant \tilde{W}(s_j)$, so

$$\max\{V(s,u):(s,u)\in\mathbb{R}\times[-a,a]\} \leqslant \|\tilde{W}\|_\infty.$$

Consequently, the curvature–induced potential term can be estimated by

$$\sum_{j=1}^{N} (V(s_j,u_j)g\psi, g\psi) \leqslant \|\tilde{W}\|_\infty N\|g\psi\|^2.$$

Furthermore, on the support of g, we have

$$|\mathbf{r}_j-\mathbf{r}_k|\leqslant 2\sqrt{\|s\|_\infty^2+a^2}\leqslant\sqrt{3\beta^2+4a^2},$$

because $\|s\|_\infty\leqslant\frac{3}{2}\beta$ holds there. At the same time, $\beta>2b>a$, so we arrive at the estimate

$$|\mathbf{r}_j-\mathbf{r}_k|\leqslant\sqrt{7}\beta,$$

which yields

$$\sum_{1\leqslant<k\leqslant N}(\|\mathbf{r}_j-\mathbf{r}_k\|^{-1}g\psi,g\psi)\geqslant\frac{N(N-1)}{2\beta\sqrt{7}}\|g\psi\|^2.$$

Now we can combine the above estimates with the inequality $C_0/\beta<e^2/18\sqrt{2}$, which follows from (4.14) to get the bound

$$L_1[g\psi]\geqslant\delta_+^{-2}\|\nabla_s g\;\psi\|^2+\|\nabla_u g\;\psi\|^2+\left[-N\|\tilde{W}\|_\infty+\frac{e^2N(N-1)}{2\beta\sqrt{7}}-\frac{e^2}{18\beta\sqrt{2}}\right]\|g\psi\|^2. \quad (4.17)$$

Now we can put the above results together. In view of the inequality (4.15) and of (2.5), the last bound tells us that H_N has no discrete spectrum for $N\geqslant 2$, provided

$$\delta_+^{-2}\|\nabla_s g\;\psi\|^2+\|\nabla_u g\;\psi\|^2+\left[\frac{e^2N(N-1)}{2\beta\sqrt{7}}-\frac{e^2}{18\beta\sqrt{2}}-N\|\tilde{W}\|_\infty-N\left(\frac{\pi}{2a}\right)^2\right]\|g\psi\|^2\geqslant 0, \quad (4.18)$$

for some β, which satisfies the condition

$$\beta\geqslant\max\left\{2b,\frac{18\sqrt{2}C_0}{e^2}\right\}. \quad (4.19)$$

The first two terms in (4.18) are nothing else than the quadratic form of the $2N$-dimensional Laplacian on R_β^N—cf. (4.1). By the Pauli principle each eigenvalue may appear only twice, thus one has to take the orthogonal sum of two copies of the Laplacian on R_β and to sum the first N eigenvalues of such an operator. This is exactly the quantity that we have called $T_\beta(N)$.

To finish the proof, it remains to estimate C_0, which appears in the conditions (4.14) and (4.19). We will not attempt an optimal bound and, put simply,

$$v(\xi):=\sin(4\pi\xi^2(1-2\xi^2)),$$

for $t-1=:\xi\in(0,\frac{1}{2})$; then

$$v'(\xi)^2+g'(\xi)^2=(8\pi)^2\xi^2(1-4\xi^2)^2$$

has the maximum value $2\sqrt{2}(8\pi)^2/3\approx 595.5$. ■

V. CONCLUSIONS

Since the present study is rather a foray into an unchartered territory, the result is naturally far from optimal. Let us add a few remarks. First of all, it is clear that the overall size of the curved region affects substantially the number of particles that the waveguide can bind. We know that *any* curved tube has a one-particle bound state,[1,8] hence a tube with N slight bends that very far from each other (so far that the repulsion is much smaller that the gap between the bound state energy and the continuum) can certainly bind N particles for N arbitrarily large.

The method we use is borrowed from atomic physics, where it yields bounds on ionization of an atom. Of course, there are differences. The binding is due to the curved hard wall of the waveguide rather than by the electrostatic attraction to the nucleus, and the spectrum of our one-particle operator (2.1) is finite. Consequently, there is a maximum number of particles that a given curved tube can bind as long as the particles are fermions. Bosons can occupy naturally a single state, and the idea of a *Bose condensate* of neutral spin–zero atoms in a curved hollow optical fiber is rather appealing.

On the other hand, a nonzero particle charge changes the picture, and even the number of bosons bind by a curved tube is limited: notice that the condition (4.3) is satisfied for large enough N without respect to the Pauli-principle term $T_\beta(N)$. Of course, the fermionic nature reduces the maximum number N further, since $T_\beta(N)$ growth for large N is between $o(N^3)$ in the limit $a \to 0$ and $o(N^2)$ for $2b \sim a$. At the same time, the maximum number also depends on the value of the charge. Since $1/\sqrt{7} - 1/18\sqrt{2} > 0$ and the remaining terms in (4.3) are independent of e, we see that $\sigma_{\mathrm{disc}}(H_N) = \emptyset$ for any $N \geqslant 2$, provided e is large enough. Thus, our result confirms the natural expectation that for a given curved tube and sufficiently charged particles just one-particle bound states can survive.

We have not addressed in this paper the question about the minimum number of particles that a curved quantum waveguide can bind. The gap between the trivial result that follows from the one-particle theory[1,7,8] and the condition (4.3) leaves a lot of space for improvements. Moreover, it is a natural question whether strongly curved tubes that can bind many particles allow for some semiclassical description analogous to the case of the quantum dots.[6] This is a task for a future work.

(Received 30 March 1999; accepted for publication 22 April 1999)

We propose a new general BRST approach to string and string-like theories that have a wider range of applicability than, e.g., the conventional conformal field theory method. The method involves a simple general regularization of all basic commutators, which makes all divergent sums expressible in terms of zeta functions from which finite values then may be extracted in a rigorous manner. The method is particularly useful in order to investigate possible state space representations to a given model. The method is applied to three string models: The ordinary bosonic string, the tensionless string, and the conformal tensionless string. We also investigate different state spaces for these models. The tensionless string models are treated in detail. Although we mostly rederive known results, they appear in a new fashion that deepens our understanding of these models. Furthermore, we believe that our treatment is more rigorous than most of the previous ones. In the case of the conformal tensionless string we find a new solution for $d=4$. © *1999 American Institute of Physics.* [S0022-2488(99)02010-1]

I. INTRODUCTION AND PRESENTATION OF THE METHOD

The usual operator formulation of BRST quantization of string theories are based on the following ingredients: First, specify a BRST-invariant vacuum state and then normal order the BRST operator in order to finally check in which dimension the BRST operator is nilpotent.[1] Even the conformal field theory method is based on these ingredients.[2] These methods have been very successful when applied to conventional string theories. However, there are models to which these methods are not applicable. We have, e.g., the tensionless string models that do not have a conventional vacuum state.[3,4] In this paper we present a new rigorous and very general approach to the operator version of BRST quantization, which not only makes it possible to consistently treat the conventional models, but also the tensionless string models. The method is particularly useful in order to investigate possible state space representations to a given model. The method seems, furthermore, to cast new light on the BRST method as a whole.

What we advocate here is the following general procedure in the BRST quantization.

(1) Construct a Hermitian and formally nilpotent BRST operator Q.

(2) Find a state space such that the properties above are true as operator equations in this space and for which the equation $Q|\phi\rangle=0$ has nontrivial solutions.

(3) Use a general precise regularization of the basic commutators in the above analysis.

The idea to start with a nilpotent BRST operator and then look for possible solutions is, of

[a)]Electronic mail: Stephen.Hwang@hks.se
[b)]Electronic mail: tferm@fy.chalmers.se
[c)]Electronic mail: P.Saltsidis@damtp.cam.ac.uk

course, very natural. However, usually one prescribes the setting first, which is what mathematicians would tell us to do. Usually the state space governs how we construct the BRST charge. But here this is not required. We only require a formally nilpotent BRST charge to start with. Then we look for possible state spaces. This freedom seems quite large. However, it is what a physicist likes to play with since physical models should also allow for our physical intuition to act. The structure of possible solutions of such a general prescription for finite degrees of freedom was given in Ref. 5 and further developed in Ref. 6. One may note that a Hermitian, nilpotent BRST charge may be constructed for a very large class of models in terms of a power expansion in $\hbar$ and in the ghost fields.[7] A solution is naturally obtained in a Weyl ordered form. However, these properties are only formal, since we must also find a state space in which the BRST charge makes sense. In order to do this in the case of infinite degrees of freedom we must make use of a regularization procedure. For instance, in the string models we encounter divergent sums. Such sums must be regularized in some way. Here we consider a simple general regularization of the basic commutators, a regularization that will make all infinite sums expressible as zeta functions. This regularization, which is presented in Sec. II, is therefore such that when the regulator is removed it will give finite results through analytic continuation in all cases considered. This makes it possible to rigorously compute all operator equations. Furthermore, and which is important, it allows us to investigate possible state spaces both rigorously and efficiently. We emphasize that the zeta function regularization here is used in a much more general and precise form than what one usually finds since here it appears from one single regularization of the basic commutators. (For applications of zeta regularization and for literature on the subject, see, e.g., Ref. 8.)

Instead of giving a detailed description of how the method is supposed to be applied, we treat three string models in detail: the closed ordinary bosonic string, the closed tensionless string, and the closed conformal tensionless string. The closed ordinary bosonic string is mainly treated for pedagogical reasons. However, it should be interesting to see how we investigate alternative state space representations. Our main interest is in the tensionless strings. Here we give a rather exhaustive analysis from which we are able to give precise results for all proposed versions.

Critical dimensions in string theories appear in connection with a particular state space. In our method they appear through an inconsistency: The formally nilpotent BRST charge is *not* nilpotent or is not appropriate on the considered state space. In our investigation of three string models we first look for a BRST-invariant vacuum state. Then we check whether or not the formally nilpotent BRST charge is nilpotent on this vacuum state. The conventional closed bosonic string turns out to be the most intricate example here. The conventional vacuum state is investigated in Sec. III. The appropriate BRST charge turns out to be the formally nilpotent charge shifted by a regulator-dependent term [Eq. (3.22)]. This charge is, however, only nilpotent at $d=26$. Thus, the standard results are obtained but in a different way than usually. This treatment demonstrates how our method works and maybe it also deepens our understanding of this well-known model. The second model we treat is the tensionless string.[9–11] In Sec. IV we recover the known result of no critical dimension in Ref. 10 for one vacuum state, and in Sec. V we find the critical dimension 26, as was found in Ref. 11 for another vacuum state. Our final example is the conformal tensionless string. In Sec. VI we first investigate the state space considered in Ref. 4. Here we find that the BRST charge is nilpotent in any dimension. However, the vacuum state is only BRST invariant in two dimensions and we have not found any BRST-invariant states in other dimensions. In Sec. VII we also consider another state space, which to our knowledge has not been considered previously. In this state space the BRST charge is again nilpotent in arbitrary dimensions, but the vacuum state is only BRST invariant in $d=4$. For other values of d we have not found any BRST-invariant states in this state space. In Sec. VII we also investigate the alternative vacuum state considered in Ref. 3, in which case we find that the BRST charge is not nilpotent in any dimensions and, hence, that there is no consistent BRST treatment at all, which is in agreement with the result of Ref. 3. In Secs. VIII and IX we investigate alternative vacua also for the ordinary bosonic string. Note that unlike some previous calculations our regularization makes all results finite, which makes us believe that the treatment given here is, in general, more rigorous than previous ones.

Normally a consistent BRST quantization requires BRST-invariant states with positive norms.

In fact, such a condition should really be inserted into condition 2 above. However, this would then exclude all models we treat, except possibly the ordinary bosonic string. The reason is that all our calculations are performed in the minimal sector, which is the sector with no dynamical Lagrange multipliers and antighosts. An artifact of this sector is that one cannot, in general, work on a truly inner product space. Consistent BRST-invariant states $|\phi\rangle$ requires here the existence of a dual BRST-invariant state $|\overline{\phi}\rangle$, satisfying the condition[5]

$$\langle\overline{\phi}|\phi\rangle \text{ is finite and} \neq 0. \tag{1.1}$$

This condition restricts the possible solutions. To work on truly inner product spaces one has to consider a BRST quantization in the complete sector with dynamical Lagrange multipliers and antighosts.[12] However, inconsistent solutions in the minimal sector will remain inconsistent in the complete sector. Furthermore, solutions containing BRST-invariant negative norm states in the minimal sector will retain these in the complete sector. In Sec. IX we present a state space representation for the conventional bosonic string model, which yields a finite set of BRST-invariant states, which, however, are shown to contain negative norm states. The same is true for the special solutions of the tensionless string in Sec. V. Both these options have therefore to be excluded. The consistency of the tensionless string model in Sec. IV seems unclear, since it has a vacuum solution that is not associated with any oscillators. The BRST-invariant states are not inner product states at all in the minimal sector. Although we expect that there exists a positive normed solution in the complete sector, this remains to be investigated.

It is, of course, also possible to investigate the fermionic extensions of the models considered here.[11,13] We expect such calculations to be quite straightforward using the method we present here. One may also consider other theories like, e.g., brane theories[14] and conventional field theories. We believe that also here our method should be important for rigorous results.

II. OUR REGULARIZATION

In string theory the string coordinates $X^{\mu}(\tau,\sigma)$ and the corresponding conjugate momenta $P_{\mu}(\tau,\sigma)$ satisfy the basic nonzero equal-time commutator (we suppress τ in the following):

$$[X^{\mu}(\sigma),P_{\nu}(\sigma')]=i\delta^{\mu}_{\nu}\delta(\sigma-\sigma'). \tag{2.1}$$

Since we shall only consider closed strings, we let $X^{\mu}(\sigma)$ and $P_{\mu}(\sigma)$ be periodic functions with period π. Thus, we may set ($\Sigma_n \equiv \Sigma_{n=-\infty}^{\infty}$ in the following)

$$X^{\mu}(\sigma)=\frac{1}{\sqrt{\pi}}\sum_n x^{\mu}_n e^{-2in\sigma}, \quad P^{\mu}(\sigma)=\frac{1}{\sqrt{\pi}}\sum_n p^{\mu}_n e^{-2in\sigma}, \tag{2.2}$$

and replace (2.1) by

$$[x^{\mu}_n,p_{m\nu}]=i\delta^{\mu}_{\nu}\delta^{0}_{n+m}. \tag{2.3}$$

The delta function in (2.1) is then the periodic delta function,

$$\delta(\sigma-\sigma')=\frac{1}{\pi}\sum_n e^{2in(\sigma-\sigma')}. \tag{2.4}$$

It is the appearance of a delta function in the commutator (2.1) that causes infinities in the quantum string theory. In order to handle these infinities in a well-defined manner we have to regularize the delta function, i.e., we have to make it an ordinary well-defined function. We have therefore to consider a modified or regularized commutator. We choose it to be of the form

$$[x^{\mu}_n,p_{m\nu}](s)=i\delta^{\mu}_{\nu}\delta^{0}_{n+m}f(|n|,s), \tag{2.5}$$

where $f(|n|,s)$ is a real function that satisfies the condition

$$f(|n|,0)=1. \tag{2.6}$$

It can only depend on the absolute value of n in order for x_n and p_n to retain their hermiticity properties from (2.2), even in the regularized case, i.e., $(x_n)^\dagger = x_{-n}$ and $(p_n)^\dagger = p_{-n}$. The choice of regulator function $f(|n|,s)$ is dictated by two considerations. First, in the computations that will follow, e.g., a calculation of the BRST nilpotency, the regulator should lead to a finite result as the regulator is removed $(s\to 0)$. Second, we would like our regulator to be as general as possible. A precise choice of $f(|n|,s)$ that satisfies these criteria is

$$f^{(\alpha)}(|n|,s)=\begin{cases}(|n|+\alpha)^{-s}, & |n|\geqslant -A+1,\\ 1, & |n|\leqslant -A,\end{cases} \tag{2.7}$$

where α is a real constant, which may be chosen to have any value, and where A is the closest integer to α satisfying $A\geqslant\alpha$. This choice will make all infinite sums expressible in terms of zeta functions (see below). This in turn will allow us to rigorously treat all infinite sums. Other regularizations are, of course, possible to use and should yield equivalent results. However, we think that the choice (2.7) is the most general one.

In the following BRST treatment of the various string models, we have also the fermionic ghost variable $c^I(\sigma)$ and $b^I(\sigma)$. Their basic commutators must be regularized in exactly the same way as in (2.5). For ghosts c_n^I, b_n^I (where I labels different types of ghosts) we have

$$[b_m^I, c_n^J](s)=\delta^0_{m+n}\delta^{IJ} f^{(\alpha)}(|n|,s). \tag{2.8}$$

The same is true for all other canonical variables one introduces. (We use graded commutators throughout.)

When calculating commutators we often get infinite sums of the form $\Sigma_n f^{(\alpha)}(|n|,s)$ that converge for $s>1$. However, by analytic continuations they may yield a finite value for $s<1$ and, in particular, for $s=0$. The choice (2.7) makes these sums expressible in terms of zeta functions. We have

$$\sum_n f^{(\alpha)}(|n|,s)=\begin{cases}1-2A+2\zeta(s|1+\alpha-A), & \alpha\leqslant 0,\\ -\alpha^{-s}-2\displaystyle\sum_{n=0}^{A-2}(n+1+\alpha-A)^{-s}+2\zeta(s|1+\alpha-A), & \alpha>0,\end{cases} \tag{2.9}$$

where $\zeta(s|a)$ is the Hurwitz zeta function defined for $0<a\leqslant 1$, $s>1$ by[15]

$$\zeta(s|a)\equiv\sum_{n=0}^{\infty}\frac{1}{(n+a)^s}. \tag{2.10}$$

By analytic continuation one finds the following value at $s=0$ $(0<a\leqslant 1)$:[15]

$$\zeta(0|a)=\tfrac{1}{2}-a, \tag{2.11}$$

which implies that [notice that the finite sums for $\alpha\leqslant 0$ and $\alpha>0$ are equal for $s=0$ in (2.9)]

$$\sum_n f^{(\alpha)}(|n|,0)=-2\alpha. \tag{2.12}$$

We have similarly, e.g. (we set $s=0$ for the finite sums),

$$\sum_{n=1}^{\infty} n f^{(\alpha)}(|n|,s) = \zeta(s-1|1+\alpha-A) - \alpha\zeta(s|1+\alpha-A) + \frac{1}{2}A(A-1),$$
$$\sum_{n=1}^{\infty} n^2 f^{(\alpha)}(|n|,s) = \zeta(s-2|1+\alpha-A) - 2\alpha\zeta(s-1|1+\alpha-A) + \alpha^2\zeta(s|1+\alpha-A) - \frac{1}{6}A(A-1)(2A-1), \tag{2.13}$$

which implies that

$$\lim_{s\to 0}\sum_{n=1}^{\infty} n f^{(\alpha)}(|n|,s) = \frac{1}{2}\alpha^2 - \frac{1}{12}, \quad \lim_{s\to 0}\sum_{n=1}^{\infty} n^2 f^{(\alpha)}(|n|,s) = -\frac{1}{3}\alpha^3, \tag{2.14}$$

since $\zeta(-1|a) = (6a-6a^2-1)/12$ and $\zeta(-2|a) = a(3a-2a^2-1)/6$.

The regularization (2.5) and (2.7) correspond by (2.1) to the following regularized delta function:

$$\delta_s(\sigma-\sigma') = \frac{1}{\pi}\left\{\sum_n f^{(\alpha)}(|n|,s)e^{2in(\sigma-\sigma')}\right\}, \tag{2.15}$$

which is a well-defined function for $s>1$ and by Eq. (2.12) gives a regularization such that $\lim_{s\to 0}\delta_s(0) = -2\alpha/\pi$. Note here that depending on the value of α we can get any value in this limit. This is one argument supporting our belief that our regularization gives the most general result possible. Notice also that $\lim_{s\to 0}\delta_s^{(k)}(0)$ is finite for any order of derivative k.

III. THE BOSONIC STRING

As an illustration of our method we first treat the ordinary bosonic string. The bosonic string is classically characterized by the constraints

$$\frac{1}{4T}(P+TX')^2(\sigma) = 0, \quad \frac{1}{4T}(P-TX')^2(\sigma) = 0, \tag{3.1}$$

where T is the string tension. The Fourier modes of the corresponding Hermitian constraint operators are

$$L_n \equiv \frac{1}{2}\sum_k \alpha_{n-k}\cdot\alpha_k, \quad K_n \equiv \frac{1}{2}\sum_k \tilde{\alpha}_{n-k}\cdot\tilde{\alpha}_k, \tag{3.2}$$

where

$$\alpha_n^\mu \equiv \left(\frac{1}{2\sqrt{T}}p_n^\mu - i\sqrt{T}nx_n^\mu\right), \quad \tilde{\alpha}_n^\mu \equiv \left(\frac{1}{2\sqrt{T}}p_{-n}^\mu - i\sqrt{T}nx_{-n}^\mu\right), \tag{3.3}$$

in terms of the x_n and p_n modes in (2.2). The regularized commutator (2.5) with the regularized function (2.7) implies that

$$[\alpha_n^\mu,\alpha_m^\nu](s)=n\,\eta^{\mu\nu}f^{(\alpha)}(|n|,s)\,\delta_{n+m}^0,\quad [\alpha_n^\mu,\tilde{\alpha}_m^\nu](s)=0,$$
$$[\tilde{\alpha}_n^\mu,\tilde{\alpha}_m^\nu](s)=n\,\eta^{\mu\nu}f^{(\alpha)}(|n|,s)\,\delta_{n+m}^0, \tag{3.4}$$

where $\eta^{\mu\nu}$ is a Minkowski metric, diag$(\eta^{\mu\nu})=(-1,+1,+1,+1)$. We consider now a corresponding BRST theory in which the manifestly Hermitian BRST charge is given by

$$Q=\sum_k (L_{-k}c_k^L+K_{-k}c_k^K)+\frac{1}{4}\sum_{k,l}(k-l)$$
$$\times(b_{k+l}^Lc_{-l}^Lc_{-k}^L+b_{k+l}^Kc_{-l}^Kc_{-k}^K-c_{-k}^Lc_{-l}^Lb_{k+l}^L-c_{-k}^Kc_{-l}^Kb_{k+l}^K), \tag{3.5}$$

where c_k^L,b_k^L and c_k^K,b_k^K are fermionic ghost modes satisfying (2.8). In the $s\to 0$ limit this BRST charge is formally nilpotent. A consequence of this nilpotency is that the extended constraints, $[Q,b_k^I]$, satisfy a closed algebra without any central extensions. The extended constraints to L_n and K_n are

$$\tilde{L}_n\equiv[Q,b_n^L]=L_n-\frac{1}{2}\sum_k (k+n)(c_k^Lb_{n-k}^L-b_{n-k}^Lc_k^L), \tag{3.6}$$

$$\tilde{K}_n\equiv[Q,b_n^K]=K_n-\frac{1}{2}\sum_k (k+n)(c_k^Kb_{n-k}^K-b_{n-k}^Kc_k^K). \tag{3.7}$$

For nonzero s we have, e.g., the following crucial commutator:

$$[\tilde{L}_m,\tilde{L}_{-m}](s)=\frac{1}{2}m\sum_k (\alpha_{-k}\cdot\alpha_k+k(c_{-k}^Lb_k^L-b_k^Lc_{-k}^L))(f^{(\alpha)}(|m+k|,s)+f^{(\alpha)}(|m-k|,s))$$
$$+\frac{1}{2}\sum_k (k\alpha_{-k}\cdot\alpha_k+(2m^2-k^2)(b_k^Lc_{-k}^L-c_{-k}^Lb_k^L))(f^{(\alpha)}(|m+k|,s)$$
$$-f^{(\alpha)}(|m-k|,s)), \tag{3.8}$$

which in the limit $s\to 0$ becomes

$$[\tilde{L}_m,\tilde{L}_{-m}](0)=2m\tilde{L}_0, \tag{3.9}$$

which is consistent with the fact that the BRST charge (3.5) is nilpotent in the $s\to 0$ limit. Now the crucial point is that the $s\to 0$ limit has no meaning before we specify on which state space the operators act. Below we show that the conventional choice of state space imply the expected result that we have a nilpotent BRST charge only in spacetime dimensions $d=26$ in the $s\to 0$ limit.

The standard choice of a vacuum state, $|0\rangle$, satisfies

$$\alpha_m|0\rangle=\tilde{\alpha}_m|0\rangle=0,\quad \forall m>0. \tag{3.10}$$

In order for this vacuum to be BRST invariant, $Q|0\rangle=0$, we must require the consistency conditions

$$[Q,\alpha_m^\mu]|0\rangle=0\Rightarrow mf^{(\alpha)}(|m|,s)\sum_{k=m}^{\infty} c_k^L\alpha_{m-k}^\mu|0\rangle=0\Rightarrow c_m^L|0\rangle=0,\quad \forall m>0,$$
$$[Q,\tilde{\alpha}_m^\mu]|0\rangle=0\Rightarrow mf^{(\alpha)}(|m|,s)\sum_{k=m}^{\infty} c_k^K\tilde{\alpha}_{m+k}^\mu|0\rangle=0\Rightarrow c_m^K|0\rangle=0,\quad \forall m>0. \tag{3.11}$$

These conditions in turn allow for the additional conditions

$$b_m^L|0\rangle = b_m^K|0\rangle = 0, \quad \forall m \geqslant 0, \tag{3.12}$$

for which the consistency conditions are

$$\begin{aligned} [Q, b_m^L]|0\rangle &\equiv \tilde{L}_m|0\rangle = 0, \quad \forall m \geqslant 0, \\ [Q, b_m^K]|0\rangle &\equiv \tilde{K}_m|0\rangle = 0, \quad \forall m \geqslant 0. \end{aligned} \tag{3.13}$$

They are satisfied for $m > 0$, but for $m = 0$ the situation is unclear. For nonzero s we have

$$\tilde{L}_0(s)|0\rangle = \frac{1}{2}\left(\alpha_0^2 + (d-2)\sum_{k=1}^{\infty} k f^{(\alpha)}(|k|,s)\right)|0\rangle, \tag{3.14}$$

which in the $s \to 0$ limit leads to the following finite expression:

$$\tilde{L}_0|0\rangle = \frac{1}{2}\left(\alpha_0^2 + (d-2)\left(\frac{1}{2}\alpha^2 - \frac{1}{12}\right)\right)|0\rangle, \tag{3.15}$$

where we have made use of the relation (2.14). The conditions (3.13) with the property (3.15) and a similar one for $\tilde{K}_n$ require the vacuum state to be an eigenstate to the momentum operator p_0^μ, with an eigenvalue that depends on the parameter α in the regularization function (2.7). [Notice that (3.3) implies that $\alpha_0^2 = \tilde{\alpha}_0^2 = p_0^2/4T$.] This is an unsatisfactory result. It means that the conventional vacuum state is not BRST invariant under the formally nilpotent BRST charge above. In fact, Q is not even nilpotent on the conventional vacuum state.

That the BRST operator (3.5) is *not* nilpotent on the above vacuum state may be seen by calculating the commutator $[\tilde{L}_m, \tilde{L}_{-m}]$ on the vacuum state for nonzero s. We find, from Eq. (3.8), that

$$\begin{aligned} [\tilde{L}_m, \tilde{L}_{-m}](s)|0\rangle = \Bigg(& m f^{(\alpha)}(|m|,s)\alpha_0^2 + \frac{1}{2} d \sum_{k=1}^{m} k(m-k) f^{(\alpha)}(|k|,s) f^{(\alpha)}(|k-m|,s) \\ & - \sum_{k=1}^{m} (2m-k)(k+m) f^{(\alpha)}(|k|,s) f^{(\alpha)}(|k-m|,s)\Bigg)|0\rangle. \end{aligned} \tag{3.16}$$

In the $s \to 0$ limit the right-hand side becomes

$$\left(m\alpha_0^2 + \frac{1}{12}(d-26)m^3 - \frac{1}{12}(d-2)m\right)|0\rangle, \tag{3.17}$$

which only is zero if $d = 26$ and if the eigenvalue of α_0^2 is 2, which is a regulator-independent condition. The reason for the different results from (3.9) and (3.15) is due to the fact that on the right-hand side of (3.8) the factor $f^{(\alpha)}(|m+k|,s) - f^{(\alpha)}(|m-k|,s)$, which is zero in the $s \to 0$ limit, is multiplied by an operator that is infinite on the above vacuum state. This means that $\tilde{L}_0$ and $\tilde{K}_0$ are not zero on the vacuum state $|0\rangle$ when (3.17) is zero. The solution of this dilemma is found when we rewrite the right-hand side of the commutator (3.8) by means of the regularized commutators (3.4) as follows:

$$[\tilde{L}_m,\tilde{L}_{-m}](s)=m\sum_{k=1}^{\infty}(\alpha_{-k}\cdot\alpha_k+kb^L_{-k}c^L_k+kc^L_{-k}b^L_k)(f^{(\alpha)}(|m+k|,s)+f^{(\alpha)}(|m-k|,s))$$
$$+\sum_{k=1}^{\infty}(k\alpha_{-k}\cdot\alpha_k+(k^2-2m^2)(b^L_{-k}c^L_k+c^L_{-k}b^L_k))(f^{(\alpha)}(|m+k|,s)-f^{(\alpha)}(|m-k|,s))$$
$$+mf^{(\alpha)}(|m|,s)\alpha_0^2+\frac{1}{2}d\sum_{k=1}^{m}k(m-k)f^{(\alpha)}(|k|,s)f^{(\alpha)}(|k-m|,s)$$
$$-\sum_{k=1}^{m}(2m-k)(k+m)f^{(\alpha)}(|k|,s)f^{(\alpha)}(|k-m|,s). \tag{3.18}$$

This expression implies that

$$[\tilde{L}_m,\tilde{L}_{-m}]=2m\left(\frac{1}{2}\alpha_0^2+\sum_{k=1}^{\infty}(\alpha_{-k}\cdot\alpha_k+kb^L_{-k}c^L_k+kc^L_{-k}b^L_k)\right)$$
$$+\tfrac{1}{12}(d-26)m^3-\tfrac{1}{12}(d-2)m, \tag{3.19}$$

in the $s\to 0$ limit, in agreement with (3.16) and (3.17). This may be rewritten as follows:

$$[\tilde{L}_m,\tilde{L}_{-m}]=2m\tilde{L}_0+\tfrac{1}{12}(d-26)m^3-\tfrac{1}{2}m(d-2)\alpha^2, \tag{3.20}$$

where

$$\tilde{L}_0=\frac{1}{2}\alpha_0^2+\sum_{k=1}^{\infty}(\alpha_{-k}\cdot\alpha_k+kb^L_{-k}c^L_k+kc^L_{-k}b^L_k)+\frac{1}{2}(d-2)\left(\frac{1}{2}\alpha^2-\frac{1}{12}\right) \tag{3.21}$$

is the original $\tilde{L}_0$ rewritten for finite s and taking the limit $s\to 0$. Equation (3.20) demonstrates the inconsistency with a nilpotent BRST charge obtained above and the reason why the conventional vacuum state is not BRST invariant. The remedy is obvious and expected: first, we notice that we may get a closed algebra at $d=26$ if we redefine the extended constraint $\tilde{L}_0$. This in turn may be accomplished by a redefinition of the original BRST charge: Simply replace Q in (3.5) by

$$Q'=Q-\frac{d-2}{4}\alpha^2(c_0^L+c_0^K), \tag{3.22}$$

which is not formally nilpotent for $d\neq 2$. The corresponding extended constraints are

$$\tilde{L}'_m=[Q',b^L_m]=\begin{cases}\tilde{L}_0-\dfrac{1}{4}(d-2)\alpha^2, & m=0,\\ \tilde{L}_m, & m\neq 0.\end{cases} \tag{3.23}$$

Note that $\tilde{L}'_0$ in distinction to $\tilde{L}_0$ in (3.21) is independent of the regulator parameter α. We have

$$\tilde{L}'_0=\frac{1}{2}\alpha_0^2+\sum_{k=1}^{\infty}(\alpha_{-k}\cdot\alpha_k+kb^L_{-k}c^L_k+kc^L_{-k}b^L_k)-\frac{(d-2)}{24}. \tag{3.24}$$

The spectrum is therefore regulator independent, as it should be. For $d=26$ we find now from (3.20),

$$[\tilde{L}'_m,\tilde{L}'_{-m}]=2m\tilde{L}'_0, \tag{3.25}$$

which is consistent with a nilpotent Q' for $d=26$, and that the conventional BRST vacuum is BRST invariant under Q'.

In Secs. VIII and IX we investigate other vacuum states for the bosonic string theory.

IV. THE BOSONIC TENSIONLESS STRING

The bosonic tensionless string (see Ref. 9) is characterized by the constraints

$$P^{\mu}(\sigma)P_{\mu}(\sigma)=0, \quad P^{\mu}(\sigma)X'_{\mu}(\sigma)=0. \tag{4.1}$$

These constraints follow from the bosonic string by dropping the term $T^2(X'(\sigma))^2$, which is assumed to be negligible in the $T\rightarrow 0$ limit. The Fourier modes of the corresponding Hermitian constraint operators are

$$\phi_n^{-1}\equiv\frac{1}{2}\sum_k p_k\cdot p_{n-k}, \quad \phi_n^L\equiv -i\frac{1}{2}\sum_k k(x_k\cdot p_{n-k}+p_{n-k}\cdot x_k). \tag{4.2}$$

Here a formally nilpotent BRST charge operator is given by

$$Q=\sum_k (\phi_{-k}^{-1}c_k^{-1}+\phi_{-k}^L c_k^L)-\frac{1}{2}\sum_{k,l}(k-l) \times\left(c_{-k}^{-1}c_{-l}^L b_{k+l}^{-1}+b_{k+l}^{-1}c_{-k}^{-1}c_{-l}^L+\frac{1}{2}c_{-k}^L c_{-l}^L b_{k+l}^L+\frac{1}{2}b_{k+l}^L c_{-k}^L c_{-l}^L\right). \tag{4.3}$$

We can check the nilpotency of Q by calculating the algebra of the extended constraints, given by

$$\tilde{\phi}_n^{-1}\equiv[Q,b_n^{-1}]=\phi_n^{-1}-\sum_k (n+k)c_k^L b_{n-k}^{-1},$$

$$\tilde{\phi}_n^L\equiv[Q,b_n^L]=\phi_n^L-\frac{1}{2}\sum_k (k+n)(c_k^{-1}b_{n-k}^{-1}-b_{n-k}^{-1}c_k^{-1}+c_k^L b_{n-k}^L-b_{n-k}^L c_k^L). \tag{4.4}$$

A straightforward calculation of the commutators yields

$$[\tilde{\phi}_m^{-1},\tilde{\phi}_n^L]=(m-n)\tilde{\phi}_{m+n}^{-1}, \quad [\tilde{\phi}_m^L,\tilde{\phi}_n^L]=(m-n)\tilde{\phi}_{m+n}^L. \tag{4.5}$$

Hence, we conclude that the BRST charge (4.3) is nilpotent.

We now look for a possible BRST-invariant vacuum state. Following Refs. 4 and 10, we consider a vacuum state defined by

$$p_n^{\mu}|0\rangle=b_n^{-1}|0\rangle=b_n^L|0\rangle=0, \quad \forall n. \tag{4.6}$$

[The crucial part is the first conditions. They may be viewed as the $T\rightarrow 0$ limit of (3.10) using (3.3).] In order for this vacuum state to be BRST invariant it has to satisfy the consistency conditions

$$[Q,p_n^{\mu}]|0\rangle=[Q,b_n^{-1}]|0\rangle=[Q,b_n^L]|0\rangle=0, \quad \forall n, \tag{4.7}$$

where

$$[Q,p_n^{\mu}]=-n\sum_k p_{n-k}^{\mu}c_k^L. \tag{4.8}$$

The first two conditions and the last one for $n\neq 0$ are easily seen to be satisfied due to (4.6). The only nontrivial condition is the last one for $n=0$. However, we have

$$\tilde{\phi}_0^L|0\rangle \equiv [Q,b_0^L]|0\rangle = \left(\phi_0^L - \frac{1}{2}\sum_k k[c_k^{-1}b_{-k}^{-1} - b_{-k}^{-1}c_k^{-1} + c_k^L b_{-k}^L - b_{-k}^L c_k^L]\right)|0\rangle$$

$$= -\frac{1}{2}\sum_k kp(i[p_{-k}^{\mu},x_{k\mu}] - [b_{-k}^{-1},c_k^{-1}] - [b_{-k}^L,c_k^L])|0\rangle$$

$$= -\frac{1}{2}(d-2)\sum_k kf^{(\alpha)}(|k|,s)|0\rangle = 0. \tag{4.9}$$

[It is zero for any choice of regulator function $f(|k|,s)!.$] It is then easily seen that

$$Q|0\rangle = 0, \tag{4.10}$$

which means that $|0\rangle$ defined by (4.6) is a BRST-invariant vacuum state for any dimension d. We must finally check that the BRST charge is nilpotent on the vacuum state. This may be accomplished by checking the algebra of the extended constraints. The most nontrivial one is $[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L]$, for which we find

$$[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L](s) = \frac{i}{2}\sum_k (k+m)kf^{(\alpha)}(|k+m|,s)(x_{-k}\cdot p_k - x_k\cdot p_{-k} + p_k\cdot x_{-k} - p_{-k}\cdot x_k)$$

$$+\frac{1}{2}\sum_k (k+2m)(k-m)f^{(\alpha)}(|k+m|,s)(b_{-k}^{-1}c_k^{-1} - b_k^{-1}c_{-k}^{-1}$$

$$+c_{-k}^{-1}b_k^{-1} - c_k^{-1}b_{-k}^{-1} + b_{-k}^L c_k^L - b_k^L c_{-k}^L + c_{-k}^L b_k^L - c_k^L b_{-k}^L). \tag{4.11}$$

A straightforward calculation yields that $[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L](0)|0\rangle$ is zero, which is consistent with Eq. (4.9). To conclude, within our regularization scheme we have shown that there exists a BRST-invariant vacuum state in any dimension. Furthermore, the BRST charge is nilpotent in the state space containing this vacuum state. This result is in agreement with the results of Ref. 10. Note that there exists a dual vacuum state $|\bar{0}\rangle$ satisfying $\langle\bar{0}|0\rangle$ finite and different from zero. $|\bar{0}\rangle$ satisfies $x_n^{\mu}|\bar{0}\rangle = c_n^{-1}|\bar{0}\rangle = c_n^L|\bar{0}\rangle = 0$ for all n together with their consistency conditions.

V. ALTERNATIVE QUANTIZATION OF THE BOSONIC TENSIONLESS STRING

Instead of a vacuum state satisfying (4.6) we follow Ref. 11 and consider

$$p_m^{\mu}|0\rangle = x_m^{\mu}|0\rangle = 0, \quad m>0. \tag{5.1}$$

The consistency conditions are

$$[Q,p_m^{\mu}]|0\rangle = [Q,x_m^{\mu}]|0\rangle = 0, \quad m>0, \tag{5.2}$$

and they require

$$c_m^{-1}|0\rangle = c_m^L|0\rangle = 0, \quad m>0, \tag{5.3}$$

for which

$$[Q,c_m^{-1}]|0\rangle = [Q,c_m^L]|0\rangle = 0, \quad m>0, \tag{5.4}$$

are automatically satisfied. This vacuum is then ghost fixed by

$$b_m^{-1}|0\rangle = b_m^L|0\rangle = 0, \quad m \geqslant 0. \tag{5.5}$$

The corresponding consistency conditions,

$$\tilde{\phi}_m^{-1}|0\rangle = \tilde{\phi}_m^L|0\rangle = 0, \quad m \geqslant 0, \tag{5.6}$$

are automatically satisfied for $m > 0$. For $m = 0$ we have

$$\tilde{\phi}_0^{-1}|0\rangle = 0 \Leftrightarrow p_0^2|0\rangle = 0. \tag{5.7}$$

For such a condition to be meaningful the vacuum state should be an eigenstate to p_0^μ, i.e., $p_0^\mu|p\rangle = p^\mu|p\rangle$. Equation (5.7) requires then the vacuum to be massless ($p^2 = 0$). For $m = 0$ we also have

$$\tilde{\phi}_0^L|p\rangle = (d-2)\left(\tfrac{1}{2}\alpha^2 - \tfrac{1}{12}\right)|p\rangle, \tag{5.8}$$

which satisfies (5.6) only for $d = 2$. For $s \neq 0$ we have

$$\tilde{\phi}_0^L(s) = i\sum_{k=1}^{\infty} k(x_{-k}\cdot p_k - p_{-k}\cdot x_k) + \sum_{k=1}^{\infty} k(b_{-k}^{-1}\cdot c_k^{-1} + c_{-k}^{-1}\cdot b_k^{-1} + b_{-k}^L\cdot c_k^L + c_{-k}^L\cdot b_k^L)$$
$$+ (d-2)\sum_{k=1}^{\infty} k f^{(\alpha)}(|k|,s). \tag{5.9}$$

From the commutator (4.11) we find

$$\lim_{s\to 0}[\tilde{\phi}_m^L, \tilde{\phi}_{-m}^L](s)|p\rangle = \tfrac{1}{6}\big((d-26)m^3 - (d-2)m\big)|p\rangle. \tag{5.10}$$

In fact, in the $s \to 0$ limit we have

$$[\tilde{\phi}_m^L, \tilde{\phi}_{-m}^L] = 2m\tilde{\phi}_0^L - \tfrac{1}{2}\alpha^2(d-2)m + \tfrac{1}{6}(d-26)m^3, \tag{5.11}$$

where $\tilde{\phi}_0^L$ on the right-hand side is the $s \to 0$ limit of (5.9). If we redefine Q by

$$Q' \equiv Q - \tfrac{1}{4}\alpha^2(d-2)c_0^L, \tag{5.12}$$

then the extended constraint operator $\tilde{\phi}_0^L$ is replaced by

$$\tilde{\phi}'^L_0 = \tilde{\phi}_0^L - \tfrac{1}{4}\alpha^2(d-2). \tag{5.13}$$

This operator together with $\tilde{\phi}_m^L$, $m \neq 0$ satisfy then an anomaly free algebra for $d = 26$, from which we conclude that Q' is nilpotent for $d = 26$. However, from (5.8) we have

$$\tilde{\phi}_0'^L|p\rangle = -\tfrac{1}{12}(d-2)|p\rangle. \tag{5.14}$$

It follows that we have no BRST-invariant vacuum of the above form for $d = 26$. However, there are BRST-invariant states in $d = 26$. In Ref. 16 it was shown that there are massless states with spin 0, 1 and 2. In Sec. IX we show that these states do not have positive norms. (From the results of Ref. 11 it seems that a BRST-invariant vacuum state only exists in the Ramond sector of the spinning tensionless string, in which case the critical dimension is 10.)

VI. THE BOSONIC CONFORMAL STRING

The conformal string is a tensionless string that is made manifestly conformally invariant.[3,4] By adding two extra dimensions, one timelike and one spacelike, one forms new coordinates that transform as $SO(d,2)$ vectors. By means of $SO(d,2)$-invariant constraints, one obtains then an $SO(d,2)$ conformally invariant formulation by construction. Let $X^M=(X^\mu,X^+,X^-)$ be the new coordinate vector, where the metric of the new coordinates is $\eta_{++}=\eta_{--}=0$, $\eta_{+-}=\eta_{-+}=1$. Classically the constraints are

$$\Phi^{-1}(\sigma)\equiv P^M(\sigma)P_M(\sigma)=0, \quad \Phi^0(\sigma)\equiv P^M(\sigma)X_M(\sigma)=0,$$
$$\Phi^1(\sigma)\equiv X^M(\sigma)X_M(\sigma)=0, \quad \Phi^L(\sigma)\equiv P^M(\sigma)X'_M(\sigma)=0, \tag{6.1}$$

and they reduce to the constraints (4.1) of the tensionless string by means of the gauge fixing conditions,

$$P^+(\sigma)=0, \quad X^+(\sigma)-1=0. \tag{6.2}$$

(A corresponding construction for particles were given in Ref. 17.) The Hermitian BRST charge operator is given by

$$Q=\sum_k (\phi^1_{-k}c^1_k+\phi^0_{-k}c^0_k+\phi^{-1}_{-k}c^{-1}_k+\phi^L_{-k}c^L_k)-\frac{1}{2}\sum_{k,l}\Big(2ic^1_{-k}c^{-1}_{-l}b^0_{k+l}+ic^1_{-k}c^0_{-l}b^1_{k+l}$$
$$-ic^{-1}_{-k}c^0_{-l}b^{-1}_{k+l}+(k+l)c^1_{-k}c^L_{-l}b^1_{k+l}+(k-l)c^{-1}_{-k}c^L_{-l}b^{-1}_{k+l}+kc^0_{-k}c^L_{-l}b^0_{k+l}$$
$$+\frac{1}{2}(k-l)c^L_{-k}c^L_{-l}b^L_{k+l}+\text{h.c.}\Big), \tag{6.3}$$

where h.c. are Hermitian conjugate terms and

$$\phi^{-1}_n\equiv\frac{1}{2}\sum_k p_k\cdot p_{n-k}, \quad \phi^0_n\equiv\frac{1}{4}\sum_k (x_k\cdot p_{n-k}+p_{n-k}\cdot x_k),$$
$$\phi^1_n\equiv\frac{1}{2}\sum_k x_k\cdot x_{n-k}, \quad \phi^L_n\equiv -i\frac{1}{2}\sum_k k(x_k\cdot p_{n-k}+p_{n-k}\cdot x_k), \tag{6.4}$$

which are the Fourier modes of the Hermitian operator constraints corresponding to (6.1). The BRST charge (6.3) is formally nilpotent and a consistent BRST quantization is possible if there exists a BRST-invariant vacuum state on which we have a nilpotent BRST operator. In order to investigate the existence of such a vacuum state, we need the extended constraint operators defined by

$$\tilde{\phi}^{-1}_n\equiv[Q,b^{-1}_n]=\phi^{-1}_n+\sum_k (2ic^1_kb^0_{n-k}+ic^0_kb^{-1}_{n-k}-(n+k)c^L_kb^{-1}_{n-k}),$$

$$\tilde{\phi}^0_n\equiv[Q,b^0_n]=\phi^0_n+\frac{1}{2}\sum_k (ic^1_kb^1_{n-k}-ib^1_{n-k}c^1_k-2nc^L_kb^0_{n-k}-ic^{-1}_kb^{-1}_{n-k}+ib^{-1}_{n-k}c^{-1}_k),$$
$$\tag{6.5}$$
$$\tilde{\phi}^1_n\equiv[Q,b^1_n]=\phi^1_n-\sum_k (2ic^{-1}_kb^0_{n-k}+ic^0_kb^1_{n-k}+(n-k)c^L_kb^1_{n-k}),$$

$$\tilde{\phi}_n^L \equiv [\mathcal{Q}, b_n^L] = \phi_n^L - \frac{1}{2}\sum_k ((k+n)(c_k^{-1}b_{n-k}^{-1} - b_{n-k}^{-1}c_k^{-1} + c_k^L b_{n-k}^L - b_{n-k}^L c_k^L)$$
$$+(k-n)(c_k^1 b_{n-k}^1 - b_{n-k}^1 c_k^1) + k(c_k^0 b_{n-k}^0 - b_{n-k}^0 c_k^0)]).$$

These operators are shown to satisfy the following commutator algebra:

$$[\tilde{\phi}_m^1, \tilde{\phi}_n^{-1}] = 2i\tilde{\phi}_{m+n}^0, \quad [\tilde{\phi}_m^L, \tilde{\phi}_n^L] = (m-n)\tilde{\phi}_{m+n}^L, \quad [\tilde{\phi}_m^0, \tilde{\phi}_n^L] = m\tilde{\phi}_{m+n}^0,$$
$$[\tilde{\phi}_m^1, \tilde{\phi}_n^0] = i\tilde{\phi}_{m+n}^1, \quad [\tilde{\phi}_m^{-1}, \tilde{\phi}_n^0] = -i\tilde{\phi}_{m+n}^{-1}, \tag{6.6}$$
$$[\tilde{\phi}_m^1, \tilde{\phi}_n^L] = (m+n)\tilde{\phi}_{m+n}^1, \quad [\tilde{\phi}_m^{-1}, \tilde{\phi}_n^L] = (m-n)\tilde{\phi}_{m+n}^{-1}.$$

These commutators are nonanomalous, as required by the formal nilpotence of Q.

Following Ref. 4, we consider now a vacuum state that satisfies the conditions

$$p_n^M|0\rangle = b_n^{-1}|0\rangle = c_n^1|0\rangle = 0, \quad \forall n. \tag{6.7}$$

These conditions are consistent with a BRST-invariant vacuum state, since

$$[Q, p_n^M]|0\rangle = \tilde{\phi}_n^{-1}|0\rangle = [Q, c_n^1]|0\rangle = 0, \quad \forall n, \tag{6.8}$$

are satisfied due to (6.7). Now these conditions do not specify a unique vacuum. We need further conditions for that. We may ghost fix the vacuum by the conditions

$$b_n^0|0\rangle = b_n^L|0\rangle = 0, \quad \forall n. \tag{6.9}$$

Their consistency conditions are

$$\tilde{\phi}_n^0|0\rangle = \tilde{\phi}_n^L|0\rangle = 0, \quad \forall n, \tag{6.10}$$

and are satisfied for $n \neq 0$ due to (6.7). By means of the regularization (2.7) we find, furthermore, that

$$\tilde{\phi}_0^L|0\rangle = 0, \tag{6.11}$$

for any s due to the symmetry properties we had in (4.9). Using (2.12) we have by a direct calculation,

$$\tilde{\phi}_0^0|0\rangle = \frac{i}{2}(d-2)\alpha|0\rangle, \tag{6.12}$$

in the limit $s \to 0$. Thus, $\tilde{\phi}_0^0$ has an imaginary continuous spectrum. The above vacuum state is therefore only BRST invariant for $d=2$. (There might exist BRST-invariant states built from the above vacuum state. However, we have not found any.)

If we define a new charge like in the bosonic string by

$$Q' = Q - \frac{i}{2}(d-2)\alpha c_0^0, \tag{6.13}$$

then the above vacuum state is BRST invariant under the new charge Q' for any dimension d. However, Q' is then neither Hermitian nor nilpotent for $d \neq 2$.

In fact, Q is nilpotent on $|0\rangle$ for any dimension d. This may be checked as in the previous models, by computing the algebra of the extended constraints acting on the vacuum state. The most nontrivial of these equations read as

$$[\tilde{\phi}_m^{-1},\tilde{\phi}_{-m}^1](s)|0\rangle=\frac{2-d}{2}\sum_k f^{(\alpha)}(|k|,s)f^{(\alpha)}(|k+m|,s)|0\rangle. \tag{6.14}$$

Here

$$\sum_k f^{(\alpha)}(|k|,s)f^{(\alpha)}(|k+m|,s)=\zeta\left(s,\alpha+\frac{1}{2}|m|,-\frac{m^2}{4}\right)+\zeta\left(s,\alpha-\frac{1}{2}|m|,-\frac{m^2}{4}\right)+g(m,s), \tag{6.15}$$

where we have introduced the zeta function,[8]

$$\zeta(s,a,b)\equiv\sum_k \frac{1}{[(k+a)^2+b]^s}, \tag{6.16}$$

and $g(m,s)$ involves only finite sums and $g(m,0)=-1$. Now since (we are indebted to Per Salomonson for this simple argument)

$$\left.\frac{d\zeta}{db}\right|_{s=0}=s\sum_k \left.\frac{1}{[(k+a)^2+b]^{s+1}}\right|_{s=0}=0, \tag{6.17}$$

we have

$$\zeta(0,a,b)=\zeta(0,a,0)=\zeta(0|a)=\tfrac{1}{2}-a, \tag{6.18}$$

which implies that

$$\sum_k f^{(\alpha)}(|k|,s)f^{(\alpha)}(|k+m|,s)\Big|_{s=0}=-2\alpha. \tag{6.19}$$

Hence

$$[\tilde{\phi}_m^{-1},\tilde{\phi}_{-m}^1]|0\rangle=(d-2)\alpha|0\rangle, \tag{6.20}$$

which is consistent with (6.6) and (6.12). Commutators of other constraint operators may similarly be shown to consistently act on the vacuum state, in accordance with Eq. (6.6). Thus, the nilpotency of the BRST operator holds as a true operator equation in the chosen state space. For $d\neq 2$ the considered vacuum state is not BRST invariant. Furthermore, we have not been able to find any BRST-invariant state in the state space. If there does not exist BRST-invariant states, the theory is nontrivial only in $d=2$.

Now instead of the conditions (6.9) we may also ghost fix the vacuum state by the conditions

$$c_n^0|0\rangle=b_n^L|0\rangle=0,\quad \forall n. \tag{6.21}$$

In this case all consistency conditions are satisfied, which means that this vacuum is BRST invariant under the original formally nilpotent BRST charge (6.3) for any dimension d. Hence, we have found two vacua: one that is BRST invariant only for $d=2$ and another that is BRST invariant for all dimensions. However, since we work in the minimal sector, we must make sure that there exists a dual vacuum state $|\overline{0}\rangle$. It is straightforward to show that $|\overline{0}\rangle$ exists for any dimensions in the first case above but only for $d=2$ in the second case. Thus, both solutions yield equivalent results, and we have found a BRST-invariant vacuum only for $d=2$, in agreement with the result of Ref. 4. That we have two solutions requires a selection condition. (What we have here is a noncanonical situation in the language of Ref. 5.)

VII. ALTERNATIVE QUANTIZATIONS OF THE BOSONIC CONFORMAL STRING

Here we will consider two alternative sets of state spaces to the one treated in the previous section.

A. A consistent solution at $d=4$

First we consider a state space with a vacuum state defined through the conditions

$$p_n^\mu|0\rangle=p_n^+|0\rangle=x_n^+|0\rangle=b_n^{-1}|0\rangle=c_n^1|0\rangle=b_n^0|0\rangle=b_n^L|0\rangle=0, \quad \forall n. \tag{7.1}$$

It is easily checked that this vacuum state satisfies

$$\tilde{\phi}_n^{-1}|0\rangle=\tilde{\phi}_n^L|0\rangle=0, \quad \forall m. \tag{7.2}$$

Furthermore,

$$\tilde{\phi}_0^0|0\rangle=\frac{i}{2}(d-4)\alpha|0\rangle, \tag{7.3}$$

in the limit $s\rightarrow 0$. By the same reasoning as in the previous section, this leads to the conclusion that the above vacuum state is only BRST invariant for $d=4$. We must also check the closure of the extended constraints when acting on the vacuum state. In precisely the same way that leads to Eq. (6.20), one finds in this case,

$$[\tilde{\phi}_m^{-1},\tilde{\phi}_{-m}^1]|0\rangle=(d-4)\alpha|0\rangle, \tag{7.4}$$

which is consistent with (6.6) and (7.3). Other commutators of constraint operators may similarly be shown to consistently act on the vacuum state. Concluding, we have a nonanomalous theory for any d, and the vacuum state is BRST invariant for $d=4$. We have not been able to find BRST-invariant states for other d. The vacuum dual to $|0\rangle$ is defined by

$$x_n^\mu|\overline{0}\rangle=x_n^-|\overline{0}\rangle=p_n^-|\overline{0}\rangle=c_n^{-1}|\overline{0}\rangle=b_n^1|\overline{0}\rangle=c_n^0|\overline{0}\rangle=c_n^L|\overline{0}\rangle=0, \quad \forall n. \tag{7.5}$$

It is easily shown that this vacuum is BRST invariant for any d.

The state space that we have defined here treats the $x^\pm$ coordinates differently than the x^μ coordinates. Thus, we have lost manifest $d+2$-dimensional $SO(d,2)$ covariance. However, as the x^μ coordinates are regarded as the physical ones [in the sense of the gauge fixing conditions (6.2)], we still have manifest Lorentz covariance in this physical subspace. (If we do not insist on manifest Lorentz covariance, we may treat x^0 and one of the space coordinates in a similar fashion as $x^\pm$ and get a BRST-invariant vacuum in $d=6$.)

B. An inconsistent solution

We now consider another choice of state space. In analogy with the alternative treatment of the tensionless string in Sec. V, we may for the conformal string try a vacuum state satisfying

$$p_m^M|0\rangle=x_m^M|0\rangle=0, \quad m>0. \tag{7.6}$$

This alternative quantization was investigated in Ref. 3. The consistency conditions to (7.6) requires

$$c_m^{-1}|0\rangle=c_m^0|0\rangle=c_m^1|0\rangle=c_m^L|0\rangle=0, \quad m>0. \tag{7.7}$$

The conditions (7.6) and (7.7) allow for a ghost fixing of the form

$$c_0^1|0\rangle=0, \quad b_m^1|0\rangle=0, \quad m>0, \tag{7.8}$$

$$b_m^{-1}|0\rangle=b_m^0|0\rangle=b_m^L|0\rangle=0, \quad m\geqslant 0. \tag{7.9}$$

The consistency conditions for (7.8) are automatically satisfied as well as those of (7.9) for $m>0$. However,

$$\tilde{\phi}_0^{-1}|0\rangle=0 \tag{7.10}$$

and

$$\tilde{\phi}_0^0|0\rangle=0 \tag{7.11}$$

yields further conditions on the vacuum state. They may be satisfied. [Equation (7.11) fixes the conformal dimension of the vacuum state.] The problem is the last one, which yields

$$\tilde{\phi}_0^L|0\rangle=(d-2)\left(\frac{1}{2}\alpha^2-\frac{1}{12}\right)|0\rangle. \tag{7.12}$$

Checking the commutation relations, we find

$$\lim_{s\to 0}[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L](s)=2m\tilde{\phi}_0^L+\tfrac{1}{6}(d-26)m^3-m(d-2)\alpha^2, \tag{7.13}$$

where $\tilde{\phi}_0^L$ on the right-hand side is the normal ordered operator in (7.12). Notice that (7.13) coincides almost exactly with (5.11), although we here have $d+2$ coordinates and four ghost fields. It looks now as if the situation is the same as for the tensionless string in Sec. V, i.e., it looks as if we may follow the arguments after (5.11), leading to a consistent BRST quantization in $d=26$. However, for the conformal string there is an additional nontrivial commutator, for which we find

$$\lim_{s\to 0}[\tilde{\phi}_m^1,\tilde{\phi}_{-m}^{-1}](s)|0\rangle=\left(2i\tilde{\phi}_0^0-\frac{1}{2}(d-6)m\right)|0\rangle, \tag{7.14}$$

where $\tilde{\phi}_0^0$ on the right-hand side is the normal ordered operator that follows from (6.5) through our regularization, i.e.,

$$\tilde{\phi}_0^0=\frac{1}{4}(x_0p_0+p_0x_0)+\frac{1}{2}\sum_{k=1}^{\infty}(p_{-k}\cdot x_k+x_{-k}\cdot p_k)+i(c_0^1b_0^1-c_0^{-1}b_0^{-1})$$
$$+i\sum_{k=1}^{\infty}(b_{-k}^{-1}\cdot c_k^{-1}-c_{-k}^{-1}\cdot b_k^{-1}-b_{-k}^1\cdot c_k^1+c_{-k}^1\cdot b_k^1). \tag{7.15}$$

The relation (7.14) says that Q can only be nilpotent in $d=6$, which contradicts the above result that required $d=26$. It follows that there is no consistent BRST quantization of the conformal string on the vacuum considered here. This result agrees with Ref. 3.

VIII. ALTERNATIVE STATE SPACE FOR THE BOSONIC STRING

In view of the treatments in Secs. IV and V, one may wonder if one may not have a corresponding vacuum state also in the ordinary bosonic string case. Below we demonstrate that this is not the case. The classical constraints (3.1) may also be written as

$$P^{\mu}(\sigma)P_{\mu}(\sigma)+T^2X^{\mu\prime}(\sigma)X'_{\mu}(\sigma)=0, \quad P^{\mu}(\sigma)X'_{\mu}(\sigma)=0. \tag{8.1}$$

The Fourier modes of the corresponding Hermitian constraint operators are

$$\begin{aligned}\Phi_n^{-1}&\equiv\frac{1}{2}\sum_k p_k\cdot p_{n-k}-2T^2\sum_k k(n-k)x_k\cdot x_{n-k},\\ \phi_n^L&\equiv -i\frac{1}{2}\sum_k k(x_k\cdot p_{n-k}+p_{n-k}\cdot x_k).\end{aligned} \tag{8.2}$$

The Hermitian and formally nilpotent BRST charge (3.5) may be rewritten as

$$\begin{aligned}Q=\sum_k (\Phi_{-k}^{-1}c_k^{-1}+\phi_{-k}^L c_k^L)-\frac{1}{2}\sum_{k,l}(k-l)\bigg(&c_{-k}^{-1}c_{-l}^L b_{k+l}^{-1}+\frac{1}{2}c_{-k}^L c_{-l}^L b_{k+l}^L\\ &+4T^2c_{-k}^{-1}c_{-l}^{-1}b_{k+l}^L+b_{k+l}^{-1}c_{-k}^{-1}c_{-l}^L+\frac{1}{2}b_{k+l}^L c_{-k}^L c_{-l}^L\bigg).\end{aligned} \tag{8.3}$$

[Notice that the ghost variables c_k^L, b_k^L here are not the same as in (3.5).] Here the extended constraints are given by

$$\begin{aligned}\tilde{\phi}_n^L&\equiv[Q,b_n^L]=\phi_n^L-\frac{1}{2}\sum_k (n+k)(c_k^{-1}b_{n-k}^{-1}-b_{n-k}^{-1}c_k^{-1}+c_k^L b_{n-k}^L-b_{n-k}^L c_k^L),\\ \tilde{\Phi}_n^{-1}&\equiv[Q,b_n^{-1}]=\Phi_n^{-1}-\sum_k (n+k)(c_k^L b_{n-k}^{-1}+4T^2c_k^{-1}b_{n-k}^L).\end{aligned} \tag{8.4}$$

A direct calculation of the commutator $[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L]$ gives

$$\begin{aligned}[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L](s)=m\sum_k &(-ikx_k\cdot p_{-k}-kc_k^L b_{-k}^L-kc_k^{-1}b_{-k}^{-1})(f^{(\alpha)}(|m+k|,s)+f^{(\alpha)}(|m-k|,s))\\ &+\sum_k (-ik^2x_k\cdot p_{-k}+(2m^2-k^2)(c_k^L b_{-k}^L+c_k^{-1}b_{-k}^{-1}))\\ &\times(f^{(\alpha)}(|m+k|,s)-f^{(\alpha)}(|m-k|,s)).\end{aligned}$$

The $s\to 0$ limit yields

$$[\tilde{\phi}_m^L,\tilde{\phi}_{-m}^L]=2m\tilde{\phi}_0^L, \tag{8.5}$$

which is consistent with the fact that the BRST charge (8.3) is nilpotent. One may note here that the second line in the last relation goes to zero as s goes to zero, if the operator

$$\Psi_{k,m}\equiv -ik^2x_k\cdot p_{-k}+(2m^2-k^2)(c_k^L b_{-k}^L+c_k^{-1}b_{-k}^{-1}), \tag{8.6}$$

is well defined. This is true for a state space where the vacuum has the form of the tensionless string vacuum defined by the condition

$$p_n^{\mu}|0\rangle=0, \quad \forall n. \tag{8.7}$$

However, this vacuum state is not appropriate for the tensile bosonic string. Consistency conditions of the form

$$[Q,p_n^{\mu}]|0\rangle=0, \quad \forall n \tag{8.8}$$

would require the ghost part of such a state to satisfy the relations

$$c_n^{-1}|0\rangle=0, \quad \forall n, \tag{8.9}$$

for which the consistency conditions,

$$[Q,c_n^{-1}]|0\rangle=0, \quad \forall n, \tag{8.10}$$

are satisfied. In fact, it is possible to ghost fix this vacuum state in a BRST-invariant way using the original BRST charge, which then also is nilpotent for any dimension d. However, there exists no dual vacuum state, $|\overline{0}\rangle$, to this solution. Note that $|\overline{0}\rangle$ must satisfy

$$x_n^{\mu}|\overline{0}\rangle=b_n^{-1}|\overline{0}\rangle=0, \tag{8.11}$$

for which the consistency condition,

$$[Q,b_n^{-1}]|\overline{0}\rangle=0, \tag{8.12}$$

cannot be satisfied.

IX. ALTERNATIVES WITH NEGATIVE NORM STATES

In the alternative treatments in Secs. V and VII, we considered a vacuum state of the type

$$p_m^{\mu}|0\rangle=x_m^{\mu}|0\rangle=0, \quad m>0. \tag{9.1}$$

It leads to a ''consistent'' BRST quantization for the bosonic tensionless string in $d=26$. In fact, even the ordinary bosonic string has a vacuum state satisfying (9.1). To see this one may notice that (9.1) is equivalent to (we let $|0\rangle$ be an eigenstate of p_0^{μ}, i.e., we set $|0\rangle=|p\rangle$),

$$\alpha_m^{\mu}|p\rangle=0, \quad \tilde{\alpha}_{-m}^{\mu}|p\rangle=0, \quad m>0, \tag{9.2}$$

due to the relations (3.3). Now (9.2) is different from the standard vacuum (3.10). The consistency conditions of the latter condition requires

$$c_{-m}^{K}|p\rangle=0, \quad m>0, \tag{9.3}$$

which means that the vacuum may be ghost fixed by

$$b_{-m}^{K}|p\rangle=0, \quad m\geqslant 0, \tag{9.4}$$

together with

$$c_m^{L}|p\rangle=0, \quad m>0; \quad b_m^{L}|p\rangle=0, \quad m\geqslant 0. \tag{9.5}$$

Calculating commutators for finite s and then taking the limit $s\to 0$, we find

$$[\tilde{K}_m,\tilde{K}_{-m}]=2m\tilde{K}_0-\tfrac{1}{12}(d-26)m^3+\tfrac{1}{2}m(d-2)\alpha^2, \tag{9.6}$$

where

$$\tilde{K}_0=\frac{1}{2}\alpha_0^2+\sum_{k=1}^{\infty}(\tilde{\alpha}_k\cdot\tilde{\alpha}_{-k}-kb_k^{K}c_{-k}^{K}-kc_k^{K}b_{-k}^{K})-\frac{1}{2}(d-2)\left(\frac{1}{2}\alpha^2-\frac{1}{12}\right). \tag{9.7}$$

We may then define a new BRST charge by

$$Q' = Q - \frac{d-2}{4}\alpha^2 (c_0^L - c_0^K), \tag{9.8}$$

which then is nilpotent for $d=26$. In $d=26$ the new extended constraints are

$$\begin{aligned} \tilde{L}_0' &= \frac{1}{2}\alpha_0^2 + \sum_{k=1}^{\infty} (\alpha_{-k}\cdot\alpha_k + kb_{-k}^L c_k^L + kc_{-k}^L b_k^L) - 1, \\ \tilde{K}_0' &= \frac{1}{2}\alpha_0^2 + \sum_{k=1}^{\infty} (\tilde{\alpha}_k \cdot \tilde{\alpha}_{-k} - kb_k^K c_{-k}^K - kc_k^K b_{-k}^K) + 1. \end{aligned} \tag{9.9}$$

However, $\tilde{L}_0'|p\rangle = 0$ requires $p^2 = 8T$ while $\tilde{K}_0'|p\rangle = 0$ requires $p^2 = -8T$. It follows that neither of these vacua are BRST invariant, or, in other words, we have no BRST-invariant vacuum satisfying (9.1). Still there are BRST-invariant states and they are massless with spin 0, 1, and 2, and spinless with $p^2 = \pm 8T$. Note, however, that since $\tilde{\alpha}_m^\mu$, $m>0$ act as creation operators, the space components $\tilde{\alpha}_m^i$ yield negative normed states. Thus, the BRST-invariant state spaces have negatively normed states. The same feature was also found for the alternative treatment of the tensionless string in Sec. V. (This alternative treatment has only massless states.[16]) It is clear that the existence of indefinite metric states in the BRST-invariant sector makes both these models inconsistent.

(Received 10 August 1998; accepted for publication 7 July 1999)

An explicit, order-by-order perturbative solution, valid over extended time scales, for the time dependence of operators of anharmonic oscillators, is developed within the framework of the method of normal forms. The freedom of choice of the zeroth-order term and, concurrently in the higher-order corrections, is exploited to develop a minimal normal form (MNF). The expansion for the eigenvalues of the perturbed Hamiltonian in a standard form is independent of the choice. However, the simple form obtained for the time dependence of the perturbative solution is more suitable than any other choice for application to high-lying excited states, as it offers a renormalized form for the propagator. © *1999 American Institute of Physics.* [S0022-2488(99)02310-5]

The issue of finding perturbative approximations, that are valid for long times, for the time dependence of quantum systems had been raised years ago in Ref. 1. Recently, it has been addressed again in the context of anharmonic oscillators. References 2 and 3 presented a detailed analysis of the quantum Duffing oscillator within the framework of the method of multiple time scales,[4,5] and in Ref. 6 this oscillator was analyzed within the framework of the method of normal forms.[7–9]

In the case of classical oscillator systems with nonlinear couplings, the freedom, inherent in the expansion, of the choice of the zeroth-order term and the concurrent modifications in the higher-order corrections, has been exploited for the derivation of *minimal normal forms* (MNF).[6,10] The errors incurred in approximations to the full solutions in the MNF choice grow appreciably more slowly, making the approximations valid for longer time spans, than in commonly employed expansion choices. This is demonstrated by several examples in Refs. 10 and 11.

One may naturally ask whether a MNF expansion can be employed advantageously also in the quantum mechanical case. Using the normal form expansion method, we obtain for the time dependence of the operators of the anharmonic oscillator an explicit, order-by-order, perturbative solution, valid over extended time scales. We show that the expansion for the eigenvalues of the perturbed Hamiltonian in a standard form is independent of the choice of the zeroth-order term. However, the simplicity and usefulness of the functional form of the time dependence found for the approximate solution is affected by the choice. The functional form obtained in the MNF choice is simpler and is more suitable than all other choices for application to high-lying excited states. It provides an order-by-order procedure for renormalizing the propagator.

Consider the quantum mechanical Hamiltonian of an anharmonic oscillator (in units of $\hbar\omega$):

$$H = a^\dagger a + \frac{1}{2} + \frac{1}{2^{p/2}p}\,\epsilon(a^\dagger + a)^p,$$

$$x = \frac{(a+a^\dagger)}{\sqrt{2}}, \quad \dot{x} = \frac{(a-a^\dagger)}{\sqrt{2}i}, \quad [a,a^\dagger] = 1.$$

The perturbation is turned on at $t=0$, so that the initial condition for the operator is

$$a(t=0)=a_0,$$

where a_0 is the unperturbed annihilation operator.

The normal form expansion entails the order-by-order parallel computation of two infinite series: The near-identity transformation (NIT), that relates the full solution for a, to the zeroth-order term, b,

$$a=b+\epsilon T_1(b^\dagger,b)+\epsilon^2 T_2(b^\dagger,b)+\cdots, \tag{1}$$

and the equation for the time dependence of the zeroth-order term (the normal form),

$$\frac{db}{dt}=U_0+\epsilon U_1+\epsilon^2 U_2+\cdots. \tag{2}$$

To be specific, we study in detail the case $p=4$, corresponding to the quantum Duffing oscillator. (The method clearly applies to any integer $p\geqslant 0$.) The time dependence of a is determined by

$$\frac{da}{dt}=ia+\frac{1}{4}i\epsilon(a^\dagger+a)^3=ia+\frac{1}{4}i\epsilon\begin{pmatrix} a^{\dagger^3}+3a^{\dagger^2}a+a^3+3a^\dagger \\ \underline{+3a^\dagger a^2+3a} \end{pmatrix}. \tag{3}$$

Inserting Eqs. (1) and (2) in Eq. (3), one obtains in each order, n, a relation between T_n and U_n that does not enable their unique determination. This nonuniqueness is partially reduced by choosing T_n not to depend explicitly on time (a permissible choice, as the system under study is autonomous). The remaining ambiguity is further reduced by requiring that the approximate solution constitutes a valid approximation over extended time scales. This requires that secular errors (errors that evolve linearly in time and limit the validity of the approximation to short times only) are eliminated in the approximate solution in each order. In the method of normal forms, one exploits the freedom in the expansion to meet this requirement by assigning all *resonant* terms [of the form $(b^\dagger\cdot b)^k\cdot b$, similar in form to the underlined terms in Eq. (3)], that arise in the nth-order dynamical equation, to U_n. The functional form of U_n is, thus,

$$U_n(b^\dagger,b)=g_n(b^\dagger\cdot b)b. \tag{4}$$

This accounts for the full effect of the perturbation on the zeroth-order term, b [Eq. (2)] in $O(\epsilon^n)$. All nonresonant terns are used for constructing T_n.

This division of terms between T_n and U_n enables the unique determination of U_n, but, still, not of T_n. The latter is determined up to a *free resonant term* [similar in form to Eq. (4)], which affects U_k and T_k in all orders $k\geqslant n+1$. For instance, in $O(\epsilon)$, U_1 is determined uniquely, while T_1 is not:

$$U_1=\tfrac{3}{4}i(b^\dagger\cdot b+1)b, \tag{5a}$$

$$T_1=-\tfrac{1}{16}b^{\dagger^3}-\tfrac{3}{8}b^{\dagger^2}b+\tfrac{1}{8}b^3-\tfrac{3}{8}b^\dagger+F_1(b^\dagger\cdot b)\cdot b; \tag{5b}$$

$F_1\cdot b$, the free resonant term in T_1, does not enter the $O(\epsilon)$ relation between T_1 and U_1. However, it affects all higher-order equations. In the following, we show its effect on U_2.

As all known terms in $O(\epsilon)$ are either cubic or linear in b and $b^\dagger$, one may choose for the free term in Eq. (5b):

$$F_1(b^\dagger\cdot b)\cdot b=\gamma b^\dagger\cdot b^2+\nu b. \tag{6}$$

With this choice, the expansion in powers of ϵ yields for U_2 the following expression (an asterisk denotes complex conjugation):

$$U_2=\tfrac{3}{4}i\{[(\gamma+\gamma^*)-\tfrac{17}{16}](b^\dagger b)^2+[(\nu+\nu^*)-(\gamma+\gamma^*)-\tfrac{17}{8}](b^\dagger b)-\tfrac{3}{2}\}b. \tag{7}$$

The commutator of b and $b^\dagger$ is

$$[b,b^\dagger]=1-\epsilon\{[a,T_1^\dagger]+[T_1,a^\dagger]\}+O(\epsilon^2)=1-\epsilon\{2(\gamma+\gamma^*)b^\dagger b+(\nu+\nu^*)\}+O(\epsilon^2). \tag{8}$$

In general, the NIT is not unitary, and the commutator is not equal 1, as b and $b^\dagger$ do not represent a wave function that is normalized to unity. Unitarity amounts to a specific choice of the free terms in T_n, in every order. For instance, in $O(\epsilon)$, it requires that γ and ν are purely imaginary.

One can show by induction that, for all n, U_n have an overall multiplicative i, with all remaining coefficients real. Thus, the structure of the normal form is

$$\frac{db}{dt}=i\left\{1+\sum_{n\geqslant 1}\epsilon^n f_n(b^\dagger\cdot b)\right\}b, \tag{9}$$

where f_n are real functions of $(b^\dagger\cdot b)$. Equation (9) implies that, within the framework of perturbation theory, $(b^\dagger\cdot b)$ is constant, and the solution for b is given explicitly by

$$b=\exp\left[i\left\{1+\sum_{n\geqslant 1}\epsilon^n f_n(b_0^\dagger\cdot b_0)\right\}t\right]b_0. \tag{10}$$

For a general NIT, this solution is cumbersome. In particular, the powers of $(b_0^\dagger\cdot b_0)$ in $f_n(b_0^\dagger\cdot b_0)$ increase with the order, n, in the sum in Eq. (10). This implies that the convergence (or asymptotic) characteristics of the phase factor in Eq. (10) become worse as one goes to high-lying excited states, for which the eigenvalues of $(b^\dagger\cdot b)$ (approximately, the occupation numbers of the unperturbed states) are large. For example, the ϵ term in the phase factor is uniquely determined and contains the monomials $(b^\dagger\cdot b)^k$, with $k=0,1$. In general, the ϵ^2 term will contain monomials $(b^\dagger\cdot b)^k$, with $k=0,1,2$, but is not unique. It depends on the choice of the free resonant term in T_1. In a similar manner, for $n\geqslant 2$, the functional form of the ϵ^n term in Eq. (10) depends on the choice of the free functions in T_k in the near identity transformation, Eq. (1), in all orders $k<n$.

The nonuniqueness of the expansion can be exploited to greatly simplify the solution by invoking the MNF choice. The latter corresponds to a specific choice of the free functions in the NIT, in all orders. We show the procedure in detail for the $O(\epsilon^2)$ contribution and sketch the main points for the analysis of the $O(\epsilon^3)$ contribution. Choosing the free parameters in F_1 to have the values

$$\gamma+\gamma^*=\tfrac{17}{16},\qquad \nu+\nu^*=\tfrac{27}{16},$$

one eliminates the quintic monomial in the expression for U_2 [Eq. (7)] and obtains

$$U_2=-\tfrac{3}{2}U_1. \tag{11}$$

Thus, U_2, now also contains only cubic and linear terms in b and $b^\dagger$.

To show how the MNF idea is extended to U_3, we note that, in $O(\epsilon^2)$, T_2 may include the following nonresonant terms:

$$b^{\dagger^5},b^{\dagger^4}b,b^{\dagger^3}b^2,b^\dagger b^4,b^5,b^{\dagger^3},b^{\dagger^2}b,b^3,b^\dagger.$$

The coefficients of these terms are determined uniquely by the $O(\epsilon^2)$ dynamical equation (which relates T_2 and U_2). In addition, T_2 may contain the following free resonant terms:

$$b^{\dagger^2}b^3,b^\dagger b^2,b,$$

which do not affect the $O(\epsilon^2)$ dynamical equation [just as the resonant terms in T_1 did not affect the $O(\epsilon)$ dynamical equation]. However, these free terms do affect the form of U_3. The coefficients of these three resonant terms are arbitrary. In general, U_3 may include the following resonant terms:

$$(b^\dagger b)^3 \cdot b, \quad (b^\dagger b)^2 \cdot b, \quad (b^\dagger b) \cdot b, \quad b.$$

One can choose the free parameters in T_2, to make U_3 also proportional to U_1, as in Eq. (11), so that it will also contain only cubic and linear terms in b and $b^\dagger$. The procedure can be repeated in higher orders, and the normal form becomes

$$\frac{db}{dt} = ib + \left(\epsilon - \frac{3}{2}\epsilon^2 + \cdots \right) U_1 = ib + \tfrac{3}{4} i(\epsilon - \tfrac{3}{2}\epsilon^2 + \cdots)(b^\dagger b + 1)\cdot b. \tag{12}$$

Equation (12) is solved by

$$b = \exp\{it\}\exp\{\tfrac{3}{4} i(\epsilon - \tfrac{3}{2}\epsilon^2 + \cdots)(b_0^\dagger b_0 + 1)t\}\cdot b_0. \tag{13}$$

Once the solution for b is known, a may be computed to the desired accuracy, using the NIT, Eq. (1). We note that the power of $(b_0^\dagger \cdot b_0)$ is the same for *all orders* in the exponent in Eq. (13), providing an approximation scheme that is more useful, even for high-lying excited states, than the general solution, Eq. (10), where the powers of $(b_0^\dagger \cdot b_0)$ in f_n increase with the order n. Thus, the MNF choice provides an order-by-order procedure for the derivation of a renormalized propagator.

As an example for the for the resulting time dependence, we show the action of b on the vacuum of the unperturbed a states. We denote the nth excited state of the oscillator by $|n,t\rangle_a$, so that $|n,t=0\rangle_a$ is the unperturbed state at $t=0$. Inverting Eq. (1) through $O(\epsilon)$ and using Eqs. (5b), (6), and (13), one finds

$$b(t)|0\rangle_a = \epsilon \exp(it)\left\{ \frac{\sqrt{6}}{16}\exp(3\epsilon it)|3,t=0\rangle_a + \frac{3}{8}\exp(3/2\epsilon it)|1,t=0\rangle_a \right\} + O(\epsilon^2), \quad t \leqslant O(1/\epsilon) \tag{14}$$

To compute the energy levels, we note that, through $O(\epsilon)$, the diagonalized Hamiltonian becomes

$$H = b^\dagger b + \tfrac{1}{2} + \epsilon[(\tfrac{3}{8} + (\gamma+\gamma^*))(b^\dagger b)^2 + (\tfrac{1}{2} + (\nu+\nu^*) - (\gamma+\gamma^*))(b^\dagger b) + \tfrac{1}{4}] + O(\epsilon^2). \tag{15}$$

To compute the eigenvalues of H, we need to find eigenstates of the operator $B = (b^\dagger \cdot b)$, which, as pointed out earlier, is time independent. We denote an eigenstate of B with eigenvalue β, by $|\beta\rangle$ and expand it in eigenfunctions of the unperturbed oscillator, using the notation of Eq. (13):

$$|\beta\rangle = |n,t=0\rangle_a + \epsilon \sum_{k\neq n} \alpha_k |k,t=0\rangle_a. \tag{16}$$

Inverting the NIT [Eq. (1)], and employing Eqs. (5b) and (6), one finds through $O(\epsilon)$,

$$\beta = n\{1 - \epsilon[(\gamma+\gamma^*)(n-1) + (\nu+\nu^*)]\} + O(\epsilon^2). \tag{17}$$

Only a states with population $n\pm 4$ and $n\pm 2$ are admixed into $|\beta\rangle$ through $O(\epsilon)$, with coefficients

$$\alpha_{n+4} = \frac{1}{16}\,\frac{\sqrt{(n+1)(n+2)(n+3)(n+4)}}{n},$$

$$\alpha_{n+2}=\frac{1}{8}\frac{(2n+3)\sqrt{(n+1)(n+2)}}{n},$$

$$\alpha_{n-2}=\frac{1}{8}\frac{(2n-1)\sqrt{n(n-1)}}{n}\quad(n\geqslant 2),$$

$$\alpha_{n-4}=\frac{1}{16}\frac{\sqrt{n(n-1)(n-2)(n-3)}}{n}\quad(n\geqslant 4).$$

We note that each eigenvalue of $B=(b^\dagger\cdot b)$ is close to an eigenvalue n of the unperturbed number operator, $(a^\dagger\cdot a)$. Also, the deviation of β from n depends on $(\gamma+\gamma^*)$ and on $(\nu+\nu^*)$.

Inserting Eq. (17) for β in Eq. (15), we find the energy of a $|\beta\rangle$ eigenstate to be

$$E_\beta=n+\tfrac{1}{2}+\epsilon(\tfrac{3}{8}n^2+\tfrac{1}{2}n+\tfrac{1}{4})+O(\epsilon^2). \tag{18}$$

This result is *independent* of γ and ν, namely, of the free resonant term in T_1. Clearly, the energy of an eigenstate of the perturbed Hamiltonian, when expressed in terms of the quantum number of the reference adjacent unperturbed state, is independent of the choice of the free functions in any order. Thus, for computing the eigenvalues through a given order in ϵ, there is no advantage in a specific choice (e.g., a unitary NIT) of the free resonant terms.

The choice of the free parameters depends on what one wishes to achieve. For a unitary NIT, b and $b^\dagger$ represent wave functions that are normalized to unity, obeying $[b,b^\dagger]=1$, so that $B=(b^\dagger\cdot b)$ is a true number operator. In $O(\epsilon)$, unitarity of the NIT implies: $\gamma+\gamma^*=\nu+\nu^*=0$. One then has

$$\beta=n.$$

Thus, the number eigenvalue for a b state is equal to the number eigenvalue of the adjacent unperturbed a state. H then becomes

$$H=b^\dagger b+\tfrac{1}{2}+\epsilon[\tfrac{3}{8}(b^\dagger b)^2+\tfrac{1}{2}(b^\dagger b)+\tfrac{1}{4}]+O(\epsilon^2).$$

In this case, computation of the time dependence of a is cumbersome, because the functional form of higher-order terms will not be the same as that of the first-order one. For a nonunitary NIT, one has $[b,b^\dagger]=1+O(\epsilon)$ [see Eq. (8)]. In the particular case of the MNF choice, one obtains

$$H=b^\dagger b+\tfrac{1}{2}+\epsilon[\tfrac{23}{16}(b^\dagger b)^2+\tfrac{9}{8}(b^\dagger b)+\tfrac{1}{4}]+O(\epsilon^2).$$

Here the time dependence of a is simpler, and is easily found to any desired order [Eq. (13)] and the result applies more readily also to high-lying excited states.

We mention in passing that when the perturbation has two terms,

$$H=a^\dagger a+\frac{1}{2}+\frac{1}{2^{p/2}p}\,\epsilon(a^\dagger a)^p+\frac{1}{2^{q/2}q}\,\epsilon^2(a^\dagger+a)^q,$$

with $p\leqslant q$, then a reduction of the normal form to a MNF, similar in structure to Eq. (12), can be affected, starting from $O(\epsilon^2)$. If $p>q$, so that (in the corresponding classical system) a competition of scales occurs, the normal form can be reduced to a MNF, starting only from $O(\epsilon^3)$.

In summary, the freedom in the choice of the zeroth-order approximation, inherent in any perturbation expansion scheme, may be exploited to construct a unitary NIT that yields a simple form for the diagonalized Hamiltonian, or a MNF, to obtain a simple form, that may be useful also for high-lying excited states, for the time dependence of the operators. The latter alternative provides an order-by-order algorithm for obtaining a renormalized propagator. The MNF choice may be also relevant in the study of coherent states, where nonunitary transformations have been considered,[12] and in non-Hermitian Hamiltonian problems that have recently received renewed attention,[13–17] and where unitarity of the NIT is not required. Finally, while the method of normal forms has been used in the present analysis, a parallel procedure can be easily formulated for the method of multiple time scales. Denoting the time scales by $\tau_n = \epsilon^n t$, the MNF constraints on the free resonant terms in T_1, $T_2, \ldots,$ correspond to specific requirements on the $\tau_2, \tau_3, \ldots,$ dependence of the solution in the latter method.

Nonassociative structure of quantum mechanics in curved space–time

Edward H. Kerner
Sharp Physics Laboratory, University of Delaware, Newark, Delaware 19716

(Received 19 May 1999; accepted for publication 16 July 1999)

de Sitter space gives a local, osculating (and therefore prototypical) representation of a curved space–time. The de Sitter geodesics allow a description as uniform straight-line motion with respect to a family of preferred frames that are inertial frames interconnected by a projective (fractional-linear) transformation. Use of these frames overcomes the ambiguities of general covariance in stating commutation rules and Hamiltonian structure. But the Hamiltonian for a particle running on a geodesic then necessitates nonassociative elements. The latter are worked out as elements of a Cayley–Dickson algebra of 16 dimensions (doubled octonions, or decahexions), wherein a standard Hilbert space type of format for quantum mechanics is ruled out. A formal Schrödinger wave equation is devised, and exhibits antilinear as well as linear terms in the decahexion components of the wave function. All the same, the Heisenberg laws of motion for a dynamical variable are neatly and unambiguously formulated, giving a full account of the quantum time evolution of the dynamical variable (although the Heisenberg program of diagonalizing the Hamiltonian cannot be executed).
[S0022-2488(99)04510-7]

I. INTRODUCTION

The structure of spinors in a curved space was broached by Schrödinger[1] and by Bargmann[2] in the early days of quantum theory, and their formulation has since continued to hold sway.[3] The idea was simply to uplift the flat-space Dirac equation,

$$(\gamma^{\mu}\partial_{\mu}+m)\psi=0,$$

to a curved-space version,

$$(\gamma^{\mu}(x)\boldsymbol{\nabla}_{\mu}+m)\psi=0,$$

with covariant derivatives $\boldsymbol{\nabla}_{\mu}$ replacing ∂_{μ}, under general covariance guidelines, while requiring, among other things

$$[\gamma^{\mu}(x),\gamma^{\nu}(x)]=2g^{\mu\nu}(x),$$

that generalize the flat-space anticommutators.

The principal point is that, by explicit design, curvature is assumed to leave the fundamental gross format inherited from flat space untouched. The design is in itself clearly a purely formal recipe, failing to connect with underlying commutation rules or Hamiltonian structure, which is where the force of Planck's constant is ordinarily brought into full physical play. The failure, of course, is due at bottom to the amorphousness and vagueness of general covariance upon which the recipe insists.

In contrast, in the present note we aim to show that, from an *a priori* and unambiguous reckoning of the Hamiltonian H of a particle running along a geodesic path in curved space, and from the simplest physically based *a priori* commutation rules relating to that path, the spinor structure in the curved space is qualitatively, inevitably altered from the familiar flat-space Dirac format. This owes to the necessity for extracting a square root of H^2, as in ordinary Dirac theory, which, however, for geodesic motion in a curved space (typified here as a space of constant curvature) simply cannot be done at all *unless elements of a nonassociative algebra are admitted. It is these elements, constituting some sort of novel internal degrees of freedom, that necessarily enter the description of curved-space spinors*, and distinguish them at a basic structural level as something quite different from embellished flat-space spinors.

The present preliminary discussion is limited to geodesic motion in the simplest possible curved space. de Sitter space of symmetry $\mathcal{O}(3,2)$ of constant positive curvature, whose quantum theory has been appreciably discussed.[4] This restriction is less severe than appears at first glance, since it has been shown[5] that de Sitter spaces are the local osculating spaces to more generally curved Riemann spaces, seizing the local characterization of curvature, via higher order of contact, that is beyond reach from the low-order contact of mere tangent (Minkowski) spaces. In this sense, de Sitter space, so far from being highly specialized, comes close to being prototypical. The bubble of de Sitter space far overmatches the flake of Minkowski space in depicting the local geometric situation.

II. de SITTER SPACE HAMILTONIAN

A remarkable, if not widely familiar, feature of de Sitter space[6] is that its symmetry group of five-dimensional rotations $\mathcal{O}(3,2)$, can also and equivalently be read in terms of specialized projective (fractional-linear) transformations,

$$x_i' = \frac{A_{i\alpha}x_\alpha + B_i}{R_\alpha x_\alpha + 1}, \tag{1}$$

of space (x_1, x_2, x_3) and time (x_0 or t) coordinates (sum on repeated Greek indices understood). These projective transformations send unaccelerated free-particle motions into other free-particle motions, as with the familiar linear transformations of Galilean and special relativity. For example, if

$$x' = x_0' + v't',$$

then

$$x' = \frac{A_{11}x + A_{10}t + B_1}{R_1 x + R_0 t + 1}, \quad t' = \frac{A_{01}x + A_{00}t + B_0}{R_1 x + R_0 t + 1},$$

produces, owing to the common denominator,

$$x = x_0 + vt.$$

The projective transformations are *bona fide* inertial-frame transformations, in fact, the most general ones.

The tracing of the connection between projective and de Sitter groups is worked out in detail in Sec. III. Suffice it to say, the connection is encapsulated by the invariance under linear homogeneous transformations of the quadratic form,

$$X_1^2 + X_2^2 + X_3^2 + X_4^2 + f^2(X_4 - X_5)^2 = \text{invariant}, \tag{2}$$

where x_i has been written X_i/U in homogeneous coordinates, and where $X_4 \equiv icX_0$ and $X_5 \equiv ibU$ (b is a universal fundamental length and f a dimensionless constant). The homogeneous transformations in X_1, X_2, X_3, X_4, X_5 are essentially five-dimensional rotations that convert back to fractional-linear transformations in physical coordinates x_1, x_2, x_3, x_0. Based on Eq. (2), the infinitesimal invariant line element ds^2 in dt and $d\mathbf{r} \equiv (dx, dy, dz)$ is readily produced, and readily identifiable as one characterizing a space–time of constant curvature $a \equiv fb$.

Thus, notwithstanding the constant curvature of space–time, *the geodesics of de Sitter space one and all may be brought forth as the global free-particle motions*,

$$\frac{d^2\mathbf{r}}{dt^2}=0,$$

with the de Sitter group giving in projective language the description of motion from the viewpoints of equivalent inertial frames. This projective rephrasing of curvature works because the de Sitter free particle does not travel off to a remote place and stay there, as in flat space: it rides *through* a projective-geometric ''point at infinity,'' corresponding to the vanishing of the denominator $1+R_\alpha X_\alpha$ in Eq. (1), and reappears on the local scene (in fact, there is no distinction between the ''local'' and the ''infinitely remote'' scenes).

The inertial frames that here are interconnected in a projective account of the de Sitter group are clearly as distinguished for de Sitter space, as are the familiar linearly connected inertial frames of the Poincaré group for Minkowski space. All physical experience of the latter now leads to the basic physical hypothesis of the present work: *the inertial frame coordinates of a free particle, whether in de Sitter or Minkowski space, are the distinguished ones for prescribing commutation rules of the usual type* $(x,p_x)=i\hbar$, *etc., and building quantum theory along Hamiltonian lines*.

This abandonment of general covariance in favor of physically identifiable preferred inertial frames overcomes a longstanding difficulty of general covariance *vìs-a-vìs* quantum theory. Namely, if every kind of transformation is admitted between coordinate systems, all taken to be on the same footing, the formulation of commutation rules—showing at the deepest level just how and where Planck's constant enters physics—becomes completely ambiguous. This omnipresent ambiguity of general covariance is set aside once *distinguished* coordinates are recognized; and an approach is afforded to a basic background problem of general relativity, viz., the quantum theory of geodesics in a prescribed Riemannian geometric setting.

Of course, *after* preferred frames and clear commutation rules have been identified, any sort of coordinate transformation may be invoked according to convenience. An appreciably convenient transformation is, in fact,

$$\tan\frac{c\tau}{a}=\frac{ct/a}{1-ct/b},\qquad \boldsymbol{\rho}=\frac{\mathbf{r}}{\left[\left(\frac{ct}{a}\right)^2+\left(1-\frac{ct}{b}\right)^2\right]^{1/2}},$$

from $\mathbf{r},t$ to $\boldsymbol{\rho},\tau$, which carries the geodesics from $d^2\mathbf{r}/dt^2=0$ to the harmonic oscillator form

$$\frac{d^2\boldsymbol{\rho}}{d\tau^2}+\frac{c^2}{a^2}\boldsymbol{\rho}=0,$$

otherwise familiar in de Sitter space. Since τ depends on t alone, equal-t commutation rules go over simply to equal-τ ones. This gives a ladder spectrum of Klein–Gordon energy eigenvalues E with the correct[7] zero-point frequency c/a.

One last transformation,

$$\boldsymbol{\rho}=\frac{\mathbf{R}}{\left(1+\frac{R^2}{a^2}\right)^{1/2}}\quad(\tau\ \text{unchanged}),$$

brings a finally useful representation of the square of the Hamiltonian of a particle of mass m, running along a geodesic of de Sitter space, that springs out of the above inertially framed view of that space:

$$\frac{H^2}{c^2}=\left[\mathbf{P}^2+\frac{\mathbf{L}^2}{a^2}+\frac{\hbar^2}{a^2}\right]+\kappa^2\left[\frac{\hbar^2}{a^2}\left(1+\frac{\mathbf{R}^2}{a^2}\right)\right]=\left[\frac{H_1^2}{c^2}\right]+\kappa^2\left[\frac{H_2^2}{c^2}\right], \tag{3}$$

where

$$\mathbf{P}\equiv\frac{1}{2}\left(I+\frac{\mathbf{RR}}{a^2}\right)\cdot\mathbf{P}_c+\text{h.c.},\quad \mathbf{L}=\mathbf{R}\times\mathbf{P},$$

$$\kappa^2=\frac{m^2c^2a^2}{\hbar^2}-\frac{1}{4},$$

and $\mathbf{P}_c$ is the canonical mate $-i\hbar\boldsymbol{\nabla}$ to $\mathbf{R}$ stemming from the primitive commutation rules on the primitive geodesics $d^2\mathbf{r}/dt^2=0$. This places the floor $m^2\geqslant\frac{1}{4}\hbar^2/c^2a^2$ on masses so as to guarantee positive definite H^2.

III. EVOLUTION OF NONASSOCIATIVE ELEMENTS

The problem now is the same as that brought forth by Dirac over half a century ago in flat space: what is H when one knows the structure of H^2 from the fundamental commutation rules? The issue is unavoidable once the path of commutation rules and Hamiltonian structure is taken as fundamental in quantum theory $-H$, and not any function of it, is the master dynamical variable, and its character needs to be established if quantum physics is to be understood.

The central point is that *no Dirac square root of* H^2 *above exists* (except for $\kappa=0$). To see this, notice first that H_1 and H_2 separately are certainly Dirac calculable, for example,

$$H_1=\boldsymbol{\alpha}\cdot\mathbf{P}+\hat{\boldsymbol{\sigma}}\cdot\mathbf{L}-1,$$

$$H_2=\beta+\boldsymbol{\alpha}\cdot\mathbf{R}, \tag{4}$$

where, from here on, all of $\hbar,c,a=1$ and β, $\boldsymbol{\alpha}$ are standard Dirac matrices, with $\hat{\sigma}_x=i\alpha_y\alpha_z$, etc. These are not unique, merely illustrative of a large family.

Now H clearly must be linear in κ, and therefore must be of the form

$$H=AH_1+\kappa BH_2,$$

where A and B are suitable quantities placed into a Kronecker product (understood) with H_1 and H_2. Squaring produces ($\kappa\neq0$)

$$H^2=A^2H_1^2+\kappa(ABH_1H_2+BAH_2H_1)+\kappa^2B^2H_2^2,$$

so that, of course, A and B must be square roots of unity, while the cross terms must vanish.

It is easy to see that for H_1 and H_2 as in the example of Eq. (4), the cross-terms cannot cancel one another. Nor indeed can they cancel for any H_1 and H_2 whatever. For their cancellation, it is required that $H_1H_2=\pm H_2H_1$ or say kH_2H_1 and then it is enough that $AB=-kBA$ (i.e., A and B anticommuting or commuting). Multiplying on the left by H_1 and on the right by H_2 then gives

$$H_1^2H_2^2=k(H_1H_2)^2=k^3(H_2H_1)^2=k^3H_2(H_1H_2)H_1=k^3H_2(kH_2H_1)H_1=H_2^2H_1^2.$$

The separate squares H_1^2 and H_2^2 are unambiguous as given in Eq. (3), and a direct computation shows that H_1^2 and H_2^2 do not commute as required. In short, as the example, Eq. (4), clearly foretells, H_1H_2 and H_2H_1 are always so different as to disallow their cancellation: the cross-terms must *separately* vanish.

It is required in all, then, that

$$A^2=1=B^2, \tag{5}$$

$$AB=0=BA, \tag{6}$$

in order that H be extractable from H^2. Clearly, if A and B are elements of an associative algebra, conditions (5) and (6) are impossible. For associativity tells by (6) that $A(AB)=0$ means $(A^2)B=0$ or that $B=0$, and this contradicts $B^2=1$. Similarly, $(AB)B=0$ brings the contradiction that $A=0$ while $A^2=1$ is demanded. This argument rules out not only associative algebras $X(YZ)=(XY)Z$ but also those nonassociative algebras (such as the octonions) that are alternative, viz., $X(XY)=(X^2)Y,\ (XY)Y=X(Y^2)$.

This concludes the central point of the present paper: *The curvature of space–time necessarily induces a strictly nonassociative structure into the Hamiltonian for a particle going along a geodesic.* ($\kappa=0$ *excepted*).

IV. REALIZATION OF NONASSOCIATIVE ELEMENTS *A,B*

None of the familiar algebras—real numbers, complex numbers, quaternions,[8] octonions[9]—will do for *A,B*, as the first three are associative and the last alternative. But all after the first have a common root in the Cayley–Dickson doubling process,[10] wherein

- complex numbers are doublets of reals,
- quaternions are doublets of complexes,
- octonions are doublets of quaternions.

And now one further doubling, where the novel

- *decahexions* are doublets of octonions,

will be shown to answer to the requirements for *A* and *B*. The decahexions, which evidently have seen negligible development heretofore, probably for want of any applications, are the lowest in the Cayley–Dickson (infinite) hierarchy admitting explicit formation of *A* and *B*.

The members of a Cayley–Dickson algebra are of the form of ''hypercomplex'' numbers,

$$X\equiv x_0e_0+x_1e_1+x_1e_2+\cdots+x_ne_n\,,$$

with e_0 being an idemfactor (usually replaced by 1), and $e_i^2=-1$ $(i=1,2,3,...,n)$, and a suitable multiplication table for the basic elements $e_1,e_2,\ldots$ featuring anticommutativity $e_ie_j=-e_je_i$ (but $e_ie_0=e_0e_i=e_i$). The Cayley–Dickson hypercomplex numbers enjoy physically congenial properties, such as

$$\text{a conjugate}\quad \overline{X}=x_0-x_1e_1-x_2e_2-\cdots-x_ne_n,$$

$$\text{a trace}\quad \tfrac{1}{2}(X+\overline{X})=x_0,$$

$$\text{a norm}\quad X\overline{X}=\overline{X}X=x_0^2+x_1^2+x_2^2+\cdots+x_n^2,\qquad \text{and}$$

$$\text{a product conjugation}\quad \overline{XY}=\overline{Y}\,\overline{X}.$$

Usually the coefficients x_i are taken to be real, but occasionally may be taken to be imaginary or complex.

The doubling rule is as follows: If $X_1,\ X_2,\ Y_1,\ Y_2$ are members of one algebra, the doubled algebra consists of pairs such as $(X_1|X_2),\ (Y_1|Y_2)$, etc., with the product of doublets following the rule

$$(X_1|X_2)(Y_1|Y_2)\equiv(X_1Y_1-Y_2\overline{X}_2|\overline{X}_1Y_2+Y_1X_2)\equiv(Z_1|Z_2). \tag{7}$$

For example, for X,Y themselves simple two-element doublets,

$$X_1=(x_0,x_1)=x_0+e_1x_1,$$

$$X_2=(x_3,x_2)=x_3+e_1x_2,$$

$$Y_1=(y_0,y_1)=y_0+e_1y_1,$$

$$Y_2=(y_3,y_2)=y_3+e_1y_2,$$

one finds

$$Z_1=x_0y_0-x_1y_1-x_2y_2-x_3y_3+e_1(x_1y_0+x_0y_1+x_2y_3-x_3y_2),$$

$$Z_2=x_0y_3+x_3y_0+x_1y_2-x_2y_1+e_1(x_0y_2+x_2y_0+x_3y_1-x_1y_3). \tag{8}$$

In short, one gets a representation of quaternions whose standard format (with $e_3e_1=e_2$ cyclically),

$$Q_x=x_0+x_1e_1+x_2e_2+x_3e_3, \quad \text{or} \quad x_0+[\mathbf{x}],$$

$$Q_y=y_0+y_1e_1+y_2e_2+y_3e_3, \quad \text{or} \quad y_0+[\mathbf{y}],$$

with $\mathbf{x}$, $\mathbf{y}$ three-dimensional vectors (x_1,x_2,x_3), (y_1,y_2,y_3), may equally be written as

$$Q_x=(x_0+x_1e_1)+e_3(x_3+x_2e_1),$$

$$Q_y=(y_0+y_1e_1)+e_3(y_3+y_2e_1),$$

so as to show exact correspondence with the above Cayley–Dickson doublet of doublets. The convenient condensed multiplication rule,

$$Q_z=Q_xQ_y=x_0y_0-\mathbf{x}\cdot\mathbf{y}+[x_0\mathbf{y}+\mathbf{x}y_0+\mathbf{x}\times\mathbf{y}], \tag{9}$$

and the Cayley–Dickson rule (8) simply rephrase each other. The quaternion units e_1, e_2, e_3 can be represented through Pauli spin matrices σ_1, σ_2, σ_3 according to $e_k=-i\sigma_k$.

Next come doublets of quaternions, that is, octonions. In the Cayley–Dickson scheme,

$$\mathcal{O}_x=(x_0,x_1,x_2,x_3|x_7,x_4,x_5,x_6),$$

or, introducing the element e_7 (paralleling e_3 for quaternions),

$$\mathcal{O}_x=x_0+e_1x_1+e_2x_2+e_3x_3+e_7(x_7+x_4e_1+x_5e_2+x_6e_3).$$

This is, under the (partial) multiplication rules $e_7e_1=e_4$, $e_7e_2=e_5$, $e_7e_3=e_6$, the conventional representation,

$$\mathcal{O}_x=x_0+e_1x_1+e_2x_2+e_3x_3+x_4e_4+x_5e_5+x_6e_6+x_7e_7$$

(paralleling the conventional Q_x), with a product rule $\mathcal{O}_x\mathcal{O}_y$ that is easily worked out from the Cayley–Dickson fundament, Eq. (7).

Finally, the decahexions as Cayley–Dickson doublets of octonions are

$$\mathcal{D}=(\mathcal{O}_1|\mathcal{O}_2).$$

It is more convenient, however, to use the simple and associative quaternions as a subunit, representing each octonion in $\mathcal{D}$ as a pair of quaternions, so that $\mathcal{D}$ is equivalently a quartet of quaternions (or quatroquaternion):

$$\mathcal{D}_U=(U_1|U_2|U_3|U_4).$$

To obtain on this basis the multiplication rule for decahexions, we need only apply the Cayley–Dickson doubling rule twice in succession—once using $\mathcal{D}$ as an octonion pair, and then, in the resulting products of octonions, using each octonion as a quaternion pair. This gives the quadrupling rule, quite generally, as

$$\begin{gathered}\mathcal{D}_U\mathcal{D}_V=(U_1|U_2|U_3|U_4)(V_1|V_2|V_3|V_4)=(W_1|W_2|W_3|W_4),\\ W_1=U_1V_1-V_2\overline{U}_2-V_3\overline{U}_3-U_4\overline{V}_4,\\ W_2=\overline{U}_1V_2+V_1U_2+\overline{V}_3U_4-\overline{U}_3V_4,\\ W_3=\overline{U}_1V_3+V_4\overline{U}_2+V_1U_3-U_4\overline{V}_2,\\ W_4=U_1V_4-V_3U_2+\overline{V}_1U_4+U_3V_2.\end{gathered}\tag{10}$$

There are many ways now to attend to the algebraic requirements of Eqs. (5) and (6). One of the simplest is as follows. With A,B written as $(A_1|A_2|A_3|A_4)$ and $(B_1|B_2|B_3|B_4)$, take all the A_i quaternions to be traceless and to have vector parts that are collinear, say, along the unit three-dimensional sector $\hat{\mathbf{m}}$,

$$A_i=0+[\alpha_i\hat{\mathbf{m}}],\quad i=1,2,3,4.$$

Similarly, choose

$$B_i=0+[\beta_i\hat{\mathbf{n}}],$$

and, further, choose $\hat{\mathbf{m}}$ and $\hat{\mathbf{n}}$ to be orthogonal, $\hat{\mathbf{m}}\cdot\hat{\mathbf{n}}=0$. Then in the quaternion products occurring in AB according to Eq. (10), each product is of the form $0+[(\alpha\beta)\hat{\mathbf{m}}\times\hat{\mathbf{n}}]$, i.e., each resultant quaternion W_i, like A_i and B_i, is traceless and has vector parts all collinear to $\hat{\mathbf{m}}\times\hat{\mathbf{n}}$. One reads off at once,

$$AB=\begin{pmatrix}W_1\\W_2\\W_3\\W_4\end{pmatrix}=0+\begin{pmatrix}\alpha_1&-\alpha_2&-\alpha_3&\alpha_4\\-\alpha_2&-\alpha_1&\alpha_4&\alpha_3\\-\alpha_3&\alpha_4&-\alpha_1&\alpha_2\\\alpha_4&\alpha_3&\alpha_2&\alpha_1\end{pmatrix}\begin{pmatrix}\beta_1\\\beta_2\\\beta_3\\\beta_4\end{pmatrix}[\hat{\mathbf{m}}\times\hat{\mathbf{n}}].$$

Now, choose $\alpha_1,\alpha_2,\alpha_3,\alpha_4=(\xi,\eta,-\eta,\xi)$, so that $AB=0$ means

$$\begin{pmatrix}\xi&-\eta&\eta&\xi\\-\eta&-\xi&\xi&-\eta\\\eta&\xi&-\xi&\eta\\\xi&-\eta&\eta&\xi\end{pmatrix}\begin{pmatrix}\beta_1\\\beta_2\\\beta_3\\\beta_4\end{pmatrix}=(M)\beta=0.$$

The matrix M is of rank two and possesses two null vectors, $\mathrm{col}(x,0,0,-x)$ and $\mathrm{col}(0,y,y,0)$. Consequently, $\beta=\mathrm{col}(\beta_1,\beta_2,\beta_3,\beta_4)$ can be written as $\mathrm{col}(x,y,y,-x)$. And now $BA=0$ means similarly

$$\begin{pmatrix} x & -y & -y & -x \\ -y & -x & -x & y \\ -y & -x & -x & y \\ -x & y & y & x \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \alpha_4 \end{pmatrix} = 0,$$

and this is satisfied by $(\alpha_1, \alpha_2, \alpha_3, \alpha_4) = (\xi, \eta, -\eta, \xi)$.

The squares of A and B are now simply the scalars

$$A^2 = -2(\xi^2 + \eta^2) e_0,$$

$$B^2 = -2(x^2 + y^2) e_0,$$

so it suffices to take all of ξ, η, x, y to be purely imaginary to achieve $A^2 = 1 = B^2$:

$$\xi = i\gamma, \quad \eta = i\delta, \quad x = iu, \quad y = iv,$$

$$\gamma^2 + \delta^2 = \tfrac{1}{2}, \quad u^2 + v^2 = \tfrac{1}{2}.$$

That is, we obtain two one-parameter families of decahexions,

$$\gamma = \frac{1}{\sqrt{2}} \cos\theta, \quad \delta = \frac{1}{\sqrt{2}} \sin\theta \quad \text{and} \quad u = \frac{1}{\sqrt{2}} \cos\varphi, \quad v = \frac{1}{\sqrt{2}} \sin\varphi.$$

In summary, the decahexions, with orthogonal $\hat{\mathbf{m}}$ and $\hat{\mathbf{n}}$,

$$A = (A_1 | A_2 | A_3 | A_4) = (i\gamma[\hat{\mathbf{m}}] | i\delta[\hat{\mathbf{m}}] | -i\delta[\hat{\mathbf{m}}] | i\gamma[\hat{\mathbf{m}}]),$$

$$B = (B_1 | B_2 | B_3 | B_4) = (iu[\hat{\mathbf{n}}] | iv[\hat{\mathbf{n}}] | iv[\hat{\mathbf{n}}] | -iu[\hat{\mathbf{n}}]), \tag{11}$$

and normalization as above, meet the fundamental algebraic requirements of Eqs. (5) and (6). The occurrence of imaginary elements in the quaternionic components can be interpreted as a shift from the quaternion basis e_1, e_2, e_3 to the basis ie_1, ie_2, ie_3, that is, to Pauli spin matrices σ_1, σ_2, σ_3, as noted previously.

V. ISSUES OF QUANTIZATION

Since Albert's theorem,[11] it has been known that a probability interpretation, conforming to standard inherited precepts for quantum theory, has to rest on the algebra of real numbers, or complex numbers, or quaternions, or octonions. The first three can form bases for a Hilbert space formulation of quantum mechanics in which state vectors obey a superposition principle with, respectively, real, complex, or quaternionic coefficients, as in ordinary standard (complex) quantum theory. But the octonions, together with all other nonassociative systems, are ruled out, since, for example, scalar products like

$$\int \bar{\theta} N \phi \, d\mathbf{R},$$

are ambiguous, owing to the distinction between $(\overline{\theta} N)\phi$ and $\overline{\theta}(N\phi)$ with nonassociative θ, N, ϕ, an omnipresent ambiguity for all triadic products.

The decahexions are ruled out, not only because of their nonassociativity, cutting even more deeply than for octonions, but also because they do not form a division algebra (one for which $XY \neq 0$ when $X \neq 0$ and $Y \neq 0$—the above A,B by construction admit $AB = 0$ for nonzero A and B).

In short, *there appears to be an inevitable clash between the rudiments of space–time curvature* (as locally embraced by de Sitter space) *and the rudiments of quantum theory, as ordinarily understood*. This clash has not to do with general relativity in itself, but simply with curvature as such as reflected in the Hamiltonian structure for the geodesics.

Clash notwithstanding, it remains of interest to see what shape a Schrödinger wave equation takes,

$$i\hbar \frac{\partial \psi}{\partial \tau} = H\psi, \tag{12}$$

where ψ lies in the same algebra as $H = AH_1 + \kappa BH_2$, while $i\hbar\,\partial/\partial\tau$ signifies still that H generates time translations. The simplest construction is over the miniature algebra A,B,O (null), and I (idemfactor), irrespective of any explicit representation of A,B. First, iteration, in general, brings

$$-\hbar^2 \frac{\partial^2}{\partial \tau^2}\psi = H(H\psi),$$

but, of course,

$$H(H\psi) \neq (H^2)\psi = (H_1^2 + \kappa^2 H_2^2)\psi.$$

Next, place

$$\psi = I\psi_0 + A\psi_1 + B\psi_2,$$

in Eq. (12) and equate separate I,A,B components:

$$i\hbar\dot{\psi}_0 = H_1\psi_1 + \kappa H_2\psi_2,$$

$$i\hbar\dot{\psi}_1 = H_1\psi_0,$$

$$i\hbar\dot{\psi}_2 = \kappa H_2\psi_0.$$

Using a spin-tower col(ψ_0,ψ_1,ψ_2), this is

$$i\hbar\begin{pmatrix}\dot{\psi}_0\\ \dot{\psi}_1\\ \dot{\psi}_2\end{pmatrix} = \begin{pmatrix} 0 & H_1 & \kappa H_2\\ H_1 & 0 & 0\\ \kappa H_2 & 0 & 0\end{pmatrix}\begin{pmatrix}\psi_0\\ \psi_1\\ \psi_2\end{pmatrix}.$$

Iteration gives

$$-\hbar^2\begin{pmatrix}\ddot{\psi}_0\\ \ddot{\psi}_1\\ \ddot{\psi}_2\end{pmatrix} = \begin{pmatrix} H_1^2+\kappa^2 H_2^2 & 0 & 0\\ 0 & H_1^2 & \kappa H_1 H_2\\ 0 & \kappa H_2 H_1 & H_2\end{pmatrix}\begin{pmatrix}\psi_0\\ \psi_1\\ \psi_2\end{pmatrix},$$

so that, as expected, the scalar element ψ_0 satisfies the Klein–Gordon equation. There is a differential conservation law here [using row $(\psi_0^\dagger,\psi_1^\dagger,\psi_2^\dagger)$, and H_1 from Eq. (4)],

$$\frac{\partial\rho}{\partial\tau} + \nabla_{\mathbf{R}}\cdot\mathbf{j} = 0,$$

$$\rho \equiv \psi_0^\dagger\psi_0 + \psi_1^\dagger\psi_1 + \psi_2^\dagger\psi_2,$$

$$\mathbf{j} \equiv \psi_0^\dagger[\boldsymbol{\alpha}\cdot(I+\mathbf{RR}) + \hat{\boldsymbol{\sigma}}\times\mathbf{R}]\psi_1 + \psi_1^\dagger[\boldsymbol{\alpha}\cdot(I+\mathbf{RR}) + \hat{\boldsymbol{\sigma}}\times\mathbf{R}]\psi_0.$$

While the spin towers thus appear to admit a touch of associativity, this falsifies the fundamental difficulties of the underlying and irremediable nonassociativity, for which $\theta(N\varphi)$ is distinct from $(\theta N)\varphi$ (operator N being the triplet $N_0+AN_1+BN_2$ with operator N_i, and vectors θ and φ being triplets $\theta_0+A\theta_1+B\theta_2$ and $\varphi_0+A\varphi,+B\varphi_2$). In fact, direct calculation gives

$$\theta(N\varphi)-(\theta N)\varphi=A(\theta_1N_2\varphi_2-\theta_2N_2\varphi_1)+B(\theta_2N_1\varphi_1-\theta_1N_1\varphi_2),$$

which, of course, is out of sight from any 3×3 matrix operator in N_0,N_1,N_2 and spin towers in $\theta_0,\theta_1,\theta_2$ and $\theta_0,\theta_1,\theta_2$.

Going now to the decahexion representation for A and B, a decahexion format for ψ must also be introduced, or in quatroquaternion terms,

$$\psi=(\psi_1|\psi_2|\psi_3|\psi_4).$$

Here each ψ_k is a quaternion, with coefficients that are Dirac spinors that are to be acted upon finally by H_1 and H_2:

$$\psi_k=\psi_{k0}e_0+\psi_{k1}e_1+\psi_{k2}e_2+\psi_{k3}e_3,$$

$$\psi_{ku}=\begin{pmatrix}\psi_{ku1}\\ \psi_{ku2}\\ \psi_{ku3}\\ \psi_{ku4}\end{pmatrix}.$$

In all, the components ψ_{kuv} are $4\times4\times4=64$ in number (quartets of quartets of quartets). The wave equation reads

$$\overline{i\hbar}(\dot\psi_1|\dot\psi_2|\dot\psi_3|\dot\psi_4)=H_1(A_1|A_2|A_3|A_4)(\psi_1|\psi_2|\psi_3|\psi_4)+\kappa H_2(B_1|B_2|B_3|B_4)(\psi_1|\psi_2|\psi_3|\psi_4),$$

where, using the fundamental multiplication rule, Eq. (10),

$$(A_1|A_2|A_3|A_4)(\psi_1|\psi_2|\psi_3|\psi_4)=(A_1\psi_1-\psi_2\overline{A_2}-\psi_3\overline{A_3}-A_4\overline{\psi_4}|\overline{A_1}\psi_2+\psi_1A_2+\overline{\psi_3}A_4-\overline{A_3}\psi_4|\overline{A_1}\psi_3$$
$$+\psi_4\overline{A_2}+\psi_1A_3-A_4\overline{\psi_2}|A_1\psi_4-\psi_3A_2+\overline{\psi_1}A_4+A_3\psi_2)$$

(similarly for $B\psi$ by replacing A_k by B_k).

The scheme may be viewed as an ensemble of interlocking quaternionic wave equations. They contain not only the quaternions $\psi_1,\psi_2,\psi_3,\psi_4$ but also terms in their (quaternionic) conjugates $\overline{\psi_1},\overline{\psi_2},\overline{\psi_3},\overline{\psi_4}$. These terms, mandated by the decahexion algebra, are of the nature of antilinear elements akin to complex conjugates in ordinary quantum mechanics.

We may finally turn away from Schrödinger models of quantum theory toward Heisenberg models. The power and primitiveness of the latter far surpass the former, since the central proposition is at its core simply the fundamental Heisenberg equations of motion, without a glance at a superposition principle, or Hilbert space, or even a probability interpretation. The dynamical law for any quantity F is the celebrated

$$\frac{dF}{d\tau}=\frac{1}{i\hbar}(F,H)=\frac{1}{i\hbar}(FH-HF).$$

This is compatible with $d(FG)/d\tau=(dF/d\tau)G+F(dG/d\tau)$ only if the underlying algebra is flexible Lie admissable,[9] which the present decahexion algebra is not. This does not prevent the sequence of derivatives $dF/d\tau,d^2F/d\tau^2,\ldots,$ from being computed and yielding a Maclaurin series expansion for F, as below. H cannot be diagonalized since H_1,H_2 do not commute.

For simplicity, we may limit the discussion to the miniature algebra A,B,O,I instead of the full decahexion algebra. The general (time-independent) dynamical variable is

$$F = F_0 + AF_1 + BF_2,$$

where F_i are functions of coordinates **R** and momenta **P** as well as Dirac matrices. Then F is a conserved quantity when (F,H) vanishes,

$$(F,H) = (F_1,H_1) + (F_2,H_2) + A(F_0,H_1) + \kappa B(F_0,H_2) = 0,$$

that is, when

$$(F_1,H_1) + (F_2,H_2) = 0,$$

$$(F_0,H_1) = 0,$$

$$(F_0,H_2) = 0.$$

It is quite possible now to have conserved quantities that involve arbitrary functions. An example is $F = BF_2(\mathbf{R})$ with arbitrary $F_2(\mathbf{R})$, since H_2, being independent of **P**, commutes with any $F_2(\mathbf{R})$. Thus, also $AH_1 + BF_2(\mathbf{R})$ is conserved.

The conventional Heisenberg rendition for $F(\tau)$,

$$F(\tau) = e^{(i/\hbar)H\tau} F e^{(-i/\hbar)H\tau},$$

will not work for nonassociative $H = AH_1 + \kappa BH_2$, because H is not power associative, e.g.,

$$H(H^2) = (AH_1 + \kappa BH_2)(H_1^2 + \kappa^2 H_2^2) = AH_1^3 + \kappa^2 AH_1H_2^2 + \kappa BH_2H_1^2 + \kappa^3 BH_2^3,$$

while $(H^2)H$ is different,

$$(H^2)H = AH_1^3 + \kappa^2 AH_2^2H_1 + \kappa BH_1^2H_2 + \kappa^3 BH_2^3.$$

Consequently the power series for $\exp((i/\hbar)H\tau)$ is ill defined.

Instead, computing successive derivatives of, say, $F_0(\mathbf{R},\mathbf{P})$, yields

$$\frac{dF_0}{d\tau} = \frac{1}{i\hbar}(F_0, AH_1 + \kappa BH_2) = \frac{1}{i\hbar}(A(F_0,H_1) + \kappa B(F_0,H_2)) = \frac{1}{i\hbar}(AD_1F_0 + BD_2F_0), \quad (13)$$

where the separate commutators are written as

$$D_1F_0 \equiv F_0H_1 - H_1F_0, \quad D_2F_0 \equiv \kappa(F_0H_2 - H_2F_0).$$

Then

$$\frac{d^2F_0}{d\tau^2} = \frac{1}{(i\hbar)^2}[D_1^2F_0 + D_2^2F_0],$$

$$\frac{d^3F_0}{d\tau^3} = \frac{1}{(i\hbar)^3}[AD_1(D_1^2 + D_2^2)F_0 + BD_2(D_1^2 + D_2^2)F_0],$$

$$\frac{d^4F_0}{d\tau^4} = \frac{1}{(i\hbar)^4}[D_1^2(D_1^2 + D_2^2)F_0 + D_2^2(D_1^2 + D_2^2)F_0],$$

$$= \frac{1}{(i\hbar)^4}[(D_1^2 + D_2^2)^2F_0], \quad \text{etc.}$$

More simply, writing the final result for $F_0(\tau)$ as

$$F_0(\tau)=f_0+Af_1+Bf_2,$$

gives, on the one hand,

$$\frac{dF_0(\tau)}{d\tau}=\frac{df_0}{d\tau}+A\frac{df_1}{d\tau}+B\frac{df_2}{d\tau},$$

and on the other hand,

$$\frac{dF_0}{d\tau}=\frac{1}{i\hbar}(f_0+Af_1+Bf_2,AH_1+\kappa BH_2)=\frac{1}{i\tau}(D_1f_1+D_2f_2+AD_1f_0+BD_2f_0).$$

Thereupon follows the triplet:

$$\frac{df_0}{d\tau}=\frac{1}{i\hbar}(D_1f_1+D_2f_2)$$

$$\frac{df_1}{d\tau}=\frac{1}{i\hbar}D_1f_0$$

$$\frac{df_2}{d\tau}=\frac{1}{i\hbar}D_2f_0.$$

By differentiating the first and using the other two,

$$\frac{d^2f_0}{d\tau^2}=\frac{1}{(i\hbar)^2}(D_1^2+D_2^2)f_0=-\left(\frac{D_1^2+D_2^2}{\hbar^2}\right)f_0,$$

so that f_0 can be written symbolically as

$$f_0(\tau)=\cos\left(\frac{\sqrt{D_1^2+D_2^2}\tau}{\hbar}\right)f_0=\cos(\Omega\tau)f_0,$$

and then

$$f_1(\tau)=\frac{1}{i\hbar}\left(D_1\frac{1}{\Omega}\sin\Omega\tau\right)f_0,$$

$$f_2(\tau)=\frac{1}{i\hbar}\left(D_2\frac{1}{\Omega}\sin\Omega\tau\right)f_0.$$

The meaning is that in the power series expansions of cosine and sine the individual terms recover the Maclaurin series,

$$F_0(\tau)=F_0+\frac{dF_0}{d\tau}\tau+\frac{d^2F_0}{d\tau^2}\frac{\tau^2}{2!}+\ldots,$$

built directly from the derivatives of F_0 as, given above.

In a similar fashion, the time evolution of AF_1 and of BF_2 may be obtained. The Heisenberg equations of motion, in short, are equal to describing in full the quantal time-evolution of dynamical variables using multiple commutators, just as Hamilton's equations of motion describe classical time evolution using multiple Poisson brackets.

Finally, it should be remarked that the nonassociative elements A and B do not appear to be observationally directly accessible, though their guiding hand may be revealed covertly, for instance, in the even-ordered derivatives $d^2F_0/d\tau^2$, $d^4F_0/d\tau^4$, etc., above, which are independent of A and B: or in squares like

$$\left(\frac{dF_0}{d\tau}\right)^2 = -\frac{1}{\hbar^2}[(D_1F_0)^2+(D_2F_0)^2]$$

[similarly to how the velocity $c\alpha$ in Dirac theory is not open to direct observation while $(c\alpha)^2 = c^2 = (\text{velocity})^2$ is].

VI. CONCLUSION

We may summarize as follows. The geodesics in a curved space—locally an osculating de Sitter space, which then is prototypical—admit description as uniform straight-line motion with respect to preferred frames of reference that are inertial frames interconnected by projective (fractional-linear) transformation. The preferred frames overcome the ambiguity of commutation rules and Hamiltonian structure inherent under general covariance. But the construction of the Hamiltonian then requires nonassociative elements, which can be realized as those of a Cayley–Dickson algebra having 16 basis elements (doubled octonions, or decahexions). The nonassociativity produces a serious conflict with a Hilbert space and probabilistic rendition of quantum mechanics like the standard type. The formal statement of a Schrödinger wave equation necessitates antilinear as well as linear terms. Nevertheless, the Heisenberg laws of motion can be unambiguously formulated, leading to a full rendition of the quantal time evolution of any dynamical variable (while the Heisenberg program of diagonalizing the Hamiltonian cannot be carried out). The nonassociative elements appear not to be directly observable, but they show themselves indirectly in terms in the time evolution of a dynamical variable.

(Received 9 February 1999; accepted for publication 14 June 1999)

We consider the Wilson loop expectation in $SU(2)$ lattice gauge theory in the presence of constraints. The constraints eliminate gauge field configurations, which, in physical terms, allow the presence of thick center vortices linking with the loop. We prove that, for dimension $d \geqslant 3$, the so-constrained Wilson loop follows perimeter law, i.e., nonconfining behavior, at weak coupling (low temperature). © *1999 American Institute of Physics.* [S0022-2488(99)02709-7]

I. INTRODUCTION

The precise physical mechanism(s) by which $SU(N)$ gauge theories in their critical dimension apparently avoid a phase transition and thus remain in a confining phase for arbitrarily weak coupling is currently receiving renewed attention (see, e.g., Ref. 1). The proposal that extended thick vortices are the configurations responsible for this behavior has been strongly supported by recent numerical simulations in the case of the $SU(2)$[2–4] and $SU(3)$[5] gauge groups. The string tension of the full Wilson loop at weak coupling is found in these simulations to be fully reproduced solely by the contribution of thick vortices. In this paper we give a proof of the converse statement, also suggested by the simulations. We consider the Wilson loop in the presence of constraints eliminating field configurations, which, in physical terms, allow thick vortices linking with the loop. We then show that the so-constrained Wilson loop exhibits nonconfining (perimeter law) behavior at weak coupling.

Rigorous consideration of the vortex mechanism of confinement was initiated in Ref. 6. There, in addition to developing a precise formulation on the lattice, a sufficiency criterion for confinement was derived in terms of the behavior of vortices enclosed in ''vortex containers'' linking with the Wilson loop. Furthermore, it was proven that in the presence of constraints eliminating all $Z(2)$ monopoles in the theory, the t'Hooft disorder operator exhibits nonconfining (i.e., area law) behavior at weak coupling. This operator provides an external color magnetic source, which, in the absence of such monopoles, can no longer be screened. As already pointed out in Ref. 6, however, elimination of the $Z(2)$ monopoles does not eliminate the presence of closed thick magnetic vortices, which may still link with and give confining behavior to the Wilson loop operator. A result pertinent to this question was subsequently obtained in Ref. 7. There it was proven that, in the presence of constraints eliminating vortices winding around the (periodic) lattice, the electric-flux-free energy order parameter exhibits nonconfining behavior at large β. This observable has been proven rigorously[8] only to form an upper bound on the Wilson loop. Thus, it only provides a sufficient criterion for confinement: confining behavior of the electric-flux-free energy implies confining behavior for the Wilson loop, but not the converse. At any rate, the electric flux is an order parameter that refers to the entire lattice. It is clearly important to obtain a statement concerning the effect of the constraints eliminating vortices on the Wilson loop itself, since it directly represents the actual potential between two external sources (quarks), as the lattice is taken to the thermodynamic limit. This is the question addressed in this paper.

The distinction between ''thick,'' ''thin,'' and ''hybrid'' vortices is crucial to the physical picture of the action of vortices at small gauge coupling (large β).[2] We cannot adequately review the underlying physical picture here; we refer to Ref. 2 for a recent physical discussion, as well as earlier references to these ideas. This paper is devoted to the proof of nonconfining behavior for the Wilson loop in the absence of linked vortices. An appropriate framework for these considerations is obtained by expressing the $SU(N)$ lattice gauge theory in terms of new separate $Z(N)$ and $SU(N)/Z(N)$ variables.[6,9] We employ this formulation in Sec. II, where we also consider a variety of alternative lattice actions for which we subsequently obtain our result. We also introduce the appropriate constraints for eliminating linking thick and hybrid vortices. The proof that the so-constrained Wilson loop follows perimeter law is given in Sec. III. We explicitly consider only the case of $SU(2)$, which exhibits all the relevant physical features of the general N case.

Notation: We work on a simple hypercubic lattice $\Lambda \subset \mathbf{Z}^d$ of size $L_\mu = 2^{N_\mu}$, integer N_μ, and lattice coordinates integer n^μ, $\mu = 1,...,d$. Elementary cells c^r, $(r = 0,1,...,d)$, in Λ will be denoted more explicitly as s (sites), b (bonds), p (plaquettes), c (3-cubes), etc. Each r-cell is assigned an orientation; $-c^r$ then denotes the oppositely oriented cell. The number of cells in a collection S of r-cells will be denoted by $|S|$.

We employ the standard formalism of lattice gauge theory. With each bond we associate a copy G_b of the gauge group G. The gauge field U_b is an element of G_b, with the assignment $U_{-b} = U_b^{-1}$. The configuration space is then $\Omega_\Lambda = \otimes_{b \in \Lambda} G_b$, and a field configuration $U_\Lambda = \{U_b\}_{b \in \Lambda}$ is an element of Ω_Λ. In the following we do not distinguish explicitly between the abstract group element U_b and its matrix representation, which, unless otherwise indicated, will always be the fundamental representation.

We will introduce various lattice variables, taking values in the center of the group G. If K is an Abelian group, multiplicatively written, a K-valued r-form α is the map α: $c^r \to \alpha[c^r] \in K$, with $\alpha[-c^r] = \alpha[c^r]^{-1}$. The exterior difference operator is then defined by

$$(d\alpha)[c^{r+1}] = \prod_{c^r \in \partial c^{r+1}} \alpha[c^r]. \tag{1.1}$$

Given any set Q of c^k cells, we generally employ the shorthand notation

$$\alpha[Q] = \alpha\left[\prod_{k \in Q} c^k\right] = \prod_{k \in Q} \alpha[c^k] \equiv \alpha_Q. \tag{1.2}$$

Thus, e.g., for a 1-form γ we write γ_b, $(d\gamma)_p$, and so on. In this paper $G = SU(2)$, $K = Z(2)$.

II. ACTIONS AND CONSTRAINTS

The Euclidean functional measure of the standard lattice $SU(2)$ theory is given by

$$d\mu_\Lambda(U) = Z_\Lambda^{-1} \prod_{b \in \Lambda} dU_b \exp\left(\sum_p A_p(U_p)\right), \tag{2.1}$$

where dU_b denotes normalized Haar measure on $SU(2)$, and A_p the plaquette action, which is a function of $U_p = \Pi_{b \in \partial p} U_b$, the product of bond variables U_b around the plaquette p. The partition function Z_Λ is defined by $\int d\mu_\Lambda(U) = 1$, and for any observable $F(U)$, i.e. (complex-valued) function on Ω_Λ,

$$\langle F(U) \rangle = \int d\mu_\Lambda(U) F(U). \tag{2.2}$$

The usual minimal plaquette action is the Wilson action,

$$A_p(U_p) = \beta \operatorname{tr} U_p, \tag{2.3}$$

which is a special case of the action,

$$A_p(U_p) = \beta \operatorname{tr} U_p + \lambda \operatorname{sign} \operatorname{tr} U_p . \tag{2.4}$$

(2.4) extrapolates between the Wilson action ($\lambda=0$) and the ''positive plaquette model'' action ($\lambda\to\infty$). Another action we consider in this paper is

$$A_p(U_p) = \beta \operatorname{tr} U_p + \ln(\theta(|\operatorname{tr} U_p| - k)), \tag{2.5}$$

where $\theta(x)=1$ if $x>0$, 0 if $x<0$, and $0<k<2$; in particular, k a constant, or any function of β such that $k\beta\to\infty$ as $\beta\to\infty$, e.g., $k(\beta)=\beta^{-1/2}$. All these actions have, of course, the same naive continuum limit. More generally, they are expected to be physically equivalent for sufficiently large β, where each plaquette becomes highly peaked around the perturbative vacuum $\operatorname{tr} U_p \to \operatorname{tr} 1$. Use of such alternative actions provides a check of the requirement that long distance physics should not depend on short distance details, such as the precise form of the latticized action. We will first prove our result working with the action (2.5) since, as it turns out, it allows a rather simpler proof of the result. We will then obtain the result for the more standard, but in fact physically equivalent, action (2.4).

To formulate our argument we rewrite the $SU(2)$ theory (2.1) in the $SO(3)\times Z(2)$ form.[6,9] Consider the configuration space Ω_Λ split into equivalence classes, each class the coset bond variable configuration $\hat{U}_\Lambda = \{\hat{U}_b\}_{b\in\Lambda}$, $\hat{U}_b \in SU(2)/Z(2) \sim SO(3)$. Thus, two configurations U_Λ, $U'_\Lambda \in \Omega_\Lambda$ are representatives of the same coset configuration $\hat{U}_\Lambda$ iff one has $U'_b = U_b \gamma_b$, for some $\gamma \in Z(2)$, $\forall b \in \Lambda$. Let $\eta_p(U) \equiv \operatorname{sign} \operatorname{tr} U_p$. Then

$$(d\eta)_c(\hat{U}) = \prod_{p\in\partial c} \eta_p \tag{2.6}$$

depends, as indicated, only on the coset configuration, since it is invariant under $U_b \to U_b \gamma_b$, $\gamma \in Z(2)$. Let σ be a $Z(2)$-valued 2-form on Λ. Adopt periodic boundary conditions (b.c.), and let $\{S^\alpha\}$, $\alpha=1,...,\binom{d}{2}$, be a set of 2-dimensional nonbounding closed surfaces forming a 2-cycle basis on $\Lambda = T^d(N_1,\ldots,N_d)$. Then the $SU(2)$ theory (2.1)–(2.2) can be expressed in the $SO(3) \times Z(2)$ form given by:

$$d\mu_\Lambda(U,\sigma) = Z_\Lambda^{-1} \prod_{b\in\Lambda} dU_b \prod_{p\in\Lambda} d\sigma_p \prod_{c\in\Lambda} \delta((d\eta)_c(d\sigma)_c) \prod_\alpha \delta(\eta[S^\alpha]\sigma[S^\alpha])$$
$$\times \exp\left(\sum_{p\in\Lambda} A_p(|\operatorname{tr} U_p|, \sigma_p) \right). \tag{2.7}$$

In (2.7), $\int d\sigma_p(\cdots) \equiv \frac{1}{2}\Sigma_{\sigma_p=\pm 1}(\cdots)$ denotes Haar measure over $Z(2)$, and

$$\delta(\alpha) \equiv \int d\tau\, \chi_\tau(\alpha) = \frac{1}{2}[1+\alpha] \tag{2.8}$$

defines the delta function on the group $Z(2)$. Here $\chi_\tau(\alpha)=\alpha$ if $\tau=-1$, and 1 otherwise, are the characters of $Z(2)$. The partition function Z_Λ is defined by $\int d\mu_\Lambda(\hat{U},\sigma)=1$. The plaquette action is given by

$$A_p(|\operatorname{tr} U_p|, \sigma_p) = \beta |\operatorname{tr} U_p| \sigma_p + \lambda \sigma_p \tag{2.9}$$

and

$$A_p(|\operatorname{tr} U_p|, \sigma_p) = \beta |\operatorname{tr} U_p| \sigma_p + \ln(\theta(|\operatorname{tr} U_p| - k)), \tag{2.10}$$

corresponding to (2.4) and (2.5), respectively. (2.7) is easily seen to be independent of the choice of basis $\{S^\alpha\}$. Note that (2.7) is indeed a measure on the coset configuration space since it is invariant under $U_b \to U_b \gamma_b$, for any $Z(2)$-valued 1-form γ. If $\hat{F}(\hat{U},\sigma)$ expresses a gauge-invariant observable $F(U)$ in the new variables, the expectation (2.2) then satisfies

$$\langle F(U)\rangle = \int d\mu_\Lambda(U,\sigma)\hat{F}(\hat{U},\sigma). \tag{2.11}$$

Free b.c. on $U_{\partial\Lambda}$ results in (2.7) without the product of δ functions over 2-cycles, and free b.c. on $\hat{U}_{\partial\Lambda}$, $\sigma_{\partial\Lambda}$. By selective omission of factors in this product, one may consider any mixture of free and periodic b.c. (2.7) may be straightforwardly generalized to accommodate other useful types of b.c.,[10] and indeed applied to Λ of any torsionless homology.

We are interested in the expectation of a Wilson loop subject to constraints whose physical effect is the elimination of its interaction with those vortices that are *not* energetically directly suppressed by the plaquette action at large β. These are extended vortices in the $\hat{U}_\Lambda$ configurations, ''thick'' vortices.[11] Thin vortices, vortices in the σ_Λ configurations, are directly suppressed by action cost proportional to their length. There are also hybrid vortices formed by the joining of ''punctured'' thick and thin vortices along their common coboundary, which represents a magnetic current ''loop,'' i.e., a coclosed set of 3-cubes $\mathcal{L}$ with $(d\eta)_c = (d\sigma)_c = -1$, $\forall c \in \mathcal{L}$. Such hybrids with a minimal short thin section but extended thick section can also affect long distance behavior at large β. We refer to Refs. 2, and 6, 7, 12, for a discussion of the physical interpretation of the constraints we now introduce.

We consider the constrained Wilson loop expectation:

$$W[C] = \langle \mathrm{tr}\, U[C]\,\theta[\mathrm{tr}\, U[C]\,\eta_S]\rangle, \tag{2.12}$$

where now $\langle - \rangle$ denotes expectations in the restriction of the measure (2.1) to

$$d\mu_\Lambda(U) = Z_\Lambda^{-1}\, d\nu_\Lambda(U) \exp\left(\sum_{p\in\Lambda} A_p(U_p)\right), \tag{2.13}$$

with

$$d\nu_\Lambda(U) = \prod_{b\in\Lambda} dU_b \prod_{c\in\Lambda} \delta((d\eta)_c) \prod_\alpha \delta(\eta[S^\alpha]), \tag{2.14}$$

and periodic b.c. (Z_Λ defined by $\langle 1\rangle = 1$). The constraint[6]

$$\prod_c \delta((d\eta)_c) \tag{2.15}$$

in the measure (2.13) eliminates all monopoles, and hence all hybrid vortices in the theory. The constraint[7]

$$\prod_\alpha \delta(\eta[S^\alpha]) \tag{2.16}$$

in (2.13) eliminates all thick vortices completely winding around the lattice, i.e., vortices rendered topologically stable by the nontrivial lattice topology (torus T^d) due to the periodic b.c. The factor[2,7]

$$\theta[\mathrm{tr}\, U[C]\,\eta_S], \tag{2.17}$$

where $\eta_S \equiv \Pi_{p\in S}\eta_p$, constraining the Wilson loop observable $\mathrm{tr}\, U[C]$ in (2.12), forbids the linking of a thick vortex (any odd number of thick vortices) with the loop (while still allowing thin vortices). Here S is any surface bounded by the loop. The expectation (2.12) is easily seen to be independent of the choice of S.

It should be noted that this last constraint may be included in the measure (2.13)–(2.14), as the constraints (2.15), (2.16) are, instead of as part of the observable, i.e., consider the expectation of $\mathrm{tr}\, U[C]$ with the factor (2.17) included in (2.14). Since, however, we are interested in a lower bound on the expectation, and, trivially, (2.17) is bounded from above by unity, its presence in the denominator in the normalized measure (2.13) may be removed, and one may as well consider the expectation (2.12) as defined above.

We pass then to $SO(3)\times Z(2)$ variables in which (2.12) assumes the form

$$W[C]=Z_\Lambda^{-1}\int d\nu_\Lambda(U)\prod_{p\in\Lambda} d\sigma_p \prod_{c\in\Lambda}\delta((d\eta)_c(d\sigma)_c)\prod_\alpha \delta(\eta[S^\alpha]\sigma[S^\alpha])$$
$$\cdot \exp\left(\sum_p A_p(|\mathrm{tr}\, U_p|,\sigma_p)\right)\mathrm{tr}\, U[C]\eta_S\sigma_S\ \theta[\mathrm{tr}\, U[C]\eta_S] \tag{2.18}$$

$$=Z_\Lambda^{-1}\int d\nu_\Lambda(U)\prod_{b\in\Lambda} d\gamma_b \exp\left(\sum_p A_p(|\mathrm{tr}\, U_p|,(d\gamma)_p)\right)$$
$$\times\theta[\mathrm{tr}\, U[C]\eta_S]\ \mathrm{tr}\, U[C]\eta_S\gamma[C], \tag{2.19}$$

where γ is a $Z(2)$-valued 1-form. The second equality is obtained by solving the constraints on σ_Λ that result from the restriction to (2.14):

$$(d\sigma)_c=1,\quad \forall c,\quad \delta(\sigma[S^\alpha])=1,\quad \forall\alpha\ \Rightarrow\ \sigma_p=\prod_{b\in\partial p}\gamma_b=(d\gamma)_p,$$
$$\sigma_S\equiv\prod_{p\in S}\sigma_p=\prod_{b\in C}\gamma_b=\gamma[C]. \tag{2.20}$$

Now,

$$\theta[\mathrm{tr}\, U[C]\eta_S]\ \mathrm{tr}\, U[C]\eta_S=\theta[\mathrm{tr}\, U[C]\eta_S]\ |\mathrm{tr}\, U[C]|, \tag{2.21}$$

so we can write (2.12) in the form

$$W[C]=\langle\theta[\mathrm{tr}\, U[C]\eta_S]\ |\mathrm{tr}\, U[C]|\ \gamma[C]\rangle_{SO(3)\otimes Z(2)}, \tag{2.22}$$

where

$$\langle - \rangle_{SO(3)\otimes Z(2)}=\int d\mu_\Lambda(U,\gamma)(-), \tag{2.23}$$

with

$$d\mu_\Lambda(U,\gamma)\equiv Z_\Lambda^{-1}\, d\hat\nu_\Lambda(U)\prod_{b\in\Lambda} d\gamma_b \exp\left(\sum_{p\in\Lambda} K_p(U)(d\gamma)_p\right) \tag{2.24}$$

and periodic b.c. $d\hat\nu_\Lambda(U)$ and $K_p(U)=K_p(\hat U)$ are defined as

$$d\hat\nu_\Lambda(U)\equiv d\nu_\Lambda(U),$$
$$K_p(U)\equiv\beta|\mathrm{tr}\, U_p|+\lambda \tag{2.25}$$

for the action (2.9), and

$$d\hat{\nu}_\Lambda(U) \equiv d\nu_\Lambda(U) \prod_{p\in\Lambda} \theta(|\mathrm{tr}\, U_p| - k),$$
$$K_p(U) \equiv \beta |\mathrm{tr}\, U_p| \tag{2.26}$$

for the action (2.10). It is easily verified that (2.24) is a reflection positive measure in $(d-1)$-dimensional planes with sites.

Our task in the following is to bound the constrained Wilson loop expectation (2.22) from below.

III. ABSENCE OF CONFINEMENT

We formulate our main result as the following.

Theorem III.1: *For sufficiently large* β*, and dimension* $d\geqslant 3$ *the constrained Wilson loop expectation given by (2.12), or, equivalently, (2.22), exhibits perimeter law, i.e., there exist constants* α, $\alpha_1(d)$, $\alpha_2(d)$ *such that*

$$W[C] \geqslant \alpha \exp(-\alpha_2 e^{-\alpha_1\beta}|C|). \tag{3.1}$$

From now on all expectation signs are meant in the measure (2.24), and, for brevity, we drop the label $SO(3)\otimes Z(2)$.

Choose the loop C so that it is bisected into two equal pieces by a $(d-1)$-dim plane with sites. Then reflection positivity (RP) of the measure (2.24) implies

$$\langle \mathrm{tr}\, U[C]\,\eta_S \gamma[C]\rangle \geqslant 0. \tag{3.2}$$

(Without loss of generality, the surface S may always be assumed to be also reflection symmetric in the hyperplane bisecting C.) Inserting

$$1 = \theta[\mathrm{tr}\, U[C]\,\eta_S] + \theta[-\mathrm{tr}\, U[C]\,\eta_S]$$

in (3.2), we then have

$$\begin{aligned} 0 &\leqslant \langle \theta[\mathrm{tr}\, U[C]\,\eta_S]\,\mathrm{tr}\, U[C]\,\eta_S\gamma[C]\rangle + \langle \theta[-\mathrm{tr}\, U[C]\,\eta_S]\,\mathrm{tr}\, U[C]\,\eta_S\gamma[C]\rangle \\ &= \langle \theta[\mathrm{tr}\, U[C]\,\eta_S]|\,\mathrm{tr}\, U[C]|\,\gamma[C]\rangle - \langle \theta[-\mathrm{tr}\, U[C]\,\eta_S]|\,\mathrm{tr}\, U[C]|\,\gamma[C]\rangle. \end{aligned} \tag{3.3}$$

On the other hand,

$$\langle |\mathrm{tr}\, U[C]|\,\gamma[C]\rangle = \langle \theta[\mathrm{tr}\, U[C]\,\eta_S]|\,\mathrm{tr}\, U[C]|\,\gamma[C]\rangle + \langle \theta[-\mathrm{tr}\, U[C]\,\eta_S]|\,\mathrm{tr}\, U[C]|\,\gamma[C]\rangle. \tag{3.4}$$

Adding (3.3) and (3.4), we have

$$\langle \theta[\mathrm{tr}\, U[C]\,\eta_S]|\,\mathrm{tr}\, U[C]|\,\gamma[C]\rangle \geqslant \tfrac{1}{2}\langle |\mathrm{tr}\, U[C]|\,\gamma[C]\rangle. \tag{3.5}$$

Hence from (2.22) we obtain

$$W[C] \geqslant \tfrac{1}{2}\langle |\mathrm{tr}\, U[C]|\,\gamma[C]\rangle. \tag{3.6}$$

Now

$$\frac{1}{2}\langle|\mathrm{tr}\, U[C]|\,\gamma[C]\rangle = Z_\Lambda^{-1}\int d\hat{\nu}_\Lambda(U)\,\frac{|\mathrm{tr}\, U[C]|}{2}\cdot\int\prod_{b\in\Lambda} d\gamma_b\,\gamma[C]\exp\left(\sum_{p\in\Lambda} K_p(U)(d\gamma)_p\right)$$

$$= \int d\hat{\mu}_\Lambda(U)\,\frac{|\mathrm{tr}\, U[C]|}{2}\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\}), \tag{3.7}$$

where

$$d\hat{\mu}_\Lambda(U) \equiv Z_\Lambda^{-1}\, d\hat{\nu}(U) Z_{Z(2),\Lambda}(\{K_p(U)\}), \tag{3.8}$$

and

$$\langle - \rangle_{Z(2)}(\{K_p\}) = Z_{Z(2),\Lambda}^{-1}(\{K_p\})\int\prod_{b\in\Lambda} d\gamma_b(-)\exp\left(\sum_{p\in\Lambda} K_p\gamma_p\right) \tag{3.9}$$

denotes expectations in the $Z(2)$ lattice gauge theory with plaquette couplings K_p, and partition function $Z_{Z(2),\Lambda}$ defined by $\langle 1\rangle_{Z(2)}(\{K_p\})=1$. In (3.7) we have the U-dependent couplings $K_p(U)\geqslant 0$ given by (2.25), (2.26). By the Griffiths inequalities[13] applied to (3.9):

$$\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\})\geqslant 0, \tag{3.10}$$

whereas

$$\tfrac{1}{2}|\mathrm{tr}\, U[C]| \geqslant \tfrac{1}{4}|\mathrm{tr}\, U[C]|^2 = \tfrac{1}{4}|\chi_F(U[C])|^2 = \tfrac{1}{4}[\chi_A(U[C])+1], \tag{3.11}$$

where χ_F and χ_A denote the $SU(2)$ characters in the fundamental and adjoint representation, respectively. Combining (3.10), (3.11) with (3.7) then gives

$$\frac{1}{2}\langle|\mathrm{tr}\, U[C]|\,\gamma[C]\rangle \geqslant \frac{1}{4}\int d\hat{\mu}_\Lambda(U)\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\}) + \frac{1}{4}\int d\mu_\Lambda(U,\gamma)\chi_A(U[C])\,\gamma[C]. \tag{3.12}$$

Now by RP the second term on the rhs in (3.12) is non-negative. So, from (3.6), we obtain

$$W[C] \geqslant \frac{1}{4}\int d\hat{\mu}_\Lambda(U)\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\}). \tag{3.13}$$

Action (2.10): Completing the proof of the result in the case of the action (2.10) is now straightforward. Applying again Griffiths inequalities, one has

$$\langle\gamma[C]\rangle_{Z(2)}(\{K_p\}) \geqslant \langle\gamma[C]\rangle_{Z(2)}(\{K_p'\}), \quad K_p\geqslant K_p', \quad \forall p. \tag{3.14}$$

With the measure given by (2.26), (3.8), use of (3.14) in (3.13) gives

$$W[C] \geqslant \tfrac{1}{4}\langle\gamma[C]\rangle_{Z(2)}(k\beta). \tag{3.15}$$

The rhs is the loop expectation in the $Z(2)$ gauge theory with $K_p = k\beta$, $\forall p$.

It is a well-known result that, for sufficiently large β and $d\geqslant 3$:

$$\langle\gamma[C]\rangle_{Z(2)}(\beta) \geqslant \mathrm{const}\,\exp(-\rho(\beta)|C|), \tag{3.16}$$

i.e., the expectation exhibits perimeter law. A proof[14] is by standard polymer expansion either as low-temperature expansion in ‘‘contours’’[15] or, after a duality transformation, as high-temperature expansion. Hence, (3.15) gives perimeter-law lower bound on $W[C]$ for all β such that $k\beta$ large enough. This concludes the proof of the theorem in the case of the action (2.10).

Action (2.9): A coclosed set of plaquettes that cannot be decomposed into two disjoint coclosed sets will be called a contour. (Two plaquettes are defined to be disjoint if they share no link.) Given a configuration $\{\gamma_b\}_{b\in\Lambda}$, the set of plaquettes on which $(d\gamma)_p=-1$ is a coclosed set ($(d-2)$-dim closed set on the dual lattice Λ^*). Such a coclosed set Γ can be uniquely decomposed into disjoint contours $\zeta_1,\ldots,\zeta_{|\Gamma|}$. Each such contour then is the site of a thin vortex. We expand the expectation $\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\})$ in (3.13) in a contour expansion. The partition function in the denominator is expanded in the form

$$Z_{Z(2),\Lambda}(\{K_p(U)\})=\left(2^{-|\Lambda|}\prod_{p\in\Lambda}e^{K_p(U)}\right)\sum_{\Gamma\subset\Lambda}z_\Gamma(U). \tag{3.17}$$

The sum is over all sets Γ of disjoint (compatible) contours $\{\zeta_1,\ldots,\zeta_{|\Gamma|}\}$ and

$$z_\Gamma(U)\equiv\prod_{\zeta\in\Gamma}z_\zeta(U), \tag{3.18}$$

with

$$z_\zeta(U)\equiv\prod_{p\in\zeta}\exp(-2K_p(U)) \tag{3.19}$$

the activity of contour ζ, and $K_p(U)$ given by (2.25). Noting that $\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\})=\langle\gamma[S]\rangle_{Z(2)}(\{K_p(U)\})$, where $\partial S=C$, it is easily seen that the expansion of the numerator

$$Z^C_{Z(2),\Lambda}(U)\equiv Z_{Z(2),\Lambda}(U)\langle\gamma[C]\rangle_{Z(2)}(\{K_p(U)\})$$

is given by the expansion (3.17) after replacement of the contour activities $z_\zeta(U)$, Eq. (3.19), by

$$z^C_\zeta(U)=(-1)^{l(C,\zeta)}z_\zeta(U),\quad l(C,\zeta)=|S\cap\zeta|\quad(\mathrm{mod}\,2). \tag{3.20}$$

(Here $l(C,\zeta)$ is the (mod 2) linking number of the contour ζ with the loop C.)

Letting

$$\mathcal{Z}_{Z(2),\Lambda}=\sum_{\Gamma\subset\Lambda}z_\Gamma(U),\quad \mathcal{Z}^C_{Z(2),\Lambda}=\sum_{\Gamma\subset\Lambda}z^C_\Gamma(U), \tag{3.21}$$

and applying Jensen's inequality in (3.13) gives

$$\begin{aligned}W[C]&\geqslant\frac{1}{4}\int d\hat\mu_\Lambda(U)\exp(\ln\mathcal{Z}^C_{Z(2),\Lambda}(U)-\ln\mathcal{Z}_{Z(2),\Lambda}(U))\\&\geqslant\frac{1}{4}\exp\left(\int d\hat\mu_\Lambda(U)(\ln\mathcal{Z}^C_{Z(2),\Lambda}(U)-\ln\mathcal{Z}_{Z(2),\Lambda}(U))\right)\equiv\frac{1}{4}\exp\mathcal{F}(\beta,\lambda).\end{aligned} \tag{3.22}$$

Noting that $\mathcal{Z}_{Z(2),\Lambda}(U)=1$ at $z_\zeta(U)=0$, we may define $\ln\mathcal{Z}_{Z(2),\Lambda}(U)$ as that continuous branch of the logarithm that vanishes at vanishing contour activity, and similarly for $\ln\mathcal{Z}^C_{Z(2),\Lambda}(U)$. A closed form representation of $\mathcal{F}(\beta,\lambda)$ is given by the Möbius inversion representation of $\ln\mathcal{Z}_{Z(2),\Lambda}(U)$ and of $\ln\mathcal{Z}^C_{Z(2),\Lambda}(U)$ as a finite series (for finite Λ) of logarithms of partition functions of linked clusters of single multiplicity.[16] Expanding these logarithms leads to the standard expansion of linked clusters of repeated multiplicities:

$$\mathcal{F}(\beta,\lambda)=\int d\hat\mu_\Lambda(U)\left(\sum_{Q\subset\Lambda}a(Q)(z^C_Q(U)-z_Q(U))\right). \tag{3.23}$$

The sum is over all linked clusters $Q=\{\zeta_1,\ldots,\zeta_{n_Q}\}$ of contours with the property that at least one contour in each Q winds around C. Multiple copies of a contour are allowed to appear as distinct members in a cluster, and

$$a(Q)=\sum_{G(Q)}(-1)^{|G(Q)|}. \tag{3.24}$$

Here the sum is over all connected graphs $G(Q)$ on the vertex set $\{\zeta,\ldots,\zeta_{n_Q}\}$ with a line connecting two vertices if they represent incompatible (not disjoint) contours. $|G(Q)|$ denotes the number of lines in $G(Q)$.

The expansion in (3.23) converges for sufficiently small activities $z_\zeta(U)$. Let $|z_\zeta(U)|\leqslant\exp(-b|\zeta|)$. The number of contours of size q with one plaquette fixed is bounded by $[10(d-2)]^{10(d-2)q}$. Applying well-known results on the convergence of the polymer-type cluster expansion,[17] it follows that the expansion on the rhs of (3.23) is absolutely convergent, uniformly in $|\Lambda|$ and over Ω_Λ, provided

$$b\geqslant 10(d-2)\ln 10(d-2)+\ln 5; \tag{3.25}$$

hence, by (2.25), λ sufficiently large. Uniform convergence allows integration term by term, so we have

$$\mathcal{F}(\beta,\lambda)=\sum_{Q\subset\Lambda}a(Q)(\langle z_Q^C(U)\rangle-\langle z_Q(U)\rangle). \tag{3.26}$$

We now observe that, for β sufficiently large, the series (3.26) converges for all $\lambda\geqslant 0$. To show this, we bound $\langle z_Q(U)\rangle$ uniformly in $|\Lambda|$ by chessboard estimates.[18] One finds (Appendix)

$$\langle z_Q(U)\rangle\leqslant\prod_{\zeta\in Q}\hat{z}(\beta,\lambda)^{|\zeta|}, \tag{3.27}$$

where

$$\hat{z}(\beta,\lambda)=c_1e^{-c_2\beta-2\lambda} \tag{3.28}$$

with positive constants $c_1(d)$, $c_2(d)$ depending only on the dimension d. It follows that (3.26) converges absolutely and uniformly in $|\Lambda|$, provided $|\hat{z}(\beta,\lambda)|\leqslant e^{-b}$ with b satisfying (3.25); hence for β large enough, and all $\lambda\geqslant 0$. Uniqueness of analytic continuation then implies that the representation of $\mathcal{F}$ by the cluster expansion in (3.26), originally obtained in the domain of large Re λ, is valid in this extended convergence domain Re $\lambda\geqslant 0$.

The leading contribution to (3.26) comes from the shortest possible contours, each consisting of $2(d-1)$ plaquettes forming the coboundary of a bond on the loop C, and there are $|C|$ of them. A bound on the remainder by the same as leading $\mathcal{O}(|C|)$-type behavior is a standard corollary of the polymer expansion convergence proof (e.g., Ref. 17). This concludes the proof of Theorem III.1 for the action (2.9).

APPENDIX: CHESSBOARD ESTIMATE

Let Π_e denote the set of ''even'' two-dimensional $[\kappa\lambda]$ planes: $x^\mu=2n^\mu$, integer n^μ, $\mu\neq\kappa$, λ. If $|\Pi_e|$ and $|\Lambda|$ denote the number of plaquettes in Π_e and Λ, respectively, we have $|\Pi_e|=|\Lambda|/s$, where $s=2^{d-3}d(d-1)$. Consider now a cluster Q, and let $\zeta_e\equiv\zeta\cap\Pi_e$. Using RP to reflect repeatedly in $(d-1)$-dimensional planes with sites $x^{\mu}=(2n^{\mu}+1)$, $\mu\neq\kappa$, λ; $x^{\mu}=n^{\mu}$, $\mu=\kappa$, λ, and the fact that $\exp(-2\beta|\mathrm{tr}\,U_p|)\leqslant 1$, one straightforwardly obtains the chessboard estimate

$$\begin{aligned}\langle z_Q(U)\rangle &= e^{-2\lambda|Q|}\left\langle \prod_{\zeta\in Q}\prod_{p\in\zeta} e^{-2\beta|\mathrm{tr}\,U_p|}\right\rangle\\ &\leqslant e^{-2\lambda|Q|}\left\langle \prod_{\zeta\in Q}\prod_{p\in\zeta_e} e^{-2\beta|\mathrm{tr}\,U_p|}\right\rangle\\ &\leqslant e^{-2\lambda|Q|}\left\langle \prod_{p\in\Pi_e} e^{-2\beta|\mathrm{tr}\,U_p|}\right\rangle^{|Q_e|/|\Pi_e|},\end{aligned} \tag{A1}$$

where $|Q|=\Sigma_{\zeta\in Q}|\zeta|$, and $|Q_e|=\Sigma_{\zeta\in Q}|\zeta_e|$. To estimate the last expectation on the rhs in (A1), it now suffices to bound the numerator from above by its maximum:

$$\left\langle \prod_{p\in\Pi_e} e^{-2\beta|\mathrm{tr}\,U_p|}\right\rangle \leqslant Z_\Lambda^{-1} e^{\lambda|\Lambda|} e^{2\beta(|\Lambda|-|\Pi_e|)}. \tag{A2}$$

The partition function in the denominator is bounded from below by restricting γ_b to 1, and each U_b integration to a small neighborhood of the identity such that $|\mathrm{tr}\,U_p|\geqslant 2e^{-\delta}$ for all p. Let τ_δ be the volume of this neighborhood. The constraints in $d\hat{\nu}_\Lambda(U)$ are then automatically satisfied, and we have

$$Z_\Lambda \geqslant \left(\left(\frac{\tau_\delta}{2}\right)^{2/(d-1)} e^{2\beta e^{-\delta}+\lambda}\right)^{|\Lambda|}. \tag{A3}$$

Now, given a cluster Q, we are free to pick the definition[19] of the "even" planes Π_e so that $|\zeta_e|\geqslant|\zeta|/s$, i.e., $|Q_e|\geqslant|Q|/s=|Q|/2^{(d-3)}d(d-1)$. Combining this with (A2), (A3), we find

$$\left\langle \prod_{p\in\Pi_e} e^{-2\beta|\mathrm{tr}\,U_p|}\right\rangle^{|Q_e|/|\Pi_e|} \leqslant \hat{a}(\beta)^{|Q|}, \tag{A4}$$

where we defined

$$\hat{a}\equiv\min_{\delta}\left(\left(\frac{2}{\tau_\delta}\right)^{2/(d-1)}\exp\left(-\frac{2\beta}{s}[1-s(1-e^{-\delta})]\right)\right). \tag{A5}$$

Thus $\hat{a}(\beta)\to 0$ exponentially as $\beta\to\infty$. (A1) with (A4) and

$$\hat{z}(\beta,\lambda)=e^{-2\lambda}\hat{a}(\beta) \tag{A6}$$

then produces the bound (3.27).

A more refined chessboard estimate, utilizing reflections onto every d-cell (dual site) of the lattice is possible (cf. Ref. 7), and results into elimination of the factor $1/s$ multiplying β in the exponent in (A5), a substantial numerical improvement. The simpler estimate given here, however, suffices for our purposes.

Covariant phase observables in quantum mechanics

Pekka Lahti[a)] and Juha-Pekka Pellonpää[b)]
Department of Physics, University of Turku, FIN-20014 Turku, Finland

(Received 12 February 1999; accepted for publication 14 July 1999)

In this paper we characterize all the phase shift covariant normalized positive operator measures, i.e., phase observables, and we investigate some of their examples. We also characterize those phase observables which arise from the phase space observables as their polar coordinate angle margins. © *1999 American Institute of Physics.* [S0022-2488(99)04810-0]

I. INTRODUCTION

The definition of the phase of an electromagnetic field has long been a problem in quantum physics. Many different approaches have been used to characterize the phase as a quantum observable. The traditional way of representing observables as self-adjoint operators in quantum mechanics has led to the search for self-adjoint phase operators. Apart from some partial success, all the attempts in this line of research have more or less failed; for an overview, see, e.g., Refs. 1–3. The reason for the failure of these approaches must be seen in the fact that the concept of an observable as a self-adjoint operator is unnecessarily restrictive; there is no spectral measure which is covariant under the shifts generated by the number observable of a single-mode field. The concept of an observable as a normalized positive operator measure (semispectral measure) has emerged from detailed investigations of the conceptual and mathematical foundations of quantum mechanics, and it has found ample applications in many important areas of quantum physics, as documented, for instance, in monographs.[4–7] In this approach a phase observable can be characterized in terms of its natural covariance condition together with the choice of the range of the phase variable, see, e.g., Ref. 5 or 7.

In this paper we adopt a formulation of a phase observable as a covariant normalized positive operator measure (Definition 2.1), and we prove a structure theorem, the phase theorem 2.2, for such observables. This result could be obtained as a special case of Theorem 4 of Ref. 8 which characterizes generalized imprimitivity systems for commutative groups. Here we give a direct constructive proof of the theorem without using any group theoretical arguments. The phase theorem allows us to exhibit classes of examples of phase observables (Sec. III), and it leads to a characterization of those phase space observables whose polar coordinate angle margins are phase observables (Sec. IV). Finally, we exhibit the conditions for the first moment operator of a phase observable to form a Heisenberg pair together with the number operator (Section V).

II. COVARIANT PHASE OBSERVABLES

In this section we characterize phase observables as a particular class of phase shift covariant operator measures defined on the Borel subsets of the real interval $[0,2\pi)$. To introduce these notions and to characterize them we need a few notations.

Let $\mathcal{H}$ denote a complex separable infinite-dimensional Hilbert space, with the inner product $\langle\cdot|\cdot\rangle$. For any two unit vectors $\psi,\varphi\in\mathcal{H}$, we let $|\psi\rangle\langle\varphi|$ denote the rank-one linear operator $\mathcal{H}\ni\eta\mapsto\langle\varphi|\eta\rangle\psi\in\mathcal{H}$. Let $\mathcal{K}:=\{\varphi_n\}_{n=0}^{\infty}$ be an orthonormal basis of $\mathcal{H}$, and let $N=\sum_{n=0}^{\infty}n|\varphi_n\rangle\langle\varphi_n|$ denote the self-adjoint operator with the domain $\mathcal{D}(N)=\{\psi\in\mathcal{H}|\sum_{n=0}^{\infty}n^2|\langle\varphi_n|\psi\rangle|^2<\infty\}$. We call N the *number operator* associated with $\mathcal{K}$. Let $\mathcal{B}[0,2\pi)$ denote the Borel subsets of the interval

a)Electronic mail: pekka.lahti@utu.fi
b)Electronic mail: juhpello@utu.fi

$[0,2\pi)$, and let $\mathcal{L}(\mathcal{H})$ denote the set of bounded operators on $\mathcal{H}$. We say that a positive normalized operator measure $E:\mathcal{B}[0,2\pi)\to\mathcal{L}(\mathcal{H})$ is a phase observable if it is covariant under the shifts generated by N. In other words, we adopt the following definition.

Definition 2.1: A map $E:\mathcal{B}[0,2\pi)\to\mathcal{L}(\mathcal{H})$ is a *phase observable* if

(i) $E(X)\geqslant O$ for all $X\in\mathcal{B}[0,2\pi)$ (positivity),
(ii) $E[0,2\pi)=I$ (normalization),
(iii) if $\{X_n\}_{n=1}^{\infty}\subset\mathcal{B}[0,2\pi)$ is a disjoint sequence, i.e., $X_n\cap X_m=\emptyset$, for $n\neq m$, then $E(\cup_{n=1}^{\infty}X_n)=\Sigma_{n=1}^{\infty}E(X_n)$, where the series converges in the weak operator topology (σ-additivity),
(iv) $e^{i\theta N}E(X)e^{-i\theta N}=E(X+\theta)$ for all $X\in\mathcal{B}[0,2\pi)$ and for all $\theta\in[0,2\pi)$, where $X+\theta:=\{x\in[0,2\pi)|(x-\theta)(\mathrm{mod}\,2\pi)\in X\}$ (covariance).

We recall that for positive operator measures the σ-additivity with respect to the weak operator topology is sufficient for the σ-additivity in the strong operator topology (Ref. 9, Proposition 1, p. 6). We have chosen the interval $[0,2\pi)$ as the range of a phase variable $\theta\in[0,2\pi)$, but any other interval $[a,a+2\pi)$, $a\in\mathbf{R}$, would do equally well.

For any bounded operator $A\in\mathcal{L}(\mathcal{H})$, let $A_{n,m}:=\langle\varphi_n|A\varphi_m\rangle$ denote its matrix elements with respect to $\mathcal{K}$. To shorten the notations we shall from now on write $\langle n|A|m\rangle$ and $|n\rangle\langle m|$ instead of $\langle\varphi_n|A\varphi_m\rangle$ and $|\varphi_n\rangle\langle\varphi_m|$, respectively. We let $\mathbf{C}$, $\mathbf{R}$, $\mathbf{Z}$, and $\mathbf{Z}^+$ denote the set of complex numbers, real numbers, integers, and positive integers, respectively, and we put $\mathbf{N}=\mathbf{Z}^+\cup\{0\}$. Let $I_k:=\Sigma_{n=0}^{k}|n\rangle\langle n|\in\mathcal{L}(\mathcal{H})$, $k\in\mathbf{N}$, so that $\{I_k\}_{k=0}^{\infty}$ is an increasing sequence of projection operators, with the unit operator I as the least upper bound. Therefore, $s\text{-}\lim_{k\to\infty}I_k=I$, and $s\text{-}\lim_{k\to\infty}AI_k=s\text{-}\lim_{k\to\infty}(I_kA)=A$, $A\in\mathcal{L}(\mathcal{H})$, as well as

$$A=s\text{-}\lim_{k\to\infty}(s\text{-}\lim_{l\to\infty}I_lAI_k)=s\text{-}\lim_{l\to\infty}(s\text{-}\lim_{k\to\infty}I_lAI_k),$$

so that we may write

$$A=\sum_{n,m=0}^{\infty}A_{n,m}|n\rangle\langle m|,$$

with the understanding that in the double summation the summation order is irrelevant and the series converge in the weak operator topology. We may now formulate the basic theorem of the paper.

Phase Theorem 2.2: Let $E:\mathcal{B}[0,2\pi)\to\mathcal{L}(\mathcal{H})$ be a phase observable. Then for any $X\in\mathcal{B}[0,2\pi)$,

(a) $E(X)=\Sigma_{n,m=0}^{\infty}c_{n,m}(2\pi)^{-1}\int_X e^{i(n-m)\theta}d\theta|n\rangle\langle m|$, where the series converge in the weak operator topology, and where
(b) $\{c_{n,m}|n,m\in\mathbf{N}\}\subset\mathbf{C}$, with $c_{n,n}=1$, for all $n\in\mathbf{N}$, and
(c) $\Sigma_{n,m=0}^{k}c_{n,m}|n\rangle\langle m|\geqslant O$, for all $k\in\mathbf{N}$.

Conversely, any family of complex numbers $\{c_{n,m}\in\mathbf{C}|n,m\in\mathbf{N}\}$ which has the properties (b) and (c), defines a unique phase observable of the form (a).

Proof: Let $\{c_{n,m}|n,m\in\mathbf{N}\}$ be a family of complex numbers such that $c_{n,n}=1$, for all $n\in\mathbf{N}$, and $\Sigma_{n,m=0}^{k}c_{n,m}|n\rangle\langle m|\geqslant O$, for all $k\in\mathbf{N}$. Then, for each $\theta\in[0,2\pi)$,

$$e^{iN\theta}\sum_{n,m=0}^{k}c_{n,m}|n\rangle\langle m|e^{-iN\theta}=\sum_{n,m=0}^{k}c_{n,m}e^{i(n-m)\theta}|n\rangle\langle m|\geqslant O,$$

which implies that

$$O \leqslant \frac{1}{2\pi}\int_X \sum_{n,m=0}^{k} c_{n,m} e^{i(n-m)\theta} |n\rangle\langle m| d\theta \leqslant \frac{1}{2\pi}\int_0^{2\pi} \sum_{n,m=0}^{k} c_{n,m} e^{i(n-m)\theta}|n\rangle\langle m| d\theta$$

$$= \sum_{n,m=0}^{k} c_{n,m}\left(\frac{1}{2\pi}\int_0^{2\pi} e^{i(n-m)\theta} d\theta\right)|n\rangle\langle m| = \sum_{n=0}^{k} |n\rangle\langle n| \leqslant I, \tag{1}$$

for all $k \in \mathbf{N}$, and for all $X \in \mathcal{B}[0,2\pi)$. Let $\mathrm{lin}\,\mathcal{K}$ be the linear hull of $\mathcal{K}$, and define, for each $X \in \mathcal{B}[0,2\pi)$, the sesquilinear function $B_X : \mathrm{lin}\,\mathcal{K} \times \mathrm{lin}\,\mathcal{K} \to \mathbf{C}$ as follows:

$$B_X(\varphi,\psi) := \sum_{n=0}^{k}\sum_{m=0}^{l} c_{n,m}\left(\frac{1}{2\pi}\int_X e^{i(n-m)\theta} d\theta\right)\langle\varphi|n\rangle\langle m|\psi\rangle,$$

where $\varphi = \Sigma_{n=0}^{k}\langle n|\varphi\rangle|n\rangle$, $\psi = \Sigma_{m=0}^{l}\langle m|\psi\rangle|m\rangle \in \mathrm{lin}\,\mathcal{K}$, $k,l \in \mathbf{N}$. From (1) one gets $|B_X(\varphi,\psi)| \leqslant \|\varphi\|\|\psi\|$, and $B_X(\varphi,\varphi) \geqslant 0$, for all $\varphi,\psi \in \mathrm{lin}\,\mathcal{K}$. Since $\overline{\mathrm{lin}\,\mathcal{K}} = \mathcal{H}$, the form B_X has a unique sesquilinear extension $\tilde{B}_X$ to $\mathcal{H}\times\mathcal{H}$ which has the following properties: $|\tilde{B}_X(\varphi,\psi)| \leqslant \|\varphi\|\|\psi\|$, and $\tilde{B}_X(\varphi,\varphi) \geqslant 0$, for all $\varphi,\psi \in \mathcal{H}$. Hence, there is a unique operator $E(X) \in \mathcal{L}(\mathcal{H})$ such as $\tilde{B}_X(\varphi,\psi) = \langle E(X)\varphi|\psi\rangle$, for all $\varphi,\psi \in \mathcal{H}$, and $O \leqslant E(X) \leqslant I$. The matrix elements of $E(X)$ with respect to $\mathcal{K}$ are

$$\langle n|E(X)|m\rangle = B_X(|n\rangle,|m\rangle) = c_{n,m}\frac{1}{2\pi}\int_X e^{i(n-m)\theta} d\theta, \quad n,m \in \mathbf{N}. \tag{2}$$

Therefore,

$$E(X) = \sum_{n,m=0}^{\infty} c_{n,m}\frac{1}{2\pi}\int_X e^{i(n-m)\theta} d\theta |n\rangle\langle m|,$$

for all $X \in \mathcal{B}[0,2\pi)$. Clearly, $E[0,2\pi) = I$.

Let $\{X_n\}_{n=1}^{\infty}$ be a family of disjoint sets of $\mathcal{B}[0,2\pi)$, and define the operators $E_k := E(\cup_{n=1}^{k} X_n)$, for all $k \in \mathbf{Z}^+$. From (2) one gets $E_k = \Sigma_{n=1}^{k} E(X_n)$, $k \in \mathbf{Z}^+$. Since $E_{k+1} - E_k = E(X_{k+1}) \geqslant O$, it follows that $O \leqslant E_k \leqslant E_{k+1} \leqslant I$, $k \in \mathbf{Z}^+$. Hence, the least upper bound $S \in \mathcal{L}(\mathcal{H})$ of the sequence $\{E_k\}_{k=1}^{\infty}$ exists, and $s\text{-}\lim_{k\to\infty} E_k = w\text{-}\lim_{k\to\infty} E_k = S$. Due to σ-additivity of the Lebesgue integral, the matrix elements of S with respect to $\mathcal{K}$ are

$$\begin{aligned}\langle n|S|m\rangle &= \lim_{k\to\infty}\langle n|E_k|m\rangle \\ &= \lim_{k\to\infty} c_{n,m}\frac{1}{2\pi}\int_{\cup_{n=1}^{k}X_n} e^{i(n-m)\theta} d\theta \\ &= c_{n,m}\frac{1}{2\pi}\int_{\cup_{n=1}^{\infty}X_n} e^{i(n-m)\theta} d\theta \\ &= \langle n|E(\cup_{n=1}^{\infty}X_n)|m\rangle.\end{aligned}$$

This concludes the proof that the map $\mathcal{B}[0,2\pi) \ni X \mapsto E(X) \in \mathcal{L}(\mathcal{H})$ is a positive normalized operator measure. The covariance condition (iv) is an immediate consequence of the structure of E. Hence E is a phase observable.

Assume now that $E : \mathcal{B}[0,2\pi) \to \mathcal{L}(\mathcal{H})$ is a phase observable. To show that it has the structure of (a), we determine the matrix elements of $E(X)$, $X \in \mathcal{B}[0,2\pi)$, with respect to $\mathcal{K}$. The covariance condition (iv) implies that

$$E_{n,m}(X+\theta) = e^{i(n-m)\theta}E_{n,m}(X), \tag{3}$$

for all $X\in\mathcal{B}[0,2\pi)$, $\theta\in[0,2\pi)$, and for all $n,m\in\mathbf{N}$. Therefore, for all $n,m\in\mathbf{N}$, and $k\in\mathbf{Z}^+$, we have

$$\begin{aligned}E_{n,m}[0,2\pi)&=E_{n,m}\left(\bigcup_{l=0}^{k-1}[l2\pi k^{-1},(l+1)2\pi k^{-1})\right)\\&=\sum_{l=0}^{k-1}E_{n,m}([0,2\pi k^{-1})+l2\pi k^{-1})\\&=\left[\sum_{l=0}^{k-1}e^{i2\pi(n-m)k^{-1}l}\right]E_{n,m}[0,2\pi k^{-1})\\&=\begin{cases}kE_{n,m}[0,2\pi k^{-1}) & \text{when } (n-m)k^{-1}\in\mathbf{Z},\\ 0 & \text{when } (n-m)k^{-1}\notin\mathbf{Z}.\end{cases}\end{aligned}\tag{4}$$

Suppose that $n,m\in\mathbf{N}$ and $k\in\mathbf{Z}^+$ are such that $(n-m)k^{-1}\notin\mathbf{Z}$. Then $\int_0^{2\pi k^{-1}}e^{i(n-m)\theta}d\theta\neq 0$, and we can define

$$c_{n,m}(k):=\frac{E_{n,m}[0,2\pi k^{-1})}{(2\pi)^{-1}\int_0^{2\pi k^{-1}}e^{i(n-m)\theta}d\theta},$$

so that

$$E_{n,m}[0,2\pi k^{-1})=c_{n,m}(k)\,\frac{1}{2\pi}\int_0^{2\pi k^{-1}}e^{i(n-m)\theta}d\theta=c_{n,m}(k)\,\frac{e^{i(n-m)2\pi k^{-1}}-1}{i(n-m)2\pi}.$$

On the other hand, for all $r\in\mathbf{Z}^+$, $(n-m)(rk)^{-1}\notin\mathbf{Z}$, and

$$\begin{aligned}E_{n,m}[0,2\pi k^{-1})&=E_{n,m}\left(\bigcup_{l=0}^{r-1}[l2\pi(rk)^{-1},(l+1)2\pi(rk)^{-1})\right)\\&=\left[\sum_{l=0}^{r-1}e^{i2\pi(n-m)(rk)^{-1}l}\right]E_{n,m}[0,2\pi(rk)^{-1})=c_{n,m}(rk)\,\frac{e^{i(n-m)2\pi k^{-1}}-1}{i(n-m)2\pi}.\end{aligned}$$

This shows that $c_{n,m}(k)=c_{n,m}(rk)$, $r\in\mathbf{Z}^+$. Since $(n-m)(|n-m|+1)^{-1}\notin\mathbf{Z}$, one has $c_{n,m}(k)=c_{n,m}((|n-m|+1)k)=c_{n,m}(|n-m|+1)$. Thus, for all $k\in\mathbf{Z}^+$, for which $(n-m)k^{-1}\notin\mathbf{Z}$, the number $c_{n,m}(k)$ is the same, and we may define $c_{n,m}:=c_{n,m}(|n-m|+1)$ for all $n,m\in\mathbf{N}$ and $n\neq m$.

If $(n-m)k^{-1}\in\mathbf{Z}$, $n,m\in\mathbf{N}$, $k\in\mathbf{Z}^+$, Eq. (4) gives

$$E_{n,m}[0,2\pi k^{-1})=\frac{\delta_{n,m}}{k}=\frac{1}{2\pi}\int_0^{2\pi k^{-1}}e^{i(n-m)\theta}\mathrm{d}\theta.\tag{5}$$

Thus, if we define $c_{n,n}:=1$, $n\in\mathbf{N}$, we get

$$E_{n,m}[0,2\pi k^{-1})=c_{n,m}\frac{1}{2\pi}\int_0^{2\pi k^{-1}}e^{i(n-m)\theta}\mathrm{d}\theta,\tag{6}$$

for all $k\in\mathbf{Z}^+$, and $n,m\in\mathbf{N}$.

Let $n,m\in\mathbf{N}$. From (3) one gets

$$E_{n,m}\left(\bigcup_{p=1}^{\infty}\{p^{-1}\}\right)=E_{n,m}(\{0\})\sum_{p=1}^{\infty}e^{i(n-m)p^{-1}},$$

which implies that $E_{n,m}(\{0\})=0$. Thus the measure $E_{n,m}$ is nonatomic, i.e., $E_{n,m}(\{x\})=e^{ix(n-m)}E_{n,m}(\{0\})=0$, $x\in[0,2\pi)$, which implies that the function $x\mapsto E_{n,m}[0,x)$ is continuous. Since, from (6) it follows that for all $k\in\mathbf{Z}^{+}$, $p\in\{1,2,...,k\}$,

$$E_{n,m}[0,2\pi pk^{-1})=E_{n,m}\left(\bigcup_{l=0}^{p-1}[l2\pi k^{-1},(l+1)2\pi k^{-1})\right)=c_{n,m}\frac{1}{2\pi}\int_{0}^{2\pi pk^{-1}}e^{i(n-m)\theta}\mathrm{d}\theta, \quad (7)$$

and since the function $x\mapsto E_{n,m}[0,x)$ is continuous, and the set $\{2\pi pk^{-1}\in[0,2\pi)|k\in\mathbf{Z}^{+},\ p\in\{1,2,...,k\}\}$ is dense in $[0,2\pi)$ it follows that for all $x\in(0,2\pi]$

$$E_{n,m}[0,x)=c_{n,m}\frac{1}{2\pi}\int_{0}^{x}e^{i(n-m)\theta}\mathrm{d}\theta.$$

Hence, by Hahn extension theorem

$$E_{n,m}(X)=c_{n,m}\frac{1}{2\pi}\int_{X}e^{i(n-m)\theta}\mathrm{d}\theta \quad (8)$$

for all $X\in\mathcal{B}[0,2\pi)$ and $n,m\in\mathbf{N}$.

Finally, we prove that

$$\sum_{n,m=0}^{k}c_{n,m}|n\rangle\langle m|\geqslant O, \quad (9)$$

for all $k\in\mathbf{N}$. Since $E(X)=E(X)^{*}$, $X\in\mathcal{B}[0,2\pi)$, we get

$$c_{n,m}=\overline{c_{m,n}}, \quad (10)$$

for all $n,m\in\mathbf{N}$. It follows from (10) that $\Sigma_{n,m=0}^{k}c_{n,m}\langle\psi|n\rangle\langle m|\psi\rangle\in\mathbf{R}$, for all $k\in\mathbf{N}$, $\psi\in\mathcal{H}$. Hence, if (9) does not hold, one may choose a $\varphi\in\mathcal{H}$ and an $l\in\mathbf{Z}^{+}$ such that $\Sigma_{n,m=0}^{l}c_{n,m}\langle\varphi|n\rangle\times\langle m|\varphi\rangle<0$, and define a function

$$f:[0,2\pi)\to\mathbf{R},\theta\mapsto f(\theta):=\sum_{n,m=0}^{l}c_{n,m}e^{i(n-m)\theta}\langle\varphi|n\rangle\langle m|\varphi\rangle.$$

Due to the continuity of f one can choose an $\epsilon\in(0,2\pi)$ such that $\int_{0}^{\epsilon}f(\theta)\mathrm{d}\theta<0$. Thus

$$\langle I_{l}\varphi|E[0,\epsilon)I_{l}\varphi\rangle=\frac{1}{2\pi}\int_{0}^{\epsilon}f(\theta)\mathrm{d}\theta<0,$$

which contradicts with the positivity of E. □

To close this section we note the following two points. If $c_{n,m}\neq 0$, choose $\psi=|n\rangle-|c_{n,m}|c_{n,m}^{-1}|m\rangle$, and substitute it to (c) to deduce that $c_{n,n}-|c_{n,m}|-|c_{n,m}|+c_{m,m}\geqslant 0$. This implies that

$$|c_{n,m}|\leqslant 1,$$

for all $n,m\in\mathbf{N}$. If E is a phase observable it can be seen directly from the phase theorem that

$$c_{n,m} = 2\pi \lim_{\epsilon\to 0} \frac{E_{n,m}[0,\epsilon)}{\epsilon},$$

for all $n,m \in \mathbf{N}$.

III. SOME EXAMPLES OF PHASE OBSERVABLES

The phase theorem fixes the structure of a phase observable E in terms of a set of complex numbers $c_{n,m}$, $n,m \in \mathbf{N}$:

$$E(X) = \sum_{n,m=0}^{\infty} c_{n,m} \left(\frac{1}{2\pi} \int_X e^{i(n-m)\theta} \mathrm{d}\theta \right) |n\rangle\langle m|, \quad X \in \mathcal{B}[0,2\pi). \tag{11}$$

Exhibiting various sets $\{c_{n,m} \in \mathbf{C} | n,m \in \mathbf{N}\}$, which fulfill conditions (b) and (c) of the phase theorem, one gets various examples of phase observables. In this section we shall give a few examples. Before doing that we shall notice the following obvious facts concerning any phase observable E. First, the phase probabilities in any number state $|n\rangle$, $n \in \mathbf{N}$, are uniform, that is,

$$\langle n|E(X)|n\rangle = \frac{1}{2\pi} \int_X \mathrm{d}\theta, \quad X \in \mathcal{B}[0,2\pi),$$

showing that phase is totally random in the number states. Second, since

$$\langle n|E(X)^2|n\rangle = \sum_{s=0}^{\infty} |c_{n,s}|^2 \left| \frac{1}{2\pi} \int_X e^{i(n-s)\theta} \mathrm{d}\theta \right|^2$$

and $|c_{n,s}| \leq 1$, choosing, for instance, $X = [0,\pi)$ and $n=0$, one gets $\langle 0|E[0,\pi)^2|0\rangle \leq \frac{3}{8}$, which, when compared with $\langle 0|E[0,\pi)|0\rangle = \frac{1}{2}$, confirms the well-known fact that there is no spectral measure having the structure (11). Finally, since the probabilities $\langle n|E(X)|n\rangle$, $X \in \mathcal{B}[0,2\pi)$, do not depend on $|n\rangle$, there is no informationally complete phase observable.[7] We now turn to the examples.

Example 3.1: Consider a set $\{c_{n,m} | n,m \in \mathbf{N}\} \subset \mathbf{C}$ such that $c_{n,n} = 1$, $n \in \mathbf{N}$, and $\Sigma_{n>m=0}^{\infty} |c_{n,m}| \leq 1$. Then the formula (11) determines a phase observable. To check this we need only to confirm that the operators $\Sigma_{n,m=0}^{k} c_{n,m} |n\rangle\langle m|$, $k \in \mathbf{N}$, are positive. Let $\psi = \Sigma_{n=0}^{\infty} d_n |n\rangle \in \mathcal{H}$, $d_n = |d_n| e^{i\theta_n} \in \mathbf{C}$, and write $c_{n,m} = |c_{n,m}| e^{i\theta_{n,m}}$, $n,m \in \mathbf{N}$, so that, for all $k \in \mathbf{N}$,

$$\sum_{n,m=0}^{k} c_{n,m} \langle \psi|n\rangle\langle m|\psi\rangle = \|\psi\|^2 + 2 \sum_{n>m=0}^{k} |c_{n,m}| |d_n| |d_m| \cos(\theta_{n,m} - \theta_n + \theta_m).$$

To prove that the right-hand side of the above equation is non-negative we observe that for any $0 \leq a$, $b \leq 1$ such that $a^2 + b^2 \leq 1$, one has $ab \leq 2^{-1}$. Therefore,

$$|d_n| |d_m| \leq 2^{-1} \|\psi\|^2$$

for all $n,m \in \mathbf{N}$. Since $\cos(x) \geq -1$, $x \in \mathbf{R}$, we then have

$$\|\psi\|^2 + 2 \sum_{n>m=0}^{k} |c_{n,m}| |d_n| |d_m| \cos(\theta_{n,m} - \theta_n + \theta_m) \geq \|\psi\|^2 \left(1 - \sum_{n>m=0}^{k} |c_{n,m}| \right) \geq 0,$$

which concludes the proof of the positivity of the operator $\Sigma_{n,m=0}^{k} c_{n,m} |n\rangle\langle m|$.

Example 3.2: Example 3.1 shows that if $s \neq t \in \mathbf{N}$, $z \in \mathbf{C}$, $|z| \leq 1$, then for all $X \in \mathcal{B}[0,2\pi)$,

$$E(X)=\frac{1}{2\pi}\int_X d\theta\, I+z\,\frac{1}{2\pi}\int_X e^{i(s-t)\theta}\mathrm{d}\theta|s\rangle\langle t|+\bar{z}\frac{1}{2\pi}\int_X e^{i(t-s)\theta}\mathrm{d}\theta|t\rangle\langle s|$$

is a phase observable. This example exhibits the fact that the only commutative phase observable is the trivial one $X\mapsto((1/2\pi)\int_X \mathrm{d}\theta)I$, and the degree of noncommutativity of E is the stronger, the more there are nonzero nondiagonal structure constants $c_{n,m}$, $n\neq m$, in (11).

Example 3.3: If we choose $c_{n,m}:=a_n\overline{a_m}=|a_n||a_m|e^{i(\nu_n-\nu_m)}$ for all $n,m\in\mathbf{N}$, where $a_n=|a_n|e^{i\nu_n}\in\mathbf{C}$ is arbitrary for all $n\in\mathbf{N}$, then $|a_n|^2=c_{n,n}=1$, $n\in\mathbf{N}$. Hence $c_{n,m}=e^{i(\nu_n-\nu_m)}$, $n,m\in\mathbf{N}$, where $\nu_n\in\mathbf{R}$, $n\in\mathbf{N}$. Since

$$\sum_{n,m=0}^{k} c_{n,m}\langle\psi|n\rangle\langle m|\psi\rangle=\sum_{n=0}^{k}\overline{d_n e^{-i\nu_n}}\sum_{m=0}^{k} d_m e^{-i\nu_m}=\left|\sum_{n=0}^{k} d_n e^{-i\nu_n}\right|^2\geqslant 0,$$

for all $\psi=\sum_{n=0}^{\infty} d_n|n\rangle\in\mathcal{H}$, and $k\in\mathbf{N}$, the set $\{e^{i(\nu_n-\nu_m)}|\nu_n,\nu_m\in\mathbf{R},n,m\in\mathbf{N}\}$ defines a phase observable

$$E(X)=\sum_{n,m=0}^{\infty}\frac{1}{2\pi}\int_X e^{i[(n-m)\theta+\nu_n-\nu_m]}\mathrm{d}\theta|n\rangle\langle m|,\quad X\in\mathcal{B}[0,2\pi).$$

Example 3.4: Put $\nu_n=0$, $n\in\mathbf{N}$, in the above example. Then

$$E(X)=\sum_{n,m=0}^{\infty}\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\mathrm{d}\theta|n\rangle\langle m|,\quad X\in\mathcal{B}[0,2\pi).$$

This phase observable is the unique positive operator measure in the polar decomposition $a=(\int_0^{2\pi}e^{i\theta}\mathrm{d}E(\theta))\sqrt{N}$ of the lowering operator $a=\sum_{n=0}^{\infty}\sqrt{n+1}|n\rangle\langle n+1|$ associated with the number operator N, see, e.g., Ref. 7.

IV. THE PHASE OBSERVABLES ARISING FROM THE PHASE SPACE OBSERVABLES

The polar coordinate angle margins of the phase space observables constitute a physically relevant class of potential phase observables. In this section we characterize those phase space observables which give rise to phase observables. We introduce first the relevant phase space observables. Let $a=\sum_{n=0}^{\infty}\sqrt{n+1}|n\rangle\langle n+1|$ and $a^*=\sum_{n=0}^{\infty}\sqrt{n+1}|n+1\rangle\langle n|$ be the lowering and raising operators associated with the number operator $N=a^*a$, with the appropriate domains. Let $\lambda:\mathcal{B}(\mathbf{C})\to[0,\infty]$ be the two-dimensional Lebesgue measure. Let $D(z)=e^{za^*-\bar{z}a}$, $z\in\mathbf{C}$, be the unitary shift operator, and let T be any state, that is, a positive trace-one operator on $\mathcal{H}$. The set function

$$\mathcal{B}(\mathbf{C})\ni Z\mapsto A^T(Z):=\frac{1}{\pi}\int_Z D(z)TD(z)^*\mathrm{d}\lambda(z)\in\mathcal{L}(\mathcal{H}),$$

is then a positive normalized operator measure, the phase space observable defined by the state T.[4,10] We recall that the set of states is a closed σ-convex subset of the Banach space of the set of trace class operators on $\mathcal{H}$ (in trace norm). In particular, if $\{T_i\}_{i=1}^{\infty}$ is a sequence of states and if $\{\lambda_i\}_{i=1}^{\infty}$ is a sequence of non-negative numbers such that $\sum_{i=1}^{\infty}\lambda_i=1$, then the series $\sum_{i=1}^{\infty}\lambda_i T_i$ converges in trace norm to a state T, and we write $T=\sum_{i=1}^{\infty}\lambda_i T_i$, and we say that T is a mixture of the states T_i with the weights λ_i. Assume now that $T=\sum_{i=1}^{\infty}\lambda_i T_i$. By the dominated convergence theorem the phase space observables A^T and A^{T_i} are then related as follows: $A^T(Z)=\sum_{i=1}^{\infty}\lambda_i A^{T_i}(Z)$ for each $Z\in\mathcal{B}(\mathbf{C})$ (with the convergence in the weak operator topology). In that case, we write $A^T=\sum_{i=1}^{\infty}\lambda_i A^{T_i}$.

Writing $\mathbf{C}\ni z=|z|e^{i\arg z}\equiv re^{i\theta}$, $(r,\theta)\in[0,\infty)\times[0,2\pi)$, we may define the polar coordinate marginal measures of A^T:

$$\mathcal{B}[0,\infty) \ni R \mapsto A^T(R \times [0,2\pi)) =: F^T(R) \in \mathcal{L}(\mathcal{H}),$$

$$\mathcal{B}[0,2\pi) \ni X \mapsto A^T([0,\infty) \times X) =: E^T(X) \in \mathcal{L}(\mathcal{H}).$$

If T is a number state $|s\rangle$, $s \in \mathbf{N}$, that is $T = |s\rangle\langle s|$, or a mixture of number states, that is, $T = \Sigma_{s=0}^{\infty} \lambda_s |s\rangle\langle s|$, for some $0 \leqslant \lambda_s \leqslant 1$, $\Sigma_{s=0}^{\infty} \lambda_s = 1$, then the operator measures F^T and E^T are known to represent an unsharp number observable and the conjugate unsharp phase observable, respectively.[5,7] The next theorem identifies the phase space observables A^T whose angle margins E^T are phase observables, that is, for which

$$e^{i\theta N} E^T(X) e^{-i\theta N} = E^T(X + \theta),$$

for all $X \in \mathcal{B}[0,2\pi), \theta \in [0,2\pi)$.

Theorem 4.1: The angle margin E^T of the phase space observable A^T is a phase observable if and only if T is of the form $\Sigma_{s=0}^{\infty} \lambda_s |s\rangle\langle s|$, for some non-negative numbers $\lambda_s \in \mathbf{R}$, for which $\Sigma_{s=0}^{\infty} \lambda_s = 1$.

Proof: If T is of the form $T = \Sigma_{s=0}^{\infty} \lambda_s |s\rangle\langle s|$ for some $\lambda_s \geqslant 0$, $\Sigma_{s=0}^{\infty} \lambda_s = 1$, then the facts that $E^T = \Sigma_{s=0}^{\infty} \lambda_s E^{|s\rangle\langle s|}$ and $e^{i\theta N} D(z) = D(z e^{i\theta}) e^{i\theta N}$, $z \in \mathbf{C}$, imply that

$$e^{i\theta N} E^T(X) e^{-i\theta N} = E^T(X + \theta), \quad X \in \mathcal{B}[0,2\pi), \quad \theta \in [0,2\pi).$$

Assume now, that E^T is a phase observable. The structure constants $c_{n,m} \in \mathbf{C}$, $n,m \in \mathbf{N}$, of E^T can then be deduced from the following equations:

$$\langle n|E^T(X)|m\rangle = c_{n,m} \frac{1}{2\pi} \int_X e^{i(n-m)\theta} \mathrm{d}\theta = \frac{1}{2\pi} \int_X \int_0^{\infty} \langle n|D(re^{i\theta}) T D(re^{i\theta})^* |m\rangle \mathrm{d}r^2 \, \mathrm{d}\theta \tag{12}$$

for all $X \in \mathcal{B}[0,2\pi)$. Let $\phi_n^s(z) := \langle s|D(z)^*|n\rangle$ for all $s,n \in \mathbf{N}$ and $z \in \mathbf{C}$. These functions ϕ_n^s are easily seen to be of the form

$$\phi_n^s(re^{i\theta}) = e^{i(s-n)\theta} \phi_n^s(r) = e^{i(s-n)\theta} (-1)^{\max\{0,s-n\}} \sqrt{\frac{(\min\{n,s\})!}{(\max\{n,s\})!}} e^{-r^2/2} r^{|s-n|} L_{\min\{n,s\}}^{|s-n|}(r^2), \tag{13}$$

for all $r \in [0,\infty)$, $\theta \in [0,2\pi)$, where L_m^k, $m,k \in \mathbf{N}$, is the associated Laguerre polynomial. From (12) we get for all $n,m \in \mathbf{N}$ and $\mathrm{d}\theta$-almost every $\theta \in [0,2\pi)$,

$$c_{n,m} e^{i(n-m)\theta} = \int_0^{\infty} \sum_{s,t=0}^{\infty} T_{s,t} \overline{\phi_n^s(re^{i\theta})} \phi_m^t(re^{i\theta}) \mathrm{d}r^2 = \int_0^{\infty} \sum_{s,t=0}^{\infty} T_{s,t} \phi_n^s(r) \phi_m^t(r) e^{i(n-s+t-m)\theta} \mathrm{d}r^2.$$

Multiplying the above equation by $(2\pi)^{-1} e^{-il\theta}$, $l \in \mathbf{N}$, and integrating it over the interval $[0,2\pi)$ yields

$$\begin{aligned} c_{n,m} \delta_{n-m,l} &= \frac{1}{2\pi} \int_0^{2\pi} \int_0^{\infty} \sum_{s,t=0}^{\infty} T_{s,t} \phi_n^s(r) \phi_m^t(r) e^{i(n-s+t-m-l)\theta} dr^2 \, \dot{d}\theta \\ &= \sum_{s=0}^{\infty} T_{s,s} \int_0^{\infty} \phi_n^s(r) \phi_m^s(r) dr^2 \, \delta_{n-m,l} + \sum_{s \neq t=0}^{\infty} T_{s,t} \int_0^{\infty} \phi_n^s(r) \phi_m^t(r) dr^2 \, \delta_{n-m+t-s,l} \\ &= \sum_{s=0}^{\infty} T_{s,s} \int_0^{\infty} \phi_n^s(r) \phi_m^s(r) dr^2 \, \delta_{n-m,l} + \sum_{k=1}^{\infty} \sum_{s=0}^{\infty} T_{s,s+k} \int_0^{\infty} \phi_n^s(r) \phi_m^{s+k}(r) dr^2 \, \delta_{n-m+k,l} \\ &\quad + \sum_{k=1}^{\infty} \sum_{t=0}^{\infty} T_{t+k,t} \int_0^{\infty} \phi_n^{t+k}(r) \phi_m^t(r) dr^2 \, \delta_{n-m-k,l}. \end{aligned}$$

If we choose $l=n-m$, then

$$c_{n,m}=\sum_{s=0}^{\infty} T_{s,s}\int_0^\infty \phi_n^s(r)\phi_m^s(r)dr^2, \tag{14}$$

and, by choosing $l=n-m+k$ (notice that k is fixed now)

$$\sum_{s=0}^{\infty} T_{s,s+k}\int_0^\infty \phi_n^s(r)\phi_m^{s+k}(r)dr^2=0, \tag{15}$$

for all $n,m\in\mathbf{N}$ and $k\in\mathbf{Z}^+$. This equation allows us to show that $T_{s,s+k}=0$ for all $s\in\mathbf{N}$ and $k\in\mathbf{Z}^+$. Indeed, using the equations [Ref. 11, Eqs. 8.973(1), and 7.414(11) or Ref. 12, Eq. (4β), p. 119]

$$\begin{gathered}L_0^s(r^2)=1, \quad r\geqslant 0, \quad s\in\mathbf{N},\\ \int_0^\infty e^{-r^2}r^{2(\gamma-1)}L_n^\mu(r^2)dr^2=\frac{\Gamma(\gamma)\Gamma(1-\gamma+\mu+n)}{n!\Gamma(1-\gamma+\mu)}, \quad \gamma>0, \quad \mu,n\in\mathbf{N},\end{gathered} \tag{16}$$

it follows from (13) that

$$\int_0^\infty \phi_0^s(r)\phi_{2l+k}^{s+k}(r)dr^2=\begin{cases}0 & \text{when } s\geqslant l,\\ \dfrac{(-1)^s l!(l+k-1)!}{(l-s-1)!\sqrt{s!(s+k)!(2l+k)!}} & \text{when } 0\leqslant l\end{cases}$$

for all $l,k\in\mathbf{Z}^+$, since for each $m\in\mathbf{N}$, $|\Gamma(-m+\epsilon)|\to\infty$, $\epsilon\to 0$, and the right-hand side of (16) is zero when $1-\gamma+\mu=-m$. If one chooses $n=0$, and $m=2l+k$, $l\in\mathbf{Z}^+$, in (15), one gets

$$\sum_{s=0}^{l-1} T_{s,s+k}\int_0^\infty \phi_0^s(r)\phi_{2l+k}^{s+k}(r)dr^2=0. \tag{17}$$

We next fix $k\in\mathbf{Z}^+$. When one substitutes $l=1$ in (17), it follows that $T_{0,k}=0$. If $T_{s,s+k}=0$ for all $s\leqslant h-1$, $h\in\mathbf{Z}^+$, we substitute $l=h+1$ to (17) to get $T_{h,h+k}=0$. We conclude that if E^T is a phase observable, then T is diagonal in the number basis, and thus of the form $T=\sum_{s=0}^\infty \lambda_s|s\rangle\langle s|$, $\lambda_s\geqslant 0$, $s\in\mathbf{N}$ and $\sum_{s=0}^\infty \lambda_s=1$. This concludes the proof of the theorem. □

Remark 4.2: The proof of the above theorem shows that if $E^T(X)=A^T([0,\infty)\times X)$, $X\in\mathcal{B}[0,2\pi)$, is a phase observable, then the structure constants $c_{n,m}$, $n,m\in\mathbf{N}$, of E^T are

$$c_{n,m}=\sum\nolimits_{s=0}^{\infty} T_{s,s}\int_0^\infty \phi_n^s(r)\phi_m^s(r)dr^2. \tag{18}$$

One may thus easily confirm that $c_{n,n}=1$, $n\in\mathbf{N}$. Indeed, since the associated Laguerre polynomials satisfy the relation [Ref. 11, Eq. 7.414(3)]

$$\int_0^\infty e^{-r^2}r^{2\alpha}L_n^\alpha(r^2)L_m^\alpha(r^2)dr^2=\frac{(\alpha+n)!}{n!}\delta_{n,m}, \quad \alpha,n,m\in\mathbf{N}, \tag{19}$$

we have

$$\int_0^\infty \phi_n^s(r)\phi_n^s(r)dr^2=1, \quad n,s\in\mathbf{N}.$$

Therefore, it follows from (18) that

$$c_{n,n}=\sum_{s=0}^{\infty} T_{s,s}\int_0^{\infty}\phi_n^s(r)\phi_n^s(r)dr^2=\sum_{s=0}^{\infty} T_{s,s}=\mathrm{tr}(T)=1, \quad n\in\mathbf{N}.$$

Since $T\geqslant O$, we also observe that $c_{n,m}\in\mathbf{R}$, $n,m\in\mathbf{N}$. For all $\psi\in\mathcal{H}$, $k\in\mathbf{N}$, one gets

$$\sum_{n,m=0}^{k} c_{n,m}\langle\psi|n\rangle\langle m|\psi\rangle=\sum_{s=0}^{\infty} T_{s,s}\int_0^{\infty}\left|\sum_{m=0}^{k}\phi_m^s(r)\langle m|\psi\rangle\right|^2 dr^2\geqslant 0,$$

which confirms that the operators $\Sigma_{n,m=0}^{k} c_{n,m}|n\rangle\langle m|$, $k\in\mathbf{N}$, are positive. It is also easy to verify the condition $|c_{n,m}|\leqslant 1$, $n,m\in\mathbf{N}$, directly by using the Cauchy–Schwarz inequality:

$$\begin{aligned}|c_{n,m}|&\leqslant\sum_{s=0}^{\infty} T_{s,s}\left|\int_0^{\infty}\phi_n^s(r)\phi_m^s(r)dr^2\right|\\ &\leqslant\sum_{s=0}^{\infty} T_{s,s}\sqrt{\int_0^{\infty}\phi_n^s(r)\phi_n^s(r)dr^2}\sqrt{\int_0^{\infty}\phi_m^s(r)\phi_m^s(r)dr^2}\\ &=\mathrm{tr}(T)=1,\end{aligned}$$

for all $n,m\in\mathbf{N}$.

We note finally that there are phase observables which are not angle margins of some phase space observables. For instance, if we assume that there is a state T such that the phase observable E of Example 3.4 is of the form $E=E^T$, then (18) and (16) give

$$1=c_{0,2}=T_{0,0}\frac{1}{\sqrt{2}}.$$

But this means that $T_{0,0}=\sqrt{2}>1$, which is impossible.

V. THE FIRST MOMENT OPERATOR OF A PHASE OBSERVABLE AND THE NUMBER OPERATOR AS A HEISENBERG PAIR

The phase observables $E:\mathcal{B}[0,2\pi)\rightarrow\mathcal{L}(\mathcal{H})$ are compactly supported real operator measures. Therefore, their moment operators of all order $k\in\mathbf{N}$, $E^{(k)}:=\int_0^{2\pi}\theta^k\,\mathrm{d}E(\theta)$, are bounded self-adjoint operators. In particular,

$$E^{(1)}=\sum_{n\neq m=0}^{\infty}\frac{ic_{n,m}}{m-n}|n\rangle\langle m|+\pi I,$$

and one may calculate the formal commutator of the number operator N and $E^{(1)}$:

$$[N,E^{(1)}]=iI-i\sum_{n,m=0}^{\infty} c_{n,m}|n\rangle\langle m|$$

This shows that the operators $E^{(1)}$ and N form a Heisenberg pair[13] exactly when the series $\Sigma_{n,m=0}^{\infty} c_{n,m}|n\rangle\langle m|$ vanishes in a dense subspace of $\mathcal{H}$ which is contained in the domain of the commutator $[N,E^{(1)}]$.

The first moment operator of the phase observable of Example 3.4 and the number operator N form a Heisenberg pair.[14] In Example 3.3 we have $c_{n,m}=e^{i(\nu_n-\nu_m)}$, $\nu_n\in\mathbf{R}$, $n,m\in\mathbf{N}$. The related phase observables are obtained from Example 3.4 by the simple unitary transformation $|n\rangle\mapsto e^{i\nu_n}|n\rangle$. Thus the first moment operators of the observables of Example 3.4 form also Heisenberg pairs with N. The domains of commutators are then

$$\mathcal{D}_E := \left\{ \psi \in \mathcal{D}(N) \,\middle|\, \sum_{m=0}^{\infty} e^{-i\nu_m} \langle m|\psi\rangle = 0 \right\},$$

in which $[N,E^{(1)}]=iI$. Apart from that it is to be stressed that the moment operator $E^{(1)}$ is of a very limited use. First, since the phase observable E is not a projection valued measure, its first moment operator $E^{(1)}$ does not suffice to determine E. Second, it carries an essential nonuniqueness, since $e^{i\theta N}E^{(1)}e^{-i\theta N}=E^{(1)}-\theta I+2\pi E[0,\theta),\ \theta\in[0,2\pi)$. Third, though $\mathcal{D}_E$ is a dense subset of $\mathcal{H}$, it does not contain physically relevant vector states, as entailed by the well-known no-go theorem for the existence of a canonical phase operator.[3]

The phase observable of Example 3.2 gives an example of a pair $(E^{(1)},N)$ which is not a Heisenberg pair. Indeed, in that case we have

$$[N,E^{(1)}]=-i(z|s\rangle\langle t|+\overline{z}|t\rangle\langle s|)\neq iI$$

in $\mathcal{H}\setminus\{0\}$.

The semispin groups in string theory

Brett McInnes[a]

(Received 30 March 1999; accepted for publication 12 May 1999)

In string theory, an important role is played by certain Lie groups which are locally isomorphic to $\mathrm{SO}(4m)$, $m \leqslant 8$. It has long been known that these groups are actually isomorphic not to $\mathrm{SO}(4m)$ but rather to the groups for which the half-spin representations are faithful, which we propose to call $\mathrm{Semispin}(4m)$. (They are known in the physics literature by the ambiguous name of ''$\mathrm{Spin}(4m)/Z_2$.'') Recent work on string duality has shown that the distinction between $\mathrm{SO}(4m)$ and $\mathrm{Semispin}(4m)$ can have a definite physical significance. This work is a survey of the relevant properties of $\mathrm{Semispin}(4m)$ and its subgroups. © *1999 American Institute of Physics.* [S0022-2488(99)03510-0]

I. INTRODUCTION

From a physical point of view, gauge theories have a serious drawback: the construction works equally well for all compact Lie groups. Even when the Lie algebra of the gauge group is known, the global structure of the group itself is not fixed by any fundamental principle. For example, it can be argued that the gauge group of the standard model[1] is ''really'' $[\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1)]/Z_6$ rather than $\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1)$; but since all known particles fall into multiplets which can be regarded as representations of *both* of these groups, there is (at present) no way of deciding the issue other than by an appeal to parsimony.

It is one of the many virtues of string theory that it puts an end to all uncertainty on this score.[2] The theory not only specifies the dimension of the gauge group (at 496 in the Type I and heterotic theories) but also its global structure within each version. In the heterotic ''$E_8\times E_8$'' theory, this is quite straightforward. First, there is in any case *only one* connected group with the Lie algebra of $E_8\times E_8$, namely $E_8\times E_8$ itself. Second, there is *only one* nontrivial disconnected Lie group with $E_8\times E_8$ as an identity component, namely the semidirect product $(E_8\times E_8)\lhd Z_2$, where Z_2 acts by exchanging the E_8 factors. As the corresponding string theory (initially) treats the two factors symmetrically, we conclude that the global version of the gauge group is $(E_8\times E_8)\lhd Z_2$. (The significance of disconnected gauge groups is discussed in Refs. [3–6]. By ''nontrivial'' we mean to exclude, for example, direct products of finite groups with $E_8\times E_8$, which are of little or no physical interest.)

The ''SO(32)'' cases (Type I and heterotic) are much less straightforward, because there are many nontrivial groups with the same Lie algebra as $\mathrm{SO}(n)$; in fact, there are eight nontrivial groups with the ''SO(32)'' algebra. It has been known from the beginning[7] that string theory selects from these eight a group known in the physics literature as $\mathrm{Spin}(32)/Z_2$, a most unfortunate convention, which only exacerbates the tendency to confuse this group with SO(32). This group is closely associated with (and is essentially defined by) the *half-spin* representations of Spin(32), and so we propose the name Semispin(32) for it. As we shall see, there is no non-trivial disconnected Lie group with Semispin(32) as identity component, so the gauge group is connected in this case.

To summarize, the heterotic string theories fix the global structures of their gauge groups. One theory uses the disconnected but simply connected group $(E_8\times E_8)\lhd Z_2$, while the other uses the connected but not simply connected group Semispin(32).

[a]Electronic mail: matmcinn@nus.edu.sg

The semispin groups are perhaps the least familiar of the compact simple Lie groups, and there is a venerable tradition of treating Semispin$(4m)$ as if it were the same as SO$(4m)$. We wish to argue that this tradition has outlived its usefulness, that string theory forces us to be fully aware of the differences between Semispin$(4m)$ and the other groups with the same algebra. There are two physically significant kinds of distinction, one representation theoretic, the other topological.

First, note that while such ambiguities have often arisen in the past, one of the groups in question has always been a *cover* of the other. For example, ''SO(10)'' grand unification[8] uses a certain 16-dimensional multiplet which does *not* correspond to any representation of SO(10). It is, of course, a representation of Spin(10). One can solve this ''problem'' by simply reading Spin(10) for SO(10); no harm is done, but only because every representation of SO(10) is automatically a representation of Spin(10), the latter being a *cover* of the former. In the opposite direction, one normally writes SU(3)×SU(2)×U(1) for (SU(3)×SU(2)×U(1)/Z_6, the ''true'' group,[1] with no ill effects because every representation of the latter is a representation of the former. The novelty in string theory is that *neither* SO(32) *nor* Semispin(32) is a cover of the other. Consequently, *both* have representations which cannot be regarded as representations of the other. The situation here is quite different to the superficially analogous ambiguities arising in earlier gauge theories.

Second, there exist Semispin(32) gauge configurations (over topologically nontrivial space–times) which are of considerable physical importance, but which *cannot* be interpreted as SO(32) gauge configurations.[9,10] The reader might argue that one can likewise construct SO(10) configurations which do not lift to Spin(10). The point, however, is just that ordinary gauge theory does not provide any fundamental justification for thinking that SO(10) is important. String theory, by contrast, does favor Semispin(32) over SO(32). The analysis of Semispin(32) bundles which cannot be regarded as Spin(32) or SO(32) bundles is therefore physically significant.

Finally, the study of duality[11] brings both points together in a potentially very confusing way. The *T*-duality between the two heterotic theories relies on relating ''$E_8 \times E_8$'' and ''SO(32)'' through their supposed common subgroup, ''SO(16)×SO(16).'' A global investigation shows that *no such common subgroup exists*; worse still, neither of the actual respective subgroups covers the other; worse yet again, each has representations which are *not* representations of the other, but which *are* crucial in establishing duality. Solving this problem leads to further topological obstructions, and, in the background, one has ''Wilson loops'' behaving in a way that depends very delicately on the global structure of various subgroups of Semispin(32) and Semispin(16). In short, the local simplicity of the duality argument conceals considerable complexity at the global level.

The purpose of this work is not to solve all of these problems, but rather to give a useful survey of those aspects of the Semispin groups (and their subgroups) which are most directly relevant to string theory. The main emphasis is on the structure of the groups themselves rather than their representations, since the latter are well understood and since it is the former which is needed for dealing with topological obstructions and for analyzing the effect of Wilson loops.

We begin with a brief survey of the family of nontrivial Lie groups with the algebra of SO(n).

II. GROUPS WITH THE ALGEBRA OF SO(n)

In order to understand the ways in which Semispin$(4m)$ differs from the other groups with the same Lie algebra, it is useful to begin with a complete classification. We refer the reader to Ref. 12 for the basic techniques, or to Ref. 13 for a much simpler account.

We shall not assume that the gauge group is connected; we have already seen that this would not be justifiable in one heterotic theory. On the other hand, it is true that most disconnected Lie groups are of little physical interest. Every compact Lie group can be expressed as a finite union of connected components,

$$G = G_0 \cup \gamma_1 \bullet G_0 \cup \gamma_2 \bullet G_0 \cup \cdots ,$$

where G_0 contains the identity and the γ_i are not elements of G_0. The nonidentity components of a gauge group are particularly important if space–time is not simply connected, since in that case parallel transport of particles around noncontractible paths (''Wilson loops'') can affect conserved charges.[3–5] However, a given component, $\gamma_i \bullet G_0$, can only give rise to such effects if γ_i *cannot* be chosen so as to commute with every element of G_0. The physically interesting disconnected groups are those such that none of the γ_i can be chosen to commute with every element of G_0. Such a group is called a *natural extension* of its identity component. For example, $(E_8 \times E_8) \lhd Z_2$ is a natural extension of $E_8 \times E_8$, and it is in fact the only other natural extension. (It is convenient to adopt the convention that a connected group is a natural extension of itself.) Henceforth, we confine attention to disconnected groups which are natural extensions of their identity components.

Next, some definitions. Let $\mathrm{Pin}(n), n \geqslant 2$, be defined as usual[14] in terms of a Clifford algebra with a basis $\{e_i\}$. We can write $\mathrm{Pin}(n)$ as a natural extension of $\mathrm{Spin}(n)$, when n is even,

$$\mathrm{Pin}(2m) = \mathrm{Spin}(2m) \cup e_1 \bullet \mathrm{Spin}(2m).$$

Notice that this is not necessarily a semidirect product, since $(e_1)^2 = -1 \in \mathrm{Spin}(2m)$. However, $\mathrm{Spin}(2m) \lhd Z_2$ can be defined (with the generator of Z_2 acting in the same way as conjugation by e_1); it is actually isomorphic to $\mathrm{Pin}(2m)$ if m is even, but not if m is odd. It, too, is a natural extension of $\mathrm{Spin}(2m)$. (There is no natural extension of $\mathrm{Spin}(n)$, other than itself, when n is odd.)

Let $\hat{K}_{m,n}$ be defined by

$$\hat{K}_{m,n} = \prod_{i=m}^{n} e_i$$

and set $\hat{K}_m = \hat{K}_{1,m}$. Then the center of $\mathrm{Spin}(n)$ is $\{\pm 1\}$ if n is odd, while the center of $\mathrm{Spin}(2m)$ is $\{\pm 1, \pm \hat{K}_{2m}\}$. Since $(\hat{K}_{2m})^2 = (-1)^m$, the center is Z_4 if m is odd, but $Z_2 \times Z_2$ if m is even.[15] Here we think of $\{1, \hat{K}_{2m}\}$ as the first Z_2, $\{1, -\hat{K}_{2m}\}$ as the second, and $\{\pm 1\}$ as the diagonal. Of course, we have

$$\mathrm{Spin}(n)/\{\pm 1\} = \mathrm{SO}(n) \quad \text{for all} \quad n \geqslant 2.$$

When n is odd, $\mathrm{SO}(n)$ has no natural extension other than itself, but when n is even it has two others. The first is $\mathrm{O}(2m)$, which may be expressed as

$$\mathrm{O}(2m) = \mathrm{SO}(2m) \cup A_{2m} \bullet \mathrm{SO}(2m),$$

where A_{2m} is a $(2m) \times (2m)$ orthogonal matrix satisfying $A_{2m}^2 = I_{2m}, \det A_{2m} = -1$. Thinking of $\mathrm{O}(2m)$ as the real subgroup of $\mathrm{U}(2m)$, we can also define

$$\mathrm{Oi}(2m) = \mathrm{SO}(2m) \cup i A_{2m} \bullet \mathrm{SO}(2m);$$

this group is also a natural extension of $\mathrm{SO}(2m)$, and it is not isomorphic to $\mathrm{O}(2m)$.

When n is even, $\mathrm{SO}(n)$ has a nontrivial quotient,

$$\mathrm{PSO}(2m) = \mathrm{SO}(2m)/\{\pm I_{2m}\},$$

the projective special orthogonal group. We can define $\mathrm{PO}(2m)$ as the same quotient of $\mathrm{O}(2m)$, and it is a natural extension of $\mathrm{PSO}(2m)$. Notice that $\mathrm{PSO}(2m)$ can be obtained directly from $\mathrm{Spin}(2m)$ by factoring out the entire center.

When n is a multiple of 4, we can also consider the quotients $\mathrm{Spin}(4m)/\{1, \hat{K}_{4m}\}$ and $\mathrm{Spin}(4m)/\{1, -\hat{K}_{4m}\}$. Let $\mathrm{Ad}(e_1)$ denote conjugation by e_1 in $\mathrm{Pin}(4m)$; then $\mathrm{Ad}(e_1)$ is an automorphism of $\mathrm{Spin}(4m)$, and

$$\mathrm{Ad}(e_1)\hat{K}_{4m} = -\hat{K}_{4m}.$$

It follows that $\mathrm{Spin}(4m)/\{1,\hat{K}_{4m}\}$ and $\mathrm{Spin}(4m)/\{1,-\hat{K}_{4m}\}$ are mutually isomorphic. Thus we obtain only one group in this way, not two. We define

$$\mathrm{Semispin}(4m) = \mathrm{Spin}(4m)/\{1,\hat{K}_{4m}\}.$$

This group is isomorphic to $\mathrm{SO}(4m)$ only if $\mathrm{Spin}(4m)$ admits an automorphism which maps $\hat{K}_{4m}$ to -1; but no such automorphism exists, except when $m=2$. Leaving that case to one side, $\mathrm{Ad}(e_1)$ is, up to inner automorphisms, the only outer automorphism of $\mathrm{Spin}(4m)$. Since $\mathrm{Ad}(e_1)$ does not map $\{1,\hat{K}_{4m}\}$ into itself, we see that, unlike $\mathrm{Spin}(4m)$, $\mathrm{SO}(4m)$, and $\mathrm{PSO}(4m)$, $\mathrm{Semispin}(4m)$ has no outer automorphism if $m \neq 2$. If, therefore, G is a compact disconnected group with $\mathrm{Semispin}(4m)$ as its identity component,

$$G = \mathrm{Semispin}(4m) \cup \gamma_1 \bullet \mathrm{Semispin}(4m) \cup \cdots,$$

then $\mathrm{Ad}(\gamma_i)$ must, for all i, be inner; $\mathrm{Ad}(\gamma_i) = \mathrm{Ad}(s_i)$ for some s_i in $\mathrm{Semispin}(4m)$. Thus $\gamma_i s_i^{-1}$ commutes with every element of $\mathrm{Semispin}(4m)$, and so we see that, when $m \neq 2$, $\mathrm{Semispin}(4m)$ has no natural extension other than itself.

When $m=2$, we have Spin(8), which has the triality map,[14] an automorphism of order three. This combines with $\mathrm{Ad}(e_1)$ to give D_6, the dihedral group of order six. Triality maps $\hat{K}_8$ to -1, so in fact

$$\mathrm{Semispin}(8) = \mathrm{SO}(8).$$

This is the only dimension in which the Semispin construction gives nothing new. Triality does not descend to SO(8) (because it does not preserve $\{\pm 1\}$) but it does descend to PSO(8).

We are now in a position to state the following theorem, the proof of which is an application of techniques given in Refs. 12 and 13.

Theorem 1: Let G be a compact Lie group which is a natural extension of its identity component. If the Lie algebra of G is isomorphic to that of $\mathrm{SO}(n)$, $n \geq 2$, then G is globally isomorphic to a group in the following list:

(1) $n=2$: SO(2), O(2), Pin(2).
(2) $n=$ odd: $\mathrm{SO}(n)$, $\mathrm{Spin}(n)$.
(3) $n=4m+2$, $m \geq 1$: $\mathrm{Spin}(n)$, $\mathrm{Pin}(n)$, $\mathrm{Spin}(n) \lhd Z_2$, $\mathrm{SO}(n)$, $\mathrm{O}(n)$, $\mathrm{Oi}(n)$, $\mathrm{PSO}(n)$, $\mathrm{PO}(n)$.
(4) $n=4m$, $m \neq 2$: $\mathrm{Spin}(n)$, $\mathrm{Pin}(n)$, $\mathrm{SO}(n)$, $\mathrm{O}(n)$, $\mathrm{Oi}(n)$, $\mathrm{PSO}(n)$, $\mathrm{PO}(n)$, $\mathrm{Semispin}(n)$.
(5) $n=8$: Spin(8), Pin(8), $\mathrm{Spin}(8) \lhd Z_3$, $\mathrm{Spin}(8) \lhd D_6$, SO(8), O(8), Oi(8), PSO(8), PO(8), $\mathrm{PSO}(8) \lhd Z_3$, $\mathrm{PSO}(8) \lhd D_6$.

Note that $\mathrm{Spin}(4) = \mathrm{SU}(2) \times \mathrm{SU}(2)$, $\mathrm{PSO}(4) = \mathrm{SO}(3) \times \mathrm{SO}(3)$, and $\mathrm{Semispin}(4) = \mathrm{SU}(2) \times \mathrm{SO}(3)$.

These, then, are the nontrivial distinct groups corresponding to the $\mathrm{SO}(n)$ algebra. When n is 32, there are no fewer than eight candidates. String theory selects a particular group from among these eight in the following extraordinary way. In the heterotic theories, gauge fields arise in connection with the lattice of momenta on a 16-dimensional torus. The lattice must be even and self-dual. The crucial point is that these requirements impose conditions not merely on the root system of the gauge group, *but also on its integral lattice*.[16] However, there is a deep connection between the integral lattice and the global structure of a compact, connected Lie group. Thus string theory provides a route from strictly physical conditions directly to the global structure of the (identity component of the) gauge group. As is well known, Semispin(32) satisfies these conditions, while SO(32), Spin(32), and PSO(32) do not. The argument is now completed by a glance at Theorem 1; we see that Spin(32) and PSO(32) each have a nontrivial disconnected version, and SO(32) has two, but Semispin(32) has none. The precise global structure of the gauge group is thereby fixed; it is Semispin(32).

We close this section with some remarks on the representation theory of Spin$(4m)$, Semispin$(4m)$, SO$(4m)$, and PSO$(4m)$. Recall that the basic faithful representation of Spin$(4m)$, obtained[14] by suitably restricting an irreducible representation of the Clifford algebra, has a canonical decomposition

$$\Delta_{4m}=\Delta_{4m}^{+}\oplus\Delta_{4m}^{-},$$

where Δ_{4m}^{+} is a representation with kernel $\{1,\hat{K}_{4m}\}$ and Δ_{4m}^{-} has kernel $\{1,-\hat{K}_{4m}\}$. Thus, neither Δ_{4m}^{+} nor Δ_{4m}^{-} is faithful; one must take their sum. Hence Δ_{4m}^{+} and Δ_{4m}^{-} are called the *half-spin representations*. Evidently they are faithful not on Spin$(4m)$ but on the group we (accordingly) call Semispin$(4m)$. The half-spin representations are of dimension 2^{2m-1}. Thus the so-called ''128-dimensional representation of SO(16)'' which plays a prominent role in string theory is in fact the defining representation of Semispin(16). Again, the defining representation of Semispin(32) is 32 768-dimensional, a decidedly inconvenient value. Fortunately, we have

$$\mathrm{PSO}(32)=\mathrm{Semispin}(32)/Z_2,$$

and so every representation of PSO(32) is automatically a representation of Semispin(32); thus, the latter has a more manageable (but unfaithful) 496-dimensional representation, which is also an unfaithful representation of SO(32) and Spin(32), namely, the adjoint. Similarly PSO(16) yields a 120-dimensional representation of Semispin(16), and so the latter has a *faithful* 248-dimensional representation defined by the direct sum, $\mathbf{120}\oplus\mathbf{128}$. As the representation is faithful, and as the (likewise faithful) adjoint of E_8 decomposes as $\mathbf{248}=\mathbf{120}\oplus\mathbf{128}$, this immediately shows that E_8 contains Semispin(16) and *not*, as is so often said, SO(16). Thus $(E_8\times E_8)\lhd Z_2$ has a maximal subgroup of the form $(\mathrm{Semispin}(16)\times\mathrm{Semispin}(16))\lhd Z_2$, and so we see that *the Semispin groups appear in both heterotic string theories*. In fact, Witten[17] has recently argued that the same is true of the Type I theory. The gauge group of Type I at the perturbative level is PO(32) (see Theorem 1). As this group is disconnected, while Semispin(32) has no nontrivial disconnected version, this appears to obstruct the supposed *S*-duality between the Type I and the ''SO(32)'' heterotic string theories.[11] However, Witten shows that a subtle nonperturbative effect breaks PO(32) to $\mathrm{PSO}(32)=\mathrm{Semispin}(32)/Z_2$; furthermore, there appear to be Type I nonperturbative states transforming ''spinorially'' under the gauge group. (Note that, like a spinor, a ''semispinor'' is odd under a 2π rotation; the nontrivial element in the center of Semispin(32) is the projection of -1 in Spin(32).) In short, the gauge group of Type I string theory is undoubtedly Semispin(32) precisely, not SO(32). The Semispin groups appear in all three string theories with nontrivial gauge groups.

All this appears to bode well for duality: in particular, since $(E_8\times E_8)\lhd Z_2$ contains $(\mathrm{Semispin}(16)\times\mathrm{Semispin}(16))\lhd Z_2$, one would expect this same group to appear on the Semispin(32) side. In fact, this is *not* the case, as we now show.

III. SUBGROUPS OF SEMISPIN$(4m)$ CORRESPONDING TO SO$(k)\times$SO$(4m-k)$

Evidently SO(32) contains SO(16)×SO(16) block-diagonally; more generally, SO$(4m)$ contains SO$(k)\times$SO$(4m-k)$, $k\geqslant 2$. The product is indeed direct, since SO(k) and SO$(4m-k)$ intersect trivially, in $\{I_{4m}\}$. However, Spin$(4m)$ *does not* contain Spin$(k)\times$Spin$(4m-k)$, because both factors contain $\{\pm 1\}$. In fact, the subgroup is Spin$(k)\bullet$Spin$(4m-k)$, a local direct product, where

$$\mathrm{Spin}(k)\bullet\mathrm{Spin}(4m-k)=(\mathrm{Spin}(k)\times\mathrm{Spin}(4m-k))/Z_2,$$

with Z_2 generated by $(-1,-1)$.

There is another important difference between SO$(4m)$ and Spin$(4m)$ in this area. It is clear that, when $k=2j$ is even, Spin$(k)\bullet$Spin$(4m-k)$ can be characterized as the group of all Spin$(4m)$ elements which commute with (that is, as the *centralizer* of) $\hat{K}_{2j}$. Now $\hat{K}_{2j}$ projects to the SO$(4m)$ matrix diag$(-I_{2j},I_{4m-2j})=K_{2j}$, but the SO$(4m)$ centralizer of K_{2j} is not SO$(2j)\times$SO$(4m-2j)$; rather, it is the disconnected subgroup $S(\mathrm{O}(2j)\times\mathrm{O}(4m-2j))$, the set of all pairs ($A$, B) in O$(2j)\times$O$(4m-2j)$ such that det A=det B. That is, a Wilson loop that breaks Spin$(4m)$ to a *connected* subgroup will break SO$(4m)$ to a *disconnected* subgroup. (Recall[2] that a Wilson loop in a gauge theory is a closed curve in space–time which has a nontrivial holonomy element even in the vacuum. The gauge group is broken to the centraliser of the (usually finite) subgroup generated by the holonomy element.)

Now we turn to the case of the Semispin$(4m)$. Suppose first that k is odd. Then Spin$(k)\bullet$Spin$(4m-k)$ does not contain $\hat{K}_{4m}$, and so it is unaffected by the projection from Spin$(4m)$ to Semispin$(4m)$. Thus, when k is odd, the subgroup of Semispin$(4m)$ corresponding to SO$(k)\times$SO$(4m-k)$ is globally isomorphic to Spin$(k)\bullet$Spin$(4m-k)$. Next, suppose that $k=2j$ is even but not a multiple of 4. Then $4m-2j$ is likewise even but not a multiple of 4, and so Spin$(2j)$ and Spin$(4m-2j)$ have Z_4 centers generated, respectively, by $\hat{K}_{2j}$ and $\hat{K}_{2j+1,4m}$. We have

$$\hat{K}_{2j}\hat{K}_{4m}=-\hat{K}_{2j+1,4m}$$

and

$$\hat{K}_{2j+1,4m}\hat{K}_{4m}=-\hat{K}_{2j},$$

and so the effect of factoring by $\hat{K}_{4m}$ is to identify the *entire* center of Spin$(4m-2j)$ with that of Spin$(2j)$. We have, when j is odd,

$$\mathrm{Spin}(2j)\mathbf{:}\mathrm{Spin}(4m-2j)=(\mathrm{Spin}(2j)\times\mathrm{Spin}(4m-2j))/Z_4$$

as the subgroup of Semispin$(4m)$ corresponding to SO$(2j)\times$SO$(4m-2j)$.

Finally, if $k=4j$ is a multiple of 4, then so is $4m-4j$ and both Spin$(4j)$ and Spin$(4m-4j)$ have centers isomorphic to $Z_2\times Z_2$. These centres are $\{\pm 1,\pm\hat{K}_{4j}\}$ and $\{\pm 1,\hat{K}_{4j+1,4m}\}$, respectively, and since we have

$$\pm\hat{K}_{4j}\hat{K}_{4m}=\pm\hat{K}_{4j+1,4m}$$

and

$$\pm\hat{K}_{4j+1,4m}\hat{K}_{4m}=\pm\hat{K}_{4j},$$

we see that, once again, the effect of the projection Spin$(4m)\to$Semispin$(4m)$ is to identify the entire center of Spin$(4m-4j)$ with that of Spin$(4j)$. We use the notation

$$\mathrm{Spin}(4j)\mathbf{:}\mathrm{Spin}(4m-4j)=(\mathrm{Spin}(4j)\times\mathrm{Spin}(4m-4j))/(Z_2\times Z_2).$$

Next, recall that, from a physical point of view, we are interested in obtaining all these groups as centralizers of some element in Semispin$(4m)$. We saw earlier that the centralizer of $\hat{K}_{2j}$ in Spin$(4m)$ is connected, but that of K_{2j} in SO$(4m)$ is not. Let K^*_{2j} be the projection of $\hat{K}_{2j}$ to Semispin$(4m)$. The centralizer of K^*_{2j} will include Spin$(2j)$**:**Spin$(4m-2j)$, but it will also include any Semispin$(4m)$ element L^* such that $\hat{L}$, a lift of L^* to Spin$(4m)$, satisfies $\hat{L}\hat{K}_{2j}=\hat{K}_{4m}\hat{K}_{2j}\hat{L}$. Projecting this to SO$(4m)$, we find that the corresponding matrices satisfy

$$LK_{2j}L^{-1}=-K_{2j},$$

whence Trace $K_{2j}=4(m-j)=0$. Thus if $j\neq m$, L^* does not exist, and so the centraliser of K^*_{2j} in Semispin$(4m)$ is precisely Spin$(2j)$**:**Spin$(4m-2j)$. If $j=m$, then we have

$$J_{2m}K_{2m}J_{2m}^{-1}=-K_{2m},$$

where

$$J_{2m}=\begin{pmatrix} 0 & -I_{2m} \\ I_{2m} & 0 \end{pmatrix}.$$

This solution is essentially unique. The corresponding element of Spin$(4m)$ is (see Ref. 16, p. 174, and modify suitably)

$$\hat{J}_{2m}=2^{-m}(1-e_1e_{1+2m})(1-e_2e_{2+2m})\cdots(1-e_{2m}e_{4m}).$$

Now,

$$\begin{aligned}\hat{K}_{2m}\hat{J}_{2m}&=2^{-m}(e_1+e_{1+2m})(e_2+e_{2+2m})\cdots(e_{2m}+e_{4m})\\ &=2^{-m}(e_{1+2m}+e_1)(e_{2+2m}+e_2)\cdots(e_{4m}+e_{2m})=\hat{J}_{2m}\hat{K}_{1+2m,4m}\\ &=(-1)^m\hat{K}_{4m}\hat{J}_{2m}\hat{K}_{2m},\end{aligned}$$

since $(\hat{K}_{2m})^2=(-1)^m$ and $\hat{K}_{2m}\hat{K}_{1+2m,4m}=\hat{K}_{4m}$. Thus if m is even, the projections to Semispin$(4m)$ satisfy $K_{2m}^*J_{2m}^*=J_{2m}^*K_{2m}^*$ as required. If m is odd, we project instead to Spin$(4m)/\{1,-\hat{K}_{4m}\}$ and recall that this is isomorphic to Semispin$(4m)$. A further exercise in Clifford algebra shows that

$$(\hat{J}_{2m})^2=(-1)^m\hat{K}_{4m},$$

and so the appropriate projections are of order two. The effect on Spin$(2m)$**:**Spin$(2m)$ of conjugation by J_{2m}^* is to exchange the two factors. We conclude that the *centralizer* of K_{2j}^* in Semispin$(4m)$ is

$$\text{Spin}(2j)\mathbf{:}\text{Spin}(4m-2j)\quad\text{if}\quad j\neq m,$$

$$(\text{Spin}(2m)\mathbf{:}\text{Spin}(2m))\lhd Z_2\quad\text{if}\quad j=m.$$

Finally, let us consider the specific case of Semispin(32). Its ''SO(16)×SO(16)'' subgroup is actually (Spin(16)**:**$Spin(16)$)$\lhd Z_2$ where the full center of each Spin(16) is identified with that of the other, and where Z_2 exchanges the two factors. Compare this with the ''SO(16)×SO(16)'' subgroup of $(E_8\times E_8)\lhd Z_2$, which is (Semispin(16)×Semispin(16))$\lhd Z_2$. Both groups have the ''exchange'' Z_2, which is welcome from the point of view of T-duality. But Spin(16)**:**Spin(16) *is not isomorphic to* Semispin(16)×Semispin(16). Both are $Z_2\times Z_2$ quotients of Spin(16)×Spin(16), but $Z_2\times Z_2$ acts differently in each case. This implies that neither is a cover of the other, and so they each have representations which cannot be regarded as representations of the other. For example, by factoring out $\{\pm 1\}$ in Spin(16)**:**Spin(16), we obtain SO(16)·SO(16), where the dot means that the two factors have a nontrivial intersection, $\{\pm I_{16}\}$. The tensor product of the vector with itself, (**16**, **16**), is faithful for this group, and so it is a representation of Spin(16)**:**Spin(16). This representation contains faithful copies of SO(16), something which is impossible for any representation of Semispin(16)×Semispin(16). On the other hand, let $(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$ be the defining representation of Semispin(16)×Semispin(16); this representation distinguishes the centers of the two Semispin(16) factors, which cannot happen in any representation of Spin(16)**:**Spin(16). (If we take the quotient of Spin(16)**:**Spin(16) by $\{1,\hat{K}_{16}\}$, then we obtain Semispin(16)•Semispin(16), in which the two factors intersect in $\{\pm 1\}$, where we use -1 to denote the projection of -1 in Spin(16); but $(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$ does not descend to a representation of this group.) The two groups do have some representations in common, such as (**128**,**128**) and $(\mathbf{120},\mathbf{1})\oplus(\mathbf{1},\mathbf{120})$, the latter being the defining representation for PSO(16)×PSO(16), which is a $Z_2\times Z_2$ quotient of both Semispin(16)×Semispin(16) and Spin(16)**:**Spin(16). However, while $(\mathbf{120},\mathbf{1})\oplus(\mathbf{1},\mathbf{120})$ is important for duality, so also are $(\mathbf{16},\mathbf{16})$ and $(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$.

We see, then, that the appearance of Semispin groups in both heterotic theories was somewhat deceptive; for Semispin$(4m)$ is strangely unlike Spin$(4m)$ and SO$(4m)$. While these last contain subgroups of the same kind as themselves, Spin$(2j)\bullet$Spin$(4m-2j)$ and SO$(2j)\times$SO$(4m-2j)$ respectively, Semispin$(4m)$ *does not contain* Semispin$(2j)\bullet$Semispin$(4m-2j)$. Instead, it contains Spin$(2j)$**:**Spin$(4m-2j)$. Thus we arrive at the disconcerting fact that while $E_8\times E_8$ contains Semispin groups, Semispin(32) itself does not. The ''common SO(16)×SO(16) subgroup'' which appears in the duality literature not only fails to be isomorphic to SO(16)×SO(16); it simply *does not exist*.

One way to approach this problem is to find a group which covers both Semispin(16)×Semispin(16) and Spin(16)**:**Spin(16), since all of the representations of *both* groups will then be representations of that group. One obvious choice is Spin(16)×Spin(16), but there is a better alternative, constructed as follows. Write Spin(16)×Spin(16) as $\text{Spin}(16)^L \times \text{Spin}(16)^R$ and let $\{\pm 1^L, \pm \hat{K}_{16}^L\}$, $\{\pm 1^R, \pm \hat{K}_{16}^R\}$ be the respective centers. We define

$$\text{Spin}(16)*\text{Spin}(16)=(\text{Spin}(16)\times\text{Spin}(16))/\{(1^L,1^R),(\hat{K}_{16}^L,\hat{K}_{16}^R)\}.$$

That is, we identify $\hat{K}_{16}^R$ with $\hat{K}_{16}^L$. Further factoring by this element produces Semispin(16)×Semispin(16), while factoring by $(-1^L,-1^R)$ produces Spin(16)**:**Spin(16). That is, Spin(16)∗Spin(16) is a double cover of *both* Semispin(16)×Semispin(16) *and* Spin(16)**:**Spin(16). Hence $(\mathbf{16},\mathbf{16})$, $(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$, and $(\mathbf{120},\mathbf{1})\oplus(\mathbf{1},\mathbf{120})$ are all (unfaithful) representations of Spin(16)∗Spin(16), and $(\mathbf{16},\mathbf{16})\oplus(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$ is a *faithful* representation of Spin(16)∗Spin(16), though it is not a representation of Semispin(16)×Semispin(16) or Spin(16)**:**Spin(16), much less SO(16)×SO(16). (It is faithful because $\hat{K}_{16}$, the one nontrivial element of Spin(16)∗Spin(16) mapped to the identity by $(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$, acts as -1 in $(\mathbf{16},\mathbf{16})$.)

In fact, Spin(16)∗Spin(16) is the gauge group of the unique tachyon-free ten-dimensional nonsupersymmetric heterotic string theory,[18,19] which plays a central role in recent investigations of strong-coupling duality.[20] The massless spectrum of this theory consists of a gravity multiplet, space–time vectors assigned to $(\mathbf{120},\mathbf{1})\oplus(\mathbf{1},\mathbf{120})$, and space–time spinors assigned to the ''SO(16)×SO(16)'' representation $(\mathbf{16},\mathbf{16})\oplus(\mathbf{128},\mathbf{1})\oplus(\mathbf{1},\mathbf{128})$, which, as we have seen, is a faithful representation of Spin(16)∗Spin(16).

We claim, then, that the string theorist's ''SO(16)×SO(16)'' is actually Spin(16)∗Spin(16). The strange feature of this conclusion is that Spin(16)∗Spin(16) *is not a subgroup of either* $E_8 \times E_8$ or Semispin(32). (Nor can it be embedded in Spin(32), SO(32), or PSO(32).) Thus *it does not make sense* to speak of breaking $E_8\times E_8$ or Semispin(32) to Spin(16)∗Spin(16) by a Wilson loop or in any other way. We believe that the way to solve this problem is through a study of ''generalized Stiefel–Whitney classes.''[9,10] For example, to establish the duality of a certain Semispin(32) configuration with an $(E_8\times E_8)\lhd Z_2$ configuration, one breaks Semispin(32) to (Spin(16)**:**Spin(16))$\lhd Z_2$, lifts this to a (Spin(16)∗Spin(16))$\lhd Z_2$ structure (checking that the appropriate generalized Stiefel–Whitney class vanishes), projects this to a (Semispin(16)×Semispin(16))$\lhd Z_2$ structure, and then extends to $(E_8\times E_8)\lhd Z_2$ The details of this process will be described elsewhere.

Let us summarize as follows: SO$(4m)$, $m>2$, has important subgroups of the form SO(k) ×SO$(4m-k)$, though in fact this is just the identity component of $S(\text{O}(k)\times \text{O}(4m-k))$. The other three connected groups locally isomorphic to SO$(4m)$, namely, Spin$(4m)$, Semispin$(4m)$, and PSO$(4m)$, have analogous subgroups given by the following Theorem.

Theorem 2: The Lie algebra inclusion $\mathcal{SO}(k)\oplus\mathcal{SO}(4m-k)\rightarrow\mathcal{SO}(4m)$ has the following counterparts at the Lie group level:

$$S(\text{O}(k)\times\text{O}(4m-k))\rightarrow\text{SO}(4m),$$

$$\mathrm{Spin}(k)\bullet\mathrm{Spin}(4m-k)\rightarrow\mathrm{Spin}(4m),$$

$$\mathrm{PS}(\mathrm{O}(k)\times\mathrm{O}(4m-k))\rightarrow\mathrm{PSO}(4m),$$

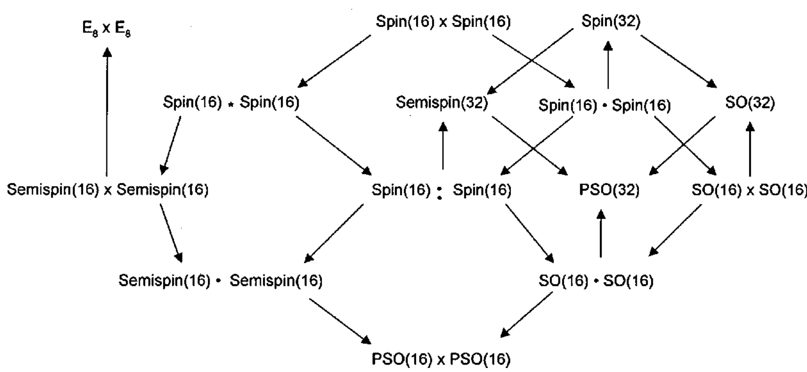
$$\mathrm{Spin}(k)\bullet\mathrm{Spin}(4m-k)\rightarrow\mathrm{Semispin}(4m)(k\ \ \text{odd}),$$

$$\mathrm{Spin}(2j)\mathbf{:}\mathrm{Spin}(4m-2j)\rightarrow\mathrm{Semispin}(4m)(k=2j,j\neq m),$$

$$(\mathrm{Spin}(2m)\mathbf{:}\mathrm{Spin}(2m))\lhd Z_2\rightarrow\mathrm{Semispin}(4m).$$

Here a single dot denotes a factoring by a diagonal Z_2, as also does the prefix P, while the double dot denotes a factoring by a diagonal Z_4 or by $Z_2\times Z_2$ as the case may be.

For the particularly important case of ''SO(16)×SO(16),'' we have the following diagram.



Here, an upward arrow indicates a subgroup, a downward arrow corresponds to a Z_2 factoring. The rows in the diagram therefore reflect the size of the fundamental group; the top row groups are simply connected, the next row has Z_2 as a fundamental group, and so down to PSO(16)×PSO(16), with fundamental group isomorphic to $Z_2\times Z_2\times Z_2\times Z_2$. From the diagram we see at once that Spin(16)**:**Spin(16) is a subgroup of Semispin(32), but there is no chain of arrows leading from Spin(16)**:**Spin(16) to $E_8\times E_8$. Finally, note that, with the sole exception of Semispin(32), every group G in the diagram has a natural extension of the form $G\lhd Z_2$.

IV. SUBGROUPS OF SEMISPIN $(4m)$ CORRESPONDING TO U$(2m)$

Another subgroup of SO$(4m)$ which plays an important role in the string literature (see, for example, Refs. 9, 20, 21) is the unitary group U$(2m)$. If $A+iB$ is any element of U$(2m)$, where A and B are real, then $\begin{pmatrix} A & -B \\ B & A \end{pmatrix}$ is an element of SO$(4m)$. The unitary subgroup can also be characterized as the centraliser of the matrix J_{2m} defined in the preceding section. (Notice that J_{2m} is SO$(4m)$-conjugate to diag $\left(\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\cdots\right)$, and the reader can take J_{2m} to be defined in this way if that is convenient.)

Now U$(2m)$ is *not* isomorphic to U(1)×SU$(2m)$, because U(1) and SU$(2m)$ intersect non-trivially. Let z be a primitive $(2m)$th root of unity, and let Z_{2m} act on U(1)×SU$(2m)$ by

$$(u,s)\rightarrow(uz^{-1},zs).$$

Then (U(1)×SU$(2m)$)/Z_{2m} is isomorphic to U$(2m)$. Elements of U$(2m)$ may therefore be represented as equivalence classes, $[u,s]_{2m}$.

Now we ask, what is the subgroup of Spin$(4m)$ which projects onto U$(2m)$? It is useful to notice that the answer cannot be isomorphic to U$(2m)$, for U$(2m)$ would be of maximal rank in Spin$(4m)$, and so the center of Spin$(4m)$ would be contained in the center of U$(2m)$; that is, we would have $Z_2\times Z_2$ contained in U(1), which is impossible. (This argument would not work for the $U(2m+1)$ subgroup of $SO(4m+2)$, and indeed the cover of $U(2m+1)$ in $Spin(4m+2)$ is again isomorphic to $U(2m+1)$.) In fact, it is not difficult to see that $Spin(4m)$ contains $(U(1)\times SU(2m))/Z_m$, which consists of pairs $[u,s]_m$. In this group, $[z^{-1},zI_{2m}]_m$ is not the identity, though $[z^{-1},zI_{2m}]_{2m}=1$; therefore $[z^{-1},zI_{2m}]_m$ corresponds to -1 in $Spin(4m)$. There is another important element of order two in this group, $[1,-I_{2m}]_m$, but of course there are others, such as $[z^{-1},-zI_{2m}]_m$. In order to determine the structure of the subgroup of $Semispin(4m)$ corresponding to $U(2m)$, we must determine which of these corresponds to $\hat{K}_{4m}$.

Theorem 3: Let $SemiU(2m)$ denote the projection of $(U(1)\times SU(2m))/Z_m$ to $Semispin(4m)$. Then the global structure of $SemiU(2m)$ is given as follows:

$$SemiU(2m)=[U(1)\times(SU(2m)/Z_2)]/Z_{m/2},\quad m \text{ even}$$
$$=[U(1)\times SU(2m)]/Z_m,\quad m \text{ odd}.$$

Proof: Under the embedding of $U(2m)$ in $SO(4m)$, the matrix J_{2m} arises from the $U(2m)$ matrix iI_{2m}, which is $[i,I_{2m}]_{2m}$. Thus we see that the $Spin(4m)$ element $\hat{J}_{2m}$ defined in the preceding section must be either $[i,I_{2m}]_m$ or $[iz^{-1},zI_{2m}]_m$. In either case we have $(\hat{J}_{2m})^2=[-1,I_{2m}]_m$. Now recall that $(\hat{J}_{2m})^2=(-1)^m\hat{K}_{4m}$ and that we have agreed to define $Semispin(4m)$ by $Spin(4m)/\{1,(-1)^m\hat{K}_{4m}\}$ for convenience, so that J^*_{2m} is always of order two. (See the remarks at the end of this section.) Thus when m is odd, we must factor by

$$-\hat{K}_{4m}=[-1,I_{2m}]_m\neq[1,-I_{2m}]_m.$$

Clearly, the factoring will affect U(1) but not $SU(2m)$. However, $U(1)/Z_2=U(1)$, since the map $u\rightarrow u^2$ is a group epimorphism for this infinite Abelian group. Thus we obtain $[U(1)\times SU(2m)]/Z_m$ when m is odd. When m is even, $\hat{K}_{4m}$ is $[-1,I_{2m}]_m$, which is equal to $[1,-I_{2m}]_m$. The factoring will affect both U(1) and $SU(2m)$ in this case, and, after it, the Z_2 in Z_m will act trivially; so we obtain $(U(1)/Z_2)\times(SU(2m)/Z_2)$, with an effective action by $Z_{m/2}$. Hence the group is $[(U(1)\times(SU(2m)/Z_2)]/Z_{m/2}$, and this completes the proof.

Notice that, according to this theorem,

$$SemiU(2)=[U(1)\times SU(2)]/Z_1=SO(2)\times SU(2),$$

which is indeed a subgroup of $Semispin(4)=SO(3)\times SU(2)$. Again,

$$SemiU(4)=[U(1)\times(SU(4)/Z_2)]/Z_1=SO(2)\times SO(6),$$

which is contained in $SO(8)=Semispin(8)$.

Clearly $SemiU(2m)$ is the identity component of the centralizer, in $Semispin(4m)$, of J^*_{2m}, the projection of $\hat{J}_{2m}$. Recall that, unlike J_{2m} in $SO(4m)$ and $\hat{J}_{2m}$ in $Spin(4m)$ (which are both of order 4), $\hat{J}^*_{2m}$ is of order 2; this is important for applications.[9,21] For example, consider a Semispin(32) heterotic theory compactified on a $K3$ surface which is a Kummer surface at an orbifold limit, with a pointlike instanton at the singular point.[21] Excising this point, we obtain a neighborhood which retracts to the projective sphere, S^3/Z_2. If J^*_{16} were of order four, then it could not be realized as a holonomy element over S^3/Z_2, and so the gauge group would not break. But J^*_{16} is of order two, and so it *can* be realized as a holonomy over S^3/Z_2. (In the literature it is always *assumed* that a finite group F can always be realised as a holonomy group over manifolds of the form M/F. This is true—with very mild conditions—but not at all obvious.[6]) Then (unless one arranges to avoid it[21]) Semispin(32) will break to the centralizer of J^*_{16} in Semispin(32). This includes SemiU(16), but it also includes K^*_{16}, as we saw in the preceding section. The matrix $K_{16}=\mathrm{diag}(-I_{16},I_{16})$ acts by complex conjugation on U(16), that is,

$$K_{16}\begin{pmatrix}A & -B\\ B & A\end{pmatrix}K_{16}^{-1}=\begin{pmatrix}A & B\\ -B & A\end{pmatrix}.$$

Similarly, conjugation by K_{16}^* maps elements of SemiU(16) to their complex conjugates. (A typical element of SemiU(16) $=[\mathrm{U}(1)\times(\mathrm{SU}(16)/Z_2)]/Z_4$ has the form $[u^2,[s]_2]_4$, with complex conjugate $[(\overline{u}^2,[\overline{s}]_2]_4$; bear in mind that Z_4 acts on $\mathrm{U}(1)\times(\mathrm{SU}(16)/Z_2)$ by $(u^2,[s]_2)\rightarrow(iu^2,[zs]_2)$, with $z^8=1$). As $(K_{16}^*)^2=1$, we see that J_{16}^* breaks Semispin(32) to SemiU(16)$\lhd Z_2$ and *not*[9,21] to U(16) or U(16)/Z_2, which are quite different to SemiU(16). Notice the differences with SO(32); J_{16} is of order four, and its centralizer in SO(32) is the connected group U(16), while J_{16}^* is of order two, with Semispin(32) centraliser isomorphic to the *disconnected* group SemiU(16)$\lhd Z_2$. On the other hand, J_{16} cannot break SO(32) over S^3/Z_2, but J_{16}^* can break Semispin(32). (Note also that there do exist bundles over S^3/Z_2 having the full disconnected group SemiU(16)$\lhd Z_2$ as holonomy group.[6])

In the same way, J_8^* is of order two, and it breaks Semispin(16) to SemiU(8)$\lhd Z_2$, with Z_2 generated by K_8^*, and with SemiU(8)$=[\mathrm{U}(1)\times(\mathrm{SU}(8)/Z_2)]/Z_2$. However, Semispin(16) is mainly of interest because it is a maximal subgroup of E_8. If J_8^* is embedded in E_8 through Semispin(16), then of course its centraliser must contain SemiU(8)$\lhd Z_2$; however, this cannot be the full centraliser, since the centralizer of any element of a simply connected compact Lie group (such as E_8, but not Semispin(16)) must be connected. Hence the centralizer of J_8^* must be a connected subgroup of E_8 containing SemiU(8)$\lhd Z_2$. Of course, Semispin(16) is such a subgroup, but there is another. The exceptional Lie group E_7 has a maximal rank subgroup[22] isomorphic to SU(8)/Z_2, and in fact one can prove that E_7 contains a disconnected subgroup with two connected components, one being SU(8)/Z_2. Combining this with a Pin(2) subgroup of SU(2), we obtain, after suitable identifications, SemiU(8)$\lhd Z_2$ as a subgroup of SU(2)$\bullet E_7$, which is a maximal subgroup of E_8. In fact, the centralizer of J_8^* in E_8 is SU(2)$\bullet E_7$, while that of $-J_8^*$ turns out to be just Semispin(16); this is important in applications.[9]

One of the most interesting and important applications where the distinction between SO($4m$) and Semispin($4m$) is crucial concerns $K3$ compactifications of the $(E_8\times E_8)\lhd Z_2$ heterotic theory. When the instanton numbers are assigned symmetrically to the two factors, one finds[9] that the corresponding (T-dual) ''SO(32)'' configuration corresponds to a Semispin(32) bundle which *does not* lift to a Spin(32) bundle. This is the Semispin analogue of the failure of the orthonormal frame bundles over certain Riemannian manifolds[14] to lift to spin bundles. If a Semispin(32) bundle does lift to a Spin(32) bundle, then it will automatically define (by projection) an SO(32) bundle; and so a Semispin(32) bundle which fails to lift to a Spin(32) bundle is said to lack a ''vector structure.''

Examples of such Semispin($4m$) bundles can be given by once again exploiting the fact that J_{2m}^* is of order two, whereas $\hat{J}_{2m}$, its counterpart in Spin($4m$), satisfies $(\hat{J}_{2m})^2=(-1)^m\hat{K}_{4m}$ and so is of order four (like J_{2m}). This makes it possible to construct a nontrivial U(1) bundle over a two-cycle in the base, such that connections on this bundle satisfy the usual (''Dirac'') integrality conditions, but their pullbacks to a covering bundle would not. When this U(1) bundle is extended to a Semispin(32) bundle, therefore, the latter cannot be lifted to a double cover. It is in precisely this way that the dual partner of the above[9] $(E_8\times E_8)\lhd Z_2$ compactification is constructed. One could not wish for a more striking confirmation of the importance of the distinction between SO($4m$) and Semispin($4m$).

In this spirit, we ask whether U(1) is indeed the precise global form of the gauge group in question. This U(1) may be identified as the explicit U(1) in $[\mathrm{U}(1)\times(\mathrm{SU}(16)/Z_2)]/Z_4$, but we know that this group is most naturally regarded as the identity component of SemiU(16)$\lhd Z_2$. Therefore one should really regard the canonical U(1) in Semispin(32) as the identity component of U(1)$\lhd Z_2$ or O(2) in the notation of Theorem 1. The corresponding subgroup of SO(32) consists of all 32×32 matrices of the form

$$\begin{pmatrix} I_{16}\cos\theta & -I_{16}\sin\theta \\ I_{16}\sin\theta & I_{16}\cos\theta \end{pmatrix},\quad \begin{pmatrix} -I_{16}\cos\theta & I_{16}\sin\theta \\ I_{16}\sin\theta & I_{16}\cos\theta \end{pmatrix}.$$

More generally, Semispin($4m$) has a canonical subgroup of the form

$$\mathrm{U}(1)\cup K^*_{2m}\bullet \mathrm{U}(1),$$

where U(1) corresponds to the Lie algebra element

$$\begin{pmatrix} 0 & -I_{2m} \\ I_{2m} & 0 \end{pmatrix},$$

or to its conjugate

$$\mathrm{diag}\left(\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},\ \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},\dots\right)$$

if one prefers. Recalling that $(K^*_{2m})^2=(-1)^m$, we see that the global structure is O(2) if m is even, but Pin(2) if m is odd (see Theorem 1). One can actually prove that Semispin$(4m)$ has no Pin(2) subgroup containing U(1) when m is even, and no O(2) subgroup containing U(1) when m is odd.

In constructing Semispin$(4m)$ bundles without ''vector structure,'' then, one should really begin with nontrivial O(2) or Pin(2) bundles. (Of course, if the base manifold is simply connected, such a bundle will always reduce to a U(1) bundle, but realistic string compactifications are not likely to be simply connected.) Now we know that a U(1) instanton breaks Semispin$(4m)$ to SemiU$(2m)$; what is the corresponding subgroup for O(2) or Pin(2)? Since K^*_{2m} acts by complex conjugation on all of SemiU$(2m)$, the answer is the real subgroup of SemiU$(2m)$. The real subgroup of SU$(2m)$ is SO$(2m)$, while that of SU$(2m)/Z_2$ is PSO$(2m)$, and U(1) contributes J^*_{2m}; finally, -1, the central element of Semispin$(4m)$, must of course also be included. Thus an O(2) or Pin(2) instanton will break Semispin$(4m)$ to

$$Z_2\times Z_2\times \mathrm{PSO}(2m),\quad m\ \text{even},$$

$$Z_2\times Z_2\times \mathrm{SO}(2m),\quad m\ \text{odd},$$

with one Z_2 generated by -1 and the other by J^*_{2m}. In particular, then, an O(2) instanton in a Semispin(32) theory will reveal itself by the presence of PSO(16), where SemiU(16) might be expected. (Note that this same PSO(16) arises in the Spin(16)**:**Spin(16) subgroup of Semispin(32), as the diagonal subgroup.)

Before concluding this section, we draw the reader's attention to the following point. While it is true that Spin$(4m)/\{1,-\hat{K}_{4m}\}$ is isomorphic to Spin$(4m)/\{1,\hat{K}_{4m}\}$, the isomorphism is through an outer automorphism of Spin$(4m)$ which can change the way in which a given subalgebra is embedded in the algebra of Spin$(4m)$, and this in turn can affect the global structure of the subgroup to which that subalgebra exponentiates. A simple example is provided by Spin(4)=SU(2)×SU(2). Obviously SU(2)×SO(3) is isomorphic to SO(3)×SU(2), but it is true that a given, fixed SU(2) algebra exponentiates either to SU(2) or to SO(3), depending on whether one factors by $\{1,\hat{K}_4\}$ or $\{1,-\hat{K}_4\}$. We have chosen to define Semispin$(4m)$ by factoring $\{1,-\hat{K}_{4m}\}$ when m is odd, but one could decide to factor by $\{1,\hat{K}_{4m}\}$, though in that case J^*_{2m} will not commute with K^*_{2m} and it will not be of order two. If one does this, then $[\mathrm{U}(1)\times \mathrm{SU}(2m)]/Z_m$ no longer projects to $[(\mathrm{U}(1)/Z_2)\times \mathrm{SU}(2m)]/Z_m$. Instead we have

$$\hat{K}_{4m}=-(\hat{J}_{2m})^2=[-z^{-1},zI_{2m}]_m,$$

where z is a primitive $(2m)$th root of unity. This gives us $\hat{K}_{4m}=[z^{m-1},zI_{2m}]_m=[1,z^mI_{2m}]_m$, because, since m is odd, $m-1$ is even. Thus in fact $\hat{K}_{4m}=[1,-I_{2m}]_m$, and so the quotient of $(\mathrm{U}(1)\times \mathrm{SU}(2m))/Z_m$ by $\{1,\hat{K}_{4m}\}$ is isomorphic to $[\mathrm{U}(1)\times(\mathrm{SU}(2m)/Z_2)]/Z_m$, which is not isomorphic to $[\mathrm{U}(1)/Z_2\times \mathrm{SU}(2m)]/Z_m$. Thus there is no unique subgroup of Semispin$(4m)$ corresponding to U$(2m)$ unless one specifies precisely which projection from Spin$(4m)$ to Semispin$(4m)$ one proposes to use.

Our point of view is that for physical applications it is important that J^*_{2m} should be of order two rather than, like J_{2m} and $\hat{J}_{2m}$, of order four. This is stressed repeatedly, for example, in Ref. 9. This fixes the projections; we must factor out $\{1,\hat{K}_{4m}\}$ when m is even, and $\{1,-\hat{K}_{4m}\}$ when m is odd.

V. SUBGROUPS OF SEMISPIN(4*m*) CORRESPONDING TO Sp(1)•Sp(*m*)

Another subgroup of $\mathrm{SO}(4m)$ which is important in various applications (see, for example, Ref. 21) is the symplectic group $\mathrm{Sp}(m)$, which embeds through $\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)$. The latter has the global structure $[\mathrm{Sp}(1)\times\mathrm{Sp}(m)]/Z_2$. The corresponding subgroup of $\mathrm{Semispin}(4m)$ is given as follows.

Theorem 4: The Lie algebra inclusion $\mathcal{S}p(1)\oplus\mathcal{S}p(m)\rightarrow\mathcal{SO}(4m)$ has the following counterparts at the Lie group level:

$$\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)\rightarrow\mathrm{SO}(4m),$$

$$\mathrm{Sp}(1)\times\mathrm{Sp}(m)\rightarrow\mathrm{Spin}(4m)\quad m\ \text{odd},$$

$$\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)\rightarrow\mathrm{Spin}(4m)\quad m\ \text{even},$$

$$\mathrm{SO}(3)\times\mathrm{PSp}(m)\rightarrow\mathrm{PSO}(4m),$$

$$\mathrm{SO}(3)\times\mathrm{Sp}(m)\rightarrow\mathrm{Semispin}(4m)\quad m\ \text{odd},$$

$$\mathrm{SO}(3)\times\mathrm{PSp}(m)\rightarrow\mathrm{Semispin}(4m)\quad m\ \text{even}.$$

Here a dot denotes a factoring by a diagonal Z_2, and $\mathrm{PSp}(m)=\mathrm{Sp}(m)/Z_2$.

Proof: Consider first the case of $\mathrm{Spin}(4m)$. We know that $\mathrm{Spin}(4m)$ contains a subgroup of the form $[\mathrm{U}(1)\times\mathrm{SU}(2m)]/Z_m$, consisting of pairs $[u,s]_m$. Evidently we have

$$[-1,I_{2m}]_m=[1,-I_{2m}]_m,$$

when m is even, but not when m is odd. That is, the Z_2 in U(1) is identified with the Z_2 in $\mathrm{SU}(2m)$ when m is even, but not when m is odd. However, this U(1) is contained in Sp(1), and $\mathrm{SU}(2m)$ contains $\mathrm{Sp}(m)$; furthermore the central Z_2 in Sp(1) is the Z_2 in U(1), and the central Z_2 in $\mathrm{Sp}(m)$ is identical to the Z_2 in $\mathrm{SU}(2m)$. Thus we see that the central Z_2 in Sp(1) is identified, in $\mathrm{Spin}(4m)$, with the central Z_2 in $\mathrm{Sp}(m)$, if and only if m is even. Hence the group is $\mathrm{Sp}(1)\times\mathrm{Sp}(m)$ if m is odd, but $\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)$ if m is even.

We saw, in the proof of Theorem 3, that $(-1)^m\hat{K}_{4m}=[-1,I_{2m}]_m$, the generator of the Z_2 in Sp(1). Hence $\mathrm{Sp}(1)\times\mathrm{Sp}(m)$ projects to $(\mathrm{Sp}(1)/Z_2)\times\mathrm{Sp}(m)$ when m is odd, while $\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)$ projects to $(\mathrm{Sp}(1)/Z_2)\times(\mathrm{Sp}(m)/Z_2)$ when m is even. Recalling that $\mathrm{Sp}(1)/Z_2=\mathrm{SO}(3)$ and $\mathrm{Sp}(m)/Z_2=\mathrm{PSp}(m)$, we have the stated results. Similarly, in $\mathrm{SO}(4m)$, the central Z_2 coincides with the Z_2 in Sp(1) and $\mathrm{Sp}(m)$, so taking the quotient throughout $\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)\rightarrow\mathrm{SO}(4m)$, we obtain $\mathrm{SO}(3)\times\mathrm{PSp}(m)\rightarrow\mathrm{PSO}(4m)$. This completes the proof.

Notice that the theorem asserts that SO(3)×Sp(1) is contained in Semispin(4), which is correct since the latter is SO(3)×SU(2) and SU(2)=Sp(1). It also asserts that Semispin(8)=SO(8) contains SO(3)×PSp(2), which is correct since Sp(2)=Spin(5) and so PSp(2)=SO(5). The theorem gives us SO(3)×PSp(8) as the subgroup of Semispin(32) corresponding to Sp(1)•Sp(8) in SO(32); this agrees with Ref. 21, where the importance of the SO(3) factor, appearing unexpectedly as a subgroup of Semispin(32), is explained. (Note that the full cover of $\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)$ in $\mathrm{Spin}(4m)$, m even, is actually $Z_2\times\mathrm{Sp}(1)\bullet\mathrm{Sp}(m)$, where $Z_2=\{\pm1\}$; this projects to $Z_2\times\mathrm{SO}(3)\times\mathrm{PSp}(m)$, so one might give this as the correct subgroup of $\mathrm{Semispin}(4m)$.)

VI. CONCLUSION

The Semispin groups are of fundamental importance in string theory. The gauge groups of Type I and one of the heterotic theories are both Semispin(32) precisely, while E_8 contains Semispin(16); the latter in turn contains (see Theorem 2) Spin(6)**:**Spin(10)$=[SU(4)\times$Spin(10)$]/Z_4$, and so it provides a possible route to Spin(10) grand unification.

These facts alone warrant a detailed study of the Semispin groups and their remarkable subgroups. Theorem 1 places Semispin($4m$) in the context of the entire family of nontrivial groups locally isomorphic to SO(n), while Theorems 2, 3, and 4 list the most important subgroups. We hope that these theorems will be a useful reference for string theorists.

The most surprising finding of this investigation is no doubt the fact that Semispin groups do not contain smaller Semispin groups. This implies that the ''common SO(16)$\times$SO(16) subgroup of $E_8\times E_8$ and Semispin(32)'' simply does not exist, which is obviously a problem for duality. This problem can be overcome by going to a common double cover, but only if certain topological obstructions vanish. In some circumstances, therefore, duality can be obstructed topologically. We shall study this phenomenon elsewhere.

Quantum superstring field theory in the $\mathcal{B}_0$-gauge and the physical scattering amplitudes

Seichi Naito[a)]
Department of Physics, Osaka City University, Sumiyoshiku, Osaka, Japan

(Received 21 September 1998; accepted for publication 22 February 1999)

We propose the (BRST-*invariant*) quantum open superstring field theory in the ''$\mathcal{B}_0$-gauge,'' based on Neveu–Schwarz (NS) strings in 1 picture and Ramond (R) strings in $\frac{1}{2}$ picture. We give the propagators of these open NS and R superstrings. In order to obtain the BRST-invariant interaction terms among these superstrings, we *modify* the interaction terms among *three* superstrings (i.e., among NS–NS–NS and R–R–NS) by subtracting the infinite number of counter terms, each of which involves interaction terms among ''*more than four* superstrings.'' The modified action can be obtained successively, so that resulting amplitudes in **g**-loops should become BRST invariant. Thus obtained amplitudes are referred to as the ''*amputated scatts*,'' with the help of which the *physical* scattering amplitudes can be expressed. These physical scattering amplitudes among N_B bosonic (N_F fermionic) particles are *calculated* by using the *analytic inlint gluing operator* (which has already been proposed and used in the quantum bosonic string field theory ''in the $\mathcal{B}_0=0$ gauge'').

I. INTRODUCTION AND PRELIMINARIES

There exist just five superstring theories:[1] type I and the two heterotic theories (all of which have $N=1$ supersymmetry in ten-dimensional space–time), type IIA (having two supercharges with the opposite chirality), and type IIB (having two supercharges with the same chirality). Type I theory is based on unoriented open and closed superstrings, while the other four theories are based on oriented closed superstrings. (These different superstring theories might be related with each other nonperturbatively.[2]) These superstring theories are very attractive ones, which are expected to unify interactions in nature, including the Yang–Mills theory as well as the gravitational theory. In order to make sure if these superstring theories are the realistic ones, we must clarify nonperturbative properties of these theories, which can be compared with experimental results. For this purpose, quantum superstring field theory (QSFT) might be expected to be helpful.

Since heterotic *super*string theories involve oriented *closed* bosonic string, Witten's quantum *open bosonic* string field theory[3] (open QBFT) in the ''$\mathcal{B}_0=0$ gauge'' (which does not include any *closed* string) is not realistic one, but it will be still useful. Unoriented open strings could be obtained by truncating the formulas in oriented open strings to those invariant under the ''twisting.'' Manifest factorization (in closed string channels) which is absent in Witten's open QBFT can be restored by including bosonic closed strings. In closed QBFT, there appear various complications, since we must include infinite numbers of the interaction terms among closed bosonic strings. These complications in *closed* QBFT have been analyzed[4] in detail. Based on these analyses, we think that various techniques[5] (which are useful in Witten's *open* QBFT) would be useful also in *closed* QBFT. In other words, Witten's open QBFT is useful as a mathematical model, in clarifying mathematical structures of physically realistic theories. On the other hand, all five superstring theories involve closed *super*strings, while type I *super*string theory involves the

[a)]Electronic mail: naito-@mx6.mesh.ne.jp

additional (unoriented) open *bosonic* string. Witten[6] has proposed the quantum (oriented) open superstring field theory (to be referred to as open QSFT) based on the Ramond[7]–Neveu–Schwarz[8] (RNS) superstrings, being suggested by Friedan–Martinec–Schenker's (FMS) work.[9] Compared with Witten's open QBFT, Witten's open QSFT involves many additional complications: We have fermionic particles as well as bosonic particles. Furthermore, there occur problems related with the (*so-called*) pictures. Unfortunately, Witten's open QSFT (based on open NS states in 0 picture and open R states in $\frac{1}{2}$ picture) is plagued with (Wendt's[10]) singularities, since *local* picture-changing operators can happen to collide with each other. Thus, Witten's open QSFT is not satisfactory, even at the perturbative level. In order to avoid this difficulty, another *open* QSFT (different from the Witten's one) has been proposed by Preitschopf–Thorn–Yost (PTY),[11] based on open NS superstring in 1 picture and open R superstring in $\frac{1}{2}$ picture. However, PTY have extensively considered open NS superstrings under the two special gauge-fixing conditions $\mathcal{B}_1+\mathcal{B}_{-1}=0$ or $\mathcal{B}_0-\frac{1}{2}\sqrt{-1}(\mathcal{B}_1-\mathcal{B}_{-1})=0$, where propagators in the open NS superstring involve respectively the factor $(L_1+L_{-1})^{-1}$ or $(L_0-\frac{1}{2}\sqrt{-1}(L_1-L_{-1}))^{-1}$, both of which are so much different from the ordinary $1/L_0$ (in QBFT[5]). We doubt if their formalism (with these propagators) would be useful in calculating physical scattering amplitudes.

In this paper, we exclusively analyze the (oriented) *open* QSFT in the ''$\mathcal{B}_0$-gauge,'' the possibility of which has only briefly been remarked on in Ref. 11. As preliminaries, we hereafter introduce ''fieldinos,'' etc. (which are to be used in QSFT). In defining them, we use various external operators which are given in appendices. In the case when the rth open superstring is in the $\pi(r)$ sector $[\pi(r)$ being either NS or R], we have in the open QSFT the following rth fieldino $|\Psi^{\pi(r)}\rangle_r$ in the $\pi(r)$ sector:

$$|\Psi^{\rm NS}\rangle_r \equiv P_r^{\rm NS}({\rm GSO})\left(\sum_B |B\rangle_r\cdot\phi_B\right)\quad \text{for}\ \ \pi(r)={\rm NS}, \tag{1.1}$$

and

$$|\Psi^{R}\rangle_r \equiv P_r^{R}({\rm GSO})\left(\sum_F |F\rangle_r\cdot\psi_F\right)\quad \text{for}\ \ \pi(r)={\rm R}. \tag{1.2}$$

Operators ϕ_B's (ψ_F's) in Eq. (1.1) [(1.2)] will be referred to as the *bose* fields [*fermi* fields] in the ten-dimensional space–time. The rth external GSO-projection operator $P_r^{\rm NS}$ (GSO) [P_r^R(GSO)] used in Eqs. (1.1) [(1.2)] will be defined soon by Eq. (1.11), and it GSO *projects out* NS states $|B\rangle_r$'s (R states $|F\rangle_r$'s), some of which might be *physical states* $|b\rangle_r$'s ($|f\rangle_r$'s). As we shall see later, all of these physical states $|b\rangle_r$'s ($|f\rangle_r$'s) can be *made* Grassman *odd* (*even*), by using *proper* cocycle factors. Operators ϕ_b's (ψ_f's) [which will be referred to as *physical* bose fields (fermi fields)] become subsequently Grassman *even* (*odd*). On the other hand, *unphysical* ϕ_B's (ψ_F's) might be Grassman *even* in some case and Grassman *odd* in another case. In this paper, $|\Psi^{\rm NS}\rangle_r$ in (1.1) and $|\Psi^{R}\rangle_r$ in (1.2) will be projected into the following fieldino in the ''$\mathcal{B}_0$-gauge,''[11] i.e., into the rth NS fieldino $|\Psi(1)\rangle_r$ ''in picture 1'' and R fieldino $|\Psi(\frac{1}{2})\rangle_r$ ''in picture $\frac{1}{2}$,'' respectively:

$$\begin{aligned}|\Psi(1)\rangle_r &\equiv \mathcal{P}_r^{\rm NS}|\Psi^{\rm NS}\rangle_r \quad \text{for}\ \ \pi(r)={\rm NS},\\ |\Psi(\tfrac{1}{2})\rangle_r &\equiv \mathcal{P}_r^{\rm R}|\Psi^{\rm R}\rangle_r \quad \text{for}\ \ \pi(r)={\rm R},\end{aligned} \tag{1.3}$$

where $\mathcal{P}_r^{\pi(r)}$ is the projection operator defined by

$$\begin{aligned}\mathcal{P}_r^{\rm NS} &\equiv P_r(1)\cdot P_r(\mathcal{B}_0)\cdot P_r(1) \quad \text{for}\ \ \pi(r)={\rm NS},\\ \mathcal{P}_r^{R} &\equiv P_r(\tfrac{1}{2})\cdot P_r(\mathcal{B}_0)\cdot P_r(\tfrac{1}{2}) \quad \text{for}\ \ \pi(r)={\rm R}.\end{aligned} \tag{1.4}$$

In Eq. (1.4), we have used $P_r(\mathcal{B}_0)$ defined by

$$P_r(\mathcal{B}_0) \equiv 1 - \mathcal{Q}_r^{\pi(r)} \cdot \frac{\mathcal{B}_{0,r}}{L_{0,r}} = \frac{\mathcal{B}_{0,r}}{L_{0,r}} \cdot \mathcal{Q}_r^{\pi(r)}, \tag{1.5}$$

which is the projection operator since it satisfies

$$(P_r(\mathcal{B}_0))^2 = P_r(\mathcal{B}_0). \tag{1.6}$$

[In Eq. (1.5), we have used operators $\mathcal{B}_{0,r}$ in (A25), $L_{0,r}$ in (B9b), and the BRST chargino $\mathcal{Q}_r^{\pi(r)}$ in (B27), together with the ''contacting formula'' (B38b)]. On the other hand, $P_r(1)$ and $P_r(\frac{1}{2})$ in Eq. (1.4) are respectively defined[11] by

$$P_r(1) \equiv \left(\sum_{\pm} \frac{1}{2} \cdot X_{\pm,r}^{1/2} \cdot X_{\mp,r}^{1/2} \right) Y[\overline{r}] \cdot Y[r] \cdot P_r^{\mathrm{NS}}(\mathrm{GSO}), \tag{1.7a}$$

and

$$P_r(\tfrac{1}{2}) \equiv X_r^0 \cdot Y[\overline{r}] \cdot P_r^{\mathrm{R}}(\mathrm{GSO}). \tag{1.7b}$$

In Eqs. (1.7a) and (1.7b), we have used the *nonlocal* picture-changing operators $X_{\pm,r}^{1/2}$ in (C25) (which has been introduced by Preitschopf–Thorn–Jost[11]), as well as X_r^0 in (C14).[12] On the other hand, the rth external operator $Y[\overline{r}]$ and $Y[r]$ are respectively the *lower* and *upper* inverse picture-changing operator defined [see $Y_r(w_r)$ in (C8)] by

$$Y[\overline{r}] \equiv Y_r(-\sqrt{-1}) \quad \text{and} \quad Y[r] \equiv Y_r(+\sqrt{-1}). \tag{1.8}$$

The rth external operator $P_r(1)$ in (1.7a) and $P_r(\frac{1}{2})$ in (1.7b) are respectively the projection operators (into 1 picture and $\frac{1}{2}$ picture), since we find

$$(P_r(p))^2 = P_r(p) \quad \text{for } p = 1 \quad \text{and } \tfrac{1}{2}, \tag{1.9}$$

by using Eqs. (C22)–(C24) and (C32)–(C36). With the help of the ''commutability'' (C38) and (C39), it can be proved[11] that

$$(\mathcal{P}_r^{\pi(r)})^2 = \mathcal{P}_r^{\pi(r)}. \tag{1.10}$$

Hereafter, $\mathcal{P}_r^{\pi(r)}$ will be referred to as the ''projection operator into the $\mathcal{B}_0$-gauge.'' We impose that both fieldino's $|\Psi^{\mathrm{NS}}\rangle_r$ in (1.1) and $|\Psi^{\mathrm{R}}\rangle_r$ in (1.2) are Grassman *odd*, and we should use in Eq. (1.1) [(1.2)] the following (rth external) GSO-projection operator[13] $P_r^{\pi(r)}$ (GSO) [for $\pi(r) = \mathrm{R}$, NS]:

$$P_r^{\pi(r)}(\mathrm{GSO}) \equiv \left(\frac{1}{2} + \frac{1}{2} \varepsilon^{\pi(r)} \cdot \exp\left(\sqrt{-1} \cdot \pi \left(p_r(\phi) + \sum_{j=0}^{4} p_r(\phi^j) \right) \right) \right)$$
$$\times \left(\prod_{\varphi = \varphi^j, \phi} \left(\frac{1}{2} + \frac{1}{2} \varepsilon^{\pi(r)} \cdot \exp(\sqrt{-1} \cdot 2\pi p_r(\varphi)) \right) \right), \tag{1.11}$$

where the constant $\varepsilon^{\pi(r)}$ is defined by

$$\varepsilon^{\pi(r)} \equiv \begin{cases} -1 & \text{for } \pi(r) = \mathrm{R}, \\ +1 & \text{for } \pi(r) = \mathrm{NS}. \end{cases} \tag{1.12}$$

In Eq. (1.11), $p_r(\phi)$ $[p_r(\phi^j)]$ is the zero-mode's operator in the fracting operator ϕ (the jth spining operator ϕ^j for $j=0-4$) defined by Eq. (A3). [In this paper, eigenvalues of $p_r(\phi)$ and $p_r(\phi^j)$ will be called respectively the fracting number and the jth spining number, and all of them should be integers (half-integers) in the NS (R) sector.] The last factor on the right-hand side of Eq. (1.11) shows that any eigenvalue $p_r(\varphi)$ (for $\varphi=\phi^j,\phi$) should be some (half-)integer in the NS (R) sector, while the first factor on the right-hand side of Eq. (1.11) shows that the eigenvalue of $p_r(\phi)+\Sigma_{j=0}^4 p_r(\phi^j)$ should be some even (odd) integer in the (rth external) GSO-allowed NS (R) sector.

At this stage, we summarize briefly our previously obtained[14] results on *physical* [rth external] NS (R) states, especially from the point of the projection operators $P_r(\mathcal{B}_0)$ in (1.5) and $P_r^{\rm NS}(1)$ in (1.7a)] ($P_r^R(1/2)$ in (1.7b)); (the rth external) Grassman *odd* physical NS states $|b(0)\rangle_r$ (in 0 picture) and $|b(1)\rangle_r$ (in 1 picture) have been constructed[14] respectively by Eqs. (D1) and (D5). In the on-shell limit (D4), these (rth external) *physical* NS states can be proved to have the following properties:

$$\mathcal{Q}_r^{\rm NS}|b(p)\rangle_r=\mathcal{B}_{0,r}|b(p)\rangle_r=L_{0,r}|b(p)\rangle_r=0 \quad (\text{for } \ p=0,1) \tag{1.13}$$

and

$$P_r^{\rm NS}(1)|b(1)\rangle_r=|b(1)\rangle_r. \tag{1.14}$$

Equations (1.13) and (1.14) show that physical states $|b(1)\rangle_r$ in (D5) are the *simultaneous* eigenstates of both $P_r(\mathcal{B}_0)$ and $P_r^{\rm NS}(1)$. As for the (rth external) Grassman *even* physical R states $|f(\pm\frac{1}{2})\rangle_r$ in $\pm\frac{1}{2}$ picture, they can be constructed[14] by Eqs. (D12) and (D13). [Incidentally, $\exp(\frac{1}{2}\cdot\phi^j)$ for $j=0-4$ will always be assumed to be Grassman even, by choosing proper cocycle factors.[15] In this paper, quantities named by ''-on'' (''-ino'') will be Grassman *even* (*odd*). Then, the last part on the right-hand side of the FMS spinor[9] in (A24) has been called the ''octon'' (''octino'')[14] in the case when $\Sigma_{j=1}^4\varepsilon_{h(r)}^j=$even (odd), while $\exp(\frac{1}{2}\cdot\phi^0)$ has been called the ''spinon.'' [14] On the other hand, we *can* consider *two* cases when the operator $\exp(-\frac{1}{2}\cdot\phi)$ is *either* Grassman even *or* odd, by choosing the different cocycle factors. In the *even* (*odd*) case, it will be referred to as the ''fracton'' (''fractino''). Therefore, the Grassman *even physical* state (D13) can be obtained in the ''fracton'' (''fractino'') case, by using the ''octon'' (''octino'') in Eq. (D13). This fact is important in constructing type IIA and type IIB closed superstring theories. Although we exclusively consider the ''fracton'' case in this paper, the ''fractino'' case can be similarly analyzed. Incidentally, GSO-projection operator (1.11) in the R sector is the one to be used in the ''fracton'' case. In the on-shell limit (D14), the [rth external] *physical* R states (D12) and (D13) are shown to have the following properties:

$$\mathcal{Q}_r^{\rm R}|f(\pm\tfrac{1}{2})\rangle_r=\mathcal{B}_{0,r}|f(\pm\tfrac{1}{2})\rangle_r=L_{0,r}|f(\pm\tfrac{1}{2})\rangle_r=0, \tag{1.15}$$

as well as

$$P_r^{\rm R}(\tfrac{1}{2})|f(+\tfrac{1}{2})\rangle_r=|f(+\tfrac{1}{2})\rangle_r. \tag{1.16}$$

The ''rth external BRST chargino in the π-representation'' is denoted by $\mathcal{Q}_r^\pi$ (for $\pi=$NS,R), which will be defined by Eq. (B27) and has been used in Eqs. (1.13) and (1.15). Incidentally, $\mathcal{Q}_r$ in (B28) will be referred to as the ''rth external BRST-chargino in the bo-(sonized) representation.'' These BRST charginos in *three* representations can be proved to be just equal to each other;

$$\mathcal{Q}_r^{\rm NS}=\mathcal{Q}_r^{\rm R}=\mathcal{Q}_r \quad [\text{see Eq. (B29)}]. \tag{1.17}$$

With the help of $|\Psi(1)\rangle_r$ in (1.3) and $|\Psi(\frac{1}{2})\rangle_r$ in (1.4), we investigate the open QSFT in the ''$\mathcal{B}_0$-gauge,'' which is described by the following gauge-fixed action $S_{\rm GF}(\Psi)$:

$$S_{\mathrm{GF}}(\Psi)=S_{\mathrm{KIN}}(\Psi)+S_{\mathrm{INT}}(\Psi), \tag{1.18}$$

where the kinetic term $S_{\mathrm{KIN}}(\Psi)$ is given by

$$S_{\mathrm{KIN}}(\Psi)\equiv\tfrac{1}{2}\cdot\langle\nu_{\mathcal{S}}(r,s)|Y[\overline{r}]\cdot Y[r]\cdot\mathcal{Q}_r^{\mathrm{NS}}(:|\Psi(1)\rangle_r\cdot|\Psi(1)\rangle_s:)$$
$$+\tfrac{1}{2}\cdot\langle\nu_{\mathcal{S}}(r,s)|Y[\overline{r}]\cdot\mathcal{Q}_r^{\mathrm{R}}(:|\Psi(\tfrac{1}{2})\rangle_r\cdot|\Psi(\tfrac{1}{2})\rangle_s:), \tag{1.19}$$

while the interaction term $S_{\mathrm{INT}}(\Psi)$ is given by

$$S_{\mathrm{INT}}(\Psi)\equiv\tfrac{1}{3}G\cdot\langle\nu_{\mathcal{S}}(r,s,t)|Y[\overline{r}]\cdot Y[r](:|\Psi(1)\rangle_r|\Psi(1)\rangle_s|\Psi(1)\rangle_t:)$$
$$+G\cdot\langle\nu_{\mathcal{S}}(r,s,t)|Y[\overline{r}](:|\Psi(1)\rangle_r|\Psi(\tfrac{1}{2})\rangle_s|\Psi(\tfrac{1}{2})\rangle_t:), \tag{1.20}$$

G being some (dimensionless) coupling constant. The (*cycle-symmetric*) *elementary* N-vertex functino $\langle\nu_{\mathcal{S}}(1,2,...,N)|$ used in Eq. (1.19) [(1.20)] is defined later by Eq. (2.14) as the function of the rth external operators φ_r's (for $r=1-N$) (where φ_r's represent $X^{\pm j}$, ϕ^j, σ, ϕ, χ for $j=0-4$). The expectation value over *all* external operators is taken in Eqs. (1.19) and (1.20), so that the gauge-fixed action $S_{\mathrm{GF}}(\Psi)$ in (1.18) is the function of the *quantized* bose fields ϕ_B's and the *quantized* fermi fields ψ_F's. We notice that the kinetic term $S_{\mathrm{KIN}}(\Psi)$ in (1.19) is the linear sum over *all* normal-ordered products: $\phi_B\phi_{B'}$:'s and $:\psi_F\psi_{F'}:$'s, while the interaction term $S_{\mathrm{INT}}(\Psi)$ in (1.20) is the linear sum over *all* normal-ordered products $:\phi_B\phi_{B'}\phi_{B''}:$'s and $:\phi_B\psi_F\psi_{F'}:$'s, coefficients of these products being just c numbers. [Normal ordering : : will be defined later by the operator product expansions (1.25)–(1.27) among fieldinos.]

We consider the scattering amplitude among N_B *physical* bosonic particles and N_F *physical* fermionic particles, each of which are excited modes of open NS (R) superstring. Each of these *physical* bosonic [fermionic] particles are specified by the quantum number b_r for $r=1-N_B$ [f_r for $r=(N_B+1)-(N_B+N_F)$]. Then we construct (for $r=1$–N) the operators $B_{b_r}\{\phi\}$ and $F_{f_r}\{\psi\}$ by the following formulas:

$$B_{b_r}\{\phi\}=\langle\nu_{\mathcal{S}}(r',r)|\mathcal{Q}_{r'}^{\mathrm{NS}}\cdot Y[\overline{r'}]\cdot Y[r']|\Psi(1)\rangle_{r'}\cdot|b_r(1)\rangle_r\quad\text{for } r=1-N_B \tag{1.21a}$$

and

$$F_{f_r}\{\psi\}=\langle\nu_{\mathcal{S}}(r',r)|\mathcal{Q}_{r'}^{\mathrm{R}}\cdot Y[\overline{r'}]|\Psi(1/2)\rangle_{r'}\cdot|f_r(1/2)\rangle_r\quad\text{for } r=(N_B+1)-(N_B+N_F). \tag{1.21b}$$

Expectation values over external operators are taken in Eq. (1.21a) [(1.21b)], so that $B_b\{\phi\}$ ($F_f\{\psi\}$) is the *linear* sum of *quantized* bose fields ϕ_B's (fermi fields ψ_F's), and it will be called the *physical* operator of the b (f) particle. [Quantization of ϕ_B's and ψ_F's will be imposed later by the ''operator product expansion among fieldinos,'' contractions among NS and R fieldinos being given by the formulas (1.26) and (1.27), respectively. Furthermore, we shall modify $S_{\mathrm{INT}}(\Psi)$ in (1.20) into $S_{\mathrm{INT}}^{\mathcal{M}}(\Psi)$ in (3.55).] We propose that the scattering amplitude among these *physical* NS and R particles (the number of which being respectively equal to N_B and N_F) is given by the following formula:

$$(N_B,N_F)\equiv\langle\phi=\psi=0|(\vec{T}_{X^0}\cdot\exp(S_{\mathrm{INT}}^{\mathcal{M}}(\Psi)))_{\text{connected}}$$
$$\times\left(\prod_{r=1}^{N_B}B_{b_r}\{\phi\}\right)\cdot\left(\prod_{r=N_B+1}^{N_B+N_F}F_{f_r}\{\Psi\}\right)|\phi=\psi=0\rangle, \tag{1.22}$$

where the expectation value over *all quantized* bose fields ϕ_B's and fermi fields ψ_F's should be taken. [The suffix ''*connected*'' in Eq. (1.22) shows the *connected* part of $\vec{T}_{X^0}\cdot\exp(S_{\mathrm{INT}}^{\mathcal{M}}(\Psi))$. See

Eq. (3.56). We remark that the formula (1.22) in the open QSFT corresponds to the LSZ reduction formula in the quantum field theory (QFT).[16]] In Eq. (1.22), the bra state $\langle \phi = \psi = 0|$ and the ket state $|\phi = \psi = 0\rangle$ satisfy respectively that

$$\langle \phi = \psi = 0|\phi_B(-) = 0 = \langle \phi = \psi = 0|\phi_F(-) \quad \text{for any negative frequency parts} \quad \phi_B(-) \quad \text{and} \quad \psi_F(-) \tag{1.23a}$$

and

$$\phi_B(+)|\phi = \psi = 0\rangle = 0 = \phi_F(+)|\phi = \psi = 0\rangle \quad \text{for any positive frequency parts} \quad \phi_B(+) \quad \text{and} \quad \psi_F(+), \tag{1.23b}$$

together with the following normalization condition:

$$\langle \phi = \psi = 0|\phi = \psi = 0\rangle = 1. \tag{1.24}$$

Furthermore, the time-ordered products among *quantized* bose fields ϕ_B's (*quantized* fermi fields ψ_F's) in Eq. (1.22) are given in terms of the ''time-ordered product among fieldinos'' as follows;

$$T_{X^0}(|\Psi(p(\gamma))\rangle_\gamma \cdot |\Psi(p(\delta))\rangle_\delta) \equiv :|\Psi(p(\gamma))\rangle_\gamma \cdot |\Psi(p(\delta))\rangle_\delta: + \overbrace{|\Psi(p(\gamma))\rangle_\gamma \cdot |\Psi(p(\delta))\rangle_\delta}, \tag{1.25a}$$

to be referred to as the ''operator product expansion'' (OPE) among fieldinos. In OPE (1.25a), we have used the picture number $p(r)$ [for $r = \gamma,\ \delta$] defined by

$$p(r) = \begin{cases} 1 & \text{for } \pi(r) = \text{NS}, \\ \frac{1}{2} & \text{for } \pi(r) = \text{R}. \end{cases} \tag{1.25b}$$

The first term on the right-hand side of the OPE (1.25) represents the normal-ordered product among fieldinos, which is to be obtained by moving any negative frequency parts $\phi_B(-)$ and $\psi_F(-)$ to the left of any positive frequency part $\phi_B(+)$ and $\psi_F(+)$. On the other hand, by taking account of Eq. (3.35) in Ref. 11, the *contraction* among the open NS fieldinos is given by

$$\overbrace{|\Psi(1)\rangle_\gamma \cdot |\Psi(1)\rangle_\delta} = \mathcal{P}_\gamma^{\text{NS}} \cdot \mathcal{P}_\delta^{\text{NS}} \cdot \left(\sum_{\pm} \frac{1}{2} \cdot X_{\pm,\gamma}^{1/2} \cdot X_{\mp,\gamma}^{1/2} \right) \frac{\mathcal{B}_{0,\gamma}}{L_{0,\gamma}} |\nu_{\mathcal{S}}(\gamma,\delta)\rangle, \qquad \text{for } \pi(\gamma) = \pi(\delta) = \text{NS}, \tag{1.26}$$

while the contraction among the open R fieldinos is given by

$$\overbrace{|\Psi(1/2)\rangle_\gamma \cdot |\Psi(1/2)\rangle_\delta} = \mathcal{P}_\gamma^{\text{R}} \cdot \mathcal{P}_\delta^{\text{R}} \cdot \left(\frac{X_\gamma^0 \cdot \mathcal{B}_{0,\gamma}}{L_{0,\gamma}} \right) |\nu_{\mathcal{S}}(\gamma,\delta)\rangle, \quad \text{for } \pi(\gamma) = \pi(\delta) = \text{R}, \tag{1.27}$$

which just corresponds to Eq. (3.17) in Ref. 11. In Eqs. (1.26) and (1.27) we have used $\mathcal{P}_r^{\pi(r)}$ in (1.4).

Comment: Our propagator (1.26) of the open NS superstring involves the symmetrization among $X_{+,\gamma}^{1/2} \cdot X_{-,\gamma}^{1/2}$ and $X_{-,\gamma}^{1/2} \cdot X_{+,\gamma}^{1/2}$, so that it can be *rewritten* [with the help of the ''commutability'' (C39)] into the expression (3.1). The explicit formula of the *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ [which is antisymmetric under $\gamma \leftrightarrow \delta$ and to be used in the contractions (1.26) and

(1.27)] will be given later by the formulas (2.16)–(2.19). It is to be noticed that the contraction among fieldinos (1.26) [(1.27)] represents the contraction among *quantized* bose (fermi) fields, i.e., $\phi_B\cdot\phi_{B'}$ $[\psi_F\cdot\psi_{F'}]$.

In this paper, we will show in detail how we can calculate the physical scattering amplitude (1.22), which will be found to satisfy the definite conservation laws of the following quantum numbers G, F, and H (in each **g**-loop). The operator $\mathcal{G}_r$ given by

$$\mathcal{G}_r\equiv:\exp(g_{\mathcal{G}}\cdot\sigma_r(y_r))\cdot\exp(f_{\mathcal{G}}\cdot\phi_r(y_r))\cdot\exp(h_{\mathcal{G}}\cdot\chi_r(y_r)) \tag{1.28}$$

is assigned with the ghosting number G, the fracting number F, and the hilberting number H, which are defined respectively by

$$(G,F,H)\equiv(g_{\mathcal{G}},f_{\mathcal{G}},h_{\mathcal{G}}). \tag{1.29}$$

These quantum numbers $K(\mathcal{G}_r)$ $[K(\mathcal{G}_r')]$ for $\mathcal{G}_r$ $[\mathcal{G}_r']$ are assumed to be additive, so that we have for $K=G,F,H$ that

$$K(\mathcal{G}_r\cdot\mathcal{G}_r')\equiv K(\mathcal{G}_r)+K(\mathcal{G}_r'). \tag{1.30}$$

Later in this paper, we shall find it convenient to define the picturing number P by

$$P\equiv G+F, \tag{1.31}$$

since any component $\mathcal{Q}_r^{(g)}$ [see Eq. (C2)] of the BRST chargino has the equal picturing number $P=1$. Incidentally, we will find later [in Eq. (2.12)] that $\mathcal{G}_r$ in (1.28) is the primary operator of the conformal weight given by

$$\tfrac{1}{2}\cdot g_{\mathcal{G}}(g_{\mathcal{G}}-3)-\tfrac{1}{2}\cdot f_{\mathcal{G}}(f_{\mathcal{G}}+2)+\tfrac{1}{2}\cdot h_{\mathcal{G}}(h_{\mathcal{G}}-1). \tag{1.32}$$

In Sec. II, we define the ''inlayed coordinate system s(*phere*)'' (ICS s) by using Gidding–Martinec's fundamental equation (GM-$\mathcal{FE}$). We introduce inlaying operators $W^{\varphi}[\cdots]$'s (for $\varphi=\vec{X},\ \phi^j,\ \sigma,\ \phi,\ \chi$). For each φ-mode, we construct the inlaying vertex function ${}_s\langle IV^{\varphi}(1,...,N)|$ in the ''ICS s,'' which inlay the rth *external* primary operators (at the rth disk coordinate w_r) into the *inlint* operators [at the rth inlayed coordinate $z_{rs}(w_r)$]. Then we propose formulas, which give the *small* gluing functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ [*large* gluing function $|V_L(\gamma,\delta)\rangle$]. Then we can prove the ''gluing theorem,'' which exhibits the $\gamma\delta$-gluing effect caused by the *small* vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$. In Sec. III, we first point out that our original $S_{\mathrm{INT}}(\Psi)$ in (1.20) does *not* lead to the BRST-invariant theory. Therefore, we are forced to introduce the counter term $\Delta S_{\mathrm{INT}}(\Psi)$, in such way that our *modified* action $S_{\mathrm{INT}}^{\mathcal{M}}(\Psi)$ given by

$$S_{\mathrm{INT}}(\Psi)\rightarrow S_{\mathrm{INT}}^{\mathcal{M}}(\Psi)\equiv S_{\mathrm{INT}}(\Psi)-\Delta S_{\mathrm{INT}}(\Psi) \tag{1.33}$$

leads to the (BRST-*invariant*) ''*amputated N-scatts*'' [denoted by ${}^{\mathcal{M}}\langle S^{\mathcal{C}}[\dots]|$], which satisfy the ''general conservation of the *total* BRST chargino'' (GCTC). The ''amputated N-scatts'' as well as $\Delta S_{\mathrm{INT}}(\Psi)$ can be calculated successively. (It should be noticed that there does not exist any colliding Wendt's singularity in our amplitudes, since they involve only *nonlocal* picture-changing operators.) In Sec. IV, we calculate the physical scattering amplitudes in **g**-loops, applying the method developed in our previous paper. With the help of Samuel's fundamental equation (S-$\mathcal{FE}$), we introduce the ''inlayed coordinate system (*genus*) **g**'' (ICS **g**). Then we propose the explicit formula for the *analytic inlint gluing operator* $\langle\Omega_{\mathbf{g}}(g_B,g_F)\rangle$ (in QSFT), with the help of which we can derive various trace-formulas in **g**-loops. In Sec. V, we summarize and conclude our results. In Appendix A, we define various (external and inlint) operators φ's (i.e., $\varphi=X^{\pm j},\ \phi^j,\ \sigma,\ \phi,\ \chi$) used in this paper. We also define the normal orderings and contractions in the NS-, R-, Σ-, and bo-representations. In Appendix B, we define the stress operators (T's) (BRST charginos $\mathcal{Q}$'s) in the NS-, R-, and bo-representations. These operators in *three* representations are shown to be just equal to each other in the case when $D=10$, where D is the space–time dimension. [See Eq. (1.17) for $\mathcal{Q}$'s.] We also derive inlaying identities for these operators T's ($\mathcal{Q}$'s). Then, we prove that any inlaying N-vertex function in the ''ICS s'' (denoted by $_s\langle IV(1,...,N)|$) conserves the total BRST chargino, and this result will be referred to as the ''special conservation of the total chargino'' (SCTC). In Appendix C, we give various operators of *local* (inverse) picture-changing operators X's (Y's). We also derive *nonlocal* picture-changing operators [which are to be used in Eqs. (1.7a) and (1.7b)]. In Appendix D, we summarize various results of *physical vertex operators* in the NS and R sectors, which are used in describing external physical NS and R particles, respectively. In Appendix E, we construct the *small* gluing vertex functino (*large* gluing vertex function) and we derive gluing identities and gluing relations satisfied by this gluing vertex functino (function). It is to be noticed that the gluing theorem can be obtained by using the *small* gluing vertex functino. Finally we remark how *elementary* N-vertex functinos $\langle \nu_{\mathcal{S}}(1,...,N)|$ [to be used in $S_{\mathrm{KIN}}(\Psi)$ in (1.19), $S_{\mathrm{INT}}(\Psi)$ in (1.20), etc.] can be constructed by using the ''inlayed coordinate system m(*idpoint*)'' (ICS m), which is defined by using the Gross–Jevicki's fundamental equation (GJ-$\mathcal{FE}$). Then, applying the gluing theorem to these elementary vertex functinos, we derive various useful formulas among them.

II. INLAYING VERTEX FUNCTIONS, INLAYING IDENTITIES, AND GLUING THEOREM

In our previous paper[5] on quantum open bosonic string field theory (open QBFT) in the ''$\mathcal{B}_0=0$ gauge,'' we have introduced various techniques which can be generalized into those which make us possible to calculate the physical scattering amplitudes (1.22) in open QSFT. In this section, we shall briefly explain how *elementary* N-vertex functino $\langle \nu_{\mathcal{S}}(1,2,...,N)|$ [which is *cycle-symmetric* under $1\rightarrow 2\rightarrow\cdots\rightarrow N\rightarrow 1$ and to be used in defining $S_{\mathrm{KIN}}(\Psi)$ in (1.19), $S_{\mathrm{INT}}(\Psi)$ in (1.20), $B_b\{\phi\}$ in (1.21a), and $F_f\{\psi\}$ in (1.21b)] can be explicitly given in terms of the rth external operators φ's (for $r=1-N$).

In open QSFT, the *tree* physical scattering amplitudes can be calculated by using the Riemann *surface* $\mathcal{R}$ with *one* boundary (which is located on the real axis in the complex z plane). All punctures Z_{rs}'s (for $r=1-N$) are located on the real axis, and all interaction points $\mathcal{Y}^s_{+\iota}$'s [for $\iota=1-(N-2)$] among open strings exist in the upper-half complex z plane [to be denoted by $\mathbb{H}^+$]. Relabeling N punctures (except for the relabeling which is reduced to some cyclic-permutation) produces various different amplitudes. We construct the Schottky double $\mathcal{D}$ of $\mathcal{R}$, by taking *two copies of* $\mathcal{R}$ and gluing together identical parts of the boundary. Thus we can enlarge the Riemann surface $\mathcal{R}$ even into the lower-half complex z plane (to be denoted by $\mathbb{H}^-$).

In the following, we briefly explain how the Schottky double $\mathcal{D}$ can be described by using the following ''Gidding–Martinec's fundamental equation'' (GM-$\mathcal{FE}$), which holds within the *whole* complex z plane $\mathbb{C}(=\mathbb{H}^+ + \mathbb{H}^-)$:

$$\frac{dz_s}{d\rho_s}=\nu_s(z_s)=R_s\cdot\frac{\Pi_{r=1}^{N}(z_s-Z_{rs})}{(\Pi_{\iota=1}^{N-2}(z_s-\mathcal{Y}^s_{+\iota})\cdot(z_s-\mathcal{Y}^s_{-\iota}))^{1/2}}. \tag{2.1}$$

We notice that GM-$\mathcal{FE}$ (2.1) gives the strip coordinate $\rho_s=\tau+\sqrt{-1}\sigma$ in terms of the inlayed coordinate z_s [say, by $\rho_s=\rho_s(z_s)$]. With the help of $\rho_s(z_s)$ (for any $z_s\in\mathbb{C}$), the Schottky double $\mathcal{D}$ can be drawn with the strip coordinate ρ_s. Inversely solving $\rho_s=\rho_s(z_s)$, we find $z_s=z_s(\rho_s)$ which means the strip coordinate ρ_s is inlayed into the inlayed coordinate $z_s(\in\mathbb{C})$. In order for GM-$\mathcal{FE}$ (2.1) to be able to describe the Schottky double $\mathcal{D}$, the parameters in GM-$\mathcal{FE}$ (2.1) should be chosen so as to satisfy following conditions (1) and (2): (1) The change of the variable σ should be $\pm 2\pi$ when z goes along *any* small circle around the rth puncture Z_{rs} (for $r=1-N$). (2) The imaginary part of $\rho_s(\mathcal{Y}^s_{\pm\iota})$ at *any* interacting point $\mathcal{Y}^s_{\pm\iota}$ should be equal to $\pm\pi/2$ for any $\iota=1-(N-2)$. With the help of ''equal-τ curves'' passing through any interacting point $\mathcal{Y}^s_{\pm\iota}$, we can divide $\mathbb{C}$ into N punctured ring domains *plus* $(N-3)$ unpunctured ring domains (which do not include any Z_{rs}). When condition (1) is satisfied, the rth punctured ring domain (which includes the rth puncture Z_{rs}) is located within the unit disk $|w_r|<1$, where the rth disk coordinate[5] w_r is defined by the following Eq. (2.2):

$$w_r \equiv \sqrt{-1}\cdot \exp(\mp(\rho_s(z_s)-\rho_s(\mathcal{Y}^s_{+\iota}))) \quad \text{for } \operatorname{Re}\rho_s(Z_{rs})=\pm\infty. \tag{2.2}$$

On the boundary $|w_r|=1$ of the rth punctured ring domain, two interacting points (say, $\mathcal{Y}^s_{\pm\iota}$) are located at the rth disk coordinate $w_r=\pm\sqrt{-1}$. On the other hand, the Ith *un*punctured ring domain [for $I=1-(N-3)$] describes the open string, which is freely propagating between two upper interacting points (say, from $\mathcal{Y}^s_{+\iota}$ and to $\mathcal{Y}^s_{+\kappa}$). Then, $T_I[\equiv|\rho_s(\mathcal{Y}^s_{+\iota})-\rho_s(\mathcal{Y}^s_{+\kappa})|]$ will be referred to as the the Ith propagating strip-time (of the Ith unpunctured ring domain). We have seen[5] that T_I's [for $I=1-(N-3)$] can be used as the modular parameters, which specify the Riemann surface $\mathcal{R}$ (having one boundary) with N punctures. The inlayed coordinate system s(*phere*) [''ICS s''] is defined to be the system with the inlayed coordinate $z_s(\rho_s)$, which is obtained by using GM-$\mathcal{FE}$ (2.1). In particular, the ''ICS m(*idpoint*)'' [5] is the special case of the ''ICS s(*phere*)'' where there does *not* exist any *un*punctured ring domain.

Comment: Gross–Jevicki[17] have investigated the ''inlayed coordinate system m(*idpoint*)'' (ICS m) which is defined by Eq. (E36). On the other hand, Gidding–Martinec and Samuel–Bluhm have used[18] Eq. (2.1) in calculating the tree amplitudes. Therefore, Eq. (2.1) [(E36)] will be referred to as ''Gidding–Martinec's fundamental equation'' (GM-$\mathcal{FE}$) [''Gross-Jevicki's fundamental equation'' (GJ-$\mathcal{FE}$)].

In open QSFT, we use various modes' operators $X^{\pm j}$, ϕ^j, σ, ϕ, and χ, (introduced by Friedan–Martinec–Schenker[9]), i.e., the string coordinate $X^{\pm j}$, the jth spinning operator ϕ^j (for $j=0-4$), the ghosting operator σ, the fracting operator ϕ, and the hilberting operator χ, all of which are defined by Eqs. (A3)–(A5b). The argument of the rth *external* string's operators is taken to be the rth disk coordinate w_r, so that the rth *external* operators live only within the *unit* disk $|w_r|<1$. On the other hand, the argument of the *inlint* string's operators within the rth punctured ring domain is the rth inlayed coordinate $z_{rs}(w_r)$, which is determined as the function of w_r by solving $w_r\to\rho_s\to z_s$. [See Eq. (1.10) in Ref. 5.] For each rth punctured ring domain, we introduce the *following* rth inlaying operator $W^{\varphi}_r[z_{rs}(w_r)]$ (for each φ-mode), which is defined by the following formula as the functional of the inlint operator $\varphi(z_{rs}(w_r))$ as well as $\varphi_r(w_r;+)$ [which is the positive-frequency part of the rth external operator $\varphi_r(w_r)$], w_r being integrated along a *small* closed path enclosing 0 in the anti-clockwise direction]: As for $\vec{X}$-modes, we have[5]

$$\begin{aligned} W^{\vec{X}}_r[z_{rs}(w_r)] \equiv \exp\Bigg(& \sum_{j=0}^{4} \oint_0 \frac{dw_r}{2\pi\sqrt{-1}} \oint_0 \frac{dw'_r}{2\pi\sqrt{-1}} \partial_{w_r} X^{+j}_r(w_r;+)\partial_{w'_r} X^{-j}_r(w'_r;+) \\ & \cdot \log\frac{z_{rs}(w_r)-z_{rs}(w'_r)}{w_r-w'_r}\Bigg) \\ & \times :\exp\Bigg(\sum_{\pm}\sum_{j=0}^{4} \oint_0 \frac{dw_r}{2\pi\sqrt{-1}} X^{\pm j}(z_{rs}(w_r))\cdot \partial_{w_r} X^{\mp j}_r(w_r;+)\Bigg):, \end{aligned} \tag{2.3}$$

while we have for $\varphi(=\phi^j,\sigma,\phi,\chi)$-mode that

$$\begin{aligned} & W^{\varphi}_r[z_{rs}(w_r)] \\ & \equiv \exp\left(\frac{\varepsilon^{\phi}_{\varphi}}{2}\oint_0 \frac{dw_r}{2\pi\sqrt{-1}}\oint_0 \frac{dw'_r}{2\pi\sqrt{-1}}\partial_{w_r}\varphi_r(w_r;+)\partial_{w'_r}\varphi_r(w'_r;+)\log\frac{z_{rs}(w_r)-z_{rs}(w'_r)}{w_r-w'_r}\right) \\ & \times :\exp\left(\varepsilon^{\phi}_{\varphi}\cdot \oint_0 \frac{dw_r}{2\pi\sqrt{-1}}\left(\varphi(z_{rs}(w_r))+\varepsilon^{\phi}_{\varphi}\cdot\frac{Q(\varphi)}{2}\log(z^{(1)}_{rs}(w_r))\right)\cdot\partial_{w_r}\varphi_r(w_r;+)\right):. \end{aligned} \tag{2.4}$$

{The inlaying operator $W^{\sigma}[\cdots]$ given by Eq. (2.4) has been denoted by $W^{\varphi}[\cdots]$ in Ref. 5.} In the formulas (2.3) and (2.4), we have used $\varepsilon_{\varphi}^{\phi}$ in (A5b) and the following background charges $Q(\varphi)$'s:

$$Q(X^{\pm j})=Q(\phi^j)=0,\quad Q(\sigma)=-3,\quad Q(\phi)=+2,\quad Q(\chi)=-1. \tag{2.5}$$

With the help of the formulas (2.3)–(2.5), we define that

$$W_r[z_{rs}(w_r)]\equiv\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi,\chi}W_r^{\varphi}[z_{rs}(w_r)]\quad\text{for } r=1-N. \tag{2.6}$$

For each $\varphi(=\vec{X},\phi^j,\sigma,\phi,\chi)$-mode, the ''standard ket state'' $|p_r(\varphi)=0\rangle_r$ and the ''standard bra state'' ${}_r\langle q_r(\varphi)=0|$ are defined respectively as states satisfying conditions (A6) and (A7). On the other hand, the ''*dual* standard bra state'' ${}_s\langle p_s(\varphi)=0|$ is defined by Eq. (A9). These states are normalized so as to satisfy normalization conditions (A8) and (A10). Then, with the help of the techniques used in Ref. 5, we introduce in this paper the following inlaying *N*-vertex function ${}_s\langle IV^{\varphi}(1,2,...,N)|$ in the ''ICS *s*'' [for $\varphi(=\vec{X},\phi^j,\sigma,\phi,\chi)$-mode]:

$${}_s\langle IV^{\varphi}(1,2,...,N)|\equiv\vec{R}\cdot\left(\prod_{r=1}^{N}{}_r\langle q_r(\varphi)=0|W_r^{\varphi}[z_{rs}(w_r)]\right)\quad\text{for }\varphi=\vec{X},\phi^j,\sigma,\phi,\chi, \tag{2.7}$$

$\vec{R}$ being the *radial ordering* defined by Eq. (A12). With the help of the formulas (2.6) and (2.7), we shall introduce the following (Grassman even) inlaying *N*-vertex function in the ''ICS *s*:''

$$\begin{aligned}{}_s\langle IV(1,2,...,N)|&\equiv\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi,\chi}{}_s\langle IV^{\varphi}(1,2,...,N)|\\&\equiv\langle q_{\text{ext}}=0|\vec{R}\cdot\left(\prod_{r=1}^{N}W_r[z_{rs}(w_r)]\right),\end{aligned} \tag{2.8}$$

where $\langle q_{\text{ext}}=0|$ is the ''standard bra state'' given by

$$\langle q_{\text{ext}}=0|\equiv\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi,\chi}\left(\prod_{r=1}^{N}{}_r\langle q_r(\varphi)=0|\right). \tag{2.9}$$

In much the same way as in our previous paper,[5] we can prove the following *inlaying identity* in the ''ICS *s*:'' For any *external* primary operator $\mathcal{G}_r(w')$ [of the conformal weight $d(\mathcal{G})$], we have that

$${}_s\langle IV^{\varphi}(1,2,...,N)|\mathcal{G}_r(w')={}_s\langle IV^{\varphi}(1,2,...,N)|(z_{rs}^{(1)}(w'))^{d(\mathcal{G})}\cdot\mathcal{G}(z_{rs}(w')), \tag{2.10}$$

which shows that the *r*th external primary operator $\mathcal{G}_r(w')$ at the arbitrarily given w' (for $|w'|<1$) is *inlayed* into the *inlint* primary operator $\mathcal{G}(z_{rs}(w'))$ at the *r*th inlayed coordinate $z_{rs}(w')$, which has already been *radial ordered* with respect to any inlint operator in the inlaying vertex function ${}_s\langle IV^{\varphi}(\ldots)|$.

Comment: Although the inlint operator $\mathcal{G}(z_{rs}(w'))$ is located on the right of $(\vec{R}\cdot\Pi W_r^{\varphi}[\cdots])$ [in Eq. (2.10)], $\mathcal{G}(z_{rs}(w'))$ is *actually* located at the *radial-ordered* place *amid* $(\vec{R}\cdot\Pi W_r^{\varphi}[\cdots])$. This is because the *external* $\mathcal{G}_r(w')$ is exchanged with (i.e., *inlayed* into) the *inlint* $\mathcal{G}(z_{rs}(w'))$, $\mathcal{G}$ being created *out* (at the *radial-ordered* place) from $(\vec{R}\cdot\Pi W_r^{\varphi}[\cdots])$. [See the proof of Eqs. (2.23)–(2.25) in Ref. 5 for more details.]

Hereafter, the inlaying identity (2.10) will simply be expressed by

$$\mathcal{G}_r(w') \overset{\mathcal{I}}{\Rightarrow} (z_{rs}^{(1)}(w'))^{d(\mathcal{G})} \cdot \mathcal{G}(z_{rs}(w')) \quad \text{(to be referred to as the ``inlaying identity'').} \tag{2.11}$$

As we have proved ''Eq. (2.25) in Ref. 5,'' we can similarly prove that

$$:\exp(p\cdot\varphi_r(w')): \overset{\mathcal{I}}{\Rightarrow} (z_{rs}^{(1)}(w'))^{\varepsilon_\varphi^\phi\cdot(1/2)p(p+Q(\varphi))} :\exp(p\cdot\varphi(z_{rs}(w'))): \quad \text{for } \varphi=\phi^j,\sigma,\phi,\chi, \tag{2.12}$$

where we have used the constant $\varepsilon_\varphi^\phi\,[Q(\varphi)]$ defined by Eq. (A5b) [(2.5)]. Incidentally, $\varepsilon_\varphi^\phi \cdot \frac{1}{2}p(p+Q(\varphi))$ is the conformal weight of the primary operator: $\exp(p\cdot\varphi(*))$:. [See the conformal weight (1.32).]

The N-vertex funct*ino* ${}_s\langle V(1,2,...,N)|$ in the ''ICS s'' is constructed from the inlaying vertex function (2.8) by

$${}_s\langle V(1,2,...,N)| \equiv (\langle \mathcal{Q}=0|\xi_0)\cdot {}_s\langle IV(1,2,...,N)|(|\mathcal{Q}=0\rangle), \tag{2.13}$$

ξ_0 being the *zero-mode* of the *inlint* hilbertino (A27). Then the *elementary* N-vertex functino $\langle \nu_{\mathcal{S}}(1,2,...,N)|$ [used in Eqs. (1.19)–(1.21b)] is constructed by using the inlayed coordinates $z_{rm}(w_r)$'s in the ''ICS m'' [see Eq. (E34)] and it is given by

$$\langle \nu_{\mathcal{S}}(1,2,...,N)| \equiv {}_m\langle V(1,2,...,N)|, \tag{2.14}$$

which is *cycle-symmetric* under the cyclic permutation $1\to2\to\cdots\to N\to1$. [See cycle-symmetric coordinates $z_r(w_r)$'s in (E35).] In Eq. (2.13), $\langle\mathcal{Q}=0|$ is the ''*inlint* dual standard bra state'' defined by

$$\langle\mathcal{Q}=0| = (|\mathcal{Q}=0\rangle)^\dagger. \quad \text{[See Eq. (D2) for } r=0.] \tag{2.15}$$

At this stage, we define the *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$, which is to be used in defining the propagator (1.26) of the open NS superstring [the propagator (1.27) of the open R superstring]. The *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ (which is antisymmetric under $\gamma\leftrightarrow\delta$) is constructed by

$$|\nu_{\mathcal{S}}(\gamma,\delta)\rangle = \eta_{0,\gamma}|V_L(\gamma,\delta)\rangle, \tag{2.16}$$

where the *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ is given by

$$|V_L(\gamma,\delta)\rangle \equiv \prod_{\varphi=\vec{X},\phi^j,\sigma,\phi,\chi} |V^\varphi(\gamma,\delta)\rangle. \tag{2.17}$$

Furthermore, each $|V^\varphi(\gamma,\delta)\rangle$ (for $\varphi=\vec{X},\ \phi^j,\ \sigma,\ \phi,\ \chi$) in Eq. (2.17) is constructed by the following formulas: For $\vec{X}$-modes, we have that

$$\begin{aligned}|V^{\vec{X}}(\gamma,\delta)\rangle \equiv \exp\left(-\sum_{n=1}^\infty\sum_\pm\sum_{j=0}^4 \frac{(-)^n}{n} J_{-n,\gamma}(X^{\pm j})\cdot J_{-n,\delta}(X^{\mp j})\right)\\ \times\left(\sum_{\{p^{\pm j}\}}\exp\left(\sum_\pm\sum_{j=0}^4 \sqrt{-1}\cdot p^{\pm j}\cdot q_\gamma(X^{\mp j})\right)\right.\\ \left.\times\exp\left(-\sum_\pm\sum_{j=0}^4\sqrt{-1}\cdot p^{\pm j}\cdot q_\delta(X^{\mp j})\right)\right)|p_\gamma(\vec{X})=0\rangle_\gamma\cdot|p_\delta(\vec{X})=0\rangle_\delta,\end{aligned} \tag{2.18}$$

while we have for $\varphi[=\phi^j,\sigma,\phi(,\chi)]$ that

$$|V^{\varphi}(\gamma,\delta)\rangle \equiv \exp\left(-\sum_{n=1}^{\infty} \varepsilon_{\varphi}^{\phi}\cdot\frac{(-)^n}{n}\cdot J_{-n,\gamma}(\varphi)\cdot J_{-n,\delta}(\varphi)\right)$$
$$\times\left(\sum_{p\in Z(+1/2)} \exp(p\cdot q_{\gamma}(\varphi))\cdot\exp(-(p+Q(\varphi))q_{\delta}(\varphi))\right)|p_{\gamma}(\varphi)=0\rangle_{\gamma}\cdot|p_{\delta}(\varphi)=0\rangle_{\delta}$$
$$\text{for } \varphi=\phi^j,\sigma,\phi(,\chi), \tag{2.19}$$

where background charges $Q(\varphi)$'s are those given by Eq. (2.5). Incidentally, $|V^{\varphi}(\gamma,\delta)\rangle$ (for $\varphi=\vec{X},\ \phi^j,\ \phi$) is Grassman *even*, while $|V^{\varphi}(\gamma,\delta)\rangle$ (for $\varphi=\sigma,\chi$) is Grassman *odd*. [See Appendix E for more details.]

Using the techniques in Ref. 5, we can prove the following gluing theorem (which will be useful in calculating tree amplitudes[5]).

Gluing theorem: For any primary operator $\mathcal{G}_{\gamma}(w_{\gamma})$ of conformal weight $d(\mathcal{G})$, we have that

$$((\langle\mathcal{Q}=0|\xi_0)\cdot{}_l\langle IV(1,...,N,\gamma)|(|\mathcal{Q}=0\rangle))\cdot\mathcal{G}_{\gamma}(w_{\gamma})$$
$$\times((\langle\tilde{\mathcal{Q}}=0|\tilde{\xi}_0)\cdot{}_r\langle\tilde{I}V(\delta,N+1,...,N+M)|(|\tilde{\mathcal{Q}}=0\rangle))\cdot\left(\frac{1}{L_{0,\gamma}}\cdot|\nu_{\mathcal{S}}(\gamma,\delta)\rangle\right)$$
$$=\int_0^{\infty}dT_{\gamma}(\langle\mathcal{Q}=0|\xi_0)({}_g\langle IV(1,...,N,N+1,...,N+M)|(z_{\gamma g}^{(1)}(w_{\gamma}))^{d(\mathcal{G})}\cdot\mathcal{G}(z_{\gamma g}(w_{\gamma})))(|\mathcal{Q}=0\rangle), \tag{2.20}$$

where the *small* vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ is the one given by the formulas (2.16)–(2.19).

Proof: The gluing theorem (2.20) can be proved similarly to ''Eq. (5.10) in Ref. 5,'' provided that we make the following observations. First, the inlaying $(N+1)$-vertex function ${}_l\langle IV(1,...,N,\gamma)|$ in the ''ICS $l(eft)$'' inlays the γth external operator $\mathcal{G}_{\gamma}(w_{\gamma})$ into the inlint operator $(z_{\gamma l}^{(1)}(w_{\gamma}))^{d(\mathcal{G})}\cdot\mathcal{G}(z_{\gamma l}(w_{\gamma}))$, which is subsequently conformally mapped into $(z_{\gamma g}^{(1)}(w_{\gamma}))^{d(\mathcal{G})}\cdot\mathcal{G}(z_{\gamma g}(w_{\gamma}))$ by the conformal mapping operator $U_{-\gamma\delta}$ [given by Eq. (5.17) in Ref. 5]. We should notice that $z_{\gamma g}(w_{\gamma})$ is the inlayed coordinate within the unpunctured ring domain in the ''ICS $g(lued)$,'' while $z_{\gamma l}(w_{\gamma})$ is the γth inlayed coordinate within the γth punctured ring domain in the ''ICS $l(eft)$.'' The argument w_{γ} in $z_{\gamma g}(w_{\gamma})$ has been used to show that the strip-coordinate ''ρ'' for $z_{\gamma g}(w_{\gamma})$ is just equal to the strip-coordinate ''ρ'' for $z_{\gamma l}(w_{\gamma})$. [See ''Eqs. (5.25) and (5.26) in Ref. 5.''] (Q.E.D.)

Comment: On the left-hand side of Eq. (2.20), we have used two inlaying vertex functions; ${}_l\langle IV(1,...,N,\gamma)|$ in the ''ICS $s=l(eft)$'' is given in terms of *inlint* operators φ's, while ${}_r\langle\tilde{I}V(\delta,N+1,...,N+M)|$ in the ''ICS $s=r(ight)$'' is given in terms of inlint operators $\tilde{\varphi}$'s. Inlint operators φ's and $\tilde{\varphi}$'s are independent of each other. On the other hand, ${}_g\langle IV(1,...,N+M)|$ on the right-hand side of Eq. (2.20) is the inlaying vertex function in the ''ICS $s=g(lued)$.'' The ''ICS $s=g$'' is the ICS obtained by $\gamma\delta$-gluing the ''ICS $s=l$'' to the ''ICS $s=r$'' as follows. *All three* ''ICS $s=l,\ r,\ g$'' can be described by three GM-$\mathcal{FE}$'s (2.1) (with *different* modular parameters), provided that the numbers of punctured ring domains of three GM-$\mathcal{FE}$'s are respectively just equal to $N+1$, $M+1$, and $N+M$, respectively. Furthermore, the propagating strip-times of the $(N+M-4)$ unpunctured ring domains in the ''ICS $s=g$'' are *just equal to* those of the $(N-2)$ unpunctured ring domains in the ''ICS $s=l$'' and the $(M-2)$ unpunctured ring domains in the ''ICS $s=r$.'' Finally, ''T_{γ}'' (in the ''ICS g'') on the right-hand side of Eq. (2.20) is the *new* propagating strip-time of the ''$\gamma\delta$th unpunctured ring domain in the ICS $s=g$,'' which has been *created* by gluing the ''γth punctured ring domain in the ICS $s=l$'' to the ''δth punctured ring domain in the ICS $s=r$.'' This propagating strip-time T_{γ} on the right-hand side of Eq. (2.16) has been obtained through

$$\frac{1}{L_{0,\gamma}}=\int_0^\infty dT_\gamma\, x^{L_{0,\gamma}} \quad \text{and} \quad T_\gamma \equiv \log\left(\frac{1}{x}\right). \tag{2.21}$$

Incidentally, $z_{\gamma g}(w_\gamma)$ in Eq. (2.20) is the inlayed coordinate within the $\gamma\delta$th unpunctured ring domain. (See our previous paper[5] for more details.)

III. ‘‘AMPUTATED SCATTS’’ AND THE ‘‘GENERAL CONSERVATION OF THE TOTAL BRST CHARGINO’’

By using the ‘‘commutability’’ (C39) and formulas (C32)–(C36), the formula (1.26) is reduced to

$$\overbrace{|\Psi(1)\rangle_I\cdot|\Psi(1)\rangle_J}=\left(\sum_{\pm}\frac{1}{2}\cdot X^{1/2}_{\pm,I}\cdot X^{1/2}_{\mp,I}\right)\frac{\mathcal{B}_{0,I}}{L_{0,I}}\cdot P_I^{\mathrm{NS}}(\mathrm{GSO})|\nu_{\mathcal{S}}(I,J)\rangle \quad \text{in the case} \quad \pi(I)=\mathrm{NS}, \tag{3.1}$$

which is referred to as the propagator of the open NS superstring. On the other hand, by using the ‘‘commutability’’ (C38) and formulas (C22)–(C24), the formula (1.27) is also reduced to

$$\overbrace{|\Psi(\tfrac{1}{2})\rangle_I\cdot|\Psi(\tfrac{1}{2})\rangle_J}=X_I^0\cdot\frac{\mathcal{B}_{0,I}}{L_{0,I}}\cdot P_I^{\mathrm{R}}(\mathrm{GSO})|\nu_{\mathcal{S}}(I,J)\rangle \quad \text{in the case} \quad \pi(I)=\mathrm{R}, \tag{3.2}$$

which is referred to as the propagator of the open R superstring.

In general, the operator $\vec{T}_{X^0}\cdot\exp(S^{(\mathcal{M})}_{\mathrm{INT}}(\Psi))$ [with $S^{(\mathcal{M})}_{\mathrm{INT}}(\Psi)$ in (1.33)] can be calculated with the help of Wick's theorem,[16] by using the propagator (3.1) [(3.2)] of the open NS (R) superstring. The result obtained by applying Wick's theorem can be expressed by

$$\vec{T}_{X^0}\cdot\exp(s^{(\mathcal{M})}_{\mathrm{INT}}(\Psi))\equiv 1+\sum_{N=0}^{\infty}\sum_{\{p(r)\}}{}^{(\mathcal{M})}\langle S[p(1),p(2),\ldots,p(N)]|\cdot\frac{1}{N!}:\left(\prod_{r=1}^{N}|\Psi(p(r))\rangle_r\right): \tag{3.3a}$$

$$\equiv:\exp\left(\sum_{N=0}^{\infty}\sum_{\{p(r)\}}{}^{(\mathcal{M})}\langle S^{\mathcal{C}}[p(1),p(2),\ldots,p(N)]|\cdot\frac{1}{N!}:\left(\prod_{r=1}^{N}|\Psi(p(r))\rangle_r\right):\right):. \tag{3.3b}$$

Hereafter, the quantities with(out) the superscript ‘‘$\mathcal{M}$’’ will be referred to as the *(un)modified* ones. In the expansions (3.3a) and (3.3b), any ${}^{(\mathcal{M})}\langle S^{(\mathcal{C})}[p(1),p(2),\ldots,p(N)]|$ (which does *not* involve any operator ϕ_B and ψ_F) is obtained by *contractions* and it is assumed to be completely antisymmetric under any permutation of arguments, and we have used the following shorthand notation for the summation:

$$\sum_{\{p(r)\}}\equiv\prod_{r=1}^{N}\sum_{p(r)=1/2,1}. \tag{3.4}$$

Furthermore, ${}^{(\mathcal{M})}\langle S^{\mathcal{C}}[p(1),p(2),\ldots,p(N)]|$ is the *connected* part in ${}^{(\mathcal{M})}\langle S[p(1),p(2),\ldots,p(N)]|$. In Eqs. (3.3a) and (3.3b) and hereafter, the ordering in the product among external operators will be defined by

$$\prod_{r=1}^{N}F_r\equiv F_1\cdot F_2\cdots F_N, \tag{3.5}$$

for any Grassman even or odd operators F_r's. In Eqs. (3.3a) and (3.3b), any *quantized* bose field ϕ_B and *quantized* fermi field ψ_F is included in the *normal-ordered* product of fieldinos, where the normal ordering: : should be taken with respect to any quantized bose field ϕ_B and fermi field ψ_F.

We first notice that

$$\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\frac{1}{N!}\cdot\langle S[p(1),p(2),\ldots,p(N)]|\left(1+\varepsilon\left(\sum_{r=1}^{N}\mathcal{Q}_r\right)\right):\left(\prod_{r=1}^{N}|\Psi(p(r))\rangle_r\right):$$
$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\frac{1}{N!}\cdot\langle S[p(1),p(2),\ldots,p(N)]|:\left(\prod_{r=1}^{N}(1+\varepsilon\cdot\mathcal{Q}_r)|\Psi(p(r))\rangle_r\right):+O(\varepsilon^2),\tag{3.6}$$

ε being an arbitrary Grassmann *odd* constant. [Actually, $\varepsilon^2\equiv 0$ in Eq. (3.6) and hereafter.] Hereafter, we investigate the interaction term $S_{\mathrm{INT}}(\mathring{\Psi})$ which is obtained from $S_{\mathrm{INT}}(\Psi)$ by the following replacements:

$$|\Psi(p(r))\rangle_r\to(1+\varepsilon\cdot\mathcal{Q}_r)|\Psi(p(r))\rangle_r(\equiv|\mathring{\Psi}(p(r))\rangle_r)\quad\text{for } r=1-N.\tag{3.7}$$

Since the elementary three-vertex function (2.14) satisfies that

$$\langle\nu_{\mathcal{S}}(r,s,t)|(\mathcal{Q}_r+\mathcal{Q}_s+\mathcal{Q}_t)=0\quad[\text{see Eq. (B34)}],\tag{3.8}$$

we find that

$$S_{\mathrm{INT}}(\mathring{\Psi})=S_{\mathrm{INT}}(\Psi).\tag{3.9}$$

Thus, we are lead to investigate

$$\vec{T}_{X^0}\cdot\exp(S_{\mathrm{INT}}(\mathring{\Psi}))(\equiv\vec{T}_{X^0}\cdot\exp(S_{\mathrm{INT}}(\Psi)))$$
$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\frac{1}{N!}\cdot\langle\mathring{S}[p(1),p(2),\ldots,p(N)]|:\left(\prod_{r=1}^{N}|\mathring{\Psi}(p(r))\rangle_r\right):\tag{3.10a}$$
$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\frac{1}{N!}\cdot\langle S[p(1),p(2),\ldots,p(N)]|:\left(\prod_{r=1}^{N}|\Psi(p(r))\rangle_r\right):,\tag{3.10b}$$

which is found to give that

$$\langle\mathring{S}[p(1),p(2),\ldots,p(N)]|-\langle S[p(1),p(2),\ldots,p(N)]|=\langle S[p(1),p(2),\ldots,p(N)]|\left(-\varepsilon\cdot\sum_{r=1}^{N}\mathcal{Q}_r\right).\tag{3.10c}$$

Furthermore, the difference $(\langle\mathring{S}[\cdots]|-\langle S[\cdots]|)$ on the left-hand side of Eq. (3.10c) can be found by calculating $\overbrace{S_{\mathrm{INT}}(\mathring{\Psi})\cdot S_{\mathrm{INT}}(\mathring{\Psi})}$ up to the "first order of ε." First, we find in the NS sector that

$$|\overbrace{\Psi(1)\rangle_I\cdot|\Psi(1)}\rangle_J=\left(\sum_{\pm}\frac{1}{2}\cdot X^{1/2}_{\pm,I}\cdot X^{1/2}_{\mp,I}\right)\frac{\mathcal{B}_{0,I}}{L_{0,I}}\cdot P^{\mathrm{NS}}_I(\mathrm{GSO})|\nu_{\mathcal{S}}(I,J)\rangle\to|\overbrace{\mathring{\Psi}(1)\rangle_I\cdot|\mathring{\Psi}(1)}\rangle_J$$
$$=|\overbrace{\Psi(1)\rangle_I\cdot|\Psi(1)}\rangle_J+\varepsilon\cdot\left(\sum_{\pm}\frac{1}{2}\cdot X^{1/2}_{\pm,J}\cdot X^{1/2}_{\mp,J}\right)\cdot P^{\mathrm{NS}}_J(\mathrm{GSO})|\nu_{\mathcal{S}}(I,J)\rangle,\tag{3.11}$$

while in the R sector we find that

$$\overbrace{|\Psi(\tfrac{1}{2})\rangle_I\cdot|\Psi(\tfrac{1}{2})\rangle_J}=X_I^0\cdot\frac{\mathcal{B}_{0,I}}{L_{0,I}}\cdot P_I^{\mathrm{R}}(\mathrm{GSO})|\nu_{\mathcal{S}}(I,J)\rangle\to\overbrace{|\mathring{\Psi}(\tfrac{1}{2})\rangle_I\cdot|\mathring{\Psi}(\tfrac{1}{2})\rangle_J}$$
$$=\overbrace{|\Psi(\tfrac{1}{2})\rangle_I\cdot|\Psi(\tfrac{1}{2})\rangle_J}+\varepsilon\cdot X_J^0\cdot P_J^{\mathrm{R}}(\mathrm{GSO})|\nu_{\mathcal{S}}(I,J)\rangle. \tag{3.12}$$

With the help of the formulas (3.11) and (3.12), we can calculate the following contractions:

$$:\overbrace{S_{\mathrm{INT}}(\mathring{\Psi})\cdot S_{\mathrm{INT}}(\mathring{\Psi})}:\equiv\sum_{\{p\}}\langle\mathring{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(b),p(C),p(D),p(E)]|$$
$$\times\frac{1}{4!}:|\mathring{\Psi}(p(B))\rangle_B|\mathring{\Psi}(p(C))\rangle_C|\mathring{\Psi}(p(D))\rangle_D|\mathring{\Psi}(p(E))\rangle_E: \tag{3.13}$$

and

$$:\overbrace{S_{\mathrm{INT}}(\Psi)\cdot S_{\mathrm{INT}}(\Psi)}:\equiv\sum_{\{p\}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|$$
$$\times\frac{1}{4!}:|\Psi(p(B))\rangle_B|\Psi((C))\rangle_C|\Psi(p(D))\rangle_D|\Psi(p(E))\rangle_E:. \tag{3.14}$$

Thus it is concluded that

$$\sum_{\{p\}}\frac{1}{4!}(\langle\mathring{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|-\langle S^{C}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|)$$
$$\times:|\Psi(p(B))\rangle_B|\Psi(p(C))\rangle_C|\Psi(p(D))\rangle_D|\Psi(p(E))\rangle_E:$$
$$=-\varepsilon\cdot G^2\langle\nu_{\mathcal{S}}(B,C,D,E)|(Y[\overline{I}]\cdot Y[I]:(|\Psi(1)\rangle_B|\Psi(1)\rangle_C|\Psi(1)\rangle_D|\Psi(1)\rangle_E):$$
$$+Y[\overline{I}]:(|\Psi(\tfrac{1}{2})\rangle_B|\Psi(\tfrac{1}{2})\rangle_C)X^{1/2}_{+BC}(|\Psi(\tfrac{1}{2})\rangle_D|\Psi(\tfrac{1}{2})\rangle_E):)$$
$$-\varepsilon\cdot G^2\langle\nu_{\mathcal{S}}(B,C,D,E)|(:(|\Psi(1)\rangle_B|\Psi(\tfrac{1}{2})\rangle_C)Y[\overline{I}](|\Psi(1)\rangle_D|\Psi(\tfrac{1}{2})\rangle_E):$$
$$+:(|\Psi(1)\rangle_B|\Psi(\tfrac{1}{2})\rangle_C)Y[\overline{I}](|\Psi(\tfrac{1}{2})\rangle_D|\Psi(1)\rangle_E):$$
$$+:(|\Psi(\tfrac{1}{2})\rangle_B|\Psi(1)\rangle_C)Y[\overline{I}](|\Psi(1)\rangle_D|\Psi(\tfrac{1}{2})\rangle_E):$$
$$+:(|\Psi(\tfrac{1}{2})\rangle_B|\Psi(1)\rangle_C)Y[\overline{I}](|\Psi(\tfrac{1}{2})\rangle_D|\Psi(1)\rangle_E):$$
$$+:(|\Psi(1)\rangle_B|\Psi(1)\rangle_C)Y[\overline{I}]Y[I]X^{1/2}_{+,DE}(|\Psi(\tfrac{1}{2})\rangle_D|\Psi(\tfrac{1}{2})\rangle_E):$$
$$+:(|\Psi(\tfrac{1}{2})\rangle_B|\Psi(\tfrac{1}{2})\rangle_C)Y[\overline{I}]Y[I]X^{1/2}_{+,DE}(|\Psi(1)\rangle_D|\Psi(1)\rangle_E):), \tag{3.15}$$

where we have used the *cycle-symmetric* elementary vertex functino $\langle\nu_{\mathcal{S}}(A,B,C,D)|$, which is obtained by applying the gluing theorem (E33b). Unfortunately, Eq. (3.15) does not vanish identically, and it is just equal to

$$-\varepsilon\cdot G^2\langle \nu_{\mathcal{S}}(B,C,D,E)|Y[\overline{I}](X^{1/2}_{+BC}-X[\overline{I}]):(|\Psi(\tfrac{1}{2})\rangle_B|\Psi(\tfrac{1}{2})\rangle_C|\Psi(\tfrac{1}{2})\rangle_D|\Psi(\tfrac{1}{2})\rangle_E):$$
$$-\varepsilon\cdot G^2\langle \nu_{\mathcal{S}}(B,C,D,E)|Y[\overline{I}]Y[I](X^{1/2}_{+,BC}-X[I]):(|\Psi(1)\rangle_B|\Psi(1)\rangle_C|\Psi(\tfrac{1}{2})\rangle_D|\Psi(\tfrac{1}{2})\rangle_E$$
$$+|\Psi(\tfrac{1}{2})\rangle_B|\Psi(\tfrac{1}{2})\rangle_C|\Psi(1)\rangle_D|\Psi(1)\rangle_E):. \tag{3.16}$$

With the help of

$$X^{1/2}_{+BC}-X[\overset{(-)}{I}]\equiv\{\mathcal{Q}_B+\mathcal{Q}_C,\overset{(-)}{\Delta}_{+BC}\},\ \text{[see Eqs. (C3) and (C25)]}, \tag{3.17}$$

the term (3.16) can be rewritten into

$$-\varepsilon\cdot G^2\langle \nu_{\mathcal{S}}(B,C,D,E)|Y[\overline{I}]\cdot\overline{\Delta}^{1/2}_{+BC}\cdot(\tilde{\mathcal{Q}}_B+\tilde{\mathcal{Q}}_C+\tilde{\mathcal{Q}}_D+\tilde{\mathcal{Q}}_E):(|\Psi(\tfrac{1}{2})\rangle_B|\Psi(\tfrac{1}{2})\rangle_C|\Psi(\tfrac{1}{2})\rangle_D|\Psi(\tfrac{1}{2})\rangle_E):$$
$$-\varepsilon\cdot G^2\langle \nu_{\mathcal{S}}(B,C,D,E)|Y[\overline{I}]Y[I]\cdot\Delta^{1/2}_{+BC}\cdot(\tilde{\mathcal{Q}}_B+\tilde{\mathcal{Q}}_C+\tilde{\mathcal{Q}}_D+\tilde{\mathcal{Q}}_E)$$
$$\times:(|\Psi(1)\rangle_B|\Psi(1)\rangle_C|\Psi(\tfrac{1}{2})\rangle_D|\Psi(\tfrac{1}{2})\rangle_E+|\Psi(\tfrac{1}{2})\rangle_B|\Psi(\tfrac{1}{2})\rangle_C|\Psi(1)\rangle_D|\Psi(1)\rangle_E): \tag{3.18a}$$

$$\equiv\sum_{\{p\}}\frac{1}{4!}\cdot\langle\Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|(-\varepsilon)(\tilde{\mathcal{Q}}_B+\tilde{\mathcal{Q}}_C+\tilde{\mathcal{Q}}_D+\tilde{\mathcal{Q}}_E)$$
$$\times:|\Psi(p(B))\rangle_B|\Psi(p(C))\rangle_C|\Psi(p(D))\rangle_D|\Psi(p(E))\rangle_E:. \tag{3.18b}$$

With the help of the counter term $\langle\Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|$ determined by Eq. (3.18b), the (BRST-invariant) ''amputated 4-scatt'' ${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|$ in 0-loop can be constructed by

$${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|\equiv\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(C),p(D),p(E)]|$$
$$-\langle\Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|. \tag{3.19}$$

The amputated 4-scatt in (3.19) has been constructed so as to satisfy the following ''general conservation of the total BRST chargino,''

$${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|(\tilde{\mathcal{Q}}_B+\tilde{\mathcal{Q}}_C+\tilde{\mathcal{Q}}_D+\tilde{\mathcal{Q}}_E)=0$$
$$\text{(to be referred to as the ''GCTC'')}. \tag{3.20}$$

It should be noticed that the *counter term* $\langle\Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\ldots,p(4)]|$ in Eq. (3.19) does not contain *any* propagator. Thus the interaction is partly modified from $S_{\mathrm{INT}}(\Psi)$ in (1.20) into $S^{\mathcal{M}}_{\mathrm{INT}}(4,0)$, which is given by

$$S^{\mathcal{M}}_{\mathrm{INT}}(4,0)\equiv S_{\mathrm{INT}}(\Psi)-\sum_{\{p\}}\frac{1}{4!}\cdot\langle\Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(B),p(C),p(D),p(E)]|$$
$$\times:|\Psi(p(B))\rangle_B|\Psi(p(C))\rangle_C|\Psi(p(D))\rangle_D|\Psi(p(E))\rangle_E:. \tag{3.21}$$

Similarly, we can calculate ${}^{\mathcal{M}}\langle\tilde{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\ldots,p(5)]|$ in the following formula, $S^{\mathcal{M}}_{\mathrm{INT}}(4,0)$ being given by Eq. (3.21).

$$\vec{T}_{X^0}\cdot \exp(S^{\mathcal{M}}_{\rm INT}(4,0)) \equiv 1+\sum_{N=3}^{4}\sum_{\{p(r)\}} {}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),p(2),\dots,p(N)]| \cdot \frac{1}{N!} : \left(\prod_{r=1}^{N} |\Psi(p(r))\rangle_r\right): + \sum_{\{p(r)\}} {}^{\mathcal{M}}\langle \tilde{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(1),p(2),\dots,p(5)]| \cdot \frac{1}{5!} : \left(\prod_{r=1}^{5} |\Psi(p(r))\rangle_r\right): + \text{other terms}. \tag{3.22}$$

[We notice that thus obtained ${}^{\mathcal{M}}\langle \tilde{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|$ is *partly* modified from $\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|$ by the effect due to the counter term in ''$S^{\mathcal{M}}_{\rm INT}(4.0)$.''] Even if we take account of the ''GCTC'' in (3.20), we shall still find that

$${}^{\mathcal{M}}\langle \tilde{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|\left(\sum_{r=1}^{5} \mathcal{Q}_r\right) \neq 0. \tag{3.23}$$

However, the term (3.23) can be expressed by

$$\langle \Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|\left(\sum_{r=1}^{5} \mathcal{Q}_r\right), \tag{3.24}$$

where the number of propagators in (the counter term) $\langle \Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|$ is *less* than that in ${}^{\mathcal{M}}\langle \tilde{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|$. {This situation will be imagined by comparing the counter term $\langle \Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(4)]|$ with $\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(4)]|$.} Then new modified action is (up to this approximation) constructed by

$$S^{\mathcal{M}}_{\rm INT}(4,0) \to S^{\mathcal{M}}_{\rm INT}(5,0) = S_{\rm INT}(\Psi) - \sum_{\{p\}}\sum_{n=4}^{5}\frac{1}{n!}\cdot \langle \Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),p(2),\dots,p(n)]| \times :|\Psi(p(1))\rangle_1 |\Psi(p(2))\rangle_2 \cdots |\Psi(p(n))\rangle_n :. \tag{3.25}$$

The (BRST-invariant) ''amputated 5-scatt'' ${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|$ in 0-loop is also constructed by

$${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)] \equiv {}^{\mathcal{M}}\langle \tilde{S}^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]| - \langle \Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|, \tag{3.26}$$

so as to satisfy the following ''GCTC.''

$${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\dots,p(5)]|\left(\sum_{r=1}^{5} \mathcal{Q}_r\right) = 0. \tag{3.27}$$

In the following, we shall show how to derive the *completely modified action* $S^{\mathcal{M}}_{\rm INT}(\Psi)$, which together with the formula (3.3b) gives the following (BRST-invariant) ''*amputated N-scatt*'' ${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}}[p(1),\dots,p(N)]|$ in **g**-loops;

$${}^{\mathcal{M}}\langle S^{\mathcal{C}}[p(1),\dots,p(N)]| = \sum_{\mathbf{g}=0}^{\infty} {}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}}[p(1),\dots,p(N)]|, \tag{3.28}$$

which satisfies the following ''GCTC:''

$${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}}[p(1),\dots,p(N)]|\left(\sum_{r=1}^{N} \mathcal{Q}_r\right) = 0. \tag{3.29}$$

Suggested by Eqs. (3.11), (3.12), and (3.16)–(3.21), we find that BRST-invariant amputated N-scatt ${}^{\mathcal{M}}\langle S^{\mathcal{C}}[p(1),\ldots,p(N)]|$ in (3.28) can be obtained as follows: Instead of $S_{\mathrm{INT}}(\Psi)$ in (1.20), we consider that

$$\begin{aligned}S_{\mathrm{INT}}^{\mathcal{T}}(\Psi+\Delta\widetilde{\Psi})\equiv\tfrac{1}{3}G\cdot\langle\nu_{\mathcal{S}}(r,s,t)|Y[\overline{r}]\cdot Y[r]{:}(|\Psi(1)\rangle_r+|\Delta\widetilde{\Psi}(1)\rangle_r)(|\Psi(1)\rangle_s\\ +|\Delta\widetilde{\Psi}(1)\rangle_s)(|\Psi(1)\rangle_t+|\Delta\widetilde{\Psi}(1)\rangle_t){:}+G\cdot\langle\nu_{\mathcal{S}}(r,s,t)|Y[\overline{r}]{:}(|\Psi(1)\rangle_r\\ +|\Delta\widetilde{\Psi}(1)\rangle_r)(|\Psi(\tfrac{1}{2})\rangle_s+|\Delta\widetilde{\Psi}(\tfrac{1}{2})\rangle_s)(|\Psi(\tfrac{1}{2})\rangle_t+|\Delta\widetilde{\Psi}(\tfrac{1}{2})\rangle_t){:}.\end{aligned}\tag{3.30}$$

The rth operators $|\Delta\widetilde{\Psi}(1)\rangle_r$ and $|\Delta\widetilde{\Psi}(\tfrac{1}{2})\rangle_r$ used in Eq. (3.30) will be referred to as the *counter* fieldinos, and they are defined respectively to have following properties. Correspondingly to Eqs. (1.25)–(1.27), we have

$$\begin{aligned}\vec{T}_{X^0}(|\Delta\widetilde{\Psi}(p(\gamma))\rangle_\gamma\cdot|\Delta\widetilde{\Psi}(p(\delta))\rangle_\delta)\\ \equiv{:}|\Delta\widetilde{\Psi}(p(\gamma))\rangle_\gamma\cdot|\Delta\widetilde{\Psi}(p(\delta))\rangle_\delta{:}+|\Delta\widetilde{\Psi}\overline{(p(\gamma))\rangle_\gamma\cdot|\Delta\widetilde{\Psi}(}p(\delta))\rangle_\delta,\end{aligned}\tag{3.31}$$

where contractions are given by

$$|\Delta\widetilde{\Psi}\overline{(1)\rangle_\gamma\cdot|\Delta\widetilde{\Psi}(1)}\rangle_\delta=-\Theta_\gamma^{\mathrm{NS}}\cdot P^{\mathrm{NS}}(\mathrm{GSO})|\nu_{\mathcal{S}}(\gamma,\delta)\rangle\tag{3.32}$$

and

$$|\Delta\widetilde{\Psi}\overline{(\tfrac{1}{2})\rangle_\gamma\cdot|\Delta\widetilde{\Psi}}(\tfrac{1}{2})\rangle_\delta=-\Theta_\gamma^{\mathrm{R}}\cdot P^{\mathrm{R}}(\mathrm{GSO})|\nu_{\mathcal{S}}(\gamma,\delta)\rangle.\tag{3.33}$$

The operators $\Theta_\gamma^{\mathrm{NS}}$ in Eq. (3.32) and $\Theta_\gamma^{\mathrm{R}}$ in Eq. (3.33) are those satisfying respectively that

$$\{\mathcal{Q}_r,\Theta_\gamma^{\pi(\gamma)}\}\equiv\mathcal{X}_\gamma^{\pi(\gamma)}\quad\text{for}\quad\pi(\gamma)=\mathrm{NS,R},\tag{3.34}$$

where $\mathcal{X}_\gamma^{\pi(\gamma)}$ is defined by

$$\mathcal{X}_I^{\pi(I)}\equiv\begin{cases}\displaystyle\sum_\pm\frac{1}{2}\cdot X_{\pm,I}^{1/2}\cdot X_{\mp,I}^{1/2} & \text{for}\quad\pi(I)=\mathrm{NS},\\ X_I^0\quad\text{for}\quad\pi(I)=\mathrm{R}.\end{cases}\tag{3.35}$$

On the other hand, the contractions among any $|\Delta\widetilde{\Psi}(\cdot)\rangle$ and any $|\Psi(\cdot)\rangle$ are just equal to zero, so that we have that

$$\begin{aligned}\vec{T}_{X^0}(|\Psi(p(\gamma))\rangle_\gamma+|\Delta\widetilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\widetilde{\Psi}(p(\delta))\rangle_\delta)\\ \equiv{:}(|\Psi(p(\gamma))\rangle_\gamma+|\Delta\widetilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\widetilde{\Psi}(p(\delta))\rangle_\delta){:}\\ +(|\overline{\Psi(p(\gamma))\rangle_\gamma+|\Delta\widetilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\widetilde{\Psi}}(p(\delta))\rangle_\delta).\end{aligned}\tag{3.36}$$

The last contraction term on the right-hand side of Eq. (3.36) is found to be given by

$$(|\Psi(p(\gamma))\rangle_\delta+|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\tilde{\Psi}(p(\delta))\rangle_\delta)$$
$$=\left(\mathcal{X}_\gamma^{\pi(\gamma)}\cdot\frac{\mathcal{B}_{0,\gamma}}{L_{0,\gamma}}-\Theta_\gamma^{\pi(\gamma)}\right)\cdot P^{\pi(\gamma)}(\mathrm{GSO})|\nu_{\mathcal{S}}(\gamma,\delta)\rangle. \tag{3.37}$$

Similarly to Eqs. (3.13) and (3.14), we easily find from Eqs. (3.34) and (3.37) the following important identities:

$$(\mathcal{Q}_\gamma+\mathcal{Q}_\delta)\cdot(|\Psi(p(\gamma))\rangle_\gamma+|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\tilde{\Psi}(p(\delta))\rangle_\delta)=0. \tag{3.38}$$

Correspondingly to Eqs. (1.23) and (1.24), we introduce the *counter* bra state $\langle\tilde{\phi}=\tilde{\psi}=0|$ and the *counter* ket state $|\tilde{\phi}=\tilde{\psi}=0\rangle$, on which operates any *counter* fieldino $|\Delta\tilde{\Psi}(1)\rangle_r$ and $|\Delta\tilde{\Psi}(\frac{1}{2})\rangle_s$. Furthermore, the normal product among any *counter* fieldino satisfies

$$\langle\tilde{\phi}=\tilde{\psi}=0|:(|\Delta\tilde{\Psi}(1)\rangle_r\cdot|\Delta\tilde{\Psi}(\tfrac{1}{2})\rangle_s\cdots):|\tilde{\phi}=\tilde{\psi}=0\rangle=0 \tag{3.39}$$

and

$$\langle\tilde{\phi}=\tilde{\psi}=0|\tilde{\phi}=\tilde{\psi}=0\rangle=1. \tag{3.40}$$

In order to analyze

$$\vec{T}_{X^0}\cdot\exp(S_{\mathrm{INT}}^{\mathcal{T}}(\Psi+\Delta\tilde{\Psi})), \tag{3.41}$$

we consider the following transformation:

$$(|\Psi(p(r))\rangle_r+|\Delta\tilde{\Psi}(p(r))\rangle_r)\to(1+\varepsilon\cdot\mathcal{Q}_r)(|\Psi(p(r))\rangle_r+|\Delta\tilde{\Psi}(p(r))\rangle_r)$$
$$\equiv(|\mathring{\Psi}(p(r))\rangle_r+|\Delta\mathring{\tilde{\Psi}}(p(r))\rangle_r). \tag{3.42}$$

Similarly to Eq. (3.9), we find that

$$S_{\mathrm{INT}}^{\mathcal{T}}(\Psi+\Delta\tilde{\Psi})=S_{\mathrm{INT}}^{\mathcal{T}}(\mathring{\Psi}+\Delta\mathring{\tilde{\Psi}}). \tag{3.43}$$

On account of Eq. (3.38), we obtain that

$$(|\mathring{\Psi}(p(\gamma))\rangle_\gamma+|\Delta\mathring{\tilde{\Psi}}(p(\gamma))\rangle_\gamma)\cdot(|\mathring{\Psi}(p(\delta))\rangle_\delta+|\Delta\mathring{\tilde{\Psi}}(p(\delta))\rangle_\delta)$$
$$=(|\Psi(p(\gamma))\rangle_\gamma+|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\tilde{\Psi}(p(\delta))\rangle_\delta). \tag{3.44}$$

Therefore, we find in

$$:S^{\mathcal{T}}_{\mathrm{INT}}(\mathring{\Psi}+\Delta\mathring{\tilde{\Psi}})\cdot S^{\mathcal{T}}_{\mathrm{INT}}(\mathring{\Psi}+\Delta\mathring{\tilde{\Psi}}):\equiv\sum_{\{p\}}\ {}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),p(2),p(3),p(4)]|\frac{1}{4!}\times:\left(\prod_{r=1}^{4}(|\mathring{\Psi}(p(r))\rangle_r+|\Delta\mathring{\tilde{\Psi}}(p(r))\rangle_r\right): \tag{3.45}$$

that ${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[\ldots]|$ is just equal to the one obtained by

$$:S^{\mathcal{T}}_{\mathrm{INT}}(\Psi+\Delta\tilde{\Psi})\cdot S^{\mathcal{T}}_{\mathrm{INT}}(\Psi+\Delta\tilde{\Psi}):\equiv\sum_{\{p\}}\ {}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),p(2),p(3),p(4)]|\frac{1}{4!}\times:\left(\prod_{r=1}^{4}(|\Psi(p(r))\rangle_r+|\Delta\tilde{\Psi}(p(r))\rangle_r\right):, \tag{3.46}$$

which can be calculated by using contractions given by Eq. (3.37). Thus, we find from Eqs. (3.43), (3.45), and (3.46) that

$$\vec{T}_{X^0}\cdot\exp(S^{\mathcal{T}}_{\mathrm{INT}}(\mathring{\Psi}+\Delta\mathring{\tilde{\Psi}}))(\equiv\vec{T}_{X^0}\cdot\exp(S^{\mathcal{T}}_{\mathrm{INT}}(\Psi+\Delta\tilde{\Psi})))$$

$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\ {}^{\mathcal{M}}\langle S[p(1),p(2),\ldots,p(N)]|\frac{1}{N!}:\left(\prod_{r=1}^{N}(|\mathring{\Psi}(p(r))\rangle_r+|\Delta\mathring{\tilde{\Psi}}(p(r))\rangle_r\right): \tag{3.47}$$

$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\ {}^{\mathcal{M}}\langle S[p(1),p(2),\ldots,p(N)]|\frac{1}{N!}:\left(\prod_{r=1}^{N}(|\Psi(p(r))\rangle_r+|\Delta\tilde{\Psi}(p(r))s\rangle_r\right):. \tag{3.48}$$

Equating Eq. (3.47) to Eq. (3.48), we finally have proved the following ''general conservation of total chargino'' (GCTC):

$${}^{\mathcal{M}}\langle S[p(1),p(2),\ldots,p(N)]|\left(\sum_{r=1}^{N}\mathcal{Q}_r\right)=0, \tag{3.49}$$

(to be referred to as ''GCTC'')

Furthermore, we find from Eq. (3.48) that

$$\langle\tilde{\phi}=\tilde{\psi}=0|\vec{T}_{X^0}\cdot\exp(S^{\mathcal{T}}_{\mathrm{INT}}(\Psi+\Delta\tilde{\Psi}))|\tilde{\phi}=\tilde{\psi}=0\rangle$$

$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\ {}^{\mathcal{M}}\langle S[p(1),p(2),\ldots,p(N)]|\cdot\frac{1}{N!}$$

$$\times\langle\tilde{\phi}=\tilde{\psi}=0|:\left(\prod_{r=1}^{N}(|\Psi(p(r))\rangle_r+|\Delta\tilde{\Psi}(p(r))\rangle_r\right):|\tilde{\phi}=\tilde{\psi}=0\rangle$$

$$=\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\ {}^{\mathcal{M}}\langle S[p(1),p(2),\ldots,p(N)]|\cdot\frac{1}{N!}:\left(\prod_{r=1}^{N}(|\Psi(p(r))\rangle_r\right):$$

$$\equiv:\exp\left(\sum_{N=0}^{\infty}\sum_{\{p(r)\}}\ {}^{\mathcal{M}}\langle S^{\mathcal{C}}[p(1),p(2),\ldots,p(N)]|\cdot\frac{1}{N!}:\left(\prod_{r=1}^{N}|\Psi(p(r))\rangle_r\right):\right):, \tag{3.50}$$

in the second step of which we have used Eqs. (3.39) and (3.40). Therefore, we can use the identification

$$\vec{T}_{X^0}\cdot\exp(S^{\mathcal{M}}_{\rm INT}(\Psi))\equiv\langle\tilde{\phi}=\tilde{\psi}=0|\vec{T}_{X^0}\cdot\exp(S^{\mathcal{T}}_{\rm INT}(\Psi+\Delta\tilde{\Psi}))|\tilde{\phi}=\tilde{\psi}=0\rangle, \tag{3.51}$$

which gives ${}^{\mathcal{M}}\langle S[p(1),\ldots,p(N)]|$ satisfying the ''GCTC'' (3.49). In the following, we explain how $S^{\mathcal{M}}_{\rm INT}(\Psi)$ on the left-hand side of Eq. (3.51) can be determined by terms on the right-hand side of Eq. (3.51). For this purpose, we first rewrite *counter* fieldinos within the time-ordered product into the normal-ordered form, with the help of Wick's theorem[16] by using the operator product expansion Eqs. (3.32)–(3.34) (among *counter* fieldinos). At this stage, fieldinos are still kept time ordered. For an example, we use

$$\begin{aligned}
&\vec{T}_{X^0}(|\Psi(p(\gamma))\rangle_\gamma+|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma)\cdot(|\Psi(p(\delta))\rangle_\delta+|\Delta\tilde{\Psi}(p(\delta))\rangle_\delta)\\
&=\vec{T}_{X^0}(|\Psi(p(\gamma))\rangle_\gamma\cdot|\Psi(p(\delta))\rangle_\delta+|\Psi(p(\gamma))\rangle_\gamma|\Delta\tilde{\Psi}(p(\delta))\rangle_\delta\\
&\quad+|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma\cdot|\Psi(p(\delta))\rangle_\delta)+:|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma\cdot|\Delta\tilde{\Psi}(p(\delta))\rangle_\delta:\\
&\quad+\overbrace{|\Delta\tilde{\Psi}(p(\gamma))\rangle_\gamma\cdot|\Delta\tilde{\Psi}}(p(\delta))\rangle_\delta.
\end{aligned} \tag{3.52}$$

Carrying out these procedures, we are lead to

$$\vec{T}_{X^0}\cdot\exp(S^{\mathcal{T}}_{\rm INT}(\Psi+\Delta\tilde{\Psi}))\equiv\vec{T}_{X^0}:\exp(S^{\mathcal{M}}_{\rm INT}(\Psi)+\Sigma_{\rm INT}(\Psi;\Delta\tilde{\Psi})):. \tag{3.53}$$

The normal ordering : : on the right-hand side of Eq. (3.53) has been taken with respect *only* to *counter* fieldinos, and $\Sigma_{\rm INT}\{\Psi;\Delta\tilde{\Psi}\}$ is composed of various terms involving (*more than one*) counter fieldinos $\Delta\tilde{\Psi}$'s in the *normal-ordered form*. Therefore, Eq. (3.39) gives

$$\langle\tilde{\phi}=\tilde{\psi}=0|:(\Sigma_{\rm INT}(\Psi;\Delta\tilde{\Psi})\cdots\Sigma_{\rm INT}(\Psi;\Delta\tilde{\Psi})):|\tilde{\phi}=\tilde{\psi}=0\rangle=0. \tag{3.54}$$

On the other hand, the modified action $S^{\mathcal{M}}_{\rm INT}(\Psi)$ *determined* by Eq. (3.53) would be obtained in the following form:

$$S^{\mathcal{M}}_{\rm INT}(\Psi)=S_{\rm INT}(\Psi)-\sum_{n=1}^{\infty}\Delta S_{\rm INT}(\Psi;n), \tag{3.55}$$

where $\Delta S_{\rm INT}(\Psi;n)$ is the term resulting from contractions (of n times) among *counter* fieldinos, and it should *not* involve any *counter* fieldino. Furthermore, $\Delta S_{\rm INT}(\Psi;n)$ involves only fieldinos which are given in the *time-ordered* form. Thus we have *proved* the following *theorem*.

Theorem: With the help of $S^{\mathcal{M}}_{\rm INT}(\Psi)$ in (3.55) determined by Eq. (3.54),

$$\vec{T}_{X^0}\cdot\exp(S^{\mathcal{M}}_{\rm INT}(\Psi))\equiv:\exp\left(\sum_{N=0}^{\infty}\sum_{\{p(r)\}}{}^{\mathcal{M}}\langle S^{\mathcal{C}}[p(1),\ldots,p(N)]|\cdot\frac{1}{N!}:\left(\prod_{r=1}^{N}|\Psi(p(r))\rangle_r\right):\right), \tag{3.56}$$

where the (BRST-invariant) ''amputated N-scatt'' ${}^{\mathcal{M}}\langle S^{\mathcal{C}}[p(1),\ldots,p(N)]|$ contains any contribution in **g**-loops [which satisfies the ''general conservation of the total chargino'' (3.29)]. Our final result (or rule) in calculating the ''amputated N-scatt'' ${}^{\mathcal{M}}\langle S^{\mathcal{C}}[p(1),\ldots,p(N)]|$ is quite simple. Amputated scatts can be calculated by using the *un*modified interaction term $S_{\rm INT}(\Psi)$ in (1.20), provided that *all* propagators are *effectively* modified as follows:

$$\mathcal{X}_{\gamma}^{\pi(\gamma)}\cdot\frac{\mathcal{B}_{0,\gamma}}{L_{0,\gamma}}\cdot P^{\pi(\gamma)}(\mathrm{GSO})|\nu_{\mathcal{S}}(\gamma,\delta)\rangle\rightarrow\left(\mathcal{X}_{\gamma}^{\pi(\gamma)}\cdot\frac{\mathcal{B}_{0,\gamma}}{L_{0,\gamma}}-\Theta_{\gamma}^{\pi(\gamma)}\right)\cdot P^{\pi(\gamma)}(\mathrm{GSO})|\nu_{\mathcal{S}}(\gamma,\delta)\rangle. \tag{3.57}$$

Finally, we prove that the physical scattering amplitude (N_B,N_F) in (1.22) is given by

$$(N_B,N_F)=\sum_{\mathbf{g}=0}^{\infty}(N_B,N_F)_{\mathbf{g}}, \tag{3.58}$$

$(N_B,N_F)_{\mathbf{g}}$ being given by

$$\begin{aligned}(N_B,N_F)_{\mathbf{g}}\equiv{}^{\mathcal{M}}\langle S_{\mathbf{g}}^{\mathcal{C}}[p(1),p(2),\ldots,p(N_B+N_F)]|\langle\phi=\psi=0|\cdot\frac{1}{N_B!}\\ \times:\left(\prod_{r''=1}^{N_B}|\Psi(1)\rangle_{r''}\right)\cdot\frac{1}{N_F!}\left(\prod_{r''=N_B+1}^{N_B+N_F}|\Psi(\tfrac{1}{2})\rangle_{r''}\right):\left(\prod_{r=1}^{N_B}B_{b_r}\{\phi\}\right)\\ \times\left(\prod_{r=N_B+1}^{N_B+N_F}F_{f_r}\{\psi\}\right)|\phi=\psi=0\rangle\quad\text{with }N=N_B+N_F\\ [\text{see Eqs. (1.22) and (3.56)}]\end{aligned} \tag{3.59}$$

$$\begin{aligned}=\pm{}^{\mathcal{M}}\langle S_{\mathbf{g}}^{\mathcal{C}}[p(1),p(2),\ldots,p(r),\ldots,p(N_B+N_F)]|\\ \times\left(\prod_{r=1}^{N_B}|b_r(1)\rangle_r\right)\cdot\left(\prod_{r=N_B+1}^{N_B+N_F}|f_r(\tfrac{1}{2})\rangle_r\right).\end{aligned} \tag{3.60}$$

The signature $\pm$ in Eq. (3.60) is necessary, since we reorder Grassman odd operators for the purpose of using the following formulas [in the process of deriving Eq. (3.60)]:

$$\begin{aligned}|\Psi\overbrace{(1)\rangle_{r''}\cdot B_{b_r}}\{\phi\}\quad\text{for }r=1-N_B\quad[\text{use Eq. (1.21a)}]\\ =\langle\nu_{\mathcal{S}}(r',r)|\mathcal{Q}_{r'}\cdot Y[\bar{r}']Y[r']\cdot|\Psi(1)\rangle_{r''}\cdot|\Psi(1)\rangle_{r'}\\ \cdot|b_r(1)\rangle_r\quad[\text{use Eq. (3.1)}]\\ =\langle\nu_{\mathcal{S}}(r',r)|\mathcal{Q}_{r'}\cdot\frac{\mathcal{B}_{0,r'}}{L_{0,r'}}|\nu_{\mathcal{S}}(r'',r')\rangle(P_r(1)|b_r(1)\rangle_r)\quad[\text{use Eq. (D6)}]\\ =(\langle\nu_{\mathcal{S}}(r',r)|\nu_{\mathcal{S}}(r'',r')\rangle)|b_r(1)\rangle_r\quad[\text{use Eq. (E40)}]\\ -\langle\nu_{\mathcal{S}}(r',r)|\frac{\mathcal{Q}_{r'}}{L_{0,r'}}|\nu_{\mathcal{S}}(r'',r')\rangle(\mathcal{B}_{0,r}|b_r(1)\rangle_r)\quad[\text{use Eq. (D7)}]\\ =\delta_{rr''}\cdot|b_r(1)\rangle_r\end{aligned} \tag{3.61}$$

and

$$\langle\Psi\overbrace{(\tfrac{1}{2})\rangle_{r''}\cdot F_{f_r}}\{\psi\}=\delta_{rr''}\cdot|f_r(\tfrac{1}{2})\rangle_r\quad\text{for }r=(N_B+1)-(N_B+N_F), \tag{3.62}$$

which can be obtained similarly to Eq. (3.61) by using Eqs. (1.21b), (3.2), (D16), and (D19).

IV. PHYSICAL SCATTERING AMPLITUDES IN g-LOOPS

We have seen in Sec. III that the formula (3.60) gives the physical scattering amplitude $(N_B,N_F)_{\mathbf{g}}$ [in **g**-loops] among N_B *physical* bosonic and N_F *physical* fermionic particles, by using the (BRST-invariant) ''amputated N-scatt'' $\langle S_{\mathbf{g}}^{\mathcal{C}}[p(1),\ldots,p(N)]|$, which can be given by the formulas (3.50) and (3.28). [We have found that amputated scatts can be calculated by using unmodified interaction term $S_{\mathrm{INT}}(\Psi)$ in (1.20), provided that any propagator is *effectively* modified accordingly to Eq. (3.57).] As we have seen in our previous paper[5] on QBFT, physical scattering amplitudes (3.60) can be calculated by using the ''inlayed coordinate system *genus* **g**'' (ICS **g**), which describes the Riemann *surface* $\mathcal{R}$ with *B-boundaries* and *H-handles*, with $\mathbf{g}+1=B+H$. In this paper, we only consider Riemann surface $\mathcal{R}$ with $B=\mathbf{g}+1$ and $H=0$, i.e., we do *not* calculate the contribution obtained by gluing two *open* string punctures on different boundaries, since each gluing of this kind adds one handle to the Riemann surface $\mathcal{R}$. We notice that H handles in Riemann surface $\mathcal{R}$ represent contributions from H closed channels. Therefore, in order to restore the manifest factorization in the H channels (of closed string), we must include the closed string from the beginning, based on the open-closed string field theory. Then we could obtain the factorizable amplitudes in genus $\mathbf{g}=H+B-1$, where $H(B)$ is the number of handles (boundaries). We point out that *closed* QBFT has been already proposed.[4]

At this stage, we summarize properties of the Riemann surface $\mathcal{R}$ which is to be used in calculating $(N_B,N_F)_{\mathbf{g}}$ in (3.60) in **g**-loops. The Riemann surface $\mathcal{R}$ is punctured at $(N+2\mathbf{g})$ points on the real axis. The Schottky double $\mathcal{D}$ of the Riemann surface $\mathcal{R}$ has the Ith unpunctured ring domain, which has the Ith propagating strip-time T_I [for $1\leqslant I\leqslant(N+2\mathbf{g}-3)$]. This Schottky double $\mathcal{D}$ has been described by GM-$\mathcal{FE}$ in (2.1) [with $(N+2\mathbf{g})$ punctures]. Next, in constructing the Riemann surface $\mathcal{R}'$ with $(\mathbf{g}+1)$-boundaries, $2\mathbf{g}$-punctured ring domains in the Riemann surface $\mathcal{R}$ should be glued into **g**-*un*punctured ring domains. As we see from the (Wick's) expansion (3.3), this can be realized by the following **g**-contractions among fieldinos:

$$\prod_{h=1}^{\mathbf{g}} |\Psi(\overbrace{p(\gamma^h))\rangle_{\gamma^h}|\Psi(p}(\delta^h))\rangle_{\delta^h}$$
$$=\left(\prod_{\pi(\gamma^h)=NS}\left(\sum \frac{1}{2}\cdot X^{1/2}_{\pm\gamma^h}\cdot X^{1/2}_{\mp\delta^h}\right)\right)\left(\prod_{\pi(\gamma^h)=R} X^0_{\gamma^h}\right)$$
$$\times\prod_{h=1}^{\mathbf{g}}\left(\frac{\mathcal{B}_{0,\gamma^h}\cdot\eta_{0,\gamma^h}}{L_{0,\gamma^h}}\cdot P^{\pi(\gamma^h)}_{\gamma^h}(\mathrm{GSO})|V_L(\gamma^h,\delta^h)\rangle\right)\quad\text{with}\quad \mathbf{g}\equiv g_B+g_F, \tag{4.1}$$

where we have used the formulas (E31) and (E32). Thus we need the following N-vertex functino ${}_s\langle V(1,2,...,N)|_{(g_B,g_F)}$ ''in $\mathbf{g}(=g_B+g_F)$-loops'' in the *large* Hilbert space:

$${}_s\langle V(1,2,...,N)|_{(g_B,g_F)}\quad\text{with}\quad \mathbf{g}=g_B+g_F$$
$$\equiv(\langle\mathcal{Q}=0|\xi_0)\cdot{}_s\langle IV(1,2,...,N+2\mathbf{g})|\cdot(|\mathcal{Q}=0\rangle)$$
$$\times\prod_{h=1}^{\mathbf{g}}(\exp(-T_{\gamma^h}\cdot L_{0,\gamma^h}\cdot P^{\pi(\gamma^h)}_{\gamma^h}(\mathrm{GSO})|V_L(\gamma^h,\delta^h)\rangle) \tag{4.2}$$

$$\equiv\mathrm{Tr}_{\varphi}\,\Omega^N_s((g_B,g_F)), \tag{4.3}$$

$\Omega^N_s((g_B,g_F))$ being defined by

$$\Omega^N_s((g_B,g_F))\equiv\{{}_sN^{2\mathbf{g}}\}\cdot\prod_{h=1}^{\mathbf{g}}(P^{\pi(\gamma^h)}_{\gamma^h}(\mathrm{GSO})|V_L(\gamma^h,\delta^h)\rangle). \tag{4.4}$$

The operator $\Omega_s^N((g_B, g_F))$ in (4.4) is the function of N *external* operators as well as the *inlint* operators in the ''ICS s'' (representing the Riemann surface $\mathcal{R}$ with $N+2\mathbf{g}$ punctures). In Eqs. (4.1) and (4.2), the number of h satisfying $\pi(\gamma^h)=\mathrm{NS}$ (R) is denoted by g_B (g_F), and the operator $\{_s N^{2\mathbf{g}}\}$ in Eq. (4.4) is defined by

$$\{_s N^{2\mathbf{g}}\} \equiv \vec{R}\cdot(|\mathcal{Q}=0\rangle\cdot\langle\mathcal{Q}=0|\xi_0)\cdot\left(\prod_{h=1}^{\mathbf{g}}\prod_{\varphi}\left(_{\delta^h}\langle q_{\delta^h}(\varphi)=0|W^{\varphi}_{\delta^h}[z_{\delta^h s}(w_{\delta^h})]\right)\right)$$

$$\times\left(\prod_{r=1}^{N}\prod_{\varphi}\left(_r\langle q_r(\varphi)=0|W_r^{\varphi}[z_{rs}(w_r)]\right)\right)$$

$$\times\left(\prod_{h=1}^{\mathbf{g}}\prod_{\varphi}\left(_{\gamma^h}\langle q_{\gamma^h}(\varphi)=0|W^{\varphi}_{\gamma^h}[z_{\gamma^h s}(x_{\gamma^h}\cdot w_{\gamma^h})]\right)\right). \tag{4.5}$$

$W^{\varphi}[\cdots]$'s being inlaying operators given by Eqs. (2.4)–(2.6). Incidentally, the γ^h-th propagating strip-time T_{γ^h} in the formula (4.2) has been introduced through

$$\frac{1}{L_{0,\gamma^h}}=\int_0^{\infty} dT_{\gamma^h}\exp(-T_{\gamma^h}\cdot L_{0,\gamma^h}) \quad \text{for } h=1-\mathbf{g} \tag{4.6a}$$

with

$$x_{\gamma^h}\equiv\exp(-T_{\gamma^h}) \quad [\text{in Eq. (4.5)}]. \tag{4.6b}$$

Tr_{φ} in Eq. (4.3) [Π_{φ} in Eq. (4.5)] is the trace (product) over all *inlint* φ-modes (for $\varphi=\vec{X},\phi^j,\sigma,\phi,\chi$).

We notice that contractions (4.1) induce the hth $\gamma^h\delta^h$-gluing (for $h=1-\mathbf{g}$) which glues the γ^hth ring domain (punctured at $Z_{\gamma^h s}$) to the δ^hth ring domain (punctured at $Z_{\delta^h s}$) in the Schottky double $\mathcal{D}$, resulting to create the new hth *un*punctured ring domain which has the hth propagating strip-time $T_{\gamma^h s}\equiv\log(1/x_{\gamma^h})$ (for $h=1-\mathbf{g}$). Thus, the new Riemann surface $\mathcal{R}'$ (which has been obtained from the original Riemann surface $\mathcal{R}$ by the $\gamma\delta$-gluings) has N punctures on the real axis, having $(\mathbf{g}+1)$-*boundaries* on the real axis. Furthermore, the Schottky double $\mathcal{D}'$ [of this Riemann surface $\mathcal{R}'$] has the Ith unpunctured ring domain which has the propagating strip-time T_I [for $I=1-(N+2\mathbf{g}-3)$], as well as the hth *un*punctured ring domain having the hth propagating strip-time $\log(1/x_{\gamma^h})$ (for $h=1-\mathbf{g}$). Therefore, when the number of the punctures (boundaries) is N $(\mathbf{g}+1)$, the total number of modular parameters is just equal to $(N+3\mathbf{g}-3)$. In our previous paper,[5] we have proved that thus obtained Riemann surface $\mathcal{R}'$ can be conformally mapped [see Eqs. (6.16)–(6.18) in Ref. 5] to the other Riemann surface described by the ''ICS **g**,'' which will be explained in the following.

In order to describe the ''ICS **g**,'' we have used (in open QBFT[5]) the following ''Samuel's fundamental equation'' (S-$\mathcal{FE}$) in (4.7).[19] We briefly review our previous results, hereafter. (See Ref. 5 for more details.)

$$\frac{dz_{\mathbf{g}}}{d\rho_{\mathbf{g}}}=\nu_{\mathbf{g}}(z_{\mathbf{g}}) \quad \text{with} \quad \mathbf{g}=g_B+g_F. \tag{4.7}$$

[The coordinate $z_{\mathbf{g}}(\rho_{\mathbf{g}})$ satisfying S-$\mathcal{FE}$ (4.7) has been referred to as the inlayed coordinate $z_{\mathbf{g}}(\rho_{\mathbf{g}})$ in the ''inlayed coordinate system in (*genus*) **g**'' (ICS **g**).] We impose Witten's midpoint interactions in Eq. (4.7). Samuel[19] has imposed that

$$d\rho_{\mathbf{g}}=\frac{dz_{\mathbf{g}}}{\nu_{\mathbf{g}}(z_{\mathbf{g}})}=\frac{dS_h(z_{\mathbf{g}})}{\nu_{\mathbf{g}}(S_h(z_{\mathbf{g}}))} \quad \text{for each } h=1-\mathbf{g}, \tag{4.8}$$

where $S_h(z_{\mathbf{g}})$ is the SL$(2R)$ mapping defined by

$$S_h(z_{\mathbf{g}})\equiv\frac{\alpha_h\cdot z_{\mathbf{g}}+\beta_h}{\gamma_h\cdot z_{\mathbf{g}}+\delta_h}. \tag{4.9}$$

Furthermore, Samuel has found[19] that the function $\nu_{\mathbf{g}}(z_{\mathbf{g}})$ given by

$$(\nu_{\mathbf{g}}(z))^{-2}\equiv R_{\mathbf{g}}^{-2}\cdot\Theta\left(\vec{\Delta}^{z_0}-\sum_{\iota=1}^{\mathbf{g}}\int_{z_0}^{y_\iota^{\mathbf{g}}}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}+\int_{z_0}^{z}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}\middle|\tau\right)$$
$$\times\frac{(\Pi_{\iota=g+1}^{2N+4\mathbf{g}-4}E(z,y_\iota^{\mathbf{g}}|\tau))}{(\Pi_{r=1}^{N}(E(z,Z_{r\mathbf{g}}|\tau))^2)}\cdot(\sigma(z))^3\quad\text{with}\quad N=N_B+N_F \tag{4.10}$$

can satisfy the **g**-*conditions* (4.8), *provided* that the following **g**-*constraints* are imposed on modular parameters in $\nu_{\mathbf{g}}(z_{\mathbf{g}})$ in (4.10):

$$4\cdot\Delta_h^{z_0}-2=\sum_{\iota=1}^{2N+4\mathbf{g}-4}\int_{z_0}^{y_\iota^{\mathbf{g}}}dz'\frac{\omega_h(z')}{2\pi\sqrt{-1}}-\sum_{r=1}^{N}2\int_{z_0}^{Z_{r\mathbf{g}}}dz'\frac{\omega_h(z')}{2\pi\sqrt{-1}}\quad(h=1-\mathbf{g}). \tag{4.11}$$

[Unfortunately, there exist misprints in ''Eqs. (6.8) and Eq. (6.11) in Ref. 5,'' which are corrected in Eqs. (4.10) and (4.11).] In the following, we explain various functions used in Eqs. (4.10) and (4.11). Functions τ, ω, $\Delta_h^{z_0}$, E, σ, and Θ are the same as those given in VPFHLS's paper,[20] corresponding equations of which being given as follows: The period matrix (3.11), the holomorphic differential $\vec{\omega}(z)dz\equiv(\omega_1,\omega_2,\ldots,\omega_{\mathbf{g}})$ [with the *one-form* $\omega_h\equiv\omega_h(z)\cdot dz$ in (3.12) for $h=1-\mathbf{g}$] being bases for the holomorphic differentials of the Riemann surface, the **g**-*dimensional vector* of Riemann constants $\vec{\Delta}^{z_0}\equiv(\Delta_1^{z_0},\Delta_2^{z_0},\ldots,\Delta_{\mathbf{g}}^{z_0})$ in (3.13), the prime form (3.14), the sigma function ''σ'' (3.15), and the Riemann theta function (3.18). [Hereafter, the **g**-*dimensional vector space* is denoted by $V_{\mathbf{g}}$, so that $\vec{\omega}(z)$, $\vec{\Delta}^{z_0}\in V_{\mathbf{g}}$ in Eq. (4.10) and hereafter.] We notice that the *one-form* $\omega_h\equiv dz\cdot\omega_h(z)$ in (3.12) in VPFHLS[20] is written [in Samuel's paper] by the *one-form* $2\pi\sqrt{-1}\cdot\omega_h$ in (3.6).[19] The point $z_0\in F_{D\mathbf{g}}$ is arbitrary. [The boundary of the *fundamental region* $F_{D\mathbf{g}}$ in the ''ICS **g**'' has been given by Eq. (6.12) in Ref. 5.] Incidentally, the **g**-constraints in (4.11) [which should be imposed in order for $\nu_{\mathbf{g}}(z_{\mathbf{g}})$ in (4.10) to satisfy **g**-conditions in (4.8)] have been derived[19] by using the following formulas in VPFHLS's notations.[20] [See Table I and Eq. (3.18) of Ref. 19.]

$$E(S_h(z),z')\quad\text{for each}\quad S_h\quad(h=1-\mathbf{g})$$
$$=-\exp\left(-\tau_{hh}\sqrt{-1}\cdot\pi-\int_{z'}^{z}dz''\omega_h(z'')\right)\cdot\left(\frac{dS_h(z)}{dz}\right)^{1/2}\cdot E(z,z'), \tag{4.12}$$

$$\Theta\begin{pmatrix}\vec{a}\\\vec{b}\end{pmatrix}\left(\vec{\xi}+\int_{z_0}^{S_h(z)}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}\middle|\tau\right)\quad\text{for each}\quad S_h\quad[h=1-\mathbf{g}]$$

$$=\exp\left(-\tau_{hh}\sqrt{-1}\cdot\pi-\int_{z_0}^{z}dz'\omega_h(z')-2\pi\sqrt{-1}(\xi_h+b_h)\right)\Theta\begin{pmatrix}\vec{a}\\\vec{b}\end{pmatrix}$$
$$\times\left(\vec{\xi}+\int_{z_0}^{z}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}\middle|\tau\right), \tag{4.13}$$

$$\sigma(S_h(z))=(-)^{\mathbf{g}}\cdot\exp\left(\tau_{hh}(\mathbf{g}-1)\sqrt{-1}\cdot\pi-2\pi\sqrt{-1}\Delta_h^{z_0}+(\mathbf{g}-1)\int_{z_0}^{z}dz'\,\omega_h(z')\right)$$

$$\times\left(\frac{dS_h(z)}{dz}\right)^{-\mathbf{g}/2}\cdot\sigma(z)\quad\text{for each } S_h\quad[h=1-\mathbf{g}],\tag{4.14}$$

and

$$\frac{\sigma(\tilde{z})}{\sigma(z)}=\frac{\Theta\left(\Sigma_{i=1}^{\mathbf{g}}\int_{z_0}^{z_i}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}-\int_{z_0}^{\tilde{z}}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}-\vec{\Delta}^{z_0}\middle|\tau\right)}{\Theta\left(\Sigma_{i=1}^{\mathbf{g}}\int_{z_0}^{z_i}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}-\int_{z_0}^{z}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}-\vec{\Delta}^{z_0}\middle|\tau\right)}\cdot\frac{(\Pi_{i=1}^{\mathbf{g}}E(z_i,z))}{(\Pi_{i=1}^{\mathbf{g}}E(z_i,\tilde{z}))}.\tag{4.15}$$

Furthermore, we have used [in Eqs. (4.13) and (4.15)] the following Riemann theta function Θ in *genus* $\mathbf{g}$:

$$\Theta\begin{pmatrix}\vec{a}\\\vec{b}\end{pmatrix}(\vec{\xi}|\tau),\tag{4.16}$$

where and hereafter $\vec{a},\vec{b},\vec{\xi}(\in V_{\mathbf{g}})$ are shorthand notations for the $\mathbf{g}$-set of variables given by

$$\vec{a}\equiv(a_1,a_2,\dots a_{\mathbf{g}})\quad\text{and}\quad\vec{b}\equiv(b_1,b_2,\dots,b_{\mathbf{g}})\tag{4.17}$$

and

$$\vec{\xi}\equiv(\xi_1,\xi_2,\dots,\xi_{\mathbf{g}}).\tag{4.18}$$

The Riemann theta function (4.16) is defined by

$$\Theta\begin{pmatrix}\vec{a}\\\vec{b}\end{pmatrix}(\vec{\xi}|\tau)\equiv\sum_{\{n_h\}\in Z}\exp\left(2\pi\sqrt{-1}\left(\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}(n_i+a_i)\tau_{ih}(n_h+a_h)+\sum_{h=1}^{\mathbf{g}}(n_h+a_h)(\xi_h+b_h)\right)\right),\tag{4.19}$$

τ_{ih} being the period matrix elements. Furthermore, we shall use the following shorthand notation:

$$\Theta(\vec{\xi}|\tau)\equiv\Theta\begin{pmatrix}\vec{0}\\\vec{0}\end{pmatrix}(\vec{\xi}|\tau).\tag{4.20}$$

There exist various parameters in $\nu_{\mathbf{g}}(z)$ in (4.10): Constant $R_{\mathbf{g}}$ is some real normalization constant. The rth puncture $Z_{r\mathbf{g}}$ (for $r=1-N$) is located somewhere on the real axis (in the fundamental region $F_{D\mathbf{g}}$ in the ''ICS $\mathbf{g}$''), while the interacting points $\mathcal{Y}^{\mathbf{g}}_{\pm\iota}$ [for $\iota=1-(N-2)$], and $\mathcal{Y}^{\mathbf{g}}_{\pm\gamma^h}$, $\mathcal{Y}^{\mathbf{g}}_{\pm\delta^h}$ (for $h=1-\mathbf{g}$) are complex conjugates of each other among $\pm$ and all of them exist within $F_{D\mathbf{g}}$. Interacting points $\mathcal{Y}^{\mathbf{g}}_{\iota}$'s used in $\nu_{\mathbf{g}}(z)$ in (4.10) are differently numbered $(2N+4\mathbf{g}-4)$ coordinates of interacting points in $F_{D\mathbf{g}}$. In addition to these parameters, there exist $3\mathbf{g}$ real parameters characterizing hyperbolic $\mathrm{SL}(2R)$ matrices S_h (for $h=1-\mathbf{g}$), which are used in defining the functions Θ, E, τ, $\vec{\Delta}^{z_0}$, and $\vec{\omega}(z)dz$ in the formula $\nu_{\mathbf{g}}(z)$ in (4.10). Thus, we have $3N+7\mathbf{g}-3[=1+N+(2N+4\mathbf{g}-4)+3\mathbf{g}]$ *real* parameters *in total*. On the other hand, any one among $(N+3\mathbf{g}-3)$ unpunctured ring domains and N punctured ring domains in the ''ICS $\mathbf{g}$'' should have the same width 2π. Furthermore, propagating strip-times [i.e., T_I's for $I=1-(N+2\mathbf{g}-3)$ and T_{γ^h}'s for $h=1-\mathbf{g}$ in Eq. (4.6a)] can be arbitrary non-negative real numbers, and they can be used as *modular parameters*. Together with the $\mathbf{g}$-constraints in (4.11), we have $3N+7\mathbf{g}-6[=(N+3\mathbf{g}-3)+N+(N+3\mathbf{g}-3)+\mathbf{g}]$ constraints *in total*. Thus, *all* parameters in $\nu_{\mathbf{g}}(z)$

in (4.10) are determined in terms of $(N+3\mathbf{g}-3)$ modular parameters (i.e., propagating strip-times T_I's and T_{γ^h}'s), *except for* three free (real) parameters, existence of which reflects the fact that there remains still *one* SL$(2R)$ ambiguity in defining the ''ICS **g**.''[5]

With the help of the ''ICS **g**,'' $\Omega_{\mathbf{g}}^N((g_B,g_F))$ (in the ''ICS **g**'') is defined by

$$\Omega_{\mathbf{g}}^N(g_B,g_F)\equiv\{_{\mathbf{g}}N^{2\mathbf{g}}\}\cdot\left(\prod_{h=1}^{\mathbf{g}} P_{\gamma^h}^{\pi(\gamma^h)}(\mathrm{GSO})|V_L(\gamma^h,\delta^h)\rangle\right)$$

$$[\text{cf. Eqs. (6.4) and (6.19) in Ref. 5}], \tag{4.21}$$

where $\{_{\mathbf{g}}N^{2\mathbf{g}}\}$ (in the ''ICS **g**'') is given by

$$\{_{\mathbf{g}}N^{2\mathbf{g}}\}\equiv\vec{R}\cdot(U_s|\mathcal{Q}=0\rangle\cdot\langle\mathcal{Q}=0|\xi_0\cdot U_s^{-1})\cdot\left(\prod_{r=1}^{N}\prod_{\varphi}\left(_r\langle q_r^{\varphi}=0|W_r^{\varphi}[z_{r\mathbf{g}}]\right)\right),$$

$$\times\left(\prod_{h=1}^{\mathbf{g}}\prod_{\varphi}\left(_{\gamma^h}\langle q_{\gamma^h}^{\varphi}=0|W_{\gamma^h}^{\varphi}[z_{\gamma^h\mathbf{g}}]\right)\cdot\left(_{\delta^h}\langle q_{\delta^h}^{\varphi}=0|W_{\delta^h}^{\varphi}[z_{\delta^h\mathbf{g}}]\right)\right)$$

$$[\text{see Eq. (6.19) in Ref. 5}], \tag{4.22}$$

where the *inlint* conformal mapping operator U_s is the one given by Eqs. (6.16) and (6.17) in Ref. 5. [In Eq. (4.22), the existence of the inlint zero-mode ξ_0 is essential.]

The (rth external) physical vertex operators $\mathcal{G}_r(0)$'s [with the conformal weight $d(\mathcal{G})$] are *expressed* to be inlayed into inlint operators $\mathcal{G}$ (r; ''ICS **g**'') in the ''ICS **g**'' as follows:

$$\mathcal{G}_r(0)\overset{\mathcal{I}}{\Rightarrow}\left(\frac{dz_{r\mathbf{g}}(w)}{dw}\right)^{d(\mathcal{G})}\cdot\mathcal{G}(z_{r\mathbf{g}}(w))\bigg|_{w=0}\equiv\mathcal{G}(r;\text{``ICS }\mathbf{g}\text{''}). \tag{4.23}$$

As for various *nonlocal* operators, we also use the following (similar) shorthand notations for representing inlaying identities:

$$\Sigma\tfrac{1}{2}\cdot X_{\pm\gamma^h}^{1/2}\cdot X_{\mp\gamma^h}^{1/2}\overset{\mathcal{I}}{\Rightarrow}\Sigma\tfrac{1}{2}\cdot X_{\pm}^{1/2}(\gamma^h;\text{``ICS }\mathbf{g}\text{''})\cdot X_{\mp}^{1/2}(\gamma^h;\text{``ICS }\mathbf{g}\text{''})\quad\text{for }\pi(\gamma^h)=\mathrm{NS}, \tag{4.24}$$

$$X_{\gamma^h}^0\overset{\mathcal{I}}{\Rightarrow}X^0(\gamma^h;\text{``ICS }\mathbf{g}\text{''})\quad\text{for }\pi(\gamma^h)=\mathrm{R}, \tag{4.25}$$

$$\begin{aligned}\mathcal{B}_{0,I}&\equiv\oint_0\frac{w_I dw_I}{2\pi\sqrt{-1}}\mathcal{B}_I(w_I)\overset{\mathcal{I}}{\Rightarrow}\mathcal{B}_0(I;\text{``ICS }\mathbf{g}\text{''})\\&\equiv\oint_0\frac{w_I dw_I}{2\pi\sqrt{-1}}(z_{I\mathbf{g}}^{(1)}(w_I))^2\cdot\mathcal{B}(z_{I\mathbf{g}}(w_I))\\&=\oint_{C_{I\mathbf{g}}}\frac{dz_{\mathbf{g}}}{2\pi\sqrt{-1}}\nu_{\mathbf{g}}(z_{\mathbf{g}})\cdot\mathcal{B}(z_{\mathbf{g}})\quad\text{for }I=1-(N+2\mathbf{g}-3),\end{aligned} \tag{4.26}$$

$$\begin{aligned}\mathcal{B}_{0,\gamma^h} &\equiv \oint_0 \frac{w_{\gamma^h} dw_{\gamma^h}}{2\pi\sqrt{-1}} \mathcal{B}_{\gamma^h}(w_{\gamma^h}) \overset{\mathcal{I}}{\Rightarrow} \mathcal{B}_0(\gamma^h;\text{``ICS }\mathbf{g}\text{''}) \\ &\equiv \oint_0 \frac{w_{\gamma^h} dw_{\gamma^h}}{2\pi\sqrt{-1}} (z^{(1)}_{\gamma^h\mathbf{g}}(w_{\gamma^h}))^2 \cdot \mathcal{B}(z_{\gamma^h\mathbf{g}}(w_{\gamma^h})) \\ &= \oint_{C_{\gamma^h\mathbf{g}}} \frac{dz_{\mathbf{g}}}{2\pi\sqrt{-1}} \nu_{\mathbf{g}}(z_{\mathbf{g}}) \cdot \mathcal{B}(z_{\mathbf{g}}) \quad \text{for } h=1-\mathbf{g} \end{aligned} \tag{4.27}$$

and

$$\eta_{0,\gamma^h} \equiv \oint_0 \frac{dw_{\gamma^h}}{2\pi\sqrt{-1}} \eta_{\gamma^h}(w_{\gamma^h}) \overset{\mathcal{I}}{\Rightarrow} \eta_0(\gamma^h;\text{``ICS }\mathbf{g}\text{''}) \equiv \oint_{C_{\gamma^h\mathbf{g}}} \frac{dz_{\mathbf{g}}}{2\pi\sqrt{-1}} \eta(z_{\mathbf{g}}) \quad \text{for } h=1-\mathbf{g}. \tag{4.28}$$

Thus, $\mathcal{X}^{\pi(\gamma^h)}_{\gamma^h}$ defined by Eq. (3.35) is inlayed as follows:

$$\begin{aligned}&\mathcal{X}^{\pi(\gamma^h)}_{\gamma^h} \overset{\mathcal{I}}{\Rightarrow} \mathcal{X}^{\pi(\gamma^h)}(\gamma^h;\text{``ICS }\mathbf{g}\text{''}) \\ &\equiv \begin{cases} \Sigma\ \frac{1}{2} \cdot X^{1/2}_{\pm}(\gamma^h;\text{``ICS }\mathbf{g}\text{''}) \cdot X^{1/2}_{\mp}(\gamma^h;\text{``ICS }\mathbf{g}\text{''}) & \text{for } \pi(\gamma^h)=\text{NS}, \\ X^0(\gamma^h;\text{``ICS }\mathbf{g}\text{''}) \quad \text{for } \pi(\gamma^h)=\text{R}. \end{cases}\end{aligned} \tag{4.29}$$

In the case when three superstrings (say, the rth, sth, and tth superstring) interact with each other at the (upper and lower) ιth interacting points $[\text{for } \iota=1-(N+2\mathbf{g}-2)]$, the inverse picture-changing (external) operator $Y_{\pm\iota}$ is defined by

$$Y_{\pm\iota} \equiv Y_r(\pm\sqrt{-1}) \equiv Y_s(\pm\sqrt{-1}) \equiv Y_t(\pm\sqrt{-1}) \quad \text{for } \iota=1-(N+2\mathbf{g}-2). \tag{4.30}$$

At the ιth interacting point, there exists either $Y_{-\iota}\cdot Y_{+\iota}$ (in the case of interacting three strings NS–NS–NS) or $Y_{-\iota}$ (in the case of interacting three strings R–R–NS). This result will be expressed by

$$Y_{\text{``}\iota\text{''}} \equiv \begin{cases} Y_{-\iota}\cdot Y_{+\iota} & \text{for NS–NS–NS interacting point}, \\ Y_{-\iota} & \text{for R–R–S interacting point}. \end{cases} \tag{4.31}$$

The inverse picture-changing operator $Y_{\text{``}\iota\text{''}}$ would be inlayed as

$$\begin{aligned}&Y_{\text{``}\iota\text{''}} \overset{\mathcal{I}}{\Rightarrow} Y_{\text{``}\iota\text{''}}(\text{``ICS } g\text{''}) \quad \text{for } \iota=1-(N+2\mathbf{g}-2) \\ &\equiv \begin{cases} Y(\mathcal{Y}^*_{\iota\mathbf{g}})\cdot Y(\mathcal{Y}_{\iota\mathbf{g}}) & \text{for NS–NS–NS interacting point} \\ Y(\mathcal{Y}^*_{\iota\mathbf{g}}) & \text{for R–R–NS interacting point}, \end{cases}\end{aligned} \tag{4.32}$$

$\mathcal{Y}_{\iota\mathbf{g}}$ ($\mathcal{Y}^*_{\iota\mathbf{g}}$) being the inlayed coordinate [in the ''ICS **g**''] of the ιth upper (lower) interacting point. In much the same way as we have shown Eq. (6.21) in Ref. 5, we can show that

$$
\begin{aligned}
&(\mathcal{Q}=0|\xi_0)\cdot {}_s\langle IV(1,2,\dots,N+2\mathbf{g})|\cdot\left(\prod_{\iota=1}^{N+2\mathbf{g}-2} Y_{``\iota''}\right)\cdot\left(\prod_{I=1}^{N+2\mathbf{g}-3} \mathcal{X}_I^{\pi(I)}\cdot\mathcal{B}_{0,I}\right)\\
&\quad\times\left(\prod_{h=1}^{\mathbf{g}} \mathcal{X}_{\gamma^h}^{\pi(\gamma^h)}\cdot\mathcal{B}_{0,\gamma^h}\cdot\eta_{0,\gamma^h}\right)\cdot\left(\prod_{r=1}^{N}\mathcal{G}_r(0)\right)\cdot\left(\prod_{r=1}^{N}|\mathcal{Q}_r=0\rangle_r\right)\\
&\quad\times\prod_{h=1}^{\mathbf{g}}(\exp(-T_{\gamma^h}\cdot L_{0,\gamma^h})\cdot P_{\gamma^h}^{\pi(\gamma^h)}(\mathrm{GSO})|V_L(\gamma^h,\delta^h)\rangle)\cdot(|\mathcal{Q}\\
&=0\rangle)\\
&\quad=\mathop{\mathrm{Tr}}_{\varphi}\Bigg(\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle\cdot\left(\prod_{r=1}^{N}\mathcal{G}(r;``\mathrm{ICS}\ \mathbf{g}'')\right)\cdot\left(\prod_{\iota=1}^{N+2\mathbf{g}-2}Y_{``\iota''}(``\mathrm{ICS}\ \mathbf{g}'')\right)\\
&\quad\times\left(\prod_{I=1}^{N+2\mathbf{g}-3}\mathcal{X}^{\pi(I)}(I;``\mathrm{ICS}\ \mathbf{g}'')\cdot\mathcal{B}_0(I,``\mathrm{ICS}\ \mathbf{g}'')\right)\\
&\quad\times\left(\prod_{h=1}^{\mathbf{g}}\mathcal{X}^{\pi(\gamma^h)}(\gamma^h;``\mathrm{ICS}\ \mathbf{g}'')\cdot\mathcal{B}_0(\gamma^h;``\mathrm{ICS}\ \mathbf{g}'')\cdot\eta_0(\gamma^h;``\mathrm{ICS}\ \mathbf{g}'')\right)\Bigg),
\end{aligned}
\tag{4.33}
$$

where we have used the ''*analytic inlint gluing operator*'' $\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle$ defined by

$$
\begin{aligned}
\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle&\equiv\Omega_{\mathbf{g}}^N((g_B,g_F))\left(\prod_{r=1}^{N}|\mathcal{Q}_r=0\rangle_r\right)\\
&=(U_s|\mathcal{Q}=0\rangle\cdot\langle\mathcal{Q}=0|\xi_0\cdot U_s^{-1})\cdot\vec{R}\cdot\left(\prod_{h=1}^{\mathbf{g}}\prod_{\varphi}({}_{\delta^h}\langle q_{\delta^h}(\varphi)=0|W_{\delta^h}^{\varphi}[z_{\delta^h g}(w_{\delta^h})])\right)\\
&\quad\times\left(\prod_{h=1}^{\mathbf{g}}\prod_{\varphi}({}_{\gamma^h}\langle q_{\gamma^h}(\varphi)=0|W_{\gamma^h}^{\varphi}[z_{\gamma^h\mathbf{g}}(w_{\gamma^h})])\right)\\
&\quad\times\left(\prod_{h=1}^{\mathbf{g}}P_{\gamma^h}^{\pi(\gamma^h)}(\mathrm{GSO})|V_L(\gamma^h,\gamma^h)\rangle\right)\quad\text{with }\ \mathbf{g}=g_B+g_F
\end{aligned}
\tag{4.34}
$$

[cf. Eq. (6.22) in Ref. 5]. Similarly to Eq. (6.23) in Ref. 5, we can show that $\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle$ in (4.34) in the ''ICS $\mathbf{g}$'' satisfies the following *boundary conditions* for any *inlint* primary operator $\mathcal{G}(z')$ [of conformal weight $d(\mathcal{G})$]:

$$
\vec{R}\cdot\langle\Omega_{\mathbf{g}}(g_B,g_F)\rangle\cdot\mathcal{G}(z')=\left(\frac{dS_h(z')}{dz'}\right)^{d(\mathcal{G})}\cdot\vec{R}\cdot\langle\Omega_{\mathbf{g}}(g_B,g_F)\rangle\cdot\mathcal{G}(S_h(z'))
$$

$$
\text{for }\ h=1-\mathbf{g}\quad\text{and}\quad z'\in\partial F_{D\mathbf{g}}.
\tag{4.35}
$$

Comment: Equation (4.34) shows that $\langle\Omega_{\mathbf{g}}(g_B,g_F)\rangle$ is the function of only *inlint* operators [on the boundary $\partial F_{D\mathbf{g}}$ in the ''ICS $\mathbf{g}$'']. [5] It is important that the term on the left-hand side of (4.33) can be calculated by the term on the right-hand side of Eq. (4.33), the latter of which does *not* involve any *external* operator *but* involves only *inlint* operators having the argument in the ''ICS $\mathbf{g}$.'' We have proved[5] that the ''*analytic inlint gluing operator*'' $\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle$ can be expressed as the functional on inlint operators only on the boundary $\partial F_{D\mathbf{g}}$, so that the boundary conditions (4.35) are expected to determine $\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle$ up to the constant factor.

Using the method used in proposing Eqs. (6.27)–(6.32) in Ref. 5, we *propose* that

$$\langle \Omega_{\mathbf{g}}(g_B,g_F)\rangle = \left(\prod_{\varphi=\vec{X},\sigma,\chi} \langle \Omega_{\mathbf{g}}^{\varphi}(g_B,g_F)\rangle\right)\left(\prod_{\varphi=\phi^j,\phi} \langle \Omega_{\mathbf{g}}^{\varphi\{@\}}(g_B,g_F)\rangle\right) \times \prod_{h=1}^{\mathbf{g}} \left(\frac{1}{2}+\frac{1}{2}\varepsilon^{\pi(h)}\exp\left(\sqrt{-1}\,\pi\left(p_h(\phi)+\sum_{j=0}^{4} p_h(\phi^j)\right)\right)\right), \tag{4.36}$$

where the constant $\varepsilon^{\pi(h)}$ is the one given by Eq. (2.15). In Eq. (4.36), we have used the following formulas for the ''*analytic inlint gluing operator*'' $\langle \Omega_{\mathbf{g}}^{\varphi}((g_B,g_F))\rangle$ in each φ-mode. As for $\vec{X}$-modes, we propose that

$$\langle \Omega_{\mathbf{g}}^{\vec{X}}(g_B,g_F)\rangle = Z_1^{-5}(|p(\vec{X})=0\rangle\cdot\langle p(\vec{X})=0|)\cdot\left(\left(\prod_{h=1}^{\mathbf{g}}\int \frac{d^{10}k_h}{(2\pi)^{10}}\right) \times :\exp(C^{(2)}(\vec{X}))\cdot\exp\left(\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}\vec{k}_i\cdot C_{ih}^{(0)}\cdot\vec{k}_h+\sum_{h=1}^{\mathbf{g}}\vec{k}_h\cdot\vec{C}_h^{(1)}(\vec{X})\right):\right), \tag{4.37a}$$

with the inner products $\vec{k}_h\cdot\vec{C}_h$ and $\vec{k}_i\cdot\vec{k}_h$ defined respectively by

$$\begin{aligned}\vec{k}_h\cdot\vec{C}_h &\equiv -\sum_{\pm}\sum_{j=0}^{4} k_h^{\pm j}\cdot C_h^{\mp j} = -\sum_{\pm} k_h^{\pm 0}\cdot C_h^{\mp 0}+\sum_{j=1}^{8} k_h^{j}\cdot C_h^{j},\\ \vec{k}_i\cdot\vec{k}_h &\equiv -\sum_{\pm}\sum_{j=0}^{4} k_i^{\pm j}\cdot k_h^{\mp j} = -\sum_{\pm} k_i^{\pm 0}\cdot k_h^{\mp 0}+\sum_{j=1}^{8} k_i^{j}\cdot k_h^{j}.\end{aligned} \tag{4.37b}$$

[Hereafter, the ten-dimensional (space–time) vector space is denoted by V_{10}, so that $\vec{X}$, $\vec{k}_i$, $\vec{k}_h$, $\vec{C}_h\in V_{10}$ in Eqs. (4.37a) and (4.37b) and hereafter.] As for the $\vec{\phi}$-modes we propose that

$$\begin{aligned}\langle \Omega_{\mathbf{g}}^{\vec{\phi}\{@\}}(g_B,g_F)\rangle &\equiv \prod_{j=0}^{4}\langle \Omega_{\mathbf{g}}^{\phi^j\{@\}}(g_B,g_F)\rangle = Z_1^{-5/2}\left(\prod_{j=0}^{4}|p(\phi^j)=0\rangle\cdot\langle p(\phi^j)=0|\right)\\ &\times\left(\left(\prod_{h=1}^{\mathbf{g}}\prod_{j=0}^{4}\sum_{n_h(\phi^j)\in Z}\right):\exp\left(\sum_{j=0}^{4}C^{(2)}(\phi^j)\right)\cdot\exp\left(\sum_{j=0}^{4}\sum_{h=1}^{\mathbf{g}}\sqrt{-1}\,\pi\cdot n_h(\phi^j)\right)\right.\\ &\times\exp\left(\sum_{j=0}^{4}\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}\left(n_i(\phi^j)+\frac{1}{2}\delta_{\pi(i)}^{R}\right)C_{ih}^{(0)}\left(n_h(\phi^j)+\frac{1}{2}\delta_{\pi(h)}^{R}\right)\right)\\ &\times\left.\exp\left(\sum_{j=0}^{4}\sum_{h=1}^{\mathbf{g}}\left(n_h(\phi^j)+\frac{1}{2}\delta_{\pi(h)}^{R}\right)C_h^{(1)}(\phi^j)\right):\right),\end{aligned} \tag{4.38}$$

where the constant $\delta_{\pi(h)}^{R}$ is the one defined by

$$\delta_{\pi(h)}^{R}\equiv\begin{cases}1 & \text{for } \pi(h)=\mathrm{R},\\ 0 & \text{for } \pi(h)=\mathrm{NS}.\end{cases} \tag{4.39}$$

Furthermore, we propose the following formulas for $\varphi[=\sigma,\phi,\chi]$-modes;

$$\langle \Omega_{\mathbf{g}}^{\sigma}(g_B, g_F)\rangle = Z_1^{-1/2}(|p(\sigma)=0\rangle\cdot\langle p(\sigma)=0|\exp(+3\mathbf{g}\cdot q(\sigma))) \times\left(\left(\prod_{h=1}^{\mathbf{g}}\sum_{n_h(\sigma)\in Z}\right):\exp(C^{(2)}(\sigma))\cdot\exp\left(\sum_{h=1}^{\mathbf{g}}\sqrt{-1}\pi\cdot n_h(\sigma)\right)\right. \left.\times\exp\left(\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}n_i(\sigma)\cdot C_{ih}^{(0)}\cdot n_h(\sigma)+\sum_{h=1}^{\mathbf{g}}n_h(\sigma)\cdot C_h^{(1)}(\sigma)\right):\right), \tag{4.40}$$

$$\langle \Omega_{\mathbf{g}}^{\phi\{@\}}(g_B, g_F)\rangle = Z_1^{-1/2}(|p(\phi)=0\rangle\cdot\langle p(\phi)=0|\exp(-2\mathbf{g}\cdot q(\phi))) \times\left(\left(\prod_{h=1}^{\mathbf{g}}\sum_{n_h(\phi)\in Z}\right):\exp(C^{(2)}(\phi))\cdot\exp\left(\sum_{h=1}^{\mathbf{g}}\sqrt{-1}\pi\cdot n_h(\phi)\right)\right. \times\exp\left(\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}\left(n_i(\phi)-\frac{1}{2}\delta_{\pi(i)}^R\right)(-C_{ih}^{(0)})\left(n_h(\phi)-\frac{1}{2}\delta_{\pi(h)}^R\right)\right) \left.\times\exp\left(\sum_{h=1}^{\mathbf{g}}\left(n_h(\phi)-\frac{1}{2}\delta_{\pi(h)}^R\right)C_h^{(1)}(\phi)\right):\right) \text{with } \delta_{\pi(h)}^R \text{ being given by Eq. (4.39)}, \tag{4.41}$$

and

$$\langle \Omega_{\mathbf{g}}^{\chi}(g_B, g_F)\rangle = Z_1^{-1/2}(|p(\chi)=0\rangle\cdot\langle p(\chi)=0|\exp((\mathbf{g}+1)\cdot q(\chi))) \times\left(\left(\prod_{h=1}^{\mathbf{g}}\sum_{n_h(\chi)\in Z}\right):\exp(C^{(2)}(\chi))\cdot\exp\left(\sum_{h=1}^{\mathbf{g}}\sqrt{-1}\pi\cdot n_h(\chi)\right)\right. \left.\times\exp\left(\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}n_i(\chi)\cdot C_{ih}^{(0)}\cdot n_h(\chi)\right)\exp\left(\sum_{h=1}^{\mathbf{g}}n_h(\chi)\cdot C_h^{(1)}(\chi)\right):\right), \tag{4.42}$$

where we have used the bra state $\langle p(\chi)=0|$ satisfying Eqs. (A34)–(A35b). [Incidentally, $\exp((\mathbf{g}+1)\cdot q(\chi))$ in Eq. (4.42) has been obtained by $\exp(\mathbf{q}\cdot q(\chi))\cdot\exp(q(\chi))$, the latter of which comes from ξ_0 in Eq. (4.22).] In Eqs. (4.38) and (4.40)–(4.42), sums of $n_h(\varphi)$ [for $h=1-\mathbf{g}$ and $\varphi=\phi^j,\ \sigma,\ \phi,\ \chi$] should be taken over all *integers*. Provided that we choose cocycle factors[15] properly, we can consider in Eq. (4.38) [(4.41)] the case when $\exp(+\frac{1}{2}\phi^j)$ for $j=0-4$ [exp $(-\frac{1}{2}\phi)$] is Grassman even (even). Therefore, we have assured in Eqs. (4.38) and (4.40)–(4.42) that the *fermionic* loops have the sign opposite to the bosonic ones by inserting a sign factor $\exp(\Sigma_{h=1}^{\mathbf{g}}\sqrt{-1}\pi\cdot n_h(\varphi))$ (for $\varphi=\phi^j,\ \sigma,\ \phi,\ \chi$). [Incidentally, the proper cocycle factor gives Grassman even (odd) $\exp(-\frac{1}{2}\phi)$, which has been called the fracton (fractino).[3] Type II A superstring theory uses the fracton (fractino) in the left (right) moving modes of closed superstrings.]

In the formulas (4.37)–(4.42), $C_{ih}^{(0)}$ is given by the periodic matrix τ_{ih} as

$$C_{ih}^{(0)} \equiv 2\pi\sqrt{-1}\cdot\tau_{ih} \quad (i,h=1-\mathbf{g}), \tag{4.43}$$

while $C_h^{(1)}$ ($C^{(2)}$) for each φ-mode is expressed as the function of linear (quadratic) inlint operators on the boundary $\partial F_{D\mathbf{g}}$ [which is defined by Eqs. (6.12)–(6.14) in Ref. 5] as follows. As for $C_h^{(1)}(\varphi)$'s, we have that

$$\frac{\vec{C}_h^{(1)}(\vec{X})}{2\pi\sqrt{-1}} \equiv \oint_{\partial F_{D\mathbf{g}}}\frac{dz}{2\pi\sqrt{-1}}\sqrt{-1}\partial_z\vec{X}(z)\int_{z_0}^{z}dz'\frac{\omega_h(z')}{2\pi\sqrt{-1}} \quad (\in V_{10}) \tag{4.44}$$

and

$$\frac{C_h^{(1)}(\varphi)}{2\pi\sqrt{-1}} \equiv \oint_{\partial F_{D\mathbf{g}}} \frac{dz}{2\pi\sqrt{-1}} \partial_z \varphi(z) \int_{z_0}^{z} dz' \frac{\omega_h(z')}{2\pi\sqrt{-1}} - \varepsilon_\varphi^\phi Q(\varphi)\left(\Delta_h^{z_0} + \frac{1}{2}\right)$$

$$\text{for } \varphi = \phi^j, \sigma, \phi, \chi, \quad \text{with } \varepsilon_\varphi^\phi \text{ in (A5b)} \quad \text{and } Q(\varphi) \text{ in (2.5)}, \tag{4.45}$$

while we obtain for $C^{(2)}(\varphi)$'s that

$$C^{(2)}(\vec{X}) \equiv \frac{1}{2} \oint_{\partial F_{D\mathbf{g}}} \frac{dz}{2\pi\sqrt{-1}} \oint_{\partial F_{D\mathbf{g}}} \frac{dz'}{2\pi\sqrt{-1}} \sqrt{-1}\,\partial_z \vec{X}(z) \cdot \sqrt{-1}\,\partial_{z'} \vec{X}(z') \cdot \log\left(\frac{E(z,z')}{z-z'}\right), \tag{4.46}$$

and

$$C^{(2)}(\varphi) \equiv \varepsilon_\varphi^\phi \frac{1}{2} \oint_{\partial F_{D\mathbf{g}}} \frac{dz}{2\pi\sqrt{-1}} \partial_z \varphi(z) \oint_{\partial F_{D\mathbf{g}}} \frac{dz' 1}{2\pi\sqrt{-1}} \partial_{z'} \varphi(z') \log\left(\frac{E(z,z')}{z-z'}\right)$$
$$+ Q(\varphi) \oint_{\partial F_{D\mathbf{g}}} \frac{dz}{2\pi\sqrt{-1}} \partial_z \varphi(z) \log(\sigma(z))$$

$$\text{for } \varphi = \phi^j, \sigma, \phi, \chi, \quad \text{with } \varepsilon_\varphi^\phi \text{ in (A5b)} \quad \text{and } Q(\varphi) \text{ in (2.5)}. \tag{4.47}$$

It should be noticed that the integrations in Eqs. (4.44)–(4.47) have been carried out along the boundaries $\partial F_{D\mathbf{g}}$. [In Eq. (4.47), the sigma function $\sigma(z)$ in $\log(\sigma(z))$ is the one used in $\nu_{\mathbf{g}}(z)$ in (4.10), and it should *not* be confused with the ghosting operator σ in (A3).] The determinantal function Z_1 in the formulas (4.37)–(4.42) does *not* depend on inlint operators *but* depends only on modular parameters S_h's (for $h=1-\mathbf{g}$) used in Eq. (4.8),[19] and it has been calculated by Verlinde–Verlinde [and their result[21] will be given later by Eq. (4.66)].

For the general $z_r(\in \mathbb{C})$ *within* the fundamental region $F_{D\mathbf{g}}$ in the ''ICS **g**'' (i.e., for $z \in F_{D\mathbf{g}}$), the analytic inlint gluing operator $\langle \Omega_{\mathbf{g}}(g_B, g_F)\rangle$ in (4.36)–(4.42) gives following trace-formulas in **g**-loops. For ϕ^j's modes, we have that

$$\mathrm{Tr}_{\phi^j} \vec{R} \cdot \left(\prod_{r=1}^{N} :\exp(s_r^j \cdot \phi^j(z_r)): \langle \Omega_{\mathbf{g}}^{\phi^j\{@\}}(g_B, g_F)\rangle \right) \quad \text{for } j=0-4$$
$$= Z_1^{-1/2} \delta\left(\sum_{r=1}^{N} s_r^j\right) \exp\left(-\sum_{h=1}^{\mathbf{g}} \frac{\pi}{2}\sqrt{-1}\cdot \delta_{\pi(h)}^R\right)$$
$$\times \Theta_+^{\{@\}}\left(\sum_{r=1}^{N} s_r^j \int_{z_0}^{z_r} dz' \frac{\vec{\omega}(z')}{2\pi\sqrt{-1}} + \frac{1}{2}\cdot \vec{1} \,\middle|\, + \tau\right) \cdot \left(\prod_{\substack{r,t=1\\ r(<)t}}^{N} E(z_r, z_t)_R^{s_r^j \cdot s_t^j}\right), \tag{4.48}$$

where $\vec{\omega}$, $\vec{1} \in V_{\mathbf{g}}$. Furthermore, we also have the following trace-formulas for $\varphi[=\sigma,\phi,\chi]$-modes:

$$\mathrm{Tr}_\sigma \vec{R}\cdot\left(\prod_{r=1}^{N} :\exp(g_r\cdot\sigma(z_r)):\langle\Omega_{\mathbf{g}}^{\sigma}(g_B,g_F)\rangle\right)$$
$$=Z_1^{-1/2}\delta\left(\sum_{r=1}^{N} g_r+3\mathbf{g}-3\right)\cdot\Theta\left(\sum_{r=1}^{N} g_r\cdot\int_{z_0}^{z_r}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}+3\vec{\Delta}^{z_0}\middle|+\tau\right)$$
$$\times\left(\prod_{\substack{r,t=1\\ r(<)t}}^{N} E(z_r,z_t)_R^{g_r\cdot g_t}\right)\left(\prod_{r=1}^{N}\sigma(z_r)^{-3g_r}\right), \tag{4.49}$$

$$\mathrm{Tr}_\phi \vec{R}\cdot\left(\prod_{r=1}^{N} :\exp(f_r\cdot\phi(z_r)):\langle\Omega_{\mathbf{g}}^{\phi\{@\}}(g_B,g_F)\rangle\right)$$
$$=Z_1^{-1/2}\delta\left(\sum_{r=1}^{N} f_r-2\mathbf{g}+2\right)\cdot\exp\left(\sum_{h=1}^{\mathbf{g}}\frac{\pi}{2}\sqrt{-1}\cdot\delta^R_{\pi(h)}\right)$$
$$\times\Theta_-^{\{@\}}\left(-\sum_{r=1}^{N} f_r\int_{z_0}^{z_r}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}+2\vec{\Delta}^{z_0}+\frac{3}{2}\cdot\vec{1}\middle|-\tau\right)$$
$$\times\left(\prod_{\substack{r,t=1\\ r(<)t}}^{N} E(z_r,z_t)_R^{-f_r\cdot f_t}\right)\left(\prod_{r=1}^{N}\sigma(z_r)^{-2f_r}\right), \tag{4.50}$$

and

$$\mathrm{Tr}_\chi \vec{R}\cdot\left(\prod_{r=1}^{N} :\exp(h_r\cdot\chi(z_r)):\langle\Omega_{\mathbf{g}}^{\chi}(g_B,g_F)\rangle\right)$$
$$=Z_1^{-1/2}\delta\left(\sum_{r=1}^{N} h_r+\mathbf{g}\right)\cdot\Theta\left(\sum_{r=1}^{N} h_r\int_{z_0}^{z_r}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}+\vec{\Delta}^{z_0}\middle|+\tau\right)$$
$$\times\left(\prod_{\substack{r,t=1\\ r(<)t}}^{N} E(z_r,z_t)_R^{h_r\cdot h_t}\right)\left(\prod_{r=1}^{N}\sigma(z_r)^{-h_r}\right). \tag{4.51}$$

[Incidentally, we have $\vec{\omega}$, $\vec{\Delta}$, $\vec{1}\in V_{\mathbf{g}}$ in Eqs. (4.49)–(4.51) and hereafter.] In the trace formulas (4.48)–(4.51) [in $\mathbf{g}$-loops], we have used ''radial-ordered arguments'' [denoted by $(\dots)_R$] defined by Eq. (A12). In Eqs. (4.48) and (4.50), $\Theta_\pm^{\{@\}}(\vec{\xi}|\pm\tau)$ is defined by

$$\Theta_\pm^{\{@\}}(\vec{\xi}|\pm\tau)\equiv\Theta\begin{pmatrix}\pm\frac{1}{2}\vec{\delta}^{\{@\}}\\ \vec{0}\end{pmatrix}(\vec{\xi}|\pm\tau), \tag{4.52a}$$

where and hereafter we use the following shorthand notations:

$$\pm\frac{1}{2}\vec{\delta}^{@}=\left(\pm\frac{1}{2}\delta^R_{\pi(1)},\pm\frac{1}{2}\delta^R_{\pi(2)},\dots,\pm\frac{1}{2}\delta^R_{\pi(\mathbf{g})}\right)\quad(\in V_{\mathbf{g}})$$
$$\vec{0}=(0,0,...,0)\quad(\in V_{\mathbf{g}}),\quad \vec{1}=(1,1,...,1)\quad(\in V_{\mathbf{g}}). \tag{4.52b}$$

In order to take account of the last GSO-projection factor in Eq. (4.36), we notice that $\exp(\sqrt{-1}\cdot p_\rho)$ operates as

$$\exp(\sqrt{-1}\pi\cdot p_\rho)\cdot\Theta\begin{pmatrix}\vec{a}\\ \vec{0}\end{pmatrix}(\vec{\xi}|\pm\tau)\quad(\text{for}\ \ \rho=1-\mathbf{g})$$

$$\equiv\sum_{\{n_h\}\in Z}\exp(\sqrt{-1}\pi(n_\rho+a_\rho))$$

$$\times\exp\left(2\pi\sqrt{-1}\left(\sum_{i,h=1}^{\mathbf{g}}\frac{1}{2}(n_i+a_i)(\pm\tau_{ih})(n_h+a_h)+\sum_{h=1}^{\mathbf{g}}(n_h+a_h)\xi_h\right)\right),$$

$$=\Theta\begin{pmatrix}\vec{a}\\ \vec{0}\end{pmatrix}(\vec{\hat{\xi}}(\rho)|\tau),\tag{4.53}$$

where the following shorthand notation has been used:

$$\vec{\hat{\xi}}(\rho)\equiv(\xi_1,\ldots,\xi_{\rho-1},\xi_\rho+\tfrac{1}{2},\xi_{\rho+1},\ldots,\xi_{\mathbf{g}})\quad(\in V_{\mathbf{g}}).\tag{4.54}$$

Then, we find from Eq. (4.53) that

$$\exp\left(\sqrt{-1}\pi\left(p_\rho(\phi)+\sum_{j=0}^{4}p_\rho(\phi^j)\right)\right)\Theta_-^{\{@\}}(\vec{\xi}|-\tau)\left(\prod_{j=0}^{4}\Theta_+^{\{@\}}(\vec{\xi}^j|+\tau)\right)$$

$$=\Theta_-^{\{@\}}(\vec{\hat{\xi}}(\rho)|-\tau)\cdot\left(\prod_{j=0}^{4}\Theta_+^{\{@\}}(\vec{\hat{\xi}}^j(\rho)|+\tau)\right)\quad\text{for}\ \ \rho=1-\mathbf{g}.\tag{4.55}$$

For any $z_r\in F_{D\mathbf{g}}$, we can similarly derive the following trace-formula [for $\vec{X}$-modes]:

$$\mathrm{Tr}_{\vec{X}}\vec{R}\cdot\left(:\exp\left(\sum_{r=1}^{N}\sqrt{-1}\cdot\vec{p}_r\cdot\vec{X}(z_r)\right):\langle\Omega_{\mathbf{g}}^{\vec{X}}(g_B,g_F)\rangle\right)$$

$$=Z_1^{-5}(2\pi)^{10}\cdot\delta^{10}\left(\sum_{r=1}^{N}\vec{p}_r\right)\left(\left(\prod_{h=1}^{\mathbf{g}}\int\frac{d^{10}k_h}{(2\pi)^{10}}\right)\right.$$

$$\left.\times\exp\left(\sum_{i,h=1}^{\mathbf{g}}\pi\sqrt{-1}\cdot\vec{k}^i\cdot\tau_{ih}\cdot\vec{k}^h\right)\cdot\langle\mathrm{mod};\vec{k}|:\exp\left(\sum_{r=1}^{N}\sqrt{-1}\cdot\vec{p}_r\cdot\vec{X}(z_r)\right):|\mathrm{mod};\vec{k}\rangle\right).\tag{4.56}$$

In Eq. (4.56), both i and h (for $i,h=1-\mathbf{g}$) denote the labels of the ''glued lines'' in Eq. (4.1). Furthermore, we have used in Eq. (4.56) the following *function* $\langle\mathrm{mod};\vec{k}|\ldots|\mathrm{mod};\vec{k}\rangle$ defined by

$$\langle\mathrm{mod};\vec{k}|:\exp\left(\sum_{r=1}^{N}\sqrt{-1}\cdot\vec{p}_r\cdot\vec{X}(z_r)\right):|\mathrm{mod};\vec{k}\rangle$$

$$\equiv\exp\left(\sum_{r=1}^{N}\sum_{h=1}^{\mathbf{g}}\vec{p}_r\cdot\vec{k}_h\int_{z_0}^{z_r}dz'\ \omega_h(z')+\sum_{\substack{r,t=1\\ r(<)t}}^{N}\vec{p}_r\cdot\vec{p}_t\log\left(\frac{E(z_r,z_t)}{z_r-z_t}\right)\right),\tag{4.57}$$

which leads to the following expectation value of the *overally radial-ordered product*:

$$\langle \mathrm{mod};\vec{k}|\vec{R}\cdot\left(\prod_{r=1}^{N} :\exp(\sqrt{-1}\cdot\vec{p}_r\cdot\vec{X}(z_r)):\right)|\mathrm{mod};\vec{k}\rangle$$
$$\equiv\exp\left(\sum_{r=1}^{N}\sum_{h=1}^{\mathbf{g}}\vec{p}_r\cdot\vec{k}_h\int_{z_0}^{z_r}dz'\,\omega_h(z')\right)\times\left(\prod_{\substack{r,t=1\\ r(<)t}}^{N}E(z_r,z_t)_R^{\vec{p}_r\cdot\vec{p}_t}\right). \tag{4.58}$$

[We notice that $\vec{X},\vec{p}_r,\vec{p}_t,\vec{k}_h\in V_{10}$ in Eqs. (4.56)–(4.58) and hereafter.] Similarly, the trace-formula for $\vec{\phi}$-modes are given as follows:

$$\mathrm{Tr}_{\vec{\phi}}\vec{R}\cdot\left(:\exp\left(\sum_{r=1}^{N}\sum_{j=0}^{4}s_r^j\cdot\phi^j(z_r)\right):\langle\Omega_{\mathbf{g}}^{\vec{\phi}\{@\}}(g_B,g_F)\rangle\right)$$
$$=Z_1^{-5/2}\cdot\delta_K^5\left(\sum_{r=1}^{N}\vec{s}_r\right)\left(\prod_{h=1}^{\mathbf{g}}\sum_{\vec{n}_h}\right)\left(\exp\left(\sum_{i,h=1}^{\mathbf{g}}\pi\sqrt{-1}\cdot\vec{n}_i^{\pi(i)}\cdot\tau_{ih}\cdot\vec{n}_h^{\pi(h)}\right)\right.$$
$$\left.\times\exp\left(\sum_{j=0}^{4}\sum_{h=1}^{\mathbf{g}}\sqrt{-1}\pi\cdot n_h(\phi^j)\right)\cdot\langle\mathrm{mod};\vec{n}|:\exp\left(\sum_{r=1}^{N}\sum_{j=0}^{4}s_r^j\cdot\phi^j(z_r)\right):|\mathrm{mod};\vec{n}\rangle\right), \tag{4.59}$$

where we have introduced the following *function* $\langle\mathrm{mod};\vec{n}|\ldots|\mathrm{mod};\vec{n}\rangle$ defined by

$$\langle\mathrm{mod};\vec{n}|:\exp\left(\sum_{r=1}^{N}\sum_{j=0}^{4}s_r^j\cdot\phi^j(z_r)\right):|\mathrm{mod};\vec{n}\rangle$$
$$\equiv\exp\left(\sum_{r=1}^{N}\sum_{h=1}^{\mathbf{g}}\vec{n}_h^{\pi(h)}\cdot\vec{s}_r\int_{z_0}^{z_r}dz'\,\omega_h(z')+\sum_{\substack{r,t=1\\ r(<)t}}^{N}\vec{s}_r\cdot\vec{s}_t\cdot\log\left(\frac{E(z_r,z_t)}{z_r-z_t}\right)\right), \tag{4.60}$$

inner products $\vec{n}_h^{\pi(h)}\cdot\vec{s}_r$ and $\vec{s}_r\cdot\vec{s}_t$ being defined respectively by

$$\vec{n}_h^{\pi(h)}\cdot\vec{s}_r\equiv\sum_{j=0}^{4}(\vec{n}_h^{\pi(h)})^j\cdot s_r^j=\sum_{j=0}^{4}\left(n_h(\phi^j)+\frac{1}{2}\delta_{\pi(h)}^R\right)\cdot s_r^j\quad\text{for }\ n_h(\phi^j)\in Z,$$

and

$$\vec{s}_r\cdot\vec{s}_t\equiv\sum_{j=0}^{4}s_r^j\cdot s_t^j. \tag{4.61}$$

[The sum over $\vec{n}_h$ in Eq. (4.59) means the summation over all integers $n_h(\phi_j)$'s.] Therefore, we find from Eq. (4.60) that the expectation value of the *overally radial-ordered product* is given by the following formula:

$$\langle\mathrm{mod};\vec{n}|\vec{R}\cdot\left(\sum_{r=1}^{N}:\exp\left(\sum_{j=0}^{4}s_r^j\cdot\phi^j(z_r)\right):\right)|\mathrm{mod};\vec{n}\rangle$$
$$\equiv\exp\left(\sum_{r=1}^{N}\sum_{h=1}^{\mathbf{g}}\vec{n}_h^{\pi(h)}\cdot\vec{s}_r\int_{z_0}^{z_r}dz'\,\omega_h(z')\right)\cdot\left(\prod_{\substack{r,t=1\\ r(<)t}}^{N}E(z_r,z_t)_R^{\vec{s}_r\cdot\vec{s}_t}\right). \tag{4.62}$$

[The five-dimensional vector space will be denoted by V_5, so that we have $\vec{\phi},\vec{n}_h,\vec{s}_r,\vec{s}_t\in V_5$ in Eqs. (4.59)–(4.62) and hereafter.]

The total factor $Z_1^{-9}=Z_1^{-5}\cdot Z_1^{-5/2}\cdot(Z_1^{-1/2})^3$ [contributed from Eqs. (4.56), (4.59), and (4.49)–(4.51)] is quite important, since it gives the complicate integration measure factor in the following expression:

$$(N_B,N_F)_{\mathbf{g}}\equiv {}^{\mathcal{M}}\langle S_{\mathbf{g}}^{\mathcal{C}}[p(1),\ldots,p(N)]|\cdot\left(\prod_{r=1}^{N}\mathcal{G}_r(0)\right)\cdot\left(\prod_{r=1}^{N}|\mathcal{Q}_r=0\rangle_r\right)$$
$$=\sum_{\mathrm{SSD}}C_{\mathrm{SSD}}\left(\int_0^\infty\prod_{I=1}^{N+2\mathbf{g}-3}dT_I\right)\left(\int_0^\infty\prod_{h=1}^{\mathbf{g}}dT_{\gamma^h}\right)F(\{T_I\},\{T_{\gamma^h}\}), \tag{4.63}$$

where the summation is over all superstring (Feynman) diagrams (SSDs), C_{SSD}'s being constants determined from the Wick's expansion (3.50). On the other hand, the integrand $F(\{T_I\},\{T_{\gamma^h}\})$ is the one given by the term on the right-hand side of Eq. (4.33), $\mathcal{G}(r;\text{``ICS}\,\mathbf{g}\text{''})$'s being given as follows. In calculating $(N_B,N_F)_{\mathbf{g}}$ in (4.63) with the help of the trace-formulas (4.48)–(4.62), we use the *physical* NS state in 1 picture which is given by Eq. (D5) with (D1), as well as the *physical* R state in $\frac{1}{2}$ picture which is given by Eq. (D12). Therefore, $\mathcal{G}_r(0)$'s and $\mathcal{G}(r;\text{``ICS}\,\mathbf{g}\text{''})$'s are those given as follows. In Eq. (4.33), we use that

$$\mathcal{G}_r(0)\equiv\begin{cases}X_{\pm r}^{1/2}:\exp(+\sigma_r(0))::\exp(-\phi_r(0)):V_r^{0b}(0) & \text{for}\ \ \pi(r)=\mathrm{NS},\\ :\exp(+\sigma_r(0))::\exp(-\tfrac{1}{2}\phi_r(0)):V_r^{1f}(0)\cdot S_{\{h\},r}(0) & \text{for}\ \ \pi(r)=\mathrm{R}\end{cases} \tag{4.64}$$

and

$$\mathcal{G}(r;\text{``ICS}\ \ \mathbf{g}\text{''})$$
$$\equiv\begin{cases}X_{\pm}^{1/2}(r;\text{``ICS}\ \ \mathbf{g}\text{''}):\exp(+\sigma(Z_{r\mathbf{g}}))::\exp(-\phi(Z_{r\mathbf{g}})):V^{0b}(Z_{r\mathbf{g}}) & \text{for}\ \ \pi(r)=\mathrm{NS}\\ :\exp(+\sigma(Z_{r\mathbf{g}}))::\exp(-\tfrac{1}{2}\phi(Z_{r\mathbf{g}})):V^{1f}(Z_{r\mathbf{g}})\cdot S_{\{h\}}(Z_{r\mathbf{g}}) & \text{for}\ \ \pi(r)=\mathrm{R}.\end{cases} \tag{4.65}$$

[All operators in Eq. (4.65) are *inlint* operators, $Z_{r\mathbf{g}}$'s being punctures in Samuel $\mathcal{FE}$ (4.7).] Verlinde and Verlinde[21] has calculated the determinatal function Z_1 (up to a pure numerical constant C) and their result is given by

$$Z_1^{3/2}=C\cdot\frac{\Theta\left(\sum_{t=1}^{\mathbf{g}}\int_{z_0}^{z_t}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}-\int_{z_0}^{Z}dz'\frac{\vec{\omega}(z')}{2\pi\sqrt{-1}}-\vec{\Delta}^{z_0}\middle|\tau\right)}{(\det_{\mathbf{g}\times\mathbf{g}}\omega_s(z_t))\left(\prod_{t=1}^{\mathbf{g}}E(z_t,Z)\right)\cdot\sigma(Z)}\left(\prod_{1\leqslant t<s\leqslant g}E(z_t,z_s)\right)\left(\prod_{t=1}^{\mathbf{g}}\sigma(z_t)\right). \tag{4.66}$$

Samuel has explicitly shown[19] that the determinantal function (4.66) *actually* depends *only* on $(3\mathbf{g}-3)$ modular parameters [in $\mathrm{SL}(2R)$ group elements $(S_1,S_2,\ldots,S_{\mathbf{g}})$], which are those used in S-$\mathcal{FE}$ (4.7).

V. CONCLUSIONS AND DISCUSSIONS

In this paper, we have formulated (BRST-*invariant*) open quantum superstring field theory in the "$\mathcal{B}_0$-gauge." Since we use only *nonlocal* (i.e., we do *not* use *local*) picture-changing operators in our theory, there does not exist any singularity caused by colliding[10] of *local* picture-changing operators. Our QSFT has been analyzed by applying the method[5] which has been successfully used in calculating physical scattering amplitudes in open quantum bosonic string field theory (open QBFT) in the "$\mathcal{B}_0=0$ gauge." Hereafter, we summarize our main results obtained in this paper. In Sec. I, open QSFT in the "$\mathcal{B}_0$-gauge" is described by using the open NS (R) fieldino (1.3) in picture 1 ($\frac{1}{2}$). In the beginning, open QSFT is proposed to be given by the gauge-fixed action $S_{\mathrm{GF}}(\Psi)$" in (1.18) with the kinetic term $S_{\mathrm{KIN}}(\Psi)$ in (1.19) and the interaction term

$S_{\rm INT}(\Psi)$ in (1.20), which has been given by using NS (R) fieldinos $|\Psi(1)\rangle$'s in picture 1 [$|\Psi(\frac{1}{2})\rangle$'s in picture$\frac{1}{2}$] defined by Eq. (1.3). Bose fields ϕ_B's [in the fieldinos $|\Psi^{\rm NS}\rangle$'s in (1.1)] and fermi fields ψ_F's [in the fieldinos $|\Psi^R\rangle$'s in (1.2)] are *quantized* by imposing the operator product expansion (1.25) among fieldinos, where the contraction among open NS (R) fieldinos is given by the propagator (1.26) [(1.27)] of open NS (R) superstring. The propagator (1.26) involves the symmetrization among $X^{1/2}_{+,\gamma}\cdot X^{1/2}_{-,\gamma}$ and $X^{1/2}_{-,\gamma}\cdot X^{1/2}_{+,\gamma}$, so that it can be *rewritten* [with the help of the "commutability" (C39)] into the expression (3.1). Physical scattering amplitudes among N_B bosonic (N_F fermionic) particles are proposed to be given by the formula (1.22), which corresponds to the LSZ reduction formula in QFT.[16] [Throughout our analyses on open QSFT in the "$\mathcal{B}_0$-gauge," we have used the ghosting number G, the fracting number F, the hilberting number H, and the picturing number P defined by Eqs. (1.28)−(1.31).] In Sec. II, GM-$\mathcal{FE}$ (2.1) is used for the purpose of defining the "inlayed coordinate system s(*phere*) (ICS s) (with the help of which we can calculate physical scattering amplitudes in 0-loop). We have defined the rth disk coordinate w_r in (2.2) and used the rth inlayed coordinate[5] $z_{rs}(w_r)$ (to be used in the r_{th} punctured ring domain in the "ICS s"). We construct the r_{th} inlaying operator $W_r[z_{rs}(w_r)]$ in (2.6) (for $r=1-N$) by the formulas (2.3)–(2.5), which is the functional of the r_{th} *external* operators $\varphi_r(w_r;+)$'s, as well as the *inlint* operators $\varphi(z_{rs}(w_r))$ (within the r_{th} punctured ring domain). Then, the inlaying N-vertex functions ${}_s\langle IV(1,2,...,N)|$ (in the "ICS s") is constructed by the formulas (2.7)–(2.9). Furthermore, we find the inlaying identities (2.10) [which are simply expressed by Eq. (2.11)]. Finally, the N-vertex functino ${}_s\langle V(1,2,...,N)|$ (in the "ICS s") is constructed by the formula (2.13), where we have used the *inlint* zero-mode ξ_0. In the special case when the "ICS s" is just equal to the "inlayed coordinate system m(*idpoint*)" (ICS m) (where there does not exist any *un*punctured ring domain), the *elementary* N-vertex functino $\langle \nu_{\mathcal{S}}(1,2,...,N)|$ is given by the *cycle-symmetric* ${}_m\langle V(1,2,...,N)|$ in (2.14). [*Elementary* vertex functinos are to be used in the action (1.18)–(1.20), and it can be explicitly constructed by using the inlayed coordinates given by Eq. (E34).] The formula (2.16) shows that the *small* gluing vertex function $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ in (2.16) (which is *antisymmetric* under $\gamma\leftrightarrow\delta$) can be obtained from the *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ in (2.17)–(2.19). (The word "*small*" means "being without ξ_0-mode.") Then, we can prove the gluing theorem (2.20) [which is useful in calculating tree amplitudes], with the help of the similar techniques[5] to those used in open QBFT. In Sec III, we use that the contraction (1.26) [(1.27)] among open NS (R) fieldinos is just equal to Eq. (3.1) [(3.2)], which is referred to as the propagator of the open NS (R) superstring. With the help of Wick's theorem,[16] we have given the operator product expansion (3.3) among fieldinos, where (un)modified ${}^{(\mathcal{M})}\langle S\cdots]|$'s are terms obtained by various contractions which can be represented by *superstring* (Feynman) *diagrams*, so that they do *not* involve any quantized bose field ϕ_B as well as any fermi field ψ_F in ten-dimensional space–time. The *connected* part of ${}^{(\mathcal{M})}\langle S_{\mathbf{g}}[\cdots]|$ is denoted by ${}^{(\mathcal{M})}\langle S^{\mathcal{C}}_{\mathbf{g}}[\cdots]|$. [See Eqs. (3.3a) and (3.3b).] Unfortunately, the nonvanishing term (3.18) shows that the interaction term $S_{\rm INT}(\Psi)$ in (1.20) does not give the BRST-invariant amplitude, since the term (3.18) is nonvanishing. In order to obtain the BRST-invariant part out from $\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\ldots,p(4)]|$, we must subtract the proper counter term $\langle \Delta S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\ldots,p(4)]|$ which can be determined by Eq. (3.18b). Thus obtained result ${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\ldots,p(4)]|$ in (3.19) is shown to be BRST invariant. [See Eq. (3.20).] The subtracting process in Eq. (3.19) can be induced by the *effect* due to the counter term in the modified action $S^{\mathcal{M}}_{\rm INT}](4,0)$ in (3.21). We have proved that these procedures in obtaining the BRST-*invariant* amplitude ${}^{(\mathcal{M})}\times\langle S^{\mathcal{C}}_{\mathbf{g}=0}[p(1),\ldots,p(4)]|$ can be carried out to any order of perturbation. Our analyses and results on these procedures have been finally summarized in the *Theorem* [i.e., Eq. (3.56)]. In particular, the counter term $\Delta S_{\rm INT}(\Psi;n)$ in $S^{\mathcal{M}}_{\rm INT}(\Psi)$ in (3.55) is determined by solving Eq. (3.53). We have found that the "*amputated N-scatts* in **g**-loops" ${}^{\mathcal{M}}\langle S^{\mathcal{C}}_{\mathbf{g}}[p(1),\ldots,p(N)]|$ in Eq. (3.50) can be calculated by using unmodified interaction term $S_{\rm INT}(\Psi)$ in (1.20), provided that any propagator is *effectively* modified accordingly to Eq. (3.57). In Sec. IV, the *physical* scattering amplitude $(N_B,N_F)_{\mathbf{g}}$ in (3.60) among N_B bosonic (N_F fermionic) particles have been calculated by using the method developed in our previous paper on QBFT. First we use the S-$\mathcal{FE}$ (4.7) to describe the "inlayed coordinate system in *genus* **g**" (ICS **g**). The function $\nu_{\mathbf{g}}(z_{\mathbf{g}})$ in (4.10) can be chosen to satisfy the **g**-*conditions* (4.8) by imposing **g**-*constraints* (4.11) among modular parameters in the function $\nu_{\mathbf{g}}(z_{\mathbf{g}})$ in $\mathcal{FE}$ (4.7). Then S-$\mathcal{FE}$ (4.7) in the ''ICS **g**'' can describe the Riemann surface $\mathcal{R}'$ having $B=\mathbf{g}+1$ boundaries. Then, we have introduced the ''*analytic inlint gluing operator*'' $\langle\Omega_{\mathbf{g}}(g_B,g_F)\rangle$ in (4.34), with the help of which the term on the left-hand side of Eq. (4.33) can be calculated by the *trace* on the right-hand side of Eq. (4.33). Thus $(N_B,N_F)_{\mathbf{g}}$ in (3.62) can be calculated, since the term on the right-hand side of Eq. (4.33) [substituted with inlint operators (4.65)] can be calculated by using formulas (4.36)–(4.47) for $\langle\Omega_{\mathbf{g}}(g_B,g_F)\rangle$ in (4.34). [The trace in these calculations can be found by using trace-formulas (4.48)–(4.62) in **g**-loops]. In Appendix A, we define[9] various (*external* as well as *inlint*) operators used in the present paper, i.e., the string coordinate $X^{\pm j}$, the jth spinning operator ϕ^j, the ghosting operator σ, the fracting operator ϕ, the hilberting operator χ [given by Eq. (A3)], the anti-ghostino $\mathcal{B}$ in (A16), the ghostino $\mathcal{C}$ in (A17), the hilbertino ξ in (A18), the anti-hilbertino η in (A19), the anti-ghoston β in (A20), the ghoston γ in (A21), the string coordino $\Psi^{\pm j}$ in (A22), and the *FMS* spinor $S_{\{h\}}$ in (A24). The normal ordering : [the contraction ⌐¬] in the bo-representation is defined by Eq. (A14) [(A15)], while the normal ordering $: :_\pi$ [the contraction ⌐ $\boldsymbol{\pi}$ ¬] in the $\pi(=\mathrm{NS,R})$-representation is defined by Eq. (A47) [(A43)–(A46)]. The standard ket states $|p(\varphi)=0\rangle$'s, the standard bra states $\langle q(\varphi)=0|$'s, and the dual standard bra states $\langle p(\varphi)=0|$'s are those states satisfying conditions (A6), (A7), and (A9), respectively. In Appendix B, we define the stress operator T_r^π in (B4) [T_r in (B8)] and the BRST currentino $\mathcal{J}_r^\pi$ in (B17) [$\mathcal{J}_r$ in (B21)] in the π [bo]-representation. In the case when the dimension D of space–time is just equal to 10, these three operators T_r^{NS}, T_r^{R}, and T_r are shown to be equal to each other. [See Eq. (B9).] On the other hand, *three* BRST currentinos $\mathcal{J}_r^{\mathrm{NS}}$, $\mathcal{J}_r^{\mathrm{R}}$, and $\mathcal{J}_r$ satisfy Eqs. (B25) and (B26), so that they are *not* equal to each other even for $D=10$. *However*, in the case $D=10$, the ''BRST chargino in the π-representation'' [denoted by $\mathcal{Q}_r^{\mathrm{NS}}$ and $\mathcal{Q}_r^{\mathrm{R}}$] and the ''BRST chargino in the bo-representation'' [denoted by $\mathcal{Q}$] are just equal to each other, on account of the integration in the definitions (B27) and (B28). [See Eq. (B29).] We also prove in the case $D=10$ the inlaying identity (B11) [(B33)] for stress operators T's (BRST charginos $\mathcal{Q}$'s). Thus, we can prove the ''special conservation of the total BRST chargino'' (B34), the ''nilpotency'' (B38), and the ''contacting formula'' (B38b). In Appendix C, we define the *local* (inverse) picture-changing operator $X(Y)$ by Eqs. (C3)–(C7) [Eq. (C8)]. Furthermore, (*non-local*) picture-changing operators X^p (C14) (for any $p\in Z$, $Z+\frac{1}{2}$) and $X^p_\pm$ in (C25) (for any $p\in Z+\frac{1}{2}$) are explicitly given respectively by formulas (C15) and (C27). In particular, *nonlocal* operators $X^0[X^{1/2}_\pm]$ have been used for defining the projection operator $P_r(\frac{1}{2})[P_r(1)]$ in (1.7). We have also given various formulas (C22)–(C24) [(C32)–(C40)] satisfied by $X^0[X^{1/2}_\pm]$. In Appendix D, external *physical* NS (R) particles are given[14] by Eqs. (D1) and (D5) [(D12) and (D13)], which involve *physical* vertex operators $V^{nb}(V^{nf})$ for $n=0,1$ in the NS (R) sector. These results are based on the operator product expansions (OPEs)[14] (D24)–(D26) [(D28)–(D31)] among physical vertex operators in the NS (R) sector and the stress (stressino) operator. [Since we essentially use these OPEs, we have to use the *external* stress operator $T_r^{\mathrm{NS}}(T_r^{\mathrm{R}})$ in (B4) and *external* BRST charginos $\mathcal{Q}_r^{\mathrm{NS}}(\mathcal{Q}_r^{\mathrm{R}})$ in (B27) in the NS (R)-representation. On the other hand, the stress operator T_r in (B8) and the BRST chargino $\mathcal{Q}_r$ in (B28) in the bo-representation are also useful in open QSFT, since they are inlayed into *inlint* operators T and $\mathcal{Q}$ in the ''ICS *s*'' as well as the ''ICS **g**.'' In Appendix E, we construct the *small* gluing vertex function $|\mathcal{V}_{\mathcal{S}}^{\chi}(\gamma,\delta)\rangle$ in (E12) in $\xi\eta$-mode [*large* gluing vertex functino $|\nu_{\mathcal{L}}^{\chi}(\ldots)\rangle$ in (E18) in $\xi\eta$-mode]. Thus we find that the *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ in (E30) is related with the *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ in (E32) by the formula (E31). This $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ in (E30) satisfies the gluing *identity* (E29) and the gluing *relation* (E41) in the *small* Hilbert space, while $|V_L(\gamma,\delta)\rangle$ in (E32) satisfies the gluing relation (E44) in the *large* Hilbert space. It should be noticed that we have used the *small* gluing vertex function $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ in the gluing theorem (2.20). Finally, elementary vertex functinos have been constructed by using the inlayed coordinates given by Eq. (E34) in the ''ICS *m*,'' which satisfy the GJ-$\mathcal{FE}$ (E36). Then, applying the gluing theorem to these elementary vertex functinos, we have derived various useful formulas (E37)–(E40).

In our previous paper,[5] we have derived the generating functional (7.28) which generates *all* physical scattering amplitudes in QBFT. We should make *two* following corrections in ''Eqs. (7.22) and (7.29) of Ref. 5,'' respectively; Using notations in Ref. 5, we have that

$$
\begin{aligned}
&{}_k\langle \mathrm{mod;tr}|:\exp\left(\sum_{r=1}^{N}\sum_{\mu=1}^{24} i\cdot \oint \frac{dw_r}{2\pi i}P_r^{\mu\dagger}(w_r)\cdot X^{\mu}(z_r(w_r))\right):|\mathrm{mod;tr}\rangle_k \\
&\equiv \exp\left(\sum_{\mu=1}^{24}\sum_{r=1}^{N}\sum_{i=1}^{g} k_i^{\mu}\cdot \oint \frac{dw_r}{2\pi\cdot\sqrt{-1}}P_r^{\mu\dagger}(w_r)\int_{z_0}^{z_r(w_r)}\omega_i\right. \\
&\quad +\sum_{\mu=1}^{24}\sum_{r=1}^{N}\frac{1}{2}\oint\frac{dw_r}{2\pi i}\oint\frac{dw_r'}{2\pi i}P_r^{\mu\dagger}(w_r)\cdot P_r^{\mu\dagger}(w_r')\cdot\log\frac{E(z_r(w_r),z_r(w_r'))}{z_r(w_r)-z_r(w_r')} \\
&\quad \left.+\sum_{\mu=1}^{24}\sum_{\substack{r,s=1\\ r(<)s}}^{N}\oint\frac{dw_r}{2\pi i}\oint\frac{dw_s}{2\pi i}P_r^{\mu\dagger}(w_r)\cdot P_s^{\mu\dagger}(w_s)\cdot\log\frac{E(z_r(w_r),z_s(w_s))}{z_r(w_r)-z_s(w_s)}\right)
\end{aligned}
\tag{5.1}
$$

and

$$
\begin{aligned}

&\left.+\sum_{\mu=1}^{24}\sum_{r=1}^{N}\frac{1}{2}\oint\frac{dw_r}{2\pi i}\oint\frac{dw_r'}{2\pi i}P_r^{\mu\dagger}(w_r)\cdot P_r^{\mu\dagger}(w_r')\cdot\log\frac{E(\tilde{z}_r(w_r;k^{+}),\tilde{z}_r(w_r';k^{+}))}{w_r-w_r'}\right).
\end{aligned}
\tag{5.2}
$$

Although we have not given in this paper the results in QSFT (to be obtained by applying the method in Sec. VII of Ref. 5), these results might be straightforwardly (but tediously) obtained, if we use the generating functional of physical vertex operators in each NS and R sector.[14] In the following, we shall briefly comment how the *physical* scattering amplitudes $(N_B,N_F)_{\mathbf{g}}$ in (4.63) can be calculated. First we consider the case when the integrand $F(\{T_I\},\{T_{\gamma^h}\})$ in Eq. (4.63) (in **g**-loops) is given by the *superstring* (Feynman) *diagram* composed of $I_B(I_F)$ propagators and $V_B(V_F)$ interaction vertices among NS–NS–NS (R–R–NS). These numbers are related to each others as follows:

$$2I_B+N_B=3V_B+V_F \tag{5.3}$$

and

$$2I_F+N_F=2V_F. \tag{5.4}$$

In any *connected* superstring (Feynman) diagrams in **g**-loops, we have the following relation among I's and V's:

$$V_B+V_F-1=I_B+I_F-\mathbf{g}. \tag{5.5}$$

In order for $(N_B,N_F)_{\mathbf{g}}$ to give nonvanishing physical amplitudes, the *total* quantum number K [being defined by Eq. (1.30)] of $F(\{T_I\},\{T_{\gamma^h}\})$ should satisfy the following *three* conditions (''conservation laws in **g**-loops''):

$$(G,F,H)=(3-3\mathbf{g},-2+2\mathbf{g},-\mathbf{g}). \tag{5.6}$$

For simplicity of notations, $F(\{T_I\},\{T_{\gamma^h}\})$ in (4.63) will be *shortly* denoted by

$$F(\{T_I\},\{T_{\gamma^h}\})\cong \mathrm{Tr}(\langle \Omega_{\mathbf{g}}((g_B,g_F))\rangle \cdot (X\cdot \exp(\sigma-\phi)\cdot V^{0b})^{N_B} \times(\exp(\sigma-1/2\cdot\phi)\cdot V^{1f}\cdot S_h)^{N_F}(\overline{Y}\cdot Y)^{V_B}\cdot(\overline{Y})^{V_F}(\mathcal{B}_0\cdot X\cdot X)^{I_B}\cdot(\mathcal{B}_0\cdot X)^{I_F}\cdot(\eta_0)^{\mathbf{g}}), \tag{5.7}$$

where $(X\cdot\exp(\sigma-\phi)\cdot V^{0b})^{N_B}$ *symbolically* represents N_B physical NS states in 1 picture, while $(\exp(\sigma-\frac{1}{2}\cdot\phi)\cdot V^{1f}\cdot S_h)^{N_F}$ *symbolically* represents N_F physical R states. [See Eq. (4.65).] In the following, we can count the total quantum numbers K's of $F(\{T_I\},\{T_{\gamma^h}\})$ in (5.7). We first notice that there always appears one factor $e^{+\chi}$ from each $\overline{Y}(Y)$ [see Eqs. (4.30) and (C8)], so that $(\overline{Y}\cdot Y)^{V_B}\cdot(\overline{Y})^{V_F}$ gives the factor $\exp((2V_B+V_F)\chi)$ in total, while $(\eta_0)^{\mathbf{g}}$ gives the factor $e^{-\mathbf{g}\chi}$. Then, since the condition $H=-\mathbf{g}$ must be satisfied for the term (5.7) to be nonvanishing, there should appear the factor $(e^{-\chi})^{2V_B+V_F}$ from $(X\cdot X)^{I_B}\cdot(X)^{I_F}$. On the other hand, each X involves the component having the factor $\mathcal{F}^{(\mathcal{B}\gamma)}\propto e^{-\chi}$, as seen from Eqs. (C15) and (C27). By noticing that this component of X has the same quantum numbers as those of $X^{(-1)}$ in (C7), this component of X will hereafter be *symbolically* expressed by $X^{(-1)}$. Thus, the nonvanishing contribution in the term (5.7) comes from

$$\begin{aligned}F(\{T_I\},\{T_{\gamma^h}\})&\\ \propto X^{N_B+2I_B+I_F-2V_B-V_F}&\cdot\exp((-N_B-\tfrac{1}{2}\cdot N_F)\phi)\cdot\exp((N_B+N_F-I_B-I_F)\sigma)\\ &\cdot\exp(-\mathbf{g}\cdot\chi)(\overline{Y}\cdot Y\cdot X^{(-1)}\cdot X^{(-1)})^{V_B}\cdot(\overline{Y}\cdot X^{(-1)})^{V_F}.\end{aligned} \tag{5.8}$$

It is remarkable that the last two terms on the right-hand side of Eq. (5.8) do *not* have any quantum number (G,F,H). Therefore, the last four terms on the right-hand side of Eq. (5.8) satisfy the *two* conditions $G=3-3\mathbf{g}$ and $H=-\mathbf{g}$ by themselves, because of the relation

$$N_B+N_F-I_B-I_F=3-3\mathbf{g}, \tag{5.9}$$

which can be derived by substituting the relations (5.3) and (5.4) into (5.5). Thus, the first term on the right-hand side of Eq. (5.8) should have *only* the nonvanishing fracting number F (G and H being equal to zeros). This is possible only in the case when we use the X's component involving the factor $\mathcal{F}^{(\vec{X}\cdot\vec{\Psi})}$, as seen from Eqs. (C15) and (C27). [Since this component of the *picture-changing operator* X has the same quantum number as those of $X^{(0)}$ in (C6), this component will hereafter be *symbolically* expressed by $X^{(0)}$.] Our conclusion at this stage is that we should use only the component $X^{(0)}$ in the first term of Eq. (5.8), so that the first *two* terms on the right-hand side of Eq. (5.8) lead [with the help of Eqs. (5.3)–(5.5)] to

$$\begin{aligned}(X^{(0)})^{N_B+2I_B+I_F-2V_B-V_F}&\cdot\exp((-N_B-\tfrac{1}{2}\cdot N_F)\phi)\\ &\propto\exp((2I_B+I_F-2V_B-V_F-1/2\cdot N_F)\phi)\\ &=\exp(\tfrac{2}{3}(I_B+I_F-N_B-N_F)\phi)\\ &=\exp((-2+2\mathbf{g})\phi).\end{aligned} \tag{5.10}$$

Equation (5.10) shows that the condition $F=-2+2\mathbf{g}$ can be satisfied. Thus *all three* conditions (5.6) can be satisfied by some terms in $F(\{T_I\},\{T_{\gamma^h}\})$ something like

$$F(\{T_I\},\{T_{\gamma^h}\})\cong \mathrm{Tr}(\langle\Omega_{\mathbf{g}}((g_B,g_F))\rangle\cdot(\exp(\sigma-\phi)\cdot V^{0b})^{N_B}$$
$$\times(\exp(\sigma-\tfrac{1}{2}\cdot\phi)\cdot V^{1f}\cdot S_h)^{N_F}\cdot(X^{(0)})^{N_B+2I_B+I_F-2V_B-V_F}(\overline{Y}\cdot Y\cdot X^{(-1)}\cdot X^{(-1)})^{V_B}$$
$$\times(\overline{Y}\cdot X^{(-1)})^{V_F}(\mathcal{B}_0)^{I_B+I_F}\cdot(\eta_0)^{\mathbf{g}}), \tag{5.11}$$

where the factor $\exp(\sigma-\phi)\cdot V^{0b}[\exp(\sigma-\frac{1}{2}\cdot\phi)\cdot V^{1f}\cdot S_h]$ is the one in the physical NS state (D1) in 0 picture [R state (D12) in $\frac{1}{2}$ picture], while we have *symbolically* used the abovementioned $X^{(-1)}[X^{(0)}]$. Since any Θ^{NS} and Θ^{R} [in the *modified* propagator (3.37)] give *effectively* one $X^{(+1)}$ (instead of $X^{(0)}$ or $X^{(-1)}$), they do not contribute to the amplitude (5.11).

APPENDIX A: DEFINITIONS OF VARIOUS EXTERNAL AND INLINT OPERATORS

In this Appendix, we shall give the definition of various operators φ $(=X^{\pm j},\ \phi^j,\ \sigma,\ \phi,\ \chi,\ \text{for}\ j=0-4)$ introduced by Friedan–Martinec–Schenker[9] and used in this paper. In calculating physical scattering amplitudes (N_B,N_F) in (1.22) among N_B bosonic and N_F fermionic physical particles (with $N\equiv N_B+N_F$), we use the rth *external* operator $\varphi_r(w_r)$ (for $r=1-N$) which lives within the *unit* disk $|w_r|<1$, and the *inlint* operator $\varphi_0(z)$ which lives within the *whole* complex z plane. In order to express both inlint and external operators altogether, we shall introduce notations $\varphi_r(y_r)$'s (for $r=0-N$) as follow. The argument y_r (for $r=1-N$) is equal to the rth disk coordinate w_r in (2.2), while y_0 is equal to the inlayed coordinate $z(\in\mathbb{C})$. Furthermore, the *inlint* operator $\varphi_0(z)$ is simply denoted by $\varphi(z)$, while $\varphi_r(w_r)$'s (for $r=1-N$) are *external* operators.

First, any ten-dimensional vector A^μ (for $\mu=0-9$) is transformed into the component $A^{\pm j}$ (for $j=0-4$) as follows:

$$A^{\pm 0}\equiv\frac{1}{\sqrt{2}}(A^0\pm A^9),$$
$$A^{\pm j}\equiv\frac{1}{\sqrt{2}}(-\sqrt{-1}\cdot A^j\pm A^{j+4})\quad\text{for}\ \ j=1-4, \tag{A1}$$

so that the Lorentz scalar product among A^μ and B^ν is expressed by

$$\vec{A}\cdot\vec{B}\equiv-\sum_{\pm}\sum_{j=0}^{4}A^{\pm j}\cdot B^{\mp j}\left(\equiv-\sum_{\pm}A^{\pm 0}\cdot B^{\mp 0}+\sum_{j=1}^{8}A^j\cdot B^j\right). \tag{A2}$$

In open QSFT, we have the string coordinate $X^{\pm j}$ (for $j=0-4$), the jth spining operator ϕ^j (for $j=0-4$), the ghosting operator σ, the fracting operator ϕ, and the Hilberting operator χ. These operators (represented by φ's) are coupled with background charges $Q(\varphi)$'s in (2.5). For any $r=0-N$, the operator $\varphi_r(y_r)$ is defined by

$$\varepsilon_\varphi^\phi\cdot\varphi_r(y_r)\equiv\left(p_r(\varphi)\cdot\log(y_r)-\sum_{n=1}^{\infty}\frac{1}{n}\cdot J_{n,r}(\varphi)\cdot y_r^{-n}\right)+\left(\varepsilon_\varphi^\phi\cdot q_r(\varphi)+\sum_{n=1}^{\infty}\frac{1}{n}\cdot J_{-n,r}(\varphi)\cdot y_r^{n}\right)$$
$$\equiv\varphi_r(y_r;+)+\varphi_r(y_r;-)\quad\text{for}\ \ \varphi=X^{\pm j},\phi^j,\sigma,\phi,\chi,\quad\text{and}\ \ j=0-4. \tag{A3a}$$

Incidentally, the string coordinate $X^{\pm j}$ in (A3) is the same as the one in Ref. 13, since we have the following relations among them:

$$p_r(X^{\pm j}) = -\sqrt{-1}\cdot p_r^{\pm j}, \quad q_r(X^{\pm j}) = q_r^{\pm j},$$
$$J_{n,r}(X^{\pm j}) = -\sqrt{-1}\cdot\sqrt{n}\cdot a_{n,r}^{\pm j}, \quad J_{-n,r}(X^{\pm j}) = -\sqrt{-1}\cdot\sqrt{n}\cdot a_{-n,r}^{\pm j}. \tag{A3b}$$

Operators in Eq. (A3) satisfy the following commutation relations (for r, $t = 0-N$ and $n,m = 1,2,3,\ldots$]:

$$[J_{n,r}(X^{\pm j}), J_{-m,t}(X^{\mp k})] = n\cdot\delta_{nm}\cdot\delta_{rt}\cdot\delta_{jk} \quad \text{for } j,k = 0-4,$$
$$[p_r(X^{\pm j}), q_t(X^{\mp k})] = \delta_{rt}\cdot\delta_{jk} \quad \text{for } j,k = 0-4, \tag{A4}$$

and

$$[J_{n,r}(\varphi), J_{-m,t}(\varphi')] = n\cdot\delta_{nm}\cdot\delta_{rt}\cdot\delta_{\varphi\varphi'}\cdot\varepsilon_\varphi^\phi \quad \text{for } \varphi,\varphi' = \phi^j,\sigma,\phi,\chi, \quad \text{and } j = 0-4,$$
$$[p_r(\varphi), q_t(\varphi')] = \delta_{rt}\cdot\delta_{\varphi\varphi'} \quad \text{for } \varphi,\varphi' = \phi^j,\sigma,\phi,\chi, \quad \text{and } j = 0-4, \tag{A5a}$$

all other commutators being equal to zero. In Eq. (A5a), we have used the constant ε_φ^ϕ defined by

$$\varepsilon_\varphi^\phi \equiv \begin{cases} -1 & \text{for } \varphi = \phi, \\ +1 & \text{for } \varphi(\neq\phi). \end{cases} \tag{A5b}$$

The (Grassman even) standard ket states[5] $|p_r(\vec{X}) = 0\rangle_r$ and $|p_r(\varphi) = 0\rangle_r$ (for $r = 0-N$) are states satisfying respectively that

$$X_r^{\pm j}(y_r;+)|p_r(\vec{X}) = 0\rangle_r = 0 \quad \text{for } j = 0-4,$$
$$\varphi_r(y_r;+)|p_r(\varphi) = 0\rangle_r = 0 \quad \text{for } \varphi = \phi^j,\sigma,\phi,\chi, \quad \text{and } j = 0-4, \tag{A6}$$

while the (Grassman even) standard bra states[5] ${}_r\langle q_r(\vec{X}) = 0|$ and ${}_r\langle q_r(\varphi) = 0|$ (for $r = 0-N$) are states satisfying respectively that

$${}_r\langle q_r(\vec{X}) = 0|X_r^{\pm j}(y_r;-) = 0 \quad \text{for } j = 0-4,$$
$${}_r\langle q_r(\varphi) = 0|\varphi_r(y_r;-) = 0 \quad \text{for } \varphi = \phi^j,\sigma,\phi,\chi, \quad \text{and } j = 0-4. \tag{A7}$$

Normalizations of these states are respectively fixed by

$${}_r\langle q_r(\vec{X}) = 0|p_t(\vec{X}) = 0\rangle_t = \delta_{rt},$$
$${}_r\langle q_r(\varphi) = 0|p_t(\varphi') = 0\rangle_t = \delta_{rt}\cdot\delta_{\varphi\varphi'} \quad \text{for } \varphi = \phi^j,\sigma,\phi,\chi, \quad \text{and } j = 0-4. \tag{A8}$$

Furthermore, the "dual standard bra states" ${}_r\langle p_r(\vec{X}) = 0|$ and ${}_r\langle p_r(\varphi) = 0|$ (for $r = 0-N$) are defined respectively by

$${}_r\langle p_r(\vec{X}) = 0| \equiv (|p_r(\vec{X}) = 0)_r)^\dagger,$$
$${}_r\langle p_r(\varphi) = 0| \equiv (|p_r(\varphi) = 0\rangle_r)^\dagger \quad \text{for } \varphi = \phi^j,\sigma,\phi,\chi, \quad \text{and } j = 0-4. \tag{A9}$$

We also impose the following normalization conditions:

$$ {}_r\langle p_r(\vec{X})=0|\exp\left(\sum_{\pm}\sum_{j=0}^{4} -\sqrt{-1}p^{\pm j}\cdot X_r^{\mp j}(y_r)\right)|p_t(\vec{X})=0\rangle_t=\delta_{rt}\left(\prod_{\mu=0}^{9} 2\pi\delta(p^\mu)\right), \tag{A10} $$

$$ {}_r\langle p_r(\varphi)=0|\exp(-Q(\varphi)\varphi_r(y_r))|p_t(\varphi')=0\rangle_t=\delta_{rt}\delta_{\varphi\varphi'} \quad \text{for } \varphi,\varphi'=\phi^j,\sigma,\phi,\chi, \quad \text{and } j=0-4, $$

where the background charges $Q(\varphi)$'s are given by Eq. (2.5). [Real numbers p^μ's are related with $p^{\pm j}$'s by Eq. (A1).] We finally remark that the Hermitian conjugation, ''†'' is given by

$$ (\varphi_r(1/y_r^*))^\dagger=\varphi_r(y_r)+\varepsilon_\varphi^\phi\cdot Q(\varphi)\cdot\log(y_r) \quad \text{for } \varphi=\sigma,\phi,\chi, \tag{A11a} $$

so that we find from Eq. (A3) that

$$ -(p_r(\varphi))^\dagger=p_r(\varphi)+Q(\varphi). \tag{A11b} $$

We find that ${}_r\langle p_r(\varphi)=0|$ is Grassman even (odd) for $\varphi=\vec{X},\phi^j,\ \phi$ (for $\varphi=\sigma,\ \chi$). The ''normal ordering in the bo-(sonized) representation'' is denoted by : :, which is defined to be placing any negative frequency part $\varphi_r(y_r;-)$ always to the left of any positive frequency part $\varphi_t'(y_t';+)$ [for any $\varphi,\varphi'=X^{\pm j},\phi^j,\sigma,\phi,\chi$]. Furthermore, the radial ordering operator $\vec{R}$ is defined to be rearranging any product [of external or inlint operators] according to the absolute values of operators' arguments:

$$ \vec{R}\cdot(\varphi_r(y_r)\cdot\varphi_t'(y_t'))\equiv\begin{cases}\varphi_r(y_r)\cdot\varphi_t'(y_t') & \text{for } |y_r|>|y_t'|,\\ \varphi_t'(y_t')\cdot\varphi_r(y_r) & \text{for } |y_t'|>|y_r|,\end{cases} $$
$$ \text{for } \varphi,\varphi'=X^{\pm j},\phi^j,\sigma,\phi,\chi, \quad \text{and } j=0-4. \tag{A12} $$

If we define the *radial-ordered* argument $(y_r-y_t')_R$ by

$$ (y_r-y_t')_R\equiv\begin{cases}(y_r-y_t') & \text{for } |y_r|>|y_t'|,\\ (y_t'-y_r) & \text{for } |y_t'|>|y_r|.\end{cases} \tag{A13} $$

Commutation relations (A3)–(A5) are found to lead to the following operator product expansions (OPEs):

$$ \vec{R}\cdot(\varphi_r(y_r)\cdot\varphi_t'(y_t'))=\overbrace{\varphi_r(y_r)\cdot\varphi_t'(y_t')}+:(\varphi_r(y_r)\cdot\varphi_t'(y_t')): $$
$$ \text{for } \varphi,\varphi'=X^{\pm j},\phi^j,\sigma,\phi,\chi, \quad \text{and } j=0-4. \tag{A14} $$

The first (second) term on the right-hand side of Eq. (A14) will be called the ''contraction (the normal-ordered product) in the bo-representation.'' All of nonvanishing contractions in Eqs. (A14) are those given by

$$ \overbrace{X_r^{\pm j}(y_r)\cdot X_t^{\mp k}(y_t')}=\delta_{rt}\cdot\delta_{jk}\cdot\log(y_r-y_t')_R \quad \text{for } j,k=0-4 $$
$$ \overbrace{\varphi_r(y_s)\cdot\varphi_t(y_t')}=\varepsilon_\varphi^\phi\cdot\delta_{rt}\cdot\log(y_r-y_t')_R \quad [\text{see } \varepsilon_\varphi^\phi \text{ (A5a)}] $$
$$ \text{for } \varphi=\phi^j,\sigma,\phi,\chi, \quad \text{and } j=0-4. \tag{A15} $$

(Throughout this paper, we will explicitly write out the radial ordering operator $\vec{R}$ in various formulas.)

[Hereafter, the conformal weight of the primary operator $\mathcal{G}$ will be denoted by $d(\mathcal{G})$.] The anti-ghostino $\mathcal{B}_r$ and the ghostino $\mathcal{C}_r$ are defined respectively [in terms of the ghosting operator σ_r in (A3)] by

$$\mathcal{B}_r(y_r)\equiv:\exp(-\sigma_r(y_r)): \quad [d(\mathcal{B})=+2] \tag{A16}$$

and

$$\mathcal{C}_r(y_r)\equiv:\exp(+\sigma_r(y_r)): \quad [d(\mathcal{C})=-1], \tag{A17}$$

cocycle factors[15] being abbreviated here and hereafter.

On the other hand, Friedan–Martinec–Schenker (FMS) have introduced[9] the hilbertino ξ_r, the anti-hilbertino η_r, the anti-ghoston β_r, the ghoston γ_r, and the string coordino $\Psi_r^{\pm j}$ (for $j=0-4$), which can respectively be constructed [in terms of the hilberting operator χ_r, the fracting operator ϕ_r, and the jth spining operator ϕ_r^j given by Eq. (A3)] as follows:

$$\xi_r(y_r)\equiv:\exp(+\chi_r(y_r)): \quad [d(\xi)=0], \tag{A18}$$

$$\eta_r(y_r)\equiv:\exp(-\chi_r(y_r)): \quad [d(\eta)=+1], \tag{A19}$$

$$\beta_r(y_r)\equiv\partial_{y_r}\xi_r(y_r):\exp(-\phi_r(y_r)): \quad [d(\beta)=+\tfrac{3}{2}], \tag{A20}$$

$$\gamma_r(y_r)\equiv:\exp(+\phi_r(y_r)):\eta_r(y_r) \quad [d(\gamma)=-\tfrac{1}{2}], \tag{A21}$$

and

$$\Psi_r^{\pm j}(y_r)\equiv:\exp(\pm\phi_r^j(y_r)): \quad \text{for } j=0-4 \quad [d(\Psi)=+\tfrac{1}{2}]. \tag{A22}$$

The rth punctured ring domain in the $\pi(r)=\mathrm{R}$ sector is characterized by the presence of the following external (inlint) operator at $w_r=0$ [at the rth puncture $Z_{r_\flat}$]:

$$:\exp(+\sigma_r(y_{0r}))::\exp(-\tfrac{1}{2}\phi_r(y_{0r})):S_{\{h(r)\},r}(y_{0r}). \tag{A23}$$

[See Eq. (D12).] In particular, the FMS spinor[9] $S_{\{h(r)\},r}(y_{0r})$ represents the fermionic spinor at y_{0r} and it is defined by

$$S_{\{h(r)\},r}(y_{0r})\equiv:\exp(+\tfrac{1}{2}\cdot\phi_r^0(y_{0r})):\prod_{j=1}^{4}:\exp(\varepsilon_{h(r)}^j\cdot\phi_r^j(y_{0r})):, \tag{A24a}$$

with

$$\varepsilon_{h(r)}^j\equiv\pm\tfrac{1}{2} \quad \text{for } h(r)=\pm. \tag{A24b}$$

[In Eqs. (A18)–(A24) and hereafter, cocycle factors[15] will be abbreviated.] We notice that $:\exp(\pm\varphi_r(y_r)):$ involves the factor $(y_r)^{\mp p_r(\varphi)}$ (for $\varphi=\sigma,\chi$), where eigenvalues $p_r(\varphi)$ are integer valued in *both* the Neveu–Schwarz (NS) and Ramond (R) sectors. Since any of $\mathcal{B}_r(y_r)$ in (A16), $\mathcal{C}_r(y_r)$ in (A17), $\xi_r(y_r)$ in (A18), and $\eta_r(y_r)$ in (A19) is single valued, each can respectively be Laurent expanded at $y_r=0$ as

$$\mathcal{B}_r(y_r)=\left(\sum_{n=-1}^{\infty}\mathcal{B}_{n,r}\cdot y_r^{-n-2}\right)+\left(\sum_{n=2}^{\infty}\mathcal{B}_{-n,r}\cdot y_r^{n-2}\right)\equiv\mathcal{B}_r(y_r;+)+\mathcal{B}_r(y_r;-) \quad \text{with } \mathcal{B}_{n,r}^{+}=\mathcal{B}_{-n,r}, \tag{A25}$$

$$\mathcal{C}_r(y_r)=\left(\sum_{n=2}^{\infty}\mathcal{C}_{n,r}\cdot y_r^{-n+1}\right)+\left(\sum_{n=-1}^{\infty}\mathcal{C}_{-n,r}\cdot y_r^{n+1}\right)\equiv\mathcal{C}_r(y_r;+)+\mathcal{C}_r(y_r;-)\quad\text{with }\mathcal{C}_{n,r}^{\dagger}=\mathcal{C}_{-n,r},\tag{A26}$$

$$\xi_r(y_r)=\left(\sum_{n=1}^{\infty}\xi_{n,r}\cdot y_r^{-n}\right)+\left(\sum_{n=0}^{\infty}\xi_{-n,r}\cdot y_r^{n}\right)\equiv\xi_r(y_r;+)+\xi_r(y_r;-)\quad\text{with }\xi_{n,r}^{\dagger}=\xi_{-n,r},\tag{A27}$$

and

$$\eta_r(y_r)=\left(\sum_{n=0}^{\infty}\eta_{n,r}\cdot y_r^{-n-1}\right)+\left(\sum_{n=1}^{\infty}\eta_{-n,r}\cdot y_r^{n-1}\right)\equiv\eta_r(y_r;+)+\eta_r(y_r;-)\quad\text{with }\eta_{n,r}^{\dagger}=\eta_{-n,r}.\tag{A28}$$

Finally, the ''normal ordering in the Σ-representation'' (denoted by $: :_\Sigma$) is defined by

$$:\mathcal{G}_r(y_r)\cdot\mathcal{G}'_t(y'_t):_\Sigma\equiv\vec{R}\cdot\mathcal{G}_r(y_r)\cdot\mathcal{G}'_t(y'_t)-\overbrace{\mathcal{G}_r(y_r)\cdot\mathcal{G}'_t(y'_t)}^{\Sigma}\quad\text{for }\mathcal{G},\mathcal{G}'=\mathcal{B},\mathcal{C},\xi,\eta,\vec{X},\tag{A29}$$

where the ''contractions in the Σ-representation''

$$\overbrace{\quad}^{\Sigma}$$

are given by

$$\overbrace{\mathcal{B}_r(y_r)\cdot\mathcal{C}_t(y'_t)}^{\Sigma}=-\overbrace{\mathcal{C}_t(y'_t)\cdot\mathcal{B}_r(y_r)}^{\Sigma}=\overbrace{\xi_r(y_r)\cdot\eta_t(y'_t)}^{\Sigma}=-\overbrace{\eta_t(y'_t)\cdot\xi_r(y_r)}^{\Sigma}=\frac{\delta_{rt}}{y_r-y'_t}\tag{A30a}$$

and

$$\overbrace{X_r^{\pm j}(y_r)\cdot X_t^{\mp k}(y'_t)}^{\Sigma}=\delta_{rt}\cdot\delta_{jk}\cdot\log(y_r-y'_t)_R,\tag{A30b}$$

all other contractions in the Σ-representation among $\mathcal{G}$ and $\mathcal{G}'$ (for $\mathcal{G},\mathcal{G}'=\mathcal{B},\mathcal{C},\xi,\eta,\vec{X}$) being equal to zero. Incidentally, $: :_\Sigma$ defined by Eq. (A29) is equivalent to placing any negative frequency part to the left of any positive frequency part (of operators $\mathcal{B}$, $\mathcal{C}$, ξ, η, $\vec{X}$).

Noticing that

$$:\exp(\pm\varphi_r(y_r)):|p_r(\varphi)=0\rangle_r=:\exp(\pm\varphi_r(y_r;-)):|p_r(\varphi)=0\rangle_r\quad\text{for }\varphi=\phi,\chi\tag{A31}$$

is analytic at $y_r=0$, we find from Eqs. (A25)–(A28) that

$$\begin{aligned}\mathcal{B}_r(y_r;+)|p_r(\sigma)=0\rangle_r&=\mathcal{C}_r(y_r;+)|p_r(\sigma)=0\rangle_r\\&=\xi_r(y_r;+)|p_r(\chi)=0\rangle_r\\&=\eta_r(y_r;+)|p_r(\chi)=\rangle_r\\&=0.\end{aligned}\tag{A32}$$

Similarly, we find from Eq. (A7) that

$$\begin{aligned}{}_r\langle q_r(\sigma)=0|\mathcal{B}_r(y_r;-)={}_r\langle q_r(\sigma)=0|\mathcal{C}_r(y_r;-)\\ &={}_r\langle q_r(\chi)=0|\xi_r(y_r;-)\\ &={}_r\langle q_r(\chi)=0|\eta_r(y_r;-)=0.\end{aligned} \tag{A33}$$

Since we have that

$$_r\langle p_r(\chi)=0|\begin{pmatrix}\xi_{0,r}\\ 1\end{pmatrix}|p_t(\chi)=0\rangle_t=\begin{pmatrix}\delta_{rt}\\ 0\end{pmatrix}, \tag{A34}$$

we find that ${}_r\langle p_r(\chi)=0|$ is Grassman *odd*. Furthermore, Eqs. (A8) and (A34) lead to

$$\begin{aligned}{}_r\langle q_r(\chi)=0| &= {}_r\langle p_r(\chi)=0|\xi_{0,r}\\ &={}_r\langle p_r(\chi)=0|\xi_r(+\infty) \quad [\text{from Eqs. (A9), (A27), and (A33)}],\end{aligned} \tag{A35a}$$

$$\begin{aligned}&={}_r\langle p_r(\chi)=0|{:}\exp(+\chi_r(+\infty)){:}, \quad [\text{from Eq. (A18)}],\\ &={}_r\langle p_r(\chi)=0|\exp(+q_r(\chi))\\ &\quad [\text{from Eqs. (A3), (A7), (A9), and (A11)}].\end{aligned} \tag{A35b}$$

On the other hand, the anti-ghoston β in (A20) and the ghoston γ in (A21) and the string coordino $\Psi^{\pm j}$ in (A22) in the R sector should be treated differently from those in the NS sector. Especially in the case $\pi(r)=\mathrm{R}$, the operator (A23) exists at y_{0r}. Incidentally, the presence of the operator (A23) (of conformal weight 0) reflects the presence of the rth external physical R-state in (D12) [in $\frac{1}{2}$ picture] at the puncture y_{0r} within the rth punctured ring domain. The presence of the operator (A23) induces in β in (A20), γ in (A21), and $\Psi^{\pm j}$ in (A22) the *branch point* at y_{0r}, which should be taken into account in Laurent expanding these operators. The branch point in the string coordino $\Psi^{\pm j}$ has been completely analyzed in our previous papers,[14] so that we have only to apply previous techniques to the analyses of β and γ. [On the other hand, we point out that there is no essential need to discriminate $\mathcal{B}$ in (A25), $\mathcal{C}$ in (A26), ξ in (A27), and η in (A28) in the NS sector from those in the R sector.] In the following, formulas with (without) the branch point are those in the R (NS) sector: In the special case when $y_{0r}=0$, the anti-ghoston β in (A20) [of conformal weight $d(\beta)=\frac{3}{2}$], the ghoston γ in (A21) [of $d(\gamma)=-\frac{1}{2}$], and the string coordino $\Psi^{\pm j}$ in (A22) [of $d(\Psi^{\pm j})=\frac{1}{2}$] can be respectively Laurent expanded at $y_r=0$ in the following forms. For $\pi(r)=\mathrm{R}$ (NS), we find that

$$\begin{aligned}\beta_r(y_r)&=\frac{1}{(\sqrt{y_r})^3}\left(\sum_{n=0}^{\infty}\beta_{n(-1/2),r}\cdot y_r^{-n(+1/2)}\right)\\ &\quad+\frac{1}{(\sqrt{y_r})^3}\left(\sum_{n=1}^{\infty}\beta_{-n(-1/2),r}\cdot y_r^{n(+1/2)}\right)\\ &=\beta_r(y_r;+)+\beta_r(y_r;-) \quad \text{with} \quad \beta^{\dagger}_{n(-1/2),r}=\beta_{-n(+1/2),r},\end{aligned} \tag{A36}$$

$$\begin{aligned}\gamma_r(y_r)&=\sqrt{y_r}\left(\sum_{n=1}^{\infty}\gamma_{n(+1/2),r}\cdot y_r^{-n(-1/2)}\right)+\sqrt{y_r}\left(\sum_{n=0}^{\infty}\gamma_{-n(+1/2),r}\cdot y_r^{n(-1/2)}\right)\\ &=\gamma_r(y_r;+)+\gamma_r(y_r;-) \quad \text{with} \quad \gamma^{\dagger}_{n(+1/2),r}=-\gamma_{-n(-1/2),r},\end{aligned} \tag{A37}$$

and

$$\Psi_r^{\pm j}(y_r)=\frac{1}{\sqrt{y_r}}\left(\sum_{n\in Z}\psi_{n(+1/2),r}^{\pm j}\cdot y_r^{-n(-1/2)}\right). \tag{A38}$$

[The suffix $-n(+1/2)$ means the suffix $-n$ $(-n+1/2)$ should be used in the R (NS) sector.] The expansion in the general case $y_{0r}\neq 0$ will be obtained in much the same way as we have obtained the expansions (2.24) and (2.28) in the first paper of Ref. 14.

At this stage, we introduce the following super-coordinate $X_r^{\pm j}(y_r,\theta_r)$, the super-ghostino $\mathcal{C}_r(y_r,\theta_r)$, and the super-antighoston $\beta_r(y_r,\theta_r)$:

$$X_r^{\pm j}(y_r,\theta_r)\equiv X_r^{\pm j}(y_r)+\theta_r\cdot\Psi_r^{\pm j}(y_r), \tag{A39}$$

$$\mathcal{C}_r(y_r,\theta_r)\equiv\mathcal{C}_r(y_r)+\theta_r\cdot\gamma_r(y_r), \tag{A40}$$

and

$$\beta_r(y_r,\theta_r)\equiv\beta_r(y_r)+\theta_r\cdot\mathcal{B}_r(y_r). \tag{A41}$$

We shall later use the following partial differentiation [of operators (A39)–(A41)]:

$$\mathcal{D}_{\theta_r}\equiv\frac{\partial}{\partial\theta_r}+\theta_r\cdot\frac{\partial}{\partial y_r}. \tag{A42}$$

The "contractions in the π-representation"

$$\overset{\sqcap\,\pi\,\sqcap}{}$$

[for $\pi=$R,NS] are those respectively defined by

$$\overbrace{X_r^{\pm j}(y_r,\theta_r)\cdot X_t^{\mp k}}^{\text{NS}}(y_t',\theta_t')\equiv\delta_{rt}\cdot\delta_{jk}\cdot\log(y_r-y_t'-\theta_r\theta_t')_R, \tag{A43}$$

$$\overbrace{\beta_r(y_r,\theta_r)\cdot\mathcal{C}_t}^{\text{NS}}(y_t',\theta_t')\equiv\delta_{rt}\cdot\frac{\theta_r-\theta_t'}{y_r-y_t'-\theta_r\theta_t'}, \tag{A44}$$

and

$$\overbrace{X_r^{\pm j}(y_r,\theta_r)\cdot X_t^{\mp k}}^{\text{R}}(y_t',\theta_t')\equiv\delta_{rt}\cdot\delta_{jk}\cdot\log\left(y_r-y_t'-\left(\frac{y_r-y_{0r}}{y_t'-y_{0t}}\right)^{\pm\varepsilon_h^j}\theta_r\theta_t'\right)_R, \tag{A45}$$

$$\overbrace{\beta_r(y_r,\theta_r)\cdot\mathcal{C}_t}^{\text{R}}(y_t',\theta_t')\equiv\frac{\delta_{rt}}{y_r-y_t'-\theta_r\theta_t'}\left(\theta_r\left(\frac{y_t'-y_{0t}}{y_r-y_{0r}}\right)-\theta_t'\left(\frac{y_t'-y_{0t}}{y_r-y_{0r}}\right)^{1/2}\right). \tag{A46}$$

In the formulas (A43) and (A45), we have used the radial-ordered argument $(\dots)_{\mathrm{R}}$ defined by Eq. (A13). Then, we can *define* the "normal-ordered product in the π-representation" (denoted by $:\,:_\pi$) as follows:

$$:G_r(y_r,\theta_r)\cdot H_t(y_t',\theta_t'):_\pi\equiv\vec{R}\cdot G_r(y_r,\theta_r)\cdot H_t(y_t',\theta_t')-\overbrace{G_r(y_r,\theta_r)\cdot H_t}^{\pi}(y_t',\theta_t')\quad\text{for }\ \pi=\text{NS,R}. \tag{A47}$$

We should notice that the formula (A46) has been chosen so as to involve the factor $(y_t' - y_{0t})/(y_r - y_{0r})$, reflecting the effect due to the existence of $:\exp(\sigma_r(y_{0r})):$ $[:\exp(\sigma_t(y_{0t}))]$, which is needed to make the conformal weight of the $r(t)$th external primary operators (A23) equal to zero. [See Eqs. (D12), (D14), and (D28).]

APPENDIX B: IDENTITIES $T_r^{\mathrm{R}} = T_r^{\mathrm{NS}} = T_r$ AND $\mathcal{Q}_r^{\mathrm{R}} = \mathcal{Q}_r^{\mathrm{NS}} = \mathcal{Q}_r$

In this appendix, $: :_\pi(: \;:)$ always means the ''normal ordering in the π- (bo-)representation'' defined by Eq. (A47) [(A14)], where we should use contractions (A43)–(A46) [(A15)]. Then, $\mathcal{F}_r^\pi(y_r, \theta_r)$ is the ''super-stressino operator in the π-representation'' defined by

$$\mathcal{F}_r^\pi(y_r,\theta_r)\left(\equiv \frac{1}{2}\cdot \mathcal{F}_r^\pi(y_r) + \theta_r \cdot T_r^\pi(y_r)\right) \quad \text{for } r = 0 - N \tag{B1}$$

$$\equiv \sum_{\pm} \sum_{j=0}^{4} \frac{1}{2} :\partial_{y_r} X_r^{\pm j}(y_r,\theta_r)\cdot \mathcal{D}_{\theta_r} X_r^{\mp j}(y_r,\theta_r):_\pi$$
$$+ :(-\mathcal{C}_r(y_r,\theta_r)\cdot \partial_{y_r}\beta_r(y_r,\theta_r) + \tfrac{1}{2}\cdot \mathcal{D}_{\theta_r}\mathcal{C}_r(y_r,\theta_r)\cdot \mathcal{D}_{\theta_r}\beta_r(y_r,\theta_r)$$
$$- \tfrac{3}{2}\cdot \partial_{y_r}\mathcal{C}_r(y_r,\theta_r)\cdot \beta_r(y_r,\theta_r)):_\pi \tag{B2}$$

$$\equiv :\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}(y_r,\theta_r):_\pi + :\mathcal{F}_r^{(gh)}(y_r,\theta_r):_\pi \quad \text{for } \pi = \mathrm{R,NS}, \tag{B3}$$

where $\mathcal{D}_{\theta_r}$ is defined by Eq. (A42). By substituting Eqs. (A39)–(A42) into Eq. (B2), $T_r^\pi(y_r)$ in (B1) (to be referred to as the ''stress operator in the π-representation'') is found to be given by

$$T_r^\pi(y_r) \equiv :T_r^{(\vec{X})}(y_r):_\pi + :(T_r^{(\vec{\Psi})}(y_r) + T_r^{(\mathcal{BC})}(y_r) + T_r^{(\beta\gamma)}(y_r)):_\pi \quad \text{for } \pi = \mathrm{R,NS} \text{ and } r = 0 - N, \tag{B4a}$$

where [and in Eq. (B3)] the operator $T^{(G)}$ $[\mathcal{F}^{(G)}]$ represents the component given in terms of G-modes. For examples, we have that

$$:T_r^{(\mathcal{BC})}(y_r):_\pi \equiv :\mathcal{C}_r(y_r)\cdot \partial_{y_r}\mathcal{B}_r(y_r):_\pi + 2:\partial_{y_r}\mathcal{C}_r(y_r)\cdot \mathcal{B}_r(y_r):_\pi \tag{B4b}$$

and

$$:T_r^{(\beta\gamma)}(y_r):_\pi \equiv -\tfrac{1}{2}:\gamma_r(y_r)\cdot \partial_{y_r}\beta_r(y_r):_\pi - \tfrac{3}{2}:\partial_{y_r}\gamma_r(y_r)\cdot \beta_r(y_r):_\pi . \tag{B4c}$$

{See also Eqs. (C16)–(C18) for $\mathcal{F}^{(G)}$'s [with $(G) = (\vec{X}\cdot\vec{\Psi}),(\beta\mathcal{C}),(\mathcal{B}\gamma)$] and Eq. (D22) for $T^{(G)}$ [with $(G) = (\vec{X}),(\vec{\Psi})$], which are to be given later.} On the other hand, $T_r^{(\varphi)}(y_r)$ (to be referred to as the ''φ-mode's stress operator in the bo-representation'') is defined by[9]

$$T_r^{(\varphi)}(y_r) \equiv \varepsilon_\varphi^\phi \cdot \frac{1}{2}:(\partial_{y_r}\varphi_r(y_r))^2: - \frac{Q(\varphi)}{2}\cdot \partial_{y_r}^2 \varphi_r(y_r) \quad \text{for } \varphi = \phi^j, \sigma, \phi, \chi, \tag{B5}$$

where we have used the background charges $Q(\varphi)$'s in (2.5) and the constant ε_φ^ϕ in (A5b). Using techniques in Ref. 5, we find after straightforward calculations (in the general space–time dimension D) that $T_r^\pi(y_r)$ in (B4) is given in terms of $T_r^{(\varphi)}(y_r)$'s in (B5) as follows:

$$T_r^\pi(y_r) = T_r(y_r) + \left(-\frac{D}{16} + \frac{5}{8}\right)\frac{\delta_\pi^{\mathrm{R}}}{(y_r - y_{0r})^2} \quad \text{for } \pi = \mathrm{R,NS}, \tag{B6}$$

where the constant δ_π^{R} is defined by

$$\delta_\pi^{\mathrm{R}} \equiv \begin{cases} 1 & \text{for } \pi = \mathrm{R}, \\ 0 & \text{for } \pi = \mathrm{NS}, \end{cases} \tag{B7}$$

while $T_r(y_r)$ (to be referred to as the ''stress operator in the bo-representation'') is defined by

$$T_r(y_r) \equiv :T_r^{(\vec{X})}(y_r):_\pi + \sum_{\varphi = \phi^j, \sigma, \phi, \chi} T_r^{(\varphi)}(y_r), \tag{B8}$$

where $T_r^{(\varphi)}(y_r)$'s are defined by Eq. (B5), while $T_r^{(\vec{X})}(y_r)$ is given by the first term on the right-hand side of Eq. (D22). Since we have $:T_r^{(\vec{X})}(y_r):_\pi \equiv :T_r^{(\vec{X})}(y_r):_\Sigma$, we find that

$$T_r^{\mathrm{R}}(y_r) = T_r^{\mathrm{NS}}(y_r) = T_r(y_r) \quad \text{for } D = 10 \quad \text{and } r = 0 - \mathrm{N} \tag{B9a}$$

$$\equiv \sum_{n=-\infty}^{\infty} L_{n,r} \cdot y_r^{-n-2} \quad [d(T) = 2]. \tag{B9b}$$

Furthermore, straightforward calculations lead to the following inlaying identity among the stress operators in the NS-representation:

$$T_r^{\mathrm{NS}}(w_r) \overset{\mathcal{I}}{\Rightarrow} (z_{r\mathfrak{z}}^{(1)}(w_r))^2 \cdot T^{\mathrm{NS}}(z_{r\mathfrak{z}}(w_r)) + \left(\frac{D}{8} - \frac{5}{4}\right)\left(\frac{z_{r\mathfrak{z}}^{(3)}(w_r)}{z_{r\mathfrak{z}}^{(1)}(w_r)} - \frac{3}{2}\left(\frac{z_{r\mathfrak{z}}^{(2)}(w_r)}{z_{r\mathfrak{z}}^{(1)}(w_r)}\right)^2\right). \tag{B10}$$

With the help of Eq. (B9), the inlaying identity (B10) is reduced (in the case $D=10$) to

$$T_r^{\pi(r)}(w_r) \overset{\mathcal{I}}{\Rightarrow} (z_{r\mathfrak{z}}^{(1)}(w_r))^2 \cdot T(z_{r\mathfrak{z}}(w_r)) \quad \text{for } r = 1 - N \quad \text{and in the case } D = 10. \tag{B11}$$

On the right-hand side of Eq. (B11), we have used the ''*inlint* stress operator in the bo-representation.'' Finally, the stressino operators in *three* representations are just equal to each other:

$$\mathcal{F}_r^{\mathrm{R}}(y_r) = \mathcal{F}_r^{\mathrm{NS}}(y_r) = \mathcal{F}_r(y_r) \quad \text{for } r = 0 - N. \tag{B12}$$

We can easily see that the stressino operator $\mathcal{F}_r^{\pi(r)}(w_r)$ is inlayed into the *inlint* stressino operator $\mathcal{F}(z_{r\mathfrak{z}}(w_r))$ as follows:

$$\mathcal{F}_r^{\pi(r)}(w_r) \overset{\mathcal{I}}{\Rightarrow} (z_{r\mathfrak{z}}^{(1)}(w_r))^{3/2} \cdot \mathcal{F}(z_{r\mathfrak{z}}(w_r)) \quad \text{for } r = 1 - N. \tag{B13}$$

It is tedious but straightforward to derive the following OPE among superstressino operators $\mathcal{F}_r^{\mathrm{NS}}(y_r, \theta_r)$'s in (B1) in the NS-representation:

$$\begin{aligned} &\vec{R} \cdot \mathcal{F}_r^{\mathrm{NS}}(y_r, \theta_r) \cdot \mathcal{F}_t^{\mathrm{NS}}(y_t', \theta_t') \quad \text{for } r, t = 0 - N \\ &= \frac{(D/4 - \frac{10}{4})\,\delta_{rt}}{(y_r - y_t' - \theta_r\theta_t')^3} + \frac{\frac{3}{2}(\theta_r - \theta_t')\,\delta_{rt}}{(y_r - y_t' - \theta_r\theta_t')^2} \cdot \mathcal{F}_t^{\mathrm{NS}}(y_t', \theta_t') \\ &\quad + \frac{(\theta_r - \theta_t')\,\delta_{rt}}{y_r - y_t' - \theta_r\theta_t'} \cdot \partial_{y_t'}\mathcal{F}_t^{\mathrm{NS}}(y_t', \theta_t') + \frac{\frac{1}{2}\delta_{rt}}{y_r - y_t' - \theta_r\theta_t'} \cdot \mathcal{D}_{\theta_t'}\mathcal{F}_t^{\mathrm{NS}}(y_t', \theta_t') \\ &\quad + (\text{terms regular at } y_r = y_t'). \end{aligned} \tag{B14}$$

Based on Friedan–Martinec–Schenker's work,[9] we introduce the following ''BRST supercurrent operator in the π-representation'' [to be denoted by $J_r^\pi(y_r, \theta_r)$] defined by

$$J_r^{\pi}(y_r,\theta_r)\equiv -:\mathcal{C}_r(y_r,\theta_r)(\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}(y_r,\theta_r)+\tfrac{1}{2}\cdot\mathcal{F}_r^{(gh)}(y_r,\theta_r)):_\pi + \tfrac{3}{4}:\mathcal{D}_{\theta_r}(\mathcal{C}_r(y_r,\theta_r)\cdot\mathcal{D}_{\theta_r}\mathcal{C}_r(y_r,\theta_r)\cdot\beta_r(y_r,\theta_r)):_\pi \tag{B15}$$

$$[\equiv j_r^{\pi}(y_r)+\theta_r\cdot\mathcal{J}_r^{\pi}(y_r)], \tag{B16}$$

where we have used Eqs. (A42), (B2), and (B3). Therefore, $\mathcal{J}_r^{\pi}(y_r)$ in (B16) (to be referred to as the BRST currentino in the π-representation) is given by

$$\mathcal{J}_r^{\pi}(y_r)\equiv\sum_{m=0}^{2}\mathcal{J}_r^{\pi}(m;y_r)\quad\text{for } r=0-N, \tag{B17}$$

where each component $\mathcal{J}_r^{\pi}(m;y_r)$ is given by the following term (involving the mth power of γ):

$$-2\cdot\mathcal{J}_r^{\pi}(0;y_r)\equiv -2\cdot\mathcal{C}_r(y_r):T_r^{(\vec{X},\vec{\Psi})}(y_r):_\pi - :\mathcal{C}_r(y_r)\cdot T_r^{(\mathcal{BC})}(y_r):_\pi, \tag{B18}$$

$$-2\cdot\mathcal{J}_r^{\pi}(1;y_r)= -\mathcal{C}_r(y_r):T_r^{(\beta\gamma)}(y_r):_\pi+\gamma_r(y_r)\cdot\mathcal{F}_r^{(\vec{X},\vec{\Psi})}(y_r)+\tfrac{1}{2}:\gamma_r(y_r)\cdot\mathcal{F}_r^{(\beta\mathcal{C})}(y_r):_\pi, \tag{B19}$$

and

$$-2\cdot\mathcal{J}_r^{\pi}(2;y_r)=\tfrac{1}{2}:\gamma_r^2(y_r):_\pi\cdot\mathcal{B}_r(y_r). \tag{B20}$$

On the other hand, $\mathcal{J}_r(y_r)$ (to be referred to as the ''BRST currentino in the bo-representation'') is defined by

$$\mathcal{J}_r(y_r)\equiv\sum_{g=-1}^{1}\mathcal{J}_r^{(g)}(y_r)\quad\text{for } r=0-N, \tag{B21}$$

where each component $\mathcal{J}_r^{(g)}(y_r)$ [involving the factor $:\exp(g\sigma):$] is given by

$$\mathcal{J}_r^{(1)}(y_r)\equiv :\exp(+\sigma_r(y_r)):\left(T_r^{(\vec{X})}(y_r)+\sum_{j=0}^{4}T_r^{(\phi^j)}(y_r)+T_r^{(\phi)}(y_r)+T_r^{(\chi)}(y_r)\right): + :\exp(\sigma_r(y_r))(-\tfrac{1}{2}(\partial_{y_r}\sigma_r(y_r))^2+\tfrac{1}{2}\partial_{y_r}^2\sigma_r(y_r)):, \tag{B22}$$

$$\mathcal{J}_r^{(0)}(y_r)\equiv -\frac{1}{2}\left(\sum_{\pm}\sum_{j=0}^{4}\partial_{y_r}X_r^{\pm j}(y_r):\exp(\mp\phi_r^j(y_r)):\right):\exp(+\phi_r(y_r))::\exp(-\chi_r(y_r)): = -\tfrac{1}{2}\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}(y_r)\cdot\gamma_r(y_r), \tag{B23}$$

and

$$\mathcal{J}_r^{(-1)}(y_r)\equiv\tfrac{1}{4}:\exp(-\sigma_r(y_r))::\exp(+2\phi_r(y_r))::\exp(-2\chi_r(y_r)):. \tag{B24}$$

After carrying out extremely tedious but straightforward calculations (by using techniques in Ref. 5), we find that these *local* BRST currentinos in *three* representations are *not* equal to each other. Actually, they are related to each other by

$$\mathcal{J}_r^{\mathrm{R}}(y_r)-\mathcal{J}_r^{\mathrm{NS}}(y_r)=\frac{-D+6}{16}\cdot\frac{\mathcal{C}_r(y_r)}{(y_r-y_{0r})^2}+\frac{1}{4}\cdot\frac{\partial_{y_r}\mathcal{C}_r(y_r)}{y_r-y_{0r}}\quad \text{for } r=0-N$$
$$=\frac{1}{4}\cdot\partial_{y_r}\left(\frac{\mathcal{C}_r(y_r)}{y_r-y_{0r}}\right)\quad \text{in the special case } D=10, \tag{B25}$$

and

$$\mathcal{J}_r^{\mathrm{NS}}(y_r)=\mathcal{J}_r(y_r)+\tfrac{3}{2}\cdot\partial_{y_r}(\mathcal{C}_r(y_r)\partial_{y_r}\phi_r(y_r))\quad \text{for } r=0-N. \tag{B26}$$

[Incidentally, y_{0r} in Eq. (B25) is the one in the formulas (A45) and (A46) and it is the (disk or inlayed) coordinate of the operator (A23) in the R sector.]

At this stage, $\mathcal{Q}_r^{\pi}$ (to be referred to as the ''BRST chargino in the π-representation'') is defined by

$$\mathcal{Q}_r^{\pi}\equiv\oint_{y_{0r}}\frac{dy_r}{2\pi\sqrt{-1}}\mathcal{J}_r^{\pi}(y_r)\quad \text{for } r=0-N\quad [\text{see the formulas (B17)–(B20)}], \tag{B27}$$

while $\mathcal{Q}_r$ (to be referred to as the ''BRST chargino in the bo-representation'') is defined by

$$\mathcal{Q}_r\equiv\oint_{y_{0r}}\frac{dy_r}{2\pi\sqrt{-1}}\mathcal{J}_r(y_r)\quad \text{for } r=0-N\quad [\text{see the formulas (B21)–(B24)}). \tag{B28}$$

Fortunately, since BRST charginos [(B27) and (B28)] are obtained by integrating the BRST currentinos, we find from Eqs. (B25) (*in the case* $D=10$) and (B26) that

$$\mathcal{Q}_r^{\mathrm{NS}}=\mathcal{Q}_r^{\mathrm{R}}=\mathcal{Q}_r\quad \text{for } r=0-N. \tag{B29}$$

Thus BRST charginos in *three* representations are shown to be just *equal* to each other.

Comment: Equivalence of three BRST charginos is *not at all* the trivial result, as seen from the nonequalities of three BRST currentino's [i.e., Eqs. (B25) and (B26)]. Fortunately, we can *explicitly* prove the equality (B29) in the special case $D=10$. Incidentally, we give the following formula which will be useful in the actual calculations:

$$\mathcal{Q}_r^{(1)}\equiv\oint_{y_{0r}}\frac{dy_r}{2\pi\sqrt{-1}}\mathcal{J}_r^{(1)}(y_r)\quad (\text{in the bo-representation})$$
$$=\oint_{y_{0r}}\frac{dy_r}{2\pi\sqrt{-1}}\mathcal{C}_r(y_r):\left(T_r^{(\vec{X})}(y_r)+T_r^{(\vec{\Psi})}(y_r)+\frac{\frac{5}{8}\cdot\delta_\pi^R}{(y_r-y_{0r})^2}\right):_\pi\quad (\text{in the } \pi\text{-representation})$$
$$+\oint_{y_{0r}}\frac{dy_r}{2\pi\sqrt{-1}}\mathcal{C}_r(y_r)(T_r^{(\xi\eta)}(y_r)+T_r^{(\phi)}(y_r))$$
$$+\oint_{y_{0r}}\frac{dy_r}{2\pi\sqrt{-1}}:\mathcal{C}_r(y_r)\cdot\partial_{y_r}\mathcal{C}_r(y_r)\cdot\mathcal{B}_r(y_r):_\Sigma\quad (\text{in the } \Sigma\text{-representation}), \tag{B30}$$

where we have used the constant δ_π^R in (B7) and the operator $T_r^{(\xi\eta)}(y_r)$ defined by

$$T_r^{(\xi\eta)}(y_r)\equiv:\partial_{y_r}\xi_r(y_r)\cdot\eta_r(y_r):_\Sigma=T_r^{(\chi)}(y_r)\quad \text{for } r=0-N. \tag{B31}$$

[See Eq. (B5)].

In the following, we shall prove the inlaying identity relevant to the BRST chargino. In proving the inlaying identity of the BRST currentino, it is useful to use $\mathcal{J}_r^{\rm NS}(y_r)$, i.e., the ''BRST currentino in the NS-representation.'' After extremely tedious calculations using techniques in Ref. 5, we can prove the following inlaying identity:

$$\mathcal{J}_r^{\rm NS}(w_r)\overset{\mathcal{I}}{\Rightarrow} z_{r_s}^{(1)}(w_r):\mathcal{J}^{\rm NS}(z_{r_s}(w_r))$$
$$+\left(\frac{D}{8}-\frac{5}{4}\right)\cdot\frac{z_{r_s}^{(3)}(w_r)}{z_{r_s}^{(1)}(w_r)}+\left(-\frac{3D}{16}+\frac{15}{8}\right)\cdot\left(\frac{z_{r_s}^{(2)}(w_r)}{r_{r_s}^{(1)}(w_r)}\right)^2\cdot\frac{\mathcal{C}(z_{r_s}(w_r))}{z_{r_s}^{(1)}(w_r)}, \tag{B32a}$$

which is reduced (when $D=10$) to

$$\mathcal{J}_r^{\rm NS}(w_r)\overset{\mathcal{I}}{\Rightarrow} z_{r_s}^{(1)}(w_r):\mathcal{J}^{\rm NS}(z_{r_s}(w_r)) \quad \text{for } r=1-N \quad \text{and } D=10. \tag{B32b}$$

Therefore, the inlaying identity (B32b) [together with the equality (B29)] leads to

$$\mathcal{Q}_r^{\pi(r)}\equiv \oint_0 \frac{dw_r}{2\pi\sqrt{-1}}\mathcal{J}_r^{\pi(r)}(w_r) \quad \text{for } r=1-N$$
$$\overset{\mathcal{I}}{\Rightarrow}\mathcal{Q}[r]\equiv \oint_0 \frac{dw_r}{2\pi\sqrt{-1}} z_{r_s}^{(1)}(w_r)\cdot\mathcal{J}(z_{r_s}(w_r))$$
$$=\oint_{Z_{r_s}}\frac{dz_r}{2\pi\sqrt{-1}}\mathcal{J}(z_r)$$
$$\text{for } r=1-N \quad \text{and in the case } D=10, \tag{B33}$$

where $z_{r_s}(0)=Z_{r_s}$ is the rth puncture in GM-$\mathcal{FE}$ in (2.1). Inlaying identity (B33) shows that the rth *external* BRST chargino $\mathcal{Q}_r^{\pi(r)}$ [in the $\pi(r)$-representation] is inlayed into the *inlint* BRST chargino $\mathcal{Q}[r]$ in the rth punctured ring domain.

Comment: Although $\mathcal{Q}[r]$ was originally given by the integration over the rth disk coordinate w_r, it could subsequently be rewritten (*in the case* $D=10$) into the *integration over the complex variable* z (in the complex plane) along the path enclosing each puncture Z_{r_s} in the rth punctured ring domain. This result will play very important roles in proving the following theorem (B34).

Theorem [''Special conservation of the total BRST chargino'' (SCTC)]:

$${}_s\langle IV(1,2,...,N)|\left(\sum_{r=1}^{N}\mathcal{Q}_r^{\pi(r)}\right)=0 \quad [\text{to be referred to as the ''SCTC''}]. \tag{B34}$$

Proof: With the help of the inlaying identity (B33), the left-hand side of Eq. (B34) is just inlayed into

$${}_s\langle IV(1,2,...,N)|\left(\sum_{r=1}^{N}\mathcal{Q}[r]\right), \tag{B35a}$$

where we have that

$$\sum_{r=1}^{N}\mathcal{Q}[r]=\sum_{r=1}^{N}\oint_{Z_{r_s}}\frac{dz_r}{2\pi\sqrt{-1}}\mathcal{J}(z_r). \tag{B35b}$$

Since the inlint BRST currentino $\mathcal{J}(z)$ in Eq. (B35b) is *analytic* throughout various ring domains in the ''ICS *s*,'' we can *deform* the integration contours (in the complex *z* plane) of various *inlint* $\mathcal{Q}[r]$'s in Eq. (B35b). Thus the sum on the right-hand side of Eq. (B35b) is furthermore reduced to the integration enclosing each interacting point $\mathcal{Y}^s_{\pm\iota}$. Finally, the latter integration is found to be vanishing, since the integrand $\mathcal{J}(z)$ is *analytic* (as the function of *z*) *even* at any interacting point $\mathcal{Y}^s_{\pm\iota}$ [in GM-$\mathcal{FE}$ in (2.1)]. Thus we obtain that

$$\sum_{r=1}^{N} \mathcal{Q}[r]=0, \tag{B36}$$

which together with Eq. (B34b) leads to Eq. (B34). (Q.E.D.)

Comment: It should be noticed that the rth inlayed coordinate $z_{r\mathcal{J}}(w_r)$ (as the function of w_r) is *singular* at $w_r=\pm\sqrt{-1}$, i.e., at any interacting point, so that $D=10$ is essential in proving Eq. (B34).

At this stage, we can explain the *reason* why it is useful to introduce *three* $\mathcal{Q}_r^{\mathrm{NS}}$, $\mathcal{Q}_r^{\mathrm{R}}$, and $\mathcal{Q}_r$, which are fortunately just equal to each other in the special case $D=10$. [See Eq. (B29).] In proving (in Appendix D) that the rth *external* physical NS- or R-states (for $r=1-N$) are invariant under the *external* BRST chargino $\mathcal{Q}_r^{\pi(r)}$, we can use the OPEs[14] (D24) and (D28) among $:T_r^{(\vec{X},\vec{\Psi})}(y'_r):_{\pi(r)}$ in (D22) (which are given in the ''$\pi(r)$-representation'') and ''external physical vertex operators in the $\pi(r)$ sector'' {i.e., $V_r^{nb}(y_{0r})$ [for $\pi(r)=NS$] and $V_r^{nf}(y_{0r})\cdot S_{\{h\},r}(y_{0r})$ [for $\pi(r)=R$]}. On the other hand, the ''*inlint* BRST chargino $\mathcal{Q}[r]$ in the bo-representation'' is used in Eq. (B35b) in proving that the ''SCTC'' in (B34) holds for the inlaying vertex function $_{\mathcal{J}}\langle IV(1,...,N)|$ in the ''ICS *s*.'' [See Eqs. (B35) and (B36).]

Friedan–Martinec–Schenker[9] have proved that the BRST chargino is nilpotent when $D=10$. Therefore, their result together with Eq. (1.58) leads to

$$(\mathcal{Q}_r^{\pi(r)})^2=(\mathcal{Q}[r])^2=0 \quad \text{for } D=10 \quad \text{and } r=1-N$$
$$\text{(to be referred to as the ``nilpotency''),} \tag{B37}$$

and we have the following anticommutation relation:

$$\{\mathcal{Q}_r,\mathcal{B}_r(y_r)\}=T_r(y_r) \quad \text{for } r=0-N. \tag{B38a}$$

The anticommutation relation (B38) leads to

$$\left\{\mathcal{Q}_r,\frac{\mathcal{B}_{0,r}}{L_{0,r}}\right\}=1 \quad \text{for } r=0-N \quad \text{(to be referred to as the ``contacting formula'').} \tag{B38b}$$

APPENDIX C: FORMULAS OF (INVERSE) PICTURE-CHANGING OPERATORS

We give explicit formulas of the *local* (inverse-) picture-changing operator $X_r(y_r)$ [$Y_r(y_r)$] used in this paper. The ''BRST chargino $\mathcal{Q}_r$ in the bo-representation'' is defined by Eq. (B28), i.e.,

$$\mathcal{Q}_r\equiv\sum_{g=-1}^{1}\mathcal{Q}_r^{(g)}, \tag{C1}$$

where the component $\mathcal{Q}_r^{(g)}$ is given by

$$\mathcal{Q}_r^{(g)}\equiv\oint_{y_r}\frac{dy'_r}{2\pi\sqrt{-1}}\mathcal{J}_r^{(g)}(y'_r), \tag{C2}$$

$\mathcal{J}_r^{(g)}(y_r')$ (for each $g=\pm 1,0$) being given by the formulas (B22)–(B24). With the help of the BRST chargino $\mathcal{Q}_r$ in (C1), the *local* picture-changing operator $X_r(y_r)$ is defined by[9]

$$X_r(y_r)\equiv\{-2\mathcal{Q}_r,\xi_r(y_r)\}\equiv\{-2\mathcal{Q}_r,\Theta(\beta_r(y_r))\}=\sum_{g=-1}^{1}\{-2\mathcal{Q}_r^{(g)},\xi_r(y_r)\}\equiv\sum_{g=-1}^{1}X_r^{(g)}(y_r), \tag{C3}$$

so that $X_r(y_r)$ in (C3) is BRST invariant, i.e.,

$$[\mathcal{Q}_r,X_r(y_r)]=0. \tag{C4}$$

The component $X_r^{(g)}(y_r)$ in Eq. (C3) (for each $g=\pm 1,0$) is given by

$$X_r^{(1)}(y_r)=-2{:}\exp(+\sigma_r(y_r)){:}\,\partial_{y_r}\xi_r(y_r), \tag{C5}$$

$$X_r^{(0)}(y_r)=-{:}\exp(+\phi_r(y_r)){:}\left(\sum_{\pm}\sum_{j=0}^{4}\partial_{y_r}X_r^{\pm j}(y_r)\cdot{:}\exp(\mp\phi_r^j(y_r)){:}\right), \tag{C6}$$

and

$$\begin{aligned}X_r^{(-1)}(y_r)=&-\tfrac{1}{2}{:}\exp(+2\phi_r(y_r)){:}{:}\exp(-\sigma_r(y_r)){:}\,\partial_{y_r}\eta_r(y_r)\\&-\tfrac{1}{2}\cdot\partial_{y_r}({:}\exp(+2\phi_r(y_r)){:}{:}\exp(-\sigma_r(y_r)){:}\,\eta_r(y_r)).\end{aligned} \tag{C7}$$

On the other hand, the *local* inverse picture-changing operator $Y_r(y_r)$ (of conformal weight 0) is given by[6]

$$Y_r(y_r)\equiv-2{:}\exp(-2\phi_r(y_r)){:}{:}\exp(+\sigma_r(y_r)){:}\,\partial_{y_r}\xi_r(y_r)[=2{:}\exp(+\sigma_r(y_r)){:}\,\delta^{(1)}(\gamma_r(y_r))], \tag{C8a}$$

with

$$\delta(\gamma_r(y_r))\equiv{:}\exp(-\phi_r(y_r)){:}, \tag{C8b}$$

and $Y_r(y_r)$ in (C8) has explicitly been shown to be BRST invariant, i.e.,

$$[\mathcal{Q}_r,Y_r(y_r)]=0. \tag{C9}$$

Furthermore, we can easily find that

$$\vec{R}\cdot(Y_r(y_r')\cdot X_r(y_r))=1+O(y_r'-y_r), \tag{C10a}$$

since we have that

$$Y_r(y_r)\cdot X_r^{(g)}(y_r)=\delta_{g,-1}\quad\text{for }\ g=\pm 1,0. \tag{C10b}$$

We find from the definitions (1.28)–(1.31) that $X_r^{(g)}$'s (for $g=\pm 1,0$) and Y_r have the following quantum numbers:

$$\begin{aligned}P(X_r^{(g)})&=G(X_r^{(g)})+F(X_r^{(g)})=g+(1-g)=1,\\P(Y_r)&\equiv G(Y_r)+F(Y_r)=1-2=-1,\end{aligned} \tag{C11}$$

and

$$G(X_r^{(g)})-H(X_r^{(g)})=g-g=0,$$
$$G(Y_r)-H(Y_r)=1-1=0. \tag{C12}$$

[Incidentally, Eq. (C11) shows that any component $X^{(g)}$ has the *same* picturing number $P=1$. This is the reason why we have defined P by Eq. (1.31). It is to be noticed that many other authors have called our ''F'' the ''picture number.'']

Hereafter, we give the nonlocal picture-changing operators X_r^p [for any $p\in Z$ $(Z+\frac{1}{2})$ in the $\pi(r)=\mathrm{R}$ (NS) sector] *and* $X_{\pm,r}^p$ [for any $p\in Z+\frac{1}{2}$ in the case $\pi(r)=\mathrm{NS}$] of the rth *external* operator. We expand any primary operator $G_r(y_r)$ [of conformal weight $d(G)$] by

$$G_r(Y_r)=\sum_{n\in Z(Z+1/2)} G_{n,r}\cdot y_r^{-n-d(G)}, \tag{C13a}$$

where mode operators $G_{n,r}$ are given by

$$G_{n,r}=\oint_0\frac{dy_r}{2\pi\sqrt{-1}}y_r^{d(G)+n-1}\cdot G_r(y_r). \tag{C13b}$$

Then, the nonlocal picture-changing operator's X_r^p [$p\in Z$ $(Z+\frac{1}{2})$ in the $\pi(r)=\mathrm{R}$ (NS) sector] are defined respectively by

$$X_r^p\equiv\{-2\cdot\mathcal{Q}_r^{\pi(r)},\Theta(\beta_{p,r})\}\quad\text{for}\;\;p\in Z\quad(Z+\tfrac{1}{2}). \tag{C14}$$

Then, we find that

$$X_r^p=(\mathcal{F}_{p,r}^{(\vec{X}\cdot\vec{\Psi})}+\mathcal{F}_{p,r}^{(\beta\mathcal{C})}+\mathcal{F}_{p,r}^{(\mathcal{B}\gamma)})\cdot\delta(\beta_{p,r})-\tfrac{1}{2}\cdot\mathcal{B}_{2p,r}\cdot\delta^{(1)}(\beta_{p,r})$$
$$\text{for}\;\;p\in Z\quad(Z+\tfrac{1}{2})\;\;\text{in the}\;\;\pi(r)=\mathrm{R}\;\;(\mathrm{NS})\;\;\text{sector}, \tag{C15}$$

where we have used that

$$\mathcal{F}_{p,r}^{(\vec{X}\cdot\vec{\Psi})}=\oint_0\frac{dw_r}{2\pi\sqrt{-1}}w_r^{p+1/2}\left(\sum_{\pm}\sum_{j=0}^{4}\partial_{w_r}X_r^{\pm j}(w_r)\cdot\Psi_r^{\mp j}(w_r)\right), \tag{C16}$$

$$\mathcal{F}_{p,r}^{(\beta\mathcal{C})}=\oint_0\frac{dw_r}{2\pi\sqrt{-1}}w_r^{p+1/2}(-2\cdot\mathcal{C}_r(w_r)\partial_{w_r}\beta_r(w_r)-3\cdot\partial_{w_r}\mathcal{C}_r(w_r)\cdot\beta_r(w_r)), \tag{C17}$$

$$\mathcal{F}_{p,r}^{(\mathcal{B}\gamma)}=\oint_0\frac{dw_r}{2\pi\sqrt{-1}}w_r^{p+1/2}\cdot\gamma_r(w_r)\cdot\mathcal{B}_r(w_r), \tag{C18}$$

and

$$\mathcal{B}_{2p,r}=\oint_0\frac{dw_r}{2\pi\sqrt{-1}}w_r^{1+2p}\cdot\mathcal{B}_r(w_r). \tag{C19}$$

Operators $\delta^{(n)}(\beta_{p,r})$ (for $n=0,1$) in Eq. (C15) can be calculated by

$$\delta^{(n)}(\beta_{-f-3/2,r})=\sum_{m=0}^{\infty}\sum_{k=0}^{m}\frac{(n+m)!}{(m-k)!k!(n+k)!}$$

$$\times(\beta_{-f-3/2,r})^k\oint_0\frac{dw_r}{2\pi\sqrt{-1}}w_r^{-1+(n+k+1)f}\cdot\delta^{(n+k)}(\beta_r(w_r)), \tag{C20}$$

with

$$\beta_{-f-3/2,r}=\oint_0\frac{dw_r'}{2\pi\sqrt{-1}}w_r'^{-1-f}\cdot\beta_r(w_r') \tag{C21a}$$

and

$$\delta(\beta_r(y_r))\equiv:\exp(+\phi_r(y_r)):. \tag{C21b}$$

Furthermore, it can be shown [for $p\in Z$ $(Z+\frac{1}{2})$] that

$$Y_r(\pm\sqrt{-1})\cdot X_r^p\cdot Y_r(\pm\sqrt{-1})=Y_r(\pm\sqrt{-1}), \tag{C22}$$

$$X_r^p\cdot Y_r(\pm\sqrt{-1})\cdot X_r^p=X_r^p \tag{C23}$$

and

$$Y_r(+\sqrt{-1})\cdot Y_r(-\sqrt{-1})=Y_r(-\sqrt{-1})\cdot Y_r(+\sqrt{-1}). \tag{C24}$$

Exclusively in the $\pi(r)=\mathrm{NS}$ sector, we construct the nonlocal picture-changing operators $X_{\pm,r}^p$ (for any $p\in Z+\frac{1}{2}$) as follows:

$$X_{\pm,r}^p\equiv\{-2\cdot\mathcal{Q}_r,\Theta(\beta_{\pm,r}^p)\}\quad(\text{for }\ p\in Z+\tfrac{1}{2}), \tag{C25}$$

with

$$\beta_{\pm,r}^p\equiv\tfrac{1}{2}((\pm\sqrt{-1})^p\cdot\beta_{-p,r}+(\pm\sqrt{-1})^{-p}\cdot\beta_{p,r}). \tag{C26}$$

Then, we find that

$$X_{\pm,r}^p=((\mathcal{F}^{(\vec{X}\cdot\vec{\Psi})})_{\pm,r}^p+(\mathcal{F}^{(\beta\mathcal{C})})_{\pm,r}^p+(\mathcal{F}^{(\mathcal{B}\gamma)})_{\pm,r}^p)\cdot\delta(\beta_{\pm,r}^p)-\tfrac{1}{2}\cdot\mathcal{B}_{\pm,r}^{\sharp 2p}\cdot\delta^{(1)}(\beta_{\pm,r}^p), \tag{C27}$$

with

$$(\mathcal{F}^{(M)})_{\pm,r}^p\equiv\tfrac{1}{2}((\pm\sqrt{-1})^p\cdot\mathcal{F}_{-p,r}^{(M)}+(\pm\sqrt{-1})^{-p}\cdot\mathcal{F}_{+p,r}^{(M)})\quad\text{for }(M)=(\vec{X}\cdot\vec{\Psi}),(\beta\mathcal{C}),(\mathcal{B}\gamma). \tag{C28a}$$

[Various operators in Eq. (C28) have been defined by Eqs. (C16)–(C18).] In particular, we find that

$$(\mathcal{F}^{(\mathcal{B}\gamma)})_{\pm,r}^p=\gamma_{\pm,r}^p\cdot\mathcal{B}_{\pm,r}^{\sharp 2p}+\gamma_{\mp,r}^p\cdot\mathcal{B}_{\oplus,r}^{2p}+(\text{terms which do not involve }\ \gamma_{\pm,r}^p), \tag{C28b}$$

where we have used that

$$\gamma_{\pm,r}^p\equiv(\pm\sqrt{-1})^p\cdot\gamma_{-p,r}+(\pm\sqrt{-1})^{-p}\cdot\gamma_{p,r}, \tag{C29}$$

$$\mathcal{B}_{\pm,r}^{\sharp 2p}\equiv\tfrac{1}{2}(\mathcal{B}_{0,r}\pm\mathcal{B}_{\natural,r}^{2p})=\tfrac{1}{2}\mathcal{B}_{0,r}+\tfrac{1}{4}((\pm\sqrt{-1})^{2p}\mathcal{B}_{-2p,r}+(\pm\sqrt{-1})^{-2p}\mathcal{B}_{+2p,r}), \tag{C30}$$

and

$$\mathcal{B}^{2p}_{\oplus,r} \equiv \tfrac{1}{4}(\mathcal{B}_{+2p,r} + \mathcal{B}_{-2p,r}). \tag{C31}$$

With the help of $X^p_{\pm,r}$ in (C27), we can prove (for any $p \in Z + \frac{1}{2}$) that

$$X^p_{\pm,r} \cdot Y_r(\pm\sqrt{-1}) \cdot X^p_{\pm,r} = X^p_{\pm,r}, \tag{C32}$$

$$Y_r(\pm\sqrt{-1}) \cdot X^p_{\pm,r} \cdot Y_r(\pm\sqrt{-1}) = Y_r(\pm\sqrt{-1}), \tag{C33}$$

$$X^p_{\pm,r} \cdot Y_r(\mp\sqrt{-1}) = Y_r(\mp\sqrt{-1}) \cdot X^p_{\pm,r}, \tag{C34}$$

$$\begin{aligned} Y_r(+\sqrt{-1}) \cdot Y_r(-\sqrt{-1}) &= Y_r(-\sqrt{-1}) \cdot Y_r(+\sqrt{-1}) \\ &= Y_r(+\sqrt{-1}) \cdot Y_r(-\sqrt{-1})(X^p_{+,r} \cdot X^p_{-,r}) Y_r(+\sqrt{-1}) \cdot Y_r(-\sqrt{-1}), \end{aligned} \tag{C35}$$

and

$$Y_r(\pm\sqrt{-1})[X^p_{+,r}, X^p_{-,r}] Y_r(\pm\sqrt{-1}) = 0. \tag{C36}$$

We remark that X^p_r in (C14) [for $p \in Z$ $(Z + \frac{1}{2})$] and $X^p_{\pm,r}$ in (C25) (for $p \in Z + \frac{1}{2}$) satisfy respectively that

$$[\mathcal{Q}_r, X^p_r] = 0 \quad \text{for any} \quad p \in Z, Z + \tfrac{1}{2}, \tag{C37a}$$

and

$$[\mathcal{Q}^{\mathrm{NS}}_r, X^p_{\pm,r}] = 0 \quad \text{for any} \quad p \in Z + \tfrac{1}{2}. \tag{C37b}$$

Furthermore, we have found the following "commutability:"

$$[\mathcal{B}_{0,r}, X^p_r] = [L_{0,r}, X^p_r] = 0 \quad \text{for any} \quad p \in Z, Z + \tfrac{1}{2}, \quad \text{(to be referred to as the "commutability")} \tag{C38}$$

and

$$\left[\mathcal{B}_{0,r}, \sum_{\pm} \frac{1}{2} \cdot X^p_{\pm,r} \cdot X^p_{\mp,r}\right] = \left[L_{0,r}, \sum_{\pm} \frac{1}{2} \cdot X^p_{\pm,r} \cdot X^p_{\mp,r}\right] = 0 \quad \text{for any} \quad p \in Z + \tfrac{1}{2} \quad \text{(to be referred to as the "commutability")}, \tag{C39}$$

together with

$$[L_{0,r}, \delta(\beta^p_{+,r}) \cdot \delta(\beta^p_{-,r})] = 0 \quad \text{for any} \quad p \in Z + \tfrac{1}{2}. \tag{C40}$$

APPENDIX D: PHYSICAL NEVEU–SCHWARZ AND RAMOND STATES

When the rth (external) open NS superstring is in some physical state (specified by the quantum number, say, b), this (Grassman *odd*) *physical* NS state in 0 picture can be described by[14]

$$|b(0)\rangle_r \equiv :\exp(+\sigma_r(0))::\exp(-\phi_r(0)):V^{0b}_r(0)|\mathcal{Q}_r = 0\rangle_r \quad \text{for} \quad \pi(r) = \mathrm{NS}, \tag{D1}$$

where any (Grassman *odd*) *physical* vertex operator $V_r^{0b}(0)$ [having the conformal weight $(-\Sigma_{j=0}^4 p_b^{+j}\cdot p_b^{-j}+N_b)$] has been explicitly constructed (in our papers in Ref. 14) as the functions of $\vec{X}$ and $\vec{\Psi}$. In Eq. (D1), the standard ket state $|\mathcal{Q}_r=0\rangle_r$ is given by

$$|\mathcal{Q}_r=0\rangle_r \equiv \prod_{\varphi=\vec{X},\vec{\phi},\sigma,\phi,\chi} |p_r(\varphi)=0\rangle_r, \tag{D2a}$$

with

$$|p_r(\vec{\phi})=0\rangle \equiv \prod_{j=0}^{4} |p_r(\phi^j)=0\rangle_r. \tag{D2b}$$

With the help of the ''operator product expansions'' (OPEs) [i.e., (D24)–(D26) to be given later,] we can prove that (Grassman *odd*) physical state $|b(0)\rangle_r$ in (D1) has the following properties:

$$\mathcal{Q}_r^{\rm NS}|b(0)\rangle_r=\mathcal{B}_{0,r}|b(0)\rangle_r=0 \quad [\text{see } \mathcal{Q}_r^{\rm NS} \text{ in (B27)}] \tag{D3}$$

in the *on-shell* limit, i.e.,

$$-\sum_{j=0}^{4} p_b^{+j}\cdot p_b^{-j}+N_b \to \frac{1}{2}. \tag{D4}$$

We notice that the *physical* (Grassman *odd*) NS states in 1 picture [which are denoted by $|b(1)\rangle_r$] can be constructed by using $|b(0)\rangle_r$'s in (D1) as[14]

$$|b(1)\rangle_r = X_{\pm,r}^{1/2}|b(0)\rangle_r = X_r^{-1/2}|b(0)\rangle_r \quad \text{for } \pi(r)=\text{NS}$$

$$=:\exp(+\sigma_r(0)):V_r^{1b}(0)|\mathcal{Q}_r=0\rangle_r-\frac{1}{2}:\exp(+\phi_r(0)):\eta_r(0):V_r^{0b}(0)|\mathcal{Q}_r=0\rangle_r, \tag{D5}$$

which has[11] the following properties:

$$P_r(1)|b(1)\rangle_r=|b(1)\rangle_r \quad [\text{see } P_r(1) \text{ in (1.7)}] \tag{D6}$$

and

$$\mathcal{Q}_r^{\rm NS}|b(1)\rangle_r=\mathcal{B}_{0,r}|b(1)\rangle_r=0 \quad [\text{see } \mathcal{Q}_r^{\rm NS} \text{ in (B27)}]. \tag{D7}$$

Incidentally, the conformal weights ''*d*'' of each factor in Eq. (D5) are given respectively by

$$d(e^{\sigma})+d(V^{1b})=-1+2\left(-\sum_{j=0}^{4} p_{b+}^{j}\cdot p_b^{-j}+N_b\right)=0 \tag{D8}$$

and

$$d(\gamma)+d(V^{0b})=-\frac{1}{2}+\left(-\sum_{j=0}^{4} p_b^{+j}\cdot p_b^{-j}+N_b\right)=0, \tag{D9}$$

where we have used the *on-shell limit* (D4). Finally, we remark that the *physical* (Grassman *odd*) NS states $|b(0)\rangle_r$ in (D1) and $|b(1)\rangle_r$ in (D5) are related to each other by the *local* (inverse) picture-changing operator by

$$\lim_{w\to 0} \vec{R}\cdot X_r(w)\cdot|b(0)\rangle_r=|b(1)\rangle_r \tag{D10}$$

and

$$\lim_{w\to 0} \vec{R}\cdot Y_r(w)\cdot|b(1)\rangle_r=|b(0)\rangle_r . \tag{D11}$$

On the other hand, when the rth open R superstring is in some *physical* state (specified by the quantum number, say, f), this (Grassman *even*) *physical* R state in $\pm\frac{1}{2}$ picture can be described by[14]

$$|f(+\tfrac{1}{2})\rangle_r \equiv :\exp(+\sigma_r(0))::\exp(-\tfrac{1}{2}\phi_r(0)):V_r^{1f}(0)\cdot S_{\{h\},r}(0)|\mathcal{Q}_r=0\rangle_r , \tag{D12}$$

$$|f(-\tfrac{1}{2})\rangle_r \equiv :\exp(+\sigma_r(0))::\exp(-\tfrac{3}{2}\phi_r(0)):V_r^{0f}(0)\cdot S_{\{h\},r}(0)|\mathcal{Q}_r=0\rangle_r , \quad \text{for} \;\; \pi(r)=R, \tag{D13}$$

where Grassman *odd* (*even*) $V_r^{1f}(0)\cdot S_{\{h\},r}(0)$'s $[V_r^{0f}(0)\cdot S_{\{h\},r}(0)$'s$]$ have been explicitly constructed (in our papers in Ref. 14) as the functions of $\vec{X}$ and $\vec{\Psi}$. [We have also proved the OPEs given later by Eqs. (D28)–(D31).] Both of Eqs. (D12) and (D13) have zero conformal weight in the following *on-shell* limit;

$$-\sum_{j=0}^{4} p_f^{+j}\cdot p_f^{-j}+N_f\rightarrow 0. \tag{D14}$$

Furthermore, we find that the *physical* (Grassman *even*) $|f(+1/2)\rangle_r$ in (D12) is related with the *physical* $|f(-1/2)\rangle_r$ in (D13) by

$$|f(+1/2)\rangle_r \equiv X_r^0|f(-1/2)\rangle_r . \tag{D15}$$

Therefore, we find that

$$\begin{aligned} P_r(\tfrac{1}{2})|f(+\tfrac{1}{2})\rangle_r &= X_r^0\cdot Y_r(-\sqrt{-1})|f(+\tfrac{1}{2})_r \quad [\text{from Eq. (1.7)}] \\ &= X_r^0\cdot Y_r(-\sqrt{-1})\cdot X_r^0|f(-\tfrac{1}{2})\rangle_r \quad [\text{from Eq. (D15)}] \\ &= X_r^0|f(-\tfrac{1}{2})\rangle_r \quad [\text{from Eq. (C23)}] \\ &= |f(+\tfrac{1}{2})\rangle_r \quad [\text{from Eq. (D15)}]. \end{aligned} \tag{D16}$$

Incidentally, with respect to the *local* operators $X_r(0)$ and $Y_r(0)$, we find that

$$|f(+\tfrac{1}{2})\rangle_r=\lim_{w\to 0}\vec{R}\cdot X_r(w)|f(-\tfrac{1}{2})\rangle_r \tag{D17}$$

and

$$\begin{aligned} \lim_{w\to 0}\vec{R}\cdot Y_r(w)|f(+1/2)\rangle_r &= :\exp(+2\cdot\sigma_r(0))::\exp(-\tfrac{5}{2}\cdot\phi_r(0)) \\ &\quad \times :\partial\xi_r(0)\cdot V_r^{1f}(0)\cdot S_{\{h\},r}(0)|\mathcal{Q}_r=0\rangle_r . \end{aligned} \tag{D18}$$

Physical R states (D12) and (D13) can be shown to have the following properties:

$$\mathcal{Q}_r^{\mathrm{R}}|f(\pm\tfrac{1}{2})\rangle_r=\mathcal{B}_{0,r}|f(\pm\tfrac{1}{2})\rangle_r=0 \quad [\text{see } \mathcal{Q}_r^{\mathrm{R}} \text{ in (B27)}]. \tag{D19}$$

In Eqs. (D12) and (D13), we have used the *external* FMS spinor $S_{\{h\},r}(0)$ in (A24) (for $r=1-N$). On the other hand, the rth *physical* vertex operators V_r^{0f} (V_r^{1f}) and V_r^{0b} (V_r^{1b}) [given as functions of $(X_r^{\pm j},\Psi_r^{\pm j})$'s] can be obtained from previously obtained[14] *physical* vertex operators V^{0f} (V^{1f}) and V^{0b} (V^{1b}) [given as functions of $(X^{\pm j},\Psi^{\pm j})$'s] by

$$X^{\pm j}(z)\to X_r^{\pm j}(y_r) \tag{D20}$$

and

$$\Psi^{\pm j}(z)\equiv :\exp(\pm\phi^j(z)):\to\Psi_r^{\pm j}(y_r)\equiv :\exp(\pm\phi_r^j(y_r)):. \tag{D21}$$

(See our papers in Ref. 14 for more details.)

In the following, we give various OPEs which have been derived in our previous papers.[14] The ''stress operator $:T_r^{(\vec{X},\vec{\Psi})}(y_r'):_\pi$ in the π-representation'' and the ''stressino operator $\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}\times(y_r')$'' are defined respectively by

$$\begin{aligned} :T_r^{(\vec{X},\vec{\Psi})}(y_r'):_\pi &\equiv :T_r^{(\vec{X})}(y_r'):_\pi + :T_r^{(\vec{\Psi})}(y_r'):_\pi \quad [\text{see Eq. (B4)}] \\ &= \sum_{j=0}^{4} :\partial_{y_r'}X_r^{+j}(y_r')\cdot\partial_{y_r'}X_r^{-j}(y_r'):_\pi \\ &\quad + \sum_{\pm}\sum_{j=0}^{4}\frac{1}{2}:\partial_{y_r'}\Psi_r^{\pm j}(y_r')\cdot\Psi_r^{\mp j}(y_r'):_\pi \quad \text{for } \pi=\text{NS,R} \end{aligned} \tag{D22}$$

and

$$\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}(y_r')\equiv\sum_{\pm}\sum_{j=0}^{4}\partial_{y_r'}X_r^{\pm j}(y_r')\cdot\Psi_r^{\mp j}(y_r') \tag{D23a}$$

$$\equiv\begin{cases}\displaystyle\sum_{n=-\infty}^{\infty}\mathcal{F}_{n,r}^{(\vec{X}\cdot\vec{\Psi})}\cdot y_r'^{\,-n-3/2} & \text{for } \pi(r)=R \\ \displaystyle\sum_{n=-\infty}^{\infty}\mathcal{F}_{n+1/2,r}^{(\vec{X}\cdot\vec{\Psi})}\cdot y_r'^{\,-n-2} & \text{for } \pi(r)=\text{NS}.\end{cases} \tag{D23b}$$

In Ref. 12, we have derived OPEs of the physical vertex operator V_r^{nf} (which is normal ordered in the R-representation) as well as of the *physical* vertex operator V_s^{nb} (which is normal ordered in the NS-representation). In the case $\pi(r)=\text{NS}$, we find the following OPEs with respect to the stress operator (which is normal ordered in the NS-representation):

$$\begin{aligned} &\vec{R}\cdot(:T_r^{(\vec{X},\vec{\Psi})}(y_r'):_{\text{NS}}\cdot V_r^{nb}(y_{0r})) \quad \text{for } n=0,1 \\ &= \frac{1}{(y_r'-y_{0r})^2}\left(\frac{1}{2}\cdot\delta_{n,0}-\sum_{j=0}^{4}p_b^{+j}\cdot p_b^{-j}+N_b\right)V_r^{nb}(y_{0r}) \\ &\quad + \frac{1}{y_r'-y_{0r}}\cdot\partial_{y_{0r}}V_r^{nb}(y_{0r})+O(1), \end{aligned} \tag{D24a}$$

where we have derived[14] that

$$:T_r^{(\vec{X},\vec{\Psi})}(y_r'):_{\text{NS}}=:T_r^{(\vec{X})}(y_r'):_\Sigma+\sum_{j=0}^{4}T_r^{(\phi^j)}(y_r'). \tag{D24b}$$

On the other hand, OPEs with respect to the stressino operator are given by

$$\vec{R}\cdot(\mathcal{F}_r^{(\vec{X},\vec{\Psi})}(y_r')\cdot V_r^{0b}(y_{0r}))=\frac{1}{y_r'-y_{0r}}\cdot V_r^{1b}(y_{0r})+O(1) \tag{D25}$$

and

$$\vec{R}\cdot(\mathcal{F}_r^{(\vec{X},\vec{\Psi})}(y_r')\cdot V_r^{1b}(y_{0r}))$$
$$=\frac{2}{(y_r'-y_{0r})^2}\left(\sum_{j=0}^{4} p_b^{+j}\cdot p_b^{-j}+N_b\right)V_r^{0b}(y_{0r})+\frac{1}{y_r'-y_{0r}}\cdot\partial_{y_{0r}}V_r^{0b}(y_{0r})+O(1). \tag{D26}$$

In OPEs (D24) and (D26), the number operator N_b (in the NS sector) is defined by

$$N_b=\sum_{\pm}\sum_{j=1}^{4}\sum_{n=1}^{\infty}\left(n\cdot e_b(n,\pm j)+\left(n-\frac{1}{2}\right)\cdot\tilde{e}_b\left(n-\frac{1}{2},\pm j\right)\right). \tag{D27}$$

On the other hand, we find in the case $\pi(r)=\mathrm{R}$ the following OPEs with respect to the stress operator (which is normal ordered in the R-representation):

$$\vec{R}\cdot(:T_r^{(\vec{X},\vec{\Psi})}(y_r'):_R\cdot(V_r^{nf}(y_{0r})\cdot S_{\{h\},r}(y_{0r})))\quad\text{for } n=0,1$$
$$=\frac{1}{(y_r'-y_{0r})^2}\left(-\sum_{j=0}^{4} p_f^{+j}\cdot p_f^{-j}+N_f\right)(V_r^{nf}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))$$
$$+\frac{1}{y_r'-y_{0r}}\cdot\partial_{y_{0r}}(V_r^{nf}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))+O(1), \tag{D28a}$$

where we have derived[14] that

$$:T_r^{(\vec{X},\vec{\Psi})}(y_r'):_{\mathrm{R}}=:T_r^{(\vec{X})}(y_r'):_{\Sigma}+\sum_{j=0}^{4} T_r^{(\phi^j)}(y_r')-\frac{\frac{5}{8}}{(y_r'-y_{0r})^2}, \tag{D28b}$$

while the number operator N_f (in the R sector) is defined by

$$N_f\equiv\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4} n(e_f(n,\pm j)+\tilde{e}_f(n,\pm j)). \tag{D29}$$

Furthermore, we have found following OPEs with respect to the stressino operator:

$$\vec{R}\cdot(\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}(y_r')\cdot(V_r^{0f}(y_{0r})\cdot S_{\{h\},r}(y_{0r})))$$
$$=\frac{1}{(\sqrt{y_r'-y_{0r}})^3}(V_r^{1f}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))$$
$$+\frac{1}{\sqrt{y_r'-y_{0r}}}\cdot(\hat{V}_r^{3f}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))+O(\sqrt{y_r'-y_{0r}}) \tag{D30}$$

and

$$\vec{R}\cdot(\mathcal{F}_r^{(\vec{X}\cdot\vec{\Psi})}(y_r')(V_r^{1f}(y_{0r})\cdot S_{\{h\},r}(y_{0r})))$$
$$=\frac{-1}{(\sqrt{y_r'-y_{0r}})^3}\left(-\sum_{j=0}^{4}p_f^{+j}\cdot p_f^{-j}+N_f\right)(V_r^{0f}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))$$
$$-\frac{1}{\sqrt{y_r'-y_{0r}}}\cdot\partial_{y_{0r}}(V_r^{0f}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))+\frac{1}{\sqrt{y_r'-y_{0r}}}(\hat{V}_r^{4f}(y_{0r})\cdot S_{\{h\},r}(y_{0r}))$$
$$+O(\sqrt{y_r'-y_{0r}}). \tag{D31}$$

At this stage, we remark that Eq. (B6) has been derived from Eqs. (D24b) and (D28b) (in the case $D=10$), together with

$$:T_r^{(\mathcal{BC})}(y_r'):_\pi=T_r^{(\sigma)}(y_r')+\frac{\delta_\pi^R}{(y_r'-y_{0r})^2} \tag{D32}$$

and

$$:T_r^{(\beta\gamma)}(y_r'):_\pi=T_r^{(\phi)}(y_r')+T_r^{(\chi)}(y_r')-\frac{\frac{3}{8}\delta_\pi^R}{(y_r'-y_{0r})^2}, \tag{D33}$$

where we have used Eq. (B7). The presence of the last term of Eq. (D32) is induced by the following contraction in the R sector:

$$\overset{\sqcap\,\mathrm{R}\,\sqcap}{\mathcal{B}_r(y_r)\mathcal{C}_t(y_t')}\equiv\frac{\delta_{rt}}{y_r-y_t'}\cdot\left(\frac{y_t'-y_{0t}}{y_r-y_{0r}}\right)\quad[\text{see Eq. (A46)}]. \tag{D34}$$

APPENDIX E: SMALL GLUING VERTEX FUNCTINO, LARGE GLUING VERTEX FUNCTION, GLUING IDENTITIES, AND GLUING RELATIONS

In this appendix, we derive the *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ (which is useful in tree calculations), the *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ (which is useful in loop calculations), *gluing identities* and *gluing relations* (which are valid within the *small* or *large* Hilbert space). First, the *large* (*small*) Hilbert space[9] is the space with [without] ξ_0-mode, so that the difference among the *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ and the *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ exists only in the hilberting modes $[\chi,\ \xi,\ \eta]$.

In order to discuss ξ_0-mode, we use the following inlaying operator $\mathcal{W}_r^\chi[z_{r_\mathcal{J}}(w_r)]$ ''in $\xi\eta$-mode,'' rather than $W_r^\chi[z_{r_\mathcal{J}}(w_r)]$ (2.5) ''in χ-mode;''

$$\mathcal{W}_r^\chi[z_{r_\mathcal{J}}(w_r)]\equiv\exp\left(-\oint_0\frac{dw_r}{2\pi\sqrt{-1}}\oint_0\frac{dw_r'}{2\pi\sqrt{-1}}\xi_r(w_r;+)\,\eta_r(w_r';+)\right.$$
$$\left.\times\left(\frac{z_{r_\mathcal{J}}^{(1)}(w_r)}{z_{r_\mathcal{J}}(w_r)-z_{r_\mathcal{J}}(w_r')}-\frac{1}{w_r-w_r'}\right)\right):\exp\left(\oint_0\frac{dw_r}{2\pi\sqrt{-1}}(z_{r_\mathcal{J}}^{(1)}(w_r)\cdot\eta(z_{r_\mathcal{J}}(w_r))\right.$$
$$\left.\cdot\,\xi_r(w_r';+)+\xi(z_{r_\mathcal{J}}(w_r))\cdot\eta_r(w_r';+))\right):_\Sigma. \tag{E1}$$

Replacing $W_r^\chi[\cdots]$ in (2.7) with $\mathcal{W}_r^\chi[\cdots]$ in (E1) (''in $\xi\eta$-mode''), we can construct *another* inlaying N-vertex function ${}_\mathcal{J}\langle IV^\chi(1,2,...,N)|$ ''in $\xi\eta$-mode,'' which can be shown to satisfy the following inlaying identities for the hilbertino ξ and anti-hilbertino η:

$$_s\langle IV^\chi(1,2,...,N)|\mathcal{G}_r(w')={}_s\langle IV^\chi(1,2,...,N)|(z_{rs}^{(1)}(w'))^{d(\mathcal{G})}\mathcal{G}(z_{rs}(w'))$$
$$\text{for } \mathcal{G}=\xi,\eta \quad \text{with } d(\xi)=0,\ d(\eta)=1. \tag{E2}$$

Furthermore, we can derive from Eq. (E1) the following results:

$$\mathcal{W}_\gamma^\chi[w_\gamma]|p(\chi)=0\rangle=\exp\left(\sum_{n=1}^{\infty}\eta_{-n}\cdot\xi_{n,\gamma}+\sum_{n=0}^{\infty}\xi_{-n}\cdot\eta_{n,\gamma}\right)|p(\chi)=0\rangle \tag{E3}$$

and

$$(\langle\tilde{p}(\chi)=0|\tilde{\xi}_0)\tilde{\mathcal{W}}_\delta^\chi\left[\frac{-1}{w_\delta}\right]=(\langle\tilde{p}(\chi)=0|\tilde{\xi}_0)\exp\left(-\sum_{n=0}^{\infty}(-)^n\cdot\tilde{\eta}_n\cdot\xi_{n\delta}+\sum_{n=1}^{\infty}(-)^n\cdot\tilde{\xi}_n\cdot\eta_{n\delta}\right). \tag{E4}$$

It should be noticed that there exist zero-modes $\xi_0\cdot\eta_{0,\gamma}$ and $\tilde{\eta}_0\cdot\xi_{0,\delta}$ within the exponential factor on the right-hand side of Eqs. (E3) and (E4), respectively. Then, $\langle\mathcal{V}_S^\chi(\gamma,\delta)|$ is defined by

$$\langle\mathcal{V}_S^\chi(\gamma,\delta)|=\langle\mathcal{V}_S^\chi(\delta,\gamma)|\equiv({}_\gamma\langle p_\gamma(\chi)=0|\xi_{0,\gamma})({}_\delta\langle p_\delta(\chi)=0|\xi_{0,\delta})$$
$$\times(\langle p(\chi)=0|\xi_0)\mathcal{W}_\delta^\chi\left[\frac{-1}{w_\delta}\right]\cdot\mathcal{W}_\gamma^\chi[w_\gamma](|p(\chi)=0\rangle). \tag{E5}$$

Substituting Eqs. (E3) and (E4) into Eq. (E5), we find that

$$\langle\mathcal{V}_S^\chi(\gamma,\delta)|=({}_\gamma\langle p_\gamma(\chi)=0|\xi_{0,\gamma})({}_\delta\langle p_\delta(\chi)=0|\xi_{0,\delta})\exp\left(\sum_{n=1}^{\infty}(-)^n\cdot\xi_{n\delta}\cdot\eta_{n\gamma}-\sum_{n=1}^{\infty}(-)^n\cdot\eta_{n\delta}\cdot\xi_{n\gamma}\right), \tag{E6}$$

which does *not* have any zero-mode contribution within the exponential factor. [Hereafter, $\langle\mathcal{V}_S^\chi(\gamma,\delta)|$ will be referred to as the *small* two-point vertex function ''in $\xi\eta$-mode.''] On the other hand, with the help of

$$({}_\gamma\langle p_\gamma(\chi)=0|\xi_{0,\gamma})({}_\delta\langle p_\delta(\chi)=0|\xi_{0,\delta})=({}_\gamma\langle p_\gamma(\chi)=0|)({}_\delta\langle p_\delta(\chi)=0|\xi_{0,\delta})\exp(-\eta_{0,\delta}\cdot\xi_{0,\gamma})\cdot\xi_{0,\gamma}$$
$$=({}_\gamma\langle p_\gamma(\chi)=0|\xi_{0,\gamma})({}_\delta\langle p_\delta(\chi)=0|)\exp(+\xi_{0,\delta}\cdot\eta_{0,\gamma})\cdot\xi_{0,\delta}, \tag{E7}$$

$\langle\mathcal{V}_S^\chi(\gamma,\delta)|$ in (E6) ''in $\xi\eta$-mode'' can be rewritten into

$$\langle\mathcal{V}_S^\chi(\gamma,\delta)|=\langle\nu_\mathcal{L}^\chi(\gamma,\delta)|\xi_{0,\gamma}=\langle\nu_\mathcal{L}^\chi(\gamma,\delta)|\xi_{0,\delta}, \tag{E8}$$

$\langle\nu_\mathcal{L}^\chi(\gamma,\delta)|$ being given by

$$\langle\nu_\mathcal{L}^\chi(\gamma,\delta)|=\langle\nu_\mathcal{L}^\chi(\delta,\gamma)|\equiv({}_\gamma\langle p_\gamma(\chi)=0|)({}_\delta\langle p_\delta(\chi)=0|\xi_{0,\delta})$$
$$\times\exp\left(\sum_{n=1}^{\infty}(-)^n\cdot\xi_{n\delta}\cdot\eta_{n\gamma}-\sum_{n=0}^{\infty}(-)^n\cdot\eta_{n\delta}\cdot\xi_{n\gamma}\right), \tag{E9}$$

which has the zero-mode contribution within the exponential factor. [Hereafter, $\langle\nu_\mathcal{L}^\chi(\gamma,\delta)|$ will be referred to as the *large* two-point vertex functino ''in $\xi\eta$-mode.''] Furthermore, with the help of

$$({}_\gamma\langle p_\gamma(\chi)=0|)({}_\delta\langle p_\delta(\chi)=0|)\xi_{0,\delta}(1-\eta_{0,\delta}\cdot\xi_{0,\gamma})\,\eta_{0,\delta}$$
$$=({}_\gamma\langle p_\gamma(\chi)=0|)({}_\delta\langle p_\delta(\chi)=0|)$$
$$=-({}_\gamma\langle p_\gamma(\chi)=0|)({}_\delta\langle p_\delta(\chi)=0|)\xi_{0,\delta}(1-\eta_{0,\delta}\cdot\xi_{0,\gamma})\,\eta_{0,\gamma}, \tag{E10}$$

we find that

$$\langle \nu_{\mathcal{L}}^{\chi}(\gamma,\delta)|\eta_{0,\delta} = -\langle \nu_{\mathcal{L}}^{\chi}(\gamma,\delta)|\eta_{0,\gamma}. \tag{E11}$$

At this stage, $|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle$ is introduced by

$$|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle \equiv \exp\left(\sum_{n=1}^{\infty}(-)^{n}\cdot\eta_{-n,\gamma}\cdot\xi_{-n,\delta} - \sum_{n=1}^{\infty}(-)^{n}\cdot\xi_{-n,\gamma}\cdot\eta_{-n,\delta}\right)|p_{\gamma}(\chi)=0\rangle_{\gamma}\cdot|p_{\delta}(\chi)=0\rangle_{\delta}, \tag{E12}$$

which does not have any zero-mode component. Hereafter, $|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle$ will be referred to as the *small* gluing vertex function ''in $\xi\eta$-mode.'' It is to be noticed that $|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle$ in (E12) is related with $\langle\mathcal{V}_{S}^{\chi}(\gamma,\delta')|$ in (E6) ''in $\xi\eta$-mode'' by

$$\langle\mathcal{V}_{S}^{\chi}(\gamma,\delta')|\mathcal{V}_{S}^{\chi}(\delta',\delta)\rangle = ({}_{\gamma}\langle p_{\gamma}(\chi)=0|\xi_{0,\gamma})\cdot\exp\left(\sum_{n=1}^{\infty}\xi_{-n,\delta}\cdot\eta_{n,\gamma} + \sum_{n=1}^{\infty}\eta_{-n,\delta}\cdot\xi_{n,\gamma}\right)\cdot(|p_{\delta}(\chi)=0\rangle_{\delta}), \tag{E13}$$

which does not have any zero-mode component within the exponential factor. Incidentally, the operator (E13) maps the γth external $\xi_{-n,\gamma}$ ($\eta_{-n,\gamma}$) into the δth external $\xi_{-n,\delta}$ ($\eta_{-n,\delta}$) for nonzero modes (i.e., for $n\neq 0$). Since we have that

$$0 = \eta_{0,\gamma}|p_{\gamma}(\chi)=0\rangle_{\gamma}|p_{\delta}(\chi)=0\rangle_{\delta} = \eta_{0,\delta}|p_{\gamma}(\chi)=0\rangle_{\gamma}|p_{\delta}(\chi)=0\rangle_{\delta}, \tag{E14}$$

we can find that $|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle$ in (E12) ''in $\xi\eta$-mode'' satisfies the following *gluing relations* in the *small* Hilbert space:

$$\partial_{w}\xi_{\gamma}(w)|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle = \partial_{w}\xi_{\delta}(-1/w)|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle \tag{E15}$$

and

$$w^{2}\cdot\eta_{\gamma}(w)|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle = \eta_{\delta}(-1/w)|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle. \tag{E16}$$

Furthermore, $|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle$ in (E12) ''in $\xi\eta$-mode'' can be expressed by

$$|\mathcal{V}_{S}^{\chi}(\gamma,\delta)\rangle = \eta_{0,\gamma}|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle = -\eta_{0,\delta}|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle, \tag{E17}$$

$|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle$ being defined by

$$\begin{aligned}|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle &= -|\nu_{\mathcal{L}}^{\chi}(\delta,\gamma)\rangle \\ &\equiv \exp\left(\sum_{n=0}^{\infty}(-)^{n}\cdot\eta_{-n,\gamma}\cdot\xi_{-n,\delta} - \sum_{n=1}^{\infty}(-)^{n}\cdot\xi_{-n,\gamma}\cdot\eta_{-n,\delta}\right) \\ &\quad\times(\xi_{0,\gamma}|p_{\gamma}(\chi)=0\rangle_{\gamma})(|p_{\delta}(\chi)=0\rangle_{\delta}),\end{aligned} \tag{E18}$$

which has zero modes within the exponential factor, so that we find the following *gluing* relations even for the zero-mode $\xi_{0,\gamma}$:

$$\xi_{0,\gamma}|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle = \xi_{0,\delta}|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle. \tag{E19a}$$

Therefore, we find from Eqs. (E15)–(E17) and (E19) that $|\nu_{\mathcal{L}}^{\chi}(\gamma,\delta)\rangle$ in (E18) ''in $\xi\eta$-mode'' satisfies the following gluing relations within the *large* Hilbert space:

$$\xi_\gamma(w)|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle=\xi_\delta(-1/w)|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle,$$
$$w^2\cdot\eta_\gamma(w)|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle=\eta_\delta(-1/w)|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle. \tag{E19b}$$

[Hereafter, $|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle$ in (E18) will be referred to as the *large* gluing vertex functino ''in $\xi\eta$-mode.''] On the other hand, the gluing vertex functino $|V^\chi(\gamma,\delta)\rangle$ in (2.19) (''in χ-mode'') has the same gluing relations as those (E19b) satisfied by $|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle$ in (E18) ''in $\xi\eta$-mode.'' Therefore, $|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle$ in (E18) ''in $\xi\eta$-mode'' is just equal to $|V^\chi(\gamma,\delta)\rangle$ in (2.20) ''in χ-mode,'' i.e.,

$$|\nu_{\mathcal{L}}^\chi(\gamma,\delta)\rangle=|V^\chi(\gamma,\delta)\rangle. \tag{E20}$$

As for $|V^\varphi(\gamma,\delta)\rangle$'s in (2.19) and (2.20) [for $\varphi=\vec{X},\phi^j,\sigma,\phi(,\chi)$], they are found to satisfy the following *gluing identities*: By using the inlint standard ket states $|p(\varphi)=0\rangle$ [satisfying Eq. (A6)] and the inlint dual standard bra states $\langle p(\varphi)=0|$ in (A9) [for $\varphi=\vec{X},\phi^j,\sigma,\phi(,\chi)$, and $j=0-4$], we find for $\vec{X}$-modes that

$$_\gamma\langle q_\gamma(\vec{X})=0|\cdot{}_\delta\langle q_\delta(\vec{X})=0|(W_\gamma^{\vec{X}}[w_\gamma]|p(\vec{X})=0\rangle)\left(\langle\tilde{p}(\vec{X})=0|\tilde{W}_\delta^{\vec{X}}\left[\frac{-1}{w_\delta}\right]\right)|V^{\vec{X}}(\gamma,\delta)\rangle \tag{E21a}$$

$$=\left(:\exp\left(\sum_\pm\sum_{j=0}^4\sum_{n=1}^\infty\frac{1}{n}\cdot J_{-n}(X^{\pm j})\cdot\tilde{J}_n(X^{\mp j})\right)\right)$$
$$\times\left(\sum_{\{p^{\pm j}\}}\exp\left(\sum_\pm\sum_{j=0}^4 p^{\pm j}\cdot q(X^{\mp j})\right)|p(\vec{X})=0\rangle\right.$$
$$\left.\times\langle\tilde{p}(\vec{X})=0|\exp\left(-\sum_\pm\sum_{j=0}^4 p^{\pm j}\cdot\tilde{q}(X^{\mp j})\right)\right): \tag{E21b}$$

$$\equiv E_{\vec{X}}(J(\vec{X}),\tilde{J}(\vec{X})), \tag{E21c}$$

while we find for φ-modes [$\varphi=\phi^j,\sigma,\phi(,\chi)$] that

$$_\gamma\langle q_\gamma(\varphi)=0|\cdot{}_\delta\langle q_\delta(\varphi)=0|(W_\gamma^\varphi[w_\gamma]|p(\varphi)=0\rangle)\left(\langle\tilde{p}(\varphi)=0|\tilde{W}_\delta^\varphi\left[\frac{-1}{w_\delta}\right]\right)|V^\varphi(\gamma,\delta)\rangle \tag{E22a}$$

$$=:\exp\left(\sum_{n=1}^\infty\varepsilon_\varphi^\phi\cdot\frac{1}{n}\cdot J_{-n}(\varphi)\cdot\tilde{J}_n(\varphi)\right)$$
$$\times\left(\sum_{p\in Z(+1/2)}\exp(p\cdot q(\varphi))|p(\varphi)=0\rangle\langle\tilde{p}(\varphi)=0|\exp(-(p+Q(\varphi))\tilde{q}(\varphi))\right): \tag{E22b}$$

$$\equiv E_\varphi(J(\varphi),\tilde{J}(\varphi))\quad\text{for}\ \ \varphi=\phi^j,\sigma,\phi(,\chi). \tag{E22c}$$

In Eqs. (E21) and (E22), we have used inlaying operators $W^\varphi[\dots]$'s (2.4) and (2.5) ''in φ-modes.'' Incidentally, for any state $H(\tilde{J}(\vec{X}))|\tilde{p}(\vec{X})=0\rangle$ and $G(\tilde{J}(\varphi))|\tilde{p}(\tilde{\varphi})=0\rangle$, we find that

$$E_{\vec{X}}(J(\vec{X}),\tilde{J}(\vec{X}))\cdot H(\tilde{J}(\vec{X}))|\tilde{p}(\vec{X})=0\rangle=H(J(\vec{X}))|p(\vec{X})=0\rangle \tag{E23}$$

and

$$E_\varphi(J(\varphi),\tilde{J}(\varphi))\cdot G(\tilde{J}(\varphi))|\tilde{p}(\varphi)=0\rangle=G(J(\varphi))|p(\varphi)=0\rangle\quad\text{for}\ \ \varphi=\phi^j,\sigma,\phi(,\chi). \tag{E24}$$

[Incidentally, Eq. (E24) for $\varphi=\chi$ is the gluing identity within the *large* Hilbert space.] On the other hand, with the help of the inlaying operator $\mathcal{W}^{\chi}[\ldots]$ in (E1) ''in $\xi\eta$-mode'' and the *small* gluing vertex function $|\mathcal{V}_S^{\chi}(\gamma,\delta)\rangle$ in (E17) ''in $\xi\eta$-mode,'' we find from Eqs. (E3) and (E4) the following gluing identity within the *small* Hilbert space:

$$ {}_{\gamma}\langle q_{\gamma}(\chi)=0|\cdot{}_{\delta}\langle q_{\delta}(\chi)=0|(\mathcal{W}_{\gamma}^{\chi}[w_{\gamma}]|p(\chi)=0\rangle)\left((\langle\tilde{p}(\chi)=0|\tilde{\xi}_0)\cdot\tilde{\mathcal{W}}_{\delta}^{\chi}\left[\frac{-1}{w_{\delta}}\right]\right)|\mathcal{V}_S^{\chi}(\gamma,\delta)\rangle \tag{E25a}$$

$$ =:\exp\left(\sum_{n=1}^{\infty}\eta_{-n}\cdot\tilde{\xi}_n+\sum_{n=1}^{\infty}\xi_{-n}\cdot\tilde{\eta}_n\right)(|p(\chi)=0\rangle\cdot\langle\tilde{p}(\chi)=0|\tilde{\xi}_0):_{\Sigma} \tag{E25b}$$

$$ =\mathcal{E}_{\chi}(\mathcal{J}_{\chi},\tilde{\mathcal{J}}_{\chi}). \tag{E25c}$$

It should be noticed that zero-mode terms $\xi_0\cdot\eta_{0,\gamma}$ and $\tilde{\eta}_0\cdot\xi_{0,\delta}$ in Eqs. (E3) and (E4) are *absent* in the exponential factor of Eq. (E25b), since we have that

$$ {}_{\delta}\langle q_{\delta}(\chi)=0|\xi_{0,\delta}=0=\eta_{0,\gamma}|p_{\gamma}(\chi)=0\rangle_{\gamma}=0. \tag{E26}$$

Thus, $\mathcal{J}_{\chi}$ $[\tilde{\mathcal{J}}_{\chi}]$ in Eq. (E25c) represents inlint operators *without* ξ_0-mode (those *without* $\tilde{\xi}_0$-mode). Furthermore, we obtain for any state $K(\tilde{\mathcal{J}}_{\chi})|\tilde{p}(\chi)=0\rangle$ (without zero modes) that

$$ \mathcal{E}_{\chi}(\mathcal{J}_{\chi},\vec{\mathcal{J}}_{\chi})(K(\tilde{\mathcal{J}}_{\chi})|\tilde{p}(\chi)=0\rangle)=(K(\mathcal{J}_{\chi})|p(\chi)=0\rangle). \tag{E27}$$

The normal ordering operations : : in Eqs. (E21b), (E22b), and (E25b) mean that any operator with the superscript ''$\sim$'' should be moved and placed to the right of $\langle p(\varphi)=0|$ (for $\varphi=\vec{X},\varphi^j,\sigma,\phi$) or $\langle\tilde{p}(\chi)=0|\tilde{\xi}_0$.

Identities (E21)=(E21c), (E22)=(E22c), and (E25)=(E25c) will be hereafter referred to as the ''*gluing identities*,'' on the left-hand sides of which the γth punctured ring domain and the δth punctured ring domain exist, since we have both the inlaying operators $W_{\gamma}[w_{\gamma}]$ and $\tilde{W}_{\delta}[-1/w_{\delta}]$. On the other hand, we have not any punctured ring domains on the right-hand sides of the ''gluing identities.'' This fact suggests that $|V^{\varphi}(\gamma,\delta)\rangle$ in (2.18) and (2.19) (for $\varphi\neq\chi$) and $|\mathcal{V}_S^{\chi}(\gamma,\delta)\rangle$ in (E12) ''in $\xi\eta$-mode'' have the the following *gluing effect*: They *glue* the γth punctured ring domain and the δth punctured ring domain into one *un*punctured ring domain (described by *common* inlint operators, within the *small* Hilbert space). Combining all these ''gluing identities'' in various modes, we finally obtain one (GSO projected) ''gluing identity'' (in the *small* Hilbert space) which is symbolically expressed by

$$\begin{aligned}
&\left(\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi}{}_{\gamma}\langle q_{\gamma}(\varphi)=0|W_{\gamma}^{\varphi}[w_{\gamma}]\right)(({}_{\gamma}\langle p_{\gamma}(\chi)=0|\xi_{0,\gamma})\mathcal{W}_{\gamma}^{\chi}[w_{\gamma}])\\
&\quad\times\left(\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi,\chi}|p(\varphi)=0\rangle\right)\cdot\left(\prod_{\tilde{\varphi}=\tilde{\vec{X}},\tilde{\phi}^j,\tilde{\sigma},\tilde{\phi},\tilde{\chi}}\langle p(\tilde{\varphi})=0\right)\tilde{\xi}_0\\
&\quad\times\left(\prod_{\tilde{\varphi}=\tilde{\vec{X}},\tilde{\phi}^j,\tilde{\sigma},\tilde{\phi}}{}_{\delta}\langle q_{\delta}(\tilde{\varphi})=0|W_{\delta}^{\tilde{\varphi}}\left[\frac{-1}{w_{\delta}}\right]\right)\left(({}_{\delta}\langle p_{\delta}(\tilde{\chi})=0|\tilde{\xi}_{0,\delta})\cdot\mathcal{W}_{\delta}^{\tilde{\chi}}\left[\frac{-1}{w_{\delta}}\right]\right)\\
&\quad\times P_{\gamma}^{\pi(\gamma)}(\mathrm{GSO})|\mathcal{V}_S^{\chi}(\gamma,\delta)\rangle\left(\prod_{\varphi=\vec{X},\phi^J,\sigma,\phi}|V^{\varphi}(\gamma,\delta)\rangle\right)\\
&\quad=P^{\pi(\gamma)}(\mathrm{GSO})\cdot E(J,\tilde{J}),
\end{aligned}\tag{E28a}$$

with

$$E(J,\tilde{J}) \equiv E_{\vec{X}}(J(\vec{X}),\tilde{J}(\vec{X}))\cdot \mathcal{E}_{\chi}(\mathcal{J}_{\chi},\tilde{\mathcal{J}}_{\chi})\left(\prod_{\varphi=\phi^j,\sigma,\phi} E_{\varphi}(J(\varphi),\tilde{J}(\varphi))\right). \tag{E28b}$$

In Eq. (E28), $P_{\gamma}^{\pi(\gamma)}$ (GSO) [for $\pi(\gamma)=$NS,R] is the γth external GSO-projection operator and $P^{\pi(\gamma)}$ (GSO) is the inlint GSO-projection operator, both of which are defined by Eq. (1.11). The gluing identity (E28) is valid for any ket (bra) state in the *small* Hilbert space. Hereafter, the gluing identity (E25) will be simply expressed by

$$({}_{\gamma}\langle q_{\gamma}=0|W_{\gamma}[w_{\gamma}]|\mathcal{Q}=0\rangle)\cdot\left((\langle\tilde{\mathcal{Q}}=0|\tilde{\xi}_0)\times{}_{\delta}\langle q_{\delta}=0|\tilde{W}_{\delta}\left[\frac{-1}{w_{\delta}}\right]\right)(P_{\gamma}^{\pi}(\text{GSO})|\nu_{\mathcal{S}}(\gamma,\delta)\rangle)$$

$$=P^{\pi}(\text{GSO})\cdot E(J,\tilde{J})\quad(\text{to be referred to as the gluing identity}). \tag{E29}$$

In Equation (E29), we have used the *small* gluing vertex funct*ino* $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$, which has been constructed by

$$|\nu_{\mathcal{S}}(\gamma,\delta)\rangle\equiv|\mathcal{V}_{\mathcal{S}}^{\chi}(\gamma,\delta)\rangle\left(\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi}|V^{\varphi}(\gamma,\delta)\rangle\right). \tag{E30a}$$

Incidentally, we have also that

$$\langle\nu_{\mathcal{S}}(\gamma,\delta)|\equiv\langle\mathcal{V}_{\mathcal{S}}^{\chi}(\gamma,\delta)|\left(\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi}\langle V^{\varphi}(\gamma,\delta)|\right)\quad[\text{see Eq. (2.14)}]. \tag{E30b}$$

It is remarkable that the *small* gluing vertex funct*ino* $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ constructed by Eq. (E30) can be alternatively given by

$$|\nu_{\mathcal{S}}(\gamma,\delta)\rangle=\eta_{0,\gamma}|V_L(\gamma,\delta)\rangle\quad[\text{see Eq. (E17)}], \tag{E31}$$

where the *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ *can* be constructed in terms of φ-modes (i.e., without using $\xi\eta$-modes) by

$$|V_L(\gamma,\delta)\rangle\equiv\prod_{\varphi=\vec{X},\phi^j,\sigma,\phi,\chi}|V^{\varphi}(\gamma,\delta)\rangle, \tag{E32}$$

$|V^{\vec{X}}(\gamma,\delta)\rangle$ ($|V^{\varphi}(\gamma,\delta)\rangle$) being given by Eq. (2.18) [(2.19)]. [As we shall see in Sec. IV, $|V_L(\gamma,\delta)\rangle$ is useful especially in loop calculations, since it gives gluing identities within the *large* Hilbert space.]

With the help of the gluing identity (E29) in the *small* Hilbert space, we can prove the gluing theorem in the tree calculations [i.e., Eq. (2.20)], using the techniques used in Ref. 5. In particular, the elementary vertex functino $\langle\nu_{\mathcal{S}}(\ldots)|$'s satisfy the following gluing theorem:

$$\langle\nu_{\mathcal{S}}(1,2,...,n,\gamma)|\cdot\langle\nu_{\mathcal{S}}(\delta,n+1,n+2,...,n+m)|\nu_{\mathcal{S}}(\gamma,\delta)\rangle=\langle\nu_{\mathcal{S}}(1,2,...,n,n+1,n+2,...,n+m)| \tag{E33a}$$

$$[=\langle\nu_{\mathcal{S}}(2,...,n+m,1)|,\quad\text{being cycle symmetric}], \tag{E33b}$$

so that $\langle\nu_{\mathcal{S}}(1,2,...,N)|$ in (2.14) is found to be constructed by using the inlayed coordinate $z_{rm}(w_r)$ (for $r=1-N$) in the ''inlayed coordinate system m(*idpoint*)'' (ICS m), which is given by

$$z_{rm}(w_r)=\exp\left(\frac{\pi\sqrt{-1}}{N}\right)\cdot\frac{z_r(w_r)-1}{z_r(w_r)-\exp(2\pi\sqrt{-1}/N)}\quad\text{for } r=1-N, \tag{E34}$$

with

$$z_r(w_r)\equiv\left(\exp\frac{2\pi\sqrt{-1}}{N}(r-1)\right)\left(\frac{1+\sqrt{-1}\cdot w_r}{1-\sqrt{-1}\cdot w_r}\right)^{2/N}. \tag{E35}$$

Incidentally, there exist *only* N punctured ring domains and *not any* unpunctured ring domain in ''ICS m,'' and the inlayed coordinate ''z_m'' satisfies the following Gross–Jevicki fundamental equation (GJ-$\mathcal{FE}$):[17]

$$\frac{dz_m}{d\rho_m}=(-)^N\cdot\frac{\Pi_{r(\neq 2)}(z_m-z_{rm}(0))}{((z_m-\mathcal{Y}_+^m)\cdot(z_m-\mathcal{Y}_-^m))^{(N-2)/2}}, \tag{E36a}$$

with

$$\mathcal{Y}_\pm^m\equiv\exp(\pm\pi\sqrt{-1}/N). \tag{E36b}$$

It is to be noticed that GJ-$\mathcal{FE}$ (E36) leads to the rth inlayed coordinate $z_{rm}(w_r)$'s in (E34). [Unfortunately there exist misprints in Eq. (1.15) of Ref. 5, which are corrected in Eq. (E36).] We notice that the elementary vertex functino on the right-hand side of Eq. (E33) is *symmetric* under the *cyclic* permutation. [See the cycle-symmetric coordinate $z_r(w_r)$'s in (E35).] Therefore, we also have that

$$\langle\nu_{\mathcal{S}}(n+1,n+2,...,n+m,\delta)|\cdot\langle\nu_{\mathcal{S}}(\gamma,1,2,...,n)|\nu_{\mathcal{S}}(\delta,\gamma)\rangle=\langle\nu_{\mathcal{S}}(n+1,n+2,...,n+m,1,2,...,n)|. \tag{E37}$$

Since any elementary vertex functino $\langle\nu_{\mathcal{S}}(\dots)|$ is Grassman odd, comparing Eq. (E37) with Eq. (E33) leads to the fact that the *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ is odd under $\gamma\leftrightarrow\delta$, i.e.,

$$|\nu_{\mathcal{S}}(\gamma,\delta)\rangle=-|\nu_{\mathcal{S}}(\delta,\gamma)\rangle. \tag{E38}$$

Since we have from Eqs. (E38) that

$$\begin{aligned}\langle\nu_{\mathcal{S}}(1,2,...,n)|&=\langle\nu_{\mathcal{S}}(1,\gamma)|\cdot\langle\nu_{\mathcal{S}}(\delta,2,3,...,n)|\nu_{\mathcal{S}}(\gamma,\delta)\rangle\\&=-\langle\nu_{\mathcal{S}}(\delta,2,3,...,n)|(\langle\nu_{\mathcal{S}}(1,\gamma)|\nu_{\mathcal{S}}(\gamma,\delta)\rangle),\end{aligned} \tag{E39}$$

we also find that

$$\langle\nu_{\mathcal{S}}(\alpha,\gamma)|\nu_{\mathcal{S}}(\gamma,\delta)\rangle=-E_{\alpha,\delta}, \tag{E40}$$

where $E_{\alpha,\delta}$ is the operator changing the αth external operator $\mathcal{G}_\alpha$ into the δth external operator $\mathcal{G}_\delta$ (i.e., $E_{\alpha,\delta}|\mathcal{G}\rangle_\alpha=|\mathcal{G}\rangle_\delta$).

For any primary operator $\mathcal{G}$ (*without* ξ_0-mode) of conformal weight $d(\mathcal{G})$, we have the following *gluing relation* in the *small* Hilbert space satisfied by the total *small* gluing vertex functino $|\nu_{\mathcal{S}}(\gamma,\delta)\rangle$ in (E31):

$$\left((w^{2d(\mathcal{G})})\mathcal{G}_\gamma(w)-\mathcal{G}_\delta\left(\frac{-1}{w}\right)\right)|\nu_{\mathcal{S}}(\gamma,\delta)\rangle=0. \tag{E41}$$

Therefore, using

$$\mathcal{G}_r(w)=\frac{1}{w^{d(\mathcal{G})}}\left(\sum_{n=-\infty}^{\infty}g_{n,r}\cdot w^{-n}\right)\quad(\text{for}\ \ r=\gamma,\delta), \tag{E42}$$

we find from Eq. (E41) the following *gluing relations* for various modes (in the *small* Hilbert space):

$$g_{n,\gamma}|\nu_{\mathcal{S}}(\gamma,\delta)\rangle=(-)^{d(\mathcal{G})+n}\cdot g_{-n,\delta}|\nu_{\mathcal{S}}(\gamma,\delta)\rangle. \tag{E43}$$

It is quite important in loop calculations that the total *large* gluing vertex function $|V_L(\gamma,\delta)\rangle$ in (E32) "in φ-modes" satisfies the following gluing relations:

$$\left((w^{2d(\mathcal{G})})\mathcal{G}_\gamma(w)-\mathcal{G}_\delta\left(\frac{-1}{w}\right)\right)|V_L(\gamma,\delta)\rangle=0, \tag{E44}$$

which holds for any primary operator (with or without the ξ_0-mode).

Asymptotics of Clebsch–Gordan coefficients

Matthias W. Reinsch and James J. Morehead
Department of Physics, University of California, Berkeley, California 94720

(Received 4 April 1999; accepted for publication 30 June 1999)

Asymptotic expressions for Clebsch–Gordan coefficients are derived from an exact integral representation. Both the classically allowed and forbidden regions are analyzed. Higher-order approximations are calculated. These give, for example, six digit accuracy when the quantum numbers are in the hundreds. © *1999 American Institute of Physics.* [S0022-2488(99)01210-4]

I. INTRODUCTION

This paper contains a detailed study of the asymptotics of Clebsch–Gordan coefficients and includes the derivation of new results. We use the term ''Clebsch–Gordan coefficient'' in its colloquial sense, i.e., the vector addition coefficients of SU(2). Thus our results also give the asymptotics of the $3j$-symbols. We consider the case in which all of the quantum numbers get large together. What this means is multiplying all of the quantum numbers by a number and studying the asymptotic behavior of the Clebsch–Gordan coefficient as this multiplier gets large. Such a multiplier is often called $1/\hbar$, so that the limit of large quantum numbers is the limit of small $\hbar$.

The history of this subject dates back to the early days of quantum mechanics and the study of the classical limit of quantum mechanical quantities. Numerous papers have been written in this area. We summarize the literature briefly here. In 1959, Wigner[1] discussed the physical interpretation and classical limits of Clebsch–Gordan coefficients. He described a certain average behavior, and did not analyze the oscillatory nature of the Clebsch–Gordan coefficients. There are references in this work to Edmonds[2] and Brussaard and Tolhoek.[3] In 1968, Ponzano and Regge[4] presented asymptotic expressions that included the oscillations. Their work included an interpretation of certain angles that occur in their results and in ours. Additionally, they discussed the allowed and forbidden regions. However, their derivation is, in their words, ''rather heuristic.'' It was borne out in their comparisons with the exact values. William Miller[5] derived similar expressions using semiclassical methods in 1974, but did not treat the forbidden region. Another work that relates to the present paper is that of Srinivasa Rao and V. Rajeswari.[6] It contains exact expressions for Clebsch–Gordan coefficients and their relationship to certain hypergeometric series. There is more information in the work of Biedenharn and Louck.[7]

In this paper, we start by deriving an exact integral representation for the Clebsch–Gordan coefficients. Then the methods of stationary phase are used to approximate this integral. The allowed and forbidden regions are treated separately, and the resulting expressions are related to the literature. These methods are then used to derive higher-order results, that is, the next order in an expansion in $\hbar$. These formulas are accurate to five or six digits when the quantum numbers are in the hundreds.

Possible applications of this work include high-angular momentum calculations and theoretical investigations which contain sums over large numbers of Clebsch–Gordan coefficients.[8,9]

II. EXACT EXPRESSIONS FOR THE CLEBSCH–GORDAN COEFFICIENT

Our starting point is an exact expression for the Clebsch–Gordan (vector-addition) coefficient, due to Wigner [see, for example, Eq. (3.6.11) of Ref. 2],

$$\begin{aligned}\langle j_1 m_1 j_2 m_2 | jm\rangle &= [(2j+1)(j_1+j_2-j)!(j_1-j_2+j)!(-j_1+j_2+j)!/(j_1+j_2+j+1)!]^{1/2}\\ &\quad\times[(j_1+m_1)!(j_1-m_1)!(j_2+m_2)!(j_2-m_2)!(j+m)!(j-m)!]^{1/2}\\ &\quad\times\sum_z \frac{(-1)^z}{z!(j_1+j_2-j-z)!(j_1-m_1-z)!(j_2+m_2-z)!(j-j_2+m_1+z)!(j-j_1-m_2+z)!}.\end{aligned} \tag{2.1}$$

A factor of δ_{m,m_1+m_2} has been omitted; throughout this paper we will assume that m is equal to m_1+m_2. Also, unless otherwise specified, sums over an index are sums over all integers. It will turn out, though, that the summand is nonzero for only finitely many values of the index.

We begin by deriving the following exact expression for the Clebsch–Gordan coefficient,

$$\begin{aligned}\langle j_1 m_1 j_2 m_2 | jm\rangle &= (-1)^{j+m} N_{j_1 m_1 j_2 m_2 jm} \frac{1}{(j_1-m_1)!(j_2-m_2)!}\left(\frac{d}{du}\right)^{j_1-m_1}\left(\frac{d}{dt}\right)^{j_2-m_2}\\ &\quad\times[(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}]\big|_{u=0,t=0},\end{aligned} \tag{2.2}$$

where $N_{j_1 m_1 j_2 m_2 jm}$ is defined to be

$$N_{j_1 m_1 j_2 m_2 jm} = \left[\frac{(2j+1)(j_1+m_1)!(j_1-m_1)!(j_2+m_2)!(j_2-m_2)!(j+m)!(j-m)!}{(j_1+j_2+j+1)!(j_1+j_2-j)!(j_1-j_2+j)!(-j_1+j_2+j)!}\right]^{1/2}. \tag{2.3}$$

Because the quantity being differentiated in Eq. (2.2) is a polynomial in the variables u and t, the operation of differentiating this quantity and then evaluating the result at $u=0$ and $t=0$ simply selects a particular coefficient in the polynomial. Thus, Eq. (2.2) expresses the Clebsch–Gordan coefficient as a certain coefficient in a polynomial that can be written in closed form. This equation can be derived from results in the literature,[10] but we give here an independent derivation of Eq. (2.2) from Eq. (2.1) to verify that all of the conventions involved are consistent.

In order to prove Eq. (2.2), we start by finding the coefficient of $u^{j_1-m_1}t^{j_2-m_2}$ in the polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$. This is equal to the coefficient of $u^{j_1-m_1}$ in the polynomial that is given by $(u-1)^{j+j_1+j_2}$ times the u-dependent coefficient of $t^{j_2-m_2}$ in the polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}$. Using the binomial theorem, we get

$$(t-1)^{j+j_2-j_1} = \sum_k \binom{j+j_2-j_1}{k} t^k (-1)^{j+j_2-j_1-k}, \tag{2.4}$$

and

$$(t-u)^{j_1+j_2-j} = \sum_l \binom{j_1+j_2-j}{l} t^l (-u)^{j_1+j_2-j-l}. \tag{2.5}$$

The coefficient of $t^{j_2-m_2}$ in the product of these is

$$\begin{aligned}&\sum_k \binom{j+j_2-j_1}{k}(-1)^{j+j_2-j_1-k}\binom{j_1+j_2-j}{j_2-m_2-k}(-u)^{j_1+j_2-j-(j_2-m_2-k)}\\ &\quad=(-1)^{j_2+m_2}u^{j_1-j+m_2}\sum_k \binom{j+j_2-j_1}{k}\binom{j_1+j_2-j}{j_2+m_2-k}u^k.\end{aligned} \tag{2.6}$$

As explained above, we need to multiply this polynomial by

$$(u-1)^{j+j_1-j_2}=\sum_l \binom{j+j_1-j_2}{l} u^l(-1)^{j+j_1-j_2-l}, \tag{2.7}$$

and find the coefficient of $u^{j_1-m_1}$. The result is

$$\begin{aligned}(-1)^{j_2+m_2}\sum_k &\binom{j+j_2-j_1}{k}\binom{j_1+j_2-j}{j_2-m_2-k}\binom{j+j_1-j_2}{j-m-k}(-1)^{j_1-j_2+m+k}\\ &=(-1)^{j+m}\sum_z (-1)^z\binom{j+j_2-j_1}{j_2+m_2-z}\binom{j_1+j_2-j}{z}\binom{j+j_1-j_2}{j_1-m_1-z},\end{aligned} \tag{2.8}$$

where we have redefined the index of summation according to $k=j-j_1-m_2+z$ in the final line of this equation and made use of the identity $\binom{a}{b}=\binom{a}{a-b}$. Since $j+m$ is always an integer, $(-1)^{2(j+m)}$ is equal to one, and we have shown that the right-hand side of Eq. (2.2) is equal to

$$\begin{aligned}N_{j_1m_1j_2m_2jm}&\sum_z (-1)^z\binom{j+j_2-j_1}{j_2+m_2-z}\binom{j_1+j_2-j}{z}\binom{j+j_1-j_2}{j_1-m_1-z}\\ &=\sum_z \frac{(-1)^z N_{j_1m_1j_2m_2jm}(j+j_2-j_1)!(j_1+j_2-j)!(j+j_1-j_2)!}{(j-j_1-m_2+z)!(j_2+m_2-z)!(j_1+j_2-j-z)!z!(j_1-m_1-z)!(j-j_2+m_1+z)!}.\end{aligned} \tag{2.9}$$

This is the same as the right-hand side of Eq. (2.1) and completes the proof of Eq. (2.2). An alternative proof begins by introducing a factor of x^z into the sum in Eq. (2.1) and deriving a third-order differential equation for the resulting function of x. This differential equation can be solved using hypergeometric functions, and the result eventually leads to the expression shown in Eq. (2.2).

Equation (2.2) can be used to obtain an exact expression for the Clebsch–Gordan coefficient as an integral. One uses the orthogonality of the functions $\exp(in\theta)$ on the interval $[-\pi, \pi]$ to select the desired coefficients in the polynomials. Thus, we substitute $\exp(i\theta)$ for t and $\exp(i\phi)$ for u in the polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$ in Eq. (2.2), multiply by $\exp[-i(j_1-m_1)\phi-i(j_2-m_2)\theta]$, and integrate the two variable from $-\pi$ to π. The resulting expression for the Clebsch–Gordan coefficient is

$$\begin{aligned}\langle j_1m_1j_2m_2|jm\rangle&=(-1)^{j+m}N_{j_1m_1j_2m_2jm}\,\frac{1}{(2\pi)^2}\\ &\quad\times\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} e^{-i(j_1-m_1)\phi-i(j_2-m_2)\theta}(e^{i\theta}-1)^{j+j_2-j_1}(e^{i\theta}-e^{i\phi})^{j_1+j_2-j}\\ &\quad\times(e^{i\phi}-1)^{j+j_1-j_2}\,d\theta\,d\phi.\end{aligned} \tag{2.10}$$

This may be rewritten using the definition of the sin function, whereupon it becomes natural to redefine the angles by a factor of 2. The resulting form is

$$\begin{aligned}\langle j_1m_1j_2m_2|jm\rangle&=(-1)^{j+m}(2i)^{j+j_1+j_2}\pi^{-2}N_{j_1m_1j_2m_2jm}\\ &\quad\times\int_{-\pi/2}^{\pi/2}\int_{-\pi/2}^{\pi/2} e^{2im_1\phi+2im_2\theta}\sin^{j+j_2-j_1}\theta\,\sin^{j_1+j_2-j}(\theta-\phi)\\ &\quad\times\sin^{j+j_1-j_2}\phi\,d\theta\,d\phi.\end{aligned} \tag{2.11}$$

It is this integral expression for the Clebsch–Gordan coefficient that we use in the following sections to derive formulas for the asymptotic behavior of these coefficients.

It is also possible to express the Clebsch–Gordan coefficient as a coefficient of a term in a polynomial in one variable, and thus as a one-dimensional integral. Equation (2.2) shows how the Clebsch–Gordan coefficient is related to the coefficient of $u^{j_1-m_1}t^{j_2-m_2}$ in the polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$. This is the same as the coefficient of $u^{j_1-m_1}(u^M)^{j_2-m_2}$ in the polynomial $(u^M-1)^{j+j_2-j_1}(u^M-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$ (that is, t has been replaced by u^M) for sufficiently large integers M. This can be seen as follows. We start by imagining the polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$ expanded out into a sum of monomials. If t is replaced by u^M, each of the monomials is now just a coefficient times a power of u. We do not want any of these terms to have the same power of u, otherwise they would combine and the coefficients would change. Thus, we look at the original polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$ and ask what the highest power of u is. This is $(j_1+j_2-j)+(j+j_1-j_2)=2j_1$. We therefore select M to be $2j_1+1$. The result is that the coefficient of $u^{j_1-m_1}t^{j_2-m_2}$ in the polynomial $(t-1)^{j+j_2-j_1}(t-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$ is the same as the coefficient of $u^{j_1-m_1+(2j_1+1)(j_2-m_2)}$ in the polynomial $(u^{2j_1+1}-1)^{j+j_2-j_1}(u^{2j_1+1}-u)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$. We may drop an overall factor of $u^{j_1+j_2-j}$, so this coefficient is the same as the coefficient of $u^{j-m+2j_1(j_2-m_2)}$ in the polynomial $(u^{2j_1+1}-1)^{j+j_2-j_1}(u^{2j_1}-1)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}$. The resulting expression for the Clebsch–Gordan coefficient as a coefficient in a polynomial in one variable is

$$\langle j_1m_1j_2m_2|jm\rangle=(-1)^{j+m}N_{j_1m_1j_2m_2jm}\frac{1}{[j-m+2j_1(j_2-m_2)]!}\left(\frac{d}{du}\right)^{j-m+2j_1(j_2-m_2)}$$
$$\times[(u^{2j_1+1}-1)^{j+j_2-j_1}(u^{2j_1}-1)^{j_1+j_2-j}(u-1)^{j+j_1-j_2}]|_{u=0}. \tag{2.12}$$

As above, the selection of the coefficient in the polynomial can also be carried out with an integral,

$$\langle j_1m_1j_2m_2|jm\rangle=(-1)^{j+m}N_{j_1m_1j_2m_2jm}\frac{1}{2\pi}\int_{-\pi}^{\pi}e^{-i[j-m+2j_1(j_2-m_2)]\phi}$$
$$\times(e^{i(2j_1+1)\phi}-1)^{j+j_2-j_1}(e^{i2j_1\phi}-1)^{j_1+j_2-j}(e^{i\phi}-1)^{j+j_1-j_2}\,d\phi. \tag{2.13}$$

This may be rewritten as

$$\langle j_1m_1j_2m_2|jm\rangle=(-1)^{j+m}N_{j_1m_1j_2m_2jm}\frac{(2i)^{j+j_1+j_2}}{2\pi}$$
$$\times\int_{-\pi}^{\pi}e^{i(2j_1m_2+m)\phi}\sin^{j+j_2-j_1}[(j_1+1/2)\phi]$$
$$\times\sin^{j_1+j_2-j}(j_1\phi)\sin^{j+j_1-j_2}(\phi/2)\,d\phi, \tag{2.14}$$

and this may be simplified to the form

$$\langle j_1m_1j_2m_2|jm\rangle=(-1)^{j+m}N_{j_1m_1j_2m_2jm}\pi^{-1}2^{j+j_1+j_2}\int_0^{\pi}\cos\left[(2j_1m_2+m)\phi+\frac{\pi}{2}(j+j_1+j_2)\right]$$
$$\times\sin^{j+j_2-j_1}[(j_1+1/2)\phi]\sin^{j_1+j_2-j}(j_1\phi)\sin^{j+j_1-j_2}(\phi/2)\,d\phi. \tag{2.15}$$

Although this is a one-dimensional integral (as opposed to the two-dimensional integral presented above), it seems to be not as useful for the study of asymptotics because of the presence of the magnetic quantum numbers in the argument of the cosine function.

III. STATIONARY-PHASE APPROXIMATION OF THE INTEGRAL EXPRESSION FOR THE CLEBSCH–GORDAN COEFFICIENT

In order to carry out a stationary-phase approximation of the integral expression for the Clebsch–Gordan coefficient presented in the previous section, we begin by writing the expression in Eq. (2.11) in the form

$$\langle j_1 m_1 j_2 m_2 | jm \rangle = (-1)^{j+m}(2i)^{j+j_1+j_2}\pi^{-2}N_{j_1 m_1 j_2 m_2 jm}\int_{-\pi/2}^{\pi/2}\int_{-\pi/2}^{\pi/2} e^{g(\theta,\phi)}\,d\theta\,d\phi, \tag{3.1}$$

where the function $g(\theta,\phi)$ is defined to be

$$g(\theta,\phi) = 2im_1\phi + 2im_2\theta + (j+j_2-j_1)\ln(\sin\theta) + (j_1+j_2-j)\ln[\sin(\theta-\phi)] + (j+j_1-j_2)\ln(\sin\phi). \tag{3.2}$$

Note that $g(\theta,\phi)$ has singularities where it goes to $-\infty$, but the integral is still well defined because the integrand is $\exp(g)$.

To find the stationary-phase points (as explained in Appendix A), we must first compute the first derivatives of the function g,

$$\frac{\partial g}{\partial\theta} = 2im_2 + (j+j_2-j_1)\cot\theta + (j_1+j_2-j)\cot(\theta-\phi), \tag{3.3}$$

$$\frac{\partial g}{\partial\phi} = 2im_1 - (j_1+j_2-j)\cot(\theta-\phi) + (j+j_1-j_2)\cot\phi. \tag{3.4}$$

Setting these first derivatives equal to zero results in a system of two equations in two variables. The identity

$$\cot(\theta-\phi) = \frac{1+\cot\theta\cot\phi}{\cot\phi-\cot\theta} \tag{3.5}$$

may be used to transform this system to an equivalent system,

$$2im + (j+j_2-j_1)\cot\theta + (j+j_1-j_2)\cot\phi = 0, \tag{3.6}$$

$$2im_2 + (j+j_2-j_1)\cot\theta + (j_1+j_2-j)\,\frac{1+\cot\theta\cot\phi}{\cot\phi-\cot\theta} = 0. \tag{3.7}$$

In order to be clear on phase conventions, choices of signs, and branch cuts, we write out the steps involved in solving this system of two equations for $\cot\theta$ and $\cot\phi$. We start by multiplying the second equation by $(j+j_1-j_2)(\cot\phi-\cot\theta)$ and substituting in first one:

$$[2im_2 + (j+j_2-j_1)\cot\theta]\{-[2im + (j+j_2-j_1)\cot\theta] - (j+j_1-j_2)\cot\theta\} + (j_1+j_2-j)\{(j+j_1-j_2) - \cot\theta[2im + (j+j_2-j_1)\cot\theta]\} = 0. \tag{3.8}$$

This is a quadratic equation in $\cot\theta$:

$$\cot^2\theta\ [(j+j_2-j_1)(-2j) - (j_1+j_2-j)(j+j_2-j_1)] + \cot\theta\ [(j+j_2-j_1)(-2im) + 2im_2(-2j) + (j_1+j_2-j)(-2im)] + 2im_2(-2im) + (j_1+j_2-j)(j+j_1-j_2) = 0. \tag{3.9}$$

Simplifying this results in

$$-\cot^2\theta\ (j+j_2-j_1)(j_1+j_2+j)-4i\cot\theta\ (j_2m+m_2j)$$

$$+4m_2m+(j_1+j_2-j)(j+j_1-j_2)=0. \tag{3.10}$$

The two solutions for the quantities $\cot\theta$ and $\cot\phi$ are (the upper choice of sign is one solution and the lower choice of sign is the other)

$$\cot\theta=\frac{-2i(j_2m+m_2j)\mp\beta}{(j_1+j_2+j)(j+j_2-j_1)},$$
$$\cot\phi=\frac{-2i(j_1m+m_1j)\pm\beta}{(j_1+j_2+j)(j+j_1-j_2)}, \tag{3.11}$$

where β is defined to be

$$\beta=\sqrt{4m_1m_2j^2-4mm_1j_2^2-4mm_2j_1^2+(j_1+j_2-j)(j+j_2-j_1)(j+j_1-j_2)(j_1+j_2+j)}. \tag{3.12}$$

In this equation, we use the usual choice of branch cut for the square-root function: if the argument is negative, then the result is a positive number times the imaginary unit. As discussed in Sec. III A, the quantity β is real for classically allowed sets of quantum numbers, and it is pure imaginary for classically forbidden sets of quantum numbers. It should be noted that this is the same definition for the symbol β as in Ref. 5.

The stationary-phase approximation of the integral $\int_{-\pi/2}^{\pi/2}\int_{-\pi/2}^{\pi/2}e^{g(\theta,\phi)}\,d\theta\,d\phi$ that appears in the expression for the Clebsch–Gordan coefficient in Eq. (3.1) is given by a sum of terms of the form

$$\frac{2\pi}{\sqrt{\det\partial^2 g/\partial(\theta,\phi)^2}}e^{g(\theta,\phi)}, \tag{3.13}$$

summed over stationary-phase points. The branch cut for the square root function is just below the negative imaginary axis, as is usual. The symbol $\partial^2 g/\partial(\theta,\phi)^2$ denotes the 2×2 Hessian matrix of second-order derivatives of the function $g(\theta,\phi)$, whose entries are given by

$$\frac{\partial^2 g}{\partial\theta^2}=-(j+j_2-j_1)\csc^2\theta-(j_1+j_2-j)\csc^2(\theta-\phi),$$

$$\frac{\partial^2 g}{\partial\theta\partial\phi}=(j_1+j_2-j)\csc^2(\theta-\phi), \tag{3.14}$$

$$\frac{\partial^2 g}{\partial\phi^2}=-(j_1+j_2-j)\csc^2(\theta-\phi)-(j+j_1-j_2)\csc^2\phi.$$

Using the identity $\csc^2\theta=1+\cot^2\theta$ these quantities can be expressed in terms of the cotangents in Eq. (3.11) without addressing the issue of branch cuts of the arc-cotangent function. The value of $\csc^2(\theta-\phi)$ can be determined from the quantities in Eq. (3.11) using the identity $\sin(\theta-\phi)=\sin\theta\cos\phi-\sin\phi\cos\theta=\sin\theta\sin\phi(\cot\phi-\cot\theta)$. The determinant becomes

$$\det\frac{\partial^2 g}{\partial(\theta,\phi)^2}=(j+j_2-j_1)\csc^2\theta(j+j_1-j_2)\csc^2\phi$$
$$+(j_1+j_2-j)\csc^2(\theta-\phi)[(j+j_2-j_1)\csc^2\theta+(j+j_1-j_2)\csc^2\phi],$$
$$=(1+\cot^2\theta)(1+\cot^2\phi)\Bigg\{(j+j_2-j_1)(j+j_1-j_2)$$
$$+\frac{(j_1+j_2-j)}{(\cot\phi-\cot\theta)^2}[(j+j_2-j_1)(1+\cot^2\theta)+(j+j_1-j_2)(1+\cot^2\phi)]\Bigg\}. \tag{3.15}$$

In this form the determinant is expressed entirely in terms of the cotangents of θ and ϕ. The quantity $e^{g(\theta,\phi)}$ can also be expressed in this way. Choices of branch cuts are not necessary when expressing $\sin\theta$ and $\sin\phi$ in terms of the cotangents because only even powers of the sine functions appear. Using the identity

$$e^{i\theta}=\cos\theta+i\sin\theta=\sin\theta\ \ (\cot\theta+i), \tag{3.16}$$

we obtain for the factor $e^{g(\theta,\phi)}$ in Eq. (3.13),

$$e^{2im_1\phi+2im_2\theta}\sin^{j+j_2-j_1}\theta\sin^{j_1+j_2-j}(\theta-\phi)\sin^{j+j_1-j_2}\phi$$
$$=(i+\cot\phi)^{2m_1}(i+\cot\theta)^{2m_2}\sin^{j+j_2-j_1+2m_2}\theta\sin^{j_1+j_2-j}(\theta-\phi)\sin^{j+j_1-j_2+2m_1}\phi$$
$$=(i+\cot\phi)^{2m_1}(i+\cot\theta)^{2m_2}\sin^{2j_2+2m_2}\theta(\cot\phi-\cot\theta)^{j_1+j_2-j}\sin^{2j_1+2m_1}\phi$$
$$=(i+\cot\phi)^{2m_1}(i+\cot\theta)^{2m_2}(1+\cot^2\theta)^{-j_2-m_2}(\cot\phi-\cot\theta)^{j_1+j_2-j}(1+\cot^2\phi)^{-j_1-m_1}$$
$$=\frac{(i+\cot\phi)^{m_1-j_1}}{(-i+\cot\phi)^{j_1+m_1}}\frac{(i+\cot\theta)^{m_2-j_2}}{(-i+\cot\theta)^{j_2+m_2}}(\cot\phi-\cot\theta)^{j_1+j_2-j}. \tag{3.17}$$

Using this equation and Eq. (3.15), all of the quantities in the expression in Eq. (3.13) can be expressed in term of the cotangents of θ and ϕ, given in Eq. (3.11). It should be noted that all of the exponents in Eq. (3.17) are integers, so choices of branch cuts are not necessary.

A. Allowed region

It is useful to introduce the concepts of a triangle-allowed region and a classically allowed region of the space of values for the quantum numbers. We define the triangle-allowed region to be the set of quantum numbers for which j_1, j_2, and j satisfy the triangle inequalities and for which the inequalities $|m|\leqslant j$ and $\{|m_i|\leqslant j_i,\ i=1,2\}$ hold. The Clebsch–Gordan coefficient is zero outside of this region, so it is only within this region that asymptotic expressions are desired. The triangle-allowed region is divided into a classically allowed region and a classically forbidden region. As is usual, we call these the allowed and forbidden regions for brevity. The allowed region is defined to be the set of quantum numbers for which it is possible to define **j**-vectors in a three-dimensional space in such a way that their lengths are equal to the *j*-values and their *z*-components are equal to the *m*-values (and, of course, such that $\mathbf{j}=\mathbf{j}_1+\mathbf{j}_2$). An example of such a construction for a set of allowed quantum numbers is shown in Fig. 1. It follows from the definition that the allowed region is contained in the triangle-allowed region. Examples of classically forbidden points are easily found in extreme cases, such as $m_1=j_1$. In this case, there is only one classically allowed value for m_2 (assuming a set of triangle-allowed *j*-values have been given), because the $\mathbf{j}_1$-vector must point in the *z* direction, and thus the *j*-triangle lies in a vertical plane.

The allowed region is the same as the region in which the three λ-values defined in Eq. (3.25) satisfy the triangle inequalities. This is because the λ-values are the lengths of the projections of

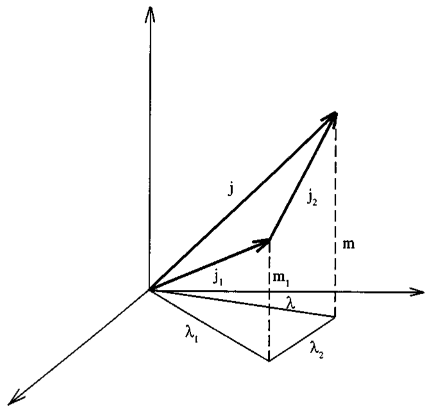

FIG. 1. An example of a choice of three **j**-vectors, demonstrating that a set of quantum numbers is classically allowed.

the **j**-vectors into the *xy* plane. If the λ-values satisfy the triangle inequalities, then it is possible to draw a triangle in the *xy* plane with sides equal to the λ-values. From this, one can construct the **j**-vectors by simply including the *m*-values as *z*-components. Conversely, if the **j**-vectors can be constructed, then their projections into the *xy* plane form a triangle (with the tail of $\mathbf{j}_2$ at the tip of $\mathbf{j}_1$), and the λ-values satisfy the triangle inequalities.

It is explained later in this paper that the λ-values satisfy the triangle inequalities if and only if the quantity $(-\lambda_1+\lambda_2+\lambda_3)(\lambda_1-\lambda_2+\lambda_3)(\lambda_1+\lambda_2-\lambda_3)$ is non-negative (that is, it is not possible for two of the factors to be negative). This observation together with the fact that the quantity β defined in Eq. (3.12) may be written as

$$\beta=\sqrt{(\lambda_1+\lambda_2+\lambda_3)(-\lambda_1+\lambda_2+\lambda_3)(\lambda_1-\lambda_2+\lambda_3)(\lambda_1+\lambda_2-\lambda_3)} \tag{3.18}$$

leads us to the result that the sign of β^2 distinguishes the allowed and forbidden regions: it is positive in the allowed region, and it is negative in the forbidden region. In the allowed region, β is four times the area of the triangle whose sides are the λ-values. This triangle is the projection of the *j*-triangle into the *xy* plane (see Fig. 1). From Eq. (3.12) it is apparent that for fixed values of the *j* quantum numbers, β^2 is a quadratic polynomial in the *m* quantum numbers. Thus, in the (m_1,m_2) plane the boundary between the allowed and forbidden regions is an ellipse. This is shown in Fig. 2 for one choice of values for j_1, j_2, and *j*. The boundary of the triangle-allowed region is the irregular hexagon. The forbidden region is composed of six subregions. The points that separate them are indicated in Fig. 2. These are the points where the ellipse that separates the allowed and forbidden regions is tangent to the hexagon that defines the triangle-allowed region. The coordinates of these points can be calculated from the expression for β and the equations for the straight-line sections of the boundary of the triangle-allowed region. The resulting coordinates of these points are indicated in the figure.

The calculations involved in the stationary-phase approximation of the integral expression for the Clebsch–Gordan coefficient are different in the allowed and forbidden regions. We will treat the allowed region first. The sum over stationary-phase points for the case where the set of quantum numbers is in the allowed region is a sum over both of the solutions for the cotangents of θ and ϕ given in Eq. (3.11). This is analogous to the behavior demonstrated in Appendix A, and it is also the same as in the calculation of the stationary-phase approximation of the Airy integral, which is the canonical example of a stationary-phase calculation. In the case of the Airy integral, there are allowed and forbidden regions in position space, and in the allowed region the contour of integration is deformed to run over both of the stationary-phase points. We define c_θ and c_ϕ to be the first solution for the cotangents in Eq. (3.11):

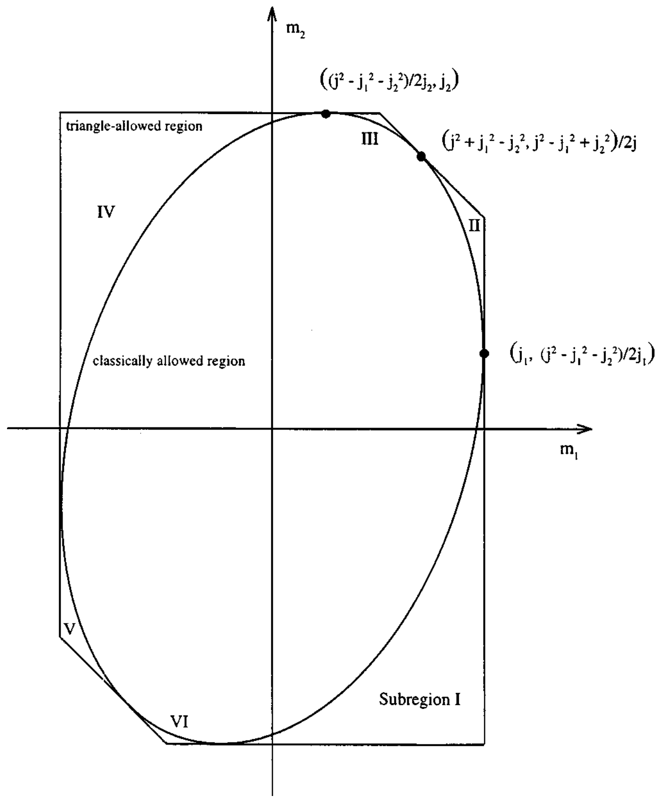

FIG. 2. The triangle-allowed region and the classically allowed region, shown in the m_1-m_2 plane, for the case of j-values in the ratio $j:j_1:j_2=4:2:3$. The six forbidden subregions are labeled with Roman numerals.

$$c_\theta=\frac{-2i(j_2m+m_2j)-\beta}{(j+j_2-j_1)(j_1+j_2+j)},$$
$$c_\phi=\frac{-2i(j_1m+m_1j)+\beta}{(j_1+j_2+j)(j+j_1-j_2)}. \tag{3.19}$$

Because of the form of the two solutions given in Eq. (3.11), the second solution is obtained from this one by multiplying by -1 and complex conjugating. Note this is only valid in the allowed region, where the quantity β is real. The first term in the sum over stationary-phase points is given by plugging the expression for $\det[\partial^2 g/\partial(\theta,\phi)^2]$, given in Eq. (3.15), and the expression for $e^{g(\theta,\phi)}$, given in Eq. (3.17), into the quantity in Eq. (3.13), using c_θ and c_ϕ for the cotangents. The second term in the sum over stationary-phase points is the same, except $-c_\theta^*$ and $-c_\phi^*$ are used for the cotangents. The result for the determinant in the second term is obtained by simply complex conjugating the first value, since all of the cotangents in this expression are squared. As for the $e^{g(\theta,\phi)}$ factor in the second term, we start by considering the expression for this factor in the first term:

$$\frac{(i+c_\phi)^{m_1-j_1}}{(-i+c_\phi)^{j_1+m_1}}\frac{(i+c_\theta)^{m_2-j_2}}{(-i+c_\theta)^{j_2+m_2}}(c_\phi-c_\theta)^{j_1+j_2-j}. \tag{3.20}$$

The complex conjugate of this is

$$\frac{(-i+c_\phi^*)^{m_1-j_1}}{(i+c_\phi^*)^{j_1+m_1}}\frac{(-i+c_\theta^*)^{m_2-j_2}}{(i+c_\theta^*)^{j_2+m_2}}(c_\phi^*-c_\theta^*)^{j_1+j_2-j}$$
$$=(-1)^{j_1+j_2+j}\frac{(i-c_\phi^*)^{m_1-j_1}}{(-i-c_\phi^*)^{j_1+m_1}}\frac{(i-c_\theta^*)^{m_2-j_2}}{(-i-c_\theta^*)^{j_2+m_2}}(-c_\phi^*+c_\theta^*)^{j_1+j_2-j}. \qquad (3.21)$$

This shows that the $e^{g(\theta,\phi)}$ factor in the second term [which appears after the $(-1)^{j_1+j_2+j}$ in the last line of Eq. (3.21)] is $(-1)^{j_1+j_2+j}$ times the complex conjugate of the $e^{g(\theta,\phi)}$ factor in the first term. Thus the second term is $(-1)^{j_1+j_2+j}$ times the complex conjugate of the first term. It is therefore convenient to obtain the sum over stationary-phase points by taking $i^{j_1+j_2+j}$ times the first term, adding the complex conjugate of this product, and then dividing by $i^{j_1+j_2+j}$. Using the fact that the real part of a quantity x is given by $\mathcal{R}[x]=(x+x^*)/2$, our stationary-phase approximation for the integral expression for the Clebsch–Gordan coefficient in Eq. (3.1) can be written as

$$\langle j_1m_1j_2m_2|jm\rangle\approx(-1)^{j+m}(2i)^{j+j_1+j_2}\pi^{-2}N_{j_1m_1j_2m_2jm}\frac{2}{i^{j_1+j_2+j}}\mathcal{R}\left[\frac{2\pi i^{j_1+j_2+j}}{\sqrt{\det[\partial^2 g/\partial(\theta,\phi)^2]}}e^{g(\theta,\phi)}\right]$$
$$=(-1)^{j+m}2^{j+j_1+j_2+2}\pi^{-1}N_{j_1m_1j_2m_2jm}\mathcal{R}\left[\frac{i^{j_1+j_2+j}}{\sqrt{\det[\partial^2 g/\partial(\theta,\phi)^2]}}e^{g(\theta,\phi)}\right], \qquad (3.22)$$

where the quantities $\det[\partial^2 g/\partial(\theta,\phi)^2]$ and $e^{g(\theta,\phi)}$ are obtained from Eqs. (3.15) and (3.17) using the c_θ and c_ϕ given in Eq. (3.19).

Although the expression in Eq. (3.22) gives a value that is a real number, it involves intermediate quantities that are complex. It is possible to transform this expression so that only real quantities are involved. This transformation is very lengthy, and it is not practical to describe it in detail here. Instead, we present an expression that is exactly equal to the expression in Eq. (3.22) in the allowed region. This equality can be verified most convincingly by substituting numerical values into the expressions and evaluating the results to high numerical precision (much higher than the level at which discrepancies would occur if order $\hbar$ terms were dropped). A brief description of the transformation is the following. Every complex quantity $x+iy$ that occurs in Eq. (3.22) is written as the product of a modulus and a phase, $\sqrt{x^2+y^2}\exp[i\tan^{-1}(y/x)]$, where care must be taken that correct branches are used for each $x+iy$, that is, one must examine the quantities x and y to determine the range of phase factors $(x+iy)/\sqrt{x^2+y^2}$ that can occur in the allowed region, and make branch choices accordingly. At some stages in the calculation, large polynomials are involved, and computer-aided symbol manipulation becomes useful in working with these. Our result may be put in the form

$$\langle j_1m_1j_2m_2|jm\rangle\approx 2I_{j_1m_1j_2m_2jm}\sqrt{\frac{j}{\pi\beta}}\cos\left[\chi+\frac{\pi}{4}-\pi(j+1)\right], \qquad (3.23)$$

where χ is defined to be

$$\chi=\left(j_1+\frac{1}{2}\right)\cos^{-1}\left[\frac{(-m)(j_1^2+j_2^2-j^2)-m_2(j_1^2+j^2-j_2^2)}{\alpha\lambda_1}\right]$$
$$+\left(j_2+\frac{1}{2}\right)\cos^{-1}\left[\frac{m_1(j^2+j_2^2-j_1^2)-(-m)(j_2^2+j_1^2-j^2)}{\alpha\lambda_2}\right]$$
$$+\left(j+\frac{1}{2}\right)\cos^{-1}\left[\frac{m_2(j_1^2+j^2-j_2^2)-m_1(j^2+j_2^2-j_1^2)}{\alpha\lambda_3}\right]$$
$$-m_1\cos^{-1}\left[\frac{\lambda_1^2+\lambda_3^2-\lambda_2^2}{2\lambda_1\lambda_3}\right]+m_2\cos^{-1}\left[\frac{\lambda_3^2+\lambda_2^2-\lambda_1^2}{2\lambda_2\lambda_3}\right], \tag{3.24}$$

and

$$\alpha=\sqrt{(j+j_1+j_2)(-j+j_1+j_2)(j-j_1+j_2)(j+j_1-j_2)},$$
$$\lambda_i=\sqrt{j_i^2-m_i^2}\quad i=1,2, \tag{3.25}$$
$$\lambda_3=\sqrt{j^2-m^2}.$$

(The quantity α is four times the area of the j-triangle shown in Fig. 1.) Note that the $\cos^{-1}$ functions in Eq. (3.24) are the usual principal branch, whose range is the interval from zero to π. The quantity $I_{j_1m_1j_2m_2jm}$ is defined to be

$$I_{j_1m_1j_2m_2jm}=\sqrt{\frac{(j+1/2)(j+j_1+j_2)}{j(j+j_1+j_2+1)}}$$
$$\times\frac{f(j_1+m_1)f(j_1-m_1)f(j_2+m_2)f(j_2-m_2)f(j+m)f(j-m)}{f(j_1+j_2+j)f(j_1+j_2-j)f(j_1-j_2+j)f(-j_1+j_2+j)}, \tag{3.26}$$

where the function f is defined to be

$$f(n)=\sqrt{\frac{n!}{\sqrt{2\pi n}n^ne^{-n}}}, \tag{3.27}$$

that is, $f(n)$ is the square root of the ratio of $n!$ to the Stirling approximation of $n!$ Note that for large n, $f(n)$ approaches one. Thus, for large quantum numbers, $I_{j_1m_1j_2m_2jm}$ approaches one. It differs from unity by a correction that is order $\hbar$, as can be deduced from the discussion of the Stirling approximation in Appendix A. As mentioned above, we present our approximation in the form given in Eq. (3.23) so that the exact equality of this expression and the complex expression given in Eq. (3.22) can be verified numerically. The factor $I_{j_1m_1j_2m_2jm}$ may be dropped without reducing the quality of the approximation, that is, the ratio of our approximation to the exact value differs from unity by a quantity that is order $\hbar$. Thus, we may write our approximation in the form

$$\langle j_1m_1j_2m_2|jm\rangle\approx 2\sqrt{\frac{j}{\pi\beta}}\cos\left[\chi-\pi\left(j+\frac{3}{4}\right)\right]. \tag{3.28}$$

Ponzano and Regge[4] give a geometrical interpretation of the five angles that occur in the expression for χ in Eq. (3.24). An equation similar to Eq. (3.28) also appears in Ref. 5, but the $(j+1/2)$ factors in χ are included at the end of the calculation to improve the accuracy, and the $\pi(j+1)$ in Eq. (3.23) is missing so that the formula gives the wrong sign for even j-values and does not give the right magnitude for half-integer j values.

TABLE I. For each forbidden subregion, the choice of root in Eq. (3.11), the sign function as in Eq. (3.30), and the largest λ [which determines the form of χ, as in Eq. (3.31)] are given.

Forbidden subregion	Choice of root	Sign function	Largest λ
I	lower	1	λ_3
II	upper	$(-1)^{j_1-m_1}$	λ_2
III	lower	$(-1)^{j_1-j+m_2}$	λ_1
IV	upper	$(-1)^{j_1+j_2-j}$	λ_3
V	lower	$(-1)^{j_2-j-m_1}$	λ_2
VI	upper	$(-1)^{j_2+m_2}$	λ_1

B. Forbidden region

In the forbidden region, only one of the stationary-phase points is used in the approximation. This is analogous to the situation in the Airy function problem mentioned above, where there are dominant and subdominant branches, and in the forbidden region only the subdominant branch exists. Similarly, the model problem in Appendix A shows how for the case of $m>n$, two stationary-phase points are used, while for the case $m<n$ only one stationary-phase point is involved. The choice of which of the two roots in Eq. (3.11) is to be used for our approximation of the Clebsch–Gordan coefficient is indicated in Table I. Given the m-values of a point in the forbidden region in Fig. 2, it is inconvenient to determine which subregion it is in by using nested if–then statements, because the relative ordering of, say, the m_2-coordinates of the points on the boundaries between the forbidden subregions changes as the j-values are changed. A much simpler way to determine which branch to use is to find the sign of a certain polynomial which we describe here. As can be seen from Table I, the choice of branch alternates as one goes around the diagram in Fig. 2. Thus we use the sign of the product of three expressions that flip signs in the right way. Given the coordinates of one of the boundary points in the (m_1,m_2)-plane, a vector perpendicular to it can be constructed by exchanging the coordinates and changing the sign of one of them. The dot-product of this vector and (m_1,m_2) is a function on the (m_1,m_2)-plane that changes sign at the boundary between the two subregions in question. Thus we are led to consider the sign of the function

$$[(m_1,m_2)\cdot(-2j_2^2,j^2-j_1^2-j_2^2)][(m_1,m_2)\cdot(-j^2+j_1^2-j_2^2,j^2+j_1^2-j_2^2)]$$
$$\times[(m_1,m_2)\cdot(-j^2+j_1^2+j_2^2,2j_1^2)].$$

If this quantity is positive (negative), then the upper (lower) choice of root in Eq. (3.11) is used. Once the cotangents of the angles at the stationary-phase point are determined, the approximation of the Clebsch–Gordan coefficient can be evaluated from the expression

$$\langle j_1m_1j_2m_2|jm\rangle\approx(-1)^{j+m}(2i)^{j+j_1+j_2}\pi^{-2}N_{j_1m_1j_2m_2jm}\frac{2\pi e^{g(\theta,\phi)}}{\sqrt{\det[\partial^2 g/\partial(\theta,\phi)^2]}}. \tag{3.29}$$

All of the quantities needed to evaluate this expression were expressed in terms of the cotangents of the angles in Eqs. (3.15) and (3.17). It may be noted that in the forbidden region the cotangents become pure imaginary, as can be seen from Eq. (3.11). This behavior is similar to that in the model problem in Appendix A, where the angle suddenly jumps in terms of its real part (but the analogy is not perfect because in the model problem the cotangent is pure imaginary in both the region $m>n$ and the region $m<n$).

Evaluating Eq. (3.29) results in a real value, although complex numbers are involved at intermediate steps. As in the case of our analysis in the allowed region, the expression may be transformed to a form that involves only operations with real numbers. This can be done in a way that parallels the previous calculation, with hyperbolic functions playing the role of trigonometric functions. The transformation involves choices of branch cuts and depends on which of the six subregions of the forbidden region one is working in. Thus there are six different all-real expressions for the forbidden region. In the interest of brevity, we will present only one of these here. In subregion VI, the expression in Eq. (3.29) is exactly equal to

$$(-1)^{j_2+m_2} 2 I_{j_1 m_1 j_2 m_2 j m} \sqrt{\frac{j}{\pi|\beta|}} \exp(-\chi^{(\mathrm{vi})}), \tag{3.30}$$

where $\chi^{(\mathrm{vi})}$ is defined to be

$$\begin{aligned}\chi^{(\mathrm{vi})}=&\left(j_1+\frac{1}{2}\right)\cosh^{-1}\left[\frac{-m(j_1^2+j_2^2-j^2)-m_2(j_1^2+j^2-j_2^2)}{\alpha\lambda_1}\right]\\&-\left(j_2+\frac{1}{2}\right)\cosh^{-1}\left[\frac{-m_1(j^2+j_2^2-j_1^2)-m(j_2^2+j_1^2-j^2)}{\alpha\lambda_2}\right]\\&-\left(j+\frac{1}{2}\right)\cosh^{-1}\left[\frac{-m_2(j_1^2+j^2-j_2^2)+m_1(j^2+j_2^2-j_1^2)}{\alpha\lambda_3}\right]\\&-m\cosh^{-1}\left[\frac{\lambda_1^2+\lambda_3^2-\lambda_2^2}{2\lambda_1\lambda_3}\right]-m_2\cosh^{-1}\left[\frac{\lambda_1^2+\lambda_2^2-\lambda_3^2}{2\lambda_2\lambda_1}\right].\end{aligned} \tag{3.31}$$

This all-real expression was derived by a very lengthy calculation, as in the case of the analysis in the allowed region. Again, an exact equality such as the one above can be checked easily by substituting in test numbers and evaluating to sufficient precision. As before, to actually use the approximation, one would drop the factor of $I_{j_1 m_1 j_2 m_2 j m}$ since it can be approximated by unity, to the order that we are working in this section. All-real expressions for the other subregions of the forbidden region can most easily be obtained by using the symmetries of the Clebsch–Gordan coefficients to related the expressions for the different subregions. If one prefers not to work with six different expressions for the forbidden region, one can use the polynomial discussed above to select the required stationary-phase point and then plug this into the approximation given in Eq. (3.29). This requires operations with complex numbers, but is easier to implement in a computer program. Alternatively, to obtain an approximate value for the Clebsch–Gordan coefficient for a given point in the forbidden region, one could work with only one all-real expression for a particular forbidden subregion and use the symmetries of the Clebsch–Gordan coefficients to map the given point to a point that is within the subregion for which the expression is valid.

It is interesting to compare the all-real expressions obtained in the allowed region, Eq. (3.23), and in the forbidden region, Eq. (3.30). They are similar in form, but the behavior is oscillatory in the allowed region and exponentially decaying in the forbidden region. This is the behavior expected in quantum mechanical problems that have an allowed region and a forbidden region.

In the forbidden region, writing the approximation in an all-real form is illuminating because it makes it apparent that sign functions exist. We call the factor $(-1)^{j_2+m_2}$ in Eq. (3.30) a sign function. The remaining factors in that equation are all positive, so the sign function gives the sign of the result. However, since the result is an approximation of a Clebsch–Gordan coefficient, the sign function also gives the sign of the Clebsch–Gordan coefficient, at least in the asymptotic regime. Thus, the sign functions are actually properties of the Clebsch–Gordan coefficients themselves, for a given choice of phase conventions. We are using the conventions defined by Eq. (2.1). The existence of sign functions was not clear from Eq. (2.1), which was our starting point. The sign functions for each of the six forbidden subregions are given in Table I.

The angle χ, given in Eq. (3.24), that appears in our approximation in the allowed region can be rewritten in several different ways. The reason is that the angles that multiply the m's in the equation for χ are two of the interior angles in the triangle formed by the three λ-values. If we call these angles α_1, α_2, and α_3 (where α_i is the angle opposite the side of length λ_i), then we have

$$\begin{aligned} m_1+m_2&=m, \\ \alpha_1+\alpha_2+\alpha_3&=\pi. \end{aligned} \tag{3.32}$$

Thus, the vectors $(m_1, m_2, -m)$ and $(\alpha_1, \alpha_2, \alpha_3-\pi)$ are both perpendicular to (1, 1, 1), and their cross product is parallel to (1, 1, 1). Each of the three components of their cross product are thus equal, and each one could be used as part of χ in the allowed region,

$$m_1\alpha_2-m_2\alpha_1=m_2(\alpha_3-\pi)+m\alpha_2=-m\alpha_1-m_1(\alpha_3-\pi). \tag{3.33}$$

In the forbidden region there is no such flexibility in how to write the corresponding terms, because there do not exist three angles corresponding to α_1, α_2, and α_3. This is because it is not possible to form a triangle using the three λ-values. Three different quantities like

$$\frac{\lambda_3^2+\lambda_1^2-\lambda_2^2}{2\lambda_3\lambda_1} \tag{3.34}$$

can be written down by cyclically permuting the indices, but only two of these can be used as arguments of the $\cosh^{-1}$ function in an all-real expression. This can be seen in the following way. The λ's are non-negative and if three non-negative numbers fail to satisfy the triangle inequalities, exactly one triangle inequality is violated. [Proof: Let $\lambda_{\max}$ be the largest value, λ_{mid} be the middle value, and $\lambda_{\min}$ be the smallest. Then $-\lambda_{\min}+\lambda_{\text{mid}}+\lambda_{\max}\geqslant 0$ and $\lambda_{\min}-\lambda_{\text{mid}}+\lambda_{\max}\geqslant 0$, so we must have $\lambda_{\min}+\lambda_{\text{mid}}-\lambda_{\max}<0$.] Now we consider rewriting the expression

$$\frac{\lambda_3^2+\lambda_1^2-\lambda_2^2}{2\lambda_3\lambda_1}=1+\frac{(\lambda_3-\lambda_1)^2-\lambda_2^2}{2\lambda_3\lambda_1}=1-\frac{(\lambda_1+\lambda_2-\lambda_3)(\lambda_2+\lambda_2-\lambda_1)}{2\lambda_3\lambda_1}. \tag{3.35}$$

This shows that of the three permutations of the expression in Eq. (3.34), exactly two will be greater than unity. It is these two that must be used as arguments of the $\cosh^{-1}$ function in an all-real expression. Thus there is no flexibility in ways to write the m-terms in χ as in the allowed region. Throughout each one of the six subregions of the forbidden region, a single triangle inequality for the λ's is violated. It is not possible that one triangle inequality is violated in one part of a subregion and another triangle inequality is violated in another part of the same subregion because at the boundary between these two parts β would be zero, as can be seen from Eq. (3.18). However, β^2 is a quadratic polynomial in m_1 and m_2 [see Eq. (3.12)], the zero-contour of which is the ellipse in Fig. 2, so it is not possible for it to be zero along a curve in the forbidden region. The λ that is largest in each subregion is indicated in Table I. The forms of all-real expressions in each of the forbidden subregions will reflect the fact that in each one of the subregions one of the λ's is larger than the sum of the other two.

It remains to discuss the case of points that are on the boundary between the allowed and forbidden regions. The quantity β in Eq. (3.12) is zero on this boundary, and since β is invariant under the full 72-element symmetry group of the 3-j symbol,[10] the Clebsch–Gordan coefficient cannot be approximated on the boundary with the formulas presented in this paper. The reason is that β occurs in the denominator in Eqs. (3.28) and (3.30). Since β^2 is a homogeneous polynomial in the quantum numbers, it will be zero for sets of quantum numbers equal to any multiple of a set of quantum numbers for which β is zero. The behavior of the Clebsch–Gordan coefficients in the direction transverse to the boundary should be similar to that of the Airy function (see Ref. 4).

The invariance of β under the 72-element symmetry group of the 3-j symbols may be shown as follows. We begin by constructing the 3×3 Regge array of linear combinations of quantum numbers, given in Ref. 10. For any integer n, we define the polynomial p_n to be the sum of the nth powers of the nine elements of this matrix. These polynomials are invariant under the symmetry group, because if two sets of quantum numbers are related by a Regge symmetry, we can construct the 3×3 Regge array for each set and compute p_n. The results are the same because of the commutativity of addition. It is possible to write β^2 in terms of the p_n:

$$\beta^2=(p_1^4-6p_2p_1^2-27p_2^2+108p_4)/324. \tag{3.36}$$

The coefficients in this equation may be simplified slightly by using the relation $p_1=3(j_1+j_2+j)$. This equation proves the invariance of β under the symmetry group.

An example of quantum numbers for which β is zero is

$$(j_1,m_1,j_2,m_2,j,m)=(3,-2,6,4,7,2). \tag{3.37}$$

This point is not on the edge of the triangle-allowed region. Points for which β is zero and which are on the edge of the triangle-allowed region are easier to find. For example, one can choose $(j_1,m_1)=(j_2,m_2)=\frac{1}{2}(j,m)$. For such a point, j_1+j_2-j is zero.

The reason we are unable to approximate the Clebsch–Gordan coefficient for cases in which β is zero is that the determinant of the 2×2 matrix of second derivatives of $g(\theta,\phi)$ is zero at the stationary-phase points. This can be shown by plugging the solutions for the cotangents of θ and ϕ at a stationary-phase point into Eq. (3.15) for the determinant; the result has an overall factor of β after being simplified [see Eq. (B7)]. This determinant appears in the denominator of Eq. (3.13), so our method cannot be applied. Note that when β is zero, the two solutions for the cotangents at the stationary-phase point are the same [see Eq. (3.11)]. Also, it should be noted that if any of the m-values has its absolute value close to the corresponding j, then the corresponding λ will be small [see Eq. (3.25)], and the area of the λ-triangle will be small. Thus, β will be small, and the set of quantum numbers is close to the boundary. In contrast to this, there is no difficulty with the approximation if the m values are close to zero. These considerations are mirrored in the approximation (using Stirling's formula) of $N_{j_1m_1j_2m_2jm}$, defined in Eq. (2.3); no factorials of m-values appear, only factorials of $j-m, j+m$, etc.

IV. HIGHER-ORDER APPROXIMATION

The methods used in the previous sections can be extended to higher order. In this section, we derive the next correction to the previous results. The approximation that is obtained in this way gives results that are accurate to six digits, for example, when the quantum numbers are in the hundreds.

Let (θ_0,ϕ_0) be a stationary-phase point, i.e., a point at which $\partial g/\partial\theta=\partial g/\partial\phi=0$. We write the Taylor expansion of the function $g(\theta,\phi)$ about the point (θ_0,ϕ_0) as a sum of homogeneous polynomials,

$$g(\theta_0+x,\phi_0+y)=g_0+g_2+g_3+g_4+\cdots, \tag{4.1}$$

where

$$\begin{aligned} g_0&=g(\theta_0,\phi_0),\\ g_2&=g_{\theta\theta}x^2/2+g_{\theta\phi}xy+g_{\phi\phi}y^2/2,\\ g_3&=g_{\theta\theta\theta}x^3/6+g_{\theta\theta\phi}x^2y/2+g_{\theta\phi\phi}xy^2/2+g_{\phi\phi\phi}y^3/6,\\ g_4&=g_{\theta\theta\theta\theta}x^4/24+g_{\theta\theta\theta\phi}x^3y/6+g_{\theta\theta\phi\phi}x^2y^2/4+g_{\theta\phi\phi\phi}xy^3/6+g_{\phi\phi\phi\phi}y^4/24, \end{aligned} \tag{4.2}$$

where, for example, $g_{\theta\theta\phi}$ is defined to be $\partial^3g/\partial\theta^2\partial\phi$ at the stationary-phase point.

To obtain the next higher stationary-phase approximation for the Clebsch–Gordan coefficient, we terminate the series in Eq. (4.1) at the fourth-order term. The reason for this is explained below. Thus, the approximation of the function g has derivatives at the stationary-phase point (θ_0,ϕ_0) that agree with those of g through fourth order. Our approximation of the integrand $\exp(g)$ is

$$\begin{aligned}\exp[g(\theta_0+x,\phi_0+y)]&\approx\exp(g_0)\exp(g_2)\exp(g_3)\exp(g_4)\\&=\exp(g_0)\exp(g_2)(1+g_3+g_3^2/2\cdots)(1+g_4+g_4^2/2+\cdots).\end{aligned}\tag{4.3}$$

When this is multiplied out, each of the terms may be integrated over the xy plane in closed form. We are interested in the asymptotic behavior of the resulting terms. The question is how the terms behave when all of the quantum numbers (j_1,m_1,j_2,m_2,j,m) are multiplied by the same factor (such a factor is called $1/\hbar$, as explained in the Introduction). The stationary-phase point (θ_0,ϕ_0) is independent of the factor, i.e., (θ_0,ϕ_0) is order $\hbar^0$, as can be seen from Eq. (3.11). The second derivatives of g at (θ_0,ϕ_0) are order $1/\hbar$, as can be seen from Eq. (3.14), so to see how the integral of $\exp(g_2)$ depends on $\hbar$, we define new variables of integration to be the old variables times $\hbar^{-1/2}$. From this it follows that the integral of $\exp(g_2)$ is order $\hbar$. By the same reasoning, the integral of a homogeneous quartic polynomial times $\exp(g_2)$ is order $\hbar^3$, and the integral of a homogeneous sixth-order polynomial times $\exp(g_2)$ is order $\hbar^4$. The polynomials g_4 and g_3^2 have coefficients that are order $1/\hbar$ and $1/\hbar^2$, respectively, so the integrals of these times $\exp(g_2)$ are both order $\hbar^2$. This is one order of $\hbar$ smaller than the integral of $\exp(g_2)$. The integral of a homogeneous polynomial of odd degree times $\exp(g_2)$ vanishes due to antisymmetry. Thus, the next-higher-order approximation of the integral of $\exp(g)$ is obtained by integrating

$$\exp(g_0)\,\exp(g_2)(1+g_4+g_3^2/2).\tag{4.4}$$

Terms coming from g_5, etc., contribute at higher orders.

To find the ratio of the integral of $g_4\exp(g_2)$ to the integral of $\exp(g_2)$ the following integrals are necessary:

$$\begin{aligned}i_1&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\exp(g_2)\,dx\,dy,\\i_2&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^4\exp(g_2)\,dx\,dy,\\i_3&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^3y\exp(g_2)\,dx\,dy,\\i_4&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^2y^2\exp(g_2)\,dx\,dy.\end{aligned}\tag{4.5}$$

We will need the ratios i_2/i_1, i_3/i_1, and i_4/i_1. The integrals are tabulated and these ratios can be worked out without the use of any information about relationships between the various derivatives of the function g at the stationary-phase point. The results are

$$\begin{aligned}i_2/i_1&=\frac{3g_{\phi\phi}^2}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^2},\\i_3/i_1&=\frac{-3g_{\theta\phi}g_{\phi\phi}}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^2},\\i_4/i_1&=\frac{2g_{\theta\phi}^2+g_{\theta\theta}g_{\phi\phi}}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^2}.\end{aligned}\tag{4.6}$$

It may be noted that $g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2$ is the determinant of the 2×2 matrix of second partial derivatives of the function g.

The ratio, which we denote by δ_4, of the integral of $g_4 \exp(g_2)$ to the integral of $\exp(g_2)$ works out to be

$$\delta_4=\frac{g_{\theta\theta\theta\theta}g_{\phi\phi}^2-4g_{\theta\theta\theta\phi}g_{\theta\phi}g_{\phi\phi}+2g_{\theta\theta\phi\phi}(2g_{\theta\phi}^2+g_{\theta\theta}g_{\phi\phi})-4g_{\theta\phi\phi\phi}g_{\theta\theta}g_{\theta\phi}+g_{\phi\phi\phi\phi}g_{\theta\theta}^2}{8(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^2}. \tag{4.7}$$

Next, we move on to the g_3^2 term in Eq. (4.4). To find the ratio of the integral of $\frac{1}{2}g_3^2 \exp(g_2)$ to the integral of $\exp(g_2)$ the following integrals are necessary:

$$\begin{aligned}
i_5&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^6 \exp(g_2)\,dx\,dy,\\
i_6&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^5 y \exp(g_2)\,dx\,dy,\\
i_7&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^4 y^2 \exp(g_2)\,dx\,dy,\\
i_8&=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}x^3 y^3 \exp(g_2)\,dx\,dy.
\end{aligned} \tag{4.8}$$

We will need the ratios i_5/i_1, i_6/i_1, i_7/i_1, and i_8/i_1. As in the case of the g_4 calculation, the integrals are tabulated and these ratios can be worked out without the use of any information about relationships between the various derivatives of the function g at the stationary-phase point. The results are

$$\begin{aligned}
i_5/i_1&=\frac{-15g_{\phi\phi}^3}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^3},\\
i_6/i_1&=\frac{15g_{\theta\phi}g_{\phi\phi}^2}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^3},\\
i_7/i_1&=\frac{-3g_{\phi\phi}(4g_{\theta\phi}^2+g_{\theta\theta}g_{\phi\phi})}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^3},\\
i_8/i_1&=\frac{3g_{\theta\phi}(2g_{\theta\phi}^2+3g_{\theta\theta}g_{\phi\phi})}{(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^3}.
\end{aligned} \tag{4.9}$$

The ratio, which we denote by δ_6, of the integral of $\frac{1}{2}g_3^2 \exp(g_2)$ to the integral of $\exp(g_2)$ works out to be

$$\begin{aligned}
\delta_6=[&2g_{\theta\phi}(3g_{\theta\theta}g_{\phi\phi}+2g_{\theta\phi}^2)(g_{\theta\theta\theta}g_{\phi\phi\phi}+9g_{\theta\theta\phi}g_{\theta\phi\phi})\\
&-3(g_{\theta\theta}g_{\phi\phi}+4g_{\theta\phi}^2)(2g_{\theta\theta\theta}g_{\theta\phi\phi}g_{\phi\phi}+2g_{\phi\phi\phi}g_{\phi\theta\theta}g_{\theta\theta}+3g_{\theta\theta\phi}^2g_{\phi\phi}+3g_{\phi\phi\theta}^2g_{\theta\theta})\\
&+30g_{\theta\phi}(g_{\theta\theta\theta}g_{\theta\theta\phi}g_{\phi\phi}^2+g_{\phi\phi\phi}g_{\phi\phi\theta}g_{\theta\theta}^2)-5(g_{\theta\theta\theta}^2g_{\phi\phi}^3+g_{\phi\phi\phi}^2g_{\theta\theta}^3)]/[24(g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2)^3].
\end{aligned} \tag{4.10}$$

The only remaining matter is to find the necessary values of the higher derivatives of the function g at the stationary-phase point. The definition of g, given in Eq. (3.3), can be used to find its second derivatives, given in Eq. (3.14), its third derivatives,

$$\frac{\partial^3 g}{\partial\theta^3}=2(j+j_2-j_1)\csc^2\theta\ \cot\theta+2(j_1+j_2-j)\ \csc^2(\theta-\phi)\cot(\theta-\phi),$$

$$\frac{\partial^3 g}{\partial\theta^2\partial\phi}=-2(j_1+j_2-j)\ \csc^2(\theta-\phi)\ \cot(\theta-\phi),$$

$$\frac{\partial^3 g}{\partial\theta\partial\phi^2}=2(j_1+j_2-j)\ \csc^2(\theta-\phi)\ \cot(\theta-\phi), \tag{4.11}$$

$$\frac{\partial^3 g}{\partial\phi^3}=2(j_1+j_2-j)\csc^2(\theta-\phi)\ \cot(\phi-\theta)+2(j+j_1-j_2)\ \csc^2\phi\cot\phi,$$

and its fourth derivatives,

$$\frac{\partial^4 g}{\partial\theta^4}=-2(j+j_2-j_1)\ \csc^2\theta\ \ (3\cot^2\theta+1)-2(j_1+j_2-j)\csc^2(\theta-\phi)[3\cot^2(\theta-\phi)+1],$$

$$\frac{\partial^4 g}{\partial\theta^3\partial\phi}=2(j_1+j_2-j)\ \csc^2(\theta-\phi)[3\cot^2(\theta-\phi)+1],$$

$$\frac{\partial^4 g}{\partial\theta^2\partial\phi^2}=-2(j_1+j_2-j)\ \csc^2(\theta-\phi)[3\cot^2(\theta-\phi)+1], \tag{4.12}$$

$$\frac{\partial^4 g}{\partial\theta\partial\phi^3}=2(j_1+j_2-j)\ \csc^2(\theta-\phi)[3\cot^2(\theta-\phi)+1],$$

$$\frac{\partial^4 g}{\partial\phi^4}=-2(j_1+j_2-j)\ \csc^2(\theta-\phi)[3\cot^2(\theta-\phi)+1]-2(j+j_1-j_2)\ \csc^2\phi\ \ (3\cot^2\phi+1).$$

Given the values of the cotangents of θ and ϕ at a stationary-phase point, these derivatives can be evaluated without having to find the angles, i.e., without having to make any choices of branch cuts. One way to do this is to use Eq. (3.5) to evaluate $\cot(\theta-\phi)$ and the identity $\csc^2\theta=1+\cot^2\theta$ to evaluate the squared cosecants.

The relationship between the Clebsch–Gordan coefficient and the integral of exp (g) is given in Eq. (3.1). Combining this with our higher-order approximation for the integral results in the following higher-order approximation for the Clebsch–Gordan coefficient. Each stationary-phase point contributes

$$(-1)^{j+m}(2i)^{j+j_1+j_2}\pi^{-2}N_{j_1m_1j_2m_2jm}\frac{2\pi e^{g(\theta_0,\phi_0)}}{\sqrt{g_{\theta\theta}g_{\phi\phi}-g_{\theta\phi}^2}}(1+\delta_4+\delta_6). \tag{4.13}$$

As explained in the previous sections, for points in the allowed region the sum over stationary-phase points is a sum over both of the solutions for the cotangents of θ and ϕ given in Eq. (3.11), and for points in the forbidden region only one of these solutions contributes. Given values for $\cot\theta$ and $\cot\phi$, Eqs. (3.14), (4.11), and (4.12) are used to evaluate the higher derivatives of the function g at the stationary-phase point. Then Eqs. (4.7) and (4.10) are used to obtain δ_4 and δ_6.

As shown in Eq. (3.17), the quantity $e^{g(\theta_0,\phi_0)}$ can also be evaluated using the values of the cotangents of θ and ϕ. The quantity $N_{j_1 m_1 j_2 m_2 j m}$ can be approximated to sufficient accuracy using the next correction to Stirling's approximation for the factorials.

Finally, we present some numerical examples. We begin with the allowed region.

For $(j_1,m_1,j_2,m_2,j,m)=(200,\ 100,\ 300,\ 150,\ 400,\ 250)$, the values are

$$\begin{aligned} \text{exact} &= 0.070\,349\,9, \\ \text{approx} &= 0.070\,349\,6. \end{aligned} \tag{4.14}$$

For $(j_1,m_1,j_2,m_2,j,m)=(200,\ 100,\ 300+\frac{1}{2},\ 150+\frac{1}{2},\ 400+\frac{1}{2},\ 250+\frac{1}{2})$, the values are

$$\begin{aligned} \text{exact} &= 0.073\,063\,6, \\ \text{approx} &= 0.073\,063\,3. \end{aligned} \tag{4.15}$$

In the forbidden region, the Clebsch–Gordan coefficients are much smaller. The following examples are from subregion I.

For $(j_1,m_1,j_2,m_2,j,m)=(200,\ 150,\ 300,-250,\ 400,-100)$, the values are

$$\begin{aligned} \text{exact} &= 3.089\,61\times 10^{-19}, \\ \text{approx} &= 3.089\,58\times 10^{-19}. \end{aligned} \tag{4.16}$$

For $(j_1,m_1,j_2,m_2,j,m)=(200,\ 150,\ 300+\frac{1}{2},-250+\frac{1}{2},\ 400+\frac{1}{2},-100+\frac{1}{2})$, the values are

$$\begin{aligned} \text{exact} &= 5.327\,18\times 10^{-19}, \\ \text{approx} &= 5.327\,12\times 10^{-19}. \end{aligned} \tag{4.17}$$

Further examples of results from the higher-order approximation are discussed in Appendix B.

V. CONCLUSION

The methods presented in this paper provide simple formulas for calculating first-order approximations to Clebsch–Gordan coefficients in the allowed region and in all of the forbidden subregions. Additionally, a higher-order approximation is derived, although the expressions are more complicated. We do not know if the quantity $\delta_4+\delta_6$ in Eq. (4.13) can be simplified when expressed in terms of the quantum numbers (see Appendix B for a special case). It appears to be complicated, as is often the case for higher-order approximations. The geometrical structure is not as clear.

Our higher-order approximation provides the only known way to compute certain digits of some Clebsch–Gordan coefficients. By this we mean that given any computer, we can always find quantum numbers large enough so that the exact calculation is not feasible. The beginning digits may be calculated using first-order approximations; the higher-order approximation makes it possible to compute further digits.

The methods of this paper could also be used to derive asymptotic expressions for the $6j$-symbols, etc. The starting point would again be an exact expression for the quantity of interest. One would then have to construct a polynomial with the property that the coefficient of one of its terms is this exact expression. Then an integral expression would be obtained, and finally this integral would be approximated using the stationary-phase method.

As mentioned in the Introduction, this work could have applications in high-angular momentum calculations and theoretical investigations which contain sums over large numbers of Clebsch–Gordan coefficients.[8,9]

Our analysis in the forbidden region led us to the realization that simple sign functions exist there that give the sign of the exact Clebsch–Gordan coefficients. These are summarized in Table I.

A subject for future work is the approximation of Clebsch–Gordan coefficients and $6j$-symbols near the boundary between the allowed and forbidden regions. Ponzano and Regge[4] have conjectured and supplied numerical evidence for a typical Airy function caustic behavior. Also, of course, it should be possible to extend the present calculations to even higher orders.

APPENDIX A: A ONE-DIMENSIONAL EXAMPLE

In this appendix we consider a one-dimensional example of an integral that gives a Fourier coefficient of a function which is an integer power of a fixed function. We are interested in the asymptotics of the result for large values of the two integers involved.

We define the function $F(m,n)$ for positive integers m and n by

$$F(m,n)=\int_{-\pi/2}^{\pi/2}\cos^n x\, e^{imx}\, dx. \tag{A1}$$

It is possible to evaluate this integral exactly in closed form:

$$F(m,n)=\begin{cases} 2^{-n}\pi\binom{n}{(n-m)/2}, & n-m \text{ even} \\ (-1)^{(n+1-m)/2}\, 2^{n+2} n!\dfrac{[(m+n+1)/2]!\,(m-n-1)!}{(m+n+1)!\,[(m-n-1)/2]!}, & n-m \text{ odd}, n<m \\ 2^{n+2} n!\dfrac{[(n+1-m)/2]!\,[(n+1+m)/2]!}{(n+1-m)!\,(n+1+m)!}, & n-m \text{ odd}, n>m\,. \end{cases} \tag{A2}$$

In deriving these results, one uses the definition of the beta function, $B(z+1,w+1)=\int_0^1 t^z(1-t)^w\,dt$, and the relation between the beta function and the gamma function, $B(z,w)=\Gamma(z)\Gamma(w)/\Gamma(z+w)$. One also uses the results that for integers $k\geqslant 0$,

$$\begin{aligned}\Gamma\left(k+\frac{1}{2}\right)&=\frac{\sqrt{\pi}(2k)!}{2^{2k}k!},\\ \Gamma\left(-k+\frac{1}{2}\right)&=(-1)^k\frac{2^{2k}\sqrt{\pi}k!}{(2k)!}.\end{aligned} \tag{A3}$$

1. Asymptotics of the exact expressions

In order to compare the stationary-phase approximations derived in the following subsection with the exact value of $F(m,n)$, we will use Stirling's approximation for the factorials in the exact expressions in Eq. (A2). The accuracy to which we will work is that the ratio of the exact value to the approximation should go to unity as n and m go to infinity, holding the ratio of n to m fixed. The difference between the logarithm of the exact expression and the logarithm of the approximation thus goes to zero as the two integers get large (the errors are of order $1/n$).

Stirling's approximation, through order unity (for the logarithms), is

$$x!\approx\sqrt{2\pi x}\,x^x e^{-x}. \tag{A4}$$

The next correction to this is a multiplicative factor of $e^{1/(12x)}$. Thus, the ratio of $x!$ to the approximation given in Eq. (A4) approaches unity as x goes to infinity.

Our approximation of the exact expression for $F(m,n)$ works out to be

$$F(m,n)\approx\begin{cases}\sqrt{\dfrac{2\pi}{n}}\left(\dfrac{1-m/n}{1+m/n}\right)^{m/2}\left[1-\left(\dfrac{m}{n}\right)^2\right]^{-(n+1)/2}, & n>m;\\ 0, \quad n-m \text{ even}, n<m;\\ (-1)^{(n+1-m)/2}\,2\sqrt{\dfrac{2\pi}{n}}\left(\dfrac{m/n-1}{m/n+1}\right)^{m/2}\left[\left(\dfrac{m}{n}\right)^2-1\right]^{-(n+1)/2}, & n-m \text{ odd}, n<m.\end{cases} \tag{A5}$$

In deriving this result, we have used the fact that the inequality $n>m$ implies $n-m\gg 1$. This is true because we are holding the ratio of the two integers fixed while letting them become large. In other words, errors of order $1/n$ are the same order as errors of order $1/(n-m)$. Thus the Stirling approximation is used for quantities such as $(n-m)!$. Similar remarks apply to the inequality $n<m$.

In Eq. (A5), only positive quantities are raised to powers that could be noninteger. Thus there are no phase ambiguities. If one is sloppy about phases, the last expression appears to be the same as the first, differing only be a factor of 2. The origin of this factor of two has a simple interpretation in the stationary-phase approximation, described in the next subsection.

It is remarkable that the first expression (for the case $n>m$, $n-m$ even) and the third expression (for the case $n>m$, $n-m$ odd) in Eq. (A2) have the same asymptotics to the order at which we are working. A calculation is involved in showing this. The result that comes from applying the Stirling approximation to the third expression is

$$\sqrt{\frac{2\pi}{n}}\left(\frac{1-m/(n+1)}{1+m/(n+1)}\right)^{m/2}\left[1-\left(\frac{m}{n+1}\right)^2\right]^{-(n+1)/2}.$$

To the accuracy to which we are working, this turns out to be the same as the first expression in Eq. (A5), although some work is required to show this.

2. Stationary-phase approximation

To do a stationary-phase approximation for the function $F(m,n)$, we write the function as

$$F(m,n)=\int_{-\pi/2}^{\pi/2} e^{ng(x)}\,dx, \tag{A6}$$

where the function g is defined by

$$g(z)=\ln\cos z+i\frac{m}{n}z. \tag{A7}$$

With the usual choice of branch cut for the logarithm function, the function $g(z)$ is analytic everywhere in the complex plane except for vertical lines that intersect the real axis at odd multiples of π, and at the intervals on the real axis where $\cos z$ is nonpositive. The identity

$$\cos(x+iy)=\cos x\cosh y-i\sin x\sinh y \tag{A8}$$

is useful in showing this. Knowledge of the region of analyticity of g allows us to deform the contour of integration in Eq. (A6) without changing the value of the integral. We would like to deform the contour so that the phase of the integrand $e^{ng(z)}$ is constant. To do this, we need to know the imaginary part of $g(z)$. With the help of Eq. (A8) we find that this is

$$\Im[g(x+iy)]=-\tan^{-1}(\tan x\tanh y)+\frac{m}{n}x. \tag{A9}$$

If a contour is selected in such a way that this function is a constant, then $g(x+iy)$ will equal an imaginary constant plus a real-valued function along the contour. The integrand $e^{ng(z)}$ will then equal a constant phase factor raised to the nth power times a fixed real-valued function raised to the nth power. This fixed real-valued function may be approximated by a Gaussian, and the integral may then be evaluated. Stationary-phase points z_s satisfy the condition

$$g'(z_s)=0. \tag{A10}$$

This is equivalent to the condition

$$\tan z_s = i\,\frac{m}{n}. \tag{A11}$$

We note that the value of g'' at a stationary-phase point is

$$g''(z_s) = -\sec^2 z_s = \left(\frac{m}{n}\right)^2 - 1. \tag{A12}$$

It is necessary to distinguish two cases, the case $m<n$ and the case $m>n$ (recall that m and n are both positive by assumption). We first consider the case $m<n$. In this case, it follows from a study of Eq. (A9) that a constant phase contour exists that connects the endpoints of the integral and passes through the stationary-phase point

$$z_s = i\,\tanh^{-1}\frac{m}{n} \tag{A13}$$

in a direction that is parallel to the real axis. The integrand is approximated by

$$e^{ng(z_s)+ng''(z_s)(z-z_s)^2/2},$$

and the result for the integral is

$$\sqrt{\frac{2\pi}{-ng''(z_s)}}\,e^{ng(z_s)} = \sqrt{\frac{2\pi}{n}}\left(\frac{1-m/n}{1+m/n}\right)^{m/2}\left[1-\left(\frac{m}{n}\right)^2\right]^{-(n+1)/2}, \tag{A14}$$

which agrees with the result in Eq. (A5).

We now move on to the case $m>n$. In this case, no single contour exists with the properties that it connect the endpoints of the integral and that the quantity in Eq. (A9) be constant. Instead, we choose a contour consisting of three straight-line pieces. The first part, C_1, is defined to start at $-\pi/2$ and go vertically upwards to $-\pi/2+iY$, Y being a large positive real number. The second part, C_2, is defined to go from $-\pi/2+iY$ to $\pi/2+iY$, and the third part, C_3, goes straight down to the $\pi/2$ endpoint of the integral. The parts C_1 and C_3 contain stationary-phase points, which we call z_{s-} and z_{s+}, and which are given by

$$z_{s\pm} = \pm\frac{\pi}{2} + i\,\tanh^{-1}\frac{n}{m}. \tag{A15}$$

For the integral along C_1 the integrand is approximated by

$$e^{ng(z_{s-})+ng''(z_{s-})(z-z_{s-})^2/2}.$$

We parametrize the curve C_1 by $z=z_{s-}+it$, where t is a real parameter. Then dz is $i\,dt$ and the resulting approximation for the integral along C_1 is

$$i\sqrt{\frac{2\pi}{+ng''(z_{s-})}}\,e^{ng(z_{s-})}. \tag{A16}$$

Similarly, the approximation for the integral along C_3 is

$$-i\sqrt{\frac{2\pi}{+ng''(z_{s+})}}\,e^{ng(z_{s+})}. \tag{A17}$$

Because of the condition $m>n$ the integral along the curve C_2 goes to zero as Y goes to infinity. The approximation for $F(m,n)$ is thus the sum of the expressions given in Eqs. (A16) and (A17). If $m-n$ is odd the sum is zero, in agreement with the exact value. If $m-n$ is even, the sum agrees with the approximation of the exact result, given in Eq. (A5).

Thus we see that depending on the ratio m/n, different numbers of stationary-phase points must be considered due to fundamental changes in the form of the stationary-phase contours as m/n goes from one side of the critical value of 1 to the other side. On either side of the critical value of 1, a stationary-phase approximation is possible. The behavior near the critical value is discussed briefly in the main part of this paper.

APPENDIX B: THE CASE OF VANISHING MAGNETIC QUANTUM NUMBERS

Clebsch–Gordan coefficients for the case of vanishing magnetic quantum numbers ($m_1 = m_2 = m = 0$) are of interest in atomic and nuclear physics. Many of the expressions derived in this paper simplify in this case. Also, comparisons with the asymptotics of the exact closed-form expression, given in Eq. (B11), are possible.

The vanishing of the magnetic quantum numbers implies that β, defined in Eq. (3.12), is real. The case $\beta=0$ is simple because one of the j quantum numbers is then equal to the sum of the other two, and the integral in Eq. (2.11) may be evaluated exactly with a small amount of effort. Thus, we will consider the case $\beta>0$. Two other facts that will be used throughout this appendix are that the set of quantum numbers is in the allowed region (since β is real) and that the j quantum numbers are integers (since $j_i - m_i$ is always an integer).

First, we work out the simplifications that occur in the all-real expression in Eq. (3.28). Equation (3.24) becomes

$$\chi = \frac{\pi}{2}\left(j + j_1 + j_2 + \frac{3}{2}\right), \tag{B1}$$

and Eq. (3.28) becomes

$$\langle j_1 0 j_2 0 | j 0\rangle \approx 2\sqrt{\frac{j}{\pi\beta}}\cos\left[\frac{\pi}{2}(j_1 + j_2 - j)\right]. \tag{B2}$$

This agrees with the first-order approximation of the exact expression, which can be obtained from the higher-order approximation [Eq. (B12)] of the exact result, given in Eq. (B11). If $j_1 + j_2 - j$ is odd, then both of the expressions are zero. (In this case, $j_1 + j_2 + j$ is also odd since $2j$ is even.) If $j_1 + j_2 - j$ is even, then both have a sign of $(-1)^{(j_1+j_2-j)/2}$.

Next, we move on to the higher-order approximation. From Eq. (3.11) it is apparent that the two solutions for the contangents of θ and ϕ are related by simply reversing the signs. It follows from Eqs. (3.14), (4.11), and (4.12) that the values of the second- and fourth-order derivatives of $g(\theta,\phi)$ are unchanged, while the third-order derivatives have their signs flipped. Equations (4.7) and (4.10) imply that the quantities δ_4 and δ_6 are unchanged. Finally, Eq. (3.17) implies that the quantity $e^{g(\theta_0,\phi_0)}$ gets multiplied by $(-1)^{j_1+j_2-j}$ for the second root. Because j is an integer, this phase factor is the same as $(-1)^{j_1+j_2+j}$. Since we are in the allowed region, we must sum over both stationary-phase points. We see that for odd values of j_1+j_2+j the result is zero, while for even values of j_1+j_2+j the result is twice the contribution obtained from one of the stationary-phase points.

The values of the second derivatives of $g(\theta,\phi)$ at the stationary-phase points are obtained from Eqs. (3.11) and (3.14), and the results simplify quite a bit:

$$g_{\theta\theta}=-\frac{4j_2(j_1+j)}{j_1+j_2+j}, \tag{B3}$$

$$g_{\theta\phi}=\frac{4j_1j_2}{j_1+j_2+j}, \tag{B4}$$

$$g_{\phi\phi}=-\frac{4j_1(j_2+j)}{j_1+j_2+j}. \tag{B5}$$

From these equations results the following expression for the determinant of the 2×2 Hessian matrix of second derivatives of $g(\theta,\phi)$:

$$\det\frac{\partial^2 g}{\partial(\theta,\phi)^2}=\frac{16j_1j_2j}{j_1+j_2+j}. \tag{B6}$$

We note that this result is nonzero, and it does not vanish in any special cases that have nonzero j quantum numbers, which seems to contradict the statement made at the end of Sec. III about the vanishing of the determinant when β vanishes. The resolution of this apparent contradiction has to do with the fact that in the stationary-phase analysis of this paper we do not simultaneously consider the cases $m_1=m_2=m=0$ and $\beta=0$. These two conditions together would imply α is zero. The quantity α is defined in Eq. (3.25). It vanishes when $j=j_1+j_2$, $j_1=j_2+j$ or $j_2=j+j_1$. In general, as long as α is nonzero, the expression for the determinant can be put (after some work) in the form

$$\det\frac{\partial^2 g}{\partial(\theta,\phi)^2}=\frac{\beta P_1+\beta^2P_2}{\alpha^2(j+j_1+j_2)^2}, \tag{B7}$$

where P_1 and P_2 are (large) polynomials in the quantum numbers. This equation justifies the statement that the determinant is zero in cases where β is zero. On the other hand, in cases where $m_1=m_2=m=0$, P_1 vanishes and α and β are equal, and the result simplifies to that shown in Eq. (B6). The case of $m_1=m_2=m=0$ and $\beta=0$ requires a separate treatment. It is necessary to go back to the original integral representation for the Clebsch–Gordan coefficient. The integral may be approximated by the methods of stationary phase, but it is simpler just to evaluate it or Eq. (2.15) exactly, which is possible at that point.

Higher-order derivatives of $g(\theta,\phi)$ at the stationary-phase points simplify as well. Equations (4.7) and (4.10) for δ_4 and δ_6 yield results that are much simpler than for the general case of nonzero magnetic quantum numbers:

$$\begin{aligned}\delta_4+\delta_6=(&j_1^5j_2-2j_1^3j_2^3+j_1j_2^5+j_1^5j-j_1^3j_2^2j-j_1^2j_2^3j+j_2^5j-j_1^3j_2j^2-10j_1^3j_2^2j^2-j_1j_2^3j^2-2j_1^3j^3\\&-j_1^2j_2j^3-j_1j_2^2j^3-2j_2^3j^3+j_1j^5+j_2j^5)/(12jj_1j_2\beta^2).\end{aligned} \tag{B8}$$

This expression may be rewritten in a more compact form, as explained after Eq. (B12). As discussed above, for odd values of $j+j_1+j_2$ the higher-order approximation of the Clebsch–Gordan coefficient vanishes identically. For even values of $j+j_1+j_2$, the result reduces to

$$\langle j_1 0 j_2 0 | j 0\rangle \approx 2(-1)^{(j_1+j_2-j)/2}\sqrt{\frac{2j+1}{2\pi\beta}}\sqrt{\frac{j+j_1+j_2}{j+j_1+j_2+1}}(1+\delta_4+\delta_6) \times\left[1+\frac{1}{24}\left(\frac{2}{j}+\frac{2}{j_1}+\frac{2}{j_2}-\frac{1}{j+j_1+j_2}-\frac{1}{-j+j_1+j_2}-\frac{1}{j-j_1+j_2}-\frac{1}{j+j_1-j_2}\right)\right], \tag{B9}$$

where we have approximated the factorials in $N_{j_1m_1j_2m_2jm}$ using the form of Stirling's approximation that is appropriate for this order,

$$x! \approx \sqrt{2\pi x}\, x^x e^{-x}\left(1+\frac{1}{12x}\right). \tag{B10}$$

The exact value of the Clebsch–Gordan coefficient is (Ref. 7, p. 87, and Ref. 11)

$$\langle j_1 0 j_2 0 | j 0\rangle = \begin{cases} 0 & j+j_1+j_2 \text{ odd}, \\ (-1)^{(j_1+j_2-j)/2}\sqrt{2j+1}\dfrac{\sqrt{(-j_1+j_2+j)!(j_1-j_2+j)!(j_1+j_2-j)!/(j_1+j_2+j+1)!}}{[((-j_1+j_2+j)/2)!((j_1-j_2+j)/2)!((j_1+j_2-j)/2)!]/((j_1+j_2+j)/2)!}, & j+j_1+j_2 \text{ even}, \end{cases} \tag{B11}$$

and this may be approximated using Eq. (B10). The result is

$$\langle j_1 0 j_2 0 | j 0\rangle \approx \begin{cases} 0, & j+j_1+j_2 \text{ odd} \\ 2(-1)^{(j_1+j_2-j)/2}\sqrt{\dfrac{2j+1}{2\pi\beta}}\sqrt{\dfrac{j+j_1+j_2}{j+j_1+j_2+1}}\left(1-\dfrac{jj_1j_2}{\beta^2}\right), & j+j_1+j_2 \text{ even} \end{cases}. \tag{B12}$$

To the order that we are working, the higher-order stationary-phase result, given in Eq. (B9), and the corresponding approximation of the exact result, given in Eq. (B12), agree. Equation (B9) contains two factors that have the form of unity plus a small correction. If these are multiplied out and only the first-order terms are kept, the result is the factor of $(1-jj_1j_2/\beta^2)$ in Eq. (B12). This shows that Eqs. (B9) and (B12) are equivalent, and it also provides an alternative way of writing the expression in Eq. (B8).

(Received 29 March 1999; accepted 22 June 1999)

The Landau–Lifshitz equation is derived as a first-order iteration of the Lorentz–Dirac equation for the charged particle. In those cases with null electromagnetic field's gradient, the Landau-Lifshitz gives the so named Herrera equation. A general method for the solution of the latter equation is presented and applied to the motion of a particle in a uniform electromagnetic field. © *1999 American Institute of Physics.* [S0022-2488(99)01610-2]

I. INTRODUCTION

Classical electrodynamics has two main parts; the theory of Maxwell's equations and the dynamics of the charged particles. The first one is universally accepted, but the same is not true for the dynamics of the particle when one considers the effect of radiation. A charged accelerated particle in an applied field radiates energy. In return, the radiation affects the motion of the particle. Accordingly, the mathematical theory of classical electrodynamics should comprise two basic sets of equations; one, which describes the resulting fields, is represented by the Maxwell's equation; and the other, which includes the effect of both the applied field and the radiative reaction, specifies the motion of the particle. General equations of the motion are obtained from very fundamental principles; relativistic covariance and conservation of the four-momentum and we can add another two, simplicity and mass renormalization. In addition, the equation should also reduce to the Lorentz force equation when radiation can be neglected. A partial differential equation which satisfies all four conditions was derived some time ago by Dirac.[1] But as it is well known,[2] the so named Lorentz–Dirac equation is one of the most controversial equations in the history of physics. Indeed, the appearance of the third time derivative brings the equation outside of the dynamical equation which uniquely specifies the trayectory of a particle once the initial conditions of position and velocity are given. A natural solution of the Lorentz–Dirac equation leads to runaway acceleration which can be eliminated by imposing asymptotic conditions, but then the solutions give preacceleration violating the physical causality.[2]

In the following, we consider the approach of Landau and Lifshitz.[3] They start from the Lorentz–Dirac equation and by a first order iteration of the same, they arrive to an equation considered as exact. Indeed Spohn[4] has recently demostrated that the Landau–Lifshitz equation is the effective second order equation that restricts the solution of the Lorentz–Dirac equation to the critical surface on which all solutions are guaranteed not to run to infinity. The Landau procedure reduces to the Herrera equation[5,6] when the gradient of the field is null. Though quadratic in the fields, the differential equation involves only first derivatives in the velocity, and so, does not have the undesirable properties of the Lorentz–Dirac equation. In the paper, we have utilized the Ansatz of Shen[7] for solving the Lorentz–Dirac equation in his approximation. So doing one separates the contribution of the reaction force.

The paper is organized as follows: In Sec. II, we present the basic steps to the Landau–Lifshitz equation and as a special case of the last equation, the Herrera equation. In Sec. III, is presented our Ansätz to the solving of the Herrera equation. In Sec. IV we apply the method for two cases. In Sec. V, we summarize the main ideas and results.

II. EQUATION OF MOTION

The Lorentz–Dirac equation for a charged particle of rest mass m and charge e in a field given by the antisymmetric Faraday's tensor $F_{\mu\nu}$, is

$$\dot{v}^{\mu}(\tau)=\frac{e}{mc}F^{\mu}{}_{\nu}v^{\nu}(\tau)+\tau_0\ddot{v}^{\mu}(\tau)-\frac{\tau_0}{c^2}v^{\mu}(\tau)\dot{v}_{\nu}\dot{v}^{\nu}. \tag{1}$$

In the equation, we have introduced the time-parameter $\tau_0=\frac{2}{3}(e^2/mc^3)$, and the units are Gaussian. The dot-point denotes differentiation with respect to the particle proper time τ. The four-velocity has the components

$$v^{\mu}(\tau)=\gamma(c,v^k(\tau)=\dot{x}^k(\tau)), \tag{2}$$

where the Latin subscript k takes on values 1–3, the Greek subscripts assume values 0–3.

In the iteration of Eq. (1) one assumes that the coefficients of the second and third terms on the right-hand side of Eq. (1) are small and that the applied field does not depend explicitly on the time τ, i.e., $F_{\mu\nu}=F_{\mu}(x(\tau))$. So, for the first order in τ_0, we have,

$$\dot{v}^{\mu}(\tau)=aF^{\mu}_{\nu}v^{\nu}+bK^{\mu}_{\nu\sigma}v^{\nu}v^{\sigma}+\varepsilon F^{\mu}_{\nu}F^{\nu}_{\sigma}\dot{v}^{\sigma}-\frac{\varepsilon v^{\mu}(\tau)}{c^2}F^{\lambda}_{\nu}F^{\nu}_{\sigma}v_{\lambda}v^{\sigma}, \tag{3}$$

in which $a=(e/mc)$, $b=(\tau_0 e/mc)$, $K^{\mu}_{\nu\sigma}=(\partial F^{\mu}_{\nu}/\partial x^{\sigma})$, and $\varepsilon=(\tau_0 e^2/m^2c^2)$.

Equation (3) is the Landau–Lifshitz equation and in the case when the gradient $K^{\mu}_{\nu\sigma}=0$, one obtains the Herrera equation,

$$\dot{v}^{\mu}(\tau)=aF^{\mu}_{\nu}v^{\nu}(\tau)+\varepsilon F^{\mu}_{\nu}F^{\nu}_{\sigma}v^{\sigma}(\tau)-\frac{\varepsilon v^{\mu}(\tau)}{c^2}F^{\lambda}_{\nu}F^{\nu}_{\sigma}v_{\lambda}v^{\sigma}. \tag{4}$$

Herrera notes that Eq. (4) is of the Newtonian class in which the right-hand side is the total applied four-force made up of the Lorentz force linear in the applied field and two other terms quadratic in the field. Furthermore, the equation has none of the problems of the Lorentz–Dirac equation, there are no runaway solutions and no preaccelerations. It has to be pointed out that Herrera claimed unsubstaintiated that his equation is exact because it does not possess the dificulties of the Lorentz–Dirac one. Nevertheless as we mentioned above, the equation which is substantially supported is the Landau–Lifshitz equation as Spohn[4] showed.

It is interesting to compare the Herrera equation with equation of motion of M_0-Papas,

$$\dot{v}^{\mu}(\tau)=\frac{e}{mc}F^{\mu}_{\nu}(v^{\nu}(\tau)+\tau_0\dot{v}^{\mu}(\tau))+\frac{\tau_0}{m}F^{\lambda}_{\sigma}v^{\sigma}_{\lambda}\dot{v}_{\lambda}v^{\mu}.$$

The Herrera equation, derived as a first-order iteration of the Lorentz–Dirac equation has the added force term which is quadratic in the applied field and the term is equivalent to a Poynting-type momentum being transfered to the particle. The Mo–Papas equation assumes new intuitive ideas: radiation reaction should be expressible by the external fields and the charge's kinematics, a charge experiences, in addition to the Lorentz force, another external force proportional to its acceleration and finally, inertia plus radiation is balanced by these two external forces. Nevertheless since this last equation possesses a third derivative with respect to the time, it will present similar difficulties as the Lorentz–Dirac equation and consequently our method will not apply for this case.

Even if our main point it is to solve the Landau–Lifshitz equation, we will consider as a first step, just the case when $K_{\nu\tau}=0$. That is the Herrera equation case.

Using the fundamental identity,

$$F_{\mu\nu}=(\delta_{\mu o}\delta_{\nu j}-\delta_{\mu j}\delta_{\nu o})E_j-\delta_{\mu j}\delta_{\nu k}\varepsilon_{jkl}B_l\,. \tag{5}$$

Herrera has succeeded in to expressing Eq. (3) in the form, explicitly in the fields,

$$\dot{\mathbf{v}}(\tau)=\frac{e}{m}\left(\gamma\mathbf{E}+\frac{\mathbf{v}\times\mathbf{B}}{c}\right)-\varepsilon\mathbf{v}\left[\gamma^2(\mathbf{E}^2+\mathbf{B}^2)-\left(\frac{\mathbf{v}\cdot\mathbf{E}}{c}\right)^2-\left(\frac{\mathbf{v}\cdot\mathbf{B}}{c}\right)^2-2\gamma\mathbf{v}\cdot\left(\frac{\mathbf{E}\times\mathbf{B}}{c}\right)\right]$$
$$+\varepsilon(\mathbf{E}(\mathbf{v}\cdot\mathbf{E})+\mathbf{B}(\mathbf{v}\cdot\mathbf{B})+c\gamma\mathbf{E}\times\mathbf{B}), \tag{6a}$$

and

$$\dot{\gamma}(t)=\frac{e}{mc^2}\mathbf{v}\cdot\mathbf{E}-\varepsilon\gamma\left[(\gamma^2-1)(\mathbf{E}^2+\mathbf{B}^2)-\left(\frac{\mathbf{v}\cdot\mathbf{E}}{c}\right)^2-\left(\frac{\mathbf{v}\cdot\mathbf{B}}{c}\right)^2\right]+\varepsilon(2\gamma^2-1)\mathbf{v}\cdot(\mathbf{E}\times\mathbf{B}). \tag{6b}$$

Equations (6a) and (6b) are the point of depart for the two applications of Herrera[4] to the motion of the charged particle in a uniform magnetic field and uniform electric field.

III. EXACT SOLUTION OF THE HERRERA EQUATION OF MOTION

It can be easily verified that if the four-vector $f^\mu(\tau)$ is a solution of equation

$$\dot{f}^\mu(\tau)=T^\mu_\lambda f^\lambda(\tau), \tag{7}$$

where

$$T^\mu_\lambda=aF^\mu_\lambda+\varepsilon F^\mu_\nu F^\nu_\lambda, \tag{8}$$

then

$$v^\mu(\tau)=\eta(\tau)f^\mu(\tau), \tag{9}$$

is a solution of the Herrera equation in the form of Eq. (4), with

$$\eta(\tau)=\left[1+\frac{2\varepsilon}{c^2}\int_0^\tau F_{\nu\varepsilon}F^\nu_\lambda f^\varepsilon f^\lambda d\tau\right]^{-1/2}. \tag{10}$$

$\eta(\tau)$ represents the damping effect due to the radiation reaction. Therefore, once the solution to Eq. (7) is found at least a formal expression can be immediately written down for the solution of the Herrera equation.

We can solve Eq. (7) formally, by means of an exponential expression, if the applied field $F_{\mu\nu}$ is constant in space and time,

$$f^\mu(\tau)=\exp[(aF^\mu_\nu+\varepsilon F^\lambda_\nu F^\mu_\lambda)\tau]f^\nu(0). \tag{11}$$

Also, the method can be applied to obtain solutions to the equations of motion in cases of physical interest if the fields $F_{\mu\nu}$ are just dependent on the time since we can always solve Eq. (7).

Introducing Eqs. (11) and (10) into Eq. (9), we find a formal solution for the Herrera equation,

$$v^\mu(\tau)=\frac{\exp[(aF^\mu_\nu+\varepsilon F^\mu_\lambda F^\lambda_\nu)\tau]f^\nu(0)}{\left[1+\frac{2\varepsilon}{c^2}\int_0^\tau F_{\nu\varepsilon}F^\nu_\lambda f^\varepsilon f^\lambda d\tau\right]^{1/2}} \tag{12}$$

for the case of uniform electromagnetic fields.

For further developement of Eq. (12) we can apply to it the methods of Kumar[8] on the expansion of a function of noncommunting operators and on expanding the exponential. Nevertheless, we prefer to solve Eq. (7) more directly and simultaneously to give a physical insight into the force-term $\varepsilon F^{\mu}_{\nu} F^{\mu}_{\sigma} v^{\sigma}$. To this end, we made the Ansatz,

$$f^{\mu}(\tau)=e^{\alpha(\tau)} f^{\mu}_{L}(\tau), \tag{13}$$

where $f^{\mu}_{L}(\tau)$ is any solution of the Lorentz equation,[7,8] without radiation. One can readly show that $\alpha(\tau)$ is of the form,

$$\alpha(\tau)=\frac{\varepsilon}{c^2}\int_0^{\tau} F^{\mu}_{\lambda} F^{\lambda}_{\nu} f^{\nu}_{L}(\tau') f_{\mu L}(\tau') d\tau' \tag{14}$$

with the normalization condition, $f^{\mu}_{L}(\tau') f_{\mu L}(\tau')=c^2$.

Introducing Eqs. (14), (13), and (10) in Eq. (9), the solution of the Herrera equation reads

$$v^{\mu}(\tau)=\frac{\exp\left[\frac{\varepsilon}{c^2}\int_0^{\tau} F^{\mu}_{\lambda} F^{\lambda}_{\nu} f^{\nu}_{L}(\tau') f_{\mu L}(\tau') d\tau'\right]}{\left[1+\frac{2\varepsilon}{c^2}\int_0^{\tau} F_{\nu\varepsilon} F^{\nu}_{\lambda} f^{\varepsilon} f^{\lambda} d\tau'\right]^{-1/2}} f^{\mu}_{L}(\tau). \tag{15}$$

Let us consider the case of a uniform electromagnetic field. Using the fact that $F_{\mu\nu}$ is antisymmetric and the tensor $\dot{f}^{\mu}_{L} \dot{f}_{\nu L}$ is symmetric and the product of a symmetric tensor with an antisymmetric tensor gives identically zero, we find

$$\frac{d}{d\tau}(F^{\mu}_{\lambda} F^{\lambda}_{\nu} f^{\nu}_{L} f_{\mu L})=2F_{\mu\lambda} f^{\lambda}_{L} F^{\mu\nu} \dot{f}_{\nu L}=2F^{\mu\nu} \dot{f}_{\mu L} \dot{f}_{\nu L}=0, \tag{16}$$

i.e., $F^{\mu}_{\lambda} F^{\lambda}_{\nu} f^{\nu}_{L} f_{\mu L}$ is a constant of time.

Therefore, in a constant field

$$\alpha(\tau)=\frac{\varepsilon}{c^2} F^{\mu}_{\lambda} F^{\lambda}_{\nu} f^{\nu}_{L} f_{\mu L} \tau. \tag{17}$$

To compute $v^{\mu}(\tau)$, one needs to find $f^{\mu}_{L}(\tau)$ first.

For a charged particle in a constant electric and magnetic field this has become a standard textbook exercise. Piña and recently Muñoz and Hyman[9–11] present a fully covariant solution to the problem of a charged particle in a spatially uniform electromagnetic field $F_{\alpha\beta}$. The integration method naturally leads to a solution in manifestly covariant form. Shen,[7] applies a more elegant method for obtaining formal solutions to the Lorentz equation using the projection operators, first given by Rosen[12] for finite transformation in SU(3) space. Nevertheless as we will see in the next section, our method has the advantage of simplicity.

IV. APPLICATIONS

A. Motion in a uniform magnetic field

The relativistic motion of a particle in a field specified by $B_k=(0,0,B_0)$ it is a good testing ground for applying an equation of motion. Writing $\omega_0=(eB_0/mc)$ and $B_0^2=\lambda\omega_0$, where $\lambda=(m^2c^2/e^2)\,\omega_0$ we find that Eqs. (10), (14) are then expressed as

$$\alpha(\tau)=-\varepsilon\lambda\,\omega_0\tau, \tag{18}$$

and

$$\eta(\tau)=(\gamma^2(0)-(\gamma^2(0)-1)e^{-2\lambda w_0\tau})^{-1/2}, \tag{19}$$

where we have chosen $v_3(0)=0$.

For a particle in a uniform magnetic field, Eq. (15) now yields the solution in a closed form

$$v^\mu(\tau)=\frac{e^{-\lambda w_0\tau}}{(\gamma^2(0)-(\gamma^2(0)-1)e^{-2\lambda w_0\tau})^{1/2}}f_L^\mu(\tau), \tag{20}$$

with $f_L^\mu(\tau)$ any solution of the Lorentz equation. Equation (20) coincides with the results obtained by a parametrization of the Larmor formula and averaging it.[13]

B. Motion in a uniform electric field

Another example is the motion in a uniform electric field given by $E_k=(E_0,0,0)$; the general solution is also in this case, obtainable in closed form.

In writing the relations, we have introduced, following Herrera, the abbreviation $\Im(t)=(v_2^2+v_3^2)/c^2$ corresponding to the square of the transverse four-velocity. The exact solution with the proper time τ as the independent variable is

$$v^\mu(\tau)=\frac{e^{2\varepsilon E_0^2\tau}f_L^\mu(\tau)}{[\gamma^2(o)\Im(0)-(1+\gamma^2(o)\Im(0))e^{2\varepsilon E_0^2\tau}]^{1/2}}, \tag{21}$$

where the Lorentz solutions are given by the expressions

$$\begin{aligned} f_L^0(\tau)&=f_L'(0)\sin h(\kappa\tau)+\gamma_L(0)\cos h(\kappa\tau)\\ f_L'(\tau)&=\gamma_L(0)\sin h(\kappa\tau)+f_L'(0)\cos h(\kappa\tau), \end{aligned} \tag{22}$$

where $\kappa=e\tau_0/mc$ and $f_L^\mu=\gamma(c,\mathbf{v})$.

This is the same result that Herrera[6] obtained.

V. CONCLUSION

The Landau–Lifshitz equation, derived as a first-order iteration of the Lorentz–Dirac equation, is considered as the exact equation of motion for classical electrodynamics of a charged particle. The equation is of the Newtonian class since the total applied force is made up of the Lorentz force and two other terms quadratic in external fields. Therefore, there are no runaway solutions and no preacceleration. We have solved exactly the equation in two cases of physical importance: uniform magnetic and electric fields, and the results are quite similar to those obtained by Herrera in both situations. The method can be extended to the domain of oscillatory field. In those circumstances the Herrera equation is not valid and the Landau–Lifshitz equation has to be used. Similar methods can be used to solve it in a future paper. But the fundamental question of whether the Landau–Lifshitz equation of motion or for that matter, the Lorentz–Dirac equation and other proposed equations are in agreement with the experiment, is an open question. Finally, in accordance with Spohn[4] and the limits of classical electrodynamics,[13] that is where quantum effects are not important, the equation of Landau–Lifshitz is a good candidate to be tested experimentally.[13]

(Received 17 March 1999; accepted for publication 19 June 1999)

We derive transport theoretic boundary conditions for acoustic wave reflection at a weakly rough boundary in an inhomogeneous half space. We use the Wigner distribution to go from waves to energy transport in the high frequency limit. We generalize known results on the reflection of acoustic plane waves in a homogeneous medium. We analyze higher order corrections, which include a enhanced backscattering effect in the back direction. © *1999 American Institute of Physics.* [S0022-2488(99)02009-5]

I. INTRODUCTION

Wave propagation in weakly fluctuating random media over distances large compared to the wavelength can be described by incoherent energy transport. This is the radiative transport regime.[1,2] Near boundaries and interfaces, waves undergo coherent or partially coherent reflection. Angularly resolved energy reflection and transmission in homogeneous media in average, has been studied extensively in the past.[3–6] Recently, the problem has been revisited in the transport theoretic context using a plane wave decomposition; see Ref. 7. There, the boundary conditions for the transport equations in a domain with rough boundaries of small amplitude and homogeneous background are derived. In this paper, we derive boundary conditions in the case of inhomogeneous domains. We systematically use the Wigner transform to study the reflection of angularly resolved acoustic energy density from a Dirichlet surface. The scale of the volume inhomogeneities is large compared to the wave length. The boundary conditions are a direct generalization of those obtained in the case of a homogeneous medium, with a reflection operator depending upon the position at the boundary. Our main ingredient is a perturbation analysis around the flat boundary case studied in Ref. 8.

A. Transport equations for the energy density

As we recall in Sec. II, the phase space acoustic energy density $\mu(\mathbf{x},\mathbf{k})$ satisfies the transport equation

$$\nabla_{\mathbf{k}}\omega_+ \cdot \nabla_{\mathbf{x}}\mu - \nabla_{\mathbf{x}}\omega_+ \cdot \nabla_{\mathbf{k}}\mu = 0. \tag{1}$$

Here $\omega_+(\mathbf{x},\mathbf{k})$ is the eigenfrequency of the acoustic waves given by

$$\omega_+ = c|\mathbf{k}|, \quad c = \frac{1}{\sqrt{\kappa\rho}}, \tag{2}$$

where $\rho(\mathbf{x})$ is the density and $\kappa(\mathbf{x})$ is the compressibility of the background medium. These equations hold in the high frequency regime for monochromatic waves, when the wavelength is

[a]bal@math.stanford.edu
[b]papanico@math.stanford.edu
[c]ryzhik@math.uchicago.edu

much smaller than the variations of the density and compressibility. They were derived in domains without boundaries or interfaces by several authors in the context of geometrical optics (see for instance Ref. 9).

B. Scattering from a rough boundary in a homogeneous medium

In the preceding section, the free transport equation (1) is posed in the whole space, with no boundary. In realistic applications, it is important to consider problems in bounded domains with correct boundary conditions.

We assume that the domain is given by $H_\epsilon = \{\mathbf{x} \in R^n : x_n > \epsilon \eta h(\mathbf{x}'/\epsilon)\}$. The function $h(\mathbf{x}')$ is a mean zero stationary random process with covariance function $R(\mathbf{y}')$ defined by

$$\langle h(\mathbf{x}'+\mathbf{y}')h(\mathbf{x}')\rangle = R(\mathbf{y}'). \tag{3}$$

The power spectrum $\hat{R}(\mathbf{k}')$ is the Fourier transform of $R(\mathbf{y}')$:

$$R(\mathbf{y}') = \int \frac{d\mathbf{p}}{(2\pi)^{d-1}} e^{i\mathbf{p}'\cdot\mathbf{y}'} \hat{R}(\mathbf{p}'). \tag{4}$$

The boundary of our domain is varying on the scale of the wavelength ϵ, which gives rise to scattering of incoherent, or diffuse, energy from the boundary. The small parameter $\eta \ll 1$ is measuring the height of the surface relative to the wavelength.

One finds by a direct computation using a plane wave decomposition that the average energy of reflected waves going in the direction $\mathbf{k}^+(\mathbf{k}')$ is given, for Dirichlet boundary conditions, by

$$\mu_{\text{out}}(\mathbf{x}',\mathbf{k}') = \mu_{\text{out}}^{\text{spec}} + \mu_{\text{out}}^{\text{diff}} = \left(1 - \eta^2 \int \frac{d\mathbf{p}'}{(2\pi)^{n-1}} \hat{R}(\mathbf{k}'-\mathbf{p}') p_n^+ k_n^+ \right) \mu_{\text{in}}(\mathbf{x}',\mathbf{k}')$$
$$+ \eta^2 \int \frac{d\mathbf{p}'}{(2\pi)^{n-1}} \hat{R}(\mathbf{k}'-\mathbf{p}') (p_n^+)^2 \mu_{\text{in}}(\mathbf{x}',\mathbf{p}'). \tag{5}$$

Here we have defined for every horizontal wave vector $\mathbf{k}'$:

$$\mathbf{k}^\pm(\mathbf{k}') = (\mathbf{k}', k_n^\pm), \quad |\mathbf{k}'|^2 + (k_n^\pm)^2 = K^2 = \frac{\omega_+^2}{c^2}. \tag{6}$$

Notice that $\mathbf{k}^+$ corresponds to outgoing waves, and $\mathbf{k}^-$ corresponds to incoming waves.

A detailed computation both for the Dirichlet and Neumann problems can be found, for instance, in Refs. 3–6. The first term in (5) represents the specular reflection including a correction due to surface roughness. The second term is produced by the diffuse scattering from the rough boundary.

The plane wave decomposition used in this calculation is not available in non homogeneous media. Thus one cannot directly generalize the above calculations to variable media. We have recently derived in Ref. 8 transport boundary conditions for the energy in inhomogeneous media with boundaries which vary on a large scale compared to the wavelength. We treat here the Dirichlet problem in an inhomogeneous domain with rough boundary for $\eta \ll 1$ as a perturbation of the smooth boundary considered in Ref. 8. We show that the results of Ref. 8 allow us to compute the higher corrections in η of the reflected energy, which coincide with (5) in the case of a homogeneous medium.

It is known that the Born expansion we use in this paper diverges for the Neumann and impedance problems at grazing angles and we do not consider them here. However, our method can be adapted to incorporate the smoothing method (Refs. 7, 10, and 11). Then, we can reproduce the results obtained in Refs. 12 and 13 for uniform media including the coherent backscattering effect, now in the setup of a variable media.

The paper is organized as follows. In Sec. II, we review the results of Ref. 8 and some basic facts from the Wigner distribution theory. We state our results for rough boundaries in Sec. III. The perturbation expansion is treated in Sec. IV up to second order in η. Finally, we investigate higher order corrections in Sec. V.

II. ENERGY PROPAGATION IN A HALF SPACE

A. The Wigner distribution

One way to describe scattering of phase space resolved energy is to consider the Wigner distribution matrix of the family $\mathbf{w}_\epsilon$ of the solutions of (12). A detailed exposition to the theory of Wigner distributions can be found in Refs. 14 and 8. Given a family of vector-valued functions $\mathbf{u}_\epsilon(\mathbf{x})$ bounded in $L^2(R^n)$, its Wigner transform matrix is defined by

$$\mathbf{W}_\epsilon(\mathbf{x},\mathbf{k}) = \int \frac{d\mathbf{y}}{(2\pi)^n} e^{i\mathbf{k}\cdot\mathbf{y}} \mathbf{u}_\epsilon\left(\mathbf{x} - \frac{\epsilon\mathbf{y}}{2}\right) \mathbf{u}_\epsilon^*\left(\mathbf{x} + \frac{\epsilon\mathbf{y}}{2}\right). \tag{7}$$

The family $\mathbf{W}_\epsilon$, possibly after extracting a subsequence, has a weak limit as $\epsilon \to 0$ in the sense of Schwartz distributions. The limit matrix $\mathbf{W}(\mathbf{x},\mathbf{k})$, called the Wigner distribution, has a number of important properties, which we summarize in the following proposition.

Proposition 1: The matrix $\mathbf{W}(\mathbf{x},\mathbf{k})$ *is self-adjoint and non-negative. Given a bounded continuous function* $\theta(\mathbf{x})$, *the Wigner distribution of the family* $g_\epsilon(\mathbf{x}) = \theta(\mathbf{x}) f_\epsilon(\mathbf{x})$ *is*

$$\mathbf{W}[g_\epsilon](\mathbf{x},\mathbf{k}) = \theta(\mathbf{x}) \mathbf{W}[f_\epsilon](\mathbf{x},\mathbf{k}) \theta^*(\mathbf{x}). \tag{8}$$

Given a differential operator $L(\mathbf{x},D)$ *with smooth coefficients, the Wigner matrix of the family* $p_\epsilon(\mathbf{x}) = L(\mathbf{x},\epsilon D) f_\epsilon(\mathbf{x})$ *is*

$$\mathbf{W}[p_\epsilon](\mathbf{x},\mathbf{k}) = L(\mathbf{x},i\mathbf{k}) \mathbf{W}[f_\epsilon](\mathbf{x},\mathbf{k}) [L(\mathbf{x},i\mathbf{k})]^*. \tag{9}$$

If the family f_ϵ *is* ϵ*-oscillatory,*[14] *then*

$$\mathrm{Tr} \int \mathbf{W}(\mathbf{x},d\mathbf{k}) = \lim_{\epsilon\to 0} |\mathbf{u}_\epsilon(\mathbf{x})|^2. \tag{10}$$

The property (8) allows one to consider the Wigner distributions of families bounded in $L^2_{\mathrm{loc}}(R^n)$. This is important in dealing with time-harmonic solutions of the acoustic equations. The property (9) allows one to deal with high frequency waves in variable media. The last property shows that the Wigner matrix captures the energy of high frequency waves, which oscillate at a frequency of order ϵ^{-1} at most.

One can also consider the Wigner matrix of two different families $\mathbf{u}_\epsilon, \mathbf{v}_\epsilon$, defined as the limit of

$$\mathbf{W}[\mathbf{u}_\epsilon,\mathbf{v}_\epsilon](\mathbf{x},\mathbf{k}) = \int \frac{d\mathbf{y}}{(2\pi)^n} e^{i\mathbf{k}\cdot\mathbf{y}} \mathbf{u}_\epsilon\left(\mathbf{x} - \frac{\epsilon\mathbf{y}}{2}\right) \mathbf{v}_\epsilon^*\left(\mathbf{x} + \frac{\epsilon\mathbf{y}}{2}\right).$$

It has similar properties.[14]

B. Acoustic wave transport

The time harmonic acoustic equations for the acoustic velocity $\mathbf{v} = (v_1,\ldots,v_n)$, $n = 2,3$, and pressure p, in the high frequency regime, are

$$\begin{aligned} \epsilon\nabla p_\epsilon &= i\omega\rho(\mathbf{x})\mathbf{v}_\epsilon, \\ \epsilon\nabla\cdot\mathbf{v}_\epsilon &= i\omega\kappa(\mathbf{x})p_\epsilon. \end{aligned} \tag{11}$$

Here ρ and κ are the density and compressibility of the medium, and the parameter $\epsilon \ll 1$ is the ratio of the wave length to the typical scale of the variations of $\rho(\mathbf{x})$ and $\kappa(\mathbf{x})$. Equations (11) can be rewritten as a reduced symmetric hyperbolic system

$$\sum_{j=1}^{n} \epsilon D^j \frac{\partial \mathbf{w}_\epsilon}{\partial x_j} - i\omega A(\mathbf{x})\mathbf{w}_\epsilon = 0 \tag{12}$$

for the vector $\mathbf{w}_\epsilon = (\mathbf{v}_\epsilon, p_\epsilon) \in C^{n+1}$. Here the diagonal matrix $A(\mathbf{x}) = \mathrm{diag}(\rho,\rho,\rho,\kappa)$, for $n=3$, and the symmetric matrices D^j are defined appropriately from (11).

Let $\mathbf{w}_\epsilon$ be an ϵ-oscillatory family of solutions of (12) bounded in $L^2_{\mathrm{loc}}(R^n)$. Then the limit Wigner matrix $\mathbf{W}(\mathbf{x},\mathbf{k})$ is described as follows. The dispersion matrix of the system (12) is (in three dimensions)

$$L = A^{-1}\sum_{j=1}^{n} k_j D^j = \begin{pmatrix} 0 & 0 & 0 & k_1/\rho \\ 0 & 0 & 0 & k_2/\rho \\ 0 & 0 & 0 & k_3/\rho \\ k_1/\kappa & k_2/\kappa & k_3/\kappa & 0 \end{pmatrix}. \tag{13}$$

The eigenvector $\mathbf{b}$ of the matrix L that corresponds to forward propagating waves is

$$\mathbf{b} = \left(\frac{\hat{\mathbf{k}}}{\sqrt{2\rho(\mathbf{x})}}, \frac{1}{\sqrt{2\kappa(\mathbf{x})}} \right), \tag{14}$$

where $\hat{\mathbf{k}} = \mathbf{k}/|\mathbf{k}|$. The corresponding eigenfrequency is given by

$$\omega_+ = c(\mathbf{x})|\mathbf{k}|, \quad c(\mathbf{x}) = \frac{1}{\sqrt{\kappa(\mathbf{x})\rho(\mathbf{x})}}. \tag{15}$$

The solutions of (12) have frequency ω, thus we introduce the resonant wave number $K(\mathbf{x}) = \omega\sqrt{\kappa(\mathbf{x})\rho(\mathbf{x})}$. Then, the positive definite matrix $\mathbf{W}(\mathbf{x},\mathbf{k})$ has the form

$$\mathbf{W}(\mathbf{x},\mathbf{k}) = \mu(\mathbf{x},\mathbf{k})\mathbf{b}(\mathbf{x},\mathbf{k})\mathbf{b}^*(\mathbf{x},\mathbf{k}).$$

Here the scalar measure $\mu(\mathbf{x},\mathbf{k})$ is supported on the set

$$\mathcal{S} = \{(\mathbf{x},\mathbf{k}): \ |\mathbf{k}| = K(\mathbf{x})\}. \tag{16}$$

This statement is a generalization of the eikonal equation of geometrical optics. The measure μ satisfies the transport equation (1).[14,2]

The scalar measure $\mu(\mathbf{x},\mathbf{k})$ can be considered as the phase space resolved energy density of acoustic waves in the high frequency limit. Namely, the high frequency limit of the physical space energy density is given by[2]

$$\lim_{\epsilon\to 0} \mathcal{E}_\epsilon(\mathbf{x}) = \int \mu(\mathbf{x}, d\mathbf{k}).$$

Here the acoustic energy density is

$$\mathcal{E}_\epsilon(\mathbf{x}) = \frac{\rho|\mathbf{v}_\epsilon|^2}{2} + \frac{\kappa|p_\epsilon|^2}{2}.$$

The limit energy flux $\mathcal{F} = \frac{1}{2}(p_\epsilon \overline{\mathbf{v}_\epsilon} + \overline{p_\epsilon}\mathbf{v}_\epsilon)$ is expressed via μ by

$$\lim_{\epsilon\to 0}\mathcal{F}_\epsilon(\mathbf{x})=c(\mathbf{x})\int \hat{\mathbf{k}}\mu(\mathbf{x},d\mathbf{k}).$$

C. Acoustic energy transport in a half space

We review here briefly the results of Ref. 8. Let $\mathbf{w}_\epsilon$ be an ϵ-oscillatory family of solutions of the acoustic equations (12) in the half space $x_n>0$ (without imposing any boundary conditions yet). We assume that the family $\mathbf{w}_\epsilon(\mathbf{x})$ and the family

$$\mathbf{r}_\epsilon(\mathbf{x}')=\mathbf{w}_\epsilon(\mathbf{x}',0) \tag{17}$$

of its boundary traces are bounded in $L^2_{\text{loc}}(R^n)$ and $L^2_{\text{loc}}(R^{n-1})$, respectively. Here and below we use the notation $\mathbf{x}',\mathbf{k}'$ for the position on the boundary and the tangential component of the wave vector, respectively. In addition we assume that the measure of the resonant set $B_{cr}=\{(\mathbf{x}',\mathbf{k}')\in R^{n-1}\times R^{n-1}:c(\mathbf{x}')|\mathbf{k}'|=\omega\}$ of grazing rays with respect to the Wigner measure $\nu(\mathbf{x}',\mathbf{k}')$ of the family $\mathbf{r}_\epsilon$ is zero. The grazing rays in the phase space energy context were studied recently in Refs. 15 and 16 and we avoid these technical complications. Physically, our assumption means that grazing rays are not charged. Then we have the following proposition.

Proposition 2: Under the above-mentioned assumptions the following holds.

(i) *The Wigner matrix $\boldsymbol{\nu}(\mathbf{x}',\mathbf{k})$ of the family $\mathbf{r}_\epsilon(\mathbf{x}')$ has the form*

$$\boldsymbol{\nu}=\nu_\alpha\mathbf{b}(\mathbf{k}_-)\mathbf{b}^*(\mathbf{k}_-)+\nu_\beta\mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_+)+\nu_{\alpha\beta}\mathbf{b}(\mathbf{k}_-)\mathbf{b}^*(\mathbf{k}_+)+\overline{\nu_{\alpha\beta}}\mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_-) \tag{18}$$

with $\nu_{\alpha,\beta,\alpha\beta}$ being distributions so that the matrix $\begin{pmatrix}\nu_\alpha & \nu_{\alpha\beta}\\ \overline{\nu_{\alpha\beta}} & \nu_\beta\end{pmatrix}$ is positive definite.

(ii) *The Wigner matrix $\mathbf{W}(\mathbf{x},\mathbf{k})$ of the family $\mathbf{w}_\epsilon(\mathbf{x})$ has the form*

$$\mathbf{W}(\mathbf{x},\mathbf{k})=\mu(\mathbf{x},\mathbf{k})\mathbf{b}(\mathbf{x},\mathbf{k})\mathbf{b}^*(\mathbf{x},\mathbf{k}). \tag{19}$$

The scalar measure μ is supported on the set (16) and satisfies weakly the transport equation

$$\nabla_{\mathbf{k}}\omega_+\cdot\nabla_{\mathbf{x}}\mu-\nabla_{\mathbf{x}}\omega_+\cdot\nabla_{\mathbf{k}}\mu=c\hat{k}_n(\mu_{\text{in}}\delta(k_n-k_n^-)+\mu_{\text{out}}\delta(k_n-k_n^+)). \tag{20}$$

Here the measures μ_{in} and μ_{out} are given by

$$\mu_{\text{in}}(\mathbf{x}',\mathbf{k}')=\nu_\alpha(\mathbf{x}',\mathbf{k}'),\quad \mu_{\text{out}}(\mathbf{x}',\mathbf{k}')=\nu_\beta(\mathbf{x}',\mathbf{k}') \tag{21}$$

with ν_α,ν_β defined by (18), $\omega_+(\mathbf{x},\mathbf{k})=c(\mathbf{x})|\mathbf{k}|$ is given by (2), and the wave vector $\mathbf{k}^\pm$ is defined by (6) with $K=K(\mathbf{x}')=\omega\sqrt{\kappa(\mathbf{x}')\rho(\mathbf{x}')}$.

Note also that if the measure μ is continuous up to the boundary $x_n=0$, then the weak form (20) is equivalent to the boundary value problem:

$$\nabla_{\mathbf{k}}\omega_+\cdot\nabla_{\mathbf{x}}\mu-\nabla_{\mathbf{x}}\omega_+\cdot\nabla_{\mathbf{k}}\mu=0, \tag{22}$$

$$\mu(\mathbf{x}',0,\mathbf{k})=\mu_{\text{in}}\delta(k_n-k_n^-)+\mu_{\text{out}}\delta(k_n-k_n^+). \tag{23}$$

Thus we can interpret ν_α as the phase space resolved energy of the incoming waves at the boundary, and ν_β as the energy of the outgoing waves.

D. Boundary conditions for the transport equation

The boundary conditions for the transport equation (22) can be obtained from those for the acoustic equations (12), by using the relations (21) and (23). Consider the Dirichlet boundary condition in the upper half space

$$w_{\epsilon,n+1}(\mathbf{x}',0)=0. \tag{24}$$

Then the $(\mathbf{n}+1)$-row and column of the matrix $\boldsymbol{\nu}$ vanish. Using (18), the explicit form (14) of the eigenvectors $\mathbf{b}(\mathbf{x},\mathbf{k})$, and (6), we get

$$\nu_\alpha = \nu_\beta = -\nu_{\alpha\beta}. \tag{25}$$

Then (23) implies that

$$\mu(\mathbf{x}',0,\mathbf{k}',k_n) = \mu(\mathbf{x}',0,\mathbf{k}',-k_n), \tag{26}$$

which is the boundary condition for (22).

The Neumann boundary condition

$$w_{\epsilon,n}(\mathbf{x}',0) = 0 \tag{27}$$

implies that the nth row and column of the matrix $\boldsymbol{\nu}$ vanish. Then we obtain, similarly to (25), that

$$\nu_\alpha = \nu_\beta = \nu_{\alpha\beta}, \tag{28}$$

so that (26) still holds. A convenient way to rewrite (26) is

$$\mu_{\text{out}}(\mathbf{x}',\mathbf{k}') = \mu_{\text{in}}(\mathbf{x}',\mathbf{k}'),$$

so that all the energy is reflected specularly as expected.

III. ENERGY REFLECTION AT A ROUGH SURFACE

We consider scattering of acoustic waves described by (12) from a rough surface. The surface ∂H_ϵ is described by the equation $x_n = \epsilon\eta h(\mathbf{x}'/\epsilon)$. The small parameter η is the ratio of the height of the surface to the wavelength. The height of the surface is varying on the scale of the wavelength ϵ. Recall that the random process $h(\mathbf{y}')$ has mean zero, and is stationary, with covariance function $R(\mathbf{y}')$ and with power spectrum $\hat{R}(\mathbf{k}')$, given by (3) and (4), respectively. We assume that $h(\mathbf{y}') \in C^1(R^{n-1})$ a.s. so that solutions of the Dirichlet problem exist for every positive ϵ. The Dirichlet boundary condition for (12), corresponding to a vanishing pressure, is given by

$$w_{\epsilon,n+1}(\mathbf{x}',\epsilon\eta h(\mathbf{x}'/\epsilon)) = 0. \tag{29}$$

We seek the solution $\mathbf{w}_\epsilon$ of (12) as a power series in the parameter η:

$$\mathbf{w}_\epsilon(\mathbf{x}) = \mathbf{w}_\epsilon^0(\mathbf{x}) + \eta\mathbf{w}_\epsilon^1(\mathbf{x}) + \eta^2\mathbf{w}_\epsilon^2(\mathbf{x}) + \cdots \tag{30}$$

with all the terms bounded in $L^2_{\text{loc}}(R^n)$ and their boundary values $\mathbf{r}_\epsilon^j(\mathbf{x}') = \mathbf{w}_\epsilon^j(\mathbf{x}',0)$ bounded in $L^2_{\text{loc}}(R^{n-1})$. Our main assumption is that such an expansion exists, i.e., that the rest in (30) is bounded uniformly in η and ϵ by $o(\eta^2)$. We also assume that the medium is homogeneous above a certain height $x_n = L$ with L arbitrarily large. This assumption is purely technical and allows us to formulate an outgoing condition at infinity. Namely, for $x_n > L$, the plane wave decomposition is valid, and we assume then that the amplitudes of the incoming waves $\alpha_\epsilon(\mathbf{k}')$ are deterministic and given. The correctors $\mathbf{w}_\epsilon^j$ are all outgoing in that region, so that $\alpha_\epsilon^j(\mathbf{k}') = 0$ for $j \geqslant 1$. The characteristics of the transport equation (22) are given by

$$\frac{d\mathbf{x}}{ds} = \nabla_{\mathbf{k}}\omega_+(\mathbf{x},\mathbf{k}),$$

$$\frac{d\mathbf{k}}{ds} = -\nabla_{\mathbf{x}}\omega_+(\mathbf{x},\mathbf{k}).$$

We assume that the characteristics that leave the surface $x_n = 0$ reach the level $x_n = L$ and vice versa. Moreover, we assume that these characteristics do not come back. Then we have the following theorem.

Theorem 1: *Under the above assumptions, the Wigner matrix* $\mathbf{W}(\mathbf{x},\mathbf{k})$ *of the family* $\mathbf{w}_\epsilon$ *of solutions of the Dirichlet problem (29) is supported on the set* $\mathcal{S}=\{(\mathbf{x},\mathbf{k})\colon c(\mathbf{x})|\mathbf{k}|=\omega\}$, *and has the form (19). The scalar measure* μ *has the form* $\mu(\mathbf{x},\mathbf{k})=\mu'(\mathbf{x},\mathbf{k})+o(\eta^2)$. *The measure* $\mu'(\mathbf{x},\mathbf{k})$ *is a solution of the transport equation (20). The average measure* $\langle \mu'_{\mathrm{out}}(\mathbf{x}',\mathbf{k}')\rangle$ *is given in terms of* $\mu'_{\mathrm{in}}(\mathbf{x}',\mathbf{k}')$ *by*

$$\langle \mu'_{\mathrm{out}}(\mathbf{x}',\mathbf{k}')\rangle=\left[1-4\eta^2\int \frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{k}'-\mathbf{p}')p_n^+(\mathbf{x}',\mathbf{p})k_n^+(\mathbf{x}',\mathbf{k}')\right]\mu'_{\mathrm{in}}(\mathbf{x}',\mathbf{k}')$$

$$+4\eta^2\int \frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{k}'-\mathbf{p}')(p_n^+(\mathbf{p}'))^2\mu'_{\mathrm{in}}(\mathbf{x}',\mathbf{p}') \tag{31}$$

with $\mathbf{k}^+$ *and* $\mathbf{p}^+$ *given by (6) with* $K=K(\mathbf{x}')$. *Here* $K(\mathbf{x}')$, *determined by* $c(\mathbf{x}')K(\mathbf{x}')=\omega$, *is the radius of the sphere* $\mathcal{S}$ *of wave vectors, on which the measure* μ *is supported.*

The first term in (31) corresponds to the specular reflection and provides the correction to the reflection coefficient. The second term is the result of the diffuse scattering at the surface. It appears because the boundary is varying on the scale of the wavelength. Note that the total mean flux across the boundary $x_n=0$ vanishes:

$$\langle \mathcal{F}_n(\mathbf{x}',0)\rangle=c(\mathbf{x}')\int d\mathbf{k}\,\hat{k}_n\langle\mu(\mathbf{x}',0,\mathbf{k})\rangle$$

$$=c(\mathbf{x}')\int d\mathbf{k}'[\hat{k}_n^+ +\hat{k}_n^-]\mu_{\mathrm{in}}(\mathbf{x}',\mathbf{k}')+4\eta^2c(\mathbf{x}')\int d\mathbf{k}'\,d\mathbf{p}'\,\hat{R}(\mathbf{k}'-\mathbf{p}')$$

$$\times\{(p_n^+)^2\hat{k}_n^+\mu_{\mathrm{in}}(\mathbf{x}',\mathbf{k}')-p_n^+k_n^+\hat{k}_n^+\mu_{\mathrm{in}}(\mathbf{x}',\mathbf{p}')\}=0.$$

The expression (31) reduces in a homogeneous medium to (5) as one would expect.

The statement regarding the support and form of the matrix $\mathbf{W}(\mathbf{x},\mathbf{k})$ is proved exactly as in Ref. 8, so we will not repeat it here. We derive (31) in the following sections. Note that we can treat more general interface problems in a similar way, at least for incident energy fluxes away from grazing angle. The result is then a direct generalization of the formulas given in Ref. 7 for homogeneous media.

IV. THE PERTURBATION ANALYSIS

Now, we show how the diffusive scattering is obtained when the wave equation satisfies Dirichlet boundary conditions. We derive (31) in three steps. First we analyze the asymptotic expansion (30) in Sec. IV A. Then the diffuse part of the scattered energy is computed in Sec. IV B. At last, we derive the correction to the reflection coefficient in Sec. IV C.

A. The asymptotic expansion

We note that since the series (30) is asymptotic in $L^2_{\mathrm{loc}}(R^n)$, the Wigner matrix $\mathbf{W}$ is approximated by the Wigner matrix of the sum of the first N terms up to order $o(\eta^N)$. Thus we can compute the Wigner measure of the first three terms in the expansion (30) in order to approximate $\mathbf{W}$ up to $o(\eta^2)$. The terms $\mathbf{w}_\epsilon^j$, $j=0,1,2$ solve the acoustic equations (12) in the upper half space with the following boundary conditions:

$$w^0_{\epsilon,n+1}(\mathbf{x}',0)=0, \tag{32}$$

$$w^1_{\epsilon,n+1}(\mathbf{x}',0)=-h\left(\frac{\mathbf{x}'}{\epsilon}\right)\epsilon\frac{\partial w^0_{\epsilon,n+1}}{\partial x_n}(\mathbf{x}',0), \tag{33}$$

$$w^2_{\epsilon,n+1}(\mathbf{x}',0) = -\frac{1}{2}h^2\left(\frac{\mathbf{x}'}{\epsilon}\right)\epsilon^2\frac{\partial^2 w^0_{\epsilon,n+1}}{\partial x_n^2}(\mathbf{x}',0) - h\left(\frac{\mathbf{x}'}{\epsilon}\right)\epsilon\frac{\partial w^1_{\epsilon,n+1}}{\partial x_n}(\mathbf{x}',0). \tag{34}$$

These boundary conditions are constructed so as to satisfy the Dirichlet boundary conditions (29) on the rough surface ∂H_ϵ up to order η^2. The boundary conditions at infinity, where the medium is homogeneous above the level $x_n = L$, are as described above: $\mathbf{w}^0_\epsilon$ has prescribed incoming flux, and $\mathbf{w}^{1,2}_\epsilon$ are outgoing for $x_n > L$.

The boundary conditions (33) and (34) can be rewritten using the acoustic equations for $\mathbf{w}^0_\epsilon$ and $\mathbf{w}^1_\epsilon$ and the Dirichlet boundary condition (32) as

$$r^1_{\epsilon,n+1}(\mathbf{x}') = -i\omega\rho(\mathbf{x}')h\left(\frac{\mathbf{x}'}{\epsilon}\right)r^0_{\epsilon,n}(\mathbf{x}') \tag{35}$$

and

$$r^2_{\epsilon,n+1}(\mathbf{x}') = -\frac{i\epsilon\omega}{2}\frac{\partial\rho}{\partial x_n}(\mathbf{x}',0)h^2\left(\frac{\mathbf{x}'}{\epsilon}\right)r^0_{\epsilon,n}(\mathbf{x}') - i\omega\rho(\mathbf{x}')h\left(\frac{\mathbf{x}'}{\epsilon}\right)r^1_{\epsilon,n}(\mathbf{x}'). \tag{36}$$

Here $\mathbf{r}^j_\epsilon(\mathbf{x}')$ is the value of $\mathbf{w}^j_\epsilon$ at the boundary. The Wigner matrix of the sum of the first three terms in (30) has the form

$$\mathbf{W} = \mathbf{W}_0 + \eta(\mathbf{W}_{01} + \mathbf{W}_{10}) + \eta^2(\mathbf{W}_1 + \mathbf{W}_{02} + \mathbf{W}_{20}) + o(\eta^2), \tag{37}$$

where $\mathbf{W}_0 = \mathbf{W}[\mathbf{w}^0_\epsilon]$, $\mathbf{W}_1 = \mathbf{W}[\mathbf{w}^1_\epsilon]$, $\mathbf{W}_{01} = \mathbf{W}[\mathbf{w}^0_\epsilon, \mathbf{w}^1_\epsilon]$, etc. The leading order term in the expansion (37) has the form

$$\mathbf{W}_0 = \mu_0(\mathbf{x},\mathbf{k})\mathbf{b}(\mathbf{x},\mathbf{k})\mathbf{b}^*(\mathbf{x},\mathbf{k}) \tag{38}$$

since $\mathbf{w}^0_\epsilon$ solves the acoustic equations. The Dirichlet boundary conditions (32) for $\mathbf{w}^0_\epsilon$ imply that the Wigner measure $\boldsymbol{\nu}^0$ of $\mathbf{r}^0_\epsilon$ has the form (18) with the coefficients $\nu_{\alpha,\beta,\alpha\beta}$ related by (25):

$$\boldsymbol{\nu}^0(\mathbf{x}',\mathbf{k}') = \nu^0_\alpha(\mathbf{x}',\mathbf{k}')[\mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_+) + \mathbf{b}(\mathbf{k}_-)\mathbf{b}^*(\mathbf{k}_-) - \mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_-) - \mathbf{b}(\mathbf{k}_-)\mathbf{b}^*(\mathbf{k}_+)]. \tag{39}$$

Then the outgoing Wigner measure μ^0_{out} is

$$\mu^0_{\text{out}} = \mu_{\text{in}}, \tag{40}$$

where the measure μ_{in} is known. Notice that $\langle \mathbf{w}^1_\epsilon(\mathbf{x})\rangle = 0$, and since $\mathbf{w}^0_\epsilon$ is deterministic, we get

$$\langle \mathbf{W}_{01}\rangle = \langle \mathbf{W}_{10}\rangle = 0. \tag{41}$$

Thus we have to compute only $\langle \mathbf{W}_1\rangle$ and $\langle \mathbf{W}_{02} + \mathbf{W}_{20}\rangle$. The first term gives rise to the diffuse scattering and is treated in the following section. The second term produces the correction to the energy reflection coefficient and is considered in Sec. IV C.

B. The diffuse reflected wave

The matrix $\mathbf{W}^1$, being the Wigner matrix of a family of solutions $\mathbf{w}^1_\epsilon$ of the acoustic equations, has the form

$$\mathbf{W}_1 = \mu_1(\mathbf{x},\mathbf{k})\mathbf{b}(\mathbf{x},\mathbf{k})\mathbf{b}^*(\mathbf{x},\mathbf{k}).$$

The solution $\mathbf{w}_\epsilon^1$ is outgoing at infinity. Since we assumed that characteristics do not come back to the boundary, it is equivalent to being outgoing at the boundary. Then we have $\nu_\alpha^1=\mu_{\rm in}^1=0$. Since the matrix $\begin{pmatrix}\nu_\alpha^1 & \nu_{\alpha\beta}^1\\ \bar\nu_{\alpha\beta}^1 & \nu_\beta^1\end{pmatrix}$ is non-negative and definite, we also have $\nu_{\alpha\beta}^1=0$. Then the boundary Wigner measure $\boldsymbol{\nu}^1$ of $\mathbf{r}_\epsilon^1$ has the form

$$\boldsymbol{\nu}^1=\nu_\beta^1\mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_+) \tag{42}$$

and the boundary value of the measure μ_1 is

$$\mu_1(\mathbf{x}',0,\mathbf{k})=\nu_\beta^1(\mathbf{x}',\mathbf{k}')\,\delta(k_n-k_n^+),$$

hence $\mu_{\rm out}^1=\nu_\beta^1(\mathbf{x}',\mathbf{k}')$. The measure ν_β^1 is determined as follows. We have from (42),

$$\nu_{n+1,n+1}^1=\frac{1}{2\kappa(\mathbf{x}')}\,\nu_\beta^1, \tag{43}$$

where the left side is the $(n+1,n+1)$ entry of the matrix $\boldsymbol{\nu}^1(\mathbf{x}',\mathbf{x}')$. This entry is the Wigner measure of $r_{\epsilon,n+1}^1(\mathbf{x}')$, which is explicitly given by the boundary condition (35). Therefore,

$$\nu_{n+1,n+1}^1=\omega^2\rho^2(\mathbf{x}')\,\nu\left[h\left(\frac{\mathbf{x}'}{\epsilon}\right)r_{\epsilon,n}^0\right]$$

and so the average $\langle\nu_{n+1,n+1}^1\rangle$ is given by

$$\langle\nu_{n+1,n+1}^1\rangle=\omega^2\rho^2(\mathbf{x}')\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat R(\mathbf{k}'-\mathbf{p}')\,\nu_{n,n}^0(\mathbf{x}',\mathbf{p}'). \tag{44}$$

We use expression (39) for $\boldsymbol{\nu}^0$ to get

$$\langle\nu_{n+1,n+1}^1\rangle(\mathbf{x}',\mathbf{k}')=\omega^2\rho^2(\mathbf{x}')\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat R(\mathbf{k}'-\mathbf{p}')\,\frac{4\nu_\alpha^0(\mathbf{p}')p_n^{+2}}{2\rho(\mathbf{x}')|\mathbf{p}^+|^2}.$$

Insert this into (43) and use the relations $|\mathbf{p}^+|^2=\omega^2/c^2(\mathbf{x}')=\omega^2\kappa(\mathbf{x}')\rho(\mathbf{x}')$ and $\mu_{\rm in}=\nu_\alpha^0$ yields

$$\langle\mu_{\rm out}^1\rangle=\langle\nu_\beta^1\rangle(\mathbf{x}',\mathbf{k}')=4\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat R(\mathbf{k}'-\mathbf{p}')p_n^{+2}\mu_{\rm in}(\mathbf{x}',\mathbf{p}'). \tag{45}$$

This is the second term in (31).

C. Correction to the reflection coefficient

The correction to the coherent, or specular reflection coefficient arises from the term $\langle\mathbf{W}_{02}+\mathbf{W}_{20}\rangle$ in (37). Our analysis of this term proceeds in several steps. In Sec. IV C 1 we reduce the computation to evaluating the average $\langle\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1]\rangle$ of the cross Wigner distribution of $\mathbf{r}_\epsilon^0$ and the conjugated wave function $\mathbf{u}_\epsilon^1$ defined by (51). This Wigner distribution is described by Lemma 1. We use this lemma in Sec. IV C 2 to derive (31). Finally we prove Lemma 1 in Sec. IV C 3.

1. The reduction to the conjugated wave functions

The functions $\mathbf{w}_\epsilon^0,\mathbf{w}_\epsilon^2$ and $\mathbf{w}_\epsilon^0+\mathbf{w}_\epsilon^2$ are solutions of the acoustic equations, so the Wigner matrices $\mathbf{W}[\mathbf{w}^0],\mathbf{W}[\mathbf{w}^2]$ and $\mathbf{W}[\mathbf{w}^0+\mathbf{w}^2]$ are all of the form (19), and then

$$\mathbf{W}_{02}+\mathbf{W}_{20}=\mathbf{W}[\mathbf{w}^0+\mathbf{w}^2]-\mathbf{W}[\mathbf{w}^0]-\mathbf{W}[\mathbf{w}^2]$$
$$=(\mu[\mathbf{w}^0+\mathbf{w}^2]-\mu[\mathbf{w}^0]-\mu[\mathbf{w}^2])\mathbf{b}(\mathbf{k})\mathbf{b}^*(\mathbf{k})$$
$$=\mu_{02}\mathbf{b}(\mathbf{k})\mathbf{b}^*(\mathbf{k}), \tag{46}$$

so that $\mathbf{W}_{02}+\mathbf{W}_{20}$ has the same form as $\mathbf{W}_0$ and $\mathbf{W}_1$. The value of μ_{02} on the boundary is

$$\mu_{02}(\mathbf{x}',0,\mathbf{k})=(\mu[\mathbf{w}^0+\mathbf{w}^2]-\mu[\mathbf{w}^0]-\mu[\mathbf{w}^2])(\mathbf{x}',0,\mathbf{k})$$
$$=(\nu_\beta[\mathbf{r}^0+\mathbf{r}^2]-\nu_\beta[\mathbf{r}^0]-\nu_\beta[\mathbf{r}^2])(\mathbf{x}',\mathbf{k}')\,\delta(k_n-k_n^+)$$
$$=(\nu_\beta[\mathbf{r}^0,\mathbf{r}^2]+\nu_\beta[\mathbf{r}^2,\mathbf{r}^0])\,\delta(k_n-k_n^+)=\nu_\beta^{02}\,\delta(k_n-k_n^+). \tag{47}$$

The terms involving the incoming wave vector $\mathbf{k}_-$ cancel out since $\mathbf{w}^2$ is outgoing at the boundary and thus $\mu_{\text{in}}[\mathbf{w}^2]=0$, and $\mu_{\text{in}}[\mathbf{w}^0+\mathbf{w}^2]=\mu_{\text{in}}[\mathbf{w}^0]$. Thus we have to find $\nu_\beta^{02}=\nu_\beta[\mathbf{r}^0,\mathbf{r}^2]+\nu_\beta[\mathbf{r}^2,\mathbf{r}^0]$ to finish the computation. We note that the matrix Wigner measure $\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{r}^2]+\boldsymbol{\nu}[\mathbf{r}^2,\mathbf{r}^0]$ has the form

$$\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{r}^2]+\boldsymbol{\nu}[\mathbf{r}^2,\mathbf{r}^0]=(\nu_\beta[\mathbf{r}^0,\mathbf{r}^2]+\nu_\beta[\mathbf{r}^2,\mathbf{r}^0])\mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_+)$$
$$+\nu_{\alpha\beta}^{02}\mathbf{b}(\mathbf{k}_-)\mathbf{b}^*(\mathbf{k}_+)+\overline{\nu}_{\alpha\beta}^{02}\mathbf{b}(\mathbf{k}_+)\mathbf{b}^*(\mathbf{k}_-) \tag{48}$$

since $\mathbf{r}_\epsilon^2$ is outgoing. Evaluating the entry $(n+1,n+1)$ of both sides of (48), we get that ν_β^{02} is real. Moreover, evaluating the entry $(n,\,n+1)$ of the two sides of (48) we obtain

$$\mu_{\text{out}}^{02}=\nu_\beta^{02}=\frac{2\sqrt{\kappa\rho}}{\hat{k}_n^+}\,\text{Re}\,\nu[r_n^0,r_{n+1}^2]. \tag{49}$$

Thus we have reduced our problem to computing $\nu[r_n^0,r_{n+1}^2]$. Recall that $r_{\epsilon,n+1}^2(\mathbf{x}')$ is given by (36) and observe that the first term in (36) vanishes in the limit $\epsilon\to 0$ in L^2_{loc}. Then we have

$$\nu[r_n^0,r_{n+1}^2]=\nu\left[r_n^0(\mathbf{x}'),-h\left(\frac{\mathbf{x}'}{\epsilon}\right)i\omega\rho(\mathbf{x}')r_{\epsilon n}^1(\mathbf{x}')\right]$$
$$=i\omega\rho(\mathbf{x}')\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{h}(\mathbf{p}')\,\nu_{nn}[\mathbf{r}^0,\mathbf{u}^1](\mathbf{x}',\mathbf{k}',\mathbf{p}'). \tag{50}$$

Here we have introduced the conjugated wave functions $\mathbf{u}_\epsilon^1$:

$$\mathbf{u}_\epsilon^1(\mathbf{x}',\mathbf{p}')=\mathbf{r}_\epsilon(\mathbf{x}')e^{-i\mathbf{p}\cdot\mathbf{x}'/\epsilon}, \tag{51}$$

where the vector $\mathbf{p}'$ plays the role of a parameter. The Wigner matrix $\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1]$ is described by the following Lemma.

Lemma 1: The Wigner distribution matrix $\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1]$ *has the form*

$$\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1]=\tilde{\nu}_\alpha\mathbf{b}(\mathbf{k}^+)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+)-\tilde{\nu}_\alpha\mathbf{b}(\mathbf{k}^-)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+), \tag{52}$$

where $\tilde{\nu}_\alpha$ *is some distribution.*

We prove Lemma 1 in Sec. IV C 3.

2. The average reflection coefficient

We use Lemma 1 to evaluate $\nu_{nn}[\mathbf{r}^0,\mathbf{u}^1]$ in (50) and get

$$\left\langle \nu\left[r_n^0,h\left(\frac{\mathbf{x}'}{\epsilon}\right)r_{\epsilon n}^1\right]\right\rangle=\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\langle\hat{h}(\mathbf{p}')\tilde{\nu}_\alpha(\mathbf{x}',\mathbf{k}',\mathbf{p}')\rangle\frac{k_n^+(\mathbf{k}+\mathbf{p})^+}{|\mathbf{k}^+||(\mathbf{k}+\mathbf{p})^+|\rho(\mathbf{x})}. \tag{53}$$

The average $\langle \hat{h}(\mathbf{p})\tilde{\nu}_\alpha\rangle$ is evaluated as follows. We have from the boundary conditions (35),

$$u^1_{\epsilon,n+1}(\mathbf{x}')=e^{-i\mathbf{p}'\cdot\mathbf{x}'/\epsilon}r^1_{\epsilon,n+1}(\mathbf{x}')=-e^{-i\mathbf{p}'\cdot\mathbf{x}'/\epsilon}i\omega\rho(\mathbf{x}')h\left(\frac{\mathbf{x}'}{\epsilon}\right)r^0_{\epsilon,n}(\mathbf{x}')$$

and hence

$$\langle h(\mathbf{p}')\nu_{n,n+1}[\mathbf{r}^0,\mathbf{u}^1]\rangle=i\omega\rho(\mathbf{x})\hat{R}(\mathbf{p}')\nu^0_{nn}(\mathbf{x}',\mathbf{k}'). \tag{54}$$

But we also have from the representation (52),

$$\langle \hat{h}(\mathbf{p}')\nu_{n,n+1}[\mathbf{r}^0,\mathbf{u}^1]\rangle=\langle \hat{h}(\mathbf{p}')\tilde{\nu}_\alpha\rangle\frac{k_n^+}{|\mathbf{k}^+|\sqrt{\rho\kappa}},$$

so that (54) implies

$$\langle \hat{h}(\mathbf{p}')\tilde{\nu}_\alpha\rangle\frac{k_n^+}{|\mathbf{k}^+|\sqrt{\rho}}=\sqrt{\kappa}\hat{R}(\mathbf{p}')i\omega\rho(\mathbf{x}')\nu^0_{nn}.$$

We insert this into (53) and get

$$\begin{aligned}\left\langle \nu\left[r^0_{\epsilon n},h\left(\frac{\mathbf{x}'}{\epsilon}\right)r^1_{\epsilon n}\right]\right\rangle&=\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{p}')\sqrt{\kappa\rho}i\omega\nu^0_{nn}(\mathbf{x}',\mathbf{k}')\frac{(\mathbf{k}+\mathbf{p})_n^+}{|(\mathbf{k}+\mathbf{p})^+|}\\&=\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{k}'-\mathbf{p}')\sqrt{\kappa\rho}i\omega\hat{p}_n^+\nu^0_{nn}(\mathbf{x}',\mathbf{k}').\end{aligned} \tag{55}$$

Then we insert (55) into (50) and obtain

$$\langle \nu[r_n^0,r^2_{n+1}]\rangle=-\omega^2\rho(\mathbf{x}')\sqrt{\kappa(\mathbf{x}')\rho(\mathbf{x}')}\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{k}'-\mathbf{p}')\frac{p_n^+}{|\mathbf{p}_+|}\nu^0_{nn}(\mathbf{x}',\mathbf{k}').$$

Recall that we have from (39)

$$\nu^0_{nn}(\mathbf{x}',\mathbf{k}')=\frac{4\nu^0_\alpha(\hat{k}_n^+)^2}{2\rho}.$$

Then we get from (49) and (55)

$$\begin{aligned}\langle\mu^{02}_{\text{out}}\rangle=\langle\nu^{02}_\beta\rangle&=-\frac{2\sqrt{\kappa\rho}}{\hat{k}_n^+}\frac{\omega^2\rho}{c}\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{k}'-\mathbf{p}')\hat{p}_n^+\frac{4\nu^0_\alpha(\hat{k}_n^+)^2}{2\rho}\\&=-4\nu^0_\alpha(\mathbf{x}',\mathbf{k}')\int\frac{d\mathbf{p}'}{(2\pi)^{n-1}}\hat{R}(\mathbf{k}'-\mathbf{p}')p_n^+k_n^+\end{aligned} \tag{56}$$

because $|\mathbf{k}_+|=|\mathbf{p}_+|=\omega/c$.

Putting together (40), (45), and (56), we get (31).

3. Proof of Lemma 1

The proof of Lemma 1 is similar to that of the first part of Theorem 2, which is given in Ref. 8. The functions $\mathbf{u}^1_\epsilon(\mathbf{x}')$ satisfy the system

$$\sum_{j=1}^{n-1} \epsilon D^j \frac{\partial \mathbf{u}_\epsilon^1}{\partial x_j} + i\sum_{j=1}^{n-1} p_j D^j \mathbf{u}_\epsilon^1 - i\omega A(\mathbf{x}')\mathbf{u}_\epsilon^1 = -\epsilon D^n \frac{\partial \mathbf{w}_\epsilon^1}{\partial x_n}(\mathbf{x}',0), \tag{57}$$

while $\mathbf{r}_\epsilon^0(\mathbf{x}') = \mathbf{w}_\epsilon^0(\mathbf{x}',0)$ satisfy the system

$$\sum_{j=1}^{n-1} \epsilon D^j \frac{\partial \mathbf{r}_\epsilon^0}{\partial x_j} - i\omega A(\mathbf{x}')\mathbf{r}_\epsilon^0 = -\epsilon D^n \frac{\partial \mathbf{w}_\epsilon^0}{\partial x_n}(\mathbf{x}',0). \tag{58}$$

Let us define the reduced dispersion matrix

$$L'(\mathbf{x},\mathbf{k}) = \sum_{j=1}^{n-1} k_j D^j - \omega A(\mathbf{x}).$$

Let P be any matrix such that $PD^n = 0$, then (57) implies that

$$PL'(\mathbf{k}+\mathbf{p})\boldsymbol{\nu}[\mathbf{u}^1,\mathbf{r}^0] = 0$$

and (58) implies that

$$PL'(\mathbf{k})\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1] = 0.$$

Then the Wigner matrix $\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1]$ has the specific form

$$\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1] = \tilde{\nu}_\alpha \mathbf{b}(\mathbf{k}^+)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+) + \tilde{\nu}_\beta \mathbf{b}(\mathbf{k}^{-1})\mathbf{b}^*((\mathbf{k}+\mathbf{p})^-) + \tilde{\nu}_{\alpha\beta}\mathbf{b}(\mathbf{k}^+)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^-)$$
$$+ \tilde{\nu}_{\beta\alpha}\mathbf{b}(\mathbf{k}^-)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+). \tag{59}$$

Recall that $\mathbf{u}_\epsilon^1$ is outgoing, so (59) reduces to

$$\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1] = \tilde{\nu}_\alpha \mathbf{b}(\mathbf{k}^+)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+) + \tilde{\nu}_{\beta\alpha}\mathbf{b}(\mathbf{k}^-)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+). \tag{60}$$

The Dirichlet boundary conditions for $\mathbf{w}_\epsilon^0(\mathbf{x})$ imply that the fourth row of the matrix $\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1]$ vanishes. Then $\tilde{\nu}_{\alpha\beta} = -\tilde{\nu}_\alpha$, and (60) becomes

$$\boldsymbol{\nu}[\mathbf{r}^0,\mathbf{u}^1] = \tilde{\nu}_\alpha \mathbf{b}(\mathbf{k}^+)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+) - \tilde{\nu}_\alpha \mathbf{b}(\mathbf{k}^-)\mathbf{b}^*((\mathbf{k}+\mathbf{p})^+), \tag{61}$$

which is (52).

V. HIGHER ORDER ANISOTROPIC EFFECTS

The scattering cross-sections in the correctors of order η^2 in (31) depend upon the outgoing direction only through the power spectrum $\hat{R}(\mathbf{k}'-\mathbf{p}')$. We show in this section that some anisotropy of the scattered field is captured in the higher order terms. We obtain, in particular, a peak in the backscattering direction. This peak is similar to the coherent backscattering effect in the Neumann and impedance problems in homogeneous media studied in Refs. 17, 12, 13, and 18, although much broader for Dirichlet boundary conditions. The nature of this peak is also the constructive interference between direct and reverse paths of scattered waves. The singular behavior of the reflection operator at grazing angles in the Neumann and impedance problems makes this effect much more pronounced. The study of the coherent backscattering effect for these cases in an inhomogeneous medium requires appropriate modifications and the smoothing method.[19]

A. The backscattering for the Dirichlet problem

The angularly resolved energy density of the second order corrector in the Dirichlet problem is described by the following proposition.

Proposition 3: Assume that $h(\mathbf{y})$ is a mean zero Gaussian process with covariance matrix $R(\mathbf{y})$. Then the Wigner matrix $\mathbf{W}_2$ of the second order term $\mathbf{w}_\epsilon^2$ in the asymptotic expansion (30) of the solution of the Dirichlet problem has the form $\mathbf{W}_2=\mu_2(\mathbf{x},\mathbf{k})\mathbf{b}(\mathbf{x},\mathbf{k})\mathbf{b}^*(\mathbf{x},\mathbf{k})$. The scalar measure $\mu_2(\mathbf{x},\mathbf{k})$ is supported on the sphere $\mathcal{S}(\mathbf{x})=\{\mathbf{k}:|\mathbf{k}|=\omega/c(\mathbf{x})\}$ and satisfies the transport equation (20) with $\mu_2^{\text{in}}=0$ and

$$\langle\mu_2^{\text{out}}(\mathbf{x}',\mathbf{k}')\rangle=4\int\frac{d\mathbf{p}'\,d\mathbf{q}'}{(2\pi)^{2d-2}}\hat{R}(\mathbf{k}'-\mathbf{p}')\hat{R}(\mathbf{p}'-\mathbf{q}')q_n^2p_n[p_n+(\mathbf{q}'+\mathbf{k}'-\mathbf{p}')_n]\mu_{\text{in}}'(\mathbf{q}')$$
$$+4\int\frac{d\mathbf{p}'\,d\mathbf{q}'}{(2\pi)^{2d-2}}\hat{R}(\mathbf{k}'-\mathbf{p}')\hat{R}(\mathbf{k}'-\mathbf{q}')p_nq_nk_n^2\mu_{\text{in}}'(\mathbf{k}'). \tag{62}$$

Here $k_n(\mathbf{x},\mathbf{k}')=\sqrt{\omega^2/c^2(\mathbf{x})}$ is the normal component of the outgoing wave vector in $\mathcal{S}$, which has horizontal component $\mathbf{k}'$ and is pointing upwards, and μ_{in}' is as in Theorem 1.

The first term in (62) corresponds to the diffusive scattering. The second term provides a correction to the reflection coefficient. The differential scattering cross-section in (62) is no longer isotropic, and is centered in the backscattered direction. This can be seen as follows. Let us assume that the incident energy density has the form $\mu_{\text{in}}'(\mathbf{q}')=C(\mathbf{x}')\delta(\mathbf{q}'-\mathbf{q}_0')$, so that waves are coming from a single direction $\mathbf{q}_0$. Then the diffusive scattering is maximal in the direction with tangential component $\mathbf{k}'=-\mathbf{q}_0'$ because both terms in the diffusive scattering cross section are the same. The second term in this cross section is smaller in other directions, because when $\mathbf{k}+\mathbf{q}_0\neq 0$, then the integration in $\mathbf{p}'$ in that term is carried over the region where both $\mathbf{p}'$ and $\mathbf{k}'+\mathbf{q}_0'-\mathbf{p}'$ lie in the disk of radius $K=\omega/c$. This region is shrinking as $\mathbf{k}$ moves away from $-\mathbf{q}_0$, and so the contribution of this term diminishes. In particular, if $\mathbf{q}_0'$ is close to the boundary of the disk, and the incident wave is close to the grazing angle, then the contribution of this term in the forward direction $\mathbf{k}'=\mathbf{q}_0'$ vanishes. This can be interpreted as an enhanced backscattering phenomenon, since the contribution of this term in (62) corresponds to the interference of the direct and reverse paths, as will be seen in the derivation of (62).

B. Derivation of the scattering cross-section

The statements regarding the form of the Wigner matrix $\mathbf{W}_2$ and the support of the measure μ_2 in Proposition 3 follow immediately from Proposition 2, and from the fact that $\mathbf{w}_\epsilon^2$ is outgoing at infinity, together with our assumption that characteristics do not come back to the boundary. Thus, the only part we have to verify is the expression (62) for the measure μ_2 at the boundary. Let $\mathbf{r}_\epsilon^2(\mathbf{x}')=\mathbf{w}_\epsilon^2(\mathbf{x}',0)$ be the boundary value of $\mathbf{w}_2$. Then we have, using (36)

$$\mu_2^{\text{out}}(\mathbf{x}',\mathbf{k}')=2\kappa(\mathbf{x}')\nu[r_{\epsilon,n+1}^2]=2\kappa(\mathbf{x}')\omega^2\rho^2(\mathbf{x}')\nu[h(\mathbf{x}'/\epsilon)r_{\epsilon,n}^1]. \tag{63}$$

This can be rewritten with the help of the conjugated wave functions (51):

$$\nu[h(\mathbf{x}'/\epsilon)r_{\epsilon,n}^1]=\int\frac{d\mathbf{p}'\,d\mathbf{q}'}{(2\pi)^{2d-2}}\hat{h}(\mathbf{p}')\hat{h}(\mathbf{q}')\nu[u_{\epsilon,n}^1(\mathbf{x}',-\mathbf{p}'),u_{\epsilon,n}^1(\mathbf{x}',\mathbf{q}')].$$

It is easy to check that, similarly to Lemma 1 we have for any $\mathbf{p}_1',\mathbf{p}_2'$:

$$\boldsymbol{\nu}[\mathbf{u}_\epsilon^1(\mathbf{p}_1'),\mathbf{u}_\epsilon^1(\mathbf{p}_2')](\mathbf{x}',\mathbf{k}')=\theta(\mathbf{x}',\mathbf{k}',\mathbf{p}_1',\mathbf{p}_2')\mathbf{b}(\mathbf{k}'+\mathbf{p}_1')\mathbf{b}^*(\mathbf{k}'+\mathbf{p}_2') \tag{64}$$

with θ being some unknown distribution. Thus we have

$$\langle\nu[h(\mathbf{x}'/\epsilon)r_{\epsilon,n}^1]\rangle=\int\frac{d\mathbf{p}'\,d\mathbf{q}'}{(2\pi)^{2d-2}}\langle\hat{h}(\mathbf{p}')\hat{h}(\mathbf{q}')\theta(\mathbf{x}',\mathbf{k}',-\mathbf{p}',\mathbf{q}')\rangle b_n(\mathbf{k}'-\mathbf{p}')b_n(\mathbf{k}'+\mathbf{q}') \tag{65}$$

and we need to evaluate the average inside the integral. Expression (64) implies that

$$\langle \hat{h}(\mathbf{p}')\hat{h}(\mathbf{q}')\theta(\mathbf{x}',\mathbf{k}',-\mathbf{p}',\mathbf{q}')\rangle = 2\kappa\langle \hat{h}(\mathbf{p}')\hat{h}(\mathbf{q}')\nu[u^1_{\epsilon,n+1}(-\mathbf{p}'),u^1_{\epsilon,n+1}(\mathbf{q}')](\mathbf{x}',\mathbf{k}')\rangle. \tag{66}$$

The average on the right side can be computed using the expression (35) for $r^1_{\epsilon,n+1}$ in terms of $r^0_{\epsilon,n}$, and the assumption that $h(\mathbf{y})$ is a Gaussian random process so that

$$\langle \hat{h}(\mathbf{p})\hat{h}(\mathbf{q})\hat{h}(\mathbf{p}_2)\hat{h}(\mathbf{q}_2)\rangle = \langle \hat{h}(\mathbf{p})\hat{h}(\mathbf{q})\rangle\langle \hat{h}(\mathbf{p}_2)\hat{h}(\mathbf{q}_2)\rangle + \langle \hat{h}(\mathbf{p})\hat{h}(\mathbf{q}_2)\rangle\langle \hat{h}(\mathbf{q})\hat{h}(\mathbf{p}_2)\rangle + \langle \hat{h}(\mathbf{p})\hat{h}(\mathbf{p}_2)\rangle\langle \hat{h}(\mathbf{q})\hat{h}(\mathbf{q}_2)\rangle. \tag{67}$$

Then we get

$$\langle \hat{h}(\mathbf{p}')\hat{h}(\mathbf{q}')\nu[u^1_{\epsilon,n+1}(-\mathbf{p}'),u^1_{\epsilon,n+1}(\mathbf{q}')](\mathbf{x}',\mathbf{k}')\rangle = \mathrm{I}+\mathrm{II}+\mathrm{III}, \tag{68}$$

where

$$\mathrm{I} = \omega^2\rho^2(\mathbf{x}')\hat{R}(\mathbf{p}')\delta(\mathbf{p}'+\mathbf{q}')\int d\mathbf{p}_1'\hat{R}(\mathbf{p}_1')\nu^0_{nn}(\mathbf{k}'-\mathbf{p}'-\mathbf{p}_1'),$$

$$\mathrm{II} = \omega^2\rho^2(\mathbf{x}')\hat{R}(\mathbf{p}')\hat{R}(\mathbf{q}')\nu^0_{nn}(\mathbf{k}'+\mathbf{q}'-\mathbf{p}'),$$

and

$$\mathrm{III} = \omega^2\rho^2(\mathbf{x}')\hat{R}(\mathbf{p}')\hat{R}(\mathbf{q}')\nu^0_{nn}(\mathbf{k}').$$

The three terms in (68) have a natural interpretation in terms of wave scattering from a collection of discrete random scatterers.[18] The first term in (68) comes from the first term in (67) and corresponds to the interaction of a path with itself. It produces a scattering cross-section that is essentially isotropic. The second term in (68) comes from the second term in (67) and corresponds to the interaction of a path and its reverse one in the discrete picture. It has a peak in the backscattering direction as explained in the previous section. The last term arises from paths scattering twice on the same scatterer. It contributes to the specular reflection coefficient.

Finally we note that $\nu^0_{nn}(\mathbf{k}') = (k_n^2/2\rho|\mathbf{k}|^2)4\mu'_{\mathrm{in}}(\mathbf{x}',\mathbf{k}')$, and putting this together with (63), (65), (66), we obtain (62). This completes the proof of Proposition 3.

VI. CONCLUSIONS

We have derived the boundary conditions for the transport equation for the phase space resolved energy density in an inhomogeneous medium. Our derivation is based on the assumption that the asymptotic expansion (30) holds. These boundary conditions can be used for the radiative transport equation for acoustic waves[1,2] when randomness of the medium is independent of the randomness of the surface. Moreover, one can use similar boundary conditions for more general radiative transport equations[2] for electromagnetic, elastic and other waves in domains with rough boundaries. Our result may also be generalized to reflection and transmission at interfaces between two inhomogeneous media. The results are then a generalization of the diffuse energy reflection and transmission at a rough interface considered in Ref. 7.

The analysis of the Neumann problem in an inhomogeneous medium with a rough boundary requires the smoothing method or any equivalent regularization technique. We plan to address this in a separate note.[19] This allows one to incorporate the coherent backscattering effect into the boundary conditions for the radiative transport equation.

(Received 28 January 1998; accepted for publication 22 March 1999)

We derive transport equations from a general class of equations of form $iu_t = H(X,D)u + V(X,D)u$ where $H(X,D)$ and $V(X,D)$ are pseudodifferential operators (Weyl operator) with symbols $H(x,k)$ and $V(x,k)$, where $H(x,k)$ being polynomial in k and smooth in $x, V(x,k)$ is a mean zero random function and is stationary in space variable. We also consider system of equations in the above form. Such equations cover many of the equations that arise in wave propagations, such as those considered in a paper by Ryzhik, Papanicolaou, and Keller [Wave Motion **24**, 327–370 (1996)]. Our results generalize those by Ryzhik, Papanicolau, and Keller. [S0022-2488(99)03209-0]

I. INTRODUCTION

There have been growing interests in the studies of transport equations for wave propagations. Radiative transport theory was introduced phenomenologically in order to describe the propagation of light energy through the atmosphere.[2] It is well known[1] that radiative transport equations will provide a good description of wave energy transport when (i) typical wavelengths are short compared to macroscopic features of the medium (high frequency approximation), (ii) correlation lengths of the inhomogeneities are comparable to wavelengths, and (iii) the fluctuations of the inhomogeneities are weak.

In a simple form, transport theory is as follows: a wave with wave vector $\mathbf{k}'$ at a point $\mathbf{x}$ in a randomly inhomogeneous medium may be scattered into any direction $\hat{\mathbf{k}}$ with wave vector $\mathbf{k}$, where $\hat{\mathbf{k}} = \mathbf{k}/|\mathbf{k}|$. Therefore, one must consider the angularly resolved, wave vector dependent, scalar energy density $a(t,\mathbf{x},\mathbf{k})$ defined for all $\mathbf{k}$ at each point $\mathbf{x}$ and time t. Energy conservation is expressed by the transport equation

$$\frac{\partial a(t,\mathbf{x},\mathbf{k})}{\partial t} + \nabla_{\mathbf{k}}\omega(\mathbf{x},\mathbf{k}) \cdot \nabla_{\mathbf{x}} a(t,\mathbf{x},\mathbf{k}) - \nabla_{\mathbf{x}}\omega(\mathbf{x},\mathbf{k}) \cdot \nabla_{\mathbf{k}} a(t,\mathbf{x},\mathbf{k})$$
$$= \int \sigma(\mathbf{x},\mathbf{k},\mathbf{k}') a(t,\mathbf{x},\mathbf{k}') d\mathbf{k}' - \Sigma(\mathbf{x},\mathbf{k}) a(t,\mathbf{x},\mathbf{k}). \tag{1}$$

Here $\omega(\mathbf{x},\mathbf{k})$ is the frequency at $\mathbf{x}$ of the wave with wave vector $\mathbf{k}$, $\sigma(\mathbf{x},\mathbf{k},\mathbf{k}')$ is the differential scattering cross-section, the rate at which energy with wave vector $\mathbf{k}'$ is converted to wave energy with wave vector $\mathbf{k}$ at position $\mathbf{x}$, and

$$\int \sigma(\mathbf{x},\mathbf{k}',\mathbf{k}) d\mathbf{k}' = \Sigma(\mathbf{x},\mathbf{k})$$

is the total scattering cross-section. The theory was applied to underwater sound propagation[3] and seismology.[4] It was realized in the 1960s that such theory arises rather naturally in wave propagation through random media. The equation (1) has been derived from equations governing the particular wave motion under consideration by various authors (see Ref. 1). These derivations also determine the functions $\omega(\mathbf{x},\mathbf{k})$ and $\sigma(\mathbf{x},\mathbf{k},\mathbf{k}')$ and show how a is related to the wave field.

In Ref. 1, transport equations for various types of waves and waves in random media were derived and studied more systematically. It is shown that the theory can be derived from the governing equations for light and for other waves of any type, in a randomly inhomogeneous medium. Their derivation motivated us to study this problem in a more general framework.

In this paper, we consider a general class of equations of form

$$i\epsilon u_t = H(X,\epsilon D)u + \sqrt{\epsilon}V\left(\frac{1}{\epsilon}X,\epsilon D\right)u \tag{2}$$

in the high frequency regime. Here $H(X,D)$ is a Weyl quantization of symbol $H(x,k)$ which is polynomial in k and smooth in x. In the case of system, we assume $\mathbf{H}(x,k)$ be a $n\times n$ matrix valued function of $C^\infty(\mathbf{R}_x^n\times\mathbf{R}_k^n)$. We show that transport equation can be derived from (2) in the high frequency limit. Equation (2) is general enough to cover various physical examples given in Ref. 1 by choosing different symbols. Our results generalized those in Ref. 1. By going into a more abstract notion of pseudo-differential operator or Weyl quantization, we can use many of its nice properties and thus simplify the calculations.

As in Ref. 1, an essential step in our approach to deriving radiative transport equations from wave equations is the use of the Wigner distribution. Wigner distribution was introduced first by Wigner[5] in the context of semiclassical quantum mechanics. The paper of Lions and Paul[6] contains many basic facts about the Wigner distribution as well as some interesting applications. The Wigner distribution are closely related to the representation theory of Heisenberg group and pseudodifferential operator theory.[7] The advantage with Wigner distribution is that it can be regarded as wave number resolved wave intensity. In particular, in the case of high frequency limit, it is a good candidate to analyze the evolution of wave energy.

The paper is organized as follows. In Sec. II, we review some of the basic properties of Weyl quantization and Wigner distribution. In Sec. III, we consider a scaled generalized Schrödinger evolution equation with Hamiltonian related to a symbol $H(x,k)$. In the high frequency limit, the limiting Wigner distribution W satisfies a Liouville-type transport equation

$$\frac{\partial W(t)}{\partial t} + \{W(t),H\} = 0. \tag{3}$$

We then consider the equation with small random perturbation. Using the method of multiple scale expansion, we obtain the transport equations for the leading order term $W^{(0)}$ of W^ϵ

$$\frac{\partial W^{(0)}}{\partial t} + \{W^{(0)},H\} = 2\pi\int \mathcal{F}_1 R\left(k-q,k+\frac{q}{2},k+\frac{q}{2}\right)(W^{(0)}(t,x,q) - W^{(0)}(t,x,k))\cdot\delta(H(x,q)-H(x,k))\,dq. \tag{4}$$

Equation (4) is exactly in the form of Eq. (1), where $W^{(0)}$ is the energy density and the symbol Hamiltonian $H(x,k)$ is the frequency $\omega(\mathbf{x},\mathbf{k})$ and the integral kernel of the right-hand side of (4) is the differential scattering cross section σ and total scattering cross section Σ. In Sec. IV, we treat the system of scaled generalized Schrödinger evolution equations. The Wigner distributions are matrix valued. In the high frequency limit, we show that the projections $a^{(s)}$ of limit Wigner distribution on certain eigenspaces satisfy the following Liouville equations:

$$\frac{\partial a^{(s)}}{\partial t} + \{a^{(s)},\lambda_s\} = 0, \tag{5}$$

where λ_s denote dispersion laws of the given Hamiltonian symbol $\mathbf{H}(x,k) = (H_{i,j}(x,k))$. We further show this process also incorporates the system of evolution equations with small random perturbations. We derive in Proposition 9 the system of radiative transport equations which leads to the appearance of the scattering terms on the right-hand side of Eq. (71) similar to (1). We also treat the polarization case which is more physically relevant and can find applications in acoustic wave, electromagnetic waves and elastic waves.

We note that rigorous results have also appeared recently for some simpler cases. In Ref. 8, derivations of transport equations in some cases are proved rigorously for equations without random perturbations. Efforts are also made to include some special random perturbations.[9]

II. WEYL QUANTIZATION AND WIGNER DISTRIBUTION

A. Weyl quantization

The idea of Weyl quantization is to assign to a function (symbol) on the phase space an operator according to the Weyl quantization rule. The procedure was proposed by Weyl not long after the invention of quantum mechanics. Weyl's prescription for assigning an operator $a(X,D)$ to a function $a(x,k)$ amounts to postulating that the exponential function $\exp i(q\cdot x+p\cdot k)((q,p)\in \mathbf{R}^n)$ should correspond to the operator $\rho(q,p)=\exp i(q\cdot X+p\cdot D)$. Once this is granted, one can expand an ''arbitrary'' $a(x,k)$ in terms of exponentials via the Fourier transform,

$$a(X,D)=\frac{1}{(2\pi)^n}\int \hat{a}(q,p)\exp i(q\cdot X+p\cdot D)dq\,dp, \tag{6}$$

where $\hat{a}(q,p)$ denotes the Fourier transform of $a(q,p)$.

For $(q,p)\in \mathbf{R}^n\times\mathbf{R}^n$, let $q\cdot X=\Sigma q_jX_j$, $p\cdot D=\Sigma p_jD_j$ where X_j's are multiplication operators, D_j's are first-order differential operators, i.e., for $\forall f\in L^2(\mathbf{R}^n,dx)$ we have

$$X_jf(x)=x_jf(x), \qquad D_jf(x)=\frac{1}{i}\frac{\partial f(x)}{\partial x_j}. \tag{7}$$

We define a unitary operator $\rho(q,p)=\exp i(q\cdot X+p\cdot D)$ on $L^2(\mathbf{R}^n,dx)$ as follows: For $f\in L^2(\mathbf{R}^n,dx)$,

$$\rho(q,p)f(x)=e^{i(1/2)q\cdot p}e^{iq.x}f(x+p). \tag{8}$$

The function a in (6) is usually called the symbol of the operator $a(X,D)$. The integral is an ordinary Bochner integral if $\hat{a}\in L^1(\mathbf{R}^n\times\mathbf{R}^n)$. If $a\in S$ (the Schwartz class), the Weyl operator is an integral operator

$$a(X,D)f(x)=\frac{1}{(2\pi)^n}\int a\left(\frac{x+y}{2},z\right)e^{i(x-y)z}f(z)dy\,dz \tag{9}$$

and $a(X,D)$ maps S into S. $a(X,D)$ can be defined even for any tempered distribution function a as a continuous linear operator from $S(\mathbf{R}^n)$ to $S'(\mathbf{R}^n)$. In particular, if $a(x,k)$ is a polynomial in (x,k), then $a(X,D)$ is a differential operator.

Example 1. Let $a(x,k)=\frac{1}{2}|k|^2+V(x)$, then

$$a(X,D)=-\tfrac{1}{2}\Delta+V(x).$$

Example 2. Let

$$a(x,k)=\sum_{j=1}^n A_j(x)k_j-\frac{1}{2}i\sum_{j=1}^n\frac{\partial A_j(x)}{\partial x_j},$$

then

$$a(X,D)=\sum_{j=1}^{n} A_j(x)D_j .$$

B. Wigner transformation

Wigner transform plays an important role in the derivation of transport equations from wave equations. We first introduce the so-called Fourier–Wigner transform. For $u,v\in L^2(\mathbf{R}^n)$, the Fourier–Wigner transform is defined as

$$V(u,v)(q,p)=(\rho(q,p)u,v), \tag{10}$$

where the bracket denotes the inner product of $L^2(\mathbf{R}^n)$ and $\rho(q,p)$ is given by (8). $V(u,v)$ is a bounded continuous function on $\mathbf{R}^n\times\mathbf{R}^n$. It maps $S(\mathbf{R}^n)\times S(\mathbf{R}^n)$ into $S(\mathbf{R}^{2n})$ and may be extended to an operator from $S'(\mathbf{R}^n)\times S'(\mathbf{R}^n)$ to $S'(\mathbf{R}^n\times\mathbf{R}^n)$.

Now the Wigner transformation for $u,v\in L^2(\mathbf{R}^n)$ is defined by

$$W(u,v)(x,k)=\frac{1}{(2\pi)^n}\int e^{-i(x\cdot q+k\cdot p)}V(u,v)(q,p)dq\,dp \tag{11}$$

$$=\int e^{-ik\cdot p}u\left(x+\frac{p}{2}\right)\overline{v}\left(x-\frac{p}{2}\right)dp. \tag{12}$$

$W(u,v)$ is a bounded continuous function on the phase space. It maps $S(\mathbf{R}^n)\times S(\mathbf{R}^n)\to S(\mathbf{R}^n\times\mathbf{R}^n)$, and may extend to an operator from $S'(\mathbf{R}^n)\times S'(\mathbf{R}^n)$ to $S'(\mathbf{R}^n\times\mathbf{R}^n)$. When $u=v$, we shall call $W(u,u)$ the Wigner distribution or Wigner transform of u. It is easy to see that

$$\int W(u,u)(x,k)dk=|u(x)|^2,$$

so that we may think of $W(x,k)$ as wave number resolved energy density, if u is a wave function. We list below some of the properties of the Fourier–Wigner and Wigner transform without proving it (see, e.g., Ref. 7). Let u, v and $u_1,v_1,u_2,v_2\in L^2(\mathbf{R}^n)$, we have

(1)

$$\|V(u,v)\|_\infty=\|u\|_2\|v\|_2;$$

(2)

$$(V(u_1,v_1),V(u_2,v_2))=(u_1,u_2)\overline{(v_1,v_2)};$$

(3)

$$V(\rho(a,b)u,v)(q,p)=e^{i/2(pa-bq)}V(u,v)(q+a,p+b),$$

$$V(u,\rho(c,d)v)(q,p)=e^{i/2(pc-qd)}V(u,v)(q-c,p-d);$$

(4)

$$\|W(u,v)\|_\infty=\|u\|_2\|v\|_2;$$

(5)

$$(W(u_1,v_1),W(u_2,v_2))=(u_1,u_2)\overline{(v_1,v_2)};$$

(6)

$$W(v,u)=\overline{W(u,v)},$$

$$W(\hat{u},\hat{v})(x,k)=W(u,v)(-k,x);$$

(7)

$$W(\rho(a,b)u,v)(x,k)=e^{i(x\cdot a+b\cdot k)}W(u,v)\left(x+\frac{b}{2},k-\frac{a}{2}\right),$$

$$W(u,\rho(c,d)v)(x,k)=e^{-i(x\cdot c+k\cdot d)}W(u,v)\left(x+\frac{d}{2},k-\frac{c}{2}\right);$$

(8)

$$\int W(u,v)(x,k)dk=|u(x)|^2,$$

$$\int W(u,v)(x,k)dx=|\hat{u}(k)|^2,$$

$$\int x_j W(u,u)(x,k)dx\,dk=\int x_j|u(x)|^2dx=(X_ju,u),$$

$$\int k_j W(u,u)(x,k)dx\,dk=\int k_j|\hat{u}(x)|^2dk=(D_ju,u).$$

III. THE SCALAR EVOLUTION EQUATIONS

A. Generalized Schrödinger equation

We consider the symbol $H(x,k)\in C^\infty(\mathbf{R}_x^n\times\mathbf{R}_k^n)$ being real valued polynomial in k-variable and Schwartz class in x-variable, then its Weyl operator is a differential operator with smooth coefficient. Let $u(t,x)$ be the solution of the initial value problem of the generalized Schrödinger equation

$$i\frac{\partial u}{\partial t}=H(X,D)u,$$
$$u(0,x)=\varphi(x)\in L^2(\mathbf{R}^n) \tag{13}$$

and its Wigner distribution be

$$W(t,x,k)=W(u(t),u(t))(x,k). \tag{14}$$

Then we have,

Proposition 1: The Wigner distribution $W(t,x,k)$ satisfies

$$i\frac{\partial W(t,x,k)}{\partial t}=\frac{1}{(2\pi)^n}\int \hat{H}(q,p)e^{i(x\cdot q+k\cdot p)}\left[W\left(t,x+\frac{p}{2},k-\frac{q}{2}\right)-W\left(t,x-\frac{p}{2},k+\frac{q}{2}\right)\right]dq\,dp$$
$$W(0,x,k)=W(\varphi,\varphi)(x,k). \tag{15}$$

Proof: Differentiate $W(t,x,k)$ with respect to t, we have

$$\frac{\partial W(t,x,k)}{\partial t}=W\left(\frac{\partial u(t)}{\partial t},u(t)\right)(x,k)+W\left(u(t),\frac{\partial u(t)}{\partial t}\right)(x,k)$$
$$=\frac{1}{i}W(Hu(t),u(t))(x,k)-\frac{1}{i}W(u(t),Hu(t))(x,k).$$

Using (6), (8), (11), and Property (7) in Sec. II B, we have

$$W(H(X,D)u,u)(x,k)=\frac{1}{(2\pi)^n}\int \hat{H}(q,p)W(\rho(q,p)u,u)(x,k)dq\,dp$$
$$=\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)W(u,u)\left(x+\frac{p}{2},k-\frac{q}{2}\right)dq\,dp,$$

$$W(u,H(X,D)u)(x,k)=\frac{1}{(2\pi)^n}\int \overline{\hat{H}}(q,p)W(u,\rho(q,p)u)(x,k)dq\,dp$$
$$=\frac{1}{(2\pi)^n}\int e^{-i(x\cdot q+k\cdot p)}\hat{H}(-q,-p)W(u,u)\left(x+\frac{p}{2},k-\frac{q}{2}\right)dq\,dp$$
$$=\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)W(u,u)\left(x-\frac{p}{2},k+\frac{q}{2}\right)dq\,dp.$$

Therefore,

$$i\frac{\partial W(t,x,k)}{\partial t}=\frac{1}{(2\pi)^n}\int \hat{H}(q,p)e^{i(x\cdot q+k\cdot p)}\left[W\left(t,x+\frac{p}{2},k-\frac{q}{2}\right)-W\left(t,x-\frac{p}{2},k+\frac{q}{2}\right)\right]dq\,dp,$$

and we have the Lemma.

We now consider the problem in the high frequency regime. High frequency asymptotics requires the symbol $H(x,k)$ vary slowly in space variable x, i.e., on the long scale. We introduce a dimensionless small parameter $\epsilon>0$ and redefine time and space variables $t\to t/\epsilon$, $x\to x/\epsilon$. The scaled wave function $u^\epsilon(t,x)=u(t/\epsilon,x/\epsilon)$ satisfies the scaled generalized Schrödinger equation

$$i\varepsilon\frac{\partial u^\varepsilon}{\partial t}=H(X,\varepsilon D)u^\varepsilon \qquad u^\varepsilon(0,x)=\varphi(x). \tag{16}$$

Note that there is no small parameter ϵ before the multiplications operator X in the scaled Weyl operator H, which means the symbol is slowly varying in the original space variable. Also the initial data does not depend on ϵ which means the initial data in (13) is slowly varying in the original space variables. We define the rescaled Wigner distribution by

$$W^\varepsilon(t,x,k)=\frac{1}{\varepsilon^n}W(u^\varepsilon(t),u^\varepsilon(t))\left(x,\frac{k}{\varepsilon}\right). \tag{17}$$

With this scaling, Proposition 1 becomes

Proposition 2: The Wigner distribution W^ε satisfies

$$i\varepsilon \frac{\partial w^{\varepsilon}(t,x,k)}{\partial t} = \frac{1}{(2\pi)^n} \int \hat{H}(q,p) e^{i(x\cdot q+k\cdot p)} \left[W^{\varepsilon}\left(t,x+\frac{\varepsilon}{2}p,k-\frac{\varepsilon}{2}q\right) - W^{\varepsilon}\left(t,x-\frac{\varepsilon}{2}p,k+\frac{\varepsilon}{2}q\right)\right] dq\,dp$$

$$W^{\varepsilon}(0,x,k) = \frac{1}{\varepsilon^n} W(\varphi,\varphi)\left(x,\frac{k}{\varepsilon}\right). \tag{18}$$

To calculate the high frequency limit of W^{ϵ} as $\epsilon \to 0$, consider the formal expansion

$$W^{\varepsilon}(t,x,k) = W(t,x,k) + \varepsilon W_1(t,x,k) + \cdots. \tag{19}$$

The equation for the leading order term can be calculated formally and we have

Proposition 3: $W(t,x,k)$ satisfies the following transport equation:

$$\frac{\partial W(t)}{\partial t} + \{W(t),H\} = 0, \tag{20}$$

where the bracket is the Lie bracket on the space of the functions on phase space

$$\{a,b\} = \sum_j \left(\frac{\partial a}{\partial x_j}\frac{\partial b}{\partial k_j} - \frac{\partial a}{\partial k_j}\frac{\partial b}{\partial x_j}\right). \tag{21}$$

Note that $H(x,k)$ plays the role of frequency function $\omega(x,k)$ in (1) and there is no scattering in the equation.

Proof: From (18), we take limit $\varepsilon \to 0$, we have that

$$\begin{aligned} i\frac{\partial W}{\partial t} &= \frac{1}{(2\pi)^n} \int e^{i(x\cdot q+k\cdot q)} \hat{H}(q,p)\left(p\cdot \frac{\partial W}{\partial x} - q\cdot \frac{\partial W}{\partial k}\right) dq\,dp \\ &= \frac{1}{(2\pi)^n} \frac{\partial W}{\partial x} \frac{1}{i} \frac{\partial}{\partial k}\left(\int e^{i(x\cdot q+k\cdot p)} \hat{H}(q,p)\,dq\,dp\right) \\ &\quad - \frac{1}{(2\pi)^n} \frac{\partial W}{\partial k} \frac{1}{i} \frac{\partial}{\partial x}\left(\int e^{i(x\cdot q+k\cdot q)} \hat{H}(q,p)\,dq\,dp\right) \\ &= \frac{1}{i}\left(\frac{\partial W}{\partial x}\frac{\partial H}{\partial k} - \frac{\partial W}{\partial k}\frac{\partial H}{\partial x}\right) = \frac{1}{i}\{W,H\}. \end{aligned}$$

B. Generalized Schrödinger equation with small random perturbation

We now consider the case with random potential. Let $V(x,k)$ be a mean zero random function, stationary in space variable, its correlations are homogeneous in space, so that

$$\langle V(x,k)V(x',k')\rangle = R(x-x',k,k') \tag{22}$$

and

$$\langle \hat{V}(q,p)\hat{V}(q',p')\rangle = \hat{R}(q,p,p')\,\delta(q+q'), \tag{23}$$

where

$$\hat{R}(q,p,p') = \frac{1}{(2\pi)^{3n/2}} \int e^{i(xq+kp+k'p')} R(x,k,k')\,dk\,dk'.$$

We also assume that

$$\operatorname{Im}\mathcal{F}_1R(q,k,k')=0, \tag{24}$$

which is equivalent to

$$\operatorname{Im}\mathcal{F}_1R(q,k,k')=\operatorname{Im}\mathcal{F}_1R(-q,k,k'), \tag{25}$$

where $\mathcal{F}_1R$ stands for the Fourier transform of the correlation function in first variable.

Consider the solution $u^\epsilon(t,x)$ of equation

$$i\epsilon u_t^\epsilon=\left(H(X,\epsilon D)+\sqrt{\epsilon}V\left(\frac{1}{\epsilon}X,\epsilon D\right)\right)u^\epsilon$$

and its scaled Wigner distribution W^ϵ defined by (17). As pointed out in Ref. 1, in order to find the correct result as $\epsilon\to 0$, we need to use multiple scale expansion. Let $\xi=x/\varepsilon$ be the fast space variable and rewrite $W^\varepsilon(t,x,k)=W^\varepsilon(t,x,x/\varepsilon,k)$ as $W^\varepsilon(t,x,\xi,k)$. It is easy to show that $W^\varepsilon(t,x,\xi,k)$ satisfies the following proposition:

Proposition 4:

$$\begin{aligned}
i\frac{\partial W^\varepsilon(t,x,\xi,k)}{\partial t}=&\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)\frac{1}{\varepsilon}\left[W^\varepsilon\left(t,x+\frac{\varepsilon}{2}p,\xi+\frac{p}{2},k-\frac{\varepsilon}{2}q\right)\right.\\
&\left.-W^\varepsilon\left(t,x-\frac{\varepsilon}{2}p,\xi-\frac{p}{2},k+\frac{\varepsilon}{2}q\right)\right]dq\,dp\\
&+\frac{1}{(2\pi)^n}\int e^{i(\xi\cdot q+k\cdot p)}\hat{V}(q,p)\frac{1}{\sqrt{\varepsilon}}\left[W^\varepsilon\left(t,x+\frac{\varepsilon}{2}p,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right.\\
&\left.-W^\varepsilon\left(t,x,-\frac{\varepsilon}{2}p,\xi-\frac{p}{2},k+\frac{q}{2}\right)\right]dq\,dp.
\end{aligned} \tag{26}$$

To study the limit as $\epsilon\to 0$, we introduce an expansion of form

$$W^\epsilon(t,x,\xi,k)=W^{(0)}(t,x,k)+\sqrt{\varepsilon}W^{(1)}(t,x,\xi,k)+\varepsilon W^{(2)}(t,x,\xi,k)+\cdots, \tag{27}$$

where we assume that the leading term $W^{(0)}$ does not depend upon the fast variable and also it is deterministic. Substitute (27) into (26) and collect the terms at different powers of ϵ, we have that at order $\epsilon^{-1/2}$,

$$\begin{aligned}
&\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)\left[W^{(1)}\left(t,x,\xi+\frac{p}{2},k\right)-W^{(1)}\left(t,x,\xi-\frac{p}{2},k\right)\right]dq\,dp\\
&\quad+\frac{1}{(2\pi)^n}\int e^{i(\xi\cdot p+k\cdot p)}\hat{V}(q,p)\left[W^{(0)}\left(t,x,k-\frac{q}{2}\right)-W^{(0)}\left(t,x,k+\frac{q}{2}\right)\right]dq\,dp=0,
\end{aligned} \tag{28}$$

at order ϵ^0:

$$i\frac{\partial W^{(0)}(t,x,k)}{\partial t}=\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)\left[W^{(2)}\left(t,x,\xi+\frac{p}{2},k\right)-W^{(2)}\left(t,x,\xi-\frac{p}{2},k\right)\right]dq\,dp$$
$$+\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)\left(p\frac{\partial}{\partial x}-q\frac{\partial}{\partial k}\right)W^{(0)}(t,x,k)dq\,dp$$
$$+\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\hat{V}(q,p)\left[W^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right.$$
$$\left.-W^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\right]dq\,dp. \tag{29}$$

Since we have, from ergodicity,

$$\left\langle\frac{\partial W^{(2)}}{\partial \xi}\right\rangle=0,$$

after averaging (29), we get

$$i\frac{\partial W^{(0)}(t,x,k)}{\partial t}+\{W^{(0)},H\}(t,x,k)=\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\left\langle\hat{V}(q,p)\left[W^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right.\right.$$
$$\left.\left.-W^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\right]dq\,dp\right\rangle. \tag{30}$$

In order to get a closed equation for $W^{(0)}$, we need to compute $W^{(1)}$ from (28). Let F be the Fourier transform in ξ of $W^{(1)}$, i.e.,

$$W^{(1)}(t,x,\xi,k)=\frac{1}{(2\pi)^{n/2}}\int e^{i\xi\cdot q'}F(t,x,q',k)dq'.$$

Plug in (28), we have

$$\frac{1}{(2\pi)^{3n/2}}\int\int e^{i\xi\cdot q'}F(t,x,q',k)[e^{i(x\cdot q+(k+q'/2)p)}\hat{H}(q,p)-e^{i(x\cdot q+(k-q'/2)p)}\hat{H}(q,p)]$$
$$\times dq\,dp\,dq'+\frac{1}{(2\pi)^n}\int e^{i(\xi\cdot q+k\cdot p)}\hat{V}(q,p)\left[W^{(0)}\left(t,x,k-\frac{q}{2}\right)-W^{(0)}\left(t,x,k+\frac{q}{2}\right)\right]dq\,dp=0,$$

which implies

$$\frac{1}{(2\pi)^{n/2}}\int e^{i\xi\cdot q'}F(t,x,q',k)[H(x,k+q'/2)-H(x,k-q'/2)]dq'$$
$$+\frac{1}{(2\pi)^n}\int e^{i\xi\cdot q}\int e^{ik\cdot p}\hat{V}(q,p)dp\left[W^{(0)}\left(t,x,k-\frac{q}{2}\right)-W^{(0)}\left(t,x,k+\frac{q}{2}\right)\right]dq=0.$$

Taking inverse Fourier transform in ξ, we get

$$F(t,x,q',k)=\frac{1}{(2\pi)^{n/2}}\frac{\int e^{ik\cdot p}\hat{V}(q',p)dp[W^{(0)}(t,x,k-q'/2)-W^{(0)}(t,x,k+q'/2)]}{H(x,k+q'/2)-H(x,k-q'/2)+i\theta}. \quad (31)$$

The term $i\theta$ is a regularization term. Using (23), we compute the integrand of the right-hand side of (30),

$$\left\langle \hat{V}(q,p)\left[W^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)-W^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\right]\right\rangle$$
$$=\frac{1}{(2\pi)^{n/2}}\left\langle \hat{V}(q,p)\left[\int e^{i(\xi+p/2)q'}F\left(t,x,q',k-\frac{1}{2}\right)dq'\right.\right.$$
$$\left.\left.-\int e^{i(\xi-p/2)q'}F\left(t,x,q',k+\frac{q}{2}\right)dq'\right]\right\rangle$$
$$=\frac{1}{(2\pi)^n}\left\langle \hat{V}(q,p)\int e^{i(\xi+p/2)q'+i(k-q/2)p'}\hat{V}(q',p')\right.$$
$$\left.\times\frac{W^{(0)}\left(t,x,k-\frac{q}{2}+\frac{q'}{2}\right)-W^{(0)}\left(t,x,k-\frac{q}{2}-\frac{q'}{2}\right)}{H\left(x,k-\frac{q}{2}+\frac{q'}{2}\right)-H\left(x,k-\frac{q}{2}-\frac{q'}{2}\right)+i\theta}dq'\,dp'\right\rangle$$
$$-\frac{1}{(2\pi)^n}\left\langle \hat{V}(q,p)\int e^{i(\xi-p/2)q'+i(k+q/2)p'}\hat{V}(q',p')\right.$$
$$\left.\times\frac{W^{(0)}\left(t,x,k+\frac{q}{2}+\frac{q'}{2}\right)-W^{(0)}\left(t,x,k+\frac{q}{2}-\frac{q'}{2}\right)}{H\left(x,k+\frac{q}{2}+\frac{q'}{2}\right)-H\left(x,k+\frac{q}{2}-\frac{q'}{2}\right)+i\theta}dq'\,dp'\right\rangle$$
$$=\frac{1}{(2\pi)^n}\int e^{i(\xi+p/2)q'+i(k-q/2)p'}\hat{R}(q,p,p')\delta(q+q')$$
$$\times\frac{W^{(0)}\left(t,x,k-\frac{q}{2}+\frac{q'}{2}\right)-W^{(0)}\left(t,x,k-\frac{q}{2}-\frac{q'}{q}\right)}{H\left(x,k-\frac{q}{2}+\frac{q'}{2}\right)-H\left(x,k-\frac{q}{2}-\frac{q'}{2}\right)+i\theta}dq'\,dp'$$
$$-\frac{1}{(2\pi)^n}\int e^{i(\xi-p/2)q'+i(k+q/2)p'}\hat{R}(q,p,p')\delta(q+q')$$

$$\times \frac{W^{(0)}\left(t,x,k+\frac{q}{2}+\frac{q'}{2}\right)-W^{(0)}\left(t,x,k+\frac{q}{2}-\frac{q'}{2}\right)}{H\left(x,k+\frac{q}{2}+\frac{q'}{2}\right)-H\left(x,k+\frac{q}{2}-\frac{q'}{2}\right)+i\theta}\,dq'\,dp'$$

$$=e^{-i(\xi+p/2)q}\left(\int e^{i(k-q/2)p'}\hat{R}(q,p,p')dp'\right)\frac{W^{(0)}(t,x,k-q)-W^{(0)}(t,x,k)}{H(x,k-q)-H(x,k)+i\theta}-e^{-i(\xi-p/2)q)}$$

$$\times\left(\int e^{i(k+q/2)p'}\hat{R}(q,p,p')dp'\right)\frac{W^{(0)}(t,x,k)-W^{(0)}(t,x,k+q)}{H(x,k)-H(x,k+q)+i\theta}.$$

Therefore,

$$\left\langle \frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\hat{V}(q,p)\left[W^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)-W^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\right]dq\,dp\right\rangle$$

$$=\int \mathcal{F}_1R\left(q,k-\frac{q}{2},k-\frac{q}{2}\right)\frac{W^{(0)}(t,x,k-q)-W^{(0)}(t,x,k)}{H(x,k-q)-H(x,k)+i\theta}\,dq$$

$$-\int \mathcal{F}_1R\left(q,k+\frac{q}{2},k+\frac{q}{2}\right)\frac{W^{(0)}(t,x,k)-W^{(0)}(t,x,k+q)}{H(x,k)-H(x,k+q)+i\theta}\,dq$$

$$=\int \mathcal{F}_1R\left(k-q,k+\frac{q}{2},k+\frac{q}{2}\right)\frac{W^{(0)}(t,x,q)-W^{(0)}(t,x,k)}{H(x,q)-H(x,k)+i\theta}\,dq$$

$$-\int \mathcal{F}_1R\left(k-q,k+\frac{q}{2},k+\frac{q}{2}\right)\frac{W^{(0)}(t,x,k)-W^{(0)}(t,x,q)}{H(x,k)-H(x,q)+i\theta}\,dq$$

$$=\int \mathcal{F}_1R\left(k-q,k+\frac{q}{2},k+\frac{q}{2}\right)\frac{2i\theta(W^{(0)}(t,x,q)-W^{(0)}(t,x,k))}{(H(x,q)-H(x,k))^2+\theta^2}\,dq.$$

Since

$$\frac{\theta}{x^2+\theta^2}\to\pi\delta(x),\quad \text{as}\quad \theta\to 0$$

we have, from (30), the following Proposition.

Proposition 5: $W^{(0)}$ satisfies the following equation:

$$\frac{\partial W^{(0)}}{\partial t}+\{W^{(0)},H\}=2\pi\int \mathcal{F}_1R\left(k-q,k+\frac{q}{2},k+\frac{q}{2}\right)(W^{(0)}(t,x,q)-W^{(0)}(t,x,k))\cdot\delta(H(x,q)-H(x,k))dq. \tag{32}$$

IV. THE SYSTEM OF EVOLUTION EQUATIONS

A. The generalized vector Schrödinger equations

In this section, we derive transport equations for a system of generalized Schrödinger equations.

Let $\mathbf{H}(x,k)=(H_{ij}(x,k))$ be a $n\times n$ matrix valued function. Assume that $H_{ij}\in C^\infty(\mathbf{R}_x^n\times\mathbf{R}_k^n)$. We always assume that for every $x,k,\mathbf{H}(x,k)$ is diagonalizable. Let $\mathbf{U}^\epsilon(t)=(u_1^\epsilon(t),\ldots,u_n^\epsilon(t))^t$ be the solution of the following system of equations:

$$i\epsilon\frac{\partial \mathbf{U}^\epsilon}{\partial t}=\mathbf{H}(X,\epsilon D)U^\epsilon$$

$$\mathbf{U}^\epsilon(0,x)=\varphi(x), \tag{33}$$

where $\mathbf{H}(X,D)=(H_{ij}(X,D))$ denotes the Weyl quantization of the energy symbol $\mathbf{H}(x,k)$.

Define the scaled Wigner distribution matrix as

$$\mathbf{W}^\epsilon(t,x,k)=(W_{ij}^\epsilon(t,x,k)), \tag{34}$$

where

$$W_{ij}^\varepsilon(t,x,k)=\frac{1}{\varepsilon^n}W(u_i^\varepsilon(t),u_j^\epsilon(t))\left(x,\frac{k}{\varepsilon}\right). \tag{35}$$

The matrix $\mathbf{W}^\epsilon$ is Hermitian as is easily seen by definition (11).

Proposition 6: $\mathbf{W}^\epsilon$ satisfies the following equation:

$$\begin{aligned} i\epsilon\frac{\partial \mathbf{W}^\varepsilon(t,x,k)}{\partial t}&=\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{\mathbf{H}}(q,p)\mathbf{W}^\epsilon\left(t,x+\frac{\varepsilon}{2}p,k-\frac{\varepsilon}{2}q\right)dq\,dp\\ &\quad-\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\mathbf{W}^\epsilon\left(t,x-\frac{\varepsilon}{2}p,k+\frac{\varepsilon}{2}q\right)\widehat{\mathbf{H}^*}(q,p)dq\,dp\\ \mathbf{W}^\varepsilon(0,x,k)&=\frac{1}{\varepsilon^n}\mathbf{W}(\varphi_i,\varphi_j)\left(x,\frac{k}{\varepsilon}\right), \end{aligned} \tag{36}$$

where $\widehat{\mathbf{H}^*}$ is the Fourier transform of Hermitian adjoint matrix of $\mathbf{H}^*$.

The proof of the proposition is similar to that of the scalar case.

Again, we consider the expansion

$$\mathbf{W}^\varepsilon(t,x,k)=\mathbf{W}^{(0)}(t,x,k)+\varepsilon\mathbf{W}^1(t,x,k)+\varepsilon^2\cdots. \tag{37}$$

Substitute (37) into (36) and collect the terms at different powers of ϵ, we have, for the coefficient of ε^{-1} term

$$\mathbf{H}(x,k)\cdot\mathbf{W}^{(0)}(t,x,k)-\mathbf{W}^{(0)}(t,x,k)\cdot\mathbf{H}^*(x,k)=0; \tag{38}$$

and for the coefficient of ε^0 term

$$\begin{aligned} i\frac{\partial \mathbf{W}^{(0)}(t,x,k)}{\partial t}&=\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}[\hat{H}(q,p)\cdot\mathbf{W}^{(1)}(t,x,k)-\mathbf{W}^{(1)}(t,x,k)\cdot\hat{H}^t(q,p)]dq\,dp\\ &\quad+\frac{1}{2(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\hat{H}(q,p)\cdot\left(p\frac{\partial}{\partial x}-q\frac{\partial}{\partial k}\right)\mathbf{W}^{(0)}(t,x,k)dq\,dp\\ &\quad-\frac{1}{2(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\left(-p\frac{\partial}{\partial x}+q\frac{\partial}{\partial k}\right)\mathbf{W}^{(0)}(t,x,k)\cdot\hat{H}^*(q,p)dq\,dp. \end{aligned} \tag{39}$$

Let $\mathbf{A}=(a_{ij}(x,k))$, $\mathbf{B}=(b_{ij}(x,k))$ be matrix valued functions and $f(x,k)$ be scalar function on $\mathbf{R}_x^n\times\mathbf{R}_k^n$. We define a matrix bracket $\{\mathbf{A}\otimes\mathbf{B}\}$ as

$$\{\mathbf{A}\otimes\mathbf{B}\}(x,k)=(c_{ij}(x,k)) \tag{40}$$

with

$$c_{ij}(x,k)=\sum_{l=1}^{n}\{a_{il},b_{lj}\}(x,k), \tag{41}$$

where $\{\cdot,\cdot\}$ is defined by (21). We also define a bracket of a matrix with a scalar function, $\{\mathbf{A},f\}$ as

$$\{\mathbf{A},f\}=(\{a_{ij},f\}).$$

We introduce several operators on $\mathrm{Mat}_n(C)\rightarrow\mathrm{Mat}_n(C)$ as follows:

$$\begin{aligned}
\mathcal{L}(x,k)Z&=\mathbf{H}(x,k)Z-Z\mathbf{H}^*(x,k)\\
\tilde{\mathcal{L}}(x,k)Z&=\mathbf{H}(x,k)Z\\
\mathcal{L}^*(x,k)Z&=\mathbf{H}^*(x,k)Z-Z\mathbf{H}(x,k)\\
\tilde{\mathcal{L}}^*(x,k)Z&=\mathbf{H}^*(x,k)Z.
\end{aligned} \tag{42}$$

For fixed x,k, the kernel of the operator $\mathcal{L}$ is invariant under $\tilde{\mathcal{L}}$. The operator $\tilde{\mathcal{L}}$ is diagonalizable as an operator acting on the vector space $\mathrm{Mat}_n(C)$ if $\mathbf{H}$ is a diagonalizable. That means that any invariant subspace of $\tilde{\mathcal{L}}$ is spanned by its eigenvectors (which are matrices), therefore $\ker\mathcal{L}$ is spanned by some of the eigenvectors of $\tilde{\mathcal{L}}$, namely, by those which belong to $\ker\mathcal{L}$. And each eigenvalue of $\tilde{\mathcal{L}}$ is also an eigenvalue of $\mathbf{H}$.

We will consider two separated cases, i.e., the case without polarization and the case with polarization.

1. Distinct eigenvalue case (without polarizations)

Suppose that the matrix $\mathbf{H}(x,k)$ has distinct real eigenvalues $\lambda_j(x,k)$, $j=1,\ldots,n$, which are C^1 function of x,k. The last assumption is not important but it is convenient. Let $b^{(j)}$ be the corresponding real eigenvectors which are column vectors

$$\mathbf{H}(x,k)b^{(j)}(x,k)=\lambda_j(x,k)b^{(j)}(x,y),\quad j=1,2,\ldots,n.$$

Denote

$$\mathbf{B}^{(j)}(x,k)=b^{(j)}(x,k)b^{(j)*}(x,k), \tag{43}$$

which are Hermitian matrices. Then, we have

$$\tilde{\mathcal{L}}(x,k)\mathbf{B}^{(j)}(x,k)=\lambda_j(x,k)\mathbf{B}^{(j)}(x,k)$$

and

$$\mathcal{L}(x,k)\mathbf{B}^{(j)}(x,k)=0.$$

Moreover $\mathbf{B}^{(j)}(x,k)$, $j=1,\ldots,n$, span the space $\ker\mathcal{L}(x,k)$. Suppose that $c^{(j)}(x,k)$, $j=1,\ldots,n$ are eigenvectors of matrix $\mathbf{H}^*(x,k)$ corresponding to eigenvalues $\lambda_j(x,k)$, $j=1,\ldots n$. $c^{(j)}$ and $b^{(j)}$ satisfy the orthogonal relation

$$c^{(i)*}(x,k)b^{(j)}(x,k)=f_i(x,k)\,\delta_{ij}.$$

Denote

$$\mathbf{C}^{(j)}(x,k)=c^{(j)}(x,k)c^{(j)*}(x,k),$$

we have

$$\tilde{\mathcal{L}}^*(x,k)\mathbf{C}^{(j)}(x,k)=\lambda_j(x,k)\mathbf{C}^{(j)}(x,k),$$

$$\mathcal{L}^*(x,k)\mathbf{C}^{(j)}(x,k)=0,$$

and $\mathbf{C}^{(j)}(x,k)$, $j=1,...,n$, span the space $\ker \mathcal{L}^*(x,k)$.

We introduce an inner product on the space $\mathrm{Mat}_n(C)$ as

$$\langle X,Y\rangle=\mathrm{tr}\, X^*Y.$$

Then $\mathcal{L}^*$ is the adjoint operator of $\mathcal{L}$.

Using notations introduced above, (38) and (39) can be rewritten as

$$\mathcal{L}\mathbf{W}^{(0)}(t)=0, \tag{44}$$

$$i\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{i}{2}\{\mathbf{H} \mathbin{\S} \mathbf{W}^{(0)}(t)\}+\frac{i}{2}\{\mathbf{W}^{(0)}(t) \mathbin{\S} \mathbf{H}^*\}=\mathcal{L}\mathbf{W}^{(1)}(t), \tag{45}$$

or

$$\mathbf{W}^{(0)}(t)\in \ker \mathcal{L}, \tag{46}$$

$$\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{1}{2}\{\mathbf{H} \mathbin{\S} \mathbf{W}^{(0)}(t)\}+\frac{1}{2}\{\mathbf{W}^{(0)}(t) \mathbin{\S} \mathbf{H}^*\}\in \mathrm{Im}\, \mathcal{L}. \tag{47}$$

Since space $\ker \mathcal{L}$ is spanned by $\mathbf{B}^{(j)}=b^{(j)}b^{(j)*}$, $j=1,...,n$. We can write

$$\mathbf{W}^{(0)}(t,x,k)=\sum_{j=1}^{n} a^{(j)}(t,x,k)\mathbf{B}^{(j)}(x,k), \tag{48}$$

where the coefficients $a^{(j)}(t,x,k)$ are real valued functions. Then we have the following proposition from (44) and (45).

Proposition 7: There exists a normalized bases $\mathbf{B}^{(j)}$ of $\ker \mathcal{L}$ such that the coefficients $a^{(j)}\times(t,x,k)$ satisfy the following Liouville equations

$$\frac{\partial a^{(s)}(t)}{\partial t}+\{a^{(s)}(t),\lambda_s\}=0, \quad s=1,...,n. \tag{49}$$

Proof: Substitute (48) into the left-hand side of (45), we have

$$\begin{aligned}
&\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{1}{2}\{\mathbf{H} \mathbin{\S} \mathbf{W}^{(0)}(t)\}+\frac{1}{2}\{\mathbf{W}^{(0)}(t) \mathbin{\S} \mathbf{H}^*\}\\
&\quad=\frac{\partial a^{(s)}}{\partial t}\mathbf{B}^{(s)}-\frac{1}{2}\{\mathbf{H} \mathbin{\S} a^{(s)}\mathbf{B}^{(s)}\}+\frac{1}{2}\{a^{(s)}\mathbf{B}^{(s)} \mathbin{\S} \mathbf{H}^*\}\\
&\quad=\frac{\partial a^{(s)}}{\partial t}\mathbf{B}^{(s)}-\frac{1}{2}a^{(s)}(\{\mathbf{H} \mathbin{\S} \mathbf{B}^{(s)}\}-\{\mathbf{B}^{(s)} \mathbin{\S} \mathbf{H}^*\})-\frac{1}{2}\{\mathbf{H},a^{(s)}\}\mathbf{B}^{(s)}+\frac{1}{2}\mathbf{B}^{(s)}\{a^{(s)},\mathbf{H}^*\}.
\end{aligned}$$

Since

$$\{\mathbf{H},a^{(s)}\}\mathbf{B}^{(s)}=\{\mathbf{H}\mathbf{B}^{(s)},a^{(s)}\}-\mathbf{H}\{\mathbf{B}^{(s)},a^{(s)}\}$$
$$=\{\lambda_s\mathbf{B}^{(s)},a^{(s)}\}-\mathbf{H}\{\mathbf{B}^{(s)},a^{(s)}\}$$
$$=\{\lambda_s,a^{(s)}\}\mathbf{B}^{(s)}+\lambda_s\{\mathbf{B}^{(s)},a^{(s)}\}-\mathbf{H}\{\mathbf{B}^{(s)},a^{(s)}\}$$

and

$$\mathbf{B}^{(s)}\{a^{(s)},\mathbf{H}^*\}=\{a^{(s)},\mathbf{B}^{(s)}\mathbf{H}^*\}-\{a^{(s)},\mathbf{B}^{(s)}\}\mathbf{H}^*=-\{\lambda_s,a^{(s)}\}\mathbf{B}^{(s)}+\{a^{(s)},\mathbf{B}^{(s)}\}(\lambda_s-\mathbf{H}^*).$$

Therefore

$$\frac{\partial\mathbf{W}^{(0)}(t)}{\partial t}-\frac{1}{2}\{\mathbf{H}\otimes_s\mathbf{W}^{(0)}(t)\}+\frac{1}{2}\{\mathbf{W}^{(0)}(t)\otimes_s\mathbf{H}^*\}$$
$$=\left(\frac{\partial a^{(s)}}{\partial t}-\{\lambda_s,a^{(s)}\}\right)\mathbf{B}^{(s)}-\frac{1}{2}a^{(s)}\{\mathbf{H}\otimes_s\mathbf{B}^{(s)}\}+\frac{1}{2}a^{(s)}\{\mathbf{B}^{(s)}\otimes_s\mathbf{H}^*\}$$
$$-\frac{1}{2}(\lambda_s-\mathbf{H})\{\mathbf{B}^{(s)},a^{(s)}\}+\frac{1}{2}\{a^{(s)},\mathbf{B}^{(s)}\}(\lambda_s-\mathbf{H}^*)\in\operatorname{Im}\mathcal{L},\tag{50}$$

where the right-hand side is the summation over s. Using the fact that $\mathbf{C}^{(p)}$ are orthogonal to $\operatorname{Im}\mathcal{L}$ and

$$\langle\mathbf{C}^{(p)},\mathbf{B}^{(q)}\rangle=f_p\overline{f_p}\delta_{pq},$$

where $f_p=(c^{(p)},b^{(p)})=c^{(p)*}b^{(p)}$. Taking inner product of (50) with $\mathbf{C}^{(p)}$, we have

$$\left(\frac{\partial a^{(s)}}{\partial t}-\{\lambda_s,a^{(s)}\}\right)\delta_{ps}|f_p|^2-\frac{1}{2}a^{(s)}\langle\mathbf{C}^{(p)},\{\mathbf{H}\otimes_s\mathbf{B}^{(s)}\}-\{\mathbf{B}^{(s)}\otimes_s\mathbf{H}^*\}\rangle$$
$$-\frac{1}{2}(\lambda_s-\lambda_p)\langle\mathbf{C}^{(p)},\{\mathbf{B}^{(s)},a^{(s)}\}\rangle+\frac{1}{2}(\lambda_s-\lambda_p)\langle\mathbf{C}^{(p)},\{a^{(s)},\mathbf{B}^{(s)}\}\rangle=0.\tag{51}$$

When $p\neq s$, we have

$$\langle\mathbf{C}^{(p)},\{\mathbf{B}^{(s)},a^{(s)}\}\rangle=\left\langle\mathbf{C}^{(p)},\frac{\partial\mathbf{B}^{(s)}}{\partial x}\right\rangle\frac{\partial a^{(s)}}{\partial k}-\left\langle\mathbf{C}^{(p)},\frac{\partial\mathbf{B}^{(s)}}{\partial k}\right\rangle\frac{\partial a^{(s)}}{\partial x},$$

$$\left\langle\mathbf{C}^{(p)},\frac{\partial\mathbf{B}^{(s)}}{\partial x}\right\rangle=(b^{(s)},c^{(p)})\left(c^{(p)},\frac{\partial b^{(s)}}{\partial x}\right)+\left(\frac{\partial b^{(s)}}{\partial x},c^{p}\right)(c^{(p)},b^{(s)})=0,$$

where a_s are real functions. Similarly,

$$\left\langle\mathbf{C}^{(p)},\frac{\partial\mathbf{B}^{(s)}}{\partial k}\right\rangle=0.$$

It follows that, when $p\neq s$

$$(\lambda_p-\lambda_s)\langle\mathbf{C}^{(p)},\{\mathbf{B}^{(s)},a^{(s)}\}\rangle=0.$$

Similar calculation shows that, when $p\neq s$

$$(\lambda_s-\lambda_p)\langle\mathbf{C}^{(p)},\{a^{(s)},\mathbf{B}^{(s)}\}\rangle=0.$$

Next, we show that for $p\neq s$

$$\langle \mathbf{C}^{(p)}, \{\mathbf{H} \otimes \mathbf{B}^{(s)}\} - \{\mathbf{B}^{(s)} \otimes \mathbf{H}^*\} \rangle = 0. \tag{52}$$

Since $\mathbf{B}^{(s)}\mathbf{C}^{(p)} = 0$, we have

$$\begin{aligned}
0 &= \mathrm{tr}\{\mathbf{H} \otimes \mathbf{B}^{(s)}\mathbf{C}^{(p)}\} \\
&= \mathrm{tr}\{\mathbf{H} \otimes \mathbf{B}^{(s)}\}\mathbf{C}^{(p)} - \mathrm{tr}\{\mathbf{C}^{(p)} \otimes \mathbf{H}\}\mathbf{B}^{(s)} \\
&= \mathrm{tr}\{\mathbf{C}^{(p)}\mathbf{H} \otimes \mathbf{B}^{(s)}\} + \mathrm{tr}\{\mathbf{B}^{(s)} \otimes \mathbf{C}^{(p)}\}\mathbf{H} - (\mathrm{tr}\{\mathbf{C}^{(p)} \otimes \mathbf{H}\mathbf{B}^{(s)}\} + \mathrm{tr}\, \mathbf{H}\{\mathbf{B}^{(s)} \otimes \mathbf{C}^{(p)}\}) \\
&= \mathrm{tr}\{\lambda_p \mathbf{C}^{(p)} \otimes \mathbf{B}^{(s)}\} - \mathrm{tr}\{\mathbf{C}^{(p)} \otimes \lambda_s \mathbf{B}^{(s)}\} \\
&= (\lambda_p - \lambda_s)\mathrm{tr}\{\mathbf{C}^{(p)} \otimes \mathbf{B}^{(s)}\},
\end{aligned}$$

therefore, when $p \neq s$,

$$\mathrm{tr}\{\mathbf{C}^p \otimes \mathbf{B}^{(s)}\} = 0.$$

It follows that

$$\begin{aligned}
\langle \mathbf{C}^{(p)}, \{\mathbf{H} \otimes \mathbf{B}^{(s)}\} \rangle &= \mathrm{tr}\, \mathbf{C}^{(p)}\{\mathbf{H} \otimes \mathbf{B}^{(s)}\} = \mathrm{tr}\{\mathbf{C}^{(p)}\mathbf{H} \otimes \mathbf{B}^{(s)}\} + \mathrm{tr}\{\mathbf{B}^{(s)} \otimes \mathbf{C}^{(p)}\}\mathbf{H} = \mathrm{tr}\{\lambda_p \mathbf{C}^{(p)} \otimes \mathbf{B}^{(s)}\} \\
&\quad + \mathrm{tr}\{\mathbf{B}^{(s)} \otimes \mathbf{C}^{(p)}\}\mathbf{H} = \mathrm{tr}\{\mathbf{B}^{(s)} \otimes \mathbf{C}^{(p)}\}\mathbf{H} = \sum_{m,n,l} \{b_m^{(s)}\overline{b_n^{(s)}}, c_n^{(p)}\overline{c_l^{(p)}}\}\mathbf{H}_{lm} \\
&= \sum_{m,n,l} \{b_m^{(s)}c_n^{(p)}\}\overline{b_n^{(s)}}\,\overline{c_l^{(p)}}\mathbf{H}_{lm} + \sum_{m,n,l} \{\overline{b_n^{(s)}}, \overline{c_l^{(p)}}\}b_m^{(s)}c_n^{(p)}\mathbf{H}_{lm} \\
&\quad + \sum_{m,n,l} \{\overline{b_n^{(s)}}, \overline{c_n^{(p)}}\}\overline{c_l^{(p)}}\mathbf{H}_{lm}b_m^{(s)} = \lambda_p \sum_{m,n,l} \{b_m^{(s)}, c_n^{(p)}\}\overline{b_n^{(s)}}\,\overline{c_m^{(p)}} \\
&\quad + \lambda_s \sum_{l,n} \{\overline{b_n^{(s)}}, \overline{c_l^{(p)}}\}b_l^{(s)}c_n^{(p)}.
\end{aligned}$$

Similarly

$$\langle \mathbf{C}^{(p)}, \{\mathbf{B}^{(s)} \otimes \mathbf{H}^*\} \rangle = \mathrm{tr}\, \mathbf{H}^*\{\mathbf{C}^{(p)} \otimes \mathbf{B}^{(s)}\} = \lambda_p \sum_{nl} \{\overline{c_l^{(p)}}, \overline{b_n^{(s)}}\}b_l^{(s)}c_n^{(p)} + \lambda_s \sum_{mn} \{c_n^{(p)}, b_m^{(s)}\}\overline{b_n^{(s)}}\,\overline{c_m^{(p)}}.$$

Therefore

$$\begin{aligned}
\langle \mathbf{C}^{(p)}, \{\mathbf{H} \otimes \mathbf{B}^{(s)}\} - \{\mathbf{B}^{(s)} \otimes \mathbf{H}^*\} \rangle &= (\lambda_p + \lambda_s)\left(\sum_{mn} \{b_m^{(s)}, c_n^{(p)}\}\overline{b_n^{(s)}}\,\overline{c_m^{(p)}} + \sum_{mn} \{\overline{b_n^{(s)}}\,\overline{c_n^{(p)}}\}b_m^{(s)}c_n^{(p)} \right) \\
&= (\lambda_p + \lambda_s)\mathrm{tr}\{\mathbf{B}^{(s)} \otimes \mathbf{C}^{(p)}\} = 0.
\end{aligned}$$

It follows that (51) becomes

$$\left(\frac{\partial a^{(s)}}{\partial t} - \{\lambda_s, a^{(s)}\} \right)|f_s|^2 - \frac{1}{2}a^{(s)}\langle \mathbf{C}^{(s)}, \{\mathbf{H} \otimes \mathbf{B}^{(s)}\} - \{\mathbf{B}^{(s)} \otimes \mathbf{H}^*\} \rangle = 0.$$

To show that (49) holds, we prove that $b^{(s)}$ can be normalized so that

$$\langle \mathbf{C}^{(s)}, \{\mathbf{H} \otimes \mathbf{B}^{(s)}\} - \{\mathbf{B}^{(s)} \otimes \mathbf{H}^*\} \rangle = 0. \tag{53}$$

To achieve that, let $\tilde{\mathbf{B}}^{(s)} = g(x,k)\mathbf{B}^{(s)}$ where $\mathbf{B}^{(s)}$ is fixed. We will show that there exists a function g such that (53) holds for $\tilde{\mathbf{B}}^{(s)}$:

$$\langle \mathbf{C}^{(s)},\{\mathbf{H}\otimes\tilde{\mathbf{B}}^{(s)}\}-\{\tilde{\mathbf{B}}^{(s)}\otimes\mathbf{H}^*\}\rangle = g\langle \mathbf{C}^{(s)},\{\mathbf{H}\otimes\mathbf{B}^{(s)}\}-\{\mathbf{B}^{(s)}\otimes\mathbf{H}^*\}\rangle + 2\langle \mathbf{C}^{(s)},\mathbf{B}^{(s)}\rangle\{\lambda_s,g\}.$$

Then Eq. (53) becomes

$$2\langle \mathbf{C}^{(s)},\mathbf{B}^{(s)}\rangle\{\lambda_s,g\} + g\langle \mathbf{C}^{(s)},\{\mathbf{H}\otimes\mathbf{B}^{(s)}\}-\{\mathbf{B}^{(s)}\otimes\mathbf{H}^*\}\rangle = 0. \tag{54}$$

This is a first order PDE for g and has always a solution which is nonzero everywhere provided λ_s is not a constant. Therefore (51) reduces to (49).

2. Multiple eigenvalue case (with polarization)

We turn our attention to the case with polarization. We assume that Hamiltonian $\mathbf{H}(x,k)$ is diagonalizable but the eigenvalues are not distinct. We assume throughout that the eigenvalues of $\mathbf{H}(x,k)$ have constant multiplicity independent of x and k. This hypothesis is satisfied in the hyperbolic system of acoustic, electromagnetic and elastic waves. Let $\lambda_s(x,k)$ be a real eigenvalue of $H(x,k)$ of multiplicity r. Denote

$$V_{\lambda_s}(x,k) = \{v \in C^n: \quad H(x,k)v = \lambda_s(x,k)v\}$$

and choose $b^{(s1)},\ldots,b^{(sr)}$ to be an orthogonal basis of V_{λ_s}. Let

$$\mathbf{V}_{\lambda_s}(x,k) = \{Z \in \mathrm{Mat}_n(C): \tilde{\mathcal{L}}(x,k)Z = \lambda_s(x,k)Z, \quad \mathcal{L}(x,k)Z = 0\},$$

then $\dim \mathbf{V}_{\lambda_s}(x,k) = r^2$ and it has a basis $\mathbf{B}_{ij}^{(s)} = b^{(si)}b^{(sj)*}$, $i,j = 1,\ldots,r$. Again, from (44), we assume that

$$\mathbf{W}^{(0)}(t,x,k) = \sum_{s,i,j} a_{i,j}^{(s)}(t,x,k)\mathbf{B}_{i,j}^{(s)}(x,k), \tag{55}$$

where $a_{i,j}^{(s)}(t,x,k)$ are scalar functions. Define the $r\times r$ coherence matrices $\mathbf{A}^{(s)}(t,x,k)$ by

$$\mathbf{A}_{i,j}^{(s)}(t,x,k) = a_{i,j}^{(s)}(t,x,k), \quad i,j = 1,\ldots,r.$$

The multiplicity r of the eigenvalue λ_s depends on s but we do not indicate this explicitly.

Proposition 8: The coherence matrices $\mathbf{A}^{(s)}(t,x,k)$ satisfy the following Liouville type transport equation:

$$\frac{\partial \mathbf{A}^{(s)}(t)}{\partial t} + \{\mathbf{A}^{(s)}(t),\lambda_s\} + \mathbf{A}^{(s)}(t)M^{(s)} - M^{(s)*}\mathbf{A}^{(s)}(t) = 0,$$

where $M^{(s)} = (M_{lm}^{(s)}(x,k))$ and

$$M_{lm}^{(s)}(x,k) = \frac{1}{2}\sum_{\alpha} \frac{C_\alpha^{(sm)}}{\overline{f_m^{(s)}}}\left(\sum_r \{\overline{b_r^{(sl)}},\overline{H}_{\alpha r}\} - \{\lambda_p,\overline{b_\alpha^{(sl)}}\}\right).$$

Proof: The eigenspace of $H^*(x,k)$ corresponding to eigenvalue $\lambda_s(x,k)$ is also r dimensional. Let $c^{(s1)},\ldots,c^{(sr)}$ be the basis of this space which is dual to the basis $b^{(s1)},\ldots,b^{(sr)}$ of $V_{\lambda_s}(x,k)$. Denote $\mathbf{C}_{ij}^{(s)} = c^{(si)}\cdot c^{(sj)*}$ and let $(c^{(sl)},b^{(sm)}) = \delta_{lm}f_m^{(s)}$ then

$$\langle C_{lm}^{(p)},B_{ij}^{(s)}\rangle = \delta_{sp}\delta_{li}\delta_{mj}f_l^{(s)}\overline{f_m^{(s)}}.$$

Substitute (55) into (45), we have

$$\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{1}{2}\{\mathbf{H} \otimes \mathbf{W}^{(0)}(t)\}+\frac{1}{2}\{\mathbf{W}^{(0)}(t) \otimes \mathbf{H}^*\}$$
$$=\sum_{s,i,j}\left(\frac{\partial a_{ij}^{(s)}}{\partial t}-\{\lambda_s, a_{ij}^{(s)}\}\right)\mathbf{B}_{ij}^{(s)}-\frac{1}{2}a_{ij}^{(s)}(\{\mathbf{H}\otimes \mathbf{B}_{ij}^{(s)}\}-\{\mathbf{B}_{ij}^{(s)}\otimes \mathbf{H}^*\})$$
$$-\frac{1}{2}(\lambda_s-\mathbf{H})\{\mathbf{B}_{ij}^{(s)}, a_{ij}^{(s)}\}+\frac{1}{2}\{a_{ij}^{(s)}, \mathbf{B}_{ij}^{(s)}\}(\lambda_s-\mathbf{H}^*)\in \operatorname{Im}\mathcal{L}. \tag{56}$$

Taking inner product of (56) with $\mathbf{C}_{lm}^{(p)}$, we have

$$\left(\frac{\partial a_{lm}^{(p)}}{\partial t}-\{\lambda_p, a_{lm}^{(p)}\}\right) f_l^{(p)}\overline{f_m^{(p)}}-\frac{1}{2}\sum_{s,i,j} a_{ij}^{(s)}\langle \mathbf{C}_{lm}^{(p)}, \{\mathbf{H}\otimes \mathbf{B}_{ij}^{(s)}\}-\{\mathbf{B}_{ij}^{(s)}\otimes \mathbf{H}^*\}\rangle$$
$$-\frac{1}{2}(\lambda_s-\lambda_p)\sum_{s,i,j}\langle \mathbf{C}_{lm}^{(p)}, \{\mathbf{B}_{ij}^{(s)}, a_{ij}^{(s)}\}\rangle+\frac{1}{2}(\lambda_s-\lambda_p)\sum_{s,i,j}\langle \mathbf{C}_{lm}^{(p)}, \{a_{ij}^{(s)}, \mathbf{B}_{ij}^{(s)}\}\rangle=0. \tag{57}$$

Similar calculations as in the case of distinct eigenvalue show that the third and the fourth term of the left-hand side of (57) disappear. In the second term, only terms with $s=p$ remains. Therefore we have

$$\left(\frac{\partial a_{lm}^{(p)}}{\partial t}-\{\lambda_p, a_{lm}^{(p)}\}\right) f_l^{(p)}\overline{f_m^{(p)}}-\frac{1}{2}\sum_{p,i,j} a_{ij}^{(p)}\langle \mathbf{C}_{lm}^{(p)}, \{\mathbf{H}\otimes \mathbf{B}_{ij}^{(s)}\}-\{\mathbf{B}_{ij}^{(p)}\otimes \mathbf{H}^*\}\rangle=0, \tag{58}$$

where

$$\langle \mathbf{C}_{lm}^{(p)}, \{\mathbf{H}\otimes \mathbf{B}_{ij}^{(s)}\}-\{\mathbf{B}_{ij}^{(p)}\otimes \mathbf{H}^*\}\rangle=\sum_{\alpha\beta\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}(\{\mathbf{H}_{\beta\gamma}, b_\gamma^{(pi)}\overline{b_\alpha^{(pj)}}\}-\{b_\beta^{(pi)}\overline{b_\gamma^{(pj)}}, \overline{H}_{\alpha\gamma}\})=\Delta_1+\Delta_2,$$

with

$$\Delta_1=\sum_{\beta,\gamma}\overline{c_\beta^{(pl)}}\{\mathbf{H}_{\beta\gamma}, b_\gamma^{(pi)}\}\delta_{mj}\overline{f_m^{(p)}}-\sum_{\alpha,\gamma} c_\alpha^{(pm)}\{\overline{b_\gamma^{(pi)}}, \overline{H}_{\alpha\gamma}\}\delta_{li} f_l^{(p)}, \tag{59}$$

$$\Delta_2=\sum_{\alpha,\beta,\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}} b_\gamma^{(pi)}\{\mathbf{H}_{\beta\gamma}, \overline{b_\alpha^{(pj)}}\}$$
$$-\sum_{\alpha,\beta,\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)} b_\gamma^{(pj)}}\{b_\beta^{(pi)}, \overline{\mathbf{H}}_{\alpha\gamma}\}$$
$$=\sum_{\alpha,\beta,\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}\{\mathbf{H}_{\beta\gamma} b_\gamma^{(pi)}, \overline{b_\alpha^{(pj)}}\}$$
$$-\sum_{\alpha,\beta,\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}\{b_\beta^{(pi)}, \overline{\mathbf{H}}_{\alpha\gamma}\overline{b_\gamma^{(pj)}}\}-\sum_{\alpha,\beta,\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}\mathbf{H}_{\beta\gamma}\{b_\gamma^{(pi)}, \overline{b_\alpha^{(pj)}}\}$$
$$+\sum_{\alpha,\beta,\gamma} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}\overline{\mathbf{H}}_{\alpha\gamma}\{b_\beta^{(pi)}, \overline{b_\gamma^{(pj)}}\}$$
$$=\sum_{\alpha,\beta} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}\{\lambda_p b_\beta^{(pi)}, \overline{b_\alpha^{(pj)}}\}-\sum_{\alpha,\beta} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}\{b_\beta^{(pi)}, \lambda_p\overline{b_\alpha^{(pj)}}\}$$
$$-\sum_{\alpha,\gamma}\lambda_p c_\alpha^{(pm)}\overline{c_\gamma^{(pl)}}\{b_\gamma^{(pi)}, \overline{b_\alpha^{(pj)}}\}+\sum_{\beta,\gamma}\lambda_p c_\gamma^{(pm)}\overline{c_\beta^{(pl)}}\{b_\beta^{(pi)}, \overline{b_\gamma^{(pj)}}\}$$

$$=\sum_{\alpha,\beta} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}}b_\beta^{(pi)}\{\lambda_p,\overline{b_\beta^{(pj)}}\}-\sum_{\alpha,\beta} c_\alpha^{(pm)}\overline{c_\beta^{(pl)}b_\alpha^{(pj)}}\{b_\beta^{(pi)},\lambda_p\}$$

$$=\sum_\alpha c_p^{(pm)}\{\lambda_p,\overline{b_\alpha^{(pj)}}\}\delta_{il}f_l^{(p)}-\sum_\beta \overline{c_\beta^{(pl)}}\{b_\beta^{(pi)},\lambda_p\}\delta_{mj}\overline{f_m^{(p)}}.$$

Therefore

$$-\frac{1}{2}\sum_{i,j} a_{i,j}^{(p)}\langle \mathbf{C}_{lm}^{(p)},\{\mathbf{H}\otimes\mathbf{B}_{ij}^{(p)}\}-\{\mathbf{B}_{ij}^{(p)}\otimes\mathbf{H}^*\}\rangle$$

$$=\frac{1}{2}\sum_j a_{lj}^{(p)}\left(\sum_{\alpha,\gamma} c_\alpha^{(pm)}\{\overline{b_\gamma^{(pj)}},\overline{\mathbf{H}}_{\alpha\gamma}\}-\sum_\alpha c_\alpha^{(pm)}\{\lambda_p,\overline{b_\alpha^{(pj)}}\}\right)f_l^{(p)}$$

$$-\frac{1}{2}\sum_i\left(\sum_{\beta,\gamma}\overline{c_\beta^{(pl)}}\{\mathbf{H}_{\beta\gamma},b_\gamma^{(pi)}\}-\sum_\beta\overline{c_\beta^{(pl)}}\{b_\beta^{(pi)},\lambda_p\}\right)a_{im}^{(p)}\overline{f_m^{(p)}}$$

$$=((A^{(p)}M)_{lm}-(M^*\cdot A^{(p)})_{lm})f_l^{(p)}\overline{f_m^{(p)}},$$

where

$$M^{(p)}=(M_{lm}^{(p)}),$$

$$M_{lm}^{(p)}=\frac{1}{2}\sum_\alpha \frac{c_\alpha^{(pm)}}{\overline{f_m^{(p)}}}\left(\sum_\gamma\{\overline{b_\gamma^{(pl)}},\overline{H}_{\alpha\gamma}\}-\{\lambda_p,\overline{b_\alpha^{(pl)}}\}\right).$$

Thus we have

$$\frac{\partial A^{(p)}}{\partial t}-\{\lambda_p,A^{(p)}\}+A^{(p)}M^{(p)}-M^{(p)*}A^{(p)}=0 \tag{60}$$

and the proof is complete.

B. The vector Schrödinger equations with small random perturbations

Let $\mathbf{V}(x,k)$ be a real matrix valued random function in phase space with mean zero. Suppose that it is stationary in x. We denote the correlation functions by

$$R_{\alpha\beta\lambda\delta}(y-x,k,k')=\langle V_{\alpha\beta}(x,k)V_{\lambda\delta}(y,k')\rangle, \tag{61}$$

which are assumed to be homogeneous in space. It is easy to see that

$$R_{\alpha\beta\lambda\delta}(x,k,k')=R_{\lambda\delta\alpha\beta}(-x,k,k').$$

Denote $\mathcal{F}_1R_{\alpha\beta\lambda\delta}(q,k,k')$ as the Fourier transform of $R_{\alpha\beta\lambda\delta}(x,k,k')$ in x, we have

$$\langle\mathcal{F}_1V_{\alpha\beta}(q,k)\mathcal{F}_1V_{\lambda\delta}(q',k')\rangle=\mathcal{F}_1R_{\alpha\beta\lambda\delta}(q,k,k')\delta(q+q'). \tag{62}$$

We also assume that for any α, β, λ, δ, and all k,k'

$$\operatorname{Im}\mathcal{F}_1R_{\alpha\beta\lambda\delta}(q,k,k')=0,$$

which is equivalent to say that the correlation functions is even in x. Then we have the following symmetry

$$R_{\alpha\beta\lambda\delta}(x,k,k')=R_{\lambda\delta\alpha\beta}(x,k,k')$$

and

$$\mathcal{F}_1 R_{\alpha\beta\lambda\delta}(q,k,k')=\mathcal{F}_1 R_{\lambda\delta\alpha\beta}(q,k,k'). \tag{63}$$

Consider the scaled Wigner distribution matrix

$$\mathbf{W}^{\varepsilon}(t,x,k)=\frac{1}{\varepsilon^n}\mathbf{W}(\mathbf{U}^{\varepsilon}(t),\mathbf{U}^{\varepsilon}(t))\left(x,\frac{k}{\varepsilon}\right), \tag{64}$$

where $\mathbf{U}^{\epsilon}(t)$ be the solution of the following system of equations

$$i\frac{\partial \mathbf{U}^{\epsilon}(t,x)}{\partial t}=\left(\mathbf{H}(x,\epsilon D)+\sqrt{\epsilon}\mathbf{V}\left(\frac{1}{\epsilon}x,\epsilon D\right)\right)\mathbf{U}^{\epsilon}(t,x)$$

$$\mathbf{U}^{\epsilon}(0,x)=\varphi(x). \tag{65}$$

Let $\xi=x/\epsilon$ be the fast space variable and rewrite $\mathbf{W}^{\epsilon}(t,x,k)=\mathbf{W}^{\epsilon}(t,x,x/\epsilon,k)$ by $\mathbf{W}^{\epsilon}(t,x,\xi,k)$, we obtain the equation

$$\begin{aligned}
i\frac{\partial \mathbf{W}^{\varepsilon}(t,x,\xi,k)}{\partial t}=&\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\frac{1}{\epsilon}\left[\hat{\mathbf{H}}(q,p)\mathbf{W}^{\epsilon}\left(t,x+\frac{\varepsilon}{2}p,\xi+\frac{p}{2},k-\frac{\varepsilon}{2}q\right)\right.\\
&\left.-\mathbf{W}^{\epsilon}\left(t,x-\frac{\varepsilon}{2}p,\xi-\frac{p}{2},k+\frac{\varepsilon}{2}q\right)\widehat{\mathbf{H}^*}(q,p)\right]dq\,dp\\
&+\frac{1}{(2\pi)^n}\int e^{i(\xi\cdot q+k\cdot p)}\frac{1}{\sqrt{\epsilon}}\left[\hat{\mathbf{V}}(q,p)\mathbf{W}^{\epsilon}\left(t,x+\frac{\varepsilon}{2}p,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right.\\
&\left.-\mathbf{W}^{\epsilon}\left(t,x-\frac{\varepsilon}{2}p,\xi-\frac{p}{2},k+\frac{q}{2}\right)\hat{\mathbf{V}}^t(q,p)\right]dq\,dp,
\end{aligned} \tag{66}$$

where $\widehat{\mathbf{H}^*}$ is the Fourier transform of $\mathbf{H}^*=\overline{\mathbf{H}}^t$. Consider the formal expansion

$$\mathbf{W}^{\varepsilon}(t,x,\xi,k)=\mathbf{W}^{(0)}(t,x,k)+\sqrt{\epsilon}\mathbf{W}^{(1)}(t,x,\xi,k)+\epsilon\mathbf{W}^{(2)}(t,x,\xi,k)+\cdots.$$

We assume that the leading term does not depend on the fast variable and it is deterministic. We have, as before, at order ϵ^{-1},

$$\mathbf{W}^{(0)}(t,x,k)\in\ker\mathcal{L},$$

where $\mathcal{L}$ is defined by (42). At order $\epsilon^{-1/2}$,

$$\begin{aligned}
&\frac{1}{(2\pi)^n}\int e^{i(x\cdot q+k\cdot p)}\left[\hat{\mathbf{H}}(q,p)\mathbf{W}^{(1)}\left(t,x,\xi+\frac{p}{2},k\right)-\mathbf{W}^{(1)}\left(t,x,\xi-\frac{p}{2},k\right)\widehat{\mathbf{H}^*}(q,p)\right]dq\,dp\\
&\quad+\frac{1}{(2\pi)^n}\int e^{i(\xi\cdot q+k\cdot p)}\left[\hat{\mathbf{V}}(q,p)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right)-\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\hat{\mathbf{V}}^t(q,p)\right]dq\,dp=0.
\end{aligned} \tag{67}$$

At order ϵ^0, we have

$$\begin{aligned}
&\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{i}{2}\{\mathbf{H}\otimes \mathbf{W}^{(0)}(t)\}+\frac{i}{2}\{\mathbf{W}^{(0)}(t)\otimes \mathbf{H}^*\}\\
&\quad=\frac{1}{(2\pi)^n}\int e^{i(xq+kp)}\left[\hat{\mathbf{H}}(q,p)\mathbf{W}^{(2)}\left(t,x,\xi+\frac{p}{2},k\right)-\mathbf{W}^{(2)}\left(t,x,\xi-\frac{p}{2},k\right)\hat{\mathbf{H}}^*(q,p)\right]dq\,dp\\
&\qquad+\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\left[\hat{\mathbf{V}}(q,p)\mathbf{W}^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right.\\
&\qquad\left.-\mathbf{W}^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\hat{\mathbf{V}}^t(q,p)\right]dq\,dp. \qquad (68)
\end{aligned}$$

Similarly, from ergodicity, we have

$$\left\langle \frac{\partial \mathbf{W}^{(2)}(t,x,\xi,k)}{\partial \xi}\right\rangle=0.$$

Averaging (68), we get

$$\begin{aligned}
&i\left(\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{1}{2}\{\mathbf{H}\otimes \mathbf{W}^{(0)}(t)\}+\frac{1}{2}\{\mathbf{W}^{(0)}(t)\otimes \mathbf{H}^*\}\right)\\
&\quad-\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\left\langle \hat{\mathbf{V}}(q,p)\mathbf{W}^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right\rangle dq\,dp\\
&\quad+\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\left\langle \mathbf{W}^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\mathbf{V}^t(q,p)\right\rangle dq\,dp\\
&\quad=\mathcal{L}(x,k)\langle \mathbf{W}^{(2)}(t,x,\xi,k)\rangle\in \mathrm{Im}\,\mathcal{L}(x,k). \qquad (69)
\end{aligned}$$

Again, we want to express $\mathbf{W}^{(1)}(t)$ in terms of $\mathbf{W}^{(0)}(t)$, then insert it into the above equation and take the inner product with the generators of $\ker \mathcal{L}^*$. Denote $\mathbf{F}(t,x,q,k)$ as the Fourier transform of $\mathbf{W}^{(1)}(t,x,\xi,k)$ in fast space variable ξ, i.e.,

$$\mathbf{W}^{(1)}(t,x,\xi,k)=\frac{1}{(2\pi)^{n/2}}\int e^{i\xi q'}\mathcal{F}(t,x,q',k)dq',$$

we have from (67)

$$\begin{aligned}
&\frac{1}{(2\pi)^{n/2}}\int e^{i(x\cdot q+k\cdot p)+i(\xi+p/2)q'}\hat{\mathbf{H}}(q,p)\mathbf{F}(t,x,q',k)dq'\,dq\,dp\\
&\quad-\frac{1}{(2\pi)^{n/2}}\int e^{i(x\cdot q+k\cdot p)+i(\xi-p/2)q'}\mathbf{F}(t,x,q',k)\hat{\mathbf{H}}^*(q,p)dq'\,dq\,dp\\
&\quad+\int e^{i(\xi\cdot q+k\cdot p)}\left[\hat{\mathbf{V}}(q,p)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right)-\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\hat{\mathbf{V}}^t(q,p)\right]dq\,dp=0,
\end{aligned}$$

$$\int e^{i\xi\cdot q'}\mathbf{H}\left(x,k+\frac{q'}{2}\right)\mathbf{F}(t,x,q',k)dq'-\int e^{i\xi\cdot q'}\mathbf{F}(t,x,q',k)\mathbf{H}^*\left(x,k-\frac{q'}{2}\right)dq'$$
$$+\frac{1}{(2\pi)^{n/2}}\int e^{i(\xi\cdot q+k\cdot p)}\hat{\mathbf{V}}(q,p)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right)dq\,dp$$
$$-\frac{1}{(2\pi)^{n/2}}\int e^{i(\xi\cdot q+k\cdot p)}\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\hat{\mathbf{V}}^t(q,p)dq\,dp=0.$$

Take Fourier inverse transform in ξ, we have

$$\mathbf{H}\left(x,k+\frac{q}{2}\right)\mathbf{F}(t,x,q,k)-\mathbf{F}(t,x,q,k)\mathbf{H}^*\left(x,k-\frac{q}{2}\right)$$
$$+\mathcal{F}_1\mathbf{V}(q,k)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right)-\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}^t(q,k)=0.$$

1. Distinct eigenvalue case

Since $\{\mathbf{B}^{(j)}(x,k),j=1,...,n\}$ [defined as in (43)] spans the space $\ker\mathcal{L}(x,k)$, we write

$$\mathbf{W}^{(0)}(t,x,k)=a_s(t,x,k)\mathbf{B}^{(s)}(x,k).$$

In this case, we define

$$\mathbf{E}^{(s,t)}(x,q,k)=b^{(s)}\left(x,k+\frac{q}{2}\right)b^{(t)*}\left(x,k-\frac{q}{2}\right),$$

and

$$\mathbf{D}^{(s,t)}(x,q,k)=c^{(s)}\left(x,k+\frac{q}{2}\right)c^{(t)*}\left(x,k-\frac{q}{2}\right).$$

The matrices $\mathbf{E}^{(s,t)}$ and $\mathbf{D}^{(s,t)}$ satisfy the bi-orthogonal relations

$$\langle\mathbf{D}^{(r,s)},\mathbf{E}^{(m,n)}\rangle=\delta_{m,r}\delta_{n,s}f_m\left(x,k+\frac{q}{2}\right)\overline{f_n}\left(x,k-\frac{q}{2}\right),$$

and for every fixed x,q,k, the set $\{\mathbf{E}^{(s,t)}(x,q,k),1\leqslant s,t\leqslant n\}$ spans the matrix space $\mathrm{Mat}_n(C)$. Thus let

$$\mathbf{F}(t,x,q,k)=\sum_{i,j}F^{(i,j)}(t,x,q,k)\mathbf{E}^{(i,j)}(x,q,k).$$

We have

$$F^{(i,j)}(t,x,q,k)\left(\mathbf{H}\left(x,k+\frac{q}{2}\right)\mathbf{E}^{(i,j)}(x,q,k)-\mathbf{E}^{(i,j)}(x,q,k)\mathbf{H}^*\left(x,k-\frac{q}{2}\right)\right)$$
$$=\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}^t(q,k)-\mathcal{F}_1\mathbf{V}(q,k)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right),$$

$$F^{(i,j)}(t,x,q,k)\left(\lambda_i\left(x,k+\frac{q}{2}\right)-\lambda_j\left(x,k-\frac{q}{2}\right)\right)\mathbf{E}^{(i,j)}(x,q,k)$$
$$=\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}^t(q,k)-\mathcal{F}_1\mathbf{V}(q,k)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right).$$

Multiplying by $\mathbf{D}^{(s,r)}(x,q,k)$, we obtain

$$F^{(s,r)}(t,x,q,k)\left(\lambda_s\left(x,k+\frac{q}{2}\right)-\lambda_r\left(x,k-\frac{q}{2}\right)\right)f_s\left(x,k+\frac{q}{2}\right)\overline{f_r}\left(x,k-\frac{q}{2}\right)$$
$$=\left\langle\mathbf{D}^{(s,r)}(x,q,k),\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}^t(q,k)-\mathcal{F}_1\mathbf{V}(q,k)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right)\right\rangle$$

and

$$\mathbf{F}(t,x,q,k))=\frac{\left\langle\mathbf{D}^{(s,r)}(x,q,k),\mathbf{W}^{(0)}\left(t,x,k+\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}^t(q,k)-\mathcal{F}_1\mathbf{V}(q,k)\mathbf{W}^{(0)}\left(t,x,k-\frac{q}{2}\right)\right\rangle}{\left(\lambda_s\left(x,k+\frac{q}{2}\right)-\lambda_r\left(x,k-\frac{q}{2}\right)+i\theta\right)f_s\left(x,k+\frac{q}{2}\right)\overline{f_r}\left(x,k-\frac{q}{2}\right)}$$
$$\times\mathbf{E}^{(s,r)}(x,q,k),$$

where the term $i\theta$ is a regularization term, eventually we will let $\theta\to 0$. Insert into the expansion

$$\mathbf{W}^{(0)}(t,x,k)=a_s(t,x,k)\mathbf{B}^{(s)}(x,k),$$

we get

$$F^{(s,r)}(t,x,q,k)=\frac{1}{\lambda_r\left(x,k-\frac{q}{2}\right)-\lambda_s\left(x,k+\frac{q}{2}\right)+i\theta}$$
$$\cdot\left\{\frac{a_r\left(t,x,k-\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}_{\alpha\beta}(q,k)b_\beta^{(r)}\left(x,k-\frac{q}{2}\right)\overline{c_\alpha^{(s)}}\left(x,k+\frac{q}{2}\right)}{f_s\left(x,k+\frac{q}{2}\right)}\right.$$
$$\left.-\frac{a_s\left(t,x,k+\frac{q}{2}\right)\mathcal{F}_1\mathbf{V}_{\beta\alpha}^t(q,k)c_\alpha^{(r)}\left(x,k-\frac{q}{2}\right)\overline{b_\beta^{(s)}}\left(x,k+\frac{q}{2}\right)}{\overline{f_r}\left(x,k-\frac{q}{2}\right)}\right\}.$$

Let

$$I_1=\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\left\langle\hat{\mathbf{V}}(q,p)\mathbf{W}^{(1)}\left(t,x,\xi+\frac{p}{2},k-\frac{q}{2}\right)\right\rangle dq\,dp,$$

$$I_2=\frac{1}{(2\pi)^n}\int e^{i(\xi q+kp)}\left\langle\mathbf{W}^{(1)}\left(t,x,\xi-\frac{p}{2},k+\frac{q}{2}\right)\hat{\mathbf{V}}^t(q,p)\right\rangle dq\,dp.$$

From Eq. (69), we have

$$\left\langle \mathbf{C}^{(r)}(x,k), i\left(\frac{\partial \mathbf{W}^{(0)}(t,x,k)}{\partial t} - \frac{1}{2}\{\mathbf{H}^* \circledS \mathbf{W}^{(0)}(t)\}(x,k) + \frac{1}{2}\{\mathbf{W}^{(0)}(t) \circledS \mathbf{H}^*\} \right) \right\rangle$$
$$= \langle \mathbf{C}^{(r)}(x,k), I_1\rangle - \langle \mathbf{C}^{(r)}(x,k), I_2\rangle. \tag{70}$$

From the last subsection, we know that for appropriate normalized eigenvectors $b^{(m)}(x,k)$, the left-hand side of (70) is

$$i\left(\frac{\partial a_s(t,x,k)}{\partial t} - \{\lambda_s, a_s\}(x,k) \right) \delta_{rs} |f_r(x,k)|^2.$$

Thus, we only need to calculate $\langle \mathbf{C}^{(r)}, I_1\rangle$ and $\langle \mathbf{C}^{(r)}, I_2\rangle$

$$I_1 = \frac{1}{(2\pi)^{3n/2}} \int e^{i(\xi q + kp) + i(\xi + p/2)q'} \left\langle \hat{\mathbf{V}}(q,p) \mathbf{F}\left(t,x,q',k - \frac{q}{2} \right) \right\rangle dq'\, dq\, dp$$
$$= \frac{1}{(2\pi)^n} \int e^{i\xi(q+q')} \sum_{l,m} \left\langle F^{(l,m)}\left(t,x,q',k-\frac{q}{2}\right) \mathcal{F}_1 \mathbf{V}\left(q, k + \frac{q'}{2}\right) \right\rangle \mathbf{E}^{(l,m)}\left(x,q',k-\frac{q}{2}\right) dq'\, dq.$$

$\langle \mathbf{C}^{(r)}, I_1\rangle$

$$= \frac{1}{(2\pi)^n} \int e^{i\xi(q+q')} \sum_{l,m} \mathbf{C}^{(r)}_{\alpha\beta}(x,k)$$
$$\cdot \left\langle F^{(l,m)}\left(t,x,q',k-\frac{q}{2}\right) \mathcal{F}_1 \mathbf{V}_{\beta\delta}\left(q,k+\frac{q'}{2}\right) \right\rangle \mathbf{E}^{(l,m)}_{\delta\alpha}\left(x,q',k-\frac{q}{2}\right) dq'\, dq$$
$$= \frac{1}{(2\pi)^n} \sum_{l,m} \int e^{i\xi(q+q')} \frac{\mathbf{C}^{(r)}_{\alpha\beta}(x,k) \mathbf{E}^{(l,m)}_{\delta\alpha}\left(x,q',k-\frac{q}{2}\right) \delta(q+q')}{\lambda_m\left(x,k-\frac{q}{2}-\frac{q'}{2}\right) - \lambda_l\left(x,k-\frac{q}{2}+\frac{q'}{2}\right) + i\theta}$$
$$\cdot \left\{ \frac{a_m\left(t,x,k-\frac{q}{2}-\frac{q'}{2}\right) \mathcal{F}_1 \mathbf{R}_{\alpha'\beta'\beta\delta}\left(q,k-\frac{q}{2},k+\frac{q'}{2}\right) b^{(m)}_{\beta'}\left(x,k-\frac{q}{2}-\frac{q'}{2}\right) \overline{c^{(l)}_{\alpha'}}\left(x,k-\frac{q}{2}+\frac{q'}{2}\right)}{f_l\left(x,k-\frac{q}{2}+\frac{q'}{2}\right)} \right.$$
$$\left. - \frac{a_l\left(t,x,k-\frac{q}{2}+\frac{q'}{2}\right) \mathcal{F}_1 \mathbf{R}_{\beta'\alpha'\beta\delta}\left(q,k-\frac{q}{2},k+\frac{q}{2}\right) c^{(m)}_{\alpha'}\left(x,k-\frac{q}{2}-\frac{q'}{2}\right) \overline{b^{(l)}_{\beta'}}\left(t,k-\frac{q}{2}+\frac{q'}{2}\right)}{\overline{f_m}\left(x,k-\frac{q}{2}-\frac{q'}{2}\right)} \right\}$$
$$\times dq\, dq'$$
$$= \sum_{lm} \int \frac{c^{(r)}_{\alpha}(x,k) \overline{c^{(r)}_{\beta}}(x,k) b^{(l)}_{\delta}(x,k-q) \overline{b^{(m)}_{\alpha}}(x,k)}{\lambda_m(x,k) - \lambda_l(x,k-q) + i\theta}$$

$$\cdot\left\{\frac{a_m(t,x,k)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q,k-\frac{q}{2},k-\frac{q}{2}\right)b_{\beta}^{(m)}(x,k)\overline{c_{\alpha'}^{(l)}}(x,k-q)}{f_l(x,k-q)}\right.$$

$$\left.-\frac{a_l(t,x,k-q)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q,k-\frac{q}{2},k-\frac{q}{2}\right)c_{\alpha'}^{(m)}(x,k)\overline{b_{\beta'}^{(l)}}(t,k-q)}{\overline{f_m}(x,k)}\right\}dq$$

$$=\sum_l\int\frac{\overline{f_r}(x,k)\overline{c_{\beta}^{(r)}}(x,k)b_{\delta}^{(l)}(x,q)}{\lambda_r(x,k)-\lambda_l(x,q)+i\theta}$$

$$\cdot\left\{\frac{a_r(t,x,k)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)b_{\beta'}^{(r)}(x,k)\overline{c_{\alpha'}^{(l)}}(x,q)}{f_l(x,q)}\right.$$

$$\times c_{\alpha'}^{(r)}(x,k)\overline{b_{\beta'}^{(l)}}(x,q)\overline{c_\beta^{(r)}}(x,k)b_\delta^{(l)}(x,q)dq,$$

where we have used the symmetric property (63) for $\mathcal{F}_1R$ in the last equality. Therefore,

$$\langle\mathbf{C}^{(r)},I_1\rangle-\langle\mathbf{C}^{(r)},I_2\rangle=\sum_l \int a_r(t,x,k)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)\mathrm{Re}\left[\frac{f_r(x,k)}{\overline{f_l}(x,q)}c_{\alpha'}^{(l)}(x,q)\overline{b_{\beta'}^{(r)}}\right.$$

$$\left.\times(x,k)c_\beta^{(r)}(x,k)\overline{b_\delta^{(l)}}(x,k)\right]\frac{2i\theta}{(\lambda_r(x,k)-\lambda_l(x,q))^2+\theta^2}dq$$

$$-i\sum_l \int a_r(t,x,k)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)\mathrm{Im}\left[\frac{f_r(x,k)}{\overline{f_l}(x,q)}c_{\alpha'}^{(l)}\right.$$

$$\left.\times(x,q)\overline{b_{\beta'}^{(r)}}(x,k)c_\beta^{(r)}(x,k)\overline{b_\delta^{(l)}}(x,k)\right]\frac{2(\lambda_r(x,k)-\lambda_l(x,q))}{(\lambda_r(x,k)-\lambda_l(x,q))^2+\theta^2}dq$$

$$-\sum_l \int a_l(t,x,q)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)c_{\alpha'}^{(r)}(x,k)\overline{b_{\beta'}^{(l)}}(x,q)\overline{c_\beta^{(r)}}$$

$$\times(x,k)b_\delta^{(l)}(x,k)\frac{2i\theta}{(\lambda_r(x,k)-\lambda_l(x,q))^2+\theta^2}dq,$$

as $\theta\to 0,\ \theta/y^2+\pi^2\to\pi\delta(y),$ we have

$$\langle\mathbf{C}^{(r)},I_1\rangle-\langle\mathbf{C}^{(r)},I_2\rangle\to 2\pi i\sum_l \int a_r(t,x,k)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)$$

$$\cdot\mathrm{Re}\left[\frac{f_r(x,k)}{\overline{f_l}(x,q)}c_{\alpha'}^{(l)}(x,q)\overline{b_{\beta'}^{(r)}}(x,k)c_\beta^{(r)}(x,k)\overline{b_\delta^{(l)}}(x,k)\right]\delta(\lambda_r(x,k)$$

$$-\lambda_l(x,q))dq-2i\sum_l \int a_r(t,x,k)\frac{\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)}{\lambda_r(x,k)-\lambda_l(x,q)}$$

$$\cdot\mathrm{Im}\left[\frac{f_r(x,k)}{\overline{f_l}(x,q)}c_{\alpha'}^{(l)}(x,q)\overline{b_{\beta'}^{(r)}}(x,k)c_\beta^{(r)}(x,k)\overline{b_\delta^{(l)}}(x,k)\right]dq$$

$$-2\pi i\sum_l \int a_l(t,x,q)\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)\cdot c_{\alpha'}^{(r)}(x,k)\overline{b_{\beta'}^{(l)}}$$

$$\times(x,q)\overline{c_{\beta}^{(r)}}(x,k)b_{\delta}^{(l)}(x,q)\,\delta(\lambda_r(x,k)-\lambda_l(x,k))dq,$$

where the integration over terms involving $1/(\lambda_r(x,k)-\lambda_l(x,q))$ is in certain principal value sense when singularity occurs. Let

$$\sigma_{rl}(x,k,q)=2\pi\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)\frac{c_{\alpha'}^{(r)}(x,k)\overline{b_{\beta'}^{(l)}}(x,q)\overline{c_{\beta}^{(r)}}(x,k)b_{\delta}^{(l)}(x,q)}{|f_r(x,k)|^2}$$
$$\cdot\,\delta(\lambda_l(x,q)-\lambda_r(x,k))$$

$$\Sigma_r=2\pi\int\sum_l\ \mathrm{Re}\left[\frac{c_{\alpha'}^{(l)}(x,q)\overline{b_{\beta'}^{(r)}}(x,k)c_{\beta}^{(r)}(x,k)\overline{b_{\delta}^{(l)}}(x,q)}{\overline{f_l}(x,q)\overline{f_r}(x,k)}\right]$$
$$\cdot\,\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)\delta(\lambda_l(x,q)-\lambda_r(x,k))dq$$

$$-2\int\sum_l\ \mathrm{Im}\left[\frac{c_{\alpha'}^{(l)}(x,q)\overline{b_{\beta'}^{(r)}}(x,k)c_{\beta}^{(r)}(x,k)\overline{b_{\delta}^{(l)}}(x,q)}{\overline{f_l}(x,q)\overline{f_r}(x,k)}\right]\frac{\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\beta\delta}\left(q-k,\frac{k+q}{2},\frac{k+q}{2}\right)}{\lambda_l(x,q)-\lambda_r(x,k)}dq,$$

then we have the following proposition:

Proposition 9: The transport equations for the coefficients a_r are

$$\frac{\partial a_r(t,x,k)}{\partial t}+\{a_r(t),\lambda_r\}(x,k)=\int\sigma_{rj}(x,k,q)a_j(t,x,q)dq-\Sigma_r a_r(t,x,k). \tag{71}$$

2. Multiple eigenvalue case

Now we turn to the multiple eigenvalue case. In this case, we define the matrices

$$E_{l,m}^{(s,r)}(x,q,k)=b^{(sl)}\left(x,k+\frac{q}{2}\right)b^{(rm)*}\left(x,k-\frac{q}{2}\right)$$

$$D_{l,m}^{(s,r)}(x,q,k)=c^{(sl)}\left(x,k+\frac{q}{2}\right)c^{(rm)*}\left(x,k-\frac{q}{2}\right).$$

The matrices $E_{l,m}^{(s,r)}$ and $D_{l,m}^{(s,r)}$ satisfy the following double bi-orthogonal relations

$$\langle D_{l,m}^{(s,r)},E_{p,t}^{(s,r)}\rangle=\delta_{sp}\delta_{rt}\delta_{li}\delta_{mj}f_l^{(s)}\left(x,k+\frac{q}{2}\right)\overline{f_m^{(r)}}\left(x,k-\frac{q}{2}\right),$$

where

$$(c^{(sl)}(x,k),b^{(sl)}(x,k))=f_l^{(s)}(x,k).$$

For every fixed x,q,k, the set of all $E_{l,m}^{(s,r)}(x,q,k)$ spans the space $\mathrm{Mat}_n(\mathbf{C})$. This allows us to express $\mathbf{F}$ as $\mathbf{F}=\Sigma F_{l,m}^{(s,r)}E_{l,m}^{(s,r)}$ where $\mathbf{F}$ is the Fourier transform of $W^{(1)}$ in fast variable ξ. Similar to the calculations in the case of distinct eigenvalue, we have from (67) and the expansion

$$W^{(0)}=\sum a_{ij}^{s}\mathbf{B}_{ij}^{s}. \tag{72}$$

The coefficients of $\mathbf{F}$ in the basis of $\{E_{l,m}^{(s,r)}\}$ are

$$F_{l,m}^{(s,r)}(t,q,k)=\frac{1}{\lambda_s\left(k+\frac{q}{2}\right)-\lambda_r\left(k-\frac{q}{2}\right)+i\theta}$$

$$\times\left\{\sum_j \frac{\alpha_{lj}^{(s)}\left(t,k+\frac{q}{2}\right)}{\overline{f_m^{(r)}}\left(k-\frac{q}{2}\right)}\mathcal{F}_1 V_{\alpha\beta}(q,k)c_\alpha^{(rm)}\left(k-\frac{q}{2}\right)\overline{b_\beta^{(sj)}}\left(k+\frac{q}{2}\right)\right.$$

$$\left.-\sum_j \frac{\alpha_{jm}^{(r)}\left(t,k-\frac{q}{2}\right)}{f_l^{(s)}\left(k+\frac{q}{2}\right)}\mathcal{F}_1 V_{\alpha\beta}(q,k)\overline{c_r^{(sl)}}\left(k+\frac{q}{2}\right)b_\beta^{(rj)}\left(k-\frac{q}{2}\right)\right\}. \tag{73}$$

From (69), we have

$$\left\langle \mathbf{C}_{lm}^{(p)},i\left(\frac{\partial \mathbf{W}^{(0)}(t)}{\partial t}-\frac{1}{2}\{\mathbf{H}\otimes \mathbf{W}^{(0)}(t)\}+\frac{1}{2}\{\mathbf{W}^{(0)}(t)\otimes \mathbf{H}^*\}\right)\right\rangle=\langle \mathbf{C}_{lm}^{(p)},I_1\rangle-\langle \mathbf{C}_{lm}^{(p)},I_2\rangle. \tag{74}$$

From the last section, we know that the left-hand side of the above equation is

$$i\left(\frac{\partial A^{(p)}}{\partial t}-\{\lambda_p,A^{(p)}\}+A^{(p)}M^{(p)}-M^{(p)*}A^{(p)}\right)f_l^{(p)}\overline{f_m^{(p)}}. \tag{75}$$

Thus, we only need to calculate $\langle \mathbf{C}_{lm}^{(p)},I_1\rangle$ and $\langle \mathbf{C}_{lm}^{(p)},I_2\rangle$. After some tedious calculations, we have

$$\langle \mathbf{C}_{lm}^{(p)},I_1\rangle=\int\sum_{s,j}\frac{\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\alpha\beta}\left(q,\frac{k+q}{2},\frac{k+q}{2}\right)}{\lambda_s(q)-\lambda_p(k)+i\theta}\left(\sum_h a_{jh}^{(s)}(q)c_{\alpha'}^{(pm)}(k)\overline{b_{\beta'}^{(sh)}}(q)\overline{c_\alpha^{(pl)}}(k)b_\beta^{(sj)}(q)\right.$$

$$\left.-\sum_n a_{n,m}^{(p)}(k)\frac{\overline{f_m^{(p)}}(k)}{f_j^{(s)}(q)}\overline{c_{\alpha'}^{(sj)}}(q)b_{\beta'}^{(pn)}(k)\overline{c_\alpha^{(pl)}}(k)b_\beta^{(sj)}(q)\right)dq \tag{76}$$

and

$$\langle \mathbf{C}_{lm}^{(p)},I_2\rangle=\int\sum_{s,j}\frac{\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\alpha\beta}\left(q,\frac{k+q}{2},\frac{k+q}{2}\right)}{\lambda_s(q)-\lambda_p(k)-i\theta}\left(\sum_h a_{jh}^{(s)}(q)c_{\alpha'}^{(pm)}(k)\overline{b_{\beta'}^{(sh)}}(q)\overline{c_\alpha^{(pl)}}(k)b_\beta^{(sj)}(q)\right.$$

$$\left.-\sum_n a_{l,n}^{(p)}(k)\frac{f_l^{(p)}(k)}{\overline{f_j^{(s)}}(q)}c_{\alpha'}^{(sj)}(q)\overline{b_{\beta'}^{(pn)}}(k)c_\alpha^{(pm)}(k)\overline{b_\beta^{(sj)}}(q)\right)dq. \tag{77}$$

On the right-hand side of the above equations, the sum over s runs all eigenvalues λ_s,j runs from 1 to multiplicity of λ_s,n runs from 1 to multiplicity of λ_p. From (74), (75), (76), and (77), we have

Proposition 10: The coherence matrices $A^{(p)}(t,x,k)$ satisfy the following Liouville type transport equation:

$$\frac{\partial A^{(p)}(t)}{\partial t}+\{A^{(p)}(t),\lambda_p\}+A^{(p)}(t)M^{(p)}-M^{(p)*}A^{(p)}(t)$$
$$=2\pi\int\sum_s \sigma^{(p,s)}(A^{(s)}(t))dq+i(\Sigma^{(p)}A^{(p)}-A^{(p)}\Sigma^{(p)})-\Lambda^{(p)}\,\mathrm{diag}\,A^{(p)}, \tag{78}$$

where

$$\sigma^{(p,s)}(A^{(s)}(t))=\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\alpha\beta}\left(q,\frac{k+q}{2},\frac{k+q}{2}\right)\sigma^{(p)}_{\alpha\alpha'}(k)\langle\sigma^{(s)}_{\beta\beta'}(q),A^{(s)}(t,q)\rangle,$$

in which the matrices are

$$\sigma^{(s)}_{\beta\beta'}(q)=(\sigma^{(s)}_{\beta\beta',jh}(q))\quad\text{with}\quad\sigma^{(s)}_{\beta\beta',jh}(q)=\overline{b^{(sj)}_{\beta}}(q)b^{(sh)}_{\beta'}(q),$$

$$\sigma^{(p)}_{\alpha\alpha'}(k)=(\sigma^{(p)}_{\alpha\alpha',lm}(k))\quad\text{with}\quad\sigma^{(p)}_{\alpha\alpha',lm}(k)=\frac{c^{(pm)}_{\alpha'}(k)\overline{c^{(pl)}_{\alpha}}(k)}{f^{(p)}_l(k)\overline{f^{(p)}_m}(k)},$$

and where

$$\Sigma^{(p)}(k)=(\Sigma^{(p)}_{lm}(k))\quad\text{with}\quad\Sigma^{(p)}_{lm}(k)$$
$$=\int\sum_{s,j}\frac{\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\alpha\beta}\left(q,\frac{k+q}{2},\frac{k+q}{2}\right)}{\lambda_s(q)-\lambda_p(k)}\,\frac{\overline{c^{(sj)}_{\alpha'}}(q)b^{(pm)}_{\beta'}(k)\overline{c^{(pl)}_{\alpha}}(k)b^{(sj)}_{\beta}(q)}{f^{(p)}_l(k)f^{(s)}_j(q)}\,dq,$$

$$\Lambda^{(p)}(k)=\mathrm{diag}(\tau^{(p)}_1,\ldots,\tau^{(p)}_r)\quad\text{with}\quad\tau^{(p)}_l(k)=2\pi\int\Sigma_{s,j}\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\alpha\beta}\left(q,\frac{k+q}{2},\frac{k+q}{2}\right)$$
$$\cdot\,\mathrm{Re}\left(\frac{\overline{c^{(sj)}_{\alpha'}}(q)b^{(pm)}_{\beta'}(k)\overline{c^{(pl)}_{\alpha}}(k)b^{(sj)}_{\beta}(q)}{f^{(p)}_l(k)f^{(s)}_j(q)}\right)\delta(\lambda_s(q)-\lambda_p(k))dq,$$

$$\mathrm{diag}\,A^{(p)}=\mathrm{diag}(a^{(p)}_{11},\ldots,a^{(p)}_{rr}).$$

In particular,

$$\sigma^{(p,s)}=\mathcal{F}_1\mathbf{R}_{\alpha'\beta'\alpha\beta}\left(q,\frac{k+q}{2},\frac{k+q}{2}\right)\sigma^{(p)}_{\alpha\alpha'}(k)\otimes\sigma^{(s)}_{\beta\beta'}(q),$$

where r is the multiplicity of λ_p.

(Received 22 January 1998; accepted for publication 2 April 1999)

Let $\Omega\subset\mathbb{R}^3$ be a bounded simply connected obstacle with boundary $\partial\Omega$ locally Lipschitz, we consider the scattering of a time harmonic electromagnetic wave that hits Ω when $\partial\Omega$ is assumed to be perfectly conducting. The scattered electromagnetic field is the solution of an exterior boundary value problem for the vector Helmholtz equation. Under suitable hypotheses we prove the existence and uniqueness of the solution of this boundary value problem and we give a new numerical method to compute this solution. The numerical method proposed is based on a perturbative series and is highly parallelizable. Some numerical results obtained with the numerical method proposed on test problems are presented and discussed from the numerical and the physical point of view. © *1999 American Institute of Physics.* [S0022-2488(99)03409-X]

I. INTRODUCTION

Let $\mathbb{R}$ be the set of real numbers, $\mathbb{R}^3$ be the three dimensional real Euclidean space and $\underline{x}=(x_1,x_2,x_3)^T\in\mathbb{R}^3$ be a generic vector, where the superscript T denotes the transposition operation. For $\underline{x},\underline{y},\underline{z}\in\mathbb{R}^3$ we denote with $(\underline{x},\underline{y})$ the Euclidean scalar product of $\underline{x}$ and $\underline{y}$, with $\|\underline{x}\|$ the Euclidean vector norm of $\underline{x}$, with $[\underline{x},\underline{y}]$ the Euclidean vector product of $\underline{x}$ and $\underline{y}$, and with $(\underline{x},\underline{y},\underline{z})$ the usual triple product, that is $(\underline{x},\underline{y},\underline{z})=([\underline{x},\underline{y}],\underline{z})$. Let $\mathbb{C}$ be the set of complex numbers for $z\in\mathbb{C}$ we denote with $\overline{z}$ the complex conjugate of z, with $|z|$ the modulus of z and with $\mathrm{Re}\, z$, $\mathrm{Im}\, z$ the real and imaginary part of z, respectively. Let $\mathbb{C}^3$ be the three-dimensional complex vector space and $\underline{w}=(w_1,w_2,w_3)^T\in\mathbb{C}^3$ be a generic vector. In the following the symbols $(.,.)$, $[.,.]$ will be used also with complex vectors as arguments, in this case we denote, respectively, the real Euclidean product and the real Euclidean vector product of complex vectors. Let $A\subset\mathbb{R}^3$ be an open set, $\overline{A}$ be the closure of A, we denote with A^c the set $A^c=\mathbb{R}^3\backslash\overline{A}$. Let $\Omega\subset\mathbb{R}^3$ be an open bounded simply connected set, we say that Ω is of class $C^{0,1}$ if the boundary of Ω, $\partial\Omega$, is a locally Lipschitz boundary, that is each point $\underline{x}$ on the boundary of Ω has a neighborhood $U_{\underline{x}}$ such that $\partial\Omega\cup U_{\underline{x}}$ is the graph of a Lipschitz continuous function. Let $\underline{n}(\underline{x})$ be the outward unit normal vector to $\partial\Omega$.

[a]Electronic mail: recchioni@posta.econ.unian.it; Tel: +39+71+2207056; Fax: +39+71+2207058.

We note that when Ω is of class $C^{0,1}$ the outward unit normal vector exists almost everywhere on $\partial\Omega$ (see Ref. 1 Lemma 2.4.2 page 88). Let $\underline{g}(\underline{x})=(g_1(\underline{x}),g_2(\underline{x}),g_3(\underline{x}))^T$ be a complex-valued vector field defined on $\partial\Omega$ tangential to $\partial\Omega$, that is such that $(\underline{g}(\underline{x}),\underline{n}(\underline{x}))=0$ almost everywhere for $\underline{x}\in\partial\Omega$. Let $\Omega\in C^{0,1}$ and $\underline{g}(\underline{x})$ be a tangential vector field defined on $\partial\Omega$, we consider the following boundary value problem for the vector Helmholtz equation:

$$(\Delta+k^2)\underline{E}(\underline{x})=\underline{0},\quad \underline{x}\in\Omega^c \tag{1.1}$$

$$\operatorname{div}\underline{E}(\underline{x})=0,\quad \underline{x}\in\Omega^c \tag{1.2}$$

$$[\underline{n},\underline{E}](\underline{x})=\underline{g}(\underline{x}),\quad \underline{x}\in\partial\Omega \tag{1.3}$$

and

$$[\operatorname{curl}\underline{E}(\underline{x}),\hat{\underline{x}}]-ik\underline{E}(\underline{x})=o\left(\frac{1}{\|\underline{x}\|}\right),\quad \|\underline{x}\|\to\infty \tag{1.4}$$

where $\underline{0}=(0,0,0)^T$, $\hat{\underline{x}}=x/\|\underline{x}\|$ for $\underline{x}\neq\underline{0}$, and $o(\cdot)$ is the Landau symbol. The complex constant k is the wave number, later we assume either $\operatorname{Im}k>0$ or $\operatorname{Im}k=0$ and $\operatorname{Re}k>0$. Moreover $\underline{E}(\underline{x})=(E_1(\underline{x}),E_2(\underline{x}),E_3(\underline{x}))^T$, $\operatorname{div}\underline{E}(\underline{x})=\Sigma_{j=1}^3(\partial E_j/\partial x_j)(\underline{x})$, $\Delta(\cdot)=\Sigma_{j=1}^3\partial^2(\cdot)/\partial x_j^2$, $\Delta\underline{E}(\underline{x})=(\Delta E_1(\underline{x}),\Delta E_2(\underline{x}),\Delta E_3(\underline{x}))^T$, and $\operatorname{curl}\underline{E}(\underline{x})=((\partial E_3/\partial x_2)(\underline{x})-(\partial E_2/\partial x_3)(\underline{x}),(\partial E_1/\partial x_3)(\underline{x})-(\partial E_3/\partial x_1)(\underline{x}),(\partial E_2/\partial x_1)(\underline{x})-(\partial E_1/\partial x_2)(\underline{x}))^T$.

We consider a time harmonic electromagnetic field that hits the surface $\partial\Omega$ of the obstacle Ω. Let $\underline{E}^i(\underline{x})$, $\underline{x}\in\Omega^c$, be the part dependent from the spatial coordinates $\underline{x}$ of the incident electric field. In the following we call $\underline{E}^i(\underline{x})$ incident electric field. We assume that the medium that surrounds the obstacle Ω is a homogeneous isotropic medium that does not contain free electric charges, and that the incident electric field $\underline{E}^i$ satisfies (1.1) and (1.2) in $\mathbb{R}^3$. Let $\underline{E}^s(\underline{x})$, $\underline{x}\in\Omega^c$, be the electric field scattered by the perfectly conducting surface $\partial\Omega$ when hit by $\underline{E}^i(\underline{x})$. To be precise $\underline{E}^s(\underline{x})$ is only the part depending from the spatial coordinates of the scattered electric field. Then the scattered field $\underline{E}^s$ is solution of the boundary value problem (1.1), (1.2), (1.3), and (1.4) where the function $\underline{g}(\underline{x})$ appearing in (1.3) is given by (see Ref. 2 page 121):

$$\underline{g}(\underline{x})=-[\underline{n},\underline{E}^i](\underline{x}),\quad \underline{x}\in\partial\Omega. \tag{1.5}$$

In this paper we study the problem of the existence and uniqueness of the solution of problem (1.1), (1.2), (1.3), and (1.4) and we propose a new numerical method to compute it. First of all we prove that under some hypotheses the following formula for the vector field $\underline{E}$ solution of (1.1), (1.2), (1.3), and (1.4) holds:

$$\underline{E}(\underline{x})=\frac{e^{ik\|\underline{x}\|}}{4\pi\|\underline{x}\|}\sum_{n=0}^{\infty}\frac{\underline{E}^{(n)}(\hat{\underline{x}})}{\|\underline{x}\|^n},\quad \|\underline{x}\|\geqslant R \tag{1.6}$$

where $\underline{E}^{(n)}(\hat{\underline{x}})$, $n=0,1,2,\ldots$ are appropriate coefficients of the series expansion (1.6) and R is the radius of a sphere that contains $\overline{\Omega}$. The leading term $\underline{E}^{(0)}(\hat{\underline{x}})$ of the series (1.6) is called far field pattern associated to $\underline{E}(\underline{x})$. Then through the solution of some auxiliary problems we reformulate the boundary value problem (1.1), (1.2), (1.3), and (1.4) as a system of integral equations. That is we reduce problem (1.1), (1.2), (1.3), and (1.4) to the following system of integral equations:

$$(I+\tau)\underline{f}=\underline{F}, \tag{1.7}$$

where the vector functions $\underline{f},\underline{F}$ belong to a Hilbert space, I is identity operator and τ is a compact operator acting on the Hilbert space. Given $\underline{F}$ we prove existence and uniqueness for the solution of (1.7) using the Riesz theory for compact operators. This implies the claimed existence result for the solution of (1.1), (1.2), (1.3), and (1.4). The uniqueness result follows from (1.6) and the assumption on the wave number k. We note that our existence and uniqueness theorem holds for $\Omega \in C^{0,1}$, that is when $\partial\Omega$ is only locally Lipschitz, while the usual existence and uniqueness theorems assume more regularity for $\partial\Omega$. For example, when $\partial\Omega$ is assumed to be of class C^2 the existence and the uniqueness of the solution of the boundary value problems for the Helmholtz equation or for the vector Helmholtz equation can be proved reducing the boundary value problems to boundary integral equations and applying the Riesz–Fredholm theory for compact operators.[2] In fact the operators involved in these boundary integral equations are compact operators acting on the normed space of complex valued continuous functions defined on $\partial\Omega$. When $\partial\Omega$ is only Lipschitz continuous reducing the boundary value problems to boundary integral equations leads to integral equations with singular kernels that are not easy to solve. The study of layer potentials and of boundary value problems in the Lipschitz case goes back to Refs. 3 and 4. Since then it has become an active research field, we mention only Ref. 5 for the study of the Laplace equation, Ref. 6 for the study of the time harmonic Maxwell equations, and Ref. 7 for a survey of the subject.

We deal with the same difficult, i.e., $\partial\Omega$ only locally Lipschitz, when we prove the existence of the solution of the boundary value problem (1.1), (1.2), (1.3), and (1.4) for the vector Helmholtz equation. We overcome the difficulty avoiding layer potentials and singular integral operators. In fact the integral equations (1.7) involves compact integral operators and can be treated using Riesz–Fredholm theory. However, the functions f and F appearing in (1.7) are not defined on $\partial\Omega$ as it will be the case if we had used a boundary integral method but are defined on an annulus surrounding Ω, that is we consider a kind of volume potentials. In the Lipschitz case the use of layer potentials and boundary integral methods to establish the existence of the solution of the elliptic boundary value problems is based on several deep results in analysis. In the case of the boundary value problem (1.1), (1.2), (1.3), and (1.4) our approach establishes the existence of the solution using only elementary results in functional analysis.

Without loss of generality we can assume that Ω contains the origin. Let $a>0$ be a constant, $B_a=\{\underline{x}\in\mathbb{R}^3/\|\underline{x}\|<a\}$ be the sphere of radius a and center the origin and let ∂B_a be its boundary. In the following B_1 and ∂B_1 will be denoted also with B and ∂B. The set Ω contains the sphere $\overline{B_a}$ for some $a>0$. Let (r,θ,ϕ) be the canonical spherical coordinates of $\underline{x}\in\mathbb{R}^3$, for $\underline{x}\neq\underline{0}$, we have

$$\hat{\underline{x}}(\theta,\phi)=\frac{\underline{x}}{\|\underline{x}\|}=(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta)^T, \tag{1.8}$$

where $0\leqslant\theta\leqslant\pi,\ 0\leqslant\phi<2\pi$.

In order to introduce a new numerical method to compute the vector field $\underline{E}(\underline{x})$ solution of the boundary value problem (1.1), (1.2), (1.3), and (1.4), we assume that

$$\Omega=\{\underline{x}=r\hat{\underline{x}}\in\mathbb{R}^3/0\leqslant r<\xi(\hat{\underline{x}}),\hat{\underline{x}}\in\partial B\}, \tag{1.9}$$

where ξ is a single valued sufficiently regular function defined on ∂B. So that

$$\partial\Omega=\{\underline{x}=r\hat{\underline{x}}\in\mathbb{R}^3/r=\xi(\hat{\underline{x}}),\hat{\underline{x}}\in\partial B\} \tag{1.10}$$

is a starlike surface with respect to the origin, that is the boundary of the obstacle $\partial\Omega$ can be represented by a single valued function in spherical coordinates. We note that the choice of spherical coordinates is not essential and that our numerical method can be developed for other coordinate systems. The numerical method introduced here is based on a formalism that generalizes the formalism introduced by Milder in Refs. 8 and 9 to study the scattering of acoustic waves from a rough unbounded surface that divides the three-dimensional space in two ''disturbed'' half spaces and further developed by Milder[10] and by Piccolo, Recchioni, and Zirilli[11] to electromagnetic scattering from unbounded perfectly conducting surfaces of the previous type and by Smith[12] to the scattering of electromagnetic waves from dielectric surfaces. Later Misici, Pacelli, and

Zirilli[13] have generalized Milder's formalism to the scattering of acoustic waves from a bounded obstacle. The numerical method introduced here simplifies the original Milder's formalism since avoids the need to obtain $[\underline{n},\mathrm{curl}\,\underline{E}](\underline{x})$, $\underline{x}\in\partial\Omega$ from the knowledge of $[\underline{n},\underline{E}](\underline{x})$, $\underline{x}\in\partial\Omega$. This simplification gives a substantial reduction in the computational cost of the method proposed. Similar simplified Milder's methods can be developed for the acoustic and electromagnetic problems considered in the previously mentioned papers. The numerical method proposed here constructs the vector field $\underline{E}$ solution of (1.1), (1.2), (1.3), and (1.4) on Ω^c from the knowledge of $[\underline{n},\underline{E}]$ on $\partial\Omega$. Let

$$\Phi(\underline{x},\underline{y})=\frac{e^{ik\|\underline{x}-\underline{y}\|}}{4\pi\|\underline{x}-\underline{y}\|} \tag{1.11}$$

be the fundamental solution of the Helmholtz equation in $\mathbb{R}^3$ with the Sommerfeld radiation condition at infinity. We assume for $\underline{E}(\underline{x})$ solution of (1.1), (1.2), (1.3), and (1.4) the following representation formula:

$$\underline{E}(\underline{x})=\mathrm{curl}_{\underline{x}}\int_{\mathbb{R}^3}\Phi(\underline{x},\underline{y})\,\underline{v}(\hat{\underline{y}})\,\delta(\|\underline{y}\|-a)\,d\underline{y}, \tag{1.12}$$

where $\mathrm{curl}_{\underline{x}}$ is the curl operator with respect to the $\underline{x}$ variable, $\underline{v}(\hat{\underline{y}})$ is a suitable vector density function and $\delta(\|\underline{y}\|-a)$ is a ''Dirac's delta'' concentrated on ∂B_a, finally remember that $a>0$ is chosen such that $\overline{B_a}\subset\Omega$. We obtain for $\underline{v}$ and consequently for $\underline{E}(\underline{x})$ and its associated far field pattern $\underline{E}^{(0)}(\hat{\underline{x}})$, a formal series expansion in ''powers'' of $\delta\xi=\xi-1$ where 1 represents the boundary of the unit sphere whose surface is assumed as reference surface, that is as ''base point'' of the ''power series expansion.'' We note that the surface of the unit sphere is chosen as reference surface only for convenience. A similar formal ''power'' series expansion for $\underline{E}(\hat{\underline{x}})$ or $\underline{E}^{(0)}(\hat{\underline{x}})$ can be obtained when more general surfaces are used as reference surfaces. The terms of the series expansion in ''powers'' of $\delta\xi$ are integrals independent one from the other that can be computed in parallel. So that the efficiency of the numerical method proposed here is due to its highly parallelizable structure. Finally we present some numerical experience on test problems where the incident field is a plane linearly polarized time harmonic wave. When the domain $\Omega\in C^{0,1}$ is bounded with smooth boundary we compare the far field patterns $\underline{E}^{(0)}(\hat{\underline{x}})$ obtained with the method proposed here with those obtained with the *T*-matrix method (see Ref. 14).

This comparison shows that the two methods give similar results. Moreover we compute the far field pattern $\underline{E}^{(0)}(\hat{\underline{x}})$ of the scattered field solution of the boundary value problem (1.1), (1.2), (1.3), and (1.4) when Ω is a domain with locally Lipschitz boundary or with smooth boundary with multiscale corrugations. The obstacles with locally Lipschitz boundary that we consider are polyhedra. The relation between the geometry (i.e., facets, edges, vertices) of the surface of a polyhedron and the corresponding far field pattern is investigated (see Figs. 6 and 7). The obstacles with multiscale corrugations are represented by ''corrugated'' spheres (see Figs. 2 and 3). When the obstacle is a corrugated sphere we show that for some special values of the wave number k there is a ''resonance phenomenon'' due to the corrugation (see Figs. 4 and 5).

In Sec. II we prove formula (1.6) and we prove the existence and uniqueness theorem for the solution of the boundary value problem (1.1), (1.2), (1.3), and (1.4). In Sec. III we describe the numerical method proposed to compute the solution $\underline{E}(\underline{x})$ of (1.1), (1.2), (1.3), and (1.4) and we give the ''power'' series expansion in powers of $\delta\xi=\xi-1$ of $\underline{E}(\underline{x})$ and of the associated far field pattern $\underline{E}^{(0)}(\hat{\underline{x}})$. Finally in Sec. IV the method developed in Sec. III is applied to some test electromagnetic scattering problems, some numerical results are shown and their physical meaning illustrated.

II. AN EXISTENCE AND UNIQUENESS THEOREM FOR THE SOLUTION OF A BOUNDARY VALUE PROBLEM FOR THE VECTOR HELMHOLTZ EQUATION

Let $A \subseteq \mathbb{R}^3$ be an open set, let $C^k(A)$, $k=0,1,2,...$, be the space of real- or complex-valued k-times continuously differentiable functions in A and let $C_0^k(A)$ be the space of functions belonging to $C^k(A)$ with compact support in A. We denote with $C^\infty(A)$ the space of real- or complex-valued infinitely continuously differentiable functions defined in A, and with $C_0^\infty(A)$ the space of functions in $C^\infty(A)$ with compact support in A.

Let $L^p(A)$, $1 \leqslant p \leqslant \infty$, be the usual Lebesgue space of index p of complex valued functions. We denote with $\|\cdot\|_p$ the $L^p(A)$ norm and with $\|\cdot\|_\infty$ the $L^\infty(A)$ norm. Let α_i, $i=1,2,3$ be non-negative integers and $\underline{\alpha}=(\alpha_1,\alpha_2,\alpha_3)^T$ be a multi-index, we denote with $|\underline{\alpha}|=\Sigma_{i=1}^3 \alpha_i$ the length of $\underline{\alpha}$. Let m be a non-negative integer and $W^{m,p}(A)$ be the space of the functions $u \in L^p(A)$ such that $D^{\underline{\alpha}} u \in L^p(A)$ for any multi-index $\underline{\alpha}$ such that $0 \leqslant |\underline{\alpha}| \leqslant m$, where $D^{\underline{\alpha}} u = (\partial^{\alpha_1}/\partial x_1^{\alpha_1})(\partial^{\alpha_2}/\partial x_2^{\alpha_2})(\partial^{\alpha_3}/\partial x_3^{\alpha_3})u$ denotes the weak derivative of u of order given by the multi-index $\underline{\alpha}$. We denote with $\|\cdot\|_{m,p}$ the norm of $W^{m,p}(A)$ that is

$$\|u\|_{m,p}=\left\{\sum_{0\leqslant|\underline{\alpha}|\leqslant m}\|D^{\underline{\alpha}}u\|_p^p\right\}^{1/p}, \quad 1\leqslant p<\infty, \quad u\in W^{m,p}(A), \tag{2.1}$$

$$\|u\|_{m,\infty}=\max_{0\leqslant|\underline{\alpha}|\leqslant m}\|D^{\underline{\alpha}}u\|_\infty, \quad u\in W^{m,\infty}(A). \tag{2.2}$$

Let $\mathcal{W}^{m,p}(A)$ be the space of functions defined on A such that $u \in W^{m,p}(A\cap U)$ for any open set U such that $\overline{U}$ is compact and $A\cap U$ is not empty.

Let

$$(L^p(A))^3=\{\underline{E}=(E_1,E_2,E_3)^T/E_i\in L^p(A), i=1,2,3\}, \tag{2.3}$$

$$(W^{m,p}(A))^3=\{\underline{E}=(E_1,E_2,E_3)^T/E_i\in W^{m,p}(A), i=1,2,3\}. \tag{2.4}$$

In a similar way we define $(\mathcal{W}^{m,p}(A))^3$ and the other product spaces that appear in the following. The scalar products on $(L^2(A))^3$ and $(W^{m,2}(A))^3$ are given by

$$(\underline{E},\underline{F})_{(L^2)^3}=\sum_{i=1}^3\int_A E_i\overline{F_i}\,d\underline{x}=\int_A(\underline{E},\overline{\underline{F}})d\underline{x}, \forall \underline{E},\underline{F}\in(L^2(A))^3, \tag{2.5}$$

$$\begin{aligned}(\underline{E},\underline{F})_{(W^{m,2})^3}&=\sum_{i=1}^3\sum_{0\leqslant|\underline{\alpha}|\leqslant m}\int_A D^{\underline{\alpha}}E_i\overline{D^{\underline{\alpha}}F_i}\,d\underline{x}\\ &=\sum_{0\leqslant|\underline{\alpha}|\leqslant m}\int_A(D^{\underline{\alpha}}\underline{E},\overline{D^{\underline{\alpha}}\underline{F}})d\underline{x}, \forall \underline{E},\underline{F}\in(W^{m,2}(A))^3.\end{aligned} \tag{2.6}$$

Let $U\subset\mathbb{R}^3$ be a bounded open set with locally Lipschitz boundary ∂U and let $u\in W^{1,2}(U)$, from Theorem 4.2, page 84 of Ref. 1 we have that the trace of u on ∂U, $u|_{\partial U}$, belongs to $L^2(\partial U)$. In the following in order to simplify the notation instead of $u|_{\partial U}$ we continue to use u to denote the trace of u on ∂U.

Lemma 2.1: Let U be as above and let $u,v\in W^{1,2}(U)$, we have

$$\int_U v\frac{\partial u}{\partial x_i}d\underline{x}=\int_{\partial U}vun_i\,d\sigma-\int_U u\frac{\partial v}{\partial x_i}d\underline{x}, \quad i=1,2,3, \tag{2.7}$$

where $d\sigma$ denotes the surface measure on ∂U and $\underline{n}(\underline{x})=(n_1(\underline{x}),n_2(\underline{x}),n_3(\underline{x}))^T$ is the outward unit normal vector to ∂U in $\underline{x}\in\partial U$.

Proof: See Ref. 1, page 121, Theorem 1.1. ∎

Lemma 2.2: Let U be as above and let $u \in W^{2,2}(U), v \in W^{1,2}(U)$, then

$$\sum_{i=1}^{3} \int_U v \frac{\partial^2 u}{\partial x_i^2} d\underline{x} = \sum_{i=1}^{3} \int_{\partial U} v \frac{\partial u}{\partial x_i} n_i \, d\sigma - \sum_{i=1}^{3} \int_U \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_i} d\underline{x}. \tag{2.8}$$

Proof: The proof follows from Lemma 2.1 applied to the functions $\partial u/\partial x_i \in W^{1,2}(U)$, $i = 1,2,3$, and $v \in W^{1,2}(U)$. ■

Moreover when vector functions are considered we have

Theorem 2.3: Let U be as above and let $\underline{E} \in (W^{1,2}(U))^3$, $\underline{F} \in (W^{2,2}(U))^3$ be two vector functions; we have

$$\int_U \{(\underline{E}, \Delta \underline{F}) + (\mathrm{curl}\, \underline{E}, \mathrm{curl}\, \underline{F}) + \mathrm{div}\, \underline{E}\ \mathrm{div}\, \underline{F}\} d\underline{x}$$

$$= \int_{\partial U} \{(\underline{n}, \underline{E}, \mathrm{curl}\, \underline{F}) + (\underline{n}, \underline{E}) \mathrm{div}\, \underline{F}\} d\sigma. \tag{2.9}$$

Proof: Formula (2.9) is the so-called vector Green's formula and follows immediately from the scalar Green's formulas (2.7) and (2.8). ■

Lemma 2.4: Let $k \in \{z \in \mathbb{C} / \mathrm{Im}\, z > 0\} \cup \{z \in \mathbb{C} / \mathrm{Re}\, z > 0, \mathrm{Im}\, z = 0\}$, $\Omega \in C^{0,1}$, and let $u \in \mathcal{W}^{2,2}(\Omega^c)$ be a solution of the scalar Helmholtz equation

$$\Delta u + k^2 u = 0, \quad \underline{x} \in \Omega^c \tag{2.10}$$

satisfying the Sommerfeld radiation condition at infinity:

$$\left(\frac{\underline{x}}{\|\underline{x}\|}, \nabla u \right) - iku = o\left(\frac{1}{\|\underline{x}\|} \right), \quad \|\underline{x}\| \to \infty, \tag{2.11}$$

where $\nabla = (\partial/\partial x_1, \partial/\partial x_2, \partial/\partial x_3)^T$ is the gradient operator, and let $R > 0$ be such that $B_R \supset \overline{\Omega}$. Then u has an expansion on the form

$$u(\underline{x}) = \frac{e^{ik\|\underline{x}\|}}{4\pi\|\underline{x}\|} \sum_{n=0}^{\infty} \frac{u^{(n)}(\hat{\underline{x}})}{\|\underline{x}\|^n}, \quad \|\underline{x}\| \geqslant R, \tag{2.12}$$

where $u^{(n)}(\hat{\underline{x}})$, $n = 0,1,2,\ldots$ are suitable functions.

Proof: We note that if $u \in \mathcal{W}^{2,2}(\Omega^c)$ for the couple $u(\underline{x})$, $v(\underline{x}) = 1$ Green's formula (2.8) holds in $\Omega^c \cap U$, for any open set U with locally Lipschitz boundary and such that $\overline{U}$ is compact and $U \supset \overline{\Omega}$ so that we can proceed as in Ref. 2, Theorem 3.6, page 72. ■

Theorem 2.5: Let k be as in Lemma 2.4, let $\underline{E} \in (\mathcal{W}^{2,2}(\Omega^c))^3$ be a solution of the vector Helmholtz equation satisfying the radiation condition (1.4) and let $R > 0$ be such that $B_R \supset \overline{\Omega}$. Then $\underline{E}$ has an expansion on the form

$$\underline{E}(\underline{x}) = \frac{e^{ik\|\underline{x}\|}}{4\pi\|\underline{x}\|} \sum_{n=0}^{\infty} \frac{\underline{E}^{(n)}(\hat{\underline{x}})}{\|\underline{x}\|^n}, \quad \|\underline{x}\| \geqslant R, \tag{2.13}$$

where $\underline{E}^{(n)}(\hat{\underline{x}})$, $n = 0,1,2,\ldots$ are suitable functions.

Proof: We observe that the Cartesian components of $\underline{E} = (E_1, E_2, E_3)^T$ satisfy the scalar Helmholtz equation and the Sommerfeld radiation condition at infinity, therefore we can apply Lemma 2.4 with $u = E_i$, $i = 1,2,3$ and we obtain (2.13). ■

Lemma 2.6: Let k be real and positive and let $u \in \mathcal{W}^{2,2}(\Omega^c)$ be a solution of the scalar Helmholtz equation satisfying the Sommerfeld radiation condition at infinity such that

$$\lim_{R\to+\infty}\int_{\partial B_R}|u|^2 ds=0, \tag{2.14}$$

where ds denotes the surface measure on ∂B_R then $u=0$ in Ω^c.

Proof: The proof follows using (2.12) and arguing as in Ref. 2, Lemma 3.11, page 77. ■

Theorem 2.7: *(Uniqueness):* Let k be as in Lemma 2.4, $\Omega\in C^{0,1}$, $\underline{g}\in(L^2(\partial\Omega))^3$ and let $\underline{E},\underline{F}\in(\mathcal{W}^{2,2}(\Omega^c))^3$ be two solutions of the boundary value problem (1.1), (1.2), (1.3), and (1.4). Then $\underline{E}=\underline{F}$ in $(\mathcal{W}^{2,2}(\Omega^c))^3$.

Proof: We consider the vector function $\underline{W}=\underline{E}-\underline{F}$. The function $\underline{W}$ satisfies the homogeneous problem:

$$(\Delta+k^2)\underline{W}(\underline{x})=\underline{0},\quad \underline{x}\in\Omega^c \tag{2.15}$$

$$\operatorname{div}\underline{W}(\underline{x})=0,\quad \underline{x}\in\Omega^c \tag{2.16}$$

$$[\underline{n},\underline{W}](\underline{x})=\underline{0},\quad \underline{x}\in\partial\Omega \tag{2.17}$$

$$[\operatorname{curl}\underline{W}(\underline{x}),\hat{\underline{x}}]-ik\underline{W}(\underline{x})=o\left(\frac{1}{\|\underline{x}\|}\right),\quad \|\underline{x}\|\to\infty. \tag{2.18}$$

From (2.18) follows that

$$\lim_{R\to\infty}\int_{\partial B_R}\sum_{j=1}^{3}\left|\left[\operatorname{curl}\underline{W},\frac{\underline{x}}{\|\underline{x}\|}\right]_j-ikW_j\right|^2 ds=0, \tag{2.19}$$

where $[\operatorname{curl}\underline{W},\underline{x}/\|\underline{x}\|]_j$, denotes the $\underline{j}$ component of $[\operatorname{curl}\underline{W},\underline{x}/\|\underline{x}\|]$ $j=1,2,3$. From standard arguments using Lemma 2.6 we obtain $\underline{W}=\underline{0}$ in Ω^c, therefore $\underline{E}=\underline{F}$ in $(\mathcal{W}^{2,2}(\Omega^c))^3$. ■

Let U be an open bounded set with locally Lipschitz boundary ∂U, $K(U)$ be the vector subspace of $(L^2(U))^3$ defined by

$$K(U)=\{\underline{E}\in(W^{2,2}(U))^3:\ \operatorname{div}\underline{E}=0\ \text{ on }\ \partial U\ \text{ and }\ [\underline{E},\underline{n}]=\underline{0}\ \text{ on }\ \partial U\}. \tag{2.20}$$

We note that for $\underline{E}\in(W^{2,2}(U))^3$ the trace operators $\underline{E}\to(\operatorname{div}\underline{E})|_{\partial U}$ and $\underline{E}\to[\underline{E},\underline{n}]|_{\partial U}$ are linear bounded operators from $(W^{2,2}(U))^3$ to $L^2(\partial U)$ and from $(W^{2,2}(U))^2$ to $(L^2(\partial U))^3$, respectively (see Ref. 1, Theorem 4.2, page 84).

Definition 2.8: Let

$$T:\ K(U)\subset(L^2(U))^3\to(L^2(U))^3 \tag{2.21}$$

be the linear differential operator defined by

$$T\underline{E}=-\Delta\underline{E}=(-\Delta E_1,-\Delta E_2,-\Delta E_3)^T,\quad \underline{E}\in K(U). \tag{2.22}$$

Theorem 2.9: The linear operator T: $K(U)\subset(L^2(U))^3\to(L^2(U))^3$ defined by (2.22) is closed, symmetric and non-negative.

Proof: The thesis follows using Theorem 2.3, formula (2.8) and from standard arguments. ■

Theorem 2.10: The linear operator T given in Definition 2.8 is self-adjoint.

Proof: The proof follows with an easy computation applying the vector Green's formula (2.9). ■

We have

Theorem 2.11: Let $C\subset\mathbb{R}^3$ be an open cube, let $K(C)$ be defined as in (2.20), the spectrum of the operator

$$T: \ K(C) \subset (L^2(C))^3 \rightarrow (L^2(C))^3 \tag{2.23}$$

defined in Definition 2.8 is discrete.

Proof: Without loss of generality we can restrict our attention to the unit cube $C_1 = \{\underline{x} \in \mathbb{R}^3 : 0 < x_i < 1, i = 1,2,3\}$.

The eigenvalue problem for T becomes

$$(\Delta + \lambda^2)\underline{E}(\underline{x}) = \underline{0}, \quad \underline{x} \in C_1 \tag{2.24}$$

$$\operatorname{div} \underline{E}(\underline{x}) = 0, \quad \underline{x} \in \partial C_1 \tag{2.25}$$

$$[\underline{n}, \underline{E}](\underline{x}) = \underline{0}, \quad \underline{x} \in \partial C_1 . \tag{2.26}$$

We seek the values of the parameter λ^2 such that problem (2.24), (2.25), and (2.26) have a nonzero solution $\underline{E}(\underline{x}) \in K(C_1) \subset (L^2(C_1))^3$.

The eigenvalue problem (2.24), (2.25), and (2.26) is easily solved by separation of variables. The eigenvalues of T are

$$\lambda^2_{m,n,p} = (m^2 + n^2 + p^2)\pi^2, \quad m,n,p = 1,2,..., \tag{2.27}$$

and it is easy to see that the corresponding eigenfunctions are a complete system in $(L^2(C_1))^3$ and the eigenvalues are isolated points of the spectrum and have finite multiplicity. Hence the spectrum of the operator T is discrete. Let $\mu^{(k)}$ be the kth eigenvalue when the eigenvalues in (2.27) are reordered in increasing order, we have $\lim_{k\rightarrow\infty} \mu^{(k)} = \infty$. ■

Theorem 2.12: Let $\Omega \in C^{0,1}$, $C \subset \mathbb{R}^3$ be an open cube such that $\overline{\Omega} \subset C$ and let $V = \Omega^c \cap C$. Let $K(V)$ be defined as in (2.20) then the operator T:

$$T: \ K(V) \subset (L^2(V))^3 \rightarrow (L^2(V))^3 \tag{2.28}$$

defined in (2.22) has discrete spectrum.

Proof: Given $\underline{E} \in (L^2(V))^3$ we define the vector function $\tilde{\underline{E}}$

$$\tilde{\underline{E}}(\underline{x}) = \begin{cases} \underline{E}(\underline{x}), & \underline{x} \in V \\ \underline{0}, & \underline{x} \in \overline{\Omega}. \end{cases} \tag{2.29}$$

Let $\mathcal{Q}_C$ be the quadratic form associated to the operator T on $K(C)$ and $\mathcal{D}(\mathcal{Q}_C)$ be its domain, in a similar way let $\mathcal{Q}_V$ be the quadratic form associated to the operator T on $K(V)$ and $\mathcal{D}(\mathcal{Q}_V)$ be its domain. When $\underline{E} \in \mathcal{D}(\mathcal{Q}_V)$ we have that $\tilde{\underline{E}}$ given by (2.29) belongs to $\mathcal{D}(\mathcal{Q}_C)$ moreover we have $\mathcal{Q}_V(\underline{E},\underline{E}) = \mathcal{Q}_C(\tilde{\underline{E}},\tilde{\underline{E}})$. Hence from Theorem 2.11 and from Theorem XIII.2, page 78,[15] the operator T: $K(V) \subset (L^2(V))^3 \rightarrow (L^2(V))^3$ has discrete spectrum. ■

Let us consider now the boundary value problem (1.1), (1.2), (1.3), and (1.4) for the vector Helmholtz equation. We begin with some preliminary results.

Theorem 2.13: Let k be as in Lemma 2.4, $\Omega \in C^{0,1}$ and let $\underline{E} \in (\mathcal{W}^{2,2}(\Omega^c))^3$ be a solution of the vector Helmholtz equation (1.1) that verifies the radiation condition (1.4) and the boundary condition

$$\operatorname{div} \underline{E}(\underline{x}) = 0, \quad \underline{x} \in \partial\Omega, \tag{2.30}$$

then we have

$$\operatorname{div} \underline{E}(\underline{x}) = 0, \quad \underline{x} \in \Omega^c. \tag{2.31}$$

Proof: Since $\underline{E}$ is solution of the vector Helmholtz equation and $\underline{E}$ satisfies condition (1.4), we have that $u=\operatorname{div}\underline{E}$ verifies the scalar Helmholtz equation (2.10) and the Sommerfeld radiation condition at infinity (2.11). Moreover, we have assumed that $u=\operatorname{div}\underline{E}=0$ on $\partial\Omega$.

Let $R>0$ be such that $\overline{\Omega}\subset B_R$, from (2.8) applied to the domain $\Omega^c\cap B_R$ and the radiation condition (2.11) since $u=0$ on $\partial\Omega$ we have

$$\lim_{R\to\infty}\left\{\int_{\partial B_R}\left[\left|\frac{\partial u}{\partial \underline{n}}\right|^2+|k|^2|u|^2\right]ds+2\,\operatorname{Im}k\int_{\Omega^c\cap B_R}\left[|k|^2|u|^2+\sum_{i=1}^{3}\left|\frac{\partial u}{\partial x_i}\right|^2\right]d\underline{x}\right\}=0,$$

hence if $\operatorname{Im}k>0$ we have

$$\lim_{R\to\infty}\int_{\Omega^c\cap B_R}|u|^2\,d\underline{x}=0,$$

that is $u=0$ in Ω^c, if $\operatorname{Im}k=0$ and $\operatorname{Re}k>0$ we have

$$\lim_{R\to\infty}\int_{\partial B_R}|u|^2\,ds=0$$

so that from Lemma 2.6, we can conclude $u=0$ in Ω^c. ■

Now we reformulate problem (1.1), (1.2), (1.3), and (1.4) in precise mathematical form, that is we state the hypotheses on the vector field $\underline{g}(\underline{x})$ appearing in the boundary condition (1.3) and declare the functional class where we seek the solution of the problem considered.

Problem 2.1: Let k be as in Lemma 2.4, $\Omega\in C^{0,1}$, we seek a vector field $\underline{E}\in(\mathcal{W}^{2,2}(\Omega^c))^3$ such that

$$(\Delta+k^2)\underline{E}(\underline{x})=\underline{0},\quad \underline{x}\in\Omega^c \tag{2.32}$$

$$\operatorname{div}\underline{E}(\underline{x})=0,\quad \underline{x}\in\partial\Omega \tag{2.33}$$

$$[\underline{n},\underline{E}](\underline{x})=\underline{D}(\underline{x}),\quad \underline{x}\in\partial\Omega \tag{2.34}$$

and

$$[\operatorname{curl}\underline{E}(\underline{x}),\hat{\underline{x}}]-ik\underline{E}(\underline{x})=o\left(\frac{1}{\|\underline{x}\|}\right),\quad \|\underline{x}\|\to\infty \tag{2.35}$$

where $\underline{E}\in(L^2(\partial\Omega))^3$ is a given vector field and there exists $\underline{G}=(G_1,G_2,G_3)^T\in(\mathcal{W}^{2,2}(\mathbb{R}^3))^3$ such that

$$\text{(i)}\quad \operatorname{div}\underline{G}(\underline{x})=0,\quad \underline{x}\in\partial\Omega$$

$$\text{(ii)}\quad \underline{D}(\underline{x})=[\underline{n},\underline{G}](\underline{x}),\quad \underline{x}\in\partial\Omega.$$

We note that the datum of the scattering problem mentioned in Sec. I, $\underline{D}(\underline{x})=-[\underline{n},\underline{E}^i](\underline{x})$, satisfies the hypotheses given above when $\underline{E}^i\in(\mathcal{W}^{2,2}(\mathbb{R}^3))^3$. More general classes of data $\underline{D}(\underline{x})$ can be considered. We note that from Theorem 2.13 follows that a solution of Problem 2.1 solves (1.1), (1.2), (1.3), and (1.4) with $\underline{g}(\underline{x})=\underline{D}(\underline{x})$, $\underline{x}\in\partial\Omega$. We restate Problem 2.1 in several equivalent forms.

Let $C\subset\mathbb{R}^3$ an open cube such that $\overline{\Omega}\subset C$ then there exists a function $\phi\in C_0^\infty(\mathbb{R}^3)$ with support in C and such that $\phi(\underline{x})=1$ if $\underline{x}\in\overline{\Omega}$.

We can consider the vector function

$$\hat{\underline{E}}(\underline{x}) = \underline{E}(\underline{x}) - \phi(\underline{x})\underline{G}(\underline{x}), \quad \underline{x} \in \Omega^c. \tag{2.36}$$

It is easy to see that $\underline{E}$ satisfies Problem 2.1 if and only if $\hat{\underline{E}}$ is solution of the following problem.

Problem 2.2: Let k be as in Lemma 2.4 $\Omega \in C^{0,1}$, V as in Theorem 2.12, we seek a vector function $\hat{\underline{E}} \in (\mathcal{W}^{2,2}(\Omega^c))^3$ such that

$$(\Delta + k^2)\hat{\underline{E}}(\underline{x}) = \underline{A}(\underline{x}), \quad \underline{x} \in \Omega^c \tag{2.37}$$

$$\operatorname{div} \hat{\underline{E}}(\underline{x}) = 0, \quad \hat{x} \in \partial\Omega \tag{2.38}$$

$$[\underline{n}, \hat{\underline{E}}](\underline{x}) = \underline{0}, \quad \underline{x} \in \partial\Omega \tag{2.39}$$

and

$$[\operatorname{curl} \hat{\underline{E}}(\underline{x}), \hat{\underline{x}}] - ik\hat{\underline{E}}(\underline{x}) = o\left(\frac{1}{\|\underline{x}\|}\right), \quad \|\underline{x}\| \to \infty \tag{2.40}$$

where

$$\underline{A} = -(\Delta + k^2)(\phi \underline{G}). \tag{2.41}$$

The function $\underline{A}$ is a vector function belonging to $(L^2(\Omega^c))^3$ with support in $V = \Omega^c \cap C$. Note that $\operatorname{div}(\phi \underline{G}) = \Sigma_{i=1}^3 (\partial\phi/\partial x_i) G_i + \phi \operatorname{div} \underline{G} = 0$ on $\partial\Omega$, in fact $\operatorname{div} \underline{G} = 0$ on $\partial\Omega$ and $\partial\phi/\partial x_i = 0$, $i = 1,2,3$ on $\partial\Omega$ in virtue of the properties of ϕ and $\partial\Omega$.

Let $\Phi(\underline{x}, \underline{y})$ be given by (1.11) we have the following result.

Theorem 2.14: Let V be as above, $\underline{a}(\underline{x}) \in (L^2(V))^3$ be a vector function and let

$$\underline{v}(\underline{x}) = \int_V \Phi(\underline{x}, \underline{y}) \underline{a}(\underline{y}) d\underline{y}, \quad \underline{x} \in \mathbb{R}^3 \tag{2.42}$$

then $\underline{v} \in (\mathcal{W}^{2,2}(\mathbb{R}^3))^3$ so that in particular $\underline{v} \in (\mathcal{W}^{2,2}(\Omega^c))^3$ and for any open set U such that $\overline{U}$ is compact and $\Omega^c \cap U$ is not empty we have

$$\|\underline{v}\|_{(W^{2,2}(\Omega^c \cap U))^3} \leq \alpha_U \|\underline{a}\|_{(L^2(V))^3}, \tag{2.43}$$

where α_U is a positive constant that depends on U.

Proof: From Schwarz inequality for $i = 1,2,3$ we have that

$$|v_i(\underline{x})| = \left| \int_V \Phi(\underline{x}, \underline{y}) a_i(\underline{y}) d\underline{y} \right| \leq \left(\int_V |\Phi(\underline{x}, \underline{y})|^2 d\underline{y} \right)^{1/2} \left(\int_V |a_i(\underline{y})|^2 d\underline{y} \right)^{1/2} < \infty, \tag{2.44}$$

therefore, since

$$(\Delta + k^2)\underline{v} = \hat{\underline{a}}, \quad \underline{x} \in \mathbb{R}^3, \tag{2.45}$$

where $\hat{\underline{a}} = -\underline{a}$ in V and $\hat{\underline{a}} = \underline{0}$ in $\mathbb{R}^3 \backslash V$, we have that $\underline{v} \in (W^{2,2}(\Omega^c \cap U))^3$ and $\|\underline{v}\|_{(W^{2,2}(\Omega^c \cap U))^3} \leq \alpha_U \|\underline{a}\|_{(L^2(V))^3}$ for any open set U such that $\overline{U}$ is compact and $\Omega^c \cap U$ is not empty. ■

We introduce the following auxiliary problems.

Problem 2.3: Let V as above, $\underline{a} \in (L^2(V))^3$ and let μ^2 be a constant that is not an eigenvalue of T on $K(V)$, we seek a vector function $\underline{W} \in (W^{2,2}(V))^3$ such that

$$(\Delta + \mu^2)\underline{W}(\underline{x}) = \underline{0}, \quad \underline{x} \in V \tag{2.46}$$

$$\operatorname{div} \underline{W}(\underline{x}) = 0, \quad \underline{x} \in \partial C \tag{2.47}$$

$$\operatorname{div} \underline{W}(\underline{x}) = -\operatorname{div}\left(\int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y} \right), \quad \underline{x} \in \partial\Omega \tag{2.48}$$

$$[\underline{n},\underline{W}](\underline{x}) = \underline{0}, \quad \underline{x} \in \partial C \tag{2.49}$$

$$[\underline{n},\underline{W}](\underline{x}) = -\left[\underline{n}(\underline{x}), \int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y} \right], \quad \underline{x} \in \partial\Omega. \tag{2.50}$$

Problem 2.4: Let V,μ^2 be chosen as in Problem 2.3, and $\underline{a} \in (L^2(V))^3$, we seek a vector function $\underline{\tilde{W}} \in (W^{2,2}(V))^3$ such that

$$(\Delta + \mu^2)\underline{\tilde{W}}(\underline{x}) = \underline{B}(\underline{x}), \quad \underline{x} \in V \tag{2.51}$$

$$\operatorname{div} \underline{\tilde{W}}(\underline{x}) = 0, \quad \underline{x} \in \partial V \tag{2.52}$$

$$[\underline{n},\underline{\tilde{W}}](\underline{x}) = \underline{0}, \quad \underline{x} \in \partial V \tag{2.53}$$

where $\underline{B}(\underline{x}) = (\Delta + \mu^2)(\phi(\underline{x})\int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y})$.

We remember that $\phi \in C_0^\infty(\mathbb{R}^3)$ with support in C and $\phi(\underline{x}) = 1$ if $\underline{x} \in \overline{\Omega}$ so that $\underline{B} \in (L^2(V))^3$.

Theorem 2.15: Let $\underline{a} \in (L^2(V))^3$ be a vector function and let μ^2 be not an eigenvalue of the operator T on $K(V)$ then there exists an unique vector function $\underline{W} \in (W^{2,2}(V))^3$ solution of Problem 2.3.

Proof: We note that Theorem 2.12 implies that there exists μ^2 that satisfies the previous conditions. Later we choose μ^2 such that $\operatorname{Im}\mu^2 \neq 0$. From Theorem 2.14 the vector function $\underline{v}(\underline{x}) = \int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}$ belongs to $(\mathcal{W}^{2,2}(\Omega^c))^3$ hence there exists the trace of $\underline{v}$ on $\partial\Omega$ and $\underline{v}|_{\partial\Omega}$ belongs to $(L^2(\partial\Omega))^3$.

Let us consider the vector function $\underline{\tilde{W}}$ defined by

$$\underline{\tilde{W}}(\underline{x}) = \underline{W}(\underline{x}) + \phi(\underline{x}) \int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}, \quad \underline{x} \in V. \tag{2.54}$$

It is easy to see that

$$\underline{W}(\underline{x}) = \underline{\tilde{W}}(\underline{x}) - \phi(\underline{x}) \int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}, \quad \underline{x} \in V \tag{2.55}$$

is solution of Problem 2.3 if and only if $\underline{\tilde{W}}$ is solution of Problem 2.4.

Since μ^2 is not eigenvalue of the operator T defined on $K(V)$ there exists an unique vector function $\underline{\tilde{W}} \in (W^{2,2}(V))^3$ solution of the Problem 2.4. Therefore $\underline{W}(\underline{x}) = \underline{\tilde{W}}(\underline{x}) - \phi(\underline{x})\int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}$ is solution of Problem 2.3. ■

We observe that $\underline{W}(\underline{x})$ depends with continuity from the function $\underline{v}(\underline{x}) = \int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}$, that is the operator which to any $\underline{a} \in (L^2(V))^3$ associates $\underline{W} \in (W^{2,2}(V))^3$ given by (2.55) is a continuous operator from $(L^2(V))^3$ to $(W^{2,2}(V))^3$. We seek a solution of Problem 2.2 in the form

$$\underline{\hat{E}}(\underline{x}) = -\int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y} + \phi(\underline{x})\underline{W}(\underline{x}), \quad \underline{x} \in \Omega^c, \tag{2.56}$$

where $\underline{W}$ is the function given in (2.55) extended with $\underline{0}$ in $\Omega^c \setminus C$. That is we want to determine $\underline{a} \in (L^2(V))^3$ in such a way that $\underline{\hat{E}}(\underline{x})$ is a solution of Problem 2.2.

It is easy verify that $\hat{\underline{E}}$ given by (2.56) satisfies the conditions (2.38) and (2.39), moreover since Φ satisfies the Sommerfeld radiation condition (2.11) and $\underline{a}\in(L^2(V))^3$, $\hat{\underline{E}}$ satisfies the radiation condition (2.40). Therefore $\hat{\underline{E}}$ is solution of Problem 2.2 if $\hat{\underline{E}}$ verifies in Ω^c equation (2.37).

Substituting the expression of $\hat{\underline{E}}$ (2.56) in (2.37) we have that Eq. (2.37) is always verified for $\underline{x}\in\mathbb{R}^3\backslash C$, while for $\underline{x}\in V$ we obtain the following equation that $\underline{a}$ must satisfy

$$\underline{a}+(\Delta+k^2)(\phi\underline{W})=\underline{A},\quad \underline{x}\in V. \tag{2.57}$$

We note that, since $\underline{W}$ is solution of Eq. (2.46) we have

$$(\Delta+k^2)(\phi\underline{W})=\underline{W}\Delta\phi+2(\nabla\phi,\nabla)\underline{W}+(k^2-\mu^2)\phi\underline{W},\quad \underline{x}\in V, \tag{2.58}$$

hence Eq. (2.57) becomes

$$(I+\tau)\underline{a}=\underline{A},\quad \underline{x}\in V \tag{2.59}$$

where I is the identity operator and

$$\tau\underline{a}=\underline{W}\Delta\phi+2(\nabla\phi,\nabla)\underline{W}+(k^2-\mu^2)\phi\underline{W},\quad \underline{x}\in V. \tag{2.60}$$

Theorem 2.16: The operator τ: $(L^2(V))^3\rightarrow(L^2(V))^3$ defined in (2.60) is a compact operator.

Proof: From Theorem 2.14 the operator which associates to any vector function $\underline{a}\in(L^2(V))^3$ the vector function $\underline{W}\in(W^{2,2}(V))^3$ given by (2.55) is continuous, hence τ is a continuous operator from $(L^2(V))^3$ to $(W^{1,2}(V))^3$ since it is composition of continuous operators. Rellich's theorem [see Ref. 16, Theorem 6.2, page 144] implies that the immersion

$$i:\ (W^{1,2}(V))^3\rightarrow(L^2(V))^3$$

is compact, therefore

$$\tau:\ (L^2(V))^3\rightarrow(L^2(V))^3$$

is a compact operator. ■

Theorem 2.17: The operator $I+\tau$: $(L^2(V))^3\rightarrow(L^2(V))^3$ where τ is defined by (2.60) is injective.

Proof: Let $\underline{a}\in(L^2(V))^3$ be such that

$$\underline{a}+\underline{W}\Delta\phi+2(\nabla\phi,\nabla)\underline{W}+(k^2-\mu^2)\phi\underline{W}=\underline{0},\quad \underline{x}\in V, \tag{2.61}$$

then

$$\hat{\underline{E}}(\underline{x})=-\int_V\Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}+\phi(\underline{x})\underline{W}(\underline{x}),\quad \underline{x}\in\Omega^c, \tag{2.62}$$

is solution of

$$(\Delta+k^2)\hat{\underline{E}}(\underline{x})=\underline{0},\quad \underline{x}\in\Omega^c \tag{2.63}$$

and satisfies (2.38), (2.39), and (2.40), hence from Theorem 2.7 $\hat{\underline{E}}=\underline{0}$ in Ω^c. So that we have

$$\int_V\Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y}=\phi(\underline{x})\underline{W}(\underline{x}),\quad \underline{x}\in\Omega^c, \tag{2.64}$$

therefore

$$\underline{v}(\underline{x}) = \int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y} = \underline{0}, \quad \underline{x} \in \mathbb{R}^3 \backslash C. \tag{2.65}$$

Let us define the vector function $\underline{a}(\underline{x})$ as follows:

$$\underline{\alpha}(\underline{x}) = \begin{cases} \underline{v}(\underline{x}), & \underline{x} \in \Omega, \text{ or } \underline{x} \in \mathbb{R}^3 \backslash C \\ \underline{W}(\underline{x}), & \underline{x} \in V \end{cases} \tag{2.66}$$

where $\underline{v}(\underline{x})$ is given by (2.42) and $\underline{W}(\underline{x})$, $\underline{x} \in V$ is given by (2.55). We observe that

$$(\Delta + k^2)\underline{\alpha}(\underline{x}) = (\Delta + k^2)\underline{v}(\underline{x}) = \underline{0}, \quad \underline{x} \in \Omega \tag{2.67}$$

$$(\Delta + \mu^2)\underline{\alpha}(\underline{x}) = (\Delta + \mu^2)\underline{W}(\underline{x}) = \underline{0}, \quad \underline{x} \in V \tag{2.68}$$

$$(\Delta + k^2)\underline{\alpha}(\underline{x}) = (\Delta + k^2)\underline{v}(\underline{x}) = \underline{0}, \quad \underline{x} \in \mathbb{R}^3 \backslash C. \tag{2.69}$$

Let $B_R \supset \overline{C}$, we have

$$0 = \int_{B_R} ((\Delta + \nu^2)\underline{\alpha}(\underline{x}), \overline{\underline{\alpha}(\underline{x})})d\underline{x} = \int_{B_R} (\Delta \underline{\alpha}(\underline{x}), \overline{\underline{\alpha}(\underline{x})})d\underline{x} + \int_{B_R} \nu^2 \sum_{j=1}^{3} |\alpha_j(\underline{x})|^2 \, d\underline{x},$$

where $\nu^2 = k^2$ if $\underline{x} \in \mathbb{R}^3 \backslash V$, $\nu^2 = \mu^2$ if $\underline{x} \in V$, hence

$$-\int_{B_R} \left(\sum_{j=1}^{3} |(\text{curl}\, \underline{\alpha}(\underline{x}))_j|^2 + |\text{div}\, \underline{\alpha}(\underline{x})|^2 \right) d\underline{x} + \int_{B_R} \nu^2 \sum_{j=1}^{3} |\alpha_j(\underline{x})|^2 \, d\underline{x} = 0.$$

Therefore if we have chosen μ^2 such that $\text{Im}\, \mu^2 \neq 0$ we have

$$\int_V \nu^2 \sum_{j=1}^{3} |\alpha_j(\underline{x})|^2 \, d\underline{x} = 0 \tag{2.70}$$

that is

$$\underline{\alpha}(\underline{x}) = \underline{0}, \quad \underline{x} \in V. \tag{2.71}$$

In particular from (2.71) follows that $\underline{W} = \underline{0}$ in V and from (2.61) $\underline{a} = \underline{0}$ in V, therefore $I + \tau$ is an injective operator. ■

We know that since τ is compact if the operator $I + \tau$ is injective there exists the inverse operator $(I + \tau)^{-1}$ and it is continuous. So that Eq. (2.57) has an unique solution belonging to $(L^2(V))^3$. For any $\underline{A} \in (L^2(V))^3$ exists and is unique a function $\underline{a} \in (L^2(V))^3$ such that $(I + \tau)\underline{a} = \underline{A}$ and therefore Problem 2.2 has a solution $\hat{\underline{E}}$ so that using (2.36) and (2.56) it follows that Problem 2.1 has a solution $\underline{E}$ given by

$$\underline{E}(\underline{x}) = -\int_V \Phi(\underline{x},\underline{y})\underline{a}(\underline{y})d\underline{y} + \phi(\underline{x})\underline{W}(\underline{x}) + \phi(\underline{x})\underline{G}(\underline{x}), \quad \underline{x} \in \Omega^c. \tag{2.72}$$

This concludes the existence proof. ■

III. THE COMPUTATIONAL METHOD

We remind that the content of this section is mainly formal. That is no convergence proof is given for the numerical method proposed. We develop our method assuming that the boundary of the obstacle $\partial\Omega$ is a starlike surface with respect to the origin, i.e. [see (1.10)],

$$\partial\Omega=\{\underline{x}=r\underline{\hat{x}}\in\mathbb{R}^3/r=\xi(\underline{\hat{x}}),\underline{\hat{x}}\in\partial B\},\tag{3.1}$$

where $\underline{\hat{x}}=\underline{\hat{x}}(\theta,\phi)$ is given by (1.8) and $\xi(\underline{\hat{x}})$ is a single valued function. Moreover, we assume that the wave number k is a positive real number. A method analogous to the one described here can be obtained substituting the previous choice of the spherical coordinate system with some other coordinate system. Let $0<a<1$, B_a, $\underline{n}(\underline{x})$, $\underline{x}\in\partial\Omega$ be as specified previously, in particular let $\overline{B_a}\subset\Omega$. The computational method proposed is based on the assumption that the solution $\underline{E}$ of the boundary value problem (1.1), (1.2), (1.3), and (1.4) can be extended to $\underline{x}\in\mathbb{R}^3\backslash\overline{B_a}$ and that this extension $\underline{F}$ can be represented as follows:

$$\underline{F}(\underline{x})=a^2\int_{\partial B}\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},a\underline{\hat{y}})\underline{v}(\underline{\hat{y}})\}ds(\underline{\hat{y}}),\quad \underline{x}\in\mathbb{R}^3\backslash\overline{B_a},\tag{3.2}$$

where ds is the surface measure on ∂B and $\underline{v}(\underline{\hat{y}})$ is a suitable (complex valued) vector density function defined on ∂B, tangential to ∂B, that is such that

$$(\underline{v}(\underline{\hat{x}}),\underline{\hat{x}})=0,\quad \underline{\hat{x}}\in\partial B.\tag{3.3}$$

We note that when $\underline{v}(\underline{x})$ is a complex vector function with (3.3) we mean real euclidean product of complex vectors. It is easy to see that a vector field $\underline{F}(\underline{x})$ given by (3.2) satisfies

$$(\Delta+k^2)\underline{F}(\underline{x})=\underline{0},\quad \underline{x}\in\mathbb{R}^3\backslash\overline{B_a},\tag{3.4}$$

$$\mathrm{div}\,\underline{F}(\underline{x})=0,\quad \underline{x}\in\mathbb{R}^3\backslash\overline{B_a},\tag{3.5}$$

and the radiation condition at infinity (1.4) for any choice of the density $\underline{v}$ that makes possible differentiation under the integral sign in (3.2). Since $\overline{B_a}\subset\Omega$ from (3.4) and (3.5) follows that (1.1) and (1.2) hold. We impose the ''boundary'' condition (1.3) to the vector field $\underline{F}(\underline{x})$ given by (3.2) that is we impose that $\underline{F}(\underline{x})$ extends $\underline{E}(\underline{x})$, so that we have an equation for the density $\underline{v}$, that is

$$\left[\underline{n}(\underline{x}),a^2\int_{\partial B}\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},a\underline{\hat{y}})\underline{v}(\underline{\hat{y}})\}ds(\underline{\hat{y}})\right]=\underline{g}(\underline{x}),\quad \underline{x}\in\partial\Omega.\tag{3.6}$$

We note that when $\partial\Omega$ is only Lipschitz continuous (3.6) holds only almost everywhere in $\underline{x}\in\partial\Omega$. The numerical solution of (3.6) as an integral equation in the unknown $\underline{v}(\underline{\hat{y}})$ can be carried out using a boundary integral method. The use of a boundary integral method involves the solution of a computationally very expensive linear system. Instead of using a boundary integral method we solve equation (3.6) with a formal power series using $\partial B=\{\underline{x}\in\mathbb{R}^3|\|\underline{x}\|=1\}$ as base point, that is we look for a solution of (3.6) given by a formal series expansion of the form

$$\underline{v}(\underline{\hat{y}})=\sum_{s=0}^{+\infty}\frac{(\xi(\underline{\hat{y}})-1)^s}{s!}\underline{v}_s(\underline{\hat{y}}),\quad \underline{\hat{y}}\in\partial B,\tag{3.7}$$

where we assume $0!=1$ and the ''coefficients'' $\underline{v}_s(\underline{\hat{y}})$, $\underline{\hat{y}}\in\partial B$, $s=0,1,2,\ldots$, are vector fields tangential to ∂B to be determined. This perturbative procedure is preferable to the solution of the linear system coming from the use of a boundary integral method since the coefficients $\underline{v}_s$, $s=0,1,\ldots$, are defined by recursive formulas involving double integrals. These integrals are independent one from the other so that they can be computed in parallel. We note that $\underline{v}(\underline{\hat{y}})$ given by (3.7) is only an auxiliary unknown and that $\underline{F}(\underline{x})$ can be determined knowing only the action of some appropriate operators on $\underline{v}_s(\underline{\hat{y}})$ without knowing $\underline{v}_s(\underline{\hat{y}})$, $s=0,1,2,\ldots$. We note that the computational method proposed here relies on the assumption $a<1$ that is $B_a\subset B$ since ∂B is chosen as base point of the ''power series'' expansion (3.7). The computational method proposed here can be developed with only minor changes using for example the surface ∂B_R, $R>0$ with $R\neq 1$ as base point of the expansion (in this case $a<R$) or more in general any starlike surface with respect to the origin that defines a bounded region that contains B_a. The choice ∂B_R, $R>a>0$, is more convenient than the choice of a generic starlike surface since for ∂B_R some explicit class of functions such as the vector spherical harmonics and some useful formulas about them are available. In the numerical experience described in Sec. IV we always use ∂B_R as base point, the radius R is chosen in such a way that $\max_{\hat{\underline{x}}\in\partial B}|\xi(\hat{\underline{x}})-R|$ is approximately minimized to improve the ''convergence'' of the series (3.7).

Let $\underline{f}(\hat{\underline{x}})$ be a vector field defined on ∂B and tangential to ∂B; we define the operators p_s, $\hat{p}_s$, $s=0,1,2,\ldots$ as follows:

$$(p_s\underline{f})(\underline{x})=a^2\int_{\partial B}\frac{\partial^s}{\partial\|\underline{x}\|^s}\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},a\hat{\underline{y}})\underline{f}(\hat{\underline{y}})\}ds(\hat{\underline{y}}),\quad \|\underline{x}\|>a,\quad s=0,1,\ldots, \tag{3.8}$$

$$(\hat{p}_s\underline{f})(\hat{\underline{x}})=(p_s\underline{f})(\hat{\underline{x}}),\quad \hat{\underline{x}}\in\partial B,\quad s=0,1,\ldots. \tag{3.9}$$

For later use we define the operator $\hat{l}_0$ which acts on a vector field $\underline{f}$ defined on ∂B and tangential to ∂B through the following equation:

$$[\hat{\underline{x}},(\hat{p}_0(\hat{l}_0\underline{f}))(\hat{\underline{x}})]=\underline{f}(\hat{\underline{x}}),\quad \hat{\underline{x}}\in\partial B, \tag{3.10}$$

where $\hat{p}_0$ is the operator given in (3.9) when $s=0$. We note that Eq. (3.10) is a special case of Eq. (3.6), that is the case when $\partial\Omega=\partial B$. In Lemma 3.4 under some extra hypotheses a formula to solve Eq. (3.10) is given. Substituting (3.7) in (3.2) using the power series expansion of $\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},a\hat{\underline{y}})\underline{v}(\hat{\underline{y}})\}$ as a function of $\|\underline{x}\|$ with base point $\|\underline{x}\|=1$ and using (3.8) and (3.9) we obtain the formal expansion of $\underline{F}(\underline{x})$, $\underline{x}\in\mathbb{R}^3\setminus\overline{B_a}$:

$$\underline{F}(\underline{x})=\sum_{s=0}^{+\infty}\sum_{l=0}^{s}\frac{(\|\underline{x}\|-1)^{s-l}}{(s-l)!}\left(\hat{p}_{s-l}\left(\underline{v}_l\frac{(\xi-1)^l}{l!}\right)\right)(\hat{\underline{x}}),\quad \underline{x}=\|\underline{x}\|\hat{\underline{x}},\quad \underline{x}\in\mathbb{R}^3\setminus\overline{B_a}. \tag{3.11}$$

From (3.11) and Theorem 2.5 we obtain the formal series expansion of the far field $\underline{F}^{(0)}(\hat{\underline{x}})$ associated to $\underline{F}(\underline{x})$, in ''powers'' of $(\xi-1)$, that is

$$\underline{F}^{(0)}(\hat{\underline{x}})=\frac{a^2\imath k}{4\pi}\sum_{l=0}^{+\infty}\int_{\partial B}\exp(-\imath ka(\hat{\underline{x}},\hat{\underline{y}}))\left[\hat{\underline{x}},\underline{v}_l(\hat{\underline{y}})\frac{(\xi(\hat{\underline{y}})-1)^l}{l!}\right]ds(\hat{\underline{y}}),\quad \hat{\underline{x}}\in\partial B. \tag{3.12}$$

The problem of determining a formal power series to compute $\underline{F}(\underline{x})$ solution of (1.1), (1.2), (1.3), and (1.4) or the corresponding far field $\underline{F}^{(0)}(\hat{\underline{x}})$ is reduced to the problem of determining the coefficients $\underline{v}_s(\hat{\underline{y}})$, $s=0,1,2,\ldots$, of (3.7) using Eq. (3.6). Let

$$\hat{\underline{x}}_\theta=\frac{\partial\hat{\underline{x}}}{\partial\theta}(\theta,\phi)=(\cos\theta\cos\phi,\cos\theta\sin\phi,-\sin\theta)^T,\quad 0\leqslant\theta\leqslant\pi,\quad 0\leqslant\phi<2\pi, \tag{3.13}$$

$$\hat{\underline{x}}_\phi=\frac{\partial\hat{\underline{x}}}{\partial\phi}(\theta,\phi)=(-\sin\theta\sin\phi,\sin\theta\cos\phi,0)^T,\quad 0\leqslant\theta\leqslant\pi,\quad 0\leqslant\phi<2\pi, \tag{3.14}$$

and when $\xi(\hat{\underline{x}})$ is sufficiently regular we define

$$\begin{gathered}\tilde{\underline{n}}(\underline{x})=\hat{\underline{x}}(\theta,\phi)-\frac{\hat{\underline{x}}_\theta(\theta,\phi)}{\xi(\hat{\underline{x}}(\theta,\phi))}\frac{\partial\xi}{\partial\theta}(\hat{\underline{x}}(\theta,\phi))-\frac{1}{\sin^2\theta}\frac{\hat{\underline{x}}_\phi(\theta,\phi)}{\xi(\hat{\underline{x}}(\theta,\phi))}\frac{\partial\xi}{\partial\phi}(\hat{\underline{x}}(\theta,\phi)),\\ \underline{x}=\xi(\hat{\underline{x}}(\theta,\phi))\hat{\underline{x}}(\theta,\phi)\in\partial\Omega,\quad 0\leqslant\theta\leqslant\pi,\quad 0\leqslant\phi<2\pi\end{gathered} \tag{3.15}$$

so that we have

$$\underline{n}(\underline{x}) = \frac{\underline{\tilde{n}}(\underline{x})}{\|\underline{\tilde{n}}(\underline{x})\|}, \quad \underline{x} \in \partial\Omega, \tag{3.16}$$

where $\underline{n}(\underline{x})$ is the outward unit normal vector to $\partial\Omega$ in $\underline{x} \in \partial\Omega$. When we consider obstacles Ω with $\partial\Omega$ only locally Lipschitz we assume that formulas (3.15) and (3.16) are valid almost everywhere $\underline{x}$ for $\underline{x} \in \partial\Omega$. For example, this assumption is satisfied when Ω is a polyhedron, that is one of the choices considered in Sec. IV. For simplicity in the following abusing the notation we use ξ as an independent variable, so that $O((\xi-1)^l)$, when $\xi \to 1$ becomes a meaningful notation. It is easy to see that

$$\underline{\tilde{n}}(\underline{x}) = \sum_{l=0}^{+\infty} \underline{n}_l(\hat{\underline{x}}), \quad \underline{x} = \|\underline{x}\|\hat{\underline{x}} \in \partial\Omega,$$

where

$$\underline{n}_0(\hat{\underline{x}}) = \hat{\underline{x}}(\theta,\phi), \quad \hat{\underline{x}}\partial B, \tag{3.17}$$

$$\underline{n}_1(\hat{\underline{x}}) = -\left(\frac{\partial \xi}{\partial \theta}(\hat{\underline{x}}(\theta,\phi))\hat{\underline{x}}_\theta(\theta,\phi) + \frac{1}{\sin^2\theta}\frac{\partial \xi}{\partial \phi}(\hat{\underline{x}}(\theta,\phi))\hat{\underline{x}}_\phi(\theta,\phi)\right), \quad \hat{\underline{x}} \in \partial B \tag{3.18}$$

$$\underline{n}_l(\hat{\underline{x}}) = (-1)^{l-1}(\xi(\hat{\underline{x}}(\theta,\phi))-1)^{l-1}\underline{n}_1(\hat{\underline{x}}), \quad l=2,3,\ldots, \quad \hat{\underline{x}} \in \partial B, \tag{3.19}$$

and $\underline{n}_l(\hat{\underline{x}}) = O((\xi(\hat{\underline{x}})-1)^l)$, $l=0,1,2,\ldots$, when $\xi \to 1$, $\hat{\underline{x}} \in \partial B$. We remark that the expansion in ''powers'' of $(\xi-1)$ that we present is only formal and we consider the terms $\partial\xi/\partial\theta, \partial\xi/\partial\phi$ to be $O((\xi-1))$ when $\xi \to 1$ in fact formally $\partial\xi/\partial\theta = \partial/\partial\theta(\xi-1)$ and $\partial\xi/\partial\phi = (\partial/\partial\phi)(\xi-1)$. Since the vector field $\underline{g}$ in (1.3) is tangential to $\partial\Omega$ we can write $\underline{g}$ as follows:

$$\underline{g}(\underline{x}) = -[\underline{n},\underline{b}](\underline{x}), \quad \underline{x} \in \partial\Omega, \tag{3.20}$$

for a suitable choice of the vector field $\underline{b}(\underline{x})$. For example, $\underline{b}(\underline{x}) = [\underline{n},\underline{g}](\underline{x})$, $\underline{x} \in \partial\Omega$ is a possible choice. Using (3.16) and (3.20), Eq. (3.6) can be rewritten as follows:

$$\left[\underline{\tilde{n}}(\underline{x}), a^2 \int_{\partial B} \mathrm{curl}_{\underline{x}}\{\Phi(\underline{x}, a\hat{\underline{y}})\underline{v}(\hat{\underline{y}})\} ds(\hat{\underline{y}})\right] = -[\underline{\tilde{n}},\underline{b}](\underline{x}), \quad \underline{x} \in \partial\Omega. \tag{3.21}$$

Lemma 3.1: Let n_l, $l=0,1,2,\ldots$, be given by (3.17), (3.18), and (3.19), let $\underline{b}$ be as in (3.20) and let $\underline{\tilde{b}}(\hat{\underline{x}}) = \underline{b}(\xi(\hat{\underline{x}})\hat{\underline{x}})$, $\hat{\underline{x}} \in \partial B$, let $\underline{F}$, given by (3.2), be an extension of the solution of (1.1), (1.2), (1.3), and (1.4) and let $\underline{F}(\xi(\hat{\underline{x}})\hat{\underline{x}}) = \Sigma_{l=0}^{+\infty}\underline{F}_l(\hat{\underline{x}})$, with $\underline{F}_l(\hat{\underline{x}}) = O((\xi(\hat{\underline{x}})-1)^l)$, when $\xi \to 1$, $l=0,1,2,\ldots$, then the following recursive formulas for $\underline{F}_l$, $l=0,1,2,\ldots$ hold:

$$[\underline{n}_0,\underline{F}_0](\hat{\underline{x}}) = -[\underline{n}_0,\underline{\tilde{b}}](\hat{\underline{x}}), \quad \hat{\underline{x}} \in \partial B, \tag{3.22}$$

$$[\underline{n}_0,\underline{F}_\nu](\hat{\underline{x}}) = -(\xi-1)^{\nu-1}(-1)^{\nu-1}[\underline{n}_1,\underline{\tilde{b}}](\hat{\underline{x}}) - \sum_{s=0}^{\nu-1}(\xi-1)^{\nu-s-1}(-1)^{\nu-s-1}[\underline{n}_1,\underline{F}_s](\hat{\underline{x}}),$$
$$\nu=1,2,\ldots,\hat{\underline{x}} \in \partial B. \tag{3.23}$$

We observe that formulas (3.22) and (3.23) are compatible if in fact we have

$$\left(\underline{n}_0(\hat{\underline{x}}), \sum_{s=0}^{\nu-1}(\xi-1)^{\nu-s-1}(-1)^{\nu-s-1}[\underline{n}_1,\underline{F}_s](\hat{\underline{x}}) + (\xi-1)^{\nu-1}(-1)^{\nu-1}[\underline{n}_1\underline{\tilde{b}}](\hat{\underline{x}})\right) = 0,$$
$$\nu=1,2,\ldots, \quad \hat{\underline{x}} \in \partial B. \tag{3.24}$$

Proof: Imposing (3.21) order by order in ''powers'' of $(\xi-1)$ we have equations (3.22) and (3.23). We prove (3.24) by induction on ν. From (3.22) we have

$$(\underline{n}_1(\underline{\hat{x}}),[\underline{n}_0,\underline{F}_0+\underline{\tilde{b}}](\underline{\hat{x}}))=0, \quad \underline{\hat{x}}\in\partial B$$

so that when $\nu=1$ (3.24) holds in fact:

$$(\underline{n}_0(\underline{\hat{x}}),[\underline{n}_1,\underline{F}_0+\underline{\tilde{b}}](\underline{\hat{x}}))=(\underline{n}_1(\underline{\hat{x}}),[\underline{n}_0,\underline{F}_0+\underline{\tilde{b}}](\underline{\hat{x}})).$$

Now we assume by induction that formula (3.24) holds when $\nu=k$ and we prove that (3.24) holds when $\nu=k+1$. We have

$$\begin{aligned}&\left(\underline{n}_0(\underline{\hat{x}}),\sum_{s=0}^{k}(\xi-1)^{k-s}(-1)^{k-s}[\underline{n}_1,\underline{F}_s](\underline{\hat{x}})+(\xi-1)^k(-1)^k[\underline{n}_1,\underline{\tilde{b}}](\underline{\hat{x}})\right)-(\xi-1)\\&\quad\times\left(\underline{n}_0(\underline{\hat{x}}),\sum_{s=0}^{k-1}(\xi-1)^{k-s-1}(-1)^{k-s-1}[\underline{n}_1,\underline{F}_s](\underline{\hat{x}})+(\xi-1)^{k-1}(-1)^{k-1}[\underline{n}_1,\underline{\tilde{b}}](\underline{\hat{x}})\right)\\&\quad+(\underline{n}_0(\underline{\hat{x}}),[\underline{n}_1,\underline{F}_k](\underline{\hat{x}}))=(\underline{n}_1(\underline{\hat{x}}),[\underline{n}_0,\underline{F}_k](\underline{\hat{x}})), \quad \underline{\hat{x}}\in\partial B, \end{aligned} \tag{3.25}$$

so that the thesis follows using formula (3.23) for $\underline{F}_k$. ■

Now we can write the formulas which give the coefficients $\underline{v}_s$, $s=0,1,2,...$ of (3.7) using the operator $\hat{l}_0$ defined in (3.10). In Lemma 3.4 we give an explicit formula for $\hat{l}_0$.

Theorem 3.2: Let $\underline{\tilde{b}}$ be as in Lemma 3.1 and $\underline{v}$ be a vector field defined on ∂B satisfying (3.3) such that the vector field $\underline{F}$, given by (3.2), coincides with the solution of the boundary value problem (1.1), (1.2), (1.3), and (1.4) in $\mathbb{R}^3\backslash\Omega$. Then formulas (3.7) and (3.11) hold with

$$\frac{(\xi-1)^s}{s!}\underline{v}_s(\underline{\hat{x}})=(\hat{l}_0\underline{h}_s)(\underline{\hat{x}}), \quad s=0,1,..., \quad \underline{\hat{x}}\in\partial B, \tag{3.26}$$

where

$$\underline{h}_0(\underline{\hat{x}})=-[\underline{n}_0,\underline{\tilde{b}}](\underline{\hat{x}}), \quad \underline{\hat{x}}\in\partial B, \tag{3.27}$$

$$\begin{aligned}\underline{h}_s(\underline{\hat{x}})=&-\left[\underline{n}_0,\sum_{m=0}^{s-1}\frac{(\xi-1)^{s-m}}{(s-m)!}\left(\hat{p}_{s-m}\left(\underline{v}_m\frac{(\xi-1)^m}{m!}\right)\right)\right](\underline{\hat{x}})-\sum_{\nu=0}^{s-1}(\xi(\underline{\hat{x}})-1)^{s-1-\nu}(-1)^{s-1-\nu}\\&\times\left[\underline{n}_1,\sum_{l=0}^{\nu}\frac{(\xi-1)^{\nu-l}}{(\nu-l)!}\left(\hat{p}_{\nu-l}\left(\underline{v}_l\frac{(\xi-1)^l}{l!}\right)\right)\right](\underline{\hat{x}})-(-1)^{s-1}(\xi(\underline{\hat{x}})-1)^{s-1}[\underline{n}_1,\underline{\tilde{b}}](\underline{\hat{x}}),\\&\underline{\hat{x}}\in\partial B, \quad s=1,2,..., \end{aligned} \tag{3.28}$$

where $\hat{p}_s$, $s=0,1,...$, and $\hat{l}_0$ are the operators defined in (3.9) and (3.10).

Proof (formal): It is easy to see that the vector fields $\underline{h}_s$, $s=0,1,2,...$ are tangential to ∂B. The proof follows from the integral representation formula (3.2), Lemma 3.1, and Eq. (3.21) using the Cauchy rule in the product of the series expansion in powers of $(\xi-1)$ of $\underline{\tilde{n}}$ and of $\underline{F}$ given by (3.11). ■

Now we give some Lemmas that will be used in Sec. IV.

Let $\{\underline{B}_{\sigma,m,l}(\underline{\hat{x}}),\underline{C}_{\sigma,m,l}(\underline{\hat{x}}),\underline{P}_{\sigma,m,l}(\underline{\hat{x}})\}_{\sigma=0,1,l=\sigma,\sigma+1,...,m=\sigma,...,l}$ be the complete orthonormal set of $(L^2(\partial B))^3$ made of vector spherical harmonics functions (see Ref. 17, Chap. 13, page 1898). Since $\partial\Omega$ is a starlike surface with respect to the origin and we use an expansion with ∂B as base point, we can expand data and unknown of Eq. (3.21) with respect to this set of vector functions.

This choice makes easy the computation of the coefficients $\underline{v}_s$, $s=0,1,2,\ldots$, of (3.7). In fact in Lemmas 3.3 and 3.4 we show that the operators $\hat{l}_0$, $\hat{p}_s$, $s=0,1,\ldots$, are represented by simple matrices in this basis.

Lemma 3.3: Let $\underline{f}$ be a vector field defined on ∂B and tangential to ∂B, i.e.,

$$(\underline{f}(\underline{\hat{x}}),\underline{\hat{x}})=0, \quad \underline{\hat{x}}\in\partial B. \tag{3.29}$$

Moreover let $\underline{f}$ be given by the following by the following expansion:

$$\underline{f}(\underline{\hat{x}})=\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{+\infty}\sum_{m=\sigma}^{l}\{f_{C_{\sigma,m,l}}\underline{C}_{\sigma,m,l}(\underline{\hat{x}})+f_{B_{\sigma,m,l}}\underline{B}_{\sigma,m,l}(\underline{\hat{x}})\}, \quad \underline{\hat{x}}\in\partial B, \tag{3.30}$$

where $\{f_{C_{\sigma,m,l}},f_{B_{\sigma,m,l}}\}$, $\sigma=0,1$, $l=\sigma,\sigma+1,\ldots$, $m=\sigma,\sigma+1,\ldots,l$ are the generalized Fourier coefficients of $\underline{f}$ and let $\hat{p}_s$, $s=0,1,2,\ldots$, be the operators given by (3.9), then we have

$$\begin{aligned}(\hat{p}_s\underline{f})(\underline{\hat{x}})=\iota k^2a^2\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{+\infty}\sum_{m=\sigma}^{l}\Bigg\{&\underline{P}_{\sigma,m,l}(\underline{\hat{x}})f_{C_{\sigma,m,l}}j_l(ka)\sqrt{l(l+1)}\left(k^s\sum_{q=0}^{s}\binom{s}{q}(-1)^q q!\,\frac{h_l^{(s-q)}(k)}{k^{q+1}}\right)\\&+\underline{B}_{\sigma,m,l}(\underline{\hat{x}})j_l(ka)f_{C_{\sigma,m,l}}\left((l+1)k^s\sum_{q=0}^{s}\binom{s}{q}(-1)^q q!\,\frac{h_l^{(s-q)}(k)}{k^{q+1}}-k^sh_{l+1}^{(s)}(k)\right)\\&+k^s\underline{C}_{\sigma,m,l}(\underline{\hat{x}})h_l^{(s)}(k)\left(\frac{(l+1)j_l(ka)}{ka}-j_{l+1}(ka)\right)f_{B_{\sigma,m,l}}\Bigg\}, \quad \underline{\hat{x}}\in\partial B,\end{aligned} \tag{3.31}$$

where $h_l(z)$, $j_l(z)$, $l=0,1,2,\ldots$ are the spherical Hankel and the spherical Bessel functions, respectively.

Proof: The proof follows by an easy computation using the so called Green's dyadic for free space (see Ref. 17, Chap. 13, page 1875). ■

Lemma 3.4: Let $\underline{f}$ be a vector field defined on ∂B such that (3.29) and (3.30) hold, let $\hat{l}_0$ be the operator given by (3.10) and let the wave number k be such that

$$j_l(ka)\neq 0, \quad l=0,1,2,\ldots, \tag{3.32}$$

$$((l+1)j_l(ka)-kaj_{l+1}(ka))\neq 0, \quad l=0,1,2,\ldots, \tag{3.33}$$

then we have

$$\begin{aligned}(\hat{l}_0\underline{f})(\underline{\hat{x}})=\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{+\infty}\sum_{m=\sigma}^{l}\Bigg\{&\frac{\underline{B}_{\sigma,m,l}(\underline{\hat{x}})f_{B_{\sigma,m,l}}}{\iota kah_l(k)((l+1)j_l(ka)-kaj_{l+1}(ka))}\\&-\frac{\underline{C}_{\sigma,m,l}(\underline{\hat{x}})f_{C_{\sigma,m,l}}}{\iota ka^2j_l(ka)((l+1)h_l(k)-kh_{l+1}(k))}\Bigg\}, \quad \underline{\hat{x}}\in\partial B.\end{aligned} \tag{3.34}$$

Proof: It is easy to see that $h_l(k)\neq 0$ and $(l+1)h_l(k)-kh_{l+1}(k))\neq 0$, $l=0,1,\ldots$, for k real and positive by virtue of the properties of the spherical Hankel functions (see Ref. 18, page 439). The proof follows using (3.31) with $s=0$, Eq. (3.10) and the fact that

$$(\underline{n}_0(\underline{\hat{x}}),\underline{P}_{\sigma,m,l}(\underline{\hat{x}}))=0, \ \ \underline{\hat{x}}\in\partial B, \ \ \sigma=0,1, \ \ l=\sigma,\sigma+1,\ldots, \ \ m=\sigma,\sigma+1,\ldots,l.$$

■

Remark: We observe that the conditions (3.32) and (3.33) are necessary due to the choices made in the factorization of the operators involved in Eq. (3.10). A different factorization will make these conditions not necessary. This will appear more clearly in Lemma 3.5. Moreover it is

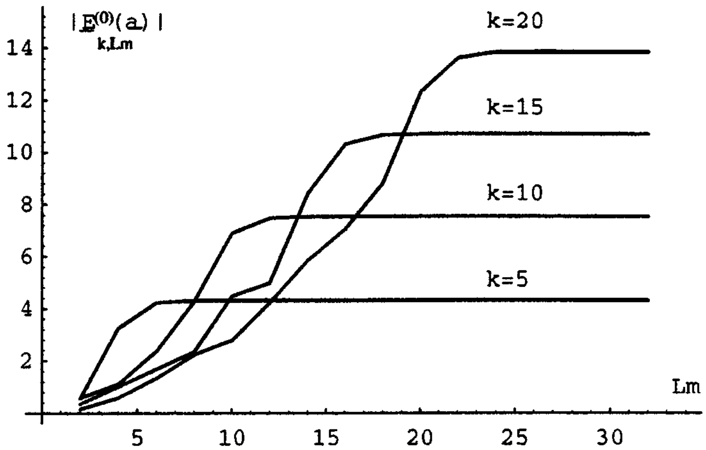

FIG. 1. $|\underline{E}_{k,L_m}(\underline{a})|$ as function of L_m and k relative to the sphere of radius $R=1$.

always possible to choose the radius a such that (3.32) and (3.33) hold, since the zeros of (3.32) and (3.33) are a measure zero set in the interval $\{a\in\mathbb{R}|0<a<1\}$. Finally in practice when using the computational method it is not necessary to choose the radius a to satisfy (3.32) and (3.33) in fact (3.32) and (3.33) are always satisfied numerically.

Lemma 3.5: Let $\hat{p}_s$, $s=0,1,2,\ldots,\hat{l}_0$ be the operators given by (3.9) and (3.10), respectively, and let $\underline{f}$ be a vector field defined on ∂B such that (3.29) and (3.30) hold, then we have

$$(\hat{p}_s(\hat{l}_0\underline{f}))(\underline{\hat{x}})=\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{+\infty}\sum_{m=\sigma}^{l}\Bigg\{-\underline{P}_{\sigma,m,l}(\underline{\hat{x}})\frac{f_{C_{\sigma,m,l}}k\sqrt{l(l+1)}}{((l+1)h_l(k)-kh_{l+1}(k))}$$
$$\times\left(k^s\sum_{q=0}^{s}\binom{s}{q}(-1)^q q!\,\frac{h_l^{(s-q)}(k)}{k^{q+1}}\right)-\underline{B}_{\sigma,m,l}(\underline{\hat{x}})\frac{f_{C_{\sigma,m,l}}k}{((l+1)h_l(k)-kh_{l+1}(k))}$$
$$\times\left((l+1)k^s\sum_{q=0}^{s}\binom{s}{q}(-1)^q q!\,\frac{h_l^{(s-q)}(k)}{k^{q+1}}-k^sh_{l+1}^{(s)}(k)\right)$$
$$+k^s\underline{C}_{\sigma,m,l}(\underline{\hat{x}})h_l^{(s)}(k)\frac{f_{B_{\sigma,m,l}}}{h_l(k)}\Bigg\},\quad \underline{\hat{x}}\in\partial B,\quad s=0,1,2,\ldots,\tag{3.35}$$

where $h_l(z)$, $j_l(z)$, $l=0,1,2,\ldots$ are the spherical Hankel and the spherical Bessel functions, respectively.

Proof: It follows using (3.31) and (3.34) by an easy computation. ■

We note that substituting formula (3.35) into (3.28) we can compute $\underline{h}_s$, given by (3.28), by a recursive formula involving only the vector fields $\underline{h}_\nu$, $\nu=0,1,\ldots,s-1$ and not $\underline{v}_\nu(\xi-1)^\nu/\nu!$, $\nu=0,1,\ldots,s-1$, by doing so we avoid the conditions (3.32), and (3.33) since $\hat{l}_0$ is never considered standing alone but always appears in products such as $\hat{p}_s\hat{l}_0$, $s=0,1,2,\ldots$.

4	4.00e-04	7.12e-04	6.80e-04
6	1.13e-03	4.13e-03	1.11e-02
8	2.72e-03	2.47e-02	2.44e-02
10	6.53e-03	9.91e-02	9.67e-02

The possibility of computing $\underline{h}_s$ using a recursive formula involving only $\underline{h}_\nu$, $\nu=0,1,...,(s-1)$ [i.e., Eq. (3.28)] is the basis of the computational cost estimates given in Sec. IV (see Table I).

Lemma 3.6: Let $\underline{h}_s(\hat{\underline{x}})$, $\hat{\underline{x}}\in\partial B$, $s=0,1,2,...$ be the vector field given by (3.28) and let $\underline{h}_s$ be given by the following expansion:

$$\underline{h}_s(\hat{\underline{x}})=\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{+\infty}\sum_{m=\sigma}^{l}\{h_{s,B_{\sigma,m,l}}\underline{B}_{\sigma,m,l}(\hat{\underline{x}})+h_{s,C_{\sigma,m,l}}\underline{C}_{\sigma,m,l}(\hat{\underline{x}})\},\quad s=0,1,...,\quad \hat{\underline{x}}\in\partial B, \tag{3.36}$$

where $h_{s,B_{\sigma,m,l}}$, $h_{s,C_{\sigma,m,l}}$, $s=0,1,...$, $\sigma=0,1$, $l=\sigma$, $\sigma+1,...$, $m=\sigma$, $\sigma+1,...,l$, are the generalized Fourier coefficients of $\underline{h}_s(\hat{x})$, then the far field $\underline{F}^{(0)}(\hat{x})$ given by (3.11) has the following expansion:

$$\underline{F}^{(0)}(\hat{\underline{x}})=\sum_{s=0}^{+\infty}\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{+\infty}\sum_{m=\sigma}^{l}\left\{\frac{\underline{B}_{\sigma,m,l}(\hat{\underline{x}})h_{s,C_{\sigma,m,l}}}{\iota^{l+2}((l+1)h_l(k)-kh_{l+1}(k))}+\frac{\underline{C}_{\sigma,m,l}(\hat{\underline{x}})h_{s,B_{\sigma,m,l}}}{\iota^{l+1}kh_l(k)}\right\},\quad \hat{\underline{x}}\in\partial B. \tag{3.37}$$

Proof (formal): The proof follows using the integral representation formula (3.2), the Green's dyadic (Ref. 17, Chap. 13, page 1874) and the following asymptotic expansion of the spherical Hankel functions:

$$h_l(k\|\underline{x}\|)=\iota^{-(l+1)}\frac{\exp(\iota k\|\underline{x}\|)}{k\|\underline{x}\|}+O\left(\frac{1}{(k\|\underline{x}\|)^2}\right),\quad \|\underline{x}\|\to+\infty,\quad l=0,1,\dots. \tag{3.38}$$

■

IV. SOME COMPUTATIONAL RESULTS

We apply the computational method proposed in Sec. III to the electromagnetic scattering problem of Sec. I. That is we consider the scattering problem associated to a linearly polarized electromagnetic plane wave that hits the obstacle Ω. We restrict our attention to the study of the far field pattern associated to the scattered field that is to the computation of (3.37). Let $\underline{E}^i$ be the space dependent part of the electric field associated to the incoming plane wave, we have

$$\underline{E}^i(\underline{x})=\underline{P}\exp(\iota k(\underline{x},\underline{a})), \tag{4.1}$$

where $\underline{P}$, $\underline{a}\in\mathbb{R}^3$, $\|\underline{a}\|=1$ are given and k is the wave number. We assume k to be a positive real number. The vector $\underline{a}$ is the propagation direction of the plane wave and $\underline{P}$ is the polarization vector of the plane wave. We assume

$$\operatorname{div}\underline{E}^i(\underline{x})=\iota k(\underline{P},\underline{a})\exp(\iota k(\underline{x},\underline{a}))=0, \tag{4.2}$$

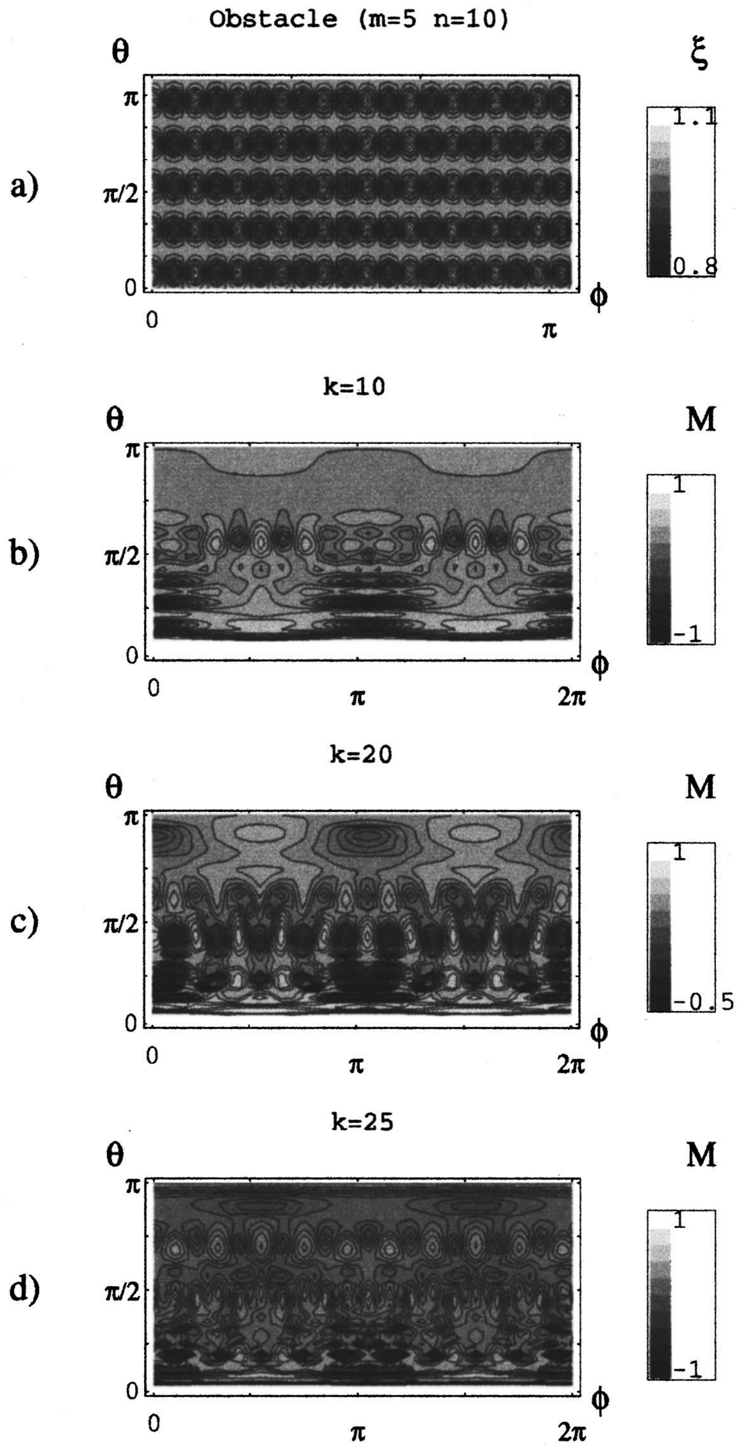

FIG. 2. (a) Contour plot of the corrugated sphere for $m=5$, $n=10$; (b), (c), (d) contour plots of $M(\theta,\phi)$ relative to the geometry for different values of k.

that is $\underline{P}$ and $\underline{q}$ are orthogonal. Let α, β, γ be such that $0\leqslant\alpha\leqslant\pi, 0\leqslant\beta<2\pi, -\pi/2\leqslant\gamma\leqslant\pi/2$ we can parametrize the vectors $\underline{q}$, $\underline{P}$ as follows:

$$\underline{q}=(\sin\alpha\cos\beta,\sin\alpha\sin\beta,\cos\alpha)^T, \tag{4.3}$$

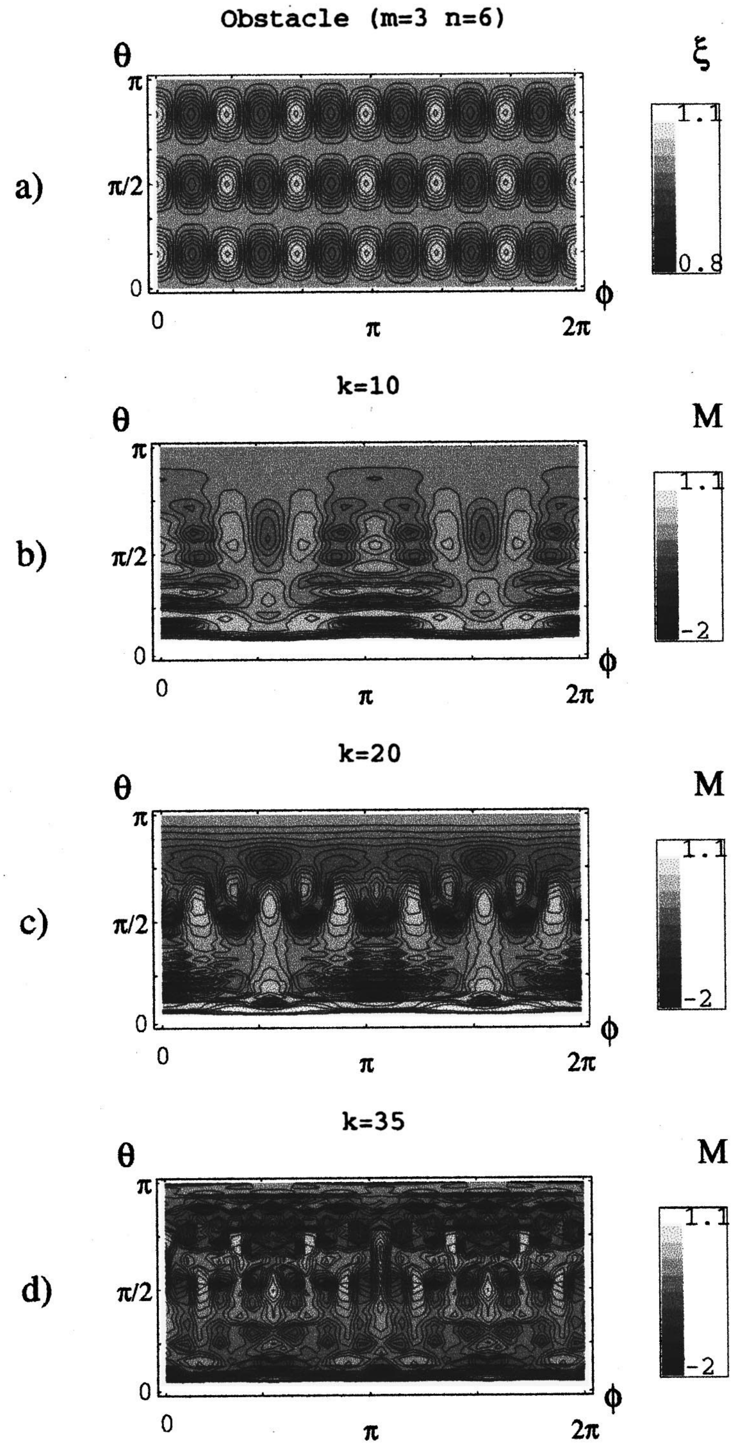

FIG. 3. (a) Contour plot of the corrugated sphere for $m=3$, $n=6$; (b), (c), (d) contour plots of $M(\theta,\phi)$ relative to the geometry for different values of k.

$$\underline{P}=(-\sin\gamma\sin\beta+\cos\gamma\cos\alpha\cos\beta,\sin\gamma\cos\beta+\cos\gamma\cos\alpha\sin\beta,-\cos\gamma\sin\alpha)^{T}. \quad (4.4)$$

We note that when the incoming wave is given by (4.1), the zero-order term of the expansion in powers of $\xi-1$ of the far field $\underline{E}^{(0)}(\hat{\underline{x}})$ associated to the scattering problem (1.1), (1.2), (1.3), and (1.4) with $\underline{g}$ given by (1.3) has an explicit formula given by a series of vector spherical harmonics

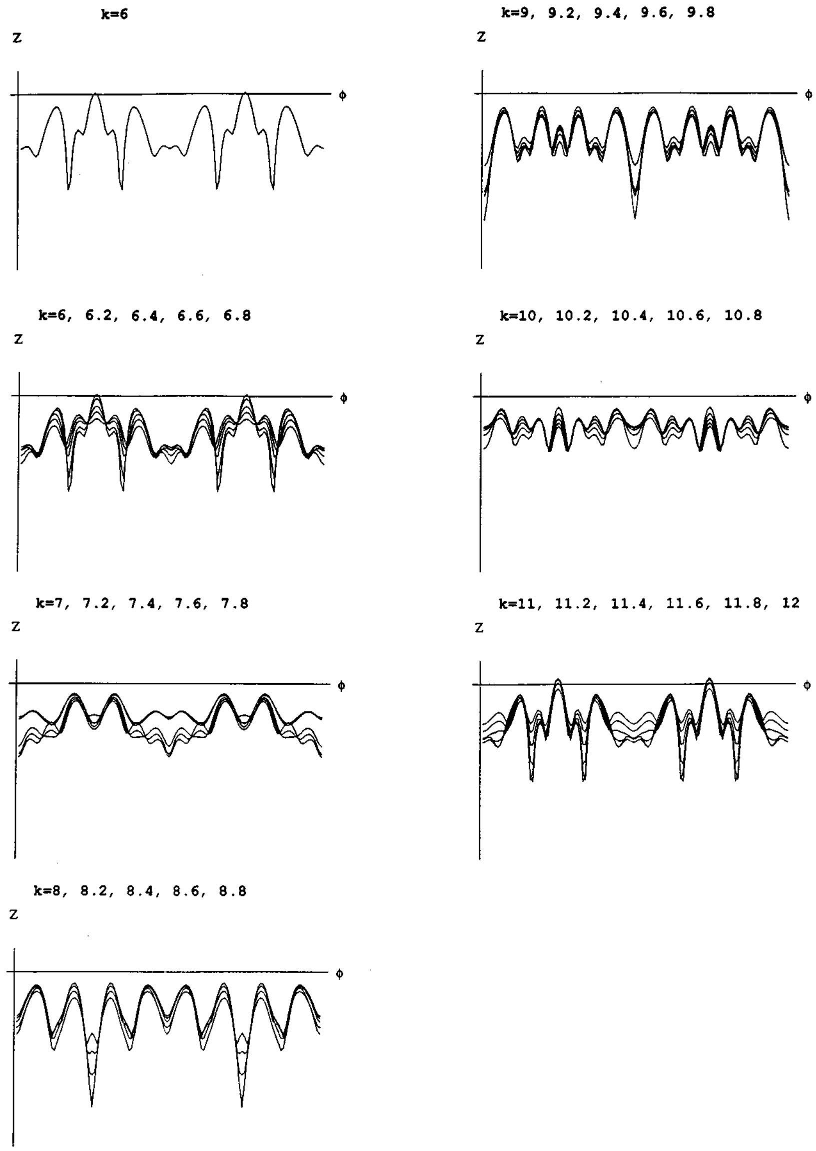

FIG. 4. $Z(\phi)$ versus ϕ relative to a corrugated sphere $m=4$, $n=8$ for different values of k.

(see Ref. 17, Chap. 13, page 1866) and coincides with the formula of the far field pattern generated by the sphere of radius one and center the origin when hit by the incoming wave (4.1).

Using the assumptions and the results of Sec. III we can say that $\underline{E}^{(0)}(\hat{\underline{x}})$ coincides with $\underline{F}^{(0)}(\hat{\underline{x}})$ given by (3.37).

First of all we consider the problem of where to truncate the series expansion (3.37) for $\underline{F}^{(0)}(\hat{\underline{x}})$ to have satisfactory approximation of the far field $\underline{E}^{(0)}(\hat{\underline{x}})$. To do this we consider the series expansion associated with the far field pattern generated by the sphere of radius one (i.e., $\Omega=B$) when hit by the incoming wave (4.1) truncated at $L_m>0$ that is

$$\underline{E}^{(0)}_{k,L_m}(\hat{\underline{x}})=\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{L_m}\sum_{m=\sigma}^{l}\left\{\frac{\underline{C}_{\sigma,m,l}(\hat{\underline{x}})(-1)^{l}\iota^{l+1}h_{0,B_{\sigma,m,l}}}{kh_l(k)}+\frac{\underline{B}_{\sigma,m,l}(\hat{\underline{x}})(-1)^{l+1}\iota^{l+2}h_{0,C_{\sigma,m,l}}}{(l+1)h_l(k)-kh_{l+1}(k)}\right\},$$

$$\hat{\underline{x}}\in\partial B, \tag{4.5}$$

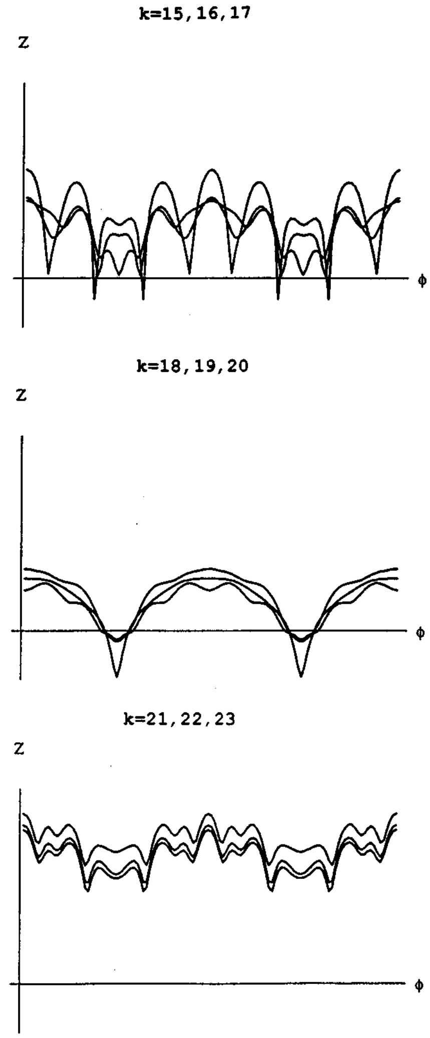

FIG. 5. $Z(\phi)$ versus ϕ relative to a corrugated sphere $m=4$, $n=8$ for different values of k.

we note that $h_l(k)$ and $(l+1)h_l(k)-kh_{l+1}(k)$, $l=0,1,...$, are not zero (see Lemma 3.4). The Fourier coefficients $\{h_{0,C_{\sigma,m,l}},h_{0,B_{\sigma,m,l}}\}$, $\sigma=0,1$, $l=\sigma,\ \sigma+1,...,L_m$, $m=\sigma,\ \sigma+1,...,l$, of the vector field $\underline{h}_0$ defined in (3.27) are given by

$$h_{0,B_{\sigma,m,l}}=-\epsilon_m \iota^l j_l(k)\frac{(2l+1)(l-m)!}{(l+m)!}(\underline{A},\underline{C}_{\sigma,m,l}(\underline{a})), \tag{4.6}$$

$$h_{0,C_{\sigma,m,l}}=-\epsilon_m \iota^{l+1}\frac{(l+1)j_l(k)-kj_{l+1}(k)}{k}\frac{(2l+1)(l-m)!}{(l+m)!}(\underline{A},\underline{B}_{\sigma,m,l}(\underline{a})), \tag{4.7}$$

where

$$\epsilon_m=\begin{cases}1 & m=0\\ 2 & m\neq 0\end{cases}.$$

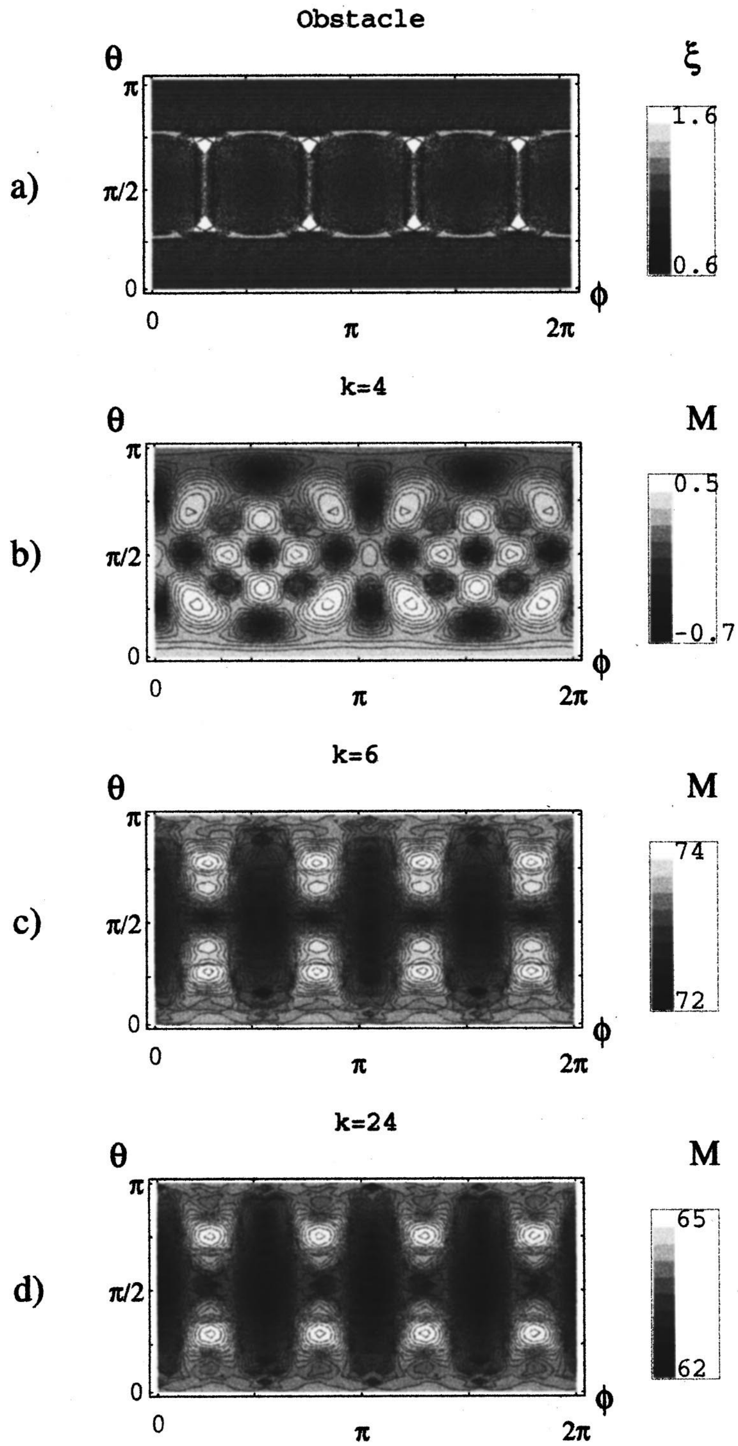

FIG. 6. (a) Contour plot of the cube; (b), (c), (d) contour plots of $M(\theta,\phi)$ relative to the geometry for different values of k.

We look for the smallest value of L_m such that ''numerical convergence'' is reached. We declare that ''numerical convergence'' has been reached when the following test is satisfied:

$$||\underline{E}^{(0)}_{k,L_m+1}(\hat{\underline{x}})|-|\underline{E}^{(0)}_{k,L_m}(\hat{\underline{x}})||\leq 10^{-6}|\underline{E}^{(0)}_{k,L_m}(\hat{\underline{x}})|, \quad \hat{\underline{x}}\in\partial B. \tag{4.8}$$

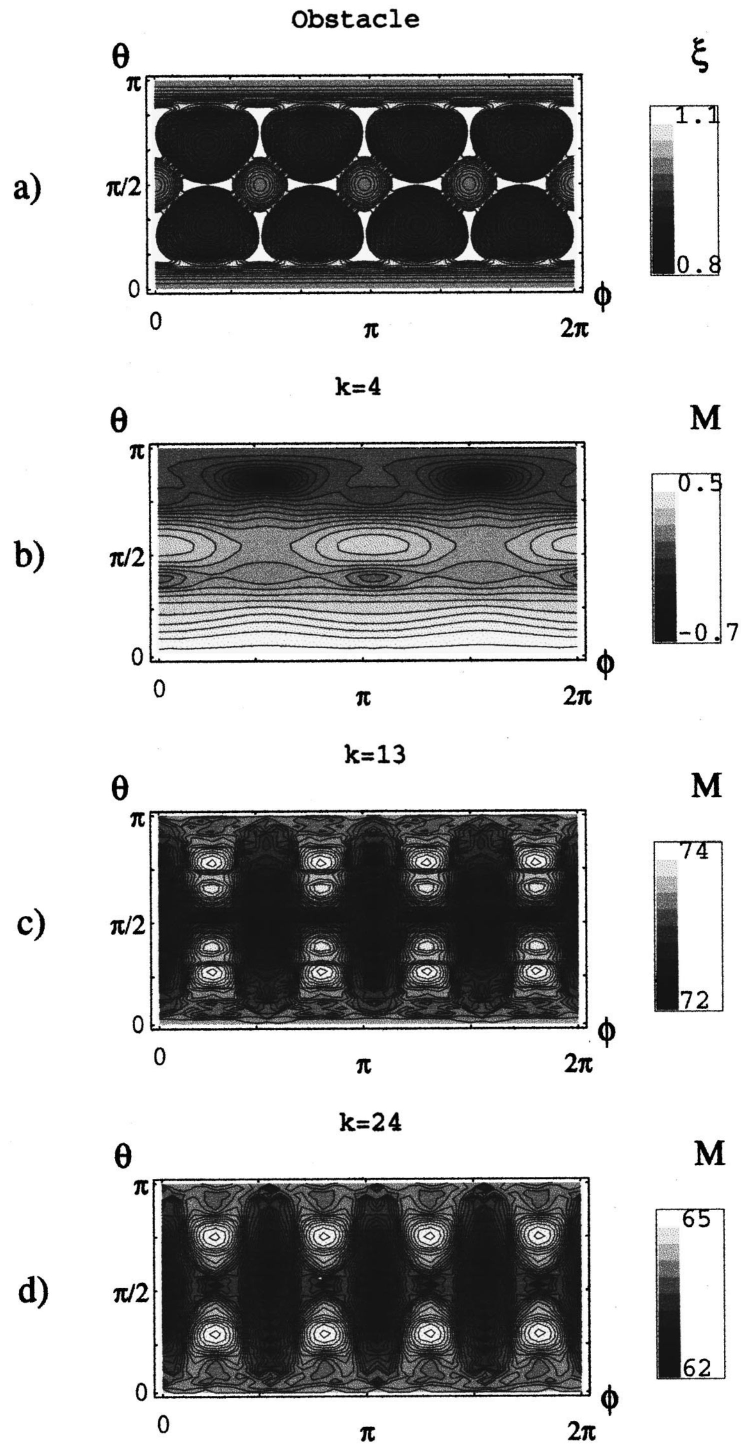

FIG. 7. (a) Contour plot of the octahedron; (b), (c), (d) contour plots of $M(\theta,\phi)$ relative to the geometry for different values of k.

We remind that if $\underline{E}=(E_1,E_2,E_3)^T$ then $|\underline{E}|=[\Sigma_{j=1}^{3}(E_j,\overline{E_j})]^{1/2}$, see Sec. II. From Fig. 1 we can conclude that when k increases the smallest value of L_m such that (4.8) is satisfied increases. The results shown in Fig. 1 are limited to the case of the sphere (i.e., $\Omega=B$) when $\hat{\underline{x}}=\underline{a}$ but these are relevant results since we expect that for a more general Ω and for a general $\hat{\underline{x}}$ the value of L_m that ensures numerical convergence will be greater or equal than the corresponding L_m relative to the case of the sphere when $\hat{\underline{x}}=\hat{a}$. Next we consider the computational cost of the method proposed in Sec. III in terms of the number of double integrals that given L_m must be computed in order to evaluate the expansion in ''powers'' of $(\xi-1)$ of the far field (3.37) up to order s that is

$$\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}})=\sum_{\nu=0}^{s}\sum_{\sigma=0}^{1}\sum_{l=\sigma}^{L_m}\sum_{m=\sigma}^{l}\left\{\underline{C}_{\sigma,m,l}(\hat{\underline{x}})\frac{h_{\nu,B_{\sigma,m,l}}}{\iota^{l+1}kh_l(k)}+\underline{B}_{\sigma,m,l}(\hat{\underline{x}})\frac{1}{\iota^{l+2}}\frac{h_{\nu,C_{\sigma,m,l}}}{(l+1)h_l(k)-kh_{l+1}(k)}\right\},$$

$$\hat{\underline{x}}\in\partial B, \tag{4.9}$$

where $\{h_{\nu,C_{\sigma,m,l}},h_{\nu,B_{\sigma,m,l}}\}$, $\nu=0,1,...,s$ $\sigma=0,1$, $l=\sigma$, $\sigma+1,...,L_m$, $m=\sigma$, $\sigma+1,...,l$, are the coefficients of the expansion of the vector field $\underline{h}_\nu$, $\nu=0,1,...,s$ given by (3.28). This is compared with the number of double integrals necessary to evaluate the T-matrix[14] when the T-matrix is evaluated using an expansion in vector spherical harmonics truncated at L_m. The T-matrix method is an alternative way to compute the far field $\underline{E}^{(0)}(\hat{\underline{x}})$.

Table I shows the result of this comparison. We note that the computational cost of the method proposed in Sec. III is given by a polynomial in s times a polynomial in L_m. That is relatively large values of s and L_m can be used. Moreover at a given order in ''perturbation theory'' (i.e., the contribution of the terms of order i, $i=1,2,...,s$) the computation is fully parallelizable with respect to the number of vector spherical harmonics involved (i.e., the value of L_m chosen). Table II shows a comparison between the far fields obtained with the perturbation series (4.9) and the far fields obtained with the T-matrix method for three axial symmetric obstacles.

We consider the following obstacles:

(1) Sphere: $\xi(\hat{\underline{x}}(\theta,\phi))=1.05$, $0\leqslant\theta\leqslant\pi$, $0\leqslant\phi<2\pi$.
(2) Ellipsoid: $\xi(\hat{\underline{x}}(\theta,\phi))=[(\sin\theta/1.05)^2+(\cos\theta/0.95)^2]^{-1/2}$, $0\leqslant\theta\leqslant\pi$, $0\leqslant\phi<2\pi$.
(3) Platelet: $\xi(\hat{\underline{x}}(\theta,\phi))=1.0+0.05\cos 2\theta$, $0\leqslant\theta\leqslant\pi$, $0\leqslant\phi<2\pi$.

For the incoming wave (4.1) we choose $\underline{a}=(0,0,1)^T$, $\underline{P}=(1,0,0)^T$. In Table II we denote with $\epsilon_{L_2}^{|\underline{E}^{(0)}|}$ the following quantity:

$$\epsilon_{L_2}^{|\underline{E}^{(0)}|}=\left[\frac{\Sigma_{j=0}^{20}||\underline{E}_T^{(0)}(\hat{\underline{x}}_j)|-|\underline{E}_{k,7,3}^{(0)}(\hat{\underline{x}}_j)||^2}{\Sigma_{j=0}^{20}|\underline{E}_T^{(0)}(\hat{\underline{x}}_j)|^2}\right]^{1/2}, \tag{4.10}$$

where $\hat{\underline{x}}_j=(\sin\theta_j,0,\cos\theta_j)^T$, with $\theta_j=j\pi/20$, $j=0,1,...,20$, $\underline{E}_T^{(0)}$ is the far field obtained with the T-matrix method when the T-matrix is approximated with an expansion in vector spherical harmonics truncated at $L_m=7$. Finally $\underline{E}_{k,7,3}^{(0)}$ given by (4.9) is the far field obtained with the expansion in (3.37) up to order $s=3$ in powers of $(\xi-1)$ with $L_m=7$.
We note that $\epsilon_{L_2}^{|\underline{E}^{(0)}|}$ is always small and depends on $k(\xi-1)$, in particular when $k\leqslant 10$ and $\max_{\theta,\phi}|\xi(\hat{\underline{x}}(\theta,\phi))-1|\leqslant 0.05$ we have $\epsilon_{L_2}^{|\underline{E}^{(0)}|}$ less than 3%. The previous choice of obstacles and incoming waves is a generic choice that gives a good sample of the behavior of the method in comparison with other computational methods such as the T-matrix method. We consider now obstacles with more complicated geometries. That is we consider obstacles with multiscale corrugations and obstacles with Lipschitz continuous boundaries such as polyhedra. We consider the following obstacles.

(4) Corrugated sphere: $\xi(\hat{\underline{x}}(\theta,\phi))=r_0+d\sin^2 m\theta\cos n\phi$ where $r_0>0$, $d\in\mathbb{R}$, $|d|<r_0$, m,n are integers [see Figs. 2(a) and 3(a)].
(5) Cube [see Fig. 6(a)].
(6) Cutted octahedron [see Fig. 7(a)].

The analytical expression of $\xi(\hat{\underline{x}}(\theta,\phi))$ for the cube and the cutted octahedron are involved and will be omitted. We only remark that the origin is the center of mass of these obstacles and that the largest sphere contained in the cube has radius 1 and the largest sphere contained in the cutted octahedron has radius 0.965. Figures 2 and 3 are relative to the corrugated sphere for different corrugations that is different choices of *n,m* in the previously given formula for $\xi(\hat{\underline{x}}(\theta,\phi))$.

Figures 2, 3, 6, 7 show the contour plots of the geometry of the obstacles [i.e., Figs. 2(a), 3(a), 6(a), 7(a)] and the contour plots of $\log_{10}|\underline{E}^{(0)}_{k,L_m,s}|$ for different values of the wave number k and of the parameters L_m,s [i.e., Figs. 2(b), 2(c), 2(d), 3(b), 3(c), 3(d), 6(b), 6(c), 6(d), 7(b), 7(c), 7(d)]. In all these figures the parameter s is fixed to be 10 and the parameter L_m is chosen depending on k in such a way that the numerical convergence (4.8) is reached. Moreover, Figs. 2(a), 3(a), 6(a), and 7(a) show $\xi(\hat{\underline{x}}(\theta,\phi))$ and Figs. 2(b), 2(c), 2(d), 3(b), 3(c), 3(d), 6(b), 6(c), 6(d), 7(b), 7(c), 7(d) show the quantity $\log_{10}|\underline{E}^{(0)}_{k,L_m,s}|$. In Figs. 2, 3, 6, 7 we denote with M the function $M(\theta,\phi)=\log_{10}|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\theta,\phi))|$, and in Figs. 4 and 5 we denote with Z the function $Z(\phi)=\log_{10}|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\pi/2,\phi))|$. Figures 2 and 3 show that the corrugations of the sphere become visible for values of the wave number k large enough. While for small wave number the corrugated sphere appears as a sphere without corrugation. Moreover we can see that since the size of the corrugated sphere is of order one at values of k of approximately 20 we are already in the geometrical optics limit [see Figs. 2(d) and 3(d)]. Figures 4 and 5 are relative to a corrugated sphere with $r_0=1$, $d=0.15$, $n=8$, $m=4$ and show the occurrence of a resonance phenomenon. This resonance phenomenon is due to the presence of the corrugation. That is

(i) For $k=6$ [Fig. 4(a)] $\log_{10}|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\pi/2,\phi))|$, $0\leqslant\phi<2\pi$ shows eight peaks.

(ii) Figures 4(b) and 4(c) show with stepsize $\delta k=0.2$ the quantity $\log_{10}|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\pi/2,\phi))|$, $0\leqslant\phi<2\pi$ as a function of k for $6\leqslant k\leqslant 12$. We note that the peaks at $k=6$ becomes valleys at $k=8$ and come back to peaks at $k=12$.

(iii) Figure 5 shows with stepsize $\delta k=1$ the quantity $\log_{10}|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\pi/2,\phi))|$, $0\leqslant\phi<2\pi$ as a function of k for $15\leqslant k\leqslant 23$. The same phenomenon discussed in (ii) appears here. Moreover at $k=20$ the far field $|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\pi/2,\phi))|$, $0\leqslant\phi<2\pi$ looks like the far field of the sphere.

The number of peaks and valleys (i.e., 8 peaks and valleys) shown in Figs. 4 and 5 is related to the corrugation of the obstacle (i.e., $n=8$). The qualitative change in $\log_{10}|\underline{E}^{(0)}_{k,L_m,s}(\hat{\underline{x}}(\pi/2,\phi))|$, $0\leqslant\phi<2\pi$ as a function of k, that is, the sequence: peak, far field of the sphere, valley, peak, that is shown for increasing values of k in Figs. 4(b), 4(c) and 5 is what we call resonance phenomenon. We note that the peaks and the valleys of the far field of the sphere (see Fig. 5) depend on the polarization vector of the incoming wave.

Figures 6 and 7 are relative to the cube and to the cutted octahedron, respectively. In these figures we can see that for increasing values of k appear first the facets then the edges and finally the vertices of the polyhedron considered. In particular, Fig. 6(d) shows that for k large enough the energy irradiated from the cube when hit by an incoming plane wave comes essentially from the vertices. We note that the cut octahedron is more ''similar'' to the sphere than the cube. In fact for $k=4$ the far field of the cutted octahedron is similar to the farfield of the sphere. On the contrary for the same value of k the far field of the cube shows some elements of the geometry of the cube. For $k=6$ the edges and the facets of the cube are already visible and for $k=24$ only the vertices remain visible. The far field of the cutted octahedron shows the same behavior of the far field of the cube but for larger value of k, that is $k=13$ and $k=24$. In particular for $k=24$ the edges and the eight facets of the cutted octahedron are visible.

(Received 3 December 1998; accepted for publication 24 May 1999)

Diffraction of time-harmonic E-polarized electromagnetic waves by an infinite dielectric cylinder of arbitrary cross section located inside a wedge parallel to its axis is considered. By the methods of potential theory, the transmission problem is reduced to a system of two one-dimensional Fredholm integral equations with the kernels having logarithmic singularities; integration is performed over the boundary of the cylinder cross section. Existence and uniqueness of solutions are proved both for the system of integral equations and the transmission problem. The kernels of integral equations are represented as rapidly convergent series. © *1999 American Institute of Physics.* [S0022-2488(99)00109-7]

I. INTRODUCTION

Free-space transmission problems were investigated in classical formulation by Kupradze,[1] Werner,[2] Kleinman and Kittappa,[3] Kress and Roach,[4] and other authors. The main attention was paid to the acoustic case, when consideration of boundary value problems for both two- and three-dimensional Helmholtz equations may be physically justified. The amount and quality of the results obtained for electromagnetic problems are much less significant—maybe because of more complicated formulations of the problems (see Macdonald[5] and Colton and Kress[6]). On the other hand, until recently, the uniqueness and solvability of transmission problems for (cylindrical) dielectric obstacles in a wedge have not been proved. This was caused, in particular, by the lack of results concerning the properties of corresponding potentials for the two-dimensional Helmholtz equation. Podlipenko[7,8] developed essential elements of the potential theory for a wedge. In this paper, we apply these results to derive weakly singular boundary integral equations and prove the uniqueness and solvability for the problem of scattering of electromagnetic waves by an infinite dielectric cylinder of arbitrary cross section located in a wedge. In general, this study may be considered as an extension of the approach developed by Kress and Roach[4] as applied to the wedge problem.

II. FORMULATION OF THE PROBLEM

Introduce in $\mathbf{R}^3$ the cylindrical coordinate system r,ϕ,z and denote by $W=\{(r,\phi,z)\in\mathbf{R}^3|r>0,0<\phi<\Phi,-\infty<z<+\infty\}$ a wedge with perfectly conducting walls, the vertex angle $\Phi(0<\Phi\leq 2\pi)$, and the edge coinciding with the z axis. Denote by C an infinite dielectric cylinder with the axis parallel to the edge of the wedge. Domains $W\backslash\overline{C}$ and C are supposed to be filled with homogeneous isotropic media having the permittivities ϵ_1 and ϵ_2, permeabilities μ_1 and μ_2, and conductivities σ_1 and σ_2, respectively.

[a)]Electronic mail:shestop@cs.musu.su

Let Ω and D be the domains obtained as a result of intersection of wedge W and cylinder C by the plane $z=0$, respectively. We will assume that $\overline{D}\subset\Omega$ and domain D is bounded, simply connected, and has a C^2-boundary ∂D. Denote by $\partial\Omega$ the boundary of angular domain Ω.

Let a source of a time-harmonic cylindrical wave be an infinitely long thread located in domain $W\backslash\overline{C}$ parallel to the edge of the wedge; the electric current of a constant amplitude and phase flows along the thread.

We will consider diffraction by cylinder C of the E-field excited by this source. We will mark the components of the initial, scattered, and reflected electromagnetic fields by the upper indices i, s, and r, respectively. The problem is to determine the field components that do not depend on z; these components can be represented in terms of two potential functions $u_1(P)=E_z^{(s)}(P)$, $P\in\Omega\backslash\overline{D}$, and $u_2(P)=E_z^{(r)}(P)$, $P\in D$, $P=(r,\phi)$, solving the following transmission problem:

$$\Delta u_1(r,\phi)+k_1^2u_1(r,\phi)=0, \quad ,(r,\phi)\in\Omega\backslash\overline{D}, \tag{1}$$

$$\Delta u_2(r,\phi)+k_2^2u_2(r,\phi)=0, \ (r,\phi)\in D; \tag{2}$$

$$u_1-u_2=f, \quad \lambda_1\frac{\partial u_1}{\partial n}-\lambda_2\frac{\partial u_2}{\partial n}=g, \ \text{on} \ \partial D; \tag{3}$$

$$u_1=0, \ \text{on} \ \partial\Omega; \tag{4}$$

$$\frac{\partial u_1(r,\phi)}{\partial r}-ik_1u_1(r,\phi)=o\left(\frac{1}{\sqrt{r}}\right), \quad r\to\infty, \tag{5}$$

uniformly with respect to ϕ; and

$$\int_{\Omega\cap\delta}(|u_1|^2+|\text{grad}u_1|^2)dS<\infty. \tag{6}$$

Here, $\lambda_j=1/\mu_j$, $k_j=\omega\sqrt{\epsilon_j'\mu_j}$, $\epsilon_j'=\epsilon_j+i\sigma_j/\omega$, $\Im k_j\geqslant 0$, $j=1,2$, ω is the field frequency (the time dependence $e^{-i\omega t}$ is assumed), Δ is the Laplace operator in polar coordinates, δ is a neighborhood of the origin of the polar coordinate system, n is the unit normal to ∂D drawn in the direction from D to $\Omega\backslash\overline{D}$,

$$f=-E_z^{(i)}|_{\partial D}, \quad g=-\lambda_1\frac{\partial E_z^{(i)}}{\partial n}\bigg|_{\partial D},$$

and

$$E_z^{(i)}(r,\phi)=\frac{-\omega\mu_1 I\pi}{\Phi}\sum_{m=1}^{\infty}\sin(\nu_m\phi^*)\sin(\nu_m\phi)J_{\nu_m}(k_1\min(r^*,r))H_{\nu_m}^{(1)}(k_1\max(r^*,r)),$$

where $(r^*,\phi^*)\in\Omega\backslash\overline{D}$ is the point of intersection of the line source with the plane $z=0$, $J_\nu(x)$ and $H_\nu^{(1)}(x)$ are the Bessel and Hankel functions of the order ν, $\nu_m=m\pi/\Phi$, $m=1,2,\ldots$, and I is the complex amplitude of the current flowing along the thread.

We make the following comments concerning the problem statement: the functions

$$E_z^{(i)}(r,\phi), \quad H_r^{(i)}(r,\phi)=-\frac{i}{r\omega\mu_1}\frac{\partial E_z^{(i)}(r,\phi)}{\partial\phi}, \quad H_\phi^{(i)}(r,\phi)=\frac{i}{\omega\mu_1}\frac{\partial E_z^{(i)}(r,\phi)}{\partial r},$$

are the nonzero components of the field $\mathbf{E}^{(i)}$, $\mathbf{H}^{(i)}$ excited by the source[5] in the wedge W; radiation condition (5) excludes[5] waves coming from infinity; the Meixner condition (6) ensures the absence of energy flux radiated by the edge of the wedge; and boundary condition (4) corresponds to the case of perfectly conducting wedge faces. Transmission condition (3) guarantees continuity of normal components of the total electromagnetic field $\mathbf{E}^{(1)}=(0,0,E_z^1)$, $\mathbf{H}^{(1)}=(H_r^1,H_\phi^1,0)$ and $\mathbf{E}^{(2)}=(0,0,E_z^2)$, $\mathbf{H}^{(2)}=(H_r^2,H_\phi^2,0)$ in the domains $W\setminus\overline{C}$ and C, respectively, when the lateral area (interface) of the cylinder ∂C is crossed; these components are determined by the formulas

$$E_z^{(1)}(r,\phi)=E_z^{(i)}(r,\phi)+u_1(r,\phi),\quad H_r^{(1)}(r,\phi)=H_r^{(i)}(r,\phi)-\frac{i}{r\omega\mu_1}\frac{\partial u_1(r,\phi)}{\partial\phi},$$

$$H_\phi^{(1)}(r,\phi)=H_\phi^{(i)}(r,\phi)+\frac{i}{\omega\mu_1}\frac{\partial u_1(r,\phi)}{\partial r},\quad (r,\phi)\in\Omega\setminus\overline{D},$$

$$E_z^{(2)}(r,\phi)=u_2(r,\phi),\quad H_r^{(2)}(r,\phi)=-\frac{i}{r\omega\mu_2}\frac{\partial u_2(r,\phi)}{\partial\phi},$$

$$H_\phi^{(2)}(r,\phi)=\frac{i}{\omega\mu_2}\frac{\partial u_2(r,\phi)}{\partial r},\quad (r,\phi)\in D.$$

Below, we will consider a more general transmission problem: find functions $u_1\in C^2(\Omega\setminus\overline{D})\cap C^1(\Omega\setminus D)\cap C(\overline{\Omega}\setminus\overline{D})$ and $u_2\in C^2(D)\cap C^1(\overline{D})$ that solve (1)–(6), where $f\in C^{1,\alpha}(\partial D)$, $g\in C^{0,\alpha}(\partial D)$ $(0<\alpha\leq 1)$ are given functions on ∂D, and k_1, k_2, λ_1, and λ_2 are nonzero complex numbers with $0\leq\arg k_j<\pi/2$, $j=1,2$.

Our aim is to establish the uniqueness and existence of solution to (1)–(6) by reducing this problem to an operator equation suitable for further computations.

III. UNIQUENESS

First, we prove the uniqueness theorem for the considered transmission problem.

Theorem 1: *Let* $k_1,k_2\in\mathbf{C}\setminus\{\mathbf{0}\}$, $0\leq\arg k_1<\pi/2$, $0\leq\arg k_2<\pi/2$, *and* $\lambda_1,\lambda_2\in\mathbf{C}\setminus\{\mathbf{0}\}$ *be such that* $\rho:=\lambda_2\overline{k_2^2}(\lambda_1\overline{k_1^2})^{-1}\in\mathbf{R}$, $\rho>0$. *Then, the solution to transmission problem* (1)–(6), *if it exists, is unique.*

Proof: It is sufficient to prove that homogeneous transmission problem (1)–(6) with $f=g=0$ has only the trivial solution.

Assume that u_1 and u_2 satisfy (1), (2), (4)–(6) and the transmission conditions

$$u_1-u_2=0,\quad \lambda_1\frac{\partial u_1}{\partial n}-\lambda_2\frac{\partial u_2}{\partial n}=0,\ \text{on}\ \partial D. \tag{7}$$

Choose a number R_0 so that $\overline{D}\subset\Omega_R:=\{(r,\phi)\in\Omega|r<R\}$ when $R\geq R_0$ and apply the first Green's formula to functions $u_1,\overline{u_1}$ and $u_2,\overline{u_2}$ in domains $\Omega_R\setminus\overline{D}$ and D, respectively, taking into account Eqs. (1) and (2). As a result, we obtain

$$-\overline{k_1^2}\lambda_1\int_{\Omega_R\setminus\overline{D}}|u_1|^2\,dS=-\lambda_1\int_{\partial D}u_1\frac{\partial\overline{u_1}}{\partial n}dl+\lambda_1\int_{C_R}u_1\frac{\partial\overline{u_1}}{\partial n}dl-\lambda_1\int_{\Omega_R\setminus\overline{D}}|\text{grad }u_1|^2\,dS$$

$$-\overline{k_2^2}\lambda_2\int_D|u_2|^2\,dS=\lambda_2\int_{\partial D}u_2\frac{\partial\overline{u_2}}{\partial n}dl-\lambda_2\int_D|\text{grad }u_2|^2\,dS,$$

where $C_R:=\{(r,\phi)\in\mathbf{R}^2|0\leq\phi\leq\Phi,r=R\}$. Note that here we can use the Green's formula in the domain $\Omega_R\setminus\overline{D}$ because $u_1,\text{grad }u_1,\Delta u_1\in L_2(\Omega_R\setminus\overline{D})$ by virtue of the edge condition (6) and Theorem 3.27, Colton and Kress.[6] Using the latter relationships and transmission conditions (7), we obtain

$$\lambda_1 \int_{C_R} u_1 \frac{\partial \overline{u_1}}{\partial n} dl = \lambda_1 \int_{\Omega_R \setminus \overline{D}} |\text{grad } u_1|^2 dS + \lambda_2 \int_D |\text{grad } u_2|^2 \, dS$$

$$- \overline{k_1^2} \lambda_1 \int_{\Omega_R \setminus \overline{D}} |u_1|^2 \, dS - \overline{k_2^2} \lambda_2 \int_D |u_2|^2 \, dS. \tag{8}$$

Dividing both sides of (8) by $\overline{k_1^2}\lambda_1$ and taking the imaginary part, we have

$$\Im\left(\frac{1}{\overline{k_1^2}} \int_{C_R} u_1 \frac{\partial \overline{u_1}}{\partial n} dl \right) = \Im\left(\frac{1}{\overline{k_1^2}} \int_{\Omega_R \setminus \overline{D}} |\text{grad } u_1|^2 \, dS \right) + \rho \Im \int_D \left(\frac{1}{\overline{k_2^2}} |\text{grad } u_2|^2 \right) dS. \tag{9}$$

Using relationship (9), we first prove the assertion of the theorem under the condition $\Im k_1 > 0$. In this case, we will show that the left-hand side of (9) tends to zero for a certain subsequence C_{R_m} as $R_m \to \infty$. Taking the imaginary part of the equality

$$k_1 \int_{C_R} u_1 \frac{\partial \overline{u_1}}{\partial n} dl = k_1 \int_{\partial D} u_1 \frac{\partial \overline{u_1}}{\partial n} dl - \overline{k_1} |k_1|^2 \int_{\Omega_R \setminus \overline{D}} |u_1|^2 \, dS + k_1 \int_{\Omega_R \setminus \overline{D}} |\text{grad } u_1|^2 \, dS,$$

obtained as a result of applying the first Green's formula to functions $u_1, \overline{u_1}$ in the domain $\Omega_R \setminus \overline{D}$ and substituting the resulting expression into the formula

$$0 = \lim_{R \to \infty} \int_{C_R} \left| \frac{\partial u_1}{\partial n} - i k_1 u_1 \right|^2 dl = \lim_{R \to \infty} \int_{C_R} \left\{ \left| \frac{\partial u_1}{\partial n} \right|^2 + |k_1|^2 |u_1|^2 + 2 \Im \left(k_1 u_1 \frac{\partial \overline{u_1}}{\partial n} \right) \right\} dl, \tag{10}$$

that follows from radiation condition (5), we find that

$$\lim_{R \to \infty} \left\{ \int_{C_R} \left(\left| \frac{\partial u_1}{\partial n} \right|^2 + |k_1|^2 |u_1|^2 \right) dl + 2 \Im k_1 \int_{\Omega_R \setminus \overline{D}} (|k_1|^2 |u_1|^2 + |\text{grad } u_1|^2) dS \right\}$$

$$= -2 \Im \left(k_1 \int_{\partial D} u_1 \frac{\partial \overline{u_1}}{\partial n} dl \right). \tag{11}$$

All terms on the left-hand side of (11) are non-negative because $\Im k_1 > 0$. Therefore, each of them is bounded, since their sum tends to a finite limit. In particular,

$$\lim_{R \to \infty} \int_{\Omega_R \setminus \overline{D}} (|k_1|^2 |u_1|^2 + |\text{grad } u_1|^2) dS < \infty,$$

which means that $u_1 \in W_2^{(1)}(\Omega \setminus \overline{D})$. For sufficiently large $R' > R_0$, we have

$$\left| \int_{R'}^{\infty} \int_{C_R} u_1 \frac{\partial \overline{u_1}}{\partial n} dl \, dR \right|^2 \leq \int_{\Omega \setminus \overline{\Omega}_{R'}} |u_1|^2 \, dS \int_{\Omega \setminus \overline{\Omega}_{R'}} \left| \frac{\partial u_1}{\partial n} \right|^2 \, dS$$

$$\leq \int_{\Omega \setminus \overline{D}} |u_1|^2 \, dS \int_{\Omega \setminus \overline{D}} |\text{grad } u_1|^2 \, dS < \infty.$$

Therefore, there exists a sequence C_{R_m} such that

$$\int_{C_{R_m}} u_1 \frac{\partial \overline{u_1}}{\partial n} dl,$$

and the sequence

$$\Im\left(\frac{1}{\overline{k_1^2}}\int_{C_{R_m}} u_1 \frac{\partial \overline{u_1}}{\partial n} dl\right)$$

tends to zero as $R_m \to \infty$. Passing to the limit in (9) over the sequence C_{R_m}, we obtain

$$\frac{\Re k_1 \Im k_1}{|k_1|^4}\int_{\Omega \setminus \overline{D}} |\text{grad } u_1|^2 \, dS + \rho \frac{\Re k_2 \Im k_2}{|k_2|^4}\int_D |\text{grad } u_2|^2 \, dS = 0. \tag{12}$$

Then, from (12), it follows that $\int_{\Omega\setminus\overline{D}} |\text{grad } u_1|^2 \, dS = 0$, and $|\text{grad } u_1| = 0$ in $\Omega\setminus\overline{D}$. Therefore, $u_1 = \text{const}$ in $\Omega\setminus\overline{D}$. The radiation condition yields $u_1 = 0$ in $\Omega\setminus\overline{D}$, and from the transmission conditions we obtain $u_2 = \partial u_2/\partial n = 0$ on ∂D. Consequently, from the integral representation for a solution of the Helmholtz equation, it follows that $u_2 = 0$ in D.

Now we consider the case $\Im k_1 = 0$. Since $\rho > 0$, condition (9) yields

$$\Im \int_{C_R} u_1 \frac{\partial \overline{u_1}}{\partial n} dl \geqslant 0.$$

As a consequence of the radiation condition, we have

$$\frac{\partial \overline{u_1}(R,\phi)}{\partial n} + ik_1 \overline{u_1}(R,\phi) = o\left(\frac{1}{\sqrt{R}}\right), \quad R \to \infty. \tag{13}$$

Multiplying (13) by u_1 and integrating over C_R, we obtain

$$\int_{C_R} u_1 \frac{\partial \overline{u_1}(R,\phi)}{\partial n} \, dl + ik_1 \int_{C_R} |u_1(R,\phi)|^2 dl = \int_{C_R} u_1(R,\phi) o\left(\frac{1}{\sqrt{R}}\right) dl, \quad R \to \infty. \tag{14}$$

Any solution $u_1(r,\phi)$ of the Helmholtz equation (1) that satisfies boundary condition (4), radiation condition (5), and edge condition (6), also satisfies[8] the condition

$$u_1(r,\phi) = O\left(\frac{1}{\sqrt{r}}\right), \quad r \to \infty,$$

uniformly with respect to $\phi \in [0,\Phi]$. Using this fact and taking the imaginary part of Eq. (14), we find that

$$k_1 \int_{C_R} |u_1|^2 \, dl + \Im \int_{C_R} u_1 \frac{\partial \overline{u_1}}{\partial n} dl = o(1),$$

as $R \to \infty$. Taking into account that both summands on the left-hand side are non-negative, we conclude that

$$\int_{C_R} |u_1|^2 \, dl = \int_0^\Phi R |u_1(R,\phi)|^2 \, d\phi = o(1), \tag{15}$$

as $R \to \infty$. At the next stage of the proof, we set $u_m(r,\phi) := H^{(1)}_{\nu_m}(k_1 r)\sin(\nu_m \phi)$, where $\nu_m = m\pi/\Phi$. Applying the second Green's formula to functions $u_1(r,\phi)$ and $u_m(r,\phi)$ in the domains $\Omega_R \setminus \overline{\Omega}_{R_0}$ and taking into account that function $u_m(r,\phi)$ satisfies Eq. (1) in this domain and boundary condition (4), we obtain

$$0=\int_{C_{R_0}}\left\{u_1(r,\phi)\frac{\partial u_m(r,\phi)}{\partial n}-u_m(r,\phi)\frac{\partial u_1(r,\phi)}{\partial n}\right\}dl$$
$$+\int_0^{\Phi}\left\{u_1(R,\phi)\frac{dH^{(1)}_{\nu_m}(k_1R)}{dR}-H^{(1)}_{\nu_m}(k_1R)\frac{\partial u(R,\phi)}{\partial R}\right\}\sin(\nu_m\phi)R\,d\phi=:I_{R_0}+I_R. \qquad (16)$$

One can easily show that

$$I_R=\int_0^{\Phi}u_1(R,\phi)\left\{\frac{dH^{(1)}_{\nu_m}(k_1R)}{dR}-ik_1H^{(1)}_{\nu_m}(k_1R)\right\}\sin(\nu_m\phi)R\,d\phi$$
$$-\int_0^{\Phi}H^{(1)}_{\nu_m}(k_1R)\left\{\frac{\partial u_1(R,\phi)}{\partial R}-ik_1u_1(R,\phi)\right\}\sin(\nu_m\phi)R\,d\phi$$
$$=:J_1+J_2. \qquad (17)$$

Let us estimate integral J_1. Using the relationship

$$\frac{dH^{(1)}_{\nu_m}(k_1r)}{dr}-ik_1H^{(1)}_{\nu_m}(k_1r)=O(r^{-3/2}),\quad r\to\infty, \qquad (18)$$

and applying the Schwarz inequality in combination with (15), we obtain

$$|J_1|=\left|\int_0^{\Phi}u_1(R,\phi)\left\{\frac{dH^{(1)}_{\nu_m}(k_1R)}{dR}-ik_1H^{(1)}_{\nu_m}(k_1R)\right\}\sin(\nu_m\phi)R\;d\phi\right|$$
$$\leqslant\left|\frac{dH^{(1)}_{\nu_m}(k_1R)}{dR}-ik_1H^{(1)}_{\nu_m}(k_1R)\right|R\left(\int_0^{\Phi}|u_1(R,\phi)|^2d\phi\right)^{1/2}\Phi^{1/2}$$
$$=O(R^{-3/2})R\,o(R^{-1/2})=o\left(\frac{1}{R}\right),\quad R\to\infty. \qquad (19)$$

By virtue of radiation condition (5) and the estimate $H^{(1)}_{\nu_m}(k_1R)=O(R^{-1/2}),\quad R\to\infty$, we have

$$|J_2|\leqslant R|H^{(1)}_{\nu_m}(k_1R)|\int_0^{\Phi}\left|\frac{\partial u_1(R,\phi)}{\partial R}-ik_1u_1(R,\phi)\right|d\phi=RO(R^{-1/2})o(R^{-1/2})=o(1),\quad R\to\infty. \qquad (20)$$

Estimates (19) and (20) imply that the second term on the right-hand side of (16) tends to zero as $R\to\infty$. Since the first integral I_{R_0} in (16) does not depend on R, this yields $I_{R_0}=0$. Hence, $I_R=0$ for any R; that is,

$$\frac{dH^{(1)}_{\nu_m}(k_1R)}{dR}R\int_0^{\Phi}u_1(R,\phi)\sin(\nu_m\phi)d\phi-RH^{(1)}_{\nu_m}(k_1R)\int_0^{\Phi}\frac{\partial u_1(R,\phi)}{\partial R}\sin(\nu_m\phi)d\phi=0.$$

Introducing the notation

$$\alpha_m(k_1R):=\int_0^{\Phi}u_1(R,\phi)\sin(\nu_m\phi)d\phi, \qquad (21)$$

we rewrite the last equality as

$$\alpha_m(k_1R)\frac{dH^{(1)}_{\nu_m}(k_1R)}{dR}-H^{(1)}_{\nu_m}(k_1R)\frac{d\alpha_m(k_1R)}{dR}=0;$$

consequently, $\alpha_m(k_1R)=a_mH^{(1)}_{\nu_m}(k_1R)$, where a_m is a constant. Relation (21) means that $\alpha_m(k_1R)$, $m=1,2,\ldots$, are the Fourier coefficients of the function $u_1(R,\phi)$ over the complete system of functions $\{\sin(\nu_m\phi)\}_{m=1}^{\infty}$ on the interval $[0,\Phi]$. Therefore, Parseval's equality yields

$$\int_0^{\Phi}R|u_1(R,\phi)|^2\,d\phi=\frac{\Phi}{2}\sum_{m=1}^{\infty}R|\alpha_m(k_1R)|^2=\frac{\Phi}{2}\sum_{m=1}^{\infty}R|a_m|^2|H^{(1)}_{\nu_m}(k_1R)|^2. \tag{22}$$

The latter equalities in combination with (15) imply that $R|a_m|^2||H^{(1)}_{\nu_m}(k_1R)|^2\to 0$ as $R\to\infty$. However, according to the asymptotic formula

$$H^{(1)}_{\nu_m}(k_1R)\sim\left(\frac{2}{\pi k_1R}\right)^{1/2}e^{i(k_1R-\pi\nu_m/2-\pi/4)},\quad R\to\infty,$$

and, for large values of R, the product remains greater than a certain positive number; hence, $a_m=0$, i.e., $a_m(k_1R)\equiv 0$. Consequently, by virtue of (22), we have $u_1\equiv 0$ on the arc C_R of a sufficiently large radius, and, therefore, $u_1(P)=0$ at all points $P(r_P,\phi_P)\in\Omega$, for which $r_P\geqslant R_0$. We may conclude that $u_1\equiv 0$ everywhere in the domain $\Omega\backslash D$, because a solution of the Helmholtz equation is an analytical function. The theorem is proved.

IV. POTENTIALS

Let us define the potentials

$$u_1(M)=\lambda_1^{-1}\int_{\partial D}\left(\frac{\partial G_{k_1}(M,P)}{\partial n_P}\phi(P)+c_1G_{k_1}(M,P)\psi(P)\right)dl_P,\quad M\in\Omega\backslash\partial D, \tag{23}$$

$$u_2(M)=\lambda_2^{-1}\int_{\partial D}\left(\frac{\partial G_{k_2}(M,P)}{\partial n_P}\phi(P)+c_2G_{k_2}(M,P)\psi(P)\right)dl_P,\quad M\in\Omega\backslash\partial D, \tag{24}$$

with the densities $\phi\in C^{1,\alpha}(\partial D)$ and $\psi\in C^{0,\alpha}(\partial D)$, where $c_1,c_2\in\mathbf{C}\backslash\{\mathbf{0}\}$ are fixed constants and the function $G_{k_j}(M,P)$, $j=1,2$ is defined by the formula

$$G_{k_j}(M,P)=\frac{i\pi}{\Phi}\sum_{m=1}^{\infty}\left\{\begin{matrix}J_{\nu_m}(k_jr_P)H^{(1)}_{\nu_m}(k_jr_M)\\ J_{\nu_m}(k_jr_M)H^{(1)}_{\nu_m}(k_jr_P)\end{matrix}\right\}\sin(\nu_m\phi_M)\sin(\nu_m\phi_P). \tag{25}$$

Here and in all subsequent similar formulas, the upper and lower terms correspond, respectively, to the cases $r_P\leqslant r_M$ and $r_P\geqslant r_M$.

Functions $G_{k_j}(M,P)$ and $\partial G_{k_j}(M,P)/\partial n_P$ can be represented in the form[7,8]

$$G_{k_j}(M,P)=G_0(k_j;M,P)+\frac{1}{4\pi}\ln\Psi(M,P), \tag{26}$$

where $G_0(k_j;M,P)$ is a regular function in Ω, which can be represented as a series

$$G_0(k_j;M,P)=\frac{i\pi}{\Phi}\sum_{m=1}^{\infty}\left\{\begin{bmatrix}J_{\nu_m}(k_jr_P)H^{(1)}_{\nu_m}(k_jr_M)\\ J_{\nu_m}(k_jr_M)H^{(1)}_{\nu_m}(k_jr_P)\end{bmatrix}+\frac{i}{\pi\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right\}\sin(\nu_m\phi_M)\sin(\nu_m\phi_P), \tag{27}$$

whose general term decreases as $O(1/\nu_m^3)$ when $m\to\infty$. Here and below, we use the notation $R=\mathrm{sign}(r_M-r_P)$.

Function $\Psi(M,P)$ can be expressed explicitly,

$$\Psi(M,P)=\frac{\sin^2\frac{\pi}{2\Phi}(\phi_P+\phi_M)+\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_M}{r_P}\right)}{\sin^2\frac{\pi}{2\Phi}(\phi_P-\phi_M)+\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_M}{r_P}\right)},\tag{28}$$

and has a singularity of the type $1/r_{M,P}^2$, where $r_{M,P}$ denotes the distance between points M and P; therefore, the following relationship holds:

$$\frac{1}{4\pi}\ln\Psi(M,P)=\frac{1}{2\pi}\ln\frac{1}{r_{M,P}}+\phi(M,P),$$

where $\phi(M,P)$ is an analytical function with respect to all variables. Thus, we can write the following expressions:

$$\frac{\partial G_{k_j}(M,P)}{\partial n_P}=\frac{1}{4\pi}\frac{\partial}{\partial n_P}\ln\Psi(M,P)+\sum_{q=1}^{3}G_q^{(1)}(k_j;M,P),\quad j=1,2,\tag{29}$$

where

$$G_1^{(1)}(k_j;M,P)=\frac{i\pi}{\Phi}\cos\alpha(P)\sum_{m=1}^{\infty}\left\{k_j\left[\frac{J'_{\nu_m}(k_jr_P)H^{(1)}_{\nu_m}(k_jr_M)}{J_{\nu_m}(k_jr_M)H^{(1)\prime}_{\nu_m}(k_jr_P)}\right]+R\frac{i}{\pi r_P}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right.$$
$$\left.+\frac{i}{\pi r_P}\frac{k_j^2(r_M^2-r_P^2)}{4\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right\}\sin(\nu_m\phi_M)\sin(\nu_m\phi_P),\tag{30}$$

$$G_2^{(1)}(k_j;M,P)=\frac{i\pi}{\Phi}\sin\alpha(P)\sum_{m=1}^{\infty}\left\{\frac{\nu_m}{r_P}\left[\frac{-J_{\nu_m}(k_jr_P)H^{(1)}_{\nu_m}(k_jr_M)}{-J_{\nu_m}(k_jr_M)H^{(1)}_{\nu_m}(k_jr_P)}\right]-\frac{i}{\pi r_P}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right.$$
$$\left.-R\frac{i}{\pi r_P}\frac{k_j^2(r_M^2-r_P^2)}{4\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right\}\sin(\nu_m\phi_M)\sin(\nu_m\phi_P),\tag{31}$$

$$G_3^{(1)}(k_j;M,P)=\cos\alpha(P)\frac{k_j^2(r_M^2-r_P^2)}{16\pi r_P}\ln\Psi(M,P)$$
$$-R\sin\alpha(P)\frac{k_j^2(r_M^2-r_P^2)}{8\pi r_P}(\Phi_1(M,P)+\Phi_2(M,P));\tag{32}$$

functions $\Phi_i(M,P),\ i=1,2$, are defined by the formulas

$$\Phi_{1,2}(M,P)=\arctan\frac{\sin\frac{\pi}{\Phi}(\phi_M\pm\phi_P)}{\left(\frac{r_P}{r_M}\right)^{-R(\pi/\Phi)}-\cos\frac{\pi}{\Phi}(\phi_M\pm\phi_P)},$$

$\alpha(P)$ is the angle between the vector of point P and the unit normal n_P to the curve ∂D. The terms in series (30) and (31) decrease as $O[(1/\nu_m^2)(r_P/r_M)^{\nu_mR}]$.

From relationships (26) and (29), it follows that potentials (23) and (24) are well defined on the curve ∂D. The following estimates are valid:[8]

$$|G_{k_1}(M,P)|\leqslant Ar_M^{\pi/\Phi}, \quad \left|\frac{\partial G_{k_1}(M,P)}{\partial n_P}\right|\leqslant Br_M^{\pi/\Phi},$$

where A and B are constants that do not depend on $M\in\delta\cap\Omega$, $P\in\partial D$, and δ denotes a neighborhood of the origin O of the polar coordinate system. It is easy to see that functions u_1 and u_2 defined by formulas (23) and (24) belong to the classes $C^2(\Omega\setminus\overline{D})\cap C^1(\Omega\setminus D)\cap C(\overline{\Omega}\setminus\overline{D})$ and $C^2(D)\cap C^1(\overline{D})$, respectively, if we set by continuity $u_1(O)=0$.

Functions $G_{k_1}(M,P)$ and $\partial G_{k_1}(M,P)/\partial n_P$ satisfy radiation condition (6) uniformly[8] in $0<\phi_M<\Phi$, $P\in\partial D$. This implies that potentials (23) and (24) satisfy radiation condition (5) and edge condition (6). In addition to this, potentials (23) and (24) satisfy[8] Eqs. (1) and (2), respectively, and vanish on $\partial\Omega$.

We will need also a representation similar to (26) for the functions

$$\frac{\partial^2 G_{k_j}(M,P)}{\partial n_M\ \partial n_P}, \quad j=1,2,$$

where n_M is the outward (with respect to D) unit normal on ∂D at the point $M\in\Omega$. To this end, we use the following result.

Lemma 1: For the Bessel, $J_\nu(z)$, and Hankel, $H_\nu(z)$, functions at fixed $z\in\mathbf{C}\setminus\mathbf{0}$, $0\leqslant\arg z<\pi/2$, the following asymtotic estimates hold:

$$J_\nu(z)=\frac{1}{(2\pi\nu)^{1/2}}\left(\frac{ez}{2\nu}\right)^\nu\left(1-\frac{1+3z^2}{12\nu}+\frac{9z^4+78z^2+1}{288\nu^2}+O\left(\frac{1}{\nu^3}\right)\right), \quad \nu\to+\infty, \tag{33}$$

$$H_\nu^{(1)}(z)=\frac{1}{i}\left(\frac{2}{\pi\nu}\right)^{1/2}\left(\frac{2\nu}{ez}\right)^\nu\left(1+\frac{1+3z^2}{12\nu}+\frac{9z^4+78z^2+1}{288\nu^2}+O\left(\frac{1}{\nu^3}\right)\right), \quad \nu\to+\infty. \tag{34}$$

Differentiating formula (29) with respect to the normal n_M and separating, with the help of Lemma 2, in the resulting relationship the principal asymptotical term of the series on the right-hand side, we obtain the representations 7 for $\partial^2 G_{k_j}(M,P)/\partial_M\partial n_P$, $j=1,2$ similar to those for functions $G_{k_j}(M,P)$ [see (26)] but much more bulky. From these expressions, it follows that the considered functions have a logarithmic singularity when their arguments coincide.

V. REDUCTION TO INTEGRAL EQUATIONS

Now we reduce the transmission problem (1)–(6) to a system of Fredholm integral equations. Then, we will use Theorem 1 to prove the unique solvability both of this system and initial problem (1)–(6).

Looking for a solution of transmission problem (1)–(6) in the form of potentials (23) and (24) in the domains $\Omega\setminus\overline{D}$ and D, respectively, taking into account the representations for functions $G_{k_j}(M,P)$ and their normal derivatives obtained above, and using the properties of harmonic potentials,[9] we derive the relationships that are valid on ∂D:

$$u_1(M)-u_2(M)=\frac{1}{2}(\lambda_1^{-1}+\lambda_2^{-1})\phi(M)+\int_{\partial D}\left(\lambda_1^{-1}\frac{\partial G_{k_1}(M,P)}{\partial n_P}-\lambda_2^{-1}\frac{\partial G_{k_2}(M,P)}{\partial n_P}\right)\phi(P)dl_P$$
$$+\int_{\partial D}(\lambda_1^{-1}c_1G_{k_1}(M,P)-\lambda_2^{-1}c_2G_{k_2}(M,P))\psi(P)dl_P, \tag{35}$$

$$\lambda_1 \frac{\partial u_1(M)}{\partial n_M} - \lambda_2 \frac{\partial u_2(M)}{\partial n_M} = -\frac{1}{2}(c_1+c_2)\psi(M) + \int_{\partial D}\left(\frac{\partial^2 G_{k_1}(M,P)}{\partial n_M \partial n_P} - \frac{\partial^2 G_{k_2}(M,P)}{\partial n_M \partial n_P}\right)\phi(P)\,dl_P$$
$$+ \int_{\partial D}\left(c_1 \frac{\partial G_{k_1}(M,P)}{\partial n_M} - c_2 \frac{\partial G_{k_2}(M,P)}{\partial n_M}\right)\psi(P)\,dl_P, \quad M \in \partial D, \quad (36)$$

where the following representations are valid:

$$\frac{\partial^2 G_{k_1}(M,P)}{\partial n_M\, \partial n_P} - \frac{\partial^2 G_{k_2}(M,P)}{\partial n_M\, \partial n_P} = \sum_{q=1}^{8} G_q^{(2)}(k_1,k_2;M,P), \quad (37)$$

$$G_1^{(2)}(k_1,k_2;M,P) = \sum_{m=1}^{\infty} \left\{ \frac{i\pi}{\Phi} \begin{bmatrix} k_1^2 J'_{\nu_m}(k_1 r_P) H_{\nu_m}^{(1)\prime}(k_1 r_M) - k_2^2 J'_{\nu_m}(k_2 r_P) H_{\nu_m}^{(1)\prime}(k_2 r_M) \\ k_1^2 J'_{\nu_m}(k_1 r_M) H_{\nu_m}^{(1)\prime}(k_1 r_P) - k_2^2 J'_{\nu_m}(k_2 r_M) H_{\nu_m}^{(1)\prime}(k_2 r_P) \end{bmatrix} \right.$$
$$\left. + RA(r_M,r_P;k_1,k_2)\left(\frac{r_P}{r_M}\right)^{\nu_m R} + B_1^{(-)}(r_M,r_P;k_1,k_2)\frac{1}{\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_m R} \right\}$$
$$\times \sin(\nu_m \phi_M)\sin(\nu_m \phi_P)\cos\alpha(M)\cos\alpha(P), \quad (38)$$

$$G_2^{(2)}(k_1,k_2;M,P) = -\sum_{m=1}^{\infty} \left\{ \frac{i\pi\nu_m}{r_M \Phi} \begin{bmatrix} k_1 J'_{\nu_m}(k_1 r_P) H_{\nu_m}^{(1)}(k_1 r_M) - k_2 J'_{\nu_m}(k_2 r_P) H_{\nu_m}^{(1)}(k_2 r_M) \\ k_1 J_{\nu_m}(k_1 r_M) H_{\nu_m}^{(1)\prime}(k_1 r_P) - k_2 J_{\nu_m}(k_2 r_M) H_{\nu_m}^{(1)\prime}(k_2 r_P) \end{bmatrix} \right.$$
$$\left. - A(r_M,r_P;k_1,k_2)\left(\frac{r_P}{r_M}\right)^{\nu_m R} - RB_2^{(+)}(r_M,r_P;k_1,k_2)\frac{1}{\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_m R} \right\}$$
$$\times \cos(\nu_m \phi_M)\sin(\nu_m \phi_P)\sin\alpha(M)\cos\alpha(P), \quad (39)$$

$$G_3^{(2)}(k_1,k_2;M,P) = -\sum_{m=1}^{\infty} \left\{ \frac{i\pi\nu_m}{r_P \Phi} \begin{bmatrix} k_1 J_{\nu_m}(k_1 r_P) H_{\nu_m}^{(1)\prime}(k_1 r_M) - k_2 J_{\nu_m}(k_2 r_P) H_{\nu_m}^{(1)\prime}(k_2 r_M) \\ k_1 J'_{\nu_m}(k_1 r_M) H_{\nu_m}^{(1)}(k_1 r_P) - k_2 J'_{\nu_m}(k_2 r_M) H_{\nu_m}^{(1)}(k_2 r_P) \end{bmatrix} \right.$$
$$\left. + A(r_M,r_P;k_1,k_2)\left(\frac{r_P}{r_M}\right)^{\nu_m R} + RB_2^{(-)}(r_M,r_P;k_1,k_2)\frac{1}{\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_m R} \right\}$$
$$\times \sin(\nu_m \phi_M)\cos(\nu_m \phi_P)\cos\alpha(M)\sin\alpha(P), \quad (40)$$

$$G_4^{(2)}(k_1,k_2;M,P) = \sum_{m=1}^{\infty} \left\{ \frac{i\pi\nu_m^2}{r_M r_P \Phi} \begin{bmatrix} J_{\nu_m}(k_1 r_P) H_{\nu_m}^{(1)}(k_1 r_M) - J_{\nu_m}(k_2 r_P) H_{\nu_m}^{(1)}(k_2 r_M) \\ J_{\nu_m}(k_1 r_M) H_{\nu_m}^{(1)}(k_1 r_P) - J_{\nu_m}(k_2 r_M) H_{\nu_m}^{(1)}(k_2 r_P) \end{bmatrix} \right.$$
$$\left. - RA(r_M,r_P;k_1,k_2)\left(\frac{r_P}{r_M}\right)^{\nu_m R} - B_1^{(+)}(r_M,r_P;k_1,k_2)\frac{1}{\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_m R} \right\}$$
$$\times \cos(\nu_m \phi_M)\cos(\nu_m \phi_P)\sin\alpha(M)\sin\alpha(P), \quad (41)$$

$$G_5^{(2)}(k_1,k_2;M,P)=[-\operatorname{sign}(r_M-r_P)\tilde{A}(r_M,r_P;k_1,k_2)\Psi_1(M,P) \\ -\tilde{B}_1^{(-)}(r_M,r_P;k_1,k_2)\Psi_2(M,P)]\cos\alpha(M)\cos\alpha(P), \tag{42}$$

$$G_6^{(2)}(k_1,k_2;M,P)=[-\tilde{A}(r_M,r_P;k_1,k_2)\Psi_3(M,P) \\ -R\tilde{B}_2^{(+)}(r_M,r_P;k_1,k_2)\Psi_4(M,P)]\sin\alpha(M)\cos\alpha(P), \tag{43}$$

$$G_7^{(2)}(k_1,k_2;M,P)=[\tilde{A}(r_M,r_P;k_1,k_2)\Psi_5(M,P) \\ +R\tilde{B}_2^{(-)}(r_M,r_P;k_1,k_2)\Psi_6(M,P)]\cos\alpha(M)\sin\alpha(P), \tag{44}$$

$$G_8^{(2)}(k_1,k_2;M,P)=[R\tilde{A}(r_M,r_P;k_1,k_2)\Psi_7(M,P) \\ +\tilde{B}_1^{(+)}(r_M,r_P;k_1,k_2)\Psi_8(M,P)]\sin\alpha(M)\sin\alpha(P), \tag{45}$$

$$A(r_M,r_P;k_1,k_2)=(k_1^2-k_2^2)\frac{r_M^2-r_P^2}{4\Phi r_M r_P},$$

$$B_1^{(\pm)}(r_M,r_P;k_1,k_2)=\frac{k_1^2-k_2^2}{32\Phi r_M r_P}[(k_1^2+k_2^2)(r_M^2-r_P^2)^2\pm 8(r_M^2+r_P^2)],$$

$$B_2^{(\pm)}(r_M,r_P;k_1,k_2)=\frac{k_1^2-k_2^2}{32\Phi r_M r_P}[(k_1^2+k_2^2)(r_M^2-r_P^2)\pm 8](r_M^2-r_P^2),$$

$$\tilde{A}(r_M,r_P;k_1,k_2)=\tfrac{1}{8}A(r_M,r_P;k_1,k_2),$$

$$\tilde{B}_1^{(\pm)}=\frac{\Phi}{4\pi}B_1^{(\pm)}(r_M,r_P;k_1,k_2),\qquad \tilde{B}_2^{(\pm)}=\frac{\Phi}{2\pi}B_2^{(\pm)}(r_M,r_P;k_1,k_2),$$

$$\Psi_{1,7}(M,P)=\mp\frac{\cos\frac{\pi}{\Phi}(\phi_M+\phi_P)-\left(\frac{r_P}{r_M}\right)^{R(\pi/\Phi)}}{\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_P}{r_M}\right)+\sin^2\frac{\pi}{2\Phi}(\phi_M+\phi_P)}+\frac{\cos\frac{\pi}{\Phi}(\phi_M-\phi_P)-\left(\frac{r_P}{r_M}\right)^{R(\pi/\Phi)}}{\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_P}{r_M}\right)+\sin^2\frac{\pi}{2\Phi}(\phi_M-\phi_P)},$$

$$\Psi_{3,5}(M,P)=\frac{\sin\frac{\pi}{\Phi}(\phi_M+\phi_P)}{\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_P}{r_M}\right)+\sin^2\frac{\pi}{2\Phi}(\phi_M+\phi_P)}\mp\frac{\sin\frac{\pi}{\Phi}(\phi_M-\phi_P)}{\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_P}{r_M}\right)+\sin^2\frac{\pi}{2\Phi}(\phi_M-\phi_P)},$$

$$\Psi_{4,6}(M,P)=\Phi_1(M,P)\mp\Phi_2(M,P),\qquad \Psi_2(M,P)=\ln\Psi(M,P),$$

$$\Psi_8(M,P)=-\ln\left\{16\left[\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_P}{r_M}\right)+\sin^2\frac{\pi}{2\Phi}(\phi_M-\phi_P)\right]\right. \\ \left.\times\left[\sinh^2\left(\frac{\pi}{2\Phi}\ln\frac{r_P}{r_M}\right)+\sin^2\frac{\pi}{2\Phi}(\phi_M+\phi_P)\right]\right\}-R\frac{2\pi}{\Phi}\ln\frac{r_P}{r_M},$$

$$\frac{\partial G_{k_j}(M,P)}{\partial n_M}=\frac{1}{4\pi}\frac{\partial}{\partial n_M}\ln\Psi(M,P)+\sum_{q=1}^{3}G_q^{(3)}(k_j;M,P),\quad j=1,2; \tag{46}$$

in the latter expression,

$$G_1^{(3)}(k_j;M,P)=\frac{i\pi}{\Phi}\cos\alpha(M)\sum_{m=1}^{\infty}\left\{k_j\begin{bmatrix}J_{\nu_m}(k_jr_P)H_{\nu_m}^{(1)\prime}(k_jr_M)\\J'_{\nu_m}(k_jr_M)H_{\nu_m}^{(1)}(k_jr_P)\end{bmatrix}-R\frac{i}{\pi r_M}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right.$$
$$\left.-\frac{i}{\pi r_m}\frac{k_j^2(r_M^2-r_P^2)}{4\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right\}\sin(\nu_m\phi_M)\sin(\nu_m\phi_P), \tag{47}$$

$$G_2^{(3)}(k_j;M,P)=\frac{i\pi}{\Phi}\sin\alpha(M)\sum_{m=1}^{\infty}\left\{\frac{\nu_m}{r_M}\begin{bmatrix}-J_{\nu_m}(k_jr_P)H_{\nu_m}^{(1)}(k_jr_M)\\-J_{\nu_m}(k_jr_M)H_{\nu_m}^{(1)}(k_jr_P)\end{bmatrix}-\frac{i}{\pi r_M}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right.$$
$$\left.-R\frac{i}{\pi r_M}\frac{k_j^2(r_M^2-r_P^2)}{4\nu_m}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right\}\cos(\nu_m\phi_M)\sin(\nu_m\phi_P), \tag{48}$$

$$G_3^{(3)}(k_j;M,P)=-\cos\alpha(M)\frac{k_j^2(r_M^2-r_P^2)}{16\pi r_M}\ln\Psi(M,P)$$
$$-\operatorname{sign}(r_M-r_P)\sin\alpha(M)\frac{k_j^2(r_M^2-r_P^2)}{8\pi r_M}(\Phi_1(M,P)-\Phi_2(M,P)).$$

As follows from Lemma 1, general terms of series (38)–(41), (47), and (48) decrease as

$$O\left[\frac{1}{\nu_m^2}\left(\frac{r_P}{r_M}\right)^{\nu_mR}\right].$$

VI. SOLVABILITY OF INTEGRAL EQUATIONS AND BOUNDARY VALUE PROBLEM

Introducing the integral operators

$$(A_{11}\phi)(M):=2\int_{\partial D}\left(\lambda_1^{-1}\frac{\partial G_{k_1}(M,P)}{\partial n_P}-\lambda_2^{-1}\frac{\partial G_{k_2}(M,P)}{\partial n_P}\right)\phi(P)dl_P, \tag{49}$$

$$(A_{12}\psi)(M):=2\int_{\partial D}(\lambda_1^{-1}c_1G_{k_1}(M,P)-\lambda_2^{-1}c_2G_{k_2}(M,P))\psi(P)dl_P, \tag{50}$$

$$(A_{21}\phi)(M):=2\int_{\partial D}\left(\frac{\partial^2G_{k_1}(M,P)}{\partial n_M\,\partial n_P}-\frac{\partial^2G_{k_2}(M,P)}{\partial n_M\,\partial n_P}\right)\phi(P)dl_P, \tag{51}$$

$$(A_{22}\psi)(M):=2\int_{\partial D}\left(c_1\frac{\partial G_{k_1}(M,P)}{\partial n_M}-c_2\frac{\partial G_{k_2}(M,P)}{\partial n_M}\right)\psi(P)dl_P, \tag{52}$$

defined by the right-hand sides of relationships (35) and (36), we see that these operators have weakly singular kernels. In fact, for operators A_{11}, A_{12}, A_{22}, this statement follows from representations (26), (29), and (46) (the kernel of operator A_{12} has a logarithmic singularity and the kernels of A_{11}, A_{22} are continuous), and for operator A_{21}, it follows from the fact that the sum of two last summands on the right-hand sides of (42) and (45) have singularities of the form

$(1/4\pi)(k_1^2-k_2^2)\ln(1/r_{MP})$while the rest of summands in (37) are bounded as $P\rightarrow M$. Therefore, these operators are compact in the space $C(\partial D)$ and they map $C(\partial D)$ into $C^{0,\alpha}(\partial D)$ and $C^{0,\alpha}(\partial D)$, into $C^{1,\alpha}(\partial D)$.

Hence, using operator notation (49)–(52), relationships (35)–(36), and the transmission conditions, we can prove the following assertion.

Theorem 2: *The potentials u_1 and u_2 defined by formulas (23) and (24) solve transmission problem (1)–(6) provided that densities ϕ and ψ solve the system of integral equations with weakly singular kernels,*

$$(\lambda_1^{-1}+\lambda_2^{-1})\phi+A_{11}\phi+A_{12}\psi=2f,$$

$$(c_1+c_2)\psi-A_{21}\phi-A_{22}\psi=-2g. \tag{53}$$

Introduce in the space $C(\partial D)\times C(\partial D)$ the operators E and A defined as

$$E:=\begin{bmatrix}(\lambda_1^{-1}+\lambda_2^{-1})I & 0\\ 0 & (c_1+c_2)I\end{bmatrix},\quad A:=\begin{bmatrix}-A_{11} & -A_{12}\\ A_{21} & A_{22}\end{bmatrix},$$

where I is the identity operator on $C(\partial D)$. If we set $\Xi:=[{\psi \atop \phi}]$, then the system of integral equations (53) can be rewritten in the form

$$(E-A)\Xi=F, \tag{54}$$

where

$$F:=\begin{bmatrix}f\\ -g\end{bmatrix}.$$

Theorem 3: *Under the conditions of Theorem 1, system of integral equations (53) [or what is the same, integral equation (54)] has a unique solution $\phi\in C^{1,\alpha}(\partial D)$, $\psi\in C^{0,\alpha}(\partial D)$ if $\lambda_1+\lambda_2\neq 0$ and the numbers c_1 and c_2 are chosen so that the following conditions are valid:*

$$(i)\quad c_1+c_2\neq 0,$$

$$(ii)\quad \eta:=\frac{c_2\overline{k_1^2}}{c_1\overline{k_2^2}}\in\mathbf{R},\quad \text{where}\quad \eta>0.$$

Proof. A is a compact operator; therefore, using the assumptions introduced above, the fact that E is a bounded and invertible operator in $C(\partial D)\times C(\partial D)$, and Corollaries 1.17 and 1.20, Colton and Kress,[6] we can show that the inhomogeneous integral equation (54) has the unique solution $\Xi=({\psi \atop \phi})\in C(\partial D)\times C(\partial D)$ if the homogeneous equation,

$$(E-A)\Xi=0, \tag{55}$$

has only the trivial solution. Moreover, in this case, due to properties of the operator of system (53) and the smoothness condition $f\in C^{1,\alpha}(\partial D)$, $g\in C^{0,\alpha}(\partial D)$, we obtain that $\phi\in C^{1,\alpha}(\partial D)$, $\psi\in C^{0,\alpha}(\partial D)$.

So, it remains to prove that homogeneous integral Eq. (55) has only the trivial solution. Let $\Xi=[{\psi \atop \phi}]$ be a solution to Eq. (55). Then, potentials u_1 and u_2 defined by (23) and (24) solve homogeneous transmission problem (1)–(6). Therefore, from the uniqueness Theorem 1, we have

$$u_1=0,\ \text{in}\ \Omega\setminus\overline{D},\quad u_2=0,\ \text{in}\ \overline{D}. \tag{56}$$

Using formulas (23) and (24), representations for function $G_{k_j}(M,P)$ and its normal derivatives obtained above, and the discontinuity properties of potentials, we obtain the equalities

$$u_i^+ - u_i^- = \lambda_i^{-1}\phi, \quad \text{on} \quad \partial D, \quad \frac{\partial u_i^+}{\partial n} - \frac{\partial u_i^-}{\partial n} = -\lambda_i^{-1} c_i \psi, \quad \text{on} \quad \partial D, \quad i=1,2, \tag{57}$$

where $u_i^+(M) := \lim_{P\to M, P\in\Omega\setminus\overline{D}} u(P)$, $u_i^-(M) := \lim_{P\to M, P\in D} u(P), M\in\partial D$. Relationships (57) and (56) imply that

$$\lambda_2 u_2^+ + \lambda_1 u_1^- = 0, \quad \frac{\lambda_2}{c_2}\frac{\partial u_2^+}{\partial n} + \frac{\lambda_1}{c_1}\frac{\partial u_1^+}{\partial n} = 0. \tag{58}$$

Now, let us introduce the functions

$$v_2(M) = \lambda_2 u_2(M) = \int_{\partial D}\left(\frac{\partial G_{k_2}(M,P)}{\partial n_P}\phi(P) + c_2 G_{k_2}(M,P)\psi(P)\right) dl_P, \quad M\in\Omega\setminus\overline{D}, \tag{59}$$

$$v_1(M) = -\lambda_1 u_1(M) = -\int_{\partial D}\left(\frac{\partial G_{k_1}(M,P)}{\partial n_P}\phi(P) + c_1 G_{k_1}(M,P)\psi(P)\right) dl_P, \quad M\in D. \tag{60}$$

Then, from the above considerations and formulas (58)–(60), it follows that functions $v_1 \in C^2(D)\cap C^1(\overline{D})$ and $v_2\in C^2(\Omega\setminus\overline{D})\cap C^1(\Omega\setminus D)\cap C(\overline{\Omega}\setminus\overline{D})$ satisfy the homogeneous transmission problem

$$\Delta v_1 + k_1^2 v_1 = 0, \quad \text{in} \quad D, \quad \Delta v_2 + k_2^2 v_2 = 0, \quad \text{in} \quad \Omega\overline{D},$$

$$v_2 - v_1 = 0, \ \text{on } \partial D, \quad \frac{1}{c_2}\frac{\partial v_2}{\partial n} - \frac{1}{c_1}\frac{\partial v_1}{\partial n} = 0, \ \text{on } \partial D, \quad v_1 = 0, \quad \text{on } \partial\Omega,$$

$$\frac{\partial v_2}{\partial r} - ik_2 v_2 = o\left(\frac{1}{\sqrt{r}}\right), \quad r\to\infty,$$

$$\int_{\Omega\cap\delta}(|v_2|^2 + |\text{grad} v_2|^2)\, dS < \infty.$$

Condition (ii) enables us to apply in this case the uniqueness theorem, so that $v_1=0$ in $\overline{D}$ and $v_2=0$ in $\Omega\setminus\overline{D}$; therefore, $u_1=0$ in $\overline{D}$ and $u_2=0$ in $\Omega\setminus\overline{D}$. Using relations (57) and (56), we see that $\phi=\psi=0$ on ∂D. The theorem is proved.

Theorems 3 and 2 imply the following result.

Corollary 1:

Assume that conditions of Theorem 3 are valid and $\phi\in C^{1,\alpha}(\partial D)$, $\psi\in C^{0,\alpha}(\partial D)$ *is a solution of the system of integral equations* (53). *Then, potentials* (23) *and* (24) *with densities* ϕ *and* ψ *solve transmission problem* (1)–(6).

In conclusion, we make the following remarks.

1. The above analysis shows that representations (26), (29), (46), and (37) for functions $G_{k_j}(M,P)$ and their normal derivatives are not only of theoretical but also of practical interest, since they enable one to compute the kernels of the system of integral equations in the case when their arguments are close. In this connection, it should be noted that formula (25) and the representations obtained as a result of its differentiation are not suitable for this purpose. In fact, series (25) are not absolutely convergent, its general term decreases as $O(1/\nu_M)$ for $r_P=r_M$, ϕ_P

$\neq \phi_M$, whereas the series obtained by termwise differentiation with respect to r and ϕ are divergent for $r_P = r_M$, $\phi_P \neq \phi_M$. In addition to this, unlike formulas (26) and (37), the logarithmic singularity is not extracted explicitly from series (25).

2. Transmission problem (1)–(6) may be reduced to a uniquely solvable system of integral equations using another approach, when a solution to (1)–(6) is sought in the form (23) and (24), where $G_{k_2}(M,P) = (i/4) H_0^{(1)}(k_2 r_{M,P})$. In order to verify the validity of Theorems 2 and 3 in this case, one should assume, at the end of the proof of Theorem 3 when referring to Theorem 1 that $\Omega = \mathbf{R}^2$ (the corresponding result can be obtained by literally repeating the arguments).[4]

3. All the results obtained in this paper can be generalized without any serious changes to the transmission problem in the case when the boundary ∂D consists of a finite number of closed nonintersecting Lyapynov contours.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 10 OCTOBER 1999

Jacobi's principle for magnetic interactions

G. F. Torres del Castillo[a)]
Departamento de Física Matemática, Instituto de Ciencias de la Universidad Autónoma de Puebla, 72570 Puebla, Pue., Mexico

(Received 24 September 1998; accepted for publication 3 June 1999)

It is shown that the trajectories of a charged particle in a static magnetic field and a velocity-independent potential in a three-dimensional space are (the projection of) the geodesics of a suitably defined metric in a four-dimensional space. It is shown that each one-parameter group of isometries of the original configuration space that leaves the magnetic field invariant gives rise to a one-parameter group of isometries of the metric defined on the four-dimensional space and, hence, to a constant of the motion. It is also shown, similarly, that the Schrödinger equation for a charged particle in a static magnetic field is equivalent to the Schrödinger equation for a free particle in the four-dimensional space mentioned above. © *1999 American Institute of Physics.* [S0022-2488(99)02809-1]

I. INTRODUCTION

As is well known in classical mechanics, the orbits in the configuration space of a particle, or a system of particles, whose Hamiltonian is of the form

$$H=\tfrac{1}{2}g^{ij}p_ip_j+V(q^i),$$

$(i,j,\ldots=1,\ldots,n)$, are the geodesics of the metric

$$(E-V)g_{ij}\,dq^i\,dq^j$$

(Jacobi's principle). This result does not apply to the case where there are magnetic forces present; however, as shown in Refs. 1 and 2, in the latter case, the following result holds: the orbits corresponding to the Hamiltonian,

$$H=\frac{1}{2}\,\gamma^{ij}\left(p_i-\frac{e}{c}A_i\right)\left(p_j-\frac{e}{c}A_j\right)+V,$$

where γ^{ij}, A_i, and V depend only on the coordinates q^i, are projections of the geodesics of an $(n+1)$-dimensional space with a metric tensor made out of γ^{ij}, A_i, and V. [Actually, in Refs. 1 and 2, only the case $n=3$ was considered, but it is easy to see that the expressions obtained there apply to all values of n; furthermore, in Refs. 1 and 2 it was assumed that the $(n+1)$th coordinate is a time coordinate, but one can leave the nature of the additional variable unspecified.]

Thus, by increasing the dimension of the space, one can absorb the electromagnetic forces, and other conservative forces present, into the geometry. This geometrization of the electromagnetic interaction also allows one to deal with the gauge transformations in the Hamiltonian formalism in an easy way (see below) (cf. Ref. 3). The manner in which the magnetic interaction is incorporated into the geometry of a space of higher dimension here and in Refs. 1 and 2 is similar to that followed in the Kaluza–Klein theory, where the electromagnetic and gravitational fields in the four-dimensional spacetime of general relativity are incorporated into the metric of a five-dimensional space in such a way that the Einstein–Maxwell equations correspond to the vanishing of the Ricci tensor of the five-dimensional metric. In fact, some of the equations given in Sec. II

a)Electronic mail: gtorres@fcfm.buap.mx

[e.g., Eqs. (3)–(5), (9), and (10)] are analogous to the corresponding formulas in the Kaluza–Klein theory; however, since we are not interested in the curvature of the auxiliary higher dimension space, we have some freedom in the definition of the metric of the auxiliary space, which is employed to make the parameter of the geodesics of the auxiliary space to coincide with the time, even when there is a velocity-independent potential present [Eq. (6) below].

Our aim in this paper is to show that a similar connection exists in the case of the Schrödinger equation; specifically, we shall show that the solution of the (time-independent) Schrödinger equation for a charged particle in a static magnetic field can be obtained from the solution of the Schrödinger equation for a free particle in an $(n+1)$-dimensional space. It should be noticed that in the context of the Kaluza–Klein theory, one would consider an equation like the Klein–Gordon equation, rather than the Schrödinger equation. In Sec. II we consider the motion of a charged particle in a magnetic field in the framework of classical mechanics, showing the relationship of this problem with the motion of a free particle in a space with an extra dimension. The metric of this higher dimension space is different from that introduced in Refs. 1 and 2 and, as pointed out above, it has the advantage that the time parameters conjugate to the original and the auxiliary Hamiltonians coincide. We show that even though the vector potential may not be invariant under a group of isometries that leave the magnetic field invariant, one can find a local group of isometries of the metric defined in the extended space, which, however, may not be isomorphic to the original group. Two examples are given, which turn out to be related to metrics in four-dimensional spaces of interest in general relativity. A similar result can be obtained in the Kaluza–Klein theory; for any group of isometries of the spacetime metric that leave the electromagnetic field tensor invariant, it is possible to find a local group of isometries of the metric of the five-dimensional space. In Sec. III we consider the Schrödinger equation for a charged particle in a static magnetic field, showing that the solutions of this equation can be obtained from those of the Schrödinger equation for a free particle in the extended space employed in Sec. II. The generators of the isometries of this latter space correspond to operators that commute with the Hamiltonian.

II. MAGNETIC FIELDS AND GEOMETRY

The Hamiltonian of a particle of mass m and electric charge e in a static magnetic field and a velocity-independent potential ϕ is given by

$$H=\frac{1}{2m}\,\gamma^{ij}\left(p_i-\frac{e}{c}A_i\right)\left(p_j-\frac{e}{c}A_j\right)+\phi, \tag{1}$$

where (γ^{ij}) is the inverse of the matrix (γ_{ij}) formed by the components of the metric tensor with respect to a coordinate system x^i $(i,j,\ldots=1,2,3)$, A_i are the components of a (time-independent) vector potential corresponding to the given magnetic field and $\phi=\phi(x^i)$. We now introduce the auxiliary Hamiltonian,

$$h\equiv\frac{1}{2m}g^{\alpha\beta}p_\alpha p_\beta, \tag{2}$$

of a free particle of mass m in a four-dimensional space $(\alpha,\beta,...=0,1,2,3)$, with

$$g^{00}=\frac{1}{g_{00}}+\frac{A_iA^i}{c^2},\quad g^{0i}=-\frac{A^i}{c},\quad g^{ij}=\gamma^{ij}, \tag{3}$$

where g_{00} is a function of x^i only, to be specified later, and $A^i=\gamma^{ij}A_j$. It can be readily verified that the inverse of $(g^{\alpha\beta})$, denoted by $(g_{\alpha\beta})$, is given by

$$g_{0i}=g_{00}\frac{A_i}{c},\quad g_{ij}=\gamma_{ij}+g_{00}\frac{A_iA_j}{c^2}; \tag{4}$$

therefore, the orbits corresponding to the Hamiltonian (2) are the geodesics of the metric,

$$ds^2 = g_{\alpha\beta}\, dx^\alpha\, dx^\beta = g_{00}\left(dx^0 + \frac{A_i}{c} dx^i \right)^2 + \gamma_{ij}\, dx^i\, dx^j. \tag{5}$$

From Eqs. (1)–(3) it is easy to see that

$$h = H + \frac{(p_0 - e)}{2m} \frac{A^i}{c}\left(\frac{A_i}{c}(p_0 + e) - 2p_i \right) + \frac{p_0^2}{2mg_{00}} - \phi. \tag{6}$$

Thus, choosing g_{00} in such a way that

$$\frac{e^2}{2mg_{00}} = \phi + \text{const}, \tag{7}$$

it follows that on the submanifold

$$p_0 = e, \tag{8}$$

$\partial h/\partial x^i = \partial H/\partial x^i$ and $\partial h/\partial p_i = \partial H/\partial p_i$. Hence, the projection on the phase space of the original Hamiltonian (1) of the orbits determined by h [Eq. (2)], with $p_0 = e$, coincides with the orbits of H. Since the Hamiltonian h does not depend on x^0, p_0 is a constant of the motion.

Thus, we have shown that the solutions of the equations of motion determined by the Hamiltonian (1) correspond to the geodesics of the metric (5). For a given magnetic field, the vector potential A_i is defined up to the gauge transformations,

$$A_i' = A_i + \partial_i \xi, \tag{9}$$

where ξ is an arbitrary function of the x^i. From Eq. (5) we see that the gauge transformation (9) is equivalent to the substitution of the coordinate x^0 by

$$x'^0 = x^0 - \xi/c. \tag{10}$$

Applying Hamilton's equations to the Hamiltonian (2), it follows that $p_\alpha = mg_{\alpha\beta}\dot{x}^\beta$. Making use of Eqs. (4), this leads to

$$p_0 = mg_{00}\left(\dot{x}^0 + \frac{A_i \dot{x}^i}{c} \right), \quad p_i = m\gamma_{ij}\dot{x}^j + mg_{00}\frac{A_i}{c}\left(\dot{x}^0 + \frac{A_j \dot{x}^j}{c} \right),$$

hence, $p_i = m\gamma_{ij}\dot{x}^j + A_i p_0/c$, which, on the submanifold $p_0 = e$ [Eq. (8)] reduces to the well-known relation

$$p_i = m\gamma_{ij}\dot{x}^j + \frac{e}{c} A_i, \tag{11}$$

which also follows from the Hamiltonian (1).

In the rest of this paper we shall assume that only the magnetic field is present in (1), taking $\phi = 0$; therefore, in what follows, g_{00} will be taken as a constant [see Eq. (7)].

The symmetry of the magnetic field need not be shared by the vector potential; however, if the magnetic field is invariant under a one-parameter group of motions on the original configuration space, one can find a one-parameter (local) group of isometries of (5), which leads to a constant of the motion for both Hamiltonians. More precisely, let $K^i\partial_i$ be a Killing vector field (i.e., the generator of a one-parameter group of isometries) of the metric $\gamma_{ij}\, dx^i\, dx^j$ of the original configuration space,

$$K^i \partial_i \gamma_{jk} + 2\gamma_{i(j}\partial_{k)}K^i = 0, \tag{12}$$

where the parentheses denote symmetrization on the indices enclosed, which leaves the magnetic field 2-form $B = d(A_i\,dx^i)$ invariant; this means that the Lie derivative of $d(A_i\,dx^i)$ along $K^i\partial_i$ vanishes. Then, since the Lie derivative commutes with the differential, the Lie derivative of $A_i\,dx^i$ along $K^i\partial_i$ must be locally exact, i.e., there exists (locally) a function K^0 of the x^i only, such that $\pounds_{K^i\partial_i}(A_j\,dx^j) = -c\,dK^0$, or

$$K^i \partial_i A_j + A_i \partial_j K^i = -c\,\partial_j K^0. \tag{13}$$

Then, we can show that the vector field $K^\alpha\partial_\alpha = K^0\partial_0 + K^i\partial_i$ is a Killing vector field of the metric $g_{\alpha\beta}\,dx^\alpha\,dx^\beta$. Indeed, the components of the Lie derivative of $g_{\alpha\beta}\,dx^\alpha\,dx^\beta$ along $K^\alpha\partial_\alpha$,

$$K^\rho \partial_\rho g_{\alpha\beta} + 2g_{\rho(\alpha}\partial_{\beta)}K^\rho = K^i \partial_i g_{\alpha\beta} + 2g_{0(\alpha}\partial_{\beta)}K^0 + 2g_{i(\alpha}\partial_{\beta)}K^i,$$

are

$$K^i \partial_i g_{00} + 2g_{00}\partial_0 K^0 + 2g_{i0}\partial_0 K^i,$$

which vanishes since the components K^α do not depend on x^0 and in the present case ($\phi=0$) g_{00} is constant,

$$K^i \partial_i g_{0j} + g_{00}\partial_j K^0 + g_{i0}\partial_j K^i = K^i \partial_i\left(g_{00}\frac{A_j}{c}\right) + g_{00}\partial_j K^0 + g_{00}\frac{A_i}{c}\partial_j K^i = 0,$$

by virtue of Eqs. (4) and (13), and

$$\begin{aligned} &K^i \partial_i g_{jk} + 2g_{0(j}\partial_{k)}K^0 + 2g_{i(j}\partial_{k)}K^i \\ &\quad = K^i \partial_i \gamma_{jk} + 2\gamma_{i(j}\partial_{k)}K^i + 2\frac{g_{00}}{c^2}A_{(j}(K^i \partial_i A_{k)} + c\,\partial_{k)}K^0 + A_i\,\partial_{k)}K^i) = 0, \end{aligned}$$

where we have made use of Eqs. (4), (12), and (13). [The conclusion can also be obtained directly from Eq. (5), by noting that Eq. (13) means that the Lie derivative of $dx^0 + A_i\,dx^i/c$ along $K^\alpha\partial_\alpha$ vanishes.] It may be noticed that the same conclusion applies if ϕ is invariant under the group generated by $K^i\partial_i$, not necessarily a constant.

The invariance of the Hamiltonian (2) under the flow generated by $K^\alpha\partial_\alpha$ implies the conservation of $K^\alpha p_\alpha$, therefore, taking into account the constraint (8) and the fact that the Poisson bracket between $K^\alpha p_\alpha$ and p_0 vanishes, the function

$$K^i p_i + eK^0 \tag{14}$$

is also a constant of the motion for the original Hamiltonian (1) (see the examples below). Note that K^0 is defined by Eq. (13) up to an additive constant.

If there exist r Killing vector fields, $K^i_{(a)}\partial_i$ $(a,b,\ldots=1,2,\ldots,r)$, of $\gamma_{ij}\,dx^i\,dx^j$ that leave the magnetic field invariant such that

$$[K^i_{(a)}\partial_i, K^j_{(b)}\partial_j] = c^d_{ab}K^i_{(d)}\partial_i, \tag{15}$$

for some constants c^d_{ab}, then each Killing vector field can be locally ''lifted'' to a Killing vector field, $K^\alpha_{(a)}\partial_\alpha$ of the metric (5), with $K^0_{(a)}$ given by Eq. (13) up to an additive constant. Making use of Eq. (13) one finds that the commutation relations of the vector fields $K^\alpha_{(a)}\partial_\alpha$ are given by

$$[K^\alpha_{(a)}\partial_\alpha, K^\beta_{(b)}\partial_\beta] = (K^i_{(a)}\partial_i K^0_{(b)} - K^i_{(b)}\partial_i K^0_{(a)})\partial_0 + c^d_{ab}K^i_{(d)}\partial_i = c^d_{ab}K^\alpha_{(d)}\partial_\alpha + f_{ab}\partial_0, \tag{16}$$

where

$$f_{ab} \equiv -c^d_{ab} K^0_{(d)} + K^i_{(a)}\, \partial_i K^0_{(b)} - K^i_{(b)}\, \partial_i K^0_{(a)} \tag{17}$$

are constants that can be different from zero [see, e.g., Eq. (28) below]. (The fact that the f_{ab} are constant can be proven making use of Eq. (13) and of the property of the Lie derivative $\pounds_{[X,Y]} = [\pounds_X, \pounds_Y]$.) Since the vector fields $K^\alpha_{(a)}\partial_\alpha$ (and, hence, the constants of the motion $K^\alpha_{(a)} p_\alpha$ with the Poisson bracket) satisfy the commutation relations (16), if $f_{ab} \neq 0$, they generate a central extension of the Lie algebra generated by the vector fields $K^i_{(a)}\partial_i$. (Note that ∂_0 commutes with the Killing vector fields $K^\alpha_{(a)}\partial_\alpha$.)

Examples

The vector potential given by

$$A_i\, dx^i = -g \cos\theta\, d\varphi, \tag{18}$$

in terms of the spherical coordinates (r, θ, φ), corresponds to the field of a magnetic monopole of charge g. Substituting Eq. (18) and the metric of the Euclidean three-dimensional space into Eq. (5) one obtains the metric

$$ds^2 = g_{00}(g/c)^2 (d\chi + \cos\theta\, d\varphi)^2 + dr^2 + r^2 (d\theta^2 + \sin^2\theta\, d\varphi^2), \tag{19}$$

where we have introduced the dimensionless variable $\chi \equiv -(c/g)x^0$. The magnetic field of the monopole is invariant under the rotations about the origin [though the potential (18) is not]; therefore the vector fields,

$$\begin{aligned} K_{(1)} &\equiv K^i_{(1)}\partial_i = -\sin\varphi\,\partial_\theta - \cot\theta\cos\varphi\,\partial_\varphi, \\ K_{(2)} &\equiv K^i_{(2)}\partial_i = \cos\varphi\,\partial_\theta - \cot\theta\sin\varphi\,\partial_\varphi, \\ K_{(3)} &\equiv K^i_{(3)}\partial_i = \partial_\varphi, \end{aligned} \tag{20}$$

which generate rotations about the coordinate axes in the three-dimensional Euclidean space, give rise to Killing vector fields of (19). Substituting Eqs. (18) and (20) into Eq. (13), one finds that $K^0_{(1)} = -(g/c)\operatorname{cosec}\theta\cos\varphi$, $K^0_{(2)} = -(g/c)\operatorname{cosec}\theta\sin\varphi$, $K^0_{(3)} = 0$ (setting to zero the integration constants); thus, the vector fields,

$$\begin{aligned} \tilde{K}_{(1)} &\equiv K^\alpha_{(1)}\partial_\alpha = -\sin\varphi\,\partial_\theta - \cot\theta\cos\varphi\,\partial_\varphi + \operatorname{cosec}\theta\cos\varphi\,\partial_\chi, \\ \tilde{K}_{(2)} &\equiv K^\alpha_{(2)}\partial_\alpha = \cos\varphi\,\partial_\theta - \cot\theta\sin\varphi\,\partial_\varphi + \operatorname{cosec}\theta\sin\varphi\,\partial_\chi, \\ \tilde{K}_{(3)} &\equiv K^\alpha_{(3)}\partial_\alpha = \partial_\varphi, \end{aligned} \tag{21}$$

are Killing vector fields of (19). One can easily verify that the vector fields $K_{(a)}$ and $\tilde{K}_{(a)}$ obey the commutation relations $[K_{(a)}, K_{(b)}] = -\epsilon_{abc}K_{(c)}$ and $[\tilde{K}_{(a)}, \tilde{K}_{(b)}] = -\epsilon_{abc}\tilde{K}_{(c)}$, respectively (i.e., $f_{ab} = 0$). The three constants of the motion associated with the isometries (21) are [see Eq. (14)]

$$\begin{aligned} L_1 &= -\sin\varphi\, p_\theta - \cot\theta\cos\varphi\, p_\varphi - (eg/c)\operatorname{cosec}\theta\cos\varphi, \\ L_2 &= \cos\varphi\, p_\theta - \cot\theta\sin\varphi\, p_\varphi - (eg/c)\operatorname{cosec}\theta\sin\varphi, \\ L_3 &= p_\varphi, \end{aligned} \tag{22}$$

or, making use of Eq. (11), one finds that $(L_1, L_2, L_3) = \mathbf{r} \times m\dot{\mathbf{r}} - (eg/c)\mathbf{r}/r$. Since the mapping $K^\alpha\partial_\alpha \mapsto K^\alpha p_\alpha$ is a Lie algebra homomorphism, it follows that the functions L_a satisfy the Poisson bracket relations $\{L_a, L_b\} = -\epsilon_{abc}L_c$. It may be pointed out, finally, that the metric (19), with

$g_{00}>0$, is a Euclidean Taub–NUT metric (see, e.g., Ref. 4) and that the vector fields (21) form a basis for the right-invariant vector fields on SO(3), with φ, θ, and χ being Euler angles.

As a second example, we shall consider the potential,

$$A_i\,dx^i=\tfrac{1}{2}B_0(x\,dy-y\,dx), \tag{23}$$

in Cartesian coordinates, where B_0 is a constant, which corresponds to a uniform magnetic field. In this case the four-dimensional metric (5) is given by

$$ds^2=g_{00}(dx^0+(B_0/2c)(x\,dy-y\,dx))^2+dx^2+dy^2+dz^2. \tag{24}$$

The vector fields,

$$K_{(1)}\equiv\partial_x,\quad K_{(2)}\equiv\partial_y,\quad K_{(3)}\equiv\partial_z,\quad K_{(4)}\equiv x\partial_y-y\partial_x, \tag{25}$$

are Killing vector fields of the three-dimensional Euclidean space, that leave invariant the magnetic field generated by the vector potential (23) and whose nonvanishing commutators are

$$[K_{(1)},K_{(4)}]=K_{(2)},\quad [K_{(2)},K_{(4)}]=-K_{(1)}. \tag{26}$$

Making use of Eqs. (13), (23), and (25) one obtains the following Killing vector fields of the metric (24):

$$\tilde{K}_{(1)}\equiv\partial_x-\frac{B_0y}{2c}\partial_0,\quad \tilde{K}_{(2)}\equiv\partial_y+\frac{B_0x}{2c}\partial_0,\quad \tilde{K}_{(3)}\equiv\partial_z,\quad \tilde{K}_{(4)}\equiv x\partial_y-y\partial_x. \tag{27}$$

The only nonvanishing commutators of these vector fields are

$$[\tilde{K}_{(1)},\tilde{K}_{(2)}]=\frac{B_0}{c}\partial_0,\quad [\tilde{K}_{(1)},\tilde{K}_{(4)}]=\tilde{K}_{(2)},\quad [\tilde{K}_{(2)},\tilde{K}_{(4)}]=-\tilde{K}_{(1)}. \tag{28}$$

Thus, in this case $f_{12}=B_0/c$ [Eq. (16)] and the vector fields $\tilde{K}_{(a)}$ are part of a basis of a Lie algebra of dimension 5, which is not isomorphic to the Lie algebra generated by the vector fields (25). The constants of the motion corresponding to the Killing vector fields (27) on the submanifold $p_0=e$, are

$$\begin{gathered}p_x-\frac{eB_0}{2c}y=m\dot{x}-\frac{eB_0}{c}y,\quad p_y+\frac{eB_0}{2c}x=m\dot{y}+\frac{eB_0}{c}x,\\ p_z=m\dot{z},\\ xp_y-yp_x=m(x\dot{y}-y\dot{x})+\frac{eB_0}{2c}(x^2+y^2).\end{gathered} \tag{29}$$

As pointed out in Ref. 1, the metric (24) with $g_{00}=-1$ corresponds to the Som–Raychaudhuri spacetime;[5] thus, as a byproduct, we have shown that this spacetime possesses at least five Killing vector fields.

III. MAGNETIC INTERACTIONS IN THE SCHRÖDINGER EQUATION

Now we shall consider the time-independent Schrödinger equation for a particle of mass m and electric charge e in a static magnetic field with a (time-independent) vector potential **A**,

$$\frac{1}{2m}\left(\frac{\hbar}{i}\boldsymbol{\nabla}-\frac{e}{c}\mathbf{A}\right)^2\psi=E\psi, \tag{30}$$

or, equivalently,

$$-\hbar^2\nabla^2\psi - \frac{\hbar e}{ic}\boldsymbol{\nabla}\cdot(\mathbf{A}\psi) - \frac{\hbar e}{ic}\mathbf{A}\cdot\boldsymbol{\nabla}\psi + \left(\frac{e}{c}\right)^2\mathbf{A}^2\psi = 2mE\psi \tag{31}$$

(without imposing any gauge condition on **A**). If, as in the preceding section, γ_{ij} are the components of the metric tensor with respect to a coordinate system x^i, $(i,j,\ldots=1,2,3)$ and (γ^{ij}) denotes the inverse of (γ_{ij}), then Eq. (31) reads as

$$-\hbar^2\frac{1}{\sqrt{\gamma}}\partial_i(\sqrt{\gamma}\gamma^{ij}\partial_j\psi) - \frac{\hbar e}{ic}\frac{1}{\sqrt{\gamma}}\partial_i(\sqrt{\gamma}A^i\psi) - \frac{\hbar e}{ic}A^i\,\partial_i\psi + \left(\frac{e}{c}\right)^2 A_iA^i\psi = 2mE\psi, \tag{32}$$

where $\gamma\equiv\det(\gamma_{ij})$.

From Eqs. (4) it follows that $g\equiv\det(g_{\alpha\beta})$ is related to γ by means of

$$g = g_{00}\gamma. \tag{33}$$

(Note that g is used with two different meanings.) Therefore, making use of Eqs. (3) and (33), with g_{00} constant, one finds that Eq. (32) amounts to

$$-\hbar^2\frac{1}{\sqrt{g}}\partial_\alpha(\sqrt{g}g^{\alpha\beta}\partial_\beta\Psi) = (2mE + e^2/g_{00})\Psi, \tag{34}$$

provided that

$$\Psi(x^0,x^1,x^2,x^3) = \psi(x^1,x^2,x^3)\exp(iex^0/\hbar). \tag{35}$$

Equation (34) is an explicit expression of

$$-\frac{\hbar^2}{2m}{}^{(4)}\nabla^2\Psi = E'\Psi, \tag{36}$$

where ${}^{(4)}\nabla^2$ is the Laplace operator for the metric (5) and $E' = E + e^2/(2mg_{00})$. Equation (36) is the Schrödinger equation for a free particle of mass m (or the Helmholtz equation) in the four-dimensional space with metric (5).

Note that, by contrast with the operator appearing on the left-hand side of Eq. (30), the left-hand side of Eq. (36) does not contain the charge of the particle. Since the metric (5) does not depend on x^0, the operator $C\equiv -i\hbar\partial_0$ commutes with the free particle Hamiltonian $(-\hbar^2/2m){}^{(4)}\nabla^2$; the functions of the form (35) are the eigenfunctions of C,

$$C\Psi = e\Psi, \tag{37}$$

and the eigenvalue of C is the electric charge of the particle [cf. Eq. (8)].

As pointed out in Sec. II, the effect of a gauge transformation (9) is equivalent to the coordinate change (10); therefore, from Eq. (35) we see that a gauge transformation produces the change,

$$\psi'(x^i) = \psi(x^i)\exp\left(\frac{ie}{\hbar c}\xi\right), \tag{38}$$

as is well known. Furthermore, a Killing vector field $K^i\partial_i$ of the metric $\gamma_{ij}\,dx^i\,dx^j$ that leaves the magnetic field invariant, locally yields a Killing vector field $K^\alpha\partial_\alpha$ of the metric (5), which means that the operator,

$$\mathcal{K}\equiv -i\hbar K^\alpha\partial_\alpha, \tag{39}$$

commutes with the operator $(-\hbar^2/2m)^{(4)}\nabla^2$. In the case where we have a set of Killing vector fields $K_{(a)}=K^i_{(a)}\partial_i$ of $\gamma_{ij}\,dx^i\,dx^j$ that leave the magnetic field invariant satisfying Eq. (15), from Eqs. (16) and (39) it follows that the corresponding operators $\mathcal{K}_{(a)}$ obey the commutation relations,

$$[\mathcal{K}_{(a)},\mathcal{K}_{(b)}]=-i\hbar(c^d_{ab}\mathcal{K}_{(d)}+f_{ab}C). \tag{40}$$

For example, making use of Eqs. (3), (18), (33), and (34), one finds that the Schrödinger equation for a free particle in the four-dimensional geometry (19) is given by

$$\frac{1}{r^2}\partial_r(r^2\,\partial_r\Psi)+\frac{1}{r^2}\left[\frac{1}{\sin\theta}\partial_\theta(\sin\theta\,\partial_\theta\Psi)+\frac{1}{\sin^2\theta}(\partial^2_\chi\Psi-2\cos\theta\partial_\chi\,\partial_\varphi\Psi+\partial^2_\varphi\Psi)\right]$$
$$+\left(\frac{(c/g)^2}{g_{00}}-\frac{1}{r^2}\right)\partial^2_\chi\Psi=-\frac{2mE'}{\hbar^2}\Psi. \tag{41}$$

This equation admits separable solutions of the form

$$\Psi(\chi,r,\theta,\varphi)=R(r)e^{is\chi}{}_sY_{jm}(\theta,\varphi), \tag{42}$$

where the ${}_sY_{jm}$ are spin-weighted spherical harmonics[6] [which can be related to the Wigner D functions[7,8] and to the Jacobi polynomials (see, e.g., Refs. 9 and 10)] and $R(r)$ is a spherical Bessel function (cf. Refs. 11 and 12).

A comparison of Eqs. (35) and (42), taking into account that $\chi=-(c/g)x^0$, shows that $\psi(r,\theta,\varphi)=R(r){}_sY_{jm}(\theta,\varphi)$ is a separable solution of the Schrödinger equation (30) in the field of a magnetic monopole, with $s=-(eg)/(\hbar c)$. The operators $\mathcal{K}_{(a)}=-i\hbar K^\alpha_{(a)}\partial_\alpha$ $(a=1,2,3)$ [Eq. (39)], where the $K^\alpha_{(a)}\partial_\alpha$ are the Killing vector fields of (19) given by Eqs. (21), restricted to the subspace (37), reduce to the ‘‘generalized angular momentum’’ operators given, e.g., in Refs. 10 and 12.

(Received 8 December 1998; accepted for publication 14 July 1999)

Euclidean and Minkowski four-space uniqueness theorems are derived which yield a new perspective of classical four-vector fields. The Euclidean four-space uniqueness theorem is based on a Euclidean four-vector identity which is analogous to an identity used in Helmholtz's theorem on the uniqueness of three-vector fields. A Minkowski space identity and uniqueness theorem can be formulated from first principles and the space components of this identity turn out to reduce to the three-vector Helmholtz's identity in a static Newtonian limit. A further result is a uniqueness theorem for scalar fields based on an identity which is proved to be a static Newtonian limit of the zeroth or scalar component of the Minkowski space extension of the Helmholtz identity. Last, the three-vector Helmholtz identity and uniqueness theorem and their four-space extensions to Minkowski space are generalized to mass damped fields.

I. INTRODUCTION

In Sec. II a review of Helmholtz's theorem on the uniqueness of three-vector fields is first presented. Helmholtz's theorem is concerned with irrotational fields, which have zero curl everywhere in space, and solenoidal fields, which have zero divergence everywhere in space. Now, the divergence and curl of a vector field over all of a Euclidean three-space uniquely determine this vector field. Based on these properties a theorem, that will be called the Helmholtz theorem, states that the most general continuous three-vector field defined everywhere in a Euclidean three-space, that along with its first derivatives vanishes sufficiently rapidly at infinity, may be uniquely represented as a sum of an irrotational and a solenoidal part, up to a possible additive vector constant. The theorem can be extended to finite volumes as well. In proving Helmholtz's theorem, a vector identity is used that is commonly referred to as the Helmholtz identity, which in turn is derived from a delta function property of the Laplacian operator.

A comparison of the three-space Laplacian operator with the Minkowski space d'Alembertian operator then suggests that a three-divergence and a three-curl naturally generalize into a four-divergence and a four-curl when a fourth dimension is added. A review of the Sommerfeld four-space integral solution of the four-vector potential d'Alembertian wave equation, translated into modern notation, is then presented.

In Secs. III and IV a number of theorems are put forward. Of these theorems, Theorems I, II, IV, V, and VII–XII appear to be new results for three-vector and four-vector fields in a flat space. The new four-vector results of this paper follow from a different starting point than another series of attempts to extend Helmholtz's theorems to Minkowski four-space[1] in that the present paper adopts a definition of the four-curl as given by the Maxwell field tensor $F^{\mu\nu}$, Eq. (14b), following the definition in Møller,[2] while these other attempts choose the dual of the Maxwell field tensor as their four-curl. This later definition appears to be oriented toward the analysis of the uniqueness of electromagnetic fields in the presence of hypothetical magnetic monopoles. The advantage of the approach of the present paper, on the other hand, is that it leads to a more natural generalization

[a)]Electronic mail: dalew@physics.mq.edu.au

of Helmholtz's three-space theorems to four-space. In particular, it yields a four-space Helmholtz identity whose space components reduce to the three-space Helmholtz identity in a static Newtonian limit.

In Sec. III a comparison of Sommerfeld's four-space integral solution with a Green's function approach yields a four-space Euclidean Laplacian delta function identity. On observing that the original three-space Helmholtz identity is commonly derived from an analogous three-space Laplacian operator delta function identity, a parallel approach is taken and the four-vector Euclidean Laplacian delta function identity is used to derive a Euclidean four-space generalization of the Helmholtz identity. As with Sommerfeld's Euclidean four-space integral, the Euclidean four-space delta function identity can be analytically continued to Minkowski space by choosing an appropriate integration contour which takes timelike causality into account. Rather than working with this analytic continuation technique to derive a Minkowski space result, it turns out to be more convenient to derive the Minkowski four-space extension of the Helmholtz identity from first principles using a Minkowski space retarded Green's function. These Euclidean and Minkowski four-space extensions of the three-space Helmholtz identity are explicitly stated in Theorems I and II, respectively, and form the basis for several uniqueness theorems for four-vector fields.

Next, it is shown that this Minkowski four-space identity reduces to the three-space Helmholtz identity in a static Newtonian limit. The zeroth or scalar component of this Minkowski four-space extension of the Helmholtz identity is then shown to reduce to a three-vector integral identity for scalar fields in a static Newtonian limit. This three-vector integral identity for scalar fields, explicitly stated in Theorem III, is also proved by direct application of the three-space Laplacian operator delta function identity.

Uniqueness theorems in Euclidean and Minkowski four-spaces, Theorems IV and V, are then proved using their respective four-vector Helmholtz identities. It is found that the specification of the *four-curl* and *four-divergence* of the four-vector field throughout the four-volume V_4, as well as the *four-tangential* and *four-normal projections* of the four-vector field everywhere on the bounding three-surface Σ, are sufficient to obtain a unique four-vector field. A further result based on Theorems IV and V, and stated later in Theorem X in Sec. IV, is that a four-vector field is uniquely specified by the sum of a *four-irrotational* and a *four-solenoidal* part. This latter theorem corresponds to a four-space generalization of Helmholtz's uniqueness theorem.

Also in Sec. III, a uniqueness theorem for scalar fields, Theorem VI, is proved using the scalar field integral identity of Theorem III. In this three-vector field case it is found that the gradient of the scalar field throughout the volume V, as well as the magnitude of the scalar field on the bounding surface S, are sufficient to obtain a unique scalar field in a Euclidean three-space.

Finally, in Sec. IV there is a discussion on whether or not the Helmholtz identity and its relativistic extensions to Euclidean and Minkowski spaces can be generalized to fields with mass. First, by adding an exponential damping factor for the mass to the Euclidean three-space Laplacian delta function identity, an exponentially damped three-vector Helmholtz identity is stated in Theorem VII. A uniqueness theorem, Theorem VIII, is then proved using this three-vector identity. Next, in the Euclidean four-vector case it is shown that adding an exponential damping factor for the mass leads to a Euclidean four-space Laplacian delta function identity with an additional cross term which makes the development of an analogous four-vector identity problematic. On the other hand, in the Minkowski four-space case, the existence of a massive scalar Green's function over timelike separations allows one to obtain an exponentially damped Minkowski space four-vector identity which is explicitly stated in Theorem IX. But the four-space extension of Helmholtz's uniqueness theorem does not appear to carry over to the exponentially damped case. However, an exponentially damped version of uniqueness Theorem V is stated in Theorem XII, which relies on a theorem on the vanishing of a four-vector field, i.e., Theorem XI.

Although it is tempting to interpret the exponentially damped results as generalizations of the earlier results to massive four-vector fields, no limitation was imposed on their derivations other than that the four-vector fields are assumed to be sufficiently smooth. The exponentially damped results do, however, appear to be oriented toward application to massive vector fields or alternately to fields undergoing spatial diffusion in three or four dimensions, respectively.

II. HISTORICAL AND MATHEMATICAL BACKGROUND

A. Historical survey of uniqueness theorems in three dimensions

A natural starting point in the development of a uniqueness theorem for classical four-vector fields is an examination of the various statements of uniqueness theorems for ordinary three-vector fields in a flat Euclidean three-space. Historically, the first statement of a uniqueness theorem for three-vector fields is found in Stokes' article on diffraction in 1849.[3] The next statement is found in Helmholtz's article on the hydrodynamics of vortex motion in 1858.[4] Modern texts often attach Helmholtz's name to a uniqueness theorem for three-vector fields, but Sommerfeld[5] makes a point of acknowledging Stokes' contribution as well. Also, modern statements of uniqueness theorems for three-vector fields adopt vector notation, which is absent from their 1850's counterparts, and in addition differ in their emphasis and presentation.[6–9] A short review of these modern uniqueness statements is therefore warranted.

First, it is important to note that the defining properties of irrotational and solenoidal fields are the essential underpinnings of the uniqueness theorems for three-vector fields. Namely, an irrotational field has zero curl everywhere in space, i.e.,

$$0=\nabla\times\mathbf{A}, \tag{1a}$$

while a solenoidal field has zero divergence everywhere in space, i.e.,

$$0=\nabla\cdot\mathbf{A}. \tag{1b}$$

Next, a preliminary uniqueness theorem can be stated as follows:

Theorem U: *The divergence and curl of a three-vector field over a volume V in a Euclidean three-space, along with its normal components on a closed surface S bounding the volume V, uniquely determines the three-vector field over the volume V and on the surface S.*

In other words, one must specify

$$\nabla\times\mathbf{F}=\mathbf{j}(x,y,z), \tag{2a}$$

$$\nabla\cdot\mathbf{F}=\rho(x,y,z), \tag{2b}$$

over the volume V, and the normal component $\mathbf{F}_n(x,y,z)$ on the surface S, where for example in an electromagnetic context, $\mathbf{j}$ is a ''circulation current density'' and ρ is a ''source charge density.'' A proof of this theorem is given in Arfken.[8]

A uniqueness theorem that can be attributed to Helmholtz can now be stated as follows:

Theorem H1 (Helmholtz's theorem on the uniqueness of three-vector fields over all of a Euclidean three-space): *A general continuous three-vector field defined everywhere in a Euclidean three-space, that along with its first derivatives vanishes sufficiently rapidly at infinity, may be uniquely represented as a sum of an irrotational and a solenoidal part, up to a possible additive constant vector*.

A proof of this theorem is given in Sommerfeld.[5]

A modern alternate form of this theorem can be stated by restricting the domain of definition of the three-vector field to a finite volume as follows:

Theorem H2 (Alternate form of Theorem H1 for a finite volume in a Euclidean three-space): *A general continuous three-vector field that is defined everywhere in a finite volume V of a Euclidean three-space and whose tangential and normal components on the bounding closed surface S are given may be uniquely represented as a sum of an irrotational and a solenoidal part*.

In order to prove either Theorem H1 or Theorem H2, it turns out that it is sufficient to prove only that the three-vector $\mathbf{F}$ can be written as

$$\mathbf{F}(x,y,z)=-\nabla\Phi(x,y,z)+\nabla\times\mathbf{A}(x,y,z), \tag{3}$$

since by the three-vector identity

$$\nabla\times\nabla\Phi\equiv 0, \tag{4}$$

one has by (1a) that $-\nabla\Phi$ is irrotational, and since by the three-vector identity

$$\nabla\cdot\nabla\times\mathbf{A}\equiv 0, \tag{5}$$

one has by (1b) that $\nabla\times\mathbf{A}$ is solenoidal. In fact, Eq. (3) is used by King as a brief statement of his version of Helmholtz's theorem.[9] In another notable case, Eq. (3) is referred to in the very extensive treatment by Plonsey and Collin as ''the mathematical statement of the second part of Helmholtz's theorem.''[7]

The proof of (3) is based on the assumption that there exists a solution for the three-vector potential **A** of the vector Poisson equation in Cartesian coordinates, which in the electromagnetic case reads

$$\nabla^2\mathbf{A}(x,y,z)=-\mu_0\mathbf{J}(x,y,z), \tag{6}$$

where $\mu_0=1/\epsilon_0 c^2$ is the free space permeability. Now, in Cartesian coordinates, the three components of **A** are each separately a solution of a scalar Poisson equation. The scalar Poisson equation can then be solved in terms of a two-point scalar Green's function $G(\mathbf{r},\mathbf{r}')$ which connects its unit delta function source located at the source point $\mathbf{r}'=(x',y',z')$ to a measurement at the field point $\mathbf{r}=(x,y,z)$, i.e.,

$$\nabla^2 G(\mathbf{r},\mathbf{r}')=-\delta^3(\mathbf{r}-\mathbf{r}')=-\delta(x-x')(y-y')(z-z'). \tag{7}$$

The well-known identity over the Euclidean three-space $\mathbb{R}^3$, namely

$$\nabla^2\frac{1}{4\pi r}\equiv-\delta^3(\mathbf{r}-\mathbf{r}')\quad\forall\mathbf{r},\mathbf{r}'\in\mathbb{R}^3, \tag{8}$$

where $r\equiv|\mathbf{r}-\mathbf{r}'|$, yields by comparison with (7) for the case of an infinite spatial domain, the Green's function of the Laplacian operator as $G(\mathbf{r},\mathbf{r}')=1/4\pi r$. The inhomogeneous solution of (6) for the vector potential then follows from the integral

$$\mathbf{A}(\mathbf{r})=\int_{V'}\mu_0\mathbf{J}(\mathbf{r}')G(\mathbf{r},\mathbf{r}')d^3\mathbf{r}'=\int_{V'}\frac{\mu_0\mathbf{J}(\mathbf{r}')}{4\pi|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}'. \tag{9}$$

Although (9) is an inhomogeneous solution to the vector Poisson equation (6) in an infinite spatial domain, it is the delta function property of the vector identity (8) which is of importance in the proof of Theorems H1 or H2, namely

$$\mathbf{F}(x,y,z)=\int_{V'}\mathbf{F}(x',y',z')\delta^3(\mathbf{r}-\mathbf{r}')d^3\mathbf{r}'=\int_{V'}\mathbf{F}(x',y',z')\nabla^2\left(\frac{-1}{4\pi r}\right)d^3\mathbf{r}'. \tag{10}$$

Then, since the Laplacian operator acts only on the field coordinates, it can be brought outside of the integration. At this point, one makes a decomposition of the Laplacian operator using identity (20), the significance of which is discussed in Sec. II B. The identity $\nabla(1/r)=-\nabla'(1/r)$ and a fair amount of vector analysis then yields the identity[6,7]

$$\mathbf{F}(x,y,z)=-\nabla\left[\int_{V'}\frac{\nabla'\cdot\mathbf{F}(x',y',z')}{4\pi r}dV'-\oint_{S'}\frac{\mathbf{F}(x',y',z')\cdot\mathbf{n}'}{4\pi r}dS'\right]$$
$$+\nabla\times\left[\int_{V'}\frac{\nabla'\times\mathbf{F}(x',y',z')}{4\pi r}dV'+\oint_{V'}\frac{\mathbf{F}(x',y',z')\times\mathbf{n}'}{4\pi r}dS'\right], \tag{11a}$$

where $\mathbf{n}'$ is the unit surface normal pointing out of the volume V' bounded by the closed surface S'. The proof of the volume integral terms of (11a) can be traced back to Stokes.[3] Proof of the surface integral terms of (11a) can be found in *Field Theory of Guided Waves* by Collin.[6] Equation (11a) is of the desired form (3) and can therefore be considered as completing the proof of Theorem H2, provided of course that the integrals are well defined. In order for the integrals to be well defined, one must make the additional assumption that the field $\mathbf{F}$ must vanish sufficiently rapidly at infinity, i.e., at least as fast as $1/r^2$ in order to avoid logarithmic divergences. To prove H1, one takes the surface S as going to infinity to include all of Euclidean three-space. The surface integral terms vanish as $r\rightarrow\infty$ under the same assumption that the field $\mathbf{F}$ falls off at least as fast as $1/r^2$. Equation (11a), but without the surface integral terms, is sometimes referred to as the ''Helmholtz identity'' (cf. Ref. 10). However, the more general result, the full equation (11a), will be referred to as the Helmholtz identity in this article.

It should be noted in passing that application of identity (11a) to a field $\mathbf{F}$ falling off only as fast as $1/r$ (e.g., a potential), would presumably require a cut-off procedure in the integrals. However, the vector derivatives which stand in front of the integrals act only on the field point coordinates so that, for a twice continuously differentiable vector field $\mathbf{F}$, one can move these derivatives inside of the integrals over the source point coordinates to give

$$\mathbf{F}(x,y,z)=-\left[\int_{V'}\nabla\left(\frac{\nabla'\cdot\mathbf{F}(x',y',z')}{4\pi r(\mathbf{r},\mathbf{r}')}\right)dV'-\oint_{S'}\nabla\left(\frac{\mathbf{F}(x',y',z')\cdot\mathbf{n}'}{4\pi r(\mathbf{r},\mathbf{r}')}\right)dS'\right]$$
$$+\left[\int_{V'}\nabla\times\left(\frac{\nabla'\times\mathbf{F}(x',y',z')}{4\pi r(\mathbf{r},\mathbf{r}')}\right)dV'+\oint_{S'}\nabla\times\left(\frac{\mathbf{F}(x',y',z')\times\mathbf{n}'}{4\pi r(\mathbf{r},\mathbf{r}')}\right)dS'\right], \quad (11b)$$

as an alternate form of the Helmholtz identity. Now, since the integrands of identity (11b) involve an extra vector derivative over the field point coordinates $\mathbf{r}$, the convergence properties of the integrands are improved and the integrals are now well defined for vector potentials $\mathbf{F}$ falling off only as fast as $1/r$.

Note, Eqs. (11a) and (11b) should be thought of as identities for representing a general (static) three-vector field rather than as a general solution to a partial differential equation. Indeed, Eqs. (11a) and (11b) follow from the vector identity (8) over an infinite spatial domain and its subsequent use in the delta function property (10). Consequently, Eqs. (11a) and (11b) are vector identities that apply to all of the Euclidean three-space, and so must hold for a finite subvolume of it as well. The Green's function for an inhomogeneous vector Poisson equation in an infinite spatial domain is only mentioned in passing, and certainly no use is made of the solutions of the associated source free homogeneous vector Laplace equation. This does not necessarily reduce the utility or applicability of (11a), for example. In fact, if one makes the replacements (2), for suitable volume source densities, and then makes the replacements

$$\sigma\equiv-\mathbf{F}\cdot\mathbf{n}, \quad (12a)$$

$$\mathbf{K}\equiv\mathbf{F}\times\mathbf{n}, \quad (12b)$$

with for example σ taken as a surface ''charge'' density and $\mathbf{K}$ taken as a surface ''current'' density, one can deduce from a general point of view basically all of the (static) macroscopic integral equations for an electromagnetic field in material media expressed in terms of its sources. This program, i.e., using (11a), is carried to its logical completion for the electromagnetic case in the thorough treatment of Plonsey and Collin.[7]

From the point of view of the present article, it turns out that identity (11a), as well as Theorems H1 or H2, are actually static, (i.e., nontime varying), cases of a more general identity and theorem in a pseudo-Euclidean $3+1$ space, (hereafter taken to be Minkowski space). Indeed, in the nontime varying case, identity (11a) follows as the space components of a four-vector identity in a static Newtonian limit, and in addition, a three-space identity arises from the fourth or scalar component of the four-vector identity. In the general time varying case in Minkowski space, the new identity and uniqueness theorem imply that the three-space notions of uniquely specifying a general vector field by its divergence and curl in a Euclidean volume V, along with its normal and tangential components on the closed bounding surface S, must be generalized to specifying its *four-divergence* and its *four-curl* in a four-volume V_4 of Minkowski space, along with its *four-normal* and *four-tangential* components on the closed bounding three-surface Σ.

B. Lagrangian formulation of four-vector fields in the flat space–time of special relativity

Before proceeding, a few preliminary definitions and assumptions are made. First, the nonzero components of the flat space Minkowski metric tensor $\eta_{\mu\nu}$ are taken as: $-\eta_{00}=\eta_{11}=\eta_{22}=\eta_{33}=1$. So, the ordinary four-vector derivatives are taken as: $\partial_\mu=((1/c)\partial/\partial t,\nabla)$ and $\partial^\mu=(-(1/c)\partial/\partial t,\nabla)$. Similarly, the position four-vector $x^\nu=(ct,x,y,z)$, and so $x_\nu=(-ct,x,y,z)$. [The adoption of this $(-+++)$ signature metric in this article will aid in the comparison of the results of this article with historical results expressed using complex Minkowski space notation, here taken as $x_\nu=(ict,x,y,z)$.]

Next, it is assumed that the most general form of Lagrangian density for a four-vector field, which is no more than quadratic in its variables and their derivatives, is given by the so-called Stueckelberg Lagrangian density,[11,12] (in SI units where ϵ_0 is the free space permittivity and c is the speed of light),

$$\mathcal{L}=-\frac{\epsilon_0 c^2}{4}F_{\mu\nu}F^{\mu\nu}+j_\mu A^\mu-\frac{\lambda\epsilon_0 c^2}{2}(\partial_\mu A^\mu)^2-\frac{\epsilon_0 c^2\mu^2}{2}(A_\mu A^\mu), \tag{13}$$

where $j^\mu=(\rho c,\mathbf{j})$ is the usual four-vector current, where the positive real constant λ is a Lagrange multiplier for the Lorentz constraint term, and where $\mu=2\pi/\lambda_C=2\pi mc/h$ is the Compton wave number for photons of mass m. A choice of $\lambda=0$ and $\mu=0$ yields what many physicists believe to be the electromagnetic theory, with its massless photons, i.e., when an appropriate constraint is externally imposed. However, the choice of $\lambda=0$ has the distinct disadvantage of implying a vanishing momentum canonically conjugate to the zeroth component of the four-vector potential $A^\nu=(\phi/c,\mathbf{A})$. The incorporation of the Lorentz constraint term, with its $\partial\phi/\partial t$ functionality, eliminates this deficiency, and yields an added bonus in terms of the ease of renormalization of the theory. A particularly simple choice of $\lambda=1$, (and $\mu=0$), then yields a Lagrangian density which is equivalent (i.e., differs by no more than a four-divergence), to the so-called Fermi Lagrangian density.[13] The Fermi Lagrangian density is the most straightforward take off point for field quantization in terms of harmonic oscillators which correspond to massless photons (cf. Ref. 13). The Stueckelberg Lagrangian density (13) also has the advantage of explicitly including the four-divergence and four-curl of A^μ, which are in turn sufficient for the unique specification of a four-vector field as is shown in Secs. II F and III B. Therefore, the point of view is taken that the choice $\lambda=1$ in (13) is the most natural choice for the development of a uniqueness theorem for four-vector fields.

The Maxwell field tensor $F_{\mu\nu}$ in terms of A_ν is taken as following from a Bianchi identity, namely

$$\partial_\lambda F_{\mu\nu}+\partial_\mu F_{\nu\lambda}+\partial_\nu F_{\lambda\mu}=0 \tag{14a}$$

$$\Rightarrow F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu. \tag{14b}$$

The covariant form of the Euler–Lagrange equations of motion

$$\partial_\mu\left(\frac{\partial\mathcal{L}}{\partial(\partial_\mu A_\nu)}\right)-\frac{\partial\mathcal{L}}{\partial A_\nu}=0, \tag{15}$$

then yields for the Stueckelberg Lagrangian density (13), the covariant equation of motion

$$(\partial_\mu \partial^\mu - \mu^2) A^\nu - (1-\lambda) \partial^\nu (\partial_\sigma A^\sigma) = - j^\nu / \epsilon_0 c^2. \tag{16}$$

In the so-called Feynman gauge, one takes $\lambda = 1$ so that (16) reduces to the following:

$$\Box A^\nu - \mu^2 A^\nu = - j^\nu / \epsilon_0 c^2, \tag{17}$$

where $\Box \equiv \partial_\mu \partial^\mu$ is the d'Alembertian operator.

One can now rewrite the d'Alembertian operator acting on A^ν by adding and subtracting a term, i.e.,

$$\Box A^\nu = \partial_\mu \partial^\mu A^\nu - \partial_\mu \partial^\nu A^\mu + \partial_\mu \partial^\nu A^\mu. \tag{18}$$

The first two terms combine naturally using the field tensor $F^{\mu\nu}$, while the ordinary four-vector derivatives in the last term commute in flat space–time to yield the identity

$$\Box A^\nu \equiv \partial_\mu \partial^\mu A^\nu = \partial_\mu F^{\mu\nu} + \partial^\nu (\partial_\mu A^\mu). \tag{19}$$

Equation (19) is a special relativistic generalization to $3+1$ space–time of the well-known three-space identity

$$\nabla^2 \mathbf{A} \equiv - \nabla \times (\nabla \times \mathbf{A}) + \nabla (\nabla \cdot \mathbf{A}). \tag{20}$$

Specifically, the curl of **A** is generalized into the four-curl of A^ν (i.e., $F^{\mu\nu}$), the divergence of **A** is generalized into the four-divergence of A^μ (i.e., $\partial_\mu A^\mu$), and the Laplacian is generalized into the d'Alembertian.

This special relativistically invariant decomposition, using the identity (19), is the defining property which leads to a uniqueness theorem for four-vector fields in a flat space–time. Indeed, in the same way that the delta function property (10), with its Laplacian operator, leads to the Helmholtz identity (11a), so too does a more general Minkowski space delta function property, with a d'Alembertian operator, lead to a new special relativistically invariant identity.

C. Integration of the four-vector potential wave equation

Assuming that the four-vector potential wave equation (17), as following from the Stueckelberg Lagrangian (13) with $\lambda = 1$, is the most natural starting point for a four-dimensional analysis, one now proceeds in a manner analogous to the three-dimensional case outlined in Sec. II A. Initially, however, μ is taken as zero yielding the massless four-vector potential wave equation as

$$\Box A^\mu(x^\nu) \equiv \left(\nabla^2 - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) A^\mu(x^\nu) = - \frac{j^\mu(x^\nu)}{\epsilon_0 c^2}. \tag{21}$$

In Sec. IV B the mass term is restored and an attempt at a more general result is made. Now, the first step in the analysis leading to a uniqueness theorem for classical four-vector fields is to integrate the four-vector potential wave equation (21).

The integration of the massless four-vector potential wave equation (21) was first done in a special relativistically invariant way by Arnold Sommerfeld in an important article in 1910.[14] The method was later translated into English and appeared in Volume III: Electrodynamics of his well-known *Lectures on Theoretical Physics*.[15] Additional revealing descriptions of the method were given by Møller[2] and Stratton[16] in their classic texts.

To formulate the integral, Sommerfeld replaces Newton's $1/r$ potential in three dimensions by an analogous four-dimensional scalar potential, i.e.,

$$U = \frac{1}{R^2}, \tag{22}$$

where R is the distance in a Euclidean four-space between the source point x'^{ν} and field point x^{ν},

$$R \equiv |x^{\nu}-x'^{\nu}| = \sqrt{(x_{\nu}-x'_{\nu})(x^{\nu}-x'^{\nu})}, \tag{23}$$

and where the Euclidean metric tensor is just $\eta_{\mu\nu}=\mathbf{I}$, the identity matrix. As pointed out by Møller,[2] Sommerfeld derives the integral in Euclidean space, and then in order to get physically reasonable results, he analytically continues the four-current density by deforming the time integration from the real axis onto the imaginary axis in such a way as to take timelike causality into account as is appropriate for the *complex* Minkowski space used in his treatment. On the other hand, modern notation using covariant and contravariant indices is used in this partial review of Sommerfeld's method. Therefore, after the analytic continuation from Euclidean four-space to complex Minkowski space is done, the results are adjusted to take into account the replacement of the Euclidean metric tensor by the Minkowski metric tensor. The contour integration itself is described in Refs. 15 and 2.

Just as the three-space Laplacian of Newton's $1/r$ potential is zero everywhere except at the source point $\mathbf{r}'$, [see (8)], the *Euclidean* version of the d'Alembertian, (i.e., the four-space Laplacian Δ^{ν}_{ν}), of the scalar potential U is likewise zero everywhere except at the four-space source point x'^{ν}. To demonstrate this one first calculates

$$\frac{\partial}{\partial x^{\nu}}\left(\frac{1}{R^2}\right) = -\frac{2}{R^3}\frac{\partial R}{\partial x^{\nu}} = -\frac{2(x_{\nu}-x'_{\nu})}{R^4}, \tag{24}$$

where use is made of the four-vector derivative of R as follows:

$$\frac{\partial R}{\partial x^{\nu}} = \frac{1}{2R}\frac{\partial((x_{\nu}-x'_{\nu})(x^{\nu}-x'^{\nu}))}{\partial x^{\nu}} = \frac{(x_{\nu}-x'_{\nu})}{R}. \tag{25}$$

It is obvious from the calculation (24) that one also has the useful identity:

$$\frac{\partial}{\partial x'^{\nu}}\left(\frac{1}{R^2}\right) = -\frac{\partial}{\partial x^{\nu}}\left(\frac{1}{R^2}\right). \tag{26}$$

The Euclidean four-space Laplacian of U now follows from a four-vector derivative contraction of (24) as

$$\Delta^{\nu}_{\nu}\left(\frac{1}{R^2}\right) \equiv \frac{\partial}{\partial x_{\nu}}\frac{\partial}{\partial x^{\nu}}\left(\frac{1}{R^2}\right) = -\frac{\partial}{\partial x_{\nu}}\left(\frac{2(x_{\nu}-x'_{\nu})}{R^4}\right) = \frac{-2\cdot 4}{R^4} + \frac{2\cdot 4(x_{\nu}-x'_{\nu})}{R^5}\frac{\partial R}{\partial x_{\nu}}. \tag{27}$$

Substitution of a contravariant version of (25) into (27) yields finally

$$\Delta^{\nu}_{\nu}\left(\frac{1}{R^2}\right) = 0 \quad \forall x^{\nu} \neq x'^{\nu}, \tag{28}$$

that is except at the singular point at $R=0$.

Next, using a Green's theorem integral approach, Sommerfeld obtains the Euclidean four-space integral: (cf. Refs. 15, 2, and 16 for details)

$$\phi(x^{\nu}) = -\int_{V'_4}\frac{\partial'^{\mu}\partial'_{\mu}\phi(x'^{\nu})}{4\pi^2 R^2(x^{\nu},x'^{\nu})}\,d^4x', \tag{29}$$

where the surface area $2\pi^2R^2$ of a three-sphere of radius R is incorporated in the denominator of (29). As pointed out by Møller[2] Eq. (29) holds for any regular (i.e., analytic), function ϕ, so if $\phi = A^0 c$ is taken as satisfying the zeroth component of (21), i.e., of $\partial'^{\mu}\partial'_{\mu}\phi(x') = -\rho(x')/\epsilon_0$, one obtains

$$\phi(x^{\nu}) = \int_{V'_4} \frac{\rho(x'^{\nu})}{4\pi^2\epsilon_0 R^2(x^{\nu},x'^{\nu})} d^4x'. \tag{30a}$$

Equation (30a) allows one to calculate ϕ at every point in V'_4 when the source charge density ρ is known over all of V'_4. However, in real life physical problems ρ is given only for purely imaginary x'^0 values corresponding to $\mathrm{Im}(x^0) > \mathrm{Im}(x'^0)$ i.e., the zeroth component of (21) is a Minkowski space relation and the integral (30a) can no longer be limited to Euclidean space. This timelike causality assumption requires that a signal from the source point reaches the field point only after traveling the distance R at a the finite speed c. Therefore, to take into account the timelike causal data required for the charge density ρ, one can then analytically continue in $x'^0 = ct'$ in the integrand of (30a). The analytically continued version of (30a) is therefore

$$\phi(x^{\nu}) = \int_{V'} \left[\oint_{t'} \frac{\rho(x'^{\nu})}{4\pi^2\epsilon_0 R^2(x^{\nu},x'^{\nu})} c\,dt' \right] d^3x', \tag{30b}$$

where a suitable integration contour in the complex t' plane has to be chosen to satisfy timelike causality of the data. That is, such a contour integration is taken as being compatible with timelike causality. Performance of the integral (30b) under the specified timelike causal data yields, in terms of a ''retarded'' charge density, a Minkowski space result. In order to obtain results in modern metric notation, the complex Minkowski space result is then mapped to a Minkowski metric space by replacement of the Euclidean metric tensor by the Minkowski metric tensor (thus absorbing any factors of the imaginary unit i), which here amounts to retention of raised and lowered index notation. An analytic continuation in the complex t' plane of a time integral of the type in (30b) is detailed in Refs. 15 and 2.

Again, as pointed out by Møller,[2] since Eq. (29) holds for any regular function of ϕ it will hold for the A^1, A^2, and A^3 spatial Cartesian components of A^{μ} in the massless four-vector potential wave equation (21). The combined result for the four-vector potential A^{μ} at the space–time field point x^{ν}, is therefore given by a four-dimensional integration over the space–time source coordinates x'^{ν} of the timelike causal four-vector current density j^{μ}, i.e.,

$$A^{\mu}(x^{\nu}) = \int_{V'_4} \frac{j^{\mu}(x'^{\nu})}{4\pi^2\epsilon_0 c^2 R^2(x^{\nu},x'^{\nu})} d^4x' = \int_{V'_4} \frac{\mu_0 j^{\mu}(x'^{\nu})}{4\pi^2|x^{\nu}-x'^{\nu}|^2} d^4x', \tag{31}$$

where the integral (31) is to be interpreted as a Minkowski space integral in the same sense as in (30b). Equation (31) is the integral result first obtained by Sommerfeld,[14] retraced here in modern notation, as desired.

III. DERIVATION OF UNIQUENESS THEOREMS

A. Green's function approach and a delta function identity

Rather than pursuing further the inhomogeneous four-vector wave equation (21), it turns out to be more convenient for the purpose of this article to focus instead on the inhomogeneous *scalar* wave equation for the scalar potential ϕ,

$$\Box\phi(x^{\nu}) = \left(\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2} \right) \phi(x^{\nu}) = -\frac{\rho(x^{\nu})}{\epsilon_0}. \tag{32}$$

The wave equation (32) can then be solved in terms of a two-point scalar Green's function $G(x^\nu, x'^\nu)$ which connects its unit delta function source located at the space–time source point x'^ν to a measurement at the space–time field point x^ν in Minkowski space, i.e.,

$$\Box G(x^\nu, x'^\nu) = \left(\nabla^2 - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) G(x^\nu, x'^\nu) = -\delta^{(4)}(x^\nu - x'^\nu), \tag{33}$$

where $\delta^{(4)}(x^\nu - x'^\nu) = \delta(x^0 - x'^0)\delta^3(\mathbf{r} - \mathbf{r}')$. If the Green's function $G(x^\nu, x'^\nu)$ is known *over all space–time*, the inhomogeneous solution of (32) then follows from the Minkowski space integral

$$\phi(x^\nu) = \int_{V_4'} \frac{\rho(x'^\nu)}{\epsilon_0} G(x^\nu, x'^\nu) d^4x'. \tag{34}$$

Interestingly, Eq. (34) is of the same general form as the Euclidean space integral (30a). Therefore, if one starts with (30b), i.e., the analytic continuation of (30a) to Minkowski space, it should be possible to extract a Green's function $G(x^\nu, x'^\nu)$ through simple comparison of (34) and (30b), which would integrate to the same result under mutually compatible causality conditions. As additional evidence notice that for $x^\nu \neq x'^\nu$, Eq. (33) reduces to the following Minkowski space result:

$$\Box G(x^\nu, x'^\nu) = 0 \quad \forall x^\nu \neq x'^\nu. \tag{35}$$

The Euclidean four-space result (28) has the same general form as Eq. (35). And, the result (28) holds in Minkowski space as well, (since, e.g., $\partial^\nu x_\nu = 4$ in either space). This implies (by the uniqueness of the solutions of the Cauchy problem for constant coefficient wave equations) that the Green's function $G(x^\nu, x'^\nu)$ can be taken as the scalar field $U = 1/R^2$ times a numerical constant. It is reasonable to assume therefore that the numerical constant can be obtained from a comparison of (30b) and (34) and is just $1/4\pi^2$. The desired Green's function $G(x^\nu, x'^\nu)$ is therefore given by the ansatz

$$G(x^\nu, x'^\nu) = \frac{1}{4\pi^2 R^2}, \tag{36}$$

where $R^2 = |x^\nu - x'^\nu|^2$. It should be emphasized that (36) is an appropriate Green's function for Minkowski space only in the context of an analytically continued time integral as in (30b), and therefore appropriate causality conditions must subsequently be applied to obtain physically reasonable results. Equation (36) would of course be suitable in a Euclidean four-space without any assumptions involving analytic continuation.

The result (36) differs from the familiar retarded Green's function as derived for example in Cushing[17] or Jackson,[18] which for the metric signature $(-+++)$ and sign of the source term in (32) would be

$$G_{\text{ret}}(\mathbf{r}, \mathbf{r}'; t, t') = \frac{1}{4\pi} \frac{\delta(|\mathbf{r} - \mathbf{r}'| - c(t - t'))}{|\mathbf{r} - \mathbf{r}'|} \quad \forall t > t'. \tag{37}$$

This is because the retarded Green's function (37) is derived via a spectral decomposition of the delta function, while also taking into account homogeneous boundary conditions on a closed spatial surface, as well as timelike causality with the initial conditions

$$G(\mathbf{r}, \mathbf{r}'; t, t') = 0, \quad \partial G(\mathbf{r}, \mathbf{r}'; t, t')/\partial t = 0 \quad \forall t > t', \tag{38}$$

and with the Green's function symmetry relation

$$G(\mathbf{r},\mathbf{r}';t,t')=G(\mathbf{r}',\mathbf{r};-t',-t). \tag{39}$$

On the other hand, in obtaining the result (36), no such spectral decomposition is made and the calculation of the time integral, with an appropriate contour taking causality into account, is performed only later in this article. In contradistinction to the Green's function (37), (36) might therefore be referred to as an ''acausal'' Minkowski space Green's function, or more simply as a Euclidean four-space Green's function.

Substitution of (36) into a Euclidean space version of (33) then yields a delta function identity over all of the Euclidean four-space $\mathbb{R}^4$ as follows:

$$\Delta_\alpha{}^\alpha\left(\frac{1}{4\pi^2R^2}\right)=-\delta^{(4)}(x^\nu-x'^\nu),\quad \forall x^\nu,x'^\nu\in\mathbb{R}^4. \tag{40}$$

Although (40) follows from ostensibly Euclidean space calculations it can be applied to a space–time integral when an analytic continuation of the time integral is performed under appropriate causality conditions in order to obtain a Minkowski space result.

Equation (34) with the Green's function (36) is, under suitable analytic continuation of the time integral, the same result as (30b). [Indeed, the numerical constant $1/4\pi^2$ in (36) was obtained by a short cut comparison between the two.] And since the A^1, A^2, A^3 spatial Cartesian components of (21) separately satisfy a scalar wave equation like (32), one can then write the inhomogeneous solution of (21) for the four-vector potential A^μ as

$$A^\mu(x^\nu)=\int_{V_4'}\frac{j^\mu(x'^\nu)}{\epsilon_0c^2}G(x^\nu,x'^\nu)d^4x'=\int_{V'}\left[\oint_{t'}\frac{j^\mu(x'^\nu)}{4\pi^2\epsilon_0c^2R^2(x^\nu,x'^\nu)}c\,dt'\right]d^3x', \tag{41}$$

which is the same result as (31). Compare (36), (40), and (41) with the three-dimensional case (8) and (9). It is shown in Sommerfeld[15,14] in terms of retarded potentials that an expression like (9), as well as a scalar potential integral, follows from (31) via a contour integration over the time coordinate.

Although the result (31) is a historically important result, it is the delta function property of identity (40) which is of importance in the proof of a vector identity in Minkowski space analogous to the Helmholtz identity, namely

$$A^\mu(x^\nu)=\int_{V_4'}A^\mu(x'^\nu)\delta^{(4)}(x^\nu-x'^\nu)d^4x'=\int_{V'}\left[\oint_{t'}A^\mu(x'^\nu)\Delta_\alpha{}^\alpha\left(\frac{-1}{4\pi^2R^2}\right)c\,dt'\right]d^3x'. \tag{42}$$

Equation (42) and a Euclidean four-space version of (42) are used by the author in the next section to derive four-vector identities analogous to the three-vector Helmholtz identity (11a).

B. Euclidean and Minkowski four-space analogs of the Helmholtz identity

Equation (42) is now used by the author to derive four-vector identities analogous to, but more general than, the three-vector Helmholtz identity (11a). To a certain extent, the derivation parallels the three-vector derivation of (11a) as detailed in Refs. 6 and 7.

Initially, a theorem containing a four-vector identity is stated and proved for Euclidean space. Next, a corollary to the Euclidean theorem is stated for four-vectors in Minkowski space based on the contour integral used in (42). Subsequently, a second theorem containing a four-vector identity is stated which is based on a direct relativistically invariant integration over Minkowski space involving a Minkowski space Green's function of the form (37).

It is assumed in what follows, unless otherwise stated, that the term ''sufficiently smooth'' refers to functions which are scalar fields or components of vector fields that are $C^2(\overline{V}_4)$, i.e., twice continuously differentiable functions on the closure of V_4 which in turn is comprised of the union of V_4 and its bounding three-surface Σ (i.e., $\overline{V}_4 = V_4 \cup \Sigma$). The boundary three-surface Σ is itself assumed to be sufficiently smooth.

Theorem I: *The following identity holds for sufficiently smooth four-vector fields $A^\mu(x^\sigma)$ in the Euclidean four-space $\mathbb{R}^4$:*

$$A^\mu(x^\sigma) = -\partial^\mu \left[\int_{V_4'} \frac{\partial_\nu' A^\nu(x'^\sigma)}{4\pi^2 R^2(x^\sigma, x'^\sigma)} d^4x' - \oint_{\Sigma'} \frac{A^\nu(x'^\sigma) n_\nu'}{4\pi^2 R^2(x^\sigma, x'^\sigma)} d\Sigma' \right]$$
$$- \partial_\alpha \left[\int_{V_4'} \frac{\partial'^\alpha A^\mu(x'^\sigma) - \partial'^\mu A^\alpha(x'^\sigma)}{4\pi^2 R^2(x^\sigma, x'^\sigma)} d^4x' + \oint_{\Sigma'} \frac{A^\alpha(x'^\sigma) n'^\mu - A^\mu(x'^\sigma) n'^\alpha}{4\pi^2 R^2(x^\sigma, x'^\sigma)} d\Sigma' \right], \tag{43}$$

where $R^2(x^\sigma, x'^\sigma) = |x^\sigma - x'^\sigma|^2$, and where n'^μ is the four-vector outward unit normal of the three-surface Σ' which encloses the four-volume V_4'.

Proof: The proof is based on a Euclidean space version of the four-vector delta function property (42), namely

$$A^\mu(x^\nu) = \int_{V_4'} A^\mu(x'^\nu)\, \delta^{(4)}(x^\nu - x'^\nu) d^4x' = \int_{V_4'} A^\mu(x'^\nu) \Delta_\alpha{}^\alpha \left(\frac{-1}{4\pi^2 R^2} \right) d^4x'. \tag{44}$$

The important thing to realize about (44) is that the Euclidean four-space Laplacian operator acts only on the four-space field coordinates x^ν and so for sufficiently smooth four-vector fields $A^\mu(x'^\nu)$ it can be brought outside of the integration over the four-space source coordinates x'^ν as follows:

$$A^\mu(x^\nu) = \int_{V_4'} A^\mu(x'^\nu) \Delta_\alpha{}^\alpha \left(\frac{-1}{4\pi^2 R^2} \right) d^4x' = -\Delta_\alpha{}^\alpha \int_{V_4'} \frac{A^\mu(x'^\nu)}{4\pi^2 R^2} d^4x'. \tag{45}$$

At this point, one makes a decomposition of the Euclidean Laplacian operator Δ_α^α, analogous to that discussed in (18), by adding and subtracting a term in (45) yielding

$$A^\mu(x) = -\partial_\alpha \partial^\alpha \int_{V_4'} \frac{A^\mu(x')}{4\pi^2 R^2} d^4x' + \partial_\alpha \partial^\mu \int_{V_4'} \frac{A^\alpha(x')}{4\pi^2 R^2} d^4x' - \partial_\nu \partial^\mu \int_{V_4'} \frac{A^\nu(x')}{4\pi^2 R^2} d^4x', \tag{46}$$

where the four-vector superscripts in the functional dependencies are again suppressed. Now, in Euclidean space, (and also in flat Minkowski space), one can commute the derivatives in the third term of (46). And since the four-vector derivatives act only on the field coordinates they can be passed inside the integrations over the source coordinates. Also identity (26) and its contravariant derivative counterpart

$$\partial^\mu \left(\frac{1}{R^2} \right) = -\partial'^\mu \left(\frac{1}{R^2} \right), \tag{47}$$

allow one to change the unprimed field point derivatives of $1/R^2$ in (46) into primed source point derivatives. The net result is that one can rewrite (46) as

$$A^{\mu}(x)=\partial_{\alpha}\left[\int_{V_4'}\frac{A^{\mu}(x')}{4\pi^2}\partial'^{\alpha}\left(\frac{1}{R^2}\right)d^4x'-\int_{V_4'}\frac{A^{\alpha}(x')}{4\pi^2}\partial'^{\mu}\left(\frac{1}{R^2}\right)d^4x'\right]$$
$$+\partial^{\mu}\left[\int_{V_4'}\frac{A^{\nu}(x')}{4\pi^2}\partial'_{\nu}\left(\frac{1}{R^2}\right)d^4x'\right]. \tag{48}$$

Setting the bracketed part of the first term of (48) equal to $A^{\alpha\mu}$, i.e.,

$$A^{\alpha\mu}\equiv\left[\int_{V_4'}\frac{A^{\mu}(x')}{4\pi^2}\partial'^{\alpha}\left(\frac{1}{R^2}\right)d^4x'-\int_{V_4'}\frac{A^{\alpha}(x')}{4\pi^2}\partial'^{\mu}\left(\frac{1}{R^2}\right)d^4x'\right], \tag{49}$$

and the bracketed part of the second term of (48) equal to A, i.e.,

$$A\equiv\left[\int_{V_4'}\frac{A^{\nu}(x')}{4\pi^2}\partial'_{\nu}\left(\frac{1}{R^2}\right)d^4x'\right], \tag{50}$$

allows one to write (48) as

$$A^{\mu}=\partial_{\alpha}A^{\alpha\mu}+\partial^{\mu}A, \tag{51}$$

which is reminiscent of the decomposition (19).

Working on (50) first using the four-vector derivative product rule while using a Euclidean four-space version of Gauss' divergence theorem on the appropriate term of the resulting equation then yields

$$A=\oint_{\Sigma'}\frac{A^{\nu}(x')n'_{\nu}}{4\pi^2R^2}d\Sigma'-\int_{V_4'}\frac{\partial'_{\nu}A^{\nu}(x')}{4\pi^2R^2}d^4x', \tag{52}$$

where n'_{ν} is the four-vector outward unit normal of the three-surface Σ' which encloses the four-volume V_4'. Equation (52) is in its final form.

Working on (49) next using the four-vector derivative product rule on both terms yields after some rearrangement

$$A^{\alpha\mu}=\int_{V_4'}\partial'^{\alpha}\left(\frac{A^{\mu}(x')}{4\pi^2R^2}\right)d^4x'-\int_{V_4'}\partial'^{\mu}\left(\frac{A^{\alpha}(x')}{4\pi^2R^2}\right)d^4x'-\int_{V_4'}\frac{\partial'^{\alpha}A^{\mu}(x')-\partial'^{\mu}A^{\alpha}(x')}{4\pi^2R^2}d^4x'. \tag{53}$$

The third term of (53) is in its final form. It remains then to show that the four-vector derivative ∂_{α} [see (51)] of the first two terms of (53) combine to yield the Euclidean four-space identity

$$\partial_{\alpha}\int_{V_4'}\left(\partial'^{\alpha}\left(\frac{A^{\mu}(x')}{4\pi^2R^2}\right)-\partial'^{\mu}\left(\frac{A^{\alpha}(x')}{4\pi^2R^2}\right)\right)d^4x'=-\partial_{\alpha}\oint_{\Sigma'}\frac{A^{\alpha}(x')n'^{\mu}-A^{\mu}(x')n'^{\alpha}}{4\pi^2R^2}d\Sigma'. \tag{54}$$

To prove (54), one can define a four-vector a_{μ} with constant magnitude and constant but arbitrary direction in Euclidean four-space which is chosen once and then held fixed. Next consider the two-point function

$$K_{\mu}(x^{\sigma},x'^{\sigma})\equiv a_{\mu}\left(\partial_{\alpha}\left(\frac{A^{\alpha}(x'^{\sigma})}{4\pi^2R^2(x^{\sigma},x'^{\sigma})}\right)\right). \tag{55}$$

Using a Euclidean four-space version of Gauss' divergence theorem on (55), namely

$$\int_{V_4'} (\partial'^{\mu} K_{\mu}) d^4x' = \oint_{\Sigma'} K_{\mu} n'^{\mu} d\Sigma', \tag{56}$$

where in (56) and in what follows n'^{μ} is the four-vector outward unit normal of the three-surface Σ' which encloses the four-volume V_4', one obtains

$$a_{\mu} \int_{V_4'} \left(\partial'^{\mu} \left(\partial_{\alpha} \left(\frac{A^{\alpha}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right) \right) d^4x' = a_{\mu} \oint_{\Sigma'} \left(\partial_{\alpha} \left(\frac{A^{\alpha}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right) n'^{\mu} d\Sigma', \tag{57}$$

where the four-vector a_{μ} factors out of the integral since it is a constant. Now, since $|a_{\mu}| \neq 0$ and a_{μ} has an arbitrary fixed direction, then its four-contractions in (57) cannot everywhere vanish and so (57) reduces to the identity

$$\partial_{\alpha} \int_{V_4'} \left(\partial'^{\mu} \left(\frac{A^{\alpha}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right) d^4x' = \partial_{\alpha} \oint_{\Sigma'} \left(\frac{A^{\alpha}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) n'^{\mu} d\Sigma', \tag{58}$$

where the field point derivatives ∂_{α} have been moved out of the source point integrations and where the field and source point derivatives on the left-hand side (lhs) of (58) have been commuted. Equation (58) shows that the second term on the lhs of (54) is equal to the first term on the right-hand side (rhs) of (54). The remaining two terms in (54) follow in a similar fashion. One can again define a four-vector a_{μ} with constant magnitude and constant but arbitrary direction in the Euclidean four-space which is chosen once and then held fixed. Next consider the two-point function

$$I_{\alpha}(x^{\sigma},x'^{\sigma}) \equiv a_{\mu} \left(\partial_{\alpha} \left(\frac{A^{\mu}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right). \tag{59}$$

Using (59) in the Euclidean four-space Gauss' divergence theorem (56) one obtains

$$a_{\mu} \int_{V_4'} \left(\partial'^{\alpha} \left(\partial_{\alpha} \left(\frac{A^{\mu}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right) \right) d^4x' = a_{\mu} \oint_{\Sigma'} \left(\partial_{\alpha} \left(\frac{A^{\mu}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right) n'^{\alpha} d\Sigma', \tag{60}$$

where the four-vector a_{μ} factors out of the integral since it is a constant. Now, since $|a_{\mu}| \neq 0$ and a_{μ} has an arbitrary fixed direction, then its four-contractions in (60) cannot everywhere vanish and so (60) reduces to the identity

$$\partial_{\alpha} \int_{V_4'} \left(\partial'^{\alpha} \left(\frac{A^{\mu}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) \right) d^4x' = \partial_{\alpha} \oint_{\Sigma'} \left(\frac{A^{\mu}(x'^{\sigma})}{4\pi^2 R^2(x^{\sigma},x'^{\sigma})} \right) n'^{\alpha} d\Sigma', \tag{61}$$

where the field point derivatives ∂_{α} have been moved out of the source point integrations and where the field and source point derivatives on the lhs of (60) have been commuted. Equation (61) shows that the first term on the lhs of (54) is equal to the second term on the rhs of (54), which when combined with (58) completes the proof of the Euclidean four-space identity (54).

Combining the results (51), (52), (53), and (54) completes the proof of the Euclidean four-space identity (43) and Theorem I. ♣

Note the similarity in structure of identity (43) and the Helmholtz identity (11a). In particular, the factors of $1/4\pi r$ in (11a) appropriate for spherically symmetric functions in $\mathbb{R}^3$ are replaced in (43) by factors of $1/4\pi^2 R^2$ which are appropriate for hyperspherically symmetric functions in $\mathbb{R}^4$. It appears then that identity (43) is a Euclidean four-space generalization of the (Euclidean three-space) Helmholtz identity (11a). Therefore, just as (11a) can be used to prove the Helmholtz uniqueness theorems H2 and H1 of (static) three-vector fields, identity (43) is used later in this article to prove a uniqueness theorem for four-vector fields in the Euclidean four-space $\mathbb{R}^4$.

A corollary is now stated which extends the Euclidean four-space Theorem I to Minkowski space.

Corollary I to Theorem I: When, in the complex t' plane, a time integration contour is taken which is compatible with timelike causality, and for sufficiently smooth four-vector fields $A^{\mu}(x^{\sigma})$, the following identity holds in the Minkowski space $\mathbb{R}^{3+1}$:

$$A^{\mu}(x^{\sigma}) = -\partial^{\mu}\left[\int_{V'}\left[\oint_{t'}\frac{\partial'_{\nu}A^{\nu}(x'^{\sigma})}{4\pi^2R^2}c\,dt'\right]d^3x' - \int_{V'}\left[\oint_{t'}\partial'_{\nu}\left(\frac{A^{\nu}(x'^{\sigma})}{4\pi^2R^2}\right)c\,dt'\right]d^3x'\right]$$
$$-\partial_{\alpha}\left[\int_{V'}\left[\oint_{t'}\frac{\partial'^{\alpha}A^{\mu}(x'^{\sigma})-\partial'^{\mu}A^{\alpha}(x'^{\sigma})}{4\pi^2R^2(x^{\sigma},x'^{\sigma})}c\,dt'\right]d^3x'\right.$$
$$\left.-\int_{V'}\left[\oint_{t'}\partial'^{\alpha}\left(\frac{A^{\mu}(x'^{\sigma})}{4\pi^2R^2}\right)c\,dt'\right]d^3x' + \int_{V'}\left[\oint_{t'}\partial'^{\mu}\left(\frac{A^{\alpha}(x'^{\sigma})}{4\pi^2R^2}\right)c\,dt'\right]d^3x'\right], \qquad (62)$$

where $R^2(x^{\sigma},x'^{\sigma}) = |x^{\sigma}-x'^{\sigma}|^2$ in $\mathbb{R}^4$, and where V' is a spatial volume in $\mathbb{R}^3$.

Proof: The proof is based on the four-vector delta function property (42) and in all important respects parallels the proof of the Euclidean four-space identity (43) of Theorem I. The details of the basic approach are not repeated here. However, in order to express the time integration in terms of a contour integral over the complex t' plane, it is convenient to forgo the transformations from four-volume to three-surface integrals as in (52) and (54). The result is identity (62). An integration contour compatible with timelike causality is specified in order to interpret the identity as a Minkowski space integral. These contours are discussed in general in Refs. 15 and 2. The contour integration is performed using the residue theorem and assumes that the integrand, aside from the poles in the $1/R^2$ factor, is analytic and without singularities over the domain enclosed by or on the chosen contour. The actual details of the choice of contour, as well as performing the integration itself are not necessary for the proof of Corollary I to Theorem I. It is only necessary for the sake of a physical interpretation that a contour compatible with timelike causality is chosen. ♣

The similarity in structure of identity (62) and the Helmholtz identity (11a) is now only apparent through the four-volume integrals in (62) containing the four-divergence and four-curl of A^{ν}. The normal and tangential three-surface integrals in (43) no longer appear in (62). That (62) can be interpreted as a Minkowski space integral instead of an integral in $\mathbb{R}^4$ is a result of the analytic continuation of the time integral. Identity (62) could be interpreted as a Minkowski space generalization of the (Euclidean three-space) Helmholtz identity (11a).

However, identity (62) is not of the same general form as identity (11a) because it lacks surface integral terms. Consequently, identity (62) is not a convenient starting point for proving a four-vector uniqueness theorem analogous to the three-space Helmholtz uniqueness theorem H2. Therefore, a second theorem is now developed in $\mathbb{R}^{3+1}$, through a direct integration in Minkowski space, which states an identity that is formally analogous to identity (43) in $\mathbb{R}^4$.

It is central to the development of this second theorem that identities for the four-vector derivatives of the Green's functions satisfying (33) in $\mathbb{R}^{3+1}$ analogous to (26) and (47) in $\mathbb{R}^4$ be obtained. A reciprocal four-space integral representation of the Green's functions satisfying (33) appears to be the easiest way to obtain the desired derivative properties. Therefore, a spectral decomposition of the delta function $\delta^{(4)}(x^{\nu}-x'^{\nu})$ appearing in (33) is made via the Fourier integral

$$\delta^{(4)}(x^{\nu}-x'^{\nu}) = \frac{1}{\sqrt{(2\pi)^4}}\int\left[\frac{e^{-ik_{\mu}x'^{\mu}}}{\sqrt{(2\pi)^4}}\right]e^{ik_{\mu}x^{\mu}}d^4k = \frac{1}{(2\pi)^4}\int e^{ik_{\mu}(x^{\mu}-x'^{\mu})}d^4k. \qquad (63)$$

In the usual way, Green's functions satisfying (33) then follow from

$$G(x^\nu,x'^\nu)=-\Box^{-1}\left(\frac{1}{(2\pi)^4}\int e^{ik_\mu(x^\mu-x'^\mu)}d^4k\right)=\frac{1}{(2\pi)^4}\int\frac{e^{ik_\mu(x^\mu-x'^\mu)}}{k^2}d^4k. \tag{64}$$

The desired covariant and contravariant derivative properties in $\mathbb{R}^{3+1}$ follow immediately from the result (64), for any appropriate contour, as

$$\partial_\mu G(x^\nu,x'^\nu)=-\partial'_\mu G(x^\nu,x'^\nu), \tag{65a}$$

$$\partial^\mu G(x^\nu,x'^\nu)=-\partial'^\mu G(x^\nu,x'^\nu), \tag{65b}$$

which are of the same general form as the properties (26) and (47) in $\mathbb{R}^4$, as might be expected.

An example of a Green's function which satisfies (64) is the retarded Green's function (37). However, as a manifestly covariant identity is desired for this theorem, the retarded Green's function, and optionally an advanced Green's function, must be able to be restated in relativistically covariant form. This is readily done using the delta function identity[18]

$$\begin{aligned}\delta((x^\nu-x'^\nu)^2)&=\delta(|\mathbf{r}-\mathbf{r}'|^2-c^2(t-t')^2)\\&=\delta((|\mathbf{r}-\mathbf{r}'|-c(t-t'))(|\mathbf{r}-\mathbf{r}'|+c(t-t')))\\&=\left[\frac{\delta((|\mathbf{r}-\mathbf{r}'|-c(t-t'))+\delta(|\mathbf{r}-\mathbf{r}'|+c(t-t')))}{2|\mathbf{r}-\mathbf{r}'|}\right].\end{aligned} \tag{66}$$

Using (66), the retarded Green's function (37), along with an advanced Green's function $G_{\rm adv}$, can be stated in relativistically covariant form as follows:[18]

$$G_{\rm ret}(x,x')=\frac{1}{2\pi}\theta(x^0-x'^0)\,\delta((x-x')^2), \tag{67a}$$

$$G_{\rm adv}(x,x')=\frac{1}{2\pi}\theta(x'^0-x^0)\,\delta((x-x')^2), \tag{67b}$$

where the theta function is defined as follows:

$$\theta(x^0-x'^0)=\begin{cases}1 & \text{for } x^0>x'^0\\ 0 & \text{for } x'^0>x^0.\end{cases} \tag{68}$$

A theorem can now be stated for four-vector fields in Minkowski space.

Theorem II: *Given a covariant scalar two-point Green's function $G(x^\nu,x'^\nu)$ which is a solution of (33) and which satisfies the derivative properties (65a), (65b), the following identity holds for sufficiently smooth four-vector fields $A^\mu(x^\sigma)$ in the Minkowski space $\mathbb{R}^{3+1}$:*

$$\begin{aligned}A^\mu(x)=&-\left[\int_{V'_4}\partial^\mu((\partial'_\nu A^\nu(x'))G(x,x'))d^4x'-\oint_{\Sigma'}\partial^\mu((A^\nu(x')n'_\nu)G(x,x'))d\Sigma'\right]\\&-\left[\int_{V'_4}\partial_\alpha((\partial'^\alpha A^\mu(x')-\partial'^\mu A^\alpha(x'))G(x,x'))d^4x'+\oint_{\Sigma'}\partial_\alpha((A^\alpha(x')n'^\mu\right.\\&\left.-A^\mu(x')n'^\alpha)G(x,x'))d\Sigma'\right],\end{aligned} \tag{69}$$

where n'^μ is the four-vector outward unit normal of the three-surface Σ' which encloses the four-volume V'_4, and where the three-surface Σ' is defined covariantly with respect to a general Lorentz transformation.

Proof: In contradistinction to identity (43) of Theorem I, the unprimed four-vector derivatives are now included in the integrands of identity (69) of Theorem II. Consequently, the convergence properties of these integrands are improved in comparison to those in (43) and so the integrals in (69) are well defined for four-vector fields A^μ falling off only as fast as $1/r$. For sufficiently smooth four-vector fields the unprimed derivatives can still be factored out of the integrals over the primed coordinates if required.

The proof is based on a Minkowski space version of the four-vector delta function property (42), but now written in terms of a covariant scalar two-point Green's function $G(x^\nu,x'^\nu)$ which is assumed to be a solution of (33), as follows:

$$A^\mu(x^\nu)=\int_{V_4'}A^\mu(x'^\nu)\delta^{(4)}(x^\nu-x'^\nu)d^4x'=\int_{V_4'}A^\mu(x'^\nu)\Box(-G(x^\nu,x'^\nu))d^4x'. \tag{70}$$

At this point, one makes a decomposition of the d'Alembertian operator as in (18), by adding and subtracting a term in (70), yielding

$$A^\mu(x)=-\int_{V_4'}\partial_\alpha\partial^\alpha(A^\mu(x')G(x,x'))d^4x'+\int_{V_4'}\partial_\alpha\partial^\mu(A^\alpha(x')G(x,x'))d^4x'$$
$$-\int_{V_4'}\partial_\nu\partial^\mu(A^\nu(x')G(x,x'))d^4x', \tag{71}$$

where the four-vector superscripts in the functional dependencies are again suppressed. The rest of the proof proceeds in a manner parallel to the proof of the Euclidean four-space identity (43) of Theorem I and most of the details will be condensed. In flat Minkowski space one can commute the derivatives in the third term of (71). Then certain unprimed derivatives can be commuted with primed coordinate dependent fields. Then using identities (65a) and (65b) one can change the unprimed field point derivatives of $G(x,x')$ in (71) into primed source point derivatives. The net effect of these changes allows one to rewrite (71) as

$$A^\mu(x)=\partial_\alpha\left[\int_{V_4'}A^\mu(x')\partial'^\alpha G(x,x')d^4x'-\int_{V_4'}A^\alpha(x')\partial'^\mu G(x,x')d^4x'\right]$$
$$+\partial^\mu\left[\int_{V_4'}A^\nu(x')\partial_\nu' G(x,x')d^4x'\right], \tag{72}$$

where for sufficiently smooth four-vector fields, certain unprimed derivatives have been factored out of the primed coordinate integrals of (72) for later reference. Setting the first bracketed term of (72) equal to $A^{\alpha\mu}$, i.e.,

$$A^{\alpha\mu}\equiv\left[\int_{V_4'}A^\mu(x')\partial'^\alpha G(x,x')d^4x'-\int_{V_4'}A^\alpha(x')\partial'^\mu G(x,x')d^4x'\right], \tag{73}$$

and the bracketed part of the second term of (72) equal to A, i.e.,

$$A\equiv\left[\int_{V_4'}A^\nu(x')\partial_\nu' G(x,x')d^4x'\right], \tag{74}$$

allows one to write (72) as

$$A^\mu=\partial_\alpha A^{\alpha\mu}+\partial^\mu A, \tag{75}$$

which is reminiscent of the decomposition (19). This decomposition of a four-vector field into the sum of a four-irrotational and a four-solenoidal part will be used in Sec. IV B in connection with Theorem X.

Next, working on the second bracketed term of (72) first (but without the unprimed derivatives factored out), using the four-vector derivative product rule, while at the same time using a Minkowski four-space version of Gauss' divergence theorem as appropriate for a second rank tensor integrand, (cf. p. 130 of Ref. 2), namely

$$\int_{V_4'} \partial_\nu' Z^{\mu\nu}\, d^4x' = \oint_{\Sigma'} Z^{\mu\nu}\, d\sigma_\nu' = \oint_{\Sigma'} Z^{\mu\nu} n_\nu'\, d\Sigma', \tag{76}$$

on the appropriate term of the resulting equation (i.e., after commuting ∂^μ and ∂_ν'), then yields

$$\int_{V_4'} \partial^\mu (A^\nu(x')\partial_\nu' G(x,x'))d^4x' = \oint_{\Sigma'} \partial^\mu (A^\nu(x') n_\nu' G(x,x'))d^4x' - \int_{V_4'} \partial^\mu ((\partial_\nu' A^\nu(x'))G(x,x'))d^4x', \tag{77}$$

where n_ν' is the four-vector outward unit normal of the three-surface Σ' which encloses the four-volume V_4'. Equation (77) is in its final form.

Working on the first bracketed term of (72) next (but again without the unprimed derivatives factored out), using the four-vector derivative product rule on both terms yields after some rearrangement

$$\begin{aligned}\int_{V_4'} \partial_\alpha (A^\mu(x')\partial'^\alpha G(x,x'))d^4x' - \int_{V_4'} \partial_\alpha (A^\alpha(x')\partial'^\mu G(x,x'))d^4x' \\ = \int_{V_4'} \partial_\alpha \partial'^\alpha (A^\mu(x') G(x,x'))d^4x' - \int_{V_4'} \partial_\alpha \partial'^\mu (A^\alpha(x') G(x,x'))d^4x' \\ - \int_{V_4'} \partial_\alpha ((\partial'^\alpha A^\mu(x') - \partial'^\mu A^\alpha(x'))G(x,x'))d^4x'.\end{aligned} \tag{78}$$

The third term on the rhs of (78) is in its final form. It can be shown in an entirely analogous manner as for the Euclidean four-space identity (54), (using a four-vector a_μ with constant magnitude and constant but arbitrary direction in Minkowski space), that the first two terms on the rhs of (78) combine to yield the Minkowski space identity

$$\begin{aligned}\int_{V_4'} \partial_\alpha \partial'^\alpha (A^\mu(x') G(x,x'))d^4x' - \int_{V_4'} \partial_\alpha \partial'^\mu (A^\alpha(x') G(x,x'))d^4x' \\ = - \oint_{\Sigma'} \partial_\alpha ((A^\alpha(x') n'^\mu - A^\mu(x') n'^\alpha) G(x,x'))d\Sigma'.\end{aligned} \tag{79}$$

Combining the results (77), (78), and (79) completes the proof of the Minkowski space identity (69) and Theorem II. ♣

In passing, consider a representative case where the Green's function is chosen to be the covariant retarded Green's function (67a). A convenient covariant three-surface Σ', (bounding a Minkowski four-volume V_4'), could then be taken as the union of a finite section of the forward light cone Σ_C', (a lightlike hypersurface), and its end cap comprised for example by an intersecting three-spherical conic section Σ_{cap}' (a spacelike hypersurface). The outward surface normal n'^μ to the forward light cone is a spacelike unit four-vector, while the outward surface normal to the three-spherical end cap of a finite section of the forward light cone is a timelike unit four-vector.

But since the forward light cone is the only surface where the retarded Green's function is different than zero, only the surface integrals over the finite section of the forward light cone Σ_C' can be nonzero!

Finally, note the similarity in structure of the Minkowski space identity (69) and the Euclidean four-space identity (43). Aside from the incorporation of the unprimed derivatives in the integrals of (69) (which was done to improve the convergence of the integrals), the only difference is that the Euclidean four-space Green's function $1/4\pi^2R^2$ is replaced by an appropriate Minkowski space Green's function $G(x,x')$.

It will be shown in Sec. III D that identity (69) is a Minkowski space generalization of the (Euclidean three-space) Helmholtz identity (11a). Therefore, just as (11a) can be used to prove the Helmholtz uniqueness theorems H2 and H1 of (static) three-vector fields, identity (69) will be used in Secs. III E and IV B to prove uniqueness theorems for four-vector fields in $\mathbb{R}^{3+1}$.

C. Scalar field identity in Euclidean three-space

The Euclidean three-space identity (8) is next substituted into a delta function property as follows:

$$\phi(\mathbf{r})=\int_{V'}\phi(\mathbf{r}')\,\delta^3(\mathbf{r}-\mathbf{r}')\,d^3\mathbf{r}'=\int_{V'}\phi(\mathbf{r}')\nabla^2\left(\frac{-1}{4\pi r}\right)d^3\mathbf{r}'. \tag{80}$$

Identity (80) is now used to state a theorem.

Theorem III: *The following identity holds for twice continuously differentiable (static) scalar fields ϕ in the Euclidean three-space $\mathbb{R}^3$:*

$$\phi(\mathbf{r})=\nabla\cdot\left[\int_{V'}\frac{-\nabla'\phi(\mathbf{r}')}{4\pi r}\,dV'+\oint_{S'}\frac{\phi(\mathbf{r}')\mathbf{n}'}{4\pi r}\,dS'\right], \tag{81}$$

where the three-dimensional distance $r\equiv|\mathbf{r}-\mathbf{r}'|$, and where $\mathbf{n}'$ is the three-vector outward unit normal of the two-surface S' which encloses the three-volume V'.

Proof: Starting with (80), for a twice continuously differentiable field ϕ, one can factor part of the Laplacian operator acting on the unprimed field point coordinates out of the integration over the primed source point coordinates to yield

$$\phi(\mathbf{r})=\nabla\cdot\left[\int_{V'}\frac{-\phi(\mathbf{r}')}{4\pi}\nabla\left(\frac{1}{r}\right)d^3x'\right]. \tag{82}$$

Using the vector identity

$$\nabla\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right)=-\nabla'\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right), \tag{83}$$

one can rewrite (82) as

$$\phi(\mathbf{r})=\nabla\cdot\left[\int_{V'}\frac{\phi(\mathbf{r}')}{4\pi}\nabla'\left(\frac{1}{r}\right)d^3x'\right]. \tag{84}$$

The vector identity

$$\nabla(\phi\psi)=\phi\nabla\psi+\psi\nabla\phi, \tag{85}$$

with $\psi\equiv1/|\mathbf{r}-\mathbf{r}'|$ becomes

$$\nabla\left(\frac{\phi}{|\mathbf{r}-\mathbf{r}'|}\right)=\phi\nabla\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right)+\frac{\nabla\phi}{|\mathbf{r}-\mathbf{r}'|},\tag{86}$$

allowing one to rewrite (84) as

$$\phi(\mathbf{r})=\nabla\cdot\left[\int_{V'}\frac{1}{4\pi}\left(\nabla'\left(\frac{\phi(\mathbf{r}')}{r}\right)-\frac{\nabla'\phi(\mathbf{r}')}{r}\right)d^3x'\right].\tag{87}$$

Now, using the vector identity[7]

$$\int_V \nabla\Phi\, dV=\oint_S \Phi\mathbf{n}\, dS,\tag{88}$$

which follows from Gauss' divergence theorem in a *flat space–time*, on the first term of (87) yields immediately identity (81), proving Theorem III. Identity (81) is of a form which is reminiscent of the Helmholtz identity (11a), but is applicable to static scalar fields. ♣

D. Derivation of the Helmholtz identity and a scalar field identity from a Minkowski space Helmholtz identity

The author will now show that identity (69) of Theorem II is a Minkowski space generalization of the (Euclidean three-space) Helmholtz identity (11a) in a static Newtonian limit. In addition, the fourth or scalar field component of (69) will be shown to yield identity (81) in a similar static Newtonian limit.

To prove that the Helmholtz identity (11a) follows from identity (69) in a static Newtonian limit, it is convenient to start with an identity which follows from (69), i.e.,

$$\begin{aligned}A^\mu(x)=&-\partial^\mu\left[\int_{V_4'}\frac{\partial_\nu' A^\nu(x')}{4\pi r}\,\delta(r-c(t-t'))d^4x'-\int_{V_4'}\partial_\nu'\left(\frac{A^\nu(x')}{4\pi r}\,\delta(r-c(t-t'))\right)d^4x'\right]\\&-\partial_\alpha\left[\int_{V_4'}\frac{\partial'^\alpha A^\mu(x')}{4\pi r}\,\delta(r-c(t-t'))d^4x'-\int_{V_4'}\frac{\partial'^\mu A^\alpha(x')}{4\pi r}\,\delta(r-c(t-t'))d^4x'\right.\\&\left.-\int_{V_4'}\partial'^\alpha\left(\frac{A^\mu(x')}{4\pi r}\,\delta(r-c(t-t'))\right)d^4x'+\int_{V_4'}\partial'^\mu\left(\frac{A^\alpha(x')}{4\pi r}\,\delta(r-c(t-t'))\right)d^4x'\right],\end{aligned}\tag{89}$$

where $r\equiv|\mathbf{r}-\mathbf{r}'|$. Identity (89) follows from (69) as a result of using the retarded Green's function (37), Gauss' divergence theorem on the surface integral in the first bracketed term of (69), and identity (79) on the surface integral in the second bracketed term of (69), while at the same time factoring the unprimed derivatives out of all the integrals.

One next takes the following as an intermediate approximation of the space components of identity (89):

$$\begin{aligned}A^j(x)=&-\partial^j\left[\int_{V_4'}\frac{\partial_k' A^k(x')}{4\pi r}\,\delta(r-c(t-t'))d^4x'-\int_{V_4'}\partial_k'\left(\frac{A^k(x')}{4\pi r}\,\delta(r-c(t-t'))\right)d^4x'\right]\\&-\partial_i\left[\int_{V_4'}\frac{\partial'^i A^j(x')}{4\pi r}\,\delta(r-c(t-t'))d^4x'-\int_{V_4'}\frac{\partial'^j A^i(x')}{4\pi r}\,\delta(r-c(t-t'))d^4x'\right.\\&\left.-\int_{V_4'}\partial'^i\left(\frac{A^j(x')}{4\pi r}\,\delta(r-c(t-t'))\right)d^4x'+\int_{V_4'}\partial'^j\left(\frac{A^i(x')}{4\pi r}\,\delta(r-c(t-t'))\right)d^4x'\right].\end{aligned}\tag{90}$$

Note, all terms involving partial time derivatives, e.g., $\partial_0 = (1/c)\partial/\partial t$, are omitted in (90) since a detailed dimensional analysis in the speed of propagation c shows that these terms vanish in a Newtonian limit where $c \to \infty$. The author will delay the application of the Newtonian limit for the terms retained in (90), however, until later in this derivation. As usual, Roman indices i,j,k, etc., are used here and in what follows to denote three-vectors. One next performs the t' time integrations in (90) yielding

$$\mathbf{A}(\mathbf{r},t) = -\nabla\left[\int_{V'} \frac{\nabla'\cdot\mathbf{A}(\mathbf{r}',t-r/c)}{4\pi r}dV' - \int_{V'} \nabla'\cdot\left(\frac{\mathbf{A}(\mathbf{r}',t-r/c)}{4\pi r}\right)dV'\right] + \nabla\times\left[\int_{V'} \frac{\nabla'\times\mathbf{A}(\mathbf{r}',t-r/c)}{4\pi r}dV' - \int_{V'} \nabla'\times\left(\frac{\mathbf{A}(\mathbf{r}',t-r/c)}{4\pi r}\right)dV'\right]. \tag{91}$$

It should be noted in passing that (91) is only an intermediate result where time derivative terms have already been neglected. Taking a Newtonian limit where $c \to \infty$ reduces (91) further to

$$\mathbf{A}(\mathbf{r},t) = -\nabla\left[\int_{V'} \frac{\nabla'\cdot\mathbf{A}(\mathbf{r}',t)}{4\pi r}dV' - \int_{V'} \nabla'\cdot\left(\frac{\mathbf{A}(\mathbf{r}',t)}{4\pi r}\right)dV'\right] + \nabla\times\left[\int_{V'} \frac{\nabla'\times\mathbf{A}(\mathbf{r}',t)}{4\pi r}dV' - \int_{V'} \nabla'\times\left(\frac{\mathbf{A}(\mathbf{r}',t)}{4\pi r}\right)dV'\right]. \tag{92}$$

Now, applying Gauss' divergence theorem to the second term of the first bracketed term of (92), while using the three-vector identity[6,7]

$$-\int_{V'} \nabla'\times\frac{\mathbf{A}(\mathbf{r}')}{4\pi r}dV' = \oint_{S'} \frac{\mathbf{A}(\mathbf{r}')\times\mathbf{n}'}{4\pi r}dS' \tag{93}$$

on the second term of the second bracketed term of (92), and taking $t=0$ for convenience, yields identity (11) as desired (since the t dependence is the same on both sides of the resulting equation and can be ignored in what amounts to a static field assumption). The Helmholtz identity (11a) therefore follows from the space components of (69) in a static Newtonian limit.

Next, to prove that identity (81) of Theorem III follows directly from the Minkowski space Helmholtz identity (69) in a static Newtonian limit, it is convenient to again start with identity (89) which follows from (69). One next takes the following as an intermediate approximation of the zeroth component of identity (89):

$$A^0(x) = -\partial_i\left[\int_{V_4'} \frac{\partial'^i A^0(x')}{4\pi r}\delta(r-c(t-t'))d^4x' - \int_{V_4'} \partial'^i\left(\frac{A^0(x')}{4\pi r}\delta(r-c(t-t'))\right)d^4x'\right]. \tag{94}$$

Note, all terms involving partial time derivatives, e.g., $\partial_0 = (1/c)\partial/\partial t$, are omitted in (94) since a detailed dimensional analysis in the speed of propagation c shows that these terms vanish in a Newtonian limit where $c \to \infty$. The author will delay the application of the Newtonian limit for the terms retained in (94), however, until later in this derivation. One next performs the t' time integrations in (94), while using three-vector notation and setting $\phi = cA^0$, yielding

$$\phi(\mathbf{r},t) = \nabla\cdot\left[\int_{V'} \frac{-\nabla'\phi(\mathbf{r}',t-r/c)}{4\pi r}dV' + \int_{V'} \nabla'\cdot\left(\frac{\phi(\mathbf{r}',t-r/c)}{4\pi r}\right)dV'\right]. \tag{95}$$

It should be noted in passing that (95) is only an intermediate result where time derivative terms have already been neglected. Taking a Newtonian limit where $c \to \infty$ reduces (95) further to

$$\phi(\mathbf{r},t)=\nabla\cdot\left[\int_{V'}\frac{-\nabla'\phi(\mathbf{r}',t)}{4\pi r}dV'+\int_{V'}\nabla'\cdot\left(\frac{\phi(\mathbf{r}',t)}{4\pi r}\right)dV'\right]. \tag{96}$$

Now, applying the three-vector Gauss' divergence theorem to the second term on the rhs of (96) and taking $t=0$ for convenience, yields identity (81) as desired, (since the t dependence is the same on both sides of the resulting equation and can be ignored in what amounts to a static field assumption). The scalar field identity (81) of Theorem III therefore follows from the zeroth or time component of (69) in a static Newtonian limit.

So, in a static Newtonian limit the space components of the Minkowski space identity (69) reduce to the Helmholtz identity (11a) and the zeroth component of (69) reduces to the scalar field identity (81). It seems reasonable to conclude therefore that identity (69) is a Minkowski space generalization of the (three-space) Helmholtz identity (11a).

E. Uniqueness theorems for four-vector fields in Euclidean and Minkowski four-spaces

In this section, two uniqueness theorems will be proved. First, a uniqueness theorem for four-vector fields in Euclidean space will be proved using identity (43) of Theorem I, i.e., using the Euclidean four-space generalization of the Helmholtz identity. Then, a uniqueness theorem for four-vector fields in Minkowski space will be proved using identity (69) of Theorem II, i.e., using the Minkowski four-space generalization of the Helmholtz identity.

A uniqueness theorem for four-vector fields in Euclidean four-space is now stated.

Theorem IV: *A sufficiently smooth four-vector field A^ν in the Euclidean four-space $\mathbb{R}^4$ is uniquely specified by giving its four-divergence and its four-curl within a four-space region V_4, as well as its normal and tangential components on the bounding three-surface Σ. That is, one must specify the following:*

$$\partial_\nu A^\nu(x^\sigma)\equiv s, \tag{97a}$$

$$A^\nu(x^\sigma)n_\nu\equiv A_{\text{norm}}(x^\sigma), \tag{97b}$$

$$\partial^\alpha A^\mu(x^\sigma)-\partial^\mu A^\alpha(x^\sigma)\equiv c^{\alpha\mu}, \tag{97c}$$

$$A^\alpha(x^\sigma)n^\mu-A^\mu(x^\sigma)n^\alpha\equiv A^{\alpha\mu}_{\text{tang}}(x^\sigma), \tag{97d}$$

where n^ν is the four-vector outward unit normal of the three-surface Σ which encloses the four-volume V_4.

Proof: In order to demonstrate the uniqueness of the four-vector field A^ν, one first postulates the existence of a second four-vector B^ν, which also satisfies Eq. (97). That is, one only replaces A^ν on the lhs of Eq. (97) by B^ν while the rhs of Eq. (97) remains unchanged. The four-vector field A^ν is unique if one can show that

$$W^\nu\equiv A^\nu-B^\nu=0. \tag{98}$$

Now, taking the four-divergence of W^ν and using (97a) yields

$$\partial_\nu W^\nu=\partial_\nu A^\nu-\partial_\nu B^\nu=s-s=0, \tag{99}$$

everywhere in the four-volume V_4. Also, calculating the magnitude of the normal component of W^ν along the surface normal n^ν and using (97b) yields

$$W_{\text{norm}}\equiv W^\nu n_\nu=A^\nu n_\nu-B^\nu n_\nu=A_{\text{norm}}-A_{\text{norm}}=0, \tag{100}$$

everywhere on the bounding three-surface Σ. Next, taking the four-curl of W^ν and using (97c) yields

$$\partial^{\alpha}W^{\mu}-\partial^{\mu}W^{\alpha}=(\partial^{\alpha}A^{\mu}-\partial^{\mu}A^{\alpha})-(\partial^{\alpha}B^{\mu}-\partial^{\mu}B^{\alpha})=c^{\alpha\mu}-c^{\alpha\mu}=0, \tag{101}$$

everywhere in the four-volume V_4. Also, calculating the rank two tangential components with respect to n^{ν} of W^{ν} and using (97d) yields

$$W^{\alpha}n^{\mu}-W^{\mu}n^{\alpha}=(A^{\alpha}n^{\mu}-A^{\mu}n^{\alpha})-(B^{\alpha}n^{\mu}-B^{\mu}n^{\alpha})=A^{\alpha\mu}_{\text{tang}}-A^{\alpha\mu}_{\text{tang}}=0, \tag{102}$$

everywhere on the bounding three-surface Σ. Finally, substituting the results (99)–(102) for the four-vector field W^{ν} into identity (43) of Theorem I, one obtains the result $W^{\nu}=0$ which implies [via (98)] that $A^{\nu}=B^{\nu}$ everywhere in the four-space region V_4' and on its bounding three-surface Σ'. This proves that the four-vector field A^{ν} is uniquely determined by Eq. (97) thus proving Theorem IV on the uniqueness of four-vector fields in Euclidean four-space. ♣

A uniqueness theorem for four-vector fields in Minkowski space is now stated.

Theorem V: *A sufficiently smooth four-vector field $A^{\mu}(x^{\sigma})$ in the Minkowski space $\mathbb{R}^{3+1}$ which satisfies identity* (69) (*i.e., Theorem II*) *is uniquely specified by giving its four divergence and its four-curl within a space–time region V_4, as well as its normal and tangential components on the bounding three-surface Σ. That is, one must specify the following:*

$$\partial_{\nu}A^{\nu}(x^{\sigma})\equiv s, \tag{103a}$$

$$\partial^{\alpha}A^{\mu}(x^{\sigma})-\partial^{\mu}A^{\alpha}(x^{\sigma})\equiv c^{\alpha\mu}, \tag{103b}$$

throughout the space–time region V_4, as well as

$$A^{\nu}(x^{\sigma})n_{\nu}\equiv A_{\text{norm}}(x^{\sigma}), \tag{103c}$$

$$A^{\alpha}(x^{\sigma})n^{\mu}-A^{\mu}(x^{\sigma})n^{\alpha}\equiv A^{\alpha\mu}_{\text{tang}}(x^{\sigma}), \tag{103d}$$

everywhere on the bounding three-surface Σ, where n^{ν} is the four-vector outward unit normal of the three-surface Σ which encloses the space–time four-volume V_4.

Proof: The proof is based on the Minkowski space Theorem II. The proof proceeds in a parallel manner to the proof of the Euclidean four-space Theorem IV. One postulates the existence of a second four-vector B^{ν} which also satisfies Eq. (103). The four-vector field A^{ν} is unique if one can show, as in Theorem IV, that

$$W^{\nu}\equiv A^{\nu}-B^{\nu}=0. \tag{104}$$

Equation (103) then leads, as before with (97), to results analogous to (99)–(102), which when substituted into identity (69) shows that $W^{\nu}=0$ which implies [via the definition of W^{ν} in (104)] that $A^{\nu}=B^{\nu}$ everywhere in the Minkowski space region V_4' and on its bounding three-surface Σ'. This proves that the four-vector field A^{ν} is uniquely determined by Eq. (103) specified over Minkowski space, thus proving Theorem V on the uniqueness of four-vector fields in Minkowski space. ♣

It has already been demonstrated that identity (69) of Theorem II reduces to the Helmholtz identity (11a) when an appropriate (static) Newtonian limit is taken. And it is known that the Helmholtz identity (11a) can be used to prove the Helmholtz uniqueness theorem for a finite volume of $\mathbb{R}^3$, i.e., Theorem H2. Theorems IV and V are later used in Sec. IV B to prove Theorem X, which extends Theorem H2 to four-vector fields in Euclidean and Minkowski spaces. [If one makes the usual assumption that the four-vector fields A^{μ} vanish sufficiently rapidly at infinity, then the surface integral terms in (43) or (69) vanish and so a four-space generalization of the Helmholtz uniqueness Theorem H1 over the entire four-volume of Euclidean or Minkowski space follows from Theorem X as well.] Also, Theorem's IV and V can be interpreted as extensions of Theorem U in Sec. II A to four-vector fields in Euclidean and Minkowski spaces, respectively. The Helmholtz identity (11a) and the three-vector uniqueness theorems U, H1, and H2 of Sec. II A can therefore be generalized readily to four-vector fields in Euclidean and Minkowski spaces.

F. Uniqueness theorem for scalar fields in Euclidean three-space

In this section, a uniqueness theorem for scalar fields in Euclidean three-space will be proved using identity (81) of Theorem III. The theorem will now be stated.

Theorem VI: *A twice continuously differentiable (static) scalar field $\phi(\mathbf{r})$ in the Euclidean three-space $\mathbb{R}^3$ is uniquely specified by giving its gradient everywhere within a spatial volume V, as well as its value on the bounding surface S.* That is, one must specify the following:

$$-\nabla\phi(\mathbf{r})\equiv\mathbf{E}(\mathbf{r}) \tag{105a}$$

throughout the volume V, as well as

$$\phi(\mathbf{r})|_S\equiv\phi_S(\mathbf{r}) \tag{105b}$$

on the bounding surface S.

Proof: In order to demonstrate the uniqueness of the scalar field $\phi(\mathbf{r})$, one first postulates the existence of a second scalar field $\xi(\mathbf{r})$, which also satisfies Eq. (105). That is, one replaces $\phi(\mathbf{r})$ on the lhs of Eq. (105) by $\xi(\mathbf{r})$, while the rhs of Eq. (105) remains unchanged. The scalar field $\phi(\mathbf{r})$ is unique if one can show that

$$\Phi(\mathbf{r})\equiv\phi(\mathbf{r})-\xi(\mathbf{r})=0. \tag{106}$$

Now, taking minus one times the gradient of $\Phi(\mathbf{r})$ and using (105a) yields

$$-\nabla\Phi(\mathbf{r})=-\nabla\phi(\mathbf{r})+\nabla\xi(\mathbf{r})=\mathbf{E}(\mathbf{r})-\mathbf{E}(\mathbf{r})=0 \tag{107}$$

for all $\mathbf{r}$ in the spatial volume V. Next, evaluating Φ on the boundary surface S and using (105b) yields

$$\Phi(\mathbf{r})|_S=\phi(\mathbf{r})|_S-\xi(\mathbf{r})|_S=\phi_S(\mathbf{r})-\phi_S(\mathbf{r})=0, \tag{108}$$

for all $\mathbf{r}$ on the surface S. Finally, using the results (107) and (108) for the scalar field $\Phi(\mathbf{r})$ in identity (81) of Theorem III, one obtains the result $\Phi(\mathbf{r})=0$ which implies [via the definition of $\Phi(\mathbf{r})$ in (106)] that $\phi(\mathbf{r})=\xi(\mathbf{r})$ everywhere in the three-space region V' and on its bounding surface S'. This proves that the scalar field $\phi(\mathbf{r})$ is uniquely determined by Eq. (105) thus proving Theorem VI on the uniqueness of scalar fields in Euclidean three-space. ♣

Parenthetically, one should take note of the definition of the vector field $\mathbf{E}$ in (105a), which for example in electromagnetism could be interpreted as the static electric field. From this point of view, the uniqueness of a static electric scalar potential $\phi(\mathbf{r})$ requires the specification of the static electric field in a volume V, as well as the value of the scalar potential evaluated on the bounding surface S.

It should also be noted that Theorem VI bears little resemblance to a typical statement of a uniqueness theorem for a scalar field in Euclidean three-space (cf. pp. 38–45 in Jackson—Ref. 18). This is because Theorem VI is based on identity (81) of Theorem III, which is based on identity (80) alone. Equation (80) in turn follows from a solution of the *inhomogeneous* scalar wave equation, i.e., from an *inhomogeneous* Green's function approach. The *homogeneous* solutions which would have lead to Dirichlet or Neumann boundary conditions have not been included. The importance of Theorem VI appears to be that it emphasizes the role of the electric field, i.e., the negative gradient of ϕ, in obtaining a unique scalar potential.

Essentially the same remarks as above would apply to Theorems IV and V, but in a four-vector potential context. The importance of the four-vector result appears to be that it emphasizes the role of the four-divergence and the four-curl of A^μ in obtaining a unique four-vector potential.

IV. EXTENSION TO FIELDS WITH MASS

A. Helmholtz identity and uniqueness theorem for fields with mass

In order to extend the Helmholtz identity (11a) to vector fields with mass it is convenient to start by adding a μ^2 mass term to the *scalar* Poisson equation for the static scalar potential ϕ, as follows:

$$(\nabla^2-\mu^2)\phi(x,y,z)=-\frac{\rho(x,y,z)}{\epsilon_0}. \tag{109}$$

The massive scalar Poisson equation (109) can be solved in terms of a two-point scalar Green's function $G(\mathbf{r},\mathbf{r}')$ which connects its unit delta function source located at the source point $\mathbf{r}'=(x',y',z')$ to a measurement at the field point $\mathbf{r}=(x,y,z)$, i.e.,

$$(\nabla^2-\mu^2)G(\mathbf{r},\mathbf{r}')=-\delta^3(\mathbf{r}-\mathbf{r}'). \tag{110}$$

The well-known identity (cf. Ref. 19) over the Euclidean three-space $\mathbb{R}^3$, namely

$$(\nabla^2-\mu^2)\frac{e^{-\mu r}}{4\pi r}\equiv-\delta^3(\mathbf{r}-\mathbf{r}') \quad \forall \mathbf{r},\mathbf{r}'\in\mathbb{R}^3, \tag{111}$$

where $r\equiv|\mathbf{r}-\mathbf{r}'|$, yields by comparison with (110) for the case of an infinite spatial domain, the Green's function of the $(\nabla^2-\mu^2)$ operator as

$$G(\mathbf{r},\mathbf{r}')=\frac{e^{-\mu r}}{4\pi r}=\frac{e^{-\mu|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}. \tag{112}$$

One recognizes in (111) and (112) an exponential damping factor depending in this example on the Compton wave number $\mu=2\pi/\lambda_C=mc/\hbar$ of interaction bosons of mass m. The inhomogeneous solution of (109) for the scalar potential then follows from the integral

$$\phi(\mathbf{r})=\int_{V'}\frac{\rho(\mathbf{r}')}{\epsilon_0}G(\mathbf{r},\mathbf{r}')d^3\mathbf{r}'=\int_{V'}\frac{\rho(\mathbf{r}')e^{-\mu|\mathbf{r}-\mathbf{r}'|}}{4\pi\epsilon_0|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}'. \tag{113}$$

Although (113) is an inhomogeneous solution to the massive scalar Poisson equation (109) in an infinite spatial domain, it is the delta function property of identity (111) which is of importance in the proof of the new identity, namely

$$\mathbf{F}(\mathbf{r})=\int_{V'}\mathbf{F}(\mathbf{r}')\delta^3(\mathbf{r}-\mathbf{r}')d^3\mathbf{r}'=\int_{V'}\mathbf{F}(\mathbf{r}')(\nabla^2-\mu^2)\left(\frac{-e^{-\mu|\mathbf{r}-\mathbf{r}'|}}{4\pi r}\right)d^3\mathbf{r}'. \tag{114}$$

In addition, the identity $\nabla(1/r)=-\nabla'(1/r)$ used in the derivation of (11a) must be replaced by the identity

$$\nabla G(\mathbf{r},\mathbf{r}')=-\nabla' G(\mathbf{r},\mathbf{r}'), \tag{115}$$

which follows from the Green's function (112). A new identity now follows from (114) and (115) which allows one to state the following theorem.

Theorem VII: *The following identity holds for a continuous (static) three-vector field* $\mathbf{F}(\mathbf{r})$ *in a Euclidean three-space* $\mathbb{R}^3$:

$$\mathbf{F}(\mathbf{r}) = -\nabla\left[\int_{V'} \frac{\nabla'\cdot\mathbf{F}(\mathbf{r}')}{4\pi r} e^{-\mu r}\, dV' - \oint_{S'} \frac{\mathbf{F}(\mathbf{r}')\cdot\mathbf{n}'}{4\pi r} e^{-\mu r}\, dS'\right] + \nabla\times\left[\int_{V'} \frac{\nabla'\times\mathbf{F}(\mathbf{r}')}{4\pi r} e^{-\mu r} dV' + \oint_{S'} \frac{\mathbf{F}(\mathbf{r}')\times\mathbf{n}'}{4\pi r} e^{-\mu r}\, dS'\right] + \mu^2 \int_{V'} \frac{\mathbf{F}(\mathbf{r}')}{4\pi r} e^{-\mu r}\, dV', \tag{116}$$

where $r \equiv |\mathbf{r} - \mathbf{r}'|$ *and where* $\mathbf{n}'$ *is the unit surface normal pointing out of the volume* V' *bounded by the closed surface* S'.

Proof: Starting with (114), since the Laplacian operator acts only on the field coordinates, it can be brought outside of the integration. At this point, one makes a decomposition of the Laplacian operator using identity (20) as before in the derivation of (11a).[6,7] Then, since identity (115) retains the same functional form as the identity $\nabla(1/r) = -\nabla'(1/r)$ with respect to the overall derivation, the derivation retains the same form as the derivation of (11), with the minor exception that an extra μ^2 term is carried along unchanged. Equation (116) therefore follows readily as a new identity for static three-vector fields thus proving Theorem VII. ♣

In contrast to the Helmholtz identity (11a), the integrands of identity (116) contain an additional exponential mass damping factor which improves their convergence. The integrals are therefore well defined even for fields **F** falling off only as fast as $1/r$ (e.g., potentials).

Note, Eq. (116) should be thought of as an identity for representing a general (static) three-vector field rather than as a general solution to a partial differential equation. Indeed, (116) follows from the identity (111) over an infinite spatial domain and its subsequent use in the delta function property (114). Consequently, (116) is a vector identity that applies to all of the Euclidean three-space, and so must hold for a finite volume of it as well. The Green's function for an *inhomogeneous* massive scalar Poisson equation in an infinite spatial domain is only mentioned in passing, and certainly no use is made of the solutions of the associated source free *homogeneous* scalar equation.

It is interesting at this point to inquire whether or not identity (116) of Theorem VII can be used to obtain an alternate version of Theorem H2 of Sec. II A. However, the first thing to note about identity (116) is that **F** is no longer simply of the form (3) i.e., involving only the gradient of a scalar field (an irrotational part), and the curl of a vector field (a solenoidal part), but is now of the form

$$\mathbf{F}(\mathbf{r}) = -\nabla\Phi(\mathbf{r}) + \nabla\times\mathbf{A}(\mathbf{r}) + \mu^2 \int_{V'} \frac{\mathbf{F}(\mathbf{r}')}{4\pi r} e^{-\mu r}\, dV', \tag{117}$$

where the first and second bracketed terms on the rhs of (116) are set equal to $\Phi(\mathbf{r})$ and $\mathbf{A}(\mathbf{r})$, respectively, and where the last term on the rhs of (117) is an extra nonzero term which is neither irrotational nor solenoidal. Consequently, an alternate version of Theorem H2 does not appear to follow from identity (116).

On the other hand, one can use identity (116) to prove the following uniqueness theorem for three-vector fields.

Theorem VIII: *A twice continuously differentiable (static) three-vector field* $\mathbf{F}(\mathbf{r})$ *in the Euclidean three-space* $\mathbb{R}^3$, *which satisfies identity* (116), *is uniquely specified by giving its divergence and curl within the volume* V, *its normal and tangential components on the bounding surface S, and the value of the real constant* μ. *That is, one must specify the constant* μ *and the following:*

$$\nabla\cdot\mathbf{F} = \rho, \tag{118a}$$

$$\nabla\times\mathbf{F} = \mathbf{j}, \tag{118b}$$

throughout the volume V, *along with the normal and tangential components*

$$\mathbf{F}\cdot\mathbf{n}=-\sigma, \tag{118c}$$

$$\mathbf{F}\times\mathbf{n}=\mathbf{K}, \tag{118d}$$

respectively, on the surface S bounding the volume V, where **n** *is the outward unit normal vector of the surface S which encloses the volume V.*

Proof: In order to demonstrate the uniqueness of massive vector fields which satisfy identity (116) and Eqs. (118a)–(118d), one first postulates the existence of a second vector **G** which also satisfies identity (116) and Eqs. (118a)–(118d). That is, one replaces **F** on the lhs of Eqs. (118a)–(118d) by **G** while the rhs of these equations remain unchanged. The vector field **F** is unique if one can show that

$$\mathbf{W}\equiv\mathbf{F}-\mathbf{G}=0. \tag{119}$$

Now, taking the divergence of **W** and using (118a) yields

$$\nabla\cdot\mathbf{W}=\nabla\cdot\mathbf{F}-\nabla\cdot\mathbf{G}=\rho-\rho=0, \tag{120}$$

everywhere in the volume V. Also, calculating the magnitude of the normal component of **W** along the surface normal **n** and using (118c) yields

$$\mathbf{W}_{\text{norm}}\equiv\mathbf{W}\cdot\mathbf{n}=\mathbf{F}\cdot\mathbf{n}-\mathbf{G}\cdot\mathbf{n}=-\sigma-(-\sigma)=0, \tag{121}$$

everywhere on the bounding surface S. Next, taking the curl of **W** and using (118b) yields

$$\nabla\times\mathbf{W}=\nabla\times\mathbf{F}-\nabla\times\mathbf{G}=\mathbf{j}-\mathbf{j}=0, \tag{122}$$

everywhere in the volume V. Also, calculating the tangential components with respect to **n** of **W** and using (118d) yields

$$\mathbf{W}_{\text{tang}}\equiv\mathbf{W}\times\mathbf{n}=\mathbf{F}\times\mathbf{n}-\mathbf{G}\times\mathbf{n}=\mathbf{K}-\mathbf{K}=0, \tag{123}$$

everywhere on the bounding surface S. Finally, substituting the results (120)–(123) for the vector field **W** into identity (116) yields

$$\mathbf{W}(\mathbf{r})=\mu^2\int_{V'}\frac{\mathbf{W}(\mathbf{r}')}{4\pi r}e^{-\mu r}\,dV'. \tag{124}$$

Then, if one applies the operator $(\nabla^2-\mu^2)$, which acts only on the unprimed coordinates, to (124), while using (111) and (114), one obtains

$$(\nabla^2-\mu^2)\mathbf{W}(\mathbf{r})=\mu^2\int_{V'}\mathbf{W}(\mathbf{r}')(\nabla^2-\mu^2)\frac{e^{-\mu r}}{4\pi r}\,dV'=-\mu^2\int_{V'}\mathbf{W}(\mathbf{r}')\,\delta(\mathbf{r}-\mathbf{r}')\,dV'=-\mu^2\mathbf{W}(\mathbf{r}). \tag{125}$$

The μ^2 terms in (125) cancel and so **W** satisfies the vector Laplace equation

$$\nabla^2\mathbf{W}(\mathbf{r})=0. \tag{126}$$

Equation (126) also follows from a direct expansion of the Laplacian operator using (20) as follows:

$$\nabla^2\mathbf{W}=\nabla(\nabla\cdot\mathbf{W})-\nabla\times(\nabla\times\mathbf{W})=0, \tag{127}$$

where the first term in (127) vanishes by (120) and the second term in (127) vanishes by (122). A further restriction on **W** is that its normal component vanishes on the surface S by (121), which combined with the fact that **W** is irrotational by (122) and is therefore expressible as **W**

$=-\nabla\phi$, implies via Green's theorem that $\mathbf{W}=0$ throughout the volume V as well.[8] So, only the trivial solution $\mathbf{W}=0$ of (124) satisfies the boundary conditions and therefore [via (119)], the vector field $\mathbf{F}=\mathbf{G}$ everywhere in the volume V and on its bounding surface S. This proves that a static vector field $\mathbf{F}$ in a Euclidean three-space satisfying identity (116) is uniquely determined by specifying the real scalar constant μ and relations (118a)–(118d), thus proving Theorem VIII.♣

It is tempting to interpret Theorem VIII as a uniqueness theorem for static massive vector fields, i.e., those which satisfy the inhomogeneous massive *vector* Poisson equation

$$(\nabla^2-\mu^2)\mathbf{F}(\mathbf{r})=-\mathbf{j}(\mathbf{r}). \tag{128}$$

However, the Green's function which was used to derive identity (116) followed from an inhomogeneous massive scalar Poisson equation which is a much simpler problem. That is, equations of the form (128) would in general use, for example, a solution technique which involves a two-point dyadic Green's function, i.e., a Green's function which is not a three-vector.[20] Nevertheless, a close inspection of the proofs of identity (116) and Theorem VIII reveals that no limitations are imposed on the vector field $\mathbf{F}$ other than that its components must be twice continuously differentiable. The vector field $\mathbf{F}$ could therefore be either a massless or a massive vector field. Naturally, identity (116) appears to be oriented toward application to massive vector fields due to its incorporation of a mass damping factor. Alternately, identity (116) could be used in situations involving spatial diffusion, where the parameter μ would be interpreted as a diffusion parameter.

B. Extending the four-space Helmholtz identities and uniqueness theorems to four-vector fields with mass

In attempting to extend the four-space Helmholtz identities to four-vector fields with mass, one can start by adding a μ^2 mass term to (32), the inhomogeneous scalar wave equation for the scalar potential ϕ, as follows:

$$\Box\phi(x^\nu)-\mu^2\phi(x^\nu)=-\rho(x^\nu)/\epsilon_0, \tag{129}$$

where $\Box\equiv\partial_\mu\partial^\mu$ is the d'Alembertian operator, and where the $(-\ +\ +\ +)$ metric signature is again convenient. One can then attempt a solution of the massive inhomogeneous scalar wave equation (129) in terms of a two-point massive scalar Green's function $G(x^\nu,x'^\nu)$ as in (33), but now with a μ^2 mass term as follows:

$$(\Box-\mu^2)G(x^\nu,x'^\nu)=\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}-\mu^2\right)G(x^\nu,x'^\nu)=-\delta^{(4)}(x^\nu-x'^\nu), \tag{130}$$

where $\delta^{(4)}(x^\nu-x'^\nu)=\delta(x^0-x'^0)\,\delta^3(\mathbf{r}-\mathbf{r}')$. For the previous scalar field case with the mass factor $\mu=0$, comparison of the Euclidean space analytically continued integral (30b) with the Minkowski space integral (34) yielded the Euclidean four space Green's function (36). One could therefore try to follow a course paralleling the three-space analysis in Sec. IV A by simply adding a mass damping factor to the Euclidean four-space Green's function (36) thereby obtaining a trial Green's function

$$G_{\text{trial}}(x^\nu,x'^\nu)\equiv\frac{e^{-\mu R}}{4\pi^2R^2}=\frac{e^{-\mu|x^\nu-x'^\nu|}}{4\pi^2|x^\nu-x'^\nu|^2}, \tag{131}$$

where R is the distance in a *Euclidean* four-space between the source point x'^ν and field point x^ν as defined previously in (23). However, it turns out that G_{trial} satisfies a different identity, namely

$$\left(\Box-\mu^2-\frac{\mu}{R}\right)G_{\text{trial}}(x^\nu,x'^\nu)=-\delta^{(4)}(x^\nu-x'^\nu), \tag{132}$$

where the third term on the lhs of (132) is an additional cross term. To demonstrate this one uses the result $\partial^\nu x_\nu = 4$ to calculate

$$\Box\left(\frac{e^{-\mu R}}{R^2}\right) = -4\pi^2\delta^{(4)}(x^\nu - x'^\nu)e^{-\mu R} + (2-4+3)\frac{\mu}{R^3}e^{-\mu R} + \frac{\mu^2}{R^2}e^{-\mu R}, \tag{133}$$

which proves (132) since the exponential in the first term on the rhs of (133) drops out in a delta function distribution integral context. Contrast (133) with the Euclidean three-space identity (110) rewritten in index notation, and using the result $\partial^j x_j = 3$, as

$$\frac{\partial}{\partial x_j}\frac{\partial}{\partial x^j}\left(\frac{e^{-\mu r}}{r}\right) = -4\pi\delta^3(x^j - x'^j)e^{-\mu r} + (1-3+2)\frac{\mu}{r^2}e^{-\mu r} + \frac{\mu^2}{r}e^{-\mu r}, \tag{134}$$

where the additional cross term, the middle term on the rhs of (134), clearly drops out.

However, a solution for the massive scalar two-point Green's function has been obtained by DeWitt[21] using a Fourier ''momentum'' space method for the case of timelike separations $(x^\nu - x'^\nu)^2 < 0$ as follows:

$$G_M(x^\nu, x'^\nu) = -\frac{\mu^2}{8\pi}\frac{H_1^{(2)}(i\mu R)}{i\mu R}, \tag{135}$$

where $H_1^{(2)}$ is the Hankel function of the second kind of order 1 with an integral representation[21]

$$H_1^{(2)}(z) = \frac{1}{i\pi}\int_C \frac{1}{u^2}\exp\left[\frac{1}{2}z\left(1-\frac{1}{u}\right)\right]du, \tag{136}$$

over the contour C defined in Ref. 21. Since $z = i\mu R = i\mu|x^\nu - x'^\nu|$ in (136), the four-vector derivative of the massive scalar Green's function (135) has the property

$$\frac{\partial}{\partial x'^\nu}G_M(x^\nu, x'^\nu) = -\frac{\partial}{\partial x^\nu}G_M(x^\nu, x'^\nu), \tag{137}$$

which is of the same functional form as properties (65a) and (65b). Consequently, (137) can be used in the same way as in the derivation of identity (69). An alternate form of Theorem II can therefore be stated as follows:

Theorem IX: *Given that a massive scalar two-point Green's function $G_M(x^\nu, x'^\nu)$ exists for timelike separations $(x^\nu - x'^\nu)^2 < 0$, whose dependencies on the coordinates x^ν and x'^ν occur only through the variable $R = |x^\nu - x'^\nu|$, the following identity holds for sufficiently smooth four-vector fields $A^\mu(x^\sigma)$ in the Minkowski space $\mathbb{R}^{3+1}$ for timelike separations $(x^\nu - x'^\nu)^2 < 0$:*

$$\begin{aligned} A^\mu(x) = &-\left[\int_{V_4'}\partial^\mu((\partial'_\nu A^\nu(x'))G_M(x,x'))d^4x' - \oint_{\Sigma'}\partial^\mu((A^\nu(x')n'_\nu)G_M(x,x'))d\Sigma'\right] \\ &-\left[\int_{V_4'}\partial_\alpha((\partial'^\alpha A^\mu(x') - \partial'^\mu A^\alpha(x'))G_M(x,x'))d^4x' + \oint_{\Sigma'}\partial_\alpha((A^\alpha(x')n'^\mu \right. \\ &\left. - A^\mu(x')n'^\alpha)G_M(x,x'))d\Sigma'\right] + \mu^2\int_{V_4'}A^\mu(x')G_M(x,x')d^4x', \end{aligned} \tag{138}$$

where n'^μ is the four-vector outward unit normal of the three-surface Σ' which encloses the four-volume V_4', and where the three-surface Σ' is defined covariantly with respect to a general Lorentz transformation.

Proof: The proof is based on the four-vector delta function property (42) which in the present case uses (130) for representing the four-space delta function as follows:

$$A^{\mu}(x)=\int_{V_4'}A^{\mu}(x')\,\delta^{(4)}(x-x')d^4x'=-\int_{V_4'}A^{\mu}(x')(\Box-\mu^2)G_M(x,x')d^4x'. \tag{139}$$

Then since the property (137) is of the same functional form as in (65), the proof of (138) parallels the proof of (69) in all important respects, except that an extra μ^2 mass term is carried along unchanged from (139), and so the details will not be repeated. ♣

It is interesting at this point to inquire whether or not one can use identity (138) of Theorem IX to state a four-space analog of the three-vector Theorem H2 of Sec. II A. For a sufficiently smooth four-vector field one can factor the unprimed field point derivatives out of the integrals over the primed source point coordinates in (138). However, the first thing to note about such a factored version of identity (138) is that A^{μ} is no longer simply of the form (75), i.e., involving only the four-gradient of a scalar field (a four-irrotational part), and the four-curl of a four-vector field (a four-solenoidal part), but is now of the form

$$A^{\mu}(x)=\partial^{\mu}A(x)+\partial_{\alpha}A^{\alpha\mu}(x)+\mu^2\int_{V_4'}A^{\mu}(x')G_M(x,x')d^4x', \tag{140}$$

where the first and second bracketed terms on the rhs of (138) are set equal to $-A(x)$ and $-A^{\alpha\mu}(x)$, respectively, and where the last term on the rhs of (140) is an extra nonzero term which is neither four-irrotational nor four-solenoidal. Therefore a four-space analog of the three-vector Theorem H2 of Sec. II A does not appear to follow from (138). However, it is possible to state a theorem for four-vector fields based on identity (43) of Theorem I or on identity (69) of Theorem II as follows:

Theorem X: *A sufficiently smooth four-vector field $A^{\mu}(x^{\sigma})$ that is defined everywhere in a finite volume V_4 in a Euclidean four-space $\mathbb{R}^4$ or in a Minkowski space $\mathbb{R}^{3+1}$ and whose tangential and normal components on the bounding three-surface Σ are given may be uniquely represented as a sum of a four-irrotational and a four-solenoidal part.*

Proof: It has already been shown that (44) leads to (51) in the Euclidean case, while in a similar fashion (70) leads to (75) in the Minkowski case. Now, the second term of (51) or (75), is four-irrotational

$$\partial^{\mu}(\partial^{\nu}A)-\partial^{\nu}(\partial^{\mu}A)=0, \tag{141}$$

i.e., its four-curl is zero. Also, the first term of (51) or (75) is four-solenoidal

$$\partial_{\mu}(\partial_{\alpha}A^{\alpha\mu})=0, \tag{142}$$

i.e., its four-divergence is zero, since it is a contraction of a symmetric factor $\partial_{\mu}\partial_{\alpha}$ and an antisymmetric factor (53) or (73). The decomposition defined by Eq. (51) or (75) is therefore a sum of a four-irrotational and a four-solenoidal part and by identity (43) and (69) and by the arguments of the Euclidean uniqueness Theorem IV and the Minkowski space uniqueness Theorem V the field A^{μ} is unique under this decomposition, thereby proving Theorem X. ♣

A theorem will now be stated that will be used later in this section.

Theorem XI: *A sufficiently smooth four-vector field $A^{\mu}(x^{\sigma})$ vanishes in a compact nonempty region $\overline{V_4}=V_4\cup\Sigma$ of the Minkowski space $\mathbb{R}^{3+1}$ when the four-divergence and four-curl of $A^{\mu}(x^{\sigma})$ vanish over the space–time region V_4 and the four-normal and four-tangential components of $A^{\mu}(x^{\sigma})$ vanish over the bounding three-surface Σ. That is, one must specify the following:*

$$\partial_{\nu}A^{\nu}(x^{\sigma})=0, \tag{143a}$$

$$\partial^{\alpha}A^{\mu}(x^{\sigma})-\partial^{\mu}A^{\alpha}(x^{\sigma})=0, \tag{143b}$$

throughout the space–time region V_4*, as well as*

$$A_{\text{norm}}(x^\sigma)\equiv A^\nu(x^\sigma)n_\nu=0, \tag{143c}$$

$$A_{\text{tang}}^{\alpha\mu}(x^\sigma)\equiv A^\alpha(x^\sigma)n^\mu - A^\mu(x^\sigma)n^\alpha=0, \tag{143d}$$

everywhere on the bounding three-surface Σ*, where* n^ν *is the four-vector outward unit normal of the three-surface* Σ *which encloses the space–time four-volume* V_4.

Proof: Since it is assumed that A^μ and n^ν are four-vectors, then $A_{\text{norm}}(x^\sigma)$ and $A_{\text{tang}}^{\alpha\mu}(x^\sigma)$ are covariant with respect to general Lorentz transformations and identity (69) of Theorem II, which is defined under similar constraints, can be used. Substitution of (143a)–(143d) into identity (69) then yields the result $A^\mu(x^\sigma)=0$ throughout $\overline{V_4}$, thus proving Theorem XI. ♣

The next step is to state a four-vector uniqueness theorem analogous to the three-vector Theorem VIII as follows:

Theorem XII: *A sufficiently smooth four-vector field* $A^\mu(x^\sigma)$ *in the Minkowski space* $\mathbb{R}^{3+1}$ *which satisfies identity (138) (i.e., Theorem IX), is uniquely specified by giving its four-divergence and four-curl within the space-time region* V_4*, its normal and tangential components on the bounding three-surface* Σ*, and the value of the real constant* μ*. That is, one must specify the constant* μ *and the following:*

$$\partial_\nu A^\nu(x^\sigma)\equiv s, \tag{144a}$$

$$\partial^\alpha A^\mu(x^\sigma) - \partial^\mu A^\alpha(x^\sigma)\equiv c^{\alpha\mu}, \tag{144b}$$

throughout the space–time region V_4*, as well as*

$$A_{\text{norm}}(x^\sigma)\equiv A^\nu(x^\sigma)n_\nu, \tag{144c}$$

$$A_{\text{tang}}^{\alpha\mu}(x^\sigma)\equiv A^\alpha(x^\sigma)n^\mu - A^\mu(x^\sigma)n^\alpha, \tag{144d}$$

everywhere on the bounding three-surface Σ*, where* n^ν *is the four-vector outward unit normal of the three-surface* Σ *which encloses the space–time four-volume* V_4.

Proof: The proof proceeds in a parallel manner to the proof of Theorem V. One postulates the existence of a second four-vector B^ν which also satisfies Eqs. (144a)–(144d). The four-vector field A^ν is unique if one can show, as in Theorem V, that

$$W^\nu\equiv A^\nu - B^\nu=0. \tag{145}$$

Equations (144a)–(144d) then lead, as before with (97a)–(97d), to results analogous to (99)–(102), which when substituted into identity (138) yields the result

$$W^\mu(x)=\mu^2\int_{V_4'} W^\mu(x')G_M(x,x')d^4x'. \tag{146}$$

Then, if one applies the operator $(\Box-\mu^2)$, which acts only on the unprimed coordinates x^ν, to (146) while using (139), one obtains

$$\begin{aligned}(\Box-\mu^2)W^\mu(x)&=\mu^2\int_{V_4'} W^\mu(x')(\Box-\mu^2)G_M(x,x')d^4x'\\ &=-\mu^2\int_{V_4'} W^\mu(x')\,\delta^{(4)}(x-x')d^4x' = -\mu^2 W^\mu(x).\end{aligned} \tag{147}$$

The μ^2 terms in (147) cancel and so $W^\mu(x)$ satisfies the homogeneous wave equation

$$\Box W^{\mu}(x)=0. \tag{148}$$

Equation (148) also follows from a direct expansion of the d'Alembertian operator using (19) as follows:

$$\Box W^{\mu}=\partial_{\nu}(\partial^{\nu}W^{\mu}-\partial^{\mu}W^{\nu})+\partial^{\mu}(\partial_{\nu}W^{\nu})=0, \tag{149}$$

where the first bracketed term of (149) vanishes because the four-curl vanishes by a result analogous to (101) and the second bracketed term of (146) vanishes because the four-divergence vanishes by a result analogous to (99). It should be clear from the result (149) that it is not necessary to solve the Cauchy problem for the wave equation (148) to find $W^{\mu}(x)$ since each bracketed term in (149) separately vanishes. In fact, each of the conditions (143a)–(143d) are satisfied for $W^{\mu}(x)$ throughout $\overline{V}_4$, and so by Theorem XI $W^{\mu}(x)=0$ throughout $\overline{V}_4$. Thus, only the trivial solution $W^{\mu}(x)=0$ of (148) satisfies the boundary conditions and therefore, [via (145)], the four-vector field $A^{\mu}(x)=B^{\mu}(x)$ everywhere in the four-volume V_4 and on its bounding three-surface Σ. This proves that a four-vector field $A^{\mu}(x)$ in a Minkowski $3+1$ space–time satisfying identity (138) is uniquely specified by specifying the real scalar constant μ and the relations (144a)–(144d), thus proving Theorem XII. ♣

It is tempting to interpret Theorem XII as a uniqueness theorem for massive four-vector fields, i.e., those which satisfy the inhomogeneous massive four-*vector* wave equation

$$(\Box-\mu^2)F^{\mu}(x)=-j^{\mu}(x). \tag{150}$$

However, the Green's function $G_M(x,x')$, e.g., (135), which was used in identity (138) followed from an inhomogeneous massive *scalar* wave equation which is a much simpler problem. That is, equations of the form (150) would in general use a solution technique which involves a two-point second rank tensor Green's function.[22,23] Nevertheless, a close inspection of the proofs of identity (138) and Theorem XII reveals that no limitations are imposed on the four-vector field $A^{\mu}(x)$ other than that its components must be sufficiently smooth. The four-vector field $A^{\mu}(x)$ could therefore be either a massless or a massive four-vector field. Naturally, identity (138) appears to be oriented toward application to massive four-vector fields $A^{\mu}(x)$ due to its incorporation of a mass damping factor.

V. CONCLUSION

In conclusion, the three-space Helmholtz identity and its associated uniqueness theorems, which focus on the curl and divergence of a vector field, provide insight into irrotational and solenoidal fields. The extension of the Helmholtz identity and associated uniqueness theorems to Euclidean and Minkowski four-spaces presented in this article demonstrates that the curl and divergence of a three-vector field generalize into the four-curl and four-divergence of a four-vector field, and that irrotational and solenoidal three-vector fields naturally generalize into four-irrotational and four-solenoidal four-vector fields, respectively.

Now, a four-solenoidal field is essentially a four-vector field in the Lorentz gauge (sometimes referred to as a *relativistic transverse gauge*), with zero four-divergence, as for example in the case of the electromagnetic field. The author is currently investigating the associated concept of a four-irrotational four-vector field. This leads to the development of what the author shall call a ''*relativistic longitudinal gauge*'' where the Maxwell field tensor itself is set to zero, while the four-divergence of the four-vector field can in general be nonzero. Consider the case of a so-called ''pure gauge'' field which arises in connection with the Meissner effect deep in a superconductor, where the magnetic field is required to vanish (cf. Ref. 24). Interestingly, pure gauge fields which are defined by the relation

$$A^{\mu}\equiv\partial^{\mu}\Lambda, \tag{151}$$

satisfy a ''*relativistic longitudinal gauge condition*'' as defined by the vanishing of its Maxwell field tensor:

$$F^{\mu\nu}=\partial^{\mu}A^{\nu}-\partial^{\nu}A^{\mu}=\partial^{\mu}\partial^{\nu}\Lambda-\partial^{\nu}\partial^{\mu}\Lambda=0, \tag{152}$$

and further are four-irrotational since the four-curl of A^{μ}, i.e., $F^{\mu\nu}$, is zero by (152). If they also have nonzero four-divergence throughout a region V_4 where (152) holds, i.e.,

$$\partial_{\mu}A^{\mu}(x)=\partial_{\mu}\partial^{\mu}\Lambda(x)\neq 0 \quad \forall x\in V_4, \tag{153}$$

they would provide an example of a four-vector field in the relativistic longitudinal gauge. Indeed, if a pure gauge field, defined for example over an unbounded space–time region, satisfied $\partial_{\mu}A^{\mu}=0$, then by Theorem XI one would have the field A^{μ} vanishing everywhere! In a finite space–time region, on the other hand, one could still possibly have $\partial_{\mu}A^{\mu}=0$, $F^{\mu\nu}=0$, and $A^{\mu}\neq 0$ all holding true if either (143c) and/or (143d) were nonzero on the three-surface Σ bounding the four-volume V_4.

ACKNOWLEDGMENTS

The style and presentation of this article has benefited from detailed discussions with the author's thesis adviser Associate Professor John Corbett. The author is deeply indebted to Professor Corbett for allowing him to freely develop his own ideas while at the same time making him aware of their mathematical significance and limitations. This work is a partial reporting of the results of the author's Ph.D. thesis. The thesis was submitted on 28 August, 1998 to the Department of Physics at Macquarie University–Sydney, Australia, in partial fulfillment of the requirements for the degree Doctor of Philosophy. Tuition exemption from the Higher Education Contribution Scheme (HECS) was obtained via the Ph.D. by Research program.

(Received 25 September 1998; accepted for publication 27 April 1999)

For any d-dimensional self-interacting fermionic model, all coefficients in the high-temperature expansion of its grand canonical partition function can be put in terms of multivariable Grassmann integrals. A new approach to calculate such coefficients, based on direct exploitation of the Grassmannian nature of fermionic operators, is presented. We apply the method to the soluble Hatsugai–Kohmoto model, reobtaining well-known results.
[S0022-2488(99)00310-2]

I. INTRODUCTION

A quantum system at thermal equilibrium can be completely described provided that one knows its grand canonical partition function, which can be expressed as a path integral. For bosonic systems, an advantageous feature of the path integral approach is that of employing commuting functions instead of noncommuting operators. For fermionic systems, however, such an advantage is not obvious to hold, as the integration variables are also noncommuting.

In 1980, Kubo[1] used the path integral approach to calculate the grand canonical partition function of the Hubbard model, using the strong coupling limit and performing a perturbative expansion in the hopping constant (t). Even though his result is valid for any temperature, one does not have the exact coefficient of $\beta(\beta=1/kT)$ of the high-temperature expansion of the partition function. Since then, improvements on the calculation of the high-temperature expansion up to order $(\beta t)^9$ for the Hubbard model in two and three dimensions have been reported in the literature.[2]

Recently, Grandati *et al.*[3] presented a method to calculate the grand canonical partition function of self-interacting fermions by writing that function on a lattice and using the properties of the Grassmann algebra to calculate its expansion in powers of the coupling constant. They calculated the first two terms for the bi-dimensional chiral Gross–Neveu model, obtaining an analytical result; however, their approach is model dependent. More recently, Creutz[4] used a numerical algorithm to calculate the generating functional of a fermionic model, rewritten on a lattice. He applied his algorithm to a unidimensional fermionic system involving a thousand Grassmannian variables. He pointed out that this approach does not have the sign problems that generally hamper the application of the Monte Carlo method to fermionic models.

We do not write the grand canonical partition function of a self-interacting fermionic model on a lattice; instead, we present a new method to obtain the coefficients of its high-temperature expansion in d dimensions, where $d\geqslant 1$. However, for the expansion in β, this method does *not* involve any other perturbative expansion (such as, say, in the coupling constant of the model). In Sec. II we present the method, an extension to the one used to calculate the grand canonical partition function of the anharmonic fermionic oscillator,[5] a quantum model in $d=0$ space dimension. In Ref. 6, the properties of the Grassmann algebra were used to calculate the moments of Grassmannian Gaussian integrals. This general result, together with the diagonalization of matrices $\mathbf{A}^{\sigma\sigma}(\sigma=\uparrow,\downarrow)$—matrices that appear when the trace of any fermionic operator is expressed in terms of a multivariable Grassmann integral [see Eq. (9)]—allows us to develop a general approach to obtain analytical expressions for the coefficients of the high-temperature expansion of the grand canonical partition function of any self-interacting fermionic model in d dimensions, even in the thermodynamical limit. In Sec. III we apply the method to the Hatsugai–Kohmoto model, a simple toy model that was used by Hatsugai and Kohmoto to explain the metal-insulator transition. The solution of this model is very simple, and does not require all of the features developed in Sec. II. In Sec. IV we present our conclusions and future applications of the present approach. In the Appendix, the diagonalization of the matrices $\mathbf{A}^{\sigma\sigma}$, for arbitrary lattice dimension and arbitrary number of points in the lattice, is described.

II. EXPANSION IN THE HIGH-TEMPERATURE LIMIT AND THE GRASSMANN MULTIVARIABLE INTEGRALS

The grand canonical partition function of any quantum system in the high-temperature limit can be expanded in terms of β as

$$\mathcal{Z}(\beta;\mu)=\mathrm{Tr}\,(e^{-\beta\mathbf{K}})=\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\mathrm{Tr}[\mathbf{K}^n]\beta^n, \tag{1}$$

where $\mathbf{K}$ is given by

$$\mathbf{K}=\mathbf{H}-\mu\mathbf{N}, \tag{2}$$

$\mathbf{H}$ is the Hamiltonian of the system, μ is the chemical potential, and $\mathbf{N}$ is the total number of particles operator.

The fermionic creation ($\mathbf{a}_i^\dagger$) and destruction ($\mathbf{a}_j$) operators can be mapped into generators of the Grassmann algebra $\{\overline{\eta_i},\eta_j\}$ as follows:[7–9]

$$\mathbf{a}_i^\dagger\rightarrow\overline{\eta_i} \quad \text{and} \quad \mathbf{a}_j\rightarrow\frac{\partial}{\partial\overline{\eta_j}}, \tag{3}$$

where $i,j=1,2,...,\mathcal{N}$. The generators of this Grassmann algebra of dimension $2^{2\mathcal{N}}$, written explicitly as $\{\overline{\eta_1},\ldots,\overline{\eta_\mathcal{N}};\eta_1,\ldots,\eta_\mathcal{N}\}$, satisfy the following anticommutation relations:

$$\{\eta_i,\eta_j\}=0, \quad \{\overline{\eta_i},\overline{\eta_j}\}=0, \quad \text{and}\ \{\overline{\eta_i},\eta_j\}=0. \tag{4}$$

The trace of any normal-ordered fermionic operator $\mathbf{O}$ is[7]

$$\mathrm{Tr}[\mathbf{O}]=\int\prod_{i=1}^{\mathcal{N}}d\eta_i d\overline{\eta_i}\,\mathcal{O}^{ⓝ}(\overline{\eta},\eta)e^{\Sigma_{j=1}^{\mathcal{N}}2\overline{\eta_j}\eta_j}, \tag{5}$$

where we use the shorthand notation, $\overline{\eta}\equiv\{\overline{\eta_1},\ldots,\overline{\eta_\mathcal{N}}\}$ and $\eta\equiv\{\eta_1,\ldots,\eta_\mathcal{N}\}$, and $\mathcal{O}^{ⓝ}(\overline{\eta},\eta)$ is the kernel of the fermionic operator $\mathbf{O}$ in the normal order. (By ''normal-ordered operator'' we mean an operator in which all destruction operators are to placed to the right of all creation operators.) Naively, it can be said that the Grassmannian function $\mathcal{O}^{ⓝ}(\overline{\eta},\eta)$ is obtained by replacing $\mathbf{a}_i^\dagger\rightarrow\overline{\eta_i}$ and $\mathbf{a}_i\rightarrow\eta_i$ in operator $\mathbf{O}$.[5,7]

Let us consider from now on the case where the creation and destruction operators are characterized by the indices $(\vec{\ell};\sigma)$, where $\vec{\ell}$ is a d-dimensional lattice vector ($d=1,2,3,...$) and σ is the spin component. The components of vector $\vec{\ell}$ need not be orthogonal. This lattice vector could equally represent either the space vector $\vec{\mathbf{x}}$ or the momentum vector $\vec{\mathbf{k}}$. If the fermionic operator $\mathbf{O}$ is a product of n normal-ordered fermionic operators $\mathbf{Q}$, we have[5]

$$\mathrm{Tr}[\mathbf{Q}^n]=\int \prod_{\vec{\ell}} \prod_{\sigma=\pm 1} \prod_{\alpha=0}^{n-1} d\eta_\sigma(\vec{\ell};\alpha)d\overline{\eta}_\sigma(\vec{\ell};\alpha)e^{\Sigma_{\vec{\ell}}\Sigma_{\nu=0}^{n-1}\overline{\eta}_\sigma(\vec{\ell};\nu)[\eta_\sigma(\vec{\ell};\nu)-\eta_\sigma(\vec{\ell};\nu+1)]}$$
$$\times \mathcal{Q}^{ⓝ}(\overline{\eta}_\sigma(\vec{\ell};0),\eta_\sigma(\vec{\ell};0))\mathcal{Q}^{ⓝ}(\overline{\eta}_\sigma(\vec{\ell};1),\eta_\sigma(\vec{\ell};1))\times\cdots$$
$$\times \mathcal{Q}^{ⓝ}(\overline{\eta}_\sigma(\vec{\ell};n-1),\quad \eta_\sigma(\vec{\ell};n-1)), \tag{6}$$

where we define $\sigma=\uparrow\equiv+1$ and $\sigma=\downarrow\equiv-1$. The Grassmann variables in Eq. (6) satisfy the boundary conditions

$$\eta_\sigma(\vec{\ell};n)=-\eta_\sigma(\vec{\ell};0) \quad \text{and} \quad \eta_\sigma(\vec{\ell};\nu)=0, \quad \text{for} \quad \nu>n, \tag{7}$$

with $\sigma=\pm 1$ and $\vec{\ell}$ stands for any vector on the lattice. Equation (6) is still valid for a product of n-ordered operators, not necessarily equal.

Relation (6) is used to write the terms of the expansion of the grand canonical partition function in the high-temperature limit as multivariable Grassmann integrals. For a d-dimensional fermionic model, the coefficients of the expansion $\mathcal{Z}(\beta,\mu)$ in Eq. (1) become

$$\mathrm{Tr}[\mathbf{K}^n]=\int \prod_{\vec{\ell}} \prod_{\sigma=\pm 1} \prod_{\alpha=0}^{n-1} d\eta_\sigma(\vec{\ell};\alpha)d\overline{\eta}_\sigma(\vec{\ell};\alpha)e^{\Sigma_{\vec{\ell}}\Sigma_{\sigma=\pm 1}\Sigma_{\nu=0}^{n-1}\overline{\eta}_\sigma(\vec{\ell};\nu)[\eta_\sigma(\vec{\ell};\nu)-\eta_\sigma(\vec{\ell};\nu+1)]}$$
$$\times \mathcal{K}^{ⓝ}(\overline{\eta}_\sigma(\vec{\ell};0),\eta_\sigma(\vec{\ell};0))\mathcal{K}^{ⓝ}(\overline{\eta}_\sigma(\vec{\ell};1),\eta_\sigma(\vec{\ell};1))\times\cdots$$
$$\times \mathcal{K}^{ⓝ}(\overline{\eta}_\sigma(\vec{\ell};n-1),\quad \eta_\sigma(\vec{\ell};n-1)). \tag{8}$$

The boundary conditions (7) still hold for the generators $\eta_\sigma(\vec{\ell};\nu)$.

It is much easier to handle generators with one index. Then we map the generators $\eta_\sigma(\vec{\ell},\nu)$ and $\overline{\eta}_\sigma(\vec{\ell},\nu)$ into single-indexed anti-commuting variables. The sum in the exponential on the rhs of Eq. (8) can be written as

$$\sum_{\vec{\ell}} \sum_{\sigma=\pm 1} \sum_{\nu=0}^{n-1} \overline{\eta}_\sigma(\vec{\ell};\nu)[\eta_\sigma(\vec{\ell};\nu)-\eta_\sigma(\vec{\ell};\nu+1)]\equiv\sum_{I,J=1}^{2nN^d} \overline{\eta}_I A_{IJ}\eta_J. \tag{9}$$

Note that the argument of the exponential on the rhs of Eq. (8) is diagonal in the indices $\vec{\ell}$ and σ. Having the components of the column vector η_J (or the line vector $\overline{\eta}$) grouped according to the values of σ, and then each subset ordered according to ν, and finally each subsubset ordered according to $\vec{\ell}$, the matrix $\mathbf{A}$ will have the block-structure

$$\mathbf{A}=\begin{pmatrix} \mathbf{A}^{\uparrow\uparrow} & \mathbb{O} \\ \mathbb{O} & \mathbf{A}^{\downarrow\downarrow} \end{pmatrix}, \tag{10}$$

whose entries are matrices of dimension $nN^d\times nN^d$ and d is the dimension of the vector $\vec{\ell}$. The indices I,J are such that $I,J=1,2,...,2nN^d$, where N^d is the number of points in the lattice. The matrices $\mathbf{A}^{\uparrow\uparrow}$ and $\mathbf{A}^{\downarrow\downarrow}$ are identical. Taking into account the anti-periodic condition in temperature (7) in Eq. (9), the matrices $\mathbf{A}^{\sigma\sigma}$, where $\sigma=\uparrow,\downarrow$, are found to have the following block-structure:

$$\mathbf{A}^{\uparrow\uparrow}=\mathbf{A}^{\downarrow\downarrow}=\begin{pmatrix} \mathbb{1}_{N^d\times N^d} & -\mathbb{1}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} \\ \mathbb{0}_{N^d\times N^d} & \mathbb{1}_{N^d\times N^d} & -\mathbb{1}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} \\ \vdots & & & & \vdots \\ \mathbb{1}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & \mathbb{1}_{N^d\times N^d} \end{pmatrix}. \tag{11}$$

The symbols $\mathbb{1}_{N^d\times N^d}$ and $\mathbb{0}_{N^d\times N^d}$ stand for the identity and null matrices of dimension $N^d\times N^d$, respectively. Any lattice vector $\vec{\ell}$ can be written as

$$\vec{\ell}=\ell_1\,\vec{\mathbf{u}}_1+\ell_2\,\vec{\mathbf{u}}_2+\cdots+\ell_d\,\vec{\mathbf{u}}_d, \tag{12}$$

where $\ell_i=1,2,...,N(i=1,2,...,d)$, and N is the number of points in the lattice in the direction of the d-dimensional basis vector $\vec{\mathbf{u}}_i$. A particular basis, for which $\mathbf{A}^{\sigma\sigma}$ has the block-form shown in (11), yields the following mapping:

$$\eta_\sigma(\vec{\ell};\nu)\rightarrow\eta_{[[(1-\sigma)/2]n+\nu]N^d+\ell_1+(\ell_2-1)N+\cdots+(\ell_d-1)N^{(d-1)}}. \tag{13}$$

The generators $\overline{\eta}_\sigma(\vec{\ell};\nu)$ have an analogous mapping. With the newly indexed generators, the expression of $\mathrm{Tr}[\mathbf{K}^n]$ [Eq. (8)] becomes

$$\mathrm{Tr}[\mathbf{K}^n]=\int\prod_{I=1}^{2nN^d}d\eta_I\,d\overline{\eta}_I\;e^{\sum_{I,J=1}^{2nN^d}\overline{\eta}_I A_{IJ}\eta_J}\times\mathcal{K}^{\circledR}(\overline{\eta},\eta;\nu=0)\mathcal{K}^{\circledR}(\overline{\eta},\eta;\nu=1)\cdots\mathcal{K}^{\circledR}(\overline{\eta},\eta;\nu=n-1). \tag{14}$$

Note that expression (14), up to the constant $-1/n!$, is the coefficient at order β^n of the expansion in the high-temperature limit of the grand canonical partition function for any self-interacting fermionic model. The specific model to be studied is represented by the Grassmannian function $\mathcal{K}^{\circledR}$, but the matrix $\mathbf{A}$ is the same for all fermionic models. Once the submatrices $\mathbf{A}^{\uparrow\downarrow}$ and $\mathbf{A}^{\downarrow\uparrow}$ are null, the multivariable integral (14) is equal to the product of the contributions coming from the sectors: $\sigma\sigma=\uparrow\uparrow$ and $\sigma\sigma=\downarrow\downarrow$ separately. The Grassmann functions $\mathcal{K}^{\circledR}$ are polynomials in the generators of the algebra. Therefore, the rhs of Eq. (14) are moments of the multivariable Grassmann Gaussian integrals. In Ref. 6 it is shown that these integrals can be written as cofactors of the matrix $\mathbf{A}$.

The integrals in Eq. (14), for sector $\sigma\sigma=\uparrow\uparrow$, have the form

$$M(L,K)=\int\prod_{i=1}^{nN^d}d\eta_i d\overline{\eta}_i\;\overline{\eta}_{l_1}\eta_{k_1}\cdots\overline{\eta}_{l_m}\eta_{k_m}e^{\sum_{i,j=1}^{nN^d}\overline{\eta}_i A_{ij}^{\uparrow\uparrow}\eta_J}, \tag{15}$$

with $L=\{l_1,\ldots,l_m\}$ and $K=\{k_1,\ldots,k_m\}$. The products $\overline{\eta}\eta$ are ordered in such a way that $l_1<l_2<\cdots<l_m$ and $k_1<k_2<\cdots<k_m$. From Ref. 6, the result of this type of integrals is equal to

$$M(L,K)=(-1)^{(l_1+l_2+\cdots+l_m)+(k_1+k_2+\cdots+k_m)}A(L,K), \tag{16}$$

where $A(L,K)$ is the determinant of the matrix obtained from matrix $\mathbf{A}^{\uparrow\uparrow}$ by deleting the lines $\{l_1,\ldots,l_m\}$ and the columns $\{k_1,\ldots,k_m\}$. $M(L,K)$ is a cofactor of matrix $\mathbf{A}^{\uparrow\uparrow}$. The Grassmann integrals to be calculated in sector $\downarrow\downarrow$ are the same type as Eq. (15). Evaluating determinants of nondiagonal matrices of dimension $nN^d\times nN^d$ is still a hard task, even if we have restricted ourselves to multivariable integrals of a fixed sector $\sigma\sigma$. Calculating such determinants is a suitable task for computers, and it obviously depends on hardware and software resources. Fixing n, for instance, there is an upper practical limit for N, so that the calculation of determinants is feasible. One possibility for evaluating Eq. (14) is that of assigning different values for N and, from the results obtained, trying to extrapolate for an arbitrary value of N. If we are lucky, some recursion expression for Eq. (14) for all N could be recognized.

Our approach to calculate the integral (15) is, for fixed n and arbitrary N, to explore the block-structure of matrices $\mathbf{A}^{\sigma\sigma}$, $\sigma=\uparrow$ and $\sigma=\downarrow$, diagonalizing it through a similarity transformation

$$\mathbf{P}^{-1}\mathbf{A}^{\sigma\sigma}\mathbf{P}=\mathbf{D}, \tag{17}$$

where the matrix $\mathbf{D}$ is

$$\mathbf{D}=\begin{pmatrix} \lambda_1 \mathbb{1}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} \\ \mathbb{0}_{N^d\times N^d} & \lambda_2 \mathbb{1}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} \\ \vdots & & & \vdots \\ \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & \lambda_n \mathbb{1}_{N^d\times N^d} \end{pmatrix}, \tag{18}$$

and λ_i, $i=1,2,...,n$, are the eigenvalues of matrices $\mathbf{A}^{\sigma\sigma}$, $\sigma=\uparrow,\downarrow$, and calculate the cofactors of the matrix $\mathbf{D}$. The jth column of matrix $\mathbf{P}$ is the eigenvector of $\mathbf{A}^{\sigma\sigma}$ associated to the eigenvalue λ_j. Each eigenvalue of matrix $\mathbf{A}^{\sigma\sigma}$ has degeneracy N^d. The matrices are not Hermitian, thus some eigenvalues are complex. In the following, we will be working on the $\sigma\sigma=\uparrow\uparrow$ sector; however, the results for the $\sigma\sigma=\downarrow\downarrow$ sector are analogous since $\mathbf{A}^{\uparrow\uparrow}=\mathbf{A}^{\downarrow\downarrow}$.

We will apply the following transformation of variables,

$$\eta'=\mathbf{P}^{-1}\eta \quad \text{and} \quad \overline{\eta'}=\overline{\eta}\mathbf{P}, \tag{19}$$

where $\eta'\equiv\{\eta'_1,\dots,\eta'_{nN^d}\}$ and $\overline{\eta'}\equiv\{\overline{\eta'_1},\dots,\overline{\eta'_{nN^d}}\}$. The Jacobian of the transformation (19) is equal to one.

Due to the fact that $\mathbf{A}^{\uparrow\uparrow}$ is a block matrix, the matrix $\mathbf{P}$ also has a block structure. This fact implies that transformations (19) do not mix up lattice indices.

In a schematic way, the integrals $M(L,K)$ [Eq. (15)] become

$$M(L,K)=\int \prod_{i=1}^{nN^d} d\eta_i \, d\overline{\eta_i}\, (\overline{\eta}\mathbf{P}^{-1})_{l_1}(\mathbf{P}\eta)_{k_1}\cdots(\overline{\eta}\mathbf{P}^{-1})_{l_m}(\mathbf{P}\eta)_{k_m} e^{\Sigma_{i,j=1}^{nN^d}\overline{\eta}_i D_{ij}\eta_j}, \tag{20}$$

where D_{ij} are the entries of the diagonal matrix $\mathbf{D}$. The expression $M(L,K)$ fits into the form of Eq. (15), and hence corresponds to some cofactor of the diagonalized matrix $\mathbf{D}$ [Eq. (16)]. It is very simple to calculate these cofactors, and the matrix $\mathbf{P}$ is the same for any self-interacting fermionic model.

In the Appendix we present the derivation of the eigenvalues and eigenvectors of matrix $\mathbf{D}$ for arbitrary values of n and N. From Eqs. (A25) and (A26), for arbitrary value of n, we have that

$$p_{\nu\nu'}^{(n)}=\frac{1}{\sqrt{n}} e^{(i\pi/n)(2\nu'+1)(\nu+1)}, \tag{21}$$

and

$$q_{\nu'\nu}^{(n)}=\frac{1}{\sqrt{n}} e^{-(i\pi/n)(2\nu'+1)(\nu+1)}, \tag{22}$$

with ν, $\nu'=0,1,...,n-1$, and

$$\mathbf{P}=\begin{pmatrix} p_{00}^{(n)}\mathbb{1}_{N^d\times N^d} & \cdots & p_{0,n-1}^{(n)}\mathbb{1}_{N^d\times N^d} \\ \vdots & & \vdots \\ p_{n-1,0}^{(n)}\mathbb{1}_{N^d\times N^d} & \cdots & p_{n-1,n-1}^{(n)}\mathbb{1}_{N^d\times N^d} \end{pmatrix} \tag{23}$$

and

$$\mathbf{P}^{-1}=\begin{pmatrix} q_{00}^{(n)}\mathbb{1}_{N^d\times N^d} & \cdots & q_{0,n-1}^{(n)}\mathbb{1}_{N^d\times N^d} \\ \vdots & & \vdots \\ q_{n-1,0}^{(n)}\mathbb{1}_{N^d\times N^d} & \cdots & q_{n-1,n-1}^{(n)}\mathbb{1}_{N^d\times N^d} \end{pmatrix}. \tag{24}$$

The diagonal elements of matrix $\mathbf{D}$ are

$$\lambda_\nu^{(n)}=1-e^{(i\pi/n)(2\nu+1)}, \quad \nu=0,1,..., n-1, \tag{25}$$

where the eigenvalues are N^d-fold degenerated, N^d being the number of lattice sites. Due to lattice translation symmetry, we should note that the elements $p_{\nu\nu'}^{(n)}$ and $q_{\nu\nu'}^{(n)}$ do not carry any lattice site index.

This is a general approach, and it can be applied to any self-interacting fermionic model. The important point here is that the relations (21)–(25) are valid for any self-interacting fermionic model with space translation symmetry.

III. APPLICATION TO HATSUGAI–KOHMOTO MODEL

The calculation of an exactly soluble model is a nice way to test a new approach. Hatsugai and Kohmoto[10] proposed a toy model (HK model) that shares the atomic and band limits of the Hubbard model.[11] Using the Green's function and path integral approaches, Nogueira and Anda[12] established the equivalence of this model (with unrestricted hopping) and the Hubbard model (with infinite-range hopping).

In this section we derive the grand canonical partition function of the HK model using the results presented in Sec. II. The Hamiltonian of the HK model in momentum space is[12]

$$\mathbf{H}=\sum_{\vec{k}}\sum_{\sigma=\uparrow,\downarrow}\varepsilon(\vec{k})\mathbf{n}_\sigma(\vec{k})+U\sum_{\vec{k}}\mathbf{n}_\uparrow(\vec{k})\mathbf{n}_\downarrow(\vec{k})\equiv\sum_{\vec{k}}\mathbf{H}(\vec{k}), \tag{26}$$

where $\mathbf{n}_\sigma(\vec{k})\equiv\mathbf{a}_\sigma^\dagger(\vec{k})\mathbf{a}_\sigma(\vec{k})$ and $\mathbf{a}_\sigma^\dagger(\vec{k})[\mathbf{a}_\sigma(\vec{k})]$ is the creation (destruction) operator of an electron with momentum $\vec{k}$ and spin σ. The function $\varepsilon(\vec{k})=-2t\Sigma_{i=1}^3\cos k_i$, $\vec{k}=(k_1,k_2,k_3)$, corresponds to the nearest hopping of the electrons in the dual-space lattice. U is the strength of the repulsion between electrons with the same momentum $\vec{k}$ but opposite spin conponents.

From Eqs. (1) and (26), the grand canonical partition function of the HK model is

$$\mathcal{Z}(\beta;\mu)=\mathrm{Tr}\left[\prod_{\vec{k}} e^{-\beta\mathbf{K}(\vec{k})}\right]=\prod_{\vec{k}}[\mathrm{Tr}_{\vec{k}}\, e^{-\beta\mathbf{K}(\vec{k})}]. \tag{27}$$

We have

$$\mathbf{K}(\vec{k})=\sum_{\sigma=\uparrow,\downarrow}\Delta(\vec{k})\mathbf{n}_\sigma(\vec{k})+U\mathbf{n}_\uparrow(\vec{k})\mathbf{n}_\downarrow(\vec{k}), \tag{28}$$

where we define $\Delta(\vec{k})\equiv\varepsilon(\vec{k})-\mu$, and μ is the chemical potential. In Eq. (27), the symbol $\mathrm{Tr}_{\vec{k}}$ stands for the trace for a fixed vector $\vec{k}$, whereas Tr represents the trace for all $\vec{k}$'s.

The high-temperature expansion for the grand canonical partition function $\mathcal{Z}(\beta;\mu)$ is

$$\mathrm{Tr}_{\vec{k}}[e^{-\beta\mathbf{K}(\vec{k})}]=\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\beta^n\,\mathrm{Tr}_{\vec{k}}[\mathbf{K}^n(\vec{k})]. \tag{29}$$

Since all the operators on the rhs of Eq. (28) commute, we can apply the Newton's multinomial expression to write $\mathrm{Tr}_{\vec{k}}[\mathbf{K}^n(\vec{k})]$ as

$$\mathrm{Tr}_{\vec{k}}[\mathbf{K}^n(\vec{k})]=\sum_{n_1,n_2,n_3=0}^{n}{}'\ \frac{n!}{n_1!n_2!n_3!}\Delta^{n_1+n_2}(\vec{k})U^{n_3}\,\mathrm{Tr}_{\vec{k}}[\mathbf{n}_\uparrow^{n_1+n_3}(\vec{k})\mathbf{n}_\downarrow^{n_2+n_3}(\vec{k})]. \tag{30}$$

The symbol Σ' means that the summation indices satisfy the condition $n_1+n_2+n_3=n$.

Let l_1, l_2, and l_3 be the integers that determine the lattice vector $\vec{k}$. The mapping (13) takes the index $\vec{k}$ into the index $L\equiv l_1+(l_2-1)N+(l_3-1)N^2$, where N is the number of points in the momentum lattice in each direction. In the sum on the rhs of Eq. (30), we calculate the trace for a fixed $\vec{k}$, which means that in Eq. (6) we take a single point in the momentum lattice $(N=1)$. Then,

$$\mathrm{Tr}_{\vec{k}}[\mathbf{n}_\uparrow^{n_1+n_3}(\vec{k})\mathbf{n}_\downarrow^{n_2+n_3}(\vec{k})]=\mathcal{I}^{\uparrow\uparrow}_{n_1,n_3}\times\mathcal{I}^{\downarrow\downarrow}_{n_2,n_3}, \tag{31}$$

where

$$\begin{aligned}\mathcal{I}^{\uparrow\uparrow}_{n_1,n_3}\equiv\int\prod_{I=1}^{n}\ d\eta_I(L)d\overline{\eta_I}(L)\ e^{\sum_{I,J=1}^{n}\overline{\eta}_I(L)A^{\uparrow\uparrow}_{IJ}\eta_J(L)}\\ \times\overline{\eta}_0(L)\,\eta_0(L)\cdots\overline{\eta}_{n_1-1}(L)\,\eta_{n_1-1}(L)\,\overline{\eta}_{n_1+n_2}(L)\,\eta_{n_1+n_2}(L)\cdots\overline{\eta}_{n-1}(L)\,\eta_{n-1}(L),\end{aligned} \tag{32}$$

and

$$\begin{aligned}\mathcal{I}^{\downarrow\downarrow}_{n_2,n_3}\equiv\int\prod_{J=n+1}^{2n}\ d\eta_J(L)d\overline{\eta_J}(L)\ e^{\sum_{I,J=n+1}^{2n}\overline{\eta}_I(L)A^{\downarrow\downarrow}_{IJ}\eta_J(L)}\\ \times\overline{\eta}_{n+n_1}(L)\,\eta_{n+n_1}(L)\cdots\overline{\eta}_{n+n_1+n_2-1}(L)\,\eta_{n+n_1+n_2-1}(L)\\ \times\overline{\eta}_{n+n_1+n_2}(L)\,\eta_{n+n_1+n_2}(L)\cdots\overline{\eta}_{2n-1}(L)\,\eta_{2n-1}(L).\end{aligned} \tag{33}$$

The matrices $\mathbf{A}^{\sigma\sigma}$, $\sigma=\uparrow,\downarrow$, are given by Eq. (11) with $N=1$. According to Eqs. (15) and (16), the presence of $\overline{\eta}$'s (and η's) in the integrand on the rhs of Eqs. (32) and (33) allows one to evaluate the integrals as the determinants of matrices obtained after deletion of lines (and columns) of the matrices $\mathbf{A}^{\sigma\sigma}$, $\sigma=\uparrow,\downarrow$. For this particular model, it turns out easier to apply Eq. (16) directly, rather than using the similarity transformation (17), since the lattice is unidimensional. We should mention that for $N=1$, we recover the case of the anharmonic fermionic oscillator, which has been considered in a previous work.[5] Now we discuss the values of $\mathcal{I}^{\uparrow\uparrow}_{n_1,n_3}$ [Eq. (32)], in view of the possible values of the indices (n_1,n_2,n_3).

(i) $n_1=n$, $n_2=0$, and $n_3=0$.

In this case the first n lines and the first n columns of matrix $\mathbf{A}^{\uparrow\uparrow}$ are deleted; hence,

$$\mathcal{I}^{\uparrow\uparrow}_{n,0}=1. \tag{34}$$

(ii) $n_1=0$, $n_2=n$, and $n_3=0$.

In this case no lines or columns are deleted in $\mathbf{A}^{\uparrow\uparrow}$; so,

$$\mathcal{I}^{\uparrow\uparrow}_{0,0}=\det(\mathbf{A}^{\uparrow\uparrow})=2. \tag{35}$$

(iii) $n_1=0$, $n_2=0$, and $n_3=n$.

This case is equal to case i and, therefore,

$$\mathcal{I}_{0,n}^{\uparrow\uparrow}=1. \tag{36}$$

(iv) $n_1\neq 0$, $n_2\neq 0$, and $n_3\neq 0$.

In this case, the first n_1 lines and columns are deleted, as well as the last n_3 lines and columns of matrix $\mathbf{A}^{\uparrow\uparrow}$. The triangular matrix thus obtained has its determinant equal to 1, for any value of n. Then,

$$\mathcal{I}_{n_1,n_3}^{\uparrow\uparrow}=1. \tag{37}$$

Equivalent results are valid for $\mathcal{I}_{n_2,n_3}^{\downarrow\downarrow}$.

From the results (34)–(37) and the equivalent results for $\mathcal{I}_{n_2,n_3}^{\downarrow\downarrow}$, we have

$$\mathrm{Tr}_{\vec{k}}[\mathbf{n}_{\uparrow}^{n_1+n_3}(\vec{k})\mathbf{n}_{\downarrow}^{n_2+n_3}(\vec{k})]=(1+\delta_{n_1+n_3,0})(1+\delta_{n_2+n_3,0}), \tag{38}$$

which, substituted in Eq. (30), gives

$$\mathrm{Tr}_{\vec{k}}[\mathbf{K}^n(\vec{k})]=[2\Delta(\vec{k})+U]^n+2\Delta^n(\vec{k}). \tag{39}$$

Returning to Eqs. (27) and (29), we finally get

$$\mathcal{Z}(\beta;\mu)=\prod_{\vec{k}}\,[1+e^{-\beta(2\Delta(\vec{k})+U)}+2e^{-\beta\Delta(\vec{k})}], \tag{40}$$

which gives the same free energy density found in Ref. 12.

IV. CONCLUSIONS

Calculations involving fermionic fields do demand some extra care, in comparison to the manipulation of bosonic fields. For this reason, fermionic models are usually bosonized, in a strategy designed to avoid the ''annoying'' fermionic features. However, moments of Grassmannian multivariable integrals can be easily calculated, as shown in Eqs. (15) and (16). In this paper we have presented a new approach, based on the explicit use of Grassmann algebra properties, to the problem of calculating the coefficients of the high temperature expansion of the grand canonical partition function for any d-dimensional self-interacting fermionic model ($d=1,2,3,...$). We have explored the results (15) and (16) and the possibility of performing the similarity transformation (17) for a system with arbitrary dimension d and arbitrary number of lattice points N^d. It is important to point out that the matrices $\mathbf{A}^{\sigma\sigma}(\sigma=\uparrow,\downarrow)$ are model independent; they are solely related to kinetical aspects of the approach. To simplify the notation, we considered that the number of points in each direction of the lattice is the same, but the results derived are still valid if this is not true. The fact that our results are analytical allows us to obtain the thermodynamical limit for any self-interacting fermionic model.

As a simple example of application of the method (that does not explore all of its features, though), we have considered the Hatsugai–Kohmoto model, which is diagonal in momentum space and had been solved by other approaches. We have derived its grand canonical partition function, and obtained the same free energy density found in the literature.[12]

The most important features of this method appear when the Hamiltonian has noncommuting terms and, consequently, Newton's multinomial expansion does not apply. Equations (15) and (16) and the similarity transformation (17) then become the keystone of our analytical results. That is the case of the Hubbard model;[11] the grand canonical partition function for the unidimensional version of this model is known in integral form.[13] A closed expression for this function was obtained by Takahashi,[13] within certain limits only. By the application of the approach we have presented here, we are currently calculating the coefficients of that partition function, up to order β^5 and for any value of the parameters of the model, as well for any value of the chemical potential. These calculations will soon be submitted for publication.

APPENDIX: CALCULATION OF EIGENVALUES AND EIGENVECTORS OF MATRIX $\mathbf{A}^{\sigma\sigma}$

This appendix is devoted to calculating the eigenvalues and eigenvectors of the matrix $\mathbf{A}^{\sigma\sigma}$, defined in Eq. (11), as well as determining the matrices $\mathbf{P}$ and $\mathbf{P}^{-1}$ that diagonalize it [see Eq. (17)].

The characteristic equation for $\mathbf{A}^{\sigma\sigma}$ is

$$\det\begin{pmatrix} (1-\lambda)\mathbb{1}_{N^d\times N^d} & -\mathbb{1}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} \\ \mathbb{0}_{N^d\times N^d} & (1-\lambda)\mathbb{1}_{N^d\times N^d} & -\mathbb{1}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & (1-\lambda)\mathbb{1}_{N^d\times N^d} & -\mathbb{1}_{N^d\times N^d} \\ \mathbb{1}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \mathbb{0}_{N^d\times N^d} & \cdots & \mathbb{0}_{N^d\times N^d} & (1-\lambda)\mathbb{1}_{N^d\times N^d} \end{pmatrix}=0. \tag{A1}$$

Observe that this matrix (of total dimension $nN^d\times nN^d$) consists of a $n\times n$ block matrix, each block having dimension $N^d\times N^d$. Moreover, these blocks are either null matrices $\mathbb{0}_{N^d\times N^d}$ or proportional to the identity matrix $\mathbb{1}_{N^d\times N^d}$.

We will demonstrate a useful property of the determinant of a block matrix in which all blocks are diagonal, such as the previous matrix. Take a block-matrix $\mathbf{M}$ composed of blocks $\mathbf{B}^{[i,j]}$, namely,

$$\mathbf{M}=\begin{pmatrix} \mathbf{B}^{[1,1]} & \mathbf{B}^{[1,2]} & \cdots & \mathbf{B}^{[1,n]} \\ \mathbf{B}^{[2,1]} & \mathbf{B}^{[2,2]} & \cdots & \mathbf{B}^{[2,n]} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{B}^{[n,1]} & \mathbf{B}^{[n,2]} & \cdots & \mathbf{B}^{[n,n]} \end{pmatrix}, \tag{A2}$$

where each block $\mathbf{B}^{[i,j]}$ is diagonal:

$$(\mathbf{B}^{[i,j]})_{\alpha\beta}=\delta_{\alpha\beta}\mathbf{b}_\alpha^{[i,j]}, \tag{A3}$$

where $\alpha,\beta=1,2,...,N^d$. (No summation over repeated indices is implied.) We define a ''determinant like'' matrix function $\mathbf{F}$ upon the blocks $\mathbf{B}^{[i,j]}$ as

$$\mathbf{F}\equiv\sum_{\theta_1,\theta_2,\dots,\theta_n=1}^{n}\varepsilon_{\theta_1,\theta_2,\dots,\theta_n}\mathbf{B}^{[1,\theta_1]}\mathbf{B}^{[2,\theta_2]}\cdots\mathbf{B}^{[n,\theta_n]}, \tag{A4}$$

where $\varepsilon_{\theta_1,\theta_2,\dots,\theta_n}$ is the Levi-Civita symbol in n-dimension. Obviously, $\mathbf{F}$ and the blocks $\mathbf{B}^{[i,j]}$ have all the same dimensions, $N^d\times N^d$. Using Eq. (A3), we have

$$F_{ab}=\delta_{a,b}\sum_{\theta_1,\theta_2,\dots,\theta_n=1}^{n}\varepsilon_{\theta_1,\theta_2,\dots,\theta_n}(\mathbf{b}_a^{[1,\theta_1]}\mathbf{b}_a^{[2,\theta_2]}\cdots\mathbf{b}_a^{[n-1,\theta_{n-1}]}\mathbf{b}_a^{[n,\theta_n]}). \tag{A5}$$

From Eq. (A5) and the definition of the determinant, we obtain

$$\det \mathbf{F} = \det \boldsymbol{\Gamma}_1 \det \boldsymbol{\Gamma}_2 \cdots \det \boldsymbol{\Gamma}_n, \tag{A6}$$

where we have defined n matrices $\boldsymbol{\Gamma}_p$ of dimension $N^d \times N^d$ as

$$(\boldsymbol{\Gamma}_p)_{uv} \equiv \mathbf{b}_p^{[u,v]}, \tag{A7}$$

so that

$$\det \boldsymbol{\Gamma}_p = \sum_{\omega_1,\omega_2,\ldots,\omega_N=1}^{N} \varepsilon_{\omega_1,\omega_2,\ldots,\omega_n} (\mathbf{b}_p^{[1,\omega_1]} \mathbf{b}_p^{[2,\omega_2]} \cdots \mathbf{b}_p^{[n-1,\omega_{n-1}]} \mathbf{b}_p^{[n,\omega_n]}). \tag{A8}$$

Thus, the evaluation of $\det \mathbf{F}$ is equivalent to the evaluation of the determinant of a block matrix $\boldsymbol{\Gamma}$, defined as

$$\boldsymbol{\Gamma} \equiv \begin{pmatrix} \boldsymbol{\Gamma}_1 & \mathbb{O}_{N^d \times N^d} & \cdots & \mathbb{O}_{N^d \times N^d} \\ \mathbb{O}_{N^d \times N^d} & \boldsymbol{\Gamma}_2 & \cdots & \mathbb{O}_{N^d \times N^d} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbb{O}_{N^d \times N^d} & \mathbb{O}_{N^d \times N^d} & \cdots & \boldsymbol{\Gamma}_n \end{pmatrix}. \tag{A9}$$

However, $\boldsymbol{\Gamma}$ and $\mathbf{M}$ only differ by an even number of permutations of lines and columns! More specifically, $\mathbf{M}$ can be recovered from $\boldsymbol{\Gamma}$ if we reorder the lines of the latter according to the pattern

$$\begin{aligned}(1,2,\ldots,nN^d) \rightarrow (&1,N^d+1,\, 2N^d+1,\ldots,(n-1)N^d+1,\, 2,N^d+2,2N^d+2,\ldots,(n-1)N^d+2,\ldots,\\ &N^d-1,2N^d-1,3N^d-2,\ldots,nN^d-1,N^d,2N^d,3N^d,\ldots,nN^d),\end{aligned} \tag{A10}$$

i.e., the 1st line is left untouched, the 2nd line is replaced by the $(N^d+1)^{th}$ line, etc., and then have the *columns* of the resulting matrix reordered in the same fashion. (The same result is obtained if we reorder columns before lines.) As the total number of permutations is even, we have

$$\det \mathbf{M} = \det \boldsymbol{\Gamma}. \tag{A11}$$

Combining (A11), (A6), and (A4), we finally obtain

$$\det \mathbf{M} = \det \mathbf{F} = \det \left(\sum_{\theta_1,\theta_2,\ldots,\theta_n=1}^{n} \varepsilon_{\theta_1\theta_2,\ldots,\theta_n} \mathbf{B}^{[1,\theta_1]} \mathbf{B}^{[2,\theta_2]} \cdots \mathbf{B}^{[n,\theta_n]} \right). \tag{A12}$$

In conclusion, if the matrix $\mathbf{M}$ is composed of diagonal blocks $\mathbf{B}^{[i,j]}$, the determinant of $\mathbf{M}$ is equal to the determinant of the matrix $\mathbf{F}$, defined as a ''determinantlike'' function upon the blocks $\mathbf{B}^{[i,j]}$.

Turning our attention back to Eq. (A1), we expand the determinant in terms of ''cofactors'', based on the last ''line'' of blocks:

$$\det \left((-1)^{1+n} \mathbb{1}_{N^d \times N^d} (-\mathbb{1}_{N^d \times N^d})^{n-1} + (-1)^{n+n} (1-\lambda) \mathbb{1}_{N^d \times N^d} (1-\lambda)^{n-1} \mathbb{1}_{N^d \times N^d}^{n-1}\right) = 0, \tag{A13}$$

which yields the characteristic equation

$$(1 + (1-\lambda)^n)^{N^d} = 0. \tag{A14}$$

There are n distinct eigenvalues λ_k, each one with multiplicity N^d, given by

$$\lambda_k = 1 - e^{i(\pi/n)(2k+1)}, \tag{A15}$$

where $k=0,1,2,...,n-1$. Observe that if λ_k is an eigenvalue, so is its complex conjugate: $\lambda_k^* = \lambda_{n-k-1}$. Let us denote by $\mathbf{V}_k$ an eigenvector of $\mathbf{A}^{\sigma\sigma}$ associated to λ_k. It has the structure

$$\mathbf{V}_k = \begin{pmatrix} \mathbf{v}_1 \\ \mathbf{v}_2 \\ \vdots \\ \mathbf{v}_n \end{pmatrix}, \tag{A16}$$

where each $\mathbf{v}_i$, $i=1,2,...,n$, is a $1\times N^d$ matrix. We obtain

$$\mathbf{v}_i = -(1-\lambda_k)^i \xi, \quad \text{where } i=1,...,n-1 \tag{A17}$$

and $\xi=\mathbf{v}_n$ is an *arbitrary* column vector of dimension N^d. There are N^d possible linearly independent choices for ξ, corresponding to N^d distinct eigenvectors associated to the same eigenvalue λ_k. We choose them to be

$$\xi_k^{(1)} = \begin{pmatrix} -1 \\ 0 \\ \vdots \\ 0 \\ 0 \end{pmatrix}, \quad \xi_k^{(2)} = \begin{pmatrix} 0 \\ -1 \\ \vdots \\ 0 \\ 0 \end{pmatrix}, \quad \ldots, \quad \xi_k^{(N^d-1)} = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ -1 \\ 0 \end{pmatrix}, \quad \xi_k^{(N^d)} = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ -1 \end{pmatrix}, \tag{A18}$$

so that each $\xi_k^{(l)}$ corresponds to an eigenvector $\mathbf{V}_k^{(l)}$, where $l=1,2,...,N^d$, associated to the eigenvalue λ_k.

The matrix $\mathbf{P}$ that diagonalizes $\mathbf{A}^{\sigma\sigma}$ can be obtained by concatenating all eigenvectors $\mathbf{V}_k^{(l)}$ for all eigenvalues λ_k, $k=0,1,...,n-1$, up to a normalizing factor R:

$$\mathbf{P} = \begin{pmatrix} p_{00}^{(n)} \mathbb{1}_{N^d\times N^d} & \cdots & p_{0,n-1}^{(n)} \mathbb{1}_{N^d\times N^d} \\ \vdots & & \vdots \\ p_{n-1,0}^{(n)} \mathbb{1}_{N^d\times N^d} & \cdots & p_{n-1,n-1}^{(n)} \mathbb{1}_{N^d\times N^d} \end{pmatrix}, \tag{A19}$$

where

$$p_{\nu\nu'}^{(n)} = R\ e^{(i\pi/n)(2\nu'+1)(\nu+1)}, \tag{A20}$$

with $\nu,\nu'=0,1,...,n-1$. The matrix

$$\mathbf{P}^{-1} = \begin{pmatrix} q_{00}^{(n)} \mathbb{1}_{N^d\times N^d} & \cdots & q_{0,n-1}^{(n)} \mathbb{1}_{N^d\times N^d} \\ \vdots & & \vdots \\ q_{n-1,0}^{(n)} \mathbb{1}_{N^d\times N^d} & \cdots & q_{n-1,n-1}^{(n)} \mathbb{1}_{N^d\times N^d} \end{pmatrix}, \tag{A21}$$

where

$$q_{\nu'\nu}^{(n)} = R' e^{-(i\pi/n)(2\nu'+1)(\nu+1)} \tag{A22}$$

is the inverse of $\mathbf{P}$, upon a suitable choice of R and R'; i.e.,

$$R = R' = 1/\sqrt{n}, \tag{A23}$$

so that they satisfy the relation

$$\sum_{\nu=0}^{n-1} p_{\nu_1\nu}^{(n)} q_{\nu\nu_2}^{(n)} = \delta_{\nu_1\nu_2}. \tag{A24}$$

Hence,

$$p^{(n)}_{\nu\nu'} = \frac{1}{\sqrt{n}} e^{(i\pi/n)(2\nu'+1)(\nu+1)}, \tag{A25}$$

$$q^{(n)}_{\nu'\nu} = \frac{1}{\sqrt{n}} e^{-(i\pi/n)(2\nu'+1)(\nu+1)}. \tag{A26}$$

Uniqueness of Gibbs states in the one-dimensional antiferromagnetic model with very long-range interaction is established. © *1999 American Institute of Physics.* [S0022-2488(99)03309-5]

I. INTRODUCTION

We study a model on the lattice $\mathbf{Z}^1$ with the Hamiltonian

$$\mathbf{H}(\varphi(x)) = \sum_{x,y\in\mathbf{Z}^1;x>y} U(x-y)\varphi(x)\varphi(y) - \mu\sum_{x\in\mathbf{Z}^1}\varphi(x), \tag{1}$$

where the spin variable $\varphi(x)$ takes the values 0 and 1, μ is a chemical potential. The antiferromagnetic potential $U(x)>0$ satisfies the following conditions:

(1) $U(x+y)+U(x-y)>2U(x);x,y\in\mathbf{Z}^1,x>y$.

(2) The function $U(x)$ can be extended to a twice continuously differentiable function such that $U(x)\sim A(x)^{-\gamma}$, $U'\sim -A\gamma x^{-\gamma-1}$ and $U''(x)\sim A\gamma(\gamma+1)x^{-\gamma-2}$ at $x\to\infty$; where $\gamma>1$, and A is a strong positive constant.

The first convexity condition plays a significant role for the structure of the set of all ground states of the model (1). The second condition determines the character of the potential's decrease at infinity and is important in further calculations.

The hypothesis on the uniqueness of the Gibbs states in the model (1) was stated by Sinai in 1983 (see Ref. 1, Problem 1).

It is well known that the condition $\Sigma_{x\in\mathbf{Z}^1,x>0}xU(x)<\infty$ automatically implies the uniqueness of the Gibbs states.[2–4] We investigate the phase transition problem in the model (1) in the alternative case, when $U(x)\sim Ax^{-\gamma}$, where $\gamma=1+\alpha$, $0<\alpha<1$.

The ferromagnetic version of this model [when the potential $U(x)$ is negative] was considered by Dyson in his well-known papers.[5,6] He proved the existence of two extreme limit Gibbs states P^+ and P^- corresponding to the ground states $\varphi(x)=+1$ and $\varphi(x)=-1$ at low temperatures.

A series of papers has been devoted to the investigation of the antiferromagnetic model (1).[1,7–13]

The validity of Sinai's hypothesis for rational values of the density (for almost each value of the external field) at low temperatures was proved in Ref. 13.

The main purpose of this paper is to extend the result of Ref. 13 to all values of the external field and to all values of the temperature.

Theorem 1: *The model (1) has a unique limit Gibbs state at all values of the temperature* β^{-1}.

Let us introduce necessary definitions. The set of all periodic configurations we denote by Φ^{per}. For every $\varphi\in\Phi^{\mathrm{per}}$, we define $q=\Sigma_{y=x+1}^{x+p}\varphi(x)$, where p is the period of φ. It is obvious that q does not depend on x. Therefore, the density of each periodic configuration is $\kappa=q/p$. It is more convenient to work with the reciprocal of the density, $\eta(\varphi(x))=p/q$, which represents the average distance between neighboring points at which $\varphi(x)=1$. For every configuration $\varphi\in\Phi^{\mathrm{per}}$ the mean energy $h(\varphi)$ is defined as follows:

$$h(\varphi(x))=\frac{1}{p}\sum_{y=x+1}^{x+p}\varphi(x)\sum_{z>0}U(z)\varphi(y+z).$$

The last expression does not depend on x.

The following definition is useful for describing the zero temperature phase diagram of the model (1).

We fix a positive rational number p/q.

A configuration $\varphi_0(x)\in\Phi^{\mathrm{per}}$ with $\eta(\varphi_0(x))=p/q$ is called a special ground state[1] if

$$h(\varphi(x))=\inf_{\varphi\in\Phi^{\mathrm{per}},\,\eta(\varphi)=p/q}h(\varphi).$$

Hubbard's criterion (Refs. 1 and 7): Let $\varphi\in\Phi^{\mathrm{per}}$ and $r_i(x;\varphi)$ denotes the distance between a particle placed at $x\in\mathbf{Z}^1$ and ith particle on the right. If for each x and i

$$[i\eta]\leqslant r_i(x;\varphi)\leqslant[i\eta]+1,$$

(the square brackets denote the integer part of the enclosed number) then φ is a special ground state.

The existence of configurations satisfying Hubbard's criterion (the special ground states) is shown in Ref. 1. The remarkable elegant formula for the special ground states was offered by Aubry. Here we give the construction of the special ground states for each fixed rational value of the density κ.[1]

Every rational number p/q has a unique decomposition into a finite continued fraction:
$p/q=[n_0,n_1,\dots,n_s]$, this means that

$$n_0+\cfrac{1}{n_1+\cfrac{1}{n_2+\dots+\cfrac{1}{n_s}}}.$$

The ground state for a configuration with $\eta=[n_0,n_1,\dots,n_s]$ will be constructed by recursion.

(1) $\eta=n_0\geqslant 1$, n_0 is an integer. The periodic configuration with equally distant x at which $\varphi(x)=1$ satisfies Hubbard's criterion i.e., is a special ground state. In this case $r_i(x;\varphi)=in_0$, $i>0$.

(2) $\eta=n_0+1/n_1$, where n_0 and n_1 are integers, $n_0\geqslant 1$, $n_1>1$. Then the (n_0n_1+1) periodic configuration

$$0\,\underbrace{\underbrace{0\dots01}_{n_0}\dots\underbrace{0\dots01}_{n_0}}_{n_1\ \text{times}}$$

also satisfies Hubbard's criterion and is a special ground state.

(3) $\eta=[n_0,n_1,\dots,n_s]$, where $n_0,n_1,\dots,n_s$ are integers, $n_0,n_1,\dots,n_s\geqslant 1$. For $s=0$ and $s=1$ the required configurations are already constructed. Suppose we have already constructed a ground state with $s=m$ and $\kappa=[n_0,n_1,\dots,n_m]$. Then the following configuration with $s=m+1$ and $\kappa=[n_0,n_1,\dots,n_{m+1}]$ is constructed as

$$\varphi(n_0,\dots,n_{m+1})=\varphi(n_0,\dots,n_{m-1})\,\underbrace{\varphi(n_0,\dots n_m)\dots\varphi(n_0,\dots,n_m)}_{n_{m+1}\ \text{times}}.$$

Here, $\varphi(n_0,\dots,nj)$, $j=m-1$, $m,m+1$, are the blocks from which the ground states for $\eta=[n_0,\dots,n_j]$ are obtained by periodic continuations.

The constructed configuration satisfies Hubbard's criterion and therefore is a special ground state for $\eta=[n_0,n_1,\dots,n_m,n_{m+1}]$.[1]

The following explicit expression for the mean energy of the special ground state follows from Hubbard's criterion:[1]

$$h_\kappa = \kappa \sum_{i=1}^{\infty} U(m_i)\pi_i + U(m_i+1)(1-\pi_i), \tag{2}$$

where $m_i = [i\eta]$, $\pi_i = 1 + m_i - i\eta$.

This formula shows that the function of mean energy as a function of the density κ is continuous on the set of all rationals and can be extended to a continuous function defined on whole segment [0, 1].

Theorem 2: *(Refs. 9 and 1.)* (1) *The function h_κ is convex.*

(2) *In each rational point the function h_κ has a left-hand derivative μ_κ^- and a right-hand derivative μ_κ^+, with $\mu_\kappa^+ > \mu_\kappa^-$.*

(3) *The Lebesgue measure of the complement of the set $\cup_\kappa(\mu_\kappa^-, \mu_\kappa^+)$ in the real line $\mathbf{R}$ is zero.*

The following theorem gives the full description of the set of all special ground states of the model (1) at rational densities.

Theorem 3: *(Ref. 12.) Suppose that the value of the external field μ of the model (1) belongs to the interval $(\mu_\kappa^-, \mu_\kappa^+)$ for some number $\kappa = q/p$. Then the special ground state of the model* (1) *is unique up to translations.*

Following Theorem 4 generalizes the main result of Ref. 13 for all values of the temperature and is a special case (rational densities) of Theorem 1.

Theorem 4: Suppose that the value of the external field μ of the model (1) belongs to the interval $(\mu_\kappa^-, \mu_\kappa^+)$ for some number $\kappa = q/p$.

Then the model (1) has a unique limit Gibbs state at all values of the temperature β^{-1}.

Suppose that the value of the external field μ of the model (1) belongs to the interval $(\mu_\kappa^-, \mu_\kappa^+)$ for some number $\kappa = q/p$.

Let us consider an arbitrary configuration $\varphi(x)$. We say that $\varphi([a,b])$; $a,b \in \mathbf{Z}^1$ is a preregular phase, if there exists a special ground state φ_κ, such that the restriction of this configuration to $[a,b]$ coincides with $\varphi([a,b])$. We say that $\varphi([c,d])$; $c,d \in \mathbf{Z}^1$ is a regular phase, if there exists a preregular phase $\varphi([a,b])$; $a,b \in \mathbf{Z}^1$, such that $c - a > d_0 p$ and $b - d > d_0 p$. Thus, right and left $d_0 p$ extensions of a regular phase are ground states.

Let us consider a set $A = \cup_i [a_i, b_i]$, where $\varphi([a_i, b_i])$ is a regular phase and supp PB is the complement of A in $\mathbf{Z}^1$. The connected components of supp PB defined in such a way are called supports of precontours and are denoted by supp PK: supp $PK = \cup_{i \in \mathrm{Ind}}$ supp PK_i.

For each fixed rational density κ the constant d_0 satisfies some technical conditions.[13] In this work we do not need the explicit value of d_0.

Definition 1 (Ref. 13): The pair $PK = (\mathrm{supp}\, PK, \varphi'(\mathrm{supp}\, PK))$ is called a precontour. The set of all precontours is called a preboundary PB of the configuration $\varphi'(x)$. Two precontours PK_1 and PK_2 are said to be connected if dist(supp PK_1, supp PK_2) $< N_b$. The set of precontours (PK_i; $i \in$ Ind) is called connected if for any two precontours PK_c and PK_d; $c,d \in$ Ind there exists a collection $(PK_{j_1} = PK_c, \ldots, PK_{j_i}, \ldots, PK_{j_{n-1}}, PK_{j_n} = PK_d)$; $j_i \in$ Ind, $i = 1,...,n$; such that any two precontours PK_{j_i} and $PK_{j_{i+1}}$, $i = 1,...,n-1$ are connected. Let $\cup_{i=1}^n PK_i$ be some maximal connected component of the preboundary PB. Suppose that supp $PK_i = [a_i, b_i]$ and $b_i < a_{i+1}$; $i = ,\ldots, n-1$.

The pair $K = (\mathrm{supp}\, K, \varphi'(\mathrm{supp}\, PK))$, where supp $K = [a_1, b_n]$ is called a contour. The set of all contours is called a boundary B of the configuration $\varphi'(x)$.

In this work we do not need the exact value of the constant N_b.[12] From Ref. 12 it becomes clear that $\lim_{p\to\infty} N_b = \infty$. Thus, for irrational values of the density κ N_b is not defined, but as will be seen below, we do not need to define N_b for irrational densities.

Note that supp $K = (\cup_{i=1}^n \mathrm{supp}\, PK_i) \cup ([a_1, b_n] - (\cup_{i=1}^n \mathrm{supp}\, PK_i)) = \mathrm{supp}^1 K \cup \mathrm{supp}^2 K$.

The sets $\mathrm{supp}^1 K$ and $\mathrm{supp}^2 K$ will be, respectively, called the essential and regular parts of the support $\mathrm{supp}\, K$.

Let the boundary conditions $\overline{\varphi}(x)=[\varphi(x),x\in(-\infty,-V-1]\cup[V+1,\infty)]$ be fixed. The set of all configurations $\varphi(x)$; $x\in[-V,V]$ we denote via $\Phi(V)$.

It is obvious that for each contour K, such that $\mathrm{supp}\, K\in[-V+(d_0+1)p,V-(d_0+1)p]$, there exists a configuration $\psi_K([-V,V])$ such that the boundary of the configuration $\psi_K([-V,V])$ includes the contour K only:

$$B(\psi_K([-V,V]))=K.$$

Let $\mathrm{supp}\, K=[a,b]$. It is obvious that the restrictions of the configuration $\psi_K([-V,V])$ to the segments $[-V,a-1]$ and $[b+1,V]$ coincide with two ground states $\varphi_\kappa^1(x)$ and $\varphi_\kappa^2(x)$.

A contour K is called an interface contour, if $\varphi_\kappa^1(x)\neq\varphi_\kappa^2(x)$.

Note that, $\varphi_\kappa^1(x)$ can be obtained by some shifting of the configuration $\varphi_\kappa^2(x)$.

An interface contour will be denoted as IK.

Let K be a usual contour (not an interface contour) $K,\mathrm{supp}\, K\subset[-V,V]$ and $\psi K(x)=\psi([-V,V])$ *if* $x\in[-V,V]$, and $\overline{\varphi}(x)$ if $x\in(-\infty,-V-1]\cup[V+1,\infty)$; $IK,\mathrm{supp}\, IK\subset[-V,V]$ be an interface contour and $\psi_{IK}(x)=\psi([-V,V])$ if $x\in[-V,V]$, and $\overline{\varphi}(x)$ if $x\in(-\infty,V-1]\cup[V+1,\infty)$; and $\overline{\varphi}_\kappa^1(x)=\varphi_\kappa^1(x)$, if $x\in[-V,V]$, and $\overline{\varphi}(x)$ if $x\in(-\infty,-V-1]\cup[V+1,\infty)$.

Below the configuration $\overline{\varphi}_\kappa^1(x)$ defined for usual contours will be denoted by $\overline{\varphi}_\kappa(x)$.

The weights of the usual contour K and interface contour IK will be calculated by the following formulas:

$$\gamma(K)=H(\psi_K(x))-H(\overline{\varphi}_\kappa(x)), \tag{3}$$

$$\gamma(IK)=H(\psi_{IK}(x))-H(\overline{\varphi}_\kappa^1(x)). \tag{4}$$

The proof of Theorem 4 is based on the following idea. Let the boundary conditions $\overline{\varphi}(x)=[\varphi(x),x\in(-\infty,-V-1]\cup[V+1,\infty)]$ be fixed. The set of all configurations $\varphi(x)$; $x\in[-V,V]$ we denote via $\Phi(V)$. Suppose a configuration $\varphi_{\min}(x)\in\Phi(V)$ be a configuration with the minimal energy:

$$H(\varphi_{\min}(x))=\min_{\varphi(x)\in\Phi(V)}H(\varphi(x))\,.$$

Then the configuration $\varphi_{\min}(x)$ almost coincides with a special ground state of the model (1) (Lemma 1 in Sec. II). This fact allows us, based on special ground states, to define a common (for all boundary conditions) contour model and after that by using well-known trick[14] (this trick, which was introduced in Ref. 14 for some special extensions of Pirogov–Sinai theory, is directly applicable to one-dimensional models with long-range interaction) to come to noninteracting clusters from interacting contours. Consider an arbitrary segment I, a sufficiently large volume V, two arbitrary boundary conditions $\varphi^1(x)$ and $\varphi^2(x)$. It turns out that the dependence of the expression $\mathbf{P}^1(\varphi'(I))/\mathbf{P}^2(\varphi'(I))$ on the boundary conditions $\varphi^1(x)$ and $\varphi^2(x)$ can be estimated through the sum of statistical weights of super clusters connecting the segment I with the boundary and this sum is negligible. Thus, two arbitrary extreme Gibbs states are relatively continuous and hence coincide. In Ref. 13 we developed this method [the estimation of dependence of the expression $\mathbf{P}^1(\varphi'(I))/\mathbf{P}^2(\varphi'(I))$ on the boundary conditions through the sum of statistical weights of super clusters connecting the segment I with the boundary] at low temperatures. It turns out that after some modification the method works at all temperatures.

The contents of this paper are as follows. In Sec. II we prove Theorem 4, in Sec. III we complete the proof of Theorem 1.

II. UNIQUENESS OF GIBBS STATES: THE DENSITY κ IS p/q

Let us now introduce some necessary facts.

Suppose that the value of the external field μ of the model (1) belongs to the interval $(\mu_\kappa^-, \mu_\kappa^+)$ for some number $\kappa = q/p$.

Let the boundary conditions $\varphi^1(x) = [\varphi^1(x), x \in (-\infty, -V-1] \cup [V+1, \infty)]$ be fixed and

$$H(\varphi(x)|\varphi^1(x)) = -\mu \sum_{x \in \mathbf{Z}^1, x \in [-V,V]} \varphi(x) + \sum_{x,y \in \mathbf{Z}^1, x>y; x,y \in [-V,V]} U(x-y)\varphi(x)\varphi(y)$$
$$+ \sum_{x,y \in \mathbf{Z}^1, x>y; x \in [-V,V]; y \notin [-V,V]} U(x-y)\varphi(x)\varphi^1(y)$$
$$+ \sum_{x,y \in \mathbf{Z}^1, x>y; x \notin [-V,V], y \in [-V,V]} U(x-y)\varphi^1(x)\varphi(y). \tag{5}$$

Lemma 1: Let $\varphi_{\min}(x) \in \Phi(V)$ *be a configuration with the minimal energy:*

$$H(\varphi_{\min}(x)|\varphi^1(x)) = \min_{\varphi(x) \in \Phi(V)} H(\varphi(x)|\varphi^1(x)) .$$

Then the configuration $\varphi_{\min}(x)$ *has the following structure.*

The restriction of the configuration $\varphi_{\min}(x)$ on the set $[-V+N_b, V-N_b]$ *contains at most* $p-1$ *contours, moreover, all of them are interface contours* $IK_{i,}$, $i=1,...,m$, *where* $m<p-1$ *and* $|\mathrm{supp}\, IK_i| < 3d_0 p + N_b$.

Lemma 1 was proved in Ref. 13 [see Lemma 12 (Ref. 13) and Sec. 5 of Ref. 13].

Let $H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x))$ denote the relative energy of a configuration $\varphi(x)$ [with respect to $\varphi_{\min}(x)$]:

$$H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x)) = H(\varphi(x)|\varphi^1(x)) - H(\varphi_{\min}(x)|\varphi^1(x)).$$

Consider the Gibbs distribution $\mathbf{P}^1$ on $\Phi(V)$ corresponding to the boundary conditions $\varphi^1(x) = [\varphi^1(x), x \in (-\infty, -V-1] \cup [V+1, \infty)]$:

$$\mathbf{P}^1(\varphi'(x)) = \frac{\exp(-\beta(H(\varphi'(x)|\varphi^1(x), \varphi_{\min}(x))))}{\sum_{\varphi(x) \in \Phi(V)} \exp(-\beta(H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x))))}. \tag{6}$$

Let $\varphi(x) \in \Phi(V)$ be an arbitrary configuration, the boundary of the $\varphi(x)$ includes a finite number of usual contours K_i; $i=1,...,n$, and a finite number of interface contours IK_i; $i=n+1,...,n+m$. Let $K_i = K_i$; $i=1,...,n$; $K_i = IK_i$; $i=n+1,...,n+m$. The set of all contours of the boundary conditions $\varphi^1(x)$ will be denoted by K_0.

The statistical weights of contours and interface contours are

$$w(K_i) = \exp(-\beta\gamma(K_i)). \tag{7}$$

The following equation is a direct consequence of the formulas (3), (4), and (7)

$$\exp(-\beta H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x))) = Q_1 \prod_{i=1}^{n+m} w(K_i) \exp(-\beta G(K_0, K_1, \ldots, K_{n+m}), \tag{8}$$

where the multiplier $G(K_0, K_1, \ldots, K_{n+m})$ corresponds to the interaction between contours (usual and interface), and with the boundary conditions $\varphi^1(x)$

$$G(K_0, K_1, \ldots, K_{n+m}) = \sum_{i,j=0; i<j}^{n+m} G(K_i, K_j) = \sum_{i,j; i<j} \sum_{(x,y) \in \mathrm{Int}(K_i, K_j)} f(x,y,\varphi) \tag{9}$$

and the multiplier $Q_1 = Q_1(V, \varphi(x), \varphi^1(x))$ is uniformly bounded from below and above: $0 < \mathrm{const}_1 < Q_1 < \mathrm{const}_2$. The factor Q_1 appears due to the facts that the configuration $\varphi_{\min}(x)$ not necessarily coincides with a special ground state and is bounded due to Lemma 1.

Now we write down the value of the interaction between the contours K_i and K_j, the value of the interaction between the interface contours IK_i and IK_j and the value of the interaction between contour K_i and interface contour IK_j.

Suppose $\operatorname{supp} K_l=[a_l,b_l]$; $\operatorname{supp} IK_l=[a_l,b_l]$.

Let

$$\operatorname{supp} IK_i^+=[b_i,a_{i+1}] \quad \text{and} \quad \operatorname{supp} IK_i^-=[b_{i-1},a_i],$$

where $b_0=c$, if there exists $K\in B(\varphi'(x))$, such that $\operatorname{supp} K=[-\infty,c]$ and $b_0=-\infty$ otherwise; $a_{m+1}=d$, if there exists $K\in B(\varphi'(x))$, such that $\operatorname{supp} K=[d,\infty]$ and $a_{m+1}=\infty$ otherwise.

(1) The contour $K_i\in B(\varphi'(x))$ interacts with the contour $K_j\in B(\varphi'(x))$ through all pairs (x,y), such that $(x,y)\in \operatorname{Int}(K_i,K_j)$ and $f'(x,y,\varphi)\neq 0$ where

$$\operatorname{Int}(K_i,K_j)=[(x,y):x,y\in \mathbf{Z}^1; x\in \operatorname{supp} K_i, y\in \operatorname{supp} K_j].$$

The value of the interaction

$$f'(x,y,\varphi)=U(x-y)(\varphi'(x)\varphi'(y)-\psi_{K_i}(x)\psi_{K_i}(y)+\overline{\varphi^i_\kappa}(x)\overline{\varphi^i_\kappa}(y)$$
$$-\psi_{K_j}(x)\psi_{K_j}(y)+\overline{\varphi^j_\kappa}(x)\overline{\varphi^j_\kappa}(y)).$$

(2) The interface contour $IK_i\in B(\varphi'(x))$ interacts with the interface contour $IK_j\in B(\varphi'(x))$ (let $a_j>b_i$) through all pairs (x,y), such that $(x,y)\in \operatorname{Int}(IK_i,IK_j)$ and $f''(x,y)\neq 0$, where

$$\operatorname{Int}(IK_i,IK_j)=\operatorname{Int}^1(IK_i,IK_j)+\operatorname{Int}^2(IK_i,IK_j)+\operatorname{Int}^3(IK_i,IK_j)+\operatorname{Int}^4(IK_i,IK_j),$$

$$\operatorname{Int}^1(IK_i,IK_j)=[(x,y):x,y\in \mathbf{Z}^1; x\in \operatorname{supp} IK_i \text{ and } y\in \operatorname{supp} IK_j],$$

$$\operatorname{Int}^2(IK_i,IK_j)=[(x,y):x,y\in \mathbf{Z}^1; x\in \operatorname{supp} IK_i \text{ and } y\in \operatorname{supp} IK_j^+],$$

$$\operatorname{Int}^3(IK_i,IK_j)=[(x,y):x,y\in \mathbf{Z}^1; x\in \operatorname{supp} IK_i^- \text{ and } y\in \operatorname{supp} IK_j],$$

$$\operatorname{Int}^4(IK_i,IK_j)=[(x,y):x,y\in \mathbf{Z}^1; x\in \operatorname{supp} IK_i^- \text{ and } y\in \operatorname{supp} IK_j^+].$$

The value of the interaction

$$f''(x,y,\varphi)=f''_1(x,y)=U(x-y)(\varphi'(x)\varphi'(y)-\psi_{IK_i}(x)\psi_{IK_i}(y)$$
$$+\overline{\varphi^i_\kappa}(x)\overline{\varphi^i_\kappa}(y)-\psi_{IK_j}(x)\psi_{IK_j}(y)+\overline{\varphi^j_\kappa}(x)\overline{\varphi^j_\kappa}(y))$$

if $(x,y)\in \operatorname{Int}^2(IK_i,IK_j)$,

$$f''(x,y)=f''_2(x,y)=U(x-y)(\varphi'(x)\varphi'(y)-\psi_{IK_i}(x)\psi_{IK_i}(y)+\overline{\varphi^i_\kappa}(x)\overline{\varphi^i_\kappa}(y))$$

if $(x,y)\in \operatorname{Int}^2(IK_i,IK_j)$,

$$f''(x,y)=f''_3(x,y)=U(x-y)(\varphi'(x)\varphi'(y)-\psi_{IK_j}(x)\psi_{IK_j}(y))+\overline{\varphi^j_\kappa}(x)\overline{\varphi^j_\kappa}(y))$$

if $(x,y)\in \operatorname{Int}^3(IK_i,IK_j)$,

$$f''(x,y)=f''_4(x,y)=U(x-y)(\varphi'(x)\varphi'(y)-\overline{\varphi^{1,i}_\kappa}(x)\overline{\varphi^{1,i}_\kappa}(y)-\overline{\varphi^{2,j}_\kappa}(x)\overline{\varphi^{2,j}_\kappa}(y))$$

if $(x,y)\in \operatorname{Int}^4(IK_i,IK_j)$.

(3) The contour $K_i \in B(\varphi'(x))$ interacts with the interface contour $IK_j \in B(\varphi'(x))$ through all pairs (x,y), such that $(x,y) \in \mathrm{Int}(K_i, IK_j)$ and $f'''(x,y) \neq 0$, where

$$\mathrm{Int}(K_i, IK_j) = \mathrm{Int}^1(K_i, IK_j) + \mathrm{Int}^2(K_i, IK_j),$$

$$\mathrm{Int}^1(K_i, IK_j) = [(x,y): x,y \in \mathbf{Z}^1; x \in \mathrm{supp}\, K_i \quad \text{and} \quad y \in \mathrm{supp}\, IK_j],$$

$$\mathrm{Int}^2(K_i, IK_j) = [(x,y): x,y \in \mathbf{Z}^1; x \in \mathrm{supp}\, K_i \quad \text{and} \quad y \in \mathrm{supp}\, IK_j^+]$$

if $a_j > b_i$, and

$$\mathrm{Int}^2(K_i, IK_j) = [(x,y): x,y \in \mathbf{Z}^1; x \in \mathrm{supp}\, K_i \quad \text{and} \quad y \in \mathrm{supp}\, IK_j^-]$$

if $a_i > b_j$.
The value of the interaction

$$f'''(x,y) = f_1'''(x,y) = U(x-y)(\varphi'(x)\varphi'(y) - \psi_{K_i}(x)\psi_{K_i}(y) + \overline{\varphi^i_\kappa}(x)\overline{\varphi^i_\kappa}(y) - \psi_{IK_j}(x)\psi_{IK_j}(y)) + \overline{\varphi^j_\kappa}(x)\overline{\varphi^j_\kappa}(y))$$

if $(x,y) \in \mathrm{Int}^1(K_i, IK_j)$,

$$f'''(x,y) = f_2'''(x,y) = U(x-y)(\varphi'(x)\varphi'(y) - \psi_{K_i}(x)\psi_{K_i}(y) + \overline{\varphi^i_\kappa}(x)\overline{\varphi^i_\kappa}(y))$$

if $(x,y) \in \mathrm{Int}^2(K_i, IK_j)$.

For simplicity K_i, $i = 1,...,n+m$ will be denoted by K_i, $i \in \mathrm{Ind}$, where the statistical weights $w(K_i)$ are defined by the formulas (7), (3), and (4). Thus, the formula (8) has the form

$$\exp(-\beta H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x))) = Q_1 \prod_{i \in \mathrm{Ind}} w(K_i) \exp(-\beta G(K_0, K_1, \ldots, K_{n+m})). \tag{10}$$

The set of all pairs (x,y) in the double sum (9) will be denoted by $Y = Y(K_0, K_1, \ldots, K_{n+m})$. Write (10) as follows:

$$\exp(-\beta H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x))) = Q_1 \prod_{i \in \mathrm{Ind}} w(K_i) \prod_{(x,y) \in Y} (1 + \exp(-\beta f(x,y,\varphi) - 1). \tag{11}$$

From (11) we get

$$\exp(-\beta H(\varphi(x)|\varphi^1(x), \varphi_{\min}(x))) = Q_1 \prod_{G' \subset G} \prod_{i \in \mathrm{Ind}} w(K_i) \prod_{(x,y) \in Y'; f(x,y,\varphi) \neq 0} g(x,y), \tag{12}$$

where the summation is taken over all subsets Y' (including the empty set) of the set Y, and $g(x,y,\varphi) = \exp(-\beta f(x,y,\varphi)) - 1$.

Consider an arbitrary term of the sum (12), which corresponds to the subset $Y' \subset Y$. Let the bond $(x,y) \in Y'$. Below, contours and interface contours will be called contours. Consider the set $\mathbf{K}$ of all contours such that for each contour $K \subset \mathbf{K}$, the set $\mathrm{supp}\, K \cap (x \cup y)$ contains one point. We call any two contours from $\mathbf{K}$ connected. The set of contours $\mathbf{K}$ is called Y' connected if for any two contours K_a and K_b there exists a collection $(K_1 = K_a, K_2, \ldots, K_n = K_b)$ such that any two contours K_i and K_{i+1}, $i = 1,...,n-1$, are connected by some bond $(x,y) \in Y'$.

The pair $D = [(K_i, i = 1,...,s); Y']$, where Y' is some set of bonds, is called a cluster provided there exists a configuration $\varphi(x)$ such that $K_i \in B(\varphi(x))$; $i = 1,...,s$; $Y' \subset Y$; and the set $(K_i$, $i = 1,...,s)$ is Y' connected. The statistical weight of a cluster D is defined by the formula.

$$w(D)=\prod_{i=1}^{s} w(K_i) \prod_{(x,y)\in Y'} g(x,y,\varphi). \tag{13}$$

Two clusters D_1 and D_2 are called compatible provided any two contours K_1 and K_2 belonging to D_1 and D_2, respectively, are compatible and not connected. A set of clusters is called compatible provided any two clusters of it are compatible.

If $D=[(K_i,i=1,...,s);Y']$, then we say that $K_i\in D$; $i=1,...,s$.

The following lemma is a direct consequence of the definitions.

Lemma 2: Let the boundary conditions $\varphi^1(x)=[\varphi^1(x),x\in(-\infty,-V-1]\cup[V+1,\infty)]$ *be fixed.*

If $[D_1,\ldots,D_m]$ *is a compatible set of clusters and* $\cup_{i=1}^m \operatorname{supp} D_i\subset[-V,V]$, *then there exists a configuration* $\varphi(x)$ *which contains this set of clusters. For each configuration* $\varphi(x)$ *we have*

$$\exp(-\beta H(\varphi(x)|\varphi^1(x),\varphi_{\min}(x)))=Q_1\sum_{Y'\subset Y}\prod w(D_i),$$

where the clusters D_i *are completely determined by the set* Y'. *The partition function is*

$$\Xi(\varphi^1(x))=Q\sum w(D_1)\cdots w(D_m),$$

where the summation is taken over all nonordered compatible collections of clusters and the factor $Q=Q(V,\varphi^1(x))$ *is uniformly bounded:* $0<\text{const}<Q<\text{const}_2$.

Lemma 2 shows that we come to noninteracting clusters from interacting contours.

Let $\mathbf{P}^1$ and $\mathbf{P}^2$ be two Gibbs states of the model (1) corresponding to the boundary conditions $\varphi^1(x)$ and $\varphi^2(x)$, respectively.

The following lemma has a key role in the proof of Theorem 4.

Lemma 3: Suppose that the value of the external field μ *of the model (1) belongs to the interval* $(\mu_\kappa^-,\mu_\kappa^+)$ *for some number* $\kappa=q/p$.

Then the measures $\mathbf{P}^1$ *and* $\mathbf{P}^2$ *are absolutely continuous with respect to each other.*

Proof: Let $I=[a,b]$ be an arbitrary segment and $\varphi'(I)$ be an arbitrary configuration.

In order to prove the lemma we show that there exist two positive constants s and S not depending on I, $\varphi^1(x)$, $\varphi^2(x)$ and $\varphi'(I)$, such that

$$s\leq \mathbf{P}^1(\varphi'(I))/\mathbf{P}^2(\varphi'(I))\leq S. \tag{14}$$

Let $\mathbf{P}_\mathbf{V}^\mathbf{1}$ and $\mathbf{P}_\mathbf{V}^\mathbf{2}$ be Gibbs measures corresponding to the boundary conditions $\varphi^1(x)$, and $\varphi^2(x)$, $x\in\mathbf{Z}^1-I_V$, respectively, where $I_V=[-V,V]$.

Therefore,

$$\lim_{V\to\infty}\mathbf{P}_\mathbf{V}^\mathbf{1}=\mathbf{P}^\mathbf{1} \quad \text{and} \quad \lim_{V\to\infty}\mathbf{P}_\mathbf{V}^\mathbf{2}=\mathbf{P}^\mathbf{2},$$

where by convergence we mean weak convergence of probability measures.

In order to establish the inequality (14) it will be proved that for each fixed interval I, $I\subset[-M,M]$ there exists a number $V_0(M)$, which depends on M only, such that

$$s\leq \mathbf{P}_\mathbf{V}^\mathbf{1}(\varphi'(I))/\mathbf{P}_\mathbf{V}^\mathbf{2}(\varphi'(I))\leq S \tag{15}$$

if $V>V_0$.

Consider

$$\mathbf{P}_{\mathbf{V}}^{\mathbf{1}}(\varphi'(I))=\frac{\sum_{\varphi(I_V):\varphi(I)=\varphi'(I)}\exp(-\beta H(\varphi(I_V)|\varphi^1(x),\varphi_{\min}(x)))O(\varphi(I),V,\varphi^1)}{\sum_{\varphi(I_V)}\exp(-\beta H(\varphi(I_V)|\varphi^1(x),\varphi_{\min}(x)))O(\varphi(I),V,\varphi^1)}$$
$$=\frac{\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))O(\varphi(I),V,\varphi^1)}{\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^1(x),\varphi''(I),\varphi_{\min}(x))O(\varphi(I),V,\varphi^1)}$$

where $\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))$ denotes the partition function corresponding to the boundary conditions $\varphi^1(x),\ x\in\mathbf{Z}^1-I_V,\ \varphi'(I),\ x\in I$ and

$$O(\varphi(I),V,\varphi^1)=\exp(-\beta\sum_{x,y\in\mathbf{Z}^1;x\in\mathbf{Z}^1-I_V,y\in I}U(x-y)(\varphi^1(x)\varphi(y)-\varphi^1(x)\varphi_{\min}(x))).$$

We can express $\mathbf{P}_{\mathbf{V}}^{\mathbf{2}}(\varphi'(I))$ in just the same way.

In order to prove the inequality (15) it is enough to establish inequality (16) and inequality (17):

$$1/2<O(\varphi(I),V,\varphi^i(x))<2,\quad i=1,2 \tag{16}$$

[where the inequalities in (16) are held uniformly with respect to $\varphi(I)$ and φ^i: for each I there exists V, not depending on $\varphi(I)$ and φ^i] and

$$1/S\leqslant\frac{\Xi(I_V-I|\varphi^1(x),\varphi''(I),\varphi_{\min}(x))}{\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))}\Bigg/\frac{\Xi(I_V-I|\varphi^2(x),\varphi''(I),\varphi_{\min}(x))}{\Xi(I_V-I|\varphi^2(x),\varphi'(I),\varphi_{\min}(x))}\leqslant1/s \tag{17}$$

for arbitrary $\varphi''(I)$.

Indeed, if the inequality (17) holds, then

$$\frac{\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))}{\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^1(x),\varphi''(I),\varphi_{\min}(x))}\Bigg/\frac{\Xi(I_V-I|\varphi^2(x),\varphi'(I),\varphi_{\min}(x))}{\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^2(x),\varphi''(I),\varphi_{\min}(x))}$$
$$=\mathbf{A}_{\mathbf{V}}^{\mathbf{1}}(\varphi'(I))/\mathbf{A}_{\mathbf{V}}^{\mathbf{2}}(\varphi'(I))$$
$$=1\Bigg/\left(\frac{\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^1(x),\varphi''(I),\varphi_{\min}(x))}{\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))}\Bigg/\frac{\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^2(x),\varphi''(I),\varphi_{\min}(x))}{\Xi(I_V-I|\varphi^2(x),\varphi'(I),\varphi_{\min}(x))}\right)$$
$$=1\Bigg/\frac{(\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^1(x),\varphi''(I,\varphi_{\min}(x)))\Xi(I_V-I|\varphi^2(x),\varphi'(I),\varphi_{\min}(x))}{(\sum_{\varphi''(I)}\Xi(I_V-I|\varphi^2(x),\varphi''(I),\varphi_{\min}(x)))\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))}.$$

Therefore,

$$1/(1/s)\leqslant\mathbf{A}_{\mathbf{V}}^{\mathbf{1}}(\varphi'(I))/\mathbf{A}_{\mathbf{V}}^{\mathbf{2}}(\varphi'(I))\leqslant1/(1/S)$$

since the quotient of $\sum_{i=1}^n a_i/\sum_{i=1}^n b_i$ lies between $\min(a_i/b_i)$ and $\max(a_i/b_i)$.

Thus, if in addition, the inequality (16) holds, then

$$2^{-4}s<\mathbf{P}_{\mathbf{V}}^{\mathbf{1}}(\varphi'(I)):\mathbf{P}_{\mathbf{V}}^{\mathbf{2}}(\varphi'(I))<2^4S.$$

Now we start to prove the inequalities (16) and (17).

It can be easily shown that (16) is a direct consequence of the condition $U(x)\sim Ax^{-\gamma}$, at $x\to\infty$; where $\gamma>1$, and A is a strong positive constant.

So, in order to complete the proof of Lemma 3 we must establish the following inequality [which is just transformed inequality (17)]:

$$1/S \leqslant \frac{\Xi(I_V-I|\varphi^1(x),\varphi''(I),\varphi_{\min}(x)))\Xi(I_V-I|\varphi^2(x),\varphi'(I),\varphi_{\min}(x))}{\Xi(I_V-I|\varphi^2(x),\varphi''(I),\varphi_{\min}(x)))\Xi(I_V-I|\varphi^1(x),\varphi'(I),\varphi_{\min}(x))} = \frac{\Xi^{1,''}\Xi^{2,'}}{\Xi^{2,''}\Xi^{1,'}} \leqslant 1/s. \tag{18}$$

Consider

$$\Xi^{1,''}\Xi^{2,'} = \Xi(I_V-I|\varphi^1(x),\varphi''(I),\varphi_{\min}(x))\Xi(I_V-I|\varphi^2(x),\varphi'(I),\varphi_{\min}(x)).$$

The following generalization of the definition of the compatibility allows us to represent $\Xi^{1,''}\Xi^{2,'}$ as a single partition function.

A set of clusters is called super compatible provided any of its two parts coming from two partitions sums is compatible. In other words, in super compatibility an intersection of supports of two clusters is allowed.

The following lemma is an analogue of Lemma 2.

Lemma 4: Let boundary conditions $\varphi^1(x)=[\varphi^1(x), x\in(-\infty,-V-1]\cup[V+1,\infty)]$ *and* $\varphi^2(x)=[\varphi^2(x), x\in(-\infty,-V-1]\cup[V+1,\infty)]$ *be fixed.*

If $[D_1,\ldots,D_m]$ *is a super compatible set of clusters and* $\cup_{i=1}^m \operatorname{supp} D_i \subset [-V,V]$, *then there exist two configurations* $\varphi^3(x)$ *and* $\varphi^4(x)$ *which contain this set of clusters. For each two configurations* $\varphi^3(x)$ *and* $\varphi^4(x)$ *we have*

$$\exp(-\beta H(\varphi^3(x)|\varphi^1(x),\varphi_{\min}(x))\exp(-\beta H(\varphi^4(x)|\varphi^1(x),\varphi_{\min}(x)) = Q_1 \sum_{G'\subset G, G''\subset G} \prod w(D_i),$$

where the clusters D_i *are completely determined by the sets* G' *and* G''. *The super partition function is*

$$\Xi^{1,'',2,'} = \Xi^{1,''}\Xi^{2,'} = Q\sum w(D_1)\cdots w(D_m),$$

where the summation is taken over all nonordered super compatible collections of clusters and the factor $Q=Q(V,\varphi^1(x),\varphi^2(x))$ *is uniformly bounded:* $0<\text{const}_1<Q<\text{const}_2$.

Lemma 4 is a direct consequence of the definitions.

An arbitrary connected component of an arbitrary super compatible set of clusters will be called a super clusters. A super cluster $SD=[(K_i, i=1,...,r);G']$ is said to be long if the intersection of the set $(\cup_{i=1}^m \operatorname{supp} K_i))\cup G'$ with both I and $\mathbf{Z}^1-I_V=(-\infty,-V-1]\cup[V+1,\infty)$ is nonempty. In other words, a long super cluster connects the boundary with the segment I.

A set of super clusters is called compatible provided the set of all clusters belonging to these super clusters are super compatible.

It turns out that in our estimates long super clusters are negligible.

Lemma 5: For each fixed interval I, there exists a number $V_0(I)$, *which depends on I only, such that if* $V>V_0(I)$

$$1/2\Xi^{1,',2,''} < \Xi^{1,',2,'',(n.l.)} = \sum w(SD_1)\cdots w(SD_m) < 3/2\Xi^{1,',2,''},$$

where the summation is taken over all nonlong, nonordered compatible collections of super clusters $[SD_1,\ldots,SD_m]$, $\cup_{i=1}^m \operatorname{supp}(SD_i)\subset I_N-I$ *corresponding to the boundary conditions* $\varphi^1(x),\varphi^2(x)$, $x\in\mathbf{Z}^1-I_V$; $\varphi'(x)$ *and* $\varphi''(x)$, $x\in I$.

Consider a collection of contours $K_0,K_1,\ldots,K_n$. The value of the interaction of the contour K_0 with the contours $K_1,\ldots,K_n$ we denote by $G(K_0|K_1,\ldots,K_n)$:

$$G(K_0|K_1,\ldots,K_n) = \prod_{B\in IG(0|1,\ldots,n)} (1+\exp(-\beta f(B)-1)), \tag{19}$$

where $IG(0|1,...,n)$ is the set of all interaction elements intersecting the support of the contour K_0.

Lemma 6:

$$G(K_0|K_1,\ldots,K_n)=\prod_{B\in IG(0|1,...,n)}|(1+\exp(-\beta f(B)-1))$$
$$\leqslant \mathrm{const}(\mathrm{dist}(0|1,...,n))^{-\alpha}(|\mathrm{supp}(K_0)|)^{1-\alpha}, \tag{20}$$

where $\mathrm{dist}(0|1,...,n)$ *is the distance between the support of* K_0 *and the union of the supports of contours* $K_1,\ldots,K_n$.

In other words, the interaction of $K_1,\ldots,K_n$ on K_0 tends to zero when the distance between them increases, and value of the interaction increases with a rate less than the length of the support of K_0.

The technical Lemma 6 follows from the decreasing conditions of the potential $U(x)$. For the rigorous proof see Ref. 13, Lemma 4.

The following lemma is an analogue of Lemma 5 for clusters (not super clusters).

Lemma 7: For each fixed interval I, there exists a number $V_0(I)$, *which depends on I only, such that if* $V>V_0(I)$

$$1/2\Xi^{1,'}<\Xi^{1,',(n.l.)}=\sum w(D_1)\ldots w(D_m)<3/2\Xi^{1,'},$$

where the summation is taken over all nonlong, nonordered compatible collections of clusters $[D_1,\ldots,D_m]$, $\cup_{i=1}^m \mathrm{supp}\, D_i\subset I_N-I$ *corresponding to the boundary conditions* $\varphi^1(x)$, $x\in \mathbf{Z}^1-I_V$; $\varphi'(x)$, $x\in I$.

Proof:

$$\Xi^{1,'}=\Xi^{1,',(n.l.)}+(\Xi^{1,'}-\Xi^{1,',(n.l.)})=\Xi^{1,',(n.l.)}+\Xi^{1,',(l.)},$$

where the summation in $\Xi^{1,',(l.)}$ is taken over all nonordered compatible collections of clusters $[D_1,\ldots,D_m]$ containing at least one long cluster, $\cup_{i=1}^m \mathrm{supp}\, D_i\subset I_N-I$ corresponding to the boundary conditions $\varphi^1(x)$, $x\in\mathbf{Z}^1-I_V$; $\varphi'(x)$, $x\in I$.

By dividing both sides of the last equality by $\Xi^{1,'}$, we get

$$1=\Xi^{1,',(n.l.)}/\Xi^{1,'}+\Xi^{1,',(l.)}/\Xi^{1,'}. \tag{21}$$

Now we are going to show that the second term (which is not necessarily positive) is negligible, that is the absolute value of it is less than 1/2 (actually we can show that the absolute value of the second term is less than any fixed positive number at sufficiently large values of V).

The term $\Xi^{1,',(l.)}/\Xi^{1,'}$ can be interpreted as a ''probability'' P (Long) of the event that there exists at least one long cluster.

We show that the absolute value of this ''probability'' is less than 1/2 by the following method. We estimate the density of long clusters: the probability that a given segment belongs to the support of some long cluster. Since some statistical weights of clusters are positive and some negative, we estimate the absolute values of these ''probabilities.'' We show that for a fixed segment the ''probability'' that this segment belongs to the support of some long cluster with positive ''probability'' minus the ''probability'' that this segment belongs to the support of some long cluster with negative ''probability'' is less than one. Since the density is less than one, by the law of large numbers a ''typical'' long cluster has not very long support, and therefore has long bonds. When V tends to infinity, the total length of bonds tends to infinity, and the impact of these bonds tends to zero.

Now we replace a statistical weight $w(D_i)$ of each cluster D_i belonging to the configuration containing at least one long cluster with its absolute value (and ''probability'' of long cluster becomes positive) and the expression $\Xi^{1,',(l.)}/\Xi^{1,'}$ transfers into $\Xi^{1,',(l.\mathrm{abs})}/\Xi^{1,',(\mathrm{abs})}$. It can be easily shown that, without loss of generality we can suppose that $\Xi^{1,',(l.)}\geqslant 0$. Obviously,

$$|\Xi^{1,',(l.)}/\Xi^{1,'}|\leqslant \Xi^{1,',(l.\mathrm{abs})}/\Xi^{1,',(\mathrm{abs})}.$$

Now the expression $\Xi^{1,',(l.\mathrm{abs})}/\Xi^{1,',(\mathrm{abs})}$ can be interpreted as a ''absolute probability'' P^{abs} (Long) of the event that there is at least one long cluster.

Now our aim is to estimate the ''absolute probability'' P^{abs} of the event that a given segment belongs to the support of long cluster. In other words, we are going to estimate the statistical weights of long clusters after replacing of the values of all negative bonds in configurations containing at least one long cluster with their absolute values.

Let $\varphi(I_V-I)$ be an arbitrary subconfiguration which contains contours $K_1,\ldots,K_l$, belonging to long clusters, $\mathbf{K}=\cup_1^l \mathrm{supp}^1 K_i$, $\mathbf{K^1}=\mathbf{K}\cap[-V,-(|I|/2)]$ and $\mathbf{K^2}=\mathbf{K}\cap[|I|/2,V]$.

Put $C^1(\varphi(I_V-I))=|\mathbf{K^1}|$ and $C^2(\varphi(I_V-I))=|\mathbf{K^2}|$. We have

$$\begin{aligned}|P(\mathrm{Long})|&=|\Xi^{1,',(l.)}/\Xi^{1,'}|\\ &\leqslant P^{\mathrm{abs}}(\mathrm{Long})\\ &=\sum w^{\mathrm{abs}}(D_1)\cdots w(D_m)/\Xi^{1,',(\mathrm{abs})}\\ &=\sum^{p,1} w^{\mathrm{abs}}(D_1)\ldots w^{\mathrm{abs}}(D_m)/\Xi^{1,',(\mathrm{abs})}+\sum^{p,2} w^{\mathrm{abs}}(D_1)\ldots w^{\mathrm{abs}}(D_m)/\Xi^{1,',(\mathrm{abs})}\\ &=P^{\mathrm{abs}}(\mathrm{Long},>p)+P^{\mathrm{abs}}(\mathrm{Long},\leqslant p),\end{aligned}$$

where $w^{\mathrm{abs}}(D_i)=|w(D_i)|$ for all clusters belonging to the configuration containing at least one long cluster and $w^{\mathrm{abs}}(D_i)=w(D_i)$ for other clusters [note that the statistical weight $w^{\mathrm{abs}}(D_i)$ of fixed cluster in one configuration can be positive, in other negative], last two summations are taken over all nonordered compatible collections of clusters $[D_1,\ldots,D_m]$ containing at least one long cluster, $\cup_{i=1}^m \mathrm{supp}\, D_i\subset I_V-I$ corresponding to the boundary conditions $\{\varphi^1(x),x\in\mathbf{Z}^1-I_V;\varphi'(x),x\in I\}$, the summation in $\Sigma^{p,1}$ is taken over all configurations $\varphi(I_V):\varphi(I)=\varphi'(I)$; $2C^1(\varphi(I_V-V))/(|I_V|-|I|)>p$; $2C^2(\varphi(I_V-V))/(|I_V|-|I|)>p$, the summation in $\Sigma^{p,2}$ is taken over all configurations $\varphi(I_V):\varphi(I)=\varphi'(I)$; $2C^1(\varphi(I_V-V))/(|I_V|-|I|)\leqslant p$; $2C^2(\varphi(I_V-V))/(|I_V|-|I|)\leqslant p$. It means that the density of contours belonging to long clusters in each configuration from $\Sigma^{p,1}$ ($\Sigma^{p,2}$) in both segments $[-V,-(|I|/2)]$ and $[|I|/2,V]$ is greater than p (is not greater than p).

We fixed the value of p as $1-q/2l$, where the values of q and l will be defined in the proof of Lemma 9.

It turns out that the long clusters are negligible.

Lemma 8: For each fixed interval I there exists a value of V_0, such that if $V>V_0$

$$P^{\mathrm{abs}}(\mathrm{Long})=P^{\mathrm{abs}}(\mathrm{Long},>p)+P^{\mathrm{abs}}(\mathrm{Long},\leqslant p)<1/2. \tag{22}$$

Lemma 8 is a consequence of the following two lemmas.

Lemma 9: For each fixed interval I there exists a value of V_0, such that if $V>V_0$

$$P^{\mathrm{abs}}(\mathrm{Long},>p)<1/4.$$

Lemma 10: For each fixed interval I there exists a value of V_0, such that if $V>V_0$

$$P^{\mathrm{abs}}(\mathrm{Long},\leqslant p)<1/4.$$

Proof of Lemma 9: Consider the partition of $\mathbf{Z}^1$ into segments $T_k = T_k(lp)$, where $T_k(lp)$ is the segment with the center at $x=(lp/2)+klp$ and with the length lp (T_k consists of l segments I_k with the length p, where p is the period of the special ground state). The value of l will be defined later. Let us consider an arbitrary configuration $\varphi(x)$. We say that a segment I_k is regular, if I_k does not belong to the support of some long cluster. We say that a segment T_k is super-regular, if T_k contains at least one regular segment.

Let $\mathbf{P_V}$ be a Gibbs measure corresponding to the boundary conditions $\varphi^1(x)$, $x\in\mathbf{Z^1}$, $\varphi'(I)$, $x\in I$.

Let the segment $I_V - I$ consist of n segments T_k; $k=1,...,n$.

We define a sample space Ω consisting of 2^n elementary events $A^j=[\sigma(1),\ldots,\sigma(n)]$, where $\sigma(k)$, $k=1,...,n$ takes two values: $\sigma(k)=0$ corresponds to the case when the segment T_k is super-regular and $\sigma(k)=1$ corresponds to the case when the segment T_k is not super-regular. On the sample space Ω we define two different probability spaces $(\Omega,\mathbf{P_1})$ and $(\Omega,\mathbf{P_2})$ by the following formulas:

$$\mathbf{P_1}(A^j)=\mathbf{P_1}[\sigma(1),\ldots,\sigma(n)]=\mathbf{P_V}[\sigma(1),\ldots,\sigma(n)],$$

where $\mathbf{P_V}$ is the Gibbs distribution $\mathbf{P_V}$, corresponding to the boundary conditions $\varphi^1(x)$, $x\in\mathbf{Z^1}$, $\varphi'(I)$, $x\in I$ and

$$\mathbf{P_2}(A^j)=\mathbf{P_2}[\sigma(1),\ldots,\sigma(n)]=q^{n-s}(1-q)^s,$$

where s denotes the total number of 1 entries of the vector $A^j=[\sigma(1),\ldots,\sigma(n)]$.

We define a random vector $(\eta(1),\eta(2),\ldots,\eta(n))$ on the probability space $(\Omega,\mathbf{P_1})$ and, respectively, a random vector $(\xi(1),\xi(2),\ldots,\xi(n))$ on the probability space $(\Omega,\mathbf{P_2})$ by the formulas:

$$\eta(k)(A^j)=\sigma(k) \quad \text{and} \quad \xi(k)(A^j)=\sigma(k)\,.$$

The random variables $\eta(k)$ and $\xi(k)$ are defined on the same sample space but on different probability spaces.

Due to the definitions, the random variables $\eta(k)$ are dependent, and the random variables $\xi(k)$ are independent and identically distributed.

Consider the two sums $\Sigma_{k=1}^n \eta(k)$ and $\Sigma_{k=1}^n \xi(k)$.

Suppose that

$$\mathbf{P}(\eta(m)=1|\text{any conditions outside } T_m)\leqslant 1-q. \tag{23}$$

Note that $\mathbf{P}(\eta(m)=1|\text{any conditions outside} T_m)\leqslant 1-q=\mathbf{P}(\xi(m)=1)$ and therefore the following natural lemma holds.

Lemma 11:

$$\mathbf{P}\left(\sum_{k\in K}\eta(k)\geqslant l\right)\leqslant\mathbf{P}\left(\sum_{k\in K}\xi(k)\geqslant l\right)$$

for all natural values of l.

The proof of the probabilistically clear Lemma is omitted. For the detailed proof see the Proposition in Ref. 15.

The random variables $\xi(k)$ are independent and identically distributed. The mathematical expectation of $\xi(k)$ equals $1-q$.

Now we show that

$$P^{\text{abs}}(\eta(m)=1|\text{any conditions outside } T_m)\leqslant 1-q. \tag{24}$$

Let $\mathbf{P_V}$ be a Gibbs measure corresponding to arbitrary boundary conditions and T_k be an arbitrary segment. Consider the set of all configurations on the interval T_k and the restriction of the measure $\mathbf{P_V}$ on this set. We show that at some value of l the ''absolute probability'' P^{abs} that in T_k there is at least one regular segment I_k is greater than $q>0$ for some constant q not depending on k. The event $\eta(k)=1$ means that all segments belonging to T_k are nonregular.

Suppose that a fixed configuration $\varphi'(T_m)$ does not coincide with the ground state at all $I_i \in T_m$.

The Peierls argument method directly imply that for some positive constant t_0

$$P^{\text{abs}}(\varphi'(T_m)|\text{conditions outside } T_m \text{ are } \varphi^{gr}(x)) \leqslant \exp(-\beta t_0 l).$$

Note that when we increase the value of l the influence of the conditions outside T_m on the configuration in T_m increases with the rate less than l and therefore at some value of l and for some positive constant t we have

$$P^{\text{abs}}(\varphi'(T_k)|\text{any conditions outside } T_m) \leqslant \exp(-\beta t l) \leqslant 1-q_0.$$

Thus, the probability $P^{\text{abs}}(\eta(m)=1|\text{any conditions outside } T_m)$ as a union of at most 2^{lp} events with probabilities less than $1-q_0$, is bounded by some number $1-q$. The inequality (24) is proved.

Now Lemma 9 is a direct consequence of the strong law of large numbers for $\xi(k)$ and the Lemma 11. Indeed, consider independent Bernoulli trials when the probability of success at each trial is $1-q$. According to the law of large numbers, the probability of the event that the density of successes exceeds $1-q'$; $0<q'<q$, is less than 1/4, when V tends to infinity. It means that the ''absolute probability'' of the event that the density of non-super-regular segments T_k is greater than $1-q'$ is less than 1/4. Due to Lemma 11, this probability is greater than the P^{abs} probability of the event that the density of non-super-regular segments T_m is greater than $1-q'$. In other words, the P^{abs} probability of the event that the density of super-regular segments T_m is less than $1-q'$ is less than 1/4. Thus, the P^{abs} probability of the event that the density of super-regular segments T_m is greater than $1-q'$ is greater than 1/4. Taking into account that each super-regular segment T_m contains at least one regular segment, one can see that the last statement implies the Lemma 9 if the parameter p is chosen from the open interval $(1-q'/l,1)$. We choose the value of p as $1-q/2l$.

Lemma 9 is proved.

Proof of Lemma 10: Let us consider the set of all long clusters D_i with the density of supports less than p. Let $\text{supp}(D)=\cup_{i=j}^{r}\text{supp}(K_j)$. These supports K_i are connected between themselves and with the boundary. Since the density of supports is not greater than $p<1$, the sum of the lengths of bonds in both halves $[-V,-|I|/2$ and $[|I|/2,V]$ is not less than $(V-|I|/2)(1-p)$. When V goes to infinity the sum of lengths of bonds of any long cluster with the density less than p tends to infinity. As it becomes apparent from the proof of Lemma 8 $P^{\text{abs}}(\text{Long},>p)$ does not exceed one. And it does not exceed one, if we omit the factor $g(x,y)$ corresponding to the long bond and since $g(x,y,\varphi)=\exp(-\beta f(x,y,\varphi))-1$ [see (12)] the impact of these bonds tends to zero. By choosing the appropriate value of V we complete the proof of Lemma 10.

Lemma 10 is proved.

We omit the huge proof of Lemma 5 since it is absolutely analogous to the proof of Lemma 6. The only difference is the fact that in $\Xi^{1',2''}$ overlapped clusters are allowed, so the density of nonregular segments of typical configurations in Lemmas 8,9 instead of p will be a number less than $1-(1-p)(1-p)$.

Partition functions including only non-long-super clusters satisfy the following key lemma which has a geometrically-combinatorial explanation.

Lemma 12:

$$\Xi^{1',2'',(n.l.)}=Q\,\Xi^{1'',2',(n.l.)}$$

where the factor $Q = Q(\varphi^1(x), \varphi^2(x), \varphi'(x), \varphi''(x))$ *is uniformly bounded:* $0 < \mathrm{const}_1 < Q < \mathrm{const}_2$.

The factor appears due to the fact that configurations with minimal energy corresponding to the different boundary conditions do not coincide everywhere (they coincide to within shifts, everywhere but finite area).

Proof of Lemma 12: Due to the constant Q without loss of generality we assume that the configurations with minimal energy $\varphi_{\min}$ for both boundary conditions coincide.

According to the definitions and Lemma 4

$$\Xi^{1,'',2',(n.l.)} = Q' \sum^{*} w(SD_1) \cdots w(SD_m),$$

where the summation is taken over all nonlong, nonordered compatible collections of super clusters.

According to the definition of the super cluster

$$Q' \sum^{*} w(SD_1) \cdots w(SD_m) = Q' \sum^{1,',*} w(D_1) \cdots w(D_k) \sum^{2,'',*} w(D_1) \cdots w(D_l)$$

in $\Sigma^{1,',*}$ and $\Sigma^{2,'',*}$ the summation is taken over all nonordered collections of clusters $w(D_1^{1,'}) \cdots w(D_k^{1,'})$ and $w(D_1^{2,''}) \cdots w(D_l^{2,''})$ such that their product belongs to Σ^*.

Similarly,

$$\Xi^{1,'',2,',(n.l.)} = Q'' \sum^{**} w(SD_1) \cdots w(SD_m)$$
$$= Q'' \sum^{1,'',**} w(D_1) \cdots w(D_k) \sum^{2,',**} w(D_1) \cdots w(D_l).$$

In order to prove Lemma 12 we put one-to-one correspondence between $\Sigma^* w(SD_1) \ldots w(SD_m)$ and $\Sigma^{**} w(SD_1) \ldots w(SD_m)$.

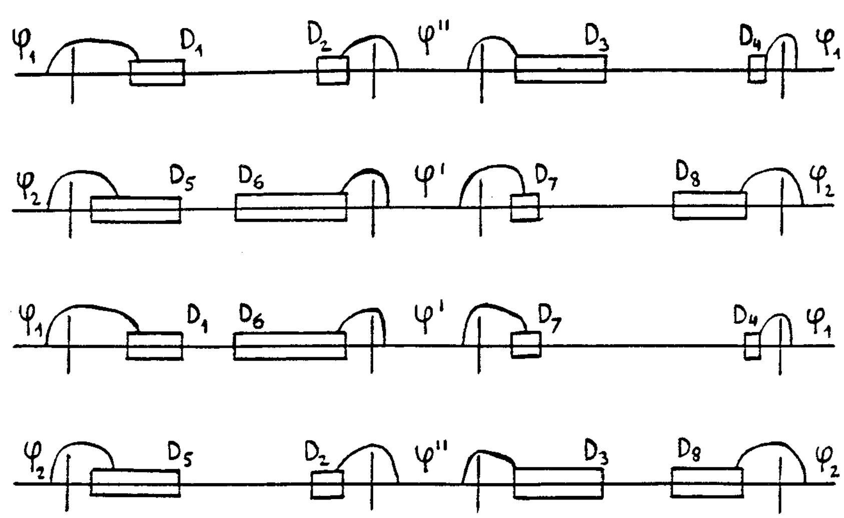

FIG. 1.

Let us consider an arbitrary term $U=w(SD_1)\ldots w(SD_a)$ of Σ^*. By definitions

$$U=w(D_1^{1,\prime})\cdots w(D_m^{1,\prime})w(D_1^{2,\prime\prime})\cdots w(D_k^{2,\prime\prime}),$$

where the factor $w(D_1^{1,\prime})\cdots w(D_m^{1,\prime})$ belongs to the $\Sigma^{1,\prime,*}$ and the factor $w(D_1^{2,\prime\prime})\cdots w(D_k^{2,\prime\prime})$ belongs to the $\Sigma^{2,\prime\prime,*}$.

A cluster $D=[(K_i,i=1,...,r);G'']$ is said to be basic, if the set $((\cup_{i=1}^m \mathrm{supp}\, D_i)\cup G'')\cap((\mathbf{Z}^1-I_N)\cup I))$ is not empty. In Fig. 1 all clusters are basic.

Consider the set of all clusters $\mathbf{W}(U)$ of the term U: $\mathbf{W}(U)=\cup_{i=1}^m D_i^{1,\prime\prime}\cup_{i=1}^k D_i^{2,\prime}$ and four subsets of $\mathbf{W}(U)$:

$$W'=\left[D'=[(K_i,i=1,...,r);G']\in\Xi^{2,\prime}:\left(\left(\bigcup_{i=1}^{k}\mathrm{supp}\, D_i\right)\cup G'\right)\cap I \text{ is not empty}\right],$$

$$W''=\left[D''=[(K_i,i=1,...,r);G']\in\Xi^{1,\prime\prime}:\left(\left(\bigcup_{i=1}^{m}\mathrm{supp}\, D_i\right)\cup G'\right)\cap I \text{ is not empty}\right],$$

$$W^1=\left[D^1=[(K_i,i=1,...,r);G']\in\Xi^{1,\prime\prime}:\left(\left(\bigcup_{i=1}^{m}\mathrm{supp}\, D_i\right)\cup G'\right)\cap(\mathbf{Z}^1-I_N) \text{ is not empty}\right],$$

$$W^2=\left[D^2=[(K_i,i=1,...,r);G']\in\Xi^{2,\prime}:\left(\left(\bigcup_{i=1}^{k}\mathrm{supp}\, D_i\right)\cup G'\right)\cap(\mathbf{Z}^1-I_N) \text{ is not empty}\right].$$

Note that the subsets W',W'',W^1,W^2 contain only basic clusters and the union of them contain all basic clusters of the term U.

Let us consider an arbitrary term $U=w(SD_1)\cdots w(SD_b)$ of Σ^{**}. By the definitions

$$U'=w(D_1^{1,\prime\prime})\cdots w(D_l^{1,\prime\prime})w(D_1^{2,\prime})\cdots w(D_n^{2,\prime}),$$

where the factor $w(D_1^{1,\prime\prime})\cdots w(D_m^{1,\prime\prime})$ belongs to the $\Sigma^{1,\prime\prime,**}$ and the factor $w(D_1^{2,\prime})\cdots w(D_k^{2,\prime})$ belongs to the $\Sigma^{2,\prime,**}$.

Consider the set of all clusters $W(U')$ of the term $U':W(U')=\cup_{i=1}^m D_i^{1,\prime\prime}\cup_{i=1}^k D_i^{2,\prime}$. In just the same way we can define four subsets of $W(U')$.

Consider a term $U=w(D_1)\cdots w(D_k)\in\Sigma^*$, containing only basic clusters. By definition $\cup_{i=1}^k D_i$ can be represented as $\cup_{i=1}^k D_i=(\cup_{i=1}^m D_i)\cup(\cup_{i=m+1}^k D_j)$, where the clusters $\cup_{i=1}^m D_i =W^1\cup W'$; and $\cup_{i=m+1}^k D_j=W^2\cup W''$.

From the definition of nonlong clusters and W',W'',W^1,W^2 it easily follows that there exists the same term $U'=w(D_1)\ldots w(D_k)\in\Sigma^{**}$, such that $\cup_{i=1}^k D_i=(\cup_{i=1}^m D_i)\cup(\cup_{i=m+1}^k D_j)$, where the clusters $\cup_{i=1}^m D_i=W^1\cup W'$; and $\cup_{i=m+1}^k D_j=W^2\cup W''$.

Figure 1 shows four collections of clusters $\mathrm{COL}_1=[D_1^{1,\prime\prime},D_2^{1,\prime\prime},D_3^{1,\prime\prime},D_4^{1,\prime\prime}]$, $\mathrm{COL}_2 =[D_5^{2,\prime},D_6^{2,\prime},D_7^{2,\prime},D_8^{2,\prime}]$, $\mathrm{COL}_3=[D_1^{1,\prime},D_6^{1,\prime},D_7^{1,\prime},D_4^{1,\prime}]$, $\mathrm{COL}_4=[D_5^{2,\prime\prime},D_2^{2,\prime\prime},D_3^{2,\prime\prime},D_8^{2,\prime\prime}]$.

Two coincident terms $U=U'=\Pi_{i=1}^8 w(D_i)$ belonging to the sums Σ^* and Σ^{**} are constructed by the Cartesian product of the collections COL_1, COL_2, and COL_3, COL_4, respectively.

We see that between terms $U\in\Sigma^*$ and $U'\in\Sigma^{**}$ containing only basic clusters we easily can put a one-to-one correspondence.

Consider a term $U=w(D_1)\cdots w(D_k)w(D_{k+1})\cdots w(D_n)\in\Sigma^*$, containing basic clusters $D_1\cdots D_k$ and not basic clusters $D_{k+1}\cdots D_n$.

It can be easily shown that there exists a term $U'=w(D_1)\cdots w(D_k)w(D_{k+1})\cdots w(D_n)\in\Sigma^{**}$ coinciding with the term $U\in\Sigma^*$. Indeed, suppose that there is no term U'

$=w(D_1)\cdots w(D_k)w(D_{k+1})\cdots w(D_n)\in\Sigma^{**}$ coinciding with the term $U\in\Sigma^*$. Then, according to the definition of the long clusters, we directly get that, the term U contains long super cluster, which contradicts the definition of Σ^*.

Lemma 12 is proved.

Remark: The essential point of the proof of the important Lemma 12 (therefore, of this paper) is the amusing fact that $\Sigma^* w(SD_1)\cdots w(SD_m)$ and $\Sigma^{**} w(SD_1)\cdots w(SD_m)$ coincide.

Now the demanded inequality (18) is a direct consequence of Lemmas 5 and 12. The inequality (18), therefore Lemma 3 is proved.

Let $\mathbf{P^1}$ and $\mathbf{P^2}$ be two different extreme Gibbs states of the model (1) corresponding to the boundary conditions $\varphi^1(x)$ and $\varphi^2(x)$, respectively.

Theorem 5: (Ref. 16.) $\mathbf{P^1}$ *and* $\mathbf{P^2}$ *are singular or coincide*.

Proof of Theorem 4: Let $\mathbf{P^1}$ and $\mathbf{P^2}$ be two different extreme Gibbs states of the model (1) corresponding to the boundary conditions $\varphi^1(x)$ and $\varphi^2(x)$ respectively. According to Lemma 3 $\mathbf{P^1}$ and $\mathbf{P^2}$ are not singular. Therefore, according to Theorem 5 $\mathbf{P^1}$ and $\mathbf{P^2}$ coincide, which contradicts the assumption. Theorem 4 is proved.

III. UNIQUENESS OF GIBBS STATES

In this section we prove the main Theorem 1.

The statement of Theorem 1 for rational densities coincides with Theorem 4. Thus, in order to complete the proof of Theorem 1, we have to prove the following theorem, which covers the case when the density of the special ground state is irrational.

Theorem 6: *Suppose that the value of the external field* μ *of the model (1) belongs to the set* $\mathbf{C^{ir}}=\mathbf{R^1}-\cup_\kappa(\mu_\kappa^-,\mu_\kappa^+)$. *Then the model (1) has a unique Gibbs state at all values of the temperature* β^{-1}.

It can be easily shown that the special ground states of the model (1) are not stable when the density is irrational. In other words, the Peierls constant t for the special ground state tends to zero, when $p\to\infty$. The essence of this fact is the following.

For the fixed irrational number $\eta=[n_0,n_1,\ldots,n_s,\ldots]$ consider the corresponding special ground state $\varphi_\kappa(x)$ and its arbitrary perturbation $\varphi_\kappa'(x)$. The configuration $\varphi_\kappa'(x)$ is not a special ground state, therefore for some pair of points, say x and $y\in\mathbf{Z^1}$; $\varphi_\kappa'(x)=\varphi_\kappa'(y)=1$, we have a violation of Hubbard's criterion. Let x and y be closest points with this property. When the distance between x and y tends to infinity, the Peierls constant tends to zero.

In the irrational case the special ground states are not stable, but this fact is not crucial for our method. Since the essence of our method is the estimation of long super clusters connecting the boundary with the segment I, small clusters not satisfying Peierls condition cannot ''help'' to connect the boundary with I, and it turns out that big clusters satisfy the Peierls stability condition and the method works. One can say that the special ground states in the irrational case are ''stable in general.''

Below we give the mathematical details of the last observation.

Consider $\eta(s)=[n_0,n_1,\ldots,n_s]$.

Lemma 13: Suppose that the value of the external field μ *of the model (1) belongs to the interval* $(\mu_{\kappa(s)}^-,\mu_{\kappa(s)}^+)$ *for some number* $\kappa(s)=\eta(s)^{-1}$. *Let* $\varphi'(x)$ *be an arbitrary finite perturbation of the special ground state* $\varphi_{\kappa(s)}(x)$ *such that the boundary B of the configuration* $\varphi'(x)$ *includes a unique contour K. Then there exists a positive constant* t_s *depending only on the Hamiltonian (1), such that*

$$H(\varphi'(x))-H(\varphi_{\kappa(s)}(x))\geq t_s|\mathrm{supp}\,B|$$

where $|\mathrm{supp}\,B|$ *is the total area of the support of the boundary*.

Lemma 13 was proved in Ref. 13 [see Lemma 1 and Sec. 5 (Ref. 13)].

Thus, for each nonnegative integer s the number t_s is defined. Suppose that a positive number t less than t_1 is fixed. Let s be the maximal number meeting the condition $t_s>t$.

Now we are ready to define the notion of a contour in the irrational case.

Let us consider an arbitrary configuration $\varphi(x)$. Let $C=\cup_{i\in \mathrm{Ind}}[x_i,y_i]$, where $x_i,y_i\in \mathbf{Z}^1$ and $x_i\neq y_i$ has the following properties:

(1) For each segment $[a_i,b_i]$ from the set $\mathbf{Z}^1-C$ there exists a special ground state φ_κ, such that the restriction of this configuration on $[a_i,b_i]$ coincides with $\varphi([a_i,b_i])$.

(2) For any $C'\subset C$; $C'\neq C$ the property 1 is not held.

It can be easily shown that the set $C=C(\varphi(x))$ is not uniquely defined. Suppose that, some rule uniquely determines the set C for each configuration $\varphi(x)$. Let $\mathbf{Z}^1-C=\cup_i[a_i,b_i]$. We say that $\varphi([a_i,b_i])$; is a preregular phase. Consider any segment $[x_i,y_i]$ belonging to C. The segment $[x_i,y_i]$ is said to be t-negligible, if for each segment $[v_i,w_i]$ covering $[x_i,y_i], w_i-v_i=p$ [p is the numerator of $\eta(s)$] there exists a special ground state $\varphi_{\kappa(s)}$, such that the restriction of this configuration on $[v_i,w_i]$ coincides with $\varphi([v_i,w_i])$. Let $C=\cup_{i\in \mathrm{Ind}}[x_i,y_i]=(\cup_{i\in \mathrm{Ind}(t)}\times[x_i,y_i])\cup(\cup_{i\in \text{Ind-Ind}(t)}[x_i,y_i])$, where $\mathrm{Ind}(t)$ means that the union is taken over all t-negligible segments. The support of the preboundary $\mathrm{supp}\,PB$ of the configuration $\varphi(x)$ will be defined as $\mathrm{supp}\,PB=(\cup_{i\in \mathrm{Ind}(t)}[x_i,y_i])\cup(\cup_{i\in \text{Ind-Ind}(t)}[x_i-d_0p,y_i+d_0p])=\mathrm{supp}\,PB(\mathrm{main})\cup\mathrm{supp}\,PB(t)$. Each segment belonging to the union $\mathrm{supp}\,PB$ will be called a support of a precontour and is denoted by $\mathrm{supp}\,PK$. The support $[x_i,y_i]$ of a precontour is said to be t-negligible, if $[x_i,y_i]$ belongs to $\mathrm{supp}\,PB(t)$.

We define contours as in the Definition 1. The constants p,d_0 and N_b for irrational density η^{-1} will be constants defined for rational density $\eta(s)^{-1}$.

The pair $PK=(\mathrm{supp}\,PK,\varphi'(\mathrm{supp}\,PK))$ is called a precontour. The set of all precontours is called a preboundary PB of the configuration $\varphi'(x)$. Two precontours PK_1 and PK_2 are said to be connected if $\mathrm{dist}(\mathrm{supp}\,PK_1,\mathrm{supp}\,PK_2)<N_b$ and at least one of them is not t-negligible. The set of precontours $(PK_i;i\in \mathrm{Ind})$ is called connected if for any two precontours PK_c and $PK_d;c,d\in \mathrm{Ind}$ there exists a collection $(PK_{j_1}=PK_c,\ldots,PK_{j_i},\ldots,PK_{j_{n-1}},PK_{j_n}=PK_d)$; $j_i\in \mathrm{Ind}$, $i=1,...,n$; such that any two precontours PK_{j_i} and $PK_{j_{i+1}}$, $i=1,...,$ $n-1$ are connected. Let $\cup_{i=1}^n PK_i$ be some maximal connected component of the preboundary PB. Suppose that $\mathrm{supp}\,PK_i=[a_i,b_i]$ and $b_i<a_{i+1}$; $i=,\ldots,n-1$.

The pair $K=(\mathrm{supp}\,K,\varphi'(\mathrm{supp}\,PK))$, where $\mathrm{supp}\,K=[a_1,b_n]$ is called a contour. The set of all contours is called a boundary B of the configuration $\varphi'(x)$.

A contour is said to be t-negligible, if its support is t-negligible.

By the definitions, the distance between the supports of two t-negligible contours exceeds p, where p is the numerator of $\eta(s)$ and the length of the support of any t-negligible contour is one.

The following lemma is reformulation of Lemma 13 for irrational densities.

Lemma 14: Suppose that the value of the external field μ *of the model (1) belongs to the set* $\mathbf{C}^{\mathbf{ir}}=\mathbf{R}^1-\cup_\kappa(\mu_\kappa^-,\mu_\kappa^+)$. *Let* $\varphi'(x)$ *be an arbitrary finite perturbation of the special ground state* $\varphi_\kappa(x)$ *such that the boundary B of the configuration* $\varphi'(x)$ *includes a unique contour (not t-negligible contour) K. Then there exists a positive constant* t_s *depending only on the Hamiltonian (1), such that*

$$H(\varphi'(x))-H(\varphi_\kappa(x))\geqslant t_s|\mathrm{supp}\,B|$$

where $|\mathrm{supp}\,B|$ *is the total area of the support of the boundary.*

Suppose that the value of the external field μ of the model (1) belongs to the set $\mathbf{C}^{\mathbf{ir}}=\mathbf{R}^1-\cup_\kappa(\mu_\kappa^-,\mu_\kappa^+)$. Let $t,0<t<t_1$ is fixed and t_s is chosen as above.

Lemma 15: Let $\varphi_{\min}(x)\in\Phi(V)$ *be a configuration with the minimal energy:*

$$H(\varphi_{\min}(x)|\varphi^1(x))=\min_{\varphi(x)\in\Phi(V)}H(\varphi(x)|\varphi^1(x)).$$

Then the configuration $\varphi_{\min}(x)$ *has the following structure:*

The restriction of the configuration $\varphi_{\min}(x)$ *on the set* $[-V+N_b,V-N_b]$ *contains t-negligible contours and* $p-1$ *non t-negligible contours, moreover the sum of weights of all t-negligible* *contours is bounded by constant, not depending on the boundary conditions, all of* $p-1$ *non t-negligible contours are interface contours* IK_i, $i=1,...,m$, *where* $m<p-1$ *and* $|\mathrm{supp}\, IK_i| < 3d_0p+N_b$.

The proof of Lemma 15 is very similar to the proof of Lemma 1[13] and will be omitted.

From Lemma 15 follows that the density of possible *t*-negligible contours of $\varphi_{\min}(x)$ tends to zero, when V goes to infinity.

Now the proof of Theorem 6 principally coincides with the proof of Theorem 3 and will be omitted. Theorem 6, and hence main Theorem 1 is proved.

IV. FINAL REMARKS

The unique limit Gibbs state of the model (1) is translationally invariant. This result was proved independently in Ref. 1 by using of the method of the equivalence of boundary conditions,[17] and in Ref. 11 by using of energy–entropy inequalities.

At low temperatures, the sum of the statistical weights of all clusters having fixed support has an exponential estimation (see Lemma 16, Ref. 13) and each limit Gibbs state of the model (1) is a ''small perturbation of special ground states'' (see Lemma 17, Ref. 13).

The essential points in the proof of the uniqueness of Gibbs states are the geometrically combinatorial Lemma 12 and the estimation of long super clusters, connecting the boundary with the segment *I*. This estimation mainly works due to the fact that ground states of the model (1) degenerate. In Ref. 13 we proved Theorem 4 at low temperatures. The temperature restriction was related with the fact that at low temperatures the weight of the support of a cluster has an exponential estimation [Lemmas 16 and 17 (Ref. 13)] and hence long clusters are negligible (Ref. 13). But at any temperature an exponential estimation is absent. In the general case, when we estimate the statistical weight of long super clusters, a key role plays the Lemma 6 on the estimation of the value of the interaction between contours.

In Ref. 15 at low temperatures the result of Ref. 13 is extended to more abstract models. The method of the proof of Theorem 1 shows that the result of Ref. 15 can be extended to all values of the temperatures.

(Received 24 March 1999; accepted for publication 5 May 1999)

We establish rigorously the scaling properties of the Lanczos process applied to an arbitrary extensive many-body system which is carried to convergence $n\rightarrow\infty$ and the thermodynamic limit $N\rightarrow\infty$ taken. In this limit the solution for the limiting Lanczos coefficients are found exactly and generally through two equivalent sets of equations, given initial knowledge of the exact cumulant generating function. The measure and the orthogonal polynomial system associated with the Lanczos process in this regime are also given explicitly. Some important representations of these Lanczos functions are given, including Taylor series expansions, and theorems controling their general properties are proven. © *1999 American Institute of Physics.* [S0022-2488(99)01510-8]

I. INTRODUCTION

The Lanczos algorithm is one of the few reliable and general methods for computing the ground state and excited state properties of strongly interacting quantum many-body systems. It has been traditionally employed as a numerical technique on small finite systems, with attendant round-off error problems, although the main obstacle to its further development has been the rapid growth of the number of basis states with system size. The reader is referred to a review of the applications of this method[1] in strongly correlated electron problems. In this work we examine the Lanczos process in the context of the extensive quantum many-body systems, where it is employed entirely in an exact manner and where the thermodynamic limit is taken. So, in complete contrast to the traditional use of the Lanczos algorithm, we completely circumvent the issues of loss of orthogonality due to round-off errors and the inability to approach the thermodynamic limit because of the requirement to construct a full basis on the cluster. The systems we have in mind are those with an infinite number of degrees of freedom, yet are extensive, in that all total averages of any physical quantity scale linearly with the numbers of degrees of freedom however quantified. These would include all condensed matter systems with sufficiently local interactions (the precise conditions need to be clarified, but it is clear which specific systems obey extensivity) and quantum field theories, with the proviso that the spectrum is bounded below (in some cases there is also an upper bound, too).

After noting some of the advantageous features of the algorithm in general we discuss the scaling behavior of the Lanczos process as it approaches convergence and as the thermodynamic limit is taken. Central to this approach is the manifestation of extensivity through a description based on the cumulant generating function (CGF) which we take to be given. We then derive a set of general integral equations which define the scaled Lanczos functions in the thermodynamic limit, which can be explicitly and exactly solved for certain integrable models, or employed in a truncated manner for nonintegrable models. An alternative formulation is also given which ex-

[a)]Electronic mail: nsw@physics.unimelb.edu.au

presses the equivalence of the Lanczos process with the continuum Toda lattice model treated as a boundary value problem. Finally, we state some general results concerning the behavior of the Lanczos functions.

II. THE LANCZOS PROCESS, ORTHOGONAL POLYNOMIALS, AND MOMENTS

The Lanczos algorithm or process[2–4] begins with a trial state $|\psi_0\rangle$ appropriate to the model and the symmetries of the phase being investigated. From this the Lanczos recurrence generates a sequence of orthonormal states $\{|\psi_n\rangle\}_{n=1}^{\infty}$ and Lanczos coefficients $\{\alpha_n(N)\}_{n=0}^{\infty}$ and $\{\beta_n(N)\}_{n=1}^{\infty}$, thus

$$\hat{H}|\psi_n\rangle=\beta_n|\psi_{n-1}\rangle+\alpha_n|\psi_n\rangle+\beta_{n+1}|\psi_{n+1}\rangle, \tag{1}$$

with the Lanczos coefficients being defined

$$\begin{aligned}\alpha_n&=\langle\psi_n|\hat{H}|\psi_n\rangle,\\ \beta_n&=\langle\psi_{n-1}|\hat{H}|\psi_n\rangle.\end{aligned} \tag{2}$$

We distinguish a total or extensive operator or variable such as H from its density or intensive counterpart by $\hat{H}$. In this basis the transformed Hamiltonian takes the following tridiagonal form

$$T_n=\begin{pmatrix}\alpha_0 & \beta_1 & & & & \\ \beta_1 & \alpha_1 & \beta_2 & & & \\ & & \ddots & & & \\ & & & \beta_{n-1} & \alpha_{n-1} & \beta_n \\ & & & & \beta_n & \alpha_n\end{pmatrix}. \tag{3}$$

As such the Lanczos process is one of the Krylov subspace methods[5] in that at a finite step n, the eigenvectors belong to the Krylov subspace Span$\{|\psi_0\rangle,\hat{H}|\psi_0\rangle,\hat{H}^2|\psi_0\rangle,\ldots,\hat{H}^n|\psi_0\rangle\}$.

In the many-body context one would iterate the Lanczos process until termination whereupon the Hilbert space is exhausted (at this point one of the $\beta_{n_T}=0$, where n_T is the dimension of the Hilbert space in the sector defined by the ground state), or until the process has converged according to some arbitrary criteria $n\to n_C$. Then one would perform the thermodynamic limit $N\to\infty$ where it should be understood that the above conclusion of the Lanczos process is also dependent on the system size, that is to say, $n_T(N),n_C(N)$. These cutoffs are monotonically increasing functions of the system size so they will all tend to ∞ in the thermodynamic limit as well. Taking the limits in the reverse order clearly leads to nonsensical results, as taking $N\to\infty$ with n fixed produces $\alpha_n\to c_1$ and $\beta_n\to 0$. The great virtue of the Lanczos process is that it can be shown to converge essentially exponentially fast with respect to iteration number, using the Kaniel–Paige–Saad exact bounds[6–8] for the rate of convergence. This means that convergence occurs within a very small subspace of the total Hilbert space, so that $n_C\ll n_T$.

The Lanczos process is entirely equivalent to the three-term recurrence for an orthogonal polynomial system (OPS),[9–11] however, we consider a slight generalization of the preceding process to one with a single parameter evolution (a ''time'' t). In this construction we are continuing a development begun by Lindsay[12] and Chen and Ismail,[13] which will lead to some powerful tools in treating the Lanczos process. The measure, or that component which is absolutely continuous, is defined by the weight function

$$w(\epsilon,t)=e^{-u(\epsilon)+tN\epsilon}, \tag{4}$$

on the real line $\epsilon \in \mathbb{R}$. Our system under study is described by the initial value of the system at $t=0$ and often we will suppress this argument for the sake of simplicity. This measure defines a system of monic orthogonal polynomials $\{P_n(\epsilon,t)\}_{n=0}^{\infty}$ with an orthogonality relation

$$\int_{-\infty}^{+\infty} d\epsilon\, w(\epsilon,t) P_m(\epsilon,t) P_n(\epsilon,t) = h_n(t)\,\delta_{mn}, \tag{5}$$

and normalization $h_n(t)$. This is equivalent to the following three-term recurrence relation

$$P_{n+1}(\epsilon,t) = (\epsilon - \alpha_n(t)) P_n(\epsilon,t) - \beta_n^2(t) P_{n-1}(\epsilon,t), \tag{6}$$

with the recursion coefficients $\alpha_n(t)$ real for $n \geqslant 0$ and $\beta_n^2(t)$ real and positive for $n > 0$. By convention we take $\beta_0^2 = 1$. It can be readily shown that the Lanczos coefficients are given in terms of the normalization, thus

$$\begin{aligned} \alpha_n(t) &= \frac{1}{N h_n(t)} \frac{d}{dt} h_n(t), \\ \beta_n^2(t) &= \frac{h_n(t)}{h_{n-1}(t)}. \end{aligned} \tag{7}$$

The direct connection between the Lanczos process and the OPS is given by the determinant relation of the characteristic polynomial

$$P_{n+1}(\epsilon) = (-)^{n+1} |T_n - \epsilon I_{n+1}|, \tag{8}$$

so that the zeros of the orthogonal polynomial are eigenvalues of Hamiltonian.

Some comments are in order regarding the differences, or more accurately the special character, of these orthogonal polynomials with respect to the generic OPS or with some of the scaling versions of the OPS.[14] These OPSs have been termed many-body OPSs, but could be equally described as extensive OPSs. They all have an additional, essential parameter to the generic OPS, the system size N, which appears in both the gross scaling factors (the ''external'' scaling such as in the energy densities ϵ defined by $E = N\epsilon$), but also internally in the three-term recurrence coefficients, in the polynomials themselves and in other derived quantities. The internal dependence in the Lanczos coefficients on the system size is not at all apparent, and the most transparent way that extensive scaling properties can be exhibited is through the cumulant generating Function (CGF), which hitherto has played no role in orthogonal polynomial theory. In fact, the CGF is central to this class of OPS, rather than the moments, and is in a practical sense the starting point in any application of the formalism to physical models. For all models it is clear that the ground state energy E_0 is proportional to N and unbounded in the thermodynamic limit, and similarly the total Lanczos coefficients (as opposed to the densities) are unbounded as $n \to \infty$ for fixed N. When everything is recast in terms of densities, the spectrum is bounded below by ϵ_0 and in many models will also be bounded above, and similarly the density Lanczos coefficients are bounded. Another difference that many-body OPSs exhibit in comparison to general OPS is, as we have noted above, the three-term recurrence will terminate exactly at $n = n_T$, although this will never present any problems as this is exponentially large.

The Lanczos process is intimately connected with the Hamburger moment problem[15,16] via the Resolvent operator

$$R(\epsilon) = \left\langle \frac{1}{\epsilon - \hat{H}} \right\rangle, \quad \epsilon \notin \text{Supp}\,[d\rho]. \tag{9}$$

Its formal Laurent series establishes a direct link with Hamiltonian moments

$$R(\epsilon)=\sum_{i=0}^{\infty}\frac{\mu_i}{\epsilon^{i+1}}, \tag{10}$$

where these moments are defined as expectation values with respect to the trial state referred to above

$$\mu_n \equiv \langle \hat{H}^n \rangle, \quad \mu_0 = 1. \tag{11}$$

The resolvent has a real Jacobi-fraction continued fraction representation[17,18]

$$R(\epsilon)=-\mathbf{K}_{n=0}^{\infty}-\left(\frac{\beta_n^2}{\epsilon-\alpha_n}\right), \tag{12}$$

with elements coming from the Lanczos coefficients.

An equivalent description to that of the Hamiltonian moments is to formulate everything in terms of cumulants or connected moments[19,20] $\{\nu_n\}_{n=1}^{\infty}$, and to ignore all corrections which vanish in the thermodynamic limit $N\to\infty$. Cumulants scale directly with the size of the system so that for the extensive many-body problem we have

$$\nu_n = c_n N + o(1) \tag{13}$$

in the ground state sector, or

$$\nu_n = c_n N + m_n + o(1) \tag{14}$$

in any other sector.[21] This also means that no finite-size scaling can be performed given that only the limiting quantities are retained here and boundary condition effects do not appear. The foundation ingredient is the moment generating function which is related to the cumulant generating function in the following way.

Definition 1: The moment generating function (MGF) $M(t)$ and the cumulant generating functions (CGF) $F(t)$ are defined by

$$M(t)\equiv\langle e^{tH}\rangle=\sum_{n=0}^{\infty}\mu_n\frac{t^n}{n!}=\exp\left(\sum_{n=1}^{\infty}\nu_n\frac{t^n}{n!}\right)\equiv\exp(NF(t)). \tag{15}$$

Some examples of cumulant generating functions include the isotropic *XY* model using the z-polarized Néel state as the trial state,[22]

$$F(t)=\frac{1}{\pi}\int_0^{\pi/2} dq\,\log\cosh(t\cos q), \tag{16}$$

and the Ising model in a transverse field using the disordered state as the trial state, and coupling constant x (Ref. 23),

$$F(t)=\frac{1}{2\pi}\int_0^{\pi} dq\,\ln\left[\cosh(2t\epsilon_q)-\frac{(\cos q+x)}{\epsilon_q}\sinh(2t\epsilon_q)\right], \tag{17}$$

where the quasiparticle energies ϵ_k are defined by $\epsilon_q^2=1+x^2+2x\cos q$.

Definition 2: The determinants of the moment matrices $\Delta_n(t)$ for $n\geqslant 0$ are defined by the Hankel form:

$$\Delta_n(t)=\left|M^{(i+j-2)}(t)\right|_{i,j=1}^{n+1}. \tag{18}$$

The direct relationship from moments to the Lanczos coefficients which is established in this way is via the construction of a sequence of Hankel determinants of the moment matrices and their Selberg-type integral representation[9]

$$\Delta_n(t)=\frac{1}{(n+1)!}\int_{-\infty}^{+\infty}\prod_{k=1}^{n+1} d\epsilon_k\, w(\epsilon_k,t)\prod_{1\leq i<j\leq n+1}|\epsilon_i-\epsilon_j|^2. \tag{19}$$

These determinants are related to the normalizations via

$$\Delta_n(t)=\prod_{j\leq n} h_j(t). \tag{20}$$

Definition 3: Our final definition, that of the Lanczos L-function, is

$$N^2L_n(t)=\frac{\Delta_n(t)\Delta_{n-2}(t)}{\Delta_{n-1}^2(t)}, \tag{21}$$

for $n\geq 1$ *and* $L_0(t)=M(t)$.

The converse result is then

$$\Delta_n(t)=N^{n(n+1)}\prod_{k=0}^{n} L_k^{n+1-k}(t), \tag{22}$$

for $n\geq 1$. From these the Lanczos coefficients are given simply by

$$\alpha_n(t)=\frac{1}{N}\sum_{j=0}^{n}\frac{L_j'(t)}{L_j(t)},\qquad \beta_n^2(t)=L_n(t). \tag{23}$$

Theorem 1: *The equation of motion for the Lanczos L-function is*

$$L_n(t)=\frac{1}{N}\sum_{j=1}^{n}\frac{j}{N}D_t^2\log L_{n-j}(t), \tag{24}$$

with the initial condition on the recurrence given by $\log L_0(t)=NF(t)$ *for all t.*

The advantage of introducing evolution into the Lanczos process is that Sylvester's theorem applied to the Hankel determinants,[24]

$$\Delta_{n+1}(t)\Delta_{n-1}(t)=\Delta_n(t)\Delta_n''(t)-(\Delta_n'(t))^2, \tag{25}$$

so that the theorem follows directly from this. □

The first few members of the Lanczos L-sequence are

$$L_1(t)=\frac{1}{N}F''(t),\qquad L_2(t)=\frac{2}{N}F''(t)+\frac{1}{N^2}\frac{F^{(2)}F^{(4)}-(F^{(3)})^2}{(F^{(2)})^2}. \tag{26}$$

The consequence of Sylvester's theorem for the evolution of the Δ_n is the following theorem.

Theorem 2: *The* $\Delta_n(t)$ *obey the following differential-difference equation,*

$$\exp\{\log \Delta_{n+1}+\log \Delta_{n-1}-2 \log \Delta_n\}=D_t^2 \log \Delta_n, \tag{27}$$

with the boundary value $\log \Delta_0 = NF(t)$ *and conventionally* $\Delta_{-1}=1$.

This follows directly from Sylvester's identity. □

This evolution equation is just the finite Toda lattice equation of motion,[25] and this point has been previously noted in Ref. 13.

III. SCALING IN THE THERMODYNAMIC LIMIT

As was discussed earlier, there are two limiting processes that one must consider when the thermodynamic limit is taken in the Lanczos algorithm, both $n, N\to\infty$, and the issue then is what mutual relationship exists between them in the limit. One can view this limiting process in the $1/n$ vs $1/N$ plane and then consider along what types of paths must one approach the origin. We shall find that the general relationship is $n, N\to\infty$ with $s\equiv n/N$ fixed, although for systems at criticality it seems inevitable that s will become unbounded in the analysis. A consequence of these ideas is the confluence property of the Lanczos coefficients as $n, N\to\infty$ at fixed $s=n/N$.

$$\begin{aligned}\alpha_n(N)&=\alpha(s)+O(1/N),\\ \beta_n^2(N)&=\beta^2(s)+O(1/N).\end{aligned} \tag{28}$$

There are a number of ways to see this approach to the thermodynamic limit.

Using the explicit forms connecting cumulants and moments, and a direct evaluation of the Hankel determinants, one can prove[26] for general n and N that the Lanczos coefficients have a leading order scaling in $s=n/N$ for the first two orders of an expansion in large N. Actually, this expansion is valid for all n not just for large values and thus includes all the subdominant contributions. Thus

$$\alpha_n=c_1N+n\left[\frac{c_3}{c_2}\right]+\frac{1}{2}\,n(n-1)\left[\frac{3c_3^3-4c_2c_3c_4+c_2^2c_5}{2c_2^4}\right]\frac{1}{N}+\cdots \tag{29}$$

for $n\geqslant 0$, and

$$\begin{aligned}\beta_n^2={}&nc_2N+\frac{1}{2}\,n(n-1)\left[\frac{c_2c_4-c_3^2}{c_2^2}\right]+\frac{1}{6}\,n(n-1)(n-2)\\ &\times\left[\frac{-12c_3^4+21c_2c_3^2c_4-4c_2^2c_4^2-6c_2^2c_3c_5+c_2^3c_6}{2c_2^5}\right]\frac{1}{N}+\cdots\end{aligned} \tag{30}$$

for $n\geqslant 1$. However, this approach cannot be generalized to higher orders and therefore for the full exact Lanczos coefficients. The first two terms in the above expansions were also proven by Lindsay using the Sylvester Identity in the statistical context[12] but no further, while this form for the higher terms (but finite numbers) was conjectured in Ref. 27. We shall find that use of the Sylvester identity allows one to very easily recover this result, to in fact go to much higher orders in constructing explicit forms, and to prove this type of scaling in a completely general way.

Lemma 1: The Lanczos L-function $L_n(t,N)$ *is a rational function of* $1/N$ *for fixed n, and all t.*

The difference-differential equation (24) is of finite order in j/N and t, so the result follows. □

Also for fixed n we have

$$\lim_{N\to\infty} L_n(t,N)=0, \tag{31}$$

and specifically the leading order term is $O(N^{-1})$ which arises from the $j=n$ term in the sum. Therefore we can expand this function in a descending series in N^{-1}, thus

$$L_n(t,N)=\sum_{p\geqslant 1}\frac{l_{np}(t)}{N^p}, \tag{32}$$

and defining the connected series related by

$$\sum_{p\geqslant 1}\frac{m_{np}(t)}{N^p}\equiv\log\left(1+\sum_{p\geqslant 1}\frac{l_{np+1}/l_{n1}}{N^p}\right). \tag{33}$$

This last relation can be rendered into an explicit form

$$m_{np}=-\sum_{\Sigma_i q_i r_i=p}\left(\sum_i q_i-1\right)!\prod_i \frac{1}{q_i!}\left(\frac{-l_{nr_i+1}}{l_{n1}}\right)^{q_i}. \tag{34}$$

It is actually necessary to perform an expansion of this type because it combines the iteration number (n) dependence of the numerator and denominator which are both essential in the following results.

Then one can establish a hierarchy of equations for these coefficients:

$$l_{n1}(t)=nF''(t),$$

$$l_{n2}(t)=\sum_{j=1}^{n-1} jD_t^2 \log l_{n-j1}(t), \tag{35}$$

$$l_{np}(t)=\sum_{j=1}^{n-1} jm''_{n-jp-2}(t) \quad \text{for } p\geqslant 3,$$

for $n\geqslant 1$ while for $n=0$ we have $l_{np}(t)=0$ as $L_0(t,N)=\exp(NF(t))$. The first members of this hierarchy can be easily solved for yielding

$$l_{n1}(t)=nF''(t),$$

$$l_{n2}(t)=\frac{1}{2}n(n-1)\frac{F^{(2)}F^{(4)}-(F^{(3)})^2}{(F^{(2)})^2}, \tag{36}$$

$$l_{n3}(t)=\frac{1}{12}n(n-1)(n-2)\left(\frac{F^{(2)}F^{(4)}-(F^{(3)})^2}{(F^{(2)})^3}\right)^{(2)},$$

and from these it is easy to establish the leading-order terms already found in Eqs. (29) and (30).

Lemma 2: The hierarchy coefficients $l_{np}(t)$, $m_{np}(t)$ are polynomials in n.

These coefficients are constructed from a finite difference equation in *n*. □

Theorem 3: *The hierarchy coefficients $l_{np}(t)$, $m_{np}(t)$ are polynomials of degree p in n.*

This is proved by induction on *p* using the hierarchy equations. If we take $l_{jq}(t)$ to be of degree $q\leqslant p-2$ in *n*, then similarly for $m_{jq}(t)$ and $m''_{jq}(t)$. Now for any polynomial $P(n)$ of degree $p-2$ in its argument, then

$$\sum_{j=1}^{n-1} jP(n-j). \tag{37}$$

is a pth degree polynomial. Thus the recurrence, Eq. (35), establishes that l_{n+1p} is also a pth degree polynomial. □

From this result it is clear that the limiting forms of the Lanczos coefficients $\alpha_n(N)$, $\beta_n^2(N)$ exist when $n, N \to \infty$ with n/N fixed. If the ratio is not kept constant in this limiting operation, say with $n = o(N)$, then the Lanczos coefficients will vanish in the limit, while if the reverse is true, $N = o(n)$, then there will be divergent terms in the limit.

Given that the scaling Lanczos coefficients have been established, then all the exact theorems for the ground state properties[28,29] that were predicated on this result now are established. The first example of these theorems was the one for the ground state energy density,

$$\epsilon_0 = \inf_{s \in \mathbb{R}^+} [\alpha(s) - 2\beta(s)], \tag{38}$$

which also has an analog for the top of the spectrum, if this exists,

$$\epsilon_\infty = \sup_{s \in \mathbb{R}^+} [\alpha(s) + 2\beta(s)]. \tag{39}$$

For many models these Lanczos functions will be bounded on the positive real axis, and have limits as $s \to \infty$ on the real line. So, there is a superficial similarity to classes of orthogonal polynomials whose three-term recurrence coefficients have limiting values, such as the S class, the M class, or the $M(a,b)$ classes.[14]

IV. THE EXTENSIVE MEASURE

It is necessary to determine the OPS measure and its weight function $w(\epsilon)$, and this is not generally known at the outset, but rather the cumulant generating function is. In fact, it seems to be the case that the measures are not exactly expressible in simple terms, but the CGF or characteristic functions are. There is, of course, a direct route from a model system and a trial state to the Lanczos coefficients, but from many points of view, including practical considerations, the route beginning with a cumulant description is more useful.

Theorem 4: *Given that the cumulant generating function $F(-t)$ is analytic for $\mathcal{R}(t) > 0$ and in the neighborhood of the origin $t = 0$, the OPS weight function $w(\epsilon)$ has the following asymptotic development in the thermodynamic limit $N \to \infty$,*

$$w(\epsilon) = \sqrt{\frac{N}{2\pi F^{(2)}(\xi)}}\, e^{N[-\epsilon\xi + F(\xi)]} + O(N^{-1/2}), \tag{40}$$

where the function $\xi(\epsilon)$ is defined implicitly by

$$\epsilon = F'(\xi). \tag{41}$$

Starting with the definition of the cumulant generating function $F(t)$,

$$\langle e^{tH} \rangle \equiv \exp\{NF(t)\} = \exp\left\{ N \sum_{n=1}^{\infty} \frac{c_n}{n!} t^n \right\} \tag{42}$$

We assume here that this infinite series is not just formal but actually exists, that is, it has a finite radius of convergence in addition to its analytic character for $\mathcal{R}(t) < 0$. However, the moment generating function is simply the analytic continuation of the characteristic function and this continuation is possible given its analyticity, so that a Fourier inversion of this will yield the weight function,

$$w(\epsilon) = \frac{N}{2\pi} \int_{i\gamma-\infty}^{i\gamma+\infty} dt\ e^{N[-it\epsilon + F(it)]} = \frac{N}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} dt\ e^{N[t\epsilon + F(-t)]} \quad \mathcal{R}(\gamma) > 0. \tag{43}$$

One does not require the exact inversion, but only the leading order in N in a steepest descent approximation. In an asymptotic analysis the relevant function is

$$g(t)=t\epsilon+F(-t), \tag{44}$$

which is analytic for all $\mathcal{R}(t)>0$. We will assume the existence of a stationary point which occurs at t_0,

$$\epsilon=F'(-t_0), \tag{45}$$

and is assumed to be unique. This point is evidently real because the energy density is real and the CGF is a real function of a real argument (here we define $\xi=-t_0$ for convenience). One requires the inversion of this relation for $\xi(\epsilon)$ and this is guaranteed by the implicit function theorem because $F^{(2)}(\xi)>0$. This latter condition also implies that the saddle point is of order unity. Indeed, one clearly has the case of $F^{(2)}(t)>0$ for real values of t in the neighborhood of the saddle point and $F^{(2)}(t)<0$ for imaginary values of t in the same neighborhood. Thus the path of steepest descent through the saddle point is parallel to the imaginary axis. One can then apply the standard saddle point analysis (see Ref. 30, Sect. II.4) to arrive at the stated result. □

The corresponding example of the saddle point equation for the isotropic XY model is

$$\epsilon=\frac{1}{\pi}\int_0^{\pi/2}dq\ \cos q \tanh(\xi\cos q), \tag{46}$$

and that for the Ising model in a transverse field is

$$\epsilon=\frac{1}{\pi}\int_0^{\pi}dq\ \epsilon_q\ \frac{[(x+\cos q)/\epsilon_q]+\tanh(2\xi\epsilon_q)}{1+[(x+\cos q)/\epsilon_q]\ \tanh(2\xi\epsilon_q)}. \tag{47}$$

The first of the more obvious properties concerns the convexity of the measure arising in the thermodynamic limit,

Theorem 5: *The leading order of the negative logarithm of the weight function $u(\epsilon)$ is convex for all real energies ϵ.*

This follows from the relationship of $u(\epsilon)$ to the stationary point

$$\frac{d}{d\epsilon}u(\epsilon)=N\xi(\epsilon), \tag{48}$$

and the definition

$$\epsilon=F'(\xi). \tag{49}$$

Now it can be easily seen that $F''(t)>0$ for t real and the Hermitian Hamiltonian using the definition of $F(t)$ in terms of the expectation value $NF(t)=\ln\langle\exp(tH)\rangle$. □

Some detailed, yet general information, concerning the extensive measure in the neighborhood of the ground state is available. This arises from consideration of the overlap of the trial state with the true ground state,[31] and its relation to the Horn–Weinstein function $E(t)\equiv F'(-t)$ via

$$|\langle\Psi_{\mathrm{GS}}|\psi_0\rangle|^2=\exp\left\{-N\int_0^{\infty}dt\ [E(t)-E(\infty)]\right\}. \tag{50}$$

In general, the limit $E(t)$ as $t\to\infty$ will exist, and is the ground state energy, and so the asymptotic properties of $E(t)$ for $\mathcal{R}(t)>0$ as this tends to infinity is a means of classifying systems. This equivalent to the asymptotic properties of $\epsilon(\xi)-\epsilon(-\infty)$ as $\xi\to-\infty$ [we denote the ground state energy by ϵ_0, which is also the same as $\epsilon(-\infty)$]. In general the overlap is nonzero, so that $E(t)-E(\infty)\in L^1[0,\infty)$, but it is possible at isolated points that this is not true (critical points in the model, for example) and the overlap may vanish. For example, the overlap squared in the case of the isotropic *XY* model is $2^{-N/2}$ and that for the Ising model in a transverse field is

$$\exp\left\{\frac{N}{2\pi}\int_0^{\pi}dq\,\ln\left(\frac{\epsilon_q+x+\cos q}{2\epsilon_q}\right)\right\}. \tag{51}$$

Where the overlap is nonzero, then several possibilities for the asymptotic behavior exist, which do actually arise in the exact solutions of the example models.

(i) *gapless case*, isotropic *XY* and critical Ising model in a transverse field (Refs. 32 and 23): At a critical point, the first excited state gap vanishes and

$$\epsilon-\epsilon_0\sim A|\xi|^{-\gamma}, \tag{52}$$

as $\xi\to-\infty$ and, if the overlap is finite, then $\mathcal{R}(\gamma)>1$. Therefore, the weight function at the bottom of the spectrum takes the following form:

$$w(\epsilon)\sim(\epsilon-\epsilon_0)^{-(1+\gamma)/2\gamma}\exp\left\{N\,\frac{b}{1-1/\gamma}\,(\epsilon-\epsilon_0)^{1-1/\gamma}\right\}. \tag{53}$$

This measure is integrable on $(\epsilon_0,\epsilon_\infty)$ because of the above condition $\mathcal{R}(\gamma)>1$ and has a branch point at the ground state energy ϵ_0.

(ii) *gapped case 1*, Ising model in a transverse field, in the ordered phase with the disordered trial state (Ref. 23):

If the gap is finite, then one possibility is that

$$\epsilon-\epsilon_0\sim Ae^{-\Delta|\xi|}, \tag{54}$$

as $\xi\to-\infty$ and where the excited state gap $\Delta>0$. One can show that the weight function near the bottom edge of the spectrum is analytic, having the form

$$w(\epsilon)\sim\frac{1}{\Gamma(N[\epsilon-\epsilon_0]/\Delta+1)}. \tag{55}$$

(iii) *gapped case 2*, Ising model in a transverse field, in the disordered phase with the disordered trial state (Ref. 23):

Yet another type of gap behavior exists,

$$\epsilon-\epsilon_0\sim A|\xi|^{-\gamma}e^{-\Delta|\xi|}. \tag{56}$$

The leading-order behavior of the weight function in this case is

$$w(\epsilon)\sim(\epsilon-\epsilon_0)^{-1/2-N(\epsilon-\epsilon_0)}[-\log(\epsilon-\epsilon_0)]^{-N\gamma(\epsilon-\epsilon_0)}, \tag{57}$$

which again has a branch point at the bottom edge of the spectrum.

So generally we find the support of the measure is bounded, which excludes a number of weight function types such as the Freud or Erdös weights, but that the weight functions belong to the Szegö class on $[\epsilon_0,\ \epsilon_\infty]$,

$$\int_{\epsilon_0}^{\epsilon_\infty}d\epsilon\,\frac{\log w(\epsilon)}{\sqrt{[\epsilon_\infty-\epsilon][\epsilon-\epsilon_0]}}>-\infty. \tag{58}$$

V. EXACTLY SOLVABLE LANCZOS PROCESS

In this section we derive how the exact Lanczos functions $\alpha(s)$ and $\beta^2(s)$ can be constructed directly from the knowledge of the connected moments or cumulants, or more specifically from the cumulant generating function. This is the initial data that one uses in any analysis of quantum many-body systems with this approach, and for soluble models the full generating function may be available. However, if this is not the case, then one would use a set of low-order cumulants, up to a given order.

As a first step we recast the Hankel determinants into Selberg integral form, from the classical result[9]

$$\Delta_n(t)=\frac{1}{(n+1)!}\int_{-\infty}^{+\infty}\prod_{k=1}^{n+1} d\rho(\epsilon_k)e^{Nt\Sigma_{k=1}^{n+1}\epsilon k}\prod_{1\leq i<j\leq n+1}|\epsilon_i-\epsilon_j|^2. \tag{59}$$

For the steps leading to the two conditions which will define the Lanczos functions we follow Chen and Ismail.[13] A similar approach, but just confined to the evaluation of the Hankel determinants, was taken in Refs. 33 and 34. The Hankel determinant can be recast into the form of a partition function, which is

$$\Delta_n(t)=\frac{1}{(n+1)!}\int_{-\infty}^{+\infty}\prod_{i}^{n+1} d\epsilon_i \exp\left\{-\sum_i^{n+1} u(\epsilon_i)+Nt\sum_i^{n+1}\epsilon_i+2\sum_{i<j}^{n+1}\ln|\epsilon_i-\epsilon_j|\right\}. \tag{60}$$

One should observe that both $\Sigma_i^{n+1}u(\epsilon_i)$ and $Nt\Sigma_i^{n+1}\epsilon_i$ are of order $(n+1)N$, while the remaining term in the argument $\Sigma_{i<j}^{n+1}\ln|\epsilon_i-\epsilon_j|$ is of order $(n+1)^2$, so that the only relative scaling that remains nontrivial is one in which n/N is fixed. The alternatives would lead to completely trivial consequences. The leading-order term for this Hankel determinant as n, $N\rightarrow\infty$ is given by a steepest descent approximation (see Ref. 30, Sec. IX.5)

$$\Delta_n(t)=\frac{(2\pi)^{n+1}}{(n+1)!}\left|\frac{\partial^2 f}{\partial\epsilon_i^0\partial\epsilon_j^0}\right|^{-1/2}e^{-f(\epsilon^0)}[1+O(1/n,1/N)], \tag{61}$$

where the function $f(\epsilon)$ is defined as

$$f(\epsilon)=\sum_i^{n+1}u(\epsilon_i)-Nt\sum_i^{n+1}\epsilon_i-2\sum_{i<j}^{n+1}\ln|\epsilon_i-\epsilon_j|, \tag{62}$$

and the saddle points $\{\epsilon_i^0\}_{i=1}^{n+1}$ are given by

$$u'(\epsilon_i^0)=Nt+2\sum_{i\neq j}^{n+1}\frac{1}{\epsilon_i^0-\epsilon_j^0}. \tag{63}$$

One can easily show that the Hessian in Eq. (61) is positive definite given that $u(\epsilon)$ is convex. One can carry the continuum limit further by describing the saddle points as a charged fluid whose dynamics are governed by an energy functional $F[\sigma]$,

$$\exp(-f(\epsilon^0))\xrightarrow[n,N\rightarrow\infty]{}\exp(-F[\sigma_0]), \tag{64}$$

with a charge density $\sigma(\epsilon)$ defined on an interval of integration which is to be determined, $I=(\epsilon_-,\epsilon_+)$. The energy functional takes the following form

$$F[\sigma]=\int_I d\epsilon\,\sigma(\epsilon)[u(\epsilon)-Nt\epsilon]-\int_I d\epsilon\int_I d\epsilon'\,\sigma(\epsilon)\ln|\epsilon-\epsilon'|\sigma(\epsilon'), \tag{65}$$

where the single particle confining potential is controlled by the OPS measure and the two-body interaction is a logarithmic type. The result of minimizing this functional yields the following singular integral equation for the charge density,

$$u'(\epsilon)-Nt=2\mathrm{PV}\int_I d\epsilon' \, \frac{\sigma_0(\epsilon')}{\epsilon-\epsilon'}. \tag{66}$$

The solution of this integral equation for the minimal charge density $\sigma_0(\epsilon)$ can be found exactly and is

$$\sigma_0(\epsilon)=\frac{\sqrt{(\epsilon_+-\epsilon)(\epsilon-\epsilon_-)}}{2\pi^2}\,\mathrm{PV}\int_I d\epsilon' \, \frac{u'(\epsilon')-Nt}{(\epsilon'-\epsilon)\sqrt{(\epsilon_+-\epsilon')(\epsilon'-\epsilon_-)}}. \tag{67}$$

There are two conditions arising from this solution:

(i) the first is a supplementary condition which is necessary for the charge density solution to be well defined throughout the interval I,

$$0=\int_I d\epsilon \, \frac{u'(\epsilon)-Nt}{\sqrt{(\epsilon_+-\epsilon)(\epsilon-\epsilon_-)}}; \tag{68}$$

(ii) and the normalization condition which simply counts the number of Lanczos steps,

$$n=\frac{1}{2\pi}\int_I d\epsilon \; \epsilon \, \frac{u'(\epsilon)-Nt}{\sqrt{(\epsilon_+-\epsilon)(\epsilon-\epsilon_-)}}. \tag{69}$$

Using this solution for the charge density one can substitute this into the original defining equations for the Hankel determinants (the leading-order approximations) and establish that the Lanczos functions are simply defined by the interval I in this way, $\epsilon_\pm=\alpha\pm2\beta$.

Theorem 6: *The Lanczos functions are given implicitly by the two integral equations*

$$0=\int_{\alpha-2\beta}^{\alpha+2\beta} d\epsilon \, \frac{\xi(\epsilon)}{\sqrt{4\beta^2-(\epsilon-\alpha)^2}}, \tag{70}$$

$$s=\frac{1}{2\pi}\int_{\alpha-2\beta}^{\alpha+2\beta} d\epsilon \, \frac{\epsilon\xi(\epsilon)}{\sqrt{4\beta^2-(\epsilon-\alpha)^2}}, \tag{71}$$

where the model-dependent equation for the stationary point $\xi(\epsilon)$ is given by Eq. (49).

This theorem follows from the previous conditions, namely Eqs. (68) and (69), and the result for the logarithmic derivative of the weight function,

$$u'(\epsilon)=N\xi(\epsilon)+O(\log N). \tag{72}$$

□

Usually this later equation for the saddle point is also an implicit equation and invariably a nonlinear one. In our derivation the scaling $s=n/N$ remains finite while $n,N\to\infty$ emerges naturally and, in fact, it is difficult to see how one could avoid this confluence.

We now give an alternative result for the Lanczos functions which is based on the time evolution of the Lanczos L-function.

Theorem 7: *The Lanczos L-function, in the thermodynamic limit, is the solution of the following integro-differential equation*

$$L(s,t)=\int_0^s dr \; rD_t^2 \log L(s-r,t)+sF^{(2)}(t), \tag{73}$$

and the two Lanczos functions are derivable from this via

$$\alpha(s)=\int_0^s dr\ D_t \log L(r,0)+F'(0),$$
$$\beta^2(s)=L(s,0). \tag{74}$$

The integro-differential equation is simply derived from the discrete recurrence, namely Eq. (24), after making the observation that the $j=n$ term involving $L_0(t)$ has to be separated from the sum because it encompasses the initial conditions and is itself not generated by the recurrence. □

Finally, we give a result equivalent to the theorem above, but which involves only scaled forms of the Hankel determinants $\Delta_n(N,t)$and is the differential analog of the above theorem.

Definition 4: We make the following definition for $\delta(n,N,t)$ in terms of the Hankel determinant,

$$\Delta_n(N,t)=N^{n(n+1)}[\delta(n,N,t)]^{N^2}, \tag{75}$$

for $n\geqslant 1$ and $\Delta_0(t)=[\delta(0,t)]^N$.

Lemma 3: The function $\delta(n,N,t)$ is well defined in the scaling limit $n,N\to\infty$.

This follows naturally from the relation of the $\Delta_n(t)$and the Lanczos L-function as given in Eq. (22), and the well-defined scaling of this latter function as demonstrated in Theorem 3 above. □

Then we have the following result.

Theorem 8: *The Lanczos $\delta(s,t)$-function satisfies the following partial differential equation in the thermodynamic limit,*

$$\exp\{D_s^2 \log \delta(s,t)\}=D_t^2 \log \delta(s,t), \tag{76}$$

with the boundary condition

$$\lim_{s\to 0+}\frac{\log \delta(s,t)}{s}=F(t) \quad \forall t\in\mathbb{R}^+. \tag{77}$$

The Lanczos functions are given by

$$\alpha(s)=D_tD_s \log \delta(s,t)\big|_{t=0},$$
$$\beta^2(s)=\exp\{D_s^2 \log \delta(s,0)\}. \tag{78}$$

Using the scaling relation above, Eq. (75), and the equation of motion for $\Delta_n(t)$, Eq. (27), the result follows. □

These last two theorems relate to the dynamics of a nonlinear continuum Toda lattice in one space domain $s\in\mathbb{R}^+$ and one time domain t, with boundary conditions defined at the origin $s=0$ for all times t by the cumulant generating function $F(t)$. The object is then to find the Lanczos functions $\alpha(s),\beta^2(s)$ from a solution of this system, wherein these functions are directly related to the solution at a given time $t=0$ over all spatial points $s>0$.

VI. THE TAYLOR SERIES EXPANSION

The investigation of the Taylor series expansion of the Lanczos coefficients about $s=0$ is an essential element in the application of this Lanczos method, as was indicated earlier, where one has only a finite set of low-order cumulants available, say for nonintegrable models. Therefore, in this case, one can only construct a truncated Taylor series expansion and so issues concerning convergence, the radius of convergence of the series, and whether one can extrapolate immediately arise. In addition, one would like a direct algorithm relating the cumulants to the Lanczos functions from a purely practical point of view.

We define the Taylor series expansion of the two Lanczos functions by two new sequences of coefficients,

$$\alpha(s)=c_1+\sum_{n=0}^{\infty} a_n s^{n+1},$$
$$\beta^2(s)=\sum_{n=0}^{\infty} b_n s^{n+1}, \tag{79}$$

In order to find these coefficients one could use either of the two general solutions for the Lanczos process, Eqs. (70) and (71) or Eq. (73), and the two methods are presented below.

The first step involves the inversion of the following Taylor series expansion,

$$\epsilon=c_1+\sum_{n=1} \frac{c_{n+1}}{n!}\xi^n, \tag{80}$$

for $\xi(\epsilon)$, namely the coefficients e_k appearing in

$$\xi=\sum_{k=1} e_k(\epsilon-c_1)^k. \tag{81}$$

The coefficients c_n appearing in Eq. (80) are the cumulant coefficients. The existence of this inverse function is guaranteed because the second cumulant $c_2>0$ in all systems and we assume that the saddle point function, Eq. (49), is analytic in the neighborhood of $\xi=0$. The next step involves the solution of the two recurrences

$$0=\sum_{k=1} e_k \sum_{m=0}^{\lfloor k/2\rfloor} \binom{k}{2m} \frac{(1/2)_m}{m!}(\alpha-c_1)^{k-2m}(4\beta^2)^m,$$
$$2s=\sum_{k=1} e_k \sum_{m=0}^{\lfloor (k-1)/2\rfloor} \binom{k}{2m+1} \frac{(1/2)_{m+1}}{(m+1)!}(\alpha-c_1)^{k-2m-1}(4\beta^2)^{m+1}, \tag{82}$$

which are used to solve for the coefficients a_n, b_n appearing in Eq. (79).

In the second method we define a continuum version of the coefficients that are defined in Eq. (33) in the following way,

$$\log\frac{L(s,t)}{sl_1(t)}=\log\left(1+\sum_{p\geqslant 1}\frac{l_{p+1}}{l_1}s^p\right)\equiv\sum_{p\geqslant 1} m_p(t)s^p, \tag{83}$$

and the inverse of Eq. (34) in an explicit form,

$$\frac{l_{p+1}}{l_1}=\sum_{\Sigma_i q_i r_i=p}\prod_i \frac{1}{q_i!}m_{r_i}^{q_i}. \tag{84}$$

From these relations one can find a hierarchy of equations for these coefficients:

$$l_1(t)=F''(t),$$

$$l_2(t)=\frac{F^{(2)}F^{(4)}-(F^{(3)})^2}{2(F^{(2)})^2}, \tag{85}$$

$$l_{p+2}(t)=\frac{m_p''(t)}{(p+2)(p+1)}=l_1(t)\sum_{\Sigma_i q_i r_i=p+1}\prod_i \frac{m_{r_i}^{q_i}}{q_i!} \quad \text{for } p\geqslant 1.$$

Thus one can verify from the solution for the initial value problem above that the general Taylor series coefficients are given by

$$[(n+1)!]^2 c_2^{3n+1} a_n=\sum_{\lambda\vdash 2n+1} A(n;\lambda)\prod_{i=0}^{2n+1} c_{2+i}^{a_i},$$
$$(n+1)!n!c_2^{3n-1} b_n=\sum_{\lambda\vdash 2n} B(n;\lambda)\prod_{i=0}^{2n} c_{2+i}^{a_i}, \tag{86}$$

where the coefficients labeled by the partition $\lambda=(1^{a_1},2^{a_2},\ldots,i^{a_i})$, denoted by $A(n;\lambda)$, $B(n;\lambda)$, are listed in the table in the Appendix. There are constraints operating in the above equations, namely $\Sigma_{i=1}^{2n+1} i a_i=\Sigma_{i=0}^{2n+1} a_i=2n+1$ for the first relation and $\Sigma_{i=1}^{2n} i a_i=\Sigma_{i=0}^{2n} a_i=2n$ for the second.

Clearly the Taylor series expansion of the Lanczos functions has low-order coefficients which are constructed from the low-order cumulants, and is a form of a linked cluster expansion. However, it is not just a simple linked cluster expansion as in the Taylor series expansion of the cumulant generating function, but involves a subtle interplay and cancellation of all cumulants below a given order.

VII. GENERAL PROPERTIES

There are some very general properties that the Lanczos process in the thermodynamic limit and the associated Lanczos functions satisfy and we examine these now. Some are quite obvious and not particularly surprising; however, we state these for completeness sake, while there are some other properties which are not so immediate, but very important nevertheless.

The next, and natural, property concerns the monotonicity of the two envelope function $\epsilon_{\pm}(s)=\alpha(s)\pm 2\beta(s)$.

Theorem 9: *The envelope functions* $\epsilon_+(s),\epsilon_-(s)$ *are monotonically increasing and decreasing functions of real, positive s, respectively*.

This follows from a recasting of the normalization condition in the following way,

$$2\pi s=\int_{\xi-}^{\xi+} d\xi\ \sqrt{[\epsilon(\xi_+)-\epsilon(\xi)][\epsilon(\xi)-\epsilon(\xi_-)]}, \tag{87}$$

where the $\xi_{\pm}$ are defined by $\epsilon(\xi_{\pm})=\epsilon_{\pm}$. Now it is straightforward to write the explicit forms for the derivatives of the envelope functions with respect to s as

$$\frac{d\epsilon_+}{ds}=4\pi \Bigg/ \int_{\xi_-}^{\xi_+} d\xi\ \sqrt{\frac{\epsilon(\xi)-\epsilon(\xi_-)}{\epsilon(\xi_+)-\epsilon(\xi)}},$$
$$\frac{d\epsilon_-}{ds}=-4\pi \Bigg/ \int_{\xi_-}^{\xi_+} d\xi\ \sqrt{\frac{\epsilon(\xi_+)-\epsilon(\xi)}{\epsilon(\xi)-\epsilon(\xi_-)}}, \tag{88}$$

so that the stated properties are evident. □

It is clear that the envelope functions $\epsilon_{\pm}(s)$ are bounded in the following ways, $\epsilon_{-}(s) \geqslant \epsilon_0$ and $\epsilon_{+}(s) \leqslant \epsilon_{\infty}$.

The three-term recurrence which serves as one of the definitions of the orthogonal polynomials themselves is now going to take a definite limiting form when $n,N \to \infty$ such that s is finite. This is going to lead to a scaling form for one set of the polynomials themselves, which would be more correctly termed orthogonal functions $p(s,\epsilon)$. Heuristically one can see how this arises by the following argument. If one ensures that Lanczos densities are employed and the following scaling of the polynomials thus $P_n(E) = N^n p_n(\epsilon)$, then the three-term recurrence becomes

$$p_{n+1}(\epsilon)/p_n(\epsilon) + \beta_n^2 \frac{1}{p_n(\epsilon)/p_{n-1}(\epsilon)} = \epsilon - \alpha_n . \tag{89}$$

Now these ratios are approximated by

$$\frac{p_{n+1}(\epsilon)}{p_n(\epsilon)} \sim \exp\left(\frac{1}{N}\frac{\partial}{\partial s} \ln p(s,\epsilon)\right), \tag{90}$$

for arguments $\epsilon \in \mathbb{C} \backslash \mathrm{Supp}\,[d\rho]$, so that in the asymptotic regime the recurrence becomes

$$\exp\left(\frac{1}{N}\frac{\partial}{\partial s} \ln p(s,\epsilon)\right) + \beta^2(s) \exp\left(-\frac{1}{N}\frac{\partial}{\partial s} \ln p(s,\epsilon)\right) \sim \epsilon - \alpha(s), \tag{91}$$

whose solutions are

$$p^{\pm}(s,\epsilon) \sim p(0) \exp\left\{ N \int^{s} dt \ln \frac{1}{2} \left[\epsilon - \alpha(t) \pm \sqrt{(\epsilon - \alpha(t))^2 - 4\beta^2(t)}\right]\right\}. \tag{92}$$

These are the corresponding results for the ratio $P_n(x)/P_{n+1}(x)$ or nth root $\sqrt[n]{P_n(x)}$ asymptotics of generic orthogonal polynomials as $n \to \infty$ (Refs. 9, 11, and 35–37), or the scaled orthogonal polynomials,[14] but are rather different due to the particular nature of many-body orthogonal polynomials.

Theorem 10: *Given the scaling behavior of the Lanczos coefficients, and that they are bounded for $n,N \to \infty$, then the nth roots of the denominator orthogonal polynomials $p_n(\epsilon)$ have the limiting form uniformly for ϵ in compact subsets of $\mathbb{C} \backslash \mathrm{Supp}\,[d\rho]$:*

$$p(s,\epsilon) \equiv \lim_{n,N \to \infty} |p_n(N,\epsilon)|^{1/N} = \exp\left\{ \int_0^{s} dt \ln \frac{1}{2} \left[\epsilon - \alpha(t) + \sqrt{(\epsilon - \alpha(t))^2 - 4\beta^2(t)}\right]\right\}. \tag{93}$$

The proof of this parallels the one constructed by van Assche in Ref. 14 through the use of Turán determinants,

$$D_n \equiv p_n^2 - p_{n+1} p_{n-1} . \tag{94}$$

One can show that these obey the following recurrence relation

$$D_n = \beta_n^2 D_{n-1} + (\alpha_n - \alpha_{n-1}) p_n p_{n-1} + (\beta_n^2 - \beta_{n-1}^2) p_n p_{n-2} . \tag{95}$$

Using the partial fraction decomposition of the ratio of two successive orthogonal polynomials one can also find a bound on this ratio

$$\left|\frac{p_{n-1}(\epsilon)}{p_n(\epsilon)}\right| \leqslant \frac{C}{d} \quad \forall n \tag{96}$$

for all $\epsilon \in K$ where the compact set $K \subset \mathbb{C} \backslash \mathrm{supp}\,[d\rho]$ and d is the distance between this set and the interval $[\epsilon_0, \epsilon_\infty]$, and C is a positive constant. Using Eq. (95) we have

$$\left|\frac{D_n}{p_n^2}\right| \leqslant \sup_n(\beta_n^2)\,\frac{C^2}{d^2}\left|\frac{D_{n-1}}{p_{n-1}^2}\right| + |\alpha_n - \alpha_{n-1}|\,\frac{C}{d} + |\beta_n^2 - \beta_{n-1}^2|\,\frac{C^2}{d^2}. \tag{97}$$

Given the scaling form of the Lanczos coefficients the ratio $|D_n/p_n^2| \to 0$ as $n, N \to \infty$ uniformly in ϵ whenever d is large enough. This means that $|p_{n-1}/p_n|$ and $|p_n/p_{n+1}|$ tend to the same accumulation point which we denote by $p(s,\epsilon)$. This point is given by the solution of the quadratic equation $p + \beta^2(s)/p = \epsilon - \alpha(s)$, and the positive branch of the solution must be taken as $p \to \infty$ when $\epsilon \to \infty$. The functions $p(s,\epsilon)$ are analytic functions of $\epsilon \in K$ which are uniformly bounded, so the restriction on d can be lifted to being only nonzero. The behavior of the nth ratio then gives the nth root behavior directly as

$$|p_n|^{1/N} = \exp\left\{\frac{1}{N}\sum_{k=1}^{n} \log\left|\frac{p_k(\epsilon)}{p_{k-1}(\epsilon)}\right|\right\}, \tag{98}$$

The asymptotic behavior that we have found applies to the denominator OP only as can be seen from the observation that $p_1 = \epsilon - c_1$ and $p_2 = (\epsilon - c_1)^2 - c_3/c_2 N(\epsilon - c_1) - c_2/N$, while

$$[\epsilon - \alpha(s) + \sqrt{(\epsilon - \alpha(s))^2 - 4\beta^2(s)}] \xrightarrow[s\to 0]{} \frac{1}{\epsilon - c_1}\,((\epsilon - c_1)^2 - c_3/c_2 N(\epsilon - c_1) - c_2/N). \tag{99}$$

This establishes the result. □

VIII. SUMMARY

In this work we have demonstrated the general scaling behavior of the Lanczos process as applied to many-body systems when the process is taken to convergence and the thermodynamic limit taken. We also find explicit constructions of the limiting Lanczos coefficients in two equivalent formulations, from an initial exact solution of the moment problem, that is to say, the cumulant generating function for the system. There are explicit examples where the CGF can be found and the whole Lanczos process explicitly realized. Furthermore, we have given the corresponding results for the associated orthogonal polynomial system and the measure in this regime quite generally. However, we must emphasize that these results apply only to the bulk properties, that is to say, the ground state properties that scale extensively and the spectral properties in the interior (the ‘‘bulk’’) of the spectrum. So this does not include the delicate scaling behavior at the edges of the spectrum, nor in the neighborhood of singularities—this theory would have to be extended to treat the excited state gaps near the bottom of the spectrum. A number of general theorems are given which constrain the behavior of the Lanczos functions, and the process in general. We also indicate how a number of such constraints operating can lead to some concrete realizations or scenarios that the Lanczos process can present, namely its behavior at a critical point in the model under study. This is a significant step on the way to the goal of a rigorous classification of many-body systems in terms of their character via the Lanczos process. Other important questions that arise in the treatment of nonintegrable models, for which the general results presented here have suggested some answers, are the questions of the choice of trial state, the rate of convergence of the truncated Lanczos process, and how one might accelerate its convergence given some independent qualitative knowledge.

(Received 30 November 1998; accepted for publication 3 June 1999)

The family $\mathcal{F}_L^\kappa$ of all potentials $V(x)$ for which the Hamiltonian $H=-d^2/dx^2+V(x)$ in one space dimension possesses a high-order Lie symmetry is determined. A subfamily $\mathcal{F}_{\mathrm{SGA}}^{(2)}$ of $\mathcal{F}_L^\kappa$, which contains a class of potentials allowing a realization of $so(2,1)$ as spectrum generating algebra of H through differential operators of finite order, is identified. Furthermore and surprisingly, the families $\mathcal{F}_{\mathrm{SGA}}^{(2)}$ and $\mathcal{F}_L^\kappa$ are shown to be related to the stationary KdV hierarchy. Hence, the ''harmless'' Hamiltonian H connects different mathematical objects: high-order Lie symmetry, the realization of $so(2,1)$-spectrum generating algebra and families of nonlinear differential equations. We describe in a physical context the interplay between these objects. [S0022-2488(99)02710-3]

I. MOTIVATION AND BACKGROUND

In the two internal reports for the International Center of Theoretical Physics (ICTP),[1,2] written in the clearly 1970s, a complete classification of symmetric Hamiltonians in one space dimension on $L^2(\mathbf{R}_x^1,dx)$

$$H=\gamma\frac{d^2}{dx^2}+V(x),\qquad \gamma<0, \tag{1}$$

having the Lie algebra $so(2,1)$ as a ''spectrum generating algebra'' (SGA), has been obtained. This result has been published only recently in connection with a Barut-Memorial Lecture.[3] In Refs. 1, 2, the following definition of SGA is used: a differential operator A of the order n' has a spectrum generating (Lie) algebra L with generators $g_i\,(i=1,...,m,\ m=\dim L)$ if there exists a realization R of L through differential operators of an order $n\geqslant n'$, such that

$$A=\sum_{i=1}^{m}\alpha_i R(g_i),\qquad \alpha_i\in\mathbf{R}. \tag{2}$$

The Hamiltonian (1) is a differential operator on a suitable complex function space $\mathcal{G}$ over x with $n'=2$. A realization R of $so(2,1)$ with standard basis $\mathcal{M}$ spanned by g_1,g_2,g_3 through nth-order differential operators on $\mathcal{G}$ reads as

$$R(g_i)=\sum_{j=0}^{n} a_{ij}(x)\frac{d^j}{dx^j},\qquad i=1,2,3, \tag{3}$$

[a)]Electronic mail: asi@pt.tu-clausthal.de
[b)]Electronic mail: renat@imath.kiev.ua

where $a_{ij}(x)$ are complex functions, such that the commutation relations,

$$[R(g_1),R(g_2)]=-R(g_3),\quad [R(g_2),R(g_3)]=R(g_1),\quad [R(g_3),R(g_1)]=-R(g_2), \tag{4}$$

are fulfilled. So $R(so(2,1))$ is a SGA of (1) on $\mathcal{G}$ if there exist constants $\alpha_i\in\mathbf{R}\,(i=1,2,3)$, such that the equality,

$$H\equiv\gamma\frac{d^2}{dx^2}+V(x)=\sum_{j=1}^{3}\alpha_j R(g_j), \tag{5}$$

holds.

The relations (3)–(5) impose restrictions both on the coefficients $a_{ij}(x)$ and on the potential $V(x)$. Solving these restrictions we find two different families $\mathcal{F}_{\mathrm{SGA}}=\{\mathcal{F}^{(1)}_{\mathrm{SGA}},\mathcal{F}^{(2)}_{\mathrm{SGA}}\}$ of those potentials, which allow $so(2,1)$ as SGA for (1), and we can use properties of $R(so(2,1))$ to calculate the spectrum of *H*, if *H* and $R(so(2,1))$ act on $L^2(\mathbf{R}^1_x,dx)$. If, furthermore, $R(g_i)$ are essentially self-adjoint in a common dense domain and if the representation is integrable, then one can use the known theory for unitary representations of $so(2,1)$. This is the background of the term ''spectrum generating algebra'' as suggested in Refs. 4, 5. There were many results in this field for different Hamiltonians, Lie algebras, and physical systems (see, e.g., the recent review[6]), but no general study in the sense of Refs. 1 and 2.

The motivation of the present paper is to show (in Sec. III) that the family $\mathcal{F}^{(2)}_{\mathrm{SGA}}$ can be read from the stationary KdV hierarchy. This surprising connection between the KdV hierarchy and $so(2,1)$ has its origin in a certain higher-order Lie symmetry of the Hamiltonian (5), which has $so(2,1)$ as SGA. In Sec. II we sketch the results of Refs. 1 and 2 on which our discussion is based.

II. ON SOME KNOWN RESULTS

To classify those $V(x)$ that are solutions of (3)–(5), we reduce the calculation to special choices of parameters $\alpha_1,\alpha_2,\alpha_3$ through basis transformations, which leave $\mathcal{M}$ invariant. As a result, we only have to treat the following two cases ($\lambda\in\mathbf{R},\ \lambda\neq 0$):

$$\text{Case 1.}\quad \alpha_1^2+\alpha_2^2\neq\alpha_3^2,\quad \text{with } H=\lambda R(g_i),\quad i=1,2, \tag{6}$$

$$\text{Case 2.}\quad \alpha_1^2+\alpha_2^2=\alpha_3^2,\quad \text{with } H=\lambda(R(g_1)+R(g_3)). \tag{7}$$

Case 2 is denoted as the ''light cone case.'' Both cases (3)–(5) lead for a fixed *n* to set of coupled differential equations of the order *n* for $a_{ij}(x)$ $(i=1,2,3,\ j=0,...,n)$ and $V(x)$. We assume that $R(g_i)$ are symmetric operators and that $V(x)$ is a real function. A clumsy but straightforward calculation shows that in Case 1 a solution exists only for $n=2$ with a family $\mathcal{F}^{(1)}_{\mathrm{SGA}}$ of corresponding potentials,

$$\mathcal{F}^{(1)}_{\mathrm{SGA}}(\lambda_1,\lambda_2,c)=\{V(x)|V(x)=\lambda_1(x-c)^2+\lambda_2(x-c)^{-2},\lambda_1,\lambda_2,c\in\mathbf{R},\lambda_1\neq 0\}. \tag{8}$$

In Case 2 a solution exists for all $n\geqslant 2$. The corresponding family $\mathcal{F}^{(2)}_{\mathrm{SGA}}$ consists of potentials that are solutions of nonlinear differential equations,

$$\mathcal{F}^{(2)}_{\mathrm{SGA}}=\left\{V(x)\left|-\left(\frac{x}{2}V'+V\right)+\sum_{j=0}^{N-1}c_jF_j+F_N=0\right.\right\}, \tag{9}$$

where $N=[(n-1)/2]$, F_j are some polynomials of $V(x)$ and its derivatives up to the order $2j+1$ $(j=0,1,...,N)$, which will be given later in another context [see (12) and (13)]; $c_0,c_1,\ldots,c_{N-1}$ are arbitrary real constants.

The family $\mathcal{F}^{(2)}_{\mathrm{SGA}}$ has a peculiar structure. The facts that the equations are equal for $n=2N+1$ and $n=2N+2$, $N=1,2,...$, and that the equation for $n=n_1>n_2$ contains all terms of the equation for $n=n_2$ are two of these peculiarities. This structure was not elucidated in Refs. 1, 2, also relations to other mathematical notions and objects were not found. This was the reason why the authors of Refs. 1, 2 decided to present the results as internal reports. In the present paper we fill this gap.

In order to simplify the following calculations we scale the variable x and thus get $\gamma=-1$. So the Schrödinger operator (1) takes the form

$$H=-\frac{d^2}{dx^2}+V(x). \tag{10}$$

III. SGA, LIE SYMMETRIES, AND KdV HIERARCHY

A. Aim and strategy

We present a view on the family $\mathcal{F}_{\rm SGA}^{(2)}$ through a high-order Lie symmetry Q of type C_κ, i.e., with $[Q,H]=\kappa H$ (see Sec. III B) of the Schrödinger equation,

$$\left(-\frac{d^2}{dx^2}+V(x)\right)f(x)=0, \quad f\in\mathcal{G}, \tag{11}$$

and we show that because of this view the F_j, $(j=0,1,...,N)$ in (9) appear, surprisingly, in the stationary KdV hierarchy,

$$\sum_{j=0}^{N-1} c_j F_j+F_N=0.$$

We remind the reader that the stationary KdV hierarchy is obtained successively by the repeated action of the integrodifferential operator (the second recursive operator for the KdV equation[7–9]),

$$\mathcal{R}=-\frac{1}{4}\frac{d^2}{dx^2}-V(x)-\frac{1}{2}V'(x)\left(\frac{d}{dx}\right)^{-1}, \tag{12}$$

generating F_j, $(j=0,1,...)$ through

$$F_{j+1}=\mathcal{R}F_j, \quad j=0,1,..., \quad \text{with } F_0=-\tfrac{1}{2}V'(x). \tag{13}$$

Our strategy is the following. We construct as a first step the family $\mathcal{F}_L^0$ of all potentials $V(x)$ for which $Hf=0$ allows an nth-order Lie symmetry $Q\in\mathcal{L}$ of type C_0 (Theorem 1). In a second step, we generalize this result for a Lie symmetry of type C_κ, κ is arbitrary, (Theorem 2) and get the family $\mathcal{F}_L^\kappa$. In the special case $\kappa=-1$ we find the families $\mathcal{F}_{\rm SGA}^{(2)}$.

B. Lie symmetries

An nth-order differential operator on a suitable function space $\mathcal{G}$ over $\mathbf{R}_x^1$,

$$\tilde{Q}^{(n)}=\sum_{j=0}^{n} q_j(x)^{(n)}\frac{d^j}{dx^j}, \quad \frac{d^0}{dx^0}\overset{\rm def}{=}1, \tag{14}$$

is called an nth-order symmetry of the Schrödinger equation (11) if it transforms the set of its solutions Γ_H into itself, i.e., $\tilde{Q}^{(n)}\Gamma_H=\Gamma_H$ $(\mathcal{G}\supset\Gamma_H)$. It is reasonable to impose further properties on $\tilde{Q}^{(n)}$. A useful choice is a Lie symmetry $Q^{(n)}$ of H. Take an mth-order differential operator P and assume

$$[Q^{(n)},H]=PH, \quad \text{on } \mathcal{G}. \tag{15}$$

Obviously $Q^{(n)}$ on Γ_H is a symmetry $\tilde{Q}^{(n)}$ of (11).

In the following we use $P=\kappa\mathbf{1}$, κ is a real constant, i.e.,

$$[Q^{(n)},H]=\kappa H, \quad \text{on } \mathcal{G}, \tag{16}$$

and denote this as a Lie symmetry of type C_κ.

Together with $Q^{(n)}$, also

$$Q^{(n')}=Q^{(n)}+\sum_{j=0}^{m} \gamma_j H^j,$$

$n'<2m+n$ with arbitrary constants γ_j is a Lie symmetry of H. Hence, $Q^{(n')}$ gives no new information and is excluded from further considerations. To formalize this we introduce the equivalence relation

$$Q^{(n')}\sim Q^{(n)}, \quad \text{if } Q^{(n')}-Q^{(n)}=\sum_{j=0}^{m} \gamma_j H^j,$$

and consider representatives of these equivalence classes in the linear space of differential operators $Q^{(n)}$ satisfying (16). We denote this quotient space as $\mathcal{L}$.

The $Q^{(n)}$ of type C_κ depends on $V(x)$ and on κ. As mentioned, we denote the family of such potentials (for finite κ) as $\mathcal{F}_L^\kappa$. There is a connection between $\mathcal{F}_{\mathrm{SGA}}^{(2)}$ and $\mathcal{F}_L^\kappa$ (see Sec. III E):

$$\mathcal{F}_{\mathrm{SGA}}^{(2)}\subset\mathcal{F}_L^\kappa,$$

because in the singular case (16), the realization $R(g_2)$ of $g_2\in so(2,1)$ is a Lie symmetry (16) of H for $\kappa=-1$

$$[R(g_2),H]=-H. \tag{17}$$

It is just this higher-order Lie symmetry of H that is ''responsible'' for $\mathcal{F}_{\mathrm{SGA}}^{(2)}$. We add that $R(g_j)$, $j=1,3$ can be constructed if $R(g_2)$ is known.

C. The reduction lemma

Because a first-order Lie symmetry $Q^{(1)}$ of H is easier to analyze than an nth-order one, it would be convenient to reduce the order of $Q^{(n)}$ under the condition that no information is lost. This is possible if we use, in addition to H, the operator $H+\epsilon\mathbf{1}$. The following result holds.

Lemma 1: The Schrödinger equation $Hf=0, H=-d^2/dx^2+V(x)$ *in* $\mathcal{G}\supset\Gamma_H\cup\Gamma_{H+\varepsilon}$ *allows an* nth-*order Lie symmetry* $Q^{(n)}$ *of type* C_0 *if and only if*

$$\left(-\frac{d^2}{dx^2}+V(x)+\varepsilon\right)f=0, \quad \varepsilon\neq 0, \quad \text{real}, \tag{18}$$

admits a first-order Lie symmetry $\hat{Q}^{(1)}$ *of the form*

$$\hat{Q}^{(1)}=a(x,\varepsilon)\frac{d}{dx}+b(x,\varepsilon)\equiv\left(\sum_{j=0}^{N} a_j(x)\varepsilon^j\right)\frac{d}{dx}+\sum_{j=0}^{N} b_j(x)\varepsilon^j, \tag{19}$$

where $N=[(n-1)/2]$, $a_N=1$, *and the relations*

$$a''(x,\varepsilon)+2b'(x,\varepsilon)=0, \quad b''(x,\varepsilon)+a(x,\varepsilon)V'(x)+2a'(x,\varepsilon)(V(x)+\varepsilon)=0, \tag{20}$$

hold. Primes denote differentiations with respect to x.

Proof: (1) Consider $Q^{(n)}$. On $\mathcal{G}$ the commutator $[Q^{(n)},H]=0$ yields

$$\sum_{j=0}^{n} q_j^{(n)}\left[\frac{d^j}{dx^j},V(x)\right]+\sum_{j=0}^{n}\left(q_j^{(n)\prime\prime}+2q_j^{(n)\prime}\frac{d}{dx}\right)\frac{d^j}{dx^j}=0.$$

Equating the coefficients of d^{n+1}/dx^{n+1}, we get $q_n^{(n)}=\text{const}$. Without loss of generality we may choose $q_n^{(n)}=1$,

$$Q^{(n)}=\frac{d^n}{dx^n}+\sum_{j=0}^{n-1} q_j^{(n)}\frac{d^j}{dx^j}. \tag{21}$$

We use this and $Q^{(n)}\subset\mathcal{L}$ to construct for even n an equivalent $Q^{(n-1)}$,

$$Q^{(n-1)}=\sum_{j=0}^{n-1} q_j^{(n-1)}\left(\frac{d}{dx}\right)^j.$$

Hence, it is necessary to consider only odd n, i.e., $n=2N+1, N\in\mathbf{N}$. As $Q^{(n)}$ commutes with H it commutes with $H+\varepsilon\mathbf{1}$.

Our aim is to reduce the power n of $Q^{(n)}$ (which is a Lie symmetry with $P\equiv 0$) in an iterative procedure for the price that $P\neq 0$. Assume that $Q^{(n)}$ is a Lie symmetry of $H+\varepsilon$. Introduce a differential operator R (see Ref. 10) such that $Q^{n-1}=Q^{(n)}+R(H+\varepsilon)$ is again a Lie symmetry but of the order $n-2$. We find for R,

$$R=-q_n\left(\frac{d}{dx}\right)^{n-2},$$

and coefficients of Q^{n-1} are first-order polynomials in ε. Repeating this procedure $N-1$ times yields a first-order Lie symmetry $\hat{Q}^{(1)}$ whose coefficients are polynomials in ε of the order N, i.e., we get for $\hat{Q}^{(1)}$ an expression of the form (19). One shows by induction that $a_N=1$. The relation (20) for a_j, b_j are implied by the fact that $\hat{Q}^{(1)}$ is a Lie symmetry for $H+\varepsilon$,

$$[\hat{Q}^{(1)},H+\varepsilon]=R(H+\varepsilon), \tag{22}$$

with R as a multiplication operator.

(2) Start with $\hat{Q}^{(1)}=\Sigma_{j=0}^{N}A_j\varepsilon^j$, $A_j=a_j(x)(d/dx)+b_j(x)$. We want to cancel the ε^j and to introduce high-order differential operators through a stepwise procedure. Construct from $\hat{Q}^{(1)}$,

$$Q_1^{(2N+1)}=\hat{Q}^{(1)}-A_N(H+\varepsilon)^N=\sum_{j=0}^{N-1} A_{j,1}\varepsilon^j.$$

Because of (22) this is a Lie symmetry of order $2N+1$,

$$[Q_1^{(2N+1)},H+\varepsilon]=R_1(H+\varepsilon);$$

R_1 is an ε-dependent differential operator. A corresponding property holds for

$$Q_2^{(2N+1)}=Q_1^{(2N+1)}-A_{N-1,1}(H+\varepsilon)^{N-1},$$

with some R_2. Continuing this process we get after $N-2$ steps an ε-independent $Q_N^{(2N+1)}$ with

$$[Q_N^{(2N+1)},H+\varepsilon]=[Q_N^{(2N+1)},H]=R_N(H+\varepsilon).$$

The left-hand side is independent of ε, which implies that $R_N=0$. ▷

D. The family $\mathcal{F}_L^0$ of potentials that allow Lie symmetries Q of type C_0

The reduction lemma restricts the potentials $V(x)$ that allow an nth-order Lie symmetry of type C_0. We show that this set is the solution set of a family of nonlinear differential equations. Integrodifferential operators are applied in order to characterize the structure of this family.

Our main result is the following.

Theorem 1: *The Schrödinger equation $Hf=0, H=-d^2/dx^2+V(x)$ admits an nth-order Lie symmetry of type C_0 if and only if the potential $V(x)$ satisfies a nonlinear differential equation contained in the family*

$$\mathcal{F}_L^0=\left\{ V(x) \middle| G(V)\equiv\sum_{j=0}^{N-1} c_j F_j+F_N=0\right\}, \tag{23}$$

where $N=[(n-1)/2]$; $F_j=\mathcal{R}^j F_0$, $F_0=-\frac{1}{2}V'$, i.e., the F_j represent the stationary KdV hierarchy (13), and c_j are real constants.

Proof: The proof is simplified substantially if we use Lemma 1 and well-known techniques of soliton theory.

In the reduction lemma we insert the polynomial ε dependence for a_j, b_j and find, after integration for b_j (B_j are integration constants),

$$b_j(x)=-\tfrac{1}{2}a_j'(x)+B_j, \quad j=0,1,...,N, \tag{24}$$

and $N+2$ recurrence relations for a_j depending on $V(x)$ and on its derivatives,

$$a_N(x)=1, \quad a_{j-1}'(x)=-\tfrac{1}{4}a_j'''(x)-V(x)a_j'(x)-\tfrac{1}{2}V'(x)a_j(x), \quad a_{-1}(x)\overset{\text{def}}{=}0, \tag{25}$$

where $j=0,1,...,N$.

The first $N+1$ relations of (25) are solved by subsequent integrations yielding expressions for the functions $a_0(x),\dots,a_{N-1}(x)$ through $V(x)$ and its derivatives. Substituting these results into the last equation for $j=0$, i.e., $a_{-1}=0$, we arrive at a nonlinear differential equation for $V(x)$ of order $2N+1$. Its solutions generate all solutions of (24) and (25).

To reveal the structure of (25), especially of $a_{-1}=0$, we introduce new functions $\mathcal{U}_0(x)$, $\mathcal{U}_1(x),\dots,$ by the following recurrence relation (D_x denotes d/dx):

$$\mathcal{U}_j(x)=\mathcal{P}\mathcal{U}_{j-1}, \quad \mathcal{U}_{-1}\equiv 1, \quad \mathcal{P}=-\tfrac{1}{4}D_x^2-V(x)+\tfrac{1}{2}D_x^{-1}V'(x), \tag{26}$$

where $j=0,1,...,$ and $\mathcal{U}_{-1}(x)\overset{\text{def}}{=}1$. Note that $\mathcal{P}$ is the first recursive (integrodifferential) operator for the KdV equation (see, e.g., Refs. 7–9). The action of $\mathcal{P}$ on some (initial conserved density) $\mathcal{U}_0=-\frac{1}{2}V(x)$ yields the whole hierarchy of the conserved densities $\mathcal{U}_1,\mathcal{U}_2,\dots$. The second recursive operator $\mathcal{R}$ in (12) is related to $\mathcal{P}$ through

$$\mathcal{R}=D_x\circ\mathcal{P}\circ D_x^{-1}.$$

With this $\mathcal{U}_j(x)$ the $a_j(x)$ in (25) can be written as

$$a_{j-1}(x)=\mathcal{U}_{N-j}+\sum_{k=1}^{N-j+1} c_{N-k}\mathcal{U}_{N-j-k}, \quad j=1,...,N, \tag{27}$$

where $c_0,\dots,c_{N-1}$ are integration constants (independent of the B_j).

The equation $a_{-1}=0$ can be rewritten in a more transparent form as

$$D_x\circ\left(\sum_{j=0}^{N-1} c_j\mathcal{P}^j+\mathcal{P}^N\right)\mathcal{U}_0=0, \tag{28}$$

which shows a direct relation to the stationary higher KdV equation. Using the operator identity,

$$D_x \circ \mathcal{P}^j \equiv (D_x \circ \mathcal{P} \circ D_x^{-1})^j \circ D_x = \mathcal{R} \circ D_x,$$

(28) takes the following form:

$$\left(\sum_{j=0}^{N-1} c_j \mathcal{R}^j + \mathcal{R}^N \right) \circ D_x \mathcal{U}_0 = 0, \quad \mathcal{U}_0 = -\frac{1}{2} V'(x).$$

Because of $D_x \mathcal{U}_0 = -\frac{1}{2} V' = F_0$ and $F_j = \mathcal{R}^j F_0$ we get finally (23). ▷

E. The family $\mathcal{F}_L^\kappa$ of potentials that allow Lie symmetries of type C_κ

The results in Sec. III D for nth-order Lie symmetries of type C_0 can be utilized to construct also nth-order Lie symmetries of type C_κ for $\kappa \neq 0$. We have the following.

Theorem 2: *The Schrödinger equation* $Hf = 0, H = -d^2/dx^2 + V(x)$ *admits an* nth-*order Lie symmetry* $Q \in \mathcal{L}$ *of type* C_κ, *i.e.*, $[Q,H] = \kappa H$, *if and only if the potential* $V(x)$ *satisfies a nonlinear differential equation contained in the family*

$$\mathcal{F}_L^\kappa = \left\{ V(x) \middle| \kappa \left(\frac{x}{2} V' + V \right) + \sum_{j=0}^{N-1} c_j F_j + F_N = 0 \right\}, \tag{29}$$

where $N = [(n-1)/2]$, $F_j = \mathcal{R}^j F_0$, $F_0 = -\frac{1}{2} V'$; c_j are real constants.

Proof: With the same arguments as in the proof of the reduction lemma we get for Q [see (14)] $q_n = 1$. It is only necessary to consider odd n. We insert this Q and H in (16):

$$\sum_{j=0}^{n-1} \binom{j}{n} V^{(n-j)} \frac{d^j}{dx^j} + \sum_{i=1}^{n-1} \sum_{j=0}^{i-1} q_i \binom{j}{i} V^{(i-j)} \frac{d^j}{dx^j} + \sum_{j=0}^{n-1} \left(2 q_j' \frac{d}{dx} + q_j'' \right) \frac{d^j}{dx^j} = \kappa \left(-\frac{d^2}{dx^2} + V(x) \right). \tag{30}$$

Comparing coefficients in front of the linearly independent operators d^j/dx^j, $(j = 1,...,n)$ yields n recurrence integrodifferential relations for the coefficients $q_i(x) = q_i(x, V(x), \kappa)$, $(i = 0,1,...,n-1)$ in (14),

$$q_{n-1}(x) = \hat{c}_{n-1},$$

$$q_{j-1}(x) = -\frac{1}{2} \left(q_j'(x) + \binom{j}{n} V^{(n-j-1)}(x) + \sum_{i=j+1}^{n-1} \binom{j}{i} \int^x q_i(y) V^{(i-j)}(y) dy + \kappa \delta_{j2} x \right) + \hat{c}_{j-1}, \tag{31}$$

where $\hat{c}_j$ are integration constants and

$$\hat{c}_j = 0, \quad \text{for } j \text{ even}.$$

Note that only q_1 depends on κ through an additive part $\frac{1}{2}\kappa x$, i.e.,

$$q_1(x, V(x), \kappa) = \hat{q}_1(x, V(x)) + \tfrac{1}{2} \kappa x.$$

Collecting the terms with $(d/dx)^0$ in (30), we get a differential equation $G(V,\kappa)$ for $V(x)$ of the type

$$G(V,\kappa) \equiv q_0'' + V^{(n)} + \hat{q}_1 V' + \kappa \frac{x}{2} V' + \sum_{j=2}^{n-1} q_j V^{(j)} + \kappa V = 0. \tag{32}$$

From Theorem 1 we know the differential equation for $V(x)$ if $\kappa = 0$. Hence

$$G(V,0)=G(V). \tag{33}$$

Because the κ dependence in (32) is explicitly known, we have

$$G(V,\kappa)\equiv G(V)+\kappa\left(\frac{x}{2}V'+V\right)=0; \tag{34}$$

so we arrive at (29). ▷

This concludes the discussion of high-order Lie symmetry of the Hamiltonian $H=-d^2/dx^2+V(x)$.

IV. RELATION TO SPECTRUM GENERATING ALGEBRAS

The Lie symmetry $[Q,H]=\kappa H$ (Theorem 2) is related to the spectrum generating algebra $so(2,1)$ of H through (17), where $\kappa=-1$. The realization $R(g_2)$ of $g_2\in so(2,1)$ is given by Q of the form (14), (31) through solutions of (29) with $\kappa=-1$ and

$$\mathcal{F}^{(2)}_{\mathrm{SGA}}=\mathcal{F}^{\kappa}_{L}, \quad \kappa=-1 \tag{35}$$

holds. As $R(g_2)$ is explicitly known, we can insert $R(g_2)$ and the differential operators $R(g_1)$, $R(g_3)$ into the commutation relations of the algebra $so(2,1)$ and thus find the latter (for further details, see Refs. 1 and 2).

With the results obtained in Sec. III we can elucidate the peculiar features of the nonlinear differential equation (9) mentioned in Sec. II. The fact that the potentials $V(x)$ are identical for $n=2N+1$ and $n=2N+2$ is explained as follows. In a symmetry operator Q of order $2N+2$, the term with $(d/dx)^{2N+2}$ can be canceled because of $Q\in\mathcal{L}$, thus getting a symmetry operator of order $2N+1$ that is again a Lie symmetry of the Schrödinger equation. The stronger statement that the equations for $V(x)$ in $\mathcal{F}^{(2)}_{\mathrm{SGA}}$ are identical for $n=4k$, $4k+1$, $4k+2$, $4k+3$, $k=1,2,...$, is valid because a SGA symmetry is stronger than a Lie symmetry. The way of constructing the equations for $V(x)$ used while proving Lemma 1, makes it also evident, why this equation with some fixed $n=n_1$ contains all the terms of an equation for $V(x)$ under $n=n_2<n_1$. Indeed, the equation for $n=n_1$ is obtained from one for n_1-1 by the action of the recursive operator $\mathcal{R}$, which transforms a term F_j into F_{j+1}.

V. INTEGRABILITY

Hamiltonians (10) admitting $so(2,1)$-spectrum generating algebra have a further useful property: they are *integrable* in the sense that the corresponding Schrödinger equation (11) can be integrated by quadratures. This is so because (11) admits a first-order Lie symmetry of the form $\hat{Q}=\xi(x)(d/dx)+\eta(x)$, with

$$-\eta''+2V\xi'+V'\xi=0, \quad 2\eta'+\xi''=0, \tag{36}$$

and because one can apply for an integration of (11) the classical method (see, e.g., Refs. 10 and 11) based on its Lie symmetry. The first integral for system (36) is

$$-\eta'(\xi)+V\xi^2-\tfrac{1}{4}=\alpha\equiv\text{const.}$$

Depending on the sign of α, the general solution of the equation (11) reads as

$$f(x)=\sqrt{\xi(x)}\begin{cases} C_1\rho(x)+C_2, & \alpha=0,\\ C_1\cos a\,\rho(x)+C_2\sin a\,\rho(x), & \alpha=a^2>0,\\ C_1\cosh a\,\rho(x)+C_2\sinh a\,\rho(x), & \alpha=-a^2<0,\end{cases}$$

where

$$\rho(x)=\int \frac{dx}{\xi(x)}.$$

Now, inserting the explicit expressions for $\xi(x)$, $\eta(x)$ from (19) into the above formulas yields the general solution of (11), provided the function $V(x)$ fulfills an equation of the form (9).

VI. CONCLUDING REMARKS

Given a physical observable quantized through a linear differential operator A in $L^2(\mathbf{R}^d,dx^d)$, e.g., a Hamiltonian H (1) in one space dimension, a spectrum generating algebra for A is specified through a Lie algebra L with $\dim L=m$ with generators g_i and a realization through differential operators of the order n such that $A=\Sigma_{k=1}^{m}\alpha_k R(g_k)$, e.g., $L=so(2)$, $m=3$. A high-order Lie symmetry for the linear operator A is defined through finite-order differential operators Q,P with $[Q,A]=PA$, e.g., $A=H$ and $P=\kappa$. Both SGA and high-order Lie symmetry are different methods to model a physical symmetry with different mathematical structures.

We have shown that for the Hamiltonian (1) an $so(2,1)$ SGA and an nth-order Lie symmetry with $P=-1$ are directly related via (17). However, a Lie symmetry is more general than an $so(2,1)$ SGA symmetry. The interesting result is the connection between an nth-order C_κ Lie-symmetry of the Hamiltonian (1) and the stationary KdV hierarchy. It is understandable that for the singular case of $so(2,1)$, which reflects the light cone structure in $so(2,1)$, a family of nonlinear differential equations for $V(x)$ appears. But it is, as we already mentioned, surprising that this family is related to the stationary KdV hierarchy, a mathematical object not connected directly to a symmetry concept of observables. We suspect that this connection to the KdV hierarchy is somehow encoded in the geometry of $so(2,1)$ and its realizations. An investigation of Hamiltonians of the type (1) in higher space dimensions, their Lie symmetry in the above sense, and L-SGA with noncompact L, $m>3$, seems to be appropriate.

(Received 3 November 1998; accepted for publication 30 June 1999)

In this article, we study and settle several structural questions concerning the exact solvability of the Olshanetsky–Perelomov quantum Hamiltonians corresponding to an arbitrary root system. We show that these operators can be written as linear combinations of certain basic operators admitting infinite flags of invariant subspaces, namely the Laplacian and the logarithmic gradient of invariant factors of the Weyl denominator. The coefficients of the constituent linear combination become the coupling constants of the final model. We also demonstrate the L^2 completeness of the eigenfunctions obtained by this procedure, and describe a straightforward recursive procedure based on the Freudenthal multiplicity formula for constructing the eigenfunctions explicitly.

I. INTRODUCTION

The potentials first discovered by Calogero and Sutherland[1,2] and subsequently generalized to arbitrary root systems by Olshanetsky and Perelomov[3] play a central role in the theory of classical and quantum completely integrable systems. One of the main themes of the original work by Olshanetsky and Perelomov was to establish quantum complete integrability, that is, the existence of complete sets of commuting operators. The actual eigenfunctions of the corresponding Hamiltonians were discussed in numerous subsequent publications.[4–7]

Our purpose in this paper is study and settle a certain number of basic structural questions concerning the exact solvability of the Olshanetsky-Perelomov Hamiltonians. In order to outline the main results of our paper, we first need to give a precise definition of what we mean by exact solvability. We will adopt a promising approach, which has recently arisen in the framework of the theory of quasiexactly solvable potentials,[8–11] by defining a quantum Hamiltonian $\mathcal{H}$ to be *algebraically exactly solvable* if one can explicitly construct an ordered basis for the underlying Hilbert space such that the corresponding flag of subspaces is $\mathcal{H}$ invariant. In terms of this approach, the first step in the treatment of an exactly solvable operator must be the construction of an infinite flag of finite-dimensional vector spaces ordered by inclusion, the determination of a collection of basic operators that preserve this flag, and the demonstration that the operator in question is generated by the basic ones. The second step is to prove the L^2 completeness in the underlying Hilbert space of this family of subspaces.

In order to fit the Olshanetsky–Perelomov Hamiltonians of trigonometric type into this framework, we first recall that these Hamiltonians are indexed by irreducible root systems, with the Calogero–Sutherland potentials corresponding to type A_n root systems. We thus consider the vector space of trigonometric functions that are invariant under the Weyl group W of the given root system R. The partial order relation on dominant weights gives rise to a natural flag of finite-dimensional subspaces of this infinite-dimensional vector space. It is quite evident that the

[a)]Electronic mail: nkamran@math.mcgill.ca
[b)]Current address: McGill University, Montreal. Electronic mail: milson@math.mcgill.ca

flag in question is preserved by the ordinary, multidimensional Laplacian. Less evident is the fact that one can obtain other flag-preserving operators by factoring the Weyl denominator,

$$A=\prod_{\alpha\in R^+} e^{\alpha/2}-e^{-\alpha/2},$$

into factors corresponding to the various orbits of the Weyl group on R. It turns out (see Proposition 12) that the gradient of the logarithm of each of the resulting factors also preserves the flag in question. More generally, one obtains other flag-preserving second-order operators by taking linear combinations of the Laplacian and of these gradients. The Olshanetsky–Perelomov Hamiltonians are then obtained by a ground-state conjugation. This approach also sheds light on the presence of multiple coupling constants in some of the models; the number of coupling constants is precisely the number of invariant factors of A, i.e., the number of Weyl group orbits in R, or, equivalently, the number of distinct root lengths. We then show that if all the coupling constants are positive, then the action of the Hamiltonian on each subspace of the flag is diagonalizable. This is the first main result of our paper; it is given in Theorem 1. The second main result concerns the L^2 completeness of the resulting eigenfunctions in the underlying Hilbert space of L^2 functions on the alcove of the root system R.

It is also interesting to note that if all the coupling constants are equal to 1, then one recovers a second-order differential operator whose eigenfunctions are precisely the characters of the corresponding simple Lie algebras. For certain other values of the coupling constants, one recovers the spherical functions associated to any symmetric space G/K, where G is a semisimple real Lie group and K is a suitable compact subgroup. If the restricted root system of the symmetric space is of type A_{n-1} and m is the multiplicity of each restricted root, then the eigenfunctions corresponding to the value $k_c=m/2$ of the deformation parameter are the zonal spherical functions on G/K, as pointed out by Macdonald.[12,13] Thus the coupling constants can be regarded as parameters in a deformation of the classical characters.

In the classical case, if one reexpresses the gradient of $\log A$ in terms of a formal power series, one obtains Freudenthal's recursion formula for the character coefficients. This trick also works for the deformed characters, and leads to a recursion formula that allows one to straightforwardly compute the eigenfunctions of the Olshanetsky–Perelomov Hamiltonians. This result is presented in Sec. IV.

We should point out that the Weyl-invariant deformed characters that appear in the expressions of the eigenfunctions of the Olshanetsky–Perelomov trigonometric Hamiltonians are related by a change of variables to the multivariate Jacobi polynomials that have been investigated by Heckman and Opdam.[14] In particular, the analog of the Freudenthal multiplicity formula that is at the basis of the recursion formula we give in Proposition 19 for the eigenfunctions of the Hamiltonians also appears in the context of their study. We should also mention the interesting recent contributions of Brink, Turbiner, and Wyllard[15] in the general effort aimed at understanding the exact solvability for multidimensional systems in an algebraic context.

II. TRIGONOMETRIC-TYPE POTENTIALS ASSOCIATED TO ROOT SYSTEMS

We first recall the abstract definition of the trigonometric Olshanetsky–Perelomov Hamiltonians in terms of root systems. Let $\mathbf{V}$ be a finite-dimensional real vector space endowed with a positive-definite inner product $(u,v)\in\mathbb{R}$, u, $v\in\mathbf{V}$. We use this inner product to identify $\mathbf{V}$ with $\mathbf{V}^*$. The induced positive-definite inner product on $\mathbf{V}^*$ will also be denoted by $(\cdot,\cdot)$. Let $\Delta:C^\infty(\mathbf{V};\mathbb{R})\to C^\infty(\mathbf{V};\mathbb{R})$ and $\boldsymbol{\nabla}:C^\infty(V;\mathbb{R})\to\Gamma(TV)$ denote the corresponding Laplace–Beltrami and gradient operators.

For a nonzero $\alpha\in\mathbf{V}^*$, we set $\check{\alpha}=2\alpha/(\alpha,\alpha)$ and let s_α denote the reflection across the hyperplane orthogonal to α:

$$s_\alpha(\beta)=\beta-(\check{\alpha},\beta)\alpha,\quad \beta\in\mathbf{V}^*.$$

By a root system, we mean a finite, spanning subset R of $\mathbf{V}^*$ such that $0 \in R$, $s_\alpha(R) \subset R$ for all $\alpha \in R$ and $(\breve{\alpha},\beta) \in \mathbb{Z}$ for all $\alpha,\beta \in R$. A root system R is said to be irreducible if it cannot be partitioned into a union of root systems spanning orthogonal subspaces of $\mathbf{V}$.

To any root system R corresponds a root lattice $Q = \{\Sigma_R m_\alpha \alpha : m_\alpha \in \mathbb{Z}\}$ and a weight lattice $P = \{\lambda \in \mathbf{V}^* : (\breve{\alpha},\lambda) \in \mathbb{Z}, \forall \alpha \in R\}$. The Weyl group of R, generated by $s_\alpha, \alpha \in R$, will be denoted by W. The subgroup of W fixing a particular $\lambda \in \mathbf{V}^*$ will be denoted by W_λ.

The hyperplanes $\{\lambda \in \mathbf{V}^* : (\alpha,\lambda) = 0\}, \alpha \in R$ define a set of open Weyl chambers in $\mathbf{V}^*$. We choose a Weyl chamber C and let $R^+ = R \cap \overline{C}$ denote the corresponding subset of positive roots. Let $B \subset R^+$ denote the set of simple roots, i.e., the positive roots that cannot be written as the sum of two positive roots. Let $P^+ = R \cap \overline{C}$ denote the set of dominant weights.

We will say that a real number $c > 0$ is a *root length* if there exists a $\alpha \in R$ such that $c = \|\alpha\|$. Let c be a root length, and set

$$R_c = \{\alpha \in R : \|\alpha\| = c\},$$

$$R_c^+ = R_c \cap R^+,$$

$$U_c = \frac{c^2}{4} \sum_{\alpha \in R_c^+} \cos^2 \frac{\alpha}{2}.$$

Note[16] that if c is a root length, then, R_c is nothing but the W orbit of α.

The Olshanetsky–Perelomov Hamiltonians with trigonometric potentials associated to a root system R are defined in terms of the above data by

$$\mathcal{H} = -\Delta + \sum_c a_c U_c,$$

where the sum is taken over all root lengths, c, and where the a_c's are real coupling constants.

III. THE ALGEBRAIC EXACT SOLVABILITY OF $\mathcal{H}$

The affine hyperplanes $\{\lambda \in \mathbf{V}^* : (\alpha,\lambda) \in 2\pi\mathbb{Z}\}$ determine in $\mathbf{V}^*$ a set of isometric open bounded subsets called alcoves. Let A denote the unique alcove (usually referred to as the fundamental alcove) that is contained in C and that has the origin as a boundary point. Let m denote the Lebesgue measure on A. From now on we use the inner product to identify A with the corresponding subset of $\mathbf{V}$ and restrict the domain of functions introduced subsequently to A. Our goal is to construct a basis for the underlying Hilbert space $L^2(A,m)$ in which the algebraic exact solvability of $\mathcal{H}$ is manifest. The elements of this basis will be products of W-invariant trigonometric functions of certain linear forms on $\mathbf{V}$ with a common gauge factor vanishing along the walls $\{u \in \mathbf{V} : \alpha(u) \in 2\pi\mathbb{Z}\}$, $\alpha \in R$ of the potential terms U_c.

We now proceed to define this basis. Recall that a choice of positive roots naturally induces a partial order relation, $\leqslant$, on the weight lattice. For $\lambda \in P^+$ set

$$P_\lambda = \cup_{w \in W} \{w(\mu) : \mu \in P^+ \text{ and } \mu \leqslant \lambda\},$$

$$P_{\lambda -} = \cup_{w \in W} \{w(\mu) : \mu \in P^+ \text{ and } \mu \lneq \lambda\}.$$

For $S \subset \mathbf{V}^*$ let trig(S) denote the complex vector space spanned by functions of the form $e^{i\lambda}, \lambda \in S$. If S is a W-invariant subset of $\mathbf{V}^*$, then there is a well-defined action of W on trig(S), namely

$$w \cdot e^{i\lambda} = e^{iw(\lambda)}, \quad w \in W, \quad \lambda \in S.$$

In this case, let $\mathrm{trig}(S)^W$ denote the subspace of W-invariant functions.

Recall that a root system R is said to be reduced if for every $\alpha \in R$, the only roots homothetic to α are $-\alpha$ and α itself. A root α will be called nondivisible if $\alpha/2$ is not a root. Similarly, α will be called nonmultiplicable if 2α is not a root. Of course, if R is reduced, then all roots are both nondivisible and nonmultiplicable. An irreducible nonreduced system must be isomorphic to a root system of type BC_n for some n. To describe the latter, take $\mathbf{V} = \mathbb{R}^n$ and let $\epsilon_1, \dots, \epsilon_n$ denote the dual basis of the standard basis of $\mathbb{R}^n$. The root system in question consists of three types of roots: short roots $\pm \epsilon_i$, medium roots $\pm \epsilon_i \pm \epsilon_j$, $i \neq j$, and long roots $\pm 2\epsilon_i$.

For reasons that will become clear later, it is convenient to reexpress the coupling constants a_c appearing in $\mathcal{H}$ as follows. We let $a_c = k_c(k_c - 1)$ if c is the length of a nonmultiplicable root, and $a_c = k_c(k_c + k_{2c} - 1)$ if R is nonreduced and c is the length of the short roots. Let

$$A_c = \prod_{\alpha \in R_c^+} \sin \frac{\alpha}{2}, \quad F = \prod_c |A_c|^{k_c}, \quad \rho_c = \frac{1}{2} \sum_{\alpha \in R_c^+} \alpha, \quad \rho = \sum_c k_c \rho_c .$$

The following theorems, which are the main results of our paper, shows that the Olshanetsky–Perelomov trigonometric Hamiltonians $\mathcal{H}$ are exactly solvable in the algebraic sense, and that the corresponding eigenfunctions are physically meaningful.

Theorem 1: *Let λ be a dominant weight. If $k_c \geqslant 0$ for each root length c, then there exists a unique $\phi_\lambda \in \mathrm{trig}(P_\lambda)^W$ such that $F\phi_\lambda$ is an eigenfunction of $\mathcal{H}$ with eigenvalue $\|\lambda + \rho\|^2$. Furthermore, if $F\phi, \phi \in \mathrm{trig}(P)^W$ is an eigenfunction of $\mathcal{H}$, then $\phi = \phi_\lambda$ for some $\lambda \in P^+$.*

Theorem 2: *The subspace $F\,\mathrm{trig}(P)^W$ is dense in $L^2(A,m)$. Moreover, if $k_c \geqslant 0$ for all root lengths c, then the operator $\mathcal{H}$ is essentially self-adjoint on the domain $F\,\mathrm{trig}(P)^W \subset L^2(A,m)$.*

We begin with the proof of Theorem 2, assuming Theorem 1 to be true. We first have the following.

Lemma 3: Let D be an open, bounded subset of Euclidean space, and $f: D \to \mathbb{R}$ a bounded continuous function that does not vanish on D (but may vanish on the boundary). With these assumptions, $fL^2(D,m)$ is a dense subset of $L^2(D,m)$.

Proof: Let D_0, an open subset of D, be given, and choose D_1 such that $\overline{D_1} \subset D_0$ and such that $m(D_0) - m(D_1)$ is smaller than a given $\epsilon > 0$. Note that $h = f^{-1}\chi_{D_1}$ is a well-defined element of $L^2(D)$ and that $fh = \chi_{D_1}$. Consequently, χ_{D_0} lies in the closure of $fL^2(D)$. The conclusion follows from the fact that the characteristic functions form a dense subset of $L^2(D)$. □

Proof of Theorem 2: Let $\mathbf{T}$ denote the torus $\mathbf{V}^*/(2\pi Q)$. We use the inner product on $\mathbf{V}$ to identify $\mathbf{T}$ with the identical quotient of $\mathbf{V}$. Recall that $\mathrm{trig}(P)$ is dense in $L^2(\mathbf{T})$ by the Fourier representation theorem. Now W acts on $\mathbf{T}$ and A serves as a fundamental region for this action (Ref. 17, Chap. VI, No. 2.1). Consequently, $\mathrm{trig}(P)^W$ is dense in $L^2(T)^W$ and the latter is naturally isomorphic to $L^2(A,m)$. We therefore conclude that $F\,\mathrm{trig}(P)^W$ is dense in $L^2(A,m)$ by applying the preceding Lemma with $f = F$.

We now prove the essential self-adjointness of $\mathcal{H}$ on the domain $F\,\mathrm{trig}(P)^W$. Let $A_0 \subset A$ be an open subset with a piecewise smooth boundary. Let $\phi_1, \phi_2 \in \mathrm{trig}(P)^W$ be given. Setting $\psi_i = F\phi_i$, $i = 1,2$, we have

$$\int_{A_0} \mathcal{H}(\psi_1)\psi_2 - \psi_1 \mathcal{H}(\psi_2) = \int_{A_0} \mathrm{div}(\psi_2 \nabla \psi_1 - \psi_1 \nabla \psi_2) = \int_{\partial A_0} F^2(\phi_2 \nabla \phi_1 - \phi_1 \nabla \phi_2).$$

Hence, as the boundary of A_0 approaches the boundary of A, the above integrals tend to zero, so that the operator $\mathcal{H}$ is a symmetric. By Theorem 1 and the density of $F\,\mathrm{trig}(P)^W$ in $L^2(A,m)$, the span of eigenfunctions of $\mathcal{H}$ is dense in $L^2(A)$, and therefore $\mathcal{H}$ must be essentially self-adjoint.□

We now proceed with the proof of Theorem 1. The strategy behind the proof of this theorem is to conjugate the Olshanetsky–Perelomov Hamiltonians $\mathcal{H}$ by a suitable multiplication operator chosen in such a way that the resulting operator has a simple action on the space $\mathrm{trig}(P)^W$. This will give rise to an essential intertwining relation that will, in turn, imply the algebraic exact solvability. In order to determine this multiplicative factor, we need a series of facts about root lengths.

Let $M_c : W \to \{\pm 1\}$ be the class function defined by

$$M_c(s_\alpha) = \begin{cases} -1, & \text{if} \quad \alpha \in B \cap R_c, \\ 1 & \text{if} \quad \alpha \in B \backslash R_c. \end{cases}$$

The following result is a straightforward consequence of the definition of A_c.

Proposition 4: For $w \in W$ one has $w(A_c) = M_c(w) A_c$. In other words, A_c is a relative invariant of W with multiplier M_c. Moreover, we have the following.

Proposition 5: Let c be a root length. If $\alpha \in B$, then $(\check{\alpha}, \rho_c)$ takes one of four possible values: 1 if $\|\alpha\| = c$, 2 if $\|\alpha\| = c/2$, 1/2 if $\|\alpha\| = 2c$, 0 in all other cases.

Proof: Let $\alpha \in B$ be given. The action of s_α maps α to $-\alpha$ and permutes the elements of R^+ not homothetic to α (Ref. 17, Chap. VI, No. 1.6). Let $\beta \in R_c^+$ be given and set $\beta' = s_\alpha(\beta)$. Note that if $\beta = \beta'$, then $(\check{\alpha}, \beta) = 0$; and that if $\beta' \neq \beta$, then $(\check{\alpha}, \beta + \beta') = 0$. If $\|\alpha\| \in \{c, 2c, c/2\}$, then α is not homothetic to any element of R_c, and hence one can break up ρ_c into subterms of length one and two such that each subterm is annihilated by $\check{\alpha}$. This proves the fourth assertion of the proposition. If $\|\alpha\| = c$, then ρ_c is the sum of $\alpha/2$ and a remainder perpendicular to $\check{\alpha}$. Consequently, $(\check{\alpha}, \rho_c) = 1$, thereby proving the first assertion. If $\|\alpha\| = c/2$, then 2α is also a root, and, consequently, ρ_c is the sum of α and a remainder perpendicular to $\check{\alpha}$. This implies the second assertion. The case three assertion is proven similarly. □

Corollary 6: If c is the length of a nonmultiplicable root, then ρ_c is a weight. If R is nonreduced, and c is the length of the short roots, then ρ_c is merely a half-weight.

Corollary 7: Let c be a root length. Then for all $\alpha \in R_c$, one has $(\check{\alpha}, \rho_c) \in \mathbb{Z}$.

Proof: If c is the length of a nonmultiplicable root, then the claim follows from the preceding corollary. Suppose then that $2c$ is also a root length. For $\alpha \in R_c$ note that $2(2\alpha)\check{} = \check{\alpha}$ and that $2\rho_c = \rho_{2c}$. Hence

$$(\check{\alpha}, \rho_c) = ((2\alpha)\check{}, \rho_{2c}).$$

Since 2α is nonmultiplicable, the right-hand side is an integer by the preceding corollary. □

Corollary 8: Let c be a root length and $w \in W$. Then, $w(\rho_c) \in Q - \rho_c$.

Proof: Note that

$$w(\rho_c) = \frac{1}{2} \sum_{\alpha \in R_c^+} \sigma_\alpha(w) \alpha,$$

where $\sigma_\alpha(w)$ is either 1 or -1. Hence, $\rho_c + w(\rho_c)$ is the sum of all $\alpha \in R_c^+$ such that $\sigma_\alpha(w) = 1$. □

We are now ready for the next step leading to the required intertwining relation, which is to show that $\mathrm{trig}(P_\lambda)^W$ is an invariant subspace of $\nabla \log|A_c|$. First, we have the following.

Proposition 9: Let c be a root length. If $\phi \in \mathrm{trig}(P - \rho_c)$ is a relative invariant of W with multiplier M_c, then $\phi = A_c \phi_0$ for some $\phi_0 \in \mathrm{trig}(P)^W$.

Proof: By assumption, $\phi_1 = e^{i\rho_e}\phi$ is an element of $\mathrm{trig}(P)$. Let $\alpha \in R_c^+$ be given. The first claim is that ϕ_1 is divisible by $e^{i\alpha} - 1$ in $\mathrm{trig}(P)$. By assumption, ϕ is a linear combination of expressions of the form $e^{i\lambda} - e^{i\lambda'}$, where $\lambda + \rho_c \in P$, and $\lambda' = s_\alpha(\lambda)$. Since λ is the difference of a weight and ρ_c, Corollary 7 shows that $(\check{\alpha}, \lambda) \in \mathbb{Z}$. By switching λ and λ', if necessary, one may assume without loss of generality that $-(\check{\alpha}, \lambda) \in \mathbb{N}$. The claim follows by noting that

$$e^{i\lambda} - e^{i\lambda'} = e^{i\lambda}(1 - e^{-i(\check{\alpha}, \lambda)\alpha}),$$

and by factoring the right-hand side in the usual fashion.

Note that trig(P) with the natural function multiplication is a unique factorization domain (Ref. 17, Chap. VI, No. 3.1). Hence, the preceding claim implies that there exists a $\phi_0 \in \mathrm{trig}(P)$, such that

$$\phi_1 = \phi_0 \prod_{\alpha \in R_c^+} (e^{i\alpha} - 1).$$

The proof is concluded by noting that up to a constant factor, A_c is equal to

$$e^{-i\rho_c} \prod_{\alpha \in R_c^+} (e^{i\alpha} - 1).$$

The W invariance of ϕ_0 follows from the fact that A_c and ϕ are relative invariants with the same multiplier. □

We have:

Corollary 10: Let c be a root length. One has

$$(2i)^{\sharp R_c} A_c = \frac{1}{\sharp W_{\rho_c}} \sum_{w \in W} M_c(w) e^{iw(\rho_c)}. \tag{1}$$

Proposition 11: The differential operator $\nabla \log|A_c|$ *has a well-defined action on* $\mathrm{trig}(P)^W$.

Proof: Let $\phi \in \mathrm{trig}(P)^W$. The claim is that $(\nabla \log|A_c|)(\phi) \in \mathrm{trig}(P)^W$. By Corollaries 8 and 10, $A_c \in \mathrm{trig}(Q - \rho_c)$, and hence $\nabla A_c(\phi) \in \mathrm{trig}(P - \rho_c)$. Since ∇ is a W-invariant operator, $\nabla A_c(\phi)$ is a relative invariant of W with multiplier M_c. Hence, by Proposition 9, there exists a $\phi_0 \in \mathrm{trig}(P)^W$ such that $\nabla A_c(\phi) = A_c \phi_0$. □

We now have the following.

Proposition 12: If $\lambda \in P^+$, *then* $\mathrm{trig}(P_\lambda)^W$ *is an invariant subspace of* $\nabla \log|A_c|$.

Proof: Let $\phi \in \mathrm{trig}(P_\lambda)^W$ be given. Set $\phi_0 = (\nabla \log|A_c|)(\phi)$. By Proposition 11, $\phi_0 \in \mathrm{trig}(P)^W$. Let μ be a maximal element of $\mathrm{supp}(\phi_0)$. Consequently, $\mu + \rho_c$ is a maximal element of $\mathrm{suppl}(A_c \phi_0)$. Now

$$A_c = b_1 e^{i\rho_c} + \text{lower-order terms},$$

$$\phi = b_2 e^{i\lambda} + \text{lower-order terms},$$

where b_1, b_2 are nonzero constants, and hence,

$$(\nabla A_c)(\phi) = -b_1 b_2 (\rho_c, \lambda) e^{i(\rho_c + \lambda)} + \text{lower-order terms}.$$

Since $(\rho_c, \lambda) > 0$, one must have $\rho_c + \lambda = \rho_c + \mu$. Therefore $\mu = \lambda$, and $\phi_0 \in \mathrm{trig}(P_\lambda)^W$.

The basic identity that will give rise to the intertwining relation that we are looking for is given in the following proposition.

Proposition 13: Let $f_1, \ldots, f_n$ *be smooth real-valued functions on* $\mathbf{V}$; *let* $k_1, \ldots, k_n$ *be real constants; and let*

$$X = \sum_{i=1}^{n} 2k_i \nabla \log|f_i|, \quad F = \prod_{i=1}^{n} |f_i|^{k_i}.$$

We have the identity

$$F(-\Delta - X) = (-\Delta + U)F,$$

where

$$U=\sum_i k_i(k_i-1)\frac{\|\nabla f_i\|^2}{f_i^2}+\sum_{i\neq j} k_ik_j\frac{(\nabla f_i,\nabla f_j)}{f_if_j}+\sum_i k_i\frac{\Delta f_i}{f_i}.$$

The application of this proposition to the Olshanetsky–Perelomov Hamiltonians $\mathcal{H}$ requires a number of intermediate formulas.

Proposition 14: Let c be a root length. One has

$$\Delta A_c=-\|\rho_c\|^2A_c, \tag{2}$$

$$\|\nabla A_c\|^2=(U_c-\|\rho_c\|^2)A_c^2. \tag{3}$$

Proof: Note that for $\lambda\in\mathbf{V}^*$ one has $\Delta e^{i\lambda}=-\|\lambda\|^2e^{i\lambda}$. Formula (2) follows immediately from (1). Note that

$$\nabla A_c=\frac{A_c}{2}\sum_{\alpha\in R_c^+}\cot\frac{\alpha}{2}\nabla\alpha. \tag{4}$$

Consequently,

$$\|\nabla A_c\|^2=\left(\frac{c^2}{4}\sum_\alpha\cot^2\frac{\alpha}{2}+\frac{1}{4}\sum_{\alpha\neq\beta}(\alpha,\beta)\cot\frac{\alpha}{2}\cot\frac{\beta}{2}\right)A_c^2. \tag{5}$$

Taking the divergence of (4), one obtains

$$\frac{\Delta A_c}{A_c}=-\frac{(\sharp R_c)c^2}{4}+\frac{1}{4}\sum_{\alpha\neq\beta}(\alpha,\beta)\cot\frac{\alpha}{2}\cot\frac{\beta}{2}.$$

Solving for the second term of the right-hand side of the latter equation, substituting into (5) and applying (2), we obtain (3). □

Proposition 15:If c_1, c_2 are distinct root lengths such that the corresponding roots are not homothetic, then

$$(\nabla A_{c_1},\nabla A_{c_2})=-(\rho_{c_1},\rho_{c_2})A_{c_1}A_{c_2}. \tag{6}$$

If R is nonreduced and c is the length of the short roots, then

$$(\nabla A_c,\nabla A_{2c})=[U_c-(\rho_c,\rho_{2c})]A_cA_{2c}. \tag{7}$$

Proof: Let c_1, c_2 be given. A straightforward generalization of the argument in Proposition 9 yields

$$A_{c_1}A_{c_2}=\frac{1}{\sharp W_{\rho_{c_1}+\rho_{c_2}}}\sum_{w\in W}M_{c_1}(w)M_{c_2}(w)e^{iw(\rho_{c_1}+\rho_{c_2})}.$$

Hence,

$$\Delta(A_{c_1}A_{c_2})=-\|\rho_{c_1}+\rho_{c_2}\|^2A_{c_1}A_{c_2},$$

and the desired conclusion follows immediately from the usual product rule for the Laplacian.

Next, assume that the second of the proposition's hypotheses holds. Set $S_c=\Pi_{\alpha\in R_c}\cos(\alpha/2)$, and note that $A_{2c}=2A_cS_c$. Since R is of type BC_n, a direct calculation will show that $\Delta S_c=-\|\rho_c\|^2S_c$. Consequently,

$$2(\nabla A_c,\nabla S_c)=\tfrac{1}{2}\Delta A_{2c}-A_c\Delta S_c-S_c\Delta A_c=-\|\rho_c\|^2A_{2c}.$$

$$(\nabla A_c, \nabla A_{2c}) = -\|\rho_c\|^2 A_{2c} + 2S_c \|\nabla A_c\|^2.$$

The formula to be proved now follows from (3). □

We can now state and prove the intertwining relation, which is fundamental to the proof of our main result.

Proposition 16: Let

$$\tilde{\mathcal{H}} = -\Delta - \sum_c 2k_c \nabla \log|A_c|.$$

We have

$$F\tilde{\mathcal{H}} = \mathcal{H}F - \|\rho\|^2.$$

Proof: Apply Propositions 13, 14, and 15. □

Finally, we are ready to give the proof of Theorem 1, that is of the algebraic exact solvability of the Olshanetsky–Perelomov Hamiltonian $\mathcal{H}$. We begin with the following simple result from linear algebra.

Proposition 17: Let $\mathbf{V}$ *a finite-dimensional vector space over* $\mathbb{C}$, *and* $\mathbf{V}_1 \subset \mathbf{V}$ *a codimension 1 subspace. Let T be an endomorphism of* $\mathbf{V}$ *such that* $\mathbf{V}_1$ *is an invariant subspace, and let* $\kappa \in \mathbb{C}$ *denote the unique eigenvalue of the corresponding endomorphism of* $\mathbf{V}/\mathbf{V}_1$. *If* κ *is not an eigenvalue of* $T|_{\mathbf{V}_1}$, *then* κ *is a multiplicity 1 eigenvalue of T.*

It should be noted that the assumption $k_c \geqslant 0$ in Theorem 1 is crucial. The necessity of this assumption is explained by the following proposition. Indeed, one should remark that there exist certain negative values of k_c for which the action of $\mathcal{H}$ fails to be diagonalizable.

Proposition 18: Let $\mu < \lambda$ *be dominant weights. If* $k_c \geqslant 0$ *for each root length c, then* $\|\lambda + \rho\| > \|\mu + \rho\|$.

Proof: Note that

$$\|\lambda + \rho\|^2 - \|\mu + \rho\|^2 = \|\lambda\|^2 - \|\mu\|^2 + 2(\lambda - \mu, \rho).$$

Using the fact that $\lambda - \mu \in P^+$, one can easily show that $\|\lambda\| > \|\mu\|$. Furthermore, since $\lambda - \mu$ is a linear combination of basic roots with positive coefficients, Proposition 5 implies that $(\lambda - \mu, \rho) > 0$. □

Finally, we have the following.

Proof of Theorem 1: Let λ be a dominant weight. By Proposition 12, $\operatorname{trig}(P_\lambda)^W$ is an invariant subspace of $\tilde{\mathcal{H}}$. Using an argument similar to the one given in the proof of Proposition 12, it is not hard to verify that if $\phi \in \operatorname{trig}(P_\lambda)^W$, then

$$(\tilde{\mathcal{H}} - \|\lambda\|^2 - 2(\rho, \lambda))(\phi) \in \operatorname{trig}(P_{\lambda -})^W. \tag{8}$$

Note that $\operatorname{trig}(P_{\lambda -})^W$ is a codimension 1 subspace of $\operatorname{trig}(P_\lambda)^W$. Furthermore, by Proposition 18,

$$\|\lambda\|^2 + 2(\lambda, \rho) > \|\mu\|^2 + 2(\mu, \rho),$$

for all dominant weights $\mu < \lambda$. Hence, by Proposition 17, there exists a unique $\phi_\lambda \in \operatorname{trig}(P_\lambda)^W$ such that $\tilde{\mathcal{H}}\phi_\lambda = (\|\lambda\|^2 + 2(\rho, \lambda))\phi$. The first of the desired conclusions now follows by Proposition 16.

To prove the converse let $F\phi$ with $\phi \in \operatorname{trig}(P)^W$ be an eigenfunction of $\mathcal{H}$ with eigenvalue κ. Let $\lambda \in P^+$ be a maximal element of $\operatorname{supp}(\phi)$. Since $\operatorname{trig}(P_{\lambda -})^W$ is a codimension 1 subspace of $\operatorname{trig}(P_\lambda)^W$, (8) implies that $\kappa = \|\lambda\|^2 + 2(\lambda, \rho)$. Consequently, λ is the unique maximal element of $\operatorname{supp}(\phi)$. By Proposition 17, κ has multiplicity 1, and this gives the desired conclusion. □

IV. A RECURSION FORMULA FOR THE EIGENFUNCTIONS OF $\tilde{\mathcal{H}}$

In the present section we show how to explicitly compute the eigenfunctions of the Olshanetsky–Perelomov Hamiltonian by using a k_c-parametrized analog of the Freudenthal multiplicity formula. The generalized formula actually yields the eigenfunctions ϕ_λ of the related operator $\tilde{\mathcal{H}}$. One should mention that the eigenfunctions ϕ_λ first appeared in the investigations of Heckman and Opdam,[14] who regard these functions as multivariable generalizations of the Jacobi polynomials. The eigenfunctions of $\mathcal{H}$ are, of course, obtained by multiplication with the gauge factor F.

By way of motivation it will be useful to recall the context of the original Freudenthal formula. Suppose that R is reduced and let χ_λ, $\lambda \in P^+$ denote a character of the corresponding compact, simply connected Lie group. The Weyl character formula states that

$$\chi_\lambda = \frac{\Sigma_{w\in W}\,\mathrm{sgn}(w)e^{iw(\lambda+\tilde{\rho})}}{\Sigma_{w\in W}\,\mathrm{sgn}(w)e^{iw(\lambda)}}, \tag{9}$$

where $\tilde{\rho}$ is the half-sum of the positive roots. Now if $k_c=1$ for all c, then the potential term of $\mathcal{H}$ is zero, and the gauge factor F is nothing but the W-antisymmetric denominator of (9). Furthermore, the numerator in (9) is the unique W-antisymmetric eigenfunction of Δ with highest-order term $e^{i(\lambda+\tilde{\rho})}$. Hence, by the intertwining relation described in Proposition 16, the Weyl character formula is equivalent to the statement that χ_λ is an eigenfunction of $\tilde{\mathcal{H}}$ with eigenvalue $(\lambda,\lambda+2\tilde{\rho})$. This observation leads directly to the classical Freudenthal formula for the multiplicities of χ_λ, and to the following generalization involving the parameters k_c. (See Ref. 18 for more details regarding the Weyl and Freudenthal formulas.)

Proposition 19: Let $\phi_\lambda = e^{i\lambda} + \Sigma_{\mu<\lambda} n_\mu e^{i\mu}$ *be the eigenfunction of* $\tilde{\mathcal{H}}$ *described in the statement and proof of Theorem 1. Setting* $n_\lambda = 1$ *and* $n_\nu = 0$ *for* $\nu \not\leq \lambda$, *the remaining coefficients* n_μ, $\mu<\lambda$, *are given by the following recursion formula*:

$$(\|\lambda+\rho\|^2 - \|\mu+\rho\|^2)n_\mu = 2\sum_{\alpha\in R^+}\sum_{j\geq 1} k_{|\alpha|}(\alpha,\mu+j\alpha)n_{\mu+j\alpha}. \tag{10}$$

Proof: Rewriting

$$A_c = e^{i\rho_c}\prod_{\alpha\in R_c^+}(1-e^{-i\alpha}),$$

one obtains

$$\tilde{\mathcal{H}} = -\Delta - i\,\nabla\rho - 2i\sum_{\alpha\in R^+} k_{|\alpha|}\frac{e^{-i\alpha}}{1-e^{-i\alpha}}\nabla\alpha.$$

Let $\mathrm{trig}((P))$ denote the vector space of formal power series $\Sigma_{\mu\in P} c_\mu e^{i\mu}$. Since elements of $\mathrm{trig}(P)$ are finitely supported sums, one has a well-defined multiplication operation $\mathrm{trig}((P))\times\mathrm{trig}(P)\rightarrow\mathrm{trig}((P))$. Thus, setting the domain of $\tilde{\mathcal{H}}$ to be $\mathrm{trig}(P)$, one can extend the operator's coefficient ring and write

$$\tilde{\mathcal{H}} = -\Delta - i\,\nabla\rho - 2i\sum_{\alpha\in R^+}\sum_{j\geq 1} k_{|\alpha|}e^{-ji\alpha}\,\nabla\alpha.$$

However, because of Proposition 11 one can take the codomain of $\tilde{\mathcal{H}}$ to be $\mathrm{trig}(P)$ rather than all of $\mathrm{trig}((P))$. Acting with the right-hand side of the latter equation on ϕ_λ, collecting like terms, and using the fact that ϕ_λ is an eigenfunction with eigenvalue $(\lambda,\lambda+2\rho)$ immediately yields (10). □

It is important to remark that by Proposition 18 the coefficient of n_μ appearing in (10) is never zero. Consequently, (10) can indeed be used as a recursive formula for the coefficients n_μ. One should also remark that the W symmetry of ϕ_λ means that it suffices to use formula (10) to calculate n_μ with $\mu\in P^+$.

A loop group approach to the C. Neumann problem and Moser–Veselov factorization

Saša Krešić-Jurić
Symbol Technologies, Inc., Holtsville, New York 11742-1300

(Received 9 December 1998; accepted for publication 28 April 1999)

A geometrical description of continuous and discrete versions of the Neumann oscillator in terms of a loop group framework is investigated. It is shown that the continuous Neumann oscillator can be integrated by the Riemann–Hilbert factorization on the ''twisted'' loop group of $O(3)$, $LO(3)$. The solution of the problem is given in terms of a special class of flows on the quotient space $LO(3)/LO(3)_+$ where $LO(3)_+$ is a subgroup of positive loops in $LO(3)$. It is also shown that the Moser–Veselov algorithm for integrating a discrete version of the Neumann oscillator (Heisenberg *XYZ* chain) is induced by a discrete flow in this space. The flow can be explicitly integrated by solving the matrix Riccati equation. In both cases, discrete and continuous, conservation laws are derived from time invariance of a relation that holds for coefficients of the Fourier expansion of the flows. © *1999 American Institute of Physics.* [S0022-2488(99)03110-2]

I. INTRODUCTION

Recently there has been a growth of interest in discretization algorithms of dynamical systems which preserve certain properties of the system. For example, one may be interested in discretizations which preserve the energy or momentum, or perhaps the symplectic structure of the system. A class of such algorithms called variational integrators can be obtained by means of discretizing the Hamilton's principle which leads to discrete Euler–Lagrange equations.[1]

In this article we consider discretizations of integrable systems which have a zero-curvature representation on the Lie algebra of a loop group G. Roughly speaking, if G has a unique factorization into subgroups $G=G_-G_+$, then one can usually associate to the system a flow $g(t)G_+$ on the homogeneous space G/G_+. If the flow can be mapped into the phase space flow φ_t, then the system can be integrated by calculating $g(t)$ which is equivalent to solving a Riemann–Hilbert factorization problem on G. Now, suppose that ϕ_n is a given discretization of the continuous flow φ_t. Then one can ask if it is possible to find a discrete flow in G/G_+ which can be mapped into ϕ_n. In other words, one would like to know if the discretized system can be integrated by stepping along a discrete flow in G/G_+. This is in general a very difficult question and has to be dealt with separately for each system under consideration.

In this paper we show that it is possible to carry out the above construction for the Neumann oscillator

$$\frac{d^2S}{dt^2}=-JS+\lambda S, \quad S\in\mathbb{R}^n, \quad |S|=1, \tag{1}$$

where $J=\mathrm{diag}(J_1,...,J_n)$, $\lambda=\langle JS,S\rangle-|S_t|^2$, and its discrete version

$$J(S_{k-1}+S_{k+1})=\lambda_k S_k, \quad S_k\in\mathbb{R}^n, \quad |S_k|=1. \tag{2}$$

Here $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^n$ and the subscript t denotes the derivative with respect to t. In classical mechanics Eq. (1) describes the motion of a particle with the Hamiltonian $H=\frac{1}{2}|P|^2+\frac{1}{2}\langle JS,S\rangle$ constrained to the cotangent bundle of the $(n-1)$-sphere. In solid state physics

(1) is equivalent to the stationary Landau–Lifshitz equation[2] (t being a spatial coordinate), and the difference equation (2) represents the Heisenberg chain with classical spins.[3]

For $n=3$, Eq. (1) was originally studied by C. Neumann[4] in 1859 who integrated it by separation of variables in the Hamilton–Jacobi equation. The interest in the problem was revived when Moser[5] established the connection between (1) and certain rank-2 perturbations of a symmetric matrix. He showed that the integrals of the Neumann oscillator can be obtained in terms of the eigenvalues of the perturbed matrix. Moser's results were generalized by Adams, Harnad, and Previato[6] to general rank-r perturbations. In a recent paper[3] the discrete system (2) was investigated by Moser and Veselov through factorization of matrix polynomials $M(z)=J^2z^2+(x\otimes Jy-Jy\otimes x)z-x\otimes x,\ x,y\in\mathbb{R}^n$. They showed that Eq. (2) can be integrated by isospectral deformations of M based on a factorization of M into two first-order polynomials. We also mention the work of Deift, Li, and Tomei[7] in which the Moser–Veselov ideas were interpreted in terms of a loop group framework. In their paper a continuous flow is constructed which at integer times interpolates the Moser–Veselov algorithm.

The outline of the present paper is as follows: Sec. II begins with a brief review of the zero-curvature formulation of partial differential equations (PDE's) which is needed in our approach to the Neumann oscillator. We then introduce the twisted loop group of $O(3)$, $LO(3)$, and show that an action of $\mathbb{R}^2$ on a subset of $LO(3)$ induces Eq. (1) for $n=3$. Solutions of this equation are given in terms of a special class of flows on the quotient space $LO(3)/LO(3)_+$, where $LO(3)_+$ is the subgroup of positive loops in $LO(3)$. We remark that in this picture the Neumann oscillator appears as a special case of an infinite dimensional systems which is generated by a generic flow in $LO(3)/LO(3)_+$. The conservation laws for Eq. (1) can be deduced from algebraic relations which hold for coefficients of the Fourier expansion of the flows.

In Sec. III we present a loop group approach to the discrete system (2). We show that after a simple transformation the Moser–Veselov polynomials M become elements of the Lie algebra of $LO(3)$. This enables us to find a discrete flow $g_-^{(k)}\mapsto g_-^{(k+1)}$ in $LO(3)$ which induces the aforementioned isospectral deformations of M. The flow can be explicitly integrated by solving the matrix Riccati equation for the first coefficient of the Fourier expansion of $g_-^{(k+1)}$. The integrals of the discrete system which were discovered by Granovskii and Zhedanov[8] can be found by the same method as in Sec. II. The results of Secs. II and III generalize in a straightforward manner to arbitrary dimensions by considering the action of $\mathbb{R}^2$ on $LO(n)$.

We mentioned in the Introduction that the Moser–Veselov algorithm was interpreted in terms of a loop group framework by Deift, Li, and Tomei. We should emphasize, however, that our approach has the advantage of describing both systems (1) and (2) from a single point of view. In each case the dynamics is given by a special class of flows (Neumann flows) on the quotient space $LO(3)/LO(3)_+$, and the same method can be used to obtain the integrals of motion.

II. LOOP GROUPS AND THE NEUMANN OSCILLATOR

A. Zero-curvature representation

In this section we review the zero curvature representation on loop algebras as a method for constructing integrable systems (see Refs. 2, 9).

Let G be a Banach Lie group which contains closed Lie subgroups G_- and G_+ such that $G_-\cap G_+=\{I\}$. The set $G_-G_+=\{gh|g\in G_-,h\in G_+\}$ is open in G if and only if the Lie algebra of G splits into a direct sum of vector spaces $\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+$. Here $\mathfrak{g}_\pm$ is the Lie algebra of $G_\pm$. Suppose that G_-G_+ is open in G and consider a differentiable action of $\mathbb{R}^n$ on G defined by

$$\mathbf{t}g=\exp\left(\sum_{i=1}^{n} t_iX_i\right)g. \tag{3}$$

Here $\mathbf{t}=(t_1,\ldots,t_n)\in\mathbb{R}^n$ and $X_1,\ldots,X_n$ are pairwise commuting elements of $\mathfrak{g}_+$. Note that (3) descends to an action of $\mathbb{R}^n$ on G/G_+ by

$$\mathbf{t}(gG_+)=(\mathbf{t}g)G_+. \tag{4}$$

Now let $g\in G_-G_+$. Then there exists a neighborhood $U\subset\mathbb{R}^n$ of zero such that $\mathbf{t}g\in G_-G_+$ for all $\mathbf{t}\in U$. Hence $\mathbf{t}g$ can be written in a unique way as

$$\mathbf{t}g=g_-(\mathbf{t})g_+(\mathbf{t}), \tag{5}$$

where $g_-\in G_-$ and $g_+\in G_+$. We shall refer to (5) as the ''Riemann–Hilbert'' factorization of $\mathbf{t}g$. In view of (4) we see that the action of $\mathbb{R}^n$ induces the flow $g_-(\mathbf{t})G_+$ on the homogeneous space G/G_+.

Next we show that $g_-(\mathbf{t})$ is a ''solution'' to a hierarchy of PDE's associated with the Riemann–Hilbert factorization problem. By differentiating the Riemann–Hilbert splitting (5) and using (3) we obtain

$$g_-^{-1}X_ig_-=g_-^{-1}\frac{\partial g_-}{\partial t_i}+\frac{\partial g_+}{\partial t_i}g_+^{-1}.$$

Since the first term on the right-hand side is in $\mathfrak{g}_-$ and the second is in $\mathfrak{g}_+$, we have

$$\Pi_+(g_-^{-1}X_ig_-)=\frac{\partial g_+}{\partial t_i}g_+^{-1}, \tag{6}$$

where Π_+ is the projection of $\mathfrak{g}$ onto $\mathfrak{g}_+$. Denote

$$M_i(\mathbf{t})=\Pi_+(g_-^{-1}(\mathbf{t})X_ig_-(\mathbf{t})) \tag{7}$$

for $i=1,2,...,n$. Since the flows induced by any two vectors X_k, X_l commute, the system of equations

$$\frac{\partial g_+}{\partial t_k}(\mathbf{t})=M_k(\mathbf{t})g_+(\mathbf{t}),\quad \frac{\partial g_+}{\partial t_l}(\mathbf{t})=M_l(\mathbf{t})g_+(\mathbf{t}) \tag{8}$$

satisfies the compatibility condition $(g_+)_{kl}=(g_+)_{lk}$ which yields the zero-curvature equation

$$\frac{\partial M_k}{\partial t_l}-\frac{\partial M_l}{\partial t_k}+[M_k,M_l]=0. \tag{9}$$

Usually, G is the loop group of a linear group and the zero-curvature condition turns out to be equivalent with a nonlinear PDE satisfied by a matrix element $u(\mathbf{t})$ of M_k and M_l. Since u can be explicitly calculated in terms of $g_-(\mathbf{t})$ via (7), we have the mappings $g\mapsto g_-(\mathbf{t})\mapsto u(\mathbf{t})$. Here $u(\mathbf{t})$ is regarded as a function of t_k and t_l while the other variables are kept fixed. The Riemann–Hilbert factorization establishes local existence of $u(\mathbf{t})$, thus producing a solution of (9). Moreover, it linearizes the equation for u since multiplying g by $\exp(\Delta t_iX_i)$ corresponds to $u(\mathbf{t})$ flowing in the ''t_i-direction'' by the amount Δt_i. By choosing different values of k and l the flow $g_-(\mathbf{t})$ yields solutions to an entire hierarchy of equations represented by (9). Since the map $g\mapsto g_-(\mathbf{t})$ is invariant under the right multiplication of g by an element of G_+, we may assume that $g\in G_-$. Then by uniqueness of the splitting $g=g_-(0)$, so g contains the initial values of u.

For applications of the above method it is most convenient to work with subgroups of the group of continuous loops in $GL(n,\mathbb{C})$. More precisely, G is constructed as follows. Let $\mathcal{A}$ denote the Banach algebra,

$$\mathcal{A}=\left\{f:S^1\to\mathbb{C}\,\middle|\,f(z)=\sum_{n\in\mathbb{Z}}a_nz^n,\quad \sum_{n\in\mathbb{Z}}|a_n|<\infty,a_n\in\mathbb{C}\right\}, \tag{10}$$

with respect to the norm $\|f\|_1=\Sigma_{n\in Z}|a_n|$ and pointwise addition and multiplication. Alternatively, $\mathcal{A}$ consists of continuous functions on S^1 which have an absolutely convergent Fourier series. Let $M(n,\mathcal{A})$ be the Banach algebra of $n\times n$ matrices $g=(g_{ij})$ relative to the norm $\|g\|=\Sigma_{i,j=1}^n\|g_{ij}\|_1$. Various integrable systems can be constructed by introducing an involution on $M(n,\mathcal{A})$ such that $\|g^*\|=\|g\|$, and considering subgroups

$$G=\{g\in GL(n,\mathcal{A})|gg^*=I\} \tag{11}$$

of the Banach Lie group

$$GL(n,\mathcal{A})=\{g(z)\in M(n,\mathcal{A})|\det(g(z))\neq 0 \quad \text{for all} \quad z\in S^1\}.$$

A standard result from the theory of Banach manifolds[10] asserts that G is a regular Lie subgroup of $GL(n,\mathcal{A})$ with the Lie algebra

$$\mathfrak{g}=\{X\in M(n,\mathcal{A})|X+X^*=0\}. \tag{12}$$

Various examples of loop groups and integrable systems obtained by this method can be found in Refs. 11, 12, and 13.

B. Integration of the Neumann problem by the Riemann–Hilbert factorization

As we mentioned in the Introduction, the Neumann problem

$$\frac{d^2S}{dt^2}=-JS+\lambda S, \quad S\in\mathbb{R}^3, \quad |S|=1, \tag{13}$$

where $J=\operatorname{diag}(J_1,J_2,J_3)$ and $\lambda=\langle JS,S\rangle-|S_t|^2$, is a completely integrable Hamiltonian system which is obtained by constraining the Hamiltonian $H=\frac{1}{2}|P|^2+\frac{1}{2}\langle JS,S\rangle$ to the cotangent bundle of the 2-sphere. We assume that the spring constants J_i are nondegenerate, i.e., they satisfy $J_1<J_2<J_3$.

In order to motivate the connection between the Neumann oscillator and loop groups we state the following result attributed to Uhlenbeck.[14]

Lemma 1: Define matrices $Q=(S_iS_j)$, $L=(P_iS_j-S_iP_j)$, *and set* $U(z)=Jz^2+Lz-Q$, $V(z)=Jz+L$ *with a parameter* $z\in\mathbb{C}$. *Then the Neumann system*

$$\frac{dS_i}{dt}=P_i, \quad \frac{dP_i}{dt}=-J_iS_i+[\langle JS,S\rangle-|P|^2]S_i, \quad |S|=1, \tag{14}$$

is equivalent to the Lax equation

$$\frac{dU}{dt}=[V,U] \quad \textit{subject to constraints} \quad |S|=1,\ \langle P,S\rangle=0. \tag{15}$$

The proof is a direct computation. According to the discussion in the previous section we would like $U(z)$ and $V(z)$ to be elements of the Lie algebra of a loop group, and the Lax Eq. (15) to be a special case of the zero-curvature condition on this algebra. It turns out that this is in principle true. Since the details are somewhat nontrivial and do not seem to appear in the literature we present them here. This is instrumental in understanding the second part of the paper which deals with the discretized Neumann oscillator.

Let $\mathcal{A}_{\mathbb{R}}$ be the function algebra introduced in (10) with real-valued Fourier coefficients. Define the group $G=LO(3)$ as in (11) with $\mathcal{A}=\mathcal{A}_{\mathbb{R}}$ and the involution on $M(3,\mathcal{A}_{\mathbb{R}})$ given by

$$g^*(z)=g^T(-z).$$

We call G the ''twisted'' loop group of $O(3)$. Note that if $X(z)=\Sigma_{n\in Z}C_n z^n$ is an element of the Lie algebra of G, then $C_n^T=C_n$ for odd n, and $C_n^T=-C_n$ for even n. In order to define the Riemann–Hilbert factorization consider the closed subgroups of G,

$$G_+=\left\{g\in LO(3)\,\middle|\,g(z)=\sum_{n\geqslant 0}A_n z^n\right\},$$

$$G_-=\left\{g\in LO(3)\,\middle|\,g(z)=I+\sum_{n<0}A_n z^n\right\}.$$

Clearly, $G_-\cap G_+=\{I\}$. If $\mathfrak{g}_\pm$ denotes the Lie algebra of $G_\pm$, then $\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+$ so the set G_-G_+ is open in G. Now let $X_1(z)=Jz$, $X_2(z)=Jz^3$ and consider an action of $\mathbb{R}^2$ on G defined by

$$(t,x)g=\exp(tX_1(z)+xX_2(z))g. \tag{16}$$

The action (16) gives rise to a unique factorization of $(t,x)g$,

$$\exp(tX_1(z)+xX_2(z))g=g_-(t,x)g_+(t,x)\quad\text{for}\quad g\in G_-G_+. \tag{17}$$

The matrices $M_i=\Pi_+(g_-^{-1}X_i g_-)$, $i=1,2$, satisfy the zero-curvature equation

$$\frac{\partial M_2}{\partial t}-\frac{\partial M_1}{\partial x}+[M_2,M_1]=0, \tag{18}$$

where $\Pi_+:\mathfrak{g}\to\mathfrak{g}_+$ is the canonical projection with kernel $\mathfrak{g}_-$. The system of differential equations represented by Eq. (18) is in general very complicated and it is not known whether it describes a physical system. However, we will show that for special initial values of the flow $(t,x)g$ this equation is equivalent with Neumann problem (13).

Since we may assume $g\in G_-$, throughout this section the triple (g,g_-,g_+) will be *always* given by (17) with $g=g_-(0,0)$. Thus $M_1(0,0)=\Pi_+(g^{-1}Jzg)$ and $M_2(0,0)=\Pi_+(g^{-1}Jz^3g)$.

Let $I+\Sigma_{n=1}^{\infty}A_n z^{-n}$ be the Fourier expansion of g. The group law $gg^*=I$ implies $g^{-1}=\Sigma_{n=1}^{\infty}(-1)^n A_n^T z^{-n}$, where the matrices A_n satisfy $A_1^T=A_1$ and

$$A_n+(-1)^n A_n^T=-\sum_{k=1}^{n-1}(-1)^k A_{n-k}A_k^T\quad n\geqslant 2. \tag{19}$$

From (19) we find by a straightforward computation that

$$M_1(0,0)=Jz+L_0,\quad M_2(0,0)=Jz^3+L_0z^2-K_0z+N_0, \tag{20}$$

where $L_0=[J,A_1]$ and

$$K_0=A_1[J,A_1]-[J,A_2], \tag{21}$$

$$N_0=[J,A_3]-A_1[J,A_2]+A_2^T[J,A_1]. \tag{22}$$

We can prove now the following preliminary result.

Lemma 2: There exist elements $g=I+\Sigma_{n=1}^{\infty}A_n z^{-n}\in G_-$ *such that*

$$M_2(0,0)=\Pi_+(g^{-1}Jz^3g)=Jz^3+L_0z^2-K_0z,$$

where $K_0+\frac{1}{3}I$ *is the tensor product* $S_0\otimes S_0$ *for some unit vector* S_0 in $\mathbb{R}^3$.

Proof: First we show that one can find A_1 and A_2 so that $K_0+\frac{1}{3}I=S_0\otimes S_0$ for some $|S_0|=1$. Note that for $n=2$ Eq. (19) implies $A_2=\frac{1}{2}A_1^2+\frac{1}{2}T$, where $T=\frac{1}{2}(A_2-A_2^T)$. By substituting this into (21) we obtain

$$K_0 = \tfrac{1}{2}[A_1,[J,A_1]] - \tfrac{1}{2}[J,T]. \tag{23}$$

Denote

$$A_1 = \begin{pmatrix} a_{11} & a_3 & -a_2 \\ a_3 & a_{22} & a_1 \\ -a_2 & a_1 & a_{33} \end{pmatrix} \quad \text{and} \quad T = \begin{pmatrix} 0 & t_3 & t_2 \\ -t_3 & 0 & t_1 \\ -t_2 & -t_1 & 0 \end{pmatrix}. \tag{24}$$

Then the diagonal of K_0 is given by

$$(K_0)_{11} = (J_3 - J_1)a_2^2 + (J_2 - J_1)a_3^2,$$

$$(K_0)_{22} = (J_3 - J_2)a_1^2 + (J_1 - J_2)a_3^2,$$

$$(K_0)_{33} = (J_1 - J_3)a_2^2 + (J_2 - J_3)a_1^2, \tag{25}$$

and for the off-diagonal elements we have

$$(K_0)_{ij} = \tfrac{1}{2}(-1)^{i+j+1}[(J_i - J_j)(a_{ii} - a_{jj})a_k + (J_i + J_j - 2J_k)a_i a_j - (J_i - J_j)t_k]. \tag{26}$$

Here (i,j,k) is a cyclic permutation of (1,2,3). Now pick $S_0 = (S_1, S_2, S_3)^T \in S^2$ such that $S_1^2 - \frac{1}{3} \geqslant 0$ and $S_3^2 - \frac{1}{3} \leqslant 0$. Recalling that $J_1 < J_2 < J_3$ it is clear from (25) and (26) that one can find A_1 and T such that $K_0 = S_0 \otimes S_0 - \frac{1}{3}I$.

By similar reasoning one can show that there exists A_3 satisfying (19) which makes the free term in $M_2(0,0)$ vanish,

$$[J,A_3] = A_1[J,A_2] - A_2^T[J,A_1]. \tag{27}$$

Substituting $A_2 = \frac{1}{2}A_1^2 + \frac{1}{2}T$ into (19) with $n = 3$ yields $A_3 = \frac{1}{2}U + \frac{1}{4}(TA_1 + A_1T)$, where $U = \frac{1}{2}(A_3 + A_3^T)$. Then (27) is equivalent to

$$[J,U] = \tfrac{1}{2}[T,[J,A_1]] + \tfrac{1}{2}[A_1,[J,T]] + A_1[J,A_1]A_1. \tag{28}$$

Clearly, this equation determines the off-diagonal elements of U, while the diagonal can be chosen arbitrary. ■

For given $J = \mathrm{diag}(J_1,J_2,J_3)$ let G_J^i denote the set of all $g \in G_-$ from Lemma 2 (i stands for the special initial conditions imposed on M_2). Since the Neumann problem is given by an ordinary differential equation we will be interested in loops $g_-(t) \in G_-$ which depend only on t. The following lemma is easily proved and provides a simple characterization of such loops.

Lemma 3: Let $g \in G_-$. Then $\exp(tX_1 + xX_2)g = g_-(t)g_+(t,x)$ if and only if $g^{-1}X_2 g \in \mathfrak{g}_+$.

Let G_J^t be the set of all $g \in G_-$ such that $g^{-1}X_2 g \in \mathfrak{g}_+$. This notation is to remind us that if $g \in G_J^t$, then g_- flows only in the "t-direction." Now define the set of "Neumann loops" by $G_J^N = G_J^i \cap G_J^t \subset G_-$. One can show that the action of $\mathbb{R}^2$ on G/G_+ can be restricted to G_J^N/G_+ in the sense that if $gG_+ \in G_J^N/G_+$, then $g_-(t)G_+ \in G_J^N/G_+$ for all t sufficiently close to zero. Roughly speaking, as a consequence of this result the matrices $M_1(t)$ and $M_2(t)$ evolve along the orbits of the Neumann oscillator. This is the content of the following theorem.

Theorem 4: *Let $g \in G_J^N$, and let $M_i(t) = \Pi_+(g_-^{-1}(t)X_i g_-(t))$, $i = 1,2$. Then the matrices M_1 and M_2 satisfy the Lax equation $dM_2/dt = [M_1, M_2]$ which is equivalent with the Neumann problem (14).*

Proof: Let M_i^0 denote the initial value of $M_i(t)$, i.e., $M_i^0 = \Pi_+(g^{-1}X_i g)$. Then $M_1^0 = Jz + L_0$ with $L_0^T = -L_0$, and by Lemma 2,

$$M_2^0 = Jz^3 + L_0 z^2 - K_0 z, \quad \text{where} \quad K_0 = S_0 \otimes S_0 - \tfrac{1}{3}I, \quad |S_0| = 1. \tag{29}$$

We show that $M_2(t)$ retains the form (29) for all t for which the Riemann–Hilbert splitting is defined. Recall from (8) that $M_2(t)=(\partial g_+/\partial x)g_+^{-1}$. On the other hand, by differentiating (17) and rearranging we have $g_+(g^{-1}X_2g)g_+^{-1}=(\partial g_+/\partial x)g_+^{-1}$ because $\partial g_-/\partial x=0$. Hence $M_2(t)=g_+M_2^0g_+^{-1}$, so in view of (29) the matrix $M_2(t)$ has vanishing zero-order term. Therefore we can write

$$M_1(t)=Jz+L(t), \quad M_2(t)=Jz^3+L(t)z^2-K(t)z,$$

where L and K satisfy the initial conditions $L(0)=L_0$ and $K(0)=K_0$. Recall that M_1 and M_2 satisfy the zero-curvature Eq. (18) which reduces to

$$\frac{dM_2}{dt}=[M_1,M_2]. \tag{30}$$

We claim that $K(t)=S(t)\otimes S(t)-\frac{1}{3}I$ for some unit vector $S(t)$. It follows from 30 that $dL/dt=[K,J]$ and $dK/dt=[L,K]$. Define $Q(t)=K(t)+\frac{1}{3}I$. Then the time evolution of Q is also given by $dQ/dt=[L,Q]$ with the initial condition $Q(0)=S_0\otimes S_0$. Hence the spectrum of Q is independent of t and is given by the roots of

$$\det(Q(0)-\lambda I)=|S_0|^2\lambda^2-\lambda^3=\lambda^2-\lambda^3. \tag{31}$$

Since Q is real and symmetric this implies that $Q(t)=\omega(t)\mathrm{diag}(1,0,0)\omega^{-1}(t)$ for some orthogonal matrix $\omega(t)$. Thus we conclude $Q(t)=S(t)\otimes S(t)$, where $S(t)\in\mathbb{R}^3$. By invariance of the spectrum we have $\det(Q(t)-\lambda I)=\det(Q(0)-\lambda I)$ which implies $|S(t)|=1$ for all t.

To finish the proof let L' be the image of $L\in\mathfrak{so}(3)$ under the Lie algebra isomorphism $\mathfrak{so}(3)\approx\mathbb{R}^3$, and define $P=L'\times S\in\mathbb{R}^3$. Since L can be chosen so that L' is perpendicular to S we have $L'=P\times S$, thus $L=P\otimes S-S\otimes P$. Now set

$$V(t)=Jz+L(t) \ \text{ and } \ U(t)=Jz^2+L(t)z-Q(t).$$

Since $dM_2/dt=[M_1,M_2]$ if and only if $dU/dt=[V,U]$ the theorem follows from Lemma 1. ■

Theorem 4 shows that the Neumann problem is explicitly integrable in the sense that for $g\in G_J^N$ the differential Eq. (13) can be solved by the factorization of $\exp(tX_1+xX_2)g$. It is well known that this problem is also integrable in the sense of Liouville. Moser showed that the integrals of motion can be obtained from eigenvalues of certain rank-2 perturbations of a symmetric matrix.[5] Here we give a new proof based on the fact that the integrals are simply the diagonal elements of the matrix $S(t)\otimes S(t)-K(t)$ which, because of the special initial values of the flow $g_-(t)G_+$, are preserved along this flow.

Corollary 5: If the initial values of the Neumann problem (13) are determined by $g\in G_J^N$, then the system has the following integrals of motion:

$$F_i=S_i^2+\sum_{\substack{k=1\\k\neq i}}^{3}\frac{(P_iS_k-S_iP_k)^2}{J_i-J_k}, \quad i=1,2,3. \tag{32}$$

Proof: We have shown in Theorem 4 that $K(t)=S(t)\otimes S(t)-\frac{1}{3}I$, when $g\in G_J^N$. Hence $S\otimes S-K$ is constant along the flow. We claim that the diagonal elements $F_i=(S\otimes S-K)_{ii}$ have the form (32). To see this recall that $L(t)=[J,A_1(t)]$, where we label the elements of $A_1(t)$ as in (24). On the other hand, $L=P\otimes S-S\otimes P$, hence $[J,A_1]=P\otimes S-S\otimes P$. By solving for the off-diagonal elements of A_1 we obtain

$$a_k=(-1)^{i+j+1}\frac{P_iS_j-S_iP_j}{J_i-J_j},$$

where (i,j,k) is a cyclic permutation of (1,2,3). Substituting this into Eqs. (25) we find that $(S\otimes S)_{ii}-K_{ii}$ is given by (32). ■

We conclude our discussion with the remark that Eqs. (25) imply $S_1^2(t)\geqslant\frac{1}{3}$ and $S_3^2(t)\leqslant\frac{1}{3}$ because $J_1<J_2<J_3$. These conditions restrict the motion of the Neumann oscillator to two disjoint regions of the sphere. This corresponds to one of the four types of motion described in the original paper of Neumann (see p. 52 in Ref. 4).

III. A LOOP GROUP DESCRIPTION OF THE DISCRETIZED NEUMANN OSCILLATOR

This section is devoted to the study of a discrete version of the Neumann problem

$$J(S_{n-1}+S_{n+1})=\lambda_n S_n, \quad |S_n|=1. \tag{33}$$

S_n is the position of a point on the 2-sphere at integer time n, and the multiplier λ_n is determined from the condition $|S_{n+1}|=1$. In contrast to the continuous case λ_n is not unique,

$$\lambda_n=0 \quad \text{or} \quad \lambda_n=2\langle S_{n-1},J^{-1}S_n\rangle/|J^{-1}S_n|^2.$$

We shall assume that for all integer times we have $\lambda_n\neq 0$ since only in this case Eq. (33) corresponds to the correct limit describing continuous motion.[3]

We have shown in Sec. II that the Neumann oscillator can be integrated by constructing a continuous flow in G/G_+ where we recall $G=LO(3)$ is the twisted loop group of $O(3)$. It is natural to ask whether this property is conserved under the above discretization. More precisely, we would like to know if there is a discrete flow $g_-^{(n)}G_+\mapsto g_-^{(n+1)}G_+$ in G/G_+ which integrates Eq. (33). In this paper by integrability of (33) we mean that S_{n+1} can be calculated from S_n, i.e., that the order of the difference equation can be reduced by one. For another interpretation of integrability based on a discrete version of Liouville's theorem, see Ref. 15. Before we answer the above question we will need the following background information.

A. Moser–Veselov factorization of matrix polynomials

Moser and Veselov[3] investigated integrability of Eq. (33) with the help of an isospectral technique based on factorization of matrix polynomials $U(z)=C_0+C_1z+C_2z^2$, $z\in\mathbb{C}$. The idea is similar to the QR-algorithm of Francis designed to calculate the eigenvalues of a complex matrix. The matrix $U(z)$ is factored into a product of two first order polynomials

$$U(z)=(A_0+A_1z)(B_0+B_1z), \tag{34}$$

and the isospectral mapping Ψ is defined by exchanging the factors,

$$\Psi:U(z)\mapsto\hat{U}(z)=(B_0+B_1z)(A_0+A_1z).$$

They have shown that this technique integrates several well known classical problems, e.g., the rigid body and the billiard inside an ellipsoid. In the case of the Neumann oscillator it induces a map $(S_{n-1},S_n)\mapsto(S_n,S_{n+1})$ such that the triple (S_{n-1},S_n,S_{n+1}) satisfies the difference Eq. (33).

Our exposition of the Moser–Veselov algorithm for the Neumann oscillator is similar to the one for the rigid body problem in Ref. 3. This makes it more suitable for interpretation in terms of a discrete flow in G/G_+.

Let $\mathcal{P}$ denote the class of polynomials $U_n(z)=J^2z^2+L_nz-S_nS_n^T$, where $L_n^T=-L_n$ and $S_n=(S_n^1,S_n^2,S_n^3)^T$ is a unit vector in $\mathbb{R}^3$. Define $\Psi:\mathcal{P}\to\mathcal{P}$ as follows. Suppose that $U_n(z)$ can be factored as

$$U_n(z)=(zJ+\omega_n^T)(zJ-\omega_n). \tag{35}$$

This is possible if and only if ω_n satisfies the equations

$$\omega_n^T J - J\omega_n = L_n \quad \text{and} \quad \omega_n^T \omega_n = S_n S_n^T. \tag{36}$$

Now define $U_{n+1} = \Psi(U_n)$ by exchanging the factors in (35), i.e.,

$$U_{n+1}(z) = (zJ - \omega_n)(zJ + \omega_n^T). \tag{37}$$

Assuming for the moment that such ω_n exists we show that Ψ is well-defined, i.e., $\mathrm{Im}(\Psi) \subset \mathcal{P}$. Since

$$U_{n+1}(z) = J^2 z^2 + (J\omega_n^T - \omega_n J)z - \omega_n \omega_n^T,$$

we have $L_{n+1} = J\omega_n^T - \omega_n J$, thus L_{n+1} is antisymmetric. It remains to show that $\omega_n \omega_n^T = S_{n+1} S_{n+1}^T$ for some unit vector S_{n+1} in $\mathbb{R}^3$. This follows from the isospectrality of Ψ. Namely,

$$U_{n+1}(z) = (zJ + \omega_n^T)^{-1} U_n(z)(zJ + \omega_n^T)$$

so when $z = 0$ we have $\omega_n \omega_n^T = (\omega_n^T)^{-1}(S_n S_n^T)\omega_n^T$. Denote $T_n = \omega_n \omega_n^T$. Then T_n is a real symmetric matrix with the characteristic polynomial $\det(T_n - \lambda I) = |S_n|^2 \lambda^2 - \lambda^3 = \lambda^2 - \lambda^3$. By the argument following Eq. (31) in Sec. II, there is a unit vector S_{n+1} in $\mathbb{R}^3$ such that $T_n = S_{n+1} S_{n+1}^T$. Therefore $\mathrm{Im}(\Psi) \subset \mathcal{P}$.

Moser and Veselov now show the following. Let S_n and S_{n+1} be unit vectors in $\mathbb{R}^3$, and let $U_n(z)$ be defined by (35) with $\omega_n = S_{n+1} S_n^T$. Note that the set Σ of zeros of the polynomial $p(z) = \det(U_n(z))$ splits into $\Sigma = \Sigma_- \cup \Sigma_+$, where Σ_+, Σ_- satisfy the conditions $\overline{\Sigma_\pm} = \Sigma_\pm$ and $\Sigma_+ = -\Sigma_-$. If such a splitting is fixed and all zeros of $p(z)$ are distinct, then one can find $\omega_{n+1} = S_{n+2} S_{n+1}^T$ with $|S_{n+2}| = 1$ such that the image of U_n under Ψ is given by

$$U_{n+1}(z) = (zJ + \omega_{n+1}^T)(zJ - \omega_{n+1}). \tag{38}$$

A comparison of (37) and (38) shows that

$$J\omega_n^T - \omega_n J = \omega_{n+1}^T J - J\omega_{n+1}.$$

From here it follows at once that the vectors S_n, S_{n+1}, and S_{n+2} satisfy the difference Eq. (33). Now this procedure can be iterated starting with U_{n+1}, hence the isospectral mapping Ψ induces a discrete map $\omega_n \mapsto \omega_{n+1}$ which integrates the Neumann oscillator. This map is multivalued because it depends on a particular splitting of $\Sigma = \Sigma_- \cup \Sigma_+$.

In the next section we shall prove the existence of a discrete flow in G/G_+ which via conjugation induces the map Ψ. The multivaluedness of Ψ will correspond to the fact that the flow in G/G_+ is also multivalued because it is determined by symmetric solutions of a matrix Riccati equation. It is well known that these solutions depend on a particular factorization of the characteristic polynomial of the coefficient matrix of the equation.[16]

B. A loop group approach to the Moser–Veselov Algorithm

Here we give a group theoretic interpretation of the results described in the previous section. The motivation for this comes from the observation that the isospectral mapping $\Psi: U_n \mapsto U_{n+1}$ can be viewed as a discrete version of the Lax pair equation. Recall from Lemma 1 that the Neumann oscillator has the Lax representation

$$\frac{d}{dt}(Jz^2 + L(t)z - Q(t)) = [Jz + L(t), Jz^2 + L(t)z - Q(t)], \tag{39}$$

where $Q = (S_i S_j)$ and $L = (P_i S_j - S_i P_j)$, which is an isospectral deformation of the matrix $U(z) = Jz^2 + Lz - Q$. If we think of

$$U_n(z) = J^2 z^2 + L_n z - S_n S_n^T \tag{40}$$

as being $U(z)$ at time n (modulo the difference in the powers of J), then the mapping $\Psi: U_n \mapsto U_{n+1}$ can be viewed as a discrete analog of Eq. (39).

It was shown in Sec. II that this equation is induced by a special class of flows $g_-(t)G_+$ in G/G_+ whose initial values belong to the set of Neumann loops G_J^N. In analogy with this it is reasonable to expect that the mapping Ψ is induced by a class of discrete flows

$$\phi: g_-^{(n)} \mapsto g_-^{(n+1)} \tag{41}$$

with initial values $g_-^{(0)} \in G_{J^2}^N$. Here $G_{J^2}^N$ is the set of Neumann loops with J replaced by J^2. In other words, we would like to say that there is a mapping $g_-^{(n)} \mapsto U_n$ such that ϕ gives rise to the isospectral transformation $U_n \mapsto U_{n+1}$.

In what follows we show that such a correspondence exists and we develop an explicit algorithm for computing ϕ. Let $g_-^{(n)} \in G_{J^2}^N$, and define

$$M_2^{(n)}(z) = (g_-^{(n)}(z))^{-1} J^2 z^3 g_-^{(n)}(z). \tag{42}$$

Clearly, $M_2^{(n)}$ is an element of $\mathfrak{g}_+$, and by Lemma 2 we have

$$M_2^{(n)}(z) = J^2 z^3 + L_n z^2 - \left(S_n S_n^T - \tfrac{1}{3} I \right) z, \tag{43}$$

where $L_n^T = -L_n$ and $|S_n| = 1$. If $I + \Sigma_{i=1}^{\infty} A_i z^{-i}$ is the Fourier expansion of $g_-^{(n)}$, then following Eqs. (20) and (21) the coefficients of $M_2^{(n)}$ are given by

$$L_n = [J^2, A_1], \quad S_n S_n^T - \tfrac{1}{3} I = A_1 [J^2, A_1] - [J^2, A_2]. \tag{44}$$

Note that Eqs. (42) and (43) imply that

$$U_n(z) = (g_-^{(n)}(z))^{-1} \left(J^2 z^2 - \tfrac{1}{3} I \right) g_-^{(n)}(z). \tag{45}$$

This suggests that the flow $\phi: G_{J^2}^N \to G_{J^2}^N$ should be constructed so that it induces Ψ via the above conjugation. By writing $J^2 z^2 - \frac{1}{3} I = J^2 z^2 (I - \frac{1}{3} J^{-2} z^{-2})$ and using the Taylor's expansion for $(1-x)^{1/2}$ we obtain

$$J^2 z^2 - \frac{1}{3} I = \left[Jz \left(I - \sum_{k=1}^{\infty} \frac{(2k-3)!!}{3^k (2k)!!} J^{-2k} z^{-2k} \right) \right]^2. \tag{46}$$

The series can always be made convergent in $M(3, \mathcal{A}_{\mathbb{R}})$ because we can multiply J by a sufficiently large constant without effecting Eq. (33). Let C_k denote the coefficients in the above series. For $g_-^{(n)} \in G_{J^2}^N$ consider the following factorization:

$$Jz \left(I - \sum_{k=1}^{\infty} C_k J^{-2k} z^{-2k} \right) g_-^{(n)}(z) = h(z)(Jz - \Omega_n) \tag{47}$$

for some $h(z) = I + \Sigma_{k=1}^{\infty} B_k z^{-k}$ and Ω_n subject to conditions

$$B_1^T = B_1 \quad \text{and} \quad \Omega_n^T \Omega_n = S_n S_n^T.$$

Some algebraic manipulation shows that given B_1 the Fourier coefficients of h can be found recursively from

$$B_2 J = J A_2 + B_1 \Omega_n - C_1 J^{-1},$$

$$B_kJ=JA_k+B_{k-1}\Omega_n-\sum_{2i+j=k}C_iJ^{-2i+1}A_j-\frac{1}{2}(1+(-1)^k)C_{k/2}J^{-k+1},\quad k>2.$$

Furthermore, it follows from (47) that $\Omega_n=B_1J-JA_1$. Hence the factorization (47) can be carried out provided we can find B_1. In order to do this note that $\Omega_n^T\Omega_n=S_nS_n^T$ if and only if B_1 is a symmetric solution of the matrix Riccati equation

$$B_1^2+P^TB_1+B_1P+Q=0, \tag{48}$$

where $P=-JA_1J^{-1}$ and $Q=J^{-1}(A_1J^2A_1-S_nS_n^T)J^{-1}$. Equation (48) is indeed a Riccati equation for B_1 because Q is symmetric and (P,I) is controllable. It is well known that this equation has symmetric solutions provided the coefficient matrix

$$M=\begin{pmatrix} P & I \\ -Q & -P^T \end{pmatrix}$$

has no purely imaginary eigenvalues. In this case it can be shown[16] that $\det(tI-M)=(-1)^3p(t)p(-t)$, where the real polynomial $p(t)$ is monic and relatively prime to $p(-t)$. Then the Riccati equation has a unique symmetric solution B_1 such that $\det(tI-(P+B_1))=p(t)$, and a unique symmetric solution B_1' such that $\det(tI-(P+B_1'))=(-1)^3p(-t)$.

Suppose that B_1 has been found by solving Eq. (48) and calculate $\Omega_n=B_1J-JA_1$. Then we have $\Omega_n^T\Omega_n=S_nS_n^T$ and, since A_1 and B_1 are symmetric, it follows that $\Omega_n^TJ-J\Omega_n=[J^2,A_1]=L_n$. Thus the matrix polynomial (40) can be factored as

$$U_n(z)=(zJ+\Omega_n^T)(zJ-\Omega_n), \tag{49}$$

which is precisely the Moser–Veselov factorization. Moreover, a straightforward computation using (46), (47), and (49) shows that h is an element of G,

$$\begin{aligned}(h(z))^*h(z)&=(Jz+\Omega_n^T)^{-1}(g_-^{(n)}(z))^{-1}(J^2z^2-\tfrac{1}{3}I)g_-^{(n)}(z)(Jz-\Omega_n)^{-1}\\&=(Jz+\Omega_n^T)^{-1}U_n(z)(Jz-\Omega_n)^{-1}=I.\end{aligned}$$

Let $g_-^{(n+1)}=h$ and define

$$U_{n+1}(z)=(g_-^{(n+1)}(z))^{-1}(J^2z^2-\tfrac{1}{3})g_-^{(n+1)}(z).$$

As desired, one can show that U_{n+1} belongs to $\mathcal{P}$ and is given by switching the terms in Eq. (49). Indeed, the group law in G and (47) imply that

$$\begin{aligned}U_{n+1}(z)&=(Jz+\Omega_n^T)^{-1}(g_-^{(n)}(z))^{-1}(J^2z^2-\tfrac{1}{3})^2g_-^{(n)}(z)(Jz-\Omega_n)^{-1}\\&=(Jz+\Omega_n^T)^{-1}U_n^2(z)(Jz-\Omega_n)^{-1}=(Jz-\Omega_n)(Jz+\Omega_n^T).\end{aligned}$$

Recall from the previous section that $\Omega_n\Omega_n^T=S_{n+1}S_{n+1}^T$ for some unit vector S_{n+1}. Thus $U_{n+1}\in\mathcal{P}$, so in fact $g_-^{(n+1)}$ belongs to $G_{J^2}^N$. Now define $\phi:G_{J^2}^N\rightarrow G_{J^2}^N$ by $\phi(g_-^{(n)})=g_-^{(n+1)}$. Note that ϕ depends on the factorization of $\det(tI-M)$ which determines a particular solution of the Riccati equation for B_1. For a fixed branch of ϕ we can summarize the above results in the following theorem.

Theorem 6: *The flow $\phi:g_-^{(n)}\mapsto g_-^{(n+1)}$ induces the Moser–Veselov map $\Psi:U_n\mapsto U_{n+1}$ and gives the commutative diagram*

$$\begin{array}{ccc} \mathcal{P} & \stackrel{\Psi}{\rightarrow} & \mathcal{P} \\ C\uparrow & & \uparrow C \\ G^N_{J^2} & \stackrel{\phi}{\rightarrow} & G^N_{J^2} \end{array}$$

where $C(g)=g^{-1}(J^2z^2-\frac{1}{3})g$.

In complete analogy with the continuous model, the discretized Neumann oscillator is integrable in the sense that there are constants of the motion independent of n. As in the continuous case this is a consequence of the fact that the diagonal elements of $S_nS_n^T-K_n$ are preserved under the flow. A proof identical to that of Corollary 5 with the exception that J is replaced by J^2 shows that the diagonal elements of $S_nS_n^T-K_n$ are given by

$$\tilde{F}_i=(S_n^i)^2+\sum_{\substack{k=1\\k\neq i}}^{3}\frac{(J_iS_{n+1}^iS_n^k-J_kS_{n+1}^kS_n^i)^2}{J_i^2-J_k^2},\quad i=1,2,3.$$

It turns out that these are the integrals found by Granovskii and Zhedanov,[8] and later generalized by Veselov[17] to the n-dimensional case. The algebraic structure of $\tilde{F}_i$ clearly resembles that of F_i, the integrals of the continuous Neumann problem. Hence $\tilde{F}_i$ is a natural discrete analog of F_i.

ACKNOWLEDGMENT

The author wishes to thank his adviser Professor M. Adams for invaluable help during the preparation of this work.

(Received 1 March 1999; accepted for publication 5 April 1999)

The existence of superintegrable systems with $n=2$ degrees of freedom possessing three independent globally defined constants of motion which are quadratic in the velocities is studied on the two-dimensional sphere S^2 and on the hyperbolic plane H^2. The approach used is based on enforcing the conditions for the existence of two independent integrals (further than the energy). This is done in a way which allows us to discuss at once the cases of the sphere S^2 and the hyperbolical plane H^2, by considering the curvature κ as a parameter. Different superintegrable potentials are obtained as the solutions of certain systems of two κ-dependent second order partial differential equations. The Euclidean results are directly recovered for $\kappa=0$, and the superintegrable potentials on either the standard unit sphere (radius $R=1$) or the unit Lobachewski plane (''radius'' $R=1$) appear as the particular values of the κ-dependent superintegrable potentials for the values $\kappa=1$ and $\kappa=-1$. Some new superintegrable potentials are found, both on S^2 and H^2. The correspondence between superintegrable systems in spaces of zero and nonzero curvature is discussed.
[S0022-2488(99)02110-6]

I. INTRODUCTION

A superintegrable system is a system that is integrable (in the sense of Liouville–Arnold) and that, in addition to this, possesses more constants of motion than degrees of freedom. If the number N of independent constants takes the value $N=2n-1$ (n the number of degrees of freedom) then the system is called maximally superintegrable (see Refs. 1–23). There are three well known examples of this very particular class of systems, namely, the Kepler problem, the isotropic harmonic oscillator, and the nonisotropic oscillator with commensurable frequencies. The $n=3$ Kepler possesses not only the energy and the angular momentum as constants of motion, but also the Runge–Lenz vector; five of these integrals are functionally independent. This property is also true for n arbitrary. Concerning the harmonic oscillator, it is a system trivially integrable since it can be considered as a kind of ''direct sum'' of systems with one degree of freedom. If the oscillator is isotropic then it has the angular momentum (and/or the Fradkin tensor[24]) as an additional integral of motion. If the oscillator is nonisotropic the angular momentum is not preserved as the potential is not central; nevertheless when the quotients of the frequencies are rational the system has other additional integrals. In these three cases it is well known that all the orbits became closed for the case of bounded motions. This high degree of regularity (existence of periodic motions) is a consequence of the superintegrable character.

Most of known integrable systems are Hamilton–Jacobi separable, that is, systems with an associate Hamilton–Jacobi equation that can be solved by separation of variables after an appropriate coordinate system has been found. An important point is that separable systems have constants of motion which are linear or quadratic in the velocities. Fris *et al.*[2] studied in 1965 the two-dimensional Hamiltonians with standard Euclidean kinetic term for which the Hamilton–Jacobi equations separates in more than one coordinate system in E^2 and obtained four different families, each with a potential which is a ''linear superposition'' of three simpler potentials (they were mainly interested in the quantum viewpoint but the results obtained are also valid at the classical level). This Hamilton–Jacobi approach was also used in Ref. 3 and, later on, by other authors as Evans,[9] Grosche *et al.*[14–16] and Kalnins *et al.*[17,18] Other approaches recently studied have been the dimensional reduction of simpler systems,[12,13] or the direct obtaining of the conditions for the existence of two quadratic independent integrals[20] (further than the energy).

The dynamics for the cases where the configuration space Q is either the sphere S^2 or the hyperbolic (Lobachewski) plane H^2 is not so well known as it is in the Euclidean case E^2, and most of the studies done on the sphere have focused the attention on spherical central potentials.[25–27] There are some noncentral but rather simple problems as, e.g., the nonisotropic oscillator, that still remain as very partially understood in manifolds of nonzero curvature. In this article we will study superintegrable Lagrangian systems with quadratic constants of motion for the case in which the configuration space Q is either the two-dimensional sphere S^2 or the hyperbolic plane H^2. We will use as an approach the same strategy that proved to be successful in Ref. 20 for two different planar manifolds, $Q=\mathbb{R}^2$ with a Euclidean metric, this is E^2, and $Q=\mathbb{R}^2$ with a Minkowskian metric.

The article is organized as follows: In Sec. II we present some geometric properties of Riemannian 2D manifolds of constant curvature, taking as leading idea the introduction of a formalism with the curvature κ as a parameter. This is made so that the Euclidean results are directly recovered for $\kappa=0$ (in a natural way without the problems of a limit process) and the standard sphere of radius $R=1$ or the Lobachewski plane of ''radius'' $R=1$ will correspond to the particular values $\kappa=1$ or $\kappa=-1$. Indeed, if κ is looked as a parameter, the approach can be done simultaneously for the three cases; most computations might even be done simultaneously, at the small price of using κ dependent trigonometric functions. In Sec. III, we recall the properties of the case $Q=E^2$ from the present viewpoint.

In Sec. IV we look for superintegrable systems on both $Q=S^2$ and H^2 (with curvature κ) and we find several families which have the superintegrable Euclidean potentials (analyzed in Sec. III) as flat limits. In the first subsection the study is done in polar coordinates, and in the second subsection in parallel coordinates. Some of the superintegrable potentials we obtain are already known,[14–16] but other are, as far as we know, new. We find several noncentral superintegrable spherical potentials, and in particular the spherical and hyperbolical superintegrable versions of the anisotropic 2:1 oscillator and several new superintegrable potentials in the hyperbolic plane. Finally, Sec. V provides a discussion and an outlook to the results obtained; it can be read independently and gives information enough for a reader who is not interested in the details of the derivation.

II. GEOMETRY AND DYNAMICS ON THE SPHERE S^2 AND THE HYPERBOLIC PLANE H^2

On any general two-dimensional Riemannian space (not necessarily of constant curvature) there are two distinguished types of local coordinate systems, ''geodesic parallel'' and ''geodesic polar'' coordinates. They reduce to the familiar cartesian and polar coordinates on the Euclidean plane (see, e.g., Klinberger[28]).

Both these systems are based on an origin point O and an oriented geodesic l_1 through O (Fig. 1). For any point P in some suitable neighborhood of O, there is a unique geodesic l joining O and P. The (geodesic) polar coordinates (r,ϕ) of P, relative to the origin O and the positive geodesic ray of l_1, are the (positive) distance r between O and P measured along l, and the angle ϕ between l and the positive ray l_1, measured around O. These coordinates are defined in a neighborhood of O not extending beyond the cut locus of O; polar coordinates are singular at O, and ϕ is discontinuous on the positive ray of l_1.

Now, for any point P (in some suitable strip neighborhood of l_1) consider the geodesic l_2' through P and orthogonal to l_1 and let P_1 be the intersection point of l_2' and l_1 nearest to P. The

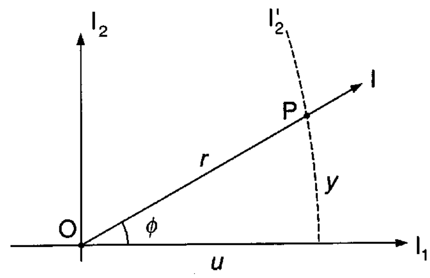

FIG. 1. Polar (r,ϕ) and parallel (u,y) coordinates based on the oriented geodesic l_1 and reference point O. All these coordinates are lengths or angles measured in the intrinsic metric of the space of constant curvature. The figure follows the pattern of a stereographic projection of the sphere from the South pole, with O at the North pole, but the geometrical meaning of these coordinates holds for any value of the curvature.

(geodesic) parallel coordinates (u,y) of P, relative to the origin O and base geodesic l_1, are defined as the distance u between O and P_1, measured along l_1, and the distance y, between P_1 and P, measured along l_2'. Again these coordinates will be regular and without singularities in some strip centered in l_1. If instead of l_1 another line is taken as base, we obtain another system of geodesic parallel coordinates. Figure 2 also displays the particular case with base l_2, orthogonal to l_1 through O; these second set of parallel coordinates will be denoted (v,x) and will also play some role in our discussion.

These systems are suitable for most general purposes, because the coordinates (r,ϕ), (u,y), and (v,x) have a *direct* geometric significance, as distances and angles measured in the intrinsic metric of the surface. Closed expressions are usually only possible for spaces of *constant curvature*. In the constant *positive* curvature case, i.e., the sphere, the geodesics are great circles, and relations among distances and angles are the subject of spherical geometry. Polar coordinates on the sphere are singular at the origin (pole) O and also at its antipodal point (the cut locus of O). Parallel coordinates are singular in the two poles of the base geodesic. While in the Euclidean plane a line orthogonal to both l_1 and l_2 do not exist (nor does it exist in the hyperbolic plane), there is such a line l_3 for the sphere (the polar of the point O), so we have here a third set of parallel coordinates. These three sets are based on three geodesics mutually orthogonal by pairs and the third system with base l_3 is essentially equivalent to the polar coordinates whose center is the pole of l_3.

The notation has been chosen to emphasize the similarities with the Euclidean case. For a point P, r is the distance measured in either S^2 or H^2 (with curvature κ) from P to the origin point O, and ϕ determines the orientation of the line OP through O. On the other side, x, y are the geodesic distances from P to the two ''coordinate axes'' l_1,l_2; there are other two quantities, u, v which are distances, measured along l_1,l_2, between O and the orthogonal projections of P on l_1,l_2. In the Euclidean case, we have the identities $x=u$, $y=v$, but once we deal with nonzero

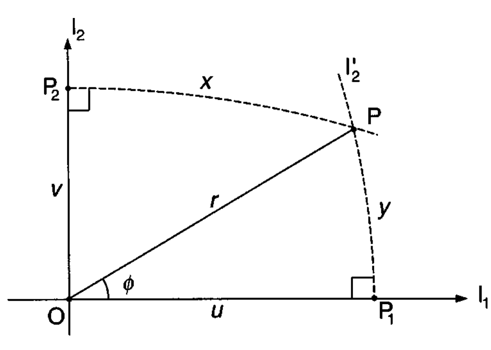

FIG. 2. The three coordinate systems (r,ϕ), (u,y), and (v,x) of a point P. Relationships among these coordinates are discussed in the text for any curvature value κ.

curvature these equalities are no longer true; recall that y is the distance from P to the ''x'' coordinate axe, but u *is not* the distance from P to the ''y'' coordinate axe. Both polar (r,ϕ) and the two systems of parallel coordinates (u,y) and (v,x) are always *orthogonal*; however the coordinate system (x,y) made up of the distances to the two coordinate axes is only orthogonal in the Euclidean plane, but *not* in S^2 nor in H^2.

For a sphere of radius R (curvature $\kappa = 1/R^2$), the ''geographic'' coordinates (θ,ϕ) (where θ is the latitude and ϕ the longitude) are closely related to both polar and parallel type coordinate systems; $(R(\pi/2-\theta),\phi)$ are *polar* coordinates with its origin in the North pole, while $(R\phi,R\theta)$ are *parallel* coordinates with the equator as the baseline. This equivalence does not exist in the Euclidean and hyperbolic case, where polar and parallel coordinates are different, so there are reasons to keep their consideration separate, even for the sphere, in the context we are working. The structure of the superintegrable systems on planes of constant curvature and in their limiting Euclidean case will be more clearly seen this way.

The metric of the sphere of curvature $\kappa = 1/R^2$ is given in parallel and polar coordinates by

$$ds^2 = \cos^2(y/R)\,du^2 + dy^2, \quad ds^2 = dr^2 + R^2 \sin^2(r/R)\,d\phi^2$$

reducing to $du^2 + dy^2$ and $dr^2 + r^2 d\phi^2$ when $\kappa \to 0$ (or, equivalently $R \to \infty$). It is possible to write these expressions in a form which holds simultaneously for the sphere, the Euclidean plane and the hyperbolic plane, by introducing the ''tagged'' trigonometric functions $\mathrm{C}_\kappa(x)$, $\mathrm{S}_\kappa(x)$, and $\mathrm{T}_\kappa(x)$ defined by

$$\mathrm{C}_\kappa(x) = \begin{cases} \cos\sqrt{\kappa}x & \text{if } \kappa > 0, \\ 1 & \text{if } \kappa = 0, \\ \cosh\sqrt{-\kappa}x & if \ \kappa < 0, \end{cases} \qquad \mathrm{S}_\kappa(x) = \begin{cases} \dfrac{1}{\sqrt{\kappa}} \sin\sqrt{\kappa}x & \text{if } \kappa > 0, \\ x & \text{if } \kappa = 0, \\ \dfrac{1}{\sqrt{-\kappa}} \sinh\sqrt{-\kappa}x & \text{if } \kappa < 0, \end{cases}$$

and

$$\mathrm{T}_\kappa(x) = \frac{\mathrm{S}_\kappa(x)}{\mathrm{C}_\kappa(x)}.$$

When the constant κ is nonzero, it can be reduced to either 1 or -1 by length rescaling (this is tantamount to choose units of length so that $R=1$). When $\kappa=1$ the three ''tagged'' functions are the ordinary trigonometrical functions sine, cosine and tangent, i.e., $\mathrm{S}_1(x) = \sin x$, $\mathrm{C}_1(x) = \cos x$, $\mathrm{T}_1(x) = \tan x$. For $\kappa = 0$ one gets the ''parabolic'' sine $\mathrm{S}_0(x) = x$, cosine $\mathrm{C}_0(x) = 1$, and tangent $\mathrm{T}_0(x) = x$. For $\kappa = -1$, these functions are the hyperbolic cosine, sine, and tangent. Therefore, in the flat case $\kappa = 0$ all $\mathrm{C}_\kappa(x)$ are replaced by 1, while all $\mathrm{S}_\kappa(x)$, $\mathrm{T}_\kappa(x)$ are replaced by its variable x; this suggests that in the curved case, $\mathrm{C}_\kappa(x)$ should be looked at as a kind of ''curved'' deformation of the function 1, while both $\mathrm{S}_\kappa(x)$ and $\mathrm{T}_\kappa(x)$ are two kinds of deformations of the linear function x.

The consistent use of the ''tagged'' functions allow to describe simultaneously the geometry of spaces with a positive-definite metric of constant curvature κ. For instance, the metric of either the sphere, the Euclidean plane or the hyperbolic plane (according as $\kappa > 0, = 0, < 0$) is written in parallel and polar coordinates as

$$ds^2 = \mathrm{C}_\kappa^2(y)\,du^2 + dy^2, \quad ds^2 = dr^2 + \mathrm{S}_\kappa^2(r)\,d\phi^2,$$

and the nonzero Christoffel symbols are, in either coordinate systems,

$$\Gamma^y_{uu} = \kappa \mathrm{S}_\kappa(y)\mathrm{C}_\kappa(y), \quad \Gamma^u_{uy} = -\kappa \mathrm{T}_\kappa(y),$$

$$\Gamma^r_{\phi\phi} = -\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r), \quad \Gamma^\phi_{r\phi} = 1/\mathrm{T}_\kappa(r).$$

The relations between the different coordinates (u,y), (v,x), (r,ϕ), of a point P are obtained from trigonometry. In fact, the points O, P, and P_1 or P_2 determine (see Fig. 2) two rectangular triangles P_1PO (resp. P_2PO). We state these relations in a way that holds regardless of the value of κ; in the cases $\kappa>0$ or $\kappa<0$ they reduce to standard formulas of spherical or hyperbolic trigonometry, while for $\kappa=0$ they are well-known Euclidean relations.

In any rectangular triangle, as P_1PO in the figure, the three sides r,u,y and the angle ϕ at O are related by the following equations:

$$\mathrm{S}_\kappa(y) = \mathrm{S}_\kappa(r)\sin\phi, \quad \mathrm{C}_\kappa(r) = \mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y),$$

$$\mathrm{T}_\kappa(u) = \mathrm{T}_\kappa(r)\cos\phi, \quad \mathrm{T}_\kappa(y) = \mathrm{S}_\kappa(u)\tan\phi.$$

When these equations are applied to the two rectangular triangles P_1PO (sides r,u,y, angle ϕ at O) and P_2PO (sides r,v,x, angle $\pi/2-\phi$ at O), we get many relations with a rather symmetrical appearance in the pairs x,y, and u,v. In particular,

$$\mathrm{S}^2_\kappa(r) = \mathrm{S}^2_\kappa(x) + \mathrm{S}^2_\kappa(y), \quad \mathrm{C}^2_\kappa(r) = \mathrm{C}_\kappa(x)\mathrm{C}_\kappa(y)\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(v), \quad \mathrm{T}^2_\kappa(r) = \mathrm{T}^2_\kappa(u) + \mathrm{T}^2_\kappa(v),$$

$$\mathrm{S}_\kappa(x) = \mathrm{C}_\kappa(y)\mathrm{S}_\kappa(u) = \mathrm{C}_\kappa(r)\mathrm{T}_\kappa(u), \quad \mathrm{C}_\kappa(x) = \frac{\mathrm{C}_\kappa(r)}{\mathrm{C}_\kappa(v)}, \quad \mathrm{T}_\kappa(x) = \mathrm{C}_\kappa(v)\mathrm{T}_\kappa(u),$$

$$\mathrm{S}_\kappa(y) = \mathrm{C}_\kappa(x)\mathrm{S}_\kappa(v) = \mathrm{C}_\kappa(r)\mathrm{T}_\kappa(v), \quad \mathrm{C}_\kappa(y) = \frac{\mathrm{C}_\kappa(r)}{\mathrm{C}_\kappa(u)}, \quad \mathrm{T}_\kappa(y) = \mathrm{C}_\kappa(u)\mathrm{T}_\kappa(v),$$

$$\sin\phi = \frac{\mathrm{T}_\kappa(v)}{\mathrm{T}_\kappa(r)} = \frac{\mathrm{S}_\kappa(y)}{\mathrm{S}_\kappa(r)}, \quad \cos\phi = \frac{\mathrm{T}_\kappa(u)}{\mathrm{T}_\kappa(r)} = \frac{\mathrm{S}_\kappa(x)}{\mathrm{S}_\kappa(r)}, \quad \tan\phi = \frac{\mathrm{T}_\kappa(v)}{\mathrm{T}_\kappa(u)} = \frac{\mathrm{T}_\kappa(y)}{\mathrm{S}_\kappa(u)} = \frac{\mathrm{S}_\kappa(v)}{\mathrm{T}_\kappa(x)},$$

as well as

$$\mathrm{T}_\kappa(x)\mathrm{T}_\kappa(y) = \mathrm{S}_\kappa(u)\mathrm{S}_\kappa(v), \quad \mathrm{S}_\kappa(x)\mathrm{S}_\kappa(y) = \mathrm{C}^2_\kappa(r)\mathrm{T}_\kappa(u)\mathrm{T}_\kappa(v).$$

The change from *polar* to *parallel* coordinates in any constant curvature plane can be read from these equations, and allow several equivalent expressions. Perhaps the way closer to the Euclidean one is

$$\mathrm{T}_\kappa(u) = \mathrm{T}_\kappa(r)\cos\phi, \quad \mathrm{S}^2_\kappa(r) = \mathrm{C}^2_\kappa(y)\mathrm{S}^2_\kappa(u) + \mathrm{S}^2_\kappa(y),$$

$$\mathrm{S}_\kappa(y) = \mathrm{S}_\kappa(r)\sin\phi, \quad \tan\phi = \frac{\mathrm{T}_\kappa(y)}{\mathrm{S}_\kappa(u)}.$$

Another form for the formulas in the first line is

$$\mathrm{S}_\kappa(u) = \frac{\mathrm{S}_\kappa(r)\cos\phi}{\mathrm{C}_\kappa(y)} = \frac{\mathrm{S}_\kappa(r)\cos\phi}{\sqrt{1-\kappa\mathrm{S}^2_\kappa(r)\sin^2\phi}},$$

$$\mathrm{T}^2_\kappa(r) = \mathrm{T}^2_\kappa(u) + \mathrm{T}^2_\kappa(v) = \mathrm{T}^2_\kappa(y) + \frac{\mathrm{T}^2_\kappa(u)}{\mathrm{C}^2_\kappa(y)}.$$

Indeed $\mathrm{T}_\kappa^2(r)$ allows several alternative expressions in terms of y,u,x,v which can be considered as constant curvature versions of Pythagorean theorem,

$$\mathrm{T}_\kappa^2(r)=\mathrm{T}_\kappa^2(u)+\frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(u)}=\frac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)}+\mathrm{T}_\kappa^2(y)=\mathrm{T}_\kappa^2(v)+\frac{\mathrm{T}_\kappa^2(x)}{\mathrm{C}_\kappa^2(v)}=\frac{\mathrm{T}_\kappa^2(v)}{\mathrm{C}_\kappa^2(x)}+\mathrm{T}_\kappa^2(x).$$

The Euclidean case corresponds to $\kappa=0$; there some of the equations imply $u=x$ and $v=y$, and the nontrivial remaining equations reduce to the Euclidean ones.

III. SUPERINTEGRABLE SYSTEMS ON THE EUCLIDEAN PLANE WITH QUADRATIC CONSTANTS OF MOTION

In this section we give a short résumé of the approach developed in Ref. 20, where superintegrable systems with standard kinetic term on the Euclidean plane and integrals of motion (further than the energy) quadratic in the velocities are determined. This can be considered as the $\kappa=0$ particular case, for the later study in S^2 or H^2 where $\kappa\neq 0$; we shall emphasize those aspects which will turn out relevant for the case of nonzero curvature.

The systems we are studying are described by a Lagrangian of mechanical class living in the Euclidean plane. Let us first use Cartesian coordinates (x,y). The parallel coordinate system (u,y) reduces to the Cartesian one (x,y) in the Euclidean plane because $u=x$, so there is no reason here to depart from the conventional notation. The Lagrangian is

$$L=\tfrac{1}{2}(v_x^2+v_y^2)-V(x,y).$$

Assume there exists a constant of motion $I=I_{22}+I_{20}$, where I_{22} is the quadratic term in the velocities v_x, v_y, and I_{20} is a velocity-independent term. Write $I_{22}=av_x^2+2bv_xv_y+cv_y^2$, with a, b, c, depending on x,y. Then the functions a, b, c, and the term I_{20} cannot be arbitrary, but must satisfy the equations

$$a_x=0,\quad a_y+2b_x=0,\quad c_x+2b_y=0,\quad c_y=0,$$

$$I_{20x}=2aV_x+2bV_y,\quad I_{20y}=2bV_x+2cV_y.$$

The compatibility condition for the last two equations leads to

$$b(V_{yy}-V_{xx})+(a-c)V_{xy}+(a_y-b_x)V_x+(b_y-c_x)V_y=0,$$

so a potential $V(x,y)$ having *any* constant of motion quadratic in the velocities must satisfy this very particular differential equation. The equation is V-independent, so the solution for V is determined up to an additive constant k_0; this is expected for a potential.

The first set of four equations, which are independent of the potential $V(x,y)$, determine the possible forms for a, b, c. By integration we obtain

$$a(x,y)=a_0+a_1y+a_2y^2,$$

$$b(x,y)=(\tfrac{1}{2})(b_0-a_1x-c_1y-2a_2xy),$$

$$c(x,y)=c_0+c_1x+a_2x^2,$$

where $\{a_0,b_0,c_0;a_1,c_1;a_2\}$ are real parameters; the subindex making reference to the order in x or y of each term. Every choice of these parameters determine a partial differential equation and, hence, a family of potentials $V=V[f(x,y),g(x,y)]$ depending on two functions, and such that all these potentials have a constant of motion I_2 quadratic in the velocities. For the values $\{a_0=e_0,0,\ c_0=e_0;0,0;0\}$ the equation reduces to an identity, so it is satisfied for an arbitrary potential V, and the integral I_2 reduces to the energy $I=(1/2)(v_x^2+v_y^2)+V(x,y)$. Any other ''nontrivial'' choice of $\{a_0,b_0,c_0;a_1,c_1;a_2\}$ will correspond to constants of motion further than the energy. The fundamental equation for V can be written in the alternative way,

$$b(V_{yy}-V_{xx})+(a-c)V_{xy}-3b_xV_x+3b_yV_y=0.$$

For a fixed set of parameters $\{a_0,b_0,c_0;a_1,c_1;a_2\}$ this is a linear equation for V; conversely, for fixed V, it is a *linear* equation for these six parameters, whose solutions will determine a linear subspace in the ''parameter space'' $\mathbb{R}^6$ with coordinates $\{a_0,b_0,c_0;a_1,c_1;a_2\}$. The dimension m of this submanifold will depend on the potential, and it is at least equal to 1 (generated by the vector {101;00;0}) for *any* potential. A dimension $m=2$ will mean the existence, further than the energy, of one (and only one) additional integral of motion quadratic in the velocities. For the characterization of such potentials see Perelomov;[29] they belong to one of the four types,

$$V=\frac{1}{r_1r_2}(A(r_1+r_2)+B(r_1-r_2)),$$

$$V=A(r)+\frac{1}{r^2}B(\phi),$$

$$V=\frac{1}{r}(A(r+x)+B(r-x)),$$

$$V=A(x)+B(y),$$

where r_1, r_2, are the two distances to two fixed points in the plane, and r,ϕ; x,y, are a suitable choice of polar and Cartesian coordinates. The first case is the generic one, the others being limiting cases where the two points either coincide, one go to infinity or two go to infinity. Which of the four cases applies is determined by the values of the parameters $\{a_0,b_0,c_0;a_1,c_1;a_2\}$; except for the trivial case {101;00;0}, any other parameter vector can be considered as determining the position of *two* points in the (completed) Euclidean plane and in either case the potential depends on *two* arbitrary functions of a *single* variable.

The next case will be $m=3$; here the potential $V(x,y)$ should be solution of a system of *two* partial differential equations, determined by *two* different sets of parameters (further than {101;00;0}), which will be denoted by lower case letters $(a_0,b_0,c_0;a_1,c_1;a_2)$ and the corresponding upper case ones $(A_0,B_0,C_0;A_1,C_1;A_2)$. We shall consider here *seven* cases (labeled V^a, $\tilde{V}^a$, V^b, V^c, $\tilde{V}^c$, V^d, and V^e). Within each case, the potential which solves the system appear as a ''linear combination'' of three particular solutions and a constant term

$$V^r=k_0+k_1V_1^r+k_2V_2^r+k_3V_3^r,\quad V^r=V^a,\tilde{V}^a,V^b,V^c,\tilde{V}^c,V^d,V^e.$$

Table I contains the seven sets of ''basic'' potentials V_1^r, V_2^r, V_3^r, and for each set, the three vectors generating the associated three-dimensional parameter subspace in the space $(a_0,b_0,c_0;a_1,c_1;a_2)$.

Several comments are in order.

(1) The pairs of families denoted *with* and *without* a tilde are clearly equivalent, the transformation relating them being simply the interchange $(x,y)\leftrightarrow(y,x)$ which geometrically is the reflection in the line $x=y$. The three families V^b, V^d, V^e, are invariant under this transformation.

(2) Each family V^r includes one of the three ''fundamental'' superintegrable potentials with quadratic constants of motion (nonisotropic 2:1 oscillator, isotropic oscillator, and Kepler problem). The general potential in each family may be considered as a kind of ''superintegrable deformation'' of these ''basic'' potentials (the values k_2, k_3 representing the ''intensity'' of the deformation). This has been known for some time, and the existence of ''super-

TABLE I. The Euclidean maximally superintegrable potentials.

$\begin{pmatrix}1,0,0;0,0;0\\0,1,0;0,0;0\\0,0,1;0,0;0\end{pmatrix}$	$(a_0,b_0,c_0)\equiv$ (a_0,b_0) or (b_0,c_0)	V^e	x^2+y^2,	x,	y

integrable deformations'' which do not destroy a fragile property like the superintegrability of the Kepler and oscillator potentials, is remarkable in itself. From a purely mathematical point of view, every V_i^r is an element of a basis in a vector space; hence the choice of certain particular potentials as fundamental ones is due to properties related with dynamics.

(3) For any fixed nonconstant potential V, the maximal dimension for the associated parameter subspace appears to be $m=4$ (the trivial constant potential $V_0=1$ has $m=6$). Only four potentials reach the maximal dimension. Next we give these potentials together with the general form of the associated vectors

$$V=x^2+y^2 \quad (a_0,b_0,c_0;0,0;a_2),$$
$$V=y \quad (a_0,b_0,c_0;a_1,0;0),$$
$$V=1/y^2 \quad (a_0,0,c_0;0,c_1;a_2),$$
$$V=1/\sqrt{x^2+y^2} \quad (e_0,0,e_0;a_1,c_1;a_2).$$

(4) The Kepler potential admits two possibilities of deformation preserving superintegrability since it belongs to two different families, V^c and V^d. The same is also true for the isotropic oscillator that belongs to both V^b and V^e (however in the case of V^e the ''deformed'' oscillator is again another oscillator, unlike in V^b). The anisotropic 2:1 oscillator admits only one family of superintegrable deformations. The reason for this lies in the different value for the dimension of the associated subspaces, which is $m=4$ for Kepler and oscillator, but $m=3$ for the 2:1 anisotropic oscillator.

(5) The potential $1/y^2$ (or $1/x^2$) appear also in three different families. This potential is important because it is superintegrable by itself and also because it turns out to be ''linearly compatible'' with all the three well known superintegrable potentials.

(6) The family V^e was not considered in Refs. 2, 14, or 20 (neither in Ref. 9 that studies the $n=3$ systems). It can be considered as rather trivial since the general potential in V^e is just an isotropic oscillator with center at an arbitrary point (with another choice of origin this has

been already considered in V^b). Nevertheless we have decided to include it because its extension to the nonzero curvature case will prove to be interesting (''curvature versions'' of simple potentials in E^2 can become rather complicate functions in S^2 or H^2).

Under a general change of coordinates, the potential V will behave as a scalar field, and the functions a, b, c, are the three components of a covariant symmetric tensor. As a previous step for the study in S^2 or H^2 we will obtain the explicit expressions in planar polar coordinates. The Lagrangian is given by

$$L=\tfrac{1}{2}(v_r^2+r^2v_\phi^2)-V(r,\phi)$$

and the constant of motion I can be written as, $I=I_{22}+I_{20}(r,\phi)$, $I_{22}=av_r^2+2bv_rv_\phi+cv_\phi^2$, where now a, b, c, are functions of r, ϕ (notice that these new three functions a, b, c, are not simply equal to the former ones expressed in terms of (r,ϕ), because of the tensorial character). These four functions a, b, c, and I_{20}, must satisfy the following equations:

$$a_r=0, \quad 2b_r-(4/r)b+a_\phi=0,$$

$$c_r-(4/r)c+2ra+2b_\phi=0, \quad c_\phi+2rb=0,$$

$$I_{20r}=2aV_r+2(b/r^2)V_\phi, \quad I_{20\phi}=2bV_r+2(c/r^2)V_\phi.$$

The first set of equations can be solved for a, b, c, and leads to

$$a(r,\phi)=(\tfrac{1}{2})[(a_0+c_0)+(a_0-c_0)\cos 2\phi+b_0\sin 2\phi],$$

$$b(r,\phi)=(\tfrac{1}{2})r[(c_0-a_0)\sin 2\phi+b_0\cos 2\phi]+(\tfrac{1}{2})r^2(-a_1\cos\phi+c_1\sin\phi),$$

$$c(r,\phi)=(\tfrac{1}{2})r^2[(a_0+c_0)+(c_0-a_0)\cos 2\phi-b_0\sin 2\phi]+r^3(c_1\cos\phi+a_1\sin\phi)+a_2r^4.$$

In Cartesian coordinates, $a(x,y)$, $b(x,y)$, and $c(x,y)$ were nonhomogeneous quadratic polynomials in x, y (with some special relations for the coefficients); in polar coordinates $a(r,\phi)$, $b(r,\phi)$, $c(r,\phi)$, have Fourier series for the ϕ dependence up to the terms in $\cos(2\phi)$, $\sin(2\phi)$ (also with special relations for the coefficients and the radial dependence).

Making use of these expressions we get the most general form of the function I_{22} as

$$I_{22}=a_0I_{22}(a_0)+b_0I_{22}(b_0)+c_0I_{22}(c_0)+a_1I_{22}(a_1)+c_1I_{22}(c_1)+a_2I_{22}(a_2),$$

where

$$I_{22}(a_0)=(v_r\cos\phi-rv_\phi\sin\phi)^2,$$

$$I_{22}(b_0)=(v_r\cos\phi-rv_\phi\sin\phi)(v_r\sin\phi+rv_\phi\cos\phi),$$

$$I_{22}(c_0)=(v_r\sin\phi+rv_\phi\cos\phi)^2,$$

$$I_{22}(a_1)=(v_r\cos\phi-rv_\phi\sin\phi)(r^2v_\phi),$$

$$I_{22}(c_1)=(v_r\sin\phi+rv_\phi\cos\phi)(r^2v_\phi),$$

$$I_{22}(b_2)=(r^2v_\phi)^2$$

(notice that in the above expressions the coefficients in brackets are just labels and not variables). The function I_{20} exists if and only if V satisfies the following equation:

TABLE II. Polar expressions of the basic Euclidean superintegrable potentials.

$(a_0,c_0,c_1)\equiv$ (a_0,c_1) or (c_0,c_1)	V^a	$r^2(1+3\cos^2\phi)$	$r\cos\phi$	$\frac{1}{r^2\sin^2\phi}$
$(a_0,c_0,a_1)\equiv$ (a_0,a_1) or (c_0,a_1)	$\tilde{V}^a$	$r^2(1+3\sin^2\phi)$	$r\sin\phi$	$\frac{1}{r^2\cos^2\phi}$
$(a_0,c_0,a_2)\equiv$ (a_0,a_2) or (c_0,a_2)	V^b	r^2	$\frac{1}{r^2\cos^2\phi}$	$\frac{1}{r^2\sin^2\phi}$
(c_1,a_2)	V^c	$\frac{1}{r}$	$\frac{\cos\phi}{r^2\sin^2\phi}$	$\frac{1}{r^2\sin^2\phi}$
(a_1,a_2)	$\tilde{V}^c$	$\frac{1}{r}$	$\frac{\sin\phi}{r^2\cos^2\phi}$	$\frac{1}{r^2\cos^2\phi}$
(a_1,c_1)	V^d	$\frac{1}{r}$	$\frac{\sqrt{1+\cos\phi}}{r^{1/2}}$	$\frac{\sqrt{1-\cos\phi}}{r^{1/2}}$
$(a_0,b_0,c_0)\equiv$ (a_0,b_0) or (b_0,c_0)	V^e	r^2	$r\cos\phi$	$r\sin\phi$

$$b(V_{\phi\phi}-r^2V_{rr})+(c-r^2a)V_{r\phi}+\left(\frac{r^2}{2}\right)\left[\left(\frac{4}{r}\right)b-3a_\phi\right]V_r+\left[\left(\frac{2}{r}\right)(c-r^2a)-3b_\phi\right]V_\phi=0.$$

Consequently, superintegrability arises for potentials satisfying *two* (nontrivial) equations of such a particular form. The following proposition states this property.

Proposition 1: Let the function V be the solution of the following system of two partial differential equations:

$$b(V_{\phi\phi}-r^2V_{rr})+(c-r^2a)V_{r\phi}+\left(\frac{r^2}{2}\right)\left[\left(\frac{4}{r}\right)b-3a_\phi\right]V_r+\left[\left(\frac{2}{r}\right)(c-r^2a)-3b_\phi\right]V_\phi=0,$$

$$B(V_{\phi\phi}-r^2V_{rr})+(C-r^2A)V_{r\phi}+\left(\frac{r^2}{2}\right)\left[\left(\frac{4}{r}\right)B-3A_\phi\right]V_r+\left[\left(\frac{2}{r}\right)(C-r^2A)-3B_\phi\right]V_\phi=0,$$

where $(a(r,\phi),b(r,\phi),c(r,\phi))$, *and* $(A(r,\phi),B(r,\phi),C(r,\phi))$, *are two sets of three functions determined by two sets of nontrivial real constants* (a_i,b_i,c_i), *and* (A_i,B_i,C_i), *respectively. Suppose that these two sets of constants are such that the two above second-order equations are independent. Then, if T denotes the Euclidean kinetic function* $T=(1/2)(v_r^2+r^2v_\phi^2)$, *the Lagrangian* $L=T-V(r,\phi)$ *is superintegrable with quadratic constants of motion.*

For further convenience, we sum up in the Table II the polar expressions for the sets of ''basic'' potentials V_1, V_2, V_3, in each of the families, as well as the associated sets of parameters.

We close this section with some observations. Any superintegrable potential should be associated to *two* different sets of constants (a_i,b_i,c_i) and (A_i,B_i,C_i), in addition to the trivial one $\{a_0=e_0,0,\ c_0=e_0;0,0;0\}$, which corresponds to the energy for all potentials. These two sets of values are (c_1,a_2) (i.e., $\{0,0,0;0,c_1;0\}$ and $\{0,0,0;0,0;a_2\}$) for V^c, (a_1,a_2) for $\tilde{V}^c$ and (a_1,c_1) for V^d. The situation for other families is a bit more subtle. V^b appears for two different choices for the two sets of constants, say (a_0,a_2) *or* (c_0,a_2), and V^e appears for (a_0,b_0) *or* (b_0,c_0). In both cases this twofold description is possible because the integral of motion associated to a_0, together with the energy—which is always present—implies the presence of another constant of motion associated to c_0, and conversely. Indeed, one can check that the systems of two fundamental equations for (a_0,a_2) and for (c_0,a_2) are equivalent. As far as V^a is concerned, the two possibilities (a_0,c_1) and (c_0,c_1) coincide again for the same reason, and the same happens for $\tilde{V}^a$. This will be relevant when discussing the situation for the case of nonzero curvature.

Overall, the simplest expression for these potentials is not in terms of any system of coordinates, but of *distances* to a given point O and/or to a pair of mutually orthogonal lines through O. In terms of these geometrical quantities r; $x=v$, $y=u$, we have

$$V^a=k_0+k_1(4x^2+y^2)+k_2x+k_3\frac{1}{y^2},$$

$$V^b=k_0+k_1r^2+k_2\frac{1}{x^2}+k_3\frac{1}{y^2},$$

$$V^c=k_0+k_1\frac{1}{r}+k_2\frac{1}{r}\frac{x}{y^2}+k_3\frac{1}{y^2},$$

$$V^d=k_0+k_1\frac{1}{r}+k_2\frac{1}{r}(r+x)^{1/2}+k_3\frac{1}{r}(r-x)^{1/2},$$

$$V^e=k_0+k_1r^2+k_2x+k_3y.$$

As we will see, superintegrable systems with two quadratic constants of motion in 2D spaces of constant curvature will have a comparable description.

IV. SUPERINTEGRABLE SYSTEMS ON THE TWO-DIMENSIONAL SPHERE S^2 AND HYPERBOLIC PLANE H^2 WITH QUADRATIC CONSTANTS OF MOTION

As observed in the Introduction, existing studies of potentials on the sphere have been mainly concerned with central potentials. There are some rather simple noncentral problems as, e.g., the nonisotropic oscillator or the Hénon–Heiles system, that have been highly studied in the plane but still remain very little analyzed in the sphere or the hyperbolic plane.

We now perform for the case of constant curvature κ a study similar to the one outlined for the Euclidean plane. We first use polar coordinates, and afterwards we shall give the expressions in parallel coordinates.

A. Polar coordinates

Let us consider the following Lagrangian:

$$L=\tfrac{1}{2}(v_r^2+\mathrm{S}_\kappa^2(r)v_\phi^2)-U(r,\phi)$$

corresponding to a system with configuration space Q (S^2 if $\kappa>0$ or H^2 if $\kappa<0$). In both cases κ is the curvature of Q. We will follow the same two step approach developed in Sec. III. The first step is concerned with the existence of *one* quadratic integral of motion (integrability). The second step corresponds with the existence of two quadratic integrals of motion (superintegrability). The following proposition summarizes the first step:

Proposition 2: Let L be the following two-degrees of freedom Lagrangian:

$$L=(\tfrac{1}{2})(v_r^2+\mathrm{S}_\kappa^2(r)v_\phi^2)-U(r,\phi)$$

corresponding to a system with a configuration space of constant curvature κ, and suppose that L has a constant of the motion $I=I(r,\phi,v_r,v_\phi)$ that is quadratic in the velocities

$$I=I_{22}+I_{20}(r,\phi),\quad I_{22}=av_r^2+2bv_rv_\phi+cv_\phi^2,$$

where a, b, and c, are functions of r and ϕ. Then,

(i) The three functions a, b, and c must take the form

$$a = a_0 \cos^2\phi + c_0 \sin^2\phi + b_0 \sin\phi\cos\phi,$$

$$b = (\tfrac{1}{2})\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)[(c_0-a_0)\sin 2\phi + b_0\cos 2\phi] + (\tfrac{1}{2})\mathrm{S}_\kappa^2(r)(-a_1\cos\phi + c_1\sin\phi),$$

$$c = (\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r))^2(a_0\sin^2\phi + c_0\cos^2\phi - b_0\sin\phi\cos\phi) + \mathrm{S}_\kappa^3(r)\mathrm{C}_\kappa(r)(c_1\cos\phi + a_1\sin\phi) + a_2\mathrm{S}_\kappa^4(r),$$

where a_0, b_0, c_0; a_1, c_1; a_2 are real parameters.

(ii) The potential $U(r,\phi)$ must be solution of the following differential equation:

$$b(\mathrm{S}_\kappa^2(r)U_{rr} - U_{\phi\phi}) + (c - a\mathrm{S}_\kappa^2(r))U_{r\phi} + \mathrm{S}_\kappa^2(r)\left[2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)b - \left(\frac{3}{2}\right)a_\phi\right]U_r + \left[2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)(c - a\mathrm{S}_\kappa^2(r)) - 3b_\phi\right]U_\phi = 0.$$

Proof: Assume there exists a constant of motion $I = I_{22} + I_{20}$, where I_{22} takes the form $I_{22} = a v_x^2 + 2b v_x v_y + c v_y^2$, with the functions a, b, c depending on r,ϕ. These functions must satisfy the following four equations:

$$a_r = 0,$$

$$2b_r - 4\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)b + a_\phi = 0,$$

$$c_r - 4\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)c + (2\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r))a + 2b_\phi = 0,$$

$$c_\phi + (2\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r))b = 0.$$

Solving this system we obtain the expressions in statement (i) in the Proposition.

The function I_{20} is related to the potential U by the following system:

$$I_{20r} = 2aU_r + \frac{2bU_\phi}{\mathrm{S}_\kappa^2(r)}, \quad I_{20\phi} = 2bU_r + \frac{2cU_\phi}{\mathrm{S}_\kappa^2(r)}.$$

Taking derivatives, and using (i), we obtain the equation in point (ii) for the potential U.

Concerning (i), the most remarkable property of the expressions obtained for the three functions a, b, c, is that they depend on the *same* number of parameters $\{a_0, b_0, c_0;\ a_1, c_1;\ a_2\}$, as in the flat $\kappa=0$ case (then $\mathrm{S}_\kappa(r)\to r$ and $\mathrm{C}_\kappa(r)\to 1$ so all these equations coincide with the ones obtained in Sec. III for $Q=E^2$). In this κ-dependent form, the case where the configuration space is Euclidean appears not as a limit but simply as the particular case $\kappa=0$; generically r appears through $\mathrm{S}_\kappa(r)$, and there are also some factors which in the curved case appear through a tagged cosine of r, $\mathrm{C}_\kappa(r)$ which in the Euclidean case degenerates to $\mathrm{C}_0(r)\equiv 1$ and which therefore becomes invisible; of course these terms turn visible once we deal with the case of nonzero curvature κ.

As a, b, c are linear in the parameters a_i, b_i, c_i, the most general form for I_{22} is

$$I_{22} = a_0 I_{22}(a_0,\kappa) + b_0 I_{22}(b_0,\kappa) + c_0 I_{22}(c_0,\kappa) + a_1 I_{22}(a_1,\kappa) + c_1 I_{22}(c_1,\kappa) + a_2 I_{22}(a_2,\kappa),$$

where

$$I_{22}(a_0,\kappa)=(\cos\phi v_r-\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)\sin\phi v_\phi)^2,$$

$$I_{22}(b_0,\kappa)=(\cos\phi v_r-\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)\sin\phi v_\phi)(\sin\phi v_r+\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)\cos\phi v_\phi),$$

$$I_{22}(c_0,\kappa)=(\sin\phi v_r+\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)\cos\phi v_\phi)^2,$$

$$I_{22}(a_1,\kappa)=\mathrm{S}_\kappa^2(r)(\cos\phi v_r-\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)\sin\phi v_\phi)v_\phi,$$

$$I_{22}(c_1,\kappa)=\mathrm{S}_\kappa^2(r)(\sin\phi v_r+\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)\cos\phi v_\phi)v_\phi.$$

$$I_{22}(a_2,\kappa)=\mathrm{S}_\kappa^4(r)v_\phi^2.$$

A direct calculation shows that

$$I_{22}(a_0,\kappa)+I_{22}(c_0,\kappa)+\kappa[I_{22}(a_2,\kappa)]=v_r^2+\mathrm{S}_\kappa^2(r)v_\phi^2$$

so in any configuration space of nonzero constant curvature κ the kinetic term can always be written as a sum of *three* summands, one of which carries the curvature κ and vanishes into the limit $\kappa\to 0$. In the particular cases where the total energy $E=T+U$ becomes totally separable, it will appear as a sum, not of two (as in E^2), but of three components. This is an interesting characteristic of this trivial first integral of the motion making the analysis of the different families of superintegrable potentials in the sphere and the hyperbolic plane richer than in the Euclidean case.

The above Proposition 2 relates integrability with the property of satisfying a *single* differential equation for the potential. In $Q=S^2$ or $Q=H^2$, as in $Q=E^2$, two independent integrals of motion (further than the energy) are required for the superintegrability of the system. The following proposition 3 states the relation of superintegrability in configuration spaces of constant curvature with the fact that the potential should satisfy a system of two such equations.

Proposition 3: Let the potential U be a solution of the following system of two partial differential equations,

$$b(\mathrm{S}_\kappa^2(r)U_{rr}-U_{\phi\phi})+(c-a\mathrm{S}_\kappa^2(r))U_{r\phi}+\mathrm{S}_\kappa^2(r)\left[2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)b-\left(\frac{3}{2}\right)a_\phi\right]U_r$$
$$+\left[2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)(c-a\mathrm{S}_\kappa^2(r))-3b_\phi\right]U_\phi=0,$$

$$B(\mathrm{S}_\kappa^2(r)U_{rr}-U_{\phi\phi})+(C-A\mathrm{S}_\kappa^2(r))U_{r\phi}+\mathrm{S}_\kappa^2(r)\left[2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)B-\left(\frac{3}{2}\right)A_\phi\right]U_r$$
$$+\left[2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)(C-A\mathrm{S}_\kappa^2(r))-3B_\phi\right]U_\phi=0,$$

where $(a(r,\phi),b(r,\phi),c(r,\phi))$, *and* $(A(r,\phi),B(r,\phi),C(r,\phi))$, *are two sets of three functions determined as in Prop. 2(i) by two sets of nontrivial real constants* (a_i,b_i,c_i), *and* (A_i,B_i,C_i), *respectively. Suppose that these two sets of constants are not only different but such that the two above second-order equations are independent. Then, if* $T=(1/2)(v_r^2+\mathrm{S}_\kappa^2(r)v_\phi^2)$ *denotes the kinetic function in a configuration space of constant curvature* κ, *the Lagrangian* $L=T-U(r,\phi)$ *describes a superintegrable system on either the sphere* $(\kappa>0)$, *the Euclidean plane* $(\kappa=0)$ *or the hyperbolic plane* $(\kappa<0)$, *with quadratic constants of motion.*

We will study now the spherical or hyperbolic versions of the superintegrable potentials already presented for the Euclidean plane. For consistency with the flat case we will denote them as U^a, $\widetilde{U}^a$, U^{aa}, $\widetilde{U}^{aa}$, U^b, U^c, U^d, U^e, and $\widetilde{U}^e$. They correspond to the choices of parameters given in Table III.

TABLE III. Parameters and non-Euclidean families of potentials.

$(a_0,c_1);(c_0,a_1)$	$U^a;\tilde{U}^a$
$(c_0,c_1);(a_0,a_1)$	$U^{aa};\tilde{U}^{aa}$
$(a_0,c_0,a_2)\equiv(a_0,a_2)$ or (c_0,a_2) or (a_0,c_0)	U^b
$(c_1,a_2);(a_1,a_2)$	$U^c;\tilde{U}^c$
(a_1,c_1)	U^d
$(a_0,b_0);(b_0,c_0)$	$U^e;\tilde{U}^e$

The family U^b is again characterized by three independent parameter vectors {100;00;0}, {001;00;0} and {000;00;1}; the vector corresponding to the energy is already contained in the subspace generated by these three vectors. In other cases, the parameter vector corresponding to the energy will be assumed without explicit mention. The family V^a, which in the flat case corresponded *simultaneously* to two pairs pairs (a_0,c_1) and (c_0,c_1) will now split into two *different* families U^a and U^{aa}, associated, respectively, with (a_0,c_1) and (c_0,c_1). A similar splitting occurs for the flat families $\tilde{V}^a$ and V^e. As we shall see shortly, and likewise as in $Q=E^2$, it is again remarkable that the general solution for U appears also as a linear combination of simpler particular nontrivial solutions (three for almost all families), in addition to the constant potential $U_0=1$, which is of course superintegrable and has associated the full the six-dimensional parameter space.

1. Superintegrable systems on the unit sphere

We first present a detailed study of the resolution of the equations for the particular case $\kappa=1$. The complete rewriting of the solutions for any arbitrary (positive or negative) value of κ is done afterwards.

a. Family U^a. Notice that the case (a_0,c_0,c_1) is not possible for $\kappa\neq 0$. In fact we have obtained that it splits in two different subcases (a_0,c_1) and (c_0,c_1).

We first consider the two linear second-order equations associated to (a_0,C_1), that is, to the vectors $\{a_0 00;00;0\}$ and $\{000;0C_1;0\}$. When $\kappa=1$ they are

$$\left(\frac{\cos r}{\sin r}\right)(\sin\phi\cos\phi)(\sin^2 r\,U_{rr}-U_{\phi\phi})+(\cos^2\phi-\cos^2 r\sin^2\phi)U_{r\phi}$$
$$+(2\cos^2 r-3)(\sin\phi\cos\phi)U_r+\left(\frac{\cos r}{\sin r}\right)[(3-2\cos^2 r)\sin^2\phi-\cos^2\phi]U_\phi=0,$$

$$\sin\phi(\sin^2 r\,U_{rr}-U_{\phi\phi})+2(\sin r\cos r\cos\phi)U_{r\phi}+2(\sin r\cos r\sin\phi)U_r$$
$$-\cos\phi(3-4\cos^2 r)U_\phi=0.$$

The first equation, that corresponds to $a_0\neq 0$, can be reduced to canonical form by means of the following change of variables

$$(r,\phi)\to(w_a,z_a),\quad w_a=\sin r\sin\phi,\quad z_a=\tan r\cos\phi.$$

The general solution takes the form

$$U(r,\phi;a_0)=F(w_a)+\frac{G(z_a)}{1-w_a^2}=F(\sin r\sin\phi)+\frac{G(\tan r\cos\phi)}{1-(\sin r\sin\phi)^2}.$$

Substituting in the equation for $C_1\neq 0$ we have found the following potentials:

$$U^a=U^a(r,\phi;a_0,C_1)=k_0+k_1U_1^a+k_2U_2^a+k_3U_3^a,$$

$$U_1^a=\frac{1}{1-w_a^2}\left[4\left(\frac{z_a}{1-z_a^2}\right)^2+w_a^2\right]=\frac{1}{1-(\sin r\sin\phi)^2}\left[4\left(\frac{\tan r\cos\phi}{1-(\tan r\cos\phi)^2}\right)^2+(\sin r\sin\phi)^2\right],$$

$$U_2^a=\frac{1}{1-w_a^2}\left[\frac{(1+z_a^2)z_a}{(1-z_a^2)^2}\right]=\frac{\tan r\cos\phi}{(\cos^2 r)[1-(\tan r\cos\phi)^2]^2},$$

$$U_3^a=\frac{1}{w_a^2}=\frac{1}{(\sin r\sin\phi)^2},$$

where k_0 and k_i, $i=1,2,3$, are arbitrary constants (we display explicitly the constant term k_0, linked to the constant potential $U_0=1$ which will appear in all families). The two constants of motion, I_2^a and I_3^a, take the form

$$I_2^a=(\cos\phi v_r-\sin r\cos r\sin\phi v_\phi)^2+\frac{8k_1(\tan r\cos\phi)^2}{[1-(\tan r\cos\phi)^2]^2}+\frac{2k_2[1+(\tan r\cos\phi)^2](\tan r\cos\phi)}{[1-(\tan r\cos\phi)^2]^2},$$

$$I_3^a=(\sin r)^2(\sin\phi v_r+\sin r\cos r\cos\phi v_\phi)v_\phi-\frac{2k_1(\tan^3 r\cos\phi\sin^2\phi)}{[1-(\tan r\cos\phi)^2]^2}-\frac{k_2[1+(\tan r\cos\phi)^2](\tan r\sin\phi)^2}{2[1-(\tan r\cos\phi)^2]^2}+\frac{2k_3\cos r\cos\phi}{\sin r\sin^2\phi}.$$

b. Family $\tilde{U}^a$. We can also consider the family of potentials associated with (c_0,A_1). The equations are

$$\left(\frac{\cos r}{\sin r}\right)(\sin\phi\cos\phi)(\sin^2 r U_{rr}-U_{\phi\phi})+(\cos^2 r\cos^2\phi-\sin^2\phi)U_{r\phi}+(2\cos^2 r-3)(\sin\phi\cos\phi)U_r+\left(\frac{\cos r}{\sin r}\right)[\sin^2\phi-(3-2\cos^2 r)\cos^2\phi]U_\phi=0,$$

$$\cos\phi(\sin^2 r U_{rr}-U_{\phi\phi})-2(\sin r\cos r\sin\phi)U_{r\phi}+2(\sin r\cos r\cos\phi)U_r-\sin\phi(3-4\cos^2 r)U_\phi=0.$$

The first equation, that corresponds to $c_0\neq 0$, can be reduced to canonical form making use of the following change:

$$(r,\phi)\to(w_c,z_c),\quad w_c=\sin r\cos\phi,\quad z_c=\tan r\sin\phi.$$

The general solution takes the form

$$\tilde{U}(r,\phi;c_0)=\tilde{F}(w_c)+\frac{\tilde{G}(z_c)}{1-w_c^2}=\tilde{F}(\sin r\cos\phi)+\frac{\tilde{G}(\tan r\sin\phi)}{1-(\sin r\cos\phi)^2}.$$

Substituting this general expression into the equation for $A_1\neq 0$ we have found the following potentials:

$$\tilde{U}^a=\tilde{U}^a(r,\phi;c_0,A_1)=k_0+k_1\tilde{U}_1^a+k_2\tilde{U}_2^a+k_3\tilde{U}_3^a,$$

$$\tilde{U}_1^a = \frac{1}{1-w_c^2}\left[w_c^2 + 4\left(\frac{z_c}{1-z_c^2} \right)^2 \right] = \frac{1}{1-(\sin r \cos \phi)^2}\left[(\sin \cos \phi)^2 + 4\left(\frac{\tan r \sin \phi}{1-(\tan r \sin \phi)^2} \right)^2 \right],$$

$$\tilde{U}_2^a = \frac{1}{1-w_c^2}\left[\frac{(1+z_c^2)z_c}{(1-z_c^2)^2} \right] = \frac{\tan r \sin \phi}{(\cos^2 r)[1-(\tan r \sin \phi)^2]^2},$$

$$\tilde{U}_3^a = \frac{1}{w_c^2} = \frac{1}{(\sin r \cos \phi)^2}.$$

c. Family U^{aa}. When $\kappa \neq 0$ we can also consider the system of second-order equations associated with (c_0, C_1), that is, to the vectors $\{00c_0;00;0\}$ and $\{000;0C_1;0\}$. They are

$$\left(\frac{\cos r}{\sin r} \right)(\sin \phi \cos \phi)(\sin^2 r U_{rr} - U_{\phi\phi}) + (\cos^2 r \cos^2 \phi - \sin^2 \phi)U_{r\phi} + (2\cos^2 r - 3)(\sin \phi \cos \phi)U_r + \left(\frac{\cos r}{\sin r} \right)[\sin^2 \phi - (3 - 2\cos^2 r)\cos^2 \phi]U_\phi = 0,$$

$$\sin \phi(\sin^2 r U_{rr} - U_{\phi\phi}) + 2(\sin r \cos r \cos \phi)U_{r\phi} + 2(\sin r \cos r \sin \phi)U_r - \cos \phi(3 - 4\cos^2 r)U_\phi = 0.$$

We have found the following solutions:

$$U^{aa} = U^{aa}(r,\phi;c_0,C_1) = k_0 + k_1 U_1^{aa} + k_2 U_2^{aa} + k_3 U_3^{aa},$$

$$U_1^{aa} = \frac{w_c}{\sqrt{1-w_c^2}} = \frac{\sin r \cos \phi}{\sqrt{1-(\sin r \cos \phi)^2}},$$

$$U_2^{aa} = \frac{\sqrt{1+z_c^2}}{(1-w_c^2)z_c^2} = \frac{\cos r}{(\sin r \sin \phi)^2 \sqrt{1-(\sin r \cos \phi)^2}},$$

$$U_3^{aa} = \frac{1+z_c^2}{(1-w_c^2)z_c^2} = \frac{1}{(\sin r \sin \phi)^2},$$

and the following two constants of motion:

$$I_2^{aa} = (\sin \phi v_r + \sin r \cos r \cos \phi v_\phi)^2 + \frac{2k_2 \cos r \sqrt{1-(\sin r \cos \phi)^2}}{(\sin r \sin \phi)^2} + \frac{2k_3 \cos^2 r}{(\sin r \sin \phi)^2},$$

$$I_3^{aa} = (\sin r)^2(\sin \phi v_r + \sin r \cos r \cos \phi v_\phi)v_\phi + \frac{k_1 \cos r}{\sqrt{1-(\sin r \cos \phi)^2}} + \frac{k_2 \cos \phi[2\cos^2 r + (\sin r \sin \phi)^2]}{(\sin r \sin \phi)^2 \sqrt{1-(\sin r \cos \phi)^2}} + \frac{2k_3 \cos r \cos \phi}{\sin r \sin^2 \phi}.$$

d. Family $\tilde{U}^{aa}$. Similarly, the general solution of the system $(a_0 \neq 0,\ A_1 \neq 0)$, that we will denote by $\tilde{U}^{aa} = \tilde{U}^{aa}(r,\phi;a_0,A_1)$, is given by

$$\widetilde{U}^{aa}=\widetilde{U}^{aa}(r,\phi;a_0,A_1)=k_0+k_1\widetilde{U}_1^{aa}+k_2\widetilde{U}_2^{aa}+k_3\widetilde{U}_3^{aa},$$

$$\widetilde{U}_1^{aa}=\frac{w_a}{\sqrt{1-w_a^2}}=\frac{\sin r\sin\phi}{\sqrt{1-(\sin r\sin\phi)^2}},$$

$$\widetilde{U}_2^{aa}=\frac{\sqrt{1+z_a^2}}{(1-w_a^2)z_a^2}=\frac{\cos r}{(\sin r\cos\phi)^2\sqrt{1-(\sin r\sin\phi)^2}},$$

$$\widetilde{U}_3^{aa}=\frac{1+z_a^2}{(1-w_a^2)z_a^2}=\frac{1}{(\sin r\cos\phi)^2}.$$

e. Family U^b. The two linear second-order equations are those associated with (a_0,C_0), that is, to the vectors $\{a_000;00;0\}$ and $\{00C_0;00;0\}$. Before proceeding, we note that any of the alternative choices (a_0,A_2) or (c_0,A_2) would lead exactly to the same family. The two equations for a_0 and C_0 are

$$\left(\frac{\cos r}{\sin r}\right)(\sin\phi\cos\phi)(\sin^2 rU_{rr}-U_{\phi\phi})+(\cos^2\phi-\cos^2 r\sin^2\phi)U_{r\phi}+(2\cos^2 r-3)$$
$$\times(\sin\phi\cos\phi)U_r+\left(\frac{\cos r}{\sin r}\right)[(3-2\cos^2 r)\sin^2\phi-\cos^2\phi]U_\phi=0,$$

$$\left(\frac{\cos r}{\sin r}\right)(\sin\phi\cos\phi)(\sin^2 rU_{rr}-U_{\phi\phi})+(\cos^2 r\cos^2\phi-\sin^2\phi)U_{r\phi}+(2\cos^2 r-3)$$
$$\times(\sin\phi\cos\phi)U_r+\left(\frac{\cos r}{\sin r}\right)[\sin^2\phi-(3-2\cos^2 r)\cos^2\phi]U_\phi=0.$$

The general solution of the first equation, that corresponds to $a_0\neq 0$, takes the form

$$U(r,\phi;a_0)=F(w_a)+\frac{G(z_a)}{1-w_a^2}=F(\sin r\sin\phi)+\frac{G(\tan r\cos\phi)}{1-(\sin r\sin\phi)^2}.$$

Notice that, in the parallel coordinates (u,y), the canonical variables can be written as $w_a=\sin y$, $z_a=\tan u$, so $U(r,\phi;a_0)$ can also be written as

$$U(r,\phi;a_0)=f(\sin y)+\frac{g(\tan u)}{\cos^2 y}.$$

Concerning the second equation, corresponding to $C_0\neq 0$, the canonical coordinates are $w_c=\sin r\cos\phi$, $z_c=\tan r\sin\phi$, which can be alternatively rewritten as $w_c=\sin x$, $z_c=\tan v$. The corresponding general solution takes the form

$$\widetilde{U}(r,\phi;c_0)=\widetilde{F}(w_c)+\frac{\widetilde{G}(z_c)}{1-w_c^2}=\widetilde{F}(\sin r\cos\phi)+\frac{\widetilde{G}(\tan r\sin\phi)}{1-(\sin r\cos\phi)^2}=\widetilde{f}(\sin x)+\frac{\widetilde{g}(\tan v)}{\cos^2 x}.$$

The corresponding general solution for the potential U, that we will denote by $U^b=U^b(r,\phi;a_0,C_0)$, must be expressible simultaneously as $U(r,\phi;a_0)$ and as $U(r,\phi;C_0)$; this is enforced by requiring that the explicit form for the general solution of the equation for $a_0\neq 0$ solves the equation for $C_0\neq 0$. This leads to the following solutions for U:

$$U^b=U^b(r,\phi;a_0,C_0)=k_0+k_1U_1^b+k_2U_2^b+k_3U_3^b,$$

$$U_1^b=\frac{w_a^2+z_a^2}{1-w_a^2}=\frac{w_c^2+z_c^2}{1-w_c^2}=\left(\frac{\sin r}{\cos r}\right)^2,$$

$$U_2^b=\frac{1+z_a^2}{(1-w_a^2)z_a^2}=\frac{1}{w_c^2}=\frac{1}{(\sin r\cos\phi)^2},$$

$$U_3^b=\frac{1}{w_a^2}=\frac{1+z_c^2}{(1-w_c^2)z_c^2}=\frac{1}{(\sin r\sin\phi)^2},$$

where k_0 and k_i, $i=1,2,3$, are arbitrary constants. As indicated, these potentials are automatically solution of the equation for $a_2\neq 0$.

The two constants of motion, I_2^b and I_3^b, take the form

$$I_2^b=(\cos\phi v_r-\sin r\cos r\sin\phi v_\phi)^2+2k_1\left(\frac{\sin r}{\cos r}\right)^2\cos^2\phi+2k_2\left(\frac{\cos r}{\sin r\cos\phi}\right)^2,$$

$$I_3^b=(\sin\phi v_r+\sin r\cos r\cos\phi v_\phi)^2+2k_1\left(\frac{\sin r}{\cos r}\right)^2\sin^2\phi+2k_3\left(\frac{\cos r}{\sin r\sin\phi}\right)^2.$$

Notice that, in this particular case, we can consider as the first integral of motion the following function:

$$I_1^b=(\sin r)^4v_\phi^2+2\left(\frac{k_2}{\cos^2\phi}\right)+2\left(\frac{k_3}{\sin^2\phi}\right).$$

f. Family U^c. The second-order equations correspond to $\{000;00;a_2\}$ and $\{000;0C_1;0\}$. They are

$$\sin r U_{r\phi}+2\cos r U_\phi=0,$$

$$\sin\phi(\sin^2 r U_{rr}-U_{\phi\phi})+2(\sin r\cos r\cos\phi)U_{r\phi}+2(\sin r\cos r\sin\phi)U_r$$
$$-\cos\phi(3-4\cos^2 r)U_\phi=0.$$

The first equation, that corresponds to $a_2\neq 0$, has as general solution the following family of functions:

$$U(r,\phi;a_2)=F(r)+\frac{G(\phi)}{(\sin r)^2}.$$

Substituting $U(r,\phi;a_2)$ in the second equation, that corresponds to $C_1\neq 0$, we obtain the following potentials:

$$U^c=U^c(r,\phi;a_2,C_1)=k_0+k_1U_1^c+k_2U_2^c+k_3U_3^c,$$

$$U_1^c=\frac{\cos r}{\sin r},\quad U_2^c=\frac{\cos\phi}{(\sin r\sin\phi)^2},\quad U_3^c=\frac{1}{(\sin r\sin\phi)^2}.$$

The two constants of motion I_2^c, and I_3^c, take the form

$$I_2^c = (\sin r)^4 v_\phi^2 + 2k_2\left(\frac{\cos\phi}{\sin^2\phi}\right) + 2k_3\left(\frac{\cos\phi}{\sin\phi}\right)^2,$$

$$I_3^c = (\sin r)^2(\sin\phi v_r + \sin r\cos r\cos\phi v_\phi)v_\phi + k_1\cos\phi$$
$$+k_2\left(\frac{\cos r(1+\cos^2\phi)}{\sin r\sin^2\phi}\right) + 2k_3\left(\frac{\cos r\cos\phi}{\sin r\sin^2\phi}\right).$$

g. Family $\tilde{U}^c$. The second-order equations correspond to $\{000;00;a_2\}$ and $\{000;0A_1;0\}$. They are

$$\sin r U_{r\phi} + 2\cos r U_\phi = 0,$$

$$\cos\phi(\sin^2 r U_{rr} - U_{\phi\phi}) - 2(\sin r\cos r\sin\phi)U_{r\phi}$$
$$+2(\sin r\cos r\cos\phi)U_r + \sin\phi(3-4\cos^2 r)U_\phi = 0.$$

In a rather similar way to the previous case, we have obtained the following potentials:

$$\tilde{U}^c = \tilde{U}^c(r,\phi;a_2,A_1) = k_0 + k_1\tilde{U}_1^c + k_2\tilde{U}_2^c + k_3\tilde{U}_3^c,$$

$$\tilde{U}_1^c = \frac{\cos r}{\sin r}, \quad \tilde{U}_2^c = \frac{1}{(\sin r\cos\phi)^2}, \quad \tilde{U}_3^c = \frac{\sin\phi}{(\sin r\cos\phi)^2}.$$

h. Family U^d. The two linear second-order equations corresponding to $\{000;a_10;0\}$ and to $\{000;0C_1;0\}$ are the following:

$$\sin\phi(\sin^2 r U_{rr} - U_{\phi\phi}) + 2(\sin r\cos r\cos\phi)U_{r\phi}$$
$$+2(\sin r\cos r\sin\phi)U_r - \cos\phi(3-4\cos^2 r)U_\phi = 0,$$

$$\cos\phi(\sin^2 r U_{rr} - U_{\phi\phi}) - 2(\sin r\cos r\sin\phi)U_{r\phi}$$
$$+2(\sin r\cos r\cos\phi)U_r + \sin\phi(3-4\cos^2 r)U_\phi = 0,$$

that can be equivalently rewritten as

$$2\sin r\cos r U_{r\phi} + (4\cos^2 r - 3)U_\phi = 0,$$

$$2\sin r\cos r U_r + (\sin^2 r U_{rr} - U_{\phi\phi}) = 0.$$

The general solution for the first equation is $F(r) + G(\phi)/\sqrt{\sin r\cos^3 r}$. Substituting this expression in the second one we arrive at $F(r) = k_0 + k_1(\cos r/\sin r)$, and $G=0$. Thus the most general form of a potential in the family U^d is given by

$$U^d = U^d(r,\phi;a_1,C_1) = k_0 + k_1 U_1^d,$$

$$U_1^d = \frac{1}{\tan r},$$

where k_0 and k_1 are again arbitrary constants.

The two constants of motion, I_2^d and I_3^d, take the form

$$I_2^d = (\sin r)^2(\sin\phi v_r - \sin r\cos r\cos\phi v_\phi)v_\phi - k_1\sin\phi,$$

$$I_3^d = (\sin r)^2(\cos\phi v_r + \sin r\cos r\sin\phi v_\phi)v_\phi + k_1\cos\phi.$$

i. Family U^e. The two linear second-order equations are those associated with $(a_0\neq 0,\ B_0\neq 0)$, that is, to the vectors $\{a_0 00;00;0\}$ and $\{0B_0 0;00;0\}$. The two equations for a_0 and B_0 are

$$\left(\frac{\cos r}{\sin r}\right)(\sin\phi\cos\phi)(\sin^2 r\,U_{rr}-U_{\phi\phi})+(\cos^2\phi-\cos^2 r\,\sin^2\phi)U_{r\phi}$$
$$+(2\cos^2 r-3)(\sin\phi\cos\phi)U_r+\left(\frac{\cos r}{\sin r}\right)[(3-2\cos^2 r)\sin^2\phi-\cos^2\phi]U_\phi=0,$$

and

$$\left(\frac{\cos r}{\sin r}\right)(\cos^2\phi-\sin^2\phi)(\sin^2 r\,U_{rr}-U_{\phi\phi})-2(1+\cos^2 r)(\cos\phi\sin\phi)U_{r\phi}$$
$$+(\cos^2 r-\sin^2 r-2)(\cos^2\phi-\sin^2\phi)U_r+4\left(\frac{\cos r}{\sin r}+\cos r\sin r\right)(\cos\phi\sin\phi)U_\phi=0.$$

The general solution of this system, that we will denote by $U^e=U^e(r,\phi;a_0,B_0)$, turns out to be

$$U^e=U^e(r,\phi;a_0,B_0)=k_0+k_1U_1^e+k_2U_2^e+k_3U_3^e,$$

$$U_1^e=\frac{w_a^2+z_a^2}{1-w_a^2}=(\tan r)^2,$$

$$U_2^e=\frac{z_a\sqrt{1+z_a^2}}{1-w_a^2}=\frac{\tan r\cos\phi}{(\cos r)\sqrt{1-(\sin r\sin\phi)^2}},$$

$$U_3^e=\frac{w_a}{\sqrt{1-w_a^2}}=\frac{\sin r\sin\phi}{\sqrt{1-(\sin r\sin\phi)^2}},$$

and the associated two constants of motion, I_2^e and I_3^e, are given by

$$I_2^e=(\cos\phi v_r-\sin r\cos r\sin\phi v_\phi)^2+2k_1(\tan r\cos\phi)^2+2k_2\left(\frac{\sin r\cos\phi}{\cos^2 r}\right)\sqrt{1-(\sin r\sin\phi)^2},$$

$$I_3^e=(\cos\phi v_r-\sin r\cos r\sin\phi v_\phi)(\sin\phi v_r+\sin r\cos r\cos\phi v_\phi)+2k_1\tan^2 r\sin\phi\cos\phi$$
$$+k_2\sin r\sin\phi\left(\frac{1+2\tan^2 r\cos^2\phi}{\sqrt{1-(\sin r\sin\phi)^2}}\right)+\frac{k_3\sin r\cos\phi}{\sqrt{1-(\sin r\sin\phi)^2}}.$$

j. Family $\tilde U^e$. Similarly, the general solution of the system $(b_0\neq 0,\ C_0\neq 0)$, that we will denote by $\tilde U^e=\tilde U^e(r,\phi;b_0,C_0)$, is given by

$$\tilde U^e=U^e(r,\phi;b_0,C_0)=k_0+k_1\tilde U_1^e+k_2\tilde U_2^e+k_3\tilde U_3^e,$$

$$\tilde U_1^e=\frac{w_c^2+z_c^2}{1-w_c^2}=(\tan r)^2,$$

$$\tilde U_2^e=\frac{w_c}{\sqrt{1-w_c^2}}=\frac{\sin r\cos\phi}{\sqrt{1-(\sin r\cos\phi)^2}},$$

$$\widetilde{U}_3^e = \frac{z_c\sqrt{1+z_c^2}}{1-w_c^2} = \frac{\tan r \sin\phi}{(\cos r)\sqrt{1-(\sin r\cos\phi)^2}}.$$

2. Superintegrable systems on a 2D space of constant curvature

Next we present the results obtained for the potentials U^r and the integrals of motion I_2, I_3, for more general values (positive, zero or negative) of the curvature κ. Thus, the following expressions simultaneously includes spherical, Euclidean, and hyperbolic potentials. We have not included the tilded families $\widetilde{U}^a$, $\widetilde{U}^{aa}$, $\widetilde{U}^c$, and $\widetilde{U}^e$, which for all values of κ can be obtained from U^a, U^{aa}, U^c, and U^e by reflection in the geodesic $x=y$, which in polar coordinates amounts to the interchange $\cos\phi \leftrightarrow \sin\phi$.

a. Family U^a. The general κ-dependent form of the potential U^a is given by

$$U^a = U^a(r,\phi,\kappa;a_0,C_1) = k_0 + k_1 U_1^a + k_2 U_2^a + k_3 U_3^a,$$

$$U_1^a = \frac{1}{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}\left[4\left(\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right)^2 + (\mathrm{S}_\kappa(r)\sin\phi)^2\right],$$

$$U_2^a = \frac{\mathrm{T}_\kappa(r)\cos\phi}{\mathrm{C}_k^2(r)[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2},$$

$$U_3^a = \frac{1}{\mathrm{S}_\kappa^2(r)\sin^2\phi},$$

and the two κ-dependent constants of motion, I_2^a and I_3^a, take the form

$$I_2^a = I_{22}(a_0,\kappa) + \frac{8k_1(\mathrm{T}_\kappa(r)\cos\phi)^2}{[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2} + \frac{2k_2[1+\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2](\mathrm{T}_\kappa(r)\cos\phi)}{[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2},$$

$$I_3^a = I_{22}(c_1,\kappa) - \frac{2k_1\mathrm{T}_\kappa^3(r)\cos\phi\sin^2\phi}{[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2} - \frac{k_2[1+\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2](\mathrm{T}_\kappa(r)\sin\phi)^2}{2[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2} + \frac{2k_3\mathrm{C}_\kappa(r)\cos\phi}{\mathrm{S}_\kappa(r)\sin^2\phi}.$$

Notice that for the particular case $\kappa=0$ we obtain

$$U^a = k_0 + k_1 r^2(4\cos^2\phi + \sin^2\phi) + k_2 r\cos\phi + \frac{k_3}{(r\sin\phi)^2},$$

$$I_2^a = (v_r\cos\phi - r v_\phi\sin\phi)^2 + 8k_1(r\cos\phi)^2 + 2k_2 r\cos\phi,$$

$$I_3^a = (v_r\sin\phi + r v_\phi\cos\phi)(r^2 v_\phi) - 2k_1 r^3\cos\phi\sin^2\phi - \left(\frac{1}{2}\right)k_2(r\sin\phi)^2 + \frac{2k_3\cos\phi}{r\sin^2\phi}$$

that coincide with the corresponding expressions obtained in Sec. III for the Euclidean plane.

b. Family U^{aa}. The general κ-dependent form of the potential U^{aa} is given by

$$U^{aa} = U^{aa}(r,\phi,\kappa;c_0,C_1) = k_0 + k_1 U_1^{aa} + k_2 U_2^{aa} + k_3 U_3^{aa},$$

$$U_1^{aa} = \frac{\mathrm{S}_\kappa(r)\cos\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}},$$

$$U_2^{aa} = \frac{1}{[\mathrm{S}_\kappa(r)\sin\phi]^2}\,\frac{\mathrm{C}_\kappa(r)}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}},$$

$$U_3^{aa} = \frac{1}{[\mathrm{S}_\kappa(r)\sin\phi]^2},$$

and the two κ-dependent constants of motion, I_2^{aa} and I_3^{aa}, take the form

$$I_2^{aa} = I_{22}(c_0,\kappa) + \frac{2k_2\mathrm{C}_\kappa(r)}{[\mathrm{S}_\kappa(r)\sin\phi]^2}\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2} + \frac{2k_3\mathrm{C}_\kappa^2(r)}{[\mathrm{S}_\kappa(r)\sin\phi]^2},$$

$$I_3^{aa} = I_{22}(c_1,\kappa) + \frac{k_1\mathrm{C}_\kappa(r)}{\kappa\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}} + \frac{k_2\cos\phi[2\mathrm{C}_\kappa^2(r)+\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2]}{\mathrm{S}_\kappa(r)\sin^2\phi\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}} + \frac{2k_3\mathrm{C}_\kappa(r)\cos\phi}{\mathrm{S}_\kappa(r)\sin^2\phi}.$$

c. Family U^b. The general κ-dependent form of the potential U^b is given by

$$U^b = U^b(r,\phi,\kappa;a_0,C_0) = k_0 + k_1U_1^b + k_2U_2^b + k_3U_3^b,$$

$$U_1^b = \mathrm{T}_\kappa^2(r), \quad U_2^b = \frac{1}{(\mathrm{S}_\kappa(r)\cos\phi)^2}, \quad U_3^b = \frac{1}{(\mathrm{S}_\kappa(r)\sin\phi)^2},$$

and the two κ-dependent constants of motion, I_2^b and I_3^b, take the form

$$I_2^b = I_{22}(a_0,\kappa) + 2k_1\mathrm{T}_\kappa^2(r)\cos^2\phi + 2k_2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)\cos\phi}\right)^2,$$

$$I_3^b = I_{22}(c_0,\kappa) + 2k_1\mathrm{T}_\kappa^2(r)\sin^2\phi + 2k_3\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)\sin\phi}\right)^2.$$

d. Family U^c. The general κ-dependent form of the potential U^c is given by

$$U^c = U^c(r,\phi,\kappa;a_2,C_1) = k_0 + k_1U_1^c + k_2U_2^c + k_3U_3^c,$$

$$U_1^c = \frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}, \quad U_2^c = \frac{\cos\phi}{(\mathrm{S}_\kappa(r)\sin\phi)^2}, \quad U_3^c = \frac{1}{(\mathrm{S}_\kappa(r)\sin\phi)^2},$$

and the two κ-dependent constants of motion, I_2^c and I_3^c, take the form

$$I_2^c = I_{22}(a_2,\kappa) + 2k_2\left(\frac{\cos\phi}{\sin^2\phi}\right) + 2k_3\left(\frac{\cos\phi}{\sin\phi}\right)^2$$

$$I_3^c = I_{22}(c_1,\kappa) + k_1\cos\phi + k_2\left(\frac{\mathrm{C}_\kappa(r)(1+\cos^2\phi)}{\mathrm{S}_\kappa(r)\sin^2\phi}\right) + 2k_3\left(\frac{\mathrm{C}_\kappa(r)\cos\phi}{\mathrm{S}_\kappa(r)\sin^2\phi}\right).$$

e. Family U^d. The general κ-dependent form of the potential U^d is given by

TABLE IV. Superintegrable potentials with curvature κ: Polar coordinates.

U^a	$\dfrac{4\left(\dfrac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right)^2+(\mathrm{S}_\kappa(r)\sin\phi)^2}{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}$	$\dfrac{[\mathrm{T}_\kappa(r)/\mathrm{C}_k^2(r)]\cos\phi}{[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2}$	$\dfrac{1}{\mathrm{S}_\kappa^2(r)\sin^2\phi}$
U^{aa}	$\dfrac{\mathrm{S}_\kappa(r)\cos\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}}$	$\dfrac{\mathrm{C}_\kappa(r)/[\mathrm{S}_\kappa(r)\sin\phi]^2}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}}$	$\dfrac{1}{\mathrm{S}_\kappa^2(r)\sin^2\phi}$
U^b	$\mathrm{T}_\kappa^2(r)$	$\dfrac{1}{\mathrm{S}_\kappa^2(r)\cos^2\phi}$	$\dfrac{1}{\mathrm{S}_\kappa^2(r)\sin^2\phi}$
U^c	$\dfrac{1}{\mathrm{T}_\kappa(r)}$	$\dfrac{\cos\phi}{\mathrm{S}_\kappa^2(r)\sin^2\phi}$	$\dfrac{1}{\mathrm{S}_\kappa^2(r)\sin^2\phi}$
U^d	$\dfrac{1}{\mathrm{T}_\kappa(r)}$		
U^e	$\mathrm{T}_\kappa^2(r)$	$\dfrac{[\mathrm{T}_\kappa(r)/\mathrm{C}_k(r)]\cos\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\sin\phi]^2}}$	$\dfrac{\mathrm{S}_\kappa(r)\sin\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\sin\phi]^2}}$

$$U^d = U^d(r,\phi,\kappa;a_1,C_1) = k_0 + k_1 U_1^d,$$

$$U_1^d = \frac{1}{\mathrm{T}_\kappa(r)},$$

and the two κ-dependent constants of motion, I_2^d and I_3^d, take the form

$$I_2^d = I_{22}(a_1,\kappa) - k_1 \sin\phi,$$

$$I_3^d = I_{22}(c_1,\kappa) + k_1 \cos\phi.$$

f. Family U^e. The general κ-dependent form of the potential U^e is given by

$$U^e = U^e(r,\phi,\kappa;a_0,B_0) = k_0 + k_1 U_1^e + k_2 U_2^e + k_3 U_3^e,$$

$$U_1^e = \mathrm{T}_\kappa^2(r), \quad U_2^e = \frac{\mathrm{T}_\kappa(r)\cos\phi}{\mathrm{C}_k(r)\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\sin\phi]^2}}, \quad U_3^e = \frac{\mathrm{S}_\kappa(r)\sin\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\sin\phi]^2}},$$

and the two κ-dependent constants of motion, I_2^e and I_3^e, take the form

$$I_2^e = I_{22}(a_0,\kappa) + 2k_1(\mathrm{T}_\kappa(r)\cos\phi)^2 + 2k_2\left(\frac{\mathrm{S}_\kappa(r)\cos\phi}{\mathrm{C}_k^2(r)}\right)\sqrt{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2},$$

$$I_3^e = I_{22}(b_0,\kappa) + 2k_1\mathrm{T}_\kappa^2(r)\sin\phi\cos\phi + k_2\mathrm{S}_\kappa(r)\sin\phi\left(\frac{1+2\kappa\mathrm{T}_\kappa^2(r)\cos^2\phi}{\sqrt{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}}\right)$$
$$+\frac{k_3\mathrm{S}_\kappa(r)\cos\phi}{\sqrt{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}}.$$

We close this subsection with Table IV that summarizes the expressions obtained for the κ-dependent ''basic'' potentials, U^r, $r = a, aa, b, c, d, e$.

B. Parallel coordinates

When looking for superintegrable potentials in the Euclidean plane, Cartesian coordinates allow a simpler approach than polar ones. On the sphere or hyperbolic plane the situation is reversed. However, we can make an independent check to the results obtained so far by discussing the problem on the sphere in terms of the parallel coordinates (u,y) introduced in Sec. II. The Lagrangian is

$$L=(\tfrac{1}{2})(\mathrm{C}_\kappa^2(y)v_u^2+v_y^2)-U(u,y).$$

Denoting now $I_{22}=av_u^2+2bv_uv_y+cv_y^2$, assume as in previous sections that $I=I_{22}+I_{20}(u,y)$ is a constant of motion. Then a, b, c, and I_{20}, must satisfy

$$a_u-\kappa(2b\mathrm{S}_\kappa(y)\mathrm{C}_\kappa(y))=0,$$

$$a_y+2b_u+\kappa(4a\mathrm{T}_\kappa(y)-2c\mathrm{S}_\kappa(y)\mathrm{C}_\kappa(y))=0,$$

$$c_u+2b_y+\kappa(4b\mathrm{T}_\kappa(y))=0,$$

$$c_y=0,$$

and

$$I_{20u}=\frac{2aU_u}{\mathrm{C}_\kappa^2(y)}+2bU_y\,,\quad I_{20y}=\frac{2bU_u}{\mathrm{C}_\kappa^2(y)}+2cU_y\,.$$

The compatibility condition of the two last equations leads to the following differential equation for the potential:

$$(a-\mathrm{C}_\kappa^2(y)c)U_{uy}+b(\mathrm{C}_\kappa^2(y)U_{yy}-U_{uu})+(a_y-b_u+2\kappa a\mathrm{T}_\kappa(y))U_u+\mathrm{C}_\kappa^2(y)(b_y-c_u)U_y=0.$$

Again the terms involving the first derivatives of the potential U can be written in different alternative ways. When $\kappa=0$, all these equations reduce to the expressions obtained in Sec. III for $Q=E^2$ with Cartesian coordinates (x,y). When comparing with the approach of Sec. IV using polar coordinates on the sphere or the hyperbolic plane, we must remark the *explicit* appearance of the curvature κ; in polar coordinates κ only appeared in the ‘‘tagged’’ trigonometric functions.

The first set of four equations can be solved for $a=a(u,y)$, $b=b(u,y)$, and $c=c(u,y)$. We have obtained

$$a=\alpha_0\mathrm{C}_\kappa^2(y)+\kappa\alpha_1\mathrm{C}_\kappa^2(y)\mathrm{S}_\kappa(y)+\kappa^2c_0(\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y))^2,$$

$$b=(\tfrac{1}{2})[\beta_0\mathrm{C}_\kappa(y)+\kappa\beta_1\mathrm{C}_\kappa(u)\mathrm{S}_\kappa(u)\mathrm{S}_\kappa(y)],$$

$$c=c_0\mathrm{C}_\kappa^2(u)+c_1\mathrm{C}_\kappa(u)\mathrm{S}_\kappa(u)+a_2\mathrm{S}_\kappa^2(u),$$

where α_0, α_1, β_0, and β_1, are given by

$$\alpha_0=a_0\mathrm{C}_\kappa^2(y)+a_1\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)+a_2\mathrm{C}_\kappa^2(u)\mathrm{S}_\kappa^2(y),$$

$$\alpha_1=b_0\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)-c_1\mathrm{C}_\kappa(u)\mathrm{S}_\kappa(u)\mathrm{S}_\kappa(y),$$

$$\beta_0=b_0\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y)-a_1\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)-c_1\mathrm{C}_\kappa^2(u)\mathrm{S}_\kappa(y)-2a_2\mathrm{C}_\kappa(u)\mathrm{S}_\kappa(u)\mathrm{S}_\kappa(y),$$

$$\beta_1=2c_0\mathrm{C}_\kappa(u)+c_1\mathrm{S}_\kappa(u).$$

TABLE V. Superintegrable potentials with curvature κ: Parallel coordinates.

U^a	$\mathrm{T}_\kappa^2(y)+\dfrac{\mathrm{T}_\kappa^2(2u)}{\mathrm{C}_\kappa^2(y)}$	$\mathrm{T}_\kappa(u)\mathrm{C}_\kappa^2(2u)\mathrm{C}_\kappa^2(y)$	$\dfrac{1}{\mathrm{S}_\kappa^2(y)}$
U^{aa}	$\dfrac{\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(u)}{\sqrt{1-\kappa[\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(u)]^2}}$	$\dfrac{\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y)}{\mathrm{S}_\kappa^2(y)\sqrt{1-\kappa[\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(u)]^2}}$	$\dfrac{1}{\mathrm{S}_\kappa^2(y)}$
U^b	$\mathrm{T}_\kappa^2(y)+\dfrac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)}$	$\dfrac{1}{\mathrm{C}_\kappa^2(y)\mathrm{S}_\kappa^2(u)}$	$\dfrac{1}{\mathrm{S}_\kappa^2(y)}$
U^c	$\left(\mathrm{T}_\kappa^2(y)+\dfrac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)}\right)^{-1/2}$	$\dfrac{\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(u)}{\mathrm{S}_\kappa^2(y)\sqrt{\mathrm{C}_\kappa^2(y)\mathrm{S}_\kappa^2(u)+\mathrm{S}_\kappa^2(y)}}$	$\dfrac{1}{\mathrm{S}_\kappa^2(y)}$
U^d	$\left(\mathrm{T}_\kappa^2(y)+\dfrac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)}\right)^{-1/2}$		
U^e	$\mathrm{T}_\kappa^2(y)+\dfrac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)}$	$\dfrac{\mathrm{S}_\kappa(u)}{\mathrm{C}_\kappa^2(u)\mathrm{C}_\kappa^2(y)}$	$\mathrm{T}_\kappa(y)$

Alternatively, these can also be found by transforming the polar expressions by means of the tensor transformation laws. When $\kappa=0$ these reduce to the Euclidean expressions for a,b,c in Cartesian coordinates.

The explicit form of the integrable and superintegrable potentials are obtained by solving the different particular cases of the equation for $U(u,y)$. We simply remark the relation of the auxiliar variables w_a,z_a and w_c,z_c with the parallel coordinates (u,y) and (v,x) in the general case of curvature κ,

$$w_a=\mathrm{S}_\kappa(y),\quad z_a=\mathrm{T}_\kappa(u),\quad w_c=\mathrm{S}_k(x),\quad z_c=\mathrm{T}_\kappa(v).$$

We omit the details and give directly the results obtained in Table V. These potentials coincide with the expressions obtained in Sec. IV A in polar coordinates. This can be checked directly by making use of the geometrical relations given in Sec. II. For most potentials, the expressions in parallel coordinates are much less transparent than in polar ones, though the 2:1 anisotropic oscillator U_1^a and the potential U_3^e are simpler here. We recall that the potentials in the families $\tilde{U}^a$, $\tilde{U}^{aa}$, $\tilde{U}^c$, and $\tilde{U}^e$ are obtained from U^a, U^{aa}, U^c, and U^e simply by reflection in the geodesic $x=y$. This reflection maps the parallel coordinate system (u,y) into the parallel system (v,x); therefore the expression for these ''tilded'' potentials is obtained from their ''untilded'' family in Table V by the replacements $u\leftrightarrow v$, $y\leftrightarrow x$.

V. DISCUSSION OF RESULTS AND COMMENTS

When using the three distances r, x, y, from P to O, l_2, and l_1, and the two distances u, v, between O and the orthogonal projection of P on l_1, and l_2, the families of potentials can be rewritten in the ''simplest'' way as follows:

$$U^a=k_0+k_1\left(\mathrm{T}_\kappa^2(y)+\frac{\mathrm{T}_\kappa^2(2u)}{\mathrm{C}_\kappa^2(y)}\right)+k_2\mathrm{T}_\kappa(u)\mathrm{C}_\kappa^2(2u)\mathrm{C}_\kappa^2(y)+k_3\frac{1}{\mathrm{S}_\kappa^2(y)},$$

$$U^{aa}=k_0+k_1\mathrm{T}_\kappa(x)+k_2\frac{\mathrm{C}_\kappa(v)}{\mathrm{S}_\kappa^2(y)}+k_3\frac{1}{\mathrm{S}_\kappa^2(y)},$$

$$U^b=k_0+k_1\mathrm{T}_\kappa^2(r)+k_2\frac{1}{\mathrm{S}_\kappa^2(x)}+k_3\frac{1}{\mathrm{S}_\kappa^2(y)},$$

$$U^c = k_0 + k_1 \frac{1}{\mathrm{T}_\kappa(r)} + k_2 \frac{\mathrm{S}_\kappa(x)}{\mathrm{S}_\kappa(r)\mathrm{S}_\kappa^2(y)} + k_3 \frac{1}{\mathrm{S}_\kappa^2(y)},$$

$$U^d = k_0 + k_1 \frac{1}{\mathrm{T}_\kappa(r)},$$

$$U^e = k_0 + k_1 \mathrm{T}_\kappa^2(r) + k_2 \frac{\mathrm{S}_\kappa(u)}{\mathrm{C}_\kappa^2(r)} + k_3 \mathrm{T}_\kappa(y).$$

These potentials extend, and include as a particular case, the Euclidean expressions obtained in Sec. III for $\kappa=0$.

The use of the curvature κ as a parameter has lead to an unified approach that highlights some facts which would be more difficult to appreciate with a separate analysis of the three spherical, Euclidean and hyperbolic cases. Contractions are built-in in the procedure, so there is not any additional need to consider separately the study of contraction of spherical or hyperbolic superintegrable potentials to the Euclidean ones. We now make several comments which are grouped in two sets. First, in Sec. A, we give some comments on the potentials we have obtained, and then, in the following subsections, a group of observations of somewhat broader scope.

A. Comments on the potentials obtained

(a) The results we have obtained give several families of potentials which remain superintegrable when the configuration space curvature κ varies and which are not trivial in the flat limit (here simply described as the particular case $\kappa=0$). We are not implying that these families must be considered as a *complete and not redundant* set of families of superintegrable potentials with quadratic constants of motion on 2D spaces of constant curvature (see below).

(b) There are two *central* potentials for any value of the curvature, either on the sphere and on the hyperbolic plane. The potential

$$U_K = -kU_1^c = -kU_1^d = -\frac{k}{\mathrm{T}_\kappa(r)}, \quad k>0$$

is the ''Kepler potential,'' which on the sphere was first studied by Schrödinger in Ref. 25. Likewise, the potential

$$U_{HO} = (\tfrac{1}{2})k^2 U_1^b = (\tfrac{1}{2})k^2 U_1^e = (\tfrac{1}{2})k^2 \mathrm{T}_\kappa^2(r)$$

plays the role of the ''harmonic oscillator'' on either the sphere or the hyperbolic plane. The spherical version was studied by Higgs in Ref. 26 and is known as the Higgs oscillator.

(c) All other potentials found appear to be ''noncentral'' in the sense they depend not only on the distance to the origin point, but also on the angular coordinate. However, a function involving ϕ may turn out depending only on the distance to some given point (not the origin). This is what happens in the case $\kappa>0$ (sphere) with the two potentials, $U_3^a = 1/(\mathrm{S}_\kappa(r)\sin\phi)^2 = 1/\mathrm{S}_\kappa^2(y)$ and $U_3^e = \mathrm{T}_k(y)$. These two particular potentials, that depend only on x or on y, can be considered as ''central'' if this is understood as ''depending on the distance to some fixed point in the sphere,'' not necessarily the coordinate origin. Notice that this property is a consequence of the geometric properties of S^2. Thus it is not true for the Euclidean or the hyperbolic cases.

(d) The spherical and hyperbolic families U^b and U^c, whose potentials are three parametrical superintegrable deformations of the harmonic oscillator and of the ''Kepler problem'' appear, e.g., in Grosche–Pogosyan Refs. 14–16. In the spherical case these are the only previously known families.

(e) An interesting—and as far as we know, new—outcome is the existence of superintegrable spherical and hyperbolic versions of the Euclidean anisotropic 2:1 oscillator $4x^2+y^2$ (or x^2+4y^2). They are the two potentials U_1^a, (or $\tilde{U}_1^a$),

$$U_1^a=\frac{1}{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}\left[4\left(\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right)^2+(\mathrm{S}_\kappa(r)\sin\phi)^2\right]=\mathrm{T}_\kappa^2(y)+\frac{\mathrm{T}_\kappa^2(2u)}{\mathrm{C}_\kappa^2(y)},$$

$$\tilde{U}_1^a=\frac{1}{1-\kappa(\mathrm{S}_\kappa(r)\cos\phi)^2}\left[(\mathrm{S}_\kappa(r)\cos\phi)^2+4\left(\frac{\mathrm{T}_\kappa(r)\sin\phi}{1-\kappa(\mathrm{T}_\kappa(r)\sin\phi)^2}\right)^2\right]=\mathrm{T}_\kappa^2(x)+\frac{\mathrm{T}_\kappa^2(2v)}{\mathrm{C}_\kappa^2(x)}.$$

These two functions both have the correct Euclidean limit, i.e., $\lim_{\kappa\to 0} U_1^a=r^2(4\cos^2\phi+\sin^2\phi)=4x^2+y^2$ and $\lim_{\kappa\to 0}\tilde{U}_1^a=r^2(\cos^2\phi+4\sin^2\phi)=x^2+4y^2$. However, their structure in polar coordinates is complicated, and do not reduce to a radial harmonic oscillator with a purely angular modulation as it is in the flat case. If the Higgs isotropic oscillator $U_1^b=\mathrm{T}_\kappa^2(r)$ is rewritten as $U_1^b=[\mathrm{T}_\kappa^2(r)/Z_1]Z_2$ with $Z_1=1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2$, $Z_2=\cos^2\phi+\mathrm{C}_\kappa^2(r)\sin^2\phi$, then the changes required to obtain the superintegrable 2:1 anisotropic oscillator are, not only the numerical coefficient 4 (as is the case in E^2), but also the κ-dependent function $1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2$ in the denominator of one of the two summands of Z_2. It is important to notice that the same process is easier in parallel coordinates; starting from the Higgs oscillator $U_1^b=\mathrm{T}_\kappa^2(r)=\mathrm{T}_\kappa^2(u)/\mathrm{C}_\kappa^2(y)+\mathrm{T}_\kappa^2(y)$, the replacement of u by $2u$ as the argument of the function $\mathrm{T}_\kappa(u)$ gives directly the 2:1 anisotropic oscillator.

(f) The family U^a in the curved case is new. The two families U^b,U^c were already known in either S^2, E^2, H^2, and to the family U^d is rather trivial in the curved case, as it contains only the Kepler potential. Further to these families, we also obtain two additional families of superintegrable potentials, U^{aa} and U^e, which both in the sphere or in the hyperbolic plane are also new. The family U^e includes the Higgs harmonic oscillator and two new superintegrable spherical and hyperbolic potentials whose flat limits are the two linear potentials $r\cos\phi=x$ and $r\sin\phi=y$. The planar family V^a admits two different curved deformations, $U^a(a_0,C_1)$ and $U^{aa}(c_0,C_1)$. Notice that the Euclidean limits of U^a and U^{aa} are given by

$$\lim_{\kappa\to 0} U^a=k_1V_1^a+k_2V_2^a+k_3V_3^a,$$

$$\lim_{\kappa\to 0} U^{aa}=k_1V_2^a+k_2V_3^a+k_3V_3^a,$$

so the potential U^a must be considered as the appropriate ''curved version'' of V^a. Concerning U^{aa} it must be considered, not as a ''curved version'' of V^a taken as a whole, but only of the subspace generated by the the two potentials $V_2^a=x$ and $V_3^a=1/y^2$ (the 2:1 oscillator V_1^a is not present).

(g) In Sec. III we have seen that the ''Stark'' potential $V(x,y)=x$ is superintegrable in E^2 and is linearly compatible with both the nonisotropic oscillator $V_1^a=4x^2+y^2$ and the isotropic one $V_1^e=x^2+y^2$. It is interesting that this potential admits *three* different superintegrable spherical or hyperbolic versions given by

$$U_2^a=\frac{[\mathrm{T}_\kappa(r)/\mathrm{C}_k^2(r)]\cos\phi}{[1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]^2}=\mathrm{T}_\kappa(u)\mathrm{C}_\kappa(2u)\mathrm{C}_\kappa^2(y)\qquad \lim_{\kappa\to 0} U_2^a=r\cos\phi=x,$$

$$U_2^e=\frac{[\mathrm{T}_\kappa(r)/\mathrm{C}_k(r)]\cos\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\sin\phi]^2}}=\frac{\mathrm{S}_\kappa(u)}{\mathrm{C}_\kappa^2(u)\mathrm{C}_\kappa^2(y)}\qquad \lim_{\kappa\to 0} U_2^e=r\cos\phi=x,$$

$$\tilde{U}_3^e=\frac{\mathrm{S}_\kappa(r)\cos\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\cos\phi]^2}}=\mathrm{T}_\kappa(x)\qquad \lim_{\kappa\to 0}\tilde{U}_2^e=r\cos\phi=x.$$

Each of these three constant curvature versions of the linear potential is linearly compatible with one of the two oscillators; U_2^a with the 2:1 nonisotropic oscillator, and U_2^e and $\tilde{U}_3^e$ with the isotropic oscillator.

(h) For any fixed nonconstant potential V in a configuration space of a constant curvature κ, the maximal dimension for the associated parameter subspace appears to be $m=4$, independently of κ. The following four potentials reach the maximal dimension:

$$U_1^b = U_1^e = \mathrm{T}_k^2(r) = \mathrm{T}_\kappa^2(y) + \frac{\mathrm{T}_\kappa^2(2u)}{\mathrm{C}_\kappa^2(y)} \quad (a_0, b_0, c_0; 0,0; a_2),$$

$$U_3^e = \widetilde{U}_1^{aa} = \frac{\mathrm{S}_\kappa(r)\sin\phi}{\sqrt{1-\kappa[\mathrm{S}_\kappa(r)\sin\phi]^2}} = \mathrm{T}_k(y) \quad (a_0, b_0, e_0; a_1, 0; \kappa e_0),$$

$$U_3^a = U_3^b = U_3^c = \frac{1}{\mathrm{S}_\kappa^2(r)\sin^2\phi} = \frac{1}{\mathrm{S}_\kappa^2(y)} \quad (a_0, 0, c_0; 0, c_1; a_2),$$

$$U_1^c = U_1^d = \frac{1}{\mathrm{T}_k(r)} = \left(\mathrm{T}_\kappa^2(y) + \frac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)} \right)^{-1/2} \quad (e_0, 0, e_0; a_1, c_1; a_2).$$

This means that *all* flat superintegrable potentials with the maximal dimension of the associated parameter subspace allow a ''curvature'' version. This remark also accounts for the special role played by these four curvature versions of the flat harmonic oscillator, Kepler potential, linear potential, and centrifugal barrier. The curvature version of the potential $1/y^2$, i.e., $U_3^a = U_3^b = U_3^c = 1/(\mathrm{S}_\kappa(r)\sin\phi)^2 = 1/\mathrm{S}_\kappa^2(y)$, is a very remarkable system endowed with a level of superintegrability compatible with the constant curvature versions of either the oscillator, Kepler problem, and also the anisotropic 2:1 oscillator.

After these particular comments, we now discuss some more general questions.

B. Equivalence

A complete *classification* of superintegrable potentials with constants of motion which are quadratic in the velocities, in either the sphere or the hyperbolic plane would require to introduce some equivalence criteria. We do not intend to do this here, but some remarks may be relevant. From the present point of view a most natural idea is to look a superintegrable family in the space of constant curvature κ, associated with a pair of sets of parameter values (a_i, b_i, c_i) and (A_i, B_i, C_i) as *equivalent* to another one, with parameters (a_i', b_i', c_i') and (A_i', B_i', C_i') if the equation for (a_i, b_i, c_i) (resp. (A_i, B_i, C_i)) is transformed into the equation for (a_i', b_i', c_i') (resp. (A_i', B_i', C_i')) under the regular action of the isometry group of the configuration space. As a consequence, the general potential in the first family is transformed into the general potential in the second family. These transformations preserve the kinetic term, and clearly two families of potentials which can be transformed among themselves by a rigid motion of the configuration space should be considered as essentially equivalent. This has been implicitly done when denoting with a tilde some families which are equivalent in this sense to those without a tilde; the transformation of the configuration space realizing the equivalence is the reflection in the line $x = y$.

Forgetting about the tilded families which are equivalent to the untilded ones, we are left with the families U^a, U^{aa}, U^b, U^c, U^d, U^e, which are all different, and the question of their possible equivalence should be addressed. The classification will produce different results in the three cases $\kappa > 0$, $\kappa = 0$, $\kappa < 0$, and the number of equivalence classes of families should be expected to be largest in the hyperbolic plane $\kappa < 0$. Grosche and Pogosyan give our hyperbolic families U^b, U^c, and three hyperbolic families we have not discussed here, even though it is easy to check that their potentials satisfy the basic equation for suitable choices of pairs of parameter vectors (these are called V_3, V_4, V_5, in Refs. 15, 16). The hyperbolic families U^a, U^{aa}, U^e, do not appear in Refs. 15 and 16. All these hyperbolic families seem to be inequivalent, and there might be still more inequivalent superintegrable families of potentials on the hyperbolic plane.

However, in the spherical $\kappa > 0$ case, the three families U^{aa}, U^c, and U^e are equivalent. The transformation of the configuration space which permutes cyclically the three families, i.e., $U^{aa} \to U^e \to \widetilde{U}^c \to U^{aa}$ ($\widetilde{U}^{aa} \to \widetilde{U}^e \to U^c \to \widetilde{U}^{aa}$), is the spherical rotation which permutes cyclically the three mutually orthogonal coordinate axes in the ambient space (around the center of the positive octant, with an angle of $2\pi/3$). Therefore, as far as equivalence classes, only the four families U^a, U^b, U^c, U^d, must be considered. We strongly believe that these four families are inequivalent. If we restrict ourselves to the particular case where each of the two extra constants of motion is associated to a parameter vector which has a *single* nonzero component in the natural basis $(a_0,b_0,c_0,\ldots)$, like the ones in Table III, then we can state that the four families of potentials we have given *exhaust* this type of superintegrable potentials in the sphere. As the reader can check, the choices (b_0,a_2), (b_0,a_1), and (c_0,a_1) which have been not discussed in the paper, are equivalent on the sphere to some of those discussed (respectively, to U^a, U^d, and U^d).

C. Superintegrable potentials with constant flat limit

In addition to the constant potential $U_0 \equiv 1$, which trivially belongs to all the families of superintegrable potentials, the families U^b, U^e, and $\tilde{U}^e$, contain one nonconstant superintegrable deformation of the trivial planar potential $V_0=1$, and the families U^a, and $\tilde{U}^a$, contain two different (hence a one parameter infinite family) of such nonconstant superintegrable deformations of $V_0=1$. They have the following expressions:

$$U_0^b = U_0^e = \tilde{U}_0^e = \frac{1}{\mathrm{C}_\kappa^2(r)},$$

$$U_{0(\pm)}^a = \frac{1}{[\mathrm{C}_\kappa(r) \pm \sqrt{\kappa}\mathrm{S}_\kappa(r)\cos\phi]^2} = \frac{1}{[\mathrm{C}_\kappa(r) \pm \sqrt{\kappa}\mathrm{S}_\kappa(x)]^2},$$

$$\tilde{U}_{0(\pm)}^a = \frac{1}{[\mathrm{C}_\kappa(r) \pm \sqrt{\kappa}\mathrm{S}_\kappa(r)\sin\phi]^2} = \frac{1}{[\mathrm{C}_\kappa(r) \pm \sqrt{\kappa}\mathrm{S}_\kappa(y)]^2}.$$

These functions represent superintegrable potentials with quadratic integrals (one of them of the Noether class). In the limit $\kappa \to 0$, all of them go into the trivial constant potential,

$$\lim_{\kappa\to 0} U_{0(\pm)}^a = \lim_{\kappa\to 0} \tilde{U}_{0(\pm)}^a = \lim_{\kappa\to 0} U_0^b = U_0 \equiv 1,$$

so each of these potentials can be considered as a nontrivial superintegrable ''curvature version'' of the constant planar potential (notice that in the hyperbolic case $U_{0(\pm)}^a$ and $\tilde{U}_{0(\pm)}^a$ are complex). This property (existence of nontrivial superintegrable dynamics in $Q=S^2$ or $Q=H^2$ reducing to the free motion when $\kappa \to 0$) points out the great level of complexity of the dynamics in configuration spaces of constant curvature.

Each of the potentials $U_{0(\pm)}^a$, $\tilde{U}_{0(\pm)}^a$, and U_0^b can be expressed in terms of the constant potential U_0 and the three ''basic'' solutions U_1, U_2, U_3, within each family. Alternatively, by inverting the former expressions, some of the ''basic solutions'' U_1, U_2, U_3, within each family can be expressed as a ''linear superposition'' of these potentials. In particular, the isotropic and 2:1 anisotropic oscillators can be rewritten in the following form:

$$U_1^b = \mathrm{T}_k^2(r) = \left(\frac{1}{\kappa}\right)(U_0^b - U_0),$$

$$U_1^a = \mathrm{T}_\kappa^2(y) + \frac{\mathrm{T}_\kappa^2(2u)}{\mathrm{C}_\kappa^2(y)} = \left(\frac{1}{\kappa}\right)(U_0^a - U_0),$$

where we have used the notation

$$U_0^a = (\tfrac{1}{2})[U_{0(+)}^a + U_{0(-)}^a]$$

(a similar relation is obtained for $\tilde{U}_1^a$ and $\tilde{U}_{0(\pm)}^a$). Thus, the isotropic and the anisotropic 2:1 oscillator potentials in a curved configuration space are proportional to the difference between two superintegrable potentials in the same family and with a common Euclidean limit.

The right-hand side of the above two expressions is well defined even for $\kappa \to 0$. This can be checked directly in these particular examples, but it is indeed a *general* property. If two superintegrable potentials U_1, U_2 in a configuration space of constant curvature κ are in the same family of superintegrable potentials (characterized by a given pair of sets of parameter vectors), and have the same Euclidean limit, $\lim_{\kappa\to 0} U_1 = \lim_{\kappa\to 0} U_2$, then we can write an expansion for the difference $U_1 - U_2$ in powers of κ, which starts in the linear term

$$U_1 - U_2 = \kappa\left(\left[\frac{dU_1}{d\kappa}\right]_{\kappa=0} - \left[\frac{dU_2}{d\kappa}\right]_{\kappa=0}\right) + O(\kappa^2).$$

Hence the function V_{12} given by

$$V_{12} = \lim_{k\to 0}\left[\left(\frac{1}{\kappa}\right)(U_1 - U_2)\right] = \left[\frac{dU_1}{d\kappa}\right]_{\kappa=0} - \left[\frac{dU_2}{d\kappa}\right]_{\kappa=0}$$

is well defined and superintegrable in E^2, with the same pair of parameter vectors as U_1, U_2. For the two families, U^b and U^a, the Euclidean potential V_{12} represent the isotropic oscillator in the first case ($U_1 = U_0^b$, $U_2 = U_0$) and the anisotropic 2:1 in the second case ($U_1 = U_0^a$, $U_2 = U_0$). So, in a sense, these two well-known superintegrable Euclidean oscillators can be considered as a kind of ''residue'' in E^2 of the existence of different superintegrable potentials in configuration spaces of constant curvature within the same family and with the same Euclidean limit.

D. ''Correspondence'' between potentials on constant nonzero and zero curvature spaces

Our procedure gives directly a correspondence between *superintegrable* potentials in the nonzero curvature spaces and in the flat Euclidean space. All superintegrable flat potentials in the families V^a, V^b, V^c, V^e, admit a superintegrable ''curvature'' version on either the sphere and the hyperbolic plane. This property fails for the flat family V^d, where we have not found any curvature version of the superintegrable potentials V_2^d, V_3^d. If such curvature version exists, it should necessarily be associated with *mixed* parameter vectors, which should exhibit an explicit dependence of the curvature κ similar to the one found in the energy.

A somewhat surprising result is that a flat superintegrable potential may have several *different* ''curvature versions'' which still are *superintegrable*. For the constant potential $V_0 = 1$ this has been already discussed in the previous paragraph. But once at least two (and then a one-parameter infinity of) different superintegrable versions of the constant potential exists in a given superintegrable family, each of their members admits also a one-parameter infinity of different ''curvature versions'' of the same flat potential, all of which belong to the same family. If we drop the requirement of being in the same family, there are even more examples of *different* curvature versions of the same flat potential. For instance, U_2^a, U_2^e, and $\tilde{U}_3^e$, are all superintegrable curved versions of the linear flat potential $V = x$.

Given a potential $V = V(r,\phi)$ in E^2 we can construct many different potentials in the space of constant curvature κ ($Q = S^2$ or $Q = H^2$), $U = U(r,\phi;\kappa)$ with V as a Euclidean limit, i.e., $\lim_{\kappa\to 0} U = V$. Additional requirements may successively narrow the choice; for instance, if V is integrable (superintegrable) in E^2, we may require U to be integrable (superintegrable) in S^2 or H^2 and so on. As an example, let us consider the general anisotropic planar oscillator, $V = Ax^2 + By^2$. Consider the two following spherical or hyperbolic potentials:

$$\frac{A\mathrm{T}_\kappa^2(r)\cos^2\phi + B\mathrm{S}_\kappa^2(r)\sin^2\phi}{1 - \kappa(\mathrm{S}_\kappa(r)\sin\phi)^2} = A\frac{\mathrm{T}_\kappa^2(u)}{\mathrm{C}_\kappa^2(y)} + B\mathrm{T}_\kappa^2(y),$$

$$\frac{A\mathrm{S}_\kappa^2(r)\cos^2\phi+B\mathrm{T}_\kappa^2(r)\sin^2\phi}{1-\kappa(\mathrm{S}_\kappa(r)\cos\phi)^2}=A\mathrm{T}_\kappa^2(x)+B\frac{\mathrm{T}_\kappa^2(v)}{\mathrm{C}_\kappa^2(x)}.$$

Both are integrable, with constant of motion associated with a_0 and c_0, respectively, and they are apparently reasonable spherical/hyperbolic versions of the general anisotropic planar oscillator V in the sense that both satisfy the correct Euclidean limit, i.e., Ax^2+By^2, and they reduce to the spherical/hyperbolic harmonic oscillator $\mathrm{T}_\kappa^2(r)$ when $B=A$. Nevertheless if we look for *superintegrable* spherical/hyperbolic versions of the general anisotropic planar oscillator, we must reject these candidates in S^2 and H^2 since they are integrable but not superintegrable, and the orbits will be open curves. The appropriate superintegrable spherical/hyperbolic versions of the oscillators $(A=4,\ B=1)$ and $(A=1,\ B=4)$ are the potentials U_1^a and $\tilde{U}_1^a$. As far as we know, whether or not there exists superintegrable $\kappa\neq0$ versions of the special known cases of superintegrable anisotropic planar potentials (with nonquadratic constants of motion) is an open problem.

E. Coordinate systems and superintegrability

The approach we have presented here can be compared with the search for superintegrable potentials by requiring separation in at least two of those coordinate systems which allow complete separation of variables for the Laplace–Beltrami equation. This requirement for the potential turns out to be equivalent to satisfying the differential equation for the potential U for some choice of the parameter vector. Therefore, the nontrivial parameter vectors are in correspondence with the possible coordinate systems of the required type. In the simplest cases, this is clear from the expressions we have given; a potential which satisfies the a_2 (resp. a_0, c_0) equation separates in the polar (r,ϕ) coordinates (resp. in the parallel system (u,y), (x,v)). If one starts from the flat case, several coordinate systems which are *different* whenever $\kappa\neq0$ (actually, all those associated to the parameter vectors $\{a_0,0,c_0;00;0\}$) coalesce into a single very ''degenerate'' Cartesian system. Therefore the analysis of superintegrability in terms of separability in several coordinate systems should be better done in the generic $\kappa\neq0$ case, where the coordinate systems which coalesce in the $\kappa=0$ case are still different.

Degenerate Frobenius manifolds and the bi-Hamiltonian structure of rational Lax equations

I. A. B. Strachan[a)]
Department of Mathematics, University of Hull, Hull, HU6 7RX, England

(Received 25 March 1999; accepted for publication 20 May 1999)

The bi-Hamiltonian structure of certain multicomponent integrable systems, generalizations of the dispersionless Toda hierarchy, is studied for systems derived from a rational Lax function. One consequence of having a rational rather than a polynomial Lax function is that the corresponding bi-Hamiltonian structures are degenerate, i.e., the metric that defines the Hamiltonian structure has a vanishing determinant. Frobenius manifolds provide a natural setting in which to study the bi-Hamiltonian structure of certain classes of hydrodynamic systems. Some ideas on how this structure may be extended to include degenerate bi-Hamiltonian structures, such as those given in the first part of the paper, is given. © *1999 American Institute of Physics.* [S0022-2488(99)02210-0]

I. INTRODUCTION

Poisson brackets of a hydrodynamic type were introduced by Dubrovin and Novikov in Ref. 1, where they gave a complete description of Poisson brackets of the form

$$\{u^i(x),u^j(y)\}=g^{ij}[u(x)]\,\delta'(x-y)+\Gamma^{ij}_k[u(x)]u^k(x)\,\delta(x-y), \tag{1}$$

under the nondegenerate condition $\det(g^{ij})\neq 0$. This defines a skew-symmetric Poisson bracket on functionals,

$$\{I,J\}=\int dx\,\frac{\delta I}{\delta u^i(x)}\widehat{A^{ij}}\frac{\delta J}{\delta u^j(x)},$$

where

$$\widehat{A^{ij}}=g^{ij}[u(x)]\,\frac{d}{dx}+\Gamma^{ij}_k[u(x)]u^k_x(x).$$

The conditions on g^{ij} and Γ^{ij}_k necessary in order for (1) to define a Hamiltonian structure, under the nondegenerate condition $\det(g^{ij})\neq 0$, have a natural geometric interpretation.[1]

Theorem 1: *Under the nondegenerate condition* $\det(g^{ij})\neq 0$, *the bracket* (1) *defines a Hamiltonian structure if and only if (a)* $\mathbf{g}=(g^{ij})^{-1}$ *defines a (pseudo-) Riemannian metric; (b)* $\Gamma^{ij}_k=-g^{is}\Gamma^j_{sk}$, *where* Γ^j_{sk} *are the Christoffel symbols of the Riemannian connection defined by* $\mathbf{g}$; *(c) the Riemann curvature tensor of* $\mathbf{g}$ *vanishes*.

This result, and its interpretation in terms of differential geometry, rests on the nondegeneracy condition on the metric. However, this is not a necessary condition for (1) to define a Hamiltonian structure and the full result, with no *a priori* restriction on g^{ij} was derived by Grinberg[2] and Dorfmann.[3]

Theorem 2: *The bracket* (1) *defines a Hamiltonian structure if and only if the pair* (g,Γ) *satisfy the conditions*

[a)]Electronic mail: i.a.b.strachan@hull.ac.uk

$$g^{ij} = g^{ji}; \tag{2}$$

$$\frac{\partial g^{ij}}{\partial u^k} = \Gamma_k^{ij} + \Gamma_k^{ji}; \tag{3}$$

$$g^{ij}\Gamma_i^{rs} = g^{ri}\Gamma_i^{js}; \tag{4}$$

$$\Gamma_t^{ij}\Gamma_r^{tk} - \Gamma_t^{ik}\Gamma_r^{tj} = g^{ti}\left(\frac{\partial\Gamma_r^{jk}}{\partial u^t} - \frac{\partial\Gamma_t^{jk}}{\partial u^r}\right), \tag{5}$$

and

$$\sum_{\text{cyclic sum on } i,j,k}\left[\left(\frac{\partial\Gamma_t^{ij}}{\partial u^q} - \frac{\Gamma_q^{ij}}{\partial u^t}\right)\Gamma_r^{tk} + \left(\frac{\partial\Gamma_t^{ij}}{\partial u^r} - \frac{\Gamma_r^{ij}}{\partial u^t}\right)\Gamma_q^{tk}\right] = 0. \tag{6}$$

If $\det g^{ij} \neq 0$ *then the last equation is a consequence of the earlier equations.*
[*N.B.:* there is a minor error in Ref. 2 in the order of the indices in Eq. (4)]. In this more general situation it is not possible to give a clear geometric interpretation of these equations. They define an integrable distribution, but their differential geometric content is less clear. One can define a covariant derivative-like object,

$$\nabla^i \xi^j = \partial^i \xi^j - \Gamma_k^{ij}\xi^k,$$

where $\partial^i = g^{ij}\partial_j$, with the property (when suitably extended to tensors) that $\nabla^i g^{jk} = 0$, though the ''connection'' cannot be defined in terms of the ''metric.'' With such a covariant derivative one can introduce a ''curvature'' by the equation

$$(\nabla^r\nabla^s - \nabla^s\nabla^r)\xi^t = -R_k^{rst}\xi^k,$$

and the third equation above is now just the vanishing of this curvature. Such a description is not very natural; one cannot lower indices and the interpretation of the last equation remains unclear. However, the terms ''metric'' and ''connection'' will be used to denote these objects, and a pair satisfying these equations will be called a (g,Γ) pair.

Our purpose in this paper is to study the bi-Hamiltonian structure of dispersionless integrable systems defined by the Lax equation (the variables τ_n will be used to denote the times, t being reserved for flat coordinates in which the components η^{ij} are constants),

$$\frac{\partial\mathcal{L}}{\partial\tau_n} = \{(\mathcal{L}^{n/(N-M)})_+, \mathcal{L}\}_{PB} \tag{7}$$

where $\{f,g\}_{PB} = p(\partial_p f\,\partial_x g - \partial_x f\,\partial_p g)$, $\mathcal{L}$ is given by a rational function,

$$\mathcal{L} = \frac{\text{polynomial of degree } N}{\text{polynomial of degree } M}$$

with the single constraint $N > M$, and $(\quad)_+$ denotes the projection onto non-negative powers of p under a formal expansion in powers of p. In an earlier paper[4] this system was studied but a complete description of the Hamiltonian structure was not given. The simplest example of such a system is the continuum Toda equations

$$S_\tau = P_x,$$

$$P_\tau = PS_x, \tag{8}$$

which is generated for the above Lax equation (7) with a Lax function

$$\mathcal{L}=p^2+S(x,t)+\frac{P(x,t)}{p}.$$

This paper aims to extend these earlier results from polynomial Lax functions to rational Lax functions and to relate these results to the theory of Frobenius manifolds.[5] It will turn out that in the rational case the Hamiltonian structure is degenerate, so the more general description of Grinberg and Dorfmann will have to be utilized to give a complete description of the bi-Hamiltonian structure of the hierarchy. This in turn implies that a new concept of a degenerate Frobenius manifold is required.

In the next section a summary of the pertinent result of Ref. 4 will be given, and this will also serve to fix the notation used. Full details will not be given and the reader should consult the earlier paper for the proofs. In Sec. III the polynomial case will be studied in more detail (and this will relate the results of Ref. 4 to more recent work of Dubrovin and Zhang[6]) before the full rational case is studied in Sec. IV. The properties of a degenerate Frobenius manifold are introduced by way of an extended example in Sec. V.

Throughout this paper various different coordinate systems will be used, and the resulting transformations from one system to another will be important. The notation $g^{ij}(s)$ will be used to denote the components of the metric in the s^i-coordinate system, so the transformation from s^i to t^i coordinates will be written

$$g^{ij}(t)=\frac{\partial t^i}{\partial s^p}\frac{\partial t^j}{\partial s^q}g^{pq}(s),$$

rather than using different fonts and alphabets for the different coordinate systems.

II. CONSERVATION LAWS AND EVOLUTION EQUATIONS

In order to study rational functions it is convenient, and indeed necessary in order to obtain some results, to factorize the numerator and denominator of the rational function, so

$$\mathcal{L}=\frac{\Pi_{i=1}^{N}(p+u^i)}{\Pi_{i=N+1}^{N+M}(p+u^i)},$$

$$=\prod_{i=1}^{N+M}(p+u^i)^{\varepsilon_i}.$$

Here it will be assumed that $\varepsilon_i=\pm 1$ and that the numerator and denominator have no common root. With these conditions and $N>M$ the Lax function is of the general form

$$\mathcal{L}=\text{polynomial of degree }(N-M)+\sum_{i=N+1}^{N+M}\text{ simple poles.}$$

Such a factorization of the Lax function was introduced by Kupershmidt[7] (though this could also be viewed as a Vieté transformation) and the variables u^i will be called modified variables. One advantage of such a factorization is that it puts all the fields on an egalitarian footing, i.e., the permutation group S^N acts on the zeros of $\mathcal{L}$ and the permutation group S^M acts on the roots of $\mathcal{L}$, and this drastically reduces the complexity of the calculations.

The flows are given by the Lax equation (7) which may be calculated explicitly

$$u^i_{\tau_n}=A_i^{(n)}u^i_x+\sum_{j\neq i}u^iB_{ij}^{(n)}u^j_x, \tag{9}$$

where

$$A_i^{(n)}=\left(\frac{\varepsilon_i n}{N-M}-1\right)\sum_{\{r_j:\Sigma_{j=1}^{N+M}r_j=n\}}\left[\prod_{\substack{k=1\\k\neq i}}^{N+M}\binom{\frac{\varepsilon_k n}{N-M}}{r_k}(u^k)^{r_k}\right]\binom{\frac{\varepsilon_i n}{N-M}-2}{r_i-1}(u^i)^{r_i}$$

and

$$B_{ij}^{(n)}=\frac{\varepsilon_j n}{N-M}\sum_{\{r_j:\Sigma_{j=1}^{N+M}r_j=n-1\}}\left[\prod_{\substack{k=1\\k\neq i,j}}^{N+M}\binom{\frac{\varepsilon_k n}{N-M}}{r_k}(u^k)^{r_k}\right]\binom{\frac{\varepsilon_i n}{N-M}-1}{r_i}(u^i)^{r_i}\binom{\frac{\varepsilon_j n}{N-M}-1}{r_j}(u^j)^{r_j}.$$

Care has to be taken in evaluating the binomial coefficients for negative and fractional numbers. These must be interpreted in terms of Γ-function, so

$$\binom{a}{b}=\frac{\Gamma(a+1)}{\Gamma(a-b+1)\Gamma(b+1)}.$$

It also follows from the proof of these results (though not explicitly mentioned in Ref. 4) that

$$\mathcal{C}=\mathcal{L}|_{p=0},$$

$$=\prod_{i=1}^{M+N}(u^i)^{\varepsilon_i}$$

is independent of all the times, i.e.,

$$\frac{\partial\mathcal{C}}{\partial\tau_n}=0\qquad n=1,...,\infty.$$

The functions $\mathcal{C}$ will turn out to be a Casimir for the bi-Hamiltonian structure of this hierarchy.

Conservation laws are similarly defined, the conserved charges being given by

$$Q^{(n)}=\frac{1}{2\pi i}\oint\mathcal{L}^{n/(N-M)}\frac{dp}{p}. \tag{10}$$

These may be derived explicitly

$$Q^{(n)}=\sum_{\{r_i:\Sigma_{i=1}^{N+M}r_i=n\}}\left\{\prod_{i=1}^{N+M}\binom{\frac{\varepsilon_i n}{N-M}}{r_i}(u^i)^{r_i}\right\}.$$

Under a suitable change of variable, these polynomials take the form of generalized hypergeometric functions, a result which remains to be exploited. The corresponding functionals

$$H^{(n)}=\int Q^{(n)}dx \tag{11}$$

will turn out to be the Hamiltonians of the system (9).

III. POLYNOMIAL LAX EQUATIONS

In this section the bi-Hamiltonian structure of the hierarchy defined by a Lax function,

$$\mathcal{L}=p^{-M}\prod_{i=1}^{N}(p+u_i),\quad 0<M<N,$$

will be derived, this generalizing the results of Ref. 4, where the special case $M=1$ was studied. Having derived one Hamiltonian structure, the intersection form in the language of a Frobenius manifold, one may use a result of Dubrovin to find a second compatible Hamiltonian structure.

Proposition 3: The Hamiltonian structure of the hierarchy defined by Eq. (7) is given by the nondegenerate metric,

$$g^{ij}(u)=\begin{cases}[1-(N-M)]u^iu^i, & \text{if } i=j,\\ u^iu^j, & \text{if } i\neq j.\end{cases}\tag{12}$$

Comment: This is clearly a flat, nondegenerate metric, and so defines a Hamiltonian structure. What is less clear is whether this structure, coupled to the Hamiltonians given by (11), gives rise to the flows defined by (7). This may be shown to be the case by direct calculation. An alternative proof, viewing the polynomial as a reduction of the rational case, will follow from the Theorem 7 in Sec. IV.

A bi-Hamiltonian structure is more than just two Hamiltonian structures; the two structures $\{,\}_1$ and $\{,\}_2$ have to be compatible, i.e., $\{,\}=\{,\}_1+\lambda\{,\}_2$ must be a Hamiltonian structure for all values of λ. For nondegenerate Poisson brackets of a hydrodynamic type, this compatibility condition implies that, for arbitrary λ, (a) the metric $g^{ij}=g_1^{ij}+\lambda g_2^{ij}$ is flat (such a metric is sometimes referred to as a flat pencil); (b) the metric connection for this metric has the form $\Gamma_k^{ij}=\Gamma_{1k}^{ij}+\lambda\Gamma_{2k}^{ij}$.

A result of Dubrovin[5] (actually a special case of a more general result of Magri[8]) will enable the bi-Hamiltonian structure to be found.

Lemma 4: If for a flat metric in some coordinate system $x^1,\ldots,x^n$, both the components $g^{ij}(x)$ of the metric and $\Gamma_k^{ij}(x)$ of the corresponding metric connection depend linearly on the coordinate $x^{\bullet}$, then the metrics,

$$g_1^{ij}=g^{ij},$$

$$g_2^{ij}=\partial_{\bullet}g^{ij},$$

form a flat pencil, under the assumption that $\det[g_2^{ij}]\neq 0$. *The corresponding metric connection has the form*

$$\Gamma_{1k}^{ij}=\Gamma_k^{ij},$$

$$\Gamma_{2k}^{ij}=\partial_{\bullet}\Gamma_k^{ij}.$$

The proof of this result is straightforward, and an alternative proof to that given in Ref. 5 will follow from a result given in the next section where this lemma is extended to degenerate Hamiltonian structures.

In order to find such a coordinate system, it is necessary to perform a number of coordinate transformations on the metric (12). This will be achieved in two stages. First, define variables,[6]

$$z^1=+x^1,$$

$$z^i=+x^i-x^{i-1},\quad i=1,\ldots,N-1,$$

$$z^N=-x^{N-1}$$

(so $\Sigma_{i=1}^{N} z^i = 0$), and then

$$u^i = e^{(1/N)x^N - z^i}, \quad i = 1,...,N.$$

Such a coordinate transformation has a nature interpretation in terms of the Weyl group $W(A_{N-1})$, which act by permutation of the coordinates z^i on the hyperplane $\Sigma_{i=1}^{N} z^i = 0$. In this x-coordinate system the components of the metric become, up to an overall factor of $(M-N)$,

$$g^{ij}(x) = \left(\begin{array}{ccccc|c} 2 & -1 & 0 & \cdots & 0 & 0 \\ -1 & 2 & -1 & \cdots & 0 & 0 \\ 0 & -1 & 2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 2 & 0 \\ \hline 0 & 0 & 0 & \cdots & 0 & -\dfrac{M}{N(N-M)} \end{array} \right) = \left(\begin{array}{c|c} \text{Cartan matrix of } A_{N-1} & 0 \\ \hline 0 & -d_M^{-1} \end{array} \right).$$

The final entry is defined naturally using the Weyl group structure on A_{N-1},

$$\begin{aligned} d_M &= \frac{M(N-M)}{N}, \\ &= (\omega_M, \omega_M), \end{aligned}$$

where (,) is the Euclidean inner product and ω_i are the fundamental weights.[6]

What these coordinate transformation show is that the Hamiltonian structure coincides with those found by Dubrovin and Zhang, so their results may be used to complete the second part of this argument. In particular, they show that in terms of the symmetric functions,

$$\begin{aligned} s^1 &= \sum_i u^i, \\ s^2 &= \sum_{i<j} u^i u^j, \\ &\vdots \qquad \vdots \\ s^N &= \prod_i u^i, \end{aligned}$$

the metric (12) will be linear in the variable s^M, and hence Lemma 4 may be used to find the bi-Hamiltonian structure. The Jacobian of this transformation from modified to the original variables is just the Vandemonde determinant,

$$\frac{\partial(s^1,\ldots,s^N)}{\partial(u^1,\ldots,u^N)} = \left| \begin{array}{cccc} 1 & 1 & \cdots & 1 \\ \sum_{i\neq 1} u^i & \sum_{i\neq 2} u^i & \cdots & \sum_{i\neq N} u^i \\ \vdots & \vdots & \ddots & \vdots \\ \prod_{i\neq 1} u^i & \prod_{i\neq 2} u^i & \cdots & \prod_{i\neq N} u^i \end{array} \right| = \prod_{i<j} (u^i - u^j).$$

This defines the discriminant hypersurface, a caustic, on which $\mathcal{L}$ has multiple roots. By assumption $\varepsilon_i = \pm 1$, so all the roots are simple and hence the fields are well defined away from this surface. Hence Ref. 6.

Lemma 5 The metric (12), *when written in terms of the symmetric variables s^i, is linear in the variable s^M.*

Before performing these calculations one should note that in terms of these symmetric variables, the Lax function takes the more familiar form,

$$\mathcal{L} = p^{-M}[p^N + p^{N-1}s^1 + \cdots + s^N],$$

these symmetric variables coinciding with the original, unmodified variables. It also follows from the Lax equation (7) that the variable s^M is special for another reason, namely, it is the single variable for which the conserved charges $Q^{(n)}$ obey the relation

$$Q^{(n-1)} = \text{const}\,\frac{\partial Q^{(n)}}{\partial_s M}.$$

Proposition 6: The first Hamiltonian structure, in terms of the modified variables, is given by

$$\eta^{ij}(u) = \mathcal{L}_{\partial/\partial s^\bullet} g^{ij}(u),$$

$$= \frac{\partial}{\partial s^\bullet} g^{ij} - \frac{\partial \alpha^i_\bullet}{\partial u^k} g^{kj} - \frac{\partial \alpha^j_\bullet}{\partial u^k} g^{ik},$$

where the functions $\alpha^i_\bullet(u)$ are defined by

$$\frac{\partial}{\partial s^\bullet} = \alpha^i_\bullet(u)\,\frac{\partial}{\partial u^i},$$

and $\mathcal{L}_{\partial/\partial s^\bullet}$ is the Lie derivative along the vector field $\partial/\partial s^\bullet$.

Proof: The transformation between the modified variables and the symmetric variables induces the transformation

$$\begin{pmatrix} \dfrac{\partial}{\partial u^1} \\ \vdots \\ \dfrac{\partial}{\partial u^N} \end{pmatrix} = \begin{pmatrix} 1 & \sum_{j\neq 1} u^j & \cdots & \prod_{j\neq 1} u^j \\ \vdots & \vdots & \ddots & \vdots \\ 1 & \sum_{j\neq N} u^j & \cdots & \prod_{j\neq N} u^j \end{pmatrix} \begin{pmatrix} \dfrac{\partial}{\partial s^1} \\ \vdots \\ \dfrac{\partial}{\partial s^N} \end{pmatrix},$$

and hence by inverting the Vandemonde determinant,

$$\frac{\partial}{\partial s^\bullet} = \alpha^i_\bullet(u)\,\frac{\partial}{\partial u^i},$$

this defining the functions $\alpha^i_\bullet(u)$. By Lemmas 4 and 5, it follows, by starting with the metric (12) in the u^i variables, transforming to the s^i variables, differentiating with respect to $s^\bullet$, and then transforming back to the u^i variables, that

$$\eta^{ij}(u) = \frac{\partial u^i}{\partial s^m}\frac{\partial u^j}{\partial s^n}\frac{\partial}{\partial s^\bullet}\left[\frac{\partial s^m}{\partial u^r}\frac{\partial s^n}{\partial u^s} g^{rs}(u)\right]$$

is the required flat metric, which defines the second Hamiltonian structure. Expanding yields

$$\eta^{ij}(u)=\frac{\partial}{\partial s^{\bullet}}g^{ij}+\frac{\partial u^i}{\partial s^m}\left(\frac{\partial}{\partial s^{\bullet}}\frac{\partial s^m}{\partial u^r}\right)g^{rj}+\frac{\partial u^j}{\partial s^n}\left(\frac{\partial}{\partial s^{\bullet}}\frac{\partial s^n}{\partial u^s}\right)g^{is}.$$

But

$$\left[\frac{\partial}{\partial s^{\bullet}},\frac{\partial}{\partial u^k}\right]=\left[\alpha^i_{\bullet}\frac{\partial}{\partial u^i},\frac{\partial}{\partial u^k}\right],$$
$$=-\frac{\partial\alpha^j_{\bullet}}{\partial u^k}\frac{\partial}{\partial u^j}.$$

This, together with the definition of the Lie derivative and

$$\frac{\partial s^{\beta}}{\partial s^{\bullet}}=\delta^{\beta}_{\bullet},$$

yields the result.

□

This proposition is just an application of Magri's more general result.[8]

Example 1: For arbitrary N and $M=1$ the distinguished coordinate is s^N (so $\bullet=N$ in the above formulas) and the functions α^i_N are

$$\alpha^i_N=\frac{u^i}{\Pi_{r\neq i}(u^N-u^r)},$$

and hence one may calculate η^{rs} explicitly:

$$\eta^{ij}(u)=(N-1)\frac{u^iu^j}{u^i-u^i}[\alpha^i_N-\alpha^j_N],\quad r\neq s,$$

$$\eta^{ii}(u)=2(N-1)\frac{(u^i)^2}{\Pi_{k\neq i}(u^i-u^k)}\left[1-u^i\sum_{n\neq i}\frac{1}{u^i-u^n}\right].$$

This, together with (12), *constitutes the bi-Hamiltonian structure for the hierarchy* (7), *also known as the continuum Toda hierarchy.*

If $N=2$, then

$$\eta^{ij}(u)=\frac{uv}{(u-v)^2}\begin{pmatrix}-2u & u+v\\ u+v & -2v\end{pmatrix}.$$

This example also shows an interesting result of the transformation from the original to the modified variables; in the original variables the form of g^{ij} is more complicated than the form of η^{ij} while in the modified variables the complexities are interchanged.

These results depend crucially on the properties of d_M. To see this consider the flat metric,

$$h^{ij}(u,v,w)=\begin{pmatrix}au^2 & uv & uw\\ uv & av^2 & vw\\ uw & vw & aw^2\end{pmatrix},$$

this being (12) with $N=3$ and $1-(N-M)$ replaced with an arbitrary constant a. We assume that this metric is invertible (so $a\neq 1,-2$). In terms of symmetric variables $S=u+v+w$, $P=uv+vw+wu$, and $Q=uvw$ this takes the form

$$h^{ij}(S,P,Q)=\begin{pmatrix} as^2+2(1-a)P & (1+a)SP+3(1-a)Q & (2+a)SQ \\ (1+a)SP+3(1-a)Q & 2(1+a)P^2+2(1-a)SQ & 2(2+a)PQ \\ (2+a)SQ & 2(2+a)PQ & 3(2+a)Q^2 \end{pmatrix}.$$

For general values of a, the entries are not linear in any of the variables. The metric cannot depend on Q linearly, as this would imply $a=-2$. For the entries to depend linearly on Q would imply $a=-1$, and this corresponds to (12) with $M=1$. For the entries to depend linearly on S would imply $a=0$, and this corresponds to (12) with $M=2$. Thus, any requirement that the metric depends linearly on one of the symmetric variables forces the metric to take one of the above known forms. Of course, this does not rule out the possibility that in some other coordinate systems the components of the metric do become linear in some variable.

IV. RATIONAL LAX EQUATIONS

In this section the evolution equations (9) will be written in Hamiltonian form. The resulting Hamiltonian structure turns out to be degenerate, so the results of Dubrovin used in the last section to derive the bi-Hamiltonian structure cannot be used without modification. These modifications turn out to be minor and a version of Lemma 4 will hold for degenerate Hamiltonian systems.

Theorem 7: (a) *In terms of the variables* $\tilde{u}^i=\log u^i$ *the evolution equations (9) may be written in Hamiltonian form,*

$$\tilde{u}^i_{\tau_n}=\sum_j m^{ij}\mathcal{D}\left(\frac{\delta H^{(n)}}{\delta\tilde{u}^j}\right),$$

where m^{ij} *is the constant matrix,*

$$m^{ij}=\begin{pmatrix} \alpha_1 & 1 & 1 & \cdots & 1 \\ 1 & \alpha_2 & 1 & \cdots & 1 \\ 1 & 1 & \alpha_3 & \cdots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & 1 & \cdots & \alpha_{N-M} \end{pmatrix}, \tag{13}$$

$\alpha_i=1-\varepsilon_i(N-M)$, *and*

$$H^{(n)}=\int dx \sum_{\{r_i:\Sigma_{i=1}^{N+M}r_i=n\}}\left\{\prod_{i=1}^{N+M}\begin{pmatrix}\frac{\varepsilon_i n}{N-M}\\ r_i\end{pmatrix}e^{r_i\tilde{u}^i}\right\}.$$

(B) In terms of the original variables the (g,Γ) *pair,*

$$g^{ij}(u)=m^{ij}u^iu^j,$$

$$\Gamma^{ij}_k(u)=\delta^j_k m^{ij}u^i,$$

define a degenerate Hamiltonian structure, satisfying the conditions of Theorem 2.

Proof: (a) In terms of the u^i variables, the system,

$$\tilde{u}^i_{\tau_n}=\sum_j m^{ij}\mathcal{D}\left(\frac{\delta H^{(n)}}{\delta\tilde{u}^j}\right), \tag{14}$$

becomes

$$u^i_{\tau_n} = \sum_i \alpha_i u^i \mathcal{D}\left(u^i \frac{\delta H^{(n)}}{\delta u^i} \right) + \sum_{j \neq i} u^i \mathcal{D}\left(u^j \frac{\delta H^{(n)}}{\delta u^j} \right).$$

Expanding this yields

$$u^i_{\tau_n} = \left[\frac{1}{n} \sum_{\{r_i : \Sigma_{i=1}^{N+M} r_i = n\}} [\alpha_i r_i^2 + r_i(n - r_i)] \prod_{k=1}^{N+M} \binom{\frac{\varepsilon_k n}{N-M}}{r_k} (u^k)^{r_k} \right] u^i_x$$
$$+ \sum_{j \neq i} \left[\frac{1}{n} \sum_{\{r_i : \Sigma_{i=1}^{N+M} r_i = n\}} [\alpha_i r_i r_j + r_j(n - r_i)](u^j)^{-1} \prod_{k=1}^{N+M} \binom{\frac{\varepsilon_k n}{N-M}}{r_k} (u^k)^{r_k} \right] u^j_x .$$

Using $\alpha_i = 1 - \varepsilon_i (N-M)$ and various binomial identities reduces this to

$$u^i_{\tau_n} = A_i^{(n)} u^i_x + \sum_{j \neq i} u^i B_{ij}^{(n)} u^j_x ,$$

where

$$A_i^{(n)} = \left(\frac{\varepsilon_i n}{N-M} - 1 \right) \sum_{\{r_j : \Sigma_{j=1}^{N+M} r_j = n\}} \left[\prod_{\substack{k=1 \\ k \neq i}}^{N+M} \binom{\frac{\varepsilon_k n}{N-M}}{r_k} (u^k)^{r_k} \right] \binom{\frac{\varepsilon_i n}{N-M} - 2}{r_i - 1} (u^i)^{r_i},$$

and

$$B_{ij}^{(n)} = \frac{\epsilon_j n}{N-M} \sum_{\{r_j : \Sigma_{j=1}^{N+M} r_j = n-1\}} \left[\prod_{\substack{k=1 \\ k \neq i,j}}^{N+M} \binom{\frac{\epsilon_k n}{N-M}}{r_k} (u^k)^{r_k} \right]$$
$$\times \binom{\frac{\epsilon_j n}{N-M} - 1}{r_i} (u^i)^{r_i} \binom{\frac{\epsilon_j n}{N-M} - 1}{r_j} (u^j)^{r_j},$$

that is, to the equations obtained from the Lax equation (7). Hence the result.

(b) Rewriting (14) in terms of a (g,Γ) pair yields

$$g^{ij}(u) = m^{ij} u^i u^j,$$

$$\Gamma^{ij}_k(u) = \delta^j_k m^{ij} u^i.$$

The above argument does not show that the pair (g,Γ) defines a Hamiltonian structure, as the corresponding bracket (1) must define a Hamiltonian structure for all functionals, not just the specific functionals used above. In order to show that this pair does define such a structure, one must verify that the equations (2)–(6) hold. This is entirely straightforward, so the details will be omitted. The degeneracy of the metric follows from the result, easily proved using elementary row and column operations, that

$$\det\left(\begin{array}{cccc|ccc} 1-a & 1 & \cdots & 1 & 1 & \cdots & 1 \\ 1 & 1-a & \cdots & 1 & 1 & \cdots & 1 \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ 1 & 1 & \cdots & 1-a & 1 & \cdots & 1 \\ \hline 1 & 1 & \cdots & 1 & 1+a & \cdots & 1 \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ 1 & 1 & \cdots & 1 & 1 & \cdots & 1+a \end{array}\right) = (-1)^N a^{N+M-1}[a-(N-M)],$$

where the diagonal blocks are $N\times N$ and $M\times M$ matrices. For the matrix m_{ij} $a=N-M$ [since $\alpha_i = 1-\varepsilon_i(N-M)$], and hence $\det(g^{ij})=0$. It also follows from these operations that $\mathrm{rank}(g^{ij}) = (N+M)-1$. □

This also shows that this system is only mildly degenerate; the coordinate transformation that reduces g^{ij} to a metric with constant entries simultaneously reduce the Γ^{ij}_k to zero. For a degenerate metric this need not be the case, and some nonzero Γ^{ij}_k can remain.[2]

Lemma 8: Let the pair (g,Γ) *define a degenerate Hamiltonian structure. If the components of the pair* (g,Γ) *in some coordinate system* $x^1,\ldots,x^n$ *depend linearly on the coordinate* $x\bullet$, *then the pair,*

$$(g+\lambda\,\partial_\bullet g, \Gamma+\lambda\,\partial_\bullet\Gamma), \tag{15}$$

defines a degenerate Hamiltonian structure for all values of λ. *Hence, one obtains a degenerate bi-Hamiltonian structure.*

Proof: All that is required is to show that the pair (15) satisfies the conditions of Theorem 2, given the original (g,Γ) pair. This is straightforward, the first two conditions being trivial. Consider, for example, condition (4) in Theorem 2:

$$[(\Gamma^{ij}_k + \lambda_\bullet \Gamma^{ij}_t)(g^{tk}+\lambda\,\partial_\bullet g^{tk}) - (k\leftrightarrow i)] = \left(1+\lambda\partial_\bullet + \frac{\lambda^2}{2}\partial_\bullet^2\right)[(\Gamma^{ij}_k - (k\leftrightarrow i)],$$

this following from that fact that if g and Γ depend linearly on $x^\bullet$, then

$$\partial_\bullet^2(\Gamma g) = 2\,\partial_\bullet\Gamma\,\partial_\bullet g.$$

Hence, if (g,Γ) satisfies condition (4), so does (15). The remaining conditions are all quadratic in g and Γ, and so the proof is identical. □

One may perform a similar sequence of coordinate transformation to those in Sec. III. Explicitly, let

$$z^1 = +x^1,$$

$$z^i = +x^i - x^{i-1}, \quad i=1,\ldots,N,$$

$$z^N = -x^{N-1},$$

$$z^{N+1} = +x^{N+1},$$

$$z^i = +x^i - x^{i-1}, \quad i=N+1,\ldots,N+M,$$

$$z^{N+M} = -x^{N+M-1},$$

and

$$u^i = e^{(1/N)x^N - z^i}, \quad i=1,\ldots,N+M.$$

After a permutation is the labels the metric becomes (up to an overall factor)

$$g^{ij}(x)=\left(\begin{array}{c|c|c} +\begin{pmatrix}\text{Cartan matrix}\\ \text{of } A_{N-1}\end{pmatrix} & 0 & 0 \\ \hline 0 & -\begin{pmatrix}\text{Cartan matrix}\\ \text{of } A_{N+M-1}\end{pmatrix} & 0 \\ \hline 0 & 0 & -d_M\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}\end{array}\right).$$

This is a considerable scope for the investigation of bi-Hamiltonian structures based on such block decompositions.

Having derived one Hamiltonian structure it is necessary, before the above lemma can be applied, to find a suitable coordinate system in which the metric given in Theorem 7 becomes linear in one of the coordinates. This will be done only for the $M=1$ case, i.e., a rational Lax function with a single pole. Extending these results to an arbitrary number of poles presents certain problems, which will be discussed later.

The new variable s^i are defined by the following expansion of the rational function $\mathcal{L}$:

$$\begin{aligned}\mathcal{L}&=\text{polynomial of degree}(N-1)+\frac{\text{function}}{p+\text{pole}},\\ &=\sum_{n=0}^{N-1} p^n s^{N-1-n}+\frac{s^N}{p+s^{N+1}}.\end{aligned}$$

To express the s^i as functions of the variables u^i, it is convenient to introduce the basic symmetric functions of the variables $u^1,\ldots,u^N$:

$$\sigma^0=1,\quad \sigma^1=\sum_i u^i,\quad \sigma^2=\sum_{i<j} u^i u^j,\ldots,\sigma^N=\prod_i u^i,$$

so

$$\prod_{i=1}^{N}(p+u^i)=\sum_{i=0}^{N} p^i\sigma^{N-i}.$$

By expanding the various expressions for $\mathcal{L}$, one obtains

$$\begin{aligned}s^0&=1,\\ s^r&=\sum_{n=0}^{r}(-1)^n\sigma^{r-n}(u^{N+1})^n,\quad r=1,\ldots,N,\\ s^{N+1}&=u^{N+1}.\end{aligned}\tag{16}$$

It is in these variables that the pair (g,Γ) will become linear in one of the variables.

Example 2: For $N=3$, $M=1$,

$$\begin{aligned}\mathcal{L}&=\frac{(p+u)(p+v)}{p+w},\\ &=p+(u+v-w)+\frac{(u-w)(v-w)}{p+w},\end{aligned}$$

and hence

$$s^1 = u + v - w,$$

$$s^2 = uv - w(u+v) + w^2,$$

$$s^3 = w,$$

in accordance with (16).

The following result will be required in the next theorem.

Lemma 9: With the variables s^m defined above,

$$\frac{\partial s^m}{\partial u^i} + \frac{\partial s^m}{\partial u^{N+1}} = (u^{N+1} - u^i)\{\text{polynomial of degree } \alpha - 2\}, \quad m,i = 1,\dots,N;$$

Proof: One may write σ^n as $\sigma^n = u^i \tilde{\sigma}^{n-1} + \tilde{\sigma}^n$ so

$$\frac{\partial \sigma^n}{\partial u^i} = \tilde{\sigma}^{n-1}.$$

Hence

$$\left.\frac{\partial s^m}{\partial u^{N+1}}\right|_{u^{N+1}=u^i} = \sum (-1)^n (u^i \tilde{\sigma}^{n-1} + \tilde{\sigma}^n)(\alpha - n)(u^i)^{\alpha - n - 1},$$

$$= \sum (-1)^{n+1} \tilde{\sigma}^{n-1} (u^i)^{\alpha - n}.$$

So

$$\left.\left(\frac{\partial s^m}{\partial u^i} + \frac{\partial s^m}{\partial u^{N+1}}\right)\right|_{u^{N+1}=u^i} = 0.$$

The result now follows from the homogeneities of the functions involved. □

Theorem 10: The terms of the coordinates s^i defined above (16) the (g,Γ) pair depend linearly on the variable s^{N-1}.

Proof: In terms of the u^i variables the (g,Γ) pair is given by

$$g^{ij}(u) = m^{ij} u^i u^j,$$

$$\Gamma^{ij}_k(u) = \delta^j_k m^{ij} u^i,$$

where

$$m^{ij} = \begin{pmatrix} 2-N & 1 & \cdots & 1 & 1 \\ 1 & 2-N & \cdots & 1 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & 2-N & 1 \\ 1 & 1 & \cdots & 1 & N \end{pmatrix}.$$

The components of the metric in terms of the s^i coordinates are given by

$$g^{ij}(s)=\frac{\partial s^i}{\partial u^p}\,\frac{\partial s^j}{\partial u^q}\,g^{pq}(u)$$

and it follows from the symmetry of this equation that the entries will be polynomial in the new variables. It also follows from this that the degrees of the entries are

$$\deg g^{ij}(s)=\begin{cases} i+j & \text{if } 1\leqslant i,j\leqslant N,\\ 1+j & \text{if } i=N+1 \text{ and } j\neq N+1,\\ 1+i & \text{if } j=N+1 \text{ and } i\neq N+1,\\ 2 & \text{if } i=j=N+1. \end{cases}$$

The degrees of the terms in the lower right corner of $g^{ij}(u)$ are given schematically below:

$$\left(\begin{array}{cccc|c} & & & & \vdots\\ & & & 2N-2 & N-1\\ & & 2N-2 & 2N-1 & N\\ & 2N-2 & 2N-1 & 2N & N+1\\ \hline \dots & N-1 & N & N+1 & 2 \end{array}\right). \tag{17}$$

Thus there are only four terms where $g^{ij}(s)$ could possibly contain a term quadratic in s^{N-1} (or six terms if $N=2$ or five terms if $N=3$, but these special cases may be disposed of by direct computation). The result will follow if it can be shown that these terms contain a factor s^N, that is if

$$g^{N-1,N-1}(s)=s^N\{\text{polynomial of degree } N-2\},$$

$$g^{N,k}(s)=s^N\{\text{polynomial of degree } k\},\quad k=N,N-1,N-2,$$

since the polynomials cannot be quadratic in s^{N-1} without violating the overall degree of the term.

From these formulas,

$$g^{N,\alpha}=\sum_{i,j=1}^{N}\frac{\partial s^N}{\partial u^i}\,\frac{\partial s^\alpha}{\partial u^j}\,g^{ij}+\sum_{i=1}^{N}\frac{\partial s^N}{\partial u^{N+1}}\,\frac{\partial s^\alpha}{\partial u^i}\,g^{N-1,i}\sum_{i=1}^{N}\frac{\partial s^N}{\partial u^i}\,\frac{\partial s^\alpha}{\partial u^{N+1}}\,g^{N-1,i}+\frac{\partial s^N}{\partial u^{N-1}}\,\frac{\partial s^\alpha}{\partial u^{N-1}}\,g^{N-1,N-1}.$$

Since

$$s^N=\prod_{i=1}^{N}(u^i-u^{N+1}),$$

it follows from Euler's theorem that

$$\sum_{i=1}^{N+1}u^i\frac{\partial s^N}{\partial u^i}=Ns^N,$$

and these may be used to simplify the above. After somewhat tedious calculations one obtains

$$\frac{\partial s^N}{\partial u^{N-1}}=\alpha s^N s^\alpha+(1-N)s^N\left\{(u^{N+1})^2\left[\frac{\dfrac{\partial s^\alpha}{\partial u^i}+\dfrac{\partial s^\alpha}{\partial u^{N+1}}}{u^i-u^{N+1}}\right]-u^{N+1}\left[\frac{\partial s^\alpha}{\partial u^{N+1}}-\frac{\partial s^\alpha}{\partial u^i}\right]\right\}.$$

The result now follows from the above lemma.

The corresponding result for $g^{N-1,N-1}$ is similar and rest on proving, in a similar manner as above, that

$$g^{N-1,N-1}(s)=(N-1)s^N \underbrace{\sum_{i\neq j}\prod_{\substack{r=1\\ r\neq i,j}}^{N}(u^r-u^{N+1})}_{\text{symmetric polynomial in the } s \text{ variables of degree } (N-2)}.$$

These results show that in the s^i-coordinates the metric is linear in the coordinate s^{N-1}. The second half of the proof, showing that $\Gamma^{ij}_k(s)$ is also linear in s^{N-1} is similar, and follows from the transformation properties of Γ^{ij}_k. □

In what follows this second degenerately flat metric $\partial g^{ij}/\partial s^{\bullet}$ will be denoted by η^{ij}.

Example 3: N=2, *M*=1. With these values,

$$m^{ij}=\begin{pmatrix} 0 & 1 & 1\\ 1 & 0 & 1\\ 1 & 1 & 2\end{pmatrix},$$

and a short computation yields

$$g^{ij}(s)=\begin{pmatrix} 2s^2 & s^2(s^1-3s^3) & s^3(s^1-s^3)\\ s^2(s^1-3s^3) & 2s^2(s^2-s^1s^3+2(s^3)^2) & s^3(2s^2-s^1s^3)\\ s^3(s^1-s^3) & s^3(2s^2-s^1s^3) & 2(s^3)^2\end{pmatrix}.$$

This is linear in s^1 and hence

$$\eta^{ij}(s)=\frac{\partial g^{ij}(s)}{\partial s^1},$$

$$=\begin{pmatrix} 0 & s^2 & s^3\\ s^2 & -2s^2s^3 & -(s^3)^2\\ s^3 & -(s^3)^2 & 0\end{pmatrix}.$$

One may easily introduce degenerate flat coordinates in which the entries of η^{ij} are constant. These flat coordinates are

$$t^1=s^1,$$

$$t^2=\frac{s^2}{s^3},$$

$$t^3=\log(s^3)$$

and in these coordinates

$$g^{ij}(t)=\begin{pmatrix} 2t^2e^{t^3} & -2t^2e^{t^3} & +t^1-e^{t^3}\\ -2t^2e^{t^3} & +2t^2e^{t^3} & -t^1+e^{t^3}\\ +t^1-e^{t^3} & -t^1+e^{t^3} & 2\end{pmatrix}.$$

This is linear in t^1 and hence

$$\eta^{ij}(t)=\begin{pmatrix} 0 & 0 & +1 \\ 0 & 0 & -1 \\ +1 & -1 & 0 \end{pmatrix}.$$

Example 4: $N=3$, $M=1$. With these values,

$$m^{ij}=\begin{pmatrix} -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & +3 \end{pmatrix},$$

and a short computation yields the degenerate metric $g^{ij}(s)$. These components are linear in s^2 and so define a new metric

$$\eta^{ij}(s)=\frac{\partial g^{ij}(s)}{\partial s^2},$$

$$=\begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 0 & 2s^3 & 2s^4 \\ 0 & 2s^3 & -4s^3s^4 & -2(s^4)^2 \\ 0 & 2s^4 & -2(s^4)^2 & 0 \end{pmatrix}.$$

The degenerate flat coordinates are defined by

$$t^1=s^1,$$

$$t^2=s^2,$$

$$t^3=\frac{s^3}{s^4},$$

$$t^4=\log(s^4),$$

and in these flat coordinates the original metric metric takes the form

$$g^{ij}(t)=\begin{pmatrix} -(t^1)^2+4t^2 & +6t^3e^{t^4} & -6t^3e^{t^4} & t^1-2e^{t^4} \\ +6t^3e^{t^4} & +4t^1t^3e^{t^4}-8t^3e^{2t^4} & -4t^1t^3e^{t^4}+8t^3e^{2t^4} & +2t^2-2t^1e^{t^4}+2e^{2t^4} \\ -6t^3e^{t^4} & -4t^1t^3e^{t^4}+8t^3e^{2t^4} & +4t^1t^3e^{t^4}-8t^3e^{2t^4} & -2t^2+2t^1e^{t^4}-2e^{2t^4} \\ t^1-2e^{t^4} & +2t^2-2t^1e^{t^4}+2e^{2t^4} & -2t^2+2t^1e^{t^4}-2e^{2t^4} & 3 \end{pmatrix}.$$

The entries are linear in t^2 and, hence, one obtains the second metric,

$$\eta^{ij}(t)=\begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & -2 \\ 0 & 2 & -2 & 0 \end{pmatrix}. \tag{18}$$

V. DEGENERATE FROBENIUS MANIFOLDS

The natural geometric setting in which to understand the bi-Hamiltonian structure of hydrodynamic systems is the Frobenius manifold.[5] One way to define such manifolds is to construct a function $F(t^1,\ldots,t^n)$ such that the associated functions,

$$c_{ijk}=\frac{\partial^3 F}{\partial t^i\,\partial t^j\,\partial t^k},$$

satisfy the following conditions.

(i) The matrix $\eta_{ij}=c_{1ij}$ is constant and nondegenerate. This together with the inverse matrix η^{ij} are used to raise and lower indices. On such a manifold one may interpret η_{ij} as a flat metric.

(ii) The functions $c^i_{jk}=\eta^{ir}c_{rjk}$ defined an associative commutative algebra with a unity element. This defines a Frobenius algebra on each tangent space $T^t\mathcal{M}$. This multiplication will be denoted by $u\cdot v$.

(iii) The functions F satisfies a quasihomogeneity condition, which may be expressed as

$$\mathcal{L}_{\mathrm{E}}F=d_F F+\{\text{quadratic terms}\}, \tag{19}$$

where E is a vector field known as the Euler vector field.

These conditions constitute the Witten–Dijkgraaf–Verlinde–Verlinde (or WDVV) equations. On such a manifold one may introduce a second flat metric defined by

$$g^{ij}=E(dt^i\cdot dt^j). \tag{20}$$

This metric, together with the original metric η^{ij}, define a flat pencil (i.e., $\eta^{ij}+\lambda g^{ij}$ is flat for all values of λ). Thus, one automatically obtains a bi-Hamiltonian structure from a Frobenius manifold. The corresponding Hamiltonians are defined recursively by the formula

$$\frac{\partial^2 h^{(n)}}{\partial t^i\,\partial t^j}=c^k_{ij}\frac{\partial h^{(n-1)}}{\partial t^k}. \tag{21}$$

The integrability conditions for this systems are automatically satisfied when the c^k_{ij} are defined as above.

One basic assumption in this definition is that the metric η_{ij} is nondegenerate, and it follows from this that the bi-Hamiltonian structures are also nondegenerate. Thus the degenerate bi-Hamiltonian structures obtained in the preceding section cannot be obtained from this construction. However, one may formulate the new notion of a degenerate Frobenius manifold in which the corresponding bi-Hamiltonian structures are degenerate.

Rather than develop the theory of degenerate Frobenius manifolds in full generality, an extended example will be given here based on the study of the hydrodynamic system,

$$u_\tau=u(v_x-w_x),$$

$$v_\tau=v(u_x-w_x),$$

$$w_\tau=w(u_x+v_x-2w_x),$$

obtained from the rational Lax function

$$\mathcal{L}=\frac{(p+u)(p+v)}{p+w}.$$

The bi-Hamiltonian structure of this system has already been derived in Example 3 in Sec. IV. To recapitulate, in the flat coordinates given by

$$t^1 = u + v - w,$$

$$t^2 = \frac{(u-w)(v-w)}{w},$$

$$t^3 = \log w,$$

the degenerate metrics that give rise to the degenerate bi-Hamiltonian structures are

$$\eta^{ij}(t) = \begin{pmatrix} 0 & 0 & +1 \\ 0 & 0 & -1 \\ +1 & -1 & 0 \end{pmatrix}, \tag{22}$$

$$g^{ij}(t) = \begin{pmatrix} 2t^2 e^{t^3} & -2t^2 e^{t^3} & +t^1 - e^{t^3} \\ -2t^2 e^{t^3} & +2t^2 e^{t^3} & -t^1 + e^{t^3} \\ +t^1 - e^{t^3} & -t^1 + e^{t^3} & 2 \end{pmatrix}. \tag{23}$$

The first few Hamiltonian densities (suitably normalized) are given by the formula (10), and in the flat coordinates these become

$$h^{(1)} = t^1,$$

$$h^{(2)} = \tfrac{1}{2}[(t^1)^2 + 2t^2 e^{t^3}],$$

$$h^{(3)} = \tfrac{1}{6}[(t^1)^3 + 6t^1 t^2 e^{t^3} - 3t^2 e^{2t^3}],$$

$$h^{(4)} = \tfrac{1}{24}[(t^1)^4 + 12(t^1)^2 t^2 e^{t^3} + 6(t^2)^2 e^{2t^3} - 12t^1 t^2 e^{2t^3} + 4t^2 e^{3t^3}].$$

From these and the recursion equation (21), one may reconstruct the structure functions c^i_{jk} and verify that they form a commutative and associative algebra with a unity element. Explicitly the structure constants are given by $c^i_{1j} = \delta^i_j$ and

$$\begin{pmatrix} c^1_{22} & c^2_{22} & c^3_{22} \\ c^1_{23} & c^2_{23} & c^3_{23} \\ c^1_{33} & c^2_{33} & c^3_{33} \end{pmatrix} = \begin{pmatrix} 0 & 1 & -1/t^2 \\ +e^{t^3} & -e^{t^3} & 0 \\ +t^2 e^{t^3} & -t^2 e^{t^3} & -e^{t^3} \end{pmatrix}.$$

From these structure functions one may raise an index using η^{ij} and determine the Euler vector field from Eq. (20). For this example this vector field is

$$E = t^1 \frac{\partial}{\partial t^1} + t^2 \frac{\partial}{\partial t^2} + \frac{\partial}{\partial t^3}.$$

In addition, the structure functions satisfy the relations

$$\frac{\partial c^r_{jk}}{\partial t^i} - \frac{\partial c^r_{ik}}{\partial t^k} = 0,$$

and this, together with the symmetry $c^k_{ij} = c^k_{ji}$, enables one to write them as

$$c^i_{jk} = \frac{\partial^2 f^i}{\partial t^j\,\partial t^k},$$

for some set of functions f^i. For the above structure constants these turn out to be (up to linear terms)

$$f^1 = \tfrac{1}{2}(t^1)^2 + t^2 e^{t^3},$$

$$f^2 = \tfrac{1}{2}(t^2)^2 + t^1 t^2 - t^2 e^{t^3},$$

$$f^3 = t^1 t^3 - t^2 \log t^2 - e^{t^3}.$$

At this stage one normally lowers the i index and uses another symmetry to write c_{ijk} as the third derivative of some function F. This, however, assumes that the metric η^{ij} is invertible, which, for the metric given by (22), is not the case. However, one may write the f^i as

$$f^i(t) = \eta^{ij}\frac{\partial F}{\partial t^j} + h^i(t^1 + t^2).$$

Since the matrix η^{ij} is of rank 2, it follows it has a nontrivial kernel, so there exists a nonzero vector ζ_i such that $\eta^{ij}\zeta_j = 0$, and the functions h^i are functions of the combination $\zeta_i t^i$, which in this example is just $t^1 + t^2$. These functions h^i satisfy the single constraint $h^1 + h^2 = 1/2(t^1 + t^2)^2$. To obtain the above structure functions one possible such F is

$$F = \tfrac{1}{2}(t^1)^2 t^3 + t^2 e^{t^3} + \tfrac{1}{2}(t^2)^2 \log t^2,$$

and

$$h^1 = 0,$$

$$h^2 = \tfrac{1}{2}(t^1 + t^2)^2,$$

$$h^3 = 0,$$

and this satisfies the homogeneity condition (19) with $d_F = 2$. There is much freedom in these functions. One may transform, for arbitrary constant k,F,

$$F \to F + k t^3 (t^1 + t^2)^2,$$

and the homogeneity property is unchanged. This induced a change in the functions h^i but leaves unchanged the structure functions defining the Frobenius algebra.

From this extended example one may distill the basic properties of a degenerate Frobenius manifold. One starts with a basic function $F(t^i)$ satisfying some homogeneity condition and degenerate metric η^{ij}, the entries of which are constant in the t^i coordinates. The metric is not related to the third derivatives of F, as for nondegenerate Frobenius manifolds. The structure functions, which form a Frobenius algebra with a degenerate inner product, are defined by

$$c^i_{jk} = \eta^{ir}\partial_r \partial_j\,\partial_k F + \partial_j \partial_k h^i, \tag{24}$$

where the functions h^i are functions that depend on the kernel of the degenerate matrix η^{ij}. Thus, for degenerate Frobenius manifolds one has a set of extra functions related to the fact that the matrix η^{ij} is not of maximal rank. The associativity conditions result in a complicated set over-determined partial differential equations for F, the degenerate analog of the WDVV equations. One avenue for future research is to develop the concept of a degenerate Frobenius manifold more axiomatically.

Example 5: For $N=3$, $M=1$ the metrics $g^{ij}(t)$ and $\eta^{ij}(t)$ have been calculated in Example 4. One may repeat the calculations above and obtain the following: Euler vector field:

$$E=\frac{t^1}{2}\frac{\partial}{\partial t^1}+t^2\frac{\partial}{\partial t^2}+t^3\frac{\partial}{\partial t^3}+\frac{1}{2}\frac{\partial}{\partial t^4};$$

prepotential F:

$$F=\tfrac{1}{8}(t^1)^2t^2+\tfrac{1}{4}(t^2)^3-\tfrac{1}{192}(t^1)^4+\tfrac{1}{2}t^1t^3e^{t^4}-\tfrac{1}{4}t^3e^{2t^4}-\tfrac{1}{4}(t^3)^2\log t^3;$$

and associated nonzero potentials h^i:

$$h^3=\tfrac{1}{2}(t^2+t^3)^2.$$

From these, and the constant matrix η^{ij} given by (18), one may construct a degenerate Frobenius algebra with structure functions given by Eq. (24) and second degenerate flat metric given by (20).

In Sec. IV the bi-Hamiltonian structures were shown to exist for arbitrary N, but $M=1$. It is clear that the ideas will generalize to arbitrary M, and hence to degenerate Frobenius manifolds for arbitrary N and M. The following example is for $N=3$, $M=2$.

Example 6: For $N=3$, $M=2$ the flat coordinates are defined by the expansion

$$\mathcal{L}=p+t^1+\frac{t^2e^{t^4}}{p+e^{t^4}}+\frac{t^3e^{t^5}}{p+e^{t^5}}.$$

In these coordinates,

$$\eta^{ij}(t)=\begin{pmatrix}0&0&0&1&1\\0&0&0&-1&0\\0&0&0&0&-1\\1&-1&0&0&0\\1&0&-1&0&0\end{pmatrix},$$

and the Frobenius data is the following: Euler vector field:

$$E=t^1\frac{\partial}{\partial t^1}+t^2\frac{\partial}{\partial t^2}+t^3\frac{\partial}{\partial t^3}+\frac{\partial}{\partial t^4}+\frac{\partial}{\partial t^5};$$

prepotential F:

$$\begin{aligned}F&=+t^2e^{t^4}+t^3e^{t^5}+\tfrac{1}{2}t^2t^3\log(e^{t^4}-e^{t^5})^2+\tfrac{1}{2}((t^2)^2\log t^2+(t^3)^2\log t^3)\\&=-\tfrac{1}{2}t^2t^4(2t^1+t^2+2t^3)-\tfrac{1}{2}t^3t^5(2t^1+2t^2+t^3);\end{aligned}$$

and associated nonzero potentials h^i:

$$h^1=\tfrac{1}{2}(t^1+t^2+t^3)^2.$$

From this data the Frobenius algebra structure functions given by Eq. (24) and the second degenerate flat metric given by (20).

The form of these results suggest the following.

Conjecture 1: The metric given in Theorem 7 is linear in the coordinate s^{N-M}, where the coordinates s^i are defined in terms of the expansion of the rational Lax function,

$$\mathcal{L}=p^{N-M}+s^1p^{N-M-1}+\cdots+s^{N-M}+\frac{s^{N-M+1}}{p+s^{N+1}}+\cdots+\frac{s^N}{p+s^{N+M}}.$$

Moreover, there exist flat coordinates t^i *such that the variables* s^i *are polynomial functions of the variables* $t^1,\ldots,t^N,e^{t^{N+1}},\ldots e^{t^M}$, *and in which the entries* $\eta^{ij}(t)$ *are all constants.*

One would hope to be able to modify the results of Ref. 6 to prove this conjecture; the vanishing of the determinants of the metrics means that the results cannot be used directly. One should be able to modify the Gauss–Manin equations for the flat coordinates to include these degenerate examples.

VI. COMMENTS

One notable difference between the bi-Hamiltonian structure of the hierarchies considered here, these being multicomponent generalizations of Toda and Benney hierarchies,[4] and the bi-Hamiltonian structures of dispersionless KP-type hierarchies, is the degeneracy of the structures. The dispersionless KP-type hydrodynamic systems involve rationale such as (see, for example, those in Ref. 9)

$$\mathcal{L}=\frac{1}{2}p^2+S(x,t)+\frac{P(x,t)}{p-Q(x,t)},$$

and the Lax equation similar to Eq. (7), but with a Poisson bracket,

$$\{f,g\}_{PB}=(\partial_p f\,\partial_x g-\partial_x f\,\partial_p g).$$

The bi-Hamiltonian structure of these equations is not degenerate.[5,9] These rational Lax functions may be considered as a reduction of an infinite component Lax function $\mathcal{L}=\Sigma_{i=-\infty}^{N}s^ip^i$ and it may be of interest to see how constraining the resulting Hamiltonian structures results in the degenerate structures studied here.

The existence of a nontrivial Casimir for these systems is of interest. One possible reduction of these systems is to restrict the dynamics to the surface given by

$$\mathcal{C}=\text{const},$$

for example, the $(N=2,\ M=1)$ system,

$$u_\tau=u(v_x-w_x),$$

$$v_\tau=v(u_x-w_x),$$

$$w_\tau=w(u_x+v_x-2w_x),$$

when restricted to the surface $w=uv$ results in the system

$$u_\tau=u[(1-u)v_x-vu_x],$$

$$v_\tau=v[(1-v)u_x-uv_x].$$

How the Hamiltonian structure behaves under such a constraint is unknown. For nondegenerate Hamiltonian structures one may use the result of Ferapontov,[10] though this work would need to be generalized to include a degenerate Hamiltonian structure such as those considered here. More generally, one may restrict the above system to the surface $w=uvf(x)$ for some arbitrary function $f(x)$ (i.e., $\mathcal{C}=f^{-1}$.). This results in the system

$$u_\tau=u[(1-u)v_x-vu_x]-u^2vf'(x),$$

$$v_\tau = v[(1-v)u_x - uv_x] - v^2 u f'(x),$$

an example of inhomogeneous hydrodynamic system with specific x dependence. It may also be possible to obtain the Hamiltonian structure of these systems.[11]

The idea of a degenerate Frobenius manifold requires further elucidation. One complicating factor is that for a degenerate structure the transformation that reduces the components of the metric to constants will not, in general, reduce all of the components Γ_k^{ij} to zero.[2] The systems in this paper are special in this respect since in flat coordinates the components of Γ_k^{ij} are automatically zero, which is not the generic situation; the systems here are doubly degenerate. It has recently been shown by Kodama[12] that the degenerate Frobenius manifold constructed here may be embedded in a nondegenerate, higher-dimensional, Frobenius manifold under a somewhat singular limit. Clearly these ideas require further work.

Finally, this paper has only dealt with dispersionless systems. For polynomial Lax equations one has discrete counterparts, the simplest example being the Toda Lattice,

$$S_{n,\tau} = P_n - P_{n+1},$$

$$P_{n,\tau} = P_n(S_{n-1} - S_n),$$

which reduces to (8) in the continuum limit; the lattice variable becoming the continuous variable x. The bi-Hamiltonian structure of such systems have been studied in Ref. 7. Indeed, the structures obtained here could also be derived by taking certain limits of those structures, if they where known explicitly for arbitrary M and N. How to extend these results to rational discrete systems is unclear. One approach would be to use the ideas in Ref. 13, which deals with the interpretation of the inverse operator $(e^\partial + u)^{-1}$, or the ideas of Ref. 14, where one would consider term-by-term deformation of the underlying dispersionless system.

S. M. Mahajan
Institute for Fusion Studies, The University of Texas at Austin, Austin, Texas 78712

(Received 13 April 1999; accepted for publication 1 July 1999)

The two-fluid model of a plasma describes the strong coupling between the magnetic and the fluid aspects of the plasma. The Beltrami condition that demands alignment of vortices and flows becomes a system of simultaneous equations in the magnetic field and the flow velocity. Combining these equations yields the double curl Beltrami equation. General solvability of the equation has been proved using the spectral theory of the curl operator. The set of solutions contains field configurations that can be qualitatively different from the conventional constant-α-Beltrami fields (which are naturally included in the set). The larger new set may help us understand a variety of structures generated in plasmas. © *1999 American Institute of Physics.* [S0022-2488(99)02810-8]

I. INTRODUCTION

The Beltrami condition, an expression of the alignment of a vorticity with its flow, describes the simplest and perhaps the most fundamental equilibrium state in a vortex dynamics system (Sec. II). The resulting Beltrami fields constitute a null set for the generator of the evolution equation describing the vortex dynamics. It is also believed that the Beltrami fields are accessible and robust in the sense that they emerge as the nonlinear dynamics of vortices tends to self-organize the system through a weakly dissipative process (Appendix A).

The simplest example of a Beltrami condition is provided by a three-dimensional solenoidal field (flow) $\mathbf{u}$, obeying

$$\begin{cases} \nabla\times\mathbf{u}=\lambda\mathbf{u} \quad (\text{in } \Omega), \\ \mathbf{n}\cdot\mathbf{u}=0 \quad (\text{on } \partial\Omega), \end{cases} \tag{1}$$

where λ is a real (or complex) constant number, Ω $(\subset\mathbf{R}^3)$ is a bounded domain with a smooth boundary $\partial\Omega$ and $\mathbf{n}$ is the unit normal vector onto $\partial\Omega$. This system of linear equations is regarded as an eigenvalue problem with respect to the curl operator. The spectral theory of the curl operator reveals an interesting relation of this problem with the cohomology theory.[1] We have the following theorem.

(i) If Ω is simply connected, then (1) has a nonzero solution for special λ included in a set of discrete real numbers; these numbers represent the point spectrum of the self-adjoint part of the curl operator.

(ii) If Ω is multiply connected, then (1) has a nonzero solution for every $\lambda\in\mathbf{C}$.[2]

Our aim in this paper is to generalize this theory for ''coupled'' (or higher-order) Beltrami conditions[3] that describe structures far richer than the ones contained in the single curl Beltrami equation (1). In an ideal plasma, the coupling between the magnetic field and the plasma flow yields the ''double curl Beltrami equation,''

[a)]Electronic mail: yoshida@plasma.q.t.u-tokyo.ac.jp

$$\begin{aligned} &\nabla\times(\nabla\times\mathbf{u})+\alpha\nabla\times\mathbf{u}+\beta\mathbf{u}=0 \quad (\text{in } \Omega),\\ &\mathbf{n}\cdot\mathbf{u}=0, \quad \mathbf{n}\cdot(\nabla\times\mathbf{u})=0 \quad (\text{on } \partial\Omega), \end{aligned} \tag{2}$$

where $\mathbf{u}$ is either the magnetic field or the flow velocity of the plasma (Sec. III). Applying the spectral theory of the curl operator, we will show that (2) has a nonzero solution for arbitrary complex numbers α and β, if the domain Ω is multiply connected (Sec. IV). The method of present theory applies for general multicurl Beltrami equations obtained from simultaneous Beltrami conditions in coupled systems.

II. VORTEX DYNAMICS AND BELTRAMI CONDITION

We start with reviewing the prototype equation for vortex dynamics. Let $\boldsymbol{\omega}$ be a three-dimensional vector field representing a certain vorticity (contravariant vector field) in $\mathbf{R}^3$. We consider an incompressible flow $\mathbf{U}$ that transports $\boldsymbol{\omega}$. When the circulation associated with the vorticity is conserved everywhere, this $\boldsymbol{\omega}$ obeys the equation

$$\frac{\partial}{\partial t}\boldsymbol{\omega}-\nabla\times(\mathbf{U}\times\boldsymbol{\omega})=0. \tag{3}$$

In $\mathbf{R}^2$, the vorticity becomes a pseudoscalar field ω, and the vortex dynamics equation can be cast in the form of a Liouville equation,

$$\frac{\partial}{\partial t}\omega+\{\phi,\omega\}=0, \tag{4}$$

where ϕ is the Hamiltonian of an incompressible flow and $\{\ ,\ \}$ is the Poisson bracket, i.e.,

$$\mathbf{U}=\begin{pmatrix} \partial\phi/\partial y\\ -\partial\phi/\partial x\end{pmatrix}, \quad \{\phi,\omega\}=\frac{\partial\phi}{\partial y}\frac{\partial\omega}{\partial x}-\frac{\partial\phi}{\partial x}\frac{\partial\omega}{\partial y}. \tag{5}$$

The Beltrami condition with respect to (3) is

$$\mathbf{U}=\mu\boldsymbol{\omega}, \tag{6}$$

where μ is a certain scalar function. This condition assures the vanishing of the generator of the vortex dynamics equation (3). For (4), the Beltrami condition is simply

$$\phi=f(\omega), \tag{7}$$

which implies the commutation of the vorticity and the Hamiltonian of the flow.

The simplest example of the vortex dynamics equation is that of the Euler equation of incompressible ideal flows. Let $\mathbf{U}$ be an incompressible flow that obeys

$$\frac{\partial}{\partial t}\mathbf{U}+(\mathbf{U}\cdot\nabla)\mathbf{U}=-\nabla p, \tag{8}$$

where p is the pressure. Taking the curl of (8), we obtain the evolution equation for the vorticity $\boldsymbol{\omega}=\nabla\times\mathbf{U}$, which reads, in $\mathbf{R}^3$, as (3), and in $\mathbf{R}^2$, as (4). In the Beltrami flow, $\boldsymbol{\omega}$ parallels $\mathbf{U}$, i.e.,

$$\nabla\times\mathbf{U}=\mu\mathbf{U}. \tag{9}$$

We note that (9) is not Galilean invariant. We thus consider a bounded domain and impose a boundary condition [see (1)] to remove the freedom of the Galilei transform. Taking the divergence of (9), we find that the scalar function μ must satisfy

$$\mathbf{U}\cdot\nabla\mu=0, \tag{10}$$

demanding that μ must remain constant along each streamline of the flow $\mathbf{U}$. An analysis of the nonlinear system of elliptic–hyperbolic partial differential equations (9)–(10) involves extremely difficult mathematical issues. The characteristic curve of (10) is the streamline of the unknown flow $\mathbf{U}$, which can be chaotic (nonintegrable) in general three-dimensional problems. If we assume, however, that μ is a constant number, the analysis reduces into a simple but nontrivial problem, i.e., the eigenvalue problem of the curl operator. In this paper, our analysis is restricted to this mathematically well-defined subclass of Beltrami fields.

We end this section by reviewing another example of vortex dynamics; the magnetohydrodynamic (MHD) description of a plasma. The two principal equations of the ideal (dissipationless) conducting-fluid model are

$$\mathbf{E}+\mathbf{U}\times\mathbf{B}=0, \tag{11}$$

$$\frac{\partial}{\partial t}\mathbf{U}+(\mathbf{U}\cdot\nabla)\mathbf{U}=\frac{1}{\rho}(\mathbf{J}\times\mathbf{B}-\nabla p), \tag{12}$$

where $\mathbf{U}$, $\mathbf{J}$, $\mathbf{E}$, and $\mathbf{B}$ are, respectively, the flow velocity, the current density, the electric field, and the magnetic field measured in certain fixed coordinates, and ρ is the fluid mass density that is assumed to be constant. We may write

$$\mathbf{E}=-\frac{\partial}{\partial t}\mathbf{A}-\nabla\phi, \tag{13}$$

$$\mathbf{J}=\frac{1}{\mu_0}\nabla\times\mathbf{B}, \tag{14}$$

in terms of a vector potential $\mathbf{A}$ (such that $\nabla\times\mathbf{A}=\mathbf{B}$) and a scalar potential ϕ. Using Faraday's law,

$$\partial\mathbf{B}/\partial t=-\nabla\times\mathbf{E},$$

and taking the curl of (11) and (12), we obtain

$$\frac{\partial}{\partial t}\mathbf{B}-\nabla\times(\mathbf{U}\times\mathbf{B})=0, \tag{15}$$

$$\frac{\partial}{\partial t}\boldsymbol{\omega}-\nabla\times\left(\frac{\mathbf{J}\times\mathbf{B}}{\rho}+\mathbf{U}\times\boldsymbol{\omega}\right)=0, \tag{16}$$

where $\boldsymbol{\omega}=\nabla\times\mathbf{U}$. The Beltrami conditions for this system of vortex dynamics equations are

$$\mathbf{J}=\mu_1\mathbf{B}=\mu_2\mathbf{U}=\mu_3\boldsymbol{\omega}. \tag{17}$$

Using (14) in the first equality of (17), we get

$$\nabla\times\mathbf{B}=\mu\mathbf{B}, \tag{18}$$

which implies that $\mathbf{B}$ parallels its own vorticity [cf. (9)]. This configuration, for which the magnetic stress $\mathbf{J}\times\mathbf{B}$ vanishes, is aptly called ''force-free.''

In order to characterize the stellar magnetic fields, solutions to (18) were intensively studied in the 1950s.[4–6] For $\mu\neq0$, the magnetic field $\mathbf{B}$ has a finite curl, and, hence, the field lines are twisted. The current (proportional to $\nabla\times\mathbf{B}$), flowing parallel to the twisted field lines, creates what may be termed as ''paramagnetic'' structures. Such twisted magnetic field lines appear commonly in many different plasma systems such as the magnetic ropes created in solar and geomagnetic systems,[7] and galactic jets.[8] Some laboratory experiments have also shown that the ''relaxed state'' generated through turbulence is well described as solutions of the force-free equation.[9,10]

In the next section, we will show that a more adequate formulation of the plasma dynamics allows a much wider class of special equilibrium solutions. The set of new solutions contains field configurations that can be qualitatively different from the force-free magnetic fields.

III. DOUBLE CURL BELTRAMI FIELD

The two-fluid model for the macroscopic dynamics of a plasma differentiates between the electron and ion velocities. Denoting the electron (ion) flow velocity by $\mathbf{V}_e(\mathbf{V}_i)$, the macroscopic evolution equations become

$$\frac{\partial}{\partial t}\mathbf{V}_e+(\mathbf{V}_e\cdot\boldsymbol{\nabla})\mathbf{V}_e=\frac{-e}{m}(\mathbf{E}+\mathbf{V}_e\times\mathbf{B})-\frac{1}{mn}\boldsymbol{\nabla}p_e, \tag{19}$$

$$\frac{\partial}{\partial t}\mathbf{V}_i+(\mathbf{V}_i\cdot\boldsymbol{\nabla})\mathbf{V}_i=\frac{e}{M}(\mathbf{E}+\mathbf{V}_i\times\mathbf{B})-\frac{1}{Mn}\boldsymbol{\nabla}p_i, \tag{20}$$

where $\mathbf{E}$ is the electric field, p_e and p_i are, respectively, the electron and the ion pressures, e is the elementary charge, n is the number density of both electrons and ions (we consider a quasineutral plasma with singly charged ions), and m and M are, respectively, the electron and the ion masses. In the electron equation, the inertial terms [the left-hand side of (19)] can be safely neglected, because of their small mass $(m\ll M)$.[11] Therefore, (19) reduces to

$$\mathbf{E}+\mathbf{V}_e\times\mathbf{B}+\frac{1}{en}\boldsymbol{\nabla}p_e=0. \tag{21}$$

When electron mass is neglected, $\mathbf{V}_i=\mathbf{V}$, the fluid velocity. We introduce the following set of dimensionless variables:

$$\begin{gathered}\mathbf{x}=\lambda_i\hat{\mathbf{x}},\quad \mathbf{B}=B_0\hat{\mathbf{B}},\\ t=(\lambda_i/V_{\mathrm{A}})\hat{t},\quad p=(B_0^2/\mu_0)\hat{p},\quad \mathbf{V}=V_{\mathrm{A}}\hat{\mathbf{V}},\\ \mathbf{A}=(\lambda_iB_0)\hat{\mathbf{A}},\quad \phi=(V_{\mathrm{A}}\lambda_iB_0)\hat{\phi},\end{gathered} \tag{22}$$

where the ion skin depth,

$$\lambda_i=\frac{c}{\omega_{pi}}=\frac{V_{\mathrm{A}}}{\omega_{ci}}=\sqrt{\frac{M}{\mu_0ne^2}},$$

is a characteristic length scale of the system, and the Alfvén speed is given by $V_{\mathrm{A}}=B_0/\sqrt{\mu_0Mn}$ (we assume $n=$const, for simplicity), with B_0 as an appropriate measure of the magnetic field.

Writing $\hat{\mathbf{E}}=-\partial\hat{\mathbf{A}}/\partial\hat{t}-\hat{\boldsymbol{\nabla}}\hat{\phi}$, the dimensionless version of (21) and (20) now reads as

$$\frac{\partial}{\partial\hat{t}}\hat{\mathbf{A}}=(\hat{\mathbf{V}}-\hat{\boldsymbol{\nabla}}\times\hat{\mathbf{B}})\times\hat{\mathbf{B}}-\hat{\boldsymbol{\nabla}}(\hat{\phi}+\hat{p}_e), \tag{23}$$

$$\frac{\partial}{\partial \hat{t}}(\hat{\mathbf{V}}+\hat{\mathbf{A}})=\hat{\mathbf{V}}\times(\hat{\mathbf{B}}+\hat{\boldsymbol{\nabla}}\times\hat{\mathbf{V}})-\hat{\boldsymbol{\nabla}}(\hat{V}^2/2+\hat{p}_i+\hat{\phi}). \tag{24}$$

In what follows, we shall drop the overcaret for a simpler notation. Taking the curl of (23) and (24), we can cast them in a revealing symmetric form,

$$\frac{\partial}{\partial t}\boldsymbol{\omega}_j-\boldsymbol{\nabla}\times(\mathbf{U}_j\times\boldsymbol{\omega}_j)=0 \quad (j=1,2), \tag{25}$$

in terms of a pair of generalized vorticities,

$$\boldsymbol{\omega}_1=\mathbf{B}, \quad \boldsymbol{\omega}_2=\mathbf{B}+\boldsymbol{\nabla}\times\mathbf{V},$$

and the effective flows,

$$\mathbf{U}_1=\mathbf{V}-\boldsymbol{\nabla}\times\mathbf{B}, \quad \mathbf{U}_2=\mathbf{V}.$$

The simplest equilibrium solution to (25) is given by the ''Beltrami conditions,''

$$\mathbf{U}_j=\mu_j\boldsymbol{\omega}_j \quad (j=1,2), \tag{26}$$

which implies the alignment of the vorticities and the corresponding flows. Writing $a=1/\mu_1$ and $b=1/\mu_2$, and assuming that a and b are constants, the Beltrami conditions (26) read as a system of simultaneous linear equations in **B** and **V**,

$$\mathbf{B}=a(\mathbf{V}-\boldsymbol{\nabla}\times\mathbf{B}), \tag{27}$$

$$\mathbf{B}+\boldsymbol{\nabla}\times\mathbf{V}=b\mathbf{V}. \tag{28}$$

These equations have a simple and significant connotation; the electron flow $(\mathbf{V}-\boldsymbol{\nabla}\times\mathbf{B})$ parallels the magnetic field **B**, while the ion flow **V** follows the ''generalized magnetic field'' $(\mathbf{B}+\boldsymbol{\nabla}\times\mathbf{V})$. This generalized magnetic field contains the Coriolis' force induced by the ion inertia effect on a circulating flow.

Combining (27) and (28) yields a second-order partial differential equation,

$$\boldsymbol{\nabla}\times(\boldsymbol{\nabla}\times\mathbf{B})+\alpha\boldsymbol{\nabla}\times\mathbf{B}+\beta\mathbf{B}=0, \tag{29}$$

where

$$\alpha=\frac{1}{a}-b, \quad \beta=1-\frac{b}{a}.$$

The double curl Beltrami equation (29) encompasses a wide class of steady-state equations of mathematical physics. The conventional force-free-field equation (18), which describes paramagnetic fields, is included in this system as a special case: $\alpha=0$ and $\beta<0$. On the other hand, when $\alpha=0$ and $\beta>0$, (29) resembles London's equation of superconductivity with its well-known fully diamagnetic solutions. We note that, in this version of the London equation, the characteristic shielding length for the magnetic field is the ion skin depth c/ω_{pi}, instead of the usual electron skin depth c/ω_{pe}, because it is the ion dynamics that brings about the coupling of the magnetic field with the collective motion of the medium.

In the next section, we will study the mathematical structure of the double curl Beltrami equation with arbitrary complex α and β.[12]

IV. BELTRAMI FIELDS AND HARMONIC FIELDS

The single Beltrami condition (1) is known to have a nonzero solution for arbitrary complex number λ, if the domain Ω is multiply connected.[1] The harmonic field that represents the cohomology class of the differential forms in Ω plays an essential role to generate the Beltrami field. A similar relation holds in the double curl Beltrami equations (2). Here, we study the relation between the topology of the domain Ω and the degree of freedom in the solution of the double curl Beltrami fields.

It is convenient to denote the curl derivative $\nabla\times$ by ''curl'' to use it as an operator. Let us rewrite the differential equation of (2) in the form

$$(\mathrm{curl}-\lambda_+)(\mathrm{curl}-\lambda_-)\mathbf{u}=0, \tag{30}$$

where

$$\lambda_\pm=\tfrac{1}{2}[-\alpha\pm(\alpha^2-4\beta)^{1/2}]. \tag{31}$$

Because the two operators $(\mathrm{curl}-\lambda_\pm)$ commute, the general solution to (30) is given by a linear combination of two Beltrami fields. Let $\mathbf{G}_\pm$ be the Beltrami field, such that

$$\begin{cases}(\mathrm{curl}-\lambda_\pm)\mathbf{G}_\pm=0 \quad (\text{in } \Omega),\\ \mathbf{n}\cdot\mathbf{G}_\pm=0 \quad (\text{on } \partial\Omega).\end{cases}$$

Then, for arbitrary constants $c_\pm$, the sum

$$\mathbf{u}=c_+\mathbf{G}_+ + c_-\mathbf{G}_- \tag{32}$$

solves (30). Since $\mathbf{n}\cdot(\nabla\times\mathbf{G}_\pm)=\lambda_\pm\mathbf{n}\cdot\mathbf{G}_\pm=0$ on $\partial\Omega$, $\mathbf{u}$ satisfies the boundary conditions given in (2). Therefore, the existence of a nontrivial solution to the double curl Beltrami equations (2) will be predicated on the existence of the appropriate pair of single Beltrami fields (cf. Appendix B). Let us briefly review the mathematical theory of single Beltrami fields.[1]

Suppose that $\Omega(\subset\mathbf{R}^3)$ is a bounded domain with a smooth boundary $\partial\Omega=\cup_{i=1}^n\Gamma_i$. We consider cuts of the domain Ω. Let $\Sigma_1,\ldots,\Sigma_\nu$ $(\nu\geqslant 0)$ be the cuts such that $\Sigma_i\cap\Sigma_j=\emptyset$ $(i\neq j)$, and such that $\Omega\setminus(\cup_{j=1}^\nu\Sigma_j)$ becomes a simply connected domain. The number ν of such cuts is the first Betti number of Ω. When $\nu>0$, we define the flux through each cut by

$$\Phi_j(\mathbf{u})=\int_{\Sigma_j}\mathbf{n}\cdot\mathbf{u}\,ds \quad (j=1,\ldots,\nu),$$

where $\mathbf{n}$ is the unit normal vector on Σ_j with an appropriate orientation. By Gauss' formula, $\Phi_j(\mathbf{u})$ is independent of the place of the cut Σ_j, if $\nabla\cdot\mathbf{u}=0$ in Ω and $\mathbf{n}\cdot\mathbf{u}=0$ on $\partial\Omega$.

Let $L^2(\Omega)$ the Lebesgue space of square-integrable (complex) vector fields in Ω, which is endowed with the standard inner product,

$$(\mathbf{a},\mathbf{b})=\int_\Omega \mathbf{a}\cdot\overline{\mathbf{b}}\,dx.$$

We define the following subspaces of $L^2(\Omega)$:

$$L^2_\Sigma(\Omega)=\{\mathbf{w};\nabla\cdot\mathbf{w}=0 \text{ in } \Omega,\ \mathbf{n}\cdot\mathbf{w}=0 \text{ on } \partial\Omega,\ \Phi_j(\mathbf{w})=0\ (j=1,\ldots,\nu)\},$$

$$L^2_H(\Omega)=\{\mathbf{h};\nabla\cdot\mathbf{h}=0,\ \nabla\times\mathbf{h}=0 \text{ in } \Omega,\ \mathbf{n}\cdot\mathbf{h}=0 \text{ on } \partial\Omega\},$$

$$L^2_G(\Omega)=\{\nabla\phi;\ \Delta\phi=0 \text{ in } \Omega\},$$

$$L_F^2(\Omega)=\{\nabla\phi;\ \ \phi=c_i(\in\mathbf{C})\ \text{ on }\ \Gamma_i\ \ (i=1,...,n)\},$$

in terms of which we have an orthogonal decomposition,[13]

$$L^2(\Omega)=L_\Sigma^2(\Omega)\oplus L_H^2(\Omega)\oplus L_G^2(\Omega)\oplus L_F^2(\Omega).$$

The space of the solenoidal vector fields with vanishing normal components on $\partial\Omega$ is

$$L_\sigma^2(\Omega)=L_\Sigma^2(\Omega)\oplus L_H^2(\Omega).$$

The subspace $L_H^2(\Omega)$ corresponds to the cohomology class, whose member is a harmonic vector field and $\dim L_H^2(\Omega)=\nu$ (the first Betti number of Ω). When Ω is simply connected, then $\nu=0$ and $L_H^2(\Omega)=\emptyset$. We have the following expression:

$$L_\Sigma^2(\Omega)=\{\nabla\times\mathbf{w};\mathbf{w}\in H^1(\Omega),\ \ \nabla\cdot\mathbf{w}=0\ \text{ in }\ \Omega,\ \ \mathbf{n}\times\mathbf{w}=0\ \text{ on }\ \partial\Omega\},$$

where $H^1(\Omega)$ is the Sobolev space of first order. This says that a member of $L_\Sigma^2(\Omega)$ can be expressed as the curl of a vector potential with the boundary condition $\mathbf{n}\times\mathbf{w}=0$.

The spectral theory of the curl operator provides the basic understanding of the mathematical structure of the Beltrami equations. We repeat Theorem 1 of Yoshida–Giga.[1]

Theorem 1: *Suppose that Ω is a smoothly bounded domain in $\mathbf{R}^3$. We define a curl operator $\mathcal{S}$ in the Hilbert space $L_\Sigma^2(\Omega)$ by*

$$\mathcal{S}\mathbf{u}=\nabla\times\mathbf{u},$$

$$D(\mathcal{S})=\{\mathbf{u}\in L_\Sigma^2(\Omega);\ \ \nabla\times\mathbf{u}\in L_\Sigma^2(\Omega)\}.$$

The $\mathcal{S}$ is a self-adjoint operator. The spectrum of $\mathcal{S}$ consists of only point spectrum $\sigma_p(\mathcal{S})$, which is a discrete set of real numbers.

This theorem says that the Beltrami equation (1) together with the zero-flux condition [see the definition of the space $L_\Sigma^2(\Omega)$] has a nonzero solution only for special discrete real numbers $\lambda\in\sigma_p(\mathcal{S})$. If Ω is simply connected $(\nu=0)$, the topological flux $\Phi_j(\ )$ does not exist, so that $L_\Sigma^2(\Omega)=L_\sigma^2(\Omega)$. If Ω is multiply connected $(\nu\geqslant 1)$, however, we can remove the zero-flux condition assumed in Theorem 1, and consider a wider set of functions to find solutions of (1). This is done by considering the curl operator defined in the space $L_\sigma^2(\Omega)$. Let us trace the method of Yoshida–Giga.[1]

Lemma 1: For every $\mathbf{f}\in L_\sigma^2(\Omega)$, the equation,

$$\nabla\times\mathbf{u}=\mathbf{f}\quad(\text{in }\ \Omega),\tag{33}$$

has a unique solution in $L_\Sigma^2(\Omega)$.

Proof: Let $\mathbf{f}$ be the 0-extension of $\mathbf{f}$ over $\mathbf{R}^3$, i.e.,

$$\tilde{\mathbf{f}}(x)=\begin{cases}\mathbf{f}(x), & x\in\Omega,\\ 0, & x\notin\Omega.\end{cases}$$

Since $\mathbf{f}\in L_\sigma^2(\Omega)$, we have $\nabla\cdot\tilde{\mathbf{f}}=0$ in $\mathbf{R}^3$. We denote by $(-\Delta)^{-1}$ the vector Newtonian potential. We define

$$\mathbf{w}_0=\nabla\times[(-\Delta)^{-1}\tilde{\mathbf{f}}],\quad\text{in }\ \Omega.$$

We denote by $\mathcal{P}_\Sigma$ the orthogonal projection in $L^2(\Omega)$ onto $L_\Sigma^2(\Omega)$, and define $\mathbf{u}_0=\mathcal{P}_\Sigma\mathbf{w}_0$. Since $L_\Sigma^2(\Omega)$ is orthogonal to Ker(curl), we observe

$$\nabla\times\mathbf{u}_0=\nabla\times\mathbf{w}_0=\nabla\times\{\nabla\times[(-\Delta)^{-1}\tilde{\mathbf{f}}]\}.$$

Since $\nabla\cdot[(-\Delta)^{-1}\tilde{\mathbf{f}}]=0$, we obtain

$$\nabla\times\{\nabla\times[(-\Delta)^{-1}\tilde{\mathbf{f}}]\}=-\Delta[(-\Delta)^{-1}\tilde{\mathbf{f}}]=\tilde{\mathbf{f}}.$$

We thus find that $\mathbf{u}_0$ $[\in L^2_\Sigma(\Omega)]$ is the solution of (33). Since $L^2_\Sigma(\Omega)$ is orthogonal to Ker(curl), this $\mathbf{u}_0$ is the unique solution. □

This lemma shows that every solenoidal vector field [member of $L^2_\sigma(\Omega)$] has a unique vector potential in the space $L^2_\Sigma(\Omega)$. We apply this result to determine the vector potential of the harmonic field [member of $L^2_H(\Omega)$]. Let $\nu(\geqslant 1)$ be the dimension of $L^2_H(\Omega)$ (first Betti number of Ω), and $\mathbf{h}_j$ $(j=1,...,\nu)$ be the orthogonal basis of $L^2_H(\Omega)$, such that

$$\Phi_i(\mathbf{h}_j)=\int_{\Sigma_i}\mathbf{n}\cdot\mathbf{h}_j\,ds=\delta_{i,j}\,. \tag{34}$$

By solving (33) for $\mathbf{f}=\mathbf{h}_j$, we obtain the corresponding vector potential, which we denote by $\mathbf{g}_j$, i.e.,

$$\nabla\times\mathbf{g}_j=\mathbf{h}_j \quad (\text{in }\ \Omega), \quad \mathbf{g}_j\in L^2_\Sigma(\Omega) \quad (j=1,...,\nu).$$

Let us consider an arbitrary harmonic field and its vector potential, and write them as

$$\mathbf{h}=\sum_{j=1}^{\nu}\xi_j\mathbf{h}_j\,, \quad \mathbf{g}=\sum_{j=1}^{\nu}\xi_j\mathbf{g}_j\,. \tag{35}$$

For every $\lambda\notin\sigma_p(\mathcal{S})$, the resolvent operator $(\mathcal{S}-\lambda)^{-1}$ defines a unique continuous map on $L^2_\Sigma(\Omega)$. We consider

$$\mathbf{v}=\lambda\mathbf{g}+\lambda^2(\mathcal{S}-\lambda)^{-1}\mathbf{g}.$$

This $\mathbf{v}$ is the unique solution [in $L^2_\Sigma(\Omega)$] of

$$(\text{curl}-\lambda)\mathbf{v}=\lambda\mathbf{h} \quad (\text{in }\ \Omega). \tag{36}$$

Now we find that $\mathbf{u}=\mathbf{v}+\mathbf{h}$ solves

$$\begin{cases}(\text{curl}-\lambda)\mathbf{u}=0 & (\text{in }\ \Omega),\\ \mathbf{n}\cdot\mathbf{u}=0 & (\text{on }\ \partial\Omega).\end{cases}$$

Since $\mathbf{h}[\in L^2_H(\Omega)]$ and $\mathbf{v}[\in L^2_\Sigma(\Omega)]$ are orthogonal, $\mathbf{u}\not\equiv 0$.

We have shown that the single curl Beltrami equation (1) has a nonzero solution for every complex number λ, if the domain Ω is multiply connected. For $\lambda\notin\sigma_p(\mathcal{S})$, the solution is uniquely determined by the harmonic field $\mathbf{h}$. Although (1) appears as a homogeneous equation, the harmonic field (member of the kernel of curl) plays a role of a hidden inhomogeneous term; see (36). On the other hand, for $\lambda\in\sigma_p(\mathcal{S})$, the solution is given by the eigenfunction of the self-adjoint curl operator $\mathcal{S}$. Therefore, the solution is a zero-flux field, and $\mathbf{h}$ must be set to zero. The solution is not unique in the sense that any constant multiple of the eigenfunction is a solution.

Because of (32), it is now straightforward to generalize the theory for the double curl (and multicurl) Beltrami equations.

Theorem 2: *For a multiply connected smoothly bounded domain Ω, and for all complex numbers λ_1 and λ_2, the equation,*

$$(\text{curl}-\lambda_1)(\text{curl}-\lambda_2)\mathbf{u}=0, \tag{37}$$

has a nonzero solution.

Let us examine the relations among the solutions, the harmonic fields and the fluxes. If $\lambda_1,\lambda_2 \notin \sigma_p(\mathcal{S})$, then the solution is given by

$$\mathbf{u}=c_1\mathbf{u}_1+c_2\mathbf{u}_2,$$

$$\mathbf{u}_j=\mathbf{h}+\lambda_j\mathbf{g}+\lambda_j^2(\mathcal{S}-\lambda_j)^{-1}\mathbf{g} \quad (j=1,2),$$

where $\mathbf{h}\in L^2_H(\Omega)$, $\nabla\times\mathbf{g}=\mathbf{h}$, and $\mathbf{g}\in L^2_\Sigma(\Omega)$. Let us decompose $\mathbf{h}$ in terms of the normalized bases as (35). The coefficients $c_1,c_2,\xi_1,\ldots,\xi_\nu$ are related to the fluxes of $\mathbf{u}$ and $\nabla\times\mathbf{u}$ by

$$\begin{aligned}(c_1+c_2)\xi_j&=\Phi_j(\mathbf{u}),\\ (c_1\lambda_1+c_2\lambda_2)\xi_j&=\Phi_j(\nabla\times\mathbf{u}),\end{aligned} \quad (j=1,\ldots,\nu),$$

where $\Phi_j(\,)$ is the flux through the cut Σ_j. When $\nu=1$ (as in the case of a simple toroid), we can give the fluxes of both $\mathbf{u}$ and $\nabla\times\mathbf{u}$ independently to determine ξ_1 and c_1 with setting $c_2=1-c_1$ (cf. Appendix B). For $\nu>1$, the fluxes of $\nabla\times\mathbf{u}$ are not totally independent.

If $\lambda_1\in\sigma_p(\mathcal{S})$ and $\lambda_2\notin\sigma_p(\mathcal{S})$, we take $\mathbf{u}_1$ to be the eigenfunction corresponding to λ_1. Then, $\mathbf{u}_1$ is a zero-flux function, and, hence, c_1 is an arbitrary constant. The other component $\mathbf{u}_1$ carries fluxes. Taking $c_2=1$, we can determine

$$\xi_j=\Phi_j(\mathbf{u}) \quad (j=1,\ldots,\nu).$$

If $\lambda_1,\lambda_2\in\sigma_p(\mathcal{S})$, then both $\mathbf{u}_1$ and $\mathbf{u}_2$ are the corresponding eigenfunctions. A solution exists only for $\xi_j=0$ $(j=1,\ldots,\nu)$.

V. SUMMARY

The study of the solvability of the double curl equation is warranted both by physical as well as mathematical considerations. A more adequate modeling of plasma dynamics, containing a coupling of the magnetic and fluid aspects of a plasma, necessarily leads to a departure from the conventional single Beltrami equilibria (1), which are restricted to only force-free equilibria. This departure, then, leads to an immensely larger class of physically interesting equilibria, which can be constructed by a superposition of several different Beltrami fields. In the example dealt with in this paper (where the coupling is introduced by the Hall term), a superposition of two Beltrami fields suffices. Notice that in the nonlinear vortex dynamics models such as (3) with coupled $\boldsymbol{\omega}$ and $\mathbf{U}$, a linear combination of Beltrami fields is no longer a Beltrami field. Hence, a finite pressure and coupled flows can exist in conjunction with the magnetic field, and the structures that are far richer than those of single Beltrami fields come within the scope of the theory.[3]

The mathematical content of the paper may be summarized as follows: We have elucidated the general relation between the (double curl) Beltrami fields and the harmonic fields, which, being members of Ker(curl), play the role of a hidden inhomogeneous term in the Beltrami equations. The existence of harmonic fields invokes the multiply connectedness of the domain. For every $\lambda\in\mathbf{C}\backslash\sigma_p(\mathcal{S})$ (point spectrum of the self-adjoint curl operator), a harmonic field generates a nonzero unique Beltrami field corresponding to λ. When $\lambda\in\sigma_p(\mathcal{S})$, the corresponding eigenfunction gives the Beltrami field. The linear combination of two Beltrami fields yields the double curl Beltrami field.

APPENDIX A: VARIATIONAL PRINCIPLE AND RELAXATION THEORY

The Beltrami condition can be derived by a variational principle invoking the ‘‘helicity.’’ Woltjer[14] derived the force-free equation (18) by minimizing the magnetic energy with the constraint that the magnetic helicity is conserved. Here, the magnetic helicity is, for a magnetic field **B** and its vector potential **A**,

$$H=\frac{1}{2}\int_\Omega \mathbf{A}\cdot\mathbf{B}\,dx.$$

Minimization of the magnetic field energy,

$$E=\frac{1}{2}\int_\Omega |\mathbf{B}|^2\,dx=\frac{1}{2}\int_\Omega |\nabla\times\mathbf{A}|^2\,dx,$$

with keeping H constant is represented by the variational principle

$$\delta(E-\lambda H)=0, \tag{A1}$$

where λ is the Lagrange multiplier. Assuming a boundary condition,

$$\mathbf{n}\times\mathbf{A}=0 \quad (\text{on } \partial\Omega) \tag{A2}$$

[note that $\mathbf{n}\cdot\mathbf{B}=0$ (on $\partial\Omega$) follows from (A2)], the formal Euler–Lagrange equation with respect to (A1) yields (18); see Ref. 15 for a more rigorous treatment of the variational principle.

Using Maxwell's equations, we obtain

$$\frac{\partial}{\partial t}(\mathbf{A}\cdot\mathbf{B})=-2\mathbf{E}\cdot\mathbf{B}-\nabla\cdot(\phi\mathbf{B}+\mathbf{E}\times\mathbf{A}).$$

In an ideal plasma, $\mathbf{E}\cdot\mathbf{B}=0$ [see (11)]. When Ω is surrounded by a perfectly conducting wall, we find that H is a constant of motion. Taylor[16] introduced the far-reaching concept of relaxation; he conjectured that a small amount of resistivity would tend to relax all constraints restricting an ideal plasma leaving only the ‘‘rugged’’ constraint on the global helicity H. When the magnetic energy achieves its minimum under the constraint on H, the ‘‘relaxed state’’ is characterized by the variational principle (A1), and, hence, the magnetic field satisfies the force-free equation (18). Many authors have examined the selective dissipation of the magnetic field energy E with respect to the helicity H (see Hasegawa[17] and papers cited there). Montgomery *et al.*[18] studied the statistical mechanical properties of the relaxed state using the Beltrami functions to expand fields (see also Ref. 19).

The conservation of helicity applies for general vortex dynamics. Let $\boldsymbol{\omega}$ be a vorticity that satisfies (3) and boundary condition,

$$\mathbf{n}\times(\mathbf{U}\times\boldsymbol{\omega})=0 \quad (\text{on } \partial\Omega).$$

The general ‘‘helicity’’ is defined as

$$\mathcal{H}=\frac{1}{2}\int_\Omega (\text{curl}^{-1}\,\boldsymbol{\omega})\cdot\boldsymbol{\omega}\,dx,$$

where curl^{-1} is the inverse operator of the curl that is represented by the Biot–Savart integral (see Lemma 1 for a more suitable treatment). By this definition, we easily verify the conservation of $\mathcal{H}$. For our two-fluid MHD model, we have two helicities:

$$H_1=\frac{1}{2}\int_\Omega \mathbf{A}\cdot\mathbf{B}\,dx, \qquad H_2=\frac{1}{2}\int_\Omega (\mathbf{A}+\mathbf{V})\cdot(\mathbf{B}+\nabla\times\mathbf{V})dx.$$

The total energy,

$$E=\frac{1}{2}\int_\Omega (|\mathbf{B}|^2+|\mathbf{V}|^2)dx,$$

is also conserved. The variation $\delta(E-\mu_1 H_1-\mu_2 H_2)=0$ will directly lead us to (27) and (28) (cf. Ref. 20).

APPENDIX B: EXAMPLES OF SOLUTIONS

Some explicit forms of the Beltrami fields may help understanding of the structures of the solutions.

When we consider a cubic volume that has sides of length a and assume the periodic boundary condition, we have the so-called *ABC* flow. Let *A, B,* and *C* be real (complex) constants and $\lambda=2\pi n/a$ $(n\in\mathbf{N})$. In the Cartesian coordinates, we define

$$\mathbf{u}=\begin{pmatrix} A\sin\lambda z+C\cos\lambda y\\ B\sin\lambda x+A\cos\lambda z\\ C\sin\lambda y+B\cos\lambda x\end{pmatrix}. \tag{B1}$$

We easily verify that (B1) gives an eigenfunction of the curl belonging to an eigenvalue λ. The linear combination of two *ABC* flows give the double curl Beltrami flow.

Solutions with the zero-normal boundary conditions are known for a cylindrical domain. In the (r,θ,z) cylindrical coordinates, the Chandrasekhar–Kendall function[6] is defined as

$$\mathbf{u}=\lambda(\nabla\psi\times\nabla z)+\nabla\times(\nabla\psi\times\nabla z), \tag{B2}$$

with

$$\lambda=\pm(\mu^2+k^2)^{1/2} \tag{B3}$$

$$\psi=J_m(\mu r)e^{i(m\varphi-kz)}, \quad k=2\pi n/L, \quad m,n\in\mathbf{N}, \tag{B4}$$

where J_m is the ordinary Bessel function and L is the length of the periodic cylinder. We find that $\mathbf{u}$ is an eigenfunction of the curl corresponding to the eigenvalue $\lambda(\in\mathbf{R})$. The eigenvalue is determined by the boundary condition that the normal component of $\mathbf{u}$ vanishes on the surface of the cylindrical domain. This condition becomes trivial when $k=m=0$. For these axisymmetric modes, we impose the ''zero-flux condition,''

$$\Phi(\mathbf{u})=\int_\Sigma \mathbf{n}\cdot\mathbf{u}\,ds=0, \tag{B5}$$

where Σ is a cut of the cylinder (cf. Theorem 1).

When we do not impose the zero-flux condition, however, the eigenvalue μ can be an arbitrary real (and even complex) number for the $k=m=0$ mode.[2] Therefore, we have nonzero Beltrami fields for arbitrary λ. For such a solution that has a finite flux $\Phi(\mathbf{u})$, the flux can be regarded as the variable of state. The double curl Beltrami field is a combination of two Beltrami fields, and, hence, the degree of freedom is two and two fluxes $\Phi(\mathbf{u})$ and $\Phi(\nabla\times\mathbf{u})$ can be assigned.

In a two-dimensional system, we can apply the Clebsch representation of solenoidal vector fields [cf. (4) and (5)]. For example, let us assume that the fields are homogeneous in the direction of z in the Cartesian coordinates x-y-z. We write $\mathbf{B}$ in a contravariant–covariant combination form,

$$\mathbf{B}=\nabla\psi\times\mathbf{e}+\phi\mathbf{e}, \tag{B6}$$

where $\mathbf{e}=\nabla z$. The ψ and ϕ are scalar functions of x and y. We have

$$\nabla\times\mathbf{B}=\nabla\phi\times\mathbf{e}+(-\Delta\psi)\mathbf{e},$$

$$\nabla\times(\nabla\times\mathbf{B})=\nabla(-\Delta\psi)\times\mathbf{e}+(-\Delta\phi)\mathbf{e}.$$

Using these expressions in the double curl Beltrami equation (29), we obtain a system of coupled Helmholtz equations,

$$-\Delta\psi+\alpha\phi+\beta\psi=C, \qquad -\Delta\phi-\alpha\Delta\psi+\beta\phi=0, \tag{B7}$$

where C is a constant. Biasing the potential ψ with $-C/\beta$, we can eliminate this constant. The system (B7) can be casted into a symmetric form,

$$\Delta\begin{pmatrix}\psi\\ \phi\end{pmatrix}=\begin{pmatrix}\beta & \alpha\\ -\alpha\beta & \beta-\alpha^2\end{pmatrix}\begin{pmatrix}\psi\\ \phi\end{pmatrix}. \tag{B8}$$

Similar algebra applies for the case of axisymmetric (toroidal) systems, where we must take $\mathbf{e}=\nabla\theta$ in (B6) and assume that ψ and ϕ are functions of r and z in the r-θ-z cylindrical coordinates. Then, the Laplacian Δ is replaced by the Grad–Shafranov operator,

$$L=r\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial}{\partial r}\right)+\frac{\partial^2}{\partial z^2}.$$

The coupled Grad–Shafranov equation of the type (B7) was derived previously for the analysis of toroidal equilibrium in a plasma–beam system, where the inertia force of the beam particles brings about coupling of the magnetic field and the beam flow.[21]

[12] We remark that the solution $\mathbf{u}$ is a real function, if α and β are real. Indeed, if $\mathbf{u}$ is a solution for real α and β, then $\overline{\mathbf{u}}$ is also a solution (take the complex conjugate of the equations). Since the solution is unique (see Sec. IV), $\mathbf{u}=\overline{\mathbf{u}}$, and hence $\mathbf{u}$ is a real function.

(Received 25 March 1999; accepted for publication 30 June 1999)

A qualitative analysis is presented for a class of homogeneous cosmologies derived from the string effective action when a cosmological constant is present in the matter sector of the theory. Such a term has significant effects on the qualitative dynamics. For example, models exist which undergo a series of oscillations between expanding and contracting phases due to the existence of a heteroclinic cycle in the phase space. Particular analytical solutions corresponding to the equilibrium points are also found.

I. INTRODUCTION

Very early universe cosmology provides one of the few environments where the predictions of fundamental theories of physics, and in particular string theories, can be investigated. String theory is the most promising candidate for a unified theory of the fundamental interactions. It introduces significant modifications to the standard, hot big bang model based on conventional Einstein gravity and a study of string-inspired cosmologies is therefore important.

String theories predict the existence of a graviton, $g_{\mu\nu}$, a scalar ''dilaton'' field, Φ, and an antisymmetric two-form potential, $B_{\mu\nu}$, with a field strength $H_{\mu\nu\lambda}\equiv\partial_{[\mu}B_{\nu\lambda]}$.[1,2] In four dimensions, the three-form field strength is dual to a one-form, $\nabla_\mu\sigma$, such that $H^{\mu\nu\lambda}\equiv e^{\Phi}\epsilon^{\mu\nu\lambda\kappa}\nabla_\kappa\sigma$, where $\epsilon^{\mu\nu\lambda\kappa}$ is the covariantly constant four-form.[3] The one-form may be interpreted as the gradient of a scalar ''axion'' field. The string field equations can then be derived from the effective action,[3]

$$S=\int d^4x\sqrt{-g}e^{-\Phi}\left[R+(\nabla\Phi)^2-\frac{1}{2}e^{2\Phi}(\nabla\sigma)^2\right]+S_M, \tag{1}$$

where S_M represents the action for perfect fluid matter sources, R is the Ricci curvature of the space–time and $g\equiv\det g_{\mu\nu}$. The dilaton-graviton sector of action (1) may be interpreted as a Brans–Dicke theory, where the coupling parameter between the two fields takes the specific value $\omega=-1$.[4] The value of the dilaton field determines the effective value of Newton's ''constant,'' $G_{\rm eff}\propto e^{\Phi}$.

The general solutions to the field equations of action (1) are known analytically when $S_M=0$ for both the spatially flat and isotropic Friedmann–Robertson–Walker (FRW) universes and

[a)]Electronic mail: jaf@mscs.dal.ca
[b)]Electronic mail: aac@mscs.dal.ca
[c)]Electronic mail: jlidsey@astr.cpes.susx.ac.uk

the anisotropic Bianchi type I models.[5,6] The purpose of the present paper is to qualitatively investigate the consequences of introducing a cosmological constant, Λ_M, into the matter sector of Eq. (1),

$$S=\int d^4x\sqrt{-g}\left\{e^{-\Phi}\left[R+(\nabla\Phi)^2-\frac{1}{2}e^{2\Phi}(\nabla\sigma)^2\right]-\Lambda_M\right\}. \tag{2}$$

This term may be interpreted as a perfect fluid matter stress with an equation of state $p=-\rho$. It could be generated by a slowly moving scalar field, with a kinetic energy contribution dominated by a self-interaction potential, $p\approx -V\approx -\rho$. Analytical FRW solutions have not been found for this model when the axion field is trivial and $\Lambda_M>0$.[7,8] Moreover, the combined effects of the cosmological constant and axion field have not been considered previously.

We determine the general structure of the phase space of solutions for spatially flat FRW and axisymmetric Bianchi type I cosmologies derived from action (2) for arbitrary Λ_M. This complements the work of Refs. 9–13, where the qualitative effects of introducing a cosmological constant, $\Lambda_M\propto e^{-\Phi}$, into the gravitational sector of Eq. (1) were determined.

The paper is organized as follows. In Sec. II, the cosmological field equations and solutions for a zero cosmological constant are presented. The qualitative behavior of the models with positive and negative Λ_M is determined in Secs. III and IV, respectively. The phase portraits are interpreted in Sec. V and we conclude with a discussion in Sec. VI.

II. COSMOLOGICAL FIELD EQUATIONS

The metric for the Bianchi type I model may be written in the form

$$ds^2=-dt^2+h_{ab}dx^a dx^b, \quad a,b=1,2,3, \tag{3}$$

where $h_{ab}(t)$ is a function of cosmic time t only and represents the metric on the surfaces of homogeneity. The axisymmetric model may be parametrized by $h_{ab}=e^{2\alpha(t)}(e^{2\beta(t)})_{ab}$, where $e^{3\alpha}$ denotes the effective spatial volume of the universe. The traceless, diagonal matrix $\beta_{ab}\equiv\mathrm{diag}[\beta,\beta,-2\beta]$ determines the shear of the models and we refer to β as the shear parameter.[14] The spatially flat, isotropic FRW model is recovered in the limit where $\beta=0$ and, in this case, e^{α} represents the scale factor of the universe.

Substituting the metric (3) into the action (2) and integrating over the spatial variables implies that

$$S=\int dt\, e^{3\alpha}\left\{e^{-\Phi}\left[6\dot{\alpha}\dot{\Phi}-6\dot{\alpha}^2+6\dot{\beta}^2-\dot{\Phi}^2+\frac{1}{2}e^{2\Phi}\dot{\sigma}^2\right]-\Lambda_M\right\}, \tag{4}$$

where the comoving volume has been normalized to unity without loss of generality and a dot denotes differentiation with respect to t. The field equations derived from Eq. (4) are given by

$$\ddot{\alpha}=\dot{\alpha}\dot{\varphi}+\dot{\varphi}^2-3\dot{\alpha}^2-6\dot{\beta}^2-\tfrac{3}{2}\Lambda_M e^{\varphi+3\alpha}, \tag{5}$$

$$\ddot{\varphi}=3\dot{\alpha}^2+6\dot{\beta}^2+\tfrac{1}{2}\Lambda_M e^{\varphi+3\alpha}, \tag{6}$$

$$\ddot{\sigma}=-(\dot{\varphi}+6\dot{\alpha})\dot{\sigma}, \tag{7}$$

$$\ddot{\beta}=\dot{\beta}\dot{\varphi}, \tag{8}$$

where

$$\varphi\equiv\Phi-3\alpha \tag{9}$$

defines the ''shifted'' dilaton field and the generalized Friedmann constraint takes the form

$$3\dot{\alpha}^2-\dot{\varphi}^2+6\dot{\beta}^2+\tfrac{1}{2}\dot{\sigma}^2e^{2\varphi+6\alpha}+\Lambda_M e^{\varphi+3\alpha}=0. \tag{10}$$

Equations (5)–(10) may be simplified by introducing the new time coordinate

$$\frac{d}{d\theta}\equiv e^{-(\varphi+3\alpha)/2}\frac{d}{dt} \tag{11}$$

and employing the generalized Friedmann constraint Eq. (10) to eliminate the axion field. The remaining field equations are then given by

$$\alpha''=\varphi'^2-\tfrac{9}{2}\alpha'^2+\tfrac{1}{2}\alpha'\varphi'-6\beta'^2-\tfrac{3}{2}\Lambda_M, \tag{12}$$

$$\varphi''=3\alpha'^2+6\beta'^2-\tfrac{1}{2}\varphi'^2-\tfrac{3}{2}\alpha'\varphi'+\tfrac{1}{2}\Lambda_M, \tag{13}$$

$$\beta''=\tfrac{1}{2}\beta'(\varphi'-3\alpha'), \tag{14}$$

where a prime denotes differentiation with respect to θ.

The general solution to Eqs. (5)–(10) is known when the cosmological constant vanishes.[5] It is given by

$$e^{\alpha}=e^{\alpha_*}\left|\frac{s}{s_*}\right|^{1/2}\left[\left|\frac{s}{s_*}\right|^{r}+\left|\frac{s}{s_*}\right|^{-r}\right]^{1/2},$$

$$e^{\Phi}=\frac{e^{\Phi_*}}{2}\left[\left|\frac{s}{s_*}\right|^{r}+\left|\frac{s}{s_*}\right|^{-r}\right],$$

$$\sigma=\sigma_*\pm e^{-\Phi_*}\left[\frac{|s/s_*|^{-r}-|s/s_*|^{r}}{|s/s_*|^{-r}+|s/s_*|^{r}}\right],$$

$$e^{\beta}=e^{\beta_*}\left|\frac{s}{s_*}\right|^{q}, \tag{15}$$

where $s\equiv\int^t dt'\,e^{-\alpha(t')}$ is conformal time, $\{\alpha_*,s_*,\Phi_*,\sigma_*,\beta_*\}$ are arbitrary constants, and $\{r,q\}$ satisfy the constraint equation $r=(3-12q^2)^{1/2}$.

The solutions to Eqs. (5)–(10) for a trivial axion field and zero cosmological constant have a power-law form,

$$e^{\alpha}=e^{\alpha_*}|t|^{\pm h_*},$$

$$e^{\Phi}=e^{\Phi_*}|t|^{\pm 3h_*-1},$$

$$e^{\beta}=e^{\beta_*}|t|^{\pm\sqrt{(1-3h_*^2)/6}}, \tag{16}$$

where h_* is a constant such that $|h_*|\leq 1/\sqrt{3}$. Solution (15) asymptotes to these power-law models at early and late times and the axion field is therefore dynamically negligible in these limits. When an axion field it present, as in Eq. (15), the universe undergoes a smooth transition between the two power-law solutions (16) and exhibits a bounce when $s\approx s_*$. In the isotropic limit, $h_*^2=1/3$, and the time-reversal of the $e^{\alpha}\propto|t|^{-1/\sqrt{3}}$ solution is inflationary. It corresponds to the prebig bang cosmology, where the inflationary expansion is driven by the kinetic energy of the dilaton field.[15]

In the next section we determine the phase portraits for the generalized model with a nontrivial axion field and $\Lambda_M>0$. The effect of the cosmological constant on the solutions (15) can then be established.

III. POSITIVE COSMOLOGICAL CONSTANT

When $\Lambda_M > 0$, we can rewrite Eqs. (12)–(14) using new variables defined by

$$h \equiv \alpha', \quad \psi \equiv \varphi', \quad N \equiv \beta'. \tag{17}$$

Equation (10) then implies that

$$\psi^2 \geqslant 3h^2 + 6N^2 + \Lambda_M \geqslant 0, \tag{18}$$

and consequently we may normalize with ψ. We therefore define

$$x \equiv \frac{\sqrt{3}h}{\psi}, \tag{19}$$

$$y \equiv \frac{6N^2}{\psi^2}, \tag{20}$$

$$z \equiv \frac{\Lambda_M}{\psi^2}, \tag{21}$$

$$\frac{d}{d\Theta} \equiv \frac{1}{\psi}\frac{d}{d\theta}, \tag{22}$$

and assume that $\psi > 0$. (The case $\psi < 0$ is related to a time-reversal of the system and the qualitative behavior is similar.) The three-dimensional system (12)–(14) is therefore given by

$$\frac{dx}{d\Theta} = (x + \sqrt{3})[1 - x^2 - y - z] + \frac{1}{2}z[x - \sqrt{3}], \tag{23}$$

$$\frac{dy}{d\Theta} = 2y\left\{[1 - x^2 - y - z] + \frac{1}{2}z\right\}, \tag{24}$$

$$\frac{dz}{d\Theta} = 2z\left\{[1 - x^2 - y - z] - \frac{1}{2}(1 - z - \sqrt{3}x)\right\}. \tag{25}$$

It follows from definitions (19)–(21) that the phase space is bounded with $0 \leqslant \{x^2, y, z\} \leqslant 1$ subject to the constraint $1 - x^2 - y - z \geqslant 0$. The invariant set $1 - x^2 - y - z = 0$ corresponds to a zero axion field. The dynamics of the system (23)–(25) is determined primarily by the dynamics in the invariant sets $y = 0$ and $z = 0$. These correspond to a zero shear parameter and a zero cosmological constant, respectively. The dynamics is also determined by the fact that the right-hand side of Eq. (24) is positive-definite so that y is a monotonically increasing function. This guarantees that there are no closed or recurrent orbits in the three-dimensional phase space.

A. Isotropic model for $\Lambda_M > 0$

The isotropic FRW cosmology corresponds to the invariant set $y = 0$, where the shear parameter is trivial. The system (23)–(25) reduces to the following plane system in this case:

$$\frac{dx}{d\Theta} = (x + \sqrt{3})[1 - x^2 - z] + \frac{1}{2}z[x - \sqrt{3}], \tag{26}$$

$$\frac{dz}{d\Theta} = 2z\left\{[1 - x^2 - z] - \frac{1}{2}(1 - z - \sqrt{3}x)\right\}. \tag{27}$$

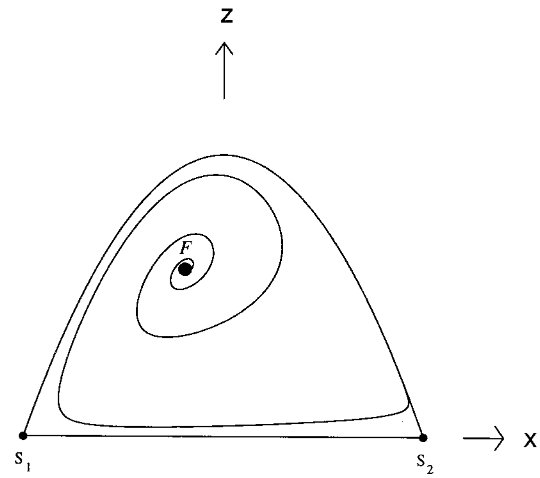

FIG. 1. Phase portrait of the system (26)–(27), corresponding to the isotropic FRW model with $\Lambda_M>0$. Equilibrium points are denoted by dots and the labels in all figures correspond to those equilibrium points (and hence the exact solutions they represent) discussed in the text. We shall adopt the convention throughout that large black dots represent sources (i.e., repellors), large gray-filled dots represent sinks (i.e., attractors), and small black dots represent saddles. Arrows on the trajectories have been suppressed since the direction of increasing time is clear using this notation. Note that in this phase space orbits are future asymptotic to a heteroclinic cycle.

The equilibrium points and their associated eigenvalues are given by

$$S_1: x=-1,\ \ z=0;\ \ \lambda_1=2(\sqrt{3}-1),\ \ \lambda_2=-(1+\sqrt{3}), \tag{28}$$

$$S_2: x=1,\ \ z=0;\ \ \lambda_1=-2(\sqrt{3}+1),\ \ \lambda_2=(\sqrt{3}-1), \tag{29}$$

$$F: x=-\frac{1}{3\sqrt{3}},\ \ z=\frac{16}{27};\ \ \lambda_{1,2}=\frac{1}{3}\pm\frac{i}{9}\sqrt{231}. \tag{30}$$

The points S_1 and S_2 are saddles and F is a repelling focus. The phase portrait is given in Fig. 1.

In the invariant set $1-x^2-z=0$, corresponding to the case of a zero axion field, Eqs. (26) and (27) reduce to the single ordinary differential equation,

$$\frac{dx}{d\Theta}=\frac{1}{2}(1-x^2)(x-\sqrt{3}), \tag{31}$$

which can be integrated to yield an exact solution in terms of Θ-time.

B. Anisotropic model for $\Lambda_M>0$

In the full system (23)–(25), corresponding to the anisotropic model with a nontrivial shear parameter, there exists the isolated equilibrium point (and their associated eigenvalues)

$$F:\quad x=-\frac{1}{3\sqrt{3}},\quad y=0,\quad z=\frac{16}{27}$$

$$(\lambda_1,\lambda_2,\lambda_3)=\left(\frac{1}{3}+\frac{i}{9}\sqrt{231},\frac{1}{3}-\frac{i}{9}\sqrt{231},\frac{4}{3}\right), \tag{32}$$

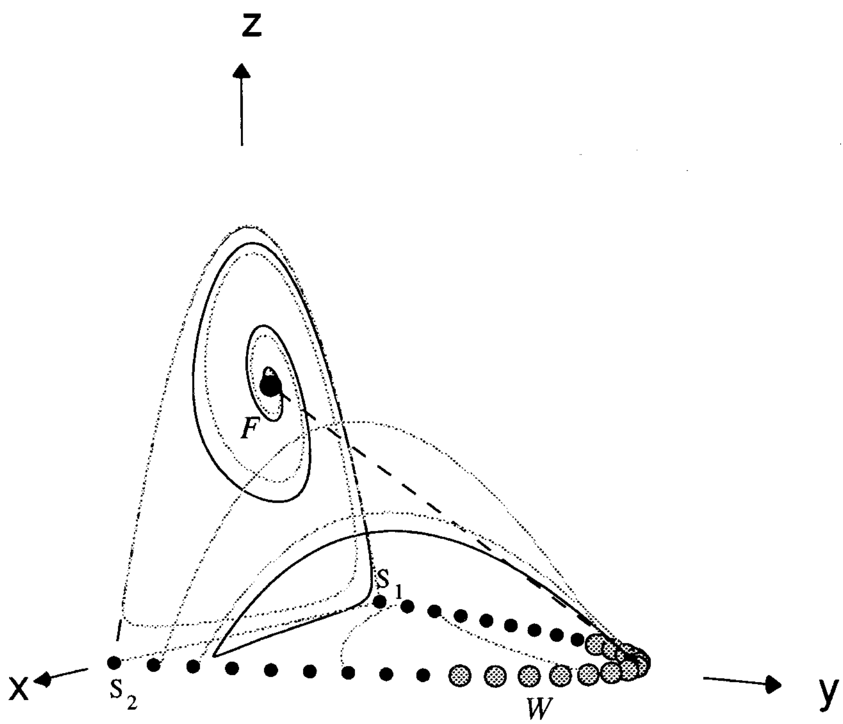

FIG. 2. Phase portrait of the system (23)–(25) corresponding to the axisymmetric Bianchi type I cosmology with $\Lambda_M > 0$. Note that W denotes a line of nonisolated equilibrium points. The dashed line represents the exact $x=$constant solution (34)–(36). See caption to Fig. 1 for notation. Gray lines represent typical trajectories found within the two-dimensional invariant sets, and solid black lines are typical trajectories within the full three-dimensional phase space.

$$W: \quad y=1-x^2, \quad z=0 \quad (x \text{ arbitrary})$$

$$(\lambda_1,\lambda_2,\lambda_3)=\left(-2\sqrt{3}\left[x+\frac{1}{\sqrt{3}}\right],\sqrt{3}\left[x-\frac{1}{\sqrt{3}}\right],0\right). \tag{33}$$

Hence, F is a global source. The set W lies in the invariant set $z=0$ on the boundary $y=1-x^2$. Points on W with $x\in(-1/\sqrt{3},1/\sqrt{3})$ are local sinks, while the remaining points are saddles in the full three-dimensional phase space {in the invariant set $z=0$ equilibrium points with $x\in[-1,-1/\sqrt{3})$ are repelling and those with $x\in(-1/\sqrt{3},1]$ are attracting}. The phase portrait for this system is given in Fig. 2 and Table I lists each equilibrium set and its stability.

We note that there exists an exact, anisotropic solution of Eqs. (23)–(25), where

$$x=-\frac{1}{3\sqrt{3}}=\text{constant} \tag{34}$$

TABLE I. Equilibrium sets for anisotropic model with $\Lambda_M > 0$, and their stability (the equations where each sets is defined is also listed).

Equilibrium point	Stability
F: Eq. (32)	Repellor (source)
W: Eq. (33)	Attractor (sink) for $(-1/\sqrt{3})<x<(1/\sqrt{3})$
	Saddle otherwise

and

$$y = -\frac{13}{8}\left(z - \frac{16}{27}\right). \tag{35}$$

This implies that

$$\frac{dz}{d\Theta} = \frac{9}{4} z\left(z - \frac{16}{27}\right) \tag{36}$$

and Eq. (36) can be integrated explicitly in terms of Θ-time.

In the following section we determine the effects of a negative cosmological constant. This allows a direct comparison to be made with the $\Lambda_M > 0$ models considered above.

IV. NEGATIVE COSMOLOGICAL CONSTANT

In the case where $\Lambda_M < 0$, the generalized Friedmann constraint Eq. (10) implies that

$$\psi^2 - \Lambda_M \geqslant 3h^2 + 6N^2 \geqslant 0. \tag{37}$$

We may therefore normalize by employing the quantity $\sqrt{\psi^2 - \Lambda_M}$. Defining the new variables

$$u \equiv \frac{\sqrt{3}h}{\sqrt{\psi^2 - \Lambda_M}}, \tag{38}$$

$$v \equiv \frac{\psi}{\sqrt{\psi^2 - \Lambda_M}}, \tag{39}$$

$$w \equiv \frac{6N^2}{\psi^2 - \Lambda_M}, \tag{40}$$

where $0 \leqslant \{u^2, v^2, w\} \leqslant 1$, and the new time variable

$$\frac{d}{d\Xi} = \frac{1}{\sqrt{\psi^2 - \Lambda_M}} \frac{d}{d\Theta} \tag{41}$$

implies that Eqs. (12)–(14) become

$$\frac{du}{d\Xi} = \frac{\sqrt{3}}{2}(1-u^2)(1-v^2) + (1-u^2-w)(\sqrt{3}+uv), \tag{42}$$

$$\frac{dv}{d\Xi} = -\frac{1}{2}(1-v^2)(1-2u^2-2w+\sqrt{3}uv), \tag{43}$$

$$\frac{dw}{d\Xi} = w[2v(1-u^2-w) - \sqrt{3}u(1-v^2)]. \tag{44}$$

The phase space is bounded by the sets $v = \pm 1$ and $w = 1 - u^2$, where the latter corresponds to a zero axion field. The dynamics is determined by the fact that the right-hand side of Eq. (42) is positive definite so that u is a monotonically increasing function.

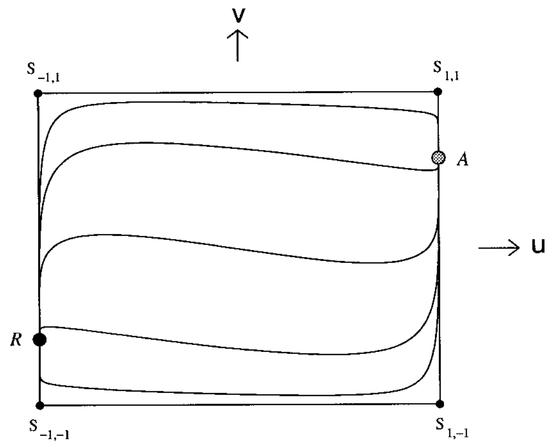

FIG. 3. Phase portrait of the system (45)–(46) corresponding to the isotropic FRW model with $\Lambda_M<0$. See caption to Fig. 1.

A. Isotropic model for $\Lambda_M<0$

In the invariant set $w=0$, corresponding to the isotropic FRW model $(\beta=0)$, the system (42)–(44) reduces to the following two-dimensional system:

$$\frac{du}{d\Xi}=\frac{1}{2}(1-u^2)(2uv+\sqrt{3}[3-v^2]), \tag{45}$$

$$\frac{dv}{d\Xi}=\frac{1}{2}(1-v^2)(2u^2-1-\sqrt{3}uv). \tag{46}$$

The lines $u^2=1$ and $v^2=1$ are invariant sets, containing four equilibrium points $S_{u,v}$. These points are all saddles and are located at the intersections of the lines. Their eigenvalues are given by

$$S_{1,1}: \lambda_1=\sqrt{3}-1,\ \ \lambda_2=-2(\sqrt{3}+1), \tag{47}$$

$$S_{-1,1}: \lambda_1=2(\sqrt{3}-1),\ \ \lambda_2=-(\sqrt{3}+1), \tag{48}$$

$$S_{1,-1}: \lambda_1=-2(\sqrt{3}-1),\ \ \lambda_2=(\sqrt{3}+1), \tag{49}$$

$$S_{-1,-1}: \lambda_1=-(\sqrt{3}-1),\ \ \lambda_2=2(\sqrt{3}+1). \tag{50}$$

The remaining two equilibrium points and their eigenvalues are

$$R: (u_-,v_-)=\left(-1,-\frac{1}{\sqrt{3}}\right);\ \ \lambda_1=\frac{1}{\sqrt{3}},\ \ \lambda_2=\frac{10}{\sqrt{3}}, \tag{51}$$

$$A: (u_+,v_+)=\left(1,\frac{1}{\sqrt{3}}\right);\ \ \lambda_1=-\frac{1}{\sqrt{3}},\ \ \lambda_2=-\frac{10}{\sqrt{3}}. \tag{52}$$

Consequently, R is a source and A is a sink. Figure 3 depicts the phase plane of the system (45)–(46).

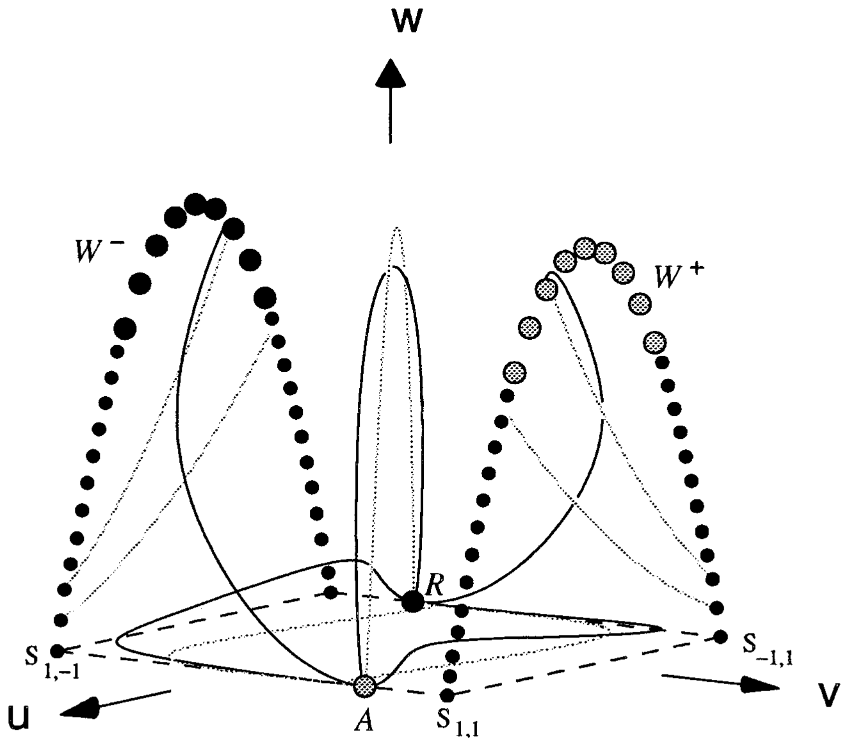

FIG. 4. Phase portrait of the system (42)–(44) corresponding to the axisymmetric Bianchi type I model with $\Lambda_M<0$. Note that $W^{\pm}$ denote lines of nonisolated equilibrium points. See captions to Figs. 1 and 2.

B. Anisotropic model for $\Lambda_M<0$

In the full system (42)–(44) with a nontrivial shear parameter, the equilibrium points and their respective eigenvalues are

$$W^{\pm}: v=\pm 1,\ u^2+w=1;\ (\lambda_1,\lambda_2,\lambda_3)=\left(0,\sqrt{3}\left[u\mp\frac{1}{\sqrt{3}}\right],-2\sqrt{3}\left[u\pm\frac{1}{\sqrt{3}}\right]\right), \tag{53}$$

$$R: v=-\frac{1}{\sqrt{3}},\ u=-1,\ w=0;\ (\lambda_1,\lambda_2,\lambda_3)=\frac{1}{\sqrt{3}}(1,2,10), \tag{54}$$

$$A: v=\frac{1}{\sqrt{3}},\ u=1,\ w=0;\ (\lambda_1,\lambda_2,\lambda_3)=-\frac{1}{\sqrt{3}}(1,2,10). \tag{55}$$

The saddle points $S_{\pm 1,-1}$ in Sec. IV A are the endpoints to the line W^-. This line represents early-time attracting solutions for $-1/\sqrt{3}<u<1/\sqrt{3}$ and saddles otherwise. The saddle points $S_{\pm 1,1}$ are the endpoints to the line W^+. This corresponds to late-time attracting solutions for $-1/\sqrt{3}<u<1/\sqrt{3}$ and saddles otherwise. Hence, there are two early-time attractors given by the point R and the line W^- for $-1/\sqrt{3}<u<1/\sqrt{3}$. There are also two late-time attractors corresponding to the point A and the line W^+ for $-1/\sqrt{3}<u<1/\sqrt{3}$. Figure 4 depicts the three-dimensional phase space and Table II lists each equilibrium set and its stability.

This concludes the derivation of the phase portraits for the spatially flat and homogeneous cosmologies derived from Eq. (2). We proceed in the following section to discuss their properties.

TABLE II. Equilibrium sets for anisotropic model with $\Lambda_M<0$, and their stability (the equations where each set is defined is also listed).

Equilibrium point	Stability
W^-: Eq. (53)	Repellor (source) for $(-1/\sqrt{3})<u<(1/\sqrt{3})$ Saddle otherwise
W^+: Eq. (53)	Attractor (sink) for $(-1/\sqrt{3})<u<(1/\sqrt{3})$ Saddle otherwise
R: Eq. (54)	Repellor (source)
A: Eq. (55)	Attractor (sink)

V. INTERPRETATION OF THE PHASE PORTRAITS

The dynamics of the isotropic cosmology described by the system (26)–(27) is of interest from a mathematical point of view due to the existence of the quasiperiodic behavior. The orbits are future asymptotic to a *heteroclinic cycle*, consisting of the two saddle equilibrium points S_1 and S_2 and the single (boundary) orbits in the invariant sets $z=0$ and $1-x^2-z=0$ joining S_1 and S_2 (see Fig. 1). The former set corresponds to the zero Λ_M solution [given by Eqs. (15) with $q=0$] and the latter to the solution with constant axion field [see Eq. (31)]; to our knowledge this exact solution was not previously known. In a given ''cycle,'' an orbit spends a long time close to S_1 and then moves quickly to S_2 shadowing the orbit in the invariant set $z=0$. It is then again quasistationary and remains close to the equilibrium point S_2 before quickly moving back to S_1 shadowing the orbit in the invariant set $1-x^2-z=0$. We stress that the motion is *not* periodic, and on each successive cycle a given orbit spends more and more time in the neighborhood of the equilibrium points S_1 and S_2.

In Fig. 1, the exact solution corresponding to the equilibrium point F is a power-law solution,

$$a=a_*(-t)^{1/3},$$

$$\Phi=\ln\left(\frac{16}{3\Lambda_M}\right)-2\ln(-t),$$

$$\sigma=\sigma_*\pm\frac{\sqrt{15}\Lambda_M}{16}(-t)^2,$$

$$\dot{\beta}=0, \tag{56}$$

where t is defined over the range $-\infty<t<0$ by a suitable choice of an integration constant. This new solution represents a cosmology that collapses monotonically to zero volume at $t=0$. The curvature and coupling are both singular at this point. The universe is initially in a weak coupling regime, since $G_{\rm eff}\to 0$ as $t\to-\infty$, and the effective energy density of the axion field also vanishes in this limit.

All orbits in Fig. 1 begin at F. The cyclical nature of these orbits can be physically understood by reinterpreting the axion field in terms of a membrane. The homogeneity of the axion field, $\sigma=\sigma(t)$, implies that the two-form potential, $B_{\mu\nu}$, must be independent of cosmic time, and this in turn implies that its field strength must be proportional to the volume form of the three-space. If the topology of the spatial sections is given by a three-torus, $S^1\times S^1\times S^1$, the behavior of the axion field is dynamically equivalent to that of a membrane that has been wrapped around this torus.[16] The collapse is resisted by this membrane and the universe undergoes a bounce. As the volume increases, however, the influence of the membrane is diminished, because the energy density of the axion is rapidly red-shifted away. Consequently, the cosmological constant becomes important.

The subsequent effect of the cosmological constant can be determined by viewing Eq. (2) in terms of a Brans–Dicke action, where the dilaton-graviton coupling parameter is given by $\omega=-1$.[4] The Brans–Dicke FRW models containing only a cosmological constant in the matter sector have been discussed previously by Barrow and Maeda, but their solutions only apply for $\omega>-5/6$.[7,8] The behavior of the general solution for $\omega<-5/6$ is different and can be established by performing a conformal transformation to a frame where the dilaton field is minimally coupled to gravity. In such a frame the term containing Λ_M may be viewed as an exponential, self-interaction potential for the dilaton, where the exponent is uniquely determined by the value of ω.[17] When $\omega>-5/6$, the late-time attractor is a scaling solution, where the kinetic and potential energies of the dilaton field redshift in direct proportion.[18] For $\omega<-5/6$, however, the potential is so steep that the dilaton effectively becomes massless.[19] Thus, the late-time attractor when $\omega=-1$ corresponds to the solution (16) where $h_*^2=1/3$.

Further insight may be gained by defining new variables in the reduced action (4),

$$\chi\equiv 4\alpha-\Phi,$$

$$\gamma\equiv\Phi-6\alpha,$$

$$\tilde{t}=\int dt e^{\varphi}. \tag{57}$$

In the case where $\dot{\beta}=\dot{\sigma}=0$, Eq. (4) reduces to

$$S=\int d\tilde{t}\left[-\frac{3}{2}\left(\frac{d\chi}{d\tilde{t}}\right)^2+\frac{1}{2}\left(\frac{d\gamma}{d\tilde{t}}\right)^2-\Lambda_M e^{-\gamma}\right]. \tag{58}$$

The momentum conjugate to the variable χ is constant, i.e., $d\chi/d\tilde{t}=C$, and the field equation for γ is a Liouville equation,

$$\frac{d^2\gamma}{d\tilde{t}^2}=\Lambda_M e^{-\gamma}. \tag{59}$$

The general solution to Eq. (59) satisfying the Hamiltonian constraint can be found. When $C>0$, it can be shown that $\gamma\propto\sqrt{3C^2}\tilde{t}$ in the late-time limit. Since the Hubble parameter is given by

$$\dot{\alpha}=-\frac{1}{2}e^{\varphi}\left(C+\frac{d\gamma}{d\tilde{t}}\right), \tag{60}$$

the late-time attractor corresponds to the *collapsing* solution in Eq. (16).

In effect, therefore, the cosmological constant resists the expansion and ultimately causes the universe to recollapse and asymptotically approach the saddle point S_1. On the other hand, the collapse causes the axion field to become relevant once more and a further bounce ensues. The process is then repeated with the universe undergoing a series of bounces. The orbits move progressively closer towards the two saddles, $S_{1,2}$, and spend increasingly more time near to these points. This behavior is related to the fact that the kinetic energy of the shifted dilaton field increases monotonically with time, since Eq. (6) implies that $\ddot{\varphi}>0$.

When shear is included $(y\neq 0)$, F still represents the *only* source in the system. The orbits follow cyclical trajectories in the neighborhood of the invariant set $y=0$ and they spiral outwards monotonically, since Eq. (24) implies that $dy/d\Theta>0$. After a finite (but arbitrarily large) number of cycles the kinetic energy associated with the shear parameter, β, begins to dominate the axion and cosmological constant. The orbits then asymptote to the power-law solutions (16). All orbits in the full three-dimensional phase space actually spiral outwards around the orbit represented by the dashed line in Fig. 2 which corresponds to the exact solutions (34)–(36) with $x=\text{constant}$. In terms of cosmic time, t, this exact solution satisfies

$$\Lambda_M - \frac{16}{27}\psi^2 + \frac{48}{13}N^2 = 0 \tag{61}$$

and

$$\dot{\alpha} = -\frac{1}{9}\dot{\varphi}, \tag{62}$$

whence from Eqs. (5)–(10) we obtain

$$\ddot{\varphi} = \dot{\varphi}^2 + k_\varphi^2 e^{2\varphi}, \tag{63}$$

where k_φ is an integration constant. Defining

$$\varrho \equiv \frac{e^{-\varphi}}{k_\varphi} \tag{64}$$

simplifies Eq. (63) to

$$\varrho\ddot{\varrho} = -1 \tag{65}$$

and Eq. (65) can be integrated exactly to obtain $\dot{\varphi}$.[20] A second integration then yields φ in terms of the inverse error function, so that in principle we can obtain the scale factor as a function of time, t, from Eq. (62).

This cyclical behavior does not arise if $\Lambda_M < 0$ (see Fig. 3). The equilibrium points A and R represent the power-law solutions,

$$\begin{aligned} a &= \frac{a_*}{\sqrt{\pm 2t}}, \\ \Phi &= \Phi_* - \ln[\pm\sqrt{-2\Lambda_M t}]^2, \\ \beta &= \beta_*, \\ \sigma &= \sigma_*, \end{aligned} \tag{66}$$

where the $+$ sign corresponds to the point R and the $-$ sign to the point A. Initially the universe is collapsing and the axion field induces a bounce, but this field can not dominate the dynamics again once the volume of the universe has increased sufficiently.

Figure 4 depicts the axisymmetric Bianchi type I model when $\Lambda_M < 0$. In this phase space, for $-1/\sqrt{3} < u < 1/\sqrt{3}$ the line W^- represents the positive branch of the solution (16) for $h_* \in (-1/3, 1/3)$. Likewise, for $-1/\sqrt{3} < u < 1/\sqrt{3}$ the line W^+ represents the ''$-$'' solution in Eq. (16) for $h_* \in (-1/3, 1/3)$. The four saddle points $S_{u,v}$ correspond to the power-law solutions (16) with $h_* = \pm 1/\sqrt{3}$. From Fig. 4 we see that generically trajectories asymptote away from either the line W^- or the point R and move towards the expanding power-law solutions W^+ or A. Hence, the cosmological constant is important in determining both the early- and late-time dynamics. Since u is monotonically increasing [see (42)] we note that the occurrence of a bounce in these cosmological models is a typical feature.

VI. DISCUSSION

In this paper we have presented a qualitative analysis of spatially flat FRW and Bianchi type I cosmologies containing nontrivial dilaton and axion fields with a cosmological constant in the matter sector of the theory. The action we considered reduces to the string effective action when the cosmological constant vanishes. A complete stability analysis was performed in all cases by finding variables that led to a compactification of the phase space. We found that a cosmological constant has a significant effect on the dynamics of the string cosmologies (15).

One of the more interesting mathematical features of the models we have considered is the existence of quasi-periodic behavior. This occurs in the isotropic cosmologies, where the orbits are future asymptotic to a heteroclinic cycle (see Fig. 1). The solutions interpolate between the saddles S_1 and S_2 corresponding to the power-law models (16) with $|h_*|=1/\sqrt{3}$. It would be interesting to consider the implications of this behavior for the prebig bang inflationary scenario.[15] We note that the phase portrait depicted in Fig. 1 is similar to that of Fig. 1(e) in Ref. 21 that describes the locally rotationally symmetric submanifold of the stationary Bianchi type I perfect fluid models in general relativity, although in this latter case the independent variable is spacelike.

The general Bianchi cosmology, where the shear matrix is given by

$$\beta_{ab}=\text{diag}[\beta_+ + \sqrt{3}\beta_- , \beta_+ - \sqrt{3}\beta_- , -2\beta_+] \tag{67}$$

can be analyzed directly by defining the variable N in Eqs. (17) and (20) via $N^2=\Sigma_{i=\pm}N_i^2$. Orbits in the full phase space of Fig. 2 with nontrivial shear term (represented by the variable y) are repelled from the source F. The variable y increases monotonically and the orbits spiral around the exact solution given by Eqs. (61)–(63), as represented by the dashed line in Fig. 2. [See also Fig. 1(f) and the Appendix in Ref. 21.] This implies that solutions are asymptotic in the past to the solution given by Eq. (56). At early times the orbits ''shadow'' the orbits in the invariant set $y=0$ and undertake cycles between the saddles (in three-dimensional phase space) on the equilibrium set W close to S_1 and S_2. These saddles on W may be interpreted as Kasner-type solutions.[21,22] Note that $y=0$ at S_1 and S_2, however, and there is no shear term in these cases. The orbits thus experience a finite number of cycles in which the solutions interpolate between different Kasner-type states. The orbits eventually asymptote towards a source on the line W.

This is perhaps reminiscent of the mixmaster behavior that occurs in the Bianchi type VIII and IX cosmologies.[22,23] These are the most general models in the Bianchi class A of spatially homogeneous universes.[24] In these models, Taub orbits joining equilibrium points of the Kasner set K lead to the existence of infinite heteroclinic sequences which approximate the past asymptotic behavior of generic orbits. (These heteroclinic sequences are defined by a map of K onto itself.) Mixmaster oscillations also occur in less general (i.e., lower-dimensional) Bianchi models with a magnetic field[25] or Yang–Mills fields.[26] It is interesting to note in the string context that mixmaster behavior also occurs in scalar-tensor theories of gravity in general and in the Brans–Dicke theory in particular.[27]

This analogy is only suggestive. We note that if a nonzero central charge deficit is included, the quasiperiodic behavior in the full (higher-dimensional) phase space does indeed persist.[28] Unlike the mixmaster oscillations, however, the orbits in Fig. 2 eventually spiral away from $y=0$, although there are orbits that experience a finite but arbitrarily large number of oscillations. However, it would be interesting to further explore any correspondence with possible mixmaster behavior, particularly by including additional anisotropic or matter degrees of freedom.

Some of the dynamics discussed in this paper is also relevant to higher-dimensional cosmological models. Kaluza–Klein compactification of ten-dimensional supergravity theories[2] onto an isotropic six-torus of radius e^{β} introduces an additional modulus field into the effective four-dimensional action (1). Integration over the spatial variables for a spatially flat FRW model then leads to an action that is formally identical to that of Eq. (4) when we specify $\Lambda_M=0$. In this sense, therefore, the action (4) can be recast into a higher-dimensional context, where the shear term β plays the role of the modulus field and Λ_M is interpreted as a cosmological constant that is introduced after compactification.

More generally, type II supergravity theories contain Ramond–Ramond form-fields that do not couple directly to the dilaton field in the string frame.[2] Under dimensional reduction, these fields give rise to terms in the effective action of the form $Q^2 \exp(c\beta)$, where Q and c are constants;[29] i.e., Ramond–Ramond charges give rise to exponential potentials for the modulus field rather than a simple constant term such as that considered in this work. However, from the analysis in Sec. III A, there will be string solutions containing Ramond–Ramond fields that asymptote towards solutions with $\beta=$constant ($y=0$ in Fig. 2), in which case $Q^2 \exp(c\beta)$ is effectively constant. It might then be expected that the heteroclinic cycle that occurs in the invariant set $y=0$ (see Fig. 1) will play an important rôle in describing the dynamics of these string cosmologies.

(Received 1 March 1999; accepted for publication 14 July 1999)

An Euclidean approach for investigating quantum aspects of a scalar field living on a class of *D*-dimensional static black hole space–times, including the extremal ones, is reviewed. The approach makes use of a near-horizon approximation of the metric and ζ-function formalism for evaluating the partition function and the expectation value of the field $\langle \phi^2(x) \rangle$. After a review of the nonextreme black hole case, the extreme one is considered in some detail. In this case, there is no conical singularity, but the finite imaginary time compactification introduces a cusp singularity. It is found that the ζ-function regularized partition function can be defined, and the vacuum expectation value of the field, is finite on the horizon, as soon as the cusp singularity is absent, namely, the manifold is smooth and the corresponding temperature is $T=0$. It is suggested that the requirement of having a smooth near-horizon geometry always selects the correct black hole equilibrium temperature. © *1999 American Institute of Physics.* [S0022-2488(99)03910-9]

I. INTRODUCTION

The issue of determining the equilibrium (Unruh–Hawking) temperature of a black hole, is important. In fact, one can extract thermodynamical information from its knowledge, for example, the Bekenstein–Hawking entropy (i.e., the tree-level contribution to the entropy) can be defined as the response of the free energy of the black hole to the change of this equilibrium temperature. Furthermore, it defines the admissible temperatures of thermal states of free scalar fields in a static and globally hyperbolic space–time region with horizons.

As is well known, there exist several methods for evaluating the possible equilibrium temperature of a stationary black hole. Within the simplest of these methods, one has to make a Wick rotation of the time coordinate (passing in this way to the Euclidean time $\tau=it$), and eliminate all the metric (conical) singularities connected to the horizon by an opportune choice of the time periodicity β_M.[1] Then, one has to impose the KMS condition for thermal states,[2–5] i.e., to impose the periodicity condition on the imaginary time dependence of the thermal Wightman functions, and interpret the common period β_T as the inverse of the temperature T of the state. Although this procedure determines the correct Unruh–Hawking temperature in the case of a nonextreme black hole, it does not apply to the extreme case (for example, to the case of an extreme Reissner–Nordström black hole), since one is unable to determine the time periodicity of the manifold β_M.

Later, a more sophisticated Lorentzian method was introduced in Ref. 6 and successively developed in Refs. 7–9. Without entering in the details of this approach, we only recall that the method is connected to the well known Hadamard expansion of the two-point Green functions in a curved background and in the limit of coincidence of the arguments. Basically in Ref. 6 was proved that assuming fairly standard axioms of quantum (quasifree) field theory (such as local

[a)]Electronic mail: binosi@alpha.science.unitn.it
[b)]Electronic mail: zerbini@science.unitn.it

definiteness and local stability in a stationary space–time region), in the scaling limit, the thermal Wightman functions in the interior of this region will transform into nonthermal and massless Wightman functions in Minkowski space–time. This point coincidence behavior of the Wightman functions, must hold for any physically sensible state (thermal or not), and, in the case that the space–time region one is dealing with is just a part of the whole manifold separated by event horizons, it must hold on the horizons. This constraint actually selects the correct temperatures $T=\beta_T^{-1}=\beta_M^{-1}$, in the case of Rindler and Schwarzschild space–times. Then these results have been generalized in Ref. 7 to a large class of space–times admitting an appropriate reflection isometry.

Both Haag's method[6] and Kay–Wald approach,[7] which, as they stand, work only for space–times with an intersection between past and future horizons, were extended in Refs. 8, 9 for working in more physical situations than the ethernal black holes one, including the extreme case.

However, all of these ''Lorentzian'' methods involve a certain amount of calculations (for example the procedure developed in Ref. 9 requires the evaluation of all the possible geodesics which start from the horizon); for this fact, even if it is not difficult to foresee a possible generalization to, say, *D*-dimensional extreme black holes, the concrete computation does not appear an easy task. In this paper, making use of Euclidean approach, we would like to obtain some information about the equilibrium temperature of a class of static, *D*-dimensional black holes, evaluating quantities such as the field fluctuations and the one-loop partition function. The inverse of the temperature is formally introduced as the period of the compactified imaginary time $0\leq\tau\leq\beta$.

In order to deal with explicit calculations, we will make use of a near-horizon approximation of the metric. This approximation may also be justified observing that only near the horizon interesting physical effects are supposed to be relevant.

First, the case of nonextreme black holes is reconsidered. Here, as is well known, a conical singularity is present. We will show that its presence leads to divergences of the vacuum expectation value of the field on the horizon. However in this case it is known that as soon as the smoothness of the manifold is required, the Hawking temperature, as well as the absence of the divergences, is recovered.

The analysis is extended to the extreme black holes case. In this case, our mathematical results are, no conical singularity is present, but the compactification of the imaginary time and the related periodic identification, induces an isometry containing parabolic elements (translation in τ), so that a cusp singularity appears. Its presence leads to the following features:

(1) The vacuum expectation value of the scalar field has divergences on the horizon;
(2) The global ζ-function, besides the horizon divergences, does not exist, and requires a further regularization.

These undesired features disappear as soon as the imaginary time period is taken to be ∞, namely the associated temperature is to be $T=0$, in agreement with the four-dimensional results obtained in Refs. 10, 9.

The main objection to the approach proposed here could be the use of a near-horizon approximation of the metric. However, we stress that in Ref. 6 only the limit form of the metric near the horizon was used in order to obtain the Unruh–Hawking temperature; moreover also the results in Refs. 10, 9 were derived in a near horizon approximation contest.

The paper is organized as follows: In Sec. II we review the evaluation of the vacuum expectation value of the field within the ζ-function regularization procedure, while in Sec. III we will derive a near-horizon approximation of the generic line element describing a nonextreme and an extreme black hole. Then in Secs. IV and V we will discuss in detail these two cases, taking advantage of the approximation done. The paper ends with some concluding remarks in Sec. VI.

II. EVALUATING THE VACUUM EXPECTATION VALUE OF THE FIELD WITHIN THE ζ-FUNCTION PROCEDURE

In this section, we evaluate the vacuum expectation value of the field $\langle\phi^2(x)\rangle$, in the framework of the ζ-function regularization procedure. Within this approach (see Ref. 11 for an exhaustive discussion) one has[12,13]

$$\langle\phi^2(x)\rangle=-\frac{2}{\sqrt{g(x)}}\frac{\delta S_{\mathrm{eff}}}{\delta J(x)}\bigg|_{J(x)\equiv 0}=\frac{1}{\sqrt{g(x)}}\frac{d}{ds}\left[\frac{\delta\zeta(s|Al^2)}{\delta J(x)}\right]\bigg|_{s=J(x)=0}, \tag{2.1}$$

where $J(x)$ is a classical source, and l is the usual arbitrary parameter (with the dimension of mass^{-1}) necessary from dimensional considerations.

By a direct calculation, it follows that the ζ-regularized field fluctuations turns out to be

$$\langle\phi^2(x)\rangle_{\mathrm{ren}}=l^2\frac{d}{ds}[s\zeta(s+1;x|Al^2)]\bigg|_{s=0}, \tag{2.2}$$

with the ζ-function evaluated when the source $J(x)$ vanishes.

By making use of the Laurent expansion of $\zeta(s+1;x|Al^2)$, and extracting from the ζ-function the l^2 dependence, we can rewrite (2.2) as

$$\langle\phi^2(x)\rangle_{\mathrm{ren}}=\lim_{s\to 0}\left[\zeta(s+1;x|A)-\frac{1}{s}\mathrm{Res}\ \ \zeta(s+1;x|A)-\mathrm{Res}\,\zeta(s+1;x|A)\ln l^2\right]. \tag{2.3}$$

Notice that when the manifold is smooth, the meromorphic structure of the ζ-function is known (Seeley's Theorem). In particular for a differential elliptic operator of the second order (Laplacian) one has

$$\Gamma(z)\zeta(z;\mathbf{x}|L_N)=\sum_{r=0}^{\infty}\frac{A_r(\mathbf{x}|L_N)}{z+r-\frac{N}{2}}+\text{analytic part},\quad A_r(\mathbf{x}|L_N)=\frac{a_r(\mathbf{x}|L_N)}{(4\pi)^{N/2}}. \tag{2.4}$$

The spectral coefficients $a_r(\mathbf{x}|L_N)$ are computable functions known as the Seeley–de Witt coefficients.

As a consequence, if the dimension of the smooth manifold is odd, the ζ-function is regular at $z=1$ $(s=0)$ and the dependence on the scale parameter l disappears and one gets

$$\langle\phi^2(x)\rangle_{\mathrm{ren}}=\zeta(1;x|A). \tag{2.5}$$

On the other hand, if the dimension is even, there is a simple pole at $z=1$, and the l ambiguity will be present.

III. NEAR-HORIZON APPROXIMATION OF THE METRIC

The metric for a general static spherically symmetric D-dimensional space–time, analytically continued into the Euclidean space, reads

$$ds^2=f(r)d\tau^2+\frac{1}{h(r)}dr^2+r^2d\Sigma_N^2,\quad x=(\tau,r,\mathbf{x}), \tag{3.1}$$

where $\tau=it$ is the Euclidean time, f and h are arbitrary functions of r (which are constant in the $r\to\infty$ limit, if the space–time has to be asymptotically flat), and $d\Sigma_N^2$ represent the line element of a smooth N-dimensional (transverse) manifold without boundary ($\mathbf{x}$ are the transverse coordinates).

For this metric representing a black hole, one demands the presence, at $r=r_+$, of a zero in both f and h, so that, according to the nature of this zero, one finds the following two interesting cases.

A. Nonextremal case

In the case of a nonextremal black hole, one has a simple zero at $r=r_+$, so that the functions f and h can be expanded as[14]

$$f(r)\simeq f'(r_+)(r-r_+), \quad h(r)\simeq h'(r_+)(r-r_+). \tag{3.2}$$

Thus, after changing to the coordinates (ρ, θ, $\mathbf{x}$) by means of

$$\rho^2=\frac{4}{h'(r_+)}(r-r_+), \quad \theta=\tfrac{1}{2}\sqrt{f'(r_+)h'(r_+)}\tau, \tag{3.3}$$

the geometry near the event horizon is described by the approximated line element

$$ds^2\simeq d\rho^2+\rho^2 d\theta^2+r_+^2 d\Sigma_N^2. \tag{3.4}$$

We may generalize the argument to black hole solutions in semiclassical gravity. In this case, near the horizon, one has

$$f(r)\simeq C_f(r-r_+)^{c_1}, \quad h(r)\simeq C_h(r-r_+)^{c_2}, \tag{3.5}$$

with the constants $C_f>0, C_h>0, c_1>0, 0<c_2<2$. Here c_1 may be less than one, and the first derivative may not exist at the horizon. However, if $c_1=2-c_2$, it is easy to show that by means of the following coordinates transformation

$$(r-r_+)^{c_1/2}=\frac{c_1}{2}\sqrt{C_h}\rho, \quad \theta=\frac{c_1}{2}\sqrt{C_hC_f}\tau, \tag{3.6}$$

the line black hole element reduces again to the line element (3.4). For example, the previous case corresponds to $c_1=c_2=1$, and very recently, in Ref. 15 the case $c_1=1/2$ and $c_2=3/2$ have been considered; in any case notice that since $c_2<2$, the proper radial distance to the horizon is finite.

Now, finite temperature effects are assumed to arise when the Euclidean time τ (correspondingly θ) is compactified requiring $0\leqslant\tau\leqslant\beta$ $(0\leqslant\theta\leqslant\gamma)$, with β the inverse of the temperature. So, for arbitrary β (γ), the manifold $\mathcal{M}^D$ shows, near the horizon, the topology of $\mathcal{C}_\gamma\times\Sigma^N$, $\mathcal{C}_\gamma$ being the simple two-dimensional flat cone with deficit angle $2\pi-\gamma$.

In such a space–time, one usually determines the temperature of the black hole, by requiring the absence of the conical singularity;[1] the manifold, in fact, is not smooth, showing a conical singularity at $\rho=0$ unless $\gamma=2\pi$. In this way the temperature is found to be

$$T=\frac{\sqrt{f'(r_+)h'(r_+)}}{4\pi}, \quad T=\frac{c_1}{4\pi}\sqrt{C_hC_f}, \tag{3.7}$$

respectively, which are the Unruh–Hawking temperatures of the black holes.

We will show that $\gamma=2\pi$ is the only possible requirements for having a well-behaved $\langle\phi^2(x)\rangle$ on the horizon.

B. Extreme case

In the case of an extreme black hole, one has a double zero at $r=r_+$, so that the behavior of f and h near the horizon, is[14]

$$f(r)\simeq \tfrac{1}{2}f''(r_+)(r-r_+)^2, \quad h(r)\simeq \tfrac{1}{2}h''(r_+)(r-r_+)^2. \tag{3.8}$$

Thus, if we define the new coordinates (ρ, θ, $\mathbf{x}$) by means of

$$\rho=\sqrt{\frac{2}{f''(r_+)}}(r-r_+)^{-1}, \quad \theta=\sqrt{\frac{h''(r_+)}{2}}\tau=\frac{\tau}{b}, \tag{3.9}$$

we get the approximated line element

$$ds^2\simeq\frac{b^2}{\rho^2}(d\rho^2+d\theta^2)+r_+^2 d\Sigma_N^2. \tag{3.10}$$

So, once the compactification in the Euclidean time is carried over, the manifold shows the topology $H^2/\Gamma\times\Sigma^N$, H^2 being the two-dimensional hyperbolic space, and Γ being the (discontinuous and fixed-point-free) group of isometry induced by the identification $\theta\sim\theta+n\gamma$.

Notice that in this case it is not possible to determine the temperature by using the method of the conical singularity, since no conical singularity is present. However, it does not seem correct to deduce from this fact that such a manifold admits any temperature.[16] In fact, the evaluation of the stress-energy tensor of a free quantized field,[10] which is found to be finite only for $T=0$, and the scaling argument of Ref. 9 suggest that $T=0$ is the only physical admissible temperature in the case of a four-dimensional extreme Reissner–Nordström black hole (which can be recovered by setting $d\Sigma_N^2=d\Omega_2$ in (3.10)). Further evidence in favor of this fact comes from the absence of the Hawking radiation in the extreme Reissner–Nordström black hole.[17]

Again we will see that when $\beta=\infty$, corresponding to $T=0$, one gets a well behaved $\langle\phi^2(x)\rangle$ on the horizon, and the related extreme black hole Euclidean manifold becomes smooth.

Without loss of generality, we set b^2 as well as r_+ equal to 1.

IV. FIRST CASE: $\mathcal{M}^D=\mathcal{C}_\gamma\times\Sigma^N$

As we mentioned in the Introduction, we now evaluate the expectation value of the squared of the scalar field, using the ζ-function regularization technique. We start by reviewing the evaluation of the heat kernel and the local ζ-function on $\mathcal{M}^D=\mathcal{C}_\gamma\times\Sigma^N$ (for a complete discussion, see Ref. 18).

We consider a massless and minimally coupled scalar field on $\mathcal{C}_\gamma$, so that the associated operator is the pure Laplacian $L_\gamma=-\nabla_\gamma=\partial_\rho^2+(1/\rho)\partial_\rho+(1/\rho^2)\partial_\theta^2$; the spectral properties of this operator are well known, and, in fact, a complete set of normalized eigenfunctions is easily found to be

$$\psi_{n\lambda}=\frac{1}{\sqrt{\gamma}}e^{(2\pi ni/\gamma)}J_{\nu_n}(\lambda\rho), \quad \nu_n=\frac{2\pi|n|}{\gamma}, \quad n\in Z, \tag{4.1}$$

together with its complex conjugate.

Here λ^2 ($\lambda\geqslant 0$) is the eigenvalue corresponding to ψ and ψ^*, while J_ν is the regular Bessel function. So, using the standard separation of variables, it is easy to get the spectrum and eigenfunctions of the operator $L_D=-\nabla_\gamma+L_N$ on $\mathcal{M}^D=\mathcal{C}_\gamma\times\Sigma^N$, L_N being a Laplace-type operator on Σ^N including, eventually, a mass and a scalar curvature coupling term. Moreover, since we suppose Σ^N an arbitrary smooth manifold without boundary, all known results concerning the heat kernel and the ζ-function for L_N on Σ^N (which we assume to be known) are applicable.

In particular the heat kernel has the usual asymptotic expansion (see also Sec. II),

$$K(t;\mathbf{x}|L_N)\simeq\sum_{r=0}^{\infty}A_r(\mathbf{x}|L_N)t^{r-(N/2)}, \tag{4.2}$$

and the meromorphic structure of the local ζ-function reads

$$\Gamma(s)\zeta(s;\mathbf{x}|L_N)=\sum_{r=0}^{\infty}\frac{A_r(\mathbf{x}|L_N)}{s+r-\frac{N}{2}}+J(s;\mathbf{x}|L_N), \tag{4.3}$$

where $J(s;\mathbf{x}|L_N)$ is the (generally unknown) analytic part. Here we have supposed the absence of zero modes, but one can easily take them into account with a simple modification of the formulas.

We can now derive the meromorphic structure of $\zeta_\gamma(s;x|L_D)$ on $\mathcal{M}^D=\mathcal{C}_\gamma\times\Sigma^N$. To this aim, one can use the factorization property of the heat kernel

$$K_\gamma(t;x|L_D)=K(t;\theta,\rho|L_\gamma)K(t;\mathbf{x}|L_D), \tag{4.4}$$

in which the heat kernels of the Laplace-type operators on $\mathcal{M}^D$, $\mathcal{C}_\gamma$, and Σ^N, respectively, appear. By taking the Mellin transform of (4.4), one usually gets the Dikii–Gelfand representation of the ζ-function, from which the meromorphic structure can be deduced.

Anyway in dealing with the conical manifold one has a convergence obstruction, in the meaning that there are no values of s for which the Mellin transform of (4.4) is a finite quantity. The solution to this problem has been suggested by Cheeger,[19] and simply consist in a separation between higher and lower eigenvalues. In practice we split the sum which appears in the heat kernel (and in the related ζ-function) in two sums, the first over the lower eigenvalues, and the second over the higher ones; then, after the analytic continuation is performed, one may define the full ζ-function by summing up the two contributions obtained in this way (of course such a definition has all the requested properties and coincides with the usual one if the manifold is smooth).

So we set

$$\zeta_<(s;x|L_D)=\int_0^\infty dt t^{s-1}K_<(t;\theta,\rho|L_\gamma)K(t;\mathbf{x}|L_N), \tag{4.5}$$

$$\zeta_>(s;x|L_D)=\int_0^\infty dt t^{s-1}K_>(t;\theta,\rho|L_\gamma)K(t;\mathbf{x}|L_N), \tag{4.6}$$

where $K_<(t;\theta,\rho|L_D)$ and $K_>(t;\theta,\rho|L_D)$ are, respectively, the ''lower'' and the ''higher'' heat kernels, which are related to the corresponding ζ-function by the relations

$$K_<(t;\theta,\rho|L_\gamma)=\frac{1}{2\pi i}\int_{1/2<\mathrm{Re}(s)<1} ds t^{-s}\Gamma(s)\zeta_<(s;\theta,\rho|L_\gamma), \tag{4.7}$$

$$K_>(t;\theta,\rho|L_\gamma)=\frac{1}{2\pi i}\int_{1/2<\mathrm{Re}(s)<1+\nu_1} ds t^{-s}\Gamma(s)\zeta_>(s;\theta,\rho|L_\gamma), \tag{4.8}$$

$$\zeta_<(s;\theta,\rho|L_\gamma)=\frac{1}{\Gamma(s)}\int_0^\infty dt t^{s-1}K_<(t;\theta,\rho|L_\gamma),\quad \tfrac{1}{2}<\mathrm{Re}(s)<1, \tag{4.9}$$

$$\zeta_>(s;\theta,\rho|L_\gamma)=\frac{1}{\Gamma(s)}\int_0^\infty dt t^{s-1}K_>(t;\theta,\rho|L_\gamma),\quad \tfrac{1}{2}<\mathrm{Re}(s)<1+\nu_1, \tag{4.10}$$

and, by definition,

$$K_\gamma(t;\theta,\rho|L_\gamma)=K_<(t;\theta,\rho|L_\gamma)+K_>(t;\theta,\rho|L_\gamma), \tag{4.11}$$

$$\zeta_\gamma(s;\theta,\rho|L_\gamma)=\zeta_<(s;\theta,\rho|L_\gamma)+\zeta_>(s;\theta,\rho|L_\gamma). \tag{4.12}$$

Now, making use of the Mellin–Parseval identity and paying attention to the range of convergence, one gets, for $\mathrm{Re}(s)>1+(N/2)$, the following representation:[18]

$$\zeta_\gamma(s;x|L_D)\simeq\frac{\zeta(s-1;\mathbf{x}|L_N)}{2\gamma(s-1)}+\frac{1}{\gamma\Gamma(s)}\sum_{r=0}^{P}A_r(\mathbf{x}|L_N)I_\gamma\left(s+r-\frac{N}{2}\right)\rho^{2s+2r-D}+\mathcal{O}(\rho^{2s+2P-D}),\tag{4.13}$$

where P is an arbitrary large integer, while

$$I_\gamma(s)=\frac{\Gamma(s-\frac{1}{2})}{\sqrt{\pi}}[G_\gamma(s)+G_{2\pi}(s)].\tag{4.14}$$

For $\mathrm{Re}(s)>1$,

$$G_\gamma(s)=\sum_{n=1}^{\infty}\frac{\Gamma(\nu_n-s+1)}{\Gamma(\nu_n+s)},\quad G_{2\pi}=-\frac{\Gamma(1-s)}{2\Gamma(s)}.\tag{4.15}$$

It is possible to show that $G_\gamma(s)$ admits an analytical continuation, and the properties of I_γ and G_γ on the whole complex plane are studied in detail in the Appendix of Ref. 18; an important property is that the analytical continued I_γ as well as G_γ, has only a simple pole at $s=1$, with residue

$$\mathrm{Res}\, I_\gamma(s)|_{s=1}=\frac{1}{2}\left(\frac{\gamma}{2\pi}-1\right).\tag{4.16}$$

Having found the meromorphic structure of the ζ-function on our manifold, we can determine the vacuum expectation value of the fluctuation of a scalar field. With regard to this, it is convenient to distinguish between odd- and even-dimensional space-times.

We first consider the case in which N (or, equivalently, D) is odd, so that I_γ is finite at $s=1$. To begin with, notice that the first term in (4.13) depends only on the transverse coordinates and is finite on the horizon. As a result, making use of the meromorphic structure of $\zeta(s;\mathbf{x}|L_N)$, we get

$$\langle\phi^2(x)\rangle\simeq\frac{1}{2\gamma}\left[\sum_{r=0}^{\infty}\frac{A_r(\mathbf{x}|L_N)}{r-\frac{N}{2}}+J(0;\mathbf{x}|L_n)\right]+\frac{1}{\gamma}\sum_{r=0}^{P}A_r(\mathbf{x}|L_N)I_\gamma\left(1+r-\frac{N}{2}\right)\rho^{2r-N}+\mathcal{O}(\rho^{2P-N}).\tag{4.17}$$

It is now easy to see that the above expression contains $[N/2]$ (where $[\,]$ means ‘‘integer part’’) terms which are divergent as ρ^{2r-N} $(r<[N/2])$ in the limit $\rho\to0$, and so on the horizon (see (3.3)). Thus, if we want a good behavior on it, we must demand that all the I_γ's vanish for $r<[N/2]$, i.e., $\gamma=2\pi$. In particular notice that within this value of γ all of the I_γ's actually vanish.

We now come to the case in which $N(D)$ is even. In this case, the ζ-function (4.13) has a pole at $s=1$, coming from the first and the I_γ term in (4.13). From (2.3) one gets

$$\langle\phi^2(x)\rangle_{\mathrm{ren}}\simeq\frac{1}{2\gamma}\left[\sum_{r=0}^{\infty}{}'\,\frac{A_r(\mathbf{x}|L_N)}{r-\frac{N}{2}}+J(0;\mathbf{x}|L_n)\right]-\frac{1}{4\pi}A_{N/2}(\mathbf{x}|L_N)\ln\mu^2$$
$$+\frac{1}{\gamma}\sum_{r=0}^{P}{}'\,A_r(\mathbf{x}|L_N)I_\gamma\left(1+r-\frac{N}{2}\right)\rho^{2r-N}+\mathcal{O}(\rho^{2P-N}),\tag{4.18}$$

where the $'$ in the sums means omission of the $r=N/2$ term.

Again, as long as $r<N/2$, we get divergent terms on the horizon, unless we require the I_γ's to vanish, i.e., $\gamma=2\pi$ as in the odd-dimensional case.

As a result, for a manifold $\mathcal{M}^D$ whose near-horizon geometry is described by $\mathcal{C}_\gamma\times\Sigma^N$, the requirement of having a well behaved $\langle\phi^2(x)\rangle$ on the horizon, selects $\gamma=2\pi$, and so the Unruh–Hawking temperature, according to the conical singularity method. We are also reminded that the choice $\gamma=2\pi$ makes the manifold smooth, getting rid of the conical singularity otherwise present in $\rho=0$.

The computation of the partition function for arbitrary γ has been done in Ref. 18, and it has been used in order to discuss thermodynamical properties. Only the horizon divergences are present, and these are still present in the on-shell ($\gamma=2\pi$) entropy.

V. SECOND CASE: $\mathcal{M}^D=H^2/\Gamma\times\Sigma^N$

After having checked that our procedure works at least in the case of nonextreme black holes, we can tackle the case of the extreme ones, i.e., manifold whose topology near the horizon is described by $H^2/\Gamma\times\Sigma^N$.

Again, one can start by making use of the factorization property of the heat kernel, writing that

$$K_\gamma(t;x|L_D)=K(t;\theta,\rho|L_\gamma)K(t;\mathbf{x}|L_N), \tag{5.1}$$

where the heat kernels of the Laplace-type operators on $\mathcal{M}^D$, H^2/Γ, and Σ^N, respectively appear. As in the previous case, we suppose that L_γ is the operator associated with a massless and minimally coupled scalar field on H^2, while L_N is a Laplace-type operator on Σ^N including eventually, mass and scalar curvature coupling term (so that the expansions (4.2) and (4.3) are still valid). In this way, $L_\gamma=-\Delta_\gamma=-\rho^2(\partial_\theta^2+\partial_\rho^2)$, and a complete set of normalized eigenfunctions is easily found to be

$$\psi_{\lambda k}=\sqrt{\frac{y}{2\pi}}e^{ik\theta}K_{i\lambda}(|k|y), \tag{5.2}$$

together with its complex conjugate. Here λ^2 ($\lambda\geqslant0$) is the eigenvalue corresponding to ψ and ψ^*, while K_ν is the MacDonald function. Thus the spectral representation of the (off-diagonal) heat kernel associated with L_γ on H^2 reads (see, for example, Ref. 20)

$$K_{H^2}(t;\theta,\rho;\theta',\rho'|L_\gamma)=\frac{1}{2\pi}\int_0^\infty d\lambda\lambda\tanh(\pi\lambda)e^{-(\lambda^2+(1/4))t}P_{i\lambda-(1/2)}(\cosh\sigma), \tag{5.3}$$

where P is the associated Legendre function, while σ is the H^2 geodesic distance between (θ,ρ) and (θ',ρ').

As previously remarked, for studying thermal effects, one has to deal with the quotient space H^2/Γ, with Γ the (discontinuous and fixed-point-free) group of isometry induced by the time compactification $0\leqslant\theta\leqslant\gamma$. In our case we have translations, corresponding to parabolic elements. By applying the method of images, the diagonal heat kernel turns out to be

$$K(t;\theta,\rho|L_\gamma)=\frac{1}{2\pi}\int_0^\infty d\lambda\lambda\tanh(\pi\lambda)e^{-(\lambda^2+(1/4))t}$$
$$+\frac{1}{\pi}\sum_{n=1}^\infty\int_0^\infty d\lambda\lambda\tanh(\pi\lambda)e^{-(\lambda^2+(1/4))t}P_{i\lambda-(1/2)}(\cosh\sigma_n), \tag{5.4}$$

where now

$$\cosh\sigma_n = 1 + \frac{n^2\gamma^2}{2\rho^2}. \tag{5.5}$$

Let us show that the partition function does not exist, and requires, besides the horizon divergence regularization, a further regularization. The partition function is proportional to the first derivative at zero of the ζ-function, which may be defined by the Mellin transform of the heat kernel trace. The latter may be obtained integrating over the manifold coordinates. As a result,

$$\zeta(s|L_\gamma) = \frac{\gamma}{4\pi\epsilon}\frac{1}{s-1}\zeta\left(1-s\middle|L_N+\frac{1}{4}\right) + \frac{\gamma}{2\pi\epsilon}\int_0^\infty d\lambda\,\frac{\lambda}{1+e^{2\pi\lambda}}\zeta\left(s\middle|L_N+\lambda^2+\frac{1}{4}\right)$$
$$+\frac{1}{\sqrt{\pi}}\zeta_R(1+\delta)\zeta\left(s-\frac{1}{2}\middle|L_N+\frac{1}{4}\right)+\mathcal{O}(\delta), \tag{5.6}$$

where ζ_R is the Riemann ζ-function, and we have introduced the horizon cutoff ϵ in the identity contribution, and the cusp regularization parameter $\delta>0$ in the topological contribution. With regard to this, it should be noticed the divergence for $\delta=0$, which is usually present when one is dealing with parabolic elements.[21]

As far as the vacuum expectation value of the field is concerned, we only need the expression of the local ζ-function near the horizon. Thus with regard to the sum over n, we may apply the simplest version of the Euler–MacLaurin resummation formula, namely,

$$\sum_{n=1}^{\infty} f(n) = \int_1^\infty dx f(x) - \frac{1}{2}f(1) + \int_1^\infty dx\left(x-[x]-\frac{1}{2}\right)f'(x). \tag{5.7}$$

As a result, for large ρ,

$$\sum_{n=1}^{\infty} P_{i\lambda-(1/2)}(\cosh\sigma_n) = \frac{\rho}{\sqrt{2}\gamma}\frac{1}{\lambda\tanh(\pi\lambda)} + C(\lambda) + \mathcal{O}\left(\frac{\gamma}{\rho}\right), \tag{5.8}$$

where $C(\lambda)$ does not depend on ρ. Thus, the diagonal part of the heat-kernel may be rewritten as

$$K(t;\theta,\rho|L_\gamma) = \frac{1}{2\pi}\int_0^\infty d\lambda\,\lambda\tanh(\pi\lambda)e^{-(\lambda^2+(1/4))t} + \frac{\rho}{2\gamma\sqrt{2\pi t}}e^{-(t/4)} + \mathcal{O}(1) + \mathcal{O}\left(\frac{\gamma}{\rho}\right). \tag{5.9}$$

As a result, the related local ζ-function reads

$$\zeta_\gamma(s;x|L_D) = \zeta(s;\mathbf{x}|L_D) + \frac{\rho}{2\gamma\sqrt{2\pi}}\frac{\Gamma(s-\frac{1}{2})}{\Gamma(s)}\zeta\left(s-\frac{1}{2};\mathbf{x}\middle|L_N+\frac{1}{4}\right) + \mathcal{O}(1) + \mathcal{O}\left(\frac{\gamma}{\rho}\right). \tag{5.10}$$

The first term on the right-hand side of the above relation, is the local ζ-function associated with the smooth manifold $\mathcal{M}^D = H^2\times\Sigma^N$ and it depends only on the transverse coordinates $\mathbf{x}$. The other terms are the asymptotic contribution for large ρ. As a result, we have obtained the meromorphic structure of $\zeta(s;x|L_D)$ via the meromorphic structure of $\zeta_\gamma(s;\mathbf{x}|L_D)$ and $\zeta(s-\frac{1}{2};\mathbf{x}|L_N+\frac{1}{4})$. It should be noticed that the second term, which is the relic of the sum over images, contains the shift $s-1/2$. This means that, with regard to the evaluation of the vacuum expectation value of the field, one has a simple pole at $s=1$ for any D, not only for D even. This violation of Seeley's Theorem is related to the presence of parabolic elements, which make the manifold singular.

On the other side, no matter the dimension of the space-time, the vacuum expectation value of the field contains terms proportional to ρ/γ which are divergent on the horizon ($\rho\to\infty$, see (3.9)), unless we demand $\gamma=\infty$, and so $T=0$, according to the result obtained in Refs. 9, 10 in the four-dimensional case. We finally notice that if $\gamma=\infty$, the partition function contains only the usual volume divergence associated with the noncompact nature of the Euclidean section.

VI. CONCLUSIONS

In this paper, making use of an Euclidean approach, we have evaluated the expectation value and the global zeta function, whose derivative with respect to s evaluated at $s=0$ gives the partition function, of a scalar field in a D-dimensional static black hole. A near-horizon approximation has lead to quite explicit expressions for the local ζ-function related to such a field propagating in the Euclidean section of the black hole space–time. The period of the compactified imaginary time has been interpreted as the inverse of the temperature. The fact is then stressed that this quantity is finite on the horizon as soon as one selects a distinguished period of the imaginary time (temperature), which coincides with the Hawking–Unruh temperature in the nonextreme case, and with the zero temperature in the extreme one. With regard to the partition function, no problem exists in the conical singularity case, while in the presence of the cusp singularity, a new divergence shows up in the global ζ-function, and, strictly speaking, the partition function does not exist. This drawback disappears if the cusp singularity is absent, the near-horizon geometry is smooth and namely the temperature is again zero.

With regard to the local quantities, we also notice that the regular behavior of the vacuum expectation value of the fields on the horizon, leads also to the regular behavior of the expectation value of the stress tensor. This can be verified by means of a direct calculation, starting from the local off-diagonal ζ-function which can be obtained with our approach.

As far as the extreme black holes are concerned, all the properties we have been deriving, and the lack of the Hawking radiation,[17] strongly suggest that the only admissible temperature is the zero one, in agreement with the four-dimensional case studied in Ref. 10. As a consequence, within the Euclidean approach, requiring the smoothness of the near-horizon geometry seems to select, in general, the correct Hawking temperature. The only class of space–times for which our analysis seems to have no direct application is the one in which the double zero occurs at $r_+=0$. As an example, we may recall the so called massless ground state of the asymptotically AdS toroidal black holes.[22–25] In fact these black holes have

$$f(r)=\frac{1}{h(r)}=\left(\frac{l^2}{r^2}-\frac{C_D M}{r^{D-1}}\right), \tag{6.1}$$

where C_D is a constant, M is the mass of the black hole, and the parameter l is related to the cosmological constant, namely, $\Lambda=-l^{-2}$. For $D=3$, one recovers the celebrated BTZ black hole.[26] The ground state of this class of black holes is the zero mass solution, and the Euclidean metric becomes

$$ds^2=\frac{r^2}{l^2}d\tau^2+\frac{l^2}{r^2}dr^2+r^2 dT_N^2, \tag{6.2}$$

where dT_N^2 represents the metric of an N-dimensional torus. In the above metric, $r=0$ is a naked coordinate singularity. If one compactifies the Euclidean time and makes the coordinate transformation $r=l^2/\rho$, one gets

$$ds^2=\frac{l^2}{\rho^2}[d\rho^2+d\tau^2+l^2 dT_N^2]. \tag{6.3}$$

This metric describes locally the D-dimensional hyperbolic space H^D.

For the zero temperature case and in $D=3$ and $D=4$, the vacuum expectation value of the field, as well as the expectation value of the stress tensor has been computed in Refs. 27, 21, and 28, respectively, and divergences have been found as ρ goes to infinity. In this case, our analysis does not select any distinguished temperature. However, it should be noticed that in this case, it is not reasonable to neglect the back-reaction effects. In fact, in Refs. 27, 21, 28 it has been shown that there is a quantum implementation of the Cosmic Censorship Principle due to the back-reaction on the metric.

(Received 24 November 1998; accepted for publication 15 January 1999)

This is the first part of a series of two papers. In this article we study the linearization stability of the Einstein equation in the presence of matter. We have slightly changed the classic definition of this concept for the vacuum spacetime and a more general one adapted to our case is given. We consider a Robertson–Walker model (V,g,T) where V stands for the spacetime, g for a Robertson–Walker metric, and T for a stress-energy tensor of a perfect fluid. We write $V=S\times I$ where S is a spacelike hypersurface of V and I an $\mathbb{R}$-interval. We show that in the case S has a constant curvature K equal to 0, the Einstein equation $G(g)=\chi T$ is linearization stable at g. In a subsequent paper we shall prove that in the case $K=1$ the opposite occurs. The case $K=-1$ remains as an open question. © *1999 American Institute of Physics.* [S0022-2488(99)02109-X]

I. INTRODUCTION

This is the first part of a series of two papers. The aim of this series is to study the linearization stability of the Einstein equation when a Robertson–Walker model is considered. On this subject we have to cite D'Eath[1] who showed the existence of certain families of solutions to the Einstein equation in a small neighborhood of a Robertson–Walker metric and also discussed its linearization stability. Nevertheless, our initial point of view is different from that of D'Eath, and hence we can say that we are dealing with a very different problem. The question we consider is the following: interpret the universe as a Robertson–Walker model of metric g and stress-energy tensor T, related by the Einstein equation $G(g)=\chi T$, where $G(g)=\mathrm{Ric}(g)-\frac{1}{2}\mathrm{R}g$ is the Einstein tensor of g, and χ is a universal constant. Let δT be a small perturbation of the tensor T, originated, for example, by a distant supernova explosion (though T is the stress-energy tensor of a perfect fluid, $T+\delta T$ is not necessarily so). This perturbation of T gives raise to another perturbation δg of g. In order to study the propagation in the universe of the effects of that explosion, we wonder if it is admissible to deal with the linearized Einstein equation $(D_g G)(\delta g)=\chi\delta T$, instead of dealing with the true equation $G(g+\delta g)=\chi(T+\delta T)$. In other words, we want to know whether the Einstein equation is linearization stable at the initial Robertson–Walker metric g.

The linearization stability of the *empty space* Einstein equation has originated many research articles (in Section 3 of Refs. 2 and 3 one can find a brief description of the history of the subject, as well as the basic bibliography). Here we mention the works of Moncrief,[4,5] who established a necessary and sufficient condition for the linearization stability in terms of the geometry of the spacetime. However, not much literature has been published about the linearization stability of the Einstein equation *with matter*. We have to cite the article of Bao, Marsden, and Walton[6] who pointed out that linearization stability methods do not work in the presence of matter. The first difficulty we have encountered is the stability definition itself. The definition used by the authors that deal with vacuum spacetime is not entirely valid to study the linearization stability in the presence of matter. Although in Sec. IV of this paper we discuss in detail this subject, we now summarize the principal ideas we develop in that section.

Basically, the main problem of the linearization stability of the *empty space* Einstein equation is the following: Let $V=M\times I$ be a product manifold, where M is a 3-manifold and I an $\mathbb{R}$-interval. One starts from an initial Lorentz metric g on V that satisfies $G(g)=0$. Then one is interested in the metrics $g'=g+h$ close to g that satisfy $G(g')=0$. Now, in order to solve $G(g')=0$, it is common to linearize this equation, $(D_gG)(h)=0$, where $(D_gG)(h)$ means the linear term in h of $G(g+h)$, in such a way that $G(g+h)=G(g)+(D_gG)(h)+\cdots$. This simplification, however, only makes sense if each solution h of the linearized equation $(D_gG)(h)=0$ is tangent to a curve $\lambda\to g'(\lambda)$ of exact solutions of the true equation $G(g')=0$. That is, for any solution h of $(D_gG)(h)=0$ there exists a curve $g'(\lambda)$ such that $G(g'(\lambda))=0$, with $g'(\lambda)=g+h\lambda+\cdots$. When this is the case, one says that the Einstein equation is linearization stable at the initial metric g (see, for example, Ref. 7).

Let us see what happens in the presence of matter. For that purpose, we remember briefly the initial Einstein's point of view about the linearization of his equation in a small neighborhood of the Minkowski metric [see Refs. 8 and 9]. The Minkowski metric η of $\mathbb{R}^4$ satisfies the empty space Einstein equation $G(\eta)=0$. Now, let T' be a stress-energy tensor close to zero and look for the metrics g' close to η satisfying the Einstein equation with matter $G(g')=\chi T'$. Einstein solved the linearized equation $(D_\eta G)(h)=\chi T'$ of the previous equation and he wrote the solutions h (with vanishing asymptotic conditions) in terms of T'. But this analysis would be valid if for each solution h of $(D_\eta G)(h)=\chi T'$, $\eta+h$ were *close* to a solution g' of the true equation $G(g')=\chi T'$. Choquet-Bruhat and Deser,[10] and later Choquet-Bruhat, Fischer, and Marsden[11] showed that the Einstein equation is linearization stable at the Minkowski metric η (stable in the sense of the previous paragraph). Because of this, one can substitute the equation $G(g')=0$ by its linear one $(D_\eta G)(h)=0$. But this has nothing to do with Einstein's procedure because he does not solve the equation $(D_\eta G)(h)=0$, but he deals with $(D_\eta G)(h)=\chi T'$ for a small T'. However, we must say that this difficulty is somewhat formal because the results of Ref. 11 really do answer the question of whether the initial Einstein's point of view is valid or not, as Theorem 1 of Sec. IV assures.

At the end of Sec. IV we give a definition of linearization stability adapted to the matter case. Shortly speaking it says that the Einstein equation $G(g)=\chi T$ is linearization stable at the initial metric g in the direction of $\mathcal{F}$, $\mathcal{F}$ being a vector subspace of the space of stress-energy tensors, if for any $H\in\mathcal{F}$ *close* to zero and for any small solution h of the linear equation $(D_gG)(h)=\chi H$, $g+h$ is *close* to a solution g' of the true equation $G(g')=\chi(T+H)$ (later we will explain in detail what we mean by the word *close*). Note that if $\mathcal{F}=\{0\}$ and $T=0$ one obtains the old definition. If the Einstein equation is linearization stable at a given metric g in the direction of any subspace $\mathcal{F}$ of stress-energy tensors, we simply say that it is linearization stable.

Now we summarize the rest of the sections. Section I is devoted to the expression of the Einstein equation using Gauss coordinates and in Sec. II we deal with the Cauchy problem for the Einstein equation with matter. Finally, in Secs. V and VI we express the main result of this paper: Let $V=M\times I$ be a Robertson-Walker model (I an $\mathbb{R}$-interval and M a connected 3-Riemannian manifold of constant curvature K). We assume M to be simply connected. We show that if $K=0$ then the Einstein equation is linearization stable at the Robertson–Walker metric g. In a subsequent paper we will show that if $K>0$ there exists no vector subspace $\mathcal{F}$ of the space of stress-energy tensors for which the Einstein equation is linearization stable at g in the direction of $\mathcal{F}$. In the proof of our result for curvature $K=0$ we use a theorem of Cantor (Refs. 12 and 13) concerning the usual Laplace operator in $\mathbb{R}^3$. If there existed an analogous result for the De Rham Laplace operator (acting on 1-forms) associated to the metric of the 3-hyperbolic space of curvature -1 we would be able to adapt our proof of stability in the case $K=0$ to curvature $K<0$, but at present we do not know such a result.

II. THE EXPRESSION OF EINSTEIN TENSOR IN GAUSS COORDINATES

Let $(V,\tilde{g})$ be a time-orientable Lorentz manifold (we assume the signature of $\tilde{g}$ to be $+++-$). Let M be a spacelike hypersurface of V. To each $x\in M$ let N_x be the normal unit future-pointing timelike vector of M [this means that $\tilde{g}_x(N_x, N_x) = -1$]. Let $\varphi_t(x)$ be the geodesic at x with N_x as a tangent vector. We will assume that there exists a $\epsilon > 0$ so that the mapping

$$\Psi:\ M \times (-\epsilon, \epsilon) \to V$$

$$(x,t) \to \varphi_t(x)$$

gives a diffeomorphism between $M \times (-\epsilon, \epsilon)$ and a certain neighborhood V_M of M in V. This diffeomorphism is called the Gauss representation of V_M associated to the hypersurface M. We denote by t the coordinate of the interval $(-\epsilon, \epsilon)$. The notation $\partial/\partial t$ will stand for the field in V_M that corresponds to the field $\partial/\partial t$ of $M \times (-\epsilon, \epsilon)$ in the diffeomorphism Ψ. The field $\partial/\partial t$ when $t=0$ is orthogonal to M by construction. The well-known Gauss lemma assures that $\partial/\partial t$ is orthogonal to $M_t = \varphi_t(M)$ for all t.

We denote by g_t the restriction of $\tilde{g}$ to the hypersurface M_t, by ∇_t the connection on M_t associated to g_t, by Ric_t the Ricci tensor of g_t and by R_t the scalar curvature of g_t. Sometimes we will drop the subindex t of g_t, ∇_t, Ric_t and R_t assuming any M_t, without specifying t. We will write $\tilde{\nabla}$, $\widetilde{\mathrm{Ric}}$ and $\tilde{R}$ for the connection on V_M, the Ricci tensor and the scalar curvature of $\tilde{g}$, respectively. Let S_t be the second fundamental form of M_t; recall that this is defined by $S_t(X,Y) = -\tilde{g}(\tilde{\nabla}_X Y, \partial/\partial t)$ for X and Y vector fields on M_t. We write $k_t = 2S_t$.

Every local coordinate system (x^1, x^2, x^3) of M induces by means of the Gauss representation Ψ a coordinate system (x^1, x^2, x^3, t) in a certain open set of V_M; such systems will be called Gauss normal coordinates. Sometimes we write $x^4 = t$. Throughout this paper we assume that latin indices $i, j, k, \ldots$ run from 1 to 3, and greek indices $\alpha, \beta, \gamma, \ldots$ run from 1 to 4. With all these conventions in mind, the components $\tilde{R}_{\alpha\beta}$ of $\widetilde{\mathrm{Ric}}$ are expressed in Gauss normal coordinates in the following way:

$$\tilde{R}_{ij} = \frac{1}{2}\frac{\partial k_{ij}}{\partial t} - \frac{1}{2}(k \times k)_{ij} + R_{ij} + \frac{1}{4}(\mathrm{tr}_g\, k) k_{ij}, \tag{1}$$

$$\tilde{R}_{4i} = \tfrac{1}{2}\nabla^r (k_{ir} - (\mathrm{tr}_g\, k) g_{ir}), \tag{2}$$

$$\tilde{R}_{44} = -\frac{1}{2} g^{ij}\left(\frac{\partial k_{ij}}{\partial t} - \frac{1}{2}(k \times k)_{ij}\right) \tag{3}$$

(see, for instance Ref. 14). The expression $k \times k$ means $(k \times k)_{ij} = g^{rs} k_{ir} k_{js}$, or in other words, $(k \times k)(X,Y) = k(X, P(Y))$, where P is the associated endomorphism to k relative to the metric g. The expression $\mathrm{tr}_g\, k$ means the trace of k relative to the metric g, that is $g^{ij} k_{ij}$. Formulas (1), (2), and (3) are a consequence of the Gauss and Codazzi equations of the hypersurfaces M_t.

Let $\tilde{G}(\tilde{g})$ be the Einstein tensor of $\tilde{g}$ defined by $\tilde{G}(\tilde{g}) = \widetilde{\mathrm{Ric}} - (1/2)\tilde{R}\tilde{g}$. Later we will be interested in similar expressions to (1), (2), and (3) for the components $\tilde{G}_{4i}$ and $\tilde{G}_{44}$ of Einstein tensor. Bearing in mind that $\tilde{g}_{4i} = 0$ is fulfilled in Gauss coordinates, we get

$$\tilde{G}_{4i} = \tilde{R}_{4i} - \tfrac{1}{2}\tilde{R}\tilde{g}_{4i} = \tilde{R}_{4i}. \tag{4}$$

On the other hand, $\tilde{R} = \tilde{g}^{\alpha\beta}\tilde{R}_{\alpha\beta} = -\tilde{R}_{44} + g^{ij}\tilde{R}_{ij}$, and so by (1) and (3) one obtains

$$\tilde{G}_{44} = -\tfrac{1}{8} k \cdot k + \tfrac{1}{8}(\mathrm{tr}_g\, k)^2 + \tfrac{1}{2} R, \tag{5}$$

where $k \cdot k$ indicates the dot product of k by k given by the metric g, that is, $g^{ir} g^{js} k_{rs} k_{ij} = k^{ij} k_{ij}$.

III. THE CAUCHY PROBLEM FOR THE EINSTEIN EQUATION WITH MATTER

We want to study the Cauchy problem for the Einstein equation $\tilde{G}(\tilde{g})=\chi\tilde{T}$, where $\tilde{T}$ is the stress-energy tensor of matter and χ a universal constant.

Let V be a 4-manifold. Let M be a spacelike hypersurface of V. We assume the diffeomorphism

$$\Psi:\ M\times(-\epsilon,\epsilon)\rightarrow V_M,$$

is given, where V_M is a certain neighborhood of M in V. Besides M and the diffeomorphism Ψ, we will assume also that the following is given:

(a) a 2-covariant symmetric tensor field T on V_M, satisfying $i(\partial/\partial t)T=0$, where $i(\vec{v})$ indicates the inner contraction of $\vec{v}$ (later, we will choose the components of T in Gauss coordinates as the components $\tilde{T}_{ij}$ of the stress-energy tensor).
(b) A function F on M (later it will be chosen as $\tilde{T}_4^4$).
(c) A vector field X on M (chosen as $X^i=\tilde{T}_4^i$).
(d) A Riemannian metric g on M, and a 2-covariant symmetric tensor field k on M.

With this data we want to find a Lorentz metric $\tilde{g}$ and a 2-covariant symmetric tensor field $\tilde{T}$ on V_M (or possibly in a certain neighborhood of M on V_M), in such a way that the following conditions are fulfilled:

(1) $\tilde{G}(\tilde{g})=\chi\tilde{T}$.
(2) $\tilde{g}(\partial/\partial t,\partial/\partial t)=-1$.
(3) For all t, the hypersurface $M_t=\Psi(M\times\{t\})$ is orthogonal to $\partial/\partial t$ in the metric $\tilde{g}$.
(4) The restriction of $\tilde{g}$ to M is g.
(5) Twice the second quadratic form of M with respect to the metric $\tilde{g}$ is k.
(6) In Gauss normal coordinates the relations $\tilde{T}_{ij}=T_{ij}$ hold on V_M.
(7) In Gauss normal coordinates the relations $\tilde{T}_4^4=F$ and $\tilde{T}_4^i=X^i$ hold on M, where $\tilde{T}_4^\alpha$ means $\tilde{g}^{\alpha\beta}\tilde{T}_{4\beta}$.

In order to deal with this problem we begin by noting that conditions (2) and (3) are written $\tilde{g}_{44}=-1$ and $\tilde{g}_{4i}=0$ in Gauss normal coordinates. It is easy to see that both conditions force the field $\partial/\partial t$ to be geodesic and hence we can use the formulas of the last section. Condition (7) gives $\tilde{T}_{44}=-F$ and $\tilde{T}_{4i}=X_i$ because $\tilde{g}_{44}=-1$ and $\tilde{g}_{4i}=0$.

The metric $\tilde{g}$ we look for will be determined by the knowledge of the $g_t=\tilde{g}|_{M_t}$ for all t in an interval of the origin of $\mathbb{R}$ [because $\tilde{g}_{44}=-1$, $\tilde{g}_{4i}=0$, and $\tilde{g}_{ij}(x,t)=(g_t)_{ij}(x)$]. In a similar way the knowledge of the tensor $\tilde{T}$ we look for will be determined by the knowledge, for all t, of the function F_t defined on M_t by $F_t=\tilde{T}_4^4|_{M_t}$, and by the family of vector fields X_t on each M_t defined by $(X_t)^i(x)=\tilde{T}_4^i(x,t)$ (since the components $\tilde{T}_{ij}=T_{ij}$ are given).

The Einstein equation $\tilde{G}(\tilde{g})=\chi\tilde{T}$ can be written in the equivalent form:

$$\tilde{R}_{\alpha\beta}=\chi(\tilde{T}_{\alpha\beta}-\tfrac{1}{2}(\mathrm{tr}_{\tilde{g}}\tilde{T})\tilde{g}_{\alpha\beta}). \tag{6}$$

We will write Einstein equation in the form $\tilde{G}(\tilde{g})=\chi\tilde{T}$ for some components, whereas we will use the form (6) for others. Concretely, we will use

$$\begin{aligned}\tilde{G}_{4\alpha}&=\chi\tilde{T}_{4\alpha},\\ \tilde{R}_{ij}&=\chi(\tilde{T}_{ij}-\tfrac{1}{2}(\mathrm{tr}_{\tilde{g}}\tilde{T})\tilde{g}_{ij}).\end{aligned} \tag{7}$$

By means of (4), (5), and (2), the four equations in (7) for the $\tilde{G}_{4\alpha}$ can be written in the following way:

$$\begin{gathered} \tfrac{1}{8}(k\cdot k-(\mathrm{tr}_g\, k)^2-4R)=\chi F, \\ \tfrac{1}{2}\nabla^r(k_{ir}-(\mathrm{tr}_g\, k)g_{ir})=\chi X_i\,. \end{gathered} \tag{8}$$

This means that the Cauchy data (g,k,F,X) on M are not independent but must satisfy the constraints (8). Since $\tilde{T}$ equals a constant times the Einstein tensor, it must have zero divergence. Taking into account that in Gauss normal coordinates one has

$$\tilde{\Gamma}^k_{ij}=\Gamma^k_{ij}, \quad \tilde{\Gamma}^4_{4j}=0, \quad \tilde{\Gamma}^\alpha_{44}=0,$$

this fact is written

$$0=\partial_4\tilde{T}^{4\beta}+\partial_i\tilde{T}^{i\beta}+\tilde{\Gamma}^i_{ij}\tilde{T}^{j\beta}+\tilde{\Gamma}^i_{i4}\tilde{T}^{4\beta}+2\tilde{\Gamma}^\beta_{4i}\tilde{T}^{4i}+\tilde{\Gamma}^\beta_{ij}\tilde{T}^{ij}, \tag{9}$$

where ∂_α indicates $\partial/\partial x^\alpha$. Now, $\tilde{T}^{44}=\tilde{T}_{44}=-F$ and $\tilde{T}^{i4}=-\tilde{T}^i_4=-X^i$. Moreover, $\tilde{\Gamma}^4_{ij}=S_{ij}$ where $S_{ij}=k_{ij}/2$ is the second fundamental form of the hypersurfaces M_t. One has $\tilde{\Gamma}^r_{4j}=S^r_j$, too. Writing now condition (9) for $\beta=4$ one obtains

$$\partial_t F=-\mathrm{div}_g\,\chi-\tfrac{1}{2}(\mathrm{tr}_g\, k)F+\tfrac{1}{2}k\cdot T, \tag{10}$$

For $\beta=r$, condition (9) is written in a similar way

$$\partial_t X^r=\nabla_i T^{ir}-\tfrac{1}{2}(\mathrm{tr}_g\, k)X^r-k^r_i X^i. \tag{11}$$

The second equation of (7) is written, by (1),

$$\partial_t k_{ij}=\chi T_{ij}-\tfrac{1}{2}\chi(F+\mathrm{tr}_g\, T)g_{ij}+(k\times k)_{ij}-2R_{ij}-\tfrac{1}{2}(\mathrm{tr}_g\, k)k_{ij}\,. \tag{12}$$

It is well known that in Gauss coordinates one has

$$\partial_t g_{ij}=k_{ij}\,. \tag{13}$$

Equations (10), (11), (12), and (13) give the evolution of F_t, X_t, k_t, and g_t with respect to t, respectively. The system of equations (10), (11), (12), and (13) is similar to the one studied in Refs. 15 and 16. It is well-known the existence, for small t, of a unique solution (F_t,X_t,k_t,g_t) with initial conditions (F,X,k,g) on M (corresponding to $t=0$) that satisfy constraints (8). Also, it is well-known that the solution (F_t,X_t,k_t,g_t) satisfies then (8) for all t, and hence the solution (F_t,X_t,k_t,g_t) defines a metric $\tilde{g}$ and a tensor $\tilde{T}$ satisfying the Einstein equation.

Remark 1: The Cauchy problem splits into a problem of initial conditions (the search for Cauchy data satisfying $\tilde{G}_{4\alpha}=\chi\tilde{T}_{4\alpha}$ on M), and a problem of evolution (the integration of the equations $\tilde{G}_{ij}=\chi\tilde{T}_{ij}$ in V_M for the previous initial conditions). This is the reason why the components $\tilde{T}_{ij}$ have to be given on V_M, not only on M.

Remark 2: If we require the stress-energy tensor $\tilde{T}$ to be that of a perfect fluid with null pressure, that is, $\tilde{T}=\rho u\otimes u$, with u a timelike unit vector $(\tilde{g}(u,u)=-1)$, then $\tilde{T}_{ij}$ remains determined by the initial conditions (g,k). Indeed, write $u=r(\partial/\partial t)+v$ with v tangent to M_t. One has $u_i=\tilde{g}_{i\alpha}u^\alpha=g_{ij}u^j=g_{ij}v^j=v_i$, $u_4=\tilde{g}_{44}u^4=-r$. Then $X_i=\tilde{T}_{4i}=\rho u_4 u_i=-\rho r v_i$, $F=-\tilde{T}_{44}=-\rho r^2$. On the other hand, $\tilde{g}(u,u)=-1$, hence $g(v,v)=-1+r^2$. Then the 5 scalar equations

$$X_i=-\rho r v_i, \quad F=-\rho r^2, \quad g(v,v)=-1+r^2$$

determine the 5 variables ρ, r, and v_i in terms of F, X_i, and g. By (8) F and X are related to (g,k), and hence T_{ij} depends only on (g,k). The same occurs in a perfect fluid with pressure when a state equation relates both the pressure and density (see Ref. 15).

IV. REVISION OF THE CONCEPT OF LINEARIZATION STABILITY OF AN EQUATION

Before the definition of this concept we remember the initial Einstein's point of view with respect to the linearization of his equation in a small neighborhood of the Minkowski metric (see Refs. 8 and 9). Let

$$\tilde{G}(\tilde{g}')=\chi\tilde{T}' \tag{14}$$

be the Einstein equation. The metric $\tilde{g}'=\eta=\mathrm{Diag}[1,1,1,-1]$ in $\mathbb{R}^4$ satisfies this equation without matter $(\tilde{T}'=0)$. Let $\tilde{T}'$ be a small stress-energy tensor (components close to zero) and look for the metrics $\tilde{g}'$ close to η that fulfills (14). Since Einstein tensor has zero divergence, $\mathrm{div}_{\tilde{g}'}\tilde{T}'=0$ has to be satisfied for any $\tilde{g}'$ solution of (14). This is a condition that links $\tilde{T}'$ and the solutions $\tilde{g}'$ of (14) corresponding to this $\tilde{T}'$. Let $\tilde{g}'=\eta+\tilde{h}$ be a metric close to η. We design by ψ the 2-tensor defined in terms of $\tilde{h}$ by

$$\psi_{\alpha\beta}=\tilde{h}_{\alpha\beta}-\tfrac{1}{2}(\mathrm{tr}_\eta\tilde{h})\,\eta_{\alpha\beta}.$$

Einstein realized that if $\tilde{h}$ satisfies $\mathrm{div}_\eta\psi=0$, the linear equation in $\tilde{h}$ obtained from $\tilde{G}(\eta+\tilde{h})=\chi\tilde{T}'$ can be written with respect to ψ in the following form:

$$-\frac{1}{2}\left(\frac{\partial^2}{\partial x_1^2}+\frac{\partial^2}{\partial x_2^2}+\frac{\partial^2}{\partial x_3^2}-\frac{\partial^2}{\partial x_4^2}\right)\psi_{\alpha\beta}=\chi\tilde{T}'_{\alpha\beta}. \tag{15}$$

Einstein also realized that for any $\tilde{h}$ there exists an appropriate *gauge* in which the condition $\mathrm{div}_\eta\psi=0$ is fulfilled, and therefore this supplementary condition is physically irrelevant. Then Einstein gave the solutions ψ of (15) vanishing at infinity in terms of $\tilde{T}'$ using the retarded-potential method. Briefly, given a tensor $\tilde{T}'$ close to zero for which (14) has a solution, he solves the linear equation $(d\tilde{G})_\eta(\tilde{h})=\chi\tilde{T}'$ instead of $\tilde{G}(\eta+\tilde{h})=\chi\tilde{T}'$ for the same $\tilde{T}'$.

In general, we are dealing with the following problem: we begin with spacetime $(V,\tilde{g})$ where the metric $\tilde{g}$ satisfies the Einstein equation $\tilde{G}(\tilde{g})=\chi\tilde{T}$ for a given stress-energy tensor $\tilde{T}$. Then we consider stress-energy tensors $\tilde{T}'=\tilde{T}+\delta\tilde{T}$ close to $\tilde{T}$ (small variations of $\tilde{T}$) and we look for metrics $\tilde{g}'=\tilde{g}+\tilde{h}$ close to $\tilde{g}$ satisfying (14). But instead of working with $\tilde{G}(\tilde{g}+\tilde{h})=\chi(\tilde{T}+\delta\tilde{T})$, we deal with $(d\tilde{G})_{\tilde{g}}(\tilde{h})=\chi\delta\tilde{T}$. Is it admissible ?

So let us express this idea in a more exact form using the results of the preceding section. Consider a spacelike hypersurface M of $(V,\tilde{g})$. The tensors $\tilde{T}'=\tilde{T}+\delta\tilde{T}$ close to $\tilde{T}$ for which (14) has a solution in a certain neighborhood of M in V can be given in the following form: (a) Give a diffeomorphism Ψ of $M\times(-\epsilon,\epsilon)$ on an open neighborhood V_M of M in V. (b) Give a vector field X' and a function F' on M close to the field $(\tilde{T})^i_4|_M$ and to the function $(\tilde{T})^4_4|_M$ on M, respectively. (c) Give a 2-symmetric tensor T' in V_M satisfying $i(\partial/\partial t)T'=0$, in such a way that T'_{ij} be close to $(\tilde{T})_{ij}$. With this data, any (g',k') solution of the equations obtained from (8) replacing g, k, ∇, R, F, and X by g', k', ∇', R', F', and X', defines a metric $\tilde{g}'$ in a neighborhood of M in V and a tensor $\tilde{T}'$ such that $\tilde{G}(\tilde{g}')=\chi\tilde{T}'$. Thus the only equations we have to study for the linearization stability of a given F' and X' are the ones in (8).

The notations $S_2(M)$, $\mathcal{F}(M)$, and $\mathcal{X}(M)$ will stand for the 2-covariant symmetric tensors spaces, function spaces and vector field spaces on M, respectively. Later we will specify the topology of these spaces as well as the derivability and asymptotic conditions on the coefficients. For the moment we assume that all these spaces are Banach spaces. Let $\mathcal{H}(g',k')$ be the first member of the first equation of (8), that is

$$\mathcal{H}(g',k')=(1/8)(k'\cdot_{g'}k'-(\mathrm{tr}_{g'}k')^2-4R').$$

Let $\gamma(g',k')$ be the 1-form on M given by the first member of the second equation of (8), that is,

$$\gamma(g',k')_i=(1/2)\nabla'^r(k'_{ir}-(\mathrm{tr}_{g'}k')g'_{ir}).$$

1-forms on M are related to vector fields by the metric g'. Consider the mapping

$$\Phi:\ S_2(M)\times S_2(M)\to\mathcal{F}(M)\times\mathcal{X}(M)$$

$$(g',k')\to(\mathcal{H}(g',k'),\gamma(g',k')).$$

[The mapping Φ is only defined on the open set $S_2(M)\times S_2(M)$ of the pairs (g',k') such that g' is positive defined.] The initial metric $\tilde{g}$ of V corresponds to an initial pair (g,k). Given an element $\mathcal{T}'=(F',X')$ of $\mathcal{F}(M)\times\mathcal{X}(M)$ close to $((\tilde{T})_4^4|_M,(\tilde{T})_4^i|_M)$, we want to solve the linear equation $(d\Phi)_{(g,k)}(h,K)=\chi(\mathcal{T}'-\mathcal{T})$ instead of the true equation $\Phi(g',k')=\chi\mathcal{T}'$ in a neighborhood of (g,k). Obviously, in order to be meaningful, the solutions of the linear equations would have to be close to those of the true equation. We now write this in terms of a mapping between two Banach spaces.

Hence, let E_1 and E_2 be two Banach spaces. Let $p_0\in E_1$. Let U be a neighborhood of p_0 in E_1 and f: $U\to E_2$ a continuously differentiable mapping. For all $q\in E_2$ close to the origin, we want to compare the set H_q of $p\in U$ that are solution of $f(p)-f(p_0)=q$ with the set L_q of $p\in U$ that are solution of the linear equation $(df)_{p_0}(p-p_0)=q$ and make this comparison only for those p close enough to p_0. With respect to this problem, we enunciate the following theorem, a consequence of the inverse function theorem:

Theorem 1: *Let E_1 and E_2 be two Banach spaces. Let $p_0\in E_1$. Let U be a neighborhood of p_0 in E_1 and let f: $U\to E_2$ be a continuously differentiable mapping. For any $q\in E_2$ let H_q be the set of $p\in U$ such that $f(p)-f(p_0)=q$ and L_q the set of $p\in E_1$ such that $(df)_{p_0}(p-p_0)=q$. Let L be the kernel of $(df)_{p_0}$. We assume that L has a splitting kernel, that is, it has a topological complement S in E_1 in such a way that $E_1=L\oplus S$ [this enables us to write every element of E_1 as a pair (x,y) with $x\in L$ and $y\in S$]. If the tangent linear mapping $(df)_{p_0}$: $E_1\to E_2$ is surjective, then there exists an open neighborhood U' of p_0 in U, an open neighborhood V of the origin in E_2, an open neighborhood W of the origin in L, a linear mapping α: $E_2\to S$ and a differentiable mapping β: $V\times W\to S$ such that for any $q\in V,H_q\cap U'$ is a differentiable submanifold of U' parametrized by*

$$\varphi_q:\ W\to H_q\cap U'$$

$$x\to p_0+(x,\beta(q,x))$$

and L_q is a linear submanifold of E_1 parametrized by

$$\psi_q:\ L\to L_q$$

$$x\to p_0+(x,\alpha(q)),$$

and if for any $q\in V$ we denote by $E_q(x)$ the error done when considering $\psi_q(x)\in L_q$ instead of $\varphi_q(x)\in H_q\cap U'$ [that is, $E_q(x)=\varphi_q(x)-\varphi_q(x)=(0,\beta(q,x)-\alpha(q))$], one can assure that

$$\lim_{(x,q)\to(0,0)} \frac{E_q(x)}{\sqrt{\|x\|^2+\|q\|^2}}=0. \tag{16}$$

In other words, the error $E_q(x)$ is a high-order infinitesimal with respect to the distance of $(x,q)\in L\times E_2$ to the origin.

This theorem (whose proof is given later) leads us to introduce the following two definitions.

Definition 1: Let f: $U\to E_2$ be a continuously differentiable mapping between an open set U of a Banach space E_1 and another Banach space E_2. Let $p_0\in U$. Let F be a closed vector subspace E_2. For any $q\in F$ we denote by $H_q=\{p\in U$ such that $f(p)-f(p_0)=q\}$ and by $L_q=\{p\in E_1$ such that $(df)_{p_0}(p-p_0)=q\}$. We say f is linearization stable at the initial point p_0 in the direction of F if $(df)_{p_0}$ has a splitting kernel L and there exists an open neighborhood U' of *p_0 in U, an open neighborhood V of the origin in F, an open neighborhood W of the origin in L, a linear mapping α: $F\to S$ and a differentiable mapping $\beta: V\times W\to S$ such that for any $q\in V, H_q\cap U'$ is a differentiable submanifold of U' parametrized by*

$$\varphi_q:\; W\to H_q\cap U'$$

$$x\to p_0+(x,\beta(q,x)),$$

L_q is a linear submanifold of E_1 parametrized by

$$\psi_q:\; L\to L_q$$

$$x\to p_0+(x,\alpha(q)),$$

and for any $q\in V$ the error $E_q(x)$ done in considering $\psi_q(x)\in L_q$ instead of $\varphi_q(x)\in H_q\cap U'$ is a high-order infinitesimal with respect to the distance of $(x,q)\in L\times F$ to the origin [that is, (16) is fulfilled].

Definition 2: Let f: $U\to E_2$ be a continuously differentiable mapping between an open set U of a Banach space E_1 and another Banach space E_2. Let $p_0\in U$. We say f is linearization stable at the initial point p_0 if f is linearization stable at p_0 in the direction of E_2 (that is, when the previous definition is fulfilled for $F=E_2$).

Remarks on these definitions: (1) The fact that a mapping *f* between an open set *U* of a Banach space E_1 and another Banach space E_2 is linearization stable at $p_0\in U$ in the direction of a subspace F of E_2 means that, instead of solving the equation $f(p_0+h)=f(p_0)+q$, for small $q\in F$ and $h\in E_1$, one can deal with the linearized equation $(df)_{p_0}(h)=q$ without making a serious error because by (16) the solutions of each one are close enough.

(2) With the previous definitions in mind, Theorem 1 can be rewritten in the following form: if $(df)_{p_0}$ is surjective and has a splitting kernel, then *f* is linearization stable at p_0.

(3) In the case of Einstein equation, the mapping whose linearization stability we want to study is

$$\Phi:\; S_2(M)\times S_2(M)\to\mathcal{F}(M)\times\mathcal{X}(M)$$

$$(g',k')\to(\mathcal{H}(g',k'),\gamma(g',k')),$$

which is the same mapping one encounters when dealing with *empty space* Einstein equation. Nevertheless, in the empty space case this mapping is studied in a neighborhood of a pair (g,k) such that $\Phi(g,k)=0$, whereas in the presence of matter Φ must be studied in a neighborhood of a pair (g,k) such that $\Phi(g,k)=\chi\mathcal{T}$.

(4) If the subspace F of E_2 is $F=\{0\}$, definition 1 agrees with that of Ref. 7. These authors required every solution of the linear equation $(df)_{p_0}(p-p_0)=0$ to be tangent to a curve $p(t)$ of exact solutions of $f(p)-f(p_0)=0$. Let us see that the definition of these authors can be deduced

from condition (16). For that purpose let $v=p-p_0$ be a solution of the linear equation $(df)_{p_0}(v)=0$ (v will be in L). Let $p'(t)$ be the the straight line in L_0 defined by $p'(t)=p_0+tv$. Using $E_1=L\oplus S$ the straight line $p'(t)$ is written as $p'(t)=p_0+(tv,0)$. Consider the curve $p(t)=p_0+(tv,\beta(0,tv))$ of H_0. We wonder if v is the tangent vector to this curve at the point of parameter $t=0$. So one has to show that $(d\beta(0,tv)/dt)_{t=0}=0$. First, notice that (16) implies that $E_0(0)=0$, and since $E_0(0)=(0,\beta(0,0)-\alpha(0))$ and $\alpha(0)=0$, one has $\beta(0,0)=0$. By Taylor expansion,

$$\beta(0,tv)=\left(\frac{d\beta(0,tv)}{dt}\right)_{t=0}t+t^2h(t).$$

Hence,

$$\lim_{t\to 0}\frac{E_0(tv)}{\|tv\|}=\lim_{t\to 0}\frac{\beta(0,tv)}{\|tv\|}=\pm\frac{1}{\|v\|}\left(\frac{d\beta(0,tv)}{dt}\right)_{t=0}.$$

Therefore, if $(d\beta(0,tv)/dt)_{t=0}$ were $\neq 0$ the previous limit would be $\neq 0$. On the other hand, condition (16) requires this limit to be zero. This completes the proof.

Finally, notice that if f is linearization stable at p_0 according to Definition 2, then, even though H_0 is tangent to L_0, H_q is not tangent to L_q for $q\neq 0$. However, condition (16) assures us that the error done in considering L_q instead of H_q is small.

Proof of the theorem: If $(df)_{p_0}$: $E_1=L\oplus S\to E_2$ is surjective, its restriction to S gives raise to an isomorphism from S to E_2. We denote by α: $E_2\to S$ the inverse isomorphism. For any $p\in E_1$, $p-p_0$ factorizes as $x+y$ with $x\in L$ and $y\in S$. For all $q\in E_2$ the submanifold $L_q=\{p\in E_1$ such that $(df)_{p_0}(p-p_0)=q\}$ is parametrized by ψ_q: $x\to p=p_0+x+\alpha(q)$, since

$$(df)_{p_0}(p-p_0)=(df)_{p_0}(x+\alpha(q))=((df)_{p_0}\alpha)(q)=q.$$

f being differentiable at p_0, we have $f(p_0+x+y)=f(p_0)+(df)_{p_0}(y)+\epsilon(x,y)$, with

$$\lim_{(x,y)\to(0,0)}\frac{\epsilon(x,y)}{\sqrt{\|x\|^2+\|y\|^2}}=0.$$

Consider the mapping

$$\gamma:\ E_1\to L\times E_2$$

$$p_0+x+y\to(x,f(p_0+x+y)-f(p_0)).$$

Since $(d\gamma)_{p_0}$ is an isomorphism, the inverse function theorem states the existence of a neighborhood U' of p_0 in E_1 and of a neighborhood $W\times V$ of (0, 0) in $L\times E_2$ in such a way that γ gives an isomorphism between U' and $W\times V$. Let

$$\gamma^{-1}:\ W\times V\to U'\subset E_1$$

$$(x,q)\to\gamma^{-1}(x,q)$$

be the inverse isomorphism. Obviously, for any $q\in V,\varphi_q$: $x\to\gamma^{-1}(x,q)$ is a parametrization of $H_q\cap U'$. Now, we claim that $\gamma^{-1}(x,q)$ is written as p_0+x+y with $y\in S$. Indeed, we have

$$\gamma^{-1}(x,q)=p_0+x'+y$$

with $x'\in L$ and $y\in S$. We have to show that $x'=x$. To do this we write

$$(x,q)=\gamma\gamma^{-1}(x,q)=\gamma(p_0+x'+y)=(x',f(p_0+x'+y)-f(p_0)).$$

This implies $x=x'$. In $\gamma^{-1}(x,q)=p_0+x+y$ the element $y\in S$ depends differentiably on x and q. We write $\gamma^{-1}(x,q)=p_0+x+\beta(q,x)$. This is the function β whose existence the theorem claims. Only (16) remains to be shown. Notice that

$$\gamma\varphi_q(x)=\gamma\gamma^{-1}(x,q)=(x,q)$$

and that

$$\gamma\psi_q(x)=\gamma(p_0+x+\alpha(q))=(x,f(p_0+x+\alpha(q))-f(p_0)).$$

Hence

$$\gamma\psi_q(x)-\gamma\varphi_q(x)=(0,f(p_0+x+\alpha(q))-f(p_0)-q).$$

Now,

$$f(p_0+x+\alpha(q))-f(p_0)-q=(df)_{p_0}(\alpha(q))+\epsilon(x,\alpha(q))-q.$$

But $(df)_{p_0}(\alpha(q))=q$ and thus $f(p_0+x+\alpha(q))-f(p_0)-q=\epsilon(x,\alpha(q))$. Therefore, we have

$$\|\gamma\varphi_q(x)-\gamma\psi_q(x)\|_{L\times E_2}=\|\epsilon(x,\alpha(q))\|_{E_2}.$$

Since the inverse function theorem states that the mapping

$$(d\gamma)^{-1}:\ W\times V\to\mathcal{L}(L\times E_2,E_1)$$

is continuous, given a $K>0$ there exists a neighborhood A of (0, 0) in $W\times V$ such that for any $z\in A$ one has $\|(d\gamma)^{-1}(z)\|<K$. If z_1 and z_2 belong to A, by the mean value theorem $\|\gamma^{-1}(z_1)-\gamma^{-1}(z_2)\|<K\|z_1-z_2\|$. Apply this when $z_1=\gamma\varphi_q(x)$ and $z_2=\gamma\psi_q(x)$. Suppose that x and q are close enough to the origins of L and E_2 in order that z_1 and z_2 belong to A. Then

$$\|\varphi_q(x)-\psi_q(x)\|<K\|\gamma\varphi_q(x)-\gamma\psi_q(x)\|=K\|\epsilon(x,\alpha(q))\|.$$

Now, let $C=1/\|\alpha\|$. Since $\|\alpha(q)\|\leqslant\|\alpha\|\|q\|$, we have

$$\frac{\|\varphi_q(x)-\psi_q(x)\|}{\sqrt{\|x\|^2+\|q\|^2}}<\frac{K\|\epsilon(x,\alpha(q))\|}{\sqrt{\|x\|^2+C^2\|\alpha(q)\|^2}}.$$

If $C^2\geqslant 1$ one has $\sqrt{\|x\|^2+\|\alpha(q)\|^2}\leqslant\sqrt{\|x\|^2+C^2\|\alpha(q)\|^2}$, and if $C^2<1$ then $C\sqrt{\|x\|^2+\|\alpha(q)\|^2}\leqslant\sqrt{\|x\|^2+C^2\|\alpha(q)\|^2}$. In both cases we get, finally

$$\frac{\|\varphi_q(x)-\psi_q(x)\|}{\sqrt{\|x\|^2+\|q\|^2}}<K'\frac{\|\epsilon(x,\alpha(q))\|}{\sqrt{\|x\|^2+\|\alpha(q)\|^2}}\to 0.$$

This ends the proof.

V. LINEARIZATION STABILITY IN ROBERTSON–WALKER MODELS: EXPOSITION OF RESULTS

(S,g) will stand for a 3-Riemannian manifold with constant curvature K. Let $V=S\times I$, where I is an $\mathbb{R}$-interval. A Lorentzian metric of the form $\tilde{g}=-dt^2+\zeta(t)^2g$ is given on V, where t is the coordinate of I. In V we consider a perfect fluid with $u=\partial/\partial t$ as a velocity field, so that the stress-energy tensor of the fluid has the form $\tilde{T}=(\rho+p)u^*\otimes u^*+p\tilde{g}$, where u^* is the 1-form associated to u by $\tilde{g}$. Obviously, the metric $\tilde{g}$ and the tensor $\tilde{T}$ are related by the Einstein equation $\tilde{G}(\tilde{g})=\chi\tilde{T}$, which gives a well-known relations between ρ, p, ζ and the curvature K of g. From these relations one obtains, in particular, that ρ and p depend only on t. The Lorentz manifold $(V,\tilde{g})$ with the stress-energy tensor $\tilde{T}$ is called a Robertson–Walker model. We suppose that the Riemannian manifold (S,g) is connected and simply connected, and hence S will be a sphere in the case $K>0$, the Euclidean space $\mathbb{R}^3$ in the case $K=0$ or the hyperbolic space of curvature K in the case $K<0$.

We wonder if the equation $\tilde{G}(\tilde{g}')=\chi\tilde{T}'$ can be linearizated at the initial metric $\tilde{g}$ corresponding to a Robertson–Walker model $(V,\tilde{g},\tilde{T})$. That is, given a perturbation $\delta\tilde{T}$ of a stress-energy tensor $\tilde{T}$, is it legitimate to deal with the linear equation $(d\tilde{G})_{\tilde{g}}(\tilde{\delta}g)=\chi\delta\tilde{T}$ instead of working with the true equation $\tilde{G}(\tilde{g}+\tilde{h})=\chi(\tilde{T}+\delta\tilde{T})$? In the next section we show that if the curvature K of (S,g) vanishes then the Einstein equation is linearization stable at the initial metric $\tilde{g}$ of Robertson–Walker. In a subsequent paper we will show that if $K>0$ there exists no vector subspace $\mathcal{F}$ of the space of stress-energy tensors for which the Einstein equation is linearization stable at g in the direction of $\mathcal{F}$.

VI. RESULTS FOR $K=0$

Let $\mathcal{C}_c^\infty$ be the space of functions C^∞ with compact support on $\mathbb{R}^3$. For any positive integer p consider the norm $|\ |_p$ on $\mathcal{C}_c^\infty$ defined by

$$|f|_p=\left(\left|\int_{\mathbb{R}^3} f(x)^p\, dx\right|\right)^{1/p}.$$

Let $\mathbb{R}^+=\{x\in\mathbb{R} \text{ with } x\geq 0\}$ and $\mathbb{Z}^+=\mathbb{Z}\cap\mathbb{R}^+$. For all $s\in\mathbb{Z}^+$, p positive integer and $\delta\in\mathbb{R}^+$ consider on $\mathcal{C}_c^\infty$ the norm $|\ |_{p,s,\delta}$ defined by

$$|f|_{p,s,\delta}=\sum_{|\alpha|\leq s}|(D^\alpha f)(x)(\sqrt{1+|x|^2})^{|\alpha|+\delta}|_p .$$

Let $\mathcal{F}^p_{s,\delta}$ be the completion of $\mathcal{C}_c^\infty$ with respect to $|\ |_{p,s,\delta}$ (weighted Sobolev spaces). See Refs. 12 and 13 for the properties of these spaces. We mention here that for $s>(3/p)+k$ one has $\mathcal{F}^p_{s,\delta}\subset\mathcal{C}^k$, where $\mathcal{C}^k$ is the space of functions of class $\mathcal{C}^k$ on $\mathbb{R}^3$. Also, when $s>3/p$ the pointwise multiplication of functions $(f,g)\to f\cdot g$ induces a continuous mapping

$$\mathcal{F}^p_{s,\delta}\times\mathcal{F}^p_{s,\delta}\to\mathcal{F}^p_{s,\delta}.$$

From now on we will always suppose that $s>3/p$ so that the previous property will be satisfied and one has $\mathcal{F}^p_{s,\delta}\subset\mathcal{C}^0$.

We denote by $S^p_{s,\delta}$ and by $\mathcal{X}^p_{s,\delta}$ the spaces of 2-covariant symmetric tensors over $\mathbb{R}^3$ and vector fields over $\mathbb{R}^3$, respectively, whose components are functions of $\mathcal{F}^p_{s,\delta}$.

We will suppose given in $\mathbb{R}^3$ a Riemannian metric g, a 2-covariant symmetric tensor k, a vector field X and a function F such that the data (g,k,F,X) satisfy (8). $\mathcal{F}^p_{s,\delta}(F)$ will stand for the set of continuous functions F' over $\mathbb{R}^3$ such that $F'-F\in\mathcal{F}^p_{s,\delta}$. Hence we have $\mathcal{F}^p_{s,\delta}(F)=F+\mathcal{F}^p_{s,\delta}$. The space $\mathcal{F}^p_{s,\delta}(F)$ may be topologized by declaring the mapping $f\to F+f$ from $\mathcal{F}^p_{s,\delta}$ to $\mathcal{F}^p_{s,\delta}(F)$ to be an homeomorphism.

Similarly, we define $\mathcal{R}^p_{s,\delta}(g)$, $S^p_{s,\delta}(k)$, and $\mathcal{X}^p_{s,\delta}(X)$ by the following manner: $\mathcal{R}^p_{s,\delta}(g)$ is the set of continuous Riemannian metrics g' of $\mathbb{R}^3$ such that $g'-g\in S^p_{s,\delta}$; $S^p_{s,\delta}(k)$ is the set of continuous 2-covariant symmetric tensors k' over $\mathbb{R}^3$ such that $k'-k\in S^p_{s,\delta}$; $\mathcal{X}^p_{s,\delta}(X)$ is the set of continuous vector fields X' over $\mathbb{R}^3$ such that $X'-X\in\mathcal{X}^p_{s,\delta}$.

Consider the mapping

$$\Phi:\ \mathcal{R}^p_{s,\delta}(g)\times S^p_{s-1,\delta+1}(k)\to\mathcal{F}^p_{s-2,\delta+2}(F)\times\mathcal{X}^p_{s-2,\delta+2}(X)$$

$$(g',k')\to(\mathcal{H}(g',k'),\gamma(g',k'))$$

where, as usual,

$$\mathcal{H}(g',k')=(1/8)(k'\cdot_{g'}k'-(\mathrm{tr}_{g'}\,k')^2-4R(g'))$$

$$\gamma(g',k')_i=(1/2)\nabla'^r(k'_{ir}-(\mathrm{tr}_{g'}\,k')g'_{ir}).$$

With these conventions in mind we can state the following theorem.

Theorem 2: *If* $p>3$, $s>(3/p)+2$ *and* $0\leqslant\delta<(3(p-1)/p)-2$ *and if the initial data* (g,k,F,X) *satisfy* $\mathrm{tr}_g\,k=\text{constant}$, $X=0$ *and g is the Euclidean metric then the differential of* Φ *at the point* (g,k)

$$D_{(g,k)}\Phi:\ S^p_{s,\delta}\times S^p_{s-1,\delta+1}\to\mathcal{F}^p_{s-2,\delta+2}\times\mathcal{X}^p_{s-2,\delta+2}$$

is surjective and has a splitting kernel.

Remark: This theorem is a generalization of that of Choquet-Bruhat, Fischer, and Marsden[11] in the presence of matter and its proof reduces to show that the statements and calculus of Ref. 11 still remain valid in this new situation. Since Ref. 11 always uses (explicit and implicit) the condition $\mathcal{H}(g,k)=0$, which now is not satisfied, we think is worth briefly summarizing again the calculus of Ref. 11 in our situation.

Proof of the theorem: We begin by evaluating the differentials $D_{(g,k)}\mathcal{H}$ and $D_{(g,k)}\gamma$. To do this we replace g' by $g+h$ and k' by $k+K$ in the expressions of $\mathcal{H}(g',k')$ and of $\gamma(g',k')$ and only keep the linear terms in h and K bearing in mind that the difference between the Christoffel symbols Γ'^r_{ij} of g' and the symbols Γ^r_{ij} of g is written

$$\Gamma'^r_{ij}-\Gamma^r_{ij}=\tfrac{1}{2}g'^{rs}(\nabla_i h_{js}+\nabla_j h_{si}-\nabla_s h_{ij}),$$

and hence the linear term in h of this expression is $(1/2)g^{rs}(\nabla_i h_{js}+\nabla_j h_{si}-\nabla_s h_{ij})$. Also, the linear term in h of the difference $R(g')-R(g)$ between the scalar curvatures of g' and g is written as

$$R(g')-R(g)\cong -h^{ij}R_{ij}+\nabla^i\nabla^s h_{is}-\nabla^s\nabla_s\,\mathrm{tr}\,h$$

(the sign $\cong$ means equality up to terms of order >1 in h and K). Then a straight-forward computation gives

$$(D_{(g,k)}\mathcal{H})(h,K)=\tfrac{1}{8}[-2h\cdot(k\times k)+2k\cdot K-2(\mathrm{tr}\,k)(\mathrm{tr}\,K)+2h\cdot k\,\mathrm{tr}\,k$$
$$+4h\cdot\mathrm{Ric}(g)-4\nabla^i\nabla^j h_{ij}+4\nabla^i\nabla_i\,\mathrm{tr}\,h],$$

$$(D_{(g,k)}\gamma)(h,K)_i=\tfrac{1}{2}[\nabla^s K_{is}-\partial_i(\mathrm{tr}\,K)-h^{rs}\nabla_r k_{is}+h^{rs}\nabla_i k_{rs}$$
$$+\tfrac{1}{2}(\nabla_i h_{rs})k^{rs}-(\nabla^s h_{sm})k^m_i+\tfrac{1}{2}\nabla^l(\mathrm{tr}\,h)k_{il}].$$

For each function τ on $\mathbb{R}^3$ and each vector field Y on $\mathbb{R}^3$ we consider $h=2g\tau$ and $K=L_Y g-(\mathrm{div}\,Y)g-\tau k+\tau(\mathrm{tr}\,k)g$ where $\mathrm{div}\,Y$ means $\nabla^i Y_i$. For the moment, we only deal with these pairs (h,K) that depends on (τ,Y). Replacing these h and K in $D_{(g,k)}\mathcal{H}$ and $D_{(g,k)}\gamma$ we get

$$(D_{(g,k)}\mathcal{H})(Y,\tau)=\tfrac{1}{8}(-6\tau k\cdot k+2k\cdot L_Y g+2\tau(\mathrm{tr}\,k)^2+8\tau R(g)-16\Delta\tau),$$

where $\Delta\tau$ means $-g^{ij}\nabla_i\nabla_j\tau$. Analogously

$$(D_{(g,k)}\gamma)(Y,\tau)_i=\tfrac{1}{2}(-(\delta L_Y g)_i-3\tau\nabla^s k_{is}-\tau\nabla_i\,\mathrm{tr}\,k),$$

where δ means the Hodge operator that assigns to each 2-covariant symmetric tensor ω the 1-form $(\delta\omega)_i = -\nabla^j \omega_{ji}$. Since the initial data satisfy (8), we can replace $(\operatorname{tr} k)^2$ by $k\cdot k - 4R - 8\chi F$ and $\nabla^s k_{is}$ by $2\chi X_i + \nabla_i \operatorname{tr} k$. Using now the hypothesis $\operatorname{tr} k = \text{constant}$ and $X=0$, we finally have

$$(D_{(g,k)}\mathcal{H})(Y,\tau) = \tfrac{1}{8}(-4\tau k\cdot k + 2k\cdot L_Y g - 16\chi\tau F - 16\Delta\tau)$$

$$(D_{(g,k)}\gamma)(Y,\tau)_i = -\tfrac{1}{2}(\delta L_Y g)_i .$$

As a consequence of a theorem of Cantor[13,12] for those p, s, δ satisfying the hypothesis of the theorem, the operators $Y \to \delta L_Y g$ of $\mathcal{X}^p_{s,\delta} \to \mathcal{X}^p_{s-2,\delta+2}$ and $\tau \to \Delta\tau$ of $\mathcal{F}^p_{s,\delta} \to \mathcal{F}^p_{s-2,\delta+2}$ are isomorphisms.

Now we are ready to show that $D_{(g,k)}\Phi$ is surjective. Given a $(f,Z) \in \mathcal{F}^p_{s-2,\delta+2} \times \mathcal{X}^p_{s-2,\delta+2}$ there exists a unique Y such that $(D_{(g,k)}\gamma)(Y,\tau) = -(1/2)\delta L_Y g = Z$. Now, we look for a function τ such that

$$\tfrac{1}{8}(-4\tau k\cdot k + 2k\cdot L_Y g - 16\chi\tau F - 16\Delta\tau) = f.$$

or what is the same

$$-4\tau k\cdot k - 16\chi\tau F - 16\Delta\tau = 8f - 2k\cdot L_Y g.$$

Since Δ is an isomorphism, so is $-16\Delta - 4k\cdot k - 16\chi F$. Therefore there exists a unique τ such that $(D_{(g,k)}\mathcal{H})(\tau,Y) = f$. From this function τ and this field Y we form h and K given by $h = 2g\tau$ and $K = L_Y g - (\operatorname{div} Y)g - \tau k + \tau(\operatorname{tr} k)g$. Clearly, $(D_{(g,k)}\Phi)(h,K) = (f,Z)$. Therefore $D_{(g,k)}\Phi$ is surjective. To see that $D_{(g,k)}\Phi$ has a splitting kernel for any pair (h,K) we consider the unique pair (h',K') of the form $h' = 2g\tau$ and $K' = L_Y g - (\operatorname{div} Y)g - \tau k + \tau(\operatorname{tr} k)g$ such that $(D_{(g,k)}\Phi) \times (h,K) = (D_{(g,k)}\Phi)(h',K')$ [unique because $D_{(g,k)}\Phi$ is an isomorphism restricted to the pairs (h',K')]. Then

$$(h,K) = (h-h', K-K') + (h',K')$$

gives us the desired splitting. This completes the proof.

Let us apply theorem 2 to a $(V = S\times I, \tilde{g}, \tilde{T})$ Robertson–Walker model with curvature $K=0$. We assume that S is connected and simply connected. If the curvature K of (S,g) is zero then S is $\mathbb{R}^3$ and g the Euclidian metric. From the form of the metric $\tilde{g} = -dt^2 + \zeta(t)^2 g$ it follows that the vector field $\partial/\partial t$ is geodesic and therefore the Gauss representation of the hypersurface $M_0 = S \times \{0\}$ is the identity $S\times I \to S\times I$. The restriction of $\tilde{g}$ to the hypersurfaces $M_t = S\times\{t\}$ is $g_t = \zeta(t)^2 g$. Therefore, from (13), we have $k_t = \partial_t g_t = 2\zeta\dot{\zeta} g = 2(\dot{\zeta}/\zeta) g_t$. That is, when $t=0$ we get $g_0 = \zeta(0)^2 g$ and $k_0 = 2(\dot{\zeta}(0)/\zeta(0)) g_0$. Note that $\operatorname{tr} k_0 = 6(\dot{\zeta}(0)/\zeta(0))$ is constant. Since the stress-energy tensor $\tilde{T}$ of the Robertson–Walker model satisfies $\tilde{T}_{44} = \rho$ and $\tilde{T}_{4i} = 0$, we have $F_t = \tilde{T}^4_4|_{M_t} = -\rho_t$ and $X^i_t(x) = \tilde{T}^i_4(x) = 0$. Thus, the hypotheses of Theorem 2 are all fulfilled. Then, Theorem 1 assures that the Einstein equations are linearization stable at the initial Robertson–Walker metric $\tilde{g}$.

(Received 24 November 1998; accepted for publication 15 January 1999)

In a previous paper (referred to here as paper I) we showed that the Einstein equation is linearization stable when a Robertson–Walker model of curvature $K=0$ is considered. For that purpose, a slightly different definition of linearization stability was introduced. In this paper we show that in case the curvature K is equal to 1 the Einstein equation $G(g)=\chi T$ is not linearization stable at the Robertson–Walker metric. © *1999 American Institute of Physics.* [S0022-2488(99)02209-4]

I. INTRODUCTION

This is the second part of a series of two papers. For motivations, notations, and references see Paper I.[1] Recall that in Paper I we dealt with a Robertson–Walker model $V=S\times I$ where (S,g) was a Riemannian 3-manifold of constant curvature K and V was endowed with a Lorentz metric of the form $\tilde{g}=-dt^2+\zeta(t)g$. In V we considered also a perfect fluid with stress-energy tensor $\tilde{T}$. We wondered whether the Einstein equation $\tilde{G}(\tilde{g}')=\chi\tilde{T}'$ could be linearized at the initial metric $\tilde{g}$ corresponding to the Robertson–Walker model $(V,\tilde{g},\tilde{T})$. The main result of this article (contained in Sec. III) is the linearization instability of the Einstein equation at the initial metric $\tilde{g}$ when the curvature K of (S,g) is positive. In Sec. I we write the notation used throughout this paper and we express the mapping $\Phi(g,k)=(\mathcal{H}(g,k),\gamma(g,k))$ of paper I in terms of a more suitable pair of variables (g,p) for subsequent calculus. In Sec. II we compute the expressions for $D_{(g,p)}\Phi$, $(D_{(g,p)}\Phi)^*$ and $D^2_{(g,p)}\gamma$ needed in the proof of the main theorem.

II. THE Φ MAPPING

Let M be a compact 3-manifold. Unlike paper 1, we use common Sobolev spaces with $p=2$ without weights. For all $s\in\mathbb{R}^+$, $\mathcal{F}^s(M)$ will stand for the space of functions on M of Sobolev class s, $S_2^s(M)$ the space of 2-covariant symmetric tensor fields over M of Sobolev class s, $\mathcal{R}^s(M)$ the open set in $S_2^s(M)$ of the Riemannian metrics, and $\mathcal{X}^s(M)$ the space of vector fields on M of Sobolev class s. Suppose that a Riemannian metric g, a 2-symmetric covariant tensor k, a function F and a vector field X are given on M in such a way that the data (g,k,F,X) satisfy

$$\begin{cases}\frac{1}{8}(k\cdot k-(\mathrm{tr}_g\,k)^2-4R)=\chi F\\ \frac{1}{2}\nabla^r(k_{ir}-(\mathrm{tr}_g\,k)g_{ir})=\chi X_i\end{cases}. \tag{1}$$

Consider the mapping

$$\Phi:\mathcal{R}^s(M)\times S_2^s(M)\to\mathcal{F}^{s-2}(M)\times\mathcal{X}^{s-1}(M)$$

$$(g',k')\to(\mathcal{H}(g',k'),\gamma(g',k'))$$

where $\mathcal{H}$ and γ denote the left hand side of (1)

In order to simplify the calculus we define $p' = k' - (\mathrm{tr}_{g'} k')g'$ and we will work with the new variables (g',p') instead of the old ones (g',k'). A straightforward computation shows that $\mathcal{H}$ and γ are then given by

$$\mathcal{H}(g',p') = \tfrac{1}{8}(p' \cdot_{g'} p' - 4R(g') - \tfrac{1}{2}(\mathrm{tr}_{g'} p')^2)$$

$$\gamma(g',p')_i = \tfrac{1}{2}\nabla'^j p'_{ij}.$$

The initial metric g induces an inner product at each point $x \in M$ in the following way:

$$(h,P)_x \cdot (h',P')_x = g^{ir}(x) g^{js}(x)(h_{ir} h'_{js}(x) + P_{ir} P'_{js}(x)).$$

We then extend it to $S_2^s(M) \times S_2^s(M)$ by

$$\langle (h,P),(h',P') \rangle = \int_{x \in M} (h,P)_x \cdot (h',P')_x dx,$$

where dx is the volume element of M by g. Also we define in $\mathcal{F}^{s-2}(M) \times \mathcal{X}^{s-1}(M)$ an inner product by

$$\langle (f,Y),(f',Y') \rangle = 4\int_M f(x) f'(x) dx + 4\int_M g(Y,Y')_x dx.$$

(The factor 4 will simplify subsequent formulas.)

The linear tangent mapping of Φ at (g,p) induces a mapping

$$D_{(g,p)}\Phi: \ S_2^\infty(M) \times S_2^\infty(M) \to \mathcal{F}^\infty(M) \times \mathcal{X}^\infty(M),$$

with an adjoint operator with respect to both inner products

$$(D_{(g,p)}\Phi)^*: \ \mathcal{F}^\infty(M) \times \mathcal{X}^\infty(M) \to S_2^\infty(M) \times S_2^\infty(M)$$

defined by

$$\langle (D_{(g,p)}\Phi)(h,P),(f,Y) \rangle = \langle (h,P),(D_{(g,k)}\Phi)^*(f,Y) \rangle. \tag{2}$$

This operator induces an operator for any Sobolev class s

$$(D_{(g,p)}\Phi)^*: \ \mathcal{F}^{s-2}(M) \times \mathcal{X}^{s-1}(M) \to S_2^{s-4}(M) \times S_2^{s-4}(M).$$

III. EXPRESSIONS FOR $D_{(g,p)}\Phi$, $(D_{(g,p)}\Phi)^*$ AND $D^2_{(g,p)}\gamma$

Later on we will need the expressions of $D_{(g,p)}\Phi$, $(D_{(g,p)}\Phi)^*$ and $D^2_{(g,p)}\gamma$ (γ being the second component of $\Phi = (\mathcal{H},\gamma)$). The expressions of these operators can be found in several papers (Refs. 2–5 for instance) when the initial conditions (g,p) satisfy $\mathcal{H}(g,p) = 0$, $\gamma(g,p) = 0$. However, now $\mathcal{H}(g,p) = \chi F$ and $\gamma(g,p) = \chi X$.

In Sec. VI of paper I we have already calculated the expressions of $D_{(g,k)}\mathcal{H}$ and $D_{(g,k)}\gamma$ using the (g,k) variables. In the same way, working with the (g,p) variables, we must calculate $\mathcal{H}(g + h, p + P)$ and $\gamma(g + h, p + P)$ and keep the linear terms in h and P. Then

$$(D_{(g,p)}\mathcal{H})(h,P)=\tfrac{1}{8}[2p\cdot P-2h\cdot(p\times p)+4h\cdot Ric(g)-4\nabla^i\nabla^j h_{ij}$$
$$+4\nabla^i\nabla_i \operatorname{tr} h-(\operatorname{tr} p)(\operatorname{tr} P)+(\operatorname{tr} p)h\cdot p]$$
$$(D_{(g,p)}\gamma)(h,P)_i=\tfrac{1}{2}[\nabla^s P_{is}-h^{rs}\nabla_r p_{is}+h^{rs}\nabla_i k_{rs}-\tfrac{1}{2}(\nabla_i h_{rm})p^{rm}-(\nabla^s h_{sm})p_i^m+\tfrac{1}{2}\nabla_m(\operatorname{tr} h)p_i^m]. \tag{3}$$

Keeping the quadratic terms in h and P of $\gamma(g+h,p+P)$ we obtain

$$(D^2_{(g,p)}\gamma)(h,P)_i=\tfrac{1}{2}[\nabla_r((h\times h)^{rs}p_{is})+h^{rs}(\nabla_i h_{rm})p_s^m-\tfrac{1}{2}h^{rs}(\nabla_m h_{rs})p_i^m-\tfrac{1}{2}h^{lm}(\nabla_m \operatorname{tr} h)p_{il}$$
$$-\tfrac{1}{2}(\nabla_i h_{rm})P^{mr}+\tfrac{1}{2}(\nabla_m \operatorname{tr} h)P_i^m-\nabla_r(h^{rs}P_{is})]. \tag{4}$$

Let us now evaluate $(D_{(g,p)}\Phi)^*$, defined by the identity (2). If we denote by A and B the two components of $(D_{(g,p)}\Phi)^*$, the identity (2) is written

$$4\int_M (D_{(g,p)}\mathcal{H})(h,P)_x f(x)dx+4\int_M g((D_{(g,p)}\gamma)(h,P)_x,Y_x)dx$$
$$=\int_M hA(f,Y)_x\,dx+\int_M P\cdot B(f,Y)_x\,dx. \tag{5}$$

In order to calculate the two integrals of the first member of (5), once (3) is used, one must handle with care the terms containing derivatives in h or in P. For example, consider the expression of $(D_{(g,p)}\mathcal{H})(h,P)f$ and its term $-(1/2)\nabla^i\nabla^j h_{ij}f$ containing two derivatives on h. This term can be written

$$-\tfrac{1}{2}(\nabla^i\nabla^j h_{ij})f=\tfrac{1}{2}(\nabla^j h_{ij})\nabla^i f+\text{divergence}=-\tfrac{1}{2}h_{ij}\nabla^j\nabla^i f+\text{divergence}.$$

Doing the same in all the terms containing derivatives in h or in P and bearing in mind that the integral of a divergence is zero (because M is compact), we obtain the following expressions for A and B:

$$A(f,Y)=-fp\times p+2f\,\text{Ric}(g)-2\,\text{Hess}(f)-2(\Delta f)g+\tfrac{1}{2}f(\operatorname{tr} p)p$$
$$+L_Y p+(\operatorname{div} Y)p-\tfrac{1}{2}(p\cdot L_Y g)g-2g(\gamma(g,p),Y)$$
$$B(f,Y)=-L_Y g+fp-\tfrac{1}{2}f(\operatorname{tr} p)g, \tag{6}$$

where $(\text{Hess}\,f)_{ij}$ means the hessian $\nabla_i\nabla_j f$ and Δf the Laplacian $-\nabla^i\nabla_i f$. In the computations of (6) the following expression for the Lie derivative $L_Y\alpha$ of a 2-covariant tensor α has been used:

$$(L_Y\alpha)_{ij}=Y^k\nabla_k\alpha_{ij}+(\nabla_i Y^k)\alpha_{kj}+(\nabla_j Y^k)\alpha_{ik}\,.$$

Since the initial data (g,p) satisfy $\gamma(g,p)=\chi X$, the last term of A in (6) can be written in the form $-2\chi g(X,Y)$.

IV. THE MAIN RESULT

Consider a Robertson-Walker model $V=S^3\times I$, where S^3 is the 3-sphere endowed with a Riemannian metric g of constant curvature $K=1$ on S^3 and I an $\mathbb{R}$-interval. Let $\tilde{g}$ be a Lorentzian metric on V of the form $\tilde{g}=-dt^2+\zeta(t)^2 g$ and $\tilde{T}=(\rho+p)dt\otimes dt+p\tilde{g}$ the stress-energy tensor of a perfect fluid. Following the analysis of paper I, the hypersurface M of V is $M=S^3\times\{0\}$ and the Gauss representation of M is the identity $S^3\times I\to S^3\times I$ because $\partial/\partial t$ is a geodesic vector field of $\tilde{g}$. Since the hypersurface M has constant curvature 1 its curvature tensor satisfies

$$R^r_{kij}=\delta^r_i g_{kj}-\delta^r_j g_{ki}\,.$$

By contracting, $R_{kj}=R^r_{krj}=2g_{kj}$ and contracting again, $R=g^{ij}R_{ij}=6$. The restriction of $\tilde{g}$ to the hypersurface $M_t=S^3\times\{t\}$ is $g_t=\zeta(t)^2 g$. We have $k_t=\partial_t g_t=2(\dot{\zeta}/\zeta)g_t$. Then,

$$\begin{aligned} &\mathrm{Ric}(g_t)=\frac{2g_t}{\zeta(t)^2}; \quad R(g_t)=\frac{6}{\zeta(t)^2}; \quad k_t=\frac{\partial g_t}{\partial t}=\frac{2\dot{\zeta}(t)g_t}{\zeta(t)};\\ &k_t\times_{g_t}k_t=4\left(\frac{\dot{\zeta}(t)}{\zeta(t)}\right)^2 g_t; \quad k_t\cdot_{g_t}k_t=12\left(\frac{\dot{\zeta}(t)}{\zeta(t)}\right)^2; \quad \mathrm{tr}_{g_t}k_t=\frac{6\dot{\zeta}(t)}{\zeta(t)}. \end{aligned} \tag{7}$$

In our case $F_t=\tilde{T}^4_4|_{M_t}=-\rho_t$ and for any $x\in M_t$ we have $X^i_i(x)=\tilde{T}^i_4(x,t)=0$. The linearization stability of the Einstein equation at the initial Robertson–Walker metric $\tilde{g}$ leads us to the study of the stability of the mapping

$$\Phi:\ \mathcal{R}^s(S^3)\times S^s_2(S^3)\to\mathcal{F}^{s-2}(S^3)\times\mathcal{X}^{s-1}(S^3)$$

$$(g',p')\to(\mathcal{H}(g',p'),\gamma(g',p'))$$

at (g_0,p_0). Now, $p_0=k_0-(\mathrm{tr}_{g_0}k_0)g_0=-4(\dot{\zeta}(0)/\zeta(0))g_0$ and $\Phi(g_0,p_0)=(-\chi\rho_0,0)$ since $F=-\rho$ and $X=0$.

We state the following theorem.

Theorem 1: *There is no neighborhood U of (g_0,p_0) in $\mathcal{R}^s(S^3)\times S^s_2(S^3)$ such that the set of the pairs $(g',p')\in U$ satisfying $\Phi(g',p')=\chi(-\rho_0,0)$ is a differentiable submanifold of U.*

As a consequence of this theorem, we have:

Corollary. There exists no subspace $\mathcal{F}$ of $\mathcal{F}^{s-2}(S^3)\times\mathcal{X}^{s-1}(S^3)$ such that Φ is linearization stable at the initial point (g_0,p_0) in the direction of $\mathcal{F}$.

Proof of the corollary. The definition of linearization stability relative to any subspace $\mathcal{F}$ given in paper I requires $\Phi^{-1}(\Phi(g_0,p_0))$ to be a differential manifold in a neighborhood of (g_0,p_0), which is inconsistent with the theorem.

Proof of theorem 1. Suppose there exists a neighborhood U of (g_0,p_0) in $S^s_2(S^3)\times S^s_2(S^3)$ such that the set of $(g',p')\in U$ satisfying $\Phi(g',p')=-\chi(\rho_0,0)$ has the structure of a differential manifold of U. Let $\lambda\to(g'(\lambda),p'(\lambda))$ be a curve of this manifold passing through (g_0,p_0) for $\lambda=0$. Let $(h,P)\in S^s_2(S^3)\times S^s_2(S^3)$ be the tangent vector to this curve at (g_0,p_0). Denote by (h',P') the second derivative $d^2(g'(\lambda),p'(\lambda))/d\lambda^2$ at $\lambda=0$. Since $\Phi(g'(\lambda),p'(\lambda))=-\chi(\rho_0,0)$ for any λ, evaluating its first derivative at $\lambda=0$ one obtains $(D_{(g_0,p_0)}\Phi)(h,P)=0$. Differentiating again at $\lambda=0$ one gets

$$(D^2_{(g_0,p_0)}\Phi)(h,P)+(D_{(g_0,p_0)}\Phi)(h',P')=0. \tag{8}$$

Now, let (f,Y) be any element of $\mathcal{F}^\infty(S^3)\times\mathcal{X}^\infty(S^3)$. Computing the inner product of (f,Y) with both members of (8), one gets

$$\langle(D^2_{(g_0,p_0)}\Phi)(h,P),(f,Y)\rangle+\langle(D_{(g_0,p_0)}\Phi)(h',P'),(f,Y)\rangle=0.$$

Taking into account that

$$\langle(D_{(g_0,p_0)}\Phi)(h',P'),(f,Y)\rangle=\langle(h',P'),(D_{(g_0,p_0)}\Phi)^*(f,Y)\rangle$$

it follows that for any $(h,P)\in S^s_2(S^3)\times S^s_2(S^3)$ in $\ker(D_{(g_0,p_0)}\Phi)$ and for any $(f,Y)\in\mathcal{F}^\infty(S^3)\times\mathcal{X}^\infty(S^3)$ in $\mathrm{Ker}(D_{(g_0,p_0)}\Phi)^*$

$$\langle(D^2_{(g_0,p_0)}\Phi)(h,P),(f,Y)\rangle=0. \tag{9}$$

is fulfilled.

To prove Theorem 1 (making use of an idea of Ref. 6) we look for a pair (h,P) of the kernel of $D_{(g_0,p_0)}\Phi$ and a pair (f,Y) of the kernel of $(D_{(g_0,p_0)}\Phi)^*$ for which (9) is not satisfied. From previous calculus we know that $(D_{(g_0,p_0)}\Phi)^*(f,Y)=(A,B)$, where A and B are given by (6). In our case, using (7) and the fact that $X=0$ we have

$$A(f,Y)=8\left(\frac{\dot{\zeta}(0)^2+4}{\zeta(0)^2}\right)fg_0-4\frac{\dot{\zeta}(0)}{\zeta(0)}L_Yg_0-2\text{ Hess }\ f-2(\Delta f)g_0$$

$$B(f,Y)=2\frac{\dot{\zeta}(0)}{\zeta(0)}fg_0-L_Yg_0.$$

The metric $g_0=\zeta(0)^2g$ is the restriction of the euclidean metric of $\mathbb{R}^4$ to the sphere of radius $\zeta(0)$ and center at the origin. Let us denote by $S^3(\zeta(0))$ this sphere. We choose $f=0$ and Y a Killing field on $S^3(\zeta(0))$ relative to the metric g_0 (this means $L_Yg_0=0$) as an element of $\mathrm{Ker}(D_{(g_0,p_0)}\Phi)^*$. For any $(h,P)\in\mathrm{Ker}(D_{(g_0,p_0)}\Phi)$ and a pair of the form $(0,Y)\in\mathrm{Ker}(D_{(g_0,p_0)}\Phi)^*$ we have

$$\langle(D^2_{(g_0,p_0)}\Phi)(h,P),(0,Y)\rangle=4\int_M g((D^2_{(g_0,p_0)}\gamma)(h,P),Y)dv,$$

where dv stands for the volume element of $M=S^3(\zeta(0))$ by g_0. To evaluate $(D^2_{(g_0,p_0)}\Phi)\times(h,P)$ given by (4) when a Robertson–Walker model is considered, we make use of the formulas $p_{ij}=-4C(g_0)_{ij}$, where $C=\dot{\zeta}(0)/\zeta(0)$. Then

$$(D^2_{(g_0,p_0)}\gamma)(h,P)_i=\tfrac{1}{2}[-4C\nabla^r(h\times h)_{ri}-2Ch^{rm}\nabla_ih_{rm}+2Ch_{im}\nabla^m\operatorname{tr}h-\tfrac{1}{2}(\nabla_ih^{rm})P_{mr}+\tfrac{1}{2}(\nabla^m\operatorname{tr}h)P_{im}-\nabla_r(h^{rs}P_{is})].\tag{10}$$

Hence, $g((D^2_{(g_0,p_0)}\gamma)(h,P),Y)$ can be written in the following form:

$$g((D^2_{(g_0,p_0)}\gamma)(h,P),Y)=\tfrac{1}{2}\{4C(\nabla^rY^i)(h\times h)_{ri}-2Ch^{rm}(\nabla_Yh)_{rm}-2C(\nabla^mY^i)h_{im}\operatorname{tr}h-2CY^i(\nabla^mh_{im})\operatorname{tr}h-\tfrac{1}{2}(\nabla_Yh)^{rm}P_{mr}-\tfrac{1}{2}Y^i(\nabla^mP_{im})\operatorname{tr}h-\tfrac{1}{2}(\nabla^mY^i)P_{im}\operatorname{tr}h-Y^i\nabla_r(h^{rs}P_{is})\}+\mathrm{div}.\tag{11}$$

Now we require (h,P) to belong to the kernel of $D_{(g_0,p_0)}\Phi$; therefore both components of (3) must be zero. From the vanishing of the second expression of (3) [and since $p_{ij}=-4C(g_0)_{ij}$], one obtains $\nabla^mP_{im}=-4C\nabla^mh_{im}$. Substituting this into (11),

$$g((D^2_{(g_0,p_0)}\gamma)(h,P),Y)=\tfrac{1}{2}\{-2Ch\cdot\nabla_Yh-\tfrac{1}{2}(\nabla_Yh)\cdot P-Y^i\nabla_r(h^{rs}P_{is})\}+\mathrm{div}.$$

When integrating the previous identity on $M=S^3(\zeta(0))$, the term $\int_M(h\cdot\nabla_Yh)dv$ will be zero. Indeed

$$h\cdot\nabla_Yh=h_{rm}Y^i\nabla_ih^{rm}=-h_{rm}(\nabla_iY^i)h^{rm}-(\nabla_ih_{rm})Y^ih^{rm}+\mathrm{div}.$$

Since Y is a Killing field, it has zero divergence and therefore the first term of the second member vanishes. Integrating on M one gets $\int_M(h\cdot\nabla_Yh)dv=-\int_M(h\cdot\nabla_Yh)dv$ and so this integral is zero. Finally:

$$4\int_M g((D^2_{(g_0,p_0)}\gamma)(h,P),Y)dv=-\int_M(\nabla_Yh\cdot P)dv-2\int_M Y^i\nabla_r(h^{rs}P_{is})dv.\tag{12}$$

So our problem consists in finding h and P in $\operatorname{Ker} D_{(g_0,p_0)}\Phi$ and a Killing field Y on the sphere $S^3(\zeta(0))$ for which (12) is not zero.

Consider $S^3(\zeta(0))\subset\mathbb{R}^4$. Let (x,y,z,t) be the canonical coordinates of $\mathbb{R}^4$. Let e_1, e_2, e_3 be three vector fields of $\mathbb{R}^4$ with the following components in the canonical basis of $\mathbb{R}^4$: $e_1=(y,-x,t,-z)$, $e_2=(z,-t,-x,y)$, $e_3=(t,z,-y,-x)$. The Lie brackets of these fields are $[e_1,e_2]=2e_3$, $[e_2,e_3]=2e_1$, $[e_3,e_1]=2e_2$. Consider the radial vector field $N=(x,y,z,t)$. The fields $e_i (i=1,2,3)$ are orthogonal to N by the Euclidean metric of $\mathbb{R}^4$. Hence, their restriction to the sphere $S^3(\zeta(0))$ are tangent fields that at each point are mutually orthogonal and have norm $\zeta(0)$. The formula

$$2g_0(\nabla_U V,W)=U(g_0(V,W))+V(g_0(W,U))-W(g_0(U,V))$$
$$-g_0(U,[V,W])-g_0(V,[U,W])-g_0(W,[V,U])$$

that links the covariant derivative with the metric, gives $\nabla_{e_i}e_j=-\nabla_{e_j}e_i=e_k$ provided that i,j,k be a cyclic permutation of 1,2,3. Also $\nabla_{e_i}e_i=0$. If Γ_{ij}^k stands for the Christoffel symbols in the basis $\{e_1,e_2,e_3\}$ defined by $\nabla_{e_i}e_j=\Gamma_{ij}^k e_k$, one has $\Gamma_{ij}^k=\epsilon(i,j,k)$, where $\epsilon(i,j,k)$ indicates the sign of the permutation (i,j,k) when the three indices are different, and zero otherwise. A Killing vector field Y of $S^3(\zeta(0))$ satisfies $g_0(\nabla_{e_i}Y,e_j)=-g_0(\nabla_{e_j}Y,e_i)$. In particular, the fields e_1, e_2, e_3 are Killing fields.

Now, choose $Y=e_1$, $h=e_1\otimes e_2+e_2\otimes e_1$, $P=e_1\otimes e_3+e_3\otimes e_1$. We want to see that (Y,h,P) satisfy the desired conditions. We begin by showing that these h and P make the right hand side of (3) to vanish. In a Robertson-Walker model, the expressions (3) take the form:

$$(D_{(g_0,p_0)}\mathcal{H})(h,P)=\frac{1}{8}\left[4C\operatorname{tr}P+\left(16C^2+\frac{8}{\zeta(0)^2}\right)\operatorname{tr}h-4\nabla^i\nabla^j h_{ij}-4\nabla\operatorname{tr}h\right]$$
$$(D_{(g_0,p_0)}\gamma)(h,P)_i=\tfrac{1}{2}\nabla^s(4Ch+P)_{is}. \tag{13}$$

Here, both the trace of h and P vanish since, for instance, $\operatorname{tr}h=(g_0)^{ij}h_{ij}=(1/\zeta(0)^2)(\Sigma_i h_{ii})=0$. On the other hand, if both h and P have zero divergence then the expressions (13) would be consequently satisfied. Hence, let $A=A^{ij}e_i\otimes e_j$ be a symmetric tensor with constant components A^{ij}. Then $\nabla_i A^{ij}=e_i(A^{ij})+\Gamma_{ir}^i A^{rj}+\Gamma_{ir}^j A^{ir}$. The first term is zero because A^{ij} are constant. The second term is zero because $\Gamma_{ij}^k=\epsilon(i,j,k)$, and the third is also zero because Γ_{ij}^k is skew symmetric in the indices i,j but A^{ij} is symmetric in the same indices.

Finally, let us to see that (12) is not zero. We have $\nabla_Y h=\nabla_{e_1}(e_1\otimes e_2+e_2\otimes e_1)=e_1\otimes e_3+e_3\otimes e_1=P$. Hence, $(\nabla_Y h)\cdot P=P\cdot P=2/\zeta(0)^2$. On the other hand, since $Y=e_1$ and h has zero divergence, we get

$$Y^i\nabla_r(h^{rs}P_{is})=h^{rs}\nabla_r P_{1s}=h^{12}\nabla_1 P_{12}+h^{21}\nabla_2 P_{11}=(1/\zeta(0))^2(\nabla_1 P_{12}+\nabla_2 P_{11}).$$

A short computation shows that $\nabla_1 P_{12}=-1$ and $\nabla_2 P_{11}=2$. Therefore,

$$Y^i\nabla_r(h^{rs}P_{is})=1/\zeta(0)^2.$$

Substituting these results in (12) we get

$$4\int_M g((D^2_{(g_0,p_0)}\gamma)(h,P),Y)dv=-\int_M(\nabla_Y h\cdot P)dv-2\int_M Y^i\nabla_r(h^{rs}P_{is})dv$$
$$=(1/\zeta(0))^2(-4\operatorname{vol}(S^3(\zeta(0))))\neq 0.$$

This completes the proof of the theorem.

(Received 9 March 1999; accepted for publication 14 June 1999)

Chruściel and Galloway constructed a Cauchy horizon that is nondifferentiable on a dense set. We prove that in a certain class of Cauchy horizons densely nondifferentiable Cauchy horizons form a dense set. We show that our class of densely nondifferentiable Cauchy horizons implies the existence of densely nondifferentiable Cauchy horizons arising from partial Cauchy surfaces and also the existence of densely nondifferentiable black hole event horizons. © *1999 American Institute of Physics.* [S0022-2488(99)01909-X]

I. INTRODUCTION

Recently Chruściel and Galloway[1] have constructed an example of a Cauchy horizon which fails to be differentiable on a dense subset. In this paper we show that densely nondifferentiable Cauchy horizons appear to be generic in a certain class of Cauchy horizons. Chruściel and Galloway have also shown that their example implies the existence of a densely nondifferentiable black hole event horizon. They point out that these examples raise definite questions concerning some major arguments that have been given in the past where smoothness assumptions were implicitly made. In the light of these new examples, it is clear that there is a real need for a deeper understanding of the differentiability properties of horizons.

In a spacetime with a partial Cauchy surface S the Cauchy horizon $H(S)$ is the boundary of the set of points where, in theory, one may calculate everything in terms of the initial data on S. Cauchy horizons are *achronal* (i.e., no two points on the horizon may be joined by a timelike curve) and this implies that Cauchy horizons (locally) satisfy a Lipschitz condition. This, in turn, implies that Cauchy horizons are differentiable almost everywhere. Because they are differentiable except for a set of (three-dimensional) measure zero, it seems that they have often been assumed to be smooth except for a set which may be more or less neglected. However, one must remember in the above that (1) differentiable only refers to being differentiable at a single point and (2) sets of measure zero may be quite widely distributed.

For a closed achronal set S each point p of a Cauchy horizon $H^+(S)$ lies on at least one null generator.[2] However, null generators may or may not remain on the horizon when they are extended in the future direction. If a null generator leaves the horizon, then there is a last point where it remains on the horizon. This last point is said to be an *endpoint* of the horizon. Endpoints where two or more null generators leave the horizon are points where the horizon must fail to be differentiable.[3,1] In addition, Chruściel and Galloway[1] have shown that Cauchy horizons are differentiable at points which are not endpoints. Beem and Królak have shown[4] that Cauchy horizons are differentiable at endpoints where only one generator leaves the horizon. These results give a complete classification of (pointwise) differentiability for Cauchy horizons in terms of null generators and their endpoints. Beem and Królak have also shown[4] that if we consider an open subset W of the Cauchy horizon $H^+(S)$ and assume that the horizon has no endpoints on W, then the horizon must be differentiable at each point of W and, in fact, that the horizon must be at least of class C^1 on W. Conversely, the differentiability on an open set W implies there are no endpoints on W.

For general spacetimes, horizons may fail to be stable under small metric perturbations; however, some sufficiency conditions for various stability questions have been obtained.[5,6]

II. PRELIMINARIES

Definition 1: A space-time (M,g) is a smooth n-dimensional, Hausdorff manifold M with a semi-Riemannian metric g of signature (−,+,...,+), a countable basis, and a time orientation.

A set S is said to be *achronal* if there are no two points of S with timelike separation.

We give definitions and state our results in terms of the future horizon $H^+(S)$, but similar results hold for any past Cauchy horizon $H^-(S)$.

Definition 2: The future Cauchy development $D^+(S)$ *consists of all points* $p\in M$ *such that each past endless and past directed causal curve from p intersects the set S. The future Cauchy horizon is* $H^+(S)=\overline{(D^+(S))}-I^-(D^+(S))$.

Let p be a point of the Cauchy horizon; then there is at least one null generator of $H^+(S)$ containing p. Each null generator is at least part of a null geodesic of M. When a null generator of $H^+(S)$ is extended into the past it either has no past endpoint or has a past endpoint on edge (S) (see Ref. 2, p. 203). However, if a null generator is extended into the future it may have a last point on the horizon which is then said to be an *endpoint* of the horizon. We define the *multiplicity* (see Ref. 4) of a point p in $H^+(S)$ to be the number of null generators containing p. Points of the horizon which are not endpoints must have multiplicity one. The multiplicity of an endpoint may be any positive integer or infinite. We call the set of endpoints of multiplicity two or higher the *crease set*, compare Ref. 1. By a basic Proposition due to Penrose (Ref. 2, Proposition 6.3.1) $H^+(S)$ is an $n-1$ dimensional Lipschitz topological submanifold of M and is achronal. Since a Cauchy horizon is Lipschitz it follows from a theorem of Rademacher that it is differentiable almost everywhere (i.e., differentiable except for a set of $n-1$ dimensional measure zero). This does not exclude the possibility that the set of nondifferentiable points is a dense subset of the horizon. An example of such a behavior was given by Chruściel and Galloway.[1]

Following Ref. 4 let us introduce the notion of differentiability of a Cauchy horizon. Consider any fixed point p of the Cauchy horizon $H^+(S)$ and let x^0,x^1,x^2,x^3 be local coordinates defined on an open set about $p=(p^0,p^1,p^2,p^3)$. Let $H^+(S)$ be given near p by an equation of the form

$$x^0=f_H(x^1,x^2,x^3).$$

The horizon $H^+(S)$ is *differentiable* at the point p iff the function f_H is differentiable at the point (p^1,p^2,p^3). In particular, if $p=(0,0,0,0)$ corresponds to the origin in the given local coordinates and if

$$\Delta x=(x^1,x^2,x^3)$$

represents a small displacement from p in the $x^0=0$ plane, then $H^+(S)$ is differentiable at p iff one has

$$f_H(\Delta x)=f_H(0)+\sum a_i x^i+R_H(\Delta x)=0+\sum a_i x^i+R_H(\Delta x),$$

where the ratio $R_H(\Delta x)/|\Delta x|$ converges to zero as $|\Delta x|$ goes to zero. Here we use

$$|\Delta x|=\sqrt{(x^1)^2+(x^2)^2+(x^3)^2}.$$

If $H^+(S)$ is differentiable at the point p, then there is a well-defined three-dimensional linear subspace N_0 in the tangent space $T_p(M)$ such that N_0 is tangent to the three-dimensional surface $H^+(S)$ at p. In the above notation a basis for N_0 is given by $\{a_i\partial/\partial x^0+\partial/\partial x^i|i=1,2,3\}$.

Theorem 1: *(Chruściel and Galloway[1]). There exists a connected set* $K\subset R^2=\{t=0\}\subset R^{2,1}$, *where* $R^{2,1}$ *is a* $2+1$ *dimensional Minkowski space-time, with the following properties:*

(1) *The boundary* $\partial K = \overline{K} - \mathrm{int}\, K$ *of K is a connected, compact, Lipschitz topological submanifold of* R^2. *K is the complement of a compact set in* R^2.
(2) *There exists no open set* $\Omega \subset R^{2,1}$ *such that* $\Omega \cap H^+(K) \cap \{0 < t < 1\}$ *is a differentiable submanifold of* $R^{2,1}$.

Proposition 1 (Beem and Królak[4]): Let W be an open subset of the Cauchy horizon $H^+(S)$. *Then the following are equivalent:*

(1) $H^+(S)$ *is differentiable on W.*
(2) $H^+(S)$ *is of class* C^r *on W for some* $r \geq 1$.
(3) $H^+(S)$ *has no endpoints on W.*
(4) *All points of W have multiplicity one.*

Note that the four parts of Proposition 1 are logically equivalent for an open set *W*, but that, in general, they are not necessarily equivalent for sets which fail to be open. Using the equivalence of parts (1) and (3) of Proposition 1, it now follows that near each endpoint of multiplicity one there must be points where the horizon fails to be differentiable. Hence, each neighborhood of an endpoint of multiplicity one must contain endpoints of higher multiplicity. This yields the following corollary.

Corollary 1 (Ref. 4): If p is an endpoint of multiplicity one on a Cauchy horizon $H^+(S)$, *then each neighborhood* $W(p)$ *of p on* $H^+(S)$ *contains points where the horizon fails to be differentiable. Hence, the set of endpoints of multiplicity one is in the closure of the crease set.*

III. A GENERIC DENSELY NONDIFFERENTIABLE CAUCHY HORIZON

We shall construct a densely nondifferentiable Cauchy horizon in the three-dimensional Minkowski space-time $R,^{2,1}$ but our construction can be generalized in a natural way to higher dimensions. Let Σ be the surface $t=0$, and let K be a compact, convex subset of Σ. Let ∂K denote the boundary of K. Let $\rho(x,R)$ and $D(x,R)$ be, respectively, a circle and a disc with center at x and radius R.

Definition 3: A circle $\rho(x,R)$ *is internally tangent to the boundary* ∂K *of K if the disc enclosed by* ρ *is contained in K and for all* $\epsilon > 0$ *the disc of radius* $R+\epsilon$ *and center x is not contained in K.*

Let $\rho(x,R)$ be internally tangent to ∂K; then the point $(x,R) \in R^{2,1}$ belongs to the future Cauchy horizon $H^+(K)$ and conversely, if a point $(x,R) \in R^{2,1}$ belongs to $H^+(K)$ then the circle $\rho(x,R)$ is internally tangent to ∂K. If $\rho(x,R)$ is internally tangent in at least two points of ∂K then it follows from Proposition 1 that $H^+(K)$ is not differentiable at the point (x,R) and the point (x,R) has multiplicity at least two.

We shall first construct a continuous curve that is not differentiable on any open subset. Let us take a line segment l_0 and let us consider an isosceles triangle with base l_0 and let α_0 be the angle at the base and let l_1 denote the broken line consisting of two equal arms of the triangle. In the next step we construct two isosceles triangles with bases that are segments of the broken line l_1 and we choose the angles α_1 at the base equal $q \times \alpha_0$ where $q < 1/2$. We iterate the above construction. At the Nth step of the construction the number of nondifferentiable points of the curve increases by $2N-1$. After the Nth step of the iterative procedure the vertex angle of the isosceles triangle obtained in the ith step is given by

$$\angle_N(x_i) = \pi - 2\alpha_1 \left[q^{i-1} - \frac{q^i - q^N}{1-q} \right]. \tag{1}$$

In the limit $N \to \infty$ the ith vertex angle is given by $\pi - 2\alpha_1 q^i[(q^{-1}-2)/(1-q)]$ and is strictly less than π as $q < 1/2$.

Let us call the nowhere differentiable continuous curve constructed above a *rough curve*. Let us call a region of Σ that is bounded by a rough curve and two straight lines perpendicular to the rough curve at its two endpoints (this notion is unambiguous, as the slope of the rough curve at an endpoint is given by a well-defined limit) a *fan*. The above construction can be generalized to higher dimensions, for example in the four-dimensional Minkowski space-time we construct a *rough surface* in the following way. We consider a triangle and the first step is to construct a pyramid with the triangle as a base and all angles between the base and the sides of the pyramid equal to the same angle α_1; we then iterate the construction decreasing at each step the angle α between the base and the sides of the pyramid by a factor $q<1/2$ as in the three-dimensional case. As a result we obtain a nowhere differentiable surface and we define a three-dimensional fan as the region of Σ bounded by the rough surface and planes perpendicular to the rough surface passing through the sides of the initial triangle.

Theorem 2: *Let b be a rough curve and F the corresponding fan. Then the set of points of F that are centers of circles tangent to b in at least two points of b is dense in the interior of the fan F.*

Proof: Each point of F is the center of a circle tangent to b at at least one point. If the claim of the theorem were false, then there would exist a disc $D(x,R)$ with nonempty interior with the property that every point $a\in \operatorname{int} D$ is the center of a circle tangent to the rough curve at exactly one point.

(1) A vertex point cannot be a point of tangency of any circle with center in $\operatorname{int} F$.
(2) By construction the set of vertices of b is dense in b. Thus the complement of the set of vertices in b is totally disconnected (i.e., only one-element subsets are connected).

Let us consider a map P from the disc to b that assigns to every point y of D a point on b that is tangent to the circle centered at y. By assumption this point is unique and thus the map is well-defined.

Let us show that the map P is continuous. It is enough to prove that if $a_n \rightarrow a$ then $P(a_n) \rightarrow P(a)$. As b is compact, $P(a_n)$ has a subsequence that converges to a point c on b. Since the distance $d(a_n, P(a_n))$ is continuous on D we have $d(c,a)=d(a,P(a))$. Hence c is a tangency point of a circle centered at a and consequently $c=P(a)$.

By the Darboux theorem the image $P(D(x,R))$ is connected and by 1. and 2. above, it is a one-point set. It then follows that $R=0$ which is a contradiction. **QED**

The above theorem generalizes to the three-dimensional case. In the case of a three-dimensional fan F there exists a dense subset of F such that every ball with the center in this subset has at least two tangency points to the rough surface. All steps of the proof of Theorem 2 carry over to this case in the natural way.

Let $\mathcal{H}$ be the set of Cauchy horizons arising from compact convex sets $K\subset\Sigma$. The topology on $\mathcal{H}$ is induced by the Hausdorff distance on the set of compact and convex regions K.

Theorem 3: *Let $\mathcal{H}$ be the set of future Cauchy horizons $H^+(K)$ where K are compact and convex regions of Σ. The subset of densely nondifferentiable horizons is dense in $\mathcal{H}$.*

Proof: Any compact and convex region K can be approximated in the sense of Hausdorff distance by a (sequence of) convex polygons contained in K. Each of the vertex angles of such a polygon is strictly less than π. Over each side of the polygon we construct a rough curve in such a way that the fans corresponding to the rough curves cover the polygon. This is always possible, since we may choose the starting angle α_1 in the rough curve's construction to obey the condition

$$\phi+\frac{2\alpha_1}{1-q}<\pi, \tag{2}$$

where ϕ is the largest vertex angle of the original polygon. When α_1 decreases to 0 the rough-edged polygon converges to the original polygon in the sense of Hausdorff topology. **QED**

It is clear that the above theorem generalizes to higher dimensions.

IV. SOME EXAMPLES OF DENSELY NONDIFFERENTIABLE HORIZONS

In this section we show that the construction of the preceding section implies the existence of densely nondifferentiable Cauchy horizons of partial Cauchy surfaces and also the existence of black hole event horizons.

Definition 4: A partial Cauchy surface S is a connected, acausal, edgeless $n-1$ *dimensional submanifold of (M,g).*

Example 1: A rough wormhole.

Let $R^{3,1}$ be the four-dimensional Minkowski space-time and let K be a compact subset of the surface $\{t=0\}$ such that its Cauchy horizon is nowhere differentiable in the sense of the construction given in Sec. III. We consider a space-time obtained by removing the complement of the interior of the set K in the surface $t=0$ from the Minkowski space-time. Let us consider the partial Cauchy surface $S=\{t=-1\}$. The future Cauchy horizon of S is the future Cauchy horizon of set $K-\text{edge}(K)$, since $\text{edge}(K)$ has been removed from the space-time. Thus the future Cauchy horizon is nowhere differentiable and it is generated by past-endless null geodesics. The interior of the set K can be thought of as a ''wormhole'' that separates two ''worlds,'' one in the past of surface $\{t=0\}$ and one in its future.

Example 2: A transient black hole.

Let $R^{3,1}$ be the four-dimensional Minkowski space-time and let K be a compact subset of the surface $\{t=0\}$ such that its *past* Cauchy horizon is nowhere differentiable in the sense of the construction given in Sec. III. We consider a space-time obtained by removing from Minkowski space-time the closure of the set K in the surface $t=0$. Let us consider the event horizon $E \coloneqq \dot{J}^-(\mathcal{J}^+)$. The event horizon E coincides with $H^-(K)-\text{edge}(K)$ and thus it is not empty and nowhere differentiable. The event horizon disappears in the future of surface $\{t=0\}$ and thus we can think of the black hole (i.e., the set $B\coloneqq R^{3,1}-J^-(\mathcal{J}^+)$) in the space-time as ''transient.''

Well-posed forms of the 3+1 conformally-decomposed Einstein equations

Simonetta Frittelli[a)]

Oscar A. Reula[b)]
FaMAF, Universidad Nacional de Córdoba, Ciudad Universitaria, 5000 Córdoba, Argentina

(Received 23 April 1999; accepted for publication 25 May 1999)

We show that well-posed, conformally-decomposed formulations of the 3+1 Einstein equations can be obtained by densitizing the lapse and by combining the constraints with the evolution equations. We compute the characteristics structure and verify the constraint propagation of these new well-posed formulations. In these formulations, the trace of the extrinsic curvature and the determinant of the 3-metric are singled out from the rest of the dynamical variables, but are evolved as part of the well-posed evolution system. The only free functions are the lapse density and the shift vector. We find that there is a 3-parameter freedom in formulating these equations in a well-posed manner, and that part of the parameter space found consists of formulations with causal characteristics, namely, characteristics that lie only within the lightcone. In particular there is a 1-parameter family of systems whose characteristics are either normal to the slicing or lie along the lightcone of the evolving metric.
[S0022-2488(99)01910-6]

I. INTRODUCTION

Analytical work in recent years has produced a number of systems of evolution equations which are equivalent to the Einstein equations at the constraint manifold, and which have a well posed initial value formulation.[1–7]

What motivates interest in this type of result is a general understanding (see, for instance, Ref. 8) that explicit well-posedness would be relevant in implementing consistent and stable numerical algorithms to integrate blackhole space–times.

The well-posed schemes for which a numerical code has been implemented appear not to exibit significant improvements over other methods, there being several factors relevant to numerical implementation which play a significant role. What is puzzling, however, is that, on the other hand, there have been numerical simulations with apparently better behavior, but which are based on systems which do not seem to have the well-posed character. One preponderant feature of these numerically more robust schemes is that they are built on a decomposition of the intrinsic metric into a metric of unit determinant and the determinant itself, and of the extrinsic curvature into trace and trace-free part. With slight variations, this way of evolving the 3+1 Einstein equations has been considered by Refs. 9 and 10. Quite recently, this form has been shown to possess striking computational advantages over the standard form.[11] We refer to this general scheme as a conformally-decomposed formulation of the 3+1 Einstein equations.

It is difficult to explain the success of these systems as opposed to the well-posed evolution schemes, or even to the standard (ADM) evolution schemes. The relative sizes of the fields of well-posed systems are roughly the same for different spectral frequencies in a Fourier represen-

a)Electronic mail: simo@mayu.physics.duq.edu
b)Electronic mail: reula@fis.uncor.edu

tation, which helps explain the stability of the system via numerical analysis. However, in the conformally-decomposed systems this does not happen in general (for standard norms), as it does not happen for the standard ADM system, thus making it more difficult to justify their relative better behavior.

We can speculate on two features that can possibly bear relevance to well-behaved numerical evolution. One feature is that good behavior in evolution is related to constraint violations. If the system preserves more accurately the constraints, then the evolution remains closer to the constraint submanifold, which contains the physical solutions. Outside this submanifold the solutions are unphysical; thus, there is no compelling reason to rule out fast growths for seemingly tame initial data for unphysical solutions. Thus, we suggest that controlling the constraint violations may lead to well-behaved numerical evolution. In this respect, it has been shown,[12] that (at least in the linearized case) there are well-posed modifications of the Einstein equations outside the constraint submanifold which make that submanifold an attractor, thus improving the chances of building numerical codes with better behaved constraint propagation. Another possible cause of concern for generating numerical instabilities is the nature of the boundary conditions which are usually imposed. There are only two existing treatments of the initial-boundary value problem in general relativity (see Ref. 13 for a complete theory of boundary values for the conformal Einstein equations in frame variables, and Ref. 14 for a linearized study of the ADM equations in well-posed first-order form), and no numerical simulations applying these treatments have yet appeared in the literature. The initial-boundary value problem for systems used in numerical simulations of the Einstein equations were instabilities have been found has generally not been studied, thus the set of boundary conditions for which the constraint equations are satisfied is not known for these cases. In dealing with this problem, establishing well-posedness for the Cauchy problem is a necessary first step.

The other feature which could give rise to numerical instabilities is the relative sizes of the ''longitudinal'' and the ''radiative'' modes in general relativity. In all nontrivial asymptotically flat solutions (either vacuum or with matter satisfying the appropriate energy conditions) the positivity of the mass implies the existence of longitudinal modes, and there are many astrophysically relevant cases where there is an approximate local notion of longitudinal vs transverse modes, and where the former are several orders of magnitude bigger than the latter. If they are not properly separated in the numerical algorithms, the errors caused by finite differencing might be of the order of the ''radiative'' modes, and bad behavior can be expected. The separation of the conformal freedom in the more successful codes can perhaps be thought of as a way of dealing with this issue, or at least isolating it.

In this work, we focus on this latter aspect. A technique for taking advantage of the conformal factor to partially decouple the ''longitudinal'' and ''transversal'' modes was used to obtain results on the Newtonian limit of general relativity.[2] In that case the conformal field was fixed via an elliptic equation, decoupling in this way the more prominent Newtonian potential to first order from the radiative degrees of freedom. Further studies on this problem would be critical to obtain realistic simulations of most astrophysically relevant problems.

Here we construct 3-parameter families of first-order well-posed systems which share some of the properties of the more successful systems, such as the conformal decomposition of the fundamental fields, in the hope that their study would help understand what is causing them to behave better than others. In Sec. II we apply techniques similar to those we used in Refs. 5 and 7 in order to obtain versions of the $3+1$ equations that are conformally-decomposed but which are well posed. Additionally, we calculate the structure of characteristics and show that for a open region in parameter space the resulting equations are metric-causal, namely they have all propagation cones inside or coincident with the light cone. There is even a one parameter subfamily for which propagation is either along the light cone or normal to the slices.

Furthermore we show that the constraints are propagated by these well-posed evolution equations. As opposed to Ref. 15, where also analytical studies of systems with this decomposition have been done, in this work the trace of the extrinsic curvature and the determinant of the intrinsic metric are considered dynamical variables and are evolved jointly with the rest of the system.

II. SYSTEM II

The conformally-decomposed system that we take as starting point has appeared in Ref. 11, and is a variation of the system used by Shibata and Nakamura.[10] It is a system of 15 equations for 15 variables ($\phi, K, \tilde{\gamma}_{ij}, \tilde{A}_{ij}, \tilde{\Gamma}^i$), and is referred to as System II in Ref. 11, to distinguish it from the standard 3+1 Einstein equations.[16] These variables are related to the intrinsic metric γ_{ij} and extrinsic curvature K_{ij} as follows:

$$e^{4\phi}=\det(\gamma_{ij})^{1/3}, \tag{1a}$$

$$\tilde{\gamma}_{ij}=e^{-4\phi}\gamma_{ij}, \tag{1b}$$

$$K=\gamma^{ij}K_{ij}, \tag{1c}$$

$$\tilde{A}_{ij}=e^{-4\phi}(K_{ij}-\tfrac{1}{3}\gamma_{ij}K), \tag{1d}$$

$$\tilde{\Gamma}^i=-\tilde{\gamma}^{ij}{}_{,j}, \tag{1e}$$

where $\tilde{\gamma}^{ij}$ is the inverse of $\tilde{\gamma}_{ij}$. The Einstein equations in terms of these variables are equivalent to the following:

$$\frac{d}{dt}\phi=-\frac{1}{6}\alpha K, \tag{2a}$$

$$\frac{d}{dt}\tilde{\gamma}_{ij}=-2\alpha\tilde{A}_{ij}, \tag{2b}$$

$$\frac{d}{dt}K=-\gamma^{ij}D_iD_j\alpha+\alpha\left(\tilde{A}_{ij}\tilde{A}^{ij}+\frac{1}{3}K^2\right)+\frac{1}{2}\alpha(\rho+S), \tag{2c}$$

$$\frac{d}{dt}\tilde{A}_{ij}=e^{-4\phi}(-(D_iD_j\alpha)^{\mathrm{TF}}+\alpha(R_{ij}^{\mathrm{TF}}-S_{ij}^{\mathrm{TF}}))+\alpha(K\tilde{A}_{ij}-2\tilde{A}_{il}\tilde{A}^l_j), \tag{2d}$$

$$\frac{\partial}{\partial t}\tilde{\Gamma}^i=-2\tilde{A}^{ij}\alpha_j+2\alpha\left(\tilde{\Gamma}^i_{jk}\tilde{A}^{kj}-\frac{2}{3}\tilde{\gamma}_{ij}K_{,j}-\tilde{\gamma}^{ij}S_j+6\tilde{A}^{ij}\phi_{,j}\right)$$
$$-\frac{\partial}{\partial x^j}\left(\beta^l\tilde{\gamma}^{ij}{}_{,l}-2\tilde{\gamma}^{m(j}\beta^{i)}{}_{,m}+\frac{2}{3}\tilde{\gamma}^{ij}\beta^l{}_{,l}\right). \tag{2e}$$

Here α is the lapse function, β^i is the shift vector, and $\tilde{\Gamma}^i_{jk}$ are the connection coefficients of $\tilde{\gamma}_{ij}$. The superscript TF denotes trace-free part, e.g., $R_{ij}^{\mathrm{TF}}=R_{ij}-\gamma_{ij}R/3$. Indices are raised and lowered with $\tilde{\gamma}^{ij}$ and its inverse. We use the shorthand notation

$$\frac{d}{dt}\equiv\frac{\partial}{\partial t}-\mathcal{L}_\beta, \tag{2f}$$

where $\mathcal{L}_\beta$ is the Lie derivative along β^i. We have, as well,

$$R_{ij}^{\mathrm{TF}}=R_{ij}-\tfrac{1}{3}\gamma^{ij}\gamma^{kl}R_{kl}, \tag{2g}$$

$$R_{ij}=\tilde{R}_{ij}+R^{\phi}_{ij}, \tag{2h}$$

$$R^{\phi}_{ij}=-2\overline{D}_i\overline{D}_j\phi-2\overline{\gamma}_{ij}\overline{\gamma}^{kl}\overline{D}_k\overline{D}_l\phi+4\overline{D}_i\phi\overline{D}_j\phi-4\overline{\gamma}_{ij}\overline{\gamma}^{kl}\overline{D}_k\phi\overline{D}_l\phi, \tag{2i}$$

$$\tilde{R}_{ij}=-\tfrac{1}{2}\tilde{\gamma}^{kl}\tilde{\gamma}_{ij,kl}+\tilde{\gamma}_{k(i}\tilde{\Gamma}^{k}{}_{,j)}+\tilde{\Gamma}^{k}\tilde{\Gamma}_{(ij)k}+\tilde{\gamma}^{lm}(2\tilde{\Gamma}_{l(i}\tilde{\Gamma}_{j)km}+\tilde{\Gamma}^{k}{}_{il}\tilde{\Gamma}_{kmj}), \tag{2j}$$

$$\tilde{\Gamma}^{k}_{ij}=\tfrac{1}{2}\tilde{\gamma}^{kl}(\tilde{\gamma}_{il,j}+\tilde{\gamma}_{jl,i}-\tilde{\gamma}_{ij,l}). \tag{2k}$$

This system is first-order in time and second-order in space, thus it is of second order overall. We show how System II can be handled in order to be turned into a well-posed form. First, we reduce the system to a straightforward first order form, and subsequently we densitize the lapse and combine the constraints into the evolution equations.

A. System II reduced to first-order form

We define a set of 12 additional variables

$$V_{ijk}\equiv\tilde{\gamma}_{ij,k}-\tfrac{3}{5}\tilde{\gamma}_{k(i}\tilde{\gamma}_{j)n,s}\tilde{\gamma}^{ns}+\tfrac{1}{5}\tilde{\gamma}_{ij}\tilde{\gamma}_{kn,s}\tilde{\gamma}^{ns}, \tag{3a}$$

which is trace free in all its indices, namely, $V_{ijk}\tilde{\gamma}^{ij}=0$ and $V_{ijk}\tilde{\gamma}^{jk}=V_{ijk}\tilde{\gamma}^{ik}=0$, and another set of 3 additional variables,

$$Q_i\equiv\phi_{,i}\,. \tag{3b}$$

Evolution equations for these new variables are obtained by taking a time derivative of (3) and commuting time and spatial derivatives in the resulting right-hand sides. The complete system of equations is now

$$\frac{d}{dt}\phi=-\frac{1}{6}\alpha K, \tag{4a}$$

$$\frac{d}{dt}\tilde{\gamma}_{ij}=-2\alpha\tilde{A}_{ij}, \tag{4b}$$

$$\frac{d}{dt}K=-\tilde{\gamma}^{ij}D_iD_j\alpha+\alpha\left(\tilde{A}_{ij}\tilde{A}^{ij}+\frac{1}{3}K^2\right)+\frac{1}{2}\alpha(\rho+S), \tag{4c}$$

$$\frac{d}{dt}\tilde{A}_{ij}=e^{-4\phi}(-(D_iD_j\alpha)^{\mathrm{TF}}+\alpha(R^{\mathrm{TF}}_{ij}-S^{\mathrm{TF}}_{ij}))+\alpha(K\tilde{A}_{ij}-2\tilde{A}_{il}\tilde{A}^{l}{}_{j}), \tag{4d}$$

$$\begin{aligned}\dot{\tilde{\Gamma}}^{i}-\beta^{l}\tilde{\Gamma}^{i}{}_{,l}={}&-2\tilde{A}^{ij}\alpha_{,j}+2\alpha(\tilde{\Gamma}^{i}{}_{jk}\tilde{A}^{kj}-\tfrac{2}{3}\tilde{\gamma}^{ij}K_{,j}-\tilde{\gamma}^{ij}S_j+6\tilde{A}^{ij}Q_j)-\beta^{l}{}_{,j}\tilde{\gamma}^{ij}{}_{,l}+\tilde{\Gamma}^{m}\beta^{i}{}_{,m}\\&+\tilde{\gamma}^{mi}{}_{,j}\beta^{j}{}_{,m}+2\tilde{\gamma}^{m(i}\beta^{j)}{}_{,mj}+\tfrac{2}{3}\tilde{\Gamma}^{i}\beta^{l}{}_{,l}+\tfrac{2}{3}\tilde{\gamma}^{ij}\tilde{\Gamma}^{l}{}_{,lj},\end{aligned} \tag{4e}$$

$$\begin{aligned}\dot{V}_{ijk}-\beta^{l}V_{ijk,l}={}&-2\alpha\tilde{A}_{ij,k}+\tfrac{6}{5}\alpha\tilde{\gamma}_{k(i}\tilde{A}_{j)m,n}\tilde{\gamma}^{mn}-\tfrac{2}{5}\alpha\tilde{\gamma}_{ij}\tilde{A}_{km,n}\tilde{\gamma}^{mn}+\beta^{l}{}_{,k}V_{ijl}+\beta^{l}{}_{,i}V_{ljk}\\&+\beta^{l}{}_{,j}V_{ilk}-2\alpha_{,k}\tilde{A}_{ij}\end{aligned} \tag{4f}$$

$$+\tfrac{6}{5}\tilde{\gamma}_{k(i}\tilde{A}^{n}{}_{j)}\alpha_{,n}+\tfrac{6}{5}\alpha\tilde{A}_{k(i}\tilde{\Gamma}_{j)}-\tfrac{2}{5}\alpha\tilde{A}_{ij}\tilde{\Gamma}_{k} \tag{4g}$$

$$+\tilde{\gamma}_{l(i}\beta^{l}{}_{,j)k}-\tfrac{3}{5}\beta^{l}{}_{,l(j}\tilde{\gamma}_{i)k}+\tfrac{1}{5}\tilde{\gamma}_{ij}\beta^{l}{}_{,lk} \tag{4h}$$

$$-\beta^{l}{}_{,ns}\tilde{\gamma}^{ns}(\tfrac{3}{5}\tilde{\gamma}_{k(i}\tilde{\gamma}_{j)l}-\tfrac{1}{5}\tilde{\gamma}_{ij}\tilde{\gamma}_{kl}) \tag{4i}$$

$$+(2\alpha\tilde{A}^{ns}+\tilde{\gamma}^{ns}\beta^{s}{}_{,m})(\tfrac{3}{5}\tilde{\gamma}_{k(i}\tilde{\gamma}_{j)n,s}-\tfrac{1}{5}\tilde{\gamma}_{ij}\tilde{\gamma}_{ks,n}), \tag{4j}$$

$$\dot{Q}_i-\beta^l Q_{i,l}=-\tfrac{1}{6}\alpha K_{,i}+\beta^l{}_{,i}Q_l-\tfrac{1}{6}\alpha_{,i}K, \tag{4k}$$

where, as before, $R_{ij}^{\mathrm{TF}}=R_{ij}-\frac{1}{3}\gamma^{ij}\gamma^{kl}R_{kl}$, with $R_{ij}=\tilde{R}_{ij}+R_{ij}^{\phi}$, and

$$R_{ij}^{\phi}=-2\tilde{D}_iQ_j-2\tilde{\gamma}_{ij}\tilde{\gamma}^{kl}\tilde{D}_kQ_l+4Q_iQ_j-4\tilde{\gamma}_{ij}\tilde{\gamma}^{kl}Q_kQ_l, \tag{5a}$$

$$\begin{aligned}\tilde{R}_{ij}=&-\tfrac{1}{2}V_{ijk,}{}^{k}+\tfrac{7}{10}\tilde{\gamma}_{k(i}\tilde{\Gamma}^{k}{}_{,j)}+\tfrac{1}{10}\tilde{\gamma}_{ij}\tilde{\Gamma}^{k}{}_{,k}-\tfrac{3}{10}(\tilde{\Gamma}^{k}V_{k(ij)}+\tilde{\Gamma}_{(i}V_{j)k}{}^{k}+\tfrac{9}{10}\tilde{\Gamma}_{i}\tilde{\Gamma}_{j})\\&-\tfrac{1}{5}(V_{ijk}\tilde{\Gamma}^{k}+\tilde{\gamma}_{ij}\tilde{\Gamma}^{k}V_{km}{}^{m}-\tfrac{1}{10}\tilde{\gamma}_{ij}\tilde{\Gamma}^{k}\tilde{\Gamma}_{k)}+\tilde{\Gamma}^{k}\tilde{\Gamma}_{(ij)k}+2\tilde{\Gamma}^{kl}{}_{(i}\tilde{\Gamma}_{j)kl}+\tilde{\Gamma}^{k}{}_{il}\tilde{\Gamma}_{kj}{}^{l},\end{aligned} \tag{5b}$$

$$\tilde{\Gamma}^{k}{}_{ij}=V^{k}{}_{(ij)}-\tfrac{1}{2}V_{ij}{}^{k}-\tfrac{1}{5}\delta^{k}_{(i}\tilde{\Gamma}_{j)}+\tfrac{2}{5}\tilde{\gamma}_{ij}\tilde{\Gamma}^{k}, \tag{5c}$$

and indices are raised and lowered with $\tilde{\gamma}^{ij}$ and $\tilde{\gamma}_{ij}$, respectively. The derivatives of the form $\tilde{\gamma}_{ij,k}$ that appear in the right-hand sides of (4) must be interpreted simply as shorthands for combinations of the fields $\tilde{\Gamma}^i$ and V_{ijk}, via

$$\tilde{\gamma}_{ij,k}=V_{ijk}+\tfrac{3}{5}\tilde{\gamma}_{k(i}\tilde{\Gamma}_{j)}-\tfrac{1}{5}\tilde{\gamma}_{ij}\tilde{\Gamma}_{k}. \tag{6}$$

For this first-order system to be equivalent to the Einstein equations (in the sense that its set of solutions in the same as that of the Einstein equations), the following sets of constraints must be imposed on the initial data (and are subsequently preserved by the evolution, as will be shown in the next section):

$$\mathcal{H}=\gamma^{ij}R_{ij}-\tilde{A}_{ij}\tilde{A}^{ij}+\tfrac{2}{3}K^2-2\rho, \tag{7a}$$

$$\mathcal{P}_i=\tilde{\gamma}^{jl}D_l\tilde{A}_{ij}-\tfrac{2}{3}D_iK+4Q_l\tilde{A}^{l}{}_{i}-S_i, \tag{7b}$$

$$\mathcal{G}^i=\tilde{\Gamma}^i+\tilde{\gamma}^{ij}{}_{,j}, \tag{7c}$$

$$\mathcal{Q}_i=Q_i-\phi_{,i}, \tag{7d}$$

$$\mathcal{V}_{ijk}=V_{ijk}-\tilde{\gamma}_{ij,k}+\tfrac{3}{5}\tilde{\gamma}_{k(i}\tilde{\gamma}_{j)n,s}\tilde{\gamma}^{ns}-\tfrac{1}{5}\tilde{\gamma}_{ij}\tilde{\gamma}_{kn,s}\tilde{\gamma}^{ns}, \tag{7e}$$

where

$$\gamma^{ij}R_{ij}=e^{-4\phi}(\tilde{\Gamma}^{l}{}_{,l}-8\tilde{D}^{l}Q_l-Q^lQ_l-\tfrac{1}{2}V_{ijl}V^{ijl}-\tfrac{15}{10}\tilde{\Gamma}^{k}V_{km}{}^{m}-\tfrac{1}{5}V^{m}{}_{mk}\tilde{\Gamma}^{k} \tag{7f}$$

$$-\frac{21}{100}\tilde{\Gamma}^{k}\tilde{\Gamma}_{k}+\tilde{\Gamma}^{k}\tilde{\Gamma}^{m}{}_{mk}+2\tilde{\Gamma}^{klm}\tilde{\Gamma}_{mkl}+\tilde{\Gamma}^{mkl}\tilde{\Gamma}_{mkl}). \tag{7g}$$

Constraints (7a) and (7b) are the Hamiltonian and momentum constants of the 3+1 decomposition of the Einstein equations, written in our choice of variables. Constraints (7c), (7d), and (7e) arise in turning the original second-order system into first order.

In (4) and (7), the derivative D_l is the covariant derivative with respect to γ_{ij}, and is related to $\tilde{D}_l$ by undifferentiated terms,

$$\Gamma^{k}{}_{ij}=\tilde{\Gamma}^{k}{}_{ij}+2(Q_i\delta^{k}_{j}+Q_j\delta^{k}_{i}-Q_l\tilde{\gamma}^{kl}\tilde{\gamma}_{ij}). \tag{8}$$

B. Taking advantage of the available freedom

In this section we take advantage of two facts that have been used successfully in similar problems.[5,7,17] First, we densitize the lapse α (and in doing so we introduce a free function, referred to as ''slicing density'' in Ref. 18),

$$\alpha = e^{4a\phi}\sigma. \tag{9}$$

Like the shift vector β^i, the lapse density σ will be considered arbitrary but fixed, a source function independent of the dynamical fields. Here a is a numerical parameter, not a function of the point.

Second, the evolution equations can be combined with the constraints without altering the set of solutions. We add the scalar constraint with a factor $b\alpha$ to the evolution equation for K and we add the vector constraint to the evolution equations for $\tilde{\Gamma}^i$ and Q_i, with factors of $c\alpha$ and $d\alpha$, respectively. Here b,c,d are numerical parameters, not functions of the point. In this manner we obtain a system of the form

$$\dot{u} = \mathbf{A}^i(u)\nabla_i u + B(u). \tag{10}$$

A system of this form is known to be well posed if the matrix-valued vector $\mathbf{A}^i(u)$ admits a symmetrizer, namely, a positive definite, symmetric, bilinear form $\mathbf{H}$, in the space of the fields u, whose product with $\mathbf{A}^i(u)$ yields a symmetric-bilinear-form-valued vector. Thus, in order to determine well-posedness, it suffices to consider the principal part of the system.

In this case, the principal terms are

$$\dot{\phi} = \beta^l \phi_{,l}, \tag{11a}$$

$$\dot{\tilde{\gamma}}_{ij} = \beta^l \tilde{\gamma}_{ij,l}, \tag{11b}$$

$$\dot{K} = \beta^l K_{,l} - \alpha(4a+8b)e^{-4\phi}\tilde{\gamma}^{kl}Q_{k,l} + \alpha b e^{-4\phi}\tilde{\Gamma}^l{}_{,l}, \tag{11c}$$

$$\dot{\tilde{A}}_{ij} = \beta^l \tilde{A}_{ij,l} + e^{-4\phi}\alpha\left(-\tfrac{1}{2}\tilde{\gamma}^{kl}V_{ijk,l} + \tfrac{7}{10}\left(\tilde{\gamma}_{k(i}\tilde{\Gamma}^k{}_{,j)} - \tfrac{1}{3}\tilde{\gamma}_{ij}\tilde{\Gamma}^k{}_{,k}\right)\right) - 2(2a+1)e^{-4\phi}\alpha\left(Q_{(i,j)} - \tfrac{1}{3}\tilde{\gamma}_{ij}\tilde{\gamma}^{kl}Q_{k,l}\right), \tag{11d}$$

$$\dot{\tilde{\Gamma}}^i = \beta^l \tilde{\Gamma}^i{}_{,l} + \alpha c \tilde{A}^{il}{}_{,l} - \tfrac{2}{3}(c+2)\alpha\tilde{\gamma}^{il}K_{,l}, \tag{11e}$$

$$\dot{V}_{ijk} = \beta^l V_{ijk,l} - 2\alpha\tilde{A}_{ij,k} + \tfrac{6}{5}\alpha\tilde{\gamma}_{k(i}\tilde{A}_{j)m,n}\tilde{\gamma}^{mn} - \tfrac{2}{5}\alpha\tilde{\gamma}_{ij}\tilde{A}_{km,n}\tilde{\gamma}^{mn}, \tag{11f}$$

$$\dot{Q}_i = \beta^l Q_{i,l} - \frac{\alpha}{6}(1+4d)K_{,i} + d\alpha\tilde{\gamma}^{jl}\tilde{A}_{ij,l}. \tag{11g}$$

Our aim is to show that there exist choices of the numerical factors a,b,c,d such that the system (11) is symmetrizable, therefore, well posed. We established this result by defining a candidate symmetrizer $\mathbf{H}$ given as

$$\tilde{u}\mathbf{H}u = \phi^2 + \delta^{ik}\delta^{jl}\tilde{\gamma}_{ij}\tilde{\gamma}_{kl} + n_1^2 e^{-4\phi}K^2 + \tilde{A}^{ij}\tilde{A}_{ij} + n_2^2 e^{-4\phi}\tilde{\Gamma}^i\tilde{\Gamma}_i + \frac{e^{-4\phi}}{4}V_{ijk}V^{ijk} + n_3^2 e^{-4\phi}Q^iQ_i, \tag{12}$$

where n_1, n_2, n_3 are any fixed real numbers different from zero and bounded, so that $C^{-1}\mathbf{I} \leqslant \mathbf{H} \leqslant C\mathbf{I}$, where C is a positive constant and $\mathbf{I}$ is the identity operator on the space of u.

We can easily arrange the values of a,b,c,d so that symmetry of $\mathbf{HA^i}(u)$ is attained. To this effect, they must satisfy

$$\tfrac{7}{10}=n_2^2 c, \tag{13a}$$

$$-2(2a+1)=n_3^2 d, \tag{13b}$$

$$-(4a+8b)n_1^2=-\tfrac{1}{6}(1+4d)n_3^2, \tag{13c}$$

$$n_1^2 b=-\tfrac{2}{3}n_2^2(c+2). \tag{13d}$$

There is clearly plenty of freedom in the choice of *a,b,c,d,* since any choice that results in nonvanishing n_1, n_2, n_3 is allowed. The freedom is thus parametrized by the values of n_1^2, n_2^2, n_3^2, since these can take independent positive values. Thus our four parameters *a,b,c,d* are not all independent, but there is a relationship between them that reduces the freedom to 3 independent parameters. We can solve (13) for *a,b,c,d* in terms of n_1, n_2, n_3, which yields

$$a=\frac{9/5+8n_2^2+n_3^2/8}{(3n_1^2+2)}, \tag{14a}$$

$$b=-\frac{2}{3n_1^2}\left(\frac{7}{10}+2n_2^2\right), \tag{14b}$$

$$c=\frac{7}{10n_2^2}, \tag{14c}$$

$$d=-\frac{2}{n_3^2}\left(2\,\frac{9/5+8n_2^2+n_3^2/8}{(3n_1^2+2)}+1\right). \tag{14d}$$

It is clear from (14) that a and c will take only strictly positive values, and b and d will take only strictly negative values, for all real values of n_1, n_2, n_3 different from zero.

C. Structure of characteristics

The system (11) is of the form

$$\mathbf{A}^a\frac{\partial u}{\partial x^a}=0. \tag{15}$$

The characteristic covectors are covectors $\xi_a=(\xi_{i,}-v)$ such that $\xi_i\xi_j\gamma^{ij}=1$ and such that

$$\det(\mathbf{A}^a\xi_a)=0. \tag{16}$$

The values of v that satisfy (16) for every direction ξ_i are the characteristic speeds in that direction. In order to find these values we set up an eigenvalue problem for the principal symbol $\mathbf{A}^a\xi_a$ and find the null eigenvectors. The eigenvalue problem is

$$n^a\xi_a\phi=0, \tag{17a}$$

$$n^a\xi_a\tilde{\gamma}_{ij}=0, \tag{17b}$$

$$n^a\xi_a K=-(4a+8b)e^{-4\phi}\xi^k Q_k+be^{-4\phi}\xi_l\tilde{\Gamma}^l, \tag{17c}$$

$$n^a\xi_a\tilde{A}_{ij}=e^{-4\phi}(-\tfrac{1}{2}\xi^k V_{ijk}+\tfrac{7}{10}(\tilde{\gamma}_{k(i}\xi_{j)}\tilde{\Gamma}^k-\tfrac{1}{3}\tilde{\gamma}_{ij}\xi_k\tilde{\Gamma}^k))-2(2a+1)e^{-4\phi}(\xi_{(j}Q_{i)}-\tfrac{1}{3}\tilde{\gamma}_{ij}\xi^k Q_k), \tag{17d}$$

$$n^a\xi_a\tilde{\Gamma}^i = c\,\xi_l\tilde{A}^{il} - \tfrac{2}{3}(c+2)\xi^i K, \tag{17e}$$

$$n^a\xi_a V_{ijk} = -2\xi_k\tilde{A}_{ij} + \tfrac{6}{5}\tilde{\gamma}_{k(i}\tilde{A}_{j)m}\xi^m - \tfrac{2}{5}\tilde{\gamma}_{ij}\xi^m\tilde{A}_{km}, \tag{17f}$$

$$n^a\xi_a Q_i = -\tfrac{1}{6}(1+4d)\xi_i K + d\,\xi^j\tilde{A}_{ij}, \tag{17g}$$

where $n^a=(1,-\beta^i)\alpha^{-1}$ is the normal to the slice. Clearly, $n^a\xi_a=0$ allows for 18 eigenvectors. This is because (17e), (17f), and (17g) in this case constitute an overdetermined system of 18 homogeneous equations for 6 unknowns $(\tilde{A}_{ij},K)$, with zero as the only solution, whereas (17c) and (17d) constitute a system of 6 equations for 18 variables, which leaves out 12 of the 18 fields $(V_{ijk},\tilde{\Gamma}^i,Q)$ free. Lastly, (17a) and (17b) leave the 6 variables $(\tilde{\gamma}_{ij},\phi)$ free. If we represent the eigenvectors in the form,

$$(\tilde{\gamma}_{ij},\phi,Q_i,\tilde{\Gamma}^{(L)},\tilde{\Gamma}_i^{(T)},V_{ij}^{(L)},V_{ijk}^{(T)},K,\tilde{A}^{(LL)},\tilde{A}_i^{(LT)},\tilde{A}_{ij}^{(TT)}), \tag{18}$$

where $\tilde{\Gamma}^{(L)}:=\tilde{\Gamma}^i\xi_i$, $\tilde{\Gamma}_i^{(T)}:=\tilde{\Gamma}_i - e^{-4\phi}\xi_i\tilde{\Gamma}^k\xi_k$, $V_{ij}^{(L)}:=V_{ijk}\xi^k$, $V_{ijk}^{(T)}:=V_{ijk}-e^{-4\phi}\xi_k V_{ijl}\xi^l$, $\tilde{A}^{(LL)}:=\tilde{A}^{ij}\xi_i\xi_j$, $\tilde{A}_i^{(LT)}:=\tilde{A}_{ij}\xi^j - e^{-4\phi}\xi_i\tilde{A}^{kl}\xi_k\xi_l$, $\tilde{A}_{ij}^{(TT)}:=\tilde{A}_{ij}-2e^{-4\phi}\xi_{(i}\tilde{A}_{j)l}\xi^l + e^{-8\phi}\xi_i\xi_j\tilde{A}^{kl}\xi_k\xi_l$, then we have 5 eigenvectors corresponding to the five components of the conformal metric,

$$(\tilde{\gamma}_{ij},0,0,0,0,0,0,0,0,0,0); \tag{19a}$$

we have the determinant as an eigenfield,

$$(0,\phi,0,0,0,0,0,0,0,0,0); \tag{19b}$$

we have 7 eigenvectors corresponding to the seven transverse components of V_{ijk},

$$(0,0,0,0,0,0,V_{ijk}^{(T)},0,0,0); \tag{19c}$$

we have 3 eigenvectors corresponding essentially to the three components of Q_i,

$$\left(0,0,Q_i,\frac{4a+8b}{b}\xi^i Q_{i,}0_{,}-2(2a+1)\xi_{(i}Q_{j)}-\frac{1}{3}\tilde{\gamma}_{ij}\left(\frac{7(4a+8b)}{10b}-2(2a+1)\right)Q_l\xi^l,0,0,0,0\right); \tag{19d}$$

and we have 2 eigenvectors corresponding essentially to the two components of the transverse part of $\tilde{\Gamma}_i$,

$$(0,0,0,0,\tilde{\Gamma}_i^{(T)},\tfrac{7}{10}\xi_{(i}\tilde{\Gamma}_{j)}^{(T)},0,0,0,0). \tag{19e}$$

If $n^a\xi_a\neq 0$, then $\tilde{\gamma}_{ij}=\phi=0$, and we can solve (17e), (17f), and (17g) for $(V_{ijk},\tilde{\Gamma}^i,Q)$ in terms of ξ_a and $(\tilde{A}_{ij},K)$. We can substitute $(V_{ijk},\tilde{\Gamma}^i,Q)$ into (17c) and (17d), obtaining thus a system of 6 equations for the 6 variables $(\tilde{A}_{ij},K)$ as follows:

$$0=Ke^{4\phi}((n^a\xi_a)^2-\tfrac{1}{6}(4a+8b)(1+4d)+\tfrac{2}{3}b(c+2))+\xi\cdot\tilde{A}\cdot\xi((4a+8b)d-bc), \tag{20a}$$

$$0=\tilde{A}_{ij}e^{4\phi}(1-(n^a\xi_a)^2)-\frac{K}{3}\left(\frac{7}{5}(c+2)-(2a+1)(1+4d)\right)\left(\xi_i\xi_j-\frac{1}{3}e^{4\phi}\tilde{\gamma}_{ij}\right)$$
$$+\left(\frac{7c}{10}-\frac{3}{5}-2d(2a+1)\right)\left(\xi^l\tilde{A}_{l(i}\xi_{j)}-\frac{1}{3}\tilde{\gamma}_{ij}\xi\cdot\tilde{A}\cdot\xi\right), \tag{20b}$$

where we have used the notation

$$\xi\cdot\tilde{A}\cdot\xi := \xi_i\tilde{A}^{ij}\xi_j. \tag{21}$$

If $1-(n^a\xi_a)^2=0$, then $K=\xi\cdot\tilde{A}\cdot\xi=0$ by (20a), which implies $\xi^l\tilde{A}_{li}=0$ by (20b). However, two of the five components of $\tilde{A}_{ij}$ are thus free, which means that there are 4 eigenvectors, essentially labeled by the transverse components of $\tilde{A}_{ij}$. We have 2 eigenvectors for $n^a\xi_a=1$,

$$(0,0,0,0,0,-2\tilde{A}_{ij}^{(TT)},0,0,0,0,\tilde{A}_{ij}^{(TT)}); \tag{22a}$$

and 2 eigenvectors for $n^a\xi_a=-1$,

$$(0,0,0,0,0,2\tilde{A}_{ij}^{(TT)},0,0,0,0,\tilde{A}_{ij}^{(TT)}). \tag{22b}$$

If $1-(n^a\xi_a)^2\neq 0$, then contracting (20b) with ξ^i yields

$$0=e^{4\phi}\xi^l\tilde{A}_{lj}\left(1+\frac{1}{2}\left(\frac{7c}{10}-\frac{3}{5}-2d(2a+1)\right)-(n^a\xi_a)^2\right)-\frac{2}{9}e^{4\phi}K\xi_j\left(\frac{7}{5}(c+2)-(2a+1)(1+4d)\right)$$
$$+\frac{1}{6}\xi\cdot\tilde{A}\cdot\xi\xi_j\left(\frac{7}{10}c-\frac{3}{5}-2d(2a+1)\right). \tag{23}$$

Thus, if $1+\frac{1}{2}(7c/10-3/5-2d(2a+1))-(n^a\xi_a)^2=0$, then $K=\xi\cdot\tilde{A}\cdot\xi=0$ by (20a), which implies that (23) is identically satisfied, thus three out of the five equations (20b) are identities, the remaining two determining two components of $\tilde{A}_{ij}$. Thus two of the five components of $\tilde{A}_{ij}$ are free, which means that there are 4 eigenvectors, essentially labeled by the two longitudinal-transverse components of $\tilde{A}_{ij}$. We have 2 eigenvectors for $n^a\xi_a=\sqrt{(3/5-7c/10-2d(2a+1))/2}$, namely,

$$\left(0,0,\frac{d}{C_1}\tilde{A}_i^{(LT)},0,\frac{c}{C_1}\tilde{A}_i^{(LT)},-\frac{4}{5C_1}\xi_{(i}\tilde{A}_{j)}^{(LT)},\frac{6}{5C_1}(\tilde{\gamma}_{k(i}\tilde{A}_{j)}^{(LT)}-\xi_k\xi_{(i}\tilde{A}_{j)}^{(LT)}\right.$$
$$\left.-\frac{1}{3}\tilde{\gamma}_{ij}\tilde{A}_k^{(LT)}),0,0,\tilde{A}_i^{(LT)},0\right), \tag{24a}$$

and 2 eigenvectors for $n^a\xi_a=-\sqrt{(3/5-7c/10-2d(2a+1))/2}$, namely,

$$\left(0,0,-\frac{d}{C_1}\tilde{A}_i^{(LT)},0,-\frac{c}{C_1}\tilde{A}_i^{(LT)},\frac{4}{5C_1}\xi_{(i}\tilde{A}_{j)}^{(LT)},-\frac{6}{5C_1}(\tilde{\gamma}_{k(i}\tilde{A}_{j)}^{(LT)}-\xi_k\xi_{(i}\tilde{A}_{j)}^{(LT)}\right.$$
$$\left.-\frac{1}{3}\tilde{\gamma}_{ij}\tilde{A}_k^{(LT)}),0,0,\tilde{A}_i^{(LT)},0\right), \tag{24b}$$

where we have used the shorthand notation

$$C_1 := \sqrt{(3/5-7c/10-2d(2a+1))/2}. \tag{25}$$

But if $1+\frac{1}{2}(7c/10-3/5-2d(2a+1))-(n^a\xi_a)^2\neq 0$, then $\xi^l\tilde{A}_{lj}$ is determined by the values of K and $\xi\cdot\tilde{A}\cdot\xi$ by (23), and if plugged back into (20b) it follows that all the components of $\tilde{A}_{ij}$ are determined by K and $\xi\cdot\tilde{A}\cdot\xi$. Therefore it is necessary that K and $\xi\cdot\tilde{A}\cdot\xi$ be nonvanishing. Contracting (23) with ξ^j we obtain

$$0=-\tfrac{2}{9}e^{4\phi}K(\tfrac{7}{5}(c+2)-(2a+1)(1+4d))+\xi\cdot\tilde{A}\cdot\xi(1+\tfrac{2}{3}(\tfrac{7}{10}c-\tfrac{3}{5}-2(2a+1)d)-(n^a\xi_a)^2). \tag{26}$$

Equations (20a) and (26) form a system of two homogeneous equations for K and $\xi\cdot\tilde{A}\cdot\xi$. Thus, for K and $\xi\cdot\tilde{A}\cdot\xi$ to be nonvanishing, it is necessary that the determinant of the system be zero. The determinant is

$$\tfrac{1}{45}(-3(n^a\xi_a)^2+2a)(15(n^a\xi_a)^2-9+10bc-80bd+20d-7c). \tag{27}$$

It can be seen that, because a and c are strictly positive and b and d are strictly negative, the four roots of the determinant are real. For the roots $n^a\xi_a$ of the determinant, we have

$$K=\frac{9}{2}\,\frac{1-(n^a\xi_a)^2+\dfrac{2}{3}\left(\dfrac{7c}{10}-\dfrac{3}{5}-2d(2a+1)\right)}{\dfrac{7}{5}(c+2)-(2a+1)(1+4d)}\,e^{-4\phi}\xi\cdot\tilde{A}\cdot\xi, \tag{28a}$$

$$Q_i=\left(d-\frac{3(1+4d)}{4}\,\frac{1-(n^a\xi_a)^2+\dfrac{2}{3}\left(\dfrac{7c}{10}-\dfrac{3}{5}-2d(2a+1)\right)}{\dfrac{7}{5}(c+2)-(2a+1)(1+4d)}\right)\frac{e^{-4\phi}}{n^a\xi_a}\,\xi_i\xi\cdot\tilde{A}\cdot\xi, \tag{28b}$$

$$\tilde{\Gamma}^{(L)}=\left(c-3(c+2)\,\frac{1-(n^a\xi_a)^2+\dfrac{2}{3}\left(\dfrac{7c}{10}-\dfrac{3}{5}-2d(2a+1)\right)}{\dfrac{7}{5}(c+2)-(2a+1)(1+4d)}\right)\frac{\xi\cdot\tilde{A}\cdot\xi}{n^a\xi_a}, \tag{28c}$$

$$\tilde{\Gamma}_i^{(T)}=0, \tag{28d}$$

$$V_{ij}^{(L)}=-\frac{9}{5n^a\xi_a}\left(e^{-4\phi}\xi_i\xi_j-\frac{1}{3}\tilde{\gamma}_{ij}\right)\xi\cdot\tilde{A}\cdot\xi, \tag{28e}$$

$$V_{ijk}^{(T)}=-\frac{6}{5n^a\xi_a}(\xi_i\xi_j-\tilde{\gamma}_{k(i}\xi_{j)})e^{-4\phi}\xi\cdot\tilde{A}\cdot\xi, \tag{28f}$$

$$\tilde{A}_i^{(LT)}=0, \tag{28g}$$

$$\tilde{A}_{ij}^{(TT)}=\frac{e^{-4\phi}}{2}(e^{-4\phi}\xi_i\xi_j-\tilde{\gamma}_{ij})\xi\cdot\tilde{A}\cdot\xi. \tag{28h}$$

These are clearly four distinct eigenvectors, since there are four distinct values of $n^a\xi_a$ given by the roots of the determinant (27). These can be thought as being labeled, essentially, by K or $\xi\cdot\tilde{A}\cdot\xi$ indistinctly, or we can associate one characteristic speed to K and the other one to $\xi\cdot\tilde{A}\cdot\xi$, as we prefer to do below.

Summarizing, we have characteristic speeds obtained from the following distinct values of $n^a\xi_a$:

(a) $n^a\xi_a=0$, timelike, with eigenfields (essentially) $\tilde{\gamma}_{ij}$, ϕ, Q_i, $\tilde{\Gamma}^{(T)}$, $V_{ijk}^{(T)}$.
(b) $n^a\xi_a=1$, null, with eigenfields (essentially) $\tilde{A}_{ij}^{(TT)}$.
(c) $n^a\xi_a=(1+\frac{1}{2}(7c/10-3/5-2d(2a+1)))^{1/2}\equiv C_1$, with eigenfields (essentially) $\tilde{A}_i^{(TL)}$.
(d) $n^a\xi_a=(2a/3)^{1/2}\equiv C_2$, with eigenfield (essentially) K.
(e) $n^a\xi_a=(3/5-2bc/3+16bd/3-4d/3+7c/15)^{1/2}\equiv C_3$, with eigenfield (essentially) $\tilde{A}^{(LL)}$.

In the expressions for the characteristic speeds (c), (d), and (e), the parameters *a,b,c,d* are given in terms of n_1, n_2, n_3 via (14). These speeds may be superluminal or causal, depending on the values of n_1, n_2, n_3. We can choose n_1, n_2, n_3 so that C_1, C_2 and C_3 are all equal to 1. This is achieved by setting

$$n_1^2=\frac{4}{15}\,\frac{280n_2^2+49+400n_2^4}{60n_2^2-49}, \tag{29a}$$

$$n_3^2=\frac{6400n_2^2}{60n_2^2-49}, \tag{29b}$$

for any value of n_2^2 greater than 49/60. This means that there is a one-parameter family of well-posed conformally-decomposed systems with ''physical'' characteristics. From the analytical point of view, there does not appear to exist an argument for singling out a preferred value of n_2. It is likely that a preferred value of n_2 will be dictated by optimal numerical behavior. The expressions for *a,b,c,d* in terms of n_2, with n_1 and n_3 as above (29), are as follows:

$$a=\frac{3}{2}, \tag{30a}$$

$$b=-\frac{60n_2^2-49}{4(7+20n_2^2)}, \tag{30b}$$

$$c=\frac{7}{10n_2^2}, \tag{30c}$$

$$d=-\frac{60n_2^2-49}{800n_2^2}. \tag{30d}$$

D. Propagation of the constraints

The propagation of the constraints can be calculated by taking a time derivative of each one of the constraint expressions, and subsequently using the evolution equations (11) to eliminate the time derivative of the fields in the right-hand side in favor of spatial derivatives, which recombine to yield back the constraints. We obtain

$$\dot{\mathcal{H}}=\beta^l\mathcal{H}_{,l}+(c-8d)\alpha e^{-4\phi}\tilde{\gamma}^{kl}\mathcal{P}_{k,l}+\cdots, \tag{31a}$$

$$\dot{\mathcal{P}}_i=\beta^l\mathcal{P}_{i,l}+\frac{\alpha}{6}(1-4b)\mathcal{H}_{,i}-\frac{\alpha}{2}e^{-4\phi}\left(\tilde{\gamma}^{jl}\left(\tilde{\gamma}^{kr}\mathcal{V}_{ijk,rl}-\frac{7}{10}\tilde{\gamma}_{im}\mathcal{G}^m{}_{,jl}\right)+\frac{1}{10}\mathcal{G}^m{}_{,mi}\right)$$
$$-2\alpha(2a+1)e^{-4\phi}\tilde{\gamma}^{jl}\mathcal{Q}_{[i,l]j}+\cdots, \tag{31b}$$

$$\dot{\mathcal{G}}^i=\beta^l\mathcal{G}^i{}_{,l}+\cdots, \tag{31c}$$

$$\dot{\mathcal{Q}}_i=\beta^l\mathcal{Q}_{i,l}+\cdots, \tag{31d}$$

$$\dot{\mathcal{V}}_{ijk}=\beta^l\mathcal{V}_{ijk,l}+\cdots, \tag{31e}$$

where $\cdots$ denotes undifferentiated terms proportional to the constraints themselves. To analyze the constraint propagation we proceed to turn (31) into first order by defining several sets of variables which represent all the spatial derivatives of $\mathcal{V}_{ijk}$, $\mathcal{G}^i$, and $\mathcal{Q}_i$,

$$\mathcal{W}_{ij}=\mathcal{V}_{ijk,}{}^{k}-\tfrac{1}{5}\mathcal{G}_{(i,j)}+\tfrac{1}{15}\tilde{\gamma}_{ij}\mathcal{G}^{k}{}_{,k}\,, \tag{32a}$$

$$\mathcal{X}_{ijkl}=\mathcal{V}_{ijk,l}-\tfrac{1}{3}\tilde{\gamma}_{kl}\mathcal{V}_{ijm,}{}^{m}, \tag{32b}$$

$$\mathcal{U}_{ij}=\mathcal{Q}_{[i,j]}\,, \tag{32c}$$

$$\mathcal{Z}_{ij}=\mathcal{Q}_{(i,j)}\,, \tag{32d}$$

$$\mathcal{T}_{ij}=\mathcal{G}_{[i,j]}\,, \tag{32e}$$

$$\mathcal{J}_{ij}=\mathcal{G}_{(i,j)}+\tfrac{30}{7}A\,\mathcal{Q}_{(i,j)}\,, \tag{32f}$$

where A is a constant which will be fixed shortly. Calculating the time derivative of these we obtain the resulting first-order system of evolution of the constraints,

$$\dot{\mathcal{H}}=\beta^{l}\mathcal{H}_{,l}+\alpha(c-8d)e^{-4\phi}\mathcal{P}_{l,}{}^{l}+\cdots, \tag{33a}$$

$$\dot{\mathcal{P}}_i=\beta^{l}\mathcal{P}_{i,l}+\frac{\alpha}{6}(1-4b)\mathcal{H}_{,i}-\frac{\alpha}{2}e^{-4\phi}\mathcal{W}_{il,}{}^{l}-2\alpha(2a+1)e^{-4\phi}\mathcal{U}_{il,}{}^{l}-A\alpha e^{-4\phi}\mathcal{Z}_{il,}{}^{l}+\frac{7\alpha}{30}e^{-4\phi}\mathcal{J}_{il,}{}^{l}$$
$$+\frac{11\alpha}{30}e^{-4\phi}\mathcal{T}_{il,}{}^{l}+\cdots, \tag{33b}$$

$$\dot{\mathcal{W}}_{ij}=\beta^{l}\mathcal{W}_{ij,l}-\frac{c\alpha}{5}\mathcal{P}_{(i,j)}+\frac{c\alpha}{15}\tilde{\gamma}_{ij}\mathcal{P}_{l,}{}^{l}+\cdots, \tag{33c}$$

$$\dot{\mathcal{X}}_{ijkl}=\beta^{m}\mathcal{X}_{ijkl,m}+\cdots, \tag{33d}$$

$$\dot{\mathcal{U}}_{ij}=\beta^{l}\mathcal{U}_{ij,l}+\alpha d\mathcal{P}_{[i,j]}+\cdots, \tag{33e}$$

$$\dot{\mathcal{Z}}_{ij}=\beta^{l}\mathcal{Z}_{ij,l}+\alpha d\mathcal{P}_{(i,j)}+\cdots, \tag{33f}$$

$$\dot{\mathcal{T}}_{ij}=\beta^{l}\mathcal{T}_{ij,l}+\alpha c\mathcal{P}_{[i,j]}+\cdots, \tag{33g}$$

$$\dot{\mathcal{J}}_{ij}=\beta^{l}\mathcal{J}_{ij,l}+\alpha\left(c+\frac{30}{7}Ad\right)\mathcal{P}_{(i,j)}+\cdots, \tag{33h}$$

$$\dot{\mathcal{G}}^{i}=\beta^{l}\mathcal{G}^{i}{}_{,j}+\cdots, \tag{33i}$$

$$\dot{\mathcal{Q}}_i=\beta^{l}\mathcal{Q}_{i,l}+\cdots, \tag{33j}$$

$$\dot{\mathcal{V}}_{ijk}=\beta^{l}\mathcal{V}_{ijk,l}+\cdots. \tag{33k}$$

For this system there is a symmetrizer given by

$$\overline{u}\mathbf{H}_c u=e^{4\phi}\frac{(1-4b)}{6(c-8d)}\mathcal{H}^2+\mathcal{P}_i\mathcal{P}^i+e^{-4\phi}\frac{5}{2c}\mathcal{W}_{ij}\mathcal{W}^{ij}+\mathcal{X}_{ijkl}\mathcal{X}^{ijkl}-e^{-4\phi}\frac{2(2a+1)}{d}\mathcal{U}_{ij}\mathcal{U}^{ij}$$
$$-e^{-4\phi}\frac{A}{d}\mathcal{Z}_{ij}\mathcal{Z}^{ij}+e^{-4\phi}\frac{11}{30c}\mathcal{T}_{ij}\mathcal{T}^{ij}+e^{-4\phi}\frac{7/30}{c+Ad30/7}\mathcal{J}_{ij}\mathcal{J}^{ij}+\mathcal{G}_i\mathcal{G}^i+\mathcal{Q}_i\mathcal{Q}^i+\mathcal{V}_{ijk}\mathcal{V}^{ijk}. \tag{34}$$

Taking $A=\frac{7}{60}(-c/d)$, $\mathbf{H}_C$ is positive definite because, under the conditions (14), all the factors accompanying the squares of the fields are strictly positive. This shows that no additional restrictions on the ranges of the parameters *a,b,c,d* are necessary in order to have well posed constraint evolution.

III. CONCLUSION

We have derived a 3-parameter family of well posed versions of the conformally-decomposed 3+1 equations, perhaps amenable to successful numerical integration. One might object that there is no need for it in view of the results in Ref. 11, but we can argue rather strongly that these results may prove helpful in pinning-down the main cause of numerical instabilities. This well posed version requires the lapse to be proportional to the determinant of the intrinsic geometry of the surfaces, and requires combinations of the constraints with the evolution equations. The lapse density σ and the shift vector β^i are arbitrary nondynamical variables, which means that they must be specified as free source functions. This well posed version uses the same variables as the original system (except for the addition of the first spatial derivatives of the densitized 3-metric, referred to as ''conformal metric'' by the authors Ref. 11). In addition, this well-posed version of the original equations propagates the constraints in a stable manner, which is relevant to unconstrained evolution. We think that this is the least invasive way to turn the original conformally-decomposed system into a well posed one. In practice, a choice of the numerical parameters n_1, n_2, n_3 must be made. The characteristic speeds depend on this choice.

Optimal choices of the parameters n_1, n_2, n_3 for numerical evolution are those that ensure that the characteristics are all either null or timelike. With such a choice, the formulation would be suited to evolve blackhole space–times outside the event horizon. Among these choices, it has been suggested[19] that the preferred one would be the one for which the characteristics are all ''physical,'' namely, either null or normal to the slices. We have shown that such a choice is possible for an arbitrary $n_2>\sqrt{49/60}$.

The systems obtained in this work are not contained in our previous work.[5,7] The choice of variables in Refs. 5,7 is inadequate for decomposing the trace and trace free part of the extrinsic curvature, as well as for extracting the determinant of the 3-metric. This is clear from the fact that, in that work, the available parameters α and β are not allowed to take the value $-1/3$ without the argument breaking down.

The systems obtained here differ significantly from the system obtained in Ref. 15 by considering the trace of the extrinsic curvature K and the determinant of the intrinsic metric (and its derivatives) as dynamical variables on equal footing with the rest, rather than as free source functions. Furthermore, we have obtained a 3-parameter family of systems, one system for each appropriate choice of n_1, n_2, n_3, whereas in Ref. 15 there is only one system which preserves the trace conditions. Additionally, we have separated the divergence of the intrinsic metric $\tilde{\Gamma}^i$ from the divergence-free part of the metric. This decomposition keeps up with the spirit of Ref. 11.

We have found that in obtaining these well-posed formulations the lapse must be proportional to some power of the determinant of the intrinsic metric, since the parameter *a* cannot take the value 0. This is similar to our findings in Refs. 2,5,7, as well as other notable cases.[6,20,21,18] In our present case this is remarkable, since we have used quite general energy norms.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 10 OCTOBER 1999

The effective σ-model of multidimensional gravity

Martin Rainer[a)]
Center for Gravitational Physics and Geometry, 104 Davey Laboratory, The Pennsylvania State University, University Park, Pennsylvania 16802-6300 and Gravitationsprojekt, Mathematische Physik I, Institut für Mathematik, Universität Potsdam, PF 601553, D-11415 Potsdam, Germany

(Received 14 December 1998; accepted for publication 13 May 1999)

The properties of the effective σ-model for D-dimensional Einstein gravity based on multidimensional geometries is analyzed. Besides pure geometry additional minimally coupled scalars and $(p+2)$-forms are considered which yield an extended target space after reduction to the effective D_0-dimensional geometry. The target space is always a homogeneous space. Exact solutions exist provided an orthobrane condition is satisfied which geometrically makes the target space a locally symmetric one. New solutions with scalar fields are found which may inflate not only in time-like but in also in additional spatial directions of the effective geometry. Static spherically symmetric solutions with a particular configuration of intersecting electric and magnetic branes are investigated both, for the orthobrane case and for degenerated charges. In both cases T_H depends critically on the intersection dimension of the branes. Finally, the role of the Einstein frame for 4-geometries is addressed, and the physical frame transformation for cosmological geometries is given.
[S0022-2488(99)03408-8]

I. INTRODUCTION

Historically σ-models have turned out to be a very powerful tool in many areas of physics. In gravity the importance was soon realized[1] in the context of solution generating techniques.[2] More recently, σ-models have been also discussed in the context of string theory.[3–5]

The purpose of this paper is to clarify the geometric structure of the effective σ-model for multidimensional Einstein geometry and to demonstrate its applicability in such different directions as cosmology, (extended) string theory, and quantization of certain higher-dimensional geometric actions.

In fact it turns out to be a very powerful tool which, on one side, allows to test the geometric content of string and M-theory down to their concrete physical imprints in the physical space-time and, on the other side, prepares a well-defined class of classical higher-dimensional geometries for the canonical quantization program in dimension $D_0 \leqslant 4$ whenever this is applicable to pure Einstein gravity itself. In principle all cases with infinite number of degrees of freedom in dimension $D_0 = 4$ which can be canonically quantized have some analogous cases where additional extra dimensions add only a finite number of degrees of freedom without disturbing the integrability of the problem. These cases include of course also recently investigated midisuperspace 4-geometries. In the case of spherical symmetries, and more particular in the static case, one can find particular solutions to a classical system of the multidimensional Einstein action with scalar and antisymmetric $p+2$-form fields which are multidimensional extensions of black hole solutions. It turns out that the standard surface gravity and the Hawking temperature T_H as calculated from a Komar-like integral depend sensitively on the intersection dimension of the p-branes involved in the solution. This provides, at least in principle, an observational window to very direct geometrical properties of possible extra dimensions. Apart from that, the multidimensional

[a)]Electronic mail: rainer@phys.psu.edu

σ-model contains all kinds of multidimensional spatially homogeneous cosmological models as degenerate minisuperspace cases with a finite number of degrees of freedom only.

Below, the effective D_0-dimensional σ-model is derived from a multidimensional action of Einstein type in a higher dimension D, first for pure geometry, then with additional scalar and antisymmetric $p+2$-form matter fields. The domains of the $p+1$-form potentials of the antisymmetric $p+2$-forms are the world-sheets of p-branes. In extended string and M-theory[6–8] strings are generalized to membranes as higher-dimensional objects. Most of these unified models are modeled initially on a higher-dimensional space-time manifold, say of dimension $D>4$, which then undergoes some scheme of spontaneous compactification.

The geometric structure of the target-space is clarified. In particular it is shown that it is a always a homogeneous space. It is furthermore locally symmetric if and only if the characteristic target-space vectors satisfy a particular orthogonality condition, called the *orthobrane* relation whenever they are not identical. In any case, it turns out possible to express the *general* exact solutions in terms of elementary functions, provided the input parameters of the model satisfy them, whence the target space is locally symmetric.

Solutions of the corresponding field equations are discussed generally and with concrete examples. Particular solutions for the subcases with Ricci flat internal spaces with scalar fields only, and with intersecting p-branes are presented. In the subcase of spherically symmetric solutions the relation to particles and black p-branes is given. Although a priori one might admit all possible types of components of F-fields compatible with spherical symmetry, namely, electric, magnetic and quasiscalar ones, we concentrate on true electric and magnetic type fields, since these are the ones which admit black hole solutions.

Besides the orthobrane solutions which by now became popular in string theory, there are further families of solutions, which have another additional symmetry, e.g., coinciding F-field charges for the electromagnetic solutions. In target space this additional symmetry is expressed by a linear relation between certain column vectors of the coupling matrix. In this case the original orthobrane conditions reduce to some weaker set of orthogonality conditions.

In the case of static, spherical symmetric solutions it is demonstrated that the formal Hawking temperature T_H (as it might appear to an observer at infinity) depends sensitively on the intersection dimension of the p-branes. Hence solutions to the multidimensional σ-model allow to detect possible imprints from extra-dimensional internal factor spaces within the physical dimension $D_0=4$. The black hole solutions depend on 3 integration constants, related to the electric, the magnetic, and the mass charge. It is also shown that the Hawking temperature of such black holes depends on the intersection dimension $d_{\rm int}$ of the corresponding p-branes. In an extremal limit of the charges, the black hole temperature turns out to converge to zero for $d_{\rm int}=0$, to a finite limit for $d_{\rm int}=1$, and to infinity for $d_{\rm int}>1$.

Finally it is shown how the geometries of well-known solutions in a Brans–Dicke frame can be transformed to the physically relevant Einstein frame.

II. PURE MULTIDIMENSIONAL GRAVITY

For the purpose of this paper let a (C^∞-) *multidimensional* (MD) manifold N be topologically just defined by a C^∞-fiber bundle

$$M \hookrightarrow N \to \overline{M}_0 \tag{2.1}$$

with a direct product

$$M := \times_{i=1}^{n} M_i \tag{2.2}$$

of internal C^∞ factor spaces M_i, $i=1,\dots,n$, as a standard fiber, and a distinguished C^∞ base manifold $\overline{M}_0$. (Later, for considerations of dynamics and cosmology we will set in particular $\overline{M}_0 := \mathbb{R}\times M_0$, and for the connection representation of Einstein gravity $D_0 := 4$ will be required.)

The MD manifold N is called *internally homogeneous* if there exists a direct product group $G:=\otimes_{i=0}^{n}G_i$ with a direct product realization $\tau:=\otimes_{i=0}^{n}\tau_i$ on $\mathrm{Diff}(M):=\otimes_{i=0}^{n}\mathrm{Diff}(M_i)$ such that for $i=0,\ldots,n$ the realization

$$\tau_i: G_i \to \mathrm{Diff}(M_i) \tag{2.3}$$

yields a transitive action of $\tau_i(G_i)$ on M_i.

Definition: A (C^∞) Riemannian manifold (M,g) (of arbitrary signature) is a C^∞ manifold M equipped with a symmetric bilinear C^∞ section $g: M \to \mathfrak{T}_2^0 M$ called metric. Unless specified otherwise the metric g will always be assumed to be nondegenerate. □

Definition: Given a Riemannian manifold (M,g), a diffeomorphism $\chi \in \mathrm{Diff}(M)$ is called an *isometry* of (M,g) whenever it leaves g invariant, i.e., whenever

$$g_{\chi(p)}=g_p \;\; \forall p \in M. \tag{2.4}$$

The very fact that a given diffeomorphism $\chi \in \mathrm{Diff}(M)$ may be an isometry on some metric but not on another one is the reason why the action of $\mathrm{Diff}(M)$ is not free on the space $\mathrm{Met}(M)$ of C^∞-metrics on M, whence $\mathrm{Geom}(M):=\mathrm{Met}(M)/\mathrm{Diff}(M)$ is in general not a manifold.

Definition: A Riemannian manifold (M,g) is called homogeneous, whenever M is homogeneous with a corresponding group G having a transitive realization $\tau(G)\subset \mathrm{Diff}(M)$ which leaves g invariant, i.e.,

$$g_{\chi(p)}=g_p \;\; \forall p \in M \;\; \forall \chi \in \tau(G). \tag{2.5}$$

□

Now for $i=0,\ldots,n$, let each factor space M_i be equipped with a smooth homogeneous metric $g^{(i)}$, rendering it into a homogeneous Riemannian manifold. Furthermore, let $\bar{M}_0$ be equipped with an arbitrary C^∞-metric $\bar{g}^{(0)}$, and let $\bar{\gamma}$ and β^i, $i=1,\ldots,n$ be smooth scalar fields on $\bar{M}_0$.

Then, under any projection $\mathrm{pr}: N \to \bar{M}_0$ a pullback of $e^{2\bar{\gamma}}\bar{g}^{(0)}$ from $x \in \bar{M}_0$ to $z \in \mathrm{pr}^{-1}\{x\}\subset M$, consistent with the fiber bundle (2.1) and the homogeneity of internal spaces, is given by

$$g_{(z)}:=e^{2\bar{\gamma}(x)}\bar{g}^{(0)}_{(x)} \oplus_{i=1}^{n} e^{2\beta^i(x)} g^{(i)}. \tag{2.6}$$

The function $\bar{\gamma}$ fixes a *gauge* for the (Weyl) *conformal frame* on $\bar{M}_0$, corresponding just to a particular choice of geometrical variables.

$\bar{\gamma}$ uniquely defines the form of the effective D_0-dimensional theory. For example $\bar{\gamma}:=0$ defines the Brans–Dicke frame.

Let us now consider a multidimensional manifold N (2.1) of dimension $D=D_0+\Sigma_{i=0}^{n}d_i$, equipped with a (pseudo) Riemannian metric (2.6) where

$$g^{(i)} \equiv g_{m_i n_i}(y_i)\, dy_i^{m_i} \otimes dy_i^{n_i}, \tag{2.7}$$

are R-homogeneous Riemannian metrics on M_i (i.e., the Ricci scalar $R[g^{(i)}]\equiv R_i$ is a constant on M_i), in coordinates $y_i^{n_i}$, $n_i=1,\ldots,d_i$, and

$$x \mapsto \bar{g}^{(0)}(x)=\bar{g}^{(0)}_{\mu\nu}(x)\, dx^\mu \otimes dx^\nu \tag{2.8}$$

yielding a general, not necessarily R-homogeneous, (pseudo) Riemannian metric on $\bar{M}_0$.

With (2.6) is a multidimensional generalization of the warped product of Ref. 9, namely $N=\bar{M}_0 \times_a M$, where $a:=e^{\beta}$ is now a *vector-valued* root warping function, given by

$$\beta := \begin{pmatrix} \beta_0 \\ \vdots \\ \beta_n \end{pmatrix}. \tag{2.9}$$

Below sometimes, in particular for physical application to the Diff($\overline{M}_0$)-invariant case with $D_0 = 4$, we will assume the $i=0$ geometry to be empty and omit corresponding empty contributions to tensors, summations, etc. For later convenience we also define

$$\varepsilon(I) := \prod_{i\in I} \varepsilon_i, \quad \sigma_0 := \sum_{i=0}^{n} d_i\beta_i, \quad \sigma_1 := \sum_{i=1}^{n} d_i\beta_i, \quad \sigma(I) := \sum_{i\in I} d_i\beta_i, \tag{2.10}$$

where $\varepsilon_i := \mathrm{sign}(|g^{(i)}|)$ and $M_i \subset M$ for $i=0,\ldots,n$ are all homogeneous factor spaces. Here and below, we use the shorthand $|g| := |\det(g_{MN})|$, $|\overline{g^{(0)}}| := |\det(\overline{g^{(0)}_{\mu\nu}})|$, and analogously for all other metrics including $g^{(i)}$, $i=1,\ldots,n$.

Further, a $\overline{g^{(0)}}$-covariant derivative of a given function α w.r.t. x^μ is denoted by $\alpha_{;\mu}$, its partial derivative also by $\alpha_{,\mu}$, and $(\partial\alpha)(\partial\beta) := \overline{g^{(0)\mu\nu}}\alpha_{,\mu}\beta_{,\nu}$.

On $\overline{M}_0$, the Laplace–Beltrami operator

$$\Delta[\overline{g^{(0)}}] = \frac{1}{\sqrt{|\overline{g^{(0)}}|}} \frac{\partial}{\partial x^\mu}\left(\sqrt{|\overline{g^{(0)}}|}\,\overline{g^{(0)\mu\nu}} \frac{\partial}{\partial x^\nu}\right)$$

transforms under the conformal map $\overline{g^{(0)}} \mapsto e^{2\overline{\gamma}}\overline{g^{(0)}}$ according to

$$\begin{aligned}\Delta[e^{2\overline{\gamma}}\overline{g^{(0)}}] &= e^{-2\overline{\gamma}}\Delta[\overline{g^{(0)}}] - e^{-2\overline{\gamma}}\overline{g^{(0)\mu\nu}}(\Gamma[e^{2\overline{\gamma}}\overline{g^{(0)}}] - \Gamma[\overline{g^{(0)}}])^\lambda_{\mu\nu}\frac{\partial}{\partial x^\lambda} \\ &= e^{-2\overline{\gamma}}\left(\Delta[\overline{g^{(0)}}] + (D_0-2)g^{(0)\mu\nu}\frac{\partial\overline{\gamma}}{\partial x^\mu}\frac{\partial}{\partial x^\nu}\right),\end{aligned} \tag{2.11}$$

where Γ denotes the Levi-Civita connection.

The Levi-Civita connection Γ corresponding to (2.6) does *not* decompose multidimensionally, and neither does the Riemann tensor. The latter is a section in $\mathfrak{T}^1_3 M$ which is not given as a pullback to $\overline{M}_0$ of a section in the direct sum $\oplus_{i=1}^n \mathfrak{T}^1_3 M_i$ of corresponding tensor bundles over the factor manifolds.

However, with (2.6) the Ricci tensor decomposes again multidimensionally:

$$\mathrm{Ric}[g] = \mathrm{Ric}^{(0)}[g^{(0)},\overline{\gamma};\phi] \oplus_{i=1}^n \mathrm{Ric}^{(i)}[g^{(0)},\overline{\gamma};g^{(i)},\phi], \tag{2.12}$$

where

$$\begin{aligned}\mathrm{Ric}^{(0)}_{\mu\nu} &:= R_{\mu\nu}[g^{(0)}] + g^{(0)}_{\mu\nu}\left\{ -\Delta[g^{(0)}]\overline{\gamma} + (2-D_0)(\partial\overline{\gamma})^2 - \partial\overline{\gamma}\sum_{j=1}^n d_j\partial\phi^j\right\} \\ &\quad + (2-D_0)(\overline{\gamma}_{;\mu\nu} - \overline{\gamma}_{,\mu}\overline{\gamma}_{,\nu}) - \sum_{i=1}^n d_i(\phi^i_{;\mu\nu} - \phi^i_{,\mu}\overline{\gamma}_{,\nu} - \phi^i_{,\nu}\overline{\gamma}_{,\mu} + \phi^i_{,\mu}\phi^i_{,\nu}),\end{aligned}$$

$$\mathrm{Ric}^{(i)}_{m_i n_i} := R_{m_i n_i}[g^{(i)}] - e^{2\phi^i - 2\overline{\gamma}} g^{(i)}_{m_i n_i}\left\{ \Delta[g^{(0)}]\phi^i + (\partial\phi^i)\left[(D_0-2)\partial\overline{\gamma} + \sum_{j=1}^n d_j\partial\phi^j\right]\right\}, \quad i=1,\ldots,n, \tag{2.13}$$

The corresponding Ricci curvature scalar reads

$$R[g]=e^{-2\bar{\gamma}}R[\bar{g}^{(0)}]+\sum_{i=1}^{n} e^{-2\beta^i}R[g^{(i)}]-e^{-2\bar{\gamma}}\bar{g}^{(0)\mu\nu}\Bigg((D_0-2)(D_0-1)\frac{\partial\bar{\gamma}}{\partial x^\mu}\frac{\partial\bar{\gamma}}{\partial x^\nu}$$
$$+\sum_{i,j=1}^{n}(d_i\delta_{ij}+d_id_j)\frac{\partial\beta^i}{\partial x^\mu}\frac{\partial\beta^j}{\partial x^\nu}+2(D_0-2)\sum_{i=1}^{n}d_i\frac{\partial\bar{\gamma}}{\partial x^\mu}\frac{\partial\beta^i}{\partial x^\nu}\Bigg)$$
$$-2e^{-2\bar{\gamma}}\Delta[\bar{g}^{(0)}]\left((D_0-1)\bar{\gamma}+\sum_{i=1}^{n}d_i\beta^i\right). \tag{2.14}$$

Let us now set

$$f\equiv f[\bar{\gamma},\beta]:=(D_0-2)\bar{\gamma}+\sum_{j=1}^{n}d_j\beta^j, \tag{2.15}$$

where β is the vector field with the dilatonic scalar fields β^i as components. (Note that f can be resolved for $\bar{\gamma}\equiv\bar{\gamma}[f,\beta]$ if and only if $D_0\neq 2$. The singular case $D_0=2$ is discussed in Ref. 10.) Then, (2.14) can also be written as

$$R[g]-e^{-2\bar{\gamma}}R[\bar{g}^{(0)}]-\sum_{i=1}^{n}e^{-2\beta^i}R_i$$
$$=-e^{-2\bar{\gamma}}\left\{\sum_{i=1}^{n}d_i(\partial\beta^i)^2+(\partial f)^2+(D_0-2)(\partial\bar{\gamma})^2+2\Delta[\bar{g}^{(0)}](f+\bar{\gamma})\right\}$$
$$=-e^{-2\bar{\gamma}}\left\{\sum_{i=1}^{n}d_i(\partial\beta^i)^2+(D_0-2)(\partial\bar{\gamma})^2-(\partial f)\partial(f+2\bar{\gamma})+R_B\right\}, \tag{2.16}$$

$$R_B:=\frac{1}{\sqrt{|\bar{g}^{(0)}|}}e^{-f}\partial_\mu[2e^f\sqrt{|\bar{g}^{(0)}|}\bar{g}^{(0)\mu\nu}\partial_\nu(f+\bar{\gamma})], \tag{2.17}$$

where the last term will yield just a boundary contribution (2.22) to the action (2.21) below.

Let us assume all M_i, $i=1,\dots,n$, to be connected and oriented. The Riemann–Lebesgue volume form on M_i is denoted by

$$\tau_i:=\mathrm{vol}(g^{(i)})=\sqrt{|g^{(i)}(y_i)|}dy_i^1\wedge\cdots\wedge dy_i^{d_i}, \tag{2.18}$$

and the total internal space volume by

$$\mu:=\prod_{i=1}^{n}\mu_i,\quad \mu_i:=\int_{M_i}\tau_i=\int_{M_i}\mathrm{vol}(g^{(i)}). \tag{2.19}$$

If all of the spaces M_i, $i=1,...,n$ are compact, then the volumes μ_i and μ are finite, and so are also the numbers $\rho_i=\int_{M_i}\mathrm{vol}(g^{(i)})R[g^{(i)}]$. However, a non-compact M_i might have infinite volume μ_i or infinite ρ_i. Nevertheless, by the R-homogeneity of $g^{(i)}$ (in particular satisfied for Einstein spaces), the ratios $\rho_i/\mu_i=R[g^{(i)}]$, $i=1,\dots,n$, are just finite constants. In any case, the D-dimensional coupling constant κ can be tuned such that, under the dimensional reduction $\mathrm{pr}:M\to\bar{M}_0$,

$$\kappa_0:=\kappa\cdot\mu^{-\frac{1}{2}} \tag{2.20}$$

becomes the D_0-dimensional physical coupling constant. If $D_0=4$, then $\kappa_0^2=8\pi G_N$, where G_N is the Newton constant. The limit $\kappa\to\infty$ for $\mu\to\infty$ is in particular harmless, if D-dimensional gravity is given purely by curvature geometry, without additional matter fields. If, however, this geometry is coupled with finite strength to additional (matter) fields, one should indeed better take care to have all internal spaces M_i, $i=1,...,n$ compact. Often this can be achieved by factorizing with an appropriate finite symmetry group.

With the total dimension D, κ^2 a D-dimensional gravitational constant we consider a purely gravitational action of the form

$$S=\frac{1}{2\kappa^2}\int_N d^D z\sqrt{|g|}\{R[g]\}+S_{\mathrm{GHY}}. \tag{2.21}$$

Here a (generalized) Gibbons–Hawking–York[11,12] type boundary contribution S_{GHY} to the action is taken to cancel boundary terms. Equations (2.16) and (2.16) show that S_{GHY} should be taken in the form

$$S_{\mathrm{GHY}}:=\frac{1}{2\kappa^2}\int_N d^D z\sqrt{|g|}\{e^{-2\bar{\gamma}}R_B\}=\frac{1}{\kappa_0^2}\int_{\bar{M}_0} d^{D_0}x\,\frac{\partial}{\partial x^\lambda}\left(e^f\sqrt{|\overline{g^{(0)}}|}\,\overline{g}^{(0)\lambda\nu}\frac{\partial}{\partial x^\nu}(f+\bar{\gamma})\right), \tag{2.22}$$

which is just a pure boundary term in form of an effective D_0-dimensional flow through $\partial\bar{M}_0$.

After dimensional reduction the action (2.21) reads

$$\begin{aligned}S=\frac{1}{2\kappa_0^2}\int_{\bar{M}_0} d^{D_0}x\sqrt{|\overline{g^{(0)}}|}e^f\Bigg\{&R[\overline{g^{(0)}}]+(\partial f)(\partial[f+2\bar{\gamma}])\\&-\sum_{i=1}^n d_i(\partial\beta^i)^2-(D_0-2)(\partial\bar{\gamma})^2+e^{2\bar{\gamma}}\left[\sum_{i=1}^n e^{-2\beta^i}R_i\right]\Bigg\},\end{aligned} \tag{2.23}$$

where e^f is a dilatonic scalar field coupling to the D_0-dimensional geometry on $\bar{M}_0$.

According to the considerations above, due to the conformal reparametrization invariance of the geometry on $\bar{M}_0$, we should fix a conformal frame on $\bar{M}_0$. But then in (2.23) $\bar{\gamma}$, and with (2.15) also f, is no longer independent from the vector field β, but rather

$$\bar{\gamma}\equiv\bar{\gamma}[\beta],\quad f\equiv f[\beta]. \tag{2.24}$$

Then, modulo the conformal factor e^f, the dilatonic kinetic term of (2.23) takes the form

$$(\partial f)(\partial[f+2\bar{\gamma}])-\sum_{i=1}^n d_i(\partial\beta^i)^2-(D_0-2)(\partial\bar{\gamma})^2=-G_{ij}(\partial\beta^i)(\partial\beta^j), \tag{2.25}$$

with $G_{ij}\equiv{}^{(\bar{\gamma})}G_{ij}$, where

$${}^{(\bar{\gamma})}G_{ij}:={}^{(\mathrm{BD})}G_{ij}-(D_0-2)(D_0-1)\frac{\partial\bar{\gamma}}{\partial\beta^i}\frac{\partial\bar{\gamma}}{\partial\beta^j}-2(D_0-1)d_{(i}\frac{\partial\bar{\gamma}}{\partial\beta^{j)}}, \tag{2.26}$$

$${}^{(\mathrm{BD})}G_{ij}:=\delta_{ij}d_i-d_id_j. \tag{2.27}$$

For $D_0\neq2$, we can write equivalently $G_{ij}\equiv{}^{(f)}G_{ij}$, where

$${}^{(f)}G_{ij}:={}^{(\mathrm{E})}G_{ij}-\frac{D_0-1}{D_0-2}\frac{\partial f}{\partial\beta^i}\frac{\partial f}{\partial\beta^j}, \tag{2.28}$$

$$^{(\mathrm{E})}G_{ij} := \delta_{ij} d_i + \frac{d_i d_j}{D_0 - 2}. \tag{2.29}$$

For $D_0 = 1$, $G_{ij} = {}^{(\mathrm{E})}G_{ij} = {}^{(\mathrm{BD})}G_{ij}$ is independent of $\overline{\gamma}$ and f. Note that the metrics (2.27) and (2.29) (with $D_0 \neq 2$) may be diagonalized to $(\mp(\pm)^{\delta_{1D_0}})^{\delta_{1i}}\delta_{ij}$ respectively, by homogeneous linear minisuperspace coordinate transformations $\beta \overset{T}{\mapsto} z$ and $\beta \overset{Q}{\mapsto} \varphi$, explicitly given by components

$$z^1 := {}^{(\mathrm{BD})}q^{-1} \sum_{j=1}^{n} d_j \beta^j, \quad \varphi^1 := {}^{(\mathrm{E})}q^{-1} \sum_{j=1}^{n} d_j \beta^j,$$

$$z^i \equiv \varphi^i := [d_{i-1}/\Sigma_{i-1}\Sigma_i]^{1/2} \sum_{j=i}^{n} d_j (\beta^j - \beta^{i-1}), \tag{2.30}$$

$i = 2,\ldots,n$, where with $D' := D - D_0$ and $\Sigma_k := \Sigma_{i=k}^{n} d_i$,

$$^{(\mathrm{BD})}q := \sqrt{\frac{D'}{D'-1}}, \quad {}^{(\mathrm{E})}q := \sqrt{\frac{D'(D_0-2)}{D'+D_0-2}}. \tag{2.31}$$

So, after fixing a conformal reparametrization gauge for the geometry on M_0, (2.21) becomes a σ-model, where the vector field β (or z resp. φ) defines the coordinates of its n-dimensional target space. In the following, we will simplify notation by a summation convention for tensors over target space.

In general, for $n > 2$ and nonconstant functional $\gamma[\beta]$, the minisuperspace metric given by (2.25) and the conformally related target space metric may not even be conformally flat. However, for constant $\overline{\gamma}$, (2.26) reduces to (2.27), whence target space is conformally flat, namely it is related to n-dimensional Minkowski space by a conformal scale factor

$$\varphi \equiv \varphi(\beta) := \prod_{l=1}^{n} e^{d_l \beta^l} = e^{{}^{(\mathrm{BD})}q z^1} = e^{{}^{(\mathrm{E})}q \varphi^1}, \tag{2.32}$$

which is proportional to the total internal space volume.

In the case $D_0 \neq 2$, for nonconstant functional $f[\beta]$, the target space may again in general not be conformally flat for $n > 2$. However, for constant f, (2.28) reduces to (2.29), whence, target space is a flat n-dimensional space, namely an Euclidean one for $D_0 > 2$, and a Minkowskian one for $D_0 = 1$.

After gauging $\overline{\gamma}$, setting $m := \kappa_0^{-2}$, (2.23) yields a σ-model in the form

$$^{(\overline{\gamma})}S = \int_{\overline{M}_0} d^{D_0}x \sqrt{|\overline{g}^{(0)}|}\, {}^{(\overline{\gamma})}N^{D_0} \quad \varphi(\beta) \left\{ \frac{m}{2} {}^{(\overline{\gamma})}N^{-2} [R[\overline{g}^{(0)}] - {}^{(\overline{\gamma})}G_{ij}(\partial\beta^i)(\partial\beta^j)] - {}^{(\mathrm{BD})}V(\beta) \right\}, \tag{2.33}$$

$$\text{where} \quad {}^{(\mathrm{BD})}V(\beta) := m \left[-\frac{1}{2} \sum_{i=1}^{n} R[g^{(i)}] e^{-2\beta^i} \right], \tag{2.34}$$

$$^{(\overline{\gamma})}N := e^{\overline{\gamma}}. \tag{2.35}$$

Note that, the potential (2.34) and the conformal factor $\phi(\beta) := \Pi_{i=1}^{n} e^{d_i \beta^i}$ are gauge invariant.

Analogously, the σ-model action from (2.23) gauging f can also be written as

$$^{(f)}S=\int_{\overline{M}_0} d^{D_0}x\sqrt{|\overline{g^{(0)}}|}\,{}^{(f)}N^{D_0}\left\{\frac{m}{2}{}^{(f)}N^{-2}[R[\overline{g^{(0)}}]-{}^{(f)}G_{ij}(\partial\beta^i)(\partial\beta^j)]-{}^{(\mathrm{E})}V(\beta)\right\}, \quad (2.36)$$

$$^{(\mathrm{E})}V(\beta):=m\Omega^2\left[-\frac{1}{2}\sum_{i=1}^{n} R[g^{(i)}]e^{-2\beta^i}\right], \quad (2.37)$$

$$^{(f)}N:=e^{\frac{f}{D_0-2}}, \quad (2.38)$$

where the function Ω on $\overline{M}_0$ is defined as

$$\Omega:=\varphi^{\frac{1}{2-D_0}}. \quad (2.39)$$

Note that, with Ω also the potential (2.37) is gauge invariant, and the dilatonic target-space, though not even conformally flat in general, is flat for constant f.

In fact, Eqs. (2.33)–(2.35) and (2.36)–(2.38) show that there are at least two special frames.

The first one corresponds to the gauge $\overline{\gamma}\overset{!}{=}0$. In this case $^{(\overline{\gamma})}N=1$, the minisuperspace metric (2.26) reduces to the Minkowskian (2.27), the dilatonic scalar field becomes proportional to the internal space volume, $e^{f[\beta]}=\varphi(\beta)=\Pi_{i=1}^{n}e^{d_i\beta^i}$, and (2.33) describes a generalized σ-model with conformally Minkowskian target space. The Minkowskian signature implies a negative sign in the dilatonic kinetic term. This frame is usually called the Brans–Dicke one, because $\varphi=e^f$ here plays the role of a Brans–Dicke scalar field.

The second distinguished frame corresponds to the gauge $f\overset{!}{=}0$, where $\overline{\gamma}=[1/(2-D_0)]\Sigma_{i=1}^{n}d_i\beta^i$ is well defined only for $D_0\neq 2$. In this case $^{(f)}N=1$, the minisuperspace metric (2.28) reduces to the Euclidean (2.29), and (2.36) describes a self-gravitating σ-model with Euclidean target space. Hence all dilatonic kinetic terms have positive signs. This frame is usually called the Einstein one, because it describes an effective D_0-dimensional Einstein theory with additional minimally coupled scalar fields. For multidimensional geometries with $D_0=2$ the Einstein frame fails to exist, which reflects the well-known fact that two-dimensional Einstein equations are trivially satisfied without implying any dynamics.

For $D_0=1$, the action of both (2.33) and (2.36) was shown in Ref. 13 (and previously in Refs. 14 and 15) to take the form of a classical particle motion on minisuperspace, whence different frames correspond are just related by a time reparametrization. More generally, for $D_0\neq 2$ and $(\overline{M}_0,\overline{g}(0))$ a vacuum space-time, the σ-model (2.36) with the gauge $f\overset{!}{=}0$ describes the dynamics of a massive (D_0-1)-brane within a potential (2.37) on its target minisuperspace.

In fact, the target space is in general a conformally homogeneous space, and in the Einstein frame a homogeneous one. Once its isometry group $\mathfrak{G}$ and isotropy group $\mathfrak{H}$ are known, it is clear that the sigma model (2.36) can also be written in matrix form

$$^{(f)}S=\int_{\overline{M}_0} d^{D_0}x\sqrt{|\overline{g^{(0)}}|}N^{D_0}(\mathcal{M})\left\{\frac{m}{2}N^{-2}(\mathcal{M})[R[\overline{g^{(0)}}]+g^{(0)\mu\nu}B\,\mathrm{Tr}_{\rho}(\partial_\mu\mathcal{M}\partial_\nu\mathcal{M}^{-1})]\right.$$
$$\left.-{}^{(\mathrm{E})}U(\mathcal{M})\right\}, \quad (2.40)$$

with $\mathcal{M}\in\rho(G)$ where ρ is an appropriate coset representation of the target space $\mathfrak{M}:=\mathfrak{G}/\mathfrak{H}$, $^{(\mathrm{E})}U$ is now the corresponding potential on $\mathfrak{M}$, N a gauge function on $\mathfrak{M}$, and B a normalization.

For $D_0=4$, Eq. (2.40) can also be written in the Einstein frame as

$$^{(E)}S=\int_{\overline{M}_0}\left\{\frac{m}{2}[\mathrm{Tr}\,\Omega\wedge*\Sigma+B\,\mathrm{Tr}_{\rho}d\mathcal{M}\wedge*d\mathcal{M}^{-1}]-{}^{(\mathrm{E})}U(\mathcal{M})*1\right\}, \quad (2.41)$$

where Ω is the curvature 2-form, $\Sigma := e \wedge e$ and $\overline{g^{(0)}}$ are given by the D_0-dimensional soldering 1-form e, and the Hodge star is taken w.r.t. $(\overline{M}, g^{(0)})$. The form (2.41) is a then a convenient starting point for the canonical quantization procedure.

In the purely gravitational model consider so far $\mathfrak{M}$ is a finite dimensional and homogeneous with a transitive Abelian group. In the following section let us add minimally coupled scalar and $p+2$-form matter fields and investigate the extension of the resulting target space $\mathfrak{M}$.

III. σ-MODEL WITH MINIMALLY COUPLED SCALARS AND $p+2$-FORMS

We now couple the purely gravitational action (2.21) to additional matter fields of scalar and generalized Maxwell type, i.e. we consider now the action

$$2\kappa^2[S[g,\phi,F^a]-S_{\mathrm{GHY}}]=\int_N d^Dz\,\sqrt{|g|}\Bigg\{R[g]-C_{\alpha\beta}g^{MN}\partial_M\Phi^\alpha\partial_N\Phi^\beta - \sum_{a\in\Delta}\frac{\eta_a}{n_a!}\exp[2\lambda_a(\Phi)](F^a)^2\Bigg\} \tag{3.1}$$

of a self-gravitating σ model on M with topological term S_{GHY}. Here the l-dimensional target space, defined by a vector field ϕ with scalar components ϕ^α, $\alpha=1,\ldots,l$, is coupled to several antisymmetric n_a-form fields F^a via 1-forms λ_a, $a\in\Delta$. For consistency, we have to demand of course that all fields are internally homogeneous. We will see below how this gives rise to an effective $l+|\Delta|$-dimensional target-space extension. Note also that for convenience here we work with fields ϕ and F which differ from the actual (physical) matter fields by a rescaling with the square root of the coupling constant.

With $I\subset\{1,\ldots,n\}$, the generalized Maxwell fields F^a are located on (n_a-1)-dimensional world sheets

$$M_I:=\prod_{i\in I}M_i=M_{i_1}\times\cdots\times M_{i_k}, \tag{3.2}$$

$$n_a-1=D(I):=\sum_{i\in I}d_i=d_{i_1}+\cdots+d_{i_k} \tag{3.3}$$

of different $(n_a-2)-$branes, labeled for each a by the sets I in a certain subset Ω_a of the power set of $\{1,\ldots,n\}$. Variation of (3.1) yields the field equations

$$R_{MN}-\tfrac{1}{2}g_{MN}R=T_{MN}, \tag{3.4}$$

$$C_{\alpha\beta}\Delta[g]\phi^\beta-\sum_{a\in\Delta}\frac{\eta_a\lambda_a^\alpha}{n_a!}e^{2\lambda_a(\phi)}(F^a)^2=0, \tag{3.5}$$

$$\nabla_{M_1}[g](e^{2\lambda_a(\phi)}F^{a,M_1M_2\ldots M_{n_a}})=0, \tag{3.6}$$

$a\in\Delta$, $\alpha=1,\ldots,l$.

In (3.4) the D-dimensional energy-momentum resulting from (3.1) is given by a sum

$$T_{MN}:=\sum_{\alpha=1}^{l}T_{MN}[\phi^\alpha,g]+\eta_a\sum_{a\in\Delta}e^{2\lambda_a(\phi)}T_{MN}[F^a,g], \tag{3.7}$$

of contributions from scalar and generalized Maxwell fields,

$$T_{MN}[\phi^\alpha,g]:=C_{\alpha\beta}\partial_M\phi^\alpha\partial_N\phi^\alpha-\tfrac{1}{2}g_{MN}\partial_P\phi^\alpha\partial^P\phi^\alpha, \tag{3.8}$$

$$T_{MN}[F^a,g]:=\frac{1}{n_a!}\left[-\frac{1}{2}g_{MN}(F^a)^2+n_aF^a_{MM_2\ldots M_{n_a}}F^a{}_N{}^{M_2\ldots M_{n_a}}\right]. \tag{3.9}$$

We give now a sufficient criterion for the energy-momentum tensor (3.7) to decompose multidimensionally.

Let $W_1:=\{i|i>0,\ d_i=1\}$ be the label set of 1-dimensional factor spaces of the multidimensional decomposition, and set $n_1:=|W_1|$. Define

$$W(a;i,j):=\{(I,J)|I,J\in\Omega_a,(I\cap J)\cup\{i\}=I\not\ni j,(I\cap J)\cup\{j\}=J\not\ni i\} \tag{3.10}$$

Then the following holds.

Theorem. If for $n_1>1$ the p-branes satisfy the condition for all $a\in\Delta,\ i,j\in W_1$ with $i\neq j$, the condition

$$W(a;i,j)\overset{!}{=}\emptyset\forall a\in\Delta\forall i,j\in W_1, \tag{3.11}$$

then the energy-momentum (3.7) decomposes multidimensionally without further constraints.

Proof: The only possible obstruction to the multidimensional decomposition of (3.7) comes from the second term of (3.9), $F^a{}_{MM_2\ldots M_{n_a}}F^a{}_N{}^{M_2\ldots M_{n_a}}$ when the indices M and N take values in different index sets labeling different 1-dimensional factor spaces. The theorem then follows just from the antisymmetry of the F-fields. □

Corollary: A sufficient condition for the multidimensional decomposition of (3.7) is

$$n_1\overset{!}{\leqslant}1. \tag{3.12}$$

If condition (3.11) does not hold, multidimensional decomposability of (3.7) may impose additional nontrivial constraints on the $p+2$-form fields.

Let us now specify the components of the F-fields of generalized electric and magnetic type.

Antisymmetric fields of generalized electric type, are given by scalar potential fields $\Phi^{a,I}$, $a\in\Delta,\ I\in\Omega_a$, which compose to a $(\Sigma_{a\in\Delta}|\Omega_a|)$-dimensional vector field Φ. Magnetic type fields are just given as the duals of appropriate electric ones.

$$F^{e,I}=d\Phi^{e,I}\wedge\tau(I), \tag{3.13}$$

$$F^{m,I}=e^{-2\lambda_a(\phi)}*(d\Phi^{m,I}\wedge\tau(J)). \tag{3.14}$$

In the Einstein frame, the action then reduces to

$$\begin{aligned}{}^{(\mathrm{E})}S[g^{(0)},\beta,\phi,\Phi]=\int_{M_0}d^{D_0}x\sqrt{|g^{(0)}|}\Bigg\{\frac{m}{2}\Bigg[&R[g^{(0)}]-G_{ij}(\partial\beta^i)(\partial\beta^j)-C_{\alpha\beta}(\partial\phi^\alpha)(\partial\phi^\beta)\\ &-\sum_{a\in\Delta,I\in\Omega_a}\varepsilon_{a,I}e^{2(\lambda_a(\phi)-d_i\beta^i)}(\partial\Phi^{a,I})^2\Bigg]-{}^{(\mathrm{E})}V(\beta)\Bigg\},\end{aligned} \tag{3.15}$$

which corresponds to an purely Einsteinian σ-model on M_0 with extended $(n+l+\Sigma_{a\in\Delta}|\Omega_a|)$-dimensional target space and dilatonic potential (2.37). Here and below we will consider by default the Einstein frame, and set correspondingly $G_{ij}:={}^{(\mathrm{E})}G_{ij}$. In (3.15) and below a summation convention is assumed also on the extended target space.

For convenience, let us introduce the topological numbers

$$l_{jI}:=-\sum_{i\in I} D_i\delta^i_j, \quad j=1,\ldots,n, \tag{3.16}$$

and with $N:=n+l$ define and define a $N\times|S|$-matrix

$$L=(L_{As})=\begin{pmatrix} L_{is} \\ L_{\alpha s}\end{pmatrix}:=\begin{pmatrix} l_{iI} \\ \lambda_{\alpha a}\end{pmatrix}, \tag{3.17}$$

a N-dimensional vector field $(\sigma^A):=(\beta^i,\phi^\alpha)$, $A=1,\ldots,n,n+1,\ldots,N$, composed by dilatonic and matter scalar fields, and a nondegenerate (block-diagonal) $N\times N$-matrix

$$\hat{G}=(\hat{G}_{AB})=\begin{pmatrix} G_{ij} & 0 \\ 0 & C_{\alpha\beta}\end{pmatrix}. \tag{3.18}$$

With these definitions, (3.15) takes the form

$$S_0=\int_{M_0} d^{D_0}x\sqrt{|g^{(0)}|}\left\{\frac{m}{2}\left[R[g^{(0)}]-\hat{G}_{AB}\partial\sigma^A\partial\sigma^B-\sum_{s\in S}\varepsilon_s e^{2L_{As}\sigma^A}(\partial\Phi^s)^2\right]-{}^{(\mathrm{E})}V(\sigma)\right\}. \tag{3.19}$$

IV. SOLUTION WITH ABELIAN TARGET-SPACE

In the this section we consider the σ-model (3.15) without the Φ fields from the $p+2$-forms, whence the target-space is the $n+l$-dimensional Abelian one, and present a particularly interesting vacuum solution.

We derive for $D_0\neq 2$ an new exact Ricci flat multidimensional solution for the effective σ-model (3.15) in the harmonic gauge $(2-D_0)\overline{\gamma}\overset{!}{=}d_i\beta^i$ with zero potential (2.37) and zero Φ. The field equation then read

$$G_{ij}\partial_\mu\beta^i\partial_\nu\beta^j+C_{\alpha\beta}\partial_\mu\phi^\alpha\partial_\nu\phi^\beta=0,\quad \mu,\nu=0,\ldots,D_0-1, \tag{4.1}$$

$${}^{(\mathrm{E})}G_{ij}\Delta[\overline{g^{(0)}}]\beta^j=0,\quad i=1,\ldots,n, \tag{4.2}$$

$$C_{\alpha\beta}\Delta[\overline{g^{(0)}}]\phi^\beta=0,\quad \alpha=1,\ldots,l. \tag{4.3}$$

In particular, we now solve these equations with flat $(\overline{M}_0,\overline{g^{(0)}})$. In this case, there exist g-harmonic $\overline{M}_0$-coordinates τ^μ, $\mu=0,\ldots,D_0-1$. Let $g^{(0)}=e^{-2\gamma}\eta_{\mu\nu}d\tau^\mu d\tau^\nu$. In such harmonic coordinates, Eqs. (4.2) and (4.3) are solved by

$$\beta^i=b^i_\mu\tau^\mu+c^i,\qquad i=1,\ldots,n, \tag{4.4}$$

$$\phi^\alpha=b^{n+\alpha}_\mu\tau^\mu+c^{n+\alpha},\qquad \alpha=1,\ldots,l. \tag{4.5}$$

We set

$$\varphi^i_\mu:=\frac{\partial}{\partial\tau^\mu}\varphi^i,\quad \mu=0,\ldots,D_0-1. \tag{4.6}$$

With (4.4), the harmonic gauge condition reads

$$A_\mu:={}^{(\mathrm{E})}q\varphi^1_\mu=\sum_i d_i b^i_\mu\overset{!}{=}0,\qquad \mu=0,\ldots,D_0-1. \tag{4.7}$$

With the harmonic gauge constraint (4.7), Eq. (4.1) then reads

$$\sum_{i=2}^{n} \varphi^i_\mu \varphi^i_\nu + \sum_{\alpha\beta=1}^{l} C_{\alpha\beta} b^\alpha_\mu b^\beta_\nu = \sum_{i=1}^{n} d_i b^i_\mu b^i_\nu + \sum_{\alpha\beta=1}^{l} C_{\alpha\beta} b^\alpha_\mu b^\beta_\nu \overset{!}{=} 0,$$

$$\mu,\nu = 0,\dots,D_0-1. \tag{4.8}$$

For convenience, one can set $c^A := 0$, $A=1,\dots,n+l$. Then $\gamma=0$, whence the harmonic coordinates are simultaneously proper coordinates, and the solution reads explicitly,

$$g = \eta_{\mu\nu} d\tau^\mu \otimes d\tau^\nu + \sum_{i=1}^{n} e^{2b^i_\lambda \tau^\lambda} g^{(i)}, \tag{4.9}$$

with linear coefficients b^i_μ, $i=1,\dots,n$, $\mu=0,\dots,D_0-1$, satisfying D_0 linear constraints (4.7) (the harmonic gauge) and ${D_0}^2$ quadratic constraints (4.8) (the harmonic Wheeler–de Witt constraints).

This solution shows a generalized inflationary behavior, which extends the familiar notion of inflation w.r.t. time, as in cosmology, to inflation w.r.t. the internal degrees of freedom on the D_0-dimensional world manifold of an extended object. The constraint (4.7) implies that the total $(D-D_0)$-dimensional volume remains constant (like in a steady state universe[16]) on the world manifold M_0, although here (unlike the stationary case[16]) individual factor spaces may undergo inflationary expansion or contraction in particular directions on M_0. In the standard cosmological case $D_0=1$, this solution agrees with the one described in Ref. 17.

V. ORTHOBRANE SOLUTIONS WITH $^{(E)}V=0$

Now we present a class of solutions with $^{(E)}V=0$, where the field equations read

$$R_{\mu\nu}[g^{(0)}] = \hat{G}_{AB} \partial_\mu \sigma^A \partial_\nu \sigma^B + \sum_{s\in S} \varepsilon_s e^{2L_{As}\sigma^A} \partial_\mu \Phi^s \partial_\nu \Phi^s, \quad \mu,\nu = 1,\dots,D_0, \tag{5.1}$$

$$\hat{G}_{AB} \Delta[g^{(0)}] \sigma^B - \sum_{s\in S} \varepsilon_s L_{As} e^{2L_{Cs}\sigma^C} (\partial \Phi^s)^2 = 0, \quad A=1,\dots,N, \tag{5.2}$$

$$\partial_\mu \left(\sqrt{|g^{(0)}|} g^{(0)\mu\nu} e^{2L_{As}\sigma^A} \partial_\nu \Phi^s \right) = 0, \quad s\in S. \tag{5.3}$$

For the Abelian part of the target space metric we set $(\hat{G}^{AB}) := (\hat{G}_{AB})^{-1}$.

$$\langle X, Y \rangle := X_A \hat{G}^{AB} X_B. \tag{5.4}$$

For $s\in S$ let us now consider vectors

$$L_s = (L_{As}) \in \mathbb{R}^N. \tag{5.5}$$

Definition. A non-empty set S is called an *orthobrane* index set, iff there exists a family of real nonzero coefficients $\{\nu_s\}_{s\in S}$, such that

$$\langle L_s, L_r \rangle = (L^T \hat{G}^{-1} L)_{sr} = -\varepsilon_s (\nu_s)^{-2} \delta_{sr}, \quad s,r \in S. \tag{5.6}$$

For $s\in S$ and $A=1,\dots,N$, we set

$$\alpha^A_s := -\varepsilon_s (\nu_s)^2 \hat{G}^{AB} L_{Bs}. \tag{5.7}$$

Here, (5.6) is just an orthogonality condition for the vectors L_s, $s\in S$. Note that $\langle L_s, L_s\rangle$ has just the opposite sign of ε_s, $s\in S$. With the definition above, we obtain an existence criterion for solutions.

Theorem: Let S be an orthobrane index set with coefficients (5.7). If for any $s\in S$ there is a function $H_s>0$ on M_0 such that

$$\Delta[g^{(0)}]H_s=0, \tag{5.8}$$

i.e., H_s is harmonic on M_0, then, the field configuration

$$R_{\mu\nu}[g^{(0)}]=0, \quad \mu,\nu=1,\ldots,D_0, \tag{5.9}$$

$$\sigma^A=\sum_{s\in S}\alpha_s^A \ln H_s, \quad A=1,\ldots,N, \tag{5.10}$$

$$\Phi^s=\frac{\nu_s}{H_s}, \quad s\in S, \tag{5.11}$$

satisfies the field equations (5.1)–(5.3). □

This theorem follows just from substitution of (5.6)–(5.11) into the equations of motion (5.1)–(5.3). From (3.18), (3.17), and (5.4) we get

$$\langle L_s, L_r\rangle=G^{ij}l_{iI}l_{jJ}+C^{\alpha\beta}\lambda_{\alpha a}\lambda_{\beta b}, \tag{5.12}$$

with $s=(a,I)$ and $r=(b,J)$ in S $(a,b\in\Delta,\ I\in\Omega_a,\ J\in\Omega_b)$. Here, the inverse of the dilatonic midisuperspace metric G_{ij} is given by

$$G^{ij}=\frac{\delta_{ij}}{D_i}+\frac{1}{2-D}, \tag{5.13}$$

whence, for $I,J\in\Omega$, with topological numbers l_{iI} from (3.16), we obtain

$$G^{ij}l_{iI}l_{jJ}=D(I\cap J)+\frac{D(I)D(J)}{2-D}, \tag{5.14}$$

which is again a purely topological number.

We set $\nu_{a,I}:=\nu_{(a,I)}$. Then, due to (5.12) and (5.14), the orthobrane condition (5.6) reads

$$D(I\cap J)+\frac{D(I)D(J)}{2-D}+C^{\alpha\beta}\lambda_{\alpha a}\lambda_{\beta b}=-\varepsilon(I)(\nu_{a,I})^{-2}\delta_{ab}\delta_{I,J}, \tag{5.15}$$

for $a,b\in\Delta$, $I\in\Omega_a$, $I\in\Omega_b$. With $(a,I)=s\in S$, the coefficients (5.7) are

$$\alpha_s^i=-\varepsilon(I)G^{ij}l_{jI}\nu_{a,I}^2=\varepsilon(I)\left(\sum_{j\in I}\delta_j^i+\frac{D(I)}{2-D}\right)\nu_{a,I}^2, \quad i=1,\ldots,n, \tag{5.16}$$

$$\alpha_s^\beta=-\varepsilon(I)C^{\beta\gamma}\lambda_{\gamma a}\nu_{a,I}^2, \quad \beta=1,\ldots,l. \tag{5.17}$$

With $(\sigma^A)=(\phi^i,\varphi^\beta)$, according to (5.10),

$$\beta^i=\sum_{s\in S}\alpha_s^i \ln H_s, \quad i=1,\ldots,n, \tag{5.18}$$

$$\phi^{\beta}=\sum_{s\in S}\alpha_s^{\beta}\ln H_s\,,\quad \beta=1,\ldots,l, \tag{5.19}$$

and the harmonic gauge reads

$$\gamma=\sum_{s\in S}\alpha_s^{0}\ln H_s\,, \tag{5.20}$$

where

$$\alpha_s^{0}:=\varepsilon(I)\frac{D(I)}{2-D}\nu_{a,I}^{2}\,. \tag{5.21}$$

With $H_{a,I}:=H_{(a,I)}$, (5.16), (5.17), and (5.21), the solution of (5.9)–(5.11) reads

$$\begin{aligned} g&=\left(\prod_{s\in S}H_s^{2\alpha_s^{0}}\right)g^{(0)}+\sum_{i=1}^{n}\left(\prod_{s\in S}H_s^{2\alpha_s^{i}}\right)g^{(i)}\\ &=\left(\prod_{(a,I)\in S}H_{a,I}^{\varepsilon(I)2D(I)\nu_{a,I}^{2}}\right)^{1/(2-D)}\left\{g^{(0)}+\sum_{i=1}^{n}\left(\prod_{(a,I)\in S,I\ni i}H_{a,I}^{\varepsilon(I)2\nu_{a,I}^{2}}\right)g^{(i)}\right\},\\ &\text{with}\ \mathrm{Ric}[g^{(0)}]=0,\ \ \mathrm{Ric}[g^{(i)}]=0,\ \ i=1,\ldots n, \end{aligned} \tag{5.22}$$

$$\phi^{\beta}=\sum_{s\in S}\alpha_s^{\beta}\ln H_s=-\sum_{(a,I)\in S}\varepsilon(I)C^{\beta\gamma}\lambda_{\gamma a}\nu_{a,I}^{2}\ln H_{a,I}\,,\quad \beta=1,\ldots,l, \tag{5.23}$$

$$A^{a}=\sum_{I\in\Omega_a}\frac{\nu_{a,I}}{H_{a,I}}\tau_I\,,\quad a\in\Delta, \tag{5.24}$$

where forms τ_I are defined in (2.18), parameters $\nu_s\neq0$ and λ_a satisfy the orthobrane condition (5.15), H_s are positive harmonic functions on M_0, and $\mathrm{Ric}[g^{(i)}]$ denotes the Ricci-tensor of $g^{(i)}$. Finally recall that these solutions are subject to the *orthobrane* constraints

$$D(I\cap J)+\frac{D(I)D(J)}{2-D}+C^{\alpha\beta}\lambda_{\alpha a}\lambda_{\beta b}=-\varepsilon(I)(\nu_{a,I})^{-2}\delta_{ab}\delta_{I,J}\,,\quad 0\neq\nu_{a,I}\in\mathbb{R}, \tag{5.25}$$

for $a,b\in\Delta,\ I\in\Omega_a,\ I\in\Omega_b$. These condition lead to specific intersection rules for the p-branes involved. Some concrete examples of *orthobrane* solutions have been elaborated in Ref. 18.

For positive definite $(C_{\alpha\beta})$ [or $(C^{\alpha\beta})$] and $D_0\geqslant2$, (5.25) implies

$$\varepsilon(I)=-1, \tag{5.26}$$

for all $I\in\Omega_a,\ a\in\Delta$. Then, the restriction $g_{|M_I}$ of the metric (5.22) to a membrane manifold M_I has an odd number of negative eigenvalues, i.e., linearly independent timelike directions. However, if the metric $(C_{\alpha\beta})$ in the space of scalar fields is not positive definite, then (5.26) may be violated for sufficiently negative $C^{\alpha\beta}\lambda_{\alpha a}\lambda_{\beta b}<0$.

VI. TARGET SPACE STRUCTURE

Theorem. The target space $(\mathfrak{M},\mathfrak{g})$ is a homogeneous space.

Proof. The Killing vectors of a transitive subgroup of Isom$(\mathfrak{M})$ can be determined explicitly

$$V_s:=\frac{\partial}{\partial\Phi^{s}},\quad s\in S,$$

$$U_A := \frac{\partial}{\partial x^A} - \sum_{s\in S} U_A^s \Phi^s \frac{\partial}{\partial \Phi^s}, \quad A=1,\ldots,N. \tag{6.1}$$

Moreover, the Lie-algebra of the transitive group of isometries generated by (6.1) reads

$$[U,U]=[V,V]=0$$

$$[U_A, V_s] = L_A^s V_s, \; A=1,\ldots,N, \quad s\in S. \tag{6.2}$$

Theorem: The target space $(\mathfrak{M},\mathfrak{g})$ is locally symmetric if and only if $\langle L^s, L^r\rangle_{\hat{G}}(L^s - L^r) = 0$.

Proof: Let $\mathfrak{R}iem$ denote the Riemann tensor of $(\mathfrak{M},\mathfrak{g})$. The latter is locally symmetric, if and only if

$$\nabla \mathfrak{R}iem = 0, \tag{6.3}$$

where ∇ denotes the covariant derivative w.r.t $\mathfrak{g}$. However, the only nontrivial equations (6.3) are

$$\nabla_p \mathfrak{R}_{srqA} = k_{psrq}\langle L^s, L^r\rangle_{\hat{G}}(L_A^r - L_A^s) = 0, \; A=1,\ldots,N, \quad p,q,r,s\in S \tag{6.4}$$

with $k_{psrq} := \varepsilon_s \varepsilon_r e^{2U^s + 2U^r}(\delta_{ps}\delta_{rq} + \delta_{pr}\delta_{sq})$ nonzero for fixed s,r.

VII. SCALAR PLUS p-BRANES WITH SPHERICAL SYMMETRY

Let us now examine static, spherically symmetric, multidimensional space-times with

$$M = M_{-1}\times M_0 \times M_1 \times \cdots \times M_N, \quad \dim M_i = d_i, i=0,\ldots,N, \tag{7.1}$$

where $M_{-1}\subset \mathbb{R}$ corresponds to a radial coordinate u, $M_0 = S^2$ is a 2-sphere, $M_1 \subset \mathbb{R}$ is time, and $M_i, i>1$ are internal factor spaces. The metric is assumed correspondingly to be

$$ds^2 = \mathrm{e}^{2\alpha(u)} du^2 + \sum_{i=0}^{N} \mathrm{e}^{2\beta_i(u)} ds_i^2 \equiv -\mathrm{e}^{2\gamma(u)} dt^2 + \mathrm{e}^{2\alpha(u)} du^2 + \mathrm{e}^{2\beta_0(u)} d\Omega^2 + \sum_{i=2}^{N} \mathrm{e}^{2\beta_i(u)} ds_i^2, \tag{7.2}$$

where $ds_0^2 \equiv d\Omega^2 = d\theta + \sin^2\theta d\phi^2$ is the line element on S^2, $ds_1^2 \equiv -dt^2$ with $\beta_1 =: \gamma$, and ds_i^2, $i>1$, are u-independent line elements of internal Ricci-flat spaces of arbitrary dimensions d_i and signatures ε_i.

For simplicity here let us only consider a single scalar field denoted as φ.

An electric-type $p+2$-form $F_{\mathrm{e}I}$ has a domain given by a product manifold

$$M_I = M_{i_1} \times \cdots \times M_{i_k}, \tag{7.3}$$

where

$$I = \{i_1, \ldots, i_k\} \subset I_0 \overset{\text{def}}{=} \{0,1,\ldots,N\}. \tag{7.4}$$

The corresponding dimensions are

$$d(I) \overset{\text{def}}{=} \sum_{i\in I} d_i, \quad d(I_0) = D-1. \tag{7.5}$$

A magnetic-type F-form of arbitrary rank k may be defined as a form on a domain $M_{\bar{I}}$ with $\bar{I} \overset{\text{def}}{=} I_0 - I$, dual to an electric-type form,

TABLE I. Different types of antisymmetric $p+2$-form fields.

E	Electric ($1\in I$)	$F_{tuA_3\ldots A_n}$	A_k (coordinate) index of M_I
M	Magnetic ($1\in I$)	$F_{\theta\phi B_3\ldots B_n}$	B_l (coordinate) index of M_I^-
EQ	Electric quasiscalar ($1\notin I$)	$F_{uA_2\ldots A_n}$	A_k (coordinate) index of M_I
MQ	Magnetic quasiscalar ($1\notin I$)	$F_{t\theta\phi B_4\ldots B_n}$	B_l (coordinate) index of M_I^-

$$F_{\mathrm{m}I,\,M_1\cdots M_k}=\mathrm{e}^{-2\lambda\varphi}(*F)_{\mathrm{e}I,\,M_1\cdots M_k}\equiv \mathrm{e}^{-2\lambda\varphi}\frac{\sqrt{g}}{k!}\varepsilon_{M_1\cdots M_kN_1\cdots N_{D-k}}F_{\mathrm{e}I}^{N_1\cdots N_{D-k}}, \tag{7.6}$$

where $*$ is the Hodge operator and ε is the totally antisymmetric Levi–Civita symbol.

For simplicity we now considering a just a single n-form, i.e., a single electric type and a single dual magnetic component, whence

$$\mathrm{rank}F_{\mathrm{m}I}=D-\mathrm{rank}F_{\mathrm{e}I}=d(\overline{I}), \tag{7.7}$$

whence $k=n$ in (7.6) and

$$d(I)=n-1 \text{ for } F_{\mathrm{e}I}, \quad d(I)=d(I_0)-n=D-n-1 \text{ for } F_{\mathrm{m}I}. \tag{7.8}$$

All fields must be compatible with spherical symmetry and staticity. Correspondingly, the vector φ of scalars and the $p+2$-forms valued fields depend (besides on their domain as forms) on the radial variable u only.

Furthermore, the domain of the electric form $F_{\mathrm{e}I}$ does not include the sphere $M_0=S^2$, and $F_{\mathrm{e}I}$ is specified by a u-dependent potential form,

$$F_{\mathrm{e}I,\,uL_2\cdots L_n}=\partial_{[u}U_{L_2\cdots L_n]}, \quad U=U_{L_2,\ldots,L_n}dx^{L_2}\wedge\cdots\wedge dx^{L_n}. \tag{7.9}$$

Since the time manifold M_1 is a factor space of M_I, the form (7.9) describes an electric $(n-2)$-brane in the remaining subspace of M_I. Similarly (7.6) describes a magnetic $(D-n-2)$-brane in M_I.

Let us label all nontrivial components of F by a collective index $s=(I_s,\chi_s)$, where $I=I_s\subset I_0$ characterizes the subspace of M as described above and $\chi_s=\pm 1$ according to the rule

$$\mathrm{e}\mapsto\chi_s=+1, \quad \mathrm{m}\mapsto\chi_s=-1. \tag{7.10}$$

If $1\in I$, the corresponding p-brane evolves with t and we have a true electric or magnetic field, otherwise the potential (7.9) does not depend on $\overline{M}_0$, i.e., it is just a scalar in four dimensions. In this case we call the corresponding electric-type F component (7.9) *electric quasiscalar* and its dual, magnetic-type, F component (7.6) *magnetic quasiscalar*. So there are in general four types of F-field components (summarized in Table I): electric (E), magnetic (M), electric quasiscalar (EQ), magnetic quasiscalar (MQ). The choice of subsets I_s is only constrained by the multidimensional decomposition condition 3.11 for the energy-momentum tensor. Since antisymmetric $p+2$-form field components of type E and M (and type EQ and MQ, respectively) just complement each other, they should be considered as independent of each other. In the following we consider all F_s as independent fields (up to index permutations) each with a single nonzero component.

Let us assume Ricci-flat internal spaces. With spherical symmetry and staticity all field become independent of M_0 and M_0, respectively. And the variation reduces further from $\overline{M}_0$ to the radial manifold M_{-1}.

The reparametrization gauge on the lower dimensional manifold here is chosen as the (generalized) harmonic one.[13] Since M_{-1} is one-dimensional u is a harmonic coordinate, $\Box u=0$, such that

$$\alpha(u)=\sigma_0(u). \tag{7.11}$$

The nonzero Ricci tensor components are

$$e^{2\alpha}R^t_t = -\gamma'',$$

$$e^{2\alpha}R^u_u = -\alpha'' + \alpha'^2 - \gamma'^2 - 2\beta'^2 - \sum_{i=2}^{N} d_i \beta_i'^2,$$

$$e^{2\alpha}R^\theta_\theta = e^{2\alpha}R^\phi_\phi = e^{2\alpha-2\beta} - \beta'',$$

$$e^{2\alpha}R^{b_i}_{a_j} = -\delta^{b_i}_{a_j}\beta_i'' \quad (i,j=1,\dots,N), \tag{7.12}$$

where a prime denotes d/du and the indices a_i, b_i belong to the ith internal factor space. The Einstein tensor component G^1_1 does not contain second-order derivatives:

$$e^{2\alpha}G^1_1 = -e^{2\alpha-2\beta} + \frac{1}{2}\alpha'^2 - \frac{1}{2}\left(\gamma'^2 + 2\beta'^2 + \sum_{i=2}^{N} d_i \beta_i'^2\right). \tag{7.13}$$

The corresponding component of the Einstein equations is an integral of other components, similar to the energy integral in cosmology.

The generalized Maxwell equations give

$$F^{uM_2\dots M_n}_{eI} = Q_{eI} e^{-2\alpha-2\lambda\varphi}, \quad Q_{eI} = \text{const}, \tag{7.14}$$

$$F_{mI,\, uM_1\dots M_{d(\bar I)}} = Q_{mI}\sqrt{|g_{\bar I}|}, \quad Q_{mI} = \text{const}, \tag{7.15}$$

where $|g_{\bar I}|$ is the determinant of the u-independent part of the metric of $M_{\bar I}$ and Q_s are charges. These solutions provide then the energy momentum tensors, of the electric and magnetic $p+2$-forms written in matrix form,

$$e^{2\alpha}(T^N_M[F_{eI}]) = -\tfrac{1}{2}\eta_F \varepsilon(I) Q^2_{eI} e^{2y_{eI}} \text{diag}(+1,[1]_I,[-1]_{\bar I}),$$

$$e^{2\alpha}(T^N_M[F_{mI}]) = \tfrac{1}{2}\eta_F \varepsilon(\bar I) Q^2_{mI} e^{2y_{mI}} \text{diag}(1,[1]_I,[-1]_{\bar I}), \tag{7.16}$$

where the first position belongs to u and f operating over M_J is denoted by $[f]_J$. The functions $y_s(u)$ are

$$y_s(u) = \sigma(I_s) - \chi_s \lambda \varphi. \tag{7.17}$$

The scalar field EMT is

$$e^{2\alpha}T^N_M[\varphi] = \tfrac{1}{2}(\varphi^a)'^2 \text{diag}(+1,[-1]_{I_0}). \tag{7.18}$$

The sets $I_s \in I_0$ may be classified by types E, M, EQ, MQ according to the description in the preceding section. Denoting I_s for the respective types by I_E, I_M, I_{EQ}, I_{MQ}, we see from (7.16) that, positive electric and magnetic energy densities require

$$\eta_f = -\varepsilon(I_E) = \varepsilon(\overline{I_M}) = \varepsilon(I_{EQ}) = -\varepsilon(\overline{I_{MQ}}). \tag{7.19}$$

If t is the only time coordinate, (7.19) with $\eta_F = 1$ holds for any choices of I_s. If there exist other times, then the relations (7.19) constrain the subspaces where the different F components may be specified.

Since the total EMT on the r.h.s. of the Einstein equations has the property

$$T_u^u + T_\theta^\theta = 0, \tag{7.20}$$

the corresponding combination on the lhs becomes an integrable Liouville form

$$G_u^u + G_\theta^\theta = \mathrm{e}^{-2\alpha}[-\alpha'' + \beta_0'' + \mathrm{e}^{2\alpha - 2\beta_0}] = 0,$$

$$\mathrm{e}^{\beta_0 - \alpha} = s(k,u), \tag{7.21}$$

where k is an integration constant (IC) and the function $s(k,.)$ is defined as follows:

$$s(k,u) \overset{\text{def}}{=} \begin{cases} k^{-1}\sinh ku, & k>0 \\ u, & k=0 \\ k^{-1}\sin ku, & k<0. \end{cases} \tag{7.22}$$

Another IC is suppressed by adjusting the origin of the u coordinate.

With (7.21) the D-dimensional line element may be written in the form

$$ds^2 = \frac{\mathrm{e}^{-2\sigma_1}}{s^2(k,u)}\left[\frac{du^2}{s^2(k,u)} + d\Omega^2\right] + \sum_{i=1}^{N} \mathrm{e}^{2\beta_i} ds_i^2 \tag{7.23}$$

where σ_1 has been defined in (2.10).

Let us treat the whole set of unknowns $\beta_i(u), \varphi(u)$ as a real-valued vector function $x(u)$ in an $(N+1)$-dimensional vector space V, with components $x^A = \beta_A$ for $A = 1,\ldots,N$ and $x^{N+1} = \varphi$.

Then the field equations for β_i and φ coincide with the equations of motion corresponding to the Lagrangian of a Euclidean Toda-type system

$$L = \bar{G}_{AB} x'^A x'^B - V_Q(y), \quad V_Q(y) = \sum_s \theta_s Q_s^2 \mathrm{e}^{2y_s}, \tag{7.24}$$

where, according to (7.19), $\theta_s = 1$ if F_s is a true electric or magnetic field and $\theta_s = -1$ if F_s is quasiscalar. The nondegenerate, symmetric matrix

$$(\bar{G}_{AB}) = \begin{pmatrix} G_{ij} & 0 \\ 0 & 1 \end{pmatrix}, \quad G_{ij} = d_i d_j + d_i \delta_{ij} \tag{7.25}$$

defines a positive-definite metric in V. The energy constraint corresponding to (7.24) is

$$E = \sigma_1'^2 + \sum_{i=1}^{N} d_i \beta_i'^2 + \varphi'^2 + V_Q(y) = \bar{G}_{AB} x'^A x'^B + V_Q(y) = 2k^2 \mathrm{sign} k, \tag{7.26}$$

with k from (7.21). The integral (7.26) follows here from the (uu)-component of (3.4).

The functions $y_s(u)$ (7.17) can be represented as scalar products in V (recall that $s = (I_s, \chi_s)$):

$$y_s(u) = Y_{s,A} x^A, \quad (Y_{s,A}) = (d_i \delta_{iI_s}, -\chi_s \lambda), \tag{7.27}$$

where $\delta_{iI} := \Sigma_{j\in I} \delta_{ij}$ is an indicator for i belonging to I (1 if $i \in I$ and 0 otherwise).

The contravariant components of Y_s are found using the matrix $\bar{G}^{AB}$ inverse to $\bar{G}_{AB}$:

$$(\bar{G}^{AB}) = \begin{pmatrix} G^{ij} & 0 \\ 0 & 1 \end{pmatrix}, \quad G^{ij} = \frac{\delta^{ij}}{d_i} - \frac{1}{D-2} \tag{7.28}$$

$$(Y_s{}^A) = \left(\delta_{iI_s} - \frac{d(I_s)}{D-2}, -\chi_s \lambda \right), \tag{7.29}$$

and the scalar products of different Y_s, whose values are of primary importance for the integrability of our system, are

$$Y_{s,A} Y_{s'}{}^A = d(I_s \cap I_{s'}) - \frac{d(I_s) d(I_{s'})}{D-2} + \chi_s \chi_{s'} \lambda^2. \tag{7.30}$$

VIII. PURELY EM BLACK HOLE SOLUTIONS

In Ref. 19 it was shown that quasiscalar components of the F-fields are incompatible with orthobrane black holes. Therefore let us now consider only two F-field components, Type E and Type M according to the classification above. They will be electric as $F_{\rm e}$ and $F_{\rm m}$ and the corresponding sets $I_s \subset I_0$ as $I_{\rm e}$ and $I_{\rm m}$. Then a minimal configuration (7.1) of the manifold M compatible with an arbitrary choice of I_s has the following form:

$$N=5, \ I_0 = \{0,1,2,3,4,5\}, \quad I_e = \{1,2,3\}, \quad I_m = \{1,2,4\}, \tag{8.1}$$

so that

$$(I_0) = D-1, \ d(I_{\rm e}) = n-1, \ d(I_{\rm m}) = D-n-1, \ d(I_{\rm e} \cap I_{\rm m}) = 1 + d_2;$$

$$d_1 = 1, \ d_2 + d_3 = d_3 + d_5 = n-2. \tag{8.2}$$

The relations (8.2) show that, given D and d_2, all d_i are known.

This corresponds to an electric $(n-2)$-brane located on the subspace $M_2 \times M_3$ and a magnetic $(D-n-2)$-brane on the subspace $M_2 \times M_4$. Their intersection dimension $d_{\rm int} = d_2$ turns out to determine qualitative properties of the solutions.

The index s now takes the two values e and m and

$$Y_{{\rm e},A} = (1, d_2, d_3, 0, 0, -\lambda),$$

$$Y_{{\rm m},A} = (1, d_2, 0, d_4, 0, \lambda),$$

$$Y_{\rm e}^A = (1,1,1,0,0,-\lambda) - \frac{n-1}{D-2}(1,1,1,1,1,0),$$

$$Y_{\rm m}^A = (1,1,0,1,0,\lambda) - \frac{D-n-1}{D-2}(1,1,1,1,1,0), \tag{8.3}$$

where the last component of each vector refers to $x^{N+1} = x^6 = \varphi$.

In the solutions presented below the set of ICs will be reduced by the condition that the space-time be asymptotically flat at spatial infinity $(u=0)$ and by a choice of scales in the relevant directions. Namely, we put

$$\beta_i(0) = 0 = \varphi(0), \quad i = 1,2,3,4,5. \tag{8.4}$$

The requirement $\varphi(0)=0$ is convenient and may be always satisfied by a redefinition of the charges. The conditions $\beta_i(0)=0$ $(i>1)$ mean that the real scales of the extra dimensions are hidden in the internal metrics ds_i^2 independent of whether or not they are assumed to be compact.

In the following, both cases, orthobrane solutions and solutions with degenerate charges, are considered first generally and then for the minimal configuration (8.1)–(8.4).

A. Orthobrane black hole solutions

Assuming that the vectors Y_s are mutually orthogonal with respect to the metric $\overline{G_{AB}}$, i.e.,

$$Y_{s,A}Y_{s'}{}^{A}=\delta_{ss'}N_s^2, \tag{8.5}$$

the number of functions y_s does not exceed the number of equations, and the system becomes integrable. Due to (7.8), the norms N_s are actually s-independent:

$$N_s^2=d(I_s)\left[1-\frac{d(I_s)}{D-2}\right]+\lambda^2=\frac{(n-1)(D-n-1)}{D-2}+\lambda^2\stackrel{\text{def}}{=}\frac{1}{\nu}, \tag{8.6}$$

$\nu>0$.

Due to (8.5), the functions $y_s(u)$ obey the decoupled equations

$$y_s''=\theta_s\frac{Q_s^2}{\nu}e^{2y_s}, \tag{8.7}$$

whence

$$e^{-y_s(u)}=\begin{cases}(|Q_s|/\sqrt{\nu})s(h_s,u+u_s), & \theta=+1,\\ [|Q_s|/(\sqrt{\nu}h_s)]\cosh[h_s(u+u_s)], & h_s>0,\quad \theta=-1.\end{cases} \tag{8.8}$$

where h_s and u_s are ICs and the function s was defined in (7.22). For the functions $x^A(u)$ we obtain:

$$x^A(u)=\nu\sum_s Y_s{}^{A}y_s(u)+c^Au+\overline{c^A}, \tag{8.9}$$

where the vectors of ICs c^A and $\overline{c^A}$ satisfy the orthogonality relations $c^AY_{s,A}=\overline{c^A}Y_{s,A}=0$, or

$$c^id_i\delta_{iI_s}-\lambda c^{N+1}\chi_s=0,\quad \overline{c^i}d_i\delta_{iI_s}-\lambda\overline{c^{N+1}}\chi_s=0. \tag{8.10}$$

Specifically, the logarithms of the scale factors β_i and the scalar field φ are

$$\beta_i(u)=\nu\sum_s\left[\delta_{iI_s}-\frac{d(I_s)}{D-2}\right]y_s(u)+c^iu+\overline{c^i}, \tag{8.11}$$

$$\varphi(u)=-\lambda\nu\sum_s y_s(u)+c^{N+1}u+\overline{c^{N+1}}, \tag{8.12}$$

and the function σ_1 which appears in the metric (7.23) is

$$\sigma_1=-\frac{\nu}{D-2}\sum_s d(I_s)\,y_s(u)+c^0u+\overline{c^0} \tag{8.13}$$

with

$$c^0=\sum_{i=1}^N d_ic^i,\quad \overline{c^0}=\sum_{i=1}^N d_i\overline{c^i}. \tag{8.14}$$

Finally, (7.26) now reads

TABLE II. Orthobrane solutions with $\lambda=0$.

	n	$d(I_e)$	$d(I_m)$	d_2	B	C
$D=4m+2$ ($m\in\mathbb{N}$)	2m+1	2m	2m	m−1	1/m	1/m
D= 11	4	3	6	1	2/3	1/3
	7	6	3	1	1/3	2/3

$$E=\nu\sum_s h_s^2\mathrm{sign}h_s+\overline{G}_{AB}c^Ac^B=2k^2\mathrm{sign}k. \tag{8.15}$$

The relations (7.11), (7.14), (7.15), (7.21), (7.23), (8.8)–(8.15), along with the definitions (7.22) and (8.6) and the restriction (8.5), entirely determine the general solution.

For the minimal configuration (8.1)–(8.4), the orthogonality condition (8.5) reads

$$\lambda^2=d_2+1-\frac{1}{D-2}(n-1)(D-n-1). \tag{8.16}$$

In particular, in dilaton gravity $n=2,d_2=0$ and the integrability condition (8.16) just reads $\lambda^2=1/(D-2)$, which is a well-known relation of string gravity. The familiar Reissner-Nordström solution, $D=4,n=2$, $\lambda=0$, $d_2=0$ does *not* satisfy Eq. (8.16). (It will be recovered indeed as a degenerate case below.) Some examples of configurations satisfying the orthogonality condition (8.16) in the purely topological case $\lambda=0$ are summarized in Table II [including the values of the constants B and C from (8.28)]. In this case (8.16) is just a Diophantus equation for D, n and d_2.

The solution is entirely determined by inserting (8.3) into (8.9) with $\overline{c^A}=0$ due to (8.4),

$$x^A(u)=\nu\sum_s Y_s{}^A y_s(u)+c^Au;\quad \mathrm{e}^{-y_s(u)}=(|Q_s|/\sqrt{\nu})s(h_s,u+u_s). \tag{8.17}$$

Due to (8.16) the parameter ν is

$$\nu=1/\sqrt{1+d_2}. \tag{8.18}$$

The constants are connected by the relations

$$(|Q_{\mathrm{e,m}}|/\nu)\,s(h_{\mathrm{e,m}},u_{\mathrm{e,m}})=1;$$

$$c^1+d_2c^2+d_3c^3-\lambda c^6=0;\quad c^1+d_2c^2+d_4c^4+\lambda c^6=0;$$

$$\frac{h_{\mathrm{e}}^2\mathrm{sign}h_{\mathrm{e}}+h_{\mathrm{m}}^2\mathrm{sign}h_{\mathrm{m}}}{1+d_2}+G_{ij}c^ic^j+(c^6)^2=2k^2\mathrm{sign}k, \tag{8.19}$$

where the matrix G_{ij} is given in (7.25) and all $\overline{c^A}=0$ due to the boundary conditions (8.4). The fields φ and F are given by Eqs. (7.14), (7.15), (8.12).

This solution contains 8 nontrivial, independent ICs, namely, $Q_{\mathrm{e}},Q_{\mathrm{m}},h_{\mathrm{e}},h_{\mathrm{m}}$ and 4 others from the set c^A constrained by (8.19).

For black holes, we require that all $|\beta_i|<\infty$, $i=2,\dots,N$ (regularity of extra dimensions), $|\varphi|<\infty$ (regularity of the scalar field) and $|\beta_0|<\infty$ (finiteness of the spherical radius) as $u\to\infty$. With $y_s(u)\sim -h_su$, this leads to the following constraints on the ICs:

$$c^A=-k\sum_s(\delta_{1I_s}+\nu Y_s{}^A h_s), \tag{8.20}$$

where $A=1$ corresponds to $i=1$. Via orthonormality relations (8.10) for c^A, we obtain

$$h_s = k\delta_{1I_s}, \tag{8.21}$$

$$c^A = -k\delta_1^A + k\nu \sum_s \delta_{1I_s} Y_s{}^A, \tag{8.22}$$

and (8.15) then holds automatically.

Let us now consider the case where (8.21) and (8.22) with $\delta_{1I_s}=1$ hold. After a transformation $u \mapsto R$, to isotropic coordinates given by the relation

$$\mathrm{e}^{-2ku} = 1 - 2k/R, \tag{8.23}$$

we obtain

$$ds^2 = -\frac{1-2k/R}{P_\mathrm{e}^B P_\mathrm{m}^C} dt^2 + P_\mathrm{e}^C P_m^B \left(\frac{dR^2}{1-2k/R} + R^2 d\Omega^2 \right) + \sum_{i=2}^{5} \mathrm{e}^{2\beta_i(u)} ds_i^2, \tag{8.24}$$

$$\mathrm{e}^{2\beta_2} = P_\mathrm{e}{}^{-B} P_\mathrm{m}{}^{-C}, \quad \mathrm{e}^{2\beta_3} = (P_\mathrm{m}/P_\mathrm{e})^B,$$

$$\mathrm{e}^{2\beta_4} = (P_\mathrm{e}/P_\mathrm{m})^C, \quad \mathrm{e}^{2\beta_5} = P_\mathrm{e}{}^C P_\mathrm{m}{}^B, \tag{8.25}$$

$$e^{2\lambda\varphi} = (P_\mathrm{e}/P_\mathrm{m})^{2\lambda^2/(1+d_2)}, \tag{8.26}$$

$$F_{01M_3\ldots M_n} = -Q_\mathrm{e}/(R^2 P_\mathrm{e}), \quad F_{23M_3\ldots M_n} = Q_\mathrm{m} \sin\theta, \tag{8.27}$$

with the notations

$$P_\mathrm{e,m} = 1 + p_\mathrm{e,m}/R, \quad p_\mathrm{e,m} = \sqrt{k^2 + (1+d_2) Q_\mathrm{e,m}^2} - k;$$

$$B = \frac{2(D-n-1)}{(D-2)(1+d_2)}, \quad C = \frac{2(n-1)}{(D-2)(1+d_2)}. \tag{8.28}$$

The BH gravitational mass as determined from a comparison of (8.24) with the Schwarzschild metric for $R \to \infty$ is

$$G_N M = k + \tfrac{1}{2}(B p_\mathrm{e} + C p_\mathrm{m}), \tag{8.29}$$

where G_N is the Newtonian gravitational constant. This expression, due to $k>0$, provides a restriction upon the charge combination for a given mass, namely,

$$B|Q_\mathrm{e}| + C|Q_\mathrm{m}| < 2G_N M/\sqrt{1+d_2}. \tag{8.30}$$

The inequality is replaced by equality in the extreme limit $k=0$. For $k=0$ our BH turns into a naked singularity (at the center $R=0$) for any $d_2>0$, while for $d_2=0$ the zero value of R is not a center ($g_{22}\neq 0$) but a horizon. In the latter case, if $|Q_\mathrm{e}|$ and $|Q_\mathrm{m}|$ are different, the remaining extra-dimensional scale factors are smooth functions for all $R \geqslant 0$.

For a static, spherical BH one can define a Hawking temperature $T_H := \kappa/2\pi$ as given by the surface gravity κ. With a generalized Komar integral (see e.g., Ref. 20)

$$M(r) := -\frac{1}{8\pi} \int_{S_r} * d\xi \tag{8.31}$$

over the timelike Killing form ξ, the surface gravity can be evaluated as

$$\kappa = M(r_H)/(r_H)^2 = (\sqrt{|g_{00}|})'/\sqrt{g_{11}}|_{r=r_H} = e^{\gamma-\alpha}|\gamma'||_{r=r_H}, \tag{8.32}$$

where a prime, α, and γ are understood in the sense of the general metric (7.2) and k_B is the Boltzmann constant. The expression (8.32) is invariant with respect to radial coordinate reparametrization, as is necessary for any quantity having a direct physical meaning. It is also invariant under conformal mappings with a conformal factor which is smooth at the horizon.

Substituting g_{00} and g_{11} from (8.24), one obtains

$$T_H = \frac{1}{2\pi k_B}\frac{1}{4k}\left[\frac{4k^2}{(2k+p_e)(2k+p_m)}\right]^{1/(d_2+1)}. \tag{8.33}$$

If $d_2=0$ and both charges are nonzero, this temperature tends to zero in the extreme limit $k \to 0$; if $d_2=1$ and both charges are nonzero, it tends to a finite limit, and in all other cases it tends to infinity. Remarkably, it is determined by the p-brane intersection dimension d_2 rather than the whole space-time dimension D.

B. The solution for $Q_e^2 = Q_m^2$

In this degenerate case, solutions can be found which need not satisfy the orthobrane condition (8.5). Let us suppose that two functions (7.17), say, y_1 and y_2, coincide up to an addition of a constant (which may be then absorbed by re-defining a charge Q_1 or Q_2) while corresponding vectors Y_1 and Y_2 are neither coinciding, nor orthogonal (otherwise we would have the previously considered situation). Substituting $y_1 \equiv y_2$ into (7.27), one obtains

$$(Y_{1,A} - Y_{2,A})x^A = 0. \tag{8.34}$$

This is a constraint reducing the number of independent unknowns x^A. Furthermore, substituting (8.34) to the Lagrange equations for x^A,

$$-(Y_{1,A} - Y_{2,A})x''^A = \sum_s \theta_s Q_s^2 e^{2y_s} Y_s^A (Y_{1,A} - Y_{2,A}) = 0. \tag{8.35}$$

In this sum all coefficients of different functions e^{2y_s} must be zero. This yields new orthogonality conditions

$$Y_s^A(Y_{1,A} - Y_{2,A}) = 0, \quad s \neq 1,2, \tag{8.36}$$

now for the difference $Y_1 - Y_2$ and other Y_s, and with Eq. (8.6) the relation

$$(\nu^{-1} - Y_1^A Y_{2,A})(\theta_1 Q_1^2 - \theta_2 Q_2^2) = 0. \tag{8.37}$$

The first multiplier in (8.37) is positive ($\overline{G}_{AB}$ is positive-definite, hence a scalar product of two different vectors with equal norms is smaller than their norm squared). Therefore

$$\theta_1 = \theta_2, \quad Q_1^2 = Q_2^2. \tag{8.38}$$

Imposing the constraints (8.34), (8.36), (8.38), reduces the numbers of unknowns and integration constants, and simultaneously also reduces the number of restrictions on the input parameters [by the orthogonality conditions (8.5)]. Due to (8.38), this is only possible when the two components with coinciding charges are of equal nature: both must be either true electric/magnetic ones ($\theta_s = 1$), or quasiscalar ones ($\theta_s = -1$). Correspondingly, we now set $y(u) := y_e = y_m$ and $Q^2 := Q_e^2 = Q_m^2$.

For the minimal configuration (8.1)–(8.3), Eq. (8.34) yields

$$d_3\beta_3 - d_4\beta_4 - 2\lambda\varphi = 0. \tag{8.39}$$

Equations (8.36) are irrelevant here since we are dealing with two functions y_s only. The equations of motion for x^A now take the form

$$x^{A''}=Q^2 e^{2y}(Y^A_e+Y^A_m). \tag{8.40}$$

Their proper combination gives $y''=(1+d_2)Q^2e^{2y}$, whence

$$e^{-y}=\sqrt{(1+d_2)Q^2}s(h,u+u_1), \tag{8.41}$$

where the function s is defined in (7.22) and h,u_1 are ICs and, due to (8.4),$\sqrt{(1+d_2)Q^2}s(h,u_1)=1$. Other unknowns are easily determined using (8.40) and (8.4):

$$x^A=\nu Y^A y+c^A;\quad Y^A=Y^A_e+Y^A_m=(1,1,0,0,-1,0); \tag{8.42}$$

$$\sigma_1=-\nu y+c_0 u.$$

Here, as in (8.18), $\nu=1/(1+d_2)$, but it is now just a notation. The constants $c_0,h,c^A(A=1,\ldots,6)$ and k [see (7.21)] are related by

$$-c^0+\sum_{i=1}^{5} d_i c^i=0,\quad c^1+d_2c^2+d_3c^3-\lambda c^6=0,\quad c^1+d_2c^2+d_4c^4+\lambda c^6=0,$$

$$2k^2\text{sign}k=\frac{2h^2\text{sign}h}{1+d_2}(c^0)^2+\sum_{i=1}^{5} d_i(c^i)^2+(c^6)^2. \tag{8.43}$$

Extra-dimensional scale factors remain finite as $u\to u_{\max}$ in the case of a BH. It is specified by the following values of the ICs:

$$k=h>0,\quad c^3=c^4=c^6=0,\quad c_2=-c_5=-\frac{k}{1+d_2},\quad c_0=c^1=-\frac{d_2k}{1+d_2}. \tag{8.44}$$

The event horizon occurs at $u=\infty$. After the same transformation (8.23) the metric takes the form

$$ds^2_D=-\frac{1-2k/R}{(1+p/R)^{2\nu}}dt^2+(1+p/R)^{2\nu}\left(\frac{dR^2}{1-2k/R}+R^2d\Omega^2\right)$$
$$+(1+p/R)^{-2\nu}ds_2^2+ds_3^2+ds_4^2+(1+p/R)^{2\nu}ds_5^2 \tag{8.45}$$

with the notation

$$p=\sqrt{k^2+(1+d_2)Q^2}-k. \tag{8.46}$$

The fields φ and F are determined by the relations

$$\varphi\equiv 0,\quad F_{01L_3\cdots L_n}=-\frac{Q}{R^2(1+p/R)},\quad F_{23L_3\cdots L_n}=Q\sin\theta. \tag{8.47}$$

$$G_N M=k+p/(1+d_2), \tag{8.48}$$

The Hawking temperature can be calculated as before,

$$T=\frac{1}{2\pi k_B}\frac{1}{4k}\left(\frac{2k}{2k+p}\right)^{2/(d_2+1)}. \tag{8.49}$$

The well-known results for the Reissner–Nordström metric are recovered when $d_2=0$. In this case $T\to 0$ in the extreme limit $k\to 0$. For $d_2=1$, T tends to a finite limit as $k\to 0$ and for $d_2>1$ it tends to infinity. As is the case with two different charges, T does not depend on the space-time dimension D, but depends on the p-brane intersection dimension d_2.

IX. THE EINSTEIN FRAME FOR DYNAMICS AND COSMOLOGY

In this final section we discuss the issue of the physical frame for the particularly important case $D_0=4$. First of all, in this case a selfdual canonical formulation of dynamics is at hand, due to the particular spinor decomposition $\mathrm{so}(1,3)=\mathrm{su}(2)\oplus\mathrm{su}(2)$ of the tangent Lorentz symmetry. In the Einstein frame, the effective σ-model with $D_0=4$ admits in principle a canonical quantization of the geometry on $\overline{M}_0=\mathbb{R}\times M_0$ to the same extend and under the same assumptions as pure Einstein gravity does.

Since for a multidimensional geometry as defined above the imprint of the internal factor spaces is only by their scale factors, configuration space and phase space of such geometries will only be extended by finite a finite number of dilatonic midisuperspace fields. However, only in the Einstein frame the coupling of the dilatonic fields to the $\overline{D}_0$-geometry will be minimal such that the quantization of the latter can be executed practically independently.

Let us denote the external space-time metric $\overline{g^{(0)}}$ in the Brans–Dicke frame with $\overline{\gamma}\overset{!}{=}0$ as $\overline{g^{(\mathrm{BD})}}$ and in the Einstein frame with $f\overset{!}{=}0$ as $\overline{g^{(\mathrm{E})}}$. It can be easily seen that they are connected with each other by a conformal transformation

$$\overline{g^{(\mathrm{E})}}\mapsto\overline{g^{(\mathrm{BD})}}=\Omega^2\overline{g^{(\mathrm{E})}} \tag{9.1}$$

with Ω from (2.39).

In particular, also for spatially homogeneous cosmological models (and with $t\leftrightarrow u$ for spherically symmetric static models) solutions have to be transformed to the Einstein frame before a physical interpretation can be given.

Under any projection $\mathrm{pr}_0:\overline{M_0}\to\mathbb{R}$ a consistent pullback of the metric $-e^{2\gamma(\tau)}d\tau\otimes d\tau$ from $\tau\in\mathbb{R}$ to $x\in\mathrm{pr}_0^{-1}\{\tau\}\subset\overline{M}_0$ is given by

$$\overline{g^{(\mathrm{BD})}}(x):=-e^{2\gamma(\tau)}d\tau\otimes d\tau+e^{2\beta^0(x)}g^{(0)}. \tag{9.2}$$

In particular, for spatially (metrically-)homogeneous cosmological models all scale factors $a_i:=e^{\beta^i}$, $i=0,\dots,n$, depend only on $\tau\in\mathbb{R}$.

With (9.2) and (9.1), Eq. (2.6) reads

$$\begin{aligned} g&=-e^{2\gamma(\tau)}d\tau\otimes d\tau+a_0^2g^{(0)}+\sum_{i=1}^{n}e^{2\beta^i}g^{(i)}\\ &=-dt_{\mathrm{BD}}\otimes dt_{\mathrm{BD}}+a_{\mathrm{BD}}^2g^{(0)}+\sum_{i=1}^{n}e^{2\beta^i}g^{(i)}\\ &=-\Omega^2dt_{\mathrm{E}}\otimes dt_{\mathrm{E}}+\Omega^2a_{\mathrm{E}}^2g^{(0)}+\sum_{i=1}^{n}e^{2\beta^i}g^{(i)}, \end{aligned} \tag{9.3}$$

where $a_0:=a_{\mathrm{BD}}$ and a_{E} are the external space scale factor functions depending respectively on the cosmic synchronous time t_{BD} and t_{E} in the Brans–Dicke and Einstein frame. With (2.39) the latter is related to the former by

$$a_{\mathrm{E}}=\Omega^{-1}a_{\mathrm{BD}}=\left(\prod_{i=1}^{n} e^{d_i\beta^i}\right)^{\frac{1}{D_0-2}} a_{\mathrm{BD}}, \tag{9.4}$$

and the cosmic time of the Einstein frame is given by

$$\pm dt_{\mathrm{E}}=\Omega^{-1}e^{\gamma}d\tau=\left(\prod_{i=1}^{n} e^{d_i\beta^i}\right)^{\frac{1}{D_0-2}} dt_{\mathrm{BD}}. \tag{9.5}$$

Since $a_{\mathrm{BD}}^2(d\eta_{\mathrm{BD}})^2=\Omega^2 a_{\mathrm{E}}^2(d\eta_{\mathrm{E}})^2$, the conformal times of the Einstein and the Brans–Dicke frame agree (up to time reversal). This has sometimes guided authors to compare the frames in conformal time (see e.g., Ref. 21). However (at least for cosmology) the physical relevant time is the cosmic synchronous time, which is different for different frames, in particular for the Einstein and Brans–Dicke frame.

In Ref. 22 several reasons have been listed why minimal coupling between geometry and matter and hence the Einstein frame is the preferred choice. There also a general prescription for the transformation of well known solutions from the Brans–Dicke frame to the Einstein frame has been given. It was demonstrated explicitly that qualitative cosmological features change significantly under this transformation. This was shown for a couple of examples, including the general multidimensional Kasner solution and a special inflationary solution with constant internal volume. In particular it was shown that inflationary solutions in the Brans–Dicke frame transform into noninflationary ones in the Einstein frame. It is to be expected that this is a rather general feature, whence the multitude of solutions which appear inflationary in the Brans–Dicke frame will be indeed non-inflationary when considered in the Einstein frame.

X. DISCUSSION

The Einstein action with minimally coupled scalars and p-branes in higher dimension D can be reduced to an effective model in lower dimension D_0. This results in a (generalized) σ-model with conformally flat target space. With a purely geometrical dilaton field f, it provides a natural generalization for the well-known Brans–Dicke theory.

The orthobrane condition (5.6) allows us to find exact solutions. Furthermore, the orthobrane solution is a sufficient condition for the target space of the σ-model to be a locally symmetric space. The orthobrane case is the generic one [apart from cases with degenerate coupling matrix (3.17)] where the target space is locally symmetric.

Examples of a certain minimal static, spherically symmetric p-brane configuration are given with just one electric and one magnetic antisymmetric F component (since in four dimensions we only deal with a single electromagnetic field), which in general intersect and interact with a single scalar field. Spherical symmetry here is considered in the physical relevant $D_0=4$ case of S^2 spheres, although the extension to arbitrary spheres is straightforward.

Besides popular families of orthobrane solutions there are further families of solutions, which have another additional symmetry, e.g., coinciding F-field charges for the electromagnetic solutions. In the target space this additional symmetry is expressed by a linear dependency (8.34) between column vectors Y of the coupling matrix L defined in (3.17).

For the mentioned static solutions, Hawking temperature T_H can be formally calculated by surface gravity via a Komar-type integral. For both, the orthobrane case and the case of equal charges $Q_{\mathrm{e}}^2=Q_{\mathrm{m}}^2$, the expressions of T_H depend characteristically on the intersection dimension. This results are also interesting in the context of recent increased interest in extremal p-brane configurations with black holes.[23]

The interpretation of the extremal limit $k\to 0$ is delicate. The solutions above have been described in isotropic coordinates which cover just the asymptotically flat exterior of the black hole. A better understanding of their global causality structure would require an investigation of the maximal extension of the space-time rather than only of its exterior part. The limit $k\to 0$ was here called extremal, since via (8.29) and (8.48) in this limit the effective asymptotical Schwarzschild mass M is just given by the charges, $G_N M = \frac{1}{2}(Bp_{\rm e} + Cp_{\rm m})$ and $G_N M = p/(1+d_2)$, respectively. Further work is required to understand this type of extremality, and the related asymptotics of T_H, which remains finite for intersection dimension $d_2 = 1$ and becomes infinite for $d_2 \geqslant 2$. As it was pointed out recently in Ref. 24 particular care is needed in order to associate the correct physical charges and thermal properties of a black hole correctly with its horizon.

The multidimensional σ-model opens the door for further investigations, in particular also for covariant and canonical quantization. The effective σ-model reduction appears as a possible clue to canonical quantization within a large well defined class of higher dimensional geometries, namely the multidimensional ones. Covariant quantization techniques can be applied in any dimension D_0. In particular, they are well applicable to our new solutions with scalar fields only, when the target space is flat. The effective geometry of the D_0-dimensional model can be reformulated in terms of connections and soldering forms. For $D_0 = 4$, not only a canonical $1+3$ split can be performed, but moreover the canonical quantization of the D_0-geometry can be performed with self-dual variables in the usual manner.

Finally, in analogy to investigations in Ref. 4, it should be possible to apply solution generating techniques like the Ehlers–Harrison transformation also in the context of the multidimensional σ-model.

(Received 18 March 1999; accepted for publication 26 April 1999)

Let (P,V) be an irreducible imprimitivity system for a group H based on a dual group $\hat{A}$ of an Abelian group A and acting on a Hilbert space $\mathcal{H}$. Given $\psi \in \mathcal{H}$, we find necessary and sufficient conditions in order that the set of vectors $\{\int_{\hat{A}} \overline{\langle \hat{a},a\rangle} V_h^{-1}\, dP(\hat{a})\psi : a\in A,\, h\in H\}$ be a frame in $\mathcal{H}$. Moreover, we apply these results to some examples that are considered in the literature in the context of square-integrability modulo a coset space. © *1999 American Institute of Physics.* [S0022-2488(99)00610-6]

I. INTRODUCTION

It is well known that a large class of continuous frames is defined in terms of square-integrable representations U of locally compact groups G by means of the equation

$$G \ni g \mapsto U_g \psi \in \mathcal{H}, \tag{1}$$

where $\mathcal{H}$ is the Hilbert space carrying the representation U and ψ is any nonzero vector belonging to the domain of $K_U^{-1/2}$, where K_U is the formal degree of U. The space labelling the frame is the group G endowed with a left invariant Haar measure μ_G^l. As a consequence of the properties of square-integrable representations,[1] the above frames are tight and the frame bound can be computed using the orthogonality relation

$$\int_G \langle \phi, U_g \psi\rangle \overline{\langle \phi', U_g \psi'\rangle}\, d\mu_G^l(g) = \langle \phi,\phi'\rangle \langle K_U^{-1/2}\psi', K_U^{-1/2}\psi\rangle. \tag{2}$$

The groups that are semidirect products with an Abelian normal factor, i.e., $G=A\times' H$, are of particular interest in the applications. For these groups, there is a one-to-one correspondence between the representations U of G and the imprimitivity systems for H based on the dual group $\hat{A}$ of A, explicitly given by

$$U_a = \int_{\hat{A}} \langle \hat{a},a\rangle\, dP(\hat{a}),$$

$$V_h = U_h,$$

[b]Electronic mail: cassinelli@ge.infn.it
[c]Electronic mail: devito@unimo.it
[d]Electronic mail: levrero@ge.infn.it

where $a\in A$ and $h\in H$. Moreover, a right invariant Haar measure μ_G^r for G is simply given by $\mu_G^r=\mu_A^r\otimes\mu_H^r$, where μ_A^r and μ_H^r are right invariant Haar measures on A and H, respectively; hence it is convenient to perform in Eq. (1) the change of variable $g\mapsto g^{-1}$ in order to use the measure μ_G^r instead of μ_G^l. Taking into account these facts Eq. (1) becomes

$$A\times H\ni(a,h)\mapsto\left(\int_{\hat{A}}\overline{\langle\hat{a},a\rangle}V_h^{-1}\,dP(\hat{a})\psi\right)\in\mathcal{H},\tag{3}$$

and the corresponding frame is labeled by the points of the topological direct product $A\times H$ with the product measure $\mu_A^r\otimes\mu_H^r$.

The structure of the above relation suggests the possibility of defining frames by means of Eq. (3) also in the case that H acts on $\hat{A}$ without preserving the composition law of $\hat{A}$.

The need to consider the above classes of frames is due to the fact that there are groups G of interest in the applications, as the Euclidean group, the Galilei and Poincaré groups, that are semidirect products, but do not admit square integrable representations.

In this paper, we consider two locally compact second countable (lcsc) groups A, H such that A is Abelian and H acts on $\hat{A}$, the dual group of A, and an irreducible imprimitivity system (P,V) for H based on $\hat{A}$ and acting on a Hilbert space $\mathcal{H}$. We assume that the orbits of H in $\hat{A}$ are locally closed, so that, due to the theorem of Mackey about imprimitivity systems, see, for example, Ref. 2, there is a one-to-one correspondence between the equivalence classes of irreducible imprimitivity systems (P,V) and the couples $(X,[m])$, where X is an orbit in $\hat{A}$ and $[m]$ is an equivalence class of irreducible representations of the stability subgroup at a fixed $x_0\in X$. Hence, we can (and we do) associate the maps defined by Eq. (3) with the couples $(X,[m])$ instead of (P,V).

In Sec. III, we prove that the set of vectors given by Eq. (3) is a frame for some $\psi\in\mathcal{H}$ if and only if the Haar measure of $\hat{A}$ restricted to X is not singular with respect to the H-quasi-invariant measures on X and m is a square-integrable representation. Moreover we show that these frames are tight, that their frame bound can be computed by a *generalized orthogonality relation* and we characterize the set of admissible vectors. We stress that, with our assumptions, we have to show these last properties since orthogonality relations are not proved to exist for imprimitivity systems, but only for square-integrable representations. In the particular case that H preserves the group law of $\hat{A}$ (so that, by duality, it is defined the semidirect product $A\times' H$) we obtain the results of Ref. 3.

In Sec. IV, we restrict ourselves to the case of imprimitivity systems such that A and H are Lie groups and the stability subgroup H_0 is compact and we consider the sets of vectors of the form

$$A\times(H/H_0)\times J\ni(a,x,i)\mapsto\left(\int_{\hat{A}}\langle\hat{a},a\rangle V_{q(x)}\,dP(\hat{a})\psi_i\right)\in\mathcal{H},$$

where J is the set of the first n numbers with the counting measure μ_c (n is the dimension of the Hilbert space where m acts) and q is any measurable section from the quotient space H/H_0 to H. We prove that, with a suitable choice of the vectors ψ_i, the above set is a tight frame labeled by the points of the space $(A\times H\times J)$ endowed with the measure $\mu_A^r\otimes\mu_H^r\otimes\mu_c$.

In the literature there are attempts to define frames by the equation

$$G/G_0\ni x\mapsto U_{q(x)}\psi\in\mathcal{H},\tag{4}$$

where G_0 is a closed subgroup of G, q is a suitable section from the quotient space G/G_0 to G and the frame is labeled by the points of G/G_0 endowed with a G-quasi invariant measure (in this case U is called *square-integrable modulo a coset space*), see Ref. 4 and references therein. Nevertheless, there are no general results on the square-integrable representations modulo a coset space and one has to prove for each representation both the fact that the set given by Eq. (4) is a frame and that the frame is tight with an equation for computing the frame bound. In the examples we give in the final section we show that the frames defined by Eq. (4) are particular cases of our procedure, so that our results provide a rigorous and general framework to this class of frames. An alternative approach to this problem can be found in Ref. 5.

In the following section we introduce the mathematical notations and we give some preliminary results, as standard reference we use Ref. 2.

II. MATHEMATICAL PRELIMINARIES

Let X be a locally compact second countable Hausdorff topological space. We denote by $\mathcal{K}(X)$ the vector space of continuous functions with compact support on X, by $\mathcal{B}(X)$ the Borel σ-algebra of X and by $M(X)$ the Banach space of complex measures on $\mathcal{B}(X)$.

By lcsc group G we mean a locally compact second countable Hausdorff topological group. We denote by μ_G a right invariant Haar measure and by Δ_G its modular function.

Let A be an Abelian lcsc group. We denote by $\hat{A}$ the dual group of A. Let $\mathcal{F}$ be the Fourier transform on $M(\hat{A})$ defined as

$$(\mathcal{F}\nu)(a)=\int_{\hat{A}}\overline{\langle x,a\rangle}d\nu(x),\quad a\in A,\quad \nu\in M(\hat{A}).$$

The same symbol $\mathcal{F}$ denotes the Fourier–Plancherel operator on $L^2(\hat{A},\mu_{\hat{A}})$. We choose the Haar measure on $\hat{A}$ in such a way that $\mathcal{F}$ is unitary from $L^2(\hat{A},\mu_{\hat{A}})$ onto $L^2(A,\mu_A)$.

Let G be a lcsc group and X be a lcsc continuous G-space. We denote the action of $g\in G$ on $x\in X$ by $g[x]$, the G-orbit of $x\in X$ by $G[x]$ and the stability subgroup of G at x by G_x.

We recall the following standard results about transitive G-spaces.

Lemma 1: Let G be a lcsc topological group and $X=G[x_0]$ a transitive G-space.

(1) There exists a regular section based on x_0, i.e., a measurable map q from X to G such that

$$q(x_0)=e,$$
$$q(x)[x_0]=x\quad \forall x\in X$$

and, for any compact set K in G, the set $\{q(g[x_0]):g\in K\}$ has compact closure in G.

(2) There exists a strongly quasi-invariant measure ν on X, i.e., a Radon measure ν such that

$$\nu(g[E])=\int_E\lambda_\nu(g,y)d\nu(y),\quad g\in G,\ E\in\mathcal{B}(X),$$

where λ_ν is the cocycle of ν, i.e., it is a continuous function from $G\times X$ to $(0,\infty)$ satisfying

$$\lambda_\nu(g_1g_2,y)=\lambda_\nu(g_1,g_2[y])\lambda_\nu(g_2,y),\quad g_1,g_2\in G,\quad y\in X,$$
$$\lambda_\nu(h,x_0)=\frac{\Delta_{G_{x_0}}(h)}{\Delta_G(h)},\quad h\in G_{x_0}.$$

(3) Two strongly quasi-invariant measures on X are mutually absolutely continuous and the corresponding density is a continuous positive function.

The following lemma is a particular case of the Mackey–Bruhat formula, which allows us to compute the integrals on G as integrals on $G/H\times H$, where H is a closed subgroup of G, see Ref. 3 for an elementary proof based on the fact that G is a second countable space.

Lemma 2: Let G be a lcsc group, $X=G[x_0]$ be a transitive G-space and G_{x_0} be the stability subgroup at x_0. Given a strongly quasi-invariant measure ν and a regular section q based on x_0, define $\beta:X\times H\to G_{x_0}$ as the map

$$\beta(x,h)=q(x)h,\quad x\in X,\quad h\in G_{x_0}.$$

Then the map β is an isomorphism of measurable spaces and the image measure of

$$\frac{1}{\Delta_G(q(x))\lambda_\nu(q(x),x_0)}\,\nu(x)\otimes\mu_{G_{x_0}}(h),$$

under the map β, is a Haar measure of G.

By *Hilbert space* we mean a complex separable Hilbert space with scalar product $\langle\cdot,\cdot\rangle$, linear in the first argument. We use the word *representation* to mean a continuous unitary representation of G acting in a Hilbert space $\mathcal{H}$. If a representation U is square-integrable, we denote by K_U the corresponding *formal degree*.

Finally, we recall the notion of *square-integrability modulo, a coset space* (see Ref. 4 and references therein).

Let G be a lcsc group, X a transitive G-space and U an irreducible representation of G acting in a Hilbert space $\mathcal{H}$. The representation U is said to be *square-integrable modulo X* if there exist n nonzero vectors

$$\psi_1,\ldots,\psi_n\in\mathcal{H}$$

and a section q from X to G such that

$$\Gamma:X\times\{1,...,n\}\ni(x,i)\mapsto U_{q(x)}\psi_i\in\mathcal{H} \tag{5}$$

is a frame over the space $(X\times\{1,...,n\},\mu\otimes\mu_c)$, where μ is a strongly quasi-invariant measure on X and μ_c the counting measure on $\{1,...,n\}$.

III. FRAMES ON A DIRECT PRODUCT

Let H be a lcsc group and A an Abelian lcsc group such that H acts continuously on the dual group $\hat{A}$ of A. Let M be the direct topological product $M=A\times H$, endowed with the measure $\mu^M=\mu_A\otimes\mu_H$.

Let $x_0\in\hat{A}$ and $X=H[x_0]$ be the corresponding orbit. We assume that X is locally closed in $\hat{A}$. Fix a strongly quasi-invariant measure ν on X with cocycle λ and a regular section q from X to H based on x_0.

Let m be an irreducible representation of the stability subgroup H_0 at x_0. Define μ_X as the restriction of $\mu_{\hat{A}}$ to X (since X is locally closed, μ_X is a Radon measure) and (P,V) be the imprimitivity system based on $\hat{A}$ for the group H acting in $\mathcal{H}=L^2(X,\nu,\mathcal{K})$ as

$$(P_E\phi)(x)=\mathcal{X}(x)E\cap X(x)\phi(x), \tag{6}$$

$$(U_a\phi)(x)=\langle x,a\rangle\phi(x), \tag{7}$$

$$(V_h\phi)(x)=(\lambda(h^{-1},x))^{1/2}m(q(x)^{-1}hq(h^{-1}[x]))\phi(h^{-1}[x]), \tag{8}$$

where $x\in X$, $a\in A$, $h\in H$, $E\in\mathcal{B}(\hat{A})$, and $\phi\in L^2(X,\nu,\mathcal{K})$.

Let $\psi\in\mathcal{H}$ and define $\mathbb{F}_\psi$ as the map

$$M\ni(a,h)\mapsto V_{h^{-1}}U_{-a}\psi\in\mathcal{H},$$

and, for all $\phi\in\mathcal{H}$, the map $c_{\phi,\psi}$

$$M\ni(a,h)\mapsto\langle\phi,V_{h^{-1}}U_{-a}\psi\rangle_{\mathcal{H}}\in\mathbb{C}. \tag{9}$$

As in the case of square-integrable representations, we say that ψ is an *admissible vector* for (P,V) if the map $\mathbb{F}_\psi$ is a frame over (M,μ^M), i.e., if the following conditions are satisfied:

(1) for all $\phi\in\mathcal{H},c_{\phi,\psi}\in L^2(M,\mu^M)$;
(2) there exist two positive numbers α and β such that

$$\alpha\|\phi\|^2_{\mathcal{H}}\leqslant\|c_{\phi,\psi}\|^2_{L^2(M,\mu^M)}\leqslant\beta\|\phi\|^2_{\mathcal{H}},\quad \forall\phi\in\mathcal{H},$$

We are now in position to state the main result of the paper. We give necessary and sufficient conditions on the imprimitivity system in order that the set of admissible vectors for (P,V) is not void. Moreover, we show that the corresponding frame $\mathbb{F}_\psi$ is tight, i.e., $\alpha=\beta$, and its frame bound α can be computed by means of a sort of *orthogonality relation*, as Eq. (2).

Theorem 1: There is $\psi\in\mathcal{H}$ such that $\mathbb{F}_\psi$ is a frame in $\mathcal{H}$ over (M,μ^M) if and only if ν and μ_X are not disjoint and m is a square-integrable representation of H_0.

This theorem is a consequence of the following proposition. Let

$$\nu=\nu_s+f\mu_X \tag{10}$$

be the decomposition of ν with respect to μ_X given by the Lebesgue–Radon–Nikodym theorem where f is non-negative and measurable. Defined $\gamma:X\to(0,\infty)$ as

$$\gamma(x)=\frac{f(x)}{\Delta_H(q(x))\lambda(q(x),x_0)},$$

the following result holds.

Proposition 1: Let $\psi,\phi\in\mathcal{H}$, $\psi,\phi\neq 0$. The function $c_{\phi,\psi}$ is in $L^2(M,\mu^M)$ if and only if the following conditions hold:

(a) m is a square-integrable representation of H_0 (we denote by K_m its formal degree);
(b) $\psi(x)=0$ for ν_s-almost all $x\in X$;
(c) $\psi(x)\in\mathrm{Dom}\,K_m^{-1/2}$ for ν-almost all $x\in X$;
(d) the function

$$X\ni x\mapsto\gamma(x)\|K_m^{-1/2}\psi(x)\|^2_{\mathcal{K}}$$

is in $L^1(X,\nu)$.

In this case, we have

$$\|c_{\phi,\psi}\|^2_{L^2(G,\mu_G)}=\|\phi\|^2_{\mathcal{H}}\int_X\gamma(x)\|K_m^{-1/2}\psi(x)\|^2_{\mathcal{K}}d\nu(x). \tag{11}$$

Remark 1: We observe that

(1) the measure ν defines uniquely the density f, hence also γ, up to a ν-negligible set;
(2) the function γ is invariant, up to a positive constant factor and a ν-negligible set, if we change ν with another quasi-invariant measure;
(3) the condition that ν and μ_X are not disjoint implies that $\mu_X(X)>0$.

Proof: Let ϕ, $\psi\in\mathcal{H}$, $\psi,\phi\neq 0$. Then, for all $(a,h)\in M$,

$$c_{\phi,\psi}(a,h)=\int_X\langle x,a\rangle\langle(V_h\phi)(x),\psi(x)\rangle_{\mathcal{K}}\,d\nu(x)=(\mathcal{F}\nu_h)(-a),$$

where ν_h is the canonical extension to $\hat{A}$ of the complex measure on X having $\langle(V_h\phi)(x),\psi(x)\rangle_{\mathcal{K}}$ as density with respect to ν. Applying Fubini theorem and taking into account that A is unimodular, the condition

$$c_{\phi,\psi}\in L^2(M,\mu^M)$$

is equivalent to the following two conditions.

(1) For μ_H-almost all $h \in H$ the function

$$A \ni a \mapsto (\mathcal{F}\nu_h)(a)$$

is in $L^2(A,\mu_A)$;

(2) the function

$$H \ni h \mapsto \int_A |(\mathcal{F}\nu_h)(a)|^2 \, d\mu_A(a)$$

is in $L^1(H,\mu_H)$.

Using a standard result on Fourier transform (see, for example, Theorem 31.33 of Ref. 6) and the fact that the Fourier-Plancherel operator is unitary, the two conditions above turn out to be equivalent to the following.

(1) For μ_H almost all $h \in H$, there is $l_h \in L^2(\hat{A},\mu_{\hat{A}})$ such that

$$l_h \mu_{\hat{A}} = \nu_h .$$

(2) The function

$$H \ni h \rightarrow \int_{\hat{A}} |l_h(x)|^2 \, d\mu_{\hat{A}}(x)$$

is in $L^1(H,\mu H)$.

Since $\nu_h(\hat{A} \setminus X) = 0$, $l_h = 0$ for $\mu_{\hat{A}}$-almost any $x \notin X$ and

$$l_h(x)\mu_X = \langle (V_h\phi)(x), \psi(x) \rangle (\nu_s + f(x)\mu_X).$$

This last equation shows that the above conditions are in fact equivalent to

(a) For μ_H-almost all $h \in H$ and ν_s-almost all $x \in X$,

$$\langle (V_h\phi)(x), \psi(x) \rangle_{\mathcal{K}} = 0,$$

(b) For μ_H-almost all $h \in H$ the function

$$X \ni x \mapsto \langle (V_h\phi)(x), \psi(x) \rangle_{\mathcal{K}} f(x)$$

is in $L^2(X,\mu_X)$;

(c) the function

$$H \ni h \mapsto \int_X |\langle (V_h\phi)(x), \psi(x) \rangle_{\mathcal{K}} f(x)|^2 d\mu_X(x)$$

is in $L^1(H,\mu_H)$.

Denoted by $\mathcal{P}$ the orthogonal projection on the singular part ν_s, we claim that the first of the above conditions is equivalent to the fact that $\mathcal{P}\psi = 0$. Indeed, the first condition implies that for μ_H-almost all $h \in H$, for all $E \in \mathcal{B}(\hat{A})$ and for ν-almost all $x \in X$

$$\langle (P_E V_h \phi)(x), (\mathcal{P}\psi)(x) \rangle_{\mathcal{K}} = 0,$$

hence, by integration over X and taking into account the fact that the map $h \mapsto V_h$ is continuous with respect to the strong operator topology, one has that, for all $h \in H$ and for all $E \in \mathcal{B}(\hat{A})$,

$$\langle P_E V_h \phi, \mathcal{P}\psi \rangle_{\mathcal{H}} = 0.$$

Since $\phi \neq 0$ and (P,V) is irreducible, it follows that $\mathcal{P}\psi = 0$. The converse implication is evident. Taking into account Eq. (10), one obtains the following conditions:

(1) $\mathcal{P}\psi=0$,
(2) for μ_H-almost all $h\in H$ the function

$$X\ni x\mapsto\langle (V_h\phi)(x),\psi(x)\rangle_{\mathcal{K}}\sqrt{f(x)}$$

is in $L^2(X,\nu)$;
(3) the function

$$H\ni h\mapsto\int_X|\langle (V_h\phi)(x),\psi(x)\rangle_{\mathcal{K}}|^2 f(x)d\nu(x)$$

is in $L^1(H,\mu_H)$.

Fixed $h\in H$, performing the change of variables $x\rightarrow h[x]$, these conditions are equivalent to

(1) $\mathcal{P}\psi=0$,
(2) for μ_H-almost all $h\in H$ the function

$$X\ni x\mapsto|\langle \phi(x),m(q(x)^{-1}h^{-1}q(h[x]))\psi(h[x])\rangle_{\mathcal{K}}|^2 f(h[x])$$

is in $L^1(X,\nu)$;
(3) the function

$$H\ni h\mapsto\int_X|\langle (\phi(x),m(q(x)^{-1}h^{-1}q(h[x]))\psi(h[x])\rangle_{\mathcal{K}}|^2 f(h[x])d\nu(x)$$

is in $L^1(H,\mu_H)$.

Again by Fubini theorem and, fixed $x\in X$, performing the change of variables $h\mapsto hq(x)^{-1}$, the above conditions turn out to be equivalent to

(1) $\mathcal{P}\psi=0$,
(2) for ν-almost all $x\in X$ the function

$$H\ni h\mapsto|\langle \phi(x),m(h^{-1}q(h[x_0]))\psi(h[x_0])\rangle_{\mathcal{K}}|^2 f(h[x_0])$$

is in $L^1(H,\mu_H)$;
(3) the function

$$X\ni x\mapsto\int_H|\langle \phi(x),m(h^{-1}q(h[x_0]))\psi(h[x_0])\rangle_{\mathcal{K}}|^2 f(h[x_0])d\mu_H(h)$$

is in $L^1(X,\nu)$.

Finally, using Lemma 2 to compute the integral in the variable h and Fubini theorem, the last conditions are equivalent to

(1) $\mathcal{P}\psi=0$,
(2) for ν-almost all $x,y\in X$ the function

$$H_0\ni s\mapsto\gamma(y)|\langle \phi(x),m(s^{-1})\psi(y)\rangle_{\mathcal{K}}|^2$$

is in $L^1(H_0,\mu_{H_0})$;
(3) for ν-almost all $x\in X$ the function

$$X\ni y\mapsto\gamma(y)\int_{H_0}|\langle \phi(x),m(s^{-1})\psi(y)\rangle_{\mathcal{K}}|^2\, d\mu_{H_0}(s)$$

is in $L^1(X,\nu)$;
(4) the function

$$X \ni x \mapsto \int_X \gamma(y) \int_{H_0} |\langle \phi(x), m(s^{-1}) \psi(y) \rangle_{\mathcal{K}}|^2 d\mu_{H_0}(s) d\nu(y)$$

is in $L^1(X,\nu)$.

The equivalence of these last four conditions to the ones contained in the statement of the proposition is now consequence of the properties of the formal degree operator, see Theorem 3 of Ref. 1. Equation (11) follows from Fubini theorem. □

Proof of theorem: ''only if'': By definition of frame, there are $\psi,\phi \in \mathcal{H}$, $\psi,\phi \neq 0$, such that $c_{\phi,\psi} \in L^2(M,\mu^M)$. Applying Proposition 1, one has that $\psi(x)=0$ ν_s-almost all $x \in X$ and m is square-integrable. The first condition and the fact that $\psi \neq 0$ imply that the measures ν and μ_X are not disjoint.

''If'': Since the measures ν and μ_X are not disjoint, there is a set $C \in \mathcal{B}(X)$ such that

$$\nu(C) > 0,$$

$$\nu_s(C) = 0,$$

$$f(x) > 0 \quad \forall x \in C.$$

Since ν is a regular measure, we can always assume that C is compact. Moreover, due to the fact that m is square-integrable, there is $v \in \mathcal{K}$, $v \neq 0$, such that $v \in \mathrm{Dom}\, K_m^{-1/2}$. Define ψ: $X \to \mathcal{K}$ as

$$\phi(x) = \begin{cases} \dfrac{v}{\sqrt{f(x)}} & x \in C \\ 0 & x \notin C \end{cases}.$$

Obviously $\psi \in \mathcal{H}$, $\psi \neq 0$. Taking into account that $(\Delta_G(q(x))\lambda_\nu(q(x),x_0))^{-1}$ is bounded on the compact sets and the definition of γ, one has that the four conditions of Proposition 1 are satisfied for all $\phi \in \mathcal{H}$, $\phi \neq 0$. Hence, $c_{\phi,\psi}$ is in $L^2(M,\mu^M)$ for all $\phi \in \mathcal{H}$. □

Corollary 1: With the notations of Theorem 1, there is $\psi \in \mathcal{H}$ such that $\mathbb{F}_\psi$ is a frame in $\mathcal{H}$ over (M,μ^M) if and only if there are $\psi,\phi \in \mathcal{H},\psi$, $\phi \neq 0$, such that $c_{\phi,\psi}$ is in $L^2(M,\mu^M)$.

The admissible vectors ψ are the ones satisfying

$$\psi \neq 0,$$

$$\psi(x) = 0, \quad \nu_s \text{ almost all } x \in X,$$

$$\int_X \gamma(x) \|K_m^{-1/2} \psi(x)\|_{\mathcal{K}}^2 \, d\nu(x) < \infty,$$

and the corresponding frame $\mathbb{F}_\psi$ is tight with frame bound

$$\alpha = \int_X \gamma(x) \|K_m^{-1/2} \psi(x)\|_{\mathcal{K}}^2 d\nu(x),$$

where K_m is the formal degree of m.

Proof: It follows easily from Proposition 1. □

We are unable to prove that for the frames $\mathbb{F}_\psi$ given by Theorem 1 the singular part ν_s of the strongly quasi-invariant measure ν is zero nor can we find an example of such frames so that $\nu_s \neq 0$. Nevertheless, there are two partial results in this direction.

The first one applies to the case that H and A are Lie groups.

Corollary 2: Let H and A be Lie groups such that the action of H on $\hat{A}$ is smooth and the orbits are locally closed. There is $\psi \in \mathcal{H}$ such that $\mathbb{F}_\psi$ is a frame in $\mathcal{H}$ over (M, μ^M) if and only if the orbit X is open in $\hat{A}$ and m is a square-integrable representation of H_0.

In particular, the restriction μ_X of the Haar measure $\mu_{\hat{A}}$ to X is a strongly quasi-invariant measure, so that in Eq. (10) $\nu_s = 0$ and f can be chosen continuous and strictly positive.

The proof of the corollary is based on the following standard results on the Lebesgue measures. We recall that, if M is a manifold of dimension n, a Radon measure μ on M is said to be a *Lebesgue measure* if for each chart (U, ϕ) the image under ϕ of the induced measure μ_U is equivalent to the restriction of the Lebesgue measure of $\mathbb{R}^n$ to $\phi(U)$ with a C^∞ density. Then

(1) there exist Lebesgue measures and any two of them are equivalent (see 16.22.2 of Ref. 7).
(2) If N is a submanifold with dimension strictly lower than n and it is locally closed in M, then N is negligible with respect to any Lebesgue measure (see 16.22 of Ref. 7).
(3) If G is a Lie group, then the Haar measure of G is a Lebesgue measure (see 19.6 of Ref. 7).
(4) If G is a Lie group acting on M and the action is transitive and smooth, then a Radon measure μ is G-quasi-invariant if and only if it is equivalent to a Lebesgue measure (see, for example, Ref. 8).

Proof: As a consequence of Theorem 1, there is $\psi \in \mathcal{H}$ such that $\mathbb{F}_\psi$ is a frame in $\mathcal{H}$ over (M, μ^M) if and only if m is a square-integrable representation of H_0 and there is a measurable subset C of X such that $\nu(C) > 0$ and $\mu_{\hat{A}}(C) > 0$. So, we can assume, without loss of generality, that $\mu_{\hat{A}}(X) > 0$. Under this assumption, we show that the restriction μ_X of $\mu_{\hat{A}}$ to X is quasi-invariant. Indeed, by means of a standard result of Lie groups, the orbit X is a (locally closed) submanifold and, since $\mu_{\hat{A}}$ is a Lebesgue measure and $\mu(X) > 0$, then $\dim X = \dim \hat{A}$, i.e. X is open in $\hat{A}$, and μ_X is a Lebesgue measure (with respect to the manifold X). By the results referred above, the claim is now evident.

The statement of the corollary is now clear. □

The same conclusion can be proved if we assume that the action of H on $\hat{A}$ preserves the composition law of $\hat{A}$.

Corollary 3: Let H and A be lcsc groups with A abelian such that the action of H on $\hat{A}$ satisfies

$$h[x_1 + x_2] = h[x_1] + h[x_2], \quad h \in H, \;\; x_1, x_2 \in \hat{A}, \tag{12}$$

and the corresponding orbits are locally closed. There is $\psi \in \mathcal{H}$ such that $\mathbb{F}_\psi$ is a frame in $\mathcal{H}$ over (M, μ^M) if and only if $\mu_{\hat{A}}(X) > 0$ and m is a square-integrable representation of H_0.

In particular, the restriction μ_X of the Haar measure $\mu_{\hat{A}}$ to X is a strongly quasi-invariant measure, so that in Eq. (10) $\nu_s = 0$ and f can be chosen continuous and strictly positive.

The proof is based on the following Lemma, see, for example, Ref. 3, for the proof.

Lemma 3: For any $h \in H$ and $E \in \mathcal{B}(\hat{A})$ we have

$$\mu_{\hat{A}}(h[E]) = \rho(h^{-1}) \mu_{\hat{A}}(E),$$

where ρ: $H \to (0, \infty)$ is a continuous group homomorphism.

Proof of the corollary: Arguing as in the proof of the previous corollary, we can assume, without loss of generality, that $\mu_{\hat{A}}(X) > 0$. Hence, due to the above Lemma, the measure μ_X is a strongly quasi-invariant measure on X. The thesis in now evident. □

We observe that, if Eq. (12) holds, the frame (9) is associated in a natural way with a square-integrable representation. Indeed, since the action of H on $\hat{A}$ satisfies (12), by duality, H acts also on A in such a way that

$$h[a_1+a_2]=h[a_1]+h[a_2], \quad h\in H, \ a_1,a_2\in A,$$

and the set M acquires a structure of a lcsc group with respect to the group law

$$(a_1,h_1)(a_2,h_2)=(a_1+h_1[a_2],h_1h_2).$$

To stress the structure of group, we denote M by G in the following.

By definition, the group G is the semidirect product of A and H, and the measure $\mu_A\otimes\mu_H$ is a right invariant Haar measure. Moreover there is a one-to-one correspondence between the irreducible imprimitivity systems (P,V) and the irreducible representations U of G, explicitly given by

$$(P,V)\mapsto U_{(a,h)}:=U_aV_h,$$

where $U_a=\int_{\hat{A}}\langle x,a\rangle dP(x)$, $a\in A$. As a consequence, the fact that there is $\psi\in\mathcal{H}$ such that the map $\mathbb{F}_\psi$ given by Eq. (9) is a frame is precisely the fact that U is a square-integrable representation of G and, hence, Corollary 3 characterizes completely the square-integrable representations of groups that are semidirect products with an Abelian normal factor.[9,3]

IV. FRAMES ON A QUOTIENT SPACE

In this section, we assume that A is an Abelian Lie group and H is a Lie group acting smoothly on $\hat{A}$, the dual group of A.

Fix $x_0\in\hat{A}$ and an irreducible representation m of the stability subgroup H_0 at x_0. Let $X=H[x_0]$ be the orbit of x_0 (as usual we assume that X is locally closed) and $\mathcal{K}$ the Hilbert space where m acts. We suppose that

(1) the stability subgroup H_0 is compact;

(2) the orbit X of x_0 has positive measure with respect to the Haar measure $\mu_{\hat{A}}$ of $\hat{A}$.

From these assumptions one has the following properties.

(1) The stability subgroup H_0 is unimodular and we can normalize the Haar measure μ_{H_0} in such a way that $\mu_{H_0}(H_0)=1$.

(2) The orbit X admits an H-invariant measure ν, which is equivalent to the restriction μ_X of $\mu_{\hat{A}}$ to X. Let f be the continuous and positive function from X to $\mathbb{R}$ such that

$$\nu=f\mu_X,$$

so that the cocycle λ of μ_X is

$$\lambda(h,x)=\frac{f(x)}{f(h[x])}, \quad x\in X, \ h\in H$$

(since ν is invariant the cocycle of ν is the identity).

(3) The Hilbert space $\mathcal{K}$, in which the representation m acts, is finite dimensional, so we can assume that $\mathcal{K}=\mathbb{C}^n$. Moreover, the representation m is square-integrable and the corresponding operator of formal degree is proportional to the identity.

Let (P,V) be the imprimitivity system for H based on $\hat{A}$ and acting on $\mathcal{H}=L^2(X,\nu,\mathbb{C}^n)$ whose equivalence class corresponds to $(X,[m])$. If q is a regular section from X to H based on x_0, then the system (P,V) is explicitly given by Eqs. (6)–(8).

Choose $\Psi\in\mathcal{K}(X),\Psi\neq 0$, and define ψ from X to $\mathbb{C}$ as

$$\psi(x)=\int_{H_0}\sqrt{\frac{f(s[x])}{f(x)}}\,\Psi(s[x])\,d\mu_{H_0}(s), \tag{13}$$

the integral being finite since Ψ has compact support, f is continuous and H_0 is compact. Taking into account that H_0 is unimodular, for all $s'\in H_0$ and $x\in X$

$$\psi(s'[x])=\sqrt{\lambda(s',x)}\,\psi(x). \tag{14}$$

Indeed, we have

$$\begin{aligned}\psi(s'[x])&=\int_{H_0}\sqrt{\frac{f(ss'[x])}{f(s'[x])}}\,\Psi(ss'[x])\,d\mu_{H_0}(s)\\&=(s\mapsto ss'^{-1})\\&=\int_{H_0}\sqrt{\frac{f(s[x])}{f(s'[x])}}\,\Psi(s[x])\,d\mu_{H_0}(s)\\&=\sqrt{\frac{f(x)}{f(s'[x])}}\int_{H_0}\sqrt{\frac{f(s[x])}{f(x)}}\,\Psi(s[x])\,d\mu_{H_0}(s)\\&=\sqrt{\lambda(s',x)}\,\psi(x).\end{aligned}$$

Moreover, since H_0 is compact and $\Psi\in\mathcal{K}(X)$, still $\psi\in\mathcal{K}(X)$ and, recalling that the cocycle of ν is equal to 1, one has that

$$\alpha:=\int_X\frac{f(x)}{\Delta_H(q(x))}|\psi(x)|^2\,d\nu(x)<\infty. \tag{15}$$

Finally, let $e_1,\dots,e_n$ be the standard basis of $\mathbb{C}^n$, J be the set of the first n numbers and μ^c the corresponding counting measure.

Corollary 4: With the above notations, the map

$$A\times X\times J\ni(a,x,i)\mapsto V_{q(x)}U_a(\psi e_i)\in\mathcal{H}$$

is a tight frame in $\mathcal{H}$ over $(A\times X\times J,\mu_{\hat{A}}\otimes\nu\otimes\mu^c)$, with frame bound α.

Proof: Let V^0 and U^0 be the representations of H and A corresponding to the choice of the trivial representation m^0 of H_0 ($\mathcal{K}^0=\mathbb{C}$). Since ψ, defined as above, satisfies Eq. (15), then

$$(a,h)\mapsto V^0_{h^{-1}}U^0_{-a}\psi \tag{16}$$

is a tight frame in $L^2(X,\nu)$ over $(A\times H,\mu_{\hat{A}}\otimes\mu_H)$, with frame bound α. Now, let ϕ be any vector in $\mathcal{H}$. Then, by the fact that (16) is a frame, it follows that:

$$\begin{aligned}\alpha\|\phi\|^2_{\mathcal{H}}&=\int_{A\times H}\langle\|\phi(x)\|_{\mathbb{C}^n},V^0_{h^{-1}}U^0_{-a}\psi\rangle_{L^2(X,\nu)}\,d\mu_A(a)\otimes d\mu_H(h)\\&=\int_H\int_A\left|\int_X\|\phi(x)\|_{\mathbb{C}^n}\overline{(V^0_{h^{-1}}U^0_{-a}\psi)(x)}\,d\nu(x)\right|^2 d\mu_A(a)\,d\mu_H(h)=(x\mapsto h^{-1}[x])\\&=\int_H\int_A\left|\int_X\|\phi(h^{-1}[x])\|_{\mathbb{C}^n}\overline{(U^0_{-a}\psi)(x)}\,d\nu(x)\right|^2 d\mu_A(a)\,d\mu_H(h)\end{aligned}$$

$$=(\text{Fourier transform and } \nu=f\mu_X)=\int_H\int_X \|\phi(h^{-1}[x])\|^2_{\mathbb{C}^n}|\psi(x)|^2 f(x)\,d\nu(x)\,d\mu_H(h)$$

$$=(h\mapsto h^{-1})=\int_H\int_X \|\phi(h[x])\|^2_{\mathbb{C}^n}|\psi(x)|^2 f(x)\,d\nu(x)\,d\mu_H(h).$$

Now, using the Mackey–Bruhat formula in order to compute the integral on H as an integral on $X\times H_0$, we have

$$\alpha\|\phi\|^2_{\mathcal{H}}=\int_X\int_{H_0}\int_X \|\phi((q(y)s)[x])\|^2_{\mathbb{C}^n}|\psi(x)|^2 f(x)\,d\nu(x)\,d\mu_{H_0}(s)\,d\nu(y)$$

$$=(x\mapsto s^{-1}[x] \text{ and unitarity of } m)=\int_X\int_{H_0}\int_X \|(V_{q(y)^{-1}}\phi)(x)\|^2_{\mathbb{C}^n}$$

$$\times|\psi(s^{-1}[x])|^2 f(s^{-1}[x])\,d\nu(x)\,d\mu_{H_0}(s)\,d\nu(y)$$

$$=[\text{Eq.}(14)]=\int_X\int_{H_0}\int_X \|(V_{q(y)^{-1}}\phi)(x)\|^2_{\mathbb{C}^n}|\psi(x)|^2 f(x)\,d\nu(x)\,d\mu_{H_0}(s)\,d\nu(y).$$

At this point, recalling that we have set $\mu_{H_0}(H_0)=1$, we can perform the integral over H_0; thus, we obtain that

$$\alpha\|\phi\|^2_{\mathcal{H}}=\int_X\int_X \|(V_{q(y)^{-1}}\phi)(x)\|^2_{\mathbb{C}^n}|\psi(s^{-1}[x])|^2 f(x)\,d\nu(x)\,d\nu(y).$$

Then, since $\{e_1,\ldots,e_n\}$ is the canonical basis in $\mathbb{C}^n$, we find

$$\alpha\|\phi\|^2_{\mathcal{H}}=\int_X\int_X\sum_i |\langle (V_{q(y)^{-1}}\phi)(x),\psi(x)e_i\rangle_{\mathbb{C}^n}|^2 f(x)\,d\nu(x)\,d\nu(y)$$

$$=(\text{Fourier transform and } \nu=f\mu_X)$$

$$=\int_X\int_A\sum_i |\langle (V_{q(y)^{-1}}\phi),U_{-a}(\psi e_i)\rangle_{\mathcal{H}}|^2 d\mu_A(a)\,d\nu(y)=(a\mapsto -a)$$

$$=\int_X\int_A\sum_i |\langle \phi,V_{q(y)}U_a(\psi e_i)\rangle_{\mathcal{H}}|^2 d\mu_A(a)\,d\nu(y).$$

The thesis is now evident. □

V. EXAMPLES

In this section we apply the previous results to some specific groups that are considered in the literature.

A. The causal group

Let G be the *causal group*, namely the semidirect product

$$G=\mathbb{R}^4\times'(\mathrm{SO}_0(3,1)\times\mathbb{R}^+_*),$$

where $\mathrm{S0}_0(3,1)$ is the connected component with the identity of the Lorentz group and $\mathbb{R}^+_*$ is the multiplicative group of strictly positive real numbers. This group has been considered in the context of wavelet electrodynamics.[10]

In order to take into account the projective representations of G, we will study the universal covering group of G, i.e.,

$$G^* = \mathbb{R}^4 \times' (\mathrm{SL}(2,\mathbb{C}) \times \mathbb{R}_*^+).$$

The group G^* is the semidirect product of the Abelian group $A = \mathbb{R}^4$ and the group $H = \mathrm{SL}(2,\mathbb{C}) \times \mathbb{R}_*^+$, so by duality H acts on the dual group $\mathbb{P}^4$ of $\mathbb{R}^4$, preserving the composition law of $\mathbb{P}^4$. Hence, we can consider unitary representations of G^* instead of imprimitivity systems for H based on $\mathbb{P}^4$.

In order to apply Corollary 3, we identify the dual group $\mathbb{P}^4$ of $\mathbb{R}^4$ with $\mathbb{R}^4$ by means of the pairing

$$\langle p,a \rangle = p_0 a_0 - p_1 a_1 - p_2 a_2 - p_3 a_3 .$$

The Haar measure on $\mathbb{P}^4$ is the Lebesgue measure dp and the action of H on $\mathbb{P}^4$ is

$$(h,d)[p] = \frac{1}{d} L(h) a, \quad (h,d) \in \mathrm{SL}(2,\mathbb{C}) \times \mathbb{R}_*^+, \quad p \in \mathbb{P}^4,$$

where $L: \mathrm{SL}(2,\mathbb{C}) \to \mathrm{SO}_0(3,1)$ is the covering homomorphism. The corresponding orbits of $\mathrm{SL}(2,\mathbb{C}) \times \mathbb{R}_*^+$ can be classified in the following way:

(1) two ''massive'' orbits O^+, O^- defined by

$$O^{\pm} = G^*[p^{\pm}] = \{p \in \mathbb{R}^4 : \pm p_0 > 0, \|p\| > 0\},$$

where $p^{\pm} = (\pm 1,0,0,0)$ and $\|p\| = \sqrt{p_0^2 - p_1^2 - p_2^2 - p_3^2}$;

(2) the orbit O defined by

$$O = G^*[(0,0,0,1)] = \{p \in \mathbb{R}^4 : \|p\| < 0\};$$

(3) the singleton orbit $\{(0, 0, 0, 0)\}$.

Since the orbits are locally closed, we can apply Corollary 3 to select the square-integrable representations. The orbits having positive Lebesgue measure are $O^{\pm}, O$. The stability subgroup at $(0,0,0,1) \in O$ is the Euclidean group $E(2)$, which does not admit square-integrable representations, whereas the one associated with $O^{\pm}$ is isomorphic to SU(2). Since SU(2) is compact, every irreducible representation is square-integrable and let

$$\{D^j : j = 0, \tfrac{1}{2}, 1, \ldots\} \tag{17}$$

be the canonical maximal set of inequivalent irreducible representations of SU(2) where each D^j acts on $\mathbb{C}^{2j+1}$. Then, a maximal set of inequivalent square-integrable representations of G^* is

$$\{U^{\pm,j} := \mathrm{Ind}_{\mathbb{R}^4 \times' \mathrm{SU}(2)}^{G^*} (p^{\pm} D^j) : j = 0, \tfrac{1}{2} 1, \ldots\}.$$

Observing that the restriction ν of the measure $\|p\|^{-4}\, dp$ to the orbit $O^{\pm}$ is invariant with respect to the action of G^*, for each j the representation $U^{\pm,j}$ acts on the Hilbert space $\mathcal{H}^j := L^2(O^{\pm}, \nu, \mathbb{C}^{2j+1})$ as

$$(U^j_{(a,h,d)} \psi)(p) = e^{i\langle p,a \rangle} D^j (q(p)^{-1} (hd) q((hd)^{-1}[p])) \psi((hd)^{-1}[p])$$

where $\psi \in \mathcal{H}^j$, $(a,h,d) \in G^*$ and q is a regular section from $O^{\pm}$ into $\mathrm{SL}(2,\mathbb{C}) \times \mathbb{R}_*^+$. The corresponding set $\mathcal{A}^j$ of admissible vectors is given by Corollary 1. To this aim, notice that ν has density $f(p)=\|p\|^{-4}$ with respect to dp (according to Corollary 3, the singular part ν_s of ν with respect to dp is zero), $SL(2,\mathbb{C})\times\mathbb{R}_*^{\pm}$ is unimodular and the formal degree of the representation D^j is proportional to the identity, then

$$\mathcal{A}^j=\left\{\psi\in\mathcal{H}^j: \quad \int_{O\pm}\|\psi(p)\|^2_{\mathbb{C}^{2j+1}}\|p\|^{-4}\,d\mu(p)<\infty\right\}.$$

B. Lorentz invariant frames

It is well known that the Poincaré group does not admit square integrable representations, so that there are no frames given by Eq. (9), which, obviously, are invariant with respect to the full Poincaré group. Nevertheless we can define frames that are invariant with respect to the Lorentz group by means of the imprimitivity systems for the Lorentz group based on $\mathbb{R}^3$. The action of the Lorentz group on $\mathbb{R}^3$ is defined by identifying, as a manifold, $\mathbb{R}^3$ with with the *massive* orbit in the momentum space

$$X_m=\{(p_0,\vec{p})\in\mathbb{R}^4: p_0^2-\vec{p}^2=m^2,\ \ p_0>0\}.$$

These kinds of frames were introduced by means of suitable representations of the Poincaré group that are square-integrable modulo a coset space, see Ref. 4 and references therein.

As usual we consider the universal covering group $H=SL(2,\mathbb{C})$ of the connected component $SO_0(3,1)$ of the Lorentz group. We denote by $\mu_{SL(2,\mathbb{C})}$ a Haar measure of $SL(2,\mathbb{C})$, which is a unimodular group, and by L the covering homomorphism from $SL(2,\mathbb{C})$ onto $SO_0(3,1)$.

Let A be the Abelian Lie group $\mathbb{R}^3$. As usual, we identify the dual group $\mathbb{P}^3$ of A with $\mathbb{R}^3$ by means of the Euclidean scalar product. Define the diffeomorphism $\overline{\omega_m}$ from $\mathbb{R}^3$ onto X_m as

$$\overline{\omega_m}(\vec{p})=(\sqrt{m^2+\vec{p}^2},\vec{p})$$

with inverse

$$\overline{\omega_m}^{-1}(p_0,\vec{p})=\vec{p}.$$

The space $\mathbb{P}^3$ becomes a transitive H-space with respect to the smooth action

$$h[\vec{p}]=\overline{\omega_m}^{-1}(L(h)\overline{\omega_m}(\vec{p}))$$

with $h\in SL(2,\mathbb{C})$ and $\vec{p}\in\mathbb{P}^3$.

We recall the following facts about $\mathbb{P}^3$ as an H-space.

(1) The H-invariant measure on $\mathbb{P}^3$ is

$$\nu_m=\frac{d\vec{p}}{\sqrt{m^2+\vec{p}^2}},$$

with density $f(\vec{p})=1/\sqrt{m^2+\vec{p}^2}$ with respect to the Lebesgue measure $d\vec{p}$ of $\mathbb{P}^3$.

(2) The stability subgroup at the origin $\vec{0}$ is $H_0=SU(2)$, which is compact.

(3) The set $\{D^j\}$ given by Eq. (17) is a set of inequivalent representations of SU(2).

Fixed $j=0,\frac{1}{2},1,\ldots$, each couple $(\mathbb{P}^3,[D^j])$ defines two classes of frames in the Hilbert space $\mathcal{H}^j=L^2(\mathbb{P}^3,\nu_m,\mathbb{C}^{2j+1})$. Indeed, let

$$(U^j_{\vec{a}}\phi)(\vec{p})=e^{i\vec{a}\cdot\vec{p}}\phi(\vec{p}),$$

$$(V^j_h\phi)(\vec{p})=D^j(q(\vec{p})^{-1}hq(h^{-1}[\vec{p}]))\phi(h^{-1}[\vec{p}]),$$

where $\vec{p}\in\mathbb{P}^3$, $\phi\in\mathcal{H}^j$, $h\in H$, $\vec{a}\in A$ and q is any regular section from $\mathbb{P}^3$ to H.

We observe that the formal degree of the representations D^j is proportional to the identity and that

$$\gamma(\vec{p}) = f(\vec{p}) = \frac{1}{\sqrt{m^2+\vec{p}^2}}$$

since H is unimodular and ν_m is invariant. By means of Corollary 2 and Corollary 1, if $\psi \in \mathcal{A}^j$, where

$$\mathcal{A}^j = \left\{ \psi \in \mathcal{H} : \psi \neq 0, \frac{\psi(\vec{p})}{(m^2+\vec{p}^2)^{1/2}} \in L^2(\mathbb{P}^3, d\vec{p}, \mathbb{C}^{2j+1}) \right\},$$

then the map

$$\mathbb{R}^3 \times \mathrm{SL}(2,\mathbb{C}) \ni (a,h) \mapsto V_h^{-1} U_a^{-1} \psi \in \mathcal{H}^j \tag{18}$$

is a tight frame over $(\mathbb{R}^3 \times \mathrm{SL}(2,\mathbb{C}), d\vec{a} \otimes \mu_{\mathrm{SL}(2,\mathbb{C})})$ with frame bound

$$\alpha = \int_{p^3} \frac{\|\psi(\vec{p})\|^2_{\mathbb{C}^{2j+1}}}{(m^2+\vec{p}^2)} d\vec{p}.$$

Moreover, we notice that the measure ν_m is an H-invariant measure on $\mathbb{P}^3$ with density

$$f(\vec{p}) = \frac{1}{\sqrt{m^2+\vec{p}^2}}$$

with respect to the Lebesgue measure $d\vec{p}$ and we define J as the set of the first n numbers and μ^c the corresponding counting measure.

Let $(e_i)_{i=1}^{2j+1}$ be the standard basis of $\mathbb{C}^{2j+1}$ and $\Psi \in \mathcal{K}(\mathbb{P}^3)$. Define ψ by means of Eq. (13), then, as a consequence of Corollary 4, the map

$$\mathbb{R}^3 \times \mathbb{P} \times J \ni (\vec{a}, \vec{p}, i) \mapsto V^j_{q(\vec{p})} U^j_{\vec{a}} (\psi e_i) \in \mathcal{H}^j \tag{19}$$

is a tight frame in $L^2(\mathbb{P}^3, \nu_m, \mathbb{C}^{2j+1})$ over $(A \times \mathbb{P}^3 \times J, d\vec{a} \otimes \nu_m \otimes \mu^c)$ with frame bound

$$\alpha = \int_{p^3} \frac{\|\psi(\vec{p})\|^2_{\mathbb{C}^{2j+1}}}{(m^2+\vec{p}^2)} d\vec{p}.$$

These classes of frames were introduced in Ref. 4 by the use of an irreducible representation W of the universal covering group G of the connected component of the Poincaré group such that W be *square integrable modulo a section*. We now show the relationship between the two constructions.

Consider first the frame (18) and define $\mathbb{T}$ as the subgroup of the time translations, i.e.,

$$\mathbb{T} = \{ (p_0, \vec{0}, I) \in G : p_0 \in \mathbb{R} \}.$$

Then, the manifold $A \times H$ is diffeomorphic to the space of left cosets $G/\mathbb{T}$ and it becomes a transitive G-space. One has that the map $c: A \times H \to G$ given by

$$(\vec{a}, h) \mapsto (h[(0,\vec{a})], h)$$

is a smooth section and the measure $d\vec{a} \otimes \mu_{\mathrm{SL}(2,\mathbb{C})}$ is G-invariant.

Let $G_0 = \mathbb{R}^4 \times' \mathrm{SU}(2)$ and χ_m be the character of $\mathbb{R}^4$

$$\chi_m(a_0,\vec{a}) = e^{ia_0 m}, \quad (a,\vec{a}) \in \mathbb{R}^4,$$

then $\chi \otimes D^j$ is an irreducible representation of G_0 and we can consider the representation $W^{m,j}$ unitarily induced from G_0 to G by $\chi_m \otimes D^j$, which is explicitly given by

$$(W^{m,j}_{(a,h)}\phi)(\vec{p}) = e^{i(a_0\sqrt{m^2+\vec{p}^2} - \vec{a}\cdot\vec{p})} D^j(q_m(\vec{p})^{-1} h q_m(h^{-1}[\vec{p}]))\phi(h^{-1}[\vec{p}]),$$

where $a \in \mathbb{R}^4$, $h \in H$, $p \in \mathbb{P}^3$, and $\phi \in \mathcal{H}^j$. Comparing the form of $W^{m,j}$ with the one of U^j and V^j, it follows that

$$W^{m,j}_{c(-\vec{a},h)} = V^j_h U^j_{\vec{a}}.$$

Hence, we can conclude that, given any $\psi \in \mathcal{A}^j$, the representation $W^{m,j}$ is square integrable mod. $(\mathbb{R}^3 \times \mathrm{SL}(2,\mathbb{C}), c, \psi)$ and that the frame (18) coincides with the one defined in Ref. 4.

Now consider the frame (19). The space $A \times \mathbb{P}^3$ is a transitive G-space with respect to the action

$$(b,h)[(\vec{a},\vec{p})] := (pr_A(q(h[\vec{p}])^{-1}[b] + (q(\vec{p})^{-1} h q(h^{-1}[\vec{p}]))[\vec{a}]), q(\vec{p})),$$

where $b \in \mathbb{R}^4$, $h \in \mathrm{SL}(2,\mathbb{C})$, $\vec{a} \in A$, $\vec{p} \in \mathbb{P}^3$ and pr_A is the canonical projection from $\mathbb{R}^4$ to A, i.e.,

$$pr_A(b_0,\vec{b}) = \vec{b}.$$

Observe that

(1) the stability subgroup at $(\vec{0},\vec{0})$ is $\mathbb{T} \times' \mathrm{SU}(2)$, where $\mathbb{T}$ is the subgroup of the time translations and, since SU(2) does not act on $\mathbb{T}$ the semidirect product is in fact a direct product;

(2) a continuous section from $A \times \mathbb{P}^3$ to G is
$$\tilde{q}(\vec{a},\vec{p}) = (q(\vec{p})[(0,\vec{a})], q(\vec{p}));$$

(3) the G-invariant measure is $d\vec{a} \otimes \nu_m$.

Hence one has that

$$W^{m,j}_{\tilde{q}(-\vec{a},\vec{p})} = V^j_{q(\vec{p})} U^j_{\vec{a}}.$$

Since the map (19) is a frame, then the representation $W^{m,j}$ is a square-integrable modulo $(A \times \mathbb{P}^3, \tilde{q}_m, \psi e_1, \ldots, \psi e_{2j+1})$.

C. The Galilei group

We now consider a class of frames that are invariant under the homogeneous Galilei group.

Let $\mathcal{V} := \mathbb{R}^3$ and $d\vec{v}$ be the corresponding Lebesgue measure. Let SU(2) be the universal covering of the rotation group in $\mathbb{R}^3$ and $\mu_{\mathrm{SU}(2)}$ be the corresponding normalized Haar measure. The group SU(2) acts on $\mathcal{V}$ by means of the covering homomorphism δ and we can consider the semidirect product,

$$H := \mathcal{V} \times' \mathrm{SU}(2).$$

The group H is unimodular with Haar measure $d\vec{v} \otimes \mu_{\mathrm{SU}(2)}$.

Moreover, let $A = \mathbb{R}^3$ and $\mathbb{P}^3$ be the corresponding dual group identified with $\mathbb{R}^3$ by means of the Euclidean scalar product. The corresponding Lebesgue measures are denoted by $d\vec{a}$ and $d\vec{p}$, respectively.

Fixed $m \in \mathbb{R}$, $m \neq 0$, the space $\mathbb{P}^3$ is a transitive G space with respect to the nonlinear transitive smooth action of H

$$(\vec{v},h)[\vec{p}]=\delta(h)\vec{p}+m\vec{v}. \tag{20}$$

The measure $d\vec{p}$ is H-invariant and the stability subgroup H_0 at $\vec{0}$ is SU(2).

As in the previous case, for each $j=0,\frac{1}{2},1,...$, the couple $(\mathbb{P}^3,[D^j])$ defines two classes of frames in the Hilbert space $\mathcal{H}^j=L^2(\mathbb{P}^3,d\vec{p},\mathbb{C}^{2j+1})$. Indeed, let

$$(U^j_{\vec{a}}\phi)(\vec{p})=e^{i\vec{a}\cdot\vec{p}}\phi(\vec{p}),$$

$$(V^j_h\phi)(\vec{p})=D^j(q(\vec{p})^{-1}hq(h^{-1}[\vec{p}]))\phi(h^{-1}[\vec{p}])$$

where $\vec{a}\in A,\ h\in H,\ \vec{p}\in\mathbb{P}^3,\ \phi\in\mathcal{H}^j$ and $q:\mathbb{P}^3\rightarrow H$ is a section for the action of H on $\mathbb{P}^3$ [for example, $q(\vec{p})=(\vec{p}/m)I)$].

Indeed, by Corollary 2, for *any* nonzero $\psi\in\mathcal{H}^j$, the map

$$A\times H\ni(\vec{a},h)\mapsto V^j_{h^{-1}}U^j_{-\vec{a}}\psi\in\mathcal{H}^j \tag{21}$$

is a tight frame in $\mathcal{H}$ over $(A\times H,d\vec{a}\otimes\mu_{\mathrm{SU}(2)})$ with frame bound $\|\psi\|^2$. It is easy to prove that two frames of the type (21) corresponding to the same value of j and to the same analyzing vector ψ, but differing for the value of the mass $m\neq0$, are unitarily equivalent.

Moreover, let $(e_i)_{i=1}^{2j+1}$ be the standard basis of $\mathbb{C}^{2j+1}$, J the set of the first n numbers, and μ^c the corresponding counting measure. Given $\Psi\in\mathcal{K}(\mathbb{P}^3)$, define ψ by means of Eq. (13), then, as a consequence of Corollary 4, the map

$$(\vec{a},\vec{p},i)\mapsto V^j_{q(\vec{p})}U^j_{\vec{a}}(\psi e_i) \tag{22}$$

is a tight frame in $L^2(\mathbb{P}^3,d\vec{p},\mathbb{C}^{2j+1})$ over $(A\times\mathbb{P}^3\times J,\ d\vec{a}\otimes d\vec{p}\otimes\mu^c)$.

In this particular case, one can check by direct computation that in Eq. (22) any vector $\psi\in L^2(\mathbb{P}^3,d\vec{p})$ can be used to define a frame.

As in the previous example, we can show that the above frames can be obtained using a (projective) representation of covering group G of the full Galilei group which is square-integrable modulo a section. Let $W^{m,j}$ be the (projective) representation of G associated with the Galilei invariant quantum particle of mass m and spin j (for an explicit description of this representations see, for example, Ref. 11), then one can show, as in the case of the Poincaré group, that $W^{m,j}$ is square integrable modulo the left coset space $G/\mathbb{T}$ (where $\mathbb{T}$ is the subgroup of the time translations) since the map (21) is a frame and that $W^{m,j}$ is square integrable modulo the left coset space $G/(\mathbb{T}\times'\mathrm{SU}(2))$ since the map (22) is a frame.

D. The Weyl–Heisenberg group

Let us consider the $(2n+1)$-dimensional Weyl–Heisenberg group H_n, which is the group associated with the canonical quantization of a classical mechanical system.

Fixed $n\in\mathbb{N}$, $n>0$, let $T=\mathbb{R}$ and $A_n=\mathcal{V}_n=\mathbb{R}^n$ be the usual vector groups, then the Lie group H_n is the manifold $T\times A_n\times\mathcal{V}_n$ with the composition law

$$(\tau_1,\vec{a}_1,\vec{u}_1)(\tau_2,\vec{a}_2,\vec{u}_2)=(\tau_1+\tau_2-\tfrac{1}{2}(\vec{a}_1\cdot\vec{u}_2-\vec{a}_2\cdot\vec{u}_1),\vec{a}_1+\vec{a}_2,\vec{u}_1+\vec{u}_2).$$

The group H_n is the semidirect product of the Abelian group $T\times A_n$ and the group $\mathcal{V}_n$, whose action is given by

$$\vec{u}[(\tau,\vec{a})]=(\tau+\vec{a}\cdot\vec{u},\vec{a}),\quad (\tau,\vec{a})\in T\times A_n,\quad \vec{u}\in\mathcal{V}_n,$$

where the dot denotes the Euclidean product. Identifying the dual group $\mathbb{P}\times\mathbb{P}^n$ of $T\times A_n$ with $T\times A_n$ itself by means of the Euclidean product, the dual action of $\mathcal{V}_n$ on $\mathbb{P}\times\mathbb{P}^n$ is given by

$$\vec{u}[(h,\vec{p})]=(h,\vec{p}-h\vec{u}), \quad (h,\vec{p})\in\mathbb{P}\times\mathbb{P}^n, \;\; \vec{u}\in\mathcal{V}_n. \tag{23}$$

Then, the $\mathcal{V}_n$-orbits in $\mathbb{P}\times\mathbb{P}^n$ are the following:

(1) for all $\vec{p}\in\mathbb{R}^n$, the singleton orbits

$$\mathcal{O}_{0,\vec{p}}=\{(0,\vec{p})\};$$

(2) for all $h\in\mathbb{R}$, $h\neq 0$, the orbits

$$\mathcal{O}_h=\{(h,\vec{p})|\vec{p}\in\mathbb{R}^n\}.$$

Since all the orbits are closed, according to Corollary 3, the group H_n does not have square-integrable representations. Nevertheless, fixed $h\neq 0$, the orbit $\mathcal{O}_h$ is canonically identified with $\mathbb{P}^n$, which is the dual group of $\mathbb{R}^n$, so that we can use our procedure to define frames associated with irreducible imprimitivity systems for the group $\mathcal{V}_n$ based on the transitive $\mathcal{V}_n$-space $\mathbb{P}^n$.

Since the stability subgroup at $\vec{0}\in\mathbb{P}_n$ is the identity, we have only the couple $(\mathbb{P}_n,I)$ and it defines a class of tight frames in $\mathcal{H}=L^2(\mathbb{P}^n,d\vec{p})$.

Indeed, let

$$(U_{\vec{a}}\phi)(\vec{p})=e^{i\vec{a}\cdot\vec{p}},$$

$$(V_{\vec{u}}\phi)(\vec{p})=\phi(\vec{p}+h\vec{u}),$$

where $\vec{p}\in\mathbb{P}_n$, $\phi\in\mathcal{H}$, $\vec{u}\in\mathcal{V}_n$, and $\vec{a}\in\mathbb{R}^n$, and observe that the Lebesgue measure $d\vec{p}$ is clearly invariant with respect to the action (23).

Hence, since $\mathcal{V}_n$ is unimodular and its Haar measure is $d\vec{u}$, it follows from Corollary 2 and Corollary 1 that for any nonzero vector $\psi\in\mathcal{H}$, the map

$$\mathbb{F}^h_\psi: \quad A_n\times\mathcal{V}_n\ni(\vec{a},\vec{u})\mapsto V^h_{-\vec{u}}U_{-\vec{a}}\psi\in\mathcal{H}$$

is a tight frame in $\mathcal{H}$ over the space $(A_n\times\mathcal{V}_n,\, d\vec{a}\otimes d\vec{u})$ with frame bound $\|\psi\|$.

We remark that, given the unitary operator $\mathfrak{U}_h$, $h\in\mathbb{R}-\{0\}$, in $\mathcal{H}$ defined by

$$(\mathfrak{U}_h\phi)(\vec{p})=|h|^{-n/2}\phi(h^{-1}\vec{p}), \quad \phi\in\mathcal{H},$$

then, for any $\psi\in\mathcal{H}$ and $h_1,h_2\in\mathbb{R}-\{0\}$, we have

$$\mathbb{F}^{h_1}_\psi=\mathfrak{U}_{h_1/h_2}\circ\mathbb{F}^{h_2}_{\psi'} \qquad \text{if} \quad \psi'=\mathfrak{U}^*_{h_1/h_2}\psi,$$

namely, the frames $\mathbb{F}^{h_1}_\psi$ and $\mathbb{F}^{h_2}_{\psi'}$ are unitarily equivalent. Moreover we notice explicitly that, for $n=3$ and $h=m\in\mathbb{R}^+$, the frame $\mathbb{F}^h_\psi$ is exactly the frame (22) over the coset space $G/(\mathbb{T}\times\mathrm{SU}(2))$, where G is the Galilei group, with the choice $j=0$.

Also in this case, the frames $\mathbb{F}^h_\psi$ can be defined in terms of a representation of the group H_n that is square-integrable modulo a coset space. Indeed, for sake of simplicity, fix $h=1$ and let W be the irreducible representation of H_n acting on $\mathcal{H}=L^2(\mathbb{P}^n,d\vec{p})$ as

$$(W_{(\tau,\vec{a},\vec{u})}\phi)(\vec{p})=e^{i(\tau+(1/2)\vec{a}\cdot\vec{u}-\vec{a}\cdot\vec{p})}\phi(\vec{p}-\vec{u}), \quad \phi\in\mathcal{H}.$$

The left coset space $H_n/\mathbb{T}$ is clearly diffeomorphic to $A_n\times\mathcal{V}_n$, so that $A_n\times\mathcal{V}_n$ turns out to be a H-space where the action is explicitly given by

$$(\tau,\vec{a},\vec{u})[(\vec{a}',\vec{u}')]=(\vec{a}+\vec{a},\vec{u}+\vec{u}) \quad (\tau,\vec{a},\vec{u})\in H_n, \quad (\vec{a}',\vec{u}')\in A_n\times\nu_n.$$

One can easily check that the map

$$q\colon A_n\times\mathcal{V}_n\ni(\vec{a},\vec{u})\mapsto(\vec{u}[(0,\vec{a})],\vec{u})=(\vec{a}\cdot\vec{u},\vec{a},\vec{u})\in H_n$$

is a smooth section and $d\vec{a}\otimes d\vec{u}$ is an invariant measure on $A_n\times\mathcal{V}_n$. Finally, for any $\psi\in\mathcal{H}$, we have

$$\mathbb{F}_\psi(\vec{a},\vec{u})=W_{q(\vec{a},\vec{u})}\psi.$$

Thus, since, for any nonzero vector $\psi\in\mathcal{H},\mathbb{F}_\psi$ is a frame over the measured space $(A_n\times\mathcal{V}_n,d\vec{a}\otimes d\vec{u})$, it follows that W is square-integrable mod$(A_n\times\mathcal{V}_n,q;\psi)$.

Moreover, one can show that, for $n=3$, if the analyzing vector ψ is chosen to be a *Gaussian function*, the family of vectors

$$\{W_{q(\vec{a},\vec{u})}\psi|\vec{a}\in\mathbb{R}^3,\vec{u}\in\mathbb{R}^3\}$$

is nothing but the classical canonical family of coherent states associated to the quantum harmonic oscillator.

(Received 12 February 1999; accepted for publication 4 May 1999)

We present the general solution of the system of coupled nonlinear equations describing dynamics of D-dimensional bosonic string in the geometric (or embedding) approach. The solution is parametrized in terms of the left- and right-moving Lorentz harmonic variables providing a special coset space realization of the product of two $(D-2)$-dimensional spheres $S^{D-2}=[\mathrm{SO}(1,D-1)/\mathrm{SO}(1,1)\times \mathrm{SO}(D-2)\circledS K_{D-2}]$. © *1999 American Institute of Physics.* [S0022-2488(99)02309-9]

I. INTRODUCTION

The bosonic string (and p-brane) theory allows a geometric description in terms of extrinsic geometry of the worldsheet treated as a surface embedded into a flat D-dimensional Minkowski space.[1–4] (See Ref. 3 for a supersymmetric generalization of the classical surface theory and its application to superstrings and $N=1$ superbranes.)

In this approach the dynamics of a free relativistic string is described by the Maurer–Cartan equation supplemented with the additional conditions which insure the string worldsheet to be a minimal surface embedded into a flat target space-time. All these additional constraints can be solved algebraically, after which one is left with some $\mathrm{SO}(1,D-1)$ valued connection form whose curvature vanishes due to the Maurer–Cartan equations.[5] Thus, though the string in the geometric approach is described by nonlinear equations,[1,2,5] the latter are finally reduced to the zero curvature conditions for the $\mathrm{SO}(1,D-1)$ valued connection form properly specified in terms of the independent field variables.[5]

The system of independent equations describing a free string theory in the D-dimensional Minkowski space was derived, for the first time, by Zheltukhin.[1] In the form when all the gauge symmetries inherent in the string theory are kept unfixed, this system is constituted by the WZNW sigma-model-type equation

$$\partial_{(--)}((\partial_{(++)}G)G^T)^{ij}=e^{2W}G^{[i|k}M^{(++)k}_{(--)}M^{(--)|j]}_{(++)} \tag{1}$$

for the $\mathrm{SO}(D-2)$ valued matrix field G^{ij},

$$GG^T=I,$$

and the Liouville-type equation

$$\partial_{(++)}\partial_{(--)}W=\tfrac{1}{4}M^{(--)i}_{(++)}G^{ij}M^{(++)j}_{(--)}e^{2W} \tag{2}$$

for a ''scalar density'' e^W.[5] Thus, the considered system involves these two independent fields, as well as two chiral SO$(D-2)$ vector fields $M^{(--)i}_{(++)}$, $M^{(++)i}_{(++)}$,

$$\partial_{(--)}M^{(--)j}_{(++)}=0, \quad \partial_{(++)}M^{(++)j}_{(--)}=0, \tag{3}$$

which appear on the right-hand side.

Already at the early stage of working out the geometric approach it was observed that at least for the low dimensions D this system is exactly solvable. It is reduced to the Liouville equation for $D=3$ and a complex Liouville equation for $D=4$. The general solution for $D=5$ was found in Ref. 2. However, for the generic case the general solution of the Eqs. (1), (2), and (3) was so far unknown.

Here we present the general solution of these equations for any value of D. This proves them to provide a new example of a nontrivial system of exactly solvable nonlinear equations and opens an opportunity to study the classical and quantum string theory in terms of a new left- and right-moving variables which parametrize the general solution.

The meaning and origin of our result require a few comments.

The standard equations of motion in the string theory become linear in the conformal gauge. The general solution of these linear equations is given by the sum of chiral and antichiral functions (subjected to the Virasoro constraints). The string-inspired nonlinear equations (i.e., the equations describing bosonic string theory in the geometric approach) encode the information about just the same dynamical system. Thus it is natural to expect (and, as we demonstrate here, this is indeed the case) that these equations are exactly solvable and that their general solution should be expressible in terms of chiral data.

Thus, the first step was to seek for an adequate set of chiral variables appropriate for constructing the general solution. It turned out that the necessary variables are provided by the harmonic approach[6] adapted to the case of Lorentz groups in Refs. 7 and 8.

Namely, in Ref. 9 it was found that the ''constrained chiral twistorlike variables'' (which can be identified with the spinor SO$(1,D-1)$ Lorentz harmonics[10,11,8]) can be used to obtain a covariant solution of the chiral Virasoro constraints

$$\partial_{(++)}X^{\underline{m}}_L\partial_{(++)}X^{\underline{m}}_L=0, \quad \partial_{(--)}X^{\underline{m}}_R\partial_{(--)}X^{\underline{m}}_R=0,$$

$$\partial_{(--)}X^{\underline{m}}_L=0, \quad \partial_{(++)}X^{\underline{m}}_R=0 \quad (\underline{m}=0,1,...,D-1)$$

which are to be imposed on the solutions $X^{\underline{m}}_L, X^{\underline{m}}_R$ of the string equations of motion in the conformal gauge. The $D=3,4,6$ strings were treated in this way. It was analyzed how the fields composed from such chiral twistors are related to the corresponding string-inspired nonlinear equations.

Here, instead of solving the chiral Virasoro constraints of D-dimensional string theory, we *construct two chiral moving frames* given by the two sets of chiral SO$(1,D-1)$ Lorentz harmonic variables,[7] and identify the left- and right-moving vectors $\partial_{(++)}X^{\underline{m}}_L$ and $\partial_{(--)}X^{\underline{m}}_R$ with the lightlike components of the relevant harmonic matrix. Each set of the moving frame variables parametrizes a special coset space of the group SO$(1,D-1)$. Despite the fact that the group SO$(1,D-1)$ on its own is noncompact, this coset space is compact and is isomorphic to the D-dimensional sphere[11]

$$S^{D-2}=\mathrm{SO}(1,D-1)/[\mathrm{SO}(1,1)\times \mathrm{SO}(D-2)\otimes K_{D-2}].$$

It provides us with the appropriate chiral data for constructing the general solution of the string-inspired nonlinear equations (1)–(3). We construct such a solution explicitly and argue that this is the *general* one.

Basic notation. Our conventions basically coincide with those of Ref. 5. The indices $m,n,\ldots=0,\ 1=(++),\ (--)(\{v^m\}\equiv\{v^{\pm\pm}=v^0\pm v^1\})$ label the worldsheet vectors, while $\underline{m},\underline{n},\ldots=0,1,\ldots,(D-1)$ are the flat target space vector indices.

For the tangent space indices we use the notations $a,b,\ldots=0,1$ and $\underline{a},\underline{b},\ldots=0,1,\ldots,(D-1)$. Thus, underlined indices always correspond to the D-dimensional target manifold and its tangent space, while the nonunderlined ones refer to the two-dimensional ($d=2$) worldsheet and its tangent.

The indices $+,\ -$ denote the weights of the tangent space vectors and spinors with respect to both the worldsheet Lorentz group SO(1,1) and the SO(1,1) subgroup of the target space Lorentz group $SO(1,D-1)$. These two subgroups are identified with each other in that version of the geometric approach to string theory which we follow in the present consideration (see Refs. 3 and 5, and references therein). For example, we write $V^a=(V^0,V^1)=(\frac{1}{2}(V^{++}+V^{--}),\frac{1}{2}(V^{++}-V^{--}))$ for the $d=2$ tangent space vectors [and reserve the notations $\psi^\alpha=(\psi^+,\psi^-)$ for the $d=2$ spinors which appear in supersymmetric generalizations of our approach]. The indices $+,\ -$ within the parentheses denote the weights with respect to the $d=2$ conformal symmetry, e.g., $d\xi^m=(d\xi^0,d\xi^1)=(\frac{1}{2}(d\xi^{(++)}+d\xi^{(--)}),\frac{1}{2}(d\xi^{(++)}-d\xi^{(--)}))$. The weights with respect to the chiral affine $SO(1,1)_L$ and $SO(1,1)_R$ transformations are indicated in the same way.

We use the subscripts L and R to denote the chiral functions of the string worldsheet coordinates $\xi^m=(\xi^{(++)},\xi^{(--)})$

$$f_L=f_L(\xi^{(++)}),\quad f_R=f_R(\xi(--)),$$

$$\partial_{(--)}f_L=0,\quad \partial_{(++)}f_R=0.$$

They should not be confused with the calligraphic subscripts $\mathcal{L}$ and $\mathcal{R}$ carried by some fields. The chiral Lorentz harmonics (chiral moving frame variables) are denoted by the letters l and r, while the generic (nonchiral) Lorentz harmonics are denoted by u.

II. GEOMETRIC APPROACH TO STRING DYNAMICS AND STRING-INSPIRED NONLINEAR EQUATIONS

A. Lorentz harmonics

We begin with the definition of the moving frame variables (Lorentz harmonics[6,7]) which are the basic entities of the geometric approach to D-dimensional bosonic string theory[8,3,5]

$$u_{\underline{m}}^{\underline{a}}(\xi)\equiv(\tfrac{1}{2}(u_{\underline{m}}^{++}+u_{\underline{m}}^{--}),\quad u_{\underline{m}}^{i},\tfrac{1}{2}(u_{\underline{m}}^{++}-u_{\underline{m}}^{--}))$$
$$\underline{m}=0,1,\ldots,D-1,\quad \underline{a}=0,1,\ldots,D-1. \tag{4}$$

These objects are subjected to the following orthonormality conditions:

$$u_{\underline{a}}^{\underline{m}}u_{\underline{m}\underline{b}}=\eta_{\underline{a}\underline{b}}\equiv\mathrm{diag}(1,-1,\ldots,-1)\Leftrightarrow\begin{cases}u_{\underline{m}}^{++}u^{\underline{m}++}=0,\quad u_{\underline{m}}^{--}u^{\underline{m}--}=0,\\ u_{\underline{m}}^{++}u^{\underline{m}--}=2,\\ u_{\underline{m}}^{++}u^{\underline{m}i}=0,\quad u_{\underline{m}}^{--}u^{\underline{m}i}=0,\\ u_{\underline{m}}^{i}u^{\underline{m}j}=-\delta^{ij}\end{cases} \tag{5}$$

which imply that the $D\times D$ matrix $u_{\underline{m}}^{\underline{a}}$ (4) belongs to the group $SO(1,D-1)$

$$u_{\underline{m}}^{\underline{a}}(\xi)\in SO(1,D-1). \tag{6}$$

The completeness condition

$$u_{\underline{m}}^{\underline{a}}u_{\underline{n}\underline{a}}\equiv\tfrac{1}{2}u_{\underline{m}}^{++}u_{\underline{n}}^{--}+\tfrac{1}{2}u_{\underline{m}}^{--}u_{\underline{n}}^{++}-u_{\underline{m}}^{i}u_{\underline{n}}^{i}=\eta_{\underline{m}\underline{n}}\equiv\mathrm{diag}(1,-1,\ldots,-1) \tag{7}$$

follows from Eq. (5). In Eqs. (4) and (7) the lightlike notation is used

$$u_{\underline{m}}^{++} \equiv u_{\underline{m}}^{0} + u_{\underline{m}}^{D-1} = u_{0\underline{m}} - u_{D-1\underline{m}} = u_{--\underline{m}},$$

$$u_{\underline{m}}^{--} \equiv u_{\underline{m}}^{0} - u_{\underline{m}}^{D-1} = u_{0\underline{m}} + u_{D-1\underline{m}} = u_{++\underline{m}}. \tag{8}$$

The constraints (5) and (7) as they stand are invariant under the local SO$(1,D-1)$ transformations acting on the tangent space indices $\underline{a},\underline{b},\ldots$. Below we will see that for constructing the geometric approach description of the string theory this symmetry should be restricted to SO(1,1)$\otimes$SO$(D-2)$ in accordance with the splitting (4). Just this local symmetry is respected by the basic geometric postulate of such a description, namely by the condition that the Lorentz harmonic frame should be adapted to the string worldsheet [see Eq. (23) below]. This means that two of $(D-2)$ vectors $u_{\underline{m}}^{\underline{a}}$ are chosen to be tangent to the worldsheet while the remaining ones $u_{\underline{m}}^{i}$ are orthogonal to it. The local (gauge) symmetry SO(1,1)$\otimes$SO$(D-2)$ reflects, first, the freedom of the $d=2$ Lorentz rotation of the vectors $u_{\underline{m}}^{0,(D-1)}$ tangent to the worldsheet and, second, the freedom of SO$(D-2)$ rotations of the vectors $u_{\underline{m}}^{i}$ orthogonal to the worldsheet [in the lightlike notation (8) the $d=2$ rotations are realized as the opposite weights scaling transformations of the vectors u^{++} and u^{--}].

Thus the vectors $u_{\underline{m}}^{\underline{a}}$ appropriate for the description of the external geometry of the bosonic string worldsheet parametrize the *noncompact* coset space

$$\frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times \mathrm{SO}(D-2)}. \tag{9}$$

In other words, the harmonics (4) regarded as the worldsheet fields define a map of the worldsheet $\mathcal{M}^{(1,1)}=\{\xi^m\}$ onto the noncompact coset (9)

$$u_{\underline{m}}^{\underline{a}}:\ \ \mathcal{M}^{(1,1)}=\{\xi^m\}\rightarrow \frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times \mathrm{SO}(D-2)}. \tag{10}$$

Below we will see that the basic ingredients of the sought general solution of the string-inspired equations will be smaller sets of left- and right-moving Lorentz harmonics which parametrize some compact subspaces in two chiral copies of the coset space (9).

1. Cartan 1-forms

Differentials of the harmonic variables can be calculated with taking into account the conditions (4). Differentiating Eq. (4) produces the equation

$$du_{\underline{m}}^{\underline{a}}\, u^{\underline{b}\,\underline{m}} + u^{\underline{a}\,\underline{m}}\, du_{\underline{m}}^{\underline{b}} = 0$$

which can be solved as follows

$$du_{\underline{m}}^{\underline{a}} = u_{\underline{m}}^{\underline{b}}\Omega_{\underline{b}}^{\ \underline{a}}(d) \Leftrightarrow \begin{cases} du_{\underline{m}}^{++} = u_{\underline{m}}^{++}\omega + u_{\underline{m}}^{i} f^{++i}(d),\\ du_{\underline{m}}^{--} = -u_{\underline{m}}^{--}\omega + u_{\underline{m}}^{i} f^{--i}(d),\\ du_{\underline{m}}^{i} = -u_{\underline{m}}^{j}A^{ji} + \tfrac{1}{2}u_{\underline{m}}^{++} f^{--i}(d) + \tfrac{1}{2}u_{\underline{m}}^{--} f^{++i}(d). \end{cases} \tag{11}$$

Here

$$\Omega_{\underline{b}}^{\underline{a}} \equiv u_{\underline{b}}^{\underline{m}} du_{\underline{m}}^{\underline{a}} = \begin{pmatrix} \omega & 0 & \frac{1}{\sqrt{2}} f^{--i}(d) \\ 0 & -\omega & \frac{1}{\sqrt{2}} f^{++i}(d) \\ \frac{1}{\sqrt{2}} f^{++i}(d) & \frac{1}{\sqrt{2}} f^{--i}(d) & A^{ji}(d) \end{pmatrix}, \quad \Omega^{\underline{a}\,\underline{b}} \equiv \eta^{\underline{a}\,\underline{c}} \Omega_{\underline{c}}^{\underline{b}} = -\Omega^{\underline{b}\,\underline{a}} \tag{12}$$

are the SO(1,$D-1$) Cartan forms [in the vector representation of the SO(1,$D-1$) generators]. Due to (4), they are naturally divided into the three subsets: (i) the SO(1,1)$\times$SO($D-2$) covariant forms

$$f^{++i} \equiv u_{\underline{m}}^{++}\, du^{\underline{m}i}, \tag{13}$$

$$f^{--i} \equiv u_{\underline{m}}^{--}\, du^{\underline{m}i}, \tag{14}$$

which constitute a vielbein of the noncompact coset space SO(1,$D-1$)/SO(1,1)$\otimes$SO($D-2$), (ii) the SO(1,1) (spin) connection

$$\omega \equiv \tfrac{1}{2} u_{\underline{m}}^{--}\, du^{\underline{m}++}, \tag{15}$$

and (iii) the SO($D-2$) connections (gauge fields)

$$A^{ij} \equiv u_{\underline{m}}^{i}\, du^{\underline{m}j} \equiv -u_{\underline{m}}^{j}\, du^{\underline{m}i}. \tag{16}$$

2. Parabolic subgroup

As was mentioned above, the choice of the tangent space local group as SO(1,1)$\otimes$SO(D) [and the coset space (9) for Lorentz harmonics] is motivated by the adaptation postulate which ''solders'' harmonics to the worldsheet and is thus relevant just to the geometric description of strings. Formally, the same harmonic (moving frame) variables (4) can be used to give a geometric description of the massless particle. But in this case the adaptation of the moving frame would consist in requiring that one of the lightlike vectors, e.g., $u_{\underline{m}}^{++}$, is tangent to the worldline, while u^i and u^{--} are orthogonal to it. Such an adaptation is covariant with respect to the following right gauge transformations[11] (see also Ref. 10, where the Hamiltonian form of the corresponding $D=4$ transformations was presented)

$$u_{\underline{m}}^{++\prime} = u_{\underline{m}}^{++} V^{-1},$$

$$u_{\underline{m}}^{i\prime} = (u_{\underline{m}}^{++} V^{--j} + u_{\underline{m}}^{j}) V^{ji},$$

$$u_{\underline{m}}^{--\prime} = (u_{\underline{m}}^{--} + u_{\underline{m}}^{++} V^{--i} V^{--i} + 2 u_{\underline{m}}^{i} V^{--j}) V. \tag{17}$$

The transformations (17) form the maximal proper subgroup (parabolic subgroup) SO(1,1)$\times$SO($D-2$)$\otimes$$K_{D-2}$ of the Lorentz group SO(1,$D-1$).[11] An arbitrary element of this subgroup is characterized by the SO(1,1) transformation $V=e^{\alpha}$, the matrix V^{ij} of SO($D-2$)-orthogonal rotations and the parameters V^{--i} of the boosts K_{D-2}. Thus, in the geometric description of massless particle, *as well as in any case when the adaptation of the moving frame involves only one lightlike moving frame vector*, the harmonics $u_{\underline{m}}^{\underline{a}}$ (4) can be regarded as parameters of the compact coset space

$$S^{D-2} = \frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times \mathrm{SO}(D-2) \otimes K_{D-2}}. \tag{18}$$

It is isomorphic to a $(D-2)$-dimensional sphere S^{D-2}.[11]

The Cartan forms (13), (14), (15), and (16) are transformed under (17) as follows:

$$f^{++i\prime}=f^{++j}V^{ji}V^{-1}, \tag{19}$$

$$f^{--i\prime}=(f^{--j}+2\mathcal{D}V^{--j}-2f^{++k}(V^{--k}V^{--j}-\tfrac{1}{2}\delta^{kj}V^{--l}V^{--l}))V^{ji},$$

$$\mathcal{D}V^{--j}\equiv dV^{--j}+\omega V^{--j}-V^{--k}A^{kj}, \tag{20}$$

$$\omega'=\omega-f^{++i}V^{--i}+V\,dV^{-1}, \tag{21}$$

$$A^{ij\prime}=(V^{-1}AV)^{ij}-(V^{-1}\,dV)^{ij}-2f^{++k}V^{k[i|}V^{--l}V^{l|j]}. \tag{22}$$

Though the K_{D-2} transformations (17) with the parameters V^{--i} *are not* the gauge symmetries of the whole bosonic string theory, they play a crucial role for understanding the group-theoretical structure of the general solution of the nonlinear equations (1) and (2) (see Sec. III) [It was noticed in Ref. 5 that the boost symmetry allows one to introduce a nontrivial dependence on a spectral parameter into the connection 1-forms entering the zero curvature representation for the nonlinear equations (1) and (2).] Moreover, to define the general solution, we introduce two chiral sets of moving frame variables, $l_{\underline{m}}^{(\underline{a})}$ and $r_{\underline{m}}^{(\underline{a})}$ (see Sec. II B). Their ''adaptation'' is realized just in the ''particlelike'' fashion and thus respects covariance under the chiral counterparts of the maximal parabolic symmetry (17) [cf. (82) and (83)].

B. The first-order form of string equations and the geometric approach to string theory

The Lorentz harmonics give us a possibility to rewrite the string equations of motion in the first order form, namely, as the following set of equations[8,3,5]

$$dX^{\underline{m}}=\tfrac{1}{2}e^{++}u^{--\underline{m}}+\tfrac{1}{2}e^{--}u^{++\underline{m}}, \tag{23}$$

$$d(e^{++}u^{--\underline{m}}-e^{--}u^{++\underline{m}})=0. \tag{24}$$

Here $e^{\pm\pm}=d\xi^m e_m^{\pm\pm}$ is a worldsheet vielbein. While dealing with (23) and (24), one should take into account the restrictions (11) on the differentials of the harmonic variables.

Equation (23) is the adaptation relation already mentioned earlier. It plays the basic role in the geometric approach to strings. In particular, it implies that the intrinsic worldsheet metric is identified with the induced one

$$\tfrac{1}{2}(e_m^{++}e_n^{--}+e_m^{--}e_n^{++})=g_{mn}=\partial_m X^{\underline{m}}\partial_n X_{\underline{m}}. \tag{25}$$

The geometric meaning of Eq. (23) consists in that the string worldsheet is identified with a surface embedded into the D-dimensional Minkowski spacetime. On its own right, it has no dynamical content and gives rise to the purely geometric corollaries.

The integrability conditions $(d\,dX\equiv 0)$ for Eq. (23) are as follows:

$$T^{++}\equiv de^{++}-e^{++}\wedge\omega=0, \quad T^{--}\equiv de^{--}+e^{--}\wedge\omega=0, \tag{26}$$

$$e^{++}\wedge f^{--i}+e^{--}\wedge f^{++i}=0 \Leftrightarrow f_{--}^{--i}-f_{++}^{++i}=0. \tag{27}$$

Thus they require the torsion 2-forms $T^{\pm\pm}$ to vanish, thereby imposing proper constraints on the induced spin connection ω. Besides, they imply the SO(1,1) invariant components of the covariant 1-forms f^{++i} and f^{--i} to coincide with each other

$$f_{--}^{--i}=f_{++}^{++i}\equiv\tfrac{1}{2}h^i. \tag{28}$$

The quantity h^i can be easily recognized as the mean curvatures of the embedded surface.[4] Indeed, using Eq. (23) to express the lightlike harmonic vectors in terms of derivatives of the embedding functions X, we arrive at the standard expression for the mean curvatures

$$h^i = g^{mn} K^i_{mn}, \quad K^i_{mn} = -\partial_m \partial_n X^{\underline{m}} u^i_{\underline{m}}. \tag{29}$$

1. Minimal embedding

Using Eq. (11), one finds that Eq. (24) implies the vanishing of the mean curvatures (28)

$$h^i = 0. \tag{30}$$

Thus the surface defined by Eq. (24) is minimal.[4]

On the other hand, expressing all the auxiliary variables u and e through the derivatives of the embedding functions $X(\xi)$ and using the induced metric (25)

$$g_{mn} \equiv \partial_m X^{\underline{m}} \partial_n X_{\underline{m}}, \tag{31}$$

and its inverse g^{mn}, one can rewrite Eq. (30) [or (24)] in the form

$$\partial_m (\sqrt{-g} g^{mn} \partial_n X^{\underline{m}}) = 0, \tag{32}$$

which is the standard string equations of motion pertinent to the Nambu–Goto action (see Ref. 5 for details). Thus the strings dynamics in the geometric approach is contained just in Eq. (24).

Note that it is important for the geometric approach description that the minimal embedding is described by the covariant Cartan forms f^{++i}, f^{--i} containing in their decomposition only one of the two basic forms e^{--}, e^{++}

$$f^{++i} = e^{--} f^{++i}_{--}, \quad f^{--i} = e^{++} f^{--i}_{++} \tag{33}$$

[cf. Eqs. (28) and (30)]. Actually, Eqs. (33) encode three previous equations: (27), (28), and (30) [which amounts to (24)]. Thus the string dynamics proves to be eventually encoded just in Eqs. (33).

C. Maurer–Cartan equation and the string-inspired nonlinear equations

The integrability conditions for Eqs. (11) produce the Maurer–Cartan equations

$$d\Omega_{\underline{a}}{}^{\underline{b}} - \Omega_{\underline{a}}{}^{\underline{c}} \wedge \Omega_{\underline{c}}{}^{\underline{b}} = 0. \tag{34}$$

With making use of Eq. (4), Eqs. (34) naturally split into the following equations for the coset vielbeins $f^{\pm\pm i}$ (13) and (14) and the connection 1-forms ω, A^{ij} (15) and (16):

$$\mathcal{D} f^{++i} \equiv d f^{++i} - f^{++i} \wedge \omega + f^{++j} \wedge A^{ji} = 0, \tag{35}$$

$$\mathcal{D} f^{--i} \equiv d f^{--i} + f^{--i} \wedge \omega + f^{--j} \wedge A^{ji} = 0, \tag{36}$$

$$\mathcal{R} = d\omega = \tfrac{1}{2} f^{--i} \wedge f^{++i}, \tag{37}$$

$$R^{ij} \equiv dA^{ij} + A^{ik} \wedge A^{kj} = -f^{--[i} \wedge f^{++j]}. \tag{38}$$

Equations (35)–(38) amount to the Peterson-Codazzi, Gauss, and Ricci equations of the classical surface theory.[4]

Thus, in the geometric approach framework, the dynamics of string is described by the vielbein $e^{\pm\pm}$ and the set of Cartan forms ω, $f^{\pm\pm i}, A^{ij}$ which satisfy Eqs. (26) and (33) and the Maurer–Cartan Eqs. (35)–(38).[4,1,2,3,5]

The most essential general feature of this approach is that Eqs. (33), (26), (35), and (36) can be solved algebraically.[5]

Indeed, using the fact that any connection is integrable on any one-dimensional subspace, we can specify the expressions for the SO(1,1) and SO$(D-2)$ connection 1 forms in the following way:

$$\omega = e^{++}\nabla_{++}(W-L) - e^{--}\nabla_{--}(W+L), \tag{39}$$

$$A^{ij} = e^{++}\nabla_{++}G^{ik}_{\mathcal{R}}G^{jk}_{\mathcal{R}} + e^{--}\nabla_{--}G^{ik}_{\mathcal{L}}G^{jk}_{\mathcal{L}}, \tag{40}$$

where $G_{\mathcal{L}}$ and $G_{\mathcal{R}}$ are some SO$(D-2)$ group matrices,

$$G_{\mathcal{L}}G^T_{\mathcal{L}} = I, \quad G_{\mathcal{R}}G^T_{\mathcal{R}} = I. \tag{41}$$

Equations (39) and (40) provide a possibility to rewrite Eqs. (26), (35), and (36) as the conditions of closeness of some 1-forms

$$d(e^{++}\exp(W+L)) = 0, \quad d(e^{--}\exp(W-L)) = 0. \tag{42}$$

$$d(f^{++i}G^{ji}_{\mathcal{R}}\exp(-W+L)) = 0, \quad d(f^{--i}G^{ji}_{\mathcal{L}}\exp(-W-L)) = 0 \tag{43}$$

[Eqs. (33) have been used when deriving (43)].

The general solution to Eqs. (42) (up to some possible topological subtleties which are unessential for the present study) is provided by

$$\begin{aligned} e^{++} &= d\xi^{(++)}M^{(++)}_{(++)}(\xi^{(++)})\exp(-W-L), \\ e^{--} &= d\xi^{(--)}M^{(--)}_{(--)}(\xi^{(--)})\exp(-W+L). \end{aligned} \tag{44}$$

Here, $\xi^{(\pm\pm)}$ are some functions of the string worldsheet coordinates with the only defining demand that their differentials are linearly-independent 1-forms. It is convenient, however, to choose $\xi^{(\pm\pm)}$ as a set of local coordinates on the worldsheet

$$\xi^m = \xi^{(\pm\pm)}. \tag{45}$$

This choice fixes a gauge with respect to the worldsheet reparametrizations (general coordinate transformations), so that only two-dimensional conformal reparametrizations survive [see Eq. (61) below].

In the holonomic basis $d\xi^{(\pm\pm)}$ the components of the vielbein form $e^{\pm\pm}$ are

$$\begin{gathered} e^{++}_{(++)} = M^{(++)}_{(++)}\exp(-W-L), \quad e^{++}_{(--)} = 0, \\ e^{--}_{(++)} = 0, \quad e^{--}_{(--)} = M^{(--)}_{(--)}\exp(-W+L), \\ e^{(++)}_{--} = 0, \quad e^{(--)}_{--} = 2(M^{(--)}_{(--)})^{-1}\exp(W-L), \\ e^{(++)}_{++} = 2(M^{(++)}_{(++)})^{-1}\exp(W+L), \quad e^{(--)}_{++} = 0, \end{gathered} \tag{46}$$

the induced metric (25) is conformally flat

$$ds^2 = d\xi^m\, d\xi^n\, g_{mn} = d\xi^{(++)}\, d\xi^{(--)}\, M^{(++)}_{(++)}M^{(--)}_{(--)}e^{2W} \tag{47}$$

and the covariant derivatives are proportional to the corresponding holonomic ones

$$e^{++}\nabla_{++} = d\xi^{(++)}\,\partial_{(++)}, \quad e^{--}\nabla_{--} = d\xi^{(--)}\,\partial_{(--)}. \tag{48}$$

Hence, the expressions (39) and (40) for the gauge connections can be rewritten as follows:

$$\omega = d\xi^{(++)}\,\partial_{(++)}(W-L) - d\xi^{(--)}\,\partial_{(--)}(W+L), \tag{49}$$

$$A^{ij} = d\xi^{(++)}\,\partial_{(++)}G_{\mathcal{R}}^{ik}G_{\mathcal{R}}^{jk} + d\xi^{(--)}\,\partial_{(--)}G_{\mathcal{L}}^{ik}G_{\mathcal{L}}^{jk}. \tag{50}$$

Finally, using the holonomic basis, one can write down the general solution of the Peterson–Codazzi equations (43) for the covariant forms (33) as

$$f^{++i} = d\xi^{(--)}\,e^{W-L}G_{\mathcal{R}}^{ij}M_{(--)}^{(++)j}(\xi^{(--)}), \tag{51}$$

$$f^{--i} = d\xi^{(++)}\,e^{W+L}G_{\mathcal{L}}^{ij}M_{(++)}^{(--)j}(\xi^{(++)}), \tag{52}$$

where vector fields $M_{(--)}^{(++)j}, M_{(++)}^{(--)j}$ are chiral, similarly to the parameters $M_{(++)}^{(++)}, M_{(--)}^{(--)}$ of the solutions (44) of Eqs. (26):

$$\partial_{(++)}M_{(--)}^{(++)j} = 0, \quad \partial_{(--)}M_{(++)}^{(--)j} = 0.$$

Thus, following Ref. 5, we have solved algebraically all the equations except for the Gauss and Ricci ones (37) and (38). Substituting (49), (50), (51), and (52) into Eqs. (37) and (38), we obtain the set of nonlinear equations

$$\partial_{(++)}\partial_{(--)}W = \tfrac{1}{4}M_{(--)}^{(++)i}(G_{\mathcal{L}}^{T}G_{\mathcal{R}})^{ij}M_{(++)}^{(--)j}e^{2W}, \tag{53}$$

$$\begin{aligned}\partial_{(--)}((\partial_{(++)}G_{\mathcal{L}})G_{\mathcal{L}}^{T})^{ij} - \partial_{(++)}((\partial_{(--)}G_{\mathcal{R}})G_{\mathcal{R}}^{T})^{ij} + [(\partial_{(++)}G_{\mathcal{L}})G_{\mathcal{L}}^{T}, (\partial_{(--)}G_{\mathcal{R}})G_{\mathcal{R}}^{T}]^{ij}\\ = e^{2W}(G_{\mathcal{L}}M_{(--)}^{(++)})^{[i}(G_{\mathcal{R}}M_{(++)}^{(--)})^{j]}\end{aligned} \tag{54}$$

describing the extrinsic geometry of the string worldsheet embedded into a D-dimensional Minkowski space.

D. A zero curvature representation and the associated linear system

As we saw, most of the equations of the geometric approach (33), (26), (35), and (36) can be solved algebraically and the final set of the string-inspired nonlinear equations (53) and (54) emerges as the result of substitution of these algebraic solutions into the Gauss and Ricci equations (37) and (38). Since the latter constitute a part of the Maurer–Cartan equation (34), one can conclude that a zero curvature representation for the nonlinear equations (53) and (54) is given by the Maurer–Cartan equation (34) for the SO$(1,D-1)$ valued connection 1-forms specified by Eqs. (12), (49), (50), (51), and (52).

The associated linear system is provided by Eq. (11) with the 1-forms (34) specified by Eqs. (12), (49), (50), (51), and (52).

A nontrivial dependence on a spectral parameter can be introduced into the associated linear system by means of the parabolic subgroup transformations (17).[5]

Thus the nonlinear equations (53) and (54) possess all the features inherent in the equations which can be solved by the inverse scattering method.[12] Below we will prove that they are solvable even in a more strong sense, like the Liouville, Toda or WZNW sigma-model equations. Namely, we will deduce an explicit form of the general solution. It is interesting that the solution can be obtained by exploiting the parabolic group transformations (17). We will demonstrate this in the last section of this paper.

E. Symmetries and bridges

The obtained nonlinear equations and their zero curvature representation (34), (12), (49), (50), (51), and (52) possess a number of powerful symmetries.

As was already mentioned, the local (gauge) symmetries of the string model form the $SO(1,1)\times SO(D-2)$ group

$$\omega' = \omega + V\,dV^{-1} = \omega + \alpha, \tag{55}$$

$$A^{ij\prime} = (V^{-1}AV)^{ij} - (V^{-1}\,dV)^{ij}, \tag{56}$$

$$f^{++i\prime} = V^{-1} f^{++j} V^{ji}, \tag{57}$$

$$f^{--i\prime} = V f^{--j} V^{ji}. \tag{58}$$

The matrix fields $G_{\mathcal{L},\mathcal{R}}$ appearing in Eqs. (51), (52), and (50) are transformed homogeneously under the $SO(D-2)$ gauge symmetry

$$G^{ij\prime}_{\mathcal{L},\mathcal{R}} = G^{kj}_{\mathcal{L},\mathcal{R}} V^{ki} = (V^{-1})^{ik} G^{kj}_{\mathcal{L},\mathcal{R}}, \tag{59}$$

whereas the field L is pure gauge

$$L' = L - \alpha, \quad V = e^{-\alpha}. \tag{60}$$

In other words, it is a compensator (or Nambu–Goldstone field) for the SO(1,1) gauge symmetry.

Examining the expressions (44), (51), and (52), one concludes that our system possesses two types of infinite-dimensional global symmetries whose parameters can be combined into left-moving and right-moving (chiral) functions. One of them is the $d=2$ *conformal symmetry*

$$\begin{gathered} d\xi^{(++)\prime} = d\xi^{(++)}\, s_L(\xi^{(++)}), \quad d\xi^{(--)\prime} = d\xi^{(--)}\, s_R(\xi^{(--)}), \\ \partial_{(--)} s_L = 0, \quad \partial_{(++)} s_R = 0. \end{gathered} \tag{61}$$

The second one is realized as chiral rescalings of the chiral fields $M^{(++)}_{(++)}$ and $M^{(--)}_{(--)}$ present in Eqs. (51), and (52)

$$\begin{gathered} M^{(++)\prime}_{(++)} = M^{(++)}_{(++)} e^{h_L}, \quad M^{(--)\prime}_{(--)} = M^{(--)}_{(--)} e^{h_R}, \\ \partial_{(--)} h_L = 0, \quad \partial_{(++)} h_R = 0. \end{gathered} \tag{62}$$

Clearly, these rescalings can be treated as a sort of affine (or Kac–Moody) $SO(1,1)_L$ and $SO(1,1)_R$ symmetry transformations [i.e., as SO(1,1) transformations with the parameters depending on $\xi^{(++)}$ and $\xi^{(--)}$, respectively]. The full set of nontrivial transformations of these symmetries on the involved fields is given by

$$\begin{gathered} M^{(++)\prime}_{(++)} = M^{(++)}_{(++)} s_L^{-1} e^{h_L}, \quad M^{(--)\prime}_{(--)} = M^{(--)}_{(--)} s_R^{-1} e^{h_R}, \\ (W+L)' = (W+L) + h_L - \alpha, \quad (W-L)' = (W-L) + h_R + \alpha, \\ (M^{(--)i}_{(++)})' = M^{(--)i}_{(++)} s_L^{-1} e^{-h_L}, \quad (M^{(++)i}_{(--)})' = M^{(++)i}_{(--)} s_R^{-1} e^{-h_R}. \end{gathered} \tag{63}$$

We observe that the chiral fields $M^{(++)}_{(++)}, M^{(--)}_{(--)}$ can be regarded as the ''bridges'' relating the affine $SO(1,1)_L, SO(1,1)_R$ groups to the corresponding chiral parts of the two-dimensional conformal group, while

$$e^{W+L} = (e^{W+L})^{(++)}_{++}, \quad e^{W-L} = (e^{W-L})^{(--)}_{--}$$

as the bridges relating affine $SO(1,1)_L$ and $SO(1,1)_R$ to the gauge SO(1,1) symmetry. Since the symmetries (61) and (62) offer the possibility to choose the gauge [they also make it possible to fix the value of the norm of the chiral vector fields $M^{\pm\pm i}_{(\mp\mp)}$ (see Ref. 5)] $M^{(++)}_{(++)} = M^{(--)}_{(--)} = 1$, we, for simplicity, will make no distinction between the $SO(1,1)_{L,R}$ indices and conformal ones in what follows. We will also use the superscript $(--)$ instead of the $SO(1,1)_L$ subscript $(++)$ for the chiral vector field $M^{(--)i}_{(++)}$ (the chirality property of the latter field, $\partial_{(--)}M^{(--)i}_{(++)}=0$, excludes any confusion).

In addition, our equations possess an invariance under right multiplication of the $SO(D-2)$ valued fields $G_{\mathcal{L}}$ and $G_{\mathcal{R}}$ by chiral $SO(D-2)$ matrices H_R and H_L. So, the complete form of the appropriate symmetry transformations is

$$G'_{\mathcal{L}}=V^{-1}G_{\mathcal{L}}H_L, \quad G'_{\mathcal{R}}=V^{-1}G_{\mathcal{R}}H_R, \tag{64}$$

$$M^{(--)i\,\prime}_{(++)}=H^{ij}_L M^{(++)j}_{(--)}, \quad M^{(--)j\,\prime}_{(++)}=H^{ij}_R M^{(--)j}_{(++)}, \tag{65}$$

$$H_L H_L^T=H_R H_R^T=I, \quad \partial_{(--)}H_L=\partial_{(++)}H_R=0. \tag{66}$$

Thus the orthogonal matrix fields $G_{\mathcal{L}}$ and $G_{\mathcal{R}}$ can be regarded as bridges between the gauge $SO(D-2)$ transformations and affine chiral $SO(D-2)_L$ and $SO(D-2)_R$ transformations, respectively.

F. A simplified form of the nonlinear equations

The system of nonlinear equations (53) and (54) can be significantly simplified by using the $SO(D-2)$ gauge symmetry with parameters V^{ij} to fix the gauge

$$G_{\mathcal{L}}=1, \quad G_{\mathcal{R}}=G. \tag{67}$$

Then the sigma-model-type equation (54) acquires the simplest WZNW sigma-model-type form (1):

$$\partial_{(--)}((\partial_{(++)}G)G^T)^{ij}=e^{2W}G^{[i|k}M^{(++)k}_{(--)}M^{(--)|j]}_{(++)}, \tag{68}$$

whereas the Liouville-type equation (53) becomes form (2):

$$\partial_{(++)}\partial_{(--)}W=\tfrac{1}{4}M^{(--)i}_{(++)}G^{ij}M^{(++)j}_{(--)}e^{2W}. \tag{69}$$

The gauge (67) is invariant under the action of two chiral affine $SO(D-2)$ symmetries with the parameters $H_L(\xi^{(++)})$ and $H_R(\xi^{(--)})$. They act on the matrix field G as follows:

$$G'=H_L^{-1}GH_R, \quad \partial_{(--)}H_L=\partial_{(++)}H_R=0. \tag{70}$$

III. GENERAL SOLUTION OF THE STRING-INSPIRED NONLINEAR EQUATIONS

A. Standard string equations of motion, their solution and Virasoro constraints

We start by discussing the familiar string equations of motion and Virasoro conditions in the standard setting. The study of the relation between the solutions of these equation and the Lorentz harmonics (which, as was already mentioned, provide the associated linear system for the considered nonlinear equations) opens a possibility to construct the general solution of the nonlinear equations (69) and (68).

The equations of motion of the D-dimensional bosonic string following from the Nambu–Goto action (see Ref. 13 and references therein) has the form (32)

$$\partial_m(\sqrt{-g}g^{mn}\partial_n X^{\underline{m}})=0, \tag{71}$$

where [cf. Eq. (31)]

$$g_{mn}\equiv\partial_m X^{\underline{m}}\partial_n X_{\underline{m}} \tag{72}$$

is the induced metric, g^{mn} is its inverse and $g=\det(g_{mn})$.

In the conformal gauge (see, e.g., Ref. 13) the string equation (71) becomes linear

$$\tilde{\partial}_{(++)}\tilde{\partial}_{(--)}X^{\underline{m}}\equiv\frac{\partial}{\partial\tilde{\xi}^{(++)}}\frac{\partial}{\partial\tilde{\xi}^{(--)}}X^{\underline{m}}=0 \tag{73}$$

and has the following general solution

$$X^{\underline{m}}=X_L^{\underline{m}}+X_R^{\underline{m}}, \quad \tilde{\partial}_{(--)}X_L^{\underline{m}}=0, \quad \tilde{\partial}_{(++)}X_R^{\underline{m}}=0. \tag{74}$$

The chiral functions $X_L^{\underline{m}}(\xi^{(\tilde{+}+)}),X_R^{\underline{m}}(\xi^{(\tilde{-}-)})$ are subjected to the Virasoro constraints

$$\tilde{\partial}_{(++)}X_L^{\underline{m}}\tilde{\partial}_{(++)}X_{L\underline{m}}=0, \quad \tilde{\partial}_{(--)}X_R^{\underline{m}}\tilde{\partial}_{(--)}X_{R\underline{m}}=0. \tag{75}$$

Let us compare the solution (74) with the expressions (23) and (44) obtained in the geometric approach

$$dX^{\underline{m}}=\tfrac{1}{2}d\xi^{(++)}e^{-W-L}M_{(++)}^{(++)}u^{--\underline{m}}+\tfrac{1}{2}d\xi^{(--)}\,e^{-W+L}M_{(--)}^{(--)}u^{++\underline{m}}. \tag{76}$$

Since, due to Eq. (44), the induced metric is conformally flat in the coordinate frame $\xi^{(\pm\pm)}$, we can identify these worldsheet coordinates with the ''conformal coordinates'' $\tilde{\xi}^{(\pm\pm)}$ used in the standard string description (71)–(75)

$$\xi^{(\pm\pm)}=\tilde{\xi}^{(\pm\pm)}.$$

Thus Eqs. (76) and (74) result in

$$\begin{aligned}\partial_{(++)}X_L^{\underline{m}}(\xi^{(++)})&=\tfrac{1}{2}e^{-W-L}M_{(++)}^{(++)}(\xi^{(++)})u^{--\underline{m}},\\ \partial_{(--)}X_R^{\underline{m}}(\xi^{(--)})&=\tfrac{1}{2}e^{-W+L}M_{(--)}^{(--)}(\xi^{(--)})u^{++\underline{m}}.\end{aligned} \tag{77}$$

It is easy to verify that the Virasoro constraints (75) are satisfied for the functions (77).

It is worth noticing that the lhs of Eqs. (77) includes the chiral functions only [cf. (74)], while the rhs involves the functions $W,L,u^{\pm\pm}$ which from the very beginning were assumed to depend on both coordinates $\xi^{(\pm\pm)}$.

We will demonstrate below that the origin of this fact lies in that any solution of the string equation produces a solution of the string-inspired nonlinear equations, i.e., of the equations (53) and (68) which describe the extrinsic geometry of the string worldsheet.

B. Chiral harmonics

In Ref. 9 it was discussed how to find an appropriate set of chiral functions for obtaining explicit expressions for the fields W and $G^{ij}=(G^{-1})^{ji}$ which enter the nonlinear equations (53) and (68). Constrained twistors have been proposed as such variables for the case of bosonic string theories in dimensions $D=3,4,6$. Such twistors can be regarded as spinor Lorentz harmonics.[11,8] Their only property to be essential for our purposes is that they can be used to define the appropriate vector moving frame. This allows one to avoid complicated calculations associated with the use of the spinor moving frame or spinor harmonic formalism.[8] In this way, the solution of nonlinear equations describing the extrinsic geometry of bosonic string which moves in the Minkowski space of *arbitrary* dimension D can be obtained in terms of the vector Lorentz harmonics only.

Let us introduce two extra sets of Lorentz harmonics (moving frame variables)

$$
\begin{aligned}
r_{\underline{m}}^{(\underline{a})}(\xi^{(--)}) &= (r_{\underline{m}}^{(\pm\pm)}, r_{\underline{m}}^{i}) \in \mathrm{SO}(1,D-1),\\
l_{\underline{m}}^{(\underline{a})}(\xi^{(++)}) &= (l_{\underline{m}}^{(\pm\pm)}, l_{\underline{m}}^{i}) \in \mathrm{SO}(1,D-1),
\end{aligned}
\tag{78}
$$

each depending only on the $\xi^{(--)}$ or $\xi^{(++)}$ coordinates of the string worldsheet.

Recall that the condition (78) means

$$
r^{\underline{m}}{}_{(\underline{a})} r_{\underline{m}\,\underline{b}} = \eta_{(\underline{a})(\underline{b})} \equiv \mathrm{diag}(1,-1,\ldots,-1) \Leftrightarrow
\begin{cases}
r_{\underline{m}}^{(++)} r^{\underline{m}(++)} = 0, \quad r_{\underline{m}}^{(--)} r^{\underline{m}(--)} = 0,\\
r_{\underline{m}}^{(++)} r^{\underline{m}(--)} = 2,\\
r_{\underline{m}}^{(++)} r^{\underline{m}i} = 0, \quad r_{\underline{m}}^{(--)} r^{\underline{m}i} = 0,\\
r_{\underline{m}}^{i} r^{\underline{m}j} = -\delta^{ij}.
\end{cases}
\tag{79}
$$

$$
l^{\underline{m}}{}_{(\underline{a})} l_{\underline{m}\,\underline{b}} = \eta_{(\underline{a})(\underline{b})} \equiv \mathrm{diag}(1,-1,\ldots,-1) \Leftrightarrow
\begin{cases}
l_{\underline{m}}^{(++)} l^{\underline{m}(++)} = 0, \quad l_{\underline{m}}^{(--)} l^{\underline{m}(--)} = 0,\\
l_{\underline{m}}^{(++)} l^{\underline{m}(--)} = 2,\\
l_{\underline{m}}^{(++)} l^{\underline{m}i} = 0, \quad l_{\underline{m}}^{(--)} l^{\underline{m}i} = 0,\\
l_{\underline{m}}^{i} l^{\underline{m}j} = -\delta^{ij}.
\end{cases}
\tag{80}
$$

Further, we identify the chiral vectors $\partial_{(--)}X_R^{\underline{m}}$ and $\partial_{(++)}X_L^{\underline{m}}$ with the components $r^{(++)} = r^{(++)}(\xi^{(--)})$ and $l^{(--)} = l^{(--)}(\xi^{(++)})$ of these sets of chiral harmonics

$$
\partial_{(++)}X_L^{\underline{m}} = \tfrac{1}{2} M_{(++)}^{(++)}(\xi^{(++)}) l^{(--)\underline{m}}(\xi^{(++)}), \quad \partial_{(--)}X_R^{\underline{m}} = \tfrac{1}{2} M_{(--)}^{(--)}(\xi^{(--)}) r^{(++)\underline{m}}(\xi^{(--)}).
\tag{81}
$$

In such a way we adapt the chiral frames to the left and right sectors of the string worldsheet. Since other components of the left- and right-moving frame variables $l_{\underline{m}}^{(\underline{a})}, r_{\underline{m}}^{(\underline{a})}$ remain arbitrary, we face just a "particlelike" situation in the present case. Hence, Eqs. (81) possess the invariance under the affine

$$
(\mathrm{SO}(1,1) \otimes \mathrm{SO}(D-2) \circledS K_{D-2})_L \quad \text{and} \quad (\mathrm{SO}(1,1) \otimes \mathrm{SO}(D-2) \circledS K_{D-2})_R
$$

symmetries with chiral parameters

$$
V_L(\xi^{(++)}) = e^{h_L}, \quad V_R^{(++)i}(\xi^{(++)}), \quad V^{ij}(\xi^{(++)}) = V^{-1ji}(\xi^{(++)})
$$

and

$$
V_R(\xi^{(--)}) = e^{h_R}, \quad V_R^{(--)i}(\xi^{(--)}), \quad V^{ij}(\xi^{(--)}) = V^{-1ji}(\xi^{(--)}),
$$

respectively. [The affine symmetry $\mathrm{SO}(1,1)_L \otimes \mathrm{SO}(1,1)_R$ proves to be "soldered" to the worldsheet conformal symmetry when the gauge $M_{(++)}^{(++)} = 1 = M_{(--)}^{(--)}$ is imposed.] The corresponding transformations read

$$
\begin{aligned}
r_{\underline{m}}^{(++)\prime} &= r_{\underline{m}}^{(++)} V_R,\\
r_{\underline{m}}^{i\prime} &= (r_{\underline{m}}^{j} + r_{\underline{m}}^{(++)} V_R^{(--)j}) V_R^{ji},\\
r_{\underline{m}}^{(--)\prime} &= (r_{\underline{m}}^{(--)} + r_{\underline{m}}^{(++)} V_R^{(--)i} V_R^{(--)i} + 2 r_{\underline{m}}^{i} V_R^{--i}) V_R^{-1},
\end{aligned}
\tag{82}
$$

$$
\begin{aligned}
l_{\underline{m}}^{(--)\prime} &= l_{\underline{m}}^{(--)} V_L,\\
l_{\underline{m}}^{i\prime} &= (l_{\underline{m}}^{j} + l_{\underline{m}}^{(--)} V_L^{(++)j}) V_L^{ji},\\
l_{\underline{m}}^{(++)\prime} &= (l_{\underline{m}}^{(++)} + l_{\underline{m}}^{(--)} V_L^{(++)i} V_L^{(++)i} + l_{\underline{m}}^{i} V_L^{(++)i}) V_L^{-1}.
\end{aligned}
\tag{83}
$$

Hence, each set of chiral harmonics parametrizes the sphere (18). As they depend only on one of the worldsheet coordinates, $\xi^{(--)}$ or $\xi^{(++)}$, they map one of the lightlike sectors, $\mathcal{M}^{(0,1)}=\{\xi^{(--)}\}$ or $\mathcal{M}^{(1,0)}=\{\xi^{(++)}\}$, of the worldsheet $\mathcal{M}^{(1,1)}=\{\xi^m\}=\{\xi^{(++)},\xi^{(--)}\}$ onto two copies of this sphere

$$r_{\underline{m}}^{(\underline{a})}:\quad \mathcal{M}^{(0,1)}=\{\xi^{(--)}\}\rightarrow S^{D-2}=\frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times \mathrm{SO}(D-2)\otimes K_{D-2}}, \tag{84}$$

$$l_{\underline{m}}^{(\underline{a})}:\quad \mathcal{M}^{(1,0)}=\{\xi^{(++)}\}\rightarrow S^{D-2}=\frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times \mathrm{SO}(D-2)\otimes K_{D-2}}. \tag{85}$$

Below we denote the spaces of all possible images of these maps by $S_L^{(D-2)}$ and $S_R^{(D-2)}$, respectively.

The chiral counterparts of the Cartan forms (12) contain only one of the chiral holonomic basic 1-forms $d\xi^{(--)}$ or $d\xi^{(++)}$

$$f_R^{(++)i}=d\xi^{(--)}\, f_{(--)R}^{(++)i}=r^{(++)\underline{m}}\, dr_{\underline{m}}^{i}, \quad f_{(--)R}^{(++)i}=r^{(++)\underline{m}}\partial_{(--)}r_{\underline{m}}^{i}, \tag{86}$$

$$f_R^{(--)i}=d\xi^{(--)}\, f_{(--)R}^{(--)i}=r^{(--)\underline{m}}\, dr_{\underline{m}}^{i}, \quad f_{(--)R}^{(--)i}=r^{(--)\underline{m}}\partial_{(--)}r_{\underline{m}}^{i}, \tag{87}$$

$$\omega_R=d\xi^{(--)}\,\omega_{(--)R}=\tfrac{1}{2}r^{(--)\underline{m}}\, dr_{\underline{m}}^{(++)}, \quad \omega_{(--)R}=\tfrac{1}{2}r^{(--)\underline{m}}\partial_{(--)}r_{\underline{m}}^{(++)}, \tag{88}$$

$$A_R^{ij}=d\xi^{(--)}\, A_{(--)R}^{ij}=\tfrac{1}{2}r^{i\underline{m}}\, dr_{\underline{m}}^{j}, \quad A_{(--)R}^{ij}=\tfrac{1}{2}r^{i\underline{m}}\partial_{(--)}r_{\underline{m}}^{j}, \tag{89}$$

$$f_L^{(++)i}=d\xi^{(++)}\, f_{(++)L}^{(++)i}=l^{(++)\underline{m}}dl_{\underline{m}}^{i}, \quad f_{(++)L}^{(++)i}=l^{(++)\underline{m}}\partial_{(++)}l_{\underline{m}}^{i}, \tag{90}$$

$$f_L^{(--)i}=d\xi^{(++)}\, f_{(++)L}^{(--)i}=l^{(--)\underline{m}}dl_{\underline{m}}^{i}, \quad f_{(++)L}^{(--)i}=l^{(--)\underline{m}}\partial_{(++)}l_{\underline{m}}^{i}, \tag{91}$$

$$\omega_L=d\xi^{(++)}\,\omega_{(++)L}=\tfrac{1}{2}l^{(--)\underline{m}}\, dl_{\underline{m}}^{(++)}, \quad \omega_{(++)L}=\tfrac{1}{2}l^{(--)\underline{m}}\partial_{(++)}l_{\underline{m}}^{(++)}, \tag{92}$$

$$A_L^{ij}=d\xi^{(++)}\, A_{(++)L}^{ij}=\tfrac{1}{2}l^{i\underline{m}}\, dl_{\underline{m}}^{j}, \quad A_{(++)L}^{ij}=\tfrac{1}{2}l^{i\underline{m}}\partial_{(++)}l_{\underline{m}}^{j}. \tag{93}$$

The transformations of these 1-forms under the left and right affine $\mathrm{SO}(1,1)\otimes\mathrm{SO}(D-2)\subset\times K_{D-2}$ symmetries (82) and (83) are determined by the chiral version of Eqs. (19)–(22) and its evident ''left'' counterpart, respectively. It is worth noting that only the forms

$$f_R^{(++)i}=d\xi^{(--)}\, f_{(--)R}^{(++)i} \quad \text{and} \quad f_R^{(--)i}=d\xi^{(++)}\, f_{(++)L}^{(--)i}$$

transform covariantly under (82) and (83). These forms are vielbeins of the ''chiral spheres'' S_R^{D-2} (84) and S_R^{D-2} (85), respectively.

C. Relation of general and chiral harmonics: Solving the Liouville-type equation

Substituting Eq. (81) into Eq. (77), one obtains the expression for the chiral lightlike moving frame vector fields $l^{(--)\underline{m}}(\xi^{(++)})$, $r^{(++)\underline{m}}(\xi^{(--)})$ in terms of generic lightlike harmonics $u^{--\underline{m}},u^{++\underline{m}}$, the Liouville field W and compensator L

$$l^{(--)\underline{m}}(\xi^{(++)})=e^{-W-L}u^{--\underline{m}}, \quad r^{(++)\underline{m}}(\xi^{(--)})=e^{-W+L}u^{++\underline{m}}. \tag{94}$$

Contracting both sides of these two equations in indices $\underline{m}$, we get the expression for the field W in terms of chiral harmonics

$$e^{-2W}=\tfrac{1}{2}l^{(--)\underline{m}}r_{\underline{m}}^{(++)}. \tag{95}$$

For $D=3$, Eq. (95) produces the general solution of the Liouville equation in a special parametrization (see the Appendix).

A similar solution of the Liouville equation in the conformal gauge was presented in Ref. 9. The Cartan–Penrose representation in terms of bosonic spinors was used there for chiral lightlike vectors $l^{(--)\underline{m}}$ and $r^{(++)}_{\underline{m}}$.

In the generic case of higher D it is necessary to have the suitable representation for the $SO(D-2)$ matrices G^{ij} as well.

D. Relation of general and chiral harmonics: Solving the sigma-model-type equation

To obtain the expression for $SO(D-2)$ matrix field G, let us analyze the consequences of Eq. (94) for the moving frame vectors u^i. First of all, one finds

$$l^{(--)\underline{m}}u^i_{\underline{m}}=0, \quad r^{(++)\underline{m}}u^i_{\underline{m}}=0. \tag{96}$$

Equations (96) mean that the decompositions of the u^i harmonic over the chiral left- and right-moving ones involve no terms proportional to $l^{(++)}$ and $r^{(--)}$, respectively

$$u^i_{\underline{m}}=-(l^j_{\underline{m}}-V^j_{(--)}l^{(--)}_{\underline{m}})U^{ji}_{\mathcal{L}}, \tag{97}$$

$$u^i_{\underline{m}}=-(r^j_{\underline{m}}+V^i_{(++)}r^{(++)}_{\underline{m}})U^{ji}_{\mathcal{R}}. \tag{98}$$

The newly introduced matrices $U^{ji}_{\mathcal{L}}$ and $U^{ji}_{\mathcal{L}}$ are expressed through the contractions of chiral harmonics with the generic ones:

$$U^{ji}_{\mathcal{L}}=l^{j\underline{m}}u^i_{\underline{m}}, \quad U^{ji}_{\mathcal{R}}=r^{j\underline{m}}u^i_{\underline{m}}. \tag{99}$$

So they can easily be checked to be orthogonal matrices

$$U^{jk}_{\mathcal{L}}U^{ik}_{\mathcal{L}}=\delta^{ji}, \quad U^{jk}_{\mathcal{L}}U^{ik}_{\mathcal{L}}=\delta^{ji}. \tag{100}$$

The proof uses the unity decomposition (7) and the corollaries of Eqs. (94)

$$u^{--\underline{m}}l^i_{\underline{m}}=0, \quad u^{++\underline{m}}r^i_{\underline{m}}=0. \tag{101}$$

To find the relations between $U_{\mathcal{L},\mathcal{R}}$ and $U_{\mathcal{R},\mathcal{L}}$, one should consider the derivatives of the $U_{\mathcal{L},\mathcal{R}}$ fields

$$\partial_{(--)}U^{ji}_{\mathcal{L}}=l^{j\underline{m}}\partial_{(--)}u^i_{\underline{m}} \quad \text{and} \quad \partial_{(++)}U^{ji}_{\mathcal{R}}=r^{j\underline{m}}\partial_{(++)}u^i_{\underline{m}}$$

and use the decomposition (11) to express the derivatives of the generic harmonics in terms of components of the Cartan forms (51)–(50). In such a way one arrives at the relations

$$(\partial_{(--)}U^{kj}_{\mathcal{L}})U^{ki}_{\mathcal{L}}=(\partial_{(--)}G^{jk}_{\mathcal{R}})G^{ik}_{\mathcal{R}}, \quad (\partial_{(++)}U^{kj}_{\mathcal{R}})U^{ki}_{\mathcal{R}}=(\partial_{(++)}G^{jk}_{\mathcal{L}})G^{ik}_{\mathcal{L}}. \tag{102}$$

Equations (102) mean that the field $G_{\mathcal{L}}(G_{\mathcal{R}})$ differs from the (transposed) matrix field $U_{\mathcal{R}}(U_{\mathcal{L}})$ by an affine $SO(D-2)_L(SO(D-2)_R)$ transformation only [cf. (70)]

$$G^{ij}_{\mathcal{R}}=H^{jk}_L(\xi^{(++)})U^{ki}_{\mathcal{L}}=u^{i\underline{m}}l^k_{\underline{m}}H^{kj}_L(\xi^{(++)}), \tag{103}$$

$$G^{ij}_{\mathcal{L}}=H^{jk}_R(\xi^{(--)})U^{ki}_{\mathcal{R}}=u^{i\underline{m}}r^k_{\underline{m}}H^{jk}_R(\xi^{(--)}),$$

$$H_LH_L^T=I, \quad \partial_{(--)}H_L=0, \quad H_RH_R^T=I, \quad \partial_{(++)}H_R=0. \tag{104}$$

The expression for $V^i_{(++)}$ follows from the first equation in (96) upon substituting (98) and using Eqs. (94), (103), (95). In this way one gets

$$V^i_{(++)}=\tfrac{1}{2}e^{2W}l^{(--)\underline{m}}r^i_{\underline{m}}. \tag{105}$$

In the same manner one can obtain

$$V^i_{(--)}=\tfrac{1}{2}e^{2W}r^{(++)\underline{m}}l^i_{\underline{m}} \tag{106}$$

from Eq. (97) and the second of Eqs. (96).

Now we can rewrite Eqs. (97) and (98) in terms of chiral harmonics and the functions present in the nonlinear equations (53) and (54)

$$u^i_{\underline{m}}=G^{ik}_{\mathcal{R}}H^{kj}_L(-l^j_{\underline{m}}+e^{2W}r^{(++)\underline{n}}l^j_{\underline{n}}l^{(--)}_{\underline{m}}), \tag{107}$$

$$u^i_{\underline{m}}=G^{ik}_{\mathcal{L}}H^{kj}_R(-r^j_{\underline{m}}+e^{2W}l^{(--)\underline{n}}r^j_{\underline{n}}r^{(++)}_{\underline{m}}). \tag{108}$$

From Eqs. (107) and (108) we obtain the expression

$$(G^T_{\mathcal{L}}G_{\mathcal{R}})^{ij}=H^{ik}_L\left(-l^{k\underline{m}}r^l_{\underline{m}}+\frac{2(r^{(++)\underline{n}}l^k_{\underline{n}})(l^{(--)\underline{n}'}r^l_{\underline{n}'})}{(l^{(--)\underline{n}''}r^{(++)}_{\underline{n}''})}\right)H^{jl}_R, \tag{109}$$

which provides the general solution for the sigma-model-like equation (1) in the gauge (67)

$$G^{ij}_{\mathcal{R}}=\delta^{ij}, \quad G^{ij}_{\mathcal{L}}\equiv G^{ij},$$

$$G^{ij}=H^{ik}_L\left(-l^{k\underline{m}}r^l_{\underline{m}}+\frac{2(r^{(++)\underline{n}}l^k_{\underline{n}})(l^{(--)\underline{n}'}r^l_{\underline{n}'})}{(l^{(--)\underline{n}''}r^{(++)}_{\underline{n}''})}\right)H^{jl}_R. \tag{110}$$

To complete the description of the general solution of the string-inspired system of nonlinear equations (2) and (1), we have to present the expressions for the chiral vector fields $M^{(\mp\mp)i}_{(\pm\pm)}$ (3) in terms of the chiral harmonics. This can be easily done by applying the derivatives $\partial_{(++)}$ and $\partial_{(--)}$ to both sides of Eqs. (107) and (108) and contracting the results with the vectors $l^{(++)}$ and $r^{(--)}$, respectively. Then, using Eqs. (51) and (52), one obtains

$$M^{(++)i}_{(--)}=-H^{ij}_Rr^{(++)\underline{m}}\partial_{(--)}r^j_{\underline{m}}, \tag{111}$$

$$M^{(--)i}_{(++)}=-H^{ij}_Ll^{(--)\underline{m}}\partial_{(++)}l^j_{\underline{m}}. \tag{112}$$

Thus the chiral vectors $M^{(++)i}_{(--)}$ and $M^{(--)i}_{(++)}$ appearing in Eqs. (2) and (1) coincide with the covariant components $f^{(\mp\mp)i}_{(\pm\pm)}$ (86) and (91) of the chiral Cartan forms which constitute a basis on the ‘‘chiral spheres’’ S^{D-2}_R and S^{D-2}_L, respectively.

1. General solution of the string-inspired nonlinear equations

Equations (95), (110), (111), and (112) provide the *general solution* of the system of nonlinear equations (2), (1), and (3).

To be convinced of this, one has to take into account the following.

(i) When obtaining the expressions (95), (110), (111), and (112) for all the functions which enter Eqs. (2), (1), and (3), we started from the general solution of the bosonic string equations of motion in the standard Nambu–Goto approach and then used these solutions in the equations of the geometric approach.

(ii) As we demonstrated in Sec. I, the equations of the geometric approach describing the extrinsic geometry of the D-dimensional bosonic string worldsheet uniquely produce the system of nonlinear equations (2), (1), and (3).

(iii) The equations of geometric approach and, therefore, Eqs. (2), (1), and (3) specify the bosonic string worldsheet uniquely (up to symmetry transformations, see, e.g., Ref. 4), and thus describe exactly the same dynamical system as the ordinary (linear) string equations of motion.

(iv) The general solution (95), (110), (111), and (112) is written in terms of two sets of chiral spinor harmonics (78), which parameterize two copies of the compact coset (18)

$$S^{D-2}=\frac{SO(1,D-1)}{SO(1,1)\times SO(D-2)\circledS K_{D-2}}$$

isomorphic to the sphere S^{D-2}. Thus it contains $(D-2)$ right-moving and $(D-2)$ left-moving degrees of freedom, that is the same as the number of independent degrees of freedom of the general solution (74) of the standard string equations of motion (71).

With this reasoning in mind, we conclude that the expressions (95), (110), (111), and (112) for the functions W, G and $M_{(++)}^{(--)i}, M_{(--)}^{(++)i}$ obtained from the general solution of the standard string equations *have to provide the general solution* of the geometric approach equations (2), (1), and (3) (up to superfluous symmetry transformations).

IV. ON THE GROUP THEORETICAL AND GEOMETRICAL STRUCTURE OF THE SOLUTION

In the course of deriving the general solution (95), (110), (111), and (112) we have the expressions for the moving frame vectors (4) in terms of chiral harmonics

$$u_{\underline{m}}^{++}=e^{W-L}r_{\underline{m}}^{(++)},$$

$$u_{\underline{m}}^{i}=-(G_{\mathcal{L}}H_R)^{ij}(r_{\underline{m}}^{j}-V_{(++)}{}^{j}r_{\underline{m}}^{(++)}),$$

$$u_{\underline{m}}^{--}=e^{-(W-L)}(r_{\underline{m}}^{(--)}+r_{\underline{m}}^{(++)}V_{(++)}{}^{j}V_{(++)}{}^{j}-2r_{\underline{m}}^{i}V_{(++)}{}^{i}), \tag{113}$$

$$u_{\underline{m}}^{++}=e^{-(W+L)}(l_{\underline{m}}^{(++)}+l_{\underline{m}}^{(--)}V_{(--)}{}^{j}V_{(--)}{}^{j}-2l_{\underline{m}}^{i}V_{(--)}{}^{i}),$$

$$u_{\underline{m}}^{i}=-(G_{\mathcal{R}}H_L)^{ij}(l_{\underline{m}}^{j}-V_{(--)}{}^{j}l_{\underline{m}}^{(--)}),$$

$$u_{\underline{m}}^{--}=e^{W+L}l_{\underline{m}}^{(--)} \tag{114}$$

[more precisely, we have the first two equations in each set (113) and (114) while the third one can be restored from the orthonormality conditions (5), (79), and (80)].

If the functions W and $G_{\mathcal{L},\mathcal{R}}$ satisfy the nonlinear equations (2) and (1), then Eqs. (113) and (114) can be regarded as the solution of the corresponding associated linear system defined by Eqs. (11), with the Cartan forms (12) being specified by Eqs. (51), (52), (49), and (50).

The solution of the zero curvature representation given by the Maurer-Cartan equations (34) with the Cartan forms (12) can be obtained by differentiating (113) and (114). The solution is given by the following expressions for the generic Cartan 1-forms (13)–(16) in terms of chiral ones (86)–(89) and (90)–(93):

$$f^{++i}=e^{W-L}(G_{\mathcal{L}}H_R)^{ij}f_R^{(++)j}, \tag{115}$$

$$f^{--i}=-e^{-(W-L)}(G_{\mathcal{L}}H_R)^{ij}(f_R^{(--)j}-2\mathcal{D}_RV_{(++)}{}^{j}-2f_R^{(++)k}(V_{(++)}{}^{k}V_{(++)}{}^{j}-\tfrac{1}{2}\delta^{kj}V_{(++)}^{l}V_{(++)}{}^{l})),$$

$$\mathcal{D}_RV_{(++)}{}^{j}\equiv dV_{(++)}{}^{j}+\omega_RV_{(++)}{}^{j}-V_{(++)}{}^{k}A_R^{kj}, \tag{116}$$

$$\omega=\omega_R+f^{(++)i}V_{(++)}{}^{i}+d(W-L), \tag{117}$$

$$A^{ij}=(G_{\mathcal{L}}H_R)^{ik}(G_{\mathcal{L}}H_R)^{jl}(A_R^{kl}+(G_{\mathcal{L}}H_R)^{-1}d(G_{\mathcal{L}}H_R))^{kl}+2\,f^{(++)[k}V^{--l]}), \tag{118}$$

$$f^{--i}=e^{W+L}(G_{\mathcal{R}}H_L)^{ij}f_L^{(--)j}, \tag{119}$$

$$f^{++i}=-e^{-(W-L)}(G_{\mathcal{R}}H_L)^{ij}(f_L^{(++)j}-2\mathcal{D}_R V_{(--)}{}^j$$
$$-2\,f_L^{(--)k}(V_{(--)}{}^k V_{(--)}{}^j-\tfrac{1}{2}\delta^{kj}V_{(--)}{}^l V_{(--)}{}^l)),$$

$$\mathcal{D}_L V_{(--)}{}^j\equiv dV_{(--)}{}^j+\omega_R V_{(--)}{}^j-V_{(--)}{}^k A_L^{kj}, \tag{120}$$

$$\omega=\omega_R+f^{(--)i}V_{(--)}{}^i-d(W+L), \tag{121}$$

$$A^{ij}=(G_{\mathcal{L}}H_R)^{ik}(G_{\mathcal{L}}H_R)^{jl}(A_R^{kl}+(G_{\mathcal{L}}H_R)^{-1}d(G_{\mathcal{L}}H_R))^{kl}+2\,f^{++[k}V^{--l]}). \tag{122}$$

On the other hand, as follows from the consideration in the preceding section, the explicit form of the general solution (95) and (110), as well as the expressions (105) and (106) for the ''boost'' parameters, can be obtained algebraically from Eqs. (114) and (113) [with making use of the orthonormality constraints (5), (79), and (80) for the generic and chiral moving frame harmonics].

An intriguing point is that Eqs. (114) and (113) generating the general solution *have the form of the parabolic symmetry transformations* (83) and (82) of the chiral harmonics, but with nonchiral parameters.

Thus the prescription of how to solve the nonlinear equations (1) and (2) can be formulated as follows.

Let us introduce the two sets of chiral harmonics (78) and (79), which map the right (left) light-cone sectors of the worldsheet $\mathcal{M}^{(0,1)}\equiv\{(\xi^{(--)})\}$ $(\mathcal{M}^{(1,0)}\equiv\{(\xi^{(++)})\})$ onto the sphere S^{D-2},

$$r_{\underline{m}}^{(\underline{a})}:\ \ \mathcal{M}^{(0,1)}\equiv\{(\xi^{(--)})\}\rightarrow S^{D-2}=\frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times\mathrm{SO}(D-2)\circledS K_{D-2}},$$

$$r_{\underline{m}}^{(\underline{a})}:\ \ \mathcal{M}^{(1,0)}\equiv\{(\xi^{(++)})\}\rightarrow S^{D-2}=\frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times\mathrm{SO}(D-2)\circledS K_{D-2}}.$$

Further, let us assume that the generic harmonics (4) and (5)

$$u_{\underline{m}}^{\underline{a}}:\ \ \mathcal{M}^{(1,1)}\rightarrow\frac{\mathrm{SO}(1,D-1)}{\mathrm{SO}(1,1)\times\mathrm{SO}(D-2)}$$

are related to the chiral ones by the parabolic transformations (113) and (114) (with the chiral parameters H_L and H_R omitted for simplicity).

Then let us exploit the $\mathrm{SO}(D-2)$ gauge freedom to fix the $\mathrm{SO}(D-2)$ rotation matrix in (113) to be the unity one. The $\mathrm{SO}(D-2)$ rotation matrix in (114) taken in this gauge provides us with the solution (110) of the WZNW sigma-model-type equation (1) [with the chiral vectors $M_{(--)}^{(++)i}, M_{(--)}^{(++)i}$ determined by the homogeneously transforming components of chiral Cartan forms (86) and (91)

$$M_{(--)}^{(++)i}=f_{(--)R}^{(++)i},\quad M_{(--)}^{(++)i}=f_{(++)L}^{(--)i}$$

[cf. (112) and (111)]. The product of the SO(1,1) transformation factors from (113) and (114) produces the general solution of the Liouville-like equation (2).

Since the parabolic transformations (113) and (114) have a ''triangular'' form, one can expect that the described method of obtaining the general solution bears a tight relation to the known group-theoretical methods of solving nonlinear equations, like those developed and used in Refs.

14, 15, and 16. A detailed examination of such a relationship could provide a deeper insight into the nature of integrability and we consider it as an interesting problem for future study.

V. CONCLUSION

We have obtained the general solution of the string-inspired nonlinear equations (1), (2), and (3) describing the extrinsic geometry of the bosonic string worldsheet in the geometrical approach.[1,2,3,5]

The solution is given in terms of the two sets of chiral (left-moving and right-moving) Lorentz harmonic variables (78), (79), and (80) and has the form (after fixing a gauge with respect to some extra symmetries)

$$e^{-2W}=\tfrac{1}{2}r^{(++)}_{\underline{m}}l^{(--)\underline{m}}, \tag{123}$$

$$G^{kj}=-l^{k}_{\underline{m}}r^{j\underline{m}}+\frac{r^{(++)}_{\underline{m}}l^{k\underline{m}}l^{(--)}_{\underline{n}}r^{j\underline{n}}}{r^{(++)}_{\underline{p}}l^{(--)\underline{p}}}, \tag{124}$$

$$M^{(++)i}_{(--)}(\xi^{(--)})=r^{(++)\underline{m}}\partial_{(--)}r^{i}_{\underline{m}}, \tag{125}$$

$$M^{(--)i}_{(++)}(\xi^{(++)})=l^{(--)\underline{m}}\partial_{(++)}l^{i}_{\underline{m}}. \tag{126}$$

The analysis of the solution of the associated linear system demonstrates that the general solution we have found can be regarded as the parabolic subgroup $SO(1,1)\times SO(D-2)\otimes K_{D-2}$ transformations[11] of the chiral harmonics, the transformation parameters being nonchiral. As such transformations have the ''triangular'' form in the matrix representation, we can expect a close relation of our approach to the known group-theoretical methods of solving nonlinear equations.[14–16] It is an interesting task for further study to elaborate on the detailed form of such a relation.

A natural direction of extending our results is to look for the solution of a supersymmetric generalization of the considered nonlinear equations. Such a system describes the extrinsic geometry of the worldsheet superspace of $D=3,4,6,10$ superstring models. (Let us note that the explicit form of such supersymmetric equations are known at present only for the cases $D=3$, $N=1,2$.[17])

APPENDIX: RELATION TO THE STANDARD FORM OF GENERAL SOLUTION OF THE LIOUVILLE EQUATION

Here we demonstrate that for the $D=3$ case Eq. (95) reproduces the general solution of the nonlinear Liouville equation. Using the well-known parametrization of the SO(1,2) matrices

$$l^{m}_{(\underline{a})}=\begin{pmatrix}\cosh A_L & \sinh A_L & 0\\ \sinh A_L & \cosh A_L & 0\\ 0 & 0 & 1\end{pmatrix},$$

$$r^{\underline{m}}_{(\underline{a})}=\begin{pmatrix}\cosh A_R & -\sinh A_R & 0\\ -\sinh A_R & \cosh A_R & 0\\ 0 & 0 & 1\end{pmatrix},$$

$$\partial_{(--)}A_L=\partial_{(++)}A_R=0, \tag{A1}$$

one finds the following form of chiral harmonics (78)

$$l^{(--)\underline{m}}=(\cosh A_L, \quad \sinh A_L, \quad 1),$$

$$l^{\perp\,\underline{m}}=(\sinh A_L, \quad \cosh A_L, \quad 0), \tag{A2}$$

$$l^{(++)\underline{m}}=(\cosh A_L, \quad \sinh A_L, \quad -1),$$

$$r^{(--)\underline{m}}=(\cosh A_R, \quad -\sinh A_R, \quad 1),$$

$$r^{\perp\,\underline{m}}=(-\sinh A_R, \quad \cosh A_R, \quad 0),$$

$$r^{(++)\underline{m}}=(\cosh A_R, \quad -\sinh A_R, \quad -1). \tag{A3}$$

Substituting these expressions into the Eqs. (95), (111), and (112) with $D=3$, one gets

$$e^{-W}=\cosh\frac{A_L+A_R}{2}, \tag{A4}$$

$$M^{(++)\perp}_{(--)}(\xi^{(--)})=r^{(++)\underline{m}}\partial_{(--)}r^{\perp}_{\underline{m}}=-\partial_{(--)}A_R\,, \tag{A5}$$

$$M^{(--)\perp}_{(++)}(\xi^{(++)})=l^{(--)\underline{m}}\partial_{(++)}l^{\perp}_{\underline{m}}=\partial_{(++)}A_L\,. \tag{A6}$$

The relation to the standard parametrization of the general solution of the Liouville equation (see, e.g., Ref. 18) is given by

$$f_{L,R}=\exp A_{L,R}\,.$$

A new perturbative technique for solving integro-partial differential equations

Peter A. Becker[a)]

(Received 10 May 1999; accepted for publication 8 July 1999)

Integro-partial differential equations occur in many contexts in mathematical physics. Typical examples include time-dependent diffusion equations containing a parameter (e.g., the temperature) that depends on integrals of the unknown distribution function. The standard approach to solving the resulting nonlinear partial differential equation involves the use of predictor–corrector algorithms, which often require many iterations to achieve an acceptable level of convergence. In this paper we present an alternative procedure that allows us to separate a family of integro-partial differential equations into two related problems, namely (i) a perturbation equation for the temperature, and (ii) a linear partial differential equation for the distribution function. We demonstrate that the variation of the temperature can be determined by solving the perturbation equation *before* solving for the distribution function. Convergent results for the temperature are obtained by recasting the divergent perturbation expansion as a continued fraction. Once the temperature variation is determined, the self-consistent solution for the distribution function is obtained by solving the remaining, linear partial differential equation using standard techniques. The validity of the approach is confirmed by comparing the (input) continued-fraction temperature profile with the (output) temperature computed by integrating the resulting distribution function. © *1999 American Institute of Physics.* [S0022-2488(99)03410-6]

I. INTRODUCTION

Many of the time-dependent transport equations encountered in mathematical physics are nonlinear in nature due to the dependence of one or more of the coefficients on integrals of the unknown distribution function. In such cases, the transport equation becomes an integro-partial differential equation such as the Vlasov or Boltzmann equations. Physical applications include a large variety of diffusive and plasma phenomena[1,2] as well as nonlinear wave propagation,[3] the dynamics of self-gravitating mass distributions,[4] and the diffusion in energy space of photons due to Compton scattering.[5,6]

Integro-partial differential equations are usually solved by integrating forward in time from a given initial condition using a predictor–corrector algorithm[7,8] or a global relaxation method.[9,10] The convergence properties of such indirect methods are often difficult to predict in advance, and usually depend rather sensitively on both the governing equation and the nature of the initial conditions. In this paper we develop an alternative procedure that allows us to analyze the time variation of the integral function (in this case the temperature) using a *direct* method based upon the governing integro-partial differential equation. The temperature variation is determined by constructing a perturbation expansion via recursive application of the moment equation obtained by integrating the original nonlinear equation with respect to energy.

The coefficients of the perturbation expansion depend on the initial shape of the distribution

[a)]Electronic mail: pbecker@gmu.edu

function, and therefore the resulting temperature variation represents the self-consistent solution to the problem. With the temperature variation determined in advance, the equation governing the distribution function loses its integrodifferential character, and reduces to a linear partial differential equation which can be solved using a variety of standard techniques. The accuracy of the solution can be verified *a posteriori* by integrating the resulting distribution function over energy to obtain another (output) result for the variation of the temperature integral, which can be compared with the (input) temperature representation constructed using the information contained in the perturbation expansion.

In a certain sense, the method developed here allows us to ''separate'' the original integro-partial differential equation into two problems, the first being the determination of the self-consistent temperature variation and the second the solution of the remaining linear partial differential equation for the distribution function. The perturbation series for the temperature is divergent in general, but we demonstrate that it can be recast as a continued fraction that yields convergent results for a variety of initial distributions. In order to illustrate the technique, we focus here on a specific family of equations which is sufficiently general to admit a variety of interesting behaviors.

II. GOVERNING EQUATIONS

The primary motivation for this study is the analysis of the scattering of photons and electrons in the hot, tenuous plasma surrounding a compact astrophysical object such as a neutron star or black hole. This process, referred to as time-dependent Comptonization, is thought to be responsible for producing the variable x-ray emission observed from a variety of sources both within and outside our galaxy. The energy of the photons is modified as a result of multiple interactions with electrons, and consequently the photon energy distribution evolves over time. In this situation the photon distribution function $f(x,y)$ is governed by an integro-partial differential transport equation of the general form[5]

$$\frac{\partial f}{\partial y} = \frac{1}{x^i}\frac{\partial}{\partial x}\left\{ x^i \left[x^j \frac{f}{\theta(y)} + x^k \frac{\partial f}{\partial x} \right] \right\}, \tag{1}$$

where x represents the dimensionless photon energy, y measures the dimensionless time, and i, j, and k are constants. The function $\theta(y)$ represents the time-varying temperature, defined by the integral expression

$$\theta(y) \equiv \frac{I_\alpha(y)}{I_\alpha(0)}, \tag{2}$$

where α is a constant and the power moments of f are defined by

$$I_n(y) \equiv \int_0^\infty x^n f(x,y)\,dx. \tag{3}$$

Note that $\theta(0)=1$ by virtue of (2), and $\theta(y)>0$ for all y since $f(x,y)$ is non-negative. In the time-dependent Comptonization problem, we have $i=j=k=2$. However, we will develop the formalism for arbitrary values of i, j, and k in order to emphasize the generality of the mathematical method. For clarity in the discussion, we shall think of the test particles as ''photons'' and the scattering centers as ''electrons,'' although these identifications are arbitrary.

The total number density of the photons $N_r(y)$ is related to the photon distribution function $f(x,y)$ via

$$N_r(y) \equiv \int_0^\infty x^i f(x,y)\,dx, \tag{4}$$

so that $N_r(y)=I_i(y)$. Interpreting $x^{-i}(\partial/\partial x)x^i$ as the divergence operator in energy space, we observe that the transport equation (1) is written in explicit flux-conservation form, and therefore N_r remains constant since (1) contains no sources or sinks of photons. We seek to solve the transport equation for the distribution function $f(x,y)$ subject to the initial condition

$$f(x,0)\equiv f_0(x), \tag{5}$$

where $f_0(x)$ is a known function specified as part of the problem under consideration. The conserved number density is therefore given by $N_r=\int_0^\infty x^i f_0(x)dx$. Equation (1) drives $f(x,y)$ toward the steady state equilibrium solution given by the exponential spectrum

$$f_{\rm eq}(x)\equiv \frac{N_r p}{(p\,\theta_{\rm eq})^{(i+1)/p}\Gamma\left(\dfrac{i+1}{p}\right)}\exp\left(\frac{-x^p}{p\,\theta_{\rm eq}}\right), \quad p\equiv j-k+1, \tag{6}$$

where $\theta_{\rm eq}$ is the asymptotic equilibrium temperature and the normalization has been set so that the number density of $f_{\rm eq}$ is equal to N_r. In deriving (6) we have also assumed that $(i+1)/p>0$. Whether or not the solution $f(x,y)$ actually reaches $f_{\rm eq}(x)$ depends upon the rate at which the temperature varies in a given situation.

The underlying process modeled by (1) is a stochastic energization of the test particles due to the random motions of the scattering centers. This interpretation is made clear by using (1) to calculate the Fokker–Planck coefficients which express the rates of change of the mean energy $\langle x\rangle$ and the variance σ^2 for a monoenergetic distribution. The results obtained are

$$\frac{d\langle x\rangle}{dy}=(i+k)x^{k-1}-\frac{x^j}{\theta(y)}, \quad \frac{d\sigma^2}{dy}=2x^k, \tag{7}$$

which describe, respectively, the ''drifting'' and ''broadening'' of the distribution due to energy space diffusion.[11] In terms of these coefficients, (1) can be recast as the Fokker–Planck equation

$$\frac{\partial F}{\partial y}=-\frac{\partial}{\partial x}\left[F\frac{d\langle x\rangle}{dy}\right]+\frac{\partial^2}{\partial x^2}\left[F\frac{1}{2}\frac{d\sigma^2}{dy}\right], \tag{8}$$

where the photon number spectrum $F(x,y)$ is defined by

$$F(x,y)\equiv x^i f(x,y), \tag{9}$$

so that $N_r=\int_0^\infty F(x,y)dx$. It can be readily verified that (8) is equivalent to (1). Since i, j, and k are free parameters and $\theta(y)$ is an arbitrary power integral of F, we see that the Fokker–Planck coefficients associated with (1) encompass a large variety of microphysical scattering scenarios.

III. PERTURBATION EXPANSION FOR THE TEMPERATURE

We can obtain a relationship between the power moments by operating on (1) with $\int_0^\infty x^n\,dx$ and integrating by parts twice. This yields

$$\frac{dI_n}{dy}=(n-i)\left[(n+k-1)I_{n+k-2}(y)-\frac{I_{n+j-1}(y)}{\theta(y)}\right], \tag{10}$$

where we have assumed that the power moments I_n exist for all of the required values of n. The validity of this assumption depends on the asymptotic behavior of the initial distribution $f_0(x)$. By recursively applying (10), we can express all of the derivatives of any power moment with respect to y as closed functions of the moments.

One interesting consequence is that we can obtain the derivatives of the temperature integral function $\theta(y)$ as functions of the moments $I_n(y)$. Using (2), the zeroth derivative is given by

$$\theta(y)=\frac{I_\alpha(y)}{I_\alpha(0)}. \tag{11}$$

By making a single application of (10), we find that the first derivative can be expressed as

$$\theta^{(1)}(y)=\frac{\alpha-i}{I_\alpha(0)}\left[(\alpha+k-1)I_{\alpha+k-2}(y)-\frac{I_{\alpha+j-1}(y)}{\theta(y)}\right]. \tag{12}$$

Differentiation of (12) with respect to y yields

$$\theta^{(2)}(y)=\frac{\alpha-i}{I_\alpha(0)}\left[\frac{\theta^{(1)}(y)}{\theta^2(y)}I_{\alpha+j-1}(y)-\frac{1}{\theta(y)}\frac{dI_{\alpha+j-1}}{dy}+(\alpha+k-1)\frac{dI_{\alpha+k-2}}{dy}\right]. \tag{13}$$

Using (10) to eliminate the moment derivatives in (13), we obtain

$$\theta^{(2)}(y)=\frac{\alpha-i}{I_\alpha(0)}\left\{(\alpha+k-1)(\alpha+k-i-2)\left[(\alpha+2k-3)I_{\alpha+2k-4}(y)-\frac{I_{\alpha+k+j-3}(y)}{\theta(y)}\right]\right.$$
$$\left.+\frac{\theta^{(1)}(y)I_{\alpha+j-1}(y)}{\theta^2(y)}+(\alpha+j-i-1)\left[\frac{I_{\alpha+2j-2}(y)}{\theta^2(y)}-(\alpha+j+k-2)\frac{I_{\alpha+j+k-3}(y)}{\theta(y)}\right]\right\}. \tag{14}$$

Subsequent iterative applications of (10) can be used to derive expressions for the third and higher derivatives of $\theta(y)$.

By evaluating the derivatives sequentially starting with $\theta(y)$, we can calculate as many as desired if the required power moments $I_n(y)$ are known. Although we have no *a priori* means of evaluating the power moments $I_n(y)$ for general values of y, we *can* evaluate them for the special case $y=0$ since in this case they correspond to integrals of the known initial distribution $f_0(x)$, i.e.,

$$I_n(0)=\int_0^\infty x^n f(x,0)dx=\int_0^\infty x^n f_0(x)dx. \tag{15}$$

When $y=0$, the general expressions for the derivatives given by (11), (12), and (14) reduce to

$$\theta(0)=1, \tag{16}$$

$$\theta^{(1)}(0)=\frac{\alpha-i}{I_\alpha(0)}[(\alpha+k-1)I_{\alpha+k-2}(0)-I_{\alpha+j-1}(0)], \tag{17}$$

$$\theta^{(2)}(0)=\frac{\alpha-i}{I_\alpha(0)}\{(\alpha+k-1)(\alpha+k-i-2)[(\alpha+2k-3)I_{\alpha+2k-4}(0)-I_{\alpha+k+j-3}(0)]$$
$$+\theta^{(1)}(0)I_{\alpha+j-1}(0)+(\alpha+j-i-1)[I_{\alpha+2j-2}(0)-(\alpha+j+k-2)I_{\alpha+j+k-3}(0)]\}. \tag{18}$$

The method can be extended to evaluate the third and higher derivatives of $\theta(y)$ at $y=0$ for a given initial distribution $f_0(x)$.

Let us suppose that for some arbitrary value of M, all of the initial derivatives of $\theta(y)$ up to $\theta^{(M)}(0)$ have been determined using the method outlined above. We may then define the associated asymptotic perturbation (Taylor) series for $\theta(y)$ by writing

$$\Phi_N(y) \equiv \sum_{n=0}^{N} \frac{\theta^{(n)}(0)}{n!} y^n, \tag{19}$$

where $N \leqslant M$ indicates the truncation level of the series. Our expectation is that $\Phi_N(y)$ accurately approximates the time variation of the exact solution for $\theta(y)$ within some finite radius of convergence if N is sufficiently large. Based upon the existence of the Taylor series, we conclude that in principle the variation of $\theta(y)$ can be determined *before* solving for the unknown distribution $f(x,y)$. This accomplishes the formal ''separation'' of the original integro-partial differential equation (1) into two problems. The first problem is the determination of the variation of the integral function, which has been achieved (at least formally) by constructing the Taylor series (19). The second problem is the determination of the spectrum $f(x,y)$, which now reduces to the solution of a *linear* partial differential equation since the function $\theta(y)$ appearing in (1) can be approximated using (19). However, the convergence of the power series (19) introduces some potential complications which we address below.

IV. CONTINUED FRACTION REPRESENTATION

We have established that it is possible to develop a general computational scheme based on (10) that can be used to evaluate the initial derivatives of the self-consistent temperature integral function $\theta(y)$ in terms of the initial moments $I_n(0)$, which are easily computed using (15) once the initial distribution $f_0(x)$ is specified. From knowledge of the initial θ derivatives we are able to construct the formal Taylor series $\Phi_N(y)$ given by (19). However, a remaining difficulty centers on the convergence of this series. In many cases the radius of convergence turns out to be too small to be of any practical use, and in certain instances it may even vanish. We therefore seek an alternative means for utilizing the asymptotic information contained in the power series coefficients in order to extract a *global* representation of the function.

A global approximation can be constructed by recasting the data in the form of a continued fraction, which is equivalent to the process of Padé approximation.[12] In many instances this is a remarkably successful approach to the global modeling of an unknown function. We define the continued fraction representation using

$$\Psi_N(y) \equiv \cfrac{c_0}{1+\cfrac{c_1 y}{1+\cfrac{c_2 y}{1+\cdots\cfrac{c_{N-1} y}{1+c_N y}}}}, \tag{20}$$

where the constants $c_0,\ldots,c_N$ are the continued fraction coefficients, and the truncation level is indicated by the value of N. The continued fraction coefficients can be computed using the information contained in the θ derivatives by employing the standard two-dimensional algorithm described by Baker and Graves-Morris.[13]

To illustrate the flow of the algorithm, we assume that via successive applications of (10) we have evaluated all of the initial derivatives of the temperature integral function $\theta(y)$ up to $\theta^{(M)}(0)$ for some M. The algorithm is initialized by setting the zeroth column of the matrix $A_{n,m}$ using

$$A_{0,m} = \frac{\theta^{(m)}(0)}{m!}, \quad 0 \leqslant m \leqslant M, \tag{21}$$

and the first column of the matrix is calculated subsequently via

$$A_{1,m} = -\frac{A_{0,m+1}}{A_{0,0}}, \quad 0 \leqslant m \leqslant M-1. \tag{22}$$

The remaining elements in the matrix are obtained recursively using

$$A_{n,m}=\frac{A_{n-2,m+1}}{A_{n-2,0}}-\frac{A_{n-1,m+1}}{A_{n-1,0}}, \quad 0\leqslant m\leqslant M-n, \tag{23}$$

for $2\leqslant n\leqslant M$. The continued fraction coefficients occupy the zeroth row of the matrix, so that

$$c_n=A_{n,0}\ , \quad 0\leqslant n\leqslant M. \tag{24}$$

Note that the coefficient c_n is a function of the initial derivatives $\theta(0)$, $\theta^{(1)}(0),\ldots,\theta^{(n)}(0)$, and therefore the incorporation of higher-order derivatives into the scheme has no effect on the value of c_n.

As discussed in Sec. II, the exact solution for the temperature variation $\theta(y)$ must be positive for all $y>0$ because the distribution function f is non-negative. Hence $\theta(y)$ contains no poles in the domain $y>0$, and this must also be true of any acceptable continued fraction approximation. The singularity structure of the continued fraction $\Psi_N(y)$ can be determined by creating an equivalent rational function, and then solving for the zeros of the denominator. The presence of zeros in the domain $y>0$ causes the appearance of extraneous, unphysical poles in $\Psi_N(y)$. These unphysical poles migrate out of the computational domain as the truncation level N increases and $\Psi_N(y)$ approaches the exact solution $\theta(y)$. However, some of the lower order fractions may contain ''defects'' (poles for positive values of y), and if so they must be rejected. We consider the convergence properties of the continued fraction sequence $\Psi_0(y), \Psi_1(y),\ldots,\Psi_M(y)$ in Sec. VI, where we treat specific computational examples.

V. APPLICATION TO TIME-DEPENDENT COMPTONIZATION

In the problem of time-dependent Comptonization that serves as the primary motivation for this study, an intense distribution of radiation is scattered by hot electrons in a tenuous plasma. We suppose that the photons are injected impulsively into the plasma with a specified energy distribution at time $t=0$, and that the subsequent evolution of the distribution occurs as a result of photon–electron scattering. This process naturally leads to the production of time-variable (transient) x-ray emission. During the brightest observed x-ray transients, most of the energy is contained in the radiation field rather than in the gas, which implies that the average photon energy must remain constant even as the shape of the x-ray spectrum changes. In this case the electrons maintain a Maxwellian distribution and act mainly as catalysts in the evolution of the photon distribution, taking energy away from very energetic photons and giving it to low-energy photons until equilibrium is achieved. The electron temperature T_e depends on the shape of the radiation spectrum via an integral expression, and therefore T_e varies as a function of time as we demonstrate below. The equation governing the evolution of the radiation spectrum is consequently integro-partial differential in nature.

The time evolution of the photon spectrum under the influence of Compton scattering in an ionized, homogeneous hydrogen plasma is governed by the Kompaneets equation,[14]

$$\frac{\partial f}{\partial t}=\frac{n_e\sigma_T ckT_e(0)}{m_e c^2}\,\frac{1}{x^2}\,\frac{\partial}{\partial x}\left\{x^4\left[f+\frac{T_e(t)}{T_e(0)}\,\frac{\partial f}{\partial x}\right]\right\}, \tag{25}$$

where σ_T is the Thomson scattering cross section, k is Boltzmann's constant, c is the speed of light, and n_e and m_e denote the electron number density and mass, respectively. The dimensionless energy variable x is defined by

$$x\equiv\frac{\epsilon}{kT_e(0)}, \tag{26}$$

where ϵ is the photon energy and $T_e(0)$ denotes the electron temperature at the beginning of the transient ($t=0$). The initial spectrum $f_0(x)\equiv f(x,0)$ is assumed to be known, and f is normalized so that the total photon number density is given by

$$N_r(y)=\int_0^\infty x^2 f(x,y)\,dx=I_2(y), \tag{27}$$

where the power moments of f are defined by $I_n(y)\equiv\int_0^\infty x^n f(x,y)\,dx$ in accordance with (3). We remind the reader that N_r=constant according to the discussion in Sec. II. The associated total photon energy density is given by

$$U_r(y)=\int_0^\infty \epsilon\, x^2 f(x,y)\,dx=kT_e(0)I_3(y). \tag{28}$$

In this application, the explicit connection between the ''time parameter'' y and the true time t is established by making the definition

$$y(t)\equiv\int_0^t n_e(t)\sigma_T c\,\frac{kT_e(t')}{m_e c^2}\,dt', \tag{29}$$

where we have allowed for the possibility of a time dependence in the electron number density and we have set $y(0)=0$. Using the variables x and y our transport equation (25) can be reexpressed as

$$\frac{\partial f}{\partial y}=\frac{1}{x^2}\frac{\partial}{\partial x}\left\{x^4\left[\frac{f}{\theta(y)}+\frac{\partial f}{\partial x}\right]\right\}, \tag{30}$$

where the temperature function $\theta(y)$ is defined by

$$\theta(y)\equiv\frac{T_e(y)}{T_e(0)}. \tag{31}$$

In order to apply the method developed earlier in the paper to the current problem, we must demonstrate that the definitions for $\theta(y)$ in (2) and (31) are consistent, which can be established by showing that the right-hand side of (31) is proportional to one of the power moments of f in the Comptonization application. We begin by noting that (30) is formally equivalent to our prototype transport equation (1) if $i=j=k=2$. It follows that the power moments I_n must satisfy (10), which in this case reduces to

$$\frac{dI_n}{dy}=(n-2)\left[(n+1)I_n(y)-\frac{I_{n+1}(y)}{\theta(y)}\right]. \tag{32}$$

During a bright x-ray transient, most of the energy density is contained in the radiation field, and therefore the material gas cannot exchange a significant amount of energy with the photons. Consequently the integrated radiation energy density $U_r(y)=kT_e(0)I_3(y)$ should not change as a result of Comptonization, and therefore $I_3(y)$ must remain equal to its initial value $I_3(0)$. Setting $n=3$ in (32), we find that the condition $dI_3/dy=0$ is satisfied if

$$\theta(y)=\frac{I_4(y)}{4I_3(0)}, \tag{33}$$

which implies that T_e equals the inverse-Compton temperature of the radiation spectrum.[6] Since $\theta(0)=1$ by virtue of (31), we can rewrite (33) as

$$\theta(y)=\frac{I_4(y)}{I_4(0)}. \tag{34}$$

Note that the initial spectrum $f_0(x)$ must satisfy the condition $I_4(0)=4I_3(0)$ in order to be consistent with the requirement that $\theta(0)=1$. Equation (34) establishes the integro-partial differential nature of the governing equation (30) for this application. Hence the formal results obtained earlier in the paper can be applied to the problem of time-dependent Comptonization by setting $\alpha=4$ in (2).

The algorithm derived in Sec. III can be used to directly calculate the initial derivatives of $\theta(y)$ at $y=0$. However, in the Comptonization application under consideration here, it is more convenient to derive a differential recurrence relation between the successive moments I_n and I_{n+1} by rearranging (32) to obtain

$$I_{n+1}(y)=\frac{\theta(y)}{2-n}e^{(n+1)(n-2)y}\frac{d}{dy}[e^{-(n+1)(n-2)y}I_n(y)]. \tag{35}$$

Working in terms of the differential operator

$$\mathcal{D}_n\equiv\frac{1}{2-n}e^{(n+1)(n-2)y}\frac{d}{dy}e^{-(n+1)(n-2)y}, \tag{36}$$

we can apply (35) iteratively to find that

$$I_{n+1}(y)=\theta(y)\mathcal{D}_nI_n=\theta(y)\mathcal{D}_n\theta(y)\mathcal{D}_{n-1}\cdots\theta(y)\mathcal{D}_3I_3(y). \tag{37}$$

Since $I_3(y)=I_3(0)=\text{constant}$, we can carry out the differentiation to obtain the moments $I_n(y)$ as functions of the derivatives of $\theta(y)$. The first few results are

$$I_4(y)=4\,\theta(y)I_3(0), \tag{38}$$

$$I_5(y)=-\frac{\theta(y)}{2}[4\,\theta^{(1)}(y)-40\theta(y)]I_3(0), \tag{39}$$

$$I_6(y)=-\frac{\theta(y)}{3}[-360\theta^2(y)+76\theta(y)\,\theta^{(1)}(y)-2\,\theta^{(1)^2}(y)-2\,\theta(y)\,\theta^{(2)}(y)]I_3(0). \tag{40}$$

Similar results can be obtained for the higher moments. Note that $I_n(y)$ is a function of all of the derivatives of $\theta(y)$ up to $\theta^{(n-4)}(y)$. We have developed a computer algorithm based on (37) that efficiently derives expressions for the moments $I_n(y)$ in terms of the derivatives of $\theta(y)$. Since the values of the initial moments $I_n(0)$ are easily calculated using (15) for any initial spectrum $f_0(x)$, these expressions allow us to compute the corresponding initial derivatives $\theta^{(n)}(0)$ sequentially, beginning with the zeroth derivative which is set by (38). The development of the general expressions giving the initial moments as function of the derivatives $\theta^{(n)}(0)$ is the costliest part of the solution procedure. However, once these expressions have been established, they can be used to evaluate the initial derivatives for a variety of different initial spectra at very low cost. The initial derivatives are subsequently used to calculate the continued fraction coefficients using the algorithm discussed in Sec. IV, and the sequence of continued fraction approximations $\Psi_N(y)$ is evaluated using (20). This procedure forms the basis for the computational results presented in Sec. VI.

VI. COMPUTATIONAL EXAMPLES

In this section we apply our method to obtain quantitative results for the problem of time-dependent astrophysical Comptonization. Our computational procedure is as follows. First we calculate the initial θ derivatives and the associated continued fraction coefficients using the algorithms discussed in Secs. IV and V. In the second step we use this information to analyze the convergence properties of the sequence of continued fractions $\Psi_N(y)$ and compare them with the corresponding Taylor series $\Phi_N(y)$. In the third step we use a high-order continued fraction to approximate the temperature integral function $\theta(y)$ in the transport equation (30) and then we numerically solve the transport equation for the photon energy distribution $f(x,y)$. Finally, in the fourth step we compare the input temperature function $\Psi_N(y)$ with the result obtained for $\theta(y)$ by integrating the numerical solution for $f(x,y)$. Agreement between these two representations of the temperature confirms the accuracy of the method.

At the beginning of the x-ray transient, the radiation spectrum is given by the initial energy distribution $f_0(x)$ introduced in (5). According to the analysis presented in the preceding sections, knowledge of $f_0(x)$ is sufficient to determine the time variation of the temperature integral function $\theta(y)$. In typical astrophysical situations, the initial energy distributions of greatest interest are the optically thin electron–proton bremsstrahlung (free–free) spectrum

$$f_0(x)=x^{-3}e^{-x/4}, \tag{41}$$

and the monoenergetic spectrum

$$f_0(x)=N_0\, x_0^{-2}\,\delta(x-x_0), \tag{42}$$

where N_0 is the number density of the photons. In the latter case, we must set $x_0=4$ in order to satisfy the condition $\theta(0)=I_4(0)/4I_3(0)=1$ as required by (31) and (33).

The transport equation (30) drives the distribution $f(x,y)$ toward the steady state equilibrium solution given by the Wien spectrum

$$f_{\mathrm{eq}}(x)\equiv\frac{N_r}{2\,\theta_{\mathrm{eq}}^3}\,e^{-x/\theta_{\mathrm{eq}}}\ , \tag{43}$$

which has been obtained by setting $i=j=k=2$ in (6). Although f is always driven toward Wien form at all values of y, it may or may not reach equilibrium depending on the shape of the initial spectrum and the corresponding rate at which the temperature varies. This question can be resolved by calculating the asymptotic temperature θ_{eq} using information contained in the initial spectrum $f_0(x)$. In equilibrium, the dimensionless mean photon energy is given by

$$\overline{x}=\frac{\int_0^\infty x^3 f_{\mathrm{eq}}(x)\,dx}{\int_0^\infty x^2 f_{\mathrm{eq}}(x)\,dx}=3\,\theta_{\mathrm{eq}}, \tag{44}$$

where we have substituted for $f_{\mathrm{eq}}(x)$ using (43) to obtain the final result. Conservation of the photon number and energy densities implies that the value of $\overline{x}$ must be conserved, so that we can also write

$$\overline{x}=\frac{\int_0^\infty x^3 f_0(x)\,dx}{\int_0^\infty x^2 f_0(x)\,dx}=\frac{I_3(0)}{I_2(0)}. \tag{45}$$

Equations (44) and (45) can be combined to calculate the asymptotic temperature θ_{eq} for any initial spectrum $f_0(x)$. In the case of a monoenergetic initial spectrum with $x_0=4$, we obtain $\overline{x}=4$ and therefore $\theta_{\mathrm{eq}}=4/3$. Conversely, in the case of a bremsstrahlung initial spectrum, we obtain $\overline{x}=0$ because the number density of photons $N_r=I_2(0)=\int_0^\infty x^2 f_0(x)\,dx$ is formally infinite. This implies that in the bremsstrahlung case, $\theta_{\mathrm{eq}}=0$, and therefore no meaningful steady state exists according to (43). It is important to emphasize that our calculation of θ_{eq} has utilized an energy conservation principle that may not be available in all physical applications of the general transport equation (1).

TABLE I. Numerical results.

The values of the initial θ derivatives and the associated continued fraction coefficients obtained for the bremsstrahlung and monoenergetic initial spectra are presented in Table I. Note the rapid divergence of the derivatives in each case, implying a limited radius of convergence for the Taylor series $\Phi_N(y)$ given by (19). We compare the convergence properties of the Taylor series and the continued fractions for the bremsstrahlung and monoenergetic initial spectra below.

A. Monoenergetic initial spectrum

The first and second columns of Table I contain, respectively, the results obtained in the monoenergetic case for the initial derivatives $\theta(0)$, $\theta^{(1)}(0),\ldots,\theta^{(M)}(0)$ and the continued fraction coefficients $c_0, c_1,\ldots,c_M$ for $M=24$. This choice for M is arbitrary and of no particular significance. The corresponding sequence of truncated Taylor series $\Phi_N(y)$ is plotted in Fig. 1. The radius of convergence of the Taylor series is limited to $y\lesssim0.15$ even for large N, which reflects the rapid increase in the absolute value of the derivatives of $\theta(y)$ at $y=0$. By contrast, the continued fraction coefficients obtained in the monoenergetic case grow much more slowly in absolute value. The continued fraction sequence $\Psi_N(y)$ contains defects (extraneous poles) for some odd values of N, but $\Psi_N(y)$ converges (albeit nonuniformly) for even values of N, as can be seen in Fig. 2, where we plot the sequence of continued fractions for $N=18$, 20, 22, 24. It is clear from Fig. 2 that the continued fractions converge even for values of y far outside the radius of convergence of the Taylor series. In our search for an accurate approximation to the exact solution for $\theta(y)$, we select the continued fraction $\Psi_N(y)$ that most closely approaches the correct asymptotic value $\theta_{\rm eq}=4/3$ for large y. According to Fig. 2, the best agreement is obtained by using the highest order fraction analyzed in this example, which is $\Psi_{24}(y)$.

With $\theta(y)$ approximated using the continued fraction $\Psi_{24}(y)$, the transport equation (30) reduces to a linear, second-order partial differential equation. We solve this equation using the

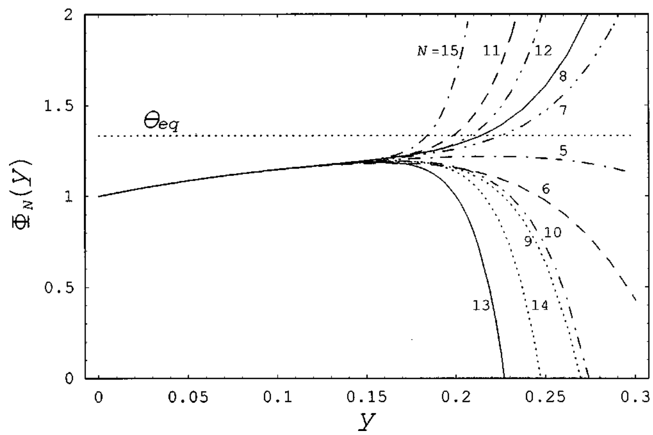

FIG. 1. Sequence of truncated Taylor series $\Phi_N(y)$ given by (19) obtained in the case of Comptonization of a monoenergetic initial spectrum (42) plotted as a function of y, with the truncation level N indicated for each curve. Note that $\Phi_N(y)$ diverges for $y \gtrsim 0.15$ even for large N, due to the rapid growth of the magnitude of the initial θ derivatives, as can be seen in Table I. The asymptotic equilibrium temperature $\theta_{eq} = 4/3$ is denoted by the dotted horizontal line.

IMSL routine DMOLCH over the range $0 \leqslant y \leqslant 2$ and $0 \leqslant x \leqslant 50$. The monoenergetic initial condition (42) imposed at $y=0$ is approximated using a Gaussian distribution with mean $\overline{x}=4$, variance $\sigma^2 = 0.01$, and photon number density $N_0 = 1$. The result obtained for the photon energy spectrum $G(x,y) \equiv x^3 f(x,y)$ is plotted in Fig. 3. It is convenient to plot G rather than f because energy conservation implies that $I_3 = \text{constant}$, and therefore $\int_0^\infty G\, dx$ is independent of y. In the monoenergetic case the initial condition (42) yields $I_3 = 4$. As y increases from zero, the distribution evolves away from the monoenergetic initial form and is well described by the equilibrium Wien distribution (43) for $y \gtrsim 1$.

B. Bremsstrahlung initial spectrum

The third and fourth columns of Table I contain, respectively, the results obtained in the bremsstrahlung case for the initial derivatives $\theta(0)$, $\theta^{(1)},\ldots,\theta^{(M)}(0)$ and the continued-fraction coefficients $c_0, c_1, \ldots, c_M$ for $M=24$. The corresponding sequence of truncated Taylor series

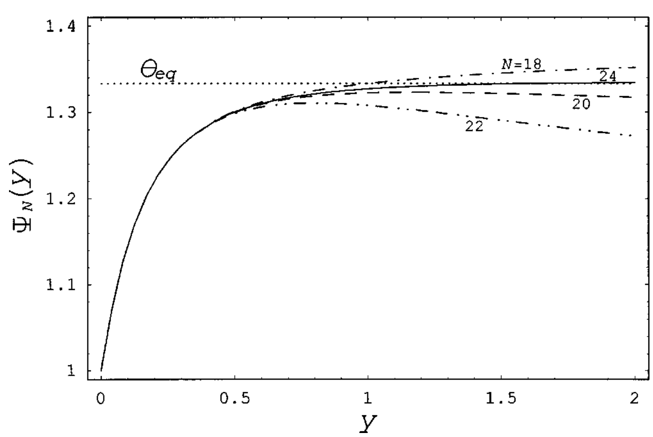

FIG. 2. Sequence of continued fractions $\Psi_N(y)$ given by (20) obtained in the case of Comptonization of a monoenergetic initial spectrum (42) plotted as a function of y, with the truncation level N indicated for each curve. We have plotted the results only for even values of N because in this example $\Psi_N(y)$ contains defects (extraneous poles) for some odd values of N. Note that $\Psi_N(y)$ converges (though nonuniformly) for even values of N throughout the entire computational domain, which extends well beyond the radius of convergence of the Taylor series depicted in Fig. 1. We require that acceptable approximations approach θ_{eq} as $y \to \infty$.

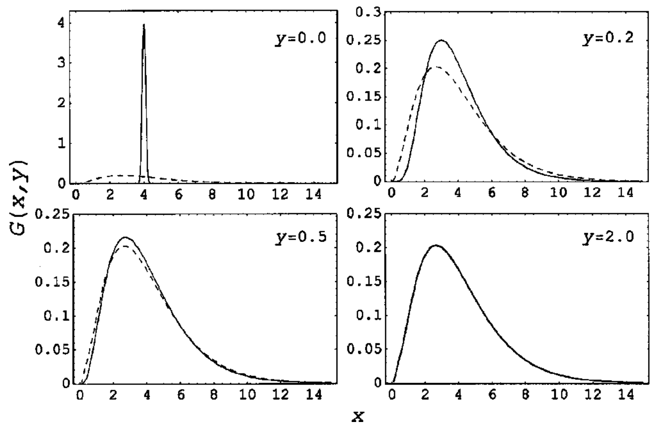

FIG. 3. Numerical result for the photon distribution $G(x,y)\equiv x^3 f(x,y)$ plotted as a function of x for the indicated values of y. In this case the initial spectrum imposed at $y=0$ corresponds to a Gaussian distribution with mean $\bar{x}=4$, variance $\sigma^2=0.01$, and total photon number density $N_0=1$, which approximates the monoenergetic initial spectrum (42). The solid lines denote G and the dashed lines represent the asymptotic equilibrium Wien spectrum given by (43). The photon spectrum is essentially given by the Wien form for $y\gtrsim 1$, and the two distributions are indistinguishable for $y=2$. The area under the curves $\int_0^\infty G\,dx=4$ due to energy conservation.

$\Phi_N(y)$ is plotted in Fig. 4, and the sequence of continued fractions $\Psi_N(y)$ is plotted in Fig. 5. Note that the radius of convergence of the Taylor series actually *decreases* with increasing truncation level N. Conversely, the sequence of continued fractions displays a pattern of uniform convergence with increasing N. The uniform convergence is a consequence of the fact that the computed continued fraction coefficients are all positive in this case, leading us to conjecture that the exact solution $\theta(y)$ is a Stieltjes function when the initial spectrum corresponds to optically thin bremsstrahlung.[12]

The pattern of uniform convergence of $\Psi_N(y)$ in the bremsstrahlung case suggests that we can obtain a reasonable approximation for the exact solution $\theta(y)$ using the continued fraction $\Psi_{24}(y)$. We impose the bremsstrahlung initial condition (41) at $y=0$ and solve the transport equation (30) using DMOLCH over the range $0\leqslant y\leqslant 2$ and $0\leqslant x\leqslant 50$. The result obtained for the function $G(x,y)\equiv x^3 f(x,y)$ is plotted in Fig. 6. The initial condition (41) combined with energy conservation implies that the area under the curve $\int_0^\infty G\,dx=4$ for all y. As y increases from zero,

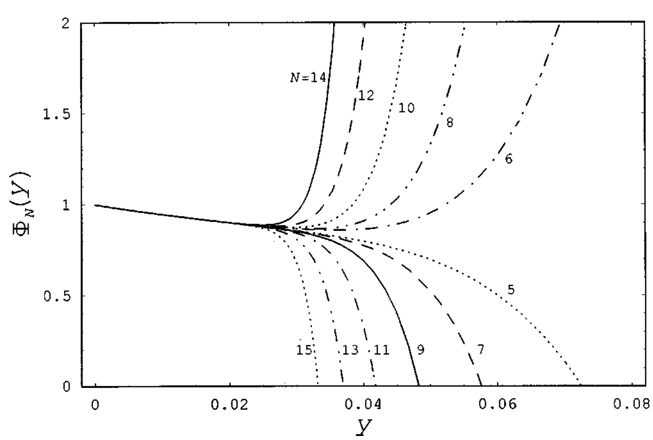

FIG. 4. Sequence of truncated Taylor series $\Phi_N(y)$ obtained in the case of Comptonization of a bremsstrahlung initial spectrum (41) plotted as a function of y, with the truncation level N indicated for each curve. Note that the radius of convergence decreases with increasing N due to the rapid growth of the initial θ derivatives (see Table I). In this case the asymptotic equilibrium temperature $\theta_{eq}=0$ due to the presence of an infinite number of zero-energy photons in the initial spectrum.

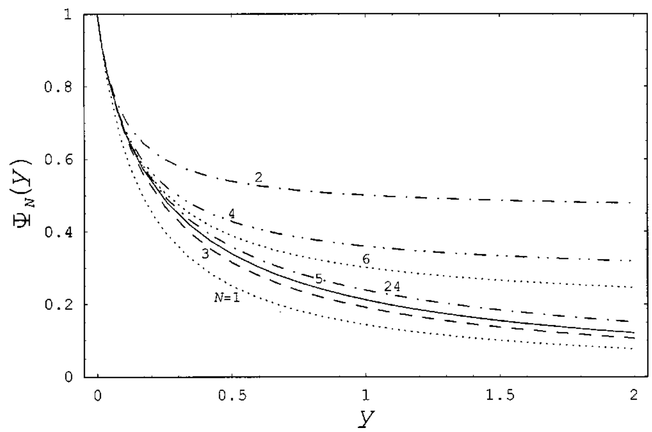

FIG. 5. Sequence of continued fractions $\Psi_N(y)$ obtained in the case of a bremsstrahlung initial spectrum (41) plotted as a function of y, with the truncation level N indicated for each curve. Note the pattern of uniform convergence for $N = 1,2,3,4,5,6$, which suggests that in this case the exact solution $\theta(y)$ is probably a Stieltjes function. For $N>6$, the results become strongly clustered around the $N=24$ curve.

the distribution evolves away from its initial bremsstrahlung form and attempts to approach the equilibrium Wien distribution (43). However, in this case the photon number density $N_r \to \infty$, and therefore the asymptotic value for the temperature $\theta_{\rm eq} = 0$ as discussed earlier. The divergence of the number density is due to the presence of an infinite number of zero-energy photons in the initial spectrum. Since these photons cannot all be upscattered to higher energies without violating overall energy conservation, the ''equilibrium'' solution for the distribution function given by (43) reduces to a pulse centered on zero energy, which is not a meaningful steady state solution. Hence equilibrium cannot be achieved in the bremsstrahlung case, in contrast to the result obtained when the initial spectrum contains a finite number density of photons, as in the monoenergetic example treated above. We analyze the self-consistency of the numerical solutions obtained in the monoenergetic and bremsstrahlung cases in Sec. VII.

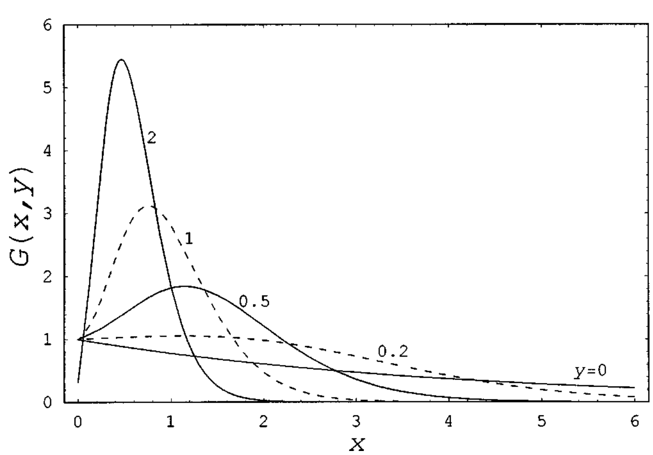

FIG. 6. Numerical results for the photon distribution $G(x,y) \equiv x^3 f(x,y)$ plotted as a function of x for the indicated values of y. In this case the initial condition is the optically thin bremsstrahlung spectrum (41). The distribution function approaches a pulse centered at zero energy as y increases due to the infinite number of zero-energy photons in the initial spectrum. The area under the curves $\int_0^\infty G\,dx = 4$ as a consequence of energy conservation.

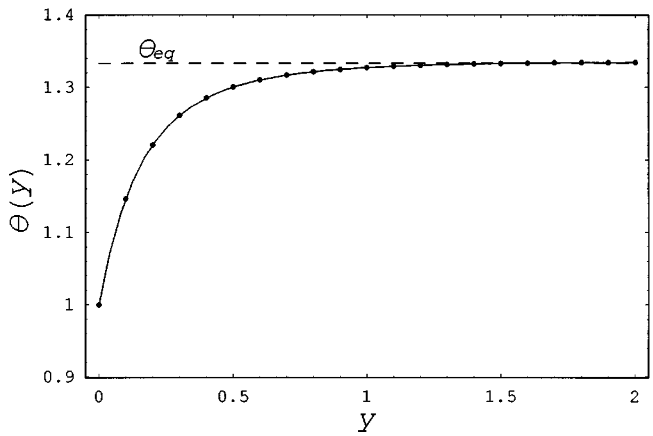

FIG. 7. Results obtained for the (input) continued fraction approximation $\Psi_{24}(y)$ (solid line) are compared with the (output) temperature calculated using the integral definition $\theta(y) \equiv I_4(y)/I_4(0)$ (closed dots) for the Comptonization of a monoenergetic initial spectrum. The dashed horizontal line indicates the asymptotic value of the temperature. The agreement between the two results confirms the self-consistency of the solution obtained for the spectrum $f(x,y)$, which validates the mathematical approach.

VII. EVALUATION OF THE METHOD

Our approach to the solution of the integro-partial differential transport equation (30) has been to approximate the exact solution for the temperature function $\theta(y)$ by using the available derivatives to construct the highest-order continued fraction that is consistent with the known asymptotic behavior of the temperature. With $\theta(y)$ approximated in this way, we have solved for the photon distribution $f(x,y)$ using a standard computer algorithm commonly available in the IMSL library. One may well ask whether there is any guarantee that the numerical solution so obtained is actually the correct physical solution. Interestingly, for the problem treated here there *is* a method that can be used to *guarantee* both the accuracy and the uniqueness of the solution. This is accomplished by integrating the numerically obtained distribution $f(x,y)$ to calculate the corresponding temperature distribution *a posteriori* using (2) and (3). In the case of astrophysical Comptonization that serves as our sample application in this paper, the corresponding expression is $\theta(y) = I_4(y)/I_4(0)$ as given by (34). A comparison between the result for $\theta(y)$ obtained in this manner and the continued fraction approximation $\Psi_N(y)$ used in the solution of the transport equation serves as the acid test of the entire mathematical and computational approach presented here. In Figs. 7 and 8 we perform this comparison for the bremsstrahlung and monoenergetic initial spectra, respectively. The agreement is clearly excellent, verifying the validity of the overall approach.

VIII. CONCLUSION

The technique developed here provides a powerful tool for determining the time dependence of the integral function in an integro-partial differential equation *before* solving for the unknown distribution. The numerical results we have obtained for the variation of the self-consistent temperature function $\theta(y)$ in the case of astrophysical Comptonization suggest that the method has acceptable accuracy and reliable convergence properties. The first step in the procedure is the determination of the initial derivatives of $\theta(y)$ at $y=0$ using the algorithm described in Sec. III, which is based on the differential equation (10) governing the power moments $I_n(y) = \int_0^\infty x^n f(x,y)\,dx$. The initial derivatives $\theta^{(n)}(0)$ are then used to calculate the continued fraction coefficients c_n appearing in the representation of the continued fraction $\Psi_N(y)$. The convergence of the continued fraction sequence is then analyzed and the highest-order fraction that can be constructed using the available set of coefficients is used to approximate the exact solution $\theta(y)$. Next, the transport equation (1) is solved numerically, using the continued fraction approximation

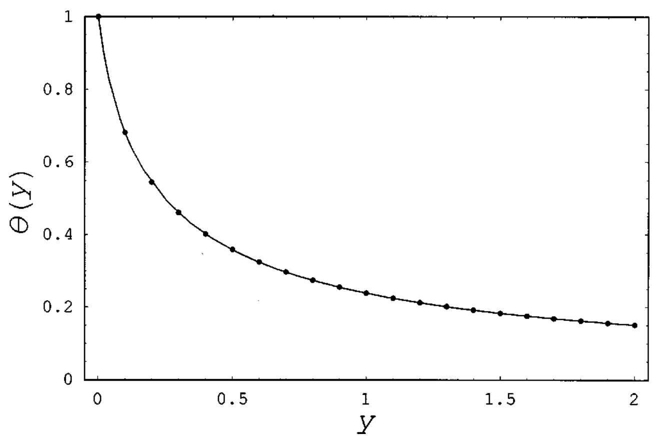

FIG. 8. Results obtained for the (input) continued fraction approximation $\Psi_{24}(y)$ (solid line) are compared with the (output) temperature calculated using the integral definition $\theta(y) \equiv I_4(y)/I_4(0)$ (closed dots) for the Comptonization of a bremsstrahlung initial spectrum. The agreement between the two results confirms the self-consistency of the solution.

as input to calculate the integral term. Finally, the self-consistency of the solution is evaluated by comparing the input continued fraction approximation $\Psi_N(y)$ with the output temperature calculated using the integral definition $\theta(y) \equiv I_\alpha(y)/I_\alpha(0)$. The level of agreement between $\Psi_N(y)$ and $\theta(y)$ provides a measure of the overall accuracy of the solution procedure.

It is interesting to contrast the behavior of the continued fraction sequence $\Psi_N(y)$ with that of the associated Taylor series $\Phi_N(y)$. Since the self-consistent solution for the temperature integral function $\theta(y)$ is positive for all real $y>0$, the limited radius of convergence of the Taylor series must reflect the presence of poles in $\theta(y)$ somewhere else in the complex plane. The existence of these poles essentially dooms any attempt to construct a useful perturbation series for the temperature. Conversely, the success of the continued fraction representation stems from its ability to produce a convergent *global* function that shares the same singularity structure as the exact solution $\theta(y)$. In general, $\Psi_N(y)$ converges toward the exact solution as the truncation level N increases, although the pattern of convergence can vary significantly from problem to problem. The cases for which $\theta(y)$ is a Stieltjes function are of particular importance because in these situations the convergence of the continued fraction sequence is uniform.[12]

In our computational examples, which focus on astrophysical Comptonization, we are able to utilize energy conservation to derive the asymptotic value of the temperature $\theta_{\rm eq}$ in the limit $y \to \infty$. This type of asymptotic information may not be available in every physical application of the general transport equation (1), but if $\theta_{\rm eq}$ can be calculated, we also have the option of including this information directly into the continued fraction using a two-point algorithm such as those given by Becker[15] and by Baker and Graves-Morris.[13] When this information is incorporated into the continued fraction, $\Psi_N(y)$ automatically approaches $\theta_{\rm eq}$ as $y \to \infty$. Note that in order to construct the two-point continued fraction we must first transform the time variable from the infinite domain $0 \leqslant y < \infty$ to an equivalent finite domain.

The method presented here bears some relation to techniques for solving partial differential equations proposed by Jumarie[16] and by Bender, Boettcher, and Milton.[17] In Jumarie's approach, a linear Fokker–Planck equation is used to generate moment equations similar to ours, which are solved using a maximum entropy principle to obtain the distribution function. Conversely, Bender, Boettcher, and Milton determine the distribution function governed by a nonlinear partial differential equation by employing a perturbation expansion followed by Padé summation, which resembles our approach to modeling the integral function $\theta(y)$. Although the procedures developed by these authors incorporate certain elements of the technique presented here, a crucial distinction is that their methods are not applicable to integro-partial differential equations.

In conclusion we point out that the procedure developed in this paper can be used as the basis for a new solution technique, or it can be incorporated into existing predictor–corrector or global iteration algorithms as a means of generating a trial solution for the integral function, which is subsequently improved upon using the standard methods. Our focus here has been upon the details of the method, and therefore we have not presented any comparisons between the efficiencies of the various algorithms available for solving integro-partial differential equations. Nonetheless, it is reasonable to expect that the method proposed here is likely to be quite efficient because the temperature variation is determined in advance of solving for the distribution function. In our computational examples we have treated the problem of astrophysical Comptonization, which is governed by the transport equation (30). However, we emphasize that the method is applicable to any equation of the form represented by (1), and that it can potentially be generalized to treat other transport equations, including those containing inhomogeneous, time-dependent source terms.

Integral representations of harmonic lattice sums

Jingfang Huang[a)]
Courant Institute of Mathematical Sciences, New York University, New York, New York 10012

(Received 7 May 1999; accepted for publication 22 June 1999)

We present new integral formulas for Coulombic lattice sums that arise in solid state physics, material science, and complex analysis. Unlike Ewald summation, which can yield approximate integral representations, the formulas described here are exact. Simple quadrature rules with modest numbers of nodes yield highly accurate results. © *1999 American Institute of Physics.* [S0022-2488(99)02910-2]

I. INTRODUCTION

Lattice sums arise in a variety of problems in mathematics, physics, biology, and chemistry. Examples include electromagnetic scattering by periodic arrays of obstacles, evaluation of the lattice energy of crystals, analysis of the thermodynamic and structural properties of electrolytes, and the computation of periodic solutions to partial differential equations. In this paper, we consider the calculation of Coulombic lattice sums. In two dimensions, these take the form

$$S_n=\sum_{\omega\in\Lambda_2}\frac{1}{\omega^n},\quad n\geqslant 3, \tag{1}$$

where $\Lambda_2=\{k_1+ik_2|k_1,k_2\in Z,k_1+ik_2\neq 0\}$. In three dimensions, the lattice sums are defined by

$$\mathcal{L}_n^m=\sum_{p\in\Lambda_3}Y_n^m(\theta_p,\phi_p)/r_p^{n+1},\quad n\geqslant 2,\quad m=0,...,n, \tag{2}$$

where $\Lambda_3=\{(k_1,k_2,k_3)|k_i\in Z,(k_1,k_2,k_3)\neq(0,0,0)\}$, (r_p,θ_p,ϕ_p) are the spherical coordinates of $p\in\Lambda_3$, and $Y_n^m(\theta_p,\phi_p)/r_p^{n+1}$ is a spherical harmonic function of degree $(-n-1)$. The spherical harmonics can be defined through the formula (Ref. 1)

$$\frac{Y_n^m(\theta,\phi)}{r^{n+1}}=A_n^m\cdot\left(\frac{\partial}{\partial x}+i\frac{\partial}{\partial y}\right)^m\left(\frac{\partial}{\partial z}\right)^{n-m}\left(\frac{1}{r}\right), \tag{3}$$

where

$$A_n^m=\frac{(-1)^n}{\sqrt{(n-m)!\cdot(n+m)!}}. \tag{4}$$

All of the lattice sums defined above are absolutely convergent. In many situations of interest, one also needs values for S_2, $\mathcal{L}_2^0$, $\mathcal{L}_2^1$, and $\mathcal{L}_2^2$. These quantities, however, are conditionally convergent and their valuation depends on the details of the physical problem.

There are several systematic techniques available for calculating such sums. The best-known method is due to Madelung and Ewald and is generally referred to as Ewald summation (Refs. 2–5). The method works by separating the lattice sum into two parts. Restricting our attention to S_n, we write

[a)]Electronic mail: huangjf@courant.nyu.edu

$$S_n = \sum_{\omega \in \Lambda_2} \frac{1}{\omega^n} \cdot F(\omega) + \sum_{\omega \in \Lambda_2} \frac{1}{\omega^n} \cdot (1 - F(\omega)),$$

where $F(\omega)$ is chosen so that the first sum converges rapidly in ''physical space,'' while the second sum decays rapidly in the Fourier domain, so that the Poisson summation formula (Ref. 6) can be used effectively. $F(\omega)$ is commonly chosen to be a simple Gaussian function. When $F(\omega)$ is the characteristic function of a subset of Λ_2, the method is occasionally referred to as the planewise summation method (see Refs. 7–9).

A rather different approach is through the use of recurrence formulas. In the two-dimensional case, there is a remarkable nonlinear relation (Ref. 10) of the form

$$(4m^2-1)(m-3)S_{2m} = 3\sum_{r=2}^{m-2} (2r-1)(2m-2r-1)S_{2r}S_{2m-2r}, \tag{5}$$

for $m \geqslant 4$. Given S_4 and S_6, all higher-order sums can be evaluated in this manner. (The odd lattice sums vanish.) Unfortunately, S_4 and S_6 are the most slowly converging, and are typically computed via Ewald summation. Furthermore, the formula (5) has no known analog in the three-dimensional case. More recently, Berman and Greengard (Ref. 11) used renormalization arguments to obtain a linear, infinite recurrence relation of the form

$$S_n - \sum_{k=n}^{\infty} A_{n-k}S_k = R_n, \tag{6}$$

where the terms A_n and R_n are simple finite sums. Their method extends to arbitrary dimensions and proceeds in the numerically attractive direction: i.e., it yields slowly converging sums in terms of rapidly converging ones. Another approach, that of Helsing and Lambert *et al.* (Refs. 12 and 13), relies on multipole expansions to accelerate the direct evaluation of the lattice sum to any desired precision and requires an amount of work that grows logarithmically with the number of lattice sites included.

In the present paper, we derive simple integral formulas (Theorems II.2 and IV.2) for the lattice sums S_n and $\mathcal{L}_n^m$. These formulas rely on ''plane-wave'' expansions of the fundamental singularity ($1/z$ in two dimensions and $1/r$ in three dimensions), which form the basis for modern versions of the fast multipole method (Refs. 14–17). We extend our analysis to the case of skewed lattices in two dimensions, where the corresponding sums play a fundamental role in the study of the Weierstrass $\wp$ function. A numerical scheme based on these formulas is extremely simple, easy to implement, and achieves very high accuracy.

II. TWO-DIMENSIONAL THEORY

Our starting point for the two-dimensional case is the plane-wave representation for a pole of degree n (Ref. 15).

Theorem II.1: *Let $z = x + iy$ denote a point in the complex plane:*

$$\textit{If}\ \ x>0,\ \ \textit{then}\ \ \frac{1}{z^n} = \frac{1}{(n-1)!}\int_0^\infty \lambda^{n-1} e^{-\lambda z}\, d\lambda;$$

$$\textit{if}\ \ x<0,\ \ \textit{then}\ \ \frac{1}{z^n} = \frac{1}{(n-1)!}\int_0^\infty (-1)^n \cdot \lambda^{n-1} e^{\lambda z}\, d\lambda;$$

$$\textit{if}\ \ y>0,\ \ \textit{then}\ \ \frac{1}{z^n} = \frac{1}{(n-1)!}\int_0^\infty (-i)^n \cdot \lambda^{n-1} e^{i\lambda z}\, d\lambda;$$

$$if \quad y<0, \quad then \quad \frac{1}{z^n}=\frac{1}{(n-1)!}\int_0^{\infty} i^n\cdot\lambda^{n-1}e^{-i\lambda z}\,d\lambda.$$

We will refer to these as the east, west, north, *and* south *formulas, respectively*.

Proof: For $n=1$, each formula is obvious by inspection. Differentiation yields the general case. ■

Theorem II.2: *Let $n\geqslant 3$. If n is not a multiple of 4, then $S_n=0$. Otherwise,*

$$S_n=\frac{4}{(n-1)!}\int_0^{\infty} e^{-\lambda}\cdot\lambda^{n-3}\cdot\left[\lambda^2\frac{1+\cos\lambda}{1-2e^{-\lambda}\cdot\cos\lambda+e^{-2\lambda}}\right]d\lambda. \tag{7}$$

Proof: If n is not a multiple of 4, simple symmetry considerations show that $S_n=0$. For $n=4l$, we divide the lattice points in the plane as follows. The *east list* is defined to be the set $\{(k,j)|k,j\in Z,k>0,-k\leqslant j\leqslant k\}$ and the *west list* is defined to be the set $\{(-k,j)|k,j\in Z,k>0,-k\leqslant j\leqslant k\}$. The *north list* is defined to be the set $\{(j,k)|j,k\in Z,k>0,-k<j<k\}$ and the *south list* is defined to be the set $\{(j,-k)|j,k\in Z,k>0,-k<j<k\}$. Note that lattice points along the diagonal lines $x=\pm y$ are preferentially assigned to the *east* and *west* lists. Making use of the integral representations in Theorem II.1, we can write

$$S_n=\frac{2}{(n-1)!}\int_0^{\infty}\lambda^{n-1}\sum_{k=1}^{\infty} e^{-\lambda k}\cdot\left(\sum_{j=-k}^{k} e^{-i\lambda j}+\sum_{j=-k+1}^{k-1} e^{-i\lambda j}\right)d\lambda.$$

The various geometric series can be summed analytically, yielding the desired results. ■

III. APPLICATION TO ELLIPTIC FUNCTIONS

The two-dimensional lattice sum S_n is a special case of the Eisenstein series G_n that arises in complex analysis and number theory, especially in the study of the Weierstrass $\wp$ function.

Definition III.1: Let $\tau=(\tau_1,\tau_2)$ be a complex number with $\tau_2>0$ and $-\frac{1}{2}<\tau_1\leqslant\frac{1}{2}$, and let Ω denote the set $\{k_1+k_2\tau|k_1,k_2\in Z,k_1+ik_2\neq 0\}$. The Weierstrass $\wp$ function is defined by

$$\wp(z)=\frac{1}{z^2}+\sum_{\omega\in\Omega}\left\{\frac{1}{(z-\omega)^2}-\frac{1}{\omega^2}\right\}.$$

If we expand the $\wp$ function as a Laurent series about the origin, we obtain

$$\wp(z)=\frac{1}{z^2}+\sum_{n=1}^{\infty}(2n+1)G_{2n+2}z^{2n},$$

where

$$G_n(\tau)=\sum_{\omega\in\Omega}\frac{1}{\omega^n}.$$

The series is valid for $0<|z|<\min\{|\omega|:\omega\in\Omega\}$.

Notice that the $G_n(\tau)$ is, in general, a skewed lattice sum. Our method, however, still applies.

Theorem III.1: *Let $n\geqslant 3$. If n is odd, then $G_n=0$. Otherwise, G_n has the integral representation*

$$G_n(\tau)=\frac{2}{(n-1)!}\int_0^{\infty}\lambda^{n-1}[f_1(\lambda,\tau)+i^n f_2(\lambda,\tau)]d\lambda, \tag{8}$$

where

$$f_1(\lambda,\tau)=\frac{e^{\lambda}-e^{\lambda\tau}+e^{\lambda+\lambda\tau}+e^{\lambda+2\lambda\tau}}{(e^{\lambda}-e^{\lambda\tau})(e^{\lambda+\lambda\tau}-1)}, \tag{9}$$

and

$$f_2(\lambda,\tau)=\frac{e^{i(\lambda+\lambda\tau)}(1+e^{i\lambda\tau})}{(e^{i\lambda\tau}-e^{i\lambda})(e^{i(\lambda+\lambda\tau)}-1)}. \tag{10}$$

Proof: Using the same decomposition as in the proof of Theorem II.2, we obtain

$$G_n(\tau)=\frac{1+(-1)^n}{(n-1)!}\int_0^\infty \lambda^{n-1}\sum_{k=1}^{\infty}\sum_{j=-k}^{k} e^{-\lambda k}e^{-\lambda j\tau}\,d\lambda$$
$$+\frac{i^n+(-i)^n}{(n-1)!}\int_0^\infty \lambda^{n-1}\sum_{j=1}^{\infty}\sum_{k=-j+1}^{j-1} e^{i\lambda k}e^{i\lambda j\tau}\,d\lambda.$$

If n is odd, it is clear that $G_n=0$. Explicit evaluation of the sums (all of which are absolutely convergent) completes the proof. ■

From the Laurent expansion for $\wp(z)$ and the fact that

$$e^z+e^{-z}=2\sum_{n=0}^{\infty}\frac{z^{2n}}{(2n)!},$$

we have the following corollary.

Corollary III.1: The Weierstrass $\wp(z)$ function has the integral representation

$$\wp(z)=\frac{1}{z^2}+\int_0^\infty \lambda[(e^{\lambda z}+e^{-\lambda z}-2)f_1(\lambda,\tau)-(e^{i\lambda z}+e^{-i\lambda z}-2)f_2(\lambda,\tau)]d\lambda. \tag{11}$$

IV. THREE-DIMENSIONAL THEORY

We turn our attention now to the lattice sums $\mathcal{L}_n^m$, with $n\geqslant 3$ and $0\leqslant m\leqslant n$. By symmetry considerations, it is easy to show that $\mathcal{L}_n^m=0$ unless n is even and m is a multiple of 4. We, therefore, restrict our attention to the nonzero cases.

In Refs. 16–17, the following plane-wave expansions are introduced and used to diagonalize certain translation operators. The cases with $n=0$ can be found in Ref. 18 and the higher-order results follow from (3).

Theorem IV.1: *Let (x,y,z) be a point with spherical coordinates (r,θ,ϕ) and let $C=1/(2\pi\sqrt{(n-m)!(n+m)!})$. If $z>0$, we have the* up *formula*

$$\frac{Y_n^m(\theta,\phi)}{r^{n+1}}=C\cdot i^m\int_0^\infty\int_0^{2\pi} e^{im\alpha}\lambda^n e^{-\lambda z+i\lambda(x\cos\alpha+y\sin\alpha)}\,d\alpha\,d\lambda. \tag{12}$$

For $z<0$, we have the down *formula*

$$\frac{Y_n^m(\theta,\phi)}{r^{n+1}}=C\cdot i^m(-1)^{n-m}\int_0^\infty\int_0^{2\pi} e^{im\alpha}\lambda^n e^{\lambda z+i\lambda(x\cos\alpha+y\sin\alpha)}\,d\alpha\,d\lambda. \tag{13}$$

For $y>0$, we have the north *formula*

$$\frac{Y_n^m(\theta,\phi)}{r^{n+1}}=C\cdot i^n(-1)^{n-m}\int_0^\infty\int_0^{2\pi}(\cos\alpha-1)^m(\sin\alpha)^{n-m}\lambda^n e^{-\lambda y+i\lambda(x\cos\alpha+z\sin\alpha)}\,d\alpha\,d\lambda. \tag{14}$$

$$\begin{aligned} f_{\mathrm{ud}} = \lambda^3 \{ & 1 + 2\cos(\lambda\cos\alpha) + 2\cos(\lambda\sin\alpha) + 4\cos(\lambda\cos\alpha)\cos(\lambda\sin\alpha) \\ & + e^{-\lambda}(1 - 2\cos(\lambda\cos\alpha) - 2\cos(\lambda\sin\alpha) - 4\cos^2(\lambda\cos\alpha) - 4\cos^2(\lambda\sin\alpha)) \\ & + e^{-2\lambda}(-1 + 4\cos(\lambda\cos\alpha)\cos(\lambda\sin\alpha)) - e^{-3\lambda} \}, \end{aligned}$$

$$\begin{aligned} f_{\mathrm{nsew}} = 2\lambda^3 \{ & 1 + \cos(\lambda\cos\alpha) + 2e^{-\lambda}(\cos(\lambda\cos\alpha) + \cos^2(\lambda\cos\alpha)) - e^{-2\lambda}(1 + \cos(\lambda\cos\alpha) \\ & + 2\cos(\lambda\sin\alpha) + 2\cos(\lambda\cos\alpha)\cos(\lambda\sin\alpha)) \}, \end{aligned}$$

and

$$d(\lambda,\alpha) = (1 - 2e^{-\lambda}\cos(\lambda(\cos\alpha - \sin\alpha)) + e^{-2\lambda})(1 - 2e^{-\lambda}\cos(\lambda(\cos\alpha + \sin\alpha)) + e^{-2\lambda}).$$

Proof: The derivation of this formula is analogous to the two-dimensional case. We omit the details, but note that the term f_{ud} collects the contributions from the *up* and *down* directions, while the term f_{nsew} collects the contributions from the other four directions. The functions $f_{\mathrm{ud}}(\lambda,\alpha)/d(\lambda,\alpha)$ and $f_{\mathrm{nsew}}(\lambda,\alpha)/d(\lambda,\alpha)$ are well defined as $\lambda \to 0$. The zeros in the denominator are canceled by zeros in the numerator. ∎

V. NUMERICAL RESULTS

To illustrate the utility of our integral formulas, we evaluate the two- and three-dimensional lattice sums using generalized Laguerre quadrature with N_λ nodes for the integral on $[0,\infty]$ with the weight function $W(x)=e^{-x}\cdot x^{n-3}$, and the trapezoidal rule with N_α nodes for the inner integral on $[0, 2\pi]$ in the three-dimensional case. The results are listed in Tables I and II.

We compare our calculations to the results obtained in Ref. 11. They agree to at least 14 significant digits.

VI. CONCLUSION

In this paper, we have developed new integral formulas for harmonic lattice sums in two and three dimensions. Our method relies on the existence of plane-wave expansions for the fundamental solution, and can be used for rectangular or skewed lattices. The approach can be extended to a variety of kernels, including screened Coulomb (Yukawa) potentials and Helmholtz potentials (Ref. 19). Work along these lines is in progress and will be reported at a later date. Applications of the integral representations to problems in analytic number theory remain to be investigated.
