$$\chi(\boldsymbol{\alpha})=\frac{1}{N^n}\prod_{I=1}^{\lambda}\left(\sum_{(m)}e^{-(1/2)g^2c_{(m)}|G_I|}p_{(m)}^{(n)}\otimes^n 1\right)_{\vec{A}_I}^{\vec{B}_I}\mathcal{C}_{\vec{C}}^{\vec{D}}\mathcal{E}_{\vec{E}}^{\vec{F}},$$

which for $\alpha_1,\ldots,\alpha_n$ contained in a quadratic lattice coincides with the results of TA^+. Here, $p_{(m)}^{(n)}$ are the projectors built from the Young tableaux (m) for $\otimes^n g$ and $c_{(m)}$ is the eigenvalue of the corresponding quadratic Casimir operator. n depends only on the decomposition of the α_i into the flags f_I. Finally, $\mathcal{C}_{\vec{C}}^{\vec{D}}$ and $\mathcal{E}_{\vec{E}}^{\vec{F}}$ are certain tensors and $\vec{A}_I$ and $\vec{B}_I$ indices whose structure is also determined by the algebraic structure of that decomposition.

For $\mathbf{G}=\mathrm{U}(1)$ we get

$$\chi(\boldsymbol{\alpha})=\prod_{I=1}^{\lambda} e^{-(1/2)g^2 n_I^2 |G_I|},$$

where n_I is the ''effective'' winding number of $\alpha_1\cdots\alpha_n$ around the domain G_I.

In conclusion we emphasize that the limits above are completely independent of the limiting process $\Gamma\to\mathbb{R}^2$ supposed $\Gamma_{\boldsymbol{\alpha}}$ is a restriction of any graph in the limiting process. Thus, the limit exists and is unique.

VII. DISCUSSION

In Sec. VI we ''derived'' the expectation values of the Wilson loop products. Actually, the word ''derived'' is an exaggeration—de facto we *defined* the values even if the Yang–Mills action on $\mathcal{A}/\mathcal{G}$ influenced the definition of χ. But we did not deduce the values of χ from S_{YM} in a mathematically correct way. Formally we got χ by

$$\chi(\boldsymbol{\alpha})=\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_0\, e^{-S_{\mathrm{YM}}(\bar{A})}T_{\alpha_1}\cdots T_{\alpha_n}=\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_0 e^{-\lim S_{\mathrm{reg}}(\bar{A})}T_{\alpha_1}\cdots T_{\alpha_n},$$

i.e., by extending S_{YM} onto $\overline{\mathcal{A}/\mathcal{G}}$, and subsequently by exchanging the limiting process and the integration

$$\chi(\boldsymbol{\alpha}):=\lim \int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_0\, e^{-S_{\mathrm{reg}}(\bar{A})}T_{\alpha_1}\cdots T_{\alpha_n}.$$

Consequently, this definition is the actual start of our considerations. In principle, that approach is a kind of constructive quantum field theory that needs a physical justification only a posteriori.

In Sec. VI A we already noted that the regularization of S_{YM} by

$$S:=\lim_{\Gamma\to\mathbb{R}^2}\sum_G \frac{N}{g^2}\frac{1}{|G|}\left(1-\frac{1}{N}\mathrm{Re}\,\mathrm{tr}\,h_{\alpha_G}\right)$$

makes no problems on $\mathcal{A}/\mathcal{G}$, but breaks down on $\overline{\mathcal{A}/\mathcal{G}}$, because the limit does not exist in general. Thus, S cannot be in $\overline{\mathcal{HA}}$. But, surprisingly the exchange of limit and integral yields very regular results. We have even shown[13] that the limit $\chi(\boldsymbol{\alpha})$ for our choice of regularization exists for all finite $\alpha\subseteq\mathcal{L}_m$ and is independent of the limiting process. Is there a deeper reason behind that?

However, we know that the given expectation values define a unique Borel measure μ on $\overline{\mathcal{A}/\mathcal{G}}$[2] because we can extend these values to a linear continuous positive functional on $\overline{\mathcal{HA}}$. Note that originally the expectation values are not mutually independent, but subjected to the so-called Mandelstam relations. Since we defined the expectation values using integrals on T_α, these relations are indeed implemented. What properties does μ have? Is μ *strictly* positive or is μ absolutely continuous with respect to the induced Haar measure μ_0? Is it even possible to define an action S on $\overline{\mathcal{A}/\mathcal{G}}$ directly, i.e., without regularization, and is it therefore possible to get the desired measure by $d\mu:=e^{-S}d\mu_0$?

The choice of regularization is also worth being discussed. In the present case the regularization of S_{YM} depends crucially on the dimension two. It cannot be extended to three or more dimensions because it uses—roughly speaking—the chance that for two-dimensional manifolds a loop has both dimension and codimension one. But the codimension is decisive. To avoid renormalization one has to regularize the d-dimensional Yang–Mills theory by

$$\lim_{\sup\ \mathrm{diam}\, G\to 0} \frac{N}{g^2}\frac{1}{\mathrm{vol}\, G}\sum_{\{G\}}\left(1-\frac{1}{N}\mathrm{Re}\,\mathrm{tr}\,\mathcal{P}\exp\left(-ig\int_{\partial G}A\right)\right),$$

where $\{G\}$ is a decomposition of the base manifold into certain d-dimensional objects. How to connect $\mathcal{P}\exp(-ig\int_{\partial G}A)$ and $\mathcal{P}\exp(-ig\int_{\alpha}A)$? Moreover, the used propositions for planar graphs cannot be applied to higher dimensions. Thus, from dimension three on problems of knot theory will be important and so will methods of the topological quantum field theory. Perhaps using algebraic topology or invariant theory one can specify a class of constructible models.

Let us return finally to the concrete generalization of the two-dimensional Yang–Mills theory within the Ashtekar approach. In the last few years some papers were published that calculated the expectation values of the Wilson loops in $\mathcal{A}/\mathcal{G}$ (e.g., Refs. 14–16) and performed the continuum limit. They provided an area law, an indication for the confinement in the theory. All in all these papers delivered the same result as the Ashtekar approach does today. Thus, we get a little justification for our choice of the regularization. Perhaps it is possible to translate further models into the new approach and to confirm that way the results got on $\mathcal{A}/\mathcal{G}$. However, it seems to be unlikely that one gets—at least in the next time—general assertions for the equivalence of the ''classical'' and the Ashtekar approach. But, from the mathematical point of view this would be very interesting because some problems of the classical approach could be circumvented.

ACKNOWLEDGMENTS

I am very grateful to Gerd Rudolph for his great support while I wrote my diploma thesis and the present paper. I thank the Studienstiftung des deutschen Volkes for its long-time grant and the Max-Planck-Institut für Mathematik in den Naturwissenschaften for its generous promotion.

APPENDIX: PROOF OF PROPOSITION 3.1

Lemma A.1.: Let γ be a Jordan path in M contained completely in a chart U_i with trivialization χ_i and p any point in the fiber over $\gamma(0)$. Furthermore, let $\mathbf{G}$ be compact and connected and $\epsilon \in]0,\frac{1}{2}[$ arbitrary.

Then $\tau_{\gamma,\mathcal{A}_{\epsilon,\gamma,i}}(p)=P_{\gamma(1)}$, where $\mathcal{A}_{\epsilon,\gamma,i}$ is defined by $\mathcal{A}_{\epsilon,\gamma,i}:=\{A\in\mathcal{A}|A_i(\gamma(t))\equiv 0$ for $t\notin[\epsilon,1-\epsilon]\}$, i.e., any point of $P_{\gamma(1)}$ can be reached by parallel transport starting in p with respect to connections in $\mathcal{A}_{\epsilon,\gamma,i}$. $[\tau_{\gamma,A}(p):P\to P$ is the parallel transport of p along γ with respect to the connection A and $\tau_{\gamma,p}(A)$ the corresponding group element.]

Proof: (1) Let $p\equiv p_i:=s_i(\gamma(0)):=\chi_i^{-1}(\gamma(0),e_{\mathbf{G}})$. Then $\tau_{\gamma,p}(A)=\mathcal{P}\exp[-\int_\gamma A_i(\dot\gamma)dt]$, where $\dot\gamma$ is the tangential vector field to γ and A_i is the connection A in the local trivialization χ_i. (We dropped the factor ig.)

(2) Obviously, there is a one-form $a_i:TU_i\to\mathbb{C}$ with $a_i(\dot\gamma)|_{\gamma([0,\epsilon]\cup[1-\epsilon,1])}\equiv 0$ and $-\int_\gamma a_i(\dot\gamma)dt=1\neq 0$.

(3) Set $A_{\lambda,i}:=a_i\otimes\lambda$ for any $\lambda\in\mathbf{g}$ and extend $A_{\lambda,i}$ to a connection A_λ on TP. (This is possible, see, e.g., Ref. 17, p. 67.) Obviously, $A_\lambda\in\mathcal{A}_{\epsilon,\gamma,i}$ for any $\lambda\in\mathbf{g}$.

(4) For λ constant, we have $\tau_{\gamma,p}(A_\lambda)=\mathcal{P}\exp[-(\int_\gamma a_i(\dot\gamma)dt)\lambda]=e^\lambda$.

(5) Since the image of the Lie algebra $\mathbf{g}$ under the exponential map is the connected component of unity of the Lie group $\mathbf{G}$, we have $\mathbf{G}\supseteq\tau_{\gamma,p}(\mathcal{A}_{\epsilon,\gamma,i})\supseteq\{\tau_{\gamma,p}(A_\lambda)|\lambda\in\mathbf{g}\}=\{e^\lambda|\lambda\in\mathbf{g}\}=\mathbf{G}$, i.e., $\mathbf{G}=\tau_{\gamma,p}(\mathcal{A}_{\epsilon,\gamma,i})$ and thus $\tau_{\gamma,\mathcal{A}_{\epsilon,\gamma,i}}(p)=P_{\gamma(1)}$.

(6) Now let p be arbitrary. Since the parallel transport commutes with the right action, we have $\tau_{\gamma,\mathcal{A}_{\epsilon,\gamma,i}}(p)=(\mathrm{Ad}\,\psi_g)\tau_{\gamma,\mathcal{A}_{\epsilon,\gamma,i}}(p_i)=(\mathrm{Ad}\,\psi_g)=P_{\gamma(1)}=P_{\gamma(1)}$ because $\mathbf{G}$ acts freely on P. We chose g, such that $p=p_i\cdot g$. **qed**

Proof: (Proposition 3.1) Let $\boldsymbol{\alpha}:=\{\alpha_1,\ldots,\alpha_n\}$ be a set of moderately independent loops. We have to show that for any n-tupel $(g_1,\ldots,g_n)\in\mathbf{G}^n$ there is an $A\in\mathcal{A}$ with $h_{\alpha_i}(A)=g_i\ \forall 1\leqslant i\leqslant n$. (Note, that we have fixed a trivialization χ and therefore a base point p in P_m from the very beginning.)

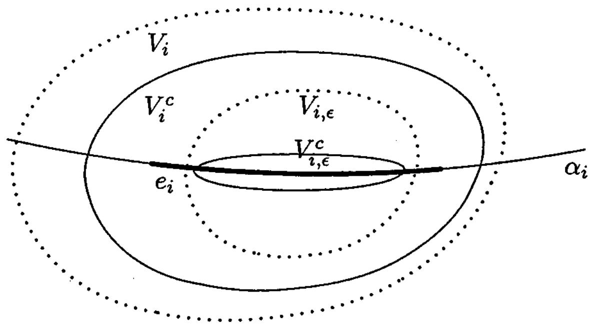

FIG. 8. The domains V_i, V_i^c, $V_{i,\epsilon}$, and $V_{i,\epsilon}^c$.

Fix a covering $\{U_k\}$ of M. Choose a free segment e_i to any $\alpha_i \in \boldsymbol{\alpha}$ due to Definition 3.2, such that

(1) $\alpha_i = f_i^- e_i f_i^+$ with $f_i^\pm \cap e_i = \emptyset$ and $\alpha_j \cap e_i = \emptyset, \forall_j < i$ and
(2) any free segment lies completely in a chart U_i.

Next, choose open neighborhoods V_i of e_i, such that $V_i \subseteq U_i$ are mutually disjoint and that $\alpha_j \cap V_i = \emptyset$ for any $j < i$, and modify the covering of M in that way, that V_i lies in exactly one chart (denoted again by U_i). Furthermore, choose open $V_{i,\epsilon}$ and compact sets $V_i^c, V_{i,\epsilon}^c$ with some $\epsilon \in]0,\frac{1}{2}[$, $e_i \subseteq V_i^c \subseteq V_i$ and $V_{i,\epsilon}^c \subseteq V_{i,\epsilon} \subseteq V_i^c$, $V_{i,\epsilon} \cap f_i^\pm = \emptyset$ and $\gamma_i(t) \in V_{i,\epsilon}^c \Leftrightarrow t \in [\epsilon, 1-\epsilon]$, where $\gamma_i : [0,1] \to e_i$ is a parametrization of e_i. (See Fig. 8.)
It is a well-known fact that there exists a $\phi \in C^\infty(M)$ with $\phi \equiv 1$ on $\cup V_i^c$ and $\phi \equiv 0$ on $M \setminus \cup V_i$ and analogously a $\phi_{i,\epsilon} \in C^\infty(M)$ with $\phi_{i,\epsilon} \equiv 1$ auf $V_{i,\epsilon}^c$ and $\phi_{i,\epsilon} \equiv 0$ on $M \setminus V_{i,\epsilon}$ for all i.
Let $B \in \mathcal{A}$ be some connection.

(1) $i = 0$.

$A^{(0)} := B - \phi B$ is again a connection. (This simple notation means: There is an $A^{(0)}$ for that B, such that $A_i^{(0)} = (1-\phi) B_i$ on $\cup V_i$ and elsewhere $B = A^{(0)}$ since because of the special selection of V_i the compatibility conditions of chart changes are not touched.) We have now $A_j^{(i)} \equiv 0$ on e_j for all $j > i = 0$ (and obviously $h_{\alpha_j}(A^{(i)}) = g_j$ for all $j \leqslant i = 0$).

(2) $i > 0$.

Let $p_{i,-} := \tau_{f_i^-, A^{(i-1)}}(p) \in P_{\gamma_i(0)}$ be the parallel transport to $A^{(i-1)}$ of p along f_i^- and $p_{i,+} := \tau^{-1}_{f_i^+, A^{(i-1)}}(p \cdot g_i)$ the "inverse" parallel transport with respect to $A^{(i-1)}$ along f_i^+ leading from $P_{\gamma_i(1)}$ to $p \cdot g_i$. Due to the lemma above there is an $A' \in \mathcal{A}_{\epsilon,\gamma_i,i}$ with $p_{i,+} = \tau_{e_i,A'}(p_{i,-})$ and we have

$$p \cdot g_i = \tau_{f_i^+, A^{(i-1)}}(\tau_{e_i, A'}(\tau_{f_i^-, A^{(i-1)}}(p)))$$

$$= \tau_{f_i^+, A^{(i-1)} + \phi_{i,e} A'}(\tau_{e_i, A'}(\tau_{f_i^{-1}, A^{(i-1)} + \phi_{i,e} A'}(p))) \quad (\text{due to } \phi_{i,\epsilon} \equiv 0 \text{ on } f_i^\pm)$$

$$= \tau_{f_i^+, A^{(i-1)} + \phi_{i,e} A'}(\tau_{e_i A^{(i-1)} + \phi_{i,e} A'}(\tau_{f_i^-, A^{(i-1)} + \phi_{i,e} A'}(p)))$$

$$(\text{due to } A_i^{(i-1)}|_{e_i \equiv 0} \text{ and } \phi_{i,\epsilon}|_{\text{supp}\, A_i' \cap e_i} \equiv 1)$$

$$= \tau_{f_i^- e_i f_i^+, A^{(i-1)} + \phi_{i,e} A'}(p) = \tau_{\alpha_i, A^{(i)}}(p),$$

where we set $A^{(i)}:=A^{(i-1)}+\phi_{i,\epsilon}A'$. Obviously, $A^{(i)}$ is a connection, and we get $h_{\alpha_i}(A^{(i)})=g_i$. Since $A^{(i)}=A^{(i-1)}$ outside V_i and $V_i\cap\alpha_j=\emptyset$ $\forall_j<i$, we have also $h_{\alpha_j}(A^{(i)})=h_{\alpha_j}(A^{(i-1)})$ $=g_j$, $\forall_j<i$ by induction. Furthermore, we have $A_j^{(i)}\equiv 0$ on e_j for all $j>i$.

The proof ends setting $A:=A^{(n)}$. **qed**

We develop a cannonical quantization for massive vector fields on a globally hyperbolic Lorentzian manifold. © *1999 American Institute of Physics.* [S0022-2488(99)04506-5]

I. INTRODUCTION

Rigorous theories have been developed for scalar, Dirac, and electromagnetic quantum fields on globally hyperbolic manifolds.[1–6] However, apparently few rigorous results exist for massive vector fields on such manifolds.[7] A particle described by such a field is the ω-meson with a mass $m_\omega = 783$ MeV.[8] In this article, we develop a canonical quantization for massive vector fields on a globally hyperbolic Lorentzian manifold. The analysis is divided into two parts, the classical problem and the quantum problem.

For the classical problem, we start with the equations of motion $(\delta^{(4)}d^{(4)} + m^2)\mathcal{A} = 0$ which are the curved space–time generalizations of Proca's equations. We reduce these to a hyperbolic system $(\Box + m^2)\mathcal{A} = 0$, and a constraint $\delta^{(4)}\mathcal{A} = 0$. The hyperbolic system has global fundamental solutions $E_m^{\pm(1)}$ and a propagator $E_m^{(1)} = E_m^{+(1)} - E_m^{-(1)}$.[9–12] We introduce a series of operators $\rho_{(0)}$, $\rho_{(d)}$, $\rho_{(\delta)}$, and $\rho_{(n)}$ that map a solution $\mathcal{A}$ to its Cauchy data $A_{(0)}$, $A_{(d)}$, $A_{(\delta)}$, and $A_{(n)}$, respectively. These operators have transposes $\rho'_{(0)}$, $\rho'_{(d)}$, $\rho'_{(\delta)}$, and $\rho'_{(n)}$. We construct a series of operators $E_m^{(1)}\rho'_{(0)}$, $E_m^{(1)}\rho'_{(d)}$, $E_m^{(1)}\rho'_{(\delta)}$, and $E_m^{(1)}\rho'_{(n)}$ and show that these operators collectively map Cauchy data to a unique field solution. We apply these operators to obtain a global solution for Proca's equations wherein we satisfy the constraint by restricting the Cauchy data. Our representation of the solution is apparently new, and especially useful for field quantization as we demonstrate. This method also applies to Maxwell's equations. Since these equations are also of interest, but not needed for our quantum problem, we treat them separately in an appendix.

For the quantum problem, we start with a representation $(\phi, \pi, \mathcal{H})$ of the CCRs on an arbitrary Cauchy surface. We construct a space–time field operator $\mathcal{A}$ in terms of the data (ϕ, π) in accordance with the classical initial value problem. We then pass to the Weyl form W of the CCRs and study the C^* algebra of observables $\mathfrak{A}$ generated by W. We show that $\mathfrak{A}$ is independent of the representation on a given Cauchy surface, and also independent of the Cauchy surface. This work generalizes Dimock's treatment of scalar fields.[3]

II. PRELIMINARY CONCEPTS

Let $(\mathcal{M}, g)$ be a globally hyperbolic, orientable, time-orientable, space–time consisting of a smooth four-dimensional manifold $\mathcal{M}$ endowed with a smooth Lorentzian metric g with signature $(-1,1,1,1)$. As a consequence of global hyperbolicity, there is a (nonunique) smooth time coordinate t, and $(\mathcal{M}, g)$ can be foliated by a one-parameter family of Cauchy surfaces $\{t\} \times \Sigma_t$ giving it the topology $\mathcal{M} \approx \mathbb{R} \times \Sigma$.[2,13] Each Cauchy surface Σ inherits a smooth, proper Riemannian metric γ. We label events in $\mathcal{M}$ using (t,x) where $x \in \Sigma$, and adopt the standard convention in which Greek subscripts apply to $(\mathcal{M}, g)$ taking values from 0 to 4, and Latin subscripts apply to (Σ, γ) and range from 1 to 3.

Let $\mathcal{E}^{(p)}(\mathcal{M})$ denote the space of smooth, real-valued p-forms on $(\mathcal{M}, g)$ and $\mathfrak{D}^{(p)}(\mathcal{M})$ specify such forms with compact support. These spaces have duals $\mathcal{E}'^{(p)}(\mathcal{M})$ and $\mathfrak{D}'^{(p)}(\mathcal{M})$ with topologies similar to those defined for the corresponding spaces on $\mathbb{R}^n$.[10–12] We use the standard notation $\langle \mathcal{T},\mathcal{F}\rangle$ to denote the action of a distribution $\mathcal{T}$ on a test function $\mathcal{F}\in\mathfrak{D}^{(p)}(\mathcal{M})$. Specializing to $\mathcal{T}\in\mathfrak{D}^{(p)}(\mathcal{M})\subset\mathfrak{D}'^{(p)}(\mathcal{M})$ we have $\langle \mathcal{T},\mathcal{F}\rangle=\langle \mathcal{T},\mathcal{F}\rangle_{\mathcal{M}}$, where

$$\langle \mathcal{T},\mathcal{F}\rangle_{\mathcal{M}}\equiv\int_{\mathcal{M}}\mathcal{T}\wedge *^{(4)}\mathcal{F}, \tag{1}$$

is the global inner product, and $*^{(4)}:\mathfrak{D}^{(p)}(\mathcal{M})\rightarrow\mathfrak{D}^{(4-p)}(\mathcal{M})$ is the Hodge star operator with respect to g $((*^{(4)})^2=(-1)^{p+1})$. On $(\mathcal{M},g)$ we have an exterior derivative $d^{(4)}$ and codifferential $\delta^{(4)}=*^{(4)}d^4*^{(4)}$ which are the formal adjoints of one another $\langle d^{(4)}\mathcal{A},\mathcal{F}\rangle_{\mathcal{M}}=\langle\mathcal{A},\delta^{(4)}\mathcal{F}\rangle_{\mathcal{M}}$, where $\mathcal{A}\in\mathfrak{D}^{(p-1)}(\mathcal{M})$ and $\mathcal{F}\in\mathfrak{D}^{(p)}(\mathcal{M})$. There is also the D'Alembertian $\Box=(\delta^{(4)}d^{(4)}+d^{(4)}\delta^{(4)})$ which is formally self-adjoint (on Minkowski space $\Box=\partial_0^2-\nabla^2$).[14,15]

Let $\mathcal{E}^{(k)}(\Sigma)$, $\mathfrak{D}^{(k)}(\Sigma)$, $\mathcal{E}'^{(k)}(\Sigma)$ and $\mathfrak{D}'^{(k)}(\Sigma)$ denote the corresponding spaces on (Σ,γ). For $T\in\mathfrak{D}^{(k)}(\Sigma)\subset\mathfrak{D}'^{(k)}(\Sigma)$ we have $\langle T,F\rangle=\langle T,F\rangle_{\Sigma}$, where

$$\langle T,F\rangle_{\Sigma}\equiv\int_{\Sigma}T\wedge *^{(3)}F, \tag{2}$$

is the global inner product on (Σ,γ), and $*^{(3)}$: $\mathfrak{D}^{(k)}(\Sigma)\rightarrow\mathfrak{D}^{(3-k)}(\Sigma)$ is the Hodge star operator with respect to γ $((*^{(3)})^2=1)$. The exterior derivative $d^{(3)}$ and codifferential $\delta^{(3)}=(-1)^k*^{(3)}d^{(3)}*^{(3)}$ on (Σ,γ) are formal adjoints of one another $\langle d^{(3)}A,F\rangle_{\Sigma}=\langle A,\delta^{(3)}F\rangle_{\Sigma}$, with $A\in\mathfrak{D}^{(k-1)}(\Sigma)$ and $F\in\mathfrak{D}^{(k)}(\Sigma)$. The Laplace–Beltrami operator $\triangle=\delta^{(3)}d^{(3)}+d^{(3)}\delta^{(3)}$ is formally self-adjoint.[14,15] Finally, we work in units in which $c=1$.

III. PROCA'S EQUATIONS

We study the initial value problem for a vector field $\mathcal{A}$ of mass $m\in(0,\infty)$ satisfying the curved space–time generalization of Proca's equations

$$(\delta^{(4)}d^{(4)}+m^2)\mathcal{A}=0. \tag{3}$$

These equations reduce to the hyperbolic system

$$(\Box+m^2)\mathcal{A}=0, \tag{4}$$

and a constraint

$$\delta^{(4)}\mathcal{A}=0. \tag{5}$$

The system (4) has unique fundamental solutions $E_m^{\pm^{(1)}}(p,q)\in\mathfrak{D}'^{(1)}(\mathcal{M}_p\times\mathcal{M}_q)$ where $E_m^{\pm^{(1)}}(p,q):\mathfrak{D}^{(1)}(\mathcal{M}_q)\rightarrow\mathcal{E}^{(1)}(\mathcal{M}_p)$ ($p,q\in\mathcal{M}$ represent space–time events and $\mathcal{M}_p$, $\mathcal{M}_q$ identify the action of $E_m^{\pm^{(1)}}(p,q)$).[9,10,16] These solutions satisfy

$$(\Box_p+m^2)E_m^{\pm^{(1)}}(p,q)=\delta^{(1)}(p,q), \tag{6}$$

where $\delta^{(1)}(p,q)$ is the Dirac 1-tensor kernel, and supp $E_m^{\pm^{(1)}}(\cdot,q)\subset J^{\pm}(q)$. Also $\mathcal{A}^{\pm}(p)=\langle E_m^{\pm^{(1)}}(p,q),\mathcal{F}(q)\rangle_{\mathcal{M}_q}$ satisfies $(\Box+m^2)\mathcal{A}^{\pm}=\mathcal{F}$, with

$$\mathrm{supp}(\mathcal{A}^{\pm})\subset J^{\pm}(\mathrm{supp}(\mathcal{F})), \tag{7}$$

where $J^{\pm}(S)$ is the set of point in $(\mathcal{M},g)$ that can be reached from the set $S\subset\mathcal{M}$ by a future/past directed causal curve.[10]

The kernels $E_m^{\pm^{(1)}}(p,q)$ are identified with operators $E_m^{\pm^{(1)}}:\mathfrak{D}^{(1)}(\mathcal{M})\rightarrow\mathcal{E}^{(1)}(\mathcal{M})$ and from (6),

$$E_m^{\pm(1)}(\Box+m^2)=(\Box+m^2)E_m^{\pm(1)}=I. \tag{8}$$

The $E_m^{\pm(1)}$, which are linear and continuous, give rise to transpose operators $E_m^{\pm\prime(1)}:\mathcal{E}'^{(1)}(\mathcal{M})\to\mathfrak{D}'^{(1)}(\mathcal{M})$ which are also continuous.[17] Since $\Box+m^2$ is formally self-adjoint $E_m^{\pm\prime(1)}=E_m^{\mp(1)}$ on $\mathfrak{D}^{(1)}(\mathcal{M})$. Moreover, since $E_m^{\pm\prime(1)}$ are linear and continuous on $\mathcal{E}'^{(1)}(\mathcal{M})$ we extend $E_m^{\pm(1)}$ from $\mathfrak{D}^{(1)}(\mathcal{M})\subset\mathcal{E}'^{(1)}(\mathcal{M})$ to $\mathcal{E}'^{(1)}(\mathcal{M})$, i.e.,

$$E_m^{\mp(1)}=E_m^{\pm\prime(1)}:\mathcal{E}'^{(1)}(\mathcal{M}_p)\to\mathfrak{D}'^{(1)}(\mathcal{M}_q). \tag{9}$$

Lastly, we introduce the propagator

$$E_m^{(1)}=E_m^{+(1)}-E_m^{-(1)},\quad \text{(propagator)},$$

where $(\Box+m^2)E_m^{(1)}=0$. This operator has a transpose $E_m'^{(1)}=E_m^{+\prime(1)}-E_m^{-\prime(1)}$ and from (9) we have

$$E_m'^{(1)}=-E_m^{(1)}:\mathcal{E}'^{(1)}(\mathcal{M}_p)\to\mathfrak{D}'^{(1)}(\mathcal{M}_q). \tag{10}$$

Next, we introduce a series of operators that collectively map a solution of (4) to its data. Choose any Cauchy surface say $\{0\}\times\Sigma$, and let $i:\Sigma\to\mathcal{M}$ be the inclusion operator with pullback i^*. We define the operators

$$\begin{aligned}\rho_{(0)}&\equiv i^* \quad \text{(pullback)}\\ \rho_{(d)}&\equiv -*^{(3)}i^**^{(4)}d^{(4)} \quad \text{(forward normal derivative)}\\ \rho_{(\delta)}&\equiv i^*\delta^{(4)} \quad \text{(pullback of divergence)}\\ \rho_{(n)}&\equiv -*^{(3)}i^**^{(4)} \quad \text{(forward normal)},\end{aligned} \tag{11}$$

where $\rho_{(0)}$, $\rho_{(d)}:\mathcal{E}^{(1)}(\mathcal{M})\to\mathcal{E}^{(1)}(\Sigma)$, and $\rho_{(\delta)}$, $\rho_{(n)}:\mathcal{E}^{(1)}(\mathcal{M})\to\mathcal{E}^{(0)}(\Sigma)$. These operators can be applied to any smooth p-form. The motivation for (11) comes from an analysis of Green's identity for $\Box+m^2$ (Appendix A).

Next, let $\mathcal{A}\in\mathcal{E}^{(1)}(\mathcal{M})$ and define

$$A_{(0)}\equiv\rho_{(0)}\mathcal{A}, \tag{12}$$

$$A_{(d)}\equiv\rho_{(d)}\mathcal{A}, \tag{13}$$

$$A_{(n)}\equiv\rho_{(n)}\mathcal{A}, \tag{14}$$

and

$$A_{(\delta)}\equiv\rho_{(\delta)}\mathcal{A}, \tag{15}$$

with $A_{(0)}$, $A_{(d)}\in\mathcal{E}^{(1)}(\Sigma)$ and $A_{(n)}$, $A_{(\delta)}\in\mathcal{E}^{(0)}(\Sigma)$. Specifying $A_{(0)}$, $A_{(d)}$, $A_{(n)}$, and $A_{(\delta)}$ is equivalent to specifying the Cauchy data for $\mathcal{A}$. To see this, let (n,e_i) be a surface normal reference frame for (Σ,γ), then (12) and (14) specify $\mathcal{A}_\mu(0,x)$ from which we obtain $\nabla_k\mathcal{A}_\mu(0,x)$. Given $\nabla_k\mathcal{A}_\mu(0,x)$, (13) specifies $\nabla_0\mathcal{A}_k(0,x)$ and finally, (15) gives $\nabla_0\mathcal{A}_0(0,x)$. Thus, the operators (11) collectively map a solution $\mathcal{A}$ to its Cauchy data $(\mathcal{A}_\mu, n^\alpha\nabla_\alpha\mathcal{A}_\mu)$. Alternatively, we view $A_{(0)}$, $A_{(d)}$, $A_{(\delta)}$ and $A_{(n)}$ as Cauchy data for (4).

The operators (11) which are continuous and linear, give rise to continuous transpose operators $\rho'_{(0)}$, $\rho'_{(d)}:\mathcal{E}'^{(1)}(\Sigma)\to\mathcal{E}'^{(1)}(\mathcal{M})$, and $\rho'_{(n)}$, $\rho'_{(\delta)}:\mathcal{E}'^{(0)}(\Sigma)\to\mathcal{E}'^{(1)}(\mathcal{M})$.[17] We construct the following continuous operators $E_m^{(1)}\,\rho'_{(d)}$, $E_m^{(1)}\,\rho'_{(n)}$, $E_m^{(1)}\,\rho'_{(\delta)}$, and $E_m^{(1)}\,\rho'_{(0)}$, where

$$E_m^{(1)}\rho_{(0)}',E_m^{(1)}\rho_{(d)}':\mathfrak{D}^{(1)}(\Sigma)\subset\mathcal{E}'^{(1)}(\Sigma)\to\mathfrak{D}'^{(1)}(\mathcal{M}),\tag{16}$$

and

$$E_m^{(1)}\rho_{(\delta)}',E_m^{(1)}\rho_{(n)}':\mathfrak{D}^{(0)}(\Sigma)\subset\mathcal{E}'^{(0)}(\Sigma)\to\mathfrak{D}'^{(1)}(\mathcal{M}).\tag{17}$$

These play a crucial role in the classical Cauchy problem as is now shown.

Theorem 1: *Let $A_{(0)}$, $A_{(d)}\in\mathfrak{D}^{(1)}(\Sigma)$, and $A_{(n)}$, $A_{(\delta)}\in\mathfrak{D}^{(0)}(\Sigma)$ specify Cauchy data on (Σ,γ), and let $m\in[0,\infty)$. Then,*

$$\mathcal{A}'=-E_m^{(1)}\rho_{(d)}'A_{(0)}-E_m^{(1)}\rho_{(n)}'A_{(\delta)}+E_m^{(1)}\rho_{(\delta)}'A_{(n)}+E_m^{(1)}\rho_{(0)}'A_{(d)}\tag{18}$$

is the unique smooth solution of $(\Box+m^2)\mathcal{A}'=0$ with these data. Moreover, $\mathcal{A}'\in\mathcal{E}^{(1)}(\mathcal{M})$ is continuously dependent on the data.

Proof: First, from (16) and (17) we know that (18) makes sense. Let $\mathcal{F}\in\mathfrak{D}^{(1)}(\mathcal{M})$ be any 1-form test function, and consider

$$\langle\mathcal{A}',\mathcal{F}\rangle=\langle A_{(0)},\rho_{(d)}E_m^{(1)}\mathcal{F}\rangle_\Sigma+\langle A_{(\delta)},\rho_{(n)}E_m^{(1)}\mathcal{F}\rangle_\Sigma-\langle A_{(n)},\rho_{(\delta)}E_m^{(1)}\mathcal{F}\rangle_\Sigma-\langle A_{(d)},\rho_{(0)}E_m^{(1)}\mathcal{F}\rangle_\Sigma .$$

From Theorem 5 we know that if $\mathcal{A}$ is a smooth solution with data (12)–(15), then $\langle\mathcal{A}',\mathcal{F}\rangle=\langle\mathcal{A},\mathcal{F}\rangle_{\mathcal{M}}$ which implies that $\mathcal{A}'=\mathcal{A}$ in a distributional sense. Thus $\mathcal{A}'$ is identified with the unique smooth solution $\mathcal{A}\in\mathcal{E}^{(1)}(\mathcal{M})$.

It remains to show that $\mathcal{A}'$ is continuously dependent on the data. For this result, we assume that Σ is compact. From the first part of the proof we have $E_m^{(1)}\rho_{(0)}'$, $E_m^{(1)}\rho_{(d)}':\mathfrak{D}^{(1)}(\Sigma)\to\mathcal{E}^{(1)}(\mathcal{M})$ and $E_m^{(1)}\rho_{(\delta)}',E_m^{(1)}\rho_{(n)}':\mathfrak{D}^{(0)}(\Sigma)\to\mathcal{E}^{(1)}(\Sigma)$. It suffices to show that these restrictions are continuous. The same analysis applies to both sets of operators so we need only consider the former. Recall that $E_m^{(1)}\rho_{(0)}'$, $E_m^{(1)}\rho_{(d)}':\mathcal{E}'^{(1)}(\Sigma)\to\mathfrak{D}'^{(1)}(\mathcal{M})$ are continuous with respect to the weak topologies of dual spaces. Thus, the graphs of the restrictions $E_m^{(1)}\rho_{(0)}'$, $E_m^{(1)}\rho_{(d)}'$ $\mathfrak{D}^{(1)}(\Sigma)\to\mathcal{E}^{(1)}(\mathcal{M})$ are closed with respect to these weak topologies and it follows that they are closed with respect to the topologies of $\mathfrak{D}^{(1)}(\Sigma)$ and $\mathcal{E}^{(1)}(\mathcal{M})$ as well. Finally, since $\mathfrak{D}^{(1)}(\Sigma)$ and $\mathcal{E}^{(1)}(\mathcal{M})$ are Frechet spaces (assuming Σ is compact) it follows from the closed graph theorem that the restrictions of $E_m^{(1)}\rho_{(0)}'$ and $E_m^{(1)}\rho_{(d)}'$ are continuous. As noted, a similar analysis applies to the restrictions of $E_m^{(1)}\rho_{(\delta)}'$ and $E_m^{(1)}\rho_{(n)}'$ and therefore $\mathcal{A}'\in\mathcal{E}^{(1)}(\mathcal{M})$ is continuously dependent on the data. This presumably holds for noncompact Σ as well. ■

Thus, we obtain a global solution to (4) as a mapping of Cauchy data. Notice that Theorem 1 applies for $m=0$ which we use in our study of Maxwell's equations (Appendix B).

Corollary 1: On $\mathfrak{D}^{(1)}(\Sigma)$ we have

$$\rho_{(0)}E_m^{(1)}\rho_{(d)}'=-I,\quad \rho_{(d)}E_m^{(1)}\rho_{(d)}'=0,\quad \rho_{(\delta)}E_m^{(1)}\rho_{(d)}'=0,\quad \rho_{(n)}E_m^{(1)}\rho_{(d)}'=0,\tag{19}$$

$$\rho_{(0)}E_m^{(1)}\rho_{(0)}'=0,\quad \rho_{(d)}E_m^{(1)}\rho_{(0)}'=I,\quad \rho_{(\delta)}E_m^{(1)}\rho_{(0)}'=0,\quad \rho_{(n)}E_m^{(1)}\rho_{(0)}'=0,\tag{20}$$

and on $\mathfrak{D}^{(0)}(\Sigma)$ we have

$$\rho_{(0)}E_m^{(1)}\rho_{(n)}'=0,\quad \rho_{(d)}E_m^{(1)}\rho_{(n)}'=0,\quad \rho_{(\delta)}E_m^{(1)}\rho_{(n)}'=-I,\quad \rho_{(n)}E_m^{(1)}\rho_{(n)}'=0,\tag{21}$$

$$\rho_{(0)}E_m^{(1)}\rho_{(\delta)}'=0,\quad \rho_{(d)}E_m^{(1)}\rho_{(\delta)}'=0,\quad \rho_{(\delta)}E_m^{(1)}\rho_{(\delta)}'=0,\quad \rho_{(n)}E_m^{(1)}\rho_{(\delta)}'=I.\tag{22}$$

Proof: These identities follow from (18). For example, the first identity in (19) is obtained by applying $\rho_{(0)}$ to (18) with $A_{(\delta)}$, $A_{(n)}$, $A_{(d)}=0$. The remaining indentities are obtained in a similar fashion. □

We are finally ready for the main result of this section. Notice that Theorem (1) gives a global solution to (4). We apply it to Proca's equations and obtain a global solution to the initial value problem by restricting the data.

Theorem 2: *Let* $A_{(0)}$, $A_{(d)} \in \mathfrak{D}^{(1)}(\Sigma)$, *and* $A_{(n)}$, $A_{(\delta)} \in \mathfrak{D}^{(0)}(\Sigma)$ *specify Cauchy data on* Σ *and let* $m \in [0,\infty)$. *Set*

$$A_{(\delta)} = 0, \tag{23}$$

and

$$\delta^{(3)} A_{(d)} = m^2 A_{(n)} . \tag{24}$$

Then,

$$\mathcal{A} = -E_m^{(1)} \rho'_{(d)} A_{(0)} + E_m^{(1)} \rho'_{(\delta)} A_{(n)} + E_m^{(1)} \rho'_{(0)} A_{(d)} \tag{25}$$

is the unique smooth solution of $(\delta^{(4)} d^{(4)} + m^2)\mathcal{A} = 0$ *with these data. Moreover,* $\mathcal{A} \in \mathcal{E}^{(1)}(\mathcal{M})$ *is continuously dependent on the data. When* $m > 0$ (*Proca's equations) we satisfy (24) with arbitrary* $A_{(d)}$ *and* $A_{(n)} = [\delta^{(3)} A_{(d)} / m^2]$, *thus*

$$\mathcal{A} = -E_m^{(1)} \rho'_{(d)} A_{(0)} + E_m^{(1)} \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) \rho'_{(0)} A_{(d)} \quad (m > 0), \tag{26}$$

where we have used $\rho'_{(\delta)} \delta^{(3)} = d^{(4)} \delta^{(4)} \rho'_{(0)}$ *on* $\mathfrak{D}^{(1)}(\Sigma)$. *When* $m = 0$ *we satisfy (24) with arbitrary* $A_{(n)}$, *and with* $A_{(d)}$ *satisfying* $\delta^{(3)} A_{(d)} = 0$ (*see Maxwell's equations in Appendix B).*

Proof: We show that $\mathcal{A}$ is a smooth solution of $(\Box + m^2)\mathcal{A} = 0$ with $\delta^{(4)}\mathcal{A} = 0$. The former follows from Theorem 1. For the latter, it suffices to show that $\langle \delta^{(4)}\mathcal{A}, f\rangle_M = 0$, for all $f \in \mathfrak{D}^{(0)}(\mathcal{M})$. Consider,

$$\begin{aligned} \langle \delta^{(4)} \mathcal{A}, f \rangle_{\mathcal{M}} &= \langle \mathcal{A}, d^{(4)} f \rangle_{\mathcal{M}} , \\ &= \langle A_{(0)} , \rho_{(d)} E_m^{(1)} d^{(4)} f \rangle_\Sigma - \langle A_{(n)} , \rho_{(\delta)} E_m^{(1)} d^{(4)} f \rangle_\Sigma , \\ &\quad - \langle A_{(d)} , \rho_{(0)} E_m^{(1)} d^{(4)} f \rangle_\Sigma . \end{aligned} \tag{27}$$

Now, since $E_m^{(1)} d^{(4)} = d^{(4)} E_m^{(0)}$ on $\mathfrak{D}^{(0)}(\mathcal{M})$ we have $\rho_{(d)} E_m^{(1)} d^{(4)} f = 0$ and the first term on the right-hand side of (27) is zero. Consider the second term on the right-hand side of (27),

$$\begin{aligned} \rho_{(\delta)} E_m^{(1)} d^{(4)} f &= i^* \delta^{(4)} E_m^{(1)} d^{(4)} f, \\ &= i^* \delta^{(4)} d^{(4)} E_m^{(0)} f, \\ &= i^* (\Box - d^{(4)} \delta^{(4)}) E_m^{(0)} f, \\ &= -\rho_{(0)} m^2 E_m^{(0)} f, \end{aligned} \tag{28}$$

where we have used $(\Box + m^2) E_m^{(0)} f = 0$, and $\delta^{(4)} E_m^{(0)} f = 0$ ($E_m^{(0)} f$ is a function). Substituting (28) into (27) and making use of $\rho_{(0)} E_m^{(1)} d^{(4)} f = d^{(3)} \rho_{(0)} E_m^{(0)} f$ we have

$$\begin{aligned} \langle \delta^{(4)} \mathcal{A}, f \rangle_{\mathcal{M}} &= \langle A_{(n)} , \rho_{(0)} m^2 E_m^{(0)} f \rangle_\Sigma - \langle A_{(d)} , d^{(3)} \rho_{(0)} E_m^{(0)} f \rangle_\Sigma \\ &= \langle m^2 A_{(n)} - \delta^{(3)} A_{(d)} , \rho_{(0)} E_m^{(0)} f \rangle_\Sigma , \\ &= 0, \end{aligned}$$

where, in the last step we have used (24). Thus $\delta^{(4)}\mathcal{A}=0$ which is compatible with (23).

Lastly, from Theorem 1 we know that $\mathcal{A}$ is unique. We also have that $\mathcal{A}$ is continuously dependent on the data when Σ is compact. ■

From Theorem 2 we have the following additional result which is need for the quantum problem.

Corollary 2: The operator identity

$$\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)E_m^{(1)}=-E_m^{(1)}\rho'_{(d)}\rho_{(0)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)E_m^{(1)}+E_m^{(1)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)\rho'_{(0)}\rho_{(d)}E_m^{(1)}, \quad (29)$$

holds on $\mathfrak{D}^{(1)}(\mathcal{M})$ *for* $m>0$.

Proof: Let $\mathcal{F}\in\mathfrak{D}^{(1)}(\mathcal{M})$. It is easy to check that $(d^{(4)}\delta^{(4)}/m^2+I)E_m^{(1)}\mathcal{F}$ is a smooth solution to Proca's equations. Thus, (29) follows from Theorem 2 with $\mathcal{A}=[(d^{(4)}\delta^{(4)}/m^2)+I]E_m^{(1)}\mathcal{F}$ and the fact that $\rho_{(d)}[d^{(4)}\delta^{(4)}/m^2]E_m^{(1)}\mathcal{F}=0$. ■

This last result completes the prerequisite classical work. We proceed to the quantum problem.

IV. THE QUANTUM PROBLEM

Our approach to field quantization closely follows the work of Dimock.[3] We start with a representation $(\phi,\Pi,\mathcal{H})$ of the CCRs on an arbitrary Cauchy surface Σ. Let $\mathfrak{h}$ denote the completion of smooth complex-valued 1-forms on Σ with respect to the norm $\|\cdot\|_{\mathfrak{h}}^2=\langle\cdot,\cdot\rangle_{\mathfrak{h}}$, where

$$\langle F,G\rangle_{\mathfrak{h}}=\int(\overline{F},G)_x\,d\tau, \quad (30)$$

and

$$(F,G)_x=F_n(x)G^n(x), \quad (n=1,2,3) \quad (31)$$

with $d\tau=\sqrt{\gamma}dx^1\wedge dx^2\wedge dx^3$, where $x=(x^1,x^2,x^2)$ are local coordinates for (Σ,γ). Next, construct the Bose–Fock space $\mathcal{H}$ over $\mathfrak{h}$,

$$\mathcal{H}=\mathbb{C}\oplus\left(\bigoplus_{n=1}^{\infty}\mathfrak{h}^{(n)}\right), \quad (32)$$

where $\mathfrak{h}^{(n)}=\otimes_s^n\mathfrak{h}$, and the subscript s denotes the symmetric tensor product. Let $\mathbf{a}(\cdot)$, $\mathbf{a}^*(\cdot)$ denote the usual creation and annihilation operators defined on finite particle vectors in $\mathcal{H}$ with $[\mathbf{a}(F),\mathbf{a}^*(G)]=\langle F,G\rangle_{\mathfrak{h}}$.[18] Let

$$\phi(F)\equiv\frac{1}{\sqrt{2}}[\mathbf{a}(F)+\mathbf{a}^*(F)], \quad (33)$$

and

$$\Pi(F)\equiv\frac{i}{\sqrt{2}}[\mathbf{a}^*(F)-\mathbf{a}(F)], \quad (34)$$

and then take the closure of (33) and (34) (keeping the same notation) to obtain self-adjoint ϕ and Π on $\mathcal{H}$ with $[\phi(F),\Pi(G)]=i\langle F,G\rangle_{\mathfrak{h}}$ for $F,G\in\mathfrak{D}^{(1)}(\Sigma)$.[18] This gives the representation $(\phi,\Pi,\mathcal{H})$.

Now, given a representation $(\phi,\Pi,\mathcal{H})$ on Σ, not necessarily as above, we define a space–time field operator

$$\mathcal{A} \equiv -E_m^{(1)} \rho'_{(d)} \phi + E_m^{(1)} \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) \rho'_{(0)} \Pi , \tag{35}$$

in accordance with the classical initial value problem (Theorem 2 with $m > 0$). This holds in a distributional sense, therefore,

$$\mathcal{A}(\mathcal{F}) = \phi(\rho_{(d)} E_m^{(1)} \mathcal{F}) - \Pi \left(\rho_{(0)} \left[\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right] E_m^{(1)} \mathcal{F} \right)$$

for $\mathcal{F} \in \mathfrak{D}^{(1)}(\mathcal{M})$. This makes sense because $E_m^{(1)} \mathcal{F} \in \mathcal{E}^{(1)}(\mathcal{M})$ and $J^{\pm}(\text{supp}(\mathcal{F})) \cap \Sigma$ is compact.[3]

Theorem 3: *Let* $(\phi, \Pi, \mathcal{H})$ *be a representation of the CCRs over* $\mathfrak{D}^{(1)}(\Sigma)$, *and let* $\mathcal{A}$ *be the field operator (35) with test functions* $\mathcal{F} \in \mathfrak{D}^{(1)}(\mathcal{M})$. *Then* $\mathcal{A}$ *satisfies the Proca's equations in a distributional sense,*

$$(\delta^{(4)} d^{(4)} + m^2) \mathcal{A} = 0, \tag{36}$$

and

$$[\mathcal{A}(\mathcal{F}), \mathcal{A}(\mathcal{F}')] = -i \left\langle \mathcal{F}, \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) E_m^{(1)} \mathcal{F}' \right\rangle_{\mathcal{M}} . \tag{37}$$

Proof: First we verify (36). Consider,

$$\begin{aligned}
(\delta^{(4)} d^{(4)} + m^2) \mathcal{A}(\mathcal{F}) &= \mathcal{A}((\delta^{(4)} d^{(4)} + m^2) \mathcal{F}), \\
&= \phi(\rho_{(d)} E_m^{(1)} (\delta^{(4)} d^{(4)} + m^2) \mathcal{F}) \\
&\quad - \Pi \left(\rho_{(0)} \left[\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right] (\delta^{(4)} d^{(4)} + m^2) E_m^{(1)} \mathcal{F} \right), \\
&= -\phi(\rho_{(d)} d^{(4)} \delta^{(4)} E_m^{(1)} \mathcal{F}) - \Pi(\rho_{(0)} [\Box + m^2] E_m^{(1)} \mathcal{F}), \\
&= 0,
\end{aligned}$$

where we have used $\rho_{(d)} d^{(4)} = 0$ and $(\Box + m^2) E_m^{(1)} = 0$ on $\mathcal{E}^{(1)}(\mathcal{M})$.

Next, we verify (37). Consider,

$$\begin{aligned}
[\mathcal{A}(\mathcal{F}), \mathcal{A}(\mathcal{F}')] &= -i \left\langle \rho_{(d)} E_m^{(1)} \mathcal{F}, \rho_{(0)} \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) E_m^{(1)} \mathcal{F}' \right\rangle_{\Sigma} \\
&\quad + i \left\langle \rho_{(0)} \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) E_m^{(1)} \mathcal{F}, \rho_{(d)} E_m^{(1)} \mathcal{F}' \right\rangle_{\Sigma} , \\
&= i \left\langle \mathcal{F}, E_m^{(1)} \rho'_{(d)} \rho_{(0)} \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) E_m^{(1)} \mathcal{F}' \right\rangle_{\mathcal{M}} \\
&\quad - i \left\langle \mathcal{F}, E_m^{(1)} \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) \rho'_{(0)} \rho_{(d)} E_m^{(1)} \mathcal{F}' \right\rangle_{\mathcal{M}} , \\
&= -i \left\langle \mathcal{F}, \left(\frac{d^{(4)} \delta^{(4)}}{m^2} + I \right) E_m^{(1)} \mathcal{F}' \right\rangle_{\mathcal{M}} ,
\end{aligned}$$

where we have applied Corollary 2. ■

Notice from (7) that

$$\operatorname{supp}\left(\left[\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right]E_m^{(1)}\mathcal{F}'\right)\subset J^+(\operatorname{supp}(\mathcal{F}'))\cup J^-(\operatorname{supp}(\mathcal{F}')),$$

and therefore (37) implies causality. Also, (37) reduces to the usual relation on Minkowski space.[19]

We now show that a representation $(\phi,\Pi,\mathcal{H})$ on Σ induces a representation on any other Cauchy surface.

Corollary 3: Let $(\phi,\Pi,\mathcal{H})$ *be a representation of the CCRs over* $\mathfrak{D}^{(1)}(\Sigma)$, *and let* $\mathcal{A}$ *be the field operator (35). Let* $\hat{\Sigma}$ *be another Cauchy surface in* $\mathcal{M}$, *and let* $\hat{\phi}$ *and* $\hat{\Pi}$ *be data of* $\mathcal{A}$ *on* $\hat{\Sigma}$, *i.e.,*

$$\hat{\phi}\equiv\hat{\rho}_{(0)}\mathcal{A},$$

and,

$$\hat{\Pi}\equiv\hat{\rho}_{(d)}\mathcal{A}.$$

Then $(\hat{\phi},\hat{\Pi},\mathcal{H})$ *is a representation of the CCRs over* $\mathfrak{D}^{(1)}(\hat{\Sigma})$. *Furthermore, let*

$$\hat{\mathcal{A}}\equiv-E_m^{(1)}\hat{\rho}'_{(d)}\hat{\phi}+E_m^{(1)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)\hat{\rho}'_{(0)}\hat{\Pi},\tag{38}$$

then

$$\hat{\mathcal{A}}(\mathcal{F})=\mathcal{A}(\mathcal{F}).\tag{39}$$

Proof: We first show that $(\hat{\phi},\hat{\Pi},\mathcal{H})$ is a representation. Let $F\in\mathfrak{D}^{(1)}(\hat{\Sigma})$, then

$$\begin{aligned}\hat{\phi}(F)&=\mathcal{A}(\hat{\rho}'_{(0)}F),\\&=\phi(\rho_{(d)}E_m^{(1)}\hat{\rho}'_{(0)}F)-\Pi\left(\rho_{(0)}\left[\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right]E_m^{(1)}\hat{\rho}'_{(0)}F\right),\end{aligned}\tag{40}$$

and

$$\begin{aligned}\hat{\Pi}(F)&=\mathcal{A}(\hat{\rho}'_{(d)}F),\\&=\phi(\rho_{(d)}E_m^{(1)}\hat{\rho}'_{(d)}F)-\Pi\left(\rho_{(0)}\left[\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right]E_m^{(1)}\hat{\rho}'_{(d)}F\right).\end{aligned}\tag{41}$$

These make sense because $E_m^{(1)}\hat{\rho}'_{(0)},E_m^{(1)}\hat{\rho}'_{(d)}:\mathfrak{D}^{(1)}(\hat{\Sigma})\to\ \mathcal{E}^{(1)}(\mathcal{M})$ (Theorem 1) and $J^{\pm}(\operatorname{supp}(F))\cap\Sigma$ is compact.[3] Consider,

$$[\hat{\phi}(F),\hat{\Pi}(F')] = -\left[\phi(\rho_{(d)}E_m^{(1)}\hat{\rho}'_{(0)}F),\Pi\left(\rho_{(0)}\left[\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right]E_m^{(1)}\hat{\rho}'_{(d)}F'\right)\right]$$
$$+\left[\phi(\rho_{(d)}E_m^{(1)}\hat{\rho}'_{(d)}F'),\Pi\left(\rho_{(0)}\left[\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right]E_m^{(1)}\hat{\rho}'_{(0)}F\right)\right]$$
$$= -i\langle\rho_{(d)}\mathcal{F},\rho_{(0)}\mathcal{F}'\rangle_\Sigma + i\langle\rho_{(0)}\mathcal{F},\rho_{(d)}\mathcal{F}'\rangle_\Sigma$$
$$\equiv i\Omega_\Sigma(\mathcal{F},\mathcal{F}') \tag{42}$$

where $\mathcal{F}\equiv\{[d^{(4)}\delta^{(4)}/m^2]+I\}E_m^{(1)}\hat{\rho}'_{(0)}F$ and $\mathcal{F}'\equiv\{[d^{(4)}\delta^{(4)}/m^2]+I\}E_m^{(1)}\hat{\rho}'_{(d)}F'$ are smooth solutions of Proca's equations. It follows from Green's identity that $\Omega_\Sigma(\cdot,\cdot)$ is independent of the Cauchy surface for such solutions (see the vector potential formulation of Maxwell's equations).[2,4] Thus, (42) is independent of the Cauchy surface and we have

$$[\hat{\phi}(F),\hat{\Pi}(F')] = i\Omega_{\hat{\Sigma}}(\mathcal{F},\mathcal{F}')$$
$$= -i\langle\hat{\rho}_{(d)}\mathcal{F},\hat{\rho}_{(0)}\mathcal{F}'\rangle_{\hat{\Sigma}} \tag{43}$$
$$+ i\langle\hat{\rho}_{(0)}\mathcal{F},\hat{\rho}_{(d)}\mathcal{F}'\rangle_{\hat{\Sigma}}$$
$$= i\langle F,F'\rangle_{\hat{\Sigma}}, \tag{44}$$

where in the last step we have applied Corollary (1) to $\hat{\Sigma}$. Thus $(\hat{\phi},\hat{\Pi},\mathcal{H})$ is a representation.

We now verify (39). Substitute (40) and (41) into (38) and obtain

$$\hat{\mathcal{A}}(\mathcal{F}) \equiv \phi(\rho_{(d)}\hat{\mathcal{F}}) - \Pi\left(\rho_{(0)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)\hat{\mathcal{F}}\right),$$
$$= \phi(\rho_{(d)}\tilde{\mathcal{F}}) - \Pi\left(\rho_{(0)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)\tilde{\mathcal{F}}\right)$$
$$= \phi(\rho_{(d)}E_m^{(1)}\mathcal{F}) - \Pi\left(\rho_{(0)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)E_m^{(1)}\mathcal{F}\right)$$
$$= \mathcal{A}(\mathcal{F}),$$

where

$$\hat{\mathcal{F}} = \left[E_m^{(1)}\hat{\rho}'_{(0)}\hat{\rho}_{(d)}E_m^{(1)} - \hat{\rho}'_{(d)}\hat{\rho}_{(0)}\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)E_m^{(1)}\right]\mathcal{F}$$

and

$$\tilde{\mathcal{F}} = \left[\left(\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right)E_m^{(1)} - \frac{d^{(4)}\delta^{(4)}}{m^2}E_m^{(1)}\hat{\rho}'_{(0)}\hat{\rho}_{(d)}E_m^{(1)}\right]\mathcal{F}.$$

In the second step we have used Corollary 2 and in subsequent steps we have used $\rho_{(d)}d^{(4)}=0$ on $\mathcal{E}^{(1)}(\mathcal{M})$ and $\delta^{(4)}\mathcal{G}=0$ for any smooth solution $\mathcal{G}$ of Proca's equations. ■

At this point we have a field operator $\mathcal{A}$ defined in terms of a representation $(\phi,\Pi,\mathcal{H})$ on an arbitrary Cauchy surface Σ. Unlike Minkowski space–time, there is, in general, no preferred representation (i.e., no natural positive and negative frequency decomposition).[2] Thus, we must consider a class of representations, and show that the theory is independent of the representation, and independent of the Cauchy surface. To this end, we pass to the Weyl form of the CCRs, construct an algebra of observables $\mathfrak{A}$, and exploit known results on the equivalence of such algebras.

Given a representation $(\phi,\Pi,\mathcal{H})$ let

$$W(F,F')=\exp(i(\phi(F)-\Pi(F'))).$$

Then $W(\cdot,\cdot)$is a map from $\mathfrak{D}^{(1)}(\Sigma)\times\mathfrak{D}^{(1)}(\Sigma)$ to unitary operators on $\mathcal{H}$ satisfying

$$W(F,F')W(G,G')=W(F+G,F'+G')\exp(-\,i/2\,\sigma_{\Sigma}((F,F'),(G,G'))), \tag{45}$$

where

$$\sigma_{\Sigma}((F,F'),(G,G'))\equiv\langle F,G'\rangle_{\Sigma}-\langle F',G\rangle_{\Sigma}, \tag{46}$$

is symplectic on $\mathfrak{D}^{(1)}(\Sigma)\times\mathfrak{D}^{(1)}(\Sigma)$. Also, $t\rightarrow W(tF,tF')$ is strongly continuous. Thus we have the Weyl system $(W,\mathcal{H})$ with the Weyl form of the CCRs (45). As an aside, note that $\Omega_{\Sigma}(\mathcal{F},\mathcal{F}')=\sigma_{\Sigma}((\rho_{(0)}\mathcal{F},\rho_{(d)}\mathcal{F}),(\rho_{(0)}\mathcal{F}',\rho_{(d)}\mathcal{F}'))$ for smooth solutions $\mathcal{F}$ and $\mathcal{F}'$ of Proca's equations.

Alternatively, given a representation $(W,\mathcal{H})$ we recover self-adjoint ϕ and Π via Stone's Theorem, i.e.,

$$e^{i\phi(F)t}=W(tF,0), \tag{47}$$

and

$$e^{-i\mathbf{\Pi}(F)t}=W(0,tF). \tag{48}$$

We also obtain a self-adjoint field operator $\mathcal{A}(\mathcal{F})$ via Stone's Theorem,

$$e^{i\mathcal{A}(\mathcal{F})t}=W\left(t\rho_{(d)}E_m^{(1)}\mathcal{F},t\rho_{(0)}\left[\frac{d^{(4)}\delta^{(4)}}{m^2}+I\right]E_m^{(1)}\mathcal{F}\right), \tag{49}$$

where $\mathcal{F}\in\mathfrak{D}^{(1)}(\mathcal{M})$.

Next, we define an algebra of observables $\mathfrak{A}$. Given a Weyl system $(W,\mathcal{H})$ take the set of all finite sums of the form

$$\sum_{\alpha} c_{\alpha}W(F_{\alpha},F'_{\alpha}),\quad c_{\alpha}\in\mathbb{C},$$

where $F_{\alpha},F'_{\alpha}\in\mathfrak{D}^{(1)}(\Sigma)$ and define $\mathfrak{A}$ to be the norm closure of this set in the Banach space of all bounded operators on $\mathcal{H}$.

We now exploit known results on the equivalence of such algebras.

Theorem 4: *Let* $(W,\sigma_{\Sigma},\mathfrak{A},\mathcal{H})$ *and* $(\tilde{W},\sigma_{\hat{\Sigma}},\tilde{\mathfrak{A}},\tilde{\mathcal{H}})$ *be representations on Cauchy surfaces* Σ *and* $\hat{\Sigma}$, *respectively. There is a unique* $*$*-isomorphism* $\alpha:\mathfrak{A}\rightarrow\tilde{\mathfrak{A}}$ *with* $\alpha:e^{i\mathcal{A}(\mathcal{F})}\rightarrow e^{i\tilde{\mathcal{A}}(\mathcal{F})}$.

Proof: First, consider the case $\Sigma=\hat{\Sigma}$. Given $(W,\sigma_{\Sigma},\mathfrak{A},\mathcal{H})$ and $(\tilde{W},\sigma_{\Sigma},\tilde{\mathfrak{A}},\tilde{\mathcal{H}})$ over $\mathfrak{D}^{(1)}(\Sigma)\times\mathfrak{D}^{(1)}(\Sigma)$ there is a unique $*-$isomorphism $\alpha:\mathfrak{A}\rightarrow\tilde{\mathfrak{A}}$ such that $\alpha(W(F,F'))=\tilde{W}(F,F')$ (see Theorem 5.2.8 in 18). It follows from (49) that $\alpha:e^{i\mathcal{A}(\mathcal{F})}\rightarrow e^{i\tilde{\mathcal{A}}(\mathcal{F})}$. Thus $\mathfrak{A}$ is independent of the representation on Σ in this sense.

Next, let Σ and $\hat{\Sigma}$ be different, and let $(\phi,\Pi,\mathcal{H})$ and $(\hat{\phi},\hat{\Pi},\mathcal{H})$ be respective representations as defined in Corollary 3. It follows that $e^{i\mathcal{A}(\mathcal{F})}=e^{i\hat{\mathcal{A}}(\mathcal{F})}$ and therefore $\mathfrak{A}=\hat{\mathfrak{A}}$. Moreover, from the first part of the proof we have $\alpha:\hat{\mathfrak{A}}\rightarrow\tilde{\mathfrak{A}}$ and therefore $\alpha:\mathfrak{A}\rightarrow\tilde{\mathfrak{A}}$ with $\alpha:e^{i\mathcal{A}(\mathcal{F})}\rightarrow e^{i\tilde{\mathcal{A}}(\mathcal{F})}$. Thus $\mathfrak{A}$ is independent of the Cauchy surface in this sense. ∎

From this last result, we see that the Fock representation $(\phi,\Pi,\mathcal{H})$ defined by (33) and (34) gives rise to an algebra of observables $\mathfrak{A}$ that is unique up to $*-$isomorphism. This concludes the quantum problem.

V. CONCLUSION

We have obtained classical and quantum results for the propagation of massive vector fields on a globally hyperbolic Lorentzian manifold. Our classical results include solutions of the initial value problem for Proca's equations (3), the vector Klein Gordon equation (4), and Maxwell's equations (Appendix B). The form of these solutions is apparently new and useful for field quantization. Our quantum results include a causal field operator constructed from a representation of the CCRs on an arbitrary Cauchy surface. The algebra of observables generated by this field operator is independent of the representation and independent of the Cauchy surface.

ACKNOWLEDGMENT

The author would like to thank Professor J. Dimock for numerous helpful discussions.

APPENDIX A: GREEN'S IDENTITY

In this section we develop Green's identity for $\Box + m^2$. Start with Stoke's Theorem,

$$\int_{\mathcal{O}} d^{(4)}\mathcal{G} = \int_{\partial\mathcal{O}} i^*\mathcal{G}, \tag{A1}$$

where $\mathcal{O}\subset\mathcal{M}$, $\partial\mathcal{O}$ is the boundary of $\mathcal{O}$, $i:\partial\mathcal{O}\to\mathcal{O}$ is the natural inclusion, i^* is the pullback, and $\mathcal{G}\in\mathfrak{D}^{(3)}(\mathcal{M})$.[20–22] Let $\mathcal{G}^{(1)} = \delta^{(4)}\mathcal{F}\wedge *^{(4)}\mathcal{A} - \delta^{(4)}\mathcal{A}\wedge *^{(4)}\mathcal{F}$ and $\mathcal{G}^{(2)} = \mathcal{A}\wedge *^{(4)}d^{(4)}\mathcal{F} - \mathcal{F}\wedge *^{(4)}d^{(4)}\mathcal{A}$, with $\mathcal{A}$, $\mathcal{F}\in\mathfrak{D}^{(1)}(\mathcal{M})$. We apply (A1) with $\mathcal{G}=\mathcal{G}^{(1)}+\mathcal{G}^{(2)}$ and obtain

$$\int_{\mathcal{O}} \mathcal{A}\wedge *^{(4)}\Box\mathcal{F} - \mathcal{F}\wedge *^{(4)}\Box\mathcal{A} = -\int_{\partial\mathcal{O}} i^*(\mathcal{A}\wedge *^{(4)}d^{(4)}\mathcal{F} + \delta^{(4)}\mathcal{A}\wedge *^{(4)}\mathcal{F}) + \int_{\partial\mathcal{O}} i^*(\delta^{(4)}\mathcal{F}\wedge *^{(4)}\mathcal{A} + \mathcal{F}\wedge *^{(4)}d^{(4)}\mathcal{A}). \tag{A2}$$

Finally, add $\mathcal{A}\wedge *^{(4)}m^2\mathcal{F} - \mathcal{F}\wedge *^{(4)}m^2\mathcal{A}$ to the left-hand side of (A2) and obtain Green's identity for $(\Box + m^2)$,

$$\int_{\mathcal{O}} \mathcal{A}\wedge *^{(4)}(\Box + m^2)\mathcal{F} - \mathcal{F}\wedge *^{(4)}(\Box + m^2)\mathcal{A} = -\int_{\partial\mathcal{O}} i^*(\mathcal{A}\wedge *^{(4)}d^{(4)}\mathcal{F} + \delta^{(4)}\mathcal{A}\wedge *^{(4)}\mathcal{F}) + \int_{\partial\mathcal{O}} i^*(\delta^{(4)}\mathcal{F}\wedge *^{(4)}\mathcal{A} + \mathcal{F}\wedge *^{(4)}d^{(4)}\mathcal{A}). \tag{A3}$$

Next, apply (A3) to the regions $\mathcal{O}=\Sigma^{\pm}\equiv J^{\pm}(\Sigma)\setminus\Sigma$, with $\partial\mathcal{O}=\Sigma$ and obtain

$$\int_{\Sigma^{\pm}} \mathcal{A}\wedge *^{(4)}(\Box + m^2)\mathcal{F} - \mathcal{F}\wedge *^{(4)}(\Box + m^2)\mathcal{A} = \mp\{\langle\rho_{(0)}\mathcal{A},\rho_{(d)}\mathcal{F}\rangle + \langle\rho_{(\delta)}\mathcal{A},\rho_{(n)}\mathcal{F}\rangle_{\Sigma} - \langle\rho_{(n)}\mathcal{A},\rho_{(\delta)}\mathcal{F}\rangle_{\Sigma} - \langle\rho_{(d)}\mathcal{A},\rho_{(0)}\mathcal{F}\rangle_{\Sigma}, \tag{A4}$$

where $\rho_{(0)}$, $\rho_{(n)}$, $\rho_{(d)}$, and $\rho_{(\delta)}$ are as defined in (11), and, for example, $\int_{\Sigma} i^*\delta^{(4)}\mathcal{F}\wedge *^{(3)}(-*^{(3)}i^**^{(4)})\mathcal{A} = \langle\rho_{(\delta)}\mathcal{F},\rho_{(n)}\mathcal{A}\rangle_{\Sigma}$ (the standard orientation is used for both regions $\Sigma^{\pm}$).

The action of $\rho_{(0)}$ and $\rho_{(\delta)}$ is obvious, however, $\rho_{(n)}$ and $\rho_{(d)}$ are more subtle. Specifically, $\rho_{(n)}$ and $\rho_{(d)}$ are the forward normal, and pullback of the forward normal derivative operators, respectively. To see this, let $x^{\mu}=(t,x^{i})$, then $e_{\mu}=\partial_{x^{\mu}}$ represents the standard basis for the tangent space of $(\mathcal{M},g)$. Let (Σ,γ) be a Cauchy surface with forward normal n. Following the presentation of Misner, Thorne and Wheeler we have $n=n^{\mu}e_{\mu}$,

$$n=N^{-1}(\partial_t-N^{i}\partial_{x^{i}})$$

where $N=(-g^{00})^{-(1/2)}$ is the lapse function, and $N^{i}=g^{ik}g_{ok}$ are the components of the shift vector.[14] Notice that $n=-N\ dt$ in covariant form, and recall that $\sqrt{|g|}=N\sqrt{\gamma}$. Now, let $\mathcal{A}=\mathcal{A}_{\mu}dx^{\mu}$ and consider,

$$\begin{aligned}\rho_{(n)}\mathcal{A}&=-*^{(3)}i**^{(4)}\mathcal{A}_{\mu}dx^{\mu},\\&=-*^{(3)}i*\frac{1}{3!}\sqrt{|g|}\mathcal{A}^{\mu}\epsilon_{\mu\alpha\beta\eta}dx^{\alpha}\wedge dx^{\beta}\wedge dx^{\eta},\\&=-*^{(3)}\frac{1}{3!}N\sqrt{\gamma}\mathcal{A}^{0}\epsilon_{0ijk}dx^{i}\wedge dx^{j}\wedge dx^{k},\\&=-\frac{1}{3!}N\gamma\mathcal{A}^{0}\epsilon_{0lmn}\epsilon_{ijk}\gamma^{il}\gamma^{jm}\gamma^{kn},\\&=-N\mathcal{A}^{0},\\&=\mathcal{A}(n),\end{aligned}$$

where $\epsilon_{\mu\alpha\beta\eta}$ is the Levi Cevita symbol.[14]

For the analysis of $\rho_{(d)}$ it is convenient to work with a basis $\hat{e}_{\mu}$ where $\hat{e}_0=n$ and $\hat{e}_i=\partial_{x^{i}}$. The dual for this basis is $\hat{\omega}^{\mu}$ where $\hat{\omega}^{0}=Ndt$ and $\hat{\omega}^{i}=dx^{i}+N^{i}dt$.[14] We also have $|\hat{g}|=\gamma$. Let $\mathcal{A}=\hat{\mathcal{A}}_{\mu}\hat{\omega}^{\mu}$, and $\mathcal{F}=d\mathcal{A}=(1/2!)\hat{\mathcal{F}}_{\mu\nu}\hat{\omega}^{\mu}\wedge\hat{\omega}^{\nu}$. It follows that $\hat{\mathcal{F}}_{0s}=\mathcal{F}(\hat{e}_0,\hat{e}_s)=\mathcal{F}(n^{\mu}e_{\mu},e_s)=n^{\mu}\mathcal{F}_{\mu s}$ and therefore,

$$n^{\mu}\mathcal{F}_{\mu s}dx^{s}=\rho_{(0)}\mathcal{F}(n,\cdot). \tag{A5}$$

Consider,

$$\begin{aligned}\rho_{(d)}\mathcal{A}&=-*^{(3)}i**^{(4)}d^{(4)}\hat{\mathcal{A}}_{\mu}\hat{\omega}^{\mu},\\&=-*^{(3)}i**^{(4)}\frac{1}{2!}\hat{\mathcal{F}}_{\mu\nu}\hat{\omega}^{\mu}\wedge\hat{\omega}^{\nu},\\&=-*^{(3)}i*\frac{1}{2!}\sqrt{|\hat{g}|}\frac{1}{2!}\hat{g}^{\mu\alpha}\hat{g}^{\nu\beta}\hat{\mathcal{F}}_{\alpha\beta}\epsilon_{\mu\nu\sigma\tau}\hat{\omega}^{\sigma}\wedge\hat{\omega}^{\tau},\\&=-*^{(3)}\sqrt{\gamma}\hat{g}^{0\alpha}\hat{g}^{i\beta}\hat{\mathcal{F}}_{\alpha\beta}\epsilon_{0ijk}dx^{j}\wedge dx^{k},\\&=\gamma\frac{1}{2!}\hat{\mathcal{F}}_{0s}\gamma^{is}\gamma^{jm}\gamma^{kn}\epsilon_{0imn}\epsilon_{jkp}dx^{p},\\&=\frac{1}{2!}\hat{\mathcal{F}}_{0s}\epsilon_{sjk}\epsilon_{jkp}dx^{p},\\&=\hat{\mathcal{F}}_{0s}dx^{s},\\&=n^{\alpha}\mathcal{F}_{\alpha s}dx^{s}\\&=\rho_{(0)}(d^{(4)}\mathcal{A})(n,\cdot),\end{aligned}$$

where in the last step we have used (A5).

We are finally ready to prove

Theorem 5: *Let* $\mathcal{A}$ *be a smooth solution of* $(\Box+m^2)\mathcal{A}=0$ *with Cauchy data* $A_{(0)}\equiv\rho_{(0)}\mathcal{A}$, $A_{(d)}\equiv\rho_{(d)}\mathcal{A}\in\mathfrak{D}^{(1)}(\Sigma)$, *and* $A_{(n)}\equiv\rho_{(n)}\mathcal{A}$, $A_{(\delta)}\equiv\rho_{(\delta)}\mathcal{A}\in\mathfrak{D}^{(0)}(\Sigma)$. *Then,*

$$\langle\mathcal{A},\mathcal{F}\rangle_{\mathcal{M}}=\langle A_{(0)},\rho_{(d)}E_m^{(1)}\mathcal{F}\rangle_\Sigma+\langle A_{(\delta)},\rho_{(n)}E_m^{(1)}\mathcal{F}\rangle_\Sigma-\langle A_{(n)},\rho_{(\delta)}E_m^{(1)}\mathcal{F}\rangle_\Sigma-\langle A_{(d)},\rho_{(0)}E_m^{(1)}\mathcal{F}\rangle_\Sigma, \tag{A6}$$

for any test function $\mathcal{F}\in\mathfrak{D}^{(1)}(\mathcal{M})$.

Proof: Since $(\Box+m^2)\mathcal{A}=0$, the second term on the left-hand side of (A4) is zero. For the remaining integrals, substitute $\mathcal{F}=E_m^{\mp(1)}\mathcal{F}'$ for the regions $\Sigma^\pm$, respectively. All integrals are well-defined because they entail integrations of smooth functions over compact sets. Specifically, for the left-hand side of (A4) we have

$$\mathrm{supp}(E_m^{\mp(1)}\mathcal{F}')\subset J^{\mp}(\mathrm{supp}(\mathcal{F}')),$$

with $J^{\mp}(\mathrm{supp}(\mathcal{F}'))\cap J^{\pm}(\Sigma)$ compact ($\mathcal{M}$ is globally hyperbolic), and for the right-hand side, Σ is compact by assumption.[3] Next, sum the integrations over the $\Sigma^\pm$ regions substituting $(\Box+m^2)E_m^{\pm(1)}=I$ in $\Sigma^\pm$ integrals and $E_m^{(1)}=E_m^{+(1)}-E_m^{-(1)}$ in Σ integrals. The sum of the $\Sigma^\pm$ integrals gives an integral over $\mathcal{M}$ (Σ constitutes a set of measure zero relative to this integration). Finally, relabel $\mathcal{F}'\rightarrow\mathcal{F}$ and obtain (A6). This completes the proof. ■

APPENDIX B: MAXWELL'S EQUATIONS

In this section we study Maxwell's equations,

$$d^{(4)}\mathcal{F}=0 \tag{B1}$$

and

$$\delta^{(4)}\mathcal{F}=0, \tag{B2}$$

where $\mathcal{F}$ is the field strength 2-form (not a test function as above). We pose an initial value problem for these equations following the presentation in Wald.[13] Specifically, we specify the initial data for $\mathcal{F}$ in terms of the electric and magnetic fields $E\equiv\rho_{(n)}\mathcal{F}$ and $B\equiv\rho_{(0)}\mathcal{F}$, respectively, which are regarded as a 1-form and 2-form on Σ, respectively. This data satisfies additional constraints $\delta^{(3)}E=0$ and $d^{(3)}B=0$. Given these data, we obtain a field solution $\mathcal{F}$ that satisfies (B1) and (B2) on $\mathcal{M}$. Our approach is similar to Dimock's; the differences being that our emphasis is on the fields rather than the vector potential, and we give an explicit representation for $\mathcal{F}$.[4]

Before we proceed, we make a further restriction on $\mathcal{M}$. Specifically, we assume that Σ is compact and contractible. If Σ is contractible then any closed p-form on Σ is exact, that is, $K\in\mathfrak{D}^{(p)}(\Sigma)$ with $d^{(3)}K=0\Rightarrow K=d^{(3)}H$ for some $H\in\mathfrak{D}^{(p-1)}(\Sigma)$ $(p>0)$.[20,21]

Theorem 6: *Let* $E\in\mathfrak{D}^{(1)}(\Sigma)$ *and* $B\in\mathfrak{D}^{(2)}(\Sigma)$ *be data for the field strength* $\mathcal{F}$, *i.e.,*

$$\rho_{(n)}\mathcal{F}=E, \tag{B3}$$

and

$$\rho_{(0)}\mathcal{F}=B, \tag{B4}$$

where

$$\delta^{(3)}E=0, \tag{B5}$$

and

$$d^{(3)}B=0. \tag{B6}$$

Then, given these data, there is a smooth potential $\mathcal{A}$ such that $\mathcal{F}=d^{(4)}\mathcal{A}$ satisfies Maxwell's equations $d^{(4)}\mathcal{F}=0$ and $\delta^{(4)}\mathcal{F}=0$, as well as (B3)–(B6). Moreover, any two such potentials are gauge equivalent i.e., they differ by the exterior derivative of a scalar. Here we assume that Σ is compact and contractible.

Proof: Existence: We choose data for $\mathcal{A}$ as follows:

$$A_{(d)}=E, \tag{B7}$$

$$d^{(3)}A_{(0)}=B, \tag{B8}$$

with

$$\delta^{(3)}A_{(d)}=0, \tag{B9}$$

$A_{(\delta)}=0$, and $A_{(n)}$ arbitrary. These choices of data are compatible with the field constraints (B5), and (B6) in that (B7) and (B9) imply (B5), and (B8) implies (B6). Regarding (B8), we know that such an $A_{(0)}$ exists because Σ is contractible and B is exact. These choices of data satisfy (23) and (24) of Theorem 2 for the $m=0$ case. Consequently, there is a unique smooth $\mathcal{A}$ that satisfies

$$\delta^{(4)}d^{(4)}\mathcal{A}=0, \tag{B10}$$

and $\mathcal{F}=d^{(4)}\mathcal{A}$ is our desired field strength. Next we show that $\mathcal{F}$ renders the data (B3) and (B4). From Theorem 2 we have

$$\mathcal{A}=-E_0^{(1)}\rho'_{(d)}A_{(0)}+E_0^{(1)}\rho'_{(\delta)}A_{(n)}+E_0^{(1)}\rho'_{(0)}A_{(d)}. \tag{B11}$$

Consider,

$$\begin{aligned}\rho_{(n)}\mathcal{F}&=-\rho_{(n)}d^{(4)}E_0^{(1)}\rho'_{(d)}A_{(0)}+\rho_{(n)}d^{(4)}E_0^{(1)}\rho'_{(\delta)}A_{(n)}+\rho_{(n)}d^{(4)}E_0^{(1)}\rho'_{(0)}A_{(d)},\\ &=-\rho_{(d)}E_0^{(1)}\rho'_{(d)}A_{(0)}+\rho_{(d)}E_0^{(1)}\rho'_{(\delta)}A_{(n)}+\rho_{(d)}E_0^{(1)}\rho'_{(0)}A_{(d)},\\ &=A_{(d)},\\ &=E,\end{aligned}$$

and

$$\begin{aligned}\rho_{(0)}\mathcal{F}&=-\rho_{(0)}d^{(4)}E_0^{(1)}\rho'_{(d)}A_{(0)}+\rho_{(0)}d^{(4)}E_0^{(1)}\rho'_{(\delta)}A_{(n)}+\rho_{(0)}d^{(4)}E_0^{(1)}\rho'_{(0)}A_{(d)},\\ &=-d^{(3)}\rho_{(0)}E_0^{(1)}\rho'_{(d)}A_{(0)}+d^{(3)}\rho_{(0)}E_0^{(1)}\rho'_{(\delta)}A_{(n)}+d^{(3)}\rho_{(0)}E_0^{(1)}\rho'_{(0)}A_{(d)},\\ &=d^{(3)}A_{(0)},\\ &=B,\end{aligned}$$

where we have used the results of Corollary 1.

Uniqueness: We want to show that any two potentials $\mathcal{A}'$ and $\tilde{\mathcal{A}}$ that satisfy (B10) with data (B7)–(B9) are gauge equivalent, i.e.,

$$\mathcal{A}'=\tilde{\mathcal{A}}+d^{(4)}f,$$

where $f\in\mathfrak{D}^{(0)}(\mathcal{M})$.[4] It suffices to show that any solution is gauge equivalent to the unique solution $\mathcal{A}$ above. Consider a solution $\mathcal{A}'$, we want to show that f' exists such that

$$\mathcal{A}=\mathcal{A}'+d^{(4)}f'.$$

Since $\mathcal{A}$ is unique, it suffices to construct $f'\in\mathfrak{D}^{(0)}(\mathcal{M})$ such that $\mathcal{A}'+d^{(4)}f'$ satisfies

$$\Box(\mathcal{A}'+d^{(4)}f')=0 \tag{B12}$$

on $\mathcal{M}$ with the same data as $\mathcal{A}$ on Σ. First, notice that (B12) is equivalent to

$$\delta^{(4)}d^{(4)}\mathcal{A}'+d^{(4)}\delta^{(4)}\mathcal{A}'+d^{(4)}\delta^{(4)}d^{(4)}f'=0. \tag{B13}$$

The first term in (B13) is zero because $\mathcal{A}'$ satisfies (B10). Therefore (B12) reduces to

$$\Box f'=-\delta^{(4)}\mathcal{A}'. \tag{B14}$$

Next, we study the data. Recall from Theorem 2 that the unique solution $\mathcal{A}$ has data $A_{(\delta)}$, $A_{(n)}$, $A_{(0)}$, and $A_{(d)}$, where

$$A_{(\delta)}=0, \tag{B15}$$

$$\delta^{(3)}A_{(d)}=0, \tag{B16}$$

and $A_{(0)}$ and $A_{(n)}$ are arbitrary. We need to construct f' so that $\mathcal{A}'+d^{(4)}f'$ renders the same data. To this end, we specify

$$\rho_{(\delta)}(\mathcal{A}'+d^{(4)}f')=0, \tag{B17}$$

$$\rho_{(n)}\mathcal{A}=\rho_{(n)}(\mathcal{A}'+d^{(4)}f'), \tag{B18}$$

$$\rho_{(0)}\mathcal{A}=\rho_{(0)}(\mathcal{A}'+d^{(4)}f'), \tag{B19}$$

and

$$\rho_{(d)}\mathcal{A}=\rho_{(d)}(\mathcal{A}'+d^{(4)}f'). \tag{B20}$$

To satisfy (B17) we impose (B14). The conditions (B18) and (B19) are satisfied when

$$\rho_{(d)}f'=\rho_{(n)}(\mathcal{A}-\mathcal{A}'), \tag{B21}$$

and

$$d^{(3)}\rho_{(0)}f'=\rho_{(0)}(\mathcal{A}-\mathcal{A}'), \tag{B22}$$

respectively. Regarding (B22), we know that such a $\rho_{(0)}f'$ exists because Σ is contractible and, by assumption, $\rho_{(0)}(\mathcal{A}-\mathcal{A}')$ is exact, i.e., $d^{(3)}\rho_{(0)}(\mathcal{A}-\mathcal{A}')=B-B=0$. Finally, (B20) is satisfied because, by assumption, $\mathcal{A}$ and $\mathcal{A}'$ satisfy (B7), and we know that $\rho_{(d)}d^{(4)}f'=0$.

Now, by assumption, we are given $\mathcal{A}$ and $\mathcal{A}'$ so we view (B14), (B21) and (B22) as specifying a Cauchy problem for the scalar field f'. That is, (B21) and (B22) specify the Cauchy data $\rho_{(d)}f'$ and $\rho_{(0)}f'$ for the nonhomogeneous linear hyperbolic equation (B14). A unique solution to this problem is known to exist which gives us the desired f'.[13] This shows that any solution $\mathcal{A}'$ is gauge equivalent to the unique $\mathcal{A}$ and therefore, given two different solutions $\mathcal{A}'$ and $\tilde{\mathcal{A}}$ we have $\mathcal{A}=\mathcal{A}'+d^{(4)}f'$, and $\mathcal{A}=\tilde{\mathcal{A}}+d^{(4)}\tilde{f}$ which shows that $\mathcal{A}'=\tilde{\mathcal{A}}+d^{(4)}f$, where $f=\tilde{f}-f'$. Thus any two such solutions give rise to the same field strength $\mathcal{F}$. This completes the proof. ■

We obtain an explicit expression for $\mathcal{F}$ as follows:

Corollary 4: Let $\mathcal{A}$ be a vector potential with data $A_{(0)}$, $A_{(d)}$, $A_{(n)}$, and $A_{(\delta)}$ satisfying the conditions of Theorem 6. The field strength is given by

$$\mathcal{F} = -d^{(4)} E_0^{(1)} \rho'_{(d)} A_{(0)} + d^{(4)} E_0^{(1)} \rho'_{(0)} A_{(d)}, \tag{B23}$$

where $\mathcal{F} \in \mathcal{E}^{(2)}(\mathcal{M})$ *is continuously dependent on* $A_{(0)}$, $A_{(d)} \in \mathfrak{D}^{(1)}(\Sigma)$.

Proof: From Theorem 2 we have

$$\mathcal{A} = -E_0^{(1)} \rho'_{(d)} A_{(0)} + E_0^{(1)} \rho'_{(\delta)} A_{(n)} + E_0^{(1)} \rho'_{(0)} A_{(d)} \tag{B24}$$

with

$$\delta^{(3)} A_{(d)} = 0. \tag{B25}$$

We show that (B23) equals $d^{(4)}\mathcal{A}$. Let $\mathcal{G} \in \mathfrak{D}^{(2)}(\mathcal{M})$ be a 2-form test function, and consider,

$$\begin{aligned}
\langle d^{(4)}\mathcal{A}, \mathcal{G}\rangle_{\mathcal{M}} &= \langle \mathcal{A}, \delta^{(4)}\mathcal{G}\rangle_{\mathcal{M}}, \\
&= \langle A_{(0)}, \rho_{(d)} E_0^{(1)} \delta^{(4)}\mathcal{G}\rangle_{\Sigma} - \langle A_{(n)}, \rho_{(\delta)} E_0^{(1)} \delta^{(4)}\mathcal{G}\rangle_{\Sigma} \\
&\quad - \langle A_{(d)}, \rho_{(0)} E_0^{(1)} \delta^{(4)}\mathcal{G}\rangle_{\Sigma} \\
&= \langle -d^{(4)} E_0^{(1)} \rho'_{(d)} A_{(0)} + d^{(4)} E_0^{(1)} \rho'_{(0)} A_{(d)}, \mathcal{G}\rangle_{\Sigma},
\end{aligned}$$

where, in the last step we have used $\rho_{(\delta)} E_0^{(1)} \delta^{(4)}\mathcal{G} = 0$. Thus, (B23) is satisfied in a distributional sense. From Theorem 1 we know that $E_0^{(1)} \rho'_{(0)}$, $E_0^{(1)} \rho'_{(d)} : \mathfrak{D}^{(1)}(\Sigma) \rightarrow \mathcal{E}^{(1)}(\mathcal{M})$ are continuous, and we also know that $d^{(4)} : \mathcal{E}^{(1)}(\mathcal{M}) \rightarrow \mathcal{E}^{(2)}(\mathcal{M})$ is continuous, therefore $\mathcal{F} \in \mathcal{E}^{(2)}(\mathcal{M})$ is continuously dependent on $A_{(0)}$ and $A_{(d)}$. ■

From this final result, we see that $\mathcal{F}$ depends only on the data $A_{(0)}$ and $A_{(d)}$. Thus, we can set $A_{(n)} = 0$ in (B24). This choice of data is useful when quantizing the electromagnetic field.[4]

Exact spectral values for discrete quantum pendulum-integrals

Johannes Kellendonk[a)]
Fachbereich Mathematik, Technische Universität Berlin, 10623 Berlin, Germany

(Received 1 July 1998; accepted for publication 19 January 1999)

For specific choice of parameters the spectrum of the discrete quantum pendulum-integral contains the eigenvalues of a finite matrix which depends analytically on the flux. Under natural continuity assumptions these eigenvalues include the spectral values which may be obtained by the algebraic Bethe ansatz. © *1999 American Institute of Physics.* [S0022-2488(99)01205-0]

I. INTRODUCTION

Discrete quantum pendulum-integrals (QP-integrals) are integrals of motion of a (1+0)-dimensional discrete integrable quantum field theory. This quantum field theory is the discrete sine–Gordon field theory with shortest possible (symmetric) periodicity in space. With space compatified in that way to one point, the model becomes that of the discrete quantum (mathematical) pendulum.[1] Coincidently, QP-integrals arise in solid state physics as well: they may be interpreted as magnetic Schrödinger operators on $\mathbb{Z}^2$ generalizing the Hofstadter Hamiltonian[2] which describes an elementary quantum–Hall system.[3] The QP-integrals so arise as self-adjoint elements of the discrete Weyl–Heisenberg algebra, which is the C^*-algebra generated by two unitary elements u and v which are subject to the relation $uv=q^{-1}vu$, $q=e^{i\gamma}$. Here γ plays here the role of the flux of the magnetic field. To define QP-integrals in this context, consider the family

$$H(a,b,k):=au+\overline{a}u^*+bv+\overline{b}v^*+k(q^{1/2}uv+q^{-1/2}v^*u^*)+k^{-1}(q^{-1/2}uv^*+q^{1/2}vu^*) \quad (1)$$

parametrized by complex continuous functions $a=a(q^{1/2})$ and $b=b(q^{1/2})$ and a strictly positive real number k. We will right away focus our attention on particular choices for a and b and write more briefly

$$\tilde{H}(z,n,k):=H(z+z^{-1},q^{n/2}+q^{-n/2},k), \quad (2)$$

$z=z(q^{1/2})$, $n\in\mathbb{N}$. In case $z(q^{1/2})$ is of modulus 1, $\tilde{H}(z,n,k)$ arises as an integral of motion of discrete sine–Gordon field theory with shortest possible periodicity in space.[4,5] For $z(q^{1/2})=q^{n/2}$, i.e., $a=b=2\cos(n\gamma/2)$, $\tilde{H}(z,n,k)$ is referred to as a QP-integral. We shall prove here that, for $z+z^{-1}\in\mathbb{R}$, the spectrum of $\tilde{H}(z,n,k)$ contains the eigenvalues of the tridiagonal matrix

$$\tilde{A}(z,n,k):=\begin{pmatrix} \tilde{x}_0 & \tilde{y}_0 & & & \\ \tilde{z}_0 & \tilde{x}_1 & \tilde{y}_1 & & \\ & \ddots & \ddots & \ddots & \\ & & & \tilde{z}_{n-2} & \tilde{x}_{n-1} \end{pmatrix}, \quad (3)$$

where

$$\tilde{x}_j=-(z+z^{-1})(kq^{(1-n)/2+j}+k^{-1}q^{(n-1)/2-j}), \quad (4)$$

[a)]Electronic mail: kellen@math.tu-berlin.de

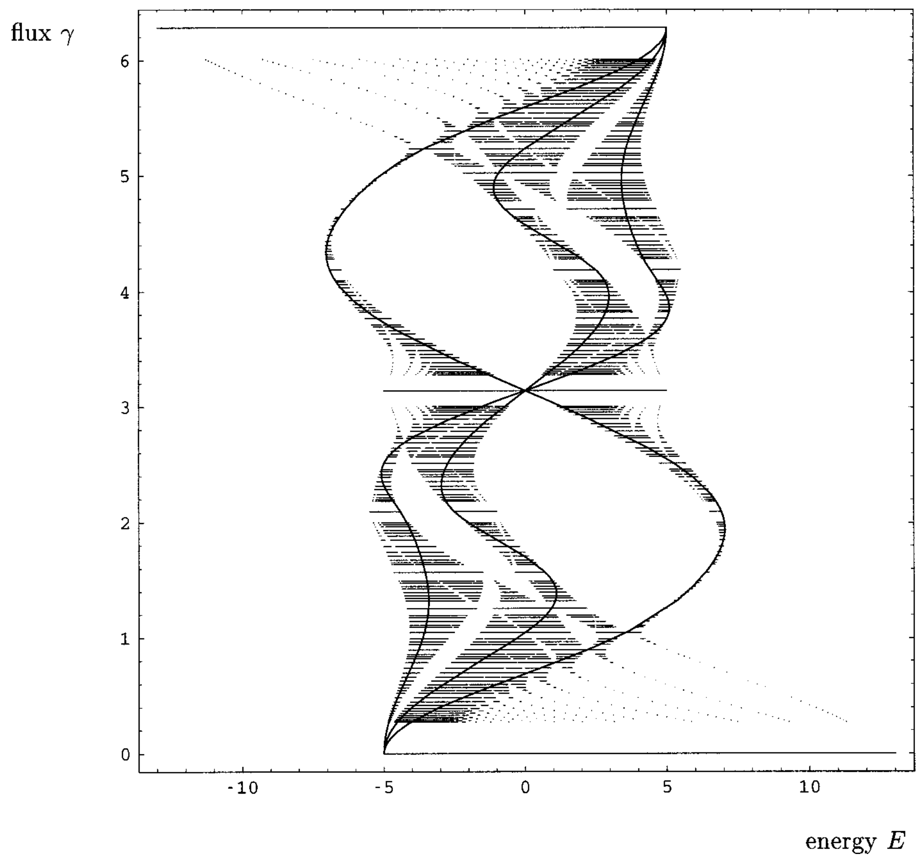

FIG. 1. Spectrum of $\tilde{H}(q^{3/2},3,2)$ (horizontal lines, for $\gamma/2\pi = M/N$ with small N) and eigenvalues of $\tilde{A}(q^{3/2},3,2)$ (continuous curves).

$$\tilde{y}_j = q^{n/2} + q^{-n/2} - (q^{j+1-n/2} + q^{n/2-j-1}), \tag{5}$$

$$\tilde{z}_j = q^{n/2} + q^{-n/2} - (k^2 q^{j+1-n/2} + k^{-2} q^{n/2-j-1}). \tag{6}$$

Figure 1 shows a plot of the spectrum of $\tilde{H}(q^{3/2},3,2)$ against γ (for rational $\gamma/2\pi$ with small denominator) together with the three curves of eigenvalues of $\tilde{A}(q^{3/2},3,2)$.

Although diagonalization of the above matrix furnishes only finitely many spectral values, we find this result surprising, since one expects the spectrum of $H(a,b,k)$ to be a Cantor set for $\gamma/2\pi \notin \mathbb{Q}$ and not much is known about spectral values of operators with Cantor spectrum.

As already mentioned, in case $z(q^{1/2})$ is of modulus 1, $\tilde{H}(z,n,k)$ is an integral of motion of an integrable discrete quantum field theory. The integrability means in particular that one may determine (generalized) eigenvalues and functions of its integrals of motion, among which are the QP-integrals. This is achieved by use of the algebraic Bethe ansatz,[6] which was adapted to the present case by Nadja Kutz.[4] It leads to the following result.[4,5]

Theorem 1: *Let $\delta \in S^1 = \mathbb{R}/2\pi\mathbb{Z}$, $n \in \mathbb{N}$, and $k > 0$. If the set of $n-1$ spectral parameters $\eta_1, \ldots, \eta_{n-1}$, which ought to be complex, pairwise different numbers, satisfies the so-called Bethe ansatz equations*

$$\prod_{j \neq i=1}^{n-1} \frac{\eta_j q - \eta_i}{\eta_j - \eta_i q} = e^{2i\delta} \frac{q^{-1/2}\eta_j^2 + \eta_j(k+k^{-1}) + q^{1/2}}{q^{1/2}\eta_j^2 + \eta_j(k+k^{-1}) + q^{-1/2}}, \tag{7}$$

then, with $q = e^{i\gamma}$,

$$E(\eta_1,\ldots,\eta_{n-1}) = -2(k+k^{-1})\cos\left(\frac{n-1}{2}\gamma+\delta\right)+4\sin\left(\frac{n-1}{2}\gamma+\delta\right)\sin\frac{\gamma}{2}\sum_{j=1}^{n-1}\eta_j^{-1}(\gamma) \quad (8)$$

lies in the spectrum of $\tilde{H}(e^{i\delta},n,k)$.

A formula for eigenfunctions (in the generalized sense, i.e., not neccessarily normalizable) corresponding to these so-called Bethe ansatz eigenvalues will be recalled later.

We expect that the so-called Bethe ansatz eigenvalues (8) coincide with the eigenvalues of $\tilde{A}(e^{i\delta},n,k)$. Indeed, we shall derive that the Bethe ansatz eigenvalues are among the eigenvalues of $\tilde{A}(e^{i\delta},n,k)$ in case $k=1$ and extend this result to $k\neq 1$ under natural assumptions on the behavior of the Bethe ansatz eigenvalues on k, z, and γ. Therefore, our result may also be understood as a simpler approach to the determination of the Bethe ansatz eigenvalues and we expect that a similar simplification occurrs in other models, too, in particular those coming from the sine–Gordon model. In fact, the Bethe ansatz equations are rather difficult to solve. Already for $n=3$ they lead to polynomial equations which have too high orders to be tractable by analytic means. In Ref. 5, solutions for $k>1$ were for that reason only obtained in case $n\leqslant 2$.

The key to compare the Bethe ansatz eigenvalues with the eigenvalues of $\tilde{A}(e^{i\delta},n,k)$ is to look first at $k=1$, a case in which the solution of the Bethe ansatz eigenvector simplifies enormously. It is shown in Ref. 5 that the Bethe ansatz eigenvector is then not only a true eigenvector, or, more precisely, a square summable vector in a particular representation on $\ell^2(\mathbb{Z})$, but it even vanishes in that representation outside $\{0,\ldots,n-1\}\subset\mathbb{Z}$. This leads us to a remark on yet another approach to determine spectral values of $\tilde{H}(z,n,k)$ which we will, however, not follow here. That approach is essentially an ansatz for eigenfunctions of $\tilde{H}(z,n,k)$ which have finite support. Formulated in a representation on $L^2(S^1)$, the Fourier space of $\ell^2(\mathbb{Z})$, the above ansatz is one for polynomial eigenfunctions. It may then also be reformulated in terms of Bethe ansatz equations[7,5] [different from (7)] which, however, are again rather difficult to solve.

After recalling some important facts about the discrete Weyl–Heisenberg algebra, which we do in the next section following mainly Ref. 5, we prove in Sec. III that the eigenvalues of $\tilde{A}(z,n,k)$ are spectral values of $\tilde{H}(z,n,k)$ by showing that the characteristic polynomial factorizes in the appropriate way. In Sec. IV we relate the Bethe ansatz eigenvalues to these eigenvalues.

II. PRELIMINARIES

The discrete Weyl–Heisenberg or rotation algebra $\mathcal{A}_\gamma$ with angle γ is the C^*-envelope of the $*$-algebra generated by two elements u and v which are subject to the relations[8]

$$uu^*=1,\quad u^*u=1,\quad vv^*=1,\quad v^*v=1,\quad uv=q^{-1}vu,$$

with $q=e^{i\gamma}$. Any element of the discrete Weyl–Heisenberg algebra $\mathcal{A}_\gamma$ may be approximated in norm by finite sums of the form $\Sigma\, c_n u^{n_1}v^{n_2}$, $n\in\mathbb{Z}^2$, $c_n\in\mathbb{C}$. A faithful representation of $\mathcal{A}_\gamma$ on the Hilbert space $\ell^2(\mathbb{Z}^2)$ is given by

$$u\cdot\psi(n)=e^{iA_1(n)}\psi(n_1-1,n_2), \quad (9)$$

$$v\cdot\psi(n)=e^{iA_2(n)}\psi(n_1,n_2-1), \quad (10)$$

where A: $\mathbb{Z}^2\to\mathbb{R}^2$ is a gauge potential with discrete rotation γ:

$$(A_2(n)-A_2(n_1-1,n_2))-(A_1(n)-A_1(n_1,n_2-1))=\gamma,$$

and we have used the convention to denote the action of an element $x\in\mathcal{A}_\gamma$ in some representation space simply by $\cdot$. In other words, $\mathcal{A}_\gamma$ is isomorphic to the norm-closure of the subalgebra of bounded operators of $\ell^2(\mathbb{Z}^2)$ generated by u and v in the above representation. The above representation yields the framework for the discretized version of the Landau model which describes an electric particle in the discretized plane $\mathbb{Z}^2$ to which a constant magnetic field is perpendicularly applied. More precisely, $\mathcal{A}_\gamma$ is the algebra of observables for that model, and the famous Hofstadter Hamiltonian, which plays the role of the discrete Landau Hamiltonian, equals $u+v+u^*+v^*$ acting in the above representation. The angle γ is proportional to the magnetic field or the flux per unit cell. The function A is for given γ unique up to a discrete gradient. Different gauges lead, in general, to different representations which are, however, unitarily equivalent. For simplicity we will call $\gamma/2\pi$ the flux.

The above representation is faithful but not irreducible. Its decomposition into irreducible components leads, for rational $\gamma/2\pi$, to a family of representations labeled by a two-torus, the two-torus of quasimomenta, or Bloch parameters. The first step of this decomposition, which applies as well to irrational $\gamma/2\pi$, leads to the family of Weyl–Schrödinger representations, labeled by an angle θ, with representation space $\ell^2(\mathbb{Z})$. They are given by

$$u\cdot\psi(n)=e^{i\theta}q^{-n}\psi(n), \tag{11}$$

$$v\cdot\psi(n)=\psi(n-1). \tag{12}$$

For irrational $\gamma/2\pi$ the Weyl–Schrödinger representations are irreducible and still faithful; for rational $\gamma/2\pi$ this is not the case. In fact, for $\gamma/2\pi=M/N$, $(M,N)=1$ (meaning that M and N are coprime), the Weyl–Schrödinger representations are neither irreducible nor faithful. In that case, the Weyl–Schrödinger representation with angle θ decomposes into a direct integral of N-dimensional irreducible representations parametrized by a second angle. Denoting the second angle by φ, u has in the irreducible representation labeled by (θ,φ) matrix representation

$$u_{(\theta,\varphi)}=e^{i\theta}\begin{pmatrix} q^{-1} & & & & \\ & \ddots & & & \\ & & q^{-1} & & \\ & & & \ddots & \\ & & & & 1 \end{pmatrix}, \tag{13}$$

which in particular is independent of φ, and v

$$v_{(\theta,\varphi)}=\begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & 0 \\ 0 & & & \ddots & 1 \\ e^{i\varphi} & 0 & \cdots & & 0 \end{pmatrix}. \tag{14}$$

Two such matrix representations, one for (θ,φ) and one for (θ',φ'), are unitarily equivalent whenever $\theta-\theta'=n\gamma$ for some $n\in\mathbb{Z}$ and $\varphi=\varphi'$, that is, if $u_\theta^N=u_{\theta'}^N$ and $v_\varphi^N=v_{\varphi'}^N$. The asymmetry appearing in the parameters (θ,φ) labeling the irreducible components is, from a physical point of view, artificial. In the (discrete) Landau model, u^N and v^N are translation operators along N sites in the one- and two-directions, respectively, and the parameters $N\theta$ and φ have the physical interpretation of quasimomentum in the x_1- and the x_2-direction, respectively. We denote by $x_{(\theta,\varphi)}$ the matrix representation of $x\in\mathcal{A}_\gamma$ in the N-dimensional representation labeled by (θ,φ).

It follows from the above consideration that the spectrum $\sigma(x)$ of any element $x\in\mathcal{A}_\gamma$ is, for irrational $\gamma/2\pi$, equal to the spectrum of x in any Weyl–Schrödinger representation, and for rational $\gamma/2\pi$ given by

$$\sigma(x)=\bigcup_{(\theta,\varphi)\in S^1\times S^1}\sigma(x_{(\theta,\varphi)}).$$

Since $x_{(\theta,\varphi)}$ is a finite-dimensional matrix, its spectrum consists of eigenvalues, the zeroes of its characteristic polynomial. It turns out that, for our family of operators, the characteristic polynomial has a very special form, namely, with $\gamma/2\pi = M/N$, $(M,N)=1$,

$$\det(H_{(\theta,\varphi)}(a,b,k)-E)=p(a,b,k;E)+h(a,b,k;\theta,\varphi),$$

where $p(a,b,k;E)$ is a polynomial in E of degree N which is independent of (θ,φ), and $h(a,b,k;\theta,\varphi)$, the so-called off-set function, is independent of E. Such a relation is called a Chambers relation. While the polynomial p may look rather complicated, the off-set function h is explicitly known.[2,5] With $T_N(z+z^{-1})/2)=(z^N+z^{-N})/2$ for any complex $z\neq 0$, it is

$$h(a,b,k;\theta,\varphi)=-2\left(T_N\left(-\frac{a}{2}\right)e^{iN\theta}+T_N\left(-\frac{b}{2}\right)e^{i\varphi}\right)+(-1)^M(k^N e^{i(N\theta+\varphi)}+k^{-N}e^{i(N\theta-\varphi)})+\text{c.c.}$$

We also write

$$\tilde{h}(z,n,k;\zeta_1,\zeta_2)=h\left(z+z^{-1},2\cos\frac{n\gamma}{2},k;\theta,\varphi\right),\quad \zeta_1=e^{iN\theta},\quad \zeta_2=e^{i\varphi}. \tag{15}$$

For the above result we have normalized $p(a,b,k;0)=0$ and c.c. stands for complex conjugate. T_N is, up to constants, the Nth Chebychev polynomial of the second kind.

Despite the irregular behavior of $p(a,b,k;E)$ on γ, the spectrum of $H(a,b,k)$ depends, in a certain sense, continuously on the flux. The collection of all $\mathcal{A}_\gamma$, $\gamma\in S^1$, can be combined into a continuous field of C^*-algebras over S^1.[9] Its continuous sections, which are in particular functions $S^1\to\cup_\gamma\mathcal{A}_\gamma$: $\gamma\mapsto x_\gamma\in\mathcal{A}_\gamma$ for which $\gamma\mapsto\|x_\gamma\|$ is continuous, form a C^*-algebra, and it is shown[10] that, under the hypothesis that all x_γ are normal, the following continuity property holds: for each open $U\subset\mathbb{C}$, the set of $\gamma\in S^1$ for which $\sigma(x_\gamma)\cap U\neq\emptyset$ and the set of $\gamma\in S^1$ for which $\sigma(x_\gamma)\in U$ are both open. In the present case, $H(a,b,k)=H_\gamma(a(\gamma),b(\gamma),k)$, which depends on γ also through the relation between u and v, is a continuous section of self-adjoint elements provided we remove one point (let's say π) from S^1. We are forced to remove one point, because $H_\gamma(a(\gamma),b(\gamma),k)$ contains square roots of $q=e^{i\gamma}$. An immediate consequence of the above property is therefore that any continuous function E: $S^1\backslash\{\pi\}\to\mathbb{C}$ which satisfies $E(\gamma)\in\sigma(H_\gamma(a(\gamma),b(\gamma),k))$ on a dense subset of S^1 must already satisfy $E(\gamma)\in\sigma(H_\gamma(a(\gamma),b(\gamma),k))$ for all $\gamma\in S^1\backslash\{\pi\}$.

III. FACTORIZATION OF THE CHARACTERISTIC POLYNOMIAL

As already mentioned in the Introduction, if $k=1$, a different ansatz to determine the eigenvalues (8) of $H(a,b,k)$ is one for eigenfunctions of finite support in a Weyl–Schrödinger representation of $\mathcal{A}_\gamma$. Denoting by $H_\theta(a,b,k)$ the operator $H(a,b,k)$ acting in such a representation with angle θ, we have

$$H_\theta(a,b,k)\psi(m)=z_{m-1}\psi(m-1)+x_m\psi(m)+y_m\psi(m+1),$$

where

$$x_m=aq^{-m}e^{i\theta}+\overline{aq}^m e^{-i\theta}, \tag{16}$$

$$y_m=b+(kq^{-m-1/2}e^{i\theta}+\text{inv.}), \tag{17}$$

$$z_m=\overline{b}+(k^{-1}q^{-m-1/2}e^{i\theta}+\text{inv.}), \tag{18}$$

$x+\text{inv.}$ standing for $x+x^{-1}$ and θ labeling the representation. Note that $H_\theta(a,b,k)$ is self-adjoint only if $k\in\mathbb{R}$. We have required this above and in Ref. 5 for the definition of QP-integrals, but below we allow k to be complex.

Lemma 1: Let $\theta\in\mathbb{C}$ *and* $n\in\mathbb{N}$. *If* $k=-q^{(n-1)/2}e^{-i\theta}$ *and* $b=2\cos(n\gamma/2)$, *then* $y_{-1}=y_{n-1}=0$.

Proof: Setting $\kappa=kq^{1/2}e^{i\theta}$ one obtains that $y_{-1}=y_{n-1}=0$ is equivalent to $-b=\kappa+\kappa^{-1}=\kappa q^{-n}+\kappa^{-1}q^{n}$. This, in turn, is equivalent to $\kappa=\epsilon q^{n/2}$ and $b=-\epsilon 2\cos(n\gamma/2)$, $\epsilon=\pm 1$, the statement of the lemma being one choice of sign. q.e.d.

In view of the above lemma we shall from now on restrict the parameter b to be

$$b=2\cos\frac{n\gamma}{2}.$$

Let P_n be the orthogonal projection onto the subspace of $\ell^2(\mathbb{Z})$ of all wave functions which vanish outside $\{0,...,n-1\}$. The operator

$$A_\theta(z,n,k):=P_n\tilde{H}_\theta(z,n,k)P_n$$

has, when restricted to the image of P_n, (tridiagonal) matrix representation

$$A_\theta(z,n,k)=\begin{pmatrix} x_0 & y_0 & & & \\ z_0 & x_1 & y_1 & & \\ & \ddots & \ddots & \ddots & \\ & & & z_{n-2} & x_{n-1} \end{pmatrix}.$$

The following result was also obtained in Ref. 5.

Theorem 2: *If* $k=1$ *and* $\theta=\pi+[(n-1)/2]\gamma$, *then the eigenvalues of* $\tilde{A}(z,n,1)$ *coincide with those eigenvalues of* $H_\theta(z,n,1)$ *whose corresponding eigenvectors vanish outside* $\{0,...,n-1\}\subset\mathbb{Z}$.

Proof: If $k=1$ and $\theta=\pi+[(n-1)/2]\gamma$, then $\tilde{A}(z,n,k)=A_\theta(z,n,k)$ and $y_{-1}=y_{n-1}=0$ and $y_j=z_j$. This implies that $H_{\pi+[(n-1)/2]\gamma}(z,n,1)$ commutes with P_n from which the statement follows. q.e.d.

Let

$$\tilde{\mathcal{B}}(z,n,k):=\left\{(\zeta_1,\zeta_2)\in\mathbb{C}\times\mathbb{C}\,\middle|\,\zeta_2=-z^N\frac{(-1)^{Mn}\zeta_1-(-1)^{M+N}k^N}{1-(-1)^{M(n-1)+N}\zeta_1k^N}\right\} \tag{19}$$

and

$$\mathcal{B}(z,n,k):=\{(\theta,\varphi)\in S^1\times S^1|(e^{iN\theta},e^{i\varphi})\in\tilde{\mathcal{B}}\}. \tag{20}$$

In Ref. 5 it was shown that $\mathcal{B}(z,n,k)$ furnishes, for stictly positive k and $|z|=1$, the set of labels (Bloch parameters) for the irreducible representations of $\mathcal{A}_\gamma$ in which the Bethe ansatz eigenvalues (8) are spectral values of $\tilde{H}_{(\theta,\varphi)}(z,n,k)$. The following lemma, which follows for stictly positive k and $|\zeta_1|=|\zeta_2|=|z|=1$ from that result, is straightforwardly verified:

Lemma 2: The off-set function $\tilde{h}(z,n,k;\zeta_1,\zeta_2)$ *is for* $z+z^{-1}\in\mathbb{R}$, *nonzero* $k\in\mathbb{C}$, *and* $n\in\mathbb{N}$ *constant on* $\tilde{\mathcal{B}}(z,n,k)$.

In the irreducible representation of $\mathcal{A}_{2\pi M/N}$ labeled by (θ,φ), $\tilde{H}(z,n,k)$ is represented by the matrix (tridiagonal apart from the entries in the corners)

$$\tilde{H}_{(\theta,\varphi)}(z,n,k)=\begin{pmatrix} x_0 & y_0 & & & z_{-1}e^{-i\varphi} \\ z_0 & x_1 & y_1 & & \\ & \ddots & \ddots & \ddots & \\ y_{-1}e^{i\varphi} & & & z_{N-2} & x_{N-1} \end{pmatrix}.$$

Theorem 3: *Let* $z+z^{-1}\in\mathbb{R}$ *and, for* $\gamma/2\pi=M/N$, $(M,N)=1$,

$$\chi(z,n,k,E):=p\left(z+z^{-1},2\cos\frac{n\gamma}{2},k;E\right)+h(z,n,k;\zeta_1,\zeta_2),$$

where $(\zeta_1,\zeta_2)\in\tilde{\mathcal{B}}(z,n,k)$. *Then*

$$\chi(z,n,k,E)=\det(\tilde{A}(z,n,k)-E)\det(\tilde{B}(z,n,k)-E), \tag{21}$$

where

$$\tilde{B}(z,n,k):=\begin{pmatrix}\tilde{x}_n & \tilde{y}_n & & & \\ \tilde{z}_n & \tilde{x}_{n+1} & \tilde{y}_{n+1} & & \\ & \ddots & \ddots & \ddots & \\ & & & \tilde{z}_{N-2} & \tilde{x}_{N-1}\end{pmatrix}.$$

In particular, the eigenvalues of $\tilde{A}(z,n,k)$ *are, even for arbitary* $\gamma/2\pi$, *spectral values of* $\tilde{H}(z,n,k)$, *their corresponding (generalized) eigenvectors occurring in irreducible representations which, for* $\gamma/2\pi=M/N$, $(M,N)=1$, *have Bloch parameters in* $\mathcal{B}(z,n,k)$.

Proof: Consider first the rational case $\gamma/2\pi=M/N$, $(M,N)=1$, in which $\chi(z,n,k,E)$ is the characteristic polynomial of $\tilde{H}_{(\theta,\varphi)}(z,n,k)$ with $(\theta,\varphi)\in\mathcal{B}(z,n,k)$. Since $\chi(z,n,k,E)$ is independent on the value of $(e^{iN\theta},e^{i\varphi})$ as long as the latter belongs to $\tilde{\mathcal{B}}(z,n,k)$, we may consider complex $k\neq 0$ and complex θ such that $k=-q^{(n-1)/2}e^{-i\theta}$. Then, using Lemma 1, the characteristic polynomial can be written as

$$\chi(z,n,k,E)=\det(A_\theta(z,n,k)-E)\det(B_\theta(z,n,k)-E)-(-1)^N e^{-i\varphi}\prod_{j=0}^{N-1} z_j,$$

where $B_\theta(z,n,k):=(1-P_n)\tilde{H}_{(\theta,\varphi)}(z,n,k)(1-P_n)$ and $(e^{iN\theta},e^{i\varphi})\in\tilde{\mathcal{B}}(z,n,k)$. (Here P_n has to be understood as the projection onto the first n components of the vectors in $\mathbb{C}^N$.) But $(e^{iN\theta},e^{i\varphi})\in\tilde{\mathcal{B}}(z,n,k)$ implies

$$e^{-i\varphi}=-z^{-N}\frac{1-(-1)^{M(n-1)+N}e^{iN\theta}(-e^{-i\theta}q^{(n-1)/2})^N}{(-1)^{Mn}e^{iN\theta}-(-1)^{M+N}(-e^{-i\theta}q^{(n-1)/2})^N}=0.$$

Furthermore, at the above value for θ we have $A_\theta(z,n,k)=\tilde{A}(z,n,k)$ and $B_\theta(z,n,k)=\tilde{B}(z,n,k)$. This proves Eq. (21). Thus all eigenvalues of $\tilde{A}(z,n,k)$ are spectral values of $\tilde{H}(z,n,k)$, at least if $\gamma/2\pi$ is rational. By the continuity property of the spectrum with respect to γ, which we mentioned in the last section, this is also the case for irrational $\gamma/2\pi$. q.e.d.

IV. COMPARISON WITH BETHE ANSATZ EIGENVALUES

As mentioned in the Introduction, the algebraic Bethe ansatz can be used to determine exact spectral values of $\tilde{H}(z,n,k)$ as well. In this section we argue that the spectral values determined in Sec. III contain the Bethe ansatz eigenvalues, the argumentation being based on natural continuity assumptions which we cannot prove yet. Much of the work has already been done, because Theorem 3 states in particular that the Bloch parameters, which label, for rational flux, the irreducible representations in which spectral values of $\tilde{H}(z,n,k)$ coincide with the eigenvalues of $\tilde{A}(z,n,k)$, belong to $\mathcal{B}(z,n,k)$. On the other hand, it has been shown in Ref. 5 that the Bethe ansatz eigenvalues (8) are spectral values of $\tilde{H}(z,n,k)$ in these representations as well. Therefore, to assert our claim in the rational case we just need to show that the spectral values of $\tilde{H}(z,n,k)$ coinciding with the eigenvalues of $\tilde{A}(z,n,k)$ on the one hand and its Bethe ansatz eigenvalues on the other belong to the same h-bands. By an h-band we mean the closure of a connected component of $p^{-1}((h_{\min},h_{\max}))$, the preimage under p understood as a polynomial in E [i.e., $p(E) = p(z+z^{-1},2\cos n\gamma/2,k;E)$] of the open interval $(h_{\min},h_{\max})$, $h_{\min}$ and $h_{\max}$ denoting the absolute minimum and maximum, respectively, of the off-set function as a function of (θ,φ). The strategy is to show this for $k=1$ by comparison of the eigenfunctions, and then to extend this result to arbitrary $k\neq 0$ by topological arguments assuming continuity.

A detailed derivation of the Bethe ansatz for the discrete sine–Gordon model and the quantum pendulum goes beyond the scope of this article, so we give only a very short description and refer the reader to the original literature[11,12,1,4] and to Ref. 5 for more information on that subject. We use mainly the notation of Ref. 5.

Doubly discrete Minkowski space–time in 1+1 dimensions is modeled by $\mathbb{Z}^2$ as a light cone lattice. This means that the two elements of its standard base, here denoted by e_l and e_r, point in left and in right moving directions of the light cone, respectively. Quantum fields of the (doubly) discrete sine–Gordon model are fields on that lattice whose values are unitary operators $Q(n)$, $n\in\mathbb{Z}^2$, which commute exept if they are neighbors on the light cone, namely in this case

$$Q(n+e_r)Q(n)=q^{-1}Q(n)Q(n+e_r),$$

$$Q(n+e_l)Q(n)=q^{-1}Q(n)Q(n+e_l).$$

Here $q=e^{i\gamma}$, where γ is a real number proportional to Planck's constant. Moreover, the fields are subject to the field equation

$$Q_{n+e_r+e_l}=\frac{k+q^{1/2}Q_{n+e_l}}{1+q^{1/2}kQ_{n+e_l}}\,\frac{k+q^{1/2}Q_{n+e_r}}{1+q^{1/2}kQ_{n+e_r}}\,Q_n^{-1}, \tag{22}$$

the discrete equation of motion. The strictly positive real number k is a parameter of the model. In particular, the quantum fields on all of the light cone lattice are uniquely determined by their values on the set $\{n\in\mathbb{Z}^2|n_1-n_2\in\{0,1\}\}$, a so-called Cauchy zig-zag. The discrete quantum pendulum arrises upon taking specific periodic boundary conditions (periodic in space). First, let us take two-periodic boundary conditions, i.e., $Q(n+2(e_r-e_l))=Q(n)$. This then implies that

$$z(n)\coloneqq Q(n)Q(n+e_r-e_l)^{-1}$$

is a unitary which commutes with all Q's. Furthermore, the $z(n)$ are invariant under time evolution. Thus the (operator-valued) degrees of freedom of the discrete sine–Gordon model which is two-periodic in space may be taken to be $\{Q(0),Q(e_l),z(0),z(e_l)\}$, in particular they generate the C^*-algebra $\mathcal{C}\coloneqq\mathcal{A}_\gamma\otimes\mathcal{C}(S^1\times S^1)$, and time evolution is given by an automorphism of $\mathcal{A}_\gamma$ extended trivially on the second factor in the tensor product. Second, fixing eigenvalues for $z(0)$ and $z(e_l)$ amounts to taking boundary conditions which make the periodicity even shorter (as short as possible), periodicity being understood here as one up to an alternating phase. The discrete quantum pendulum is the discrete sine–Gordon model with such boundary conditions but with an additional symmetry requirement that both eigenvalues are equal. How do we obtain integrals of motion for these models?

The answer to this question is based on the observation that the fields of the discrete sine–Gordon model are the gauge-invariant and spectral-parameter-independent part of a larger field algebra in which a field is assigned to each edge of the light cone lattice (or strictly speaking its dual) and the values of the field are 2×2 matrices: An edge is simply a link between n and $n+e_l$ or between n and $n+e_r$. The equivalent of a Cauchy zig-zag is therefore a sequence of edges which are every other time parallel to e_l or to e_r, respectively. Indexing these edges by integer numbers so that the sth edge is parallel to e_r if s is odd and parallel to e_l if s is even, the value of the above-mentioned field on edge s is given by

$$\mathcal{V}_s(\eta)=\begin{pmatrix} \hat{u}_s & -\eta^{1/2}k^{(-1)^s/2}\hat{v}_s^{-1} \\ \eta^{1/2}k^{(-1)^s/2}\hat{v}_s & \hat{u}_s^{-1} \end{pmatrix},$$

where $\hat{u}_s$ and $\hat{v}_s$ are unitaries satisfying $\hat{u}_s\hat{v}_s=q^{-1/2}\hat{v}_s\hat{u}_s$, i.e., generating $\mathcal{A}_{\gamma/2}$, and η is a spectral parameter. Such a matrix is called Volterra L matrix,[11] in fact, the discrete Volterra model and the discrete sine–Gordon model are related by a simple coordinate transformation. The above-mentioned sine–Gordon fields on the Cauchy zig-zag are quartic expressions in the $\hat{u}_s$ and $\hat{v}_s$ which are independent of η and their time evolution follows from a quantum analog of a zero curvature condition stated in terms of the Volterra matrices. We do not repeat the formulas here, but refer the reader to Ref. 5. The use of that formulation is that for $2p$-periodic boundary conditions (in space, i.e., there are $2p$ independent edges in the Cauchy zig-zag), the matrix trace of the monodromy matrix $\mathcal{M}(\eta)=\mathcal{V}_{2p}(\eta)\cdots\mathcal{V}_1(\eta)$ is conserved under time evolution and therefore are the coefficients of its expansion in the spectral parameter integrals of motion. In the case of the sine–Gordon model with periodicity 2 in space there are four edges in a Cauchy zig-zag, i.e., $p=2$. In that case, the relation between the sine–Gordon variables and the entries of the four Volterra L matrices is

$$Q(0)=\hat{u}_3^{-1}\hat{u}_2^{-1}\hat{v}_3^{-1}\hat{v}_2,\quad Q(e_l)=\hat{u}_2^{-1}\hat{u}_1^{-1}\hat{v}_2^{-1}\hat{v}_1,$$

$$Q(e_r)=\hat{u}_4\hat{u}_3\hat{v}_4\hat{v}_3^{-1},\quad Q(e_r-e_l)=\hat{u}_1\hat{u}_4\hat{v}_1\hat{v}_4^{-1}.$$

We now describe the monodromy matrix in this case in detail.

Its diagonal elements turn out to depend only on the sine–Gordon variables $\{Q(0),Q(e_l),z(0),z(e_l)\}$, and moreover $\mathcal{M}_{22}(\eta)^*=\mathcal{M}_{11}(\eta)$, where we treat the spectral paramater as a variable which is independent under the $*$-operation. Expansion in the spectral parameter results in

$$\mathcal{M}_{11}(\eta)=A^{(0)}-\eta A^{(1)}+\eta^2A^{(2)},$$

where $A^{(2)}$ is a unitary depending on $z(0)$, $z(e_l)$ which is the identity if $z(0)=z(e_l)$,

$$A^{(0)}=w^2A^{(2)}$$

with another unitary w depending on $z(0)$, $z(e_l)$, and

$$A^{(1)}+A^{(1)*}=H(wA^{(2)}+(wA^{(2)})^*,w+w^*,k).$$

(The precise form of $A^{(1)}$ is not of importance here.) $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,k)$, which is (1) with operator-valued a and b (and real k), should now be understood as an element of $\mathcal{C}$. The unitaries u and v of (1) are, up to factors depending on $z(0)$, $z(e_l)$, equal to $Q(e_l)^{-1}$ and $Q(0)^{-1}$, respectively. This change of variables is convenient for what follows; its precise form a bit cumbersome but straightforward and we supress it here. It can be found in Ref. 5. To summarize, there are three integrals of motion for the discrete sine–Gordon model with periodicity 2 in space, namely $A^{(0)}+A^{(0)*}$, $A^{(1)}+A^{(1)*}$, and $A^{(2)}+A^{(2)*}$. The spectra of $A^{(0)}$ and of $A^{(2)}$ are both $\{z\in\mathbb{C}||z|=1\}$ and describe the possible shortest boundary conditions. The remaining task is to determine the spectrum of $A^{(1)}+A^{(1)*}$. This can be partly achieved by the algebraic Bethe ansatz for which we need to know also the off-diagonal entries of the monodromy matrix.

The off-diagonal entries satisfy $\mathcal{M}_{21}(\eta)^*=-\mathcal{M}_{12}(\eta)$, and one may write

$$\mathcal{M}_{21}(\eta)=SC(\eta)$$

where $C(\eta)\in\mathcal{C}$ and $\mathcal{S}$ is a unitary element which satisfies the following relations with the generators of $\mathcal{C}$:

$$A^{(2)}S=q^{1/2}SA^{(2)}, \tag{23}$$

$$wS=q^{-1/2}Sw, \tag{24}$$

$$uS=q^{1/2}Su, \tag{25}$$

$$vS=qSv. \tag{26}$$

Expansion of $C(\eta)$ in powers of the spectral parameter results in

$$C(\eta)=\eta^{1/2}(C^{(1/2)}-\eta C^{(3/2)})$$

with

$$C^{(1/2)}=q^{-1/2}((k^{-1/2}+k^{1/2}q^{-1/2}wu^*)w^2A^{(2)}+(k^{-1/2}u^*+k^{1/2}q^{1/2}w)v),$$

$$C^{(3/2)}=q^{-3/2}wu^*((k^{-1/2}+k^{1/2}q^{-1/2}wu^*)qA^{(2)}+(k^{-1/2}u^*+k^{1/2}q^{1/2}w)v).$$

In distinction to Ref. 5 we have formulated here the operators in terms of the generators of $\mathcal{C}$ and, as above, written u and v for P_1 and P_2, respectively. What should be kept in mind is that $C(\eta)$ has the form

$$C(\eta)=f_1(u,w,A^{(2)},\eta)+f_2(u,w,A^{(2)},\eta)v \tag{27}$$

with two continuous functions f_1 and f_2.

The starting point of the algebraic Bethe ansatz is the construction of a so-called Bethe ansatz ground state, which is a null vector of $\mathcal{M}_{21}(\eta)$. One proceeds to construct ''excited'' states by applying the ''ladder operator'' $\mathcal{M}_{12}(\eta)$ one or several times. A Yang-Baxter equation gives rise to a commutation relation between the trace $\mathcal{M}_{11}(\eta)+\mathcal{M}_{22}(\eta)$ and $\mathcal{M}_{12}(\eta)$ which may be used to determine more eigenvalues of the trace in a purely algebraic way, i.e., just upon using these relations. Their corresponding eigenvectors arise upon application of products like $\mathcal{M}_{12}(\eta_1)\cdots\mathcal{M}_{12}(\eta_n)$ to the Bethe ansatz ground state; however, due to the nature of the above commutation relations, only with a special choice of spectral parameters $\eta_1,\ldots,\eta_n$. The system of equations which determines these spectral values is called Bethe ansatz equations. For the present case, the Bethe ansatz equations and Bethe ansatz eigenvalues are stated in Theorem 1.

A. Bethe ansatz ground state

The Bethe ansatz ground state is a null vector Ω of $\mathcal{M}_{21}(\eta)$ and therefore a solution of the two equations

$$((k^{-1/2}+k^{1/2}q^{-1/2}wu^*)w^2A^{(2)}+(k^{-1/2}u^*+k^{1/2}q^{1/2}w)v)\Omega=0, \tag{28}$$

$$(w^2-q)A^{(2)}\Omega=0. \tag{29}$$

To solve for such a null vector one has to choose a representation for $\mathcal{C}$. But since w is central in $\mathcal{C}$, we may as well take a representation of the quotient algebra which is $\mathcal{C}$ modulo the ideal generated by the element w^2-q. We choose a representation with representation space $\ell^2(\mathbb{Z})$, labeled by two angles θ and δ:

$$u\cdot\phi(n)=e^{i\theta}q^{-n}\phi(n), \tag{30}$$

$$v\cdot\phi(n)=\phi(n-1), \tag{31}$$

$$A^{(2)}\cdot\phi(n)=q^{-1/2}e^{i\delta}\phi(n). \tag{32}$$

Note that this representation extends the Weyl–Schrödinger representation for the algebra generated by u and v. Upon substituting $q^{1/2}$ for w, Eq. (28) looks in the above representation, where Ω is a function over $\mathbb{Z}$, like

$$(k^{-1/2}+k^{1/2}e^{-i\theta}q^n)q^{1/2}e^{i\delta}\Omega(n)+(k^{-1/2}e^{-i\theta}q^n+k^{1/2}q)\Omega(n-1)=0. \tag{33}$$

To solve (33) there are two cases to distinguish. The first case is that, for all $n\in\mathbb{Z}$, $ke^{\pm i\theta}q^n\neq -1$ (we require real k here). Equation (33) gives then rise to a recursion relation for Ω which can easily be solved. If $\gamma/2\pi=M/N$, then the solution of this recursion relation is N-periodic up to a phase and vanishes nowhere. For general $\gamma/2\pi$ one finds that

$$\left|\frac{\Omega(m)}{\Omega(0)}\right|=\left|\frac{k+e^{i\theta}}{k+e^{i\theta}q^m}\right|,$$

from which we see that, for $k\neq 1$, Ω is what is called an extended state, it is bounded but it does not decay at infinity. Moreover, (33) gives rise to the equation for the Bloch parameters (θ,φ) at which, for rational flux, the Bethe ansatz eigenvalue corresponding to the ground state exists, or, stated differently, which label the irreducible representations in which Ω decomposes. It is that consideration–it has been carried out in a slightly different representation in Ref. 5—which leads to the result mentioned earlier, namely that for rational flux, the Bethe ansatz eigenvalues (8) occurr in irreducible representations which are labeled by $(\theta,\varphi)\in\mathcal{B}(e^{i\delta},n,k)$.

The other case, $k=1$ and $\theta=\pi$, is of even more importance in this section. In that case $\Omega(n)=\delta_{n0}$ is a solution of (33), where δ_{mn} is the Kronecker symbol, $\delta_{mn}=1$ if $n=m$, and 0 otherwise.

B. ''Excited'' Bethe ansatz eigenstates

Since $w+w^*$ and $wA^{(2)}+(wA^{(2)})^*$ are central elements in $\mathcal{C}$, they act as scalar operators in irreducible representations of $\mathcal{C}$. We mentioned already that these scalars are integrals of motion which define boundary conditions. They may also be interpreted as quantum numbers which label a super selection sector of the two-periodic sine–Gordon model. Since the ''ladder'' operator $\mathcal{M}_{12}(\eta)$ has the form $\mathcal{M}_{12}(\eta)=-C^*(\eta)S^*$ and S does not commute with the elements of $\mathcal{C}$, it cannot be implemented as an operator in the above representation and its application to a state in a specific sector will change the sector. It is convenient to combine all these sectors into one large representation. As representation space we take $\mathcal{H}=\oplus_{n\in\mathbb{Z}}\mathcal{H}_n$, where each $\mathcal{H}_n$ is a copy of $\ell^2(\mathbb{Z})$ which is preserved by $\mathcal{C}$ and plays the role of a sector. Identifying $\mathcal{H}$ with $\ell^2(\mathbb{Z}^2)$ by denoting the component of $\Psi\in\mathcal{H}$ which belongs to $\mathcal{H}_n$ by $\Psi(\cdot,n)$ we represent the algebra generated by $\mathcal{C}$ and the element S as

$$u\cdot\Psi(n_1,n_2)=e^{i\vartheta}q^{n_2/2-n_1}\Psi(n_1,n_2), \tag{34}$$

$$v\cdot\Psi(n_1,n_2)=\Psi(n_1-1,n_2), \tag{35}$$

$$w\cdot\Psi(n_1,n_2)=q^{n_2/2}\Psi(n_1,n_2), \tag{36}$$

$$A^{(2)}\cdot\Psi(n_1,n_2)=e^{i\delta}q^{-n_2/2}\Psi(n_1,n_2), \tag{37}$$

$$S\cdot\Psi(n_1,n_2)=q^{-n_1}\Psi(n_1,n_2-1). \tag{38}$$

The angles ϑ and δ label the representation. It is straightforward to check that this definition is compatible with the relations among the elements of $\mathcal{C}$ and S.

Lemma 3: Consider the operator $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,1)$ *acting in the above representation with* $\vartheta=\pi-\gamma/2$. *It preserves the subspaces* $\mathcal{H}_n$ *and its restriction to* $\mathcal{H}_1$ *coincides with*

$\tilde{H}_\pi(e^{i\delta},1,1)$. *Moreover, a Bethe ansatz ground state for* $\tilde{H}_\pi(e^{i\delta},1,1)$ *may be identified with the vector* $\Omega(n_1,n_2)=\delta_{n_10}\delta_{n_21}$ *in* $\mathcal{H}$ *and any vector of the form* $\mathcal{M}_{12}(\eta_1)\cdots\mathcal{M}_{12}(\eta_{n-1})\Omega$ *vanishes outside the subset* $\{(0,n),\ldots,(n-1,n)\}\subset\mathbb{Z}^2$.

Proof: That $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,1)$ preserves $\mathcal{H}_n$ is straightforwardly verified. Its restriction to $\mathcal{H}_1$ clearly coincides with $\tilde{H}(e^{i\delta},1,1)$ acting in the Weyl–Schrödinger representation with angle $\theta=\vartheta+\gamma/2$. Hence, if $\vartheta=\pi-\gamma/2$, then $\Omega(n)=\delta_{n0}$ is a Bethe ansatz ground state for $\tilde{H}(e^{i\delta},1,1)$ in that Weyl–Schrödinger representation. In representation (34)–(38) Ω has to be identified with $\Omega(n_1,n_2)=\delta_{n_10}\delta_{n_21}$, i.e., it has support $\{(0,1)\}$. The lemma follows therefore from the special form (27) of $C(\eta)$ and Eqs. (35) and (38). q.e.d.

Now consider a Bethe ansatz eigenvector in the above representation on $\mathcal{H}$. It is a vector of the form $\mathcal{M}_{12}(\eta_1)\cdots\mathcal{M}_{12}(\eta_{n-1})\Omega$, $n\in\mathbb{N}$, ''excited'' when $n>1$, where $\eta_1,\ldots,\eta_{n-1}$ satisfy the Bethe ansatz equations (7). Although there are, in general, infinitely many such vectors for $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,k)$, their corresponding eigenvalues do not exhaust the spectrum of this operator. In particular, (36) and Lemma 3 imply that the eigenvalue of w on the above Bethe ansatz eigenvector $\mathcal{M}_{12}(\eta_1)\cdots\mathcal{M}_{12}(\eta_{n-1})\Omega$ has to be $q^{n/2}$. Thus, such a Bethe ansatz eigenvector is a (generalized) eigenvector of the restriction of $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,k)$ to $\mathcal{H}_n$, and this restriction coincides with the operator $H(2\cos\delta,2\cos(n\gamma/2),k)=\tilde{H}(e^{i\delta},n,k)$ acting in the Weyl–Schrödinger representation with angle $\theta+(n/2)\gamma$.

Theorem 4: *Suppose that there exist, an open interval I of the real line containing 1 and a neighborhood* $U\subset S^1$ *of* δ *such that the Bethe ansatz eigenvalues (8) depend continuously on k and* δ *when* (k,δ) *is varied inside* $I\times U$. *Then, for rational values of the flux, the Bethe ansatz eigenvalues (8) for* $\tilde{H}(e^{i\delta},n,k)$, $\delta\in S^1$, $n\in\mathbb{N}$, $k\in I$, *are eigenvalues of* $\tilde{A}(e^{i\delta},n,k)$.

Proof: First, let $k=1$ and consider $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,1)$ in a representation (34)–(38) with $\theta=\pi-\gamma/2$. Then, by the above lemma, Bethe ansatz eigenvectors of the form $\mathcal{M}_{12}(\eta_1)\cdots\mathcal{M}_{12}(\eta_{n-1})\Omega$ belong to $\mathcal{H}_n$ and have support contained in $\{(0,n),\ldots,(n-1,n)\}\subset\mathbb{Z}^2$. Restricting $H(wA^{(2)}+(wA^{(2)})^*,w+w^*,1)$ to $\mathcal{H}_n$ we obtain the operator $\tilde{H}(e^{i\delta},n,1)$ acting in the Weyl–Schrödinger representation with $\theta=\pi+[(n-1)/2]\gamma$, and we have just shown that the Bethe ansatz eigenvectors are among its eigenvectors belonging to the image of P_n. For $k=1$, the statement of the theorem follows therefore from Theorem 2. To extend this statement to $k\in I$ recall that we only have to show that the eigenvalues of which we want to show equality lie in the same h-bands. To see that this is the case, first note that the eigenvalues of $\tilde{A}(e^{i\delta},n,k)$ depend continuously on k and δ. By assumption, the Bethe ansatz eigenvalues depend continuously on (k,δ) when varied inside $I\times U$. Therefore, if the offset function does not have an absolute extremum at $(\theta,\varphi)\in\mathcal{B}(z,n,k)$, then the eigenvalues in question are spectral values in the interior of h-bands and hence cannot change bands under variation of k inside I. This is the case for an open dense set of values for δ. Using continuity in δ, the theorem follows. q.e.d.

Continuity of the Bethe ansatz eigenvalues in $\gamma\in S^1\backslash\{\pi\}$ would imply the above result to hold true for all values of γ.

V. CONCLUDING REMARKS

We have found n values in the spectrum of the operator $\tilde{H}(z,n,k)$ which are exact even for irrational flux and given evidence that these coincide with the eigenvalues obtained by the algebraic Bethe ansatz. Moreover, these spectral values depend analytically on the flux. Which role do they play for the model of our consideration? We conclude this article with two remarks which give partial answers to this question.

(1) We have seen that for $k\neq 1$ the Bethe ansatz ground state is an extended state. First results indicate that this remains true for the ''exited'' states as well. In fact, one can show that if $\gamma/2\pi$ is approximated by a sequence of rationals $(p_n/q_n)_n$ for which $\lim_{n\to\infty} q_n^2|\gamma/2\pi - p_n/q_n|=0$ (equivalently, its continued fraction expansion is unbounded), then $\Omega(n)$ is an almost periodic sequence provided $k\neq 1$. (The set of irrational numbers for which this is the case has full Lebesgue measure and is nowadays also referred to as Last-admissible numbers.)

From the specific form of the ''ladder'' operator $\mathcal{M}_{12}$ one sees that it acts on a state as a sum of two operators, one being multiplication by an almost periodic sequence and the other being the shift followed by multiplication with another almost periodic sequence. Hence, if a state is an almost periodic sequence, then its image under $\mathcal{M}_{12}$ is one, too. In particular, if the image does not vanish, then it is extended.

A similar phenomenon has been observed for tight binding models on codimension one quasicrystals[13] like the Fibonacci chain. Also there, exact spectral values could be obtained and their corresponding eigenstates are extended. Extended states are a peculiarity in these models in which, in general, an eigenstate is expected to be critical due to the self-similarity of the chain. The nature of the (generalized) eigenstates can be related to transport properties.[13]

(2) For the symmetric case of the QP-integral [i.e., $a=b=2\cos(n\gamma/2)$] at rational flux $\gamma/2\pi=M/N$ with $N\geqslant 2n$ it can be shown that the spectral values obtained in this article are points in the spectrum at which h-bands touch. This effect occurs also in Ref. 13. For $a\neq b$, however, we do not observe this band touching.

Exact ground state of several *N*-body problems with an *N*-body potential

Avinash Khare[a)]
Institute of Physics, Sachivalaya Marg, Bhubaneswar 751005, India

(Received 31 December 1997; accepted for publication 1 February 1999)

The exact (bosonic) ground state and a class of excited states are obtained for several Calogero-type *N*-body problems in *D* dimensions when the *N* bodies are also interacting via an *N*-body potential of the form $-e^2/\sqrt{\Sigma \mathbf{r}_i^2}$. © *1999 American Institute of Physics.* [S0022-2488(99)01505-4]

I. INTRODUCTION

Over the years, the exact solutions of *N*-body problems have attracted considerable attention because of their possible relevance in statistical mechanics as well as in atomic, nuclear, and gravitational many-body problems. Whereas the exact solution of several *N*-body problems in one dimension is known by now,[1,2] a class of exact solutions including the bosonic ground state have been obtained for several Calogero-type *N*-body problems in higher dimensions, when they are also interacting via an oscillator potential.[3–7] Clearly, it is of considerable interest to discover other *N*-body problems that are either completely solvable or for which at least the ground state is exactly known.

The purpose of this paper is to show that a class of exact solutions including the bosonic ground state of all the *N*-body problems in *D* dimensions discussed in Refs. 3–7 can also be obtained when the oscillator potential is replaced by an *N*-body potential of the form

$$V(\mathbf{r}_1,\mathbf{r}_2,\ldots,\mathbf{r}_N) = -\frac{e^2}{\sqrt{\Sigma_i \mathbf{r}_i^2}}. \tag{1}$$

We further show that one can also add an *N*-body potential of the form

$$V(\mathbf{r}_1,\mathbf{r}_2,\ldots,\mathbf{r}_N) = -\frac{\delta^2}{\Sigma_i \mathbf{r}_i^2}, \tag{2}$$

and the problem is still analytically solvable with that the degeneracy in the bound state spectrum being much reduced. In this context, we may add that recently we have obtained[8] a class of exact solutions of the *N*-anyon problem (in two dimensions) when they are interacting via the *N*-body potential (1). Furthermore, some time ago we also obtained the complete bound state spectrum of the *N*-particle problem in one dimension when they are interacting via a variant of the above potential.[9–11] Subsequently Gurappa *et al.*[12] showed that the complete bound state spectrum can also be obtained in one dimension when an *N*-body potential of the form $\beta^2/\Sigma_{i<j}(x_i-x_j)^2$ is added either to an oscillator or to a variant of the *N*-body potential (1).

Actually, the basic idea of this paper is quite elementary. There are several quantum mechanical *N*-body problems whose solution is ultimately reduced to solving the Schrödinger equation in an appropriate radial variable for the harmonic oscillator potential. These problems remain solvable if the oscillator potential is replaced by the ''Coulomb'' potential (1). Furthermore, both the oscillator and the Coulomb problem remain solvable with the addition of the ''centrifugal'' (in-

[a)]Electronic mail: khare@iopb.res.in

verse square) potential (2). Thus, what we are really showing in this paper is that this is exactly what happens in several N-body problems. These additional terms are susceptible of being interpreted as rather artificial many-body potentials in the original physical problem. The hope is that some of these new many-body problems may be of some applicative relevance.

The plan of the paper is as follows. In Sec. II we discuss the N-body Calogero–Marchioro[3] model in D dimensions[4] and show that one can analytically obtain some exact eigenstates, including the (bosonic) ground state when the N bodies are also interacting via the potential (1). In Sec. III we consider a model of Murthy *et al.*[5,6] in two dimensions and show that exact solutions with novel correlations can also be obtained when one replaces the oscillator potential by the potential (1). We also show that the corresponding two-body problem is completely solvable. In Sec. IV we consider a Calogero-type model in D dimensions[8] which has only two-body (and no three-body) interactions, and show that one can obtain some exact eigenstates including the (bosonic) ground state when the N bodies are interacting via the N-body potential (1). In all the above cases we also show that some exact states including the bosonic ground states can still be obtained analytically if one adds the N-body potential (2) to the N-body potential (1) (or to the oscillator potential), and that the degeneracy in the discrete spectrum is then much reduced.

II. CALOGERO–MARCHIORO MODEL WITH *N*-BODY POTENTIAL

A long time ago, in an effort to generalize the original Calogero model[2] to dimensions higher than one, Calogero and Marchioro[3] considered a model in three dimensions in which the N particles are interacting via two-body and the three-body inverse square interactions as well as by pairwise harmonic oscillator potentials, and obtained some exact eigenstates, including the bosonic ground state of the system. They also mentioned that these results could be easily extended to higher-dimensional spaces. This generalization was explicitly carried out by us recently,[4] and in the special case of two dimensions we were able to obtain all the correlation functions of a many-body theory by mapping the problem to complex random matrices. In particular, we considered the following N-body Hamiltonian in D-dimensions:

$$H=-\frac{\hbar^2}{2m}\sum_{i=1}^{N}\nabla_i^2+\frac{g\hbar^2}{2m}\sum_{i<j}\frac{1}{\mathbf{r}_{ij}^2}+\frac{G\hbar^2}{2m}\sum_{\substack{i,j,k\\ i\neq k,j\neq k}}\frac{\mathbf{r}_{ki}\cdot\mathbf{r}_{kj}}{\mathbf{r}_{ki}^2\mathbf{r}_{kj}^2}+\frac{m\omega^2}{4}\sum_{i}^{N}\mathbf{r}_i^2, \tag{3}$$

and obtained some eigenstates, including the bosonic ground state of the system provided G and g are related to each other [see Eq. (6) below]. Here $\mathbf{r}_i$ is the D-dimensional position vector of the ith particle and $\mathbf{r}_{ij}=\mathbf{r}_i-\mathbf{r}_j$ denotes the relative separation of the ith and jth particles while r_{ij} denotes its magnitude.

Let us consider the same many-body problem, as given by Eq. (3), but with the oscillator potential being replaced by the N-body potential (1). Throughout this paper, whenever we discuss the exact solutions with the N-body potential (1), we shall rescale all distances $\mathbf{r}_i\to\hbar^2\mathbf{r}_i/me^2$ and measure energy in units of $me^4/\hbar^2$ so that m, e, $\hbar$ are all scaled away. On the other hand, in the oscillator case we shall rescale all distances $\mathbf{r}_i\to\sqrt{\hbar/m\omega}\mathbf{r}$; and measure energy in units of $\hbar\omega$. On substituting the ansatz,

$$\psi=\left(\prod_{i<j}|\mathbf{r}_i-\mathbf{r}_j|^{\Lambda_D}\right)\phi(\rho) \tag{4}$$

in the Schrödinger equation, one obtains

$$\rho\phi''(\rho)+(2\Gamma_D+1)\phi'(\rho)+(2-2\rho|E|)\phi(\rho)=0. \tag{5}$$

Here Λ_D and Γ_D are given by

$$\Lambda_D\equiv\sqrt{G}=\tfrac{1}{2}[\sqrt{(D-2)^2+4g}-(D-2)], \tag{6}$$

$$\Gamma_D=\tfrac{1}{2}[DN-2+\Lambda_D N(N-1)], \tag{7}$$

while, here and always below,

$$\rho^2=\sum_i^N \mathbf{r}_i^2. \tag{8}$$

It is easily seen that the solution to this equation is

$$\phi(\rho)=\exp(-\sqrt{2|E|}\rho)L_{n_r}^{2\Gamma_D}(2\sqrt{2|E|}\rho), \tag{9}$$

with the corresponding energy eigenvalues being (in units of $me^4/\hbar^2$)

$$E_{n_r}=-\frac{1}{2(n_r+\Gamma_D+\frac{1}{2})^2}. \tag{10}$$

Several comments are in order at this stage.

(1) The exact solutions are obtained when G and g are related by Eq. (6). As $g\to 0$, we see from Eq. (6) that also $G\to 0$, and the wave function as given by Eqs. (4) and (9) becomes the ground state eigenfunction of the hyperspherical ''Coulomb problem'' in D dimensions without a centrifugal barrier and with Bose statistics. Thus, the situation is different from the one-dimensional problem,[2,10] where, as $g\to 0$, the eigenfunction is the ground state of the ''Coulomb problem,'' but with Fermi statistics. We shall see that in all the higher-dimensional many-body problems $(D>1)$, unlike in the one-dimensional case, as the coupling is switched off the eigenfunction corresponds to that of Bose statistics.

(2) The N-body problem is still solvable if, in addition to replacing the oscillator potential with the N-body potential (1), we also add the potential (2) to the Hamiltonian (3). In this case the ansatz (4) in the Schrödinger equation yields

$$\rho\phi''(\rho)+(2\Gamma_D+1)\phi'(\rho)+\left(2-\frac{\delta^2}{\rho}-2\rho|E|\right)\phi(\rho)=0, \tag{11}$$

so that the exact eigenstates are given by (in units of $me^4/\hbar^2$)

$$E_{n_r}=-\frac{1}{2(n_r+\gamma+\frac{1}{2})^2}, \tag{12}$$

$$\phi(\rho)=\rho^{(\gamma-\Gamma_D)}\exp(-\sqrt{2|E|}\rho)L_{n_r}^{2\gamma}(2\sqrt{2|E|}\rho), \tag{13}$$

where

$$\gamma=\sqrt{\Gamma_D^2+\delta^2}. \tag{14}$$

(3) In the same way, the N-body problem with the oscillator potential as given by Eq. (3) is also solvable if we add the N-body potential (2) to it. In particular, it is easily shown that the corresponding exact eigenstates are then

$$E_{n_r}=[2n_r+1+\gamma], \tag{15}$$

$$\psi_{n_r}=\left(\prod_{i<j}|\mathbf{r}_i-\mathbf{r}_j|^{\Lambda_D}\right)\exp\left(-\frac{1}{2}\rho^2\right)\rho^{(\gamma-\Gamma_D)}L_{n_r}^{\gamma}(\rho^2). \tag{16}$$

III. NOVEL CORRELATIONS WITH AN *N*-BODY POTENTIAL

In a recent paper, Murthy *et al.*[5,6] have proposed a model in two dimensions with two-body and three-body interactions. They were able to obtain the bosonic ground state and a class of excited states of the system by adding an external harmonic oscillator potential. The model was constructed in such a way that the solutions have a novel correlation of the form

$$X_{ij}=x_iy_j-x_jy_i \tag{17}$$

built into them. Note that X_{ij} is a pseudoscalar. Furthermore, unlike the Laughlin–Jastrow type of correlation, this correlation is not translationally invariant. We now show that the bosonic ground state and the radial excitations over it can also be obtained when the oscillator potential is replaced by the *N*-body potential (1). Furthermore, we also obtain the complete solution of the two-body problem. Notice that the two-body problem is nontrivial since the center of mass motion cannot be separated.

Following Murthy *et al.*,[5,6] we start with the *N*-particle Hamiltonian *H* (in the scaled variables), as given by

$$2H=-\sum_{i=1}^{N}\nabla_i^2+g_1\sum_{i\neq j}^{N}\frac{\mathbf{r}_j^2}{X_{ij}^2}+g_2\sum_{i\neq j\neq k}^{N}\frac{\mathbf{r}_j\cdot\mathbf{r}_k}{X_{ij}X_{ik}}-\frac{2}{\rho}, \tag{18}$$

where X_{ij} is given by Eq. (17) while g_1 and g_2 are the dimensionless coupling constants of the two-body and the three-body interactions, respectively. Note that this Hamiltonian differs from those considered in Refs. 5, 6 by the replacement of an external harmonic oscillator potential with the external *N*-body potential (1) [the last term on the rhs of Eq. (18)].

It is easily seen that

$$\psi_0(x_i,y_i)=\left(\prod_{i<j}^{N}|X_{ij}|^g\right)\exp(-\sqrt{2|E_0|}\rho) \tag{19}$$

is the exact ground state of this system with the corresponding ground-state energy being (in units of $me^4/\hbar^2$)

$$E_0=-\frac{1}{2[gN(N-1)+N-\frac{1}{2}]^2}, \tag{20}$$

provided g_1 and g_2 are related to g by

$$g_1=g(g-1),\quad g_2=g^2. \tag{21}$$

It may be noted that this ψ_0 is regular for $g\geqslant 0$ which implies that $g_1\geqslant -1/4$, $g_2\geqslant 0$. There is a neat way of proving that this is indeed the ground state, by using the method of operators.[13]

A. A class of excited states

As in the oscillator case, also in our case a class of excited states can be obtained analytically. To that end we consider the ansatz

$$\psi(x_i,y_i)=\left(\prod_{i<j}^{N}|X_{ij}|^g\right)\exp(-\alpha\rho)\phi(x_i,y_i). \tag{22}$$

On using Eqs. (18) and (22) it is easily seen that $\alpha^2=-2E$, while ϕ satisfies the eigenvalue equation

$$\left[-\frac{1}{2}\sum_i \nabla_i^2 + \frac{\alpha}{\rho}\sum_i \mathbf{r}_i\cdot\boldsymbol{\nabla}_i + \frac{A}{\rho} + g\sum_{i\neq j}\left(x_j\frac{\partial}{\partial y_i} - y_j\frac{\partial}{\partial x_i}\right)\right]\phi = 0, \tag{23}$$

where

$$A = \alpha[gN(N-1) + N - \tfrac{1}{2}] - 1. \tag{24}$$

It is worth remarking that ϕ is also an eigenstate of the total angular momentum operator i.e., $L\Phi = l\Phi$. One can now run through the steps of Ref. 5 and classify some exact solutions according to their angular momentum. In particular, one can show that one has a tower of excited states whose exact energy eigenvalues may be written in the form

$$E_{n_r,l} = -\frac{1}{2[n_r + gN(N-1) + N + |l| - \frac{1}{2}]^2}. \tag{25}$$

The existence of a tower is a general result applicable to all excited states of which the exact solutions shown above form a subset. This is easily proved by following the arguments given in Bhaduri *et al.*[6] Finally, the *N*-body problem is still solvable if we add the *N*-body potential (2) to the Hamiltonian (18).

B. The two-body problem: Complete solution

As in the oscillator case,[6] we now show that the two-body problem is integrable and exactly solvable when the two bodies are interacting via the *N*-body potential (1). Let us again emphasize that the two-body problem is nontrivial here since the center of mass cannot be separated.

The two-body Hamiltonian is given by [see Eq. (18)]

$$H = -\frac{1}{2}(\nabla_1^2 + \nabla_2^2) - \frac{1}{\sqrt{\mathbf{r}_1^2 + \mathbf{r}_2^2}} + \frac{g_1}{2}\frac{(\mathbf{r}_1^2 + \mathbf{r}_2^2)}{X^2}, \tag{26}$$

where $X = x_1y_2 - x_2y_1$. This two-body problem is best solved in the hyperspherical coordinates. To that end, let us parametrize the coordinates $\mathbf{r}_1$, $\mathbf{r}_2$ in terms of three angles and one length, (R,θ,ϕ,ψ).[14,15] In terms of the hyperspherical coordinates the Hamiltonian (26) is given by

$$H = -\frac{1}{2}\left[\frac{\partial^2}{\partial R^2} + \frac{3}{R}\frac{\partial}{\partial R} - \frac{\Lambda^2}{R^2} + \frac{2}{R}\right] + \frac{2g_1}{R^2\sin^2(2\theta)}, \tag{27}$$

where the operator Λ^2 is the Laplacian on the sphere S^3 and is given by

$$-\Lambda^2 = \frac{\partial}{\partial\theta^2} - \frac{2\sin(2\theta)}{\cos(2\theta)}\frac{\partial}{\partial\theta} + \frac{1}{\cos^2(2\theta)}\left[\frac{\partial^2}{\partial\phi^2} + 2\sin(2\theta)\frac{\partial^2}{\partial\phi\partial\psi} + \frac{\partial^2}{\partial\psi^2}\right]. \tag{28}$$

It is easily seen that if we write

$$\Psi(R,\theta,\phi,\psi) = F(R)\Phi(\theta,\phi,\psi), \tag{29}$$

then the eigenvalue equation $H\Psi = E\Psi$ separates into angular and radial equations. In particular, the angular equation is given by

$$\left[\Lambda^2 + \frac{4g_1}{\sin^2 2\theta}\right]\Phi = \beta(\beta+2)\Phi, \tag{30}$$

where $\beta \geqslant -1$, while the radial equation is given by

$$F''(R)+\frac{3}{R}F'(R)+\left(2E+\frac{2}{R}-\frac{\beta(\beta+2)}{R^2}\right)F(R)=0. \tag{31}$$

The radial equation is easily solved, yielding

$$F(R)=R^{\beta}\exp(-\sqrt{2|E|}R)M(a,b;2\sqrt{2|E|}R), \tag{32}$$

where $b=2\beta+3$, $a=\frac{3}{2}+\beta-1/\sqrt{2|E|}$, and $M(a,b;x)$ is the confluent hypergeometric function. Demanding $a=-n_r$, where n_r is a non-negative integer, yields the bound state energy eigenvalues

$$E=-\frac{1}{2(n_r+\beta+\frac{3}{2})^2}. \tag{33}$$

The tower structure of the eigenvalues built on the radial excitations of the ground state is obvious from this formula.

It must be emphasized here that β is still unknown and has to be obtained by solving the angular equation (30). We now note that the angular equation is, in fact, identical in the oscillator and our case, and it has been analyzed in great detail by Bhaduri *et al.*[6] We can therefore borrow their results and draw conclusions about the value of β and hence the spectrum, as given by Eq. (33).

IV. CALOGERO-TYPE MODELS IN HIGHER DIMENSIONS WITH *N*-BODY INTERACTION

In Sec II, we have considered one possible generalization of the Calogero-type models in higher dimensions. The key point there was to have a long-ranged three-body interaction term. This is in addition to the long-ranged two-body interaction term that is also present in one dimension. Only then was it possible to obtain a class of exact solutions including the bosonic ground state. Another possible generalization of the Calogero model to higher dimensions was considered recently by Ghosh.[7] In a remarkable paper[7] he introduced two models with purely two-body long-ranged interactions and in both cases he was able to obtain the exact bosonic ground state and radial excitations over it. In this section we show that the exact ground state and radial excitations over it can also be obtained if the oscillator potential in Ref. 7 is replaced by the N-body potential (1). Following Ghosh,[7] let us consider the Hamiltonian

$$H=-\frac{1}{2}\sum_{k=1}^{N}\nabla_k^2-\frac{1}{\rho}+V_1(\beta)+V_2(\beta)+W_3(\beta), \tag{34}$$

where

$$V_1(\beta)=\frac{\beta^2}{2}g(g-1)\sum_{k\neq j}\frac{|\mathbf{r}_k|^{2(\beta-1)}}{(|\mathbf{r}_k|^{\beta}-(|\mathbf{r}_j|^{\beta})^2},$$

$$V_2(\beta)=\frac{g\beta}{2}(D+\beta-2)\sum_{k\neq j}\frac{|\mathbf{r}_k|^{(\beta-2)}}{(|\mathbf{r}_k|^{\beta}-|\mathbf{r}_j|^{\beta})}, \tag{35}$$

$$W_3(\beta)=\frac{\beta^2}{2}g(g-1)\sum_{i\neq j\neq k}\frac{|\mathbf{r}_i|^{2(\beta-1)}}{(|\mathbf{r}_i|^{\beta}-|\mathbf{r}_j|^{\beta})(|\mathbf{r}_i|^{\beta}-|\mathbf{r}_k|^{\beta})},$$

with g a dimensionless constant. Note that for β=1 and β=2 the three-body interaction term W_3 vanishes. Also note that the Hamiltonian as given by Eq. (34) differs from Ref. 7 by the replacement of an external harmonic oscillator potential with the external N-body potential (1) [the second term on the rhs of (34)].

It is straightforward to obtain the bosonic ground state and the radial excitation spectrum over it. In particular, it is easily seen that the exact eigenfunctions are

$$\psi_{n_r}=\left(\prod_{i<j}(|\mathbf{r}_i|^\beta-|\mathbf{r}_j|^\beta)^g\right)M(a=-n_r,b;2\alpha\rho)\exp(-\sqrt{2|E|\rho}),\tag{36}$$

with the corresponding eigenvalues being

$$E_{n_r}=-\frac{1}{2\left[n_r+\frac{ND}{2}+\frac{g\beta}{2}N(N-1)-1\right]^2}.\tag{37}$$

Here $a=A/\alpha$, $b=2(A+1)/\alpha$ while $E=-\alpha^2/2$ and $A=\alpha[ND/2+g\beta N(N-1)/2-1]$. Similar exact solutions are also obtained if one adds the N-body potential (2) to the Hamiltonian (34).

V. SUMMARY AND OPEN PROBLEMS

In this paper, we have discussed several N-body problems in two and higher dimensions and in every case we have shown that if exact eigenstates including the N-boson ground state can be obtained when the N-particles are also interacting by an oscillator potential, then similar exact eigenstates can also be obtained when the oscillator potential is replaced by the ''Coulomblike'' N-body potential (1). Furthermore, we have shown that in both cases one can also add an inverse square N-body potential, and the problems are still analytically solvable while the degeneracy in the spectrum is much reduced. It is clearly of interest to examine other solvable many-body problems with an external harmonic oscillator potential and see if exact results can still be obtained with the replacement of the oscillator potential by the N-body potential (1).

In this paper we study the eigenvalue problems for the Ginzburg–Landau operator with a large parameter in bounded domains in $\mathbb{R}^2$ under gauge invariant boundary conditions. The estimates for the eigenvalues are obtained and the asymptotic behavior of the associated eigenfunctions is discussed. These results play a key role in estimating the critical magnetic field in the mathematical theory of superconductivity. © *1999 American Institute of Physics.* [S0022-2488(99)02806-6]

I. INTRODUCTION AND STATEMENT OF MAIN RESULTS

This paper is devoted to the asymptotic estimates, for large parameter σ, of the *first eigenvalue* $\mu(\sigma A)$ and the associated eigenfunctions of the *Ginzburg–Landau operator* $-\nabla^2_{\sigma A}$ in a smooth bounded domain Ω in $\mathbb{R}^2$. Given a real vector field $A=(A^1,A^2)$, the Ginzburg–Landau operator $-\nabla^2_A$ associated with A is defined by

$$-\nabla^2_A\psi=-\nabla_A\cdot(\nabla_A\psi)=-\nabla\psi+i[2A\cdot\nabla\psi+\psi\,\mathrm{div}\,A]+|A|^2\psi,$$

where $i=\sqrt{-1}$. We denote $\nabla_A\psi=\nabla\psi-i\psi A$, $\mathrm{curl}\,A=\partial_1A^2-\partial_2A^1$, and $\mathrm{curl}^2A=(\partial_2(\mathrm{curl}\,A),-\partial_1(\mathrm{curl}\,A))$, here $\partial_j=\partial/\partial x_j$.

Let $\mu=\mu(A)$ be the first eigenvalue of the following problem:

$$\begin{aligned}-\nabla^2_A\psi&=\mu\psi \quad \text{in } \Omega,\\ (\nabla_A\psi)\cdot\nu+\gamma\psi&=0 \quad \text{on } \partial\Omega,\end{aligned} \tag{1.1}$$

where ψ is a complex-valued function, ν is the unit outer normal to $\partial\Omega$, and $\gamma\geqslant 0$ is a given constant. Then,

$$\mu(A)=\inf_{\psi\in W^{1,2}(\Omega)}\frac{\int_\Omega|\nabla_A\psi|^2dx+\gamma\int_{\partial\Omega}|\psi|^2\,ds}{\int_\Omega|\psi|^2\,dx}. \tag{1.2}$$

It is well-known that the Ginzburg–Landau operator has the *gauge invariance* property

$$\nabla_{A+\nabla\chi}(e^{i\chi}\psi)=e^{i\chi}\nabla_A\psi,\quad \nabla^2_{A+\nabla\chi}(e^{i\chi}\psi)=e^{i\chi}\nabla^2_A\psi$$

for every real smooth function χ. The equation and the boundary condition in (1.1) as well as the functional in (1.2) are invariant under the gauge transformation $A\to A+\nabla_\chi$, $\psi\to e^{i\chi}\psi$. Therefore, $\mu(A+\nabla_\chi)=\mu(A)$. By a gauge transformation if necessary, we may assume

$$\mathrm{div}\,A=0 \quad \text{in } \Omega,\quad A\cdot\nu=0 \quad \text{on } \partial\Omega.$$

Our main result is the following

Theorem 1: *There exists a universal constant* β_0, $0<\beta_0<1$, *such that for all* $A\in C^2(\overline{\Omega})$

$$\lim_{\sigma\to\infty}\frac{\mu(\sigma A)}{|\sigma|}=\min\{\min_{x\in\Omega}|\mathrm{curl}\,A(x)|,\beta_0\min_{x\in\partial\Omega}|\mathrm{curl}\,A(x)|\}. \tag{1.3}$$

Remark 1.1: As a consequence of Theorem 1 we see that, if $\mathrm{curl}\,A(x)\equiv H$, *a nonzero constant, then*

$$\lim_{\sigma\to\infty}\frac{\mu(\sigma A)}{|\sigma|}=\beta_0|H|.$$

The universal constant β_0 stated in Theorem 1 is the number $\beta(1)$ given in Lemma 2.2. We have an estimate for β_0:

$$0.5<\beta_0<0.76,$$

see Ref. 1. It has been expected that $\beta_0\simeq 0.59$, see for instance Refs. 2 and 3. If $\mathrm{curl}\,A$ vanishes at some points, the estimates can be greatly improved, see Sec. VI. It is interesting to see that the distribution of minimum points of $|\mathrm{curl}\,A|$ determines the magnitude of $\mu(\sigma A)$ and the location of the concentration points of the eigenfunctions for large σ. This is partially due to the gauge invariance of the Ginzburg–Landau operator and due to the invariance of $\mathrm{curl}\,A$ under the gauge transformations.

To prove Theorem 1 we shall establish two estimates for $\mu(\sigma A)$, the upper bound estimate (given in Sec. VI) and the lower bound estimate (given in Sec. VII). The gauge invariance of the Ginzburg–Landau operator, the local decomposition formula of vector fields obtained in Sec. III, and the results obtained in Ref. 4 concerning the eigenvalue problems of Ginzburg–Landau operator in the entire plane and on the half plane will play essential roles to obtain these estimates. To derive the lower bound estimate we also need to show the local convergence, as $\sigma\to\infty$, of the rescaled eigenfunctions (after a series of gauge transformations). Since the eigenfunctions may concentrate either in the interior of Ω or at the boundary, both interior and boundary *a priori* estimates established in Secs. IV and V are needed to obtain the local convergence. We mention that most of the estimates given in this paper are gauge invariant. As a by-product, the asymptotic behavior of the eigenfunctions as σ goes to ∞ will also be obtained.

The technical difficulty in our problem comes from the boundary effects, which is our main concern in this paper. One may see in Sec. VI that when the eigenfunctions concentrate in the interior of Ω, the limiting equation obtained after rescaling is an eigenvalue problem in the entire plane $\mathbb{R}^2$, see (2.3). All the eigenvalues of (2.3) have been obtained in Ref. 4. However, when the concentration happens at the boundary, very technical analyses are required to get the boundary estimates and to prove the local convergence of the rescaled eigenfunctions near the boundary. In this case, the limiting equation is an eigenvalue problem in the half plane $\partial\mathbb{R}^2_+$, see (2.5). The first eigenvalue $\beta(h)$ of (2.5) was obtained in Ref. 4 after lengthy analyses, which is the difficult part of Ref. 4. Comparing Lemma 2.1 with Lemma 2.2 in Sec. II, one may see the significant difference between the problems in the domain without or with boundary.

The motivation to study such type eigenvalue problems is to estimate the value of the upper critical magnetic field at which superconductivity can nucleate.

In the mathematical theory of superconductivity, the following Ginzburg–Landau equation for (ψ, A) was proposed as a macroscopic model (see Ref. 5)

$$\begin{aligned}-\nabla^2_{\kappa A}\psi&=\kappa^2(1-|\psi|^2)\psi,\\ \mathrm{curl}^2 A&=-\frac{i}{2\kappa}(\overline{\psi}\nabla\psi-\psi\nabla\overline{\psi})-|\psi|^2A+\mathrm{curl}\,H\quad\text{in}\ \ \Omega.\end{aligned} \tag{1.4}$$

Here Ω is the region occupied by the superconducting specimen, ψ is a complex-valued function called *order parameter*, A is a real vector field called *magnetic potential*, H is the applied magnetic field, κ is the so-called *Ginzburg–Landau parameter*. The natural boundary conditions for a superconductor-other material junction are (see Ref. 6)

$$(\nabla_{\kappa A}\psi)\cdot\nu+\gamma\psi=0, \quad (\mathrm{curl}\,A-H)\times\nu=0 \quad \text{on } \partial\Omega, \tag{1.5}$$

where ν is the unit out-normal vector at the boundary of Ω and γ is a positive constant.

It is well-known that a superconductor placed in an applied magnetic field may change its phase when the field varies. Consider a *spatially homogeneous field*. If the field is sufficiently strong, it penetrates through the entire sample and the superconductor is in a normal state. As the field is gradually reduced to a certain value H_{C_3} called the *upper critical field*, the nucleation of superconductivity at surface occurs. If the field is further reduced to another value H_{C_2}, the nucleation in the interior occurs. It is important in both theory and applications to estimate the values of the critical fields, especially for type 2 superconductors with large value of κ.

The physicists Saint-James and De Gennes were the first to study the surface nucleation phenomenon for semi-infinite superconductor occupying the half space (see Ref. 2). The most amazing result they obtained was the relation $H_{C_3}/H_{C_2}=1/0.59$. The argument for this relation was nontrivial, even though they studied only the superconductor which occupies the half space and is subjected to a *spatially homogeneous* applied magnetic field.

We have been interested in estimating the value of the upper critical field for superconducting specimen occupying an *arbitrary* bounded smooth domain. In Ref. 1, to get such estimate, we considered the applied field having the form $H=\sigma H_0$ and estimated the maximal value of σ, say σ^*, so that under the applied field $\sigma^* H_0$ the nucleation of superconductivity occurs. Choosing a vector field F so that $\mathrm{curl}\,F=H_0$, we found that when κ is large, the value of σ^* is close to the number σ_* for which $\mu(\sigma_*\kappa F)=\kappa^2$. This led us to study the asymptotic estimates of $\mu(\sigma F)$ for large value of σ. In Ref. 1, by using the results in this paper, we obtained the asymptotic estimate for H_{C_3} for large κ and the location of nucleation of superconductivity.

There have been many recent works on the mathematical theory of superconductivity, see Refs. 3, 7–19, and the references therein. The works[3] by Chapman,[7] by Bauman, Phillips, and Tang, and by Bernoff and Sternberg[10] are closely related to our present paper, while Refs. 7 and 10 were found after this work had been completed. In Ref. 3, Chapman studied the half-plane problem on H_{C_3} by using formal mathematical analysis. In Ref. 7, Bauman, Phillips, and Tang rigorously estimated H_{C_3} and found the location of nucleation for a sample occupying a cylinder with two-dimensional cross section consisting of a disk. The sample is adjacent to a vacuum and is subject to a homogeneous applied magnetic field pointing in the axial direction. From the bifurcation point of view, they studied small solutions bifurcating from the eigenfunctions. In Ref. 10, Bernoff and Sternberg considered a sample occupying an infinite cylinder with two-dimensional cross section consisting of an arbitrary simply connected smooth bounded region in $\mathbb{R}^2$. The sample is adjacent to a vacuum and is subject to a homogeneous applied magnetic field pointing in the axial direction. They estimated H_{C_3} and found the location of nucleation by using formal asymptotic expansions. In this paper we study eigenvalue problems in bounded smooth domains with nonhomogeneous applied magnetic fields under the boundary conditions for a superconductor–other material junction. The result obtained in this paper was used in Ref. 1 to obtain rigorously estimates for H_{C_3} and locations of nucleation for a cylindrical sample which is placed in an applied magnetic field being parallel to the lateral surface but not necessarily spatially homogeneous and is adjacent to other material.

II. PRELIMINARIES

In this section we give some basic lemmas which will be used later to establish our main result. Throughout this paper, we let

$$\omega(x)=\tfrac{1}{2}(-x_2,x_1). \tag{2.1}$$

Note that $\operatorname{curl}\omega=1$ and $\operatorname{div}\omega=0$. Denote, for a nonzero real number h,

$$\alpha(h)=\inf_{\psi\in\mathcal{W}(\mathbb{R}^2)}\frac{\int_{\mathbb{R}^2}|\nabla_{h\omega}\psi|^2\,dx}{\int_{\mathbb{R}^2}|\psi|^2\,dx}, \tag{2.2}$$

where $\mathcal{W}(\mathbb{R}^2)=W^{1,2}_{\mathrm{loc}}(\mathbb{R}^2)\cap L^2(\mathbb{R}^2)$. Clearly, the minimizers are the L^2 eigenfunctions of the following problem associated with $\alpha=\alpha(h)$:

$$-\nabla^2_{h\omega}\psi=\alpha\psi \quad \text{in } \mathbb{R}^2. \tag{2.3}$$

Let

$$\beta(h)=\inf_{\psi\in\mathcal{W}(\mathbb{R}^2_+)}\frac{\int_{\mathbb{R}^2_+}|\nabla_{h\omega}\psi|^2\,dx}{\int_{\mathbb{R}^2_+}|\psi|^2\,dx}, \tag{2.4}$$

where $\mathcal{W}(\mathbb{R}^2_+)=W^{1,2}_{\mathrm{loc}}(\mathbb{R}^2_+)\cap L^2(\mathbb{R}^2_+)$. The associated eigenvalue problem is

$$\begin{aligned}-\nabla^2_{h\omega}\psi&=\beta\psi \quad \text{in } \mathbb{R}^2_+,\\ (\nabla_{h\omega}\psi)\cdot\nu&=0 \quad \text{on } \partial\mathbb{R}^2_+,\end{aligned} \tag{2.5}$$

where $\nu(x)=(0,-1)$ is the outer normal to $\mathbb{R}^2_+$.

Lemma 2.1: (Ref. 4). *For every $h\neq 0$, $\alpha(h)=|h|$. The associated eigenfunctions are given by*

$$\psi(x)=\begin{cases} f(x)\exp(-|h|r^2/4) & \text{if } h>0\\ \overline{f(x)}\exp(-|h|r^2/4) & \text{if } h<0,\end{cases}$$

where $r=|x|$, $f(x)$ is any function analytic in $\mathbb{R}^2$ such that $f(x)\exp(-|h|r^2/4)\in L^2(\mathbb{R}^2)$. For all $\alpha<\alpha(h)$, (2.3) *has no nontrivial bounded solution.* □

Lemma 2.2: (Ref. 4). *There exists a positive constant β_0, $0<\beta_0<1-1/\sqrt{2e\pi}$, such that $\beta(h)=\beta_0|h|$. For all $h\neq 0$, $\beta(h)$ is not achieved in $\mathcal{W}(\mathbb{R}^2_+)$, i.e., there is no L^2 eigenfunction associated with $\beta(h)$. For all $\beta<\beta(h)$,* (2.5) *has no nontrivial bounded solution.* □

III. LOCAL DECOMPOSITION OF VECTOR FIELDS

In the proof of the convergence of the rescaled eigenfunctions in later sections, we use the gauge transformations frequently. Thus, we need to decompose a vector field into a gradient part and a curl part near a given point P. When P is an interior point, this decomposition follows directly from the Taylor expansion (see Lemma 3.1). When P is a boundary point, we need to decompose the vector field in new coordinates which straighten a portion of boundary (see Lemma 3.2).

Let $A(x)=(A^1(x),A^2(x))\in C^2(\overline{B_R})$ and denote

$$a^i_j=\frac{\partial A^i}{\partial x_j}(0),\quad a^i_{jk}=\frac{\partial^2 A^i}{\partial x_j\partial x_k}(0),\quad a^1=A^1(0),\quad a^2(0)=A^2(0).$$

Let $H(x)=\operatorname{curl}A(x)$. Then, $\underline{\operatorname{curl}}^2A(x)=(\partial_2H,-\partial_1H)$.

Lemma 3.1: Let $A\in C^2(\overline{B_R})$. Then,

$$A(x)=A(0)+\nabla\xi(x)+\nabla\zeta(x)+\operatorname{curl}A(0)\,\omega(x)-\tfrac{1}{2}|x|^2\underline{\operatorname{curl}}^2A(0)+D(x), \tag{3.1}$$

where

$$\xi(x)=\tfrac{1}{2}[a_1^1x_1^2+(a_2^1+a_1^2)x_1x_2+a_2^2x_2^2],$$
$$\zeta(x)=\tfrac{1}{6}[c_1x_1^3+3c_2x_1^2x_2+3c_3x_1x_2^2+c_4x_2^3] \tag{3.2}$$

with

$$c_1=a_{11}^1+\partial_2H(0),\quad c_2=a_{12}^1,\quad c_3=a_{12}^2,\quad c_4=a_{22}^2-\partial_1H(0),$$

and $|D(x)|=o(|x|^2)$ *as* $x\to 0$. *If* $A\in C^3(\overline{B_R})$, *then* $|D(x)|\leqslant C(R)|x|^3$ *in* B_R. □

In the following we assume that Ω is a smooth (say, C^k for some $k\geqslant 3$) bounded domain in $\mathbb{R}^2$ and $0\in\partial\Omega$. Then, $\partial\Omega$ consists of a finite number of simple closed C^k curves disintersecting with each other. Every component Γ of $\partial\Omega$ can be represented as $z=z(s)$, where s is the arclength of Γ, and $\tau(s)=(\tau_1,\tau_2)=z'(s)$ is the unit tangent vector. Let $\nu(s)=(\nu_1,\nu_2)$ be the unit outer normal. We choose the positive direction of Γ in such a way that the orientation of (ν,τ) is coincident with the orientation of the x_1x_2 coordinates. Then, $\tau_1=-\nu_2$, $\tau_2=\nu_1$. From the Frenet formula we have

$$\tau'=-\kappa_r\nu,\quad \tau''=-\kappa_r'\nu-\kappa_r^2\tau,\quad \nu'=\kappa_r\tau,\quad \nu''=\kappa_r'\tau-\kappa_r^2\nu, \tag{3.3}$$

where κ_r is the relative curvature of Γ under the given orientation. Obviously, there exists a positive constant $\mu_0=\mu_0(\Omega)$ such that $|\kappa_r|\leqslant 1/\mu_0$ on $\partial\Omega$.

Fix $0<\mu<\mu_0$. Denote by $d(x)=\mathrm{dist}(x,\partial\Omega)$ the distance function, and denote $\Omega(\mu)=\{x\in\overline{\Omega}:d(x)<\mu\}$. Then, $d\in C^{k-1}(\overline{\Omega(\mu_0)})$. For every $x\in\Omega(\mu_0)$ there exists a unique point $z=z(x)\in\partial\Omega$ such that $x=z-d(x)\nu(z)$, $\nabla d(x)=-\nu(z)$. The mapping

$$x=\mathcal{F}(s,t)=z(s)-t\nu(s) \tag{3.4}$$

determines a C^1 transformation of coordinates. Set

$$g(s,t)=|\det D\mathcal{F}|=|\mathcal{F}_s\times\mathcal{F}_t|=1-t\kappa_r(s).$$

After rotating the coordinate system we may assume $\tau(0)=(1,0)$, $\nu(0)=(0,-1)$. Denote $\mathbf{e}_1=\tau$, $\mathbf{e}_2=-\nu$, $y_1=s$, $y_2=t$, $y=(y_1,y_2)$. y is the new coordinate straightening the boundary. Using (3.3) we get

$$\mathbf{e}_1(y)=\tau(y_1)=\begin{pmatrix}1\\0\end{pmatrix}+\begin{pmatrix}0\\ \kappa_r(0)y_1\end{pmatrix}+\frac{1}{2}y_1^2\begin{pmatrix}-\kappa_r^2(0)\\ \kappa_r'(0)\end{pmatrix}+O(|y_1|^3),$$

$$\mathbf{e}_2(y)=-\nu(y_1)=\begin{pmatrix}0\\1\end{pmatrix}-\begin{pmatrix}\kappa_r(0)y_1\\ 0\end{pmatrix}-\frac{1}{2}y_1^2\begin{pmatrix}\kappa_r'(0)\\ \kappa_r^2(0)\end{pmatrix}+O(|y_1|^3),$$

$$\mathcal{F}(y)=y+\frac{\kappa_r(0)}{2}\begin{pmatrix}-2y_1y_2\\ y_1^2\end{pmatrix}+O(|y|^3)\quad \text{as } y\to 0, \tag{3.5}$$

$$g(y)=1-\kappa_r(0)y_2-\kappa_r'(0)y_1y_2+O(|y|^3).$$

Denote the inverse map of $\mathcal{F}$ by $\mathcal{G}(x)$. At the point $x=\mathcal{F}(y)$ we have

$$D\mathcal{G}(x)=\begin{pmatrix}\mathcal{G}_1^1 & \mathcal{G}_2^1\\ \mathcal{G}_1^2 & \mathcal{G}_2^2\end{pmatrix}=\frac{1}{1-y_2\kappa_r(y_1)}\begin{pmatrix}-\nu_2 & \nu_1\\ -(1-y_2\kappa_r(y_1))\tau_2 & (1-y_2\kappa_r(y_1))\tau_1\end{pmatrix}. \tag{3.6}$$

For a given vector field $A(x)$ we define a new vector field $\mathbf{a}(y)$ associated with $A(x)$ by

$$\mathbf{a}(y)=\mathbf{a}^1(y)\mathbf{e}_1+\mathbf{a}^2(y)\mathbf{e}_2, \tag{3.7}$$

where

$$\mathbf{a}^1(y)=g(y)A(\mathcal{F}(y))\cdot\mathbf{e}_1(y),\quad \mathbf{a}^2(y)=A(\mathcal{F}(y))\cdot\mathbf{e}_2(y). \tag{3.8}$$

Then,

$$\begin{aligned}\mathbf{a}^1(y)=&a^1+[a_1^1+\kappa_r(0)a^2]y_1+[a_2^1-\kappa_r(0)a^1]y_2+\tfrac{1}{2}\{[a_{11}^1+\kappa_r(0)a_2^1+2\kappa_r(0)a_1^2\\&-\kappa_r(0)^2a^1+\kappa_r'(0)a^2]y_1^2+2[a_{12}^1-2\kappa_r(0)a_1^1+\kappa_r(0)a_2^2-\kappa_r^2(0)a^2-\kappa_r'(0)a^1]y_1y_2\\&+[a_{22}^1-2\kappa_r(0)a_2^1]y_2^2\}+o(|y|^2),\end{aligned}$$

$$\begin{aligned}\mathbf{a}^2(y)=&a^2+(a_1^2-\kappa_r(0)a^1)y_1+a_2^2y_2+\tfrac{1}{2}\{[a_{11}^2+\kappa_r(0)a_2^2-2\kappa_r(0)a_1^1-\kappa_r^2(0)a^2-\kappa_r'(0)a^1]y_1^2\\&+2[a_{12}^2-\kappa_r(0)a_1^2-\kappa_r(0)a_2^1]y_1y_2+a_{22}^2y_2^2\}+o(|y|^2).\end{aligned}$$

Summarizing the above discussion, we obtain

Lemma 3.2: Let Ω be a smooth domain in $\mathbb{R}^2$ with $0\in\partial\Omega$. Assume that $A\in C^2(\overline{\Omega\cap\mathcal{F}(B_R)})$. Then, in the new coordinates y straightening the boundary, the vector field $\mathbf{a}(y)$ associated with $A(x)$ has the following decomposition for $y\in B_R$:

$$\begin{aligned}(\mathbf{a}^1(y),\mathbf{a}^2(y))=&A(0)+\nabla\tilde{\xi}(y)+\nabla\tilde{\zeta}(y)+\operatorname{curl}A(0)\omega(y)\\&-\frac{|y|^2}{2}[\operatorname{curl}^2A(0)-\kappa_r(0)\operatorname{curl}A(0)\tau(0)]+\tilde{D}(y),\end{aligned} \tag{3.9}$$

where

$$\tilde{\xi}(y)=\tfrac{1}{2}[(a_1^1+\kappa_r(0)a^2)y_1^2+(a_2^1+a_1^2-2\kappa_r(0)a^1)y_1y_2+a_2^2y_2^2],$$

$$\tilde{\zeta}(y)=\tfrac{1}{6}[\tilde{c}_1y_1^3+3\tilde{c}_2y_1^2y_2+3\tilde{c}_3y_1y_2^2+\tilde{c}_4y_2^3]$$

with

$$\tilde{c}_1=a_{11}^1-a_{22}^1+a_{12}^2+\kappa_r(0)(a_1^2+a_2^1)-\kappa_r^2(0)a^1+\kappa_r'(0)a^2,$$

$$\tilde{c}_2=a_{12}^1+\kappa_r(0)(a_2^2-2a_1^1)-\kappa_r^2(0)a^2-\kappa_r'(0)a^1,$$

$$\tilde{c}_3=a_{12}^2-\kappa_r(0)(a_1^2+a_2^1),$$

$$\tilde{c}_4=a_{12}^1-a_{11}^2+a_{22}^2.$$

$|\tilde{D}(y)|=o(|y|^2)$ as $y\to0$. *If $A\in C^3(\overline{\Omega\cap\mathcal{F}(B_R)})$, then $|\tilde{D}(y)|\le C(R)|y|^3$ in B_R^+.* □

Note that in (3.9) $\nabla\tilde{\xi}(y)=(\partial_{y1}\tilde{\xi},\partial_{y2}\tilde{\xi})$. In the following we denote

$$\nabla_yf=\left(\frac{\partial f}{\partial y_1}\right)\mathbf{e}_1+\left(\frac{\partial f}{\partial y_2}\right)f\mathbf{e}_2. \tag{3.10}$$

From (3.7) and (3.10), we can write (3.9) as follows:

$$\begin{aligned}\mathbf{a}(y)=&A(0)+\nabla_y\tilde{\xi}(y)+\nabla_y\tilde{\zeta}(y)+\operatorname{curl}A(0)\tilde{\omega}(y)\\&-\frac{|y|^2}{2}[\operatorname{curl}^2A(0)-\kappa_r(0)\operatorname{curl}A(0)\tau(0)]+\tilde{D}(y),\end{aligned} \tag{3.11}$$

where $\tilde{\omega}(y) = -(y_2/2)\mathbf{e}_1 + (y_1/2)\mathbf{e}_2$. The decomposition in the form of (3.11) is more closely related to the gauge invariance of the operators involving the vector **a**, and will be used often in later sections.

IV. INTERIOR ESTIMATES

In this section we shall derive *a priori* interior estimates for the solutions ψ of the equation

$$\nabla_A^2 \psi = g \quad \text{in} \ \ \Omega, \tag{4.1}$$

where the vector field A and the function g are given. We shall establish the gauge invariant estimates which depend on $\operatorname{curl} A$ instead of A itself.

Theorem 4.1: *Assume that ψ is a smooth solution of Eq. (4.1) and $\operatorname{curl} A \in L^2(\Omega)$. Then, for any compact subset K of Ω, there exists a constant C depending only on Ω and K such that*

$$\begin{aligned} \| |\nabla_A \psi| \|^2_{H^1(K)} \leqslant \sum_{j,k} \|\nabla_{A^j}\nabla_{A^k}\psi\|^2_{L^2(K)} \leqslant 2\|\psi \operatorname{curl} A\|^2_{L^2(\Omega)} + 6\|g\|^2_{L^2(\Omega)} + C[1 + \|\operatorname{curl} A\|^4_{L^2(\Omega)}] \\ \times [\|\nabla_A \psi\|^2_{L^2(\Omega)} + \|\psi\|^2_{L^2(\Omega)}]. \end{aligned} \tag{4.2}$$

Before proving Theorem 4.1 we mention that $\|\nabla_A \psi\|_{L^2}$ can be controlled by $\|\psi\|_{L^2}$, as shown in the following

Lemma 4.2: Assume that $\psi \in W^{1,2}_{\text{loc}}(\Omega)$ is a weak solution of Eq. (4.1) for $g \in L^2_{\text{loc}}(\Omega)$. Then, for every $R > 0$ such that $B_{2R} \subset \Omega$ we have

$$\int_{B_R} |\nabla_A \psi|^2 \, dx \leqslant 2 \int_{B_{2R}} |g\psi| dx + \frac{16}{R^2} \int_{R_{2R}} |\psi|^2 \, dx.$$

Proof: Let η be a smooth cutoff function supported in B_{2R} such that $\eta = 1$ on B_R and $|\nabla \eta| \leqslant 2/R$. Multiplying Eq. (4.1) by $\eta^2 \psi$ and integrating by parts we get the conclusion. □

For convenience we denote $F_{j,k}\psi = (\nabla_{A^j}\nabla_{A^k} - \nabla_{A^k}\nabla_{A^j})\psi$, $\nabla_{A^j}\psi = (\partial_j - iA^j)\psi$ and $(\phi,\psi) = \int_\Omega \phi \overline{\psi} \, dx$.

Proposition 4:3: Let $A \in C^1(\overline{\Omega})$ and $\psi \in C^2(\overline{\Omega})$. Then,

$$\sum_{j,k} \|\nabla_{A^j}\nabla_{A^k}\psi\|^2_{L^2(\Omega)} = \|\psi \operatorname{curl} A\|^2_{L^2(\Omega)} + \|\nabla_A^2 \psi\|^2_{L^2(\Omega)} + 2\mathfrak{J}(\overline{\nabla_{A^1}\psi}\nabla_{A^2}\psi, \operatorname{curl} A) + I(\partial\Omega), \tag{4.3}$$

where

$$\begin{aligned} I(\partial\Omega) &= \int_{\partial\Omega} \left\{ \sum_{j,k} [\overline{\nabla_{A^k}\nabla_{A^j}\psi}\nabla_{A^k}\psi\nu_j] - \overline{\nabla_A^2\psi}(\nabla_A\psi)\cdot\nu \right\} ds \\ &= \int_{\partial\Omega} \left\{ \frac{1}{2}\frac{\partial}{\partial\nu}|\nabla_A\psi|^2 + (\operatorname{curl} A)[\mathfrak{J}(\overline{\psi}\nabla\psi) - |\psi|^2 A]\cdot\tau - \mathfrak{R}(\nabla_A\psi\cdot\nu)\overline{\nabla_A^2\psi} \right\} ds. \end{aligned} \tag{4.4}$$

Here τ is the unit tangent vector to $\partial\Omega$ such that the orientation of (ν,τ) is the same as the orientation of x_1x_2 coordinates.

Proof: Let $\psi_j = \nabla_{A^j}\psi$. Then,

$$\begin{aligned} (\nabla_{A^j}\nabla_{A^k}\psi, \nabla_{A^j}\nabla_{A^k}\psi) = (\nabla_{A^j}\psi_k, F_{j,k}\psi) - (\psi_k, F_{j,k}\psi_j) + (\nabla_{A^k}\psi_k, \nabla_{A^j}\psi_j) \\ + \int_{\partial\Omega} \overline{\nabla_{A^k}\psi_j}\psi_k\nu_j \, ds - \int_{\partial\Omega} \overline{\nabla_{A^j}\psi_j}\psi_k\nu_k \, ds. \end{aligned}$$

Taking summation over $1\leqslant j,\ k\leqslant 2$ we obtain

$$\begin{aligned}\sum_{j,k}\|\nabla_{A^j}\nabla_{A^k}\psi\|^2_{L^2(\Omega)}&=\sum_{j,k}[(\nabla_{A^j}\psi_k,F_{j,k}\psi)-(\psi_k,F_{j,k}\psi_j)]+\|\nabla_A^2\psi\|^2_{L^2(\Omega)}\\&\quad+\int_{\partial\Omega}\left\{\sum_{j,k}[\overline{\nabla_{A^k}\psi_j}\psi_k\nu_j]-\overline{\nabla_A^2\psi}(\nabla_A\psi)\cdot\nu\right\}ds\\&=i(\overline{\psi}[\nabla_{A^1}\psi_2-\nabla_{A^2}\psi_1]+\psi_1\overline{\psi_2}-\psi_2\overline{\psi_1},\operatorname{curl}A)\\&\quad+\|\nabla_A^2\psi\|^2_{L^2(\Omega)}+\int_{\partial\Omega}\left\{\sum_{j,k}[\overline{\nabla_{A^k}\psi_j}\psi_k\nu_j]-\overline{\nabla_A^2\psi}(\nabla_A\psi)\cdot\nu\right\}ds\\&=(|\psi|^2\operatorname{curl}A+2\mathfrak{F}(\partial_2\psi\partial_1\overline{\psi})+2\mathfrak{R}(A^1\overline{\psi}\partial_2\psi-A^2\psi\partial_1\overline{\psi}),\operatorname{curl}A)\\&\quad+\|\nabla_A^2\psi\|^2_{L^2(\Omega)}+\int_{\partial\Omega}\left\{\sum_{j,k}[\overline{\nabla_{A^k}\psi_j}\psi_k\nu_j]-\overline{\nabla_A^2\psi}(\nabla_A\psi)\cdot\nu\right\}ds\\&=\|\psi\operatorname{curl}A\|^2_{L^2(\Omega)}+\|\nabla_A^2\psi\|^2_{L^2(\Omega)}+2\mathfrak{F}(\partial_2\psi\partial_1\overline{\psi},\operatorname{curl}A)\\&\quad+2\mathfrak{R}(A^1\overline{\psi}\partial_2\psi-A^2\psi\partial_1\overline{\psi},\operatorname{curl}A)\\&\quad+\int_{\partial\Omega}\left\{\sum_{j,k}[\overline{\nabla_{A^k}\psi_j}\psi_k\nu_j]-\overline{\nabla_A^2\psi}(\nabla_A\psi)\cdot\nu\right\}ds,\end{aligned}$$

which gives (4.3). (4.3) implies that $I(\partial\Omega)$ is real and

$$I(\partial\Omega)=\mathfrak{R}\int_{\partial\Omega}\left\{\sum_{j,k}[\overline{F_{j,k}}+\overline{\nabla_{A^j}\psi_k}]\psi_k\nu_j-\overline{\nabla_A^2\psi}(\nabla_A\psi)\cdot\nu\right\}ds.$$

A computation shows

$$\begin{aligned}\mathfrak{R}\int_{\partial\Omega}\sum_{j,k}\overline{F_{j,k}}\psi_k\nu_j&=\mathfrak{R}\int_{\partial\Omega}\overline{F_{1,2}}(\nabla_{A^1}\psi\nu_2-\nabla_{A^2}\psi\nu_1)ds\\&=\mathfrak{R}\int_{\partial\Omega}i\overline{\psi}(\operatorname{curl}A)(\nabla_{A^1}\psi\nu_2-\nabla_{A^2}\psi\nu_1)ds\\&=\mathfrak{R}\int_{\partial\Omega}i\overline{\psi}(\operatorname{curl}A)(\partial_1\psi\nu_2-\partial_2\psi\nu_1)ds+\int_{\partial\Omega}|\psi|^2(\operatorname{curl}A)(A^1\nu_2-A^2\nu_1)ds\\&=\int_{\partial\Omega}(\operatorname{curl}A)[\mathfrak{F}(\overline{\psi}\nabla\psi)-|\psi|^2A]\cdot\tau\,ds;\end{aligned}$$

and

$$\begin{aligned}\mathfrak{R}\int_{\partial\Omega}\sum_{j,k}[\overline{\nabla_{A^j}\psi_k}]\psi_k\nu_j\,ds&=\mathfrak{R}\int_{\partial\Omega}\sum_{j,k}(\partial_j+iA^j)\overline{\nabla_{A^k}}\nabla_{A^k}\psi\nu_j\,ds\\&=\mathfrak{R}\int_{\partial\Omega}\sum_{j,k}\partial_j\overline{\nabla_{A^k}}\nabla_{A^k}\psi\nu_j\,ds=\frac{1}{2}\int_{\partial\Omega}\frac{\partial}{\partial\nu}|\nabla_A\psi|^2\,ds.\end{aligned}$$

So (4.4) is true. □

Proof of Theorem 4.1: For a given compact subset K of Ω, we choose a smooth real cutoff function η such that spt $\eta\subset\Omega$ and $\eta=1$ on K. Denote $\psi_j=\nabla_{A^j}\psi$. From (4.3) and the Kato's inequality it follows that

$$\begin{aligned}\|\nabla|\nabla_A(\eta\psi)|\|^2_{L^2(\Omega)}&\leqslant\sum_{j,k}\|\nabla_{A^j}\nabla_{A^k}(\eta\psi)\|^2_{L^2(\Omega)}\\&=\|\eta\psi\,\mathrm{curl}\,A\|^2_{L^2(\Omega)}+\|\nabla^2_A(\eta\psi)\|^2_{L^2(\Omega)}+2\mathfrak{F}(\overline{\nabla_{A^1}(\eta\psi)}\nabla_{A^2}(\eta\psi),\mathrm{curl}\,A)\\&\leqslant\|\eta\psi\,\mathrm{curl}\,A\|^2_{L^2(\Omega)}+\|\eta\nabla^2_A\psi+2\nabla\eta\cdot\nabla_A\psi+\psi\Delta\eta\|^2_{L^2(\Omega)}\\&\quad+2\int_\Omega|\mathrm{curl}\,A||\nabla_A(\eta\psi)|^2\,dx.\end{aligned}$$

Next, we estimate

$$\begin{aligned}\int_\Omega|\mathrm{curl}\,A||\nabla_A(\eta\psi)|^2\,dx&\leqslant\|\mathrm{curl}\,A\|_{L^2(\Omega)}\left\{\int_\Omega|\nabla_A(\eta\psi)||\nabla_A(\eta\psi)|^3\,dx\right\}^{1/2}\\&\leqslant\|\mathrm{curl}\,A\|_{L^2(\Omega)}\|\nabla_A(\eta\psi)\|^{1/2}_{L^2(\Omega)}\|\nabla_A(\eta\psi)\|^{3/2}_{L^6(\Omega)}\\&\leqslant C_1\|\mathrm{curl}\,A\|_{L^2(\Omega)}\|\nabla_A(\eta\psi)\|^{1/2}_{L^2(\Omega)}\|\nabla|\nabla_A(\eta\psi)|\|^{3/2}_{L^2(\Omega)}\\&\qquad(\text{by Sobolev inequality})\\&\leqslant\tfrac{1}{2}\|\nabla|\nabla_A(\eta\psi)|\|^2_{L^2(\Omega)}+C_2\|\mathrm{curl}\,A\|^4_{L^2(\Omega)}\|\nabla_A(\eta\psi)\|^2_{L^2(\Omega)}.\end{aligned}$$

Therefore,

$$\begin{aligned}\tfrac{1}{2}\|\nabla|\nabla_A(\eta\psi)|\|^2_{L^2(\Omega)}&\leqslant\|\eta\psi\,\mathrm{curl}\,A\|^2_{L^2(\Omega)}+3\|\eta\nabla^2_A\psi\|^2_{L^2(\Omega)}+12\|\nabla\eta\cdot\nabla_A\psi\|^2_{L^2(\Omega)}\\&\quad+3\|\psi\Delta\eta\|^2_{L^2(\Omega)}+C_2\|\mathrm{curl}\,A\|^4_{L^2(\Omega)}\|\nabla_A(\eta\psi)\|^2_{L^2(\Omega)}\\&\leqslant\|\psi\,\mathrm{curl}\,A\|^2_{L^2(\Omega)}+3\|g\|^2_{L^2(\Omega)}+C_3[\|\nabla_A\psi\|^2_{L^2(\Omega)}+\|\psi\|^2_{L^2(\Omega)}]\\&\quad+C_2\|\mathrm{curl}\,A\|^4_{L^2(\Omega)}\|\nabla_A(\eta\psi)\|^2_{L^2(\Omega)},\end{aligned}$$

where C_1,C_2,C_3 are constants depending only on Ω and K. The proof is complete. □

V. ESTIMATES NEAR BOUNDARIES

In this section we establish the boundary estimates for the solutions of the equation

$$\begin{aligned}-\nabla^2_A\psi=g\quad&\text{in }\Omega,\\(\nabla_A\psi)\cdot\nu+\gamma\psi=0\quad&\text{on }\partial\Omega.\end{aligned}\tag{5.1}$$

As mentioned in Sec. I, by making a gauge transformation if necessary, we may assume that

$$\mathrm{div}\,A=0\quad\text{in }\Omega,\quad A\cdot\nu=0\quad\text{on }\partial\Omega.$$

Of course, under the gauge transformation, function g in (5.1) will be changed to a new function $\tilde{g}$. However, since it does not effect the estimation given below, we still denote the new function $\tilde{g}$ by g.

To obtain the estimates we shall straighten a portion of boundary and study the new equation in the half ball B_R^+. We also need to extend the solutions to the entire ball. For this purpose we transform Eq. (5.1) to an equation having homogeneous boundary condition. Let u be the positive eigenfunction associated with the first eigenvalue λ of the following eigenvalue problem:

$$
\begin{aligned}
&-\Delta u=\lambda u \quad \text{in } \Omega,\\
&\frac{\partial u}{\partial \nu}+\gamma u=0 \quad \text{on } \partial\Omega.
\end{aligned}
\tag{5.2}
$$

u is smooth and positive on $\bar{\Omega}$. Set $\psi=u\phi$, $v=\log(u^2)$, $f=g/u$. Then, ϕ satisfies the equation

$$
-\nabla_A^2\phi=\nabla v\cdot\nabla_A\phi-\lambda\phi+f \quad \text{in } \Omega,
$$

$$
\frac{\partial\phi}{\partial\nu}=0 \quad \text{on } \partial\Omega.
$$

In the following we denote $\tilde{\phi}(y)=\phi(\mathcal{F}(y))$, $\tilde{v}(y)=v(\mathcal{F}(y))$, where $\mathcal{F}(y)$ is the diffeomorphism defined on B_{R_0}, see (3.4). We shall always assume $R<R_0/2$. Let $\mathbf{a}(y)$ be the vector field associated with $A(x)$ defined by (3.7). We define the following differential operators:

$$
D(g)w=D(g)_1 w\mathbf{e}_1+D(g)_2 w\mathbf{e}_2,
$$

$$
\text{where } D(g)_1=\frac{1}{g}\partial_1, \quad D(g)_2=\partial_2,
$$

$$
D(g)_{\mathbf{a}}w=[D(g)_{\mathbf{a}^1}w]\mathbf{e}_1+[D(g)_{\mathbf{a}^2}w]\mathbf{e}_2,
$$

$$
\text{where } D(g)_{\mathbf{a}^1}w=\frac{1}{g}(\partial_1-i\mathbf{a}^1)w, \quad D(g)_{\mathbf{a}^2}w=(\partial_2-i\mathbf{a}^2)w,
$$

$$
D(g)_{\mathbf{a}}^*w=[D(g)_{\mathbf{a}^1}^*w]\mathbf{e}_1+[D(g)_{\mathbf{a}^2}^*w]\mathbf{e}_2,
$$

$$
\text{where } D(g)_{\mathbf{a}^1}^*w=D(g)_{\mathbf{a}^1}w, \quad D(g)_{\mathbf{a}^2}^*w=\frac{1}{g}[\partial_2(gw)-i\mathbf{a}^2 gw],
$$

$$
\begin{aligned}
\Delta(g)_{\mathbf{a}}w&=D(g)_{\mathbf{a}^1}^*D(g)_{\mathbf{a}^1}w+D(g)_{\mathbf{a}^2}^*D(g)_{\mathbf{a}^2}w\\
&=\frac{1}{g}\left\{\partial_1\left[\frac{1}{g}(\partial_1 w-i\mathbf{a}^1 w)\right]-\frac{i\mathbf{a}^1}{g}(\partial_1 w-i\mathbf{a}^1 w)\right\}\\
&\quad+\frac{1}{g}\{\partial_2[g(\partial_2 w-i\mathbf{a}^2 w)]-i\mathbf{a}^2 g(\partial_2 w-i\mathbf{a}^2 w)\}.
\end{aligned}
$$

As in Sec. III we denote $\nabla_y\chi=(\partial_1\chi)\mathbf{e}_1+(\partial_2\chi)\mathbf{e}_2$. The operators $D(g)_{\mathbf{a}}$ and $\Delta(g)_{\mathbf{a}}$ have the following *gauge invariant properties:*

$$
D(g)_{\mathbf{a}+\nabla_y\chi}(e^{i\chi}\varphi)=e^{i\chi}D(g)_{\mathbf{a}}\varphi, \quad \Delta(g)_{\mathbf{a}+\nabla_y\chi}(e^{i\chi}\varphi)=e^{i\chi}\Delta(g)_{\mathbf{a}}\varphi.
\tag{5.3}
$$

Note that, in the above notations, $\nabla_A\phi=D(g)_{\mathbf{a}}\tilde{\phi}$, $\nabla_A^2\phi=\Delta(g)_{\mathbf{a}}\tilde{\phi}$. Thus, $\tilde{\phi}$ satisfies the equation

$$-\Delta(g)_{\mathbf{a}}\overline{\phi} = D(g)\tilde{v}\cdot D(g)_{\mathbf{a}}\tilde{\phi} - \lambda\tilde{\phi} + \tilde{f} \quad \text{on } B_R^+,$$
$$\frac{\partial\tilde{\phi}}{\partial y_2} = 0 \quad \text{on } \Gamma_R, \tag{5.4}$$

where $\Gamma_R = \{(y_1,0): |y_1| < R\}$.

Next, we extend the solution $\tilde{\phi}$ of Eq. (5.4) onto the entire ball. Note that

$$\mathbf{a}^2 = 0, \quad \partial_2\tilde{\phi} = 0 \quad \text{when } y_2 = 0.$$

Hence, we can evenly extend $\mathbf{a}^1$ and $\tilde{\phi}$ in y_2 and oddly extend $\mathbf{a}^2$ in y_2. Note that although $g(y)$ is defined on the entire ball, it is not even in y_2. Therefore, for $y_2 < 0$ we define

$$\tilde{\phi}(y_1,y_2) = \tilde{\phi}(y_1,-y_2), \quad \tilde{v}(y_1,y_2) = \tilde{v}(y_1,-y_2),$$

$$g(y_1,y_2) = g(y_1,-y_2),$$

$$\mathbf{a}^1(y_1,y_2) = \mathbf{a}^1(y_1,-y_2), \quad \mathbf{a}^2(y_1,y_2) = -\mathbf{a}^2(y_1,-y_2).$$

After such extensions, $\tilde{\phi}\in C^1(B_R)$, $\mathbf{a}\in C(B_R)$, and $\partial_j\mathbf{a}^j\in C^1(B_R)$. We further notice that $D(g)_{\mathbf{a}^1}\tilde{\phi}$ is continuous and even in y_2, $D(g)_{\mathbf{a}^2}\tilde{\phi}$ is continuous and odd in y_2, and $\Delta(g)_{\mathbf{a}}\tilde{\phi}$ is even in y_2. Although $\partial_2\tilde{v}$ is not continuous at $y_2 = 0$, it is bounded, and $D(g)_{\mathbf{a}^2}\tilde{\phi} = 0$ at $y_2 = 0$. Hence, $D(g)\tilde{v}\cdot D(g)_{\mathbf{a}}\tilde{\phi}$ is continuous.

The main result in this section is the following

Theorem 5.1: *Assume that $\tilde{\phi}$ is a solution of Eq. (5.4) and is extended as the above. Then,*

$$\begin{aligned}\sum_{j,k}\|D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\tilde{\phi}\|^2_{L^2_g(B_R)} \leq{}& 6\|\tilde{f}\|^2_{L^2_g(B_R)} + 6\int_{B_R}|D(g)\tilde{v}\cdot D(g)_{\mathbf{a}}\tilde{\phi}|^2 g\,dy + C(g,R)\|\tilde{\phi}\|^2_{L^2_g(B_R)}\\ &+ C(g,R)\{1 + \|\partial_1\mathbf{a}^2 - \partial_2\mathbf{a}^1\|^4_{L^2_g(B_R)}\}\|D(g)_{\mathbf{a}}\tilde{\phi}\|^2_{L^2_g(B_R)}\\ &+ C(g,R)\int_{B_R}|\partial_1\mathbf{a}^2 - \partial_2\mathbf{a}^1|^2|\tilde{\phi}|^2\,dy.\end{aligned} \tag{5.5}$$

To prove Theorem 5.1 we need an identity, see Proposition 5.3 below. Define

$$G_{jk}w = D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}w - D(g)_{\mathbf{a}^k}D(g)_{\mathbf{a}^j}w,$$

$$G^*_{jk} = D(g)^*_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}w - D(g)_{\mathbf{a}^k}D(g)^*_{\mathbf{a}^j}w.$$

Denote

$$[w]_{\Gamma_R} = \int_{\Gamma_R^+} w\,dy_1 - \int_{\Gamma_R^-} w\,dy_1 = \lim_{\epsilon_1,\epsilon_2\to 0}\left\{\int_{-R}^{R}[w(y_1,\epsilon_1) - w(y_1,-\epsilon_2)]dy_1\right\}.$$

If w is continuous in B_R, then $[w]_{\Gamma_R} = 0$. Note that $g = 1$ on Γ_R. We have

Lemma 5.2: Assume that ϕ and $\psi\in C^1(B_R\backslash\Gamma_R)$ and the support $\mathrm{spt}(\phi)\subset B_R$. *Then,*

$$\int_{B_R}(D(g)_{\mathbf{a}^j}\phi)\overline{\psi}g\,dy=-\int_{B_R}\phi\overline{D(g)^*_{\mathbf{a}^j}\psi}g\,dy+[\nu_j\phi\overline{\psi}]_{\Gamma_R},$$

where $\nu_1=0,\ \nu_2=-1$. *Moreover if* $\psi\in C^2(B_R\backslash\Gamma_R)$, *then*

$$\int_{B_R}(D(g)_{\mathbf{a}^j}\phi)\overline{D(g)_{\mathbf{a}^k}\psi}g\,dy=-\int_{B_R}\phi\overline{D(g)^*_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\psi}g\,dy+[\nu_j\phi\overline{D(g)_{\mathbf{a}^k}\psi}]_{\Gamma_R}.$$

For our convenience we denote by $\|\cdot\|_{L^2_g}$ the L^2 norm with the weight g, and $(\phi,w)_g=\int_{B_R}\phi\overline{w}g\,dy$.

Proposition 5.3: Assume that $\psi\in C^1(B_R)\cap C^2(B_R\backslash\Gamma_R)$ *with its support* $\mathrm{spt}(\psi)\subset B_R$, *and* ψ *is even in* y_2. *Then,*

$$\sum_{j,k}\|D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\psi\|^2_{L^2_g(B_R)}=\|\Delta(g)_{\mathbf{a}}\psi\|^2_{L^2_g(B_R)}+\|G_{12}\psi\|^2_{L^2_g(B_R)}+\int_{B_R}|D(g)_{\mathbf{a}^2}\psi|^2g\,\partial_2\left(\frac{\partial_2 g}{g}\right)dy$$
$$-2\mathfrak{F}\int_{B_R}(\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1)(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^2}\psi}\,dy-2\mathfrak{R}\int_{B_R}(\partial_2 g)$$
$$\times(D(g)_{\mathbf{a}^2}\psi)\overline{D(g)^2_{\mathbf{a}^1}\psi}\,dy+\int_{B_R}\left[\partial_1\left(\frac{\partial_2 g}{g}\right)-\frac{\partial_1 g\,\partial_2 g}{g}\right]$$
$$\times(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^2}\psi}\,dy. \tag{5.6}$$

Remark 5.1: Note that $\mathrm{curl}\,\mathbf{a}=(\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1)/g$. Although it is not continuous at $y_2=0$, it remains bounded. The term $\partial_1((\partial_2 g)/g)-(\partial_1 g)(\partial_2 g)/g$ is also bounded. Therefore, the integrals involving such terms make sense. Also note that when $y_2\neq 0$, $g\partial_2((\partial_2 g)/g)=-[\kappa_r(y_1)]^2/g\leqslant 0$. So

$$\int_{B_R}|D(g)_{\mathbf{a}^2}\psi|^2g\,\partial_2\left(\frac{\partial_2 g}{g}\right)dy\leqslant 0.$$

Proof of Proposition 5.3: The proof is similar to one of Proposition 4.3, but involves more computations. Set $\psi_j=D(g)_{\mathbf{a}^j}\psi$. Using Lemma 5.2 we have

$$\begin{aligned}&(D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\psi,D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\psi)_g\\&=(D(g)_{\mathbf{a}^j}\psi_k,G_{jk}\psi+D(g)_{\mathbf{a}^k}\psi_j)_g\\&=(D(g)_{\mathbf{a}^j}\psi_k,G_{jk}\psi)_g+(D(g)_{\mathbf{a}^j}\psi_k,D(g)_{\mathbf{a}^k}\psi_j)_g\\&=(D(g)_{\mathbf{a}^j}\psi_k,G_{jk}\psi)_g-(\psi_k,G^*_{jk}\psi_j)_g+(D(g)^*_{\mathbf{a}^k}\psi_k,D(g)^*_{\mathbf{a}^j}\psi_j)_g\\&\quad+[\nu_j\psi_k\overline{D(g)_{\mathbf{a}^k}\psi_j}]_{\Gamma_R}-[\nu_k\psi_k\overline{D(g)^*_{\mathbf{a}^j}\psi_j}]_{\Gamma_R}.\end{aligned}$$

Summing up the above over $1\leqslant j,\ k\leqslant 2$ we have

$$\sum_{j,k}\|D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\psi\|^2_{L^2_g(B_R)}=\|\Delta(g)_{\mathbf{a}}\psi\|^2_{L^2_g(B_R)}+\sum_{j,k}\{(D(g)_{\mathbf{a}^j}\psi_k,G_{jk}\psi)_g-(\psi_k,G^*_{jk}\psi_j)_g\}$$
$$+\sum_{jk}\{[\nu_j\psi_k\overline{D(g)_{\mathbf{a}^k}\psi_j}]_{\Gamma_R}-[\nu_k\psi_k\overline{D(g)^*_{\mathbf{a}^j}\psi_j}]_{\Gamma_R}\}.$$

Since $\nu_1=0$, $\nu_2=-1$, $\psi_2=D(g)_{\mathbf{a}^2}\psi=0$ on Γ_R, we have $\nu_k\psi_k=0$ on Γ_R, and

$$\sum_{jk}\{[\nu_j\psi_k\overline{D(g)_{\mathbf{a}^k}\psi_j}]_{\Gamma_R}-[\nu_k\psi_k\overline{D(g)^*_{\mathbf{a}^j}\psi_j}]_{\Gamma_R}\}=-[(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^1}\psi_2}]_{\Gamma_R}=0.$$

Here the following fact is used:

$$D(g)_{\mathbf{a}^1}\psi_2=D(g)_{\mathbf{a}^1}D(g)_{\mathbf{a}^2}\psi=\frac{1}{g}[\partial_1\partial_2\psi-i\mathbf{a}^1\partial_2\psi-i\partial_1(\mathbf{a}^2\psi)-\mathbf{a}^1\mathbf{a}^2\psi]\to 0\quad\text{as }\ y_2\to 0.$$

Therefore,

$$\begin{aligned}\sum_{j,k}\|D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}\psi\|^2_{L^2_g(B_R)}&=\|\Delta(g)_{\mathbf{a}}\psi\|^2_{L^2_g(B_R)}+(D(g)_{\mathbf{a}^1}\psi_2-D(g)_{\mathbf{a}^2}\psi_1,G_{12}\psi)_g-\sum_{jk}(\psi_k,G^*_{jk}\psi_j)_g\\&=\|\Delta(g)_{\mathbf{a}}\psi\|^2_{L^2_g(B_R)}+\|G_{12}\psi\|^2_{L^2_g(B_R)}-\sum_{jk}(\psi_k,G_{jk}\psi_j)_g+\sum_k\left(\psi_k,\psi_2D(g)_k\left[\frac{\partial_2 g}{g}\right]\right)_g.\end{aligned}\tag{5.7}$$

By computation we get

$$\sum_k\left(\psi_k,\psi_2D(g)_k\left[\frac{\partial_2 g}{g}\right]\right)_g=\int_{B_R}|D(g)_{\mathbf{a}^2}\psi|^2g\,\partial_2\left(\frac{\partial_2 g}{g}\right)dy+\int_{B_R}\partial_1\left(\frac{\partial_2 g}{g}\right)(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^2}\psi}\,dy,\tag{5.8}$$

$$\begin{aligned}\sum_{jk}(\psi_k,G_{jk}\psi_j)_g=2\mathfrak{I}\int_{B_R}(\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1)(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^2}\psi}\,dy+2\mathfrak{R}\int_{B_R}(\partial_2 g)\psi_2\overline{D(g)_{\mathbf{a}^1}\psi_1}\,dy\\+\int_{B_R}\frac{\partial_1 g\,\partial_2 g}{g}(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^2}\psi}\,dy.\end{aligned}\tag{5.9}$$

For instance, to obtain (5.9), we note that

$$\begin{aligned}\sum_{jk}(\psi_k,G_{jk}\psi_j)_g&=-(\psi_1,G_{12}\psi_2)_g+(\psi_2,G_{12}\psi_2)_g\\&=\int_{B_R}g[\psi_2\overline{G_{12}\psi_1}-\psi_1\overline{G_{12}\psi_2}]dy\\&=2\mathfrak{I}\int_{B_R}(\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1)(D(g)_{\mathbf{a}^1}\psi)\overline{D(g)_{\mathbf{a}^2}\psi}\,dy\\&\quad+\int_{B_R}(\partial_2 g)[\psi_2\overline{D(g)_{\mathbf{a}^1}\psi_1}-\psi_1\overline{D(g)_{\mathbf{a}^1}\psi_2}]dy.\end{aligned}$$

Since

$$\int_{B_R}(\partial_2 g)[\psi_2\overline{D(g)_{\mathbf{a}^1}\psi_1}-\psi_1\overline{D(g)_{\mathbf{a}^1}\psi_2}]dy$$

$$=\int_{B_R}(\partial_2 g)[\psi_2\overline{D(g)_{\mathbf{a}^1}\psi_1}+\overline{\psi_2}(D(g)_{\mathbf{a}^1}\psi_1)]dy+\int_{B_R}\frac{\partial_1 g\,\partial_2 g}{g}\,\psi_1\overline{\psi_2}\,dy$$

$$=2\Re\int_{B_R}(\partial_2 g)\,\psi_2\overline{D(g)_{\mathbf{a}^1}\psi_1}+\int_{B_R}\frac{\partial_1 g\,\partial_2 g}{g}\,\psi_1\overline{\psi_2}\,dy,$$

so (5.9) holds.

Now, (5.6) follows from (5.7) to (5.9). □

Proof of Theorem 5.1: In the proof, for simplicity we denote $\tilde{\phi}$ by ϕ and denote a constant depending only on g and R by C. Let η be a smooth cutoff function supported in B_{2R} such that $\eta=1$ on $B_{R/2}$ and η is even in y_2. Using Proposition 5.3 we have

$$\sum_{j,k}\|D(g)_{\mathbf{a}^j}D(g)_{\mathbf{a}^k}(\eta\phi)\|^2_{L^2_g(B_R)}\leqslant\|\Delta(g)_{\mathbf{a}}(\eta\phi)\|^2_{L^2_g(B_R)}+\|G_{12}\psi\|^2_{L^2_g(B_R)}$$
$$+C\{\|D(g)_{\mathbf{a}}\phi\|^2_{L^2_g(B_R)}+\|\phi\|^2_{L^2_g(B_R)}\}+J_1+2J_2, \quad (5.10)$$

where

$$J_1=\int_{B_R}|\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1||D(g)_{\mathbf{a}}(\eta\phi)|^2\,dy,$$

$$J_2=\int_{B_R}|\partial_2 g||D(g)_{\mathbf{a}^2}(\eta\phi)||D(g)^2_{\mathbf{a}^1}(\eta\phi)|dy.$$

Now, we estimate each term on the right of (5.10),

$$\|\Delta(g)_{\mathbf{a}}(\eta\phi)\|^2_{L^2_g(B_R)}\leqslant 3\|\tilde{f}\|^2_{L^2_g(B_R)}+C\{\|\phi\|^2_{L^2_g(B_R)}+\|D(g)_{\mathbf{a}}\phi\|^2_{L^2_g(B_R)}\}$$
$$+3\int_{B_R}|D(g)\tilde{v}\cdot D(g)_{\mathbf{a}}\phi|^2 g\,dy,$$

$$\|G_{12}\psi\|^2_{L^2_g(B_R)}\leqslant C\left\{\|D(g)_{\mathbf{a}}\phi\|^2_{L^2_g(B_R)}+\int_{B_R}|\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1||\phi|^2\,dy\right\},$$

$$J_1\leqslant\|\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1\|_{L^2_g(B_R)}\left\{\int_{B_R}|D(g)_{\mathbf{a}}(\eta\phi)||D(g)_{\mathbf{a}}(\eta\phi)|^3\,dy\right\}^{1/2}$$
$$\leqslant C\|\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1\|_{L^2_g(B_R)}\|D(g)_{\mathbf{a}}(\eta\phi)\|^{1/2}_{L^2_g(B_R)}\|\nabla|D(g)_{\mathbf{a}}(\eta\phi)|\|^{3/2}_{L^2_g(B_R)}$$

(by Sobolev inequality)

$$\leqslant\epsilon\|\nabla|D(g)_{\mathbf{a}}(\eta\phi)|\|^2_{L^2_g(B_R)}+\frac{C}{\epsilon}\|\partial_1\mathbf{a}^2-\partial_2\mathbf{a}^1\|^4_{L^2_g(B_R)}\|D(g)_{\mathbf{a}}(\eta\phi)\|^2_{L^2_g(B_R)},$$

and

$$J_2 \leqslant \epsilon \|D(g)^2_{\mathbf{a}^1}(\eta\phi)\|^2_{L^2_g(B_R)} + \frac{C}{\epsilon}\|D(g)_{\mathbf{a}}(\eta\phi)\|^2_{L^2_g(B_R)}$$

$$\leqslant \epsilon \sum_{jk} \|D(g)_{\mathbf{a}^j} D(g)_{\mathbf{a}^k}(\eta\phi)\|^2_{L^2_g(B_R)} + \frac{C}{\epsilon}\|D(g)_{\mathbf{a}}(\eta\phi)\|^2_{L^2_g(B_R)}.$$

Plugging the above inequalities back in (5.10), using the following

$$\|\nabla|D(g)_{\mathbf{a}}(\eta\phi)|\|^2_{L^2_g(B_R)} \leqslant C(g,R)\sum_{jk} \|D(g)_{\mathbf{a}^j} D(g)_{\mathbf{a}^k}(\eta\phi)\|^2_{L^2_g(B_R)},$$

and choosing ϵ small enough, we obtain the estimate (5.5). □

In the same fashion as the above, one can also prove the following

Lemma 5.4: Assume that $\tilde{\phi}$ *is a solution of Eq. (5.4) and is extended even in* y_2*. Then,*

$$\int_{B_{R/2}} |D(g)_{\mathbf{a}}\tilde{\phi}|^2 g\, dy \leqslant C(g,R)\int_{B_R} \{|\tilde{\phi}|^2 + |\tilde{f}|^2 + |D(g)\tilde{v}|^2 |\tilde{\phi}|^2\} g\, dy.$$

Note that after extension $\partial_1 \mathbf{a}^2 - \partial_2 \mathbf{a}^1$ is not continuous at Γ_R. Therefore, the estimates depending only on the data given on B_R^+ are needed. As a direct corollary of Theorem 5.1 we have

Theorem 5.5: *Assume that* $\tilde{\phi}$ *is a solution of Eq. (5.4). Then,*

$$\sum_{jk} \|D(g)_{\mathbf{a}^j} D(g)_{\mathbf{a}^k}\tilde{\phi}\|^2_{L^2_g(B_R^+)} \leqslant C\{\|\tilde{f}\|^2_{L^2_g(B_R^+)} + \|\tilde{\phi}\|^2_{L^2_g(B_R^+)}\}, \tag{5.11}$$

where the constant C depends on R, g, $\|D(g)\tilde{v}\|_{L^2_g(B_R^+)}$ and $\|\partial_1 \mathbf{a}^2 - \partial_2 \mathbf{a}^1\|_{L^2_g(B_R^+)}$. □

VI. UPPER-BOUND ESTIMATES

In this section, we give an upper bound for $\mu(\sigma A)/|\sigma|$. Throughout this section we assume $A \in C^2(\Omega)$.

Lemma 6.1: Assume that $A \in C^2(\Omega)$*. Then,*

$$\limsup_{\sigma\to\infty} \frac{\mu(\sigma A)}{|\sigma|} \leqslant \min_{x\in\Omega} |\mathrm{curl}\, A(x)|. \tag{6.1}$$

Proof: Let $H(x) = \mathrm{curl}\, A(x)$. First, we note that $\mu(-\sigma A) = \mu(\sigma A)$. In fact, for every $\psi \in W^{1,2}(\Omega)$ we set $\phi = \bar{\psi}$. Then, $|\nabla_{-\sigma A}\phi| = |\overline{\nabla_{\sigma A}\psi}| = |\nabla_{\sigma A}\psi|$. Therefore, we may assume $\sigma > 0$. We shall show that for every $x_0 \in \Omega$,

$$\limsup_{\sigma\to+\infty} \frac{\mu(\sigma A)}{\sigma} \leqslant |H(x_0)|.$$

Without loss of generality we may assume $x_0 = 0$.

Set $h = H(0)$. When $h = 0$ the conclusion is obvious, see Proposition 6.3 below. So, we assume $h \neq 0$. Denote $\delta = 1/\sqrt{\sigma}$. Let $R > 0$ be fixed such that $B_R \subset \Omega$. For any $\psi \in W^{1,2}(\Omega)$, we let $\psi_\delta(x) = \psi(\delta x)$ and $A_\delta(x) = A(\delta x)/\delta$. Then,

$$\frac{\mu(\sigma A)}{\sigma} \leqslant \frac{1}{\sigma} \inf_{\psi \in W_0^{1,2}(B_R)} \frac{\int_{B_R} |\nabla_{\sigma A}\psi|^2\, dx}{\int_{B_R}|\psi|^2},$$

$$= \inf_{\phi \in W_0^{1,2}(B_{R/\delta})} \frac{\int_{B_{R/\delta}} |\nabla_{A_\delta}\phi|^2\, dx}{\int_{B_{R/\delta}}|\phi|^2\, dx}.$$

Using (3.1) and noting that $\nabla\xi(\delta x) = \delta\nabla\xi(x)$, $\omega(\delta x) = \delta\omega(x)$, we have

$$A_\delta(x) = \nabla\chi_\delta(x) + h\omega(x) + B_\delta(x),$$

where

$$\chi_\delta(x) = \frac{1}{\delta}A(0)\cdot x + \xi(x) + \delta\zeta(x),$$

$$B_\delta(x) = -\frac{\delta}{2}|x|^2 \operatorname{curl}^2 A(0) + \frac{1}{\delta}D(\delta x),$$

$$|B_\delta(x)| \leqslant \frac{\delta}{2}|\operatorname{curl}^2 A(0)||x|^2[1 + o(\delta R)] \quad \text{in } B_{R/\delta}.$$

Therefore,

$$|\nabla_{A_\delta} e^{i\chi_\delta}\phi|^2 = |\nabla_{h\omega + B_\delta}\phi|^2 = |\nabla_{h\omega}\phi - iB_\delta\phi|^2 \leqslant (1+\lambda)|\nabla_{h\omega}\phi|^2 + \frac{(1+\lambda)\delta^2}{4\lambda}(1 + o(\delta R))|x|^4|\phi|^2,$$

where $0 \leqslant \lambda \leqslant 1$. So,

$$\frac{\mu(\sigma A)}{\sigma} \leqslant \inf_{\phi \in W_0^{1,2}(B_{R/\delta})} \frac{1}{\int_{B_{R/\delta}}|\phi|^2\, dx}\Bigg\{(1+\lambda)\int_{R_{R/\delta}} |\nabla_{h\omega}\phi|^2\, dx + \frac{(1+\lambda)\delta^2}{4\lambda}(1 + o(\delta R))|\operatorname{curl}^2 A(0)|^2 \int_{R_{R/\delta}} |x|^4|\phi|^2\, dx\Bigg\}.$$

Choose $\phi = \phi_m = u\,\eta_m$, where $u(x) = u(|x|) = \exp(-h^2|x|^2/4)$ and η_m is a smooth cutoff function supported in B_m such that $\eta_m \equiv 1$ on $B_{m/2}$. For fixed R and for all small δ,

$$\frac{\mu(\sigma A)}{\sigma} \leqslant \frac{1}{\int_{B_m}|\phi_m|^2\, dx}\Bigg\{(1+\lambda)\int_{R_m} |\nabla_{h\omega}\phi_m|^2\, dx + \frac{(1+\lambda)\delta^2}{4\lambda}(1 + o(\delta R))|\operatorname{curl}^2 A(0)|^2 \int_{R_m} |x|^4|\phi_m|^2\, dx\Bigg\}.$$

We first fix $m > 1$, $\lambda \in (0,1)$ and let σ approach $+\infty$ (so $\delta \to 0$), then we fix m and send λ to 0, finally we send m to $+\infty$. By using Lemma 2.1, we obtain

$$\limsup_{\sigma \to +\infty} \frac{\mu(\sigma A)}{\sigma} \leqslant \frac{\int_{\mathbb{R}^2}|\nabla_{h\omega}u|^2\, dx}{\int_{\mathbb{R}^2}|u|^2\, dx} = \alpha(h) = |h| = |H(0)|.$$

This completes the proof. □

Lemma 6.2: Assume that $A \in C^2(\overline{\Omega})$. *Then,*

$$\limsup_{\sigma\to\infty}\frac{\mu(\sigma A)}{|\sigma|}\leqslant\beta_0\min_{x\in\partial\Omega}|\mathrm{curl}\,A(x)|,\tag{6.2}$$

where β_0 is given in Lemma 2.2.

Proof: As in the proof of Lemma 6.1, we only need to show that, if $0\in\partial\Omega$ and $h=H(0)$, then

$$\limsup_{\sigma\to+\infty}\frac{\mu(\sigma A)}{|\sigma|}\leqslant\beta_0|h|.$$

Now, we need to use the local decomposition of A in the new variables which straighten a portion of boundary of $\partial\Omega$ near the point 0. We shall use the notations presented in Sec. III. For a fixed small $R>0$, we have

$$\mu(\sigma A)\leqslant\inf_{\phi\in W^*(B_R^+)}\frac{\int_{B_R^+}|D(g)_{\sigma\mathbf{a}}\phi|^2g(y)dy+\gamma\int_{-R}^{R}|\phi|^2\,dy_1}{\int_{B_R^+}|\phi|^2g(y)dy},$$

where $W^*(B_R^+)=\{\phi\in W^{1,2}(B_R^+):\mathrm{spt}(\phi)\subset\overline{B_R}\}$, $\mathbf{a}$ is the vector field associated with A given by (3.7).

For $\sigma>0$ we set $\delta=1/\sqrt{\sigma}$, $\mathbf{a}_\delta(y)=(1/\delta)\mathbf{a}(\delta y)$, $g_\delta(y)=g(\delta y)$. Then, for all small δ,

$$\frac{\mu(\sigma A)}{\sigma}\leqslant\inf_{\phi\in W^*(B_{R/\delta}^+)}\frac{\int_{B_{R/\delta}^+}|D(g_\delta)_{\mathbf{a}_\delta}\phi|^2g_\delta(y)dy+\gamma\delta\int_{-R/\delta}^{R/\delta}|\phi|^2\,dy_1}{\int_{B_{R/\delta}^+}|\phi|^2g_\delta(y)dy}.$$

From (3.11) we have

$$\mathbf{a}_\delta(y)=\nabla_y\tilde{\chi}_\delta(y)+h\tilde{\omega}(y)+\tilde{B}_\delta(y),$$

where

$$\tilde{\chi}_\delta(y)=\frac{1}{\delta}A(0)\cdot y+\tilde{\xi}(y)+\delta\tilde{\zeta}(y),$$

$$\tilde{\omega}(y)=(-y_2/2)\mathbf{e}_1+(y_1/2)\mathbf{e}_2,$$

$$\tilde{B}_\delta(y)=-\frac{\delta|y|^2}{2}[\mathrm{curl}^2A(0)-h\kappa_r(0)\tau(0)]+\frac{1}{\delta}\tilde{D}(\delta y).$$

Here $\kappa_r(0)$ is the relative curvature of $\partial\Omega$ at the point 0. Since the operator $D(g)_{\mathbf{a}}$ is gauge invariant, see (5.3), so

$$|D(g_\delta)_{\mathbf{a}_\delta}\exp(i\tilde{\chi}_\delta)\phi|^2=|D(g_\delta)_{h\omega+\tilde{B}_\delta}\phi|^2\leqslant(1+\lambda)|D(g_\delta)_{h\omega}\phi|^2+\frac{1+\lambda}{\lambda|g_\delta|^2}|\tilde{B}_\delta\phi|^2,$$

where λ is an arbitrary number lying between 0 and 1.

Choose $\phi=\psi\eta_m$, where $\psi\in\mathcal{W}(\mathbb{R}_+^2)$, η_m is the cutoff function used in the proof of Lemma 6.1. Note that $g_\delta\to1$ uniformly on each B_m^+ as $\delta\to0$. Therefore, by the same argument as in the proof of Lemma 6.1, we obtain

$$\limsup_{\sigma\to+\infty}\frac{\mu(\sigma A)}{\sigma}\leqslant\frac{\int_{\mathbb{R}_+^2}|\nabla_{h\omega}\psi|^2\,dy}{\int_{\mathbb{R}_+^2}|\psi|^2\,dy}.$$

Since the above is true for all $\psi \in \mathcal{W}(\mathbb{R}^2_+)$, using Lemma 2.2 we have

$$\limsup_{\sigma \to +\infty} \frac{\mu(\sigma A)}{\sigma} \leqslant \beta(h) = \beta_0 |h| = \beta_0 |H(0)|.$$

The proof is complete. □

If curl A vanishes at some point in $\overline{\Omega}$, the estimates (6.1), (6.2) can be greatly improved. Denote

$$\mathcal{Z}(A,\Omega) = \{x \in \Omega : \operatorname{curl} A(x) = 0\}, \quad \mathcal{Z}(A,\partial\Omega) = \{x \in \partial\Omega : \operatorname{curl} A(x) = 0\}.$$

Define, for $\tau > 0$,

$$p(\tau) = \inf_{u \in \mathcal{W}(\mathbb{R}^2)} \frac{\int_{\mathbb{R}^2} \{|\nabla u|^2 + \frac{1}{4}\tau^2 |x|^4 |u|^2\} dx}{\int_{\mathbb{R}^2} |u|^2 \, dx}. \tag{6.3}$$

Using the rescaling method we can show that $p(\tau) = p(1)|\tau|^{2/3}$ and $p(\tau)$ is achieved for every $\tau \neq 0$. Choosing $u = \exp(-|x|^3/6)$ as a test function we see that $p(1) \leqslant \sqrt[3]{3}/\Gamma(\frac{5}{3})$. Define, for a constant vector $\mathbf{a}$,

$$q(\mathbf{a}) = \inf_{\phi \in \mathcal{W}(\mathbb{R}^2_+)} \frac{\int_{\mathbb{R}^2_+} \left| \nabla \phi - \frac{i}{2} |y|^2 \mathbf{a} \phi \right|^2 dy}{\int_{\mathbb{R}^2_+} |\phi|^2 \, dy}. \tag{6.4}$$

Obviously,

$$q(\mathbf{a}) \leqslant \inf_{\phi \in \mathcal{W}(\mathbb{R}^2_+)} \frac{\int_{\mathbb{R}^2_+} \{|\nabla \phi|^2 + \frac{1}{4}|\mathbf{a}|^2 |y|^2 |\phi|^2\} dy}{\int_{\mathbb{R}^2_+} |\phi|^2 \, dy} \leqslant p(|\mathbf{a}|) = p(1)|\mathbf{a}|^{2/3} \leqslant \frac{\sqrt[3]{3}}{\Gamma(\frac{5}{3})} |\mathbf{a}|^{2/3}.$$

Proposition 6.3: Assume that $A \in C^2(\overline{\Omega})$. If $\mathcal{Z}(A,\Omega) \neq \emptyset$, *then*

$$\limsup_{\sigma \to \infty} \frac{\mu(\sigma A)}{|\sigma|^{2/3}} \leqslant p(1) \inf_{x \in \mathcal{Z}(A,\Omega)} |\operatorname{curl}^2 A(x)|^{2/3}. \tag{6.5}$$

If $\mathcal{Z}(A,\partial\Omega) \neq \emptyset$, *then*

$$\limsup_{\sigma \to \infty} \frac{\mu(\sigma A)}{|\sigma|^{2/3}} \leqslant \inf_{x \in \mathcal{Z}(A,\partial\Omega)} q(\operatorname{curl}^2 A(x)) \leqslant p(1) \inf_{x \in \mathcal{Z}(A,\partial\Omega)} |\operatorname{curl}^2 A(x)|^{2/3}. \tag{6.6}$$

Here $p(1)$ *and* $q(\mathbf{a})$ *are defined in (6.3), (6.4).*

Remark 6.1: Note that $|\operatorname{curl}^2 A(x)| = |\nabla H(x)|$, *where* $H(x) = \operatorname{curl} A(x)$.

Proof of Proposition 6.3: Assume that $0 \in \mathcal{Z}(A,\Omega)$. For $\sigma > 0$ we set $\delta = 1/\sqrt[3]{\sigma}$, $\psi_\delta(x) = \psi(\delta x)$, $A_\delta(x) = A(\delta x)/\delta^2$. From Lemma 3.1, we have

$$A_\delta(x) = \nabla \hat{\chi}_\delta(x) - \tfrac{1}{2}|x|^2 \operatorname{curl}^2 A(0) + D_\delta(x),$$

where

$$\hat{\chi}_\delta(x)=\frac{1}{\delta^2}A(0)\cdot x+\frac{1}{\delta}\xi(x)+\zeta(x),$$

$$D_\delta(x)=\frac{1}{\delta^2}D(\delta x),\quad |D_\delta(x)|=o(\delta|x|^3)\quad \text{in } B_{R/\delta}.$$

Set $\phi_m=u\eta_m$, where η_m is a smooth cutoff function as we used above and u is a real function to be determined later. Then, we have

$$\frac{\mu(\sigma A)}{\sigma^{2/3}}\leqslant\frac{1}{\int_{B_m}|\phi_m|^2\,dx}\left\{(1+\lambda)\int_{R_m}\left[|\nabla\phi_m|^2+\frac{1}{4}|\mathrm{curl}^2A(0)|^2|x|^4|\phi_m|^2\right]dx\right.$$
$$\left.+O(\delta)\left(1+\frac{1}{\lambda}\right)\int_{R_m}|x|^6|\phi_m|^2\,dx\right\}.$$

First sending δ to 0, then sending λ to 0, finally sending m to $+\infty$, we conclude that

$$\limsup_{\sigma\to+\infty}\frac{\mu(\sigma A)}{\sigma^{2/3}}\leqslant\inf_{u\in\mathcal{W}(\mathbb{R}^2)}\frac{\int_{\mathbb{R}^2}\{|\nabla u|^2+\frac{1}{4}|\mathrm{curl}^2A(0)|^2|x|^4|u|^2\}dx}{\int_{\mathbb{R}^2}|u|^2\,dx}\leqslant p(1)|\mathrm{curl}^2A(0)|^{2/3}.$$

So, (6.5) is true.

Now, we assume $0\in\mathcal{Z}(A,\partial\Omega)$. From (3.11) it follows that

$$\mathbf{a}(y)=A(0)+\nabla_y\tilde{\xi}(y)+\nabla_y\tilde{\zeta}(y)-\tfrac{1}{2}|y|^2\,\mathrm{curl}^2A(0)+\tilde{D}(y).$$

Using the similar argument we obtain (6.6). □

Remark 6.2: If there exist a smooth open subdomain $D\subset\Omega$ such that $\mathrm{curl}\,A(x)$ *vanishes in D, then*

$$\mu(\sigma A)\leqslant\inf_{\phi\in W_0^{1,2}(D)}\frac{\|\nabla_{\sigma A}\phi\|^2_{L^2(D)}}{\|\phi\|^2_{L^2(D)}}=\inf_{\phi\in W_0^{1,2}(D)}\frac{\|\nabla\phi\|^2_{L^2(D)}}{\|\phi\|^2_{L^2(D)}}=\lambda_1(D),$$

where $\lambda_1(D)$ is the first Dirichlet eigenvalue of $-\Delta$ on D.

VII. LOWER-BOUND ESTIMATES

In this section we give an lower bound of $\mu(\sigma A)/|\sigma|$ for large σ. The asymptotic behavior of the eigenfunctions as $\sigma\to\infty$ will also be discussed.

Lemma 7.1: Let Ω be a smooth bounded domain in $\mathbb{R}^2$ and $A\in C^2(\bar{\Omega})$. Then,

$$\liminf_{\sigma\to\infty}\frac{\mu(\sigma A)}{|\sigma|}\geqslant\min\{\min_{x\in\Omega}|\mathrm{curl}\,A(x)|,\beta_0\min_{x\in\partial\Omega}|\mathrm{curl}\,A(x)|\},\tag{7.1}$$

where β_0 is the positive constant given in Lemma 2.2.

Proof: Let $H(x)=\mathrm{curl}\,A(x)$,

$$m(\Omega)=\min_{\bar{\Omega}}|H(x)|,\quad \Omega_m=\{x\in\Omega:|H(x)|=m(\Omega)\},$$

$$m(\partial\Omega)=\min_{\partial\Omega}|H(x)|,\quad (\partial\Omega)_m=\{x\in\partial\Omega:|H(x)|=m(\partial\Omega)\}$$

and $m=\min\{m(\Omega),m(\partial\Omega)\beta_0\}$. We shall show that $\liminf_{\sigma\to\infty}\mu(\sigma A)/|\sigma|\geq m$. As in Sec. VI we assume $\sigma>0$ and denote $\delta=1/\sqrt{\sigma}$. Let ψ^δ be the eigenfunction associated with $\mu(\sigma A)$ satisfying $\max_{x\in\bar\Omega}|\psi^\delta(x)|=1$. Then, ψ^δ satisfies

$$-\nabla^2_{\sigma A}\psi=\mu(\sigma A)\psi \quad \text{in} \quad \Omega, \qquad (\nabla_{\sigma A}\psi)\cdot\nu+\gamma\psi=0 \quad \text{on} \quad \partial\Omega. \tag{7.2}$$

Denote by x^δ the maximum point of $|\psi^\delta|$.

Now, we assume that $\{\sigma_k\}$ is a given sequence, $\sigma_k\to+\infty$. We choose a subsequence σ_{k_j} such that

$$x^{\delta_{k_j}}\to x^0, \quad \frac{\mu(\sigma_{k_j}A)}{\sigma_{k_j}}\to a$$

for some non-negative number a. Lemma 6.1 implies $a\leq m$. We shall show $a\geq m$. Then it follows that $a=m$ for any sequence $\{\sigma_k\}$. For simplicity, we denote σ_{k_j} by σ. Let $h_\delta=H(x^\delta)$, $h=H(x^0)$.

Case 1: $x^0\in\Omega$. We shall show $a\geq m(\Omega)$. Let $\Omega_\delta=(\Omega-x^\delta)/\delta$, $\psi_\delta(x)=\psi^\delta(x^\delta+\delta x)$, $A_\delta(x)=(1/\delta)A(x^\delta+\delta x)$, $H_\delta(x)=H(x^\delta+\delta x)$. Note that $\operatorname{curl}A_\delta(x)=H_\delta(x)$. Using (7.2) we check that ψ_δ satisfies

$$-\nabla^2_{A_\delta}\psi_\delta=\frac{\mu(\sigma A)}{\sigma}\psi_\delta \quad \text{in} \quad \Omega_\delta \tag{7.3}$$

and $|\psi_\delta(0)|=1=\|\psi_\delta\|_{L^\infty}$. We shall show that $\{\psi_\delta\}$ locally converges up to gauge transformations.

Let $R>0$ be a fixed constant. Then, for δ small enough we have $B_{3R}\subset\Omega_\delta$. Since $\{|\psi_\delta|\}$ is uniformly bounded in L^2_{loc}, Lemma 4.2 implies that $\{|\nabla_{A_\delta}\psi_\delta|\}$ is also uniformly bounded in L^2_{loc}. Applying Theorem 4.1 to Eq. (7.3) we have

$$\begin{aligned}\||\nabla_{A_\delta}\psi|\|^2_{H^1(B_R)}&\leq 2\|\psi_\delta H_\delta\|^2_{L^2(2R)}+6\left[\frac{\mu(\sigma A)}{\sigma}\right]^2\|\psi_\delta\|^2_{L^2(B_{2R})}\\&\quad+C(R)[1+\|H_\delta\|^4_{L^2(B_{2R})}][\|\nabla_{A_\delta}\psi_\delta\|^2_{L^2(B_{2R})}+\|\psi_\delta\|^2_{L^2(B_{2R})}]\\&\leq C(R,\|H\|_{L^\infty})\|\psi_\delta\|^2_{L^2(B_{3R})}.\end{aligned}$$

So, $\{|\nabla_{A_\delta}\psi_\delta|\}$ is uniformly bounded in $W^{1,2}_{\text{loc}}$, hence, is relatively compact in L^2_{loc}. Since $|\nabla|\psi_\delta||\leq|\nabla_{A_\delta}\psi|$, $\{|\nabla|\psi_\delta||\}$ is uniformly bounded in L^2_{loc}. Thus, $\{|\psi_\delta|\}$ is relatively compact in L^2_{loc}. Passing to a subsequence we may assume that $|\psi_\delta|$ converges in $L^2_{\text{loc}}(\mathbb{R}^2)$ as $\delta\to 0$. It follows from Lemma 3.1 that

$$A_\delta(x)=\nabla\chi_\delta(x)+h_\delta\omega(x)+B_\delta(x),$$

where

$$\chi_\delta(x)=\frac{1}{\delta}A(x^\delta)x+\frac{1}{2}[\partial_1A^1(x^\delta)x_1^2+(\partial_1A^2(x^\delta)+\partial_2A^1(x^\delta))x_1x_2+\partial_2A^2(x^\delta)x_2^2].$$

Set $\phi_\delta(x)=\exp(-i\chi_\delta)\psi_\delta(x)$. Then, ϕ_δ satisfies

$$-\nabla^2_{h\omega}\phi_\delta=\frac{\mu(\sigma A)}{\sigma}\phi_\delta+f_\delta(x), \tag{7.4}$$

where $h=H(x^0)$ and

$$f_\delta(x)=-[i\,\mathrm{div}\,B_\delta+2h(h_\delta-h)+2h\omega\cdot B_\delta+|(h_\delta-h)\omega+B_\delta|^2]\phi_\delta \\ -2i[(h_\delta-h)\omega+B_\delta(x)]\cdot\nabla\phi_\delta .$$

Since $|\nabla_{h_\delta\omega+B_\delta}\phi_\delta|=|\nabla_{A_\delta}\psi_\delta|$ and

$$|\nabla\phi_\delta|^2\leqslant|\nabla_{h_\delta\omega+B_\delta}\phi_\delta+i(h_\delta\omega+B_\delta)\phi_\delta|^2\leqslant2|\nabla_{h_\delta\omega+B_\delta}\phi_\delta|^2+2|(h_\delta\omega+B_\delta)\phi_\delta|^2,$$

$\{|\nabla\phi_\delta|\}$ is also uniformly bounded in L^2_{loc}. Passing to another subsequence we have $\phi_\delta\rightarrow\phi_0$ weakly in $W^{1,2}_{\mathrm{loc}}$ and strongly in L^2_{loc}. Since $\mathrm{div}\,B_\delta(x)=(\mathrm{div}\,A)(x^\delta+\delta x)-(\mathrm{div}\,A)(x^\delta)\rightarrow0$, $|B_\delta(x)|\leqslant C\delta|x|^2$ and $h_\delta\rightarrow h$, we have $f_\delta\rightarrow0$ in L^2_{loc}. Hence, the limiting function ϕ_0 satisfies

$$-\nabla^2_{h\omega}\phi_0=a\phi_0 \quad \text{in } \mathbb{R}^2 \tag{7.5}$$

and $|\phi_0(x)|\leqslant1$. Applying Theorem 4.1 to Eq. (7.5) yields that ϕ_0 is smooth.

Denote $\hat\phi_\delta(x)=\phi_\delta(x)-\phi_0(x)$. From (7.4) and (7.5),

$$-\nabla^2_{h\omega}\hat\phi_\delta=a\hat\phi_\delta+\hat f_\delta, \tag{7.6}$$

where

$$\hat f_\delta=f_\delta+\left[\frac{\mu(\sigma A)}{\sigma}-a\right]\phi_\delta\rightarrow0 \quad \text{in } L^2_{\mathrm{loc}}$$

and $\hat\phi_\delta\rightarrow0$ in L^2_{loc}. Applying Lemma 4.2 to (7.6) we get $|\nabla_{h\omega}\hat\phi_\delta|\rightarrow0$ in L^2_{loc}. Since $|\nabla\hat\phi_\delta|^2\leqslant2|\nabla_{h\omega}\hat\phi_\delta|^2+2|h\omega\hat\phi_\delta|^2$ we have $|\nabla\hat\phi_\delta|\rightarrow0$ in L^2_{loc}. So,

$$\hat\phi_\delta\rightarrow0 \quad \text{in } W^{1,2}_{\mathrm{loc}}. \tag{7.7}$$

Denote $\omega=(\omega^1,\omega^2)$, $\nabla_{h\omega^j}=\partial_j-ih\omega^j$. Applying Theorem 4.1 to Eq. (7.6) we have

$$\nabla_{h\omega^j}\nabla_{h\omega^k}\hat\phi_\delta\rightarrow0 \quad \text{in } L^2_{\mathrm{loc}}. \tag{7.8}$$

Note that, for example,

$$\nabla_{h\omega^1}\nabla_{h\omega^1}\hat\phi_\delta=\frac{\partial^2}{\partial x_1}\hat\phi_\delta+ihx_2\frac{\partial}{\partial x_1}\hat\phi_\delta-\frac14|hx_2|^2\hat\phi_\delta .$$

Therefore, (7.7) and (7.8) imply that $\partial_j\partial_k\hat\phi_\delta\rightarrow0$ in L^2_{loc}. So, $\hat\phi_\delta\rightarrow0$ in L^2_{loc}.

Now, we apply the classical C^α estimates to (7.6) and conclude that $\hat\phi_\delta\rightarrow0$ in C^α_{loc}, that is, $\phi_\delta\rightarrow\phi_0$ in C^α_{loc}. Especially, we get $\phi_0(0)=\lim_{\delta\rightarrow0}\phi_\delta(0)=1$. Therefore, ϕ_0 is a nonzero bounded smooth solution of Eq. (7.5) in $\mathbb{R}^2$. From Lemma 2.1 we have

$$a\geqslant\alpha(h)=|h|=|H(x^0)|\geqslant\min_{x\in\Omega}|H(x)|=m(\Omega).$$

Since $a\leqslant m$, we conclude that $a=m$. We also see that if Case 1 happens then $m=m(\Omega)$, $x^0\in\Omega_m$ and (7.1) holds.

Case 2: $x^0\in\partial\Omega$. Now, we shall prove $a\geqslant m(\partial\Omega)$. Let $d_\delta=\mathrm{dist}(\partial\Omega,x^\delta)$, the distance between x^δ and $\partial\Omega$. Then, $B_{d_\delta/\delta}\subset\Omega_\delta$. If there exists a subsequence $\delta_j\rightarrow0$ such that $d_{\delta_j}/\delta_j\rightarrow\infty$, then the argument in Case 1 also gives that $\mu(\sigma_jA)/|\sigma_j|\rightarrow|H(x_0)|$. Therefore, we assume that d_δ/δ is bounded. Passing to a subsequence, we may assume that $d_\delta/\delta\rightarrow d_0$.

Let $\hat{x}^\delta \in \partial\Omega$ such that $|\hat{x}^\delta - x^\delta| = \mathrm{dist}(x^\delta, \partial\Omega) = d_\delta$. At each point $\hat{x}^\delta$ we take a diffeomorphism $\mathcal{F}_\delta : B^+_{R_0} \to \Omega \cap \mathcal{F}_\delta(B_{R_0})$ to straighten a portion of boundary around the point $\hat{x}^\delta$ such that $\mathcal{F}_\delta(0) = \hat{x}^\delta$. For simplicity, we denote $\mathcal{F}_\delta$ by $\mathcal{F}$. We keep in mind that the diffeomorphism $\mathcal{F}$ depends on δ. However, the constant R_0 can be chosen to be independent of δ, thus, we have uniform estimates on $\mathcal{F}$ for all small δ. Let $y^\delta \in B^+_{R_0}$ be such that $\mathcal{F}(y^\delta) = x^\delta$. Then, $|y^\delta| \leqslant C d_\delta \leqslant C\delta$.

Let $\psi^\delta(\mathcal{F}(y)) = u(\mathcal{F}(y)) \tilde{\psi}^\delta(y)$, where u is the positive eigenfunction of Eq. (5.2) associated with the first eigenvalue λ and $\|u\|_{L^\infty} = 1$. Then, $\{|\tilde{\psi}^\delta|\}$ is uniformly bounded from above and $|\tilde{\psi}^\delta(y^\delta)|$ is uniformly bounded away from zero. As in Sec. V we can check that $\tilde{\psi}^\delta$ satisfies the following equation:

$$-\Delta(g)_{\sigma\mathbf{a}} \tilde{\psi}^\delta = D(g)\tilde{v} \cdot D(g)_{\sigma\mathbf{a}} \tilde{\phi}^\delta + [\mu(\sigma A) - \lambda] \tilde{\psi}^\delta \quad \text{in } B^+_{R_0},$$
$$(D(g)_{\sigma\mathbf{a}} \tilde{\psi}^\delta) \cdot \nu = 0 \quad \text{on } \Gamma_{R_0}. \tag{7.9}$$

Here the notations involved are the same as in Secs. III and V.

Define the following rescaled functions and vector fields: $\tilde{\psi}_\delta(y) = \tilde{\psi}^\delta(\delta y)$, $\tilde{v}_\delta(y) = \tilde{v}(\delta y)$, $g_\delta(y) = g(\delta y)$, $\mathbf{a}_\delta(y) = (1/\delta)\mathbf{a}(\delta y)$. Then,

$$-\Delta(g_\delta)_{\mathbf{a}_\delta} \tilde{\psi}_\delta = D(g_\delta)\tilde{v}_\delta \cdot D(g_\delta)_{\mathbf{a}_\delta} \tilde{\psi}_\delta + \frac{\mu(\sigma A) - \lambda}{\sigma} \tilde{\psi}_\delta \quad \text{in } B^+_{R_0/\delta},$$

$$(D(g_\delta)_{\mathbf{a}_\delta} \tilde{\psi}_\delta) \cdot \nu = 0 \quad \text{on } \Gamma_{R_0/\delta}.$$

Recall that $h_\delta = H(x^\delta)$, $h = H(x^0)$. From (3.11) we have

$$\mathbf{a}_\delta(y) = \nabla_y \tilde{\chi}_\delta(y) + h_\delta \tilde{\omega}(y) + \tilde{B}_\delta(y),$$

which holds in $B^+_{R_0/\delta}$, but not in the entire ball. Set $\tilde{\phi}_\delta(y) = \exp(-i\tilde{\chi}_\delta)\tilde{\psi}_\delta$. Then,

$$-\Delta(g_\delta)_{h_\delta\tilde{\omega} + \tilde{B}_\delta} \tilde{\phi}_\delta = D(g_\delta)\tilde{v}_\delta \cdot D(g_\delta)_{h_\delta\tilde{\omega} + \tilde{B}_\delta} \tilde{\phi}_\delta + \frac{\mu(\sigma A) - \lambda}{\sigma} \tilde{\phi}_\delta \quad \text{in } B^+_{R_0/\delta}.$$

Using Theorem 5.5 we obtain

$$\tilde{\phi}_\delta \to \tilde{\phi}_0 \ \text{ weakly in } W^{1,2}_{\mathrm{loc}} \text{ and strongly in } L^2_{\mathrm{loc}}.$$

Write $\tilde{B}_\delta = \tilde{B}^1_\delta \mathbf{e}_1 + \tilde{B}^2_\delta \mathbf{e}_2$, and write the equation for $\tilde{\phi}$ as follows:

$$-\Delta(g_\delta)_{h\tilde{\omega}} \tilde{\phi}_\delta = \frac{\mu(\sigma A)}{\sigma} \tilde{\phi}_\delta + \tilde{f}_\delta \quad \text{in } B^+_{R_0/\delta},$$
$$(D(g_\delta)_{h_\delta\tilde{\omega}} \tilde{\phi}_\delta) \cdot \nu = -i\tilde{B}^2_\delta \tilde{\phi}_\delta \quad \text{on } \Gamma_{R_0/\delta}. \tag{7.10}$$

Note that $D(g_\delta)\tilde{v}_\delta \cdot D(g_\delta)_{h_\delta\tilde{\omega} + \tilde{B}_\delta} \tilde{\phi}_\delta \to 0$ in L^2_{loc} and $\tilde{B}_\delta \to 0$ in L^2_{loc}. So, $\tilde{f}_\delta \to 0$ in L^2_{loc}. We also note that $g_\delta(y) = 1 - \delta y_2 \kappa_r(\delta y_1) \to 1$. Hence, $\tilde{\phi}_0$ satisfies

$$-\nabla^2_{h\omega} \tilde{\phi}_0 = \alpha \tilde{\phi}_0 \quad \text{in } \mathbb{R}^2_+,$$
$$\nabla_{h\omega} \cdot \tilde{\phi}_0 = 0 \quad \text{on } \partial\mathbb{R}^2_+. \tag{7.11}$$

We apply Theorem 5.5 to the equation for $\tilde{\phi}-\tilde{\phi}_0$, then use the classical elliptic estimates to obtain that $\tilde{\phi}_\delta\to\tilde{\phi}_0$ in C^α_{loc}.

Recall that $|y^\delta|/\delta\leqslant C$. By passing to a subsequence, we may assume that $z^\delta\equiv y^\delta/\delta\to z^0$, hence, $\tilde{\phi}_0(z_0)=\lim\tilde{\phi}_\delta(z^\delta)\neq 0$. Therefore, $\tilde{\phi}_0\not\equiv 0$, that is, $\tilde{\phi}_0$ is a nonzero bounded smooth solution of Eq. (7.11). Using Lemma 2.2 we conclude that

$$a\geqslant\beta(h)=\beta_0|h|=\beta_0|H(x^0)|\geqslant\beta_0\min_{x\in\partial\Omega}|H(x)|=m(\partial\Omega)\beta_0.$$

Since $m(\partial\Omega)\beta_0\geqslant m\geqslant a$, we have $m=a$. We also see that if Case 2 happens then $m=m(\partial\Omega)\beta_0$, $x^0\in(\partial\Omega)_m$ and (7.1) holds. □

The proof of Lemma 7.1 has the following consequence.

Proposition 7.2: Assume that $A\in C^2(\bar{\Omega})$. *Let* ψ_σ *be the eigenfunction of Eq. (7.2) associated with the first eigenvalue* $\mu(\sigma A)$ *such that* $\|\psi_\sigma\|_{L^\infty}\leqslant C$. *Then,*

$$|\psi_\sigma|\to 0 \quad \textit{in} \ C^\alpha_{\mathrm{loc}}(\Omega\backslash\Omega_m) \ \textit{and in} \ C^\alpha_{\mathrm{loc}}(\partial\Omega\backslash(\partial\Omega)_m) \ \textit{as} \ \sigma\to\infty.$$

Proof of Theorem 1: Combining Lemmas 6.1, 6.2, 7.1 *yields Theorem 1.* □

As a corollary of Theorem 1 and Proposition 7.2, we have

Theorem 7.3: *Assume* $A\in C^2(\bar{\Omega})$ *and* $\mathrm{curl}\,A(x)\equiv H$, *a nonzero constant. Then*

$$\lim_{\sigma\to\infty}\frac{\mu(\sigma A)}{|\sigma|}=\beta_0|H|. \tag{7.12}$$

Let ψ_σ *be the eigenfunction of (7.2) satisfying* $\|\psi_\sigma\|_{L^\infty}=1$, *then* ψ_σ *concentrates at some points on* $\partial\Omega$, *that is,* $\|\psi_\sigma\|_{L^\infty(\partial\Omega)}\to 1$ *and*

$$\psi_\sigma\to \ \textit{in} \ C^\alpha(\Omega) \quad \textit{as} \ \sigma\to\infty.$$

Proposition 7.2 says that as $\sigma\to\infty$ the eigenfunctions concentrate at some points in $\Omega_m\cup(\partial\Omega)_m$. From the proof of Lemma 7.1 one easily see that, after rescaling near the maximum points and making gauge transitions, the eigenfunctions exhibit profiles of either the eigenfunction of (2.3) in the entire plane $\mathbb{R}^2$ (when interior concentration happens), or the eigenfunction of (2.5) in the half plane $\mathbb{R}^2_+$ (when boundary concentration happens). It will be interesting to find the exact location of the concentration points. In Ref. 1 the concentration behavior of minimal solutions of Ginzburg–Landau equations is studied and the location of concentration is investigated. The arguments used in Ref. 1 can be applied in a similar way to obtain the location of concentration of the eigenfunctions. We should mention that in Ref. 10 Bernoff and Sternberg obtained the location of surface nucleation of superconductivity by using the asymptotic analysis.

(Received 22 December 1998; accepted for publication 25 February 1999)

For the hydrogenlike atom, with central potential $-Z/r$, partial differential equations exist for the Slater sum $\mathcal{Z}(r,\beta)$ $[\beta=(k_\mathrm{B}T)^{-1}]$ and for its *s*-wave $(l=0)$ component $\mathcal{Z}_0(r,\beta)$. It is shown that Z can be eliminated, to lead to a result in which $\mathcal{Z}(r,\beta)$ is solely characterized by $\mathcal{Z}_0(r,\beta)$. A similar situation is exhibited for the three-dimensional isotropic harmonic oscillator, for which closed forms of both $\mathcal{Z}(r,\beta,\omega)$ and $\mathcal{Z}_0(r,\beta,\omega)$ can be obtained explicitly. Finally, a third central field problem is considered in which independent electrons are confined within a sphere of radius R, but are otherwise free. We are able to derive explicitly for this model the *s*-wave component $\mathcal{Z}_0(r,\beta,R)$. The full Slater sum $\mathcal{Z}(r,\beta,R)$ then is also analyzed in some detail. © *1999 American Institute of Physics.*

I. BACKGROUND

The single particle level density, or density of states $g(E)$, of a quantum system described by a one-particle Hamiltonian with a local effective potential $V(\mathbf{r})$ is given by the inverse Laplace transform of the canonical partition function $Z(\beta)$ divided by β, $Z(\beta)$ being obtained as the trace of the canonical density matrix

$$C(\mathbf{r},\mathbf{r}_0,\beta)=\sum_n \chi_n(\mathbf{r})\chi_n^*(\mathbf{r}_0)e^{-\beta\epsilon_n}. \tag{1}$$

Here ϵ_n are the eigenvalues of the energy for the states $\chi_n(\mathbf{r})$, and $\beta=(k_\mathrm{B}T)^{-1}$, with k_B Boltzmann's constant, and T the absolute temperature. In the context of semiclassical periodic orbit theory, the so-called "trace formula" [1] for the oscillating part of $g(E)$ provides the basis for many interesting interpretations of quantum phenomena in terms of classical orbits. Examples are given in Ref. 1 of applications in atomic nuclei, metal clusters, and semiconductor quantum dots.

In this paper we are interested in the diagonal part of the canonical density matrix, the so-called Slater sum

$$\mathcal{Z}(\mathbf{r},\beta)=C(\mathbf{r},\mathbf{r},\beta). \tag{2}$$

In particular, we construct this Slater sum for several illustrative central field problems. In the early work of March and Murray,[2] central field problems were considered for the Slater sum

$\mathcal{Z}(r,\beta)$, and for its analysis into its angular momentum components $\mathcal{Z}_l(r,\beta)$. Here, if $V(r)$ denotes a general central potential energy, and it generates radial eigenfunctions $\chi_{nl}(r)$ and corresponding eigenvalues ϵ_{nl}, then following Ref. 2

$$4\pi\mathcal{Z}_l(r,\beta)=\sum_n \chi_{nl}(r)\chi_{nl}^*(r)\exp(-\beta\epsilon_{nl}). \tag{3}$$

The full Slater sum $\mathcal{Z}(r,\beta)$ is constructed from $Z_l(r,\beta)$ as[2]

$$\mathcal{Z}(r,\beta)=\sum_{l=0}^{\infty}(2l+1)\mathcal{Z}_l(r,\beta). \tag{4}$$

In the present work, we shall focus on the *s*-wave component $l=0$, $\mathcal{Z}_0(r,\beta)$ in Eq. (3), and the way in which this can be used in specific central field problems to construct the full Slater sum $\mathcal{Z}(r,\beta)$. We turn immediately in Sec. II below to the first of three central field examples, namely the three-dimensional isotropic harmonic oscillator. In Sec. III some results concerning the Coulomb potential are derived. In Sec. IV we deal with the case of a spherical cavity of radius *R*. The *s*-wave component $\mathcal{Z}_0$ of the Slater sum is explicitly evaluated. In Sec. V we gather some discussion and a summary, while more technical details are relegated to the Appendices.

II. THREE-DIMENSIONAL ISOTROPIC OSCILLATOR

For the three-dimensional isotropic harmonic oscillator $V(r)=\omega^2r^2/2$, the evaluation of the Slater sum $\mathcal{Z}(r,\beta,\omega)$ essentially goes back to the pioneering work by Sondheimer and Wilson[3] on free electrons in an external magnetic field. These workers, in fact, obtained for this problem the canonical density matrix $C(\mathbf{r},\mathbf{r}_0,\beta,\omega)$, which is essentially equivalent to the oscillator example under discussion here (see also Ref. 4). In Appendix A, we record first the full results for the canonical density matrix from which the Slater sum $\mathcal{Z}(r,\beta,\omega)$ is immediately obtained as its diagonal element $C(\mathbf{r},\mathbf{r}_0=\mathbf{r},\beta,\omega)$:

$$\mathcal{Z}(r,\beta,\omega)=\left[\frac{\omega}{2\pi\sinh(\beta\omega)}\right]^{3/2}\exp\left[-\omega r^2\tanh\left(\frac{\beta\omega}{2}\right)\right]. \tag{5}$$

It is important to mention that Amovilli and March[5] found a differential equation satisfied by the Slater sum for the harmonic oscillator [see Eqn. (2.10) of Ref. 5], namely

$$\frac{1}{8}\frac{\partial^3\mathcal{Z}}{\partial r^3}+\frac{1}{4r}\frac{\partial^2\mathcal{Z}}{\partial r^2}-\left[\frac{1}{4r^2}+V+\frac{\partial}{\partial\beta}\right]\frac{\partial\mathcal{Z}}{\partial r}+\frac{1}{2}\frac{dV}{dr}\mathcal{Z}=0. \tag{6}$$

Going back to Eq. (5), note that as $\omega\to 0$, it reduces to

$$\mathcal{Z}_\infty(\beta)=(2\pi\beta)^{-3/2}, \tag{7}$$

which is the correct partition function for free particles, per unit volume.

What, however, is important for the present consideration is that the knowledge of the canonical density matrix $C(\mathbf{r},\mathbf{r}_0,\beta,\omega)$ allows the *s*-state component of the Slater sum $Z_0(r,\beta,\omega)$ to be directly extracted, and this is also accomplished in Appendix A. The final result for $\mathcal{Z}_0(r,\beta,\omega)$ is given there by Eqs. (A9) and (A10):

$$\mathcal{Z}_0(r,\beta,\omega)=\left[\frac{\omega}{2\pi\sinh(\beta\omega)}\right]^{3/2}\frac{e^{r^2\mu}-e^{-r^2\mu}}{2r^2\mu}\exp\left(-\frac{\omega}{2}r^2\left[\coth\frac{\beta\omega}{2}+\tanh\frac{\beta\omega}{2}\right]\right), \tag{8}$$

where

$$\mu = \frac{\omega}{2}\left[\coth\frac{\beta\omega}{2} - \tanh\frac{\beta\omega}{2}\right].$$

This reduces to the free-particle result of March and Murray,[2] when the ''force constant'' ω is reduced to zero, i.e.,

$$\mathcal{Z}_0(r,\beta,\omega\to 0) = \frac{1}{2(2\pi)^{3/2}\beta^{1/2}}\frac{[1-\exp(-2r^2/\beta)]}{r^2}. \tag{9}$$

We discuss the relation between $\mathcal{Z}(r,\beta)$ and its s-state component $\mathcal{Z}_0(r,\beta)$ in Appendix A, Sec. 2. We shall also return briefly to this example after discussing the hydrogenlike atom. However, we can generalize $\mathcal{Z}_0(r,\beta,\omega)$ in Eq. (8) to a general orbital quantum number l, the result for $\mathcal{Z}_l(r,\beta,\omega)$ being given also in Appendix A.

III. COULOMB CASE

March and Murray[2] derive for the s-state component $\mathcal{Z}_0(r,\beta)$ of the Slater sum $\mathcal{Z}(r,\beta)$ in a hydrogenlike atom with central potential energy $-Z/r$ the partial differential equation [see Ref. 2, equation (4.7)]

$$\frac{1}{8}\frac{\partial^3}{\partial r^3}(r^2\mathcal{Z}_0) - \frac{\partial^2}{\partial r\partial\beta}(r^2\mathcal{Z}_0) + \frac{Z}{r}\frac{\partial}{\partial r}(r^2\mathcal{Z}_0) - \frac{Z\mathcal{Z}_0}{2} = 0. \tag{10}$$

Let us now use in this Eq. (10) the ''generalized Kato'' result of March,[6] namely (see also Refs. 5, 7, and 8)

$$\frac{\partial\mathcal{Z}}{\partial r} = -2Z\mathcal{Z}_0. \tag{11}$$

By replacing $Z\mathcal{Z}_0$ in Eq. (10) by half the lhs of Eq. (11), one finds

$$\frac{1}{8}\frac{\partial^3}{\partial r^3}(r^2\mathcal{Z}_0) - \frac{\partial^2}{\partial r\partial\beta}(r^2\mathcal{Z}_0) = \frac{1}{2r}\frac{\partial}{\partial r}\left(r^2\frac{\partial\mathcal{Z}}{\partial r}\right) - \frac{1}{4}\frac{\partial\mathcal{Z}}{\partial r}. \tag{12}$$

This, then, is an equation relating the total Slater sum for the hydrogenlike atom directly to its s-state component, the nuclear potential energy $-Z/r$ no longer appearing explicitly. Thus Eq. (10) is the counterpart of the relation between $\mathcal{Z}$ and $\mathcal{Z}_0$ referred to in Sec. II for the harmonic oscillator [see also Eq. (6) below]. However, neither $\mathcal{Z}$ nor $\mathcal{Z}_0$ is yet known in closed form for the Coulomb case.

We can expect Eq. (12) to apply even when we ''switch off'' Z, to reach the ''free-electron limit'' in, initially, an infinite volume. In this limiting case, the function $\mathcal{Z}(r,\beta)$ will take the constant value $(2\pi\beta)^{-3/2}$ [see also Eq. (7) above], which in the units adopted here, is simply the partition function per unit volume of free electrons. Then the terms involving $\mathcal{Z}(r,\beta)$ in Eq. (12) become zero and we regain the free-particle s-state-only equation already solved by March and Murray,[2] namely

$$\frac{1}{8}\frac{\partial^3}{\partial r^3}(r^2\mathcal{Z}_0) - \frac{\partial^2}{\partial r\partial\beta}(r^2\mathcal{Z}_0) = 0, \tag{13}$$

with explicit solution given in Eq. (9) above. In fact, Eq. (13) is readily integrated with respect to r to yield

$$\frac{1}{2}\frac{\partial^2}{\partial r^2}(r^2\mathcal{Z}_0) - 4\frac{\partial}{\partial\beta}(r^2\mathcal{Z}_0) = (2\pi\beta)^{-3/2} = \mathcal{Z}_\infty(\beta), \tag{14}$$

again relating the Slater sum $\mathcal{Z}(r,\beta)\equiv\mathcal{Z}_\infty(\beta)$ directly to its s-state component $\mathcal{Z}_0(r,\beta)$ of Eq. (9).

IV. SPHERICAL BARRIER WITH FINITE RADIUS *R*

We turn to the third central field problem to be treated in the present study: namely noninteracting electrons confined by an infinite spherical barrier to move inside a sphere of radius R, but which are otherwise free. Fortunately, in this case, wave functions and energy levels can be obtained explicitly for the s states as the radial functions are given by

$$\chi_{n0}(\mathbf{r})=\sqrt{\frac{2}{R}}\,\frac{\sin(n\pi r/R)}{r}, \tag{15}$$

and the corresponding eigenvalues in atomic units $(\hbar=m=1)$ are

$$\epsilon_n=\frac{\pi^2}{2R^2}n^2. \tag{16}$$

Hence, inserting Eqs. (15) and (16) into Eq. (3), and using the definition of the Jacobi function ϑ_3 (see Ref. 9)

$$\vartheta_3(z,q)=1+2\sum_{n=1}^{\infty} q^{n^2}\cos(2nz), \quad |q|<1, \tag{17}$$

Eq. (18) below is found for $\mathcal{Z}_0(r,\beta,R)$:

$$\mathcal{Z}_0(r,\beta,R)=\frac{1}{8\pi r^2 R}\left[\vartheta_3\left(0,\exp\left(-\frac{\beta\pi^2}{2R^2}\right)\right)-\vartheta_3\left(\frac{\pi r}{R},\exp\left(-\frac{\beta\pi^2}{2R^2}\right)\right)\right]. \tag{18}$$

The off-diagonal form $C_0(r,r_0,\beta,R)$ is derived in Appendix B.

From Eq. (18) it is straightforward to derive the result

$$\frac{1}{8}\,\frac{\partial^2(r^2\mathcal{Z}_0)}{\partial r^2}-\frac{\partial(r^2\mathcal{Z}_0)}{\partial\beta}=\frac{\pi}{8}\sum_{n=0}^{\infty}\frac{1}{R}\left(\frac{n}{R}\right)^2\exp\left(-\frac{\beta\pi^2}{2}\left(\frac{n}{R}\right)^2\right), \tag{19}$$

which is just a function of β and R, and therefore is constant for $r<R$ (for $r>R$ it is zero). There is a discontinuity at $r=R$, reflecting the fact that the potential we are dealing with has a strong singularity at this boundary. Observe that the function $r^2\mathcal{Z}_0$ satisfies Eq. (10) with $Z=0$, or equivalently (13), but with a strong singularity at the border $r=R$.

We note that for large R, the limiting process included in Eq. (18) can be carried out essentially by replacing the summation involved for the theta function in Eq. (17) by an integration; such a replacement is valid only as $R\to\infty$. Then Eq. (18) can be rewritten as

$$\begin{aligned}\lim_{R\to\infty}\mathcal{Z}_0(r,\beta,R)&=\frac{1}{2\pi r^2}\lim_{R\to\infty}\sum_{n=1}^{\infty}\frac{\sin^2(\pi rn/R)}{R}e^{-(\beta\pi^2/2)(n/R)^2}\\&=\frac{1}{2\pi r^2}\int_0^\infty e^{-(\beta\pi^2/2)x^2}\sin^2(\pi rx)\,dx,\end{aligned} \tag{20}$$

which can be shown to be equivalent to

$$\mathcal{Z}_0(r,\beta,\infty)=\sum_{n=1}^{\infty}\frac{(-4r^2)^{n-1}}{(2n)!\,\pi^2}\left[\frac{2}{\beta}\right]^{n+1/2}\int_0^\infty e^{-y^2}y^{2n}\,dy. \tag{21}$$

The integration appearing in (21) is a gamma function. Therefore, after some straightforward calculation the previous result can be written as

$$\mathcal{Z}_0(r,\beta,\infty)=-\frac{1}{8\pi^2r^2}\sqrt{\frac{2\pi}{\beta}}\sum_{n=1}^{\infty}\frac{1}{n!}\left(-\frac{2r^2}{\beta}\right)^n, \tag{22}$$

which can be summed to regain the limiting form (9).

In Appendix B, some progress is made in setting up a differential equation for the Slater sum $\mathcal{Z}(r,\beta,R)$. However, in contrast to the earlier examples of the harmonic oscillator and the hydrogen atom, near-diagonal behavior of $C(\mathbf{r},\mathbf{r}_0,\beta,R)$ is required in the formalism available to date. Therefore, although the *s*-wave component $\mathcal{Z}_0(r,\beta,R)$ is completely solved, full information relating $\mathcal{Z}$ and $\mathcal{Z}_0$ is still lacking except in the limit as R tends to infinity.

V. DISCUSSION AND SUMMARY

As is evident from Eq. (12) for the hydrogenlike atom, the knowledge of the *s*-state component for the Slater sum $\mathcal{Z}_0(r,\beta)$ determines the entire sum $\mathcal{Z}(r,\beta)$ by integration of an ordinary differential equation to yield

$$\frac{\partial\mathcal{Z}}{\partial r}=f(\beta)+e^{-3r^2/4}\int^r 2re^{3r^2/4}\left[\frac{1}{8}\frac{\partial^3(r^2\mathcal{Z}_0)}{\partial r^3}-\frac{\partial^2(r^2\mathcal{Z}_0)}{\partial r\partial\beta}\right]dr, \tag{23}$$

$f(\beta)$ being an arbitrary function. Evidently then, $\mathcal{Z}(r,\beta)$ can be written explicitly by a further quadrature of Eq. (23). Naturally, physical boundary conditions must be imposed. Equation (23) makes explicit the idea motivating the present investigation: namely the characterization of the Slater sum by its *s*-state component.

For the other examples considered here, the more complex analog of (23) is embodied in Eqs. (A11) and (A12) for the three-dimensional isotropic harmonic oscillator. However, in this specific example, both $\mathcal{Z}$, already given in the work of Ref. 3, and $\mathcal{Z}_0$ derived in the present paper and given in (8), are known explicitly. Finally, new results are given for the *s*-state component $\mathcal{Z}_0$ in Eq. (18) although a satisfactory integro-differential equation for the full Slater sum $\mathcal{Z}(r,\beta,R)$ for the spherical barrier problem is not yet found (see Appendix B).

ACKNOWLEDGMENTS

One of us (NHM) made his contribution to this investigation during visits to the Theoretical Physics Department of the University of Valladolid. He wishes to thank especially Professor J. A. Alonso and his colleagues for much stimulating discussion and for generous hospitality. NHM also acknowledges partial financial support from the Leverhulme Trust, UK. APPENDIX A: SOME RESULTS FOR THE ISOTROPIC THREE-DIMENSIONAL HARMONIC OSCILLATOR

1. Canonical density matrix

As used, for example, in Eq. (2.4) of Ref. 4, if the potential energy of the oscillator is $\frac{1}{2}\omega^2r^2$, then

$$C(\mathbf{r},\mathbf{r}_0,\beta,\omega)=\left[\frac{\omega}{2\pi\sinh(\beta\omega)}\right]^{3/2}\exp\left[-\frac{\omega|\mathbf{r}-\mathbf{r}_0|^2}{4}\coth\frac{\beta\omega}{2}\right]\exp\left[-\frac{\omega|\mathbf{r}+\mathbf{r}_0|^2}{4}\tanh\frac{\beta\omega}{2}\right]. \tag{A1}$$

In the limit $\omega\rightarrow 0$ we have

$$C_{\text{free}}(\mathbf{r},\mathbf{r}_0,\beta)=\frac{1}{(2\pi\beta)^{3/2}}\exp\left[-\frac{|\mathbf{r}-\mathbf{r}_0|^2}{2\beta}\right]. \tag{A2}$$

This is translationally invariant, coming essentially from plane waves $\exp(i\mathbf{k}\cdot\mathbf{r})$.

Evidently, from Eq. (A1), the result (5) of the main text is recovered by setting $\mathbf{r}_0=\mathbf{r}$. In the limit $\omega\to 0$ this equation gives the correct result (7) above.

To get the l-state matrix $C_l(r,r_0,\beta,\omega)$, let us introduce in Eq. (A1)

$$C(\mathbf{r},\mathbf{r}_0,\beta,\omega)=\sum_{k=0}^{\infty}(2k+1)C_k(r,r_0,\beta,\omega)P_k(\cos\gamma), \tag{A3}$$

where γ is the angle between $\mathbf{r}$ and $\mathbf{r}_0$, and $P_k(x)$ are Legendre polynomials.

Now extract the "l" state C_l from (A3) by multiplying both sides by $P_l(\cos\gamma)$, and by $\sin\gamma$, and integrating from $\gamma=0$ to $\gamma=\pi$:

$$C_l(r,r_0,\beta,\omega)=\frac{\mathbb{L}_l(a)}{2}\left[\frac{\omega}{2\pi\sinh(\beta\omega)}\right]^{3/2}\exp\left[-\frac{\omega(r^2+r_0^2)}{4}\left(\coth\frac{\beta\omega}{2}+\tanh\frac{\beta\omega}{2}\right)\right]. \tag{A4}$$

The essential integral involving γ to be evaluated is

$$\mathbb{L}_l(a)=\int_0^{\pi}\exp(a\cos\gamma)\sin\gamma P_l(\cos\gamma)d\gamma=\int_{-1}^{1}\exp(as)P_l(s)ds, \tag{A5}$$

with

$$a=\frac{rr_0\omega}{2}\left[\coth\frac{\beta\omega}{2}-\tanh\frac{\beta\omega}{2}\right].$$

The last integral (A5) can be evaluated in different forms. For example, we can give an expression in terms of the derivatives of Legendre polynomials $P_l^{(n)}(s)$ evaluated at ± 1:

$$\mathbb{L}_l(a)=\left[\frac{e^{as}}{a}\sum_{n=0}^{l}\frac{(-1)^n}{a^n}P_l^{(n)}(s)\right]_{-1}^{1}=\frac{1}{a^{l+1}}\sum_{n=0}^{l}(-1)^n a^{l-n}\{e^aP_l^{(n)}(1)-e^{-a}P_l^{(n)}(-1)\}. \tag{A6}$$

However, an equivalent and more interesting expression is obtained when using the explicit form of Legendre polynomials:

$$\mathbb{L}_l(a)=\frac{1}{2^l}\sum_{m=0}^{[l/2]}(-1)^m\binom{l}{m}\binom{2l-2m}{l}\frac{d^{l-2m}\mathbb{L}_0(a)}{da^{l-2m}}. \tag{A7}$$

For example, the first terms are

$$\mathbb{L}_0(a)=\frac{e^a-e^{-a}}{a},\quad \mathbb{L}_1(a)=\frac{d\mathbb{L}_0(a)}{da}. \tag{A8}$$

Using the previous results, C_0 can be evaluated explicitly. In particular, on the diagonal $r=r_0$, and $C_0(r,r,\beta,\omega)=\mathcal{Z}_0(r,\beta,\omega)$. Hence

$$\mathcal{Z}_0(r,\beta,\omega)=\left[\frac{\omega}{2\pi\sinh(\beta\omega)}\right]^{3/2}\frac{e^{r^2\mu}-e^{-r^2\mu}}{2r^2\mu}\exp\left(-\frac{\omega}{2}r^2\left[\coth\frac{\beta\omega}{2}+\tanh\frac{\beta\omega}{2}\right]\right), \tag{A9}$$

where

$$\mu=\frac{\omega}{2}\left[\coth\frac{\beta\omega}{2}-\tanh\frac{\beta\omega}{2}\right]. \tag{A10}$$

As $\omega\to 0$, the infinite volume free particle result for $\mathcal{Z}_0$ is regained.

2. Relation between Slater sum $\mathcal{Z}(r,\beta,\omega)$ and *s*-wave component $\mathcal{Z}_0(r,\beta,\omega)$

We add here that an explicit, though somewhat complicated, relation exists between $\mathcal{Z}$ and $\mathcal{Z}_0$ for the harmonic oscillator follows by using (i) the general relation between $V(r)$ and $\mathcal{Z}_0$ and (ii) the specific relation between $V(r)$ and $\mathcal{Z}$ given in (6).

The analog of Eq. (10) for the case of the harmonic oscillator is immediately found from Eq. (4.7) of Ref. 2 by putting $V(r)=\frac{1}{2}\omega^2 r^2$. However, in the context of the present work it is helpful to note that Eq. (41) of Ref. 2 can be viewed as a first-order differential equation for $V(r)$, given the *s* state component $\mathcal{Z}_0(r,\beta)$ of the Slater sum. The integral of this equation then takes the form

$$V(r)=\frac{1}{Q^2}\int^r\left[\frac{1}{4}QQ'''-2Q\frac{\partial Q'}{\partial\beta}\right]dr,\quad Q=r^2\mathcal{Z}_0, \tag{A11}$$

which, in fact, is a quite general central field equation characterizing V and $\mathcal{Z}_0$.

The corresponding equation for $\mathcal{Z}$, but now specific for the harmonic oscillator, can be obtained from Ref. 5 as

$$V(r)=\mathcal{Z}^2\int^r\frac{2}{\mathcal{Z}^3}\left[\frac{\partial\mathcal{Z}'}{\partial\beta}-\frac{\mathcal{Z}'}{4r^2}-\frac{\mathcal{Z}''}{2r}-\frac{\mathcal{Z}'''}{8}\right]dr. \tag{A12}$$

Clearly, equating Eqs. (A11) and (A12) gives the relation between the Slater sum $\mathcal{Z}$ and its *s*-wave component $\mathcal{Z}_0$ for the three-dimensional harmonic oscillator.

APPENDIX B: CANONICAL DENSITY MATRIX FOR SPHERICAL BARRIER

1. $l=0$ component of canonical density matrix

Let us consider the $l=0$ solutions of the Schrödinger equation in three dimensions for a free particle inside a spherical barrier of radius R. Using the normalized radial eigenfunctions and the eigenvalues given in (15) and (16), we can evaluate the *s*-state component of the canonical density matrix

$$\begin{aligned}C_0(r,r_0,\beta,R)&=\frac{1}{4\pi}\sum_{n=1}^{\infty}\chi_{n0}(\mathbf{r})\chi^*_{n0}(\mathbf{r})e^{-\beta\epsilon_n}\\&=\frac{1}{4\pi rr_0R}\sum_{n=1}^{\infty}e^{-\beta n^2\pi^2/2R^2}\left(\cos\left[\frac{2n\pi(r-r_0)}{2R}\right]-\cos\left[\frac{2n\pi(r+r_0)}{2R}\right]\right)\\&=\frac{1}{8\pi rr_0R}\left[\vartheta_3\left(\frac{\pi(r-r_0)}{2R},e^{-\beta\pi^2/2R^2}\right)-\vartheta_3\left(\frac{\pi(r+r_0)}{2R},e^{-\beta\pi^2/2R^2}\right)\right].\end{aligned} \tag{B1}$$

We have used here the standard definition of one of the theta functions[9] given in (17). If we consider the limit $q\to 1$, we get a Fourier series expansion that is precisely a ''Dirac comb''[10]

$$\vartheta_3(z,1)=\pi\sum_{k=-\infty}^{\infty}\delta(z-k\pi). \tag{B2}$$

Therefore, taking the limit $\beta\to 0$ in (B1) we find

$$4\pi r r_0 C_0(r,r_0,0,R)=\sum_{k=-\infty}^{\infty}[\delta(r-r_0-2Rk)-\delta(r+r_0-2Rk)];\tag{B3}$$

for the relevant range of variation of the radial variables, only one of the Dirac delta functions contributes. Therefore,

$$4\pi r r_0 C_0(r,r_0,0,R)=\delta(r-r_0),\tag{B4}$$

and one of the required conditions on the canonical density matrix is satisfied.

By taking $r=r_0$ in (B1), we obtain the s-wave component of the Slater sum for this problem, the result being given in (18). From this expression, it is easy to prove that

$$\mathcal{Z}_0(0,\beta,R)=\frac{\pi}{2R^3}\sum_{n=1}^{\infty} n^2 e^{-\beta n^2\pi^2/2R^2}=\mathcal{Z}(0,\beta,R).\tag{B5}$$

This function presents a divergence for $\beta/R^2\rightarrow 0$, which is represented explicitly by

$$R^3\mathcal{Z}(0,\beta,R)\approx\frac{1}{(2\pi)^{3/2}}\left(\frac{\beta}{R^2}\right)^{-3/2}.\tag{B6}$$

In addition, one can easily check that the function $\mathcal{Z}_0(r,\beta,R)$ of (18) satisfies Eq. (13). This is an immediate consequence of the fact that the ϑ_3 function obeys the heat equation.[11]

2. Additional comments on the canonical density matrix

From Eq. (4.6) of March and Murray[2] for $V=0$, and after multiplication by $2r^2$ we get

$$r^2\frac{\partial^2}{\partial r^2}(rC_l)\bigg|_{r'=r}-l(l+1)(r\mathcal{Z}_l)-2r^2\frac{\partial}{\partial\beta}(r\mathcal{Z}_l)=0.\tag{B7}$$

Retaining the ‘‘pathological’’ dV/dr, we have for the diagonal quantity $\mathcal{Z}_l$, again with $V=0$:

$$\frac{1}{8r}\frac{\partial^3}{\partial r^3}(r^2\mathcal{Z}_l)-\frac{1}{2r^2}\frac{\partial}{\partial r}(rl(l+1)\mathcal{Z}_l)-\frac{1}{2}\frac{\partial V}{\partial r}(r^2\mathcal{Z}_l)-\frac{1}{r}\frac{\partial^2}{\partial\beta\partial r}(r^2\mathcal{Z}_l)=0.\tag{B8}$$

Substitute from Eq. (B7) for $l(l+1)r\mathcal{Z}_l$ into Eq. (B8) to find

$$\frac{1}{8r}\frac{\partial^3}{\partial r^3}(r^2\mathcal{Z}_l)-\frac{1}{2r^2}\left\{\frac{\partial}{\partial r}\left[r^2\frac{\partial^2}{\partial r^2}(rC_l)\bigg|_{r'=r}-2r^2\frac{\partial}{\partial\beta}(r\mathcal{Z}_l)\right]\right\}-\frac{1}{r}\frac{\partial^2}{\partial\beta\partial r}(r^2\mathcal{Z}_l)=\frac{1}{2r}\frac{\partial V}{\partial r}(r^2\mathcal{Z}_l).\tag{B9}$$

We note here that the great simplification for $l=0$, fully solved in the present work, is that the square bracket in Eq. (B9) is identically zero from Eq. (B7).

To make progress with Eq. (B9) we now appeal to the relation utilized earlier for the harmonic oscillator:

$$C_l=\int_0^{\pi} CP_l(\cos\gamma)\sin\gamma\, d\gamma,\tag{B10}$$

where P_l are Legendre polynomials. Use of Eq. (B10) moves the (as yet unknown) l dependence of C_l [expect for $R\rightarrow\infty$ where we have the March and Murray result for $\mathcal{Z}_l(r,\beta,R\rightarrow\infty)$ in terms of Bessel functions $I_{l+1/2}$, namely $4\pi r\beta\mathcal{Z}_l(r,\beta)=\exp(-r^2/\beta)I_{l+1/2}(r^2/\beta)$] entirely into the P_l's. Inserting Eq. (B10) into (B9) we can now multiply throughout by $(2l+1)$ and then sum over all l to find

$$\frac{1}{2r}\frac{\partial V}{\partial r}(r^2\mathcal{Z})=\frac{1}{8r}\frac{\partial^3}{\partial r^3}(r^2\mathcal{Z})-\frac{1}{r}\frac{\partial^2}{\partial\beta\partial r}(r^2\mathcal{Z})-\frac{1}{2r^2}\frac{\partial}{\partial r}\times\left[r^2\frac{\partial^2}{\partial r^2}\left(r\int_0^\pi\sum_{l=0}^\infty(2l+1)CP_l(\cos\gamma)\sin\gamma\,d\gamma\right)\bigg|_{r'=r}-2r^2\frac{\partial}{\partial\beta}(r\mathcal{Z})\right]. \tag{B11}$$

To our knowledge, Eq. (B11) is new. But to get an explicit differential equation for the Slater sum $\mathcal{Z}(r,\beta,R)$ for the spherical barrier, such as Amovilli and March give for both the harmonic oscillator and the hydrogen atom, one must be able to perform the sum over all l in the square brackets of Eq. (B11) and then express solely in terms of the diagonal of C, i.e., $\mathcal{Z}(r,\beta,R)$. Or, within the philosophy of the present work, one could consider relating the off-diagonal term in Eq. (B11) to the known $\mathcal{Z}_0(r,\beta,R)$ for the spherical barrier. We have, so far, not achieved such further simplification for the barrier problem.

(Received 7 July 1998; accepted for publication 12 January 1999)

Recently, the Dirac and Einstein equations were unified in a tetrad formulation of a Kaluza–Klein model with gauge group $\mathrm{SL}(2,R)\times\mathrm{U}(1)$. In this model, the self-adjoint modes of the tetrad describe gravity, whereas the isometric modes of the tetrad together with a scalar field describe fermions. This model gives precisely the usual Dirac–Einstein Lagrangian. In this paper we generalize the tensor Dirac theory to the larger gauge group $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ acting on bispinors. We show that each $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ subgroup of $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ corresponds to a different factorization of the second-order Klein–Gordon equation into a first-order Dirac equation. Since the Noether currents are different for each factorization, the solutions describe different flavors of fermions. We show that electric charge, lepton number, and baryon number are conserved in this generalization of the Dirac theory. © *1999 American Institute of Physics.* [S0022-2488(99)02904-7]

I. INTRODUCTION

Recently, the Dirac and Einstein equations were unified in a tetrad formulation of a Kaluza–Klein model which gives precisely the usual Dirac–Einstein Lagrangian.[1,2] In this model, the self-adjoint modes of the tetrad describe gravity, whereas the isometric modes of the tetrad together with a scalar field describe fermions. An analogy can be made between the tetrad modes and the elastic and rigid modes of a deformable body.[1] For a deformable body, the elastic modes are self-adjoint and the rigid modes are isometric with respect to the Euclidean metric on R^3. This analogy extends into the quantum realm since rigid modes satisfying Euler's equation can be Fermi quantized.[3]

The use of tetrads to describe gravity has a long history,[4] which includes coupling with the Dirac field as a source.[5] However, introducing a tetrad to describe both fermion and gravitational fields solves an important problem posed by current theories of fermion–graviton interaction. To define bispinors, reference tetrad fields or their equivalent must be defined on the space–time manifold.[6] These reference fields have been treated as purely boson fields in supersymmetric theories.[7] We found that the reference tetrads themselves can be taken as fundamental fields that describe both fermions and gravity.[1]

Boson gauge fields were added to the unified Dirac–Einstein Lagrangian by defining the gauge group of the Kaluza–Klein model to be a semidirect product.[2] It was shown that the semidirect product structure of the gauge group produces precisely the usual ''minimal coupling'' between bosons and fermions.

The tetrad Kaluza–Klein model is based on a constrained Yang–Mills formulation of the Dirac Theory.[1–3,8] In this formulation a bispinor field Ψ is mapped to a set of $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ gauge potentials A_α^K and a complex scalar field ρ. The gauge potentials A_α^K in the image of the map vanish, except for an $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ subgroup of $\mathrm{SL}(2,C)\times\mathrm{U}(1)$. The restriction to $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ arises because the Dirac equation has only $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ gauge symmetry, while the larger $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ gauge group acts on bispinors.

In this paper we generalize the tensor Dirac theory to the larger $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ gauge group acting on bispinors, and discuss its possible application to describing fermion flavors (e.g., quark and lepton flavors). We show that each $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ subgroup of $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ corresponds to a different factorization of the second-order Klein–Gordon equation into a first-order Dirac equation. Thus, the Yang–Mills Lagrangian (see Sec. II) for the $SL(2,C)\times U(1)$ gauge potentials A_α^K and scalar field ρ, describes solutions for different flavors of fermions. An assignment of flavor parameters to first generation leptons and quarks shows that electric charge, lepton number, and baryon number are conserved.

In Sec. II we review the derivation, which demonstrates that the Dirac bispinor Lagrangian equals a constrained Yang–Mills Lagrangian in the limit of an infinitely large coupling constant. In Sec. III we then derive the generalization that gives rise to fermion flavors. We show how the flavor symmetric tensor theory includes both the Dirac and Majorana bispinor theories as special cases. In Appendices A and B we provide a new derivation of the tensor Dirac theory from first principles, starting from trace formulas for the Pauli matrices, and ending with formulas for differentiating bispinor Fierz identities. This gauge symmetric derivation greatly simplifies computations with bispinors used in previous work on Fierz identities.[9,10]

Other authors have investigated the Fierz identities using more powerful Clifford algebra techniques.[11,12] Clifford algebra provides significant generalizations of the simple matrix algebra presented in Appendices A and B. It is clear from this work that the $SL(2,C)\times U(1)$ theory presented here can be extended to a wider class of gauge groups acting on bispinors by different representations.[13–16] A full generalization of the tensor Dirac theory with Clifford algebra techniques merits further study, as discussed in the following brief review of developments in the study of flavor symmetry.

Numerous books and journal articles have noted that different factorizations of the Klein–Gordon equation can give rise to flavor symmetry. For example, our earlier work represented a bispinor field Ψ as a triplet of complex antisymmetric tensors $\mathbf{F}_{\alpha\beta}$ of Carmeli class (G), defined in terms of A_α^K and ρ, as follows:[8]

$$\mathbf{F}_{\alpha\beta}=\rho(A_\alpha^0\mathbf{A}_\beta-\mathbf{A}_\alpha A_\beta^0+i\mathbf{A}_\alpha\times\mathbf{A}_\beta), \tag{1.1}$$

where $A_\alpha^K=(A_\alpha^0,\mathbf{A}_\alpha)$ and $\mathbf{A}_\alpha=(A_\alpha^1,A_\alpha^2,A_\alpha^3)$. Note that in this paper we denote gauge triplets, such as $\mathbf{F}_{\alpha\beta}=(F_{\alpha\beta}^1,F_{\alpha\beta}^2,F_{\alpha\beta}^3)$ and $\mathbf{A}_\alpha=(A_\alpha^1,A_\alpha^2,A_\alpha^3)$ by bolding and use $\cdot$ and $\times$ to denote the dot and cross products with respect to the gauge indices 1,2,3. Class (G) triplets $\mathbf{F}_{\alpha\beta}$ were studied by Carmeli, who classified the algebraic properties of Yang–Mills curvature tensors.[17] The $SL(2,C)\times U(1)$ gauge symmetry of the triplets $\mathbf{F}_{\alpha\beta}$ revealed the flavor symmetry of bispinors.[9,18,19] The following composite map from bispinors to Carmeli class (G) triplets $\mathbf{F}_{\alpha\beta}$:

$$\Psi\rightarrow(A_\alpha^K,\rho)\rightarrow\mathbf{F}_{\alpha\beta}, \tag{1.2}$$

which commutes with both the space–time and flavor symmetries, is an extension of the Cartan map from spinors to complex isotropic vectors.[8,20–22] Note that, similar to the Cartan map, the extension (1.2) is a holomorphic, branched double covering map with a single branch point at $\mathbf{F}_{\alpha\beta}=0$. For physically realizable solutions of the Dirac equation, the covering map (1.2) is unobservable.[8,23]

Using Clifford algebra techniques, Keller and Rodriguez-Romo generalized all of the constructions of the last paragraph, including flavor symmetry, to a wider class of gauge groups used in elementary particle physics.[11,12,24,25] We believe that the Kaluza–Klein model for the Dirac theory[1,2] also extends to this wider class of gauge groups. As a step in this direction, a specific generalization of the tensor Dirac theory to bispinor multiplets $\Psi=(\Psi_1,\ldots,\Psi_n)$ with the gauge group $SL(2n,C)\times U(1)$ will be presented in a forthcoming paper.

The tensor form of Dirac's bispinor equation itself has a long history.[1] Most noteworthy was the derivation of the tensor form of Dirac's bispinor Lagrangian by Takahashi, who ascribed a similar derivation to Zhelnorovich.[10,26] However, at that time, the flavor symmetry of Takahashi's formula [see formula (2.8) in Sec. II] was not recognized. Clifford algebra techniques could generalize Takahashi's formula (2.8) to the wider class of gauge groups investigated by Keller and

Rodriguez-Romo.[13] Moreover, studies of such generalizations could expand the number of Kaluza–Klein models suitable for the unification of the fundamental fields of elementary particle physics.

We conclude this Introduction with several remarks on the development of quantum mechanics. As discussed earlier, all the fundamental particles can be derived through the ''second'' quantization of fields unified at the classical level in a tetrad Kaluza–Klein model.[2] In this model the classical modes of a tetrad can be separated into isometric and self-adjoint modes, except near a Schwarzschild horizon.[1,27] Fermion statistics can be assumed for the isometric modes, whose classical Hamiltonian structure consists of noncanonical, unitary Lie–Poisson brackets, while only boson statistics can be assumed for the self-adjoint modes with canonical Hamiltonian structure.[1,3,28]

As previously mentioned, isometric modes of the reference frame fields, which in the tetrad Kaluza–Klein model represent fermion degrees of freedom, are treated as boson degrees of freedom in supersymmetric theories.[7] An alternative supersymmetric theory would treat only the self-adjoint modes of the reference frame fields as bosons, and these would describe gravity. The isometric modes would describe fermions. Thus, the tensor Dirac theory leads to a new formulation of the fermion–graviton interaction, which requires the modification of supersymmetric theories.

Consider first quantization. At the inception of quantum mechanics, with the realization of ''wave–particle duality,'' particles, classically conceived as points of mass and charge, were given wavelike properties through first quantization. Thus, Schrodinger's wave function Ψ for a single particle describes a matter field similar to the classical fields describing electromagnetism and gravity. Through ''second'' quantization, particles associated with the matter, electromagnetic, and gravitational fields are then represented uniformly by occupation states acted upon by creation and annihilation operators. From a practical viewpoint the occupation states and their precedent ''classical'' fields are sufficient to describe all observed phenomena.

The tetrad Kaluza–Klein model supports this viewpoint, since it shows that the ''classical'' precedents for fermions and bosons are the same *kind* of field, i.e., a classical Yang–Mills field with a classical Hamiltonian structure. Specifically, the Schrodinger wave function Ψ for a single particle (which Schrodinger originally conceived as a classical field), is the nonrelativistic limit of the Dirac field (A_α^K,ρ), which satisfies a classical Yang–Mills equation. Thus, Ψ inherits from the Dirac field (A_α^K,ρ) a classical Hamiltonian structure that admits Fermi quantization.[3] Therefore, quantum mechanics need only consist of three parts: the classical field equations, field quantization, and rules for applying the formalism to experiments. A fundamental model must account for all three parts of the theory in a unified framework. Unification of fermion and boson fields at a classical level is a step in this direction.

Supersymmetric fields have been investigated, in part, because they describe fermion fields with an anticanonical Hamiltonian structure, and hence unify fermions with bosons at a superclassical level.[7] However if supersymmetry is fundamental, a motivation other than unification at the prequantum level, is required, since the tensor Dirac theory, with its noncanonical Hamiltonian structure, achieves this unification at a classical level without resorting to supernumbers.

II. TENSOR FORM OF THE DIRAC LAGRANGIAN

In this section we review the derivation that demonstrates that the Dirac bispinor Lagrangian (2.4) equals the constrained Yang–Mills Lagrangian (2.14) in the limit of an infinitely large coupling constant. The derivation exploits the $SL(2,R)\times U(1)$ gauge symmetry of Dirac's bispinor Lagrangian.

Consider the $SL(2,R)\times U(1)$ gauge transformations, acting on the bispinor field Ψ, with infinitesimal generators τ_K for $K=0,1,2,3$, defined by

$$\begin{aligned} \tau_0\Psi &= -i\Psi, \quad \tau_1\Psi = i\Psi^C, \\ \tau_2\Psi &= \Psi^C, \quad \tau_3\Psi = i\gamma^5\Psi, \end{aligned} \tag{2.1}$$

where (using bispinor notation) Ψ^C denotes the charge conjugate of Ψ and γ^5 is the fifth Dirac matrix.[29] Note that the action of $SL(2,R)\times U(1)$ on Ψ is real linear, whereas usually only complex linear gauge transformations of bispinors are considered. The infinitesimal gauge generators τ_0, τ_1, and τ_2 generate SL(2,R) and τ_3 generates U(1).

The $SL(2,R)\times U(1)$ gauge transformations generated by τ_K commute with Lorentz transformations.[29] From formula (2.1) the commutation relations of the gauge generators τ_K are given by

$$[\tau_0,\tau_1]=2\tau_2, \quad [\tau_0,\tau_2]=-2\tau_1, \quad [\tau_1,\tau_2]=-2\tau_0, \tag{2.2}$$

and τ_3 commutes with all the τ_K. Formula (2.2) can be written more compactly as

$$[\tau_J,\tau_K]=2f_{JK}^{\mathrm{L}}\tau_{\mathrm{L}}, \tag{2.3}$$

which defines the Lie algebra structure constants f_{JK}^{L} for the gauge group $SL(2,R)\times U(1)$.

By formula (2.2), the Minkowski metric g_{JK} (with diagonal elements $\{1,-1,-1,-1\}$ and zeros off the diagonal) is an invariant metric[30] for the gauge group $SL(2,R)\times U(1)$. Gauge indices J, K, L will be lowered and raised using the Minkowski metric g_{JK} and its inverse g^{JK}. As in formula (2.3), repeated indices are to be summed from 0 to 3.

Dirac's bispinor Lagrangian L is given by

$$L=\mathrm{Re}[i\bar{\Psi}\gamma^\alpha\partial_\alpha\Psi-m_0 s], \tag{2.4}$$

where s is the complex scalar field defined by

$$\mathrm{Re}[s]=\bar{\Psi}\Psi, \qquad \mathrm{Im}[s]=i\bar{\Psi}\gamma^5\Psi, \tag{2.5}$$

where (using bispinor notation) $\bar{\Psi}=\Psi^+\gamma^0$, where Ψ^+ denotes the transpose conjugate of Ψ, and γ^α for α=0,1,2,3 are Dirac matrices.[29] Moreover, in formula (2.4), m_0 denotes the fermion mass, and ∂_α denote partial derivatives with respect to space–time coordinates. Tensor indices α, β, γ are lowered and raised using the Minkowski space–time metric, which we denote as $g_{\alpha\beta}$, and its inverse $g^{\alpha\beta}$.

Apart from the mass term, Dirac's bispinor Lagrangian is invariant under the $SL(2,R)\times U(1)$ gauge transformations (2.1). From formula (2.5), the scalar s is invariant under SL(2,R) gauge transformations, and transforms as a complex scalar under the U(1) gauge transformations generated by τ_3. To make the Lagrangian (2.4) invariant for all $SL(2,R)\times U(1)$ gauge transformations, it suffices that m_0 transform like $\bar{s}$ (the complex conjugate of s). Since m_0 appears in the Lagrangian (2.4) without derivatives, the assumption that m_0 transform like $\bar{s}$ under U(1) gauge transformations, has no effect on the Dirac equation.

From the Dirac Lagrangian (2.4) we can derive the following $SL(2,R)\times U(1)$ Noether currents:

$$j_\alpha^K=\mathrm{Re}[i\bar{\Psi}\gamma_\alpha\tau^K\Psi]. \tag{2.6}$$

The Noether currents j_α^K and scalar s satisfy an orthogonal constraint known as a Fierz identity[10] (see Appendix A for an elementary derivation):

$$j_\alpha^K j_{K\beta}=|s|^2 g_{\alpha\beta}. \tag{2.7}$$

Takahashi[10] derived the following formula for the kinetic part of the Dirac Lagrangian (2.4):

$$\mathrm{Re}[i\overline{\Psi}\gamma^\alpha\,\partial_\alpha\Psi]=-\frac{1}{4|s|^2}\mathrm{Re}[(\partial_\alpha\mathbf{J}_\beta)\cdot\mathbf{J}^\alpha\times\mathbf{J}^\beta-2i\overline{s}J^0_\alpha\,\partial^\alpha s],\tag{2.8}$$

which uses the following notation (which differs from Takahashi's):

$$J^K_\alpha=(J^0_\alpha,\mathbf{J}_\alpha)=(-j^3_\alpha,-ij^2_\alpha,ij^1_\alpha,-j^0_\alpha).\tag{2.9}$$

Thus, from Takahashi's formula (2.8), we see that the Dirac Lagrangian (2.4) can be expressed entirely in terms of the Noether currents j^K_α and the complex scalar field s, satisfying the orthogonal constraint (2.7).

Takahashi[10] derived formulas (2.7) and (2.8), along with 15 general and 75 specific Fierz identities, without exploiting the $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ gauge symmetry. The derivation of formula (2.8) from first principles given in Appendices A and B of this paper exploits this symmetry. Once the $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ gauge symmetry of formula (2.8) is recognized, the demonstration that Dirac's bispinor Lagrangian (2.4) equals a constrained Yang–Mills Lagrangian in the limit of an infinitely large coupling constant, is fairly obvious.

Indeed, we can map a subset of $\mathrm{SL}(2,C)\times\mathrm{U}(1)$ gauge potentials A^K_α and a complex scalar field ρ into (J^K_α,s) by setting

$$\begin{aligned}J^K_\alpha&=4|\rho|^2A^K_\alpha,\\ s&=4|\rho|^2\overline{\rho}.\end{aligned}\tag{2.10}$$

Since we regard the Lie algebra of $\mathrm{SL}(2,C)$ as the complexification of the Lie algebra of SU(2), the $\mathrm{SL}(2,C)$ gauge potentials $\mathbf{A}_\alpha=(A^1_\alpha,A^2_\alpha,A^3_\alpha,)$ are complex, while the U(1) gauge potential A^0_α is real. By formula (2.9) the gauge potentials A^K_α are restricted to the subset for which

$$\mathrm{Re}[A^1_\alpha]=\mathrm{Re}[A^2_\alpha]=\mathrm{Im}[A^3_\alpha]=0.\tag{2.11}$$

This subset corresponds precisely to a $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ subgroup of the gauge group $\mathrm{SL}(2,C)\times\mathrm{U}(1)$. On substituting formula (2.10) into Takahashi's formula (2.8), Dirac's Lagrangian (2.4) becomes

$$L=-\mathrm{Re}[(\partial_\alpha\mathbf{A}_\beta)\cdot\mathbf{A}^\alpha\times\mathbf{A}^\beta+2i\overline{\rho}A^0_\alpha\,\partial^\alpha\rho+4m_0|\rho|^2\overline{\rho}],\tag{2.12}$$

and the orthogonal constraint (2.7) becomes

$$A^K_\alpha A_{K\beta}=-|\rho|^2g_{\alpha\beta}.\tag{2.13}$$

Consider the following Yang–Mills Lagrangian L_g for the gauge potentials A^K_α and the complex scalar field ρ:

$$L_g=-\tfrac{1}{4}\mathrm{Re}[A^K_{\alpha\beta}A^{\alpha\beta}_K]+\overline{D_\alpha(\rho+m)}D^\alpha(\rho+m)-\tfrac{1}{2}g^2|\rho|^4,\tag{2.14}$$

where $A^K_{\alpha\beta}=(A^0_{\alpha\beta},\mathbf{A}_{\alpha\beta})$ and

$$\begin{aligned}A^0_{\alpha\beta}&=\partial_\alpha A^0_\beta-\partial_\beta A^0_\alpha,\\ \mathbf{A}_{\alpha\beta}&=\partial_\alpha\mathbf{A}_\beta-\partial_\beta\mathbf{A}_\alpha-g\mathbf{A}_\alpha\times\mathbf{A}_\beta,\\ D_\alpha(\rho+m)&=\partial_\alpha\rho+igA^0_\alpha(\rho+m),\end{aligned}\tag{2.15}$$

where g denotes the Yang–Mills coupling constant and $m_0=\frac{1}{2}mg$ is the fermion mass. From formulas (2.12) and (2.13), Dirac's bispinor Lagrangian (2.4) equals

$$L=\lim_{g\to\infty} g^{-1}L_g . \tag{2.16}$$

Note that the Euler–Lagrange equation for the Lagrangian (2.14) with the constraint (2.13) expressed using Lagrange multipliers, commutes with the restriction (2.11). Hence, the $\mathbf{A}_\alpha$ can be used to denote either $\mathrm{SL}(2,C)$ or the subset of $\mathrm{SL}(2,R)$ gauge potentials. By regarding $\mathrm{SL}(2,R)$ as embedded in the complex analytic group $\mathrm{SL}(2,C)$, we are able to use familiar vector operations to express the Lie algebra structure constants in formulas (2.12) and (2.15). The vector operations greatly simplify derivations.

Also, note that the part of the Lagrangian (2.14) for the scalar field ρ is not uniquely determined by Eq. (2.16). However, the Lagrangian (2.14) has unique additional properties discussed in Refs. 1 and 31. Specifically, the Yang–Mills equation derived from the Lagrangian (2.14) with the constraints (2.11) and (2.13) has exact plane wave solutions in one-to-one correspondence with the plane wave solutions of Dirac's bispinor equation. Because the Yang–Mills equation is nonlinear, the mass of each plane wave could depend on its amplitude, which would cause velocity splitting of wave packets.[32] However, the mass of each plane wave equals m_0, and hence is constant. Wave packets are identical to the wave packets derived from Dirac's equation, and do not exhibit velocity splitting.[31] Thus, the constrained Yang–Mills equation has solutions similar to Dirac's bispinor equation, which is a limiting case of it by formula (2.16).

However, if the coefficient g^2 in the quartic potential $V(\rho)=\frac{1}{2}g^2|\rho|^4$ of the Lagrangian (2.14) is varied, then the limit in formula (2.16) fails to exist, and the mass of each plane wave becomes dependent on amplitude. Unless the amplitude vanishes, the mass becomes infinite in the limit of an infinitely large coupling constant g. Wave packets lose their elementary character with severe velocity splitting and unobservably high mass. Thus, in the Kaluza–Klein tetrad model,[1] assuming a fixed mass parameter m, the quartic potential $V(\rho)$ determines both the coupling constant g and the fermion mass $m_0=\frac{1}{2}mg$. This property will be exploited as an alternative to Higgs fields[33] for obtaining fermion masses in a future paper, which generalizes the tensor theory to multiplets of n bispinors $\Psi=(\Psi_1,\ldots,\Psi_n)$, where each bispinor component of Ψ is associated with a different fermion mass.

Another unique property of the Lagrangian (2.14) may have significance for astrophysics. For Yang–Mills Lagrangians in general, the energy–momentum tensor $T^{\alpha\beta}$ for wave packets exhibits both mass density and pressure. However, for plane waves and wave packets derived from the Lagrangian (2.14), we can show that

$$T^{\alpha\beta}=m_0|j|v^\alpha v^\beta, \tag{2.17}$$

where m_0 is the fermion mass, $j^\alpha=|j|v^\alpha$ is the electric current, which is also called the particle current, and $v^\alpha=j^\alpha/|j|$ with $v^\alpha v_\alpha=1$ is the velocity field.[31] As for Dirac's bispinor Lagrangian, formula (2.17) exhibits an energy–momentum tensor $T^{\alpha\beta}$ for a fluid with velocity field v^α, mass density $m_0|j|$, and zero pressure. Since for a Yang–Mills Lagrangian the pressure generally grows as the square of the coupling constant g, which must be large to obtain the Dirac Lagrangian, a nonzero pressure would be highly observable, for example, in the internal dynamics of stars.

For the Lagrangian (2.14), neither the exact plane wave solutions nor their wave packets provide any information about the magnitude of the coupling constant g. Consider, however, the single-particle (unquantized) Dirac equation applied to the scattering of a single fermion particle in an external electromagnetic potential.[29] The computation of scattering cross sections with these simplifying assumptions may provide a way to estimate the magnitude of the coupling constant g.

III. FLAVOR SYMMETRY

We will show in future papers that theories using multiplets of n bispinors $\Psi=(\Psi_1,\ldots,\Psi_n)$ can be formulated as tensor theories. Such formulations are based on extensions of the Fierz identities given in Appendix A to bispinor multiplets Ψ, with the gauge group $\mathrm{SL}(2n,C)\times \mathrm{U}(1)$. We will show that any given bispinor multiplet maps to fermion gauge potentials A_α^K that vanish, except for an $SL(2,R)\times U(1)$ subgroup of $SL(2n,C)\times U(1)$. The specific $SL(2,R)\times U(1)$ subgroup for which the A_α^K are nonvanishing, determines the fermion flavor. That is, only the components of A_α^K associated with the $SL(2,R)\times U(1)$ subgroup are nonzero, and hence A_α^K reduces to the Dirac theory for a single flavor of fermion. We will also show, in particular, that the standard electroweak model can be embedded in a $SL(2n,C)\times U(1)$ tensor theory in a manner consistent with the gauge symmetries used to derive the tensor Dirac equation.

Even for a bispinor singlet $(n=1)$, which we treat in this paper, current bispinor theories do not utilize the full $SL(2,C)\times U(1)$ gauge symmetry of the tensor Dirac Lagrangian (2.14). We will show in this section that the $SL(2,C)\times U(1)$ symmetric tensor Dirac theory includes both the Dirac and Majorana bispinor theories as special cases. Furthermore, we will show that the additional symmetry can be used to model the observed conservation of electric charge, lepton number, and baryon number.

A bispinor Ψ consists of a spinor and a dual conjugate spinor [see formula (A30) in Appendix A]. Equivalently, Ψ can be represented by a spinor doublet Φ consisting of two spinors, as in formula (A18). Acting on spinor doublets Φ is the gauge group $SL(2,C)\times U(1)$ whose generators are defined in formula (A19). The bijective map $\Phi\to\Psi$ defined by formula (A30), induces an equivalent representation of the gauge group $SL(2,C)\times U(1)$ acting on bispinors Ψ.

Unitary gauge transformations form a subgroup $U(2)=SU(2)\times U(1)$ of the $SL(2,C)\times U(1)$ gauge transformations acting on spinor doublets Φ. Using the representation induced on bispinors Ψ by the bijective map $\Phi\to\Psi$, the generators T_K of the unitary group $SU(2)\times U(1)$ become

$$\begin{aligned} T_0&=\tau_3, \quad T_1=-\tau_3\tau_2, \\ T_2&=\tau_3\tau_1, \quad T_3=\tau_0, \end{aligned} \tag{3.1}$$

where the τ_K are the $SL(2,R)\times U(1)$ gauge generators acting on bispinors Ψ defined in formula (2.1). Note from formulas (A19) and (A30) in Appendix A, that the full set of generators for the gauge group $SL(2,C)\times U(1)$ acting on bispinors Ψ consists of the T_K $(K=0,1,2,3)$, which generate $SU(2)\times U(1)$ and three additional gauge generators:

$$T_1'=\tau_2, \quad T_2'=-\tau_1, \quad T_3'=\tau_3\tau_0. \tag{3.2}$$

From formula (2.1), the gauge generators T_K satisfy the following commutation relations:

$$[T_1,T_2]=2T_3, \quad [T_2,T_3]=2T_1, \quad [T_3,T_1]=2T_2. \tag{3.3}$$

T_0 commutes with all the T_K. Thus, T_1, T_2, and T_3 generate SU(2), and T_0, which is τ_3, generates U(1) as before.

Dirac's bispinor Lagrangian (2.4) can now be expressed by

$$L=\mathrm{Re}[i\bar{\Psi}\Gamma^\alpha\partial_\alpha\Psi-m_0\bar{\Psi}\Psi], \tag{3.4}$$

where $\Gamma^\alpha=i\gamma^\alpha T_3=\gamma^\alpha$. Hence, Dirac's equation can be expressed as

$$i\Gamma^\alpha\partial_\alpha\Psi=m_0\Psi. \tag{3.5}$$

We may replace T_3 with an equivalent gauge generator $T=c^K T_K$, where $c^K\in R^4$ satisfies $c^K c_K=-1$. That is, defining $\Gamma^\alpha=i\gamma^\alpha T$ generalizes the Dirac matrices γ^α. From formulas (2.1) and (3.1) we see that $T^K\gamma^\alpha=-\gamma^\alpha T_K$, and from a standard identity for Dirac matrices γ^α we get[29]

$$\Gamma_\alpha\Gamma_\beta+\Gamma_\beta\Gamma_\alpha=2g_{\alpha\beta}. \tag{3.6}$$

Formulas (3.5) and (3.6) imply that the bispinor field Ψ satisfies the Klein–Gordon equation:

$$\partial_\alpha\partial^\alpha\Psi=-m_0^2\Psi. \tag{3.7}$$

Thus, each generator $T = c^K T_K$, with $c^K c_K = -1$, gives a different factorization of the Klein–Gordon equation into a Dirac equation (3.5), with Lagrangian (3.4). The following theorem generalizes Takahashi's formula (2.8).

Theorem 1: Let Ψ be a bispinor field. Then

$$\mathrm{Re}[i\bar{\Psi}\Gamma^\alpha \partial_\alpha \Psi] = -\frac{1}{4|s|^2}\mathrm{Re}[(\partial_\alpha \mathbf{J}_\beta)\cdot \mathbf{J}^\alpha \times \mathbf{J}^\beta - 2i\bar{s}J^0_\alpha \partial^\alpha s], \tag{3.8}$$

where [see formula (2.9)]

$$J^0_\alpha = c_K j^K_\alpha, \\ \mathbf{J}_\alpha = c^0 \mathbf{j}_\alpha - \mathbf{c} j^0_\alpha + i\mathbf{c}\times \mathbf{j}_\alpha, \tag{3.9}$$

and $c^K = (c^0, \mathbf{c})$ with $\mathbf{c} = (c^1, c^2, c^3)$, and $j^K_\alpha = (j^0_\alpha, \mathbf{j}_\alpha)$ with $\mathbf{j}_\alpha = (j^1_\alpha, j^2_\alpha, j^3_\alpha)$.

Proof: A proof of Theorem 1 from first principles using simple trace formulas is provided in Appendices A and B. See formula (B15). Alternatively, Theorem 1 follows from formulas (2.8) and (2.9) by a symmetry argument. Note that the J^K_α defined by formula (3.9) are the SL$(2,C)\times$U(1) Noether currents of the bispinor Lagrangian (3.4). Formulas (2.8) and (2.9) are a special case of formulas (3.8) and (3.9) with $c^K = (0,0,0,1)$. As in formula (2.9), the nonvanishing J^K_α are associated with an SL$(2,R)\times$U(1) subgroup of SL$(2,C)\times$U(1). Since the gauge group SL$(2,C)\times$U(1) acts transitively on the Noether currents $\mathbf{J}_\alpha$ and leaves J^0_α invariant, the SL$(2,C)\times$U(1) Noether currents in formula (3.9) can be obtained from the SL$(2,R)\times$U(1) Noether currents (2.9) by a gauge transformation. The proof is completed by showing the gauge invariance of formula (3.8).

Note in Theorem 1 that c^K, j^K_α, and J^K_α are all invariant under U(1) gauge transformations. The SL$(2,C)$ gauge transformations act as SO(1,3) transformations on c^K and j^K_α, and as complex orthogonal transformations on $\mathbf{J}_\alpha$. As previously stated, J^0_α is invariant for all gauge transformations. Since the complex scalar s is invariant for all but U(1) gauge transformations, the right-hand side of formula (3.8) is invariant for all gauge transformations. The left-hand side of formula (3.8) is also invariant for all gauge transformations, as can be seen in formula (B4) in Appendix B. Q.E.D.

As a consequence of Theorem 1, we prove the following theorem.

Theorem 2: Set $J^K_\alpha = 4|\rho|^2 A^K_\alpha$ and $s = 4|\rho|^2\bar{\rho}$. Then (A^K_α, ρ) satisfy the orthogonal constraint (2.13), and the bispinor Lagrangian (3.4) equals

$$L = \lim_{g\to\infty} g^{-1} L_g, \tag{3.10}$$

where L_g is the Yang–Mills Lagrangian (2.14).

Proof: To establish the orthogonal constraint (2.13), we define an associative binary operation, denoted as $\otimes$ on C^4 as follows. For a^K, b^K, $c^K \in C^4$, we define $c = a\otimes b$ if and only if

$$c^0 = a^0 b^0 + \mathbf{a}\cdot\mathbf{b}, \\ \mathbf{c} = a^0\mathbf{b} + \mathbf{a} b^0 + i\mathbf{a}\times\mathbf{b}, \tag{3.11}$$

where $a^K = (a^0, \mathbf{a})$ with $\mathbf{a} = (a^1, a^2, a^3)$, and similarly for b^K and c^K. It is straightforward to show that the binary operation $\otimes$ is associative. Denote $\tilde{a}^K = a_K = (a^0, -\mathbf{a})$. Then formula (3.9) can be written as

$$J^K_\alpha = [j_\alpha \otimes \tilde{c}]^K, \quad \tilde{J}^K_\alpha = [c\otimes \tilde{j}_\alpha]^K, \tag{3.12}$$

where $[a\otimes b]^K$ denotes the Kth component of $a\otimes b$. Since from $c^K c_K = -1$ we have $\tilde{c}\otimes c = (-1,0,0,0)$, formulas (2.7), (3.11), and (3.12) give

$$J^K_\alpha J_{K\beta} = [J_\alpha \otimes \tilde{J}_\beta]^0 = [j_\alpha \otimes \tilde{c} \otimes c \otimes \tilde{j}_\beta]^0 = -[j_\alpha \otimes \tilde{j}_\beta]^0 = -j^K_\alpha j_{K\beta} = -|s|^2 g_{\alpha\beta}. \tag{3.13}$$

The orthogonal constraint (2.13) now follows from formulas (2.10) and (3.13). On substituting formulas (2.5) and (3.8) into the bispinor Lagrangian (3.4), formula (3.10) is a straightforward evaluation of formulas (2.12), (2.14), and (2.15). Q.E.D.

Each factorization of the Klein–Gordon equation (3.7) gives a different Dirac equation (3.5), parametrized by the choice of $c^K \in R^4$, such that $c^K c_K = -1$. The usual Dirac equation has the parameter $c^K = (0,0,0,1)$. Thus, the Yang–Mills Lagrangian (2.14) for the $\mathrm{SL}(2,C) \times \mathrm{U}(1)$ gauge potentials A^K_α and scalar field ρ describes solutions from different Dirac equations corresponding to different factorizations of the Klein–Gordon equation. We can show using formulas (2.10), (2.13), and (3.12) that A^K_α and ρ uniquely determine both the parameter c^K and the bispinor field Ψ (except for the unobservable sign of Ψ). Since the Noether currents (3.9) are different for each value of the parameter c^K, the parameter c^K describes the fermion flavor.

In the tensor theory, fermion gauge potentials A^K_α, associated with a gauge group G, can be unified with boson gauge potentials V^K_α, associated with a gauge group H that acts on G via a homomorphism $\varphi: H \rightarrow \mathrm{Aut}(G)$, by regarding (A^K_α, V^K_α) as gauge potentials associated with the semidirect product group $G_\varphi \times H$. As previously shown, the semidirect product structure of the gauge group $G_\varphi \times H$ uniquely prescribes the usual ''minimal coupling'' between fermions and bosons.[2] For flavor gauge groups let

$$\begin{aligned} G &= \mathrm{SL}(2,C) \times \mathrm{U}(1), \\ H &= \mathrm{SU}(2) \times \mathrm{U}(1), \end{aligned} \tag{3.14}$$

with φ defined as the adjoint action of H on G.

Note that the boson gauge group $\mathrm{SU}(2)\times\mathrm{U}(1)$ is a compact subgroup of the noncompact fermion gauge group $\mathrm{SL}(2,C) \times \mathrm{U}(1)$. The U(1) gauge transformations leave the flavor parameter $c^K \in R^4$ invariant; whereas the SU(2) gauge transformations leave c^0 invariant and rotate $\mathbf{c} = (c^1, c^2, c^3)$. Since for the electron we choose $c^0 = 0$ and $\mathbf{c} = (0,0,1)$, we will assume that $c^0 = 0$ for all fermion flavors. That is, we restrict the flavor parameter c^K to a single $\mathrm{SU}(2)\times\mathrm{U}(1)$ orbit for which $c^0 = 0$.

From formula (3.9) with $c^0 = 0$, the $\mathrm{SU}(2)\times\mathrm{U}(1)$ Noether currents $\mathrm{Re}[J^K_\alpha]$ can be expressed with the vector and axial currents, j^0_α and $j^5_\alpha = \mathbf{c} \cdot \mathbf{j}_\alpha$, as follows:

$$\mathrm{Re}[J^K_\alpha] = (-j^5_\alpha, -\mathbf{c} j^0_\alpha). \tag{3.15}$$

Both j^0_α and j^5_α are invariant under all $\mathrm{SU}(2)\times\mathrm{U}(1)$ gauge transformations. Thus, from formulas (2.1) and (2.6), j^0_α and j^5_α are gauge-invariant vector and axial currents, respectively, which can be identified with electroweak vector and axial currents.[33] It has been observed that the electromagnetic current is purely vector and that weak currents have both vector and axial components.

Table I shows a possible assignment of flavors c^K to first generation leptons and quarks. Note that in Table I antifermions are obtained by replacing c^K with $-c^K$. With these assignments of

TABLE I. Flavor parameters for leptons and quarks.

FERMION	$c^K = (c^0,\ c^1,\ c^2,\ c^3)$
Electron (e)	(0,0,0,1)
Neutrino (ν)	(0,1,0,0)
Up-quark (u)	$(0, \frac{1}{3}, -\frac{2}{3}, -\frac{2}{3})$
Down-quark (d)	$(0, -\frac{2}{3}, -\frac{2}{3}, \frac{1}{3})$

flavors, the following theorem identifies the Standard Model electromagnetic and neutral currents, denoted as $J_\alpha^{(Q)}$ and $J_\alpha^{(Z)}$, respectively, by expressing them as linear combinations of the SU(2)×U(1) Noether currents (3.15).

Theorem 3: With the assignment of flavors c^K to first generation leptons and quarks shown in Table I, the Standard Model electromagnetic and neutral currents are uniquely determined as follows:

$$J_\alpha^{(Q)} = \mathrm{Re}[J_\alpha^3],$$
$$J_\alpha^{(Z)} = -\frac{1}{2\sin\varphi}\mathrm{Re}[\pm J_\alpha^0 + J_\alpha^1 + (1-2\cos\varphi)J_\alpha^3], \tag{3.16}$$

where φ is twice the Weinberg angle.[33] The plus sign occurs with the U(1) current J_α^0 for an electron and down-quark and a minus sign for the neutrino and up-quark.

Proof: This is a straightforward verification by substituting values of c^K from Table I into formulas (3.15) and (3.16), and showing that the currents agree with the Standard Model.[33] Q.E.D.

One can deduce from formulas (2.1) and (3.1) that flavor symmetry generalizes the Majorana representation used in quantum field theory to massive fermions.[33] The neutrino in Table I for the case of zero mass is precisely a Majorana neutrino.

By a standard argument, conservation of electric current implies the additivity of electric charge. By a similar argument, conservation of the SU(2) vector currents, $-\mathbf{c}j_\alpha^0$, implies the additivity of the flavor parameter $c^K=(0,\mathbf{c})$. To illustrate this additivity consider the beta decay $d \rightarrow u + e + \overline{\nu}$ in which a down-quark d decays into an up-quark u, an electron e, and an antineutrino $\overline{\nu}$. Since $c^K(\overline{\nu}) = -c^K(\nu)$, we have from Table I,

$$c^K(d) = c^K(u) + c^K(e) + c^K(\overline{\nu}). \tag{3.17}$$

In all known interactions between e, ν, u, and d fermions, the c^K as defined in Table I are additive, and hence can be regarded as conserved electroweak charges associated with the SU(2) vector currents $-\mathbf{c}j_\alpha^0$.

The additivity of the c^K leads directly to the three familiar laws stated in Theorem 4 that follows.

Theorem 4: Additivity of the flavor parameter implies the conservation of electric charge, lepton number, and baryon number.

Proof: Using Table I we derive the following relations:

$$\tilde{B} = -\tfrac{1}{2}c^2 = \text{baryon number},$$
$$\tilde{L} = c^1 - \tfrac{1}{2}c^2 + c^3 = \text{lepton number}, \tag{3.18}$$
$$\tilde{Q} = -c^3 = \text{electric charge}.$$

Since $\tilde{B}$, $\tilde{L}$, and $\tilde{Q}$ are linear functions of c^K, additivity of c^K implies additivity (conservation) of $\tilde{B}$, $\tilde{L}$, and $\tilde{Q}$. Q.E.D.

Hence, the tensor theory models the conservation of electric charge, lepton number, and baryon number.

APPENDIX A: FIERZ IDENTITIES

In this appendix we will present an elementary derivation of the Fierz identities, from which the tensor form of the Dirac Lagrangian will be derived in Appendix B. The spinor Fierz identity

(A13) is a consequence of trace formulas (A3) and (A4) satisfied by the Pauli matrices. We extend the spinor Fierz identity first to pairs of spinors (spinor doublets), and then to bispinors, which are defined in formula (A30) as spinor and dual conjugate spinor pairs.

A spinor is a two-dimensional complex vector, denoted as

$$\xi=\begin{bmatrix}\xi_1\\ \xi_2\end{bmatrix}\in C^2. \tag{A1}$$

Acting on spinors ξ are the 2×2 complex Pauli matrices $\sigma^\alpha=(\sigma^0,\sigma^1,\sigma^2,\sigma^3)$ defined by

$$\sigma^0=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix},\quad \sigma^1=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},$$

$$\sigma^2=\begin{bmatrix}0 & -i\\ i & 0\end{bmatrix},\quad \sigma^3=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}. \tag{A2}$$

We define $\sigma_\alpha=(\sigma^0,-\sigma^1,-\sigma^2,-\sigma^3)$ and denote $\tilde{\sigma}^\alpha=\sigma_\alpha$ and $\tilde{\sigma}_\alpha=\sigma^\alpha$. A straightforward evaluation of the Pauli matrices gives the following trace formula:

$$\mathrm{Tr}[\sigma_\alpha\tilde{\sigma}_\beta]=2g_{\alpha\beta}, \tag{A3}$$

where $g_{\alpha\beta}$ denotes the Minkowski metric tensor (with diagonal elements $\{1,-1,-1,-1\}$ and zeros off the diagonal). A further trace formula is expressed by:

$$\mathrm{Tr}[\sigma_\alpha\tilde{\sigma}_\delta\sigma_\beta\tilde{\sigma}_\gamma]=2C_{\alpha\beta\gamma\delta}, \tag{A4}$$

where, as will be seen in formula (A13), $C_{\alpha\beta\gamma\delta}$ is a Lorentz tensor. Such a tensor is a linear combination of $g_{\alpha\beta}g_{\gamma\delta}$, $g_{\alpha\gamma}g_{\beta\delta}$, $g_{\alpha\delta}g_{\beta\gamma}$, and $\epsilon_{\alpha\beta\gamma\delta}$, where $\epsilon_{\alpha\beta\gamma\delta}$ is the permutation tensor. A straightforward derivation shows that

$$C_{\alpha\beta\gamma\delta}=g_{\alpha\gamma}g_{\beta\delta}+g_{\alpha\delta}g_{\beta\gamma}-g_{\alpha\beta}g_{\gamma\delta}-i\epsilon_{\alpha\beta\gamma\delta}. \tag{A5}$$

The tensor $C_{\alpha\beta\gamma\delta}$ satisfies numerous identities, chief of which are the symmetries:

$$C_{\alpha\beta\gamma\delta}=C_{\beta\alpha\delta\gamma}=C_{\gamma\delta\alpha\beta}=C_{\delta\gamma\beta\alpha}, \tag{A6}$$

and the inversion formula:

$$C_{\alpha\beta\gamma\delta}C^{\gamma\delta\lambda\mu}=4\delta_\alpha^\lambda\delta_\beta^\mu, \tag{A7}$$

where δ_α^β equals one if $\alpha=\beta$ and zero otherwise. Note that the tensor indices α, β, γ, δ, λ, μ are lowered and raised using the Minkowski metric tensor $g_{\alpha\beta}$ and its inverse $g^{\alpha\beta}$, and all repeated indices are to be summed from 0 to 3.

Formulas equivalent to (A6) and (A7) are discussed by Penrose and Rindler.[34] Note that formulas vary depending on how one defines the matrices σ^α. Our choice of σ^α in formula (A2) is made in order to define the standard Dirac matrices γ^α in a consistent manner [see formula (A32)].

If we set $\delta=0$ in formula (A4), noting that $\tilde{\sigma}_0=\sigma^0=I$ where I is the 2×2 identity matrix, we have

$$\mathrm{Tr}[\sigma_\alpha\sigma_\beta\tilde{\sigma}_\gamma]=2C_{\alpha\beta\gamma 0}. \tag{A8}$$

Since the Pauli matrices σ_γ are a basis for 2×2 complex matrices, the product $\sigma_\alpha\sigma_\beta$ is a linear combination of the matrices σ_γ. From formulas (A3) and (A8), this linear combination is given by

$$\sigma_\alpha \sigma_\beta = C^{\gamma 0}_{\alpha\beta} \sigma_\gamma . \tag{A9}$$

By a similar argument, setting $\alpha=0$ in formula (A4) gives

$$\tilde{\sigma}_\gamma \tilde{\sigma}_\delta = C^{0\beta}_{\gamma\delta} \tilde{\sigma}_\beta . \tag{A10}$$

Next, we consider a pair of spinors ξ and η to which we associate a complex Lorentz four-vector j^α, whose components are defined by the 2×2 matrix:

$$j = 2\,\eta\xi^+ = \begin{bmatrix} j^0 + j^3 & j^1 - i j^2 \\ j^1 + i j^2 & j^0 - j^3 \end{bmatrix}, \tag{A11}$$

where $\xi^+ = (\overline{\xi_1}, \overline{\xi_2})$ denotes the transpose conjugate of ξ. (The overbar denotes ordinary complex conjugation.) The spin group of 2×2 complex matrices with determinant one, denoted SL$(2,C)$ or Spin (1,3), acts on the spinors ξ and η. Acting on $\eta\xi^+$ in formula (A11), the spin group leaves invariant the determinant of j, and hence the Minkowski norm of j^α. Thus, j^α becomes a Lorentz four-vector.

We can solve for j^α in formula (A11) by first noting that $j = j^\beta \tilde{\sigma}_\beta$, multiplying by σ_α, and then using the trace formula (A3). This defines a map $j_\alpha : C^2 \times C^2 \to C^4$, mapping each pair of spinors ξ and η to a complex Lorentz four-vector $j_\alpha(\xi,\eta)$, given by

$$j_\alpha(\xi,\eta) = \xi^+ \sigma_\alpha \eta. \tag{A12}$$

We now derive the following Fierz identity.

Proposition 1: For all $\xi,\ \eta,\ \kappa,\ \nu \in C^2$,

$$2 j_\alpha(\xi,\eta) j_\beta(\kappa,\nu) = C^{\gamma\delta}_{\alpha\beta} j_\gamma(\xi,\nu) j_\delta(\kappa,\eta). \tag{A13}$$

(Note that since j_α, j_β, j_γ, and j_δ are Lorentz four-vectors, $C_{\alpha\beta\gamma\delta}$ is a tensor.)

Proof: From formula (A11) we have

$$2\,\eta\xi^+ = j^\alpha(\xi,\eta) \tilde{\sigma}_\alpha . \tag{A14}$$

Then the trace formula (A4) gives

$$\begin{aligned} 2 j_\alpha(\xi,\eta) j_\beta(\kappa,\nu) &= 2(\xi^+ \sigma_\alpha \eta)(\kappa^+ \sigma_\beta \nu) = 2\,\mathrm{Tr}[\sigma_\alpha(\eta\kappa^+)\sigma_\beta(\nu\xi^+)] \\ &= \tfrac{1}{2}\mathrm{Tr}[\sigma_\alpha \tilde{\sigma}_\delta \sigma_\beta \tilde{\sigma}_\gamma] j^\gamma(\xi,\nu) j^\delta(\kappa,\eta) = C_{\alpha\beta\gamma\delta} j^\gamma(\xi,\nu) j^\delta(\kappa,\eta), \end{aligned} \tag{A15}$$

which proves formula (A13). Q.E.D.

The parity map $P : C^2 \to C^2$ sends a spinor ξ, as defined in formula (A1), to its dual conjugate $\tilde{\xi}$:

$$P\xi = \tilde{\xi} = \begin{bmatrix} \overline{\xi_2} \\ -\overline{\xi_1} \end{bmatrix}. \tag{A16}$$

Formula (A2) gives $P\sigma_\alpha \xi = \tilde{\sigma}_\alpha P\xi$. Hence, $\tilde{\xi} = P\xi$ transforms under the conjugate representation of the spin group SL$(2,C)$. Since $P^2\xi = -\xi$, the parity map P is a bijection. From formulas (A11) and (A12) we have

$$j^\alpha(P\xi, P\eta) = j_\alpha(\eta,\xi) = \overline{j_\alpha(\xi,\eta)}. \tag{A17}$$

Note that a ''parity operation'' can be defined for spinor fields $\xi(x^\alpha)$, which combines the parity map P with the space reflection, sending the space–time point $x^\alpha \in R^4$ to x_α. However, as defined here, the ''parity map'' $P : C^2 \to C^2$ transforms only the spinor components $\xi \in C^2$.

A spinor doublet is a four-dimensional complex vector, denoted as

$$\Phi=\begin{bmatrix}\xi\\ \eta\end{bmatrix}\in C^4, \tag{A18}$$

where $\xi,\ \eta\in C^2$ are spinors as defined in formula (A1). Acting on spinor doublets Φ are the Pauli matrices σ^α, which extend to 4×4 matrices by the usual direct sum representation. Also, acting on Φ are the 4×4 gauge matrices $t^K=(t^0,t^1,t^2,t^3)$ defined as follows. First, note from formula (A2) that, apart from $\pm$signs, all entries of the Pauli matrices σ^α consist of 0, 1, and i. The 4×4 complex matrices t^K are similar to the 2×2 Pauli matrices σ^α, with I and iI replacing 1 and i, where I is the 2×2 identity matrix. That is,

$$\begin{gathered} t^0=\begin{bmatrix}I & 0\\ 0 & I\end{bmatrix},\quad t^1=\begin{bmatrix}0 & I\\ I & 0\end{bmatrix},\\ t^2=\begin{bmatrix}0 & -iI\\ iI & 0\end{bmatrix},\quad t^3=\begin{bmatrix}I & 0\\ 0 & -I\end{bmatrix}. \end{gathered} \tag{A19}$$

The gauge matrices t^K satisfy trace formulas similar to the Pauli matrices σ^α. We define $t_K=(t^0,-t^1,-t^2,-t^3)$ and denote $\tilde{t}^K=t_K$ and $\tilde{t}_K=t^K$. For 4×4 matrices σ_α and t_K we have, similar to formula (A3),

$$\mathrm{Tr}[\sigma_\alpha\tilde{\sigma}_\beta]=4g_{\alpha\beta},\quad \mathrm{Tr}[t_J\tilde{t}_K]=4g_{JK}, \tag{A20}$$

where g_{JK} is a Minkowski metric similar to $g_{\alpha\beta}$. Similar to formula (A4), we have

$$\begin{gathered} \mathrm{Tr}[\sigma_\alpha\tilde{\sigma}_\delta\sigma_\beta\tilde{\sigma}_\gamma]=4C_{\alpha\beta\gamma\delta},\\ \mathrm{Tr}[t_J\tilde{t}_M t_K\tilde{t}_L]=4C_{JKLM}, \end{gathered} \tag{A21}$$

where C_{JKLM} is a tensor similar to $C_{\alpha\beta\gamma\delta}$.

The 4×4 complex matrices σ_α and t_K commute for each index α and K. Moreover,

$$\mathrm{Tr}[\sigma_\alpha]\mathrm{Tr}[t_K]=4\ \mathrm{Tr}[\sigma_\alpha t_K]=16\delta^0_\alpha\delta^0_K. \tag{A22}$$

As with σ_α in formulas (A9) and (A10), products of the gauge matrices t_K (or $\tilde{t}_K$) can be expressed as linear combinations of the t_K (or $\tilde{t}_K$), e.g.,

$$\tilde{t}_L\tilde{t}_M=C^{0K}_{LM}\tilde{t}_K. \tag{A23}$$

From this observation and formula (A22), if σ is a product of matrices σ_α and t is a product of matrices t_K, then

$$\mathrm{Tr}[\sigma]\mathrm{Tr}[t]=4\ \mathrm{Tr}[\sigma t]. \tag{A24}$$

Note that, as in formula (A23), gauge indices J,K,L,M are lowered and raised using the Minkowski metric g_{JK} and its inverse g^{JK}, and all repeated indices are to be summed from 0 to 3. Now consider the map $j^K_\alpha:C^4\times C^4\to C^{16}$, mapping each pair of spinor doublets Φ and Θ to a set of four complex Lorentz four-vectors $j^K_\alpha(\Phi,\Theta)$, defined by

$$j^K_\alpha(\Phi,\Theta)=\Phi^+\sigma_\alpha t^K\Theta, \tag{A25}$$

where Φ^+ denotes the transpose conjugate of Φ. We will derive the following Fierz identity for spinor doublets.

Proposition 2: For all Φ, Θ, Φ', $\Theta' \in C^4$,

$$C^{LM}_{JK} j^J_\alpha(\Phi,\Theta) j^K_\beta(\Phi',\Theta') = C^{\gamma\delta}_{\alpha\beta} j^L_\gamma(\Phi,\Theta') j^M_\delta(\Phi',\Theta). \tag{A26}$$

Proof: The proof is similar to the proof of Proposition 1, using the definition (A25) with the trace formulas (A20), (A21), and (A24). In particular, similar to formula (A14), we derive

$$4\Theta\Phi^+ = j^{\alpha K}(\Phi,\Theta)\tilde{\sigma}_\alpha \tilde{t}_K. \tag{A27}$$

An equation similar to formula (A15) is then obtained. The inversion formula (A7) is used in the final step. Q.E.D.

The parity map $P:C^4 \to C^4$ sends a spinor doublet Φ, as defined in formula (A18), to its dual conjugate doublet:

$$P\Phi = \begin{bmatrix} P\eta \\ -P\xi \end{bmatrix}. \tag{A28}$$

Note that we use the same symbol P for both the parity map (A16) defined on spinors as well as its extension (A28) to spinor doublets. It should be clear from the context which map $P:C^2 \to C^2$ or $P:C^4 \to C^4$ is intended. Since from formula (A16), $P^2\xi = -\xi$ and $P^2\eta = -\eta$, it follows from formula (A28) that $P^2\Phi = \Phi$. Thus, the parity map $P:C^4 \to C^4$ equals its inverse, i.e., $P = P^{-1}$. From formulas (A25) and (A27), we have

$$j^K_\alpha(P\Phi, P\Theta) = j^\alpha_K(\Theta,\Phi) = \overline{j^\alpha_K(\Phi,\Theta)}. \tag{A29}$$

A bispinor Ψ consists of a spinor ξ and a dual conjugate spinor $\tilde{\eta} = P\eta$. That is,

$$\Psi = B\Phi = \begin{bmatrix} \xi \\ P\eta \end{bmatrix}, \tag{A30}$$

where $B:C^4 \to C^4$ sends the spinor doublet Φ, as defined in formula (A18), to the bispinor Ψ. The charge conjugate of Ψ is defined by

$$\Psi^C = \begin{bmatrix} \eta \\ P\xi \end{bmatrix}, \tag{A31}$$

and the Dirac matrices γ^α and γ^5 acting on Ψ are defined by

$$\gamma^\alpha \Psi = \begin{bmatrix} P\sigma^\alpha \eta \\ \sigma^\alpha \xi \end{bmatrix}, \quad \gamma^5 \Psi = \begin{bmatrix} \xi \\ -P\eta \end{bmatrix}. \tag{A32}$$

Note from formulas (A28) and (A30) that the parity map P acting on bispinors Ψ is given by $\gamma^0 = BPB^{-1}$.

From formulas (A30), (A31), and (A32), the four-vectors (A25) expressed in terms of bispinors Ψ and Ξ become

$$j^K_\alpha(\Psi,\Xi) = \mathrm{Re}[i\bar{\Psi}\gamma_\alpha \tau^K \Xi] - i\,\mathrm{Im}[i\bar{\Psi}\gamma_\alpha T^K \Xi], \tag{A33}$$

where the gauge generators τ_K and T_K are defined in formulas (2.1) and (3.1). Note that in formula (A33) we employ the bispinor notation $\bar{\Psi} = (\gamma^0\Psi)^+ = \Psi^+\gamma^0$, and Ψ^+ denotes the transpose conjugate of Ψ. Also, note that for simplicity we have written $j^K_\alpha(\Psi,\Xi)$ instead of $j^K_\alpha(B^{-1}\Psi, B^{-1}\Xi)$. That is, we suppress the bispinor map $B^{-1}:C^4 \to C^4$, which sends the bispinors Ψ and Ξ to spinor doublets Φ and Θ in definition (A25).

The Cartan map[8] is defined on bispinors by

$$b_\alpha^K(\Psi,\Xi)=j_\alpha^K(\gamma^0\Psi,\Xi). \tag{A34}$$

The map $b_\alpha^K: C^4\times C^4\to C^{16}$ generalizes the bilinear spinor map originally discovered in 1913 by Cartan.[20] The Cartan map b_α^K, whose useful properties we exploit in Appendix B, is summarized in the following proposition.

Proposition 3: For all Ψ, Ξ, Ψ', $\Xi'\in C^4$,

$$C_{JK}^{LM} b_\alpha^J(\Psi,\Xi) b_\beta^K(\Psi',\Xi')=C_{\alpha\beta}^{\gamma\delta} b_\gamma^L(\Psi,\Xi') b_\delta^M(\Psi',\Xi). \tag{A35}$$

Moreover, the Cartan map b_α^K has the following symmetry property:

$$b_\alpha^K(\Psi,\Xi)=b_K^\alpha(\Xi,\Psi) \tag{A36}$$

and the parity property:

$$b_\alpha^K(\gamma^0\Psi,\gamma^0\Xi)=\overline{b_K^\alpha(\Psi,\Xi)}. \tag{A37}$$

Proof: Set $\Phi=B^{-1}(\gamma^0\Psi)$, $\Phi'=B^{-1}(\gamma^0\Psi')$, $\Theta=B^{-1}(\Xi)$, and $\Theta'=B^{-1}(\Xi')$ in formula (A26) to obtain formula (A35). Formulas (A36) and (A37) are consequences of formula (A29) and the identity $B^{-1}\gamma^0=PB^{-1}$. Q.E.D.

Note from the symmetry property (A36) that the components of $b_\alpha^K(\Psi,\Xi)$ are either symmetric or antisymmetric in the arguments Ψ and Ξ. For example,

$$b_0^0(\Psi,\Xi)=b_0^0(\Xi,\Psi) \tag{A38}$$

is symmetric; whereas for $\mathbf{b}_0=(b_0^1,b_0^2,b_0^3)$,

$$\mathbf{b}_0(\Psi,\Xi)=-\mathbf{b}_0(\Xi,\Psi) \tag{A39}$$

is antisymmetric. When $\Psi=\Xi$, the antisymmetric components of the Cartan map vanish.

A reduced form of the Fierz identity (A35) exploits a binary associative operation, denoted as $\otimes$, defined on C^4 as follows: Let p^K, q^K, $r^K\in C^4$, and define $r=p\otimes q$ if and only if

$$r^K=C_{LM}^{0K}p^L q^M. \tag{A40}$$

From formula (A5), writing $p^K=(p^0,\mathbf{p})$, where $\mathbf{p}=(p^1,p^2,p^3)$ and similarly for q^K and r^K, formula (A40) becomes

$$\begin{gathered} r^0=p^0q^0+\mathbf{p}\cdot\mathbf{q}, \\ \mathbf{r}=p^0\mathbf{q}+\mathbf{p}q^0+i\mathbf{p}\times\mathbf{q}. \end{gathered} \tag{A41}$$

It is straightforward to show that the bilinear operation $\otimes$ is associative [compare formulas (A23) and (A40)], and with this operation C^4 becomes the algebra of complex quaternions. Setting the index $L=0$ in the Fierz identity (A35) gives for all bispinors Ψ, Ξ, Ψ', $\Xi'\in C^4$,

$$[b_\alpha(\Psi,\Xi)\otimes b_\beta(\Psi',\Xi')]^M=C_{\alpha\beta}^{\gamma\delta} b_\gamma^0(\Psi,\Xi') b_\delta^M(\Psi',\Xi), \tag{A42}$$

where the Mth component of $p\otimes q$ is denoted as $[p\otimes q]^M$. We will see that quaternion algebra simplifies computations with bispinors in Appendix B.

As a first application of the Fierz identity (A42), we will derive the following identity:

$$j_\alpha^K j_{K\beta}=|s|^2 g_{\alpha\beta}, \tag{A43}$$

where

$$j_\alpha^K = j_\alpha^K(\Psi,\Psi) = b_\alpha^K(\gamma^0\Psi,\Psi),$$
$$s = b_0^0(\gamma^0\Psi,\gamma^0\Psi). \tag{A44}$$

Note using formulas (A30), (A32), and (A33) that the definitions (2.5) and (2.6) for the complex scalar field s and the Noether currents j_α^K are consistent with formula (A44). From formulas (A36) and (A37),

$$j_K^\alpha = b_\alpha^K(\Psi,\gamma^0\Psi), \quad \overline{s} = b_0^0(\Psi,\Psi). \tag{A45}$$

From formula (A36), $\overline{s}$ and s are the only nonvanishing components of $b_0^K(\Psi,\Psi)$ and $b_0^K(\gamma^0\Psi,\gamma^0\Psi)$, respectively. Thus, on substituting $\gamma^0\Psi$, Ψ, Ψ, $\gamma^0\Psi$ for Ψ, Ξ, Ψ', Ξ', respectively, in Fierz identity (A42), and setting $M=0$, formula (A43) is obtained.

APPENDIX B: PROOF OF THEOREM 1

In this appendix we prove Theorem 1 of Sec. III using the Fierz identity (A42). Let $\Psi(x)$ denote a smooth bispinor field defined at each space–time point $x \in R^4$. For all pairs of points x, $y \in R^4$, define the following two-point functions using formulas (A44) and (A45):

$$j_\alpha^K(x,y) = b_\alpha^K(\gamma^0\Psi(x),\Psi(y)),$$
$$q^K(x,y) = b_0^K(\Psi(x),\Psi(y)),$$
$$Q_\alpha(x,y) = b_\alpha^0(\Psi(x),\Psi(y)), \tag{B1}$$
$$r(x,y) = b_0^0(\Psi(x),\Psi(y)),$$
$$\overline{r(x,y)} = b_0^0(\gamma^0\Psi(x),\gamma^0\Psi(y)).$$

As previously defined in formula (A25), the $j_\alpha^K(x,y)$ for $K=0,1,2,3$ are a tetrad of complex Lorentz four-vectors, and as will become apparent, the $q^K(x,y)$ and $Q_\alpha(x,y)$ are complex quaternions with scalar part $r(x,y)$. We also denote, setting $y=x$,

$$j_\alpha^K(x) = j_\alpha^K(x,x), \quad r(x) = r(x,x). \tag{B2}$$

Note that by formula (A36), components of $q^K(x,y)$ and $Q_\alpha(x,y)$ with $K\neq 0$ or $\alpha \neq 0$ are antisymmetric in the variables x and y, and hence vanish for $y=x$. The only nonvanishing component of $q^K(x,x)$ and $Q_\alpha(x,x)$ is $r(x) = q^0(x,x) = Q_0(x,x)$. As in formula (3.12) we define

$$J_\alpha^K(x,y) = [j_\alpha(x,y)\otimes\tilde{c}]^K,$$
$$J_\alpha^K(x) = [j_a(x)\otimes\tilde{c}]^K, \tag{B3}$$

where $c^K \in R^4$ satisfies $c^K c_K = -1$, and $\tilde{c}^K = c_K$. Since in formula (3.8), $\Gamma_\alpha = i\gamma_\alpha c^K T_K$, we have from formulas (A33) and (B3),

$$\mathrm{Re}[i\overline{\Psi(x)}\Gamma_\alpha\,\partial_\beta\Psi(x)] = -\frac{\partial}{\partial y^\beta}\mathrm{Re}[iJ_\alpha^0(x,y)]\Big|_{y=x}. \tag{B4}$$

Thus, Theorem 1 follows from the following proposition.

Proposition 4:

$$\frac{\partial}{\partial y^{\alpha}} J_{\beta}^{K}(x,y)\bigg|_{y=x} = -\frac{1}{4|s|^2}[(\partial_\alpha J_\gamma)\otimes \tilde{J}^{\gamma}\otimes J_\beta + 2\bar{s}J_\beta\,\partial_\alpha s]^K, \tag{B5}$$

where $J_\alpha^K = J_\alpha^K(x)$ and $s=\overline{r(x)}$.

Proof: We will suppress gauge indices and simply write j_α for j_α^K and $\tilde{j}_\alpha$ for $j_{K\alpha}$, etc. The Fierz identity (A42) is then expressed as

$$b_\alpha(\Psi,\Xi)\otimes b_\beta(\Psi',\Xi') = C_{\alpha\beta}^{\gamma\delta} b_\gamma^0(\Psi,\Xi')b_\delta(\Psi',\Xi). \tag{B6}$$

On substituting $\Psi(x)$, $\Psi(y)$, $\gamma^0\Psi(x)$, $\Psi(x)$ for Ψ, Ξ, Ψ', Ξ', respectively, in the Fierz identity (B6), and setting the index $\alpha=0$, we get from formulas (B1) and (B2) and the vanishing of $Q_\gamma(x,x)$, for $\gamma\neq 0$,

$$q(x,y)\otimes j_\beta(x) = r(x) j_\beta(x,y). \tag{B7}$$

Quaternion multiplication of formula (B7) on the right by $\tilde{c}^K\in R^4$ satisfying $c^K c_K=-1$, gives, using formula (B3),

$$q(x,y)\otimes J_\beta(x) = r(x) J_\beta(x,y). \tag{B8}$$

Using the inversion formula (A7), the Fierz identity (B6) can also be expressed as

$$C_{\gamma\delta}^{\alpha\beta} b_\alpha(\Psi,\Xi)\otimes b_\beta(\Psi',\Xi') = 4 b_\gamma^0(\Psi,\Xi')b_\delta(\Psi',\Xi). \tag{B9}$$

Setting $\gamma=\delta=0$ and using formulas (A5) and (A36), we have

$$b_\alpha(\Psi,\Xi)\otimes \tilde{b}^{\alpha}(\Xi',\Psi') = 4 b_0^0(\Psi,\Xi')b_0(\Psi',\Xi). \tag{B10}$$

On substituting $\gamma^0\Psi(y)$, $\Psi(y)$, $\Psi(x)$, $\gamma^0\Psi(x)$ for Ψ, Ξ, Ψ', Ξ' in formula (B10) using formulas (B1) and (B2) we get

$$j_\alpha(y)\otimes \tilde{j}^{\alpha}(x) = 4\overline{r(y,x)}q(x,y). \tag{B11}$$

Since by formula (A41) $J_\alpha = j_\alpha\otimes\tilde{c}$ implies $\tilde{J}_\alpha = c\otimes\tilde{j}_\alpha$ and, furthermore, $\tilde{c}\otimes c=(-1,0,0,0)$, formulas (B3) and (B11) give

$$J_\gamma(y)\otimes \tilde{J}^{\gamma}(x) = -4\overline{r(y,x)}q(x,y). \tag{B12}$$

Quaternion multiplication of formula (B12) on the right by $J_\beta(x)$, and using formula (B8), gives

$$J_\gamma(y)\otimes \tilde{J}^{\gamma}(x)\otimes J_\beta(x) = -4\overline{r(y,x)}r(x)J_\beta(x,y). \tag{B13}$$

Since $r(x,y)=r(y,x)$ by formulas (A36) and (B1), we get

$$\frac{\partial}{\partial y^{\alpha}} r(y,x)\bigg|_{y=x} = \frac{1}{2}\frac{\partial}{\partial x^{\alpha}} r(x). \tag{B14}$$

Partially differentiating formula (B13) with respect to y^α, and setting $y=x$ using formula (B14), we obtain formula (B5). Q.E.D.

Corollary (Theorem 1):

$$\mathrm{Re}[i\bar{\Psi}\Gamma^{\alpha}\,\partial_\alpha\Psi] = -\frac{1}{4|s|^2}\mathrm{Re}[(\partial_\alpha\mathbf{J}_\beta)\cdot\mathbf{J}^{\alpha}\times\mathbf{J}^{\beta} - 2i\bar{s}J_\alpha^0\,\partial^\alpha s], \tag{B15}$$

where $J_\alpha^K = (J_\alpha^0, \mathbf{J}_\alpha)$.

Proof: Substitute formula (B5) with $K=0$ into formula (B4) and evaluate the associative operation $\otimes$ using formula (A41), noting by formulas (2.6) and (3.9) that both J_α^0 and $\mathbf{J}_\alpha \cdot \mathbf{J}_\beta$ are real. Q.E.D.

Superconnections and the Higgs field

G. Roepstorff[a)]
Institute for Theoretical Physics, RWTH Aachen, D-52062 Aachen, Germany

(Received 5 October 1998; accepted for publication 7 January 1999)

Within the mathematical framework of Quillen, one interprets the Higgs field as part of the superconnection $\mathbb{D}$ on a superbundle. We propose to take as superbundle the exterior algebra $\wedge V$ obtained from a Hermitian vector bundle V of rank n with structure group U(n) and study the curvature $\mathbb{F}=\mathbb{D}^2$. The Euclidean action, at most quadratic in $\mathbb{F}$ and invariant under gauge transformations, depends on $n+1$ central charges. Spontaneous symmetry breaking is related to a nonvanishing constant scalar curvature in the ground state, $\mathbb{F}=L_c^2$, where L_c is the Higgs condensate. The $U(1)$ Higgs model is nothing but the familiar Ginzburg–Landau theory, whereas the $U(2)$ Higgs model relates to the electro-weak theory (without matter fields). The present formulation leads to the relation $g^2=3g'^2$ for the coupling constants, the formula $\sin^2\theta=1/4$ for the Weinberg mixing angle, and the ratio $m_W^2:m_Z^2:m_H^2=3:4:12$ for the masses of $W^\pm$, Z^0, and the Higgs boson. Experimentally observed deviations are attributed to loop corrections. © *1999 American Institute of Physics.* [S0022-2488(99)01006-3]

I. INTRODUCTION

It has been generally accepted that spontaneously broken local gauge symmetries provide the correct framework for understanding the electro-weak interactions of elementary particles.[1] The mechanism that gives masses to the $W^\pm$, Z^0, and leptons however needs the introduction of a doublet of scalar fields, the so-called Higgs field, with many puzzling features, physically as well as mathematically. The concepts of the Higgs field and the related Higgs mechanism, over the years, have triggered many investigations, either from the supersymmetry or the differential geometry point of view.

Most attempts were a response to the fact that the Lagrangian of the standard model contains a large number of free parameters, among them various gauge coupling constants, the parameters of the Higgs potential, coupling constants of matter fields, and the elements of the quark mixing matrix. Some of these constants are expected to come out of some kind of symmetry breaking mechanism occurring in some yet unknown theory while others can be chosen at our will. One therefore feels that at present one is actually dealing with an effective (low energy, long range) field theory where only some degrees of freedom appear explicitly. Consequently, no explanation for most of the constants, chosen to fit the experimental data, is offered.

As a normal mathematical setting one would perhaps regard the theory of fiber bundles[2,3] that emerged as a primary tool for studying Yang–Mills systems. Then the question may be raised: Is the Higgs field an object of geometry? Below we shall briefly survey some of the attempts to extend the formalism of gauge theory to Yang–Mills–Higgs systems before trying to give new answers.

A popular approach to the problem of assigning a geometrical role to the Higgs field comes under the heading *dimensional reduction*. Witten,[4] Manton,[5] and Fairlie[6] were first to provide interesting model theories in higher dimension. The reduction technique has been taken up again and used as a guiding principle by other authors.[7] In its simplest version it uses one extra dimension, flat space, and translational invariance. Thus, one starts from a Yang–Mills connection on

[a)]Electronic mail: roep@physik.rwth-aachen.de

the trivial principal bundle $\mathbb{R}^{n+1}\times G$ with compact semisimple Lie group G, considers the splitting $dx^0A_0+dx^iA_i$ ($i=1,...,n$) of the connection one-form, and identifies the Higgs field with A_0. The drawback is twofold; (1) the gauge field is not allowed to depend on the extra variable x^0, (2) the Higgs field is always in the adjoint representation.

As a precursor of Quillen's superconnection theory, one may regard Ne'eman's proposal[8] to make use of the supergroup SU(2|1) for an algebraically irreducible electro-weak unification. Supergroups are formal objects obtained from super-Lie algebras where commutators are replaced by supercommutators. At first, the model appeared to suffer from spin-statistics complications. The final treatment with Sternberg[9] however took full advantage of Quillen's formalism. Super-Lie algebras are also at the heart of an attempt[10] to construct a renormalizable model of gravity as a broken gauge theory.

Another approach borrows from the framework of noncommutative geometry (NCG) (Ref. 11) and leads to what has been called *algebraic Yang–Mills–Higgs theories*[12] with obvious links to the supergroup formalism. The idea is to replace the exterior algebra of differential forms (the de Rham complex) by some noncommutative $\mathbb{Z}_2$-graded differential algebra. To start with, one replaces $C^\infty(M)$ by $A\otimes C^\infty(M)$, where A is some matrix algebra together with a grading automorphism and M is spacetime. As there is a generalized notion of what should be called a connection, by a proper choice of the algebra A one can accommodate a Higgs field in the connection, be it one multiplet or several multiplets. By now, many versions of the NCG approach have appeared which successfully reformulate the standard model. In the Connes–Lott approach,[13] $A=\mathbb{C}\oplus\mathbb{C}$ whereas the Mainz–Marseille group (see Ref. 12 for details) prefers $A=M_2(\mathbb{C})$ with grading automorphism diag$(1,-1)$ in both cases. Recently, Okumura[14] proposed yet another formulation. When calculating the curvature, these authors get different results which influence the Weinberg angle, the Higgs mass and the quartic Higgs coupling. Therefore, the predictive power of the NCG approach has come under intense scrutiny.

Recently, generalized Dirac operators have been proposed as a ''model building kit'' for action functionals that include the full standard model as well as gravity by Ackermann and Tolksdorf.[15] In their scheme the bosonic part of the action is given by the Wodzicki residue and the Higgs field is intimately related to the gravitational potential. Though this approach hardly uses NCG concepts, it somehow parallels the Connes–Lott approach.

Last but not least there are attempts to add a fifth ''discrete dimension''[16] to space–time with possible relation to parity and chiral symmetry breaking. We feel, though cannot prove, that such an approach, once fully worked out, will provide but another reformulation of a specific model within the territory of noncommutative geometry.

In 1985, Quillen described his concept of a superconnection[17] (see also Ref. 18), thereby abandoning the traditional $\mathbb{Z}$-grading (of the exterior algebra of differential forms) in favor of a $\mathbb{Z}_2$-grading, giving thus more freedom to constructions in (commutative) differential geometry. Bundles carrying a $\mathbb{Z}_2$-graded structure are termed superbundles. Quillen aimed at the construction of invariants of a superbundle (Chern–Weil forms) and the definition of the Chern character of a superconnection. A serious attempt to extend the formalism of gauge theories using Quillen's concept of superconnections has been launched in 1990 by Coquereaux *et al.*[19] It still borrows from the NCG formalism. So does the work of Lee[20] and Figueroa *et al.*[21]

In the present paper, we do not rely on the NCG approach but strictly follow the guidelines of Quillen and try to paint a coherent picture of U(n) Higgs systems whose ground states have constant generalized curvature (to be defined below). The role we assign to the Higgs field is similar to the one of the NCG and the Ackermann–Tolksdorf approach. But the choice of the superbundle is new to the best of our knowledge. Here we restrict ourselves to discussing the bosonic part of the action. In a second paper we shall include fermions and introduce the Dirac operator of a Clifford superconnection to construct the action of the electro-weak theory.

The formalism we propose has applications to Ginzburg–Landau theory[22] and topological field theory.[23] We shall leave out that aspect here.

II. SUPERBUNDLES

We assume that M is an oriented Riemannian manifold of dimension m which may be arbitrary. Later we shall be more specific and think of M as the four-dimensional Euclidean space–time with flat Levi-Civita connection. We let Γ denote the algebra of smooth complex functions on M and, if B is some bundle with base M, write $\Gamma(M,B)$ for the space of smooth sections $s:M \to B$.

Pure Yang–Mills theory starts from a principal G bundle P over M, and an invariant action functional on the set $\mathcal{A}$ of connections on P. The compact semisimple Lie group G is called the *gauge group* of the theory. The set $\mathcal{A}$ is modeled on the vector space of gauge fields, i.e., the space of 1-forms A taking values in the bundle

$$\mathrm{ad}\, P = P \times_G \mathbf{g},$$

where $\mathbf{g}$ is the Lie algebra of G, and G acts on $\mathbf{g}$ via the adjoint representation. A gauge field A can locally be written as $dx^\mu A_\mu(x)$ with $A_\mu(x) \in \mathbf{g}$. The electro-weak theory, however, is based on the nonsemisimple gauge group $\mathrm{SU}(2)\times\mathrm{U}(1)$ and thus admits two independent gauge couplings. In what follows the focus will be on the nonsemisimple case. Though we work with the gauge group $\mathrm{U}(n)$, we argue in favor of only *one* coupling constant.

The notion of a gauge transformation is more subtle. Though, locally, gauge transformations may be thought of as maps from the base manifold M into the group G, they cannot be extended globally to sections of P (unless P is a trivial bundle). Instead, gauge transformations are *bundle automorphisms* of P. Automorphisms commute with the group action on P by definition. Let $\mathcal{G} = \mathrm{Aut}(P)$ denote the group of bundle automorphisms of P. A more explicit description of $\mathcal{G}$, which is closer to the physicists' notion, uses sections of the adjoint bundle,

$$\mathcal{G} = \Gamma(M, \mathrm{Ad}\, P), \quad \mathrm{Ad}\, P = P \times_G G.$$

The bundle $\mathrm{Ad}(P)$ is the associated bundle whose fibers are copies of the group G. But the group action on G is the adjoint action. The Lie algebra of $\mathcal{G}$ can now be easily constructed; $\mathrm{Lie}\,\mathcal{G} = \Gamma(M, \mathrm{ad}\, P)$.

From now on we shall assume that P is a principal bundle with structure group $G = \mathrm{U}(n)$. Let the complex vector space $\mathbb{C}^n$ be equipped with the standard scalar product so that its group of automorphisms is G. We may construct the associated bundle

$$V = P \times_G \mathbb{C}^n$$

which is a complex Hermitian vector bundle of rank n with structure group G. It is always understood that G acts on the right of P and on the left of $\mathbb{C}^n$, and the notation $\times_G$ means that we identify $(pg,z) \sim (p,gz)$ for $p \in P$, $z \in \mathbb{C}^n$, and $g \in G$.

Since algebraic constructions on vector spaces carry over to associated bundles, we may consider the exterior algebra $\wedge V$ which is a Hermitian vector bundle of rank 2^n acted upon by gauge transformations $u \in \mathcal{G}$ via the representation $\wedge$, namely, at $x \in M$ we have, for $u(x) \in \mathrm{U}(n)$,

$$\wedge u : \wedge V_x \to \wedge V_x, \quad \wedge u(v_1 \wedge \cdots \wedge v_i) = (uv_1) \wedge \cdots \wedge (uv_i). \tag{1}$$

Recall now that a *superspace* is a $\mathbb{Z}_2$-graded vector space whose elements are said to have even or odd degree (or parity). Likewise, a *superbundle* is a vector bundle whose fibers are superspaces. Furthermore, a *superalgebra* has a superspace as underlying vector space, and a product that respects the $\mathbb{Z}_2$-grading. The exterior algebra $\wedge V$ is both a superbundle and a superalgebra with grading

$$\wedge V = \wedge^+ V \oplus \wedge^- V, \quad \wedge^\pm V = \sum_{(-1)^p = \pm 1} \wedge^p V.$$

Though the subbundles $\wedge^{\pm}V$ have the same rank 2^{n-1}, there exists no natural isomorphism between them. It will soon become apparent that only a spontaneous symmetry breaking connects $\wedge^{+}V$ with $\wedge^{-}V$.

The remainder of this section is devoted to reviewing basic facts about the representation $\wedge = \Sigma_k \wedge^k$ of $G = \mathrm{U}(n)$ on $\wedge\mathbb{C}^n$. Since the subrepresentations $\wedge^k$ are irreducible and inequivalent, the commutant

$$(\wedge G)' = \{\Sigma_{k=0}^{n} c_k P_k | c_k \in \mathbb{C}\},$$

where P_k projects onto $\wedge^k\mathbb{C}^n$, is an Abelian algebra. Particular elements $C \in (\wedge G)'$ will enter the Euclidean action. If $C = \Sigma c_k P_k$, we shall refer to the numbers c_k as *central charges*.

Another consequence is that the representation $\wedge$ of G respects the $\mathbb{Z}_2$-grading of $\wedge\mathbb{C}^n$ and decomposes as $\wedge^{+} \oplus \wedge^{-}$. We thus write

$$\wedge u = \begin{pmatrix} \wedge^{+}u & 0 \\ 0 & \wedge^{-}u \end{pmatrix}, \quad u \in U(n).$$

Because the operator $\wedge u$ does not change the parity of vectors, it is said to be *even*.

Similar properties may be established for the induced representation $a \mapsto \hat{a}$ of the Lie algebra $\mathbf{g} = \mathbf{u}(n)$ given by

$$\hat{a} = \frac{d}{dt} \wedge \exp(ta)|_{t=0} = \begin{pmatrix} \hat{a}^{+} & 0 \\ 0 & \hat{a}^{-} \end{pmatrix}, \quad a \in \mathbf{u}(n), \quad \hat{a}^{\pm} \in \mathrm{End} \wedge^{\pm}\mathbb{C}^n.$$

In fact, $\hat{a}$ is the unique extension of $a \in \mathrm{End}\,\mathbb{C}^n$ to an even derivation of the algebra $\wedge\mathbb{C}^n$, i.e.,

$$\hat{a}(z \wedge z') = \hat{a}z \wedge z' + z \wedge \hat{a}z', \qquad z, z' \in \wedge\mathbb{C}^n.$$

In particular,

$$\hat{a}z = 0 \qquad z \in \wedge^0\mathbb{C}^n \cong \mathbb{C},$$

$$\hat{a}z = az \qquad z \in \wedge^1\mathbb{C}^n \cong \mathbb{C}^n.$$

An operator L on $\wedge\mathbb{C}^n$ is even (odd) if it preserves (changes) parity. This gives $\mathrm{End} \wedge\mathbb{C}^n$ the structure of superalgebra,

$$\mathrm{End} \wedge\mathbb{C}^n = \mathrm{End}^{+} \wedge\mathbb{C}^n \oplus \mathrm{End}^{-} \wedge\mathbb{C}^n.$$

Note that $\hat{a} \in \mathrm{End}^{+} \wedge\mathbb{C}^n$.

Up to normalization there exists a unique bilinear form $q(a,b)$, or equivalently a quadratic form $q(a) = q(a,a)$, on the Lie algebra $\mathbf{su}(n)$, known as the Killing form, which is invariant and nondegenerate. By contrast, the Lie algebra $\mathbf{u}(n) = \mathbf{su}(n) \oplus \mathbf{u}(1)$, where $n \geqslant 2$, has a two-parameter family of such forms (we require that they be positive definite) parameterized by g and g',

$$q(a) = -\frac{n}{g^2}\,\mathrm{tr}\left(a - \frac{1}{n}\,\mathrm{tr}\,a\right)^2 - \frac{1}{g'^2}(\mathrm{tr}\,a)^2, \quad a \in \mathbf{u}(n). \tag{2}$$

When restricted to the subalgebra $\mathbf{su}(n)$, any member of this family reduces to a multiple of the Killing form as it should,

$$\mathrm{tr}\,a = 0 \Rightarrow q(a) \sim \mathrm{tr}\,\mathrm{ad}(a)^2 = 2n\,\mathrm{tr}\,a^2.$$

In the context of the electro-weak theory, g and g' are known as the two independent gauge coupling constants. Unless one is committed to a specific representation of the Lie algebra, there will be no *a priori* relation between g and g'. On the other hand, given a distinguished faithful representation ρ, the condition $q(a)\sim -\mathrm{tr}\,\rho(a)^2$ fixes the ratio g/g' once and for all.

In fact, according to the point of view taken in this paper, the U(n) Higgs model starts from a distinguished representation, namely $\rho(a)=\hat{a}$, and thus provides a canonical choice for the value of the ratio g/g'. Writing Tr for the trace on End $\wedge\mathbb{C}^n$ (we reserve tr for traces in other circumstances) and setting

$$q(a)=-\mathrm{Tr}\,\hat{a}^2,\quad a\in\mathbf{u}(n), \tag{3}$$

we also fix the value of g which is solely a matter of convenience without intrinsic meaning.

This choice of $q(a)$ may appear as an ''article of faith'' and is certainly questionable; the matter is not being debated here. Instead, we will demonstrate how g and g' are related. Expanding both sides of the well-known formula

$$\log \mathrm{Tr}\exp\hat{a}=\mathrm{tr}\log(\mathbb{1}+e^a),$$

we get

$$\mathrm{Tr}\,\mathbb{1}=2^n,\quad \mathrm{Tr}\,\hat{a}=2^{n-1}\,\mathrm{tr}\,a,\quad \mathrm{Tr}\,\hat{a}^2=2^{n-2}((\mathrm{tr}\,a)^2+\mathrm{tr}\,a^2). \tag{4}$$

Comparison with (2) shows that $(g/g')^2=n+1$. For the electro-weak theory $(n=2)$, we get the equation $g^2=3g'^2$ apart from the value $g^2=2$ owing to our choice of normalization in (3).

To prepare for later work, we introduce a basis e_i $(i=1,...,n^2)$ in $\mathbf{u}(n)$ such that $q(e_i,e_k)=\delta_{ik}$. It is also assumed that e_i $(i=1,...,n^2-1)$ is a basis for $\mathbf{su}(n)$.

Let us now investigate the two simplest situations U(1) and U(2). In the U(1) case, it is obvious that

$$\wedge u=\begin{pmatrix}1 & 0\\ 0 & u\end{pmatrix},\quad \hat{a}=\begin{pmatrix}0 & 0\\ 0 & a\end{pmatrix},\quad u=e^a\in U(1),\quad a\in i\mathbb{R}.$$

As expected, $e_1=i$, since $q(i)=-i^2=1$.

We treat the U(2) case in greater detail. Here $2^n=4$ and so $\wedge u$ is a unitary 4×4 matrix which is block diagonal (blocks are 2×2 matrices),

$$\wedge u=\begin{pmatrix}\wedge^+u & 0\\ 0 & \wedge^-u\end{pmatrix},\quad \wedge^+u=\begin{pmatrix}1 & 0\\ 0 & \det u\end{pmatrix},\quad \wedge^-u=u\in\mathrm{U}(2).$$

It follows that

$$\hat{a}=\begin{pmatrix}\hat{a}^+ & 0\\ 0 & \hat{a}^-\end{pmatrix},\quad \hat{a}^+=\begin{pmatrix}0 & 0\\ 0 & \mathrm{tr}\,a\end{pmatrix},\quad \hat{a}=a\in\mathbf{u}(2),$$

and $q(a)=-(\mathrm{tr}\,a)^2-\mathrm{tr}(a^2)$ by (3) and (4). Setting

$$a=a^ke_k=\frac{i}{\sqrt{2}}\begin{pmatrix}\frac{1}{\sqrt{3}}a^4+a^3 & a^1-ia^2\\ a^1+ia^2 & \frac{1}{\sqrt{3}}a^4-a^3\end{pmatrix}\quad (a^k\in\mathbb{R}),$$

we obtain a basis in $\mathbf{u}(2)$ with the required property $q(a)=\Sigma_k(a^k)^2$.

III. DIFFERENTIAL FORMS

We let T^*M denote the complexified cotangent bundle of the manifold M. Sections of T^*M are said to be (complex) 1-forms. The exterior algebra $\wedge T^*M$ is a superbundle and so is $\wedge(T^*M\oplus V)$. The latter construction relates to the dimensional reduction formalism in an obvious way. For, if N is another manifold and $V=T^*N$, then $T^*M\oplus V\cong T^*(M\times N)$. Whether or not some manifold N of dimension n is lurking behind the scene, there exists a natural isomorphism

$$\wedge(T^*M\oplus V)\cong\wedge T^*M\otimes\wedge V \tag{5}$$

between $\mathbb{Z}_2$-graded algebras. The tensor product on the right-hand side of (5) is special for graded algebras. It is often called a *skew tensor product*. Generally speaking, if X and Y are $\mathbb{Z}_2$-graded algebras, the multiplication in $X\otimes Y$ is given by

$$(x\otimes y)(x'\otimes y)=(-1)^r xx'\otimes yy',\quad r=\begin{cases}1 & \text{if } x' \text{ and } y \text{ are odd}\\ 0 & \text{otherwise.}\end{cases}$$

The fact that the isomorphism (5) respects the grading means

$$\wedge^{\pm}(T^*M\oplus V)\cong\sum_{(-1)^{p+q}=\pm 1}\wedge^p T^*M\otimes\wedge^q V,$$

or stated equivalently,

$$\wedge^{+}(T^*M\oplus V)\cong(\wedge^{+}T^*M\otimes\wedge^{+}V)\oplus(\wedge^{-}T^*M\otimes\wedge^{-}V),$$

$$\wedge^{-}(T^*M\oplus V)\cong(\wedge^{-}T^*M\otimes\wedge^{+}V)\oplus(\wedge^{+}T^*M\otimes\wedge^{-}V).$$

The grading carries over to the space of $\wedge V$-valued differential forms,

$$\Omega:=\Gamma(M,\wedge T^*M\otimes\wedge V)=\Omega^{+}\oplus\Omega^{-},$$

and to the algebra of sections of the endomorphism bundle,

$$\mathcal{B}:=\Gamma(M,\wedge T^*M\otimes\mathrm{End}\wedge V)=\mathcal{B}^{+}\oplus\mathcal{B}^{-}. \tag{6}$$

Note that $\mathrm{End}\wedge V$ is a superbundle, and the tensor product in (6) is between graded algebras. Elements of $A\in\mathcal{B}$ act on Ω and are called *local operators* since they leave fibers intact. Equivalently, they commute with the multiplication by functions $f\in\Gamma$.

A local operator $A\in\mathcal{B}^{\pm}$ is said to have parity ± 1—or is referred to as an even (odd) operator—where parity is defined as follows:

$$\mathrm{par}(A)=+1 \Leftrightarrow A\Omega^{\pm}\subset\Omega^{\pm},$$

$$\mathrm{par}(A)=-1 \Leftrightarrow A\Omega^{\pm}\subset\Omega^{\mp}.$$

A different decomposition of $\mathcal{B}$ arises from the $\mathbb{Z}$-grading of $\wedge T^*M$,

$$\mathcal{B}=\sum_{p=0}^{m}\mathcal{B}^p,\quad \mathcal{B}^p=\Gamma(M,\wedge^p T^*M\otimes\mathrm{End}\wedge V).$$

Notice that $1\otimes id$ serves as the unit in the algebra $\mathcal{B}$ and that there are two natural embeddings,

$$\Gamma(M,\wedge T^*M)\to\mathcal{B},\quad \omega\mapsto\omega\otimes id,$$

$$\Gamma(M,\mathrm{End}\wedge V)\to\mathcal{B},\quad A\mapsto 1\otimes A.$$

Owing to these embeddings, various constructions on $\Gamma(M,\wedge T^*M)$ and $\Gamma(M,\mathrm{End}\wedge V)$ have extensions to $\mathcal{B}$.

For instance, the operator of exterior differentiation d on $\Gamma(M,\wedge T^*M)$ may be extended.

The trace $\mathrm{Tr}:\Gamma(M,\mathrm{End}\wedge V)\to\Gamma$ can be extended in an obvious manner,

$$\mathrm{Tr}:\Gamma(M,\wedge T^*M\otimes\mathrm{End}\wedge V)\to\Gamma(M,\wedge T^*M),\omega\otimes A\mapsto\omega\,\mathrm{Tr}\,A.$$

Any local operator A may be decomposed into homogeneous components (p-forms),

$$A=A_{[0]}+A_{[1]}+A_{[2]}+\cdots,\quad A_{[p]}\in\mathcal{B}^p.$$

The series truncates at $p=m$ where m is the dimension of the manifold M, and taking the trace of the top form, the integral

$$\mathrm{Int}(A)=\int_M \mathrm{Tr}\,A_{[m]}\in\mathbb{C},\tag{7}$$

assigns complex numbers to local operators of compact support.

The Hodge star operator on $\Gamma(M,\wedge T^*M)$ can uniquely be extended to a real-linear operator on $\mathcal{B}$ so as to satisfy

$$*(AB)=B^**A,\quad A\in\mathcal{B},B\in\mathcal{B}^0.\tag{8}$$

Let f_i $(i=1,...,m)$ be an oriented frame of the tangent bundle TM and f^i the dual frame of T^*M. For any multi-index $I\subset\{1,...,m\}$ we form the exterior product,

$$f^I=f^{i_1}f^{i_2}\cdots f^{i_p},\quad I=\{i_1,i_2,\ldots,i_p\},\quad i_1<i_2\cdots<i_p,\quad p=|I|\tag{9}$$

to obtain a frame of $\wedge T^*M$. It is assumed that $f^{\varnothing}=1$. Using (8), we have

$$*(f^I\otimes A_I)=*((f^I\otimes id)(1\otimes A_I))=(1\otimes A_I^*)(*f^I\otimes id)=(\pm 1)^{m-p}*f^I\otimes A_I^*,\quad A_I\in\Gamma(M,\mathrm{End}^{\pm}\wedge V).$$

Let $d\tau=*1=f^1f^2\cdots f^m$ denote the volume element. Then there are functions $g^I\in\Gamma$ such that $f^I*f^I=g^I\cdot d\tau$ and from (9), $g^I=\det(f^{i_k},f^{i_l})_{k,l=1,\ldots,p}>0$.

The algebra $\mathcal{B}$ may be equipped with a scalar product,

$$(A,B)=\mathrm{Int}(B*A),\quad A,B\in\mathcal{B},\tag{10}$$

and, by a straightforward calculation,

$$\|A\|^2=(A,A)=\int_M d\tau\sum_I g^I\,\mathrm{Tr}(A_IA_I^*)\geqslant 0,\quad A=\sum_I A_If^I.$$

The norm $\|\cdot\|$ on $\mathcal{B}$ will be used in Sec. V to construct the Euclidean action.

IV. SUPERCONNECTIONS

We start with a few remarks about connections. With P a principal G bundle, where $G=U(n)$, the space $\mathcal{A}$ of connections is an affine space with nontrivial topology if $n\geqslant 2$, e.g., $\pi_0(\mathcal{A})=\mathbb{Z}$. With $\mathcal{G}$ acting on $\mathcal{A}$, it seems natural to pass to the quotient

$$B\mathcal{G}=\mathcal{A}/\mathcal{G}$$

to obtain the classifying space for $\mathcal{G}$ bundles. In physics, $B\mathcal{G}$ is known as the space of gauge orbits. It corresponds to the phase space of classical mechanics. The passage to statistical mechanics is mirrored, in Euclidean field theory, by the process of quantization, i.e., the introduction of path integrals over $\mathcal{A}$. Granted the absence of anomalies, path integrals project onto $B\mathcal{G}$. The calculation, however, requires gauge fixing and the introduction of Faddeev–Popov ghosts. Gribov's discovery, also known as the *Gribov ambiguity*, may be rephrased by saying that there is no continuous global choice of gauge or, stated more formally, $\mathcal{A}$ does not admit a smooth global section. Though these intricacies are not the subject of the present paper, we should be aware that some of the formulas below hold only on local coordinate patches without explicit mentioning.

The advantage of giving a connection A on the principal bundle P is that it determines a connection on every associated bundle and thus provides covariant derivatives d_A on various vector bundles. We use the terms *connection* and *covariant derivative* interchangeably. A connection on the bundle V simply is a linear map

$$d_A:\Gamma(M,V)\rightarrow\Gamma(M,T^*M\otimes V)$$

satisfying the Leibniz rule $d_A(fs)=dfs+fd_As$ for all functions f and sections s. The connection extends in a unique way to an operator d_A on $\Gamma(M,\wedge T^*M\otimes V)$ sending p-forms to $(p+1)$-forms. Locally, $d_A=d+A$, where $A\in\Gamma(M,T^*M\otimes \mathrm{End}\,V)$ is the connection 1-form or gauge field. The 2-form $F=d_A^2\in\Gamma(M,\wedge^2T^*M\otimes\mathrm{End}\,V)$ is said to be the *curvature* of the connection d_A. In terms of physics, F is the field strength of a gauge theory. Under a gauge transformation,

$$^uA=uAu^{-1}+udu^{-1},\quad {}^uF=uFu^{-1},\quad u\in\mathcal{G}.$$

We may pass now to the superbundle $\wedge V$ and lift the fields A and F to certain local operators on Ω of definite parity,

$$\hat{A}=\begin{pmatrix}\hat{A}^+ & 0\\ 0 & \hat{A}^-\end{pmatrix}\in\mathcal{B}^-,\quad \hat{F}=\begin{pmatrix}\hat{F}^+ & 0\\ 0 & \hat{F}^-\end{pmatrix}\in\mathcal{B}^+.$$

Of course, $\hat{A}$ and $\hat{F}$ are still 1 and 2-forms, respectively. Recall that the matrix representation refers to the $\mathbb{Z}_2$-grading of $\wedge V$. In the same manner, d_A can be lifted to a connection D on the superbundle,

$$D=\begin{pmatrix}D^+ & 0\\ 0 & D^-\end{pmatrix},\quad \hat{F}=D^2.$$

Locally, we have $D=d+\hat{A}$ and $D^\pm=d+\hat{A}^\pm$. When acting on Ω, the differential operator D changes the parity, and so is of odd type.

To extend the connection D to a superconnection $\mathbb{D}=D+L$ we introduce a skew selfadjoint operator L on $\Gamma(M,\wedge V)$ of odd type,

$$L=\begin{pmatrix}0 & i\Phi^*\\ i\Phi & 0\end{pmatrix},$$

formally a section of the bundle

$$\wedge^0T^*M\otimes\mathrm{End}^-\wedge V\cong\mathrm{End}^-\wedge V,$$

and hence an element of $\mathcal{B}^-\cap\mathcal{B}^0$. The complex scalar field $\Phi(x)$ is said to be the *Higgs field* of the system. It has the following characteristic properties:

(a) At $x \in M$, the Higgs field $\dot{\Phi}(x)$ is a linear map from $\wedge^+ V_x$ to $\wedge^- V_x$. Consequently, $\Phi^*(x)$ maps $\wedge^- V_x$ to $\wedge^+ V_x$.

(b) Under a change of the gauge,

$$^u\Phi = (\wedge^- u)\Phi(\wedge^+ u)^{-1}, \quad ^u\Phi^* = (\wedge^+ u)\Phi^*(\wedge^- u)^{-1},$$

which is summarized by

$$^uL = (\wedge u)L(\wedge u)^{-1}.$$

(c) Like any section of the bundle $\mathrm{End}^- \wedge V, L$ extends to an odd operator on Ω. In more detail, L acts on $\wedge V$-valued p-forms by

$$L(dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_p} v_{\mu_1\cdots\mu_p}(x)) = (-1)^p dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_p} L(x) v_{\mu_1\cdots\mu_p}(x)$$

so as to be in accord with the skew tensor product $\wedge T^*M \otimes \mathrm{End}\wedge V$. To put it differently, L satisfies the rule $\{L, dx^\mu\} = 0$ or, equivalently, L anticommutes with the multiplication by Γ-valued 1-forms. Thus $L: \Omega^\pm \to \Omega^\mp$ is parity changing and hence $L \in \mathcal{B}^-$ by construction.

(d) Since both d and L are odd degree operators, their anticommutator (or supercommutator) $dL := \{d, L\}$ is an even operator (and a 1-form) called the covariant derivative of L. Similarly, the anticommutator,

$$DL := \{D, L\} = \begin{pmatrix} 0 & i(D\Phi)^* \\ iD\Phi & 0 \end{pmatrix},$$

provides the covariant derivatives of the Higgs field and its adjoint,

$$D\Phi := D^-\Phi + \Phi D^+ = d\Phi + \hat{A}^-\Phi + \Phi\hat{A}^+ = dx^\mu(\partial_\mu\Phi + \hat{A}^-_\mu\Phi - \Phi\hat{A}^+_\mu),$$
$$(D\Phi)^* := D^+\Phi^* + \Phi^* D^- = d\Phi^* + \hat{A}^+\Phi^* + \Phi^*\hat{A}^- = dx^\mu(\partial_\mu\Phi^* + \hat{A}^+_\mu\Phi^* - \Phi^*\hat{A}^-_\mu).$$

Here, we used the fact that Φ and Φ^* anticommute with dx^μ.

Finally, the operator

$$\mathbb{D} = D + L = \begin{pmatrix} D^+ & i\Phi^* \\ i\Phi & D^- \end{pmatrix}$$

defines a *superconnection* on the superbundle $\wedge V$ in the sense of Quillen; $\mathbb{D}$ is a differential operator of odd type on Ω, hence acts on $\wedge V$-valued differential forms. It no longer sends p-forms to $(p+1)$-forms, but sends odd elements of Ω to even elements and vice versa so as to satisfy a Leibniz formula.

In Physics, fields are viewed as varying objects. Varying both the gauge field and the Higgs field means passage from one superconnection $\mathbb{D}$ to another, say $\mathbb{D}'$, such that the difference $\mathbb{D} - \mathbb{D}'$ comes out as a local operator built upon 1-forms (the diagonal parts) and 0-forms (the off-diagonal parts). Hence the notion of a *superconnection on a superbundle* is in accordance with the requirement that, whatever the context, connections form an affine space modeled on some set of local operators.

From $\mathbb{F} = (D+L)^2 = D^2 + \{D, L\} + L^2$ we obtain the decomposition

$$\mathbb{F} = \mathbb{F}_{[0]} + \mathbb{F}_{[1]} + \mathbb{F}_{[2]} \in \mathcal{B}^+, \quad \mathbb{F}_{[p]} \in \mathcal{B}^p$$

for the curvature $\mathbb{F}$ of the superbundle $\wedge V$. In particular, the curvature is a local operator (not a differential operator). Note that the Bianchi identity $[\mathbb{D}, \mathbb{F}] = 0$ is a trivial consequence of the definition of $\mathbb{F}$.

As indicated, the curvature $\mathbb{F}$ has homogeneous components for $p=0,1,2$. The 0-form is bilinear in the Higgs field,

$$\mathbb{F}_{[0]}=L^2=\begin{pmatrix} -\Phi^*\Phi & 0 \\ 0 & -\Phi\Phi^* \end{pmatrix},$$

while the 1-form is linear in the covariant derivatives of the Higgs field,

$$\mathbb{F}_{[1]}=DL=\begin{pmatrix} 0 & i(D\Phi)^* \\ iD\Phi & 0 \end{pmatrix}.$$

Finally, the 2-form

$$\mathbb{F}_{[2]}=D^2=\hat{F}=\begin{pmatrix} \hat{F}^+ & 0 \\ 0 & \hat{F}^- \end{pmatrix}$$

gives the curvature when the Higgs field is absent.

V. EUCLIDEAN ACTION AND STATIONARY POINTS

We shall always stay within the realm of Euclidean field theory. For the remainder of this paper, M denotes the four-dimensional Euclidean flat spacetime with standard orientation, $d\tau = dx^1\wedge dx^2\wedge dx^3\wedge dx^4$.

Before describing the field equations of the Higgs model, we motivate the construction of a gauge invariant Euclidean action based on the superbundle $\wedge V$ and the gauge group $\mathrm{U}(n)$. With F the curvature of a Yang–Mills connection, one takes $S=\frac{1}{2}\|F\|^2$ as the action so that the global minimum is attained for the flat connection. Similarly, the superbundle is flat if $\mathbb{F}=0$. However, the definition $S=\frac{1}{2}\|\mathbb{F}\|^2$ gives us models that show no sign of spontaneous symmetry breaking. To our rescue comes the abelian algebra $(\wedge G)'$ of gauge invariant operators C, each of them constant on M. If C is self-adjoint, the following definition of the Euclidean action serves the purpose,

$$S=\tfrac{1}{2}\|\mathbb{F}+\mu^2 C\|^2, \quad C\in(\wedge G)'. \tag{11}$$

Euclidean actions that differ by the choice of C are said to be *phases* of the same model. As an element of an abelian algebra, C can always be written in terms of central charges $c_k, k=0,\ldots,n$. Self-adjointness of C makes these charges real numbers. We may write

$$C=\begin{pmatrix} C^+ & 0 \\ 0 & C^- \end{pmatrix}, \quad C^\pm=\sum_{(-1)^k=\pm 1} c_k P_k$$

and split the action into different parts for easier interpretation,

$$S=\tfrac{1}{2}\|\hat{F}\|^2+\tfrac{1}{2}\|DL\|^2+\tfrac{1}{2}\|L^2+\mu^2 C\|^2. \tag{12}$$

The last term involves the Higgs potential $V(\Phi)$,

$$\tfrac{1}{2}\|L^2+\mu^2 C\|^2=\int_M d\tau V(\Phi)$$

$$\begin{aligned} V(\Phi)&=\tfrac{1}{2}\,\mathrm{Tr}(L^2+\mu^2 C)^2 \\ &=\tfrac{1}{2}\,\mathrm{Tr}(\Phi^*\Phi-\mu^2 C^+)^2+\tfrac{1}{2}\,\mathrm{Tr}(\Phi\Phi^*-\mu^2 C^-)^2. \end{aligned} \tag{13}$$

In (12) we encounter the term $\frac{1}{2}\|\hat{F}\|^2$ as part of the action. To analyze it we introduce the components of the curvature F with respect to the basis dx^μ in T^*M and the basis e_k in $\mathbf{u}(n)$,

$$F=F^k e_k, \quad F^k=\tfrac{1}{2}dx^\mu\wedge dx^\nu F^k_{\mu\nu}(x).$$

The coefficients $F^k_{\mu\nu}(x)$ are real functions on M. It follows that $\hat{F}=-\hat{F}^*=F^k\hat{e}_k$ and, in view of the definitions (10) and (7),

$$\frac{1}{2}\|\hat{F}\|^2=\int_M d\tau \frac{1}{4}\sum_{k,\mu\nu}(F^k_{\mu\nu})^2.$$

This reveals that $\frac{1}{2}\|\hat{F}\|^2$ is the Euclidean action, correctly normalized, of a conventional gauge theory without Higgs field.

The positive parameter μ sets the mass scale of the model while the central charges c_k control the expectation value of the Higgs field (the so-called condensate) on the classical (or tree) level. The role of these parameters is similar when the theory is quantized using path integrals. The latter procedure replaces the classical Higgs potential by an effective potential whose minima describe the vacuum states.

One remark is in order. Recall that we have deliberately put g^2 equal to 2. It may later be necessary to work with an arbitrary value of the gauge coupling g. The introduction of g as a parameter can be achieved by an appropriate scaling,

$$S\rightarrow\lambda^{-2}S(\lambda A,\lambda\Phi), \quad 2\lambda^2=g^2.$$

Since scaling has no influence on second order terms of the action, it will not alter the results of the present paper.

Let us concentrate on the term $\frac{1}{2}\|DL\|^2$ of the action and its dependence on the connection (i.e., the gauge potential A),

$$S_L(A):=\tfrac{1}{2}\|DL\|^2=\int_M d\tau\ \mathrm{Tr}\sum_\mu (DL)^*_\mu(DL)_\mu,$$

where $DL=dx^\mu(DL)_\mu$ and $(DL)_\mu=\partial_\mu L+[\hat{A}_\mu,L]$. As usual, the response to a small change of the connection determines the current of the model,

$$S_L(A+a)=S_L(A)+(\hat{a},\{DL,L\})+O(a^2).$$

From $\{DL,L\}=dx^\mu[(DL)_\mu,L]$ and $a=dx^\mu a^k_\mu e_k$ we obtain $\hat{a}=dx^\mu a^k_\mu\hat{e}_k$ and

$$(\hat{a},\{DL,L\})=\int_M d\tau\sum_\mu a^k_\mu\,\mathrm{Tr}(\hat{e}_k[(DL)_\mu,L]).$$

Thus the current $j=dx^\mu j^k_\mu e_k$, which is Lie algebra valued 1-form, has components

$$j^k_\mu=\mathrm{Tr}(\hat{e}_k[(DL)_\mu,L]),$$

while the structure of the commutator in terms of the Higgs field Φ is as follows:

$$[(DL)_\mu,L]=\begin{pmatrix}\Phi^*(D\Phi)_\mu-(D\Phi)^*_\mu\Phi & 0\\ 0 & \Phi(D\Phi)^*_\mu-(D\Phi)_\mu\Phi^*\end{pmatrix}.$$

Let us now consider the formal adjoint operators d^*, d_A^*, and D^*. They belong to the standard repertoire of Yang–Mills systems. Adjoints are always formed with respect to the scalar product of sections. Each of the above adjoint operators maps p-forms into $(p-1)$-forms. The operator $\delta := -d^*$ is called the *coderivative* and $\Delta = -\{d, d^*\}$ the *Laplacian.*

From the condition that the action S be stationary one obtains the field equations of the U(n) Higgs model,

$$D^*\hat{F} + \hat{j} = 0, \quad D^*DL = \{L, L^2 + \mu^2 C\}.$$

For this and similar calculations, it is useful to keep in mind that $D^*\hat{F}$ is short for $[D^*, \hat{F}]$ and D^*DL is short for $[D^*, \{D, L\}]$. The current j has been lifted to obtain $\hat{j} = dx^\mu j_\mu^k \hat{e}_k$.

The field equations may also be put into a form reminiscent of previous Yang–Mills–Higgs models,

$$D_A^* F + j = 0, \quad D^*D\Phi = -2\Phi\Phi^*\Phi + \mu^2(\Phi C^+ + C^-\Phi). \tag{14}$$

Again, $d_A^* F$ is short for $[d_A^*, F]$, and $D^*D\Phi$ is obtained from

$$[D^*, \{D, L\}] = \begin{pmatrix} 0 & i(D^*D\Phi)^* \\ iD^*D\Phi & 0 \end{pmatrix}.$$

Any solution (A, Φ) of the second order field Eqs. (14) is said to be a stationary point of the action. We should be aware that not every stationary point corresponds to a local or global minimum of the action.

The global minimum is attained if $A = 0$ and if L solves of the variational problem

$$\mathrm{Tr}(L^2 + \mu^2 C)^2 = \text{minimum}. \tag{15}$$

The solutions are said to describe (classical) vacua or ground states. Granted that M is connected, any solution L_c of (15) is constant on M and is referred to as the *Higgs condensate*. The group U(n) acts upon the set of solutions, though not always freely; the residual gauge group

$$G_0 = \{u \in \mathrm{U}(n) \,|\, (\wedge u) L_c = L_c (\wedge u)\} \tag{16}$$

may well be nontrivial. Ground states that lie on the same gauge orbit are physically equivalent. We must not expect the group U(n) to act transitively; there may exist many gauge orbits.

If L_c^2 is unique, we obtain a U(n) invariant vacuum. Nonuniqueness is characteristic of a broken phase. Note also that each ground state has constant scalar curvature, $\mathbb{F} = L_c^2$. The structure of L_c is that of a constant matrix,

$$L_c = i\begin{pmatrix} 0 & \Phi_c^* \\ \Phi_c & 0 \end{pmatrix}, \quad \Phi_c = \mu v.$$

There are two special cases where the variational problem (15) can be solved with ease. First, $C = 0$ implies $L_c = 0$ giving a U(n) invariant vacuum. Second, $C = 1$ implies $L_c^2 = \mu^2$, hence $v^*v = vv^* = 1$, and v establishes an isomorphism between the spaces $\wedge^+\mathbb{C}^n$ and $\wedge^-\mathbb{C}^n$. Conversely, any isomorphism v gives us a solution of (15).

Suppose we look for exitations from some ground state, but ignore the Higgs degrees of freedom. Then L is kept constant, i.e., $L = L_c$ and $DL = \{\hat{A}, L_c\} = dx^\mu [\hat{A}_\mu, L_c]$. Provided $[\hat{A}_\mu, L_c] \neq 0$, the gauge particles acquire masses. Indeed, the mass term of the action may be written

$$\frac{1}{2}\|DL_c\|^2 = \int_M d\tau \frac{1}{2} \sum_\mu Q(A_\mu),$$

where Q is a positive semidefinite quadratic form on the Lie algebra,

$$Q(a) = -\mathrm{Tr}[\hat{a}, L_c]^2 = a^i a^k m_{ik}^2, \quad a = a^i e_i \in \mathbf{u}(n). \tag{17}$$

The eigenvalues of the matrix (m_{ik}^2) are the masses (squared) of gauge fields given by the eigenvectors where it is assumed that the eigenvectors are orthonormal with respect to the bilinear form $q(a,b)$ on the Lie algebra obtained from (3).

Suppose now that L_c' is another Higgs condensate giving rise to the quadratic form $Q'(a)$. Both L_c and L_c' lie on the same gauge orbit if $(\wedge u)L_c = L_c'(\wedge u)$ for some $u \in U(n)$. Owing to the invariance property $Q(a) = Q'(uau^{-1})$, the eigenvalues of the mass matrix stay constant along any gauge orbit.

VI. THE U(1) HIGGS MODEL

A very simple situation arises when $n=1$ since there is only one basis element $e_1 = i$ in $\mathbf{u}(1) = i\mathbb{R}$. We may thus write $A = i dx^\mu A_\mu(x)$ and $F = i\frac{1}{2} dx^\mu \wedge dx^\nu F_{\mu\nu}(x)$ with real-valued components A_μ and $F_{\mu\nu}$. In the two-dimensional cap representation of $\mathbf{u}(1)$ we have

$$\hat{A} = \begin{pmatrix} 0 & 0 \\ 0 & A \end{pmatrix}, \quad \hat{F} = \begin{pmatrix} 0 & 0 \\ 0 & F \end{pmatrix}.$$

The Higgs field is simply some complex scalar field Φ. With c_0 and c_1 the central charges, the Higgs potential becomes

$$V(\Phi) = \tfrac{1}{2}(|\Phi|^2 - \mu^2 c_0)^2 + \tfrac{1}{2}(|\Phi|^2 - \mu^2 c_1)^2 = (|\Phi|^2 - \mu^2 c)^2 + \tfrac{1}{4}\mu^2 (c_0 - c_1)^2, \quad c = \tfrac{1}{2}(c_0 + c_1).$$

Provided that $c > 0$, the minimum is attained for $\Phi = \mu c e^{i\alpha}$. Otherwise, the minimum is attained for $\Phi = 0$. There is no restriction in assuming that $c_0 = c_1$ and $c = \pm 1$. From

$$\mathbb{D} = \begin{pmatrix} d & \Phi^* \\ -\Phi & d + A \end{pmatrix}, \quad \mathbb{F} = \begin{pmatrix} -|\Phi|^2 & i(d_A \Phi)^* \\ i d_A \Phi & F - |\Phi|^2 \end{pmatrix},$$

we obtain the action of the Ginzburg–Landau theory,

$$S = \int_M d\tau \left(\frac{1}{4} \sum_{\mu\nu} F_{\mu\nu}^2 + \sum_\mu |(\partial_\mu + iA_\mu)\Phi|^2 + (|\Phi|^2 - \mu^2 c)^2 \right),$$

whose current is given by

$$j = i dx^\mu j_\mu(x), \quad j_\mu = 2\, \mathrm{Im}(\Phi^* (\partial_\mu + iA_\mu)\Phi).$$

For $c=1$, the system is in the superconducting phase, the residual gauge group is trivial, and ground states differ by a constant phase, $\Phi(x) = \mu e^{i\alpha}$. However, these states belong to a single gauge orbit and hence are equivalent. Provided Φ is kept at its ground state value, S reduces to the action of a massive photon $(m_\gamma^2 = 2\mu^2)$,

$$S = \int_M d\tau \left(\frac{1}{4} \sum_{\mu\nu} F_{\mu\nu}^2 + \mu^2 \sum_\mu A_\mu^2 \right).$$

For $c = -1$, the system is in the Coulomb phase. Exitations from the ground state show that the vector particle (i.e., the photon) has zero mass.

VII. THE U(2) HIGGS MODEL

We now come to the $n=2$ situation. The U(2) connection 1-form A may be written in the basis e_k, $k=1,...,4$ as introduced in Sec. II,

$$A=\frac{i}{\sqrt{2}}\begin{pmatrix}\frac{1}{\sqrt{3}}A^4+A^3 & A^1-iA^2\\ A^1+iA^2 & \frac{1}{\sqrt{3}}A^4-A^3\end{pmatrix},\quad A^k=dx^\mu A^k_\mu(x),$$

where $A^k_\mu(x)$ $(k=1,...,4)$ are real gauge fields. A similar decomposition holds for the curvature $F=d_A^2$. Notice that $\operatorname{tr} A=i\sqrt{2/3}A^4$. We move on to write the superconnection $\mathbb{D}$ (a 4×4 matrix) in block form,

$$\mathbb{D}=\begin{pmatrix} d+\hat{A}^+ & i\Phi^* \\ i\Phi & d+\hat{A}^-\end{pmatrix},\quad \hat{A}^+=\begin{pmatrix}0 & 0\\ 0 & i\sqrt{2/3}A^4\end{pmatrix},\quad \hat{A}^-=A.$$

Subgroups of U(2) have a specific interpretation in the context of the electro-weak theory. For instance, the U(1) subgroup consisting of phase transformations leads to the conservation of the weak hypercharge in the unbroken phase. The Higgs field Φ is some 2×2-matrix whose columns represent Higgs doublets in the fundamental representation of SU(2),

$$\Phi=\begin{pmatrix}\Phi_1 & \Phi_3\\ \Phi_2 & \Phi_4\end{pmatrix}.$$

The two doublets have opposite weak hypercharge. For an account of the physical implications of two-doublet models see the review article by Sher.[24]

There are five real second-order forms, invariant under U(2), that one may construct from the Higgs field,

$$R_1(\Phi)=|\Phi_1|^2+|\Phi_2|^2,\quad R_3(\Phi)=|\Phi_1^*\Phi_3+\Phi_2^*\Phi_4|,$$

$$R_2(\Phi)=|\Phi_3|^2+|\Phi_4|^2,\quad R_4(\Phi)+iR_5(\Phi)=\Phi_1\Phi_4-\Phi_2\Phi_3.$$

Since they satisfy the relation

$$R_1R_2=R_3^2+R_4^2+R_5^2, \tag{18}$$

only four of them are algebraically independent. It is natural to think of the manifold (18) as some moduli space related to superconnections.

In principle, any gauge invariant Higgs potential $V(\Phi)$, be it the classical or the effective potential, can be written as a function of the above invariants. Such a representation is convenient because the problem of minimizing the action is then reduced to solving a simpler problem in lower dimension. Each solution provides certain constants

$$r_i=R_i(\Phi_c),\quad i=1,...5,$$

which characterize the gauge orbit of Φ_c, and the moduli space of vacua becomes a submanifold of

$$r_1r_2=r_3^2+r_4^2+r_5^2. \tag{19}$$

Given the numbers r_i, the next step would be to determine the eigenvalues of the mass matrix m^2 of the vector bosons as defined by (17). Since the matrix elements depend on the choice of Φ_c, hence on the point of the gauge orbit chosen, we better look at the characteristic polynomial of that matrix which is gauge invariant and thus can be written entirely in terms of the variables r_i. By a tedious but straightforward calculation one finds

$$\det(m^2-\lambda)=(\lambda-r)^2(\lambda^2-\tfrac{4}{3}r\lambda+\tfrac{4}{3}r_3^2),\quad (0\leqslant 2r_3\leqslant r),\tag{20}$$

where $r=r_1+r_2=-\frac{1}{2}\operatorname{Tr}L_c^2$. An immediate consequence is the following alternative:

(1) If $r=0$, the eigenvalue zero of the mass matrix is fourfold degenerate: all vector bosons are massless.
(2) If $r>0$, the eigenvalue r of the mass matrix is twofold degenerate. We interpret r as the mass (squared) of the $W^{\pm}$ bosons. If $r_3=0$, there is an eigenvalue zero naturally associated to the photon and an eigenvalue $\frac{4}{3}r$ interpreted as the mass (squared) of the Z boson so that $m_W^2:m_Z^2=3:4$. In the latter case, the residual gauge group is isomorphic to U(1), leading to the notion of the electric charge. The $W^{\pm}$ bosons receive the charge ± 1, while the Z boson is neutral.

So far we have not fixed the value of the mass parameter μ. From now on we shall always assume that $\mu^2=r$ so that μ coincides with the W mass. In other words, it is the W mass that sets the mass scale. The U(2) Higgs model conforms to the existing empirical data only if $r_3=0$. It is therefore important to show that $r_3=0$ is not an extra assumption but follows from the Higgs potential (13). Though the Higgs potential depends on arbitrary constants c_0, c_1, and c_2, it is special among U(2) invariant fourth-order polynomials. For a simple calculation reveals that

$$V(\Phi)=(R_1(\Phi)-b_1)^2+(R_2(\Phi)-b_2)^2+2R_3(\Phi)^2+b_3^2.\tag{21}$$

Here we passed from the set c_i of constants to another more convenient set b_i given by

$$b_1=\tfrac{1}{2}\mu^2(c_0+c_1),\quad b_2=\tfrac{1}{2}\mu^2(c_2+c_1),\quad b_3=\tfrac{1}{2}\mu^2((c_0-c_1)^2+(c_2-c_1)^2)^{1/2}.$$

While b_3 is physically irrelevant, b_1 and b_2 are essential for spontaneous symmetry breaking. It is now obvious that any ground state has coordinates

$$r_i=\max(0,b_i),\quad (i=1,2),\quad r_3=0,\quad r_4^2+r_5^2=r_1r_2=\text{const},$$

which establishes two things; (1) our claim that $r_3=0$ and (2) the moduli space of vacua is the sphere S^1 provided $r_1r_2>0$, or simply a point if either $r_1=0$ or $r_2=0$. Granted the condition $r_3=0$ we can always perform a U(2) gauge transformation so that the Higgs condensate assumes the form

$$\Phi_c=\begin{pmatrix} r_1^{1/2}e^{i\alpha} & 0 \\ 0 & r_2^{1/2}\end{pmatrix},\quad r_1+r_2=\mu^2,\quad r_4+ir_5=(r_1r_2)^{1/2}e^{i\alpha},\tag{22}$$

with α parametrizing the sphere S^1. The choice of such a standard form is essential for getting a standard set of eigenvectors of the mass matrix. In fact it follows at once from (17) and (22) that

$$Q(a)=\mu^2\left(|a^1+ia^2|^2+\left(\frac{1}{\sqrt{3}}a^4+a^3\right)^2\right),$$

and thus the eigenvectors of the mass matrix are

mass^2	eigenvector
0	$\frac{1}{2}(\sqrt{3}a^4-a^3)$
$\frac{4}{3}\mu^2$	$\frac{1}{2}(\sqrt{3}a^3+a^4)$
μ^2	$a^1,\ a^2$

The residual gauge group, isomorphic to U(1), is

$$G_0=\left\{\begin{pmatrix}1 & 0\\ 0 & e^{i\alpha}\end{pmatrix}\in \mathrm{U}(2)\,\middle|\,0\leqslant\alpha\leqslant 2\pi\right\}. \tag{23}$$

We relate the photon, the Z boson, and the W boson to the above eigenvectors and thus work with the following fields:

$$A^0=\tfrac{1}{2}(\sqrt{3}A^4-A^3),\quad Z=\tfrac{1}{2}(\sqrt{3}A^3+A^4),\quad W^{\pm}=\frac{1}{\sqrt{2}}(A^1\mp iA^2). \tag{24}$$

It is common practice to write $Z=\cos\theta\,A^3+\sin\theta\,A^4$ with θ the Weinberg angle and to determine $\sin^2\theta$ by experiment. Comparison with (24) shows that $\sin^2\theta=1/4$ in the present theory while the generally accepted value obtained from experiment is $\sin^2\theta=0.231$. The value 1/4, however, has previously been predicted on different grounds (see, for instance, Refs. 6 and 8).

As a matrix, the connection 1-form may now be written in terms of A^0, Z, and W,

$$A=i\begin{pmatrix}\sqrt{\frac{2}{3}}Z & W^+\\ W^- & \sqrt{\frac{1}{2}}A^0-\sqrt{\frac{1}{6}}Z\end{pmatrix}. \tag{25}$$

To summarize, the choice of the central charges c_i does not seem to matter as long as we keep r at a fixed value, say μ^2. That this impression is false will become clear as soon as the coupling to matter is taken into account. In a forthcoming paper, the Yukawa interaction of fundamental fermions with the Higgs field results from a widening of the concept of Dirac operators and so is viewed as integral part of the gauge coupling. It will then become clear that the invariant parameters r_1 and r_2 are proportional to the masses (squared) of the pair (ν_e,e) in a purely leptonic model (one generation only). Vanishing of the neutrino mass requires that $r_1=0$. In this situation, the moduli space of vacua shrinks to a point. This puts another constraint on the parameters c_i, namely $c_0+c_1\leqslant 0$ or $b_1\leqslant 0$.

Let us now discuss the Higgs field itself. The assignment of electric charges to the four complex degrees of freedom can be read off from $\left(\begin{smallmatrix}0 & +1\\ -1 & 0\end{smallmatrix}\right)$. The one-doublet model of Salam and Weinberg is recovered if

$$\Phi=\begin{pmatrix}0 & \Phi^+\\ 0 & \Phi^0\end{pmatrix} \tag{26}$$

which is consistent with $r_1=0$ but not with $r_1>0$.

The two-doublet model we propose has eight real degrees of freedom. Three of them can be gauged away, giving an extra polarization degree of freedom to each massive gauge field. The remaining five degrees can be arranged as follows:

$$\Phi = \begin{pmatrix} X^0 & 0 \\ X^- & \sqrt{\frac{1}{2}}\phi \end{pmatrix} + \Phi_c .$$

There are two complex fields X^0 and X^-. The real field ϕ describes the Higgs particle of the conventional theory. To determine the (bare) masses of these fields we expand the Higgs potential to second order assuming $r_1=0$,

$$V(\Phi)=b_1^2+b_3^2-2b_1|X^0|^2+2(\mu^2-b_1)|X^-|^2+2\mu^2\phi^2+\cdots .$$

Recall now that $2b_1=\mu^2(c_0+c_1)<0$. Therefore,

$$m_{X^0}^2=\mu^2|c_0+c_1|, \quad m_{X^-}^2=\mu^2(2+|c_0+c_1|), \quad m_H^2=4\mu^2.$$

In this scenario, the hypthetical X particles have masses that depend on the constants c_i while the mass of the Higgs particle is not influenced by their values. We may state our results as

$$m_W^2:m_Z^2:m_H^2=3:4:12, \quad m_{X^-}^2=m_{X^0}^2+2m_W^2, \tag{27}$$

with the prediction $m_H=2m_W=161$ GeV. A value of the Higgs mass near 160 GeV has also been predicted by Okumura.[25]

To summarize, gauge potentials, Higgs fields, and the Higgs condensate can be accommodated in a single Hermitian 4×4 matrix,

$$\hat{A}+L=i\begin{pmatrix} 0 & 0 & \overline{X^0} & \overline{X^-} \\ 0 & \sqrt{\frac{1}{2}}A^0+\sqrt{\frac{1}{6}}Z & 0 & \sqrt{\frac{1}{2}}\phi+\mu \\ X^0 & 0 & \sqrt{\frac{2}{3}}Z & W^+ \\ X^- & \sqrt{\frac{1}{2}}\phi+\mu & W^- & \sqrt{\frac{1}{2}}A^0-\sqrt{\frac{1}{6}}Z \end{pmatrix}. \tag{28}$$

The electric charges 0, ±1 attributed to the entries of such a matrix may be read off from the scheme,

$$\begin{pmatrix} 0 & +1 & 0 & +1 \\ -1 & 0 & -1 & 0 \\ 0 & +1 & 0 & +1 \\ -1 & 0 & -1 & 0 \end{pmatrix}.$$

It should be kept in mind that we rely here on a classical approximation. Quantization changes the Higgs potential to some effective potential which is expected to considerably differ from the classical potential. The same proviso applies to the computation of masses since they also depend on the effective potential. To include loop corrections is one way to change predictions, perhaps not in a reliable way. Such corrections depend on the mass matrices of matter fields and thus are outside the scope of this paper. Another way is to apply renormalization group methods which also rely on loop calculations. It should also be kept in mind that the relation $\tan\theta=g'/g$ holds for g and g' defined on a sliding energy scale. Therefore, the Weinberg angle θ cannot be a constant over a large energy range. The values to be used here should come from energies comparable to the mass parameter μ.

The superconnection formalism can be extended to include matter fields as will be shown in a subsequent paper. Left-handed and right-handed leptons (or quarks) of one generation are modelled by the vector space $\wedge\mathbb{C}^2$ of dimension four. The $\mathbb{Z}_2$ grading of that space coincides with one given by the handedness of fields. To obtain the correct action of the electro-weak structure group, one associates the subspaces $\wedge^0\mathbb{C}^2$, $\wedge^1\mathbb{C}^2$, and $\wedge^2\mathbb{C}^2$ with ν_{eR}, the pair (ν_{eL}, e_L), and e_R, respectively (taking the first generation of leptons as an example).

It would also be desirable to push the theory further, so as to obtain a unified theory of weak, electromagnetic, and strong interactions as a gauge theory based on a larger group incorporating both the vector bosons of the electroweak theory and the gluons of QCD. It is not clear at the moment whether such an approach will give reasonable results.

Momentum and spin of a particle with spin unity

C. B. van Wyk[a)]
Department of Mathematics and Applied Mathematics, University of the Orange Free State, Bloemfontein, South Africa

(Received 14 January 1998; accepted for publication 19 February 1999)

The first part of this paper deals with the problem of expressing a given boost as the product of an operator which leaves the momentum of a given particle, massive or massless, invariant and a helicity conserving operator. This is done by multiplying boosts and rotations only. In this way more information is obtained than by applying the operators to the relevant vectors. An operator with the property of conserving spin while perhaps changing momentum is developed. The second part of the paper defines a spin angular momentum operator leaving two four-vectors invariant. These vectors are interpreted as the momentum and spin vectors of a massive particle and the theory is extended to accommodate a massless particle. This theory emphasizes the close association of spin and momentum in a relativistic theory. The spin angular momentum operator of a massless particle has invariance properties which resemble some of those of the gauge invariant electromagnetic theory.
 [S0022-2488(99)02306-3]

I. INTRODUCTION

The first part of this paper deals with the problem of expressing an arbitrary boost as the product of an operator conserving the momentum of a given massive particle and of an operator conserving the helicity of that particle.[1–3]

The product of two boosts can be expressed as the product of a third boost preceded or followed by a rotation, the angle of rotation being the Wigner angle. The third boost can also be preceded by a rotation and followed by another rotation. The sum of the two angles of rotation must equal the Wigner angle. The choice of these angles introduces a flexibility into the theory which facilitates the accommodation of both the momentum and helicity conserving operators in the kinematics.

We construct a momentum conserving operator for a massive particle that can be adapted to be applicable to a massless particle. We then solve our problem also for a massless particle.

In the course of our discussions we encounter products of boosts and rotations that have physical meaning. Examples are the operator conserving momentum and the one conserving spin. We show how to distinguish in a unique way between different classes of these products.

The problem discussed in Sec. III has also been studied by other authors.[2,3] Their methods differ radically from ours. For instance the angle that we call the Wigner angle plays an important part in our methods while this angle does not occur in their discussions.

In the second part of this paper we regard the momentum conserving operator having the form of a product of a boost and its inverse with a rotation between them as the Lorentz transformation of a tensor of the second rank. In this case the tensor being transformed is the rotation operator. Proceeding along these lines we define a spin angular momentum operator for a spin 1 particle. A study of this operator reveals the interrelation between the spin and momentum of a relativistic particle.

Finally we derive a spin angular momentum operator for a massless particle. Under Lorentz transformations this operator has gauge invariant properties. The operator for a massive particle does not have these properties.

[a)]Present address: Helderberg Village 210, Private Bag X19, Somerset West, 7129, South Africa.

Almost all our calculations are in coordinate free form. By multiplying operators we obtain more information than by applying these operators to the relevant vectors. We demonstrate this in Sec. IV. Another advantage of this procedure is that some of our results are valid for particles of spin unity and spin half.

II. SOME ELEMENTARY DECOMPOSITIONS

In this section we prepare for later sections by briefly restating results derived earlier but used here in another context. The decomposition of the product of two boosts into a product of a third boost and a rotation can be written as[4,5]

$$L(\hat{\mathbf{u}},\phi_1)L(\hat{\mathbf{p}},\phi)=L(\hat{\mathbf{p}}',\phi_3)R(\hat{\mathbf{n}},\theta_W). \tag{1}$$

Here $L(\hat{\mathbf{u}},\phi_1)$ denotes the boost associated with the relative velocity $\hat{\mathbf{u}}\tanh\phi_1$ while $R(\hat{\mathbf{n}},\theta)$ denotes a rotation about the direction $\hat{\mathbf{n}}$ through the angle θ. The parameters on the right-hand side of (1) are determined in terms of those on the left by the multiplication of the 2×2 Pauli matrices. This procedure consists of writing (1) in the form

$$\begin{aligned}(\cosh(\phi_1/2)+\sinh(\phi_1/2)\sigma.\hat{\mathbf{u}})(\cosh(\phi/2)+\sinh(\phi/2)\sigma.\hat{\mathbf{p}})\\=(\cosh(\phi_3/2)+\sinh(\phi_3/2)\sigma.\hat{\mathbf{p}})(\cos(\theta_W/2)+i\sin(\theta_W/2)\sigma.\hat{\mathbf{n}})\end{aligned}$$

carrying out the multiplications and then comparing coefficients of corresponding sigmas. We find

$$\cos(\theta_W/2)\cosh(\phi_3/2)=\cosh(\phi_1/2)\cosh(\phi/2)+\sinh(\phi_1/2)\sinh(\phi/2)\hat{\mathbf{u}}.\hat{\mathbf{p}},$$

$$\hat{\mathbf{p}}'\sinh\phi_3=\hat{\mathbf{u}}[\sinh\phi_1\cosh\phi+\sinh\phi(\cosh\phi_1-1)\hat{\mathbf{u}}.\hat{\mathbf{p}}]+\hat{\mathbf{p}}\sinh\phi, \tag{2}$$

$$\sin(\theta_W/2)=\sinh(\phi_1/2)\sinh(\phi/2)|\hat{\mathbf{u}}_\wedge\hat{\mathbf{p}}|/\cosh(\phi_3/2), \tag{3}$$

$$\hat{\mathbf{n}}=\hat{\mathbf{u}}_\wedge\hat{\mathbf{p}}/|\hat{\mathbf{u}}_\wedge\hat{\mathbf{p}}|, \tag{4}$$

$$\cosh\phi_3=\cosh\phi\cosh\phi_1+\sinh\phi\sinh\phi_1\hat{\mathbf{u}}.\hat{\mathbf{p}}. \tag{5}$$

The angle θ_W is of course the Wigner angle associated with the left-hand side of (1). For reasons that will become evident later we regard p and p' as the initial and final momentum of a particle, respectively.

All the parameters on the right of (1) are uniquely determined by those on the left.

An equation like (1) introduces a hyperbolic as well as an addition triangle[5] (see Fig. 1). For the hyperbolic triangle $A'B'D'$ of (1) we have

$$\sin A'/\sinh\phi_1=\sin B'/\sinh\phi=\sin D'/\sinh\phi_3. \tag{6}$$

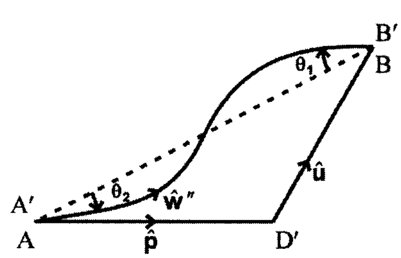

FIG. 1. The momentum diagram for (12) consists of the addition triangle ABD', the (solid) sides of which represent the momentum vectors occurring in (12). The triangle $A'B'D'$ with the dotted side $A'B'$ represents the hyperbolic triangle of this equation. In this figure we have chosen $\theta_1>0$ and $\theta_2<0$. Equation (1) has the same hyperbolic triangle as (12) but its addition triangle is obtained from Fig. 1 by replacing θ_1 by 0, θ_2 by $\theta_w>0$, and $\hat{\mathbf{w}}''$ by $\hat{\mathbf{p}}'$.

ABD' is the addition triangle of (1) and the measures of its sides and those of the hyperbolic triangle satisfy

$$A'B' = AB = \phi_3, \quad A'D' = AD' = \phi, \quad BD' = \phi_1.$$

Hence (5) holds for both the hyperbolic and the addition triangles. However the angles satisfy

$$A = A' + \theta_W, \quad B = B, \quad D' = D'. \tag{7}$$

For the hyperbolic triangle, A' is the angle between between $A'D'$ and $A'B'$. By (6)

$$\sin A' = \sinh \phi_1 |\hat{\mathbf{u}}_\wedge \hat{\mathbf{p}}| / \sinh \phi_3. \tag{8}$$

For (1) the angle between $\hat{\mathbf{p}}$ and $\hat{\mathbf{p}}'$, the directions of the initial and final momentum respectively, are given by

$$\Omega = A' + \theta_W. \tag{9}$$

where

$$\sin \Omega = Y / \sinh \phi_3, \tag{10}$$

and

$$Y = |\hat{\mathbf{u}}_\wedge \hat{\mathbf{p}}| [\sinh \phi_1 \cosh \phi + \sinh \phi (\cosh \phi_1 - 1) \hat{\mathbf{u}}.\hat{\mathbf{p}}]. \tag{11}$$

In the decomposition (12) the left-hand side is the same as in (1) but on the right we have a boost preceded and followed by a rotation[5]

$$L(\hat{\mathbf{u}}, \phi_1) L(\hat{\mathbf{p}}, \phi) = R(\hat{\mathbf{n}}, \theta_1) L(\hat{\mathbf{w}}'', \phi_3) R(\hat{\mathbf{n}}, \theta_2), \tag{12}$$

where (5) holds and

$$\sin[(\theta_1 + \theta_2)/2] = \sinh(\phi_1/2) \sinh(\phi/2) |\hat{\mathbf{u}}_\wedge \hat{\mathbf{p}}| / \cosh(\phi_3/2). \tag{13}$$

Note that (13) has the same structure as (3) whence

$$\theta_1 + \theta_2 = \theta_W \tag{14}$$

can be called the Wigner angle for decomposition (12). This decomposition can be considered as a generalization of (1). It is important to note that if the left-hand sides of (1) and (12) are the same then the same ϕ_3 and θ occur in the right-hand sides. Hence (1) and (12) have the same hyperbolic triangle $A'B'D'$ and therefore we would expect (5) to hold for (12). The angles satisfy

$$A = A' + \theta_2, \quad B = B' + \theta_1, \quad D' = D'. \tag{15}$$

The unique determination of the parameters on the right of (1) does not hold for those of (12). Equation (14) allows a choice of θ_j and this arbitrariness affects $\hat{\mathbf{w}}''$. This situation will be used in our search for the operators conserving helicity and momentum in Sec. III.

For future reference we present a formula describing the effect of a rotation on a boost. We have

$$L(\hat{\mathbf{p}}', \phi) R(\hat{\mathbf{n}}, \theta) = R(\hat{\mathbf{n}}, \theta) L(\hat{\mathbf{p}}, \phi). \tag{16}$$

For arbitrary $\hat{\mathbf{n}}$ and $\hat{\mathbf{p}}$,

$$\hat{\mathbf{p}}' = \hat{\mathbf{p}} \cos \theta + \hat{\mathbf{p}}_\wedge \hat{\mathbf{n}} \sin \theta + (1 - \cos \theta)(\hat{\mathbf{p}}.\hat{\mathbf{n}}) \hat{\mathbf{n}}.$$

If we choose $\hat{\mathbf{n}}$ and $\hat{\mathbf{p}}$ orthogonal then θ is the angle between $\hat{\mathbf{p}}$ and $\hat{\mathbf{p}}'$.

If $\hat{\mathbf{p}}$ and $\hat{\mathbf{p}}'$ are the directions of the initial and final momentum of a particle and θ is the angle between them, then the two sides of (16) are operators that leave helicity invariant and then we have two forms of the operator required in Sec. III.

The literature contains two meanings of the term Wigner angle. One group of authors[5,6] use this term for the angle denoted by θ_W in this article. Another group[2,3] use this term for the angle appearing in the usual momentum conservation operator denoted here by A'. Towards the end of Sec. III we refer to some of the properties of A'.

III. CONSERVATION OF HELICITY AND INITIAL MOMENTUM

We consider a massive particle with spin unity and momentum

$$p=(\hat{\mathbf{p}}\sinh\phi, i\cosh\phi) \tag{17}$$

and with spin along $\hat{\mathbf{p}}$ and a boost $L(\hat{\mathbf{u}},\phi_1)$. We try to factorize this operator in the form

$$L(\hat{\mathbf{u}},\phi_1)=\Lambda_h\Lambda_p, \tag{18}$$

where the operator Λ_p leaves the four-momentum (17) of the particle invariant according to

$$\Lambda_p p=p. \tag{19}$$

For the present we assume that

$$\Lambda_p=L(\hat{\mathbf{p}},\phi)R(\hat{\mathbf{n}},\theta)L^{-1}(\hat{\mathbf{p}},\phi). \tag{20}$$

Elementary considerations show that if this operator operates on a particle with momentum p the last factor reduces it to rest, R acts on the stationary particle, changing at most its spin direction while L restores the original momentum. We postpone further discussion of this momentum conservation operator to Sec. V.

The operator Λ_h leaves the helicity of the particle unchanged in the sense that if initially the spin and the momentum of the particle are parallel then after the action of Λ_h they are still parallel. Since the most general Lorentz operator can be expressed as a product of a rotation and a boost, the conservation of helicity can be achieved by an operator of the type *RL* or *LR*. We assume that

$$\Lambda_h=R(\hat{\mathbf{n}},\theta_1)L(\hat{\mathbf{p}},\phi_2). \tag{21}$$

Even if the axis $\hat{\mathbf{n}}$ and the angle θ of the rotation $R(\hat{\mathbf{n}},\theta)$ in (20) are completely arbitrary we have (19). However, if in (21) $\hat{\mathbf{n}}$ is arbitrary, then Λ_h is a very general operator containing six independent parameters.[5] Our problem can be solved by limiting $\hat{\mathbf{n}}$ in (21) to be orthogonal to $\hat{\mathbf{p}}$ in accordance with (4). Now Λ_h contains five independent parameters.

Since, according to (16), the right-hand sides of (21) and (22) are equal we can also have

$$\Lambda_h=L(\hat{\mathbf{p}}',\phi_2)R(\hat{\mathbf{n}},\theta_1). \tag{22}$$

Here $\hat{\mathbf{p}}'$ and $\hat{\mathbf{p}}$ are the vectors of Sec. II and θ_1 is the angle between them.

From (18), (20), and (21) we have

$$L(\hat{\mathbf{u}},\phi_1)=R(\hat{\mathbf{n}},\theta_1)L(\hat{\mathbf{p}},\phi_3)R(\hat{\mathbf{n}},\theta)L^{-1}(\hat{\mathbf{p}},\phi),$$

where

$$\phi_3=\phi+\phi_2. \tag{23}$$

Written in the form of (12) this equation becomes

$$L(\hat{\mathbf{u}},\phi_1)L(\hat{\mathbf{p}},\phi)=R(\hat{\mathbf{n}},\theta_1)L(\hat{\mathbf{p}},\phi_3)R(\hat{\mathbf{n}},\theta). \tag{24}$$

The only material differences between (12) and (24) are the directions of the velocities on the right-hand sides. We expect that their ϕ_3, their Wigner angles, and their hyperbolic triangles will be the same. This will be confirmed below.

We have to solve (24) for θ, θ_1, and ϕ_3 when $\hat{\mathbf{u}}$, $\hat{\mathbf{p}}$, ϕ_1, and ϕ are given. We find

$$\cosh(\phi_3/2)\cos((\theta_1+\theta)/2)=\cosh(\phi_1/2)\cosh(\phi/2)+\sinh(\phi_1/2)\sinh(\phi/2)\hat{\mathbf{u}}.\hat{\mathbf{p}}, \tag{25a}$$

$$\cosh(\phi_3/2)\sin((\theta_1+\theta)/2)=\sinh(\phi_1/2)\sinh(\phi/2)|\hat{\mathbf{u}}_{\wedge}\hat{\mathbf{p}}|, \tag{25b}$$

$$\sinh(\phi_3/2)\cos((\theta_1-\theta)/2)=\cosh(\phi_1/2)\sinh(\phi/2)+\sinh(\phi_1/2)\cosh(\phi/2)\hat{\mathbf{u}}.\hat{\mathbf{p}}, \tag{25c}$$

$$\sinh(\phi_3/2)\sin((\theta_1-\theta)/2)=\sinh(\phi_1/2)\cosh(\phi/2)|\hat{\mathbf{u}}_{\wedge}\hat{\mathbf{p}}|, \tag{25d}$$

where we have used

$$\hat{\mathbf{u}}=\hat{\mathbf{p}}(\hat{\mathbf{u}}.\hat{\mathbf{p}})-|\hat{\mathbf{u}}_{\wedge}\hat{\mathbf{p}}|\hat{\mathbf{n}}_{\wedge}\hat{\mathbf{p}} \tag{26}$$

which follows from (4). Equations (25a) and (25b) yield (5) while (25b) confirms (13) and (14) in the form

$$\theta_1+\theta=\theta_W. \tag{27}$$

Using the formulas for θ_W, A', and Ω from Sec. II, we find after some manipulation that

$$\tan(A'+\theta_W/2)=(\text{RHS of (25d)})/(\text{RHS of (25c)}) \tag{28}$$

$$=\tan((\theta_1-\theta)/2), \tag{29}$$

when considering also the left-hand sides of (25c) and (25d). Here RHS is an abbreviation for right-hand side. By (28) and (29),

$$\theta_1-\theta=2A'+\theta_W, \tag{30}$$

whence by (27) and (30),

$$\theta=-A',\quad \theta_1=A'+\theta_W=\Omega.$$

Hence (24) can be written

$$L(\hat{\mathbf{u}},\phi_1)=R(\hat{\mathbf{n}},\Omega)L(\hat{\mathbf{p}},\phi_2)L(\hat{\mathbf{p}},\phi)R(\hat{\mathbf{n}},-A')L^{-1}(\hat{\mathbf{p}},\phi), \tag{31}$$

which has the required form (18). Here we have used the notation of Sec. II and (23).

Equation (31) illustrates two points. First, the factorization (18) was achieved by using the freedom of choice of θ_j allowed by (14) to replace $\hat{\mathbf{w}}''$ in (12) by $\hat{\mathbf{p}}$. Second, the operator Λ_p contains an arbitrary parameter θ which is determined in (31) as A', an angle of an associated hyperbolic triangle. By (9) A' is linked to the Wigner angle and the angle between the relevant initial and final momentum.

The momentum diagram for (31) can be obtained from Fig. 1 by putting $\theta_2=-A'$ and $\theta_1=\Omega$ thereby satisfying (9) and (14).

The above theory enables us to replace the factorization (18) by

$$L(\hat{\mathbf{u}},\phi_1)=\Lambda_{p'}\Lambda_h,$$

where the order of the two operators on the right has been changed and the first conserves the final momentum p' of Sec. II. Using (1), (9), (16), and (23) we find in terms of the above parameters

$$L(\hat{\mathbf{u}},\phi_1)=L(\hat{\mathbf{p}}',\phi_3)R(\hat{\mathbf{n}},-A')L^{-1}(\hat{\mathbf{p}}',\phi_3)L(\hat{\mathbf{p}}',\phi_2)R(\hat{\mathbf{n}},\Omega).$$

Note that one of the factors on the right of (18) conserves momentum and the other helicity but the product does not conserve both.

IV. THE EFFECT OF A BOOST ON SPIN AND THE POINT DIAGRAM

In an effort to obtain a maximum of information we limited ourselves thus far to the multiplication of operators and tried to avoid their application to vectors. For instance, if we apply the two sides of (1) to the momentum vector of a stationary particle we only obtain (2) and (5). Since $R(\hat{\mathbf{n}},\theta)$ leaves the above-mentioned vector invariant, (3), (4) and the equation preceding (2) and therefore the Wigner angle and the rotation axis, do not appear in the calculations. When dealing with spin we have to use the spin vector.

The first topic of this section is the effect of a boost on the spin vector of a spin 1 particle. This vector is discussed in greater detail in Sec. IX. For the present we assume it to have the form

$$t=(\hat{\mathbf{t}}\cosh\phi_9,\ \ i\sinh\phi_9)$$

which is a spacelike vector with direction $\hat{\mathbf{t}}$. The parameter ϕ_9 is linked to the momentum of the particle by (32). The spin and momentum four-vectors must be orthogonal and if (17) is the momentum vector of the particle then

$$pt=\hat{\mathbf{p}}.\hat{\mathbf{t}}\cosh\phi_9\sinh\phi-\sinh\phi_9\cosh\phi=0. \tag{32}$$

When applying a boost to a four-vector we use the formula[7]

$$L(\hat{\mathbf{p}},\phi)=I+U^D\sinh\phi+(\cosh\phi-1)(U^D)^2,$$

where U^D is obtained from U of (49) by putting $\mathbf{a}=0$ and $\mathbf{b}=-i\hat{\mathbf{p}}$. This is a special case of a more general operator to be introduced in (69).

The left-hand side of (1) applied to the spin vector of a particle at rest and with spin along $\hat{\mathbf{p}}$ yields

$$L(\hat{\mathbf{u}},\phi_1)(\hat{\mathbf{p}}\cosh\phi,i\sinh\phi)=(\hat{\mathbf{t}}'\cosh\phi_5,i\sinh\phi_5),$$

where

$$\hat{\mathbf{t}}'\cosh\phi_5=\hat{\mathbf{p}}\cosh\phi+\hat{\mathbf{u}}[\sinh\phi_1\sinh\phi+(\cosh\phi_1-1)\cosh\phi(\hat{\mathbf{u}}.\hat{\mathbf{p}})],$$

$$\sinh\phi_5=\cosh\phi_1\sinh\phi+\sinh\phi_1\cosh\phi(\hat{\mathbf{u}}.\hat{\mathbf{p}}). \tag{33}$$

For the angle Ω' between $\hat{\mathbf{p}}$ and $\hat{\mathbf{t}}'$, the directions of the initial and final spin, we have by (33),

$$\sin\Omega'=|\hat{\mathbf{u}}_\wedge\hat{\mathbf{p}}|[\sinh\phi_1\sinh\phi+(\cosh\phi_1-1)\cosh\phi(\hat{\mathbf{u}}.\hat{\mathbf{p}})]/\cosh\phi_5. \tag{34}$$

By (9), Ω is the angle between the initial and final momentum in (1). Then the angle $\Omega-\Omega'$ between the final momentum $\hat{\mathbf{p}}'$ and the final spin $\mathbf{t}'$ is given by

$$\sin(\Omega-\Omega')=|\hat{\mathbf{p}}'_\wedge\hat{\mathbf{t}}'|=\sin A'/\cosh\phi_5, \tag{35}$$

where we have used (8), (10), (33), and (34). It is evident that $\Omega'<\Omega$ and that $\Omega-\Omega'<A'$.

The second topic discussed in this section is the abundance of angles generated by the equations we have studied in Secs. II and III. Almost every operator in these equations produces an angle. We distinguish between two types of angle. Angles like θ_1 and θ_2 result from the rotation

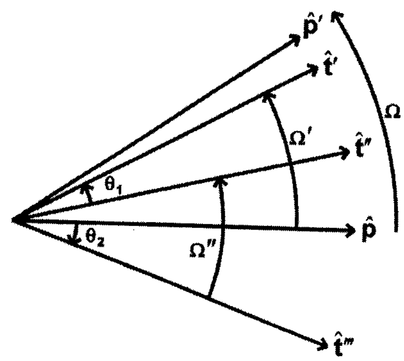

FIG. 2. This point diagram represents the effect of the right-hand side of (12) on the spin of a spin 1 particle at rest with spin along $\hat{\mathbf{p}}$. As in Fig. 1 we choose $\theta_2<0$ whence $R(\hat{\mathbf{n}},\theta_2)$ rotates the spin to the position $\hat{\mathbf{t}}'''$ ''below'' $\hat{\mathbf{p}}$. $L(\hat{\mathbf{w}}'',\phi_3)$ rotate it through Ω'' and then $R(\hat{\mathbf{n}},\theta_1)$ rotates the spin to its final position $\hat{\mathbf{t}}'$. The angles produced by rotations and boosts are indicated by small and large arcs, respectively.

factors while angles like A' and B' are caused by the boost factors. Note that the first type of angle appears in the equation while the second type does not. These ''hidden'' angles play an important part in the discussion of helicity.

We try to provide a representation of the angles which is more convenient than the momentum diagram. We introduce the point diagram in which unit vectors radiating from a common origin indicate the spin and momentum directions at each stage. To construct a point diagram like Fig. 2 we need merely consult equations, like (33).

The point diagram of the right-hand side of (12) operating on the momentum of a particle at rest can be obtained from Fig. 2. Since θ_2 does not appear, the diagram will consist merely of $\hat{\mathbf{p}}$, $\hat{\mathbf{w}}''$, and $\hat{\mathbf{p}}'$ the last two making angles $\Omega-\theta_1$ and θ, respectively, with $\hat{\mathbf{p}}$.

V. ANOTHER APPROACH TO CONSERVATION OF MOMENTUM

In Sec. III we mentioned the conservation of momentum rather superficially. We now discuss this topic in a more comprehensive way.

Since any Lorentz operator can be expressed as the product of a boost and a rotation, we look for a momentum conserving operator having the form

$$\Lambda_p = R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4) \tag{36}$$

and satisfying (19). Here θ_2 and ϕ_4 are real parameters to be determined later. We have

$$L(\hat{\mathbf{q}},\phi_4)p = p' = (\hat{\mathbf{p}}' \sinh\phi_6, i\cosh\phi_6),$$

where the last vector denotes an as yet unknown vector which is timelike for real ϕ_6. Since R changes the direction of the momentum vector only we must have $\phi_6=\phi$ whence by (2),

$$\hat{\mathbf{p}}' \sinh\phi = \hat{\mathbf{p}}\sinh\phi + \hat{\mathbf{q}}[\sinh\phi_4\cosh\phi + (\cosh\phi_4 - 1)\sinh\phi\,\hat{\mathbf{p}}.\hat{\mathbf{q}}], \tag{37}$$

and by (5) the unknown parameter ϕ_4 is given by

$$\sinh(\phi_4/2)/\cosh(\phi_4/2) = -(\sinh\phi/\cosh\phi)(\hat{\mathbf{p}}.\hat{\mathbf{q}}). \tag{38}$$

By (37) and (38),

$$\hat{\mathbf{p}}' = \hat{\mathbf{p}} - 2(\hat{\mathbf{p}}.\hat{\mathbf{q}})\hat{\mathbf{q}} \tag{39}$$

and the angle Ω between the initial and final momentum is given by

$$\cos\Omega = \hat{\mathbf{p}}'.\hat{\mathbf{p}} = 1 - 2(\hat{\mathbf{p}}.\hat{\mathbf{q}})^2 \quad \text{or} \quad \hat{\mathbf{p}}.\hat{\mathbf{q}} = -\sin(\Omega/2). \tag{40}$$

The invariance of p under (36) demands that R must rotate $\hat{\mathbf{p}}'$ back to $\hat{\mathbf{p}}$ through the angle

$$\theta_2 = \Omega. \tag{41}$$

This will be the case if $\hat{\mathbf{n}}$ is defined by

$$\cos(\theta_2/2)\hat{\mathbf{n}} = -\hat{\mathbf{p}}_\wedge\hat{\mathbf{q}}. \tag{42}$$

By (38), (40), and (41),

$$\cos(\theta_2/2)\cosh(\phi_4/2) < 1. \tag{43}$$

Now (36), with its parameters specified by (38), (42), and (43), is our momentum conserving operator. By (40) and (42) the vector left invariant by (36) has the form (17) with

$$\hat{\mathbf{p}} = -\sin(\theta_2/2)\hat{\mathbf{q}} + \cos(\theta_2/2)\hat{\mathbf{n}}_\wedge\hat{\mathbf{q}}. \tag{44}$$

Note that for given $\hat{\mathbf{p}}$ we can choose any $\hat{\mathbf{q}}$ which makes an obtuse angle with $\hat{\mathbf{p}}$.

Since (20) and (36) have the same meaning we must have

$$L(\hat{\mathbf{p}},\phi)R(\hat{\mathbf{n}},\theta)L^{-1}(\hat{\mathbf{p}},\phi) = R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4). \tag{45}$$

The axis of rotation need not be the same on the two sides of (45). However we limit ourselves to the special case where (42) holds. We find

$$\cos(\theta/2) = \cos(\theta_2/2)\cosh(\phi_4/2),$$

$$-\sin(\theta/2)\cosh\phi\,\hat{\mathbf{n}} = \sin(\theta_2/2)\cosh(\phi_4/2)\hat{\mathbf{n}}, \tag{46}$$

$$-\sin(\theta/2)\sinh\phi\,\hat{\mathbf{p}}_\wedge\hat{\mathbf{n}} = \sinh(\phi_4/2)(\cos(\theta_2/2)\hat{\mathbf{q}} + \sin(\theta_2/2)\hat{\mathbf{n}}_\wedge\hat{\mathbf{q}}), \tag{47}$$

and then (38), (40), (42), and (44) follow. The only new relations involve θ and are given by

$$\cosh^2(\phi_4/2) = \cos^2(\theta/2) + \sin^2(\theta/2)\cosh^2\phi,$$

$$\tan(\theta_2/2) = \cosh\phi\tan(\theta/2).$$

All the parameters on the left (right) of (45) are determined by those on the right (left).

Equation (45) has close links with the topics already discussed. Written in the form

$$L(\hat{\mathbf{q}},\phi_4)L(\hat{\mathbf{p}},\phi) = R(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{p}},\phi)R^{-1}(\hat{\mathbf{n}},\theta),$$

it is a special case of (12).

We conclude this approach to momentum conservation by mentioning that each of the two sides of (45) equals the operator[7]

$$\Lambda(\mathbf{a},\mathbf{b},\theta,0) = \cos(\theta/2) + i\sin(\theta/2)\sigma.(\mathbf{a} + i\mathbf{b})$$

in spinor form or in vector form

$$\Lambda(\mathbf{a},\mathbf{b},\theta,0) = \exp(iU\theta) = I + iU\sin\theta + (\cos\theta - 1)U^2. \tag{48}$$

Here

$$U=\begin{pmatrix} 0 & -ia_3 & ia_2 & b_1 \\ ia_3 & 0 & -ia_1 & b_2 \\ -ia_2 & ia_1 & 0 & b_3 \\ -b_1 & -b_2 & -b_3 & 0 \end{pmatrix}, \tag{49}$$

where

$$\mathbf{a}.\mathbf{a}-\mathbf{b}.\mathbf{b}=1, \quad \mathbf{a}.\mathbf{b}=0, \tag{50}$$

and then

$$U^3=U.$$

U has the eigenvalues 0, 0, ± 1 and the eigenvectors belonging to the zero eigenvalues are A and D, where

$$A=(\hat{\mathbf{a}},0) \quad D=(\hat{\mathbf{a}}_\wedge \mathbf{b}, ia). \tag{51}$$

The operator $\Lambda(\mathbf{a},\mathbf{b},\theta,0)$ leaves the vector

$$A \sinh\Phi + D\cosh\Phi$$

invariant. For real Φ this is a timelike vector which can be interpreted as a momentum and therefore the operator qualifies as a momentum conserving operator.

The parameters $\mathbf{a}\sin(\theta/2)$ and $\mathbf{b}\sin(\theta/2)$ of (48) for (45) are provided by (46) and (47), respectively.

We can use (36) as the momentum conserving operator to solve the problem of Sec. III. Then it takes the form

$$L(\hat{\mathbf{u}},\phi_1)=R(\hat{\mathbf{n}},\theta_1)L(\hat{\mathbf{p}},\phi_2)R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4). \tag{52}$$

Relations similar to (2), (5), and (10) can be derived by applying both sides of (52) to p yielding ϕ_2 and θ_1. If we apply both sides to $(-\hat{\mathbf{q}}\sinh\phi_4, i\cosh\phi_4)$ and use the properties of the hyperbolic triangle we obtain ϕ_4 and θ_2.

VI. THE CASE OF ZERO MASS

The Lorentz operator on the left of (45) which conserves the momentum of a massive particle, presupposes a transformation to the rest frame. Such a frame does not exist for a massless particle which means that we need a new momentum conservation operator for such a particle.

In our search for the desired operator we could apply the limiting process $\phi\rightarrow\infty$ to the relevant formulas of Sec. V and such a procedure could be rewarding.

However, we proceed to a more satisfactory derivation by concentrating on the operator on the right of (45) which now must leave a null vector invariant. Following the procedure of Sec. V we must have

$$L(\hat{\mathbf{q}},\phi_4)(\hat{\mathbf{p}},i)=(\hat{\mathbf{p}}',i), \tag{53}$$

where we have used the fact that $R^{-1}(\hat{\mathbf{n}},\theta_2)$ must rotate the vector on the right of (53) to the one on the left. From (53) follows that

$$\cosh\phi_4+(\hat{\mathbf{p}}.\hat{\mathbf{q}})\sinh\phi_4=1 \quad \text{or} \quad \hat{\mathbf{p}}.\hat{\mathbf{q}}=-\sinh(\phi_4/2)/\cosh(\phi_4/2) \tag{54}$$

and (39). After some calculation we find that (43) is replaced by

$$\sin(\theta_2/2)=\sinh(\phi_4/2)/\cosh(\phi_4/2) \quad \text{or} \quad \cos(\theta_2/2)\cosh(\phi_4/2)=1. \tag{55}$$

Hence the operator (36), with $\hat{\mathbf{n}}.\hat{\mathbf{q}}=0$, leaves the null vector on the left of (53) invariant provided that (55) holds.

In Sec. V we have given a meaning to the operator on the right of (36) in the case $\cos(\theta_2/2)\cosh(\phi_4/2)<1$ and in Sec. VII we shall do so for the case $\cos(\theta_2/2)\cosh(\phi_4/2)>1$.

We study another form of the operator leaving a null vector invariant.[7] Instead of (50) we now choose

$$\mathbf{a}.\mathbf{a}-\mathbf{b}.\mathbf{b}=0, \quad \mathbf{a}.\mathbf{b}=0, \tag{56}$$

whence

$$U^3=0$$

and then we have the singular operator, resembling (48),

$$\exp(iU)=I+iU-\tfrac{1}{2}U^2 \tag{57}$$

for the spin 1 case. In the case of the spinor the operator is

$$\exp[(i/2)\sigma.(\mathbf{a}+\mathbf{ib})]=I+(i/2)\sigma.(\mathbf{a}+\mathbf{ib}).$$

Hence we must have

$$R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4)=I+\tfrac{1}{2}i\sigma.(\mathbf{a}+\mathbf{ib}), \tag{58}$$

whence

$$\cos(\theta_2/2)\cosh(\phi_4/2)=1,$$

$$\mathbf{a}=-2\sin(\theta_2/2)\cosh(\phi_4/2)\hat{\mathbf{n}},$$

$$\mathbf{b}=-2\sinh(\phi_4/2)(\sin(\theta_2/2)\hat{\mathbf{n}}_\wedge\hat{\mathbf{q}}+\cos(\theta_2/2)\hat{\mathbf{q}}). \tag{59}$$

The operator (57) contains four independent parameters and leaves the null vector

$$p=(\hat{\mathbf{a}}_\wedge\hat{\mathbf{b}},i)=[(-\sin(\theta_2/2)\hat{\mathbf{q}}+\cos(\theta_2/2)\hat{\mathbf{n}}_\wedge\hat{\mathbf{q}}),i] \tag{60}$$

invariant. When (60) is multiplied by a suitable factor p_0, the resulting vector can be interpreted as the momentum vector of the massless particle.

Hence the operator (36) conserves momentum for a massive particle if (43) holds and for a zero mass particle if (55) holds.

Having found a general form for the operator Λ_p that leaves the momentum of a zero mass particle invariant we now consider

$$L(\hat{\mathbf{u}},\phi_1)=R(\hat{\mathbf{n}},\theta_1)L(\hat{\mathbf{p}},\phi_2)R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4), \tag{61}$$

where the last two factors on the right conserve the momentum of a massless particle having momentum p and the first two factors must be determined such that (61) holds for given $L(\hat{\mathbf{u}},\phi_1)$. Here p, $\hat{\mathbf{u}}$, and ϕ_1 are given while ϕ_2, ϕ_4, and θ_1 must be found.

We solve our problem by replacing the last two factors on the right of (61) by the operator on the right of (58). Here $\mathbf{a}$, $\mathbf{b}$, and $\hat{\mathbf{p}}$ are given by (59) and (60). We now have

$$L(\hat{\mathbf{u}},\phi_1)=P_0+\sigma.(\mathbf{P}+\mathbf{iQ}),$$

where

$$P_0=\cosh(\phi_1/2)=\cos(\theta_1/2)\cosh(\phi_2/2)+\sin(\theta_1/2)\sinh(\phi_4/2)(\cosh(\phi_2/2)+\sinh(\phi_2/2)), \tag{62}$$

$$\begin{aligned}\mathbf{P}&=\sinh(\phi_1/2)\hat{\mathbf{u}}\\&=\hat{\mathbf{p}}[\cos(\theta_1/2)\sinh(\phi_2/2)-\sin(\theta_1/2)(\cosh(\phi_2/2)+\sinh(\phi_2/2))\sinh(\phi_4/2)]\\&\quad+\hat{\mathbf{n}}_\wedge\hat{\mathbf{p}}[-\cos(\theta_1/2)\sinh(\phi_4/2)(\cosh(\phi_2/2)+\sinh(\phi_2/2))-\sin(\theta_1/2)\sinh(\phi_2/2)],\end{aligned} \tag{63}$$

$$\mathbf{Q}=\hat{\mathbf{n}}[\sin(\theta_1/2)\cosh(\phi_2/2)-\cos(\theta_1/2)\sinh(\phi_4/2)(\cosh(\phi_2/2)+\sinh(\phi_2/2))]=0. \tag{64}$$

Equation (64) follows because $\hat{\mathbf{u}}S_1$ the coefficient of σ in $L(\hat{\mathbf{u}},\phi_1)$ is real. We use (62), (63), and (64) supplemented by (26) to solve for θ_1, ϕ_2, and ϕ_4. We find

$$\tan(\tfrac{1}{2}\theta_1)=\sinh(\phi_1/2)|\hat{\mathbf{u}}_\wedge\hat{\mathbf{p}}|/[\cosh(\phi_1/2)+\sinh(\phi_1/2)\hat{\mathbf{u}}.\hat{\mathbf{p}}], \tag{65}$$

$$\exp(\phi_2)=\cosh\phi_1+\sinh\phi_1\hat{\mathbf{u}}.\hat{\mathbf{p}},$$

$$\sinh(\phi_4/2)=\sinh(\phi_1/2)\cosh(\phi_1/2)|\hat{\mathbf{u}}_\wedge\hat{\mathbf{p}}|/[\cosh\phi_1+\sinh\phi_1\hat{\mathbf{u}}.\hat{\mathbf{p}}]=\tan(\tfrac{1}{2}\theta_2), \tag{66}$$

where we have used (55).

Here we have solved for θ_1, θ_2, ϕ_2, and ϕ_4 in terms of p, $\hat{\mathbf{u}}$, and ϕ_1. In doing so we have regarded the product of the last two factors of (61) as a singular operator conserving the momentum null vector. We can however multiply both sides of (61) from the right by $L^{-1}(\hat{\mathbf{q}},\phi_4)$ yielding an equation of the type of (12) and with a Wigner angle

$$\theta_W=\theta_1-\theta_2$$

given by (65) and (66).

If $\phi\rightarrow\infty$ in (10) and (11) then $\Omega\rightarrow\Omega_\infty$ which is the same as θ_1 in (65) as can be expected.

VII. SPIN CONSERVATION AND THE OPERATOR $\Lambda(\mathbf{a},\mathbf{b},0,\phi)$

As was done for momentum we look for an operator that conserves the spin t of a particle with spin unity. We proceed as in Sec. V and we try to construct an operator

$$\Lambda=R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4)$$

resembling (36), that leaves invariant the given spacelike vector

$$t=(\hat{\mathbf{t}}\cosh\phi,i\sinh\phi).$$

The arguments used and the results obtained are almost identical to those of Sec. V. However, (38) is replaced by

$$\sinh(\phi_4/2)/\cosh(\phi_4/2)=-(\hat{\mathbf{q}}.\hat{\mathbf{t}})\cosh\phi/\sinh\phi$$

which implies that now

$$\sinh(\phi_4/2)/\cosh(\phi_4/2)>\sin(\theta_2/2)\quad\text{or}\quad\cos(\theta_2/2)\cosh(\phi_4/2)>1. \tag{67}$$

An operator having these properties has been discussed before.[7] It has the form

$$\Lambda(\mathbf{a},\mathbf{b},0,\phi)=\exp(U^D\phi)=I+U^D\sinh\phi+(\cosh\phi-1)(U^D)^2, \tag{68}$$

where, in terms of (49)

$$(U^D)_{12}=U_{34}, \quad (U^D)_{23}=U_{14}, \tag{69}$$

the other elements following by cyclic permutation of 1, 2, and 3.

The operator

$$\Lambda=L(\hat{\mathbf{p}},\phi)L(\hat{\mathbf{w}},\phi_5)L^{-1}(\hat{\mathbf{p}},\phi) \tag{70}$$

can also be expressed in the form (68) and the vectors left invariant by (70) can be found by means of the general procedure developed elsewhere.[7] However we can find, in a direct way, two linearly independent vectors by writing $\Lambda t=t$ in the form

$$L(\hat{\mathbf{w}},\phi_5)T=T, \quad T=L^{-1}(\hat{\mathbf{p}},\phi)t.$$

Now $T=(\mathbf{W},0)$ provided that $\hat{\mathbf{w}}.\mathbf{W}=0$. Then the spacelike vectors left invariant by (70) are given by

$$t=L(\hat{\mathbf{p}},\phi)T=[\mathbf{W}+(\cosh\phi-1)(\hat{\mathbf{p}}.\mathbf{W})\hat{\mathbf{p}},i(\mathbf{W}.\hat{\mathbf{p}})\sinh\phi]. \tag{71}$$

An obvious choice for $\mathbf{W}$ is $\hat{\mathbf{p}}_\wedge\hat{\mathbf{w}}$ yielding

$$t=t_1=(\hat{\mathbf{p}}_\wedge\hat{\mathbf{w}},0).$$

For the second vector we can choose $\mathbf{W}=\hat{\mathbf{p}}-(\hat{\mathbf{p}}.\hat{\mathbf{w}})\hat{\mathbf{w}}$ in (71).

In the special case where $\hat{\mathbf{w}}.\hat{\mathbf{p}}=0$ we can choose $\mathbf{W}=\hat{\mathbf{p}}$ whence

$$t=(\hat{\mathbf{p}}\cosh\phi,i\sinh\phi). \tag{72}$$

Hence if this special case applies and initially a particle has momentum (17) and spin (72) then (70) leaves the spin invariant while the momentum is transformed to $p'=(\hat{\mathbf{p}}\sinh\phi_3,i\cosh\phi_3)$.

According to (2),

$$\hat{\mathbf{p}}'\sinh\phi_3=\hat{\mathbf{w}}\sinh\phi_5+\hat{\mathbf{p}}\sinh\phi\cosh\phi_5, \quad \cosh\phi_3=\cosh\phi\cosh\phi_5,$$

and the angle Ω''' between final spin and momentum is given by

$$\sin\Omega'''=|\hat{\mathbf{p}}'_\wedge\hat{\mathbf{p}}|=\sinh\phi_5/\sinh\phi_3, \tag{73}$$

where we have used $\hat{\mathbf{w}}.\hat{\mathbf{p}}=0$.

To summarize, the operator we look for takes the general form $\Lambda(\mathbf{a},\mathbf{b},0,\phi)$ which can be expressed as (36) with (67) as well as (68) and (70).

The two operators $\Lambda(\mathbf{a},\mathbf{b},\theta,0)$ in (48) and $\Lambda(\mathbf{a},\mathbf{b},0,\phi)$ in (68), although different, have a number of corresponding properties examples of which are (43) and (67) as well as (20) and (70). Both contain five independent parameters.

VIII. A SPIN ANGULAR MOMENTUM OPERATOR

In the discussion thus far the momentum conserving operator (20) played an important part and its main properties were discussed in Secs. III and V. However this operator may also be regarded as the Lorentz transformation of the rotation operator $R(\hat{\mathbf{n}},\theta)$ when the latter is regarded as a second rank tensor.

We consider the generator for an elementary spatial rotation about the unit vector $\hat{\mathbf{m}}$ which is an antisymmetric 3×3 matrix. We generalize it to space–time to yield the 4×4 matrix,

$$J_0=\begin{pmatrix} 0 & -i\hat{m}_3 & i\hat{m}_2 & 0 \\ i\hat{m}_3 & 0 & -i\hat{m}_1 & 0 \\ -i\hat{m}_2 & i\hat{m}_1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{74}$$

We interpret this as the spin angular momentum tensor for a spin 1 particle at rest. To obtain the tensor for such a particle with momentum p in a direction other than $\hat{\mathbf{m}}$ we transform from the rest frame to find

$$J=L(\hat{\mathbf{p}},\phi)J_0L^{-1}(\hat{\mathbf{p}},\phi)=U, \tag{75}$$

where U is given by (49). We can find $\mathbf{a}$ and $\mathbf{b}$ without matrix multiplication in the usual sense by using the Pauli σ-matrix procedure. We have

$$L(\hat{\mathbf{p}},\phi)(\sigma.\hat{\mathbf{m}})L^{-1}(\hat{\mathbf{p}},\phi)=\sigma.(\mathbf{a}+\mathbf{ib}),$$

where

$$\mathbf{a}=\hat{\mathbf{m}}\cosh\phi-(\cosh\phi-1)(\hat{\mathbf{m}}.\hat{\mathbf{p}})\hat{\mathbf{p}},\quad \mathbf{b}=\hat{\mathbf{p}}_\wedge\hat{\mathbf{m}}\sinh\phi, \tag{76}$$

which are of course the parameters required in (75). They satisfy (50) leaving only four independent parameters.

To confirm that we are indeed dealing with the Lorentz transformation of a six-vector we allow $\mathbf{m}$ to be complex and not necessarily a unit vector and we replace $\mathbf{a}+\mathbf{ib}$ by $\mathbf{P}$, where

$$\mathbf{P}=\mathbf{m}\cosh\phi-(\cosh\phi-1)(\mathbf{m}.\hat{\mathbf{p}})\hat{\mathbf{p}}+i\hat{\mathbf{p}}_\wedge\mathbf{m}\sinh\phi. \tag{77}$$

Now we replace $\mathbf{P}$ by $\mathbf{E}'+\mathbf{iB}'$, $\mathbf{m}$ by $\mathbf{E}+\mathbf{iB}$. Then (77) represents the well-known Lorentz transformation linking the initial components $\mathbf{E}$ and $\mathbf{B}$ of the six-vector to the final ones $\mathbf{E}'$ and $\mathbf{B}'$.

IX. THE SPIN VECTOR

In the discussion of Sec. IV we found it convenient to introduce the spin vector of a particle in an intuitive way. Now we are able to develop this vector from the spin angular momentum operator and it is closely associated with the momentum of the particle.

By (76),

$$p_0\mathbf{b}=\mathbf{p}_\wedge\mathbf{a},$$

which implies that

$$Jp=0. \tag{78}$$

J has another eigenvector belonging to the eigenvalue zero which can be chosen orthogonal to p. The form

$$t_j=(1/2)\epsilon_{jkrs}J_{kr}p_s,\quad j,k=1,2,3,4 \tag{79}$$

for this vector clearly exhibits its transformation properties. The coefficient of p_s on the right of (79) is of course U^D defined by (69) which means that a more convenient way of introducing t is provided by

$$t=U^Dp,\quad Ut=0$$

from which follows that

$$p=U^D t, \quad tt=1,$$

where we have used $U^2+(U^D)^2=I$. We find

$$t=(\mathbf{a}p_0+\mathbf{p}_\wedge\mathbf{b},i(\mathbf{a}.\mathbf{p}))=(\hat{\mathbf{t}}\cosh\phi_9,i\sinh\phi_9). \tag{80}$$

By (76) and (80) the form for t when the particle is at rest suggests that t is its spin vector. We also have

$$\hat{\mathbf{t}}\cosh\phi_9=\hat{\mathbf{m}}+(\cosh\phi-1)(\hat{\mathbf{m}}.\hat{\mathbf{p}})\hat{\mathbf{p}},$$
$$\sinh\phi_9=(\hat{\mathbf{m}}.\hat{\mathbf{p}})\sinh\phi. \tag{81}$$

This means that

$$L(\hat{\mathbf{p}},\phi)(\hat{\mathbf{m}},0)=t. \tag{82}$$

Since the four-vector on the left is the spin vector of the particle at rest, we can interpret t as its spin when the momentum is p. Hence, the momentum and spin of a particle with spin 1 are eigenvectors of its spin angular momentum operator with eigenvalues zero.

Furthermore, for arbitrary Φ the linear combinations

$$p=D\cosh\Phi+A\sinh\Phi, \quad t=D\sinh\Phi+A\cosh\Phi,$$

with A and D given by (51) are also eigenvectors of U belonging to the eigenvalue zero. This means that U or **a** and **b** do not define p and t uniquely. Hence two particles with different but compatible spin and momentum may have the same spin angular momentum operator. For example, J_0 of (74) can be the spin angular momentum operator of a particle at rest or of a particle with spin and momentum direction $\hat{\mathbf{m}}$.

Since the fourth component of A vanishes we have

$$a^2=p_0^2-t_0^2. \tag{83}$$

If in addition to **a** and **b** we also know p_0 then we have the unique expressions

$$p=(p_0/a)D+(t_0/a)A, \quad t=(p_0/a)A+(t_0/a)D, \tag{84}$$

satisfying (32). By (84),

$$\mathbf{a}=p_0\mathbf{t}-t_0\mathbf{p}, \quad \mathbf{b}=\mathbf{p}_\wedge\mathbf{t}. \tag{85}$$

If $\hat{\mathbf{m}}.\hat{\mathbf{p}}\neq 0$ then by (81) momentum and spin have the same direction for very large momentum. In the special case where $\hat{\mathbf{p}}.\hat{\mathbf{m}}=1$ we have $\mathbf{b}=0$ and $t_0=\sinh\phi$, where $p_0=\cosh\phi$. Note that here $\hat{\mathbf{p}}=\hat{\mathbf{a}}$ while p and t have the forms (17) and (72), respectively. We have often used this form for t.

If $\hat{\mathbf{m}}.\hat{\mathbf{p}}=0$ it follows from (81) and (84) that

$$t=A, \quad p=D. \tag{86}$$

Hence in this case spin and momentum are not parallel for large momentum.

In the first few sections we discussed the effect of various operators on momentum and spin by direct application of these operators to the relevant vectors. In this way we could find for example, the angle between final spin and momentum in terms of the initial angle between them as in (35). Another way of studying momentum and spin is to find the effect of these operators on the spin angular momentum tensor.

In this regard we consider the general transformation

$$(M_0+\boldsymbol{\sigma}.\mathbf{M})\sigma.\hat{\mathbf{p}}(M_0-\sigma.\mathbf{M})=\sigma.\mathbf{P}, \tag{87}$$

where

$$M_0^2-\mathbf{M}.\mathbf{M}=1.$$

We find

$$\mathbf{P}=(M_0^2+\mathbf{M}.\mathbf{M})\hat{\mathbf{p}}-2iM_0\hat{\mathbf{p}}_\wedge\mathbf{M}-2(\hat{\mathbf{p}}.\mathbf{M})\mathbf{M} \tag{88}$$

and with

$$\mathbf{M}=\boldsymbol{\alpha}+\mathbf{i}\boldsymbol{\beta},\quad \mathbf{P}=\mathbf{a}+\mathbf{ib},$$

we find

$$\begin{aligned}\mathbf{a}&=(2M_0^2-1)\hat{\mathbf{p}}+2M_0\hat{\mathbf{p}}_\wedge\boldsymbol{\beta}-2(\hat{\mathbf{p}}.\boldsymbol{\alpha})\boldsymbol{\alpha}+2(\hat{\mathbf{p}}.\boldsymbol{\beta})\boldsymbol{\beta},\\ \mathbf{b}&=-2[M_0\hat{\mathbf{p}}_\wedge\boldsymbol{\alpha}+(\hat{\mathbf{p}}.\boldsymbol{\alpha})\boldsymbol{\beta}+(\hat{\mathbf{p}}.\boldsymbol{\beta})\boldsymbol{\alpha}].\end{aligned} \tag{89}$$

With this **b** we can use (85) in the form

$$|\hat{\mathbf{p}}_\wedge\hat{\mathbf{t}}|=b/[|\mathbf{p}||t|]=b/[\{p_0^2-1\}^{1/2}\{p_0^2-b^2\}^{1/2}]. \tag{90}$$

Here we have expressed the sine of the angle between spin and momentum in terms of the parameters **a**, **b**, and p_0 which determine p and t uniquely.

We use (90) to determine the angle between final spin and momentum in a few cases where an operator acts on the spin angular momentum operator of a particle with initial spin along its momentum.

First, we consider the effect of the momentum conserving operator with $\hat{\mathbf{n}}.\hat{\mathbf{p}}=0$ on spin. In the notation of (87) we have

$$L(\hat{\mathbf{p}},\phi)R(\hat{\mathbf{n}},\theta)L^{-1}(\hat{\mathbf{p}},\phi)=M_0+\sigma.\mathbf{M},$$

where

$$M_0=\cos(\theta/2),\quad \mathbf{M}=\sin(\theta/2)(-\hat{\mathbf{p}}_\wedge\hat{\mathbf{n}}\sinh\phi+i\hat{\mathbf{n}}\cosh\phi).$$

By (89)

$$\mathbf{b}=-\hat{\mathbf{n}}\sin\theta\sinh\phi,$$

whence by (90) the angle θ' between final momentum and spin is given by

$$\sin\theta'=\sin\theta/[1+\sinh^2\phi\cos^2\theta]^{1/2}.$$

Second, Eq. (35) applies when the above particle is boosted by $L(\hat{\mathbf{u}},\phi_1)$. By using (89) and (90) we can confirm (35).

Third, we consider the spin conserving operator of Sec. VII and try to confirm (73). We have

$$L(\hat{\mathbf{p}},\phi)L(\hat{\mathbf{w}},\phi_5)L^{-1}(\hat{\mathbf{p}},\phi)=\cosh(\phi_5/2)+\sinh(\phi_5/2)\sigma.(\hat{\mathbf{w}}\cosh\phi+i\sinh\phi\hat{\mathbf{p}}_\wedge\hat{\mathbf{w}}),$$

whence

$$M_0=\cosh(\phi_5/2),\quad \mathbf{M}=\sinh(\phi_5/2)(\hat{\mathbf{w}}\cosh\phi+i\hat{\mathbf{p}}_\wedge\hat{\mathbf{w}}\sinh\phi)$$

and if $\hat{\mathbf{p}}.\hat{\mathbf{w}}=0$, then

$$\mathbf{b} = -\sinh\phi_5 \cosh\phi \hat{\mathbf{p}}_\wedge \hat{\mathbf{w}},$$

and

$$|\hat{\mathbf{p}}_\wedge \hat{\mathbf{t}}| = \sinh\phi_5 / \sinh\phi_3$$

confirming (73).

X. GAUGE INVARIANCE

Having discussed some of the important properties of the spin angular momentum operator we now turn to its invariance properties and to the properties of the relevant transformation operators. We consider (87) in the form

$$(M_0 + \sigma.\mathbf{M})\sigma.\mathbf{m}(M_0 - \sigma.\mathbf{M}) = \sigma.\mathbf{m}. \tag{91}$$

With appropriate adjustments (88) still holds for (91). Hence for given $\mathbf{m}$ to be invariant, M_0 and $\mathbf{M}$ must satisfy

$$M_0^2 + \mathbf{M}.\mathbf{M} = 1,$$
$$\mathbf{m}.\mathbf{M} = 0, \tag{92}$$
$$\mathbf{m}_\wedge \mathbf{M} = 0.$$

We ignore the trivial case $\mathbf{M} = \mathbf{m}$ and proceed to the third equation of (92). We put

$$\mathbf{m} = \mathbf{a} + \mathbf{i}\mathbf{b}, \quad \mathbf{M} = \boldsymbol{\alpha} + \mathbf{i}\boldsymbol{\beta},$$

where these four three-vectors are real and

$$\mathbf{a}.\mathbf{b} = 0 = \boldsymbol{\alpha}.\boldsymbol{\beta}.$$

Then (92) requires that

$$\mathbf{a}_\wedge \boldsymbol{\alpha} = \mathbf{b}_\wedge \boldsymbol{\beta}, \quad \mathbf{a}_\wedge \boldsymbol{\beta} = -\mathbf{b}_\wedge \boldsymbol{\alpha},$$

which means that these four vectors must be coplanar in such a way that

$$\hat{\mathbf{a}}_\wedge \hat{\mathbf{b}} = \boldsymbol{\alpha}_\wedge \boldsymbol{\beta}. \tag{93}$$

Hence

$$a^2 = b^2, \quad \alpha^2 = \beta^2, \quad \mathbf{m}.\mathbf{m} = 0, \quad \mathbf{M}.\mathbf{M} = 0, \quad M_0 = 1, \tag{94}$$

and the second equation of (92) is also satisfied.

In terms of the operators for spin 1 particles we are therefore dealing with U and U^D for which (56) holds. We denote these singular operators, for which (94) holds, by $U(\mathbf{a},\mathbf{b})$, $U^D(\alpha,\beta)$, etc.

Provided that (93) holds we have

$$[U(\mathbf{a},\mathbf{b}), U(\alpha,\beta)] = 0.$$

Hence (91) becomes

$$\Lambda(\alpha,\beta) U(\mathbf{a},\mathbf{b}) \Lambda^{-1}(\alpha,\beta) = U(\mathbf{a},\mathbf{b}), \tag{95}$$

where

$$\Lambda(\alpha,\beta)=I+iU(\alpha,\beta)-\tfrac{1}{2}U^2(\alpha,\beta), \tag{96}$$

which resembles (57).

Therefore our study of (91) leads to the following conclusions. First, both the spin angular momentum operator and the Lorentz operator under which it is invariant must be singular operators. Second, guided by (56) and (76) we regard $U(\mathbf{a},\mathbf{b})$ as the spin angular momentum operator of a massless spin 1 particle. Third, since the operators for which (50) holds do not lead to invariance, the invariance expressed by (95) does not apply to massive particles.

The operator $U(\mathbf{a},\mathbf{b})$ has four zero eigenvalues and two linearly independent eigenvectors, A as in (51) which is spacelike and

$$D'=(\hat{\mathbf{a}}_\wedge\hat{\mathbf{b}},i)$$

a null vector uniquely representing the momentum of a zero mass particle in the form

$$p=p_0D', \quad pp=0. \tag{97}$$

It is left invariant by (96).

We try to give physical meaning to A. We find

$$U(\alpha,\beta)A=-i(\alpha.\hat{\mathbf{b}})D',$$

$$\Lambda(\alpha,\beta)A=A+(\boldsymbol{\alpha}.\hat{\mathbf{b}})D'.$$

We define

$$t=A+t_0D', \quad t_0=\alpha.\hat{\mathbf{b}}, \quad tt=1, \quad pt=0. \tag{98}$$

In this linear combination of A and D' the factor $\alpha.\hat{\mathbf{b}}$ is arbitrary in the sense that α can be any vector in the plane of $\mathbf{a}$ and $\mathbf{b}$.

Despite this arbitrariness we find that for given p_0, $\mathbf{a}$, and $\mathbf{b}$, subject of course to (56),

$$p_0\hat{\mathbf{a}}=p_0\mathbf{t}-t_0\mathbf{p}, \quad p_0\hat{\mathbf{b}}=\mathbf{p}_\wedge\mathbf{t} \tag{99}$$

which resembles (85). Here the magnitudes of $\mathbf{a}$ and $\mathbf{b}$ appear to be unimportant.

Hence for given p_0 and six-vector $\mathbf{a}$, $\mathbf{b}$ we can find the three-vector $\mathbf{p}$ and the four-vector t for which (99) holds. It is important to note that t is not defined uniquely. This situation is analogous to gauge invariance in electromagnetic theory where a given six-vector $\mathbf{E}$, $\mathbf{B}$ defines the four-potential $\mathbf{A}$, ϕ in a way which is not unique.

Hence $U(\mathbf{a},\mathbf{b})$, the spin angular momentum operator of a massless spin 1 particle, has gauge invariance properties under the operator (96) which can be called the gauge operator.

To arrive at the linear combination (98) we could have used the fact that A and D' are eigenvectors of $U(\mathbf{a},\mathbf{b})$ belonging to a degenerate eigenvalue. However the procedure used above is more useful.

In electromagnetic theory no direct physical significance is attached to the four-potential. In this case the mathematics presented above seems to suggest that t can be interpreted as the spin of the massless particle. The question whether such an interpretation could be supported by the physical evidence remains open.

Since

$$[U(\mathbf{a},\mathbf{b}),U^D(-\beta,\alpha)]=0$$

provided that (93) holds, the operator

$$I+U^D(\alpha,\beta)+\tfrac{1}{2}(U^D)^2,$$

can also be regarded as a gauge operator which leaves $U(\mathbf{a},\mathbf{b})$ invariant.

The papers by Weinberg[8] and Shnerb and Horwitz[9] also deal with massless systems but are mostly concerned with field theoretical aspects.

XI. DISCUSSION

In the above discussion of products of rotations and boosts we distinguish between three different types of product which we denote by $\Lambda(\mathbf{a},\mathbf{b},0,\phi)$, $\Lambda(\mathbf{a},\mathbf{b},\theta,0)$, and $\Lambda(\mathbf{a},\mathbf{b})$. Each of the first two types contain five independent parameters while the last one contains four.

The first type includes operators like

$$L(\hat{\mathbf{u}},\phi_1)L(\hat{\mathbf{p}},\phi), L(\hat{\mathbf{p}},\phi)L(\hat{\mathbf{w}},\phi_5)L^{-1}(\hat{\mathbf{p}},\phi) \quad \text{and} \quad \exp(U^D\phi)$$

which leave two spacelike vectors invariant. In Sec. VII we have associated spin with one of these vectors.

The product on the left of

$$L(\hat{\mathbf{u}},\phi_1)L(\mathbf{v},\phi_2)=\Lambda(\mathbf{a},\mathbf{b},0,\phi)$$

contains six independent parameters with only five on the right. This means that for every set of parameters on the right there exists an infinite number of sets of parameters on the left.[5]

$\Lambda(\mathbf{a},\mathbf{b},\theta,0)$ is a general name for operators like $L(\hat{\mathbf{p}},\phi)R(\hat{\mathbf{n}},\theta)L^{-1}(\hat{\mathbf{p}},\phi)$ and $\exp(iU\theta)$ and these operators leave a timelike vector $D\cosh\Phi + A\sinh\Phi$ invariant. Under suitable circumstances this vector can be interpreted as the momentum vector of a particle.

The product on the left of

$$L(\hat{\mathbf{p}},\phi)R(\hat{\mathbf{n}},\theta)L^{-1}(\hat{\mathbf{p}},\phi)=\Lambda(\mathbf{a},\mathbf{b},\theta,0)$$

contains six independent parameters with only five on the right. Arguments similar to those in Ref. 5 show that for every set of parameters on the right we have an infinite number of sets of parameters on the left. As is well-known the operator on the left belongs to a group.

Operators of the type

$$\Lambda(\mathbf{a},\mathbf{b})=I+(i/2)\sigma.(\mathbf{a}+i\mathbf{b}), \quad \mathbf{a}.\mathbf{a}=\mathbf{b}.\mathbf{b}, \quad \mathbf{a}.\mathbf{b}=0$$

in its spinor form, or

$$\Lambda(\mathbf{a},\mathbf{b})=I+iU(\mathbf{a},\mathbf{b})-\tfrac{1}{2}U^2(\mathbf{a},\mathbf{b})$$

in its vector form, leave the spacelike vector A and the null vector D' invariant. For any λ the spacelike vector $A+\lambda D'$ is of course also left invariant. Provided that the four three-vectors $\mathbf{a}$, $\mathbf{b}$, α, and β are coplanar and (93) is satisfied we have

$$\Lambda(\mathbf{a},\mathbf{b})\Lambda(\alpha,\beta)=\Lambda(\mathbf{a}',\mathbf{b}'),$$

where

$$\mathbf{a}'=\mathbf{a}+\alpha, \quad \mathbf{b}'=\mathbf{b}+\beta.$$

Hence these operators belong to what can be called the gauge group.

We have seen that, depending on the value of $\cos(\theta/2)\cosh(\phi/2)$, the operator $R(\hat{\mathbf{n}},\theta)L(\hat{\mathbf{q}},\phi)$ with $\hat{\mathbf{n}}.\hat{\mathbf{q}}=0$ can take any of the above three forms.

The product of any two boosts always has the form $\Lambda(\mathbf{a},\mathbf{b},0,\phi)$. To classify the product of three Lorentz operators is more complicated. We can write (1) in the form

$$L^{-1}(\hat{\mathbf{p}}',\phi_3)L(\hat{\mathbf{u}},\phi_1)L(\hat{\mathbf{p}},\phi)=R(\hat{\mathbf{n}},\theta)=\Lambda(\mathbf{a},0,\theta,0).$$

Therefore with the same notation and meaning

$$L^{-1}(\hat{\mathbf{p}}',\phi_4)L(\hat{\mathbf{u}},\phi_1)L(\hat{\mathbf{p}},\phi)=L(\hat{\mathbf{p}}',\phi_3-\phi_4)R(\hat{\mathbf{n}},\theta),$$

whence, for given θ, the magnitude of $\phi_3-\phi_4$ determines the classification according to (43), (55), and (67).

If the directions of three or more boosts are independent then we must expect their product to contain more than five independent parameters.

The operator discussed in Sec. VI is also a gauge operator. When expressed in the form

$$\Lambda(\mathbf{a},\mathbf{b})=R^{-1}(\hat{\mathbf{n}},\theta_2)L(\hat{\mathbf{q}},\phi_4),\quad \cos(\theta/2)\cosh(\phi_4/2)=1,\quad \hat{\mathbf{n}}.\hat{\mathbf{q}}=0$$

the gauge operator has structure in the sense that it is expressible as a product of a rotation and a boost. The four independent parameters on the right are determined uniquely in terms of **a** and **b**. According to the statement following (99) the magnitudes of **a** and **b** seem to be unimportant. However by (59),

$$a=b=2\sinh(\phi_4/2).$$

We conclude this paper by stating that special relativity appears to make provision for an interrelation between the spin and the momentum of a particle. This statement is supported by using (85) to express the generator U^D of any $\Lambda(\mathbf{a},\mathbf{b},0,\phi)$ in the form

$$U^D=|p\rangle\langle t|-|t\rangle\langle p|,$$

where p and t are the momentum and spin, respectively, of a fictitious particle having the spin angular momentum operator U associated with U^D.

A similar form can be obtained for a massless particle.

If it is correct to interpret the t of (98) as the spin of a massless particle then, as in (86), the spin and momentum directions of a massless particle need not coincide.

ACKNOWLEDGMENT

It is a pleasure to thank the referee for a number of valuable suggestions.

(Received 28 April 1998; accepted for publication 9 February 1999)

The supersymmetric descent equations in $N=1$ superspace are discussed by means of the introduction of two operators $\zeta^\alpha, \overline{\zeta}^{\dot\alpha}$, which allow to decompose the supersymmetric covariant derivatives $D^\alpha, \overline{D}^{\dot\alpha}$ as BRS commutators. © *1999 American Institute of Physics.* [S0022-2488(99)02006-X]

I. INTRODUCTION

It is well known nowadays that the problem of finding the anomalies and the invariant counterterms that arise in the renormalization of local field theories can be handled in a purely algebraic way by means of the BRS technique (For a recent account on the so-called *Algebraic Renormalization* see Ref. 1). This amounts to looking at the nontrivial solution of the integrated consistency condition,

$$s\int \omega_D^g = 0, \tag{I.1}$$

where s is the BRS operator and g and D denote, respectively, the ghost number and the space–time dimension. Condition (I.1), when translated at the nonintegrated level, yields a system of equations usually called descent equations (see Ref. 1 and references therein),

$$\begin{aligned}
&s\omega_D^g + d\omega_{D-1}^{g+1} = 0,\\
&s\omega_{D-1}^{g+1} + d\omega_{D-2}^{g+2} = 0,\\
&\cdots\\
&\cdots\\
&s\omega_1^{g+D-1} + d\omega_0^{g+D} = 0,\\
&s\omega_0^{g+D} = 0,
\end{aligned} \tag{I.2}$$

where $d = dx^\mu \partial_\mu$ is the exterior space–time derivative and $\omega_i^{g+D-i} (0 \leq i \leq D)$ are local polynomials in the fields of ghost number $(g+D-i)$ and form degree i. The cases $g=0,1$ correspond, respectively, to the invariant counterterms and to the anomalies. The operators s, d obey the algebraic relations

[a)]Electronic mail: LCQVILAR@SYMBCOMP.UERJ.BR

$$s^2=d^2=sd+ds=0. \tag{I.3}$$

The problem of solving the descent equations (I.2) is a problem of cohomology of s modulo d,[2,3] the corresponding cohomology classes being given by solutions of (I.2) that are not of the type

$$\omega_m^{g+D-m}=s\hat{\omega}_m^{g+D-m-1}+d\hat{\omega}_{m-1}^{g+D-m}, \quad 1\leq m\leq D,$$

$$\omega_0^{g+D}=s\hat{\omega}_0^{g+D-1},$$

with $\hat{\omega}$'s local polynomials. Notice also that at the nonintegrated level one loses the property of making integration by parts. This implies that the fields and their derivatives have to be considered as independent variables.

Of course, the knowledge of the most general nontrivial solution of the descent equations (I.2) yields the integrated cohomology classes of the BRS operator. Indeed, once the full system (I.2) has been solved, integration on space–time gives the general solution of the consistency condition (I.1).

Recently, a new method of obtaining nontrivial solutions of the tower (I.2) has been proposed[4] and successfully applied to a large number of field models such as Yang–Mills theories,[4,5] gravity,[6] topological field theories,[7–9] string[10] and superstring[11] theories as well as W_3 algebras.[12] The method relies on the introduction of an operator δ, which allows us to decompose the exterior derivative as a BRS commutator,

$$d=-[s,\delta]. \tag{I.4}$$

It is easily proven, in fact, that repeated applications of the operator δ on the cocycle ω_0^{g+D} that solves the last of the equations (I.2) will provide an explicit nontrivial solution for the higher cocycles ω_i^{g+D-i}.

One has to note that solving the last equation of the tower (I.2) is a problem of local cohomology instead of a modulo-d one. The former can be systematically analyzed by using several methods as, for instance, the spectral sequences technique.[13] It is also worth mentioning that in the case of the Yang–Mills-type gauge theories, the solutions of the descent equations (I.2) obtained via the decomposition (I.4) have been proven to be equivalent to those provided by the so-called *Russian Formula*.[14,15]

Another important geometrical aspect related to the existence of the operator δ is the possibility of encoding all the relevant informations concerning the BRS transformations of the fields and the solutions of the system (I.2) into a unique equation that takes the form of a generalized zero curvature condition,[16] i.e.,

$$\tilde{\mathcal{F}}=\tilde{d}\tilde{\mathcal{A}}-\tilde{\mathcal{A}}^2=0. \tag{I.5}$$

The operator $\tilde{d}$ and the generalized gauge connection $\tilde{\mathcal{A}}$ in Eq. (I.5) turn out to be, respectively, the δ transform of the BRS operator s and of the ghost field c corresponding to the Maurer–Cartan form of the underlying gauge algebra,

$$\tilde{d}=e^{\delta}se^{-\delta}, \quad \tilde{d}^2=0,$$

$$\tilde{\mathcal{A}}=e^{\delta}c.$$

As discussed in detail in Refs. 16, the zero curvature formulation allows us to obtain straightforwardly the cohomology classes of the operator $\tilde{d}$. The latters are deeply related to the solutions of the descent equations (I.2).

The BRS algebraic procedure can be easily adapted to include the case of the renormalizable $N=1$ superspace supersymmetric gauge theories in four space–time dimensions, for which a set of superspace descent equations have been established.[17–19] The solution of these equations as much as in the nonsupersymmetric case yields directly all the manifestly supersymmetric gauge anomalies as well as the manifestly supersymmetric BRS-invariant counterterms. One has to remark, however, that in the supersymmetric case both the derivation and the construction of a solution of the superspace version of the descent equations are more involved than the nonsupersymmetric case, due to the algebra of the spinorial covariant derivatives D_α and $\bar{D}_{\dot\alpha}$ and to the (anti)chirality constraints of some of the superfields characterizing the theory.

In order to have an idea of the differences between the superspace and the ordinary case, let us briefly consider the integrated superspace $N=1$ BRS consistency condition corresponding to the supersymmetric chiral U(1) Yang–Mills axial anomaly,[19]

$$s\int d^4x\, d^2\bar{\theta}\, K^0=0, \tag{I.6}$$

with K^0 a local power series in the gauge vector superfield with ghost number zero and dimension two. It can be proven[18,19] that condition (I.6) implies that the BRS variation of the integrand, i.e., sK^0, is a total derivative in superspace,

$$sK^0=\bar{D}_{\dot\alpha}\bar{K}^{1\dot\alpha}, \tag{I.7}$$

with $\bar{K}^{1\dot\alpha}$ local power series with ghost number one. [The absence of the term $D^\alpha K^1_\alpha$ in Eq. (I.7) is actually due to the chirality nature of the consistency condition (I.6).] Acting now on both sides of Eq. (I.7) with the nilpotent BRS operator s, we get

$$\bar{D}_{\dot\alpha} s\bar{K}^{1\dot\alpha}=0.$$

This equation admits a superspace solution (see Sec. V and Appendix A for details), which, as in the standard nonsuperspace case (I.2), entails a set of new conditions, which, together with the equation (I.7), gives the whole set of the superspace descent equations for the U(1) axial anomaly,[19] namely

$$\begin{aligned}
sK^0&=\bar{D}_{\dot\alpha}\bar{K}^{1\dot\alpha},\\
s\bar{K}^1_{\dot\alpha}&=(2D^\alpha\bar{D}_{\dot\alpha}+\bar{D}_{\dot\alpha}D^\alpha)K^2_\alpha,\\
sK^{2\alpha}&=D^\alpha K^3,\\
sK^3&=0,
\end{aligned} \tag{I.8}$$

with K^2_α and K^3 local power series of ghost number two and three.

From now on, the operator s in Eqs. (I.8), whose explicit form will be given later in Sec. II [see Eqs. (II.14)], refers to the BRS operator acting on the space of superfields of $N=1$ Yang–

Mills theories in superspace. Therefore, its integrated cohomology in the sectors of ghost number 1 and 0 will yield the possible gauge anomalies and gauge-invariant counterterms, which, being given in terms of superfields, are manifestly supersymmetric. In particular, the Eqs. (I.8) are the superspace analogous of the Wess–Zumino consistency condition (I.2) for the U(1) axial anomaly.

For the sake of clarity, it is worth emphasizing here that the existence of anomalies for the supersymmetry itself has been deeply investigated by Refs. 20 and 21, who showed, in fact, that the $N=1$ supersymmetric algebra with the usual content of superfields (i.e., scalar, chiral, and vector superfields) does not allow for anomalies of supersymmetry.

Our aim in this paper is to extend the previous works[16] to the case of the $N=1$ four-dimensional supersymmetric Yang–Mills theory, thus yielding a simple way of solving the superspace descent equations. This means that we will introduce two operators ζ_α and $\overline{\zeta}_{\dot\alpha}$, which, in analogy with the case of the operator δ of Eq. (I.4), allow us to decompose the supersymmetric covariant derivatives D_α and $\overline{D}_{\dot\alpha}$ as BRS commutators, according to

$$[\zeta_\alpha,s]=D_\alpha, \quad [\overline{\zeta}_{\dot\alpha},s]=\overline{D}_{\dot\alpha}, \tag{I.9}$$

with

$$D_\alpha\overline{D}_{\dot\alpha}+\overline{D}_{\dot\alpha}D_\alpha=2i\sigma^\mu_{\alpha\dot\alpha}\partial_\mu, \tag{I.10}$$

$\sigma^\mu_{\alpha\dot\alpha}$ being the Pauli matrices.

Moreover, as we shall see in Sec. IV [see Eq. (IV.39)], the decomposition (I.9) will lead to an algebraic structure that will close on shell, i.e., on the equations of motion of the standard $N=1$ Yang–Mills theory in superspace. In other words, we shall work without introducing the so-called antifields, which are known not to contribute to anomalies and nontrivial counterterms.[3]

We now have to remark that in the last few years the study of the BRS consistency condition for supersymmetric $N\geqslant 1$ models has been undertaken by several authors,[20–23] who faced and solved aspects that were still open. We mention, for instance, the results concerning the potential existence of susy anomalies in the presence of nonstandard constrained multiplets,[20,21] and the very useful possibility of performing a purely algebraic regularization-independent analysis of the susy gauge theories in a fully off-shell version of the Wess–Zumino gauge.[22,23] In particular, this last result has allowed for a simple discussion of the renormalization of models with extended supersymmetry (i.e., $N\geqslant 2$), yielding an algebraic proof of the ultraviolet finiteness of the $N=4$ gauge theories.[22]

However, although much is already known about the BRS cohomology of the $N=1$ gauge theories, we emphasize here that the decomposition formulas (I.9) will allow us to cast both the susy algebra and the supersymmetric BRS transformations into a unique equation, which, in complete analogy with the nonsupersymmetric case, takes the form of a generalized zero curvature condition. Moreover, by means of this zero curvature equation, we shall be able to derive the full set of superspace descent equations for the invariant action and for the U(1) axial anomaly from a unique equation of the type

$$\tilde{d}\tilde{\omega}=0, \tag{I.11}$$

$\tilde{\omega}$ being a suitable superspace cocycle and $\tilde{d}$ the generalized nilpotent operator entering the zero curvature condition. In addition, a modified version of Eq. (I.11) will allow us to also include the more complex case of the $N=1$ supersymmetric gauge anomaly, thus improving our understanding of the well-known nonpolynomial character of this anomaly.

The zero curvature equation and the related possibility of collecting the superspace descent equations into a unique condition represent the main results of this paper. Their relevance is due to the fact that, besides the possibility of recovering the solutions of the BRS consistency condition in a simple way, they provide an interesting pure geometrical framework in $N=1$ superspace.

The work is organized as follows. In Sec. II we introduce the general notations and we discuss the supersymmetric decomposition (I.9). Section III is devoted to the analysis of the algebraic relations entailed by the operators ζ_α and $\overline{\zeta}_{\dot\alpha}$. In Sec. IV we present the zero cuvature formulation of the superspace BRS transformations and of the descent equations corresponding to the invariant super Yang–Mills Lagrangian. In Sec. V we discuss the descent equations for the superspace version of the U(1) axial anomaly. In Sec. VI we deal with the case of the supersymmetric chiral gauge anomaly appearing in the quantum extension of the supersymmetric Slavnov–Taylor identity. In order to make the paper self-contained, in the final Appendices A, B, and C we collect a short summary of the main results concerning the Yang–Mills superspace BRS cohomology, as well as the solution of certain equations relevant for the superspace version of the descent equations.

II. GENERAL NOTATIONS AND DECOMPOSITION FORMULAS

In order to present the general algebraic setup, let us being by fixing the notations. (The superspace conventions used here are those of Ref. 24.) We shall work in a four-dimensional space–time with $N=1$ supersymmetry. The superfield content that will be used throughout is the standard set of the superfields of the pure $N=1$ super-Yang–Mills theories, i.e., the vector superfield ϕ and the gauge superconnections φ_α and $\overline{\varphi}_{\dot\alpha}$. They are defined as

$$\varphi_\alpha \equiv e^{-\phi} D_\alpha e^{\phi}, \quad \overline{\varphi}_{\dot\alpha} \equiv e^{\phi} \overline{D}_{\dot\alpha} e^{-\phi}, \tag{II.12}$$

where D_α and $\overline{D}_{\dot\alpha}$ are the usual supersymmetric derivatives:

$$\begin{gathered} \{D_\alpha, D_\beta\} = \{\overline{D}_{\dot\alpha}, \overline{D}_{\dot\beta}\} = 0, \\ D_\alpha \overline{D}_{\dot\alpha} + \overline{D}_{\dot\alpha} D_\alpha = 2i\sigma^\mu_{\alpha\dot\alpha}\partial_\mu . \end{gathered} \tag{II.13}$$

Introducing now the chiral and antichiral Faddeev–Popov ghosts c and $\overline{c}$,

$$\overline{D}_{\dot\alpha} c = D_\alpha \overline{c} = 0,$$

for the superspace nilpotent BRS transformations, one has

$$\begin{gathered} se^{\phi} = e^{\phi} c - \overline{c} e^{\phi}, \quad sc = -c^2, \quad s\overline{c} = -\overline{c}^2, \\ s\varphi_\alpha = -D_\alpha c - \{c, \varphi_\alpha\}, \quad s\overline{\varphi}_{\dot\alpha} = -\overline{D}_{\dot\alpha}\overline{c} - \{\overline{c}, \overline{\varphi}_{\dot\alpha}\}, \end{gathered} \tag{II.14}$$

and

$$\{s, D_\alpha\} = \{s, \overline{D}_{\dot\alpha}\} = 0.$$

Let us also give, for further use, the BRS transformations of the chiral and antichiral superfield strengths F_α and $\overline{F}_{\dot\alpha}$,

$$\begin{gathered} F_\alpha \equiv \overline{D}^2 \varphi_\alpha, \quad \overline{D}_{\dot\alpha} F_\alpha = 0, \\ \overline{F}_{\dot\alpha} \equiv D^2 \overline{\varphi}_{\dot\alpha}, \quad D_\alpha \overline{F}_{\dot\alpha} = 0, \\ sF_\alpha = -\{c, F_\alpha\}, \quad s\overline{F}_{\dot\alpha} = -\{\overline{c}, \overline{F}_{\dot\alpha}\}.‘ \end{gathered} \tag{II.15}$$

The quantum numbers, i.e., the dimensions, the ghost numbers, and the $\mathcal{R}$ weights of all the fields are assigned as follows (Table I).

TABLE I. Dim., ghost numb., and R weights.

	s	D_α	$\bar{D}_{\dot\alpha}$	ϕ	c	$\bar{c}$	φ_α	$\bar{\varphi}_{\dot\alpha}$	F_α	$\bar{F}_{\dot\alpha}$
dim	0	$\frac{1}{2}$	$\frac{1}{2}$	0	0	0	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{3}{2}$	$\frac{3}{2}$
N_g	1	0	0	0	1	1	0	0	0	0
$\mathcal{R}$	0	1	−1	0	0	0	1	−1	−1	1

The fields will be treated as commuting or anticommuting according to the fact that their total degree, here chosen to be the sum of the ghost number and of the spinorial indices, is even or odd. Otherwise stated, all the fields are Lie-algebra valued, the gauge group $\mathcal{G}$ being assumed to be a semisimple Lie group with anti-hermitian generators T^a.

The set of fields $(c,\bar{c},\phi,\varphi_\alpha,\bar{\varphi}_{\dot\alpha})$ and their covariant derivatives will define therefore the basic local space for studying the superspace descent equations. Let us also observe that due to the fact that D, $\bar{D}$ have dimension $\frac{1}{2}$, the number of covariant derivatives turns out to be limited by power counting requirements. For instance, as we shall see in the explicit examples considered in the next sections, the analysis of the superspace consistency condition for both the U(1) axial anomaly and the gauge anomaly requires the use of local formal power series in the variables $(c,\bar{c},\phi,\varphi_\alpha,\bar{\varphi}_{\dot\alpha})$ of dimension 2. We recall here that the nonpolynomial character of certain $N=1$ superspace expressions is due to the fact that the vector superfield ϕ is dimensionless. Finally, whenever the space time derivatives ∂_μ appear they are meant to be replaced by the covariant derivatives $D,\bar{D}$, according to the supersymmetric algebra (II.13).

Let us introduce now the two operators ζ_α and $\bar{\zeta}_{\dot\alpha}$ of ghost number -1, defined by

$$\zeta_\alpha c=\varphi_\alpha, \quad \bar{\zeta}_{\dot\alpha}\bar{c}=\bar{\varphi}_{\dot\alpha},$$
$$\zeta_\alpha\bar{c}=\bar{\zeta}_{\dot\alpha}c=\zeta_\alpha\phi=\bar{\zeta}_{\dot\alpha}\phi=0, \tag{II.16}$$
$$\zeta_\alpha\varphi_\beta=\bar{\zeta}_{\dot\alpha}\varphi_\beta=0.$$

Thus, it is almost immediate to check that they are of total degree zero and that they obey the following algebraic relations:

$$[\zeta_\alpha,s]=D_\alpha, \quad [\bar{\zeta}_{\dot\alpha},s]=\bar{D}_{\dot\alpha},$$
$$[\zeta_\alpha,\zeta_\beta]=[\zeta_\alpha,\bar{\zeta}_{\dot\beta}]=[\bar{\zeta}_{\dot\alpha},\bar{\zeta}_{\dot\beta}]=0, \tag{II.17}$$

yielding then the supersymmetric decomposition (I.9) we are looking for. As we shall see later on, the operators ζ_α and $\bar{\zeta}_{\dot\alpha}$ will turn out to be very useful in order to solve the superspace descent equations. Let us focus, for the time being, on the analysis of the consequences stemming from the equations (II.17).

III. ALGEBRAIC RELATIONS

To study the algebra entailed by the two operators ζ_α and $\bar{\zeta}_{\dot\alpha}$, let us first observe that they do not commute with the supersymmetric covariant derivatives D, $\bar{D}$. Instead, as one can easily check by using the equations (11.16) we have, in complete analogy with the nonsupersymmetric case,[4]

$$[\bar{\zeta}_{\dot\beta},D_\alpha]=[\zeta_\alpha,\bar{D}_{\dot\beta}]=-G_{\alpha\dot\beta}, \tag{III.18}$$

$$[\bar{\zeta}_{\dot\alpha},\bar{D}_{\dot\beta}]=[\zeta_\alpha,D_\beta]=0, \tag{III.19}$$

where the new operator $G_{\alpha\dot\beta}$ has negative ghost number -1 and acts on the fields as

TABLE II. Dim., ghost numb., and R weights.

	ζ^{α}	$\overline{\zeta}^{\dot{\alpha}}$	$G^{\alpha\dot{\alpha}}$	R^{α}	$\overline{R}^{\dot{\alpha}}$
Dim	$\frac{1}{2}$	$\frac{1}{2}$	1	$\frac{3}{2}$	$\frac{3}{2}$
N_g	-1	-1	-1	-1	-1
$\mathcal{R}$	1	-1	0	-1	1

$$G_{\alpha\dot{\alpha}}c=\overline{D}_{\dot{\alpha}}\varphi_{\alpha}, \quad G_{\alpha\dot{\alpha}}\overline{c}=D_{\alpha}\overline{\varphi}_{\dot{\alpha}},$$
$$G_{\alpha\dot{\alpha}}\phi=G_{\alpha\dot{\alpha}}\varphi_{\beta}=G_{\alpha\dot{\alpha}}\overline{\varphi}_{\dot{\beta}}=0, \tag{III.20}$$

and

$$\{G_{\alpha\dot{\alpha}},s\}=\{D_{\alpha},\overline{D}_{\dot{\alpha}}\},$$
$$[\zeta_{\alpha},G_{\beta\dot{\beta}}]=[\overline{\zeta}_{\dot{\alpha}},G_{\beta\dot{\beta}}]=\{G_{\alpha\dot{\alpha}},G_{\beta\dot{\beta}}\}=0. \tag{III.21}$$

Again, the operator $G_{\alpha\dot{\beta}}$ does not anticommute with the covariant derivatives $D,\overline{D}$. It yields, in fact,

$$\{G_{\alpha\dot{\alpha}},D_{\beta}\}=-\tfrac{1}{2}\epsilon_{\alpha\beta}\overline{R}_{\dot{\alpha}}, \quad \{G_{\alpha\dot{\alpha}},\overline{D}_{\dot{\beta}}\}=\tfrac{1}{2}\epsilon_{\dot{\alpha}\dot{\beta}}R_{\alpha}, \tag{III.22}$$

with R_{α} and $\overline{R}_{\dot{\alpha}}$ of ghost number -1 and defined as

$$R_{\alpha}c=F_{\alpha}, \quad \overline{R}_{\dot{\alpha}}\overline{c}=\overline{F}_{\dot{\alpha}},$$
$$R_{\alpha}\overline{c}=2\overline{D}_{\dot{\alpha}}D_{\alpha}\overline{\varphi}^{\dot{\alpha}}+D_{\alpha}\overline{D}_{\dot{\alpha}}\overline{\varphi}^{\dot{\alpha}}+(D_{\alpha}\overline{\varphi}_{\dot{\alpha}})\overline{\varphi}^{\dot{\alpha}}+\overline{\varphi}_{\dot{\alpha}}(D_{\alpha}\overline{\varphi}^{\dot{\alpha}}),$$
$$\overline{R}_{\dot{\alpha}}c=2D^{\alpha}\overline{D}_{\dot{\alpha}}\varphi_{\alpha}+\overline{D}_{\dot{\alpha}}D^{\alpha}\varphi_{\alpha}+(\overline{D}_{\dot{\alpha}}\varphi^{\alpha})\varphi_{\alpha}+\varphi^{\alpha}(\overline{D}_{\dot{\alpha}}\varphi_{\alpha}), \tag{III.23}$$
$$R_{\alpha}\phi=R_{\alpha}\varphi_{\beta}=R_{\alpha}\overline{\varphi}_{\dot{\beta}}=R_{\alpha}F_{\beta}=R_{\alpha}\overline{F}_{\dot{\beta}}=0,$$
$$\overline{R}_{\dot{\alpha}}\phi=\overline{R}_{\dot{\alpha}}\varphi_{\beta}=\overline{R}_{\dot{\alpha}}\overline{\varphi}_{\dot{\beta}}=\overline{R}_{\dot{\alpha}}F_{\beta}=\overline{R}_{\dot{\alpha}}\overline{F}_{\dot{\beta}}=0.$$

In addition, we have

$$[R_{\alpha},s]=[R_{\alpha},D_{\beta}]=[R_{\alpha},\overline{D}_{\dot{\beta}}]=[R_{\alpha},G_{\alpha\dot{\beta}}]=0,$$
$$[R_{\alpha},\zeta_{\beta}]=[R_{\alpha},\overline{\zeta}_{\dot{\beta}}]=[R_{\alpha},R_{\beta}]=[R_{\alpha},\overline{R}_{\dot{\beta}}]=0. \tag{III.24}$$

Let us display the quantum numbers of the operators entering the algebraic relations (II.17), (III.18), (III.22) (Table II).

In the next section, it will be shown how the operators in the Table II can be combined into a unique generalized operator by means of the introduction of a set of global parameters. These parameters will be required to fulfill a certain number of suitable conditions [see Eqs. (IV.26) in the next section], which will project the algebra (II.17), (III.18), (III.22) on the equations of motion of $N=1$ super-Yang–Mills, and will allow us to cast the BRS transformations of the superfields in the form of a zero curvature condition in superspace. In particular, the introduction of the aforementioned global parameters will have the effect of realizing the decomposition (II.17) on all the elementary superfields $(c,\overline{c},\phi,\varphi_{\alpha},\overline{\varphi}_{\dot{\alpha}})$ and their covariant derivatives on shell, i.e., modulo the equations of motion. Therefore, we can assume as the basic functional space for the forthcoming analysis that of the polynomials in the elementary superfields and their covariant

TABLE III. Dim., ghost numb., and *R* weights.

	e^{α}	$\overline{e^{\dot\alpha}}$	$\tilde{e}^{\alpha\dot\alpha}$
dim	$-\frac{1}{2}$	$-\frac{1}{2}$	-1
N_g	1	1	1
$\mathcal{R}$	0	0	0

derivatives bounded by dimension two. This limitation comes directly from superspace power-counting considerations. Moreover, all possible nontrivial counterterms and anomalies allowed by the power counting will be included.

IV. THE ZERO CURVATURE CONDITION

Having characterized all the relevant operators entailed by the consistency of the supersymmetric decomposition (II.17), let us pay attention to the geometrical aspects of the algebraic relations so far obtained. To this purpose it is useful to introduce a set of global parameters e^{α}, $\overline{e^{\dot\alpha}}$, and $\tilde{e}^{\alpha\dot\alpha}$, naturally associated to the operators ζ_{α}, $\overline{\zeta}_{\dot\alpha}$, and $G_{\alpha\dot\beta}$, of ghost number one, and obeying the relations (Table III)

$$e^{\alpha}e^{\beta}=\overline{e^{\dot\alpha}}\,\overline{e^{\dot\beta}}=\tilde{e}^{\alpha\dot\alpha}\tilde{e}^{\beta\dot\beta}=0,$$
$$[e^{\alpha},\overline{e^{\dot\beta}}]=[e^{\alpha},\tilde{e}^{\beta\dot\beta}]=[\tilde{e}^{\alpha\dot\alpha},\overline{e^{\dot\beta}}]=0. \tag{IV.25}$$

In addition, the global parameters $(e^{\alpha},\overline{e^{\dot\alpha}},\tilde{e}^{\alpha\dot\alpha})$ will be required to obey the following conditions (see also Appendix D):

$$e^{\alpha}\tilde{e}^{\beta\dot\alpha}=-\tfrac{1}{2}\epsilon^{\alpha\beta}e^{\gamma}\tilde{e}_{\gamma}^{\ \dot\alpha},\qquad \tilde{e}^{\alpha\dot\alpha}\overline{e^{\dot\beta}}=\tfrac{1}{2}\epsilon^{\dot\alpha\dot\beta}\tilde{e}^{\alpha}_{\ \dot\gamma}\overline{e^{\dot\gamma}},$$
$$e^{\alpha}\tilde{e}^{\beta\dot\alpha}\overline{e^{\dot\beta}}=-\tfrac{1}{4}\epsilon^{\alpha\beta}\epsilon^{\dot\alpha\dot\beta}e^{\gamma}\tilde{e}_{\gamma\dot\gamma}\tilde{e}^{\dot\gamma}, \tag{IV.26}$$

fixing the symmetry properties of the product of two parameters with respect to their spinorial indices. Defining now the nilpotent dimensionless operators $\zeta,\overline{\zeta}$, and G as

$$\zeta=\zeta^{\alpha}e_{\alpha},\qquad \overline{\zeta}=\overline{\zeta}_{\dot\alpha}\overline{e^{\dot\alpha}},\qquad G=G^{\alpha}_{\dot\alpha}\tilde{e}^{\dot\alpha}_{\ \alpha},$$

it is straightforward to verify that they have zero ghost number and $\mathcal{R}$ weight, respectively, 1, -1, 0, and that the subalgebra generated by ζ_{α}, $\overline{\zeta}_{\dot\alpha}$, and $G_{\alpha\dot\beta}$, i.e.,

$$[\zeta_{\alpha},\zeta_{\beta}]=[\zeta_{\alpha},\overline{\zeta}_{\dot\beta}]=[\overline{\zeta}_{\dot\alpha},\overline{\zeta}_{\dot\beta}]=0,$$

$$[\zeta_{\alpha},G_{\beta\dot\beta}]=[\overline{\zeta}_{\dot\alpha},G_{\beta\dot\beta}]=\{G_{\alpha\dot\alpha},G_{\beta\dot\beta}\}=0,$$

can be simply rewritten as

$$[\zeta,\overline{\beta}]=[\zeta,G]=[\overline{\zeta},G]=0.$$

Analogously, introducing the nilpotent operators $\tilde{G},D,\bar{D},R,\bar{R},\partial,\tilde{\partial}$

$$
\begin{aligned}
&\tilde{G}=G^{\alpha}_{\dot{\alpha}}e_{\alpha}\bar{e}^{\dot{\alpha}}, \quad G=G^{\alpha}_{\dot{\alpha}}\tilde{e}^{\dot{\alpha}}_{\alpha},\\
&D=D^{\alpha}e_{\alpha}, \quad \bar{D}=\bar{D}_{\dot{\alpha}}\bar{e}^{\dot{\alpha}},\\
&R=R^{\alpha}\tilde{e}_{\alpha\dot{\alpha}}\bar{e}^{\dot{\alpha}}, \quad \bar{R}=\bar{R}_{\dot{\alpha}}e^{\alpha}\tilde{e}^{\dot{\alpha}}_{\alpha},\\
&\tilde{\partial}=\{D^{\alpha},\bar{D}_{\dot{\alpha}}\}e_{\alpha}\bar{e}^{\dot{\alpha}}, \quad \partial=\{D^{\alpha},\bar{D}_{\dot{\alpha}}\}\tilde{e}^{\dot{\alpha}}_{\alpha},
\end{aligned}
\tag{IV.27}
$$

it is immediate to check that all the algebraic relations and field transformations of eqs. (II.16)–eqs. (III.24) may be cast into the following free index notation

$$
\begin{aligned}
&[\zeta,s]=D, \quad [\bar{\zeta},s]=\bar{D}, \quad \{\tilde{G},s\}=\tilde{\partial}, \quad [G,s]=\partial,\\
&\{s,D\}=0, \quad \{s,\bar{D}\}=0, \quad [s,\tilde{\partial}]=0, \quad \{s,\partial\}=0,\\
&[D,\tilde{\partial}]=0, \quad [\bar{D},\tilde{\partial}]=0, \quad \{D,\partial\}=0, \quad \{\bar{D},\partial\}=0,\\
&[D,\zeta]=0, \quad [\bar{D},\bar{\zeta}]=0, \quad [\bar{D},\zeta]=\tilde{G}, \quad [D,\bar{\zeta}]=\tilde{G},\\
&[\partial,\tilde{\partial}]=0, \quad [G,\tilde{G}]=0, \quad [\zeta,\tilde{G}]=0, \quad [\bar{\zeta},\tilde{G}]=0,\\
&[G,\partial]=0, \quad [\tilde{G},\tilde{\partial}]=0, \quad [G,\tilde{\partial}]=0, \quad \{\tilde{G},\partial\}=0,\\
&\{\tilde{G},D\}=0, \quad \{\tilde{G},\bar{D}\}=0, \quad 2[D,G]=\bar{R}, \quad 2[G,\bar{D}]=R,\\
&[\zeta,\tilde{\partial}]=0, \quad [\bar{\zeta},\tilde{\partial}]=0, \quad 2[\zeta,\partial]=\bar{R}, \quad 2[\partial,\bar{\zeta}]=R,\\
&[\zeta,R]=0, \quad [\zeta,\bar{R}]=0, \quad [\bar{\zeta},R]=0, \quad [\bar{\zeta},\bar{R}]=0,\\
&[R,\tilde{\partial}]=0, \quad [\bar{R},\tilde{\partial}]=0, \quad \{R,\partial\}=0, \quad \{\bar{R},\partial\}=0,\\
&\{D,R\}=0, \quad \{\bar{D},R\}=0, \quad \{D,\bar{R}\}=0, \quad \{\bar{D},\bar{R}\}=0,\\
&\{\tilde{G},R\}=0, \quad \{\tilde{G},\bar{R}\}=0, \quad [G,R]=0, \quad [G,\bar{R}]=0,\\
&\{s,R\}=0, \quad \{s,\bar{R}\}=0, \quad \{R,\bar{R}\}=0.
\end{aligned}
\tag{IV.28}
$$

Let us proceed now by showing that, as announced in the Introduction, the supersymmetric BRS transformations (II.14), (II.15) can be obtained by means of a generalized zero curvature condition. To this aim let us introduce the operator δ,

$$\delta=\zeta+\bar{\zeta}-G, \tag{IV.29}$$

from which one easily obtains the following decomposition:

$$[s,\delta]=-D-\bar{D}-\partial.$$

Defining now the δ transform of the BRS operator s as

$$\tilde{d}=e^{\delta}se^{-\delta}, \tag{IV.30}$$

one gets

$$\tilde{d} = s + D + \bar{D} + \partial - \tilde{G} + \tfrac{1}{2}\bar{R} - \tfrac{1}{2}R,$$
$$\tilde{d}\tilde{d} = 0, \tag{IV.31}$$

so that, calling $\tilde{A}$ and $\tilde{\bar{A}}$ the δ transform of the chiral and antichiral ghosts $(c,\bar{c})$,

$$\tilde{A} = e^{\delta}c = c + \varphi + \bar{D}\varphi, \quad \varphi = \varphi^{\alpha}e_{\alpha}, \tag{IV.32}$$

$$\tilde{\bar{A}} = e^{\delta}\bar{c} = \bar{c} + \bar{\varphi} + D\bar{\varphi}, \quad \bar{\varphi} = \bar{\varphi}_{\dot{\alpha}}\bar{e}^{\dot{\alpha}}, \tag{IV.33}$$

it follows that the BRS transformations of $(c,\bar{c})$ imply the zero curvature equations,

$$e^{\delta}se^{-\delta}e^{\delta}c = -e^{\delta}c^{2} \Rightarrow \tilde{d}\tilde{A} + \tilde{A}^{2} = 0 \tag{IV.34}$$

and

$$e^{\delta}se^{-\delta}e^{\delta}\bar{c} = -e^{\delta}\bar{c}^{2} \Rightarrow \tilde{d}\tilde{\bar{A}} + \tilde{\bar{A}}^{2} = 0. \tag{IV.35}$$

Equations (IV.34) and (IV.35) are easily checked to reproduce all the BRS transformations (II.14), (II.15), as well as the whole set of the equations (III.20)–(III.23). One sees, thus, that, in complete analogy with the nonsupersymmetric case,[16] the zero curvature equations (IV.34) and (IV.35) deeply rely on the existence of the operators ζ_{α} and $\bar{\zeta}_{\dot{\alpha}}$. Let us underline here that the nilpotent operator $\tilde{d}$ in Eq. (IV.31) will play a rather important role in the discussion of the superspace descent equations. For instance, as we shall see explicitly in the example given in the next section, it turns out that the superspace descent equations corresponding to the BRS-invariant counterterms can be remarkably obtained from the single equation,

$$\tilde{d}\tilde{\omega} = 0, \tag{IV.36}$$

where $\tilde{\omega}$ is an appropriate cocycle of dimension zero and ghost number three, whose components are the superspace field polynomials of the Taylor expansion of $\tilde{\omega}$ in the global parameters $(e^{\alpha},\bar{e}^{\dot{\alpha}},\tilde{e}^{\alpha\dot{\alpha}})$. Equation (IV.36) can also be applied to characterize the descent equations of the U(1) anomaly. In Sec. VI we shall see that a slight modification of Eq. (IV.36) will allow us to treat the case of the Yang–Mills gauge anomaly, as well. In all these cases the components of $\tilde{\omega}$ will not exceed dimension two, this dimension being taken as the upper limit of our superspace analysis of the descent equations. In other words, in what follows we shall limit ourselves to the study of the solutions of the superspace descent equations in the space of local functionals with dimension less or equal to two. In particular, according to Table I, this implies that the maximum number of covariant derivatives $D,\bar{D}$ present in each component of $\tilde{\omega}$ is four.

Let us conclude this section with the following important remark. Being interested in the descent equations involving superspace functionals of dimension less or equal to two, we should have checked the closure of the algebra (IV.28) built up by the operators $(s,\zeta,\bar{\zeta},G,\tilde{G},D,\bar{D},R,\bar{R},\partial,\tilde{\partial})$ on all the fields and their covariant derivatives up to reaching dimension two. It is not difficult to convince oneself that actually there is a breakdown of the closure of this algebra in the highest level of dimension two. However, as it usually happens in supersymmetry, the breaking terms turn out to be nothing but the equations of motion corresponding to the pure $N=1$ susy Yang–Mills action, thus implying an on-shell closure of the algebra. Evaluating, in fact, the commutator between the operators ζ and s on the superfield strength F, one gets

$$[\zeta,s]F = -[\varphi,F]. \tag{IV.37}$$

TABLE IV. Dim. and ghost numb.

	ω^3	$\omega^{2\alpha}$	$\overline{\omega}^2_{\dot\alpha}$	$\tilde\omega^{2\alpha}_{\dot\alpha}$	$\tilde\omega^{1\alpha}_{\dot\alpha}$	$\omega^{1\alpha}$	$\overline{\omega}^1_{\dot\alpha}$	ω^0
dim	0	$\frac{1}{2}$	$\frac{1}{2}$	1	1	$\frac{3}{2}$	$\frac{3}{2}$	2
N_g	3	2	2	2	1	1	1	0

The right-hand side of the equation (IV.37) can be rewritten as

$$[\zeta,s]F=DF-(DF+[\varphi,F]),$$

so that, recalling that

$$DF+[\varphi,F]=-\tfrac{1}{2}e^{\gamma}\tilde{e}_{\gamma\dot\gamma}\overline{e}^{\dot\gamma}(D^{\alpha}F_{\alpha}+\{\varphi^{\alpha},F_{\alpha}\})=0, \tag{IV.38}$$

are precisely the equations of motion of the pure $N=1$ susy Yang–Mills action, one obtains

$$[\zeta,s]F=DF-\text{equation of motion}. \tag{IV.39}$$

It is worth underlining here that the on-shell closure of the algebra relies precisely on the introduction of the global parameters $e^{\alpha},\overline{e}^{\dot\alpha},\tilde{e}^{\alpha\dot\alpha}$ and on the relations (IV.26). Nevertheless, this on-shell closure does not represent a real obstruction in order to solve the superspace consistency conditions. In fact, from Eq. (IV.38) and from Table I, one can observe that the equations of motion of $N=1$ super-Yang–Mills are of dimension two. Therefore, they could eventually contribute only to the highest level of the descent equations. Rather, the above on-shell closure (IV.28) is related to the absence of the so-called BRS external fields (i.e., the Batalin–Vilkoviski antifields), which are known to properly take care of the equations of motion. However, as shown by Refs. 17, 18, and 24, these external fields do not contribute to the superspace BRS cohomology in the cases considered here of the U(1) chiral anomaly, of the gauge anomaly as well as of the invariant counterterms. This is the reason why we have discarded them. In Appendix C it will be shown how the introduction of an appropriate external field takes care in a simple way of the Yang–Mills equations of motion, thus closing the algebra off shell.

A. Nonchiral descent equations for the invariant action

In order to apply the supersymmetric decomposition (II.17) to the analysis of the superspace descent equations, let us begin by considering the BRS consistency condition corresponding to the nonchiral Yang–Mills invariant action, i.e.,

$$s\int d^4x\, d^2\theta\, d^2\overline{\theta}\,\mathcal{L}^0=0\Rightarrow s\mathcal{L}^0=D^{\alpha}\mathcal{L}^1_{\alpha}+\overline{D}_{\dot\alpha}\mathcal{L}^{1\dot\alpha}, \tag{IV.40}$$

where $\mathcal{L}^0$ is a local power series of dimension two and ghost number zero. According to what was mentioned in the previous section, the full set of the superspace descent equations characterizing $\mathcal{L}^0$ can be obtained directly from the generalized equation,

$$\tilde{d}\tilde{\omega}=0, \tag{IV.41}$$

with $\tilde\omega$ a generalized cocycle of ghost number three and dimension zero, whose Taylor expansion in the global parameters $(e^{\alpha},\tilde{e}^{\alpha\dot\alpha},\overline{e}^{\dot\alpha})$ reads as

$$\tilde\omega=\omega^3+\omega^{2\alpha}e_{\alpha}+\overline{\omega}^2_{\dot\alpha}\overline{e}^{\dot\alpha}+\tilde\omega^{2\alpha}_{\dot\alpha}\tilde{e}^{\dot\alpha}_{\alpha}+\tilde\omega^{1\alpha}_{\dot\alpha}e_{\alpha}\overline{e}^{\dot\alpha}+\omega^{1\alpha}\tilde{e}_{\alpha\dot\alpha}\overline{e}^{\dot\alpha}+\overline{\omega}^1_{\dot\alpha}e^{\alpha}\tilde{e}^{\dot\alpha}_{\alpha}+\omega^0e^{\alpha}\tilde{e}_{\alpha\dot\alpha}\overline{e}^{\dot\alpha}. \tag{IV.42}$$

The coefficients $(\omega^3,\omega^{2\alpha},\overline{\omega}^2_{\dot\alpha},\tilde{\omega}^{2\alpha}_{\dot\alpha},\tilde{\omega}^{1\alpha}_{\dot\alpha},\omega^{1\alpha},\overline{\omega}^1_{\dot\alpha},\omega^0)$ are local power series in the superfields with the following quantum numbers (Table IV).

In particular, one observes that the coefficient ω^0 in the expression (IV.42) has the same dimension of the invariant action we are looking for, thus justifying the choice of the quantum numbers of $\tilde{\omega}$ in Eq. (IV.41).

The generalized condition (IV.41) is easily worked out and yields the following set of equations:

$$
\begin{gathered}
s\omega^0=-\tfrac{1}{2}D^\alpha\omega^1_\alpha+\tfrac{1}{2}\overline{D}_{\dot\alpha}\overline{\omega}^{1\dot\alpha}+\tfrac{1}{4}\overline{R}_{\dot\alpha}\overline{\omega}^{2\dot\alpha}+\tfrac{1}{4}R^\alpha\omega^2_\alpha-\tfrac{1}{4}\{D^\alpha,\overline{D}_{\dot\alpha}\}\tilde{\omega}^{1\dot\alpha}_\alpha-\tfrac{1}{4}G^{\alpha}_{\dot\alpha}\tilde{\omega}^{2\dot\alpha}_\alpha,\\
s\overline{\omega}^1_{\dot\alpha}=-\tfrac{1}{2}\{D^\alpha,\overline{D}_{\dot\alpha}\}\omega^2_\alpha-\tfrac{1}{2}D^\alpha\tilde{\omega}^2_{\alpha\dot\alpha}+\tfrac{1}{2}\overline{R}_{\dot\alpha}\omega^3,\\
s\tilde{\omega}^{1\alpha}_{\dot\alpha}=-D^\alpha\overline{\omega}^2_{\dot\alpha}-\overline{D}_{\dot\alpha}\omega^{2\alpha}+G^{\alpha}_{\dot\alpha}\omega^3,\quad s\omega^{1\alpha}=\tfrac{1}{2}\{D^\alpha,\overline{D}_{\dot\alpha}\}\overline{\omega}^{2\dot\alpha}+\tfrac{1}{2}\overline{D}_{\dot\alpha}\tilde{\omega}^{2\alpha\dot\alpha}-\tfrac{1}{2}R^\alpha\omega^3,\\
s\overline{\omega}^2_{\dot\alpha}=-\overline{D}_{\dot\alpha}\omega^3,\quad s\tilde{\omega}^{2\alpha}_{\dot\alpha}=\{D^\alpha,\overline{D}_{\dot\alpha}\}\omega^3,\quad s\omega^{2\alpha}=-D^\alpha\omega^3,\quad s\omega^3=0.
\end{gathered}
\tag{IV.43}
$$

These equations do not yet represent the final version of the superspace descent equations, due to the presence of the operators $(G_{\alpha\dot\alpha},R_\alpha,\overline{R}_{\dot\alpha})$ on their right-hand sides. However, we shall prove that these undesired terms can be rewritten as pure BRS cocycles or as total superspace derivatives, meaning that they can be eliminated by means of a redefinition of the ω's cocycles entering the equations (IV.43). Let us first observe that a particular solution of the tower (IV.43) can be fully expressed in terms of the BRS invariant cocycle ω^3. In fact, owing to the zero curvature equations (IV.30), (IV.34), and (IV.35), it is apparent that the system (IV.43) is solved by

$$\tilde{\omega}=e^\delta\omega^3, \tag{IV.44}$$

which, when written in components, yields the following expressions:

$$
\begin{gathered}
\omega^{2\alpha}=\zeta^\alpha\omega^3,\quad \tilde{\omega}^{2\alpha}_{\dot\alpha}=G^{\alpha}_{\dot\alpha}\omega^3,\\
\overline{\omega}^2_{\dot\alpha}=\overline{\zeta}_{\dot\alpha}\omega^3,\quad \omega^{1\alpha}=\tfrac{1}{2}G^{\alpha}_{\dot\alpha}\overline{\zeta}^{\dot\alpha}\omega^3,\\
\tilde{\omega}^{1\alpha}_{\dot\alpha}=\zeta^\alpha\overline{\zeta}_{\dot\alpha}\omega^3,\quad \overline{\omega}^1_{\dot\alpha}=-\tfrac{1}{2}G^{\alpha}_{\dot\alpha}\zeta_\alpha\omega^3,\\
\omega^0=\tfrac{1}{4}\zeta^\alpha G_{\alpha\dot\alpha}\overline{\zeta}^{\dot\alpha}\omega^3.
\end{gathered}
\tag{IV.45}
$$

In particular, from the results on the superspace BRS cohomology[18,19,25] (see Appendix B), it turns out that the most general form for ω^3 can be identified with the invariant ghost monomial,

$$\mathrm{Tr}\left(\frac{c^3}{3}\right), \tag{IV.46}$$

which, of course, is determined modulo a trivial exact BRS cocycle. Recalling then (Appendix B) that the difference $(\mathrm{Tr}\,c^3-\mathrm{Tr}\,\overline{c}^3)$ is cohomologically trivial, i.e.,

$$\mathrm{Tr}\,c^3-\mathrm{Tr}\,\overline{c}^3=s(\cdots),$$

we can choose for ω^3 the following symmetric expression [one should observe that due to the anti-hermiticity property of the group generators T^a, the cocycle $(\mathrm{Tr}\,c^3+\mathrm{Tr}\,\overline{c}^3)$ is real]:

$$\omega^3=\mathrm{Tr}\left(\frac{c^3}{3}\right)+\mathrm{Tr}\left(\frac{\overline{c}^3}{3}\right). \tag{IV.47}$$

On the other hand, it is easily established that all the terms $R^{\alpha}\omega^3$, $\overline{R}_{\dot{\alpha}}\omega^3$, $R^{\alpha}\omega^2_{\alpha}$, $\overline{R}_{\dot{\alpha}}\overline{\omega}^{2\dot{\alpha}}$ on the right-hand side of Eqs. (IV.43) are trivial BRS cocycles. Considering, for instance, the first term, we have, from Eqs. (III.24),

$$sR^{\alpha}\omega^3 = R^{\alpha}s\omega^3 = 0, \tag{IV.48}$$

which implies that $R^{\alpha}\omega^3$ belongs to the cohomology of s in the sector of ghost number two and dimension one-half. Therefore, being the BRS cohomology empty in this sector, it follows that

$$R^{\alpha}\omega^3 = s\Lambda^{1\alpha}, \tag{IV.49}$$

as well as

$$\overline{R}^{\dot{\alpha}}\omega^3 = s\overline{\Lambda}^{1\dot{\alpha}}. \tag{IV.50}$$

In fact, from

$$R^{\alpha}\,\mathrm{Tr}\left(\frac{c^3}{3}\right) = s\,\mathrm{Tr}(cR^{\alpha}c) = s\,\mathrm{Tr}(cF^{\alpha}),$$

$$\overline{R}^{\dot{\alpha}}\,\mathrm{Tr}\left(\frac{c^3}{3}\right) = s\,\mathrm{Tr}(c\overline{R}^{\dot{\alpha}}c),$$

and

$$R^{\alpha}\,\mathrm{Tr}\left(\frac{\overline{c}^3}{3}\right) = s\,\mathrm{Tr}(\overline{c}R^{\alpha}\overline{c}),$$

$$\overline{R}^{\dot{\alpha}}\,\mathrm{Tr}\left(\frac{\overline{c}^3}{3}\right) = s\,\mathrm{Tr}(\overline{c}\overline{R}^{\dot{\alpha}}\overline{c}) = s\,\mathrm{Tr}(\overline{c}\overline{F}^{\dot{\alpha}}),$$

we have that $\Lambda^{1\alpha}$ and $\overline{\Lambda}^{1\dot{\alpha}}$ can be identified, modulo trivial terms, with

$$\Lambda^{1\alpha} = \mathrm{Tr}(cF^{\alpha}) + \mathrm{Tr}(\overline{c}R^{\alpha}\overline{c}), \quad \overline{\Lambda}^{1\dot{\alpha}} = \mathrm{Tr}(\overline{c}\overline{F}^{\dot{\alpha}}) + \mathrm{Tr}(c\overline{R}^{\dot{\alpha}}c), \tag{IV.51}$$

where $\overline{R}^{\dot{\alpha}}c, R^{\alpha}\overline{c}$ are given in Eqs. (III.23).

In the same way, we have

$$R^{\alpha}\omega^2_{\alpha} = R^{\alpha}\zeta_{\alpha}\omega^3 = \zeta_{\alpha}R^{\alpha}\omega^3 = \zeta_{\alpha}s\Lambda^{1\alpha} = s(\zeta_{\alpha}\Lambda^{1\alpha}) + D_{\alpha}\Lambda^{1\alpha}, \tag{IV.52}$$

showing that $R^{\alpha}\omega^2_{\alpha}$ is a trivial BRS cocycle plus a total superspace derivative. The same conclusions hold for $\overline{R}_{\dot{\alpha}}\omega^3$ and $\overline{R}_{\dot{\alpha}}\overline{\omega}^{2\dot{\alpha}}$ and can be extended by similar arguments to include the G terms $G^{\alpha}_{\dot{\alpha}}\omega^3$ and $G^{\alpha}_{\dot{\alpha}}\tilde{\omega}^{2\dot{\alpha}}_{\alpha}$.

The final result is that the equations (IV.43) can be rewritten without the explicit presence of the operators R and G, thus yielding the final version of the superspace descent equations for the invariant action, i.e.,

$$\begin{aligned}
s\left(\omega^0+\tfrac{1}{4}\bar{\zeta}_{\dot\alpha}\bar{\Lambda}^{1\dot\alpha}+\tfrac{1}{4}\zeta^\alpha\Lambda^1_\alpha\right)&=-\tfrac{1}{2}D^\alpha\left(\omega^1_\alpha+\tfrac{1}{2}\Lambda^1_a\right)+\tfrac{1}{2}\bar{D}_{\dot\alpha}\left(\bar{\omega}^{1\dot\alpha}-\tfrac{1}{2}\bar{\Lambda}^{1\dot\alpha}\right),\\
s\left(\bar{\omega}^1_{\dot\alpha}-\tfrac{1}{2}\bar{\Lambda}^1_{\dot\alpha}\right)&=-\tfrac{1}{2}\bar{D}_{\dot\alpha}D^\alpha\omega^2_\alpha-D^\alpha\bar{D}_{\dot\alpha}\omega^2_\alpha-\tfrac{1}{2}D^2\bar{\omega}^2_{\dot\alpha},\\
s\left(\omega^{1\alpha}+\tfrac{1}{2}\Lambda^{1\alpha}\right)&=\tfrac{1}{2}D^\alpha\bar{D}_{\dot\alpha}\bar{\omega}^{2\dot\alpha}+\bar{D}_{\dot\alpha}D^\alpha\bar{\omega}^{2\dot\alpha}+\tfrac{1}{2}\bar{D}^2\omega^{2\alpha},\\
s\bar{\omega}^2_{\dot\alpha}&=-\bar{D}_{\dot\alpha}\omega^3,\\
s\omega^{2\alpha}&=-D^\alpha\omega^3,\\
s\omega^3&=0.
\end{aligned}\tag{IV.53}$$

In particular, the first equation of the above system explicitly shows that the invariant action $\mathcal{L}^0$ can be identified with

$$\mathcal{L}^0=\omega^0+\tfrac{1}{4}\bar{\zeta}_{\dot\alpha}\bar{\Lambda}^{1\dot\alpha}+\tfrac{1}{4}\zeta^\alpha\Lambda^1_\alpha.\tag{IV.54}$$

The above expression has to be understood modulo an exact BRS cocycle or a total superspace derivative. Its nontriviality relies on the nontriviality of the ghost cocycle (IV.47), as one can show by using a well-known standard cohomological argument.[14,15] Recalling then the expressions (IV.45), (IV.51), for $\mathcal{L}^0$, we get

$$\mathcal{L}^0=\tfrac{1}{4}\mathrm{Tr}(\varphi^\alpha F_\alpha)+\tfrac{1}{4}\mathrm{Tr}(\bar{\varphi}_{\dot\alpha}\bar{F}^{\dot\alpha}),$$

which when integrated on the full superspace $d^4x\,d^2\theta\,d^2\bar{\theta}$, yields the familiar $N=1$ supersymmetric invariant Yang–Mills Lagrangian (here we recall the useful superspace identity $\int d^4x\,d^2\theta\,d^2\bar{\theta}=\int d^4x\,d^2\theta\,\bar{D}^2$):

$$S_{\mathrm{YM}}=\int d^4x\,d^2\theta\,d^2\bar{\theta}\,\mathcal{L}^0=\frac{1}{4}\int D^4x\,d^2\theta\,\mathrm{Tr}\,F^\alpha F_\alpha+\frac{1}{4}\int d^4x\,d^2\bar{\theta}\,\mathrm{Tr}\,\bar{F}_{\dot\alpha}\bar{F}^{\dot\alpha}.$$

V. DESCENT EQUATIONS FOR THE U(1) ANOMALY

As already remarked in the Introduction the BRS consistency condition for the chiral U(1) axial anomaly reads[19,24] as

$$s\int d^4x\,d^2\bar{\theta}\,K^0=0\Rightarrow sK^0=\bar{D}_{\dot\alpha}\bar{K}^{1\dot\alpha},\tag{V.55}$$

where K^0 and $\bar{K}^{1\dot\alpha}$ have dimensions two and three half and ghost numbers zero and one, respectively. K^0 has thus the same quantum numbers of the invariant action considered in the previous section, the only difference lying in the fact that the superspace measure, i.e., $d^4x\,d^2\bar{\theta}$, is now chiral instead of the vector one $d^4x\,d^2\bar{\theta}\,d^2\theta$. Therefore the descent equations for K^0 are obtained by performing the chiral limit of the vector equations (IV.43). Acting indeed with the BRS operator on the second equation of the condition (V.55), we obtain

$$\bar{D}_{\dot\alpha}s\bar{K}^{1\dot\alpha}=0.\tag{V.56}$$

Using then the results given in Appendix A, it follows that the general solution of the equation (V.56) is given by

$$
\begin{gathered}
s\bar{K}^{1\dot{\alpha}}=(\bar{D}^{\dot{\alpha}}D^{\alpha}+2D^{\alpha}\bar{D}^{\dot{\alpha}})K^2_{\alpha},\\
\bar{D}^2K^2_{\alpha}=0,
\end{gathered}
\tag{V.57}
$$

where K^2_{α} is of dimension one-half and ghost number two. Again, acting with the BRS operator in Eq. (V.57), one gets

$$
(\bar{D}^{\dot{\alpha}}D^{\alpha}+2D^{\alpha}\bar{D}^{\dot{\alpha}})sK^2_{\alpha}=0,
\tag{V.58}
$$

which, according to Appendix A, implies that

$$
\begin{gathered}
sK^2_{\alpha}=D^{\alpha}K^3,\\
\bar{D}^2D^{\alpha}K^3=0,\quad D^2\bar{D}^{\dot{\alpha}}K^3=0,
\end{gathered}
$$

with K^3 of dimension zero and ghost number three. Finally, from

$$
D^{\alpha}sK^3=0,
$$

it follows that

$$
sK^3=0.
$$

Summarizing, the superspace descent equations for the U(1) chiral axial anomaly are

$$
\begin{gathered}
sK^0=\bar{D}_{\dot{\alpha}}\bar{K}^{1\dot{\alpha}},\\
s\bar{K}^1_{\dot{\alpha}}=(2D^{\alpha}\bar{D}_{\dot{\alpha}}+\bar{D}_{\dot{\alpha}}D^{\alpha})K^2_{\alpha},\\
sK^{2\alpha}=D^{\alpha}K^3,\quad sK^3=0,
\end{gathered}
\tag{V.59}
$$

with the constraints

$$
\begin{gathered}
\bar{D}^2K^2_{\alpha}=0,\\
\bar{D}^2D^{\alpha}K^3=D^2\bar{D}^{\dot{\alpha}}K^3=0.
\end{gathered}
\tag{V.60}
$$

Recalling then the result of the previous section, for K^3 we have

$$
K^3=\left(\mathrm{Tr}\frac{c^3}{3}+\mathrm{Tr}\frac{\bar{c}^3}{3}\right)+s\Delta^2,
\tag{V.61}
$$

for some local power series Δ^2. It is interesting to observe that in this case the constraints (V.60) fix completely the trivial part of K^3, giving, for instance,

$$
s\Delta^2=0.
$$

Acting with the operator ζ_{α} on both sides of the last of Eqs. (V.59), and making use of the decomposition (II.17), for K^2_{α} one gets

$$
K^2_{\alpha}=-\zeta_{\alpha}K^3+s\Delta^1_{\alpha}.
$$

Once more, it is not difficult to prove that the imposition of the constraints (V.60) yields a unique expression for Δ^1_α, i.e.,

$$\Delta^1_\alpha = \mathrm{Tr}(c\varphi_\alpha),$$

so that for K^2_α we get

$$K^2_\alpha = \mathrm{Tr}(cD_\alpha c).$$

One sees thus that in the chiral case, due to the constraints (V.60), the trivial BRS contributions are uniquely fixed at the lowest levels of the descent equations. Repeating now the same procedure and making use of the relations (III.18) for $\overline{K}^{1\dot\alpha}$, one obtains

$$\overline{K}^{1\dot\alpha} = G^{\alpha\dot\alpha}K^2_\alpha - \overline{\Lambda}^{1\dot\alpha} + D^\alpha\overline{D}^{\dot\alpha}\,\mathrm{Tr}(c\varphi_\alpha) + \mathrm{Tr}(\overline{c}\overline{F}^{\dot\alpha}) + s\Delta^{0\dot\alpha}, \tag{V.62}$$

where the cocycle $\overline{\Lambda}^{1\dot\alpha}$ is the same as in Eq. (IV.48), i.e.,

$$\overline{\Lambda}^{1\dot\alpha} = \mathrm{Tr}(c\overline{R}^{\dot\alpha}c) + \mathrm{Tr}(\overline{c}\overline{F}^{\dot\alpha}).$$

Thus, that it follows

$$\overline{K}^{1\dot\alpha} = -2\,\mathrm{Tr}(D^\alpha c\overline{D}^{\dot\alpha}\varphi_\alpha) + s\Delta^{0\dot\alpha}. \tag{V.63}$$

Finally, acting with the operator $\overline{\zeta}_{\dot\alpha}$ on both sides of the equation,

$$s\overline{K}^1_{\dot\alpha} = (2D^\alpha\overline{D}_{\dot\alpha} + \overline{D}_{\dot\alpha}D^\alpha)K^2_\alpha,$$

for the last level K^0, we find

$$K^0 = -\overline{\zeta}_{\dot\alpha}\overline{K}^{1\dot\alpha} + \mathrm{Tr}(2\varphi^\alpha F_\alpha + \overline{D}_{\dot\alpha}\varphi^\alpha\overline{D}^{\dot\alpha}\varphi_\alpha),$$

reproducing the well-known expression for the U(1) supersymmetric chiral anomaly,

$$K^0 = \mathrm{Tr}(2\varphi^\alpha F_\alpha - \overline{D}_{\dot\alpha}\varphi^\alpha\overline{D}^{\dot\alpha}\varphi_a) - \overline{D}_{\dot\alpha}\Delta^{0\dot\alpha}.$$

Let us conclude by remarking that the expressions of the cocycles K^3, K^2_α, $\overline{K}^{1\dot\alpha}$, and K^0 found here are completely equivalent to those of Ref. 19, i.e., the difference is an exact BRS cocycle or a total superspace derivative.

VI. THE SUPERSYMMETRIC GAUGE ANOMALY

As the last example of our superspace analysis, let us consider the case of the supersymmetric gauge anomaly. As usual, let us first focus on the derivation of the corresponding descent equations. The latter, as mentioned in the Introduction and in Sec. IV, can be obtained by adding to the right-hand side of the generalized equation (IV.41) an appropriate extra term. The presence of this term actually stems from the BRS triviality[18] of the pure ghost cocycles $(\mathrm{Tr}\,c^{2n+1} - \mathrm{Tr}\,\overline{c}^{2n+1})$, $n \geqslant 1$,

$$s\Omega^{2n} = \mathrm{Tr}\frac{c^{2n+1}}{2n+1} - \mathrm{Tr}\frac{\overline{c}^{2n+1}}{2n+1}, \tag{VI.64}$$

Ω^{2n} being a local dimensionless functional of $(\phi, c, \overline{c})$ with ghost number $2n$. Acting in fact with the operator e^δ on both sides of Eq. (VI.64) and recalling the definitions (IV.32) and (IV.33), we get the desired modified version of the generalized superspace equation (IV.41) we are looking for,

$$
\begin{aligned}
\tilde{d}\tilde{\Omega} &= \mathrm{Tr}\frac{\tilde{A}^{2n+1}}{2n+1} - \mathrm{Tr}\frac{\tilde{\tilde{A}}^{2n+1}}{2n+1}, \\
\tilde{\Omega} &= e^{\delta}\Omega^{2n}.
\end{aligned}
\tag{VI.65}
$$

The descent equations for the gauge anomaly follows then from Eq. (VI.65) when $n=2$, i.e.,

$$
\begin{aligned}
\tilde{d}\tilde{\Omega} &= \tfrac{1}{5}\,\mathrm{Tr}(\tilde{A}^5 - \tilde{\tilde{A}}^5), \\
\tilde{\Omega} &= e^{\delta}\Omega^4.
\end{aligned}
\tag{VI.66}
$$

To see that the above equation characterizes indeed the gauge anomaly, let us write it in components. Expanding $\tilde{\Omega}$ in the global parameters $(e^{\alpha},\overline{e}^{\dot{\alpha}},\tilde{e}^{\dot{\alpha}}_{\alpha})$,

$$
\tilde{\Omega} = \Omega^4 + \Omega^{3\alpha}e_{\alpha} + \overline{\Omega}^3_{\dot{\alpha}}\overline{e}^{\dot{\alpha}} + \tilde{\Omega}^{3\alpha}_{\dot{\alpha}}\tilde{e}^{\dot{\alpha}}_{\alpha} + \tilde{\Omega}^{2a}_{\dot{\alpha}}e_{\alpha}\overline{e}^{\dot{\alpha}} + \Omega^{2\alpha}\tilde{e}_{\alpha\dot{\alpha}}\overline{e}^{\dot{\alpha}} + \overline{\Omega}^2_{\dot{\alpha}}e^{\alpha}\tilde{e}^{\dot{\alpha}}_{\alpha} + \Omega^1 e^{\alpha}\tilde{e}_{\alpha\dot{\alpha}}\overline{e}^{\dot{\alpha}},
\tag{VI.67}
$$

and eliminating the G and R terms as done in Sec. IV A, we get the known descent equations for the superspace gauge anomaly,[18,25]

$$
\begin{aligned}
s\Omega^1 &= D^{\alpha}\Omega^2_{\alpha} + \overline{D}_{\dot{\alpha}}\Omega^{2\dot{\alpha}}, \\
s\Omega^2_{\alpha} &= -\overline{D}^2\Omega^3_{\alpha} + (2\overline{D}_{\dot{\alpha}}D_{\alpha} + D_{\alpha}\overline{D}_{\dot{\alpha}})\overline{\Omega}^{3\dot{\alpha}} + 2\,\mathrm{Tr}((D_{\alpha}\overline{D}_{\dot{\alpha}}\overline{c})(\overline{c}\overline{D}^{\dot{\alpha}}\overline{c} + \overline{D}^{\dot{\alpha}}\overline{cc})), \\
s\overline{\Omega}^{2\dot{\alpha}} &= D^2\overline{\Omega}^{3\dot{\alpha}} - (2D^{\alpha}\overline{D}_{\dot{\alpha}} + \overline{D}_{\dot{\alpha}}D^{\alpha})\Omega^3_{\alpha} - 2\,\mathrm{Tr}((\overline{D}^{\dot{\alpha}}D^{\alpha}c)(cD_{\alpha}c + D_{\alpha}cc)), \\
s\Omega^3_{\alpha} &= D_{\alpha}\Omega^4 + \mathrm{Tr}(c^3 D_{\alpha}c), \\
s\overline{\Omega}^{3\dot{\alpha}} &= -\overline{D}^{\dot{\alpha}}\Omega^4 + \mathrm{Tr}(\overline{c}^3\overline{D}^{\dot{\alpha}}\overline{c}), \\
s\Omega^4 &= \tfrac{1}{5}\mathrm{Tr}(c^5 - \overline{c}^5).
\end{aligned}
\tag{VI.68}
$$

One sees, in particular, that integrating the first equation of (VI.68) on superspace, the cocycle Ω^1 obeys exactly the BRS consistency condition corresponding to the possible gauge breakings,

$$
s\int d^4x\, d^2\theta\, d^2\overline{\theta}\,\Omega^1 = 0,
$$

identifying therefore Ω^1 with the supersymmetric Yang–Mills anomaly.

In order to find a solution of the descent equations (VI.68), we use the same climbing procedure of the previous examples, obtaining the following nontrivial expressions:

$$
\begin{aligned}
\Omega^3_{\alpha} &= -\zeta^{\alpha}\Omega^4 - \mathrm{Tr}(\varphi^{\alpha}c^3), \\
\overline{\Omega}^{3\dot{\alpha}} &= \overline{\zeta}_{\dot{\alpha}}\Omega^4 - \mathrm{Tr}(\overline{\varphi}_{\dot{\alpha}}\overline{c}^3), \\
\Omega^2_{\alpha} &= G_{\alpha\dot{\alpha}}\overline{\zeta}^{\alpha}\Omega^4 + \overline{D}_{\dot{\alpha}}\tilde{\overline{\zeta}}^{\dot{\alpha}}\zeta_{\alpha}\Omega^4 - \mathrm{Tr}(\overline{\varphi}_{\dot{\alpha}}(D_{\alpha}\overline{\varphi}^{\dot{\alpha}})\overline{c}^2 - \overline{\varphi}_{\dot{\alpha}}\overline{c}(D_{\alpha}\overline{\varphi}^{\dot{\alpha}})\overline{c} + \overline{\varphi}_{\dot{\alpha}}\overline{c}^2 D_{\alpha}\overline{\varphi}^{\dot{\alpha}}) \\
&\quad + 2\,\mathrm{Tr}((D_{\alpha}\overline{\varphi}_{\dot{\alpha}})(\overline{c}\overline{D}^{\dot{\alpha}}\overline{c} + \overline{D}^{\dot{\alpha}}\overline{cc})), \\
\overline{\Omega}^{2\dot{\alpha}} &= G^{\alpha\dot{\alpha}}\zeta_{\alpha}\Omega^4 + D^{\alpha}\zeta^{\dot{\alpha}}\zeta_{\alpha}\Omega^4 + \mathrm{Tr}(\varphi^{\alpha}(\overline{D}^{\dot{\alpha}}\varphi_{\alpha})\overline{c}^2 - \varphi^{\alpha}\overline{c}(\overline{D}^{\dot{\alpha}}\varphi_{\alpha})\overline{c} + \varphi^{\alpha}\overline{c}^2\overline{D}^{\dot{\alpha}}\varphi_{\alpha}) \\
&\quad - 2\,\mathrm{Tr}((\overline{D}^{\dot{\alpha}}\varphi_{\alpha})(cD_{\alpha}c + D_{\alpha}cc)),
\end{aligned}
\tag{VI.69}
$$

and for the gauge anomaly,

$$\Omega^1 = 2\zeta^\alpha G_{\alpha\dot\alpha}\overline{\zeta}^{\dot\alpha}\Omega^4 + 2\,\mathrm{Tr}(F^\alpha c\varphi_\alpha - F^\alpha\varphi_\alpha c + (\overline{D}_{\dot\alpha}\varphi^\alpha)(\overline{D}^{\dot\alpha}\varphi_\alpha)c)$$
$$-2\,\mathrm{Tr}(\overline{F}_{\dot\alpha}\overline{c}\overline{\varphi}^{\dot\alpha} - \overline{F}_{\dot\alpha}\overline{\varphi}^{\dot\alpha}\overline{c} + (D^\alpha\overline{\varphi}_{\dot\alpha})(D_\alpha\overline{\varphi}^{\dot\alpha})\overline{c}). \tag{VI.70}$$

One should observe that the explicit final expression for the gauge anomaly depends on the knowledge of the cocycle Ω^4 solution of the last of the descent equations (VI.68). This point is particularly important and deserves some further clarifying remarks.

A. Nonpolynomial character of the gauge anomaly

It is known that due to a theorem by Ferrara, Girardello, Piguet, and Stora,[26] the superspace gauge anomaly cannot be expressed as a polynomial in the variables $(\varphi_\alpha, \lambda_\alpha \equiv e^\varphi D_\alpha e^{-\varphi})$ and their covariant derivatives. In fact, all the known superspace closed expressions of the gauge anomaly so far obtained by means of homotopic transgression procedures[27–30] show up as a highly nonpolynomial character in the gauge superconnection. On the other hand, in our approach the simple knowledge of the cocycle Ω^4 would produce a closed expression for the supersymmetric gauge anomaly without any homotopic integral. Of course, this would imply a deeper understanding of this anomaly. It is not difficult, however, to convince oneself that solving the equation

$$s\Omega^4 = \tfrac{1}{5}\mathrm{Tr}(c^5 - \overline{c}^5) \tag{VI.71}$$

is not an easy task. This is actually due to the BRS transformation of the vector superfield ϕ,

$$se^\phi = e^\phi c - \overline{c}e^\phi,$$

which when written in terms of ϕ, takes the highly complex form[24]

$$s\phi = \frac{1}{2}\mathcal{L}_\phi(c+\overline{c}) + \frac{1}{2}\mathcal{L}_\phi\left[\coth\left(\frac{\mathcal{L}_\phi}{2}\right)\right](c-\overline{c}), \tag{VI.72}$$

where

$$\mathcal{L}_\phi \cdot = [\phi, \cdot],$$

and

$$\coth\left(\frac{\mathcal{L}_\phi}{2}\right) = \frac{e^{\mathcal{L}_\phi/2} + e^{-\mathcal{L}_\phi/2}}{e^{\mathcal{L}_\phi/2} - e^{-\mathcal{L}_\phi/2}}.$$

The formula (VI.72) can be expanded in powers of ϕ, allowing us to solve the equation (VI.71) order by order in the vector superfield ϕ. For instance, in the first approximation, which corresponds to the Abelian limit of retaining only the linear terms of the BRS transformations, i.e.,

$$s \to s_{ab},$$

with

$$s_{ab}\phi = c - \overline{c},$$

$$s_{ab}c = s_{ab}\overline{c} = 0,$$

one easily checks that

$$\mathrm{Tr}(c^5 - \overline{c}^5) = s_{ab}\,\mathrm{Tr}(\phi(c^4 + c^3\overline{c} + c^2\overline{c}^2 + c\overline{c}^3 + \overline{c}^4)), \tag{VI.73}$$

which shows indeed the BRS triviality[1] of $\mathrm{Tr}(c^5-\overline{c}^5)$.

To our knowledge a closed exact form for Ω^4 has not yet been established. In other words, due to the theorem of Ferrara, Girardello, Piguet, and Stora,[26] the nonpolynomiality of the supersymmetric gauge anomaly directly relies on the nonpolynomial nature of the cocycle Ω^4. Any progress in this direction will be reported as soon as possible.

Let us conclude this section by giving the explicit expression of the gauge anomaly (VI.70) up to the second order in the vector field ϕ, i.e.,

$$\Omega^1=-2\,\mathrm{Tr}(D^\alpha\phi\overline{D}^2D_\alpha\phi c+\overline{D}^2D^\alpha\phi D_\alpha\phi c-(\overline{D}_{\dot\alpha}D^\alpha\phi)(\overline{D}^{\dot\alpha}D_\alpha\phi)c)+2\,\mathrm{Tr}(\overline{D}_{\dot\alpha}\phi D^2\overline{D}^{\dot\alpha}\phi\overline{c}+D^2\overline{D}_{\dot\alpha}\phi\overline{D}^{\dot\alpha}\phi\overline{c}-(D^\alpha\overline{D}_{\dot\alpha}\phi)(D_\alpha\overline{D}^{\dot\alpha}\phi)\overline{c}), \tag{VI.74}$$

which is easily recognized to be equivalent to that of Ref. 18. One should also observe that the above expressions do not receive contributions from the term Ω^4 since they are at least of the order three in ϕ, as it can be checked by applying the combination $\zeta^\alpha G_{\alpha\dot\alpha}\overline{\zeta}^{\dot\alpha}$ on the cocycle of Eq. (VI.73).

VII. CONCLUSION

The supersymmetric version of the descent equations for the four-dimensional $N=1$ super-Yang–Mills gauge theories can be analyzed by means of the introduction of two operators, ζ^α and $\overline{\zeta}^{\dot\alpha}$, which decompose the supersymmetric derivatives D^α and $\overline{D}^{\dot\alpha}$ as BRS commutators. These operators provide an algebraic setup for a systematic derivation of the superspace descent equations. In addition, they allow us to cast both the supersymmetric BRS transformations and the descent equations into a very suggestive zero curvature formalism in superspace.

APPENDIX A

We list here the superspace algebraic solutions[18,19,24,31] of some equations needed for the analysis of the supersymmetric descent equations. All these solutions are built up by superfields. They have always to be understood modulo terms that automatically solve the corresponding equations but cannot be written in the same algebraic form as the solutions. The existence of such particular terms strongly depends on the superfield content of the particular model under consideration.

The first result states that the solution of the superspace equation,

$$\overline{D}^2Q=0,$$

can be generically written as

$$Q=\overline{D}_{\dot\alpha}\mathcal{M}^{\dot\alpha},$$

for some superfield $\mathcal{M}^{\dot\alpha}$.

The second important result concerns the solution of the following equation:

$$(2\overline{D}_{\dot\alpha}D_\alpha+D_\alpha\overline{D}_{\dot\alpha})\overline{Q}^{\dot\alpha}=\overline{D}^2Q_\alpha.$$

For the superfields $\overline{Q}^{\dot\alpha}$ and Q_α, we have now

$$\overline{Q}^{\dot\alpha}=\overline{D}^{\dot\alpha}\mathcal{M}, \quad Q_a=-D_\alpha\mathcal{M},$$

with $\mathcal{M}$ an arbitrary superfield. Let us observe that in this case the term $\mathrm{Tr}(cD_\alpha c)$, due to the fact that the ghost c is a chiral superfield, is automatically annihilated by the operator $\overline{D}^2$. Therefore it must be included in the expression given for Q_α, although it cannot be written as a total superspace derivative.

Considering now the equation

$$D^\alpha Q_\alpha=\overline{D}_{\dot\alpha}\overline{Q}^{\dot\alpha},$$

we have

$$\begin{aligned} Q_\alpha&=-\overline{D}^2\mathcal{P}_\alpha+(2\overline{D}_{\dot\alpha}D_\alpha+D_\alpha\overline{D}_{\dot\alpha})\overline{\mathcal{P}}^{\dot\alpha}+D^\beta\mathcal{N}_{(\alpha\beta)},\\ \overline{Q}^{\dot\alpha}&=-D^2\overline{\mathcal{P}}^{\dot\alpha}+(2D^\alpha\overline{D}^{\dot\alpha}+\overline{D}^{\dot\alpha}D^\alpha)\mathcal{P}_\alpha+\overline{D}_{\dot\beta}\overline{\mathcal{N}}^{(\dot\alpha\dot\beta)}, \end{aligned} \tag{A1}$$

with $\mathcal{P}_\alpha$ and $\mathcal{N}_{(\alpha\beta)}$ appropriate superfields. Of course, the existence of the symmetric superfield $\mathcal{N}_{(\alpha\beta)}$ depends on the dimension and on the ghost number of Q_α. For instance, in the case of the vector descent equations (IV.53) in which Q_α corresponds to $s(\omega^1_\alpha+\frac{1}{2}\Lambda^1_\alpha)$, it is not difficult to check that $\mathcal{N}_{(\alpha\beta)}$ is automatically absent due to the quantum numbers of the problem.

In particular, in the case of the chiral descent equations considered in Sec. V, Eqs. (A1) imply that the most general solution of Eq. (V.56) is given indeed by

$$s\overline{K}^{1\dot\alpha}=(\overline{D}^{\dot\alpha}D^\alpha+2D^\alpha\overline{D}^{\dot\alpha})K^2_\alpha,$$

with the constraint

$$\overline{D}^2K^2_\alpha=0.$$

APPENDIX B

In this appendix we summarize some useful results concerning the BRS superspace cohomology for the $N=1$ supersymmetric Yang–Mills gauge theories. The various BRS cohomolgy classes are labeled by the ghost number g and by the spinor indices.

The following results hold.[18,19,25]

(1) The BRS cohomology is empty in the space of the invariant local power series A^g with dimension 2 and positive ghost number g.

(2) The cohomology classes corresponding to local BRS invariant cocycles A^g_α or $\overline{A}^g_{\dot\alpha}$ with dimension $\frac{3}{2}$ and ghost number $g=1$, 2, or 3 are empty.

(3) The cohomology classes in the space of the BRS-invariant local power series A^g_α or $\overline{A}^g_{\dot\alpha}$ with dimension $\frac{1}{2}$ and ghost number g greater than zero are empty.

(4) The BRS cohomology classes in the space of the local power series A^g with dimension 0, ghost number g, and at least of order $g+1$ in the fields are empty.

(5) Any invariant object A^g with dimension 0 and even ghost number g greater than zero and of order g in the fields is BRS trivial.

In particular, it turns out that in the pure ghost sector the BRS cohomology classes are given by polynomials built up with monomials of the type

$$\mathrm{Tr}\frac{c^{2n+1}}{2n+1}, \quad n\geqslant 1, \tag{B1}$$

or

$$\mathrm{Tr}\frac{\bar{c}^{2n+1}}{2n+1}, \quad n \geqslant 1. \tag{B2}$$

We remark also that the two expressions above (B1) and (B2) do not actually define different cohomology classes. Instead they are equivalent, due to the triviality[18,24] of the combination,

$$\mathrm{Tr}\frac{c^{2n+1}}{2n+1} - \mathrm{Tr}\frac{\bar{c}^{2n+1}}{2n+1} = s\Omega^{2n},$$

for some local power series Ω^{2n}. This result implies that the expressions (B1) and (B2) are related to each other by means of an exact BRS cocycle.

APPENDIX C

In this appendix we show that the off-shell closure of the algebra (IV.28) can be recovered in a simple way by introducing an appropriate external field η. Indeed, let η be a superfield with dimension 2 and ghost number -1, whose BRS transformation reads as

$$s\eta = [\eta, c] + 2(DF + [\varphi, F]),$$

$$s^2\eta = 0.$$

Modifying now the operator ζ in such a way that

$$\zeta F = -\tfrac{1}{2}\eta,$$

it is easily verified that the commutator (IV.37)

$$[\zeta, s]F = -\zeta[c, F] + \tfrac{1}{2}s\eta = DF,$$

gives now the covariant derivative of F without making use of the equations of motion, closing therefore the algebra (IV.28) off shell. Let us conclude by also remarking that the external field η cannot contribute to the BRS cohomology classes relevant for the examples considered in the previous sections due to its ghost number and to its dimension.

APPENDIX D

This appendix is devoted to some technical details concerning the introduction of the global parameters e^{α}, $\overline{e^{\dot{\alpha}}}$, and $\tilde{e}^{\alpha\dot{\alpha}}$. As it has been already underlined, these parameters have been introduced in order to project the algebraic relations (II.16)–(III.24) on the equations of motion of $N=1$ super-Yang–Mills. This has been achieved by requiring that the conditions (IV.26) are fulfilled. In addition, as it is apparent from the construction of Sec. IV, the introduction of these global parameters, while collecting all the algebraic relations (II.16)–(III.24) into a unique extended generalized operator $\tilde{d}$ [see Eq. (IV.31)], is of great relevance in order to cast the BRS transformations of the superfields and the full system of superspace consistency conditions (IV.53), (V.59), and (VI.68) into a unique equation. The latter has the meaning of a zero-curvature condition [see Eqs. (IV.34)–(IV.36)). Therefore, the expansion of the equation,

$$\tilde{d}\tilde{\omega} = 0,$$

in powers of the global parameters $(e^{\alpha}, \overline{e}^{\dot{\alpha}}, \tilde{e}^{\alpha\dot{\alpha}})$, will automatically provide the full set of the superspace consistency conditions for the cocycle $\tilde{\omega}$. In this sense, the parameters $(e^{\alpha}, \overline{e^{\dot{\alpha}}}, \tilde{e}^{\alpha\dot{\alpha}})$ can be seen as a suitable basis in superspace for the zero curvature formulation of $N=1$ supersymmetry.

It is also worth remarking that this construction does not have the meaning of collecting into an extended BRS operator the various classical symmetries of a given gauge-fixed action, as done, for instance, in the case of the extended ($N \geqslant 2$) supersymmetric Yang–Mills theories.[22,23] [It is indeed rather simple to convince oneself that the operators $(\zeta_\alpha, \bar{\zeta}_{\dot{\alpha}})$ do not actually represent invariances of the gauge-fixed $N=1$ super-Yang–Mills action.] Rather, it is closer to the zero curvature formulation of the topological field theories discussed by Refs. 32 and 16 in terms of the so-called universal bundle.

(Received 23 October 1998; accepted for publication 1 February 1999)

We discuss Bloch and Wannier functions related to oscillator eigenfunctions. In particular, we construct complete sets of mutually orthogonal Bloch and Wannier functions. We show that they can be expressed in several ways in terms of theta functions and their derivatives. We also analyze their localization properties and discuss expectation values for specifically chosen Hamiltonians. © *1999 American Institute of Physics.* [S0022-2488(99)02406-8]

I. INTRODUCTION

Localized but nonorthogonal functions, like Gaussian orbitals, are widely used in physical applications (see, for instance, Ref. 1). In the case of periodic crystals, the most prominent and important functions for describing their electronic properties are Bloch[2,3] and Wannier[4] functions. Wannier was the first to consider Bloch and Wannier functions composed of Gaussian orbitals.[5] He showed that these Bloch functions can be expressed in terms of θ functions, which makes a detailed analysis of their properties possible.[6,7] Another recent work on these topics is Ref. 8.

However, in many applications it is not enough to use only Gaussian orbitals centered at the atomic sites. One approach is to use in addition Gaussian orbitals that are centered in between. Alternatively, one could use oscillator eigenfunctions that are all centered at the sites of the atoms. Thus, it is natural to study not only Bloch functions composed of Gaussian orbitals, but to investigate the more general case of Bloch and Wannier functions that are composed of oscillator eigenfunctions. This is particularly interesting since one can construct a complete set of mutually orthogonal Bloch and Wannier functions. Thus they may be used to expand any arbitrary Bloch function, which might go far beyond the usual expansion in terms of Gaussian orbitals. Moreover, this complete set of orthonormalized Bloch functions provides an alternative to the expansions in terms of plane waves. In fact, the plane waves can be seen as the limits of these orthonormal Bloch functions in the case that the oscillator frequency ω goes to zero (instead of ω we use the parameter $\alpha \sim \sqrt{\omega}$ in the following). Thus, particularly for small α the Bloch functions $\psi_n^\alpha(k,x)$, which are composed of oscillator eigenfunctions, are an alternative to the plane wave basis. On the other hand, for large α the Bloch functions $\psi_n^\alpha(k,x)$ are typical Bloch functions for tight-binding approximations. Thus, depending on the choice of α, these Bloch functions could be useful both in tight-binding approximations as well as in the case of nearly free electrons. The idea of constructing this complete set of mutually orthogonal Bloch and Wannier functions is the following: Since the (properly normalized) eigenfunctions form a complete orthonormal system of functions, the corresponding Bloch and Wannier functions should also form a complete basis. However, these functions are, in general, not mutually orthogonal. By applying an appropriate orthogonalization procedure, we construct a complete set of mutually orthonormal Bloch and Wannier functions.

[a]Electronic mail: zeiner@tph.tuwien.ac.at

All these considerations confine to the one-dimensional case. However, it is not difficult to generalize these ideas to the three-dimensional case. In the simplest case of primitive lattices the three-dimensional Bloch functions composed of the eigenfunctions of a three-dimensional harmonic oscillator are just products of three one-dimensional Bloch functions composed of eigenfunctions of one-dimensional harmonic oscillators.

In the first section of this paper we transform the oscillator eigenfunctions $u_n(x)$ into Bloch functions $\phi_n(k,x)$ and discuss their properties as well as the corresponding Wannier functions. In particular, we show that these Bloch and Wannier functions are, in general, not orthogonal for different values of n. In the following sections we construct complete orthonormal systems of Bloch and Wannier functions. We show that these Bloch functions can be represented in various ways in terms of θ functions and their derivatives. In particular, the k dependence can be expressed in terms of θ functions only. In addition, we discuss the localization properties of the corresponding Wannier functions and their symmetry properties, as well as certain limits and several expectation values.

II. BLOCH AND WANNIER FUNCTIONS COMPOSED OF OSCILLATOR EIGENFUNCTIONS

A. Harmonic oscillator

First we want to recall some basic properties of the harmonic oscillator. The normalized eigenfunctions of the Hamiltonian $H=(1/2m)P^2+(m\omega^2/2)X^2$ are given by

$$u_n^\alpha(x)=\sqrt{\alpha}(\sqrt{\pi}2^n n!)^{-1/2}H_n(\alpha x)e^{-\alpha^2x^2/2}, \tag{1}$$

where $\alpha=\sqrt{m\omega/\hbar}$ is the inverse of the classical amplitude for a harmonic oscillator whose energy is equal to the ground state energy $E_0=\frac{1}{2}\hbar\omega$. Here the symbols H_n denote the Hermite polynomials,[9] which are defined as follows:

$$H_n(x)=e^{x^2/2}\left(x-\frac{d}{dx}\right)^n e^{-x^2/2}=(-1)^n e^{x^2}\frac{d^n}{dx^n}e^{-x^2}. \tag{2}$$

Recall that the u_n^α are real, fulfilling the symmetry relations $u_n^\alpha(-x)=(-1)^n u_n^\alpha(x)$, and satisfying the orthonormality condition $\int_{-\infty}^{\infty}u_m^\alpha(x)u_n^\alpha(x)dx=\delta_{mn}$, respectively. For sake of simplicity, we set $\hbar=1$.

B. Bloch functions

Now we can investigate the Bloch functions that are composed of the oscillator eigenfunctions $u_n^\alpha(x)$, namely,

$$\phi_n^\alpha(k,x)=N_n^\alpha(k)\sum_{m=-\infty}^{\infty}e^{ikm}u_n^\alpha(x-m), \tag{3}$$

where $N_n^\alpha(k)$ is chosen positive and such that $\langle\phi_n^\alpha(k),\phi_n^\alpha(k)\rangle_1=\int_0^1 dx|\phi_n^\alpha(k,x)|^2=1/2\pi$. Recall that the Bloch functions for $n=0$ are given by[6]

$$\phi_0^\alpha(k,x)=\left(\frac{\alpha}{\sqrt{\pi}}\right)^{1/2}\frac{1}{\sqrt{2\pi}}e^{-\alpha^2x^2/2}\frac{\theta_3\left(\frac{k}{2}-i\frac{\alpha^2x}{2}\middle|\frac{i\alpha^2}{2\pi}\right)}{\sqrt{\theta_3\left(\frac{k}{2}\middle|\frac{i\alpha^2}{4\pi}\right)}}=\frac{1}{\sqrt{2\pi}}e^{ikx}\frac{\theta_3\left(\frac{i\pi}{\alpha^2}k+\pi x\middle|\frac{i2\pi}{\alpha^2}\right)}{\sqrt{\theta_3\left(\frac{i2\pi}{\alpha^2}k\middle|\frac{4i\pi}{\alpha^2}\right)}}, \tag{4}$$

$$N_0^\alpha(k)=\frac{1}{\sqrt{2\pi}}\frac{1}{\sqrt{\theta_3\left(\frac{k}{2}\middle|\frac{i\alpha^2}{4\pi}\right)}}=\frac{1}{\sqrt{2\pi}}\sqrt{\frac{\alpha}{\sqrt{4\pi}}}e^{k^2/2\alpha^2}\frac{1}{\sqrt{\theta_3\left(\frac{i2\pi}{\alpha^2}k\middle|\frac{4i\pi}{\alpha^2}\right)}},\tag{5}$$

where θ_3 is one of the well-known θ functions.[10–12] The Bloch functions $\phi_n^\alpha(k,x)$ can be expressed either in terms of theta functions or by the special Bloch functions $\phi_0^\alpha(k,x)$ and their derivatives:

$$\phi_n^\alpha(k,x)=N_n^\alpha(k)\left(\frac{\alpha}{\sqrt{\pi}2^n n!}\right)^{1/2}\sum_{m=-\infty}^{\infty}e^{ikm}H_n(\alpha(x-m))e^{-\alpha^2(x-m)^2/2}\tag{6a}$$

$$=N_n^\alpha(k)\left(\frac{\alpha}{\sqrt{\pi}2^n n!}\right)^{1/2}\left[\alpha\left(x+i\frac{\partial}{\partial k}\right)-\frac{1}{\alpha}\frac{\partial}{\partial x}\right]^n e^{-\alpha^2x^2/2}\theta_3\left(\frac{k}{2}-i\frac{\alpha^2x}{2}\middle|\frac{i\alpha^2}{2\pi}\right)\tag{6b}$$

$$=N_n^\alpha(k)(2^n n!)^{-1/2}\left[\alpha\left(x+i\frac{\partial}{\partial k}\right)-\frac{1}{\alpha}\frac{\partial}{\partial x}\right]^n\frac{\phi_0^\alpha(k,x)}{N_0^\alpha(k)}\tag{6c}$$

$$=N_n^\alpha(k)(2^n n!)^{-1/2}e^{ikx}\left[i\alpha\frac{\partial}{\partial k}-\frac{1}{\alpha}\left(\frac{\partial}{\partial x}+ik\right)\right]^n e^{-ikx}\frac{\phi_0^\alpha(k,x)}{N_0^\alpha(k)}\tag{6d}$$

$$=N_n^\alpha(k)\left(\frac{2\sqrt{\pi}}{\alpha 2^n n!}\right)^{1/2}e^{ikx}\left[i\alpha\frac{\partial}{\partial k}-\frac{1}{\alpha}\left(\frac{\partial}{\partial x}+ik\right)\right]^n e^{-k^2/2\alpha^2}\theta_3\left(\frac{i\pi}{\alpha^2}k+\pi x\middle|\frac{i2\pi}{\alpha^2}\right)\tag{6e}$$

$$=N_n^\alpha(k)\left(\frac{2\sqrt{\pi}}{\alpha 2^n n!}\right)^{1/2}(-i)^n e^{ikx}\sum_{m=-\infty}^{\infty}H_n\left(\frac{k+2\pi m}{\alpha}\right)e^{-(k+2\pi m)^2/2\alpha^2}e^{i2\pi mx}.\tag{6f}$$

The normalization constants $N_n^\alpha(k)$ read as

$$(N_n^\alpha(k))^{-2}=4\pi\frac{\sqrt{\pi}}{\alpha}(2^n n!)^{-1}\sum_{m=-\infty}^{\infty}H_n\left(\frac{k+2\pi m}{\alpha}\right)^2 e^{-(k+2\pi m)^2/\alpha^2}\tag{7a}$$

$$=2\pi\sum_{r=-\infty}^{\infty}L_n^0\left(\frac{\alpha^2r^2}{2}\right)e^{-\alpha^2r^2/4}e^{-ikr},\tag{7b}$$

where $L_n^\gamma(x)$ are the Laguerre polynomials[9]

$$L_n^\gamma(x)=\frac{1}{n!}e^x x^{-\gamma}\frac{d^n}{dx^n}x^{n+\gamma}e^{-x}=\sum_{m=0}^{n}\binom{n+\gamma}{n-m}\frac{(-x)^m}{m!}.\tag{8}$$

Note that Eq. (7b) is just the Fourier series of Eq. (7a).

The inner product of Bloch functions referring to different n values is easily calculated:

$$\langle\phi_m^\alpha(k),\phi_n^\alpha(k)\rangle_1=\frac{i^{m-2}2\sqrt{\pi}N_m^\alpha(k)N_n^\alpha(k)}{\alpha(2^{m+n}m!n!)^{1/2}}\sum_{r=-\infty}^{\infty}H_m\left(\frac{k+2\pi r}{\alpha}\right)H_n\left(\frac{k+2\pi r}{\alpha}\right)e^{-(k+2\pi r)^2/\alpha^2}\tag{9a}$$

$$=\frac{N_m^\alpha(k)N_n^\alpha(k)(2^n n!)^{1/2}}{(2^m m!)^{1/2}}\sum_{r=-\infty}^{\infty}(-\alpha r)^{m-n}L_n^{m-n}\left(\frac{\alpha^2r^2}{2}\right)e^{-\alpha^2r^2/4}e^{-ikr}.\tag{9b}$$

Again the second equation is the Fourier series of the first one. From Eq. (9b) we infer that the Bloch functions cannot be orthogonal for all k values. For special k, however, the Bloch functions may be orthogonal. For instance, if $k=0$ than $\langle \phi_m^\alpha(k), \phi_n^\alpha(k)\rangle_1 = 0$ if $m-n$ is odd.

Let us briefly discuss the symmetry properties of the Bloch functions ϕ_n^α. They have the following transformation properties:

$$(\phi_n^\alpha(k,x))^* = \phi_n^\alpha(-k,x), \tag{10}$$

$$\phi_n^\alpha(k,-x) = (-1)^n \phi_n^\alpha(-k,x), \tag{11}$$

which correspond to time reversal and inversion symmetry, respectively. These equations follow immediately from the fact that the oscillator eigenfunctions are real and even or odd, depending on $n=2m$ or $n=2m+1$, respectively. In terms of band representations (see Refs. 13–15) the symmetry of the Bloch functions ϕ_n^α is described as follows: For n even the Bloch functions ϕ_n^α transform according to the band representation of the only nontrivial one-dimensional space group $\mathbb{Z} \circledS C_2$, where the former is characterized by the Wyckoff position $w=0$ and the trivial one-dimensional irreducible unitary representation of the corresponding site symmetry group. For n odd the Bloch functions ϕ_n^α transform according to the band representation that is characterized by the Wyckoff position $w=0$ and the one-dimensional irreducible unitary representation $\{1,-1\}$ of C_2.

C. Wannier functions

We adopt the following convention for the Wannier functions:

$$W_n^\alpha(m;x) = W_n^\alpha(x-m) = \frac{1}{\sqrt{2\pi}} \int_{-\pi}^{\pi} dk\, e^{-ikm} \phi_n^\alpha(k,x), \tag{12}$$

which leads to the following symmetry relations $W_n^\alpha(x) = (-1)^n W_n^\alpha(-x)$. Unfortunately there is no explicit expression for the Wannier functions. Since the Bloch functions are unique only up to a phase factor, we could have also chosen

$$W_n^\alpha(m;x) = W_n^\alpha(x-m) = \frac{1}{\sqrt{2\pi}} \int_{-\pi}^{\pi} dk\, e^{-ikm} e^{i\gamma(k)} \phi_n^\alpha(k,x) \tag{13}$$

to define the Wannier functions, where $e^{i\gamma(k)}$ is a phase factor. This freedom of definition of the Wannier functions is exploited in Ref. 5 for $n=0$ to construct Wannier functions that can be stated explicitly. However, this is no longer possible for $n \geqslant 1$, and thus we use Eq. (12) to define the Wannier functions. For $n=0$ the Wannier functions have a remarkable property: The uncertainty of position $\Delta x = 1/2\alpha^2$ is the same for the Wannier functions and the original Gaussians.[6,7] Thus, it is interesting to see whether this result can be generalized for all n. Obviously $\langle x \rangle = 0$ holds due to the symmetry relations $W_n^\alpha(x) = (-1)^n W_n^\alpha(-x)$, and we need to compute $\langle x^2 \rangle$ only. Using several partial integrations and some well-known formulas for the Hermite polynomials,[9] we get

$$\langle x^2\rangle_{W_n^\alpha}=\frac{2n+1}{2\alpha^2}-\frac{n}{2\pi\alpha^2}\int_{-\pi}^{\pi}dk\,\frac{\sum_{m=-\infty}^{\infty}e^{-(k+2\pi m)^2/\alpha^2}H_{n-1}\left(\frac{k+2\pi m}{\alpha}\right)H_{n+1}\left(\frac{k+2\pi m}{\alpha}\right)}{\sum_{m=-\infty}^{\infty}e^{-(k+2\pi m)^2/\alpha^2}H_n\left(\frac{k+2\pi m}{\alpha}\right)^2} \tag{14a}$$

$$=\frac{2n+1}{2\alpha^2}+\frac{1}{4\pi\alpha^2}\int_{-\pi}^{\pi}dk\,\frac{\sum_{m=-\infty}^{\infty}(\alpha m)^2L_{n-1}^2\left(\frac{\alpha^2m^2}{2}\right)e^{-\alpha^2m^2/4}e^{-ikm}}{\sum_{m=-\infty}^{\infty}L_n^0\left(\frac{\alpha^2m^2}{2}\right)e^{-\alpha^2m^2/4}e^{-ikm}}, \tag{14b}$$

where the second equation is obtained by expanding the integrand into a Fourier series. Apparently $\langle x^2\rangle_{W_n^\alpha}\neq\langle x^2\rangle_{u_n^\alpha}$ and, in fact, numerical calculations suggest that $\langle x^2\rangle_{W_n^\alpha}>\langle x^2\rangle_{u_n^\alpha}$ is valid for arbitrary α, but it is an open question how to prove this statement analytically.

For large α we get the following approximation:

$$\langle x^2\rangle_{W_n^\alpha}=\frac{2n+1}{2\alpha^2}-L_{n-1}^2\left(\frac{\alpha^2}{2}\right)L_n^0\left(\frac{\alpha^2}{2}\right)e^{-\alpha^2/2}+O(\alpha^{8n-2}e^{-\alpha^2}), \tag{15}$$

hence we have, in fact, $\langle x^2\rangle_{W_n^\alpha}>\langle x^2\rangle_{u_n^\alpha}$ for sufficiently large α. For sufficiently small α the following heuristic arguments apply. The main problem are the zeros of the Hermite polynomials. Consider the integral in Eq. (14a). Of course, it would be quite tentative to neglect all terms with $m\neq0$, but in this approximation the denominator would have a zero of second order, and thus the integral would diverge. So we have to take into account also the terms for $m=\pm1$, and the denominator reads in this approximation as

$$e^{-k^2/\alpha^2}H_n\left(\frac{k}{\alpha}\right)^2+e^{-(k-2\pi)^2/\alpha^2}H_n\left(\frac{k-2\pi}{\alpha}\right)^2+e^{-(k+2\pi)^2/\alpha^2}H_n\left(\frac{k+2\pi}{\alpha}\right)^2.$$

Let us assume $n=1$ for simplicity. Then the only zero of the Hermite polynomial $H_1(x)=x$ is $x=0$. Hence, for $|k/\alpha|\lesssim e^{-2\pi^2/\alpha^2}$ the denominator is of order $e^{-(2\pi)^2/\alpha^2}$. On the other hand, for $|k/\alpha|\gtrsim e^{-2\pi^2/\alpha^2}$ we may neglect all terms with $m\neq0$, and hence the integrand may be approximated by $H_{n-1}(k/\alpha)H_{n+1}(k/\alpha)/H_n(k/\alpha)^2$, which should contribute less to the integral than the interval $|k/\alpha|\lesssim e^{-2\pi^2/\alpha^2}$. Thus, we infer that the integral in question is of order $\sim O(e^{2\pi^2/\alpha^2})$. In fact, the term of order $\sim O(e^{2\pi^2/\alpha^2})$ is positive, since $H_0(0)H_2(0)<0$. Hence $\langle x^2\rangle_{W_1^\alpha}\sim O(e^{2\pi^2/\alpha^2})\gg3/2\alpha^2$. Similarly, for all $n>1$ the main contributions to the integral arise from the zeros of the Hermite polynomial H_n, and are again approximately of order $O(e^{2\pi^2/\alpha^2})$. Again the integral is negative, since $H_{n-1}(x)H_{n+1}(x)<0$ for $H_n(x)=0$.

D. The limit $\alpha\to0$

The limits of the Bloch functions ϕ_n^α read as

$$\phi_n^0(k,x):=\lim_{\alpha\to0}\phi_n^\alpha(k,x)=\begin{cases}(-1)^{n/2}\frac{1}{\sqrt{2\pi}}e^{ikx}, & \dot{k}\in(-\pi,\pi)\setminus\{0\},\\ \frac{1}{\sqrt{2\pi}}, & k=0,\\ (-1)^{n/2}\frac{1}{\sqrt{\pi}}\cos(\pi x), & k=\pm\pi,\end{cases} \tag{16}$$

if n is even, and

$$\phi_n^0(k,x) := \lim_{\alpha\to 0} \phi_n^\alpha(k,x) = \begin{cases} -i^n \frac{1}{\sqrt{2\pi}} e^{ikx}, & k\in(0,\pi), \\ i^n \frac{1}{\sqrt{2\pi}} e^{ikx}, & k\in(-\pi,0), \\ (-1)^{(n-1)/2} \frac{1}{\sqrt{\pi}} \sin(2\pi x), & k=0, \\ (-1)^{(n-1)/2} \frac{1}{\sqrt{\pi}} \sin(\pi x), & k=\pm\pi, \end{cases} \tag{17}$$

for n odd. Convergence is uniform with respect to x and uniform with respect to k in the intervals $[-\pi+\epsilon,-\epsilon]$ and $[\epsilon,\pi-\epsilon]$. Note that except for $k=0,\pi$ the Bloch functions $\phi_n^\alpha(k,x)$ converge for all n to the same free electron wave function (up to a phase factor). Thus the limit Bloch functions do not form a complete set of Bloch functions, whereas for all $\alpha>0$ the Bloch functions $\{\phi_n^\alpha(k)\}$ form a complete (but not orthogonal) basis.

The limits of the corresponding Wannier functions are given by

$$W_{2m}^0(x) := \lim_{\alpha\to 0} W_{2m}^\alpha(x) = (-1)^m \frac{\sin \pi x}{\pi x}, \tag{18}$$

$$W_{2m+1}^0(x) := \lim_{\alpha\to 0} W_{2m+1}^\alpha(x) = 2(-1)^m \frac{\left(\sin \frac{\pi x}{2}\right)^2}{\pi x}. \tag{19}$$

III. ORTHONORMALIZED BLOCH FUNCTIONS

A. Bloch functions

We have discussed the Bloch functions composed of oscillator eigenfunctions in the preceding sections and we have seen that Bloch functions of different n values are for any given $k\in(-\pi,\pi)$, in general, not orthogonal, contrary to the oscillator eigenfunctions. In the following sections we want to construct and discuss a complete set of orthonormal Bloch functions composed of oscillator eigenfunctions. One way of constructing an orthonormal set is to apply the Gram–Schmidt procedure onto the Bloch functions $\phi_n^\alpha(k,x)$ of the preceding sections. Since the Hermite polynomials H_n are polynomials of degree n, the Bloch functions $\phi_n^\alpha(k,x)$ are just linear combinations of the following (not normalized) Bloch functions:

$$\chi_\ell^\alpha(k,x) = (-i)^\ell \sum_{m=-\infty}^{\infty} \left(\frac{k+2\pi m}{\alpha}\right)^\ell e^{-(k+2\pi m)^2/2\alpha^2} e^{i(k+2\pi m)x} \tag{20a}$$

$$= \left(-\frac{1}{\alpha}\frac{\partial}{\partial x}\right)^\ell \chi_0^\alpha(k,x) = \left(-\frac{1}{\alpha}\frac{\partial}{\partial x}\right)^n e^{ikx} e^{-k^2/2\alpha^2} \theta_3\left(\frac{i\pi^k}{\alpha^2}+\pi x \middle| \frac{i2\pi}{\alpha^2}\right), \tag{20b}$$

with $\ell=0,...,n$. Thus, we can alternatively apply the Gram–Schmidt procedure to the functions $\chi_n^\alpha(k,x)$. Then the orthogonalized Bloch functions read as

$$\eta_n^\alpha(k,x) = \det Q_n^\alpha(k,x), \tag{21}$$

where $Q_n^\alpha(k,x)$ is the $(n+1)\times(n+1)$ matrix with matrix elements $q_{n;m,\ell}^\alpha(k)$,

$$q^{\alpha}_{n;m,\ell}(k)=\langle \chi^{\alpha}_{m}(k),\chi^{\alpha}_{\ell}(k)\rangle_1, \quad \text{for } m=0,...,n-1, \quad \ell=0,...,n, \tag{22a}$$

$$q^{\alpha}_{n;n,\ell}(k,x)=\chi^{\alpha}_{\ell}(k,x), \quad \ell=0,\dots,n, \tag{22b}$$

where $\langle f,g\rangle_1$ denotes the inner product $\int_0^1 f^*(x)g(x)dx$. The norm of $\eta^{\alpha}_n(k,x)$ is easily calculated:

$$\|\eta^{\alpha}_n(k)\|=\sqrt{\Delta^{\alpha}_{n-1}(k)\Delta^{\alpha}_n(k)}, \tag{23}$$

where $\Delta^{\alpha}_n(k)=\det(\langle\chi^{\alpha}_j(k),\chi^{\alpha}_{\ell}(k)\rangle_1)_{j,\ell=0,...,n}$ denotes the Gramian determinant. To obtain an explicit expression for $\psi^{\alpha}_n(k,x)$, we note that

$$\langle \chi^{\alpha}_j(k),\chi^{\alpha}_{\ell}(k)\rangle_1=(-i)^{\ell-j}\sum_{m=-\infty}^{\infty}\left(\frac{k+2\pi m}{\alpha}\right)^{j+\ell} e^{-(k+2\pi m)^2/\alpha^2} \tag{24a}$$

$$=(-1)^j\left(-\frac{1}{\alpha}\frac{\partial}{\partial y}\right)^{j+\ell}\sum_{m=-\infty}^{\infty} e^{-(k+2\pi m)^2/\alpha^2}e^{i(k+2\pi m)y}\Bigg|_{y=0} \tag{24b}$$

is valid. Now $\eta^{\alpha}_n(k,x)$ can be written as

$$\eta^{\alpha}_n(k,x)=(-i)^n\frac{1}{n!}\left(\frac{2\pi}{\alpha}\right)^{n^2}\sum_{m_0=-\infty}^{\infty}\cdots\sum_{m_n=-\infty}^{\infty}\left(\prod_{j=0}^{n-1} e^{-(k+2\pi m_j)^2/\alpha^2}\right)e^{-(k+2\pi m_n)^2/2\alpha^2}$$
$$\times\prod_{n-1\geqslant j>\ell\geqslant 0}(m_j-m_\ell)\prod_{n\geqslant j>\ell\geqslant 0}(m_j-m_\ell)e^{i(k+2\pi m_n)^x}, \tag{25}$$

where we have made use of Vandermonde's determinant, which reads as follows:

$$\det\begin{pmatrix} 1 & 1 & \cdots & 1\\ x_0 & x_1 & \cdots & x_n\\ x_0^2 & x_1^2 & \cdots & x_n^2\\ \vdots & \vdots & & \vdots\\ x_0^n & x_1^n & \cdots & x_n^n\end{pmatrix}=\prod_{i>j}(x_i-x_j). \tag{26}$$

Similarly, we obtain

$$\Delta^{\alpha}_n(k)=\frac{(2\pi)^{n(n+1)}}{(n+1)!\,\alpha^{n(n+1)}}\sum_{m_0=-\infty}^{\infty}\cdots\sum_{m_n=-\infty}^{\infty}\left(\prod_{j=0}^{n} e^{-(k+2\pi m_j)^2/\alpha^2}\right)\left[\prod_{n\geqslant j>\ell\geqslant 0}(m_j-m_\ell)\right]^2. \tag{27}$$

There are several transformation rules for the Bloch functions $\eta^{\alpha}_n(k,x)$. For instance, by changing the summation indices appropriately we see immediately that $\eta^{\alpha}_n(k,x)$ are periodic functions:

$$\eta^{\alpha}_n(k+2\pi,x)=\eta^{\alpha}_n(k,x). \tag{28}$$

Also, the following quasiperiodicity properties can be easily proved:

$$\eta^{\alpha}_n(k+i\alpha^2,x)=e^{(n+1/2)\alpha^2}e^{-(2n+1)ik}e^{-\alpha^2 x}\eta^{\alpha}_n(k,x), \tag{29}$$

$$\eta^{\alpha}_n(k,x+1)=e^{ik}\eta^{\alpha}_n(k,x), \tag{30}$$

$$\eta_n^\alpha\left(k+i\,\frac{\alpha^2}{2},x+\frac{1}{2}\right)=e^{(n+1/2)(\alpha^2/4)}e^{-ink}e^{-(\alpha^2/2)(x+1/2)}\,\eta_n^\alpha(k,x). \tag{31}$$

In addition, $\eta_n^\alpha(k,x)$ have the following symmetry properties:

$$\eta_n^\alpha(k,-x)=(-1)^n\,\eta_n^\alpha(-k,x), \tag{32}$$

$$(\eta_n^\alpha(k,x))^*=\eta_n^\alpha(-k,x), \tag{33}$$

which are the analogs of Eqs. (11) and (10). Thus, the Bloch functions $\eta_n^\alpha(k,x)$ transform according to the same band representations as the nonorthogonalized Bloch functions $\phi_n^\alpha(k,x)$.

The equations (28) and (29) are crucial since they determine the k dependence of the Bloch functions nearly completely. It is shown in Appendix A 1 that a function with the properties (28) and (29) can be written as

$$\eta_n^\alpha(k,x)=e^{ikx}e^{-[(2n+1)/2\alpha^2]k^2}\sum_{r=-n}^{n}d_r^{\alpha,n}(x)\,\theta_3\left(\frac{i\pi}{\alpha^2}k+\frac{\pi}{2n+1}(x-r)\,\middle|\,i\,\frac{2\pi}{(2n+1)\alpha^2}\right), \tag{34}$$

where the functions $d_r^{\alpha,n}(x)$ are independent of k. Note the simple structure of $\eta_n^\alpha(k,x)$ with respect to k: It is a sum of $2n+1$ theta functions multiplied by a Gaussian $e^{-[(2n+1)/2\alpha^2]k^2}$ and the plane wave factor e^{ikx}. Only the dependence on x is rather complicated. Next we take Eq. (30) into account and infer

$$d_r^{\alpha,n}(x+1)=d_{r-1}^{\alpha,n}(x). \tag{35}$$

Hence $d_r^{\alpha,n}(x)$ may be expressed by $d_0^{\alpha,n}(x)$, and thus we have

$$\eta_n^\alpha(k,x)=e^{ikx}e^{-[(2n+1)/2\alpha^2]k^2}\sum_{r=-n}^{n}d_0^{\alpha,n}(x-r)\,\theta_3\left(\frac{i\pi}{\alpha^2}k+\frac{\pi}{2n+1}(x-r)\,\middle|\,i\,\frac{2\pi}{(2n+1)\alpha^2}\right). \tag{36}$$

From Eqs. (31), (32), and (33) we infer the following properties of $d_0^{\alpha,n}(x)$:

$$d_0^{\alpha,n}(x+n+\tfrac{1}{2})=d_0^{\alpha,n}(x), \tag{37}$$

$$d_0^{\alpha,n}(-x)=(-1)^n d_0^{\alpha,n}(x), \tag{38}$$

$$(d_0^{\alpha,n}(x))^*=d_0^{\alpha,n}(x). \tag{39}$$

Let us determine the function $d_0^{\alpha,n}(x)$. To this end, note that $\eta_n^\alpha(k,x)$ is a linear combination of the $2n+1$ functions $\theta_3((i\pi/\alpha^2)k+[\pi/(2n+1)](x-r)|i[2\pi/(2n+1)\alpha^2])$ with the coefficients $d_0^{\alpha,n}(x-r)$, which are independent of k. Determining the function $d_0^{\alpha,n}(x)$ is, of course, equivalent to compute the $2n+1$ coefficients $d_0^{\alpha,n}(x-r)$. Thus, we need $2n+1$ equations for the coefficients $d_0^{\alpha,n}(x-r)$. These can be obtained from Eq. (36) by choosing $2n+1$ values for k. A convenient choice is $k=i\alpha^2[s/(2n+1)]$ for $s=-n,\ldots,n$. The resulting convolution equation,

$$\eta_n^\alpha\left(i\alpha^2\frac{s}{2n+1},x\right)e^{\alpha^2[s/(2n+1)]x}e^{-\alpha^2s^2/2(2n+1)}$$
$$=\sum_{r=-n}^{n}d_0^{\alpha,n}(x-r)\,\theta_3\left(\frac{\pi}{2n+1}(x-r-s)\,\middle|\,i\,\frac{2\pi}{(2n+1)\alpha^2}\right), \tag{40}$$

can be solved easily:

$$d_0^{\alpha,n}(x-r)=\frac{1}{2n+1}\sum_{\ell=-n}^{n}\frac{e^{i[2\pi r\ell/(2n+1)]}\Sigma_{s=-n}^{n}e^{i[2\pi s\ell/(2n+1)]}e^{\alpha^2[s/(2n+1)]x}e^{-\alpha^2s^2/2(2n+1)}\eta_n^{\alpha}\left(i\alpha^2\frac{s}{2n+1},x\right)}{\Sigma_{s=-n}^{n}e^{i[2\pi s\ell/(2n+1)]}\theta_3\left(\frac{\pi}{2n+1}(x-s)\middle|i\frac{2\pi}{(2n+1)\alpha^2}\right)} \tag{41}$$

$$=\frac{1}{(2n+1)^2}\sum_{\ell=-n}^{n}\frac{e^{[2\pi^2/(2n+1)\alpha^2]\ell^2}\Sigma_{s=-n}^{n}e^{-i[2\pi(x-r-s)\ell/(2n+1)]}e^{\alpha^2[s/(2n+1)]x}e^{-\alpha^2s^2/2(2n+1)}\eta_n^{\alpha}\left(i\alpha^2\frac{s}{2n+1},x\right)}{\theta_3\left(\pi x+\frac{i2\pi^2}{\alpha^2}\ell\middle|i\frac{2\pi(2n+1)}{\alpha^2}\right)}. \tag{42}$$

Various alternative expressions for $d_0^{\alpha,n}(x)$ can be obtained if one chooses, for instance, $k=\kappa+i\alpha^2[s/(2n+1)]$ in the derivation above. In particular, the choice $k=i\alpha^2[(x+s)/(2n+1)]$ yields the Fourier series for $d_0^{\alpha,n}(x)$.

A formula analogous to Eq. (36) can also be derived for the functions $\Delta_n^{\alpha}(k)$. The periodicity and quasiperiodicity properties,

$$\Delta_n^{\alpha}(k+2\pi)=\Delta_n^{\alpha}(k), \tag{43}$$

$$\Delta_n^{\alpha}\left(k+i\frac{\alpha^2}{2}\right)=e^{(n+1)(\alpha^2/4)}e^{-i(n+1)k}\Delta_n^{\alpha}(k), \tag{44}$$

imply that $\Delta_n^{\alpha}(k)$ may be written as follows:

$$\Delta_n^{\alpha}(k)=\sum_{r=0}^{n}b_r^{\alpha,n}e^{-[(n+1)/\alpha^2]k^2}\theta_3\left(\frac{i2\pi}{\alpha^2}k-\frac{\pi}{n+1}r\middle|i\frac{4\pi}{(n+1)\alpha^2}\right). \tag{45}$$

The coefficients $b_r^{\alpha,n}$ can be determined as before. Analogously the norm square $\|\eta_n^{\alpha}(k)\|^2$ can be expressed as a linear combination of θ functions:

$$\|\eta_n^{\alpha}(k)\|^2=\sum_{r=-n}^{n}c_r^{\alpha,n}e^{-[(2n+1)/\alpha^2]k^2}\theta_3\left(\frac{i2\pi}{\alpha^2}k-\frac{\pi}{2n+1}r\middle|i\frac{4\pi}{(2n+1)\alpha^2}\right), \tag{46}$$

with appropriate coefficients $c_r^{\alpha,n}$, respectively.

B. Another representation of the Bloch functions

To get more insight into the x dependence of the Bloch functions $\eta_n^{\alpha}(k,x)$, we derive another expression for them. To this end we need, in addition to Eqs. (28)–(31), the information how $\eta_n^{\alpha}(k,x)$ transforms if we replace x by $x+i(\alpha^2/2)$. This transformation law is more complicated than the other ones, since $\eta_n^{\alpha}(k,x)$ is not quasiperiodic in the complex x direction. We may write the Bloch functions $\eta_n^{\alpha}(k,x)$ as follows:

$$\eta_n^{\alpha}(k,x)=(-i)^n\frac{1}{n!}\left(\frac{2\pi}{\alpha}\right)^{n^2}e^{ikx}e^{-(n+1/2)k^2/\alpha^2}\sum_{\ell=0}^{n}a^{\alpha,n,\ell}(k)b^{\alpha,n,n-\ell}(k,x), \tag{47}$$

with the factors

$$b^{\alpha,n,\ell}(k,x) := e^{k^2/2\alpha^2} e^{-ikx} \sum_{m=-\infty}^{\infty} e^{-(k+2\pi m)^2/2\alpha^2} e^{i(k+2\pi m)x} m^{\ell}$$

$$= \frac{1}{(2i)^{\ell}} \frac{\partial^{\ell}}{\partial z^{\ell}} \theta_3\left(\frac{i\pi k}{\alpha^2} + \pi x + z \middle| \frac{2\pi i}{\alpha^2} \right) \Bigg|_{z=0}, \tag{48}$$

$$a^{\alpha,n,\ell}(k) := (-1)^{\ell} e^{n(k^2/\alpha^2)} \sum_{m_0=-\infty}^{\infty} \cdots \sum_{m_{n-1}=-\infty}^{\infty} \left(\prod_{j=0}^{n-1} e^{-(k+2\pi m_j)^2/\alpha^2} \right)$$

$$\times \left[\prod_{n-1 \geqslant j > \ell \geqslant 0} (m_j - m_{\ell}) \right]^2 \sum_{n-1 \geqslant j_1 > \cdots j_{\ell} \geqslant 0} m_{j_1} \cdots m_{j_{\ell}}. \tag{49}$$

One verifies easily that $a^{\alpha,n,\ell}(k)$ transforms according to the following rules:

$$a^{\alpha,n,\ell}\left(k + i\frac{\alpha^2}{2} \right) = a^{\alpha,n,\ell}(k), \tag{50}$$

$$a^{\alpha,n,\ell}(k+2\pi) = e^{[(2\pi)^2 n/\alpha^2]} e^{(4\pi nk/\alpha^2)} \sum_{s=0}^{\ell} \binom{n-\ell+s}{s} a^{\alpha,n,\ell-s}(k). \tag{51}$$

Thus, $a^{\alpha,n,\ell}(k)$ may be written as the following linear combination of θ functions and their derivatives (see Appendix A 2):

$$a^{\alpha,n,\ell}(k) = \sum_{p=0}^{n-1} e^{-[(2\pi)^2/n\alpha^2]p^2} e^{(4\pi/\alpha^2)kp} \sum_{s=0}^{\ell} \binom{n-\ell+s}{s} d_p^{\alpha,n,\ell-s}$$

$$\times \frac{1}{(2i)^s} \frac{\partial^s}{\partial z^s} \theta_3\left(-\frac{2\pi ink}{\alpha^2} + \frac{i4\pi^2 p}{\alpha^2} + z \middle| \frac{4\pi in}{\alpha^2} \right) \Bigg|_{z=0}. \tag{52}$$

Hence, $\eta_n^{\alpha}(k,x)$ reads as

$$\eta_n^{\alpha}(k,x) = (-i)^n \frac{1}{n!} \left(\frac{2\pi}{\alpha} \right)^{n^2} e^{ikx} e^{-k^2/2\alpha^2} \sum_{p=0}^{n-1} e^{-(n/\alpha^2)(k-2\pi p/n)^2} \sum_{q=0}^{n} d_p^{\alpha,n,n-q} \frac{1}{(2i)^q}$$

$$\times \frac{\partial^q}{\partial z^q} \left(\theta_3\left(-\frac{2\pi ink}{\alpha^2} + \frac{i4\pi^2 p}{\alpha^2} + z \middle| \frac{4\pi in}{\alpha^2} \right) \theta_3\left(\frac{i\pi k}{\alpha^2} + \pi x + z \middle| \frac{2\pi i}{\alpha^2} \right) \right) \Bigg|_{z=0}, \tag{53}$$

which is obtained by changing the summation indices appropriately: $\Sigma_{\ell=0}^{n} \Sigma_{s=0}^{\ell} = \Sigma_{q=0}^{n} \Sigma_{r=0}^{q}$, with $q = n-(\ell-s)$, $r = n-\ell$. The coefficients $d_p^{\alpha,n,\ell}$ read as

$$d_p^{\alpha,n,\ell} = e^{(2\pi p)^2/n\alpha^2} \sum_{m_0+\cdots+m_{n-1}=p}^{\infty} \left(\prod_{j=0}^{n-1} e^{-(2\pi m_j)^2/\alpha^2} \right)$$

$$\times \left[\prod_{n-1 \geqslant j > \ell \geqslant 0} (m_j - m_{\ell}) \right]^2 \sum_{n-1 \geqslant j_1 > \cdots > j_{\ell} \geqslant 0} m_{j_1} \cdots m_{j_{\ell}}, \tag{54}$$

which we can derive by comparing the Fourier coefficients of Eqs. (A17) and (49).

C. Expressions for Bloch functions suitable for large α

In the preceding sections we have derived various expressions for the Bloch functions $\eta_n^{\alpha}(k,x)$, but for numerical calculations these expressions are suitable only for small values of α. Thus, we want to derive some expressions for the orthogonalized Bloch functions, which are suitable for large α. This can be achieved by using Jacobi's transformation for θ functions. Note that it is not sufficient to apply Jacobi's transformation to the θ functions in Eqs. (36) and (53) since we still need Eq. (25) to determine the coefficients $d_n^{\alpha,n}(x-r)$ and $d_p^{\alpha,n,\ell}$, respectively. Using Jacobi's transformation we get the equations

$$\chi_n^\alpha(k,x)=\frac{\alpha}{\sqrt{2\pi}}\left(-\frac{1}{\alpha}\frac{\partial}{\partial x}\right)^n e^{-(\alpha^2/2)x^2}\theta_3\left(-\frac{k}{2}+i\frac{\alpha^2}{2}x\middle|\frac{i\alpha^2}{2\pi}\right), \tag{55}$$

$$=2^{-n/2}\frac{\alpha}{\sqrt{2\pi}}\sum_{m=-\infty}^{\infty} e^{ikm}H_n\left(\frac{\alpha}{\sqrt{2}}(x-m)\right)e^{-(\alpha^2/2)(x-m)^2} \tag{56}$$

and

$$\langle\chi_j^\alpha(k),\chi_\ell^\alpha(k)\rangle_1=(-1)^j\frac{\alpha}{\sqrt{4\pi}}\left(-\frac{1}{\alpha}\frac{\partial}{\partial y}\right)^{j+\ell} e^{-(\alpha^2/4)y^2}\theta_3\left(-\frac{k}{2}+i\frac{\alpha^2}{4}y\middle|\frac{i\alpha^2}{4\pi}\right)\Bigg|_{y=0}, \tag{57}$$

$$=(-1)^\ell\frac{\alpha}{\sqrt{4\pi}}2^{-j-\ell}\sum_{m=-\infty}^{\infty} e^{ikm}H_{j+\ell}\left(\frac{\alpha}{2}m\right)e^{-(\alpha^2/4)m^2}. \tag{58}$$

Thus, the orthonormalized Bloch functions $\psi_n^\alpha(k,x)=(1/\sqrt{2\pi})[\eta_n^\alpha(k,x)/\sqrt{\Delta_{n-1}^\alpha(k)\Delta_n^\alpha(k)}]$ read as

$$\psi_n^\alpha(k,x)=\frac{\sqrt{\alpha}}{\sqrt[4]{\pi}}\frac{1}{\sqrt{2\pi}}\frac{1}{\sqrt{\Lambda_{n-1}^\alpha(k)\Lambda_n^\alpha(k)}}\sum_{m_0=-\infty}^{\infty}\cdots\sum_{m_n=-\infty}^{\infty}\left(\prod_{j=0}^{n-1} e^{ikm_j}e^{-(\alpha^2/4)m_j^2}\right)$$
$$\times e^{ikm_n}e^{-(\alpha^2/2)(x-m_n)^2}\det M_{n;m_0,\ldots,m_{n-1}}^\alpha(x-m_n), \tag{59}$$

where the $(n+1)\times(n+1)$ matrix $M_{n;m_0,\ldots,m_{n-1}}^\alpha(x-m_n)$ is defined by its matrix elements $m_{n;m_0,\ldots,m_{n-1};j,\ell}^\alpha(x-m_n)$:

$$m_{n;m_0,\ldots,m_{n-1};j,\ell}^\alpha(x-m_n)=(-1)^\ell 2^{-j-\ell}H_{j+\ell}\left(\frac{\alpha}{2}m_j\right), \tag{60}$$

for $j=0,\ldots,n-1$, $\ell=0,\ldots,n$ and

$$m_{n;m_0,\ldots,m_{n-1};n,\ell}^\alpha(x-m_n)=2^{-(\ell/2)}H_\ell\left(\frac{\alpha}{\sqrt{2}}(x-m_n)\right), \tag{61}$$

for $\ell=0,\ldots,n$, and $\Lambda_n^\alpha(k)$ is given by

$$\Lambda_n^\alpha(k)=(-1)^{n(n+1)/2}2^{-n(n+1)}$$
$$\times\sum_{m_0=-\infty}^{\infty}\cdots\sum_{m_n=-\infty}^{\infty}\left(\prod_{j=0}^{n} e^{ikm_j}e^{-(\alpha^2/4)m_j^2}\right)\det\left(H_{j+\ell}\left(\frac{\alpha}{2}m_j\right)\right)_{j,\ell=0,\ldots,n}. \tag{62}$$

It might be surprising that $\psi_n^\alpha(k,x)$ is of the form

$$\psi_n^\alpha(k,x)=\sum_{\ell=0}^{n} b_{n;\ell}^\alpha(k)\sum_{m=-\infty}^{\infty} e^{ikm}H_\ell\left(\frac{\alpha}{\sqrt{2}}(x-m)\right)e^{-(\alpha^2/2)(x-m)^2}, \tag{63}$$

whereas one would have expected that $\psi_n^\alpha(k,x)$ reads as

$$\psi_n^\alpha(k,x)=\sum_{\ell=0}^{n} c_{n;\ell}^\alpha(k)\phi_l^\alpha(k,x)=\sum_{\ell=0}^{n} c_{n;\ell}^\alpha(k)\sum_{m=-\infty}^{\infty} e^{ikm}H_\ell(\alpha(x-m))e^{-(\alpha^2/2)(x-m)^2}, \quad (64)$$

with appropriate coefficients $c_{n;l}^\alpha(k)$. This is due to the fact that we have applied the orthogonalization procedure on the functions $\chi_j^\alpha(k)$ instead on $\phi_l^\alpha(k,x)$. But Eq. (63) can be easily transformed into Eq. (64) by using the addition theorem[9]

$$\sum_{\ell=0}^{n}\binom{n}{\ell}H_\ell(2^{1/2}x)H_{n-\ell}(2^{1/2}y)=2^{n/2}H_n(x+y). \quad (65)$$

Thus the coefficients $c_{n;\ell}^\alpha(k)$ in Eq. (64) are given by

$$c_{n;\ell}^\alpha(k)=\frac{1}{\sqrt{2\pi}}\frac{(-1)^{n(n+1)/2}}{2^{n^2}}\frac{(2^\ell\ell!)^{1/2}}{N_n^\alpha(k)}\frac{1}{\sqrt{\Lambda_{n-1}^\alpha(k)\Lambda_n^\alpha(k)}}$$
$$\times\sum_{m_0=-\infty}^{\infty}\cdots\sum_{m_{n-1}=-\infty}^{\infty}\left(\prod_{j=0}^{n-1}e^{ikm_j}e^{-(\alpha^2/4)m_j^2}\right)D_{n;\ell;m_0,\ldots,m_{n-1}}^\alpha, \quad (66)$$

where $D_{n;\ell;m_0,\ldots,m_{n-1}}^\alpha$ denotes the determinant of the $(n+1)\times(n+1)$ matrix $B^\alpha(n;\ell;m_0,\ldots,m_{n-1})$, with the matrix elements

$$b_{pq}^\alpha(n,\ell,m_p)=H_{p+q}\left(\frac{\alpha}{2}m_p\right),\quad \text{for } p=0,\ldots,n-1,\quad q=0,\ldots,n, \quad (67)$$

$$b_{nq}^\alpha(n,\ell)=0,\quad \text{for } q=0,\ldots,\ell-1, \quad (68)$$

$$b_{nq}^\alpha(n,\ell)=(-1)^q\binom{q}{\ell}H_{q-\ell}(0),\quad \text{for } q=\ell,\ldots,n. \quad (69)$$

One expects that the orthogonalized Bloch functions $\psi_n^\alpha(k,x)$ are approximately the same as the nonorthogonalized Bloch functions $\phi_n^\alpha(k,x)$ in the limit of large α, and this is, in fact, true. More precisely, we have

$$c_{n;\ell}^\alpha(k)=O(\alpha^{2n-1}e^{-\alpha^2/4}),\quad \text{for } \ell<n, \quad (70)$$

$$c_{n;n}^\alpha(k)=1+O(\alpha^{2n}e^{-\alpha^2/4}). \quad (71)$$

For proving the first equation, it is sufficient to show that the determinant $D_{n;\ell;m_0,\ldots,m_{n-1}}^\alpha$ is zero for $m_0=\cdots=m_{n-1}=0$. To this end, we show that the last row of the matrix $B^\alpha(n;\ell;0,\ldots,0)$ is a linear combination of the first ℓ rows. Let $r_p:=\{H_{p+q}(0)\}$ be the pth row and let $\rho_\ell=\{0,\ldots,0,(-1)^q\binom{q}{\ell}H_{q-\ell}(0)\}$ be the last one. In the case of even ℓ, one can prove

$$\sum_{p'=0}^{\ell'}\binom{\ell'}{p'}\frac{p'!}{(2p')!}r_{2p'}=2^{2\ell'}\ell'!\rho_{2\ell'}, \quad (72)$$

where we have set $\ell=2\ell'$, $p=2p'$ and $q=2q'$. The case for odd ℓ is very similar. Defining $\ell=2\ell'+1$, $p=2p'+1$, $q=2q'+1$, the essential equation is

$$\sum_{p'=0}^{\ell'}\binom{\ell'}{p'}\frac{(p'+1)!}{(2p'+2)!}r_{2p'+1}=2^{2\ell'}\ell'!\rho_{2\ell'+1}. \quad (73)$$

Equation (71) can be proved by using the facts

$$\Lambda_n^\alpha(k)=(-1)^{n(n+1)/2}2^{-n(n+1)}\det A_n+O(\alpha^{2n}e^{-\alpha^2/4}), \tag{74}$$

$$N_n^\alpha(k)=\frac{1}{\sqrt{2\pi}}+O(\alpha^{2n}e^{-\alpha^2/4}), \tag{75}$$

$$D^\alpha_{n;n;0,\dots,0}=(-1)^{n(n-1)/2}2^{-n^2}\det A_{n-1}, \tag{76}$$

$$\det A_n=(-1)^n 2^n n!\det A_{n-1}, \tag{77}$$

where A_n is the $(n+1)\times(n+1)$ matrix $A_n := (H_{j+l}(0))_{j,l=0,\dots,n}$. Thus

$$\psi_n^\alpha(k,x)=\phi_n^\alpha(k,x)+\epsilon_n^\alpha(k,x) \tag{78}$$

hold true, where $\epsilon_n^\alpha(k,x)$ are linear combinations of $\phi_0^\alpha(k,x),\dots,\phi_{n-1}^\alpha(k,x)$, whose coefficients are all of order $O(\alpha^{2n}e^{-\alpha^2/4})$.

D. Limit $\alpha\to 0$

We know already that the Bloch functions $\psi_0^\alpha(k,x)$ converge with $\alpha\to 0$ to the free electron wave functions.[6] In fact, this is also valid for general n, i.e., the Bloch functions $\psi_n^\alpha(k,x)$ converge to the free electron wave functions corresponding to the k vectors of the $(n+1)$th Brillouin zone. To prove this, recall Eqs. (25) and (27). Obviously, in Eqs. (25) and (27) only the terms where all indices m_j are different do not vanish. In other words, only those terms are nonzero for which the values $k+2\pi m_j$ lie all in different Brillouin zones. Thus, the leading terms are those for which $k+2\pi m_0,\dots,k+2\pi m_{n-1}$ are elements of the first n Brillouin zones, and $k+2\pi m_n$ is a member of the $(n+1)$th Brillouin zone. For $n=2m$ the limit $\alpha\to 0$ of the orthonormalized Bloch function $\psi_n^\alpha(k,x)$ reads as

$$\psi_{2m}^0(k,x)=\lim_{\alpha\to 0}\psi_{2m}^\alpha(k,x)=\frac{(-1)^m}{\sqrt{2\pi}}\begin{cases} e^{i(k+2\pi m)x}, & k\in(0,\pi),\\ e^{i(k-2\pi m)x}, & k\in(-\pi,0),\\ \sqrt{2}\cos(2\pi m x), & k=0,\\ \sqrt{2}\cos(\pi(2m+1)x), & k=\pm\pi. \end{cases} \tag{79}$$

For $n=2m+1$, we have

$$\psi_{2m+1}^0(k,x)=\lim_{\alpha\to 0}\psi_{2m+1}^\alpha(k,x)=\frac{(-1)^m}{\sqrt{2\pi}}\begin{cases} ie^{i(k-2\pi(m+1))x}, & k\in(0,\pi),\\ -ie^{i(k+2\pi(m+1))x}, & k\in(-\pi,0),\\ \sqrt{2}\sin(2\pi(m+1)x), & k=0\\ \sqrt{2}\sin(\pi(2m+1)x), & k=\pm\pi. \end{cases} \tag{80}$$

Note that these functions are Bloch functions for free electrons. In particular, the limit of the Bloch function $\psi_n^\alpha(k,x)$ is a free electron wave function of the $n+1$th band. The corresponding Wannier functions are given by

$$W_{2m}^0(x)=(-1)^m\frac{2}{\pi x}\cos\left(2\pi m+\frac{\pi}{2}\right)x\sin\frac{\pi}{2}x, \tag{81}$$

$$W_{2m+1}^0(x)=(-1)^m\frac{2}{\pi x}\sin\left(2\pi m+\frac{3\pi}{2}\right)x\sin\frac{\pi}{2}x. \tag{82}$$

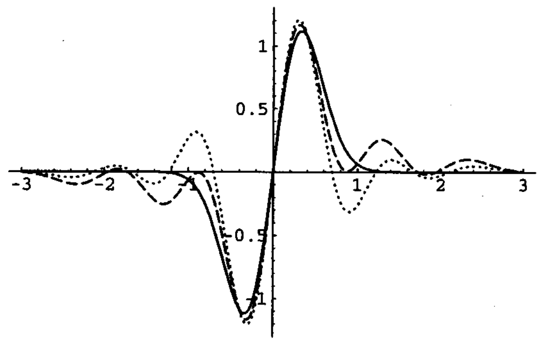

FIG. 1. Oscillator eigenfunction and Wannier functions for $n=1$ and $\alpha=3$.

E. Wannier functions

Again we use the convention

$$W_n^\alpha(m;x)=W_n^\alpha(x-m)=\frac{1}{\sqrt{2\pi}}\int_{-\pi}^{\pi}dk\, e^{-ikm}\psi_n^\alpha(k,x), \tag{83}$$

for the definition of the Wannier functions. The transformation properties,

$$(\psi_n^\alpha(k,x))^*=\psi_n^\alpha(-k,x), \tag{84}$$

$$\psi_n^\alpha(k,-x)=(-1)^n\psi_n^\alpha(-k,x), \tag{85}$$

imply again the reality and (anti-)symmetry of the Wannier functions:

$$(W_n^\alpha(x))^*=W_n^\alpha(x), \tag{86}$$

$$W_n^\alpha(x)=(-1)^n W_n^\alpha(-x). \tag{87}$$

Unfortunately there is no explicit expression for the Wannier functions. In Figs. 1–6 we compare the nonorthogonal (dashed) and the orthonormalized (dotted) Wannier functions with the original oscillator eigenfunctions (solid) for $n=1$ and $n=2$. Figures for $n=0$ can be found in Ref. 6.

The orthonormalized Wannier functions have the remarkable property that the uncertainty of position $(\Delta x)_{W_n^\alpha}$ is the same as the uncertainty of the original oscillator eigenfunction $u_n^\alpha(x)$, namely, we have $(\Delta x)^2_{W_n^\alpha}=(2n+1)/2\alpha^2$. The proof is rather lengthy and thus we omit most of the

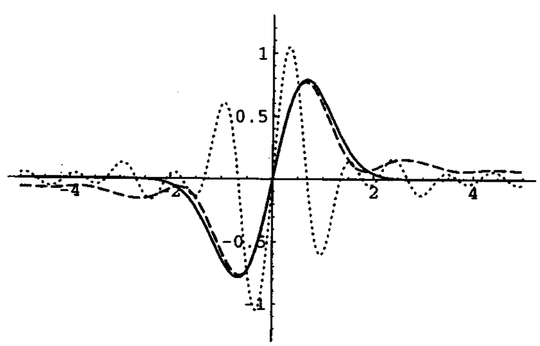

FIG. 2. Oscillator eigenfunction and Wannier functions for $n=1$ and $\alpha=1.5$.

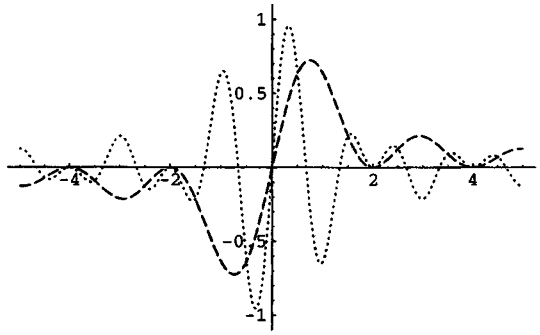

FIG. 3. Wannier functions for $n=1$ and $\alpha=0$.

details. Obviously we have $\langle x\rangle_{W_n^\alpha}=0$ and hence we need to calculate only $\langle x^2\rangle_{W_n^\alpha}$. For this purpose we express the expectation value $\langle x^2\rangle_{W_n^\alpha}$ in terms of the Bloch factor:

$$\langle x^2\rangle_{W_n^\alpha}=\int_0^1 dx\int_{-\pi}^{\pi} dk\left|\frac{\partial}{\partial k}\,\omega_n^\alpha(k,x)\right|^2, \tag{88}$$

$$\omega_n^\alpha(k,x)=e^{-ikx}\psi_n^\alpha(k,x). \tag{89}$$

According to Sec. III A the Bloch factor $\omega_n^\alpha(k,x)$ may be expressed in terms of the functions $\xi_\ell^\alpha(k,x)$,

$$\xi_\ell^\alpha(k,x)=e^{-ikx}\chi_\ell^\alpha(k,x)=(-i)^\ell\sum_{m=-\infty}^{\infty}\left(\frac{k+2\pi m}{\alpha}\right)^\ell e^{-(k+2\pi m)^2/2\alpha^2}e^{i2\pi mx}, \tag{90}$$

whose inner products are given by

$$\langle\xi_j^\alpha(k),\xi_\ell^\alpha(k)\rangle_1=(-i)^{\ell-j}\sum_{m=-\infty}^{\infty}\left(\frac{k+2\pi m}{\alpha}\right)^{j+\ell}e^{-(k+2\pi m)^2/\alpha^2}. \tag{91}$$

For writing the Bloch factor as convenient as possible we use the following notions and notations: Let $\xi_1,\ldots,\xi_n\in L^2([0,1])$; then

$$\xi_1\otimes\xi_2\otimes\cdots\otimes\xi_n\in(L^2([0,1]))^n \tag{92}$$

denotes the direct product and

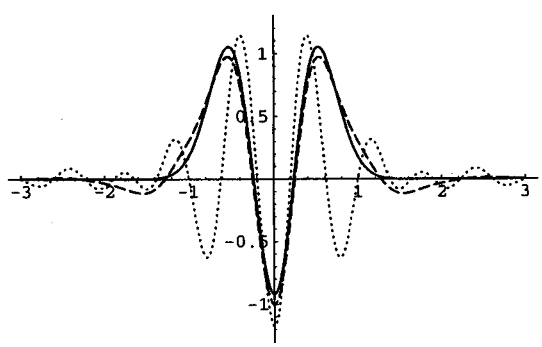

FIG. 4. Oscillator eigenfunction and Wannier functions for $n=2$ and $\alpha=3$.

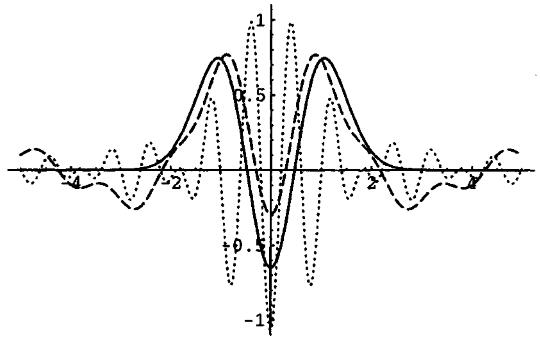

FIG. 5. Oscillator eigenfunction and Wannier functions for $n=2$ and $\alpha=1.5$.

$$\xi_1\wedge\xi_2\wedge\cdots\wedge\xi_n=\sum_{\pi\in P_n}\operatorname{sign}(\pi)\xi_{\pi(1)}\otimes\xi_{\pi(2)}\otimes\cdots\otimes\xi_{\pi(n)} \tag{93}$$

is the antisymmetrized product of the vectors $\xi_1,\ldots,\xi_n$. Here the inner product $(\cdot,\cdot)$ means the inner product of $(L^2([0,1]))^n$, where the value of n should be clear from the context. Note that

$$(\zeta_1\otimes\cdots\otimes\zeta_n,\xi_1\wedge\cdots\wedge\xi_n)=\frac{1}{n!}(\zeta_1\wedge\cdots\wedge\zeta_n,\xi_1\wedge\cdots\wedge\xi_n) \tag{94}$$

$$=(\zeta_1\wedge\cdots\wedge\zeta_n,\xi_1\otimes\cdots\otimes\xi_n). \tag{95}$$

In addition, we introduce the notation

$$(\zeta_1\otimes\cdots\otimes\zeta_n,\xi_1\wedge\cdots\wedge\xi_n)\wedge\xi_{n+1}:=\sum_{\pi\in P_{n+1}}\operatorname{sign}(\pi)(\zeta_1\otimes\cdots\otimes\zeta_n,\xi_{\pi(1)}\otimes\cdots\otimes\xi_{\pi(n)})\xi_{\pi(n+1)} \tag{96}$$

$$=\sum_{\pi\in P_{n+1}}\operatorname{sign}(\pi)\langle\zeta_1,\xi_{\pi(1)}\rangle_1\cdots\langle\zeta_n,\xi_{\pi(n)}\rangle_1\xi_{\pi(n+1)}. \tag{97}$$

In case we want to stress that $(\zeta_1\otimes\cdots\otimes\zeta_n,\xi_1\wedge\cdots\wedge\xi_n)\wedge\xi_{n+1}\in L^2([0,1])$ is a function of x, we write

$$(\zeta_1\otimes\cdots\otimes\zeta_n,\xi_1\wedge\cdots\wedge\xi_n)\wedge\xi_{n+1}(x)=[(\zeta_1\otimes\cdots\otimes\zeta_n,\xi_1\wedge\cdots\wedge\xi_n)\wedge\xi_{n+1}](x). \tag{98}$$

Thus, $\omega_n^\alpha(k,x)$ can be written as follows:

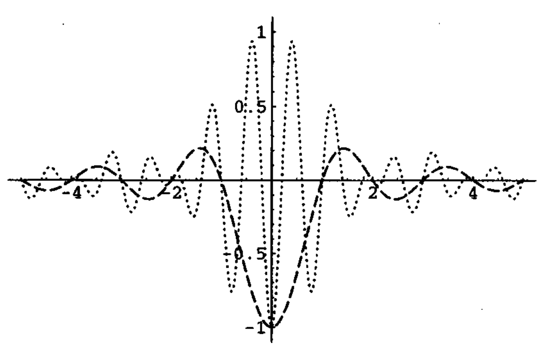

FIG. 6. Wannier functions for $n=2$ and $\alpha=0$.

$$\omega_n^\alpha(k,x)=\frac{1}{\sqrt{2\pi}}\frac{1}{\sqrt{\Delta_{n-1}^\alpha(k)\Delta_n^\alpha(k)}}(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-1}^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\xi_{n-1}^\alpha(k))\wedge\xi_n^\alpha(k,x), \tag{99}$$

$$\Delta_n^\alpha(k)=(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_n^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_n^\alpha(k)). \tag{100}$$

Note that $(\partial/\partial k)\xi_\ell^\alpha(k,x)$ is given by

$$\frac{\partial}{\partial k}\xi_\ell^\alpha(k,x)=-\frac{i}{\alpha}\xi_{\ell+1}^\alpha(k,x)-\frac{i\ell}{\alpha}\xi_{\ell-1}^\alpha(k,x). \tag{101}$$

Now a lengthy calculation with appropriate partial integrations yields

$$\langle x^2\rangle_{W_n^\alpha}=\frac{1}{2\pi}\int_{-\pi}^{\pi}dk(I_n^\alpha(k)+I_{n-1}^\alpha(k)), \tag{102}$$

where

$$I_n^\alpha(k):=\frac{1}{\Delta_n^\alpha(k)}\left(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-1}^\alpha(k)\otimes\frac{\partial}{\partial k}\xi_n^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_{n-1}^\alpha(k)\wedge\frac{\partial}{\partial k}\xi_n^\alpha(k)\right)-\frac{\dfrac{\partial^2}{\partial k^2}\Delta_n^\alpha(k)}{4\Delta_n^\alpha(k)} \tag{103}$$

$$=\frac{n+1}{2\alpha^2}+\frac{1}{2\alpha^2}\frac{1}{\Delta_n^\alpha(k)}J_n^\alpha(k). \tag{104}$$

Now one shows easily that

$$\begin{aligned}J_n^\alpha(k)=&(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-1}^\alpha(k)\otimes\xi_{n+1}^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_{n-1}^\alpha(k)\wedge\xi_{n+1}^\alpha(k))\\&+(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-2}^\alpha(k)\otimes\xi_n^\alpha(k)\otimes\xi_{n+1}^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_n^\alpha(k))\\&+(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-1}^\alpha(k)\otimes\xi_{n+2}^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_n^\alpha(k))=0\end{aligned} \tag{105}$$

is valid, where one takes into account

$$\det\begin{pmatrix}1&1&\cdots&1\\x_0&x_1&\cdots&x_n\\x_0^2&x_1^2&\cdots&x_n^2\\\vdots&\vdots&&\vdots\\x_0^{n-1}&x_1^{n-1}&\cdots&x_n^{n-1}\\x_0^{n+1}&x_1^{n+1}&\cdots&x_n^{n+1}\end{pmatrix}=\left(\sum_{i=0}^n x_i\right)\prod_{n\geqslant i>j\geqslant 0}(x_i-x_j), \tag{106}$$

$$\det\begin{pmatrix}1&1&\cdots&1\\x_0&x_1&\cdots&x_n\\x_0^2&x_1^2&\cdots&x_n^2\\\vdots&\vdots&&\vdots\\x_0^{n-1}&x_1^{n-1}&\cdots&x_n^{n-1}\\x_0^{n+2}&x_1^{n+2}&\cdots&x_n^{n+2}\end{pmatrix}=\left(\sum_{i=0}^n x_i^2+\sum_{n\geqslant i>j\geqslant 0}^n x_ix_j\right)\prod_{n\geqslant i>j\geqslant 0}(x_i-x_j), \tag{107}$$

$$\begin{pmatrix} 1 & 1 & \cdots & 1 \\ x_0 & x_1 & \cdots & x_n \\ x_0^2 & x_1^2 & \cdots & x_n^2 \\ \vdots & \vdots & & \vdots \\ x_0^{n-2} & x_1^{n-2} & \cdots & x_n^{n-2} \\ x_0^n & x_1^n & \cdots & x_n^n \\ x_0^{n+1} & x_1^{n+1} & \cdots & x_n^{n+1} \end{pmatrix} = \left(\sum_{n \geqslant i > j \geqslant 0}^{n} x_i x_j \right) \prod_{n \geqslant i > j \geqslant 0} (x_i - x_j). \tag{108}$$

Hence, $I_n^\alpha(k) = (n+1)/2\alpha^2$, and thus we have the simple result

$$\langle x^2 \rangle_{W_n^\alpha} = \frac{2n+1}{2\alpha^2}. \tag{109}$$

Note that this is also the expectation value of x^2 for the nth excited eigenstate of the harmonic oscillator. Recall that the oscillator eigenfunctions can be obtained by applying the Gram–Schmidt procedure onto the set $\{x^\ell e^{\alpha^2 x^2/2}\}_{\ell=0}^\infty$, whereas the orthonormalized Wannier functions are obtained in the following way: First construct the Wannier functions corresponding to $\{x^\ell e^{\alpha^2 x^2/2}\}_{\ell=0}^\infty$ and then orthonormalize them, a procedure that is best done in terms of Bloch functions. Although the oscillator eigenfunctions and the corresponding orthonormalized Wannier functions have been constructed in a different way and are completely different for small values of α, their uncertainty Δx is the same. This remarkable feature is quite astonishing, and naturally the question arises whether this is only pure chance or whether there is a more sophisticated reason behind it.

IV. EXPECTATION VALUES FOR THE ORTHONORMALIZED BLOCH FUNCTIONS

One of the most interesting properties of a physical system is its energy. Here we want to discuss briefly the expectation values of the kinetic energy $(1/2m)P^2$ and the potential energy V, where $V(x) = V(x+1)$ is a periodic potential.

A. Kinetic energy

1. Expectation value

The expectation value of the kinetic energy reads as

$$\begin{aligned} \langle P^2 \rangle_n^\alpha(k) &= 2\pi \langle \psi_n^\alpha(k), P^2 \psi_n^\alpha(k) \rangle_1 \\ &= -\frac{\alpha^2}{\Delta_{n-1}^a(k)} (\chi_0^\alpha(k) \otimes \cdots \otimes \chi_{n-1}^\alpha(k), \chi_0^\alpha(k) \wedge \cdots \wedge \chi_{n-3}^\alpha(k) \wedge \chi_{n-1}^\alpha(k) \wedge \chi_n^\alpha(k)) \\ &\quad + \frac{\alpha^2}{\Delta_{n-1}^\alpha(k) \Delta_n^\alpha(k)} (\chi_0^\alpha(k) \otimes \cdots \otimes \chi_{n-1}^\alpha(k), \chi_0^\alpha(k) \wedge \cdots \wedge \chi_{n-2}^\alpha(k) \wedge \chi_n^\alpha(k)) \\ &\quad \times (\chi_0^\alpha(k) \otimes \cdots \otimes \chi_n^\alpha(k), \chi_0^\alpha(k) \wedge \cdots \wedge \chi_{n-1}^\alpha(k) \wedge \chi_{n+1}^\alpha(k)) \\ &\quad - \frac{\alpha^2}{\Delta_n^\alpha(k)} (\chi_0^\alpha(k) \otimes \cdots \otimes \chi_n^\alpha(k), \chi_0^\alpha(k) \wedge \cdots \wedge \chi_{n-1}^\alpha(k) \wedge \chi_{n+2}^\alpha(k)). \end{aligned} \tag{110}$$

Of course, $\langle P^2 \rangle_n^\alpha(k) = \langle P^2 \rangle_n^\alpha(-k)$ is symmetric. For $n=0$ one can show that $\langle P^2 \rangle_0^\alpha(k)$ is monotone increasing for $k \in [-\pi, \pi]$. For general n, numerical calculations suggest that $\langle P^2 \rangle_n^\alpha(k)$ is monotone increasing or decreasing, depending on whether n is even or odd. However, the proof of the case $n=0$ cannot be easily generalized.

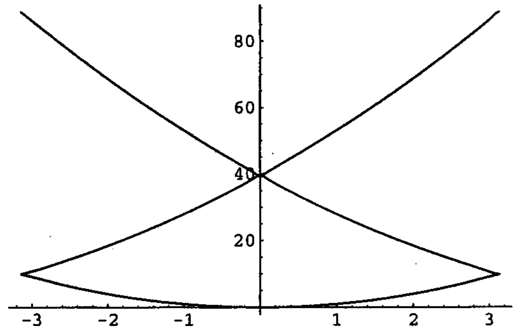

FIG. 7. Expectation values $\langle P^2\rangle_n^\alpha$ for $n=0,1,2$ and $\alpha=1$.

2. Further matrix elements

One can easily compute all the matrix elements $\langle\psi_m^\alpha(k),P^2\psi_n^\alpha(k)\rangle_1$. We have $\langle\psi_m^\alpha(k),P^2\psi_n^\alpha(k)\rangle_1=0$ for $|m-n|>2$. For $m=n+1$ and $m=n+2$ the matrix elements read as

$$\langle\psi_{n+1}^\alpha(k),P^2\psi_n^\alpha(k)\rangle_1 = \frac{1}{2\pi}\frac{\alpha^2}{\Delta_{n+1}^\alpha(k)}\Bigg[\sqrt{\frac{\Delta_{n+2}^\alpha(k)}{\Delta_n^\alpha(k)}}(\chi_0^\alpha(k)\otimes\cdots\otimes\chi_{n-1}^\alpha(k),\chi_0^\alpha(k)\wedge\cdots\wedge\chi_{n-2}^\alpha(k)\wedge\chi_n^\alpha(k)) - \sqrt{\frac{\Delta_n^\alpha(k)}{\Delta_{n+2}^\alpha(k)}}(\chi_0^\alpha(k)\otimes\cdots\otimes\chi_{n+1}^\alpha(k),\chi_0^\alpha(k)\wedge\cdots\wedge\chi_n^\alpha(k)\wedge\chi_{n+2}^\alpha(k))\Bigg], \tag{111}$$

$$\langle\psi_{n+2}^\alpha(k),P^2\psi_n^\alpha(k)\rangle_1 = -\alpha^2\sqrt{\frac{\Delta_n^\alpha(k)\Delta_{n+3}^\alpha(k)}{\Delta_{n+1}^\alpha(k)\Delta_{n+2}^\alpha(k)}}. \tag{112}$$

Figures 7–10 show the expectation values of the kinetic energy $\langle P^2\rangle_n^\alpha(k)$ and the first two or three eigenvalues of the matrices $\{\langle\psi_m^\alpha(k),P^2\psi_n^\alpha(k)\rangle\}$, where $m,n=0,1$ (2×2 matrix), $m,n=0,1,2$ (3×3 matrix), and $m,n=0,1,2,3$ (4×4 matrix), respectively. In the limit $\alpha\to0$, $\langle P^2\rangle_n^\alpha(k)$ converges to the free electron energy parabola, and hence the expectation values $\langle P^2\rangle_n^\alpha(k)$ are a very good approximation for the exact eigenvalues for small α; see Fig. 7 for $\alpha=1$. With increasing α, the difference between the correct eigenvalues of P^2 and the expectation value $\langle P^2\rangle_n^\alpha(k)$ becomes larger (see Figs. 8–10), and thus more and more matrix elements have to be taken into account if one wants to get a good approximation for the correct eigenvalues of P^2; see Figs. 8–10. Note the band gap structure for the approximate eigenvalues.

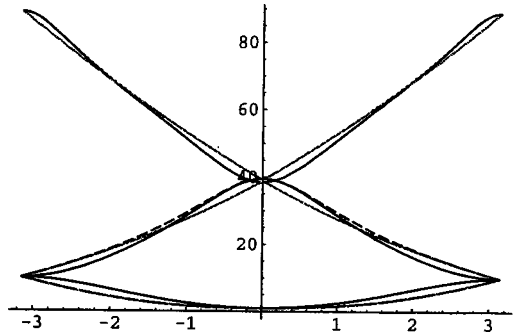

FIG. 8. Expectation values $\langle P^2\rangle_n^\alpha$ (black) for $n=0,1,2$ and $\alpha=3$ the eigenvalues of the corresponding 2×2- (dashed), 3×3- (dotted) and 4×4-matrix (grey).

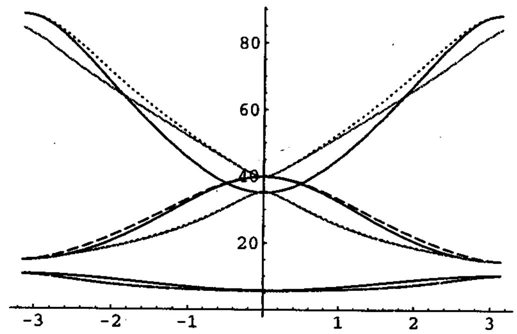

FIG. 9. Expectation values $\langle P^2\rangle_n^\alpha$ (black) for $n=0,1,2$ and $\alpha=4$ the eigenvalues of the corresponding 2×2- (dashed), 3×3- (dotted) and 4×4-matrix (grey).

B. Potential energy

Another interesting quantity is the expectation value for a periodic potential V. Let $V(x) =\Sigma_{p=-\infty}^{\infty} c_p e^{i2\pi px}$ be the Fourier series of the potential V. Then we have

$$\langle \chi_j^\alpha(k), V\chi_\ell^\alpha(k)\rangle = \sum_{s=0}^{j}\sum_{t=0}^{\ell}\binom{j}{s}\binom{\ell}{t} i^{t+s}[\langle \chi_{j-s}^\alpha(k),\chi_{\ell-t}^\alpha(k)\rangle_1 V_{s+t}^+(\alpha) + \langle \chi_{j-s}^\alpha(k+\pi),\chi_{\ell-t}^\alpha(k+\pi)\rangle_1 V_{s+t}^-(\alpha)], \tag{113}$$

where we have employed the definitions

$$V_s^+(\alpha) := \sum_{q=-\infty}^{\infty} \frac{(2\pi q)^s}{\alpha^s} c_{2q} e^{-(2\pi q)^2/\alpha^2}, \tag{114}$$

$$V_s^-(\alpha) := \sum_{q=-\infty}^{\infty} \frac{(\pi(2q+1))^s}{\alpha^s} c_{2q+1} e^{-(\pi(2q+1))^2/\alpha^2}. \tag{115}$$

Thus, the expectation value of the potential energy reads as

$$\langle V\rangle_n^\alpha = 2\pi\langle \psi_n^\alpha(k), V\psi_n^\alpha(k)\rangle_1 = \sum_{s=0}^{2n} (d_s^+(k,\alpha,n)V_s^+(\alpha) + d_s^-(k,\alpha,n)V_s^-(\alpha)), \tag{116}$$

where the coefficients $d_s^+(k,\alpha,n)$ and $d_s^-(k,\alpha,n)$ are given by

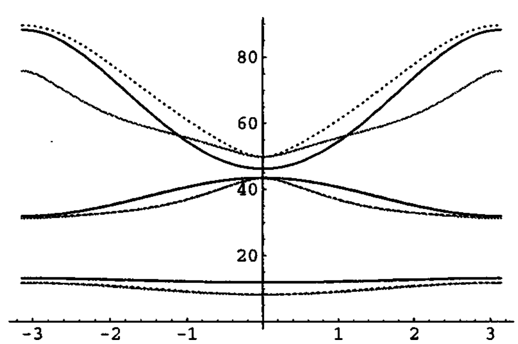

FIG. 10. Expectation values $\langle P^2\rangle_n^\alpha$ (black) for $n=0,1,2$ and $\alpha=5$ the eigenvalues of the corresponding 2×2- (dashed), 3×3- (dotted) and 4×4-matrix (grey).

$$d_s^+(k,\alpha,n):=\frac{1}{\Delta_{n-1}^\alpha(k)\Delta_n^\alpha(k)}\sum_{j,\ell=0}^{n}(-1)^{j+\ell}\sum_{t=\max(s-j,0)}^{\min(\ell,s)}\binom{j}{s-t}\binom{\ell}{t}i^s$$
$$\times(\chi_0^\alpha(k)\otimes\cdots\otimes\chi_{j-1}^\alpha(k)\otimes\chi_{j+1}^\alpha(k)\otimes\cdots\otimes\chi_n^\alpha(k),\chi_0^\alpha(k)\wedge\cdots\wedge\chi_{n-1}^\alpha(k))$$
$$\times(\chi_0^\alpha(k)\otimes\cdots\otimes\chi_{n-1}^\alpha(k),\chi_0^\alpha(k)\wedge\cdots\wedge\chi_{\ell-1}^\alpha(k)\wedge\chi_{\ell+1}^\alpha(k)\wedge\cdots\wedge\chi_n^\alpha(k))$$
$$\times\langle\chi_{j-s+t}^\alpha(k),\chi_{\ell-t}^\alpha(k)\rangle_1, \tag{117}$$

$$d_s^-(k,\alpha,n):=\frac{1}{\Delta_{n-1}^\alpha(k)\Delta_n^\alpha(k)}\sum_{j,\ell=0}^{n}(-1)^{j+\ell}\sum_{t=\max(s-j,0)}^{\min(\ell,s)}\binom{j}{s-t}\binom{\ell}{t}i^s$$
$$\times(\chi_0^\alpha(k)\otimes\cdots\otimes\chi_{j-1}^\alpha(k)\otimes\chi_{j+1}^\alpha(k)\otimes\cdots\otimes\chi_n^\alpha(k),\chi_0^\alpha(k)\wedge\cdots\wedge\chi_{n-1}^\alpha(k))$$
$$\times(\chi_0^\alpha(k)\otimes\cdots\otimes\chi_{n-1}^\alpha(k),\chi_0^\alpha(k)\wedge\cdots\wedge\chi_{\ell-1}^\alpha(k)\wedge\chi_{\ell+1}^\alpha(k)\wedge\cdots\wedge\chi_n^\alpha(k))$$
$$\times\langle\chi_{j-s+t}^\alpha(k+\pi),\chi_{\ell-t}^\alpha(k+\pi)\rangle_1. \tag{118}$$

Note that the potential enters into the expression for the expectation value $\langle V\rangle_n^\alpha$ only via the $2n+2$ constants $V_s^+(\alpha)$, $V_s^-(\alpha)$, whereas only $d_s^+(k,\alpha,n)$ and $d_s^-(k,\alpha,n)$ depend on k. For special values of s, the functions $d_s^+(k,\alpha,n)$ and $d_s^-(k,\alpha,n)$ simplify considerably:

$$d_{2n}^+(k,\alpha,n)=(-1)^n\frac{\Delta_{n-1}^\alpha(k)}{\Delta_n^\alpha(k)}\langle\chi_0^\alpha(k),\chi_0^\alpha(k)\rangle_1, \tag{119}$$

$$d_{2n}^-(k,\alpha,n)=(-1)^n\frac{\Delta_{n-1}^\alpha(k)}{\Delta_n^\alpha(k)}\langle\chi_0^\alpha(k+\pi),\chi_0^\alpha(k+\pi)\rangle_1, \tag{120}$$

$$d_0^+(k,\alpha,n)=1. \tag{121}$$

V. FURTHER PROPERTIES OF THE WANNIER FUNCTIONS

In a previous section we have seen that the uncertainty $\Delta x=\sqrt{(2n+1)/2\alpha^2}$ is the same for the orthonormalized Wannier functions and the original oscillator eigenfunctions. Here we show that an analogous result is not true for the uncertainty of momentum Δp.

Of course, $\langle P\rangle_{W_n^\alpha}=0$ due to symmetry. The expectation value $\langle P^2\rangle_{W_n^\alpha}$ can be computed with the same methods used in Sec. III E, if one starts with Eq. (110) and expresses $\langle P^2\rangle_n^\alpha(k)$ in terms of ξ_n^α instead of $\chi_n^\alpha(k)$. Then we get the result

$$\langle P^2\rangle_{W_n^\alpha}=\alpha^2\left(n+\frac{1}{2}\right)+\frac{1}{2\pi}\frac{\alpha^4}{8}\int_{-\pi}^{\pi}dk\left[\frac{\frac{\partial}{\partial k}\Delta_{n-1}^\alpha(k)}{\Delta_{n-1}^\alpha(k)}-\frac{\frac{\partial}{\partial k}\Delta_n^\alpha(k)}{\Delta_n^\alpha(k)}\right]^2$$
$$+\frac{1}{2\pi}\frac{\alpha^4}{8}\int_{-\pi}^{\pi}dk\left\{\left[\frac{\frac{\partial}{\partial k}\Delta_{n-1}^\alpha(k)}{\Delta_{n-1}^\alpha(k)}\right]^2+\left[\frac{\frac{\partial}{\partial k}\Delta_n^\alpha(k)}{\Delta_n^\alpha(k)}\right]^2\right\}+\frac{1}{2\pi}\int_{-\pi}^{\pi}dk\,K_n^\alpha(k), \tag{122}$$

where $K_n^\alpha(k)$ is defined by

$$K_n^\alpha(k)=\frac{\alpha^2}{\Delta_{n-1}^\alpha(k)}(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-2}^\alpha(k)\otimes\xi_{n+1}^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_{n-1}^\alpha(k))$$
$$+\frac{\alpha^2}{\Delta_n^\alpha(k)}(\xi_0^\alpha(k)\otimes\cdots\otimes\xi_{n-2}^\alpha(k)\otimes\xi_n^\alpha(k)\otimes\xi_{n+1}^\alpha(k),\xi_0^\alpha(k)\wedge\cdots\wedge\xi_n^\alpha(k)). \tag{123}$$

The first term in Eq. (122) is the expectation value $\langle P^2\rangle_{u_n^\alpha}$ for the original oscillator eigenfunctions, the second and third term are obviously positive, and also the last term seems to be positive, since numerical calculations suggest that $K_n^\alpha(k)\geqslant 0$. Hence

$$\langle P^2\rangle_{W_n^\alpha}>\alpha^2(n+\tfrac{1}{2}), \tag{124}$$

which means that the uncertainty of momentum Δp for the orthonormalized Wannier functions is larger than the corresponding uncertainty for the original oscillator eigenfunctions. Of course, an analogous statement is valid for the uncertainty product:

$$(\Delta x\,\Delta p)_{W_n^\alpha}>(\Delta x\,\Delta p)_{u_n^\alpha}=n+\tfrac{1}{2}. \tag{125}$$

In the special case $n=0$, we can calculate the expectation value $\langle P^2\rangle_{W_0^\alpha}$ explicitly:

$$\langle P^2\rangle_{W_0^\alpha}=\frac{\alpha^2}{2}+\frac{1}{2\pi}\frac{\alpha^4}{4}\int_{-\pi}^{\pi}dk\left[\frac{\frac{\partial}{\partial k}\theta_3\left(\frac{k}{2}\middle|\frac{i\alpha^2}{4\pi}\right)}{\theta_3\left(\frac{k}{2}\middle|\frac{i\alpha^2}{4\pi}\right)}\right]^2=\frac{\alpha^2}{2}+\frac{\alpha^4}{192}\left[\frac{\theta_1'''\left(0\middle|\frac{i\alpha^2}{4\pi}\right)}{\theta_1'\left(0\middle|\frac{i\alpha^2}{4\pi}\right)}+1\right]. \tag{126}$$

For the limits of large and small α we obtain the following simple formulas:

$$\langle P^2\rangle_{W_0^\alpha}=\frac{\alpha^2}{2}+O(\alpha^4e^{-\alpha^2/2}),\quad\text{for }\alpha\to\infty, \tag{127}$$

$$\langle P^2\rangle_{W_0^\alpha}=\frac{\pi^2}{3}+O(\alpha^4),\quad\text{for }\alpha\to 0. \tag{128}$$

The corresponding uncertainty products read as

$$(\Delta x\,\Delta p)_{W_0^\alpha}=\tfrac{1}{2}+O(\alpha^2e^{-\alpha^2/2}),\quad\text{for }\alpha\to\infty, \tag{129}$$

$$(\Delta x\,\Delta p)_{W_0^\alpha}=\frac{\pi}{\sqrt{6}\,\alpha}+O(\alpha^2),\quad\text{for }\alpha\to 0. \tag{130}$$

VI. CONCLUSIONS

We have used the eigenfunctions of the harmonic oscillator to construct a complete set of mutually orthonormal Bloch and Wannier functions. The interesting aspect for solid state physics is that these Bloch functions provide an expansion for arbitrary Bloch functions, which might go far beyond the usual expansions in terms of Gaussian orbitals. In the limit $\alpha\to 0$, these Bloch functions converge to the plane wave eigenfunctions of the free electron. Thus, the free electron wave functions may be viewed as a special case of the Bloch functions $\psi_n^\alpha(k,x)$. Hence the Bloch functions $\psi_n^\alpha(k,x)$ represent an alternative complete set of mutually orthonormal Bloch functions, which is appropriate for nearly free electrons in the case of small α. On the other hand, for large α the Bloch functions $\psi_n^\alpha(k,x)$ are typical Bloch functions for tight-binding approximations. Thus, depending on the choice of α, these Bloch functions could be useful both in tight-binding approximations as well as in the case of nearly free electrons. In addition, we have derived several expressions for these Bloch functions and calculated certain expectation values. Moreover, we have discussed the localization properties of the corresponding Wannier functions.

APPENDIX A: SOME FACTS RELATED TO THETA FUNCTIONS

1. A function related to theta functions

In this section we show that an analytic function $\eta_n^\alpha(k,x)$ with the quasiperiodicity properties,

$$\eta_n^\alpha(k+2\pi,x)=\eta_n^\alpha(k,x), \tag{A1}$$

$$\eta_n^\alpha(k+i\alpha^2,x)=e^{(n+1/2)\alpha^2}e^{-\alpha^2 x}e^{-(2n+1)ik}\eta_n^\alpha(k,x), \tag{A2}$$

can be expressed in terms of theta functions. Due to periodicity $\eta_n^\alpha(k,x)$ can be expanded into a Fourier series:

$$\eta_n^\alpha(k,x)=\sum_{m=-\infty}^{\infty} c_m^{\alpha,n}(x)e^{ikm}. \tag{A3}$$

Taking Eq. (A2) into account we obtain the following relation for the Fourier coefficients:

$$e^{-\alpha^2 m}c_m^{\alpha,n}(x)=e^{(n+1/2)\alpha^2}e^{-\alpha^2 x}c_{m+2n+1}^{\alpha,n}(x). \tag{A4}$$

The general solution of these equations is given by

$$c_{r+s(2n+1)}^{\alpha,n}(x)=e^{[-\alpha^2/2(2n+1)](r+s(2n+1)-x)^2}d_r^{\alpha,n}(x), \tag{A5}$$

where $r=-n,\dots,n$. Thus, $\eta_n^\alpha(k,x)$ can be expressed as a sum of $2n+1$ θ functions:

$$\eta_n^\alpha(k,x)=\sum_{r=-n}^{n} d_r^{\alpha,n}(x)e^{-[\alpha^2/2(2n+1)](r-x)^2}e^{irk}\theta_3\left(\frac{2n+1}{2}k+i\frac{\alpha^2}{2}(r-x)\middle| i\frac{(2n+1)\alpha^2}{2\pi}\right). \tag{A6}$$

By applying Jacobi's transformation, we get

$$\eta_n^\alpha(k,x)=\sqrt{\frac{2\pi}{(2n+1)\alpha^2}}e^{ikx}\sum_{r=-n}^{n} d_r^{\alpha,n}(x)$$
$$\times e^{-[(2n+1)/2\alpha^2]k^2}\theta_3\left(\frac{i\pi}{\alpha^2}k-\frac{\pi}{2n+1}(r-x)\middle| i\frac{2\pi}{(2n+1)\alpha^2}\right). \tag{A7}$$

2. A function related to derivatives of theta functions

Let $a^{\alpha,n,\ell}(k)$ be an analytic function obeying the following transformation rules:

$$a^{\alpha,n,\ell}\left(k+i\frac{\alpha^2}{2}\right)=a^{\alpha,n,\ell}(k), \tag{A8}$$

$$a^{\alpha,n,\ell}(k+2\pi)=e^{(2\pi)^2 n/\alpha^2}e^{4\pi nk/\alpha^2}\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}a^{\alpha,n,\ell-s}(k). \tag{A9}$$

Then this function may be expressed in terms of θ functions and their derivatives. From Eq. (A8), we infer that $a^{\alpha,n,\ell}(k)$ may be expanded into the following Fourier series:

$$a^{\alpha,n,\ell}(k)=\sum_{m=-\infty}^{\infty}c_m^{\alpha,n,\ell}e^{(4\pi/\alpha^2)km}. \tag{A10}$$

Due to Eq. (A9) we have:

$$c_{m+n}^{\alpha,n,\ell}=e^{-(4\pi^2/\alpha^2)(2m+n)}\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}c_m^{\alpha,n,\ell-s}. \tag{A11}$$

These equations can be solved recursively and it is easily seen that the solution of these equations is unique for given starting values $c_m^{\alpha,n,\ell-s}$, $s=0,...,\ell$, $m=0,...,n-1$. Using the ansatz

$$c_m^{\alpha,n,\ell}=e^{-[(2\pi)^2/n\alpha^2]m^2}d_m^{\alpha,n,\ell}, \tag{A12}$$

we obtain the simpler equations

$$d_{m+n}^{\alpha,n,\ell}=\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}d_m^{\alpha,n,\ell-s}. \tag{A13}$$

Now we use the ansatz

$$d_{p+qn}^{\alpha,n,\ell}=\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}q^s f_p^{\alpha,n,\ell,s}, \tag{A14}$$

where $f_p^{\alpha,n,\ell,0}=d_p^{\alpha,n,\ell}$. Then Eq. (A13) is fulfilled if we set

$$f_p^{\alpha,n,\ell,s}=f_p^{\alpha,n,\ell-s,0}=d_p^{\alpha,n,\ell-s}. \tag{A15}$$

Since the solution is unique, we have

$$d_{p+qn}^{\alpha,n,\ell}=\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}q^s d_p^{\alpha,n,\ell-s}, \tag{A16}$$

where $p=0,...,n-1$. Hence, $a^{\alpha,n,\ell}(k)$ may be written in the following way:

$$a^{\alpha,n,\ell}(k)=\sum_{p=0}^{n-1}\sum_{q=-\infty}^{\infty}\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}d_p^{\alpha,n,\ell-s}q^s e^{-[(2\pi)^2/n\alpha^2](p+qn)^2}e^{(4\pi/\alpha^2)k(p+qn)}$$

$$=\sum_{p=0}^{n-1}e^{-[(2\pi)^2/n\alpha^2]p^2}e^{(4\pi/\alpha^2)kp}\sum_{s=0}^{\ell}\binom{n-\ell+s}{s}d_p^{\alpha,n,\ell-s} \tag{A17}$$

$$\times\left(\frac{\alpha^2}{4\pi n}\frac{\partial}{\partial k}\right)^s\theta_3\left(-\frac{2\pi ink}{\alpha^2}+\frac{i4\pi^2 p}{\alpha^2}\middle|\frac{4\pi in}{\alpha^2}\right). \tag{A18}$$

The Lie point symmetries of a coupled system of two nonlinear differential-difference equations are investigated. It is shown that in special cases the symmetry group can be infinite dimensional, in other cases up to ten dimensional. The equations can describe the interaction of two long molecular chains, each involving one type of atoms. © *1999 American Institute of Physics.* [S0022-2488(99)03206-5]

I. INTRODUCTION

Our purpose in this article is to perform a symmetry analysis of a system of two coupled differential-difference equations of the form

$$E_1=\ddot{u}_n-F_n(t,u_{n-1},u_n,u_{n+1},v_{n-1},v_n,v_{n+1})=0,$$
$$E_2=\ddot{v}_n-G_n(t,u_{n-1},u_n,u_{n+1},v_{n-1},v_n,v_{n+1})=0. \tag{1.1}$$

The overdots denote time derivatives. The discrete variable n plays the role of a space variable; it labels positions along a one-dimensional lattice. The functions F_n and G_n represent interactions, e.g., between different atoms along a double chain of molecules (see Fig. 1). The functions F_n and G_n are *a priori* unspecified; our aim is to classify equations of the type (1.1) according to the Lie point symmetries that they allow. The interactions in such a model depend on up to six neighboring particles. For instance, we can interpret u_n and v_n as deviations from equilibrium positions of two different types of atoms, say type U and type V. The accelerations $\ddot{u}_n$ and $\ddot{v}_n$ depend on the deviations u and v of both types of atoms at the neighboring sites $n-1$, n, and $n+1$. We do not restrict to two-body forces, nor do we impose translational invariance for the chain. We do, however, assume there is no dissipation, i.e., system (1.1) does not involve first derivatives with respect to time.

Such differential-difference equations typically arise when modeling phenomena in molecular physics, biophysics, or simply coupled oscillations in classical mechanics.[1–3]

A recent article[4] was devoted to a similar problem, but was concerned with a single species, i.e., one dependent variable $u_n(t)$. The approach adopted here is similar to that of Ref. 4. Thus, we shall consider only symmetries acting on the continuous variables t, u_n, and v_n. Transformations of the discrete variable n must then be studied separately.

Several different treatments of Lie symmetries of difference and differential-difference equations exist in the literature.[4–13] The one adopted in this article is that of Refs. 4–6. It has been

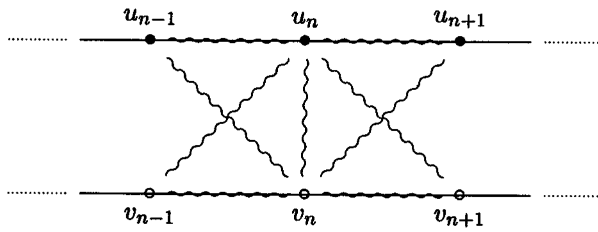

FIG. 1. Double molecular chain with two types of atoms.

called the ''intrinsic method,'' makes use of a Lie algebraic approach, and is entirely algorithmic. The Lie algebra of the symmetry group, the ''symmetry algebra'' for short, is realized by vector fields of the form

$$\hat{X}=\tau(t,u_n,v_n)\partial_t+\phi_n(t,u_n,v_n)\partial_{u_n}+\psi_n(t,u_n,v_n)\partial_{v_n}. \tag{1.2}$$

The algorithm for finding the functions τ, ϕ_n, and ψ_n in (1.2) is to construct the appropriate prolongation $\mathrm{pr}\,\hat{X}$ of $\hat{X}$ (see Refs. 4–6 and Sec. II) and to impose that it should annihilate the studied system of equations on their solution set,

$$\mathrm{pr}\,\hat{X}E_1|_{E_1=E_2=0}=0, \quad \mathrm{pr}\,\hat{X}E_2|_{E_1=E_2=0}=0. \tag{1.3}$$

Our first step is to find and classify all interactions (F_n,G_n) for which the system (1.1) allows at least a one-dimensional symmetry algebra. The next step is to specify the interactions further and to find all those that allow a higher-dimensional, possibly infinite-dimensional, symmetry algebra.

As in previous articles,[4,14] our classification will be up to conjugacy under a group of ''allowed transformations.'' These are fiber preserving locally invertible point transformations,

$$u_n=\Omega_n(\tilde{u}_n,\tilde{v}_n,\tilde{t}), \quad v_n=\Gamma_n(\tilde{u}_n,\tilde{v}_n,\tilde{t}), \quad t=t(\tilde{t}), \tag{1.4}$$

which preserve the form of Eqs. (1.1), but not necessarily the functions F_n and G_n (they go into new functions $\tilde{F}_n$ and $\tilde{G}_n$ of the new arguments).

Throughout the article we assume that both F_n and G_n depend on at least one of the quantities $u_{n-1},u_{n+1},v_{n-1},v_{n+1}$, so that nearest neighbors are genuinely involved. In the bulk of the article the interaction is assumed to be nonlinear.

In Sec. II we formulate the problem, establish the general form of the elements of the symmetry algebra, and present the determining equations for the symmetries. We also derive the ''allowed transformations'' under which we classify the interactions and their symmetries. Section III is devoted to a classification of interactions F_n, G_n, allowing at least a one-dimensional symmetry algebra. Ten classes of such interactions exist, each involving two arbitrary functions of six variables. In Sec. IV we study higher-dimensional symmetry algebras and introduce an important restriction. We first prove that four equivalence classes of symmetry algebras isomorphic to $\mathrm{sl}(2,\mathbb{R})$ exist. Then we restrict to just one of them, $\mathrm{sl}(2,\mathbb{R})_1$ generating a gauge group acting only on the fields u_n and v_n (in a global, coordinate-independent manner). We describe all symmetry algebras, containing the chosen $\mathrm{sl}(2,\mathbb{R})$ as a subalgebra. In Sec. V we obtain the invariant interactions for all algebras containing $\mathrm{sl}(2,\mathbb{R})_1$. The results are summed up and discussed in Sec. VI, where we also outline future work to be done.

II. FORMULATION OF THE PROBLEM

To find the Lie point symmetries of the system (1.1), we write the second prolongation of the vector field (1.2) in the form[4–6]

$$\mathrm{pr}^{(2)}\hat{X}=\tau(t,u_n,v_n)\partial_t+\sum_{k=n-1}^{n+1}\phi_k(t,u_n,v_n)\partial_{u_k}+\sum_{k=n-1}^{n+1}\psi_k(t,u_n,v_n)\partial_{v_k}+\phi_n^{tt}\partial_{\ddot{u}_n}+\psi_n^{tt}\partial_{\ddot{v}_n}, \tag{2.1}$$

with

$$\begin{aligned}\phi_n^{tt}&=D_t^2\phi_n-(D_t^2\tau)\dot{u}_n-2(D_t\tau)\ddot{u}_n,\\ \psi_n^{tt}&=D_t^2\psi_n-(D_t^2\tau)\dot{v}_n-2(D_t\tau)\ddot{v}_n,\end{aligned} \tag{2.2}$$

where D_t is the total time derivative. The determining equations for the symmetries are obtained by requiring that Eq. (1.3) be satisfied. The obtained equations will involve terms like $\dot{u}^k$, $\dot{v}^k$, and $\dot{u}^k\dot{v}^l$. The coefficients of each linearly independent term must vanish and this provides 16 linear differential equations that are easy to solve and do not involve the interaction functions F_n,G_n. The result is that an element $\hat{X}$ of the symmetry algebra must have the form

$$\hat{X}=\tau(t)\partial_t+\left[\left(\frac{\dot{\tau}}{2}+a_n\right)u_n+b_nv_n+\lambda_n(t)\right]\partial_{u_n}+\left[c_nu_n+\left(\frac{\dot{\tau}}{2}+d_n\right)v_n+\mu_n(t)\right]\partial_{v_n}, \tag{2.3}$$

where the overdots denote time derivatives. The functions $\tau(t)$, $\lambda_n(t)$, $\mu_n(t)$, a_n, b_n, c_n, and d_n satisfy the two remaining determining equations, namely,

$$\begin{aligned}&\frac{\dddot{\tau}}{2}u_n+\ddot{\lambda}_n+\left(a_n-\frac{3}{2}\dot{\tau}\right)F_n+b_nG_n-\tau F_{n,t}-\sum_{k=n-1}^{n+1}F_{n,u_k}\left[\left(\frac{\dot{\tau}}{2}+a_k\right)u_k+b_kv_k+\lambda_k(t)\right]\\ &\quad-\sum_{k=n-1}^{n+1}F_{n,v_k}\left[\left(\frac{\dot{\tau}}{2}+d_k\right)v_k+c_ku_k+\mu_k(t)\right]=0,\end{aligned} \tag{2.4}$$

$$\begin{aligned}&\frac{\dddot{\tau}}{2}v_n+\ddot{\mu}_n+\left(d_n-\frac{3}{2}\dot{\tau}\right)G_n+c_nF_n-\tau G_{n,t}-\sum_{k=n-1}^{n+1}G_{n,u_k}\left[\left(\frac{\dot{\tau}}{2}+a_k\right)u_k+b_kv_k+\lambda_k(t)\right]\\ &\quad-\sum_{k=n-1}^{n+1}G_{n,v_k}\left[\left(\frac{\dot{\tau}}{2}+d_k\right)v_k+c_ku_k+\mu_k(t)\right]=0.\end{aligned} \tag{2.5}$$

In Eqs. (2.3), (2.4), and (2.5) the quantities a_n, b_n, c_n, and d_n are independent of t. To proceed further, one could specify the interaction functions F_n and G_n. Instead, we shall assume that at least one symmetry generator (2.3) exists and make use of allowed transformations to simplify this vector. The second step is to find interactions F_n and G_n compatible with such a symmetry.

Substituting (1.4) into Eq. (1.1) and requiring that the form of these two equations be preserved, we find that the allowed transformations are quite restricted, namely,

$$\begin{pmatrix}u_n(t)\\ v_n(t)\end{pmatrix}=\begin{pmatrix}Q_n & R_n\\ S_n & T_n\end{pmatrix}\dot{\tilde{t}}^{-1/2}\begin{pmatrix}\tilde{u}_n(\tilde{t})\\ \tilde{v}_n(\tilde{t})\end{pmatrix}+\begin{pmatrix}\alpha_n(t)\\ \beta_n(t)\end{pmatrix},\quad \tilde{t}=\tilde{t}(t),\quad \frac{d\tilde{t}}{dt}\neq 0. \tag{2.6}$$

The entries Q_n, R_n, S_n, and T_n are independent of t; $\tilde{t}(t)$ is an arbitrary locally invertible function of t; α_n,β_n are arbitrary functions of n and t, and the matrix

$$M_n=\begin{pmatrix}Q_n & R_n\\ S_n & T_n\end{pmatrix},\quad \det M_n\neq 0, \tag{2.7}$$

is nonsingular.

It will be convenient to use a shorthand notation for the vector field X_n of Eq. (2.3), namely,

$$\left\{ \tau(t), A_n, \begin{pmatrix} \lambda_n(t) \\ \mu_n(t) \end{pmatrix} \right\}, \quad A_n = \begin{pmatrix} a_n & b_n \\ c_n & d_n \end{pmatrix}. \tag{2.8}$$

If we perform an allowed transformation (2.6), then Eq. (1.1) goes into an equation of the same form, with F_n and G_n replaced by

$$\begin{pmatrix} \tilde{F}_n \\ \tilde{G}_n \end{pmatrix} = \dot{\tilde{t}}^{-3/2} M_n^{-1} \left[\begin{pmatrix} F_n \\ G_n \end{pmatrix} - \begin{pmatrix} \ddot{\alpha}_n \\ \ddot{\beta}_n \end{pmatrix} \right] + \left(\frac{1}{2} \dddot{\tilde{t}} \dot{\tilde{t}}^{-3} - \frac{3}{4} \ddot{\tilde{t}}^2 \dot{\tilde{t}}^{-4} \right) \begin{pmatrix} \tilde{u}_n \\ \tilde{v}_n \end{pmatrix}, \tag{2.9}$$

where $\tilde{F}_n$ and $\tilde{G}_n$ are functions of the new variables.

The vector field characterized by the triplet (2.3) goes into a new one of the same form,

$$\left\{ \tilde{\tau}(\tilde{t}), \tilde{A}_n, \begin{pmatrix} \tilde{\lambda}_n(\tilde{t}) \\ \tilde{\mu}_n(\tilde{t}) \end{pmatrix} \right\}, \tag{2.10}$$

with

$$\tilde{\tau}(\tilde{t}) = \tau(t(\tilde{t}))\dot{\tilde{t}},$$

$$\tilde{A}_n = M_n^{-1} A_n M_n,$$

$$\begin{pmatrix} \tilde{\lambda}_n(\tilde{t}) \\ \tilde{\mu}_n(\tilde{t}) \end{pmatrix} = M_n^{-1} \dot{\tilde{t}}^{1/2} \left[\left(A_n + \frac{\dot{\tau}}{2} \right) \begin{pmatrix} \alpha_n \\ \beta_n \end{pmatrix} - \tau \begin{pmatrix} \dot{\alpha}_n \\ \dot{\beta}_n \end{pmatrix} + \begin{pmatrix} \lambda_n \\ \mu_n \end{pmatrix} \right].$$

We shall use the allowed transformations to simplify the vector field, rather than the equation itself.

III. SYSTEMS WITH ONE-DIMENSIONAL SYMMETRY GROUPS

Let us now assume that the system (1.1) has at least a one-dimensional symmetry group, generated by a vector field of the type (2.3). Using allowed transformations (2.6), we take $\hat{X}$ into one of ten inequivalent classes.

Indeed, for $\tau \neq 0$ we can choose the function $\tilde{t}(t)$ so as to transform $\tau(t)$ into $\tau=1$, the functions $\alpha_n(t)$ and $\beta_n(t)$ so as to annul $\lambda_n(t)$, and $\mu_n(t)$ and the matrix M_n so as to take A_n into its canonical Jordan form.

For $\tau=0$ the standardized form of $\hat{X}$ depends on the rank of the matrix A_n. For rank $A_n = 2$, we can again transform λ_n and μ_n into $\lambda_n = \mu_n = 0$ and take A_n into one of three canonical forms. For rank $A_n = 1$, only one of the functions λ_n or μ_n can be annulled. We choose it to be $\lambda_n(t) = 0$. Then A_n can be taken into one of the two standard matrices of rank 1 in $\mathbb{R}^{2\times 2}$. For rank $A_n = 0$ both $\lambda_n(t)$ and $\mu_n(t)$ survive.

We thus obtain ten mutually inequivalent one-dimensional symmetry algebras, listed below. The statement now is that any single vector field $\hat{X}$ of the form (2.3) can be transformed by an allowed transformation into precisely one of these vector fields.

The next step is to determine the interactions for which a one-dimensional symmetry group exists. To do this, we run through the canonical vector fields just obtained, substitute the corresponding τ (=1 or 0), A_n, $\lambda_n(t)$, and $\mu_n(t)$ into Eqs. (2.4) and (2.5), and solve these equations for F_n and G_n.

Following this procedure, we arrive at the following list of interactions and their one-dimensional symmetry algebras:

$A_{1,1}$
$$\hat{X}=\partial_t+a_nu_n\partial_{u_n}+d_nv_n\partial_{v_n},$$
$$F_n=e^{a_nt}f_n(\xi_k,\eta_k),$$
$$G_n=e^{d_nt}g_n(\xi_k,\eta_k),$$
$$\xi_k=u_ke^{-a_kt},\quad \eta_k=v_ke^{-d_kt},$$
$$k=n-1,n,n+1;$$

$A_{1,2}$
$$\hat{X}=\partial_t+(a_nu_n+v_n)\partial_{u_n}+a_nv_n\partial_{v_n},$$
$$F_n=e^{a_nt}[f_n(\xi_k,\eta_k)+tg_n(\chi_k,\eta_k)],$$
$$G_n=e^{a_nt}g_n(\xi_k,\eta_k),$$
$$\xi_k=(u_k-tv_k)e^{-a_kt},\quad \eta_k=v_ke^{-a_kt},$$
$$k=n-1,n,n+1;$$

$A_{1,3}$
$$\hat{X}=\partial_t+(a_nu_n+b_nv_n)\partial_{u_n}+(-b_nu_n+a_nv_n)\partial_{v_n},\quad b_n>0,$$
$$\begin{pmatrix}F_n\\G_n\end{pmatrix}=e^{a_nt}\begin{pmatrix}\cos b_nt & \sin b_nt\\ -\sin b_nt & \cos b_nt\end{pmatrix}\begin{pmatrix}f_n(\xi_k,\eta_k)\\ g_n(\xi_k,\eta_k)\end{pmatrix},$$
$$\xi_k=r_ke^{-a_kt},\quad \eta_k=\theta_k+b_kt,$$
$$u_k=r_k\cos\theta_k,\quad v_k=r_k\sin\theta_k,$$
$$k=n-1,n,n+1;$$

$A_{1,4}$
$$\hat{X}=a_nu_n\partial_{u_n}+d_nv_n\partial_{v_n},\quad |a_n|\geqslant|d_n|,$$
$$F_n=u_nf_n(\xi_\alpha,\eta_k,t),$$
$$G_n=v_ng_n(\xi_\alpha,\eta_k,t),$$
$$\xi_a=u_\alpha^{a_n}u_n^{-a_\alpha},\quad \eta_k=v_k^{a_n}u_n^{-d_k},$$
$$k=n-1,n,n+1,\quad \alpha=n-1,n+1;$$

$A_{1,5}$
$$\hat{X}=(a_nu_n+v_n)\partial_{u_n}+a_nv_n\partial_{v_n},\quad a_n\neq 0,$$
$$F_n=v_nf_n(\eta_\alpha,\xi_k,t)+v_n\ln(v_n)g_n(\eta_\alpha,\xi_k,t),$$
$$G_n=a_nv_ng_n(\eta_\alpha,\xi_k,t),$$
$$\xi_k=a_k\frac{u_k}{v_k}-\ln(v_k),\quad \eta_\alpha=v_\alpha^{a_n}v_n^{-a_\alpha},$$
$$k=n-1,n,n+1,\quad \alpha=n-1,n+1;$$

$A_{1,6}$
$$\hat{X}=v_n\partial_{u_n},$$
$$F_n=f_n(v_k,\xi_\alpha,t)+u_ng_n(v_k,\xi_\alpha,t),$$
$$G_n=v_ng_n(v_k,\xi_\alpha,t),$$
$$\xi_\alpha=-v_\alpha u_n+v_nu_\alpha,$$
$$k=n-1,n,n+1,\quad \alpha=n-1,n+1;$$

$A_{1,7}$
$$\hat{X}=(a_nu_n+b_nv_n)\partial_{u_n}+(-b_nu_n+a_nv_n)\partial_{v_n},\quad b_n>0,$$
$$\begin{pmatrix}F_n\\G_n\end{pmatrix}=e^{-(a_n/b_n)\theta_n}\begin{pmatrix}\cos\theta_n & -\sin\theta_n\\ \sin\theta_n & \cos\theta_n\end{pmatrix}\begin{pmatrix}f_n(\xi_k,\eta_\alpha,t)\\ g_n(\xi_k,\eta_\alpha,t)\end{pmatrix},$$
$$\xi_k=r_k^{b_n}e^{a_k\theta_n},\quad \eta_\alpha=b_n\theta_\alpha-b_\alpha\theta_n,$$
$$u_k=r_k\cos\theta_k,\quad v_k=r_k\sin\theta_k,$$
$$k=n-1,n,n+1,\quad \alpha=n-1,n+1;$$

$A_{1,8}$
$$\hat{X}=a_nu_n\partial_{u_n}+\mu_n(t)\partial_{v_n},\quad \mu_n\neq 0,$$
$$F_n=u_nf_n(\eta_\alpha,\xi_k,t),$$
$$G_n=\frac{\ddot{\mu}_n}{\mu_n}v_n+g_n(\eta_\alpha,\xi_k,t),$$
$$\eta_\alpha=\mu_nv_\alpha-\mu_\alpha v_n,\quad \xi_k=u_ke^{-\alpha_kv_n/\mu_n},$$
$$k=n-1,n,n+1,\quad \alpha=n-1,n+1;$$

$A_{1,9}$
$$\hat{X}=v_n\partial_{u_n}+\mu_n(t)\partial_{v_n},\quad \mu_n\neq 0,$$
$$F_n=\frac{1}{2}\frac{\ddot{\mu}_n}{\mu_n^2}v_n^2+v_n g_n(\eta_\alpha,\eta_n,\xi_\alpha,t)+f_n(\eta_\alpha,\eta_n,\xi_\alpha,t),$$
$$G_n=\frac{\ddot{\mu}_n}{\mu_n}v_n+\mu_n g_n(\eta_\alpha,\eta_n,\xi_\alpha,t),$$
$$\eta_\alpha=\mu_n^2u_\alpha+\tfrac{1}{2}\mu_\alpha v_n^2-\mu_n v_n v_\alpha,\quad \xi_\alpha=\mu_\alpha v_n-\mu_n v_\alpha,$$
$$\eta_n=\mu_n u_n-\tfrac{1}{2}v_n^2,\quad \alpha=n-1,n+1;$$

$A_{1,10}$
$$\hat{X}=\lambda_n(t)\partial_{u_n}+\mu_n(t)\partial_{v_n},\quad \lambda_n,\ \mu_n\neq 0,$$
$$F_n=\frac{\ddot{\lambda}_n}{\lambda_n}u_n+f_n(\eta_k,\xi_\alpha,t),$$
$$G_n=\frac{\ddot{\mu}_n}{\mu_n}u_n+g_n(\eta_k,\xi_\alpha,t),$$
$$\xi_\alpha=\lambda_n u_\alpha-\lambda_\alpha u_n,\quad \eta_k=\mu_k u_n-\lambda_n v_k,$$
$$k=n-1,n,n+1,\quad \alpha=n-1,n+1.$$

We mention that the variables ξ_k and η_k are to be taken exactly as above. For instance, ξ_{n+1} is not an upshift of ξ_n.

The above results are summed up quite simply. Namely, the existence of a one-dimensional symmetry algebra restricts the interaction terms F_n and G_n to two arbitrary functions of six variables, rather than the original seven variables. The algebras $A_{1,1}$, $A_{1,2}$ and $A_{1,3}$ involve time translations. Hence, the time dependence in these cases is restricted: F_n and G_n depend on time explicitly and via invariant variables ξ_k and η_k that, in turn, depend explicitly on t. The algebras $A_{1,4},\ldots,A_{1,10}$ correspond to gauge transformations: the group transformations act on dependent variables only. The time variable figures in the arbitrary functions, as does the discrete independent variable n.

IV. HIGHER-DIMENSIONAL SYMMETRY ALGEBRAS

A. General strategy

The commutator of two symmetry operators (2.3) is an operator $X_3=[X_1,X_2]$ of the same form, satisfying

$$\tau_3=\tau_1\dot{\tau}_2-\tau_2\dot{\tau}_1,\quad A_{n,3}=-[A_{n,1},A_{n,2}],$$
$$\begin{pmatrix}\lambda_{n,3}\\ \mu_{n,3}\end{pmatrix}=\tau_1\begin{pmatrix}\dot{\lambda}_{n,2}\\ \dot{\mu}_{n,2}\end{pmatrix}-\tau_2\begin{pmatrix}\dot{\lambda}_{n,1}\\ \dot{\mu}_{n,1}\end{pmatrix}-\left(A_{n,1}+\frac{\dot{\tau}_1}{2}\right)\begin{pmatrix}\lambda_{n,2}\\ \mu_{n,2}\end{pmatrix}+\left(A_{n,2}+\frac{\dot{\tau}_2}{2}\right)\begin{pmatrix}\lambda_{n,1}\\ \mu_{n,1}\end{pmatrix}. \tag{4.1}$$

To obtain a finite-dimensional Lie algebra of symmetry operators, we see that the ''differential components'' $\tau_i(t)\partial_t$ must form a Lie algebra L_d, the ''matrix components'' $A_{n,i}$ must also form a Lie algebra L_m, homomorphic to L_d. Moreover, Eq. (4.1) shows that the ''functional components'' $(\lambda_{n,i}(t),\mu_{n,i}(t))$ must satisfy certain cohomology conditions.

The algebra of diffeomorphisms of $\mathbb{R}^1$, $\{\tau(t)\partial_t\}$ has only three mutually nondiffeomorphic finite-dimensional subalgebras, namely sl$(2,\mathbb{R})$ and its subalgebras, realized, e.g., as

$$\{\partial_t,t\partial_t,t^2\partial_t\},\quad \{\partial_t,t\partial_t\},\quad \text{and } \{\partial_t\}, \tag{4.2}$$

respectively.

For n fixed, the matrices A_n generate the Lie algebra of gl$(2,\mathbb{R})$. However, since the dependence on n is arbitrary, an unlimited number of copies of gl$(2,\mathbb{R})$ and its subalgebras is available.

We shall not perform a complete classification of possible symmetry algebras here. Instead, we shall first concentrate on sl(2,$\mathbb{R}$) symmetry algebras and show that, up to allowed transformations, four different sl(2,$\mathbb{R}$) symmetry algebras can be constructed. We then consider just one of these four and study its extensions to higher-dimensional Lie algebras.

B. Equivalence classes of sl(2,$\mathbb{R}$) symmetry algebras

Since sl(2,$\mathbb{R}$) is a simple Lie algebra, it has no ideals. Hence, a homomorphism between sl(2,$\mathbb{R}$) algebras is either an isomorphism, or one of the algebras is mapped onto zero. Correspondingly, we have three possibilities to explore: we shall call them sl$(2,\mathbb{R})_d$, sl$(2,\mathbb{R})_m$, and sl$(2,\mathbb{R})_c$ (where *d* stands for ''differential,'' *m* for ''matrix,'' and *c* for ''combined'').

1. The algebra sl$(2,\mathbb{R})_d$

We have *a priori*

$$\begin{aligned} X_1&=\partial_t+\lambda_n(t)\partial_{u_n}+\mu_n(t)\partial_{v_n},\\ X_2&=t\partial_t+(\tfrac{1}{2}u_n+\rho_n(t))\partial_{u_n}+(\tfrac{1}{2}v_n+\sigma_n(t))\partial_{v_n},\\ X_3&=t^2\partial_t+(tu_n+\omega_n(t))\partial_{u_n}+(tv_n+\kappa_n(t))\partial_{v_n}. \end{aligned}\tag{4.3}$$

Using allowed transformations we transform $\lambda_n\to0$, $\mu_n\to0$. The commutation relation $[X_1,X_2]=X_1$ then requires $\dot\rho_n=\dot\sigma_n=0$. A further allowed transformation (2.6) with $\tilde t(t)=t$, $M_n=I$, and (α_n,β_n) constant will not change X_1, but take $\rho_n\to0$, $\sigma_n\to0$ (while leaving $\lambda_n=\mu_n=0$). The commutation relations $[X_2,X_3]=X_3$ and $[X_1,X_3]=2X_2$ then imply $\omega_n=\kappa_n=0$.

2. The algebra sl$(2,\mathbb{R})_m$

A priori we have

$$\begin{aligned} X_1&=b_nv_n\partial_{u_n}+\lambda_n(t)\partial_{u_n}+\mu_n(t)\partial_{v_n},\\ X_2&=a_n(u_n\partial_{u_n}-v_n\partial_{v_n})+\rho_n(t)\partial_{u_n}+\sigma_n(t)\partial_{v_n},\\ X_3&=c_nu_n\partial_{v_n}+\omega_n(t)\partial_{u_n}+\kappa_n(t)\partial_{v_n}. \end{aligned}\tag{4.4}$$

The structure constants cannot depend on *n*, so the commutation relations imply

$$a_n=a,\quad b_nc_n=bc.\tag{4.5}$$

Given that the product b_nc_n does not depend on *n*, we can use an allowed transformation to take $b_n\to b$, $c_n\to c$. A further allowed transformation will take $\rho_n\to0$, $\sigma_n\to0$. The commutation relations then imply $\lambda_n=\mu_n=0$ and $\omega_n=\kappa_n=0$.

3. The combined algebra sl$(2,\mathbb{R})_c$

In view of the above results, we can write a ''combined'' algebra as

$$\begin{aligned} X_1&=\partial_t+\alpha v_n\partial_{u_n}+\xi_n\partial_{u_n}+\eta_n\partial_{v_n},\quad \alpha\neq0,\\ X_2&=t\partial_t+[(\tfrac{1}{2}+\beta)u_n+\lambda_n]\partial_{u_n}+[(\tfrac{1}{2}-\beta)v_n+\mu_n]\partial_{v_n},\\ X_3&=t^2\partial_t+(tu_n+\rho_n)\partial_{u_n}+(\gamma u_n+tv_n+\sigma_n)\partial_{v_n}. \end{aligned}\tag{4.6}$$

We use allowed transformations to set $\alpha=1$, $\xi_n=\eta_n=0$. The commutation relations then determine $\beta=\frac{1}{2}$, $\gamma=-1$. The functions $\lambda_n(t)$, $\mu_n(t)$, $\rho_n(t)$, and $\sigma_n(t)$ are greatly restricted by the commutation relations. As a matter of fact, we either have $\lambda_n=\mu_n=\rho_n=\sigma_n=0$, or we can use allowed transformations to obtain $\lambda_n=t$, $\mu_n=1$, $\rho_n=2t^2$, $\sigma_n=2t$.

We arrive at the following result.

Theorem 1: *Precisely four classes of* sl(2,ℝ) *algebras can be realized by vector fields of the form (2.3). Any such* sl(2,ℝ) *algebra can be taken by an allowed transformation (2.6) into precisely one of the following algebras:*

$$\mathrm{sl}(2,\mathbb{R})_1: \quad \begin{aligned} &X_1=v_n\partial_{u_n},\\ &X_2=\tfrac{1}{2}(u_n\partial_{u_n}-v_n\partial_{v_n}),\\ &X_3=u_n\partial_{v_n}, \end{aligned} \tag{4.7}$$

$$\mathrm{sl}(2,\mathbb{R})_2: \quad \begin{aligned} &X_1=\partial_t,\\ &X_2=t\partial_t+\tfrac{1}{2}(u_n\partial_{u_n}+v_n\partial_{v_n}),\\ &X_3=t^2\partial_t+t(u_n\partial_{u_n}+v_n\partial_{v_n}), \end{aligned} \tag{4.8}$$

$$\mathrm{sl}(2,\mathbb{R})_3: \quad \begin{aligned} &X_1=\partial_t+v_n\partial_{u_n},\\ &X_2=t\partial_t+u_n\partial_{u_n},\\ &X_3=t^2\partial_t+tu_n\partial_{u_n}+(tv_n-u_n)\partial_{v_n}, \end{aligned} \tag{4.9}$$

$$\mathrm{sl}(2,\mathbb{R})_4: \quad \begin{aligned} &X_1=\partial_t+v_n\partial_{u_n}\\ &X_2=t\partial_t+(u_n+t)\partial_{u_n}+\partial_{v_n}\\ &X_3=t^2\partial_t+(tu_n+2t^2)\partial_{u_n}+(tv_n-u_n+2t)\partial_{v_n}. \end{aligned} \tag{4.10}$$

C. Indecomposable Lie algebras containing sl(2,ℝ)$_1$

A Lie algebra L is called indecomposable if it cannot be written as a direct sum, $L=L_1\oplus L_2$. A Lie algebra over ℝ containing sl(2,ℝ) is either simple or it allows a nontrivial Levi decomposition,[15]

$$L=S\triangleright R, \tag{4.11}$$

where S is a semisimple Lie algebra and R is the radical, that is, the maximal solvable ideal of L.

It follows from the results of Sec. IV A that the only simple Lie algebras that can be constructed from operators of the form (2.3) are the four sl(2,ℝ) algebras obtained in Sec. IV B. We can hence concentrate on Lie algebras of the form (4.11).

The algebra S is either sl(2,ℝ)$_1$ itself, or the direct sum of sl(2,ℝ)$_1$ with one or more other sl(2,ℝ) algebras.

Requiring that a symmetry operator Y should commute with all elements of sl(2,ℝ)$_1$, we find that Y must have the form

$$Y_0=\tau\partial_t+(\tfrac{1}{2}\dot{\tau}+a_n)(u_n\partial_{u_n}+v_n\partial_{v_n}). \tag{4.12}$$

It is hence possible to construct precisely one semisimple Lie algebra properly containing sl(2,ℝ)$_1$, namely, the direct sum sl(2,ℝ)$_1\oplus$sl(2,ℝ)$_2$ with sl(2,ℝ)$_2$ defined in Eq. (4.8).

Let us introduce some notations for vector fields, to be used below. We put

$$V(a_n)=a_n(u_n\partial_{u_n}+v_n\partial_{v_n}), \tag{4.13}$$

$$T(a_n)=\partial_t+a_n(u_n\partial_{u_n}+v_n\partial_{v_n}),\tag{4.14}$$

$$D(a_n)=t\partial_t+(\tfrac{1}{2}+a_n)(u_n\partial_{u_n}+v_n\partial_{v_n}),\tag{4.15}$$

$$P(a_n)=t^2\partial_t+(t+a_n)(u_n\partial_{u_n}+v_n\partial_{v_n}),\tag{4.16}$$

$$R(a_n)=(t^2+1)\partial_t+(t+a_n)(u_n\partial_{u_n}+v_n\partial_{v_n}),\tag{4.17}$$

$$Y_u(\lambda_n)=\lambda_n(t)\partial_{u_n},\quad Y_v(\lambda_n)=\lambda_n(t)\partial_{v_n}.\tag{4.18}$$

In all cases we have $\dot{a}_n=0$, but $\lambda_n(t)$ can be a function of t. Both a_n and $\lambda_n(t)$ can be functions of n.

Let us consider $S=\mathrm{sl}(2,\mathbb{R})_1$ and $S=\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2$ in Eq. (4.11) separately.

1. $S=\mathrm{sl}(2,\mathbb{R})_1$

The considered Lie algebras will have a basis $\{X_1,X_2,X_3,Y_1,\ldots,Y_n\}$ with X_i given in Eq. (4.7). The basis elements $\{Y_1,\ldots,Y_n\}$ span the radical R. The algebra S acts on R according to some linear, not necessarily irreducible, finite-dimensional representation.

We start with the Cartan subalgebra $\{X_2\}$ of $\mathrm{sl}(2,\mathbb{R})$. It can be represented by a diagonal matrix in any finite-dimensional representation. Consider $Y\in R$. We have

$$[X_2,Y]=pY,\tag{4.19}$$

with Y as in Eq. (2.3). Equation (4.19) implies

$$\begin{gathered}p\tau=0,\\ p\left(\frac{\dot\tau}{2}+a_n\right)=0,\quad \left(p+\frac{1}{2}\right)\lambda_n=0,\quad (p+1)b_n=0,\\ p\left(\frac{\dot\tau}{2}+d_n\right)=0,\quad \left(p-\frac{1}{2}\right)\mu_n=0,\quad (p-1)c_n=0.\end{gathered}\tag{4.20}$$

For $p=0$ we obtain an operator that commutes not only with X_2, but with all of $\mathrm{sl}(2,\mathbb{R})_1$, namely, Y_0 of Eq. (4.12). This is a singlet representation of $\mathrm{sl}(2,\mathbb{R})$.

For $p=1$, or $p=-1$, Eq. (4.19) forces Y to be an element of $\mathrm{sl}(2,\mathbb{R})_1$, in other words, no such $Y\in R$ exists.

For $p=\pm\frac{1}{2}$ we obtain $Y_1=\lambda_n(t)\partial_{u_n}$ and $Y_2=\mu_n(t)\partial_{v_n}$, respectively. Acting with X_1 and X_3 on these operators, we find that the only representation of $\mathrm{sl}(2,\mathbb{R})_1$ that can be realized is a doublet one, namely $\{Y_u(\lambda_n),Y_v(\lambda_n)\}$ of Eq. (4.18), with $\lambda_n(t)$ an arbitrary function of n and t. The indecomposable Lie algebra $\{X_1,X_2,X_3,Y_u(\lambda_n),Y_v(\lambda_n)\}$ is isomorphic to the special affine Lie algebra $\mathrm{saff}(2,\mathbb{R})$.

All further indecomposable symmetry algebras containing $\mathrm{sl}(2,\mathbb{R})_1$ must be extensions of $\mathrm{saff}(2,\mathbb{R})$. The objects that we can add to $\mathrm{saff}(2,\mathbb{R})$ are either $\mathrm{sl}(2,\mathbb{R})$ doublets or singlets. Let us run through all possibilities.

(1) We can add an arbitrary number k of doublets of the form (4.18), where the k functions $\{\lambda_n^1(t),\lambda_n^2(t),\ldots,\lambda_n^k(t)\}$ must be linearly independent. However, we shall see in Sec. V that the presence of three such pairs forces the functions F_n and G_n in Eq. (1.1) to be linear. Moreover, even two such pairs are compatible with a nonlinear interaction only if they are of the form (or transformable into)

$$\lambda_n^1(t)=1,\quad \lambda_n^2(t)=t.\tag{4.21}$$

(2) We can add a singlet of the form (4.12). If we have $\tau=0$, then the commutation relations $[Y_0,Y_u]$ and $[Y_0,Y_v]$ imply $a_n=a_{n+1}$ and we can set $a_n=1$. We obtain an affine Lie algebra $\mathrm{gaff}(2,\mathbb{R})_1$ consisting of $\mathrm{saff}(2,\mathbb{R})$ and $V(1)$ of Eq. (4.13).
If we have $\tau\neq0$ in Eq. (4.12) and only one operator of this type, then we can use allowed transformations to take $\tau(t)$ into $\tau(t)=1$. The commutation relations $[Y_0,Y_u]$ and $[Y_0,Y_v]$ then imply

$$\lambda_n(t)=R_n e^{(a_n+k)t}, \quad \dot{R}_n=0.$$

For $k=0$, the algebra is decomposable. For $k\neq0$ we can use allowed transformations to put $k=-1$ and $R_n=1$. We obtain a second algebra isomorphic to $\mathrm{gaff}(2,\mathbb{R})$, but not conjugate to the previous one. We have

$$\mathrm{gaff}(2,\mathbb{R})_2\sim\{X_1,X_2,X_3,Y_u(e^{(a_n-1)t}),Y_v(e^{(a_n-1)t}),T(a_n)\}. \tag{4.22}$$

In the special case of $a_n=a_{n+1}$ in Eq. (4.22), a further extension is possible. We transform $\lambda=e^{(a-1)t}$ into $\lambda=1$; then $T(a_n)$ goes into $D(b_n)$ with $b_n=b_{n+1}\equiv b\neq-\frac{1}{2}$, since for $b=-\frac{1}{2}$ the algebra is decomposable.

(3) We can add two singlets of the form (4.12). If they commute, they must be $\{V(1),T(0)\}$. The obtained algebra is decomposable. If they do not commute, they must form a two-dimensional Lie algebra, namely, $\{T(0),D(a),a_n=a_{n+1}\equiv a\}$. This implies $\lambda_n(t)\sim1$, i.e., the entire radical is $\{Y_u(1),Y_v(1),T(0),D(a)\}$ with $a\neq\frac{1}{2}$ (the case $a=\frac{1}{2}$ corresponds to a decomposable algebra).

(4) If we add three singlets, the only case corresponds to the radical $\{Y_u(1),Y_v(1),V(1),T(0),D(0)\}$. There will then be no invariant interaction (see below).

(5) Let us consider the special case of two doublets of the form (4.18), namely,

$$Y_u(1)=\partial_{u_n}, \quad Y_v(1)=\partial_{v_n}, \quad Y_u(t)=t\partial_{u_n}, \quad Y_v(t)=t\partial_{v_n}. \tag{4.23}$$

This algebra can be extended by a further element, namely,

$$Z=(\tau_0+\tau_1 t+\rho_2 t^2)\partial_t+(\tfrac{1}{2}\tau_1+\tau_2 t+a)(u_n\partial_{u_n}+v_n\partial_{v_n}),$$
$$a_n=a_{n+1}\equiv a, \tag{4.24}$$

where τ_0, τ_1, and τ_2 are constants. By allowed transformations we can take Z into one of the four operators $V(1)$, $T(a)$, $D(a)$, or $R(a)$ of (4.13), (4.14), (4.15), and (4.17), respectively.

(6) We can add a two-dimensional algebra to (4.23), namely,

$$\{T(0),D(a)\}, \quad \{T(0),V(1)\}, \quad \{V(1),D(0)\}, \text{ or } \{V(1),R(0)\}.$$

(7) We can add only one three-dimensional algebra to (4.23), namely,

$$\{T(0), \quad D(0), \quad V(1)\}.$$

This completes the list of indecomposable symmetry algebras of the form (4.11) with $S=\mathrm{sl}(2,\mathbb{R})_1$.

2. $S=\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2$

The algebra S is itself decomposable. It gives rise to precisely two indecomposable symmetry algebras. First, we have the one obtained by adding the Abelian ideal (4.23) to $\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2$. Second, we get an 11-dimensional algebra by adding $V(1)$ to the first case.

D. Decomposable Lie algebras containing $\mathrm{sl}(2,\mathbb{R})_1$

All decomposable Lie algebras L_D can be obtained from the indecomposable L_I ones, by adding their centralizers,

$$L_D = L_I \oplus C, \quad [C, L_I] = 0. \tag{4.25}$$

The centralizer C must commute with all elements of $\mathrm{sl}(2,\mathbb{R})_1$ and hence all of its elements will have the form of Y_0 of Eq. (4.12).

Let us consider the individual indecomposable algebras L_I.

1. $L_I = \mathrm{sl}(2,\mathbb{R})_1$

The centralizer C can be Abelian. Then we have the following possibilities: $C = \{V(a_{i,n}), i = 1,...,k\}$ or $C = \{V(a_{i,n}), T(b_n), i = 1,...,k\}$. The quantities $a_{1,n},\ldots,a_{k,n}$ must form a set of k linearly independent functions of n. If the centralizer is non-Abelian, then we have either $C \sim \mathrm{sl}(2,\mathbb{R})_2$ or $C = \{T(0), D(a)\}$. Both of these centralizers can be further extended by adding $V(a_{i,n})$, $i = 1,...,k$, (with $a_{1,n},\ldots,a_{k,n}$ linearly independent).

2. $L_I = \mathrm{saff}(2,\mathbb{R})$

We must require Y_0 of Eq. (4.12) to commute with $Y_u(\lambda_n)$ and $Y_v(\lambda_n)$ of Eq. (4.18). We obtain

$$\lambda_n\left(\tfrac{1}{2}\dot{\tau} + a_n\right) - \tau\dot{\lambda}_n = 0. \tag{4.26}$$

For $\tau = 0$, Eq. (4.26) implies $\lambda_n a_n = 0$, and this is not allowed. For $\tau \neq 0$ we take $\tau \to 1$ by an allowed transformation, and Eq. (4.26) then implies $\lambda_n(t) = \gamma_n e^{a_n t}$. A further allowed transformation will take $\gamma_n \to 1$. We obtain the decomposable Lie algebra $\mathrm{saff}(2,\mathbb{R}) \oplus T(a_n)$. In the special case $a_n = a_{n+1}$ we transform $\lambda_n(t) \to 1$ and obtain a larger centralizer, namely, $\{T(0), D(-\tfrac{1}{2})\}$.

3. $L_I = \mathrm{gaff}(2,\mathbb{R})_1$

A nontrivial centralizer exists only if we have $\lambda_n(t) = e^{a_n t}$ in $\mathrm{saff}(2,\mathbb{R})$. In the case $a_n \neq 0$, the centralizer is $C = \{T(a_n)\}$. If $a_n = 0$ the centralizer is $C = \{T(0), D(-\tfrac{1}{2})\}$.

4. $L_I = \mathrm{gaff}(2,\mathbb{R})_2$

The centralizer is $C = \{T(a_n) - V(1)\}$. This algebra corresponds to the first one obtained in the case $L_I = \mathrm{gaff}(2,\mathbb{R})_1$ above.

E. Summary of possible symmetry algebras containing $\mathrm{sl}(2,\mathbb{R})_1$

The classification of possible symmetry algebras can now be summed up rather simply. In addition to $\mathrm{sl}(2,\mathbb{R})_1$ of Eq. (4.7), we have a further algebra L_C (the ''complementary'' algebra). The structure of each symmetry algebra is

$$L = \mathrm{sl}(2,\mathbb{R})_1 \dotplus L_C, \quad [\mathrm{sl}(2,\mathbb{R})_1, L_C] \subseteq L_C, \quad [L_C, L_C] \subseteq L_C. \tag{4.27}$$

The symbol $\dotplus$ denotes a direct sum of vector spaces. Moreover, Eq. (4.27) shows that L is either a direct sum or a semidirect one. The algebra L_C is also a representation space for $\mathrm{sl}(2,\mathbb{R})_1$. Irreducible representations in this case can be of dimension 1 or 2. All higher-dimensional representations are completely reducible into sums of one- and two-dimensional representations.

For further use it is convenient to split the symmetry algebras into four series, according to the structure of the Lie algebra L_C. In all cases L contains $\mathrm{sl}(2,\mathbb{R})_1$. We shall just specify L_C.

1. Series A

L_C is solvable and each element is a $\mathrm{sl}(2,\mathbb{R})_1$ singlet. There exist three different infinite-dimensional Lie algebras of this type:

$$A_1. \quad \{V(a_{k,n})\}, \tag{4.28}$$

$$A_2. \quad \{T(b_n), V(a_{k,n})\}, \tag{4.29}$$

$$A_3.\ \{T(0), D(b_n), V(a_{k,n})\}. \tag{4.30}$$

In each case we have $k=1,2,\ldots,$ and the expressions a_k must be linearly independent functions of n. Taking $1 \leqslant k \leqslant N$ for some finite N, we obtain finite-dimensional subalgebras.

2. Series B

L_C is solvable and contains precisely one $\mathrm{sl}(2,\mathbb{R})_1$ doublet,

$$B_1 = \{Y_u(\lambda_n), Y_v(\lambda_n)\}. \tag{4.31}$$

This is the indecomposable algebra $\mathrm{saff}(2,\mathbb{R})$ [B_1 together with $\mathrm{sl}(2,\mathbb{R})_1$]. We have $\dim L=5$,

$$B_2 = \{Y_u(\lambda_n), Y_v(\lambda_n), V(1)\}. \tag{4.32}$$

B_2 corresponds to the indecomposable algebra $\mathrm{gaff}(2,\mathbb{R})_1$ with $\dim L=6$,

$$B_3 = \{Y_u(e^{(a_n-1)t}), Y_v(e^{(a_n-1)t}), T(a_n)\}. \tag{4.33}$$

B_3 corresponds to the Lie algebra $\mathrm{gaff}(2,\mathbb{R})_2$, isomorphic but not conjugate to B_2,

$$B_4 = \{Y_u(e^{a_n t}), Y_v(e^{a_n t}), T(a_n)\}. \tag{4.34}$$

This algebra is $\mathrm{saff}(2,\mathbb{R}) \oplus T(a_n)$,

$$B_5 = \{Y_u(1), Y_v(1), T(0), D(a)\}. \tag{4.35}$$

The algebra B_5 is indecomposable (except if $a=-\frac{1}{2}$),

$$B_6 = \{Y_u(e^{(a_n-1)t}), Y_v(e^{(a_n-1)t}), T(a_n), V(1)\}. \tag{4.36}$$

The algebra B_6 is decomposable,

$$B_7 = \{Y_u(1), Y_v(1), T(0), D(0), V(1)\}. \tag{4.37}$$

The algebra B_7 is indecomposable.

3. Series C

L_C contains two $\mathrm{sl}(2,\mathbb{R})$ doublets. The doublets could be characterized by any two functions $\lambda_{1,n}(t)$ and $\lambda_{2,n}(t)$. However, we shall only be interested in the case $\lambda_1=1$, $\lambda_2=t$. The others do not lead to invariant interactions. Similarly, we do not need algebras containing three or more doublets. In all cases the algebra L_C contains the elements (4.23). For $\dim L_C \geqslant 5$ it contains further elements. We have

$$C_1 = \{Y_u(1), Y_v(1), Y_u(t), Y_v(t)\}. \tag{4.38}$$

Further, we just list the additional elements,

$$C_2.\ \{T(a)\},\quad a=0 \ \text{ or } \ 1, \tag{4.39}$$

$$C_3.\ \{D(a)\}, \tag{4.40}$$

$$C_4.\ \{R(a)\}, \tag{4.41}$$

$$C_5.\ \{V(1)\}, \tag{4.42}$$

$$C_6.\ \{T(0), D(a)\}. \tag{4.43}$$

In all cases above, a does not depend on $n(a_{n+1}=a_n)$,

$$C_7.\ \{V(1),T(0)\}, \tag{4.44}$$

$$C_8.\ \{V(1),D(0)\}, \tag{4.45}$$

$$C_9.\ \{V(1),R(0)\}, \tag{4.46}$$

$$C_{10}.\ \{T(0),D(0),P(0)\}\sim \mathrm{sl}(2,\mathbb{R})_2, \tag{4.47}$$

$$C_{11}.\ \{T(0),D(0),V(1)\}, \tag{4.48}$$

$$C_{12}.\ \{T(0),D(0),P(0),V(1)\}. \tag{4.49}$$

4. Series D

L_C contains $\mathrm{sl}(2,\mathbb{R})_2$ and (possibly) further elements, namely,

$$D_1.\ \text{None}, \tag{4.50}$$

$$D_2.\ \{V(a_n)\}, \tag{4.51}$$

$$D_3.\ \{V(a_{1,n}),V(a_{2,n})\}, \tag{4.52}$$

$$D_4.\ \{Y_u(1),Y_v(1),Y_u(t),Y_v(t)\}, \tag{4.53}$$

$$D_5.\ \{Y_u(1),Y_v(1),Y_u(t),Y_v(t),V(1)\} \tag{4.54}$$

(D_4 coincides with C_{10} and D_5 with C_{12}).

V. THE INVARIANT INTERACTIONS

A. General procedure and interactions invariant under $\mathrm{SL}(2,\mathbb{R})_1$

In this section we shall find all interaction functions, invariant under symmetry groups, containing $\mathrm{SL}(2,\mathbb{R})_1$. We make use of the subalgebra classification provided in Sec. IV.

We first establish the form of the interaction, invariant under $\mathrm{SL}(2,\mathbb{R})_1$ itself. To do this we set $\tau(t)=\lambda_n(t)=\mu_n(t)=0$ in the determining equations (2.4) and (2.5) and consider the equations obtained for $a_n=-d_n=1$, $b_n=c_n=0$, then $b_n=1$, $a_n=-d_n=c_n=0$, and, finally, $c_n=1$, $a_n=-d_n=b_n=0$. The general solution of the obtained system of six equations can be written in the following form:

$$F_n=u_{n+1}f_n+u_ng_n, \quad G_n=v_{n+1}f_n+v_ng_n, \tag{5.1}$$

where f_n and g_n are functions of four variables each, namely,

$$t,\ \ \xi_n=u_{n+1}v_{n-1}-u_{n-1}v_{n+1}, \quad \xi_\alpha=u_\alpha v_n-u_nv_\alpha, \quad \alpha=n\pm 1. \tag{5.2}$$

Note that ξ_n, ξ_{n+1}, and ξ_{n-1} are as given in Eq. (5.2). They are not upshifts or downshifts of each other.

We shall proceed further by dimension of the symmetry algebra and by its structure. Thus, we can successively add $\mathrm{sl}(2,\mathbb{R})$ singlets of the form (4.12) or doublets of the form (4.18). We continue adding symmetry elements until the interaction is completely specified, i.e., it involves no further arbitrary functions. We then solve the ''inverse problem.'' That is, we substitute the functions F_n and G_n back into the determining equations and solve for the symmetries. This provides a verification of previous calculations. More important, this procedure will find the largest symmetry algebra allowed by any given interaction.

Obviously, all invariant interactions will have the form (5.1). It is the functions f_n and g_n that will be further refined, and their dependence on the variables ξ_k and t will be restricted.

For future convenience we write down two further forms of the $\mathrm{SL}(2,\mathbb{R})_1$ invariant interaction functions, equivalent to (5.1). The first is

$$F_n = u_{n+1}\frac{\xi_{n-1}}{\xi_n}h_n + u_n k_n, \quad G_n = v_{n+1}\frac{\xi_{n-1}}{\xi_n}h_n + v_n k_n, \tag{5.3}$$

where h_n and k_n are arbitrary functions of the variables (5.2). The second convenient form is

$$\begin{aligned} F_n &= (\lambda_{n-1}u_{n+1} - \lambda_{n+1}u_{n-1})\phi_n + (\lambda_{n+1}u_n - \lambda_n u_{n+1})\psi_n + \frac{\ddot{\lambda}_n}{\lambda_{n+1}}u_{n+1}, \\ G_n &= (\lambda_{n-1}v_{n+1} - \lambda_{n+1}v_{n-1})\phi_n + (\lambda_{n+1}v_n - \lambda_n v_{n+1})\psi_n + \frac{\ddot{\lambda}_n}{\lambda_{n+1}}v_{n+1}, \end{aligned} \tag{5.4}$$

where $\lambda_n(t)$ is some arbitrary function of n and t and ϕ_n and ψ_n depend in an unspecified manner on the variables (5.2).

B. Interactions invariant under four-dimensional symmetry groups

As was shown in Sec. IV, two types of four-dimensional symmetry algebras containing $\mathrm{sl}(2,\mathbb{R})_1$ can exist. Both are decomposable according to the pattern $4=3+1$. Here and below we shall always list the operators that we can add to $\mathrm{sl}(2,\mathbb{R})_1$.

1. $V(a_n) = a_n(u_n\partial_{u_n} + v_n\partial_{v_n})$

The invariant interactions will have the form (5.3), but h_n and k_n will depend on three variables only.

(i) $a_{n-1}+a_{n+1}\neq 0$. The variables are

$$t, \quad \eta_\alpha = (\xi_\alpha)^{a_{n-1}+a_{n+1}}(\xi_n)^{-a_n-a_\alpha}, \quad \alpha = n\pm 1. \tag{5.5}$$

(ii) $a_{n-1}+a_{n+1}=0$. The variables are

$$t, \quad \xi_n, \quad \eta = (\xi_{n+1})^{a_{n+1}-a_n}(\xi_{n-1})^{a_{n+1}+a_n}. \tag{5.6}$$

2. $T(b_n) = \partial_t + b_n(u_n\partial_{u_n} + v_n\partial_{v_n})$

The invariant interaction will again have the form (5.3), however, in this case h_n and k_n are arbitrary functions of the three variables,

$$\zeta_n = \xi_n e^{-(b_{n-1}+b_{n+1})t}, \quad \zeta_\alpha = \xi_\alpha e^{-(b_n+b_\alpha)t}, \quad \alpha = n\pm 1. \tag{5.7}$$

We see that adding further singlets of the type $V(a_n)$ will restrict the variables in the functions h_n and k_n, not, however, the general form of Eq. (5.3).

C. Five-dimensional symmetry groups

From the results of Sec. IV, we know that three decomposable and one indecomposable symmetry algebras of dimension 5 can exist. Let us run through all four possibilities.

1. Decomposition 5=3+1+1

a. $V(a_{i,n}) = a_{i,n}(u_n\partial_{u_n} + v_n\partial_{v_n})$ $i=1,2$, $a_{2,n}\neq \lambda a_{1,n}$. The interaction is of the form (5.3). The functions h_n and k_n depend on two variables each, namely, time t and

$$\eta = (\xi_{n-1})^A(\xi_{n+1})^B(\xi_n)^C, \tag{5.8}$$

$$A=a_{1,n}(a_{2,n+1}+a_{2,n-1})+a_{1,n+1}(a_{2,n-1}-a_{2,n})-a_{1,n-1}(a_{2,n+1}+a_{2,n}),$$

$$B=-a_{1,n}(a_{2,n+1}+a_{2,n-1})+a_{1,n+1}(a_{2,n-1}+a_{2,n})-a_{1,n-1}(a_{2,n+1}-a_{2,n}), \tag{5.9}$$

$$C=a_{1,n}(a_{2,n+1}-a_{2,n-1})-a_{1,n+1}(a_{2,n-1}+a_{2,n})+a_{1,n-1}(a_{2,n+1}+a_{2,n}).$$

Note that the variable η always exists since the condition $A=B=C=0$ (and hence η=const) only occurs for $a_{1,n-1}a_{2,n}-a_{1,n}a_{2,n-1}=0$, which implies $a_{2,n}=\lambda a_{1,n}$, λ=const, and this is not allowed.

b. $V(a_n)=a_n(u_n\partial_{u_n}+v_n\partial_{v_n})$, $T(b_n)=\partial_t+b_n(u_n\partial_{u_n}+v_n\partial_{v_n})$. The invariant interaction is as in Eq. (5.3) with h_n and k_n functions of two variables each. Namely, the following.

(i) $a_{n+1}+a_{n-1}\neq 0$:

$$\rho_\alpha=(\zeta_\alpha)^{a_{n+1}+a_{n-1}}(\zeta_n)^{-a_\alpha-a_n}, \quad \alpha=n\pm 1, \tag{5.10}$$

with ζ_α, ζ_n as in Eq. (5.7).

(ii) $a_{n+1}+a_{n-1}=0$:

$$\rho_n=\zeta_n, \quad \sigma_n=(\zeta_{n-1})^{a_{n+1}+a_n}(\zeta_{n+1})^{a_{n+1}-a_n}. \tag{5.11}$$

2. Decomposition 5=3+2

a. $T(0)=\partial_t$, $D(b_n)=t\partial_t+(\frac{1}{2}+b_n)(u_n\partial_{u_n}+v_n\partial_{v_n})$. We impose $b_n\neq -\frac{1}{2}$; otherwise we have no invariant interaction. We must distinguish two subcases here.

(1) $b_{n+1}+b_{n-1}+1\neq 0$. The interaction as in Eq. (5.3), with

$$h_n=(\xi_n)^{-2/(b_{n+1}+b_{n-1}+1)}p_n, \quad k_n=(\xi_n)^{-2/(b_{n+1}+b_{n-1}+1)}q_n, \tag{5.12}$$

where p_n and q_n depend on two variables, namely,

$$\chi_\alpha=(\xi_\alpha)^{b_{n+1}+b_{n-1}+1}(\xi_n)^{-b_n-b_\alpha-1}, \quad \alpha=n\pm 1. \tag{5.13}$$

(2) $b_{n+1}+b_{n-1}+1=0$, $b_{n+1}+b_n+1\neq 0$:

$$h_n=(\xi_{n+1})^{-2/(b_{n+1}+b_n+1)}p_n, \quad k_n=(\xi_{n+1})^{-2/(b_{n+1}+b_n+1)}q_n, \tag{5.14}$$

where p_n and q_n depend on

$$\chi_n=(\xi_{n-1})^{b_{n+1}+b_n+1}(\xi_{n+1})^{-b_{n-1}-b_n-1}, \quad \xi_n. \tag{5.15}$$

Note that for $b_{n+1}+b_{n-1}+1=0$, $b_{n+1}+b_n+1=0$, we have $b_n=-\frac{1}{2}$, and there is no invariant interaction.

3. Indecomposable Lie algebra

$$Y_u(\lambda_n)=\lambda_n(t)\partial_{u_n}, \quad Y_v(\lambda_n)=\lambda_n(t)\partial_{v_n}. \tag{5.16}$$

The invariant interaction is as in Eq. (5.4), but the functions ϕ_n and ψ_n depend on only two variables, namely,

$$t, \quad \omega=\lambda_{n-1}\xi_{n+1}-\lambda_n\xi_n-\lambda_{n+1}\xi_{n-1}. \tag{5.17}$$

D. Six-dimensional symmetry groups

1. Decomposition 6=3+1+1+1

a. $V(a_{i,n})=a_{i,n}(u_n\partial_{u_n}+v_n\partial_{v_n})$, $i=1,2,3$. The invariant interaction is as in Eq. (5.3), but h_n and k_n are functions of t only. We see that the coefficients $a_{i,n}$ do not figure in the interaction.

Hence, we can add an arbitrary number of vector fields $V(a_{i,n})$, $i\in\mathbb{Z}$ to the symmetry algebra. In other words, the symmetry algebra for the interaction (5.3) with h_n and k_n depending on t alone is infinite dimensional.

b. $V(a_{i,n})=a_{i,n}(u_n\partial_{u_n}+v_n\partial_{v_n}),\ i=1,2,\ T(b_n)=\partial_t+b_n(u_n\partial_{u_n}+v_n\partial_{v_n})$. The invariant interaction is as in Eq. (5.3), but h_n and k_n depend on one variable only, namely,

$$\omega=\eta e^{-2t|M|},\quad M=\begin{pmatrix} b_{n-1} & b_n & b_{n+1} \\ a_{1,n-1} & a_{1,n} & a_{1,n+1} \\ a_{2,n-1} & a_{2,n} & a_{2,n+1}\end{pmatrix}, \tag{5.18}$$

with η as in Eq. (5.8).

2. Decomposition 6=3+2+1

a. $V(a_n)=a_n(u_n\partial_{u_n}+v_n\partial_{v_n}),\ T(0)=\partial_t,\ D(c_n)=t\partial_t+(\frac{1}{2}+c_n)(u_n\partial_{u_n}+v_n\partial_{v_n})$. We start from Eq. (5.3). The presence of $T(0)=\partial_t$ implies that h_n and k_n do not depend on t. We first notice that if we have

$$\gamma_n=c_n+\tfrac{1}{2}=0 \quad \text{or} \quad \gamma_n=c_n+\tfrac{1}{2}=\lambda a_n, \tag{5.19}$$

then we must have $h_n=k_n=0$ (no invariant interaction). In all other cases, invariance under $V(a_n)$ and $D(c_n)$ implies

$$\begin{gathered} h_n=(\xi_n)^{\mu}(\xi_{n+1})^{\nu}(\xi_{n-1})^{\rho}p_n(\omega),\quad k_n=(\xi_n)^{\mu}(\xi_{n+1})^{\nu}(\xi_{n-1})^{\rho}q_n(\omega),\\ \omega=(\xi_{n-1})^{A}(\xi_{n+1})^{B}(\xi_n)^{C}, \end{gathered} \tag{5.20}$$

with A, B, and C as in Eq. (5.9), with the substitutions

$$a_{1,n}\rightarrow c_n+\tfrac{1}{2},\quad a_{2,n}\rightarrow a_n.$$

The constants μ, ν, and ρ in Eq. (5.20) satisfy

$$\begin{gathered} (a_{n+1}+a_{n-1})\mu+(a_{n+1}+a_n)\nu+(a_{n-1}+a_n)\rho=0,\\ (\gamma_{n+1}+\gamma_{n-1})\mu+(\gamma_{n+1}+\gamma_n)\nu+(\gamma_{n-1}+\gamma_n)\rho=-2. \end{gathered} \tag{5.21}$$

Thus, for $C\neq 0$ we can put

$$\mu=0,\quad \nu=2\,\frac{a_n+a_{n-1}}{C},\quad \rho=-2\,\frac{a_n+a_{n+1}}{C}.$$

For $C=0$, $A\neq 0$,

$$\mu=2\,\frac{a_n+a_{n+1}}{A},\quad \nu=-2\,\frac{a_{n+1}+a_{n-1}}{A},\quad \rho=0.$$

For $C=A=0$, $B\neq 0$,

$$\mu=-2\,\frac{a_{n-1}+a_n}{B},\quad \nu=0,\quad \rho=2\,\frac{a_{n+1}+a_{n-1}}{B}.$$

The case $A=B=C=0$ corresponds to Eq. (5.19) and hence to the absence of an invariant interaction.

3. Decomposition 6=3+3

a. $\mathrm{sl}(2,\mathbb{R})_1 \oplus \mathrm{sl}(2,\mathbb{R})_2$. The algebra $\mathrm{sl}(2,\mathbb{R})_2$ is as in Eq. (4.8) and the invariant interaction is

$$F_n=\frac{1}{(\xi_n)^2}\left[u_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n(\chi_{n+1},\chi_{n-1})+u_nq_n(\chi_{n+1},\chi_{n-1})\right],$$

$$G_n=\frac{1}{(\xi_n)^2}\left[v_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n(\chi_{n+1},\chi_{n-1})+v_nq_n(\chi_{n+1},\chi_{n-1})\right], \tag{5.22}$$

$$\chi_{n+1}=\frac{\xi_{n+1}}{\xi_n},\quad \chi_{n-1}=\frac{\xi_{n-1}}{\xi_n}.$$

4. Decomposition 6=5+1

a. $\mathrm{saff}(2)\oplus A_1$. We have

$$Y_u(e^{a_nt})=e^{a_nt}\partial_{u_n},\quad Y_v(e^{a_nt})=e^{a_nt}\partial_{v_n},\quad T(a_n)=\partial_t+a_n(u_n\partial_{u_n}+v_n\partial_{v_n}).$$

The invariant interaction will be as in Eq. (5.4) with $\lambda_n=e^{a_nt}$. The functions ϕ_n and ψ_n will satisfy

$$\phi_n=e^{(a_n-a_{n-1}-a_{n+1})t}K_n(\omega),\quad \psi_n=e^{-a_{n+1}t}L_n(\omega),$$
$$\omega=e^{-(a_n+a_{n+1})t}\xi_{n+1}-e^{-(a_{n+1}+a_{n-1})t}\xi_n-e^{-(a_{n-1}+a_n)t}\xi_{n-1}. \tag{5.23}$$

5. Indecomposable symmetry algebras

It was shown in Sec. IV that two inequivalent gaff(2) symmetry algebras exist.

a. $\mathrm{gaff}(2,\mathbb{R})_1$.

$$Y_u(\lambda_n)=\lambda_n(t)\partial_{u_n},\quad Y_v(\lambda_n)=\lambda_n(t)\partial_{v_n},\quad V(1)=u_n\partial_{u_n}+v_n\partial_{v_n}.$$

The interaction is as in Eq. (5.4), however, ϕ_n and ψ_n depend only on t. This means that the equations are linear and, moreover, the equations (1.1) for u_n and v_n are decoupled.

b. $\mathrm{gaff}(2,\mathbb{R})_2$. The algebra is as in Eq. (4.22) [or (4.33)], the interaction as in Eq. (5.4) with $\lambda_n(t)=e^{(a_n-1)t}$. The functions ϕ_n and ψ_n satisfy

$$\phi_n=e^{-(a_{n+1}+a_{n-1}-a_n-1)t}K_n(\omega),\quad \psi_n=e^{(-a_{n+1}+1)t}L_n(\omega), \tag{5.24}$$

with ω as in Eq. (5.23).

E. Seven-dimensional symmetry groups

1. Decomposition 7=3+1+1+1+1

We exclude the case

$$V(a_{i,n})=a_{i,n}(u_n\partial_{u_n}+v_n\partial_{v_n}),\quad i=1,...,4,$$

since the only invariant interaction is (5.3) with h_n and k_n functions of t. We already know that the symmetry algebra is infinite dimensional.

a. $V(a_{i,n})=a_{i,n}(u_n\partial_{u_n}+v_n\partial_{v_n}),\ i=1,2,3,\ T(b_n)=\partial_t+b_n(u_n\partial_{u_n}+v_n\partial_{v_n})$. The interaction is as in Eq. (5.3) with h_n and k_n constants (depending on n). The algebra is actually infinite dimensional: we can take any number of operators $V(a_{i,n})$.

2. Decomposition 7=3+2+1+1

a. $V(a_{i,n})=a_{i,n}(u_n\partial_{u_n}+v_n\partial_{v_n})$, $i=1,2$, $T(0)=\partial_t$, $D(c_n)=t\partial_t+(\frac{1}{2}+c_n)(u_n\partial_{u_n}+v_n\partial_{v_n})$. We put $\gamma_n=c_n+\frac{1}{2}$. An invariant interaction exists if and only if we have

$$\Delta=\det\begin{pmatrix}\gamma_n & \gamma_{n+1} & \gamma_{n-1}\\ a_{1,n} & a_{1,n+1} & a_{1,n-1}\\ a_{2,n} & a_{2,n+1} & a_{2,n-1}\end{pmatrix}\neq 0. \tag{5.25}$$

The invariant interaction is that of Eq. (5.3), with

$$h_n=\eta^k p_n,\quad k_n=\eta^k q_n,\quad k=-\frac{2}{\Delta}. \tag{5.26}$$

The variable η is as in Eq. (5.8); p_n and q_n are constants.

3. Decomposition 7=3+3+1

a. $\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2\oplus A_1$. We have $A_1=\{V(a_n)\}$. The invariant interaction can be obtained from Eq. (5.22). The additional invariance implied by the presence of $V(a_n)$ restricts p_n and q_n to

$$p_n=\left(\frac{\xi_{n+1}}{\xi_n}\right)^{2(a_{n+1}+a_{n-1})/(a_n-a_{n-1})} r_n(\omega),$$

$$q_n=\left(\frac{\xi_{n+1}}{\xi_n}\right)^{2(a_{n+1}+a_{n-1})/(a_n-a_{n-1})} s_n(\omega), \tag{5.27}$$

$$\omega=(\xi_{n+1})^{a_{n+1}-a_n}(\xi_{n-1})^{a_n-a_{n-1}}(\xi_n)^{a_{n-1}-a_{n+1}},$$

and we must impose $a_n\neq a_{n-1}$ (otherwise we have $F_n=G_n=0$).

4. Decomposition 7=6+1

The algebra $\mathrm{gaff}(2,\mathbb{R})_1$ does not allow any nonlinear interactions. Let us consider $\mathrm{gaff}(2,\mathbb{R})_2$ of Eq. (4.22).

a. $\mathrm{gaff}(2,\mathbb{R})_2\oplus\{U=u_n\partial_{u_n}+v_n\partial_{v_n}\}$. The interaction is as in Eq. (5.4), with ϕ_n and ψ_n as in Eq. (5.24). Invariance under the dilations corresponding to U implies that ϕ_n and ψ_n do not depend on ω. Hence, the interaction is linear and decoupled.

5. Indecomposable Lie algebras

a. $Y_u(\lambda_n)=\lambda_n(t)\partial_{u_n}$, $Y_v(\lambda_n)=\lambda_n(t)\partial_{v_n}$, $Y_u(\mu_n)=\mu_n(t)\partial_{u_n}$, $Y_v(\mu_n)=\mu_n(t)\partial_{v_n}$. We start from Eq. (5.4) with ϕ_n and ψ_n functions of t and ω as in Eq. (5.17). If ϕ_n and ψ_n do not depend on ω, the interaction is already linear and decoupled. Hence, ω must be invariant under the transformations corresponding to $Y_u(\mu_n)$ and $Y_v(\mu_n)$. This implies that λ_n and μ_n are independent of n. Further, invariance implies

$$\frac{\ddot{\lambda}_n}{\lambda_n}=\frac{\ddot{\mu}_n}{\mu_n}=\tilde{k}, \tag{5.28}$$

with $\tilde{k}=\mathrm{const}$. Equation (5.28) allows solutions,

$$\begin{pmatrix}\lambda_n\\ \mu_n\end{pmatrix}=\begin{pmatrix}\sin kt\\ \cos kt\end{pmatrix},\quad \begin{pmatrix}\sinh kt\\ \cosh kt\end{pmatrix},\quad \begin{pmatrix}1\\ t\end{pmatrix}. \tag{5.29}$$

These solutions are all equivalent under allowed transformations. We choose $\lambda_n=1$, $\mu_n=t$, i.e.,

$$Y_u(1)=\partial_{u_n},\quad Y_v(1)=\partial_{v_n},\quad Y_u(t)=t\partial_{u_n},\quad Y_v(t)=t\partial_{v_n}. \tag{5.30}$$

The invariant interaction is

$$\begin{aligned} F_n&=(u_{n+1}-u_{n-1})\phi_n(\omega,t)+(u_n-u_{n+1})\psi_n(\omega,t),\\ G_n&=(v_{n+1}-v_{n-1})\phi_n(\omega,t)+(v_n-v_{n+1})\psi_n(\omega,t), \end{aligned} \tag{5.31}$$

with

$$\omega=\xi_{n+1}-\xi_{n-1}-\xi_n. \tag{5.32}$$

b. $Y_u(1)=\partial_{u_n}$, $Y_v(1)=\partial_{v_n}$, $T(0)=\partial_t$, $D(b)=t\partial_t+(\frac{1}{2}+b)(u_n\partial_{u_n}+v_n\partial_{v_n})$, $b\neq-\frac{1}{2}$, $b=\text{const}$. The invariant interaction is as in Eq. (5.31), with

$$\phi_n=k_n\omega^{-2/(2b+1)},\quad \psi_n=p_n\omega^{-2/(2b+1)}, \tag{5.33}$$

with k_n and p_n constants, ω as in Eq. (5.32). For $b=-\frac{1}{2}$ there is no invariant interaction. For $b\neq-\frac{1}{2}$ the symmetry algebra is actually larger and includes $Y_u(t)=t\partial_{u_n}$ and $Y_v(t)=t\partial_{v_n}$.

F. Symmetry groups of dimensions 8, 9, and 10

By now, all invariant interactions have been specified up to arbitrary constants (depending on n), except those involving symmetry algebras containing the subalgebra $\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2$, or the subalgebra $\{Y_u(1),Y_v(1),Y_u(t),Y_v(t)\}$ of Eq. (5.30). Let us consider the remaining nonlinear interactions.

1. $\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2\oplus\{V(a_{1,n})\}\oplus\{V(a_{2,n})\}$

The invariant interaction is obtained from Eq. (5.27) by specifying $r_n(\omega)$ and $s_n(\omega)$ to be specific powers of ω. The result is

$$\begin{aligned} F_n&=\xi_n^{-2}\left[u_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n+u_nq_n\right](\xi_{n-1})^{-2A/D}(\xi_{n+1})^{-2B/D}(\xi_n)^{2[(A+B)/D]},\\ G_n&=\xi_n^{-2}\left[v_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n+v_nq_n\right](\xi_{n-1})^{-2A/D}(\xi_{n+1})^{-2B/D}(\xi_n)^{2[(A+B)/D]}. \end{aligned} \tag{5.34}$$

Here p_n and q_n are constants, A and B are as in Eq. (5.9), and

$$D=a_{1,n}(a_{2,n+1}-a_{2,n-1})+a_{1,n+1}(a_{2,n-1}-a_{2,n})+a_{1,n-1}(a_{2,n}-a_{2,n+1}). \tag{5.35}$$

We assume $D\neq0$; otherwise there is no invariant interaction. In particular, we have $a_{1,n}\neq a_{1,n+1}$, $a_{2,n}\neq a_{2,n+1}$.

2. Algebras containing $(Y_u(1),Y_v(1),Y_u(t),Y_v(t))$ *of (5.30) plus one additional operator* Z

The interaction is as in Eq. (5.31) with a restriction on ϕ_n and ψ_n.

(i) $Z=T(a)=\partial_t+a(u_n\partial_{u_n}+v_n\partial_{v_n})$, $a\equiv a_n=a_{n+1}$,

$$\phi_n=\phi_n(\eta),\quad \psi_n=\psi_n(\eta),\quad \eta=\omega e^{-2at}. \tag{5.36}$$

(ii) $Z=D(a)=t\partial_t+(\frac{1}{2}+a)(u_n\partial_{u_n}+v_n\partial_{v_n})$, $a\equiv a_n=a_{n+1}$,

$$\phi_n=\frac{1}{t^2}r_n(\eta),\quad \psi_n=\frac{1}{t^2}s_n(\eta),\quad \eta=\omega t^{-(2a+1)}. \tag{5.37}$$

(iii) $Z=R(b)=(t^2+1)\partial_t+(t+b)(u_n\partial_{u_n}+v_n\partial_{v_n}),\ b\equiv b_n=b_{n+1}$,

$$\phi_n=\frac{1}{(t^2+1)^2}r_n(\eta),\quad \psi_n=\frac{1}{(t^2+1)^2}s_n(\eta),$$
$$\eta=\frac{\omega}{1+t^2}e^{-2b\arctan t}, \tag{5.38}$$

with ω as in Eq. (5.32) in all cases.

(iv) $Z=V(1)$. Then ϕ_n and ψ_n depend only on t and the interaction is linear.

We can add two operators to those of Eq. (5.30)

$$T(0)=\partial_t,\quad D(b)=t\partial_t+(\tfrac{1}{2}+b)(u_n\partial_{u_n}+v_n\partial_{v_n}).$$

The invariant interaction coincides with that of Eq. (5.33).

Finally, the interaction (5.31) is invariant under a ten-dimensional symmetry algebra of the form

$$(\mathrm{sl}(2,\mathbb{R})_1\oplus \mathrm{sl}(2,\mathbb{R})_2)\rhd\{Y_u(1),Y_v(1),Y_u(t),Y_v(t)\},$$

for

$$\phi_n=k_n\omega^{-2},\quad \psi_n=p_n\omega^{-2}, \tag{5.39}$$

i.e., $b=0$ in Eq. (5.33).

VI. SUMMARY AND CONCLUSIONS

Let us first sum up the results on invariant interactions and the corresponding symmetry algebras. We shall follow the summary of possible symmetry algebras outlined in Sec. IV E. The results are presented in the following tables.

Table I. The Series A of symmetry algebras. The algebra L_C of Eq. (4.27) consists entirely of $\mathrm{sl}(2,\mathbb{R})_1$ singlets. In the first column of Table I we list the symmetry algebras. The number in brackets [e.g., $A_1(3)$] denotes the dimension of the symmetry algebra. The notation for basis elements in column 2 are as in Eqs. (4.13)–(4.18). Note that if the functions h_n and k_n in the interaction (5.3) depend only on t or are constants, then the symmetry algebra is infinite dimensional, although the interaction is nonlinear.

The case $A_3(7)$ corresponds to an algebra L with $\dim L=7$ and the interaction is completely specified [see (5.3), (5.25)–(5.26)]. In other cases the functions h_n and k_n depend on one, two, or three variables involving u_k and v_k.

Table II. The Series B of symmetry algebras. The symmetry algebras are either five or six dimensional. The interactions are as in Eq. (5.4) and involve two arbitrary functions, ϕ_n and ψ_n. A B-type symmetry allows ϕ_n and ψ_n to depend on just one variable involving u_k and v_k. Any extension of the B-type algebras will restrict $\lambda_n(t)$ to be $\lambda_n=1$ and will involve a further pair with $\lambda_n=t$. This takes us into the series C of symmetry algebras.

The algebras B_2, B_6, and B_7 of Eqs. (4.32), (4.36), and (4.37) lead to linear interactions. Any interaction invariant with respect to B_5 will be invariant under a larger group, corresponding to a Lie algebra in the series C. We do not include linear interactions in the tables and we list interactions together with their *maximal* symmetry algebras.

Table III. The Series C of symmetry algebras. The interaction will be as in Eq. (5.31), involving a variable ω as in Eq. (5.32). The algebras $C_5(8),C_7(9),C_8(9),C_9(9),C_{11}(10),C_{12}(11)$, absent in the table, lead to a linear interaction.

TABLE I. Series A of symmetry algebras. The interaction has the form (5.3).

No.	L_C	Restrictions on h_n and k_n	Variables and comments
$A_1(3)$	$\cdots$	$\cdots$	$t,\xi_{n+1},\xi_{n-1},\xi_n$ (5.2)
$A_1(4)$	$V(a_n)$	$\cdots$	$\begin{cases} t,\eta_{n+1},\eta_{n-1} & (5.5) \\ t,\xi_n,\eta & (5.6)\end{cases}$
$A_1(5)$	$V(a_{1,n}),V(a_{2,n})$	$\cdots$	t, η (5.8)
$A_1(\infty)$	$V(a_{i,n}),i\in\mathbb{Z}^{>}$	$\cdots$	t
$A_2(4)$	$T(b_n)$	$\cdots$	$\zeta_{n+1},\zeta_{n-1},\zeta_n$ (5.7)
$A_2(5)$	$T(b_n),V(a_n)$	$\cdots$	$\begin{cases} \rho_{n-1},\rho_{n+1} & (5.10) \\ \rho_n,\sigma_n & (5.11)\end{cases}$
$A_2(6)$	$T(b_n),V(a_{1,n}),V(a_{2,n})$	$\cdots$	η (5.18)
$A_2(\infty)$	$T(b_n),V(a_{k,n}),k\in\mathbb{Z}^{>}$	h_n,k_n constants	None
$A_3(5)$	$T(0),D(b_n)$	(5.12) or (5.14)	(5.13) or (5.15)
$A_3(6)$	$T(0),D(c_n),V(a_n)$	(5.20)	ω (5.20)
$A_3(7)$	$T(0),D(c_n),V(a_{1,n})V(a_{2,n})$	(5.26)	None

For $C_6(9)$ and $C_{10}(10)$ the interactions are specified up to constants (that can depend on n). In all other cases, the arbitrary functions depend on one variable, involving u_k and v_k.

Table IV. The Series D of symmetry algebras. There are three such algebras of dimension 6, 7, and 8, respectively. They all lead to nontrivial invariant interactions of the form (5.22). For $D_3(8)$, the interaction is completely specified. We do not list $D_4(10)$ in Table IV since it coincides with $C_{10}(10)$ of Table III. The algebra $D_5(11)$ corresponds to a linear interaction.

For each interaction we have verified that the given symmetry algebra is the maximal one.

A few words about the interpretation of the invariant interactions. From Eq. (5.1) and the variables (5.2) we see that invariance under $\mathrm{sl}(2,\mathbb{R})_1$ imposes very strong restrictions.

(1) In particular, if the interaction is linear and $\mathrm{sl}(2,\mathbb{R})_1$ invariant, we must have

$$F_n=\sum_{k=n-1}^{n+1} A_k(t)u_k, \quad G_n=\sum_{k=n-1}^{n+1} A_k(t)v_k, \tag{6.1}$$

i.e., the equations (1.1) for u_k and v_k decouple (into identical equations for u_n and v_n separately).

(2) If the interaction terms F_n and G_n in Eq. (5.1) are nonlinear, they always involve many-body forces. That is, they cannot be written as sums of terms of the type $h_n(u_n,v_n)$ or $h_n(u_n,v_{n+1})$, etc. Indeed, each invariant variable $\xi_n,\xi_{n+1},\xi_{n-1}$ itself involves four of the original variables u_i,v_i simultaneously. This many-body character becomes more pronounced when the invariance algebra is larger.

(3) The operators $V(a_n)$ correspond to site-depending dilations,

TABLE II. Series B of symmetry algebras. The algebra includes one pair $Y_u(\lambda_n)$, $Y_v(\lambda_n)$. The interaction has the form (5.4).

No.	Restrictions on λ_n, additional Elements of L_C	Restrictions on ϕ_n and ψ_n	Variables and comments
$B_1(5)$	$\cdots$	$\cdots$	t, ω as in (5.17)
$B_4(6)$	$\lambda_n=e^{a_n t},T(a_n)$	(5.23)	ω (5.23)
$B_3(6)$	$\lambda_n=e^{(a_n-1)t},T(a_n)$	(5.24)	ω (5.23)

TABLE III. Series C symmetry algebras. The algebras contain $\mathrm{sl}(2,\mathbb{R})_1, Y_u(1), Y_v(1), Y_u(t), Y_v(t)$, and possibly additional elements. The interaction is as in Eq. (5.31).

No.	Additional elements	Conditions on ϕ_n and ψ_n	Variables
$C_1(7)$	–	$\cdots$	ω, t (5.32)
$C_2(8)$	$T(a)$	$\cdots$	$\eta=\omega e^{-2at}$
$C_3(8)$	$D(a)$	$\phi_n=t^{-2}r_n(\eta),\ \psi_n=t^{-2}s_n(\eta)$	$\eta=\omega t^{-(2a+1)}$
$C_4(8)$	$R(b)$	$\phi_n=(t^2+1)^{-2}r_n(\eta)$, $\psi_n=(t^2+1)^{-2}s_n(\eta)$	$\eta=\omega(t^2+1)^{-1}$ $e^{-2b\ \arctan t}$
$C_6(9)$	$T(0),D(a)$	$\phi_n=k_n\omega^{-2/(2a+1)},\ \psi_n=p_n\omega^{-2(2a+1)}$ $k_n,\ p_n$ constants, $2a+1\neq 0$	None
$C_{10}(10)$	$T(0),D(0),P(0)$	$\phi_n=k_n\omega^{-2},\ \psi_n=p_n\omega^{-2}$	None

$$\tilde{u}_n=e^{\epsilon a_n}u_n, \quad \tilde{v}_n=e^{\epsilon a_n}v_n. \tag{6.2}$$

Invariance under two such one-dimensional symmetry groups, generated by $\{V(a_{1,n}),V(a_{2,n})\}$, where $a_{1,n}$ and $a_{2,n}$ are two linearly independent functions of n, introduces the symmetry variable

$$\omega_D\equiv(\xi_{n-1})^A(\xi_{n+1})^B(\xi_n)^C, \tag{6.3}$$

as in Eq. (5.8). Here all six variables are coupled together.

(4) The pair of operators $Y_u(\lambda_n),Y_v(\lambda_n)$ induces site-dependent (and time-dependent) shifts of the dependent variables,

$$\tilde{u}_n=u_n+\epsilon\lambda_n(t), \quad \tilde{v}_n=v_n+\epsilon\lambda_n(t). \tag{6.4}$$

The corresponding invariant variable again involves all six variables [see Eq. (5.17)],

$$\omega_T\equiv\lambda_{n-1}\xi_{n+1}-\lambda_n\xi_n-\lambda_{n+1}\xi_{n-1}. \tag{6.5}$$

A special case of the variable ω_T is obtained setting $\lambda_n=\lambda_{n-1}=\lambda_{n+1}=1$. This is the case of Eq. (5.32), where

$$\omega=\omega_S=\xi_{n+1}-\xi_n-\xi_{n-1} \tag{6.6}$$

is invariant with respect to two such translations:

$$\tilde{u}_n=u_n+\epsilon_1+\epsilon_2 t, \quad \tilde{v}_n=v_n+\epsilon_1+\epsilon_2 t \tag{6.7}$$

(ϵ_1 and ϵ_2 are group parameters and hence constants).

A continuation of this study is in progress. It involves several aspects.

The first is a study of the integrability properties of the equations that are completely specified by their symmetries. These are, first of all, those with infinite-dimensional symmetry groups, namely

$$\ddot{u}_n=u_{n+1}\frac{\xi_{n-1}}{\xi_n}h_n+u_nk_n, \quad \ddot{v}_n=v_{n+1}\frac{\xi_{n-1}}{\xi_n}h_n+v_nk_n, \tag{6.8}$$

TABLE IV. Series D of symmetry algebras. The algebra contains $\mathrm{sl}(2,\mathbb{R})_1\oplus\mathrm{sl}(2,\mathbb{R})_2$. The interaction has the form (5.22).

No.	Additional elements in L_C	Conditions on p_n and q_n	Variables
$D_1(6)$	$\cdots$	$\cdots$	χ_{n+1}, χ_{n-1} as in (5.22)
$D_2(7)$	$V(a_n)$	(5.27)	η as in (5.27)
$D_3(8)$	$V(a_{1,n}),\ V(a_{2,n})$	(5.34)	$\cdots$

with h_n and k_n functions of t or constants [see $A_1(\infty)$ and $A_2(\infty)$ in Table I].

Completely specified equations with finite-dimensional symmetry algebras L are the following ones.

(i)

$$\ddot{u}_n=\left(u_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n+u_nq_n\right)\omega_D^{-2/\Delta}, \quad \ddot{v}_n=\left(v_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n+v_nq_n\right)\omega_D^{-2/\Delta}, \tag{6.9}$$

with ω_D as in Eq. (6.3), Δ as in Eq. (5.25). This is case $A_3(7)$ of Table I.

(ii)

$$\ddot{u}_n=[(u_{n+1}-u_{n-1})p_n+(u_n-u_{n+1})q_n]\omega_S^{-2/(2a+1)},$$

$$\ddot{v}_n=[(v_{n+1}-v_{n-1})p_n+(v_n-v_{n+1})q_n]\omega_S^{-2/(2a+1)}, \tag{6.10}$$

with ω_S as in Eq. (6.6), $p_n, q_n, a\neq -\frac{1}{2}$ const. This is case $C_6(9)$ of Table III.

(iii) For $a=0$, Eq. (6.10) is invariant under a ten-dimensional symmetry algebra, namely $C_{10}(10)$ of Table III.

(iv)

$$\ddot{u}_n=(\xi_{n-1})^{-2A/k}(\xi_{n+1})^{-2B/D}(\xi_n)^{[2(A+B-D)/D]}\left[u_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n+u_nq_n\right],$$

$$\ddot{v}_n=(\xi_{n-1})^{-2A/D}(\xi_{n+1})^{-2B/D}(\xi_n)^{[2(A+B-D)/D]}\left[v_{n+1}\frac{\xi_{n-1}}{\xi_n}p_n+v_nq_n\right],$$

with p_n and q_n depending only on n. The constants A and B are given in Eq. (5.9), D in Eq. (5.35).

A further task is to complete the classification, that is, to treat the cases of other sl(2,$\mathbb{R}$) algebras and also of solvable symmetry algebras.

Dissipative canonical flows in classical and quantum mechanics

John Gough
Department of Mathematical Physics, National University of Ireland Maynooth, Maynooth, Ireland

(Received 20 February 1998; accepted for publication 14 February 1999)

A theory of stochastic flows over the algebra of observables of a dynamical system is presented in which the main objective is to ensure that the overall canonical/symplectic structure on the algebra is preserved. We study both classical and quantum systems and the importance of physical interpretation in the Stratonovich interpretation is stressed. We find the natural formulation of quantum dissipative systems to be given in terms of quantum stochastic calculus. This treatment allows for a physically meaningful treatment of both constant and nonlinear dissipation. As an application, we quantize a mechanical system with the same nonlinear damping mechanism as the van der Pol oscillator. © *1999 American Institute of Physics.* [S0022-2488(99)00206-6]

I. INTRODUCTION

The theory of open systems has been developed widely in both classical and quantum situations. To quantize a classical dynamical system, it is necessary to have an underlying Hamiltonian mechanism and there is a problem whenever the dynamical system is dissipative. By dissipative, we mean that the Poisson structure is not preserved under the dynamical evolution. Typically, an open system is viewed as a subcomponent of a larger Hamiltonian system and the dynamical equations of the system (observed on its own) are approximations to the actual regular motion. In this paper we consider classical stochastic flows wherein the fluctuation-dissipation has a geometric content, or perhaps more exactly a symplecto-geometric content. That is, the fluctuations balance the Poisson structure dissipation. In doing so, we discover the natural way in which to compare classical open systems to quantum ones and, in the process, learn how to quantize some standard classical dissipative models.

The program to quantize dissipative mechanical systems is now at least easy to state; first quantize the system-reservoir and then trace out the reservoir degrees of freedom. Under suitable assumptions one may obtain Markovian approximations for the reduced system evolutions, the correct approach to this is detailed in Ref. 1 and also Chap. XVI of Ref. 2 for a review and further references.

Before pursuing this program further, it is important to take a closer look at the difficulties encountered in the classical case. In particular, we find that many of the mathematical treatments of quantum dissipative processes designed to parallel the Langevin approach fall down at the most fundamental level of physical interpretation. The Langevin approach, as emphasized by van Kampen especially in Sec. IX.5 of Ref. 2, cannot be applied indiscriminately to problems where the noise coefficient, denoted by σ in this paper, is nonlinear in the variables of the system. A common mistake is to construct a Langevin equation by taking a deterministic macroscopic term and adding on a noise term with coefficient σ arrived at by independent considerations. Van Kampen blames this on the disregard of physicists for possible physical origins of the fluctuations and on a belief that ''...*stochasticity is part and parcel of the mathematics and requires no physical cause*.'' This is, if anything doubly true in the quantum domain. The essential problem is, of course, that Langevin approach is justifiable only in the Stratonovich interpretation of stochastic calculus while it is in the Ito interpretation where most research is formulated. In point of fact, the

Ito version is the one appropriate for mathematical analysis while the Stratonovich is the one appropriate for physical insight.

In this paper we examine the notion of canonical flows as the correct description of the evolution of physical functions of phase variables. The classical situation is described first and we introduce both deterministic and stochastic canonical flows and study the latter in both Ito and Stratonovich interpretations. We show that the quantum analog of this is given in terms of quantum stochastic processes in the sense of Hudson and Parthasarathy,[3] in particular we employ the notion of a quantum stochastic flows and derivations which was introduced by Accardi and Hudson.[4] As an application of our ideas we construct a quantum process with the same nonlinear damping mechanism as the van der Pol oscillator. We conclude with several remarks on the physical status of our investigations.

Notations: Let $\mathcal{A}$ be a unital $*$-algebra throughout. The algebra of observables of a dynamical system is described as a Poisson manifold, that is, a pair $(\mathcal{A}, \wp)$ where $\wp$ gives a Poisson structure. In classical systems, the geometry (kinematics) is distinct from Poisson structure (dynamics), however, for quantum systems this is not so as the Poisson structure is typically algebraic. We outline some definitions below to fix our ideas.

Definition 1: A Poisson Structure $\wp$ on $\mathcal{A}$, compatible with the $*$-involution, is a bilinear map $\wp:\mathcal{A}\times\mathcal{A}\mapsto\mathcal{A}$ satisfying

(i) $\wp(a,1)=0$;
(ii) $\wp(a,b)=-\wp(b,a)$;
(iii) $\wp(a,bc)=\wp(a,b)c+b\wp(a,c)$;
(iv) $\wp(a,\wp(b,c))+\wp(b,\wp(c,a))+\wp(c,\wp(a,b))=0$;
(v) $\wp(a,b)^*=\wp(a^*,b^*)$.

Definition 2: The distension of a $*$-linear map λ on $\mathcal{A}$ is the bilinear map $\mathcal{D}(\lambda)$ defined by

$$\mathcal{D}(\lambda;a,b):=\lambda(ab)-\lambda(a)b-a\lambda(b). \tag{1.1}$$

Definition 3: A $*$-linear map μ: $\mathcal{A}\mapsto\mathcal{A}$ is said to be canonical with respect to a Poisson structure $\wp$ on $\mathcal{A}$ if

$$\mu\wp(a,b)=\wp(\mu a,b)+\wp(a,\mu b). \tag{1.2}$$

The dissipation of a $*$-linear map λ with respect to the Poisson structure $\wp$ on $\mathcal{A}$ is the bilinear map $D(\lambda)$ defined by

$$D(\lambda;a,b):=\lambda\wp(a,b)-\wp(\lambda a,b)-\wp(a,\lambda b). \tag{1.3}$$

The distension measures how far a map is from being a derivation and as such is an algebraic concept independent of whether a Poisson structure exists. The dissipation measures how far a map deviates from being a canonical with respect to a given Poisson structure and as such is a dynamical concept. The set of derivations is $\mathrm{Ker}\,\mathcal{D}$. We take $\mathrm{Can}(\Gamma, \wp)$ to be the kernel space of D when restricted to $\mathrm{Ker}\,\mathcal{D}$, that is, the set of canonical derivations.

Definition 4: For each $H\in\mathcal{A}_S$, the Hamiltonian map X_H generated by H is defined to be

$$X_H(a):=\wp(a,H). \tag{1.4}$$

By property (iii) of the Poisson structure, Hamiltonian maps are derivations. By property (iv), they are also canonical with respect to $\wp$. We denote the set of Hamiltonian maps by $\mathrm{Ham}(\Gamma, \wp)$.

Definition 5: A Poisson algebra $\mathcal{A}$ is said to be $\wp$-simple if every canonical map is Hamiltonian (wrt. $\wp$).

II. CLASSICAL FLOWS

Let $\mathcal{A}$ denote the $*$-algebra of observables of a dynamical system. A stationary flow $(u_t)_{t\geqslant 0}$ is a continuous one-parameter group of $*$-homomorphisms on $\mathcal{A}$ which, by Stone's theorem, possesses a generator $\mathcal{L}$; that is $u_t=\exp\{t\mathcal{L}\}$. Let $u_t^0=\exp\{t\mathcal{L}^0\}$ be a second stationary flow which we take as reference or unperturbed dynamics. The perturbation is then described by $\mathcal{L}-\mathcal{L}^0$. A standard device is to transfer to the interaction picture of the flow u_t with respect to u_t^0 which is given in terms of the family $(j_t)_{t\geqslant 0}$ of automorphisms defined by

$$j_t:=u_t\circ(u_t^0)^{-1}. \tag{2.1}$$

The family $(j_t)_{t\geqslant t}$ does not form a semigroup but instead is a u^0-cocycle, that is,

$$j_{t+s}=j_s\circ u_s^0\circ j_t\circ(u_s^0)^{-1}. \tag{2.2}$$

The dynamical equations of motion are $du_tf=u_t(\mathcal{L}f)dt$ which, when transferred to the interaction picture, become

$$dj_tf=j_t(\mathcal{L}_t'f)dt, \tag{2.3}$$

where $\mathcal{L}_t':=u_t^0\circ\mathcal{L}'\circ(u_t^0)^{-1}$.

Stochastic flows on phase space

Let Γ be the phase space (finite dimensional manifold) of a classical dynamical system and $(\Gamma, \mathcal{G}, \mu)$ a probability space. Let B_t be the Wiener process with standard representation on the Wiener space $(\Omega,\mathcal{F},P)$ and let $\mathcal{F}_{t]}$, $\mathcal{F}_{(t}$ denote the past, respectively, future filtrations generated by the process at time t. Consider the SDE on Γ given by

$$dX_t=b(X_t)dt+\sigma(X_t)dB_t, \tag{2.4}$$

where b and σ are vector fields on Γ satisfying global Lipschitz conditions so as to guarantee uniqueness of the solution.[5] For Y a random variable independent of $\mathcal{F}_{(s}$, we shall denote by $X_t^{(Y,s)}$ the solution to the SDE for times $t>s$ which satisfies the initial condition $X_s=Y$. By uniqueness of the solution we have the identity P-a.s.

$$X_{t+s}^{(x_0,0)}=X_t^{(X_s^{(x_0,0)},s)}, \quad \forall x_0\in\Gamma, \tag{2.5}$$

however, it is more useful to refer only to diffusions starting at initial time zero and so in place of (2.5) we have P-a.s.,

$$X_{t+s}^{(x_0,0)}(\omega)=X_t^{(X_s^{(x_0,0)}(\omega),0)}(\theta_s\omega), \tag{2.6}$$

where θ_s is the time shift map on the Ω give by $(\theta_s\omega)_t=\omega_{t+s}-\omega_s$ for each sample path $\omega\in\Omega$.

A family of $*$-homomorphisms $j_t:L^\infty(\Gamma,\mu)\mapsto L^\infty(\Gamma,\mu)\otimes\mathcal{B}(L^2(\Omega,\mathcal{F},P))$ is defined for $t>0$ by

$$j_tf(x_0,\omega):=f\circ X_t^{(x_0,0)}(\omega); \tag{2.7}$$

j_t is then trivially extended from $L^\infty(\Gamma,\mu)$ to $L^\infty(\Gamma,\mu)\otimes\mathcal{B}(L^2(\Omega,\mathcal{F},P))$ by setting $j_t(f\otimes\xi_{(t)}):=(j_tf)\otimes\xi_{(t}$ for $\xi_{(t}\in\mathcal{B}(L^2(\Omega,\mathcal{F}_{(t},P))$.

Introducing the time shift u_t^0 induced by θ_t, that is $u_t^0Z(\omega):=Z(\theta_t\omega)$, the following property is readily obtained

$$j_{t+s}f=j_s(u_s^0(j_t(f))). \tag{2.8}$$

Bearing in mind that the u^0 act trivially on $L^\infty(\Gamma,\mu)$, it follows that $(j_t)_{t\geqslant 0}$ is a u_0-cocycle.

III. CLASSICAL CANONICAL FLOWS

Let $\mathcal{A}=\mathcal{C}^\infty(\Gamma)$ be the algebra of smooth complex functions on phase space with complex conjugation being involution. We shall denote a Poisson structure $\wp$ on $\mathcal{A}$ using bracket notation. The existence of a Poisson structure is equivalent to the existence of a second order tensor Λ such that

$$\{f,g\}=\Lambda(df,dg). \tag{3.1}$$

In terms of local coordinates (x^i) on Γ, $\{f,g\}=\Lambda^{ij}f_{,i}g_{,j}$ and the components Λ^{ij} are required to satisfy the conditions

$$\Lambda^{ij}+\Lambda^{ji}=0; \quad \Lambda^{il}\Lambda^{jk}{}_{,l}+\Lambda^{jl}\Lambda^{ki}{}_{,l}+\Lambda^{kl}\Lambda^{ij}{}_{,l}=0. \tag{3.2}$$

In general $\mathrm{Ham}(\mathcal{A},\wp)\subseteq\mathrm{Can}(,\wp)\subseteq T\Gamma$. For $\wp\equiv 0$, every tangent vector field is canonical but only the zero vector field is Hamiltonian. We, however, shall only deal with the situation where the algebra is simple with respect to Poisson bracket structure. Two important examples are given below.[6]

(i) *Symplectic manifolds.* Let $(\Gamma,\ \omega)$ be a $2n$-dimensional symplectic manifold. Poisson brackets are given by $\{f,g\}=\omega(X_f,X_g)$ and in this way the mapping $f\mapsto X_f$ defines a Lie algebra homomorphism. The Hamiltonian vector fields span $T\Gamma$ since the symplectic form ω is, by definition, nondegenerate. The prototype for a symplectic manifold is the cotangent space T^*M over an n-dimensional manifold (configuration space) and there always exist local coordinates $(q^1,\dots,q^n,p_1,\dots,p_n)$, called canonical coordinates, such that $\omega=dq^i\wedge dp_i$.

(ii) *Angular momentum algebra.* Take Γ to be three-dimensional Euclidean space with Cartesian coordinates (x^1,x^2,x^3) and define Λ as the tensor with Cartesian components $\Lambda^{ij}=\epsilon_{ijk}x^k$. This leads to a degenerate Poisson structure since any function Φ of $r=\sqrt{(x^1)^2+(x^2)^2+(x^3)^2}$ has the property that $\{f,\Phi(r)\}=0$, for all $f\in C^\infty(\Gamma)$. In fact, the Hamiltonian vector fields span a two-dimensional subspace of the tangent space to Γ at any point.

In general, let (x^i) be a local coordinate system on Γ, then the map $v=v^i\partial_i\in T\Gamma$ is characterized by the dissipation tensor $D^{ij}(v)$ given by

$$D^{ij}(v):=D(v;x^i,x^j)\equiv v^k\Lambda^{ij}{}_{,k}-v^i{}_{,k}\Lambda^{kj}-v^j{}_{,k}\Lambda^{ik}. \tag{3.3}$$

A. Stochastic symplectic flows

A stochastic flow on Γ can be described by the system of SDEs,

$$d_IX_t^i=\tilde{v}^i(X_t)\quad dt+\sigma^i(X_t)d_IB_t. \tag{3.4}$$

This equation is termed nonlinear if components of σ depend on the phase point x. Here, B_t is the Wiener process and we take the differentials to be the Ito type, that is $d_IZ(t):=Z(t+dt)-Z(t)$.

For $f\in\mathcal{A}$, we obtain for the corresponding cocycle j_t,

$$d_Ij_tf=j_t(d_ILf), \tag{3.5}$$

where, by the Ito rules of stochastic calculus,

$$d_Ij_tf:=j_t(\tilde{v}^if_{,i}+\tfrac{1}{2}f_{,ij}\sigma_i\sigma_j)dt+j_t(\sigma^if_{,i})d_IB_t, \tag{3.6}$$

that is,

$$d_Ij_t=j_t\circ l\,dt+j_t\circ\sigma d_IB_t, \tag{3.7}$$

where

$$l := \tilde{v} + \tfrac{1}{2}\sigma^i \sigma^j \partial_i \partial_j , \quad \tilde{v} := \tilde{v}^i \partial_i , \text{ and } \sigma = \sigma^i \partial_i . \tag{3.8}$$

It is convenient to introduce a shifted vector field v defined by

$$v^i = \tilde{v}^i - \tfrac{1}{2}\sigma^j \sigma^i{}_{,j} \tag{3.9}$$

in which case the second order partial differential operator l becomes

$$l = v + \tfrac{1}{2}\sigma \circ \sigma. \tag{3.10}$$

Definition 6: A stochastic flow j_t is canonical if

$$d_I j_t \{f,g\} = \{d_I j_t f, j_t g\}_t + \{j_t f, d_I j_t g\}_t + \{d_I j_t f, d_I j_t g\}_t ; \quad \forall f,g \in \mathcal{A}, \tag{3.11}$$

where $\{a,b\} := j_t \{j_t^{-1} a, j_t^{-1} b\}$.

A formal infinitesimal generator $d_I L$ is then given by

$$d_I L := j_t^{-1} d_I j_t \equiv l\,dt + \sigma B_{dt} , \tag{3.12}$$

where we used the identity $j_t^{-1} d_I B_t = (u_t^0)^{-1}(B_{t+dt} - B_t) = B_{dt}$. As such the condition reduces to

$$d_I L\{f,g\} = \{d_I L f, g\} + \{f, d_I L g\} + \{d_I L f, d_I L g\} \tag{3.13}$$

or

$$(D(v;f,g) + \tfrac{1}{2}\sigma \circ \sigma\{f,g\} - \tfrac{1}{2}\{\sigma \circ \sigma f, g\} - \tfrac{1}{2}\{f, \sigma \circ \sigma g\} + \{\sigma f, \sigma g\})dt + D(\sigma; f,g) B_{dt} = 0. \tag{3.14}$$

Both the dt and B_{dt} coefficients must vanish. Clearly the dissipation of σ must be zero and so σ is Hamiltonian, say $\sigma = \{.,F\} \equiv X_f$. Next of all, if we note the identity

$$X_F \circ X_F \{f,g\} = \{X_F \circ X_F f, g\} + 2\{X_F f, X_F g\} + \{f, X_F \circ X_F g\},$$

then the vanishing of the dt coefficient reduces to the requirement $D(v;f,g) = 0$ and so v must likewise be Hamiltonian, say $v = X_H$.

Theorem: A stochastic flow j_t, driven by a single Wiener process, is canonical if and only if there exist $H,F \in C^\infty(\Gamma)$ such that

$$d_I j_t(f) = j_t(\{f,H\} + \tfrac{1}{2}\{\{f,F\},F\})dt + j_t(\{f,F\}) d_I B_t . \tag{3.15}$$

B. Remarks

(1) If $d_I L_{(\alpha)}$ are infinitesimal generators of canonical stochastic flows, then so too is $\Sigma_\alpha d_I L_{(\alpha)} + \Sigma_{\alpha \neq \beta} d_I L_{(\alpha)} \circ d_I L_{(\beta)}$. In this way the generators form an algebra. The nontensorality and nonadditivity of generators comes from the Ito calculus. If we switch to the Stratonovich calculus we find that the SDE (3.4) becomes

$$d_S X_t^i = v^i(X_t) dt + \sigma^i(X_t) d_S B_t , \tag{3.16}$$

while in place of (3.6) we get

$$d_S j_t(f) = j_t(vf) dt + j_t(\sigma f) d_S B_t . \tag{3.17}$$

Thus we see that v is the phase velocity in the Stratonovich calculus. The infinitesimal generator in Stratonovich form then reduce to first order form, they can then be added vectorially, and so the apparent nonadditivity emerges only when we convert back to Ito form.

Moreover, the condition (3.11) for a flow to be canonical now reads as $d_S\{f_t,g_t\}_t=\{d_Sf_t,g_t\}_t+\{f_td_Sg_t\}_t$ since the ordinary rules of calculus now hold. In fact, we may write

$$d_Sj_t=j_t\circ X_H dt+j_t\circ X_F d_SB_t \tag{3.18}$$

which suggests that we may partially recover the picture of deterministic flows by introducing a formal stochastic Hamiltonian $F_t=H+Fd_SB_t/dt$ were we able to give an appropriate meaning to the derivative of the Wiener process in Stratonovich calculus.

From the physical point of view this is reasonable. The SDEs using the Wiener process can only possibly be approximations to a regular random dynamical evolution. As is well-known,[12] if the system was governed by the actual Hamiltonian $H+FdB_t^{(\lambda)}/dt$ with $B_t^{(\lambda)}$ a regular stochastic process which converged to the Wiener process as, say, $\lambda\to 0$, then this limit would lead to the Stratonovich SDEs (3.16–3.17). This gives strong hope that the stochastic flows can be derived from microscopic dynamics.

(2) Define the forward derivative of an adapted stochastic process Z_t to be $D_t^+Z_t:=\lim_{r\to 0}E_{t]}[(Z_{t+r}-Z_t)/r]$. We have $D_t^+j_t=j_t\circ l$ and specifically $D_t^+X_t^i=\tilde{v}^i(X_t)$. As remarked above, $\tilde{v}$ is typically not covariant with respect to (deterministic) canonical transformations.

(3) The differential operator l is an example of what is known as a second order tangent vector field and their relevance to stochastic processes on manifolds is well-known.[7]

(4) So far we have worked exclusively with diffusions, however, the generalization to continuous semimartingales, in the present context, does not change our findings.[7]

(5) In a local coordinate system (x^i), a second order vector λ can be uniquely decomposed as $\lambda_I+\lambda_{II}$ where $\lambda_I=\lambda_I^i\partial_i$ and $\lambda_{II}=\lambda_{II}^{ij}\partial_i\partial_j$ (with λ_{II}^{ij} symmetric). We have $D(\lambda)=D(\lambda_I)+D(\lambda_{II})$, however, the dissipation tensor only gives characteristics of λ_I since $D^{ij}(\lambda_{II})\equiv 0$.

As a result, for l and $\tilde{v}$ as above, we have $D^{ij}(\tilde{v})=D^{ij}(l)$. Now $D^{ij}(l)=\frac{1}{2}D^{ij}(\sigma\circ\sigma)\equiv\{\sigma^i,\sigma^j\}$. Therefore, we have a fluctuation-dissipation relation

$$D^{ij}(\tilde{v})=\{\sigma^i,\sigma^j\} \tag{3.19}$$

but this is not a complete characterization. In reality, for a given $\tilde{v}$, there can exist several inequivalent choices for H and F such that $\tilde{v}^i=l(x^i)$ with $l=X_H+\frac{1}{2}X_F\circ X_F$.

(6) The dissipation of $l=X_H+\frac{1}{2}X_F\circ X_F$ is given explicitly as

$$D(l;f,g)=\{\{f,F\},\{g,F\}\}. \tag{3.20}$$

Note that $D(l;f^*,f)=|\{f,F\}|^2$ is then positive.

IV. SYSTEMS WITH ONE DEGREE OF FREEDOM

Let (q,p) be local canonical coordinates on a symplectic manifold (Γ,ω) and consider the fields $\tilde{v}=\tilde{v}_q\partial_q+\tilde{v}_p\partial_p$, $\sigma=\sigma_q\partial_q+\sigma_p\partial_p$. The dissipation tensor has only $\gamma:=D^{qp}(\tilde{v})=-D^{pq}(\tilde{v})$ as entries which are possibly nonzero on account of antisymmetry. In terms of the field $\tilde{v}$ we have

$$\gamma=-\tilde{v}_{q,q}-\tilde{v}_{p,p}, \tag{4.1}$$

that is, minus the divergence of $\tilde{v}$ on Γ.

Our requirement is that $d\{q_t,p_t\}=\{dq_t,p_t\}+\{q_t,dp_t\}+\{dq_t,dp_t\}\equiv 0$, or equivalently

$$(\{\sigma_q,\sigma_p\}-\gamma)dt+(\sigma_{q,q}+\sigma_{p,p})dB_t=0. \tag{4.2}$$

Therefore, in the case that Γ is just two-dimensional, the conditions that the Poisson structure is preserved is that, if M is the 2×2-matrix with entries $\sigma_{\alpha,\beta}$, then

$$\text{(i)}\det M=\gamma, \quad \text{(ii)}\ \operatorname{tr} M=0. \tag{4.3}$$

Equivalently, by the Cayley–Hamilton theorem, the condition is that $M^2=-\gamma I_2$.

The noise coefficients σ are derivable from a Hamiltonian F; $\sigma_q \equiv F_{,p}$, $\sigma_p \equiv -F_{,q}$. The fluctuation-dissipation relation (3.19) then reduces to

$$\gamma(q,p) = -(F_{,qp})^2 + F_{,qq}F_{,pp}. \tag{4.4}$$

Likewise the Stratonovich fields v are given by (3.9),

$$v_q = \tilde{v}_q - \tfrac{1}{2}F_{,qp}F_{,p} + \tfrac{1}{2}F_{,pp}F_{,q} \equiv H_{,p}; \quad v_p = \tilde{v}_p + \tfrac{1}{2}F_{,qq}F_{,p} - \tfrac{1}{2}F_{,qp}F_{,q} \equiv -H_{,q}. \tag{4.5}$$

V. EXAMPLES OF QUANTUM SYMPLECTIC FLOWS

A. Linear damping

Starting from the equation $\ddot{q} + \xi\dot{q} + V'(q) = 0$, $(\xi > 0)$, which is linearly damped we see that

$$\dot{q} = \tilde{v}_q \equiv p; \quad \dot{p} = \tilde{v}_p \equiv -\xi p - V'(q). \tag{5.1}$$

The dissipation is $\gamma = \xi$ and it suffices to take the noise coefficients σ_α linear in the phase coordinates

$$\sigma_\alpha \equiv M_{\alpha\beta}x_\beta. \tag{5.2}$$

Here the matrix M is the same as above except now that its entries are constant. The Stratonovich version of the fields are given by $v_\alpha = \tilde{v}_\alpha - \frac{1}{2}M_{\alpha\beta}M_{\beta\mu}x_\mu$, however, since we require the stochastic flow to be canonical we have $M^2 = -\gamma I_2$ and so

$$v_\alpha = \tilde{v}_\alpha + \tfrac{1}{2}\xi x_\alpha. \tag{5.3}$$

The corresponding functions H and F introduced in Sec. III are then given by

$$H = \tfrac{1}{2}p^2 + \tfrac{1}{2}\xi qp + V(q); \quad F = \tfrac{1}{2}x^T JMx; \tag{5.4}$$

where $x = \binom{q}{p}$ and $J := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. As possible choice we may take $M = \begin{pmatrix} 0 & \xi^{-1/2} \\ -\xi^{3/2} & 0 \end{pmatrix}$, in which case $F \equiv \frac{1}{2}\xi^{-1/2}(p^2 + \xi^2 q^2)$. Note that we have chosen the units of mass to be unity; it therefore follows that ξ has dimensions s^{-1} and F has dimensions $m^2 s^{-3/2}$.

The canonical transformation $(q,p) \mapsto (Q,P)$ given by $Q := q$, $P := p + \frac{1}{2}\xi q$ leads to

$$H = \tfrac{1}{2}P^2 + V(Q) - \tfrac{1}{8}\xi^2 Q^2 \tag{5.5}$$

and

$$F = \tfrac{1}{2}\xi^{-1/2}(P^2 - \xi PQ + \tfrac{5}{4}\xi^2 Q^2). \tag{5.6}$$

B. Nonlinear damping

We consider as an example the equation $\ddot{q} + \xi(q^2 - a^2)\dot{q} + V'(q)$, $(\xi > 0, a > 0)$, which has the same damping mechanism as the van der Pol oscillator.[8] In terms of phase space coordinates we have

$$\dot{q} = \tilde{v}_q \equiv p; \quad \dot{p} = \tilde{v}_p \equiv -\xi(q^2 - a^2)p - V'(q). \tag{5.7}$$

The dissipation is

$$\gamma = -\tilde{v}_{q,q} - \tilde{v}_{p,p} = \xi(q^2 - a^2), \tag{5.8}$$

which is positive for $|q| > a$ and negative for $|q| < a$ and moreover independent of p. We shall look for a candidate for F of the form $\frac{1}{2}cp^2 + \phi(q)$. From dimensional arguments, here ξ has dimensions $m^{-2}s^{-1}$, we find that a solution to (5.4) is given by

$$F=\frac{1}{a}\xi^{-1/2}\left[\frac{1}{2}p^2+a^2\xi^2\left(\frac{q^4}{12}-\frac{q^2a^2}{2}\right)\right]. \tag{5.9}$$

The v fields are from (5.5),

$$v_q=p+\frac{1}{2}\xi\left(\frac{q^2}{3}-qa^2\right),\quad v_p=-\frac{1}{2}\xi(q^2-a^2)p-V'(q); \tag{5.10}$$

which are derivable from the Hamiltonian

$$H=\frac{1}{2}p^2+V(q)+\frac{1}{2}\xi\left(\frac{q^3}{3}-qa^2\right)p. \tag{5.11}$$

As in the linear case, we can introduce a canonical transformation, this time $(q,p)\mapsto(Q,P)$ where $Q:=q,\ P:=p+\frac{1}{2}\xi[(q^3/3)-qa^2]$, and so we have

$$H=\frac{1}{2}P^2+V(Q)-\frac{1}{8}\xi^2\left(\frac{Q^3}{3}-Qa^2\right)^2 \tag{5.12}$$

and

$$F=\frac{1}{a}\xi^{-1/2}\left[\frac{1}{2}P^2-\frac{1}{2}\xi P\left(\frac{Q^3}{3}-Qa^2\right)+\xi^2\left(\frac{Q^6}{72}-\frac{3Q^2a^4}{8}\right)\right]. \tag{5.13}$$

VI. QUANTUM STOCHASTIC SYMPLECTIC EVOLUTIONS

Let $\mathcal{A}$ be a C^*-algebra. The extension of a map l on $\mathcal{A}$ to the matrix algebra $M_n(\mathcal{A})$ is denoted by $l^{(n)}$ and l is called positive if it and its extensions are positive. For commutative algebras, positivity automatically implies complete positivity. Following Lindblad,[9] a bounded $*$-map l is called completely dissipative if $\mathcal{D}(l^{(n)};a^*,a)\geqslant 0$ for all n and $a\in M_n(\mathcal{A})$. We remark that Lindblad refers to our $\mathcal{D}$ rather than D as the dissipation, however, for quantum algebras the Poisson structure is given by

$$\wp(a,b):=\frac{1}{i\hbar}[a,b] \tag{6.1}$$

and so

$$D(l;a,b)\equiv\frac{1}{i\hbar}\{\mathcal{D}(l;a,b)-\mathcal{D}(l;b,a)\}. \tag{6.2}$$

The distension $\mathcal{D}(l)$ determines l up to a Hamiltonian map $X_H\equiv(1/i\hbar)[.,H]$. It was proved by Gorini, Kossakowski, and Sudarshan[10] (for finite dimensional algebras) and by Lindblad[9] (for the more general case of hyperfinite factors) that, for $\Phi_t=e^{tl}$ a norm-continuous, completely positive identity preserving semigroup on $\mathcal{A}$, its generator l must be completely dissipative and that the space of such generators is convex with extremal (pure) elements of the type

$$l(a)=\frac{1}{i\hbar}[a,H]+\frac{1}{\hbar^2}\left(F^*aF-\frac{1}{2}aF^*F-\frac{1}{2}F^*Fa\right)\equiv X_H(a)+\frac{1}{2}(F^\dagger X_F(a)-X_{F^\dagger}(a)F), \tag{6.3}$$

for H (self-adjoint) and F,F^* in $\mathcal{A}$.

The distension for the pure Lindblad generator above is then

$$\mathcal{D}(l;a,b)=\frac{1}{\hbar^2}[F^*,a][b,F]=(X_{F^*})(X_F b), \tag{6.4}$$

and so $\mathcal{D}(l,a^*,a)=(1/\hbar^2)[F,a]^*[F,a]\geqslant 0$. The dissipation (in the sense of our definition 3) is then

$$D(l;a,b)=\frac{1}{i\hbar}\{X_{F^*}aX_Fb-X_{F^*}bX_Fa\}. \tag{6.5}$$

Notice that taking F to be also self-adjoint leads to $l=X_H+\frac{1}{2}X_F\circ X_F$ which is formally the same as what we have obtained for classical canonical flows.

Quantum stochastic flows

We now describe how quantum stochastic calculus can be used to construct quantum stochastic flows j_t such that $\Phi_t=E_{0]}\circ j_t$ has Lindblad generator.

In the following $\Gamma_B(h)$ shall denote the Bose Fock space over a Hilbert space h and $A^\sharp(f)$ the creation and annihilation operators with test function $f\in h$. Let $\mathcal{H}_0$ be the Hilbert space of states for a quantum mechanical system. The system is to be considered as open and its evolution operator V_t satisfying the following QSDE on $\mathcal{H}_0\otimes\Gamma_B(L^2[0,\infty))$ driven by the Hudson–Parthasarathy quantum Wiener processes $A_t^\dagger=A^\sharp(\chi_{[0,t]})$,

$$d_IV_t=\frac{1}{i\hbar}\left(F\otimes d_IA_t^\dagger+F^*\otimes d_IA_t+\left(H-\frac{1}{2\hbar}F^*F\right)\otimes dt\right)V_t, \tag{6.6}$$

with initial condition $V_0=1$. Now, if K were also self-adjoint then we could combine the noise terms into $K\otimes(d_IA_t^\dagger+d_IA_t)$ in which case it would be much simpler to deal with just the standard Wiener process, however as this is an exceptional case, we are quite generally forced to use the quantum stochastic processes instead. It should be remarked that there are alternative representations, for instance a single quantum Wiener process can be described by two standard ones; however the choice of quantum stochastic processes is the most natural.

The quantum stochastic flow is given on the set of observables $\mathcal{A}=\mathcal{B}(\mathcal{H})$ by the family of maps $(j_t)_{t\geqslant 0}$ defined by

$$j_tX:=V_t^\dagger(X\otimes 1)V_t,\quad \forall X\in\mathcal{A}. \tag{6.7}$$

The differential form of the noisy equations of motion is the given by the quantum Langevin equation

$$d_Ij_tX=j_t\left(\frac{1}{i\hbar}[X,F]\right)\otimes d_IA_t^\dagger+j_t\left(\frac{1}{i\hbar}[X,F^*]\right)\otimes d_IA_t+j_t(l(X))\otimes dt, \tag{6.8}$$

where l is the generator (6.3). The quantum stochastic process V_t is unitary on the combined system-noise Hilbert space. Moreover it respects the canonical commutation structure; to see this let $d_IL:=j_t^{-1}d_Ij_t=A_{dt}^\dagger X_F+A_{dt}X_{F^*}+dtl$ then we must show that, for arbitrary $X,Y\in\mathcal{A}$, that

$$d_IL[X,Y]:=[d_ILX,Y]+[X,d_ILY]+[d_ILX,d_ILY]. \tag{6.9}$$

To this end, we can use the Jacobi identity for commutators at several places. We also have to calculate the Ito shift and here we use the fact that $A_{dt}A_{dt}^\dagger=dt$ with all other products of differentials equal to zero,[3]

$$[d_ILa,d_ILb]=(X_{F^*}aX_Fb-X_{F^*}bX_Fa)dt=i\hbar D(l;a,b)dt. \tag{6.10}$$

Here we see explicitly the quantum fluctuation-dissipation relations.

VII. QUANTIZATION OF DISSIPATIVE EVOLUTIONS

In Sec. VI we introduced a scheme for finding the classical Hamiltonians H and F, while in Sec. V we did this for the case of linear and nonlinear damping. Both these models are relatively easy to quantize. We use the Weyl quantization procedure to produce self-adjoint operators H and F which we can insert into the QSDE (6.6). For the situations in Sec. V, we end up with the equations $E_{t]}d_I q_t = \tilde{v}_q(q_t, p_t)$ and $E_{t]}d_I p_t = \tilde{v}_p(q_t, p_t)$ where now $\tilde{v}_i$ are the symmetrically-ordered versions of the originals.

The operator ordering ambiguities are not apparent here yet because the special form of the Hamiltonians encountered in Sec. V. However, this will in general be a complicating feature which will in general mean that F will have to have a modified form from the Weyl quantization of its classical counterpart. We also mention that canonical transformations will not generally respect given orderings.

VIII. CONCLUSIONS

At the heart of our presentation is the notion that a physical flow, whether classical stochastic, quantum mechanical, or quantum stochastic, should be canonical in some sense. The QSDE (6.1) is of the most general type defining a unitary process driven by the quantum stochastic process $A_t^\dagger$ and A_t.[3] We now wish to make several remarks.

(1) The Ornstein–Uhlenbeck process, and consequently any approach which seeks to generalize it, is not symplectic. Here the Langevin equations are $\dot{q} = p$, $dp = b_p dt = \sigma_p dB_t$; that is $\sigma_q \equiv 0$. The matrix M introduced in Sec. V therefore has first row equal to zero and so condition (i) of (5.3) cannot be satisfied.

(2) In the quantized models in Sec. V, we meet a Hamiltonian $\tilde{H} := \frac{1}{2}p^2 + V(q)$ however we eventually deal with the Hamiltonian H and we have from (5.5) and (5.12) that $H = \tilde{H} - U(q)$, where $U(q) = \frac{1}{8}\xi^2 q^2$ in the linear case and $U(q) = \frac{1}{8}\xi^2[(q^3/3) - q]^2$ in the nonlinear case. We therefore have three Hamiltonians, F,H, and $\tilde{H}$, at our disposal. From our point of view it is H which is the physical Hamiltonian and not $\tilde{H}$! The discrepancy between $\tilde{H}$ and H is, as already in the classical theory, a Stratonovich–Ito dilemma. Therefore, although we would agree with the approach of Sinha[11] to construct a symplectic quantum stochastic flow for the linearly damped model, we disagree with the arguments introduced to justify the use of a QSDE driven by two independent quantum Wiener processes wherein the second serves to account for the convective drift, see (3.9). There the argument was that, if $\tilde{H}$ had bounded-below spectrum, then this property would not generally follow for $\tilde{H} - U$.

(3) Returning to our program to deduce the stochastic flow from a microscopic Hamiltonian flow, we make the following observation. Suppose we obtain ODEs describing the evolution of the system observables driven by a stochastic process relating to the reservoir. In general, this process, though noisy, is not white. However, taking τ to measure the autocorrelation time for the reservoir processes we may expect to obtain SDEs of the type (3.7) in the limit τ goes to zero. If indeed this is the case and the reservoir forcing term does converge to white noise, then the result of Wong and Zakai[12] tells us that the limit SDEs will have the identical form as the pre-limit ODEs provided we take the Stratonovich interpretation. Therefore, it is the Hamiltonians H and F which are physically relevant. Recall the stochastic derivation (3.18) which identified $H + FW_S(t)$ as the effective physical Hamiltonian. The Hamiltonian $\tilde{H}$ is therefore to be viewed as derived from H and not vice versa.

(4) In Refs. 13, 14 we have introduced a treatment of Stratonovich calculus in a noncommutative setting and discussed the quantum version of the Wong–Zakai theorem. The Stratonovich QSDE corresponding to (6.6) is of the form

$$d_S V_t = \frac{1}{i\hbar}(F a_t^\dagger + F^\dagger a_t + H dt)V_t. \tag{8.1}$$

The $a_t^\sharp$ are formal operators with action on exponential states $\Psi(f)$ of $\Gamma_B(L^2[0,\infty))$ given by

$$a_t\Psi(f) := \tfrac{1}{2}(f(t^+) + f(t^-))\Psi(f). \tag{8.2}$$

However it should be noted that the integrators $a_t^\sharp dt$ do not commute with adapted integrands, contrary to the Ito situation, and the QSDEs can only be compared when (8.2) is placed into normal-ordered form. The passage from Stratonovich to Ito (Hudson–Parthasarathy) form leads, however, to (8.1) being equivalent to (6.6). This can be extended to include the so-called conservation process also.

Moreover, it is reasonable to expect (8.2) as the weak coupling limit of a physical system-reservoir dynamics, typically the emission-absorption-type interaction, as detailed in Ref. 15.

A new first integral for a binary rigid body collision of arbitrarily short duration

Patrick L. Nash[a]
Division of Earth and Physical Sciences, The University of Texas at San Antonio, San Antonio, Texas 78249-0663

(Received 21 September 1998; accepted for publication 22 February 1999)

A standard classical model of a so-called rigid two-body collision that employs the dynamic Coulomb friction law to model friction is studied. For arbitrary object geometries and initial conditions it is known that the direction of the relative sliding velocity continuously changes during the impact. A (new) exact analytical solution for the relative sliding speed u_{tr} of the two objects in terms of initial conditions and sliding direction is derived. This solution is formulated in terms of a first integral, which is used to rigorously prove that the dynamic Coulomb friction law does not allow either instantaneous sticking or stable sticking to evolve from an initially nonzero u_{tr}, except for certain very special cases. The first integral also yields a new procedure for accurately and efficiently computing the final center of mass velocity and the final angular velocity of each of the objects in the model two-body collision. Accurate solutions such as these are essential for analyzing and controlling impacts, which is important, for example, in robot manipulation. Efficient solutions are critically important for producing real-time simulations of rigid two-body collisions. © *1999 American Institute of Physics.* [S0022-2488(99)01206-2]

I. INTRODUCTION

Well over a century ago Routh[1,2] laid out a formalism for analyzing a rigid two-body collision of arbitrarily short duration. Routh showed that during an impact the point of contact must, in general, slide. He argued that if the friction forces are strong enough then sliding results in sticking, possibly followed by rolling. Otherwise, the contact point slides continuously during the collision, possibly reversing direction during the course of the impact. Long after Routh's work the problems of: (i) formulating a fundamental model describing the basic classical collision process; (ii) increasing the accuracy and efficiency of the numerical solution to a particular model; and (iii) extending the known analytical results; continue to receive a great deal of attention.[3–17] With regard to the analytical solution to the general problem, Routh suggested that there was, in fact, no closed form solution, and currently there appears to be a consensus that there may be no nonperturbative solution to this scattering problem.[12] However much progress has been made. Recently in remarkable papers, Stronge[4,6] has shown how to generalize both Newton's Impact Law and that of Poisson by giving a new definition of the coefficient of restitution that is consistent with conservation of energy (previous impact laws did not always conserve energy). In addition, Bhatt and Koechling,[12] among others, have clearly shown for arbitrary object shapes and initial conditions, that the direction of the relative sliding velocity continuously changes throughout the duration of sliding, and have offered a classification of the possible motions.

In this paper we consider a small part of the unsolved problem, that of analytically calculating the relationship between the transverse relative speed (sliding speed) and the direction of the transverse relative velocity (sliding velocity) during the impact of two rigid bodies that suffer an arbitrarily short collision. *Arbitrarily short* so that during the collision we may neglect all external forces other than the impulsive forces of impact that the two colliding objects exert on one

[a]Electronic mail: nsh@susan.ep.utsa.edu

another, and so that the collision matrix [defined below in Eq. (6)] has constant matrix elements. In order to produce exact analytical results the dynamic Coulomb friction law is assumed to describe friction during the scattering. This model asserts that the force $\mathbf{f}=\mathbf{f}_{\text{normal}}+\mathbf{f}_{\perp}$ that one body exerts on the other has a transverse component $\mathbf{f}_{\perp}$ that is directed opposite to the transverse component of the relative velocity, and has a magnitude given by μf_{normal}, where μ is the coefficient of kinetic friction. We derive an exact analytical expression for the transverse relative speed of the two objects in terms of initial conditions and sliding direction, which is formulated as a first integral [see Eq. (26)]. Using it we prove a somewhat surprising result, namely, that the dynamic Coulomb friction law, strictly imposed, does not allow either instantaneous sticking or stable sticking to evolve from an initially nonzero u_{tr}, except possibly for certain special cases. We also show that this does not contradict the conventional view of possible (stable or unstable) sticking during a collision.

The dynamic Coulomb friction law is assumed to model sliding with friction because it (i) is widely used in computations; (ii) is a valid starting point for more detailed investigation; and (iii) admits an analytical solution. On a macroscopic level the dynamic Coulomb friction law may be justified by the Bowden–Tabor adhesion model, which is based on the elastic and plastic properties of the colliding objects.[8,7] However, Coulomb's laws of friction often oversimplify very complex phenomena involving elastomechanical, plastic, and even chemical interactions that usually operate on very different scales of time and length.[15] In fact, deviations from the dynamic Coulomb friction law are often encountered in practice.[8,10,11] For example, the force of kinetic friction is known to depend on the sliding speed. Heslot *et al.*[10] have demonstrated that under some circumstances the force of dry friction first decreases, passes through a minimum, and then finally increases. Bhushan *et al.*,[11] working with a thin lubrication layer a few monolayers thick, found that the force of kinetic friction first increases, goes through a maximum, and then finally decreases. Notwithstanding these observations, since the dynamic Coulomb friction law is widely used as a starting point in modeling friction, we believe that there is value in knowing exactly what the dynamic Coulomb friction law predicts when applied to a rigid two-body collision. The possibility of performing reproducible friction experiments on mesoscopic and nanoscopic scales increases the interest in comparing the predictions of an exact (albeit incomplete) theory with the results of experiment.[7,15]

An outline of the content of this paper is as follows. We first develop our notation by briefly reviewing the basic theory; although the basic theory is very well known, the notation used to formulate this theory has not been standardized, and we would like to reduce possible ambiguities. Next, the equations for the relative velocity of the contact point of the impact are reformulated, followed by an examination of the projection of the motion into the natural tangent plane (defined below). This leads, after a series of steps, to the statement of the new first integral (conservation law). Finally we apply these results to specific examples.

II. OVERVIEW AND KINEMATICS

We shall assume that the impact begins at $t_{\text{initial}}=0$ and contact terminates at t_{final}, assuming that the objects do not stick together. When two physical bodies collide they always experience deformation over time comprised generally of compression and restoration phases. Conceptually therefore, this two-body collision is resolved into two periods: a compression phase of quasielastic deformation of each of the bodies that begins with first contact at t_{initial} and terminates at the time of maximum compression $t_{\text{max compression}}$, and a restitution phase that begins at $t_{\text{max compression}}$ and ends at time t_{final}.

The standard model approximates this collision in the zeroth order as being an instantaneous impact between *rigid* bodies with the relative velocity being discontinuous with respect to time, *but not with respect to other parameters such as the normal component of the total impulse*. We let J_z denote the normal component of the total impulse. The zeroth-order approximation invokes a phenomenological law such as Newton's Impact Law or Poisson's Hypothesis[3] to relate initial and final normal components of the relative velocity to one another, and employs integrations with respect to J_z to calculate the transverse component discontinuity (with respect to time, not J_z) of the relative velocity. This approach bears a definite resemblance to a ''Born approximation'' for the scattering in which we approximate the contact point of the impact as fixed with respect to time in the zeroth order, and the moments of inertia of the two bodies as constant during the collision.

Position: The two colliding bodies are labeled by $\alpha=1,2$. Let us mentally divide each object up into a large number of macroscopically small but microscopically large volume elements. Let N_α = number of volume elements of the αth body. $\mathbf{r}_{(\alpha)i}$ locates the ith volume element of the αth body and $m_{(\alpha)i}$ denotes its mass, where $i=0,\ldots,N_\alpha-1$. $\mathbf{r}_{(1)0}$ and $\mathbf{r}_{(2)0}$ locate the (fixed, in the zeroth-order approximation) point of impact of the two bodies. The z axis is perpendicular to the plane of contact, directed from body 2 to body 1. The $x-y$ plane is tangent to the surface of each object at the point of contact. Transverse (i.e., tangential) components of vectors lie in the $x-y$ plane.

The center of mass and position vector are defined as usual: let m_α denote the mass of the αth body, $m_\alpha=\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}$. The center of mass $\mathbf{R}_\alpha$ is defined through $m_\alpha\mathbf{R}_\alpha=\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}\mathbf{r}_{(\alpha)i}$. The relative position vector $\delta\mathbf{r}_{(\alpha)i}$ of $m_{(\alpha)i}$ with respect to $\mathbf{R}_\alpha$ is $\mathbf{r}_{(\alpha)i}=\mathbf{R}_\alpha+\delta\mathbf{r}_{(\alpha)i}$, and we find that the usual constraint identity holds:

$$m_\alpha\mathbf{R}_\alpha=\sum_{i=0}^{N_\alpha-1} m_{(\alpha)i}\mathbf{r}_{(\alpha)i}\Rightarrow 0=\sum_{i=0}^{N_\alpha-1} m_{(\alpha)i}\delta\mathbf{r}_{(\alpha)i}. \tag{1}$$

Velocity: Let $\dot{\mathbf{R}}_\alpha$ denote the velocity of the center of mass of the αth object, where the dot denotes differentiation with respect to time. A rigid body rotation about the center of mass is specified according to $\delta\dot{\mathbf{r}}_{(\alpha)i}=\omega_\alpha\times\delta\mathbf{r}_{(\alpha)i}$, where ω_α is the angular velocity of the αth body. Define the three standard 3×3 antisymmetric matrices $\mathbf{S}=(S_{(1)},S_{(2)},S_{(3)})=(S_x,S_y,S_z)$ as follows: let $\mathbf{A}$ and $\mathbf{B}$ be vectors, and define $\mathbf{S}$ by $(\mathbf{A}\cdot\mathbf{S})B=\mathbf{A}\times\mathbf{B}$. In terms of matrix elements, $S_{(j)ik}=\epsilon_{ijk}$, where the Levi-Civita tensor, $\epsilon_{123}=+1$.

Let $\mathbf{S}_{(\alpha)i}=\delta\mathbf{r}_{(\alpha)i}\cdot\mathbf{S}$. Since $\delta\dot{\mathbf{r}}_{(\alpha)i}=\omega_\alpha\times\delta\mathbf{r}_{(\alpha)i}=-\delta\mathbf{r}_{(\alpha)i}\times\omega_\alpha=-\mathbf{S}_{(\alpha)i}\omega_\alpha$, the velocity of the ith volume element of the αth body is $\dot{\mathbf{r}}_{(\alpha)i}=\dot{\mathbf{R}}_\alpha+\delta\dot{\mathbf{r}}_{(\alpha)i}=\dot{\mathbf{R}}_\alpha-\mathbf{S}_{(\alpha)i}\omega_\alpha$.

For future reference we note that

$$\mathbf{P}_{(\alpha)i}\equiv-\mathbf{S}_{(\alpha)i}\mathbf{S}_{(\alpha)i}=\mathbf{I}_{3\times 3}|\delta\mathbf{r}_{(\alpha)i}|^2-\delta\mathbf{r}_{(\alpha)i}\otimes\delta\mathbf{r}_{(\alpha)i}, \tag{2}$$

where $\mathbf{I}_{3\times 3}$ is the 3×3 unit matrix, defines a projection operator $\mathbf{P}_{(\alpha)i}/|\delta\mathbf{r}_{(\alpha)i}|^2$ onto the plane perpendicular to $\delta\mathbf{r}_{(\alpha)i}$.

Let $\mathbf{u}=\dot{\mathbf{r}}_{(1)0}-\dot{\mathbf{r}}_{(2)0}$ be the relative velocity of the ''fixed'' point of impact. We let $\mathbf{u}_\perp=u_x\hat{\mathbf{x}}+u_y\hat{\mathbf{y}}$ denote the transverse component of the relative velocity, and $u_{\text{transverse}}=u_{\text{tr}}$ denote the magnitude of the transverse (tangential) component of the relative velocity. In this coordinate system $\mathbf{u}=u_z\hat{\mathbf{z}}+u_x\hat{\mathbf{x}}+u_y\hat{\mathbf{y}}=u_z\hat{\mathbf{z}}+u_\perp=u_z\hat{\mathbf{z}}+u_{\text{tr}}[\hat{\mathbf{x}}\cos(\theta)+\hat{\mathbf{y}}\sin(\theta)]$, where $u_x=u_{\text{tr}}\cos(\theta)$ and $u_y=u_{\text{tr}}\sin(\theta)$.

The z component of the relative velocity is subject to several conditions: $u_z(t_{\text{initial}})<0$; $u_z(t_{\text{max compression}})=0$; and $u_z(t_{\text{final}})\geqslant 0$.

Angular momentum: The angular momentum of the ith volume element of the αth body is $\mathbf{L}_{(\alpha)i}=m_{(\alpha)i}\mathbf{r}_{(\alpha)i}\times\dot{\mathbf{r}}_{(\alpha)i}=m_{(\alpha)i}(\mathbf{R}_\alpha+\delta\mathbf{r}_{(\alpha)i})\times(\dot{\mathbf{R}}_\alpha+\delta\dot{\mathbf{r}}_{(\alpha)i})$. We all know that the angular momentum of the αth body decomposes into two pieces corresponding to the center of mass motion and rotation about an axis through the center of mass: $\mathbf{L}_\alpha=\Sigma_{i=0}^{N_\alpha-1}\mathbf{L}_{(\alpha)i}=\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}(\mathbf{R}_\alpha+\delta\mathbf{r}_{(\alpha)i})\times(\dot{R}_\alpha+\delta\dot{\mathbf{r}}_{(\alpha)i})=m_\alpha\mathbf{R}_\alpha\times\dot{\mathbf{R}}_\alpha+\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}\delta\mathbf{r}_{(\alpha)i}\times\delta\dot{\mathbf{r}}_{(\alpha)i}=m_\alpha\mathbf{R}_\alpha\times\dot{\mathbf{R}}_\alpha+\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}\mathbf{S}_{(\alpha)i}(-\mathbf{S}_{(\alpha)i}\omega_\alpha)=m_\alpha\mathbf{R}_\alpha\times\dot{\mathbf{R}}_\alpha+\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}\mathbf{P}_{(\alpha)i}\omega_\alpha=m_\alpha\mathbf{R}_\alpha\times\dot{\mathbf{R}}_\alpha+\mathbf{I}_\alpha\omega_\alpha$, where we have used Eq. (1) twice. Here $\mathbf{I}_\alpha$ is the inertia tensor of the αth body defined by $\mathbf{I}_\alpha=\Sigma_{i=0}^{N_\alpha-1} m_{(\alpha)i}\mathbf{P}_{(\alpha)i}$.

III. EQUATIONS OF MOTION

Let $\mathbf{f}_{(\alpha)i}^{\text{external}}$ be the external force on the ith volume element of the αth body. In the standard approach it is assumed that during an arbitrarily short collision we may neglect all external forces other than the impulsive forces of impact that the two colliding objects exert on one another. Let $\mathbf{f}_{(1)0}^{\text{external}}=-\mathbf{f}_{(2)0}^{\text{external}}\equiv\mathbf{f}$ denote these forces.

Newton: The net force on the ith volume element of the αth body is $m_{(\alpha)i}\ddot{\mathbf{r}}_{(\alpha)i}=\Sigma_{j=0,j\neq i}^{N_\alpha-1}\mathbf{f}_{(\alpha)j\to i}+\mathbf{f}_{(\alpha)i}^{\text{external}}$, where $\mathbf{f}_{(\alpha)j\to i}$ is the internal force that the jth volume element exerts on the ith volume element of the αth body. $\mathbf{f}_{(\alpha)j\to i}$ is assumed to obey Newton's Third Law. The net force on the αth body is $m_\alpha\ddot{\mathbf{R}}_\alpha=\Sigma_{i=0}^{N_\alpha-1}m_{(\alpha)i}\ddot{\mathbf{r}}_{(\alpha)i}=\Sigma_{i=0}^{N_\alpha-1}\mathbf{f}_{(\alpha)i}^{\text{external}}=\mathbf{f}_{(\alpha)}^{\text{external}}$. Moreover a well-known simple calculation yields $\dot{\mathbf{L}}_\alpha=\mathbf{R}_\alpha\times\mathbf{f}_{(\alpha)}^{\text{external}}+\Sigma_{i=0}^{N_\alpha-1}\mathbf{S}_{(\alpha)i}\mathbf{f}_{(\alpha)i}^{\text{external}}$, which implies that $(d/dt)\mathbf{I}_\alpha\omega_\alpha=\Sigma_{i=0}^{N_\alpha-1}\mathbf{S}_{(\alpha)i}\mathbf{f}_{(\alpha)i}^{\text{external}}=\mathbf{S}_{(\alpha)0}\mathbf{f}_{(\alpha)0}^{\text{external}}$.

A. Impulses and velocity changes

The external impulse $\mathbf{J}_{(\alpha)i}$ on the ith volume element of the αth body is defined as $\mathbf{J}_{(\alpha)i}=\int_{t_{\text{initial}}}^{t_{\text{final}}}\mathbf{f}_{(\alpha)i}^{\text{external}}\,dt$. Let $\mathbf{J}_{(1)0}=-\mathbf{J}_{(2)0}\equiv\mathbf{J}$ denote the nonzero external impulses. Upon integrating the equations of motion we find that $\Delta m_\alpha\dot{\mathbf{R}}_\alpha=\Sigma_{i=0}^{N_\alpha-1}\mathbf{J}_{(\alpha)i}=\mathbf{J}_{(\alpha)0}$ so that

$$\Delta\dot{\mathbf{R}}_\alpha=\frac{\mathbf{J}_{(\alpha)0}}{m_\alpha}. \tag{3}$$

In addition, since the objects are assumed not to move during the collision, $\Delta(\mathbf{I}_\alpha\omega_\alpha)=\mathbf{I}_\alpha\Delta\omega_\alpha=\Sigma_{i=0}^{N_\alpha-1}\int\mathbf{S}_{(\alpha)i}\mathbf{f}_{(\alpha)i}dt=\int\mathbf{S}_{(\alpha)0}\mathbf{f}_{(\alpha)0}\,dt=\mathbf{S}_{(\alpha)0}\int\mathbf{f}_{(\alpha)0}\,dt=\mathbf{S}_{(\alpha)0}\mathbf{J}_{(\alpha)0}$. Therefore

$$\Delta\omega_\alpha=\mathbf{I}_\alpha^{-1}\mathbf{S}_{(\alpha)0}\mathbf{J}_{(\alpha)0}. \tag{4}$$

The impulse $\mathbf{J}$ is not yet determined. An approximation for it may be obtained using a standard approach outlined in Sec. III B.

B. Calculation of J

One may generate an equation for the impulse $\mathbf{J}$ in terms of $\Delta\mathbf{u}$ as follows: The change in the velocity of the ith volume element of the αth body is $\Delta\dot{\mathbf{r}}_{(\alpha)i}=\Delta\dot{\mathbf{R}}_\alpha+\Delta\,\delta\dot{\mathbf{r}}_{(\alpha)i}=\Delta\dot{\mathbf{R}}_\alpha-\Delta\mathbf{S}_{(\alpha)i}\omega_\alpha=\Delta\dot{\mathbf{R}}_\alpha-\mathbf{S}_{(\alpha)i}\Delta\omega_\alpha=\mathbf{J}_{(\alpha)0}/m_\alpha-\mathbf{S}_{(\alpha)i}\mathbf{I}_\alpha^{-1}\mathbf{S}_{(\alpha)0}\mathbf{J}_{(\alpha)0}=(\mathbf{I}_{3\times3}/m_\alpha-\mathbf{S}_{(\alpha)i}\mathbf{I}_\alpha^{-1}\mathbf{S}_{(\alpha)0})\mathbf{J}_{(\alpha)0}$. Therefore $\Delta\mathbf{u}=\Delta\dot{\mathbf{r}}_{(1)0}-\Delta\dot{\mathbf{r}}_{(2)0}=(\mathbf{I}_{3\times3}/m_1-\mathbf{S}_{(1)0}\mathbf{I}_1^{-1}\mathbf{S}_{(1)0})\mathbf{J}_{(1)0}-(\mathbf{I}_{3\times3}/m_2-\mathbf{S}_{(2)0}\mathbf{I}_2^{-1}\mathbf{S}_{(2)0})\mathbf{J}_{(2)0}$ or

$$\Delta\mathbf{u}=\left[\mathbf{I}_{3\times3}\left(\frac{1}{m_1}+\frac{1}{m_2}\right)-(\mathbf{S}_{(1)0}\mathbf{I}_1^{-1}\mathbf{S}_{(1)0}+\mathbf{S}_{(2)0}\mathbf{I}_2^{-1}\mathbf{S}_{(2)0})\right]\mathbf{J}\equiv\mathbf{KJ}, \tag{5}$$

where the collision matrix $\mathbf{K}$ is defined by

$$\mathbf{K}=\mathbf{I}_{3\times3}\left(\frac{1}{m_1}+\frac{1}{m_2}\right)-(\mathbf{S}_{(1)0}\mathbf{I}_1^{-1}\mathbf{S}_{(1)0}+\mathbf{S}_{(2)0}\mathbf{I}_2^{-1}\mathbf{S}_{(2)0}). \tag{6}$$

It is well known[14] that $\mathbf{K}$ is a real, positive definite, symmetric nonsingular matrix.

It is convenient to decompose $\mathbf{K}$ into row vectors $\mathbf{k}_{(a)}$, $a,b,c=1,2,3=x,y,z$, according to $\mathbf{k}_{(a)b}=\mathbf{K}_{ab}$. In this notation

$$\mathbf{K}=\begin{pmatrix}\mathbf{k}_{(1)}\\ \mathbf{k}_{(2)}\\ \mathbf{k}_{(3)}\end{pmatrix},$$

the determinant of $\mathbf{K}$ is $\mathbf{k}_{(a)}\cdot\mathbf{k}_{(b)}\times\mathbf{k}_{(c)}$ where $(a,b,c)=$even permutation of (1,2,3), and $\mathbf{K}^{-1}=1/(\mathbf{k}_{(3)}\cdot\mathbf{k}_{(1)}\times\mathbf{k}_{(2)})(\mathbf{k}_{(2)}\times\mathbf{k}_{(3)},\mathbf{k}_{(3)}\times\mathbf{k}_{(1)},\mathbf{k}_{(1)}\times\mathbf{k}_{(2)})$.

Solving for $\mathbf{J}$ in Eq. (5) yields

$$\mathbf{J}=\mathbf{K}^{-1}\Delta\mathbf{u}. \tag{7}$$

$\Delta\dot{\mathbf{R}}_\alpha$ and $\Delta\omega_\alpha$ may then be calculated using Eqs. (3) and (4).

The evaluation of $\Delta\mathbf{u}$ employs, in part, energy methods that are dependent on a phenomenological model of restitution. Relevant energy definitions and rebound models are briefly discussed in the next subsections.

Energy: Let $dW_{(\alpha)i}=(\Sigma_{j=0,j\neq i}^{N_\alpha-1}\mathbf{f}_{(\alpha)j\to i}+\mathbf{f}_{(\alpha)i}^{\text{external}})\cdot d\mathbf{r}_{(\alpha)i}$ denote the infinitesimal work done on $m_{(\alpha)i}$ in a displacement $d\mathbf{r}_{(\alpha)i}$. The total infinitesimal work done on the system is $dW=\Sigma_{\alpha=1}^{2}\Sigma_{j=0}^{N_\alpha-1}dW_{(\alpha)i}$. Since $d\mathbf{r}_{(\alpha)i}$ is tangent to the trajectory, during a binary collision we approximate this as $dW=dW_{(1)0}+dW_{(2)0}\approx\mathbf{f}_{(1)0}^{\text{external}}\cdot d\mathbf{r}_{(1)0}+\mathbf{f}_{(2)0}^{\text{external}}\cdot d\mathbf{r}_{(2)0}=\mathbf{f}\cdot(d\mathbf{r}_{(1)0}/dt-d\mathbf{r}_{(2)0}/dt)dt=\mathbf{f}\cdot\mathbf{u}dt=\mathbf{u}\cdot d\mathbf{J}$.

Impact law: A practical problem encountered in integrating the equations of motion is determining when to terminate the restitution phase of the collision. Newton, Poisson, and others have postulated different impact laws that govern this judgment. We shall adopt the hypothesis put forward by Stronge.[4,6] Stronge has given a new definition of the coefficient of restitution that is consistent with conservation of energy (previous impact laws did not always conserve energy).

Stronge decomposes dW into three scalar contributions, $dW=dW_x+dW_y+dW_z$, with $dW_z=f_zu_zdt=u_zdJ_z$ and so on. Stronge postulates that

$$W_z(t_{\text{final}})-W_z(t_{\text{max compression}})=-e^2W_z(t_{\text{max compression}}), \tag{8}$$

where e is the coefficient of restitution and $W_z(t_{\text{initial}})=0$.

IV. GOVERNING DIFFERENTIAL FORMS

Consider $d\Delta\mathbf{u}=d(\mathbf{u}(t_{\text{final}})-\mathbf{u}(t_{\text{initial}}))=d\mathbf{u}(t_{\text{final}})\equiv d\mathbf{u}$. Here $\mathbf{u}=u_z\hat{\mathbf{z}}+u_x\hat{\mathbf{x}}+u_y\hat{\mathbf{y}}$, and $d\mathbf{u}=(\hat{\mathbf{z}}(\partial u_z/\partial\lambda)+\hat{\mathbf{x}}(\partial u_x/\partial\lambda)+\hat{\mathbf{y}}(\partial u_y/\partial\lambda))d\lambda$, where λ can be any one of $\{u_z,W_z,J_z\}$, or any other arbitrary monotonically increasing (during the collision) parameter.[17] W_z is usually included as an allowed parameter because it is monotonically decreasing (respectively, increasing) on $t_{\text{initial}}\leqslant t\leqslant t_{\text{max compression}}$ (respectively, $t_{\text{max compression}}\leqslant t\leqslant t_{\text{final}}$). For completeness we mention that there are exceptional occasions in which u_z initially decreases but then monotonically increases. There are standard methods[18] for handling this case, and as this case does not affect our results, we do not consider it further.

Using Eq. (5) and $d\mathbf{J}=\mathbf{f}dt$ we find that $d\Delta\mathbf{u}=d\mathbf{u}=\mathbf{K}\,\mathbf{f}dt$. We also recall that $dW_z=f_zu_zdt$. Eliminating dt from these equations gives $dJ_z/f_z=dW_z/f_zu_z=du_z/\mathbf{k}_{(3)}\cdot\mathbf{f}=du_x/\mathbf{k}_{(1)}\cdot\mathbf{f}=du_y/\mathbf{k}_{(2)}\cdot\mathbf{f}$ or

$$dJ_z=\frac{dW_z}{u_z}=\frac{du_z}{\mathbf{k}_{(3)}\cdot(\mathbf{f}/f_z)}=\frac{du_x}{\mathbf{k}_{(1)}\cdot(\mathbf{f}/f_z)}=\frac{du_y}{\mathbf{k}_{(2)}\cdot(\mathbf{f}/f_z)}. \tag{9}$$

These differential forms and Stronge's postulate enable us to calculate $\Delta\mathbf{u}$. $\mathbf{J}$ then follows from Eq. (7).

We shall only consider the case in which u_{tr} is not identically zero and f_z does not vanish and employ the dynamic Coulomb friction law to model friction. Hence the force $\mathbf{f}$ has a transverse component that is directed opposite to the transverse component of the relative velocity, and has a magnitude given by μf_z, where μ is the coefficient of kinetic friction.

If we put

$$\xi=\frac{\mathbf{f}}{f_z}=\begin{pmatrix}-\mu\cos(\theta)\\-\mu\sin(\theta)\\1\end{pmatrix} \tag{10}$$

then, using Eq. (9), the differential system becomes

$$dJ_z=\frac{dW_z}{u_z}=\frac{du_z}{\mathbf{k}_{(3)}\cdot\xi}=\frac{du_x}{\mathbf{k}_{(1)}\cdot\xi}=\frac{du_y}{\mathbf{k}_{(2)}\cdot\xi}. \tag{11}$$

The calculation of $\Delta\mathbf{u}$ now follows from Eq. (11). We know that $u_z(t_{\text{max compression}})=0$. Formally integrating the differential system, we find that at time $t=t_{\text{max compression}}$, $W_z(t_{\text{max compression}})=\int_{W(t_{\text{initial}})}^{W(t_{\text{max compression}})} dW_z=\int_{u_z(t_{\text{initial}})}^{0}(u_z/\mathbf{k}_{(3)}\cdot\xi)du_z$ while $u_x(t_{\text{max compression}})-u_x(t_{\text{initial}})=\int_{u_z(t_{\text{initial}})}^{0}(\mathbf{k}_{(1)}\cdot\xi/\mathbf{k}_{(3)}\cdot\xi)du_z$ and $u_y(t_{\text{max compression}})-u_y(t_{\text{initial}})=\int_{u_z(t_{\text{initial}})}^{0}[(\mathbf{k}_{(2)}\cdot\xi)/\mathbf{k}_{(3)}\cdot\xi)]du_z$. Moreover, using Eq. (11) we find (formally) that at time $t=t_{\text{final}}$, $\mathbf{u}(t_{\text{final}})-\mathbf{u}(t_{\text{max compression}})=\int_{W(t_{\text{max compression}})}^{W(t_{\text{final}})=(1-e^2)W(t_{\text{max compression}})}\mathbf{K}\xi(dW_z/u_z)$, where we have used Stronge's hypothesis in the upper limit of the last integration.

A. Transverse relative velocity

Let ''pseudoforce'' components $\{F_x,F_y\}$ be defined by

$$F_x=\mathbf{k}_{(1)}\cdot\xi=-\mu\cos(\theta)K_{11}-\mu\sin(\theta)K_{12}+K_{13} \tag{12}$$

and

$$F_y=\mathbf{k}_{(2)}\cdot\xi=-\mu\cos(\theta)K_{21}-\mu\sin(\theta)K_{22}+K_{23}, \tag{13}$$

where we recall that $K_{21}=K_{12}$. Inspection of Eq. (11) shows that the equations of motion for u_x and u_y may be written as

$$\frac{du_x}{dJ_z}=a_x=F_x, \quad \frac{du_y}{dJ_z}=a_y=F_y, \tag{14}$$

where J_z is monotonically increasing during the collision. Here $\{a_x,a_y\}$ denotes the components of the ''pseudotransverse acceleration.''

The locus of all possible $\{a_x,a_y\}$ is an ellipse. To see this, substitute in Eq. (14) using Eqs. (12) and (13), solve for $\cos(\theta)$ and $\sin(\theta)$, then square and add. This yields

$$[K_{22}(a_x-K_{13})-K_{12}(a_y-K_{23})]^2+[-K_{12}(a_x-K_{13})+K_{11}(a_y-K_{23})]^2=\mu^2[K_{11}K_{22}-K_{12}K_{21}]^2. \tag{15}$$

This is the equation for an ellipse centered at (K_{13},K_{23}).

In terms of polar coordinates (u_{tr},θ), $u_x=u_{\text{tr}}\cos(\theta)$ and $u_y=u_{\text{tr}}\sin(\theta)$. Substituting this into Eq. (14) yields

$$\frac{du_{\text{tr}}}{dJ_z}=F_x\cos(\theta)+F_y\sin(\theta), \quad u_{\text{tr}}\frac{d\theta}{dJ_z}=-F_x\sin(\theta)+F_y\cos(\theta). \tag{16}$$

We denote the ''pseudotorque'' on the right-hand side of Eq. (11) by

$$\begin{aligned}D_0(\mathbf{K},\mu,\theta)&\equiv-F_x\sin(\theta)+F_y\cos(\theta)\\&=\mu\cos(\theta)\sin(\theta)K_{11}-\mu\cos(\theta)^2K_{12}+\mu\sin(\theta)^2K_{12}\\&\quad-\sin(\theta)K_{13}-\mu\cos(\theta)\sin(\theta)K_{22}+\cos(\theta)K_{23}.\end{aligned} \tag{17}$$

One observes that $D_0\equiv0$ when either $u_{\text{tr}}\equiv0$ (sticking occurs) or sliding is along a straight line given by

$$\tan(\theta)=\frac{F_y}{F_x}=\frac{-\mu\cos(\theta)K_{21}-\mu\sin(\theta)K_{22}+K_{23}}{-\mu\cos(\theta)K_{11}-\mu\sin(\theta)K_{12}+K_{13}}. \tag{18}$$

Putting $T=\tan(\theta/2)$ in Eq. (18) and solving for T in the resulting quartic equation gives the possible distinguished directions of sliding along a straight line. When sliding is along a straight line the transverse relative acceleration is either parallel or antiparallel to the transverse relative velocity, and the cosine of the included angle ϕ between $\mathbf{u}_\perp$ and $\mathbf{a}_\perp$,

$$\cos(\phi)=\frac{\mathbf{u}_\perp\cdot\mathbf{a}_\perp}{u_\perp a_\perp}=\frac{F_x\cos(\theta)+F_y\sin(\theta)}{\sqrt{F_x^2+F_y^2}}, \tag{19}$$

is ±1. If the transverse relative velocity is parallel to the transverse relative acceleration then u_{tr} is increasing and the flow of $\mathbf{u}_\perp$ in the u_x-u_y plane is called a *diverging* ray. If the transverse relative velocity is antiparallel to the transverse relative acceleration then u_{tr} is decreasing and the flow of $\mathbf{u}_\perp$ in the u_x-u_y plane is called a *converging* ray. Bhatt and Koechling[12] have shown that the total number of converging and diverging rays is 2 or 4.

We consider the case in which D_0 is not identically zero. Dividing the second of equations (16) into the first yields

$$\frac{1}{u_{\mathrm{tr}}}\frac{du_{\mathrm{tr}}}{d\theta}=\frac{F_x\cos(\theta)+F_y\sin(\theta)}{D_0(\mathbf{K},\mu,\theta)},$$

or

$$d\ln(u_{\mathrm{tr}})=\frac{F_x\cos(\theta)d\theta+F_y\sin(\theta)d\theta}{D_0(\mathbf{K},\mu,\theta)}. \tag{20}$$

The numerator of Eq. (20) may be recast using $F_x\cos(\theta)d\theta+F_y\sin(\theta)d\theta=F_x\,d\sin(\theta)-F_y\,d\cos(\theta)=d(F_x\sin(\theta)-F_y\cos(\theta))-\sin(\theta)dF_x+\cos(\theta)dF_y$. Hence

$$\begin{aligned}d\ln(u_{\mathrm{tr}})&=\frac{d(F_x\sin(\theta)-F_y\cos(\theta))-\sin(\theta)dF_x+\cos(\theta)dF_y}{-F_x\sin(\theta)+F_y\cos(\theta)}\\&=-d\ln(-F_x\sin(\theta)+F_y\cos(\theta))+\frac{-\sin(\theta)dF_x+\cos(\theta)dF_y}{-F_x\sin(\theta)+F_y\cos(\theta)}.\end{aligned}$$

Therefore

$$d\ln(u_{\mathrm{tr}})=-d\ln(D_0)+\frac{-\sin(\theta)dF_x+\cos(\theta)dF_y}{D_0(\mathbf{K},\mu,\theta)}. \tag{21}$$

The numerator of the last term of the right-hand side of Eq. (21) is $-\sin(\theta)dF_x+\cos(\theta)dF_y=(-\sin(\theta)^2K_{11}+2\cos(\theta)\sin(\theta)K_{12}-\cos(\theta)^2K_{22})d\theta$.

In terms of $T=\tan(\theta/2)$, the differential system Eq. (21) governing the dynamical evolution of the transverse speed is

$$d\ln(u_{\mathrm{tr}})=-d\ln(D_0)+\left(\frac{-\sin(\theta)dF_x+\cos(\theta)dF_y}{D_0(\mathbf{K},\mu,T)}\right)\frac{d\theta}{dT}dT.$$

After some calculation we find that

$$\left(\frac{-\sin(\theta)dF_x+\cos(\theta)dF_y}{D_0(\mathbf{K},\mu,T)}\right)\frac{d\theta}{dT}dT=-2\,\frac{T}{1+T^2}\,dT+2\,\frac{N(\mathbf{K},\mu,T)}{D(\mathbf{K},\mu,T)}\,dT$$

$$=-d\,\ln(1+T^2)+2\,\frac{N(\mathbf{K},\mu,T)}{D(\mathbf{K},\mu,T)}\,dT$$

where

$$N(\mathbf{K},\mu,T)\equiv\mu K_{22}-T(3\mu K_{12}+K_{23})+T^2(2(\mu K_{11}+K_{13})-\mu K_{22})+T^3(\mu K_{12}+K_{23}) \quad (22)$$

and

$$D(\mathbf{K},\mu,T)\equiv-(1+T^2)^2D_0(\mathbf{K},\mu,T)$$
$$=\mu K_{12}-K_{23}+2T(K_{13}+\mu(-K_{11}+K_{22}))-6T^2\mu K_{12}$$
$$+2T^3(K_{13}+\mu(K_{11}-K_{22}))+T^4(\mu K_{12}+K_{23}). \quad (23)$$

Therefore,

$$d\,\ln(u_{\mathrm{tr}})=-d\,\ln(D_0)-d\,\ln(1+T^2)+2\,\frac{N(\mathbf{K},\mu,T)}{D(\mathbf{K},\mu,T)}\,dT=-d\,\ln\frac{-D(\mathbf{K},\mu,T)}{(1+T^2)}+2\,\frac{N(\mathbf{K},\mu,T)}{D(\mathbf{K},\mu,T)}\,dT. \quad (24)$$

B. A first integral of the motion

The term $2[N(\mathbf{K},\mu,T)/D(\mathbf{K},\mu,T)]dT$ is an integrable rational form with a simple exact integral. The general form for the integral is well known and is given in, for example, Gradshteyn and Ryzhik,[19] Sec. 2.1. The precise functional form of the integral depends on the degree of $D(\mathbf{K},\mu,T)$ and the multiplicities of the roots of $D(\mathbf{K},\mu,T)$. We explicitly consider one important case here, the case when $D(\mathbf{K},\mu,T)$ has four distinct roots. Let T_r $r=1,2,3,4$ denote the simple roots of $D(\mathbf{K},\mu,T)$, $D(\mathbf{K},\mu,T)=c_4\Pi_{r=1}^{r=4}(T-T_r)$, where $c_4=\mu K_{12}+K_{23}\neq 0$ is the coefficient of T^4 in $D(\mathbf{K},\mu,T)$. Define $\psi(T)=2[N(\mathbf{K},\mu,T)/(d/dT)D(\mathbf{K},\mu,T)]$. We find that $[2N(\mathbf{K},\mu,T)/D(\mathbf{K},\mu,T)]dT=\Sigma_{r=1}^{r=4}\,\psi(T_r)d\,\ln|T-T_r|$ so that Eq. (24) becomes

$$d\,\ln(u_{\mathrm{tr}})=-d\,\ln\frac{-D(\mathbf{K},\mu,T)}{(1+T^2)}+2\,\frac{N(\mathbf{K},\mu,T)}{D(\mathbf{K},\mu,T)}\,dT=-d\,\ln\frac{-D(\mathbf{K},\mu,T)}{(1+T^2)}-\sum_{r=1}^{r=4}\,d\,\ln|T-T_r|^{-\psi(T_r)}. \quad (25)$$

This integrates to

$$\Xi(\mathbf{K},\mu,T)=-u_{\mathrm{tr}}(T)D_0(\mathbf{K},\mu,T)(1+T^2)\prod_{r=1}^{r=4}|T-T_r|^{-\psi(T_r)}$$
$$=u_{\mathrm{tr}}(T)\,\frac{D(\mathbf{K},\mu,T)}{1+T^2}\prod_{r=1}^{r=4}|T-T_r|^{-\psi(T_r)}$$
$$=u_{\mathrm{tr}}(T)\,\frac{\mu K_{12}+K_{23}}{1+T^2}\prod_{r=1}^{r=4}\frac{(T-T_r)}{|T-T_r|^{\psi(T_r)}}=\mathrm{constant}. \quad (26)$$

This is a new first integral (conservation law) for a binary rigid body collision of arbitrarily short duration, and the main result of this paper.

In Eq. (26) two of the T_r may be complex conjugates of each other, say T_3 and $T_4=T_3^*$. Then two of the $\psi(T_r)$ are complex conjugates of each other, $\psi(T_3)$ and $\psi(T_4)=\psi(T_3)^*$. Put $T_3=x+iy$ and $\psi(T_3)=\alpha+i\beta$, where x, y, α, and β are real. Consider $\Sigma_{\mathrm{complex}}\,\psi(T_r)\ln|T-T_r|$

$=\Sigma_{r=3}^{4}\psi(T_r)\ln|T-T_r|=(\alpha+i\beta)\ln[T-(x+iy)]+(\alpha-i\beta)\ln[T-(x-iy)]=\alpha\ln[(T-x)^2+y^2]+\beta(2\tan^{-1}\times([y/(T-x)])+2n\pi)$. Also $\Pi_{\text{complex}}|T-T_r|^{\psi(T_r)}=\Pi_{\text{complex}}\exp(\psi(T_r)\ln|T-T_r|)=\exp(\Sigma_{\text{complex}}\times\psi(T_r)\ln|T-T_r|)=\exp(\alpha\ln[(T-x)^2+y^2]+\beta(2\tan^{-1}([y/(T-x)]+2n\pi))=|(T-x)^2+y^2|^{\alpha}\exp[\beta\times(2\tan^{-1}([y/(T-x)])+2n\pi)]$, where n is an integer (the branch cut for the natural logarithm is on the negative real axis; if it is crossed then the phase may change discontinuously). These obvious identities may be used as needed to recast expressions involving $\Pi_{\text{complex}}|T-T_r|^{\psi(T_r)}$ into a manifestly real form.

We may use Eq. (26) to eliminate u_{tr} in the second of Eq. (16), $u_{\text{tr}}(d\theta/dJ_z)=u_{\text{tr}}(d\theta/dT)\times(dT/dJ_z)=u_{\text{tr}}[2/(1+T^2)(dT/dJ_z)]=-F_x\sin(\theta)+F_y\cos(\theta)=D_0(\mathbf{K},\mu,T)$. Let $\Xi=\Xi(\mathbf{K},\mu,T\times(\theta_{\text{initial}}))$. Multiplying on each side with $(1+T^2)^2D_0(\mathbf{K},\mu,T)\Pi_{r=1}^{r=4}|T-T_r|^{-\psi(T_r)}$ yields

$$2\Xi(dT/dJ_z)=[(1+T^2)D_0(\mathbf{K},\mu,\theta)]^2\prod_{r=1}^{r=4}[T-T_r]^{-\psi(T_r)}=\left[\frac{D(\mathbf{K},\mu,T)}{1+T^2}\right]^2\prod_{r=1}^{r=4}|T-T_r|^{-\psi(T_r)}.$$

Therefore

$$2\Xi\left(\left[\frac{1+T^2}{D(\mathbf{K},\mu,T)}\right]^2\prod_{r=1}^{r=4}|T-T_r|^{\psi(T_r)}\right)dT=2\Xi\left[\left(\frac{1+T^2}{c_4}\right)^2\prod_{r=1}^{r=4}\frac{|T-T_r|^{\psi(T_r)}}{(T-T_r)^2}\right]dT=dJ_z,$$

or

$$\frac{2\Xi}{c_4^2}\left[(1+T^2)^2\prod_{r=1}^{r=4}|T-T_r|^{\psi(T_r)-2}\right]dT=dJ_z=\frac{du_z}{\mathbf{k}_{(3)}\cdot\xi}=\frac{dW_z}{u_z}. \tag{27}$$

This result can be (numerically) integrated to determine the dynamical evolution of θ during the collision.

V. DISCUSSION

Physically, $u_{\text{tr}}=0$ corresponds to (perhaps instantaneous) sticking. During the impact u_{tr} usually changes, and the conventional wisdom is that it may become zero. This idea is based on physical insight into the problem, but not on analytical results derived from a specific analytical model of friction (the dynamic Coulomb friction law, in this case). However the conservation law of Eq. (26) guarantees that if the constant in the law is not initially zero, then u_{tr} is never zero. Analytically, therefore, the dynamic Coulomb friction law does not formally allow an initially nonzero u_{tr} to vanish, except possibly for the special cases of $\mathbf{u}_\perp$ flow along either a converging or a diverging ray. This may bear repeating: using Eq. (26) we have proven that *the dynamic Coulomb friction law does not allow either instantaneous sticking or stable sticking to evolve from an initially nonzero* u_{tr}, except possibly for the special cases of $\mathbf{u}_\perp$ flow along either a converging or a diverging ray.

This somewhat surprising prediction is certainly not a dramatic refutation of the traditional view of sticking during a two-body collision. The traditional view is based largely on observation and heuristic arguments, but not on exact analytical results founded on a mathematical model of friction (of limited validity). There is no reason for a calculation based on Eq. (26) and an accurate calculation based on the heuristic approach to significantly disagree with one another.

VI. EXAMPLE

The result of Eq. (26) may be employed to compute the transverse relative velocity during a two-body collision. Before focusing on concrete examples, let us first review the concepts of stable and unstable sticking. Consider an arbitrary model of friction and the consequences of $u_{\text{tr}}=0$. If sticking is *stable* then the governing differential system implies that $du_x=0=du_y$, which evidently requires that $\mathbf{k}_{(1)}\cdot\mathbf{f}=0=\mathbf{k}_{(2)}\cdot\mathbf{f}$. This implies that $\mathbf{f}\propto\mathbf{k}_{(1)}\times\mathbf{k}_{(2)}\propto\mathbf{K}_{(3)}^{-1}$ $[\mathbf{k}_{(1)}\times\mathbf{k}_{(2)}\neq 0$ since $\det(K)\neq 0]$. Another way to see this is to note that for the case of instantaneous sticking, the relative velocity $\mathbf{u}=u_z\hat{\mathbf{z}}$. If sticking is stable, an arbitrary time variation δt in this system preserves sticking. In order that u_x and u_y remain zero it is necessary that $\delta u_x=\dot{u}_x\delta t=0=\dot{u}_y\delta t=\delta u_y$, so that $\dot{\mathbf{u}}=\dot{u}_z\hat{\mathbf{z}}$. Therefore

$$\delta\mathbf{J}=\mathbf{f}\delta t=\mathbf{K}^{-1}\delta\Delta\mathbf{u}=\mathbf{K}^{-1}\delta\mathbf{u}=\delta u_z\mathbf{K}_{(3)}^{-1}=\mathbf{K}_{(3)}^{-1}\frac{du_z}{dJ_z}\frac{dJ_z}{dt}\delta t=\mathbf{K}_{(3)}^{-1}\frac{1}{(dJ_z/du_z)}f_z\delta t=\frac{\mathbf{K}_{(3)}^{-1}}{\mathbf{K}_{33}^{-1}}f_z\delta t.$$

We conclude that

$$\frac{\mathbf{f}}{f_z}=\frac{\mathbf{K}_{(3)}^{-1}}{\mathbf{K}_{33}^{-1}}=\frac{\mathbf{k}_{(1)}\times\mathbf{k}_{(2)}}{K_{11}K_{22}-K_{12}K_{21}} \tag{28}$$

for such a system.

The static friction force components can maintain sticking only if $(f_x)^2+(f_y)^2\leqslant\mu_{\text{static}}^2(f_z)^2$ (e.g., in 1-dim, suppose that $|f_x|$ is required for sticking, while $\mu_{\text{static}}|f_z|$ is available), which implies that $(\mathbf{K}_{31}^{-1})^2+(\mathbf{K}_{32}^{-1})^2\leqslant\mu_{\text{static}}^2(\mathbf{K}_{33}^{-1})^2$, in light of the previous result for $\mathbf{f}$. This is the well-known condition for *stable* sticking. If the pseudotransverse acceleration ellipse encircles the origin then it is known that, in principle, the frictional forces are strong enough to preserve sticking if $u_{\text{tr}}=0$, and that in this case there is no diverging ray of constant sliding direction.[12,14] This means that sliding would permanently cease if u_{tr} should ever become zero. The theory embodied in Eq. (26) tells us that once u_{tr} gets ''small'' the flow of $\mathbf{u}_\perp$ is trapped by converging rays and is driven to even smaller values of u_{tr} toward some converging ray. Thereafter changes in θ, which are proportional to $D(\mathbf{K},\mu,T)$, are also very small since $D(\mathbf{K},\mu,T)=0$ on a ray. Effectively the system is ''stuck.'' Therefore our analytical results admit stable sticking.

Otherwise, if frictional forces are not strong enough to preserve sticking and if, in some particular physical model of friction, u_{tr} evolves to zero, then slipping immediately resumes along a diverging ray. This is called *instable* sticking. It is known that if frictional forces are not strong enough to preserve sticking,[14] then there is exactly one diverging ray.[12,14] The theory described in this paper accommodates instable sticking in a natural manner, as can be seen in the following example.

In this first example the impact is characterized by a coefficient of kinetic friction $\mu=0.2$ and a collision matrix

$$\mathbf{K}=\begin{pmatrix}+8 & -2 & +1\\ -2 & +3 & -1\\ +1 & -1 & +5\end{pmatrix}. \tag{29}$$

These values are used by Mirtich in an example in Ref. 14 and we would like to compare our results with his, since our method of computing results and Mirtich's method are completely different. The determinant of $\mathbf{K}$ is $\Delta=93$ and

$$\mathbf{K}^{-1}=\frac{1}{\Delta}\begin{pmatrix}14 & 9 & -1\\ 9 & 39 & 6\\ -1 & 6 & 20\end{pmatrix}.$$

Notice that $(\mathbf{K}_{31}^{-1})^2+(\mathbf{K}_{32}^{-1})^2=(1/\Delta^2)37>\mu_{\text{static}}^2(\mathbf{K}_{33}^{-1})^2=(1/\Delta^2)16$ so that sticking is not stable. We shall not specify the coefficient of restitution because we are not trying to find θ as a function of J_z, but are instead studying the behavior of (u_x,u_y) as functions of θ.

In Fig. 1 we plot the flow lines of the transverse relative velocity as θ varies for an initial transverse relative speed of ten units; its particular magnitude is immaterial as long as it is nonzero because conservation law is a function of u_{tr} times a function of angle. The flow lines are computed using the first integral of Eq. (26) for selected values of θ^{initial}, where the constant in the

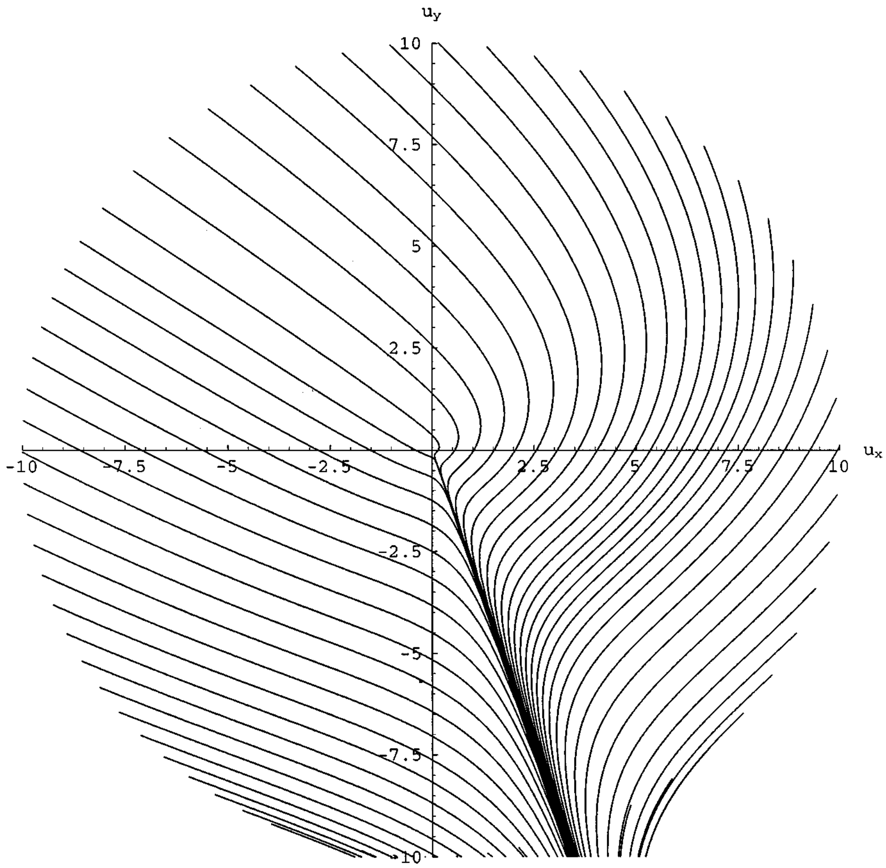

FIG. 1. Scale invariant transverse relative velocity flows for unstable sticking.

conservation law is evaluated using $u_{\mathrm{tr}}^{\mathrm{initial}}=10$ and $T^{\mathrm{initial}}=\tan(\frac{1}{2}\theta^{\mathrm{initial}})$ for each individual case. Of course, the flow lines appear qualitatively the same when plotted for other initial transverse relative speeds such as 1 unit, 0.1, 0.01, and so on. The flow exhibits a type of scale invariance that is a consequence of the fact that the conservation law is a function of u_{tr} times a function of angle.

Figure 1 confirms that there is a diverging ray (transverse relative velocity parallel to transverse relative acceleration) at $\theta_{\mathrm{diverging}}=-71.1127\,\mathrm{deg}$ that attracts outgoing trajectories and a converging ray (transverse relative velocity antiparallel to transverse relative acceleration) at $\theta_{\mathrm{converging}}=147.001\,\mathrm{deg}$. Using Eq. (19) we verify that there is a single converging ray and a single diverging ray at these angles. If the transverse relative velocity lies on one of these rays then the direction of sliding remains constant, until $u_{\mathrm{tr}}=0$.

We find that in this case there are two simple real roots and a complex conjugate pair of roots. The roots of $D(\mathbf{K},\mu,T)$ are

$$T_r=\begin{pmatrix} -0.714\,777\,790\,129\,410\,917 \\ 3.376\,057\,857\,830\,754\,29 \\ 0.097\,931\,394\,720\,756\,870\,2+0.409\,889\,210\,722\,295\,516\;i \\ 0.097\,931\,394\,720\,756\,870\,2-0.409\,889\,210\,722\,295\,516\;i \end{pmatrix},$$

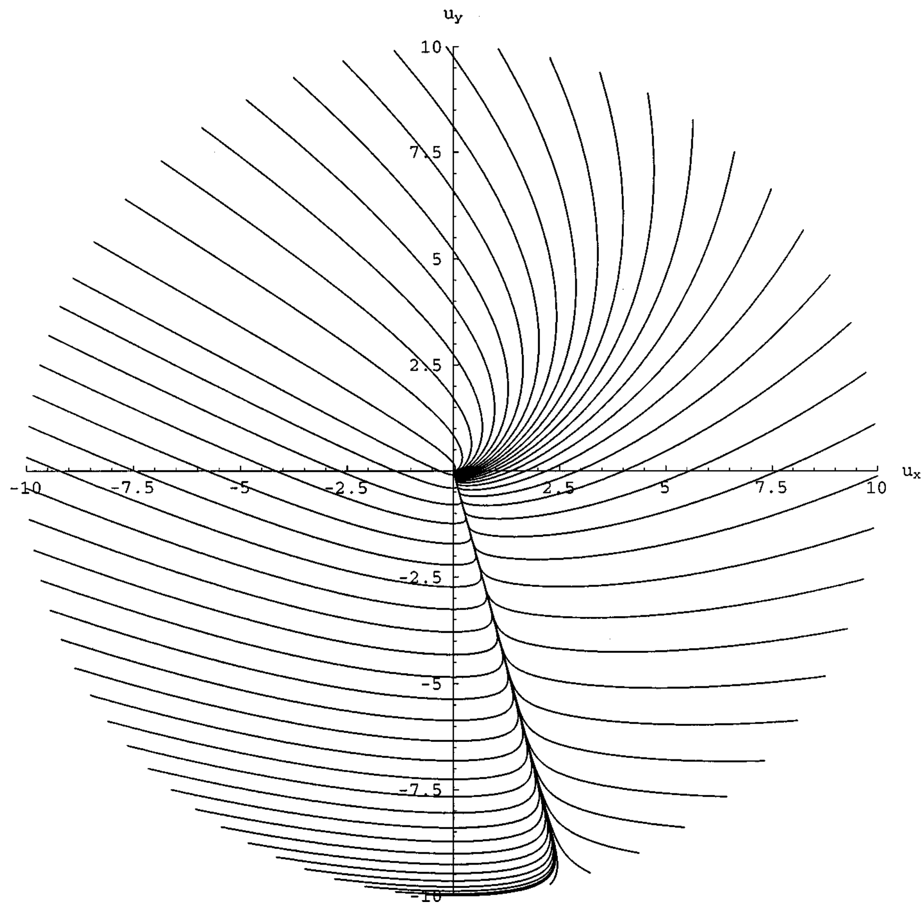

FIG. 2. Scale invariant transverse relative flows for stable sticking.

$$\psi(T_r)=\begin{pmatrix} 0.796\,175\,001\,065\,219\,056 \\ -0.210\,719\,532\,590\,733\,082 \\ 0.707\,272\,265\,762\,756\,902-0.347\,433\,352\,914\,288\,784\ i \\ 0.707\,272\,265\,762\,756\,902+0.347\,433\,352\,914\,288\,784\ i \end{pmatrix}.$$

Using the notation defined in the paragraph preceding Eq. (26)

$$\begin{pmatrix} x \\ y \\ \alpha \\ \beta \end{pmatrix}=\begin{pmatrix} 0.097\,931\,394\,720\,756\,870\,2 \\ 0.409\,889\,210\,722\,295\,516 \\ 0.707\,272\,265\,762\,756\,902 \\ -0.347\,433\,352\,914\,288\,784 \end{pmatrix}.$$

The conservation law Eq. (26) is equivalent to

$$u_{\mathrm{tr}}(T)\,\frac{\mathrm{sign}[T-T_1]\mathrm{sign}[T-T_2]}{1+T^2}|T-T_1|^{1-\psi(T_1)}|T-T_2|^{1-\psi(T_2)}\frac{[(T-x)^2+y^2]^{1-\alpha}}{\exp\left[\beta\left(2\tan^{-1}\left(\frac{y}{T-z}\right)+2\pi n\right)\right]}$$

$$=\mathrm{constant},$$

where $n=0$ for $-\pi<\theta_{\mathrm{diverging}}<\theta<\theta_{\mathrm{converging}}<\pi$ and

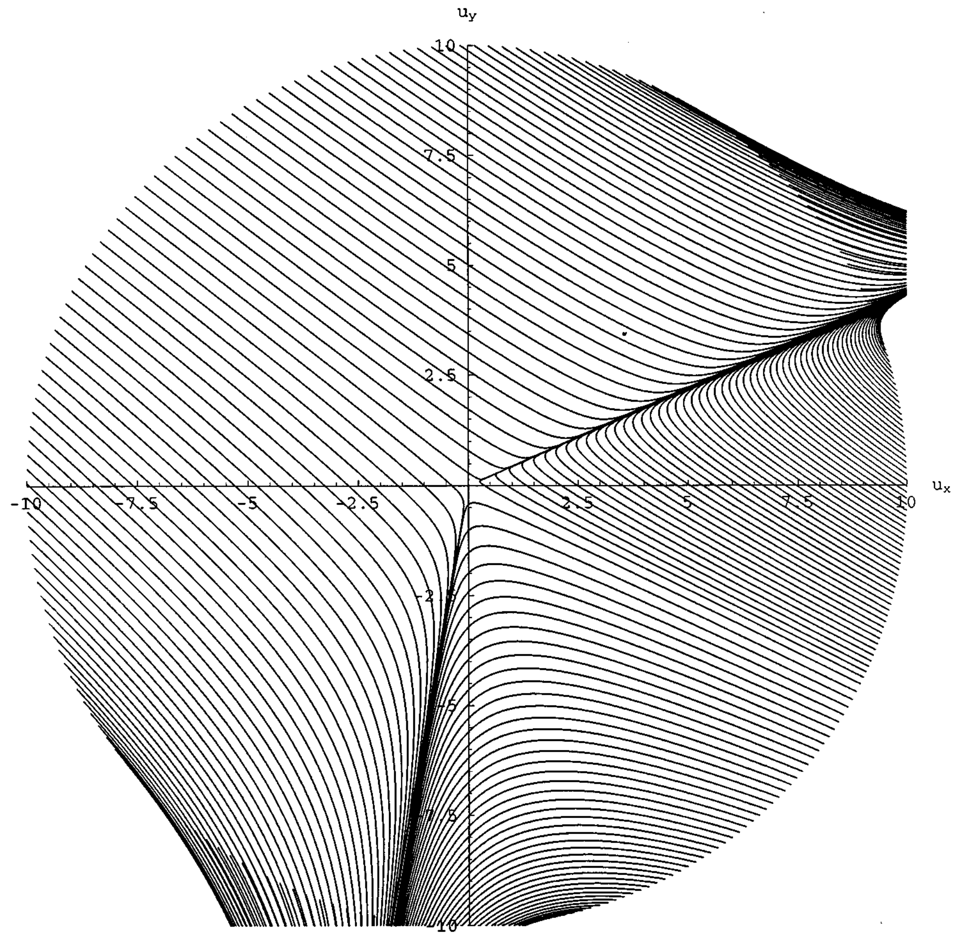

FIG. 3. Transverse relative velocity flows for unphysical **K**.

$$n=\begin{cases} 0, & u_y>0 \\ -1, & u_y<0 \end{cases}$$

for $\frac{1}{2}\pi<\theta_{\text{converging}}<\theta<2\pi+\theta_{\text{diverging}}$ (there is a branch cut for the logarithm on the negative real axis; we find that there is a change in phase of -2π across the cut). Notice that if we relabel roots and label $T_{3,4}$ as $T_{4,3}$, then $y\to -y$ and $\beta\to -\beta$; in this case $n=+1$ gives the correct change in phase of across the cut.

As previously stated, these same values for **K** and μ are used by Mirtich in an example in Ref. 14, where, however, the flow lines are computed by numerically integrating a system of ordinary differential equations equivalent to Eq. (11). The flows graphed in Fig. 1 computed using analytical methods and the flows presented in Mirtich's Figure[3.3] computed using numerical methods are in agreement.

Next, modify the collision matrix so that sticking is stable. Consider

$$\mathbf{K}=\begin{pmatrix} +12 & -2 & +1 \\ -2 & +5 & -1 \\ +1 & -1 & +1 \end{pmatrix}. \tag{30}$$

The determinant of **K** is $\Delta=43$ and

$$\mathbf{K}^{-1}=\frac{1}{\Delta}\begin{pmatrix} 4 & 1 & -3 \\ 1 & 1 & 10 \\ -3 & 10 & 56 \end{pmatrix}.$$

Since $(\mathbf{K}_{31}^{-1})^2+(\mathbf{K}_{32}^{-1})^2=(1/\Delta^2)109<\mu_{\text{static}}^2(\mathbf{K}_{33}^{-1})^2=(1/\Delta^2)125.44$, sticking is stable. In this case we find that there are two real simple roots. By Eq. (19), there are two converging rays.

In Fig. 2 we plot the flow lines of the transverse relative velocity as a function of θ. The initial transverse relative speed is again (arbitrarily) ten units and μ is unchanged. The flow lines are again computed using the conservation law Eq. (26) for selected values of θ^{initial}. Figure 2 confirms that there are two converging rays at $\theta_{\text{converging}}=-74.6983$ deg and 150.832 deg, respectively. We see that if $\mathbf{u}_{\text{tr}}$ becomes small, then it is swept into ever decreasing values as the collision progresses. Effectively, sticking occurs just as in the heuristic model.

For purposes of illustration, we modify the collision matrix so that it is not positive definite, and hence unphysical. Let

$$\mathbf{K}=\begin{pmatrix} +8 & -7 & +1 \\ -7 & +3 & -1 \\ +1 & -1 & +5 \end{pmatrix}. \tag{31}$$

The determinant of $\mathbf{K}$ is $\Delta=-122$ and

$$\mathbf{K}^{-1}=\frac{1}{\Delta}\begin{pmatrix} 14 & 34 & 4 \\ 34 & 39 & 1 \\ 4 & 1 & -25 \end{pmatrix}.$$

In this unphysical case we find that there are four real simple roots. Equation (19) reveals that there are two converging rays and two diverging rays.

In Fig. 3 we plot the flow lines of the transverse relative velocity as a function of θ. The initial transverse relative speed is again ten units and μ is unchanged. The flow lines are again computed using the conservation law Eq. (26) for selected values of θ^{initial}. Figure 3 confirms that there are a diverging rays at $\theta_{\text{diverging}}=-99.7051$ deg and 23.6415 deg and converging rays at $\theta_{\text{converging}}=-26.2886$ deg and 141.66 deg. However, this does not illustrate a possible physical motion since $\mathbf{K}$ is not positive definite.

(Received 2 September 1998; accepted for publication 1 February 1999)

Euler–Kirchhoff filaments are solutions of the static Kirchhoff equations for elastic rods with circular cross sections. These equations are known to be formally equivalent to the Euler equations for spinning tops. This equivalence is used to provide a classification of the different shapes a filament can assume. Explicit formulas for the different possible configurations and specific results for interesting particular cases are given. In particular, conditions for which the filament has points of self-intersection, self-tangency, vanishing curvature or when it is closed or localized in space are provided. The average properties of generic filaments are also studied. They are shown to be equivalent to helical filaments on long length scales. © *1999 American Institute of Physics.* [S0022-2488(99)05006-9]

I. INTRODUCTION

The study of elastic deformations in rods has a long tradition in mathematics, physics, and engineering, dating back to Euler and Lagrange. Engineers have been confronted to the problem of coiling in sub-oceanic cables and have tried to understand the process of loop formation in twisted wires.[1–3] In chemistry and biology, increasing interest is taken in the elastic character of filamentary structures such as polymers[4–7] (such as DNA molecules[8–15]) and bacterial fibers,[16–18] for which the macroscopic theory of rods provides an idealized model. Long, twisted structures also play an important role in hydrodynamic models[19] such as scroll wave propagation,[20] vortex tube motion,[21] or sun spots formation and solar corona heating.[22,23]

The Kirchhoff model (1859) (Ref. 24) provides the basic framework for the theory of elastic filaments. A remarkable feature of this model, known as the Kirchhoff kinetic analogy, is that the equations governing the static phenomena are formally equivalent to the Euler equations describing the motion of a rigid body with a fixed point under an external force field. The statics of rods is thus intimately connected to the dynamics of spinning tops, a problem to which innumerable work has been devoted. For instance, the most studied case where the filament has a circular cross section is shown to correspond to a top having an axis of revolution, in which case the equations are fully integrable. There is a rich mathematical literature on the statics of rods (see for instance, Ref. 26). In the particular case of circular cross sections and linear elasticity, various researchers have considered particular equilibrium filament shapes (helices,[25,27] rings,[28,3] localizing buckling modes,[1,29] solutions having points with vanishing curvature,[30] supercoiled helices,[31] see also Ref. 32 for a Hamiltonian formulation and Ref. 33 for a group theory approach). Recently, departing from the traditional Euler angles approach, Shi and Hearst (1994) have obtained a closed form of the general solution of the static Kirchhoff equations for circular cross sections.[34] Despite this achievement, it remains highly nontrivial to obtain a global picture of all possible static filament shapes. A step towards a general geometric classification of the equilibrium solutions is provided here by considering in more detail the analogy between filaments and spinning tops. In Sec. III, we

[a)]Electronic mail: mnizette@ulb.ac.be
[b)]Electronic mail: goriely@math.arizona.edu

rederive Shi and Hearst's general solution, keeping an explicit dependence in the constants of the motion of the spinning top, and we discuss in detail various filament configurations on the basis of the corresponding orbits of the top, recovering the aforementioned shapes as particular cases.

In this paper, we provide new results on the different configurations of Kirchhoff filaments in 2D and 3D. We give explicit formulas for the centerline coordinate and find conditions for self-tangency and self-intersection of planar filaments, conditions for vanishing curvature and average behavior of long filaments. Explicit formulas for periodic or localized (homoclinic) filaments in space are also given.

II. THE KIRCHHOFF MODEL

We first introduce the Kirchhoff model. It accounts for the dynamics of a thin elastic filament subject to internal stresses and boundary constraints. A filament is a unidimensional piece of elastic material which can be mathematically modelized by a curve in space, together with extra information about its twist, that is, how longitudinal material lines on the edge of the filament wind around it. This curve-plus-twist concept is formalized in the notion of ribbon discussed in Sec. II A as a preliminary.

A. Space curves and ribbons

We define a dynamical *space curve* $\mathbf{R}(s,t)$ as a smooth function mapping $\mathbb{R}^2$ into the physical space $\mathbb{R}^3$, and taking as variables the arc length s and the time t. For every s and t we define the Frenet basis $(\mathbf{n},\mathbf{b},\mathbf{t})$ to be the normal, binormal and tangent vectors to the curves. These vectors form the Frenet basis. The tangent vector is a unit vector given by $\mathbf{t}=(\partial\mathbf{R}/\partial s)$. The curvature κ of the curve at the point s is then given by

$$\kappa=\left|\frac{\partial\mathbf{t}}{\partial s}\right|. \tag{1}$$

At points where the curvature does not vanish, the normal vector is defined by

$$\frac{\partial\mathbf{t}}{\partial s}=\kappa\mathbf{n}. \tag{2}$$

The third unit vector $\mathbf{b}$ is

$$\mathbf{b}=\mathbf{t}\times\mathbf{n}. \tag{3}$$

Therefore, the Frenet basis is a right-handed orthonormal basis on the space curve $\mathbf{R}$. As a consequence, one has

$$\frac{\partial\mathbf{n}}{\partial s}=\tau\mathbf{b}-\kappa\mathbf{t}. \tag{4}$$

This relation defines the torsion τ, which measures the amount of rotation of the Frenet triad around the tangent $\mathbf{t}$ as the arc length increases. Finally the derivative of the binormal $\mathbf{b}$ is given in terms of the normal and tangent vector,

$$\frac{\partial\mathbf{b}}{\partial s}=-\tau\mathbf{n}. \tag{5}$$

The coupled equations (2), (4), and (5) are the Frenet–Serret equations. If the curvature κ and the torsion τ are known for all s, the Frenet triad $(\mathbf{n},\mathbf{b},\mathbf{t})$ can be obtained as the unique solution of the Frenet–Serret equations. It is then possible to reconstruct the space curve $\mathbf{R}$ by integrating the tangent vector $\mathbf{t}$.

A ribbon is a space curve $\mathbf{R}(s,t)$ supplied with a smooth unit vector field $\mathbf{d}_2(s,t)$ orthogonal to the curve. Let $\mathbf{d}_3=\mathbf{t}$ be the unit tangent vector. A third unit vector field $\mathbf{d}_1=\mathbf{d}_2\times\mathbf{d}_3$ is introduced so that the triad $(\mathbf{d}_1,\mathbf{d}_2,\mathbf{d}_3)$ forms a right-handed orthonormal basis. This basis is a generalization of the Frenet triad $(\mathbf{n},\mathbf{b},\mathbf{t})$.

The components of the derivatives of the local basis vectors $\mathbf{d}_1$, $\mathbf{d}_2$, and $\mathbf{d}_3$ with respect to the arc length s and the time t expressed in the local basis form the twist vector $\kappa(s,t)=\kappa_1\mathbf{d}_1+\kappa_2\mathbf{d}_2+\kappa_3\mathbf{d}_3$ and the spin vector $\boldsymbol{\omega}(s,t)=\omega_1\mathbf{d}_1+\omega_2\mathbf{d}_2+\omega_3\mathbf{d}_3$, defined as follows:

$$\frac{\partial \mathbf{d}_i}{\partial s}=\boldsymbol{\kappa}\times\mathbf{d}_i, \quad i=1,2,3 \tag{6a}$$

$$\frac{\partial \mathbf{d}_i}{\partial t}=\boldsymbol{\omega}\times\mathbf{d}_i. \quad i=1,2,3 \tag{6b}$$

Equations (6a) constitute the generalization of the Frenet–Serret equations for the ribbon. These equations can also be expressed in terms of the twist matrix $\mathbf{K}(s,t)$ and the spin matrix $\mathbf{W}(s,t)$, which we define as follows:

$$\mathbf{K}=\begin{pmatrix} 0 & -\kappa_3 & \kappa_2 \\ \kappa_3 & 0 & -\kappa_1 \\ -\kappa_2 & \kappa_1 & 0 \end{pmatrix}, \quad \mathbf{W}=\begin{pmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{pmatrix}. \tag{7}$$

The Frenet–Serret equations then read

$$\left(\frac{\partial \mathbf{d}_1}{\partial s}\ \frac{\partial \mathbf{d}_2}{\partial s}\ \frac{\partial \mathbf{d}_3}{\partial s}\right)=(\mathbf{d}_1\mathbf{d}_2\mathbf{d}_3)\mathbf{K}, \tag{8}$$

$$\left(\frac{\partial \mathbf{d}_1}{\partial t}\ \frac{\partial \mathbf{d}_2}{\partial t}\ \frac{\partial \mathbf{d}_3}{\partial t}\right)=(\mathbf{d}_1\mathbf{d}_2\mathbf{d}_3)\mathbf{W}. \tag{9}$$

B. The Kirchhoff equations

1. Main assumptions and derivation of the Kirchhoff equations

A thin filament, or rod, can be modelized by a ribbon constituted of a space curve $\mathbf{R}$ joining the loci of the centroids of the cross sections, together with a vector field $\mathbf{d}_2$ attached to the filament material. The space curve $\mathbf{R}$ is referred to as the centerline of the rod.

The Kirchhoff equations describe the dynamical evolution of the filament under the effect of internal elastic stresses and boundary constraints, in the absence of external force fields such as gravity. Also, only local interactions, between adjacent cross sections, are considered, ignoring the possibility for two remote segments of the filament to intersect with each other. Let $\mathbf{F}(s)$ and $\mathbf{M}(s)$ be the total force and total moment exerted on the back side of a cylinder $C(s)$ by the cylinder $C(s+ds)$ whose cross-section shape is defined by $\mathcal{S}$, the set of all the values of the couple (x_1,x_2) corresponding to a material point inside a given cross section. The conservation of linear and angular momentum yields[35]

$$\frac{\partial \mathbf{F}}{\partial s}=\rho\mathcal{A}\frac{\partial^2\mathbf{R}}{\partial t^2}, \tag{10a}$$

$$\frac{\partial \mathbf{M}}{\partial s}+\mathbf{d}_3\times\mathbf{F}=\rho\left(I_2\mathbf{d}_1\times\frac{\partial^2\mathbf{d}_1}{\partial t^2}+I_1\mathbf{d}_2\times\frac{\partial^2\mathbf{d}_2}{\partial t^2}\right), \tag{10b}$$

where $\mathcal{A}$ denotes the area of the cross section and the quantities I_1 and I_2 are the principal moments of inertia of the cross section,

$$I_1=\int_{\mathcal{S}} dx_1 dx_2 x_2^2, \quad I_2=\int_{\mathcal{S}} dx_1 dx_2 x_1^2. \tag{11}$$

Equations (10) are closed by using the constitutive relation of linear elasticity relating the torque **M** to the twist vector $\boldsymbol{\kappa}$,

$$\mathbf{M}=EI_1\kappa_1\mathbf{d}_1+EI_2\kappa_2\mathbf{d}_2+\mu J\kappa_3\mathbf{d}_3, \tag{12}$$

where E is Young's modulus, μ is the shear modulus, and J is a function of the shape $\mathcal{S}$ of the cross section. In the particular case of a circular cross section, one has

$$I_1=I_2=\frac{J}{2}=\frac{\pi R^4}{4}, \tag{13}$$

where R is the radius of the cross section. The combinations EI_1 and EI_2 are called the principal bending stiffnesses of the rod and measure how strong an applied torque must be in order to bend it, whereas the combination μJ is called the torsional stiffness and measures how large an applied torsional moment must be in order to twist the rod.

The coupled Eqs. (10) and (12) constitute the dynamical Kirchhoff equations. These are three vector equations involving the local basis $(\mathbf{d}_1,\mathbf{d}_2,\mathbf{d}_3)$ and its derivatives, the tension **F** and the torque **M**, which add up to nine degrees of freedom, hence the system is closed. In the static case (if the time dependencies is dropped), the term in **R** vanishes from Eq. (10a),

$$\mathbf{F}'=0, \tag{14a}$$

$$\mathbf{M}'+\mathbf{d}_3\times\mathbf{F}=0, \tag{14b}$$

$$\mathbf{M}=EI_1\kappa_1\mathbf{d}_1+EI_2\kappa_2\mathbf{d}_2+\mu J\kappa_3\mathbf{d}_3. \tag{14c}$$

2. The Kirchhoff equations in scaled form

In order to restrict the number of independent constants in (14), we scale the variables, by choosing combination of the length $[L]$, time $[T]$, and mass $[M]$ units in the following way:

$$[M]=\rho\sqrt{AI_1}, \quad \frac{[M][L]^3}{[T]^2}=EI_1, \tag{15}$$

with

$$a=\frac{I_2}{I_1}, \quad b=\frac{\mu J}{EI_1}=\frac{J}{2I_1(1+\sigma)}, \tag{16}$$

where σ denotes the Poisson ratio. The constant a measures the asymmetry of the cross section. Our convention is to orient the vector fields $\mathbf{d}_1$ and $\mathbf{d}_2$ such that I_1 and I_2 are, respectively, the larger and smaller bending stiffnesses. In this case, we have

$$0<a\leqslant 1, \tag{17}$$

the value 1 being reached in the symmetric case where the moments of inertia are identical. The constant b is the scaled torsional stiffness. It involves the constant $1/(1+\sigma)$ which ranges from $\frac{2}{3}$, corresponding to incompressible media (if the volume is unchanged as the material is stretched), to 1, corresponding to hyperelasticity (if there is no striction as the material is stretched). In the particular case of a circular cross section, one has

TABLE I. Analogy between rigid bodies and static filaments.

Symbol	Meaning for rods	Meaning for rigid bodies
$\boldsymbol{d}_3$	Unit tangent vector	Unit vector joining the fixed point to the center of mass
$(\boldsymbol{d}_1,\boldsymbol{d}_2,\boldsymbol{d}_3)$	Basis attached to the rod	Basis attached to the solid body
s	Arc length	Time
$\boldsymbol{F}$	Tension	Force equal and opposite to gravity
$\boldsymbol{M}$	Moment	Angular momentum
κ	Twist vector	Angular velocity vector
EI_1, EI_2	Principal bending stiffnesses	Principal moments of inertia in directions orthogonal to $\boldsymbol{d}_3$
μJ	Torsional stiffness	Principal moment of inertia along $\boldsymbol{d}_3$
a	Bending stiffnesses ratio	Ratio of the moments of inertia in directions orthogonal to $\boldsymbol{d}_3$
b	Scaled torsional stiffness	Scaled moment of inertia along $\boldsymbol{d}_3$

$$b=\frac{1}{1+\sigma}\in\left[\frac{2}{3},1\right]. \tag{18}$$

The scaled system reads now

$$\mathbf{F}'=0, \tag{19a}$$

$$\mathbf{M}'+\mathbf{d}_3\times\mathbf{F}=0, \tag{19b}$$

$$\mathbf{M}=\kappa_1\mathbf{d}_1+a\kappa_2\mathbf{d}_2+b\kappa_3\mathbf{d}_3. \tag{19c}$$

The quantities involved still have a dimension. From (19), we see that the scaled moment $\mathbf{M}$ has the dimension of the inverse of a length, and that the scaled tension $\mathbf{F}$ has the dimension of the inverse of a squared length, hence every variable involved is a length to a power. However the system cannot be further simplified by choosing the length unit $[L]$, because the remaining constants a and b are already dimensionless. It is still possible to choose a convenient length scale for a given problem. For example, if we consider a finite rod, a natural choice for the length unit will be the length of the rod. In Sec. III, we choose the length unit $[L]$ such that the norm of $\mathbf{F}$ has a given value.

The fact that the length unit $[L]$ is undetermined has yet another implication. Considering the static system (14) or (19), we see that every known solution actually determines a one-parameter family of solutions. More precisely, if $\{\mathbf{F}(s),\mathbf{M}(s),\boldsymbol{\kappa}(s)\}$ is a solution of the system, then $\{\lambda^{-2}\mathbf{F}(\lambda s),\lambda^{-1}\mathbf{M}(\lambda s),\lambda^{-1}\boldsymbol{\kappa}(\lambda s)\}$ is another solution of the system for every real nonvanishing λ. That is, the system is scale-invariant. Furthermore, if such a transformation is performed on the solution together with a rescaling of the length unit $[L]$ by a factor λ^{-1}, the solution remains unchanged, although the rod thickness is modified by a factor λ^{-1}. Hence, the statics of a filament, in the limit of the Kirchhoff model, does not depend on the rod thickness.

3. Integrability of the static Kirchhoff equations

The static Kirchhoff equations (19) are formally identical to the Euler equations describing the motion of a rigid body with a fixed point under gravity, in the particular case where the axis joining the fixed point to the center of mass lies along a principal direction of inertia. (The correspondence between rigid body variables and rod variables is shown on Table I). Therefore, they are fully integrable in two cases of interest, namely, the Lagrange and Kowalevskaya cases. Actually, the Euler equations are integrable in three cases. The third one corresponds to the motion of a rigid body with arbitrary shape in free fall and is known as the Euler case. However, one cannot speak of full integrability in the context of filaments since this case corresponds to a vanishing tension vector $\mathbf{F}$ and represents only particular boundary conditions, hence a subset of all possible configurations which can be adopted by a filament for given values of the material parameters a and b.

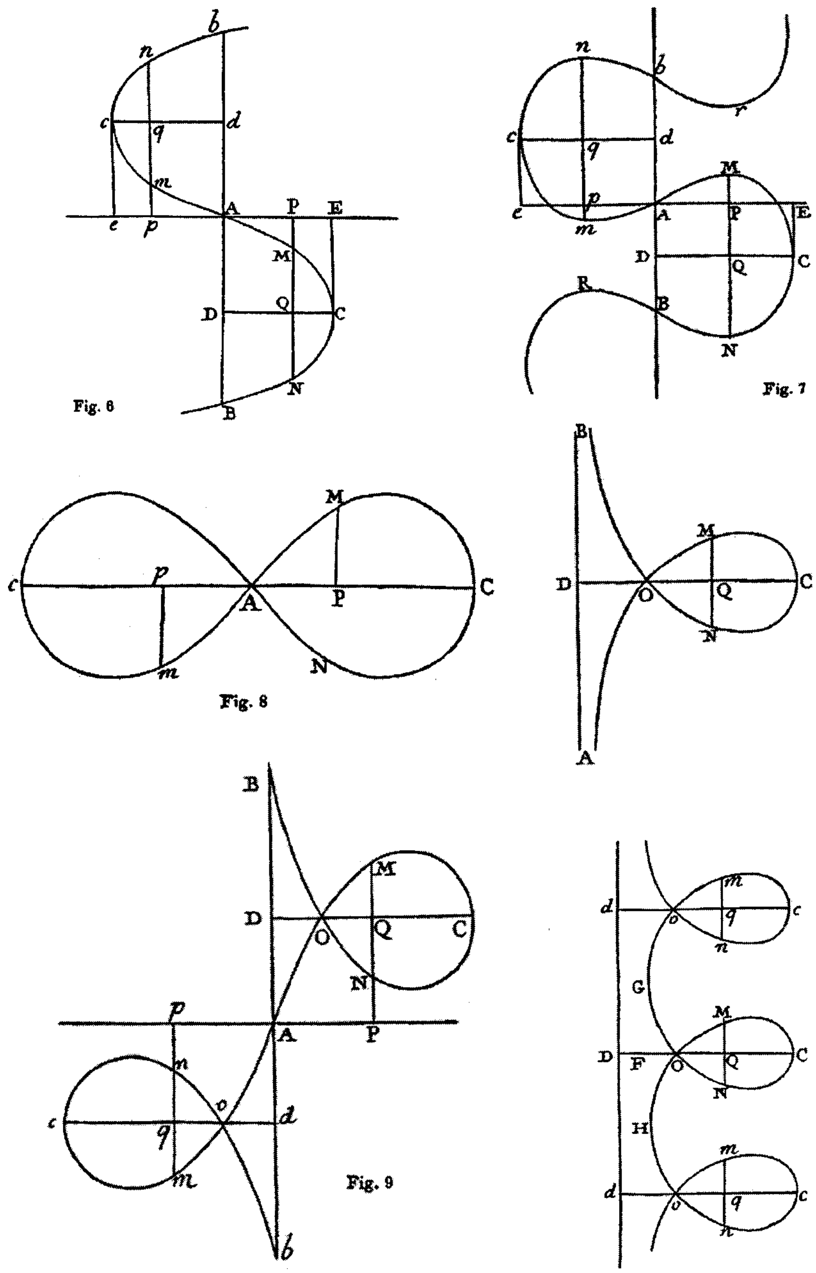

FIG. 1. Euler's drawings of planar filaments.

In the Lagrange case, the rigid body has identical moments of inertia along every direction perpendicular to the axis joining the fixed point to the center of mass, as for a symmetric top. The corresponding rods have identical bending stiffnesses in every direction, so that $a=1$. This is realized, for instance, in the very common situation where the filament cross section is circular, showing the importance of the Lagrange case for filaments. Much work has been devoted to it (Euler classified the planar solutions of the equations, see Fig. 1), and recently, Shi and Hearst (1994) (Ref. 34) have obtained a closed form for the general solution. Their results are rederived with special emphasis on the correspondence between rod and rigid body variables and developed in detail in Sec. III.

In the Kowalevskaya case, there exists an axis D, originating from the fixed point, along which the moment of inertia is half as large as the moments of inertia along directions perpendicular to D. In addition, the center of mass lies in the plane perpendicular to D. In the context of rods, this corresponds to asymmetric cross sections with $a=\frac{1}{2}$ and $b=1$. However, it turns out that the Kowalevskaya case, having a very high torsional stiffness, lies far beyond the region covered by the possible physical values of the parameters. For instance, an elliptic cross section with $a=\frac{1}{2}$ and $b=1$ would have a Poisson ratio $\sigma=-\frac{1}{3}$. This value describes a material which inflates transversally as it is stretched in length, and although this is not precluded in theory, it is not realized in practice.

III. SYMMETRIC RODS AND LAGRANGE TOPS

A. Generalities

The static Kirchhoff equations, written in terms of an appropriate set of variables, are formally equivalent to the Euler equations describing the dynamics of a heavy top. To every possible motion of the top, one can associate a particular static solution of the Kirchhoff equations. Here we focus exclusively on the analogy between tops and static rods, in one of the three cases where the equations are fully integrable; the Lagrange case, where the top has two identical principal moments of inertia. This condition is satisfied if it has a symmetry of revolution. The corresponding filament has identical bending stiffnesses in all directions, that is, we must set $a=1$ in the scaled form of the Kirchhoff equations (19).

The solutions of the Euler equations in the Lagrange case are well known and can be written as combinations of elliptic functions.[36–38] In order to obtain the centerline $\mathbf{R}$ of the corresponding static filament, we must identify the tangent vector $\mathbf{d}_3$ to a unit vector lying along the axis of revolution of the top. The centerline is then obtained by integrating $\mathbf{d}_3$ over the arc length s which, in the context of tops, corresponds to time. An obvious difficulty arises: in order to describe the behavior of real filaments under given external constraints, the space curve $\mathbf{R}$ must be available in a form that allows for boundary conditions at two distinct points. That is, it is essential to explicitly carry the integration of the tangent vector. Although it is not obvious that this integration can be performed, Shi and Hearst (1994) (Ref. 34) recently obtained expressions for the centerline $\mathbf{R}$ in cylindric coordinates in a closed analytic form involving elliptic functions. Despite this achievement, the problem is still partially unsolved. Indeed, explicit forms of the solutions are by no means sufficient to get a global insight on the large variety of possible filament shapes. Furthermore, the detailed analysis of the correspondence between spinning Lagrange tops and static symmetric rods provides a way of establishing an exhaustive geometric classification of the solutions. The aim of this paper is to provide a first step towards such a classification.

Shi and Hearst obtained their solutions by first solving the Kirchhoff equations for the curvature and torsion and then solving the Frenet–Serret equations to obtain the centerline. The resulting expressions depend on integration constants which do not have a clear meaning. Here, we depart from their approach and work consistently with variables and integration constants relevant to the top. Namely, in Sec. III C, we express the Kirchhoff–Euler equations in terms of the Euler angles. Then we compute the centerline $\mathbf{R}$ of the filament as a function of the constants of the motion for the spinning top. Once the expressions for the centerline have been obtained, we study various classes of shapes of the rod and their correspondence with the motion of the top. This analysis can be thought of an extension of Euler's work, who classified planar shapes of filaments.

In this section, we show illustrations of the spinning top orbits together with the corresponding filament shapes. A top orbit is displayed as a curve on the unit sphere which represents the extremity of the unit vector $\mathbf{d}_3$. The filament shapes are represented with a circular cross section, hence b must be set to a value lying between $\frac{2}{3}$ and 1. We have chosen $b=\frac{3}{4}$. The radius of the cross section and the zoom factor vary from one figure to another and are chosen for clarity (as seen in Sec. II, the radius is arbitrary in the static case).

In the remaining of this section, we write down the static Kirchhoff equations (19) in the case $a=1$, and identify a set of three first integrals necessary to guarantee the integrability of the system. With $a=1$, the system (19) reads

$$\mathbf{F}'=\mathbf{0}, \tag{20a}$$

$$\mathbf{M}'+\mathbf{d}_3\times\mathbf{F}=\mathbf{0}, \tag{20b}$$

$$\mathbf{M}=\kappa_1\mathbf{d}_1+\kappa_2\mathbf{d}_2+b\kappa_3\mathbf{d}_3. \tag{20c}$$

The first equation expresses the fact that the tension $\mathbf{F}$ is constant. We choose it oriented along the third vector of the fixed basis,

$$\mathbf{F}=F\mathbf{e}_Z. \tag{21}$$

In terms of spinning tops, the tension corresponds to the opposite of the top weight, $-m\mathbf{g}$, which describes an external force field. In the same spirit, we consider the tension as having a fixed value. As a consequence, we consider F as a parameter rather than a first integral. Inserting (21) into (20b) and projecting along the fixed basis vector $\mathbf{e}_Z$, we have

$$\mathbf{M}'\cdot\mathbf{e}_Z=0. \tag{22}$$

The basis vector $\mathbf{e}_Z$ being independent of s, we can extend the derivative in (22) to take effect over the whole left-hand side, leading to

$$M_Z'=0, \tag{23}$$

where M_Z denotes the component of the moment along $\mathbf{e}_Z$. It is a first integral that represents the vertical component of the angular momentum of a spinning top. By projecting (20b) along $\mathbf{d}_3$, we obtain

$$\mathbf{M}'\cdot\mathbf{d}_3=(\mathbf{M}\cdot\mathbf{d}_3)'-\mathbf{M}\cdot\mathbf{d}_3'=0. \tag{24}$$

Using the fact that $\mathbf{d}_3'=\boldsymbol{\kappa}\times\mathbf{d}_3=\mathbf{M}\times\mathbf{d}_3$, we see that the second term of (24) vanishes identically, leading to

$$M_3'=0. \tag{25}$$

That is, the torsional moment M_3 is another first integral. From (20c), we see that it corresponds to a constant twist density. For the spinning top, M_3 represents the component of the angular momentum along the axis of revolution of the top.

Finally, taking the dot product of both sides of (20b) with $\boldsymbol{\kappa}$, we have

$$\mathbf{M}'\cdot\boldsymbol{\kappa}+(\mathbf{d}_3\times\mathbf{F})\cdot\boldsymbol{\kappa}=\mathbf{M}'\cdot\boldsymbol{\kappa}+\mathbf{F}\cdot(\boldsymbol{\kappa}\times\mathbf{d}_3)=\mathbf{0}. \tag{26}$$

Using (20c) and the expressions (6a) of the derivatives of the local basis $(\mathbf{d}_1,\mathbf{d}_2,\mathbf{d}_3)$ in terms of $\boldsymbol{\kappa}$, (26) reduces to

$$\kappa_1\kappa_1'+\kappa_2\kappa_2'+\mathbf{F}\cdot\mathbf{d}_3'=(\tfrac{1}{2}\mathbf{M}\cdot\boldsymbol{\kappa}+\mathbf{F}\cdot\mathbf{d}_3)'=0, \tag{27}$$

which provides the last first integral,

$$\tfrac{1}{2}\mathbf{M}\cdot\boldsymbol{\kappa}+\mathbf{F}\cdot\mathbf{d}_3=H. \tag{28}$$

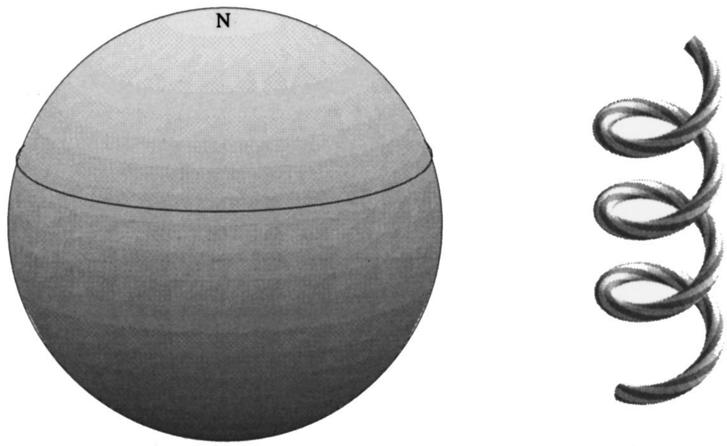

FIG. 2. An overtwisted helix ($\kappa=3$, $\tau=1$, $\kappa_3=6$).

This constant quantity H is the total elastic-plus-strain energy density of the filament and corresponds to the total kinetic-plus-potential mechanical energy of the spinning top. We now proceed to analyze different solutions of the system (20).

B. Helical filaments

1. The general helical solution

Helical solutions have constant Frenet curvature κ and torsion τ. Taking into account the fact that the twist density κ_3 is also constant, we introduce the following definitions:

(a) A Frenet helix is a helix with pure torsion, that is, $\kappa_3=\tau$.
(b) An overtwisted helix is a helix such that $(\kappa_3-\tau)$ has the same sign as τ.
(c) An undertwisted helix is a helix such that $(\kappa_3-\tau)$ and τ have opposite signs.

These three types of helices are represented in Figs. 2, 3, and 4, respectively. The undertwisted and overtwisted helices can be distinguished by the relation between the handedness of the helix itself and the handedness of the apparent twist pattern on the helix. In the case of an overtwisted helix, both hands are identical, whereas an undertwisted helix has opposite hands.

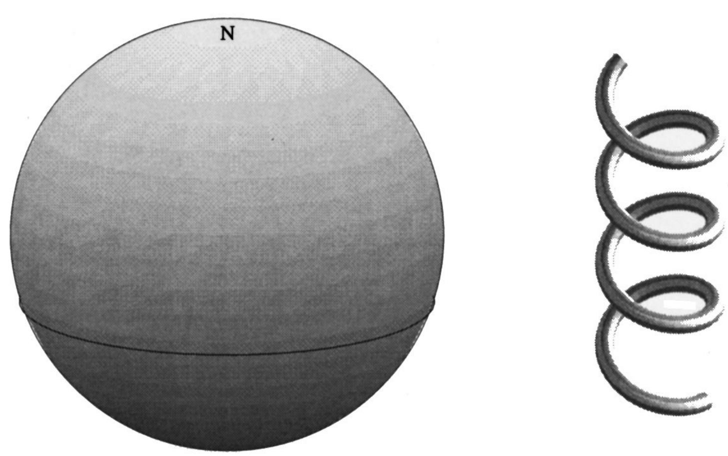

FIG. 3. A Frenet helix ($\kappa=3$, $\tau=-1$, $\kappa_3=-1$).

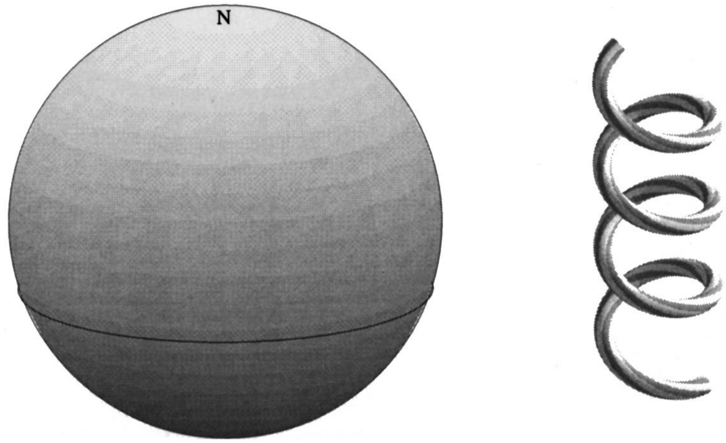

FIG. 4. An undertwisted helix ($\kappa=3$, $\tau=-1$, $\kappa_3=4$).

It is convenient to treat the cases of helical, circular (ring-like) and straight solutions of the Kirchhoff equations independently. The rings and the helical rods are easily identified as corresponding to spinning tops with the extremity describing a circle (centered at the fixed point in the case of rings), while the straight solutions correspond to the cases where the extremity of the top is at rest (the so-called sleeping tops); pointing upwards in the case of positive tension F_3 and downwards in the case of negative tension. Illustrations of these top orbits are given in Figs. 2–7. For the sake of simplicity, helical, circular, and straight filaments will be referred to as helical filaments.

We do not introduce Euler angles for the helical solutions. Instead, we introduce a fixed Frenet curvature κ and a fixed torsion τ into the expressions for the twist vector,

$$\kappa_1=\kappa \sin[(\kappa_3-\tau)(s-s_0)], \tag{29a}$$

$$\kappa_2=\kappa \cos[(k_3-\tau)(s-s_0)]. \tag{29b}$$

Substituting this into (20), we obtain one single nontrivial vector condition,

$$\mathbf{F}=(b\kappa_3-\tau)[\boldsymbol{\kappa}-(\kappa_3-\tau)\mathbf{d}_3], \tag{30}$$

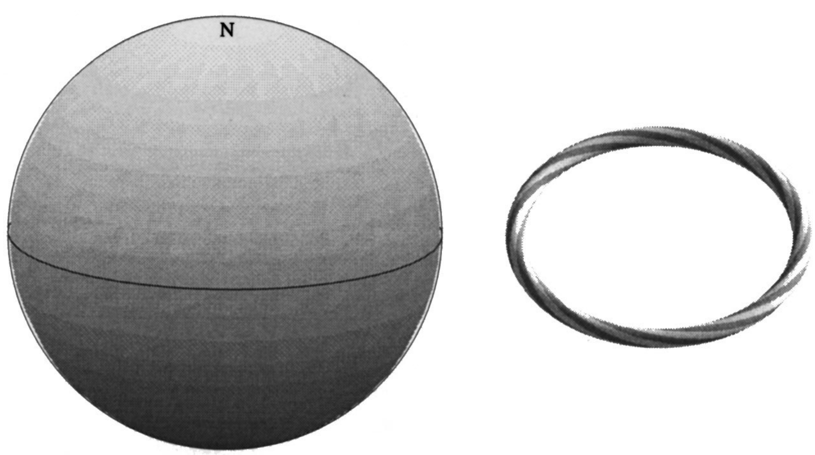

FIG. 5. A twisted ring ($\kappa=1$, $\tau=0$, $\kappa_3=3$).

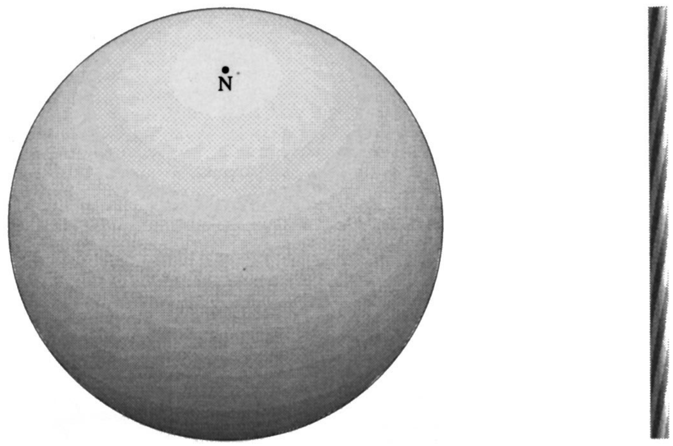

FIG. 6. A straight rod subject to extensive tension ($\kappa=0$, $\kappa_3=1$, $F_3=1$).

which simply gives the tension in the local basis as a constant combination of the other quantities. Hence, there exist helical solutions with arbitrary curvature κ, torsion τ, and twist density κ_3. This is unique to the case of symmetric rods. Indeed, in the regular case $a\neq 1$ the only possible helices are Frenet helices with either $\kappa_1=0$ or $\kappa_2=0$.[39]

Three more facts can be noticed from (30). First, in the case of rings ($\tau=0$), the tension has no longitudinal component ($\mathbf{F}\cdot\mathbf{d}_3=0$). Second, in the case of a noncircular filament ($\tau\neq 0$), a vanishing longitudinal tension implies $b\kappa_3=\tau$, hence the tension vector $\mathbf{F}$ itself vanishes. Finally, in the case of circular cross section, one has $b\leqslant 1$. This means that the Frenet helices ($\kappa_3=\tau$) have a negative longitudinal tension, and that the helices with null tension are overtwisted.

For straight solutions ($\kappa=0$), (30) does not hold and is replaced by

$$\mathbf{F}=F_3\mathbf{d}_3, \tag{31}$$

where F_3 is constant and arbitrary. Hence, there exist straight solutions with arbitrary longitudinal tension and twist density. The torsion has no meaning for straight rods. Figures 2–7 show representations of helical, ringlike, and straight solutions.

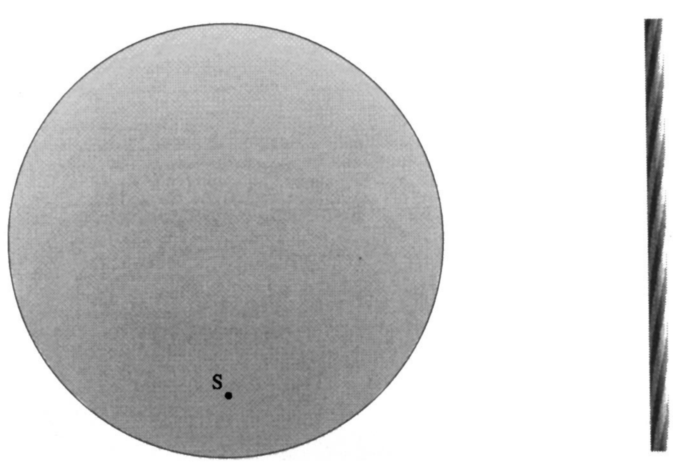

FIG. 7. A straight rod subject to compressive tension ($\kappa=0$, $\kappa_3=1$, $F_3=-1$).

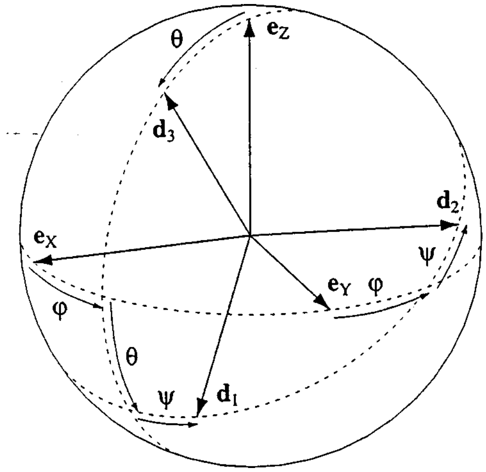

FIG. 8. The Euler angles.

2. The general solution with null tension

Substituting $\mathbf{F}=\mathbf{0}$ into (20b), we see that the moment $\mathbf{M}$ is constant. Differentiating (20c) with respect to s and projecting the resulting equation successively along $\mathbf{d}_1$, $\mathbf{d}_2$, and $\mathbf{d}_3$, we obtain

$$\kappa_1' + (b-1)\kappa_3\kappa_2 = 0, \tag{32a}$$

$$\kappa_2' + (1-b)\kappa_3\kappa_1 = 0, \tag{32b}$$

$$0 = 0, \tag{32c}$$

which, taking into account the fact that κ_3 is constant, can be integrated,

$$\kappa_1 = \kappa \sin[(1-b)\kappa_3(s-s_0)], \tag{33a}$$

$$\kappa_2 = \kappa \cos[(1-b)\kappa_3(s-s_0)], \tag{33b}$$

where κ and s_0 are integration constants. We see that (33) assumes the form (29), with $\tau = b\kappa_3$. In other words, (33) is a helix.

We conclude that all the solutions with vanishing tension are helices. In the following sections, we consider nonhelical filaments. Therefore, from now on, we assume $\mathbf{F}\neq\mathbf{0}$. This gives a precise sense to the vertical unit vector $\mathbf{e}_Z$.

C. General solution for the local basis

1. Equations for the Euler angles

We now introduce the Euler angles (φ,θ,ψ) for the local basis $(\mathbf{d}_1,\mathbf{d}_2,\mathbf{d}_3)$. The angles φ, θ, and ψ denote, respectively, the precession, nutation, and self-rotation angles (see Fig. 8). In matrix form, the local basis is obtained from the fixed trihedron $(\mathbf{e}_X,\mathbf{e}_Y,\mathbf{e}_Z)$ as follows:

$$(\mathbf{d}_1\mathbf{d}_2\mathbf{d}_3) = (\mathbf{e}_X\mathbf{e}_Y\mathbf{e}_Z)\mathbf{E}, \tag{34}$$

where the general rotation matrix $\mathbf{E}$ reads

$$\mathbf{E} = \begin{pmatrix} \cos\varphi\cos\theta\cos\psi - \sin\varphi\sin\psi & -\cos\varphi\cos\theta\sin\psi - \sin\varphi\cos\psi & \cos\varphi\sin\theta \\ \sin\varphi\cos\theta\cos\psi + \cos\varphi\sin\psi & -\sin\varphi\cos\theta\sin\psi + \cos\varphi\cos\psi & \sin\varphi\sin\theta \\ -\sin\theta\cos\psi & \sin\theta\sin\psi & \cos\theta \end{pmatrix}. \tag{35}$$

From (34) and (35) we extract the fixed vector $\mathbf{e}_Z$ as a function of the local basis,

$$\mathbf{e}_Z = \sin\theta(\sin\psi\mathbf{d}_2 - \cos\psi\mathbf{d}_1) + \cos\theta\mathbf{d}_3. \tag{36}$$

We now express the twist matrix **K** in terms of the rotation matrix **E**. Differentiating (34) yields

$$\frac{\partial}{\partial s}(\mathbf{d}_1\mathbf{d}_2\mathbf{d}_3) = (\mathbf{e}_X\mathbf{e}_Y\mathbf{e}_Z)\frac{\partial}{\partial s}\mathbf{E} = (\mathbf{d}_1\mathbf{d}_2\mathbf{d}_3)\mathbf{E}^{\mathsf{T}}\mathbf{E}', \tag{37}$$

hence, from the definition (7) of the twist matrix, we see that

$$\mathbf{K} = \mathbf{E}^{\mathsf{T}}\mathbf{E}'. \tag{38}$$

Therefore, we can express the twist vector in terms of Euler angles,

$$\kappa_1 = \theta'\sin\psi - \varphi'\sin\theta\cos\psi, \tag{39a}$$

$$\kappa_2 = \theta'\cos\psi + \varphi'\sin\theta\sin\psi, \tag{39b}$$

$$\kappa_3 = \varphi'\cos\theta + \psi'. \tag{39c}$$

Using (36) and (39), we now write the three first integrals in terms of the Euler angles,

$$M_Z = \varphi'[1 + (b-1)\cos^2\theta] + b\psi'\cos\theta, \tag{40a}$$

$$M_3 = b(\varphi'\cos\theta + \psi'), \tag{40b}$$

$$H = \frac{1}{2}\left(\theta'^2 + \varphi'^2\sin^2\theta + \frac{M_3^2}{b}\right) + F\cos\theta. \tag{40c}$$

It is convenient to introduce the following auxiliary constants:

$$h = \frac{1}{F}\left(H - \frac{M_3^2}{2b}\right), \tag{41a}$$

$$\tilde{h} = \frac{1}{F}\left(H - \frac{M_3^2}{2b} + \frac{M_3^2 - M_Z^2}{2}\right), \tag{41b}$$

which are well defined since $\mathbf{F} \neq \mathbf{0}$. We also carry out the following change of variables in Eqs. (40a)–(40c),

$$z = \cos\theta. \tag{42}$$

Note that a solution with constant z corresponds to a helical rod excluded in this discussion, hence z is not constant. We can solve (40a) to (40c) for φ', θ', and z' to obtain the final form of our equations in the Euler angles,

$$\varphi' = \frac{M_Z - M_3 z}{1 - z^2}, \tag{43a}$$

$$\psi' = \left(\frac{1}{b} - 1\right)M_3 + \frac{M_3 - M_Z z}{1 - z^2}, \tag{43b}$$

$$z'^2 = 2F(h - z)(1 - z^2) - (M_Z - M_3 z)^2 \tag{44a}$$

$$\Leftrightarrow z'^2 = 2F(\tilde{h} - z)(1 - z^2) - (M_3 - M_Z z)^2. \tag{44b}$$

2. A better choice of first integrals

The differential Eq. (44a) or (44b) is an identity between z'^2 and a cubic polynomial in z. In order to solve this equation, we must know the roots z_1, z_2, z_3 of this polynomial. Rather than computing the roots in terms of the constants M_Z, M_3, h or $\tilde{h}$, the classical approach consists in considering the roots z_1, z_2, and z_3 as three independent first integrals, and then expressing the constants M_Z, M_3, h, and $\tilde{h}$ as functions of z_1, z_2, and z_3. This is achieved by rewriting the cubic polynomial in (44a) and (44b) as a product of three factors involving z_1, z_2, and z_3,

$$z'^2 = 2F(h - z)(1 - z^2) - (M_Z - M_3 z)^2 \tag{45a}$$

$$= 2F(\tilde{h} - z)(1 - z^2) - (M_3 - M_Z z)^2 \tag{45b}$$

$$= 2F(z - z_1)(z_2 - z)(z_3 - z). \tag{45c}$$

By setting $z = \pm 1$ in (45a) or (45b), the right-hand side assumes a nonpositive value. Furthermore, if we choose F to be positive (which we can always do by defining adequately the vertical unit vector $\mathbf{e}_Z$), we see that the right-hand side of (45a) or (45b) tends to $+\infty$ as $z \to +\infty$. This means that one of the roots (conventionally, z_3) lies in the interval $[1, +\infty[$. Finally, in order to obtain solutions with real values of θ, we require that z'^2 be positive for z ranging in some interval contained in $[-1,1]$. Hence the other two roots of the polynomial must be real and lie between -1 and 1. Conventionally, we choose $z_1 \leqslant z_2$. We conclude that the physical values of our independent constants z_1, z_2 and z_3 must satisfy

$$-1 \leqslant z_1 \leqslant z_2 \leqslant 1 \leqslant z_3. \tag{46}$$

In the previous section, we showed that in order to obtain the scaled form of the Kirchhoff equations in the static case, it was not necessary to perform a complete scaling. Namely, at this level, every variable involved in the equations is a length raised to a given power, and we still have the freedom to choose an arbitrary length unit $[L]$. In the following, it is convenient to choose the length unit to be

$$[L] = \sqrt{\frac{2}{F(z_3 - z_1)}}, \tag{47}$$

which is equivalent to the substitution,

$$F = \frac{2}{z_3 - z_1}. \tag{48}$$

The right-hand side of (48) is well-defined as long as $z_1 \neq z_3$. The condition $z_1 = z_3$ implies $z_1 = z_2 = z_3 = 1$, which corresponds to a straight rod with $z = 1$, a case excluded from this discussion.

Expressions for the constants M_Z, M_3, h, and $\tilde{h}$ in terms of the roots can be obtained by identifying the coefficients of the powers of z in (45a)–(45c), or equivalently, by considering the equalities between the right-hand sides of (45a)–(45c) for three well-chosen values of z. Setting $z = \pm 1$ leads, together with (48), to

$$-(M_Z \mp M_3)^2 = \frac{4}{z_3 - z_1}(\pm 1 - z_1)(z_2 \mp 1)(z_3 \mp 1). \tag{49}$$

Equation (49) gives $M_Z - M_3$ and $M_Z + M_3$ up to sign determination. A third equality of type (45) corresponding to another value of z would lead to an equation involving h or $\tilde{h}$ and could not provide additional knowledge on M_Z or M_3 by themselves. We conclude that given values of z_1, z_2, and z_3 do not yield unique values of M_Z and M_3. Instead they give these two constants with a complete sign indetermination. By performing a mirror reflection in space, we can map any filament with $M_Z+M_3<0$ onto a filament with $M_Z+M_3>0$. Hence, we restrict our analysis to the case $M_Z+M_3\geqslant 0$. Nevertheless, we still have to supply the values of z_1, z_2, and z_3 with extra information, namely, the sign S of M_Z-M_3,

$$S=+ \quad \text{or} \quad S=-. \tag{50}$$

Now, if we set

$$M_+=\frac{M_Z+M_3}{2}\geqslant 0, \tag{51a}$$

$$M_-=\frac{|M_Z-M_3|}{2}, \tag{51b}$$

we have

$$M_Z=M_+ + SM_-, \tag{52a}$$

$$M_3=M_+ - SM_-, \tag{52b}$$

with

$$M_\pm=\sqrt{\frac{(1\pm z_1)(1\pm z_2)(z_3\pm 1)}{z_3-z_1}}. \tag{53}$$

The constants h and $\tilde{h}$ in (44a) and (44b) are obtained from suitable combinations of equalities between the coefficients of z in (45a)–(45c),

$$h=\tfrac{1}{2}[z_1+z_2+z_3-z_1z_2z_3+S(z_3-z_1)M_+M_-], \tag{54a}$$

$$\tilde{h}=\tfrac{1}{2}[z_1+z_2+z_3-z_1z_2z_3-S(z_3-z_1)M_+M_-]. \tag{54b}$$

3. General solution for the Euler angles

The solutions of Eqs. (43a)–(44) involve elliptic functions (see Appendix). With a suitable origin for the arc length s, the solution of Eq. (44) assumes the form,

$$z=z_1+(z_2-z_1)\operatorname{sn}^2(s|k), \tag{55}$$

where the modulus k ranges between 0 and 1 and is given by

$$k^2=\frac{z_2-z_1}{z_3-z_1}. \tag{56}$$

We can use the fact that $z=\cos\theta$ to obtain θ as a function of s. In the generic case where $z_1\neq -1$ and $z_2\neq 1$, the cosine never reaches its extreme values ± 1, and there is a bijective correspondence between z and θ. In this case, we can take $\theta=\arccos z$. In the degenerate cases where $z_1=-1$ or $z_2=1$, we must take care of the behavior of θ as $\cos\theta$ reaches its limiting values. This is achieved by substituting $z=\cos\theta$ in (44) and examining the behavior of θ' around $z=-1$ or $z=1$. The results are as follows:

(a) If $z_1=-1$ and $z_2\neq 1$, θ' has a nonvanishing limit as $z\to -1$, hence the sign of $\theta-\pi$ changes at $z=-1$.

(b) If $z_1 \neq -1$, $z_2 = 1$, and $z_3 \neq 1$, θ' has a nonvanishing limit as $z \to 1$, hence the sign of θ changes at $z = 1$.

(c) If $z_1 \neq -1$, $z_2 = 1$, and $z_3 = 1$, z never reaches its extreme value 1, hence we can take $\theta = \arccos z$.

(d) If $z_1 = -1$, $z_2 = 1$, and $z_3 \neq 1$, θ' has a nonvanishing limit in both cases $z \to \pm 1$, hence θ is a monotonous function of s. In this case, $M_Z = M_3 = 0$, that is, the top behaves like a plane pendulum. This corresponds to planar rods studied by Euler.

(e) If $z_1 = -1$, $z_2 = 1$, and $z_3 = 1$, θ' has a nonvanishing limit as $z \to -1$ and z never reaches its extreme value 1, hence z assumes the value -1 only at the single point $s = 0$, and θ covers the interval $]0,2\pi[$ crossing every value only once. This corresponds to the homoclinic orbit of the plane pendulum.

In order to obtain φ and ψ as functions of s, we must integrate (43a) and (43b), which, using (52a) and (52b), can be rewritten as

$$\varphi' = M_+ \frac{1}{1+z} + S M_- \frac{1}{1-z}, \tag{57a}$$

$$\psi' = \left(\frac{1}{b} - 1\right) M_3 + M_+ \frac{1}{1+z} - S M_- \frac{1}{1-z}. \tag{57b}$$

Next, we define

$$n_\pm = \mp \frac{z_2 - z_1}{1 \pm z_1}. \tag{58}$$

In the cases where $n_\pm$ have a nonvanishing denominator, we can express (57a) and (57b) using (55) as

$$\varphi' = \frac{M_+}{1+z_1} \frac{1}{1 - n_+ \mathrm{sn}^2(s|k)} + S \frac{M_-}{1-z_1} \frac{1}{1 - n_- \mathrm{sn}^2(s|k)}, \tag{59a}$$

$$\psi' = \left(\frac{1}{b} - 1\right) M_3 + \frac{M_+}{1+z_1} \frac{1}{1 - n_+ \mathrm{sn}^2(s|k)} - S \frac{M_-}{1-z_1} \frac{1}{1 - n_- \mathrm{sn}^2(s|k)}. \tag{59b}$$

Notice that we have the freedom to perform global rotations of the local basis around $\mathbf{d}_3$ and of the fixed trihedron around $\mathbf{e}_Z$, in such a way that $\varphi = 0$ and $\psi = 0$ for $s = 0$. Equations (59a) and (59b) can be integrated to yield

$$\varphi = \frac{M_+}{1+z_1} \Pi(s|n_+, k) + S \frac{M_-}{1-z_1} \Pi(s|n_-, k), \tag{60a}$$

$$\psi = \left(\frac{1}{b} - 1\right) M_3 s + \frac{M_+}{1+z_1} \Pi(s|n_+, k) - S \frac{M_-}{1-z_1} \Pi(s|n_-, k), \tag{60b}$$

where Π is the incomplete elliptic integral of the third kind in ''practical'' form, as defined in the Appendix.

In the degenerate cases where n_+ or n_- has a vanishing denominator, the correct limits of (60a) and (60b) are obtained by setting the term involving the ill-defined quantity to zero.

Expressions (60a) and (60b) together with (55) constitute the general solution of the spinning symmetric top problem. We can then use (34) to obtain the nonfixed basis $(\mathbf{d}_1, \mathbf{d}_2, \mathbf{d}_3)$ as a function of the Euler angles.

4. Particular orbits of the spinning top

The generic orbits of the spinning top are those for which the extremity of $\mathbf{d}_3$ oscillates vertically between two parallels on the unit sphere, while it revolves horizontally, either monotonously as in Figs. 21, 20, 22, and 23, or making loops as in Figs. 16 and 24. The looping orbits arise if $S=-$ and $z_3>(1-z_1z_2)/(z_2-z_1)$. This condition is obtained by allowing φ' to vanish for some value of z.

The degenerate case $S=-$, $z_3=(1-z_1z_2)/(z_2-z_1)$ separates looping orbits from monotonously precessing orbits. This corresponds to trajectories which present turnback points, as shown in Fig. 19. We shall see in the following section that the condition $z_3=(1-z_1z_2)/(z_2-z_1)$ has a clear meaning in terms of rods for both values of S.

The case $z_1=-1$ with $z_2\neq 1$ and $z_3\neq 1$ corresponds to orbits which cross periodically the south pole of the unit sphere, as shown in Fig. 18, while the case $z_2=1$ with $z_1\neq -1$ and $z_3\neq 1$ corresponds to orbits which cross the north pole, as shown in Fig. 17.

The case $z_2=z_3=1$ with arbitrary z_1 represents homoclinic orbits such as those shown in Figs. 13–15.

Next, there are the orbits for which $M_Z=M_3=0$, that is, for which the top behaves like a plane pendulum (the extremity of $\mathbf{d}_3$ is restricted to a vertical grand circle on the unit sphere). They correspond to $z_1=-1$ and either $z_2=1$ or $z_3=1$. The case $z_2=1$ describes an oscillating pendulum, whereas the case $z_3=1$ describes a revolving pendulum. The case $z_2=z_3=1$ corresponds to the homoclinic orbit of the pendulum.

Finally, there are orbits with constant z which we took apart from our preceding analysis, and which correspond to the helical, circular, and straight rods examined in Sec. III B (see Figs. 2–7).

D. Centerline in cylindrical coordinates, curvature, and torsion

1. Polar coordinates, complex curvature, and complex centerline radius

Following Shi and Hearst (1994), we introduce cylindrical coordinates R,Φ,Z for the filament centerline $\mathbf{R}$,

$$\mathbf{R}=R\cos\Phi\,\mathbf{e}_X+R\sin\Phi\,\mathbf{e}_Y+Z\mathbf{e}_Z. \tag{61}$$

Rather than adopting the method of Shi and Hearst to obtain R, Φ, and Z as functions of the arc length, we lead the calculations in a way which highlights the remarkable correspondence between the expressions for the radius R and the Frenet curvature κ, as well as between the polar angle Φ and the angle $\zeta=\int ds(\kappa_3-\tau)$ giving the orientation of the local basis $(\mathbf{d}_1,\mathbf{d}_2,\mathbf{d}_3)$ with respect to the Frenet triad $(\mathbf{n},\mathbf{b},\mathbf{d}_3)$. The computations are quite analogous and can be led in parallel.

First, we introduce the complex centerline radius $\hat{R}$, the complex curvature $\hat{\kappa}$ and the complex horizontal component of the moment $\hat{M}$,

$$\hat{R}=R\exp i\Phi, \tag{62a}$$

$$\hat{\kappa}=\kappa_1+i\kappa_2, \tag{62b}$$

$$\hat{M}=M_X+iM_Y, \tag{62c}$$

where M_X and M_Y are the components of the moment along $\mathbf{e}_X$ and $\mathbf{e}_Y$. Using (34), (35), and (39a), $\hat{\kappa}$ and $\hat{M}$ can be expressed in Euler angles as

$$\hat{\kappa}=-\frac{M_Z-M_3z+iz'}{\pm\sqrt{1-z^2}}\exp -i\psi, \tag{63a}$$

$$\hat{M}=\frac{M_3-M_Z z-iz'}{\pm\sqrt{1-z^2}}\exp i\varphi. \tag{63b}$$

The correct sign to put in front of the root in (63a) and (63b) is the one of $\sin\theta$. The key to obtain the complex centerline $\hat{R}$ is the moment equation (20b). Taking into account the fact that $\mathbf{F}=F\mathbf{e}_Z$ is constant and that $\mathbf{R}=\int ds\,\mathbf{d}_3$, we can integrate both sides of this equation, leading to

$$\mathbf{M}+F\mathbf{R}\times\mathbf{e}_Z=M_Z\mathbf{e}_Z \tag{64}$$

for an appropriate choice of origin in the tridimensional space. Taking the dot product of (64) with $\mathbf{e}_X+i\mathbf{e}_Y$, we obtain

$$\hat{R}=\frac{-i}{F}\hat{M}=\frac{-i}{F}\,\frac{M_3-M_Z z-iz'}{\pm\sqrt{1-z^2}}\exp i\varphi. \tag{65}$$

2. Frenet curvature and centerline radius

Using (63a) and (65), the Frenet curvature κ and the radius R are

$$\kappa^2=|\hat{\kappa}|^2=\frac{(M_Z-M_3z)^2+z'^2}{1-z^2}, \tag{66a}$$

$$R^2=|\hat{R}|^2=\frac{(M_3-M_Zz)^2+z'^2}{F^2(1-z^2)}. \tag{66b}$$

We now substitute the expressions (45a) and (45b) for z'^2, respectively, in (66a) and (66b) to yield the final forms of κ and R. They depend on s only through the variable z,

$$\kappa^2=2F(h-z), \tag{67a}$$

$$R^2=\frac{2}{F}(\tilde{h}-z). \tag{67b}$$

Notice that the left-hand sides of these equations are positive for all z, hence h and $\tilde{h}$ are both greater than or equal to z_2. Also, ignoring the case of straight rods, (67a) and (67b) show that κ and R can only vanish at isolated points where $z=z_2$. A natural question is: for which values of z_1, z_2, z_3 and S do the equalities $h=z_2$ or $\tilde{h}=z_2$ hold? Using expressions (48) for F and (54a)–(54b) for h and $\tilde{h}$, one can easily obtain the following results:

$$h=z_2\Leftrightarrow S=-\quad\text{and}\quad z_3=\frac{1-z_1z_2}{z_2-z_1}, \tag{68a}$$

$$\tilde{h}=z_2\Leftrightarrow S=+\quad\text{and}\quad z_3=\frac{1-z_1z_2}{z_2-z_1}. \tag{68b}$$

Condition (68a) is necessary and sufficient for the curvature to vanish at some isolated points. Remarkably, it is identical to the condition for the orbit of the spinning top to present turnback points. In the same way, (68b) is a necessary and sufficient condition for the radius R to vanish at isolated points.

In order to have a continuous dependence in s for the polar angle Φ across these isolated points where the radius R vanishes, we must change the sign of R. In the same way, the sign of κ must change wherever κ vanishes in order for the angle ζ to be a continuous function of s.

3. Frenet torsion and polar angle of the centerline

The argument of the right-hand side of (65) can be used as an expression for the polar angle Φ. However, this is not convenient. A more tractable expression can be obtained by first computing the derivative of the polar angle from (65),

$$\Phi' = \frac{\partial}{\partial s} \arg \hat{R} = \frac{\partial}{\partial s} \arctan \frac{-z'}{M_3 - M_Z z} + \varphi'. \tag{69}$$

Similarly, the Frenet torsion τ can be computed,

$$\tau = \kappa_3 + \frac{\partial}{\partial s} \arg \hat{\kappa} = \frac{M_3}{b} + \frac{\partial}{\partial s} \arctan \frac{z'}{M_Z - M_3 z} - \psi'. \tag{70}$$

Taking the derivatives in (69) and (70) leads to expressions for Φ' and τ involving z, z'^2, z'', φ', and ψ'. Using the expressions (43a)–(44) to express everything in terms of z only, we obtain

$$\Phi' = \frac{1}{2}\left(M_Z + \frac{M_3 - M_Z \tilde{h}}{\tilde{h} - z} \right), \tag{71a}$$

$$\tau = \frac{1}{2}\left(M_3 + \frac{M_3 h - M_Z}{h - z} \right). \tag{71b}$$

In the case of a nonconstant z, we see from (71) that the condition for a constant Φ is identical to the condition for the rod to be planar ($\tau = 0$); M_Z and M_3 must both vanish. This means that noncircular planar filaments correspond to the case where the spinning top behaves like a plane pendulum ($z_1 = -1$ and either $z_2 = 1$ or $z_3 = 1$).

For nonplanar rods, we define

$$n = \frac{z_2 - z_1}{h - z_1}, \tag{72a}$$

$$\tilde{n} = \frac{z_2 - z_1}{\tilde{h} - z_1}. \tag{72b}$$

We can then integrate (71a) and (71b) to yield

$$\Phi = \frac{1}{2}\left(M_Z s + \frac{M_3 - M_Z \tilde{h}}{\tilde{h} - z_1} \Pi(s|\tilde{n},k) \right) - \frac{\pi}{2}, \tag{73a}$$

$$\zeta = \frac{M_3}{b} s - \frac{1}{2}\left(M_3 s + \frac{M_3 h - M_Z}{h - z_1} \Pi(s|n,k) \right) - \frac{\pi}{2}. \tag{73b}$$

The integration constant $-(\pi/2)$ in (73a) has been determined from the complex radius $\hat{R}$ (65) in the limit $s \to 0$. The integration constant $-(\pi/2)$ in (73b) is determined from the fact that $\mathbf{d}_1$ and the binormal $\mathbf{b}$ are opposite when $\psi = 0$.

4. Vertical cartesian coordinate of the centerline

To complete the filament description, we need an expression for Z, the vertical coordinate of the centerline. It is given by

$$Z' = z, \tag{74}$$

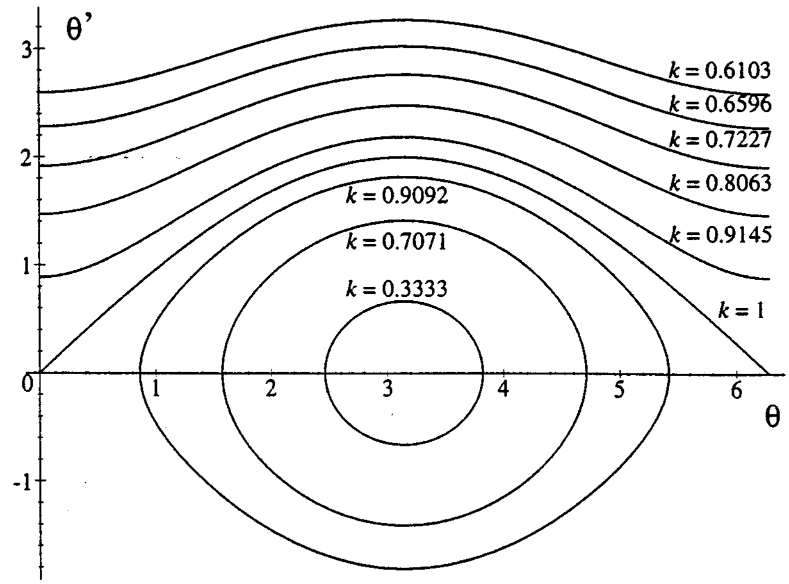

FIG. 9. Phase portrait for the plane pendulum. The closed curves represent oscillating orbits, while the open curves represent revolving orbits. The homoclinic orbit corresponds to $k=1$.

which, using (55) and (56), can be written as

$$Z'=z_3-(z_3-z_1)[1-k^2\mathrm{sn}^2(s|k)]. \tag{75}$$

The last expression is readily integrated to yield, for an appropriate choice of origin of the vertical coordinate,

$$Z=z_3s-(z_3-z_1)E(s|k), \tag{76}$$

where E is the incomplete elliptic integral of the second kind in ''practical'' form, as defined in the Appendix.

For very large z_3, Z is expressed as a difference between two large quantities, although Z itself is finite for $z_3\to\infty$. Hence, (76) could be tricky to handle numerically for large z_3.

Finally, we note that the expression for the radius R is bounded while, in general, the expression for Z is not. As a consequence, the vector $\mathbf{d}_3$, averaged over all s, has no component in the $(\mathbf{e}_X,\mathbf{e}_Y)$ plane. This means that, on average, a spinning top is vertical whatever the constants of the motion are.

E. Filament shapes

1. Planar shapes

This section is dedicated to planar filaments other than the circular and straight ones. This is essentially a modern restatement of Euler's results. As seen in the previous section, the noncircular and nonstraight planar filaments correspond to values of the constants z_1, z_2, and z_3 for which the top behaves like a plane pendulum. In this case, the sign variable S is meaningless. There are two one-parameter families of planar solutions. The first one is obtained by setting $z_1=-1$ and $z_3=1$ and keeping z_2 arbitrary; it corresponds to oscillating orbits of the pendulum. The second one is obtained by setting $z_1=-1$ and $z_2=1$ and keeping z_3 arbitrary; it corresponds to revolving orbits of the pendulum. In both cases, it is convenient to adopt the modulus k as the arbitrary parameter.

The two families of pendulum orbits are displayed on the phase portrait shown in Fig. 9. Each

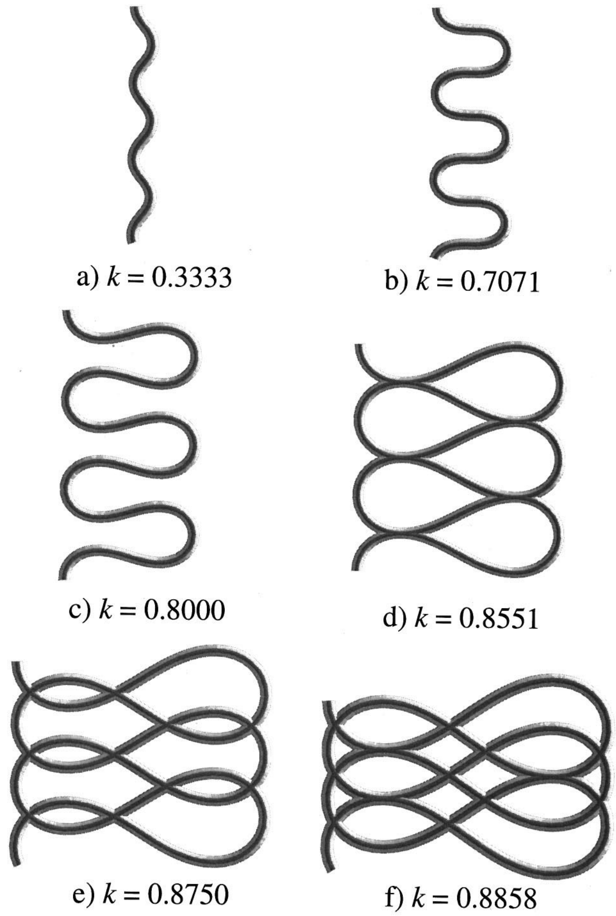

FIG. 10. Planar filaments corresponding to low amplitude oscillating orbits of the plane pendulum.

curve represents a different orbit with a given value of k in the (θ,θ') space. The closed orbits correspond to oscillating states of the pendulum, while the open orbits correspond to revolving states of the pendulum. The corresponding filament shapes are represented in Figs. 10–12. Since the scaling defined in Eq. (47) depends on k through z_3-z_1, so does the length unit for the filament, or the time unit for the pendulum. This is inadequate to draw a phase portrait, hence, in Fig. 9, we have exceptionally chosen the scaled force unit $[L]^{-2}$ to be F. This is identical to the scaling defined in (47) in the oscillating case.

We introduce the following notations for the complete elliptic integrals of the first and second kinds defined in the Appendix:

$$K=K(k), \tag{77a}$$

$$E=E(k). \tag{77b}$$

a. Oscillating orbits of the pendulum: In the case $z_3=1$, the expressions for the relevant variables *z, R,* and *Z,* reduce to

$$z=2k^2\mathrm{sn}^2(s|k)-1, \tag{78a}$$

$$R=2k\mathrm{cn}(s|k), \tag{78b}$$

$$Z=s-2E(s|k). \tag{78c}$$

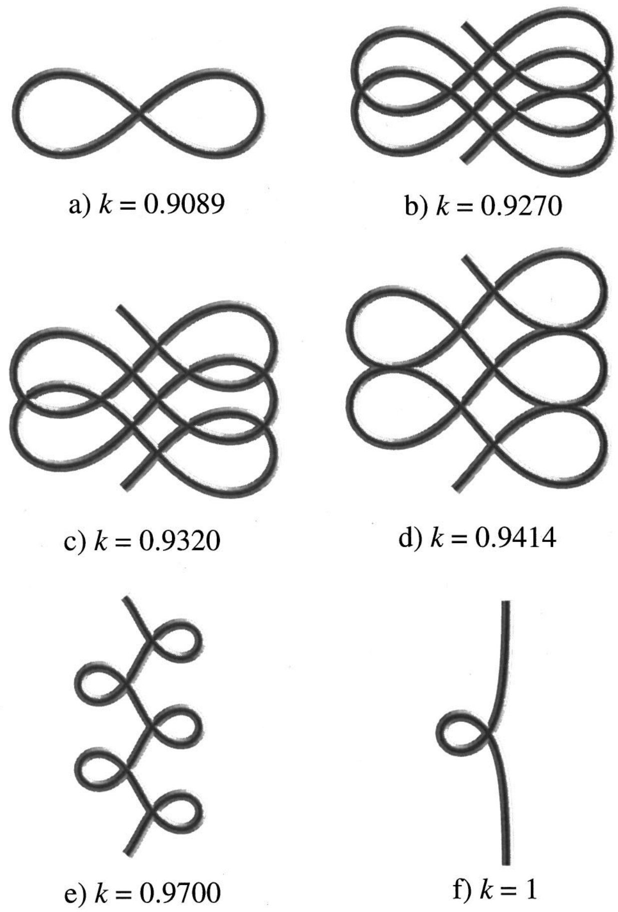

FIG. 11. Planar filaments corresponding to high amplitude oscillating orbits of the plane pendulum. The homoclinic orbit is reached in the limit $k=1$.

In the following, we define

$$f = F^A\left(\frac{1}{\sqrt{2}k}\middle| k\right), \tag{79a}$$

$$e = E^A\left(\frac{1}{\sqrt{2}k}\middle| k\right), \tag{79b}$$

where F^A and E^A are the incomplete elliptic integrals of the first and second kinds in algebraic form (see Appendix).

The extrema of Z are given by the condition $z=0$, which is satisfied for

$$\mathrm{sn}^2(s|k) = \frac{1}{2k^2} \Leftrightarrow s = \pm f + 2mK, \tag{80}$$

where m is an arbitrary integer. We see from (79a) that f is real only if $k^2 \geqslant \frac{1}{2}$. Hence, for $k^2 < \frac{1}{2}$, Z is a decreasing function of s [see Fig. 10(a)]. The limiting case $k^2 = \frac{1}{2}$ corresponds to an oscillating pendulum which has just enough energy to reach the horizontal position, as shown in Fig. 10(b). Above this critical value of k^2, Z is not monotonous, and for large enough k, the

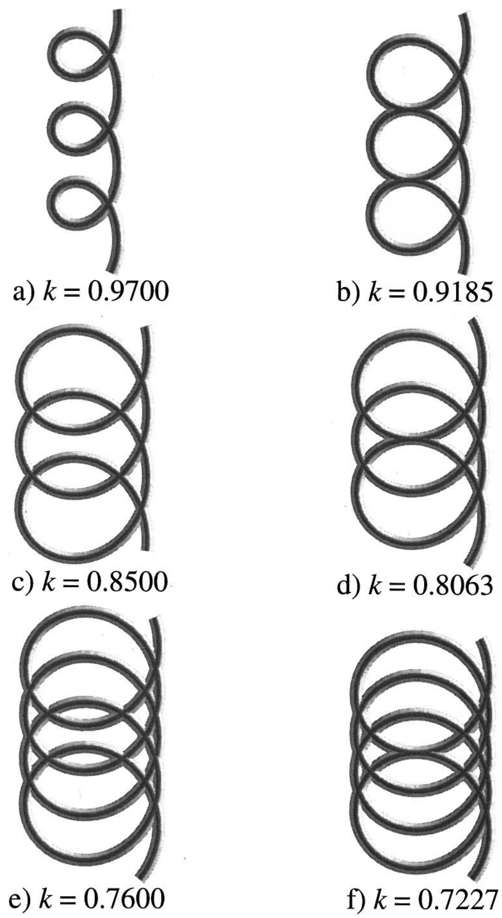

FIG. 12. Planar filaments corresponding to revolving orbits of the plane pendulum.

filaments can have points of self-tangency or self-intersection [see Figs. 10(d)–10(f)]. The cases of self-tangency are obtained by imposing the equality of Z at different points where z vanishes. This leads to the condition

$$f-2e+2m(2E-K)=0, \tag{81}$$

where m is a positive integer which denotes the number of pendulum oscillations before a self-tangency occurs. The solutions k_m of Eq. (81) for the lowest values of m are given in the first column of Table II.

Setting $m=\infty$ in Eq. (81) yields

TABLE II. Values of k corresponding to self-tangency.

$k_1=0.8551$	$k_{-1}=0.9414$	$\tilde{k}_1=0.9145$
$k_2=0.8858$	$k_{-2}=0.9270$	$\tilde{k}_2=0.8063$
$k_3=0.8942$	$k_{-3}=0.9214$	$\tilde{k}_3=0.7227$
$k_4=0.8981$	$k_{-4}=0.9185$	$\tilde{k}_4=0.6596$
$k_5=0.9004$	$k_{-5}=0.9167$	$\tilde{k}_5=0.6103$
...	...	...
$k_\infty=0.9089$	$k_{-\infty}=0.9089$	$\tilde{k}_\infty=0$

$$k_\infty = 0.9089, \tag{82}$$

for which the filament shape is the lemniscate represented in Fig. 11(a). Every value of $k < k_\infty$ corresponds to a solution Z which, on average, is a decreasing function of s, while for $k > k_\infty$, Z is, on average, an increasing function of s. The increasing solutions can also present points of intersection and self-tangency for given values of k [see Figs. 11(b)–11(e)]. The condition of self-tangency in the case $k > k_\infty$ also assumes the form (81), provided that we set m to be negative. The positive integer $-m$ counts the number of pendulum oscillations before a self-tangency occurs. The solutions k_m of Eq. (81) for the lowest values of $-m$ are given in the second column of Table II.

b. Homoclinic orbit of the pendulum: The homoclinic orbit is obtained by taking the limit $k \to 1$ in either the oscillating case or the revolving case. It is shown in Fig. 11(f). The expressions for z, R, and Z then reduce to

$$z = 1 - 2\,\mathrm{sech}^2\, s, \tag{83a}$$

$$R = 2\,\mathrm{sech}\, s, \tag{83b}$$

$$Z = s - 2\tanh s. \tag{83c}$$

c. Revolving orbits of the pendulum: In this case, we set $z_1 = -1$ and $z_2 = 1$. The expressions for θ, R, and Z read

$$\theta = \pi - 2\,\mathrm{am}(s|k), \tag{84a}$$

$$\rho = 2k^{-2}\mathrm{dn}(s|k), \tag{84b}$$

$$Z = (2k^{-2} - 1)s - 2k^{-2}E(s|k). \tag{84c}$$

Next, we define

$$\tilde{f} = F\left(\frac{1}{\sqrt{2}}\middle| k\right), \tag{85a}$$

$$\tilde{e} = E\left(\frac{1}{\sqrt{2}}\middle| k\right). \tag{85b}$$

The extrema of Z correspond to the values of s for which θ is an integer multiple of π, hence $\mathrm{am}(s|k)$ is an integer multiple of $\pi/2$, or

$$s = \pm 2\tilde{f} + 2mK, \tag{86}$$

where m is an integer. Notice that $\tilde{f}$ and $\tilde{e}$ are real for all k. As in the case of oscillating orbits, we can find a condition for the existence of points of self-tangency,

$$(2-k^2)\tilde{f} - 2\tilde{e} + m[(2-k^2)K - 2E] = 0, \tag{87}$$

where the positive integer m counts the number of pendulum revolutions before a self-tangency occurs. The solutions $\tilde{k}_m$ of Eq. (87) for the lowest values of m are given in the third column of Table II. The sequence $(\tilde{k}_m)$ has a vanishing limit for $m \to \infty$ and, in the limit $k \to 0$, the filament is a vertical ring. Some filaments corresponding to revolving orbits are shown in Fig. 12.

2. Nonplanar localizing solutions

The homoclinic orbits constitute a one-parameter family of solutions which are obtained by setting $z_2 = z_3 = 1$ while z_1 is kept arbitrary. Here again, the sign parameter S is meaningless. In terms of rods, these orbits correspond to the localizing solutions studied by Coyne (1990).[1] They connect continuously the straight state $(z_1 = 1)$ to the planar loop $(z_1 = -1)$. These solutions have constant torsion,

$$\tau = \sqrt{\frac{1+z_1}{1-z_1}}. \tag{88}$$

We see that τ is bijective in z_1 and can assume any non-negative value, from 0 in the case $z_1 = -1$ (plane pendulum) to infinity in the limit $z_1 \rightarrow 1$. Actually, for fixed tension, the torsion cannot be arbitrarily large. One must keep in mind that the parameter τ used here is the scaled torsion and that the scaling defined in (47) in turn depends on τ through z_1. As a consequence, the unscaled torsion $\tilde{\tau}$ is not simply proportional to τ, but instead is given by $\tilde{\tau}^2 = [\tilde{F}/EI_1(1+\tau^{-2})]$, where $\tilde{F}$ is the unscaled tension. Hence, the torsion has actually an upper bound proportional to the square root of the tension. In the following, we adopt the torsion τ rather than z_1 as the arbitrary parameter.

The top variables φ, z, and ψ assume the form

$$\varphi = \arctan\left(\frac{1}{\tau}\tanh s\right) + \tau s, \tag{89a}$$

$$z = 1 - \frac{2}{1+\tau^2}\operatorname{sech}^2 s, \tag{89b}$$

$$\psi = \arctan\left(\frac{1}{\tau}\tanh s\right) + \left(3 - \frac{2}{b}\right)\tau s. \tag{89c}$$

Notice that the boundary values $\frac{2}{3}$ and 1 for the variable b in the case of circular cross section take a new sense in view of expressions (89). The value $b = \frac{2}{3}$ makes the self-rotation angle ψ bounded, while $b = 1$ is the value for which $\varphi = \psi$.

The centerline variables R, Φ, and Z read

$$R = \frac{2}{1+\tau^2}\operatorname{sech} s, \tag{90a}$$

$$\Phi = \tau s - \frac{\pi}{2}, \tag{90b}$$

$$Z = s - \frac{2}{1+\tau^2}\tanh s. \tag{90c}$$

Three typical nonplanar $(\tau \neq 0)$ homoclinic orbits of the spinning top together with the corresponding filament shapes are shown in Figs. 13–15.

3. Generic filament shapes

In the most generic case, the spinning top oscillates between two parallels z_1 and z_2, while it precesses either monotonously or with backward-and-forward motion. The corresponding filament centerline $\mathbf{R}$ behaves, on average, as a helix around which it is wound.

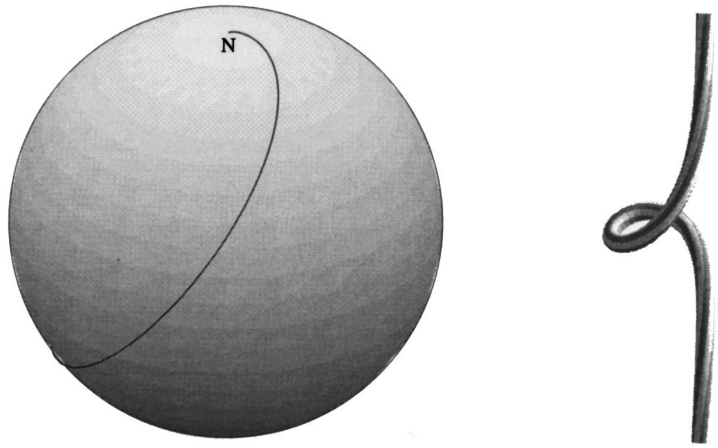

FIG. 13. A locally buckled filament with low torsion and high curvature ($\tau = \frac{1}{2}$).

a. Average helix: We define the mean helical centerline $\langle \mathbf{R} \rangle$ in the following way: We introduce cylindrical coordinates $\langle R \rangle, \langle \Phi \rangle, \langle Z \rangle$ for the helix $\langle \mathbf{R} \rangle$, and we take the mean vertical coordinate $\langle Z \rangle$ to be a linear function of s, namely,

$$\langle Z \rangle = \langle z \rangle s, \tag{91}$$

where $\langle z \rangle$ is the average of z over a period, $2K(k)$. Using (76), we have

$$\langle z \rangle = \frac{1}{2K(k)} \int_0^{2K(k)} z ds = z_3 - (z_3 - z_1) \frac{E(k)}{K(k)}. \tag{92}$$

Now, consider the expression (65) for the complex centerline radius $\hat{R}$. The polar angle Φ being the argument of $\hat{R}$, we have

$$\Phi = \arg \hat{\rho} + \varphi - \frac{\pi}{2}, \tag{93}$$

with

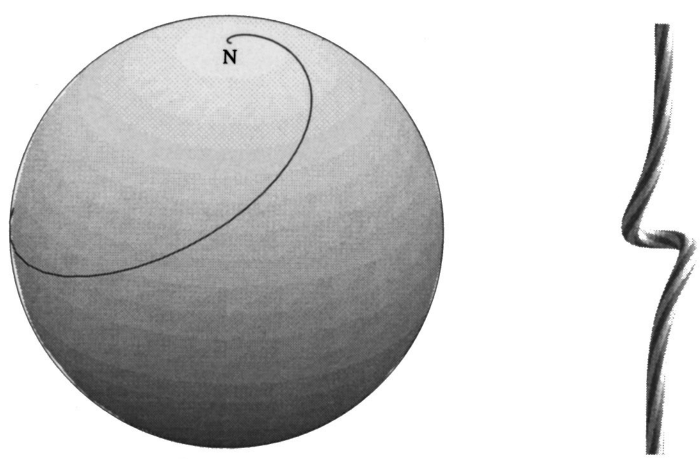

FIG. 14. A locally buckled filament with intermediate torsion and curvature ($\tau = 1$).

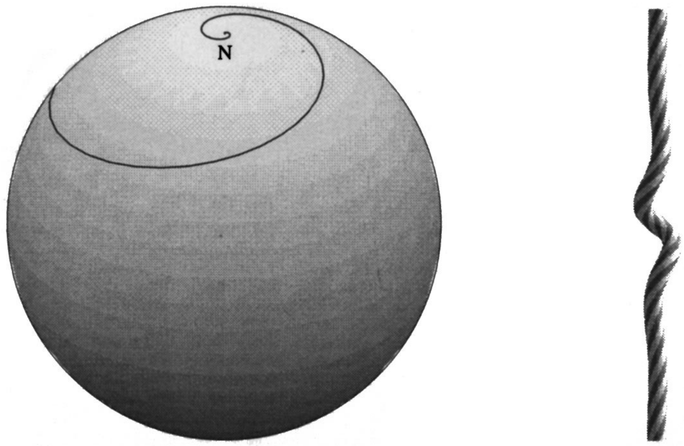

FIG. 15. A locally buckled filament with high torsion and low curvature ($\tau=2$).

$$\hat{\rho}=\frac{1}{F}\,\frac{M_3-M_Z z-iz'}{\pm\sqrt{1-z^2}}. \tag{94}$$

The function $\hat{\rho}$ depends on s through z and z' only, hence it describes a closed curve in the complex plane. If $\hat{\rho}$ does not vanish anywhere, as s increases by a period $2K(k)$, the argument of $\hat{\rho}$ increases by $2\pi m$, where m is some integer. Moreover, the real and imaginary parts of the numerator in (94) being decreasing functions of z and z', respectively, the curve defined by $\hat{\rho}$ has no self-crossing (and is parameterized clockwise by s). Hence, it turns around the origin at most once clockwise over a period $2K(k)$, so that m is restricted to the values 0 and -1. The domain in the (z_1,z_2,z_3,S) space where either value of m holds is delimited by the condition (68b) ensuring the existence of points where $\hat{\rho}$ vanishes. We find that $m=-1$ if $S=+$ and $z_3>(1-z_1z_2)/(z_2-z_1)$, and $m=0$ otherwise. As a consequence, we have

$$\varphi(s+2K(k))-\varphi(s)=\Phi(s+2K(k))-\Phi(s)+\begin{cases}2\pi & \text{if } S=+ \text{ and } z_3>\dfrac{1-z_1z_2}{z_2-z_1},\\[2ex] 0 & \text{if } S=- \text{ or } z_3<\dfrac{1-z_1z_2}{z_2-z_1}.\end{cases} \tag{95}$$

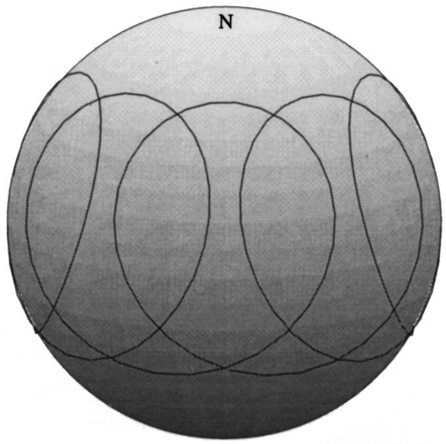
Hence, over a period of z, the precession angle φ of the top covers either the same angular distance as the polar angle Φ of the rod, or the same angular distance plus one complete revolution.

Now, using (60a) and (73a), we define the mean angular velocities $\langle\varphi'\rangle$ and $\langle\Phi'\rangle$ for the corresponding angles φ and Φ as

$$\langle\varphi'\rangle=\frac{1}{2K(k)}\int_0^{2K(k)}ds\,\varphi'=\frac{M_+}{1+z_1}\,\frac{\Pi(n_+,k)}{K(k)}+S\,\frac{M_-}{1-z_1}\,\frac{\Pi(n_-,k)}{K(k)}, \tag{96a}$$

$$\langle\Phi'\rangle=\frac{1}{2K(k)}\int_0^{2K(k)}ds\,\Phi'=\frac{1}{2}\left(M_Z+\frac{M_3-M_Z\tilde{h}}{\tilde{h}-z_1}\,\frac{\Pi(\tilde{n},k)}{K(k)}\right). \tag{96b}$$

As a consequence, these two quantities either are equal or differ from $\pi/K(k)$. The question arises then: which mean angular velocity, $\langle\varphi'\rangle$ or $\langle\Phi'\rangle$, should we use to define the polar angle $\langle\Phi\rangle$ of our average helix? The most natural choice seems to take $\langle\Phi\rangle=\langle\Phi'\rangle s$. However, expression (96b) is not continuous through the boundary (68b), making the definition of the mean polar angle $\langle\Phi\rangle$ ambiguous at that point. Therefore, we define



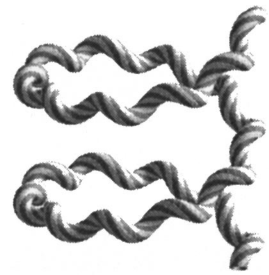


FIG. 16. A slowly precessing, nearly circular top orbit corresponds to a supercoiled helix ($z_1=-\frac{1}{2}$, $z_2=\frac{3}{4}$, $z_3=4$, $S=-$).

$$\langle\Phi\rangle=\langle\varphi'\rangle s-\frac{\pi}{2}\quad\text{for } S=-, \tag{97a}$$

$$\langle\Phi\rangle=\left(\langle\varphi'\rangle-\frac{\pi}{K(k)}\right)s-\frac{\pi}{2}\quad\text{for } S=+. \tag{97b}$$

These expressions reduce to $\langle\Phi'\rangle s$ for sufficiently large z_3, and are continuous across the boundary (68b). As we shall see, this definition is the most adequate in the case where the filament shape is a supercoiled helix (this case has a great importance in biochemical applications, in particular for DNA supercoiling.[31,40,41]) The supercoiled helices are defined and discussed below. It remains now to define the mean helix radius $\langle R\rangle$. A definition consistent with (97) is

$$\langle R\rangle=\frac{1}{2K(k)}\int_0^{2K(k)}ds\hat{R}\exp-i\langle\Phi\rangle. \tag{98}$$

Therefore, the generic filament behaves on average like an helical filament.

b. Supercoiled helices: A supercoiled helix is a curve which looks like a helix on short length scales, with the central axis itself shaped like a helix on large length scales. The condition for the centerline $\mathbf{R}$ to be a supercoiled helix, in terms of spinning tops, is that the vector $\mathbf{d}_3$ describes slowly precessing, nearly circular, oblique loops on the unit sphere. Two such examples are shown in Figs. 16 and 17. If any of these three conditions (slow precession, near-circularity, and oblicity of the top orbit) is not fulfilled, the filament shape will not look like a supercoiled helix, but rather like a deformed helix, as shown in Figs. 18–21.

The supercoiled helices can be studied systematically as solutions close to the oblique circular orbits of the spinning top. There are two ways to obtain circular orbits. The first one consists in setting $z_1=z_2$, in which case the orbit is horizontal, and not oblique. The second one is to take the limit $z_3\to\infty$. Indeed, in view of (48), the tension vanishes as z_3 grows without bound, and, as we mentioned in Sec. III B, every filament with null tension is a helix, hence every top orbit with $F=0$ is a circle. Furthermore, these asymptotic circular orbits can be arbitrarily oriented since the vertical direction $\mathbf{e}_Z$ cannot be distinguished from the other directions in the limit $F=0$. As a consequence, we can redefine a supercoiled helix as a solution with a large (''close to infinity'') value of z_3. In practice, however, z_3 does not need to be very large, so that the threshold value appearing in (95) can be reached with the centerline $\mathbf{R}$ still reasonably looking like a supercoiled helix.

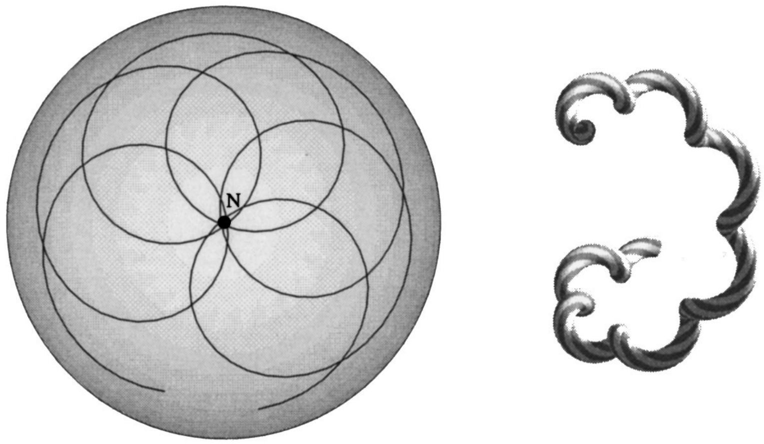

FIG. 17. A top orbit crossing periodically the north pole. The corresponding filament has a periodically vertical tangent ($z_1=\frac{1}{2}$, $z_2=1$, $z_3=3$).

In the limit of large z_3, the vertical axis joining the poles of the unit sphere is interior to precessing circular orbit in the case $S=+$, and exterior to it in the case $S=-$. As a consequence, one passes continuously from the supercoiled helices with $S=-$ to the supercoiled helices with $S=+$ by enlarging the slowly precessing orbit so that it passes through one of the poles, as in Fig. 17.

We mentioned above that our definitions of the average helix coordinates $\langle R\rangle,\langle\Phi\rangle,\langle Z\rangle$ are well adapted to supercoiled helices, in the sense that they describe consistently the large scale helical behavior of the axis around which the centerline is wound. Namely, in the limit $z_3\to\infty$, the supercoiled helix tends towards an (infinitely remote) ordinary helix, with a straight axis given by the limit of the average helix $\langle\mathbf{R}\rangle$.

c. Deformed helices: In many cases, although the centerline $\mathbf{R}$ winds around the average helix $\langle\mathbf{R}\rangle$, it does not quite look like a supercoiled helix. This happens if the criterion discussed above is not fulfilled, which can result in the following:

(1) The short scale spatial period $2K(k)$ and the large scale spatial period $2\pi/\langle\Phi\rangle'$ can be too close to each other, in which case the two orders of helicity cannot be clearly distinguished. Such a situation is shown in Fig. 18.

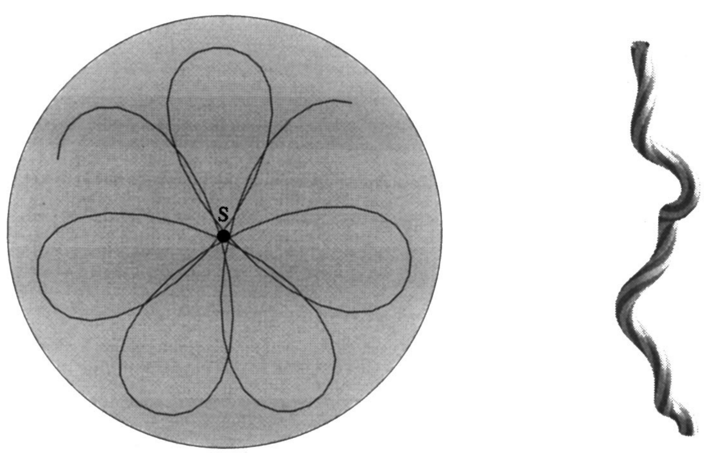

FIG. 18. A top orbit crossing periodically the south pole. The corresponding filament has a periodically vertical tangent ($z_1=-1$, $z_2=-\frac{1}{2}$, $z_3=\frac{14}{10}$, $S=-$).

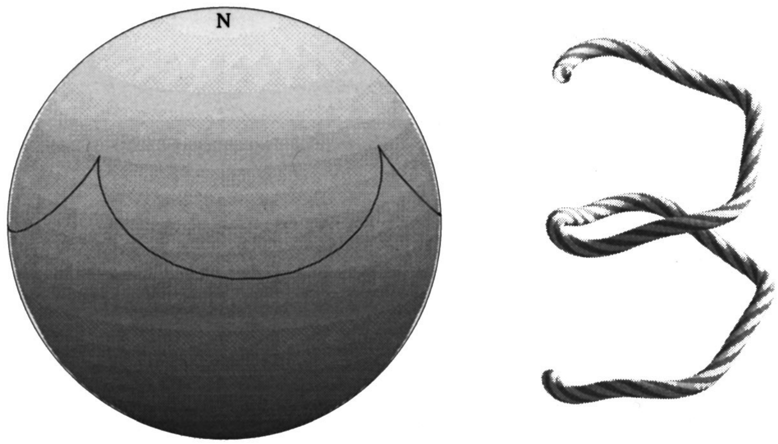

FIG. 19. A top orbit presenting turn-back points corresponds to a filament with periodically vanishing curvature ($z_1=0$, $z_2=\frac{1}{2}$, $z_3=2$, $S=$—).

(2) If the top orbit is too far away from a circle, the short scale pattern does not look like a helix. As an example, Fig. 19 shows a large-scale helix with curvature varying on short scale.
(3) For some values of the constants, the top orbit can be periodic although quite different from a circle. In this case, the filament shape is periodic in space, but different from a helix (see the ''oblique helix'' in Fig. 20).

In addition, there is the possibility for the amplitude of the short scale pattern to be large enough for two consecutive turns of the large-scale helix to overlap each other. In this case, the topology of the solution is different from the topology of an ordinary helix. Such a ''knotted helix'' is shown in Fig. 21.

4. Bounded and closed filament shapes

The filament shapes discussed so far are all unbounded in space, except for the twisted ring shown in Fig. 5 and the lemniscate shown in Fig. 11(a). In general, bounded shapes are obtained by imposing the coordinate Z to be a periodic function of s, that is, $Z=0$ for $s=2K(k)$. Using (76), the condition for boundedness reads

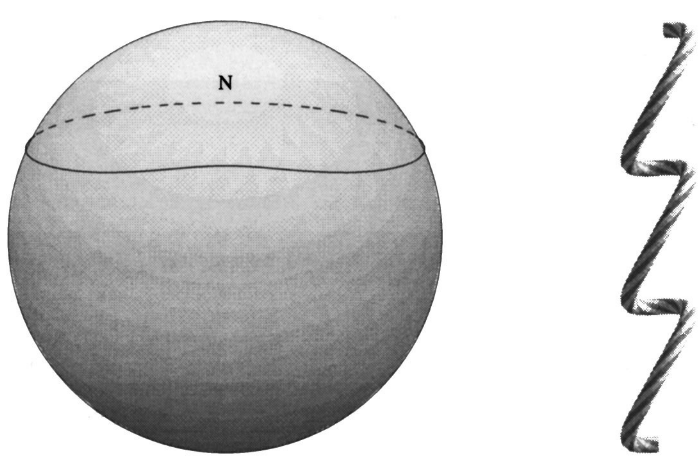

FIG. 20. A periodic top orbit results in a spatially periodic filament shape ($z_1=-0.7822$, $z_2=0.8782$, $z_3=1$, $S=$—).

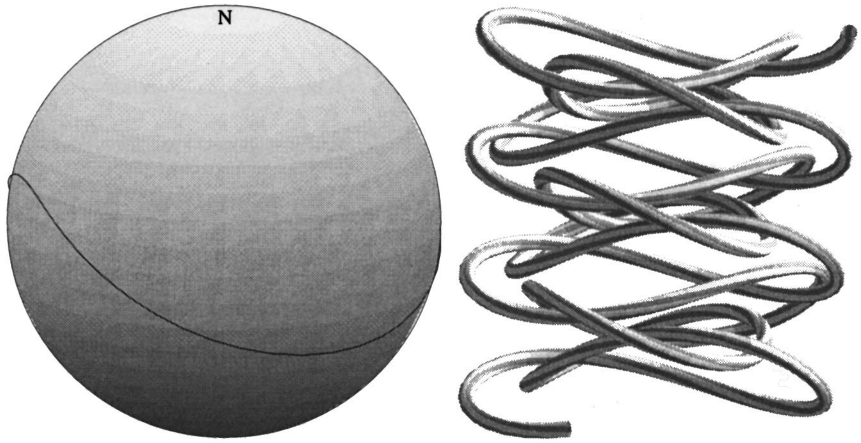

FIG. 21. An apparently simple top orbit resulting in a surprisingly complex ''knotted helix'' ($z_1=-0.4152$, $z_2=0.2800$, $z_3=1.026$, $S=$—).

$$z_3K(k)-(z_3-z_1)E(k)=0. \tag{99}$$

The condition for the space curve **R** to be closed is obtained by requiring, in addition, that the periods of the variables Z and Φ be in a ratio of integer numbers. Namely, using (73a),

$$M_ZK(k)+\frac{M_3-M_Z\tilde{h}}{\tilde{h}-z_1}\Pi(\tilde{n},k)=2\pi\frac{m_\Phi}{m_Z}, \tag{100}$$

where the integers m_Φ and m_Z denote, respectively, the number of periods of the variables Z and Φ in a complete covering of the centerline **R**.

Finally, one can impose the ribbon associated to the filament to be closed by requiring that the periods of the variables Z and ζ be in a ratio of integer numbers, or, using (73b),

$$\frac{2M_3}{b}K(k)-\left(M_3K(k)+\frac{M_3h-M_Z}{h-z_1}\Pi(n,k)\right)=2\pi\frac{m_\zeta}{m_Z}, \tag{101}$$

where m_ζ denotes the number of periods of ζ in a complete covering of the centerline **R**. The condition (101) is useful if one has, for instance, an octagonal cross section, in which case m_ζ must be set to an integer multiple of $\frac{1}{8}$, in order for the octagons at $s=0$ and at $s=2m_ZK(k)$ to match each other.

This together makes three conditions from which the constants z_1, z_2, and z_3 can be determined. However, the conditions (100) and (101) are not very tractable, because the left-hand side of (100) is proportional to the average angular velocity $\langle\Phi'\rangle$ which, as we mentioned, is not a continuous function of the constants z_1, z_2, and z_3. This holds too for the left-hand side of (101). As a consequence, numerical root solvers are inefficient in solving the systems (99)–(101). In practice, it is well advised to replace Eqs. (100) and (101) by equivalent conditions on the Euler angles φ and ψ. Remember that, over a period of Z, the angles φ and Φ cover angular distances which differ by integer multiples of 2π. A similar relation holds for the angles ψ and ζ. The conditions on φ and ψ analogous to (100) and (101) read

$$\frac{M_+}{1+z_1}\Pi(n_+,k)+S\frac{M_-}{1-z_1}\Pi(n_-,k)=\pi\frac{m_\varphi}{m_Z}, \tag{102a}$$

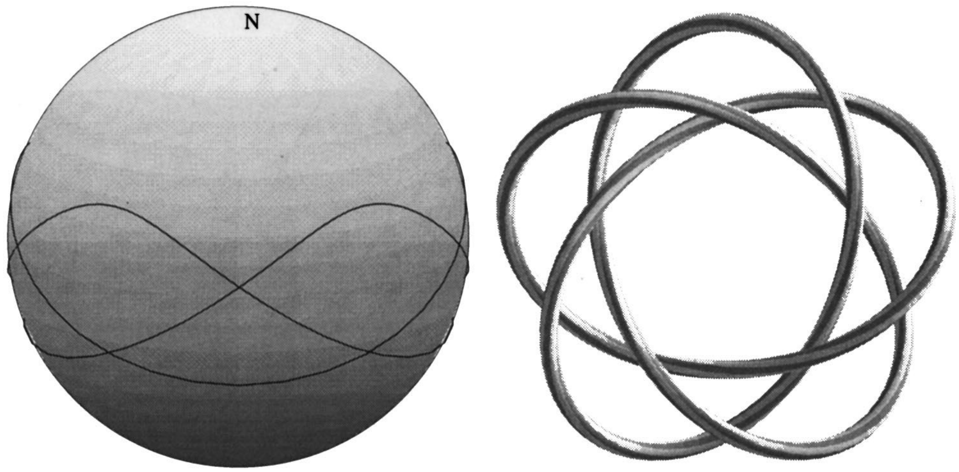

FIG. 22. A torus knot with $m_Z=5$, $m_\Phi=3$, and $m_\zeta=1$ ($z_1=-0.4152$, $z_2=0.3446$, $z_3=1.026$, $S=-$).

$$\left(\frac{1}{b}-1\right)M_3K(k)+\frac{M_+}{1+z_1}\Pi(n_+,k)-S\frac{M_-}{1-z_1}\Pi(n_-,k)=\pi\frac{m_\psi}{m_Z}, \tag{102b}$$

where m_φ and m_ψ differ from m_Φ and m_ζ, respectively, by an integer.

Examples of closed filaments are displayed in Figs. 22–24. Figures 22 and 23 show torus knots, that is, knotted curves which are topologically equivalent to closed curves lying on a torus. Figure 24 shows a supercoiled ring (notice the large value of z_3).

IV. CONCLUSIONS

In this paper we have shown how to classify the shapes of Kirchhoff filaments based on the geometry of the spinning top solutions. To do so, we have pushed the Kirchhoff analogy to its extreme and systematically obtained interesting properties of filaments based on the corresponding solutions of the Euler equations. We showed that the solutions of Kirchhoff equations can be extremely varied and that many interesting cases can be distinguished. In particular, we found explicit conditions on the boundary values for filaments to have points of self-tangency and multiple self-intersection. We also studied the case where filaments have points of vanishing

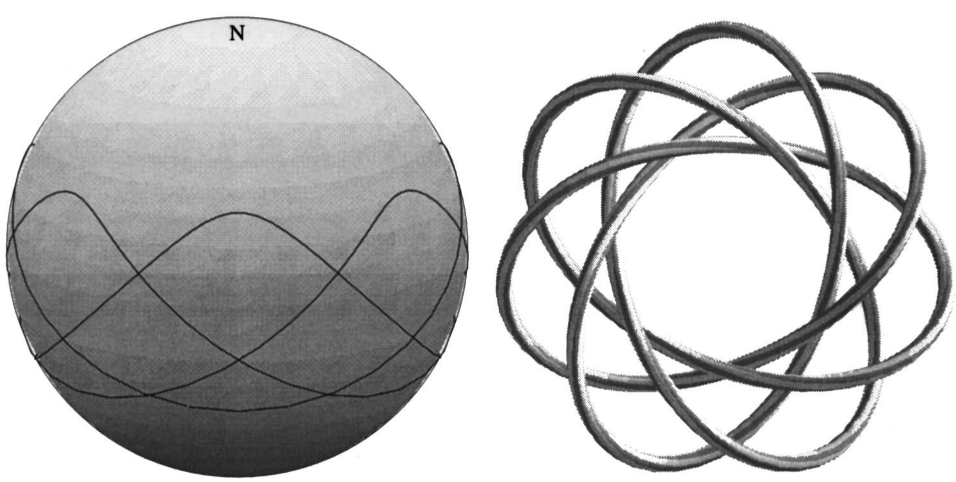

FIG. 23. A torus knot with $m_Z=7$, $m_\Phi=4$, and $m_\zeta=1$ ($z_1=-0.4997$, $z_2=0.4013$, $z_3=1.037$, $S=-$).

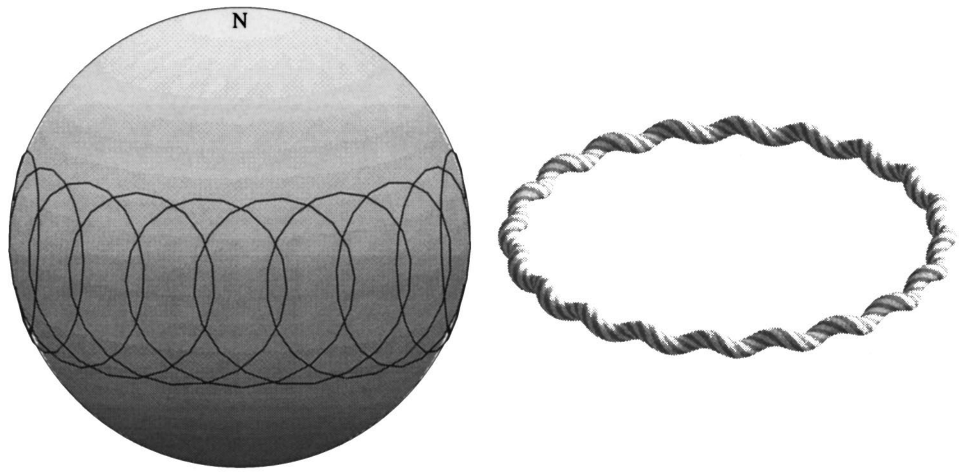

FIG. 24. A supercoiled ring with $m_Z=20$, $m_\Phi=1$, and $m_\zeta=6$ ($z_1=-0.4269$, $z_2=0.4171$, $z_3=9.084$, $S=$—).

curvature and show that they correspond to orbits of spinning tops with turnback points. We gave a complete description of localizing solutions, that is solutions which are homoclinic in the curvature-torsion space; these filaments are in space asymptotic to a straight line. In the same way, we found conditions to obtain filaments which have the topology of torus knots, that is bounded and periodic filaments (in the physical space). Finally, we studied the behavior of generic filaments and show that on long length scales they always behave like helical filaments.

Some of the particular solutions presented here have been obtained in various places by different authors. In this paper we have stressed on the geometry of these solutions and presented them in a unifying way based on the familiar framework of the spinning top.

The solutions of the Kirchhoff equations for rods with circular cross sections are often used as a first guess to study numerically physical filaments with different properties (e.g., noncircular cross sections, intrinsic curvature or torsion,...). We hope that the explicit solutions given in this paper together with their geometric classification will be useful in this context.

APPENDIX: ELLIPTIC FUNCTIONS

Remark: In the following, the constant k is called the modulus of the elliptic functions and ranges between 0 and 1, while the constant n is called the characteristic and is a real number less than 1.

1. Elliptic integrals

A. Incomplete elliptic integrals in standard form

The incomplete elliptic integrals of the first, second, and third kind in standard form are, respectively, defined by

$$F^S(\Phi|k)=\int_0^\Phi \frac{d\Phi'}{\sqrt{1-k^2\sin^2\Phi'}}, \tag{A1a}$$

$$E^S(\Phi|k)=\int_0^\Phi d\Phi'\sqrt{1-k^2\sin^2\Phi'}, \tag{A1b}$$

$$\Pi^S(\Phi|n,k)=\int_0^{\Phi}\frac{d\Phi'}{(1-n\sin^2\Phi')\sqrt{1-k^2\sin^2\Phi'}}. \tag{A1c}$$

B. Incomplete elliptic integrals in algebraic form

The algebraic forms are obtained by carrying out the following change of variable into the standard forms:

$$u=\sin\Phi. \tag{A2}$$

This yields

$$F^A(u|k)=\int_0^u\frac{du'}{\sqrt{(1-u'^2)(1-k^2u'^2)}}, \tag{A3a}$$

$$E^A(u|k)=\int_0^u du'\sqrt{\frac{1-k^2u'^2}{1-u'^2}}, \tag{A3b}$$

$$\Pi^A(u|n,k)=\int_0^u\frac{du'}{(1-nu'^2)\sqrt{(1-u'^2)(1-k^2u'^2)}}. \tag{A3c}$$

The algebraic forms are those which are implemented in the symbolic calculus software Maple. Notice that for the change of variable (A2) to be bijective, one must restrict Φ to the interval $[-(\pi/2),(\pi/2)]$.

C. Incomplete elliptic integrals in practical form

We call the following forms of the elliptic integrals of the second and third kind ''practical'' because these are the forms under which they appear the most naturally in the problems in Sec. III. These forms are obtained by carrying out the following change of variable into the standard forms:

$$s=F^S(\Phi|k). \tag{A4}$$

This yields

$$E(s|k)=\int_0^s ds'\,\mathrm{dn}^2(s'|k), \tag{A5a}$$

$$\Pi(s|n,k)=\int_0^s ds'\frac{ds'}{1-n\,\mathrm{sn}^2(s'|k)}, \tag{A5b}$$

where the functions sn and dn are defined in Sec. 2.

D. Complete elliptic integrals

The complete elliptic integrals are defined by the expressions for the corresponding incomplete elliptic integrals evaluated at $u=1$ in algebraic form. They are denoted in the following way:

$$K(k)=F^A(1|k), \tag{A6a}$$

$$E(k)=E^A(1|k), \tag{A6b}$$

$$\Pi(n,k)=\Pi^A(1|n,k). \tag{A6c}$$

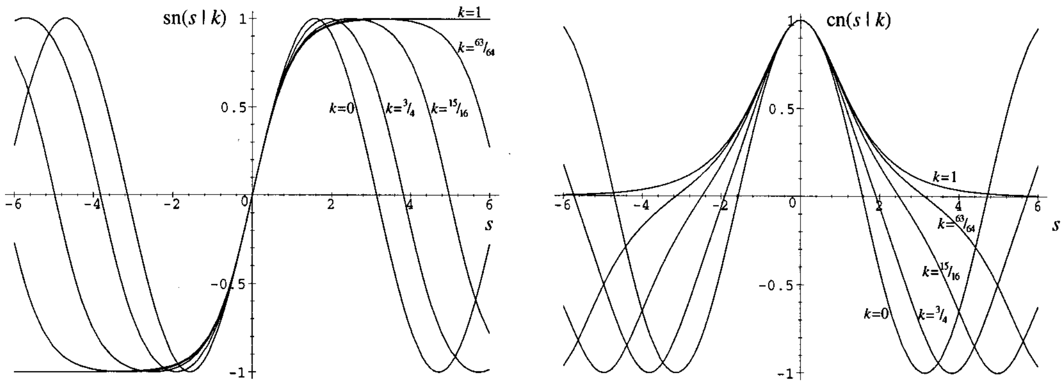

FIG. 25. The function sn and cn for various values of k.

2. Jacobi's elliptic functions

A. Definitions

The incomplete elliptic integrals, having positive integrands, define monotonous, hence invertible, functions. The function am is defined as the inverse of the standard form F^S of the incomplete elliptic integral of the first kind,

$$\mathrm{am}(s|k)=(F^S)^{-1}(s|k). \tag{A7}$$

We then define Jacobi's elliptic functions sn, cn, and dn as

$$\mathrm{sn}(s|k)=\sin \mathrm{am}(s|k), \tag{A8a}$$

$$\mathrm{cn}(s|k)=\cos \mathrm{am}(s|k), \tag{A8b}$$

$$\mathrm{dn}(s|k)=\sqrt{1-k^2\mathrm{sn}^2(s|k)}. \tag{A8c}$$

Notice that the function sn itself, restricted to the interval $[-K(k),K(k)]$, is the inverse of the algebraic form F^A of the incomplete elliptic integral of the first kind. The four functions sn, cn, dn, and am are represented in Figs. 25–26 for various values of k.

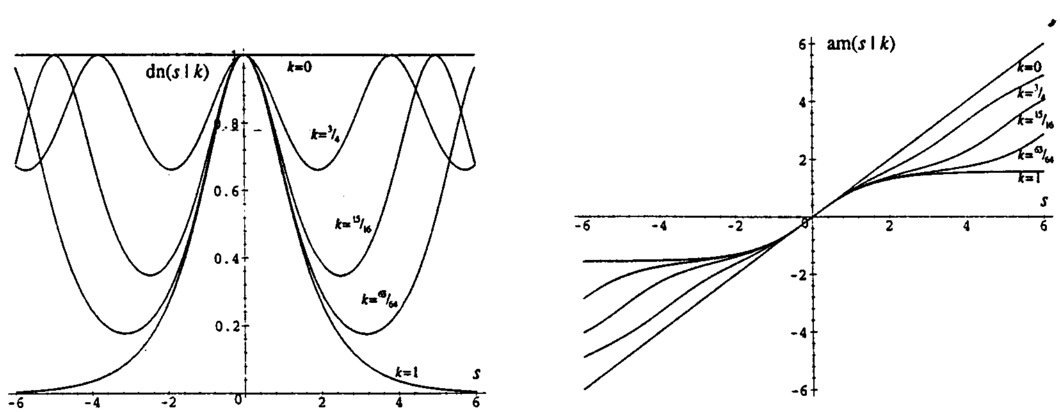

FIG. 26. The function dn and am for various values of k.

B. Elementary properties of am, sn, cn, and dn

The function am obeys the relations

$$\mathrm{am}(2nK(k)\pm s|k)=n\pi\pm\mathrm{am}(s|k), \tag{A9}$$

for any real s and integer n. Hence, the knowledge of am over the interval $[0,K(k)]$, together with (111), is sufficient to reconstruct the function over the whole real line. This holds too for the periodic functions sn, cn, and dn, which obey the following relations:

$$\mathrm{sn}(2nK(k)\pm s|k)=\pm(-1)^n\mathrm{sn}(s|k), \tag{A10a}$$

$$\mathrm{cn}(2nK(k)\pm s|k)=(-1)^n\mathrm{cn}(s|k), \tag{A10b}$$

$$\mathrm{dn}(2nK(k)\pm s|k)=\mathrm{dn}(s|k). \tag{A10c}$$

C. Limits of am, sn, cn, and dn for $k=0$ and $k=1$

These limits are obtained by considering, for $k=0$ and $k=1$, expression (A1a) defining the function F^S, and then taking the limit of am to be the inverse function. For $k=0$, one has

$$\mathrm{am}(s|0)=s, \tag{A11a}$$

$$\mathrm{sn}(s|0)=\sin s, \tag{A11b}$$

$$\mathrm{cn}(s|0)=\cos s, \tag{A11c}$$

$$\mathrm{dn}(s|0)=1, \tag{A11d}$$

whereas $k=1$ leads to

$$\mathrm{am}(s|1)=\arcsin\tanh s, \tag{A12a}$$

$$\mathrm{sn}(s|1)=\tanh s, \tag{A12b}$$

$$\mathrm{cn}(s|1)=\mathrm{sech}\, s, \tag{A12c}$$

$$\mathrm{dn}(s|1)=\mathrm{sech}\, s. \tag{A12d}$$

D. Derivatives of am, sn, cn, and dn

The derivatives of am, sn, cn, and dn are obtained by differentiating (A1a) and the definition Eqs. (A8a)–(A8c). This leads to the following differential relations:

$$\frac{d}{ds}\mathrm{am}(s|k)=\mathrm{dn}(s|k), \tag{A13a}$$

$$\frac{d}{ds}\mathrm{sn}(s|k)=\mathrm{cn}(s|k)\mathrm{dn}(s|k), \tag{A13b}$$

$$\frac{d}{ds}\mathrm{cn}(s|k)=-\mathrm{sn}(s|k)\mathrm{dn}(s|k), \tag{A13c}$$

$$\frac{d}{ds}\mathrm{dn}(s|k)=-k^2\mathrm{sn}(s|k)\mathrm{cn}(s|k). \tag{A13d}$$

An exact solution for several charges in classical electrodynamics

R. Rivera[a] and D. Villarroel
Departamento de Física, Universidad de Chile, Blanco Encalada 2008, Santiago, Chile

(Received 31 December 1998; accepted for publication 23 February 1999)

An exact solution for an arbitrary number of identical charges that are equally spaced along a circumference and that rotate at constant angular velocity is presented. The solution is valid for any velocity of the charges less than the speed of light and considers the radiation reaction effects as well as the retarded interaction between the charges. The external field that allows this motion consists of a time-independent electric field tangent to the charges' orbit and a homogeneous time-independent magnetic field that points orthogonally to the orbit plane. A detailed analytical study of the total power of radiation associated with this system of charges is carried out, and it is shown that it is in perfect agreement with the energy that the external electric field supplies to the charges. In particular, in the limit when N goes to infinity only static fields remain. © *1999 American Institute of Physics.* [S0022-2488(99)01906-4]

I. INTRODUCTION

Unlike the equation of motion of a relativistic charge,[1,2] the equations of motion for more than one charge have received little attention in the literature. In this case, besides the radiation reaction forces, the retarded interaction between the charges must also be taken into account. The equations of motion for several charges were obtained by Dirac.[3] If the mass and charge of a particle are denoted by m_k and e_k, respectively, the corresponding equation of motion is the following:

$$m_k a_k^{\mu} = (e_k/c) F_{\text{ext}}^{\mu\alpha} v_{k\alpha} + (e_k/c)\left(\sum_{i\neq k} F_{i\text{ret}}^{\mu\alpha} \right) v_{k\alpha} + (2e_k^2/3c^3)(\dot{a}_k^{\mu} - (1/c^2) a_k^{\lambda} a_{\lambda}^{k} v_k^{\mu}). \tag{1.1}$$

Here $v_{k\mu}$ and $a_{k\mu}$ denote the four-velocity and four-acceleration of charge e_k, respectively; c is the speed of light; $\dot{a}_{k\mu}$ is the proper time derivative of $a_{k\mu}$. Moreover, greek indices range from 0 to 3 and the diagonal metric of Minkowski space is $(-1, +1, +1, +1)$.

The second term on the right-hand side of Eq. (1.1) represents the force on the charge e_k due to the retarded fields of the rest of the charges. It is precisely this term that links the equations of motion of the different charges. Equations (1.1) are usually named Lorentz–Dirac equations, and, in spite of the troubles associated with the existence of preacceleration effects and the existence of unphysical runaway solutions, they are the most widely accepted equations of motion for point charges in classical electrodynamics.

In this paper we will show that Eqs. (1.1) admit as an exact solution the motion of N identical charges that are equally spaced over a circumference of radius a rotating as a rigid body at constant angular velocity ω. The external fields that make possible this motion are the same as those of a previous paper;[4] that is, a time-independent electric field tangent to the orbit circle with a fixed value on it, and a homogeneous time-independent magnetic field orthogonal to the plane where the charges are rotating. As it will be shown, these external fields exist for arbitrary values of the parameters that characterize the motion, that is, charge e, mass m, orbit radius a, angular velocity ω (such that $a\omega < c$), and a number of charges N.

---

Although Eqs. (1.1) are derived starting from the conservation law for the energy–momentum tensor of the electromagnetic field, the ambiguities associated with the divergent self-energy of a point charge make it necessary to verify the consistency of the solution with the energy that it is radiated away by the system of charges. To this end, we derived an exact formula for the total power of radiation, starting from the far-retarded field generated by the charges. On the other hand, because of the physical symmetries of the charges' motion, in this case it is easy to obtain the total power of radiation directly from the solution of Eqs. (1.1). It turns out that both ways lead to the same formula; so the Lorentz–Dirac equations correctly take into account the energy that escapes to infinity.

Let us point out that, unlike the one charge case, an exact formula for the total power of radiation of a system of several charges in the literature does not exist. The difficulty in obtaining such a formula can be illustrated by the nonexistence of a Lorentz frame, where all the charges are at rest. In general, it is also impossible to obtain any clear answer for the total power of radiation, starting from the equations of motion (1.1). Our success in obtaining an exact formula is mainly due to the physical symmetries that the charges' motion has in the present case. Although the radiation that escapes from the system of charges is determined by their far-retarded fields, the striking point of our calculation is that the physical symmetries allow us to calculate the total power of radiation by means of the fields near the charges. The formula for the total power of radiation takes, of course, full account of the interference effects between the fields of the different charges. In particular, the interference part of the total power of radiation is equal to the number of charges N times the sum of the powers due to the forces on each charge associated with the retarded electric fields of the rest of the charges.

The radiation of the system of charges under consideration here has been studied previously by Comay,[5] who used numerical techniques and considered up to $N=16$ charges. Our treatment is, however, analytic and does not have any restriction on the number of charges. Jackson, in his well-known book,[6] suggests studying the radiation emitted by these charges, starting from the spectral components of the radiation. In this paper, instead of the time-integrated energy flux, we work directly with the instantaneous energy flux.

Our formula for the total power of radiation allows us to study in detail the interference effects on the radiation as the number of charges increases. When the number of charges is very large, the system of charges under study resembles a uniformly charged ring. Now, in the case of a uniformly charged ring that rotates at constant angular velocity, the charge distribution, as well as the corresponding current, is time independent. This means that the electric and magnetic fields are static, and therefore the charges do not radiate energy. This is precisely what happens with the exact solution of the Lorentz–Dirac equation constructed in this paper when the number of charges increases without limit. Incidentally, the mathematical techniques that allow us to carry out the proof of this property are the same as those already developed by Bessel and Watson, in connection with the old Kepler's problem, which can be found in the classic book by Watson.[7] This happens because the equations that define the retarded times of the different charges are practically the same as the equation of motion in the Kepler's problem.

II. THE SOLUTION

In this section it will be shown that for an external time-independent electric field tangent to a circumference with a value fixed on it, and a homogeneous time-independent external magnetic field that points orthogonally to the plane of the circumference, the equations (1.1) admit as a solution the motion of N identical charges equally spaced on the circumference and such that the charges rotate at constant angular velocity ω. For definiteness, the electric charge of the particles is chosen as positive, and it is assumed that the orbit circle lies on the X-Y plane in such a way that the center of the circular orbit of radius a coincides with the origin of coordinates. In addition, the charges are supposed to be rotating counterclockwise, so the external magnetic field $\mathbf{B}^{\text{ext}}$ points in the negative direction of the Z axis and the external electric field $\mathbf{E}^{\text{ext}}$ is tangent to the orbit and points in the direction of the charges' motion.

The retarded electric field generated by a charge e is the following:[8]

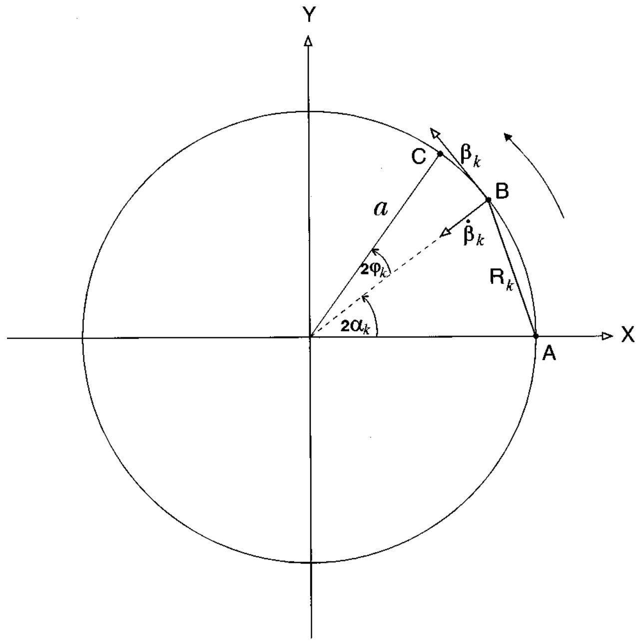

FIG. 1. Points A and C represent the positions at time $t=0$ of particles N and k, respectively. Point B corresponds to the retarded position of particle k associated to the position of particle N at $t=0$. The angular separation between the actual and retarded positions of particle k is denoted by $2\varphi_k$; and the angular separation between the retarded position of particle k and the actual position of particle N is denoted by $2\alpha_k$. Also shown are the retarded quantities $\boldsymbol{\beta}_k$, $\dot{\boldsymbol{\beta}}_k$, and R_k.

$$\mathbf{E}^{\text{ext}}(\mathbf{x},t)=e\left[\frac{(\hat{\mathbf{n}}-\boldsymbol{\beta})(1-\beta^2)}{s^3R^2}\right]+\frac{e}{c}\left[\frac{\hat{\mathbf{n}}\times\{(\hat{\mathbf{n}}-\boldsymbol{\beta})\times\dot{\boldsymbol{\beta}}\}}{s^3R}\right]. \tag{2.1}$$

In this equation, $\hat{\mathbf{n}}$ is the unit vector that points from the retarded position $\mathbf{r}(t')$ of the charge to the point $\mathbf{x}$ where the field is being considered at time t; R is the distance from the retarded position of the charge to point $\mathbf{x}$, that is, $R=|\mathbf{x}-\mathbf{r}(t')|$; $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$ are defined by $(1/c)(d\mathbf{r}(t')/dt')$ and $d\boldsymbol{\beta}/dt'$, respectively, and are both evaluated at the retarded time t', implicitly defined by $t=t'+|\mathbf{x}-\mathbf{r}(t')|/c$; and s is the positive number defined by

$$s=1-\hat{\mathbf{n}}\cdot\boldsymbol{\beta}. \tag{2.2}$$

The retarded magnetic field $\mathbf{B}(\mathbf{x},t)$ is given by

$$\mathbf{B}(\mathbf{x},t)=\hat{\mathbf{n}}\times\mathbf{E}(\mathbf{x},t). \tag{2.3}$$

It is easy to see that for the motion under discussion, the external and retarded forces over the charges in Eqs. (1.1) do not have components along the Z axis. Thus, the equations with $\mu=3$ in Eqs. (1.1) are identically satisfied for the motion of the charges in the X-Y plane. Moreover, from the symmetries of the external fields and the charges' motion, it is immediate that the radial and tangential forces are the same for all the charges and that the magnitude of these forces are time independent. In other words, it is enough to consider the forces on only one charge in order to get the values for the external electric field and external magnetic field that make possible the motion under consideration. In Fig. 1 we have drawn the positions of the charges at the actual time, which is chosen as $t=0$. Let us analyze the forces on the charge N, which is located on the X axis at $t=0$. For this charge the radial direction is along the X axis and the tangential direction is along the Y axis. Each charge has associated a number that goes from 1 to N, and where the radial direction that determines the position of the kth charge at time $t=0$ makes an angle $k(2\pi/N)$ with the positive X axis. Besides the actual position of the charge k, in Fig. 1 the retarded position of this charge with respect to the position of charge N at time $t=0$ is also shown. The angle between the radial direction that determines the retarded position of the charge k with the positive X axis is denoted by $2\alpha_k$. It is also convenient to introduce the angle $2\varphi_k$ as the angle between the radial directions of the retarded and actual position of the charge k.

All the retarded quantities associated with the charge k can be expressed in terms of the angle α_k. In fact, the retarded time of the charge k, that is, the time that it takes to go from the retarded position determined by the angle $2\alpha_k$ to its actual position determined by the angle $k(2\pi/N)$, is $2\varphi_k/\omega$. Now, since this time is the same as that light takes to travel the distance $R_k = 2a\sin\alpha_k$, we obtain the following equation that determines the angle α_k as a function of β and parameter k:

$$k\pi/N=\alpha_k+\beta\sin\alpha_k. \tag{2.4}$$

From Fig. 1 it is also easy to obtain for the quantity s_k of (2.2) the following expression:

$$s_k=1+\beta\cos\alpha_k. \tag{2.5}$$

The component with $\mu=2$ in Eq. (1.1) for the charge N located on the X axis at $t=0$ gives rise to the following equation for the determination of E^{ext}:

$$E^{\text{ext}}=\frac{2}{3}\frac{e}{a^2}\beta^3\gamma^4-\sum_{k=1}^{N-1}E_{ky}, \tag{2.6}$$

where $\gamma=(1-\beta^2)^{-1/2}$ and E_{ky} is the component along the Y axis of the retarded electric field of charge k over charge N. According to Eq. (2.1), E_{ky} turns out to be

$$E_{ky}=\frac{e}{4a^2}\left\{\frac{2\beta}{s_k^2}-\frac{\beta+\cos\alpha_k}{\gamma^2 s_k^3\sin^2\alpha_k}\right\}. \tag{2.7}$$

For some charges $E_{ky}>0$, but there are also charges for which $E_{ky}<0$. In general, the sign of E_{ky} has a rather complicated dependence on k and the charge's velocity β. However, as will be shown in Sec. IV, the sum of the Y components of the retarded fields in Eq. (2.6) is positive, as the Y component of the external electric field $\mathbf{E}^{\text{ext}}$ is. On the other hand, the radiation reaction force, that is, the first term on the right-hand side of (2.6), has a negative Y component.

The component along the X axis E_{kx} of the retarded electric field of charge k over charge N turns out to be

$$E_{kx}=\frac{e}{4a^2 s_k^3\sin\alpha_k}\{s_k^2-\beta^2\sin^2\alpha_k\}. \tag{2.8}$$

From this equation, it is easy to see that E_{kx}, in contradistinction with E_{ky}, is positive for any k; which is rather obvious since all charges are positive.

The component $\mu=1$ of Eq. (1.1) gives the following equation, which determines the external magnetic field:

$$B_z^{\text{ext}}=-\frac{mc^2\gamma\beta}{ae}-\frac{1}{\beta}\sum_{k=1}^{N-1}\{E_{kx}+\beta(E_{kx}\cos\alpha_k+E_{ky}\sin\alpha_k)\}. \tag{2.9}$$

Using Eqs. (2.7) and (2.8), the retarded field of the charge k that appears in the { } bracket in (2.9) can be written as follows:

$$\{\ \} = \frac{e}{4a^2 s_k^3 \sin\alpha_k}\left[2\beta(\beta+\cos\alpha_k)s_k + \frac{1}{\gamma^4}\right]. \tag{2.10}$$

Now, since $0<\alpha_k<\pi$ and $s_k \geqslant 1-\beta$ it is easy to see that the quantity (2.10) is positive for any k. In other words, according to Eq. (2.9) the magnitude of the external magnetic field increases as the number of charges increases. This is obviously a consequence of the fact that the repulsive forces between the charges increase as the number of charges increases.

Finally, the component $\mu=0$ in Eq. (1.1), that is, the component associated with energy conservation, reproduces once again Eq. (2.6). In order to analyze the energy conservation equation, let us multiply Eq. (2.6) by the charge e, the velocity v, and the number of charges N. In this way, (2.6) becomes

$$N(evE^{\text{ext}}) = N\left(\frac{2e^2c}{3a^2}\beta^4\gamma^4\right) - N\sum_{k=1}^{N-1} evE_{ky}. \tag{2.11}$$

The left-hand side of this equation represents the power that the external electric field supplies to the system of N charges. Now, in this case the kinetic energy of the charges remains unchanged, so, according to energy conservation, all the power supplied by E^{ext} must be radiated away. In other words, the right-hand side of Eq. (2.11) must represent the total radiated power due to the system of charges under study. But $(2e^2c/3a^2)\beta^4\gamma^4$ is the total radiated power of just one charge in circular motion. So the first term on the right-hand side of (2.11) is the rate of radiation of the system of charges, neglecting all the interference effects. Therefore, the second term on the right-hand side of (2.11) must represent that part of the radiation associated with the interference of the fields of the different charges. In the next section the total power of radiation is studied in a way independent of the equations of motion (1.1), and it will be shown that the radiation emitted does not have any connection with the troubles of mass renormalization. As a result of this calculation, the formula obtained for the total power of radiation of this system of charges is precisely the right-hand side of Eq. (2.11); so the Lorentz–Dirac equations (1.1) are in perfect agreement with energy conservation.

III. THE TOTAL POWER OF RADIATION

The total power of radiation at time t is given by

$$\left(\frac{c}{4\pi}\right)\int_{\Sigma}(\mathbf{E}\times\mathbf{B})\cdot\mathbf{d\Sigma}, \tag{3.1}$$

where Σ is the surface of a sphere of a very large radius, centered at the orbit's center; and $\mathbf{E}$, $\mathbf{B}$ are the retarded electric and magnetic fields generated by the system of charges, which are evaluated over $\mathbf{\Sigma}$ at time t. Although only the far field contributes to the instantaneous energy flux across Σ, it will be shown now that, on account of the symmetries of the charges' motion, the total power of radiation can be calculated using the electric and magnetic fields near the charge distribution. In order to do that, let us consider the instantaneous energy flux across a spherical surface Σ_r centered at the orbit's center and with a radius $r>a$, but otherwise arbitrary. Then, if (θ, φ) denote the usual spherical angles, the integral (3.1) for Σ_r can be performed by considering first the contribution of the ribbon parallel to the orbit plane defined between the angles θ and $\theta + d\theta$. On a fixed point of this ribbon the electric and magnetic fields are obviously changing with time, but since the charges are rotating at constant angular velocity, the positions of the system of charges at different times look as completely equivalent for the ribbon as a whole. This means that the instantaneous energy flux across the ribbon is time independent. Such a property is valid, of course, for any ribbon of Σ_r, so the instantaneous energy flux across Σ_r is time independent.

Let us consider now two spherical surfaces Σ_1 and Σ_2 of radii r_1 and r_2, respectively, and such that $r_2>r_1>a$. If the volume bounded by Σ_1 and Σ_2 is denoted by Ω, then at different times the charge distribution is indistinguishable with respect to Ω; and therefore the total field energy contained in Ω is time independent. The Poynting vector $\mathbf{S}=(c/4\pi)\mathbf{E}\times\mathbf{B}$ satisfies the following conservation equation in Ω:

$$\nabla\cdot\mathbf{S}+\frac{\partial u}{\partial t}=0, \tag{3.2}$$

where u is the energy density $(1/8\pi)(\mathbf{E}^2+\mathbf{B}^2)$. If Eq. (3.2) is integrated over Ω, then it follows, on account of the time independence of the total energy contained in Ω, that the instantaneous energy flux across the surface of the sphere of radius r is not only time independent, but also it does not depend on the radius of the sphere, provided $r>a$. In other words, the total radiated power (3.1) can be calculated using any spherical surface centered at the orbit's center and with a radius r larger than the orbit radius a.

Let us consider, besides the spherical surface Σ_r of radius $r>a$, a torus that encloses the charges' orbit and such that it is contained inside Σ_r. Then, by the same arguments that led to the independence of (3.1) on the radius of the spherical surface, it can be concluded that the instantaneous energy flux across the surface of the torus is precisely the total radiated power associated with the system of charges under study. Moreover, the instantaneous energy flux across the surface of the torus obviously does not depend on the radius of the torus, and therefore it has a perfectly well-defined limit when the radius of the torus goes to zero. In what follows we will use this result in order to obtain an explicit formula for the total power of radiation for the system of charges under consideration. The total power of radiation will be calculated at the laboratory time $t=0$, which is the time when the charge characterized by the number N is on the X axis.

If the electric and magnetic fields of the charge characterized by the number k are denoted by $\mathbf{E}_k$ and $\mathbf{B}_k$, respectively, the total power of radiation can be written as follows:

$$\frac{c}{4\pi}\int\{(\mathbf{E}_1+\mathbf{E}_2+\cdots+\mathbf{E}_N)\times(\mathbf{B}_1+\mathbf{B}_2+\cdots+\mathbf{B}_N)\}\cdot\mathbf{d\Sigma}, \tag{3.3}$$

where the integral is carried out over the surface of a torus that encloses the charges' orbit. In Eq. (3.3) there are N terms that involve only the fields of one charge. Now, since the above discussion about the symmetries applies also to the case of only one charge in circular motion, the integral over the surface of the torus of the Poynting vector associated with the field of one charge gives, of course, the total power of radiation of a monoenergetic electron in circular orbit, which is $(2e^2c/3a^2)\beta^4\gamma^4$. Let us emphasize that the corresponding calculation does not present any trouble in the limit when the radius of the torus goes to zero.[9]

The interference part of the rate of radiation (3.3) associated with the field of the charge N appears only in the terms

$$\frac{c}{4\pi}\int(\mathbf{E}_N\times\mathbf{B}_k+\mathbf{E}_k\times\mathbf{B}_N)\cdot\mathbf{d\Sigma}, \tag{3.4}$$

where k takes the values $1,2,...,N-1$. In Fig. 2 the surface of the torus over which the instantaneous energy flux (3.4) is evaluated is shown. This torus is characterized by the radius b of the circumference determined by the intersection of the torus surface with the planes that contain the Z axis, which, in turn, are determined by means of the azimuthal angle φ. A point over a circumference of radius b is defined by means of the angle θ, which is measured from the $X-Y$ plane and ranges between 0 and 2π.

The surface element of the torus is given by

$$\mathbf{d\Sigma}=a^2\epsilon(1+\epsilon\cos\theta)\hat{\mathbf{b}}\,d\theta\,d\varphi, \tag{3.5}$$

where $\epsilon=b/a<1$, and $\hat{\mathbf{b}}$ is the outer unit normal to the torus, given by

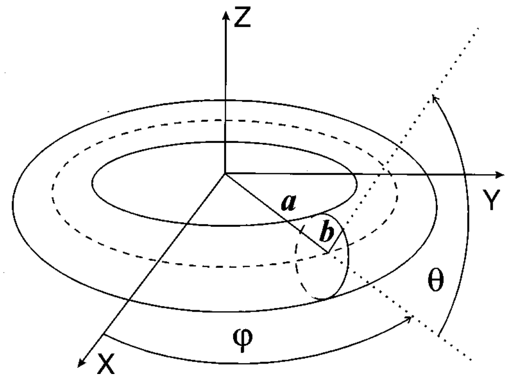

FIG. 2. The toroidal surface of radius b enclosing the electron orbit. Point P over the surface of the torus is characterized by the azimuthal angle φ that specifies a particular cross section, and the angle θ that locates P over the circumference of the latter.

$$\hat{\mathbf{b}}=(\cos\theta\cos\varphi)\hat{\mathbf{x}}+(\cos\theta\sin\varphi)\hat{\mathbf{y}}+(\sin\theta)\hat{\mathbf{z}}. \tag{3.6}$$

The detection point $\mathbf{x}$ over the surface of the torus can be written as follows:

$$\mathbf{x}=[a(1+\epsilon\cos\theta)\cos\varphi]\hat{\mathbf{x}}+[a(\mathbf{1}+\epsilon\cos\theta)\sin\varphi]\hat{\mathbf{y}}+[b\sin\theta]\hat{\mathbf{z}}. \tag{3.7}$$

Therefore the retarded times t'_N and t'_k of the charges N and k, respectively, that are associated with the point $\mathbf{x}$ of (3.7) and time $t=0$ are such that

$$\omega t=0=\omega t'_N+\beta\rho_N=\omega t'_k+\beta\rho_k, \tag{3.8}$$

where

$$\rho_N=\{\epsilon^2+2(1+\epsilon\cos\theta)(1-\cos x)\}^{1/2}, \tag{3.9}$$

and

$$\rho_k=\{\epsilon^2+2(1+\epsilon\cos\theta)(1-\cos y)\}^{1/2}. \tag{3.10}$$

In Eqs. (3.9) and (3.10), the variables x and y are the following:

$$x=\varphi-\omega t'_N, \tag{3.11}$$

$$y=\varphi-\omega t'_k-k(2\pi/N). \tag{3.12}$$

According to Eq. (3.8), the variables x and y are linked by

$$y-x+k(2\pi/N)=\beta(\rho_k-\rho_N). \tag{3.13}$$

In the limit when the radius of the torus goes to zero, that is, when the parameter ϵ tends to zero, the surface element (3.5), as well as the surface of the torus, goes to zero. But, as is already known, the integral (3.4) cannot be zero; so $\mathbf{E}_N\times\mathbf{B}_k+\mathbf{E}_k\times\mathbf{B}_N$ must be singular in some points in this limit. From a physical point of view this behavior is rather trivial because the fields of the charges N and k are singular at the points where these charges are located at $t=0$. From a mathematical point of view, the singular behavior can be easily seen, since the distances to the charges are measured by means of the quantities ρ_N and ρ_k given in (3.9) and (3.10), respectively; but ρ_N is zero for $\epsilon=0$ and $x=0$, while ρ_k is zero for $\epsilon=0$ and $y=0$. Now, for points very close to the charge N the retarded time t'_N is almost equal to the actual time t, which is zero; so according to (3.11), $x=0$ corresponds to $\varphi=0$, that it is precisely the point where the charge N is located at $t=0$. Similarly, from (3.12) it follows that y is zero for $\varphi=k(2\pi/N)$, that it is the point of the orbit where the charge k is located at $t=0$. Therefore, for a very small ϵ the integrand of (3.4) is very close to zero everywhere, with the only exception of two small vicinities around $\varphi=0$ and $\varphi=k(2\pi/N)$.

In what follows we will study the contribution of (3.4) around $\varphi=0$ for ϵ very small. The electric and magnetic fields of charge k, that is, $\mathbf{E}_k$ and $\mathbf{B}_k$, respectively, are smooth functions of φ around $\varphi=0$; so the contribution of (3.4) around $\varphi=0$ can be written in the form

$$\left(\frac{c}{4\pi}\right)\mathbf{B}_k\cdot\int_{\varphi\approx 0}(\hat{\mathbf{b}}\times\mathbf{E}_N)d\Sigma+\left(\frac{c}{4\pi}\right)\mathbf{E}_k\cdot\int_{\varphi\approx 0}(\mathbf{B}_N\times\hat{\mathbf{b}})d\Sigma. \tag{3.14}$$

Here $\hat{\mathbf{b}}\times\mathbf{E}_N$ and $\mathbf{B}_N\times\hat{\mathbf{b}}$ are sharply defined around $\varphi=0$, and thus the integrals must be carefully carried out. Since in the limit ϵ going to zero only a small vicinity around $\varphi=0$ needs to be considered, it is evident that its contribution is fully taken into account if the variable φ covers the whole range $0\leqslant\varphi<2\pi$. Moreover, instead of φ it is convenient to use the variable x defined in (3.11) to carry out the integration around the ribbon of the torus. From (3.11) and (3.8), it follows that

$$\frac{d\varphi}{dx}=s_N>0, \tag{3.15}$$

which shows that φ is a strictly increasing function of x. From (3.11) it also follows that the limits of integration in the variable x are x_0 and $x_0+2\pi$, with $x_0=-\omega t_N'(\varphi=0)=-\omega t_N'(\varphi=2\pi)$. But, as it is easy to see, the variable x appears in the integrand only as $\sin x$ and $\cos x$; thus, the integrand is a periodic function of x and, therefore, x_0 can be put equal to zero. Finally, in order to get a systematic procedure to study the different contributions in (3.14), it is convenient to replace $\sin x$ in terms of the corresponding s_N of (2.2) and $\cos x$ in terms of ρ_N given in (3.9), that is,

$$\sin x=\frac{\rho_N(1-s_N)}{\beta(1+\epsilon\cos\theta)},$$
$$\cos x=1-\frac{\rho_N-\epsilon^2}{2(1+\epsilon\cos\theta)}. \tag{3.16}$$

In this way, all the contributions to the energy flux across the ribbon of the torus between θ and $\theta+d\theta$ in (3.14) are expressed in terms of integrals of the type

$$I(n,p,q)=\epsilon^n\int_0^{2\pi}\frac{dx}{(s_N)^p(\rho_N)^q}, \tag{3.17}$$

with $n\geqslant 1$ due to Eq. (3.5) for the surface element.

Before going to the explicit evaluation of (3.17), let us remember that when (3.14) is evaluated for different values of k, that is, for $k=1,2,...,N-1$, the result will represent that part of the total power of radiation associated with the interference of the field of charge N with the field of the rest of the charges. We are not considering the second contribution that comes from the peak associated with $y=0$ in (3.4), because this will be part of the power of radiation associated with the interference of the field of charge k with the field of the rest of the charges, that is, with the field of the charges $k+1,k+2,...,N,1,2,...,k-1$. But because of the symmetries, the contribution to the total power of radiation of the interference between the field of the charge k with the rest is, of course, identical with the contribution that comes from the interference of the field of charge N with the rest of the charges.

In what follows we will study (3.17) in order to obtain the leading terms of a power series representation of the integral in the parameter ϵ, and where all the terms that vanish in the limit $\epsilon\to 0$ are thrown away. To this end, note that the quantity $\hat{\mathbf{n}}_N\cdot\boldsymbol{\beta}_N=\beta(1+\epsilon\cos\theta)\sin x/\rho_N$ in (2.2) is less than one, which allows us to expand the s_N factor in Eq. (3.17):

$$I(n,p,q)=\sum_{m=0}^{\infty}\frac{a_m^p\beta^{2m}(1+\epsilon\cos\theta)^{2m}}{[\epsilon^2+2(1+\epsilon\cos\theta)]^{(2m+q)/2}}\cdot 2\epsilon^n\int_0^{\pi}\frac{(\sin x)^{2m}dx}{(1-\delta\cos x)^{m+q/2}}, \tag{3.18}$$

where we have written Eq. (3.9) in the form

$$\rho_N=[\epsilon^2+2(1+\epsilon\cos\theta)]^{1/2}\{1-\delta\cos x\}^{1/2}, \tag{3.19}$$

with

$$\delta=\frac{2(1+\epsilon\cos\theta)}{\epsilon^2+2(1+\epsilon\cos\theta)}<1, \tag{3.20}$$

and where

$$a_m^p=\frac{(2m+p-1)!}{(2m)!(p-1)!}. \tag{3.21}$$

Note that, if we exclude a small vicinity of $x=0$ in the integral of (3.18), and since $\delta<1$ and $\cos\alpha>\cos x$ for $x>\alpha$, then

$$\epsilon^n\int_{\alpha}^{\pi}\frac{(\sin x)^{2m}dx}{(1-\delta\cos x)^r}<\frac{\epsilon^n}{(1-\cos\alpha)^r}\int_{\alpha}^{\pi}(\sin x)^{2m}dx. \tag{3.22}$$

The right-hand side of Eq. (3.22) goes to 0 when ϵ goes to 0, which shows that it is sufficient to consider an arbitrarily small vicinity around $x=0$. The use of the whole range $0\leqslant x<2\pi$ is advantageous because it makes it possible to work with analytic expressions for the integral. Thus, the following result will be used:[10]

$$\int_0^{\pi}\frac{(\sin x)^{2m}\,dx}{(1-\delta\cos x)^r}=\frac{\pi^{1/2}\Gamma(m+\frac{1}{2})}{\Gamma(m+1)}\,{}_2F_1((r+1)/2,r/2,m+1,\delta^2), \tag{3.23}$$

where $\Gamma(z)$ is the gamma function and ${}_2F_1(a,b,c,x)$ denotes the hypergeometric function.

Let us study (3.17) in the specific case $q=3$. Then we must use $r=m+\frac{3}{2}$ in (3.23). In order to see clearly the leading terms in (3.23), it is convenient to use the transformation formula[11] for the hypergeometric function,

$$F(a,b,a+b-l,\delta^2)=\frac{\Gamma(l)\Gamma(a+b-l)}{\Gamma(a)\Gamma(b)}(1-\delta^2)^{-l}\sum_{n=0}^{l-1}\frac{(a-l)_n(b-l)_n}{n!(1-l)_n}(1-\delta^2)^n$$
$$+\text{terms irrelevant to the flux}, \tag{3.24}$$

where $(z)_n$ is the Pochhammer symbol,

$$(z)_n=z(z+1)\cdots(z+n-1)=\Gamma(z+n)/\Gamma(z). \tag{3.25}$$

The advantage of using Eq. (3.24) is that, instead of the parameter δ^2 that appears in (3.23) on the right-hand side of (3.24), it appears as

$$1-\delta^2=\frac{\epsilon^2[\epsilon^2+4(1+\epsilon\cos\theta)]}{[\epsilon^2+2(1+\epsilon\cos\theta)]^2}, \tag{3.26}$$

which goes to zero as ϵ^2 when $\epsilon\to 0$. The irrelevant terms that are not explicitly given in (3.24) vanish in the limit $\epsilon\to 0$, except one of them that diverges as $\log\epsilon$. However, this is of no importance in the calculation of the energy flux because of the overall factor ϵ^n in (3.17) with $n\geqslant 1$.

Therefore, the leading term in Eq. (3.23) is

$$\epsilon^n\,{}_2F_1(m/2+\tfrac{5}{4},m/2+\tfrac{3}{4},m+1,\delta^2)=\frac{\epsilon^n\Gamma(m+1)}{\Gamma(m/2+\frac{3}{4})\Gamma(m/2+\frac{5}{4})}(1-\delta^2)^{-1}. \tag{3.27}$$

Now, using

$$\Gamma(m/2+\tfrac{3}{4})\Gamma(m/2+\tfrac{5}{4})=(2\pi)^{1/2}2^{-(m+2)}(2m+1)\Gamma(m+\tfrac{1}{2}), \tag{3.28}$$

replacing Eqs. (3.23), (3.27), and (3.26) in Eq. (3.18), and expanding the expressions containing ϵ, we get, for the leading terms of $I(n,p,3)$,

$$I(n,p,3)=2\sum_{m=0}^{\infty}\frac{a_m^p\beta^{2m}}{(2m+1)}\epsilon^{n-2}\left\{1+\frac{(2m-1)\cos\theta}{2}\epsilon+\cdots\right\}. \tag{3.29}$$

The same ideas as above are easily applied to Eq. (3.17) in the cases $q=2$ and $q=1$. In the case $q=2$, we obtain

$$I(n,p,2)=\pi\sum_m a_m^p\beta^{2m}\frac{(2m-1)!!}{(2m)!!}\epsilon^{n-1}\left\{1+\frac{(2m-1)\cos\theta-2m}{2}\epsilon+\cdots\right\}, \tag{3.30}$$

while in the case $q=1$, and since $n\geqslant 1$, it is found that $I(n,p,1)$ always vanishes in the limit when ϵ goes to zero. Of course, the cases $q\geqslant 0$ also vanish in this limit.

By using the above rules, it follows that in the limit $\epsilon\to 0$ the first term of (3.14) vanishes. In the second term, in order to simplify more easily the results, it is convenient to introduce the components of the field $\mathbf{E}_k$ under the integral sign. The following nonvanishing terms result in the limit $\epsilon\to 0$,

$$\left(\frac{e^2c}{4\pi a^2}\right)\left\{\frac{-\beta\gamma^{-4}\sin y_0}{s_k^3\rho_k^3}+\frac{\beta^2\gamma^{-4}\cos y_0}{s_k^3\rho_k^2}+\frac{\beta^3\gamma^{-2}\sin y_0}{s_k^2\rho_k}+\frac{\beta^4\gamma^{-2}\cos y_0(1-\cos y_0)}{s_k^3\rho_k^2}\right.$$
$$\left.-\frac{\beta^3\gamma^{-2}\sin y_0(1-\cos y_0)}{s_k^3\rho_k^3}\right\}\cdot\int_0^{2\pi}d\theta\int_0^{2\pi}\frac{\epsilon^2\,dx}{s_N^2\rho_N^3}, \tag{3.31}$$

where it is understood that the factors s_k and ρ_k in the curly brackets of Eq. (3.31) are evaluated at $y=y_0$, which is given by the retardation condition, Eq. (3.13), with $x=0$ and $\epsilon=0$.

The integral in Eq. (3.31) has $q=3$, $n=2$, $p=2$, so only the factor 1 in the curly brackets of (3.29) must be retained. In addition, Eq. (3.21) implies $a_m^p=(2m+1)$ and therefore the integral in Eq. (3.31) becomes

$$\int_0^{2\pi}d\theta\cdot 2\sum_{m=0}^{\infty}\beta^{2m}=4\pi\gamma^2.$$

As mentioned above, the value of y_0 in Eq. (3.31) is determined by the implicit equation

$$y_0+2k\pi/N=\beta\{2(1-\cos y_0)\}^{1/2}. \tag{3.32}$$

By plotting both sides of (3.32) as a function of y_0, it is easily seen that $-2k\pi/N < y_0 < 0$, and therefore Eq. (3.32) can be written as

$$k\pi/N = -\frac{y_0}{2} - \beta \sin\frac{y_0}{2}, \tag{3.33}$$

which, upon comparison with Eq. (2.4), shows that

$$y_0 = -2\alpha_k. \tag{3.34}$$

Then, by substituting Eq. (3.34) into Eq. (3.31) and comparing with Eq. (2.7) for the retarded field of particle k over particle N, it is easily verified that the flux over the torus in Eq. (3.4) takes the value $-evE_{ky}$, and, therefore, when the whole system of charges is considered, Eq. (2.11), derived from the Lorentz–Dirac equations, is obtained again.

IV. THE EXTERNAL ELECTRIC FIELD FOR LARGE *N*

In this section we are going to study in detail the dependence of the external electric field E^{ext} given by Eq. (2.6), as a function of the number of charges N for large values of N. For this purpose it is convenient to write the retarded electric field E_{ky} of Eq. (2.6) in a slightly different form that is more appropriate for obtaining a representation of it as a power series in the parameter β.

The retarded field E_{ky} depends, of course, in an explicit way of β, but since according to Eq. (2.4) the angle α_k is a function of β, E_{ky} also depends implicitly on β. From this last equation it is easy to obtain

$$\frac{\partial \alpha_k}{\partial \beta} = -\frac{\sin \alpha_k}{s_k}, \tag{4.1}$$

which shows that α_k is a decreasing function of β, on account of the fact that $0 < \alpha_k < \pi$ and $s_k > 0$. The partial derivation symbol is used in (4.1) because the angle α_k depends also on the variable $k\pi/N$, which is completely independent of β. With the help of (4.1) it is easy to see that (2.7) can be written in the following form:

$$E_{ky} = -\frac{e}{4a^2}\left\{(1-\beta^2)\frac{\partial}{\partial \beta}\cdot\left(\frac{1}{s_k \sin^2 \alpha_k}\right) + 2\beta^2 \frac{\partial}{\partial \beta}\left(\frac{1}{s_k}\right)\right\}. \tag{4.2}$$

The right-hand side of Eq. (4.2) can be written as a power series in β with the help of the formalism of Watson's book.[7] For this purpose it is convenient to replace the discrete variable $k\pi/N$ of Eq. (2.4) by a continuous variable ψ, that is,

$$\psi = \alpha + \beta \sin \alpha. \tag{4.3}$$

If in Eq. (4.3) β is changed by minus the parameter of eccentricity associated with the elliptical orbit of the inverse square law force, Eq. (4.3) becomes identical with the equation of motion of Kepler's problem. Watson presents a detailed treatment of Eq. (4.3) in his book.[7] The pertinent part of Watson's book will be sketched here. From Eq. (4.3), it follows that

$$\frac{\partial \alpha}{\partial \psi} = \frac{1}{s} > 0, \tag{4.4}$$

where $s = 1 + \beta \cos \alpha$ is the same that appears in Eq. (2.5), but without the subindex k. Equation (4.4) shows that α is an increasing function of ψ and the effect of increasing ψ by 2π is to increase α by 2π. Therefore, $1/(1+\beta\cos\alpha)$ is an even periodic function of ψ, and so it can be expanded in a Fourier cosines series, which turns out to be

$$\frac{1}{s}=1+2\sum_{n=1}^{\infty} J_n(-n\beta)\cos(n\psi), \tag{4.5}$$

where $J_n(x)$ is the Bessel function. When Eq. (4.5) is introduced on the right-hand side of

$$\frac{\partial}{\partial\beta}\left(\frac{1}{s\sin\alpha}\right)=-\frac{\partial}{\partial\psi}\left(\frac{1}{s}\right), \tag{4.6}$$

the following expansion is obtained for the function $1/(s\sin\alpha)$:

$$\frac{1}{s\sin\alpha}=\frac{1}{\sin\psi}+2\sum_{n=1}^{\infty} n\sin(n\psi)\int_0^{\beta} J_n(-nx)dx. \tag{4.7}$$

Now, if this equation is differentiated with respect to ψ, and taking into account that

$$\frac{\cos\alpha}{s^2\sin^2\alpha}-\frac{\beta}{s^3}=\frac{\partial}{\partial\beta}\left(\frac{1}{s\sin^2\alpha}\right), \tag{4.8}$$

the following expansion is obtained:

$$\frac{\partial}{\partial\beta}\left(\frac{1}{s\sin^2\alpha}\right)=\frac{\cos\psi}{\sin^2\psi}-2\sum_{n=1}^{\infty} n^2\cos(n\psi)\int_0^{\beta} J_n(-nx)dx. \tag{4.9}$$

Equations (4.2), (4.5), and (4.9) are reduced to those previously given by Gordeyev[12] for the case of two charges rotating at a constant angular velocity at opposite ends of a diameter.

Equations (4.5) and (4.9), with $\psi=k\pi/N$, allow us to write the tangential component of the retarded electric field E_{ky} of (4.2) as a power series in β. When (4.5), (4.9), and the power series representation for $J_n(x)$ are introduced in (4.2), the following expression for the sum of the retarded tangential electric field is obtained:

$$\sum_{k=1}^{N-1} E_{ky}=-\left(\frac{e}{2a^2}\right)\sum_{n=1}^{\infty}(-1)^n\left[\sum_{k=1}^{N-1}\cos(nk\pi/N)\right] \times\left\{(-n^2D_{n,0}+2C_{n,0})\beta^{n+1}+\sum_{m=0}^{\infty}(-n^2D_{n,m+1}+2C_{n,m+1}+n^2D_{n,m})\beta^{n+2m+3}\right\}, \tag{4.10}$$

where we used the result

$$\sum_{k=1}^{N-1}\frac{\cos(k\pi/N)}{\sin^2(k\pi/N)}=0,$$

and the coefficients C_{nm} and D_{nm} come from the power series representation of $J_n(x)$, and are the following:

$$C_{n,m}=\frac{(-1)^m(n+2m)n^{n+2m}}{2^{n+2m}m!(n+m)!}, \tag{4.11}$$

$$D_{n,m}=\frac{(-1)^m n^{n+2m}}{2^{n+2m}m!(n+m)!(n+2m+1)}. \tag{4.12}$$

The sum over k that appears in (4.10) can be explicitly carried out, since

$$\sum_{k=1}^{N-1} \cos(nk\pi/N) = \begin{cases} 0, & n \text{ odd}, \\ -1, & n \text{ even} < 2N, \\ N-1, & n = 2N, 4N, \ldots . \end{cases} \tag{4.13}$$

From this formula it follows that only odd powers of β remain in (4.10), where, because of (4.13), it is convenient to split the sum over the index n in a part with $n \leqslant 2N-2$, and the rest that contains powers of β higher than $2N+1$. In this way, (4.10) can be written as

$$\sum_{k=1}^{N-1} E_{ky} = \left(\frac{e}{a^2}\right)\Bigg\{[-2D_{2,0}+C_{2,0}]\beta^3 + \sum_{n=1}^{N-2}\Bigg[-2(n+1)^2 D_{2n+2,0} + C_{2n+2,0} + \sum_{m=0}^{n-1}(-2(n-m)^2 D_{2n-2m,m+1} + C_{2n-2m,m+1} + 2(n-m)^2 D_{2n-2m,m})\Bigg]\beta^{2n+3}\Bigg\} + O(\beta^{2N+1}), \tag{4.14}$$

which, when (4.11) and (4.12) are used, is reduced to

$$\sum_{k=1}^{N-1} E_{ky} = \left(\frac{e}{a^2}\right)\Bigg\{\frac{2}{3}\beta^3 + \sum_{n=1}^{N-2}\Bigg[\frac{2(n+2)(n+1)^{2n+3}}{(2n+3)!} + 2\sum_{m=0}^{n-1}\frac{(-1)^m (n-m)^{2n+2}(-7n^2-2n^3-2m^2-3n+4nm)}{(2n+1)(2n+3)(m+1)!(2n+1-m)!}\Bigg]\beta^{2n+3}\Bigg\} + O(\beta^{2N+1}). \tag{4.15}$$

The sums in Eq. (4.15) can be cast in a simpler way by using the new dumb indices $i=n+1$ and $l=n-m$, in terms of which Eq. (4.15) reads as

$$\sum_{k=1}^{N-1} E_{ky} = \left(\frac{e}{a^2}\right)\Bigg\{\frac{2}{3}\beta^3 + 2\sum_{i=2}^{N-1}\sum_{l=1}^{i}\frac{(-1)^{i-l} l^{2i}[2i^3-i^2-i+2l^2]}{(2i-1)(2i+1)(i-l)!(i+l)!}\beta^{2i+1}\Bigg\} + O(\beta^{2N+1}). \tag{4.16}$$

The sum over the index l that appears in the above expression can be carried out with the help of the formulas in the Appendix, and the result is

$$\sum_{k=1}^{N-1} E_{ky} = \frac{2e}{3a^2}\sum_{n=1}^{N-1} n\beta^{2n+1} + O(\beta^{2N+1}). \tag{4.17}$$

Therefore, from Eq. (2.6) the following estimate is obtained for the external electric field:

$$E^{\text{ext}} = O(\beta^{2N+1}). \tag{4.18}$$

Equation (4.18) is valid for arbitrary N, and since $\beta < 1$, it shows that the external electric field tends to zero when the number of charges increases. For a nonrelativistic motion, the interference part of the total power of radiation is very effective in supressing the energy radiated away, even with a moderate number of charges N. But for a highly relativistic motion, a very large number of charges is needed to supress the radiation. This can be understood on account of the high directionality of synchrotron radiation.[8]

We wish to thank to Comisión Nacional de Ciencia y Tecnología de Chile, CONICYT, for support through project FONDECYT 1960179 and 1990297 that has been a determinant to the development of this research. R. Rivera is thankful to Fundación Andes for a doctoral grant.

APPENDIX: SUMS TO USE IN EQ. (4.16)

In this appendix, we will show that

$$S_1=\sum_{l=1}^{i}\frac{(-1)^{i-l}l^{2i}}{(i-l)!(i+l)!}=\frac{1}{2}, \tag{A1}$$

$$S_2=\sum_{l=1}^{i}\frac{(-1)^{i-l}l^{2i+2}}{(i-l)!(i+l)!}=\frac{i(i+1)(2i+1)}{12}. \tag{A2}$$

Let us first rewrite Eq. (A1) in terms of $v=i-l$,

$$S_1=\sum_{v=0}^{i-1}\frac{(-1)^{v}(i-v)^{2i}}{(2i-v)!v!},$$

and note that

$$S_1=\frac{1}{2}\cdot\sum_{v=0}^{2i}\frac{(-1)^{v}(i-v)^{2i}}{(2i-v)!v!},$$

which can be written as

$$S_1=\frac{1}{2(2i)!}\sum_{v=0}^{2i}(-1)^{v}\binom{2i}{v}(i-v)^{2i}. \tag{A3}$$

Therefore, the identity[13]

$$\sum_{k=0}^{n}(-1)^{k}\binom{n}{k}(\alpha+k)^{n}=(-1)^{n}n! \tag{A4}$$

directly leads to Eq. (A1).

Equation (A2) can be proved by induction on i. Here it also proves convenient to write S_2 in the form

$$S_2=\frac{1}{2(2i)!}\sum_{v=0}^{2i}(-1)^{v}\binom{2i}{v}(i-v)^{2i+2}.$$

Then, we want to prove

$$\frac{1}{2(2i+2)!}\sum_{v=0}^{2i+2}(-1)^{v}\binom{2i+2}{v}(i+1-v)^{2i+4}=\frac{(i+1)(i+2)(2i+3)}{12}, \tag{A5}$$

by using the hypothesis

$$\frac{1}{2(2i)!}\sum_{v=0}^{2i}(-1)^{v}\binom{2i}{v}(i-v)^{2i+2}=\frac{i(i+1)(2i+1)}{12}. \tag{A6}$$

To this end, the identity

$$\binom{a}{b}=\binom{a-1}{b}+\binom{a-1}{b-1} \tag{A7}$$

is used twice on the left-hand side of Eq. (A5), which after relabeling the dumb indices reads as

$$\frac{1}{2(2i+2)!}\sum_{v=0}^{2i}(-1)^v\binom{2i}{v}(i+1-v)^{2i+4}-\frac{1}{(2i+2)!}\sum_{v=0}^{2i}(-1)^v\binom{2i}{v}(i-v)^{2i+4}$$
$$+\frac{1}{2(2i+2)!}\sum_{v=0}^{2i}(-1)^v\binom{2i}{v}(i-1-v)^{2i+4}. \tag{A8}$$

Here the binomial theorem is used in the first and third term of Eq. (A8) to expand the powers of $(i-v\pm1)$ into powers of $(i-v)$. After collecting terms and because of the identity[13]

$$\sum_{k=0}^{N}(-1)^k\binom{N}{k}(\alpha+k)^{n-1}=0, \quad n\leqslant N, \tag{A9}$$

only two nonvanishing sums remain. They are easily evaluated by using Eqs. (A6) and (A4), leading directly to the right-hand side of Eq. (A5).

Three-dimensional formulation of the Maxwell equations for stationary space–times

G. F. Torres del Castillo[a)]
Departamento de Física Matemática, Instituto de Ciencias de la Universidad Autónoma de Puebla, 72000 Puebla, Pue., México

J. Mercado-Pérez
Instituto Tecnológico de Toluca, Apartado postal 890, 50000 Metepec, Méx., México

(Received 7 October 1998; accepted for publication 1 February 1999)

Using the correspondence between a stationary space–time and a curved three-dimensional space with a static magnetic field and a conservative field of force, the Maxwell equations in a stationary space–time are expressed in terms of fields associated with the corresponding three-dimensional geometry. The Maxwell equations take a form analogous to the one they have in flat space–time. The Ricci tensor of the space–time is also written in terms of the three-dimensional fields. © *1999 American Institute of Physics.* [S0022-2488(99)01405-X]

I. INTRODUCTION

In the study of the null[1,2] and timelike[2] geodesics of a stationary space–time, a certain decomposition of the metric arises in a natural way in such a manner that, by a suitable change in the parametrization, the problem of finding the geodesics of a stationary space–time is equivalent to finding the orbits of a charged (nonrelativistic) particle in the three-dimensional space of trajectories of the timelike Killing vector field, with a static magnetic field and a velocity-independent potential determined by the space–time metric. When the space–time is static, this magnetic field vanishes and the metric defined on the three-dimensional space mentioned above reduces to the so-called ''optical metric,'' which has many remarkable properties (see, e.g., Refs. 3, 4 and the references cited therein). One of these properties is the fact that the Maxwell equations in a static space–time take their simplest form (the one they have in an inertial frame in flat space–time) when expressed in terms of the optical metric.[4] In this paper we show that, in a similar manner, the decomposition of the metric of a stationary space–time found in Refs. 1 and 2 is not only distinguished by the dynamics of test particles, but also by the fact that the Maxwell equations can be written in the same form as in an inertial frame in flat space–time.

In Sec. II we write down explicitly the geodesic equation in a stationary space–time and we show its equivalence with the equations of motion of a charged particle in a three-dimensional space subject to a magnetic field and a velocity-independent potential. We also show that from the symmetries of this three-dimensional space that leave the magnetic field and the velocity-independent potential invariant one can obtain symmetries of the space–time metric. In Sec. III the Maxwell equations in a stationary space–time are written in a $3+1$ form, making use of the decomposition of the metric given in Sec. II. We find that the Maxwell equations can be expressed in the same form as in flat space-time, though, among other things, in the present case the three-dimensional space can be curved. The signature of the space–time metric is taken as $(-\,+\,+\,+)$, lower case Greek indices run from 0 to 3, and lower case Latin indices run from 1 to 3.

II. DECOMPOSITION OF THE SPACE–TIME METRIC

As shown in Ref. 2, the geodesic equation for a test particle with a nonvanishing rest mass in a stationary space–time is equivalent to the equations of motion of a charged (nonrelativistic)

[a)]Electronic mail: gtorres@fcfm.buap.mx

particle in a, possibly curved, three-dimensional space in the presence of a static magnetic field and a conservative field of force. Indeed, if $ds^2 = g_{\alpha\beta}\, dx^\alpha\, dx^\beta$ is the metric of a stationary space–time expressed in a coordinate system such that

$$\frac{\partial g_{\alpha\beta}}{\partial x^0} = 0, \tag{1}$$

we have

$$\begin{aligned} ds^2 &= g_{00}(dx^0)^2 + 2g_{0i}\, dx^0\, dx^i + g_{ij}\, dx^i\, dx^j \\ &= g_{00}\left(dx^0 + \frac{g_{0i}}{g_{00}} dx^i \right)^2 + \left(g_{ij} - \frac{g_{0i}g_{0j}}{g_{00}} \right) dx^i\, dx^j \\ &= g_{00}[(dx^0 - \mathcal{A}_i\, dx^i)^2 - \gamma_{ij}\, dx^i\, dx^j], \end{aligned} \tag{2}$$

with

$$\mathcal{A}_i \equiv \frac{g_{0i}}{(-g_{00})}, \quad \gamma_{ij} \equiv (-g_{00})^{-2}(g_{0i}g_{0j} - g_{00}g_{ij}). \tag{3}$$

The metric tensor,

$$d\sigma^2 \equiv \gamma_{ij}\, dx^i\, dx^j \tag{4}$$

is conformal to the metric in the three-dimensional space of trajectories of the timelike Killing vector field $\partial/\partial x^0$.[5,6,1] When the space–time is static, there exists a coordinate system such that Eq. (1) holds and $g_{0i} = 0$ (i.e., $\mathcal{A}_i = 0$); then the metric $d\sigma^2$ [Eq. (4)] reduces to the so-called *optical metric* (see, e.g., Ref. 4 and the references cited therein).

Making use of Eqs. (2) and (3), one finds that

$$g_{ij} = (-g_{00})(\gamma_{ij} - \mathcal{A}_i\mathcal{A}_j), \quad g_{0i} = (-g_{00})\mathcal{A}_i\,, \tag{5}$$

and

$$g^{ij} = \frac{\gamma^{ij}}{(-g_{00})}, \quad g^{0i} = \frac{\gamma^{ij}\mathcal{A}_j}{(-g_{00})}, \quad g^{00} = \frac{\gamma^{ij}\mathcal{A}_i\mathcal{A}_j - 1}{(-g_{00})}, \tag{6}$$

where (γ^{ij}) denotes the inverse of (γ_{ij}). Then, a straightforward computation shows that the Christoffel symbols corresponding to the metric tensor $g_{\alpha\beta}$, $\Gamma^\alpha_{\beta\gamma}$, are given by

$$\Gamma^0_{00} = \tfrac{1}{2}\gamma^{ij}\mathcal{A}_i\partial_j \ln\phi, \quad \Gamma^i_{00} = \tfrac{1}{2}\gamma^{ij}\partial_j \ln\phi, \quad \Gamma^i_{0j} = \tfrac{1}{2}\gamma^{ik}(\mathcal{B}_{jk} - \mathcal{A}_j\partial_k \ln\phi), \tag{7}$$

where

$$\phi \equiv \tfrac{1}{2}(-g_{00}), \quad \mathcal{B}_{ij} \equiv \partial_i\mathcal{A}_j - \partial_j\mathcal{A}_i\,, \tag{8}$$

and

$$\begin{aligned} \Gamma^0_{0i} &= \tfrac{1}{2}(\partial_i \ln\phi + \gamma^{jk}\mathcal{B}_{ij}\mathcal{A}_k - \mathcal{A}_i\gamma^{jk}\mathcal{A}_k\partial_j \ln\phi), \\ \Gamma^0_{ij} &= -\tilde{\boldsymbol{\nabla}}_{(i}\mathcal{A}_{j)} + \gamma^{km}\mathcal{A}_k\mathcal{B}_{m(i}\mathcal{A}_{j)} + \tfrac{1}{2}(\mathcal{A}_i\mathcal{A}_j - \gamma_{ij})\gamma^{km}\mathcal{A}_k\partial_m \ln\phi, \\ \Gamma^i_{jk} &= \gamma^i_{jk} + \delta^i_{(j}\partial_{k)}\ln\phi + \tfrac{1}{2}(\mathcal{A}_j\mathcal{A}_k - \gamma_{jk})\gamma^{im}\partial_m \ln\phi + \gamma^{im}\mathcal{B}_{m(j}\mathcal{A}_{k)}\,, \end{aligned} \tag{9}$$

where $\tilde{\boldsymbol{\nabla}}$ denotes the covariant derivative compatible with γ_{ij}, γ^i_{jk} denotes the Christoffel symbols for the metric γ_{ij} (e.g., $\tilde{\boldsymbol{\nabla}}_i\mathcal{A}_j=\partial_i\mathcal{A}_j-\gamma^k_{ij}\mathcal{A}_k$), and the parentheses denote symmetrization on the indices enclosed. Therefore, according to Eqs. (7) and (9), the geodesic equations,

$$0=\frac{d^2x^i}{d\lambda^2}+\Gamma^i_{\alpha\beta}\frac{dx^\alpha}{d\lambda}\frac{dx^\beta}{d\lambda}=\frac{d^2x^i}{d\lambda^2}+\Gamma^i_{00}\left(\frac{dx^0}{d\lambda}\right)^2+2\Gamma^i_{0j}\frac{dx^0}{d\lambda}\frac{dx^j}{d\lambda}+\Gamma^i_{jk}\frac{dx^j}{d\lambda}\frac{dx^k}{d\lambda},$$

where λ is the proper time of the particle, amount to

$$0=\frac{d^2x^i}{d\lambda^2}+\tfrac{1}{2}\gamma^{ij}\partial_j\ln\phi\left(\frac{dx^0}{d\lambda}\right)^2+\gamma^{ik}(\mathcal{B}_{jk}-\mathcal{A}_j\partial_k\ln\phi)\frac{dx^0}{d\lambda}\frac{dx^j}{d\lambda}$$
$$+[\gamma^i_{jk}+\delta^i_j\partial_k\ln\phi+\tfrac{1}{2}(\mathcal{A}_j\mathcal{A}_k-\gamma_{jk})\gamma^{im}\partial_m\ln\phi+\gamma^{im}\mathcal{B}_{mj}\mathcal{A}_k]\frac{dx^j}{d\lambda}\frac{dx^k}{d\lambda}. \tag{10}$$

On the other hand, the condition $g_{\alpha\beta}(dx^\alpha/d\lambda)(dx^\beta/d\lambda)=-1$ (which is equivalent to the definition of the proper time), takes the form [see Eq. (2)]

$$(-g_{00})\left[\left(\frac{dx^0}{d\lambda}-\mathcal{A}_i\frac{dx^i}{d\lambda}\right)^2-\gamma_{ij}\frac{dx^i}{d\lambda}\frac{dx^j}{d\lambda}\right]=1, \tag{11}$$

and since $\partial/\partial x^0$ is a Killing vector field [see Eq. (1)], $g_{0\alpha}(dx^\alpha/d\lambda)\equiv-\epsilon$ is a constant of the motion. Making use of Eq. (5), we find that

$$\epsilon=(-g_{00})\left(\frac{dx^0}{d\lambda}-\mathcal{A}_i\frac{dx^i}{d\lambda}\right), \tag{12}$$

and substituting Eq. (12) into Eq. (11), it follows that

$$\gamma_{ij}\frac{dx^i}{d\lambda}\frac{dx^j}{d\lambda}=\frac{\epsilon^2}{(-g_{00})^2}-\frac{1}{(-g_{00})}. \tag{13}$$

Now, with the aid of Eq. (12), we can eliminate $dx^0/d\lambda$ from Eq. (10), and making use of Eq. (13) we obtain

$$0=\frac{d^2x^i}{d\lambda^2}+\frac{\epsilon}{(-g_{00})}\gamma^{ik}\mathcal{B}_{jk}\frac{dx^j}{d\lambda}+\gamma^i_{jk}\frac{dx^j}{d\lambda}\frac{dx^k}{d\lambda}+\frac{dx^i}{d\lambda}\partial_k\ln\phi\frac{dx^k}{d\lambda}+\frac{1}{2(-g_{00})}\gamma^{im}\partial_m\ln\phi. \tag{14}$$

Introducing a new parameter, τ, in place of the proper time λ by means of

$$d\tau\equiv\frac{d\lambda}{(-g_{00})}, \tag{15}$$

one can get rid of the fourth term on the right-hand side of Eq. (14) and this last equation can be written in the form

$$\frac{d^2x^i}{d\tau^2}+\gamma^i_{jk}\frac{dx^j}{d\tau}\frac{dx^k}{d\tau}=\epsilon\gamma^{ik}\mathcal{B}_{kj}\frac{dx^j}{d\tau}-\gamma^{im}\partial_m\phi, \tag{16}$$

which are the equations of motion of a nonrelativistic particle of unit mass and electric charge ϵ in a three-dimensional space with metric (4), in the presence of a magnetic field with vector potential $\mathcal{A}_i$ and a potential ϕ. If one has found the solution of the equations of motion (16), $x^i=x^i(\tau)$, then Eqs. (12) and (15) yield $dx^0/d\tau=\epsilon+\mathcal{A}_i\,dx^i/d\tau$, which determines x^0 as a function of τ, and the original affine parameter λ is given by $\lambda=\int-g_{00}(x^i(\tau))d\tau$.

In the case of the equations for the null geodesics of ds^2, the right-hand side of Eq. (11) is equal to zero, where λ is now an affine parameter of the geodesic. Then, the last term on the right-hand side of Eqs. (13), (14), and (16) is absent and one recovers the result of Ref. 1. When $\mathcal{A}_i\,dx^i$ is exact, by replacing dx^0 by $dx'^0 \equiv dx^0 - \mathcal{A}_i\,dx^i$, one finds explicitly that the space–time is static and the ''magnetic field,'' $\mathcal{B}_{ij}$, vanishes.

The symmetries of the space–time metric $g_{\alpha\beta}$ do not necessarily correspond to symmetries of the three-dimensional metric γ_{ij}. In fact, with the aid of Eqs. (5), one finds that the Killing equations, $K^\mu\,\partial_\mu g_{\alpha\beta} + 2g_{\mu(\alpha}\partial_{\beta)}K^\mu = 0$, amount to the set of equations

$$\begin{gathered} K^i\partial_i \ln\phi = -2\partial_0(K^0 - \mathcal{A}_iK^i), \\ K^j\,\partial_j\mathcal{A}_i + \mathcal{A}_j\,\partial_iK^j = \partial_0(K^0 - \mathcal{A}_jK^j)\mathcal{A}_i + \partial_iK^0 - \gamma_{ij}\,\partial_0K^j, \\ K^k\,\partial_k\gamma_{ij} + 2\gamma_{k(i}\partial_{j)}K^k = 2\partial_0(K^0 - \mathcal{A}_kK^k)\gamma_{ij} - 2\mathcal{A}_{(i}\gamma_{j)k}\,\partial_0K^k. \end{gathered} \tag{17}$$

However, if $K^i\partial_i$ is a Killing vector field of γ_{ij}, with $\partial_0K^i = 0$, and the Lie derivatives of ϕ and $\mathcal{B}_{ij}\,dx^i \wedge dx^j$ along $K^i\partial_i$ vanish, then Eqs. (17) are satisfied if we take K^0 in such a way that $\partial_0K^0 = 0$ and

$$K^j\,\partial_j\mathcal{A}_i + \mathcal{A}_j\,\partial_iK^j = \partial_iK^0. \tag{18}$$

The integrability conditions of these equations for K^0 are satisfied by virtue of the assumed invariance of $\mathcal{B}_{ij}\,dx^i \wedge dx^j$ under the transformatious generated by $K^i\partial_i$.

For example, the Taub-NUT metric,[7]

$$ds^2 = -\left[\frac{r^2 - 2mr - l^2}{r^2 + l^2}\right]\left\{(dt + 2l\cos\theta\,d\varphi)^2 - \frac{(r^2+l^2)^2\,dr^2}{(r^2 - 2mr - l^2)^2} - \frac{(r^2+l^2)^2(d\theta^2 + \sin^2\theta\,d\varphi^2)}{r^2 - 2mr - l^2}\right\}, \tag{19}$$

where m and l are arbitrary constants, is a stationary solution of the Einstein vacuum field equations in the region where $r^2 - 2mr - l^2 > 0$, which reduces to the Schwarzschild metric when $l = 0$. A comparison of Eqs. (2) and (19) shows that we can take $\mathcal{A}_i\,dx^i = -2l\cos\theta\,d\varphi$ and that the corresponding metric $\gamma_{ij}\,dx^i\,dx^j$ is invariant under rotations, i.e., the three-dimensional vector fields,

$$\begin{gathered} K^i_{(1)}\partial_i = -\sin\varphi\,\partial_\theta - \cot\theta\cos\varphi\,\partial_\varphi, \\ K^i_{(2)}\partial_i = \cos\varphi\,\partial_\theta - \cot\theta\sin\varphi\,\partial_\varphi, \\ K^i_{(3)}\partial_i = \partial_\varphi, \end{gathered} \tag{20}$$

which are the generators of rotations on the two-sphere, are Killing vector fields of $d\sigma^2 = \gamma_{ij}\,dx^i\,dx^j$. Furthermore, the Lie derivative of $\mathcal{B}_{ij}\,dx^i \wedge dx^j = 4l\sin\theta\,d\theta \wedge d\varphi$ and ϕ (which depends on r only) with respect to the vector fields (20) vanish and, therefore, by integrating Eq. (18) one obtains three Killing vector fields of the metric (19), induced by the Killing vector fields of $d\sigma^2$ given by Eqs. (20). It is easy to see that the substitution of Eqs. (20) into Eq. (18) yields (setting the constant of integration equal to zero), $K^0_{(1)} = 2l\,\mathrm{cosec}\,\theta\cos\varphi$, $K^0_{(2)} = 2l\,\mathrm{cosec}\,\theta\sin\varphi$, $K^0_{(3)} = 0$. [This computation is simplified by noticing that on the left-hand side of Eq. (18) are the components of the Lie derivative along $K^i\partial_i$ of the 1-form $\mathcal{A}_i\,dx^i$, hence, in the present case, Eq. (18) reduces to $\pounds_{K^i\partial_i}(-2l\cos\theta\,d\varphi) = dK^0$.] Thus, the vector fields,

$$K^{\alpha}_{(1)}\partial_\alpha = -\sin\varphi\,\partial_\theta - \cot\theta\cos\varphi\,\partial_\varphi + 2l\,\mathrm{cosec}\,\theta\cos\varphi\,\partial_0,$$

$$K^{\alpha}_{(2)}\partial_\alpha = \cos\varphi\,\partial_\theta - \cot\theta\sin\varphi\,\partial_\varphi + 2l\,\mathrm{cosec}\,\theta\sin\varphi\,\partial_0, \tag{21}$$

$$K^{\alpha}_{(3)}\partial_\alpha = \partial_\varphi,$$

are Killing vector fields of the space–time metric (19).

A straightfoward computation shows that the Killing vector fields (21) satisfy the same commutation relations as those of (20); however, for other stationary metrics, the Lie algebra of the Killing vector fields induced in this manner is a central extension of the Lie algebra of the three-dimensional vector fields that leave $d\sigma^2$, $\mathcal{B}_{ij}\,dx^i\wedge dx^j$, and ϕ invariant. As a matter of fact, assuming that $K^i_{(a)}\partial_i (a=1,...,r)$ are Killing vector fields of $d\sigma^2$ that leave $\mathcal{B}_{ij}\,dx^i\wedge dx^j$ and ϕ invariant with $[K^i_{(a)}\partial_i, K^j_{(b)}\partial_j] = c^d_{ab}K^i_{(d)}\partial_i$, one finds

$$[K^\alpha_{(a)}\partial_\alpha, K^\beta_{(b)}\partial_\beta] = c^d_{ab}K^\alpha_{(d)}\partial_\alpha + f_{ab}\partial_0, \tag{22}$$

where

$$f_{ab} \equiv K^i_{(a)}\partial_i K^0_{(b)} - K^i_{(b)}\partial_i K^0_{(a)} - c^d_{ab}K^0_{(d)}. \tag{23}$$

One can show that the f_{ab} are constant making use of Eq. (18).

A simple example of a stationary metric for which the f_{ab} are not all equal to zero is provided by

$$ds^2 = -\frac{Q(y)}{y^2+a^2}\left\{(du - 2ax\,dv)^2 - \frac{(y^2+a^2)^2}{Q(y)^2}[dy^2 + Q(y)(dx^2+dv^2)]\right\}, \tag{24}$$

where $Q(y) = -2My + b$, and a, b and M are real constants.[8] Taking $x^0 = u$, $\phi = Q(y)/[2(y^2+a^2)]$ and $\mathcal{A}_i\,dx^i = 2ax\,dv$ [see Eqs. (2) and (8)], we find that $\mathcal{B}_{ij}\,dx^i\wedge dx^j = 4a\,dx\wedge dv$ and, evidently, $K^i_{(1)}\partial_i = \partial_x$, $K^i_{(2)}\partial_i = \partial_v$, and $K^i_{(3)}\partial_i = x\partial_v - v\partial_x$ are three Killing vector fields of $d\sigma^2$ that leave $\mathcal{B}_{ij}\,dx^i\wedge dx^j$ and ϕ invariant. The only nonvanishing commutators between these vector fields are $[K^i_{(1)}\partial_i, K^j_{(3)}\partial_j] = K^i_{(2)}\partial_i$, and $[K^i_{(2)}\partial_i, K^j_{(3)}\partial_j] = -K^i_{(1)}\partial_i$. Then, from Eq. (18) one obtains $K^0_{(1)} = 2av$, $K^0_{(2)} = 0$, and $K^0_{(3)} = a(x^2 - v^2)$ (setting the constants of integration equal to zero) and, according to Eq. (23), $f_{12} = \partial_x K^0_{(2)} - \partial_v K^0_{(1)} = -2a$; similarly, one finds that $f_{13} = f_{23} = 0$. Thus, $K^\alpha_{(1)}\partial_\alpha = \partial_x + 2av\,\partial_u$, $K^\alpha_{(2)}\partial_\alpha = \partial_v$, and $K^\alpha_{(3)}\partial_\alpha = x\partial_v - v\partial_x + a(x^2-v^2)\partial_u$ are Killing vector fields of the metric (24) induced by Killing vector fields of $d\sigma^2$.

III. FIELD EQUATIONS

The Maxwell equations,

$$\nabla_\beta F^{\alpha\beta} = 4\pi J^\alpha \tag{25}$$

and

$$\partial_\alpha F_{\beta\gamma} + \partial_\beta F_{\gamma\alpha} + \partial_\gamma F_{\alpha\beta} = 0, \tag{26}$$

can be written in terms of the three-dimensional quantities,

$$D^i \equiv (-g_{00})^2 F^{0i}, \quad H^{ij} \equiv (-g_{00})^2 F^{ij}, \tag{27}$$

and

$$E_i \equiv F_{i0}, \quad B_{ij} \equiv F_{ij}. \tag{28}$$

Recalling that $\nabla_\beta F^{\alpha\beta}=(1/\sqrt{|g|})\partial_\beta(\sqrt{|g|}F^{\alpha\beta})$, where $g\equiv\det(g_{\alpha\beta})$, and noting that from Eqs. (5) it follows that

$$g=-(-g_{00})^4\gamma, \tag{29}$$

where $\gamma\equiv\det(\gamma_{ij})$, one finds that Eq. (25) amounts to

$$\frac{1}{\sqrt{\gamma}}\partial_i(\sqrt{\gamma}D^i)=4\pi\tilde{\rho}, \quad \frac{1}{\sqrt{\gamma}}\partial_i(\sqrt{\gamma}H^{ki})-\partial_0 D^k=4\pi\tilde{j}^k, \tag{30}$$

where we have introduced the definitions

$$\tilde{\rho}\equiv(-g_{00})^2J^0, \quad \tilde{j}^k\equiv(-g_{00})^2J^k. \tag{31}$$

Note that $(1/\sqrt{\gamma})\partial_i(\sqrt{\gamma}D^i)=\tilde{\nabla}_i D^i$ and $(1/\sqrt{\gamma})\partial_i(\sqrt{\gamma}H^{ki})=\tilde{\nabla}_i H^{ki}$. According to Eqs. (29) and (31), $\sqrt{\gamma}\tilde{\rho}=\sqrt{|g|}J^0$, therefore $\tilde{\rho}$ indeed corresponds to the charge density, according to the volume defined by (γ_{ij}).

The remaining Maxwell equations [Eqs. (26)] are equivalent to $\epsilon^{ijk}\partial_i B_{jk}=0$ and $\partial_0 B_{ij}+\partial_i E_j-\partial_j E_i=0$ [see Eqs. (28)] or, in terms of the dual of B_{ij} and E_i,

$$B^k\equiv\frac{1}{2\sqrt{\gamma}}\epsilon^{kij}B_{ij}, \quad E^{ij}\equiv\frac{1}{\sqrt{\gamma}}\epsilon^{ijk}E_k, \tag{32}$$

we have

$$\frac{1}{\sqrt{\gamma}}\partial_i(\sqrt{\gamma}B^i)=0, \quad \frac{1}{\sqrt{\gamma}}\partial_i(\sqrt{\gamma}E^{ki})+\partial_0 B^k=0. \tag{33}$$

Making use of Eqs. (5), (6), (27), and (28) one easily finds that

$$E^i=D^i+\mathcal{A}_j H^{ij}, \quad H_{ij}=B_{ij}+E_i\mathcal{A}_j-E_j\mathcal{A}_i, \tag{34}$$

with the indices of the three-dimensional quantities being raised and lowered by means of γ^{ij} and γ_{ij}. Expressions (34) are somewhat similar to those given in Ref. 9, p. 257 (cf. also Ref. 10 and the references cited therein); but when $\mathcal{A}_i=0$ (static case) our formulas yield the simple relations $E_i=D_i$, $H_{ij}=B_{ij}$, and Eqs. (30) and (33) reduce to the expressions obtained in Ref. 4.

It should be stressed that, from the physical point of view, our results are equivalent to those of, e.g., Ref. 9, or of any other formulation of the Maxwell equations. The difference in the mathematical appearance of the equations comes from the use of the three-dimensional metric (γ_{ij}), which does not define the spatial lengths [see Eq. (2)].

If $\mathcal{A}$, $\tilde{\mathbf{j}}$, $\mathbf{E}$, $\mathbf{B}$, $\mathbf{D}$, and $\mathbf{H}$ are the three-dimensional vector fields with components $\mathcal{A}^i$, $\tilde{j}^i$, E^i, B^i, D^i, and H^i (where H^i is the dual of H_{ij}), respectively, then Eqs. (30), (33), and (34) take the form

$$\begin{aligned}\operatorname{div}\mathbf{D}&=4\pi\tilde{\rho}, \quad \operatorname{curl}\mathbf{H}-\partial_0\mathbf{D}=4\pi\tilde{\mathbf{j}},\\ \operatorname{div}\mathbf{B}&=0, \quad \operatorname{curl}\mathbf{E}+\partial_0\mathbf{B}=0\end{aligned} \tag{35}$$

and

$$\mathbf{E}=\mathbf{D}+\mathcal{A}\times\mathbf{H}, \quad \mathbf{H}=\mathbf{B}-\mathcal{A}\times\mathbf{E}. \tag{36}$$

In terms of the complex combinations $\mathbf{E}+i\mathbf{H}$ and $\mathbf{D}+i\mathbf{B}$, Eqs. (35) and (36) can be rewritten as

$$\operatorname{div}(\mathbf{D}+i\mathbf{B})=4\pi\tilde{\rho}, \quad \operatorname{curl}(\mathbf{E}+i\mathbf{H})-i\partial_0(\mathbf{D}+i\mathbf{B})=4\pi i\tilde{\mathbf{j}} \tag{37}$$

and

$$\mathbf{D}+i\mathbf{B}=\mathbf{E}+i\mathbf{H}+i\mathcal{A}\times(\mathbf{E}+i\mathbf{H}), \tag{38}$$

respectively.

As pointed out in Ref. 4, by expressing the Maxwell equations in their usual form one is able to apply some standard techniques to solve them. For instance, for a time-independent solution of the source-free Maxwell equations, from the second equation (37) it follows that there exists locally a complex potential ψ, such that

$$\mathbf{E}+i\mathbf{H}=-\operatorname{grad}\psi, \tag{39}$$

then, from the first equation (37) and Eq. (38), one finds that

$$\tilde{\nabla}^2\psi+i\mathcal{B}\cdot\operatorname{grad}\psi=0, \tag{40}$$

where $\tilde{\nabla}^2$ is the Laplace operator corresponding to the metric $d\sigma^2$ [i.e., $\tilde{\nabla}^2\psi=(1/\sqrt{\gamma})\partial_i(\sqrt{\gamma}\gamma^{ij}\partial_j\psi)$] and the vector field $\mathcal{B}^i$ is the dual of $\mathcal{B}_{ij}$. The presence of the factor i in the second term of the left-hand side of the last equation implies that, if the space–time is not static (i.e., $\mathcal{B}\neq 0$), it may not be possible to have an electrostatic field alone, without a magnetostatic field, and vice versa (see below).

In the case of the space–time metric (19), one finds that Eq. (40) admits separable solutions of the form $\psi=f_j(r)Y_{jm}(\theta,\varphi)$, where the Y_{jm} are spherical harmonics, and f_j obeys the condition

$$(r^2-2mr-l^2)\frac{d}{dr}\left[(r-il)^2\frac{df_j}{dr}\right]-j(j+l)(r-il)^2f_j=0. \tag{41}$$

When $j=0$ (static monopolar field), Eq. (41) immediately gives $df_0/dr=(\alpha+i\beta)/(r-il)^2$, where α and β are real constants, and the nonvanishing components of the field generated by this solution (with $x^1=r$) are given by

$$E^1+iH^1=\frac{1}{\sqrt{4\pi}}\frac{(r^2-2mr-l^2)^2}{(r^2+l^2)^4}[\alpha(r^2-l^2)-2\beta lr+i(\beta(r^2-l^2)+2\alpha lr)], \tag{42}$$

hence, there are no values of α and β for which the field is purely electric or purely magnetic. If one looks for a solution with $j=1$, which could correspond to a uniform field, one finds that the solution of Eq. (41) grows faster than r as $r\to\infty$ if $l\neq 0$; thus, by contrast with the Schwarzschild metric,[4] the presence of the NUT parameter does not allow the existence of an asymptotically uniform field.

In the case of the Schwarzschild metric, which is given by Eq. (19) with $l=0$, we can find solutions to the source-free Maxwell equations analogous to the usual multipole fields in flat space–time (cf. Ref. 10). Since, in the present case, $\mathcal{A}=0$, we have $\mathbf{D}=\mathbf{E}$ and $\mathbf{B}=\mathbf{H}$, therefore, looking for solutions of the form

$$\mathbf{E}=\operatorname{curl}\left(\psi_{\omega j}(r)e^{-i\omega t}Y_{jm}(\theta,\varphi)\frac{\partial}{\partial r}\right), \tag{43}$$

where $\psi_{\omega j}(r)$ is a function to be determined and ω is a constant, div $\mathbf{D}$ is identically equal to zero and from the last equation (35), assuming that $\mathbf{B}$ also has a time dependence of the form $e^{-i\omega t}$, it follows that

$$\mathbf{B}=\frac{1}{i\omega}\operatorname{curl}\mathbf{E}, \tag{44}$$

and div **B** is equal to zero. The nonvanishing components of the fields (43) and (44), with $(x^1,x^2,x^3)=(r,\theta,\varphi)$, are given explicitly by

$$E^2=\frac{\gamma_{11}}{\sqrt{\gamma}}\psi_{\omega j}\,\partial_\varphi Y_{jm}\,e^{-i\omega t},\quad E^3=-\frac{\gamma_{11}}{\sqrt{\gamma}}\psi_{\omega j}\,\partial_\theta Y_{jm}\,e^{-i\omega t} \tag{45}$$

and

$$B^1=\frac{j(j+1)}{i\omega\gamma_{22}}\psi_{\omega j}Y_{jm}e^{-i\omega t},$$

$$B^2=\frac{1}{i\omega\sqrt{\gamma}}\partial_r\left(\frac{\sqrt{\gamma}}{\gamma_{22}}\psi_{\omega j}\right)\partial_\theta Y_{jm}\,e^{-i\omega t}, \tag{46}$$

$$B^3=\frac{1}{i\omega\sqrt{\gamma}}\partial_r\left(\frac{\sqrt{\gamma}}{\gamma_{22}}\psi_{\omega j}\right)\frac{1}{\sin^2\theta}\partial_\varphi Y_{jm}\,e^{-i\omega t}.$$

Then, from curl $\mathbf{H}-\partial_0\mathbf{D}=0$, one obtains the only condition,

$$\frac{d}{dr}\left[\frac{r-2m}{r}\frac{d}{dr}\left(\frac{r}{r-2m}\psi_{\omega j}\right)\right]-\frac{j(j+1)}{r(r-2m)}\psi_{\omega j}+\frac{\omega^2r^2}{(r-2m)^2}\psi_{\omega j}=0. \tag{47}$$

This radial equation, written in terms of $r\psi_{\omega j}/(r-2m)$, coincides with the Schrödinger-type equation found by other procedures [see, e.g., Ref. 11, Eq. (21) and Ref. 12, Eq. (20)]. The electromagnetic field given by Eqs. (43)–(46) is a TE multipole field (since $E^1=0$). The TM multipole fields are obtained from Eqs. (43)–(46), replacing **E** by **B** and **B** by −**E**.

Since the ''magnetic field'' $\mathcal{B}_{ij}$ and the potential ϕ are made out of the components of the metric [see Eqs. (8)], the differential relations satisfied by $\mathcal{B}_{ij}$ and ϕ depend on the conditions imposed on the metric. By means of a straightforward computation, making use of Eqs. (7)–(9), one finds that the components of the Ricci tensor of the space–time metric (2) are given by

$$R_{00}=\tfrac{1}{2}\phi^{-1}\tilde{\nabla}^2\phi+\tfrac{1}{4}\mathcal{B}_{ij}\mathcal{B}^{ij}, \tag{48}$$

$$(-g_{00})R^i_0=\tfrac{1}{2}\phi^{-1}\tilde{\boldsymbol{\nabla}}_j(\phi\mathcal{B}^{ij}), \tag{49}$$

$$(-g_{00})^2R^{ij}=\gamma^{ik}\gamma^{jl}[{}^{(3)}R_{kl}-\phi^{-1}\tilde{\boldsymbol{\nabla}}_k\tilde{\boldsymbol{\nabla}}_l\phi+\tfrac{3}{2}\phi^{-2}(\partial_k\phi)(\partial_l\phi)-\tfrac{1}{2}\phi^{-1}(\tilde{\nabla}^2\phi)\gamma_{kl}+\tfrac{1}{2}\mathcal{B}_{km}\mathcal{B}_l{}^m], \tag{50}$$

where ${}^{(3)}R_{ij}$ is the Ricci tensor of the metric $d\sigma^2$. Equations (48)–(50) are analogous to the expressions given in Ref. 5, which are based on a generalized Lewis–Papapetrou form of the space–time metric, and these equations may also be useful in the search for exact solutions of the Einstein field equations (cf. Ref. 6).

From Eqs. (48), (49), and (36) it follows that if $R_{\alpha\beta}=0$, then the electromagnetic field defined by

$$\mathbf{H}=\phi\mathcal{B},\quad \mathbf{E}=-\operatorname{grad}\phi, \tag{51}$$

satisfies the Maxwell equations (35) with $\tilde{\rho}=0$, $\tilde{\mathbf{j}}=0$. This result is a special case of the well-known fact that if K^α is a Killing vector field and $R_{\alpha\beta}=0$, then $F_{\alpha\beta}=\boldsymbol{\nabla}_\alpha K_\beta$ satisfies the source–free Maxwell equations. The electromagnetic field (51) is associated with the Killing vector field $\partial/\partial x^0$. In the case of the Taub-NUT metric, the field (51) coincides with that given by Eq. (42) if we take $\alpha+i\beta=-m+il$.

IV. CONCLUSIONS

The decomposition of the metric of a stationary space–time given by Eq. (2) allows us to deal with the particle dynamics and the Maxwell equations in terms of three-dimensional objects in a convenient way. Owing to the conformal invariance of the Maxwell equations, a similar result applies in the case of the conformally stationary space-times.

As we have shown, some symmetries of the stationary space–times can also be easily obtained from the symmetries of the equivalent three-dimensional objects. The expressions for the components of the Ricci tensor [Eqs. (48)–(50)] are relatively simple and may be useful in the integration of the Einstein equations as they stand or in combination with the spinor formalism (cf. Ref. 5).

(Received 6 October 1998; accepted for publication 26 January 1999)

The diffusion equation in physical space–time for a Brownian particle driven by an external force field has been derived by Smoluchowski in the two particular cases where the external field is uniform or varies linearly with position (elastic force). In more general cases, correction terms must be added to the Smoluchowski equation. We show here how to use a multi-scale Chapman–Enskog expansion to obtain, in the hydrodynamic limit, the first corrective terms to the Smoluchowski equation, without any restriction on the friction coefficient, and for any sufficiently small position-dependent constant force field. We also compare our approach with the works of Wilemski, Titulaer, and van Kampen. © *1999 American Institute of Physics.* [S0022-2488(99)00806-3]

I. INTRODUCTION

In 1915, Smoluchowski[1,2] raised the important question of how the usual diffusion equation should be modified in order to describe properly the collective motion of Brownian particles under the influence of a given external force field. He proved that, for at least two special choices of the force field, the diffusion process could be described by a common new equation, which now carries the name of the Austrian physicist. Some 60 years later, the problem was reconsidered by various authors,[3–9] who applied to Kramers' equation an asymptotic procedure similar in spirit to the Chapman–Enskog expansion introduced for solving the Boltzmann equation. The Smoluchowski equation could then be recovered as the first approximation to a more general diffusion equation and higher-order correction terms have also been derived.[3,4]

We believe that these important results may be improved in at least one significant direction. First, for the problem at hand, the most general asymptotics susceptible to a treatment by a Chapman–Enskog expansion actually involve, in the one-dimensional case, three *a priori* distinct small parameters; however, the results presented so far in the literature have always been obtained under the tacit assumption that a single infinitesimal quantity is sufficient to properly address the problem. The principal aim of this article is to propose a fresh investigation of this matter. In particular, we will present, using as examples cases where the external force field is sufficiently small, a new implementation of the Chapman–Enskog procedure which will hopefully make clearer the number and physical significance of the involved small parameters. An approach similar in spirit to the one adopted here has already been used successfully to derive a diffusion equation from the relativistic Ornstein–Uhlenbeck process.[10,11] We will also deduce from our investigations the first correction terms to the Smoluchowski equation for at least one possible set of asymptotics (see Secs. IV and V).

This article is organized as follows. In Sec. II, we review rapidly some fundamentals about the dynamical model of diffusion which will be used in the rest of this work. In Sec. III we elaborate on the general philosophy underlying the Chapman–Enskog expansion and present the various asymptotics considered in this article. Section IV is devoted to obtaining perturbative solutions to

Kramers' equation along the lines presented in the preceding section. In Sec. V we derive the actual ''reduced'' transport equation corresponding to all solutions obtained in Sec. IV. The work in Secs. IV and V is restricted to the few perturbation orders which are necessary to obtain the first correction terms to the Smoluchowski equation and to compare them, in Sec. VI, with those presented in the existing literature. In the conclusion of the article, we review rapidly our main results and mention some problems left open for further study.

II. FUNDAMENTALS

A. The microscopic model of diffusion

To describe the motion of a Brownian particle of mass m under the influence of a given force field $\mathbf{f}$, we start with the Langevin-like system:

$$\frac{d}{dt}\mathbf{x}=\mathbf{v},$$
$$\frac{d}{dt}\mathbf{v}=-\alpha\mathbf{v}+\frac{1}{m}\mathbf{G}+\frac{1}{m}\mathbf{f}. \tag{1}$$

Here, $\mathbf{x}$ and $\mathbf{v}$ are respectively the instantaneous position and velocity of the particle, α is a constant positive coefficient, and $\mathbf{G}$ is a stochastic force. The frictionlike term $-\alpha\mathbf{v}$ and the stochastic force $\mathbf{G}$ model the collisional interaction of the Brownian particle with the particles of the surrounding fluid. As usual, we will suppose that $\mathbf{G}$ is actually a centered Gaussian white noise or, somewhat more precisely, the derivative of a Wiener process multiplied by a constant coefficient $(m^2\alpha^2\chi)$, so that

$$\langle G_i(t_1)G_j(t_2)\rangle=+2m^2\alpha^2\chi\delta(t_2-t_1)\delta_{ij}, \quad \chi>0.$$

(The coefficient χ is the diffusion coefficient in physical space; see Sec. IV.)

Let $\Pi(t,\mathbf{x},\mathbf{v})$ be the probability distribution function (in phase space) associated to the stochastic process defined by (1). It can be shown,[5,10,12] that Π satisfies the following differential equation, known as Kramers' equation:

$$\partial_t\Pi+\nabla_{\mathbf{x}}\cdot(\mathbf{v}\Pi)+\nabla_{\mathbf{v}}\cdot(-\alpha\mathbf{v}\Pi)+\nabla_{\mathbf{v}}\cdot\left(\frac{1}{m}\mathbf{f}\Pi\right)=\alpha^2\chi\Delta_{\mathbf{v}}\Pi. \tag{2}$$

[In Ref. 10, the derivation of Kramers' equation has been carried out in the (special) relativistic framework, which straightforwardly degenerates, in the proper limit, into the Galilean case.]

B. Dimensionless Kramers' equation

To lighten further algebraic manipulations, we feel it convenient to express the external force $\mathbf{f}$ and the variables t, $\mathbf{x}$, and $\mathbf{v}$ in terms of natural units of force, time, position, and velocity.

The natural time unit that comes directly out of (1) is α^{-1}. It represents the typical microscopic relaxation time of the stochastic process. We therefore choose as dimensionless time variable:

$$\underline{t}\equiv\alpha t.$$

The typical ''thermal'' velocity $\sqrt{\alpha\chi}$ will be chosen as velocity unit. The dimensionless velocity variable is, consequently,

$$\underline{\mathbf{v}}\equiv\frac{1}{\sqrt{\alpha\chi}}\mathbf{v}.$$

A temperature T can be defined by $k_{\mathrm{B}}T = m\alpha\chi$, so that the thermal velocity $\sqrt{\alpha\chi}$ is given by the usual expression $\sqrt{k_B T/m}$ (k_{B} is the Boltzmann constant).

The natural space unit $\sqrt{\chi/\alpha}$ is simply the ratio of the velocity unit to the time unit. The dimensionless position variable is then

$$\underline{\mathbf{x}} \equiv \sqrt{\frac{\alpha}{\chi}}\,\mathbf{x}.$$

From the mass m and the natural units of space and time defined above, it is straightforward to obtain the natural unit of force: $m\sqrt{\alpha^3\chi}$. The dimensionless external force is thus defined as

$$\underline{\mathbf{f}} \equiv \frac{1}{m\sqrt{\alpha^3\chi}}\,\mathbf{f}.$$

In terms of these dimensionless variables, Kramers' equation reads

$$\partial_{\underline{t}}\Pi + \nabla_{\underline{\mathbf{x}}}\cdot(\underline{\mathbf{v}}\Pi) - \nabla_{\underline{\mathbf{v}}}\cdot(\underline{\mathbf{v}}\Pi) + \nabla_{\underline{\mathbf{v}}}\cdot(\underline{\mathbf{f}}\Pi) = \Delta_{\underline{\mathbf{v}}}\Pi. \tag{3}$$

C. Hypotheses and restrictions

Throughout this article, we will make the following assumptions:

(1) When $|\mathbf{v}|$ tends to infinity, the probability distribution $\Pi(t,\mathbf{x},\mathbf{v})$ and all its derivatives with respect to $\mathbf{v}$ vanish more rapidly than any power of $\mathbf{v}$, for all time and position:

$$\forall k,l,t,\mathbf{x},\quad \lim_{|\mathbf{v}|\to\infty} \mathbf{v}^k \partial_{v^l}\Pi(t,\mathbf{x},\mathbf{v}) = 0.$$

(2) For technical simplicity reasons, we restrict our study to the one-dimensional case. We therefore work with a one-dimensional probability distribution $\Pi(t,x,v)$ and with a one-dimensional version of (2):

$$\partial_t\Pi + \partial_x(v\Pi) - \partial_v(\alpha v\Pi) + \partial_v\left(\frac{1}{m} f\Pi\right) - \alpha^2\chi\partial_{vv}\Pi = 0. \tag{4}$$

The dimensionless form of (4) reads

$$\partial_{\underline{t}}\Pi + \partial_{\underline{x}}(\underline{v}\Pi) - \partial_{\underline{v}}(\underline{v}\Pi) + \partial_{\underline{v}}(\underline{f}\Pi) - \partial_{\underline{vv}}\Pi = 0. \tag{5}$$

(3) The typical linear size $\mathcal{L}$ of the accessible region in physical space will be assumed to be finite although very large compared to any physically relevant length scale of the problem. This gives a well-defined meaning to the notion of uniform particle-density in physical space.

(4) The probability distribution $\Pi(t,x,v)$, the external force f, and all their derivatives are supposed to exist for any value of $(t>0,x,v)$.

The main points of this article are, first, to present a new implementation of the Chapman–Enskog method applied to Kramers' equation, and, second, to derive from (4), under the above-listed hypotheses, an evolution equation for the particle density in physical space, in the so-called ''hydrodynamic'' limit.

D. The momentum hierarchy

Let us now consider the hierarchy of (evolution-) equations obtained by multiplying (5) by $\underline{v}^k$, $k\in\mathbb{N}$ and integrating the result over velocity space. Using the hypotheses presented in Sec. II C, the level k of the hierarchy takes the form

$$\partial_{\underline{t}}(n\langle\underline{v}^k\rangle) + \partial_{\underline{x}}(n\langle\underline{v}^{k+1}\rangle) + kn\langle\underline{v}^k\rangle - k\underline{f}n\langle\underline{v}^{k-1}\rangle - k(k-1)n\langle\underline{v}^{k-2}\rangle = 0,\quad \text{for } k\geqslant 0, \tag{6}$$

where the symbol $\langle\rangle$ designates the average over $\underline{v}$:

$$n\langle\psi\rangle\equiv\int_{\mathbb{R}}\psi(\underline{v})\Pi(\underline{t},\underline{x},\underline{v})\,d\underline{v}.$$

In particular, the levels $k=0$ and $k=1$ provide the balance equations for the particle and momentum density:

$$\begin{gathered}\partial_{\underline{t}}(n)+\partial_{\underline{x}}(n\langle\underline{v}\rangle)=0,\\ \partial_{\underline{t}}(n\langle\underline{v}\rangle)+\partial_{\underline{x}}(n\langle\underline{v}^2\rangle)+n\langle\underline{v}\rangle-\underline{f}n=0.\end{gathered}\tag{7}$$

The hierarchy (6) will be of crucial importance in establishing the possible asymptotic behaviors of the system in the next section.

III. THE PRINCIPLE BEHIND THE CHAPMAN–ENSKOG EXPANSION AND THE VARIOUS POSSIBLE ASYMPTOTICS

The general idea behind the Chapman–Enskog expansion as we implement it in this article is to solve perturbatively the dimensionless Kramers' equation (5) by searching for ''slowly varying'' solutions in space and time which correspond to a given spatial probability density $n(\underline{t},\underline{x})$. To be more specific, let us choose a ''sufficiently regular'' function $n(\underline{t},\underline{x})$ and try to find solutions of (5) which give back this density when integrated over the whole velocity space. The evolution equations for the various macroscopic ''hydrodynamical'' quantities will appear in this perspective as solvability conditions.

It is to be noted that this whole approach of solving Kramers' equation differs fundamentally from the more usual ''physical'' one which consists in fixing initial and boundary conditions and using them to generate the solution at all (subsequent) time. If one follows this more traditional approach, one is naturally led to distinguish, for example, between a transient regime and long time behavior. Both types of solutions appear, however, on equal footing if one uses the Chapman–Enskog method, since the very notion of ''initial condition'' is absent from the whole formalism. From the Chapman–Enskog point of view the data of the problem are Kramers' equation, and a given spatial probability density *at all positive time*.

In the special case where $\underline{f}$ vanishes identically, a possible solution of (5) corresponding to the constant density $n(\underline{t},\underline{x})=n_0$ is the global equilibrium distribution:

$$\Pi^{(\mathrm{eq})}(\underline{v})=n_0\frac{1}{\sqrt{2\pi}}\exp\left(-\frac{\underline{v}^2}{2}\right).\tag{8}$$

It seems therefore reasonable, for densities $n(\underline{t},\underline{x})$ which vary sufficiently slowly in space and time, to search for possible solutions of Kramers' equation in the form of an expansion around the local equilibrium distribution (9), at least if the force field $\underline{f}$ is sufficiently small and has also slow spatial variations:

$$\Pi^{(\mathrm{loc})}(\underline{v})=n(\underline{t},\underline{x})\frac{1}{\sqrt{2\pi}}\exp\left(-\frac{\underline{v}^2}{2}\right).\tag{9}$$

Without restricting for the moment the choice of $\underline{f}$, let us pick two ''small parameters'' (i.e., infinitesimal quantities) ϵ and η, and consider a spatial density $n(\underline{t},\underline{x})$ which, in the domain of space–time under consideration, verifies the scaling relations:

$$\frac{\partial_{\underline{x}}n}{n}=\mathcal{O}(\epsilon),\quad \frac{\partial_{\underline{t}}n}{n}=\mathcal{O}(\eta).\tag{10}$$

These relations state that the spatial variation scale of n is large compared to the mean free path $\sqrt{k_B T/m\alpha^2}$, and that its time variation scale is large compared to the mean flight time α^{-1}. The two parameters ϵ and η are *a priori* independent. However, in the degenerated case of free diffusion $(\mathbf{f}=0)$, both parameters are naturally linked by $\eta=\epsilon^2$ (see the discussion in Sec. VI B).

To make proper use of these relations, it is best to turn our attention again to the hierarchy (6). Because $n\langle \underline{v}^{2k+1}\rangle, k\in\mathbb{N}$, vanishes for the local equilibrium distribution (9), let us introduce a new ''small parameter'' ϵ' and search for solutions of Kramers' equation which verify

$$n\langle \underline{v}\rangle=\mathcal{O}(\epsilon'). \tag{11}$$

If one supposes, in agreement with the preceding paragraph, that the sought-for distribution function can be written as an expansion around (9), a simple integration by part shows that the scaling (11) is actually valid for any odd power of the velocity:

$$n\langle \underline{v}^{2k+1}\rangle=\mathcal{O}(\epsilon'), \quad k\in\mathbb{N}. \tag{12}$$

The level $k=0$ in the hierarchy (6) then delivers immediately that $\eta=\epsilon\epsilon'$ and the level $k=1$ implies that $\underline{f}$ has also to be a vanishingly small quantity, whose order will be hereafter denoted by ν. One is therefore left with the following possibilities for balancing properly the terms in (7):

$$\begin{aligned}&\text{(i)}\quad \epsilon'=\epsilon \quad\text{and}\quad \nu\leqslant\epsilon,\\ &\text{(ii)}\quad \nu=\epsilon \quad\text{and}\quad \epsilon'\leqslant\epsilon,\\ &\text{(iii)}\quad \nu=\epsilon' \quad\text{and}\quad \epsilon\leqslant\nu.\end{aligned} \tag{13}$$

Each one of these alternatives defines a particular family of solutions of Eq. (5). It is already apparent at this stage that each family subdivides into at least two subfamilies; the first one corresponds to a strict inequality in (13) and the second one to the case in which all three small parameters ϵ, ϵ', and ν are actually identical. The situation is, however, more complicated than this because ϵ, ϵ', $\eta=\epsilon\epsilon'$ and ν are not the only infinitesimal quantities *a priori* involved in the problem. Indeed, (7) also constraints the spatial variations of n with respect to those of $\underline{f}$. To investigate this matter further, it is convenient to introduce a fifth (infinitesimal) quantity ϵ'' such that

$$\frac{\partial_{\underline{x}}\underline{f}}{\underline{f}}=\mathcal{O}(\epsilon''), \tag{14}$$

and to derive the level k of the hierarchy (6) with respect to $x^p, p\in\mathbb{N}$:

$$\begin{aligned}&\partial_{\underline{t}}\partial_{\underline{x}^p}(n\langle \underline{v}^k\rangle)+\partial_{\underline{x}^{p+1}}(n\langle \underline{v}^{k+1}\rangle)-k\partial_{\underline{x}^p}(\underline{f}n\langle \underline{v}^{k-1}\rangle)\\ &\quad =k(k-1)\partial_{\underline{x}^p}(n\langle \underline{v}^{k-2}\rangle)-k\partial_{\underline{x}^p}(n\langle \underline{v}^{k}\rangle)\quad \text{for } k\geqslant 0.\end{aligned} \tag{15}$$

If k is even, then both terms on the right-hand side of (15) are of order ϵ^p and the first two terms on the left-hand side are clearly of a higher order. Let us suppose that ϵ'' is strictly superior to ϵ. Then, the main contribution to the third term on the left-hand side of (15) is of order $\nu\epsilon''^p$ and this quantity has to be inferior to ϵ^p, for all even integers p. Let us now specialize the discussion according to the family under consideration. For family (i), one can always find a non-negative integer q such that

$$\epsilon^{q+1}\leqslant\nu\leqslant\epsilon^q.$$

This implies that, for all even integers p,

TABLE I. The definition of all the infinitesimal parameters introduced in this article are recalled here.

Quantity	$\partial_x \Pi/\Pi$	$\partial_t \Pi/\Pi$	$n\langle v^{2k+1}\rangle$	f	$\partial_x f/f$
Order	$\mathcal{O}(\epsilon)$	$\mathcal{O}(\eta)$	$\mathcal{O}(\epsilon')$	$\mathcal{O}(\nu)$	$\mathcal{O}(\epsilon'')$

$$\epsilon'' \leqslant \epsilon^{(p-q-1)/p},$$

which obviously contradicts the hypothesis $\epsilon'' > \epsilon$. Similarly, for family (iii), one can again introduce a non-negative integer q verifying

$$\epsilon^{-q} \leqslant \nu \leqslant \epsilon^{-(q+1)},$$

so that, for all even integers p, one has

$$\epsilon'' \leqslant \epsilon^{(p+q)/p},$$

which again contradicts the hypothesis $\epsilon'' > \epsilon$. Finally, for family (ii), one has directly that, for all even integers p,

$$\epsilon'' \leqslant \epsilon^{(p-1)/p},$$

which delivers the same result as the one obtained for the other families. A similar argument for odd values of k delivers the same conclusion. We can therefore conclude that in all cases ϵ has to be superior or equal to ϵ''.

Taking into account all four parameters ϵ, ϵ', ϵ'', and ν as well as their possible relationships to one another, we can sum up the preceding discussion in the following way. There are three main families of solutions which are *a priori* susceptible to a treatment by the Chapman–Enskog method. Each of these families can be subdivided into four different subfamilies of solutions. In each family, the first subfamily encompasses three-parameter solutions, the second and third subfamilies both represent two-parameter solutions, the second subfamily being actually common to all main families. The fourth subfamily is also common to the three families and involves a single infinitesimal quantity. These conclusions are displayed in a more compact form in Tables I and II.

One of the advantages of the Chapman–Enskog procedure is to provide an elegant way to recover the Smoluchowski equation and its various corrections. Indeed, it actually turns out that, for a given spatial density, the whole expansion is only feasible if, at any order, the involved coefficients satisfy various constraints or solvability conditions in the form of partial differential equations. The density and the force f are the only ''data'' of the problem. It therefore follows that all coefficients in the expansion depend only on the density, the imposed force field f, and their various time and space derivatives. Consequently, the constraints satisfied by these coefficients can be transcribed, at any order, into differential equations which are to be verified by the density,

TABLE II. The characteristics of the three families of solutions and of the four subfamilies are summed up here. Each column of this table corresponds to a family, and each line to a subfamily.

	(i)	*(ii)*	*(iii)*
(−.1)	$\epsilon' = \epsilon, \quad \nu < \epsilon, \quad \epsilon'' < \epsilon$	$\nu = \epsilon, \quad \epsilon' < \epsilon, \quad \epsilon'' < \epsilon$	$\nu = \epsilon', \quad \epsilon < \epsilon', \quad \epsilon'' < \epsilon$
(−.2)		$\nu = \epsilon, \quad \epsilon' = \epsilon, \quad \epsilon'' < \epsilon$	
(−.3)	$\epsilon' = \epsilon, \quad \nu < \epsilon, \quad \epsilon'' = \epsilon$	$\nu = \epsilon, \quad \epsilon' < \epsilon, \quad \epsilon'' = \epsilon$	$\nu = \epsilon', \quad \epsilon < \epsilon', \quad \epsilon'' = \epsilon$
(−.4)		$\nu = \epsilon', \quad \epsilon = \epsilon', \quad \epsilon'' = \epsilon$	

the force *f*, and their various derivatives for the whole expansion procedure to exist. These differential equations are actually the evolution equations for the spatial density one is usually looking for.

IV. PERTURBATIVE RESOLUTION OF KRAMERS' EQUATION FOR FAMILY (II)

A. The general framework

Let us now present, in the ''hydrodynamic'' limit, a direct resolution of Kramers' equation by a generalized multi-scale Chapman–Enskog expansion. The dimensionless Kramers' equation reads

$$\partial_{\underline{t}}\Pi+\underline{v}\,\partial_{\underline{x}}\Pi+\underline{f}\,\partial_{\underline{v}}\Pi=\partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})\Pi). \tag{16}$$

Each family and/or subfamily envisaged in Sec. III corresponds to a different physical situation (see Table I). A complete examination of the problem at hand should therefore involve a detailed study of eight different cases. This lies clearly outside the scope of the present article; we will now present the perturbative solutions to Kramers' equation belonging to one of the three main families only. Let us point out, however, that preliminary calculations seem to indicate that the major steps in the Chapman–Enskog procedure are similar for all three families. There is no physical or mathematical *a priori* reason to prefer one family to the other two. In what follows, we will concentrate on family (ii).

B. The asymptotic expansion for subfamily (ii.1)

Using the small parameters presented in Sec. III, we introduce new rescaled space, time, and force variables $X=\epsilon\underline{x}, Y=\epsilon''\underline{x}, T=\epsilon\epsilon'\underline{t}, \underline{f}=\nu F$ and rewrite (16) as

$$\epsilon\epsilon'\,\partial_T\Pi+\underline{v}\,(\epsilon\partial_X\Pi+\epsilon''\partial_Y\Pi)+\nu F\,\partial_{\underline{v}}\Pi=\partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})\Pi). \tag{17}$$

A reasonable form for the Chapman–Enskog expansion corresponding to subfamily (ii.1) is

$$\Pi=\sum_{k,l,m\in\mathbb{N}^3}\epsilon^k\left(\frac{\epsilon'}{\epsilon}\right)^l\left(\frac{\epsilon''}{\epsilon}\right)^m\Pi_{klm}, \tag{18}$$

where Π_{klm} is a function of *X, Y, T*, and $\underline{v}$. Substituting expression (18) in Eq. (17) and collecting all terms of order $\epsilon^k(\epsilon'/\epsilon)^l(\epsilon''/\epsilon)^m$, we obtain

$$\partial_T\Pi_{k-2l-1m}+\underline{v}\,(\partial_X\Pi_{k-1lm}+\partial_Y\Pi_{k-1lm-1})+F\,\partial_{\underline{v}}\Pi_{k-1lm}=\partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})\Pi_{klm}), \tag{19}$$

with the convention that Π_{klm} vanishes for any strictly negative value of either *k, l*, or *m*. We rewrite Eq. (19) in the more condensed form:

$$\partial_T(P\cdot{}^\circ\Pi_{k-2l-1m})+\underline{v}\,\partial\cdot{}^\circ\Pi_{k-1lm}+F\,\partial_{\underline{v}}(P\cdot{}^\circ\Pi_{k-1lm})=\partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})P\cdot{}^\circ\Pi_{klm}), \tag{20}$$

where the vectorlike quantity ${}^\circ\Pi_{klm}$ is defined by: ${}^\circ\Pi_{klm}=\binom{\Pi_{klm}}{\Pi_{klm-1}}$. In (20), P and ∂ represent respectively the adjoint vectors (1; 0) and $(\partial_X;\partial_Y)$. The usefulness of this rather abstract vectorial formalism and of the covariant derivative $\mathcal{D}$ to be introduced in Sec. IV B 2 may not be quite apparent at this stage. The principle advantage provided by these notations is to furnish cumbersome results obtained in this article in the most possible tractable form. The conversion back to more usual notations will be carried out at the end of all calculations in Sec. V A. We will now present in full detail the resolution of (20) for $0\leqslant k\leqslant 4$.

1. Order k=0

Setting $k=0$ in Eq. (20) gives

$$\partial_{\underline{v}}((\partial_{\underline{v}}+\underline{v})P\cdot{}^{\circ}\Pi_{0lm})=0. \tag{21}$$

The only solutions of (21) compatible with hypothesis 1 are of the form

$${}^{\circ}\Pi_{0lm}={}^{\circ}A_{0lm}e^{-\underline{v}^2/2}, \tag{22}$$

where ${}^{\circ}A_{0lm}$ is a function of *X, Y*, and *T*. The A_{0lm}'s and the other similar functions to be introduced below are not arbitrary. Their link to the spatial density n will be discussed in Sec. IV F.

2. Order k=1

Setting k equal to 1 in (5) and using the expression (22) for ${}^{\circ}\Pi_{0lm}$, we obtain

$$\underline{v}\mathcal{D}\cdot{}^{\circ}A_{0lm}e^{-\underline{v}^2/2}=\partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})P\cdot{}^{\circ}\Pi_{1lm}), \tag{23}$$

where $\mathcal{D}$ is a ''covariant'' derivative defined by $\mathcal{D}=\partial-FP$. Hypothesis 1 leads us to retain, as only solutions of (23),

$${}^{\circ}\Pi_{1lm}=\{{}^{\circ}A_{1lm}-\underline{v}{}^{\circ}(\mathcal{D}\cdot{}^{\circ}A_{0lm})\}e^{-\underline{v}^2/2}, \tag{24}$$

where ${}^{\circ}A_{1lm}$ is a function of *X, Y*, and *T*. Up to this order, no solvability condition has to be imposed to obtain solutions of (20) verifying hypothesis 1.

3. Order k=2

We set k equal to 2 in (20) and use for ${}^{\circ}\Pi_{0lm}$ and ${}^{\circ}\Pi_{1lm}$ the expressions (22) and (24) to obtain

$$\begin{aligned}&\{\partial_T(P\cdot{}^{\circ}A_{0l-1m})-F(P\cdot{}^{\circ}(\mathcal{D}\cdot{}^{\circ}A_{0lm}))+\underline{v}(\mathcal{D}\cdot{}^{\circ}A_{1lm})-\underline{v}^2\mathcal{D}\cdot{}^{\circ}(\mathcal{D}\cdot{}^{\circ}A_{0lm})\}e^{-\underline{v}^2/2}\\&\quad=\partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})P\cdot{}^{\circ}\Pi_{2lm}).\end{aligned} \tag{25}$$

The commutation relation $[\mathcal{D};P]=0$ has also been used in deriving (25). To satisfy hypothesis 1, the integral over $\underline{v}$ on the left-hand side must vanish. Indeed, let us take the primitive of both sides of (25). The primitive of the right-hand side clearly vanishes when $\underline{v}$ tends to infinity if hypothesis 1 is verified. Thus, the primitive of the left-hand side must also vanish when $\underline{v}$ tends to infinity. Hence, the integral over $\underline{v}$ of the left-hand side must be zero. We thus find that a necessary (and sufficient) condition for the integral over $\underline{v}$ of the left-hand side of (25) to vanish is

$$\partial_T(P\cdot{}^{\circ}A_{0l-1m})-\partial\cdot{}^{\circ}(\mathcal{D}\cdot{}^{\circ}A_{0lm})=0. \tag{26}$$

Assuming this solvability condition to be fulfilled, the only solutions of (25) which verify hypothesis 1 are

$${}^{\circ}\Pi_{2lm}=\left\{{}^{\circ}A_{2lm}-\underline{v}{}^{\circ}(\mathcal{D}\cdot{}^{\circ}A_{1lm})+\frac{\underline{v}^2}{2}{}^{\circ}(\mathcal{D}\cdot{}^{\circ}(\mathcal{D}\cdot{}^{\circ}A_{0lm}))\right\}e^{-\underline{v}^2/2}, \tag{27}$$

where ${}^{\circ}A_{2lm}$ is again a function of *X, Y*, and *T*.

4. Order k=3

With $k=3$ in (20) and the expressions (24) and (27) for ${}^{\circ}\Pi_{1lm}$ and ${}^{\circ}\Pi_{2lm}$, respectively, we obtain

$$\left\{ \partial_T(P\cdot{}^\circ A_{1l-1m}) - F(P\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm})) + \underline{v}(\mathcal{D}\cdot{}^\circ A_{2lm} - {}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}) - \mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}))) \right.$$
$$\left. -\underline{v}^2(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm})) + \frac{\underline{v}^3}{2}(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}))) \right\} e^{-\underline{v}^2/2} = \partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})P\cdot{}^\circ\Pi_{3lm}), \tag{28}$$

where the condensed notation ${}^\circ[\mathcal{D};\partial]\cdot{}^\circ A$ stands for

$$^\circ[\mathcal{D};\partial]\cdot{}^\circ A = \mathcal{D}\cdot{}^\circ(\partial\cdot{}^\circ A) - \partial\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A).$$

Note that the straightforward commutation relations $[\mathcal{D};P]=0$ and $[\partial_T;\mathcal{D}]=0$ have been used in deriving (28). The solvability condition associated to (28) is

$$\partial_T(P\cdot{}^\circ A_{1l-1m}) - \partial\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm}) = 0. \tag{29}$$

The corresponding solutions compatible with hypothesis 1 are

$$^\circ\Pi_{3lm} = \left\{ {}^\circ A_{3lm} - \underline{v}({}^\circ(\mathcal{D}\cdot{}^\circ A_{2lm}) - {}^\circ({}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}))) + \frac{\underline{v}^2}{2}{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm})) \right.$$
$$\left. - \frac{\underline{v}^3}{6}{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}))) \right\} e^{-(\underline{v}^2/2)}, \tag{30}$$

where ${}^\circ A_{3lm}$ is a function of *X*, *Y*, and *T*.

5. Order k=4

If we set $k=4$ in (20) and give to ${}^\circ\Pi_{2lm}$ and ${}^\circ\Pi_{3lm}$ the forms (27) and (30), we have

$$\left\{ \partial_T(P\cdot{}^\circ A_{2l-1m}) - F(P\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{2lm})) + \partial\cdot{}^\circ({}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})) - \mathcal{D}\cdot{}^\circ({}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})) \right.$$
$$+\underline{v}(\mathcal{D}\cdot{}^\circ A_{3lm} - {}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm}) - \mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm}))) - \underline{v}^2\Big(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{2lm})$$
$$-\mathcal{D}\cdot{}^\circ({}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})) - \tfrac{1}{2}{}^\circ[\mathcal{D}^2;\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}) - \tfrac{1}{2}\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})))\Big)$$
$$\left. + \frac{\underline{v}^3}{2}(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{1lm}))) - \frac{\underline{v}^4}{6}(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})))) \right\} e^{-(\underline{v}^2/2)}$$
$$= \partial_{\underline{v}}((\underline{v}+\partial_{\underline{v}})P\cdot{}^\circ\Pi_{4lm}). \tag{31}$$

In deriving this expression, we have used the solvability conditions (26) and (29) and the commutation relations $[\mathcal{D};P]=0$ and $[\partial_T;\mathcal{D}]=0$. Following again the logic of Secs. IV B 3 and IV B 4, we obtain the solvability condition:

$$\partial_T(P\cdot{}^\circ A_{2l-1m}) - \partial\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{2lm}) = -\partial\cdot({}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})) - \tfrac{1}{2}{}^\circ[\mathcal{D}^2;\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}). \tag{32}$$

To obtain the desired corrections terms to the Smoluchowski equation, we will only need at this order the solvability condition (32) and no explicit expression for ${}^\circ\Pi_{4lm}$.

C. The asymptotic expansion for subfamily (ii.2)

The subfamily (ii.1) formally degenerates into (ii.2) if $\epsilon' = \epsilon$. The Chapman–Enskog expansion of Π takes therefore the form

$$\Pi = \sum_{k,m \in \mathbb{N}^2} \epsilon^k \left(\frac{\epsilon''}{\epsilon} \right)^m \Pi_{km}, \tag{33}$$

where

$$\Pi_{km} = \sum_{l \in \mathbb{N}} \Pi_{klm}.$$

The expressions for Π_{klm}, $0 \leqslant k \leqslant 3$, obtained in the preceding section furnish directly by summation over l the form of the desired Π_{km}, $0 \leqslant k \leqslant 3$. The solvability conditions associated to (33) can also be straightforwardly deduced from those given in Sec. IV B and do not need to be explicitly presented here.

D. The asymptotic expansion for subfamily (ii.3)

Contrary to (ii.2), subfamily (ii.3) cannot be directly deduced from subfamily (ii.1). The main reason for this is simply that (ii.1) and (ii.2) involve two spatial scales whereas (ii.3) only involves one. The corresponding dimensionless Kramers' equation is

$$\epsilon\epsilon' \partial_T \Pi + \underline{v}\, \epsilon \partial_X \Pi + \epsilon F \partial_{\underline{v}} \Pi = \partial_{\underline{v}}((\underline{v} + \partial_{\underline{v}})\Pi), \tag{34}$$

where Π is now a function of X, T, and $\underline{v}$ only. As in Secs. IV B and IV C, solutions of (34) are to be sought for under the form

$$\Pi = \sum_{k,l \in \mathbb{N}^2} \epsilon^k \left(\frac{\epsilon'}{\epsilon} \right)^l \Pi_{kl}. \tag{35}$$

Substituting (35) in Eq. (34) and collecting all terms of order $\epsilon^k(\epsilon'/\epsilon)^l$, we obtain

$$\partial_T \Pi_{k-2\,l-1} + \underline{v}\, \partial_X \Pi_{k-1\,l} + F \partial_{\underline{v}} \Pi_{k-1\,l} = \partial_{\underline{v}}((\underline{v} + \partial_{\underline{v}})\Pi_{kl}), \tag{36}$$

with the convention that Π_{kl} vanishes if k or l is strictly negative. There is, however, an important technical difference between (36) and (19). In (19), the index m traced back the presence of two spatial scales and motivated the introduction of the vectorial formalism used in Secs. IV B and IV C. Because (34) involves only one spatial scale, this formalism is of no use for solving (36). Solving (36) is consequently an essentially similar but simpler process than solving (19) for subfamily (ii.1). It seems therefore un-necessary to present here the corresponding cumbersome algebra.

E. The asymptotic expansion for subfamily (ii.4)

Because subfamily (ii.3) degenerates into subfamily (ii.4) for $\epsilon' = \epsilon$, all results pertaining to this last subfamily can be formally deduced from those discussed in Sec. IV D by a summation over l.

F. Choice of the coefficients in the Chapman–Enskog expansion

One usually fixes the coefficients in the Chapman–Enskog expansion by normalizing the lowest-order term to the given spatial density n and by requiring consequently that all superior orders are normalized to zero.[11,13] When applied to subfamily (ii.4), this delivers

$$\int_{\mathbb{R}} \Pi_0 \, d\underline{v} = n, \tag{37}$$

and

$$\int_{\mathbb{R}} \Pi_k \, d\underline{v} = 0 \quad \text{for } k > 0. \tag{38}$$

Equation (37) clearly determines A_0 in terms of n and (38) delivers A_k once the lower-order coefficients A_j, $j<k$, are known.

The implementation of this procedure for subfamilies (ii.3), (ii.2), and (ii.1) is more subtle. Let us start with subfamily (ii.3). There are *a priori* two different ways of fixing the coefficients of the expansion. The first one would be to normalize Π_{00} to n and all other Π_{kl}'s to 0. This would have the direct consequence of actually setting to zero all Π_{k0}'s, for $k>0$, and the corresponding expansion would not involve ϵ' but only ϵ. It is easy to check that such an expansion cannot satisfy Eq. (34). This means that the retained normalization condition is too restrictive and therefore unsuitable to subfamily (ii.3). The correct way of relating the A_{kl}'s to n is to impose

$$\int_{\mathbb{R}} \sum_{l \in \mathbb{N}} \left(\frac{\epsilon'}{\epsilon}\right)^l \Pi_{0l} \, d\underline{v} = n \tag{39}$$

and

$$\int_{\mathbb{R}} \sum_{l \in \mathbb{N}} \left(\frac{\epsilon'}{\epsilon}\right)^l \Pi_{kl} \, d\underline{v} = 0 \quad \text{for } k > 0. \tag{40}$$

Equations (39) and (40) solve the problem at the price of not fixing unambiguously every A_{kl} but only their weighed sum over l: $\Sigma_{l \in \mathbb{N}} (\epsilon'/\epsilon)^l A_{kl}$.

A similar reasoning leads for subfamily (ii.2) to the conditions

$$\int_{\mathbb{R}} \sum_{m \in \mathbb{N}} \left(\frac{\epsilon''}{\epsilon}\right)^m \Pi_{0m} \, d\underline{v} = n \tag{41}$$

and

$$\int_{\mathbb{R}} \sum_{m \in \mathbb{N}} \left(\frac{\epsilon''}{\epsilon}\right)^m \Pi_{km} \, d\underline{v} = 0 \quad \text{for } k > 0, \tag{42}$$

and, for subfamily (ii.1), to

$$\int_{\mathbb{R}} \sum_{l,m \in \mathbb{N}^2} \left(\frac{\epsilon'}{\epsilon}\right)^l \left(\frac{\epsilon''}{\epsilon}\right)^m \Pi_{0lm} \, d\underline{v} = n, \tag{43}$$

and

$$\int_{\mathbb{R}} \sum_{l,m \in \mathbb{N}^2} \left(\frac{\epsilon'}{\epsilon}\right)^l \left(\frac{\epsilon''}{\epsilon}\right)^m \Pi_{klm} \, d\underline{v} = 0 \quad \text{for } k > 0. \tag{44}$$

V. THE FIRST CORRECTION TERMS TO THE SMOLUCHOWSKI EQUATION

In classical Brownian motion theory without external force field, the spatial density n verifies, in the long-time limit, the (dimensionless) diffusion equation:

$$\partial_t n - \partial_{\underline{xx}} n = 0. \tag{45}$$

When an external (time-independent) force field is present, (45) obviously has to be modified. Smoluchowski has proved that, if $\underline{f}$ is uniform[1] or varies linearly with position,[2] the exact transport equation for n is

$$\partial_{\underline{t}} n - \partial_{\underline{xx}} n + \partial_{\underline{x}} (n \underline{f}) = 0. \tag{46}$$

For a more general force field, (46) is only valid approximately. Wilemski[3] and Titulaer[4] have obtained, for a sufficiently small force field, the lowest-order correction terms to (46), which becomes

$$\partial_{\underline{t}} n - \partial_{\underline{xx}} n + \partial_{\underline{x}} (n \underline{f}) = -\partial_{\underline{x}} \{ \partial_{\underline{x}} \underline{f} (\partial_{\underline{x}} n - \underline{f} n) \}. \tag{47}$$

Our approach, at least for family (ii), leads to the same equation for n. We will now present in full detail how to reach (47) for subfamily (ii.1). Subfamilies (ii.2), (ii.3), and (ii.4) will be also briefly discussed.

Let us define Δ as the correction to the Smoluchowski equation (46). We can write

$$\Delta = \partial_{\underline{t}} n - \partial_{\underline{xx}} n + \partial_{\underline{x}} (n \underline{f}). \tag{48}$$

Since all preceding developments involve the phase-space distribution Π, it is convenient to introduce the analog of Δ in phase space, δ, defined by

$$\delta = \partial_{\underline{t}} \Pi - \partial_{\underline{xx}} \Pi + \partial_{\underline{x}} (\Pi \underline{f}). \tag{49}$$

Here Δ can be recovered by a direct integration of δ over the velocity $\underline{v}$.

A. Subfamily (ii.1) and (ii.2)

Using the rescaled space, time, and force variables defined in Sec. IV A, Eq. (49) becomes

$$\delta = \epsilon \epsilon' \partial_T \Pi - (\epsilon^2 \partial_{X^2} \Pi + 2 \epsilon \epsilon'' \partial_{XY} \Pi + (\epsilon'')^2 \partial_{Y^2} \Pi) + \epsilon (\epsilon \partial_X (\Pi F) + \epsilon'' \partial_Y (\Pi F)). \tag{50}$$

The Chapman–Enskog expansion for Π introduced in Sec. IV B leads naturally to the following form for δ:

$$\delta = \sum_{k,l,m \in \mathbb{N}^3} \epsilon^k \left(\frac{\epsilon'}{\epsilon} \right)^l \left(\frac{\epsilon''}{\epsilon} \right)^m \delta_{klm}. \tag{51}$$

Replacing in (50) Π and δ by their respective expressions (18) and (51), we obtain

$$\begin{aligned} \delta_{klm} = {} & \partial_T \Pi_{k-2l-1m} - (\partial_{X^2} \Pi_{k-2lm} + 2 \partial_{XY} \Pi_{k-2lm-1} + \partial_{Y^2} \Pi_{k-2lm-2}) \\ & + F (\partial_X \Pi_{k-2lm} + \partial_Y \Pi_{k-2lm-1}) + F_Y \Pi_{k-2lm-1}. \end{aligned} \tag{52}$$

Because Π_{klm} vanishes for negative values of k, so do δ_{0lm} and δ_{1lm}. With the help of the vectorial formalism introduced in Sec. IV B, Eq. (52) takes the more compact form

$$\delta_{klm} = \partial_T (P \cdot {}^{\circ}\Pi_{k-2l-1m}) - \partial \cdot {}^{\circ} (\mathcal{D} \cdot {}^{\circ}\Pi_{k-2lm}). \tag{53}$$

Making use of Eq. (22) and of the solvability condition (26), Eq. (53) implies that δ_{2lm} vanishes identically for all l and m. This already proves that, at this order, the density n verifies indeed the Smoluchowski equation (46). The correction terms in Equation (47) will now be obtained by evaluating δ_{3lm} and δ_{4lm}. Considering the solvability condition (29) and the expression (24) for ${}^{\circ}\Pi_{1lm}$, we obtain from (53)

$$\delta_{3lm} = -\underline{v} (\partial_T (P \cdot {}^{\circ} (\mathcal{D} \cdot {}^{\circ} A_{0lm})) - \partial \cdot {}^{\circ} (\mathcal{D} \cdot {}^{\circ} (\mathcal{D} \cdot {}^{\circ} A_{0lm}))) e^{-(\underline{v}^2/2)}. \tag{54}$$

After integration over $\underline{v}$, this term provides an identically vanishing contribution to Δ. Finally, the substitution of (27) in (53) leads to

$$\delta_{4lm}=\Big\{\partial_T(P\cdot{}^\circ A_{2l-1m})-\partial\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{2lm})+\frac{\underline{v}^2}{2}(\partial_T(P\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0l-1m})))$$
$$-\partial\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm}))))+K(\underline{v})\Big\}e^{(-\underline{v}^2/2)}, \tag{55}$$

where $K(\underline{v})$ represents a polynomial expression in $\underline{v}$ which only involves odd powers of this variable. $K(\underline{v})$ will therefore not contribute to Δ. With the help of the solvability conditions (26) and (32) and considering the commutation relations $[P;\mathcal{D}]=0$ and $[\partial_T;\mathcal{D}]=0$, (55) becomes, after integration over $\underline{v}$,

$$\int_{\mathbb{R}}\delta_{4lm}\,d\underline{v}=-\sqrt{2\pi}\partial\cdot{}^\circ({}^\circ[\mathcal{D};\partial]\cdot{}^\circ(\mathcal{D}\cdot{}^\circ A_{0lm})). \tag{56}$$

Multiplying (56) by $\epsilon^4(\epsilon'/\epsilon)^l(\epsilon''/\epsilon)^m$ and summing over l and m yields the following expression for Δ:

$$\Delta=-\sqrt{2\pi}\epsilon^4\partial\cdot{}^\circ\left({}^\circ[\mathcal{D};\partial]\cdot{}^\circ\left(\sum_{l,m\in\mathbb{N}^2}\left(\frac{\epsilon'}{\epsilon}\right)^l\left(\frac{\epsilon''}{\epsilon}\right)^m\mathcal{D}\cdot{}^\circ A_{0lm}\right)\right)+\mathcal{O}(\epsilon^5). \tag{57}$$

According to the discussion at the end of Sec. IV, the spatial density is

$$n=\int_{\mathbb{R}}\sum_{l,m\in\mathbb{N}^2}\left(\frac{\epsilon'}{\epsilon}\right)^l\left(\frac{\epsilon''}{\epsilon}\right)^m\Pi_{0lm}\,d\underline{v}. \tag{58}$$

Consequently, the summation over l and m in Eq. (57) can be expressed in terms of the density n:

$$\epsilon\sqrt{2\pi}\sum_{l,m\in\mathbb{N}^2}\left(\frac{\epsilon'}{\epsilon}\right)^l\left(\frac{\epsilon''}{\epsilon}\right)^m(\mathcal{D}\cdot{}^\circ A_{0lm})=\underline{D}n, \tag{59}$$

where the operator $\underline{D}$ is

$$\underline{D}=\partial_{\underline{x}}-\underline{f}.$$

Substituting (59) in (57), we have

$$\Delta=-\partial_{\underline{x}}[\underline{D};\partial_{\underline{x}}](\underline{D}n). \tag{60}$$

Using the identity $[\underline{D};\partial_{\underline{x}}]=\partial_{\underline{x}}f$, (60) leads immediately to the expression (47) for the corrected Smoluchowski equation. We have seen in Sec. IV C that the Chapman–Enskog expansion for subfamily (ii.2) can be formally deduced from the one obtained in Sec. IV B for subfamily (ii.1) by a simple summation over l. By its very definition (51), δ involves a summation over l and therefore Δ does also. The correction terms to the Smoluchowski equation for subfamily (ii.2) are consequently identical to those obtained in this section for subfamily (ii.1).

B. Subfamily (ii.3) and (ii.4)

Contrary to the preceding case, it is not necessary here to introduce a vectorial formalism. The physical reason is that subfamily (ii.1) involves two space scales, whereas subfamily (ii.3) only involves one. The corresponding expression for δ in terms of Π is then

$$\delta=\epsilon\epsilon'\partial_T\Pi-\epsilon^2\partial_{X^2}\Pi+\epsilon^2\partial_X(\Pi F). \tag{61}$$

Considering the form of the Chapman–Enskog expansion for Π introduced in Sec. IV D, we write for δ

$$\delta = \sum_{k,l \in \mathbb{N}^2} \epsilon^k \left(\frac{\epsilon'}{\epsilon} \right)^l \delta_{kl}, \tag{62}$$

With the help of expressions (35) for Π and (62) for δ, (61) becomes

$$\delta_{kl} = \partial_T \Pi_{k-2l-1} - \partial_{X^2} \Pi_{k-2l} + F \partial_X \Pi_{k-2l} + F_X \Pi_{k-2l}. \tag{63}$$

The solution of (36) leads, through (63), to an expression for Δ identical to the one obtained in the preceding section [Eq. (60)]. Finally, since all results obtained in Sec. IV E can be formally deduced from those concerning subfamily (ii.3) by summation over l, Eq. (47) is also valid for subfamily (ii.4).

C. A brief summary of the preceding results

Using expression (60) for the correction Δ, the dimensionless Smoluchowski equation with the first correction terms reads

$$\partial_{\underline{t}} n - \partial_{\underline{xx}} n + \partial_{\underline{x}} (n \underline{f}) + \partial_{\underline{x}} \{ \partial_{\underline{x}} \underline{f} (\partial_{\underline{x}} n - \underline{f} n) \} = 0. \tag{64}$$

In terms of the original physical variables, Eq. (64) can be rewritten as

$$\partial_t n - \chi \partial_{xx} n + \frac{1}{m\alpha} \partial_x (nf) + \frac{\chi}{m\alpha^2} \partial_x \left\{ \partial_x f \left(\partial_x n - \frac{1}{\chi m \alpha} nf \right) \right\} = 0. \tag{65}$$

VI. DISCUSSION

A. Comparison with previous works

We would like now to discuss thoroughly the results presented in both preceding sections and compare them with those already available in the literature. Some typical recent and frequently quoted references on the topic are Refs. 3–9. Actually, Ref. 4 proposes a systematic generalization of the work presented in Ref. 3 and discusses most of the literature before 1978 at great length. Reference 5 is essentially based on Ref. 4; it proposes a derivation of the Smoluchowski equation only, without any correction terms, but it also contains some original very important physical discussions which render its reading essential to any proper evaluation of the issues raised by the present article. References 6–9 elaborate on a relatively different perturbation scheme, where the unperturbed phase space distribution is actually a *drifting* Maxwellian, in contradistinction to the unperturbed local equilibrium retained in the present article and Refs. 3–5. References 6–9 will therefore be discussed at the end of this section, after having compared carefully our results with those of Titulaer[4] and van Kampen.[5]

Titulaer envisages the problem of finding the correct solution to Kramers' equation (2) for given initial conditions. To this end, he considers different classes of solutions, each class being labeled by a non-negative integer n (which, naturally, must not be confused with the notation n used in the present article for the spatial density). In any of these classes, each solution has to be obtained by a Chapman–Enskog expansion about which more will be said later on. [Each class is actually associated to an eigenvalue of the differential operator which appears, e.g., on the right-hand side of Eq. (16); n labels the various eigenvalues of this operator.] After having constructed or explained how to construct at least the first expansion terms for solutions belonging to each class, Titulaer argues rather convincingly that the solutions which belong to a class characterized by a strictly positive integer n will decay exponentially in time on a typical time-scale $(n\alpha)^{-1}$; this apparently remains true even for spatially homogeneous solutions in homogeneous force field. This makes clear that the solutions considered in the present article, which describe the system in the hydrodynamic limit, have to be compared only with the solutions of Ref. 4 labeled by $n=0$.

As already alluded to before, these solutions are obtained by Titulaer (and van Kampen) by means of a Chapman–Enskog expansion which involves a single ''small parameter,'' the inverse of the friction coefficient α. While the corresponding expansion is formally well defined, its physical interpretation does not seem straightforward to us.

Indeed, if one wants to interpret the asymptotics presented in Refs. 4 and 5 by introducing the scale over which the distribution function Π varies in space, one can follow van Kampen (Ref. 5, Remark at the end of p. 218) and obtain the following inequality (recast in our notation):

$$\sqrt{\frac{\chi}{\alpha}}\left|\frac{\partial_x \Pi_0}{\Pi_0}-\frac{f}{m\propto\chi}\right| \ll 1. \tag{66}$$

This essentially states that the small parameter used by Titulaer and van Kampen may be considered as some kind of mixture of two fundamentally different quantities, which are respectively the ratio of the ''mean free path'' $\sqrt{\chi/\alpha}$ to the scale over, which Π varies spatially, and the ratio of the external force field to the natural force unit $m\sqrt{\alpha^3\chi}$. Moreover, both these quantities may be large and their difference may still verify (66). To our eyes, the uneasiness one might feel in trying to interpret physically (66) any further is a sign that the general asymptotics to be used in a Chapman–Enskog expansion applied to Kramers' equation does not *a priori* depend on a single small parameter only. Indeed, (66) alone strongly suggests that it might be wise to consider at least the two independent small parameters $\sqrt{\chi/\alpha}\partial_x\Pi/\Pi$ and $f/m\sqrt{\alpha^3\chi}$, namely, ϵ and ν introduced in Sec. III. As it turns out from the investigation presented in that section and from the results of Sec. IV, the most general collective behavior of point particles diffusing in a time-independent vanishingly small force field involves, in the hydrodynamic limit, three independent small parameters. This general situation can naturally degenerate into various two-parameter problems and even into a one-parameter case. Except in this last situation, the corresponding Chapman–Enskog expansions, presented in part in Sec. IV, are naturally more cumbersome than those proposed by Titulaer and van Kampen.

Let us now compare briefly our results with the work presented in Refs. 6–9. If Refs. 6 and 7 contain very interesting original material, a most useful source for the procedure they introduced seems to us to be Refs. 8 and 9, where some mathematical and physical points are more extensively discussed. What is envisaged in these references is a Chapman–Enskog expansion around a *drifting* Maxwellian, with a drift velocity v_d related to the force f by $v_d=f/\alpha$ (in our notation). Following the procedure of Refs. 3 and 4, the expansion in Refs. 8 and 9 still involves, as single small parameter, the inverse of the friction coefficient α. The possible limitations imposed by this last choice have already been discussed at great length in the preceding paragraph and will not be mentioned again. The choice of a drifting Maxwellian as local ''equilibrium'' around which the expansion is carried out seems to be useful in at least two potentially different (nonexclusive) situations. The first one would involve a non vanishingly small external force field. It is not obvious to us that the choice of v_d retained in Refs. 8 and 9 would then exhaust all physically interesting solutions. In particular, this choice seems to correspond only to an overdamped mean microscopic motion of the particle. Anyhow, the corresponding physics cannot be compared to the one presented in this article, where the force field is supposed to be vanishingly small, as in Refs. 3–5. According to Ref. 9, the choice of a drifting Maxwellian may also be useful in describing transient regimes of at least some solutions of Kramers' equation. From this point of view, it might be interesting to compare the solutions presented in Ref. 9 to those of families (iii.1) and (iii.3) of the present article. As was already discussed before, this cannot be done in the framework of the Chapman–Enskog formalism, and lies therefore outside the scope of this work.

B. An interpretation of the various subfamilies

The aim we shared with Titulaer[4] in performing these voluminous expansions was to derive from them (for a sufficiently small force field) the Smoluchowski equation and at least the first correction terms to it. The fact that Eq. (47) formally agrees with the one obtained by Titulaer (Ref. 4) hides that our derivation is more general than his, and that Eq. (47) is also valid in various

TABLE III. This table gives the orders of magnitude of all the terms in the corrected Smoluchowski equation for all the subfamilies. Each column corresponds to a subfamily, each line to a term.

Term	$(i.1)$	$(ii.1)$	$(iii.1)$	$(-.2)$	$(i.3)$	$(ii.3)$	$(iii.3)$	$(-.4)$
$\partial_t n$	ϵ^2	$\epsilon'\nu$	$\epsilon\nu$	ν^2	ϵ''^2	$\epsilon'\nu$	$\nu\epsilon''$	ν^2
$\partial_{xx}\nu$	ϵ^2	ν^2	ϵ^2	ν^2	ϵ''^2	ν^2	ϵ''^2	ν^2
$f\partial_x n$	$\epsilon\nu$	ν^2	$\epsilon\nu$	ν^2	$\nu\epsilon''$	ν^2	$\nu\epsilon''$	ν^2
$n\partial_x f$	$\nu\epsilon''$	$\nu\epsilon''$	$\nu\epsilon''$	$\nu\epsilon''$	$\nu\epsilon''$	ν^2	$\nu\epsilon''$	ν^2
$\partial_{xx}f\partial_x n$	$\epsilon\nu\epsilon''^2$	$\nu^2\epsilon''^2$	$\epsilon\nu\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu\epsilon''^3$	ν^4	$\nu\epsilon''^3$	ν^4
$nf\partial_{xx}f$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	ν^4	$\nu^2\epsilon''^2$	ν^4
$\partial_x f\partial_{xx}n$	$\epsilon^2\nu\epsilon''$	$\nu^3\epsilon''$	$\epsilon^2\nu\epsilon''$	$\nu^3\epsilon''$	$\nu\epsilon''^3$	ν^4	$\nu\epsilon''^3$	ν^4
$n(\partial_x f)^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	$\nu^2\epsilon''^2$	ν^4	$\nu^2\epsilon''^2$	ν^4
$f\partial_x f\partial_x n$	$\epsilon\nu^2\epsilon''$	$\nu^3\epsilon''$	$\epsilon\nu^2\epsilon''$	$\nu^3\epsilon''$	$\nu^2\epsilon''^2$	ν^5	$\nu^2\epsilon''^2$	ν^5

physically different situations not investigated in Ref. 4 [see in particular Eq. (66) and the discussion thereafter]. The physical meaning of expression (60) for Δ can be investigated by evaluating the order of magnitude of the various terms which appear in Eq. (65) for the four different subfamilies (ii.1)–(ii.4). The results are gathered in Table III. This table also indicates the order of magnitude of the same terms for family (i) and (iii), because preliminary calculations indicate that (47) is indeed valid for all three families. We will thus be able to discuss them together via (47) only.

This clearly reveals that, although formally identical for the three families, Eq. (65) actually describes substantially different physics in each case.

There are two main groups of subfamilies. The first one (group A) encompasses the subfamilies (see Table IV) for which the spatial variations of the density $n(\underline{x},\underline{t})$ occur on much smaller scales than those of the external force field, which can therefore be considered as nearly homogeneous ($\epsilon''<\epsilon$). The other group (group B) contains the subfamilies for which the density $n(\underline{x},\underline{t})$ and the external force vary on the same spatial scale ($\epsilon''=\epsilon$).

Each subfamily will be discussed with the help of Table III, retaining in each case the dominant terms in Eq. (64).

1. Free diffusion regime

Subfamilies (i.1) in group A and (i.3) in group B represent cases where the magnitude of the force is so small that (64) practically degenerates into the usual diffusion equation:

$$\partial_{\underline{t}}n-\partial_{\underline{xx}}n=0. \tag{67}$$

TABLE IV. This table sums up the physical discussion presented in Sec. VI B. Each row corresponds to one of the four physical regimes; columns one and two help distinguish between cases where the force can be considered nearly homogeneous or not.

	Quasi-homogeneous force group A ($\epsilon''<\epsilon$)	Heterogeneous force group B ($\epsilon''=\epsilon$)
Free diffusion regime ($\epsilon=\epsilon'$; $\epsilon>\nu$)	Family $(i.1)$ $\partial_t n-\partial_{xx}n=0$	Family $(i.3)$ $\partial_t n-\partial_{xx}n=0$
Barostatic regime ($\epsilon'<\epsilon$; $\epsilon=\nu$)	Family $(ii.1)$ $-\partial_{xx}n+f\partial_x(n)=0$	Family $(ii.3)$ $-\partial_{xx}n+\partial_x(nf)=0$
Over-damped regime ($\epsilon<\epsilon'$; $\epsilon'=\nu$)	Family $(iii.1)$ $\partial_t n+f\partial_x(n)=0$	Family $(iii.3)$ $\partial_t n+\partial_x(nf)=0$
Driven diffusion regime ($\epsilon'=\epsilon$; $\epsilon=\nu$)	Family $(-.2)$ $\partial_t n-\partial_{xx}n+f\partial_x(n)=0$	Family $(-.4)$ $\partial_t n-\partial_{xx}n+\partial_x(nf)=0$

This means that these regimes essentially describe free diffusion phenomena.

2. Barostatic regime

For subfamilies (ii.1) in group A and (ii.3) in group B, Eq. (64) degenerates respectively into

$$-\partial_{\underline{xx}} n + \underline{f} \partial_{\underline{x}}(n) = 0 \tag{68}$$

and

$$-\partial_{\underline{xx}} n + \partial_{\underline{x}}(n \underline{f}) = 0. \tag{69}$$

Quite logically, Eq. (68) is essentially identical to (69) specialized to a situation where the force field is nearly homogeneous. Equation (69) admits as solution

$$n(\underline{x}, \underline{t}) = n_0 \exp(-\Phi(x)),$$

where $\Phi(x) = -\int^x f(y) dy$ is the potential associated to f, and n_0 normalizes n to unity. We therefore call this regime ''barostatic.''

3. Overdamped regime

For subfamilies (iii.1) in group A and (iii.3) in group B, Eq. (64) degenerates respectively into

$$\partial_{\underline{t}} n + \underline{f} \partial_{\underline{x}}(n) = 0 \tag{70}$$

and

$$\partial_{\underline{t}} n + \partial_{\underline{x}}(n \underline{f}) = 0. \tag{71}$$

As before, (70) can be considered as a special case of (71) for nearly uniform force fields. Mathematically, Eq. (71) can be obtained from the microscopic equation of motion (1) by neglecting $(d/dt)\mathbf{v}$. The mean motion of the particle is then an overdamped motion in the force field $\mathbf{f}$.

4. Driven diffusion regime

For subfamily $(-.4)$ in group B, Eq. (64) essentially becomes the standard Smoluchowski equation:

$$\partial_{\underline{t}} n - \partial_{\underline{xx}} n + \partial_{\underline{x}}(\underline{f} n) = 0, \tag{72}$$

and subfamily $(-.2)$ in group A is characterized by a nearly homogeneous force field version of (72):

$$\partial_{\underline{t}} n - \partial_{\underline{xx}} n + \underline{f} \partial_{\underline{x}}(n) = 0. \tag{73}$$

These equations obviously describe regimes where both diffusion and forcing effects are of comparable importance. This justifies the terminology ''driven diffusion.''

VII. CONCLUSION

We have proposed a fresh investigation of the collective motion of point particles which diffuse stochastically under the influence of a time-independent force field. In the hydrodynamic limit, there are three different families of solutions susceptible to a treatment by the Chapman and Enskog expansion method. Each of these families subdivides into four subfamilies characterized by the nature and number of the small parameters involved in the expansion. More precisely, each family contains a class of three- (small) parameter solutions, two different classes of two-parameter solutions and a single class of one-parameter solutions which is actually common to the three main families. We have presented in full the Chapman–Enskog expansions corresponding to the four subcases for one of the three main families. We have then derived from our results, for each subcase, the Smoluchowski equation and the first correction terms to it. These are actually identical for each of the studied subfamilies. We have also discussed at great length the physical significance of our results and compared them with the ones already existing in the literature.

Various extensions of this work are possible and are currently the object of active investigation. One should first of all perform the Chapman–Enskog expansions for all subfamilies corresponding to the two main families which were not dealt with in Sec. IV. Preliminary results indicate that these expansions also lead to the Smoluchowski equation and to the same correction terms as those derived in this article. Considering the apparent ''genericity'' of these terms as well as the natural emergence of covariant derivatives ($\underline{D}$ and $\mathcal{D}$) and commutators in the Chapman–Enskog expansions, it seems to us quite possible that an elegant geometric structure exists behind all the results derived in this paper. A better understanding of the problem in this direction should prove most enlightening. This could be linked with an extension of our results to the case of a time-dependent force field or to the general relativistic realm with the help of the relativistic Ornstein–Uhlenbeck process introduced in Ref. 10.

As already noted, the Chapman–Enskog method does not permit an investigation of the possible transient nature and dynamical stability of the various regimes envisaged in this article. This could be at least partially achieved by direct numerical simulations.

(Received 2 November 1998; accepted for publication 17 March 1999)

We analyze spectral properties of a class of integral-difference collision operators arising in some nonequilibrium statistical physics models. We present analytical estimates and numerical results for the operators defined on finite intervals and corresponding to the truncated Gaussian equilibrium distribution function. Some conclusions are drawn about the spectrum of operators on whole axis. Physical limitations for these kinds of models are discussed. [S0022-2488(99)04006-2]

I. INTRODUCTION

In this paper we study analytically and numerically spectral properties of a class of integral-difference operators. These operators arise as collision operators in nonequilibrium gas models[1] in the frame of approach developed in numerous papers (see Refs. 1–5, and references therein). A rigorous spectral analysis of these operators is important for the study of the thermodynamic limit and the problem of integrability in such models. On the other hand, these operators are mathematical objects with interesting properties which need an accurate analytical treatment as well as a numerical analysis based on rigorous approximation theory.

The collision operator acts in the Hilbert space $L_2(\mathbf{R})$ as[1,6,7]

$$(\mathcal{K}_{\varphi}u)(x) \overset{\text{def}}{=} \int_{-\infty}^{\infty} \frac{\varphi(s)u(x)-\varphi(x)u(s)}{|x-s|}\, ds, \tag{1}$$

where $\varphi(x)$ stands for the function of the equilibrium distribution. It has the sense of probability, therefore $\|\varphi\|_{L_1(\mathbf{R})}=1$. In our previous papers[6,7] we proved the basic spectral properties of this operator for a wide class of the equilibrium distributions $\varphi(x)$. However, the results of papers 6 and 7 cannot be applied, for example, to the physical Gaussian equilibrium distribution $\varphi(x) = C_\beta e^{-\beta x^2}$, because they demand the condition that supp $\varphi(x)$ is compact. Actually, together with the normalization $\|\varphi\|_{L_1}=1$ that is a necessary condition to have such $\epsilon>0$ that $\varphi(x)>\epsilon$ $\forall x \in \operatorname{supp} \varphi(x)$, which is very essential for the results proved in Ref. 7. In the present paper we study analytically and numerically the spectral properties of the operator K_φ for the Gaussian distribution, which allow one to establish physical limitations for such models.

The paper is organized as follows. In Sec. II we quote preliminary analytic results. In Sec. III we formulate the main problem of this paper. In Sec. IV we discuss some numerical results toward a solution of this problem. In Sec. V we present analytical results for an asymptotic estimate of the lowest eigenvalues of operator (1). Analytical results for the higher eigenvalues are not yet obtained. Finally, Sec. VI contains a discussion of the results and induced physical limitations for the models generating such collision operators.

II. PRELIMINARY RESULTS

First of all, we need to quote some previous results.[6,7]

Lemma 1: For any real-valued function $\varphi(x)\in L_1(\mathbf{R})\cap L_2(\mathbf{R})$ *the operator* $\mathcal{K}_\varphi$ *acting in the space* $L_2(\mathbf{R})$ *in accordance with formula (1) obeys the relation*

$$\mathcal{K}_\varphi\circ\varphi=\varphi\circ\mathcal{K}_\varphi^*, \tag{2}$$

where $\mathcal{K}_\varphi^*$ *is the adjoint operator and* φ *stands for the operator of multiplication by the function* $\varphi(x)$.

The proof was obtained[6] through the Fourier transform and study of the kernels of the corresponding operators. This result obviously leads to

Corollary 1: For any positive real-valued function $\varphi(x)\in L_1(\mathbf{R})\cap L_2(\mathbf{R})$, *the operator* $\mathcal{K}_\varphi$ *is self-adjoint in the space* $L_2(\mathbf{R};\varphi^{-1}(x)dx)$.

We introduce some notations. Let $[a,b]$ be an interval on the real axis. We denote as $\chi_-(x)$, $\chi_{ab}(x)$, and $\chi_+(x)$ the indicators of the intervals $(-\infty,a)$, $[a,b]$, and (b,∞), respectively. We use the notations P_-, P_{ab}, and P_+ for the projection operators on the subspaces $L_2(-\infty,a)$, $L_2[a,b]$, and $L_2(b,\infty)$, respectively. Actually, for any function $f(x)\in L_2(\mathbf{R})$ we have $(P_{ab}f)(x)=\chi_{ab}(x)f(x)$, and similarly for $P_\pm$. By $\mathcal{K}_0$ we denote operator (1) with (non-normalized) equilibrium distribution $\varphi(x)=\chi_{-1,1}(x)$. We also use the notation $K_\varphi=P_{ab}\mathcal{K}_\varphi P_{ab}$. The operator $K_0=P_{-1,1}\mathcal{K}_0P_{-1,1}$ acts as

$$(K_0u)(x)=\int_{-1}^{1}\frac{u(x)-u(s)}{|x-s|}ds.$$

The following statement is valid.[6]

Theorem 1: *The reduced operator* $K_0=P_{-1,1}\mathcal{K}_0P_{-1,1}$ *in the Hilbert space* $L_2[-1,1]$ *is self-adjoint,* $K_0=K_0^*$. *Its spectrum* $\sigma(K_0)$ *is discrete and equal to the set of simple eigenvalues* $\sigma(K_0)=\{\mu_n\}_{n=0}^{\infty}$, *where*

$$\mu_0=0,\quad \mu_n=2\sum_{j=1}^{n}\frac{1}{j},\quad n\geqslant 1. \tag{3}$$

The corresponding eigenfunctions are Legendre polynomials $P_n(x)$.

The proof[6] is based on straightforward calculations and employs Lemma 1.

Another necessary result is the following.[7]

Theorem 2: *Let the equilibrium distribution function* $\varphi(x)$ *satisfy the following conditions*:

(i) $\varphi(x)$ *has a compact support*: $\operatorname{supp}\varphi(x)\subset[a,b]$;

(ii) $\varphi(x)$ *is bounded, positive and separated from zero on* $[a,b]$: $\exists\epsilon,A:0<\epsilon\leqslant\varphi(x)\leqslant A\,\forall x\in[a,b]$;

(iii) $\varphi(x)\in\mathrm{Lip}(\alpha)$ *for some* $\alpha>0$, *i.e.,* $\exists\alpha,C>0:|\varphi(x)-\varphi(s)|\leqslant C|x-s|^\alpha\,\forall x,s\in[a,b]$.

Then the spectrum $\sigma(\mathcal{K}_\varphi)$ *of the operator* $\mathcal{K}_\varphi$ *given by formula (1) fills the positive semiaxis* $\mathbf{R}_+$. *Additionally, the operator* $\mathcal{K}_\varphi$ *has a discrete real spectrum* $\sigma_d(\mathcal{K}_\varphi)=\{\lambda_n\}$, *semibounded from below,* $\lambda_n\to+\infty$ *when* $n\to\infty$. *This discrete spectrum* $\sigma_d(\mathcal{K}_\varphi)$ *coincides with the spectrum* $\sigma(K_\varphi)$ *of the reduced operator* $K_\varphi=P_{ab}\mathcal{K}_\varphi P_{ab}$ *(which is purely discrete). The corresponding eigenfunctions are the eigenfunctions of the operator* K_φ *multiplied by the indicator* $\chi_{ab}(x)$. *If* $\lambda\in\mathbf{R}_+\backslash\sigma(K_\varphi)$, *then it is a spectral point of double multiplicity. The corresponding generalized eigenfunctions are*

$$u_\lambda^\pm(x) = \delta(x - y_\lambda^\pm) + \chi_{ab}(x)(K_\varphi - \lambda)^{-1}\frac{\varphi(x)}{|x - y_\lambda^\pm|}, \tag{4}$$

where $y_\lambda^\pm$ *are the inverse images of the function* $q_\varphi(x) = \int_a^b \varphi(s)/|x-s|ds$ *in the point* $\lambda: q_\varphi(y_\lambda^\pm) = \lambda,\ y_\lambda^+ > b,\ y_\lambda^- < a$.

Proof of this theorem[7] is based on the decomposition of the space $L_2(\mathbf{R})$ into orthogonal sum $L_2(\mathbf{R}) = L_2(-\infty, a) \oplus L_2[a,b] \oplus L_2(b,\infty)$. It allows for reducing the problem essentially to the study of the reduced operator $K_\varphi = P_{ab}\mathcal{K}_\varphi P_{ab}$. Linear change of variables leads to transformation of the interval $[a,b]$ into the interval $[-1, 1]$ which gives a possibility to consider the operator K_φ on the space $L_2[-1,1]$. Next, we use the formula which can be obtained by a straightforward calculation:

$$K_\varphi = \varphi \circ K_0 - (K_0\varphi), \tag{5}$$

where $(K_0\varphi)$ stands for the operator of multiplication by the function $(K_0\varphi)(x)$. Indeed,

$$\begin{aligned}
(K_\varphi u)(x) &= \int_a^b \frac{u(x)\varphi(s) - u(s)\varphi(x)}{|x-s|} ds \\
&= \int_a^b \frac{u(x)\varphi(x) - u(s)\varphi(x) + u(x)\varphi(s) - u(x)\varphi(x)}{|x-s|} ds \\
&= \varphi(x)\int_a^b \frac{u(x) - u(s)}{|x-s|} ds - u(x)\int_a^b \frac{\varphi(x) - \varphi(s)}{|x-s|} ds \\
&= \varphi(x)(K_0 u)(x) - u(x)(K_0\varphi)(x).
\end{aligned}$$

Using this formula, we compare the resolvents of the operators K_0 and K_φ. Finally, spectral properties of the operator K_0 known from Theorem 1 allow one to finish the proof of Theorem 2.

III. THE PROBLEM

Our main concerns here are, on one hand, conditions (i)–(iii) of Theorem 2, and, on the other hand, the statement of Theorem 2 on the spectrum of the collision operator $\mathcal{K}_\varphi$.

Conclusions on the character of the discrete spectrum of the collision operator $\mathcal{K}_\phi$ are within physical expectations.[1] But there is not, to our knowledge, any reasonable physical interpretation of the continuous spectrum. On the other hand when used by physicists equilibrium distribution functions $\varphi(x)$ do not always satisfy conditions (i)–(iii) of Theorem 2. Namely, condition (iii) (smoothness) and positivity of $\varphi(x)$ are natural physical conjectures. At the same time condition (i) (compactness of the support) is not satisfied even for the most natural Gaussian distribution $\varphi(x) = C_\beta \exp\{-\beta x^2\}$, where C_β is the normalizing constant. Together with the normalization condition $\|\varphi\|_{L_1} = 1$ the fact that $\operatorname{supp}\varphi = \mathbf{R}$ leads to the violation of condition (ii), namely there cannot exist such $\epsilon > 0$ that $\varphi(x) > \epsilon \forall x \in \operatorname{supp}\varphi$. The latter condition is very essential for Theorem 2 (see Ref. 7). Therefore, three interrelated questions appear:

(1) What happens if condition (i) of Theorem 2 is violated? Namely, will the spectral properties of the collision operator $\mathcal{K}_\varphi$ be changed drastically?
(2) How to calculate numerically the spectrum of the operator $\mathcal{K}_\varphi$?
(3) If violation of condition (i) of Theorem 2 (e.g., using the Gaussian distribution function) does not eliminate unnatural spectral properties of the collision operator, what are possible modifications of the mathematical object under investigation and to which physical limitations in the corresponding models they lead?

The rest of our paper is devoted to answering these questions.

IV. NUMERICAL RESULTS FOR THE GAUSSIAN EQUILIBRIUM DISTRIBUTION

Let us consider the Gaussian equilibrium distribution function. Infinite integration limits in Eq. (1) are always understood as the limit of the integral over the interval $[-a,a]$ when $a\to\infty$. In fact, the truncated functions

$$\varphi_a(x)\overset{\text{def}}{=}C_a\chi_{-a,a}(x)e^{-\beta x^2}, \tag{6}$$

are very similar for different but large enough values of the parameter a. Therefore, it may seem that, for large enough a, the truncation parameter a does not influence essentially the spectral properties of the corresponding collision operator. However, that is not true. Namely, there is no regular limit of the collision operator $\mathcal{K}_{\varphi_a}$ on the truncation parameter a when $a\to\infty$. Therefore, there is no way to develop a successful perturbation theory for the spectrum of the operator $\mathcal{K}_{\varphi_a}$ with respect to the parameter $1/a$. We shall show this both numerically and analytically.

Let us make a simple remark. By change of variables one can show that the spectral problem

$$K_{\varphi_a}u=\lambda u \tag{7}$$

on the space $L_2[-a,a]$ is equivalent to the spectral problem

$$K_{\tilde{\varphi}_a}\tilde{u}=\lambda\tilde{u} \tag{8}$$

on the space $L_2[-1,1]$, where $\tilde{\varphi}_a(x)=\tilde{C}_a e^{-\beta a^2x^2}$, i.e., operators K_{φ_a} and $K_{\tilde{\varphi}_a}$ have the same (discrete) spectrum. Indeed, introducing the notations $s'=s/a$, $x'=x/a$, and $\tilde{u}(x)=u(ax)$, we can calculate the action of the operator:

$$\begin{aligned}K_{\varphi_a}u&=\int_{-a}^{a}\frac{u(x)e^{-\beta s^2}-u(s)e^{-\beta x^2}}{|x-s|}ds\\&=a\int_{-1}^{1}\frac{u(x)e^{-\beta a^2s'^2}-u(as')e^{-\beta x^2}}{|x-as'|}ds'\\&=\int_{-1}^{1}\frac{u(ax')e^{-\beta a^2s'^2}-u(as')e^{-\beta a^2x'^2}}{|x'-s'|}ds'\\&=\int_{-1}^{1}\frac{\tilde{u}(x')e^{-\beta a^2s'^2}-\tilde{u}(s')e^{-\beta a^2x'^2}}{|x'-s'|}ds'\\&=K_{\tilde{\varphi}_a}\tilde{u}.\end{aligned}$$

Furthermore, the function $u(x)$ in Eq. (7) transforms with changing of the interval into $u(ax)=\tilde{u}(x)$.

The problem for the equilibrium distribution function $\exp(-\beta x^2)$ with an arbitrary β can be reduced to one with $\beta=1$ by changing the interval. In the same manner as above, we introduce the notations $s'=\sqrt{\beta}s$, $x'=\sqrt{\beta}x$, $\tilde{u}(x)=u(x/\sqrt{\beta})$ and calculate the operator:

$$K_{\varphi_a}u=\int_{-a}^{a}\frac{u(x)e^{-\beta s^2}-u(s)e^{-\beta x^2}}{|x-s|}ds$$
$$=\frac{1}{\sqrt{\beta}}\int_{-a\sqrt{\beta}}^{a\sqrt{\beta}}\frac{u(x)e^{-s'^2}-u(s'/\sqrt{\beta})e^{-\beta x^2}}{|x-s'/\sqrt{\beta}|}ds'$$
$$=\int_{-a\sqrt{\beta}}^{a\sqrt{\beta}}\frac{\tilde{u}(x')e^{-s'^2}-\tilde{u}(s')e^{-x'^2}}{|x'-s'|}ds'.$$

Again, the function $u(x)$ on the interval $[-a,a]$ transforms into $\tilde{u}(x')$ on the interval $[-a\sqrt{\beta},a\sqrt{\beta}]$. Hence, in the following we assume $\beta=1$.

A. Numerical method

In this section we study the spectral problem (7). The equilibrium distribution function $\varphi_a(x)$ is defined in Eq. (6). The normalizing constant C_a is calculated as $\|\varphi_a(x)\|_{L_1([-a,a])}=1$ and is equal to

$$C_a^{-1}=\int_{-a}^{a}e^{-x^2}\,dx=\sqrt{\pi}\,\mathrm{erf}(a).$$

It is worth noticing that the normalizing constant has an asymptotics $C_a\sim 1/2a$ at origin and $C_a\sim 1/\sqrt{\pi}$ at infinity.

It is convenient to construct a numerical method on the interval $[-1, 1]$. As noticed above, in order to keep the same spectrum, we have to change the equilibrium distribution function to $\tilde{\varphi}_a(x)=C_a\exp(-a^2x^2)$. Being led by the spectral analysis of the operator K_0 in Theorem 1, we find eigenfunctions of $K_{\tilde{\varphi}_a}$ as an expansion with respect to the Legendre polynomials:

$$\psi(x)=\sum_{k=0}^{N}v_kP_k(x). \tag{9}$$

Acting by operator (5) on the function ψ and calculating the scalar product in $L_2([-1,1],dx/\tilde{\varphi}_a(x))$, we obtain for spectral problem (7):

$$\int_{-1}^{1}\psi(x)\int_{-1}^{1}\frac{\psi(x)-\psi(s)}{|x-s|}ds\,dx-\int_{-1}^{1}\frac{\psi^2(x)}{\tilde{\varphi}_a(x)}(K_0\tilde{\varphi}_a)(x)dx=\lambda\int_{-1}^{1}\frac{\psi^2(x)}{\tilde{\varphi}_a(x)}dx.$$

Substituting expansion (9) and using Theorem 1 for calculating the first integral, we obtain a generalized spectral problem $\tilde{K}v=\lambda\tilde{S}v$. Matrix elements K_{nm} and S_{nm} of the operators $\tilde{K}$ and $\tilde{S}$ are defined as

$$K_{nm}=\frac{2\mu_n}{2n+1}\delta_{nm}-\int_{-1}^{1}P_n(x)P_m(x)\frac{(K_0\tilde{\varphi}_a)(x)}{\tilde{\varphi}_a(x)}dx, \tag{10}$$

and

$$S_{nm}=\int_{-1}^{1}\frac{P_n(x)P_m(x)}{\tilde{\varphi}_a(x)}dx.$$

To calculate integrals in Eq. (10), we use the relationship:[8]

$$P_n(x)P_m(x)=\sum_{k=0}^{\min(n,m)} A_{nm}^k P_{n+m-2k}(x), \tag{11}$$

where

$$A_{nm}^k=\frac{a_{m-k}a_k a_{n-k}}{a_{n+m-k}}\left(\frac{2n+2m-4k+1}{2n+2m-2k+1}\right), \quad a_k=\frac{(2k-1)!!}{k!}.$$

As the function $\tilde{\varphi}_a(x)$ is symmetric, one can easily see that $(K_0\tilde{\varphi}_a)(x)$ is also symmetric. Thus, symmetric and antisymmetric solutions are separated and one can sum in Eq. (9) over even and odd indices separately. Therefore, all matrix elements in Eq. (10) can be expressed as a linear combination of integrals

$$\int_0^1 P_{2l}(x)\,\frac{f_0(x)}{\tilde{\varphi}_a(x)}\,dx, \tag{12}$$

where $f_0(x)=(K_0\tilde{\varphi}_a)(x)$ for the matrix elements of $\tilde{K}$ and $f_0(x)=1$ for those of $\tilde{S}$.

Special care must be taken concerning numerical calculations of integrals in Eq. (12) since the integrand is highly oscillating for large l and has a huge derivative for large a. These integrals can hardly be calculated with any usual quadrature method. We thus derive a special representation for them.

Let us first discuss the calculation of S_{nm}, $f_0(x)=1$. Using the Taylor expansion for $\exp(a^2x^2)$ and the orthogonality relation

$$\int_{-1}^1 x^m P_k(x)=0, \quad m<k,$$

we find that

$$I_l^{(1)}(a^2)=\frac{1}{C_a}\int_{-1}^1 P_{2l}(x)\exp(a^2x^2)\,dx=\frac{2}{C_a}\sum_{k=l}^{\infty}\frac{a^{2k}}{k!}\int_0^1 x^{2k}P_{2l}(x)\,dx. \tag{13}$$

The latter integral is calculated analytically,[8] and we can finally write

$$I_l^{(1)}(a^2)=\frac{(-1)^l}{C_a}\sum_{k=l}^{\infty}\frac{a^{2k}}{k!}\,\frac{\Gamma(l-k)\Gamma(\frac{1}{2}+k)}{\Gamma(-k)\Gamma(l+\frac{3}{2}+k)}. \tag{14}$$

The residual term of expansion (14) can be easily estimated, and the calculation of a finite sum in (14) is done by using two successive recursion relations with respect to indices l and k.

A similar idea is implemented to the calculation of integrals in K_{nm}:

$$I_l^{(2)}=\int_{-1}^1 P_{2l}\frac{(K_0\tilde{\varphi}_a)(x)}{\tilde{\varphi}_a(x)}\,dx. \tag{15}$$

We expand $\tilde{\varphi}_a(x)$ in terms of Legendre polynomials:

$$\tilde{\varphi}_a(x)=C_a\sum_{k=0}^{\infty}\frac{4k+1}{2}P_{2k}(x)I_k^{(1)}(-a^2). \tag{16}$$

As we know the action of K_0 on Legendre polynomials, we find an expression for $I_l^{(2)}$ in terms of matrix elements of the operator $\tilde{S}$:

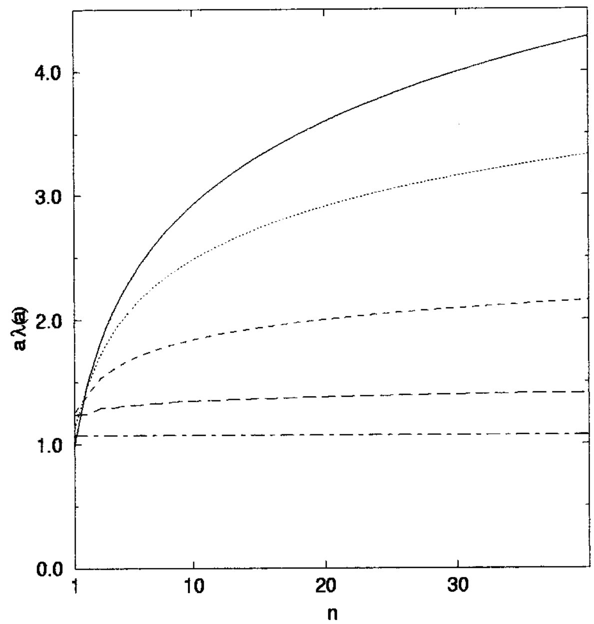

FIG. 1. Eigenvalues $a\lambda_n$ for different values of a. The solid, dotted, dashed, long-dashed, and dot-dashed lines correspond to $a=0$, 1, 1.5, 2, and 3, respectively.

$$I_l^{(2)}=C_a\sum_{k=0}^{\infty}\frac{4k+1}{2}\mu_{2k}I_k^{(1)}(-a^2)S_{2k,2l}. \tag{17}$$

Eigenvalues and eigenfunctions of the generalized matrix problem (10) are computed with standard LAPACK routines in double precision.

B. Eigenvalues and their asymptotics

In Fig. 1 we present a set of a few tens first eigenvalues for different a. (We excluded zeroth eigenvalue since $\lambda_0=0$ for all a.) One can see that an estimation $\lambda_n \geqslant 1/a$ is valid for the eigenvalues. The numerical asymptotics can be found for large n values: $\lambda_n \sim 1/a(1+\kappa(a)\ln n)$. Calculating eigenvalues with rather high accuracy, values of $\kappa(a)$ can be determined. We have found that the function $\kappa(a)$ excellently fits to the exponent. Summarizing the results of this numerical study, we obtain the following asymptotics:

$$\lambda_n \sim \frac{1}{a}(1+\tau e^{-\alpha a^2}\ln n), \quad \tau\approx 0.62, \quad \alpha\approx 0.92, \tag{18}$$

which is valid when both $n,a\to\infty$. Asymptotics (18) is numerically checked up to $n\simeq 100$ and $a\simeq 10$. We would like to say, however, that this is very accurate already for rather small values of n and a. It is also worth pointing out the analytical asymptotics of λ_n for small a:

$$\lambda_n \sim \frac{1}{2a}\mu_n, \quad a\to 0, \tag{19}$$

where μ_n are given by Eq. (3).

Let us now discuss a dependence of eigenfunctions on a. For n being fixed, any eigenfunction is ''pushed off'' the interval and is concentrated very closely to its boundaries with increase in a.

To illustrate this, we first plot three eigenfunctions for different a in Fig. 2. We can see that already for $a=2$ the eigenfunctions are localized nearby the boundary. The eigenfunctions with $a>2$ cannot be plotted in a linear scale.

As the eigenfunctions for small n and big a are nearly zero in a vicinity $x=0$, a difference in pair of symmetric and antisymmetric eigenvalues is getting small, $\lambda_n \approx \lambda_{n+1}$, $n=1,3,5,\ldots$. Evidently, this is not the case for eigenfunctions with large n which are not close to zero anywhere in the interval. To illustrate this ''pairing'' effect, we plot in Fig. 3 the first few eigenvalues as a function of parameter a.

The asymptotics (18) gives us a tool to investigate a limit of the spectrum of $K_{\tilde{\varphi}_a}$ when $a \to \infty$. Let us calculate the difference $\lambda_{n+1}-\lambda_n$ in a vicinity of a positive σ. If n_0, $\sigma=\lambda_{n_0}$, is sufficiently large, we may approximate the finite difference as the derivative, and we find

$$\left.\frac{d\lambda}{dn}\right|_{\lambda=\sigma} = \tau \frac{e^{-\alpha a^2}}{a} \exp\left(-\frac{(a\sigma-1)}{\tau} e^{\alpha a^2} \right). \tag{20}$$

One can see that $(d\lambda/dn)|_{\lambda=\sigma} \to 0$ when $a\to\infty$ for any $\sigma>0$, and $\sigma=0$ also belongs to the spectrum of the operator. Hence, the spectrum condenses into $[0,+\infty)$ when $a\to\infty$. We should note, however, that this does not necessarily mean that the interval $[0,+\infty)$ constitutes the spectrum of the operator $K_{\tilde{\varphi}_a}$ defined on the whole axis. The corresponding limiting procedure cannot be investigated numerically and needs an additional analytical support. However, the numerical results have stimulated analytical calculations presented in Sec. V.

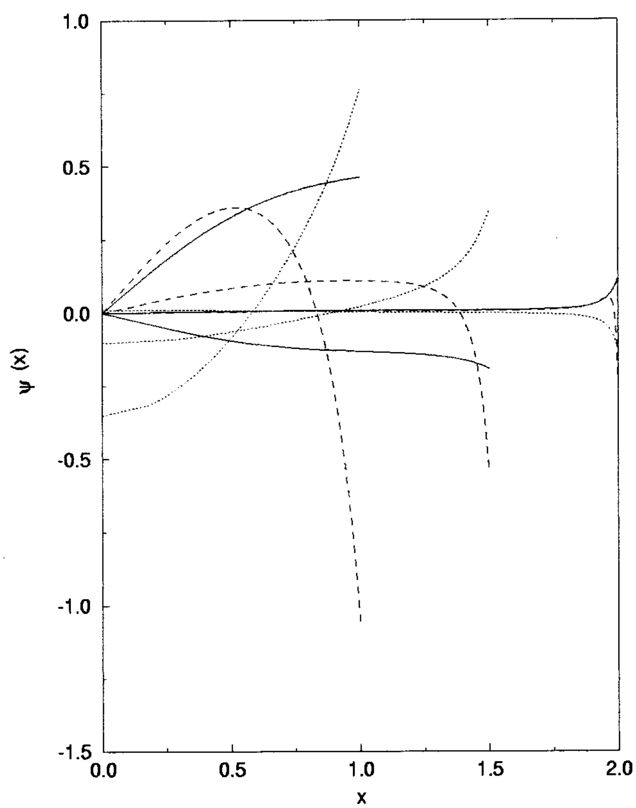

FIG. 2. Normalized eigenfunctions for $a=1$ ([0,1]), $a=1.5$([0,1.5]), and $a=2$ ([0,2]). The solid, dotted, and dashed lines correspond to $n=1$, 2, and 3, respectively.

V. ANALYTIC ESTIMATE FOR THE FIRST EIGENVALUES OF THE COLLISION OPERATOR $\mathcal{K}_{\varphi_a}(x)$ FOR $a \to \infty$

As in the previous section, we consider the collision operator K_{φ_a} restricted to the interval $[-a,a]$ and determined by the truncated Gaussian equilibrium distribution function $\varphi_a(x)$ given

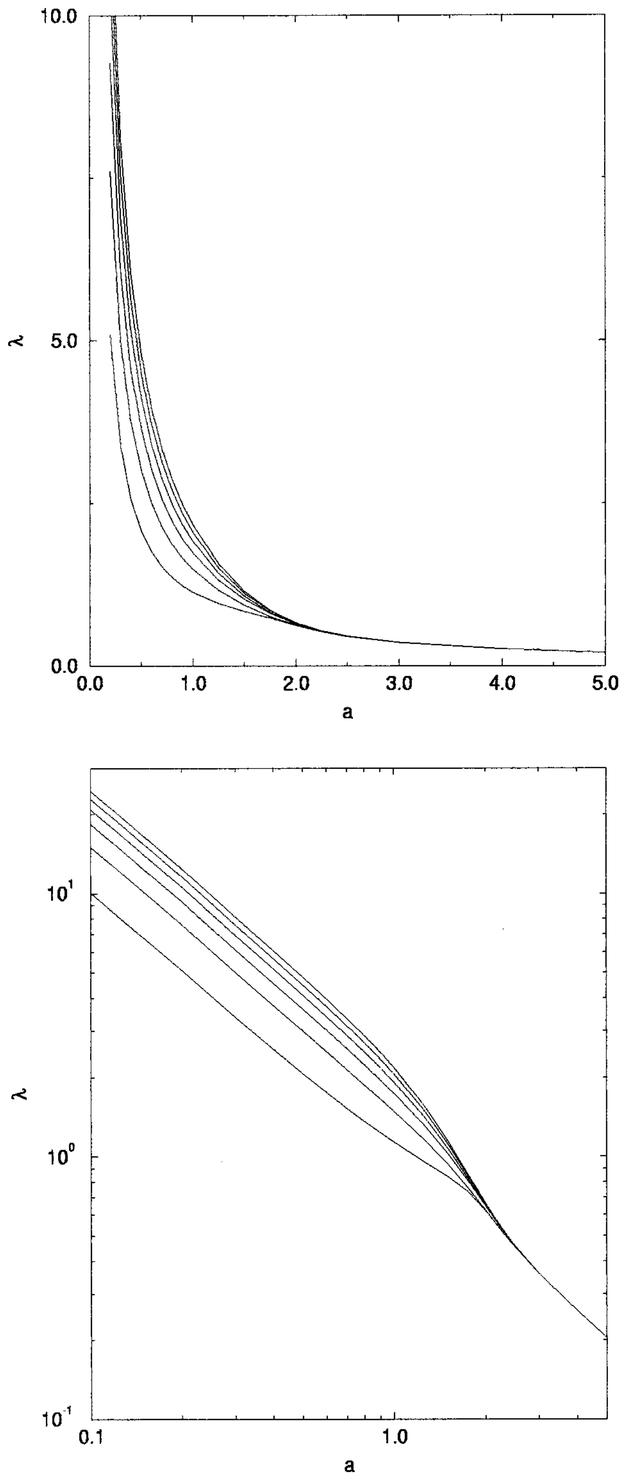

FIG. 3. First six eigenvalues as the function of a (a). The same in the double logarithmic scale (b).

by Eq. (6). We introduce the operator $\mathcal{K}_a$ which is given by formula (1) with the equilibrium distribution function $\varphi(x)=\chi_{-a,a}(x)$ and the reduced operator $K_a=P_{-a,a}\mathcal{K}_a P_{-a,a}$. Theorem 1 can obviously be generalized for the operator K_a on the space $L_2[-a,a]$. Equation (5) reads as

$$K_\varphi=\varphi\circ K_a-(K_a\varphi). \tag{21}$$

Here we prove the following analytic result which partially confirms our numerical calculations.

Theorem 3: *First eigenvalues of the operator K_{φ_a} have the following asymptotic estimates as $a\to\infty$:*

$$\lambda_{1,2}(a)\leqslant \mathrm{Const}\frac{1}{a}(1+o(1)). \tag{22}$$

Proof: The lowest eigenvalue for any a is obviously $\lambda_0=0$ with the eigenfunction $\psi_0^a(x)=\varphi_a(x)$. Operator K_{φ_a} is self-adjoint in the space $L_2([-a,a];\varphi_a^{-1}(x)dx)$ (see Theorem 2), therefore for the next eigenvalue we have:

$$\lambda_1(a)=\min_{g\perp\varphi_a}\frac{\langle K_{\varphi_a}g,g\rangle_{\varphi_a^{-1}}}{\langle g,g\rangle_{\varphi_a^{-1}}}, \tag{23}$$

where $\langle\cdot,\cdot\rangle_{\varphi_a^{-1}}$ stands for the inner product in $L_2([-a,a];\varphi_a^{-1}(x)dx)$,

$$\langle u,v\rangle_{\varphi_a^{-1}}\overset{\text{def}}{=}\int_{-a}^{a}u(x)\overline{v(x)}\varphi_a^{-1}(x)dx,$$

and $g\perp\varphi_a$ means orthogonality with respect to this inner product. The notation $(\cdot,\cdot)$ we reserve for the inner product in $L_2[-a,a]$:

$$(u,v)\overset{\text{def}}{=}\int_{-a}^{a}u(x)\overline{v(x)}dx.$$

Let us choose a test function

$$h_a(x)=x\varphi_a^{1/2}(x).$$

It is antisymmetric and obviously $h_a\perp\varphi_a$ in $L_2([-a,a];\varphi_a^{-1}(x)dx)$. Due to Eq. (23) we have

$$\lambda_1(a)\leqslant\frac{\langle K_{\varphi_a}h_a,h_a\rangle_{\varphi_a^{-1}}}{\langle h_a,h_a\rangle_{\varphi_a^{-1}}}. \tag{24}$$

First, let us calculate the denominator:

$$\langle h_a,h_a\rangle_{\varphi_a^{-1}}=\langle x^2\varphi_a,1\rangle_{\varphi_a^{-1}}=(x^2,1)=\tfrac{2}{3}a^3. \tag{25}$$

Now we shall estimate the nominator using representation (21). We shall also use the fact that operators K_{φ_a} and K_a are self-adjoint on the spaces $L_2([-a,a];\varphi_a^{-1}(x)dx)$ and $L_2[-a,a]$, respectively:

$$\begin{aligned}\langle K_{\varphi_a}h_a,h_a\rangle_{\varphi_a^{-1}}&=\langle K_{\varphi_a}(x\varphi_a^{1/2}),x\varphi_a^{1/2}\rangle_{\varphi_a^{-1}}\\&=(K_{\varphi_a}(x\varphi_a^{1/2}),x\varphi_a^{-1/2})\\&=(\varphi_aK_a(x\varphi_a^{1/2}),x\varphi_a^{-1/2})-(x\varphi_a^{1/2}K_a\varphi_a,x\varphi_a^{-1/2})\\&=(K_a(x\varphi_a^{1/2}),x\varphi_a^{1/2})-(K_a\varphi_a,x^2)\\&=(K_a(x\varphi_a^{1/2}),x\varphi_a^{1/2})-(\varphi_a,K_ax^2).\end{aligned}\tag{26}$$

Therefore, we have to estimate

$$\begin{aligned}(K_a(x\varphi_a^{1/2}),x\varphi_a^{1/2})&=C_a\int_{-a}^{a}\int_{-a}^{a}\frac{x\exp\{-x^2/2\}-s\exp\{-s^2/2\}}{|x-s|}xe^{-x^2/2}\,ds\,dx\\&=a^3C_a\int_{-1}^{1}\int_{-1}^{1}\frac{x\exp\{-a^2x^2/2\}-s\exp\{-a^2s^2/2\}}{|x-s|}xe^{-a^2x^2/2}\,ds\,dx\\&=a^3C_a\int_{-1}^{1}xf_a(x)e^{-a^2x^2/2}\,dx,\end{aligned}\tag{27}$$

where

$$f_a(x)=\int_{-1}^{1}\frac{x\exp\{-a^2x^2/2\}-s\exp\{-a^2s^2/2\}}{|x-s|}\,ds.$$

Using integration by parts, we find that the leading order of expression (27) is

$$(K_a(x\varphi_a^{1/2}),x\varphi_a^{1/2})\sim aC_a\int_{-1}^{1}f_a'(x)e^{-a^2x^2/2}\,dx.$$

Using the Laplace method[9] one can get at $a\to\infty$:

$$\int_{-1}^{1}f_a'(x)e^{-a^2x^2/2}\,dx=\sqrt{\pi}f_a'(0)a^{-1}(1+o(1)).\tag{28}$$

On the other hand,

$$\begin{aligned}f_a'(0)&=2\int_0^1\frac{1-\exp\{-a^2s^2/2\}}{s}\,ds\\&=2\int_0^{a/\sqrt{2}}\frac{1-\exp\{-t^2\}}{t}\,dt\\&=2\int_0^1\frac{1-\exp\{-t^2\}}{t}\,dt+2\int_1^{a/\sqrt{2}}\frac{1-\exp\{-t^2\}}{t}\,dt\\&\leqslant\text{Const}+2\int_1^{a/\sqrt{2}}\frac{dt}{t}\\&=\text{Const}+2\ln a.\end{aligned}\tag{29}$$

Equations (27)–(29) lead to

$$(K_a\varphi_a^{1/2},\varphi_a^{1/2})\leqslant\text{Const}\ln a(1+o(1))\quad\text{as}\quad a\to\infty.\tag{30}$$

The second term in expression (26) is easy to evaluate:

$$(\varphi_a, K_a x^2) = C_a \int_{-a}^{a} dx\, e^{-x^2} \int_{-a}^{a} \frac{x^2 - s^2}{|x-s|}\, ds = a^3 C_a \int_{-1}^{1} dx\, e^{-a^2 x^2} \int_{-1}^{1} \frac{x^2 - s^2}{|x-s|}\, ds.$$

Again using (28), we find at $a \to \infty$:

$$(\varphi_a, K_a x^2) = -\sqrt{\pi} C_a a^2. \tag{31}$$

Combining results (30), (31) and Eqs. (24)–(26), we have

$$\lambda_1(a) \leqslant \frac{3}{2} \frac{1}{a} (1 + o(1)) \quad \text{as} \quad a \to \infty. \tag{32}$$

Now let us notice that subspaces of symmetric and antisymmetric functions are invariant with respect to the operator K_{φ_a}. Therefore, to estimate the second eigenvalue

$$\lambda_2(a) = \min_{g \perp \varphi_a, g \perp \psi_1^a} \frac{\langle K_{\varphi_a} g, g \rangle_{\varphi_a^{-1}}}{\langle g, g \rangle_{\varphi_a^{-1}}}$$

we only should care about the orthogonality to the function $\varphi_a(x)$. Hence, it is natural to choose a test function

$$g(x) = x^2 \varphi_a^{1/2}(x) - \alpha_a \varphi_a(x),$$

where

$$\alpha_a = \langle x^2 \varphi_a^{1/2}, \varphi_a \rangle_{\varphi_a^{-1}} = (x^2 \varphi_a^{1/2}, 1) = C_a^{1/2} \int_{-a}^{a} x^2 e^{-x^2/2}\, dx.$$

Obviously, $g(x)$ is orthogonal both to $\varphi_a(x)$ and to the (unknown explicitly) first antisymmetric eigenfunction. Calculations with the function $g(x)$ are done in the same way as described above, and yield estimate (22). The theorem is proved.

It is interesting to consider as a test function

$$g(x) = x^k \varphi_a^{1/2}(x),$$

properly orthogonalized to φ_a for even k (the symmetric case). Repeating calculations of Theorem 3, we find the asymptotic

$$\lambda_{1,2}(a) \leqslant \frac{2k+1}{2k} \frac{1}{a} (1 + o(1)) \quad \text{as} \quad a \to \infty.$$

This result is well consistent with numerical asymptotics (18). It also confirms the ''pushing off'' effect: The more a test function is concentrated in the vicinity of interval's boundaries, the more it resembles the eigenfunction.

VI. CONCLUSIONS AND DISCUSSION

Results of the present paper directly lead to the following conclusions.

(1) As it was shown in our previous papers,[6,7] in the case when the equilibrium distribution function $\varphi(x)$ satisfies the condition of Theorem 2, collision operator (1) has a branch of continuous spectrum. To our knowledge, this has no physical interpretation.

(2) In the natural case of the Gaussian equilibrium distribution, if the truncation parameter a goes to infinity in improper integral (1), due to the normalization condition $\|\varphi\|_{L_1}=1$, this leads to the violation of condition (ii) of Theorem 2. Namely, there cannot exist such $\epsilon>0$ that $\varphi(x)>\epsilon \forall x \in \operatorname{supp} \varphi$, because $\epsilon \to 0$ when $a \to \infty$. In this case eigenvalues condense in accordance with formula (18) when the truncation parameter a goes to infinity in improper integral (1). In our paper this is proved analytically for the first eigenvalues and numerically for the others. Analytical proof for $n \geqslant 3$ is still an open question. It means that in this case we also do not have physically reasonable spectrum.

(3) The reduced operator $K_\varphi = P_{-a,a}\mathcal{K}_\varphi P_{-a,a}$ with any fixed a has a purely discrete spectrum. The eigenvalues depend essentially on the truncation parameter a.

Summarizing these results one can suggest the following. In order to get physically reasonable spectral properties of collision operator (1), one may consider it on the interval $[-a,a]$ from the very beginning. Namely, the operator K_φ instead of $\mathcal{K}_\varphi$ may be called the collision operator. The truncation parameter a should be chosen taking two things into account. First, it has to provide correct spectrum, which can be done using our analysis. Second, it has to be in agreement with the physical model. The derivation of expression (1) for the collision operator employed some physical assumptions and approximations.[1] Given the interval $[-a,a]$, where the collision operator has a reasonable spectrum, one can clarify what are the physical limitations which restrict our consideration to this interval. However, this question is rather addressed to physicists working in the field of the nonequilibrium statistical physics. Our aim was to demonstrate from the mathematical point of view the presence of such limitations and to provide a rigorous analytical and numerical tool for the investigation of the spectral properties of this class of operators.

(Received 19 February 1998; accepted for publication 29 January 1999)

This paper studies Manin–Radul supersymmetric Kadomtsev–Petviashvili hierarchy (MR-SKP) in three related aspects: (i) We find an infinite set of additional (''ghost'') symmetry flows spanning the same (anti)commutation algebra as the ordinary MR-SKP flows. (ii) The latter are used to construct consistent reductions $\mathrm{SKP}_{r/2,m/2}$ of the initial unconstrained MR-SKP hierarchy which involves a nontrivial modification for the fermionic flows. (iii) For the simplest constrained MR-SKP hierarchy $\mathrm{SKP}_{\frac{1}{2},\frac{1}{2}}$ we show that the orbit of Darboux–Bäcklund transformations lies on a supersymmetric Toda lattice being a square root of the standard one-dimensional Toda lattice, and also we find explicit Wronskian-ratio solutions for the super-tau function. © *1999 American Institute of Physics.*

I. INTRODUCTION

Supersymmetric integrable hierarchies of nonlinear evolution (''super-soliton'') equations were originally proposed[1] from purely mathematical motivations, but soon they attracted active interest also in theoretical physics mainly due to their close connections with superstring theory[2] (for related studies of supersymmetric integrable systems of Korteveg–de Vries or nonlinear-Schrödinger type, see Ref. 3).

The scope of the present paper is the supersymmetric Manin–Radul Kadomtsev–Petviashvili (MR-SKP) hierarchy[1] of integrable supersoliton nonlinear equations within the super-pseudo-differential operator formulation (see also Ref. 4; for other formulations see Ref. 5). We study extensions of the MR-SKP hierarchy incorporating additional (anti)commuting ''ghost'' symmetries, as well as reductions of MR-SKP. We use supersymmetric generalization of several basic concepts in the theory of integrable systems which up to now have been most actively pursued in the context of the ordinary (bosonic) KP hierarchy: Baker–Akhiezer wave functions and tau-functions,[6,7] eigenfunctions, and squared eigenfunction potentials (see Refs. 8 and 9, and references therein).

The advantage of constructing an infinite set of (anti)commuting ''ghost'' symmetries in the supersymmetric context (see Sec. IV below) is twofold. On the one hand, it allows us to double the original supersymmetric hierarchy according to the ''duality'' concept, recently introduced in the context of the ordinary KP hierarchy.[10] On the other hand, using the ''ghost'' symmetries we are able to define systematic reductions of the original MR-SKP model to a broad class of constrained supersymmetric KP hierarchies denoted as $\mathrm{SKP}_{r/2,m/2}$ [see Eq. (5.2) below]. These hierarchies posses correct evolution under both even and odd isospectral flows. The latter turns out to be a nontrivial problem since reductions to $\mathrm{SKP}_{r/2,m/2}$ hierarchies are *incompatible* with the original MR-SKP fermionic flows. We provide a solution to this problem by appropriately modifying

MR-SKP fermionic flows while preserving their original (anti)commutation algebra, i.e., preserving the integrability of the constrained $SKP_{r/2,m/2}$ systems.

The second part of the paper contains a detailed discussion of the simplest constrained MR-SKP hierarchy—$SKP_{1/2,1/2}$ [Eq. (5.3) below], for which we construct Darboux–Bäcklund (DB) transformations preserving both types (even and odd) of the isospectral flows. This again is achieved thanks to the above-mentioned modification of the original MR-SKP fermionic flows. Further, we study the pertinent DB orbit and discover a new supersymmetric Toda (*s*-Toda) lattice structure on it. As a consequence of this result we are able to find explicit Wronskian-ratio representation for corresponding super tau function.

Let us mention that several interesting reduced models of the supersymmetric KP hierarchy have been previously constructed in the literature in terms of super-pseudo-differential operators.[11–14] In particular, the supersymmetric version of AKNS hierarchy was found which allows a description in terms of a bosonic[13] as well as fermionic[14] super-Lax operators. The various properties and superspace formulation of these models were worked out, however, their evolution equations involve only even time flows defining them effectively as reductions of the SKP_2 hierarchy,[11] where only even time flows are present by construction.

II. BACKGROUND ON MANIN–RADUL SUPER-KP HIERARCHY

We shall use throughout the super-pseudo-differential calculus[1] with the following notations: ∂ and $\mathcal{D}=\partial/\partial\theta+\theta\partial$ denote operators, whereas the symbols ∂_x and $\mathcal{D}_\theta$ will indicate application of the corresponding operators on superfield functions. As usual, (x,θ) denote superspace coordinates. For any super-pseudo-differential operator $\mathcal{A}=\Sigma_j a_{j/2}\mathcal{D}^j$ the subscripts $(\pm)$ denote its purely differential part $(\mathcal{A}_+=\Sigma_{j\geqslant 0} a_{j/2}\mathcal{D}^j)$ or its purely pseudodifferential part $(\mathcal{A}_-=\Sigma_{j\geqslant 1} a_{-j/2}\mathcal{D}^{-j})$, respectively. For any $\mathcal{A}$ the super-residuum is defined as $\operatorname{Res}\mathcal{A}=a_{-1/2}$. The rules of conjugation within the super-pseudo-differential formalism are as follows:[13] $(\mathcal{A}\mathcal{B})^*=(-1)^{|A||B|}\mathcal{B}^*\mathcal{A}^*$ for any two elements with gradings $|A|$ and $|B|$; $(\partial^k)^*=(-1)^k\partial^k$, $(\mathcal{D}^k)^*=(-1)^{k(k+1)/2}\mathcal{D}^k$ and $u^*=u$ for any coefficient superfield.

Finally, in order to avoid confusion we shall also employ the following notations: for any super-(pseudo-)differential operator $\mathcal{A}$ and a superfield function f, the symbol $\mathcal{A}(f)$ will indicate application (action) of $\mathcal{A}$ on f, whereas the symbol $\mathcal{A}f$ will denote just operator product of $\mathcal{A}$ with the zero-order (multiplication) operator f.

MR-SKP hierarchy is defined through the *fermionic* Lax operator $\mathcal{L}$:

$$\mathcal{L}=\mathcal{D}+f_0+\sum_{j=1}^{\infty} b_j\partial^{-j}\mathcal{D}+\sum_{j=1}^{\infty} f_j\partial^{-j} \tag{2.1}$$

expressed in terms of a *bosonic* ''dressing'' operator $\mathcal{W}$:

$$\mathcal{L}=\mathcal{W}\mathcal{D}\mathcal{W}^{-1},\quad \mathcal{W}=1+\sum_{j=1}^{\infty}\alpha_j\partial^{-j}\mathcal{D}+\sum_{j=1}^{\infty}\beta_j\partial^{-j}, \tag{2.2}$$

where b_j,β_j are bosonic superfield functions whereas f_j,α_j are fermionic ones and where

$$f_0=2\alpha_1,\quad b_1=-\mathcal{D}_\theta\alpha_1,\quad f_1=2\alpha_2-\alpha_1\mathcal{D}_\theta\alpha_1-2\alpha_1\beta_1-\mathcal{D}_\theta\beta_1. \tag{2.3}$$

Remark: The square of MR-SKP Lax operator (2.1) is an even operator of the form

$$\mathcal{L}^2=\partial+\mathcal{D}_\theta b_1\partial^{-1}\mathcal{D}+(2b_2+b_1^2+\mathcal{D}_\theta f_1+b_1\mathcal{D}_\theta f_0)\partial^{-1}+\cdots. \tag{2.4}$$

Note that the zero-order term in $\mathcal{L}^2$ vanishes $\mathcal{D}_\theta f_0+2b_1=0$ due to (2.3).
The Lax evolution equations for MR-SKP read[1]

$$\frac{\partial}{\partial t_l}\mathcal{L}=-[\mathcal{L}_-^{2l},\mathcal{L}]=[\mathcal{L}_+^{2l},\mathcal{L}], \tag{2.5}$$

$$D_n\mathcal{L}=-\{\mathcal{L}_-^{2n-1},\mathcal{L}\}=\{\mathcal{L}_+^{2n-1},\mathcal{L}\}-2\mathcal{L}^{2n}, \tag{2.6}$$

$$\frac{\partial}{\partial t_l}\mathcal{W}=-(\mathcal{W}\partial^l\mathcal{W}^{-1})_-\mathcal{W}, \quad D_n\mathcal{W}=-(\mathcal{W}\mathcal{D}^{2n-1}\mathcal{W}^{-1})_-\mathcal{W}, \tag{2.7}$$

with the short-hand notations

$$D_n=\frac{\partial}{\partial\theta_n}-\sum_{k=1}^{\infty}\theta_k\frac{\partial}{\partial t_{n+k-1}}, \quad \{D_k,D_l\}=-2\frac{\partial}{\partial t_{k+l-1}}, \tag{2.8}$$

$$(t,\theta)\equiv(t_1\equiv x,t_2,\ldots;\theta,\theta_1,\theta_2,\ldots). \tag{2.9}$$

Accordingly, the super-Zakharov–Shabat (super-ZS) equations take the following form:

$$\frac{\partial}{\partial t_k}\mathcal{L}_+^{2l}-\frac{\partial}{\partial t_l}\mathcal{L}_+^{2k}-[\mathcal{L}_+^{2k},\mathcal{L}_+^{2l}]=0, \quad \frac{\partial}{\partial t_k}\mathcal{L}_+^{2l-1}-D_l\mathcal{L}_+^{2k}-[\mathcal{L}_+^{2k},\mathcal{L}_+^{2l-1}]=0, \tag{2.10}$$

$$D_k\mathcal{L}_+^{2l-1}+D_l\mathcal{L}_+^{2k-1}-\{\mathcal{L}_+^{2k-1},\mathcal{L}_+^{2l-1}\}+2\mathcal{L}_+^{2(k+l-1)}=0. \tag{2.11}$$

Remark: Let us stress that, unlike the possibility to identify $t_1\equiv x$ [since the zero-order term in $\mathcal{L}^2$ (2.4) vanishes], we *cannot* identify $\theta_1\equiv\theta$. Therefore, there is a nontrivial ''evolution'' already with respect to the lowest fermionic flow D_1 (which cannot in general be identified with $\mathcal{D}$).

The super-Baker–Akhiezer (super-BA) and the adjoint super-BA wave functions are defined as

$$\psi_{\mathrm{BA}}(t,\theta;\lambda,\eta)=\mathcal{W}(\psi_{\mathrm{BA}}^{(0)}(t,\theta;\lambda,\eta)), \quad \psi_{\mathrm{BA}}^{*}(t,\theta;\lambda,\eta)=\mathcal{W}^{*-1}(\psi_{\mathrm{BA}}^{*(0)}(t,\theta;\lambda,\eta)) \tag{2.12}$$

(with η being a fermionic ''spectral'' parameter), in terms of the ''free'' super-BA functions

$$\psi_{\mathrm{BA}}^{(0)}(t,\theta;\lambda,\eta)\equiv e^{\xi(t,\theta;\lambda,\eta)}, \quad \psi_{\mathrm{BA}}^{*(0)}(t,\theta;\lambda,\eta)\equiv e^{-\xi(t,\theta;\lambda,\eta)}, \tag{2.13}$$

$$\xi(t,\theta;\lambda,\eta)=\sum_{l=1}^{\infty}\lambda^l t_l+\eta\theta+(\eta-\lambda\theta)\sum_{n=1}^{\infty}\lambda^{n-1}\theta_n \tag{2.14}$$

for which it holds

$$\frac{\partial}{\partial t_k}\psi_{\mathrm{BA}}^{(0)}=\partial_x^k\psi_{\mathrm{BA}}^{(0)}, \quad D_n\psi_{\mathrm{BA}}^{(0)}=\mathcal{D}_\theta^{2n-1}\psi_{\mathrm{BA}}^{(0)}=\partial_x^{n-1}\mathcal{D}_\theta\psi_{\mathrm{BA}}^{(0)}. \tag{2.15}$$

Accordingly, (adjoint) super-BA wave functions satisfy

$$(\mathcal{L}^2)^{(*}\psi_{\mathrm{BA}}^{(*)}=\pm\lambda\,\psi_{\mathrm{BA}}^{(*)}, \quad \frac{\partial}{\partial t_l}\psi_{\mathrm{BA}}^{(*)}=\pm(\mathcal{L}^{2l})_+^{(*)}(\psi_{\mathrm{BA}}^{(*)}), \quad D_n\psi_{\mathrm{BA}}^{(*)}=\pm(\mathcal{L}^{2n-1})_+^{(*)}(\psi_{\mathrm{BA}}^{(*)}). \tag{2.16}$$

Correspondingly, the defining equations for arbitrary (adjoint-) super-eigenfunctions (sEFs) are

$$\frac{\partial}{\partial t_l}\Phi=\mathcal{L}_+^{2l}(\Phi), \quad D_n\Phi=\mathcal{L}_+^{2n-1}(\Phi), \quad \frac{\partial}{\partial t_l}\Psi=-(\mathcal{L}^{2l})_+^{*}(\Psi), \quad D_n\Psi=-(\mathcal{L}^{2n-1})_+^{*}(\Psi) \tag{2.17}$$

with supersymmetric ''spectral'' representations (cf. Ref. 9)

$$\Phi(t,\theta)=\int d\lambda\, d\eta\, \varphi(\lambda,\eta)\psi_{\rm BA}(t,\theta;\lambda,\eta), \quad \Psi(t,\theta)=\int d\lambda\, d\eta\, \varphi^{*}(\lambda,\eta)\psi^{*}_{\rm BA}(t,\theta;\lambda,\eta). \tag{2.18}$$

For later use let us write down the explicit expression for the ''free'' sEF $\Phi^{(0)}$ of the ''free'' $\mathcal{L}^{(0)}=\mathcal{D}$. Namely, taking into account (2.13)–(2.15) and (2.18) we get (for definiteness, consider bosonic $\Phi^{(0)}$)

$$\frac{\partial}{\partial t_k}\Phi^{(0)}=\partial_x^k\Phi^{(0)}, \quad D_n\Phi^{(0)}=\mathcal{D}_\theta^{2n-1}\Phi^{(0)}, \tag{2.19}$$

$$\begin{aligned}\Phi^{(0)}(t,\theta)&=\int d\lambda\, d\eta\, \varphi^{(0)}(\lambda,\eta)e^{\xi(t,\theta;\lambda,\eta)}\\ &=\int d\lambda\left[\left(1-\theta\sum_{n\geqslant 1}\lambda^n\theta_n\right)\varphi_B(\lambda)+\left(\theta+\sum_{n\geqslant 1}\lambda^{n-1}\theta_n\right)\varphi_F(\lambda)\right]\exp\left(\sum_{l\geqslant 1}\lambda^l t_l\right),\end{aligned} \tag{2.20}$$

where $\varphi^{(0)}(\lambda,\eta)=\varphi_F(\lambda)+\eta\varphi_B(\lambda)$ is arbitrary ''spectral'' density.

The super-tau-function $\tau(t,\theta)$ is related with the super-residues of powers of the super-Lax operator (2.1) as follows:

$$\mathrm{Res}\,\mathcal{L}^{2k}=\frac{\partial}{\partial t_k}\mathcal{D}_\theta \ln\tau, \quad \mathrm{Res}\,\mathcal{L}^{2k-1}=D_k\mathcal{D}_\theta\ln\tau. \tag{2.21}$$

Equation (2.21) follows from the identities

$$\begin{gathered}\frac{\partial}{\partial t_l}\mathrm{Res}\,\mathcal{L}^{2k}=\frac{\partial}{\partial t_k}\mathrm{Res}\,\mathcal{L}^{2l}, \quad \frac{\partial}{\partial t_l}\mathrm{Res}\,\mathcal{L}^{2k-1}=D_k\,\mathrm{Res}\,\mathcal{L}^{2l},\\ D_l\,\mathrm{Res}\,\mathcal{L}^{2k-1}+D_k\,\mathrm{Res}\,\mathcal{L}^{2l-1}+2\,\mathrm{Res}\,\mathcal{L}^{2(k+l-1)}=0,\end{gathered} \tag{2.22}$$

which in turn are easily derived from Eqs. (2.5) to (2.6). In particular, for the coefficients of $\mathcal{L}$ and $\mathcal{W}$ we have

$$b_1=\frac{\partial}{\partial t_1}\ln\tau\equiv\partial_x\ln\tau, \quad \alpha_1=D_1\ln\tau. \tag{2.23}$$

In what follows we shall encounter objects of the form $\mathcal{D}_\theta^{-1}(\Phi\Psi)=\mathcal{D}_\theta\partial_x^{-1}(\Phi\Psi)$ where Φ,Ψ is a pair of sEF and adjoint-sEF. Similarly to the purely bosonic case[15] one can show that application of the inverse derivative on such products is well-defined [up to an overall (t,θ)-independent constant]. Namely, there exists a unique superfield function—supersymmetric ''squared eigenfunction potential'' (super-SEP) $S(\Phi,\Psi)$ such that: $\mathcal{D}_\theta S(\Phi,\Psi)=\Phi\Psi$. More precisely the super-SEP satisfies the relations

$$\frac{\partial}{\partial t_k}S(\Phi,\Psi)=\mathrm{Res}(\mathcal{D}^{-1}\Psi\mathcal{L}^{2k}\Phi\mathcal{D}^{-1}), \quad D_kS(\Phi,\Psi)=\mathrm{Res}(\mathcal{D}^{-1}\Psi\mathcal{L}^{2n-1}\Phi\mathcal{D}^{-1}) \tag{2.24}$$

whose consistency follows from the super-ZS Eqs. (2.10) and (2.11). In particular, Eq. (2.24) for $k=1$ and $n=1$ read

$$\partial_x S(\Phi,\Psi)=\mathrm{Res}(\mathcal{D}^{-1}\Psi\mathcal{L}^2\Phi\mathcal{D}^{-1})=\mathcal{D}_\theta(\Phi\Psi), \quad D_1 S(\Phi,\Psi)=\mathrm{Res}(\mathcal{D}^{-1}\Psi\mathcal{L}\Phi\mathcal{D}^{-1})=\Phi\Psi. \tag{2.25}$$

III. ISSUE OF DARBOUX–BÄCKLUND TRANSFORMATIONS IN MR-SKP HIERARCHY

Consider the ''gauge'' transformation of $\mathcal{L}$ (2.1) of the form

$$\tilde{\mathcal{L}}=\mathcal{T}\mathcal{L}\mathcal{T}^{-1}, \quad \mathcal{T}=\chi\mathcal{D}\chi^{-1}, \tag{3.1}$$

which parallels the familiar DB transformation in the purely bosonic case.[15,16] Requiring the transformed Lax operator $\tilde{\mathcal{L}}$ to obey MR-SKP evolution equation of the same form (2.5)–(2.6) as $\mathcal{L}$ implies that $\mathcal{T}$ must satisfy

$$\frac{\partial}{\partial t_l}\mathcal{T}\mathcal{T}^{-1}+(\mathcal{T}\mathcal{L}_+^{2l}\mathcal{T}^{-1})_-=0, \quad D_n\mathcal{T}\mathcal{T}^{-1}-(\mathcal{T}\mathcal{L}_+^{2n-1}\mathcal{T}^{-1})_-=-2(\tilde{\mathcal{L}}^{2n-1})_-. \tag{3.2}$$

The first Eq. (3.2) is exactly analogous to the purely bosonic case and implies that χ must be a sEF (2.17) of $\mathcal{L}$ with respect to the even MR-SKP flows. However, there is a problem with the second Eq. (3.2). Namely, for the general (unconstrained) MR-SKP hierarchy it does not have solutions for χ. In particular, if χ would be a sEF also with respect to fermionic flows [cf. the second Eq. (2.17)], then the left-hand side of second Eq. (3.2) would become zero whereupon we would get the contradictory relation: $(\tilde{\mathcal{L}}^{2n-1})_-=0$.

Thus, we conclude that the DB transformations of the general MR-SKP hierarchy preserve only the bosonic flow equations. In what follows we shall look for consistent solutions of (3.2) in the framework of *constrained* MR-SKP systems which will be achieved thanks to a nontrivial modification of the fermionic MR-SKP flows preserving their anticommutation algebra (2.8).

There is a further essential distinction of DB transformations for MR-SKP hierarchy and its purely bosonic counterpart. Calculating the super-residues of the powers of the DB-transformed Lax operator we obtain

$$\mathrm{Res}\,\tilde{\mathcal{L}}^s=\mathcal{D}_\theta(\chi^{-1}\mathcal{L}_+^s(\chi))+(-1)^{s+1}\,\mathrm{Res}\,\mathcal{L}^s. \tag{3.3}$$

Note the crucial sign factor in front of the second term on the right-hand side of Eq. (3.3). Together with the first Eq. (2.21) it implies for the DB-transformed super-τ function

$$\tilde{\tau}=\chi\tau^{-1} \tag{3.4}$$

in contrast with the bosonic case (where we have $\tilde{\tau}=\chi\tau$).

IV. SUPER-''GHOST'' SYMMETRIES OF MR-SKP HIERARCHY

Consider an infinite set $\{\Phi_{j/2},\Psi_{j/2}\}_{j=0}^{\infty}$ of pairs of (adjoint-)sEFs of $\mathcal{L}$ where those with integer indices are bosonic, whereas those with half-integer indices are fermionic. Next, let us introduce the following infinite set of super-pseudo-differential operators:

$$\mathcal{M}_{s/2}=\sum_{k=0}^{s-1}\Phi_{(s-1-k)/2}\mathcal{D}^{-1}\Psi_{k/2}, \quad s=1,2,..., \tag{4.1}$$

which generate an infinite set of flows $\bar{\partial}_{s/2}(\bar{\partial}_{n-1/2}\equiv\bar{D}_n,\bar{\partial}_k\equiv\partial/\partial\bar{t}_k)$:

$$\bar{\partial}_{s/2}\mathcal{W}=\mathcal{M}_{s/2}\mathcal{W}, \quad \bar{D}_n\mathcal{L}=\{\mathcal{M}_{n-1/2},\mathcal{L}\}, \quad \frac{\partial}{\partial\bar{t}_k}\mathcal{L}=[\mathcal{M}_k,\mathcal{L}]. \tag{4.2}$$

On (adjoint-)sEFs entering $\mathcal{M}_{s/2}$ we allow a *nonhomogeneous* action of the superflows (4.2) which parallels the construction of generalized ''ghost'' symmetry flows in the bosonic case[10] (nonhomogeneous terms are absent in the traditional approach to ''ghost'' symmetry flows[17]):

$$\bar{\partial}_{s/2}\Phi_{l/2}=\mathcal{M}_{s/2}(\Phi_{l/2})-\Phi_{s+l/2}, \quad \bar{\partial}_{s/2}\Psi_{l/2}=-\mathcal{M}^{*}_{s/2}(\Psi_{l/2})+(-1)^{sl}\Psi_{s+l/2}, \tag{4.3}$$

$$\bar{\partial}_{s/2}F^{(*}=\pm\mathcal{M}^{(*)}_{s/2}(F^{(*}), \tag{4.4}$$

where $F^{(*)}$ is a generic (adjoint-)sEF not belonging to the set $\{\Phi_{j/2},\Psi_{j/2}\}$.

Using (4.3) we arrive at the following:

Proposition 1: The infinite set of superflows $\bar{\partial}_{s/2}$ *(4.1) (anti)commute both with the ordinary superflows of MR-SKP (2.5)–(2.6) as well as among themselves:*

$$\left[\frac{\partial}{\partial \bar{t}_s},\frac{\partial}{\partial t_l}\right]=\left[\frac{\partial}{\partial \bar{t}_s},D_n\right]=0, \quad \left[\bar{D}_s,\frac{\partial}{\partial t_l}\right]=\{\bar{D}_s,D_n\}=0, \tag{4.5}$$

$$\left[\frac{\partial}{\partial \bar{t}_s},\frac{\partial}{\partial \bar{t}_k}\right]=\left[\frac{\partial}{\partial \bar{t}_s},\bar{D}_n\right]=0, \quad \{\bar{D}_i,\bar{D}_j\}=-2\frac{\partial}{\partial \bar{t}_{i+j-1}} \tag{4.6}$$

meaning that $\mathcal{M}_{s/2}$ *obey the following equations:*

$$\frac{\partial}{\partial t_k}\mathcal{M}_{s/2}=[\mathcal{L}^{2k}_{+},\mathcal{M}_{s/2}]_{-}, \quad D_n\mathcal{M}_k=[\mathcal{L}^{2n-1}_{+},\mathcal{M}_k]_{-}, \quad D_n\mathcal{M}_{k-1/2}=\{\mathcal{L}^{2n-1}_{+},\mathcal{M}_{k-1/2}\}_{-}, \tag{4.7}$$

$$\frac{\partial}{\partial \bar{t}_k}\mathcal{M}_l-\frac{\partial}{\partial \bar{t}_l}\mathcal{M}_k-[\mathcal{M}_k,\mathcal{M}_l]=0, \quad \frac{\partial}{\partial \bar{t}_k}\mathcal{M}_{l-1/2}-\bar{D}_l\mathcal{M}_k-[\mathcal{M}_k,\mathcal{M}_{l-1/2}]=0, \tag{4.8}$$

$$\bar{D}_k\mathcal{M}_{l-1/2}+\bar{D}_l\mathcal{M}_{k-1/2}-\{\mathcal{M}_{k-1/2},\mathcal{M}_{l-1/2}\}=-2\mathcal{M}_{k+l-1}. \tag{4.9}$$

In checking Eqs. (4.7)–(4.9) we make use of several useful identities for super-pseudo-differential operators:

$$[\mathcal{B}_b,\Phi_{s/2}\mathcal{D}^{-1}\Psi_{k/2}]_{-}=\mathcal{B}_b(\Phi_{s/2})\mathcal{D}^{-1}\Psi_{k/2}-\Phi_{s/2}\mathcal{D}^{-1}\mathcal{B}^{*}_b(\Psi_{k/2}), \tag{4.10}$$

$$[\mathcal{B}_f,\Phi_{s/2}\mathcal{D}^{-1}\Psi_{k/2}]^{(\pm)}_{-}=\mathcal{B}_f(\Phi_{s/2})\mathcal{D}^{-1}\Psi_{k/2}+(-1)^{s}\Phi_{s/2}\mathcal{D}^{-1}\mathcal{B}^{*}_f(\Psi_{k/2}), \tag{4.11}$$

$$(\Phi_{s/2}\mathcal{D}^{-1}\Psi_{k/2})(\Phi_{j/2}\mathcal{D}^{-1}\Psi_{l/2})=\mathcal{X}_{(s,k)}(\Phi_{j/2})\mathcal{D}^{-1}\Psi_{l/2}+(-1)^{k(l+j+1)}\Phi_{s/2}\mathcal{D}^{-1}\mathcal{X}^{*}_{(j,l)}(\Psi_{k/2}), \tag{4.12}$$

$$(\Phi_{j/2}\mathcal{D}^{-1}\Psi_{l/2})^{*}=(-1)^{lj+j+l}\Psi_{l/2}\mathcal{D}^{-1}\Phi_{j/2}, \quad \mathcal{X}_{(s,k)}(\Phi)\equiv\Phi_{s/2}\mathcal{D}^{-1}_{\theta}(\Psi_{k/2}\Phi), \tag{4.13}$$

where $\mathcal{B}_b,\mathcal{B}_f$ indicate arbitrary bosonic/fermionic purely differential super-operators, and $[\cdot,\cdot]^{(\pm)}$ denotes commutator or anticommutator whenever the second element is bosonic/fermionic.

V. CONSTRAINED MR-SKP HIERARCHIES

The super-''ghost''-symmetry flows and the corresponding generating operators $\mathcal{M}_{s/2}$ (4.1) and (4.2) can be used to construct reductions of the full (unconstrained) MR-SKP hierarchy.

Namely, since according to Proposition 1 the super-''ghost'' flows obey the same algebra (4.6) as the original MR-SKP flows, we can identify an infinite subset of the latter with a corresponding infinite subset of the former:

$$\partial_{\ell r/2} = -\bar{\partial}_{\ell m/2}, \quad \ell = 1,2,\ldots, \quad \partial_k \equiv \frac{\partial}{\partial t_k}, \quad \partial_{k-1/2} \equiv D_k, \quad \bar{\partial}_k \equiv \frac{\partial}{\partial \bar{t}_k}, \quad \bar{\partial}_{k-1/2} \equiv \bar{D}_k, \tag{5.1}$$

where (r,m) are some fixed positive integers of equal parity, and retain only these flows as Lax evolution flows (this is a supersymmetric extension of the usual reduction procedure in the purely bosonic case[18]). Equation (5.1) implies the identification $(\mathcal{L}^{r\ell})_- = \mathcal{M}_{\ell m/2}$ for any ℓ and, therefore, the corresponding reduced MR-SKP hierarchy denoted as $\mathrm{SKP}_{r/2,m/2}$ is described by the following constrained super-Lax operator:

$$\mathcal{L}_{(r/2,m/2)} = \mathcal{L}_+^r + \sum_{j=0}^{m-1} \Phi_{m-1-j/2} \mathcal{D}^{-1} \Psi_{j/2}. \tag{5.2}$$

The two simplest constrained MR-SKP Lax operators read

$$\mathcal{L}_{(1/2,1/2)} \equiv \mathcal{L} = \mathcal{D} + f_0 + \Phi_0 \mathcal{D}^{-1} \Psi_0, \tag{5.3}$$

$$\mathcal{L}_{(1,1)} = \partial + \Phi_0 \mathcal{D}^{-1} \Psi_{1/2} + \Phi_{1/2} \mathcal{D}^{-1} \Psi_0, \tag{5.4}$$

where Φ_0, Ψ_0 and $\Phi_{1/2}$, $\Psi_{1/2}$ are pairs of bosonic and fermionic (adjoint-)sEFs with respect to the bosonic flows (about the fermionic flows, see below).

In what follows we shall consider in some detail the simplest constrained $\mathrm{SKP}_{1/2,1/2}$ hierarchy (5.3), and henceforth we shall skip the subscript $(\frac{1}{2}, \frac{1}{2})$ of (5.3) for brevity.

Using identities (4.10)–(4.12) we find the identity for any integer power N (for an analogous formula in the purely bosonic case, see Ref. 19):

$$(\mathcal{L}^N)_- = \sum_{j=0}^{N-1} \mathcal{L}^{N-j-1}(\Phi_0) \mathcal{D}^{-1} \mathcal{L}^{j*}(\Psi_0). \tag{5.5}$$

In particular, for the square of (5.3) we get

$$\mathcal{L}^2 = \partial + \mathcal{L}(\Phi_0) \mathcal{D}^{-1} \Psi_0 + \Phi_0 \mathcal{D}^{-1} \mathcal{L}^*(\Psi_0), \tag{5.6}$$

where again the zero-order term $\mathcal{D}_\theta f_0 + 2\Phi_0 \Psi_0 = 0$ as a particular case of (2.3).

The constrained MR-SKP Lax operator (5.3) satisfies consistently the bosonic flow Eq. (2.5). However, we need to make a nontrivial modification of the original fermionic flows (2.6) in order to keep them compatible with the reduction from the general to the constrained MR-SKP hierarchy. Indeed, taking the $(-)$ part of Eq. (2.6) for the constrained $\mathcal{L}$ (5.3) and using identity (4.11) together with (5.5) we obtain

$$\begin{aligned} &(D_n \Phi_0 - \mathcal{L}_+^{2n-1}(\Phi_0)) \mathcal{D}^{-1} \Psi_0 - \Phi_0 \mathcal{D}^{-1} (D_n \Psi_0 + (\mathcal{L}^{2n-1})_+^*(\Psi_0)) \\ &= -2(\mathcal{L}^{2n})_- = -2 \sum_{j=0}^{2n-1} \mathcal{L}^{2n-1-j}(\Phi_0) \mathcal{D}^{-1} \mathcal{L}^{j*}(\Psi_0), \end{aligned} \tag{5.7}$$

which leads to apparent contradiction.

In Ref. 8 we solved the problem of incompatibility of the standard Orlov–Schulman additional nonisospectral symmetry flows[20] with the reductions of the full bosonic KP hierarchy by appropriately modifying the original Orlov–Schulman flows. Motivated by this work[8] we arrive at the following important proposition:

Proposition 2: There exists the following consistent modification of MR-SKP flows D_n (2.6) *for constrained* $\mathrm{SKP}_{1/2,1/2}$ *hierarchy:*

$$D_n\mathcal{L}=-\{\mathcal{L}_-^{2n-1}-X^{(2n-1)},\mathcal{L}\}=\{\mathcal{L}_+^{2n-1},\mathcal{L}\}+\{X^{(2n-1)},\mathcal{L}\}-2\mathcal{L}^{2n}, \tag{5.8}$$

$$X^{(2n-1)}\equiv 2\sum_{l=0}^{n-2}\mathcal{L}^{2(n-l)-3}(\Phi_0)\mathcal{D}^{-1}(\mathcal{L}^{2l+1})^*(\Psi_0), \tag{5.9}$$

$$D_n\Phi_0=\mathcal{L}_+^{2n-1}(\Phi_0)-2\mathcal{L}^{2n-1}(\Phi_0)+X^{(2n-1)}(\Phi_0), \tag{5.10}$$

$$D_n\Psi_0=-(\mathcal{L}^{2n-1})_+^*(\Psi_0)+2(\mathcal{L}^{2n-1})^*(\Psi_0)-(X^{(2n-1)})^*(\Psi_0). \tag{5.11}$$

The modified D_n *flows obey the same anticommutation algebra (2.8) as in the original unconstrained case.*

In checking the correct anticommutation algebra for D_n (5.8) one has to verify the identities

$$D_kX^{(2l-1)}+D_lX^{(2k-1)}-\{X^{(2k-1)},X^{(2l-1)}\}-\{X^{(2k-1)},\mathcal{L}^{2l-1}\}_--\{X^{(2l-1)},\mathcal{L}^{2k-1}\}_-=0, \tag{5.12}$$

which in turn follow from the definition of $X^{(2n-1)}$ (5.9) together with identities (4.10)–(4.13).

Remark: It is straightforward to generalize Proposition 2 for arbitrary constrained $\mathrm{SKP}_{r/2,m/2}$ hierarchy (5.2). Namely, the modified fermionic flows have the same form as in (5.8) where in the expression for $X^{(2n-1)}$ [cf. (5.9)] one has to sum over all pairs of (adjoint-) sEFs entering the purely pseudodifferential part of $\mathcal{L}_{(r/2,m/2)}$ in (5.2).

Let us now consider DB transformations on $\mathcal{L}\equiv\mathcal{L}_{(1/2,1/2)}$ (5.3) preserving its constrained form:

$$\tilde{\mathcal{L}}=\mathcal{T}\mathcal{L}\mathcal{T}^{-1}=\mathcal{D}+\tilde{f}_0+\tilde{\Phi}_0\mathcal{D}^{-1}\tilde{\Psi}_0,\quad \mathcal{T}=\Phi_0\mathcal{D}\Phi_0^{-1}, \tag{5.13}$$

$$\tilde{f}_0=-f_0-2\mathcal{D}_\theta\ln\Phi_0,\quad \tilde{\Phi}_0=\mathcal{T}\mathcal{L}(\Phi_0)=\Phi_0\partial_x\ln\Phi_0+\Phi_0\mathcal{D}_\theta f_0+\Phi_0^2\Psi_0,\quad \tilde{\Psi}_0=\Phi_0^{-1}. \tag{5.14}$$

We have the following useful identities for DB-transformed quantities:

$$\tilde{\mathcal{L}}^s(\tilde{\Phi}_0)=\mathcal{T}\mathcal{L}^{s+1}(\Phi_0),$$

$$(\tilde{\mathcal{L}}^{s+1})^*(\tilde{\Psi}_0)=(-1)^{s+1}\mathcal{T}^{*-1}\mathcal{L}^{s*}(\Psi_0)=(-1)^s\Phi_0^{-1}\mathcal{D}_\theta^{-1}(\Phi_0\mathcal{L}^{s*}(\Psi_0)). \tag{5.15}$$

There is a further crucial property of the modified D_n flows (5.8)–(5.9):

Proposition 3: The conditions for preserving the fermionic flow Eqs. (5.8)–(5.9) by the Darboux–Bäcklund transformations on $\mathcal{L}\equiv\mathcal{L}_{1/2,1/2}$ *(5.3) [cf. second Eq. (3.2)]:*

$$D_n\mathcal{T}\mathcal{T}^{-1}-(\mathcal{T}\mathcal{L}_+^{2n-1}\mathcal{T}^{-1})_-=-2(\tilde{\mathcal{L}}^{2n-1})_-+\tilde{X}^{(2n-1)}+\mathcal{T}X^{(2n-1)}\mathcal{T}^{-1}, \tag{5.16}$$

where $\mathcal{T}=\Phi_0\mathcal{D}\Phi_0^{-1}$ *and the "tilde" refers to DB-transformed objects, are now satisfied.* The proof of (5.16) proceeds by using the modified D_n flow definitions (5.9)–(5.11) together with identities (4.10)–(4.13) and (5.15).

VI. THE DARBOUX–BÄCKLUND ORBIT OF THE CONSTRAINED MR-SKP HIERARCHY

The recursive expression for the chain of the DB-transformations (5.13)–(5.14) of the constrained $\mathrm{SKP}_{1/2,1/2}$ hierarchy, starting from the "free" initial $\mathcal{L}_0=\mathcal{D}$, reads (the subscript k indicating the step of DB iteration)

$$\mathcal{L}_{k+1}=\mathcal{T}_k\mathcal{L}_k\mathcal{T}_k^{-1}=\mathcal{D}+f_{k+1}+\Phi_{k+1}\mathcal{D}^{-1}\Psi_{k+1},\quad \mathcal{T}_k=\Phi_k\mathcal{D}\Phi_k^{-1}, \tag{6.1}$$

$$\mathcal{L}_1=\mathcal{T}_0\mathcal{D}\mathcal{T}_0^{-1}=\mathcal{D}-2\mathcal{D}_\theta \ln \Phi_0+\Phi_0(\partial_x \ln \Phi_0)\mathcal{D}^{-1}\Phi_0^{-1}, \tag{6.2}$$

where

$$f_{k+1}=-2\mathcal{D}_\theta \ln \Phi_k - f_k, \quad \Psi_{k+1}=\Phi_k^{-1}, \tag{6.3}$$

$$\Phi_{k+1}=\Phi_k\partial_x \ln \Phi_k+\Phi_k\mathcal{D}_\theta f_k+\Phi_k^2\Psi_k \tag{6.4}$$

and where Φ_0 is a sEF of the initial ''free'' $\mathcal{L}_0=\mathcal{D}$ satisfying the ''free'' version of Eq. (5.10) (no $X^{(2n-1)}$ term). Therefore, its explicit expression is given by Eq. (2.20) with substituting $\theta_n \to -\theta_n$. Further we have

$$\Phi_1=\partial_x\Phi_0, \quad \Psi_1=\Phi_0^{-1}, \quad f_1=-2\mathcal{D}_\theta \ln \Phi_0. \tag{6.5}$$

Note, that from (6.3) to (6.4) we find

$$2\Phi_{k+1}\Psi_{k+1}+\mathcal{D}_\theta f_{k+1}=2\Phi_k\Psi_k+\mathcal{D}_\theta f_k=\cdots=0, \tag{6.6}$$

which is consistent with the absence of a zero-order term in the square of $\mathcal{L}_k$ in (6.1).

Equation (6.3) can easily be rewritten as follows:

$$f_{k+1}=-2\mathcal{D}_\theta \sum_{i=0}^{k} (-1)^{k-i} \ln \Phi_i. \tag{6.7}$$

Recalling identity (6.6) we can alternatively rewrite Eq. (6.4) as

$$\Phi_{k+1}=-\tfrac{1}{2}\Phi_k\mathcal{D}_\theta f_{k+1}=\Phi_k\partial_x \ln \Phi_k-\Phi_k^2\Psi_k \tag{6.8}$$

from which we obtain

$$\Phi_{k+1}=\Phi_k\sum_{i=0}^{k} (-1)^{k-i}\partial_x \ln \Phi_i. \tag{6.9}$$

After making the standard substitution $\Phi_k=e^{\varphi_k}$, we find from the second equation in (6.8) a *new* super-Toda (**s**-Toda) lattice equation:

$$\partial_x\varphi_k=e^{\varphi_{k+1}-\varphi_k}+e^{\varphi_k-\varphi_{k-1}}. \tag{6.10}$$

Note, that by acting on (6.10) with ∂_x we get

$$\partial_x^2\varphi_k=e^{\varphi_{k+2}-\varphi_k}-e^{\varphi_k-\varphi_{k-2}}, \tag{6.11}$$

which has the form of the ordinary one-dimensional Toda lattice equation but with a *doubled* lattice spacing and, of course, the Toda variables $\varphi_k=\varphi_k(x,t_2,\ldots;\theta,\theta_1,\ldots)$ are now superfields. Equation (6.10) can also be rewritten as

$$e^{\varphi_{k+1}-\varphi_k}=\sum_{i=0}^{k} (-1)^{k-i}\partial_x\varphi_i \tag{6.12}$$

or

$$\varphi_{k+1}=\varphi_k+\ln\left(\sum_{i=0}^{k} (-1)^{k-i}\partial_x\varphi_i\right). \tag{6.13}$$

We now discuss the Wronskian representation for the sEFs Φ_k. The **s**-Toda lattice (6.10) can apparently be thought of as the square root of the standard Toda lattice. We can use this idea to proceed without any technical calculations. According to the construction given in Ref. 21 the EFs Φ_{2n} associated with even lattice points can be given the usual Wronskian expressions with the starting ''point'' Φ_0. For the same reason, EFs Φ_{2n+1} associated with odd lattice points of the **s**-Toda lattice will have the usual Wronskian expressions with the starting ''point'' $\Phi_1=\partial_x\Phi_0 \equiv \Phi_0^{(1)}$ (6.5).

Generally, for $n=0,1,\ldots$ we find by the above arguments

$$\Phi_{2n}=\frac{W_{n+1}[\Phi_0,\Phi_0^{(1)},\ldots,\Phi_0^{(n)}]}{W_n[\Phi_0,\Phi_0^{(1)},\ldots,\Phi_0^{(n-1)}]},\quad \Phi_{2n+1}=\frac{W_{n+1}[\Phi_0^{(1)},\Phi_0^{(2)},\ldots,\Phi_0^{(n+1)}]}{W_n[\Phi_0^{(1)},\Phi_0^{(2)},\ldots,\Phi_0^{(n)}]}, \tag{6.14}$$

where $W_k[f_1,\ldots,f_k]\equiv\det\|\partial_x^{i-1}f_j\|$, $i,j=1,\ldots,k$, denotes standard Wronskian determinant [however, with superfield entries in (6.14)] and where $\Phi_0^{(k)}\equiv\partial_x^k\Phi_0$ with Φ_0 as in (2.20) (with $\theta_n\to-\theta_n$).

Using (3.4) and the above Wronskians expressions (6.14) we find by iteration the super-tau functions obtained by $2n$ recursive steps of the DB transformations:

$$\tau^{(2n)}=\frac{\Phi_{2n-1}\Phi_{2n-3}\cdots\Phi_1}{\Phi_{2n-2}\Phi_{2n-4}\cdots\Phi_0}=\frac{W_n[\Phi_0^{(1)},\ldots,\Phi_0^{(n)}]}{W_n[\Phi_0,\Phi_0^{(1)},\ldots,\Phi_0^{(n-1)}]}, \tag{6.15}$$

$$\tau^{(2n+1)}=\frac{\Phi_{2n}\Phi_{2n-2}\cdots\Phi_0}{\Phi_{2n-1}\Phi_{2n-3}\cdots\Phi_1}=\frac{W_{n+1}[\Phi_0,\Phi_0^{(1)},\ldots,\Phi_0^{(n)}]}{W_n[\Phi_0^{(1)},\ldots,\Phi_0^{(n)}]}. \tag{6.16}$$

Moreover, since for (5.3) $\partial_x \ln\tau=\Phi_0\Psi_0$, for the k-step DB iteration we have $\partial_x \ln\tau^{(k)}=\Phi_k/\Phi_{k-1}$ by taking into account (3.4). The latter equation together with the relation $\tau^{(k+1)}=\Phi_k/\tau^{(k)}$ true for any DB-step k [cf. (3.4)] yields an alternative super-tau-function form of **s**-Toda lattice:

$$\partial_x \ln\tau^{(k)}(t,\theta)=\frac{\tau^{(k+1)}(t,\theta)}{\tau^{(k-1)}(t,\theta)} \tag{6.17}$$

with the short-hand notation (2.9).

In a subsequent paper we plan to discuss several interesting issues connected with extending the present results: (a) construction of a ''doubled'' MR-SKP hierarchy by providing a super-Lax formulation for the super-''ghost'' symmetry flows [cf. (4.5)–(4.6)]–a supersymmetric extension of the double-KP construction of Ref. 10; (b) general treatment of arbitrary constrained $\mathrm{SKP}_{r/2,m/2}$ hierarchies, including derivation of more general Wronskian-type solutions for the super-tau function and elucidating their Berezinian origin; (c) obtaining consistent formulation of supersymmetric two-dimensional Toda lattice as Darboux–Bäcklund orbit on the ''doubled'' MR-SKP hierarchy (similar to the purely bosonic case[10]) and of supersymmetric analogs of random (multi)matrix models; (d) study of possible connections of super-tau functions, on one hand, and partition functions and joint distribution functions in random matrix models in condensed matter physics (cf. Ref. 22), on the other hand.

(Received 10 March 1998; accepted for publication 10 March 1999)

Hamiltonian formalism for the nonlinear Schrödinger equation in physical space–time is developed. Owing to the fact that the equation involves the second partial derivative with respect to time, the canonical variables are shown to be u, $\overline{u}$, $-\overline{u_t}$, and $-u_t$. The first Lax equation and its variations with respect to canonical variables are very complicated, but the Poisson brackets of transition coefficients are shown to be simple, and thus the Hamiltonian formalism in terms of action-angle variables has been achieved. A peculiarity is that the continuous spectrum consists of real λ as well as pure imaginary λ. In the case of pure imaginary λ the full Jost solutions shall tend to be infinite or vanish as $|t|\to\infty$. This problem needs further investigation. [S0022-2488(99)04106-7]

I. INTRODUCTION

In the last two decades the nonlinear Schrödinger (NLS) equation has been thoroughly investigated from the inverse scattering transform,[1] Hamiltonian formalism[2–4] to the quantum inverse scattering transform.[5,6] As is well known, to describe, for example, a short temporal pulse propagation in nonlinear optical fibers the NLS equation takes a form[7–9]

$$iu_x+u_{tt}+2|u|^2u=0, \tag{1}$$

where t and x denote the time and the space coordinate in the frame of reference moving with the group velocity. This equation will be referred to as the NLS equation in physical space–time. Nevertheless, since a short temporal pulse is a soliton in time, usually the equation used to describe the propagation of the so-called optical soliton in a fiber is the conventional NLS equation[8,10]

$$iu_T+u_{XX}+2|u|^2u=0, \tag{2}$$

where T and X are not true physical time and space though we read them as time and space. Most of the investigations start from (2). In finding classical solutions, for example, soliton solutions, t, x, and T, X are just pure parameters, the solutions to (1) can be obtained from the solutions to (2) by simply exchanging variables and *vice versa*.[11,12] However, for developing Hamiltonian formalism as to the quantum inverse scattering transform, one should start from (1) where x and t are true space and time. On the other hand, Eq. (1) is also called the unstable nonlinear Schrödinger equation which has been studied in detail by Wadati *et al.*[11,13–15] It was shown that (2) can be used to describe the soliton phenomena in unstable media. (1) has been derived for two physics systems: the Rayleigh–Taylor instability and electron beam plasma. The soliton solutions of (1) and its application to the physics problem have been discussed. As is known, a Hamiltonian formalism of Eq. (1) has not yet been developed, and the quantum inverse scattering transform for (1) is still an open question.

In this paper the Hamiltonian formalism for the NLS equation in physical space–time is developed in an exact manner which provides a basis for further development of the quantum inverse scattering transform and its potential application in the physical systems mentioned above. For convenience, the boundary condition will be chosen as:

$$u \to 0 \quad \text{as} \quad |x| \to \infty. \tag{3}$$

II. GENERAL FORMALISM

The Lagrangian density $\mathcal{L}$ for (1) is given by

$$\mathcal{L} = -\frac{i}{2}\{\bar{u}_x u - \bar{u} u_x\} - \bar{u}_t u_t + \bar{u}^2 u^2. \tag{4}$$

Since Eq. (1) involves the second derivative with respect to t, the generalized coordinates are chosen as u and $\bar{u}$. This can be easily shown to be right since the Lagrangian equation

$$\frac{\partial \mathcal{L}}{\partial u} - \frac{\partial}{\partial x}\left(\frac{\partial \mathcal{L}}{\partial u_x}\right) - \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial u_t}\right) = 0, \tag{5}$$

and that for $\bar{u}$ reproduce Eq. (1) and its complex conjugate. The momentum densities conjugated to u and $\bar{u}$, π and $\bar{\pi}$, are given by

$$\pi \equiv \frac{\partial \mathcal{L}}{\partial u_t} = -\bar{u}_t, \quad \bar{\pi} \equiv \frac{\partial \mathcal{L}}{\partial \bar{u}_t} = -u_t. \tag{6}$$

Then the Hamiltonian density $\mathcal{H}$ is given by

$$\mathcal{H} \equiv \pi u_t + \overline{\pi u_t} - \mathcal{L} = \frac{i}{2}\{\bar{u}_x u - \bar{u} u_x\} - \bar{u}_t u_t - \bar{u}^2 u^2. \tag{7}$$

Since u and π, as well as $\bar{u}$ and $\bar{\pi}$, are conjugated with each other, the basic Poisson brackets are

$$\begin{aligned} &\{u(x), -\bar{u}_t(y)\} = \delta(x-y), \quad \{u(x), \bar{u}(y)\} = 0, \\ &\{\bar{u}(x), -u_t(y)\} = \delta(x-y), \quad \{u_t(x), \bar{u}_t(y)\} = 0. \end{aligned} \tag{8}$$

Suppose that S and T are functionals of u, $\bar{u}$, $-u_t$, and $-\bar{u}_t$, then the Poisson bracket of S and T is given by

$$\{S,T\} = -\int_{-\infty}^{\infty}\left(\frac{\delta S}{\delta u(x)}\frac{\delta T}{\delta \bar{u}_t(x)} + \frac{\delta S}{\delta \bar{u}(x)}\frac{\delta T}{\delta u_t(x)} - \frac{\delta S}{\delta \bar{u}_t(x)}\frac{\delta T}{\delta u(x)} - \frac{\delta S}{\delta u_t(x)}\frac{\delta T}{\delta \bar{u}(x)}\right)dx. \tag{9}$$

III. THE JOST SOLUTIONS

The first Lax equation of (1) is given by

$$\partial_x \Phi(x,\lambda) = L(x,\lambda)\Phi(x,\lambda), \tag{10}$$

where

$$L(x,\lambda) = -i2\lambda^2\sigma_3 + 2\lambda U(x,t) - i\{U^2(x,t) + U_t(x,t)\}\sigma_3, \tag{11}$$

and

$$U(x,t)=\begin{pmatrix} 0 & u(x,t) \\ -\overline{u(x,t)} & 0 \end{pmatrix}. \tag{12}$$

We define the Jost solutions by boundary condition (3),

$$\Phi(x,\lambda)\to e^{-i2\lambda^2 x\sigma_3} \quad \text{as} \quad x\to-\infty, \tag{13}$$

and then find

$$\Phi(x,\lambda)=e^{-i2\lambda^2 x\sigma_3}+\int_{-\infty}^{x} dy\, e^{-i2\lambda^2(x-y)\sigma_3}\{L(y,\lambda)+i2\lambda^2\sigma_3\}\Phi(y,\lambda). \tag{14}$$

Similarly, we define

$$\Psi(x,\lambda)\to e^{-i2\lambda^2 x\sigma_3} \quad \text{as} \quad x\to\infty. \tag{15}$$

The monodromy matrix is given by

$$T(\lambda)=\Psi^{-1}(x,\lambda)\Phi(x,\lambda) \quad \text{or} \quad \Phi(x,\lambda)=\Psi(x,\lambda)T(\lambda). \tag{16}$$

We write

$$\Phi(x,\lambda)=(\phi(x,\lambda)\tilde{\phi}(x,\lambda)), \quad \Psi(x,\lambda)=(\tilde{\psi}(x,\lambda)\psi(x,\lambda)), \quad T(\lambda)=\begin{pmatrix} a(\lambda) & -\tilde{b}(\lambda) \\ b(\lambda) & \tilde{a}(\lambda) \end{pmatrix}, \tag{17}$$

where $\phi(x,\lambda)$, etc., have two components, respectively. Since $\det\Psi(x,\lambda)=1$, from (16), we have

$$a(\lambda)=\psi_2(x,\lambda)\phi_1(x,\lambda)-\psi_1(x,\lambda)\phi_2(x,\lambda), \quad b(\lambda)=-\tilde{\psi}(x,\lambda)\phi_1(x,\lambda)+\tilde{\psi}_1(x,\lambda)\phi_2(x,\lambda), \tag{18}$$

etc., and

$$\phi(x,\lambda)=a(\lambda)\tilde{\psi}(x,\lambda)+b(\lambda)\psi(x,\lambda), \tag{19}$$

etc. These functions are defined in real λ^2, i.e., on the real axis and on the imaginary axis of complex λ plane.

From (16) we show that $\phi(x,\lambda)$ can be analytically continued into the region of $\operatorname{Im}\lambda^2>0$, i.e., in the first and the third quadrants and that $\tilde{\phi}(x,\lambda)$ can be analytically continued into the region of $\operatorname{Im}\lambda^2<0$, i.e., in the second and the fourth quadrants. Zeros of $a(\lambda)$ are located in the first and the third quadrants and are assumed to be simple. From (10) it can be shown

$$\tilde{\phi}(x,\bar{\lambda})=i\sigma_2\overline{\phi(x,\lambda)}, \quad \tilde{\psi}(x,\bar{\lambda})=-i\sigma_2\overline{\psi(x,\lambda)}, \tag{20}$$

$$\tilde{a}(\bar{\lambda})=\overline{a(\lambda)}, \quad \tilde{b}(\bar{\lambda})=\overline{b(\lambda)}, \tag{21}$$

noting that the second one of the last equation holds only for real λ^2. In the first and the third quadrants $a(\lambda)$ may have zeros. $a(\lambda)$ is assumed to have N simple zeros, λ_n, $n=1,2,...,N$. From (18) we have

$$\phi(x,\lambda_n)=b_n\psi(x,\lambda_n), \tag{22}$$

where b_n is independent of x.

IV. AN INVERSE SCATTERING TRANSFORM

Introducing

$$\Theta(x,\lambda)=\begin{cases} a(\lambda)^{-1}\phi(x,\lambda) & \text{as Im}\,\lambda^2>0 \\ \tilde{\psi}(x,\lambda) & \text{as Im}\,\lambda^2<0. \end{cases} \tag{23}$$

By using the standard procedure, we obtain the equation of inverse scattering transform in the form of Zakharov–Shabat:

$$\tilde{\psi}(x,\lambda)e^{i2\lambda^2 x}=\begin{pmatrix}1\\0\end{pmatrix}+R(x,\lambda)+J(x,\lambda), \tag{24}$$

where

$$R(x,\lambda)=\sum_n \frac{1}{\lambda-\lambda_n}c_n\psi(x,\lambda_n)e^{i2\lambda_n^2 x}, \tag{25}$$

$$J(x,\lambda)=\frac{1}{i2\pi}\int_\Gamma \frac{1}{\lambda'-\lambda}r(\lambda')\psi(x,\lambda')e^{i2\lambda'^2 x}\,d\lambda', \tag{26}$$

$$c_n=\frac{b_n}{a_n}, \quad a_n\equiv\dot{a}(\lambda_n)=\frac{d}{d\lambda}a(\lambda)\bigg|_{\lambda=\lambda_n}, \quad r(\lambda)=\frac{b(\lambda)}{a(\lambda)}, \tag{27}$$

and where Γ denotes the integral path which contains two parts.[12] One part is along the real axis from 0 to $-\infty$ and from 0 to $+\infty$, the other is along the imaginary axis from 0 to $-i\infty$ and from 0 to $+i\infty$, i.e.,

$$\int_\Gamma \mathcal{F}(x,\lambda)d\lambda=\left(\int_0^{+\infty}-\int_0^{-\infty}\right)\mathcal{F}(x,\mu)d\mu-\left(\int_0^{+\infty}-\int_0^{-\infty}\right)\mathcal{F}(x,i\nu)d(i\nu). \tag{28}$$

The time dependence is determined by the second Lax equation,

$$\partial_t\Phi(x,t,\lambda)=M(x,t,\lambda)\Phi(x,t,\lambda), \tag{29}$$

where

$$M(x,t,\lambda)=-i\lambda\sigma_3+U(x,t). \tag{30}$$

By using the second Lax equation, the time dependence is achieved by simple replacements:

$$a(\lambda)\to a(t,\lambda)=a(0,\lambda), \quad b(\lambda)\to b(t,\lambda)=b(0,\lambda)e^{i2\lambda t}, \quad b_n\to b_n(t)=b_n(0)e^{i2\lambda_n t}. \tag{31}$$

The solution is then determined by

$$\overline{u(x,t)}=\lim_{|\lambda|\to\infty}(i2\lambda)\tilde{\psi}_2(x,t,\lambda)e^{i2\lambda^2 x+i\lambda t}. \tag{32}$$

In the case of no reflections, the Zakharov–Shabat equation (24) including the time dependence (31) has the same form as that of Eq. (2) by simply exchanging[12]

$$x,t\leftrightarrow T,X, \tag{33}$$

while the locations of zeros of $a(\lambda)$ are somewhat different. In the latter case, all the zeros are in the upper half plane, while in the former case, those are in the first or third quadrants. However, as we have shown,[16] one can change a pole from the lower half plane to upper half plane in the case that these two poles are symmetric with respect to the real axis, and the final results are the same. This implies that, for finding soliton solutions, Eqs. (1) and (2) are equivalent.

V. CONSERVATIVE QUANTITIES

Since $a(\lambda)$ is assumed to have N simple poles in the first and third quadrants, $a(\lambda)$ can be expressed as

$$a(\lambda)=\prod_{n=1}^{N}\frac{\lambda-\lambda_n}{\lambda-\overline{\lambda_n}}\check{a}(\lambda), \tag{34}$$

where $\check{a}(\lambda)$ is analytical in the first and the third quadrants and has no zeros. Taking into account that

$$\ln a(\lambda)\to 0 \quad \text{as } |\lambda|\to\infty,$$

the general expression of $a(\lambda)$ is

$$a(\lambda)=\prod_{n=1}^{N}\frac{\lambda-\lambda_n}{\lambda-\overline{\lambda_n}}\exp\left\{\frac{1}{i2\pi}\int_\Gamma\frac{\ln|a(\lambda')|}{\lambda'-\lambda}d\lambda'\right\}. \tag{35}$$

The fact that $a(t,\lambda)$ is independent of t leads to infinite conservation laws. An expansion of $\ln a(\lambda)$ as $|\lambda|\to\infty$ is similar to that for (2), e.g., the second conservative quantity I_2 is[10]

$$I_2=\sum_{n=1}^{n}(\lambda_n^2-\overline{\lambda_n^2})-i\frac{2}{\pi}\int_\Gamma \ln|a(\lambda)|2\lambda\,d\lambda. \tag{36}$$

The expressions related to u for Eq. (1) are different from those related to u for (2), e.g., I_2 in the present case is (for details, see Appendix A)

$$I_2=\int_{-\infty}^{\infty}dx\{i|u_t|^2-i|u|^4+(|u|^2)_x-\overline{u}u\}. \tag{37}$$

VI. VARIATIONS WITH RESPECT TO $u(x)$ AND $\overline{u(x)}$

From (10) we have

$$\partial_x\delta\Phi(x,\lambda)=L(x,\lambda)\,\delta\Phi(x,\lambda)+\delta L(x,\lambda)\Phi(x,\lambda). \tag{38}$$

The solution is obviously

$$\delta\Phi(x,\lambda)=\int_{-\infty}^{x}dz\,\Phi(x,\lambda)\Phi^{-1}(z,\lambda)\,\delta L(z,\lambda)\Phi(z,\lambda). \tag{39}$$

We have

$$\frac{\delta L(z,\lambda)}{\delta u(x)}=\{2\lambda\sigma_+ + i\overline{u(x)}\sigma_3\}\delta(x-z), \tag{40}$$

etc., in the case of $x>z$,

$$\frac{\delta\Phi(x,\lambda)}{\delta u(z)}=\Phi(x,\lambda)\Phi^{-1}(z,\lambda)\{2\lambda\sigma_+ + i\overline{u(z)}\sigma_3\}\Phi(z,\lambda), \tag{41}$$

and then setting $z=x^-\equiv x-0$,

$$\frac{\delta\Phi(x,\lambda)}{\delta u(x^-)}=\{2\lambda\sigma_+ + i\overline{u(x)}\sigma_3\}\Phi(x,\lambda). \tag{42}$$

Similarly,

$$\frac{\delta\Phi(x,\lambda)}{\delta\overline{u(x^-)}}=\{-2\lambda\sigma_- + iu(x)\sigma_3\}\Phi(x,\lambda), \tag{43}$$

$$\frac{\delta\Phi(x,\lambda)}{\delta\overline{u_t(x^-)}}=i\sigma_-\Phi(x,\lambda), \tag{44}$$

and

$$\frac{\delta\Phi(x,\lambda)}{\delta u_t(x^-)}=-i\sigma_+\Phi(x,\lambda), \tag{45}$$

where

$$\sigma_+=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix},\quad \sigma_-=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}. \tag{46}$$

In the same way, we obtain

$$\frac{\delta\Psi^{-1}(x,\lambda)}{\delta u(x^+)}=\Psi^{-1}(x,\lambda)\{2\lambda\sigma_+ + i\overline{u(x)}\sigma_3\}, \tag{47}$$

$$\frac{\delta\Psi^{-1}(x,\lambda)}{\delta\overline{u(x^+)}}=\Psi^{-1}(x,\lambda)\{-2\lambda\sigma_- + iu(x)\sigma_3\}, \tag{48}$$

$$\frac{\delta\Psi^{-1}(x,\lambda)}{\delta\overline{u_t(x^+)}}=\Psi^{-1}(x,\lambda)i\sigma_-, \tag{49}$$

and

$$\frac{\delta\Psi^{-1}(x,\lambda)}{\delta u_t(x^+)}=-\Psi^{-1}(x,\lambda)i\sigma_+, \tag{50}$$

where $x^+\equiv x+0$.

From (16) we have

$$\delta T(\lambda)=\delta\Psi^{-1}(z,\lambda)\Phi(z,\lambda)+\Psi^{-1}(z,\lambda)\delta\Phi(z,\lambda), \tag{51}$$

and then

$$\frac{\delta T(\lambda)}{\delta u(x)}=\frac{\delta\Psi^{-1}(z,\lambda)}{\delta u(x)}\Phi(z,\lambda)+\Psi^{-1}(z,\lambda)\frac{\delta\Phi(z,\lambda)}{\delta u(x)}. \tag{52}$$

Since z is arbitrary in the above formula, we can set $z\rightarrow x^-$,

$$\frac{\delta T(\lambda)}{\delta u(x)}=\Psi^{-1}(x,\lambda)\{2\lambda\sigma_+ + i\overline{u(x)}\sigma_3\}\Phi(x,\lambda). \tag{53}$$

Similarly,

$$\frac{\delta T(\lambda)}{\delta u(x)} = \Psi^{-1}(x,\lambda)\{-2\lambda\sigma_- + iu(x)\sigma_3\}\Phi(x,\lambda), \tag{54}$$

$$\frac{\delta T(\lambda)}{\delta u_t(x)} = \Psi^{-1}(x,\lambda) i\sigma_- \Phi(x,\lambda), \tag{55}$$

and

$$\frac{\delta T(\lambda)}{\delta u_t(z)} = -\Psi^{-1}(x,\lambda) i\sigma_+ \Phi(x,\lambda). \tag{56}$$

Since

$$\delta T^{-1}(\lambda) = -T^{-1}(\lambda)\,\delta T(\lambda) T^{-1}(\lambda), \tag{57}$$

we can find variation of $T^{-1}(\lambda)$ with respect to $u(x)$, etc.

VII. BASIC POISSON BRACKETS (CONTINUOUS SPECTRUM)

Consider Poisson bracket of $\{T_{ij}(\lambda), T_{kl}^{-1}(\lambda')\}$. From (9), the integrand of the right-hand side is

$$\frac{\delta T_{ij}(\lambda)}{\delta u(x)}\frac{\delta T_{kl}^{-1}(\lambda')}{\delta u_t(x)} + \frac{\delta T_{ij}(\lambda)}{\delta u(x)}\frac{\delta T_{kl}^{-1}(\lambda')}{\delta u_t(x)} - \frac{\delta T_{ij}(\lambda)}{\delta u_t(x)}\frac{\delta T_{kl}^{-1}(\lambda')}{\delta u(x)} - \frac{\delta T_{ij}(\lambda)}{\delta u_t(x)}\frac{\delta T_{kl}^{-1}(\lambda')}{\delta u(x)}. \tag{58}$$

Substituting (52), etc., into (58) we can obtain its explicit expression. With the help of the first Lax equation, we find that (58) can be expressed as (for details, see Appendix B)

$$\frac{1}{2(\lambda-\lambda')}\partial_x\{[\Psi^{-1}(x,\lambda)\Psi(x,\lambda')]_{il}[\Phi^{-1}(x,\lambda')\Phi(x,\lambda)]_{kj}\}. \tag{59}$$

Hence we obtain

$$\{T_{ij}(\lambda), T_{kl}^{-1}(\lambda')\} = \lim_{L\to\infty}\frac{1}{2(\lambda-\lambda')}[\Psi^{-1}(x,\lambda)\Psi(x,\lambda')]_{il}[\Phi^{-1}(x,\lambda')\Phi(x,\lambda)]_{kj}\Big|_{-L}^{L}. \tag{60}$$

Taking account of (13) and (15), the right-hand side is equal to

$$\lim_{L\to\infty}\frac{1}{2(\lambda-\lambda')}[e^{i2(\lambda^2-\lambda'^2)L\sigma_3}]_{il}[T^{-1}(\lambda')e^{-i(\lambda^2-\lambda'^2)L\sigma_3}T(\lambda)]_{kj}, \tag{61}$$

plus

$$-\lim_{L\to\infty}\frac{1}{2(\lambda-\lambda')}[T(\lambda)e^{-i2(\lambda^2-\lambda'^2)L\sigma_3}T^{-1}(\lambda')]_{il}[e^{i2(\lambda^2-\lambda'^2)L\sigma_3}]_{kj}. \tag{62}$$

By employing the following relations:

$$\lim_{L\to\infty}\frac{e^{-i4(\lambda^2-\lambda'^2)L}}{2(\lambda-\lambda')} = -i\frac{1}{2}\pi\delta(\lambda-\lambda'), \tag{63}$$

and

$$\frac{1}{\lambda \pm i0} = \text{p.v.}\frac{1}{\lambda} \mp \pi i \delta(\lambda), \tag{64}$$

where p.v. denotes the Cauchy principal value.[3] Finally we obtain

$$\{a(\lambda),a(\lambda')\}=0, \quad \{a(\lambda),\tilde{a}(\lambda')\}=0, \quad \{\tilde{a}(\lambda),\tilde{a}(\lambda')\}=0, \tag{65}$$

$$\{b(\lambda),b(\lambda')\}=0, \quad \{\tilde{b}(\lambda),\tilde{b}(\lambda')\}=0, \tag{66}$$

$$\{a(\lambda),b(\lambda')\}=\frac{1}{2}\frac{1}{\lambda-\lambda'+i0}a(\lambda)b(\lambda'), \quad \{a(\lambda),\tilde{b}(\lambda')\}=-\frac{1}{2}\frac{1}{\lambda-\lambda'+i0}a(\lambda)\tilde{b}(\lambda'), \tag{67}$$

$$\{\tilde{a}(\lambda),\tilde{b}(\lambda')\}=\frac{1}{2}\frac{1}{\lambda-\lambda'-i0}\tilde{a}(\lambda)\tilde{b}(\lambda'), \quad \{\tilde{a}(\lambda),b(\lambda')\}=-\frac{1}{2}\frac{1}{\lambda-\lambda'-i0}\tilde{a}(\lambda)b(\lambda'), \tag{68}$$

and

$$\{b(\lambda),\tilde{b}(\lambda')\}=i\pi\delta(\lambda-\lambda')|a(\lambda)|^2. \tag{69}$$

In last three formulas λ and λ' are simultaneously real or simultaneously imaginary.

VIII. BASIC POISSON BRACKETS (DISCRETE SPECTRUM)

From (65) we know that $\{\ln a(\lambda),a(\lambda')\}=0$, then by (35), we have

$$\{\ln \breve{a}(\lambda),a(\lambda')\}+\sum_{n=1}^{N}\left(\frac{\{\lambda_n,a(\lambda')\}}{\lambda-\lambda_n}-\frac{\{\overline{\lambda_n},a(\lambda')\}}{\lambda-\overline{\lambda_n}}\right)=0. \tag{70}$$

This expression cannot have pole at λ_n, hence we obtain

$$\{\lambda_n,a(\lambda')\}=0. \tag{71}$$

Similarly, we also have

$$\{\overline{\lambda_n},a(\lambda')\}=0, \quad \{\lambda_n\tilde{a}(\lambda')\}=0, \quad \{\overline{\lambda_n},\tilde{a}(\lambda')\}=0. \tag{72}$$

With the same procedure from $\{\lambda_n,\ln a(\lambda')\}=0$, we obtain

$$\{\lambda_n,\lambda_m\}=0, \quad \{\lambda_n,\overline{\lambda_m}\}=0. \tag{73}$$

From (67), we obtain

$$\{\ln a(\lambda),b(\lambda')\}=-b(\lambda')\frac{1}{2}\frac{1}{\lambda-\lambda'+i0}. \tag{74}$$

Substituting (34), the left-hand side becomes

$$\{\ln \breve{a}(\lambda),b(\lambda')\}+\sum_{n=1}^{N}\left(\frac{\{\lambda_n,b(\lambda')\}}{\lambda-\lambda_n}-\frac{\{\overline{\lambda_n},b(\lambda')\}}{\lambda-\overline{\lambda_n}}\right). \tag{75}$$

Since $\mathrm{Im}\,\lambda^2>0$, λ' is real or pure imaginary, $\lambda-\lambda'+i0\neq 0$, (74) is finite, so that (74) has no poles, thus

$$\{\lambda_n, b(\lambda')\}=0. \tag{76}$$

Similarly, we have

$$\{\overline{\lambda_n}, b(\lambda')\}=0. \tag{77}$$

Poisson brackets involving b_n or $\tilde{b}_m$ can be obtained from those involving $b(\lambda)$ or $\tilde{b}(\lambda)$ by simply assuming $b_n=b(\lambda_n)$ and $\tilde{b}_m=\tilde{b}(\overline{\lambda_m})$, which are the results of the assumption of compact support[3] of u (for the derivation without compact support see Appendix C). From (67), etc., we have

$$\{a(\lambda),b_n\}=\frac{1}{2}\frac{1}{\lambda-\lambda_n}a(\lambda)b_n,\quad \{a(\lambda),\tilde{b}_m\}=-\frac{1}{2}\frac{1}{\lambda-\overline{\lambda_m}}a(\lambda)\tilde{b}_m, \tag{78}$$

$$\{\tilde{a}(\lambda),\tilde{b}_m\}=\frac{1}{2}\frac{1}{\lambda-\overline{\lambda_m}}\tilde{a}(\lambda)\tilde{b}_m,\quad \{\tilde{a}(\lambda),b_n\}=-\frac{1}{2}\frac{1}{\lambda-\lambda_n}\tilde{a}(\lambda)b_n. \tag{79}$$

Corresponding to (69), we have

$$\{b(\lambda),b_n\}=0,\quad \{b(\lambda),\tilde{b}_m\}=0,\quad \{b_n,b_m\}=0,\quad \{b_n,\tilde{b}_m\}=0. \tag{80}$$

By using a similar procedure leading to (76), etc., we have

$$\{\lambda_m,b_n\}=\delta_{mn}\tfrac{1}{2}b_n,\quad \{\overline{\lambda_m},b_n\}=0, \tag{81}$$

and

$$\{\lambda_m,\tilde{b}_n\}=\delta_{mn}\tfrac{1}{2}\tilde{b}_n,\quad \{\lambda_m\tilde{b}_n\}=0. \tag{82}$$

IX. HAMILTONIAN FORMALISM

After integration by parts, we can see that I_2 in (37) is proportional to the Hamiltonian H which is the integral of $\mathcal{H}$ in (7),

$$H=-iI_2. \tag{83}$$

Hence we have

$$H=i2\sum_{n=1}^{N}(\overline{\lambda_n^2}-\lambda_n^2)-\frac{2}{\pi}\int_\Gamma \ln|a(\lambda)|^2\lambda\, d\lambda. \tag{84}$$

The NLS equation in physical space–time can be expressed in the Hamiltonian form

$$\partial_t\pi(x,t)=\{H,\pi(x,t)\}=\frac{\delta H}{\delta u(x,t)},\quad \partial_t u(x,t)=\{H,u(x,t)\}=-\frac{\delta H}{\delta\pi(x,t)}, \tag{85}$$

etc. Substituting (84), the former leads to the complex conjugate of (1) and the latter gives an equality.

Similarly,

$$\partial_t a(t,\lambda)=\{H,a(t,\lambda)\},\quad \partial_t b(t,\lambda)=\{H,b(t,\lambda)\}. \tag{86}$$

We obtain

$$\partial_t a(t,\lambda)=0, \quad a(t,\lambda)=a(0,\lambda). \tag{87}$$

Owing to

$$\{|a(\lambda)|^2,b(\lambda')\}=i\pi\delta(\lambda-\lambda')|a(\lambda)|^2 b(\lambda'), \tag{88}$$

and then

$$\{\ln|a(\lambda)|^2,b(\lambda')\}=i\pi\delta(\lambda-\lambda')b(\lambda'), \tag{89}$$

we obtain

$$\{H,b(\lambda)\}=-\frac{2}{\pi}\int_\Gamma\{\ln|a(\lambda')|^2,b(\lambda)\}\lambda'\,d\lambda'. \tag{90}$$

This implies

$$\partial_t b(\lambda)=\{H,b(\lambda)\}=-i2\lambda b(\lambda), \tag{91}$$

and hence

$$b(\lambda,t)=b(\lambda,0)e^{-i2\lambda t}. \tag{92}$$

Similarly, since we know

$$\{|a(\lambda)|^2,b_n\}=0, \tag{93}$$

and

$$\{\lambda_m^2,b_n\}=2\lambda_m\{\lambda_m,b_n\}=\delta_{mn}\lambda_m b_n, \tag{94}$$

we can find

$$\partial_t b_n=\{H,b_n\}=-i2\lambda_n b_n, \tag{95}$$

and then

$$b_n(t)=b_n(0)e^{-i2\lambda_n t}. \tag{96}$$

X. ACTION-ANGLE VARIABLES

Now we introduce the action-angle variables for the NLS equation in physical space–time (1), for continuous spectrum,

$$P(\lambda)=\frac{1}{\pi}\ln\frac{1}{|a(\lambda)|^2}, \quad Q(\lambda)=\arg b(\lambda), \tag{97}$$

which are real, and for the discrete spectrum,

$$P_n=2\lambda_n, \quad Q_n=\ln\frac{1}{b_n}, \tag{98}$$

which are complex, and hence

$$P_n'=2\,\mathrm{Re}\,\lambda_n, \quad P_n''=2\,\mathrm{Im}\,\lambda_n, \tag{99}$$

$$Q_n' = \ln|b_n|, \quad Q_n'' = -\arg b_n. \tag{100}$$

Since they are also generalized coordinates and conjugated momentum, we must show

$$\{P(\lambda), Q(\lambda')\} = \delta(\lambda - \lambda'), \tag{101}$$

$$\{P_n', Q_m'\} = \{P_n'', Q_m''\} = \delta_{nm}, \tag{102}$$

and all other Poisson brackets vanish.

By definition (97), we know

$$\{e^{i2Q(\lambda)}, e^{i2Q(\lambda')}\} = \left\{ \frac{b(\lambda)}{\overline{\overline{b(\lambda)}}}, \frac{b(\lambda')}{\overline{\overline{b(\lambda')}}} \right\}, \tag{103}$$

the right-hand side obviously vanishes since

$$-\frac{b(\lambda')}{\overline{\overline{b(\lambda)}}\cdot\overline{\overline{b(\lambda')^2}}}\{b(\lambda), \overline{b(\lambda')}\} - \frac{b(\lambda)}{\overline{\overline{b(\lambda)^2}}\cdot\overline{\overline{b(\lambda')}}}\{\overline{b(\lambda)}, b(\lambda)\} = 0. \tag{104}$$

Hence we obtain

$$\{Q(\lambda), Q(\lambda')\} = 0. \tag{105}$$

For a function of $|a(\lambda)|^2$ as $f(|a(\lambda|^2)$, we have

$$\{f(|a(\lambda)|^2), Q(\lambda')\} = \frac{f'(|a(\lambda)|^2)}{i2} \frac{\overline{b(\lambda')}}{b(\lambda')} \left\{ |a(\lambda')|^2, \frac{b(\lambda')}{\overline{\overline{b(\lambda')}}} \right\}. \tag{106}$$

By using (88), etc., we obtain

$$\{f(|a(\lambda)|^2), Q(\lambda')\} = \pi\delta(\lambda - \lambda') \frac{f'(|a(\lambda)|^2)}{2} |a(\lambda)|^2. \tag{107}$$

Setting

$$f(|a(\lambda)|^2) = \frac{1}{\pi} \ln \frac{1}{|a(\lambda)|^2}, \tag{108}$$

(107) leads to (101). On the other hand, it is obvious

$$\{2\lambda_m, \ln b_n\} = \delta_{mn}, \tag{109}$$

and

$$\{2\lambda_m, \ln \tilde{b}_n\} = 0. \tag{110}$$

Furthermore, we must show that action variables are constants while angle variables are dependent on time periodically. Substituting (97) and (99) into (84) we obtain

$$H = 2\sum_n P_n' P_n'' + 2\int_\Gamma P(\lambda')\lambda' \, d\lambda'. \tag{111}$$

By this expression, it is easy to know that the Poisson brackets $\{H, P(\lambda)\}$, $\{H, P_n'\}$, and $\{H, P_n''\}$ vanish, so that $P(\lambda)$, P_n', and P_n'' are constants. On the other hand, since

$$\partial_t Q(\lambda)=\{H,Q(\lambda)\}=2\int_\Gamma \{P(\lambda'),Q(\lambda\}\lambda' d\lambda'=2\lambda, \tag{112}$$

we have

$$Q(\lambda,t)=Q(\lambda,0)+2\lambda t. \tag{113}$$

Similarly, one can find

$$\partial_t Q_n'=\{H,Q_n'\}=2P_n'', \quad \partial_t Q_n''=\{H,Q_n''\}=2P_n', \tag{114}$$

and hence

$$Q_n'(t)=Q_n'(0)+2P_n''t, \quad Q_n''(t)=Q_n'(0)+2P_n't. \tag{115}$$

We thus see $Q(\lambda)$, Q_n', and Q_n'' are indeed angle variables.

XI. CONCLUSION AND DISCUSSION

In previous sections, the Hamiltonian formalism for the NLS equation in physical space–time is developed. Owing to the fact that the equation involves the second partial derivative with respect to time, the generalized coordinates are chosen as u and $\overline{u}$, the canonically conjugated momentum are $\pi=-\overline{u_t}$ and $\overline{\pi}=-u_t$. The first Lax equation in the present case is more complicated, it contains the generalized coordinates as well as the canonically conjugated momentums. We find that the continuous spectrum consists of real λ as well as pure imaginary λ. Though variations of the first Lax equation with respect to u ($\overline{u}$, π, and $\overline{\pi}$) are complicated, the Poisson brackets of transition coefficients are simple, and thus the Hamiltonian formalism in terms of action-angle variables can be achieved.

As we have shown, for dealing with the soliton solution, (1) and (2) are equivalent. This is easy to understand because in the frame moving with the soliton, $u\to 0$ when x or $t\to\infty$. Nevertheless, the initial condition becomes relevant when dealing with a physics system. For example, as perturbation is involved, the initial problem will play an important role.[17] The importance of the initial condition has been pointed out by Wadati *et al.*[11,13–15] In the case of pure imaginary λ, the full Jost solutions shall tend to infinite or vanish as $|t|\to\infty$. The control of instability in physics system has been discussed by Wadati *et al.*[13,15] This problem needs further investigations.

APPENDIX A

The expression of the conservative quantity can be obtained from the asymptotic behavior of the Jost solutions. The first Lax equation (10) can be expressed as

$$\phi_{1x}=(-i2\lambda^2+i|u|^2)\phi_1+(iu_t+2\lambda u)\phi_2, \tag{A1}$$

$$\phi_{2x}=(i2\lambda^2-i|u|^2)\phi_2+(-i\overline{u_t}+2\lambda\overline{u})\phi_1. \tag{A2}$$

Here

$$\phi=\begin{pmatrix}\phi_1\\ \phi_1\end{pmatrix}.$$

Taking the derivative with respect to x in (A1), one can get an equation that just contains ϕ_1 by substituting (A2). Introducing

$$\phi_1(x,\lambda)=e^{(-i2\lambda^2 x+\hat{\phi})}, \tag{A3}$$

we have

$$\mu^2 - i4\lambda^2\mu + |iu_t + 2\lambda u|^2 - |u|^2(4\lambda^2 - |u|^2) = (iu_t + 2\lambda u)\left(\frac{i|u|^2 - \mu}{iu_t + 2\lambda u}\right)_x, \tag{A4}$$

here

$$\mu = \hat{\phi}_x. \tag{A5}$$

From (13), we know that

$$\text{as } |\lambda| \to \infty, \quad \hat{\phi} \to 0 \quad \hat{\phi}_x \to 0. \tag{A6}$$

Consequently, μ can be expanded as

$$\mu = \sum_{j=1}^{\infty} \frac{\mu_j}{(i2\lambda)^j}. \tag{A7}$$

Substituting (A7) back to (A4), one can find

$$\mu_1 = -i(u_t\bar{u} - u\bar{u}_t), \tag{A8}$$

$$\mu_2 = i|u_t|^2 - i|u|^4 + (|u|^2)_x - \bar{u}u_x, \tag{A9}$$

etc. From (A7), we can express $\hat{\phi}$ as

$$\hat{\phi} = \sum_{j=1}^{\infty} \frac{\hat{\phi}_j}{(i2\lambda)^j}. \tag{A10}$$

Here

$$\hat{\phi}_i = \int_{-\infty}^{x} dy\, \mu_i. \tag{A11}$$

On the other hand, from (16), (17), and (13), we have

$$a(t,\lambda) = \lim_{x \to \infty} \phi_1(x,t,\lambda) e^{i2\lambda^2 x}. \tag{A12}$$

Taking account of (A3), one can find

$$\ln a(t,\lambda) = \lim_{x \to \infty} \hat{\phi}(x,t,\lambda). \tag{A13}$$

By using (A10) and (A11), we have

$$\ln a(t,\lambda) = \sum_{j=1}^{\infty} \frac{I_j}{(i2\lambda)^j}. \tag{A14}$$

Here

$$I_j = \int_{-\infty}^{\infty} \mu_j(x,t)\, dx. \tag{A15}$$

Owing to the fact that $a(t,\lambda)$ is t independent, all the I_j are conservative. By substituting (A9) into (A15), we get Eq. (37).

APPENDIX B

From (53) to (57), we can find the explicit expression of (58)

$$\overline{u(x)}\Phi_{k2}^{-1}(x,\lambda')\Psi_{1l}(x,\lambda')[\Psi^{-1}(x,\lambda)\sigma_3\Phi(x,\lambda)]_{ij}-u(x)\Psi_{i1}^{-1}(x,\lambda)\Phi_{2j}(x,\lambda)$$
$$\times[\Phi^{-1}(x,\lambda')\sigma_3\Psi(x,\lambda')]_{kl}+\overline{u(x)}\Psi_{i2}^{-1}(x,\lambda)\Phi_{1j}(x,\lambda)[\Phi^{-1}(x,\lambda')\sigma_3\Psi(x,\lambda')]_{kl}$$
$$-u(x)\Phi_{k1}^{-1}(x,\lambda')\Psi_{2l}(x,\lambda')[\Psi^{-1}(x,\lambda)\sigma_3\Psi(x,\lambda)]_{ij}+2i(\lambda+\lambda')$$
$$\times\{\Psi_{i1}^{-1}(x,\lambda)\Psi_{1l}(x,\lambda')\Phi_{k2}^{-1}(x,\lambda')\Phi_{2j}(x,\lambda)-\Psi_{i2}^{-1}(x,\lambda)\Psi_{2l}(x,\lambda')\Phi_{k1}^{-1}(x,\lambda')\Phi_{1j}(x,\lambda)\}. \tag{B1}$$

On the other hand, by employing the first Lax equation (10), we have

$$\partial_x[\Psi^{-1}(x,\lambda)\Psi(x,\lambda')]_{il}=(\lambda-\lambda')\{[2i(\lambda+\lambda')[\Psi_{i1}^{-1}(x,\lambda)\Psi_{1l}(x,\lambda')$$
$$-\Psi_{i2}^{-1}(x,\lambda)\Psi_{2l}(x,\lambda')]-2[\Psi^{-1}(x,\lambda)U(x,t)\Psi(x,\lambda')]_{il}\} \tag{B2}$$

and

$$\partial_x[\Phi^{-1}(x,\lambda)\Phi(x,\lambda')]_{kj}=(\lambda-\lambda')\{[2i(\lambda+\lambda')[\Phi_{k1}^{-1}(x,\lambda)\Phi_{1j}(x,\lambda')$$
$$-\Phi_{k2}^{-1}(x,\lambda)\Phi_{2j}(x,\lambda')]-2[\Phi^{-1}(x,\lambda)U(x,t)\Phi(x,\lambda')]_{kj}\}. \tag{B3}$$

By using the above equations, we can find out the explicit expression of

$$\partial_x\{[\Psi^{-1}(x,\lambda)\Psi(x,\lambda')]_{il}[\Phi^{-1}(x,\lambda')\Phi(x,\lambda)]_{kj}\}. \tag{B4}$$

One can reach the result of (59) by comparing the expression of (B4) and (B1).

APPENDIX C

In the appendix, we provide the derivation of the Poisson bracket (78) without introducing the assumption of compact support of u. From (22), we have

$$b_n=\frac{\phi_1(x,\lambda_n)}{\psi_1(x,\lambda_n)}=\frac{\phi_2(x,\lambda_n)}{\psi_2(x,\lambda_n)}. \tag{C1}$$

Taking account of this expression and (18), to evaluate the Poisson bracket $\{a(\lambda),b_n\}$ we need to know the Poisson brackets of all components of the Jost solutions.

Since we know that

$$\frac{\delta\Phi(z,\lambda)_{ij}}{\delta u(x)}\neq 0 \quad \text{for } x<z, \tag{C2}$$

etc., and

$$\frac{\delta\Psi(z,\lambda)_{kl}}{\delta u(x)}\neq 0 \quad \text{for } x>z, \tag{C3}$$

etc., the integrand of the Poisson bracket $\{\Phi(x,\lambda)_{ij},\Psi(x,\lambda')_{kl}\}$ vanishes because two factors of each term cannot be unequal to zero simultaneously, this implies that,

$$\{\Phi(x,\lambda)_{ij},\Psi(x,\lambda')_{kl}\}=0. \tag{C4}$$

By the Jacobi property the Poisson bracket of the same components of the Jost solutions vanishes, that is,

$$\{\Phi(x,\lambda)_{ij},\Phi(x,\lambda')_{ij}\}=\{\Psi(x,\lambda)_{ij},\Psi(x,\lambda')_{ij}\}=0. \tag{C5}$$

The nonvanishing Poisson brackets of the components of the Jost solutions needed to evaluate the Poisson bracket $\{a(\lambda),b_n\}$ are $\{\phi_1(x,\lambda),\phi_2(x,\lambda')\}$ and $\{\psi_1(x,\lambda),\psi_2(x,\lambda')\}$. By using the expressions of elements of (42), etc., we find

$$\{\phi_1(x,\lambda),\phi_2(x,\lambda')\}=\frac{1}{2}\frac{1}{\lambda-\lambda'}[\phi_1(x,\lambda)\phi_2(x,\lambda')-\phi_1(x,\lambda')\phi_2(x,\lambda)], \tag{C6}$$

and

$$\{\psi_1(x,\lambda),\psi_2(x,\lambda')\}=-\frac{1}{2}\frac{1}{\lambda-\lambda'}[\psi_1(x,\lambda)\psi_2(x,\lambda')-\psi_1(x,\lambda')\psi_2(x,\lambda)]. \tag{C7}$$

The above formulas are valid when λ or λ' is equal to λ_n.

We now have

$$\{a(\lambda),b_n\}=\{a(\lambda),\phi_1(x,\lambda_n)\}\frac{1}{\psi_1(\lambda_n)}-\{a(\lambda),\psi_1(x,\lambda_n)\}\frac{\phi_1(\lambda_n)}{\psi_1(x,\lambda_n)^2}. \tag{C8}$$

By using the above formulas, we obtain

$$\{a(\lambda),\phi_1(x,\lambda_n)\}=-\psi_1(x,\lambda)\{\phi_2(x,\lambda),\phi_1(x,\lambda_n)\}, \tag{C9}$$

and

$$\{a(\lambda),\psi_1(x,\lambda_n)\}=\phi_1(x,\lambda)\{\psi_2(x,\lambda),\psi_1(x,\lambda_n)\}. \tag{C10}$$

Substituting (C6)–(C10) into (C8), we obtain

$$\{a(\lambda),b_n\}=-\frac{1}{2}\frac{1}{\lambda-\lambda_n}a(\lambda)b_n-\frac{1}{2}\frac{1}{\lambda-\lambda_n}\psi_1(x,\lambda)\phi_1(x,\lambda)\left[\frac{\phi_2(x,\lambda_n)}{\psi_1(x,\lambda_n)}-\frac{\psi_2(x,\lambda_n)\phi_1(x,\lambda_n)}{\psi_1(x,\lambda_n)^2}\right]. \tag{C11}$$

The last term vanishes by (C1). Hence we finally obtain the Poisson bracket of $\{a(\lambda),b_n\}$. Other Poisson brackets involving b_n can be found in the same way.

(Received 16 November 1998; accepted for publication 5 January 1999)

The nonlinear Schrödinger equation on the half line with mixed boundary condition is investigated. After a brief introduction to the corresponding classical boundary value problem, the exact second quantized solution of the system is constructed. The construction is based on a new algebraic structure, which is called in what follows boundary algebra and which substitutes, in the presence of boundaries, the familiar Zamolodchikov–Faddeev algebra. The fundamental quantum field theory properties of the solution are established and discussed in detail. The relative scattering operator is derived in the Haag–Ruelle framework, suitably generalized to the case of broken translation invariance in space. © *1999 American Institute of Physics.* [S0022-2488(99)01406-1]

I. INTRODUCTION

The general interest in quantization on the half line $\mathbf{R}_+ = \{x \in \mathbf{R}: x > 0\}$ stems from the recently growing number of applications in different physical areas, including open string theory, dissipative quantum mechanics, and quantum impurity problems. In the last few years, important progress has been made in this subject by means of conformal field theory. Focusing on the nonlinear Schrödinger (NLS) model on $\mathbf{R}_+$, in the present paper we explore the possibility to employ integrability.

Let us recall that when considered on the whole line $\mathbf{R}$, the NLS model represents one of the most extensively studied nonrelativistic integrable systems (see, e.g., Ref. 1). The corresponding equation of motion is

$$(i\partial_t + \partial_x^2)\Phi(t,x) = 2g|\Phi(t,x)|^2\Phi(t,x), \tag{1.1}$$

where $\Phi(t,x)$ is a classical complex field. The model on the half line is obtained restricting Eq. (1.1) on $\mathbf{R}_+$, supplemented with the boundary condition

$$\lim_{x\downarrow 0}(\partial_x - \eta)\Phi(t,x) = 0. \tag{1.2}$$

Here η is a dimensionful parameter of the theory. For $\eta = 0$ and in the limit $\eta \to \infty$ one recovers from Eq. (1.2) the familiar Neumann and Dirichlet boundary conditions respectively. To our knowledge, the boundary value problem (1.1)–(1.2) has been first investigated by Sklyanin[2] and Fokas,[3] who have shown that the integrability, which holds for the system on the whole line, persists also on the half line. Our main goal below will be to construct the exact second quantized solution of Eqs. (1.1) and (1.2), in the case $g \geqslant 0$, $\eta \geqslant 0$. Concretely, this means

(1) To construct a Hilbert space $\mathcal{H}_{g,\eta}$ describing the states of the system;

(2) To define on an appropriate dense domain in $\mathcal{H}_{g,\eta}$ an operator valued distribution $\Phi(t,x)$, $x>0$, satisfying, in a sense that will be made precise below, the equation of motion (1.1), the boundary condition (1.2) and the equal time canonical commutation relations

$$[\Phi(t,x),\Phi(t,y)]=[\Phi^*(t,x),\Phi^*(t,y)]=0, \tag{1.3}$$

$$[\Phi(t,x),\Phi^*(t,y)]=\delta(x-y), \tag{1.4}$$

where Φ^* is the Hermitian conjugate of Φ;

(3) To show the existence of a vacuum state Ω in the above mentioned domain, which is cyclic with respect to the field Φ^*.

The analogous construction in the case of the whole real line has been carried out some years ago[4–9] by means of the quantum inverse scattering transform. The basic algebraic tool of this approach is the Zamolodchikov–Faddeev[10] (ZF) algebra $\mathcal{A}_R$—an appropriate generalization of the canonical commutation relations which incorporates the two-body scattering matrix R. We will show below that the half line system can be treated in the framework of inverse scattering as well, the relevant algebraic structure being now the so called boundary algebra $\mathcal{B}_R$. In the same way as the ZF algebra has been conceived[10] to represent the factorized scattering of integrable systems on the line, the general concept of boundary algebra[11] is inspired by Cherednik's scattering theory[12] of integrable systems on the half line. The fundamental feature of $\mathcal{B}_R$ is that it encodes both the nontrivial scattering between particles and the reflection from the boundary at $x=0$.

A preliminary account without proofs, which partially covers the results presented below, is given in Ref. 13. This paper is organized as follows. In the next section we summarize some known, but useful facts, about the classical NLS model both on $\mathbf{R}$ and $\mathbf{R}_+$. Section III represents a summary of those fundamental properties of $\mathcal{B}_R$ and its Fock representations, which are needed in the quantization. In Sec. IV we define the quantum field $\Phi(t,x)$ and establish its kinematic properties, verifying the canonical commutation relations (1.3)–(1.4). The dynamics is investigated in Sec. V, where it is shown that Eqs. (1.1) and (1.2) are indeed satisfied. We sketch there also the derivation of the correlation functions. Section VI is devoted to the asymptotic theory of the NLS model on $\mathbf{R}_+$. The last section contains our conclusions.

II. THE CLASSICAL NLS MODEL

The study of the classical NLS equation has a long story. Without entering the details, we will collect in this section some basic facts providing useful hints for the quantization.

A. NLS on the real line

The equation of motion (1.1) on $\mathbf{R}$ is obtained by varying the action

$$A[\Phi,\bar{\Phi}]=\int_{\mathbf{R}} dt \int_{\mathbf{R}} dx [i\bar{\Phi}(t,x)\partial_t\Phi(t,x)-|\partial_x\Phi(t,x)|^2-g|\Phi(t,x)|^4]. \tag{2.1}$$

The system admits an infinite number of integrals of motion, the energy

$$E[\Phi,\bar{\Phi}]=\int_{\mathbf{R}} dx[|\partial_x\Phi(t,x)|^2+g|\Phi(t,x)|^4] \tag{2.2}$$

being one of them. Notice that $E[\Phi,\bar{\Phi}]$ is non-negative as long as $g\geqslant 0$. This constraint has an important role in the quantum version of the theory.

About 20 years ago Rosales[14] discovered that Eq. (1.2) on $\mathbf{R}$ admits solutions of the form

$$\Phi(t,x)=\sum_{n=0}^{\infty}(-g)^n\Phi^{(n)}(t,x), \tag{2.3}$$

where

$$\Phi^{(0)}(t,x)\equiv\tilde{\lambda}(t,x)=\int_{\mathbf{R}}\frac{dq}{2\pi}\lambda(q)e^{ixq-itq^2}, \tag{2.4}$$

solves the free Schrödinger equation and

$$\Phi^{(n)}(t,x)=\int_{\mathbf{R}^{2n+1}}\prod_{\substack{i=1\\j=0}}^{n}\frac{dp_i}{2\pi}\frac{dq_j}{2\pi}\overline{\lambda}(p_1)\cdots\overline{\lambda}(p_n)\lambda(q_n)\cdots\lambda(q_0)\frac{e^{i\Sigma_{j=0}^{n}(xq_j-tq_j^2)-i\Sigma_{i=1}^{n}(xp_i-tp_i^2)}}{\Pi_{i=1}^{n}[(p_i-q_{i-1})(p_i-q_i)]}. \tag{2.5}$$

The integration in (2.5) is defined by the principal value prescription and one assumes that $\lambda(k)$ is a function for which the integrals (2.4) and (2.5) exist and the series (2.3) converges uniformly in x for sufficiently small g. It is not difficult to argue that there is a large set of such functions; any λ belonging to the Schwartz test function space $\mathcal{S}(\mathbf{R})$ meets for instance the above requirements. In fact, expressing $\Phi^{(n)}(t,x)$ in terms of $\tilde{\lambda}(t,x)$, one finds

$$\Phi^{(n)}(t,x)=\int_{\mathbf{R}^{2n}}\left[\prod_{i=1}^{n}dy_i dz_i\bar{\tilde{\lambda}}(t,y_i)\tilde{\lambda}(t,z_i)\right]\tilde{\lambda}\left(t,x+\sum_{i=1}^{n}y_i-z_i\right)\sigma(x;y_1,z_1,\ldots,y_n,z_n), \tag{2.6}$$

where

$$\sigma(x;y_1,z_1,\ldots,y_n,z_n)=4^{-n}\prod_{i=1}^{n}\epsilon\left(x+\sum_{j=1}^{i-1}y_j-\sum_{k=1}^{i}z_k\right)\epsilon\left(\sum_{j=1}^{i}(y_j-z_j)\right), \tag{2.7}$$

and $\epsilon(x)$ denotes the sign of x. Therefore,

$$|\Phi^{(n)}(t,x)|\leq\int_{\mathbf{R}^{2n}}\left[\prod_{i=1}^{n}dy_i dz_i|\tilde{\lambda}(t,y_i)\tilde{\lambda}(t,z_i)|\right]\left|\tilde{\lambda}\left(t,x+\sum_{i=1}^{n}y_i-z_i\right)\right|. \tag{2.8}$$

At the other hand, using standard estimates one can deduce that for any $\lambda(k)\in\mathcal{S}(\mathbf{R})$ there exist two positive constants Λ_1 and Λ_2 such that

$$\int_{\mathbf{R}}dx|\tilde{\lambda}(t,x)|\leq\Lambda_1(1+|t|),\quad \sup_{x\in\mathbf{R}}|\tilde{\lambda}(t,x)|\leq\Lambda_2. \tag{2.9}$$

Combining Eqs. (2.8) and (2.9) we conclude that the series (2.3) converges uniformly in x for

$$g<[\Lambda_1(1+|t|)]^{-2}. \tag{2.10}$$

The main reason for focusing on the result of Rosales is because it turns out[5–9] that the general structure of the solutions (2.3)–(2.5) is preserved by the quantization. From this point of view it is instructive to investigate the behavior of (2.3)–(2.5) when the system is restricted on $\mathbf{R}_+$.

B. NLS on the half line

The relative action, giving rise both to the equation of motion (1.1) on $\mathbf{R}_+$ and the boundary condition (1.2) is

$$A[\Phi,\overline{\Phi}]=\int_{\mathbf{R}}dt\int_{\mathbf{R}_+}dx[i\overline{\Phi}(t,x)\partial_t\Phi(t,x)-|\partial_x\Phi(t,x)|^2-g|\Phi(t,x)|^4]-\eta\int_{\mathbf{R}}dt|\Phi(t,0)|^2. \tag{2.11}$$

This action is invariant under time translations, which leads to conservation of the energy

$$E[\Phi,\overline{\Phi}]=\int_{\mathbf{R}_+}dx[|\partial_x\Phi(t,x)|^2+g|\Phi(t,x)|^4]+\eta|\Phi(t,0)|^2. \tag{2.12}$$

Positivity implies $g\geqslant 0$ and $\eta\geqslant 0$, which is the case we are going to analyze below.

The series (2.3), being a solution of the NLS equation on **R**, is *a fortiori* a solution when restricted on $\mathbf{R}_+$. In general however, it does not satisfy the boundary condition (1.2). In this respect, one has the following:

Proposition 1: $\Phi(t,x)$ obeys the boundary condition (1.2), provided that $\lambda(k)$ satisfies

$$\lambda(k)=B(k)\lambda(-k), \tag{2.13}$$

where

$$B(k)=\frac{k-i\eta}{k+i\eta}. \tag{2.14}$$

Proof: Using (2.13), we will show that $\Phi^{(n)}(t,x)$ satisfies (1.2) for any $n\geqslant 0$. For $n=0$ the statement is obvious. So, let us focus on $\Phi^{(n)}(t,x)$ with $n\geqslant 1$. Changing variables in Eq. (2.5) according to

$$k_{2i-1}=p_i\,,\quad k_{2j}=-q_j\,,\quad i=1,...,n,\quad j=0,...,n, \tag{2.15}$$

one finds

$$\lim_{x\downarrow 0}(\partial_x-\eta)\Phi^{(n)}(t,x)=\int_{\mathbf{R}^{2n+1}}\prod_{j=0}^{2n}\frac{dk_j}{2\pi}f^{(n)}(k_0,\ldots,k_{2n})\overline{\lambda}(k_1)\cdots\overline{\lambda}(k_{2n-1})$$
$$\times\lambda(-k_{2n})\cdots\lambda(-k_0)e^{-it\Sigma_{j=0}^{2n}(-1)^jk_j^2}, \tag{2.16}$$

where

$$f^{(n)}(k_0,\ldots,k_{2n})=\frac{\Sigma_{j=0}^{2n}k_j-i\eta}{i\Pi_{j=1}^{2n}(k_j+k_{j-1})}. \tag{2.17}$$

Using the simple relations

$$B(k)B(-k)=B(k)\overline{B}(k)=1, \tag{2.18}$$

one concludes that $f^{(n)}$ in Eq. (2.16) can be equivalently replaced by its B-symmetrized counterpart

$$f_B^{(n)}(k_0,\ldots,k_{2n})=\sum_{\sigma_0,\ldots,\sigma_{2n}\in\{-1,1\}}\frac{1}{4^n}\left(\prod_{j=0}^{2n}\frac{k_j+i\sigma_j\eta}{k_j+i\eta}\right)\frac{\Sigma_{j=0}^{2n}\sigma_jk_j-i\eta}{i\Pi_{j=1}^{2n}(\sigma_jk_j+\sigma_{j-1}k_{j-1})}. \tag{2.19}$$

We shall show now that $f_B^{(n)}$ vanishes identically. Equation (2.19) can be given the more convenient form

$$f_B^{(n)}(k_0,\ldots,k_{2n})=\frac{N^{(n)}(k_0,\ldots,k_{2n})}{4^ni\Pi_{j=0}^{2n}(k_j+i\eta)\Pi_{j=1}^{2n}(k_j^2-k_{j-1}^2)},$$

where

$$N^{(n)}(k_0,\ldots,k_{2n})=\sum_{\sigma_0,\ldots,\sigma_{2n}\in\{-1,1\}}\prod_{j=0}^{2n}(k_j+i\sigma_j\eta)\prod_{j=1}^{2n}(\sigma_jk_j-\sigma_{j-1}k_{j-1})\left(\sum_{j=0}^{2n}\sigma_jk_j-i\eta\right). \tag{2.20}$$

The final step is to prove then that the numerator $N^{(n)}$ vanishes. One way to show the validity of this quite remarkable identity, is to introduce the auxiliary function

$$M^{(n)}(k_0,\ldots,k_{2n})=\sum_{\sigma_0,\ldots,\sigma_{2n}\in\{-1,1\}}(\sigma_0k_0-i\eta)\prod_{j=0}^{2n}(k_j+i\sigma_j\eta)\prod_{j=1}^{2n}(\sigma_jk_j-\sigma_{j-1}k_{j-1}). \tag{2.21}$$

Now, after some algebra one derives the recurrence relations

$$N^{(n)}(k_0,\ldots,k_{2n})=-4k_0k_1(k_1^2+\eta^2)N^{(n-1)}(k_2,\ldots,k_{2n})+4k_0k_1(k_1^2-k_0^2)M^{(n-1)}(k_2,\ldots,k_{2n}), \tag{2.22}$$

$$M^{(n)}(k_0,\ldots,k_{2n})=-4k_0k_1(k_0^2+\eta^2)M^{(n-1)}(k_2,\ldots,k_{2n}). \tag{2.23}$$

Since $N^{(0)}(k_0)=M^{(0)}(k_0)=0$, Eqs. (2.22) and (2.23) imply by induction that

$$N^{(n)}(k_0,\ldots,k_{2n})=0,\quad M^{(n)}(k_0,\ldots,k_{2n})=0, \tag{2.24}$$

which completes the argument.

We conclude here the brief introduction to the classical boundary value problem (1.1)–(1.2). Our next step will be to establish the quantum counterparts of the solution (2.3)–(2.5) and the constraint (2.13).

III. THE BOUNDARY ALGEBRA

As already mentioned in the Introduction, our basic algebraic tool will be a particular associative algebra $\mathcal{B}_R$, whose generators satisfy specific quadratic relations.

A. Definition of $\mathcal{B}_R$

The concept of boundary algebra has been introduced and investigated in a general context in Ref. 11. Here we will consider the following special case. Let $R:\mathbf{R}\times\mathbf{R}\to\mathbf{C}$ be a measurable function satisfying

$$R(k_1,k_2)R(k_2,k_1)=R(k_1,k_2)\overline{R}(k_1,k_2)=1. \tag{3.1}$$

The boundary algebra $\mathcal{B}_R$ is generated by the operator valued distributions $\{a(k),a^*(k),b(k):k\in\mathbf{R}\}$, satisfying quadratic exchange relations, which can be conveniently grouped in two sets. The first one is

$$a(k_1)a(k_2)-R(k_2,k_1)a(k_2)a(k_1)=0, \tag{3.2}$$

$$a^*(k_1)a^*(k_2)-R(k_2,k_1)a^*(k_2)a^*(k_1)=0, \tag{3.3}$$

$$a(k_1)a^*(k_2)-R(k_1,k_2)a^*(k_2)a(k_1)=2\pi\delta(k_1-k_2)+b(k_1)2\pi\delta(k_1+k_2). \tag{3.4}$$

The second set of constraints describes the exchange relations of $b(k)$ and reads

$$a(k_1)b(k_2)=R(k_2,k_1)R(k_1,-k_2)b(k_2)a(k_1), \tag{3.5}$$

$$b(k_2)a^*(k_1)=R(k_2,k_1)R(k_1,-k_2)a^*(k_1)b(k_2), \tag{3.6}$$

$$b(k_1)b(k_2)=b(k_2)b(k_1). \tag{3.7}$$

Notice that if we formally set $b(k)\to 0$, the relations (3.5)–(3.7) trivialize, while (3.2)–(3.4) reproduce the defining relations of the ZF algebra $\mathcal{A}_R$. As it is well known, the factorized scattering of $1+1$ dimensional integrable systems is encoded in $\mathcal{A}_R$, i.e., in a boundary algebra in which the so called boundary operator $b(k)$ is trivially implemented. On the contrary, it turns out[11] that whenever there is a reflecting boundary, one needs a *reflection* boundary algebra, i.e., a boundary algebra with the additional constraint

$$b(k)b(-k)=1, \tag{3.8}$$

which obviously prevents the boundary operator from being zero. In the case of the NLS on the half line, we shall need a reflection boundary algebra $\mathcal{B}_R$ with exchange factor

$$R(k_1,k_2)=\frac{k_1-k_2-ig}{k_1-k_2+ig}, \tag{3.9}$$

where $g\geqslant 0$ is the coupling constant of the NLS model. $R(k_1,k_2)$ is actually the two-body bulk scattering matrix of the NLS model[4–9] and satisfies (3.1).

B. Fock representations

Following some basic ideas of Ref. 15, we have constructed in Ref. 11 the Fock representations of $\mathcal{B}_R$. These representations are characterized by the existence of a vacuum state Ω, which is cyclic with respect $a^*(k)$ and satisfies

$$a(k)\Omega=0. \tag{3.10}$$

In the reflection case (3.8), the vacuum is[11] always an eigenvector of the boundary operator $b(k)$, i.e.,

$$b(k)\Omega=B(k)\Omega, \tag{3.11}$$

where $B(k)$ is a measurable function obeying Eq. (2.18). Conversely, any $B(k)$ of this type defines a Fock representation on a Hilbert space $\mathcal{F}_{R,B}$, whose vacuum satisfies (3.11). We will show below that the state space $\mathcal{H}_{g,\eta}$ of the NLS model on $\mathbf{R}_+$ is

$$\mathcal{H}_{g,\eta}=\mathcal{F}_{R,B}, \tag{3.12}$$

with B and R given by (2.14) and (3.9), respectively. The mere fact that our system has a boundary shows up at the algebraic level, turning the ZF algebra into a reflection boundary algebra $\mathcal{B}_R$, i.e., forcing a nonzero boundary operator $b(k)$. The details of the boundary condition (the value of the parameter η) enter at the representation level through the reflection coefficient $B(k)$. In the Fock space $\mathcal{F}_{R,B}$ one has

$$a(k)=b(k)a(-k), \tag{3.13}$$

$$a^*(k)=a^*(-k)b(-k), \tag{3.14}$$

which descend from a peculiar automorphism of $\mathcal{B}_R$, established in Ref. 11. The relation (3.13) turns out to be the correct quantum analogue of Eq. (2.13). Let us stress once more that the c-number reflection coefficient $B(k)$ must be distinguished from the boundary generator $b(k)$, which according to Eqs. (3.5) and (3.6) does not even commute with $\{a(k),a^*(k)\}$.

To the end of this section we will give some details about the structure of $\mathcal{F}_{R,B}$ which are needed for our construction. One has

$$\mathcal{F}_{R,B} \equiv \bigoplus_{n=0}^{\infty} \mathcal{H}_{R,B}^n, \tag{3.15}$$

where $\mathcal{H}_{R,B}^0 \equiv \mathbf{C}$ and the n-particle space $\mathcal{H}_{R,B}^n$ with $n \geqslant 1$ is a subspace of $L^2(\mathbf{R}^n)$ defined as follows:

(i) a L^2-function $\varphi(p_1)$ belongs to $\mathcal{H}_{R,B}^1$ if and only if

$$\varphi(p_1) = B(p_1)\varphi(-p_1); \tag{3.16}$$

(ii) a L^2-function $\varphi(p_1,\ldots,p_n)$ with $n \geqslant 2$ belongs to $\mathcal{H}_{R,B}^n$ if and only if

$$\varphi(p_1,\ldots,p_{n-1},p_n) = B(p_n)\varphi(p_1,\ldots,p_{n-1},-p_n), \tag{3.17}$$

and

$$\varphi(p_1,\ldots,p_i,p_{i+1},\ldots,p_n) = R(p_i,p_{i+1})\varphi(p_1,\ldots,p_{i+1},p_i,\ldots,p_n), \tag{3.18}$$

for any $1 \leqslant i \leqslant n-1$.

Equations (3.16)–(3.18) define a closed subspace $\mathcal{H}_{R,B}^n \subset L^2(\mathbf{R}^n)$. We will denote by $P_{R,B}^{(n)}$ the corresponding orthogonal projection operator. We introduce also the finite particle space $\mathcal{F}_{R,B}^0 \subset \mathcal{F}_{R,B}$, generated by $\{\mathcal{H}_{R,B}^n : n = 0,1,\ldots\}$. We recall that $\mathcal{F}_{R,B}^0$ is the linear space of sequences $\varphi = (\varphi^{(0)}, \varphi^{(1)}, \ldots, \varphi^{(n)}, \ldots)$ with $\varphi^{(n)} \in \mathcal{H}_{R,B}^n$ and $\varphi^{(n)} = 0$ for n large enough. The vacuum state is $\Omega = (1,0,\ldots,0,\ldots)$. The L^2-scalar product on $\mathcal{H}_{R,B}^n$ defines in the standard way the scalar product $\langle \cdot,\cdot \rangle$ in the (Hilbert) direct sum (3.15).

At this point we are in position to define on $\mathcal{F}_{R,B}^0$ the annihilation and creation operators $\{a(f), a^*(f) : f \in L^2(\mathbf{R})\}$. We set $a(f)\Omega = 0$ and

$$[a(f)\varphi]^{(n)}(p_1,\ldots,p_n) = \sqrt{n+1}\int_{\mathbf{R}} \frac{dp}{2\pi}\, \overline{f}(p)\, \varphi^{(n+1)}(p,p_1,\ldots,p_n), \tag{3.19}$$

$$[a^*(f)\varphi]^{(n)}(p_1,\ldots,p_n) = \sqrt{n}[P_{R,B}^{(n)} f \otimes \varphi^{(n-1)}](p_1,\ldots,p_n), \tag{3.20}$$

for all $\varphi \in \mathcal{F}_{R,B}^0$. The operators $a(f)$ and $a^*(f)$ are in general unbounded on $\mathcal{F}_{R,B}^0$. One can easily see however that $a(f)$ and $a^*(f)$ are bounded on each $\mathcal{H}_{R,B}^n$. In fact, for all $\varphi \in \mathcal{H}_{R,B}^n$ one has the estimates

$$\|a(f)\varphi\| \leqslant \sqrt{n}\|f\|\|\varphi\|, \quad \|a^*(f)\varphi\| \leqslant \sqrt{n+1}\|f\|\|\varphi\|, \tag{3.21}$$

$\|\cdot\|$ being the L^2-norm. Notice also that $a^*(f)$ is linear in f, whereas $a(f)$ is antilinear. The operator-valued distributions $a(p)$ and $a^*(p)$, generating the Fock representation of $\mathcal{B}_R$, are defined by

$$a(f) = \int_{\mathbf{R}} \frac{dp}{2\pi}\, \overline{f}(p) a(p), \quad a^*(f) = \int_{\mathbf{R}} \frac{dp}{2\pi}\, f(p) a^*(p), \tag{3.22}$$

and are related by Hermitian conjugation, namely

$$\langle \varphi, a(f)\psi \rangle = \langle a^*(f)\varphi, \psi \rangle, \quad \forall \varphi, \psi \in \mathcal{F}_{R,B}^0. \tag{3.23}$$

Finally, the action of the boundary generator $b(p)$ on $\mathcal{F}_{R,B}^0$ is defined by Eq. (3.11) and

$$[b(p)\varphi]^{(n)}(p_1,\ldots,p_n)$$
$$=[R(p,p_1)R(p,p_2)\cdots R(p,p_n)B(p)R(p_n,-p)\cdots R(p_2,-p)R(p_1,-p)]\varphi^{(n)}(p_1,\ldots,p_n). \tag{3.24}$$

One can show[11] that $\{a(p),a^*(p),b(p)\}$, defined above, indeed satisfy the exchange relations (3.2)–(3.7) and the reflection condition (3.8). Moreover, the vacuum Ω obeys the requirements formulated in the beginning of this subsection.

It is convenient to introduce here a domain $\mathcal{D}\subset\mathcal{F}_{R,B}$, which will be frequently used in what follows. Setting

$$\mathcal{D}^0\equiv\mathbf{C},\quad \mathcal{D}^n\equiv\left\{\int_{\mathbf{R}^n}dp_1\cdots dp_n f(p_1,\ldots,p_n)a^*(p_1)\cdots a^*(p_n)\Omega : f\in\mathcal{S}(\mathbf{R}^n), n\geqslant 1\right\}, \tag{3.25}$$

we define $\mathcal{D}$ to be the linear space of sequences $\varphi=(\varphi^{(0)},\varphi^{(1)},\ldots,\varphi^{(n)},\ldots)$, where $\varphi^{(n)}\in\mathcal{D}^n$ and $\varphi^{(n)}$ vanish for n large enough. By construction $\mathcal{D}$ is a proper subspace of $\mathcal{F}^0_{R,B}$. Nevertheless, $\mathcal{D}$ is dense in $\mathcal{F}_{R,B}$ as well. Indeed, using that the factors R and B are smooth (i.e., C^∞) bounded functions, one has that $\mathcal{D}^n$ is dense in $\mathcal{H}^n_{R,B}$, which implies the statement. We observe that

$$a(f)\mathcal{D}\subset\mathcal{D},\quad a^*(f)\mathcal{D}\subset\mathcal{D},\quad \forall f\in\mathcal{S}(\mathbf{R}). \tag{3.26}$$

Notice also that the matrix elements of $a^*(k)$ between states from $\mathcal{D}$ are smooth functions of k. More generally, one has

$$\langle\varphi,a^*(k_1)\cdots a^*(k_n)\psi\rangle\in\mathcal{S}(\mathbf{R}^n),\quad \forall\varphi,\psi\in\mathcal{D}. \tag{3.27}$$

Summarizing, we introduced in this section the boundary algebra $\mathcal{B}_R$ and its Fock representation $\mathcal{F}_{R,B}$, which are the main ingredients in the construction of the quantum solution of the boundary value problem (1.1)–(1.2).

IV. QUANTIZATION

A. The quantum field $\Phi(t,x)$

Our first step will be to introduce the quantum analog of $\Phi^{(n)}(t,x)$. For this purpose we consider

$$\Phi^{(0)}(t,x)\equiv\tilde{a}(t,x)=\int_{\mathbf{R}}\frac{dq}{2\pi}a(q)e^{ixq-itq^2}, \tag{4.1}$$

$$\Phi^{(n)}(t,x)=\int_{\mathbf{R}^{2n+1}}\prod_{\substack{i=1\\ j=0}}^{n}\frac{dp_i}{2\pi}\frac{dq_j}{2\pi}a^*(p_1)\cdots a^*(p_n)a(q_n)\cdots a(q_0)$$
$$\times\frac{e^{i\Sigma_{j=0}^n(xq_j-tq_j^2)-i\Sigma_{i=1}^n(xp_i-tp_i^2)}}{\Pi_{i=1}^n[(p_i-q_{i-1}-i\epsilon)(p_i-q_i-i\epsilon)]}, \tag{4.2}$$

thus replacing formally $\{\lambda(p),\overline{\lambda}(p)\}$ in Eqs. (2.4) and (2.5) by the generators $\{a(p),a^*(p)\}$ of $\mathcal{B}_R$ in the Fock representation $\mathcal{F}_{R,B}$ and fixing an $i\epsilon$ prescription to contour poles. Our first task will be to give meaning of $\Phi^{(n)}(t,x)$ as a quadratic form in $\mathcal{D}$.

Proposition 2: For any $\varphi,\psi\in\mathcal{D}$, the expectation value

$$\langle\varphi,\Phi^{(n)}(t,x)\psi\rangle, \tag{4.3}$$

is a C^∞ function of t,x.

Proof: The case $n=0$ is trivial. For $n\geqslant 1$ it is enough to take $\varphi\in\mathcal{D}^m$ and $\psi\in\mathcal{D}^{m+1}$ with $m>n$. Some elementary algebra leads to

$$\langle\varphi,\Phi^{(n)}(t,x)\psi\rangle=\int_{\mathbf{R}^{m+n+1}}\prod_{i_1=1}^{n}\frac{dp_{i_1}}{2\pi}\prod_{i_2=0}^{n}\frac{dq_{i_2}}{2\pi}\prod_{i_3=n+1}^{m}\frac{dk_{i_3}}{2\pi}\overline{\varphi}(p_1,\ldots,p_n,k_{n+1},\ldots,k_m)$$
$$\times\frac{e^{i\Sigma_{j=0}^{n}(xq_j-tq_j^2)-i\Sigma_{i=1}^{n}(xp_i-tp_i^2)}}{\Pi_{i=1}^{n}[(p_i-q_{i-1}-i\epsilon)(p_i-q_i-i\epsilon)]}\psi(q_0,\ldots,q_n,k_{n+1},\ldots,k_m),\qquad(4.4)$$

which, using that φ and ψ are Schwartz test functions, implies the proposition.

Taking into account that $\mathcal{D}$ contains only finite particle vectors, we conclude that also $\Phi(t,x)$ is a quadratic form on $\mathcal{D}$, smooth in both t and x. The conjugate $\Phi^*(t,x)$ is defined by

$$\langle\varphi,\Phi^*(t,x)\psi\rangle=\overline{\langle\psi,\Phi(t,x)\varphi\rangle},\qquad(4.5)$$

which is of course smooth in t and x as well. The counterparts of Eqs. (4.1) and (4.2) read

$$\Phi^{*(0)}(t,x)\equiv\tilde{a}^*(t,x)=\int_{\mathbf{R}}\frac{dq}{2\pi}a^*(q)e^{-ixq+itq^2},\qquad(4.6)$$

$$\Phi^{*(n)}(t,x)=\int_{\mathbf{R}^{2n+1}}\prod_{\substack{i=1\\ j=0}}^{n}\frac{dp_i}{2\pi}\frac{dq_j}{2\pi}a^*(q_0)\cdots a^*(q_n)a(p_n)\cdots a(p_1)$$
$$\times\frac{e^{i\Sigma_{i=1}^{n}(xp_i-tp_i^2)-i\Sigma_{j=0}^{n}(xq_j-tq_j^2)}}{\Pi_{i=1}^{n}[(p_i-q_{i-1}+i\epsilon)(p_i-q_i+i\epsilon)]}.\qquad(4.7)$$

Since the system we are considering is in $\mathbf{R}_+$, we adopt the smearing

$$\Phi(t,f)=\int dx\overline{f}(x)\Phi(t,x),\quad \Phi^*(t,f)=\int dx f(x)\Phi^*(t,x),\quad f\in C_0^\infty(\mathbf{R}_+),\qquad(4.8)$$

where $C_0^\infty(\mathbf{R}_+)$ is the set of infinitely differentiable functions with compact support in $\mathbf{R}_+$. Again, $\Phi(t,f)$ and $\Phi^*(t,f)$ have meaning as quadratic forms on $\mathcal{D}$, which are related by

$$\langle\varphi,\Phi^*(t,f)\psi\rangle=\overline{\langle\psi,\Phi(t,f)\varphi\rangle}.\qquad(4.9)$$

In order to formulate some other less obvious properties of $\Phi(t,f)$ and $\Phi^*(t,f)$, we have to introduce the following partial ordering relation in $C_0^\infty(\mathbf{R}_+)$. Let $f_1,\ f_2\in C_0^\infty(\mathbf{R}_+)$. Then

$$f_1<f_2\Leftrightarrow x_1<x_2\forall x_1\in\operatorname{supp}f_1,\quad\forall x_2\in\operatorname{supp}f_2.\qquad(4.10)$$

Instead of $f_1<f_2$, we will also write $f_2>f_1$. Denoting by $\tilde{a}^*(t,f)$ the operator

$$\tilde{a}^*(t,f)=\int dx f(x)\tilde{a}^*(t,x),\qquad(4.11)$$

one can prove the following technical

Lemma 1: Let $\varphi,\psi\in\mathcal{D}$.

(a) *The identity*

$$\langle\varphi,\Phi^*(t,h)\tilde{a}^*(t,f)\psi\rangle=\langle\varphi,\tilde{a}^*(t,f)\Phi^*(t,h)\psi\rangle,\qquad(4.12)$$

holds if $h<f$;

(b) *One has*

$$\langle\varphi,\Phi^*(t,h)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega\rangle=\langle\varphi,\tilde{a}^*(t,h)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega\rangle, \tag{4.13}$$

provided that $h>f_j$ *for any* $j=1,...,n$;

(c) *For any* $f_1>f_2>\cdots>f_n$, *one has*

$$\langle\varphi,\Phi(t,h)\tilde{a}^*(t,f_1)\tilde{a}^*(t,f_2)\cdots\tilde{a}^*(t,f_n)\Omega\rangle=\sum_{j=1}^{n}(h,f_j)\langle\varphi,\tilde{a}^*(t,f_1)\cdots\hat{\tilde{a}}^*(t,f_j)\cdots\tilde{a}^*(t,f_n)\Omega\rangle, \tag{4.14}$$

where $(\cdot,\cdot)$ *denotes the* L^2*-scalar product and the hat indicates that the corresponding field must be omitted.*

Proof: The proof of the identities (4.12)–(4.14) is analogous to that given by Davies[8] for the NLS on $\mathbf{R}$, so we skip it. We only remark that the novelty on $\mathbf{R}_+$ consists in evaluating the contributions of the boundary generator b, which stem from the exchange of a and a^*. It is easy to see that these contributions actually vanish, due to the support requirements imposed on the test functions and the condition $\eta\geqslant 0$.

Summarizing, $\Phi(t,f)$ and $\Phi^*(t,f)$ have been so far defined as quadratic forms on $\mathcal{D}$ and are Schwartz distributions with respect to f. Our main goal to the end of this subsection will be to show that $\Phi(t,f)$ and $\Phi^*(t,f)$ are actually well defined operators. In order to construct a common invariant domain for these operators, we introduce the subspace

$$\mathcal{D}_0^n\equiv \mathrm{sp}\{\tilde{a}^*(t,f_1)\tilde{a}^*(t,f_2)\cdots\tilde{a}^*(t,f_n)\Omega: f_1>f_2>\cdots>f_n\}\subset\mathcal{H}_{R,B}^n,\quad n\geqslant 1, \tag{4.15}$$

where sp indicates the linear span and $t\in\mathbf{R}$ is arbitrary but fixed. Setting $\mathcal{D}_0^0=\mathbf{C}$, we define $\mathcal{D}_0$ to be the linear space of sequences $\varphi=(\varphi^{(0)},\varphi^{(1)},\ldots,\varphi^{(n)},\ldots)$ with $\varphi^{(n)}\in\mathcal{D}_0^n$ and $\varphi^{(n)}=0$ for n large enough. Both $\mathcal{D}$ and $\mathcal{D}_0$ are subspaces of the finite particle space $\mathcal{F}_{R,B}^0$. We know already that $\mathcal{D}$ is dense in $\mathcal{F}_{R,B}$. Although it is less obvious, the same is true for $\mathcal{D}_0$.

Proposition 3: $\mathcal{D}_0$ *is dense in* $\mathcal{F}_{R,B}$.

Proof. It is enough to demonstrate that the space $\mathcal{D}_0^n$ is dense in $\mathcal{H}_{R,B}^n$ for any $t\in\mathbf{R}$ and $n\geqslant 1$. So, let us consider the matrix element

$$\tilde{A}_{t,\varphi}(x_1,\ldots,x_n)\equiv\langle\varphi,\tilde{a}^*(t,x_1)\cdots\tilde{a}^*(t,x_n)\Omega\rangle, \tag{4.16}$$

where $\varphi\in\mathcal{D}^n$ is arbitrary. According to Eq. (3.27), $\tilde{A}_{t,\varphi}\in\mathcal{S}(\mathbf{R}^n)$. In order to prove the statement, it is sufficient to show that

$$\tilde{A}_{t,\varphi}(x_1,\ldots,x_n)=0,\quad \forall x_1>x_2>\cdots>x_n>0, \tag{4.17}$$

implies $\varphi=0$. It is convenient for this purpose to investigate

$$A_{t,\varphi}(p_1,\ldots,p_n)\equiv\int_{\mathbf{R}^n}\prod_{j=1}^{n}dx_j e^{i\Sigma_{j=1}^n p_j x_j}\tilde{A}_{t,\varphi}(x_1,\ldots,x_n)$$
$$=e^{it\Sigma_{j=1}^n p_j^2}\langle\varphi,a^*(p_1)\cdots a^*(p_n)\Omega\rangle\in\mathcal{S}(\mathbf{R}^n). \tag{4.18}$$

The behavior of this function under the reflection of one of its arguments or the exchange of two consecutive arguments is determined by Eqs. (3.3), (3.6), (3.11), (3.14). Using this fact, one can verify that the function

$$B_{t,\varphi}(p_1,\ldots,p_n)\equiv\Lambda(p_1,\ldots,p_n)A_{t,\varphi}(p_1,\ldots,p_n), \tag{4.19}$$

where

$$\Lambda(p_1,\ldots,p_n)\equiv\prod_{j=1}^{n}\left[(p_j-i\eta)\prod_{\substack{k=1\\k>j}}^{n}(p_j-p_k-ig)(p_j+p_k-ig)\right] \tag{4.20}$$

satisfies

$$B_{t,\varphi}(p_1,\ldots,p_j,\ldots,p_n)=-B_{t,\varphi}(p_1,\ldots,-p_j,\ldots,p_n),\quad \forall j=1,\ldots,n, \tag{4.21}$$

$$B_{t,\varphi}(p_1,\ldots,p_j,p_{j+1},\ldots,p_n)=-B_{t,\varphi}(p_1,\ldots,p_{j+1},p_j\ldots,p_n),\quad \forall j=1,\ldots,n-1. \tag{4.22}$$

By construction $B_{t,\varphi}\in\mathcal{S}(\mathbf{R}^n)$ and

$$\widetilde{B}_{t,\varphi}(x_1,\ldots,x_n)=\int_{\mathbf{R}^n}\prod_{j=1}^{n}\frac{dp_j}{2\pi}e^{-i\Sigma_{j=1}^{n}p_jx_j}B_{t,\varphi}(p_1,\ldots,p_n)=\Lambda(i\partial_1,\ldots,i\partial_n)\widetilde{A}_{t,\varphi}(x_1,\ldots,x_n), \tag{4.23}$$

admits the same antisymmetry properties as $B_{t,\varphi}$. Therefore, using the smoothness of $\widetilde{A}_{t,\varphi}$ and Eq. (4.17), we deduce that $\widetilde{B}_{t,\varphi}$ vanishes identically, or equivalently,

$$B_{t,\varphi}(p_1,\ldots,p_n)=0,\quad \forall p_j\in\mathbf{R}. \tag{4.24}$$

Combining Eqs. (4.18), (4.19), (4.24) with the fact that $\Lambda(p_1,\ldots,p_n)\neq 0$ for any $p_j\in\mathbf{R}$, one gets

$$\langle\varphi,a^*(p_1)\cdots a^*(p_n)\Omega\rangle=0,\quad \forall p_j\in\mathbf{R}, \tag{4.25}$$

which, because of the cyclicity of Ω with respect to a^*, implies $\varphi=0$. This concludes the argument.

It is convenient in what follows to have an explicit formula for the scalar product in $\mathcal{D}_0$. It is provided by the following:

Lemma 2: Let $f_1\succ f_2\succ\cdots\succ f_n$ and $h_1\succ h_2\succ\cdots\succ h_n$. Then

$$\langle\tilde{a}^*(t,h_1)\cdots\tilde{a}^*(t,h_n)\Omega,\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega\rangle=(h_1\otimes\cdots\otimes h_n,f_1\otimes\cdots\otimes f_n). \tag{4.26}$$

Proof: It is enough to expand the left hand side, using the algebraic relations (3.4) and Eq. (3.10). Taking into account the support properties of the test functions involved, all terms, except the one in the right-hand side of (4.26), vanish.

A simple corollary of the previous lemma is now in order. Since any $\varphi\in\mathcal{D}_0^n$ can be represented as

$$\varphi=\sum_{\alpha\in A}\tilde{a}^*(t,f_1^\alpha)\cdots\tilde{a}^*(t,f_n^\alpha)\Omega,$$

where A is a finite set and $f_1^\alpha\succ f_2^\alpha\succ\cdots\succ f_n^\alpha$ for all $\alpha\in A$, one has that

$$\langle\varphi,\varphi\rangle^2\equiv\|\varphi\|^2=\left\|\sum_{\alpha\in A}f_1^\alpha\otimes\cdots\otimes f_n^\alpha\right\|^2. \tag{4.27}$$

We are now in position to show the following:

Proposition 4: The estimate

$$|\langle\varphi,\Phi(t,f)\psi\rangle|\leqslant(n+1)\|f\|\|\varphi\|\|\psi\| \tag{4.28}$$

holds for any $\varphi\in\mathcal{D}_0^n$, $\psi\in\mathcal{D}_0^{n+1}$, and $f\in C_0^\infty(\mathbf{R}_+)$.

Proof: Let

$$\varphi = \sum_{\alpha \in A} \tilde{a}^*(t,f_1^\alpha)\cdots\tilde{a}^*(t,f_n^\alpha)\Omega, \quad \psi = \sum_{\beta \in B} \tilde{a}^*(t,h_0^\beta)\cdots\tilde{a}^*(t,h_n^\beta)\Omega, \tag{4.29}$$

with $f_1^\alpha > f_2^\alpha > \cdots > f_n^\alpha$ and $h_0^\beta > h_1^\beta > \cdots > h_n^\beta$. Then

$$\begin{aligned}\langle \varphi, \Phi(t,f)\psi\rangle &= \sum_{\alpha \in A}\sum_{\beta \in B} \langle \tilde{a}^*(t,f_1^\alpha)\cdots\tilde{a}^*(t,f_n^\alpha)\Omega, \Phi(t,f)\tilde{a}^*(t,h_0^\beta)\cdots\tilde{a}^*(t,h_n^\beta)\Omega\rangle \\ &= \sum_{\alpha \in A}\sum_{\beta \in B}\sum_{j=0}^{n} (f,h_j^\alpha)(f_1^\alpha\otimes\cdots\otimes f_n^\alpha, h_0^\beta\otimes\cdots\otimes\hat{h}_j^\beta\otimes\cdots\otimes h_n^\beta) \\ &= \sum_{j=0}^{n}\left(\sum_{\alpha\in A} f_1^\alpha\otimes\cdots\otimes f_{j-1}^\alpha\otimes f\otimes f_j^\alpha\otimes\cdots\otimes f_n^\alpha, \sum_{\beta\in B} h_0^\beta\otimes\cdots\otimes h_j^\beta\otimes\cdots\otimes h_n^\beta\right),\end{aligned}$$

where use has been made of point (c) of Lemma 1. Applying now the Minkowski inequality, one finds

$$|\langle \varphi, \Phi(t,f)\psi\rangle| \leq \sum_{j=0}^{n} \|f\| \left\| \sum_{\alpha\in A} f_1^\alpha\otimes\cdots\otimes f_n^\alpha\right\| \left\| \sum_{\beta\in B} h_0^\beta\otimes\cdots\otimes h_n^\beta\right\| \leq (n+1)\|f\|\|\varphi\|\|\psi\|. \tag{4.30}$$

The above proposition shows that $\Phi(t,f)$, considered as quadratic form, is bounded on $\mathcal{D}_0^n \times \mathcal{D}_0^{n+1}$ and defines therefore a bounded operator $\mathcal{H}_{R,B}^{n+1} \to \mathcal{H}_{R,B}^n$. Since this occurs for any $n \geq 0$, we recover an operator $\Phi(t,f):\mathcal{F}_{R,B}^0 \to \mathcal{F}_{R,B}^0$, whose properties are collected in

Theorem 1: *$\Phi(t,f):\mathcal{F}_{R,B}^0 \to \mathcal{F}_{R,B}^0$ is a linear operator, satisfying*

$$\Phi(t,f)\Omega = 0, \quad \Phi(t,f):\mathcal{H}_{R,B}^{n+1} \to \mathcal{H}_{R,B}^n, \quad n \geq 0. \tag{4.31}$$

Moreover, for any $\varphi,\psi \in \mathcal{F}_{R,B}^0$, the matrix element $\langle \varphi, \Phi(t,f)\psi\rangle$ has the following properties:

(i) *It is antilinear and L^2-continuous in f;*
(ii) *It is continuous in $t \in \mathbf{R}$;*
(iii) *It is smooth in $t \in \mathbf{R}$, provided that $\varphi,\psi \in \mathcal{D}$.*

Proof: All the statements are simple corollaries of the above propositions.

The operator $\Phi(t,f)$ is densely defined and admits therefore a Hermitian conjugate $\Phi^*(t,f)$.

Theorem 2: *The field $\Phi^*(t,f)$ satisfies*

$$\Phi^*(t,f)\Omega = \tilde{a}^*(t,f)\Omega, \quad \Phi^*(t,f):\mathcal{H}_{R,B}^n \to \mathcal{H}_{R,B}^{n+1}, \quad n \geq 0, \tag{4.32}$$

and therefore leaves $\mathcal{F}_{R,B}^0$ invariant. Moreover

$$\langle \varphi, \Phi(t,f)\psi\rangle = \langle \Phi^*(t,f)\varphi, \psi\rangle, \tag{4.33}$$

holds for any $\varphi,\psi \in \mathcal{F}_{R,B}^0$.

Proof: One uses the fact that $\Phi(t,f)$ is bounded on each $\mathcal{H}_{R,B}^n$.

We will show now that the operators $\Phi(t,f)$ and $\Phi^*(t,f)$ satisfy the basic requirements for nonrelativistic quantum fields.

B. Cyclicity of Ω and commutation relations

We start with

Theorem 3 (Cyclicity)**:** *The vacuum Ω is a cyclic vector for the field Φ^*. More precisely the space*

$$\mathcal{E}_0^n \equiv \text{sp}\{\Phi^*(t,f_1)\Phi^*(t,f_2)\cdots\Phi^*(t,f_n)\Omega : f_1 \prec f_2 \prec \cdots \prec f_n\},$$

is dense in $\mathcal{H}_{R,B}^n$.

Proof: Using Eqs. (4.12)–(4.13) of Lemma 1, one easily proves by induction that

$$\Phi^*(t,f_1)\Phi^*(t,f_2)\cdots\Phi^*(t,f_n)\Omega = \tilde{a}^*(t,f_n)\cdots\tilde{a}^*(t,f_1)\Omega, \tag{4.34}$$

as long as $f_1 \prec f_2 \prec \cdots \prec f_n$. Thus $\mathcal{E}_0^n = \mathcal{D}_0^n$, and the statement follows directly from Proposition 3.

Remark: Theorem 3 is slightly stronger than the standard cyclicity,[16] because of the ordering among the functions $f_1,\ldots,f_n$ required in the definition of $\mathcal{E}_0^n$.

Let us consider now the canonical commutation relations (1.3) and (1.4). We shall prove

Theorem 4: *The equal time canonical commutation relations*

$$[\Phi(t,h_1),\Phi(t,h_2)] = [\Phi^*(t,h_1),\Phi^*(t,h_2)] = 0, \tag{4.35}$$

$$[\Phi(t,h_1),\Phi^*(t,h_2)] = (h_1,h_2), \tag{4.36}$$

hold on $\mathcal{F}_{R,B}^0$ *for any* $h_1,h_2 \in \mathcal{S}(\mathbf{R}_+)$.

Proof: In order to demonstrate Eq. (4.35), we observe that Eq. (4.14) implies

$$\Phi(t,h_2)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega = \sum_{j=1}^{n} (h_2,f_j)\tilde{a}^*(t,f_1)\cdots\hat{\tilde{a}}^*(t,f_j)\cdots\tilde{a}^*(t,f_n)\Omega,$$

where $f_1 \succ \cdots \succ f_n$. Therefore,

$$\Phi(t,h_1)\Phi(t,h_2)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega$$
$$= \sum_{j=1}^{n}\sum_{\substack{k=1\\k\neq j}}^{n} (h_2,f_j)(h_1,f_k)\tilde{a}^*(t,f_1)\cdots\hat{\tilde{a}}^*(t,f_j)\cdots\hat{\tilde{a}}^*(t,f_k)\cdots\tilde{a}^*(t,f_n)\Omega, \tag{4.37}$$

which, being symmetric under the exchange of h_1 with h_2, implies the vanishing of $[\Phi(t,h_1),\Phi(t,h_2)]$ on $\mathcal{D}_0^n$. Then one extends by continuity to $\mathcal{H}_{R,B}^n$ and by linearity to $\mathcal{F}_{R,B}^0$. The validity of $[\Phi^*(t,h_1),\Phi^*(t,h_2)] = 0$ follows applying Hermitian conjugation.

We turn now to Eq. (4.36). Let $f_1 \succ \cdots \succ f_n$ and $h_1,h_2 \in \mathcal{S}(\mathbf{R}_+)$. Assume that

$$f_k \succ h_2 \succ f_{k+1}. \tag{4.38}$$

Using Lemma 1, one gets

$$\Phi(t,h_1)\Phi^*(t,h_2)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega$$
$$= \Phi(t,h_1)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_k)\Phi^*(t,h_2)\tilde{a}^*(t,f_{k+1})\cdots\tilde{a}^*(t,f_n)\Omega$$
$$= \Phi(t,h_1)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_k)\tilde{a}^*(t,h_2)\tilde{a}^*(t,f_{k+1})\cdots\tilde{a}^*(t,f_n)\Omega$$
$$= (h_1,h_2)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega$$
$$+ \sum_{j=1}^{n} (h_1,f_j)\tilde{a}^*(t,f_1)\cdots\hat{\tilde{a}}^*(t,f_j)\cdots\tilde{a}^*(t,f_k)\tilde{a}^*(t,h_2)\tilde{a}^*(t,f_{k+1})\cdots\tilde{a}^*(t,f_n)\Omega.$$

Analogously,

$$\Phi^*(t,h_2)\Phi(t,h_1)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega$$
$$= \sum_{j=1}^{n} (h_1,f_j)\tilde{a}^*(t,f_1)\cdots\hat{\tilde{a}}^*(t,f_j)\cdots\tilde{a}^*(t,f_k)\tilde{a}^*(t,h_2)\tilde{a}^*(t,f_{k+1})\cdots\tilde{a}^*(t,f_n)\Omega.$$

Therefore,

$$[\Phi(t,h_1),\Phi^*(t,h_2)]\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega=(h_1,h_2)\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega. \tag{4.39}$$

So, Eq. (4.36) holds on states of the type $\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega$, which satisfy the condition (4.38). Observing that the couples $\{h_2,\tilde{a}^*(t,f_1)\cdots\tilde{a}^*(t,f_n)\Omega\}$ obeying (4.38) are norm dense in $L^2(\mathbf{R}_+)\otimes\mathcal{H}^n_{RB}$, Eq. (4.36) follows by continuity.

As a consequence of the commutation relations (4.35) and (4.36) one has the following useful estimate:

Proposition 5: Let A be a finite set and let $f_1^\alpha,\ldots,f_n^\alpha\in C_0^\infty$ *for any* $\alpha\in A$. *Then the norm of the operator*

$$\sum_{\alpha\in A}\Phi(t,f_1^\alpha)\Phi(t,f_2^\alpha)\cdots\Phi(t,f_n^\alpha),$$

restricted to $\mathcal{H}^m_{R,B}$ *with* $m\geq n$, *satisfies*

$$\left\|\sum_{\alpha\in A}\Phi(t,f_1^\alpha)\Phi(t,f_2^\alpha)\cdots\Phi(t,f_n^\alpha)\right\|\leq\sqrt{m(m-1)\cdots(m-n+1)}\left\|\sum_{\alpha\in A}f_1^\alpha\otimes\cdots\otimes f_n^\alpha\right\|. \tag{4.40}$$

Proof: Let $\psi\in\mathcal{D}_0^n$. Then there is some finite set B, such that ψ can be written in the form

$$\psi=\sum_{\beta\in B}\Phi^*(t,h_1^\beta)\cdots\Phi^*(t,h_m^\beta)\Omega,\quad h_1^\beta<\cdots<h_m^\beta.$$

Now, by means of the commutation relations (4.35) and (4.36) one finds

$$\left\|\sum_{\alpha\in A}\Phi(t,f_1^\alpha)\cdots\Phi(t,f_n^\alpha)\psi\right\|\leq\sqrt{m(m-1)\cdots(m-n+1)}\left\|\sum_{\alpha\in A}f_1^\alpha\otimes\cdots\otimes f_n^\alpha\right\|\|\psi\|, \tag{4.41}$$

implying Eq. (4.40) by continuity.

V. TIME EVOLUTION

In order to investigate the time evolution in the NLS model on $\mathbf{R}_+$, we consider the mapping

$$\alpha_t(a(k))=e^{-ik^2t}a(k),\quad \alpha_t(a^*(k))=e^{ik^2t}a^*(k),\quad \alpha_t(b(k))=b(k),\quad t\in\mathbf{R}. \tag{5.1}$$

It is straightforward to verify that α_t defines a 1-parameter group of automorphisms of the boundary algebra $\mathcal{B}_R$. Using the relations (3.2)–(3.6), (3.13), (3.14), one can easily check that this group is unitarily implemented in the Fock space $\mathcal{F}_{R,B}$ by means of the operator

$$U(t)=\exp(iHt),\quad H=\frac{1}{2}\int_{\mathbf{R}}\frac{dk}{2\pi}k^2a^*(k)a(k). \tag{5.2}$$

The Hamiltonian H acts on $\mathcal{D}$ according to

$$[H\varphi]^{(n)}(k_1,\ldots,k_n)=(k_1^2+\cdots+k_n^2)\varphi^{(n)}(k_1,\ldots,k_n), \tag{5.3}$$

which implies that the domain $\mathcal{D}$ is invariant both under $U(t)$ and H. Moreover, since

$$-i\frac{d}{dt}U(t)\bigg|_{t=0}=H, \tag{5.4}$$

on $\mathcal{D}$, the latter is a domain of essential self-adjointness for H.

The crucial point now is that the time evolution of the field $\Phi(t,f)$ is given by

$$\Phi(t,f)=U(t)\Phi(0,f)U(t)^{-1}. \tag{5.5}$$

This fact follows directly from the time dependence encoded in Eqs. (4.1) and (4.2) and is quite remarkable. It shows the power of both the quantum inverse scattering transform (4.2) and the algebra $\mathcal{B}_R$, which combined together allow to write down the Hamiltonian of an interacting field theory as a simple quadratic expression in a and a^*. In this form H depends only implicitly on the coupling constant g through the exchange factor R. Notice also that the boundary generator b does not evolve in time.

A. The quantum equation of motion

A preliminary problem to be faced here is to give a precise meaning on the quantum level of the cubic term $|\Phi(t,x)|^2\Phi(t,x)$ present in Eq. (1.1). For this purpose we will follow the standard approach, introducing the concept of a normal ordered :...: product involving Φ and Φ^*. As usually assumed, in such a product all creation operators a^* stand to the left of all annihilation operators a. In view of Eqs. (3.2) and (3.3) in our case one must further specify the ordering of creators and annihilators themselves. We define :...: to preserve the original order of the creators. The original order of two annihilators is preserved if both belong to the same Φ or Φ^* and inverted otherwise. The quantum version of Eq. (1.1) is then obtained by the substitution

$$|\Phi(t,x)|^2\Phi(t,x)\mapsto :\Phi\Phi^*\Phi:(t,x). \tag{5.6}$$

Concerning the relation between the above way of defining the normal product and the alternative point-splitting procedure, we observe that

$$:\Phi\Phi^*\Phi:(t,x)=\lim_{\sigma\downarrow 0}\Phi(t,x+2\sigma)\Phi^*(t,x+\sigma)\Phi(t,x), \tag{5.7}$$

holds in mean value on $\mathcal{D}$. Following Ref. 6, Eq. (5.7) can be derived by using the analyticity properties of the commutator between $a(p)$ and $\Phi(t,x)$. One can formulate at this point

Theorem 5: *The nonlinear Schrödinger equation,*

$$(i\partial_t+\partial_x^2)\langle\varphi,\Phi(t,x)\psi\rangle=2g\langle\varphi,:\Phi\Phi^*\Phi:(t,x)\psi\rangle, \tag{5.8}$$

is satisfied for any $\varphi,\psi\in\mathcal{D}$.

Proof: The first step is analogous to the proof of Proposition 2 and consists in showing that the matrix element $\langle\varphi,:\Phi\Phi^*\Phi:(t,x)\psi\rangle$ is smooth in t and x for any $\varphi,\psi\in\mathcal{D}$. The next step is to compare $(i\partial_t+\partial_x^2)\langle\varphi,\Phi^{(n)}(t,x)\psi\rangle$ with the $(n-1)$th order term in the expansion of $\langle\varphi,:\Phi\Phi^*\Phi:(t,x)\psi\rangle$ in terms of g. A straightforward computation, similar to that performed in Ref. 8 for the NLS model on **R**, shows that these terms indeed coincide.

B. Boundary conditions

We shall demonstrate now

Theorem 6: *The following boundary conditions hold for any* $\varphi,\psi\in\mathcal{D}$, *and* $t\in\mathbf{R}$,

$$\lim_{x\downarrow 0}(\partial_x-\eta)\langle\varphi,\Phi(t,x)\psi\rangle=0, \tag{5.9}$$

$$\lim_{x\to\infty}\langle\varphi,\Phi(t,x)\psi\rangle=0. \tag{5.10}$$

Let us first prove

Lemma 3: Let $\varphi,\psi\in\mathcal{F}^0_{R,B}$. *There exists a vector* $\chi\in\mathcal{H}^1_{R,B}$ *such that*

$$\langle \varphi, \Phi(t,f)\psi\rangle = \langle \Omega, \Phi(t,f)\chi\rangle. \tag{5.11}$$

Proof: Without loss of generality one can take $\varphi \in \mathcal{H}^n_{R,B}$, $\psi \in \mathcal{H}^{n+1}_{R,B}$. Suppose first that $\varphi \in \mathcal{E}^n_0 = \mathcal{D}^n_0$. Then φ is of the form

$$\varphi = \sum_{\alpha\in A} \Phi^*(t,f_1^\alpha)\Phi^*(t,f_2^\alpha)\cdots\Phi^*(t,f_n^\alpha)\Omega, \tag{5.12}$$

where A is a finite set and $f_1^\alpha \prec f_2^\alpha \prec \cdots \prec f_n^\alpha$ for all $\alpha\in A$. Using the commutation relations (4.35) and (4.36) one easily obtains

$$\langle \varphi, \Phi(t,f)\psi\rangle = \sum_{\alpha\in A} \langle \Omega, \Phi(t,f)\Phi(t,f_n^\alpha)\phi(t,f_{n-1}^\alpha)\cdots\Phi(t,f_1^\alpha)\psi\rangle. \tag{5.13}$$

In order to solve (5.11), it is then sufficient to define

$$\chi = \Phi(t,f_n^\alpha)\Phi(t,f_{n-1}^\alpha)\cdots\Phi(t,f_1^\alpha)\psi, \tag{5.14}$$

which belongs to $\mathcal{H}^1_{R,B}$ since $\psi\in\mathcal{H}^{n+1}_{R,B}$. Take now a general $\varphi\in\mathcal{H}^n_{R,B}$. By cyclicity (Theorem 3), there exists a sequence $\{\varphi_k\}\subset\mathcal{D}^n_0$ converging to φ. By Proposition 5, the corresponding vectors $\{\chi_k\}$ given by Eq. (5.14) form a Cauchy sequence, which converges to a vector $\chi\in\mathcal{H}^1_{R,B}$, satisfying (5.11) by continuity.

We can now prove Theorem 6.

Proof: Let $\varphi,\psi\in\mathcal{D}_0\subset\mathcal{F}^0_{R,B}$. From the lemma above there exists $\chi\in\mathcal{H}^1_{R,B}$ such that

$$\langle \varphi, \Phi(t,x)\psi\rangle = \langle \Omega, \Phi(t,x)\chi\rangle = \int_{\mathbf{R}} \frac{dk}{2\pi} e^{ikx - ik^2 t}\chi(k). \tag{5.15}$$

Since $\chi\in L^2$, the matrix element $\langle\varphi,\Phi(t,x)\psi\rangle$, which by Proposition 2 is smooth, is also square integrable with respect to x. Therefore it vanishes at infinity and Eq. (5.10) is satisfied. Moreover, taking the derivative with respect to x, the B-symmetry (3.16) of χ, immediately leads to Eq. (5.9).

C. Correlation functions

From the general structure of our solution it follows that

(i) the nonvanishing correlation functions involve equal number of Φ and Φ^*;
(ii) for computing the exact $2n$-point function one does not need all terms in the expansion (2.3), but at most the $(n-1)$th order contribution.

One has, for instance,

$$\langle \Omega, \Phi(t_1,x_1)\Phi^*(t_2,x_2)\Omega\rangle = \langle \Omega, \Phi^{(0)}(t_1,x_1)\Phi^{*(0)}(t_2,x_2)\Omega\rangle, \tag{5.16}$$

$$\begin{aligned}\langle \Omega, \Phi(t_1,x_1)\Phi(t_2,x_2)\Phi^*(t_3,x_3)\Phi^*(t_4,x_4)\Omega\rangle \\ = \langle \Omega, \Phi^{(0)}(t_1,x_1)\Phi^{(0)}(t_2,x_2)\Phi^{*(0)}(t_3,x_3)\Phi^{*(0)}(t_4,x_4)\Omega\rangle \\ + g^2\langle \Omega, \Phi^{(0)}(t_1,x_1)\Phi^{(1)}(t_2,x_2)\Phi^{*(1)}(t_3,x_3)\Phi^{*(0)}(t_4,x_4)\Omega\rangle.\end{aligned} \tag{5.17}$$

Since the vacuum expectation value of any number of $\{a(k),a^*(k),b(k)\}$ is known explicitly,[11] employing Eqs. (4.1), (4.2), (4.6), (4.7) one can derive integral representations for the NLS correlation functions on $\mathbf{R}_+$. For example,

$$\langle \Omega, \Phi(t_1,x_1)\Phi^*(t_2,x_2)\Omega\rangle = \int_{\mathbf{R}} \frac{dp}{2\pi} e^{-ip^2(t_1-t_2)}[e^{ip(x_1-x_2)} + B(p)e^{ip(x_1+x_2)}], \tag{5.18}$$

which coincides with that of the nonrelativistic free field on the half line. In spite of this fact, the four-point function (5.17) differs from the free one. We would like to recall in this respect that according to Jost's theorem (see, e.g., Ref. 16), such a phenomenon is forbidden in relativistic invariant models.

VI. SCATTERING THEORY

As it is well known, integrable quantum systems on the real line are characterized by a factorized scattering matrix. This means that multiparticle scattering is described by an appropriate product of two-particle scattering matrices, which in turn are subject to physical constraints like unitarity, crossing symmetry, etc.

Some years ago, Cherednik[12] proposed a version of factorized scattering, adapted to the half line case. The following physical picture emerges from his investigation. Let $|k_1,\ldots,k_n\rangle^{\text{in}}$ be an in-state, representing n particles coming from $x=+\infty$ and thus having negative momenta $k_1<k_2<\cdots<k_n<0$. These particles interact among themselves before and after being reflected by the wall at $x=0$, giving rise to an out-state $|p_1,\ldots,p_m\rangle^{\text{out}}$ composed of particles traveling towards $x=+\infty$ and thus having positive momenta $p_1>p_2>\cdots>p_m>0$. The transition amplitude between these states vanishes unless $n=m$ and $p_i=-k_i$, $i=1,\ldots,n$. Therefore, not only the total momentum, but each momentum is separately reflected. According to Ref. 12, the scattering amplitude is

$$^{\text{out}}\langle p_1,\ldots,p_m|k_1,\ldots,k_n\rangle^{\text{in}}=\delta_{mn}\prod_{i=1}^{n} 2\pi\delta(p_i+k_i)B(p_i)\prod_{\substack{i,j=1\\ i<j}}^{n} R(p_i,p_j)R(p_i,-p_j). \tag{6.1}$$

The R-factors describe the interactions among the particles in the bulk, while the B-factors take into account the reflection from the wall.

The main goal of this section is to prove that the NLS model on $\mathbf{R}_+$ perfectly fits the scheme of Cherednik. In order to do that, we must develop first the scattering theory corresponding to the off-shell quantum field $\Phi^*(t,f)$. Our framework will be the conventional Haag–Ruelle approach,[17] suitably adapted to the nonrelativistic case.

A first relation between the quantum solutions (4.6), (4.7) and Cherednik's scattering amplitude (6.1) is obtained through the identification

$$|p_1,\ldots,p_n\rangle^{\text{out}}=a^*(p_1)\cdots a^*(p_n)\Omega,\quad p_1>\cdots>p_n>0, \tag{6.2}$$

$$|k_1,\ldots,k_n\rangle^{\text{in}}=a^*(k_1)\cdots a^*(k_n)\Omega,\quad k_1<\cdots<k_n<0. \tag{6.3}$$

We recall in fact that $\mathcal{B}_R$ has been designed in such a way, that the amplitudes

$$\langle a^*(p_1)\cdots a^*(p_m)\Omega,\, a^*(k_1)\cdots a^*(k_n)\Omega\rangle, \tag{6.4}$$

precisely reproduce the right-hand side of Eq. (6.1). What is still missing therefore is the construction of suitable states, expressed in terms of $\Phi^*(t,h)$ and Ω, which approach the out-states (6.2) for $t\to\infty$ and the in-states (6.3) for $t\to-\infty$. We are now going to fill this gap.

Proposition 5 shows that $\Phi^*(t,f)$, restricted on $\mathcal{H}^n_{R,B}$ is a bounded operator of norm

$$\|\Phi^*(t,f)\|\leq\sqrt{n+1}\|f\|, \tag{6.5}$$

which in turn implies that it can be extended to any $f\in L^2(\mathbf{R}_+)$. From the estimates (3.21) we know that also $a^*(h)$ is bounded on $\mathcal{H}^n_{R,B}$, where

$$\|a^*(h)\|\leq\sqrt{n+1}\|h\|,\quad \forall h\in L^2(\mathbf{R}). \tag{6.6}$$

Combining this inequality with the definition (4.6), one finds,

$$\left\| \int_{\mathbf{R}^n} dx_1 \cdots dx_n f(x_1,\ldots,x_n) \tilde{a}^*(t,x_1)\cdots\tilde{a}^*(t,x_n)\Omega \right\| \leqslant \sqrt{n!}\|f\|, \quad \forall f \in L^2(\mathbf{R}^n). \tag{6.7}$$

In order to develop the Haag–Ruelle formalism, we will need also the following notations. Let $h(k) \in \mathcal{S}(\mathbf{R})$. Then we set

$$h^t(x) \equiv \int_{\mathbf{R}} \frac{dk}{2\pi} e^{ikx - ik^2 t} h(k), \quad h^t_+(x) \equiv \theta(x)[h^t(x) + h^t(-x)], \quad \tilde{h}(k) \equiv h(-k), \tag{6.8}$$

where $\theta(x)$ is the Heaviside step function. Notice that

$$\tilde{h}^t_+(x) = \theta(x)[\tilde{h}^t(x) + \tilde{h}^t(-x)] = \theta(x)[h^t(-x) + h^t(x)] = h^t_+(x). \tag{6.9}$$

We are now in position to formulate

Theorem 7: (Asymptotic states) *Let*

$$h_1 \succ h_2 \succ \cdots \succ h_n, \quad h_j \in \mathcal{S}(\mathbf{R}_+), \quad j = 1,\ldots,n.$$

Then one has the following strong limits:

$$\lim_{t\to+\infty} \Phi^*(t,h^t_{1+})\Phi^*(t,h^t_{2+})\cdots\Phi^*(t,h^t_{n+})\Omega = a^*(h_1)a^*(h_2)\cdots a^*(h_n)\Omega, \tag{6.10}$$

$$\lim_{t\to-\infty} \Phi^*(t,h^t_{1+})\Phi^*(t,h^t_{2+})\cdots\Phi^*(t,h^t_{n+})\Omega = a^*(\tilde{h}_1)a^*(\tilde{h}_2)\cdots a^*(\tilde{h}_n)\Omega. \tag{6.11}$$

For proving this statement, we need some preliminary results.

Lemma 4: Let $h \in \mathcal{S}(\mathbf{R}_+)$. *Then,*

$$\lim_{t\to+\infty} \|h^t_+ - h^t\| = 0, \quad \lim_{t\to-\infty} \|h^t_+ - \tilde{h}^t\| = 0. \tag{6.12}$$

Proof: A direct computation gives

$$\|h^t_+ - h^t\|^2 = 2i \int_{\mathbf{R}^2} \frac{dk}{2\pi}\frac{dp}{2\pi} \overline{h}(k)h(p) \frac{e^{it(k+p)(k-p)}}{k-p+i\epsilon}, \tag{6.13}$$

$$\|h^t_+ - \tilde{h}^t\|^2 = -2i \int_{\mathbf{R}^2} \frac{dk}{2\pi}\frac{dp}{2\pi} \overline{h}(k)h(p) \frac{e^{it(k+p)(k-p)}}{k-p-i\epsilon}. \tag{6.14}$$

Now, for proving Eq. (6.12), it is enough to take into account that supp $h > 0$ and to use the weak limit

$$\lim_{t\to\pm\infty} \frac{e^{itk}}{k \pm i\epsilon} = 0. \tag{6.15}$$

Corollary 1: Let $h_1, h_2, \ldots, h_n \in \mathcal{S}(\mathbf{R}_+)$. *Then,*

$$\lim_{t\to+\infty} \|h^t_{1+}\otimes\cdots\otimes h^t_{n+} - h^t_1\otimes\cdots\otimes h^t_n\| = 0, \tag{6.16}$$

$$\lim_{t\to-\infty} \|h^t_{1+}\otimes\cdots\otimes h^t_{n+} - \tilde{h}^t_1\otimes\cdots\otimes \tilde{h}^t_n\| = 0. \tag{6.17}$$

Lemma 5: Let $h_1, h_2 \in \mathcal{S}(\mathbf{R}_+)$ are such that $h_1 \succ h_2$. Then, the functions

$$H^t(x_1,x_2)=h_1^t(x_1)h_2^t(x_2)\,\theta(x_2-x_1), \tag{6.18}$$

$$\tilde{H}^t(x_1,x_2)=\tilde{h}_1^t(x_1)\tilde{h}_2^t(x_2)\,\theta(x_2-x_1), \tag{6.19}$$

satisfy

$$\lim_{t\to+\infty}\|H^t\|=0, \quad \lim_{t\to-\infty}\|\tilde{H}^t\|=0. \tag{6.20}$$

Proof: Let us consider for instance H^t. One has

$$\begin{aligned}\|H^t\|^2&=\int_{-\infty}^{\infty}dx_1\int_{x_1}^{\infty}dx_2|h_1^t(x_1)h_2^t(x_2)|^2\\&=\int_{\mathbf{R}^4}\frac{dk_1}{2\pi}\,\frac{dp_1}{2\pi}\,\frac{dk_2}{2\pi}\,\frac{dp_2}{2\pi}\overline{h_1}(k_1)h_1(p_1)\overline{h_2}(k_2)h_2(p_2)I(k_1,p_1,k_2,p_2)e^{(k_1^2-p_1^2+k_2^2-p_2^2)t},\end{aligned} \tag{6.21}$$

with

$$I(k_1,p_1,k_2,p_2)\equiv\int_{-\infty}^{\infty}dx_1\int_{x_1}^{\infty}dx_2e^{i[(p_1-k_1)x_1+(p_2-k_2)x_2]}.$$

The integration in x_1 and x_2 gives

$$I(k_1,p_1,k_2,p_2)=\frac{2\pi i\,\delta(k_1-p_1+k_2-p_2)}{p_2-k_2+i\epsilon}. \tag{6.22}$$

Therefore,

$$\|H^t\|^2=i\int_{\mathbf{R}^3}\frac{dp_1}{2\pi}\,\frac{dp_2}{2\pi}\,\frac{dk_2}{2\pi}\overline{h_1}(p_1-p_2+k_2)h_1(p_1)\overline{h_2}(k_2)h_2(p_2)\,\frac{e^{2i(p_1-k_2)(p_2-k_2)t}}{p_2-k_2+i\epsilon}. \tag{6.23}$$

The support properties of the function h_1 and h_2 imply that the integrand vanishes unless $p_1>k_2>0$, which completes the argument because of Eq. (6.15). Analogous considerations apply to $\tilde{H}^t$.

Corollary 2: Let

$$G^t(x_1,x_2)=h_{1+}^t(x_1)h_{2+}^t(x_2)\,\theta(x_2-x_1). \tag{6.24}$$

Then,

$$\lim_{t\to\pm\infty}\|G^t\|=0. \tag{6.25}$$

Proof: One has to combine Eqs. (6.9), (6.16), (6.17), (6.20).

The statement of Corollary 2 has the following generalization to the case of $n\geqslant 2$ variables. Suppose that $h_1,\ldots,h_n\in\mathcal{S}(\mathbf{R}_+)$ and $h_1\succ\cdots\succ h_n$. Let $\mathcal{P}_n$ be the group of all permutations of the indices $\{1,2,...,n\}$. For any $\sigma\in\mathcal{P}_n$ we define the function

$$G_\sigma^t(x_1,\ldots,x_n)\equiv h_{1+}^t(x_1)\cdots h_{n+}^t(x_n)\,\theta(x_{\sigma_1},\ldots,x_{\sigma_n}), \tag{6.26}$$

where

$$\theta(x_{\sigma_1},\ldots,x_{\sigma_n})\equiv\prod_{\substack{i,j=1\\ i<j}}^{n}\theta(x_{\sigma_i}-x_{\sigma_j}). \tag{6.27}$$

Corollary 3: For any $\sigma\in\mathcal{P}_n$ different from the identity $e=(1,2,...,n)$, one has

$$\lim_{t\to\pm\infty}\|G^t_\sigma\|=0. \tag{6.28}$$

We are now ready to prove Theorem 7.

Proof: The case $n=1$ is quite simple. Using the identities

$$\Phi^*(t,f)\Omega=\tilde{a}^*(t,f)\Omega,\quad a^*(h)=\tilde{a}^*(t,h^t), \tag{6.29}$$

one finds

$$\|\Phi^*(t,h^t_+)\Omega-a^*(h)\Omega\|=\|\tilde{a}^*(t,h^t_+)\Omega-\tilde{a}^*(t,h^t)\Omega\|\leqslant\|h^t_+-h^t\|, \tag{6.30}$$

which according to Lemma 5 tends to 0 in the limit $t\to+\infty$. Let us consider now the case $n\geqslant 2$. Applying Eq. (4.34) and

$$\theta(x_1,\ldots,x_n)=1-\sum_{\substack{\sigma\in\mathcal{P}_n\\ \sigma\neq e}}\theta(x_{\sigma_1},\ldots,x_{\sigma_n}), \tag{6.31}$$

we get

$$\begin{aligned}
&\Phi^*(t,h^t_{1+})\cdots\Phi^*(t,h^t_{n+})\Omega\\
&\quad=\int_{\mathbf{R}^n}dx_1\cdots dx_n h^t_{1+}(x_1)\cdots h^t_{n+}(x_n)\sum_{\sigma\in\mathcal{P}_n}\theta(x_{\sigma_1},\ldots,x_{\sigma_n})\tilde{a}^*(t,x_{\sigma_1})\cdots\tilde{a}^*(t,x_{\sigma_n})\Omega\\
&\quad=\tilde{a}^*(t,h^t_{1+})\cdots\tilde{a}^*(t,h^t_{n+})\Omega+\sum_{\substack{\sigma\in\mathcal{P}_n\\ \sigma\neq e}}\int_{\mathbf{R}^n}dx_1\cdots dx_n G^t_\sigma(x_1,\ldots,x_n)[\tilde{a}^*(t,x_{\sigma_1})\cdots\tilde{a}^*(t,x_{\sigma_n})\Omega\\
&\qquad-\tilde{a}^*(t,x_1)\cdots\tilde{a}^*(t,x_n)\Omega].
\end{aligned} \tag{6.32}$$

The estimate (6.7) then leads to

$$\begin{aligned}
&\|\Phi^*(t,h^t_{1+})\cdots\Phi^*(t,h^t_{n+})\Omega-a^*(h_1)\cdots a^*(h_n)\Omega\|\\
&\quad=\|\Phi^*(t,h^t_{1+})\cdots\Phi^*(t,h^t_{n+})\Omega-\tilde{a}^*(t,h^t_1)\cdots\tilde{a}^*(t,h^t_n)\Omega\|\\
&\quad\leqslant\|\tilde{a}^*(t,h^t_{1+})\cdots\tilde{a}^*(t,h^t_{n+})\Omega-\tilde{a}^*(t,h^t_1)\cdots\tilde{a}^*(t,h^t_n)\Omega\|+2\sqrt{n!}\sum_{\substack{\sigma\in\mathcal{P}_n\\ \sigma\neq e}}\|G^t_\sigma\|\\
&\quad\leqslant\sqrt{n!}\|h^t_{1+}\otimes\cdots\otimes h^t_{n+}-h^t_1\otimes\cdots\otimes h^t_n\|+2\sqrt{n!}\sum_{\substack{\sigma\in\mathcal{P}_n\\ \sigma\neq e}}\|G^t_\sigma\|,
\end{aligned} \tag{6.33}$$

which implies the strong limit (6.10). Analogous considerations give

$$\|\Phi^*(t,h_{1+}^t)\cdots\Phi^*(t,h_{n+}^t)\Omega - a^*(\tilde{h}_1)\cdots a^*(\tilde{h}_n)\Omega\| \leqslant \sqrt{n!}\|h_{1+}^t\otimes\cdots\otimes h_{n+}^t - \tilde{h}_1^t\otimes\cdots\otimes\tilde{h}_n^t\| + 2\sqrt{n!}\sum_{\substack{\sigma\in\mathcal{P}_n\\ \sigma\neq e}}\|G_\sigma^t\|, \tag{6.34}$$

which proves (6.11).

We proceed with the construction of the scattering operator S, following the general strategy developed in Ref. 18. According to Theorem 7, the asymptotic spaces $\mathcal{F}^{\rm out}$ and $\mathcal{F}^{\rm in}$ are generated by finite linear combinations of the vectors $(n\geqslant 1)$,

$$\mathcal{E}^{\rm out}=\{\Omega, a^*(h_1)\cdots a^*(h_n)\Omega : h_1 > \cdots > h_n, h_j\in\mathcal{S}(\mathbf{R}_+)\} \tag{6.35}$$

and

$$\mathcal{E}^{\rm in}=\{\Omega, a^*(\tilde{h}_1)\cdots a^*(\tilde{h}_n)\Omega : h_1 > \cdots > h_n, h_j\in\mathcal{S}(\mathbf{R}_+)\}, \tag{6.36}$$

respectively. One can show[11] moreover, that $\mathcal{F}^{\rm out}$ and $\mathcal{F}^{\rm in}$ are separately dense $\mathcal{F}_{R,B}$. This property of asymptotic completeness allows to demonstrate[11] that the mapping $S:\mathcal{E}^{\rm out}\to\mathcal{E}^{\rm in}$, defined by

$$S\Omega=\Omega, \tag{6.37}$$

$$Sa^*(h_1)a^*(h_2)\cdots a^*(h_n)\Omega = a^*(\tilde{h}_1)a^*(\tilde{h}_2)\cdots a^*(\tilde{h}_n)\Omega, \tag{6.38}$$

extends to a unitary scattering operator on $\mathcal{F}_{R,B}$. We stress that S is nontrivial, in spite of the fact that the quantum fields Φ and Φ^* realize a Fock representation of the canonical commutation relations. This feature is not in contradiction with Haag's theorem,[16] because we are dealing with a nonrelativistic system, which does not satisfy in particular relativistic local commutativity.

The construction of the scattering operator S completes the picture and concludes our quantum field theory description of the NLS model on $\mathbf{R}_+$.

VII. OUTLOOK AND CONCLUSIONS

We studied the nonlinear Schrödinger equation on the half line with mixed boundary condition. After a brief discussion of some aspects of the corresponding classical boundary value problem, we constructed the exact second quantized solution of the system, establishing its basic properties. The explicit form of our solution shows that the quantum inverse scattering transform works also on the half line, provided that the Zamolodchikov–Faddeev algebra is replaced by the boundary algebra $\mathcal{B}_R$. This is one of the main results of the present paper. It demonstrates that besides being a useful tool in scattering theory,[11] the concept of boundary algebra is essential also for the construction of off-shell interacting fields in integrable systems on $\mathbf{R}_+$. We emphasize in this respect, that our results have a straightforward generalization to all elements of the NLS hierarchy (e.g., the complex modified Korteveg–de Vries equation) on the half line. The case with internal SU(N) symmetry can also be treated analogously.

As for future extensions of the present work, it would be interesting to investigate the range $\eta<0$. The new phenomenon, which can be expected on general grounds, is the presence of boundary bound states. Taking into account that one can describe by $\mathcal{B}_R$ also degrees of freedom residing on the boundary (see the Appendix in Ref. 11), we strongly believe that our framework extends to the case $\eta<0$ as well.

The classical Boussinesq–Burgers hierarchy is decomposed into two systems of solvable ordinary differential equations with the help of the Lax representations of stationary evolution equations, from which the finite-band solutions of the higher-order classical Boussinesq–Burgers equations are obtained. © *1999 American Institute of Physics.* [S0022-2488(99)00406-5]

I. INTRODUCTION

It is well known that finite-band solutions of soliton equations are important, which also can be reduced to the multisoliton solutions and elliptic function solutions.[1] Dubrovin and Its-Matveev developed an analog of the inverse scattering theory for Hill's equation and gave an explicit formula of the periodic potentials with the finite number of gaps in the spectrum.[2,3] The periodic N-soliton solution of the KdV equation was constructed explicitly. Date[4] obtained the quasiperiodic solutions of the field equation of classical massive Thirring model via using the Lax equations of squared eigenfunctions (also see Ref. 5). In Ref. 6, Matveev and Yavor gave complex finite-band multiphase solutions of the Kaup–Boussinesq (KB) equation and used the degeneracy procedure to find multisoliton solutions. In Ref. 7, Smirnov continued the investigation of finite-band solutions of the KB equation by finding smooth real solutions and found simple reductions of the general smooth two and three-band solutions to one-dimensional Riemann theta functions. Recently, nonlinearization approach of Lax pairs[8,9] has been developed and applied to construct the finite-band solutions of soliton equations.[10,11] Very recently, Gesztesy and Ratnaseelan have proposed an alternative systematic approach based on elementary algebraic methods to get algebro-geometric solutions of the AKNS hierarchy.[12]

In this paper, we shall develop a direct method to construct finite-band solutions of the higher-order classical Boussinesq–Burgers (CBB) equations based on the Lax pairs of the stationary evolution equations and the ideas in Refs. 4, 5. Although the CBB equation can be respectively changed into the KB equation and the coupled nonlinear Schrödinger equation in the AKNS hierarchy under certain transformations,[13] yet the finite-band solutions of the higher-order KB equations are still open, and it is also nontrivial that finite-band solutions of the higher-order CBB equations are obtained with the help of the AKNS equations. The present paper is organized as follows. In Sec. II, we derive the hierarchy of the CBB equations and the corresponding stationary CBB equations. In Sec. III, solutions of the CBB hierarchy are reduced to solving two systems of solvable ordinary differential equations. In Sec. IV, a hyperelliptic Riemann surface of genus N and Abel–Jacobi coordinates are introduced to straighten the associated flows. The Jacobi's inversion problem is discussed, from which the finite-band solutions of the CBB equation and two high-order CBB equations are expressed explicitly by the Riemann theta functions.

II. THE HIERARCHY AND STATIONARY EVOLUTION EQUATIONS

Let us consider the spectral problem with a constant spectral parameter λ,

$$y_x = Uy, \quad U = \begin{pmatrix} \lambda - v & u + \beta v_x \\ -1 & -\lambda + v \end{pmatrix}, \tag{1}$$

where u and v are two potentials and β is a constant. To drive the CBB hierarchy associated with the spectral problem (1), we first define the Lenard's gradient sequence S_j, $-1 \leqslant j \in \mathbb{Z}$, by the following recursion relation:

$$KS_{j-1} = JS_j, \quad S_j|_{(u,v)=0} = 0, \quad S_{-1} = (1,0)^T, \quad j \geqslant 0, \tag{2}$$

with two skew-symmetric operators

$$K = \begin{pmatrix} \beta(1-\frac{1}{2}\beta)\partial^3 + u\partial + \partial u & \frac{1}{2}(1-\beta)\partial^2 + v\partial \\ -\frac{1}{2}(1-\beta)\partial^2 + \partial v & \frac{1}{2}\partial \end{pmatrix}, \quad J = \begin{pmatrix} 0 & \partial \\ \partial & 0 \end{pmatrix}.$$

It is easy to see that S_j is uniquely determined by the recursion relation (2). The initial condition in Eq. (2) equivalently selects constants of integration to be zero. A direct calculation gives from the recursion relation (2) that

$$S_0 = \begin{pmatrix} v \\ u \end{pmatrix}, \quad S_1 = \begin{pmatrix} \frac{1}{2}u + v^2 + \frac{1}{2}(\beta - 1)v_x \\ \beta(1-\frac{1}{2}\beta)v_{xx} + 2uv + \frac{1}{2}(1-\beta)u_x \end{pmatrix}, \tag{3a}$$

$$S_2 = \begin{pmatrix} \frac{1}{4}v_{xx} + \frac{3}{2}(\beta-1)vv_x + \frac{3}{2}uv + v^3 \\ \frac{1}{4}u_{xx} + \beta(1-\frac{1}{2}\beta)(\frac{3}{2}v_x^2 + 3vv_{xx}) - \frac{3}{2}(\beta-1)vu_x + \frac{3}{4}u^2 + 3uv^2 \end{pmatrix}. \tag{3b}$$

Assume that the time evolution of the eigenfunction y of Eq. (1) obeys the differential equation

$$y_{t_m} = V^{(m)}y, \quad V^{(m)} = \begin{pmatrix} V_{11}^{(m)} & V_{12}^{(m)} \\ V_{21}^{(m)} & -V_{11}^{(m)} \end{pmatrix}, \tag{4}$$

where

$$V_{11}^{(m)} = \sum_{j=0}^{m} \left(\frac{1}{2} S_{j-1,x}^{(1)} - vS_{j-1}^{(1)} - v_x S_{j-1}^{(1)} \right) \lambda^{m-j} + \sum_{j=0}^{m} S_{j-1}^{(1)} \lambda^{m+1-j},$$

$$V_{12}^{(m)} = \sum_{j=0}^{m} \left[\frac{\beta}{2} S_{j-1,xx}^{(1)} + (u + \beta v_x) S_{j-1}^{(1)} + \frac{1}{2} S_{j-1,x}^{(2)} \right] \lambda^{m-j}, \quad V_{21}^{(m)} = -\sum_{j=0}^{m} S_{j-1}^{(1)} \lambda^{m-j}.$$

Then the compatibility condition between Eqs. (1) and (4) yields the zero-curvature equation $U_{t_m} - V_x^{(m)} + [U, V^{(m)}] = 0$, which is equivalent to the hierarchy of nonlinear evolution equations

$$(u_{t_m}, v_{t_m})^T = X_m, \quad m \geqslant 0, \tag{5}$$

where $X_j = KS_{j-1} = JS_j$ is called the CBB vector field. If $m_0 > 1$, then $(u_{t_{m_0}}, v_{t_{m_0}})^T = X_{m_0}$ is called a higher-order CBB equation. The first two nontrivial equations in the hierarchy (5) are the CBB equation[14–16]

$$u_{t_1} = \beta\left(1 - \frac{\beta}{2}\right) v_{xxx} + \frac{1}{2}(1-\beta)u_{xx} + 2(uv)_x, \tag{6a}$$

$$v_{t_1}=\tfrac{1}{2}(\beta-1)v_{xx}+2vv_x+\tfrac{1}{2}u_x \tag{6b}$$

and a higher-order CBB equation,

$$u_{t_2}=\tfrac{1}{4}u_{xxx}+2\beta(1-\tfrac{1}{2}\beta)(3v_xv_{xx}+vv_{xxx})+\tfrac{3}{2}(1-\beta)(v_xu_x+vu_{xx})+\tfrac{3}{2}uu_x+6uvv_x+3u_xv^2, \tag{7a}$$

$$v_{t_2}=\tfrac{1}{4}v_{xxx}+\tfrac{3}{2}(\beta-1)(vv_x)_x+\tfrac{3}{2}(uv)_x+3v^3v_x. \tag{7b}$$

Assume that Eqs. (1) and (4) have two basic solutions, $\psi=(\psi_1,\psi_2)^T$ and $\phi=(\phi_1,\phi_2)^T$, which satisfy the different boundary conditions. We introduce a matrix W of three functions f, g, h by

$$W=\frac{1}{2}(\phi\psi^T+\psi\phi^T)\sigma=\begin{pmatrix} f & g \\ h & -f\end{pmatrix},\quad \sigma=\begin{pmatrix} 0 & -1 \\ 1 & 0\end{pmatrix}. \tag{8}$$

A direct calculation shows that

$$W_x=[U,W],\quad W_{t_m}=[V^{(m)},W], \tag{9}$$

which imply that the function $\det W$ is an independent constant of x and t_m. Equation (9) can be written as

$$\begin{aligned} f_x&=(u+\beta v_x)h+g,\\ g_x&=2(\lambda-v)g-2(u+\beta v_x)f,\\ h_x&=-2f-2(\lambda-v)h, \end{aligned} \tag{10}$$

and

$$\begin{aligned} f_{t_m}&=hV_{12}^{(m)}-gV_{21}^{(m)},\\ g_{t_m}&=2gV_{11}^{(m)}-2fV_{12}^{(m)},\\ h_{t_m}&=2fV_{21}^{(m)}-2hV_{11}^{(m)}. \end{aligned} \tag{11}$$

Now we suppose that the functions f, g, and h are finite-order polynomials in λ,

$$\begin{aligned} f&=\tfrac{1}{2}b_x+(\lambda-v)b,\quad h=-b,\\ g&=\frac{1}{2}c_x+ub+\beta v_xb+\frac{\beta}{2}b_{xx},\\ b&=\sum_{j=0}^{N} b_{j-1}\lambda^{N-j},\quad c=\sum_{j=0}^{N} c_{j-1}\lambda^{N-j}. \end{aligned} \tag{12}$$

Substituting Eq. (12) into Eq. (10) yields

$$KG=\lambda JG,\quad G=(b,c)^T, \tag{13}$$

that is

$$KG_{j-1}=JG_j,\quad JG_{-1}=0, \tag{14a}$$

$$KG_{N-1}=0,\ \ G_j=(b_j,c_j)^T. \tag{14b}$$

It is easy to see that the equation $JG_{-1}=0$ has the general solution,

$$G_{-1}=\alpha_0 S_{-1}+\beta_0 S_{-2},\ \ S_{-2}=(0,1)^T, \tag{15}$$

where α_0 and β_0 are integral constants. Therefore, if we take Eq. (15) as a starting point, then G_j can be recursively determined by the relation (14a). In fact, noticing $\ker J=\{a_0 S_{-1}+a_{-1}S_{-2}|\forall a_0,a_{-1}\}$, $S_{-2}\in\ker K$ and acting with the operator $(J^{-1}K)^k$ upon G_{-1} in Eq. (15), we obtain from Eqs. (14a) and (2) that

$$G_k=\sum_{j=0}^{k+1}\alpha_j S_{k-j}+\beta_{k+1}S_{-2},\ \ -1\leqslant k\leqslant N-1, \tag{16}$$

where $\alpha_0,\ldots,\alpha_{k+1}$ and β_{k+1} are integral constants. Substituting Eq. (16) into Eq. (14b) yields the following higher-order stationary CBB equation:

$$\alpha_0 X_N+\alpha_1 X_{N-1}+\cdots+a_N X_0=0. \tag{17}$$

Thus u and v satisfy certain stationary CBB equation associated with the spectral problem (1). This means that these solutions u and v are finite-band solutions.

III. THE SOLVABLE ORDINARY DIFFERENTIAL EQUATIONS

In this section, we shall show how the CBB hierarchy is decomposed into two systems of solvable ordinary differential equations. Without any loss of generality we can set $\alpha_0=1$ and $\beta_0=0$ since changing b_{-1} simple results in multiplying *f, g,* and *h* by a constant, and the constant c_{-1} vanishing by the differential operator in Eq. (12). From Eq. (16), we have

$$G_{-1}=\begin{pmatrix}1\\0\end{pmatrix},\ \ G_0=\begin{pmatrix}v+\alpha_1\\u+\beta_1\end{pmatrix}, \tag{18a}$$

$$G_1=\begin{pmatrix}\frac{1}{2}(\beta-1)v_x+\frac{1}{2}u+v^2+\alpha_1 v+\alpha_2\\ \beta\left(1-\frac{\beta}{2}\right)v_{xx}+2uv+\frac{1}{2}(1-\beta)u_x+\alpha_1 u+\beta_2\end{pmatrix}. \tag{18b}$$

By using the above expressions and Eq. (12), we get

$$f=\sum_{j=0}^{N+1}f_j\lambda^{N+1-j},\ \ g=\sum_{j=0}^{N}g_j\lambda^{N-j},\ \ h=\sum_{j=0}^{N}h_j\lambda^{N-j}, \tag{19}$$

with

$$\begin{gathered}f_0=1,\ \ f_1=\alpha_1,\ \ f_2=\tfrac{1}{2}(u+\beta v_x)+\alpha_2,\\ g_0=u+\beta v_x,\ \ h_0=-1,\ \ h_1=-v-\alpha_1,\\ h_2=\tfrac{1}{2}(1-\beta)v_x-\tfrac{1}{2}u-v^2-\alpha_1 v-\alpha_2.\end{gathered} \tag{20}$$

This means if we write h as a finite product it takes the form

$$h=-\prod_{i=1}^{N}(\lambda-\mu_i), \tag{21}$$

which implies by comparing the coefficients of the same power for λ that

$$h_1=\sum_{j=1}^{N}\mu_j,\quad h_2=-\sum_{i<j}\mu_i\mu_j=\frac{1}{2}\sum_{j=1}^{N}\mu_j^2-\frac{1}{2}\left(\sum_{j=1}^{N}\mu_j\right)^2,\ldots, \tag{22a}$$

$$h_l=(-1)^{l+1}\sum_{j_1<j_2<\cdots<j_l}\mu_{j_1}\mu_{j_2}\cdots\mu_{j_l},\quad 1\leqslant l\leqslant N. \tag{22b}$$

From Eqs. (20) and (22), we have

$$v=-\sum_{j=1}^{N}\mu_j-\alpha_1, \tag{23a}$$

$$u=\left(\sum_{j=1}^{N}\mu_j\right)^2-\sum_{j=1}^{N}\mu_j^2-2v^2+(1-\beta)v_x-2\alpha_1 v-2\alpha_2. \tag{23b}$$

If we look at the terms of λ^{N+m} and of λ^{N+m-1} for the third expression in Eq. (11), we find also Eq. (23) in view of Eq. (22). Consider the function det W, which is a $(2N+2)$th-order polynomial in λ with constant coefficients

$$-\det W=f^2+gh=\prod_{j=1}^{2N+2}(\lambda-\lambda_j)=R(\lambda). \tag{24}$$

Substituting Eq. (19) into Eq. (24) and comparing the coefficients of $\lambda^{2N+2},\lambda^{2N+1},\ldots,\lambda^{N+2}$ yield

$$2f_0f_1=-\sum_{j=1}^{2N+2}\lambda_j,$$

$$2f_l+\sum_{j=0}^{l-2}f_{j+1}f_{l-j-1}+\sum_{j=0}^{l-2}g_jh_{l-2-j}=(-1)^l\sum_{j_1<j_2<\cdots<j_l}\lambda_{j_1}\lambda_{j_2}\cdots\lambda_{j_l},\quad 2\leqslant l\leqslant N, \tag{25}$$

which shows if g_j,h_j $(j\leqslant l-2)$ and f_j $(j\leqslant l-1)$ are given then f_l can be also obtained from Eq. (25). On the other hand, noticing Eqs. (12) and (19), we have

$$h_j=-b_{j-1},\quad f_j=\tfrac{1}{2}b_{j-2,x}+b_{j-1}-vb_{j-2}, \tag{26a}$$

$$g_j=\frac{1}{2}c_{j-1,x}+(u+\beta v_x)b_{j-1}+\frac{\beta}{2}b_{j-1,xx},\quad 1\leqslant j\leqslant N-2. \tag{26b}$$

By using Eqs. (26) and (16), we obtain the following equalities:

$$f_j|_{(u,v)=0}=\alpha_j,\quad h_j|_{(u,v)=0}=\alpha_j,\quad g_j|_{(u,v)=0}=0,\quad 1\leqslant j\leqslant N, \tag{27}$$

which together with Eq. (25) implies

$$\sum_{j=0}^{l}\alpha_j\alpha_{l-j}=(-1)^l\sum_{j_1<j_2<\cdots<j_l}\lambda_{j_1}\lambda_{j_2}\cdots\lambda_{j_l},\quad(\alpha_0=1),\quad 1\leqslant l\leqslant N. \tag{28}$$

From Eq. (28), it is easy to see that α_j $(1\leqslant j\leqslant N)$ can be explicitly rerepresented by the constants $\lambda_1,\ldots,\lambda_{2N+2}$, for example,

$$\alpha_1=-\frac{1}{2}\sum_{j=1}^{2N+2}\lambda_j,\quad \alpha_2=\frac{1}{2}\sum_{i<j}\lambda_i\lambda_j-\frac{1}{8}\left(\sum_{j=1}^{2N+2}\lambda_j\right)^2, \tag{29a}$$

$$\alpha_3=-\frac{1}{2}\sum_{j_1<j_2<j_3}\lambda_{j_1}\lambda_{j_2}\lambda_{j_3}+\frac{1}{4}\left(\sum_{j=1}^{2N+2}\lambda_j\right)\left[\sum_{i<j}\lambda_i\lambda_j-\frac{1}{4}\left(\sum_{j=1}^{2N+2}\lambda_j\right)^2\right]. \tag{29b}$$

Noticing Eq. (24), we have

$$f|_{\lambda=\mu_k}=\epsilon_k\sqrt{R(\mu_k)}, \tag{30}$$

where ϵ_k is a sheet index that indicates which sheet of the Riemann surface associated with $\sqrt{R(\mu_k)}$ that μ_k lies on. By Eq. (21) and the third expression of Eq. (10), we get

$$h_x|_{\lambda=\mu_k}=-2\,f|_{\lambda=\mu_k}=\mu_{kx}\prod_{i=1,i\neq k}^{N}(\mu_k-\mu_i),\quad 1\leqslant k\leqslant N, \tag{31}$$

which together with Eq. (30) gives

$$\mu_{kx}=-\frac{2\epsilon_k\sqrt{R(\mu_k)}}{\Pi_{i=1,i\neq k}^{N}(\mu_k-\mu_i)},\quad 1\leqslant k\leqslant N. \tag{32}$$

By using Eqs. (16), (19), and (12), we have

$$b_k=-h_{k+1},\quad b_{-1}=1,\quad h_0=-1,\quad S_{-1}^{(1)}=1,$$

$$h_{k+1}=-S_k^{(1)}-\alpha_1S_{k-1}^{(1)}-\alpha_2S_{k-2}^{(1)}-\cdots-\alpha_kS_0^{(1)}-\alpha_{k+1},\quad k\geqslant 0,$$

which implies

$$S_k^{(1)}=-h_{k+1}-\gamma_1h_k-\gamma_2h_{k-1}-\cdots-\gamma_kh_1-\gamma_{k+1}h_0,\quad k\geqslant 0, \tag{33}$$

where

$$\gamma_1=-\alpha_1,\quad \gamma_2=-\alpha_1\gamma_1-\alpha_2,\quad \gamma_3=-\alpha_1\gamma_1-\alpha_2\gamma_2-\alpha_3,\quad \ldots,$$

$$\gamma_k=-\alpha_1\gamma_{k-1}-\alpha_2\gamma_{k-2}-\cdots-\alpha_{k-2}\gamma_2-\alpha_{k-1}\gamma_1-\alpha_k.$$

Therefore, we obtain from Eqs. (4) and (33) that

$$V_{21}^{(m)}|_{\lambda=\mu_k}=\sum_{n=0}^{m}\sum_{s=0}^{n}\gamma_{n-s}h_s\mu_k^{m-n}\quad(\gamma_0=1). \tag{34}$$

In a way similar to the calculation of Eq. (32), we arrive at

$$\mu_{kt_m}=\frac{2\Sigma_{n=0}^{m}\Sigma_{s=0}^{n}\gamma_{n-s}h_s\mu_k^{m-n}\epsilon_k\sqrt{R(\mu_k)}}{\Pi_{i=1,i\neq k}^{N}(\mu_k-\mu_i)}, \tag{35}$$

where $h_0=-1$, and h_s's are determined by Eq. (22). Therefore, if the $2N+2$ distinct parameters $\lambda_1,\ldots,\lambda_{2N+2}$ are given and let $\mu_k(x,t)$ be a solution of ordinary differential Eqs. (32) and (35), then $(u,\,v)$ determined by Eq. (23) is a solution of the CBB Eqs. (5).

IV. THE FINITE-BAND SOLUTIONS

In order to obtain the finite-band solutions of the higher-order CBB equations, we first introduce the Riemann surface Γ of the hyperelliptic curve $\zeta^2=R(\lambda)$. It is easy to see that the genus of this surface is N. On Γ there are two infinite points ∞_1, ∞_2, which are not branch points of Γ. Equip Γ with canonical basis cycles, $a_1,\ldots,a_N$; $b_1,\ldots,b_N$, which are independent and have intersection numbers as follows:

$$a_i \circ a_j = 0, \quad b_i \circ b_j = 0, \quad a_i \circ b_j = \delta_{ij}.$$

For the present, we will choose as our basis the following set

$$\varpi_l = \frac{\lambda^{l-1} d\lambda}{\sqrt{R(\lambda)}}, \quad 1 \leqslant l \leqslant N,$$

which are N linearly independent homomorphic differentials on Γ. By using the cycles a and b, the period matrices A and B can be constructed from

$$A_{ij} = \int_{a_j} \varpi_i, \quad B_{ij} = \int_{b_j} \varpi_i.$$

It is possible to show that the matrices A and B are invertible.[17,18] Now we define the matrices C and τ by $C = A^{-1}$, $\tau = A^{-1}B$. The matrix τ can be shown to be symmetric ($\tau_{ij} = \tau_{ji}$) and it has positive definite imaginary part (Im $\tau > 0$). If we normalize ϖ into the new basis ω_j,

$$\omega_j = \sum_{l=1}^{N} C_{jl} \varpi_l, \quad 1 \leqslant j \leqslant N,$$

then we have

$$\int_{a_i} \omega_j = \sum_{l=1}^{N} C_{jl} \int_{a_i} \varpi_l = \sum_{l=1}^{N} C_{jl} A_{li} = \delta_{ji},$$

and

$$\int_{b_i} \omega_j = \tau_{ji}.$$

Now we introduce Abel–Jacobi coordinates as follows:

$$\rho_j(x,t_m) = \sum_{k=1}^{N} \int_{p_0}^{\mu_k(x,t_m)} \omega_j = \sum_{k=1}^{N} \sum_{l=1}^{N} C_{jl} \int_{p_0}^{\mu_k} \frac{\lambda^{l-1} d\lambda}{\sqrt{R(\lambda)}}, \quad 1 \leqslant j \leqslant N, \tag{36}$$

where p_0 is chosen a base point on Γ. Noticing Eq. (32), we obtain

$$\partial_x \rho_j^{(m)} = \sum_{k=1}^{N} \sum_{l=1}^{N} C_{jl} \frac{\mu_k^{l-1} \mu_{kx}}{\epsilon_k \sqrt{R(\mu_k)}} = \sum_{k=1}^{N} \sum_{l=1}^{N} \frac{-2\mu_k^{l-1} C_{jl}}{\Pi_{i \neq k}(\mu_k - \mu_i)}, \quad \rho_j^{(m)} = \rho_j(x,t_m), \tag{37}$$

which implies

$$\partial_x \rho_j^{(m)} = -2 C_{jN}, \quad 1 \leqslant j \leqslant N, \tag{38}$$

in view of the following equality

$$\sum_{k=1}^{N} \frac{\mu_k^{l-1}}{\Pi_{i \neq k}(\mu_k - \mu_i)} = \delta_{lN}, \quad 1 \leqslant l \leqslant N. \tag{39}$$

In a similar way, we have from Eqs. (35) and (36) that

$$\partial_{t_m}\rho_j^{(m)}=\sum_{l=1}^{N}\sum_{k=1}^{N}\frac{C_{jl}\mu_k^{l-1}\mu_{kt_m}}{\epsilon_k\sqrt{R(\mu_k)}}=2\sum_{l=1}^{N}\sum_{k=1}^{N}\frac{C_{jl}\Sigma_{n=0}^{m}\Sigma_{s=0}^{n}\gamma_{n-s}h_s\mu_k^{m-n+l-1}}{\Pi_{i\neq k}(\mu_k-\mu_i)}. \tag{40}$$

For simplicity, we shall discuss the several special cases as follows:

(I) For $m=1$, Eq. (40) is reduced to

$$\partial_{t_1}\rho_j^{(1)}=2\sum_{l=1}^{N}C_{jl}\sum_{k=1}^{N}\frac{(\Sigma_{s=0}^{N}\mu_s-\gamma_1)\mu_k^{l-1}-\mu_k^{l}}{\Pi_{i\neq k}(\mu_k-\mu_i)},$$

which implies

$$\partial_{t_1}\rho_j^{(1)}=-2C_{j,N-1}-2C_{jN}\gamma_1=\Omega_j^{(1)}, \tag{41}$$

resorting to the equality

$$\sum_{k=1}^{N}\frac{\mu_k^{s}}{\Pi_{i\neq k}(\mu_k-\mu_i)}=\begin{cases}\delta_{s,N-1}, & s\leqslant N-1\\ \displaystyle\sum_{j_1+\cdots+j_N=s-N+1,j_i\geqslant 0}\mu_1^{j_1}\mu_2^{j_2}\cdots\mu_N^{j_N}, & s\geqslant N.\end{cases} \tag{42}$$

Equation (42) can be proved with the help of the following contour integral

$$\frac{1}{2\pi\sqrt{-1}}\int_C H(\lambda)d\lambda,\quad H(\lambda)=\frac{\lambda^{s}}{\Pi_{i=1}^{N}(\lambda-\mu_i)},$$

where the contour C encloses all of the poles μ_j in a counterclockwise manner. It is not difficult to calculate that

$$\begin{aligned}H(\lambda)&=\lambda^{s-N}\left(1-\frac{\mu_1}{\lambda}\right)^{-1}\left(1-\frac{\mu_2}{\lambda}\right)^{-1}\cdots\left(1-\frac{\mu_N}{\lambda}\right)^{-1}\\&=\lambda^{s-N}\sum_{j_1\geqslant 0}\sum_{j_2\geqslant 0}\cdots\sum_{j_N\geqslant 0}\lambda^{-(j_1+j_2+\cdots+j_N)}\mu_1^{j_1}\mu_2^{j_2}\cdots\mu_N^{j_N}\\&=\lambda^{s-N}\sum_{l\geqslant 0}\lambda^{-l}\sum_{j_1+j_2+\cdots+j_N=l}\mu_1^{j_1}\mu_2^{j_2}\cdots\mu_N^{j_N},\end{aligned}$$

which implies

$$-\operatorname*{Res}_{\lambda=\infty}H(\lambda)d\lambda=\begin{cases}\delta_{s,N-1}, & s\leqslant N-1\\ \displaystyle\sum_{j_1+\cdots+j_N=s-N+1,j_i\geqslant 0}\mu_1^{j_1}\mu_2^{j_2}\cdots\mu_N^{j_N}, & s\geqslant N.\end{cases}$$

Therefore, it is easily seen by the residue theorem that Eq. (42) holds.

(II) For $m=2$, Eq. (40) can be written as

$$\partial_{t_2}\rho_j^{(2)}=2\sum_{l=1}^{N}C_{jl}\sum_{k=1}^{N}\frac{-\mu_k^{l+1}+(\Sigma_{s=0}^{N}\mu_s-\gamma_1)\mu_k^{l}-(\Sigma_{i<s}\mu_i\mu_s-\gamma_1\Sigma_{s=0}^{N}\mu_s+\gamma_2)\mu_{k-1}^{l}}{\Pi_{i\neq k}(\mu_k-\mu_i)},$$

which together with Eqs. (42), (22) yields

$$\partial_{t_2}\rho_j^{(2)} = -2C_{j,N-2} - 2C_{j,N-1}\gamma_1 - 2C_{jN}\gamma_2 = \Omega_j^{(2)}. \tag{43}$$

(III) For $m=3$, applying the same approach, we have

$$\partial_{t_3}\rho_j^{(3)} = -2C_{j,N-3} - 2C_{j,N-2}\gamma_1 - 2C_{j,N-1}\gamma_2 - 2C_{jN}\gamma_3 = \Omega_j^{(3)}. \tag{44}$$

On the basis of the above results we get the following:

$$\rho_j^{(m)} = -2C_{jN}x + \Omega_j^{(m)}t_m + \gamma_j, \quad 1 \leqslant j \leqslant N, \quad 1 \leqslant m \leqslant 3, \tag{45}$$

where γ_j's are constants,

$$\gamma_j = \sum_{k=1}^{N} \int_{p_0}^{\mu_k(0,0)} \omega_j.$$

Let $\mathcal{T}$ be the lattice generated by $2N$ vectors $\{\delta_j, \tau_j\}$, where

$$\delta_j = (\underbrace{0,\ldots,0}_{j-1},1,\underbrace{0,\ldots,0}_{N-j})^T$$

and $\tau_j = \tau\delta_j$. The complex torus $\mathcal{J} = \mathbb{C}^N/\mathcal{T}$ is called the Jacobian variety of Γ. An Abel map on Γ is defined as

$$\mathcal{A}(p) = \int_{p_0}^{p} \omega, \qquad \omega = (\omega_1, \ldots, \omega_N)^T,$$

where p_0 is a fixed point on Γ, whose domain of definition can be linearly extended into the factor group $\mathrm{Div}(\Gamma)$,

$$\mathcal{A}\left(\sum n_k p_k\right) = \sum n_k \mathcal{A}(p_k).$$

Now we consider a special divisor $\Sigma_{j=1}^{N} p_k$ and assume that

$$\mathcal{A}\left(\sum_{k=1}^{N} p_k\right) = \sum_{k=1}^{N} \mathcal{A}(p_k) = \sum_{k=1}^{N} \int_{p_0}^{p_k} \omega = \rho^{(m)},$$

with $p_k = (\mu_k(x,t_m), \zeta(\mu_k))$, whose component is

$$\sum_{k=1}^{N} \int_{p_0}^{p_k} \omega_j = \rho_j^{(m)}.$$

Therefore, according to the Riemann theorem,[17,18] there exists a constant vector $M^{(m)} = (M_1^{(m)}, \ldots, M_N^{(m)})^T \in \mathbb{C}^N$ such that the function

$$F^{(m)}(\lambda) = \theta(\mathcal{A}(p) - \rho^{(m)} - M^{(m)})$$

has the only N zero points $p_1, \ldots, p_N$, with $p = (\lambda, \zeta)$. Here $M^{(m)}$ is the Riemann constant determined by Γ itself and θ is the Riemann theta function defined by

$$\theta(\xi|\tau) = \sum_{n \in \mathbb{Z}^N} \exp(\pi\sqrt{-1}\langle \tau n, \; n\rangle + 2\pi\sqrt{-1}\langle \xi, n\rangle),$$

in which $\xi = (\xi_1, \ldots, \xi_N)^T \in \mathbb{C}^N$, $\langle \cdot , \cdot \rangle$ represents the standard inner-product.

To make the function single valued the surface Γ is cut along all a_k, b_k to form a simple connected region, whose boundary is denoted by γ. Notice the fact that the integrals[16,17]

$$\frac{1}{2\pi\sqrt{-1}}\int_\gamma \lambda^k d\ln F^{(m)}(\lambda)=I_k(\Gamma)$$

are constants independent of ρ with

$$I_k(\Gamma)=\sum_{j=1}^N \int_{a_j}\lambda^k\omega_j.$$

By the residue theorem, we have

$$I_k(\Gamma)=\sum_{l=1}^N \mu_l^k+\sum_{s=1}^2 \operatorname*{Res}_{\lambda=\infty_s}\lambda^k d\ln F^{(m)}(\lambda). \tag{46}$$

In what follows, we shall compute the residues in Eq. (46) as $k=1,2$. To this end we first introduce local coordinates $z=\lambda^{-1}$ at infinity. Then the hyperelliptic curve $\zeta^2=R(\lambda)$ in the neighborhood of infinity is expressed as $\hat{\zeta}^2=\hat{R}(z)$ with $\hat{\zeta}=z^{N+1}\zeta$, $\hat{R}(z)=\Pi_{j=1}^{2N+2}(1-\lambda_j z)$, and $\infty_s=(z,(-1)^{s-1}\sqrt{\hat{R}(\lambda)})|_{z=0}=(0,(-1)^{s-1})$, $s=1,2$. It is easy to see that

$$\mathcal{A}(p)_j=-\eta_{sj}+\int_{\infty_s}^p\omega_j=-\eta_{sj}+\sum_{l=1}^N C_{jl}\int_{\infty_s}^p\frac{\lambda^{l-1}d\lambda}{(-1)^{s-1}\sqrt{R(\lambda)}},$$

with

$$\eta_{sj}=\int_{\infty_s}^{p_0}\omega_j,\quad 1\leqslant j\leqslant N,\quad s=1,2.$$

Noting the local coordinates $z=\lambda^{-1}$, we have

$$\mathcal{A}(p)_j=-\eta_{sj}-(-1)^{s-1}\sum_{l=1}^N C_{jl}\int_0^z\frac{z^{N-l}dz}{\sqrt{\hat{R}(z)}}.$$

Since the theta function is an even function, $F^{(m)}(\lambda)$ is written as

$$\begin{aligned}F^{(m)}(z^{-1})&=\theta\left(\dots,\rho_j^{(m)}+M_j^{(m)}+\eta_{sj}+(-1)^{s-1}\sum_{l=1}^N C_{jl}\int_0^z\frac{z^{N-l}dz}{\sqrt{\hat{R}(z)}},\dots\right)\\&=\theta(\dots,\rho_j^{(m)}+M_j^{(m)}+\eta_{sj}+(-1)^{s-1}[C_{jN}z+\tfrac{1}{2}(C_{j(N-1)}-\alpha_1C_{jN})z^2+O(z^3)],\dots),\end{aligned}$$

which together with Eq. (45) leads to

$$\begin{aligned}F^{(m)}(z^{-1})&=\theta_s^{(m)}+z(-1)^{s-1}\sum_{j=1}^N C_{jN}D_j\theta_s^{(m)}\\&\quad+\frac{z^2}{2}\left[(-1)^{s-1}\sum_{j=1}^N(C_{j(N-1)}-\alpha_1C_{jN})D_j\theta_s^{(m)}+\sum_{j=1}^N\sum_{k=1}^N C_{jN}C_{kN}D_jD_k\theta_s^{(m)}\right]+O(z^3),\end{aligned} \tag{47}$$

where $\theta_s^{(m)}=\theta(\rho^{(m)}+M^{(m)}+\eta_s)=\theta(\dots,\rho_j^{(m)}+M_j^{(m)}+\eta_{sj},\dots)$, D_j signifies a derivative with respect to the jth argument of $\theta_s^{(m)}$. It is easy to calculate that

$$\partial_x\theta_s^{(m)}=-2\sum_{j=1}^N C_{jN}D_j\theta_s^{(m)},\quad \partial_x^2\theta_s^{(m)}=4\sum_{k=1}^N\sum_{j=1}^N C_{jN}C_{kN}D_jD_k\theta_s^{(m)},\quad s=1,2.$$

Therefore we have

$$F^{(m)}(z^{-1})=\theta_s^{(m)}+\frac{z}{2}(-1)^s\partial_x\theta_s^{(m)}+\frac{z^2}{2}\left[(-1)^{s-1}\sum_{j=1}^N C_{j(N-1)}D_j\theta_s^{(m)}+\frac{1}{2}(-1)^{s-1}\alpha_1\partial_x\theta_s^{(m)}+\frac{1}{4}\partial_x^2\theta_s^{(m)}\right]+O(z^3), \tag{48}$$

which gives

$$\frac{d}{dz}\ln F^{(m)}(z^{-1})=r_{0s}^{(m)}+r_{1s}^{(m)}+z+O(z^2) \tag{49}$$

with

$$r_{0s}^{(m)}=\tfrac{1}{2}(-1)^s\partial_x\ln\theta_s^{(m)},$$

$$r_{1s}^{(m)}=(-1)^{s-1}\sum_{j=1}^N C_{j(N-1)}D_j\ln\theta_s^{(m)}+\frac{1}{2}(-1)^{s-1}\alpha_1\partial_x\ln\theta_s^{(m)}+\frac{1}{4}\partial_x^2\ln\theta_s^{(m)}.$$

Noticing the equality

$$\operatorname*{Res}_{\lambda=\infty_s}\lambda^k d\ln F^{(m)}(\lambda)=\operatorname*{Res}_{z=0}z^{-k}d\ln F^{(m)}(z^{-1}),$$

we have

$$\operatorname*{Res}_{\lambda=\infty_s}\lambda d\ln F^{(m)}(\lambda)=r_{0s}^{(m)},\quad \operatorname*{Res}_{\lambda=\infty_s}\lambda^2 d\ln F^{(m)}(\lambda)=r_{1s}^{(m)}. \tag{50}$$

By using Eq. (46), we have

$$\sum_{l=1}^N\mu_l(x,t_m)=I_1(\Gamma)+\frac{1}{2}\partial_x\ln\frac{\theta_1^{(m)}}{\theta_2^{(m)}},\quad 1\leqslant m\leqslant 3, \tag{51a}$$

$$\sum_{l=1}^N\mu_l^2(x,t_m)=I_2(\Gamma)+\sum_{j=1}^N C_{j(N-1)}D_j\ln\frac{\theta_2^{(m)}}{\theta_1^{(m)}}+\frac{1}{2}\alpha_1\partial_x\ln\frac{\theta_2^{(m)}}{\theta_1^{(m)}}-\frac{1}{4}\partial_x^2\ln\theta_1^{(m)}\theta_2^{(m)}. \tag{51b}$$

Substituting Eq. (51) into Eq. (23), we obtain

$$u(x,t_m)=\frac{1}{4}\partial_x^2\ln\theta_1^{(m)}\theta_2^{(m)}-\frac{1}{2}(1-\beta)\partial_x^2\ln\frac{\theta_1^{(m)}}{\theta_2^{(m)}}-\frac{1}{4}\left[\partial_x\ln\frac{\theta_1^{(m)}}{\theta_2^{(m)}}\right]^2+\kappa_1\partial_x\ln\frac{\theta_1^{(m)}}{\theta_2^{(m)}}+\sum_{j=1}^N C_{j(N-1)}D_j\ln\frac{\theta_1^{(m)}}{\theta_2^{(m)}}+\kappa_2, \tag{52a}$$

$$v(x,t_m)=-\frac{1}{2}\partial_x \ln\frac{\theta_1^{(m)}}{\theta_2^{(m)}}+\kappa_3, \quad 1\leqslant m\leqslant 3, \tag{52b}$$

with constants

$$\kappa_1=-\tfrac{1}{2}\alpha_1-I_1(\Gamma), \quad \kappa_2=-2\alpha_2-2\alpha_1 I_1(\Gamma)-I_1^2(\Gamma)-I_2(\Gamma), \quad \kappa_3=-\alpha_1-I_1(\Gamma).$$

The expressions (52) are, respectively, the finite-band solutions of the CBB equation and the first two higher-order CBB equations $(u_{t_m},v_{t_m})^T=X_m$, $1\leqslant m\leqslant 3$.

New direct linearizations for KdV and solutions of the other Cauchy problem

Pierre C. Sabatier[a)]
Laboratoire de Physique Mathématique et Théorique—URA CNRS 768, Université Montpellier II—34095 Montpellier Cedex 05, France

(Received 14 December 1998; accepted for publication 24 December 1998)

The author showed previously that there are several equations that ''directly linearize'' the Korteweg de Vries equation. They may give different classes of solutions and they correspond either to generalized Gelfand Levitan or generalized Marchenko inversion equations. The idea is developed here with a precise goal: solving by linear methods the ''other Cauchy problem'' for KdV, i.e., the boundary value problem where the solution is known at fixed x, together with its two first derivatives. After several new direct linearization equations are given and analyzed, the one that solves the problem is eventually obtained. It also corresponds to a new inverse spectral problem, whose scalar equations are fourth order, and that is first studied in the Gelfand Levitan form, and then studied and completely solved in the Marchenko form. The methods given here can be extended probably to most nonlinear integrable equations, and suggest several new problems. [S0022-2488(99)01004-X]

I. INTRODUCTION

In a previous paper,[1] we showed how the direct linearization of the Korteweg de Vries equation can be managed in such a way that the relevant inversion equation is not of the Marchenko form. As a remarkable example, we showed a case where the radial Gelfand Levitan equation is relevant. Our study also showed that various ''direct linearization equations'' (DLE) generate various classes of solutions for the Korteweg de Vries equation, so that it is sound to seek an adapted DLE for solving a given problem. So as to first remind on a simple case how we handle a DLE, we rederive rapidly this example in Sec. II (the derivation here is simpler than the previous one because it is not part of a more general derivation). In the following, we call this example (G).

The classical direct linearization of the Korteweg de Vries equation could also be considered an example of the matricial direct linearization studied in our previous paper, and it leads to the Marchenko inversion equation. We shall call it example (M). Both examples share a very important common property: they rely on one spectral measure only related to $V(x,t)$—a ''Gelfand Levitan spectral measure'' in the case of (G), ''scattering data'' in the case of (M). And so does also the matricial direct linearization we also introduced. These remarks explain our concern in the present paper, which is to derive new DLE, able to generate new solutions of KdV, with the ultimate goal of solving boundary values problem of KdV that were not solved by ''linear analysis'' up to now. Recall, in particular, the ''Cauchy Problems:''

Space Cauchy problem. Derive $V(x,t)$, $(x,t\in\mathbb{R})$ from $[V(x,0), x\in\mathbb{R}]$.

Mixed Cauchy problem. Derive $V(x,t)$ $(x\in\mathbb{R}^+, t\geqslant 0)$ from $[V(x,0), x\in\mathbb{R}^+]$ and $[V(0,t), t\geqslant 0]$.

Time Cauchy problem. Derive $V(x,t)$, $(x,t\in\mathbb{R})$ from $V(0,t)$, $V'(0,t)$, $V''(0,t)$, $t\in\mathbb{R}$.

Of course, it is well known[2] that the space Cauchy problem can be solved by the linearization (M), and also well known that it is the only boundary value problem of the Korteweg de Vries ''linearized'' up to now! What about the others: In particular, what about the time Cauchy

[a)]Electronic mail: SABATIER@LPM.UNIV-MONTP2.FR problem? It really deserves to be called ''the other Cauchy problem,'' since one would never say that the linearized Korteweg de Vries equation is integrable if one did not know how to solve both the space and the time Cauchy problems, and yet, people currently say that Korteweg de Vries is integrable by means of inverse scattering without knowing, up to now, how this ''other'' Cauchy problem can be managed!

Section III is also an introductory section, where we recall the inversion procedure and generalized inversion equations of our previous paper and discuss their relevance for handling a Cauchy problem. Although we feel that cases may be done by using this method, we do not go further because it is very clear that the method is in any case much more complicated and less complete than that using (M) to manage the space Cauchy problem, and we are much less interested by a case study than by the time Cauchy problem. What we do learn, in fact, from this section is that a Gelfand Levitan-type approach leads to a new DLE useful for generating new classes of solutions, but with spectral measures not easy to handle.

In Sec. IV, we wonder if methods showing only one spectral measure are able to deal with the time Cauchy problem. So as to get a feeling of it, we first set down the Lax pair of spectral problems associated to the Korteweg de Vries equation as matrix first-order equations, derive the Born approximations for $V(x,t)$, and thus easily see that in an example where the time Cauchy problem can be analyzed, formulas showing only one spectral measure are not convenient in the linear approximation, and there is no serious reason to be different in exact analyses. Hence, we learn from this analysis that three spectral measures formally present in the DLE is probably necessary in the general case.

After our strategy is defined by the previous sections, we begin the attack to the problem in Sec. V, where we primarily seek general representations of Lax pair solutions based on their analytic properties. The results readily lead us to a generalized Gelfand Levitan formalism and thus to a new direct linearization of KdV, involving for the first time three spectral measures. It can be used to generate classes of solutions solving ''their own'' time Cauchy problem exactly as physicists do when they use the inverse scattering method to derive, for instance multisoliton solutions solving their own ''space Cauchy problem.'' But for solving the time Cauchy problem with initial conditions $V(0,t)V'(0,t)V''(0,t)$ that are arbitrary functions in convenient sets, this approach suffers from the fact that in any Gelfand Levitan formalism, spectral measures are not directly related to (sort of) physical properties, and we shall not use it further.

Thus, in Sec. VI, we definitely rely on the Scattering theory for handling the time Cauchy problem. First we try to guess, by means of extrapolating analogy, what might be a DLE of the Marchenko form with three spectral measures (oddly enough, we obtain one!), and how scattering data may appear on time paths. After these appetizers, we derive a Marchenko-type formalism for the direct and the inverse scattering problems on time paths! It turns out that they are spectral problems with sparse matrices (not many ones in the literature) but that can be related to a class of spectral problems with ''good'' matrices already studied—this meaning that we can associate to the time scattering problem a ''transformed'' time scattering problem, and we must go back and forth from one to the other for solving eventually the inverse scattering problem. Hence, we obtain a generalized Marchenko formalism which relates at time zero the values of $V(0,t)$, $V'(0,t)$, $V''(0,t)$, to conveniently defined ''time path reflection coefficients,'' which behave as spectral measures in the DLE associated to this formalism. This DLE is given in Sec. VII. It enables the evolution of the problem as x varies, and hence the time Cauchy problem is completely solved by this new ''inverse time scattering transform,'' similar, but more complicated than the ordinary one. It turns out that this ''final'' DLE given in Sec. VII is, in fact, a set of coupled integral equations, therefore more complicated that the equation we ''guessed'' at the beginning of Sec. VI. Therefore, for the latter one should work only for a restricted class of initial conditions (but we shall not try to identify them.)

The paper contains at least three new ''direct linearizations'' of the Korteweg de Vries equation, two new Inverse Problems analyses, and the solution by Inverse Scattering of the Korteweg de Vries ''other'' Cauchy problem. Yet, it suggests considerably more work, for instance.

(1) One has to identify the classes of solutions reached by the DLE's. Some of them may be tools for deriving new solutions in the Painlevé analysis.
(2) The method (and the same sort of problems) obviously extend to all nonlinear partial differential equations integrable by Inverse Scattering Transform and which can be directly linearized (for instance, by means of an ansatz we proposed a few years ago).[1–3]
(3) The ''solitonic'' solutions that correspond to discrete spectra in the time scattering problems should be studied in general.
(4) The method yields generalized Gelfand Levitan or Marchenko formalisms in two variables. Can the linear partial differential equations of the generalized kernels be geometrically transformed so as to manage other kinds of boundary value problems? Can these formalisms be used in term as a tool for generating three variables integrable nlpde? Of course, we do not guess that any kind of boundary value problem for an integrable nonlinear partial differential equation can be linearized by similar methods. Direct linearization methods are most often available,[1,3] but the boundary value problems may be very intricate, even for the linearized equation,[4] together with the Lax pairs,[4] and, in most cases, we shall have to deal with quite unusual inverse scattering problems.[5] But I must say that this is for me the most interesting aspect of this subject.

II. A SKETCHY REDERIVATION OF FORMER RESULTS

The starting point was the spectral integral equation,

$$f_1(k,x,t)=\sin[kx+k^3t]+\int \frac{d\mu(\lambda)}{k+\lambda}\sin[(k+\lambda)x+(k^3+\lambda^3)t]f_1(\lambda,x,t). \tag{2.1}$$

We assume throughout that the support of $d\mu(\lambda)$ is contained in $\mathrm{Im}\,\lambda\geqslant 0$, and $d\mu(\lambda)$ is ''symmetric'' with respect to the imaginary axis, i.e., if it is a Stieljes measure $\mu'(\lambda)d\lambda$, $\mu'(\lambda)$ is even. We assume also that the properties of this measure are such that (2.1) is a Fredholm integral equation, for which the Fredholm alternative holds. In the generic case and/or at generic values of x and t, we use the working assumption (WA) that the homogeneous equation,

$$\varphi(k,x,t)=\int T(k,\lambda,x,t)\varphi(\lambda,x,t)d\mu(\lambda), \tag{2.2}$$

where T is the factor of f_1 in (2.1), has no solution but $\varphi=0$. As in our previous paper, we can show that if φ is the odd part of φ as a function of k, the working assumption (WA) implies that only 0 is a solution of

$$\varphi^-(k,x,t)=\int d\mu(\lambda)T^-(k,\lambda,x,t)\varphi^-(\lambda,x,t), \tag{2.3}$$

where

$$T^-(k,\lambda,x,t)=\frac{1}{2}\left\{\frac{\sin[k+\lambda)x+(k^3+\lambda^3)t]}{k+\lambda}-\frac{\sin[(k-\lambda)x+(k^3-\lambda^3)t]}{k-\lambda}\right\} \tag{2.4}$$

and that f_1 is the unique solution of

$$f_1(k,x,t)=\sin[kx+k^3t]+\int d\mu(\lambda)T^-(k,\lambda,x,t)f_1(\lambda,x,t). \tag{2.5}$$

In the method of direct linearization, which is recalled in our previous paper, differential equations for f_1 are obtained by applying differential operators to both sides of (2.1) [or (2.5)]. When the operator applies inside the integral, ''*parasite terms*'' may appear: we call so those that are not similar (modulo the exchange k, λ) to those of the left-hand side of the equation. Parasite terms are ''*reduced*'' if algebraic calculations kill for them the denominator $(k+\lambda)$, so that, thanks to the separability of $\sin[(k+\lambda)x+(k^3+\lambda^3)t]$, the former parasite terms become a combination of ''*free terms*'' (i.e., go outside the integral). The game is to obtain an operator D that produces a zero free term, so that, according to the assumption (WA), Df_1 vanishes. Thus, following exactly our previous derivations, we readily obtain the two equations for f_1:

$$\left[\frac{\partial^2}{\partial x^2}+k^2-V(x,t)\right]f_1(k,x,t)=0 \tag{2.6}$$

and

$$\left[\frac{\partial}{\partial t}-k^2\frac{\partial}{\partial x}-\frac{1}{2}V(x,t)\,\frac{\partial}{\partial x}+\frac{1}{4}V'(x,t)\right]f_1(k,x,t)=0, \tag{2.7}$$

where the ''prime'' is used to mean a differentiation with respect to x, and

$$V(x,t)=-2\,\frac{\partial}{\partial x}\int d\mu(\lambda)\sin(\lambda x+\lambda^3 t)f_1(\lambda,x,t). \tag{2.8}$$

At this point, we go away from the lines of our previous paper, where we derived the Korteweg de Vries equation from the Lax pair (2.6), (2.7) and the usual study of a consistency formula as $k\rightarrow\pm\infty$. Here, let us rather set

$$g(k,x,t,u)=f_1(k,x,t)\sin(kx+k^3u)=:fs. \tag{2.9}$$

From (2.6), written for f and for s, we get

$$g'''=\frac{\partial}{\partial x}(Vg)-4k^2g'+2Vfs'. \tag{2.10}$$

From (2.7), written for f and for s, we get

$$k^2g'=\left(s\,\frac{\partial f}{\partial t}+f\,\frac{\partial s}{\partial u}\right)-\frac{1}{2}Vf'+\frac{1}{4}V'f. \tag{2.11}$$

From (2.10) and (2.11) we readily obtain

$$g'''+4\left(\frac{\partial}{\partial t}+\frac{\partial}{\partial u}\right)g+3Vg'=0. \tag{2.12}$$

In particular, if $t=u$, (2.12) reduces to the simple equation for

$$h(k,x,t)=g(k,x,t,t), \tag{2.13}$$

$$\frac{\partial^3 h}{\partial x^3}+4\,\frac{\partial h}{\partial t}-3V(x,t)\,\frac{\partial h}{\partial x}=0. \tag{2.14}$$

If we multiply both sides of (2.14) by $d\mu(k)$ and integrate, we obtain the following equation for

$$U(x,t)=\int d\mu(\lambda)\sin(\lambda x+\lambda^3 t)f_1(\lambda,x,t), \tag{2.15}$$

$$\frac{\partial^3 U}{\partial x^3}+4\,\frac{\partial U}{\partial t}-3V\,\frac{\partial U}{\partial x}=0. \tag{2.16}$$

But according to (2.8), $V=-2U'$, so that we obtain for U and V the nonlinear evolution equation,

$$\frac{\partial U}{\partial t}+\frac{1}{4}\frac{\partial^3 U}{\partial x^3}+\frac{3}{2}\left(\frac{\partial U}{\partial x}\right)^2=0, \tag{2.17}$$

$$\frac{\partial V}{\partial t}+\frac{1}{4}\frac{\partial^3 V}{\partial x^3}-\frac{3}{2}V\frac{\partial V}{\partial x}=0; \tag{2.18}$$

Eq. (2.18) is nothing but the usual Korteweg de Vries equation.

III. REPRESENTATION OF SOLUTIONS AND INVERSION EQUATION

Again, we first recall results obtained in our previous paper. Writing down (2.4) as a sum of integrals, we obtained a generalized Povzner–Levitan representation of $f_1(k,x,t)$:

$$f_1(k,x,t)=\sin(kx+k^3t)+\int_0^x dy\,\sin(ky+k^3t)L_1(x,y,t,t)+k^2\int_0^t du\,\sin k^3u\,l_1(x,t,u)$$
$$+k\int_0^t du\,\cos k^3u\,l_1'(x,t,u)-\int_0^t du\,\sin k^3u\,l_1''(x,t,u), \tag{3.1}$$

where

$$L_1(x,y,t,u)=-\int d\mu(\lambda)f_1(\lambda,x,t)\sin(\lambda y+\lambda^3u), \tag{3.2}$$

$$l_1(x,t,u)=L_1(x,0,t,u)=-\int d\mu(\lambda)f_1(\lambda,x,t)\sin\lambda^3u, \tag{3.3}$$

$$l_1'(x,t,u)=\left[\frac{\partial}{\partial y}L_1(x,y,t,u)\right]_{y=0}=-\int d\mu(\lambda)f_1(\lambda,x,t)\lambda\,\cos(\lambda^3u), \tag{3.4}$$

$$l_1''(x,t,u)=\left[\frac{\partial^2}{\partial y^2}L_1(x,y,t,u)\right]_{y=0}=\int d\mu(\lambda)f_1(\lambda,x,t)\lambda^2\sin\lambda^3u. \tag{3.5}$$

It follows from (2.8) that

$$V(x,t)=2\frac{\partial}{\partial x}L_1(x,x,t,t)=2\left[\left(\frac{\partial}{\partial x}+\frac{\partial}{\partial y}\right)L_1(x,y,t,t)\right]_{x=y}. \tag{3.6}$$

Thus,

$$V(0,t)=\left[\frac{\partial}{\partial x}l_1(x,t,t)+l_1'(x,t,t)\right]_{x=0}. \tag{3.7}$$

We derive an integral equation from (3.1), by multiplying by $[d\mu(k)\sin(kx+k^3t)]$ and integrating.

With the notations (3.3)–(3.5), the equation reads as

$$L_1(x,y,t,u)+G_1(x,y,t,u)+\int_0^x G_1(z,y,t,u)L_1(x,z,t,t)dz-\int_0^t g_1''(y,s,u)l_1(x,t,s)ds$$
$$+\int_0^t g_1'(y,s,u)l_1'(x,t,s)ds-\int_0^t g_1(y,s,u)l_1''(x,t,s)ds=0, \tag{3.8}$$

where

$$G(x,y,t,u)=\int d\mu(\lambda)\sin(\lambda x+\lambda^3 t)\sin(\lambda y+\lambda^3 u), \tag{3.9}$$

$$g_1(y,s,u)=G(0,y,s,u)=\int d\mu(\lambda)\sin\lambda^3 s\,\sin(\lambda y+\lambda^3 u), \tag{3.10}$$

$$g_1'(y,s,u)=\left[\frac{\partial}{\partial x}G(x,y,s,u)\right]_{x=0}=\int d\mu(\lambda)\lambda\,\cos\lambda^3 s\,\sin(\lambda y+\lambda^3 u), \tag{3.11}$$

$$g_1''(y,s,u)=\left[\frac{\partial^2}{\partial x^2}G(x,y,s,u)\right]_{x=0}=-\int d\mu(\lambda)\lambda^2\sin\lambda^3 s\,\sin(\lambda y+\lambda^3 u). \tag{3.12}$$

Now this Gelfand Levitan scheme enables us to study the following incomplete Cauchy problem.

We want to construct a solution $V(x,t)$ of the Korteweg de Vries equation (2.18) such that $V(x,0)$ has prescribed values for $x\geqslant 0$. The equations (3.1), (3.2), (3.6), and (3.8) simplify. In particular, if we write $L(x,y)$ for $L(x,y,0,0)$ and $G(x,y)$ for $G(x,y,0,0)$,

$$L(x,y)=-\int d\mu(\lambda)f_1(\lambda,x,0)\sin\lambda y, \tag{3.13}$$

$$G(x,y)=\int d\mu(\lambda)\sin\lambda x\,\sin\lambda y, \tag{3.14}$$

$$L(x,y)+G(x,y)+\int_0^x L(x,z)G(z,y)dz=0. \tag{3.15}$$

These equations are the usual Gelfand Levitan equations, and it follows from (3.2) and (2.6) that $L(x,y)$ obeys the partial differential equations,

$$\left(\frac{\partial^2}{\partial x^2}-V(x)-\frac{\partial^2}{\partial y^2}\right)L(x,y)=0, \tag{3.16}$$

with $L(x,0)=0$ and $L(x,x)$ related to $V(x,0)$ by (3.6). The usual integration on characteristics yields the Volterra equation for $L(x,y)(x\geqslant y\geqslant 0)$ from $V(y,0)$ [which we write here $V(y)$]:

$$L(x,y)=\frac{1}{2}\int_{(x-y)/2}^{(z+y)/2}V(s)ds+\int_{(x-y)/2}^{(x+y)/2}ds\int_0^{(x-y)/2}du\,V(s+u)L(s+u,s-u). \tag{3.17}$$

Hence, giving $V(y)$ for $y\geqslant 0$ enables us to construct $L(x,y)$ for $x\geqslant y\geqslant 0$. Then we can construct $f_1(k,x,0)$ from $\sin kx$ by using the transformation formula (3.1); here

$$f_1(k,x,0)=\sin kx+\int_0^x L(x,y)\sin ky\,dy. \tag{3.18}$$

If $V(x,0)$ is a scattering potential, for which the Gelfand Levitan method applies, we can then construct the Jost function $F(k)$:

$$F(k)=1+\int_0^\infty e^{ikr}V(r,0)k^{-1}f_1(k,r,0)dr, \tag{3.19}$$

and $d\mu(k)$ from the modulus of the Jost function: the part corresponding to the continuous spectrum is proportional to $k(|F(k)|^{-2}-1)$, and it is easy to see that a weak condition of regularity on V [a derivative in $L_1(\mathbb{R}^+)$ is sufficient] guarantees the working assumptions we imposed to $d\mu(\lambda)$. There are also potentials that are not regular, and whose $d\mu(\lambda)$ is such that the method works. We shall not study them. In all cases, giving $d\mu(\lambda)$ gives (2.5), from which the problem is solved. In our previous paper we gave another Gelfand Levitan equation, which corresponds to a different equation (2.5) and also enables us to find (another) solution of KdV from its value on $(0,t)$. The ambiguity in this determination should not be surprising since it is obvious on the linearized problem, and it is related to our selecting from the beginning a symmetric measure.

Hence, it appears that the usual Faddeev–Marchenko scheme is probably better than the Gelfand Levitan one, since it takes the exact amount of information required for solving the space Cauchy problem without any ambiguity. But the scheme we gave here may produce solutions of the Cauchy problems in classes that are not managed by the Marchenko scheme!

IV. MATRICIAL LAX EQUATIONS AND A LINEAR ANALYSIS

The spectral equations (2.6) and (2.7) are fulfilled by a function $f_1(k,x,t)$ defined by (1). It is easy to replace (2.6) by a first-order equation for the vector

$$\mathbf{f}=\begin{pmatrix} f_1(k,x,t) \\ \dfrac{\partial}{\partial x}f_1(k,x,t)\end{pmatrix}. \tag{4.1}$$

In the following, we shall say that the vector **f** written in (3.1) ''corresponds'' to $f_1(k,x,t)$. On the other hand, if we look for solutions of (2.7) that are twice differentiable functions of x and t, we can also derive from (2.7) and (2.6) another first-order equation for **f**. These two first-order equations read as

$$\frac{\partial}{\partial x}\mathbf{f}(k,x,t)=\mathbf{M}\mathbf{f}(k,x,t), \tag{4.2}$$

$$\frac{\partial}{\partial t}\mathbf{f}(k,x,t)=\mathbf{N}\mathbf{f}(k,x,t), \tag{4.3}$$

where

$$\mathbf{M}=\begin{pmatrix} 0 & 1 \\ -k^2+V & 0\end{pmatrix},\qquad \mathbf{N}=\begin{pmatrix} -\frac{1}{4}V' & k^2+\frac{1}{2}V \\ -\frac{1}{4}V''-(k^2-V)(k^2+\frac{1}{2}V) & \frac{1}{4}V'\end{pmatrix} \tag{4.4}$$

(again we used the prime for x derivatives).

They are consistent with each other if

$$\frac{\partial \mathbf{M}}{\partial t}-\frac{\partial \mathbf{N}}{\partial x}+[\mathbf{M},\mathbf{N}]=0, \tag{4.5}$$

which holds *if and only if*

$$\frac{\partial V}{\partial t}+\frac{1}{4}V'''-\frac{3}{2}VV'=0, \tag{4.6}$$

i.e., if the Korteweg de Vries equation holds! If it does, (4.2) and (4.3) can be readily transformed into the Volterra equation,

$$\mathbf{f}(k,x,t)=\mathbf{f}(k,0,0)+\int_0^x \mathbf{M}(y,0)\mathbf{f}(k,y,0)dy+\int_0^t \mathbf{N}(0,u)\mathbf{f}(k,0,u)du+\int_0^x\int_0^t \mathbf{P}(y,u)\mathbf{f}(k,y,u)dy\,du, \tag{4.7}$$

where

$$\mathbf{P}(k,x,t)=\frac{\partial \mathbf{M}}{\partial t}+\mathbf{MN}=\frac{\partial \mathbf{N}}{\partial x}+\mathbf{NM}. \tag{4.8}$$

One can derive approximate solutions of (4.8) that are linear in V (a norm $\|V\|$ may denote the orders of a series expansion). It can be done by setting

$$\mathbf{g}(k,x,t)=\exp[-\mathbf{M}_0(x+k^2t)]\mathbf{f}(k,x,t), \tag{4.9}$$

where **M** is the matrix

$$\begin{pmatrix} 0 & 1 \\ -k^2 & 0 \end{pmatrix},$$

whose eigenvectors

$$\begin{pmatrix} 1 \\ \pm ik \end{pmatrix}$$

correspond to eigenvalues $\pm ik$. Then one notices that

$$\mathbf{M}-\mathbf{M}_0=\mathbf{m}, \quad \mathbf{N}-k^2\mathbf{M}_0=\mathbf{n} \tag{4.10}$$

are matrices with all elements of order $\|V\|$, and one derives the Volterra equation for $\mathbf{g}(k,x,t)$:

$$\mathbf{g}(k,x,t)=\mathbf{g}(k,0,0)+\int_0^x dy\,\exp[-\mathbf{M}_0y]\mathbf{m}(y)\exp[\mathbf{M}_0y]\mathbf{g}(k,y,0)$$
$$+\int_0^t du\,\exp[-k^2\mathbf{M}_0u]\mathbf{n}(u)\exp[k^2\mathbf{M}_0u]\mathbf{g}(k,0,u)+\int_0^x\int_0^t dy\,du\,\mathbf{p}(k,y,u)\mathbf{g}(k,y,u), \tag{4.11}$$

where

$$\mathbf{p}(k,x,t)=\exp[-\mathbf{M}_0(x+k^2t)][\mathbf{q}(k,x,t)]\exp[\mathbf{M}_0(x+k^2t)],$$

$$\mathbf{q}(k,x,t)=\frac{\partial \mathbf{m}}{\partial t}+\mathbf{mN}-k^2\mathbf{M}_0\mathbf{m}=\frac{\partial \mathbf{n}}{\partial x}+\mathbf{nM}-\mathbf{M}_0\mathbf{n}. \tag{4.12}$$

By using (4.12), with the parity assumption on $d\mu(\lambda)$, the reader may easily check that in the V-linear approximation, the function $f_1(k,x,0)$ that reduces at order 0 to $\sin kx$, is indeed an approximate solution of (2.5):

$$f_1(k,x,0) \simeq \sin kx + \frac{1}{2}\int d\mu(\lambda)\left[\frac{\sin(k+\lambda)x}{k+\lambda} - \frac{\sin(k-\lambda)x}{k-\lambda}\right]\sin\lambda x. \tag{4.13}$$

In this approximation, $V(x,0)$ is given by

$$V(x,0) \simeq -2\frac{\partial}{\partial x}\int d\mu(\lambda)\sin^2\lambda x\, dx, \tag{4.14}$$

from which we learn that (a) V is known for any x if it is known for $x \geqslant 0$; (b) $d\mu(\lambda)$ is known from the knowledge of $V(x,0)$ for $x \geqslant 0$, so that the solution $V(x,t)$ of KdV in this linear approximation (and with this method) is known from $V(x,0)$, $x \geqslant 0$.

On the other hand, we can study the V-linear approximation of (4.12) at $x=0$:

$$\mathbf{g}(k,0,t) = \mathbf{g}(k,0,0) + \int_0^t du\, \exp[-k^2\mathbf{M}_0 u]\mathbf{n}(u)\exp[k^2\mathbf{M}_0 u]\mathbf{g}(k,0,0), \tag{4.15}$$

with, say,

$$\mathbf{g}(k,0,0) = \begin{pmatrix} b \\ ka \end{pmatrix} = \alpha\begin{pmatrix} 1 \\ ik \end{pmatrix} + \beta\begin{pmatrix} 1 \\ -ik \end{pmatrix},$$

$$\mathbf{n}(t) = \begin{pmatrix} -\frac{1}{4}V'(0,t) & \frac{1}{2}V(0,t) \\ -\frac{1}{4}V''(0,t) + \frac{1}{2}k^2 V(0,t) & \frac{1}{4}V'(0,t) \end{pmatrix}. \tag{4.16}$$

Setting $\mathbf{g}(k,0,0) = \binom{0}{k}$, we obtain, after some direct calculations on (4.16),

$$f_1(k,0,t) \simeq \sin k^3 t + \int_0^t \left\{ -\frac{1}{4}V''(0,u)\frac{\sin k^3 u}{k}\sin k^3(t-u) \right.$$
$$\left. -\tfrac{1}{4}V'(0,u)\sin(2k^3u - k^3t) + \tfrac{1}{2}V(0,u)\cos(2k^3u - k^3t) \right\} du. \tag{4.17}$$

In the V-linear approximation, V, V', V'' should be themselves the Born approximations:

$$V(x,t) \simeq -2\int d\mu(\lambda)\lambda\, \sin[2(\lambda x + \lambda^3 t)], \tag{4.18}$$

$$V(0,t) \simeq -2\int d\mu(\lambda)\lambda\, \sin[2\lambda^3 t], \tag{4.19}$$

$$V'(0,t) \simeq -4\int d\mu(\lambda)\lambda^2 \cos[2\lambda^3 t], \tag{4.20}$$

$$V''(0,t) \simeq 8\int d\mu(\lambda)\lambda^3 \sin[2\lambda^3 t]. \tag{4.21}$$

If we substitute these results into (4.17), and take into account the symmetry of $d\mu(\lambda)$, we obtain the V-linear approximation of $f_1(k,0,t)$ as it is given by (2.5):

$$f_1(k,0,t) \simeq \sin k^3 t + \frac{1}{2}\int_0^t d\mu(\lambda)\left\{\frac{\sin(k^3+\lambda^3)t}{k+\lambda} - \frac{\sin(k^3-\lambda^3)t}{k-\lambda}\right\}\sin\lambda^3 t. \tag{4.22}$$

Hence, the linearized solution of the Lax-pair equations (4.2), (4.3) corresponding at zero order to $\sin(kx+k^3t)$ and that of (2.5) are identical. Therefore, it is essential to see what can be freely chosen in (4.19)–(4.21). As a first guess, one may hope that V'',V',V, are independent parameters. But since the derivation has been made with the linear conditions, they are given by (4.19), (4.20), and (4.21). This means that, not only V,V',V'' are determined by their values for $t\geqslant 0$ (which is a particular feature of the method), but also they must be consistent altogether with a representation using only one measure, and with at least another one involving three measures (which are here trivially dependent on each other because of the linear equation).

Indeed, let us try to solve ''linearized Korteweg de Vries equation,'' for instance,

$$\frac{\partial V}{\partial t}+\frac{1}{4}V'''=0; \tag{4.23}$$

we see that (4.18) is a solution, but using a full axis x-Fourier transform would enable us, choosing freely $V(x,0)$, whereas using the representation

$$V(x,t)=\int_{-\infty}^{+\infty}d\lambda\; e^{2ik^3t}[\gamma_0(\lambda)e^{2ikx}+\gamma_1(\lambda)e^{2ikjx}+\gamma_2(\lambda)e^{2ikj^2x}], \tag{4.24}$$

where

$$j=\exp[2i\pi/3] \tag{4.25}$$

is convenient to solve the time Cauchy problem.

Hence, methods showing one spectral measure only, and/or assuming that it is symmetric, are not convenient to solve general boundary value problems.

V. REPRESENTATION OF $f(k,x,t)$ ON TIME PATHS

A. Consistency on paths and analytic properties

The known linearizing methods all started from a representation of the wave function [and thus of the function $\mathbf{f}(k,x,t)$ defined by (4.1)] in terms of one spectral measure. Since it seems that it is not enough to deal with the second Cauchy problem, we try now to derive the most general representations of $\mathbf{f}(k,x,t)$, which are of Levitan's form *and* consistent with Eqs. (4.2) and (4.3). First, notice that we can go from $\mathbf{f}(k,x_0,t_0)$ to $\mathbf{f}(k,x,t)$ by following successively an x path and a t path (k being fixed, and dropped for a time from the notations):

$$\mathbf{f}(x,t_0)=\mathbf{f}(x_0,t_0)+\int_{x_0}^{x}dy\;\mathbf{M}(y,t_0)\mathbf{f}(y,t_0), \tag{5.1}$$

$$\mathbf{f}(x,t)=\mathbf{f}(x,t_0)+\int_{0}^{t}du\;\mathbf{N}(x,u)\mathbf{f}(x,u). \tag{5.2}$$

We could as well follow successively a t path and an x path, or, as in (4.7), combine both ones.

The solution $\mathbf{f}(x,t)$ of (5.2) is the solution of

$$\frac{\partial}{\partial t}\mathbf{f}(x,t)=\mathbf{N}(x,t)\mathbf{f}(x,t), \tag{5.3}$$

$\mathbf{f}(\mathbf{x},t_0)$ being given. Now let $\mathbf{S}(x,t)$ be the matrix solution of

$$\mathbf{S}(x,t)=\mathbf{I}+\int_{t_0}^{t}\mathbf{N}(x,u)\mathbf{S}(x,u)du, \tag{5.4}$$

where **I** is the 2×2 unit matrix.

It is clear that $\mathbf{S}(x,t)\mathbf{f}(x,t_0)$ is equal to $\mathbf{f}(x,t)$.

Suppose that the x path (5.1) has produced a function $\mathbf{f}(x,t_0)$ that satisfies the following property:

$$\frac{\partial}{\partial x}\mathbf{f}(x,t_0)=\mathbf{M}(x,t_0)\mathbf{f}(x,t_0), \tag{5.5}$$

and remind that **M** and **N** must fulfill the consistency condition (4.5). It is a matter of simple derivations, and using the solution uniqueness property of Volterra equations (5.2) and (5.4), to show that the function $\mathbf{S}(x,t)\mathbf{f}(x,t_0)$ [or $\mathbf{f}(x,t)$] satisfies for any value of t the equation

$$\frac{\partial}{\partial x}\mathbf{f}(x,t)=\mathbf{M}(x,t)\mathbf{f}(x,t). \tag{5.6}$$

Hence, if we get on the x path a representation of $\mathbf{f}(x,t_0)$ consistent with (5.6), and if we solve (5.4) on the t path, **M** and **N** fulfilling (4.5), we construct $\mathbf{f}(x,t)$, which satisfies simultaneously (5.3) and (5.6). Since we already know Gelfand Levitan or Marchenko representations of $\mathbf{f}(x,t_0)$ on the x path, we have now only to study the t path.

We shall use the convenient notations:

$$\mathbf{N}(k,x,t)=-k^4n_2+k^2n_1+n_0=N_2(k)+N_1(k,x,t), \tag{5.7}$$

where

$$n_2=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix},\quad n_1=\begin{pmatrix}0 & 1\\ V_0 & 0\end{pmatrix},\quad n_0=\begin{pmatrix}V_1 & V_0\\ V_2 & -V_1\end{pmatrix}, \tag{5.8}$$

$$V_0=\tfrac{1}{2}V(x,t),\quad V_1=-\tfrac{1}{4}V'(x,t),\quad V_2=(\tfrac{1}{2}V^2-\tfrac{1}{4}V'')(x,t), \tag{5.9}$$

$$N_2=\begin{pmatrix}0 & k^2\\ -k^4 & 0\end{pmatrix},\quad N_1=k^2V_0n_2+n_0=\mathbf{n}, \tag{5.10}$$

and, for the sake of simplicity, we choose $t_0=0$. Notice that on the path $(0,t)$, x is fixed and only t varies in V_0,V_1,V_2. We suppose that the $V_{i'}$'s are bounded for the value of x and any $t\in[-T,T]$, and let $\overline{V}(x,t)$ be their common absolute upper bound. We suppose that $\int_{-\infty}^{\infty}\overline{V}(x,t)dt$ is finite. We first prove the following.

T1. The solution $\mathbf{S}(k,t)$ of (5.4) at fixed x is an entire function of k^2. If it is written as

$$\mathbf{S}(k,t)=\mathbf{S}_0(k^3,t)+k^2\mathbf{S}_1(k^3,t)+k^4\mathbf{S}_2(k^3,t), \tag{5.11}$$

where

$$\mathbf{S}_l(k^3,t)=\tfrac{1}{3}[\mathbf{S}(k,t)+j^l\mathbf{S}(jk,t)+j^{2l}\mathbf{S}(j^2k,t)], \tag{5.12}$$

then $\mathbf{S}_0,\mathbf{S}_1,\mathbf{S}_2$ are even entire functions of k^3 of exponential type t.

Proof: From (5.4), (5.7), (5.11), and (5.12), we derive the integral equation for the vector $\hat{\sigma}$ (in fact, a 6×2 matrix) whose components are the 2×2 matrices $\mathbf{S}_0,\mathbf{S}_1,\mathbf{S}_2$,

$$\hat{\sigma}(k,t)=\widehat{\sigma_0}+\int_0^t\nu(k,u)\hat{\sigma}(k,u)du, \tag{5.13}$$

where

$$\nu(k,t)=\begin{pmatrix} n_0 & -k^6 n_2 & k^6 n_1 \\ n_1 & n_0 & -k^6 n_2 \\ -n_2 & n_1 & n_0 \end{pmatrix}, \tag{5.14}$$

$$\hat{\sigma}_0=\begin{pmatrix} \mathbf{I} \\ 0 \\ 0 \end{pmatrix}. \tag{5.15}$$

The solution of the Volterra equation (5.13) is given by the uniformly convergent series,

$$\hat{\sigma}_{n+1}(k,t)=\int_0^t \nu(k,u)\hat{\sigma}_n(k,u)du,$$

starting at $\widehat{\sigma_0}$. It follows that $\hat{\sigma}(k,t)$, like $\nu(k,t)$, is an entire function of k^6, and that each element of the 6×2 matrix $\hat{\sigma}(k,t)$ is absolutely bounded by the corresponding one of the matrix $\overline{\sigma_n}(k,t)$ that appears in the series expansion of the solution $\overline{\sigma_n}(k,t)$ of the equation,

$$\overline{\sigma}(k,t)=\widehat{\sigma_0}+\int_0^t \overline{\nu}(|k|,u)\overline{\sigma}(k,u)du, \tag{5.16}$$

where

$$\overline{\nu}|k|,t)=\begin{pmatrix} \overline{n_0} & |k|^6 n_2 & |k|^6\,\overline{n_1} \\ \overline{n_1} & \overline{n_0} & |k^6|n_2 \\ n_2 & \overline{n_1} & \overline{n_0} \end{pmatrix}, \tag{5.17}$$

$$\overline{n_0}=K^2\begin{pmatrix} K & I \\ 2K^2 & K \end{pmatrix}, \quad \overline{n_1}=\begin{pmatrix} 0 & I \\ K^2 & 0 \end{pmatrix}, \tag{5.18}$$

and the positive number K has been chosen to yield absolute bounds for the coefficients containing V and its derivatives in n_0 and n_1. Notice that $\overline{\sigma}(k,t)$ is an entire function of $|k|^6$.

Going back from $\overline{\sigma}(k,t)$ to the 2×2 matrix,

$$\tilde{\sigma}(k,t)=\overline{\sigma}(k,t)+|k|^2\overline{\sigma_1}(k,t)+|k|^4\,\overline{\sigma_2}(k,t), \tag{5.19}$$

we readily derive

$$\tilde{\sigma}(k,t)=I+\int_0^t \tilde{n}(|k|,u)\tilde{\sigma}(k,u)du, \tag{5.20}$$

where

$$\tilde{n}(|k|,u)=\begin{pmatrix} K^3 & \chi^2 \\ \chi^4 & K^3 \end{pmatrix} \tag{5.21}$$

and

$$\chi=\sqrt{|k|^2+K^2}, \tag{5.22}$$

and the solution of (5.20) is

$$\tilde{\sigma}=e^{K^3 t}\begin{pmatrix} \cosh \chi^3 t & \sinh \dfrac{\chi^3 t}{X} \\ \chi \sinh \chi^3 t & \cosh \chi^3 t \end{pmatrix}. \tag{5.23}$$

From (5.23) one readily derives bounds for the components of $\mathbf{S}_0$, $\mathbf{S}_1$, $\mathbf{S}_2$ as $|k|\to\infty$, and from the standard definitions of Boas,[6] it follows that the functions of k^3 that appear are of order not larger than 1 and type t. Q.E.D.

T2. With the assumptions of **T1** and assuming also that $(\partial/\partial t)V(x,t)$ and $(\partial/\partial t)V'(x,t)$ are absolutely bounded for the fixed value of x and any $t\in[-t_1,t_1]$, we claim that $\mathbf{S}_i(k^3,t)$ $(i=0,1,2)$ is absolutely bounded for $k^3\in\mathbb{R}$ and $|t|<t_1$.

Proof: From (5.7) we get

$$\exp[-N_2 t]=\begin{pmatrix} \cos k^3 t & -k^{-1}\sin k^3 t \\ k \sin k^3 t & \cos k^3 t \end{pmatrix}. \tag{5.24}$$

Now set

$$T(k,t)=\begin{pmatrix} 1 & 0 \\ 0 & k^{-1} \end{pmatrix}\exp[-N_2 t]\mathbf{S}(k,t). \tag{5.25}$$

It follows from (5.4) (dropping the fixed x in notations) that

$$T(k,t)=T(k,0)+\sum_{-1}^{1}\int_0^t k^l v^{(l)}(u)n^{(l)}(k^3u)T(k,u)du, \tag{5.26}$$

where

$$v^{(-1)}(t)=-\tfrac{1}{2}V_2(t);v^{(0)}(t)=-\tfrac{1}{4}V'(t);v^{(1)}(t)=\tfrac{1}{2}V(t), \tag{5.27}$$

$$n^{(-1)}(z)=\begin{pmatrix} \sin 2z & 2\sin^2 z \\ -2\cos^2 z & -\sin 2z \end{pmatrix}, \tag{5.28}$$

$$n^{(0)}(z)=\begin{pmatrix} \cos 2z & \sin 2z \\ \sin 2z & -\cos 2z \end{pmatrix}, \tag{5.29}$$

$$n^{(1)}(z)=\begin{pmatrix} -\sin 2z & \cos 2z \\ \cos 2z & \sin 2z \end{pmatrix}. \tag{5.30}$$

It is readily seen that

$$2k^3 n^{(1)}(k^3u)=\frac{\partial}{\partial u}n^{(0)}(k^3u),\quad 2k^3n^{(0)}(k^3u)=-\frac{\partial}{\partial u}n^{(1)}(k^3u). \tag{5.31}$$

Using (5.31) for integrating by parts the term with $l=1$, and noticing that $\partial T/\partial u$ can be expressed by means of (5.26) and that

$$[n^0(z)]^2=I,\quad n^0(z)n^+(z)=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \tag{5.32}$$

we obtain

$$[1-\tfrac{1}{4}k^{-4}(v^{(1)}(t))^2]T(k,t)=[1+\tfrac{1}{2}k^{-2}n^{(0)}(k^3t)v^{(1)}(t)]$$
$$\times\Bigg\{\bigg[1-\frac{1}{2}k^{-2}v^{(1)}(0)\bigg]T(k,0)+\sum_{-1}^{0}k^l\int_0^l v^{(l)}(u)n^{(l)}(k^3u)T(k,u)du$$
$$-\frac{1}{2}\int_0^t du\Bigg\{-k^{-3}v^{(-1)}(u)n^{(-1)}(k^3u)+k^{-2}$$
$$\times\bigg[v^{(0)}(u)+\frac{\partial}{\partial u}v^{(1)}(u)n^{(0)}(k^3u)\bigg]+k^{-1}v^{(1)}(u)$$
$$\times\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\Bigg\}T(k,u)\Bigg\}. \tag{5.33}$$

This Volterra equation can be studied by means of a majorant equation, all the coefficients being trivially bounded as $|k|$ becomes large, and it follows that the elements of $T(k,t)$, at finite t, are absolutely bounded by those of

$$\overline{T}(k,t)=C(t)\begin{pmatrix}1 & k^{-1}\\ 1 & k^{-1}\end{pmatrix}, \tag{5.34}$$

where C is an appropriate function. We can then improve the asymptotic behavior of $T(k,t)$ as $|k|\to\infty$ on $\mathbb{R}$ by integrating by parts also the term $\int_0^t v^{(0)}(u)n^{(0)}(k^3u)T(k,u)du$, obtaining

$$T(k,t)\begin{pmatrix}1 & 0\\ 0 & k^{-1}\end{pmatrix}=\begin{pmatrix}O(|k|^{-1}) & O(k^{-2})\\ O(|k|^{-1}) & O(k^{-2})\end{pmatrix}, \tag{5.35}$$

from which it follows that

$$\left|\mathbf{S}(k,t)-\begin{pmatrix}\cos k^3t & k^{-1}\sin k^3t\\ -k\sin k^3t & \cos k^3t\end{pmatrix}\right| \tag{5.36}$$

is bounded for fixed t, real k, and so are therefore (Q.E.D.)

$$\mathbf{S}_0(k,t),\quad \mathbf{S}_1(k,t),\quad \mathbf{S}_2(k,t). \tag{5.37}$$

Since $\mathbf{S}(k,t)$ enables us to write down any solution of (5.3) whose value and derivative are fixed at $t=0$, it follows from **T1** and **T2** that we can derive generalized Povzner–Levitan representations of such solutions.

B. Representation of the wave function

As a matter of fact, if φ is the first component of a vector $\mathbf{f}$ solution of

$$\frac{\partial \mathbf{f}}{\partial t}=\mathbf{N}f \tag{5.38}$$

(which, in standard scalar form, would be a fourth-order spectral problem), φ is a solution of

$$D_t(k)\varphi=:\bigg[(k^2+V_0)\bigg(\frac{\partial^2}{\partial t^2}+k^6+\alpha k^2+\beta\bigg)-\frac{\partial V_0}{\partial t}\bigg(\frac{\partial}{\partial t}-V_1\bigg)\bigg]\varphi(k,t)=0, \tag{5.39}$$

where V_0, V_1, V_2, are defined by (5.9), and

$$\alpha=-(V_0^2+V_2),\quad \beta=-\bigg(V_1^2+V_0V_2+\frac{\partial V_1}{\partial t}\bigg). \tag{5.40}$$

We can define two independent solutions of the time spectral problem (5.39) by initial (i.e., $t=0$) conditions and, after some elementary algebra, write down their generalized Povzner–Levitan representations,

$$\varphi_1(k,t)=k^{-1}\sin k^3 t+\int_0^t du\{k^{-1}\sin k^3 u\,\psi_-(t,u)+\cos k^3 u\,\psi_0(t,u)+k\sin k^3 u\,\psi_+(t,u)\},\tag{5.41}$$

$$\varphi_2(k,t)=\cos k^3 t+\chi(t)k^{-1}\sin k^3 t+\int_0^t du\{k^{-1}\sin k^3 u\,\chi_-(t,u)+\cos k^3 u\,\chi_0(t,u)+k\sin k^3 u\,\chi_+(t,u)\}.\tag{5.42}$$

Inserting (5.41) into (5.39), we find boundary conditions to be satisfied by the functions ψ:

$$\psi_-(t,0)=\psi_+(t,0)=\left[\frac{\partial}{\partial u}\psi_0(t,u)\right]_{u=0}=\left[\frac{\partial^2}{\partial t^2}\psi_+(t,u)\right]_{u=0}=\left[\frac{\partial^2}{\partial u^2}\psi_+(t,u)\right]_{u=0}=0,\tag{5.43}$$

$$2\frac{d}{dt}\psi_+(t,t)+\alpha=0,\tag{5.44}$$

$$2\frac{d}{dt}\psi_0(t,t)-\alpha\psi_+(t,t)-\frac{\partial V_0}{\partial t}=0,\tag{5.45}$$

$$2\frac{d}{dt}\psi_-(t,t)+\alpha\psi_0(t,t)-\frac{\partial V_0}{\partial t}\psi_+(t,t)+\beta=0,\tag{5.46}$$

$$\left[\left(\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}\right)\psi_+(t,u)\right]_{t=u}+\alpha\psi_-(t,t)+\frac{\partial V_0}{\partial t}\psi_0(t,t)+(\beta+\alpha V_0)\psi_+(t,t)-2V_0\frac{d}{dt}\psi_0(t,t)=0,\tag{5.47}$$

$$\left[\left(\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}\right)\psi_0(t,u)\right]_{t=u}+\alpha\left[\frac{\partial}{\partial u}\psi_+(t,u)\right]_{t=u}+(\alpha V_0+\beta)\psi_0(t,t)-\frac{\partial V_0}{\partial t}\psi_-(t,t)+2V_0\frac{d}{dt}\psi_-(t,t)=0,\tag{5.48}$$

and we also find the partial differential equations to be satisfied by the functions ψ:

$$\left(\frac{\partial^3}{\partial u^3}-\frac{\partial^3}{\partial t^2\,\partial u}\right)\psi_0(t,u)-\alpha\frac{\partial^2}{\partial u^2}\psi_+(t,u)+V_0\left(\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}\right)\psi_-(t,u)-(\beta+V_0\alpha)\frac{\partial}{\partial u}\psi_0(t,u)-\frac{\partial V_0}{\partial t}\frac{\partial}{\partial t}\psi_-(t,u)+\left(V_0\beta+V_1\frac{\partial V_0}{\partial t}\right)\psi_-(t,u)=0,\tag{5.49}$$

$$\left(\frac{\partial^3}{\partial t^2\,\partial u}-\frac{\partial^3}{\partial u^3}\right)\psi_+(t,u)+V_0\left(\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}\right)\psi_0(t,u)+(\beta+V_0\alpha)\frac{\partial}{\partial u}\psi_+(t,u)+\alpha\frac{\partial}{\partial u}\psi_-(t,u)-\frac{\partial V_0}{\partial t}\frac{\partial}{\partial t}\psi_0(t,u)+\left(\beta V_0+V_1\frac{\partial V_0}{\partial t}\right)\psi_0(t,u)=0,\tag{5.50}$$

$$\left(\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}\right)\psi_-(t,u)+V_0\left(\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}\right)\psi_+(t,u)-\alpha\frac{\partial}{\partial u}\psi_0(t,u)$$
$$-\frac{\partial V_0}{\partial t}\frac{\partial}{\partial t}\psi_+(t,u)+(\beta+\alpha V_0)\psi_-(t,u)+\left(\beta V_0+V_1\frac{\partial V_0}{\partial t}\right)\psi_+(t,u)=0. \tag{5.51}$$

Similar results hold for $\varphi_2(k,t)$. It is clear that all these results remind us of those of the Gelfand Levitan approach to the space spectral problem, and it is likely they can be used to construct solvable examples of Korteveg de Vries equation, but it is also clear that they are much too complicated for doing more. We can simplify their management if we notice that setting

$$\psi_-(t,u)=\int_{-\infty}^{+\infty}d\lambda\,\sin\lambda^3u\lambda\,\tilde{\psi}_{-1}(t,\lambda), \tag{5.52}$$

$$\psi_0(t,u)=\int_{-\infty}^{+\infty}d\lambda\,\cos\lambda^3u\,\tilde{\psi}_0(t,\lambda), \tag{5.53}$$

$$\psi_+(t,u)=\int_{-\infty}^{+\infty}d\lambda\,\sin\lambda^3u\lambda^{-1}\tilde{\psi}_{+1}(t,\lambda), \tag{5.54}$$

where the $\tilde{\psi}_i(t,\lambda)$ are even functions of λ, and setting

$$\Psi_0(t,\lambda)=\tilde{\psi}_{-1}(t,\lambda)+\tilde{\psi}_0(t,\lambda)+\tilde{\psi}_{+1}(t,\lambda), \tag{5.55}$$

$$\Psi_-(t,\lambda)=j^2\tilde{\psi}_{-1}(t,\lambda)+\tilde{\psi}_0(t,\lambda)+j\tilde{\psi}_{+1}(t,\lambda), \tag{5.56}$$

$$\Psi_+(t,\lambda)=j\tilde{\psi}_{-1}(t,\lambda)+\tilde{\psi}_0(t,\lambda)+j^2\tilde{\psi}_{+1}(t,\lambda), \tag{5.57}$$

we readily prove that ψ_-, ψ_0, and ψ_+ are solutions of (5.49), (5.50), (5.51) if and only if Ψ_0, Ψ_-, Ψ_+, are solutions of

$$D_t(\lambda)\Psi_0=0=D_t(j\lambda)\Psi_-=D_t(j^2\lambda)\Psi_+. \tag{5.58}$$

Hence, we can express the Ψ's (and the similar functions obtained from the χ's), by means of linear combinations of $\varphi_1(\lambda,t)$, $\varphi_2(\lambda,t)$ (and their values for $j\lambda$ and $j^2\lambda$). Taking into account the parity, the coefficients of these linear combinations give a way for representing a solution of the time spectral problem (5.39) in terms of three measures. For instance, suppose we stick at $\varphi_1(k,t)$, as it should be done (we guess it) in a Gelfand Levitan approach of the Cauchy problem. Setting Ψ_0, Ψ_-, Ψ_+, respectively, proportional to $\varphi_1(\lambda,t)$, $\varphi_1(j\lambda,t)$, $\varphi_1(j^2\lambda,t)$, we obtain for $\tilde{\Psi}_0$, $\tilde{\Psi}_{-1}$, $\tilde{\Psi}_{+1}$, the expansions

$$\tilde{\psi}_i(t,\lambda)=\sum_{l=-1}^{l=+1}a_l(\lambda)j^{il}\varphi_1(j^{2l}\lambda,t), \tag{5.59}$$

where the a_l's are even functions of λ. On the other hand, inserting (5.52), (5.53), and (5.54) into (5.41), we obtain

$$\varphi_1(k,t)-k^{-1}\sin k^3t=\int_{-\infty}^{+\infty}d\lambda\Bigg\{\left[\tilde{\psi}_{-1}(t,\lambda)+\frac{k}{\lambda}\tilde{\psi}_{+1}(t,\lambda)\right]\int_0^t du\,\sin\lambda^3u\,\sin k^3u$$
$$+\tilde{\psi}_0(t,\lambda)\int_0^t du\,\cos\lambda^3u\,\cos k^3u\Bigg\}. \tag{5.60}$$

Setting now

$$f(k,t)=k\varphi_1(k,t), \tag{5.61}$$

and inserting (5.59) into (5.60) (with this new notation), we get, after elementary algebra,

$$f(k,t)=\sin k^3t+\sum_{l=-1}^{l=+1}\int d\mu_l(\lambda)T^-(k,j^l\lambda,0,t)f(j^l\lambda,t), \tag{5.62}$$

where T^- has been defined by (2.4), and the measures $d\mu(\lambda)$ are symmetric (i.e., they reduce to even functions of λ times $d\lambda$ when they are Stieltjes measures on the real axis). It is possible to derive from (5.62) a representation valid for any x,t by combining the x path and the t path (as we shall do in Sec. VI). It is better to use (5.62) as the cornerstone of a guess and to prove this guess by setting a new direct linearization of the Korteveg de Vries equation.

C. A new direct linearization of KdV

Guess: The following integral equation yields a direct linearization of the Korteweg de Vries equation:

$$f(k,x,t)=\sin(kx+k^3t)+\sum_{l=-1}^{l=+1}\int d\mu_l(\lambda)T^-(k,j^l\lambda,x,t)f(j^l\lambda,x,t), \tag{5.63}$$

where $T^-(k,\lambda,x,t)$ is defined by (2.4).

Proof: (1) As in all direct linearizations, we assume that for a given free term [here $\sin(kx+k^3t)$], (5.63) has only one solution. As a matter of fact, (5.63) can be gathered with the two other equations, respectively, obtained by substituting jk and j^2k to k. The system that is obtained is a Fredholm system, which can be used to derive f. It is clear that the uniqueness property holds for the system only if it does for Eq. (5.63).

(2) We need five formulas, readily derived from (2.4):

$$\frac{\partial}{\partial x}T^-(k,\lambda,x,t)=-\sin(kx+k^3t)\sin(\lambda x+\lambda^3t), \tag{5.64}$$

$$\frac{\partial^2}{\partial x^2}T^-(k,\lambda,x,t)=-k\cos(kx+k^3t)\sin(\lambda x+\lambda^3t)-\lambda\sin(kx+k^3t)\cos(\lambda x+\lambda^3t), \tag{5.65}$$

$$(k^2-\lambda^2)T^-(k,\lambda,x,t)=k\cos(kx+k^3t)\sin(\lambda x+\lambda^3t)-\lambda\sin(kx+k^3t)\cos(\lambda x+\lambda^3t), \tag{5.66}$$

$$\left(\frac{\partial}{\partial t}-k^2\frac{\partial}{\partial x}\right)T^-(k,\lambda,x,t)=-\lambda k\cos(kx+k^3t)\cos(\lambda x+\lambda^3t)-\lambda^2\sin(kx+k^3t)\sin(\lambda x+\lambda^3t), \tag{5.67}$$

$$\left(\frac{\partial^3}{\partial x^3}+k^2\frac{\partial}{\partial x}\right)T^-(k,\lambda,x,t)=-2\lambda k\cos(kx+k^3t)\cos(\lambda x+\lambda^3t)+\lambda^2\sin(kx+k^3t)\sin(\lambda x+\lambda^3t). \tag{5.68}$$

(3) Let us now apply $(\partial^2/\partial x^2+k^2)$ to $f(k,x,t)$ in (5.63). Using (5.64)–(5.66) and their transforms as $\lambda\to j\lambda$, $j^2\lambda$, we see that a function $V(x,t)$ [given below in (5.72)] is such that

$$\left(\frac{\partial^2}{\partial x^2}+k^2\right)f(k,x,t)=V(x,t)\sin(kx+k^3t)+\sum_l\int d\mu_l\,T(k,j^l\lambda,x,t)\left(\frac{\partial^2}{\partial x^2}+j^{2l}\lambda^2\right)f(j\lambda,x,t), \tag{5.69}$$

whereas it follows from (5.63) that for any function V that does not depend on k, we can write down

$$V(x,t)f(k,x,t)=V(x,t)\sin(kx+k^3t)+\sum_l d\mu_l(\lambda)T(k,j^l\lambda,x,t)V(x,t)f(j\lambda,x,t). \quad (5.70)$$

Subtracting (5.70) from (5.69) and thanks to the uniqueness property we get

$$\left[\frac{\partial^2}{\partial x^2}+k^2-V(x,t)\right]f(k,x,t)=0, \quad (5.71)$$

whereas

$$V(x,t)=-2\frac{\partial}{\partial x}\sum_l \int d\mu_l(\lambda)\sin(j^l\lambda x+\lambda^3 t)f(j^l\lambda,x,t). \quad (5.72)$$

(4) Let us apply to f in (5.63) the operator $(\partial/\partial t-\frac{3}{2}k^2(\partial/\partial x)-\frac{1}{2}\partial^3/\partial x^3)$. Using (5.65), (5.67) and their transforms as $\lambda\rightarrow j\lambda$, $j^2\lambda$, we obtain

$$\left(\frac{\partial}{\partial t}-\frac{3}{2}k^2\frac{\partial}{\partial x}-\frac{1}{2}\frac{\partial^3}{\partial x^3}\right)f(k,x,t)=-\frac{3}{4}\left[\frac{\partial}{\partial x}V(x,t)\right]\sin(kx+k^3t)+\sum_l \int_{-\infty}^{+\infty}d\mu_l(\lambda)T(k,j^l\lambda,x,t)$$
$$\times\left(\frac{\partial}{\partial t}-\frac{3}{2}j^{2l}\lambda^2\frac{\partial}{\partial x}-\frac{1}{2}\frac{\partial^3}{\partial x^3}\right)f(j^l\lambda,x,t). \quad (5.73)$$

As in (5.70), it follows that

$$\left[\frac{\partial}{\partial t}-\frac{3}{2}k^2\frac{\partial}{\partial x}-\frac{1}{2}\frac{\partial^3}{\partial x^3}+\frac{3}{4}\frac{\partial}{\partial x}V(x,t)\right]f(k,x,t)=0, \quad (5.74)$$

or, combining this result with the x derivative of (5.71),

$$\left[\frac{\partial}{\partial t}-k^2\frac{\partial}{\partial x}-\frac{1}{2}V(x,t)+\frac{1}{4}V'(x,t)\right]f(k,x,t)=0, \quad (5.75)$$

where we use the "prime" notation for x derivatives.

(5) It is clear that (5.71) and (5.75) are the Lax pair already met in (2.6) and (2.7) for the "potential" $V(x,t)$ given by (5.72), which therefore yields a solution of the Korteweg de Vries equation (2.18). Q.E.D.

The integral equation (5.63) can lead us back to the generalized Povzner Levitan representation (5.41) as its simplified sister did it in our previous paper. It can also lead us to the corresponding, and very complicated, system, generalizing the Gelfand Levitan equation as in Sec. III. There is no need to write down these results, because it is clear that either (5.63) or these equations can be used for constructing solutions of KdV, but (5.63) is a simpler tool.

It is clear also that the solutions that are thus obtained satisfy parity constraints. Using also $\varphi_2(k,t)$ would get rid of this constraint. But the result would still be much more complicated than that obtained by sticking at a Marchenko approach, which we shall do in the next section.

VI. AN INVERSE "SCATTERING METHOD" ON TIME PATHS

A. A new visit to the traditional inverse method

The traditional inverse method is related to the following integral equation of direct linearization:

$$f(k,x,t)=\exp[i(kx+k^3t)]+\int d\rho(\lambda)\tau(k,\lambda,x,t)f(\lambda,x,t), \tag{6.1}$$

where

$$\tau(k,\lambda,x,t)=-i\frac{\exp[i(k+\lambda)x+i(k^3+\lambda^3)t]}{k+\lambda+i0^+}, \tag{6.2}$$

the linearization property follows from the formulas

$$\frac{\partial\tau}{\partial x}=\exp[i(kx+k^3t)+i(\lambda x+\lambda^3t)], \tag{6.3}$$

$$\frac{\partial^2\tau}{\partial x^2}=i(k+\lambda)\exp[i(kx+k^3t)+i(\lambda x+\lambda^3t)], \tag{6.4}$$

$$(k^2-\lambda^2)\tau=i(\lambda-k)\exp[i(kx+k^3t)+i(\lambda x+\lambda^3t)], \tag{6.5}$$

$$\left(\frac{\partial}{\partial t}-k^2\frac{\partial}{\partial x}\right)\tau=(\lambda^2-k\lambda)\exp[i(kx+k^3t)+i(\lambda x+\lambda^3t)], \tag{6.6}$$

$$\left(\frac{\partial^3}{\partial x^3}+k^2\frac{\partial}{\partial x}\right)\tau=-(\lambda^2+2k\lambda)\exp[i(kx+k^3t)+i(\lambda x+\lambda^3t)], \tag{6.7}$$

by proceeding exactly as in Sec. V. It satisfies the two Lax Spectral equations with

$$V(x,t)=2\frac{\partial}{\partial x}\int d\rho(\lambda)\exp[i(\lambda x+\lambda^3t)]f(\lambda,x,t). \tag{6.8}$$

We wish to generalize this approach, as we did in Sec. V. An obvious guess for a new DLE is

$$f(k,x,t)=\exp[i(kx+k^3t)]+\sum_{l=-1}^{l=+1}\int d\rho_l(\lambda)\tau(k,j^l\lambda,x,t)f(j^l\lambda,x,t). \tag{6.9}$$

Again, assuming that the homogeneous form of (6.9) has only the zero solution, and using (6.3)–(6.7) enables us to show that the solution $f(k,x,t)$ of (6.9) satisfies the Lax pair for

$$V(x,t)=2\frac{\partial}{\partial x}\sum_{l=-1}^{l=+1}\int d\rho_l(\lambda)\exp[i(j^l\lambda x+\lambda^3t)]f(j^l\lambda,x,t). \tag{6.10}$$

But two questions arise. First is (6.9), the most general approach using Jost solutions? Next, can the measures $d\rho_l(\lambda)$ be obtained as scattering data derived from $V(0,t)$ and its first two x derivatives, as $d\rho(\lambda)$ of (6.1) is obtained as scattering data derived from $V(x,0)$ in the traditional inverse method?

Some light can be put on these questions if we understand how the measure $d\rho(\lambda)$ of the traditional method is related to the scattering data of $V(x,0)$ by using only the Lax pair. We are reminded that (5.1), and (5.2) give ways, defined from the Lax pair, for going from (x_0,t_0) to (x,t)—say, using the notation F for vector solutions:

$$t-\text{paths: }\frac{\partial F}{\partial t}=\mathbf{N}F, \tag{6.11}$$

$$x-\text{paths: } \frac{\partial F}{\partial x}=\mathbf{M}F. \tag{6.12}$$

In the traditional inverse method we consider an x path, say $t=t_0$, and define the following Jost solutions $\vec{F}_\pm$ of (6.12) by their asymptotic behavior $\vec{J}_\pm$ as $x\to+\infty$, $k\in\mathbb{R}$.

$$\vec{F}_\pm(k,x,t_0) \xrightarrow{x\to\infty} \vec{J}_\pm=\begin{pmatrix} \exp[\pm ikx] \\ \pm ik \exp[\pm ikx]\end{pmatrix}, \tag{6.13}$$

and in the same way, as $x\to-\infty$,

$$\overleftarrow{F}_\mp(k,x,t_0) \xrightarrow{x\to-\infty} \overleftarrow{J}_\mp=\begin{pmatrix} \exp[\mp ikx] \\ \mp ik \exp[\mp ikx]\end{pmatrix}. \tag{6.14}$$

Now, since the trace of $\mathbf{M}$ vanishes, so does the x derivative of the determinant of any matrix made out of two vector solutions. Hence, we can write down

$$\overleftarrow{F}_-(k,x,t_0)=b(k,t_0)\vec{F}_+(k,x,t_0)+a(k,t_0)\vec{F}_-(k,x,t_0), \tag{6.15}$$

where

$$2ika(k,t_0)=\det[\overleftarrow{F}_-,\vec{F}_+], \tag{6.16}$$

$$-2ikb(k,t_0)=\det[\overleftarrow{F}_-,\vec{F}_-] \tag{6.17}$$

define the ''scattering problem.'' As a matter of fact,

$$R_x(k,t_0)=b(k,t_0)/a(k,t_0), \tag{6.18}$$

$$T_x(k,t_0)=[a(k,t_0)]^{-1}, \tag{6.19}$$

are the ''Scattering coefficients'' the index x recalls that it is on an x path. The existence of the Jost solutions of course requires that $V(x,t_0)$ goes to zero rapidly enough as $|x|\to\infty$. Assuming that this assumption holds for any real t, let us now follow a t path with $|x|$ very large, $x=x_0$ so that $V(x_0,t)$ is very small. It is clear that, asymptotically,

$$F(k,x_0,t)\underset{|x|\gg 1}{\widetilde{}} \exp[N_2(t-t_0)]F(k,x_0,t_0). \tag{6.20}$$

Hence, the evolution of the solutions at $x=x_0$ as t varies is

$$\vec{F}_\pm(k,x_0,t_0)\Rightarrow\vec{F}_\pm(k,x_0,t_0)\exp[\pm ik^3(t-t_0)], \tag{6.21}$$

$$\overleftarrow{F}_\mp(k,x_0,t_0)\Rightarrow\overleftarrow{F}_\pm(k,x_0,t_0)\exp[\mp ik^3(t-t_0)]. \tag{6.22}$$

They have no longer the right asymptotic behavior (6.13) and (6.14), and so as to recover the true Jost solutions of the x-scattering problem, say $J\vec{F}_\pm$ and $J\overleftarrow{F}_\pm$, we must set (omitting for simplicity k and x_0 in the notations)

$$J\vec{F}_\pm(t)=\exp[\mp ik^3(t-t_0)]\vec{F}_\pm(t), \tag{6.23}$$

$$J\overleftarrow{F}_\mp(t)=\exp[\pm ik^3(t-t_0)]\overleftarrow{F}_\mp(t). \tag{6.24}$$

On the other hand, since $\mathbf{N}$ is also a matrix of zero trace, the determinant of the matrix that is made of two vector solutions is an invariant. Hence, we can write from (6.23) and (6.24), and from the invariance property,

$$\det[J\overleftarrow{F}_-(t),J\vec{F}_+(t)]=\det[\overleftarrow{F}_-(t),\vec{F}_+(t)]=\det[\overleftarrow{F}_-(t_0),\vec{F}_+(t_0)]. \tag{6.25}$$

Hence, $a(k,t)$ is invariant, and so is $T(k)$. On the other hand, the same formulas yield

$$\det[J\overleftarrow{F}_-(t),J\vec{F}_-(t)]=e^{2ik^3(t-t_0)}\det[\overleftarrow{F}_-(t_0),\vec{F}_-(t_0)], \tag{6.26}$$

and so $R_x(k,t)/R_x(k,t_0)$ is equal to the factor $\exp[2ik^3(t-t_0)]$. Inserting it in the Marchencko equation yields the traditional inverse method and (6.1).

Now suppose convenient assumptions on V guarantee on any t path the existence of time Jost solutions $\vec{G}^{\pm}$ and $\overleftarrow{G}^{\mp}$ (real k):

$$\vec{G}^{\pm}(k,x_0,t)\xrightarrow{t\to\infty}e^{\pm ik^3t}\begin{pmatrix}\mp i\\ k\end{pmatrix}, \tag{6.27}$$

$$\overleftarrow{G}^{\mp}(k,x_0,t)\xrightarrow{t\to-\infty}e^{\mp ik^3t}\begin{pmatrix}\pm i\\ k\end{pmatrix}, \tag{6.28}$$

they define a scattering problem where $\det[\overleftarrow{F}_-,\vec{F}_+]$ and $\det[\overleftarrow{F}_-,\vec{F}_-]$ are ''time scattering'' coefficients. Again, for very large t, $V(x,t)$ ''small'' implies

$$G(k,x,t)\sim\exp[\mathbf{M}_0(x-x_0)]G(k,x_0,t), \tag{6.29}$$

and coefficients $\exp[\pm ik(x-x_0)]$ appear in the same manner $\exp[\pm ik^3(t-t_0)]$ did it in the analysis above. Hence, the x evolution of the measures in (6.9) can be understood on the same grounds as was the t evolution of $d\rho(\lambda)$ in (6.1). Thus, the way to check (6.9) or another DLE and to relate it to Cauchy data is by solving the inverse problem from ''time scattering'' coefficients.

B. The direct problem on time paths, put to second order

For a fixed value of x, say x_0, we study the equation (6.11), where $\mathbf{N}$ is given by (5.7)–(5.10) as N_2+N_1 (and we drop x_0 in the notations). We assume that V and its x and t derivatives go to zero as $t\to\pm\infty$ ''rapidly enough'' to warrant that the ''leading'' equation at infinite times is

$$\frac{\partial F}{\partial t}\simeq N_2F. \tag{6.30}$$

It is easy to check that the asymptotic behaviors $\vec{G}^{\infty}_{\pm}$ and $\overleftarrow{G}^{\infty}_{\mp}$ that appear as limits in (6.27) and (6.28) are indeed solutions of (6.30).

In order to study the existence and properties of Jost solutions, it is convenient to first consider the second-order problem,

$$\left(\frac{\partial}{\partial t}+\mathbf{N}\right)\left(\frac{\partial}{\partial t}-\mathbf{N}\right)F=0=\left[\frac{\partial^2}{\partial t^2}-\left(\frac{\partial\mathbf{N}}{\partial t}+\mathbf{N}^2\right)\right]F. \tag{6.31}$$

Clearly, all solutions of (6.31) are not necessarily solutions of (6.11). We shall see below in Sec. VI C how the latter are identified, and we give first a study of the second-order problem, writing (6.31) as

$$\frac{\partial^2F}{\partial t^2}+k^6F-k^2(B_1I+B_3n_2)F-AF, \tag{6.32}$$

where

$$B_1=\frac{3}{4}V^2-\frac{1}{4}V'',\quad B_3=\frac{1}{2}\frac{\partial V}{\partial t}, \tag{6.33}$$

$$A = n_0^2 + \frac{\partial n_0}{\partial t} = \begin{pmatrix} A_1 & A_2 \\ A_3 & A_4 \end{pmatrix}, \tag{6.34}$$

$$B = B_1 I + B_3 n_2 = \begin{pmatrix} B_1 & 0 \\ B_3 & B_1 \end{pmatrix}. \tag{6.35}$$

Except that F is a two-vector (or a 2×2 matrix), (6.32) is similar to equations studied by Jaulent and Jean,[7] and where the inverse problem can be managed by a method analogous to one introduced by the author[8] more than 30 years ago. So as to handle it, we first gather (6.32) and its "j transformations," ($j = e^{2i\pi/3}$):

$$\frac{\partial^2 F_l}{\partial t^2} + (k^6 - j^{2l} k^2 B - A) F_l = 0, \tag{6.36}$$

and define the three "components" of a vector $\mathbf{\Phi}$:

$$\Phi_0 = \frac{1}{3} \sum_l F_l, \tag{6.37}$$

$$\Phi_1 = \frac{1}{3} k^{-1} \sum_l j^{2l} F_l, \tag{6.38}$$

$$\Phi_2 = \frac{1}{3} k^{-2} \sum_l j^l F_l. \tag{6.39}$$

If the F_l's are 2-vectors, Φ is a 6-vector. It is a solution of the equation

$$\frac{\partial^2 \mathbf{\Phi}}{\partial t^2} + k^6 \mathbf{\Phi} - k^3 \begin{pmatrix} 0 & B & 0 \\ 0 & 0 & B \\ 0 & 0 & 0 \end{pmatrix} \mathbf{\Phi} - \begin{pmatrix} A & 0 & 0 \\ 0 & A & 0 \\ B & 0 & A \end{pmatrix} \mathbf{\Phi} = 0. \tag{6.40}$$

The notation that is used for $\mathbf{\Phi}$ in (6.40) is that of a 3-vector whose elements are 2-vectors, so that it is, in fact, a 6-vector, and of 3×3 matrices, say, $\mathcal{B}$ and $\mathcal{A}$ whose elements are 2×2 matrices so that they are, in fact, 6×6 matrices. If we wish to compare a with Jaulent Jean presentation, we would write $\mathbf{\Phi}_+$ instead of $\mathbf{\Phi}$ and introduce $\mathbf{\Phi}_-$ as a solution of the equation obtained by making $k \to -k$ in (6.40). This is avoided here by defining four Jost solutions, as we did in (6.27), (6.28).

Now, in order to study analytic properties, we introduce the "Jost matrices" of (6.40) as the four 6×6 matrices $\mathcal{M}$, which are solutions of (6.40) and have the asymptotic behaviors ($k^3 \in \mathbb{R}$):

$$\vec{\mathcal{M}}^{\pm} \to \exp[\pm i k^3 t] I (t \to \infty), \tag{6.41}$$

$$\overleftarrow{\mathcal{M}} \to \exp[\mp i k^3 t] I (t \to -\infty), \tag{6.42}$$

where I is the unit matrix. We first study the existence and properties of them, and after that we use them to construct the functions (6.27), (6.28).

From (6.40) and (6.41), we get

$$\vec{\mathcal{M}}^{\pm}(k^3,t) = I e^{\pm i k^3 t} - \int_t^{\infty} \frac{\sin k^3 (t-u)}{k^3} [k^3 \mathcal{B}(u) + \mathcal{A}(u)] \vec{\mathcal{M}}^{\pm}(k^3,u) du, \tag{6.43}$$

or setting

$$\vec{m}^{\pm}(k^3,t) = e^{\mp i k^3 t} \vec{\mathcal{M}}^{\pm}(k^3,t), \tag{6.44}$$

$$\vec{m}^{\pm}(k^3,t)=I-\int_t^{\infty}du\,\frac{e^{\mp ik^3(t-u)}\sin k^3(t-u)}{k^3}[k^3\mathcal{B}(u)+\mathcal{A}(u)]\vec{m}^{\pm}(k^3,u). \tag{6.45}$$

For any finite k, (6.45) is a Volterra integral equation whose kernel can be absolutely bounded, respectively, for $\pm\operatorname{Im}k\geqslant 0$, by $C|k|^3$ (C is a positive number), and by $(u-t)(t<u)$ which can be also replaced in these bounds by $I(t)J(u)$, where

$$I(t)=J(-t)=1+|x|\,\theta(-t), \tag{6.46}$$

as we did it for a quite similar opportunity, p. 326, Ref. 5. The result is that $|\vec{m}^{\pm}|$ can be constructed by the usual series expansion of the solution of (6.45) and that it is uniformly bounded on the real k axis, provided

$$\int_{-\infty}^{+\infty}t|B_i(t)|dt<\infty,\quad \int_{-\infty}^{+\infty}t|A_i(t)|dt<\infty,\quad i=1,2,3. \tag{6.47}$$

Going to the k^3 complex plane, a similar approach with the same assumptions shows that $\vec{\mathcal{M}}^{+}(k^3,t)$ can be extended into a holomorphic function in $\operatorname{Im}k^3>0$, with continuity to the real axis, and that $\vec{\mathcal{M}}^{-}$ has the same property in $\operatorname{Im}k^3\leqslant 0$. By the same token, we extend these results to $\overleftarrow{\mathcal{M}}^{-}$ in $\operatorname{Im}k^3\geqslant 0$ and $\overleftarrow{\mathcal{M}}^{+}$ in $\operatorname{Im}k^3\leqslant 0$. It is convenient to set hereafter $\lambda=k^3$, and to look more carefully to the behavior at large $|\lambda|$. This is done by seeking the solution of (6.43) from the ansatz

$$\vec{\mathcal{M}}^{\pm}(\lambda,t)=e^{\pm i\lambda t}\vec{P}^{\pm}(t)+\lambda^{-1}\vec{Q}^{\pm}(\lambda,t), \tag{6.48}$$

where

$$\vec{P}^{\pm}(t)=\exp\left[\mp\frac{1}{2i}\int_t^{\infty}\mathcal{B}(u)du\right], \tag{6.49}$$

has been chosen in order to match the leading asymptotic behavior in (6.43). With this ansatz and if the constraints (6.47) extend to the time derivatives of $\mathcal{B}$ elements, we can show that $|\lambda\vec{Q}^{\pm}(\lambda,t)|$ is uniformly bounded, respectively, in $\{\pm\operatorname{Im}\lambda\geqslant 0\}$. Let us sketch the proof for $\vec{Q}^{+}(\lambda,t)$. From (6.43) and (6.48) we obtain

$$\begin{aligned}\vec{Q}^{+}(\lambda,t)=&-\int_t^{\infty}\sin\lambda(t-u)\mathcal{A}(u)[e^{i\lambda u}\vec{P}^{+}(u)+\lambda^{-1}\vec{Q}^{+}(\lambda,u)]du\\&+(2i)^{-1}e^{-i\lambda t}\int_t^{\infty}(\lambda\mathcal{B}(u)+\mathcal{A}(u))[e^{2i\lambda u}\vec{P}^{+}(u)+\lambda^{-1}e^{i\lambda u}\vec{Q}^{+}(\lambda,u)]du.\end{aligned} \tag{6.50}$$

An integration by parts readily yields

$$\int_t^{\infty}e^{2i\lambda u}\mathcal{B}(u)\vec{P}^{+}(u)du=-\frac{e^{2i\lambda t}}{2i\lambda}\mathcal{B}(t)\vec{P}^{+}(t)-\int_t^{\infty}du\,\frac{e^{2i\lambda u}}{2\lambda}(\mathcal{B}'(u)+\mathcal{B}^2(u)). \tag{6.51}$$

Gathering the terms that contain Q in (6.50), and evaluating those where an integration by parts inserts $o(\lambda^{-1})$, we obtain a Volterra integral equation whose free term and kernel are absolutely bounded, except maybe at $\lambda=0$. The boundedness of Q follows for $\lambda\neq 0$, and at $\lambda=0$ it follows from our previous results.

If the bounds (6.47) also extend to second time derivatives, we can go further by the same method and show that

$$\vec{\mathcal{M}}^{\pm}(\lambda,t)=e^{\pm i\lambda t}[\vec{P}^{\pm}(t)+\lambda^{-1}\vec{Q}^{\pm}(t)+\lambda^{-2}\vec{R}^{\pm}(\lambda,t)], \tag{6.52}$$

where $\vec{P}^{\pm}(t)$ is given by (6.49), $\vec{Q}^{\pm}(t)$ is the (exactly calculable) solution of the equation:

$$\vec{Q}^{\pm}(t)=\frac{1}{4}\mathcal{B}(t)\vec{P}^{\pm}(t)\mp\frac{1}{2i}\int_t^{\infty}du[\mathcal{A}(u)\vec{P}^{\pm}(u)+\mathcal{B}(u)\vec{Q}^{\pm}(u)], \tag{6.53}$$

and $\vec{R}^{\pm}$ has its elements absolutely bounded in the adequate λ half-plane.

By the same token, starting from the equation,

$$\overleftarrow{\mathcal{M}}^{\mp}(\lambda,t)=e^{\mp i\lambda t}+\int_{-\infty}^{t}du\,\frac{\sin\lambda(t-u)}{\lambda}[\lambda\mathcal{B}(u)+\mathcal{A}(u)]\overleftarrow{\mathcal{M}}^{\mp}(\lambda,u), \tag{6.54}$$

we can show that if (6.47) extends to second-order derivatives, and if, respectively, $\pm\operatorname{Im}\lambda\geqslant 0$,

$$\overleftarrow{\mathcal{M}}^{\mp}(\lambda,t)=e^{\mp i\lambda t}[\overleftarrow{P}^{\mp}(t)+\lambda^{-1}\overleftarrow{Q}^{\mp}(t)+\lambda^{-2}\overleftarrow{R}^{\mp}(\lambda,t)], \tag{6.55}$$

where

$$\overleftarrow{P}^{\mp}(t)=\exp\left[\mp\frac{1}{2i}\int_{-\infty}^{t}\mathcal{B}(u)du\right], \tag{6.56}$$

and $\overleftarrow{Q}^{\mp}(t)$ is the (exactly calculable) solution of the equation,

$$\overleftarrow{Q}^{\mp}(t)=\frac{1}{4}\mathcal{B}(t)\overleftarrow{P}^{\mp}(t)\mp\frac{1}{2i}\int_{-\infty}^{t}du[\mathcal{A}(u)\overleftarrow{P}^{\mp}(u)+\mathcal{B}(u)\overleftarrow{Q}^{\mp}(u)]. \tag{6.57}$$

If (6.47) extends only to first-order derivatives, the first term only in (6.55) is guaranteed and the remainder is of order $O(|\lambda|^{-1})$ (in the adequate half-plane, with continuity to $\mathbb{R}$). This, however, implies that it is in $L^2(\mathbb{R})$, so that we can construct its Fourier transform, obtaining in this way the transformation formulas for the Jost matrices:

$$\vec{\mathcal{M}}^{\pm}(\lambda,t)=\vec{P}^{\pm}(t)\exp[\pm i\lambda t]+\int_t^{\infty}\vec{K}^{\pm}(t,u)\exp(\pm i\lambda u)du, \tag{6.58}$$

$$\overleftarrow{\mathcal{M}}^{\mp}(\lambda,t)=\overleftarrow{P}^{\mp}(t)\exp(\mp i\lambda t)+\int_{-\infty}^{t}\overleftarrow{K}^{\mp}(t,u)\exp(\mp i\lambda u)du. \tag{6.59}$$

C. Back to the first-order time equations

As we see below, for any fixed 6-vector $\mathbf{v}^{\pm}$, a matrix solution $\vec{\mathcal{M}}^{\pm}(t)$ of (6.40), yields a 6-vector solution $\vec{\mathcal{M}}^{\pm}\mathbf{v}^{\mp}$, denoted below as $\vec{\boldsymbol{\Psi}}^{\pm}(t)$, which is asymptotic to $\mathbf{v}^{\mp}\exp[\pm ik^3t]$ as $t\to\infty$. In the same way as F was related to $\boldsymbol{\Phi}$, we can derive from $\boldsymbol{\Psi}$ a 2-vector solution $\vec{H}^{\pm}(t)$ of (6.31), which is asymptotic to $\mathbf{w}^{\mp}\exp[\pm ik^3t]$, and (6.31) can be written as

$$\left(\frac{\partial}{\partial t}+\mathbf{N}\right)\left(\frac{\partial}{\partial t}-\mathbf{N}\right)\vec{H}^{\pm}(t)=0, \tag{6.60}$$

which implies that $(\partial/\partial t-\mathbf{N})\vec{H}^{\pm}(t)$ is a solution $y(t)$ of the equation

$$\left(\frac{\partial}{\partial t}+\mathbf{N}\right)y(t)=0. \tag{6.61}$$

So as to get a solution of (6.11), we want $y(t)=0$. It cannot be so unless its asymptotic behavior $y_{\infty}(t)$ is so, and y_{∞} is not zero unless $\mathbf{w}^{\mp}e^{\pm ik^3t}$ is a solution of

$$\left(\frac{\partial}{\partial t}-N_2\right)(\mathbf{w}^{\mp}\exp[\pm ik^3t])=0, \tag{6.62}$$

where N_2 [see (5.10)] is the leading term of $\mathbf{N}$ as $t\to\infty$. It follows after some algebra that the Jost solutions $\vec{G}^{\pm}(t)$ of (6.11) are derived from $\vec{\mathcal{M}}^{\pm}\mathbf{v}$ if (6.62) holds, i.e., if

$$\mathbf{w}^{\mp}=\begin{pmatrix}\mp i\\ k\end{pmatrix}, \tag{6.63}$$

which, indeed, defines $\vec{G}^{\pm}(t)$ in (6.27). A similar analysis holds as $t\to-\infty$, where (6.28) properly defines $\overleftarrow{G}^{\mp}(t)$, and these results pave the way going from second-order to first-order results.

We also wish appraising asymptotic behaviors as $|k|\to\infty$, fixed t, sufficiently large that V and derivatives are small compared to convenient powers of $|k|$. For this purpose, we found it useful to have exact reference solutions of a first-order problem as (6.11), whose matrix $\tilde{N}$ goes ''close'' to $\mathbf{N}$ as either t or $|k|$ goes to ∞. Here they are

$$\vec{E}^{\pm}=\omega^{\mp}\exp[\pm i\vec{\varphi}];\quad \overleftarrow{E}^{\mp}=\omega^{\pm}\exp[\mp i\overleftarrow{\varphi}], \tag{6.64}$$

where

$$\omega^{\pm}=\begin{pmatrix}\pm i(1+V_0/2k^2)\\ k(1-V_0/2k^2)\end{pmatrix}, \tag{6.65}$$

$$\vec{\varphi}=k^3t+(2k)^{-1}\int_t^{\infty}V_0^2(u)\,du, \tag{6.66}$$

$$\overleftarrow{\varphi}=\vec{\varphi}-(2k)^{-1}\int_{-\infty}^{+\infty}V_0^2(u)\,du=:\vec{\varphi}-\omega_0/k. \tag{6.67}$$

The time derivative of any solution E is $\tilde{N}E$, with

$$\tilde{N}=\begin{pmatrix}\dfrac{-2V_1}{2k^2+V_0} & \dfrac{k^2\left(1-\frac{1}{2}k^{-4}V_0^2\right)\left(1+\frac{1}{2}k^{-2}V_0\right)}{1-\frac{1}{2}k^{-2}V_0}\\[2ex] \dfrac{-k^4\left(1-\frac{1}{2}k^{-4}V_0^2\right)\left(1-\frac{1}{2}k^{-2}V_0\right)}{1+\frac{1}{2}k^{-2}V_0} & \dfrac{2V_1}{2k^2-V_0}\end{pmatrix}, \tag{6.68}$$

to be compared with $\mathbf{N}$, written as

$$\mathbf{N}=\begin{pmatrix}0 & k^2+V_0\\ -k^2(k^2-V_0) & 0\end{pmatrix}+\begin{pmatrix}V_1 & 0\\ V_2 & -V_1\end{pmatrix}. \tag{6.69}$$

One easily sees that if t is sufficiently large that $|V_0|$ be smaller than $2|k|^2$, $\mathbf{N}-\tilde{N}$ is bounded uniformly in $|k|$ by an integrable function of t, and goes to the k-independent matrix in (6.69), called U in the following, as rapidly as $|k|^{-2}$ times an integrable function of t, but the remainder is not a zero trace matrix (its trace goes to zero as $|k|^{-4}$).

We can now proceed to the first-order scattering problem. The Jost solutions G that correspond to the first-order time equation (6.11) were defined by (6.27) and (6.28). The time scattering coefficients (which are numbers) are defined from them by

$$\overleftarrow{G}^{-}(k,t)=c^{+}(k)\vec{G}^{-}(k,t)+d^{+}(k)\vec{G}^{+}(k,t), \tag{6.70}$$

$$\overleftarrow{G}^{+}(k,t)=c^{-}(k)\vec{G}^{+}(k,t)+d^{-}(k)\vec{G}^{-}(k,t). \tag{6.71}$$

By means of two ''j transformations'' we define the ''Jost vectors'' $\mathbf{G}$:

$$\mathbf{G}=\begin{pmatrix} G(k) \\ G(jk) \\ G(j^2k) \end{pmatrix}, \tag{6.72}$$

which are, in fact, 6-vectors, solutions of

$$\frac{\partial}{\partial t}\mathbf{G}(k,t)=\hat{\mathbf{N}}(k,t)\mathbf{G}(k,t), \tag{6.73}$$

with

$$\hat{\mathbf{N}}(k,)=\begin{pmatrix} \mathbf{N}(k,) & 0 & 0 \\ 0 & \mathbf{N}(jk,) & 0 \\ 0 & 0 & \mathbf{N}(j^2k,) \end{pmatrix}, \tag{6.74}$$

and, according to (6.70) and (6.71),

$$\overleftarrow{\mathbf{G}}^{\mp}(k,t)=C^{\pm}(k)\vec{\mathbf{G}}^{\mp}(k,t)+D^{\pm}(k)\vec{\mathbf{G}}^{\pm}(k,t), \tag{6.75}$$

where C and D are diagonal matrices obtained from c and d by two ''j transformations,'' for instance,

$$C^{\pm}(k)=\begin{pmatrix} c^{\pm}(k) & 0 & 0 \\ 0 & c^{\pm}(jk) & 0 \\ 0 & 0 & c^{\pm}(j^2k) \end{pmatrix}, \tag{6.76}$$

it being understood that each element that is a number is multiplied by the 2×2 unit matrix (we call this agreement the ''duplex rule''). We define now the ''transformed'' Jost vectors $\mathbf{\Psi}$ from the Jost solutions G as we defined in (6.37)–(6.39) the solutions $\mathbf{\Phi}$ of (6.40) from the solutions F of (6.32). Using (6.72), we can write

$$\mathbf{\Psi}=\tfrac{1}{3}T\mathbf{G}, \tag{6.77}$$

where

$$T=\begin{pmatrix} 1 & 1 & 1 \\ k^{-1} & j^2k^{-1} & jk^{-1} \\ k^{-2} & jk^{-2} & j^2k^{-2} \end{pmatrix} \tag{6.78}$$

(with duplex rule). The inverse matrix,

$$T^{-1}=\frac{1}{3}\begin{pmatrix}1 & k & k^2\\ 1 & jk & j^2k^2\\ 1 & j^2k & jk^2\end{pmatrix}\tag{6.79}$$

(with duplex rule), enables us to go back from $\boldsymbol{\Psi}$ to G through (6.77). The $\boldsymbol{\Psi}$'s are solutions of

$$\frac{\partial}{\partial t}\boldsymbol{\Psi}=\tilde{\mathbf{N}}\boldsymbol{\Psi},\tag{6.80}$$

$$\tilde{\mathbf{N}}=T\hat{\mathbf{N}}T^{-1}=\begin{pmatrix}n_0 & k^3n_1 & -k^6n_2\\ -k^3n_2 & n_0 & k^3n_1\\ n_1 & -k^3n_2 & n_0\end{pmatrix}.\tag{6.81}$$

It is easy to check that $\boldsymbol{\Psi}$ is also a solution of (6.40). The asymptotic behaviors of the G's can be derived from (6.27), (6.28), and (6.72), and that of the $\boldsymbol{\Psi}$'s from that of the $\mathbf{G}$'s by means of (6.77):

$$\vec{\boldsymbol{\Psi}}^{\pm}(k,t)\xrightarrow{t\to\infty}e^{\pm ik^3t}v_0^{\mp},\tag{6.82}$$

$$\overleftarrow{\boldsymbol{\Psi}}^{\mp}(k,t)\xrightarrow{t\to-\infty}e^{\mp ik^3t}v_0^{\pm},\tag{6.83}$$

where

$$v_0^{\pm}=\begin{pmatrix}\pm i\\ 0\\ 0\\ 1\\ 0\\ 0\end{pmatrix}.\tag{6.84}$$

Since the matrix Jost solutions $\mathcal{M}$ are the solutions of (6.40) that go to the identity matrix at infinite t, it follows from (6.32) that

$$\vec{\boldsymbol{\Psi}}^{\pm}(k,t)=\vec{\mathcal{M}}^{\pm}(k^3,t)v_0^{\mp},\tag{6.85}$$

$$\overleftarrow{\boldsymbol{\Psi}}^{\mp}(k,t)=\overleftarrow{\mathcal{M}}^{\mp}(k^3,t)v_0^{\pm}.\tag{6.86}$$

Hence, the Ψ's have the analytic and asymptotic properties of the corresponding $\mathcal{M}$'s. Readers may notice that in the Jaulent Jean second-order problem analysis, a vector showing only one nonzero component was used instead of v_0. It was so because such vectors were a basis of solutions of the asymptotic form of their equation replacing (6.40). Here, $v_0^{\pm}$ comes in as an eigenvector of the asymptotic form of their (6.77). Multiplying the G's in (6.27) and (6.28) by k and k^2, then deriving the $\mathbf{G}$'s and the $\boldsymbol{\Psi}$'s would lead to two other eigenvectors, $v_1^{\pm}$ and $v_2^{\pm}$, linearly independent of $v_0^{\pm}$, and the 6-dimensions space would have a basis.

From (6.75) and (6.77), we define the ''transformed scattering problem,''

$$\overleftarrow{\boldsymbol{\Psi}}^{\mp}(k,t)=\tilde{C}^{\pm}(k)\vec{\boldsymbol{\Psi}}^{\mp}(k,t)+\tilde{D}^{\pm}(k)\vec{\boldsymbol{\Psi}}^{\pm}(k,t),\tag{6.87}$$

where

$$\tilde{C}^{\pm}=TC^{\pm}T^{-1},\tag{6.88}$$

and similarly for $\tilde{D}^{\pm}$. So as to derive the analytic and asymptotic properties of $\tilde{C}^{\pm}$ and $\tilde{D}^{\pm}$, we have now to go back and forth several times between the scattering problem and the transformed scattering problem. Let Ψ_0, Ψ_1, Ψ_2 the three 2-vectors ''components'' of a $\boldsymbol{\Psi}$. From (6.77) we get in a domain of holomorphy of $k^3 \to \boldsymbol{\Psi}$,

$$G(k,t)=\Psi_0(k^3,t)+k\Psi_1(k^3,t)+k^2\Psi_2(k^3,t). \tag{6.89}$$

If we want to study, for instance, $\tilde{C}^+(k)$, we know that $\vec{\Psi}_l^+, \overleftarrow{\Psi}_l^-$, are holomorphic functions of k^3 in $\operatorname{Im} k^3 \geqslant 0$. From (6.70), we derive

$$2ikc^+=\det[\overleftarrow{G}^-,\vec{G}^+], \tag{6.90}$$

and substituting in (6.90) the respective expansions (6.89) of $\overleftarrow{G}^-$ and $\vec{G}^+$, we obtain that $c^+(k)$ is equal to

$$c^+(k)=k^{-1}[c_0^+ + c_1^+ k + c_2^+ k^2], \tag{6.91}$$

where c_0^+, c_1^+, c_2^+ are holomorphic functions of k^3 in $\operatorname{Im} k^3 \geqslant 0$, with

$$2ic_0^+=\det[\overleftarrow{\Psi}_0^-,\vec{\Psi}_0^+]. \tag{6.92}$$

It follows from (6.76) and (6.88) that

$$\tilde{C}^+=\begin{pmatrix} c_1^+ & c_0^+ & c_2^+k^3 \\ c_2^+ & c_1^+ & c_0^+ \\ c_0^+k^{-3} & c_2^+ & c_1^+ \end{pmatrix}. \tag{6.93}$$

All the coefficients of $\tilde{C}^+$ are holomorphic functions of k^3 in $\operatorname{Im} k^3 \geqslant 0$, except maybe one, which has a pole at $k=0$ unless $c_0^+(0)=0$. We can study this condition by making $\lambda \to 0$ in (6.43) and (6.54). It is exactly similar to the generic condition of no zero energy bound state in the theory of (ordinary) potential scattering, and for the sake of simplicity, we henceforth assume it, together with the symmetric one on c^-. It would not be difficult to generalize the following theory to the case $c_0^+(0)c_0^-(0)\neq 0$. The study of c^- is symmetric to the study of c^+, and yields similar results in $\operatorname{Im} k \leqslant 0$. But the study of $d^{\pm}$ can be done only on the real k axis, where arguments similar to those above show that $\tilde{D}(\lambda)$ has continuous coefficients on $\lambda \in \mathbb{R}$.

Let us now look at the asymptotic behavior of $\tilde{C}^+$ as $|\lambda| \to \infty$ in $\operatorname{Im} k \geqslant 0$ and of $\tilde{D}^+(\lambda)$ on $\mathbb{R}$. For doing it, again we go back to solutions of (6.11). We first give formulas that generalize Wronskian results of potential theory.

Let $G=\binom{G_1}{G_2}$ be any solution of (6.11), where $\mathbf{N}$ stands, and E any solution of the same equation with $\tilde{N}$, instead of $\mathbf{N}$. From (6.68) and (6.69), we can write down

$$\mathbf{N}=N^{(1)}+U, \quad \tilde{N}=\tilde{N}^{(1)}-k^{-4}\nu(k,t)I, \tag{6.94}$$

where $\nu(k,t)$ is t integrable uniformly in k for $|k|$ or t large. All the other matrices in (6.94) can be written in the general form

$$N=\begin{pmatrix} N_1 & N_2 \\ N_3 & -N_1 \end{pmatrix} \tag{6.95}$$

(notice that, more specifically, $N_1=U_2=0$).

The time derivative of

$$\Delta=\det[G,E], \tag{6.96}$$

can be calculated from (6.94), and it yields

$$\Delta(+\infty)-\Delta(-\infty)=\int_{-\infty}^{+\infty}\{G_1E_1[-U_3+\tilde{N}_3^{(1)}-N_3^{(1)}]+G_2E_2[N_2^{(1)}-\tilde{N}_2^{(1)}]$$

$$+(G_1E_2+G_2E_1)(N_1-\tilde{N}_1+U_1)+(G_1E_2-G_2E_1)k^{-4}\nu\}, \tag{6.97}$$

where $\tilde{N}_i-N_i^{(1)}$ is equal for large $|k|$ to $k^{-2}\nu_i(t)+k^{-4}\nu_i(k,t)$, the functions ν being integrable.

As for the functions G of interest, they can be appraised uniformly in t for large $|k|$ from the formula (6.52), which yields through (6.48) and (6.56) the asymptotics of $\vec{G}^+$, for instance, as

$$\vec{G}^+=\begin{pmatrix} -i+\vec{g}_1^+(t)k^{-3}+O(|k|^{-6}) \\ k-\dfrac{1}{2i}\displaystyle\int_t^\infty B_1(u)du+\vec{g}_2^+(t)k^{-2}+O(|k|^{-5}) \end{pmatrix}, \tag{6.98}$$

and similar formulas hold for $\vec{G}^-$ and $\overleftarrow{G}^{\pm}$. The undefined quantities g_1, g_2 are integrable and the numbers c,d,d_∞, which will appear below, are bounded. Setting now $\overleftarrow{G}^-$, $\overleftarrow{E}^-$ in (6.96), and using the constant ratio between $\overleftarrow{E}^-$ and $\vec{E}^-$, we obtain for large real $|k|$,

$$-2ikd^+(k)=\exp[-i\omega_0/k][d_\infty^+ +k^{-1}d+O(|k|^{-3})]. \tag{6.99}$$

A similar work on $\det[\vec{G}^+,\overleftarrow{E}^- -\overleftarrow{G}^-]$ yields

$$c^+(k)-\exp[i\omega_0/k]=(2ik)^{-1}\exp[i\omega_0/k][c_\infty^+ +k^{-2}c+O(|k|^{-4})], \tag{6.100}$$

an estimate that extends to $\operatorname{Im}k^3\geqslant 0$, and where

$$c_\infty^+=-\int_{-\infty}^{+\infty}V_2(t)dt. \tag{6.101}$$

Hence, the leading asymptotic behavior of the diagonal matrix $C^+(k)$ as $|k|\to\infty$ is the unit matrix, and since its determinant is that of the holomorphic function $\tilde{C}^+$ in $\operatorname{Im}k^3\geqslant 0$, it can vanish there only at finitely many separate points. Notice that integrating by parts in the derivation of $d^+(k)$ by means of the formula (6.97) is possible because $\overleftarrow{G}^-$ and $\overleftarrow{E}^-$ both contain the same factor $\exp[-ik^3t]$, and if the convenient assumptions on time derivatives of V hold, it yields

$$d^+(k)=O(|k|^{-4}). \tag{6.102}$$

Similar derivations hold for $c^-(k)$, $d^-(k)$, and the related 3×3 ''duplex rule'' matrices. The final result of these estimates is that

$$(\tilde{C}^{\pm}(k)]^{-1}\tilde{D}^{\pm}(k)=O(|k|^{-6}),\quad k\in\mathbb{R},\quad |k|\to\infty, \tag{6.103}$$

and that there exists upper triangular matrices, with 1 as diagonal elements, for instance,

$$\tilde{C}^+(\infty)=\begin{pmatrix} 1 & i(\omega_0-\frac{1}{2}c_\infty^+) & -\omega_0^2 \\ 0 & 1 & i(\omega_0-\frac{1}{2}c_\infty^+) \\ 0 & 0 & 1 \end{pmatrix}, \tag{6.104}$$

such that

$$\tilde{C}^{\pm}(k)-\tilde{C}^{\pm}(\infty)=0(|k|^{-3})\quad(\pm\operatorname{Im}k^3\geqslant 0). \tag{6.105}$$

D. Inversion equations

We write down (6.87) as

$$[\tilde{C}^{\pm}(\lambda)]^{-1}\overleftarrow{\boldsymbol{\Psi}}^{\mp}(\lambda,t)=\vec{\boldsymbol{\Psi}}^{\mp}(\lambda,t)+\tilde{R}^{\pm}(\lambda)\vec{\boldsymbol{\Psi}}^{\pm}(\lambda,t), \tag{6.106}$$

where the notation $\lambda=k^3$ is used instead of k, without modifying the function's name, in order to remind that they depend on λ only, and where

$$\tilde{R}^{\pm}(\lambda)=[\tilde{C}^{\pm}(\lambda)]^{-1}\tilde{D}^{\pm}(\lambda) \tag{6.107}$$

is the ''reflection matrix,'' $[\tilde{C}^{\pm}]^{-1}$ being the ''transmission matrix'' of the transformed scattering problem. Let us first focus on the upper indices, which label functions $\boldsymbol{\Psi}$ and $\tilde{C}$ that are holomorphic in $\mathrm{Im}\,\lambda\geqslant 0$. Using (6.58) and (6.85), we can write down (6.106) as

$$\mathcal{G}^{+}(\lambda,t)-\mathcal{H}^{+}(\lambda,t)=\int_t^{\infty}\vec{K}^{-}(t,w)e^{-i\lambda w}\,dw\,v_0^{+}, \tag{6.108}$$

where

$$\mathcal{G}^{+}(\lambda,t)=[\tilde{C}^{+}(\lambda)]^{-1}\overleftarrow{\boldsymbol{\Psi}}^{-}(\lambda,t)-e^{-i\lambda t}\vec{P}^{-}(t)v_0^{+}, \tag{6.109}$$

$$\mathcal{H}^{+}(\lambda,t)=\tilde{R}^{+}(\lambda)[\vec{\boldsymbol{\Psi}}^{+}(\lambda,t)-e^{i\lambda t}\vec{P}^{+}(t)v_0^{-}]+\tilde{R}^{+}(\lambda)e^{i\lambda t}\vec{P}^{+}(t)v_0^{-}. \tag{6.110}$$

From (6.103), (6.104), and (6.105), the asymptotic behaviors of $\mathcal{G}^{+}$ and $\mathcal{H}^{+}$ on the real axis are easily shown to be $O(|\lambda|^{-1})$ or less. Hence, we can make the Fourier transform of both sides of (6.108), obtaining

$$\vec{K}^{-}(t,u)v_0^{+}=S^{+}(t+u)\vec{P}^{+}(t)v_0^{-}+\int_t^{\infty}S^{+}(u+u')\vec{K}^{+}(t,u')du'v_0^{-}+g^{+}(t,u), \tag{6.111}$$

where

$$S^{+}(u)=-\frac{1}{2\pi}\int_{-\infty}^{+\infty}e^{i\lambda u}\tilde{R}^{+}(\lambda)d\lambda, \tag{6.112}$$

and $g^{+}(t,u)$ is the Fourier transform of $\mathcal{G}^{+}(\lambda,t)$ [it is defined as in (6.112)]. Now, the function $\mathcal{G}^{+}(\lambda)$ being $e^{-i\lambda t}0(\lambda^{-1})$ in $\mathrm{Im}\geqslant 0$, where it is a meromorphic function, we can evaluate $g^{+}(t,u)$ for $u\geqslant t$ by a contour integration along the real axis completed by a half-circle centered at $\lambda=0$, whose radius goes to ∞. Hence, $g^{+}(t,u)$ is equal to a finite sum of residues, each of them involving values of $\overleftarrow{\boldsymbol{\Psi}}^{-}(\lambda,t)$ or derivatives at a pole λ_m, or using (6.106), values of $\vec{\boldsymbol{\psi}}^{+}(\lambda,t)$ and derivatives at this point. In Sec. VII, we shall see how the vanishing of $\det[\overleftarrow{G}^{-},\vec{G}^{+}]$ at this point can be used to proceed, in a simplified case, and to derive an extra term for $S^{+}(t+u)$. Here we prefer, assuming for the sake of simplicity that there is no singularity of $\tilde{C}^{-1}$, so that $g^{\pm}(t,u)$ vanishes (i.e., the ''no bound state'' case of usual potential theory).

It follows that $\vec{K}^{-}$, $\vec{K}^{+}$, and S^{+}, are related by the inversion equation

$$\vec{K}^{-}(t,u)v_0^{+}=S^{+}(t+u)\vec{P}^{+}(t)v_0^{-}+\int_t^{\infty}S^{+}(u+w)\vec{K}^{+}(t,w)dw\,v_0^{-}, \tag{6.113}$$

where

$$S^{+}(u) = -\frac{1}{2\pi}\int_{-\infty}^{+\infty} e^{i\lambda u}\tilde{R}^{+}(\lambda)d\lambda. \tag{6.114}$$

Sticking to the scattering problem on the right, we can do similar derivations with the functions of the lower index in (6.106), obtaining with similar assumptions the equation

$$\vec{K}^{+}(t,u)v_0^{-} = S^{-}(t+u)\vec{P}^{-}(t)v_0^{+} + \int_t^{\infty} S^{-}(u+w)\vec{K}^{-}(t,w)dw\, v_0^{+}, \tag{6.115}$$

where

$$S^{-}(u) = -\frac{1}{2\pi}\int_{-\infty}^{+\infty} e^{-i\lambda u}\tilde{R}^{-}(\lambda)d\lambda. \tag{6.116}$$

These derivations are similar to those of Jaulent Jean. We shall see in Sec. VII that they also produce a constraint coupling $\vec{K}^{-},\vec{K}^{+},\vec{P}^{-},\vec{P}^{+}$. Constraints are nuisances in true inverse problems. Fortunately, here, either constraints or consistency conditions are not a nuisance, since we shall start from the values of V and derivatives at a point, solve the direct problem to get $K^{\pm}$, and we already know from the analysis of formula (5.5) that the consistencies are preserved in the evolution. These remarks will become more clear when we come to the DLE. Here, let us only notice that if we tried to solve the true inverse scattering problem an obvious algebraic constraints on $\tilde{C}$, or $\tilde{C}^{-1}$, $\tilde{D}$, and $\tilde{R}$, would be that they are transformed from diagonal (duplex) 3-matrices as in (6.88), so that, if *a,b,c*, are its elements on the diagonal, the tilde matrix, for instance $\tilde{R}$, should be of the form

$$\tilde{R} = \begin{pmatrix} r_0 & r_2 & r_1 \\ k^{-3}r_1 & r_0 & r_2 \\ k^{-3}r_2 & k^{-3}r_1 & r_0 \end{pmatrix}, \tag{6.117}$$

where all the elements are functions of k^3 only, and are related to *a,b,c*, by

$$r_0 = \tfrac{1}{3}(a+b+c); \quad k^{-2}r_1 = \tfrac{1}{3}(a+j^2b+jc); \quad k^{-1}r_2 = \tfrac{1}{3}(a+jb+j^2c), \tag{6.118}$$

in agreement with the fact that, in the direct problem, b and c are j transforms of $a=r(k)$.

VII. THE FINAL INTEGRAL EQUATIONS, SOLVING THE "OTHER CAUCHY PROBLEM"

A. Inversion integral equations at fixed *x*

We first derive the inversion integral equation at fixed x and the corresponding spectral measures from (6.58) and (6.113)–(6.114). For the sake of simplicity, we assume that there is no discrete term in (6.114). Equation (6.58) yields the transformation formula for $\vec{\Psi}$:

$$\vec{\Psi}^{\pm}(k^3,t) = \vec{P}^{\pm}(t)\exp[\pm ik^3t]v_0^{\mp} + \int_t^{\infty}\vec{K}^{\pm}(t,u)\exp[\pm ik^3u]du v_0^{\mp}, \tag{7.1}$$

whereas Eqs. (6.115)–(6.116) yield

$$\vec{K}^{\pm}(t,u)v_0^{\mp} = -\frac{1}{2\pi}\int_{-\infty}^{+\infty} d\lambda\, e^{\mp i\lambda u}\tilde{R}^{\mp}(\lambda)\left[\vec{P}^{\mp}(t)e^{\mp i\lambda t} + \int_t^{\infty} dw\,\vec{K}^{\mp}(t,w)e^{\mp i\lambda w}\right]v_0^{\pm}, \tag{7.2}$$

which is obviously the generalized Marchenko equation of the problem on a t path, at fixed x. As in standard inverse theories, we can insert (7.1) into (6.40) to get after some algebra the linear partial differential equation (for $t<u$) and the relations at $t=u$ relative to the kernels $K^{\pm}v_0^{\mp}$ (which vanish for $t>u$, according to the analytic properties):

$$K^{\pm}(t,u)\to 0, \quad u\to\infty, \tag{7.3}$$

$$\left\{\left[\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial u^2}-\mathcal{A}(t)\right]\vec{K}^{\pm}(t,u)\mp i\mathcal{B}(t)\frac{\partial}{\partial u}\vec{K}^{\pm}(t,u)\right\}v_0^{\mp}=0, \tag{7.4}$$

$$\left[\frac{d}{dt}\vec{K}^{\pm}(t,t)\mp\frac{i}{2i}\mathcal{B}(t)\vec{K}^{\pm}(t,t)-\mathcal{E}^{\pm}(t)\vec{P}^{\pm}(t)\right]v_0^{\mp}=0, \tag{7.5}$$

where

$$\mathcal{E}^{\pm}(t)=-\frac{1}{2}\mathcal{A}(t)\pm\frac{1}{4i}\mathcal{B}'(t)-\frac{1}{8}\mathcal{B}^2(t). \tag{7.6}$$

The equations (7.2) and (7.1) also yield a representation of $\vec{K}^{\pm}(t,u)v_0^{\mp}$:

$$\vec{K}^{\pm}(t,u)v_0^{\mp}=-\frac{1}{2\pi}\int_{-\infty}^{+\infty}d\lambda\, e^{\mp i\lambda u}\tilde{R}^{\mp}(\lambda)\vec{\Psi}^{\mp}(\lambda,t). \tag{7.7}$$

Inserting (7.7) into (7.1) yields a set of coupled integral equations for $\vec{\Psi}^{\pm}$:

$$\vec{\Psi}^{\pm}(k^3,t)=\vec{P}^{\pm}(t)e^{\pm ik^3t}v_0^{\mp}-\frac{1}{2\pi}\int_{-\infty}^{+\infty}d\lambda\,\tilde{R}^{\mp}(\lambda)\vec{\Psi}^{\mp}(\lambda,t)\int_t^{\infty}du\, e^{\pm i(k^3-\lambda\pm i0^+)u}. \tag{7.8}$$

The equations (7.7)–(7.8) are, of course, the inversion equations of the transformed time-path scattering problem. Here (7.4) and (7.5) are consistency relations involving V. Going to the true time-path scattering problem is done by using (6.118) and (6.77) for deriving **G**, using also (6.49) and (6.35) for handling the first term on the rhs of (7.8), (6.88), and (6.107) for the second one. Setting $\lambda=\mu^3$ in the integral, we obtain

$$\vec{\mathbf{G}}^{\pm}(k,t)=\vec{\mathbf{G}}_0^{\pm}(k,t)\mp\frac{i}{2\pi}T^{-1}(k)\int_{-\infty}^{+\infty}d\mu^3\,T(\mu)R^{\mp}(\mu)\vec{\mathbf{G}}^{\mp}(\mu,t)\frac{e^{\pm i(k^3-\mu^3)t}}{k^3-\mu^3\pm i0^+}, \tag{7.9}$$

where

$$\vec{\mathbf{G}}_0^{\pm}(k,t)=\begin{pmatrix}\vec{g}_0^{\pm}(k,t)\\ \vec{g}_0^{\pm}(jk,t)\\ \vec{g}_0^{\pm}(j^2k,t)\end{pmatrix}e^{\pm ik^3t}, \tag{7.10}$$

$$\vec{g}_0^{\pm}(k,t)=\begin{pmatrix}\mp i\\ k\mp(2i)^{-1}\int_t^{\infty}B_1(u)du\end{pmatrix}=:\begin{pmatrix}\mp i\\ k\pm ig(t)\end{pmatrix}, \tag{7.11}$$

and $R^{\mp}(k)$ was given by (6.117), (6.118). Notice that the values of the first ''duplex'' element of the diagonal, $r^{\pm}(k)$, yield the others by j transformation. Now, the first ''duplex'' element of the vector $\vec{\mathbf{G}}^{\pm}$ in (7.9) is easily derived:

$$\vec{G}^{\pm}(k,t)=\vec{g}_0^{\pm}(k,t)e^{\pm ik^3t}\mp\frac{i}{2\pi}\int_{-\infty}^{+\infty}d\mu\ \mu^2\sum_{l=0}^{l=2}\left(1+j^{2l}\frac{k}{\mu}+j^l\frac{k^2}{\mu^2}\right)r^{\mp}(j^l\mu)$$
$$\times\vec{G}^{\mp}(j^l\mu,t)(k^3-\mu^3\pm i0^+)^{-1}\exp[\pm i(k^3-\mu^3)t]. \tag{7.12}$$

B. The direct linearization equation

Equation (7.12) should be the fixed x reduction of the direct linearization equation we seek. It is an equation for two-vectors, but those we studied previously might also have been put in this form. What is unexpected and new is that two coupled integral equations come in. What is excellent is that the spectral measures that come in can be calculated as scattering data of the time-path scattering problem from $V(x_0,t)$, $V'(x_0,t)$, $V''(x_0,t)$, and/or time derivatives related to them by the Korteweg de Vries equation (x_0 is the fixed value of x, omitted in notations). By the way, notice that since $\mathbf{N}$ is a real matrix, $\vec{G}^-(k,t)$, $c^-(k)$, $d^-(k)r^-(k)$ are for a real k conjugate of $\vec{G}^+(k,t)$, $c^+(k)$, $d^+(k)$, $r^+(k)$, so that ''in fine,'' there are (in some way) three (complex) spectral measures r_0, r_1, r_2.

We have now to write down a direct linearization equation as x evolves. We find in (7.12) quantities inside $\vec{g}_0$ where x dependence was given from the beginning, and the scattering data. For the latter ones, we use the t-scattering analysis already sketched with the equation (6.29). More precisely, if t is so large that the Born formula (6.29) applies, we can write down, for $x_0=0$,

$$\vec{G}^{\pm}(k,x,t)=\exp[\mathbf{M}_0x]\vec{G}^{\pm}(k,0,t)\xrightarrow{t\to\infty}\begin{pmatrix}\mp i\\ k\end{pmatrix}e^{\pm i(kx+k^3t)}. \tag{7.13}$$

Hence, the ''time problem Jost solution'' $\vec{G}_J^{\pm}(k,x,t)$ is related to the solution of the time Lax equation that has evolved from 0 to x according to the space Lax equation by the restandardizing relation:

$$\vec{G}_J^{\pm}(k,x,t)=e^{\mp ikx}\vec{G}^{\pm}(k,x,t), \tag{7.14}$$

and, by the same token,

$$\overleftarrow{G}_J^{\mp}(k,x,t)=e^{\pm ikx}\overleftarrow{G}^{\mp}(k,x,t). \tag{7.15}$$

If we notice that $\mathbf{M}$ being a zero trace matrix, the determinant of two solutions of the space Lax equation is independent of x, we deduce from (7.14) (7.15), (6.70), and (6.71) that

$$c^{\pm}(k,x)=c^{\pm}(k,0);\quad d^{\pm}(k,x)=e^{\pm 2ikx}d^{\pm}(k,0), \tag{7.16}$$

$$r^{\pm}(k,x)=e^{\pm 2ikx}r^{\pm}(k,0). \tag{7.17}$$

From (7.12) and (7.17), we finally propose the direct linearization equation, which should be convenient for solving the second Cauchy problem:

$$\vec{G}^{\pm}(k,x,t)=\begin{pmatrix}\mp i\\ k\pm ig\end{pmatrix}e^{\pm iZ(k,x,t)}+\frac{1}{2\pi}\int_{-\infty}^{+\infty}d\mu\sum_{l=0}^{2}j^lr^{\mp}(j^l\mu)\vec{G}^{\mp}(j^l\mu,x,t)\sigma^{\pm}(k,j^l\mu,x,t), \tag{7.18}$$

where

$$g(x,t)=\frac{1}{2}\int_t^{\infty}B_1(u)du=\frac{1}{2}\int_x^{\infty}dy\ V(y,t), \tag{7.19}$$

$$Z(k,x,t)=kx+k^3t, \tag{7.20}$$

$$\sigma^{\pm}(k,\mu,x,t)=\mp i(k-\mu\mp i0^+)^{-1}e^{\pm i[Z(k,x,t)-Z(\mu,x,t)]}. \tag{7.21}$$

Notice that the equality between the two values of g in (7.19) is the consistency formula KdV between the two equations whose $G^{\pm}$ must be solutions. One could also say that it is one of the constraints plugged in the method to enforce that $\vec{G}^{\pm}$ solve the two Lax equations. We check now that they do it using the standard assumptions of the direct linearization methods [see them in other sections and, in particular, those after (5.63)]. Indeed, straightforward calculations show that

$$\begin{aligned}\left[\frac{\partial}{\partial x}-\begin{pmatrix}0 & 1\\ -k^2+V & 0\end{pmatrix}\right]G^{\pm}(k,x,t)\\ =\left[\begin{pmatrix}\mp ig\\ \pm i(g'+V)-kg\end{pmatrix}+\begin{pmatrix}1 & 0\\ \mp ik & 1\end{pmatrix}W^{0\mp}(x,t)\mp i\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}W^{1\mp}(x,t)\right]e^{\pm iZ(k,x,t)}\\ +\frac{1}{2\pi}\int_{-\infty}^{+\infty}d\mu\sum_0^2 j^l r^{\mp}(j^l\mu)\left[\frac{\partial}{\partial x}-\begin{pmatrix}0 & 1\\ j^{2l}\mu^2-V & 0\end{pmatrix}\right]\vec{G}^{\mp}(j^l\mu,x,t)\sigma^{\pm}(k,j^l\mu,x,t),\end{aligned} \tag{7.22}$$

where

$$W^{p\mp}(x,t)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}d\mu(j^l\mu)^p\sum_{l=0}^{2} j^l r^{\mp}(j^l\mu)\vec{G}^{\mp}(j^l\mu,x,t)e^{\mp iZ(\mu,x,t)}. \tag{7.23}$$

The free terms vanish and the space Lax equation is solved if and only if the component $\vec{G}_2^{\pm}$ is the derivative of $\vec{G}_1^{\pm}$ and the two (i.e., $\pm$) following sums satisfy

$$\vec{G}_2^{\pm}(k,x,t)=\frac{\partial}{\partial x}\vec{G}_1^{\pm}(k,x,t), \tag{7.24}$$

$$W_1^{0\mp}(x,t)=\pm ig. \tag{7.25}$$

As for the time Lax equation, we similarly proceed through

$$\begin{aligned}\left[\frac{\partial}{\partial t}-\mathbf{N}(k)\right]G^{\pm}(k,x,t)=\left[\frac{\partial}{\partial t}-\mathbf{N}(k)\right]\left[\begin{pmatrix}\mp i\\ k\pm ig\end{pmatrix}e^{\pm iZ(k,x,t)}\right]\\ +\frac{1}{2\pi}\int d\mu\sum_0^2 j^l r^{\mp}(j^l\mu)[\mathbf{N}(j^l\mu)-\mathbf{N}(k)][G^{\mp}(j^l\mu,x,t)]\sigma^{\pm}(k,\mu,x,t)\\ +\frac{1}{2\pi}\int d\mu\sum_0^2 j^l r^{\mp}(j^l\mu)G^{\mp}(j^l\mu,x,t)\frac{\partial}{\partial t}\sigma^{\pm}(k,\mu,x,t)\\ +\frac{1}{2\pi}\int d\mu\sum_0^2 j^l r^{\mp}(j^l\mu)\left[\left(\frac{\partial}{\partial t}-\mathbf{N}(j^l\mu)\right)G^{\mp}(j^l\mu,x,t)\right]\sigma^{\pm}(k,\mu,x,t),\end{aligned} \tag{7.26}$$

and the free term we obtain is equal to

$$\text{F.T.}=\begin{pmatrix} \mp ik^2 g \\ -k^3 g \pm ik^2 V_0 \pm i\dfrac{\partial g}{\partial t}\end{pmatrix} - n_0\begin{pmatrix}\mp i \\ k\pm ig\end{pmatrix} - \{(I\mp ikn_2)[k^2 W^{0\mp}(x,t)+kW^{1\mp}(x,t)+W^{2\mp}(x,t)] \pm in_1[kW^{0\mp}(x,t)+W^{1\mp}(x,t)]\mp in_2[W^{3\mp}(x,t)]\}. \tag{7.27}$$

It vanishes if (7.25) holds, and

$$W_2^{0\mp}\mp iW_1^{1\mp}\pm iV_0=0, \tag{7.28}$$

$$W_2^{1\mp}\mp iW_1^{2\mp}-V_0 g+V_1=0, \tag{7.29}$$

$$W_2^{2\mp}\pm iV_0 W_1^{1\mp}\mp iW_1^{3\mp}\pm i\frac{\partial g}{\partial t}+iV_2\pm igV_{1=0}. \tag{7.30}$$

Equations (7.25), (7.28), (7.29), (7.30), yield $V(x,t)$ and its first and second derivatives as functions of x,t, and since the two equations of the Lax pair are satisfied for these functions, they give the solution of the Korteweg de Vries equation. It is interesting and not difficult (but lengthy) to check that for $x=0$, the values of the W's can be derived from the equations (7.5), (7.6) by applying the transformations that lead to $G^{\pm}(k,t)$ and to check that (7.25) and (7.28)–(7.30) are satisfied, together with the equations

$$\frac{\partial}{\partial x}W_1^{p\mp}=\mp iW_1^{(p+1)\mp}+W_2^{p\mp}, \tag{7.31}$$

$$\frac{\partial}{\partial x}W_2^{p\mp}=-W^{(p+2)\mp}\mp iW_2^{(p+1)\mp}, \tag{7.32}$$

which are derived readily from (7.24) and the space Lax equation.

Hence, the coupled vectorial equations (7.18) have almost all properties of a DLE, but one: they cannot be written readily from the values of $V(x,t)$ at $x=0$, since $g(x,t)$ [see (7.19)] contains V, and if we knew $V(x,t)$ the problem would be solved. Obviously, this point is easy to circumvent because the kernel of (7.18) is scalar. Hence, (7.18) can be separated into two couples of scalar equations: the first one for $\vec{G}_1^{\pm}(k,x,t)$, the second one for $\vec{G}_2^{\pm}(k,x,t)$. The first one can be written and solved as soon as we know the time scattering data at $x=0$, and it yields $g(x,t)$, and $V(x,t)$, by means of the consistency condition (7.26). Using $g(x,t)$ defines the second couple of equations, whose solutions give readily various quantities, as, for instance, the other W's, and enables one to check that the method works. Hence, the following couple of scalar integral equations is really the DLE of our ''other Cauchy problem:''

$$\vec{G}_1^{\pm}(k,x,t)=\mp ie^{\pm iZ(k,x,t)}+\frac{1}{2\pi}\int_{-\infty}^{+\infty}d\mu\sum_{l=0}^{2}j^l r^{\mp}(j^l\mu)\vec{G}_1^{\mp}(j^l\mu,x,t)\sigma^{\pm}(k,j^l\mu,x,t), \tag{7.33}$$

and the potential is derived from its solution by means of the formula (7.25). The ''time inverse scattering method'' can be summarized as so

(1) At $x=0$ (say) where V and its first two x derivatives are known for any t, solve the direct problem (6.11), so as to derive the Jost solutions $\vec{G}^{\pm}(k,0,t)$ and $\overleftarrow{G}^{\mp}(k,0,t)$ defined by (6.27), (6.28).

(2) Derive det$[\overleftarrow{G}^{-},\vec{G}^{+}]$ and det$[\overleftarrow{G}^{+},\vec{G}^{-}]$ to get $c^{\pm}(k)$, $d^{\pm}(k)$ and $r^{\pm}(k)$. Check (if it is the case) that there is no pole of $\tilde{T}^{\pm}(\lambda)$ in Im $\lambda\geqslant 0$.

(3) Insert the scattering data $r^{\pm}$ into (7.33) and solve it, you get $V(x,t)$ by means of (7.25).

C. The case of poles in the transmission coefficient, with zero reflection coefficient

From (6.108), and the equation obtained by twisting indices $+$ and $-$, we saw that poles can contribute functions $g^{\pm}(t,u)$ in (6.111) and the twisted equation. The general case is complicated. We introduce three simplifying assumptions.

Assumption A: We assume that $[\tilde{C}^{\pm}(\lambda)]^{-1}$ have only simple poles in $\pm \mathrm{Im}\,\lambda > 0$.

These poles correspond to zeros of $\det \tilde{C}^{\pm}(\lambda)$ and thus of $\det C^{\pm}(k)$. For such a zero λ_0, according to the determination of the cubic root k_0, the product $c(k)$, $c(jk)c(j^2k)$ vanishes!

Assumption B: We assume that if k_n is such that $c(k_n)$ vanishes, $c(jk_n)$ and $c(j^2k_n)$ do not.

Finally, in order to obtain relatively simple formulas, and because it is not difficult to remove it by taking into account the preceding results, we also introduce the following.

Assumption C: The reflection coefficients [or $d^{\pm}(k)$] vanish for any real k. Thanks to Assumptions A and C, $\vec{K}^{-}(t,u)$ can then be directly derived from (6.108) and (6.109) by Fourier transforming $\mathcal{G}^{+}(\lambda,t)$, and the Fourier transform can be calculated for $u>t$ as a sum of the residues of $[C^{+}(\lambda)]^{-1}\overleftarrow{\boldsymbol{\Psi}}^{-}(\lambda,t)e^{i\lambda u}$ at the poles $\lambda_1^{+}, \lambda_2^{+}, \lambda_n^{+}$ [the second term in (6.109) only implies that the contribution on the infinite half-circle vanishes]. The same method (in $\mathrm{Im}\,\lambda<0$) applies to the quantities with the other $\pm$ index. The result is

$$\vec{K}^{\mp}(t,u)v_0^{\pm} = \pm i \sum_{n=1}^{N} e^{\pm i\lambda_n^{\pm}} \Gamma_n^{\pm} \overleftarrow{\boldsymbol{\Psi}}^{\mp}(\lambda_n^{\pm},t), \tag{7.34}$$

where

$$\Gamma_n^{\pm} = \lim_{\lambda\to\lambda_0^{\pm}} (\lambda-\lambda_0^{\pm})[\tilde{C}^{\pm}(\lambda)]^{-1}. \tag{7.35}$$

Inserting (7.33) into (7.1), we obtain

$$\overleftarrow{\boldsymbol{\Psi}}^{\pm}(k^3,t) = \vec{P}^{\pm}(t)\exp(\pm ik^3t]v_0^{\mp} \mp i\sum_{n=1}^{N}\int_t^{\infty} du\, \exp[\pm i(k^3-\lambda_n^{\mp})u]\Gamma_n^{\mp}\overleftarrow{\boldsymbol{\Psi}}^{\pm}(\lambda_n^{\mp},t). \tag{7.36}$$

Let us now notice that if for each $\lambda_n^{\pm}$, we define $k_n^{\pm}$ as the cubic root of $\lambda_n^{\pm}$ whose phase is such that $c^{+}(k_n^{+})$ [resp., $c^{-}(k_n^{-})$] vanishes, and thanks to the assumption B, and to the formula (6.88), we derive from (7.35),

$$T^{-1}(k_n^{\mp})\Gamma_n^{\mp}T(k_n^{\mp}) = \begin{pmatrix} 3(k_n^{\mp})^2 \lim_{k\to k_n^{\mp}} \dfrac{k-k_n^{\mp}}{c^{\mp}(k)} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \tag{7.37}$$

Applying $3T^{-1}(k)$ to both sides of (7.36), we derive an equation for $\mathbf{G}^{\pm}(k,t)$ and thanks to (7.37) we see at once that the three duplex components of the six vector carry on the same information (except for trivial j transformations). Hence, we write down

$$\vec{G}^{\pm}(k,t) = \vec{G}_0^{\pm}(k,t) + \sum_{n=1}^{N} \frac{\exp[\pm i(k^3-\lambda_n^{\mp})t]}{k^3-\lambda_n^{\mp}} (k_n^{\mp})^2 T^{-1}(k)T(k_n^{\mp})\gamma^{\mp}(k_n^{\mp})\overleftarrow{G}^{\pm}(k_n^{\mp},t), \tag{7.38}$$

where

$$\gamma^{\pm}(k_n^{\pm}) = \lim_{k\to k_n^{\pm}}\left[\frac{k-k_n^{\pm}}{c^{\pm}(k)}\right]. \tag{7.39}$$

Now, since $k_n^{\pm}$ is a zero of $c^{\pm}(k)$, $\det[\overleftarrow{G}^{\mp},\vec{G}^{\pm}]$ vanishes there, so that the functions $\overleftarrow{G}^{-}$ and $\vec{G}^{+}$, $\overleftarrow{G}^{+}$ and $\overleftarrow{G}$ are proportional when $k=k_n^{+}$, resp. $k=k_n^{-}$. Multiplying $\gamma^{\mp}(k_n^{\mp})$ by the corresponding factors yields, say, $\rho_n^{\mp}$, and expanding $T^{-1}(k)T(k_n^{\mp})$ kills partially the denominators in (7.38).

Hence, we obtain the coupled equations,

$$\vec{G}^{\pm}(k,t)=\vec{G}_0^{\pm}(k,t)+\sum_{n=1}^{N}\frac{\exp[\pm i(k^3-\lambda_n^{\mp})t]}{k-k_n^{\mp}}\rho_n^{\mp}\vec{G}^{\mp}(k_n^{\mp},t). \tag{7.40}$$

As an example, the well-known ''soliton,''

$$V(x,t)=-\frac{2\kappa^2}{\cosh^2[\kappa(x-x_0)-\kappa^3 t]}, \tag{7.41}$$

is related at fixed x, say $x=x_0$, to the following functions and numbers:

$$\vec{G}^{+}(k,t)=-i(k+i\kappa)(k-i\kappa)^{-1}F(k,t), \tag{7.42}$$

$$\vec{G}^{-}(k,t)=i(k-i\kappa)(k+i\kappa)^{-1}\tilde{F}(k,t), \tag{7.43}$$

$$\overleftarrow{G}^{+}(k,t)=-iF(k,t), \tag{7.44}$$

$$\overleftarrow{G}^{-}(k,t)=i\tilde{F}(k,t), \tag{7.45}$$

where

$$F(k,t)=e^{ik^3t}\begin{pmatrix}\dfrac{k+i\kappa(1-\alpha)}{k+i\kappa}\\ \dfrac{ik^2+k\kappa(\alpha-1)+i\kappa^2\beta}{k+i\kappa}\end{pmatrix}, \tag{7.46}$$

$$\tilde{F}(k,t)=e^{-ik^3t}\begin{pmatrix}\dfrac{k-i\kappa(1-\alpha)}{k-i\kappa}\\ \dfrac{ik^2+k\kappa(\alpha-1)-i\kappa^2\beta}{k-i\kappa}\end{pmatrix}, \tag{7.47}$$

$$\alpha=e^{\kappa^3 t}/\cosh\kappa^3 t \quad \beta=2\cosh^2\kappa^3 t, \tag{7.48}$$

$$c^{\pm}(k)=\frac{k\pm i\kappa}{k\mp i\kappa},\quad d^{\pm}(k)=0, \tag{7.49}$$

κ is positive, and it is not difficult to derive the value of $\rho_0^{\pm}$ for the (unique) pole,

$$k_0^{\pm}=\mp i\kappa,\quad \rho_0^{\mp}=\pm 2i\kappa, \tag{7.50}$$

and to check (7.40).

From (7.38) we can derive the direct linearization equation for solutions of this kind. We write readily the ''first component'' and the equations that yields the potential:

$$\vec{G}_1^{\pm}(k,x,t)=\mp ie^{\pm iZ(k,x,t)}+\sum_{n=1}^{N}\frac{\exp[\pm i(k^3t-(k_n^{\mp})^3t+kx-k_n^{\mp}x)]}{k-k_n^{\mp}}\rho_n^{\mp}\vec{G}_1^{\mp}(k_n^{\mp},x,t), \tag{7.51}$$

$$g(x,t)=\sum_{n=1}^{N} \exp[\mp i((k_n^{\mp})^3 t+k_n^{\mp}x)]\rho_n^{\mp}G_1^{\mp}(k_n^{\mp},x,t), \tag{7.52}$$

$$V(x,t)=-2\frac{\partial g(x,t)}{\partial x}. \tag{7.53}$$

They could be used to solve the ''other Cauchy problem'' for a multisolitonic solution. The reader will easily check that using (7.51) in these three formulas give back $V(x,t)$, as given by (7.41) (for $x_0=0$).

D. Final remarks

The linearization equations (7.33) and (7.51) could also be used to construct generalized two variable Marchenko equations like we did in the Gelfand Levitan case in our previous paper and recall it in Sec. III, since they can also be understood as a generalized two-variable Povzner Levitan representation for $\vec{G}^{\pm}(k,x,t)$. We shall not write down these equations, which may be a step to further generalizations.

(Received 20 January 1999; accepted for publication 14 February 1999)

A study of Hamiltonian structures associated with supersymmetric Lax operators is presented. Following a constructive approach, the Hamiltonian structures of Inami–Kanno super-KdV hierarchy and constrained modified super-KP hierarchy are investigated from the reduced supersymmetric Gelfand–Dickey brackets. By applying a gauge transformation on the Hamiltonian structures associated with these two nonstandard super-Lax hierarchies, we obtain the Hamiltonian structures of generalized Manin–Radul super-KdV and constrained super-KP hierarchies. We also work out a few examples and compare them with the known results. © *1999 American Institute of Physics.* [S0022-2488(99)02206-9]

I. INTRODUCTION

In the past decade and more, the supersymmetric integrable systems have received much attention in the literature (for recent reviews, see Refs. 1–3 and references therein), especially in the explorations of the relationship to the supersymmetric conformal field theories and string theories. On the one hand, in superconformal/superstring theories, correlation functions are governed by supersymmetric extensions of the Korteweg–de Vries (KdV) [or Kadomtsev–Petviashvili (KP)] systems. On the other hand, the knowledge of super-KdV/KP systems have motivated people to study nonperturbative properties of superstrings. These superintegrable systems share many features in common: they have supersymmetric Lax representations, infinitely many conserved quantities and soliton solutions, etc. Furthermore, it is a common belief that they also possess bi-Hamiltonian structures that define the dynamical flows on the corresponding Poisson supermanifolds. In particular, for the super-KdV-type systems, the Poisson brackets relative to their associated second Hamiltonian structures provide extended superconformal algebras (*W* superalgebras) whose quantum versions serve as the highest weight representations of some infinite-dimensional symmetries in string theories.

The main purpose of this paper is to construct the Hamiltonian structures of the generalized Manin–Radul super-KdV (MR sKdV) and constrained super-KP (csKP) hierarchies (for the definitions of these hierarchies, see Sec. IV) using the method of gauge transformation. Although the Hamiltonian structures for the simplest cases have been obtained in Refs. 4 and 5, however, to our knowledge, those for the general cases are still unexplored. Our motivation comes from the fact that, for two gauge-equivalent integrable systems, the gauge transformation between them transforms not only the Lax formulations but also the Hamiltonian structures of the corresponding hierarchies. Hence, the preparation of suitable superintegrable systems that are gauge equivalent to the generalized MR sKdV and csKP hierarchies is the key in this approach. Our strategy is the following: First, for an odd-order super-Lax operator $\hat{L}$, we consider its associated supersymmet-

[a)]Electronic mail: mhtu@math.ccu.edu.tw
[b)]Electronic mail: shaw@math.nctu.edu.tw

ric Gelfand–Dickey (GD) bracket[6] defined by the Hamiltonian map J. We then consider a usual reduction that modifies the Hamiltonian map J to J_c. Second, we construct out two nonstandard superhierarchies from $(\hat{L},J_c)$ that have super-Lax operators defined by $K_A=\hat{L}D$ and $K_B=D^{-1}\hat{L}$, respectively. The former is referred to the Inami–Kanno sKdV (IK sKdV) hierarchy,[7] whereas the latter to the constrained modified sKP (cmsKP) hierarchy.[8–10] The Hamiltonian structures associated with K_i can also be constructed from J_c and are denoted by $\Omega^{(i)}$ $(i=A,B)$. Finally, we perform a gauge transformation on the systems $(K_i,\Omega^{(i)})$ and denote the resulting systems by $(\tilde{L}_i,\Theta^{(i)})$, which describe the Lax operators and the Hamiltonian structures of the generalized MR sKdV and csKP hierarchies.

In summary, we shall follow the following steps to achieve the goal:

$$(\hat{L},J_c)\rightarrow(K_i,\Omega^{(i)})\rightarrow(\tilde{L}_i,\Theta^{(i)}). \tag{1.1}$$

It will be shown below that each step described above automatically guarantees the requirement that the associated Hamiltonian structures should obey the super-Jacobi identity.

We organize this paper as follows: In Sec. II, we recall some basic facts concerning superpseudodifferential operators (SPDOs). We then introduce the second supersymmetric GD bracket and its reduction from a Miura transformation viewpoint. In Sec. III, the IK sKdV and the cmsKP hierarchies are defined. We give a detailed construction of their associated Hamiltonian structures from the reduced supersymmetric GD bracket. We find that, up to a sign, the Poisson brackets defined by their corresponding Lax operators have the same form. In Sec. IV, we define the generalized MR sKdV and csKP hierarchies by applying a gauge transformation to the IK sKdV and cmsKP hierarchies, respectively. We also show that this gauge transformation enables us to obtain the Hamiltonian structures associated with the generalized MR sKdV and csKP hierarchies. In Sec. V, we give several examples to compare them with the known results. We present our concluding remarks in Sec. VI.

II. SUPERSYMMETRIC GELFAND–DICKEY BRACKETS

To begin with, we consider the supersymmetric Lax operator of the form

$$L=D^n+U_{n-1}D^{n-1}+\cdots+U_0, \tag{2.1}$$

where the supercovariant derivative $D\equiv\partial_\theta+\theta\partial(\partial\equiv\partial/\partial x)$ satisfies $D^2=\partial$, θ is the Grassmann variable $(\theta^2=0)$, which together with the even variable $x\equiv t_1$ defines the $(1|1)$ superspace with coordinate (x,θ). The coefficients U_i are superfields that depend on the variables θ, t_i and can be represented by $U_i=u_i(t)+\theta v_i(t)$. The parity of a superfield U is denoted by $|U|$, which is zero for U being even and one for U being odd. Since L is assumed to be homogeneous under Z_2 grading, thus $|U_i|=n+i(\mathrm{mod}\,2)$. We will introduce the Poisson bracket associated with L on functionals of the form

$$F(U)=\int_B f(U), \tag{2.2}$$

where $f(U)$ is a homogeneous differential polynomial of U_i and $\int_B\equiv\int dx\,d\theta$ is the Berezin integral, such that if $f(U)=a(u,v)+\theta b(u,v)$, then $\int_B f(U)=\int b$. The supercovariant derivative D satisfies the supersymmetric version of the Leibniz rule;[11]

$$D^iU=\sum_{k=0}^{\infty}(-1)^{|U|(i-k)}\begin{bmatrix} i \\ k \end{bmatrix}U^{[k]}D^{i-k}, \tag{2.3}$$

where $U^{[k]}\equiv(D^kU)$ and the superbinomial coefficients $\left[\begin{smallmatrix} i \\ k \end{smallmatrix}\right]$ are defined by

$$\begin{bmatrix} i \\ k \end{bmatrix} = \begin{cases} \begin{pmatrix} [i/2] \\ [k/2] \end{pmatrix} & \text{for } 0 \leqslant k \leqslant i \quad \text{and} \quad (i,k) \neq (0,1) \bmod 2, \\ (-1)^{[k/2]} \begin{bmatrix} -i+k-1 \\ k \end{bmatrix}, & \text{for } i<0, \\ 0, \quad \text{otherwise.} \end{cases} \tag{2.4}$$

For a given SPDO $P=\Sigma p_i D^i$, it is convenient to separate P into a direct sum of two linear spaces: $P=P_{\geqslant k} \oplus P_{<k}$ with $P_{\geqslant k}=\Sigma_{i \geqslant k} p_i D^i$ and $P_{<k}=\Sigma_{i<k} p_i D^i$. In particular, we denote $P_+ = \Sigma_{i \geqslant 0} p_i D^i$, $P_- = \Sigma_{i<0} p_i D^i$, and $(P)_0 = p_0$. We also define its super-residue as sres $P=p_{-1}$ and its supertrace as Str $P=\int_B \text{sres}\, P$. It can be shown that, for any two SPDOs P and Q, $\text{Str}[P,Q]=0$ for $[P,Q] \equiv PQ-(-1)^{|P||Q|}QP$, and hence $\text{Str}\, PQ=(-1)^{|P||Q|}\,\text{Str}\, QP$. Given a functional $F(U)=\int_B f(U)$, we define its gradient as

$$d_L F = \sum_{k=0}^{n-1} (-1)^k D^{-k-1} \frac{\delta f}{\delta U_k}, \tag{2.5}$$

and its variation as

$$\delta F = (-1)^{|F|+|L|+1}\, \text{Str}(\delta L\, d_L F), \tag{2.6}$$

where the variational derivative is defined by

$$\frac{\delta f}{\delta U_k} = \sum_{i=0}^{\infty} (-1)^{|U_k|i + i(i+1)/2} \left(\frac{\partial f}{\partial U_k^{[i]}} \right)^{[i]}. \tag{2.7}$$

The supersymmetric second GD bracket associated with L is given by[6,12,13]

$$\{F,G\}(L) = (-1)^{|F|+|G|+|L|+1}\, \text{Str}[J(d_L F) d_L G], \tag{2.8}$$

where the Hamiltonian map J is defined by

$$J(X) = (LX)_+ L - L(XL)_+, \tag{2.9}$$

where $X=\Sigma_k X_k D^k$. It has been shown[6,13] that (2.8) indeed defines a Hamiltonian structure, namely, it is antisymmetric and satisfies the super-Jacobi identity.

If we factorize $L=(D-\Phi_n)(D-\Phi_{n-1})\cdots(D-\Phi_1)$, which defines a supersymmetric Miura transformation between the coefficient functions U_i and the Miura fields Φ_i, then the second GD bracket (2.8) becomes

$$\{F,G\}(L) = \int_B \sum_{i=1}^{n} (-1)^i \left(D \frac{\delta f}{\delta \Phi_i} \right) \frac{\delta g}{\delta \Phi_i}, \tag{2.10}$$

which implies that the fundamental brackets of the Miura fields Φ_i are given by[6,12]

$$\{\Phi_i(X), \Phi_j(Y)\} = (-1)^i \delta_{ij} D\, \delta(X-Y), \tag{2.11}$$

where $X=(x,\theta)$, $Y=(y,\omega)$ and $\delta(X-Y) \equiv \delta(x-y)(\theta-\omega)$. This result is what we called the supersymmetric Kupershmidt–Wilson theorem. Equation (2.11) enables us to write down the fundamental brackets of U_k through the super-Miura transformation.

Next, let us consider the case when the constraint $U_{n-1}=0$ is imposed in (2.1). It can be easily shown that such constraint for odd n is second class, which will modify the Hamiltonian structure J. On the other hand, for even n, the constraint is first class and hence the induced

Poisson brackets can not be well defined. Therefore, for the odd-order operator $\hat{L}=D^{2k+1}+U_{2k-1}D^{2k-1}+\cdots+U_0$, we shall consider the factorization $\hat{L}=(D-\Phi_{2k+1})(D-\Phi_{2k})\cdots(D-\Phi_1)$. Then the modified Poisson bracket defined by $\hat{L}$ becomes

$$\{F,G\}_c=(-1)^{|F|+|G|}\,\mathrm{Str}(J_c(\hat{d}F)\hat{d}G), \tag{2.12}$$

where $\hat{d}F\equiv d_{\hat{L}}F=\Sigma_{i=0}^{2k-1}(-1)^iD^{-i-1}(\delta f/\delta U_i)$ and

$$J_c(\hat{d}F)=J(\hat{d}F)+\left[\hat{L},\int^x D\ \mathrm{sres}[\hat{L},\hat{d}F]\right]. \tag{2.13}$$

We remark that the second term is called the third GD structure, which is compatible with the second structure. Equation (2.12) yields that the modified Poisson brackets for the Miura fields Φ_i are given by

$$\{\Phi_i(X),\Phi_j(Y)\}_c=[1+(-1)^i\delta_{ij}]D\delta(X-Y), \tag{2.14}$$

which provide the free-field realizations of classical W superalgebras associated with the odd-order Lax operator $\hat{L}$.[12,14,15] Besides the usual reduction described above, there are other reductions that have been discussed in Refs. 13 and 16. Since the first Hamiltonian structure can be obtained from the second Hamiltonian structure by replacing L by $L+\lambda$, where λ is called the spectral parameter, we shall focus only on the second structure.

III. TWO NONSTANDARD SUPER-LAX HIERARCHIES

There are several superintegrable hierarchies whose Lax operators are related to the modifications or reductions of the supersymmetric Lax operator (2.1) in the literature. Here, for our purpose, we consider the following two Lax systems:

$$\frac{dK_i}{dt_k}=[(K_i^{k/n})_{\geqslant 1},K_i] \quad (i=A,B), \tag{3.1}$$

with the Lax operators K_i defined by

$$K_A=D^{2n}+V_{2n-2}D^{2n-2}+\cdots+V_1D, \tag{3.2}$$

$$K_B=D^{2n}+V_{2n-2}D^{2n-2}+\cdots+V_0+D^{-1}V_{-1}. \tag{3.3}$$

The Lax equation for K_A is referred to the IK sKdV hierarchy.[7] The simplest example in this case is just the Laberge–Mathieu super KdV (LM sKdV) hierarchy $(n=2)$, which was constructed from a $N=2$sKdV hierarchy.[17] On the other hand, the Lax equation for K_B is the generalization of the super two-boson hierarchy (sTB) $(n=1)$,[18] which we call the cmsKP hierarchy. In particular, from (3.1) it is easy to show that the coefficient function V_{-1} obeys the evolution equation

$$\frac{dV_{-1}}{dt_k}=-((K_B^{k/n})^*_{\geqslant 1}V_{-1}), \tag{3.4}$$

which implies that V_{-1} is an adjoint eigenfunction associated with the Lax operator K_B.

In general, the second Poisson brackets associated with the Lax operators K_i can be written as

$$\{F,G\}^{(i)}(K_i)=(-1)^{|F|+|G|+1}\,\mathrm{Str}(\Omega^{(i)}(d_iF)d_iG), \tag{3.5}$$

where $d_iF\equiv d_{K_i}F$, and the Hamiltonian maps $\Omega^{(i)}$ are defined by

$$\Omega^{(A)}(d_AF)=(K_Ad_AF)_+K_A-K_A(d_AFK_A)_+ +[K_A,(d_AFK_A)_0] + (-1)^{|F|}\left[\int^x D\,\mathrm{sres}[d_AF,K_A],K_A\right]+(-1)^{|F|}K_AD^{-1}\,\mathrm{sres}[d_AF,K_A], \quad (3.6)$$

$$\Omega^{(B)}(d_BF)=(K_Bd_BF)_+K_B-K_B(d_BFK_B)_+ +[K_B,(K_Bd_BF)_0] + (-1)^{|F|}\left[K_B,\int^x D\,\mathrm{sres}[d_BF,K_B]\right]+(-1)^{|F|}D^{-1}\,\mathrm{sres}[d_BF,K_B]K_B. \quad (3.7)$$

Notice that the map $\Omega^{(A)}$, in operator form, is similar to but different from $\Omega^{(B)}$. Instead of giving $\Omega^{(i)}$ by other methods,[8–10,19] we will follow a constructive approach, analogous to that of the supersymmetric GD structure,[6] to verify the Hamiltonian maps $\Omega^{(i)}$ from a supersymmetric Miura transformation point of view. To show that the maps $\Omega^{(i)}$ are indeed Hamiltonian, we have to check that the Poisson brackets defined in (3.5) are antisymmetric and obey the super-Jacobi identity. For antisymmetry, by direct computation, it can be easily shown that

$$\{F,G\}^{(i)}=-(-1)^{|F||G|}\{G,F\}^{(i)}. \quad (3.8)$$

For the super-Jacobi identity, instead of direct computation, we rewrite the Lax operator K_i as

$$K_A=\hat{L}_AD, \quad K_B=D^{-1}\hat{L}_B, \quad (3.9)$$

where $\hat{L}_A$ and $\hat{L}_B$ are superdifferential operators with order $2n-1$ and $2n+1$, respectively. Furthermore, from the relation

$$\delta F=(-1)^{|F|+1}\,\mathrm{Str}(\delta K_id_iF)=(-1)^{|F|}\,\mathrm{Str}(\delta\hat{L}_i\hat{d}_iF), \quad (3.10)$$

where $\hat{d}_i\equiv d_{\hat{L}_i}$, we have

$$\hat{d}_AF=-Dd_AF, \quad \hat{d}_BF=(-1)^{|F|}d_BFD^{-1}. \quad (3.11)$$

Substituting (3.9) and (3.11) into (3.6) and (3.7), we find

$$\Omega^{(A)}(d_AF)=-J_c(\hat{d}_AF)D, \quad \Omega^{(B)}(d_BF)=(-1)^{|F|}D^{-1}J_c(\hat{d}_BF), \quad (3.12)$$

which imply that the Poisson brackets defined by K_i can be transformed to those defined by $\hat{L}_i$ as follows:

$$\{F,G\}^{(i)}(K_i)=\eta_i\{F,G\}_c(\hat{L}_i), \quad (3.13)$$

where $\eta_A=-1$ and $\eta_B=+1$. Hence, the super-Jacobi identity associated with the maps $\Omega^{(i)}$ is automatically satisfied due to the fact that the reduced supersymmetric GD brackets defined by $\hat{L}_i$ admit Miura representations (2.14).

Therefore the maps $\Omega^{(i)}$ provide the Hamiltonian formulation for the Lax equations (3.1):

$$\frac{dK_i}{dt_k}=\{H_k^{(i)},K_i\}^{(i)}=\Omega^{(i)}(d_iH_k^{(i)}), \quad (3.14)$$

where the Hamiltonian functionals $H_k^{(i)}$ are given by

$$H_k^{(i)}=-\frac{n}{k}\,\mathrm{Str}(K_i^{k/n}). \quad (3.15)$$

Notice that the relative signs in the Hamiltonian maps $\Omega^{(i)}$ are crucial. It is this choice so that $\Omega^{(i)}(d_i H_k^{(i)})$ are differential operators of order less than $2n-2$, and Eq. (3.14) makes sense.

Before ending this section, two remarks are in order. First, we note that both Piosson brackets defined by K_i, up to a sign, are mapped to the same reduced supersymmetric GD bracket defined by $\hat{L}_i$, which is different from the situation in the bosonic case, where type A is mapped to the *difference* of the second and the third GD structures,[20] whereas type B is the *sum* of the second and the third ones.[20,21] Second, both Lax operators K_A and K_B can be factorized into multiplicative forms, i.e.,

$$K_A=(D-\Phi_{2n-1})(D-\Phi_{2n-2})\cdots(D-\Phi_1)D,$$
$$K_B=D^{-1}(D-\Phi_{2n+1})(D-\Phi_{2n})\cdots(D-\Phi_1), \tag{3.16}$$

where the Miura fields Φ_i obey the Poisson brackets,

$$\{\Phi_j(X),\Phi_k(Y)\}^{(i)}=\eta_i[1+(-1)^j\delta_{jk}]D\delta(X-Y). \tag{3.17}$$

IV. GENERALIZED MR SKDV AND CONSTRAINED SKP HIERARCHIES

Having constructed the Hamiltonian structures of two nonstandard super-Lax hierarchies in the previous section, we are now ready to discuss gauge equivalences related to these two nonstandard hierarchies. Based on the fact that gauge transformations are canonical transformations, we can use them to obtain new integrable Hamiltonian systems from the known ones. In the following, we will show that the second Hamiltonian structures of the generalized MR sKdV and csKP hierarchies are just the ones that can be obtained in this way.

Let us perform the following gauge transformation to the Lax operators K_i:

$$\tilde{L}_i=T^{-1}K_iT \quad (i=A,B), \tag{4.1}$$

where the gauge operator T is defined by $T=\exp(-\int^x V_{2n-2}/n)$, and hence the next leading term of K_i can be gauged away. The resulting differential operators $\tilde{L}_i$ are thus given by

$$\tilde{L}_A=D^{2n}+U_{2n-3}D^{2n-3}+\cdots+U_0,$$
$$\tilde{L}_B=D^{2n}+U_{2n-3}D^{2n-3}+\cdots+U_0+\phi D^{-1}\psi, \tag{4.2}$$

where $\phi\equiv T^{-1}$ and $\psi\equiv V_{-1}T$. It can be proved that T^{-1} is an even eigenfunction associated with the operator $\tilde{L}_i$, i.e., $\partial T^{-1}/\partial t_k=((\tilde{L}_i^{k/n})_+T^{-1})_0$, and the nonstandard Lax equations in (3.1) are then transformed to the standard ones,

$$\frac{d\tilde{L}_i}{dt_k}=[(\tilde{L}_i^{k/n})_+,\tilde{L}_i]. \tag{4.3}$$

Therefore the gauge transformation (4.1) provides a connection between K_i and $\tilde{L}_i$ in the Lax formulation. For $\tilde{L}_A$, the Lax equation (4.3) gives the generalization of the MR sKdV hierarchy $(n=2)$, which was originally constructed from the MR sKP hierarchy by reduction.[11] On the other hand, the Lax equation (4.3) for $\tilde{L}_B$ describes the csKP hierarchy that contains the sAKNS hierarchy $(n=1)$[5,22] as the simplest example. It can be easily shown that the Lax equation (4.3) for $\tilde{L}_B$ is consistent with the following equations:

$$\frac{\partial\phi}{\partial t_k}=((\tilde{L}_B^{k/n})_+\phi)_0, \quad \frac{\partial\psi}{\partial t_k}=-((\tilde{L}_B^{k/n})_+^*\psi)_0, \tag{4.4}$$

and thus ϕ and ψ are an even eigenfunction and an odd adjoint eigenfunction of the csKP hierarchy, respectively.

Moreover, since the hierarchy flows associated with K_i have Hamiltonian descriptions, it is quite natural to ask whether we can use such gauge equivalence to obtain the second Hamiltonian structures of the generalized MR sKdV and csKP hierarchies. The answer is yes. To see this, consider an infinitesimal gauge transformation $K_i \to K_i + Q$, where Q is a homogeneous superdifferential operator of order, at most, $2n-2$. Then, in view of (4.1), we can read off the linearized map T' and its transposed map $T'^{\dagger}$ as

$$T': Q \to T^{-1} Q T + \frac{1}{n}\left[\int^x q_{2n-2}, \tilde{L}_i\right], \tag{4.5}$$

$$T'^{\dagger}: P \to T P T^{-1} + \frac{(-1)^{|P|+1}}{n}\int^x \mathrm{sres}[P, \tilde{L}_i], \tag{4.6}$$

where P is an arbitrary SPDO, $q_{2n-2} \equiv \mathrm{sres}(Q D^{-2n+1})$, and the adjoint of an operator R is defined by $\mathrm{Str}(PRQ) = (-1)^{|R||P|}\,\mathrm{Str}(R^{\dagger} P Q)$. Using T' and $T'^{\dagger}$, a straightforward but tedius calculation (see Appendix A) shows that

$$\begin{aligned} T'\Theta^{(i)} T'^{\dagger}(P) = {} & (\tilde{L}_i P)_+ \tilde{L}_i - \tilde{L}_i (P \tilde{L}_i)_+ + \frac{1}{n}\left[\int^x \mathrm{res}[P, \tilde{L}_i], \tilde{L}_i\right] + \frac{1}{n}\left[\left(\int^x \mathrm{sres}[P, \tilde{L}_i]\right) D, \tilde{L}_i\right] \\ & - \frac{2}{n^2}\left[\int^x \left(\left(\int^{x'} \mathrm{sres}[P, \tilde{L}_i]\right) U_{2n-3}\right), \tilde{L}_i\right] \equiv \Theta^{(i)}(P). \end{aligned} \tag{4.7}$$

That means the Hamiltonian maps $\Theta^{(A)}$ and $\Theta^{(B)}$, in terms of their own Lax operators, have the same form. Since $\Theta^{(i)}$ are canonical equivalent to the Hamiltonian map $\Omega^{(i)}$, the Poisson brackets defined by $\Theta^{(i)}$ are also antisymmetric and obey the super-Jacobi identity. As a result, $\Theta^{(A)}(\Theta^{(B)})$ can be defined as the Hamiltonian map of the generalized MR sKdV (csKP) hierarchy. A further consistent check shows that $\Theta^{(i)}$ map the Hamiltonian one-forms $\tilde{d}_i \tilde{H}_k^{(i)}$ to (pseudo-) superdifferential operators of order, at most, $2n-3$. Now we can write down the Hamiltonian flows associated with the Lax operators $\tilde{L}_i$ as

$$\frac{d\tilde{L}_i}{dt_k} = \{\tilde{H}_k^{(i)}, \tilde{L}_i\} = \Theta^{(i)}(\tilde{d}_i \tilde{H}_k^{(i)}), \tag{4.8}$$

where the Hamiltonian functionals, in view of (3.15) and (4.1), are defined by

$$\tilde{H}_k^{(i)} = -\frac{n}{k}\,\mathrm{Str}\,\tilde{L}_i^{k/n}. \tag{4.9}$$

From the Hamiltonian flows (4.8) we can read off the Poisson brackets for the coefficient functions of $\tilde{L}_i$.

In fact, for $\tilde{L}_B$, we can express the associated Poisson brackets for U_i, ϕ, and ψ more precisely. Let us rewrite $\tilde{L}_B = l + \phi D^{-1}\psi$ and denote $H = \int_B h$ as one of the Hamiltonian functionals $\tilde{H}_k^{(B)}$. Then the Hamiltonian one-form can be expressed as

$$\tilde{d}_B H = d_l H + X, \tag{4.10}$$

where X is a superdifferential operator and

$$d_l H = \sum_{k=0}^{2n-3} (-1)^k D^{-k-1} \frac{\delta h}{\delta U_k}. \tag{4.11}$$

Then, from the relation

$$\delta H=-\mathrm{Str}((\delta l+\delta\phi D^{-}\psi+\phi D^{-1}\delta\psi)(d_l H+X))=-\mathrm{Str}(\delta l d_l H)+\int_B\left(\delta\phi\frac{\delta h}{\delta\phi}+\delta\psi\frac{\delta h}{\delta\psi}\right), \tag{4.12}$$

we have the following identifications:

$$\frac{\delta h}{\delta\phi}=(X^*\psi)_0, \quad \frac{\delta h}{\delta\psi}=(X\phi)_0. \tag{4.13}$$

Inserting (4.10) with X satisfying (4.13) into the Hamiltonian map $\Theta^{(B)}$ gives

$$\begin{aligned}\frac{dl}{dt}=&(ld_lH)_+l-l(d_lHl)_++((ld_lH)_+\phi D^{-1}\psi)_+-(\phi D^{-1}\psi(d_lHl)_+)_++\left(l\frac{\delta h}{\delta\psi}D^{-1}\psi\right)_+\\&-\left(\phi D^{-1}\frac{\delta h}{\delta\phi}l\right)_++\frac{1}{n}\left[\int^x\mathrm{res}[\tilde d_BH,\tilde L_B],l\right]-\frac{2}{n}\phi\psi\int^x\mathrm{sres}[\tilde d_BH,\tilde L_B]\\&+\frac{1}{n}\left[\int^x\mathrm{sres}[\tilde d_BH,\tilde L_B],l\right]+\frac{2}{n^2}\left[\int^x\left(U_{2n-3}\int^{x'}\mathrm{sres}[\tilde d_BH,\tilde L_B]\right),l\right],\\\frac{d\phi}{dt}=&((ld_lH)_+\phi)_0+\left(l\frac{\delta h}{\delta\psi}\right)_0+\phi\left[\int^x\left(D\psi\frac{\delta h}{\delta\psi}\right)-\int^x\left(D\phi\frac{\delta h}{\delta\phi}\right)\right]+\frac{1}{n}\phi\int^x\mathrm{res}[\tilde d_BH,\tilde L_B]\\&-\frac{1}{n}(D\phi)\int^x\mathrm{sres}[\tilde d_BH,\tilde L_B]+\frac{2}{n^2}\phi\int^x\left(U_{2n-3}\int^{x'}\mathrm{sres}[\tilde d_BH,\tilde L_B]\right),\\\frac{d\psi}{dt}=&-((l^*(d_lH)^*)_+\psi)_0-\left(l^*\frac{\delta h}{\delta\phi}\right)_0+\psi\left[\int^x\left(D\phi\frac{\delta h}{\delta\phi}\right)-\int^x\left(D\psi\frac{\delta h}{\delta\psi}\right)\right]-\frac{1}{n}\psi\int^x\mathrm{res}[\tilde d_BH,\tilde L_B]\\&+\frac{1}{n}\left(D\psi\int^x\mathrm{sres}[\tilde d_BH,\tilde L_B]\right)-\frac{2}{n^2}\psi\int^x\left(U_{2n-3}\int^{x'}\mathrm{sres}[\tilde d_BH,\tilde L_B]\right),\end{aligned} \tag{4.14}$$

where

$$\begin{aligned}\mathrm{res}[\tilde d_BH,\tilde L_B]&=\mathrm{res}[d_lH,l]+(D\psi)\frac{\delta h}{\delta\psi}-\phi\left(D\frac{\delta h}{\delta\phi}\right)-\mathrm{sres}(d_lH\phi\psi)-\phi(D(d_lH)^*\psi),\\\mathrm{sres}[\tilde d_BH,\tilde L_B]&=\mathrm{sres}[d_lH,l]-\psi\frac{\delta h}{\delta\psi}+\phi\frac{\delta h}{\delta\phi}.\end{aligned} \tag{4.15}$$

Equation (4.14) can be regarded as the supersymmetric generalization of the second Hamiltonian structures of constrained KP hierarchy derived by Oevel and Strampp.[23]

V. EXAMPLES

In this section we work out a number of examples to illustrate the previous results explicitly. We write down the Poisson brackets for these systems according to the formulas given above and compare them with the known results.

A. Laberge–Mathieu super-KdV hierarchy

For $K_A=\partial^2+v_2\partial+v_1D$, the first equations in (3.1) are given by

$$\frac{d}{dt_0}\begin{pmatrix}v_1\\ v_2\end{pmatrix}=\begin{pmatrix}v_{1x}\\ v_{2x}\end{pmatrix},$$
$$\frac{d}{dt_1}\begin{pmatrix}v_1\\ v_2\end{pmatrix}=\frac{1}{4}\begin{pmatrix}(v_{1xx}+3v_1(Dv_1)-\frac{3}{2}v_1v_2^2-3v_1v_{2x})_x\\ (v_{2xx}-\frac{1}{2}v_2^3+3v_1(Dv_2))_x\end{pmatrix}, \tag{5.1}$$

which represents the first equations of the LM sKdV hierarchy. The Hamiltonian formulation for these equations is given by (3.14), where the second Poisson structure can be obtained by substituting $d_AH_k^{(A)}=-D^{-2}(\delta h_k^{(A)}/\delta v_1)+D^{-3}(\delta h_k^{(A)}/\delta v_2)$ into (3.6). We find

$$\frac{d}{dt_k}\begin{pmatrix}v_1\\ v_2\end{pmatrix}=\begin{pmatrix}-2v_1\partial-v_{1x} & -\partial^2-v_2\partial+v_1D-(Dv_1)\\ \partial^2-v_2\partial+v_1D-v_{2x} & -2D^3+(Dv_2)-2v_1\end{pmatrix}\begin{pmatrix}\dfrac{\delta h_k^{(A)}}{\delta v_1}\\ \dfrac{\delta h_k^{(A)}}{\delta v_2}\end{pmatrix}, \tag{5.2}$$

where the first Hamiltonian functionals are given by

$$H_0^{(A)}=-2\,\mathrm{Str}\,K_A^{1/2}=-\int_B v_1,$$
$$H_1^{(A)}=-\frac{2}{3}\mathrm{Str}\,K_A^{3/2}=-\frac{3}{8}\int_B\left[\frac{1}{2}v_1v_2^2+v_1v_{2x}-v_1(Dv_1)\right]. \tag{5.3}$$

To compare with the known result, we consider the change of variables as follows:

$$(v_1,v_2)\to(-(Du)-\tau,-2u), \tag{5.4}$$

then the Poisson structure in (5.2) becomes

$$\frac{1}{2}\begin{pmatrix}-D\partial+\tau & 2u\partial-(Du)D+2u_x\\ 2u\partial-(Du)D+u_x & -D\partial^2+3\tau\partial+(D\tau)D+2\tau_x\end{pmatrix}, \tag{5.5}$$

which is just the form presented in Ref. 24.

B. Super-two-boson hierarchy

For $K_B=\partial+v_0+D^{-1}v_{-1}$ the first Lax equations in (3.1) are given by

$$\frac{d}{dt_1}\begin{pmatrix}v_0\\ v_{-1}\end{pmatrix}=\begin{pmatrix}v_{0x}\\ v_{-1x}\end{pmatrix},$$
$$\frac{d}{dt_2}\begin{pmatrix}v_0\\ v_{-1}\end{pmatrix}=\begin{pmatrix}v_{0xx}+2(Dv_{-1})_x+(v_0^2)_x\\ -v_{-1xx}+2(v_0v_{-1})_x\end{pmatrix}, \tag{5.6}$$

which represents the first equations of the sTB hierarchy. The Hamiltonian description for these equations are given by (3.14), where the second Poisson structure can be obtained by substituting $d_BH_k^{(B)}=D^{-1}(\delta h_k^{(B)}/\delta v_0)+(\delta h_k^{(B)}/\delta v_{-1})$ into (3.7). It turns out that

$$\frac{d}{dt_k}\begin{pmatrix} v_0 \\ v_{-1} \end{pmatrix} = \begin{pmatrix} 2D^3+(Dv_0)+2v_{-1} & \partial^2+v_0\partial+v_{-1}D+v_{0x} \\ -\partial^2+v_0\partial+v_{-1}D-(Dv_{-1}) & 2v_{-1}\partial+v_{-1x} \end{pmatrix} \begin{pmatrix} \dfrac{\delta h_k^{(B)}}{\delta v_0} \\ \dfrac{\delta h_k^{(B)}}{\delta v_{-1}} \end{pmatrix}, \tag{5.7}$$

where the first Hamiltonian functionals are given by

$$H_1^{(B)} = -\operatorname{Str} K_B = -\int_B v_{-1},$$

$$H_2^{(B)} = -\frac{1}{2}\operatorname{Str} K_B^2 = \int_B v_0 v_{-1}. \tag{5.8}$$

Equation (5.7) provides the second Hamiltonian formulation of the sTB hierarchy.

If we make the following identification:

$$(v_0, v_{-1}) \to (-(DJ_0), J_1), \tag{5.9}$$

then the second Poisson structure in (5.7) becomes

$$\begin{pmatrix} 2D+2D^{-1}J_1D^{-1}-D^{-1}J_{0x}D^{-1} & -D^3+D(DJ_0)-D^{-1}J_1D \\ D^3+(DJ_0)D+DJ_1D^{-1} & J_1D^2+D^2J_1 \end{pmatrix}, \tag{5.10}$$

which is the form of the second Poisson structure discussed in Ref. 18.

C. Manin–Radul super-KdV hierarchy

For $\tilde{L}_A = \partial^2 - \varphi D + a$, the first Lax equations in (4.3) are given by

$$\frac{d}{dt_0}\begin{pmatrix} a \\ \varphi \end{pmatrix} = \begin{pmatrix} a_x \\ \varphi_x \end{pmatrix},$$

$$\frac{d}{dt_1}\begin{pmatrix} a \\ \varphi \end{pmatrix} = \frac{1}{4}\begin{pmatrix} \varphi_{xxx}-3(\varphi(D\varphi))_x+6(a\varphi)_x \\ a_{xxx}-3(\varphi(Da))_x+3(a^2)_x \end{pmatrix}, \tag{5.11}$$

which represents the first equations of the MP sKdV hierarchy. The Hamiltonian formulation of these equations are given by (4.8), in which the first Hamiltonian functionals are given by

$$\tilde{H}_0^{(A)} = -2\operatorname{Str}\tilde{L}_A^{1/2} = \int_B \varphi,$$

$$\tilde{H}_1^{(A)} = -\frac{2}{3}\operatorname{Str}\tilde{L}_A^{3/2} = -\frac{1}{4}\int_B [\varphi(D\varphi)-2\varphi a], \tag{5.12}$$

and the second Poisson structure can be obtained by substituting $\tilde{d}_A\tilde{H}_k^{(A)} = D^{-1}(\delta\tilde{h}_k^{(A)}/\delta a) + D^{-2}(\delta\tilde{h}_k^{(A)}/\delta\varphi)$ into (4.7). It turns out that

$$\frac{d}{dt_k}\begin{pmatrix} a \\ \varphi \end{pmatrix} = \begin{pmatrix} P_{aa} & P_{a\varphi} \\ P_{\varphi a} & P_{\varphi\varphi} \end{pmatrix} \begin{pmatrix} \dfrac{\delta\tilde{h}_k^{(A)}}{\delta a} \\ \dfrac{\delta\tilde{h}_k^{(A)}}{\delta\varphi} \end{pmatrix}, \tag{5.13}$$

where the second Poisson matrix is given by

$$
\begin{aligned}
P_{aa}=&\tfrac{1}{2}[D\partial^3-3\varphi\partial^2+4aD\partial+(2(Da)-3\varphi_x)\partial+2a_xD+3\varphi(D\varphi)+(D^3a)-4a\varphi-\varphi_{xx}\\
&+\varphi D^{-1}(Da)-(Da)D^{-1}\varphi-\varphi D^{-1}\varphi D^{-1}\varphi-\varphi D^{-1}\varphi_x+\varphi_x D^{-1}\varphi],\\
P_{\alpha\varphi}=&\tfrac{1}{2}[\partial^3-2\varphi D\partial+4a\partial-\varphi_xD+2a_x+\varphi D^{-1}(D\varphi)],\\
P_{\varphi a}=&\tfrac{1}{2}[\partial^3+2\varphi D\partial+(4a-2(D\varphi))\partial+\varphi_xD+2a_x-(D^3\varphi)+(D\varphi)D^{-1}\varphi],\\
P_{\varphi\varphi}=&\tfrac{1}{2}[4\varphi\partial+2\varphi_x].
\end{aligned}
\tag{5.14}
$$

Equation (5.13) provides the second Hamiltonian formulation of the MR sKdV hierarchy reported in Ref. 4.

Starting from the Lax operator $K_A=\partial^2+v_2\partial+v_1D$ associated with the LM sKdV hierarchy, one can perform the gauge transformation $T=\exp(-\int^x v_2/2)$[7] on the Lax operator K_A as follows:

$$
K_A\rightarrow\tilde{L}_A=e^{\int^x v_2/2}K_Ae^{-\int^x v_2/2}=\partial^2+v_1D-\left(\frac{v_2^2}{4}+\frac{v_{2x}}{2}+\frac{v_1(D^{-1}v_2)}{2}\right). \tag{5.15}
$$

Then the Lax operator $\tilde{L}_A=\partial^2-\phi D+a$ associated with the MR sKdV hierarchy is related to the Lax operator K_A as

$$
\phi=-v_1,\quad a=-\left(\frac{v_2^2}{4}+\frac{v_{2x}}{2}+\frac{v_1(D^{-1}v_2)}{2}\right), \tag{5.16}
$$

which provides the gauge equivalence between the LM sKdV hierarchy (5.1) and the MR sKdV hierarchy (5.11). Moreover, it has been shown[24] that the second Hamiltonian structure (5.5) of the LM sKdV hierarchy can be transformed to the second Hamiltonian structure (5.14) of the MR sKdV hierarchy via this gauge transformation.

D. Super-AKNS hierarchy

For $\tilde{L}_B=\partial+\phi D^{-1}\psi$, the first equations in (4.3) are given by

$$
\begin{aligned}
\frac{d}{dt_1}\begin{pmatrix}\phi\\ \psi\end{pmatrix}&=\begin{pmatrix}\phi_x\\ \psi_x\end{pmatrix},\\
\frac{d}{dt_2}\begin{pmatrix}\phi\\ \psi\end{pmatrix}&=\begin{pmatrix}\phi_{xx}+2\phi(D\phi\psi)\\ -\psi_{xx}-2\psi(D\phi\psi)\end{pmatrix},
\end{aligned}
\tag{5.17}
$$

which are the first equations in the sAKNS hierarchy. Hamiltonian formulations for these equations are given by (4.14), where the first Hamiltonian functions are given by

$$
\begin{aligned}
\tilde{H}_1^{(B)}&=-\mathrm{Str}\,\tilde{L}_B=\int_B\phi\psi,\\
\tilde{H}_2^{(B)}&=-\frac{1}{2}\mathrm{Str}\,\tilde{L}_B^2=\int_B\phi_x\psi.
\end{aligned}
\tag{5.18}
$$

From (4.14), the Hamiltonian flow can be expressed as

$$\frac{d}{dt_k}\begin{pmatrix}\phi\\ \psi\end{pmatrix}=\begin{pmatrix}P_{\phi\phi} & P_{\phi\psi}\\ P_{\psi\phi} & P_{\psi\psi}\end{pmatrix}\begin{pmatrix}\dfrac{\delta\tilde{h}_k^{(B)}}{\delta\phi}\\ \dfrac{\delta\tilde{h}_k^{(B)}}{\delta\psi}\end{pmatrix}, \tag{5.19}$$

where the Poisson brackets are given by

$$\begin{aligned}P_{\phi\phi}&=-\phi D^{-1}\phi-\phi D^{-2}\phi D-(D\phi)D^{-2}\phi-2\phi D^{-2}\phi\psi D^{-2}\phi,\\ P_{\phi\psi}&=D^2+\phi D^{-1}\psi+\phi D^{-2}(D\psi)+(D\phi)D^{-2}\psi+2\phi D^{-2}\phi\psi D^{-2}\psi,\\ P_{\psi\phi}&=D^2+\psi D^{-2}\phi D+(D\psi)D^{-2}\phi+2\psi D^{-2}\phi\psi D^{-2}\phi,\\ P_{\psi\psi}&=-(D\psi)D^{-2}\psi-\psi D^{-2}(D\psi)-2\psi D^{-2}\phi\psi D^{-2}\psi,\end{aligned} \tag{5.20}$$

which is just the second Poisson structure obtained in Ref. 5. Equation (5.19) provides the second Hamiltonian formulation of the sAKNS hierarchy.

Starting from the Lax operator $K_B=\partial+v_0+D^{-1}v_{-1}$ associated with the sTB hierarchy, one can perform the gauge transformation $T=\exp(-\int^x v_0)$[22,25] to the Lax operator K_B as follows:

$$K_B\to\tilde{L}_B=e^{\int^x v_0}K_B e^{-\int^x v_0}=\partial+e^{\int^x v_0}D^{-1}e^{-\int^x v_0}. \tag{5.21}$$

Then the Lax operator $\tilde{L}_B=\partial+\phi D^{-1}\psi$ associated with the sAKNS hierarchy is related to the Lax operator K_B as

$$\phi=e^{\int^x v_0},\quad a=v_{-1}e^{-\int^x v_0}, \tag{5.22}$$

which provides the gauge equivalence between the sTB hierarchy (5.6) and the sAKNS hierarchy (5.17). Moreover, it can be proved[25] that the second Hamiltonian structure (5.10) of the sTB hierarchy can be transformed to the second Hamiltonian structure (5.20) of the sAKNS hierarchy via this gauge transformation.

VI. CONCLUDING REMARKS

In this paper, we investigate the Hamiltonian structures associated with several supersymmetric extensions of the KdV hierarchy. Starting with the reduced super-GD bracket, the Hamiltonian structures of two nonstandard super-KdV hierarchies can be constructed via supersymmetric Miura transformations. We then perform a gauge transformation on these two nonstandard Lax hierarchies to obtain the Hamiltonian structures of the generalized MR sKdV hierarchy and constrained sKP hierarchy in a unified fashion. To compare the obtained Hamiltonian structures with the known results, we work out a few examples, including the LM sKdV, sTB, MR sKdV, and sAKNS hierarchies.

Our approach on the gauge transformation relies on the algebra of superpseudodifferential operators, which provides an effective method to achieve the goal. In fact, the gauge transformation (4.1) that maps $\Omega^{(i)}$ to $\Theta^{(i)}$ is by no means unique. There is another gauge transformation triggered by $S=D^{-1}T$[25,26] that also brings $\Omega^{(i)}$ to $\Theta^{(i)}$. Since the parity of S is odd, the gauge equivalence of the Hamiltonian maps given by (4.7) should be replaced by $S'\Omega^{(i)}S'^{\dagger}=-\Theta^{(i)}$, where the minus sign will be compensated by that induced from the transformation of the Hamiltonians such that the hierarchy flows (3.14) are transformed to (4.8).

Finally, we would like to comment briefly on the algebraic structures associated with the Poisson brackets defined by the Hamiltonian maps $\Omega^{(i)}$ and $\Theta^{(i)}$. As we shows in Eq. (3.13), the Poisson brackets defined by $\Omega^{(i)}$ are encoded by the Poisson bracket defined by J_c. However, it has been shown[12,15] that in the space of the supersymmetric Lax operator of odd order, the reduced supersymmetric GD bracket (2.12) defines an infinite series of classical $N=2W$ superalgebras, which contain $N=2$ super-Virasoro algebra as a subalgebra. Therefore, through the Miura transformation, the differential polynomials of the coefficient functions V_i of K_i can be identified as the $N=2$ supermultiplets, and Eq. (3.17) provides the free-field realizations of the corresponding W superalgebras. On the other hand, for the MR sKdV and csKP hierarchies, the Poisson algebras defined by $\Theta^{(i)}$ are not quite clear so far, even for the simplest cases. It seems not so obvious to construct the super-Virasoro generator by covariantizing the supersymmetric Lax operator $\widetilde{L}_i$ due to the fact that $U_{2n-1}=U_{2n-2}=0$. Therefore, to explore the algebraic structures associated with $\Theta^{(i)}$, the decompositions of coefficient functions U_i into primary fields remain to be worked out. Work in this direction is still in progress.

ACKNOWLEDGMENTS

APPENDIX: PROOF FOR (4.7)

To prove (4.7), let P be an arbitrary superpseudodifferential operator; then

$$T'\Omega^{(A)}T'^{\dagger}P=T'Q, \tag{A1}$$

where

$$\begin{aligned} Q\equiv\Omega^{(A)}T'^{\dagger}P=&(K_AT'^{\dagger}P)_+K_A-K_A(T'^{\dagger}PK_A)_++[K_A,(T'^{\dagger}PK_A)_0]\\ &+(-1)^{|P|}\left[\int^x D\,\mathrm{sres}[T'^{\dagger}P,K_A],K_A\right]\\ &+(-1)^{|P|}K_AD^{-1}\,\mathrm{sres}[T'^{\dagger}P,K_A]. \end{aligned}\tag{A2}$$

Using (4.6), each term in Q can be calculated as follows:

$$(1)=(TLPT^{-1})_+K_A+\frac{(-1)^{|P|+1}}{n}D\left(\int^x \mathrm{sres}[P,L]\right)K_A,$$

$$(2)=-K_A(TPLT^{-1})_++\frac{(-1)^{|P|}}{n}K_A\left(D\int^x \mathrm{sres}[P,L]\right)-\frac{1}{n}\left(\int^x \mathrm{sres}[P,L]\right)D,$$

$$(3)=[K_A,(TPLT^{-1})_0]+\frac{(-1)^{|P|+1}}{n}\left[K_A,\left(D\int^x \mathrm{sres}[P,L]\right)\right],$$

$$(4)=(5)=0,$$

which imply that

$$Q=(TLPT^{-1})_+K_A-K_A(TPLT^{-1})_++[K_A,(TPLT^{-1})_0]+\frac{1}{n}\left[\left(\int^x \mathrm{sres}[P,L]\right)D,K_A\right] \tag{A3}$$

and

$$\frac{1}{n}\int^x q_{2n-2} = \frac{1}{n}\int^x \mathrm{sres}(QD^{-2n+1})$$
$$= (TPLT^{-1})_0 + \frac{1}{n}\int^x \mathrm{res}(T[P,L]T^{-1})$$
$$+ \frac{1}{n}\int^x \left[\left(\int^{x'} \mathrm{sres}[P,L]\right)\frac{(DV_{2n-2})}{n}\right] - \frac{2}{n^2}\int^x\left[\left(\int^{x'} \mathrm{sres}[P,L]\right)V_{2n-3}\right]. \tag{A4}$$

Substituting (A3) and (A4) into (4.5), we obtain the desired result (4.7).

Since the proof for K_B is parallel to the above one, we hence omit it here.

We derive an asymptotic solution of the Einstein field equations which describes the propagation of a thin, large amplitude gravitational wave into a curved space–time. The resulting equations have the same form as the colliding plane wave equations without one of the usual constraint equations. © *1999 American Institute of Physics.* [S0022-2488(99)04306-6]

I. INTRODUCTION

Gravitational wave propagation is one of the most important features of Einstein's general theory of relativity. The Einstein field equations are highly nonlinear, and a question of fundamental interest is how nonlinearity affects the propagation of gravitational waves.

Small amplitude gravitational waves are well described by the linearized Einstein equations. Large amplitude, unidirectional gravitational plane waves are described by the exact Brinkmann–Rosen solution of the vacuum Einstein equations.[1,2] Despite the nonlinearity of the Einstein equations, a unidirectional plane wave propagates into flat space–time without distortion, and there are no dynamic nonlinear effects. Thus, one of the simplest situations in which nonlinear effects are significant is when a large amplitude gravitational wave propagates into curved space–time.

If the space–time ahead of the wave is that of a counterpropagating gravitational plane wave, then the resulting space–time has a two-parameter family of spacelike isometries, and the metric is given by the exact colliding plane wave solution of the vacuum Einstein equations.[3–6] Exact solutions do not exist for more general space–time ahead of the wave.

In this paper, we derive an asymptotic solution of the Einstein equations that describes the propagation of a thin, large-amplitude, pulselike gravitational wave into a general curved space–time. The solution applies when the metric inside the wave varies much more rapidly than the metric on either side of the wave. As a result, the wave can be approximated locally by a nonlinear plane wave, which slowly distorts as it propagates into the curved space–time. For plane-polarized waves, the asymptotic solution is given by Eqs. (3.1), (3.6), (3.7), and (3.9)–(3.11) below. For nonpolarized waves, the asymptotic solution is given by (3.1), (6.3), (6.5), and (6.8)–(6.11). The asymptotic solution satisfies the colliding plane wave equations without one of the usual constraints. The colliding plane wave equations are therefore canonical equations for nonlinear gravitational waves which describe a much larger class of solutions than the ones with exact plane-wave symmetry.

The nonlinearity of the asymptotic equations may result in the development of a space–time singularity. The mechanism of singularity formation in gravitational waves is the mutual focusing of the gravitational wave and the curved space–time into which it propagates. This mechanism differs from the nonlinear steepening of waves in quasilinear hyperbolic systems that leads to the formation of shocks. A second effect of nonlinearity is the distortion of space–time by the passage of a nonplanar gravitational wave. Moreover, the wave generates a slowly varying, backscattered gravitational wave.

Isaacson [7] and Choquet-Bruhat[8] derived a short-wave asymptotic expansion of the Einstein equations that describes the propagation of a small amplitude, oscillatory gravitational wave through a slowly varying background space–time. The mean energy density of the gravitational wave curves the background space–time, and this curvature refracts the null geodesics along which the wave propagates. Some further developments of this work are described in Ref. 9. The short-wave expansion derived here applies to large amplitude, impulsive gravitational waves, and is completely new.

In Sec. II, we summarize the exact colliding plane wave solution of the Einstein equations. In Sec. III, we give an overview of the asymptotic expansion. In Sec. IV, we write out expansions of the metric components, the connection coefficients, and the Ricci curvature components. In Sec. V, we construct a coordinate system in which the metric adopts its simplest form. In Sec. VI, we complete the derivation of the asymptotic equations. In Sec. VII, we show that the same equations follow from an expansion of the variational principle for the Einstein equations. In Sec. VIII, we explain how to derive boundary conditions for the asymptotic equations, and in Sec. IX, we consider some specific physical examples.

II. COLLIDING PLANE WAVES

The vacuum Einstein field equations imply that

$$\mathbf{Ricci}=0, \tag{2.1}$$

where **Ricci** is the Ricci tensor associated with the metric tensor **g**. The plane-polarized, colliding plane wave solution of (2.1) is given by

$$\mathbf{g}=-2e^{-M}\,du\,dv+e^{-U}(e^{V}\,dy^2+e^{-V}\,dz^2), \tag{2.2}$$

where the functions $M(u,v),U(u,v),V(u,v)$ satisfy the colliding plane wave equations,

$$U_{uv}=U_uU_v\,, \tag{2.3}$$

$$V_{uv}=\tfrac{1}{2}(U_uV_v+U_vV_u), \tag{2.4}$$

$$M_{uv}=\tfrac{1}{2}(-U_uU_v+V_uV_v), \tag{2.5}$$

$$U_{uu}=\tfrac{1}{2}(U_u^2+V_u^2)-U_uM_u\,, \tag{2.6}$$

$$U_{vv}=\tfrac{1}{2}(U_v^2+V_v^2)-U_vM_v\,. \tag{2.7}$$

Equations (2.3)–(2.5) are wave equations for M,U,V in characteristic coordinates (u,v). Equations (2.6) and (2.7) are constraints which are preserved by (2.3)–(2.5). To specify a unique solution, the wave equations can be supplemented by characteristic initial data for M,U,V on the lines $u=0$ and $v=0$, which satisfy the appropriate constraint equation.

The metric which describes the collision of nonpolarized plane waves is

$$\mathbf{g}=-2e^{-M}\,du\,dv+e^{-U}(e^{V}\cosh W\,dy^2-2\sinh W\,dy\,dz+e^{-V}\cosh W\,dz^2),$$

where the functions $M(u,v),U(u,v),V(u,v),W(u,v)$ satisfy

$$U_{uv}=U_uU_v\,, \tag{2.8}$$

$$V_{uv}=\tfrac{1}{2}(U_uV_v+U_vV_u)-(V_uW_v+V_vW_u)\tanh W, \tag{2.9}$$

$$W_{uv}=\tfrac{1}{2}(U_uW_v+U_vW_u)+V_uV_v\sinh W\cosh W, \tag{2.10}$$

$$M_{uv}=\tfrac{1}{2}(-U_uU_v+V_uV_v\cosh^2 W+W_uW_v), \tag{2.11}$$

$$U_{uu}=\tfrac{1}{2}(U_u^2+V_u^2\cosh^2 W+W_u^2)-U_uM_u, \tag{2.12}$$

$$U_{vv}=\tfrac{1}{2}(U_v^2+V_v^2\cosh^2 W+W_v^2)-U_vM_v. \tag{2.13}$$

When $W=0$, this solution reduces to the plane-polarized solution. When all functions are independent of v, the solution reduces to the exact Rosen solution for a unidirectional plane wave.

III. OVERVIEW OF THE EXPANSION

In this section, we outline the main ideas in the derivation of the asymptotic solution. For simplicity, we describe the case of plane-polarized waves. The algebraic details are given in the following sections.

We consider metrics of the form

$$\begin{gathered}\mathbf{g}=\mathbf{g}\left(\frac{u(x)}{\epsilon},x;\epsilon\right),\\ \mathbf{g}(\theta,x;\epsilon)=\overset{0}{\mathbf{g}}(\theta,x)+\epsilon\overset{1}{\mathbf{g}}(\theta,x)+O(\epsilon^2),\end{gathered} \tag{3.1}$$

where ϵ is a small parameter, and u is a scalar-valued phase function with $du\neq 0$. This ansatz corresponds to a metric that varies rapidly and strongly in the u direction. The phase u is a null function of the metric, at least up to the order ϵ. That is, it satisfies

$$\mathbf{g}^\sharp(du,du)=O(\epsilon^2), \tag{3.2}$$

where $\mathbf{g}^\sharp$ is the contravariant form of the metric tensor. The component form of this equation is written out in (4.5) below. The scaled variable

$$\theta=\frac{u}{\epsilon} \tag{3.3}$$

is a ''stretched'' coordinate inside the wave. We assume that the derivatives of $\mathbf{g}(\theta,x;\epsilon)$ with respect to θ decay to zero sufficiently quickly as $\theta\to\infty$. Thus, the solution (3.1) describes a thin, pulselike gravitational wave which is located near the null surface $u=0$. For example, if the metric is independent of θ when $|\theta|$ is sufficiently large, then the solution describes a thin ''sandwich'' wave that separates slowly varying metrics on either side.

The Ricci tensor associated with the metric (3.1) has an expansion of the form

$$\mathbf{Ricci}=\frac{1}{\epsilon^2}\overset{-2}{\mathbf{Ricci}}+\frac{1}{\epsilon}\overset{-1}{\mathbf{Ricci}}+O(1). \tag{3.4}$$

At the order ϵ^{-2}, the Einstein equations (2.1) imply that

$$\overset{-2}{\mathbf{Ricci}}=0.$$

This equation is a nonlinear, second-order ordinary differential equation in ∂_θ for the leading order term of the metric in which the ''slow'' variables x occur as parameters. We write it symbolically as

$$N(\partial_\theta^2)[\overset{0}{\mathbf{g}}]=0. \tag{3.5}$$

In suitable coordinates (u,v,y,z), a solution of this equation is the plane-polarized plane wave metric

$$\overset{0}{\mathbf{g}}=-2e^{-M}\,du\,dv+e^{-U}(e^{V}\,dy^2+e^{-V}\,dz^2), \tag{3.6}$$

where M,U,V are functions of (θ,v,y,z). For a metric of the form (3.6), Eq. (3.5) reduces to the θ-constraint equation,

$$U_{\theta\theta}=\tfrac{1}{2}(U_\theta^2+V_\theta^2)-U_\theta M_\theta. \tag{3.7}$$

At the order ϵ^{-1}, the Einstein equations imply that

$$\overset{-1}{\mathbf{Ricci}}=0.$$

This is a linear equation for $\overset{1}{\mathbf{g}}$ of the form

$$L(\partial_\theta^2)\left[\overset{1}{\mathbf{g}}\right]=F(\partial_\theta,\partial_v,\partial_y,\partial_z)\left[\overset{0}{\mathbf{g}}\right], \tag{3.8}$$

where L is a second-order linear ordinary differential operator in ∂_θ acting on $\overset{1}{\mathbf{g}}$, whose coefficients depend on $\overset{0}{\mathbf{g}}$, and F is a nonlinear partial differential operator acting on $\overset{0}{\mathbf{g}}$. The equations in (3.8) are not independent. The requirement that (3.8) can be solved for $\overset{1}{\mathbf{g}}$ implies that M, U, and V satisfy the equations

$$U_{\theta v}=U_\theta U_v, \tag{3.9}$$

$$V_{\theta v}=\tfrac{1}{2}(U_\theta V_v+U_v V_\theta), \tag{3.10}$$

$$M_{\theta v}=\tfrac{1}{2}(-U_\theta U_v+V_\theta V_v). \tag{3.11}$$

Equations (3.9)–(3.11) are identical to the evolution equations (2.8)–(2.10) for the exact colliding plane wave solution, with $\theta=u/\epsilon$. The leading order solution (3.6) satisfies the constraint equation (3.7) in the ‘‘fast’’ phase variable θ, but need not satisfy the constraint equation (2.7) in the ‘‘slow’’ variable v. If the v-constraint equation does not hold, then the asymptotic expansion of the metric contains higher order terms which are absent from the exact colliding plane wave solution.

Equation (3.6) implies that $\partial_v=-e^M\mathbf{g}^\sharp\cdot du$. Thus, ∂_v is a vector on the light cone which is tangent to the null surface $u=0$, and the ‘‘slow’’ derivative with respect to v which appears in (3.9)–(3.11) is a derivative along the bicharacteristic null geodesics associated with u. The transverse variables y and z occur as parameters. Therefore, in the short-wave limit considered here, the $(1+3)$-dimensional field equations reduce to $(1+1)$-dimensional asymptotic equations along the set of null geodesics associated with the phase u. The parametric dependence of the solution on y and z allows the pulse to be compactly supported in the transverse directions, so the wave need not have infinite extent. Moreover, the asymptotic solution need not have any special exact symmetries.

The asymptotic equations for nonpolarized gravitational waves are obtained in a similar way. They consist of the general colliding plane wave equations (2.8)–(2.12) with u replaced by θ. The v-constraint equation (2.13) is not required to hold.

Since the asymptotic equations follow from the order ϵ^{-2} and order ϵ^{-1} components of the field equations, the asymptotic solution remains valid in the presence of matter with a slowly varying, order one energy–momentum tensor, $\mathbf{T}=\mathbf{T}(x)$.

One subtle point in carrying out the expansion concerns the choice of the phase function u. In order for (3.5) to have a nontrivial solution, the phase u must be a null function of the leading order metric, but u need not be a null function of the entire metric. However, it follows from the analysis in Sec. V that we can use a transformation of the form

$$u \to \epsilon \Psi\left(\frac{u}{\epsilon}, x; \epsilon\right) \tag{3.12}$$

to choose a phase which satisfies (3.2). The asymptotic solutions obtained with the use of the old and the new phases can be shown to be equivalent. When the phase satisfies (3.2), variations in the metric propagate along the null geodesics associated with the phase, and the asymptotic equations adopt their simplest form.

IV. EXPANSION OF THE METRIC AND THE CURVATURE

In this section, we write out expansions of the metric components, the connection coefficients, and the Ricci curvature components.

We use local coordinates x^α in which

$$\mathbf{g} = g_{\alpha\beta}\, dx^\alpha\, dx^\beta. \tag{4.1}$$

Here and below, Greek indices $\alpha,\beta,\mu,\nu,\ldots$ take on the values 0,1,2,3. We look for an expansion of the metric components as $\epsilon \to 0$ of the form

$$\begin{gathered} g_{\alpha\beta} = g_{\alpha\beta}\left(\frac{u(x)}{\epsilon}, x; \epsilon\right), \\ g_{\alpha\beta}(\theta,x;\epsilon) = \overset{0}{g}_{\alpha\beta}(\theta,x) + \epsilon \overset{1}{g}_{\alpha\beta}(\theta,x) + O(\epsilon^2). \end{gathered} \tag{4.2}$$

The contravariant metric components $g^{\alpha\beta}$ satisfy

$$g^{\alpha\mu} g_{\mu\beta} = \delta^\alpha_\beta.$$

Expansion of this equation in a power series in ϵ gives

$$g^{\alpha\beta} = \overset{0}{g}{}^{\alpha\beta} - \epsilon \overset{1}{g}{}^{\alpha\beta} + O(\epsilon^2). \tag{4.3}$$

In (4.3), $\overset{0}{g}{}^{\alpha\beta}$ is the inverse of $\overset{0}{g}_{\alpha\beta}$, and we use the leading order metric components to raise indices, so that

$$\overset{1}{g}{}^{\alpha\beta} = \overset{0}{g}{}^{\alpha\mu} \overset{0}{g}{}^{\beta\nu} \overset{1}{g}_{\mu\nu}. \tag{4.4}$$

With this notation, the order ϵ term in the expansion of the contravariant metric component $g^{\alpha\beta}$ is $-\overset{1}{g}{}^{\alpha\beta}$, not $\overset{1}{g}{}^{\alpha\beta}$.

In terms of the metric components, we have

$$\mathbf{g}^\sharp(du,du) = g^{\alpha\beta} \frac{\partial u}{\partial x^\alpha} \frac{\partial u}{\partial x^\beta} = \overset{0}{g}{}^{\alpha\beta} \frac{\partial u}{\partial x^\alpha} \frac{\partial u}{\partial x^\beta} - \epsilon \overset{1}{g}{}^{\alpha\beta} \frac{\partial u}{\partial x^\alpha} \frac{\partial u}{\partial x^\beta} + O(\epsilon^2). \tag{4.5}$$

Thus, the null condition (3.2) holds provided that

$$\overset{0}{g}{}^{\alpha\beta} \frac{\partial u}{\partial x^\alpha} \frac{\partial u}{\partial x^\beta} = 0, \quad \overset{1}{g}{}^{\alpha\beta} \frac{\partial u}{\partial x^\alpha} \frac{\partial u}{\partial x^\beta} = 0. \tag{4.6}$$

The first condition in (4.6) states that u is a null function of $\overset{0}{\mathbf{g}}$. The second condition is required in order for the phase to be a null function of the perturbed metric up to the order ϵ.

The Ricci tensor components $R_{\alpha\beta}$ are given by

$$R_{\alpha\beta}=\frac{\partial\Gamma^{\lambda}{}_{\alpha\beta}}{\partial x^{\lambda}}-\frac{\partial\Gamma^{\lambda}{}_{\beta\lambda}}{\partial x^{\alpha}}+\Gamma^{\lambda}{}_{\alpha\beta}\Gamma^{\mu}{}_{\lambda\mu}-\Gamma^{\mu}{}_{\alpha\lambda}\Gamma^{\lambda}{}_{\beta\mu}, \tag{4.7}$$

where $\Gamma^{\lambda}{}_{\alpha\beta}$ are the connection coefficients

$$\Gamma^{\lambda}{}_{\alpha\beta}=\frac{1}{2}g^{\lambda\mu}\left(\frac{\partial g_{\beta\mu}}{\partial x^{\alpha}}+\frac{\partial g_{\alpha\mu}}{\partial x^{\beta}}-\frac{\partial g_{\alpha\beta}}{\partial x^{\mu}}\right). \tag{4.8}$$

From (3.3), the derivative of a function $f_{\alpha\beta}(\theta,x)$, with respect to x^{μ} is given by

$$\frac{\partial f_{\alpha\beta}}{\partial x^{\mu}}=\frac{1}{\epsilon}f_{\alpha\beta,\theta}u_{\mu}+f_{\alpha\beta,\mu}, \tag{4.9}$$

where

$$u_{\mu}=\frac{\partial u}{\partial x^{\mu}},\quad f_{\alpha\beta,\theta}=\left.\frac{\partial f_{\alpha\beta}}{\partial\theta}\right|_{x},\quad f_{\alpha\beta,\mu}=\left.\frac{\partial f_{\alpha\beta}}{\partial x^{\mu}}\right|_{\theta}.$$

We use (4.2), (4.3), and (4.9) in (4.7) and (4.8) and expand the result with respect to ϵ. After some algebra, we find that

$$\begin{aligned}\Gamma^{\lambda}{}_{\alpha\beta}&=\frac{1}{\epsilon}\overset{-1}{\Gamma}{}^{\lambda}{}_{\alpha\beta}+\overset{0}{\Gamma}{}^{\lambda}{}_{\alpha\beta}+O(\epsilon),\\ R_{\alpha\beta}&=\frac{1}{\epsilon^{2}}\overset{-2}{R}{}_{\alpha\beta}+\frac{1}{\epsilon}\overset{-1}{R}{}_{\alpha\beta}+O(1),\end{aligned} \tag{4.10}$$

where

$$\begin{aligned}\overset{-1}{\Gamma}{}^{\lambda}{}_{\alpha\beta}&=\tfrac{1}{2}\overset{0}{g}{}^{\lambda\mu}(\overset{0}{g}{}_{\beta\mu,\theta}u_{\alpha}+\overset{0}{g}{}_{\alpha\mu,\theta}u_{\beta}-\overset{0}{g}{}_{\alpha\beta,\theta}u_{\mu}),\\ \overset{0}{\Gamma}{}^{\lambda}{}_{\alpha\beta}&=\tfrac{1}{2}\overset{0}{g}{}^{\lambda\mu}(\overset{0}{g}{}_{\beta\mu,\alpha}+\overset{0}{g}{}_{\alpha\mu,\beta}-\overset{0}{g}{}_{\alpha\beta,\mu})+\tfrac{1}{2}\overset{0}{g}{}^{\lambda\mu}(\overset{1}{g}{}_{\beta\mu,\theta}u_{\alpha}+\overset{1}{g}{}_{\alpha\mu,\theta}u_{\beta}-\overset{1}{g}{}_{\alpha,\beta,\theta}u_{\mu})\\ &\quad-\tfrac{1}{2}\overset{1}{g}{}^{\lambda\mu}(\overset{0}{g}{}_{\beta\mu,\theta}u_{\alpha}+\overset{0}{g}{}_{\alpha\mu,\theta}u_{\beta}-\overset{0}{g}{}_{\alpha\beta,\theta}u_{\mu}),\\ \overset{-2}{R}{}_{\alpha\beta}&=\overset{-1}{\Gamma}{}^{\mu}{}_{\alpha\beta,\theta}u_{\mu}-\overset{-1}{\Gamma}{}^{\mu}{}_{\beta\mu,\theta}u_{\alpha}+\overset{-1}{\Gamma}{}^{\mu}{}_{\alpha\beta}\overset{-1}{\Gamma}{}^{\nu}{}_{\mu\nu}-\overset{-1}{\Gamma}{}^{\mu}{}_{\alpha\nu}\overset{-1}{\Gamma}{}^{\nu}{}_{\beta\mu},\\ \overset{-1}{R}{}_{\alpha\beta}&=\overset{-1}{\Gamma}{}^{\mu}{}_{\alpha\beta,\mu}-\overset{-1}{\Gamma}{}^{\mu}{}_{\beta\mu,\alpha}+\overset{0}{\Gamma}{}^{\mu}{}_{\alpha\beta,\theta}u_{\mu}-\overset{0}{\Gamma}{}^{\mu}{}_{\beta\mu,\theta}u_{\alpha}+\overset{-1}{\Gamma}{}^{\mu}{}_{\alpha\beta}\overset{0}{\Gamma}{}^{\nu}{}_{\mu\nu}\\ &\quad+\overset{0}{\Gamma}{}^{\mu}{}_{\alpha\beta}\overset{-1}{\Gamma}{}^{\nu}{}_{\mu\nu}-\overset{-1}{\Gamma}{}^{\mu}{}_{\alpha\nu}\overset{0}{\Gamma}{}^{\nu}{}_{\beta\mu}-\overset{0}{\Gamma}{}^{\mu}{}_{\alpha\nu}\overset{-1}{\Gamma}{}^{\nu}{}_{\beta\mu}.\end{aligned} \tag{4.11}$$

The component form of the field equations (2.1) is

$$R_{\alpha\beta}=0. \tag{4.12}$$

Using (4.10) in (4.12) and equating coefficients of ϵ^{-2} and ϵ^{-1} to zero, we get that

$$\overset{-2}{R}{}_{\alpha\beta}=0, \tag{4.13}$$

$$\overset{-1}{R}{}_{\alpha\beta}=0. \tag{4.14}$$

In order to solve these equations, we first use a coordinate transformation to simplify the form of the metric.

V. COORDINATE TRANSFORMATIONS

In this section, we show that there is a choice of a local coordinate system x^α in which $u = x^0$ and the metric has the form

$$\mathbf{g} = 2\overset{0}{g}_{01}\, dx^0\, dx^1 + \overset{0}{g}_{ab}\, dx^a\, dx^b + \epsilon\{2\overset{1}{g}_{1a}\, dx^1\, dx^a + \overset{1}{g}_{ab}\, dx^a\, dx^b\} + O(\epsilon^2). \tag{5.1}$$

Here and below, indices $a,b,c,\ldots$ take on the values 2,3, while indices $i,j,k,\ldots$ take on the values 1,2,3.

The corresponding expansion of the contravariant form of the metric tensor is

$$\mathbf{g}^\sharp = 2\overset{0}{g}{}^{01}\partial_0\partial_1 + \overset{0}{g}{}^{ab}\partial_a\partial_b - \epsilon\{2\overset{0}{g}{}^{01}\overset{0}{g}{}^{ab}\overset{1}{g}_{1b}\partial_0\partial_a + \overset{0}{g}{}^{ac}\overset{0}{g}{}^{bd}\overset{1}{g}_{cd}\partial_a\partial_b\} + O(\epsilon^2). \tag{5.2}$$

For this metric, we have

$$\overset{0}{g}{}^{00} = 0, \quad \overset{1}{g}{}^{00} = 0. \tag{5.3}$$

Thus, the phase $u = x^0$ satisfies (4.6), and hence (3.2).

The most general coordinate transformation which is compatible with an expansion of the form (4.2) is

$$\frac{x^0}{\epsilon} \to \overset{1}{\Psi}{}^0\left(\frac{x^0}{\epsilon}, x\right) + \epsilon\overset{2}{\Psi}{}^0\left(\frac{x^0}{\epsilon}, x\right) + O(\epsilon^2), \tag{5.4}$$

$$x^i \to \overset{0}{\Psi}{}^i(x) + \epsilon\overset{1}{\Psi}{}^i\left(\frac{x^0}{\epsilon}, x\right) + \epsilon^2\overset{2}{\Psi}{}^i\left(\frac{x^0}{\epsilon}, x\right) + O(\epsilon^3). \tag{5.5}$$

Here, we suppose that the phase is given by $u = x^0$ in both the old and the new coordinates. Thus, the change of coordinates (5.4) implies a change in the phase of the form (3.12).

First, we simplify the leading order metric components by means of a transformation

$$x^0 \to x^0, \quad x^i \to x^i + \epsilon\overset{1}{\Psi}{}^i\left(\frac{x^0}{\epsilon}, x\right). \tag{5.6}$$

Expansion of the transformation law for the change in covariant tensor components implies that the leading order metric components transform under (5.6) according to

$$\overset{0}{g}_{00} \to \overset{0}{g}_{00} + 2\overset{1}{\Psi}{}^k_{,\theta}\overset{0}{g}_{0k} + \overset{1}{\Psi}{}^k_{,\theta}\overset{1}{\Psi}{}^l_{,\theta}\overset{0}{g}_{kl}, \tag{5.7}$$

$$\overset{0}{g}_{0i} \to \overset{0}{g}_{0i} + \overset{1}{\Psi}{}^k_{,\theta}\overset{0}{g}_{ki}, \tag{5.8}$$

$$\overset{0}{g}_{ij} \to \overset{0}{g}_{ij}. \tag{5.9}$$

If the matrix $\overset{0}{g}_{ij}$ is nonsingular, then (5.8) implies that we can transform $\overset{0}{g}_{0i}$ to zero. This contradicts the requirement that x^0 is null (cf. Ref. 2, Sec. 109). Hence, we must have

$$\det \overset{0}{g}_{ij} = 0. \tag{5.10}$$

By an appropriate renumbering of the i coordinates, we can suppose without loss of generality that

$$\det \overset{0}{g}_{ab} \neq 0. \tag{5.11}$$

From (5.7) and (5.8), we can then choose the transformation (5.6) so that

$$\overset{0}{g}_{00} = \overset{0}{g}_{02} = \overset{0}{g}_{03} = 0. \tag{5.12}$$

Solving Eq. (5.10) for $\overset{0}{g}_{11}$, we get

$$\overset{0}{g}_{11} = \overset{0}{g}{}^{ab} \overset{0}{g}_{1a} \overset{0}{g}_{1b}, \tag{5.13}$$

where $\overset{0}{g}{}^{ab}$ is the inverse of $\overset{0}{g}_{ab}$. We define

$$g^a = \overset{0}{g}{}^{ab} \overset{0}{g}_{1b}. \tag{5.14}$$

From (5.13) and (5.14), it follows that

$$\overset{0}{g}_{11} = \overset{0}{g}_{cd} g^c g^d, \quad \overset{0}{g}_{1a} = \overset{0}{g}_{ac} g^c. \tag{5.15}$$

Using (5.12)–(5.15) in (4.1), we find that, in the transformed coordinate system, the metric is

$$\mathbf{g} = 2\overset{0}{g}_{01}\, dx^0\, dx^1 + \overset{0}{g}_{ab} (dx^a + g^a\, dx^1)(dx^b + g^b\, dx^1) + O(\epsilon). \tag{5.16}$$

From (4.13), the metric (5.16) satisfies the condition

$$\overset{-2}{R}_{ab} = 0. \tag{5.17}$$

Using (5.16) in (4.11), we find that

$$\overset{-2}{R}_{ab} = -\tfrac{1}{2} (\overset{0}{g}{}^{01})^2 \overset{0}{g}_{ac} g^c_{,\theta} \overset{0}{g}_{bd} g^d_{,\theta}. \tag{5.18}$$

Equations (5.17) and (5.18) imply that

$$g^a_{,\theta} = 0,$$

so g^a is independent of θ. This fact allows us to remove g^a by a transformation

$$x^a \to \Psi^a(x^1, x^c). \tag{5.19}$$

The form of the metric (5.16) is unchanged by (5.19), and

$$\begin{gathered} \overset{0}{g}_{ab} \to \Psi^c_{,a} \Psi^d_{,b} \overset{0}{g}_{cd}, \\ g^a \to (A^{-1})^a_c (g^c + \Psi^c_{,1}), \end{gathered} \tag{5.20}$$

where $(A^a_c) = (\Psi^a_{,c})$. From (5.20), we can set $g^a = 0$. The metric (5.16) then reduces to

$$\mathbf{g} = 2\overset{0}{g}_{01}\, dx^0\, dx^1 + \overset{0}{g}_{ab}\, dx^a\, dx^b + O(\epsilon). \tag{5.21}$$

Next, we simplify the form of $\overset{1}{\mathbf{g}}$. We consider the transformation of coordinates

$$x^0 \to \epsilon \overset{1}{\Psi}{}^0\left(\frac{x^0}{\epsilon}, x\right) + \epsilon^2 \overset{2}{\Psi}{}^0\left(\frac{x^0}{\epsilon}, x\right), \quad x^i \to x^i + \epsilon^2 \overset{2}{\Psi}{}^i\left(\frac{x^0}{\epsilon}, x\right). \tag{5.22}$$

Under the action of (5.22), the form (5.21) of the metric is unchanged at order zero and

$$\overset{0}{g}_{01}\to\overset{1}{\Psi}{}^0_{,\theta}\overset{0}{g}_{01}.$$

At order one, the components transform according to

$$\overset{1}{g}_{00}\to\overset{1}{\Psi}{}^0_{,\theta}(\overset{1}{\Psi}{}^0_{,\theta}\overset{1}{g}_{00}+2\overset{2}{\Psi}{}^1_{,\theta}\overset{0}{g}_{01}),$$

$$\overset{1}{g}_{01}\to\overset{1}{\Psi}{}^0_{,\theta}\overset{1}{g}_{01}+(\overset{1}{\Psi}{}^0_{,0}+\overset{2}{\Psi}{}^0_{,\theta})\overset{0}{g}_{01},$$

$$\overset{1}{g}_{0a}\to\overset{1}{\Psi}{}^0_{,\theta}\overset{1}{g}_{0a}+\overset{2}{\Psi}{}^b_{,\theta}\overset{0}{g}_{ab},$$

$$\overset{1}{g}_{11}\to\overset{1}{g}_{11}+2\overset{1}{\Psi}{}^0_{,1}\overset{0}{g}_{01},$$

$$\overset{1}{g}_{1a}\to\overset{1}{g}_{1a}+\overset{1}{\Psi}{}^0_{,a}\overset{0}{g}_{01},$$

$$\overset{1}{g}_{ab}\to\overset{1}{g}_{ab}.$$

These transformations can be used to make

$$\overset{1}{g}_{11}=\overset{1}{g}_{0\alpha}=0. \tag{5.23}$$

The resulting metric then has the form given in (5.1).

Use of (5.1) and (5.2) in (4.11) implies that the nonzero connection coefficients at the orders ϵ^{-1} and ϵ^0 are

$$\overset{-1}{\Gamma}{}^0{}_{00}=\overset{0}{g}{}^{01}\overset{0}{g}_{01,\theta},\quad \overset{-1}{\Gamma}{}^1{}_{ab}=-\tfrac12\overset{0}{g}{}^{01}\overset{0}{g}_{ab,\theta},\quad \overset{-1}{\Gamma}{}^a{}_{0b}=\tfrac12\overset{0}{g}{}^{ac}\overset{0}{g}_{bc,\theta},$$

$$\overset{0}{\Gamma}{}^0{}_{00}=\overset{0}{g}{}^{01}\overset{0}{g}_{01,0},\quad \overset{0}{\Gamma}{}^0{}_{0a}=\tfrac12\overset{0}{g}{}^{01}(\overset{0}{g}_{01,a}+\overset{1}{g}_{1a,\theta})-\tfrac12\overset{1}{g}{}^{0b}\overset{0}{g}_{ab,\theta},$$

$$\overset{0}{\Gamma}{}^0{}_{ab}=-\tfrac12\overset{0}{g}{}^{01}\overset{0}{g}_{ab,1},\quad \overset{0}{\Gamma}{}^1{}_{11}=\overset{0}{g}{}^{01}\overset{0}{g}_{01,1},\quad \overset{0}{\Gamma}{}^1{}_{1a}=\tfrac12\overset{0}{g}{}^{01}(\overset{0}{g}_{01,a}-\overset{1}{g}_{1a,\theta}),$$

$$\overset{0}{\Gamma}{}^1{}_{ab}=-\tfrac12\overset{0}{g}{}^{01}(\overset{0}{g}_{ab,0}+\overset{1}{g}_{ab,\theta}),\quad \overset{0}{\Gamma}{}^a{}_{01}=-\tfrac12\overset{0}{g}{}^{ac}(\overset{0}{g}_{01,c}-\overset{1}{g}_{1c,\theta}),$$

$$\overset{0}{\Gamma}{}^a{}_{0b}=\tfrac12\overset{0}{g}{}^{ac}(\overset{0}{g}_{bc,0}+\overset{1}{g}_{bc,\theta})-\tfrac12\overset{1}{g}{}^{ac}\overset{0}{g}_{bc,\theta},$$

$$\overset{0}{\Gamma}{}^a{}_{1b}=\tfrac12\overset{0}{g}{}^{ac}\overset{0}{g}_{bc,1},\quad \overset{0}{\Gamma}{}^a{}_{bc}=\tfrac12\overset{0}{g}{}^{ad}(\overset{0}{g}_{bd,c}+\overset{0}{g}_{cd,b}-\overset{0}{g}_{bc,d})+\tfrac12\overset{1}{g}{}^{0a}\overset{0}{g}_{bc,\theta}.$$

The nonzero components of the Ricci curvature at the orders ϵ^{-2} and ϵ^{-1} are

$$\overset{-2}{R}_{00}=-\tfrac12(\overset{0}{g}{}^{ab}\overset{0}{g}_{ab,\theta})_{,\theta}-\tfrac14\overset{0}{g}{}^{ac}\overset{0}{g}_{bc,\theta}\overset{0}{g}{}^{bd}\overset{0}{g}_{ad,\theta}+\tfrac12\overset{0}{g}{}^{01}\overset{0}{g}_{01,\theta}\overset{0}{g}{}^{ab}\overset{0}{g}_{ab,\theta}, \tag{5.24}$$

$$\overset{-1}{R}_{01}=-(\overset{0}{g}{}^{01}\overset{0}{g}_{01,1})_{\theta}-\tfrac12(\overset{0}{g}{}^{ab}\overset{0}{g}_{ab,1})_{\theta}-\tfrac14\overset{0}{g}{}^{ac}\overset{0}{g}_{bc,\theta}\overset{0}{g}{}^{bd}\overset{0}{g}_{ad,1}, \tag{5.25}$$

$$\overset{-1}{R}_{ab}=-\overset{0}{g}{}^{01}(\overset{0}{g}_{ab,1\theta}-\tfrac12\overset{0}{g}{}^{cd}(\overset{0}{g}_{ac,\theta}\overset{0}{g}_{bd,1}+\overset{0}{g}_{ac,1}\overset{0}{g}_{bd,\theta})+\tfrac14\overset{0}{g}{}^{cd}(\overset{0}{g}_{cd,1}\overset{0}{g}_{ab,\theta}+\overset{0}{g}_{cd,\theta}\overset{0}{g}_{ab,1})), \tag{5.26}$$

$$\begin{aligned}\overset{-1}{R}_{00} = &-\tfrac{1}{2}\overset{1}{g}{}^{a}_{a,\theta\theta} - \tfrac{1}{2}\overset{0}{g}{}^{ac}\overset{0}{g}_{bc,\theta}\overset{1}{g}{}^{b}_{a,\theta} + \tfrac{1}{2}\overset{0}{g}{}^{01}\overset{0}{g}_{01,\theta}\overset{1}{g}{}^{a}_{a,\theta} - (\overset{0}{g}{}^{ab}\overset{0}{g}_{ab,\theta})_0 \\ &- \tfrac{1}{2}\overset{0}{g}{}^{ac}\overset{0}{g}_{bc,\theta}\overset{0}{g}{}^{bd}\overset{0}{g}_{ad,0} + \tfrac{1}{2}\overset{0}{g}{}^{01}\overset{0}{g}{}^{ab}(\overset{0}{g}_{01,\theta}\overset{0}{g}_{ab,0} + \overset{0}{g}_{01,0}\overset{0}{g}_{ab,\theta}),\end{aligned} \tag{5.27}$$

$$\begin{aligned}\overset{-1}{R}_{0a} = &\tfrac{1}{2}(\overset{0}{g}_{ab}\overset{0}{g}{}^{01}(\overset{0}{g}_{01}\overset{1}{g}{}^{0b})_\theta)_\theta + \tfrac{1}{4}\overset{0}{g}{}^{cd}\overset{0}{g}_{cd,\theta}\overset{0}{g}_{ab}\overset{0}{g}{}^{01}(\overset{0}{g}_{01}\overset{1}{g}{}^{0b})_\theta \\ &- \tfrac{1}{2}(\overset{0}{g}{}^{01}\overset{0}{g}_{01,a} + \overset{0}{g}{}^{cd}\overset{0}{g}_{cd,a})_\theta + \tfrac{1}{2}(\overset{0}{g}{}^{bc}\overset{0}{g}_{ab,\theta})_c + \tfrac{1}{4}\overset{0}{g}{}^{bc}\overset{0}{g}_{ab,\theta}\overset{0}{g}{}^{de}\overset{0}{g}_{de,c} + \tfrac{1}{4}\overset{0}{g}{}^{01}\overset{0}{g}_{01,a}\overset{0}{g}{}^{cd}\overset{0}{g}_{cd,\theta} \\ &- \tfrac{1}{4}\overset{0}{g}{}^{bd}\overset{0}{g}_{cd,\theta}\overset{0}{g}{}^{ce}\overset{0}{g}_{be,a}.\end{aligned} \tag{5.28}$$

VI. THE ASYMPTOTIC EXPANSION

We choose coordinates

$$(x^0,x^1,x^2,x^3) = (u,v,y,z) \tag{6.1}$$

in which the metric has the form (5.1). We introduce functions M,U,V,W of (θ,v,y,z) such that

$$\begin{aligned}\overset{0}{g}_{01} &= -e^{-M}, \\ (\overset{0}{g}_{ab}) &= \begin{pmatrix} e^{-U+V}\cosh W & -e^{-U}\sinh W \\ -e^{-U}\sinh W & e^{-U-V}\cosh W \end{pmatrix}.\end{aligned} \tag{6.2}$$

It follows from (5.1), (6.1), and (6.2) that the leading order metric has the form of the colliding plane wave metric,

$$\overset{0}{\mathbf{g}} = -2e^{-M}\,du\,dv + e^{-U}(e^{V}\cosh W\,dy^2 - 2\sinh W\,\mathrm{dy}\,dz + e^{-V}\cosh W\,dz^2). \tag{6.3}$$

From (5.24), the only component of the leading order perturbation equation (4.13) which is not identically satisfied is

$$\overset{-2}{R}_{00} = 0. \tag{6.4}$$

Using (5.24) and (6.2) in (6.4), we obtain the θ-constraint equation,

$$U_{\theta\theta} = \tfrac{1}{2}(U_\theta^2 + V_\theta^2\cosh^2 W + W_\theta^2) - U_\theta M_\theta. \tag{6.5}$$

From (5.25) to (5.28), the only components of the first-order perturbation equation (4.14) which are not identically satisfied are

$$\overset{-1}{R}_{01} = 0, \quad \overset{-1}{R}_{ab} = 0, \tag{6.6}$$

$$\overset{-1}{R}_{00} = 0, \quad \overset{-1}{R}_{0a} = 0. \tag{6.7}$$

Using (5.25)–(5.26) and (6.2) in (6.6), we get the evolution equations in the colliding plane wave equations,

$$U_{\theta v} = U_\theta U_v, \tag{6.8}$$

$$V_{\theta v} = \tfrac{1}{2}(U_\theta V_v + U_v V_\theta) - (V_\theta W_v + V_v W_\theta)\tanh W, \tag{6.9}$$

$$W_{\theta v} = \tfrac{1}{2}(U_\theta W_v + U_v W_\theta) + V_\theta V_v \sinh W \cosh W. \tag{6.10}$$

$$M_{\theta v}=\tfrac{1}{2}(-U_\theta U_v+V_\theta V_v\cosh^2 W+W_\theta W_v). \tag{6.11}$$

From (5.2) and (5.27)–(5.28), we find that the remaining equations (6.7) are satisfied by a suitable choice of the first-order metric components $\overset{1}{g}_{ab},\overset{1}{g}_{1a}$.

VII. VARIATIONAL PRINCIPLE

The variational principle for the vacuum Einstein field equations is

$$\delta S=0,\quad S=\int L\,d^4x,$$
$$L=R\sqrt{-\det g}, \tag{7.1}$$

where R is the scalar curvature,

$$R=g^{\alpha\beta}R_{\alpha\beta}.$$

Using (4.2), (4.3), and (4.10) to expand the scalar curvature, we obtain that

$$R=\frac{1}{\epsilon^2}\overset{-2}{R}+\frac{1}{\epsilon}\overset{-1}{R}+O(1),$$
$$\overset{-2}{R}=\overset{0}{g}{}^{\alpha\beta}\overset{-2}{R}_{\alpha\beta}, \tag{7.2}$$
$$\overset{-1}{R}=\overset{0}{g}{}^{\alpha\beta}\overset{-1}{R}_{\alpha\beta}-\overset{1}{g}{}^{\alpha\beta}\overset{-2}{R}_{\alpha\beta}.$$

For a metric of the form (5.21), we find that

$$\overset{-2}{R}=0,$$
$$\overset{-1}{R}=\overset{0}{g}{}^{ab}\overset{-1}{R}_{ab}+2\overset{0}{g}{}^{01}\overset{-1}{R}_{01}-\overset{1}{g}{}^{00}\overset{-2}{R}_{00}. \tag{7.3}$$

The only order one metric component which appears in (7.3) is

$$\lambda=-\overset{1}{g}{}^{00}.$$

In the derivation of the asymptotic equations, we used a coordinate system in which $\lambda=0$—see (5.3). In the variational principle, λ acts as a Lagrange multiplier for the constraint equation, so we will not set it to zero until after we take variations.

We use (7.3) in (7.1), expand the result with respect to ϵ, and write the expanded Lagrangian in terms of λ and the functions M,U,V,W, defined in (6.2). This gives

$$L=\frac{1}{\epsilon}\overset{-1}{L}+O(1),$$

$$\overset{-1}{L}=\{-2M_{\theta v}-4U_{\theta v}+3U_\theta U_v+V_\theta V_v\cosh^2 W+W_\theta W_v\}e^{-U}$$
$$+\lambda\{U_{\theta\theta}-\tfrac{1}{2}(U_\theta^2+V_\theta^2\cosh^2 W+W_\theta^2)+U_\theta M_\theta\}e^{-M-U}.$$

We make a change of variables in the integration,

$$d^4x=du\,dv\,dy\,dz=\epsilon\,d\theta\,dv\,dy\,dz,$$

and omit the integration with respect to the parametric variables (y,z). The leading order asymptotic variational principle then becomes

$$\delta \overset{0}{S}=0, \quad \overset{0}{S}=\int \overset{-1}{L}\, d\theta\, dv.$$

Variations of $\overset{0}{S}$ with respect to the first-order metric component λ give the constraint (6.5). Variations with respect to M,U,V,W give the evolution equations (6.8)–(6.11), after we set $\lambda=0$. It is permissible to set $\lambda=0$ because the constraint is a gauge-type constraint which is preserved by the evolution equations.

VIII. BOUNDARY CONDITIONS

In this section, we discuss the derivation of boundary conditions for the asymptotic equations. For simplicity, we consider a ''sandwich'' wave located near the null surface $u=0$ that varies rapidly in a thin strip

$$\theta_- \leqslant \frac{u}{\epsilon} \leqslant \theta_+ .$$

We denote the slowly varying metrics on either side of the wave by

$$\mathbf{g}=\begin{cases} \mathbf{g}_+ & \text{in } u>0 \\ \mathbf{g}_- & \text{in } u<0. \end{cases} \tag{8.1}$$

We consider a coordinate patch around a point on the surface $u=0$ with local coordinates (u,v,y,z) chosen as in the derivation of the asymptotic equations. In order for the metric outside the wave to join continuously with the metric inside, we must have

$$\mathbf{g}_\pm \rightarrow -2e^{-M_\pm}\, du\, dv + e^{-U_\pm}(e^{V_\pm}\cosh W_\pm\, dy^2 - 2\sinh W_\pm\, dy\, dz + e^{-V_\pm}\cosh W_\pm\, dz^2), \tag{8.2}$$

as $u \rightarrow 0^\pm$, where $M_\pm, U_\pm, V_\pm, W_\pm$ are functions of (v,y,z). From (6.3), (8.2), and the continuity of the metric, it follows that the solution of (6.8)–(6.11) satisfies the characteristic boundary conditions,

$$M=M_\pm, \quad U=U_\pm, \quad V=V_\pm, \quad W=W_\pm \quad \text{when} \;\; \theta=\theta_\pm . \tag{8.3}$$

This data need not satisfy the constraint (2.13).

The asymptotic equations must be supplemented by a condition which specifies the profile of the wave. For example, we can impose a characteristic initial condition

$$M=M_0, \quad U=U_0, \quad V=V_0, \quad W=W_0 \quad \text{when} \;\; v=0, \tag{8.4}$$

where M_0, U_0, V_0, W_0 are functions of (θ,y,z) which satisfy the constraint (6.5). The characteristic initial data must be compatible with the characteristic boundary data, meaning that

$$M_0(\theta_\pm, y,z)=M_\pm(0,y,z),$$

together with the analogous conditions for the other variables.

Equations (6.8)–(6.11), the characteristic initial condition (8.4) on $v=0$, and the characteristic boundary condition (8.3) on $\theta=\theta_-$ form a well-posed problem. Provided that singularities do not form, the problem has a unique solution, so the solution at $\theta=\theta_+$ is uniquely determined. Thus, in principle, the asymptotic equations (6.8)–(6.11) and the characteristic initial data (8.4) determine a set of jump relations that connect the minus and plus metrics ahead of and behind the wave, respectively. If the metric ahead of the wave is known, then the jump conditions provide characteristic boundary conditions on $u=0$ for the space–time behind the wave. Together with a characteristic initial condition on $v=0$ and $u>0$, for example, this gives a characteristic initial value problem[10] for the full field equations. This problem determines the slowly varying metric behind the wave, at least locally. The solution of this problem typically includes a slowly varying gravitational wave component which propagates in the opposite direction into the space–time behind the rapidly varying ''sandwich'' wave.

For instance, in the case of a plane polarized wave, the solution of (3.9) for U is[6]

$$U(\theta,v)=-\log[f(\theta)+g(v)]. \tag{8.5}$$

Here f and g are functions of integration, and we do not explicitly show the parametric dependence of the functions on (y,z). The solution is nonsingular provided that $f(\theta)+g(v)>0$. From (8.3), (8.4), and (8.5) we have

$$f(\theta)+g(0)=e^{-U_0(\theta)}, \quad f(\theta_-)+g(v)=e^{-U_-(v)}. \tag{8.6}$$

It follows from (8.5) to (8.6) that the jump relation for U is

$$e^{-U_+(v)}-e^{-U_-(v)}=e^{-U_0(\theta_+)}-e^{-U_0(\theta_-)}.$$

Use of (8.5) in (3.10) gives a linear wave equation for V,

$$(f+g)V_{\theta v}=\tfrac{1}{2}(g_v V_\theta+f_\theta V_v).$$

Solution of this equation with the characteristic initial data $V=V_0$ on $v=0$ and the characteristic boundary data $V=V_-$ on $\theta=\theta_-$ determines, in principle, the solution $V=V_+$ on $\theta=\theta_+$. Finally, for $W=0$, we define the v-constraint function G by

$$G=U_{vv}-\tfrac{1}{2}(U_v^2+V_v^2)+U_v M_v\,. \tag{8.7}$$

It follows from (8.7) and (3.9)–(3.11) that

$$G_\theta=U_\theta G.$$

Integration of this equation with respect to θ implies that

$$\log G_+(v)-\log G_-(v)=U_+(v)-U_-(v).$$

This equation provides a jump condition for M.

One difficulty which arises in the formulation of boundary conditions ahead of the wave is that the metric $\mathbf{g}_-$ may not be given in a coordinate system which is compatible with the coordinate system used in the derivation of the asymptotic equations. It is then necessary to construct compatible coordinates (u,v,y,z). The u coordinate is the phase, so it is a null coordinate of the metric, which can be found by solving an eikonal equation, subject to appropriate initial conditions. The v coordinate is a null coordinate that is orthogonal to u, while the y and z coordinates parametrize the null geodesics on the surface $u=v=0$.

If the gravitational wave front $u=0$ forms a caustic, then the solution of the eikonal equation becomes multivalued. When this happens, the local plane-wave approximation breaks down, and the asymptotic solution is not valid. However, the focusing at a caustic of the congruence of null geodesics associated with the phase does not necessarily imply the formation of a space–time singularity.

IX. EXAMPLES

In this section, we derive boundary conditions for the asymptotic equations which describe the propagation of a gravitational wave into Minkowski space–time, the exterior Schwarzschild space–time, and Robertson–Walker space–time. In each example, we consider the case of spherical waves, where the boundary data can be explicitly computed.

A. Nonplanar wave propagation into Minkowski space–time

We suppose that the space–time ahead of the wave is flat. In inertial coordinates $(t,\vec{x})$, with $t=x^0$ and $\vec{x}=(x^1,x^2,x^3)$, the metric is

$$\mathbf{g}_- = -dt^2 + d\vec{x}^2.$$

We consider a wave with phase

$$u=\frac{t-w(\vec{x})}{\sqrt{2}}.$$

The phase u is a null function of $\mathbf{g}_-$ if

$$|\nabla w|^2 = 1,$$

where ∇ is the gradient with respect to $\vec{x}$. We define

$$v=\frac{t+w(\vec{x})}{\sqrt{2}},$$

and choose coordinates $y(\vec{x}),z(\vec{x})$ such that $\nabla w,\nabla y,\nabla z$ are orthogonal. In the (u,v,y,z) coordinates, we have

$$\mathbf{g}_- = -2\,du\,dv + \frac{1}{|\nabla y|^2}dy^2 + \frac{1}{|\nabla z|^2}dz^2. \tag{9.1}$$

A comparison of (8.2) and (9.1) implies that the minus boundary data are given by

$$M_- = 0, \quad e^{-U_-} = \frac{1}{|\nabla y||\nabla z||_{u=0}}, \quad e^{-V_-} = \left.\frac{|\nabla y|}{|\nabla z|}\right|_{u=0}, \quad W_- = 0.$$

For example, in the case of an outgoing spherical wave, suitable coordinates are

$$u=\frac{t-r}{\sqrt{2}}, \quad v=\frac{t+r}{\sqrt{2}}, \quad y=\vartheta, \quad z=\varphi, \tag{9.2}$$

where (r,ϑ,φ) are spherical polar coordinates and $t>0$. In (u,v,y,z) coordinates, the flat space–time metric is

$$\mathbf{g}_- = -2\,du\,dv + \tfrac{1}{2}(u-v)^2(dy^2+\sin^2 y\,dz^2).$$

Evaluation of this metric at $u=0$ and a comparison with (8.2) gives the minus boundary data

$$M_-=0, \quad e^{-U_-}=\tfrac{1}{2}v^2\sin y, \quad e^{-V_-}=\sin y, \quad W_-=0,$$

where $v>0$. In this case, M_-, V_-, and W_- are independent of v, while $U=U_-$ satisfies the equation

$$U_{vv}=\tfrac{1}{2}U_v^2.$$

Thus, the boundary data satisfy the v-constraint equation (2.13). The solution is therefore identical to an exact solution for the collision of outgoing and incoming spherical waves, with an additional slow parametric dependence on the polar angles (ϑ, φ). Some exact solutions for spherical wave propagation into flat space–time are constructed in Ref. 11.

For an incoming spherical wave, we use

$$u=\frac{t+r}{\sqrt{2}},\quad v=\frac{t-r}{\sqrt{2}},$$

where $t<0$. This leads to the same boundary data as in the case of an outgoing spherical wave, but with $v<0$, instead of $v>0$.

B. Gravitational waves incident on a black hole

The exterior Schwarzschild metric is

$$\mathbf{g}_-=-a\,dt^2+\frac{1}{a}dr^2+r^2(d\vartheta^2+\sin^2\vartheta\,d\varphi^2), \tag{9.3}$$

where $r>2m$ and

$$a(r)=1-\frac{2m}{r}.$$

The contravariant metric tensor is

$$\mathbf{g}_-^\sharp=-\frac{1}{a}\partial_t^2+a\partial_r^2+\frac{1}{r^2}\left(\partial_\vartheta^2+\frac{1}{\sin^2\vartheta}\partial_\varphi^2\right).$$

For simplicity, we consider an axially symmetric phase of the form

$$u=\frac{t-w(r,\vartheta)}{\sqrt{2}}.$$

The function u is null if w satisfies the eikonal equation

$$aw_r^2+\frac{1}{r^2}w_\vartheta^2=\frac{1}{a}.$$

We define the orthogonal null coordinate v by

$$v=\frac{t+w(r,\vartheta)}{\sqrt{2}},$$

and choose a coordinate $y(r,\vartheta)$ whose gradient is orthogonal to the gradient of $w(r,\vartheta)$. That is,

$$y_r=-\frac{hw_\vartheta}{r^2},\quad y_\vartheta=haw_r,$$

where $h(r,\vartheta)$ is a suitable integrating factor. We take $z=\varphi$. In (u,v,y,z) coordinates, the Schwarzschild metric (9.3) is given by

$$\mathbf{g}_{-} \mp -2a\,du\,dv + \frac{r^2}{h^2}dy^2 + r^2\sin^2\vartheta\,dz^2. \tag{9.4}$$

Inversion of the change of coordinates $(t,r,\vartheta,\varphi)\mapsto(u,v,y,z)$ implies that $r=r_{-}(v,y)$ and $\vartheta=\vartheta_{-}(v,y)$ on $u=0$ for suitable functions r_{-} and ϑ_{-}. A comparison of (8.2) and (9.4) implies that the boundary data are given by

$$e^{-M_{-}}=a_{-}, \quad e^{-U_{-}}=\frac{r_{-}^2\sin\vartheta_{-}}{h_{-}}, \quad e^{-V_{-}}=h_{-}\sin\vartheta_{-}, \quad W_{-}=0,$$

where $a_{-}=a(r_{-})$ and $h_{-}=h(r_{-},\vartheta_{-})$.

In the case of an incoming spherical wave incident on the black hole, suitable coordinates are

$$u=\frac{t+A(r)}{\sqrt{2}}, \quad v=\frac{t-A(r)}{\sqrt{2}}, \quad y=\vartheta, \quad z=\varphi, \tag{9.5}$$

where

$$A_r=\frac{1}{a}.$$

Integration of this equation implies that

$$A(r)=r+\log(r-2m).$$

In (u,v,y,z) coordinates, the exterior Schwarzschild metric is

$$\mathbf{g}_{-}=-2a\,du\,dv+r^2(dy^2+\sin^2 y\,dz^2). \tag{9.6}$$

From (9.5), we have $r=r_{-}(v)$ on $u=0$, where

$$A(r_{-})=\frac{v}{\sqrt{2}}. \tag{9.7}$$

A comparison of (8.2) and (9.6) implies that the boundary data ahead of the incoming spherical wave are given by

$$e^{-M_{-}}=a_{-}, \quad e^{-U_{-}}=r_{-}^2\sin y, \quad e^{-V_{-}}=\sin y, \quad W_{-}=0. \tag{9.8}$$

Dropping the minus subscripts, we find that the constraint function G in (8.7) for the boundary data (9.8) is given by

$$G=2\left(\frac{a_v r_v}{ar}-\frac{r_{vv}}{r}\right).$$

Differentiation of (9.7) with respect to v implies that

$$r_v=-\frac{a}{\sqrt{2}}, \quad r_{vv}=-\frac{a_v}{\sqrt{2}}.$$

Use of this equation in the expression for G implies that $G=0$. Thus, the boundary data (9.8) satisfies the v-constraint equation (2.13).

Numerical solutions of the interaction of a spherical gravitational wave with a black hole appear in Ref. 12.

C. Gravitational waves in a Robertson–Walker space–time

The Robertson–Walker metric is

$$\mathbf{g}_- = -dt^2 + \frac{1}{R^2}\left\{ \frac{1}{1-kr^2} dr^2 + r^2 (d\vartheta^2 + \sin^2 \vartheta \, d\varphi^2) \right\}, \tag{9.9}$$

where $R(t)$ is the scale factor, and $k=-1,0,1$.

As in the Schwarzschild example, we consider an axially symmetric phase for simplicity, given by

$$u = \frac{I(t) - w(r,\vartheta)}{\sqrt{2}},$$

where

$$I_t = R, \quad (1-kr^2) w_r^2 + \frac{1}{r^2} w_\vartheta^2 = 1. \tag{9.10}$$

We define an orthogonal null coordinate v by

$$v = \frac{I(t) + w(r,\vartheta)}{\sqrt{2}}.$$

We choose a coordinate $y(r,\vartheta)$ whose gradient is orthogonal to the gradient of $w(r,\vartheta)$, so that

$$y_r = -\frac{h w_\vartheta}{r^2 \sqrt{1-kr^2}}, \quad y_\vartheta = h\sqrt{1-kr^2} w_r,$$

where $h(r,\vartheta)$ is a suitable integrating factor, and take $z=\varphi$. In (u,v,y,z) coordinates, the Robertson–Walker metric (9.9) is given by

$$\mathbf{g}_- = -\frac{2}{R^2} du\, dv + \frac{r^2}{h^2 R^2} dy^2 + \frac{r^2}{R^2} \sin^2 \vartheta \, dz^2. \tag{9.11}$$

A comparison of (8.2) and (9.11) implies that the boundary data are given by

$$e^{-M_-} = \frac{1}{R_-^2}, \quad e^{-U_-} = \frac{r_-^2 \sin \vartheta_-}{h_- R_-^2}, \quad e^{-V_-} = h_- \sin \vartheta_-, \quad W_- = 0,$$

where $r = r_-(v,y)$, $\vartheta = \vartheta_-(v,y)$, $R = R_-(v,y)$, and $h = h_-(v,y)$ on $u=0$.

For an outgoing spherical wave in a Robertson–Walker space–time, suitable coordinates are

$$u = \frac{I(t) - w(r)}{\sqrt{2}}, \quad v = \frac{I(t) + w(r)}{\sqrt{2}}, \quad y = \vartheta, \quad z = \varphi,$$

where

$$w_r = \frac{1}{\sqrt{1-kr^2}}.$$

Integration of this equation implies that

$$w(r)=\begin{cases}\sin^{-1} r & \text{if } k=1\\ r & \text{if } k=1\\ \sinh^{-1} r & \text{if } k=-1.\end{cases}$$

The corresponding boundary data are given by

$$e^{-M_-}=\frac{1}{R_-^2},\quad e^{-U_-}=\frac{r_-^2\sin y}{R_-^2},\quad e^{-V_-}=\sin y,\quad W_-=0, \tag{9.12}$$

where $t_-(v)$ and $r_-(v)$ are given by

$$I(t_-)=\frac{v}{\sqrt{2}},\quad r_-=\begin{cases}\sin(v/\sqrt{2}) & \text{if } k=1\\ v/\sqrt{2} & \text{if } k=0\\ \sinh(v/\sqrt{2}) & \text{if } k=-1\end{cases} \tag{9.13}$$

and $R_-=R(t_-)$.

Dropping the minus subscripts, we find that the constraint function G in (8.7) for the boundary data (9.12) is given by

$$G=2\left(\frac{R_{vv}}{R}-\frac{r_{vv}}{r}\right). \tag{9.14}$$

From (9.10) and (9.13), we find that

$$r_{vv}=-\tfrac{1}{2}kr,\quad R_{vv}=\frac{RR_{tt}-R_t^2}{2R^3}.$$

Use of these expressions in (9.14) gives

$$G=\frac{RR_{tt}-R_t^2}{R^4}+k.$$

Thus, in general, the boundary data (9.12) do not satisfy the v-constraint equation (2.13).

(Received 22 May 1998; accepted for publication 23 February 1999)

A four-index tensor is constructed with terms both quadratic in the Riemann tensor and linear in its second derivatives, which has zero divergence for space–times with vanishing scalar curvature. This tensor reduces in vacuum to the Bel–Robinson tensor. Furthermore, the completely timelike component referred to any observer is positive, and zero if and only if the space–time is flat (excluding some unphysical space–times). We also show that this tensor is the unique one that can be constructed with these properties. Such a tensor does not exist for general gravitational fields. Finally, we study this tensor in several examples: the Friedmann–Lemaître–Robertson–Walker space–times filled with radiation, the plane–fronted gravitational waves, and the Vaidya radiating metric. © *1999 American Institute of Physics.* [S0022-2488(99)04206-1]

I. INTRODUCTION

The investigation of conservation laws in general relativity has a long history. From its very beginning much of this research was based on pseudotensors instead of fully covariant methods. The aim of many of these works was to find differential laws which, once transformed into integral ones, were interpreted as energy balances in such a way that expressions for the energy and momentum densities of the gravitational field could be identified.

The covariant approach to this problem is mainly based on the analogy of the Bel–Robinson tensor[1] with the energy–momentum tensor of the electromagnetic field (there are other approaches based on this analogy, see e.g., Ref. 2). The Bel–Robinson tensor is conserved *in vacuum*, completely symmetric and traceless. Moreover, the completely timelike component referred to any observer (described by a timelike unit vector field) is non-negative, and its vanishing implies that the space–time is conformally flat (flat in vacuum). This is a desirable positivity property for any candidate to gravitational energy density. In spite of these good properties, the Bel–Robinson tensor has dimensions of energy density square and this fact makes its interpretation somewhat unclear. Nevertheless, it has been revealed as a very useful tool in many kinds of studies, which has led to some efforts in finding extensions of the Bel–Robinson tensor to more general cases than vacuum. Therefore, the question arises whether generalizations of the Bel–Robinson tensor exist for space–times not necessarily empty.

The Bel tensor[3] was the first attempt on this problem. It is a tensor whose completely timelike component is positive and zero only when the space–time is Minkowski. In vacuum, it reduces to the Bel–Robinson tensor, but in the general case it is no longer conserved.

For general space–times, Sachs[4] found a divergence-free tensor that coincides with the Bel–Robinson tensor in vacuum. Unfortunately, this tensor does not satisfy any positivity property and it is neither completely symmetric nor traceless.

The systematic treatment of this problem was made by Collinson,[5] who found all four-index divergence-free tensors with terms either quadratic in the Riemann tensor or linear in its second derivatives. The discovered result is that any such tensor can be derived from only *one* tensor, namely $T_{10}^{\alpha\beta\lambda\mu}$ [see Eq. (A1)], whose divergence with respect to the first index vanishes. However, there is not enough freedom to construct a tensor with its time component positive.

In this paper we show that, unlike the general case, for space–times with zero scalar curvature $(R=0)$ it is possible to construct a unique generalization of the Bel–Robinson tensor. We begin in Sec. II by proving that, when $R=0$, there exists another conserved tensor which cannot be derived from the Collinson one. In Sec. III we show that, demanding symmetry in the three free indices, there is not any other tensor independent from these two. This new tensor allows us to construct (Sec. IV) a divergence-free tensor which has the completely timelike component non-negative and zero only when the space–time is flat (excluding some cases that, via Einstein's field equations, have an unphysical matter content). This tensor is completely symmetric in its last three indices, but it is impossible to get a similar tensor symmetric in all their indices. We remark that it is not possible to construct any other tensor with such characteristics.

In order to illustrate this development, we study in Sec. V some examples in which we can define this tensor, namely: the Friedmann–Lemaître–Robertson–Walker (FLRW) models with an energy–momentum content of (incoherent) radiation $(p=\varrho/3)$, the plane-fronted gravitational waves with parallel rays (*pp waves*), and the Vaidya radiating space–time.

Finally, we recall that for purely electromagnetic space–times, and supposing that the Einstein field equations hold, Penrose and Rindler[6] also gave a generalization of the Bel–Robinson tensor by using spinor methods. This tensor is conserved, completely symmetric, and traceless in its last three indices. In Appendix B we find its tensorial expression and a new (to our knowledge) positivity property.

II. DEDUCTION OF THE NEW CONSERVED TENSOR FOR $R=0$

Unless otherwise stated, throughout this paper we will consider the metric tensor $g_{\alpha\beta}$ to have signature $(-,+,+,+)$. The convention for indices on the Riemann tensor that will be used is defined through the Ricci identities:

$$(\nabla_\alpha\nabla_\beta-\nabla_\beta\nabla_\alpha)v_\lambda=-R^\sigma{}_{\lambda\alpha\beta}v_\sigma, \tag{1}$$

where v_α is an arbitrary 1-form. The Ricci tensor and the scalar curvature are defined as usual: $R_{\alpha\beta}\equiv R^\sigma{}_{\alpha\sigma\beta}$ and $R\equiv R^\sigma_\sigma$. We also recall the Riemann symmetries and the first and second Bianchi identities:

$$\begin{gathered} R_{\alpha\beta\lambda\mu}=R_{[\alpha\beta][\lambda\mu]}=R_{\lambda\mu\alpha\beta}, \\ R_{[\alpha\beta\lambda]\mu}=0, \\ \nabla_{[\nu}R_{\alpha\beta]\lambda\mu}=0. \end{gathered} \tag{2}$$

The procedure we are going to use to find the conserved tensor starts from the expression for the divergence of the Bel tensor:[1]

$$\nabla_\alpha T^{\alpha\beta\lambda\mu}=R^\beta{}_\rho{}^\lambda{}_\sigma J^{\mu\sigma\rho}+R^\beta{}_\rho{}^\mu{}_\sigma J^{\lambda\sigma\rho}-\tfrac{1}{2}g^{\lambda\mu}R^\beta{}_{\rho\sigma\gamma}J^{\sigma\gamma\rho}, \tag{3}$$

where the Bel tensor $T^{\alpha\beta\lambda\mu}$ and $J^{\alpha\beta\lambda}$ are defined as follows:

$$\begin{gathered} T^{\alpha\beta\lambda\mu}\equiv\tfrac{1}{2}(R^{\alpha\rho\lambda\sigma}R^\beta{}_\rho{}^\mu{}_\sigma+{*R*}^{\alpha\rho\lambda\sigma}{*R*}^\beta{}_\rho{}^\mu{}_\sigma+{*R}^{\alpha\rho\lambda\sigma}{*R}^\beta{}_\rho{}^\mu{}_\sigma+R*^{\alpha\rho\lambda\sigma}R*^\beta{}_\rho{}^\mu{}_\sigma), \\ J^{\lambda\mu\beta}\equiv\nabla^\lambda R^{\mu\beta}-\nabla^\mu R^{\lambda\beta}=\nabla_\sigma R^{\mu\lambda\beta\sigma}, \end{gathered} \tag{4}$$

with the asterisk being the usual dual operator acting over any pair of antisymmetric indices:

$$*R_{\alpha\beta\lambda\mu}\equiv\tfrac{1}{2}\eta_{\alpha\beta\sigma\rho}R^{\sigma\rho}{}_{\lambda\mu},\quad R*_{\alpha\beta\lambda\mu}\equiv\tfrac{1}{2}\eta_{\lambda\mu\sigma\rho}R_{\alpha\beta}{}^{\sigma\rho},$$

$$*R*_{\alpha\beta\lambda\mu}\equiv\tfrac{1}{4}\eta_{\alpha\beta\gamma\delta}\eta_{\lambda\mu\sigma\rho}R^{\gamma\delta\sigma\rho},$$

and $\eta_{\alpha\beta\lambda\mu}$ is the canonical volume 4-form. Our purpose now is to work out the right-hand side (r.h.s.) of Eq. (3) in order to convert it into a global divergence. To that end, we will repeatedly integrate by parts and make use of Eqs. (1) and (2).

To begin with, the last term in Eq. (3) can be easily transformed into a divergence, by means of the Ricci and Bianchi identities (1) and (2):

$$-\tfrac{1}{2}g^{\lambda\mu}R^{\beta}{}_{\rho\sigma\gamma}J^{\sigma\gamma\rho}=-g^{\lambda\mu}\nabla_{\alpha}\nabla_{\rho}J^{\alpha\rho\beta}. \tag{5}$$

Next we expand the leading terms of the r.h.s. of (3) by using the definition of $J^{\alpha\beta\lambda}$ (4) and integrating by parts:

$$R^{\beta}{}_{\rho}{}^{\lambda}{}_{\sigma}\nabla^{\mu}R^{\sigma\rho}-\nabla_{\alpha}(R^{\mu\rho}R^{\beta}{}_{\rho}{}^{\lambda\alpha})+R^{\mu\rho}\nabla_{\alpha}R^{\beta}{}_{\rho}{}^{\lambda\alpha}+[\lambda\leftrightarrow\mu]. \tag{6}$$

The first term in the previous expression can be rewritten by means of the Ricci identities (1) as follows:

$$R^{\beta}{}_{\rho}{}^{\lambda}{}_{\sigma}\nabla^{\mu}R^{\sigma\rho}=(\nabla^{\lambda}\nabla_{\sigma}-\nabla_{\sigma}\nabla^{\lambda})\nabla^{\mu}R^{\sigma\beta}+[-\nabla^{\alpha}(R^{\mu}{}_{\alpha}{}^{\lambda}{}_{\sigma}R^{\sigma\beta})+R^{\sigma\beta}\nabla^{\alpha}R^{\lambda}{}_{\sigma}{}^{\mu}{}_{\alpha}]+R^{\lambda}_{\sigma}\nabla^{\mu}R^{\sigma\beta}. \tag{7}$$

Thus, we have converted the r.h.s. of Eq. (3) into a divergence plus the following terms:

$$\begin{aligned}&R^{\sigma\beta}\nabla^{\alpha}R^{\lambda}{}_{\sigma}{}^{\mu}{}_{\alpha}+R^{\sigma\lambda}\nabla^{\mu}R^{\beta}_{\sigma}+R^{\mu\rho}\nabla_{\alpha}R^{\beta}{}_{\rho}{}^{\lambda\alpha}+[\lambda\leftrightarrow\mu]\\&\quad=R^{\sigma\beta}(\nabla_{\sigma}R^{\lambda\mu}-\nabla^{\lambda}R^{\mu}_{\sigma})+R^{\sigma\lambda}\nabla^{\mu}R^{\beta}_{\sigma}+R^{\mu\rho}(\nabla_{\rho}R^{\beta\lambda}-\nabla^{\beta}R^{\lambda}_{\rho})+[\lambda\leftrightarrow\mu].\end{aligned} \tag{8}$$

Now, taking into account the contracted Bianchi identities ($\nabla_{\mu}R^{\mu\nu}=\tfrac{1}{2}\nabla^{\nu}R$), these terms can be transformed into the following expression:

$$\begin{aligned}&-\nabla^{\beta}(R^{\lambda}_{\sigma}R^{\sigma\mu})+\nabla^{\mu}(R^{\lambda}_{\sigma}R^{\sigma\beta})+\nabla^{\lambda}(R^{\mu}_{\sigma}R^{\sigma\beta})-2R^{\beta\sigma}(\nabla^{\mu}R^{\lambda}_{\sigma}+\nabla^{\lambda}R^{\mu}_{\sigma})\\&\quad+\nabla_{\sigma}(R^{\beta\lambda}R^{\mu\sigma}+R^{\beta\mu}R^{\lambda\rho}+2R^{\beta\sigma}R^{\lambda\mu})-\tfrac{1}{2}(R^{\beta\lambda}\nabla^{\mu}R+R^{\beta\mu}\nabla^{\lambda}R+2R^{\lambda\mu}\nabla^{\beta}R).\end{aligned} \tag{9}$$

The last three terms of this expression vanish when R is constant, so we are finally left with $-2R^{\beta\sigma}(\nabla^{\mu}R^{\lambda}_{\sigma}+\nabla^{\lambda}R^{\mu}_{\sigma})$. Nevertheless, notice that our final purpose is to find a conserved tensor $T''^{\alpha\beta\lambda\mu}$ whose completely timelike component referred to an observer $\vec{u},T''^{\alpha\beta\lambda\mu}u_{\alpha}u_{\beta}u_{\lambda}u_{\mu}$, is positive, which means that we are only interested in the symmetric part. Therefore, without lost of generality, we can symmetrize the whole expression and, as a consequence, the remaining terms transform themselves into a divergence:

$$-4R^{\sigma(\beta}\nabla^{\lambda}R^{\mu)}_{\sigma}=-2\nabla^{(\beta}(R^{\lambda}_{\sigma}R^{\mu)\sigma}). \tag{10}$$

So, we have finally achieved a conserved tensor if the scalar curvature vanishes (in fact, if it is constant). Collecting all the previous terms (5)–(10) we get the final result:

$$\nabla_{\alpha}T''^{\alpha\beta\lambda\mu}=-2R^{(\beta\lambda}\nabla^{\mu)}R,$$

where we have defined

$$\begin{aligned}T''^{\alpha\beta\lambda\mu}\equiv{}&T^{\alpha(\beta\lambda\mu)}-4R^{\alpha(\beta}R^{\lambda\mu)}+g^{\alpha(\beta}R^{\lambda}_{\sigma}R^{\mu)\sigma}-2\nabla^{(\beta}\nabla^{\lambda}R^{\mu)\alpha}+2\nabla^{(\beta}\nabla^{|\alpha|}R^{\lambda\mu)}-2\nabla^{\alpha}\nabla^{(\beta}R^{\lambda\mu)}\\&-2g^{\alpha(\beta}\nabla_{\sigma}\nabla^{\lambda}R^{\mu)\sigma}-\nabla_{\sigma}\nabla^{\sigma}R^{\alpha(\beta}g^{\lambda\mu)}+\nabla_{\sigma}\nabla^{\alpha}R^{\sigma(\beta}g^{\lambda\mu)}.\end{aligned} \tag{11}$$

It is a matter of checking that this tensor cannot be obtained from Collinson tensor $T_{10}^{\alpha\beta\lambda\mu}$ when it is restricted to the case $R=0$. Now, we are left with the question of its uniqueness.

III. UNIQUENESS

In this section we will prove that, in the case we are concerned with ($R=0$), no other conserved tensor exists, symmetric in its last three indices, independent from $T''^{\alpha\beta\lambda\mu}$ and the Collinson tensor, $T_{10}^{\alpha\beta\lambda\mu}$. The reasoning is the following. Suppose you are given a tensor $T'''^{\alpha\beta\lambda\mu}$ which is conserved when $R=0$. The divergence computed in the general case will be a combination of the following type (taking into account symmetries and unit dimensions):

$$\nabla_\alpha T'''^{\alpha\beta\lambda\mu}=aR^{(\beta\lambda}\nabla^{\mu)}R+bR\nabla^{(\beta}R^{\lambda\mu)}+cR^{\sigma(\beta}\nabla_\sigma Rg^{\lambda\mu)}+dRg^{(\beta\lambda}\nabla^{\mu)}R+e\nabla^{(\beta}\nabla^{\lambda}\nabla^{\mu)}R$$
$$+f\nabla^\sigma\nabla_\sigma\nabla^{(\beta}Rg^{\lambda\mu)}+h\nabla^\sigma\nabla^{(\beta}\nabla_\sigma Rg^{\lambda\mu)}+i\nabla^{(\beta}\nabla^{|\sigma|}\nabla_\sigma Rg^{\lambda\mu)},$$

a, b, c, d, e, f, h, and *i* being constants. This can be immediately cast in the following form:

$$\nabla_\alpha T'''^{\alpha\beta\lambda\mu}=(a-b)R^{(\beta\lambda}\nabla^{\mu)}R+\nabla_\alpha\tau^{\alpha\beta\lambda\mu},$$

where $\tau^{\alpha\beta\lambda\mu}$ stands for:

$$\tau^{\alpha\beta\lambda\mu}\equiv bRg^{\alpha(\beta}R^{\lambda\mu)}+c(RR^{\alpha(\beta}g^{\lambda\mu)}-\tfrac{1}{4}g^{\alpha(\beta}g^{\lambda\mu)}R^2)+d\tfrac{1}{2}g^{(\beta\lambda}g^{\mu)\alpha}R^2+eg^{\alpha(\beta}\nabla^{\lambda}\nabla^{\mu)}R$$
$$+fg^{\alpha\sigma}\nabla_\sigma\nabla^{(\beta}Rg^{\lambda\mu)}+hg^{\alpha\sigma}\nabla^{(\beta}\nabla_\sigma Rg^{\lambda\mu)}+ig^{\alpha(\beta}\nabla^{|\sigma|}\nabla_\sigma Rg^{\lambda\mu)},$$

so clearly it is a tensor that vanishes when R does. That is, if a tensor of the kind we are considering is divergence free when $R=0$, in the general case its divergence should be a multiple of $R^{(\beta\lambda}\nabla^{\mu)}R$ plus the divergence of a tensor of the type $\tau^{\alpha\beta\lambda\mu}$. If we had two such tensors, a suitable combination of them removing the term $R^{(\beta\lambda}\nabla^{\mu)}R$ would give a conserved tensor for the general case and, therefore, due to the Collinson result,[5] it could be constructed from $T_{10}^{\alpha\beta\lambda\mu}$. Given that the tensor $\tau^{\alpha\beta\lambda\mu}$ vanishes when $R=0$, the three tensors would not be independent in that case.

On the other hand, this reasoning shows that, from the very beginning, we were able to know that in the $R=0$ case at most one more conserved tensor could exist apart from Collinson's one, as finally has been the case.

IV. POSITIVITY

As it has been pointed out above, in the general case all the conserved tensors can be constructed from $T_{10}^{\alpha\beta\lambda\mu}$. This construction is based in two procedures. First, it is clear that if we perform any permutation on the last three indices we will still have a conserved tensor. Second, by taking the two traces $T_{10}^{\alpha\beta\rho}{}_{\rho}$, $T_{10}^{\alpha\rho\beta}{}_{\rho}$ and multiplying them by $g^{\lambda\mu}$ we obtain new conserved tensors. Actually, there is not any other two-index divergence-free tensor independent from them. These two tensors can be taken to be (as usually obtained by Hamiltonian differentiation):

$$t_1^{\alpha\beta}=2\nabla^\alpha\nabla^\beta R-2g^{\alpha\beta}\nabla_\mu\nabla^\mu R+\tfrac{1}{2}g^{\alpha\beta}R^2-2RR^{\alpha\beta},$$

$$t_2^{\alpha\beta}=2\nabla_\sigma\nabla^\alpha R^{\sigma\beta}-\nabla_\sigma\nabla^\sigma R^{\alpha\beta}-2R^{\alpha\sigma}R_\sigma^\beta+\tfrac{1}{2}R_{\sigma\rho}R^{\sigma\rho}g^{\alpha\beta}-\tfrac{1}{2}g^{\alpha\beta}\nabla_\mu\nabla^\mu R.$$

This is all the freedom we have in the general case.

In the $R=0$ case, there exists only one two-index conserved tensor, which is that obtained from $t_2^{\alpha\beta}$. On the other hand, as we consider tensors which are symmetric in the last three indices, from the Collinson tensor we will only have one independent tensor (apart from the two-index tensor), namely $T_{10}^{\alpha(\beta\lambda\mu)}$ or, equivalently, the Sachs tensor $T'^{\alpha\beta\lambda\mu}$,[4] which is symmetric in its last three indices.

Therefore, to construct the super-energy tensor in the $R=0$ case, we are led with three tensors: (i) the Sachs tensor $T'^{\alpha\beta\lambda\mu}$ (restricted to the $R=0$ case):

$$T'^{\alpha\beta\lambda\mu} \equiv T^{\alpha(\beta\lambda\mu)} + 2R^{\alpha\sigma}R^{(\beta}_{\sigma}g^{\lambda\mu)} - \tfrac{1}{3}g^{\alpha(\beta}R^{\lambda}_{\sigma}R^{\mu)\sigma} - \tfrac{1}{2}R_{\sigma\rho}R^{\sigma\rho}g^{\alpha(\beta}g^{\lambda\mu)}$$
$$+2\nabla^{(\beta}\nabla^{\lambda}R^{\mu)\alpha} - \tfrac{2}{3}\nabla^{(\beta}\nabla^{|\alpha|}R^{\lambda\mu)} - \tfrac{2}{3}\nabla^{\alpha}\nabla^{(\beta}R^{\lambda\mu)}$$
$$+\tfrac{4}{3}\nabla_{\sigma}\nabla^{\sigma}R^{(\beta\lambda}g^{\mu)\alpha} - 2g^{\alpha(\beta}\nabla_{\sigma}\nabla^{\lambda}R^{\mu)\sigma} - \nabla_{\sigma}\nabla^{\alpha}R^{\sigma(\beta}g^{\lambda\mu)},$$

(ii) the two-index tensor $t^{\alpha\beta}$:

$$t^{\alpha\beta} = 2\nabla_{\sigma}\nabla^{\alpha}R^{\sigma\beta} - \nabla_{\sigma}\nabla^{\sigma}R^{\alpha\beta} - 2R^{\alpha\sigma}R^{\beta}_{\sigma} + \tfrac{1}{2}R_{\sigma\rho}R^{\sigma\rho}g^{\alpha\beta},$$

and (iii) the tensor $T''^{\alpha\beta\lambda\mu}$ previously found in (11).

Now, we have to combine these three tensors in such a way that any observer measures a positive quantity. Moreover, we would like that this completely timelike component vanishes if and only if the space–time is flat.

First of all, we have to take into account that terms made of derivatives of the Ricci tensor do not have a definite sign, so it would be necessary to eliminate their contributions. This aim can only be achieved by means of the following combination:

$$A^{\alpha\beta\lambda\mu} \equiv \tfrac{1}{2}(3T'^{\alpha\beta\lambda\mu} - T''^{\alpha\beta\lambda\mu}) + \tfrac{5}{2}t^{\alpha(\beta}g^{\lambda\mu)},$$

which more explicitly reads:

$$A^{\alpha\beta\lambda\mu} = T^{\alpha(\beta\lambda\mu)} + 2R^{\alpha(\beta}R^{\lambda\mu)} - 2R^{\alpha\sigma}R^{(\beta}_{\sigma}g^{\lambda\mu)} - g^{\alpha(\beta}R^{\lambda}_{\sigma}R^{\mu)\sigma} + \tfrac{1}{2}R_{\sigma\rho}R^{\sigma\rho}g^{\alpha(\beta}g^{\lambda\mu)}$$
$$+2\nabla^{(\beta}\nabla^{\lambda}R^{\mu)\alpha} - 2\nabla^{(\beta}\nabla^{|\alpha|}R^{\lambda\mu)} + 3\nabla_{\sigma}\nabla^{\alpha}R^{\sigma(\beta}g^{\lambda\mu)}$$
$$-2g^{\alpha(\beta}\nabla_{\sigma}\nabla^{\lambda}R^{\mu)\sigma} + 2\nabla_{\sigma}\nabla^{\sigma}R^{(\beta\lambda}g^{\mu)\alpha} - 2\nabla_{\sigma}\nabla^{\sigma}R^{\alpha(\beta}g^{\lambda\mu)}. \quad (12)$$

Since we have already exhausted all the freedom, we finally examine the completely timelike component referred to any timelike unit vector $\vec{u}$:

$$A(\vec{u}) \equiv A_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu}$$
$$= T_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} + \tfrac{1}{2}R_{\sigma\rho}R^{\sigma\rho} + 2(R_{\alpha\beta}u^{\alpha}u^{\beta})^2$$
$$+3(R^{\alpha\sigma}R^{\beta}_{\sigma})u_{\alpha}u_{\beta} - (\nabla_{\sigma}\nabla^{\alpha}R^{\sigma\beta})u_{\alpha}u_{\beta}. \quad (13)$$

To check the positivity of $A(\vec{u})$ it is convenient to write out the last term of Eq. (13) in the following form:

$$\nabla_{\sigma}\nabla^{\alpha}R^{\sigma\beta} = C^{\alpha}{}_{\sigma\rho}{}^{\beta}R^{\sigma\rho} + 2R^{\alpha\sigma}R^{\beta}_{\sigma} - \tfrac{1}{2}g^{\alpha\beta}R_{\sigma\rho}R^{\sigma\rho}.$$

At this point, we introduce four spatial tensors, namely $E_{\alpha\beta}(\vec{u})$, $H_{\alpha\beta}(\vec{u})$, $M_{\alpha\beta}(\vec{u})$, and $N_{\alpha\beta}(\vec{u})$, that (together with R) wholly characterize the Riemann tensor.[7] Their definitions, properties, and some useful formulas are given in Appendix A.

Introducing the previous definitions in (13) we obtain, after some calculations:

$$A(\vec{u}) = (E_{\sigma\rho} - M_{\sigma\rho})(E^{\sigma\rho} - M^{\sigma\rho}) + H_{\sigma\rho}H^{\sigma\rho} + 3N_{\sigma\rho}N^{\sigma\rho} + (R_{\alpha\beta}u^{\alpha}u^{\beta})^2, \quad (14)$$

which is a sum of square terms (all the tensors appearing here are spatial). Therefore it is manifestly positive and its vanishing implies:

$$H_{\alpha\beta} = 0, \quad N_{\alpha\beta} = 0,$$

$$R_{\alpha\beta}u^{\alpha}u^{\beta} = 0, \quad E_{\alpha\beta} = M_{\alpha\beta}.$$

The previous expressions lead to $R_{\alpha\beta}u^{\alpha}=0$ (see Appendix A). This condition, when considering the Einstein field equations, immediately drives to an unphysical energy–momentum tensor. Hence, if we eliminate these unphysical space–times (for instance, adding any energy condition), the vanishing of $A(\vec{u})$ finally implies the Minkowski space–time.

V. SOME EXAMPLES

In this section we are going to study the tensor $A^{\alpha\beta\lambda\mu}$ (12) in some space–times with vanishing scalar curvature. In particular, we are going to consider the following examples: (i) the radiation FLRW cosmological models, (ii) the *pp waves*, and (iii) the Vaidya radiating metric. In examples (i) and (ii) we will give the expression for $A^{\alpha\beta\lambda\mu}$ and its completely timelike component $A(\vec{u})$ (14) for an arbitrary observer $\vec{u}$. In example (iii), for the sake of brevity we will give only the expression of $A(\vec{u})$, also for an arbitrary observer.

In the first example we study the case of the FLRW models (see, for instance, Ref. 8) with vanishing scalar curvature, the radiation models, whose energy–momentum tensor (of perfect-fluid type) is given by the following expression (throughout this section we will use units in which $8\pi G=c=1$):

$$T_{\alpha\beta}=\varrho U_{\alpha}U_{\beta}+ph_{\alpha\beta}, \quad p=\tfrac{1}{3}\varrho,$$

where $\vec{U}$ is the fluid velocity ($U^{\alpha}U_{\alpha}=-1$), ϱ the energy density, p the pressure, and $h_{\alpha\beta}=g_{\alpha\beta}+U_{\alpha}U_{\beta}$ the orthogonal projector to the fluid velocity. The line element of these conformally flat models can be written as

$$ds^2=-dt^2+a^2(t)\{d\chi^2+\Sigma^2(\epsilon,\chi)(d\theta^2+\sin^2\theta\delta\varphi^2)\},$$

where $\Sigma(\epsilon,\chi)$ is given by

$$\Sigma(\epsilon,\chi)=\begin{cases}\sin\chi & \text{if } \epsilon=1\\ \chi & \text{if } \epsilon=0\\ \sinh\chi & \text{if } \epsilon=-1.\end{cases}$$

The fluid velocity $\vec{U}$, the scale factor $a(t)$, and the energy density $\varrho(t)$ are

$$\vec{U}=\frac{\partial}{\partial t}, \quad a^2(t)=(t-t_0)[2A-\epsilon(t-t_0)], \quad \varrho(t)=\frac{3A^2}{a^4(t)},$$

respectively, and A and t_0 are arbitrary constants.

After some straightforward calculations, and using the special properties of these space–times, we arrive at the following expression for $A^{\alpha\beta\lambda\mu}$:

$$A^{\alpha\beta\lambda\mu}=\tfrac{4}{3}\varrho^2\{U^{\alpha}U^{\beta}U^{\lambda}U^{\mu}+U^{\alpha}U^{(\beta}h^{\lambda\mu)}+\tfrac{5}{3}h^{\alpha(\beta}U^{\lambda}U^{\mu)}+\tfrac{1}{3}h^{\alpha(\beta}h^{\lambda\mu)}\}. \tag{15}$$

As we can see, it is proportional to the energy density squared. We can also check that it is indeed divergence free. Now, let us compute the completely timelike component (14) of this tensor with respect to an arbitrary observer $\vec{u}$. To that end, we decompose $\vec{u}$ in the next way

$$\vec{u}=\gamma(\vec{U}+\vec{v}), \quad v^{\alpha}U_{\alpha}=0, \quad v^{\alpha}v_{\alpha}=v^2\geqslant 0, \quad \gamma\equiv(1-v^2)^{-1/2},$$

where the case $\vec{v}=0$ corresponds to an observer comoving with the fluid ($\vec{u}=\vec{U}$). Then, from (14), (15) we find that $A(\vec{u})$ is given by

$$A(\vec{u})=\tfrac{4}{3}\varrho^2\gamma^4\{1+\tfrac{8}{3}v^2+\tfrac{1}{3}v^4\}.$$

That is, it is function of ϱ and v only. Moreover, it increases monotonically as v increases and its minimum corresponds to the case $v=0$, in which the observer is comoving with the fluid.

Now, we are going to study the tensor $A^{\alpha\beta\lambda\mu}$ in the case of the *pp waves* space–times. The corresponding line element can be written in null coordinates $\{u,v,\zeta,\overline{\zeta}\}$ as follows (see Ref. 8 for details)

$$ds^2=-2\,du\,dv+2d\zeta\,d\overline{\zeta}-2H\,du^2,$$

where H is an arbitrary function which does not depend on $v[H=H(u,\zeta,\overline{\zeta})]$. Using the following Newman–Penrose basis $\{\ell,k,m,\overline{m}\}$,

$$\vec{\ell}=\frac{\partial}{\partial v},\quad \vec{k}=\frac{\partial}{\partial u}-H\frac{\partial}{\partial v},\quad \vec{m}=\frac{\partial}{\partial \zeta},$$

the Ricci and self-dual Weyl tensors are

$$R_{\alpha\beta}=2\Phi\ell_\alpha\ell_\beta,\quad \hat{C}_{\alpha\beta\lambda\mu}\equiv C_{\alpha\beta\lambda\mu}+i\overset{*}{C}_{\alpha\beta\lambda\mu}=2\Psi_4V_{\alpha\beta}V_{\lambda\mu}, \tag{16}$$

respectively, where the quantities Φ, Ψ_4, and $V_{\alpha\beta}$ are given by

$$\Phi\equiv H_{,\zeta\overline{\zeta}},\quad \Psi_4=H_{,\overline{\zeta}\overline{\zeta}},\quad V_{\alpha\beta}\equiv 2\ell_{[\alpha}m_{\beta]}.$$

From (16) we can see that the energy–momentum content can correspond with vacuum, Einstein–Maxwell, or pure radiation fields. Moreover, the Petrov type is *N*, with $\vec{\ell}$ being the repeated principal direction of the Weyl tensor, which in fact is a constant vector field $(\nabla_\alpha\ell_\beta=0)$.

After some calculations, we have found that the Bel tensor $T^{\alpha\beta\lambda\mu}$ and our tensor $A^{\alpha\beta\lambda\mu}$ are

$$T^{\alpha\beta\lambda\mu}=4(\Phi^2+\Psi_4\overline{\Psi}_4)\ell^\alpha\ell^\beta\ell^\lambda\ell^\mu,$$

$$\tfrac{1}{4}A^{\alpha\beta\lambda\mu}=(3\Phi^2+\Psi_4\overline{\Psi}_4)\ell^\alpha\ell^\beta\ell^\lambda\ell^\mu+\ell^\alpha\ell^{(\beta}\nabla^\lambda\nabla^{\mu)}\Phi-\ell^{(\beta}\ell^\lambda\nabla^{\mu)}\nabla^\alpha\Phi$$
$$+[g^{\alpha(\beta}\ell^\lambda\ell^{\mu)}-\ell^\alpha\ell^{(\beta}g^{\lambda\mu)}]\nabla^\sigma\nabla_\sigma\Phi.$$

From this expression, the completely timelike component is given by

$$A(\vec{u})=4(3\Phi^2+\Psi_4\overline{\Psi}_4)(\ell^\alpha u_\alpha)^4.$$

Then, the vanishing of $A(\vec{u})$ implies the Minkowski space–time.

Finally, we are going to consider the Vaidya radiating space–time (see for instance Ref. 8). For the sake of brevity we only give here the completely timelike component (14) of the tensor $A^{\alpha\beta\lambda\mu}$. The line element of this spherically-symmetric metric can be written as follows:

$$ds^2=-2F^2(u,v)du\,dv+r^2(u,v)(d\theta^2+\sin^2\theta\,d\varphi^2),$$

where

$$F^2(u,v)=f(u)\frac{\partial r}{\partial v},\quad \frac{\partial r}{\partial u}=\frac{1}{2}f(u)\left(\frac{2m(u)}{r}-1\right).$$

Here, $m(u)$ is the invariantly defined mass function. As is well known, the Petrov type of this metric is *D*. Then, taking the following Newman–Penrose adapted basis:

$$\vec{\ell}=\frac{-1}{F}\frac{\partial}{\partial v},\quad \vec{k}=\frac{-1}{F}\frac{\partial}{\partial u},\quad \vec{m}=\frac{1}{\sqrt{2}r}\left(\frac{\partial}{\partial \theta}+\frac{i}{\sin\theta}\frac{\partial}{\partial \varphi}\right),$$

where $\vec{\ell}$ and $\vec{k}$ are aligned with the principal directions of the Weyl tensor, the Ricci tensor is given by

$$R_{\alpha\beta}=2\Phi\ell_{\alpha}\ell_{\beta}, \quad \Phi\equiv-\frac{m_{,u}}{r^2 r_{,u}}.$$

And the only nonzero component of the Weyl tensor in this basis (see Ref. 8) is

$$\Psi_2=-\frac{m(u)}{r^3(u,v)},$$

which in this case is real.

In terms of these quantities, we have found the following expression for $A(\vec{u})$:

$$A(\vec{u})=2[\Psi_2+\Phi(\ell^{\alpha}u_{\alpha})^2]^2+4\Psi_2^2[36(\ell^{\alpha}u_{\alpha})^2(k^{\beta}u_{\beta})^2-18(\ell^{\alpha}u_{\alpha})(k^{\beta}u_{\beta})+1]+10\Phi^2(\ell^{\alpha}u_{\alpha})^4,$$

and again, taking into account that

$$2(\ell^{\alpha}u_{\alpha})(k^{\beta}u_{\beta})\geqslant 1 \Rightarrow 36(\ell^{\alpha}u_{\alpha})^2(k^{\beta}u_{\beta})^2-18(\ell^{\alpha}u_{\alpha})(k^{\beta}u_{\beta})+1\geqslant 1,$$

$A(\vec{u})$ vanishes if and only if the space–time is the Minkowski space–time. When we restrict ourselves to observers lying on the 2-planes generated by the principal directions $[2(\ell^{\alpha}u_{\alpha})\times(k^{\beta}u_{\beta})=1]$, which are precisely the observers that minimize $A(\vec{u})$, the result is

$$A(\vec{u})=2[\Psi_2+\Phi(\ell^{\alpha}u_{\alpha})^2]^2+4\Psi_2^2+10\Phi^2(\ell^{\alpha}u_{\alpha})^4.$$

APPENDIX A: USEFUL DEFINITIONS

We first write down the Collinson tensor:[5]

$$T_{10}^{\alpha\beta\lambda\mu}=6Q_1^{\alpha\beta\lambda\mu}+Q_2^{\alpha\beta(\lambda\mu)}+Q_3^{\alpha\beta(\lambda\mu)}, \tag{A1}$$

where

$$Q_1^{\alpha\beta\lambda\mu}=R^{\lambda}_{\sigma}R^{\beta\mu\alpha\sigma}+R^{\beta}_{\sigma}R^{\mu\alpha\lambda\sigma}+\nabla^{\mu}\nabla_{\sigma}R^{\alpha\sigma\beta\lambda}-\nabla^{\beta}\nabla_{\sigma}R^{\alpha\lambda\mu\sigma}-g^{\alpha\beta}\nabla_{\rho}\nabla_{\sigma}R^{\mu\sigma\lambda\rho},$$

$$Q_2^{\alpha\beta\lambda\mu}=-4\nabla^{\lambda}\nabla_{\sigma}R^{\alpha\sigma\beta\mu}-6\nabla^{\mu}\nabla_{\sigma}R^{\alpha\beta\lambda\sigma}-6g^{\alpha\mu}\nabla_{\sigma}\nabla^{\lambda}R^{\sigma\beta}+6g^{\alpha\mu}\nabla_{\rho}\nabla_{\sigma}R^{\sigma\lambda\beta\rho}+6\nabla^{\mu}\nabla^{\lambda}R^{\alpha\beta},$$

$$\begin{aligned}Q_3^{\alpha\beta\lambda\mu}=&-8g^{\alpha\lambda}R_{\sigma\rho}{}^{\mu}{}_{\gamma}R^{\rho\gamma\beta\sigma}+8R_{\sigma}{}^{\lambda\mu}{}_{\rho}R^{\beta\sigma\alpha\rho}+8R^{\mu}_{\sigma}R^{\beta\sigma\lambda\alpha}+8R_{\sigma}{}^{\beta\mu}{}_{\rho}R^{\lambda\sigma\alpha\rho}+2R^{\mu}_{\sigma}R^{\beta\alpha\sigma\lambda}\\&+2R_{\sigma}{}^{\mu\beta}{}_{\rho}R^{\lambda\sigma\alpha\rho}+3g^{\alpha\beta}R^{\mu}_{\sigma}R^{\lambda\sigma}-g^{\alpha\beta}R_{\sigma\rho}{}^{\mu}{}_{\gamma}R^{\rho\gamma\lambda\sigma},\end{aligned}$$

which is divergence free in the index α and whose only symmetry on the indices β, λ, and μ is $T_{10}^{\alpha\beta[\lambda\mu]}-T_{10}^{\alpha\mu[\beta\lambda]}=0$.

Next, in order to introduce other useful definitions, recall the well-known decomposition of the Riemann tensor into its irreducible parts under the full Lorentz group:

$$R_{\alpha\beta\lambda\mu}=C_{\alpha\beta\lambda\mu}+E_{\alpha\beta\lambda\mu}+G_{\alpha\beta\lambda\mu},$$

where $C_{\alpha\beta\lambda\mu}$ is the Weyl tensor and

$$E_{\alpha\beta\lambda\mu} \equiv \tfrac{1}{2}(\tilde{R}_{\alpha\lambda}g_{\beta\mu} - \tilde{R}_{\alpha\mu}g_{\beta\lambda} + \tilde{R}_{\beta\mu}g_{\alpha\lambda} - \tilde{R}_{\beta\lambda}g_{\alpha\mu}), \quad \tilde{R}_{\alpha\beta} \equiv R_{\alpha\beta} - \tfrac{1}{4}Rg_{\alpha\beta},$$

$$G_{\alpha\beta\lambda\mu} \equiv \frac{R}{12}(g_{\alpha\lambda}g_{\beta\mu} - g_{\alpha\mu}g_{\beta\lambda}),$$

with $R \equiv R^{\mu}_{\mu}$ being the scalar curvature.

The electric and magnetic parts of the Weyl tensor associated to a timelike vector field $\vec{u}$ are:

$$E_{\alpha\lambda}(\vec{u}) \equiv C_{\alpha\beta\lambda\mu}u^{\beta}u^{\mu}, \quad H_{\alpha\lambda}(\vec{u}) \equiv -\overset{*}{C}_{\alpha\beta\lambda\mu}u^{\beta}u^{\mu}.$$

These tensors are spatial (orthogonal to $\vec{u}$), symmetric, and traceless, and they fully determine the Weyl tensor.

We can proceed analogously with the tensor $E_{\alpha\beta\lambda\mu}$ and define (see Ref. 7 for a more detailed study of these matters):

$$M_{\alpha\lambda}(\vec{u}) \equiv E_{\alpha\beta\lambda\mu}u^{\beta}u^{\mu}, \quad N_{\alpha\lambda}(\vec{u}) \equiv -{*E}_{\alpha\beta\lambda\mu}u^{\beta}u^{\mu}.$$

We give here some of their properties, since they are less well known than the electric and magnetic parts of the Weyl tensor:

$$M_{\alpha\lambda} = M_{\lambda\alpha}, \quad M_{\alpha\lambda}u^{\lambda} = 0, \quad M^{\mu}_{\mu} = \tilde{R}_{\mu\nu}u^{\mu}u^{\nu},$$

$$N_{\alpha\lambda} = -N_{\lambda\alpha}, \quad N_{\alpha\lambda}u^{\lambda} = 0, \quad N^{\mu}_{\mu} = 0.$$

The tensor $M_{\alpha\lambda}$ has six independent components, while $N_{\alpha\lambda}$ has only three. Actually, they completely characterize the traceless Ricci tensor:

$$\tilde{R}_{\alpha\beta} = -2M_{\alpha\beta} - 4{*N}_{\sigma(\alpha}u^{\sigma}u_{\beta)} + M^{\sigma}_{\sigma}(g_{\alpha\beta} + 2u_{\alpha}u_{\beta}).$$

From the previous definitions, it is clear that

$$N_{\alpha\beta} = R_{\alpha\beta}u^{\alpha}u^{\beta} = R = 0 \Rightarrow R_{\alpha\beta} = -2M_{\alpha\beta},$$

and this implies, in particular, that $R_{\alpha\beta}u^{\beta} = 0$.

Let us finally give some formulas which are useful for the derivations of some expressions in Sec. IV.

$$T^{\alpha\beta\lambda\mu}u_{\alpha}u_{\beta}u_{\lambda}u_{\mu} = E_{\alpha\beta}E^{\alpha\beta} + H^{\alpha\beta}H_{\alpha\beta} + M_{\alpha\beta}M^{\alpha\beta} + N_{\alpha\beta}N^{\alpha\beta} + \frac{R^2}{48},$$

$$(\tilde{R}_{\alpha\rho}u^{\rho})(\tilde{R}^{\alpha}_{\sigma}u^{\sigma}) = 2N_{\sigma\rho}N^{\sigma\rho} - (M^{\sigma}_{\sigma})^2,$$

$$\tilde{R}_{\sigma\rho}\tilde{R}^{\sigma\rho} = 4M_{\sigma\rho}M^{\sigma\rho} - 4N_{\sigma\rho}N^{\sigma\rho}.$$

APPENDIX B: ELECTROMAGNETIC CASE

For space–times with an electromagnetic energy–momentum content, Penrose and Rindler[6] gave the following modification of the Bel–Robinson tensor (see Ref. 6 for the spinor notations and conventions):

$$t_{\alpha\beta\lambda\mu} = \Psi_{ABCD}\bar{\Psi}_{A'B'C'D'} - 2\gamma\nabla_{CD'}\varphi_{AB}\nabla_{C'D}\bar{\varphi}_{A'B'} + 6\gamma\nabla_{D(A'}\varphi_{(AB}\nabla_{C)|D'|}\bar{\varphi}_{B'C')}, \tag{B1}$$

where Ψ_{ABCD} and φ_{AB} are the Weyl and the electromagnetic spinors, respectively, and γ is the gravitational constant. This tensor is symmetric and traceless in the first three indices and has zero covariant derivative with respect to the last one, provided that the Einstein field equations hold:

$$\nabla^{\mu} t_{\alpha\beta\lambda\mu} = 0,$$

$$t_{\alpha\beta\lambda\mu} = t_{(\alpha\beta\lambda)\mu}, \quad t^{\alpha}_{\ \alpha\lambda\mu} = 0.$$

It is important to notice that the second part of this tensor is formed with $(\nabla F)^2$ terms, so it cannot be expressed by means of the Ricci tensor and its derivatives. Therefore it is independent from the tensors considered above.

The tensorial expression for (18) is rather involved but, in this case, it is useful in order to prove a positivity property. It should be noted here that in the final result we have returned to the initial signature metric $(-,+,+,+)$, and units such that $8\pi\gamma = c = 1$. With these conventions:

$$\begin{aligned} t_{\alpha\beta\lambda\mu} = {} & \tfrac{1}{4}\mathcal{T}_{\alpha\beta\lambda\mu} + 2\nabla_{(\alpha}F_{|\sigma|\beta}\nabla_{\lambda)}F^{\sigma}_{\ \mu} + 2\nabla_{(\alpha}F_{|\sigma|\beta}\nabla^{\sigma}F_{\lambda)\mu} \\ & - \tfrac{1}{2}\nabla_{(\alpha}F_{|\sigma\rho|}\nabla_{\beta}F^{\sigma\rho}g_{\lambda)\mu} + \nabla_{\sigma}F_{\rho(\alpha}\nabla^{\rho}F^{\sigma}{}_{\beta}g_{\lambda)\mu} - g_{(\alpha\beta}\nabla^{\sigma}F^{\rho}{}_{\lambda)}\nabla_{\rho}F_{\sigma\mu}, \end{aligned} \tag{B2}$$

where $\mathcal{T}_{\alpha\beta\lambda\mu}$ is the Bel–Robinson tensor and $F_{\alpha\beta}$ is the electromagnetic tensor. From this expression it is easily seen that (19) satisfies the following positivity property:

$$t_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} \geqslant 0, \quad \forall \vec{u}, \quad u_{\mu}u^{\mu} < 0,$$

$$t_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} = 0 \Leftrightarrow \begin{cases} \mathcal{T}_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} = 0 \Leftrightarrow C_{\alpha\beta\lambda\mu} = 0 \\ \dot{F}_{\lambda\mu} \equiv u^{\alpha}\nabla_{\alpha}F_{\lambda\mu} = 0. \end{cases}$$

To prove this, let us introduce the orthogonal projector to $\vec{u}$, $h_{\alpha\beta} \equiv g_{\alpha\beta} + u_{\alpha}u_{\beta}$. Then, we compute $t_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu}$:

$$\begin{aligned} t_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} &= \tfrac{1}{4}\mathcal{T}_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} + 2u^{\alpha}u^{\beta}\dot{F}_{\sigma\alpha}\dot{F}^{\sigma}{}_{\beta} + \tfrac{1}{2}(\dot{F}_{\sigma\rho}\dot{F}^{\sigma\rho}) \\ &= \tfrac{1}{4}\mathcal{T}_{\alpha\beta\lambda\mu}u^{\alpha}u^{\beta}u^{\lambda}u^{\mu} + (h^{\alpha\sigma}\dot{F}_{\alpha\beta}u^{\beta})(h_{\lambda\sigma}\dot{F}^{\lambda\mu}u_{\mu}) \\ &\quad + \tfrac{1}{2}(h^{\alpha\sigma}h^{\beta\rho}\dot{F}_{\alpha\beta})(h_{\lambda\sigma}h_{\mu\rho}\dot{F}^{\lambda\mu}) \\ &\geqslant 0, \end{aligned}$$

and the equality holds only when $C_{\alpha\beta\lambda\mu} = 0$ and

$$h^{\alpha\lambda}h^{\beta\mu}\dot{F}_{\lambda\mu} = 0, \quad h^{\alpha\sigma}\dot{F}_{\alpha\beta}u^{\beta} = 0 \Leftrightarrow \dot{F}_{\alpha\beta} = 0.$$

(Received 15 May 1998; accepted for publication 5 March 1999)

We examine the variational and conformal structures of higher-order theories of gravity that are derived from a metric-connection Lagrangian that is an arbitrary function of the curvature invariants. We show that the constrained first-order formalism when applied to these theories may lead consistently to a new method of reduction of order of the associated field equations. We show that the similarity of the field equations that are derived from appropriate actions via this formalism to those produced by Hilbert varying purely metric Lagrangians is not merely formal but is implied by the diffeomorphism covariant property of the associated Lagrangians. We prove that the conformal equivalence theorem of these theories with general relativity plus a scalar field, holds in the extended framework of Weyl geometry with the same forms of field and self-interacting potential but, in addition, there is a new ''source term'' that plays the role of a stress. We point out how these results may be further exploited and address a number of new issues that arise from this analysis. © *1999 American Institute of Physics.* [S0022-2488(99)03906-7]

I. INTRODUCTION

According to the standard variational principle (Hilbert variation) that leads to the Einstein field equations of general relativity, the gravitational action $\int R\sqrt{-g}$ is varied with respect to the metric tensor of a spacetime manifold that is taken to be a four-dimensional Lorentz manifold $(\mathcal{M},\mathbf{g})$ with metric $\mathbf{g}$ and the Levi-Civita connection ∇. However, in many instances (see Ref. 1 for a complete review), one considers a Lorentz manifold with an arbitrary connection $\tilde{\nabla}$ that is incompatible with the metric, i.e., $\tilde{\nabla}\mathbf{g}\neq 0$. A motivation for such a generalization was initially inspired by the early work of Weyl (Ref. 2). In this case, one considers the variation of an appropriate action with respect to both the metric components g_{ab} and the connection coefficients Γ^a_{bc} without imposing from the beginning that Γ^a_{bc} be the usual Christoffel symbols. In the current literature this variational principle, where the metric and the connection are considered as independent variables, is referred to as the *first-order* or *metric-connection*, or simply *Palatini variation*. (For a historical commentary of this principle of variation and related issues, we refer to Ref. 3.)

Such alternative variational methods were first analyzed in the framework of nonlinear gravitational Lagrangians by Weyl (Ref. 2), Eddington (Ref. 4), and others (Refs. 5–20). In an effort to obtain second-order field equations different from Einstein's, Stephenson (Refs. 5, 6) and Higgs (Ref. 7) applied the first-order formalism to the quadratic Lagrangians R^2, $R_{ab}R^{ab}$, $R_{abcd}R^{abcd}$ and Yang (Ref. 8) investigated the Lagrangian $R_{abcd}R^{abcd}$, by analogy with the Yang–Mills Lagrangian. However, Buchdahl (Ref. 9) pointed out a difficulty associated with this version of

[a]Electronic mail: skot@aegean.gr
[b]Electronic mail: john@env.aegean.gr
[c]Electronic mail: querella@astro.ulg.ac.be

the metric-connection variation, which is related to imposing the metricity condition, i.e., the connection coefficients equal to the Christoffel symbols, *after* completing the variation, and subsequently constructed specific examples, showing that this version of the first-order formalism is not a reliable method, in general (Ref. 10). Van den Bergh (Ref. 11) arrived at a similar conclusion in the context of general scalar-tensor theories. The $R+\alpha R^2$ theory including matter was investigated in this framework by Shahid-Saless (Ref. 12) and generalized to the $f(R)$ case by Hamity and Barraco (Ref. 13). These authors also studied conservation laws and the weak field limit of the resulting equations. More recently, Ferraris *et al.* (Ref. 14) showed that the first-order formalism applied to general $f(R)$ vacuum Lagrangians leads to a series of Einstein spaces with cosmological constants determined by the explicit form of the function *f*. Similar results were obtained in the case of $f(\mathrm{Ric}^2)$ theories by Borowiec *et al.* (Ref. 15).

A consistent way to consider independent variations of the metric and connection in the context of Riemannian geometry is to add a compatibility condition between the metric and the connection as a constraint with Lagrange multipliers. In vacuum general relativity, this *constrained first-order formalism* results in the Lagrange multipliers vanishing identically as a consequence of the field equations (Ref. 16). This method was applied to quadratic Lagrangians, with the aim of developing a Hamiltonian formulation for these theories in Ref. 17.

Consider a Lorentzian manifold $(\mathcal{M},\mathbf{g},\tilde{\nabla})$ of dimension *D*, where $\tilde{\nabla}$ is an arbitrary symmetric connection. Hence, $\tilde{\nabla}\mathbf{g}\neq 0$ that is, the connection coefficients, are functions independent of the metric components, and the Ricci tensor is a function of the connection only. In the case of general relativity without matter fields, varying the corresponding action,

$$S=\int L\sqrt{-g}\,\mathrm{d}^D x,\quad L=g^{mn}R_{mn}, \tag{1}$$

one arrives at the well-known result that variation with respect to the metric produces the vacuum Einstein's equations, whereas variation with respect to the connection reveals that the connection is necessarily the Levi-Civita connection (provided that $D\neq 2$). The integral (1) is taken over a compact region $\mathcal{U}$ of the spacetime $(\mathcal{M},\mathbf{g},\tilde{\nabla})$, and we assume that the metric and the connection are held constant on the boundary of $\mathcal{U}$. In the sequel we omit the symbol $\mathrm{d}^D x$ under the integral sign and set $w:=\sqrt{-g}$. Gothic characters denote tensor densities, for example $\mathfrak{g}_{ab}:=wg_{ab}$.

In the presence of matter fields, there is an ambiguity because the compatibility condition between the metric and the connection does not hold. The matter Lagrangian depends primarily on the field variables ψ, and assumes a form that is a generalization of its special relativistic form, which is achieved via the strong principle of equivalence and the principle of minimal coupling, according to the scheme $\eta_{ab}\rightarrow g_{ab}$ and $\partial\rightarrow\tilde{\nabla}$ (the order of the two steps being irrelevant as long as the connection is the Levi-Civita one). Variation of the total action,

$$S=\int[\mathfrak{R}(g,\Gamma)+\mathfrak{L}_m(g,\psi,\tilde{\nabla}\psi)], \tag{2}$$

gives the following pair of equations:

$$G_{ab}=T_{ab}:=-\frac{2}{w}\frac{\delta\mathfrak{L}_m}{\delta g^{ab}}, \tag{3a}$$

$$\delta_c^b\,\tilde{\nabla}_d\mathfrak{g}^{ad}+\delta_c^a\,\tilde{\nabla}_d\mathfrak{g}^{bd}-2\,\tilde{\nabla}_c\mathfrak{g}^{ab}=2\,\frac{\delta\mathfrak{L}_m}{\delta\Gamma_{ab}^c}. \tag{3b}$$

These equations are inconsistent in general unless the matter Lagrangian does not depend explicitly on the connection, i.e., $\delta\mathfrak{L}_m/\delta\Gamma_{ab}^c=0$. [It is interesting to note that in the case $D=2$ in vacuum, since the equation $\Gamma^c_{ab}=\{^{c}_{ab}\}+1/2(\delta^c_a Q_b+\delta^c_b Q_a-g_{ab}Q^c)$, with $Q_a:=-\bar{\nabla}_a \ln w=-\partial_a \ln w+\Gamma_a$, and $\Gamma_a:=\Gamma^b_{ab}$, has a vanishing trace, $(1-D/2)(\partial_a \ln\sqrt{-g}-\Gamma_a)=0$, the Γ_a part of the connection is undetermined (Ref. 18).]

In Sec. II, after a brief review of the unconstrained metric-connection variational results in higher-order gravity theories, we show how the constrained first-order formalism is used to prove that the field equations of these theories can be given in a reduced form that makes the comparison to the usual Hilbert equations direct and point out that such a correspondence is due to the diffeomorphism covariance property of the associated Lagrangians. In Sec. III, we prove that in Weyl geometry, higher-order gravity theories are conformally equivalent to general relativity plus a scalar field matter source with the same self-interacting potential as in the standard Riemannian case, together with a new ''source term'' that arises as a result of the presence of the Weyl covariant vector field. In the last section, we comment on the usefulness of the extended form of the conformal equivalence and point out how these results may be further exploited to develop this framework.

II. CONSTRAINED AND UNCONSTRAINED VARIATIONS

We begin with a Lagrangian that is a smooth function of the scalar curvature R and vary the corresponding action,

$$S=\int wf(R), \tag{4}$$

with respect to the metric tensor and the connection to obtain, respectively,

$$f'R_{(ab)}-\tfrac{1}{2}fg_{ab}=0, \tag{5a}$$

$$\bar{\nabla}_a(wf'g^{bc})=0. \tag{5b}$$

Explicitly, the Γ equation (5b) reads as

$$(\partial_a \ln w+(\ln f')'\partial_a R-\Gamma_a)g_{bc}-\partial_a g_{bc}+\Gamma^m_{ba}g_{mc}+\Gamma^m_{ca}g_{mb}=0, \tag{6}$$

and so we can solve for Γ_a and substitute back in (6) to find

$$\partial_a\tilde{g}_{bc}=\Gamma^m_{ba}\tilde{g}_{mc}+\Gamma^m_{ca}\tilde{g}_{mb}, \tag{7}$$

where we have introduced a new metric $\tilde{g}_{ab}:=f'g_{ab}$, with conformal factor f'. This means that Γ is the Levi-Civita connection for the metric $\tilde{\mathbf{g}}$.

Equation (5a) is more straightforward. On the one hand, its trace $f'(R)R=2f(R)$ is satisfied identically if $f(R)=\alpha R^2$ (up to a constant rescaling factor α), and so (5a) becomes $R_{ab}-(1/4)Rg_{ab}=0$ [provided that $f'(R)\neq 0$], which finally gives $\tilde{R}_{ab}-(1/2\alpha)\tilde{g}_{ab}=0$ so that the underlined manifold is an Einstein space with constant scalar curvature $\tilde{R}=\tilde{g}^{ab}\tilde{R}_{ab}=2/\alpha$. On the other hand, one could regard the above trace as an algebraic equation in R with roots $\rho_1,\rho_2,\ldots$. This situation was analyzed by Ferraris *et al.* (Ref. 14), who showed that such an analysis leads to a series of Einstein spaces, each having a constant scalar curvature (see also Ref. 10).

By a completely analogous procedure, one finds Einstein spaces for the choice $L=f(r)$ where $r=Q_{ab}Q^{ab}$, and Q_{ab} is the symmetric part of the Ricci tensor, and also for the Lagrangian $L=f(K)$, where $K=R_{abcd}R^{abcd}$. Note that in this last case, varying the corresponding action with respect to the metric and the connection, one obtains

$$-\tfrac{1}{2}fg_{ab}-f'R_a{}^{klm}R_{bklm}+f'R^k{}_{alm}R_{kb}{}^{lm}+2f'R^k{}_{lam}R_k{}^l{}_b{}^m=0 \tag{8}$$

and

$$\overset{\Gamma}{\nabla}_d(wf' R_a{}^{(bc)d})=0, \tag{9}$$

with trace $f'(K)K=f(K)$. Hence, either $f(K)=\alpha K$ identically or, given a function f, the trace is solved algebraically for K. In contrast to the previous cases, there exists no natural way to derive a metric $\tilde{\mathbf{g}}$ from the field equation (9) unless the Weyl tensor vanishes (Ref. 19). Notice that the field equations derived from the Lagrangian $R_{[ab]}R^{ab}$ by the Palatini variation impose only four conditions upon the 40 connection coefficients and leave the metric components entirely undetermined (Ref. 10).

Let us now introduce a vector field Q_c called the Weyl covariant vector field and assume a linear metric-connection relation,

$$\overset{\Gamma}{\nabla}_c g_{ab}=-Q_c g_{ab}, \tag{10}$$

and define

$$C^c_{ab}=\Gamma^c_{ab}-\left\{ {c \atop ab} \right\}, \tag{11}$$

where

$$\Gamma^c_{ab}=\left\{ {c \atop ab} \right\}+\tfrac{1}{2}g^{cm}(Q_b g_{am}+Q_a g_{mb}-Q_m g_{ab}). \tag{12}$$

The *constrained* first-order formalism consists of adding to the original Lagrangian the following term as a constraint (with Lagrange multipliers Λ):

$$L_c(g,\Gamma,\Lambda)=\Lambda_r{}^{mn}\left[\Gamma^r_{mn}-\left\{ {r \atop mn} \right\}-C^r_{mn}\right]. \tag{13}$$

For instance, in Riemannian geometry (13) takes the form

$$L_c(g,\Gamma,\Lambda)=\Lambda_r{}^{mn}\left[\Gamma^r_{mn}-\left\{ {r \atop mn} \right\}\right],$$

while, in Weyl geometry,

$$L_c(g,\Gamma,\Lambda)=\Lambda_r{}^{mn}\left[\Gamma^r_{mn}-\left\{ {r \atop mn} \right\}-\frac{1}{2}g^{rs}(Q_n g_{ms}+Q_m g_{sn}-Q_s g_{mn})\right].$$

As an example, consider any of the previous test Lagrangians $L(g,\Gamma,\psi)$ and vary the resulting action,

$$S=\int w[L(g,\Gamma,\psi)+L_c(g,\Gamma,\Lambda)], \tag{14}$$

with respect to the independent fields g, Γ, Λ, and ψ. We find the g equations

$$\left.\frac{\delta(wL)}{\delta g^{ab}}\right|_\Gamma+wB_{ab}=0, \tag{15}$$

where B_{ab} is defined by

$$B_{ab}:=-\tfrac{1}{2}\overset{\Gamma}{\nabla}{}^m[\Lambda_{bam}+\Lambda_{amb}-\Lambda_{mab}], \tag{16}$$

and the Γ equations

$$\left.\frac{\delta L}{\delta \Gamma^{c}{}_{ab}}\right|_{g} + \Lambda_{c}{}^{ab} = 0. \tag{17}$$

Variation with respect to the matter fields ψ yields their respective equations of motion. In the Riemannian case, in particular, we have (some of the expressions given below appear incorrectly in Ref. 17): for the Lagrangian $L=R^2$,

$$\tfrac{1}{2}R^2 g^{ab} - 2RR^{ab} + B^{ab} = 0, \tag{18a}$$

$$\Lambda_{c}{}^{ab} = (2g^{ab}\delta^{m}_{c} - g^{am}\delta^{b}_{c} - g^{mb}\delta^{a}_{c})\bar{\nabla}_{m}R, \tag{18b}$$

$$B^{ab} = -2g^{ab}\bar{\Box}R + 2\bar{\nabla}^{b}\bar{\nabla}^{a}R; \tag{18c}$$

for the Lagrangian $L=R_{mn}R^{mn}$,

$$\tfrac{1}{2}R_{mn}R^{mn}g^{ab} - R^{am}R^{b}{}_{n} - R_{m}{}^{b}R^{ma} + B^{ab} = 0, \tag{19a}$$

$$\Lambda_{c}{}^{ab} = 2\bar{\nabla}_{c}R^{ab} - \delta^{a}_{c}\bar{\nabla}_{m}R^{mb} - \delta^{b}_{c}\bar{\nabla}_{m}R^{am}, \tag{19b}$$

$$B^{ab} = -\bar{\Box}R^{ab} + 2\bar{\nabla}_{m}\bar{\nabla}^{b}R^{am} - g^{ab}\bar{\nabla}_{n}\bar{\nabla}_{m}R^{mn}; \tag{19c}$$

for the Lagrangian $L=R_{mnrs}R^{mnrs}$,

$$\tfrac{1}{2}R_{mnrs}R^{mnrs}g^{ab} - 2R^{amnr}R^{b}{}_{mnr} + B^{ab} = 0, \tag{20a}$$

$$\Lambda_{a}{}^{bc} = 2\bar{\nabla}_{m}R_{a}{}^{bcm} + 2\bar{\nabla}_{m}R_{a}{}^{cbm}, \tag{20b}$$

$$B^{ab} = 4\bar{\nabla}_{n}\bar{\nabla}_{m}R^{ambn}; \tag{20c}$$

and for the Lagrangian $L=f(R)$,

$$\tfrac{1}{2}fg_{ab} - f'R_{(ab)} + B_{ab} = 0, \tag{21a}$$

$$(2g^{bc}\delta^{m}_{a} - g^{mc}\delta^{b}_{a} - g^{bm}\delta^{b}_{a})\bar{\nabla}_{m}f' = \Lambda_{a}{}^{bc}, \tag{21b}$$

$$B^{ab} = -g^{ab}\bar{\Box}f' + \bar{\nabla}^{b}\bar{\nabla}^{a}f'. \tag{21c}$$

It is straightforward to obtain the correspondence with the Hilbert case by substituting the B_{ab}'s in the first equation in each of these above cases. They read, respectively, as

$$\tfrac{1}{4}R^2 g^{ab} - RR^{ab} + \nabla^{b}\nabla^{a}R - g^{ab}\Box R = 0, \tag{22a}$$

$$\tfrac{1}{2}R_{mn}R^{mn}g^{ab} - 2R^{bman}R_{mn} + \nabla^{b}\nabla^{a}R - \Box R^{ab} - \tfrac{1}{2}\Box R g^{ab} = 0, \tag{22b}$$

$$\tfrac{1}{2}R_{mnrs}R^{mnrs}g^{ab} - 2R^{mnrb}R_{mnr}{}^{a} + 4\nabla_{n}\nabla_{m}R^{amnb} = 0, \tag{22c}$$

$$f'R_{(ab)} - \tfrac{1}{2}fg_{ab} - \nabla_{a}\nabla_{b}f' + g_{ab}\Box f' = 0. \tag{22d}$$

Strictly speaking, compared to the usual Hilbert variation, in all cases considered so far using the first-order formalism, one starts from a *different* Lagrangian defined in a *different* function space, follows a *different* method, but nonetheless ends up in the same set of field equations. This means that although the gravitational Lagrangians in a Hilbert type of variational procedure are treated as functions of $(x^{\mu}, g, \partial g, \ldots)$, whereas in a metric-connection formalism the corresponding function spaces become sets of points of the form $(x^{\mu},g,\partial g,\Gamma,\partial\Gamma,\ldots)$, the field equations are the same. We shall now see this is not a mere formal coincidence but that the reason lies in the fact that all our test Lagrangians are *diffeomorphism covariant*.

All previous cases can be considered as specializations derived from a very general Lagrangian n-form constructed locally as follows:

$$L=L(g_{ab},\tilde{\nabla}_{a_1}g_{ab},\ldots,\tilde{\nabla}_{(a_1}\cdots\tilde{\nabla}_{a_k)}g_{ab},\psi,\tilde{\nabla}_{a_1}\psi,\ldots,\tilde{\nabla}_{(a_1}\cdots\tilde{\nabla}_{a_l)}\psi,\gamma), \tag{23}$$

that is, L is a function of dynamical fields g,ψ and also of other fields collectively referred to as γ. Referring to g and ψ as ϕ, L is called f-covariant, $f\in\mathrm{Diff}(M)$, or simply diffeomorphism covariant, if

$$L(f^*(\phi))=f^*L(\phi), \tag{24}$$

where f^* denotes the induced action of f on the fields ϕ. Note that this definition excludes the action of f^* on $\tilde{\nabla}$ or the other fields γ. It immediately follows that our test Lagrangians considered previously satisfy the above definition and as a result are diffeomorphism covariant.

It is a very interesting result, first shown by Iyer and Wald (Ref. 21), that if L in (23) is diffeomorphism covariant, then L can be reexpressed in the form

$$L=L(g_{ab},R_{bcde},\nabla_{a_1}R_{bcde},\ldots,\nabla_{(a_1}\cdots\nabla_{a_m)}R_{bcde},\psi,\nabla_{a_1}\psi,\ldots,\nabla_{(a_1}\cdots\nabla_{a_l)}\psi), \tag{25}$$

where ∇ denotes the Levi-Civita connection of g_{ab}, R_{abcd} denotes the Riemann curvature of g_{ab}, and $m=\max(k-2,l-2)$. Notice that everything is expressed in terms of the Levi-Civita connection of the metric tensor and also that all other fields γ are absent.

Applying the Iyer–Wald theorem in our test Lagrangians, we immediately see that we could have reexpressed them from the beginning in a form that involves only the Levi-Civita connection and not the original arbitrary connection $\tilde{\nabla}$, and vary them to obtain the corresponding ''Hilbert'' equations. As we showed above, we arrived at this result by treating the associated Lagrangians as *different* (indeed they are!) according to whether or not they involved an arbitrary (symmetric) or a Levi-Civita connection.

III. CONFORMAL STRUCTURE AND WEYL GEOMETRY

For the more general nonlinear Lagrangians of the form $f(q)$, where $q=R$, $R_{ab}R^{ab}$, or $R_{abcd}R^{abcd}$, where f is an arbitrary smooth function considered in the previous section, the field equations obtained by the metric-connection formalism are of second order while the corresponding ones obtained via the usual metric variation are of fourth order. This result sounds very interesting since it could perhaps lead to an alternative way to ''cast'' the field equations of these theories in a more tractable, reduced form than the one that is usually used for this purpose, namely, the conformal equivalence theorem (Ref. 22). In this way, certain interpretational issues related to the question of the physicality of the two metrics (Refs. 23, 24) associated with the conformal transformation would perhaps be avoided.

As discussed in the previous section, the constraint (13) for Weyl geometry becomes

$$L_c(g,\Gamma,\Lambda)=\Lambda_c{}^{ab}\left[\Gamma^c_{ab}-\left\{\begin{matrix}c\\ ab\end{matrix}\right\}-\frac{1}{2}g^{cm}(Q_a g_{mb}+Q_b g_{am}-Q_m g_{ab})\right]. \tag{26}$$

In order to examine the consequences of the Weyl constraint (26), we now apply the constrained first-order formalism to the Lagrangian $L=f(R)$. Variation with respect to the Lagrange multipliers recovers the expression (12) of the Weyl connection. Variation with respect to the metric yields the g equations,

$$f'R_{(ab)}-\tfrac{1}{2}fg_{ab}+B_{ab}=0, \tag{27}$$

where B_{ab} is defined by (16). Variation with respect to the connection yields the explicit form of the Lagrange mutlipliers, namely,

$$\Lambda_c{}^{ab}=\tfrac{1}{2}\delta_c^b(Q^a f'-\bar\nabla^a f')+\tfrac{1}{2}\delta_c^a(Q^b f'-\bar\nabla^b f')-g^{ab}(Q_c f'-\bar\nabla_c f'). \tag{28}$$

(We note that since we are considering only variations with respect to the dependent variables g and Γ and also the Lagrange multipliers, and since the Γ's are functions of Q_a [from Eq. (12)], the Weyl vector field Q_a essentially plays the role of an independent variable and so we refrain from considering variations with respect to Q_a.) Substituting back this last result into Eq. (16), we find

$$B_{ab}=2Q_{(a}\bar\nabla_{b)}f'-\bar\nabla_{(a}\bar\nabla_{b)}f'+f'\bar\nabla_{(a}Q_{b)}-f'Q_aQ_b-g_{ab}(2Q_m\bar\nabla^m f'-Q^2f'-\bar\Box f'+f'\bar\nabla^m Q_m). \tag{29}$$

Inserting this result into Eq. (27) we obtain the full field equations for the Lagrangian $L=f(R)$ in the framework of Weyl geometry, namely,

$$f'R_{(ab)}-\tfrac{1}{2}fg_{ab}-\bar\nabla_a\bar\nabla_b f'+g_{ab}\bar\Box f'=M_{ab}, \tag{30}$$

where M_{ab} is defined by

$$M_{ab}=-2Q_{(a}\bar\nabla_{b)}f'-f'\bar\nabla_{(a}Q_{b)}+f'Q_aQ_b+g_{ab}(2Q_m\bar\nabla^m f'-Q^2f'+f'\bar\nabla^m Q_m). \tag{31}$$

It is interesting to note that the degenerate case $Q_a=0$ corresponds to the usual field equations obtained by the Hilbert variation in the framework of Riemann geometry, namely,

$$f'R_{ab}-\tfrac{1}{2}fg_{ab}-\nabla_a\nabla_b f'+g_{ab}\Box f'=0.$$

It is known that these equations are conformally equivalent to Einstein equations with a self-interacting scalar field as the matter source (Ref. 22). In what follows, we generalize this property of the $f(R)$ field equations in Weyl geometry. To this end, we define the metric $\tilde g$ conformally related to g with f' as the conformal factor. Under a conformal transformation, the Weyl vector field transforms as

$$\tilde Q_a=Q_a-\bar\nabla_a \ln f',$$

and the field equations (30) in the conformal frame read as

$$f'\tilde R_{(ab)}-\frac{1}{2}\frac{f}{f'}\tilde g_{ab}-\tilde{\bar\nabla}_a\tilde{\bar\nabla}_b f'+\tilde g_{ab}\bar\Box f'=\tilde M_{ab},$$

where $\tilde{\bar\nabla}=\bar\nabla$, $\bar\Box\tilde g^{ab}\tilde{\bar\nabla}_a\tilde{\bar\nabla}_b=(f')^{-1}\bar\Box$, and $\tilde M_{ab}$ is given by

$$\tilde M_{ab}=f'\tilde Q_a\tilde Q_b-f'\tilde{\bar\nabla}_{(a}\tilde Q_{b)}-\tilde{\bar\nabla}_a\tilde{\bar\nabla}_b f'+\tilde g_{ab}(f'\tilde{\bar\nabla}^m\tilde Q_m-f'\tilde Q^2+\bar\Box f'). \tag{32}$$

Introducing the scalar field $\varphi=\ln f'$ and the potential $V(\varphi)$ in the ''usual'' form (Ref. 22),

$$V(\varphi)=\tfrac{1}{2}(f'(R))^{-2}(Rf'(R)-f(R)), \tag{33}$$

we find that the field equations take the final form

$$\tilde G_{ab}=\tilde M_{ab}^{Q}-\tilde g_{ab}V(\varphi), \tag{34}$$

where

$$\tilde G_{ab}=\tilde R_{(ab)}-\tfrac{1}{2}\tilde R\tilde g_{ab},$$

and

$$\tilde{M}^{Q}_{ab}=\tilde{Q}_a\tilde{Q}_b-\tilde{\nabla}_{(a}\tilde{Q}_{b)}+\tilde{g}_{ab}(\tilde{\nabla}^m\tilde{Q}_m-\tilde{Q}^2).$$

The field equations (34) are Einstein equations for a self-interacting scalar field matter source with a potential $V(\varphi)$ and a source term $\tilde{M}^{Q}_{ab}$ depending on the field $\tilde{Q}_a$. If the geometry is Riemannian, i.e., $\tilde{Q}_a=0$, one recovers the standard unconstrained variation result. This will be the case only if the original Weyl vector field is a gradient, $Q_a=\nabla_a\Phi$. Then it can be gauged away by the conformal transformation $\tilde{g}_{ab}=(\exp\Phi)g_{ab}$, and therefore the original space is not a general Weyl space but a Riemann space with an undetermined gauge (Ref. 25). We saw an example of this previously when we applied the unconstrained method to the Lagrangian $L=f(R)$. Here, the Weyl vector was deduced using Eq. (6) and turned out to be $Q_a=\nabla_a(\ln f')$. (In Ref. 20, this peculiarity is used in order to find out a subclass of theories based on a general *D*-dimensional dilaton gravity action, for which both unconstrained method and Hilbert variation yield dynamically equivalent systems.) This fact shows that unconstrained variations cannot deal with a general Weyl geometry and correspond to a degenerate case of the constrained method—the field equations obtained from the former can be recovered only by choosing specific forms of the Weyl vector field (Ref. 26).

IV. DISCUSSION

The results obtained in Sec. II and Sec. III have the interpretation that a consistent way to investigate generalized theories of gravity without imposing from the beginning that the geometry is Riemannian, is the constrained first-order formalism. Applications to quadratic and $f(R)$ Lagrangians in the framework of Riemannian and Weyl geometry reveal that unconstrained variational methods are degenerate cases corresponding to a particular gauge and that the usual conformal structure can be recovered in the limit of a vanishing Weyl vector.

The generalization of the result stated above to include arbitrary connections with torsion can be an interesting exercise. The physical interpretation of the source term [Eqs. (30) and (31)] is closely related to the choice of the Weyl vector field *Q*. However, it cannot be interpreted as a genuine stress–energy tensor in general since, for instance, choosing *Q* to be a unit timelike, hypersurface-orthogonal vector field, the sign of $M_{ab}Q^aQ^b$ depends on the signs of $f'(R)$ and the ''expansion'' ∇_aQ^a.

The generalization of the conformal equivalence theorem presented in Sec. III opens the way to analyzing cosmology in the framework of these Weyl $f(R)$ theories by methods such as those used in the traditional Riemannian case. The first steps in such a program may be as follows (Ref. 27).

(a) Analyze the structure and properties of Friedmann cosmologies, find their singularity structure, and examine the possibility of inflation.
(b) Consider the past and future asymptotic states of Bianchi cosmologies. Examine isotropization and recollapse conjectures in such universes. Look for chaotic behavior in the Bianchi VIII and IX spacetimes.
(c) Formulate and prove singularity theorems in this framework. This will differ from the analysis in the Riemannian case (cf. Ref. 22) because of the presence of the source term M_{ab}.

All the problems discussed above can be tackled by leaving the conformal Weyl vector field $\tilde{Q}_a$ undetermined while setting it to zero at the end will lead to detailed comparisons with the results already known in the Riemannian case.

A reinforced random walk on the d-dimensional lattice is considered. It is shown that this walk is equivalent to an iterated function system (IFS). Criteria for the existence of limit cycles are given. Numerical results and conjectures about the quantitative behavior of the walk are stated. © *1999 American Institute of Physics.* [S0022-2488(99)00905-6]

I. INTRODUCTION

There are a large number of different modifications and variants of the usual symmetrical random walk (RW).[1–3] Let us mention only Levy flights, biased diffusions, self-avoiding walk (SAW for short), etc. Let us confine ourselves to the random walks on the discrete lattices. In SAW a walking particle is choosing its trajectory in such a way that it does not step down onto the already visited site. If a particle runs into such a node that all neighboring sites were already visited, it stops. In Ref. 4 the interacting RW was discussed in which the parameter $0<p<\infty$ has influenced probabilities of visiting a given site and $p=1$ corresponds to usual RW. For $p\rightarrow\infty$ this RW goes on into the SAW.

In 1987 Coppersmith and Diaconis[5] introduced reinforced random walk (RRW). This walk, opposite to SAW, prefers earliest visited paths. Pemantle[6] discussed a related process on trees and proved that this process is equivalent to a random walk in a random environment. He also gave criteria for transience and recurrence of RRW. Davis[7] considered a variety of types of RRW on the integers **Z**. One of them was RRW of sequence type. This process is defined in the following way. Let w_k be an increasing sequence of non-negative numbers. Let (X_n) be a random motion on **Z**. If some interval was traversed k-times, then its weights is w_k. If $X_n=i$, then the probability that $X_{n+1}=i-1$ or $X_{n+1}=i+1$ is proportional to the weights at time n of the intervals $(i-1,i)$ and $(i,i+1)$. Davis proved that the moving point visits a finite number of integers and eventually oscillates between two adjacent integers if and only if $\Sigma_{k=0}^{\infty}w_k^{-1}<\infty$. This result was generalized to RRW sequence type on the d-dimensional lattice by Sellke.[8]

In this paper we consider another type of reinforced random walk on the d-dimensional lattice. The random point moves according to the following reinforcement convention. Let the moving point be found at time $t=n$ at a certain point $A\in\mathbf{Z}^n$. Let $p_1,\ldots,p_N$ be the probabilities of choosing one of the adjacent points $A_1,\ldots,A_N$. Assume that we choose the point A_{i_0}. If after some time the moving point returns to A, then the probabilities that at the next step it can be found at the adjacent points are equal to $p_1',\ldots,p_N'$. The values of $p_1',\ldots,p_N'$ depend on the previous values $p_1,\ldots,p_N$ and i_0. We assume that the probability of choosing a given path will increase when it was already traversed and probabilities of remaining paths emanating from a given site will decrease. In other words, the fact that some sites were already visited will be remembered. The memory of passing particular edges will be encoded in the change of probabilities. At some time

[a)]Electronic mail: mwolf@ift.uni.wroc.pl

the probability of going in some direction from a given site will reach almost 1, while probabilities to go in other directions will be practically zero. It will result in closed paths: a random walker will oscillate between a few sites with practically zero probability to escape from such a limiting cycle. We will treat such a final behavior as stopping of the random walk.

Our walk is not Markovian because the probability of choosing any direction changes in time. If we extend the phase space by adding the distributions of probabilities of passing particular edges, we obtain a Markov process which is also an iterated function system.[9] In Refs. 10 and 11 were introduced self-attracting diffusions: processes attracted by their own trajectories. It is interesting that these processes and our walk have similar features. For example, self-attracting diffusions are not Markovian, but jointly with their occupation measures are Markov processes. Moreover, their trajectories converge almost surely.

The paper is organized as follows. First we define our random walk and the notion of the limit cycle is introduced. Next we prove the theorem that this walk reaches the limit cycle. In Sec. IV the result of the Monte Carlo simulations for a particular ''memorizing'' function are presented. These computer experiments allow us to make some conjecture about the quantitative behavior of some characteristics of the walk.

II. MATHEMATICAL MODEL

A. Description of the random walk with memory

Let $\mathcal{Z}$ denote the set of all points of the d-dimensional Euclidean space which have integer coordinates, i.e., $\mathcal{Z}$ is the d-dimensional lattice. A point moves randomly over this lattice. It starts at point $\mathbf{0}=(0,...,0)$. If at time $t=n$ the moving point can be found at a certain point $x=(x_1,\ldots,x_d)$, then at the time $t=n+1$ it can be found at one of the $N=2^d$ adjacent points $y=(y_1,\ldots,y_d)$, where $y_i=x_i+1$ or $y_i=x_i-1$ for $i=1,2,...,d$. By $\mathcal{K}$ we denote the set of all possible ''steps'' during the walk, i.e.,

$$\mathcal{K}=\{(x,y)\in\mathcal{Z}\times\mathcal{Z}:|y_i-x_i|=1 \quad \text{for } i=1,...,d\}.$$

If $z=(x,y)\in\mathcal{K}$, then the points x and y are, respectively, the beginning and the end of the step z. Let $\mathcal{S}=\{1,-1\}^d$ be the set of all N steps to the nearest neighbors. If $x\in\mathcal{Z}$, $s\in\mathcal{S}$, and $y=x+s$, then $(x,y)\in\mathcal{K}$.

At time $t=0$ the probability of choosing of any adjacent point equals 2^{-d}. During the walk the point ''memorizes'' its path in the following way. Assume that the moving random walker can be found at some time $t=n$ at a certain point $x\in\mathcal{Z}$. Let $p_{x,x+s}$, $s\in\mathcal{S}$, be the probabilities that at the time $t=n+1$ it can be found at one of the adjacent points $x+s$, $s\in\mathcal{S}$. Assume that we choose the point $x+s_0$ to shift the particle from the point x. If after some time the moving point returns to x, then the probabilities that at the next step it can be found at the adjacent points are equal to $p'_{x,x+s}$, $s\in\mathcal{S}$. The numbers $p'_{x,x+s}$ are related to the previous values $p_{x,x+s}$ in the following way. Let $\mathbf{p}_x=(p_{x,x+s})_{s\in\mathcal{S}}$, $\mathbf{p}'_x=(p'_{x,x+s})_{s\in\mathcal{S}}$, and

$$\mathbf{P}=\left\{\mathbf{p}_x\in[0,1]^{\mathcal{S}}:\sum_{s\in\mathcal{S}}p_{x,x+s}=1\right\}.$$

Then

$$\mathbf{p}'_x=f_{s_0}(\mathbf{p}_x), \tag{1}$$

where $f_{s_0}:\mathbf{P}\to\mathbf{P}$ is a continuous function.

If $z\in\mathcal{K}$ and $z=(x,y)$, we will often write p_z instead of $p_{x,y}$.

B. Iterated function system

The state of the random walk with memory is described at any time t by the position of the moving point and the probability p_z for every $z \in \mathcal{K}$. Let $\mathcal{P}$ denote the set of all admissible distributions of probabilities p_z, $z \in \mathcal{K}$, i.e.,

$$\mathcal{P} = \left\{ p \in [0,1]^{\mathcal{K}} : \sum_{s \in \mathcal{S}} p_{x,x+s} = 1 \quad \text{for each} \quad x \in \mathcal{Z} \right\}.$$

Then the phase space is the set $\mathcal{X} = \mathcal{Z} \times \mathcal{P}$. Since $\mathbf{p}_x = (p_{x,x+s})_{s \in \mathcal{S}}$ for every $x \in \mathcal{Z}$, we have $\mathcal{P} = \mathbf{P}^{\mathcal{Z}}$ and $\mathcal{X} = \mathcal{Z} \times \mathbf{P}^{\mathcal{Z}}$.

Now, we define an iterated function[9] system on the phase space $\mathcal{X}$. It consists of N transformations $T_s : \mathcal{X} \to \mathcal{X}$, $s \in \mathcal{S}$. These transformations are defined as follows. Let $x \in \mathcal{Z}$ and $s \in \mathcal{S}$ be given. Then $T_s(x,p) = (x+s, p')$, where

$$\mathbf{p}'_z = \begin{cases} \mathbf{p}_z, & \text{if } z_1 \neq x, \\ f_s(\mathbf{p}_z), & \text{if } z_1 = x, \end{cases}$$

for each $z = (z_1, z_2) \in \mathcal{K}$. If (x,p) is the state of the random walk at a time t and if the next position of the moving point is $x+s$, then $T_s(x,p)$ is the next state of the random walk. The probability that at a point $\chi = (x,p)$ we choose the transformation T_s is equal $p_s(\chi) = p_{x,x+s}$.

C. Markov process on $\mathcal{X}$

Now we construct a Markov process corresponding to the iterated function system given in Sec. II B.

The phase space $\mathcal{X}$ is a metric space with some metric ρ defined as follows. The set $\mathcal{K}$ is countable, that is, $\mathcal{K} = \{z_1, z_2, z_3, \ldots\}$, where $\{z_n\}_{n \in \mathbf{N}}$, $z_n \in \mathcal{K}$, is the sequence of all possible steps. If $x \in \mathcal{X}$, $y \in \mathcal{X}$, then $x = (u, p_{z_1}, p_{z_2}, \ldots)$ and $y = (u', p'_{z_1}, p'_{z_2}, \ldots)$, where u, $u' \in \mathcal{Z}$ and $p_{z_k}, p'_{z_k} \in [0,1]$ for each $k \in \mathbf{N}$. The metric ρ is given by

$$\rho(x,y) = |u - u'| + \sum_{k=1}^{\infty} 2^{-k} |p_{z_k} - p'_{z_k}|.$$

Let $\mathcal{B}$ be the σ-algebra of Borel subsets of $\mathcal{X}$. For any $x \in \mathcal{X}$ and $A \in \mathcal{B}$ we set

$$I(x,A) = \{s \in \mathcal{S} : T_s(x) \in A\}, \quad P(x,A) = \sum_{s \in I(x,A)} p_s(x).$$

Then $P(x,A)$ is a transition probability function, i.e.,

(a) for each $x \in \mathcal{X}$ the function $A \mapsto P(x,A)$ is a probabilistic measure and
(b) for each $A \in \mathcal{B}$ the function $x \mapsto P(x,A)$ is $\mathcal{B}$-measurable.

Since the space $\mathcal{X}$ is σ-compact, there exists a homogeneous Markov process $\{\xi_n\}_{n=0}^{\infty}$ which corresponds to the transition function $P(x,A)$.[12] It means that we have some probability space $(\Omega, \mathcal{A}, \text{Prob})$ and a sequence $\{\xi_n\}_{n=0}^{\infty}$ of random elements $\xi_n : \Omega \to \mathcal{X}$ such that the sequence ξ_n is a Markov process and

$$\text{Prob}\,(\xi_{n+1} \in A | \xi_n = x) = P(x,A)$$

for each $x \in \mathcal{X}$, $A \in \mathcal{B}$, $n \geqslant 0$. Since the initial state of the system is $x_0 = (\mathbf{0}, 2^{-d}, 2^{-d}, \ldots)$, we assume that $\xi_0 = x_0$.

We assume that the probability space $(\Omega, \mathcal{A}, \text{Prob})$ is complete, i.e., if A is a measurable set and $\text{Prob}\,(A) = 0$, then every subset of A is measurable.

D. Limit cycle

A sequence $(u_0,u_1,\ldots,u_{m-1})$ of different elements of $\mathcal{Z}$ is called a cycle if there exists a sequence $(s_0,s_1,\ldots,s_{m-1})$ of elements of $\mathcal{S}$ such that $u_{k+1}=u_k+s_k$ for $k=0,...,m-1$, where $u_m=u_0$. Let $\Pi_0:\mathcal{X}\to\mathcal{Z}$ be the operator given by $\Pi_0(u,p)=u$. We say that a sequence $(x_n)_{n=0}^{\infty}$ of elements of $\mathcal{X}$ has a limit cycle if there exist a cycle $(u_0,u_1,\ldots,u_{m-1})$ and an integer $n_0\geqslant 0$ such that for every $n\geqslant n_0$ we have $\Pi_0(x_n)=u_k$, where $k=n(\mathrm{mod}\, m)$.

Let $\psi^0(t)=l$ and $\psi^n(t)=\psi\circ\psi^{n-1}(t)$.

Now we can formulate the following theorem.

Theorem 1: *Let* $\psi:[0,1]\to[0,1]$ *be a continuous nondecreasing function such that* $\psi(1)=1$ *and*

$$\sum_{n=0}^{\infty}\left[1-\psi^n\left(\frac{1}{N}\right)\right]<\infty. \tag{2}$$

We assume that there exists a continuous function $\psi:[0,1]\to[0,1]$ *such that*

$$f_{s,s}(\mathbf{p}_x)\geqslant\psi(p_{x,x+s}) \tag{3}$$

for $s\in\mathcal{S}$, *where* $f_{s,s}$ *is the s-th coordinate of* f_s. *Then there exists a measurable subset* $\Omega_0\subset\Omega$ *such that* $\mathrm{Prob}\,(\Omega_0)=1$ *and for each* $\omega\in\Omega_0$ *the sequence* $\{\xi_n(\omega)\}_{n=0}^{\infty}$ *has a limit cycle.*

The proof of Theorem 1 is given in Sec. III.

Remark 1: Let Π_z, $z\in\mathcal{K}$, be the operator $\Pi_z:\mathcal{X}\to[0,1]$ given by $\Pi_z(u,p)=p_z$. Assume that the sequence $\{\xi_n(\omega)\}_{n=0}^{\infty}$ has the limit cycle $(u_0,u_1,\ldots u_{m-1})$. Then from Theorem 1 it follows that $\lim_{n\to\infty}\Pi_z(\xi_n(\omega))=1$ for each $z=(u_k,u_{k+1})$, $k=0,...,m-1$.

Remark 2: If $\psi:[0,1]\to[0,1]$ is a continuous nondecreasing function such that $\psi(x)>x$ for $x\in(0,1)$ and $\psi'(1)>1$, then ψ satisfies (2)

III. PROOF OF THEOREM 1

A. Boundedness of trajectories

The thread of the proof of Theorem 1 is as follows. First we check that almost all paths are bounded. From this it follows that a point performing a random walk returns infinitely often to some points of the lattice $\mathcal{Z}$. Then we show that if a point $u\in\mathcal{Z}$ is visited infinitely often, then after some time the random walker chooses a fixed adjacent point to u. This implies that the random walk has a limit cycle.

Let $\eta_n(\omega)=\Pi_0(\xi_n(\omega))$. Then the random variable η_n describes the position of the moving point at time $t=n$.

Proposition 1: For almost all ω *the sequence* $\{\eta_n(\omega)\}$ *is bounded.*

We precede the proof of Proposition 1 with the following lemmas.

Lemma 1: Let $\varphi(t)=\Pi_{n=0}^{\infty}\psi^n(t)$. *Then* $\varphi(t)>0$ *for* $t\geqslant 1/N$ *and*

$$\lim_{t\to 1}\varphi(t)=1. \tag{4}$$

Proof: Since ψ is a nondecreasing function, from (2) it follows that

$$\varphi(t)\geqslant\varphi\left(\frac{1}{N}\right)<\infty \quad \text{for } t\in\left[\frac{1}{N},1\right]. \tag{5}$$

Let $\varepsilon>0$ be given. Since $\varphi(1/N)>0$ there is an integer n_0 such that

$$\prod_{n=n_0}^{\infty}\psi^n(t)\geqslant\prod_{n=n_0}^{\infty}\psi^n\left(\frac{1}{N}\right)>1-\varepsilon \quad \text{for } t\in\left[\frac{1}{N},1\right]. \tag{6}$$

The function ψ is continuous and $\psi(1)=1$. This implies that there is $\delta>0$ such that

$$\prod_{n=0}^{n_0-1} \psi^n(t)>1-\varepsilon \quad \text{for } t\in[1-\delta,1]. \tag{7}$$

From (6) and (7) it follows that $\varphi(t)>(1-\varepsilon)^2$ for $t\in[1-\delta,1]$. Consequently, $\lim_{t\to 1}\varphi(t)=1$.□

Lemma 2: Let $x\in\mathcal{Z}$ *and* $y\in\mathcal{Z}$ *be two adjacent points. Denote by A the event that the point x is visited for the first at time* $t=n_0$ *and the point y was not visited earlier. Let*

$$B=\{\omega\in\Omega:\eta_{n_0+2i-1}(\omega)=y,\quad \eta_{n_0+2i}(\omega)=x,\quad \text{for } i=1,2,...\}.$$

Then the conditional probability $\text{Prob}\,(B|A)$ *satisfies*

$$\text{Prob}\,(B|A)\geqslant\left[\varphi\left(\frac{1}{N}\right)\right]^2.$$

Proof: Let $B_0=A$ and

$$B_k=\{\omega\in\Omega:\eta_{n_0+2i-1}(\omega)=y,\quad \eta_{n_0+2i}(\omega)=x,\quad \text{for } i=1,2,...,k\}.$$

If $\omega\in B_k\cap A$, then at each time $n_0\leqslant t<n_0+2k$ and at each visit at x we have chosen the next point y and at each visit at y we have chosen the next point x. Let $s=y-x$ and $s'=x-y$. Then

$$\text{Prob}\,(\eta_{n_0+2k+1}=y|B_k\cap A)=f_{s,s}^k\left(\frac{1}{N}\right),$$

$$\text{Prob}\,(\eta_{n_0+2k+2}=x|B_k\cap A\cap\{\eta_{n_0+2k+1}=y\})=f_{s',s'}^k\left(\frac{1}{N}\right),$$

where f_s^k is the kth iterate of f_s and $f_{s,s}^k$ is the sth coordinate of f_s^k. Since ψ is a nondecreasing function, from (3) we obtain

$$f_{s,s}^k\left(\frac{1}{N}\right)\geqslant\psi\left(f_{s,s}^{k-1}\left(\frac{1}{N}\right)\right)\geqslant\psi^2\left(f_{s,s}^{k-2}\left(\frac{1}{N}\right)\right)\geqslant\cdots\geqslant\psi^k\left(\frac{1}{N}\right),$$

$$f_{s',s'}^k\left(\frac{1}{N}\right)\geqslant\psi^k\left(\frac{1}{N}\right).$$

Consequently,

$$\text{Prob}\,(B_{k+1}|B_k\cap A)\geqslant\left[\psi^k\left(\frac{1}{N}\right)\right]^2. \tag{8}$$

From (8) it follows that

$$\text{Prob}\,(B_{k+1}\cap A)\geqslant\text{Prob}\,(A)\left[\prod_{i=0}^{k}\psi^i\left(\frac{1}{N}\right)\right]^2. \tag{9}$$

If $k\to\infty$, then we obtain

$$\text{Prob}\,(B\cap A)\geqslant\text{Prob}\,(A)\left[\varphi\left(\frac{1}{N}\right)\right]^2,$$

and finally

$$\text{Prob}\,(B|A) \geqslant \left[\varphi\left(\frac{1}{N}\right)\right]^2 > 0. \qquad \square$$

Proof of Proposition 1: For $x \in \mathbf{R}^d$ we set

$$\|x\| = \max\{|x_i| : i = 1,...,d\}.$$

For $k = 1,2,...$, we define

$$C_k = \{\omega \in \Omega : \sup_n \|\eta_n \omega)\| \geqslant k\}.$$

According to Lemma 2,

$$\text{Prob}\,(C_{k+1}|C_k) \leqslant 1 - \left[\varphi\left(\frac{1}{N}\right)\right]^2. \tag{10}$$

Indeed, let $n_0(\omega)$ be the first time such that $\|\eta_{n_0}(\omega)\| = k$. If $x = \eta_{n_0}$ and y is an adjacent point to x such that $\|y\| = k+1$, then with probability $p \geqslant [\varphi(1/N)]^2$ the moving point visits only x and y at any time $t > n_0$. This implies (10). From (10) it follows that

$$\text{Prob}\,(C_k) \leqslant \left\{1 - \left[\varphi\left(\frac{1}{N}\right)\right]^2\right\}^{k-1}. \tag{11}$$

Let $C = \cap_{k=1}^{\infty} C_k$. Since a trajectory $\eta_n(\omega)$ is unbounded if and only if $\omega \in C$, from (11) it follows that almost all trajectories are bounded. $\square$

B. Stabilization of directions

From Proposition 1 it follows that almost all trajectories are bounded. Consequently, the moving point visits some points of the lattice $\mathcal{Z}$ infinitely often. Let a point $x \in \mathcal{Z}$ be given. By A we denote the event that the point x is visited infinitely often. For any $\omega \in A$ we denote by $\{k_n(\omega)\}_{n=1}^{\infty}$ successive times of visits at point x. Let $x^n(\omega)$ be the adjacent point to x visited at time $t = k_n(\omega) + 1$. We show that for almost every $\omega \in A$ there exists a point $y(\omega) \in \mathcal{Z}$ such that $x^n(\omega) = y(\omega)$ for $n > n_0(\omega)$.

The process of choosing the adjacent points can be described as an iterated function system $(f_s)_{s \in \mathcal{S}}$ on the space $\mathbf{P}$ and the probability that at the point $\mathbf{p}_x \in \mathbf{P}$ we choose the transformation f_{s_0} equals p_{x,s_0}. Indeed, let us assume that we visit the point x and let $\mathbf{p}_x = (p_{x,s})_{s \in \mathcal{S}}$ be the distribution of probability of choosing adjacent points $x+s$, $s \in \mathcal{S}$. If we choose the point $x + s_0$, then at the next visit at x, $\mathbf{p}'_x = f_{s_0}(\mathbf{p}_x)$ is the new distribution of probability of choosing adjacent points. Since x is a given point we will write $\mathbf{p}$ instead of $\mathbf{p}_x$ and p_s instead of $p_{s,x}$.

Let $\{\zeta_n\}_{n=1}^{\infty}$ be a homogeneous Markov process on the phase space $\mathbf{P}$ corresponding to the iterated function system $(f_s)_{s \in \mathcal{S}}$. The transition probability function for the process (ζ_n) is given by the formula

$$P(\mathbf{p},A) = \sum_{s \in I} \mathbf{p}_s, \quad \text{where } I = \{s \in \mathcal{S} : f_s(\mathbf{p}) \in A\}. \tag{12}$$

Denote by $x + s_n(\omega)$ the adjacent point chosen at time $t = n$. Then $\zeta_1 = (1/N,\dots,1/N)$, $\zeta_{n+1} = f_{s_n}(\zeta_n)$, and

$$\text{Prob}\,(s_n = s | \zeta_n = \mathbf{p}) = p_s. \tag{13}$$

for $\mathbf{p} \in \mathbf{P}$, $n = 1,2,...$, and $s \in \mathcal{S}$.

Proposition 2: For almost every ω *there is* $s(\omega)\in\mathcal{S}$ *and an integer* $n_0(\omega)$ *such that* $s_n(\omega)=s(\omega)$ *for* $n>n_0(\omega)$.

We precede the proof of Proposition 2 by a lemma. Let

$$\mathbf{P}_\epsilon^s=\{\mathbf{p}\in\mathbf{P}:p_s\geqslant\varepsilon\},$$

$$\mathbf{P}_\epsilon=\bigcup_{s\in\mathcal{S}}\mathbf{P}_\epsilon^s.$$

Lemma 3: Let $P^n(\mathbf{p},A)$ *be the n-step transition probability function. Then for every* $\delta<1$ *and* $\mathbf{p}\in\mathbf{P}$ *we have*

$$\lim_{n\to\infty}P^n(\mathbf{p},\mathbf{P}_\delta)=1. \tag{14}$$

Proof: Let $\varepsilon<1$ be given. First we check that for $\mathbf{p}\in\mathbf{P}_\varepsilon$ we have

$$P(\mathbf{p},\mathbf{P}_{\psi(\varepsilon)})\geqslant\varepsilon. \tag{15}$$

Indeed, if $\mathbf{p}\in\mathbf{P}_\varepsilon$, then for some s we have $\mathbf{p}\in\mathbf{P}_\varepsilon^s$ and $\mathbf{p}_s\geqslant\varepsilon$. Consequently, $f_s(\mathbf{p})\in\mathbf{P}^s_{\psi(\varepsilon)}$ and inequality (15) follows immediately from (12). From (15) it follows that

$$P^{i+1}(\mathbf{p},\mathbf{P}_{\psi^{i+1}(\varepsilon)})\geqslant\int_{\mathbf{P}_{\psi^i(\varepsilon)}}P(\mathbf{q},\mathbf{P}_{\psi^{i+1}(\varepsilon)})P^i(\mathbf{p},d\mathbf{q})\geqslant\psi^i(\varepsilon)P^i(\mathbf{p},\mathbf{P}_{\psi^i(\varepsilon)}),$$

which gives

$$P^n(\mathbf{p},\mathbf{P}_{\psi^n(\varepsilon)})\geqslant\prod_{k=0}^{n-1}\psi^k(\varepsilon)\geqslant\varphi(\varepsilon)\quad\text{for }\mathbf{p}\in\mathbf{P}_\varepsilon. \tag{16}$$

If $\varepsilon\geqslant 1/N$, then $\lim_{n\to\infty}\psi^n(\varepsilon)=1$. From (16) it follows that for every $\delta<1$, $\varepsilon\geqslant 1/N$, and $\mathbf{p}\in\mathbf{P}_\varepsilon$ we have

$$\liminf_{n\to\infty}P^n(\mathbf{p},\mathbf{P}_\delta)\geqslant\varphi(\varepsilon). \tag{17}$$

If $\mathbf{p}\in\mathbf{P}$, then $\mathbf{p}\in\mathbf{P}_{1/N}$ and, consequently,

$$\liminf_{n\to\infty}P^n(\mathbf{p},\mathbf{P}_\delta)\geqslant\varphi\left(\frac{1}{N}\right). \tag{18}$$

Since

$$P^{n+m}(\mathbf{p},\mathbf{P}_\delta)=\int_{\mathbf{P}}P^n(\mathbf{q},\mathbf{P}_\delta)P^m(\mathbf{p},d\mathbf{q})=\int_{\mathbf{P}_\delta}P^n(\mathbf{q},\mathbf{P}_\delta)P^m(\mathbf{p},d\mathbf{q})+\int_{\mathbf{P}\setminus\mathbf{P}_\delta}P^n(\mathbf{q},\mathbf{P}_\delta)P^m(\mathbf{p},d\mathbf{q}),$$

the inequalities (17) and (18) imply

$$\liminf_{n\to\infty}P^{n+m}(\mathbf{p},\mathbf{P}_\delta)\geqslant\varphi(\delta)P^m(\mathbf{p},\mathbf{P}_\delta)+\varphi\left(\frac{1}{N}\right)P^m(\mathbf{p},\mathbf{P}\setminus\mathbf{P}_\delta)=\left(\varphi(\delta)-\varphi\left(\frac{1}{N}\right)\right)P^m(\mathbf{p},\mathbf{P}_\delta)+\varphi\left(\frac{1}{N}\right). \tag{19}$$

Set

$$\alpha(\delta)=\liminf_{n\to\infty}P^n(\mathbf{p},\mathbf{P}_\delta).$$

Then from (19) it follows

$$\alpha(\delta) \geqslant \left(\varphi(\delta) - \varphi\left(\frac{1}{N}\right)\right)\alpha(\delta) + \varphi\left(\frac{1}{N}\right). \tag{20}$$

Since $\alpha(\delta)$ is a nonincreasing function there exists the limit $\lim_{\delta\to 1}\alpha(\delta) = \alpha_0$. According to Lemma 1, $\lim_{\delta\to 1}\varphi(\delta) = 1$. A passage to the limit $\delta \to 1$ in inequality (20) gives

$$\alpha_0 \geqslant \left(1 - \varphi\left(\frac{1}{N}\right)\right)\alpha_0 + \varphi\left(\frac{1}{N}\right). \tag{21}$$

From (21) we conclude that $\alpha_0 \geqslant 1$ and (14) holds. □

Proof of Proposition 2: Let $\delta \in (1/N,1)$ be a given number. Since

$$\text{Prob}\,(\zeta_n \in \mathbf{P}_\delta) = P^{n-1}(\zeta_1, \mathbf{P}_\delta),$$

from Lemma 3 it follows that there exists n_0 such that

$$\text{Prob}\,(\zeta_{n_0} \in \mathbf{P}_\delta) \geqslant \delta. \tag{22}$$

Let $A = \{\omega : \zeta_{n_0} \in \mathbf{P}_\delta\}$ and $A_s = \{\omega : \zeta_{n_0} \in \mathbf{P}_\delta^s\}$. Then $A = \cup_{s \in \mathcal{S}} A_s$ and the sets A_s, $s \in \mathcal{S}$, are pair disjoint. From (13) it follows that

$$\text{Prob}\,(s_{n_0+1} = s, \ldots, s_{n_0+m} = s \,|\, A_s) \geqslant \prod_{i=0}^{m} \psi^i(\delta) \geqslant \varphi(\delta). \tag{23}$$

Let

$$B_s = \{\omega : s_n(\omega) = s \quad \text{for } n \geqslant n_0(\omega)\},$$

$$B = \bigcup_{s \in \mathcal{S}} B_s.$$

Inequality (23) implies that

$$\text{Prob}\,(B_s | A_s) \geqslant \varphi(\delta)$$

and consequently

$$\text{Prob}\,(B_s) \geqslant \varphi(\delta)\ \text{Prob}\,(A_s). \tag{24}$$

The sets A_s, $s \in \mathcal{S}$, are pair disjoint and the sets B_s, $s \in \mathcal{S}$, are pair disjoint. From (22) and (24) we obtain

$$\text{Prob}\,(B) \geqslant \varphi(\delta)\text{Prob}\,(A) \geqslant \varphi(\delta)(1-\delta).$$

Letting $\delta \to 0$ we have $\text{Prob}\,(B) = 1$, which completes the proof. □

C. Existence of the limit cycles

Now we are ready to complete the proof of Theorem 1.

According to Proposition 1 almost every trajectory is bounded and goes through some point $u_0 \in \mathcal{Z}$ infinitely often. Let D be a bounded subset of $\mathcal{Z}$ and $u_0 \in \mathcal{Z}$ be a given point. Denote by A_0 the subset of Ω which consists of all $\omega \in \Omega$ such that the trajectory $\{\eta_n(\omega)\}$ is contained in D and goes through u_0 infinitely often. According to Proposition 2, for almost every $\omega \in A_0$ there exists $s(\omega) \in \mathcal{S}$ such that the random walker going through u_0 chooses the direction $s(\omega)$ for sufficiently

TABLE I. The numbers RW of the cycle for a few values of α.

large times. Now, we can divide the set A_0 into N disjoint subsets $B_1,\ldots,B_N$ in such a way that in each set B_k the step (u_0,u_1) is determined uniquely. Denote one of these sets by A_1. Then we can divide the set A_1 into N subsets related to the next step (u_1,u_2), etc. After some steps the moving point returns to u_0 and in this way we obtain a limit cycle. □

IV. NUMERICAL SIMULATIONS

A. Details of the studied models

The theorem proved in previous sections gives only general information about the RW with memory. To gain some insights into the more quantitative characteristics of RW with memory we have performed Monte Carlo simulations for the function

$$f_s(x)=\psi_\alpha(x)=x[2-\alpha-(1-\alpha)x], \tag{25}$$

where α is a parameter from the interval (0,1). Since for $\alpha=1$ the function $\psi_\alpha(x)$ is equal to the identical mapping, we expect that for $\alpha\to 1$, the RW with memory will tend to the usual symmetrical RW. In particular, for $\alpha\approx 1$ it should never fall into the limiting cycle. In other words some critical slowing down in reaching the limit cycle will occur for $\alpha\approx 1$.

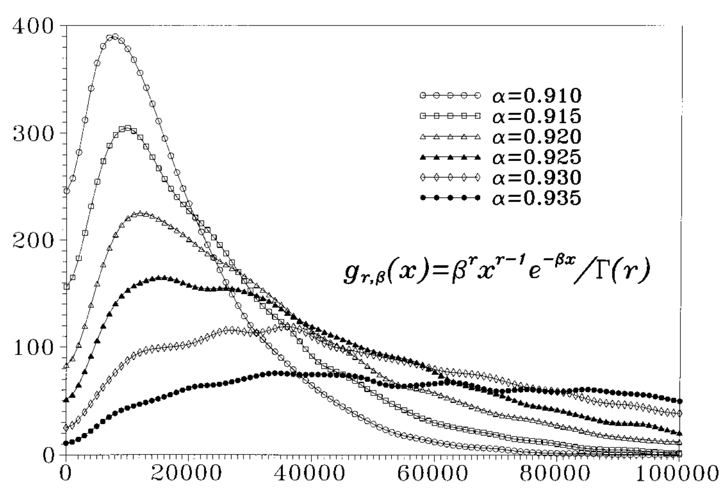

FIG. 1. The plot of the histograms of the number of steps performed by random walkers before the stop of the process for a sample of the values of α.

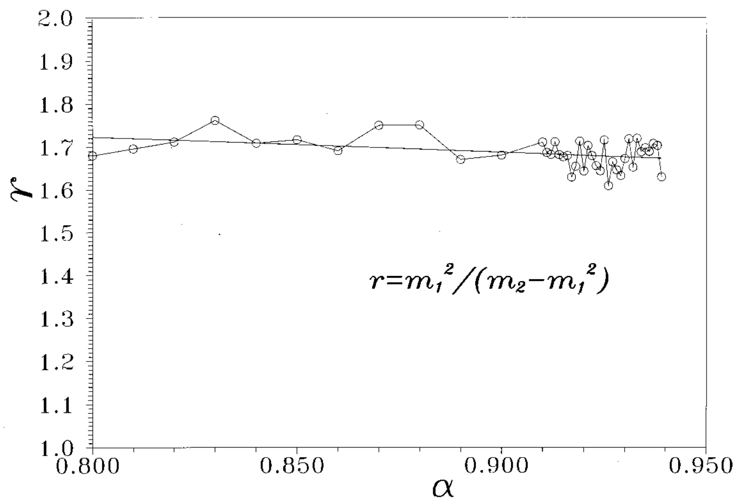

FIG. 2. The plot of the dependence of the parameter r in (26) obtained from the moments of actual data. Remarkably, this figure suggests that r does not depend on α.

B. Obtained results

We have performed the simulations only on the two-dimensional, square lattice of the size 1300×1300. In each node of the lattice we have stored probabilities of making a step in one of the four directions. Initially all p_z were set to be equal $\frac{1}{4}$. The random walker started from the origin of the lattice and after each step the probabilities were updated according to Eq. (1). A given particular simulation of the RW was finished when one p_z reached the value of 0.999 or else the total number of steps was equal to 2 000 000. We have imposed the periodic boundary conditions on the RW and we recorded the facts of crossing by RW the edges of the torus. There were rare cases of such events, most of them occurred, of course, for larger values of α. We have performed simulations for α in the range (0.8, 0.94). In the subrange (0.8, 0.91) α was changed with the step $\Delta\alpha=0.01$, while in the subinterval (0.91, 0.94) with the step $\Delta\alpha=0.001$, because the number of steps performed by random walker before the stop was increasing very rapidly with growing α. We did not continue to larger values of α, because the number of steps needed to stop the RW was too large. For each α there were 10 000 separate random walks performed. We have stored the number of steps N at which for the first time one of the probabilities reached $p_z=0.999$. The path of RW falls into the cycle (see Sec. II D) and the length of the limiting trajectory was also stored. Table I gives a sample of this data for a few values of α for the length of the cycle 2, 4,..., 18—larger cycles have occurred very randomly. The numbers in this table do not sum up to 10 000 because some RW had limit cycles larger than 18, and for large α rare samples did not fall into the limit cycle in less than 2 000 000 steps. These lengths of cycles do not follow the Poisson distribution and we do not have any conjecture describing these numbers.

The numbers of steps, for each α, varied considerably from one sample RW to another. For example, for $\alpha=0.8$ there was a RW which stabilized after $N_{\min}=63$ steps, while the largest number of steps was $N_{\max}=4114$. This gap between smallest and largest number of steps needed to stop RW increased with α, for example, for $\alpha=0.93$ the minimal and maximal number of steps before RW stopped was $N_{\min}=1034$ and $N_{\max}=590\,176$, respectively. We claim that the number of steps N is governed by the gamma distribution with parameters r, β:

$$g_{r,\beta}(x)=\beta^r x^{r-1} e^{-\beta x}/\Gamma(r), \tag{26}$$

where $\Gamma(r)$ is a generalization of the factorial:

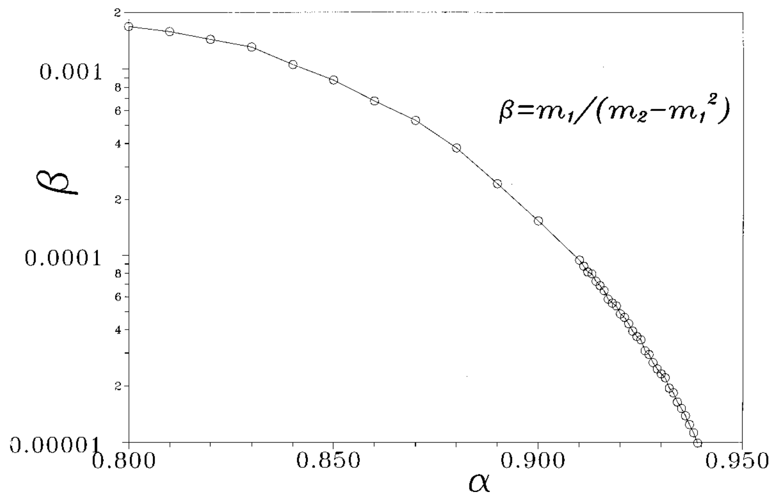

FIG. 3. The plot of the dependence of the parameter β in (26) obtained from the moments of actual data.

$$\Gamma(r)=\int_0^{\infty} e^{-t}t^{r-1}\,dt. \tag{27}$$

In Fig. 1 we present plots of the histograms of the number of steps for a few of values of α. The size of the bins was 1000, so the y axis gives the number of random walks with the number of steps in the range $(1000\times k, 1000\times k+1000)$. In Figs. 2 and 3 the values of the fitted parameters r and β for all investigated values of α are shown. Remarkably, the parameter r takes values around 1.72 and it seems not to depend on α. It is probably linked with the special choice of the function (25).

Despite the large fluctuation of N between different realizations of RW, there seems to be a simple formula describing the median μ value of N. Here μ is defined as such a value of N that the same number of sample random walks stopped in smaller than μ, as well in larger than μ steps. Since for $\alpha=1$ the RW with memory passes into the usual RW, N should diverge to infinity for

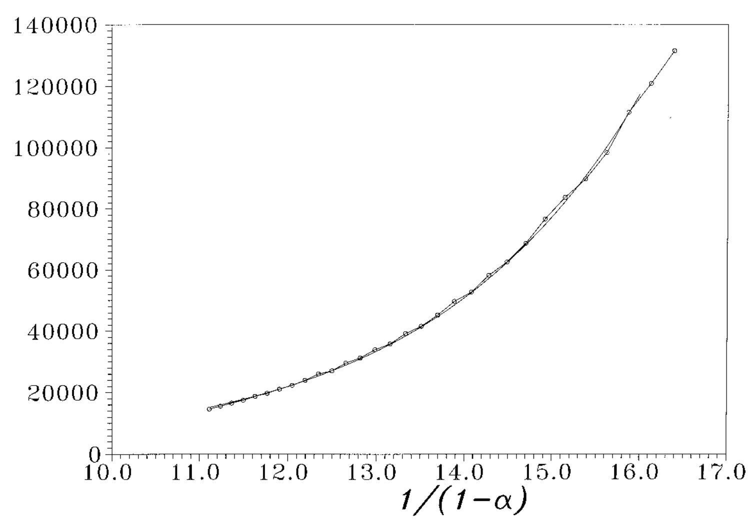

FIG. 4. The plot of dependence of the median $\mu(\alpha)$ versus $u=1/(1-\alpha)$ is shown. The solid line presents the least-square fit to the points obtained from the Monte Carlo simulations, represented by circles, under the assumption that fit is made by the exponential function.

$\alpha \to 1$, thus we guessed that μ is a function of $1/(1-\alpha)$. Hence, in Fig. 4 the plot of the median μ versus $u = 1/(1-\alpha)$ is shown. This figure suggests that $\mu(\alpha)$ grows exponentially with u—the dashed line presents the exponential fit to the actual values obtained by the least-square method:

$$\mu(\alpha) \sim \exp\left(\frac{1}{1-\alpha}\right). \tag{28}$$

Summarizing, the Monte Carlo simulations suggest that there seems to be strict, quantitative rules governing the behavior of some characteristics of the RW with memory for the function $\psi_\alpha(x)$.

Curvature conditions for the occurrence of a class of spacetime singularities

Wiesław Rudnicki[a] and Paweł Zięba[b]

(Received 15 October 1998; accepted for publication 21 January 1999)

It has recently been shown [W. Rudnicki, Phys. Lett. A **224**, 45–50 (1996)] that a generic gravitational collapse cannot result in a naked singularity accompanied by closed timelike curves. An important role in this result plays the so-called *inextendibility condition,* which is required to hold for certain incomplete null geodesics. In this paper, a theorem is proved that establishes some relations between the inextendibility condition and the rate of growth of the Ricci curvature along incomplete null geodesics. This theorem shows that the inextendibility condition may hold for a much more general class of singularities than only those of the strong curvature type. It is also argued that some earlier cosmic censorship results obtained for strong curvature singularities can be extended to singularities corresponding to the inextendibility condition. [S0022-2488(99)02106-4]

I. INTRODUCTION

Recently, one of us[1] has shown that, under certain physically reasonable conditions, a generic gravitational collapse developing from a regular initial state cannot lead to the formation of a final state resembling the Kerr solution with $a^2 > m^2$—i.e., of a naked singularity accompanied by closed timelike curves. This result supports the validity of Penrose's cosmic censorship hypothesis[2] and suggests that there may exist some deeper connection between cosmic censorship and the chronology protection conjecture put forward by Hawking.[3] An important role in this result plays the so-called *inextendibility condition* (see Sec. II), which is assumed to be satisfied for certain incomplete null geodesics. This condition enables one to rule out artificial naked singularities that could easily be created by simply removing points from otherwise well-behaved spacetimes. The inextendibility condition is based on the idea that physically essential singularities should always be associated with large curvature strengths, which are in turn usually associated with the focusing of Jacobi fields along null geodesics.

It is easily seen that the inextendibility condition will always hold for null geodesics terminating at the so-called *strong curvature singularities* defined by Tipler[4] (see below). Singularities of this type are sometimes considered to be the *only* physically reasonable singularities (cf., e.g., Refs. 5 and 6). However, strong curvature singularities can exist only if the curvature in their neighborhood diverges strong enough,[7] while it is not unlikely that some singularities occurring in generic collapse situations will involve a weaker divergence of the curvature. In fact, one cannot *a priori* exclude the existence of some ''real'' singularities near which the curvature would remain even bounded (such singularities occur, for example, in Taub-NUT space). Accordingly, since we still have no fully accepted *necessary* condition on the behavior of the curvature near generic singularities, one should try to prove any cosmic censorship result under as weak a curvature condition as possible. It would be therefore of interest, in view of the mentioned censorship result,[1] to know what are curvature conditions for the occurrence of singularities corresponding to the inextendibility condition. Furthermore, the inextendibility condition has also been used in

proving some other recent results[8,9] that restrict a class of possible causality violations in classical general relativity.

In this paper, we formulate and prove a theorem that establishes some relations between the inextendibility condition and the rate of growth of the Ricci curvature along incomplete null geodesics. This theorem shows that the inextendibility condition may hold for a much more general class of possible singularities than only those of the strong curvature type. Our theorem will be stated in Sec. II of the paper. In Sec. III, we present a proof of the theorem; our main mathematical tool in this proof is a Sturm-type comparison lemma for nonoscillatory solutions of second-order differential equations. In Sec. IV we give a few concluding remarks; in particular, we argue that some earlier cosmic censorship results obtained for strong curvature singularities can be extended to singularities corresponding to the inextendibility condition.

II. THE THEOREM

To begin with, we clearly need to recall the precise formulation of the inextendibility condition. Let $\eta(t)$ be an affinely parametrized null geodesic, and let Z_1 and Z_2 be two linearly independent spacelike vorticity-free Jacobi fields along $\eta(t)$. The exterior product of these Jacobi fields defines a spacelike area element, whose magnitude at affine parameter value t we denote by $A(t)$. If we now introduce the function $z(t)$ defined by $A(t)\equiv z^2(t)$, then one can show[4] that $z(t)$ satisfies the following equation:

$$\frac{d^2z}{dt^2}+\frac{1}{2}(R_{ab}K^aK^b+2\sigma^2)z=0, \tag{1}$$

where K^a is the tangent vector to $\eta(t)$ and σ^2 is a non-negative function of t defined as follows: $2\sigma^2\equiv\sigma_{mn}\sigma^{mn}$ $(m,n=1,2)$. Here σ_{mn} is the shear tensor (see Ref. 10, p. 88) that satisfies the equation[4]

$$\frac{d}{dt}\sigma_{mn}=-C_{manb}K^aK^b-\frac{2}{z}\frac{dz}{dt}\sigma_{mn}. \tag{2}$$

In the following, by M we shall denote a spacetime, i.e., a smooth, boundaryless, connected, four-dimensional Hausdorff manifold with a globally defined C^{2-} Lorentz metric.

Definition (cf. Refs. 1 and 8): Let $\eta:(0,a]\rightarrow M$ *be an affinely parametrized, incomplete null geodesic. Assume also that* $\eta(t)$ *generates an achronal set, i.e., a set such that no two points of it can be joined by a timelike curve. Then* $\eta(t)$ *is said to satisfy the inextendibility condition if for some affine parameter value* $t_1\in(0,a)$ *there exists a solution* $z(t)$ *of Eq. (1) along* $\eta(t)$ *such that* $z(t_1)=0$, $dz/dt|_{t_1}\neq 0$ *and* $\lim_{t\rightarrow 0}z(t)=0$.

The key idea behind the inextendibility condition is based on the fact that any two zeros of any solution of Eq. (1), which is not identically zero along a given null geodesic, correspond to a pair of conjugate points along the geodesic (see Ref. 4). From Proposition 4.5.12 of Ref. 10, it follows that incomplete null geodesics generating achronal sets cannot contain any pairs of conjugate points. One can thus easily show[8] that if a geodesic $\eta:(0,a]\rightarrow M$ satisfies the inextendibility condition, then there is *no* extension of the spacetime M, preserving all the above mentioned properties of M, in which $\eta(t)$ could be extended beyond a point $\eta(0)$. This means, according to the standard interpretation, that $\eta(t)$ should then approach a genuine singularity of the spacetime M at affine parameter value 0. [Formally, this singularity has the same status as those predicted by the familiar singularity theorems,[10] because these theorems predict, in fact, the existence of incomplete causal (usually null) geodesics in maximally extended spacetimes satisfying just the same topological and smoothness conditions as those imposed on M.]

Let us now compare the inextendibility condition with the concept of a strong curvature singularity.[4] Consider a null geodesic $\lambda:(0,a]\rightarrow M$ that terminates in a strong curvature singularity at affine parameter value 0. This means that every solution $z(t)$ of Eq. (1) along $\lambda(t)$, which vanishes for, at most, finitely many points in $(0,a]$, satisfies $\lim_{t\rightarrow 0}z(t)=0$ (cf. Ref. 5, p. 160).

Suppose now that $\lambda(t)$ generates an achronal set; then any solution of Eq. (1), which is not identically zero along $\lambda(t)$, cannot vanish for any two points in $(0,a]$ by the argument with conjugate points mentioned above. Thus, for *all* $t_1 \in (0,a]$ and for *all* solutions $z(t)$ of Eq. (1) along $\lambda(t)$ with initial conditions $z(t_1)=0$, we will have $\lim_{t\to 0} z(t)=0$. It is thus clear that any null geodesic terminating in Tipler's strong curvature singularity and generating an achronal set must always satisfy the inextendibility condition. Notice also that the terms ''all'' emphasized above imply, via Eqs. (1) and (2), that $\lambda(t)$ can terminate in the strong curvature singularity only if the curvature diverges strong enough along $\lambda(t)$ as $t\to 0$, while the inextendibility condition could actually be satisfied for $\lambda(t)$, even if the curvature along it would remain bounded. Indeed, the theorem stated below makes it clear [see condition (i)] that the curvature need not necessarily diverge along geodesics satisfying the inextendibility condition.

Theorem: *Let $\eta:(0,a]\to M$ be an affinely parametrized, incomplete null geodesic generating an achronal set. Suppose that the Ricci tensor term $r(t)\equiv R_{ab}K^aK^b$ along $\eta(t)$, where t is the affine parameter and K^a is the tangent vector to $\eta(t)$, obeys at least one of the following conditions.*

(i) *There exists an affine parameter value $b\in(0,a)$ such that* $\inf\{r(t)|0<t\leqslant b\}\geqslant 2(\pi/b)^2$.

(ii) *There exist an affine parameter value $c\in(0,a)$ and a constant $\mu\in(0,2)$ such that $r(t)\geqslant \kappa t^{-\mu}$ for all $t\in(0,c]$, where $\kappa=(\frac{2}{3})(33-26\mu+5\mu^2)c^{\mu-2}$.*

Then $\eta(t)$ satisfies the inextendibility condition.

Remark 1: From the proof of this theorem, which is given below, it may be seen that the parameter values b and c mentioned above in conditions (i) and (ii) correspond to the parameter value t_1 occurring in the definition of the inextendibility condition.

Remark 2: Since in the theorem $\eta(t)$ is assumed to be a generator of an achronal set, $\eta(t)$ cannot contain any pair of conjugate points, and so one can expect that there should exist an *upper* limit on the rate of growth of the curvature along $\eta(t)$. Indeed, from Theorems (3) and (4) of Ref. 11, it follows immediately that the Ricci tensor term $r(t)$ along $\eta(t)$ must satisfy the following two conditions: (1) there is no affine parameter value $b'\in(0,a]$ such that $\inf\{r(t)|0<t<b'\}>8(\pi/b')^2$; and (2) if $r(t)\geqslant 0$ on $\eta(t)$, then $\lim_{t\to 0}\inf t^2 r(t)\leqslant \frac{1}{2}$. Similar restrictions on the growth of the Weyl part of the curvature along $\eta(t)$ can be obtained from Proposition 1.2 of Ref. 12.

In the context of our theorem, it is worth recalling the analogous results obtained by Clarke and Królak[7] for singularities of the strong curvature type. They have been obtained for two definitions of a strong curvature singularity: the original one formulated by Tipler[4] and its modification proposed by Królak.[6] According to these results, if a null geodesic $\eta:(0,a]\to M$ terminates at affine parameter value 0 in a strong curvature singularity defined by Tipler (resp., by Królak), then there must exist some affine parameter value $c\in(0,a]$ such that $R_{ab}K^aK^b>At^{-2}$ (resp., $R_{ab}K^aK^b>At^{-1}$) on $(0,c]$, where K^a is the tangent vector to $\eta(t)$, t is the affine parameter, and A is some fixed positive constant. [Or very similar conditions on the rate of growth of the Weyl part of the curvature along $\eta(t)$ must be satisfied; see Corollary 2 of Ref. 7.] Comparing these results with condition (ii) of our theorem, we see that singularities of the strong curvature type involve a considerably stronger divergence of the Ricci tensor term $R_{ab}K^aK^b$ than singularities corresponding to the inextendibility condition. There may thus exist a large class of curvature singularities that are not strong in the sense of the definition of Tipler or Królak, but they may still satisfy the inextendibility condition. Note also that the above conditions for strong curvature singularities are the *necessary* ones, whereas conditions (i) and (ii) of our theorem are only *sufficient* to ensure that the inextendibility condition does hold for a given geodesic. This implies that the inextendibility condition might be satisfied in more general situations than only those characterized by conditions (i) and (ii).

III. PROOF OF THE THEOREM

Now we shall prove the theorem; our main tool in this proof will be the following comparison lemma.

Lemma (The comparison lemma): Suppose that $u(s)$ is a solution of the equation

$$\frac{d^2u}{ds^2}+F(s)u(s)=0,$$

on an interval (a,b] with initial conditions: $u(b)=0$ and $du/ds|_b\neq 0$. Let $v(s)$ be a solution of

$$\frac{d^2v}{ds^2}+G(s)v(s)=0,$$

on (a,b], such that $v(b)=0$, $dv/ds|_b=du/ds|_b$ and $v(s)>0$ on (a,b). Assume also that $F(s)$ and $G(s)$ are piecewise continuous on (a,b], and let $G(s)\geqslant F(s)$ on (a,b]. Then $u(s)\geqslant v(s)$ on (a,b].

Proof: The proof of this lemma is based essentially on Theorem 1.2 of Ref. 13, p. 210. To apply this theorem in its original form, it is convenient to reparametrize both of the equations in the lemma, introducing the parameter $t=-s$ instead of s. Note that this reparametrization does not change the form of the equations. Clearly, we shall now have established the lemma if we show that for any $c\in(a,b)$, $u(t)\geqslant v(t)$ on $[-b,-c]$.

Consider the ratio $u(t)/v(t)$. Since $v(t)>0$ on $(-b,-a)$, it is well defined on $(-b,-c]$. Using l'Hospital's rule, we get

$$\lim_{t\to -b}\frac{u(t)}{v(t)}=1.$$

Therefore, as $v(t)>0$ on $(-b,-c]$, to show that $u(t)\geqslant v(t)$ on $[-b,-c]$, it suffices to show that

$$\frac{d}{dt}\left[\frac{u(t)}{v(t)}\right]\geqslant 0,$$

on $(-b,-c]$. It is easy to see that this inequality holds if

$$\frac{v(t)}{\dot{v}(t)}\geqslant\frac{u(t)}{\dot{u}(t)}, \tag{3}$$

on $(-b,-c]$, where the overdot denotes the first derivative with respect to t. By Theorem 1.2 of Ref. 13, p. 210, we have

$$\tan^{-1}\left[\frac{v(t)}{\dot{v}(t)}\right]\geqslant\tan^{-1}\left[\frac{u(t)}{\dot{u}(t)}\right],$$

for all $t\in[-b,-c]$. Thus, as $\tan^{-1}$ is an increasing function, the inequality (3) does hold, as it is desirable. □

Proof of the theorem: (Part I) Suppose the condition (i) is satisfied. Let $z_0(t)$ be a solution of Eq. (1) along $\eta(t)$ such that $z_0(t)$ is not identically zero on $(0,b]$ and $z_0(b)=0$, where b is the parameter value mentioned in condition (i). Clearly, such a solution will always exist. Since $\eta(t)$ generates an achronal set, $z_0(t)$ can vanish nowhere in $(0,b)$; otherwise $\eta(t)$ would have a pair of conjugate points in $(0,b]$ (see Ref. 4), which would contradict, by Proposition 4.5.12 of Ref. 10, the achronality of $\eta(t)$. Notice also that Eq. (1) is linear, and so the function $-z_0(t)$ will be a solution of Eq. (1) as well. Thus, as $z_0\neq 0$ on $(0,b)$, without loss of generality we can assume that $z_0(t)>0$ on $(0,b)$. This implies, as $z_0(b)=0$, that $dz_0/dt|_b\leqslant 0$. Since $z_0(t)>0$ on $(0,b)$, and condition (i) holds, from Eq. (1) we see at once that $z_0(t)$ must be a concave function on $(0,b]$. This makes it obvious that $dz_0/dt|_b\neq 0$, and so we must have $dz_0/dt|_b=\alpha<0$. Let us now define the function $z_1(t)\equiv-(1/\alpha)z_0(t)$. As Eq. (1) is linear, it is clear that $z_1(t)$ will be a solution of Eq. (1) along $\eta(t)$; notice also that $z_1(t)>0$ on $(0,b)$, $z_1(b)=0$ and $dz_1/dt|_b=-1$.

Consider now the equation

$$\frac{d^2x}{dt^2}+\omega x(t)=0, \tag{4}$$

where $\omega=\frac{1}{2}\inf\{r(t)|0<t\leqslant b\}$ and $r(t)$ is the function defined in the theorem. Notice that $\omega>0$ by condition (i). Let $x_1(t)$ be a solution of Eq. (4) on $(0,b]$ with initial conditions $x_1(b)=0$ and $dx_1/dt|_b=-1$. It is a simple matter to see that $x_1(t)=\omega^{-1/2}\sin[\omega^{1/2}(b-t)]$. Let us now apply the comparison lemma to the equations (1) and (4) and their solutions $z_1(t)$ and $x_1(t)$. Since $\omega\leqslant\frac{1}{2}r(t)$ on $(0,b]$, by the comparison lemma we must have $x_1(t)\geqslant z_1(t)$ on $(0,b]$. Consequently, as $z_1(t)>0$ on $(0,b)$, we obtain $x_1(t)>0$ on $(0,b)$. This implies, by the above form of $x_1(t)$, that $\omega\leqslant(\pi/b)^2$. But $\omega\geqslant(\pi/b)^2$ by condition (1). We must thus have $\omega=(\pi/b)^2$, which gives $\lim_{t\to 0}x_1(t)=0$. Therefore $\lim_{t\to 0}z_1(t)=0$ since $x_1(t)\geqslant z_1(t)>0$ on $(0,b)$. This means that $\eta(t)$ does satisfy the inextendibility condition.

(Part II) The task is now to prove the theorem in the case when condition (ii) holds. For this purpose, let us consider the following equation:

$$\frac{d^2y}{dt^2}+Bt^{-\mu}y(t)=0, \tag{5}$$

on $(0,c]$, where $B=\kappa/2$, and κ, μ, and c are some fixed constants mentioned in the condition (ii). Let $y_1(t)$ be a solution of this equation with initial conditions $y_1(c)=0$ and $dy_1/dt|_c=-1$. Let $z_2(t)$ be a solution of Eq. (1) along $\eta(t)$, such that $z_2(c)=0$ and $dz_2/dt|_c=-1$. [There is no loss of generality in assuming $z_2(t)$ to exist; the existence of $z_2(t)$ can be established in the same manner as the existence of the analogous solution $z_1(t)$ considered in the first part of the proof.] Clearly, the solution $z_2(t)$, just as $z_1(t)$, can vanish nowhere in $(0,c)$ by the argument with conjugate points. Therefore, as $dz_2/dt|_c=-1$, we must have $z_2(t)>0$ on $(0,c)$. Let us now apply the comparison lemma to the equations (1) and (5) and their solutions $z_2(t)$ and $y_1(t)$. By condition (ii) we have $r(t)\geqslant\kappa t^{-\mu}$ on $(0,c]$. Thus, by the comparison lemma, we must have $y_1(t)\geqslant z_2(t)$ on $(0,c]$. Of course, in order to prove the theorem, it suffices to show that $\lim_{t\to 0}z_2(t)=0$. Thus, as $y_1(t)\geqslant z_2(t)>0$ on $(0,c)$, to complete the proof it suffices to show that $\lim_{t\to 0}y_1(t)=0$. We shall show below that $y_1(t)$ does possess this property.

To this end, let us first find the general solution of Eq. (5). It is easy to check that if one puts $x=t$, $\alpha=1/2$, $\beta=2\sqrt{B}(2-\mu)^{-1}$, $\gamma=(2-\mu)/2$, and $n=(2-\mu)^{-1}$ into the equation (4.1) of Ref. 14, p. 138, then this equation reduces to our equation (5). Thus, according to the solution (4.3) of Eq. (4.1) of Ref. 14, our equation (5) has the following general solution

$$y(t)=t^{1/2}[C_1J_n(\beta t^\gamma)+C_2Y_n(\beta t^\gamma)], \tag{6}$$

where C_1 and C_2 are arbitrary constants of integration, and $J_n(\beta t^\gamma)$ and $Y_n(\beta t^\gamma)$ are the Bessel functions of order n, of the first and second kind, respectively. Since $\mu\in(0,2)$, from the above relations it follows that $\frac{1}{2}<n<\infty$, $\sqrt{B}<\beta<\infty$ and $0<\gamma<1$.

Let us recall that any Bessel function of the first kind has infinitely many positive zeros (cf., e.g., Ref. 15, p. 29). Let $j_{n,1}$ be the first positive zero of the function $J_n(\beta t^\gamma)$, i.e., $J_n(j_{n,1})=0$ and $J_n(\beta t^\gamma)\neq 0$ as long as $0<\beta t^\gamma<j_{n,1}$. Since $n>\frac{1}{2}$, $j_{n,1}$ must satisfy the following relation [see Eq. (2) of Ref. 15, p. 29]:

$$j_{n,1}<2[(n+1)(n+5)/3]^{1/2}. \tag{7}$$

For $J_n(\beta t^\gamma)$ we now define L to be the number such that $j_{n,1}=L\beta c^\gamma$. Putting this into (7), and taking into account the fact that $\beta=(2\kappa)^{1/2}(2-\mu)^{-1}$, $\kappa=3^{-1}(66-52\mu+10\mu^2)c^{\mu-2}$, $\gamma=(2-\mu)/2$ and $n=(2-\mu)^{-1}$, we readily find that $L^2<1$.

Consider now Eq. (5) with B replaced by $B'=L^2B$. Let $y_2(t)$ be a solution of this equation on $(0,c]$ with initial conditions $y_2(c)=0$ and $dy_2/dt|_c=-1$. The general form of this solution is given by (6), where β should be replaced by $\beta'=2\sqrt{B'}(2-\mu)^{-1}$ (notice that $\beta'=L\beta$). Let us now insert the initial conditions for $y_2(t)$ into this general solution in order to determine for $y_2(t)$ the constants C_1 and C_2 occurring in (6). To find the first derivative of the general solution (6), we use the following recurrence formula:

$$\frac{dJ_n(x)}{dx}=-J_{n+1}(x)+\frac{n}{x}J_n(x),$$

which is also valid for $Y_n(x)$ (see Ref. 15, p. 197). We can now easily calculate the constants C_1 and C_2; the result is as follows:

$$C_1=\frac{Y_n(\beta' c^\gamma)}{\beta'\gamma c^{\gamma-1/2}[Y_n(\beta' c^\gamma)J_{n+1}(\beta' c^\gamma)-Y_{n+1}(\beta' c^\gamma)J_n(\beta' c^\gamma)]} \tag{8}$$

and

$$C_2=\frac{-J_n(\beta' c^\gamma)}{\beta'\gamma c^{\gamma-1/2}[Y_n(\beta' c^\gamma)J_{n+1}(\beta' c^\gamma)-Y_{n+1}(\beta' c^\gamma)J_n(\beta' c^\gamma)]}. \tag{9}$$

As $\beta'=L\beta$, from the above definition of L it is clear that $\beta' c^\gamma=j_{n,1}$. Thus $J_n(\beta' c^\gamma)=0$, and the numerator in (9) must vanish. As $J_n(\beta' c^\gamma)=0$, the denominator in (9) can vanish only if $Y_n(\beta' c^\gamma)J_{n+1}(\beta' c^\gamma)=0$. But the Bessel functions J_{n+1} and Y_n cannot have any common zeros with the Bessel function J_n (see Ref. 15, pp. 29–32), and so the denominator in (9) cannot vanish. We thus have $C_2=0$ and, by (6) and (8), the solution $y_2(t)$ can be written as follows:

$$y_2(t)=C_1 t^{1/2}J_n(\beta' t^\gamma), \tag{10}$$

where $C_1=[\beta'\gamma c^{\gamma-1/2}J_{n+1}(\beta' c^\gamma)]^{-1}$.

Let us now compare the solutions $y_1(t)$ and $y_2(t)$ by means of the comparison lemma. Recall that $y_1(t)$ is a solution of Eq. (5) with $B=\kappa/2$, while $y_2(t)$ is a solution of the same equation with B replaced by $B'=L^2\kappa/2$. Since $L^2<1$, by the comparison lemma we must have $y_2(t)\geqslant y_1(t)$ for all $t\in(0,c]$. We recall that any Bessel function $J_k(x)$ of the first kind with real x and $k>0$ is continuous at $x=0$ (cf. Ref. 15, p. 182). Thus, as $n>\frac{1}{2}$ and $0<\gamma<1$, from (10) it follows immediately that $\lim_{t\to 0} y_2(t)=0$. Therefore, as $y_2(t)\geqslant y_1(t)>0$ on $(0,c)$, we obtain $\lim_{t\to 0} y_1(t)=0$, which completes the proof. □

IV. CONCLUDING REMARKS

We have been concerned in this paper with the problem of determining what are curvature conditions for the occurrence of singularities corresponding to the inextendibility condition. We have found two such sufficient conditions concerning the behavior of the Ricci tensor term $R_{ab}K^aK^b$ along incomplete null geodesics—these are conditions (i) and (ii) of the theorem stated in Sec. II. This theorem shows that the inextendibility condition may hold for a considerably larger class of possible singularities than only those of the strong curvature type. In particular, condition (i) of the theorem shows that the inextendibility condition may hold, even if the curvature along incomplete geodesics would remain bounded. In this context, it is worth recalling that singularities predicted by the famous singularity theorems[10] can be interpreted as regions of the universe at which the normal classical spacetime picture and/or certain energy conditions break down, and this may occur in regions where the curvature, though extremely large, still remains finite. Accordingly, if one attempts to establish, for example, whether or not these singular regions will conform to any cosmic censorship principle, it would be well to try to characterize, if necessary, incomplete geodesics terminating in these regions by a condition that may hold even if the curvature along the geodesics would remain bounded. One possible candidate for such a condition may thus be the inextendibility condition.

It should also be stressed here that some earlier cosmic censorship theorems[6,16,17] proved for strong curvature singularities can be extended to singularities corresponding to the inextendibility condition. To see this, let us first recall that these theorems show, briefly, that under certain restrictions imposed on the causal structure, strong curvature singularities are censored (see Refs. 6, 16, and 17 for details). Proofs of these theorems are, in essence, alike. In a brief outline, they run as follows. First, one shows that if the theorem under consideration were false, then there would have to exist a sequence $\{\mu_i\}$ of future endless, future complete null geodesics converging to a null geodesic μ that terminates in the future at a strong curvature singularity. One also shows that μ and all the μ_i must be generators of achronal sets. As all μ_i are achronal, none of them can have a pair of conjugate points, and so any irrotational congruence of Jacobi fields along any μ_i cannot be refocused. As $\{\mu_i\}$ converges to μ, this must then imply, by continuity, that any irrotational congruence of Jacobi fields along μ cannot be refocused as well. However, as μ terminates in a strong curvature singularity, all irrotational congruences of Jacobi fields along μ should be refocused. This gives the required contradiction. It is not difficult to see, however, that this contradiction can equally well be obtained if μ would be assumed to satisfy the inextendibility condition, for this condition holds if at least one irrotational congruence of Jacobi fields along a given geodesic is refocused. It is thus clear that the censorship theorems given in Refs. 6, 16, and 17 are unnecessarily restricted to strong curvature singularities and they can be extended to singularities corresponding to the inextendibility condition.

(Received 10 November 1998; accepted for publication 19 February 1999)

The two-parametric quantum deformation of the algebra of coordinate functions on the (dual) supergroup Gr(1|1) via a contraction of $\mathrm{Gr}_{p,q}(1|1)$ is presented. Although the quantum superdeterminant of any element of $\mathrm{Gr}_{p,q}(1|1)$ is not central, in the two parametric Jordanian deformation of Gr(1|1) the quantum superdeterminant belongs to the center. The Hopf algebra structure of $\mathrm{Gr}_{h_1,h_2}(1|1)$ is discussed.

I. INTRODUCTION

The discussion of the *h*-deformation of the matrix Lie group GL(2) via a contraction[1] of the quantum matrix group $\mathrm{GL}_q(2)$ has led to renewed interest in the *h*-deformation of the simplest supergroup GL(1|1) (Ref. 2) and the (dual) supergroup Gr(1|1) (Ref. 3) which appears as the Jordanian deformation of the supergroups.

In recent years this deformation [*h*-deformation], which appears as a new class of quantum deformations of matrix Lie groups and algebras, has been intensively studied by many authors.[1–13] An interesting property of the *h*-deformations of GL(1|1) and Gr(1|1), is that in both cases, the deformation parameter *h* is an anticommuting Grassmann number.[2,3] In the two-parametric extension of *h*-deformation of GL(1|1), it is seen that both deformation parameters are again anticommuting Grassmann numbers.[4] Another interesting point is that the quantum superdeterminant of a matrix in $\mathrm{Gr}_{p,q}(1|1)$ does not commute with all the matrix elements, i.e., it does not belong to the center of $\mathrm{Gr}_{p,q}(1|1)$. However in the two-parametric Jordanian deformation of Gr(1|1) the quantum superdeterminant belongs to the center of the (h_1,h_2)-deformed supergroup Gr(1|1). Hence the general message of this paper may be that multiparameter deformations are more natural for *h*-deformations as compared to *q*-deformations.

The purpose of this paper is to present the two-parametric extension of the *h*-deformation of the (dual or Grassmann) supergroup Gr(1|1) using the approaches of Refs. 4 and 3. The paper is organized as follows. In Sec. II we give some notations and useful formulas which will be used in this work. In Sec. III we present the two-parameter deformation of Gr(1|1) as related to superplanes. In the following section we get a two-parameter *R*-matrix which deforms the supergroup Gr(1|1). Since the Hopf algebra structure of $\mathrm{Gr}_{h_1,h_2}(1|1)$ is related to $\mathrm{GL}_{h_1,h_2}(1|1)$ it is presented in Sec. V, as a separate section.

II. REVIEW OF $\mathrm{Gr}_{p,q}(1|1)$

A Grassmann supermatrix $\hat{T}$ which is an element of Gr(1|1) is of the form

$$\hat{T}=\begin{pmatrix} \alpha & b \\ c & \delta \end{pmatrix}$$

with two odd (Greek letters) and two even (Latin letters) matrix elements. As usual, the even elements commute with everything and the odd elements anticommute among themselves. We state briefly the properties of the (p,q)-deformed Grassmann supergroup[14] we are going to need in this work.

In this paper we denote (p,q)-deformed objects by primed quantities. Unprimed quantities represent transformed coordinates.

Let us consider the Manin[15] quantum superplane A_p and its dual A_q^*,

$$U'=\begin{pmatrix} x' \\ \xi' \end{pmatrix} \in A_p \Leftrightarrow x'\xi' - p\xi' x' = 0, \quad \xi'^2 = 0 \tag{2.1}$$

and its dual

$$V'=\begin{pmatrix} \eta' \\ y' \end{pmatrix} \in A_q^* \Leftrightarrow \eta'^2 = 0, \quad \eta' y' - q^{-1} y' \eta' = 0. \tag{2.2}$$

Suppose that the matrix elements of $\hat{T}'$ (anti-) commute with the coordinates of A_p and A_q^*. Then, the endomorphisms

$$\hat{T}':A_p \rightarrow A_q^* \quad \text{and} \quad \hat{T}':A_q^* \rightarrow A_p \tag{2.3}$$

impose the following bilinear product relations among the matrix elements:[14]

$$\begin{gathered} \alpha' b' = p^{-1} b' \alpha', \quad \alpha' c' = q^{-1} c' \alpha', \\ \delta' b' = p^{-1} b' \delta', \quad \delta' c' = q^{-1} c' \delta', \\ \alpha' \delta' + \delta' \alpha' = 0, \quad \alpha'^2 = 0 = \delta'^2, \\ b' c' = pq^{-1} c' b' + (p - q^{-1}) \delta' \alpha', \end{gathered} \tag{2.4}$$

where p and q are nonzero complex numbers and $pq \pm 1 \neq 0$. These relations define a two-parameter deformation of the algebra of coordinate functions on the Grassmann matrix supergroup $\mathrm{Gr}(1|1)$ as an associative algebra with unit, generated by the generators α, b, c, and δ.

The above relations are equivalent to the equation[14]

$$R_{p,q} \hat{T}_1' \hat{T}_2' = -\hat{T}_2' \hat{T}_1' R_{p,q}, \tag{2.5}$$

where $\hat{T}_1' = \hat{T}' \otimes I$, $\hat{T}_2' = I \otimes \hat{T}'$ and

$$R_{p,q} = \begin{pmatrix} p+q^{-1} & 0 & 0 & 0 \\ 0 & -2 & q^{-1}-p & 0 \\ 0 & p-q^{-1} & -2pq^{-1} & 0 \\ 0 & 0 & 0 & p+q^{-1} \end{pmatrix}. \tag{2.6}$$

Here we employ the convenient grading notation

$$(\hat{T}_1)_{kl}^{ij} = (\hat{T} \otimes I)_{kl}^{ij} = (-1)^{k(j+l)} \hat{T}_k^i \delta_l^j, \tag{2.7}$$

$$(\hat{T}_2)_{kl}^{ij} = (I \otimes \hat{T})_{kl}^{ij} = (-1)^{i(j+l)} \hat{T}_l^j \delta_k^i. \tag{2.8}$$

Note that although the algebra (2.4) is an associative algebra of the matrix elements of $\hat{T}'$, $R_{p,q}$ does not satisfy the graded quantum Yang–Baxter equation (QYBE),

$$R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12}. \tag{2.9}$$

However, an interesting point is that if we decompose the matrix $R_{p,q}$ in the form

$$R_{p,q}=R^1_{p,q}+R^2_{p,q}, \tag{2.10}$$

where

$$R^1_{p,q}=\begin{pmatrix} p & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & p-q^{-1} & -pq^{-1} & 0 \\ 0 & 0 & 0 & q^{-1} \end{pmatrix}, \quad R^2_{p,q}=\begin{pmatrix} q^{-1} & 0 & 0 & 0 \\ 0 & -1 & q^{-1}-p & 0 \\ 0 & 0 & -pq^{-1} & 0 \\ 0 & 0 & 0 & p \end{pmatrix}, \tag{2.11}$$

then both matrices $R^1_{p,q}$ and $R^2_{p,q}$ do satisfy the graded QYBE. Also Eq. (2.5) can be written of the form

$$R^1_{p,q}T'_1T'_2=-T'_2T'_1R^2_{p,q}. \tag{2.12}$$

This equation will be used in Sec. IV.

III. THE TWO-PARAMETRIC *h*-DEFORMATION OF Gr(1|1)

We introduce new coordinates x and ξ by

$$U=g^{-1}_{h_1}U', \quad U=\begin{pmatrix} x \\ \xi \end{pmatrix}, \tag{3.1}$$

where

$$g_{h_1}=\begin{pmatrix} 1 & 0 \\ f_1 & 1 \end{pmatrix}, \quad f_1=\frac{h_1}{p-1}. \tag{3.2}$$

Here the deformation parameter h_1 is a Grassmann number which has the following properties:

$$h_1^2=0, \quad h_1\xi=-\xi h_1. \tag{3.3}$$

Now, in the limit $p\rightarrow 1$ we get the following exchange relations:

$$x\xi=\xi x+h_1x^2, \quad \xi^2=-h_1x\xi. \tag{3.4}$$

These relations define a new deformation, which we called the h_1-deformation, of the algebra of functions on the Manin superplane generated by x and ξ, and we denote it by A_{h_1}.

Let us consider dual coordinates η and y with

$$V=g^{-1}_{h_2}V', \quad V=\begin{pmatrix} \eta \\ y \end{pmatrix}, \tag{3.5}$$

where[4]

$$g_{h_2}=\begin{pmatrix} 1 & f_2 \\ 0 & 1 \end{pmatrix}, \quad f_2=\frac{h_2}{q-1}. \tag{3.6}$$

The deformation parameter h_2 is again a Grassmann number and it has the following properties:

$$h_2^2=0, \quad h_2\eta=-\eta h_2. \tag{3.7}$$

Next, taking the $q \to 1$ limit we obtain the following relations, which define the dual h_2-superplane $A^*_{h_2}$ as generated by η and y with the exchange relations[4]

$$\eta^2 = -h_2 \eta y, \quad \eta y = y\eta - h_2 y^2. \tag{3.8}$$

We now consider the endomorphisms

$$\hat{T}: A_{h_1} \to A^*_{h_2} \quad \text{and} \quad \hat{T}: A^*_{h_2} \to A_{h_1}. \tag{3.9}$$

Then, we define the corresponding (h_1, h_2)-deformation of the Grassmann supergroup Gr$(1|1)$ as a quantum matrix group $\mathrm{Gr}_{h_1,h_2}(1|1)$ generated by α, b, c, δ which satisfy the following (h_1, h_2)-commutation relations:

$$\begin{aligned}
\alpha b &= b\alpha + h_1 b^2 - h_2(\alpha\delta + bc) - h_1 h_2 b\delta,\\
\alpha c &= c\alpha + h_1(cb - \alpha\delta) - h_2 c^2 - h_1 h_2 c\delta,\\
\alpha^2 &= h_1 \alpha b - h_2 \alpha c + h_1 h_2 \alpha\delta,\\
\delta b &= b\delta - h_1 b^2 + h_2(\alpha\delta + cb) - h_1 h_2 b\alpha,\\
\delta c &= c\delta + h_1(\alpha\delta - bc) + h_2 c^2 - h_1 h_2 c\alpha,\\
\delta^2 &= -h_1 b\delta + h_2 c\delta - h_1 h_2 \alpha\delta,\\
\alpha\delta &= -\delta\alpha + h_1(\delta b - b\alpha) + h_2(c\alpha - c\delta) - h_1 h_2(\delta\alpha + cb),\\
bc &= cb + h_1(\delta b + \alpha b) - h_2(c\delta + \alpha c) + h_1 h_2(\alpha\delta - cb),
\end{aligned} \tag{3.10}$$

provided that α and δ anticommute with ξ, η, h_1, and h_2, and

$$h_1 h_2 = -h_2 h_1. \tag{3.11}$$

When we take $h_2 = 0$, we obtain the quantum Grassmann supergroup with one parameter.[3]

These relations can be obtained from the requirement that A_{h_1} and $A^*_{h_2}$ have to be covariant under the left coactions

$$\mu: A_{h_1} \to Gr_{h_1,h_2}(1|1) \otimes A^*_{h_2}, \quad \mu^*: A^*_{h_2} \to Gr_{h_1,h_2}(1|1) \otimes A_{h_1}, \tag{3.12}$$

such that

$$\mu(U) = \hat{T} \otimes V, \quad \text{i.e.,} \quad \mu(U^i) = \hat{T}^i_j \otimes V^j, \tag{3.13}$$

$$\mu^*(V) = \hat{T} \otimes U, \quad \text{i.e.,} \quad \mu^*(V^i) = \hat{T}^i_j \otimes U^j. \tag{3.14}$$

Recall that the multiplication in the tensor product space follows the rule

$$(A \otimes B)(C \otimes D) = (-1)^{P(B)P(C)} AC \otimes BD, \tag{3.15}$$

where $P(X)$ is the z_2-grade of X. Note that Eqs. (3.13) and (3.14) do not conform to standard definitions because of (2.3).

Alternatively, the relations (3.10) can be obtained using the following similarity transformation which was given by Aghamohammadi *et al.*:[1]

$$\hat{T}' = g\hat{T}g^{-1}, \tag{3.16}$$

where in our case[4]

$$g = g_{h_1} g_{h_2}. \tag{3.17}$$

To do this, we use the relations (2.4) and then take the limits $p \to 1$, $q \to 1$. But in that case, the required steps are rather complicated and tedious.

The quantum (dual) superdeterminant of $\hat{T}$ is defined as

$$\hat{D}_{h_1,h_2} = bc^{-1} - \alpha c^{-1} \delta c^{-1} = c^{-1} b - c^{-1} \alpha c^{-1} \delta, \tag{3.18}$$

which is independent of the relations (3.10). As an interesting case, it can be verified that $\hat{D}_{h_1,h_2}$ commutes with all matrix elements of $\hat{T}$, that is, $\hat{D}_{h_1,h_2}$ belongs to the center of the algebra

$$\hat{T}\hat{D} = \hat{D}\hat{T},$$

although the quantum (dual) superdeterminant of a matrix in $\mathrm{Gr}_{p,q}(1|1)$ does not commute with all the matrix elements.

IV. *R*-MATRIX FOR $\mathrm{Gr}_{h_1,h_2}(1|1)$

We shall obtain an *R*-matrix for the quantum Grassmann supergroup $\mathrm{Gr}_{h_1,h_2}(1|1)$ from the *R*-matrix of $\mathrm{Gr}_{p,q}(1|1)$.

The algebra (2.4) is associative under multiplication and the relations (2.4) may be expressed in terms of a graded *R*-matrix condition, which we repeat here,

$$R^1_{p,q} \hat{T}'_1 \hat{T}'_2 = -\hat{T}'_2 \hat{T}'_1 R^2_{p,q} \tag{4.1}$$

[see Eqs. (2.10)–(2.12)]. Now substituting (3.16) into (4.1) and defining the *R*-matrix R_{h_1,h_2} as

$$R_{h_1,h_2} = \lim_{p \to 1} \lim_{q \to 1} (g_{h_1,h_2} R'_{p,q} g_{h_1,h_2}), \tag{4.2}$$

where

$$g_{h_1,h_2} = g_1 g_2^{-1}, \quad R'_{p,q} \in \{R^1_{p,q}, R^2_{p,q}\}, \tag{4.3}$$

we get the following *R*-matrix R_{h_1,h_2}, as the two parameter extension of the *R*-matrix in Ref. 3,

$$R_{h_1,h_2} = \begin{pmatrix} 1 - h_1 h_2 & h_2 & h_2 & 0 \\ -h_1 & -1 & -h_1 h_2 & -h_2 \\ -h_1 & -h_1 h_2 & -1 & h_2 \\ 0 & h_1 & -h_1 & 1 + h_1 h_2 \end{pmatrix}, \tag{4.4}$$

which gives the (h_1,h_2)-deformed algebra of functions on $\mathrm{Gr}_{h_1,h_2}(1|1)$ with the equation

$$R_{h_1,h_2} \hat{T}_1 \hat{T}_2 = -\hat{T}_2 \hat{T}_1 R_{-h_1,-h_2}. \tag{4.5}$$

V. HOPF ALGEBRA STRUCTURE OF $\mathrm{Gr}_{h_1,h_2}(1|1)$

We denote the algebra generated by the matrix elements α, b, c, δ of $\hat{T}$ with the relations (3.10) by $\hat{\mathcal{A}}$. To make the algebra $\hat{\mathcal{A}}$ into a Hopf algebra related to the quantum supergroup $\mathrm{GL}_{h_1,h_2}(1|1)$, we state briefly some properties of the quantum supergroup $\mathrm{GL}_{h_1,h_2}(1|1)$ we are going to need in this section.

The quantum supergroup $\mathrm{GL}_{h_1,h_2}(1|1)$ generated by four generators a, β, γ, d and the (h_1,h_2)-commutation relations[4]

$$\begin{gathered} a\beta=\beta a-h_2(a^2-\beta\gamma-ad), \quad d\beta=\beta d+h_2(d^2+\beta\gamma-da), \\ a\gamma=\gamma a+h_1(a^2+\gamma\beta-ad), \quad d\gamma=\gamma d-h_1(d^2-\gamma\beta-da), \\ \beta^2=h_2\beta(a-d), \quad \gamma^2=h_1\gamma(a-d), \\ \beta\gamma=-\gamma\beta+(h_1\beta-h_2\gamma)(d-a), \quad ad=da+h_1\beta(a-d)+h_2(a-d)\gamma. \end{gathered} \tag{5.1}$$

The generators satisfying the relations (5.1) generate the algebra called the algebra of functions on the quantum supergroup $\mathrm{GL}_{h_1,h_2}(1|1)$ and we shall denote it by $\mathcal{A}$. We know that[4] the algebra $\mathcal{A}$ is a graded Hopf algebra with the following structure: the coproduct

$$\Delta:\mathcal{A}\to\mathcal{A}\otimes\mathcal{A}, \quad \Delta(t^i_j)=t^i_k\otimes t^k_j, \tag{5.2}$$

the counit

$$\epsilon:\mathcal{A}\to\mathcal{C}, \quad \epsilon(t^i_j)=\delta^i_j, \tag{5.3}$$

and the antipode

$$S:\mathcal{A}\to\mathcal{A}, \quad S(t^i_j)=(t^i_j)^{-1}, \tag{5.4}$$

where $t^i_j\in\{a,\beta,\gamma,d\}$.

It is not difficult to check the Hopf algebra axioms.[16] If we represent the set of generators a, β, γ, d in the form of a matrix

$$T=\begin{pmatrix} a & \beta \\ \gamma & d \end{pmatrix}, \tag{5.5}$$

then the relations (5.1) are equivalent to the equation

$$RT_1T_2=T_2T_1R, \tag{5.6}$$

where[4]

$$R=\begin{pmatrix} 1-h_1h_2 & -h_2 & h_2 & 0 \\ -h_1 & 1 & -h_1h_2 & h_2 \\ h_1 & -h_1h_2 & 1 & h_2 \\ 0 & h_1 & h_1 & 1+h_1h_2 \end{pmatrix} \tag{5.7}$$

is the solution of the quantum Yang–Baxter equation.

Since the (graded) Hopf algebra structure of $\mathrm{Gr}_{h_1,h_2}(1|1)$ will be related to those of $\mathrm{GL}_{h_1,h_2}(1|1)$, it is necessary to obtain the commutation relations of the generators of $\hat{\mathcal{A}}$ with those of $\mathcal{A}$. We obtain the commutation relations between the generators of $\hat{\mathcal{A}}$ and $\mathcal{A}$ as follows:

$$\hat{T}_1 T_2 = (-1)^{p(T_2)} R^{-1} T_2 \hat{T}_1 R. \tag{5.8}$$

Equation (5.8) gives

$$\begin{aligned}
\alpha a &= a\alpha + h_1(ab+\beta\alpha) - h_2(ac+\gamma\alpha) - h_1h_2(a\delta - \beta c + \gamma b + d\alpha + 2a\alpha),\\
\alpha\beta &= -\beta\alpha + h_1\beta b + h_2(a\alpha - \beta c + d\alpha) - h_1h_2(ab - \beta\alpha - \beta\delta + db),\\
\alpha\gamma &= -\gamma\alpha + h_1(a\alpha + \gamma b + d\alpha) - h_2\gamma_c - h_1h_2(ac - \gamma\alpha - \gamma\delta + dc),\\
\alpha d &= d\alpha - h_1(\beta\alpha - db) + h_2(\gamma\alpha - dc) + h_1h_2(a\alpha - \beta c + \gamma b - d\delta),\\
ba &= ab + h_1\beta b - h_2(a\alpha + a\delta + \gamma b) - h_1h_2(ab - \beta\alpha - \beta\delta + db),\\
b\beta &= \beta b - h_2(ab - \beta\alpha - \beta\delta + db),\\
b\gamma &= \gamma b - h_1(ab + db) - h_2(\gamma\alpha - \gamma\delta) + h_1h_2(a\alpha + a\delta + d\alpha + d\delta),\\
bd &= db - h_1\beta b + h_2(\gamma b - d\alpha - d\delta) + h_1h_2(ab - \beta\alpha - \beta\delta + db),\\
ca &= ac - h_1(a\alpha + a\delta - \beta c) - h_2\gamma c - h_1h_2(ac - \gamma\alpha - \gamma\delta + dc),\\
c\beta &= \beta c + h_1(\beta\alpha + \beta\delta) - h_2(ac + dc) - h_1h_2(a\alpha + a\delta + d\alpha + d\delta),\\
c\gamma &= \gamma c - h_1(ac - \gamma\alpha - \gamma\delta + dc),\\
cd &= dc - h_1(\beta c + d\alpha + d\delta) + h_2\gamma c + h_1h_2(ac - \gamma\alpha - \gamma\delta + dc),\\
\delta a &= a\delta - h_1(ab - \beta\delta) + h_2(ac - \gamma\delta) + h_1h_2(a\alpha - \beta c + \gamma b - d\delta),\\
\delta\beta &= -\beta\delta - h_1\beta b + h_2(a\delta + \beta c + d\delta) + h_1h_2(ab - \beta\alpha - \beta\delta + db),\\
\delta\gamma &= -\gamma\delta + h_1(a\delta - \gamma b + d\beta) + h_2\gamma c + h_1h_2(ac - \gamma\alpha - \gamma\delta + dc),\\
\delta d &= d\delta - h_1(\beta\delta + db) - h_2(\gamma\delta + dc) + h_1h_2(a\delta + \beta c - \gamma b + d\alpha + 2d\delta).
\end{aligned} \tag{5.9}$$

Using these relations, it can be checked that $\hat{D}_{h_1,h_2}$, which is given by (3.18), is still a central element, i.e., $\hat{D}_{h_1,h_2}$ also commutes with the generators of $\mathcal{A}$.

Before defining a coproduct on the algebra $\hat{\mathcal{A}}$, let us note the following facts. Let $\hat{T}$ and $\hat{T}'$ be any two supercommuting quantum matrices whose elements satisfy (3.10). We denote a product $\hat{T}\hat{T}'$ by T. Then, it can be verified that the matrix elements of T satisfy the commutation relations (5.1), i.e., if

$$\hat{T}, \hat{T}' \in \mathrm{Gr}_{h_1,h_2}(1|1) \Rightarrow T = \hat{T}\hat{T}' \in \mathrm{GL}_{h_1,h_2}(1|1).$$

In view of these facts, we can say that there may be no coproduct of the form $\Delta(\hat{T}) = \hat{T}\dot{\otimes}\hat{T}$. For, this coproduct, if it existed, would be invariant under the (h_1,h_2)-commutation relations (5.1) of $\mathrm{GL}_{h_1,h_2}(1|1)$. But we can define a coproduct on the algebra $\hat{\mathcal{A}}$ as follows (see Ref. 17, for more details):

$$\hat{\Delta}: \hat{\mathcal{A}} \to \hat{\mathcal{A}} \otimes \hat{\mathcal{A}}, \quad \hat{\Delta}(\hat{T}) = \hat{T}\dot{\otimes} T + (-1)^{p(T)} T \dot{\otimes} \hat{T}. \tag{5.10}$$

Explicity,

$$\begin{aligned}
\hat{\Delta}(\alpha) &= \alpha \otimes a + b \otimes \gamma + a \otimes \alpha - \beta \otimes c, \\
\hat{\Delta}(b) &= b \otimes d + \alpha \otimes \beta + a \otimes b - \beta \otimes \delta, \\
\hat{\Delta}(c) &= c \otimes a + \delta \otimes \gamma - \gamma \otimes \alpha + d \otimes c, \\
\hat{\Delta}(\delta) &= \delta \otimes d + c \otimes \beta - \gamma \otimes b + d \otimes \delta.
\end{aligned} \tag{5.11}$$

The action on the generators of $\hat{\mathcal{A}}$ of $\hat{\epsilon}:\hat{\mathcal{A}} \to \mathcal{C}$ is

$$\hat{\epsilon}(\alpha) = \hat{\epsilon}(b) = \hat{\epsilon}(c) = \hat{\epsilon}(\delta) = 0. \tag{5.12}$$

Finally, we define the coinverse as

$$\hat{S}:\hat{\mathcal{A}} \to \hat{\mathcal{A}}, \quad \hat{S}(\hat{T}) = -(-1)^{p(T^{-1})} T^{-1} \hat{T} T^{-1}. \tag{5.13}$$

It can be checked that the maps $\hat{\Delta}$ and $\hat{\epsilon}$ are both algebra homomorphisms and $\hat{S}$ is an algebra antihomomorphism and the three maps satisfy the following properties of the costructures:

$$\begin{aligned}
(\hat{\Delta} \otimes \mathrm{id}) \circ \hat{\Delta} &= (\mathrm{id} \otimes \hat{\Delta}) \circ \hat{\Delta}, \\
\mu \circ (\hat{\epsilon} \otimes \mathrm{id}) \circ \hat{\Delta} &= \mu' \circ (\mathrm{id} \otimes \hat{\epsilon}) \circ \hat{\Delta}, \\
m \circ (\hat{S} \otimes \mathrm{id}) \circ \hat{\Delta} = \hat{\epsilon} &= m \circ (\mathrm{id} \otimes \hat{S}) \circ \hat{\Delta},
\end{aligned} \tag{5.14}$$

where id denotes the identity mapping, $\mu:\mathcal{C} \otimes \hat{\mathcal{A}} \to \hat{\mathcal{A}}$, $\mu':\hat{\mathcal{A}} \otimes \mathcal{C} \to \hat{\mathcal{A}}$ are the canonical isomorphisms, defined by $\mu(k \otimes a) = ka = \mu'(a \otimes k)$, $\forall a \in \hat{\mathcal{A}}$, $\forall k \in \mathcal{C}$, and m is the multiplication map $m:\hat{\mathcal{A}} \otimes \hat{\mathcal{A}} \to \hat{\mathcal{A}}$, $m(a \otimes b) = ab$.

(Received 11 September 1998; accepted for publication 9 March 1999)

It is shown that when a first integral of a $\mathbb{R}^3$ vector field **X** is known, instabilities are induced on the equilibrium points of **X**. © *1999 American Institute of Physics.* [S0022-2488(99)03106-0]

I. INTRODUCTION

Let **X** be an analytic (C^w) $\mathbb{R}^n$ vector field (v.f.) with an isolated singularity at the origin, i.e., $\mathbf{X}(\mathbf{0})=\mathbf{0}$. We are concerned here with establishing criteria for the instability of **X** at **0** (the origin).

It is a classical result that when the linear part $\mathbf{X}_L$ of **X** at **0** has an eigenvalue of positive real part then **0** is an unstable equilibrium point of **X** (Ref. 1). This criterion gives no information concerning instability when there are not eigenvalues of $\mathbf{X}_L$ to the right of the imaginary axis.

When $\mathbf{X}_\mathrm{H}$ is a Hamiltonian v.f. and H is an analytic function of the form

$$H=\sum_{i,j=1}^{m} p_i p_j a_{ij}(\mathbf{q})+V(\mathbf{q}) \quad (\mathbf{q}\in\mathbb{R}^m, \quad n=2m), \tag{1}$$

and (i) $a_{ij}(\mathbf{q})$ is definite positive for any **q**, (ii) **0** is a critical point of V, (iii) **0** is not a strict minimum of V, and (iv) $m=1,2$. Then **0** is an unstable equilibrium point of $\mathbf{X}_\mathrm{H}$ (Ref. 2).

When $m>2$, the instability of $\mathbf{X}_\mathrm{H}$ at **0**, under the above assumptions, is an unproved conjecture. Nevertheless, the unstable behavior of $\mathbf{X}_\mathrm{H}$ at **0** has been obtained under additional requirements on $V(\mathbf{q})$ (Ref. 3).

The stability of periodic solutions of Hamiltonian v.f. when first integrals are known has also been recently investigated (Ref. 4).

The technique proposed in this paper is valid for $\mathbb{R}^3$ v.f. with an isolated singularity (equilibrium point) at **0** and with a known C^w first integral I. The technique is illustrated with examples that show that the method is valid, even in the case of trivial center (that is, when all the eigenvalues of $\mathbf{X}_L$ lie on the imaginary axis).

The method proposed here is based on the well-known fact that the w limit of a bounded trajectory of a planar vector field must include either a singularity or a closed trajectory (Bendixon–Poincaré theorem).

The possibilities of extending the new technique to $\mathbb{R}^n$ v.f. ($n>3$) are also discussed.

II. INSTABILITY INDUCED BY FIRST INTEGRALS

Let **X** be a $\mathbb{R}^3$ dynamical system with an isolated singularity at **0** and I a C^w first integral of **X**. Assume that either

$$\text{(i)} \quad \nabla I_{|\mathbf{0}}\neq\mathbf{0},$$

or (2)

$$\text{(ii)} \quad \nabla I(\mathbf{P})=\mathbf{0},\ \ \mathbf{P}\in N_0\Rightarrow\mathbf{P}=(0,0,0),$$

and I has a saddle at the origin.

Then **0** is an unstable equilibrium point of **X**.

Remember that ∇I stands for the gradient of I. On the other hand, I by definition has a saddle at **0** if $\nabla I_{|\mathbf{0}}=\mathbf{0}$ and there are points P and Q arbitrarily near **0** on which I takes values of opposite signs. Remember that we assume in this paper that the first integral I has the value 0 at **0**.

Proof: Assume that $\nabla I_{|\mathbf{0}}\neq\mathbf{0}$. In this case local coordinates (u_1,u_2,u_3) can be introduced on N_0 (a neighborhood of **0**) on which I takes the canonical form $I=u_1$. Therefore, if **X** is assumed stable at **0** its trajectories will lie in N_0 and on the local planes $u_l=k_1$. The w limits of these trajectories must be, on account of the Poincaré–Bendixon theorem,[5] singular points of **X**, polygonals whose vertices are singular points of **X** or closed trajectories.

In any of these three cases, singular points of **X**, lying on the planes $u_1=k_1$ and arbitrarily near **0**, are obtained. But since **0** was assumed to be an isolated singularity of **X**, we get a contradiction. Therefore **X** cannot be stable at **0**.

Assume now that ∇I vanishes on N_0 just at **0** and that I has a saddle at **0**.

These assumptions imply (as we now explain) that on a certain domain $Z_0\subset N_0$ the level sets of I resemble locally topological planes, to which the above reasoning can be applied, getting again a contradiction if **0** is assumed to be a stable singularity of **X**. Therefore **0** must be an unstable singularity of **X**, as we desired to prove.

We now show that if I is an $\mathbb{R}^3$ analytic function with a saddle at **0** and $\nabla I_{|N_0}$ vanishes just at **0**, then a domain $Z_0\subset N_0$ exists on which the sets $I^{-1}(c)\cap Z_0$ are local planes (disks).

In fact, the analiticity of I implies that $I^{-1}(0)\cap N_0$ is the finite union of the surfaces C_i, $i\in J$, through **0**. Condition (ii) of Eq. (2) implies that the surfaces C_i do not intersect each other on $N_0-\{\mathbf{0}\}$. The surfaces C_i divide N_0 into solid zones Z_j, whose boundary is made up of one or several of the surfaces C_i.

By topological reasons it is not too difficult to show that one at least (say Z_0) of the zones Z_j is diffeomorphic to $\mathbb{R}^3$. This is due to the fact that C_i is, inside N_0, either a topological plane (if C_i has a tangent at **0**) or a topological cone (if C_i has not a tangent plane at **0**); in any case, each C_i separates N_0 into zones, one of which is clearly diffeomorphic to $\mathbb{R}^3$. This property, valid for any of the surfaces C_i, is the geometric reason underlying the existence of the zone Z_0.

For example, consider the functions $I_1=(x^2+y^2-z^2)z$, $I_2=(x^2+y^2-z^2)(x^2+y^2-4z^2)$. I_1 and I_2 have clearly a saddle at **0**, and it is easy to check that ∇I_i $(i=1,2)$ vanishes just at **0**. The set Z_0 diffeomorphic to $\mathbb{R}^3$ can be chosen to be

$$Z_0=\{(x,y,z)|x^2+y^2<z^2,\quad z>0\}. \tag{3}$$

Consider now the C^w curves φ_α, defined either by

$$\varphi_\alpha=I^{-1}(c)\cap Z_0\cap\pi_\alpha, \tag{4}$$

π_α standing for a family of planes through **0**, intersecting Z_0, or by

$$I_{|\pi_\alpha\cap Z_0}=c. \tag{5}$$

Calling $I_{|\pi_\alpha}$ by I^*_α, we have the following.

(1) (0,0) is a saddle of I^*_α. This is a consequence of the fact that the sign of I changes on the surfaces C_i, since otherwise $\nabla I=\mathbf{0}$ on points of $N_0-\{\mathbf{0}\}$.

(2) ∇I^*_α has an isolated zero at (0,0). In fact, if $\nabla I^*_{\alpha|\varphi}=\mathbf{0}$, where φ is a curve through (0,0) we would get $I_{|\varphi}=0$, in contradiction with the fact that $I\neq0$ inside Z_0. A similar contradiction is obtained if ∇I^*_α vanishes on a succession of points tending to (0,0).

Summarizing, the curves φ_α are the zeros of plane C^w functions with a saddle at (0,0) and an isolated critical point at (0,0). Therefore (Ref. 6), φ_α is just an open segment. The union of these segments, when the plane π_α varies is, given the topology of Z_0, a local plane (a disk).

Therefore $I^{-1}(c)\cap Z_0$ is locally a plane.

The reasoning above is sketchy and probably can be improved.

We have not been able to improve it by consultations with professional mathematicians. We now give some examples of $\mathbb{R}^3$ v.f. whose instability at $\mathbf{0}$ can be detected with the above-mentioned techniques. To our knowledge they cannot be integrated via quadratures and they are interesting since most of them have a vanishing linear part.

A. Consider the $\mathbb{R}^3$ v.f.

Here

$$\mathbf{X}=(y(1+z^2)-x-z)\partial_x+(-y-x(1+z^2))\partial_y+((x^2+y^2+xz)(1+z^2))\partial_z. \tag{6}$$

It is easy to check that this v.f. has an isolated zero at (0,0,0) and the eigenvalues of $\mathbf{X}_L$ at $\mathbf{0}$ are 0 and $-1\pm i$. Therefore the eigenvalues cannot decide between stability and instability at $\mathbf{0}$.

This v.f. has the first integral $I=\frac{1}{2}(x^2+y^2)-\arctan(z)$. Note that $\nabla I_{|\mathbf{0}}\neq\mathbf{0}$. Therefore by (i) of Eq. (2), $\mathbf{X}$ is unstable at $\mathbf{0}$.

B. Consider the v.f.

Here

$$\mathbf{X}=(x^4(y^2+z^2)+x^2+y^2)\partial_x-(2x^3(y^2+z^2)(1+y)+x^2+y^2+z^2)\partial_y+(2x(x^2+y^2)(1+y)$$
$$-x^2(x^2+y^2+z^2))\partial_z. \tag{7}$$

It is easy to check that (i) $\mathbf{0}$ is an isolated zero of $\mathbf{X}$ and that $\mathbf{X}_L$ (the linear part of $\mathbf{X}$ at $\mathbf{0}$) is identically zero; (ii) $I=x^2(1+y)-z$ is a first integral of $\mathbf{X}$. (iii) $\nabla I_{|\mathbf{0}}\neq\mathbf{0}$.

Therefore, according to (i) of Eq. (2), $\mathbf{0}$ is an unstable singular point of $\mathbf{X}$.

C. Let X be the v.f.

Here

$$\mathbf{X}=(2x(y-z)(x^2+y^2+z^2))\partial_x-((3x^2+y^2+z^2)(x^2+y^2+z^2)2x^2yz)\partial_y$$
$$+((3x^2+y^2+z^2)(x^2+y^2+z^2)+2x^2y^2)\partial_z. \tag{8}$$

It is easy to check that (i) $\mathbf{0}$ is an isolated zero of $\mathbf{X}$ and $\mathbf{X}_L=0$; (ii) $I=x(x^2+y^2+z^2)$ is a first integral of $\mathbf{X}$. The first integral has a saddle at $\mathbf{0}$ and its gradient vanishes just at $\mathbf{0}$.

According to (ii) of Eq. (2), $\mathbf{0}$ is an unstable singularity of $\mathbf{X}$.

D. Consider the $\mathbb{R}^3$ v.f.

Here

$$\mathbf{X}=-2(y^2+zx^2+zxy^2+xz^3)\partial_x+(-(z^2+3x^2)y+2xyz(x^2+y^2+z^2))\partial_y$$
$$+((x^2+y^2+z^2)(3x^2+2y^2+z^2))\partial_z. \tag{9}$$

It is easy to check that (i) $\mathbf{0}$ is an isolated zero of $\mathbf{X}$ and $\mathbf{X}_L=\mathbf{0}$; (ii) $I=z^2x+x^3-y^2$ is a first integral of $\mathbf{X}$. In addition, I has a saddle at $\mathbf{0}$ and ∇I vanishes just at $\mathbf{0}$.
Therefore, by applying (ii) of Eq. (2), we can conclude that $\mathbf{X}$ is unstable at $\mathbf{0}$.

We conclude by noting that our instability criterion can be applied to $\mathbb{R}^n$ v.f. $(n>3)$ when $(n-2)$ first integrals of $\mathbf{X}$ are known and $\operatorname{rank}(\nabla I_1,\ldots,\nabla I_{n-2})_{|\mathbf{0}}=n-2$. This can be seen by introducing local coordinates $(u_1,\ldots,u_n)$ in N_0 on which the first integrals take the local form $I_1=u_1,\ldots,I_{n-2}=u_{n-2}$.

Therefore the local level sets of $I_1,\ldots,I_{n-2}$ will be local planes (two-dimensional disks). By applying to them the considerations used to demonstrate of Eq. (2), we get instability of $\mathbf{X}$ at $\mathbf{0}$.

When $\text{rank}(\nabla I_1,\ldots,\nabla I_{n-2})_{|\mathbf{0}}<n-2$, a general criterion for instability seems difficult to get. We list now several partial results in this direction.

(i) Let $\mathbf{X}$ be a $\mathbb{R}^4$ v.f. with an isolated zero at $\mathbf{0}$ and the two first integrals:

$$I_1=(1+x^2)y^2+(1+x^4)z^2-(1+e^x)u^4,$$
$$I_2=x. \tag{10}$$

Note that $\text{rank}(\nabla I_1,\nabla I_2)_{|\mathbf{0}}=1$.

On the level set $I_2=0$, I_1 and $\mathbf{X}$ become

$$I_1^*=y^2+z^2-2u^4,$$
$$\mathbf{X}^*=a\partial_y+b\partial_z+c\partial_u. \tag{11}$$

It is clear that ∇I_1^* vanishes just at (0,0,0), that $\mathbf{X}^*$ has an isolated zero at (0,0,0), and that I_1^* has a saddle at $\mathbf{0}$. Therefore the couple $(\mathbf{X}^*,I_1^*)$ satisfies the assumptions of (ii) of Eq. (2), and we conclude that $\mathbf{X}^*$, and therefore $\mathbf{X}$, is unstable at (0,0,0,0).

Examples of this type are not only academic, since they appear in the study of systems of the type

$$\ddot{x}=V_{,x}(x,y),$$
$$\ddot{y}=V_{,y}(x,y), \tag{12}$$

whenever a pair of first integrals of a $\mathbb{R}^4$ v.f. are known and the gradient of one of them does not vanish at $\mathbf{0}$ (Ref. 7). The second first integral is, usually, linear in the components of the velocity.

In fact, via a local change of variables this first integral can be reduced to a canonical form similar to the function I_2 of (10). This fact gives generality to the couple of first integrals chosen in (10).

(ii) Let I_1 and I_2 be defined by

$$I_1=u^n-P(x,y,z),$$
$$I_2=x^m-Q(y,z), \tag{13}$$

where n and m are positive integers $(n,m>1)$, P and Q non-negative polynomials and $\text{rank}(\nabla I_1,\nabla I_2)_{|\mathbf{0}}=0$.

It is immediate to check that the level sets

$$I_1=C_1,$$
$$I_2=C_2, \tag{14}$$

are planes when $C_1,C_2>0$ (one has just to get u and x as global functions of y and z). Therefore, by using similar arguments to those given in the proof of (2), any $\mathbb{R}^4$ v.f. with an isolated zero at $\mathbf{0}$ and these first integrals is unstable at $\mathbf{0}$.

(iii) Let I_1 and I_2 be defined by

$$I_1=y^2-f(x),$$
$$I_2=xu-zy, \tag{15}$$

$f(x)$ being a non-negative function and $f'(0)=0$.

Note that I_2 has the form of an angular momentum and that $\text{rank}(\nabla I_1,\nabla I_2)_{|\mathbf{0}}=0$. On the other hand, the level sets,

$$y^2 - f(x) = C,$$
$$xu - zy = D, \tag{16}$$
$$C > 0,$$

can be globally parametrized in the form

$$\left(x, \pm\sqrt{C+f(x)}, \frac{xu-D}{\pm\sqrt{C+f(x)}}, u \right), \tag{17}$$

and they are a couple of two-dimensional planes (note that the parameters x and u are free). Therefore any v.f. with an isolated zero at **0** and the two first integrals (15) is unstable at **0**.

(Received 2 November 1998; accepted for publication 14 February 1999)

Systems of nonlinear ordinary differential equations are constructed for which the general solution is expressed algebraically in terms of a finite number of particular solutions. The equations and the corresponding nonlinear superposition formula are based on a nonlinear action of the Lie group $SL(N,\mathbb{C})$ on a homogeneous space M. The isotropy group of the origin of this space is a nonmaximal parabolic subgroup of $SL(N,\mathbb{C})$. Such equations can occur as Bäcklund transformations for soliton equations on flag manifolds.
[S0022-2488(99)00306-0]

I. INTRODUCTION

Let us consider a system of n first order ordinary differential equations (ODEs),

$$\dot{y}^{\mu}=\eta^{\mu}(\mathbf{y},t) \quad \mu=1,...,n, \tag{1.1}$$

where the dot denotes differentiation with respect to time t.

If the equations are linear we have a linear superposition formula; the general solution is a linear combination of n linearly independent particular solutions. More interestingly, even if the system (1.1) is nonlinear, it may allow a nonlinear superposition formula

$$\begin{gathered}\mathbf{y}(t)=\mathbf{F}(\mathbf{y}_1,\ldots,\mathbf{y}_m,c_1,\ldots,c_n),\\ \mathbf{y}\in\mathbb{C}^n \quad (\text{or } \ \mathbf{y}\in\mathbb{R}^n),\end{gathered} \tag{1.2}$$

where $\mathbf{y}_1,\ldots,\mathbf{y}_m$ are particular solutions, $c_1,\ldots,c_n$ are arbitrary constants and $\mathbf{y}(t)$ is the general solution.

Lie[1] established the conditions under which the system (1.1) allows a superposition formula (1.2), i.e., the general solution can be expressed as a function of a finite number m of particular solutions. Lie's result can be summed up as follows:

The system (1.1) allows a superposition formula (1.2) if and only if

(1) It has the form

$$\dot{\mathbf{y}}=\sum_{k=1}^{r} Z_k(t)\boldsymbol{\xi}_k(\mathbf{y}). \tag{1.3}$$

(2) The vector functions $\boldsymbol{\xi}_k(\mathbf{y})$ (independent of t) are such that the vector fields

---

[b)]Electronic mail: severin@km1.fjfi.cvut.cz
[c)]Electronic mail: wintern@CRM.UMontreal.CA

$$\hat{X}_k = \sum_{\mu=1}^{n} \xi_k^{\mu}(\mathbf{y})\partial_{y^{\mu}} \tag{1.4}$$

generate a finite dimensional Lie algebra L,

$$[X_k, X_l] = \sum_{j=1}^{r} f_{klj} X_j . \tag{1.5}$$

The number of solutions m needed in the superposition formula (1.2) satisfies the relation

$$mn \geqq r, \tag{1.6}$$

where n is the number of equations and r is the dimension of the Lie algebra L.

Somewhat unexpectedly, it turned out that nonlinear ordinary differential equations with superposition formulas play an important role in soliton theory[2] where they occur as Bäcklund transformations.

In turn, Bäcklund transformations provide soliton superposition formulas, i.e., explicit formulas for multisoliton solutions that asymptotically correspond to a combination of independent solitons. Thus two very different types of nonlinear superposition formulas become linked via Bäcklund transformations for integrable nonlinear partial differential equations.

The classification and construction of all systems of n nonlinear ODEs with superposition formulas amounts to a classification of all finite dimensional subalgebras of diff(n), the infinite dimensional Lie algebra of vector fields in n dimensions. For $n=1$ such a classification is quite simple. Indeed the only finite-dimensional subalgebras of diff$(1,\mathbb{C})$ are sl$(2,\mathbb{C})$ and its subalgebras. For $n=2$ a complete classification exists and this is again due to Lie.[3] For $n \geqq 3$ the problem becomes intractable.

A more resctricted problem has however been solved[4–6] and that is the classificaton of indecomposable systems of ODEs with superposition formulas. These are systems satisfying Eqs. (1.3), (1.4), and (1.5) from which it is not possible to split off a subset of $l<n$ equations that also satisfy Lie's criteria and hence have a superposition formula of their own.

The classification of these indecomposable systems is best formulated in a geometric manner. Thus, let us view the variables $\{y_1,\ldots,y_n\}$ (for fixed t), as local coordinates on some manifold M. Let G be a Lie group acting transitively and effectively on M. We can then identify M with a quotient space $M \sim G/G_0$, where $G_0 \subset G$ is the isotropy group of the origin in M.

The system (1.1) is decomposable if local coordinates on M exist that can be divided into two subsets, $\{y_1,\ldots,y_n\} \sim \{x_1,\ldots,x_l,z_{l+1},\ldots,z_n\}$ such that the vector fields (1.4) all simultaneously have the form

$$X_k = \sum_{a=1}^{l} f_k(x)\partial_{x_a} + \sum_{b=l+1}^{n} g_k(x,z)\partial_{z_b} \tag{1.7}$$

(i.e., the coefficients of ∂_{x_a} depend on the coordinates x only). Such coordinates exist if there exists a G-invariant foliation of the space M. The action of G on M is called primitive (in addition to being transitive and effective) if no such foliation exists. Locally, this can be expressed in terms of the Lie algebras L and L_0, corresponding to G and G_0. The system (1.1) is indecomposable if the pair of algebras (L_0, L) determines a transitive primitive Lie algebra. This means that L_0, the subalgebra of vector fields vanishing at the origin, must be a maximal subalgebra of L, and must not contain an ideal of L.

Transitive primitive Lie algebras have been classified.[7–11] In turn, this classification was used to classify indecomposable systems of ODEs with superposition formulas.[4–6] Several articles have been devoted to constructing systems of equations with superposition formulas, and to the superposition formulas themselves.[12–17] Supersymmetric versions of these equations have been constructed[18] as well as difference equations with superposition formulas.[19,20] All cases considered so far correspond to transitive primitive Lie algebras.

The purpose of this article is to investigate the nonprimitive case and to show how the previously studied indecomposable systems serve as building blocks for decomposable ones.

We restrict ourselves to the Lie algebras $\mathrm{sl}(N,\mathbb{C})$ (for arbitrary finite N) and make use of realizations of these algebras, constructed earlier.[21]

II. FORMULATION OF THE PROBLEM AND EXAMPLE OF SL(2,$\mathbb{C}$)

A. General formulation

Let us consider a system of ODEs as in Eq. (1.3), allowing a superposition formula. In view of Eqs. (1.4) and (1.5) the right-hand side of Eq. (1.3) determines an element of the Lie algebra L for any fixed value of time t. As t varies, this element varies along some path in L. The general form of the solution is obtained by integrating the vector fields (1.4) and composing the results. Thus the solution will be given by the corresponding group action

$$\mathbf{y}(t)=g(t)\cdot\mathbf{u}, \tag{2.1}$$

where $g(t)$ is an element of the Lie group $G=\langle\exp L\rangle$ and $\mathbf{u}$ is a constant vector, related to the initial conditions for $\mathbf{y}(t)$. The group element $g(t)$ depends on $r=\dim L$ group parameters. These in turn depend on time t in such a way that $g(t)$ follows a path in the group G, corresponding to the path in L, determined by the equation, i.e., by the coefficients $Z_k(t)$, $k=1,...,r$.

The superposition formula (1.2) is obtained from the group action (2.1), once the time dependence in $g(t)$ is established. To do this, we assume that we know m solutions $\mathbf{y}_k(t)$, $k=1,...,m$ corresponding to the initial values u_k in (2.1). The m relations

$$\mathbf{y}_k(t)=g(t)\mathbf{u}_k \tag{2.2}$$

are then used to express all parameters in $g(t)$ in terms of the known solutions. Each solution provides n equations. The condition (1.6) simply means that we must have at least as many equations as unknowns. The actual number m of different solutions needed is obtained from the requirement that the only transformation $g(t_0)$ that simultaneously stabilizes all initial conditions u_k ($u_k=g(t_0)u_k$, $k=1,...,m$) is the identity transformation $g(t_0)=I$. This requirement determines the minimal number m and also the independence conditions on $u_1,\ldots,u_m$.

B. Example of the algebra sl(2,$\mathbb{C}$)

For $n=1$ the situation is very simple. The only finite dimensional subalgebras of $\mathrm{diff}(1,\mathbb{C})$ are $\mathrm{sl}(2,\mathbb{C})$ and its one and two-dimensional subalgebras. Up to local diffeomorphisms there exists just one realization of $\mathrm{sl}(2,\mathbb{C})$ as a subalgebra of $\mathrm{diff}(1,\mathbb{C})$, namely,

$$X_1=\partial_y,\quad X_2=y\partial_y,\quad X_3=y^2\partial_y. \tag{2.3}$$

Equation (1.3) in this case is the Riccati equation

$$\dot{y}=Z_1(t)+Z_2(t)y+Z_3(t)y^2. \tag{2.4}$$

The $\mathrm{SL}(2,\mathbb{C})$ group transformations corresponding to the realization (2.3) are projective transformations of $\mathbb{C}^1$. Thus, Eq. (2.1) in this case is

$$y(t)=\frac{g_{11}u+g_{21}}{g_{12}u+g_{22}},\quad g_{11}g_{22}-g_{21}g_{12}=1. \tag{2.5}$$

In this case we have $n=1$ (one equation), $r=\dim \mathrm{sl}(2,\mathbb{C})=3$, hence the number of solutions m needed to reconstruct the group element $g(t)=\{g_{ik}(t)\}$ satisfies $m\geqq 3$. In fact we have $m=3$.

Indeed let $y_1(t)$, $y_2(t)$, and $y_3(t)$ be any 3 different solutions of Eq. (2.4), corresponding, e.g., to the choices $u_1=0$, $u_2\to\infty$, $u_3=1$, respectively. Substituting into Eq. (2.5) we express g_{12}, g_{21}, and g_{22} in terms of $y_i(t)$ and g_{11} (which cancels out) and obtain the (well known) nonlinear superposition formula

$$y(t)=\frac{uy_2(y_1-y_3)+y_1(y_3-y_2)}{u(y_1-y_3)+y_3-y_2}. \tag{2.6}$$

Choosing $u=0$ as the origin of the space M, we see that it is stabilized by the maximal parabolic subgroup of SL(2,$\mathbb{C}$) and we obtain the identification

$$M\sim\mathbb{C}\sim G/G_0,\quad G\sim \mathrm{SL}(2,\mathbb{C}),$$
$$G_0\sim\begin{pmatrix} g_{11} & g_{12}\\ 0 & g_{11}^{-1}\end{pmatrix}. \tag{2.7}$$

Now let us turn to a case that has not been considered before, namely $n=2$ when the realization of the algebra sl(2,$\mathbb{C}$) is not primitive. The group SL(2,$\mathbb{C}$) has two inequivalent one dimensional subgroups,

$$G_{0,1}\sim\begin{pmatrix} g_{11} & 0\\ 0 & g_{11}^{-1}\end{pmatrix},\quad G_{0,2}\sim\begin{pmatrix} 1 & g_{12}\\ 0 & 1\end{pmatrix}, \tag{2.8}$$

i.e., the maximal torus $G_{0,1}$ and the unipotent group $G_{0,2}$. Hence we must obtain 2 inequivalent $n=2$ realizations of sl(2,$\mathbb{C}$). In appropriate coordinates (y_1,y_2) the coefficients of ∂_{y_1} in all vector fields will depend on y_1 only, those of y_2 can depend on both y_1 and y_2 [see Eq. (1.7)]. The coefficients of ∂_{y_1} will hence be as in Eq. (2.3). The analysis is easy to perform and we simply present the result

$$X_1=\partial_{y_1},\quad X_2=y_1\partial_{y_1}+y_2\partial_{y_2},\quad X_3=y_1^2\partial_{y_1}+(2y_1y_2+ky_2^2)\partial_{y_2},$$
$$k=0 \ \text{ or } \ 1. \tag{2.9}$$

The two inequivalent realizations correspond to $k=0$ and $k=1$, respectively. Lie in his classification of the $n=2$ case gave these two reaizations in a different, but equivalent form.[3] The form (2.9) was already used by Krause and Michel.[22]

The system of ODEs (1.3) corresponding to (2.9) are

$$\dot y_1=Z_1(t)+Z_2(t)y_1+Z_3(t)y_1^2,$$
$$\dot y_2=Z_2(t)y_2+Z_3(t)(2y_1y_2+ky_2^2). \tag{2.10}$$

We now wish to obtain superposition formulas for the above system, separately for $k=0$ and $k=1$.

Integrating the vector fields (2.9) we obtain the group action

$$y_1=\frac{g_{11}u_1+g_{21}}{g_{12}u_1+g_{22}},\quad y_2=\frac{u_2}{(g_{12}u_1+g_{22})[g_{12}(u_1+ku_2)+g_{22}]}. \tag{2.11}$$

Let us choose the point $(u_1,u_2)=(0,1)$ as the origin. For $k=0$ we see that it is stabilized by the unipotent group $G_{0,2}$ of Eq. (2.8). For $k=1$ the stabilizer of the origin is the subgroup

$$\tilde{G}_{0,1} \sim \begin{pmatrix} g_{11} & g_{11} - \dfrac{1}{g_{11}} \\ 0 & \dfrac{1}{g_{11}} \end{pmatrix}. \tag{2.12}$$

This is conjugate to $G_{0,1}$ of Eq. (2.8), however if we transform $\tilde{G}_{0,1}$ into $G_{0,1}$, the origin is shifted to $(u_1, u_2) = (0, \infty)$. We prefer to stay with the more convenient origin (0,1).

The relation $mn \geqq r$ for Eq. (2.10) is $2m \geqq 3$, hence $m \geqq 2$, and it turns out that two solutions are indeed sufficient to reconstruct the group element $g(t)$.

Let us assume that (v_1, v_2) and (w_1, w_2) are solutions of Eq. (2.10). The four components of **v** and **w** are then not independent, but satisfy the relation

$$\frac{(v_1 - w_1)[v_1 - w_1 + k(v_2 - w_2)]}{v_2 w_2} = R(k), \quad k = 0,1, \tag{2.13}$$

where $R(k)$ is a constant. This relation is the analog of the famous unharmonic ratio of four solutions of the Riccati equation,

$$\frac{(y_1 - y_2)}{(y_1 - y_3)} \frac{(y_3 - y_4)}{(y_2 - y_4)} = K = \text{const.} \tag{2.14}$$

We assume

$$v_1(0) \neq w_1(0), \quad v_2(0) w_2(0) \neq 0, \tag{2.15}$$

and for $k = 1$,

$$R(1) \neq 1.$$

With no loss of generality we can assume that the initial conditions for the two known solutions are

$$\begin{pmatrix} v_1(0) \\ v_2(0) \end{pmatrix} = \begin{pmatrix} 1 \\ a \end{pmatrix}, \quad \begin{pmatrix} w_1(0) \\ w_2(0) \end{pmatrix} = \begin{pmatrix} 0 \\ b \end{pmatrix}, \quad ab \neq 0. \tag{2.16}$$

Substituting these two solutions and their initial conditions into Eq. (2.11), we can solve for $g_{ik}(t)$. We mention that the reconstruction is more efficient in the imprimitive case than in the primitive one. Indeed for the Riccati equation we need to know three solutions, for the system (2.10) only one.

Let us consider the two cases separately.

(1) $k = 0$:

We obtain

$$g_{11} = v_1 \sqrt{\frac{a}{v_2}} - w_1 \sqrt{\frac{b}{w_2}}, \quad g_{12} = \sqrt{\frac{a}{v_2}} - \sqrt{\frac{b}{w_2}}, \quad g_{21} = w_1 \sqrt{\frac{b}{w_2}}, \quad g_{22} = \sqrt{\frac{b}{w_2}}. \tag{2.17}$$

Furthermore, the invariant $R(0)$ of Eq. (2.13) is equal to

$$R(0) = \frac{(v_1 - w_1)^2}{v_2 w_2} = \frac{1}{ab}, \tag{2.18}$$

and hence

$$g_{11}g_{22}-g_{12}g_{21}=\frac{v_1-w_2}{\sqrt{v_2w_2}}\sqrt{ab}=1. \tag{2.19}$$

(2) $k=1$:
We use the invariant (2.13)

$$R(1)=\frac{(v_1-w_1)(v_1-w_1+v_2-w_2)}{v_2w_2}=\frac{a-b+1}{ab} \tag{2.20}$$

to express v_2 in terms of v_1, w_1, and w_2 and obtain

$$\begin{aligned} g_{11}&=\frac{b[w_1(v_1-w_2)-w_1^2]+(b-1)v_1w_2}{[b(1-b)w_2(w_1-v_1)(w_1+w_2-v_1)]^{1/2}},\\ g_{22}&=\frac{b(w_1+w_2-v_1)}{[b(1-b)w_2(w_1-v_1)(w_1+w_2-v_1)]^{1/2}},\\ g_{21}&=g_{22}w_1,\quad g_{12}=\frac{1}{v_1}[g_{11}+g_{22}(v_1-u_1)]. \end{aligned} \tag{2.21}$$

The results of this section can be summed up as follows:

Theorem 1: Two inequivalent realizations of sl(2,$\mathbb{C}$) by vector fields in two dimensions exist, given by Eq. (2.9) with $k=0$ or $k=1$, respectively. The corresponding group actions on the homogeneous space SL(2,$\mathbb{C}$)/$G_{0,k}$ is given in Eq. (2.11).

Theorem 2: The nonlinear ODEs (2.10) for $k=0$ and $k=1$ have superposition formulas given by the imprimitive group action (2.11). The group elements $g_{ik}(t)$, $i,k\in\{1,2\}$ are reconstructed from any two solutions $\mathbf{v}=(v_1,v_2)$ and $\mathbf{w}=(w_1,w_2)$ with the initial conditions satisfying Eq. (2.15). The explicit reconstruction formulas are given in Eq. (2.17) for $k=0$ and (2.21) for $k=1$, respectively.

III. INDUCED REPRESENTATIONS OF SL(N,$\mathbb{C}$) AND PARABOLIC SUBGROUPS

A. General theory

Let us consider the Lie algebra sl(N,$\mathbb{C}$) realized by matrices $X\in\mathbb{C}^{N\times N}$, Tr $X=0$. We shall make use of several subalgebras of sl(N,$\mathbb{C}$). The **Borel** subalgebra is the maximal solvable subalgebra and it can be realized by the set of all traceless upper triangular matrices. A **parabolic** subalgebra of sl(N,$\mathbb{C}$) is any subalgebra containing the Borel subalgebra. A **maximal** parabolic subalgebra is one that is not contained in any proper subalgebra of sl(N,$\mathbb{C}$). All parabolic subalgebras can be realized by block triangular matrices. Maximal parabolic subalgebras correspond to the case of precisely two blocks on the diagonal.

A classification of all maximal parabolic subalgebras of sl(N,$\mathbb{C}$) is obtained by taking all decompositions of N into $N=r_1+r_2$, min(r_1,r_2)$\geqq 1$ and writing all sets of matrices of the form

$$\begin{gathered} p(r_1,r_2)=\left\{X\in\mathbb{C}^{N\times N}\,\middle|\,\mathrm{Tr}\,X=0,\ X=\begin{pmatrix}A_{11} & A_{12}\\ 0 & A_{22}\end{pmatrix}\right\},\\ N=r_1+r_2,\\ A_{11}\in\mathbb{C}^{r_1\times r_1},\ A_{22}\in\mathbb{C}^{r_2\times r_2},\ A_{12}\in\mathbb{C}^{r_1\times r_2}. \end{gathered} \tag{3.1}$$

Similarly, a maximal parabolic subgroup of the group corresponds to the same partition of N and satisfies

$$P(r_1,r_2)=\left\{G\in\mathbb{C}^{N\times N}\,\middle|\,G=\begin{pmatrix}G_{11}&G_{12}\\0&G_{22}\end{pmatrix},\ \det G_{11}\det G_{22}=1\right\}. \tag{3.2}$$

The homogeneous space $M\sim\mathrm{SL}(N,\mathbb{C})/P(r_1,r_2)$ was constructed in an earlier article[14] (as a Grassmanian). Local coordinates on this space were introduced as matrix elements of a matrix $W\in\mathbb{C}^{r_1\times r_2}$. The group action on this space is represented by matrix fractional linear transformations

$$\tilde{W}=(G_{11}W+G_{12})(G_{21}W+G_{22})^{-1}. \tag{3.3}$$

The corresponding Lie algebra $\mathrm{sl}(N,\mathbb{C})$ is represented by vector fields with (specific) quadratic nonlinearities. The group action is primitive, the corresponding nonlinear ordinary differential equations with superposition formulas are matrix Riccati equations,

$$\dot{W}=A+BW+WC+WDW,$$

$$W,A\in\mathbb{C}^{r_1\times r_2},\ \ B\in\mathbb{C}^{r_1\times r_1},\ \ C\in\mathbb{C}^{r_2\times r_2},\ \ D\in\mathbb{C}^{r_2\times r_1}. \tag{3.4}$$

In particular for $r_2=1$ we obtain projective Riccati equations corresponding to the projective action of $\mathrm{sl}(N,\mathbb{C})$ on $\mathbb{C}^{N-1}$. The corresponding superposition formula is given by Eq. (3.3) in which $W=\mathrm{const}$ represents the initial data, $\tilde{W}=\tilde{W}(t)$ the general solution and the matrices $G_{ik}(t)$ can be reconstructed from $N+1$ known solutions.[13,14]

Series of nonprimitive realizations of the Lie algebra $\mathrm{sl}(N,\mathbb{C})$ for $N\geqq 3$ can be obtained using the theory of induced representations.[23,24] The homogeneous spaces that we construct are $M\sim G/G_0$, where G is $\mathrm{SL}(N,\mathbb{C})$ and G_0 is a (nonmaximal) parabolic subgroup of $\mathrm{SL}(N,\mathbb{C})$. More specifically, in this article $P(N)$ is group of matrices

$$G_0\sim g=\begin{pmatrix}g_{11}&g_{12}&\cdots&\cdots&g_{1N}\\ \cdots&\cdots&\cdots&\cdots&\cdots\\ g_{N-2,1}&\cdots&g_{N-2,N-2}&g_{N-2,N-1}&g_{N-2,N}\\ 0&\cdots&0&g_{N-1,N-1}&g_{N-1,N}\\ 0&\cdots&0&0&g_{NN}\end{pmatrix}. \tag{3.5}$$

We use the Borel subgroup $B\subset\mathrm{SL}(N,\mathbb{C})$ to induce representations of $\mathrm{SL}(N,\mathbb{C})$ on spaces of functions $f(Z)$, where Z is a point on the space $\mathrm{SL}(N,\mathbb{C})/B$.

To obtain the group action explicitly, we use the defining representation of $\mathrm{SL}(N,\mathbb{C})$ by $N\times N$ matrices and write the Gauss decomposition

$$g=\xi DZ,\quad \xi=\begin{pmatrix}1&\xi_{12}&\xi_{13}&\cdots&\xi_{1N}\\0&1&\xi_{23}&\cdots&\xi_{2N}\\0&0&\ddots&\cdots&\cdots\\0&\cdots&0&1&\xi_{N-1,N}\\0&\cdots&&0&1\end{pmatrix},\quad Z=\begin{pmatrix}1&0&&\cdots&0\\z_{21}&1&0&\cdots&0\\z_{31}&z_{32}&\ddots&\cdots&\cdots\\&\cdots&&1&0\\z_{N1}&\cdots&&z_{N,N-1}&1\end{pmatrix},$$

$$D=\mathrm{diag}(d_{11},\dots,d_{NN}). \tag{3.6}$$

The matrix elements z_{ij}, $1\leqq j<i\leqq N$ are local coordinates on $\tilde{M}\sim\mathrm{SL}(N,\mathbb{C})/B$ (the Borel subgroup is represented by the matrices ξD). The action of the group $\mathrm{SL}(N,\mathbb{C})$ on $\tilde{M}$ is given in local coordinates as

$$Zg=\xi D\tilde{Z}. \tag{3.7}$$

Explicitly we obtain the group action

$$\tilde{Z}=F(g,Z) \tag{3.8}$$

by eliminating d_{ii} and ξ_{ik} from Eq. (3.7) using a subset of these N^2 equations and substituting into the remaining $[N(N-1)]/2$ equations.

B. Example of the group SL(3,$\mathbb{C}$)

Let us illustrate the procedure for the simplest nontrivial case, namely SL(3,$\mathbb{C}$). Equation (3.7) in this case is

$$\begin{pmatrix} 1 & 0 & 0 \\ z_{21} & 1 & 0 \\ z_{31} & z_{32} & 1 \end{pmatrix}\begin{pmatrix} g_{11} & g_{12} & g_{13} \\ g_{21} & g_{22} & g_{23} \\ g_{31} & g_{32} & g_{33} \end{pmatrix}=\begin{pmatrix} 1 & \xi_{12} & \xi_{13} \\ 0 & 1 & \xi_{23} \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} d_{11} & 0 & 0 \\ 0 & d_{22} & 0 \\ 0 & 0 & d_{33} \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ \tilde{z}_{21} & 1 & 0 \\ \tilde{z}_{31} & \tilde{z}_{32} & 1 \end{pmatrix}. \tag{3.9}$$

We rewrite Eq. (3.9) symbolically as

$$R_{ik}=0.$$

Equation $R_{i3}=0$ gives us d_{33}, ξ_{23}, and ξ_{13} in terms of z_{ik} and g_{ik}. Equation $R_{3k}=0$ for $k=1$ and 2 give us $\tilde{z}_{32}$ and $\tilde{z}_{31}$ in terms of z_{ik} and g_{ik}, eq. $R_{22}=0$ and $R_{21}=0$ give us d_{22} and finally $\tilde{z}_{21}$.

Defining $z_{31}=x_1$, $z_{32}=x_2$, and $z_{21}=x_3$ and similarly for $\tilde{z}_{31}$, $\tilde{z}_{32}$, and $\tilde{z}_{21}$ we obtain the group transformations, namely,

$$\begin{aligned} \tilde{x}_1&=\frac{g_{11}x_1+g_{21}x_2+g_{31}}{g_{13}x_1+g_{23}x_2+g_{33}}, \\ \tilde{x}_2&=\frac{g_{12}x_1+g_{22}x_2+g_{32}}{g_{13}x_1+g_{23}x_2+g_{33}}, \\ \tilde{x}_3&=\frac{(-x_1+x_2x_3)A_{1123}+x_3A_{1133}+A_{2133}}{(-x_1+x_2x_3)A_{1223}+x_3A_{1233}+A_{2233}}, \end{aligned} \tag{3.10}$$

where

$$A_{ijkl}=\begin{vmatrix} g_{ij} & g_{il} \\ g_{kj} & g_{kl} \end{vmatrix}=g_{ij}g_{kl}-g_{il}g_{kj}. \tag{3.11}$$

We see that the elements of the last row in Z, namely, $z_{31}=x_1$, $z_{32}=x_2$ transform independently of the second row ($z_{21}=x_3$). Thus, we have a realization of SL(3,$\mathbb{C}$) on a flag manifold. Indeed $\{x_1,x_2\}$ are local coordinates on the space SL(3,$\mathbb{C}$)/$P(2,1)$ and we have a primitive action on this subspace (the projective action). Further $\{x_1,x_2,x_3\}$ are local coordinates on SL(3,$\mathbb{C}$)/B and on this space the action is imprimitive (we have $P(3)\sim B$).

The linear representations of SL(3,$\mathbb{C}$) on functions $f(Z)$ is given as

$$T_g f(x_1,x_2,x_3)=f(\tilde{x}_1,\tilde{x}_2,\tilde{x}_3), \tag{3.12}$$

with $\tilde{x}_i$ as in Eq. (3.10). Calculating the infinitesimal operators in this representation we find

$$\hat{E}_{31}=\partial_1,\quad \hat{E}_{32}=\partial_2,\quad \hat{E}_{21}=x_2\partial_1+\partial_3,$$

$$\hat{E}_{11}=x_1\partial_1+x_3\partial_3,\quad \hat{E}_{22}=x_2\partial_2-x_3\partial_3,\quad \hat{E}_{12}=x_1\partial_2-x_3^2\partial_3,$$

$$\hat{E}_{13}=x_1(x_1\partial_1+x_2\partial_2)-x_3(x_3x_2-x_1)\partial_3, \tag{3.13}$$

$$\hat{E}_{23}=x_2(x_1\partial_1+x_2\partial_2)-(x_3x_2-x_1)\partial_3,$$

$$\partial_i\equiv\partial_{x_i}.$$

The nonlinear ordinary differential equations with a superposition formula corresponding to the action of SL(3,ℂ) on SL(3,ℂ)/B can be read off from (3.13) using Lie's result (1.3) and (1.4). They are

$$\dot{x}_1=Z_{31}+Z_{11}x_1+Z_{21}x_2+Z_{13}x_1^2+Z_{23}x_1x_2,$$

$$\dot{x}_2=Z_{32}+Z_{12}x_1+Z_{22}x_2+Z_{13}x_1x_2+Z_{23}x_2^2, \tag{3.14}$$

$$\dot{x}_3=Z_{21}+(Z_{11}-Z_{22})x_3-Z_{12}x_3^2-Z_{13}x_3(x_3x_2-x_1)-Z_{23}(x_3x_2-x_1),$$

where $Z_{ik}=Z_{ik}(t)$ are arbitrary functions of time t.

We mention that the origin of the coordinate system in SL(3,ℂ)/$P(2,1)$ is the point $(x_1,x_2)=(0,0)$ and in SL(3,ℂ)/$P(3)$ it is $(x_1,x_2,x_3)=(0,0,0)$.

Notice that the first two equations in Eq. (3.14) involve quadratic nonlinearities, while the third equation involves cubic ones. However, if x_1 and x_2 are known (from the first two equations), then the equation for $\dot{x}_3$ reduces to a Riccati equation.

C. The group SL(4,ℂ)

For SL(4,ℂ) we no longer have $P(4)\sim B$ and the flag manifold consists of three spaces

$$\mathrm{SL}(4,\mathbb{C})/P(3,1)\subset\mathrm{SL}(4,\mathbb{C})/P(4)\subset\mathrm{SL}(4,\mathbb{C})/B. \tag{3.15}$$

We restrict ourselves to the space SL(4,ℂ)/$P(4)$, put $x_1=z_{41}$, $x_2=z_{42}$, $x_3=z_{43}$, $x_4=z_{31}$, and $x_5=z_{32}$ and use Eq. (3.7) to obtain

$$\tilde{x}_1=\frac{x_1g_{11}+x_2g_{21}+x_3g_{31}+g_{41}}{x_1g_{14}+x_2g_{24}+x_3g_{34}+g_{44}},$$

$$\tilde{x}_2=\frac{x_1g_{12}+x_2g_{22}+x_3g_{32}+g_{42}}{x_1g_{14}+x_2g_{24}+x_3g_{34}+g_{44}},$$

$$\tilde{x}_3=\frac{x_1g_{13}+x_2g_{23}+x_3g_{33}+g_{43}}{x_1g_{14}+x_2g_{24}+x_3g_{34}+g_{44}}, \tag{3.16}$$

$$\tilde{x}_4=\frac{(x_1x_5-x_2x_4)A_{1124}+(x_1-x_3x_4)A_{1134}+(x_2-x_3x_5)A_{2134}-x_4A_{1144}-x_5A_{2144}-A_{3144}}{(x_1x_5-x_2x_4)A_{1324}+(x_1-x_3x_4)A_{1334}+(x_2-x_3x_5)A_{2334}-x_4A_{1344}-x_5A_{2344}-A_{3344}},$$

$$\tilde{x}_5=\frac{(x_1x_5-x_2x_4)A_{1224}+(x_1-x_3x_4)A_{1234}+(x_2-x_3x_5)A_{2234}-x_4A_{1244}-x_5A_{2244}-A_{3244}}{(x_1x_5-x_2x_4)A_{1324}+(x_1-x_3x_4)A_{1334}+(x_2-x_3x_5)A_{2334}-x_4A_{1344}-x_5A_{2344}-A_{3344}}.$$

The infinitesimal operators can again be obtained as vector fields, using the representation $T_gf(Z)=f(\tilde{Z})$ with Z and $\tilde{Z}$ related as in Eq. (3.16). Instead of writing them out we give the corresponding nonlinear ordinary differential equations, namely,

$$\dot{x}_1=Z_{41}+Z_{11}x_1+Z_{21}x_2+Z_{31}x_3+x_1(Z_{14}x_1+Z_{24}x_2+Z_{34}x_3),$$

$$\dot{x}_2=Z_{42}+Z_{12}x_1+Z_{22}x_2+Z_{32}x_3+x_2(Z_{14}x_1+Z_{24}x_2+Z_{34}x_3),$$

$$\dot{x}_3 = Z_{43} + Z_{13}x_1 + Z_{23}x_2 + Z_{33}x_3 + x_3(Z_{14}x_1 + Z_{24}x_2 + Z_{34}x_3), \tag{3.17}$$

$$\dot{x}_4 = Z_{31} + (Z_{11} - Z_{33})x_4 + Z_{21}x_5 - x_4(Z_{13}x_4 + Z_{23}x_5) + (x_1 - x_3x_4)(Z_{14}x_4 + Z_{24}x_5 + Z_{34}),$$

$$\dot{x}_5 = Z_{32} + Z_{12}x_4 + (Z_{22} - Z_{33})x_5 - x_5(Z_{13}x_4 + Z_{23}x_5) + (x_2 - x_3x_5)(Z_{14}x_4 + Z_{24}x_5 + Z_{34}),$$

where Z_{ik} are arbitrary functions of t. Notice that $\{x_1, x_2, x_3\}$ satisfy projective Riccati equations. The last two equations involve cubic nonlinearities. However, similarly as in the $\mathrm{sl}(3,\mathbb{C})$ case the equations "decompose." If $\{x_1, x_2, x_3\}$ are known, then the equations for $\{x_4, x_5\}$ satisfy projective Riccati equations, based on algebra $\mathrm{sl}(3,\mathbb{C})$.

D. Finite transformations and vector fields for general *N*

For general $N \geqq 3$ the formulas are quite similar to the above cases $N=3,4$ only somewhat more cumbersome to write. Dropping the calculations, we just present $\mathrm{SL}(N,\mathbb{C})$ group action on the space $\mathrm{SL}(N,\mathbb{C})/P(N)$,

$$\tilde{x}_i = \frac{(\sum_{j=1}^{N-1} g_{ji}x_j) + g_{Ni}}{(\sum_{j=1}^{N-1} g_{jN}x_j) + g_{NN}}, \quad i = 1,\ldots,N-1,$$
$$\tilde{x}_{i+N-1} = F(i)/F(N-1), \quad i = 1,\ldots,N-2, \tag{3.18}$$

where

$$F(i) = \left(\sum_{k=1}^{N-3} \sum_{l=1}^{N-2-k} (x_k x_{l+N+k-1} - x_{k+l}x_{k+N-1}) A_{ki(k+l)N} \right) + \left(\sum_{k=1}^{N-2} (x_k - x_{N-1}x_{k+N-1}) A_{ki(N-1)N} \right) + \left(\sum_{k=1}^{N-2} (-x_{k+N-1}) A_{kiNN} \right) - A_{(N-1)iNN}.$$

We see that $\{x_1,\ldots,x_{N-1}\}$ transform according to the projective realization of $\mathrm{SL}(N,\mathbb{C})$. The remaining $N-2$ variables $\{x_N,\ldots,x_{2N-3}\}$ transform in a manner involving quadratic polynomials in the denominator and numerator of a fraction.

The nonlinear ODEs with superposition formulas can be read off from the vector fields representing the Lie algebra $\mathrm{sl}(N,\mathbb{C})$ in this realization, namely,

$$\hat{E}_{Nj} = \partial_j, \quad 1 \leqq j \leqq N-1,$$

$$\hat{E}_{ij} = x_i\partial_j + x_{N-1+i}\partial_{N-1+j}, \quad 1 \leqq i \leqq N-2, \quad 1 \leqq j \leqq N-2,$$

$$\hat{E}_{N-1j} = x_{N-1}\partial_j + \partial_{N+j-1}, \quad 1 \leqq j \leqq N-2,$$

$$\hat{E}_{N-1N-1} = x_{N-1}\partial_{N-1} - \sum_{m=N}^{2N-3} x_m\partial_m, \tag{3.19}$$

$$\hat{E}_{iN-1} = x_i\partial_{N-1} - x_{N-1+i}\sum_{m=N}^{2N-3} x_m\partial_m, \quad 1 \leqq i \leqq N,$$

$$\hat{E}_{iN} = x_i\sum_{j=1}^{N-1} x_j\partial_j - x_{N-1+i}\sum_{m=N}^{2N-3} (x_m x_{N-1} - x_{m-N+1})\partial_m, \quad 1 \leqq i \leqq N-2,$$

$$\hat{E}_{N-1N}=x_{N-1}\sum_{j=1}^{N-1} x_j\partial_j-\sum_{m=N}^{2N-3} (x_m x_{N-1}-x_{m-N+1})\partial_m .$$

The sl(N,ℂ) equations can now be written in a quite compact form, namely,

$$\dot{x}_j=Z_{Nj}+\sum_{i=1}^{N-1} Z_{ij}x_i+x_j\sum_{i=1}^{N-1} Z_{iN}x_i , \quad 1\leqq j\leqq N-1, \tag{3.20}$$

$$\dot{x}_{N-1+j}=Z_{N-1j}+\sum_{i=1}^{N-2} Z_{ij}x_{N-1+i}-Z_{N-1N-1}x_{N-1+j}-x_{N-1+j}\sum_{i=1}^{N-2} Z_{iN-1}x_{N-1+i}$$
$$+(x_j-x_{N-1+j}x_{N-1})\sum_{i=1}^{N-2} (Z_{iN}x_{N-1+i}+Z_{N-1N}), \quad 1\leqq j\leqq N-2. \tag{3.21}$$

In (3.20) and (3.21) Z_{ik} are arbitrary functions of t. For $N=3$ and $N=4$ these formulas coincide with (3.14) and (3.17), respectively. The same comments pertain, namely, Eq. (3.20) are projective Riccati equations based on sl(N,ℂ). Equation (3.21) are projective Riccati equations based on sl($N-1$,ℂ) if $x_1,\ldots,x_{N-1}$ are known.

IV. SUPERPOSITION FORMULAS

A. General comments

The superposition formula for the imprimitive SL(N,ℂ) equations is given by the group action formula (3.18) in which x_i, $i=1,\ldots,2N-3$ is a constant vector, related to the initial conditions. The matrix elements $g_{ik}(t)$ must be expressed in terms of m particular solutions. The number m satisfies Eq. (1.6). In our case that means that we must have

$$m(2N-3)\geqq N^2-1. \tag{4.1}$$

The actual number m, as well as conditions that must be imposed on the known solutions, is obtained from the requirement that m be the smallest number of solutions such that their joint isotropy group consists only of the identity transformation. We shall call such set a ''fundamental set of solutions.''

B. Example of SL(3,ℂ)

Equation (4.1) in this case is $3m\geqq 8$ and hence $m\geqq 3$.

The equations under consideration are given in Eq. (3.14), the superposition formula has the form (3.10).

1. The fundamental set of solutions

Let us assume that we know three solutions of Eq. (3.14), $\mathbf{x}(t)$, $\mathbf{y}(t)$, and $\mathbf{z}(t)$. Each solution is a three component vector. The group SL(3,ℂ) acts on the space $M\times M\times M$ of these three solutions. Since we have dim SL(3,ℂ)$=8$ the group can sweep out at most an eight-dimensional orbit, so there must exist at least one SL(3,ℂ) invariant in this nine-dimensional space. We denote this invariant

$$R(x_1,x_2,x_3,y_1,y_2,y_3,z_1,z_2,z_3)=K, \tag{4.2}$$

where **x**, **y**, and **z** are three solutions of Eq. (3.14). We calculate $\dot{R}=(\mathrm{d}R/\mathrm{d}t)$, replace $\dot{\mathbf{x}},\dot{\mathbf{y}},\dot{\mathbf{z}}$ using Eq. (3.14) and require $\dot{R}=0$ for all functions $Z_{ik}(t)$. This provides us with eight linear first order partial differential equations for R. These equations can be solved and we obtain a single elementary invariant, namely,

$$R=\frac{(XZ)_{321}(ZY)_{321}(YX)_{321}}{(XY)_{321}(YZ)_{321}(ZX)_{321}}, \tag{4.3}$$

where we have defined

$$(XY)_{321}=x_3(x_2-y_2)-x_1+y_1, \tag{4.4}$$

etc. The quantity $(XY)_{321}$ and similarly defined $(XZ)_{321}$, $(YX)_{321}$, $(YZ)_{321}$, $(ZX)_{321}$, and $(ZY)_{321}$ play a crucial role in the reconstruction of the group elements $g_{ik}(t)$. For SL$(3,\mathbb{C})$ the notation is somewhat redundant. However for SL$(N,\mathbb{C})$, $N\geqq 4$ we will have quantities like $(XY)_{431}, (XY)_{532}$, etc. so for uniformity we keep the subscripts for $N=3$ as well.

The initial condition for three solutions are $\mathbf{x}(0)$, $\mathbf{y}(0)$, and $\mathbf{z}(0)$. We shall use the transformation (3.10) (with constant coefficients) to standardize the initial conditions. Let us do this transformation in two steps,

$$g=g_2g_1,\quad g_1=\begin{pmatrix} g_{11} & g_{12} & 0\\ g_{21} & g_{22} & 0\\ g_{31} & g_{32} & g_{33}\end{pmatrix},\quad g_2=\begin{pmatrix} a_{11} & 0 & a_{11}-a_{33}\\ 0 & a_{22} & a_{22}-a_{33}\\ 0 & 0 & a_{33}\end{pmatrix}. \tag{4.5}$$

Let us now assume that the first two components of $\mathbf{x}(0)$, $\mathbf{y}(0)$, and $\mathbf{z}(0)$ satisfy

$$\Delta=\begin{vmatrix} x_1(0)-z_1(0) & y_1(0)-z_1(0)\\ x_2(0)-z_2(0) & y_2(0)-z_2(0)\end{vmatrix}\neq 0. \tag{4.6}$$

This condition can be rewritten as

$$\Delta=x_1(0)(y_2(0)-z_2(0))+y_1(0)(z_2(0)-x_2(0))+z_1(0)(x_2(0)-y_2(0))\neq 0,$$

so that it is actually symmetric in the three two-dimensional vectors,

$$x_{\mathrm{T}}(0)=\begin{pmatrix} x_1(0)\\ x_2(0)\end{pmatrix},\quad y_{\mathrm{T}}(0)=\begin{pmatrix} y_1(0)\\ y_2(0)\end{pmatrix},\quad z_{\mathrm{T}}(0)=\begin{pmatrix} z_1(0)\\ z_2(0)\end{pmatrix}. \tag{4.7}$$

If Eq. (4.6) is satisfied we can use the transformation (3.10) with the matrix g_1 to transform the three initial vectors into a more convenient form

$$g_1:\{\mathbf{x}(0),\mathbf{y}(0),\mathbf{z}(0)\}\to\left\{\begin{pmatrix} 1\\ 0\\ \tilde{x}_3\end{pmatrix},\begin{pmatrix} 0\\ 1\\ \tilde{y}_3\end{pmatrix},\begin{pmatrix} 0\\ 0\\ \tilde{z}_3\end{pmatrix}\right\} \tag{4.8}$$

with

$$\tilde{x}_3=\frac{(XY)_{321}-(XZ)_{321}}{(XZ)_{321}},\quad \tilde{y}_3=-\frac{(YZ)_{321}}{(YZ)_{321}-(YX)_{321}},\quad \tilde{z}_3=-\frac{(ZY)_{321}}{(ZX)_{321}}$$

(all components evaluated at $t=0$).

The initial conditions (4.8) imply that $(XY)_{321}$ and $(XZ)_{321}$ cannot vanish simultaneously (and similarly for $(YZ)_{321}$ and $(YX)_{321}$, or $(ZX)_{321}$ and $(ZY)_{321}$). To proceed further we need a stronger condition, namely, that at least one of the following relations holds:

$$(XY)_{321}(XZ)_{321}\neq 0,\quad (YZ)_{321}(YX)_{321}\neq 0,\quad (ZX)_{321}(ZY)_{321}\neq 0. \tag{4.9}$$

With no loss of generality we assume that the first of the above relations holds. We then transform further using the matrix g_2 and obtain

$$g_2 g_1 : \{\mathbf{x}(0),\mathbf{y}(0),\mathbf{z}(0)\} \rightarrow \{\mathbf{x}_S(0),\mathbf{y}_S(0),\mathbf{z}_S(0)\},$$

$$\mathbf{x}_S(0)=\begin{pmatrix}1\\0\\0\end{pmatrix},\quad \mathbf{y}_S(0)=\begin{pmatrix}0\\1\\\alpha\end{pmatrix},\quad \mathbf{z}_S(0)=\begin{pmatrix}0\\0\\\beta\end{pmatrix}, \tag{4.10}$$

where

$$\alpha=\left[-1+\frac{a_{33}}{a_{11}}\frac{(YX)_{321}}{(YZ)_{321}}\right]^{-1},\quad \beta=-\frac{a_{11}}{a_{22}}\frac{(ZY)_{321}}{(ZX)_{321}}. \tag{4.11}$$

To standardize $\mathbf{x}_S(0)$ we have already fixed the ratio a_{33}/a_{22} hence only one of the ratios a_{33}/a_{11} and a_{11}/a_{22} can be chosen freely. From Eq. (4.11) we immediately see four special cases,

$$\begin{aligned}(YX)_{321}&=0\Rightarrow\alpha=-1,\\ (YZ)_{321}&=0\Rightarrow\alpha=0,\\ (ZY)_{321}&=0\Rightarrow\beta=0,\\ (ZX)_{321}&=0\Rightarrow\beta\rightarrow\infty.\end{aligned} \tag{4.12}$$

Thus, if $(YX)_{321}(YZ)_{321}\neq 0$ we can standardize $\alpha\rightarrow 1$. Alternatively, if $(ZY)_{321}(ZX)_{321}\neq 0$ we can standardize $\beta\rightarrow 1$. The invariant R of Eq. (4.3) for the standardized initial conditions (4.10) is

$$R=-\frac{(\alpha+1)}{\alpha}\beta. \tag{4.13}$$

We recall that R is time independent and cannot be changed by group transformation of the initial conditions.

To see whether a reconstruction is possible from three solutions with initial conditions (4.10), let us calculate the stabilizer of these ''standard'' initial conditions. The stabilizer of the vector $\mathbf{x}_S(0)$ and of the first two components of the other two vectors is

$$g=\begin{pmatrix}a_{11} & 0 & a_{11}-a_{22}\\ 0 & a_{22} & 0\\ 0 & 0 & a_{22}\end{pmatrix}. \tag{4.14}$$

The remaining conditions for $\mathbf{y}_S(0)$ and $\mathbf{z}_S(0)$ to be stabilized are

$$\alpha(\alpha+1)(g_{11}-g_{22})=0,\quad \beta g_{11}=\beta g_{22}. \tag{4.15}$$

Thus, the stabilizer is $g\sim I$ if we have at least one of the following conditions:

$$\alpha(\alpha+1)\neq 0,\quad 0<|\beta|<\infty. \tag{4.16}$$

All other cases must be excluded.

Thus, if $\Delta=0$, the stabilizer is always too large. The same is true if all the products in Eq. (4.9) vanish (at $t=0$).

Thus, a reconstruction is possible if and only if

(1) $\Delta\neq 0$,
(2) at least 2 of the products in Eq. (4.9) are nonzero.

2. Reconstruction of the group element

Let us reconstruct the SL(3,ℂ) group element from the fundamental set of solutions, corresponding to the initial data (4.10) satisfying one of the conditions (4.16). We first make use of the first two components of the three solutions $\mathbf{x}(t),\mathbf{y}(t),\mathbf{z}(t)$. The first two equations in (3.10) then imply

$$x_1=\frac{g_{11}+g_{31}}{g_{13}+g_{33}},\quad y_1=\frac{g_{21}+g_{31}}{g_{23}+g_{33}},\quad z_1=\frac{g_{31}}{g_{33}},$$
$$x_2=\frac{g_{12}+g_{32}}{g_{13}+g_{33}},\quad y_2=\frac{g_{22}+g_{32}}{g_{23}+g_{33}},\quad z_2=\frac{g_{32}}{g_{33}}. \tag{4.17}$$

This allows us to express all off-diagonal elements $g_{ik}(t),\ i\neq k$ in terms of the diagonal ones and the first two components of the three known solutions,

$$g_{12}=\frac{1}{x_1}[g_{11}x_2+g_{33}(z_1x_2-x_1z_2)],\quad g_{13}=\frac{1}{x_1}[g_{11}+g_{33}(z_1-x_1)],$$
$$g_{21}=\frac{1}{y_2}[g_{22}y_1+g_{33}(y_1z_2-z_1y_2)],\quad g_{23}=\frac{1}{y_2}[g_{22}+g_{33}(z_2-y_2)], \tag{4.18}$$
$$g_{31}=g_{33}z_1,\quad g_{32}=g_{33}z_2.$$

Next, we substitute the known solutions and initial conditions (4.10) into the third equation in (3.10). We replace the off-diagonal elements using Eq. (4.18) and obtain three linear equations for the diagonal elements g_{11}, g_{22}, and g_{33},

$$\begin{pmatrix} 0 & -(XY)_{321} & y_2(XZ)_{321}-z_2(XY)_{321} \\ -\alpha(YX)_{321} & 0 & (1+\alpha)x_1(YZ)_{321}-\alpha z_1(YX)_{321} \\ \beta y_2(ZX)_{321} & x_1(ZY)_{321} & \beta z_1y_2(ZX)_{321}+x_1z_2(ZY)_{321}\end{pmatrix}\begin{pmatrix} g_{11}\\ g_{22}\\ g_{33}\end{pmatrix}=\begin{pmatrix}0\\0\\0\end{pmatrix}. \tag{4.19}$$

The rank r_M of the above matrix is $r_M\leqq 2$. A reconstruction is possible if $r_M=2$; then we can express g_{11} and g_{22} linearly in terms of g_{33}. The rank is $r_M=1$ if and only if both conditions (4.16) are violated (i.e., $\alpha=0$ or $\alpha=-1$ and simultaneously $\beta=0$ or $\beta\to\infty$).

The above results are particularly obvious at $t=0$ when Eq. (4.19) reduce to

$$\begin{pmatrix} 0 & 1 & -1 \\ -\alpha(\alpha+1) & 0 & \alpha(\alpha+1) \\ \beta & -\beta & 0\end{pmatrix}\begin{pmatrix} g_{11}\\ g_{22}\\ g_{33}\end{pmatrix}=\begin{pmatrix}0\\0\\0\end{pmatrix}. \tag{4.20}$$

Let us now sum up the results of this section as follows.

Theorem 3: (1) The general solution of the system of nonlinear ordinary differential equations (3.14) associated with the imprimitive action of SL(3,ℂ) on the space SL(3,ℂ)/P(3) is given by the formula

$$v_1(t)=\frac{g_{11}u_1+g_{21}u_2+g_{31}}{g_{13}u_1+g_{23}u_2+g_{33}},\qquad v_2(t)=\frac{g_{12}u_1+g_{22}u_2+g_{32}}{g_{13}u_1+g_{23}u_2+g_{33}},$$
$$v_3(t)=\frac{(u_2u_3-u_1)A_{11,23}+u_3A_{11,33}+A_{21,33}}{(u_2u_3-u_1)A_{12,23}+u_3A_{12,33}+A_{22,33}}, \tag{4.21}$$

$$A_{ij,kl}(t)=\begin{vmatrix} g_{ij} & g_{il} \\ g_{kj} & g_{kl} \end{vmatrix}=g_{ij}g_{kl}-g_{il}g_{kj}\,.$$

The three constants u_1, u_2, and u_3 are related to the initial conditions for the solution $\mathbf{v}(t)$.

(2) The group elements $g_{ik}(t)$ (and hence also the quantities A_{ijkl}) are reconstructed from a set of three solutions $\mathbf{x}(t)$, $\mathbf{y}(t)$, and $\mathbf{z}(t)$. This fundamental set of solutions is quite generic and is subject to just two conditions:

(i) $\Delta \neq 0$ with Δ defined in Eq. (4.6),
(ii) At lest two of the inequalities (4.9) hold with $(XY)_{321}$ defined in Eq. (4.4).

(3) The off-diagonal elements $g_{ik}(t)$, $i\neq k$ are given in Eq. (4.18). The diagonal ones are obtained by solving Eq. (4.19).

Comments: (1) The reconstruction is linear in that we only need to solve linear algebraic relations (once three solutions are known). All elements g_{ik} are proportional to $g_{33}(t)$ which cancels out from Eq. (4.21).

(2) A fundamental set of solutions for projective Riccati equations based on the primitive action of SL(3,$\mathbb{C}$) consists of four solutions. In the imprimitive case we only need three solutions.

C. The group SL(4,$\mathbb{C}$)

The sl(4,$\mathbb{C}$) ODEs are given in Eq. (3.17), the general form of the superposition formula in Eq. (3.16). The number of equations is $n=5$, the dimension of the Lie algebra is $r=15$, hence $nm \geqq r$ implies $m\geqq 3$.

We shall show that we do actually need precisely $m=3$ generically chosen particular solutions and give an explicit reconstruction of the group element. For the group SL(4,$\mathbb{C}$) we have $nm=r$ (for $m=3$) and no SL(4,$\mathbb{C}$) invariant can be formed out of three solutions.

Let us assume that we know three solutions **x**, **y**, **z**, each of them a five-component vector.

Let us assume that the first three components of these vectors satisfy an independence condition for $t=0$, namely,

$$\operatorname{rank}\begin{pmatrix} x_1(0)-z_1(0) & y_1(0)-z_1(0) \\ x_2(0)-z_2(0) & y_2(0)-z_2(0) \\ x_3(0)-z_3(0) & y_3(0)-z_3(0) \end{pmatrix}=2. \tag{4.22}$$

We can then use a constant coefficient SL(4,$\mathbb{C}$) transformation to take the initial conditions into

$$\mathbf{x}(0)=\begin{pmatrix} 1\\0\\0\\x_4(0)\\x_5(0)\end{pmatrix},\quad \mathbf{y}(0)=\begin{pmatrix} 0\\1\\0\\y_4(0)\\y_5(0)\end{pmatrix},\quad \mathbf{z}(0)=\begin{pmatrix}0\\0\\0\\0\\0\end{pmatrix}. \tag{4.23}$$

Let us make a further assumption, namely, that transformed initial conditions satisfy

$$x_5(0)y_4(0)\neq 0,\quad y_4(0)+y_5(0)\neq x_4(0)+x_5(0). \tag{4.24}$$

We can then standardize the initial conditions further, namely take them into

$$\mathbf{x}(0)=\begin{pmatrix} 1\\0\\0\\0\\1\end{pmatrix},\quad \mathbf{y}(0)=\begin{pmatrix} 0\\1\\0\\\alpha\\0\end{pmatrix},\quad \mathbf{z}(0)=\begin{pmatrix}0\\0\\0\\0\\0\end{pmatrix}. \tag{4.25}$$

The stabilizer of these three vectors in SL(4,ℂ) consists of matrices satisfying

$$g(0)=\begin{pmatrix} g_{11} & 0 & 0 & g_{11}-g_{44} \\ 0 & g_{22} & 0 & g_{22}-g_{44} \\ 0 & 0 & g_{22} & g_{44}-g_{22} \\ 0 & 0 & 0 & g_{44} \end{pmatrix}, \quad \alpha(g_{11}-g_{22})=0, \quad (\alpha-1)(g_{11}-g_{44})=0. \tag{4.26}$$

Thus, for $\alpha\neq 0$, $\alpha\neq 1$ we have $g\sim I$ and a unique reconstruction of the group elements $g_{ik}(t)$ is possible. We mention that even though α has no invariant meaning, the values $\alpha=0$ and $\alpha=1$ correspond to degenerate orbits of triplets of vectors. These values of α must be excluded from further considerations. Indeed, the stabilizer (4.26) for $\alpha=0$ or $\alpha=1$ is larger, since g_{11} and either g_{22} or g_{44} remain free.

Let us now perform a reconstruction, using 3 solutions satisfying Eq. (4.25) with $\alpha(1-\alpha)\neq 0$. Substituting the components x_i, y_i, and z_i, $i=1,2,3$ into Eq. (3.16) we obtain

$$\begin{gathered} g_{41}=g_{44}z_1, \quad g_{42}=g_{44}z_2, \quad g_{43}=g_{44}z_3, \\ g_{12}=\frac{1}{x_1}[g_{11}x_2+g_{44}(x_2z_1-x_1z_2)], \quad g_{13}=\frac{1}{x_1}[g_{11}x_3+g_{44}(x_3z_1-x_1z_3)], \\ g_{14}=\frac{1}{x_1}[g_{11}+g_{44}(z_1-x_1)], \quad g_{21}=\frac{1}{y_2}[g_{22}y_1+g_{44}(y_1z_2-y_2z_1)], \\ g_{23}=\frac{1}{y_2}[g_{22}y_3+g_{44}(y_3z_2-y_2z_3)], \quad g_{24}=\frac{1}{y_2}[g_{22}+g_{44}(z_2-y_2)]. \end{gathered} \tag{4.27}$$

Using the relations (3.16) w_4, w_5, and x_4, we obtain the remaining off-diagonal elements in terms of the diagonal ones (and known solutions),

$$\begin{gathered} g_{31}+(z_3z_4-z_1)g_{34}=g_{33}w_4, \\ g_{32}+(z_3z_5-z_2)g_{34}=g_{33}w_5, \\ g_{34}=\frac{-(a_{22}+z_2a_{44})(XY)_{431}+a_{33}y_2(x_4-z_4)+a_{44}y_2(XZ)_{431}}{y_2[x_3x_4-x_1-z_3z_4+z_1]}. \end{gathered} \tag{4.28}$$

The expressions $(XY)_{431}$ and $(XZ)_{431}$ are defined as in Eq. (4.4).

Finally using the expressions for $x_5(t)$, $y_4(t)$, and $y_5(t)$ we obtain three linear relations for the diagonal elements g_{ii}, making it possible to express g_{11}, g_{22}, and g_{33} linearly in terms of g_{44},

$$\begin{aligned} & a_{22}\{(x_3x_5-x_2-z_3z_5+z_2)(XY)_{431}-(x_3x_4-x_1-z_3z_4+z_1)(XY)_{532}\} \\ & \quad +a_{33}y_2\{(x_3x_5-x_2-z_3z_5+z_2)(-x_4+z_4)+(x_3x_4-x_1-z_3z_4+z_1)(x_5-z_5)\} \\ & \quad +a_{44}\{(x_3x_5-x_2-z_3z_5+z_2)[-y_2(XZ)_{431}+z_2(XY)_{431}] \\ & \quad +(x_3x_4-x_1-z_3z_4+z_1)[y_2(XZ)_{532}-z_2(XY)_{532}]\}=0, \end{aligned} \tag{4.29}$$

$$\begin{aligned} & -a_{11}\alpha y_2(x_3x_4-x_1-z_3z_4+z_1)(YX)_{431}+a_{22}x_1(y_3y_4-y_1-z_3z_4+z_1)(XY)_{431} \\ & \quad +a_{33}x_1y_2[(y_4-z_4)(x_3x_4-x_1-z_3z_4+z_1)-(x_4-z_4)(y_3y_4-y_1-z_3z_4+z_1)] \\ & \quad +a_{44}\{\alpha y_2(x_3x_4-x_1-z_3z_4+z_1)[-z_1(YX)_{431}+x_1(YZ)_{431}] \\ & \quad -x_1(y_3y_4-y_1-z_3z_4+z_1)[y_2(XZ)_{431}-z_2(XY)_{431}]\}=0, \end{aligned} \tag{4.30}$$

$$-a_{11}\alpha y_2(x_3x_4-x_1-z_3z_4+z_1)(YX)_{532}+a_{22}x_1(y_3y_5-y_2-z_3z_5+z_2)(XY)_{431}$$
$$+a_{33}x_1y_2[(x_3x_4-x_1-z_3z_4+z_1)(y_5-z_5)-(y_3y_5-y_2-z_3z_5+z_2)(x_4-z_4)]$$
$$+a_{44}\{\alpha y_2(x_3x_4-x_1-z_3z_4+z_1)[-z_1(YX)_{532}+x_1(YZ)_{532}]$$
$$-x_1(y_3y_5-y_2-z_3z_5+z_2)[y_2(XZ)_{431}-z_2(XY)_{431}]\}=0. \tag{4.31}$$

Again, we sum up the results as a theorem.

Theorem 4: The general solution of Eqs. (3.17) based on the imprimitive action of SL(4,$\mathbb{C}$) can be expressed in terms of three generically chosen particular solutions $\mathbf{x}(t)$, $\mathbf{y}(t)$, $\mathbf{z}(t)$. The general solution $u_a(t)$, $a=1,...,5$ is given by Eq. (3.16), where $z_1,\ldots,z_5$ are constants representing the initial conditions for $\mathbf{u}_a(t)$. The matrix elements $g_{ik}(t)$ are expressed in Eq. (4.27),...,(4.31) in terms of three solutions with initial conditions (4.25), satisfying $\alpha(\alpha-1)\neq 0$, α finite. □

Comments: (1) As in the case of SL(3,$\mathbb{C}$) the reconstruction of $g_{ik}(t)$ is linear. (2) In the primitive case we need five solutions for SL(4,$\mathbb{C}$), in the imprimitive case only three.

D. The group SL(N,$\mathbb{C}$) for $N\geqq 2$

Let us sum up without proof the main results valid for all N.

Theorem 5: (1) The nonlinear ODEs with superposition formulas, based on the action of SL(N,$\mathbb{C}$) on the space SL(N,$\mathbb{C}$)/$P(N)$ are given for all $N\geqq 3$ in Eqs. (3.20) and (3.21). The general form of the solution is given by Eq. (3.18).

(2) The number of equations for SL(N,$\mathbb{C}$) is $n=2N-3$. The group elements $g_{ij}(t)$ can be reconstructed from m particular generically chosen solutions with

$$m=\begin{cases} k+2 & \text{for } N=2k+1 \\ k+1 & \text{for } N=2k \end{cases}. \tag{4.32}$$

(3) Such a fundamental set of m solutions satisfies τ constraints with

$$\tau=mn-N^2+1=\begin{cases} 3k-2 & \text{for } N=2k+1 \\ k-2 & \text{for } N=2k \end{cases}. \tag{4.33}$$

(4) The reconstruction of the group action is linear in the sense that it requires the solution of $2N-3$ linear algebraic equations.

V. CONCLUSIONS

We mentioned in the Introduction that nonlinear ordinary equations with superposition formulas occur in soliton theory as Bäcklund transformations. For equations in the AKNS family[25] the underlying Lie algebra is sl(2,$\mathbb{R}$) and hence the Bäcklund transformations are essentially Riccati equations.

As an example consider the sine-Gordon equation and the Bäcklund transformation, relating two solutions, z_1 and z_2,

$$z_{i,xy}=\sin z_i, \quad i=1,2, \tag{5.1}$$

$$z_{1x}-z_{2x}=2a\sin\frac{z_1+z_2}{2}, \qquad z_{1y}+z_{2y}=\frac{2}{a}\sin\frac{z_1-z_2}{2}. \tag{5.2}$$

The point transformation

$$u_i=\tan\frac{z_i}{4}, \quad i=1,2 \tag{5.3}$$

takes the above system into

$$u_{i,xy}=\frac{u_i}{1+u_i^2}(2u_{i,x}^2-1+u_i^2), \tag{5.4}$$

$$u_{1,x}=\frac{1}{1+u_2^2}[au_2+u_{2,x}+a(1-u_2^2)u_1+(u_{2,x}-au_2)u_1^2],$$

$$u_{1,y}=\frac{1}{1+u_2^2}\left[-\frac{u_2}{a}-u_{2,y}+\frac{1}{a}(1-u_2^2)u_1+\left(\frac{u_2}{a}-u_{2,y}\right)u_1^2\right]. \tag{5.5}$$

Equations (5.5) are Riccati equations for u_1, once u_2 is given.

Wahlquist and Estabrook have proposed[26] a method for finding Bäcklund transformations for a given nonlinear partial differential equation. They introduced a prolongation structure, essentially an additional system of matrix equations. The compatibility conditions are solved by requiring that the right-hand sides of these equations lie in a finite-dimensional Lie algebra. This is the same condition that is required in Lie's theorem on ODEs with superposition formulas.

For integrable multifield equations the Bäcklund transformations are based on other Lie algebras and groups. Thus, for *n*-dimensional generalizations of the sine-Gordon equation and also the wave equation[27,28] the Bäcklund transformations are matrix Riccati equations. Similarly, for Toda field theories (two-dimensional generalized Toda lattices) Bäcklund transformations are given[29,30] that can be transformed into projective Riccati equations.[13] The Bäcklund transformations for nonlinear σ-models are again various types of matrix Riccati equations.[31–33]

All the above examples, and all other Bäcklund transformations for soliton equations that we are aware of, share a common feature. Namely, they have the form of nonlinear ODEs with superposition formulas based on transitive and primitive group actions.

The equations presented in this article correspond to imprimitive actions. We have a group G, in this article $SL(N,\mathbb{C})$. We have a chain of subgroups $G_1\subset G_2\subset G_3\subset\ldots\subset G_{n-1}\subset G_n\equiv G$, where G_{n-1} is maximal in G. Correspondingly, we have a flag of subspaces $G/G_n\subset G/G_{n-1}\subset\cdots\subset G/G_1$. The action of G on G/G_{n-1} is primitive, on the other spaces in the series it is not primitive.

The integrable systems discussed above ''live'' either on Lie groups, like the σ-model, or on the Grassmannians, on which the group acts primitively. Now, there also exist integrable systems on flag manifolds.[34,35] While the manifolds, in particular Grassmannians involved are *a priori*, infinite-dimensional, various reduction schemes lead to finite-dimensional ones.

It is in this direction that we hope that the equations obtained in this article will appear as Bäcklund transformations.

Center and universal *R*-matrix for quantized Borcherds superalgebras

Jin Hong[a)]
Department of Mathematics, Seoul National University, Seoul 151-742, Korea

(Received 27 October 1998; accepted for publication 24 December 1998)

We construct a nondegenerate symmetric bilinear form on quantized enveloping algebras associated to Borcherds superalgebras. With this, we study its center and its universal R matrix. © *1999 American Institute of Physics.* [S0022-2488(99)00106-1]

I. INTRODUCTION

Quantized enveloping algebras for Kac–Moody algebras were introduced independently by Drinfel'd (Ref. 1) and Jimbo (Ref. 2) in their studies of the Yang–Baxter equation. The Kac–Moody algebras were generalized (Ref. 3) by Borcherds to accommodate for his study of the monstrous moonshine (Ref. 4). And a quantized version of the enveloping algebras for Borcherds algebras (Ref. 5) was soon studied. There are also superalgebra versions of these algebras (Ref. 6). We shall study the structure of the center and find the R matrix for the quantized Borcherds superalgebras.

Much work has been done on the center of quantized enveloping algebras for finite-dimensional semisimple Lie algebras (Refs. 7–13), and there are Kac–Moody (Ref. 14) and Borcherds (Ref. 15) versions also. We will mainly follow Refs. 13 and 15 to find the center for quantized Borcherds superalgebras.

As for the universal R matrix, the quantum double construction by Drinfel'd (Ref. 16) gives its existence for any Hopf algebra satisfying some conditions. Even though there is a quantum double construction for $\mathbf{Z}_2$-graded Hopf algebras (Ref. 17), we do not use it in this paper. Instead, we explicitly construct a universal R matrix and show that it satisfies the Yang–Baxter equation.

The paper is organized as follows. In Sec. II, we define the quantized Borcherds superalgebras and give it a Hopf algebra structure. The triangular decomposition will also be mentioned. In Sec. III, the character formula for highest weight representations will be given and we prove a lemma that will be used in later sections. The next section is devoted to providing the quantized Borcherds superalgebras with a bilinear form and proving its nondegeneracy. In Sec. V, we define the Harish–Chandra homomorphism, show its injectivity, and prove some properties concerning its image. Information on the center of the quantized Borcherds superalgebra will be obtained in Sec. VI. In the last section we will give the universal R matrix and show that it satisfies the Yang–Baxter equation.

II. QUANTUM DEFORMATION OF BORCHERDS SUPERALGEBRAS

In this section, we define the quantized Borcherds superalgebras and give it a Hopf algebra structure.

Let I be a countable index set. A matrix $A=(a_{i,j})_{i,j\in I}$ with entries in the real numbers is a *Borcherds–Cartan* matrix if (i) $a_{i,i}=2$ or $a_{i,i}\leqslant 0$ for all $i\in I$; (ii) $a_{i,j}\leqslant 0$ if $i\neq j$ and $a_{i,j}\in\mathbf{Z}$ if $a_{i,i}=2$; (iii) $a_{i,j}=0$ if and only if $a_{j,i}=0$.

If there exists a diagonal matrix $D=\mathrm{diag}(s_i|i\in I,s_i>0)$ such that DA is symmetric, then A is said to be *symmetrizable*. If a symmetrizable Borcherds–Cartan matrix A further satisfies the

[a)]Electronic mail: jhong@math.snu.ac.kr

constraints, $a_{i,j}\in\mathbf{Z}$, $s_i\in\mathbf{Z}_{>0}$, for all $i,j\in I$, then it is said to be *integral*. We will be citing many results from Ref. 6. The condition $a_{i,i}\in 2\mathbf{Z}$ appearing therein is superfluous.

A complex matrix $C=(\theta_{i,j})_{i,j\in I}$ is a *coloring matrix* if $\theta_{i,j}\theta_{j,i}=1$ for all $i,j\in I$. Necessarily, $\theta_{i,i}=\pm 1$, and we say i is *even* when $\theta_{i,i}=1$, *odd* when $\theta_{i,i}=-1$. A Borcherds–Cartan matrix A is *colored by C* if for every $i\in I$ such that $a_{i,i}=2$ and $\theta_{i,i}=-1$ we have, $a_{i,j}\in 2\mathbf{Z}$ for all $j\in I$.

Throughout this paper, we shall assume that A is a symmetrizable integral Borcherds–Cartan matrix that is colored by a coloring matrix C.

Let $I^{\mathrm{re}}=\{i\in I|a_{i,i}=2\}$ and $I^{\mathrm{im}}=\{i\in I|a_{i,i}\leqslant 0\}$. Also, let $\underline{m}=(m_i|i\in I)$ be a collection of positive integers such that $m_i=1$ for all $i\in I^{\mathrm{re}}$. We call $\underline{m}$ a charge of the Borcherds–Cartan matrix A.

For a symmetrizable integral Borcherds–Cartan matrix A, which is colored by a coloring matrix C, we denote by $\mathfrak{g}(A,\underline{m},C)$ the Borcherds superalgebra of charge $\underline{m}$. (See Ref. 6.)

We set $P^\vee=(\oplus_{i\in I}\mathbf{Z}h_i)\oplus(\oplus_{i\in I}\mathbf{Z}d_i)$ and let $\mathfrak{h}=\mathbf{C}\otimes_{\mathbf{Z}}P^\vee$ be the complex vector space with basis $\{h_i,d_i|i\in I\}$. For $i\in I$, we define α_i in the dual space $\mathfrak{h}^*$ of $\mathfrak{h}$ by setting $\alpha_i(h_j)=a_{j,i}$ and $\alpha_i(d_j)=\delta_{i,j}$. Since A is assumed to be symmetrizable, there exists a nondegenerate symmetric bilinear form $(|)$ on $\mathfrak{h}$, given by $(s_ih_i|h)=\alpha_i(h)$ and $(d_i|d_j)=0$ for $i,j\in I,h\in\mathfrak{h}$.

The free Abelian group $Q=\oplus_{i\in I}\mathbf{Z}\alpha_i$ generated by the $\alpha_i(i\in I)$ is called the *root lattice* associated to A. Let $Q^+=\Sigma_{i\in I}\mathbf{Z}_{\geqslant 0}\alpha_i$ and $Q^-=-Q^+$. The coloring matrix $C=(\theta_{i,j})$ gives rise to a complex-valued mapping $\theta:Q\times Q\to\mathbf{C}^\times$, satisfying $\theta(\alpha_i,\alpha_j)=\theta_{i,j}$, $\theta(\alpha,\beta+\gamma)=\theta(\alpha,\beta)\theta(\alpha,\gamma)$, $\theta(\alpha+\beta,\gamma)=\theta(\alpha,\gamma)\theta(\beta,\gamma)$, for all $\alpha,\beta,\gamma\in Q$.

We define the binomial coefficients by setting $\{n\}_{q_i}=[(\theta_{i,i}^nq_i^n-q_i^{-n})/(\theta_{i,i}q_i-q_i^{-1})]$, $\{n\}_{q_i}!=\Pi_{t=1}^n\{t\}_{q_i}$, and $\left\{{m \atop n}\right\}_{q_i}=\{m\}_{q_i}!/\{n\}_{q_i}!\{m-n\}_{q_i}!$, where $\{0\}_{q_i}!=1$ and $q_i=q^{s_i}$. Let $\xi_i=q_i-q_i^{-1}$ and $K_i=q^{s_ih_i}$.

Definition II.1 (Ref. 6): Suppose $\mathfrak{g}=\mathfrak{g}(A,\underline{m},C)$ is the Borcherds superalgebra of charge $\underline{m}$ determined by the symmetrizable integral Borcherds–Cartan matrix A that is colored by a coloring matrix C. Let q be an indeterminant. Then the *quantized Borcherds superalgebra* $U_q(\mathfrak{g})$ associated to $\mathfrak{g}$ is the associative algebra over $\mathbf{C}(q)$ with 1, generated by the elements $q^h(h\in P^\vee)$, $e_{i,k}$, $f_{i,k}$ $(i\in I,\ k=1,2,...,m_i)$ with the defining relations:

(R1) $q^0=1,\ q^hq^{h'}=q^{h+h'},\quad \text{for } h,h'\in P^\vee,$

(R2) $q^he_{i,k}q^{-h}=q^{\alpha_i(h)}e_{i,k},\quad \text{for } h\in P^\vee,\quad i\in I,k=1,2,...,m_i,$

(R3) $q^hf_{i,k}q^{-h}=q^{-\alpha_i(h)}f_{i,k},\quad \text{for } h\in P^\vee,\quad i\in I,\quad k=1,2,...,m_i,$

(R4) $e_{i,k}f_{j,l}-\theta_{j,i}f_{j,l}e_{i,k}=\delta_{i,j}\delta_{k,l}\frac{1}{\xi_i}(K_i-K_i^{-1}),\quad \text{for } i,j\in I,\ k=1,2,...,m_i,\quad l=1,2,...,m_j,$

(R5) $\displaystyle\sum_{n=0}^{1-a_{i,j}}(-1)^n\theta_{i,j}^n\theta_{i,i}^{n(n-1)/2}\left\{{l-a_{i,j} \atop n}\right\}_{q_i}e_{i,k}^{1-a_{i,j}-n}e_{j,l}e_{i,k}^n=0,\quad \text{if } a_{i,i}=2 \text{ and } i\neq j,$

(R6) $\displaystyle\sum_{n=0}^{1-a_{i,j}}(-1)^n\theta_{i,j}^n\theta_{i,i}^{n(n-1)/2}\left\{{l-a_{i,j} \atop n}\right\}_{q_i}f_{i,k}^{1-a_{i,j}-n}f_{j,l}f_{i,k}^n=0,\quad \text{if } a_{i,i}=2 \text{ and } i\neq j,$

(R7) $e_{i,k}e_{j,l}-\theta_{i,j}e_{j,l}e_{i,k}=0,\quad \text{if } a_{i,j}=0,$

(R8) $f_{i,k}f_{j,l}-\theta_{i,j}f_{j,l}f_{i,k}=0,\quad \text{if } a_{i,j}=0.$

Proposition II.2 (Ref. 6): The algebra $U_q(\mathfrak{g})$ has a Hopf superalgebra structure with comultiplication Δ, counit ϵ, and antipode S, defined by

$$\Delta(q^h)=q^h\otimes q^h, \tag{1}$$

$$\Delta(e_{i,k})=e_{i,k}\otimes 1+K_i\otimes e_{i,k}, \tag{2}$$

$$\Delta(f_{i,k})=f_{i,k}\otimes K_i^{-1}+1\otimes f_{i,k}, \tag{3}$$

$$\epsilon(q^h)=1, \tag{4}$$

$$\epsilon(e_{i,k})=0, \tag{5}$$

$$\epsilon(f_{i,k})=0, \tag{6}$$

$$S(q^h)=q^{-h}, \tag{7}$$

$$S(e_{i,k})=-K_i^{-1}e_{i,k}, \tag{8}$$

$$S(f_{i,k})=-f_{i,k}K_i, \tag{9}$$

for $h\in P^\vee$, $i\in I$, $k=1,2,...,m_i$.

We denote by U^0 the subalgebra of $U=U_q(\mathfrak{g})$ generated by q^h for $h\in P^\vee$ and U^+ (respectively, U^-) the subalgebra of U generated by the elements $e_{i,k}$ (respectively, $f_{i,k}$) for $i\in I$, $k=1,2,...,m_i$. We also denote by $U^{\geqslant 0}$ (respectively, $U^{\leqslant 0}$) the subalgebra of U generated by the elements q^h and $e_{i,k}$ (respectively, q^h and $f_{i,k}$) for $h\in P^\vee$, $i\in I$, $k=1,2,...,m_i$. For each $\beta\in Q$, let

$$U_\beta=\{x\in U|q^h x q^{-h}=q^{\beta(h)}x, \quad \text{for all} \;\; h\in P^\vee\}. \tag{10}$$

We similarly define $U^\pm_{\pm\beta}$, $U^{\geqslant 0}_{\pm\beta}$, and $U^{\leqslant 0}_{\pm\beta}$ for $\beta\in Q^+$. We then have the following.

Proposition II.3 (Ref. 6):

(a) $U\cong U^-\otimes U^0\otimes U^+$.

(b) $U^0=\oplus_{h\in P^\vee}\mathbf{C}q^h$.

(c) $U^\pm=\oplus_{\beta\in Q^+}U^\pm_{\pm\beta}$.

(d) (R5) *and* (R7) [*respectively*, (R6) *and* (R8)] *are the fundamental relations for* U^+ (*respectively*, U^-).

We give Q^+ a partial ordering by setting $\lambda\geqslant\mu$ if and only if $\lambda-\mu\in Q^+$. We will also use the notation $K_\gamma=\Pi K_i^{n_i}$ for $\gamma=\Sigma n_i\alpha_i\in Q$.

III. REPRESENTATIONS OF $U_q(\mathfrak{g})$

For $i\in I$ define the **C**-linear functionals $\Lambda_i\in\mathfrak{h}^*$ by

$$\Lambda_i(h_j)=\delta_{i,j} \quad \Lambda_i(d_j)=0, \quad \text{for all} \;\; j\in I. \tag{11}$$

Define the lattices:

$$P=\{\lambda\in\mathfrak{h}^*|\lambda(h_i),\lambda(d_i)\in\mathbf{Z},\forall i\in I\}, \tag{12}$$

$$\overline{P}=\Big(\bigoplus_{i\in I}\mathbf{Z}\alpha_i\Big)\oplus\Big(\bigoplus_{i\in I}\mathbf{Z}\Lambda_i\Big). \tag{13}$$

P is called the *weight lattice* of $\mathfrak{g}$. An element $\lambda\in P$ is said to be a *dominant integral weight* if

$$\lambda(h_i)\in\mathbf{Z}_{\geqslant 0}, \quad \text{for all} \;\; i\in I^{\text{re}}, \tag{14}$$

$$\lambda(h_i)\in 2\mathbf{Z}_{\geqslant 0}, \quad \text{for all} \;\; i\in I^{\text{re}}\cap I^{\text{odd}}, \tag{15}$$

where I^{odd} denotes the set of $i\in I$ such that $\theta_{i,i}=-1$. Let P^+ denote the set of all dominant integral weights.

Set $\bar{\mathfrak{h}}^* = \mathbf{C}\otimes_{\mathbf{Z}}\bar{P}$. Then the nondegenerate symmetric bilinear form on $\mathfrak{h}$ gives an isomorphism between $\mathfrak{h}$ and $\bar{\mathfrak{h}}^*$ hence also induces a bilinear form on $\bar{\mathfrak{h}}^*$. We may extend this bilinear form to a symmetric bilinear form on $\mathfrak{h}^*$. We extend it so that it satisfies $(\lambda|\alpha_i)=\lambda(s_i h_i)$ and $(\lambda|\Lambda_i)=\lambda(s_i d_i)$ for every $\lambda\in\mathfrak{h}^*$. Write $\lambda\perp\mu$ if $(\lambda|\mu)=0$.

For each $i\in I$ such that $a_{i,i}\neq 0$, we define the *simple reflection* $r_i\in \mathrm{GL}(\mathfrak{h}^*)$ on $\mathfrak{h}^*$ by

$$r_i(\lambda)=\lambda-\frac{2}{a_{i,i}}\lambda(h_i)\alpha_i. \tag{16}$$

The subgroup W of $\mathrm{GL}(\mathfrak{h}^*)$ generated by $r_i (i\in I^{\mathrm{re}})$ is called the *Weyl group* of $\mathfrak{g}(A,\underline{m},C)$. We denote by $l: W\to\mathbf{Z}_{\geqslant 0}$ the natural length function.

Let R be the family of all imaginary simple roots, each root occurring as many times as its multiplicity, i.e., m_i times for α_i. For $\lambda\in P^+$, define $R(\lambda)$ to be the set of all $\mu=\sum_{j=1}^{r}\alpha_{i_j}+\sum_{k=1}^{s} l_{i_k}\beta_{i_k}\in Q^+$, where α_{i_j} (resp., β_{i_k}) are distinct even (resp., odd) roots in R, satisfying (i) $\alpha_{i_j}\perp\lambda, \beta_{i_k}\perp\lambda$, for all j,k; (ii) $\alpha_{i_j}\perp\beta_{i_k}$, for all j,k; (iii) $\alpha_{i_j}\perp\alpha_{i_k}, \beta_{i_j}\perp\beta_{i_k}$, for $j\neq k$; (iv) $\beta_{i_k}\perp\beta_{i_k}$, if $l_{i_k}\geqslant 2$. In particular, $0\in R(\lambda)$. For μ as above, we define

$$ht(\mu)=r+\sum_{k=1}^{s} d_{ik}.$$

Suppose $\rho\in\mathfrak{h}^*$ satisfies $\rho(h_i)=\frac{1}{2}a_{i,i}$ for all $i\in I$.

Proposition III.1 (Refs. 18 and 19): Let $\lambda\in P^+$. *Denote by $M^q(\lambda)$ the Verma module for $U_q(\mathfrak{g})$ with highest weight λ and let $V^q(\lambda)$ be the irreducible highest weight module over $U_q(\mathfrak{g})$ with highest weight λ. Then,*

$$\mathrm{ch}\, M^q(\lambda)=\frac{e^{\lambda}}{\prod_{\alpha\in\Phi^-}(1-\theta(\alpha,\alpha)e^{\alpha})^{\theta(\alpha,\alpha)\dim\mathfrak{g}_\alpha}}=e^{\lambda}\sum_{\beta\in Q^+}(\dim U^-_{-\beta})e^{-\beta}, \tag{17}$$

$$\mathrm{ch}\, V^q(\lambda)=\frac{\sum_{w\in W,\mu\in R(\lambda)}(-1)^{l(w)+ht(\mu)}e^{w(\lambda+\rho-\mu)-\rho}}{\prod_{\alpha\in\Phi^-}(1-\theta(\alpha,\alpha)e^{\alpha})^{\theta(\alpha,\alpha)\dim\mathfrak{g}_\alpha}}. \tag{18}$$

In this formula, Φ^- is the *set of all negative roots.*

The following is a corollary to this proposition.

Lemma III.2: Let $\gamma=\sum_{i\in I}n_i\alpha_i\in Q^+$. Suppose $\lambda\in P^+$, $\lambda(h_i)>0$ for all $i\in I^{\mathrm{im}}$ and $\lambda(h_i)\geqslant n_i$ for all $i\in I^{\mathrm{re}}$. Then we have a linear isomorphism $U^-_{-\gamma}\xrightarrow{\sim}V^q(\lambda)_{\lambda-\gamma}$ given by $u\mapsto uv_\lambda$.

Proof: $U^-_{-\gamma}\to M^q(\lambda)_{\lambda-\gamma}$ is surjective, so $U^-_{-\gamma}\to V^q(\lambda)_{\lambda-\gamma}$ is also surjective. Hence, it suffices to show $\dim U^-_{-\gamma}=\dim V^q(\lambda)_{\lambda-\gamma}$. Since $(\alpha_i|\lambda)=\lambda(s_i h_i)=s_i\lambda(h_i)>0$ for all $i\in I^{\mathrm{im}}$, no nonempty subset F of R satisfies $F\perp\lambda$, and so

$$\mathrm{ch}\, V^q(\lambda)=\frac{\sum_{w\in W}(-1)^{l(w)}e^{w(\lambda+\rho)-\rho}}{\prod_{\alpha\in\Phi^-}(1-\theta(\alpha,\alpha)e^{\alpha})^{\theta(\alpha,\alpha)\dim\mathfrak{g}_\alpha}}, \tag{19}$$

$$=\left(\sum_{w\in W}(-1)^{l(w)}e^{w(\lambda+\rho)-\rho}\right)\left(\sum_{\beta\in Q^+}(\dim U^-_{-\beta})e^{-\beta}\right). \tag{20}$$

Therefore, it suffices to show that if $w(\lambda+\rho)-\rho-\beta=\lambda-\gamma$ for some $w\in W$, $\beta\in Q^+$, then $w=1$.

We will show that if $w\neq 1$, then $\gamma+w(\lambda+\rho)-(\lambda+\rho)\notin Q^+$ by using induction on the length of w.

If $w=r_i(i\in I^{\mathrm{re}})$, then

$$\gamma+r_i(\lambda+\rho)-(\lambda+\rho)=\gamma+\lambda+\rho-(\lambda(h_i)+\rho(h_i))\alpha_i-(\lambda+\rho)=\gamma-(\lambda(h_i)+1)\alpha_i\notin Q^+.$$

If $w=w' r_i(i\in I^{\mathrm{re}})$ with $l(w)=l(w')+1$, then

$$\gamma+w(\lambda+\rho)-(\lambda+\rho)=\gamma+w'r_i(\lambda+\rho)-(\lambda+\rho)$$
$$=\gamma+w'(\lambda+\rho-(\lambda(h_i)+\rho(h_i))\alpha_i)-(\lambda+\rho)$$
$$=(\gamma+w'(\lambda+\rho)-(\lambda+\rho))-(\lambda(h_i)+1)w'\alpha_i\notin Q^+.$$

This completes the proof. □

IV. THE BILINEAR FORM ON $U_q(\mathfrak{g})$

IV.1. *The bilinear form on* $U^{\geqslant 0}\times U^{\leqslant 0}$. In this section, we define a bilinear form on $U^{\geqslant 0}\times U^{\leqslant 0}$, which is nondegenerate when restricted to $U^+_\beta\times U^-_{-\beta}$, $\beta\in Q^+$.

For $\phi\in(U_\beta)^*$, $\psi\in(U_\gamma)^*$, $x\in U_\beta$, and $y\in U_\gamma$, we define $(\phi\otimes\psi)(x\otimes y)=\theta(-\gamma,\beta)\phi(x)\psi(y)$. With this, and the Hopf algebra structure on $U_q(\mathfrak{g})$, we can give an algebra structure to $\oplus_{\alpha\in Q^+}(U^{\geqslant 0}_\alpha)^*$ by setting $(\phi_1\phi_2)(x)=(\phi_1\otimes\phi_2)(\Delta(x))$ for $\phi_1,\phi_2\in\oplus_{\alpha\in Q^+}(U^{\geqslant 0}_\alpha)^*$ and $x\in U^{\geqslant 0}$. For $h\in P^\vee$ and $i\in I$, $k=1,2,...,m_i$, we define the linear functionals $\phi_h,\psi_{i,k}\in\oplus_{\alpha\in Q^+}(U^{\geqslant 0}_\alpha)^*$ by

$$\phi_h(xq^{h'})=\epsilon(x)q^{-(h|h')}\quad(x\in U^+,h'\in P^\vee),\tag{21}$$

$$\psi_{i,k}(xq^h)=0\quad(x\in U^+_\beta,\beta\in Q^+\backslash\{\alpha_i\}),\tag{22}$$

$$\psi_{i,k}(e_{i,l}q^h)=\delta_{k,l}.\tag{23}$$

Proposition IV.1: There exists an algebra homomorphism,

$$\zeta:U^{\leqslant 0}\rightarrow\bigoplus_{\alpha\in Q^+}(U^{\geqslant 0}_\alpha)^*,\tag{24}$$

given by

$$\zeta(q^h)=\phi_h,\quad(h\in P^\vee),\tag{25}$$

$$\zeta(f_{i,k})=-\frac{1}{\xi_i}\psi_{i,k}\quad(i\in I,k=1,2,...,m_i).\tag{26}$$

Proof: By Proposition II.3, we have only to check that the relations (R1), (R3), (R6), and (R8) are preserved under the map ζ. Other cases being easy, we just sketch the (R6) part.

Define $e^{(n)}_{i,k}=e^n_{i,k}/\{n\}_{q_i}!$. We may check by induction on n that

$$\Delta(e^{(n)}_{i,k})=\sum_{s+t=n}q_i^{st}e^{(s)}_{i,k}K_i^t\otimes e^{(t)}_{i,k}.$$

This shows

$$((\Delta\otimes 1)\circ\Delta)(e^{(n)}_{i,k})=\sum_{r+s+t=n}q_i^{rs+st+tr}e^{(r)}_{i,k}K_i^{s+t}\otimes e^{(s)}_{i,k}K_i^t\otimes e^{(t)}_{i,k}.$$

We again use induction to prove

$$\psi^n_{i,k}(e^{(n)}_{i,k})=(\theta_{i,i}q_i)^{n(n-1)/2}.$$

With this, it is possible to show

$$\psi_{i,k}^{N-n}\psi_{j,l}\psi_{i,k}^{n}(e_{i,k}^{(N-m)}e_{j,l}e_{i,k}^{(m)})=\sum \theta_{i,i}^{A'}\theta_{i,j}^{B'}q_i^{C'}\begin{Bmatrix}N-n\\ \alpha\end{Bmatrix}_{q_i}\begin{Bmatrix}n\\ \beta\end{Bmatrix}_{q_i},$$

with the summation over non-negative integers α, β, γ, δ such that $\alpha+\beta=N-m$, $\gamma+\delta=m$, $\alpha+\gamma=N-n$, and $\beta+\delta=n$, and where

$$A'=\beta\gamma+(N-n)n+\tfrac{1}{2}(N-n)(N-n-1)+\tfrac{1}{2}n(n-1),$$

$$B'=\beta-\gamma+(N-n)-n,$$

$$C'=\alpha\beta+\gamma\delta+2\beta\gamma+(\beta+\gamma)a_{i,j}+\tfrac{1}{2}(N-n)(N-n-1)+\tfrac{1}{2}n(n-1).$$

Noting

$$\begin{Bmatrix}N\\ n\end{Bmatrix}_{q_i}\begin{Bmatrix}N-n\\ \alpha\end{Bmatrix}_{q_i}\begin{Bmatrix}n\\ N-m-\alpha\end{Bmatrix}_{q_i}=\begin{Bmatrix}N\\ m\end{Bmatrix}_{q_i}\begin{Bmatrix}N-m\\ \beta\end{Bmatrix}_{q_i}\begin{Bmatrix}m\\ \delta\end{Bmatrix}_{q_i},$$

we can calculate

$$\left(\sum_{n=0}^{1-a_{i,j}}(-1)^n\theta_{i,j}^{n}\theta_{i,i}^{n(n-1)/2}\begin{Bmatrix}1-a_{i,j}\\ n\end{Bmatrix}_{q_i}\psi_{i,k}^{1-a_{i,j}-n}\psi_{j,l}\psi_{i,k}^{n}\right)(e_{i,k}^{(N-m)}e_{j,l}e_{i,k}^{(m)})$$
$$=\sum_{n=0}^{N}\sum \theta_{i,i}^{A}\theta_{i,j}^{B}q_i^{C}\begin{Bmatrix}N\\ m\end{Bmatrix}_{q_i}\begin{Bmatrix}N-m\\ \beta\end{Bmatrix}_{q_i}\begin{Bmatrix}m\\ \delta\end{Bmatrix}_{q_i},$$

with the second summation over non-negative integers satisfying the same conditions as before, and where

$$A=\tfrac{1}{2}N(N-1)+m\beta+\tfrac{1}{2}\beta(\beta-1)+\tfrac{1}{2}\delta(\delta-1),$$

$$B=N-m,$$

$$C=(m-mN+\tfrac{1}{2}N(N-1))+(m+1-N)\beta+(m-1)\delta.$$

This can be written as a product of two sums that simplifies to zero. □

Define a bilinear form $(\,|\,):U^{\geqslant 0}\times U^{\leqslant 0}\rightarrow \mathbf{C}(q)$ by

$$(x|y)=\zeta(y)(x)\quad (x\in U^{\geqslant 0},y\in U^{\leqslant 0}). \tag{27}$$

For $n\in\mathbf{Z}_{>0}$, we denote by $\Delta_n:U\rightarrow U^{\otimes(n+1)}$, the algebra homomorphism defined by $\Delta_1=\Delta$, $\Delta_n=(\Delta\otimes 1)\circ\Delta_{n-1}$, and we write

$$\Delta_n(x)=\sum_{(x)_n}x_{(0)}\otimes x_{(1)}\otimes\cdots\otimes x_{(n)}. \tag{28}$$

For homogeneous elements $x_i\in U_{\beta_i}^{\geqslant 0}$, $y_i\in U_{-\gamma_i}^{\leqslant 0}$ $(i=1,2)$, we define $(x_1\otimes x_2|y_1\otimes y_2)=\theta(\beta_2,-\gamma_1)(x_1|y_1)(x_2|y_2)$ and extend it by linearity. For $x\in U_\beta$, $y\in U_\gamma$, we will write $\theta(x,y)$ to mean $\theta(\beta,\gamma)$ and define $\sigma:U\otimes U\rightarrow U\otimes U$ by $\sigma(x\otimes y)=\theta(x,y)y\otimes x$ on homogeneous elements and extend it by linearity.

Proposition IV.2: The bilinear form $(\,|\,)$ *on* $U^{\geqslant 0}\times U^{\leqslant 0}$ *defined by (27) satisfies*

$$(x|y_1y_2)=(\Delta(x)|y_1\otimes y_2)\quad (x\in U^{\geqslant 0},y_1,y_2\in U^{\leqslant 0}), \tag{29}$$

$$(x_1x_2|y)=(\sigma(x_1\otimes x_2)|\Delta(y))\quad (x_1,x_2\in U^{\geqslant 0},y\in U^{\leqslant 0}), \tag{30}$$

$$(q^h|q^{h'})=q^{-(h|h')} \quad (h,h'\in P^\vee), \tag{31}$$

$$(q^h|f_{i,k})=0, \tag{32}$$

$$(e_{i,k}|q^h)=0, \tag{33}$$

$$(e_{i,k}|f_{j,l})=-\frac{1}{\xi_i}\delta_{i,j}\delta_{k,l}, \tag{34}$$

for $i,j\in I$, $k=1,2,...,m_j$.

Moreover, the bilinear form on $U^{\geqslant 0}\times U^{\leqslant 0}$ *satisfying the above equations is unique.*

Proof: Everything including uniqueness is straightforward, except for (30). It is proved by induction. Here we just show the induction part. We suppress the summation signs for simplicity. Assume $(x^1x^2|y^i)=\theta(x^1,x^2)(x^2\otimes x^1|\Delta(y^i))$ for $i=1,2$. Then

$$\begin{aligned}
(x^1x^2|y^1y^2)&=\zeta(y^1)\zeta(y^2)(x^1x^2)\\
&=\zeta(y^1)\otimes\zeta(y^2)((x^1_{(0)}\otimes x^1_{(1)})\cdot(x^2_{(0)}\otimes x^2_{(1)}))\\
&=\zeta(y^1)\otimes\zeta(y^2)(\theta(x^1_{(1)},x^2_{(0)})x^1_{(0)}x^2_{(0)}\otimes x^1_{(1)}x^2_{(1)})\\
&=\theta(x^1_{(1)},x^2_{(0)})\theta(y^2,x^1_{(0)})\theta(y^2,x^2_{(0)})(x^1_{(0)}x^2_{(0)}|y^1)(x^1_{(1)}x^2_{(1)}|y^2)\\
&=\theta(x^1_{(0)},x^1_{(1)})\theta(x^1_{(0)},x^2_{(1)})\theta(x^2_{(0)},x^2_{(1)})\theta(x^1_{(0)},x^2_{(0)})\theta(x^1_{(1)},x^2_{(1)})\\
&\quad\times(x^2_{(0)}\otimes x^1_{(0)}|y^1_{(0)}\otimes y^1_{(1)})(x^2_{(1)}\otimes x^1_{(1)}|y^2_{(0)}\otimes y^2_{(1)})\\
&=\theta(x^1_{(0)},x^1_{(1)})\theta(x^1_{(0)},x^2_{(1)})\theta(x^2_{(0)},x^2_{(1)})(x^2_{(0)}|y^1_{(0)})(x^1_{(0)}|y^1_{(1)})(x^2_{(1)}|y^2_{(0)})(x^1_{(1)}|y^2_{(1)})\\
&=\theta(y^1_{(1)},y^2_{(0)})(\Delta(x^2)|y^1_{(0)}\otimes y^2_{(0)})(\Delta(x^1)|y^1_{(1)}\otimes y^2_{(1)})\\
&=\theta(y^1_{(1)},y^2_{(0)})\theta(y^1_{(0)}y^2_{(0)},x^1)(x^2\otimes x^1|y^1_{(0)}y^2_{(0)}\otimes y^1_{(1)}y^2_{(1)})\\
&=\theta(x^1,x^2)(x^2\otimes x^1|(y^1_{(0)}\otimes y^1_{(1)})\cdot(y^2_{(0)}\otimes y^2_{(1)}))=\theta(x^1,x^2)(x^2\otimes x^1|\Delta(y^1y^2)).
\end{aligned}$$

This completes the proof. □

Lemma IV.3: (a) $(S(x)|S(y))=(x|y)$; (b) $(xq^h|yq^{h'})=q^{-(h|h')}(x|y)$ $(h,h'\in P^\vee, x\in U^+, y\in U^-)$; (c) $(U^+_\beta|U^-_{-\gamma})=0$, *if* $\gamma\neq\beta$.

Proof: To prove (a), we set $(\ |\ )'=(S()|S())$ and show $(\ |\ )'$ satisfies conditions of Proposition IV.2. The remaining two are easy. □

Lemma IV.4: For $x\in U^{\geqslant 0}$, $y\in U^{\leqslant 0}$, *which are homogeneous, we have*

$$\theta(x,y)yx=\sum_{(x)_2,(y)_2}\Theta_{xy}(x_{(0)}|S(y_{(0)}))(x_{(2)}|y_{(2)})x_{(1)}y_{(1)} \tag{35}$$

and

$$xy=\sum_{(x)_2,(y)_2}\theta(x_{(1)},y_{(1)})\Theta_{xy}(x_{(0)}|y_{(0)})(x_{(2)}|S(y_{(2)}))y_{(1)}x_{(1)}, \tag{36}$$

with $\Theta_{xy}=\theta(x_{(1)},y_{(0)})\theta(x_{(2)},y_{(0)})\theta(x_{(2)},y_{(1)})$.

Proof: By substituting (35) onto the right-hand side of (36), we can show that (35) implies (36).

To prove (35), we use induction on y and reduce the problem to showing this true for $y=q^h$ and $y=f_{i,k}$. The case $y=q^h$ is easy. The case $y=f_{i,k}$ turns out to be equivalent to showing

$$\theta(x,f_{i,k})f_{i,k}x=\sum_{(x)_1}\{(x_{(1)}|f_{i,k})x_{(0)}+\theta(x_{(1)},f_{i,k})(x_{(1)}|K_i^{-1})x_{(0)}f_{i,k}$$
$$-\theta(x_{(1)},f_{i,k})(x_{(0)}|f_{i,k})K_i^{-1}x_{(1)}\}, \tag{37}$$

which is proved by induction on the length of x. □

Lemma IV.5: Let $\beta\in Q^+\setminus\{0\}$ *and* $y\in U^-_{-\beta}$. *If* $e_{i,k}y=\theta(\alpha_i,-\beta)ye_{i,k}$, *for all* $i\in I$, $k=1,2,...,m_i$, *then* $y=0$.

Proof: Choose $\lambda\in P^+$ satisfying the assumptions of Lemma III.2. Since $e_{i,k}(y\cdot v_\lambda)=\theta(\alpha_i,-\beta)y(e_{i,k}\cdot v_\lambda)=0$ for all $i\in I$, $k=1,2,...,m_i$, and $\mathrm{wt}(y\cdot v_\lambda)=\lambda-\beta\leqslant\lambda$, $y\cdot v_\lambda$ generates a proper submodule of $V^q(\lambda)$. Hence $y\cdot v_\lambda=0$. Lemma III. 2 now says $y=0$. □

Theorem IV.6: *For* $\beta\in Q^+$, *the bilinear form* $(\,|\,):U^{\geqslant 0}\times U^{\leqslant 0}\to\mathbf{C}(q)$ *defined by* (27) *is nondegenerate when restricted to* $U^+_\beta\times U^-_{-\beta}$.

Proof: Since $\dim U^+_\beta=\dim U^-_{-\beta}$, nondegeneracy on one side implies the nondegeneracy on the other side. So we will just prove the following statement:

$$\text{if}\ \ y\in U^-_{-\beta}\quad\text{and}\quad(U^+_\beta|y)=0,\quad\text{then}\ \ y=0. \tag{38}$$

We use induction on β.

The case $\beta=0$ or α_i is easy.

Assume (38) is true for all $\gamma<\beta$ with $\beta\in Q^+\setminus(\{0\}\cup\{\alpha_i\}_{i\in I})$. Recall the notation $K_\gamma=q\Sigma_{i\in I}n_is_ih_i$ for $\gamma=\Sigma_{i\in I}n_i\alpha_i\in Q$. By definition of Δ, we see that

$$\Delta(y)=\sum_{0\leqslant\gamma\leqslant\beta}y_\gamma(1\otimes K_{-\gamma}),\quad y_\gamma\in U^-_{-\gamma}\otimes U^-_{-(\beta-\gamma)}, \tag{39}$$

with $y_0=1\otimes y$ and $y_\beta=y\otimes 1$. Fix $0<\gamma<\beta$. For any $u\in U^+_{\beta-\gamma}$ and $v\in U^+_\gamma$, we have

$$(v\otimes u|y_\gamma)=(v\otimes u|y_\gamma(1\otimes K_{-\gamma})), \tag{40}$$

$$=(v\otimes u|\Delta(y)), \tag{41}$$

$$=\theta(\gamma,\beta-\gamma)(uv|y),\quad\text{by (30)}, \tag{42}$$

$$=0. \tag{43}$$

Hence $(U^+_\gamma\otimes U^+_{\beta-\gamma}|y_\gamma)=0$. This implies $y_\gamma=0$ by our induction hypothesis. Therefore $\Delta(y)=y\otimes K_{-\beta}+1\otimes y$. We apply Lemma IV.4 to

$$\Delta_2(e_{i,k})=e_{i,k}\otimes 1\otimes 1+K_i\otimes e_{i,k}\otimes 1+K_i\otimes K_i\otimes e_{i,k}, \tag{44}$$

$$\Delta_2(y)=y\otimes K_{-\beta}\otimes K_{-\beta}+1\otimes y\otimes K_{-\beta}+1\otimes 1\otimes y, \tag{45}$$

and get

$$\theta(\alpha_i,-\beta)ye_{i,k}=e_{i,k}y,\quad\text{for all}\ \ i\in I. \tag{46}$$

Hence, $y=0$ by Lemma IV.5. □

IV.2. *The Killing form.* Recall from Proposition II.3 that $U\cong U^+\otimes U^0\otimes S(U^-)\cong U^-\otimes U^0\otimes S(U^+)$. Using the bilinear form defined in the previous section, we define a new bilinear form,

$$\langle\,|\,\rangle:U\times U\to\mathbf{C}(q^{1/2}),$$

by setting

$$\langle x_1 q^{h_1} S(y_1) | y_2 q^{h_2} S(x_2) \rangle = (x_1|y_2)(x_2|y_1) q^{-(h_1|h_2)/2} \theta(y_1,y_2)\,\theta(y_1,x_2), \tag{47}$$

for homogeneous $x_i \in U^+$, $y_i \in U^-$, $h_i \in P^\vee$ and extending by linearity.

For homogeneous $u,v \in U$, we define

$$\mathrm{ad}(u)\cdot v = \sum_{(u)_1} \theta(u_{(1)},v) u_{(0)} v S(u_{(1)}), \tag{48}$$

$$v\cdot \widetilde{\mathrm{ad}}(u) = \sum_{(u)_1} \theta(v,u_{(0)}) S(u_0) v u_{(1)}. \tag{49}$$

It is easy to check that these define left and right actions of U on U.

The bilinear form on U defined above is *invariant*, in that we have the following.

Proposition IV.7: For $u,v,v' \in U$,

$$\langle \mathrm{ad}(u)\cdot v | v' \rangle = \langle v | v' \cdot \widetilde{\mathrm{ad}}(u) \rangle \theta(u,v)\,\theta(u,v'). \tag{50}$$

Proof: It suffices to check the formula for $u = q^{h''} (h'' \in P^\vee)$, $e_{i,k}$, $f_{i,k}$ ($i \in I$, $k = 1,2,\ldots,m_i$) and for $v = xq^h S(y)$ and $v' = y' q^{h'} S(x')$ with $x \in U^+_\beta$, $x' \in U^+_{\beta'}$, $y \in U^-_{-\gamma}$, $y' \in U^-_{-\gamma'}$ $(\beta,\beta',\gamma,\gamma' \in Q^+)$. Since the case $u = f_{i,k}$ is similar to the case $u = e_{i,k}$, we will omit the case $u = f_{i,k}$.

(i) $u = q^{h''}$. The left-hand side is

$$\langle \mathrm{ad}(u)\cdot v | v' \rangle = \langle q^{h''} v q^{-h''} | v' \rangle = q^{(\beta-\gamma)(h'')} \langle v | v' \rangle,$$

and the right-hand side is

$$\langle v | v' \cdot \widetilde{\mathrm{ad}}(u) \rangle = \langle v | q^{-h''} v' q^{h''} \rangle = q^{(\gamma'-\beta')(h'')} \langle v | v' \rangle.$$

Since $\langle v | v' \rangle \neq 0$ only when $\beta = \gamma'$ and $\beta' = \gamma$, we are done.

(ii) $u = e_{i,k}$. Applying Lemma IV.4, we obtain

$$\begin{aligned} \mathrm{ad}(u)\cdot v &= e_{i,k} x q^h S(y) + \theta(\alpha_i,\beta) q^{(\alpha_i|\beta)} x K_i q^h S(e_{i,k} y) \\ &= e_{i,k} x q^h S(y) + \theta(\alpha_i,\beta) q^{(\alpha_i|\beta)} \sum_{(y)_2} \{A - B + C\}, \end{aligned}$$

where

$$A = (e_{i,k}|y_{(0)})(1|S(y_{(2)})) x K_i q^h S(y_{(1)}),$$

$$B = q^{\alpha_i(h)} (K_i|y_{(0)})(1|S(y_{(2)})) x e_{i,k} q^h S(y_{(1)}),$$

$$C = \theta(e_{i,k},y_{(1)})(K_i|y_{(0)})(e_{i,k}|S(y_{(2)})) x q^h S(y_{(1)}),$$

and

$$\begin{aligned} v'\cdot \widetilde{\mathrm{ad}}(u) &= -\theta(\beta'-\gamma',\alpha_i) q^{(\gamma'-\alpha_i|\alpha_i)} e_{i,k} y' K_i^{-1} q^{h'} S(x') - \theta(\beta',\alpha_i) q^{(\gamma'-\beta'|\alpha_i)} y' q^{h'} S(e_{i,k} x') \\ &= -\theta(\beta'-\gamma',\alpha_i) q^{(\gamma'-\alpha_i|\alpha_i)} \sum_{(y')_2} \{A' - B' + C'\} - \theta(\beta',\alpha_i) q^{(\gamma'-\beta'|\alpha_i)} y' q^{h'} S(e_{i,k} x'), \end{aligned}$$

where

$$A' = (e_{i,k}|y'_{(0)})(1|S(y'_{(2)}))y'_{(1)}K_i^{-1}q^{h'}S(x'),$$

$$B' = \theta(\alpha_i,\beta'-\gamma')q^{(\alpha_i|\alpha_i)}q^{-\alpha_i(h')}(K_i|y'_{(0)})(1|S(y'_{(2)}))y'_{(1)}q^{h'}S(x'e_{i,k}),$$

$$C' = \theta(e_{i,k},y'_{(1)})(K_i|y'_{(0)})(e_{i,k}|S(y'_{(2)}))y'_{(1)}q^{h'}S(x').$$

There are only two cases to consider: (i) $\gamma'=\beta+\alpha_i$ and $\gamma=\beta'$; (ii) $\gamma'=\beta$ and $\gamma=\beta'+\alpha_i$.

Since the latter case is similar to the former, we will only check the first case. Assume $\gamma'=\beta+\alpha_i$ and $\gamma=\beta'$. Then, in order to have $B\neq 0$, we must have $y_{(0)},y_{(2)}\in U^0$ and $y_{(1)}\in U^-_{-\gamma'}$. Similarly, $A'\neq 0$ implies $y'_{(0)}\in U^{\leqslant 0}_{-\alpha_i}$, $y'_{(1)}\in U^{\leqslant 0}_{-\beta}$, and $y'_{(2)}\in U^0$. In this case, we get $y'_{(1)}=\tilde{y}'_1K_i^{-1}$ for some $\tilde{y}'_1\in U^-_{-\beta}$. Also, $C'\neq 0$ implies $y'_{(0)}\in U^0$, $y'_{(1)}\in U^{\leqslant 0}_{-\beta}$, and $y'_{(2)}\in U^{\leqslant 0}_{-\alpha_i}$. In this case, we have $y'_{(2)}=\tilde{y}'_2K^{-1}_{\gamma'-\alpha_i}$ for some $\tilde{y}'_2\in U^-_{-\alpha_i}$. We need to prepare one more fact. Using Proposition IV.2, we obtain the following formula:

$$(x_1x_2x_3|y)=\sum_{(y)_2}\theta(x_1x_2,x_3)\,\theta(x_1x_2,y_{(0)})\,\theta(x_1,x_2)\,\theta(x_1,y_{(1)})(x_3|y_{(0)})(x_2|y_{(1)})(x_1|y_{(2)}),$$

for any $x_i\in U^+$ $(i=1,2,3)$ and $y\in U^-$. From this formula, we get

$$(x'|y)=(x'K_i|y)=\sum_{(y)_2}(K_i|y_{(0)})(x'|y_{(1)})(1|y_{(2)}),$$

$$(xe_{i,k}|y')=\sum_{(y')_2}\theta(x,e_{i,k})\,\theta(x,y'_{(0)})(e_{i,k}|y'_{(0)})(x|y'_{(1)})(1|y'_{(2)}),$$

$$(e_{i,k}x|y')=(e_{i,k}xK_i|y')=\sum_{(y')_2}\theta(e_{i,k},x)\,\theta(e_{i,k},y'_{(1)})(K_i|y'_{(0)})(x|y'_{(1)})(e_{i,k}|y'_{(2)}).$$

Now, we obtain

$$\begin{aligned}\langle \mathrm{ad}(u)\cdot v|v'\rangle &= \langle e_{i,k}xq^hS(y)|y'q^{h'}S(x')\rangle\\ &\quad -\theta(\alpha_i,\beta)q^{(\alpha_i|\beta)}q^{\alpha_i(h)}\sum_{(y)_2}(K_i|y_{(0)})\langle xe_{i,k}q^hS(y_{(1)})|y'q^{h'}S(x')\rangle\\ &=\theta(\gamma,\gamma'-\beta')q^{-(h|h')/2}\\ &\quad\times\left\{(e_{i,k}x|y')(x'|y)-\theta(\alpha_i,\beta)q^{(\alpha_i|\beta)}q^{\alpha_i(h)}\sum_{(y)_2}(K_i|y_{(0)})(xe_{i,k}|y')(x'|y_{(1)})\right\}\\ &=\theta(\gamma,\gamma'-\beta')q^{-(h|h')/2}\sum_{(y)_2,(y')_2}(K_i|y_{(0)})(x'|y_{(1)})(x|y'_{(1)})\\ &\quad\times\{(K_i|y'_{(0)})(e_{i,k}|y'_{(2)})-\theta(x,y'_{(0)})q^{(\alpha_i|\beta)}q^{\alpha_i(h)}(e_{i,k}|y'_{(0)})\}\end{aligned}$$

and

$$\langle v|v'\cdot\widetilde{\mathrm{ad}}(u)\rangle = -\theta(\beta'-\gamma',\alpha_i)q^{(\gamma'-\alpha_i|\alpha_i)}\sum_{(y')_2}\Big\{(e_{i,k}|y'_{(0)})\langle xq^hS(y)|y'_{(1)}K_i^{-1}q^{h'}S(x')\rangle$$

$$+\theta(e_{i,k},y'_{(1)})(K_i|y'_{(0)})(e_{i,k}|S(y'_{(2)}))\langle xq^hS(y)|y'_{(1)}q^{h'}S(x')\rangle\Big\}$$

$$=\theta(\beta'-\gamma',\alpha_i)\,\theta(\gamma,\beta-\beta')q^{-(h|h')/2}q^{(\beta|\alpha_i)}\sum_{(y')_2}\Big\{\theta(e_{i,k},y'_{(1)})(K_i|y'_{(0)})$$

$$\times(e_{i,k}K_i^{-1}|\tilde{y}'_2K^{-1}_{\gamma'-\alpha_i})(x|y'_{(1)})(x'|y)-(e_{i,k}|y'_{(0)})(x|\tilde{y}'_1)(x'|y)q^{\alpha_i(h)}\Big\},$$

$$=\theta(\beta'-\gamma',\alpha_i)\,\theta(\gamma,\beta-\beta')q^{-(h|h')/2}\sum_{(y)_2,(y')_2}(K_i|y_{(0)})(x'|y_{(1)})(x|y'_{(1)})$$

$$\times\Big\{\theta(e_{i,k},y'_{(1)})(K_i|y'_{(0)})(e_{i,k}|y'_{(2)})-q^{(\alpha_i|\beta)}q^{\alpha_i(h)}(e_{i,k}|y'_{(0)})\Big\}.$$

Comparing these two, we get the desired formula. □

This proposition allows us to define a right U-module structure on some subalgebra of U^*. Define $\zeta:U\to U^*$ by setting

$$[\zeta(u)](v)=\langle v|u\rangle, \tag{51}$$

for $u,v\in U$. Here, the dual space on the right should be viewed as the set of linear maps from U to $\mathbf{C}(q^{1/2})$. For $\zeta(u)\in\zeta(U)$, $x\in U$, define $\zeta(u)\cdot x$ by,

$$[\zeta(u)\cdot x](v)=\theta(u,x)\,\theta(v,x)[\zeta(u)](\mathrm{ad}(x)\cdot v).$$

Proposition IV.7 allows us to check $\zeta(u)\cdot x=\zeta(u\cdot\widetilde{\mathrm{ad}}(x))$. So this gives a right U-module structure on $\zeta(U)$ and $\zeta:U\to\zeta(U)$ becomes a U-module homomorphism.

Proposition IV.8: The bilinear form $\langle\,|\,\rangle$ is nondegenerate. Hence, the map ζ is injective.

Proof: Let $u\in U^-_{-\alpha}U^0S(U^+_\beta)$ with $\langle v|u\rangle=0$ for all $v\in U^+_\alpha U^0S(U^-_{-\beta})$. It suffices to show $u=0$. For each $\gamma\in Q^+-\{0\}$, choose a basis $\{u_i^\gamma\}_i$ of U^+_γ. And let $\{v_i^\gamma\}_i$ be a basis of $U^-_{-\gamma}$ dual to $\{u_i^\gamma\}_i$ with respect to the nondegenerate bilinear form $(\,|\,)$. Notice that the elements $u_i^\alpha q^hS(v_j^\beta)$ with $h\in P^\vee$ and i, j going over appropriate indices, form a basis for $U^+_\alpha U^0U^-_{-\beta}$. Similarly, the elements $v_k^\alpha q^{h'}S(u_l^\beta)$ form a basis for $U^-_{-\alpha}U^0U^+_\beta$. Writing $u=\Sigma_{k,h,l}a_{k,h,l}v_k^\alpha q^{h'}S(u_l^\beta)$ with $a_{k,h,l}\in\mathbf{C}(q)$, and using

$$\langle u_i^\alpha q^hS(v_j^\beta)|v_k^\alpha q^{h'}S(u_l^\beta)\rangle=\delta_{i,k}\delta_{j,l}q^{-(h|h')/2}\theta(\beta,\alpha)\,\theta(\beta,\beta),$$

we arrive at

$$\sum_{h'\in P^\vee}a_{k,h',l}q^{-(h|h')/2}=0,$$

for each k, l, and $h\in P^\vee$. Now, each map $h\mapsto q^{-(h|h')/2}$ is a group homomorphism from $P^\vee$ to the multiplicative group $\mathbf{C}(q^{1/2})^\times$. Since $q^{1/2}$ is not a root of unity, distinct h' produces distinct homomorphisms. So, by Artin's Theorem on linear independence of characters, every $a_{k,h',l}=0$. We have $u=0$, as claimed. □

V. HARISH–CHANDRA HOMOMORPHISM

We denote the center of U by $\mathfrak{z}$. For each $i\in I$ with $a_{i,i}\neq 0$, define the *simple reflection* $r_i\in\mathrm{GL}(\mathfrak{h})$ by

$$r_i(h)=h-\frac{2}{a_{i,i}}\alpha_i(h)h_i,$$

and let $\widetilde{W}=\langle r_i|i\in I,a_{i,i}\neq 0\rangle\subset \mathrm{GL}(\mathfrak{h})$. Let $(U^0)^{\widetilde{W}}$ be the subspace of U^0 consisting of the elements $\Sigma_{h\in P^\vee}c_hq^h(c_h\in\mathbf{C}(q))$ such that $c_h\neq 0$ implies $w(h)\in P^\vee$ and $c_{w(h)}=c_h$ for any $w\in\widetilde{W}$.

We define an algebra automorphism $\phi:U^0\to U^0$ by setting $\phi(q^h)=q^{-\rho(h)}q^h$ for $h\in P^\vee$. The *Harish–Chandra homomorphism* $\xi:\mathfrak{z}\to U^0$ is the restriction to $\mathfrak{z}$ of the map

$$U\xrightarrow{\sim}U^-\otimes U^0\otimes U^+\xrightarrow{\epsilon\otimes 1\otimes\epsilon}U^0\xrightarrow{\phi}U^0.$$

For later use, we define the algebra homomorphism $\chi_\lambda:U^0\to\mathbf{C}(q)$ for each $\lambda\in P^+$ by $\chi_\lambda(q^h)=q^{\lambda(h)}$.

Proposition V.1: (a) *ξ is an algebra homomorphism*. (b) *ξ is injective*.

Proof: We will just prove (b). Let $z\in\mathfrak{z}$ be such that $\xi(z)=0$. Writing $z=\Sigma_{\beta\in Q^+}z_\beta$ with $z_\beta\in U^-_{-\beta}U^0U^+_\beta$, we see that $z_0=0$. Fix any $\beta\in Q^+$ minimal with the property that $z_\beta\neq 0$. Also choose basis $\{y_r\}_r$ and $\{x_s\}_s$ of $U^-_{-\beta}$ and U^+_β, respectively. We may write $z_\beta=\Sigma_{r,s}y_ru_{r,s}x_s$ for some $u_{r,s}\in U^0$. Then

$$0=e_{i,k}z-ze_{i,k}=\sum_{\gamma\neq\beta}(e_{i,k}z_\gamma-z_\gamma e_{i,k})+\sum_{r,s}(e_{i,k}y_r-\theta(\alpha_i,-\beta)y_re_{i,k})u_{r,s}x_s$$
$$+\sum_{r,s}y_r(\theta(\alpha_i,-\beta)e_{i,k}u_{r,s}x_s-u_{r,s}x_se_{i,k}).$$

Recalling the minimality of β, we see that only the second term on the right belongs to $U^-_{-(\gamma-\alpha_i)}U^0U^+_\gamma$. So we have $\Sigma_{r,s}(e_{i,k}y_r-\theta(\alpha_i,-\beta)y_re_{i,k})u_{r,s}x_s=0$. $\{x_s\}_s$ was chosen to be a basis, so $e_{i,k}\Sigma_ry_ru_{r,s}=\theta(\alpha_i,-\beta)\Sigma_ry_re_{i,k}u_{r,s}$ for all $i\in I$ and s.

Let $v_\lambda\in V^q(\lambda)$ denote the highest weight vector. Set $v=\Sigma_r\chi_\lambda(u_{r,s})y_rv_\lambda$. Then $e_{i,k}v=\theta(\alpha_i,-\beta)\Sigma_ry_re_{i,k}u_{r,s}v_\lambda=0$ for all $i\in I$, so the irreducibility of $V^q(\lambda)$ says $v=0$. Choosing an appropriate $\lambda\in P^+$, we may use Lemma III.2 and say $\Sigma_r\chi_\lambda(u_{r,s})y_r=0$. Again, $\{y_r\}_r$ was a basis, so $\chi_\lambda(u_{r,s})=0$ for all *r,s*. By choosing a suitable set of λ, we may show $u_{r,s}=0$ for all *r,s* and we have $z_\beta=0$. This contradicts the choice of z_β. □

We now try to close in the image of ξ. For each $J\subset\{(i,k)|i\in I,k=1,2,...,m_i\}$, let $U_J=\langle e_{i,k},f_{i,k},U^0|(i,k)\in J\rangle$. We denote by $\mathfrak{z}_J$ the center of the algebra U_J and by $\xi_J:\mathfrak{z}_J\to U^0$ the Harish–Chandra homomorphism for U_J. Let U_J^+ (respectively, U_J^-) be the subalgebra of U_J generated by $e_{i,k}$ (respectively, $f_{i,k}$) with $(i,k)\in J$, and set

$$R_J^+=\{x\in U^+|(x|U_J^-)=0\}=\{x\in U^+|(x|U_J^-U^0)=0\},\tag{52}$$

$$R_J^-=\{y\in U^-|(U_J^+|y)=0\}=\{y\in U^-|(U^0U_J^+|y)=0\},\tag{53}$$

$$R_J=R_J^-U^0U^++U^-U^0R_J^+.\tag{54}$$

The following may be proved as in Ref. 15.

Lemma V.2: (a) $U=U_J\oplus R_J$; (b) $U_JR_JU_J\subset R_J$; (c) $(\epsilon\otimes 1\otimes\epsilon)(R_J)=0$.

Define $U_r^0=\oplus_h\mathbf{C}(q)q^h$, where the direct sum is over all $h\in P^\vee$, satisfying (i) $\alpha_i(h)\in s_ia_{i,i}\mathbf{Z}$, if $i\in I^{\mathrm{ev}}$; (ii) $\alpha_i(h)\in 2s_ia_{i,i}\mathbf{Z}$, if $i\in I^{\mathrm{odd}}$ and $a_{i,i}\neq 0$.

Proposition V.3: (a) $\mathrm{Im}(\xi)\subset(U^0)^{\widetilde{W}}$. (b) $\mathrm{Im}(\xi)\subset U_r^0$. (c) $\mathrm{Im}(\xi)\subset\mathrm{Im}(\xi_J)$.

Proof: (a) Let $z\in\mathfrak{z}$. Let $v_\lambda\in M^q(\lambda)$ be the highest weight vector. Then, $zv_\lambda=\chi_{\lambda+\rho}(\xi(z))v_\lambda$. Since z commutes with every element of U, z acts as $\chi_{\lambda+\rho}(\xi(z))$ on every element of $M^q(\lambda)$. Now, fix $i\in I$ such that $a_{i,i}\neq 0$. We may calculate

$$e_{i,k}f_{i,k}^n=\theta_{i,i}^n f_{i,k}^n e_{i,k}+\theta_{i,i}^{n-1}f_{i,k}^{n-1}\frac{1}{\xi_i}\left(\frac{1-\theta_{i,i}^{-n}q_i^{-na_{i,i}}}{1-\theta_{i,i}^{-1}q_i^{-a_{i,i}}}K_i-\frac{1-\theta_{i,i}^{n}q_i^{na_{i,i}}}{1-\theta_{i,i}q_i^{a_{i,i}}}K_i^{-1}\right).$$

So that, for each $\lambda\in P$ satisfying $n(\lambda):=(2/a_{i,i})\lambda(h_i)\in\mathbf{Z}_{\geqslant 0}$, we can check that $f_{i,k}^{n(\lambda)+1}v_\lambda$ is a highest weight vector. Its weight is

$$\lambda-\left(\frac{2}{a_{i,i}}\lambda(h_i)+1\right)\alpha_i=\lambda-\frac{2}{a_{i,i}}(\lambda+\rho)(h_i)\alpha_i=r_i(\lambda+\rho)-\rho.$$

The argument at the beginning of this proof applies to any highest weight vector, and we have

$$\chi_{\lambda+\rho}(\xi(z))=\chi_{r_{i(\lambda+\rho)}}(\xi(z)),$$

under the condition $(2/a_{i,i})\lambda(h_i)\in\mathbf{Z}$. Checking $\chi_{r_i\mu}(q^h)=\chi_\mu(r_iq^h)$, for any $\mu\in\mathfrak{h}^*$, the above may now be written as

$$\chi_{\lambda+\rho}(\xi(z)-r_i\xi(z))=0,$$

for every $\lambda\in P$ satisfying $\lambda(h_i)\in(a_{i,i}/2)\mathbf{Z}_{\geqslant 0}$. By choosing a suitable set of λ, we may show $\xi(z)=r_i\xi(z)$.

(b) Let $z=\Sigma_{\beta\in Q^+}z_\beta\in\mathfrak{z}$ with $z_\beta\in U_{-\beta}^-U^0U_\beta^+$. Set $x=\Sigma_{n=0}^\infty z_{n\alpha_i}$ and $y=z-x$. Then $z=x+y$ with $x\in U_{\{(i,1)\}}$ and $y\in R_{\{(i,1)\}}$. Looking at

$$0=e_{i,k}z-ze_{i,k}=(e_{i,k}x-xe_{i,k})+(e_{i,k}y-ye_{i,k}),$$

with Lemma V.2 in mind, we see that $x\in\mathfrak{z}_{\{(i,1)\}}$. By the results of Section VI.1, all of which may be obtained by direct calculation, we have (i) $z_0\in\langle K_i,q^h|\alpha_i(h)=0\rangle$ if $i\in I^{\mathrm{ev}}$; (ii) $z_0\in\langle K_i^2,q^h|\alpha_i(h)=0\rangle$ if $i\in I^{\mathrm{odd}}$ and $a_{i,i}\neq 0$.
The result follows.

(c) For $z\in\mathfrak{z}$, write $z=x+y$ with $x\in U_J$ and $y\in R_J$. As in the proof for (b), we may show $x\in\mathfrak{z}_J$. So we have $\xi(z)=\xi(x)+\xi(y)=\xi(x)=\xi_J(x)\in\mathrm{Im}(\xi_J)$. □

VI. THE CENTER OF $U_q(\mathfrak{g})$

VI.1. *Rank 1.* In this section, we list the center for the case when the index set is of size 1. All results may be obtained by direct calculation using induction after choosing a suitable basis of $U\cong U^-\otimes U^0\otimes U^+$.
If $a_{i,i}\neq 0$, $\theta_{i,i}=1$, define

$$C_i=f_{i,1}e_{i,1}+\frac{1}{\xi_i}\left(\frac{1}{1-q^{-s_ia_{i,i}}}K_i-\frac{1}{1-q^{s_ia_{i,i}}}K_i^{-1}\right).$$

If $a_{i,i}\neq 0$, $\theta_{i,i}=-1$, define

$$C_i=f_{i,1}^2e_{i,1}^2+\frac{1}{\xi_i}f_{i,1}\left(\frac{1-q^{s_ia_{i,i}}}{1+q^{s_ia_{i,i}}}K_i-\frac{1-q^{-s_ia_{i,i}}}{1+q^{-s_ia_{i,i}}}K_i^{-1}\right)e_{i,1}-\frac{1}{\xi_i^2}\left\{\frac{1}{(1+q^{-s_ia_{i,i}})^2}K_i^2+\frac{1}{(1+q^{s_ia_{i,i}})^2}K_i^{-2}\right\}.$$

If $h\in P^\vee$ satisfy $\alpha_i(h)\neq 0$, define

$$C_{ih}=f_{i,1}q^he_{i,1}+\frac{1}{\xi_i}\frac{1}{1-q^{-\alpha_i(h)}}q^h(K_i-K_i^{-1}).$$

Proposition VI.1: (a) If $J=\{(i,1)\}$ and $a_{i,i}\neq 0$, then $\mathfrak{z}_J=\langle C_i, q^h | h\in P^\vee, \alpha_i(h)=0\rangle$.
(b) *If* $J=\{(i,1)\}$, $a_{i,i}=0$, *and* $\theta_{i,i}=1$, *then* $\mathfrak{z}_J=\langle q^h | h\in P^\vee, \alpha_i(h)=0\rangle\subset U^0$.
(c) *If* $J=\{(i,1)\}$, $a_{i,i}=0$, *and* $\theta_{i,i}=-1$, *then* $\mathfrak{z}_J=\langle C_{ih}, q^{h'} | h,h'\in P^\vee, \alpha_i(h)\neq 0, \alpha_i(h')=0\rangle$,

VI.2. *Finite type*. In this section, we give a structure theorem for the center of $U_q(\mathfrak{g})$ when the Borcherds–Cartan matrix is of finite type. We take the Borcherds–Cartan matrix to be of finite type throughout this section. To simplify arguments, we redefine

$$P^\vee=\bigoplus_{i\in I}\mathbf{Z}h_i,$$

$$\mathfrak{h}=\bigoplus_{i\in I}\mathbf{C}h_i,$$

for this section. Notice that the bilinear form $(\,|\,)$ is still nondegenerate on the redefined $\mathfrak{h}$.

The irreducible highest weight module has a natural grading,

$$V^q(\lambda)=\bigoplus_{\alpha\in Q^+}V^q(\lambda)_{\lambda-\alpha}.$$

Define a map $\eta\in\mathrm{End}(V^q(\lambda))$ by setting $\eta(v)=\theta(\alpha,\alpha)v$ for $v\in V^q(\lambda)_{\lambda-\alpha}$. When the Borcherds–Cartan matrix A is of finite type, it is known (Ref. 20) that the irreducible highest weight module $V(\lambda)$ over $\mathfrak{g}(A)$ is finite dimensional for $\lambda\in P^+$. Since the classical limit (Ref. 6) of $V^q(\lambda)$ is $V(\lambda)$, $V^q(\lambda)$ is also of finite dimension when $\lambda\in P^+$. So we may define the *supertrace* for $x\in U_q(\mathfrak{g})$ acting on $V^q(\lambda)$ by

$$\mathrm{str}(x;V^q(\lambda))=\mathrm{tr}(\eta\circ x;V^q(\lambda)). \tag{55}$$

For homogeneous elements $x,y\in U$, we can easily check

$$\mathrm{str}(xy)=\theta(x,y)\mathrm{str}(yx). \tag{56}$$

Lemma VI.2: $u\in\mathfrak{z}$ *if and only if* $u\cdot\widetilde{ad}(x)=\epsilon(x)u$ *for all* $x\in U$.

Proof: Let $u\in\mathfrak{z}$. Then, $u\in U_0$ and

$$u\cdot\widetilde{\mathrm{ad}}(x)=\sum_{(x)_1}S(x_{(0)})ux_{(1)}=u\sum_{(x)_1}S(x_{(0)})x_{(1)}=\epsilon(x)u.$$

Conversely, if $u\cdot\widetilde{\mathrm{ad}}(x)=\epsilon(x)u$ for all $x\in U$,

$$q^{-h}uq^h=u\cdot\widetilde{\mathrm{ad}}(x)=\epsilon(q^h)u=u.$$

So $u\in U_0$, and we have

$$0=\epsilon(e_{i,k})u=u\cdot\widetilde{\mathrm{ad}}(e_{i,k})=-K_i^{-1}e_{i,k}u+K_i^{-1}ue_{i,k}.$$

This shows $e_{i,k}u=ue_{i,k}$. We may similarly show $f_{i,k}u=uf_{i,k}$, and hence $u\in\mathfrak{z}$. □

For each $\lambda\in P^+$, define $f_\lambda\in U^*$ by

$$f_\lambda(u)=\mathrm{str}(uK_{2\rho}^{-1};V^q(\lambda)). \tag{57}$$

Let $\nu:\mathfrak{h}\to\mathfrak{h}^*$ denote the isomorphism given by the nondegenerate symmetric bilinear form $(\,|\,)$. Define

$$\hat{Q}=\nu(P^\vee)=\bigoplus_{i\in I}\mathbf{Z}\frac{1}{s_i}\alpha_i.$$

Recall the map $\zeta:U\to U^*$ defined in (51).

Lemma VI.3: For $\lambda\in P^+$, $f_\lambda\in\mathrm{Im}(\zeta)$ *if and only if* $\lambda\in\frac{1}{2}\hat{Q}$.

Proof: From Proposition IV.8, we see that the image of ζ is the restricted dual of $U_q(\mathfrak{g})$. So

$$\mathrm{Im}(\zeta)=\Big(\bigoplus_{\beta\in Q^+}(U^-_{-\beta})^*\Big)\otimes\Big(\bigoplus_{\mu\in(1/2)\hat{Q}}\mathbf{C}(q)\chi_\mu\Big)\otimes\Big(\bigoplus_{\beta\in Q^+}(U^+_\beta)^*\Big),$$

under the identification $U\cong U^-\otimes U^0\otimes U^+$. The finite dimensionality of $V^q(\lambda)$ allows us to show $f_\lambda\in\mathrm{Im}(\zeta)$ if and only if $\lambda\in\frac{1}{2}\hat{Q}$. □

The next proposition gives elements of the center.

Proposition VI.4: For each $\lambda\in P^+\cap\frac{1}{2}\hat{Q}$, *we have* $z_\lambda:=\zeta^{-1}(f_\lambda)\in\mathfrak{z}$.

Proof: Recall from the theory of finite-dimensional simple Lie algebras that ρ may be written as a half sum of positive roots. Since the simple roots for the super case is identical to the nonsuper case, we have $2\rho\in Q^+$ in either case. Hence, in the notation previously given, $K_{2\rho}$ is a well-defined element of U^0. Using the fact that $K_{2\rho}^{-1}xK_{2\rho}=S^2(x)$ for any $x\in U$ and using the property of supertrace given by (56), we have, for any $u\in U$,

$$\begin{aligned}(f_\lambda\cdot x)(u)&=f_\lambda(\mathrm{ad}(x)\cdot u)\theta(u,x)\\&=\sum_{(x)_1}\mathrm{str}(x_{(0)}uS(x_{(1)})K_{2\rho}^{-1};V^q(\lambda))\theta(x_{(1)},u)\theta(u,x)\\&=\sum_{(x)_1}\mathrm{str}(uS(x_{(1)})K_{2\rho}^{-1}x_{(0)};V^q(\lambda))\theta(x_{(0)},x_{(1)})\\&=\mathrm{str}\left(uS\left(\sum_{(x)_1}S(x_{(0)})x_{(1)}\right)K_{2\rho}^{-1};V^q(\lambda)\right)=\epsilon(x)\mathrm{str}(uK_{2\rho}^{-1};V^q(\lambda))=\epsilon(x)f_\lambda(u).\end{aligned}$$

Thus $f_\lambda\cdot x=\epsilon(x)f_\lambda$. Recall from Proposition IV.8 that ζ is injective, and notice

$$f_\lambda\cdot x=\zeta(\zeta^{-1}(f_\lambda))\cdot x=\zeta(\zeta^{-1}(f_\lambda)\cdot\widetilde{\mathrm{ad}}(x)).$$

This shows $\zeta^{-1}(f_\lambda)\cdot\widetilde{\mathrm{ad}}(x)=\epsilon(x)\zeta^{-1}(f_\lambda)$. From Lemma VI.2, we get $\zeta^{-1}(f_\lambda)\in\mathfrak{z}$. □

We finally show that the above elements generate the whole center.

Theorem VI.5: *Suppose that the Borcherds–Cartan matrix* $A=(a_{i,j})_{i,j\in I}$ *is indecomposable and of a finite type. Then,* $\xi:\mathfrak{z}\to(U_r^0)^{\tilde{W}}$ *is an isomorphism.*

Proof: Let us calculate $\xi(z_\lambda)$. We extend the notation K_β previously introduced to $\beta\in\hat{Q}$ by setting $K_{(1/s_i)\alpha_i}=q^{h_i}$. We have the commutative diagram,

$$\begin{array}{ccc} & \overset{\zeta}{} & \\ U & \to & U^*\\ \epsilon\otimes\mathrm{id}\otimes\epsilon\downarrow & & \downarrow\\ U^0 & \to & (U^0)^*,\end{array}$$

where the right vertical arrow is the restriction map and the lower horizontal arrow is given by $K_\mu\mapsto\chi_{-\mu/2}$. Now, as maps on U^0,

$$f_\lambda=\sum_{\mu\leqslant\lambda}\theta(\lambda-\mu,\lambda-\mu)\dim(V(\lambda)_\mu)q^{-2(\rho|\mu)}\chi_\mu.$$

This shows

$$\xi(z_\lambda)=\sum_{\mu\leqslant\lambda}\theta(\lambda-\mu,\lambda-\mu)\dim(V(\lambda)_\mu)K_{-2\mu},\tag{58}$$

for $\lambda\in P^+\cap\frac{1}{2}\hat{Q}$.

Define $\hat{P}$ to be the set of elements $\mu\in\mathfrak{h}^*$ such that $\mu(h_i)\in\mathbf{Z}$ if $i\in I$ is even and $\mu(h_i)\in 2\mathbf{Z}$ if $i\in I$ is odd. Notice $P^+\subset\hat{P}$. We can now write

$$U_r^0=\bigoplus_{\mu\in 2\hat{P}\cap\hat{Q}}\mathbf{C}(q)K_\mu.$$

Action of the Weyl groups $\tilde{W}$ and W defined on $\mathfrak{h}$ and $\mathfrak{h}^*$ are compatible with the isomorphism ν. By Proposition VI.4, it suffices to show that the elements $\xi(z_\lambda)$ with $\lambda\in P^+\cap\frac{1}{2}\hat{Q}$ generate $(U_r^0)^W$.

Set $\overline{\mu}=\Sigma_{w\in W}K_{-w\mu}$ for any $\mu\in\hat{Q}$. We know the elements $\overline{\mu}$ with $\mu\in 2P^+\cap\hat{Q}$ generate $(U_r^0)^W$. Let us use induction to show that each of them belong to Im(ξ). The element $\overline{0}\in U_r^0$ is given by $\xi(z_\lambda)$, with $\lambda=0$. Choose any $\lambda\in 2P^+\cap\hat{Q}$. Then, $\frac{1}{2}\lambda\in P^+\cap\frac{1}{2}\hat{Q}$ so that $z_{(1/2)\lambda}$ is an element of the center. Recall that Im(ξ) is invariant under the action of W (Proposition V.3). Using $\dim V^q(\frac{1}{2}\lambda)_{(1/2)\lambda}=1$, we may rewrite (58) as

$$\xi(z_{(1/2)\lambda})=\overline{\lambda}+\sum_\mu n_\mu\overline{\mu},$$

with $n_\mu\in\mathbf{Z}$ and $\frac{1}{2}\mu$ running over some set of weights of $V^q(\frac{1}{2}\lambda)$. Since all $\mu<\lambda$, induction hypothesis show that each $\overline{\mu}$ belong to Im(ξ). Hence $\overline{\lambda}\in$ Im(ξ) and the induction step is complete. □

VI.3. *Other cases*. Let 2_i, 0_i, and Θ_i denote the fact that $a_{i,i}$ is, respectively, 2, 0, and negative. We will sometimes add a $\pm$ to these to reflect the sign of $\theta_{i,i}$. So, for example, 2_i^- implies that i is an odd real index. For $i,j\in I$, let us say $\odot_i$ is *connected directly* to $\odot_j$ if $a_{i,j}\neq 0$, where $\odot$ can be any one of 2, 0, or Θ. Here are some results for the case when $|J|=2$.

Lemma VI.6: Assume one of the following.

(a) $J=\{(i,1),(i,2)\}$, *with* Θ_i
(b) $J=\{(i,1),(j,1)\}$, *with* 0_i^+ *connected directly to* 0_j^-.
(c) $J=\{(i,1),(j,1)\}$, *with* 0_i^- *connected directly to* 0_j^-.
(d) $J=\{(i,1),(j,1)\}$, *with* Θ_i *connected directly to* 0_j^-.
(e) $J=\{(i,1),(j,1)\}$, *with* 2_i *connected directly to* Θ_j.
(f) $J=\{(i,1),(j,1)\}$, *with* Θ_i *connected directly to* Θ_j.

Then, $\mathfrak{z}_J\subset U^0$.

Proof: (a) and (f) may be proved as in Ref. 15, Proposition 4.5. And (e) may be proved as in Ref. 15, Proposition 4.6. (c) is proved by explicit calculation.

Let us prove (b) and (d) simultaneously. Let $z\in\mathfrak{z}_J$. Since it commutes with q^h for all $h\in P^\vee$, $z=\Sigma z_\beta$ with $z_\beta\in U_\beta^-\otimes U^0\otimes U_\beta^+$, where the sum is over all $\beta\in\mathbf{Z}_{\geqslant 0}\alpha_i\oplus\mathbf{Z}_{\geqslant 0}\alpha_j$. Let α be maximal among those $\beta\in\mathbf{Z}_{\geqslant 0}\alpha_i\oplus\mathbf{Z}_{\geqslant 0}\alpha_j$ for which z_β is nonzero and suppose $\alpha\neq 0$. Let $\{x_\mu\}$ and $\{y_\lambda\}$ be any bases of $(U_J^+)_\alpha$ and $(U_J^-)_{-\alpha}$, respectively. We can now write

$$z=\left(\sum_{\lambda,\mu,h}c_h^{\lambda,\mu}y_\lambda q^h x_\mu\right)+z'.$$

Recall Lemma IV.4 and notice

$$\Delta_2(e_{i,k})=e_{i,k}\otimes 1\otimes 1+K_i\otimes e_{i,k}\otimes 1+K_i\otimes K_i\otimes e_{i,k},$$

$$\Delta_2(y_\lambda)=1\otimes y_\lambda\otimes K_{-\alpha}+\text{``other terms.''}$$

This shows that the only part of $e_{i,k}z-ze_{i,k}$ belonging to the direct sum component $U^-_{-\alpha}\otimes U^0\otimes U^+_{\alpha+\alpha_i}$ is

$$\left(\sum_{\lambda,\mu,h} c_h^{\lambda,\mu}\theta(\alpha_i,-\alpha)y_\lambda e_{i,k}q^h x_\mu\right)-\left(\sum_{\lambda,\mu,h} c_h^{\lambda,\mu}y_\lambda q^h x_\mu e_{i,k}\right)$$

$$=\sum_{\lambda,h} y_\lambda q^h \sum_{\mu} c_h^{\lambda,\mu}(q^{-\alpha_i(h)}\theta(\alpha,\alpha_i)e_{i,k}x_\mu - x_\mu e_{i,k}).$$

Hence, for each $h\in P^\vee$ and λ,

$$\sum_{\mu} c_h^{\lambda,\mu}(q^{-\alpha_i(h)}\theta(\alpha,\alpha_i)e_{i,k}x_\mu - x_\mu e_{i,k})=0,$$

and the same statement with i replaced by j also holds. Now, $e_{j,1}^2=0$ is the only relation in U_J^+ for the case we are considering, so we may take an explicit set of monomials in $e_{i,1}$ and $e_{j,1}$ for the basis of U_α^+ and, using these, we can show that the two equations cannot be simultaneously true.□

Proposition VI.7: Assume that A is indecomposable. Suppose that energy 0_j^- *is connected directly to a* 0_i *or a* Θ_i. *If there is a nonempty subset J of* $\{(i,k)|i\in I,k=1,...,m_i\}$ *such that* $\mathfrak{z}_J\subset U^0$, *then* $\mathfrak{z}$ *is contained in* U^0.

Proof: Let $\bar{J}=\{i\in I|(i,k)\in J \text{ for some } k\}$. For $i\in I$, set

$$T_i=\bigoplus_{h\in P^\vee,\alpha_i(h)=0}\mathbf{C}(q)q^h.$$

We then have $\mathfrak{z}\cap U^0=\cap_{i\in I}T_i$ and similarly, $\mathfrak{z}_J\cap U^0=\cap_{i\in\bar{J}}T_i$. It suffices to show $\mathrm{Im}(\xi)\subset\cap_{i\in I}T_i$.

We already have $\mathrm{Im}(\xi)\subset\mathrm{Im}(\xi_J)\subset T_i$ for every $i\in\bar{J}$. Also, if 0_i^+, we have $\mathrm{Im}(\xi)\subset\mathrm{Im}(\xi_{\{(i,1)\}})\subset T_i$ by Proposition VI.1 (b). If 0_i^-, the conditions on the matrix show we may use Lemma VI.6 to write $\mathrm{Im}(\xi)\subset T_i$.

We now show that if $a_{j,j}\neq 0$ and $a_{i,j}\neq 0$, then $T_i\cap(U^0)^{\tilde{W}}\subset T_j$. Let $c=\Sigma c_h q^h\in T_i\cap(U^0)^{\tilde{W}}$. We must have $r_j c=c\in T_i$, so if $c_h\neq 0$, then $\alpha_i(h)=0$ and $\alpha_i(r_j h)=0$. But $\alpha_i(r_j h)=-(2/a_{j,j})a_{j,i}\alpha_j(h)$ so $\alpha_j(h)=0$. We have $c\in T_j$, as wanted.

Fix any $j\in I-(\bar{J}\cup\{i|a_{i,i}=0\})$. By the indecomposability of A, there exists a finite sequence $i=i_0,i_1,\ldots,i_n=j$ such that $i\in\bar{J}\cup\{i|a_{i,i}=0\}$, $i_k\notin\bar{J}\cup\{i|a_{i,i}=0\}$ for $k\geqslant 1$, and $a_{i_k,i_{k+1}}\neq 0$ for all k. What we have found above allows us to recursively show $\mathrm{Im}(\xi)\subset T_{i_k}$ and, in particular, $\mathrm{Im}(\xi)\subset T_j$. □

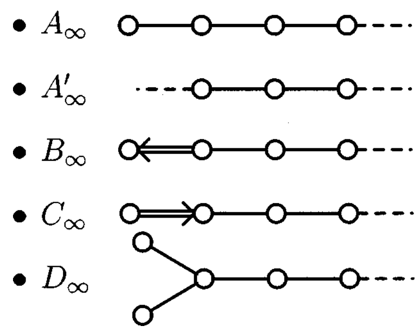
Proposition VI.8: Suppose three exists some finite $J\subset I$ *such that for every* $j\in J$, $a_{j,j}=2$ *and for which the corresponding submatrix* $A_J=(a_{i,j})_{i,j\in J}$ *is indecomposable and not of a finite type. Then,* $\mathfrak{z}_J\subset U^0$.

Proof: By Ref. 21, Proposition 4.9, we have $|W_J|=\infty$. Let $J'\subset J$ be such that $|W_{J'}|=\infty$ and $|W_{J''}|<\infty$ for all $J''\subsetneq J'$. We may use Proposition VI.7 if we can show $\mathfrak{z}_{J'}\subset U^0$. Hence, it suffices to show that if $h\in P^\vee$, $|W_{J'}(h)|<\infty$, then $\alpha_i(h)=0$, for all $i\in J'$. Give partial order to $\mathfrak{h}$ by setting $h_1\geqslant h_2$ if and only if $h_1-h_2\in(\Sigma_i\mathbf{Z}_{\geqslant 0}h_i)+(\Sigma_i\mathbf{Z}_{\geqslant 0}d_i)$. Let $h'\in W_{J'}(h)$ be maximal with respect to this order. Then, for each $i\in J'$, if $\alpha_i(h')<0$, then $h'<r_i h'$, so $\alpha_i(h')\geqslant 0$ for all $i\in J'$. Set $W_{h'}=\{w\in W|w(h')=h'\}$. By Ref. 21, Proposition 3.12(a), $W_{h'}=W_{J''}$ with $J''=\{i\in J|\alpha_i(h')=0\}$. If $J'',\subsetneq J'$, then $|W_{J'}(h')|=|W_{J'}/W_{h'}|=\infty$. Hence, we must have $J''=J'$ and $\alpha_i(h')=0$ for all $i\in J'$. $\{h'\}=W_{J'}(h')=W_{J'}(h)$. So $h=h'$ and $\alpha_i(h)=0$ for all $i\in J'$. □

Proposition VI.9: Let A be indecomposable, not of finite type, and $a_{i,i}=2$ *for all* $i\in I$. *Then,* $\mathfrak{z}\subset U^0$.

Proof: Suppose there exists some finite indecomposable submatrix that is not of finite type. Then we may use Proposition VI.7 and Proposition VI.8 to obtain the result.

If, to the contrary, every finite submatrix of A is of finite type, it must be one of the following types:



In all cases, with I naturally ordered, the matrix satisfies the following condition.

For each $i \in I$, there exists some $j > i$ such that $a_{i,j} \neq 0$, and $a_{i,k} = 0$ for $k > j$. $\qquad (*)$

Let $c = \Sigma_h c_h q^h \in \mathrm{Im}(\xi) \subset (U^0)^{\tilde{W}}$. Fix $h \in P^\vee$ for which $c_h \neq 0$. We aim to show $|\tilde{W}(h)| = \infty$ if $\alpha_j(h) \neq 0$ for some $j \in I$. We may assume that only finitely many $j \in I$ satisfy $\alpha_j(h) \neq 0$. Let $k \in I$ be the maximal of those so that $\alpha_j(h) = 0$ for all $j > k$ and $\alpha_k(h) \neq 0$. Set $i_0 = k$, and using property $(*)$, recursively choose i_n so that $i_{n+1} > i_n$ and $a_{i_n, i_{n+1}} \neq 0$. Put $h_0 = h$ and $h_{n+1} = r_{i_n} h_n$. Then, h_n cannot form a closed orbit and $|\tilde{W}(h)| = \infty$. Hence $\mathrm{Im}(\xi) \subset \oplus_{h \in P^\vee, \alpha_i(h) = 0} \mathbf{C} q^h$ and $\mathfrak{z} \subset U^0$. □

We can now collect all results and state the following.

Theorem VI.10: *Assume that the Borcherds–Cartan matrix* $A = (a_{i,j})_{i,j \in I}$ *is indecomposable and not of finite type. Suppose that every* 0_j^- *is connected directly to a* 0_i *or a* Θ_i. *Except for the case when* $|I| = 1$ *with* $m_i = 1$, *the center* $\mathfrak{z}$ *belongs to* U^0.

Proof: We apply Proposition VI.7 to each possible case.

If $|I| = 1$, the conditions imply either a 0_i^+ or a Θ_i with $m_i \geqslant 2$. These cases may be handled by Proposition VI.1 (b) and Lemma VI.6 (a), respectively.

Now suppose $|I| \geqslant 2$. Proposition VI.9 does away with the case when all $a_{i,i} = 2$. If it contains a 0_i^+, we may again use Proposition VI.1 (b). If it contains a 0_i^- but no 0_i^+, we use Lemma VI.6 (c), (d). The only other case is covered by Lemma VI.6 (e), (f). □

VII. THE UNIVERSAL *R* MATRIX

In this section, we find the universal R matrix for the quantum group $U_q(\mathfrak{g})$.

A Hopf superalgebra (or a colored Hopf algebra) H together with an element $\mathbf{R} \in H \otimes H$ is called a *quasitriangular Hopf superalgebra* if it satisfies the following: (a) $\mathbf{R}$ is invertible; (b) $\mathbf{R} \cdot \Delta(a) = \Delta'(a) \cdot \mathbf{R}$, for all $a \in H$; (c) $(\Delta \otimes 1)(\mathbf{R}) = \mathbf{R}_{13}\mathbf{R}_{23}$; (d) $(1 \otimes \Delta)(\mathbf{R}) = \mathbf{R}_{13}\mathbf{R}_{12}$, where $\Delta' = \sigma \circ \Delta$ with σ a colored transposition map, and where $\mathbf{R}_{ij}$ is an element of $H \otimes H \otimes H$, such that the ith and jth components are given by $\mathbf{R}$, and the remaining component is 1. The element $\mathbf{R}$ is called the *universal R matrix*. It satisfies the Yang–Baxter equation,

$$\mathbf{R}_{12}\mathbf{R}_{13}\mathbf{R}_{23} = \mathbf{R}_{23}\mathbf{R}_{13}\mathbf{R}_{12}. \qquad (59)$$

A Hopf superalgebra H together with an element $C \in H \otimes H$ and an algebra homomorphism $\Phi: H \otimes H \to H \otimes H$ is called a *pretriangular Hopf superalgebra* if it satisfies the following: (P1) C is invertible; (P2) $C \cdot \Delta(a) = \Phi(\Delta'(a)) \cdot C$, for all $a \in H$; (P3) $\Phi_{23} \circ \Phi_{13}(C_{12}) = C_{12}$; (P4) $\Phi_{12} \circ \Phi_{13}(C_{23}) = C_{23}$; (P5) $\Phi_{23}(C_{13}) \cdot C_{23} = (\Delta \otimes 1)(C)$; (P6) $\Phi_{12}(C_{13}) \cdot C_{12} = (1 \otimes \Delta)(C)$.

Under some conditions, it is possible to show that a pretriangular Hopf superalgebra becomes a quasitriangular Hopf superalgebra.

We set $U^{+,\beta} = \oplus_{\gamma \in Q^+, \gamma \not\leq \beta} U_\gamma^+$ for each $\beta \in Q^+$ and define the completion $\hat{U}$ of U by

$$\hat{U}=\lim_{\overleftarrow{\beta}} U/UU^{+,\beta}. \tag{60}$$

There is a natural embedding of U in $\hat{U}$ and there is a natural algebra structure on $\hat{U}$ that extends that of U under this embedding.

The completion of $U^{\otimes n}$ is similarly defined. We will write $\hat{U}\hat{\otimes}\hat{U}$ for the completion of $U\otimes U$.

Define an algebra automorphism $\Phi: U\otimes U\to U\otimes U$ by

$$\Phi(q^h\otimes q^{h'})=q^h\otimes q^{h'}, \tag{61}$$

$$\Phi(e_{i,k}\otimes 1)=e_{i,k}\otimes K_i, \quad \Phi(1\otimes e_{i,k})=K_i\otimes e_{i,k}, \tag{62}$$

$$\Phi(f_{i,k}\otimes 1)=f_{i,k}\otimes K_i^{-1}, \quad \Phi(1\otimes f_{i,k})=K_i^{-1}\otimes f_{i,k}. \tag{63}$$

It can be shown that Φ naturally extends to an algebra automorphism of $\hat{U}\hat{\otimes}\hat{U}$.

We denote by $C_\beta\in U_\beta^+\otimes U_{-\beta}^-$ the canonical element of the bilinear form $(\,|\,):U_\beta^+\times U_{-\beta}^-\to\mathbf{C}$. Define

$$C=\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_\beta|h_\beta)}(K_\beta^{-1}\otimes K_\beta)C_\beta\in\hat{U}\hat{\otimes}\hat{U}. \tag{64}$$

Lemma VII.1: (a) $C\cdot\Delta(q^h)=\Phi(\Delta'(q^h))\cdot C$ $(h\in P^\vee)$; (b) $(\Phi_{23}\circ\Phi_{13})(C_{12})=C_{12}$; (c) $(\Phi_{12}\circ\Phi_{13})(C_{23})=C_{23}$.

Proof: This is just a straightforward calculation. □

Lemma VII.2: Let $\beta\in Q^+$.

(a) $\sum_{\substack{\gamma,\delta\in Q^+\\ \gamma+\delta=\beta}}C_\gamma(K_\delta\otimes 1)(S\otimes 1)(C_\delta)=\delta_{\beta,0}$.

(b) $\sum_{\substack{\gamma,\delta\in Q^+\\ \gamma+\delta=\beta}}(K_\gamma\otimes 1)(S\otimes 1)(C_\gamma)C_\delta=\delta_{\beta,0}$.

(c) $\theta_{i,i}[1\otimes e_{i,k},C_{\beta+\alpha_i}]=C_\beta(e_{i,k}\otimes K_i^{-1})-(e_{i,k}\otimes K_i)C_\beta$.

(d) $\theta_{i,i}[f_{i,k}\otimes 1,C_{\beta+\alpha_i}]=C_\beta(K_i\otimes f_{i,k})-(K_i^{-1}\otimes f_{i,k})C_\beta$.

(e) $(\Delta\otimes 1)(C_\beta)=\sum_{\substack{\gamma,\delta\in Q^+\\ \gamma+\delta=\beta}}q^{-(h_\gamma|h_\delta)}(K_\delta\otimes 1\otimes 1)(C_\gamma)_{13}(C_\delta)_{23}$.

(f) $(1\otimes\Delta)(C_\beta)=\sum_{\substack{\gamma,\delta\in Q^+\\ \gamma+\delta=\beta}}q^{-(h_\gamma|h_\delta)}(1\otimes 1\otimes K_{-\delta})(C_\gamma)_{13}(C_\delta)_{12}$.

Proof: Here we show the proof for (a) only. Other cases may be proved in a similar spirit.

The case $\beta=0$ is trivial. So assume $\beta\in Q^+\setminus\{0\}$. The left-hand side is contained in $U_\beta^+\otimes U$, so by Theorem IV.6 it suffices to show that the application of $(\cdot|w)\otimes 1$ is zero for all $w\in U_{-\beta}^-$. We may write

$$\Delta(w)=\sum_{\substack{\gamma,\delta\in Q^+\\ \gamma+\delta=\beta}}w^{\delta,\gamma}(1\otimes K_\delta), \quad \text{with } w^{\delta,\gamma}\in U_{-\delta}^-\otimes U_{-\gamma}^-$$

and

$$w^{\delta,\gamma}=\sum_m w_{\delta,m}^{\delta,\gamma}\otimes w_{\gamma,m}^{\delta,\gamma}, \quad \text{with } w_{\delta,m}^{\delta,\gamma}\in U_{-\delta}^-, \quad w_{\gamma,m}^{\delta,\gamma}\in U_{-\gamma}^-.$$

We may also fix basis $\{x_r^\gamma\}_r$ and $\{y_r^\gamma\}_r$ of U_γ^+ and $U_{-\gamma}^-$, respectively, which are dual with respect to the bilinear form. Now

$$((\,|w)\otimes 1)(\mathrm{LHS}) = ((\,|w)\otimes 1)\left(\sum_{\gamma,\delta,r,s} \theta(y_r^\gamma, x_s^\delta) x_r^\gamma K_\delta S(x_s^\delta)\otimes y_r^\gamma y_s^\delta\right)$$

$$= \sum_{\gamma,\delta,r,s} \theta(x_r^\gamma, K_\delta S(x_s^\delta))\theta(-\gamma,\delta)(K_\delta S(x_s^\delta)\otimes x_r^\gamma|\Delta(w))y_r^\gamma y_s^\delta$$

$$= \sum_{\gamma,\delta,r,s,m} \theta(\delta,\gamma)(k_\delta S(x_s^\delta)|w_{\delta,m}^{\delta,\gamma})(x_r^\gamma|w_{\gamma,m}^{\delta,\gamma}K_{-\delta})y_r^\gamma y_s^\delta$$

$$= \sum_{\gamma,\delta,m} \theta(\delta,\gamma)\left(\sum_r (x_r^\gamma|w_{\gamma,m}^{\delta,\gamma}K_{-\delta})y_r^\gamma\right)\left(\sum_s (K_\delta S(x_s^\delta)\middle| w_{\delta,m}^{\delta,\gamma})y_s^\delta\right)$$

$$= \sum_{\gamma,\delta,m} \theta(\delta,\gamma)\left(\sum_r (x_r^\gamma|w_{\gamma,m}^{\delta,\gamma})y_r^\gamma\right)\left(\sum_s ((x_s^\delta|K_\delta^{-1}S^{-1}(w_{\delta,m}^{\delta,\gamma}))y_s^\delta)\right)$$

$$= \sum_{\gamma,\delta,m} \theta(\delta,\gamma)w_{\gamma,m}^{\delta,\gamma}K_\delta^{-1}S^{-1}(w_{\delta,m}^{\delta,\gamma})$$

$$= S^{-1}\left(\sum_{\gamma,\delta,m} w_{\delta,m}^{\delta,\gamma}S(w_{\gamma,m}^{\delta,\gamma}K_\delta^{-1})\right)$$

$$= (S^{-1}\circ m\circ(1\otimes S)\circ\Delta)(w) = \epsilon(w) = 0.$$

Hence the left-hand side is zero when $\beta \neq 0$. □

Proposition VII.3: Let

$$C' = \sum_{\beta\in Q^+} \theta(\beta,\beta)q^{(h_\beta|h_\beta)}(1\otimes K_\beta)(S\otimes 1)(C_\beta) \in \hat{U}\hat{\otimes}\hat{U}. \tag{65}$$

Then $CC' = C'C = 1$.

Proof:

$$CC' = \left(\sum_{\gamma\in Q^+} \theta(\gamma,\gamma)q^{(h_\gamma|h_\gamma)}(K_\gamma^{-1}\otimes K_\gamma)C_\gamma\right)\left(\sum_{\delta\in Q^+} \theta(\delta,\delta)q^{(h_\delta|h_\delta)}(1\otimes K_\delta)(S\otimes 1)(C_\delta)\right)$$

$$= \sum_{\beta\in Q^+} \sum_{\substack{\gamma+\delta=\beta\\ \gamma,\beta\in Q^+}} \theta(\beta,\beta)q^{(h_\gamma|h_\gamma)+(h_\delta|h_\delta)}(K_\gamma^{-1}\otimes K_\gamma)C_\gamma(1\otimes K_\delta)(S\otimes 1)(C_\delta)$$

$$= \sum_{\beta\in Q^+} \theta(\beta,\beta)q^{(h_\beta|h_\beta)}(K_\beta^{-1}\otimes K_\beta)\sum_{\substack{\gamma+\delta=\beta\\ \gamma,\beta\in Q^+}} C_\gamma(K_\delta\otimes 1)(S\otimes 1)(C_\delta).$$

We may now apply Lemma VII.2. The other part is done similary. □

Proposition VII.4: We have

$$C\cdot\Delta(e_{i,k}) = \Phi(\Delta'(e_{i,k}))\cdot C, \tag{66}$$

$$C\cdot\Delta(f_{i,k}) = \Phi(\Delta'(f_{i,k}))\cdot C. \tag{67}$$

Proof:

$$C\cdot\Delta(e_{i,k})=\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_{\beta+\alpha_i}|h_\beta)}(K_\beta^{-1}\otimes K_{\beta+\alpha_i})C_\beta(e_{i,k}\otimes K_i^{-1})$$
$$+\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_{\beta-\alpha_i}|h_\beta)}(K_{\beta-\alpha_i}^{-1}\otimes K_\beta)C_\beta(1\otimes e_{i,k}),$$

$$\Phi(\Delta'(e_{i,k}))\cdot C=\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_\beta|h_{\beta-\alpha_i})}(K_{\beta-\alpha_i}^{-1}\otimes K_\beta)(1\otimes e_{i,k})C_\beta$$
$$+\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_{\beta+\alpha_i}|h_\beta)}(K_\beta^{-1}\otimes K_{\beta+\alpha_i})(e_{i,k}\otimes K_i)C_\beta,$$

$$C\cdot\Delta(e_{i,k})-\Phi(\Delta'(e_{i,k}))\cdot C=\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_\beta|h_{\beta+\alpha_i})}(K_\beta^{-1}\otimes K_{\beta+\alpha_i})\{C_\beta(e_{i,k}\otimes K_i^{-1})$$
$$-(e_{i,k}\otimes K_i)C_\beta-\theta(\alpha_i,\alpha_i)[1\otimes e_{i,k},C_{\beta+\alpha_i}]\}.$$

We apply Lemma VII.2 to obtain the result. The other case is similar. □

Proposition VII.5: We have

$$\Phi_{23}(C_{13})\cdot C_{23}=(\Delta\otimes 1)(C),\tag{68}$$

$$\Phi_{12}(C_{13})\cdot C_{12}=(1\otimes\Delta)(C).\tag{69}$$

Proof:

$$\Phi_{23}(C_{13})=\sum_{\gamma\in Q^+}\theta(\gamma,\gamma)q^{(h_\gamma|h_\gamma)}(K_\gamma^{-1}\otimes K_\gamma^{-1}\otimes K_\gamma)(C_\gamma)_{13},$$

$$(\Phi_{23}(C_{13}))C_{23}=\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_\beta|h_\beta)}(K_\beta^{-1}\otimes K_\beta^{-1}\otimes K_\beta)$$
$$\times\sum_{\substack{\gamma,\delta\in Q^+\\ \gamma+\delta=\beta}}q^{-(h_\delta|h_\gamma)}(K_\delta\otimes 1\otimes 1)(C_\gamma)_{13}(C_\delta)_{23},$$

$$(\Delta\otimes 1)(C)=\sum_{\beta\in Q^+}\theta(\beta,\beta)q^{(h_\beta|h_\beta)}(K_\beta^{-1}\otimes K_\beta^{-1}\otimes K_\beta)(\Delta\otimes 1)(C_\beta).$$

The second case is done similarly. □

The propositions tell us that U is almost a pretriangular Hopf superalgebra.

Theorem VII.6: *The statements* $(P1)$ *and* $(P2)$ *hold in* $\hat{U}\hat{\otimes}\hat{U}$ *and the relations* $(P3)$–$(P6)$ *hold in* $\hat{U}\hat{\otimes}\hat{U}\hat{\otimes}\hat{U}$.

A weight module is *P-weighted* if all its weights belong to P. Notice $(P|P)\subset\mathbf{Z}$. This allows us to define $\mathfrak{Z}\in\mathrm{End}(V\otimes W)$ for any P-weighted $U_q(\mathfrak{g})$-modules V and W by setting,

$$\mathfrak{Z}(v\otimes w)=q^{(\mathrm{wt}(v)|\mathrm{wt}(w))}v\otimes w,\tag{70}$$

on homogeneous elements and extending by linearity. The map $\mathfrak{Z}$ is certainly invertible. There is a natural action of $U\otimes U$ on $V\otimes W$ and as endomorphisms on $V\otimes W$,

$$\Phi(a\otimes b)=\mathfrak{Z}\circ(a\otimes b)\circ\mathfrak{Z}^{-1},\tag{71}$$

for every $a\otimes b\in U\otimes U$.

Set $\mathbf{R}=\mathfrak{z}^{-1}C$. Then we finally have the following theorem.

Theorem VII.7: *Let $V_i(i=1,2,3)$ be P-weighted $U_q(\mathfrak{g})$ modules. As endomorphisms on $V_1\otimes V_2\otimes V_3$, when it can be defined,* $\mathbf{R}$ *satisfies the Yang–Baxter equation* (59).

Proof: From (P5) and Eq. (71), we have

$$\mathfrak{z}_{23}C_{13}\mathfrak{z}_{23}^{-1}C_{23}=(\Delta\otimes 1)(C), \tag{72}$$

$$\mathbf{R}_{13}\mathbf{R}_{23}=\mathfrak{z}_{13}^{-1}\mathfrak{z}_{23}^{-1}(\Delta\otimes 1)(C). \tag{73}$$

Applying $\sigma\otimes 1$ to both sides of (P5) and working as above, we get

$$\mathbf{R}_{23}\mathbf{R}_{13}=\mathfrak{z}_{23}^{-1}\mathfrak{z}_{13}^{-1}(\Delta'\otimes 1)(C). \tag{74}$$

The use of (P2) shows

$$\mathbf{R}_{23}\mathbf{R}_{13}\mathbf{R}_{12}=\mathfrak{z}_{23}^{-1}\mathfrak{z}_{13}^{-1}((\Delta'\otimes 1)(C))\mathbf{R}_{12} \tag{75}$$

$$=\mathfrak{z}_{23}^{-1}\mathfrak{z}_{13}^{-1}((\Delta'\otimes 1)(C))(\mathfrak{z}^{-1}C\otimes 1) \tag{76}$$

$$=\mathfrak{z}_{23}^{-1}\mathfrak{z}_{13}^{-1}(\mathfrak{z}^{-1}C\otimes 1)(\Delta\otimes 1)(C). \tag{77}$$

Now, the $\mathfrak{z}_{ij}$ commute with each other and (P3) with (71) says C_{12} commutes with $\mathfrak{z}_{13}^{-1}\mathfrak{z}_{23}^{-1}$, so we may use (73) to write

$$\mathfrak{z}_{23}^{-1}\mathfrak{z}_{13}^{-1}(\mathfrak{z}^{-1}C\otimes 1)(\Delta\otimes 1)(C)=\mathbf{R}_{12}\mathbf{R}_{13}\mathbf{R}_{23}. \tag{78}$$

Putting things together, we have the result. □

ACKNOWLEDGMENTS

(Received 25 March 1998; accepted for publication 22 February 1999)

Some time ago, Rideau and Winternitz introduced a realization of the quantum algebra $su_q(2)$ on a real two-dimensional sphere, or a real plane, and constructed a basis for its representations in terms of q-special functions, which can be expressed in terms of q-Vilenkin functions, and are related to little q-Jacobi functions, q-spherical functions, and q-Legendre polynomials. In their study, the values of q were implicitly restricted to $q \in \mathbb{R}^+$. In the present paper, we extend their work to the case of generic values of $q \in S^1$ (i.e., q values different from a root of unity). In addition, we unitarize the representations for both types of q values, $q \in \mathbb{R}^+$ and generic $q \in S^1$, by determining some appropriate scalar products. From the latter, we deduce the orthonormality relations satisfied by the q-Vilenkin functions. © *1999 American Institute of Physics.* [S0022-2488(99)01806-X]

I. INTRODUCTION

As is well known, most special functions of mathematical physics admit extensions to a base q, which are called q-special functions.[1–3] In the same way as Lie algebras and their representations provide a unifying framework for the former, quantum algebras[4] are relevant to the study of the latter (see, e.g., Ref. 5 and references quoted therein).

Some time ago, Rideau and Winternitz[6] introduced a realization of the quantum algebra $su_q(2)$ on a real sphere S^2 (or, via a stereographic projection, on a real plane), and constructed a basis for its irreducible representations (irreps) in terms of some functions $\Psi^J_{MNq}(\theta,\phi) \propto P^J_{MNq}(\cos\theta)\exp(-i(M+N)\phi)$. The functions $P^J_{MNq}(\cos\theta)$ were called q-Vilenkin functions because, for $q=1$, they reduce to functions $P^J_{MN}(\cos\theta)$ introduced by Vilenkin,[7,8] and related to Jacobi polynomials.

Rideau and Winternitz did establish various interesting results for the q-Vilenkin functions, including their recursion relations, explicit expression, generating function, and symmetry relations. They also compared them with other q-special functions, such as q-hypergeometric series, little q-Jacobi functions, q-spherical functions, and q-Legendre polynomials. Recently, the latter polynomials were further studied by Schmidt along similar lines.[9]

The realization of $su_q(2)$ on S^2, introduced by Rideau and Winternitz, was used by one of the present authors (MIA) to set up $su_q(2)$-invariant Schrödinger equations in the usual framework of quantum mechanics.[10] The corresponding radial equations can be easily solved for the ''free'' $su_q(2)$-invariant particle,[10] as well as for the Coulomb[10] and oscillator[11] potentials.

Although not explicitly stated in Ref. 6, the values of the deformation parameter q, considered there, are restricted to $q \in \mathbb{R}^+$. Close examination indeed shows that the explicit form of the

[a)]Electronic mail: mici@ccr.jussieu.fr
[b)]Directeur de recherches FNRS; electronic mail: cquesne@ulb.ac.be

function $Q_{Jq}(\eta)$, $\eta\equiv\cot^2(\theta/2)$, entering the definition of the q-Vilenkin functions,[6] is not valid for half-integer J values, whenever q runs over the unit circle.

Though important both from the q-special function viewpoint, and from that of their applications in quantum mechanics, the question of the $\mathrm{su}_q(2)$ irrep unitarity was also left unsolved by Rideau and Winternitz. They only noticed[6] that their realization of $\mathrm{su}_q(2)$ on S^2 is not unitary with respect to the scalar product used to unitarize the corresponding realization of su(2), and that a new scalar product should therefore be determined to cope with this drawback.

The purpose of the present paper is twofold: first, to find a solution for $Q_{Jq}(\eta)$ for generic $q\in S^1$ (i.e., for q different from a root of unity), and second, to unitarize the representations for both $q\in\mathbb{R}^+$, and generic $q\in S^1$. As a consequence, the explicit orthonormality relations of the q-Vilenkin and related functions will be established.

In Sec. II, the representations of $\mathrm{su}_q(2)$ on S^2, derived by Rideau and Winternitz, are briefly reviewed. The function $Q_{Jq}(\eta)$ is determined in Sec. III. The unitarization of the representations is dealt with in Sec. IV. Section V contains the conclusion.

II. REPRESENTATIONS OF $\mathrm{su}_q(2)$ ON S^2

Let us consider functions $f(\theta,\phi)$ on a sphere S^2, defined by $x_0^2+y_0^2+z_0^2=\frac{1}{4}$. These functions can also be viewed as functions on a real plane, via the stereographic projection $x=x_0/(\frac{1}{2}-z_0)$, $y=y_0/(\frac{1}{2}-z_0)$. In terms of spherical coordinates on S^2 and polar ones on the plane, we have

$$x_0=\tfrac{1}{2}\sin\theta\cos\phi,\quad y_0=\tfrac{1}{2}\sin\theta\sin\phi,\quad z_0=\tfrac{1}{2}\cos\theta,$$

$$x=\rho\cos\phi,\quad y=\rho\sin\phi,\quad \rho=\cot\frac{\theta}{2}, \tag{2.1}$$

$$0\leqslant\theta\leqslant\pi,\quad 0\leqslant\phi<2\pi,\quad 0\leqslant\rho<\infty.$$

Instead of the real variables x and y, one can use complex ones

$$z=x+iy=\rho e^{i\phi},\quad \overline{z}=x-iy=\rho e^{-i\phi}. \tag{2.2}$$

Functions $f(\theta,\phi)$ on S^2 can thus be projected onto functions $f(\rho,\phi)$ on the real plane, or functions $f(z,\overline{z})$ of a complex variable and its conjugate.

The $\mathrm{su}_q(2)$ generators H_3, H_+, H_- satisfy the commutation relations[4]

$$[H_3,H_\pm]=\pm H_\pm,\quad [H_+,H_-]=[2H_3]_q\equiv\frac{q^{2H_3}-q^{-2H_3}}{q-q^{-1}}, \tag{2.3}$$

and the Hermiticity properties

$$H_3^\dagger=H_3,\quad H_\pm^\dagger=H_\mp, \tag{2.4}$$

where in Eq. (2.3), we assume $q=e^\tau\in\mathbb{R}^+$, or $q=e^{i\tau}\in S^1$ (but different from a root of unity). From H_3 and $H_\pm$, one can construct a Casimir operator

$$\mathcal{C}=H_+H_-+[H_3]_q[H_3-1]_q=H_-H_++[H_3]_q[H_3+1]_q, \tag{2.5}$$

such that $[\mathcal{C},H_3]=[\mathcal{C},H_\pm]=0$.

The generators H_3, H_+, H_- can be realized[6] by the following operators, acting on functions $f(z,\overline{z})$ or $f(\theta,\phi)$,

$$H_3=-z\partial_z+\overline{z}\partial_{\overline{z}}-N=i\partial_\phi-N,$$

$$H_+=-z^{-1}[T]_q q^{\overline{T}-(N/2)}-q^{T+(N/2)}\overline{z}[\overline{T}-N]_q, \tag{2.6}$$

$$H_- = z[T+N]_q q^{\overline{T}-N/2} + q^{T+(N/2)} \overline{z}^{-1} [\overline{T}]_q ,$$

where

$$T = z\partial_z = -\tfrac{1}{2}(\sin\theta\partial_\theta + i\partial_\phi), \quad \overline{T} = \overline{z}\partial_{\overline{z}} = -\tfrac{1}{2}(\sin\theta\partial_\theta - i\partial_\phi). \tag{2.7}$$

For future use, it is also convenient to write $H_\pm$ in terms of polar coordinates on the real plane as

$$H_\pm = \mp \frac{e^{\mp i\phi}}{q-q^{-1}} \left\{ \left(\rho + \frac{1}{\rho}\right) q^{\rho\partial_\rho \mp (N/2)} - \rho q^{\mp i\partial_\phi \pm (3N/2)} - \frac{1}{\rho} q^{\pm i\partial_\phi \mp (N/2)} \right\}. \tag{2.8}$$

Basis functions $\Psi^J_{MNq}(z,\overline{z})$ for the $(2J+1)$-dimensional irrep of $\mathrm{su}_q(2)$ satisfy the relations[4]

$$\begin{gathered} H_3 \Psi^J_{MNq} = M \Psi^J_{MNq}, \quad H_\pm \Psi^J_{MNq} = ([J\mp M]_q [J\pm M+1]_q)^{1/2} \Psi^J_{M\pm 1,Nq}, \\ \mathcal{C}\Psi^J_{MNq} = [J]_q [J+1]_q \Psi^J_{MNq}, \quad M = \{-J, -J+1, ..., J\}, \quad |N| \le J, \end{gathered} \tag{2.9}$$

where J, M and N are simultaneously integers or half-integers. Let us remark that, when $q \in S^1$, the existence of such a representation implies that the factorials do not vanish, hence that q is not a root of unity.

Following Rideau and Winternitz,[6] let us write $\Psi^J_{MNq}(z,\overline{z})$ as

$$\Psi^J_{MNq}(z,\overline{z}) = N^J_{MNq} Q_{Jq}(\eta) q^{-NM/2} R^J_{MNq}(\eta) \overline{z}^{M+N}, \quad \eta = z\overline{z}. \tag{2.10}$$

Here, N^J_{MNq} is a constant, which can be expressed as

$$\begin{gathered} N^J_{MNq} = C_{JNq} \left(\frac{[J+M]_q!}{[J-M]_q! [2J]_q!} \right)^{1/2}, \\ C_{JNq} = \frac{1}{\sqrt{2\pi}} \left(\frac{[J+N]_q! [2J+1]_q!}{[J-N]_q!} \right)^{1/2} \gamma(J,N,q), \end{gathered} \tag{2.11}$$

in terms of some yet undetermined normalization constant $\gamma(J,N,q)$, and q-factorials, defined by $[x]_q! \equiv [x]_q [x-1]_q \cdots [1]_q$ if $x \in \mathbb{N}^+$, $[0]_q! \equiv 1$, and $([x]_q!)^{-1} \equiv 0$ if $x \in \mathbb{N}^-$. Equation (2.10) also contains two functions of η, $Q_{Jq}(\eta)$ and $R^J_{MNq}(\eta)$. The latter is a polynomial, whose explicit form is given by

$$R^J_{MNq}(\eta) = [J-N]_q! [J-M]_q! \sum_k \frac{(-\eta)^k}{[k]_q! [J-M-k]_q! [J-N-k]_q! [M+N+k]_q!}, \tag{2.12}$$

the summation over k being restricted by the condition that all the factorials in the denominator be positive. The former is defined by the functional equation

$$Q_{Jq}(q^2\eta)(1+\eta) = Q_{Jq}(\eta)(1+q^{-2J}\eta), \tag{2.13}$$

whose solution, only determined up to an arbitrary multiplicative factor $f_{Jq}(\eta)$ such that

$$f_{Jq}(q^2\eta) = f_{Jq}(\eta), \tag{2.14}$$

will be discussed in detail for both $q \in \mathbb{R}^+$, and generic $q \in S^+$, in the next section.

In terms of spherical coordinates, Eq. (2.10) becomes[6]

$$\Psi^J_{MNq}(\theta,\phi) = C_{JNq} \left(\frac{[J-N]_q!}{[J+N]_q! [2J]_q!} \right)^{1/2} i^{-2J+M+N} q^{-NM/2} P^J_{MNq}(\cos\theta) e^{-i(M+N)\phi}, \tag{2.15}$$

where

$$P^J_{MNq}(\xi)=i^{2J-M-N}\left(\frac{[J+M]_q![J+N]_q!}{[J-M]_q![J-N]_q!}\right)^{1/2}\eta^{(M+N)/2}Q_{Jq}(\eta)R^J_{MNq}(\eta),$$
$$\xi=\cos\theta,\quad \eta=\frac{1+\xi}{1-\xi}=\cot^2\frac{\theta}{2}, \tag{2.16}$$

are q-Vilenkin functions. For integer J values, the functions $\Psi^J_{M0q}(\theta,\phi)$ are proportional to q-spherical harmonics, while $P_{Jq}(\xi)\equiv P^J_{M0q}(\xi)$ are q-analogs of Legendre polynomials.

In the $q\to1$ limit, the $\mathrm{su}_q(2)$ realization (2.6) goes over into the su(2) realization

$$H_3=-z\partial_z+\bar{z}\partial_{\bar{z}}-N,\quad H_+=-\partial_z-\bar{z}^2\partial_{\bar{z}}+N\bar{z},\quad H_-=z^2\partial_z+\partial_{\bar{z}}+Nz, \tag{2.17}$$

the constant $\gamma(J,N,q)$ into $\gamma(J,N,1)=1$, and the q-Vilenkin functions into ordinary ones $P^J_{MN}(\xi)$. The latter are given by Eq. (2.16), where $[x]_q\to x$, and $Q_{Jq}(\eta)\to Q_J(\eta)=(1+\eta)^{-J}$. The operators (2.17) satisfy Eq. (2.4), and the functions Ψ^J_{MN}, $J=|N|,|N|+1,\ldots$, $M=-J,-J+1,\ldots,J$, form an orthonormal set with respect to the scalar product

$$\langle\psi_1|\psi_2\rangle=2\int\frac{dz\,d\bar{z}}{(1+z\bar{z})^2}\overline{\psi_1(z,\bar{z})}\psi_2(z,\bar{z})=\frac{1}{2}\int_0^\pi d\theta\sin\theta\int_0^{2\pi}d\phi\,\overline{\psi_1(\theta,\phi)}\psi_2(\theta,\phi), \tag{2.18}$$

where the integral over z, $\bar{z}$ extends over the whole complex plane.

III. DETERMINATION OF $Q_{Jq}(\eta)$

Following Rideau and Winternitz,[6] as a solution of Eq. (2.13), we may consider the function

$$Q_{Jq}(\eta)={}_1\Phi_0(q^{2J};-;q^2,-q^{-2J}\eta)={}_1\Phi_0(q^{-2J};-;q^{-2},-q^{-2}\eta), \tag{3.1}$$

where ${}_1\Phi_0$ is a basic hypergeometric series in the notations of Ref. 3.

For $q\in\mathbb{R}^+$, use of the q-binomial theorem[3] leads to the expressions

$$Q_{Jq}(\eta)=\prod_{k=0}^{\infty}\frac{(1+q^{2k}\eta)}{(1+q^{-2J+2k}\eta)} \tag{3.2}$$

if $0<q<1$, and

$$Q_{Jq}(\eta)=\prod_{k=0}^{\infty}\frac{(1+q^{-2J-2k-2}\eta)}{(1+q^{-2k-2}\eta)} \tag{3.3}$$

if $q>1$. For integer J values, both expressions reduce to the inverse of a polynomial,

$$Q_{Jq}(\eta)=\prod_{k=0}^{J-1}\left(\frac{1}{1+\eta q^{-2J+2k}}\right), \tag{3.4}$$

whereas for half-integer J values, we are left with convergent infinite products.

For generic $q\in S^1$ and integer J values, Eq. (3.4) still remains a valid solution of Eq. (2.13). However, for half-integer J values, the infinite products contained in Eqs. (3.2) and (3.3), as well as other expressions of ${}_1\Phi_0$ in terms of infinite series or products, found in Refs. 1 and 3, are divergent. We therefore have to look for another solution to Eq. (2.13).

For such a purpose, let us linearize Eq. (2.13) into

$$K_{Jq}(q^2\eta)-K_{Jq}(\eta)=\ln\frac{1+q^{-2J}\eta}{1+\eta}, \tag{3.5}$$

by setting

$$K_{Jq}(\eta)=\ln Q_{Jq}(\eta). \tag{3.6}$$

In terms of the operator $X\equiv\eta\partial_\eta$, Eq. (3.5) can be rewritten as

$$(q^{2X}-1)K_{Jq}(\eta)=(q^{-2JX}-1)\ln(1+\eta). \tag{3.7}$$

Let us consider the difference equation

$$(q^X-q^{-X})L_q(\eta)\equiv L_q(q\eta)-L_q(q^{-1}\eta)=\ln(1+\eta). \tag{3.8}$$

If we are able to find a solution to the latter, then

$$K_{Jq}(\eta)\equiv q^{-X}(q^{-2JX}-1)L_q(\eta)=L_q(q^{-2J-1}\eta)-L_q(q^{-1}\eta) \tag{3.9}$$

will be a solution of Eq. (3.7).

We will now proceed to demonstrate the following.

Lemma III.1: For $0<\eta<\infty$, and $q=e^{i\tau}$ different from a root of unity, the function

$$L_q(\eta)=\frac{1}{2\pi i}\int_0^\infty\frac{dt}{t(1+t)}\ln(1+\eta t^{\tau/\pi}),\quad if\ \ 0<\tau<\pi, \tag{3.10}$$

$$L_q(\eta)=-\frac{1}{2\pi i}\int_0^\infty\frac{dt}{t(1+t)}\ln(1+\eta t^{-\tau/\pi}),\quad if -\pi<\tau<0, \tag{3.11}$$

is a solution of Eq. (3.8).

Proof: We note that if some function $L_q(\eta)$ is a solution of Eq. (3.8) for $q=e^{i\tau}$, $0<\tau<\pi$, then $-L_{q^{-1}}(\eta)$ is also a solution of the same. Hence, Eq. (3.11) directly results from Eq. (3.10). It is also a simple matter to show that the integral on the right-hand side of Eq. (3.10) is convergent. It therefore only remains to prove that the latter satisfies Eq. (3.8). For such a purpose, we have to separately consider the integral when η is replaced by $\eta e^{i\tau}$, or by $\eta e^{-i\tau}$.

Let us introduce a function $M(v)$ of a complex variable v, defined by

$$M(v)=[v(1+v)]^{-1}\ln(1+\eta e^{-i\tau}v^{\tau/\pi}), \tag{3.12}$$

where on the right-hand side, there appear two multivalued functions $v^{\tau/\pi}$, and $\ln w$, where $w=1+\eta e^{-i\tau}v^{\tau/\pi}$.

For the function $v^{\tau/\pi}$, let us choose a branch cut along the positive real axis, so that $v^{\tau/\pi}=|v^{\tau/\pi}|\exp(i\tau\alpha/\pi)$, where $v=|v|\exp(i\alpha)$, and $0<\alpha<2\pi$. On the two sides of such a cut, the argument of the logarithm on the right-hand side of Eq. (3.12) takes the values

$$w_+=1+\eta e^{-i\tau}|v|^{\tau/\pi}\quad \text{if } \operatorname{Re}v>0, \operatorname{Im}v=+0, \tag{3.13}$$

and

$$w_-=1+\eta e^{i\tau}|v|^{\tau/\pi}\quad \text{if } \operatorname{Re}v>0, \operatorname{Im}v=-0, \tag{3.14}$$

respectively.

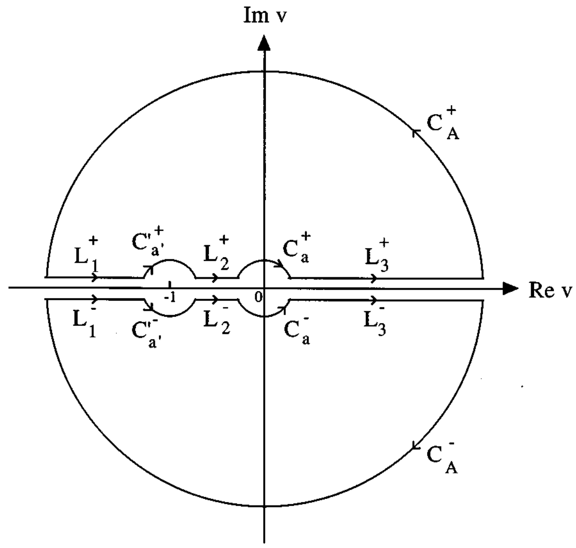

FIG. 1. Contours in the complex v plane used in the proof of Lemma III.1.

Considering next the function $\ln w$, it is easy to show that its branch point at $w=0$ and its branch cut along the negative real axis in the complex w plane cannot be reached within the truncated v plane, since the condition $\exp[i\tau(\alpha/\pi-1)]=-1$ cannot be fulfilled for $0<\tau<\pi$, and $0<\alpha<2\pi$.

Hence, when integrating the function $M(v)$ in the complex v plane, one should consider contours avoiding the branch point $v=0$, the branch cut $\mathrm{Re}\, v>0$, $\mathrm{Im}\, v=0$, and the simple pole at $v=-1$. Let us consider the two vanishing coutour integrals

$$\int_{\Gamma^+} M(v)dv = \int_{\Gamma^-} M(v)dv = 0, \tag{3.15}$$

where Γ^+ and Γ^- are the paths in the upper and lower halves of the v plane, displayed on Fig. 1. The former consists of the upper half C_A^+ of a large circle of radius A centered at the origin, and described in the counterclockwise sense, the upper halves C_a^+, $C'^+_{a'}$ of two small circles of radius a, a', centered at $v=0$ and $v=-1$, respectively, both described in the clockwise sense, and three straight lines L_1^+, L_2^+, L_3^+ lying just above the real axis, and going from $-A$ to $-1-a'$, from $-1+a'$ to $-a$, and from a to A, respectively. The latter path Γ^- is defined in a similar way.

Taking now Eqs. (3.13) and (3.14) into account, we obtain

$$2\pi i(L_q(q\eta)-L_q(q^{-1}\eta)) = \lim_{\substack{a\to 0\\ A\to\infty}} \left\{ \int_{L_3^-} M(v)dv - \int_{L_3^+} M(v)dv \right\}. \tag{3.16}$$

Owing to Eq. (3.15), each of the integrals on the right-hand side of Eq. (3.16) can be rewritten in terms of integrals along the other parts of the path Γ^- or Γ^+. Those along L_1^+ (resp. L_2^+) and L_1^- (resp. L_2^-) obviously cancel. Furthermore,

$$\lim_{A\to\infty} \left| \int_{C_A^+} M(v)dv - \int_{C_A^-} M(v)dv \right| \sim \lim_{A\to\infty} \frac{\ln A}{A} = 0, \tag{3.17}$$

and

$$\lim_{a\to 0}\left|\int_{C_a^+} M(v)dv - \int_{C_a^-} M(v)dv\right| \sim \lim_{a\to 0} a^{\tau/\pi} = 0, \tag{3.18}$$

so that

$$2\pi i(L_q(q\eta) - L_q(q^{-1}\eta)) = -\int_{C'_{a'}} M(v)dv = -2\pi i \operatorname{Res} M(-1) = 2\pi i \ln(1+\eta), \tag{3.19}$$

where $C'_{a'}$ denotes the circle of radius a' centered at $v=-1$, and described in the counterclockwise sense. Equation (3.19) completes the proof. ■

The results of the present section can be collected into the following.

Proposition III.2: The function $Q_{Jq}(\eta)$, appearing on the right-hand side of Eq. (2.10), is given by Eq. (3.4) for integer J values, and either $q \in \mathbb{R}^+$ or generic $q \in S^1$, and by Eqs. (3.2) and (3.3) for half-integer J values, and $q \in \mathbb{R}^+$. For half-integer J values, and generic $q \in S^1$, it can be expressed as

$$Q_{Jq}(\eta) = \exp\{L_q(q^{-2J-1}\eta) - L_q(q^{-1}\eta)\}, \tag{3.20}$$

where $L_q(\eta)$ admits the integral representation given in Lemma III.1.

IV. UNITARIZATION OF THE REPRESENTATIONS OF $su_q(2)$ ON S^2

In the present section, we will determine a new scalar product $\langle \psi_1 | \psi_2 \rangle_q$ that unitarizes the realization (2.6) of $su_q(2)$, and goes over into the old one $\langle \psi_1 | \psi_2 \rangle$, defined in Eq. (2.18), whenever $q \to 1$. For such a purpose, we shall first impose that Eq. (2.4) is satisfied by the realization (2.6) with respect to $\langle \psi_1 | \psi_2 \rangle_q$. The residual arbitrariness in the measure will then be lifted by demanding that $\langle \psi_1 | \psi_2 \rangle_q$ satisfies the usual properties of a scalar product.

We shall successively consider hereunder the cases where $q \in \mathbb{R}^+$, and generic $q \in S^1$.

A. The case where $q \in \mathbb{R}^+$

Let us make the following ansatz for $\langle \psi_1 | \psi_2 \rangle_q$,

$$\langle \psi_1 | \psi_2 \rangle_q = \int_0^\infty d\rho \int_0^{2\pi} d\phi \Big(\overline{A_q \psi_1(\rho,\phi,q)} f_1(\rho,q) q^{a_1 \rho \partial_\rho} \psi_2(\rho,\phi,q) + \overline{\psi_1(\rho,\phi,q)} f_2(\rho,q) q^{a_2 \rho \partial_\rho} A_q \psi_2(\rho,\phi,q) \Big), \tag{4.1}$$

in terms of the polar coordinates ρ, ϕ on the real plane, defined in Eq. (2.1). Here a_1, a_2, and $f_1(\rho,q)$, $f_2(\rho,q)$ are some yet undetermined constants and functions of the indicated arguments, respectively, and $A_q \equiv q^{-2q\partial_q}$ is the operator that changes q into q^{-1}, when acting on any function of q,

$$A_q \psi(\rho,\phi,q) = \psi(\rho,\phi,q^{-1}). \tag{4.2}$$

It is easy to check that

$$\langle \psi_1 | H_3 \psi_2 \rangle_q = \langle H_3 \psi_1 | \psi_2 \rangle_q \tag{4.3}$$

with respect to (4.1). Let us now impose the condition

$$\langle \psi_1 | H_+ \psi_2 \rangle_q = \langle H_- \psi_1 | \psi_2 \rangle_q . \tag{4.4}$$

By combining Eqs. (2.6) and (4.1), the left-hand side of this condition can be written as

$$\langle \psi_1 | H_+ \psi_2 \rangle_q = (q-q^{-1})^{-1} \int_0^\infty d\rho \int_0^{2\pi} d\phi \Big\{ \overline{\psi_1(\rho,\phi,q^{-1})} f_1(\rho,q) e^{-i\phi}$$
$$\times \left(-\left(q^{a_1}\rho + \frac{1}{q^{a_1}\rho} \right) q^{\rho\partial_\rho - (N/2)} + q^{a_1}\rho q^{-i\partial_\phi + (3N/2)} + \frac{1}{q^{a_1}\rho} q^{i\partial_\phi - (N/2)} \right)$$
$$\times \psi_2(q^{a_1}\rho,\phi,q) - \overline{\psi_1(\rho,\phi,q)} f_2(\rho,q) e^{-i\phi} \left(-\left(q^{a_2}\rho + \frac{1}{q^{a_2}\rho} \right) q^{-\rho\partial_\rho + (N/2)} \right.$$
$$\left. + q^{a_2}\rho q^{i\partial_\phi - (3N/2)} + \frac{1}{q^{a_2}\rho} q^{-i\partial_\phi + (N/2)} \right) \psi_2(q^{a_2}\rho,\phi,q^{-1}) \Big\}. \tag{4.5}$$

After integrating by parts and making some straightforward transformations, it becomes

$$\langle \psi_1 | H_+ \psi_2 \rangle_q = (q-q^{-1})^{-1} \int_0^\infty d\rho \int_0^{2\pi} d\phi e^{-i\phi} \Big\{ -\Big(\Big(q^{a_1-1}\rho + \frac{1}{q^{a_1-1}\rho} \Big)$$
$$\times f_1(q^{-1}\rho,q) q^{-\rho\partial_\rho - 1 - (N/2)} \overline{\psi_1(\rho,\phi,q^{-1})} \Big) \psi_2(q^{a_1}\rho,\phi,q)$$
$$+ \Big(\Big(\rho q^{i\partial_\phi + a_1 + 1 + (3N/2)} + \frac{1}{\rho} q^{-i\partial_\phi - a_1 - 1 - (N/2)} \Big) \overline{\psi_1(\rho,\phi,q^{-1})} \Big)$$
$$\times f_1(\rho,q) \psi_2(q^{a_1}\rho,\phi,q) + \Big(\Big(q^{a_2+1}\rho + \frac{1}{q^{a_2+1}\rho} \Big)$$
$$\times f_2(q\rho,q) q^{\rho\partial_\rho + 1 + (N/2)} \overline{\psi_1(\rho,\phi,q)} \Big) \psi_2(q^{a_2}\rho,\phi,q^{-1})$$
$$- \Big(\Big(\rho q^{-i\partial_\phi + a_2 - 1 - (3N/2)} + \frac{1}{\rho} q^{i\partial_\phi - a_2 + 1 + (N/2)} \Big) \overline{\psi_1(\rho,\phi,q)} \Big)$$
$$\times f_2(\rho,q) \psi_2(q^{a_2}\rho,\phi,q^{-1}) \Big\}. \tag{4.6}$$

On the other hand, for real q values the right-hand side of Eq. (4.4) can be written as

$$\langle H_- \psi_1 | \psi_2 \rangle_q = (q-q^{-1})^{-1} \int_0^\infty d\rho \int_0^{2\pi} d\phi e^{-i\phi}$$
$$\times \Big\{ \Big(\Big\{ -\Big(\rho + \frac{1}{\rho} \Big) q^{-\rho\partial_\rho - (N/2)} + \rho q^{i\partial_\phi + (3N/2)} + \frac{1}{\rho} q^{-i\partial_\phi - (N/2)} \Big\} \overline{\psi_1(\rho,\phi,q^{-1})} \Big)$$
$$\times f_1(\rho,q) \psi_2(q^{a_2}\rho,\phi,q) + \Big(\Big\{ \Big(\rho + \frac{1}{\rho} \Big) q^{\rho\partial_\rho + (N/2)} - \rho q^{-i\partial_\phi - (3N/2)}$$
$$- \frac{1}{\rho} q^{i\partial_\phi + (N/2)} \Big\} \overline{\psi_1(\rho,\phi,q)} \Big) f_2(\rho,q) \psi_2(q^{a_2}\rho,\phi,q^{-1}) \Big\}. \tag{4.7}$$

It now remains to equate the right-hand side of Eq. (4.6) with that of Eq. (4.7). Both of them being some linear combinations of four different types of terms, containing one of the operators $q^{-i\partial_\phi}$, $q^{i\partial_\phi}$, $q^{-\rho\partial_\rho}$, or $q^{\rho\partial_\rho}$, acting on some function, respectively, it is sufficient to separately equate such terms. The conditions on the first two classes of terms impose that

$$a_1 = -1, \quad a_2 = 1, \tag{4.8}$$

while those on the last two lead to the equations

$$q^{-1}\left(q^{-2}\rho+\frac{1}{q^{-2}\rho}\right)f_1(q^{-1}\rho,q)=\left(\rho+\frac{1}{\rho}\right)f_1(\rho,q),$$
$$q\left(q^{2}\rho+\frac{1}{q^{2}\rho}\right)f_2(q\rho,q)=\left(\rho+\frac{1}{\rho}\right)f_2(\rho,q), \tag{4.9}$$

whose solutions are given by

$$f_1(\rho,q)=\frac{B_1(q)q^{-1}\rho}{(1+\rho^2)(1+q^{-2}\rho^2)},\quad f_2(\rho,q)=\frac{B_2(q)q\rho}{(1+\rho^2)(1+q^{2}\rho^2)}, \tag{4.10}$$

in terms of two undetermined constants $B_1(q)$, and $B_2(q)$.

Let us now further restrict the sesquilinear form (4.1), where substitutions (4.8) and (4.10) have been made, by imposing that it is Hermitian, i.e.,

$$\overline{\langle\psi_1|\psi_2\rangle_q}=\langle\psi_2|\psi_1\rangle_q. \tag{4.11}$$

By a straightforward calculation, similar to that carried out for condition (4.4), it can be shown that Eq. (4.11) leads to the relation

$$B_2(q)=\overline{B_1(q)}. \tag{4.12}$$

As a consequence, there only remains a single undetermined constant $B(q)\equiv B_1(q)$ in Eq. (4.1). At this stage, it is important to notice that had we only considered a single term, instead of two, in Eq. (4.1), it would have been impossible to fulfill condition (4.11).

In addition, we remark that Eqs. (4.4) and (4.11) imply that

$$\langle\psi_1|H_-\psi_2\rangle_q=\langle H_+\psi_1|\psi_2\rangle_q. \tag{4.13}$$

Hence, all the Hermiticity conditions (2.4) on the $\mathrm{su}_q(2)$ generators are satisfied by the form defined in Eqs. (4.1), (4.8), (4.10), and (4.12). The functions $\Psi^J_{MNq}(z,\overline{z})$, defined in Eq. (2.10), and corresponding to a fixed N value, but different J and/or M values, are therefore orthogonal with respect to such a form.

To make $\langle\psi_1|\psi_2\rangle_q$ into a scalar product, it only remains to impose that it is a positive definite form. Since we also want that in the resulting Hilbert space, the functions Ψ^J_{MNq} with given J and N values, and $M=-J,\ -J+1,...,J,$ form an orthonormal basis for the $\mathrm{su}_q(2)$ irrep characterized by J, a condition that combines both requirements is

$$\langle\Psi^J_{MNq}|\Psi^J_{MNq}\rangle_q=1,\quad M=-J,-J+1,...,J. \tag{4.14}$$

By using Eqs. (2.5) and (2.9) for $M\neq J$, Eq. (4.14) can be transformed into the condition

$$\langle\Psi^J_{JNq}|\Psi^J_{JNq}\rangle_q=1. \tag{4.15}$$

In Appendix A, the squared norm of Ψ^J_{JNq} is calculated by using Eqs. (2.10), (2.11), (2.12), (3.2), and (3.3), and by taking Eqs. (4.1), (4.8), (4.10), and (4.12) into account. The resulting condition (4.15) reads

$$\frac{\ln q}{q-q^{-1}}\Big(B(q)\overline{\gamma(J,N,q^{-1})}\gamma(J,N,q)+\overline{B(q)\ \gamma(J,N,q)}\gamma(J,N,q^{-1})\Big)=1. \tag{4.16}$$

Since in the limit $q\rightarrow 1$, $\gamma(J,N,q)\rightarrow 1$, we may choose

$$\gamma(J,N,q)=1, \quad B(q)=\overline{B(q)}=\frac{q-q^{-1}}{2\ln q}=\frac{\sinh\tau}{\tau}. \tag{4.17}$$

For $q\to 1$ or $\tau\to 0$, we find that $B(q)\to 1$, so that $\langle\psi_1|\psi_2\rangle_q\to\langle\psi_1|\psi_2\rangle$, where the latter is given by Eq. (2.18), as it should be.

The results obtained can be summarized as follows:

Proposition IV.1: For $q\in\mathbb{R}^+$, the scalar product

$$\langle\psi_1|\psi_2\rangle_q=\frac{q-q^{-1}}{2\ln q}\int dz d\bar{z}\Bigg(\overline{\psi_1(z,\bar{z},q^{-1})}\frac{1}{(1+z\bar{z})(1+q^{-2}z\bar{z})}q^{-z\partial_z-\bar{z}\partial_{\bar{z}}-1}\psi_2(z,\bar{z},q)$$
$$+\overline{\psi_1(z,\bar{z},q)}\frac{1}{(1+z\bar{z})(1+q^2 z\bar{z})}q^{z\partial_z+\bar{z}\partial_{\bar{z}}+1}\psi_2(z,\bar{z},q^{-1})\Bigg), \tag{4.18}$$

or

$$\langle\psi_1|\psi_2\rangle_q=\frac{q-q^{-1}}{8\ln q}\int_0^{\pi}d\theta\sin\theta\int_0^{2\pi}d\phi$$
$$\times\Bigg(\overline{\psi_1(\theta,\phi,q^{-1})}\frac{1}{\sin^2(\theta/2)+q^{-2}\cos^2(\theta/2)}q^{\sin\theta\partial_\theta-1}\psi_2(\theta,\phi,q)$$
$$+\overline{\psi_1(\theta,\phi,q)}\frac{1}{\sin^2(\theta/2)+q^{2}\cos^2(\theta/2)}q^{-\sin\theta\partial_\theta+1}\psi_2(\theta,\phi,q^{-1})\Bigg), \tag{4.19}$$

unitarizes the $\mathrm{su}_q(2)$ realization (2.6), where N may take any integer or half-integer value. The functions $\Psi^J_{MNq}(z,\bar{z})$, or $\Psi^J_{MNq}(\theta,\phi)$, defined in Eqs. (2.10) and (2.15), where $J=|N|, |N|+1,\ldots, M=-J, -J+1,\ldots,J$, and $\gamma(J,N,q)=1$, form an orthonormal set with respect to such a scalar product.

From Proposition IV.1, we easily obtain the following corollary.

Corollary IV.2: For $q\in\mathbb{R}^+$, the q-Vilenkin functions $P^J_{MNq}(\xi)$, defined in Eq. (2.16), satisfy the orthonormality relation

$$\frac{q-q^{-1}}{4\ln q}\int_{-1}^{+1}d\xi\Bigg(\overline{P^{J'}_{MNq^{-1}}(\xi)}\frac{1}{q+q^{-1}-(q-q^{-1})\xi}q^{(\xi^2-1)\partial_\xi}P^J_{MNq}(\xi)$$
$$+\overline{P^{J'}_{MNq}(\xi)}\frac{1}{q+q^{-1}+(q-q^{-1})\xi}q^{-(\xi^2-1)\partial_\xi}P^J_{MNq^{-1}}(\xi)\Bigg)=\frac{\delta_{J',J}}{[2J+1]_q}. \tag{4.20}$$

B. The case where $q\in S^1$

Whenever $q\in S^1$, the ansatz (4.1) does not work, because though Eq. (4.6) remains valid, Eq. (4.7) is changed in such a way that both cannot be matched. Let us therefore change Eq. (4.1) into the following ansatz

$$\Big\langle\psi_1\Big|\psi_2\Big\rangle_q=\int_0^\infty d\rho\int_0^{2\pi}d\phi\Big(\overline{\psi_1(\rho,\phi,q)}f_1(\rho,q)q^{a_1\rho\partial_\rho}\psi_2(\rho,\phi,q)$$
$$+\overline{A_q\psi_1(\rho,\phi,q)}f_2(\rho,q)q^{a_2\rho\partial_\rho}A_q\psi_2(\rho,\phi,q)\Big), \tag{4.21}$$

where a_1, a_2, $f_1(\rho,q)$, $f_2(\rho,q)$, and A_q keep the same meaning as before.

Condition (4.3) is again automatically satisfied. Turning now to condition (4.4), it is easy to see that Eqs. (4.6) and (4.7) remain valid, except for the interchange of $\overline{\psi_1(\rho,\phi,q)}$ with $\overline{\psi_1(\rho,\phi,q^{-1})}$. Hence, Eq. (4.4) is also fulfilled by choosing a_1, a_2, $f_1(\rho,q)$, and $f_2(\rho,q)$ as given in Eqs. (4.8), and (4.10).

A difference with the case where $q\in\mathbb{R}^+$ appears when imposing the Hermiticity condition (4.11). The latter is now equivalent to the relations

$$\overline{B_1(q)}=B_1(q), \quad \overline{B_2(q)}=B_2(q), \tag{4.22}$$

showing that the real constants $B_1(q)$, and $B_2(q)$ remain independent. In the present case, keeping only one of the two terms on the right-hand side of Eq. (4.21) would therefore lead to a well-behaved scalar product.

As shown in Appendix B, condition (4.15) now reads

$$\frac{\ln q}{q-q^{-1}}(B_1(q)|\gamma(J,N,q)|^2+B_2(q)|\gamma(J,N,q^{-1})|^2)=1. \tag{4.23}$$

Among the infinitely many solutions of this equation, we may select the most symmetrical one,

$$\gamma(J,N,q)=1, \quad B_1(q)=B_2(q)=\frac{q-q^{-1}}{2\ln q}=\frac{\sin\tau}{\tau}. \tag{4.24}$$

Hence, whenever $q\to1$ or $\tau\to0$, the limit of $\langle\psi_1|\psi_2\rangle_q$ is again $\langle\psi_1|\psi_2\rangle$, as it should be.

In conclusion, we obtain the following proposition.

Proposition IV.3: For generic $q\in S^1$, the scalar product

$$\langle\psi_1|\psi_2\rangle_q=\frac{q-q^{-1}}{2\ln q}\int dz d\overline{z}\left(\overline{\psi_1(z,\overline{z},q)}\frac{1}{(1+z\overline{z})(1+q^{-2}z\overline{z})}q^{-z\partial_z-\overline{z}\partial_{\overline{z}}-1}\psi_2(z,\overline{z},q)\right.$$
$$\left.+\overline{\psi_1(z,\overline{z},q^{-1})}\frac{1}{(1+z\overline{z})(1+q^2z\overline{z})}q^{z\partial_x+\overline{z}\partial_{\overline{z}}+1}\psi_2(z,\overline{z},q^{-1})\right), \tag{4.25}$$

or

$$\langle\psi_1|\psi_2\rangle_q=\frac{q-q^{-1}}{8\ln q}\int_0^\pi d\theta\sin\theta\int_0^{2\pi}d\phi$$
$$\times\left(\overline{\psi_1(\theta,\phi,q)}\frac{1}{\sin^2(\theta/2)+q^{-2}\cos^2(\theta/2)}q^{\sin\theta\partial_\theta-1}\psi_2(\theta,\phi,q)\right.$$
$$\left.+\overline{\psi_1(\theta,\phi,q^{-1})}\frac{1}{\sin^2(\theta/2)+q^2\cos^2(\theta/2)}q^{-\sin\theta\partial_\theta+1}\psi_2(\theta,\phi,q^{-1})\right), \tag{4.26}$$

unitarizes the $\mathrm{su}_q(2)$ realization (2.6), where N may take any integer or half-integer value. The functions $\Psi^J_{MNq}(z,\overline{z})$, or $\Psi^J_{MNq}(\theta,\phi)$, defined in Eqs. (2.10) and (2.15), where $J=|N|,|N|+1,\ldots$, $M=-J,-J+1,\ldots,J$, and $\gamma(J,N,q)=1$, form an orthonormal set with respect to such a scalar product.

Corollary IV.4: For generic $q\in S^1$, the q-Vilenkin functions $P^J_{MNq}(\xi)$, defined in Eq. (2.16), satisfy the orthonormality relation

$$\frac{q-q^{-1}}{4\ln q}\int_{-1}^{+1}d\xi\left(\overline{P_{MNq}^{J'}(\xi)}\frac{1}{q+q^{-1}-(q-q^{-1})\xi}q^{(\xi^2-1)\partial_\xi}P_{MNq}^{J}(\xi)\right.$$
$$\left.+\overline{P_{MNq^{-1}}^{J'}(\xi)}\frac{1}{q+q^{-1}+(q-q^{-1})\xi}q^{-(\xi^2-1)\partial_\xi}P_{MNq^{-1}}^{J}(\xi)\right)=\frac{\delta_{J',J}}{[2J+1]_q}. \tag{4.27}$$

V. CONCLUSION

In the present paper, we did extend the study of the $\mathrm{su}_q(2)$ representations on a real two-dimensional sphere, carried out by Rideau and Winternitz,[6] in two ways.

First, we did prove that such representations exist not only for $q\in\mathbb{R}^+$, but also for generic $q\in S^1$. For such a purpose, we did provide an integral representation for the functions $Q_{Jq}(\eta)$, entering the definition of the q-Vilenkin functions, whenever J takes any half-integer value.

Second, we did unitarize the representations by determining appropriate scalar products for both ranges of q values. Such scalar products are expressed in terms of ordinary integrals, instead of q-integrals, as is usually the case.[5]

The resulting orthonormality relations for the q-Vilenkin and related functions should play an important role in applications to quantum mechanics, such as those considered in Refs. 10 and 11.

APPENDIX A: PROOF OF EQ. (4.16)

The purpose of this appendix is to evaluate the squared norm of the function $\Psi^J_{JNq}(z,\overline{z})$ when the scalar product (4.1) is used, and Eqs. (4.8), (4.10), and (4.12) are taken into account.

From Eqs. (2.2), (2.10), (2.11), and (2.12), Ψ^J_{JNq} can be written in polar coordinates as

$$\Psi^J_{JNq}=\frac{C_{JNq}}{[J+N]_q!}q^{-JN/2}Q_{Jq}(\rho^2)\rho^{J+N}e^{-i(J+N)\phi}. \tag{A1}$$

Its squared norm can therefore be expressed as

$$\langle\Psi^J_{JNq}|\Psi^J_{JNq}\rangle_q=\frac{\pi}{([J+N]_q!)^2}\left(B(q)\overline{C_{JNq^{-1}}}C_{JNq}q^{-J-N-1}\mathcal{I}_q+\overline{B(q)C_{JNq}}C_{JNq^{-1}}q^{J+N+1}\mathcal{I}_{q^{-1}}\right), \tag{A2}$$

in terms of the integral

$$\mathcal{I}_q=\int_0^\infty d\eta Q_{Jq^{-1}}(\eta)\frac{\eta^{J+N}}{(1+\eta)(1+q^{-2}\eta)}Q_{Jq}(q^{-2}\eta), \tag{A3}$$

and the same with q replaced by q^{-1}.

By introducing Eqs. (3.2) and (3.3) into Eq. (A3), we obtain

$$\mathcal{I}_q=\int_0^\infty d\eta\eta^{J+N}\prod_{k=0}^{\infty}\frac{(1+q^{2J+2k+2}\eta)}{(1+q^{-2J+2k-2}\eta)}=q^{2(J+1)(J+N+1)}\tilde{B}_{q^2}(J+N+1,J-N+1) \tag{A4}$$

if $0<q<1$, and

$$\mathcal{I}_q=\int_0^\infty d\eta\eta^{J+N}\prod_{k=0}^{\infty}\frac{(1+q^{-2J-2k-4}\eta)}{(1+q^{2J-2k}\eta)}=q^{-2J(J+N+1)}\tilde{B}_{q^{-2}}(J+N+1,J-N+1) \tag{A5}$$

if $q>1$. In Eqs. (A4) and (A5), we denote by $\tilde{B}_q(x,y)$ Ramanujan's continuous q-analog of the beta integral[2]

$$\tilde{B}_q(x,y)=\int_0^\infty dt\, t^{x-1}\prod_{k=0}^{\infty}\frac{(1+q^{x+y+k}t)}{(1+q^k t)},\quad 0<q<1, \tag{A6}$$

to distinguish it from the discrete q-analog of the same, known as $B_q(x,y)$ [see e.g. Eq. (1.11.7) of Ref. 3].

From Eq. (5.8) of Ref. 2, $\tilde{B}_q(x,y)$ is given for generic x values by

$$\tilde{B}_q(x,y)=\frac{\pi}{\sin \pi x}\prod_{k=1}^{\infty}\frac{(1-q^{k-x})(1-q^{x+y+k-1})}{(1-q^k)(1-q^{y+k-1})}. \tag{A7}$$

The values of x, which appear in Eqs. (A4) and (A5), being $x=J+N+1\in\mathbb{N}^+$, we have to calculate the limit of the right-hand side of Eq. (A7) when $x\to m\in\mathbb{N}^+$. Using L'Hospital's rule, we find

$$\lim_{x\to m}\frac{1-q^{m-x}}{\sin \pi x}=(-1)^m\frac{\ln q}{\pi},\quad m\in\mathbb{N}^+. \tag{A8}$$

Hence, for $x=m,\ y=n,\ m,n\in\mathbb{N}^+$, Eq. (A7) becomes

$$\tilde{B}_q(m,n)=(-1)^m(\ln q)\frac{\Pi_{k=1}^{m-1}(1-q^{k-m})}{\Pi_{k=1}^{m}(1-q^{n+k-1})}=\frac{(\ln q)q^{-m(n+m-1)/2}[m-1]_{q^{1/2}}![n-1]_{q^{1/2}}!}{(q^{1/2}-q^{-1/2})[n+m-1]_{q^{1/2}}!}, \tag{A9}$$

where in the last step, we introduced q-factorials, defined as in Sec. II.

From Eqs. (A4), (A5), and (A9), it follows that for any $q\in\mathbb{R}^+$

$$\mathcal{I}_q=\frac{2(\ln q)q^{J+N+1}[J+N]_q![J-N]_q!}{(q-q^{-1})[2J+1]_q!}. \tag{A10}$$

By taking Eq. (2.11) into account, the squared norm of Ψ^J_{JNq}, defined in Eq. (A2), therefore becomes

$$\langle\Psi^J_{JNq}|\Psi^J_{JNq}\rangle_q=\frac{\ln q}{q-q^{-1}}\left(B(q)\overline{\gamma(J,N,q^{-1})}\gamma(J,N,q)+\overline{B(q)\gamma(J,N,q)}\gamma(J,N,q^{-1})\right), \tag{A11}$$

which proves Eq. (4.16).

APPENDIX B: PROOF OF EQ. (4.23)

The purpose of this appendix is to evaluate the squared norm of the function $\Psi^J_{JNq}(z,\overline{z})$ when the scalar product (4.21) is used, and Eqs. (4.8), (4.10), and (4.22) are taken into account.

Since for $q\in S^1$, Ψ^J_{JNq} is still given by Eq. (A1), its squared norm reads

$$\langle\Psi^J_{JNq}|\Psi^J_{JNq}\rangle_q=\frac{\pi}{([J+N]_q!)^2}\left(B_1(q)|C_{JNq}|^2q^{-J-N-1}\mathcal{I}'_q+B_2(q)|C_{JNq^{-1}}|^2q^{J+N+1}\mathcal{I}'_{q^{-1}}\right). \tag{B1}$$

Here $\mathcal{I}'_q$ denotes the integral

$$\mathcal{I}'_q=\int_0^\infty d\eta F_{Jq}(\eta)\eta^{J+N} \tag{B2}$$

with

$$F_{Jq}(\eta)=\overline{Q_{Jq}(\eta)}\frac{1}{(1+\eta)(1+q^{-2}\eta)}Q_{Jq}(q^{-2}\eta). \tag{B3}$$

According to whether J is integer or half-integer, we have to insert Eq. (3.4) or Eq. (3.20) into Eq. (B3). In both cases, the result reads

$$F_{Jq}(\eta)=\prod_{p=0}^{2J+1}\frac{1}{1+q^{2J-2p}\eta}. \tag{B4}$$

This is obvious in the former case. In the latter, by using the property $\overline{L_q(\eta)}=-L_q(\eta)$, Eq. (B3) can be transformed into

$$\begin{aligned}F_{Jq}(\eta)&=\exp\{-L_q(q^{2J+1}\eta)+L_q(q\eta)\}\frac{1}{(1+\eta)(1+q^{-2}\eta)}\exp\{L_q(q^{-2J-3}\eta)-L_q(q^{-3}\eta)\}\\&=\frac{1}{(1+\eta)(1+q^{-2}\eta)}\exp\Bigg\{-\sum_{p=0}^{2J+1}[L_q(q^{2J+1-2p}\eta)-L_q(q^{2J-1-2p}\eta)]\\&\quad+[L_q(q\eta)-L_q(q^{-1}\eta)]+[L_q(q^{-1}\eta)-L_q(q^{-3}\eta)]\Bigg\}.\end{aligned} \tag{B5}$$

Repeated use of Eq. (3.8) for various arguments then directly leads to the searched for result (B4).

To evaluate $\mathcal{I}_q'$ for $F_{Jq}(\eta)$ given by Eq. (B4), we cannot use the same method as that employed in Appendix A to calculate $\mathcal{I}_q$, because in the q-analog of the beta integral, given in Eq. (A6), q is assumed real. Let us therefore rewrite the integrand of $\mathcal{I}_q'$ in the form

$$\eta^{J+N}F_{Jq}(\eta)=\sum_{p=0}^{2J+1}\frac{a_p^{(J)}}{\eta+q^{2p-2J}}, \tag{B6}$$

where the coefficient $a_p^{(J)}$ is the residue of $\eta^{J+N}F_{Jq}(\eta)$ at the pole $\eta=-q^{2p-2N}$, i.e.,

$$a_p^{(J)}=(-1)^{J+N}\frac{q^{J+1}}{(q-q^{-1})^{2J+1}}\times\frac{(-1)^p q^{N(2p-2J)}}{[p]_q![2J-p+1]_q!}. \tag{B7}$$

Then

$$G_{Jq}(\eta)\equiv\int d\eta F_{Jq}(\eta)\,\eta^{J+N}=(-1)^{J+N}\frac{q^{J+1}}{(q-q^{-1})^{2J+1}}\sum_{p=0}^{2J+1}\frac{(-1)^p q^{N(2p-2J)}}{[p]_q![2J-p+1]_q!}\ln(\eta+q^{2p-2J}). \tag{B8}$$

To calculate the values of $G_{Jq}(\eta)$ for $\eta\to\infty$ and $\eta=0$, the following identities[1] will be useful:

$$(1;\eta)_q^{2J+1}\equiv\sum_{p=0}^{2J+1}\begin{bmatrix}2J+1\\p\end{bmatrix}_q\eta^p=\prod_{p=0}^{2J}(1+q^{2p-2J}\eta), \tag{B9}$$

$$\frac{d}{d\eta}(1;\eta)_q^{2J+1}=\sum_{p=0}^{2J+1}\begin{bmatrix}2J+1\\p\end{bmatrix}_q p\,\eta^{p-1}=\sum_{p=0}^{2J}q^{2p-2J}\prod_{\substack{r=0\\r\neq p}}^{2J}(1+q^{2r-2J}\eta), \tag{B10}$$

where

$$\begin{bmatrix} n \\ p \end{bmatrix}_q \equiv \frac{[n]_q!}{[p]_q![n-p]_q!} \tag{B11}$$

is a q-binomial coefficient. From Eq. (B9), we obtain

$$(1;-q^{2N})_q^{2J+1} = \sum_{p=0}^{2J+1} (-1)^p \begin{bmatrix} 2J+1 \\ p \end{bmatrix}_q q^{2Np} = 0, \tag{B12}$$

because on the right-hand side, the factor $(1-q^{2p-2J+2N})$ vanishes for $p=J-N$. Similarly, from Eq. (B10), we get

$$\begin{aligned} \frac{d}{d\eta}(1;\eta)_q^{2J+1}\bigg|_{\eta=-q^{2N}} &= \sum_{p=0}^{2J+1} (-1)^{p-1} p \begin{bmatrix} 2J+1 \\ p \end{bmatrix}_q q^{2N(p-1)} \\ &= (-1)^{J+N}(q-q^{-1})^{2J}[J-N]_q![J+N]_q!q^{N(2J-1)}, \end{aligned} \tag{B13}$$

since on the right-hand side only the term corresponding to $p=J-N$ leads to a nonvanishing result.

By noting that for $\eta \gg 1$,

$$\ln(\eta + q^{2p-2J}) \simeq \ln(\eta) + \frac{q^{2p-2J}}{\eta} + O\left(\frac{1}{\eta^2}\right), \tag{B14}$$

it directly results from Eq. (B12) that

$$\lim_{\eta\to\infty} G_{Jq}(\eta) = 0. \tag{B15}$$

Furthermore, from Eqs. (B12) and (B13), we obtain

$$\begin{aligned} G_{Jq}(0) &= \frac{(-1)^{J+N} q^{J+1} \ln q}{(q-q^{-1})^{2J+1}} \sum_{p=0}^{2J+1} \frac{(-1)^p (2p-2J) q^{N(2p-2J)}}{[p]_q![2J-p+1]_q!} \\ &= \frac{2(-1)^{J+N} q^{J+1} \ln q}{[2J+1]_q!(q-q^{-1})^{2J+1}} \sum_{p=0}^{2J+1} (-1)^p p \begin{bmatrix} 2J+1 \\ p \end{bmatrix}_q q^{N(2p-2J)} \\ &= -\frac{2[J+N]_q![J-N]_q! q^{J+N+1} \ln q}{[2J+1]_q!(q-q^{-1})}. \end{aligned} \tag{B16}$$

By taking Eqs. (B8), (B15), and (B16) into account, we conclude that for generic $q \in S^1$, $\mathcal{I}_q'$, defined in Eq. (B2), is given by

$$\mathcal{I}_q' = \frac{2(\ln q) q^{J+N+1} [J+N]_q! [J-N]_q!}{(q-q^{-1})[2J+1]_q!}. \tag{B17}$$

By combining this result with Eqs. (2.11), (4.15), and (B1), Eq. (4.23) directly follows.

On an application of Crum–Krein transform to expansions in products of solutions of two Sturm–Liouville equations

E. Kh. Khristov
Department of Mathematics and Informatics, Sofia University, ''St. Kl. Ohridski,'' J. Bourchier 5, 1164 Sofia, Bulgaria

(Received 10 July 1998; accepted for publication 1 December 1998)

By using the Crum–Krein transform we construct explicit formulas allowing us to reduce the problem of expansions in products of solutions for two Sturm–Liouville problems on the semiaxis with general boundary conditions to the same problem for two Sturm–Liouville problems with zero boundary conditions. We also obtain the transformation formulas for the corresponding $\mathbf{\Lambda}$ operators. © *1999 American Institute of Physics.* [S0022-2488(99)01306-7]

I. INTRODUCTION

Let us consider two self-adjoint Sturm–Liouville problems with a spectral parameter $\lambda = k^2$ for the equations

$$y_n'' + (k^2 - v_n(x))y_n = 0, \quad 0 < x < \infty, \quad n = 1,2 \tag{1.1}$$

with boundary conditions

$$y_n'(0) - \gamma_n y_n(0) = 0 \quad ('=d/dx). \tag{1.2}$$

Here and below γ_n are finite real numbers and the real-valued potentials $v_n(x)$ belong to the space X_1, where

$$X_1 = \left\{ f(x): \int_0^\infty (1+x)|f(x)|dx < \infty \right\}.$$

The main purpose of this paper is the construction of transforms which allow one to obtain the expansions in products $Y(x,k) = y_1(x,k)y_2(x,k)$ of solutions of the problems (1.1), (1.2) and the operators associated with them, usually called $\mathbf{\Lambda}$ operators, starting from the problems

$$y_n'' + (k^2 - r_n(x))y_n = 0, \quad 0 < x < \infty, \quad n = 1,2, \tag{1.3}$$

$$y_n(0) = 0, \tag{1.4}$$

where $r_n(x) \in X_1$. For the problem (1.3), (1.4) the corresponding expansion formulas are well known and their proofs are simpler, see, e.g., Ref. 1. Combining the results in this paper with the previous ones[1–3] we obtain an algebraic scheme allowing us to reduce the problem of expansion in products of solutions for two radial Schrödinger equations (1.3) with $r_n^{(l)}(x) = l(l+1))x^{-2} + r_n(x)$, $l = 1,2,...$, as well as those connected with (1.1) and (1.2) to the simplest case $l = 0$ with a boundary condition $y_n(0) = 0$ and purely continuous spectrum. Let us note that each of the problems (1.1), (1.2) and (1.3), (1.4) can be treated separately for example using the method of contour integration.[1,4] In contrast with the case (1.3) and (1.4) the spectral problem for the Λ operator in the case (1.1) and (1.2) leads to nonlocal k-dependent boundary conditions. The method we present here avoids the above difficulties.

The interest in these topics is motivated mainly by the applications to the theory of the soliton equations, see, e.g., Refs. 5–8. It is also known[9] that the completeness of the products of solutions of two Sturm–Liouville problems plays an important role in various theorems concerning the associated direct and inverse problems. Articles 10–12 are among the first where expansion formulas in terms of the squared Sturm–Liouville or Zakharov–Shabat eigenstates are derived. Here we specifically mention paper 13, where expansions in products of solutions of two Sturm–Liouville problems with $v_n(x) \in L_{\mathrm{loc}}$ are considered (see also Ref. 1, where one can find a detailed bibliography and additional remarks about the spectral theory of Λ operators). As pointed out in Refs. 14 and 15, the solution of the inverse scattering problem by using the Gelfand–Levitan–Marchenko equation for the operator (1.1) and (1.2) is essentially different from that with a boundary condition $y(0)=0$, which is confirmed in the present work as well. In Refs. 16 and 17 it has been shown that by using Crum–Krein transform[18,19] the inverse problem for the operator (1.1) and (1.2) can be reduced to the inverse problem for the operator (1.3) and (1.4). Similar transforms on a finite interval have been systematically developed in Refs. 20 and 21 on the semiaxis such transforms have been well known since the pioneer works 17,19 and 22; see also Ref. 23 where, in particular, these results are stated in an operator language.

Let us introduce some notations which we shall use later on, and outline our main results. We denote by $\varphi_n(x,k)$ and $h_n(x,k)$ the regular and the Jost solutions of Eq. (1.3), which are defined by the conditions

$$\varphi_n(0,k)=0, \quad \varphi_n'(0,k)=1, \quad \lim_{x\to\infty} h_n(x,k)\exp(-ikx)=1 \quad (\operatorname{Im} k \geqslant 0),$$

and let $h_n(k)=h_n(0,k)=W(h_n,\varphi_n)(W(f,g)=fg'-f'g)$ be the characteristic function of the problem (1.3), (1.4). We also introduce the products $\Phi(x,k)=\varphi_1(x,k)\varphi_2(x,k)$, $H(x,k)=h_1(x,k)h_2(x,k)$, and $H(k)=H(0,k)=h_1(k)h_2(k)$. Furthermore, we define

$$\tilde{H}(x,k)=\frac{4}{\pi}k\,\operatorname{Im}\{H(x,k)H^{-1}(k)\}. \tag{1.5}$$

As a result we obtain

$$\tilde{H}(0,k)=0, \quad \tilde{H}'(0,k)=\frac{4}{\pi}\left\{\frac{k^2}{|h_1(k)|^2}+\frac{k^2}{|h_2(k)|^2}\right\}. \tag{1.6}$$

The following theorem deals with expansion formulas associated with the products $\Phi(x,k)$ and $H(x,k)$.[1]

Theorem 1.1: *Let the problems (1.3), (1.4) with purely continuous spectrum, i.e.,* $h_n(k)\neq 0$, $\operatorname{Im} k\geqslant 0$, $n=1,2$, *be given, and the functions* $\Phi(x,k)$ *and* $\tilde{H}(x,k)$ *be constructed as above. Then for any absolutely continuous function* $f\in X_1$ *we have*

$$f(x)=\int_0^\infty \tilde{H}(x,k)(f,\Phi'(k))dk, \quad f(x)=\int_0^\infty \Phi'(x,k)(f,\tilde{H}(k))dk. \tag{1.7}$$

If, in addition, $f\in L_1^0=\{f\in L_1=L_1(0,\infty):\int_0^\infty f(x)dx=0\}$ *then*

$$f(x)=-\int_0^\infty \tilde{H}'(x,k)(f,\Phi(k))dk, \tag{1.8}$$

where $(f,\Phi'(k))=\int_0^\infty f(x)\Phi'(x,k)dx$, *etc.*

Now in connection with the problem (1.1), (1.2) we denote by $\psi_n(x,k)$ and $f_n(x,k)$ the solutions of (1.1) for which

$$\psi_n(0,k)=1,\quad \psi_n'(0,k)=\gamma_n,\quad \lim_{x\to\infty} f_n(x,k)\exp(-ikx)=1(\operatorname{Im} k\geqslant 0),$$

and let $e_n(k)=f_n'(0,k)-\gamma_n f_n(0,k)=W(\psi_n,f_n)$ be the characteristic function of the problem (1.1), (1.2). Here we introduce the products $\Psi(x,k)=\psi_1(x,k)\psi_2(x,k)$, $F(x,k)=f_1(x,k)f_2(x,k)$, and $E(k)=e_1(k)e_2(k)$.

Let us also define the real space $\mathcal{N}=L_2(0,\infty)\oplus\mathbb{R}\ni\hat{f}=(f(x),\alpha)$ with a scalar product

$$(\hat{f},\hat{g})_1=(f,g)+\alpha\beta,\quad (f,g)=\int_0^\infty f(x)g(x)dx.$$

We will use that notation also in the case when $f\in X_1$ (or $f\in L_1$) and $g(x)\in L_\infty=L_\infty(0,\infty)$. We denote the corresponding spaces by $\mathcal{N}_1$ and $\mathcal{N}_\infty$. Let $C^k=C^k(0,\infty)$ be, as usual, the space of functions $f(x)$ with continuous kth derivatives and $C_0^k=C_0^k(0,\infty)$ be the space of functions $f(x)\in C^k$ such that $\lim_{x\to\infty} f^{(l)}(x)=0$, $l=0,1,\dots,k$. Let also $\mathcal{N}^k=C^k\oplus\mathbf{R}$, $\mathcal{N}_0^k=C_0^k\oplus\mathbf{R}$. Next, we introduce the functions from $\mathcal{N}_\infty$,

$$\hat{\tilde{F}}(x,k)=(\tilde{F}(x,k),\tilde{F}(0,k)),\quad \tilde{F}(x,k)=\frac{4}{\pi}k\operatorname{Im}\{F(x,k)E^{-1}(k)\} \tag{1.9}$$

and

$$\hat{\Psi}'(x,k)=(\Psi'(x,k),1/2). \tag{1.10}$$

Here the analog of Theorem 1.1 is the following theorem.[1,4]

Theorem 1.2: *Let the problems (1.1), (1.2) with purely continuous spectrum, i.e.,* $e_n(k)\neq 0$, $\operatorname{Im} k\geqslant 0$, $n=1,2$, *be given, and the functions* $\hat{\Psi}'(x,k)$ *and* $\hat{\tilde{F}}(x,k)$ *be constructed as above. Then for any function* $\hat{f}=(f(x),\alpha)\in\mathcal{N}_1$ *where* $f(x)$ *is absolutely continuous the following expansion formulas take place*:

$$\hat{f}=\int_0^\infty \hat{\tilde{F}}(x,k)(\hat{f},\hat{\Psi}'(k))_1\,dk,\quad \hat{f}=\int_0^\infty \hat{\Psi}'(x,k)(\hat{f},\hat{\tilde{F}}(k))_1\,dk, \tag{1.11}$$

and

$$f(x)=-\int_0^\infty \tilde{F}'(x,k)(f,\tilde{\Psi}(k))dk, \tag{1.12}$$

where $\tilde{\Psi}(x,k)=\Psi(x,k)-1/2$.

The article is organized in the following way. In Sec. I we show that the Crum operator

$$\mathcal{F}(\hat{v}_n;x)\overset{\text{def}}{=}v_n(x)-2\frac{d^2}{dx^2}\ln z_n(x)=r_n(x),\quad (\hat{v}_n=(v_n(x),\gamma_n)), \tag{1.13}$$

where $z_n(x)=\psi(x,k_0)$, $k_0=i\tau_0$, $\tau_0>0$ generates transforms which reduce the expansions in Theorem 1.2 to those in Theorem 1.1 and vice versa. In Sec. III, starting from some well-known results concerning $\mathbf{\Lambda}$ operators associated with the problems (1.3), (1.4), we construct a one-parameter family of $\mathbf{\Lambda}$ operators (τ_0 being the parameter) associated with (1.1), (1.2). The $\mathbf{\Lambda}$ operators obtained here do not coincide with the ones given in Ref. 4 even though they have the same decompositions of unity generated by the expansion formulas given in Theorem 1.2. In Sec. IV, some applications of our results to the scattering theory for the problem (1.1), (1.2) are given. In particular, here we show that if $\hat{v}_1=\hat{v}_2$ then the transform given in Sec. II can be obtained as a derivative of $\mathcal{F}(\hat{v};x)$ with respect to $\hat{v}$. Let us note that the restriction for a purely continuous spectrum of the problems considered is not essential in view of the results 1, 2 and is used only to keep the size of the paper reasonable. In Sec. V, the general case when a discrete spectrum exists is considered in brief. Some well-known results concerning the Sturm–Liouville problems considered, which we use below without reference, can be found in Refs. 15, 17, and 24.

II. TRANSFORM OF THE EXPANSION FORMULAS

The basis for our constructions as well as for those in Refs. 1–3 is the following lemma.

Lemma 2.1: Consider the equations

$$y_n''+(\lambda-v_n(x))y_n=0,\quad a<x<b,\quad n=1,2 \tag{2.1}$$

and construct the equations

$$y_n^{(1)''}+(\lambda-r_n(x))y_n^{(1)}=0,\quad r_n(x)=v_n(x)-2\,\frac{d^2}{dx^2}\ln z_n(x),$$

where $z_n(x)$ *are solutions of (2.1) for* $\lambda=\lambda_0$, $z_n(x)\neq 0$, $a<x<b$. *Then*

$$\begin{aligned} W(Z(x),Y(x,\lambda))&=(\lambda_0-\lambda)\frac{d}{dx}(Z(x)Y_1(x,\lambda)),\\ W(Z_1(x),Y_1(x,\lambda))&=(\lambda_0-\lambda)^{-1}\frac{d}{dx}(Z_1(x)Y(x,\lambda)), \end{aligned} \tag{2.2}$$

where $Y(x,\lambda)=y_1(x,\lambda)y_2(x,\lambda)$, $Y_1(x,\lambda)=y_1^{(1)}(x,\lambda)y_2^{(1)}(x,\lambda)$ *and* $Z(x)=z_1(x)z_2(x)$, $Z_1(x)=Z^{-1}(x)$.

Lemma 2.1 is a direct consequence of the well-known Crum's lemma[18] (see also Lemma 2.2 below) in view of the identity[8]

$$W(Y(x,\lambda),Z(x,\lambda_0))=\frac{1}{\lambda-\lambda_0}\frac{d}{dx}\prod_{n=1,2}W(y_n(x,\lambda),z_n(x,\lambda_0)).$$

Let us now consider, along with the problems (1.1), (1.2), the problems (1.3), (1.4) where $r_n(x)$ is defined as in (1.13). The following lemma has been obtained in Refs. 16 and 17.

Lemma 2.2. Let $z(x)=\psi(x,k_0)$ *be a solution of the Eq. (1.1) for* $k_0=i\tau_0$, $\tau_0>0$, $z(x)\neq 0$, $0\leq x<\infty$. *Then the potential* $r(x)$ *defined by (1.13) belongs to* X_1 *and the solutions* $\varphi(x,k)$ *and* $h(x,k)$ *of* (1.3) *are expressed via the solutions* $\psi(x,k)$ *and* $f(x,k)$ *as follows:*

$$\varphi(x,k)=\frac{W(z(x),\psi(x,k))}{(k_0^2-k^2)z(x)},\quad h(x,k)=\frac{W(z(x),f(x,k))}{i(k_0+k)z(x)} \tag{2.3}$$

and

$$h(k)=-i(k_0+k)^{-1}e(k). \tag{2.4}$$

Here $y(x)=z^{-1}(x)$ *is the solution of Eq. (1.3) for* $k=k_0$,

$$y(x)\sim Ce^{ik_0x},\quad x\to\infty, \tag{2.5}$$

where C is a constant.

Let us denote as usual by $\mathcal{L}(X,Y)$ the space of bounded linear operators defined in X with values in Y. Now we introduce in the space $X=X_1$ (or $X=L_\infty$) the operators

$$\mathbf{A}f=f(x)=2Z(x)\int_x^\infty Y'(t)f(t)dt,\quad \tilde{\mathbf{A}}f=f(x)-2Z'(x)\int_x^\infty Y(t)f(t)dt,$$

where

$$Y(x)=Z^{-1}(x),\quad Z(x)=\Psi(x,k_0). \tag{2.6}$$

One can directly check that

$$\mathbf{A}Y=0,\quad \tilde{\mathbf{A}}Y'=0, \tag{2.7}$$

where the second equation follows from the first one due to $d\mathbf{A}f(x)/dx=\tilde{\mathbf{A}}f'(x)$. Also, (2.5) leads to $\mathbf{A},\tilde{\mathbf{A}}\in\mathcal{L}(X_1,X_1)$ (respectively, $\mathcal{L}(L_\infty,L_\infty)$). By using the operators $\mathbf{A}$ and $\tilde{\mathbf{A}}$ we construct operators $\hat{\mathbf{A}},\hat{\tilde{\mathbf{A}}}:X_1\to\mathcal{N}_1(L_\infty\to\mathcal{N}_\infty)$ in the following way:

$$\hat{\mathbf{A}}f=(\mathbf{A}f(x),2(Y',f)),\quad \hat{\tilde{\mathbf{A}}}f=(\tilde{\mathbf{A}}f(x),-(Y,f)). \tag{2.8}$$

Next, we introduce the operators

$$\mathbf{B}f=f(x)-2Y(x)\int_0^x Z'(t)f(t)dt,\quad \tilde{\mathbf{B}}f=f(x)+2Y'(x)\int_0^x Z(t)f(t)dt.$$

In view of (2.6) for the adjoint operators $\mathbf{B}^*$ and $\tilde{\mathbf{B}}^*$ we have

$$\mathbf{B}^*=\tilde{\mathbf{A}},\quad \tilde{\mathbf{B}}^*=\mathbf{A}. \tag{2.9}$$

Further on, we construct the operators $\hat{\mathbf{B}}$ and $\hat{\tilde{\mathbf{B}}}:\mathcal{N}_1\to X_1(\mathcal{N}_\infty\to L_\infty)$ via

$$\hat{\mathbf{B}}\hat{f}=\mathbf{B}f(x)-\alpha Y(x),\quad \hat{\tilde{\mathbf{B}}}\hat{f}=\tilde{\mathbf{B}}f(x)+2\alpha Y'(x). \tag{2.10}$$

From (2.7) and (2.9) it follows that

$$\hat{\tilde{\mathbf{A}}}=\hat{\tilde{\mathbf{B}}}^{-1},\quad \hat{\mathbf{A}}=\hat{\mathbf{B}}^{-1}. \tag{2.11}$$

The next theorem gives the general transformation formulas for the functions $\hat{\Psi}(x,k)$, $\hat{\tilde{F}}(x,k)$ and $\Phi(x,k)$, $\tilde{H}(x,k)$.

Theorem 2.1: *Let the problems (1.1), (1.2) and (1.3), (1.4) be connected by the transform (1.13). Then the following representations hold:*

$$\hat{\Psi}'(x,k)=(k_0^2-k^2)\hat{\tilde{\mathbf{A}}}\Phi'(x,k),\quad \hat{\tilde{F}}(x,k)=(k_0^2-k^2)^{-1}\hat{\mathbf{A}}\tilde{H}(x,k), \tag{2.12}$$

$$\Phi'(x,k)=(k_0^2-k^2)^{-1}\hat{\tilde{\mathbf{B}}}\hat{\Psi}'(x,k),\quad \tilde{H}(x,k)=(k_0^2-k^2)\hat{\mathbf{B}}\hat{\tilde{F}}(x,k). \tag{2.13}$$

Proof: From (2.11) it follows that the equalities in (2.13) are a direct consequence of (2.12). Let us prove (2.12). By using (2.2) with $Z_1=Y(x)$, $[Y(x)$ is defined by (2.6)], $Y_1(x,\lambda)=\Phi(x,k)$, $Y(x,\lambda)=\Psi(x,k)$ and the first of the formulas in (2.3) we get

$$W(Y(x),\Phi(x,k))=(k_0^2-k^2)^{-1}\frac{d}{dx}(Y(x)\Psi(x,k)).$$

After integrating from x to ∞ and having in mind (2.5) we obtain the first formula in (2.12). The second formula in (2.12) can be obtained in a similar way taking into account (2.4). □

Now we shall show how starting from the expansion formulas given in the Theorem 1.1 one can derive the corresponding expansions in Theorem 1.2 and vice versa. We explain in more detail only the transition (1.12)$\leftrightarrow$(1.8). The transitions (1.11)$\leftrightarrow$(1.7) could be obtained analogously and so we omit its proof here.

Proof of the transition (1.12)$\leftrightarrow$(1.8)*:* First we show how starting from the expansion in (1.8) one can obtain the one in (1.12). In order to do that we put $f(x)=\tilde{\mathbf{B}}g(x)-Y'(x)\int_0^\infty g(x)dx$ in (1.8). Evidently $f\in L_1^0$. Let us mention here that if $f(x)=-\int_x^\infty f'(t)dt,\ f'(x)\in X_1$, then

$$(\hat{f},\hat{\Psi}'(k))_1=\tfrac{1}{2}(\alpha-f(0))-(f',\tilde{\Psi}(k)). \tag{2.14}$$

Now we construct the function $\hat{G}_0(x)=(G(x)=-\int_x^\infty g(t)dt,G(0))$. From (2.13) and (2.14) we obtain

$$-(\hat{\mathbf{B}}\hat{G}_0,\Phi'(k))=((\hat{\mathbf{B}}\hat{G}_0)',\Phi(k))=(k_0^2-k^2)^{-1}(g,\tilde{\Psi}(k)).$$

Therefore, (1.8) leads to

$$\tilde{\mathbf{B}}g(x)-Y'(x)\int_0^\infty g(t)dt=-\int_0^\infty \tilde{H}'(x,k)(k_0^2-k^2)^{-1}(g,\tilde{\Psi}(k))dk. \tag{2.15}$$

By applying the operator $\tilde{\mathbf{A}}$ to both sides of (2.15) we obtain the expansion (1.12) in view of (2.7), and the representation $\tilde{F}'(x,k)=(k_0^2-k^2)^{-1}\tilde{\mathbf{A}}\tilde{H}'(x,k)$ which is a direct consequence of (2.12). In connection with deriving the expansion (1.8) from (1.12) it is sufficient to mention that from (2.13) it follows $(g,\Phi(k))=(k_0^2-k^2)^{-1}(\tilde{\mathbf{A}}g,\tilde{\Psi}(k))$ where $g(x)\in L_1^0$. □

Remark 2.1: It can be proved (see, e.g., Refs. 1 and 2) that the system $\{\Phi'(x,k),0<k<\infty\}$ is biorthogonal to the system $\{\tilde{H}(x,\mu),0<\mu<\infty\}$, i.e., if $k,\mu>0$ then there exists (in a distributional sense) the limit

$$(\tilde{H}(\mu),\Phi'(k))=\lim_{N\to\infty}\int_0^N \tilde{H}(x,\mu)\Phi'(x,k)dx=\frac{\sin 2N(\mu-k)}{\pi(\mu-k)}=\delta(\mu-k). \tag{2.16}$$

From the transformation formulas given in Theorem 2.1 and using the identity $(\hat{\mathbf{B}}\hat{f},\hat{\tilde{\mathbf{B}}}\hat{g})_1=(\hat{f},\hat{g})_1$, we have that

$$(\tilde{H}(k),\Phi'(\mu))=\frac{k_0^2-k^2}{k_0^2-\mu^2}(\hat{\tilde{F}}(k),\hat{\Psi}'(\mu))_1.$$

The last relation together with (2.16) shows that the system $\{\hat{\Psi}'(x,k),0<k<\infty\}$ is biorthogonal to the system $\{\hat{\tilde{F}}(x,\mu),0<\mu<\infty\}$ with respect to the scalar product $(\cdot,\cdot)_1$.

III. Λ OPERATORS FOR THE PROBLEMS (1.1), (1.2)

In the present section we construct the $\mathbf{\Lambda}$ operators for which the expansions given in Theorem 1.2 are decomposition of unity. We shall use some of the well-known results from the Λ operator theory related with the problem (1.3), (1.4) which we introduce in the beginning. The main result of this section is Theorem 3.2 below.

In Ref. 25 it has been shown that if one introduces the operator

$$\mathbf{\Lambda}_{x_0}=\frac{1}{4}\left[-\frac{d^2}{dx^2}+2s(r;x)-\int_{x_0}^x dt\, s_t(r;t)-\int_{x_0}^x dt\,\Delta(r;t)\int_{x_0}^t dz\,\Delta(r;z)\right],$$

where $s(r;x)=r_1(x)+r_2(x)$, $\Delta(r;x)=r_1(x)-r_2(x)$ then the product $Y(x,k)=y_1(x,k)y_2(x,k)$ of any two solutions y_n of (1.3) satisfies the equation

$$\mathbf{\Lambda}_{x_0} Y(x,k) = \lambda Y(x,k) + B(x_0;x,k), \quad \lambda = k^2, \tag{3.1}$$

where

$$B(x_0;x,k) = -\frac{1}{4}\Bigg[W(y_1(x),y_2(x))\Big|_{x=x_0} \int_{x_0}^{x} \Delta(r;t)\,dt + (2\lambda - s(r;x_0))Y(x_0,k) + 2y_1'(x_0,k)y_2'(x_0,k)\Bigg].$$

Now let us introduce the operators $\mathbf{\Lambda} = \mathbf{\Lambda}_{x_0=\infty}$, $\mathbf{\Lambda}^* = (d/dx)\mathbf{\Lambda}_{x_0=0}\int_0^x$, i.e.,

$$\mathbf{\Lambda} = \frac{1}{4}\left[-\frac{d^2}{dx^2} + 2s(r;x) + \int_x^\infty dt\, s_t(r;t) - \int_x^\infty dt\, \Delta(r;t) \int_t^\infty dz\, \Delta(r;z) \right],$$

$$\mathbf{\Lambda}^* = \frac{1}{4}\left[-\frac{d^2}{dx^2} + 2s(r;x) + s_x(r;x)\int_0^x dt - \Delta(r;x) \int_0^x dt\, \Delta(r;t) \int_0^t dz \right]$$

with a definition domain

$$\mathcal{D}(\mathbf{\Lambda}) = \mathcal{D}(\mathbf{\Lambda}^*) = (f(x): f(0)=0, f(x) \in C_0^2 \cap L^1).$$

Then the operator $\mathbf{\Lambda}^*$ is adjoint to $\mathbf{\Lambda}$, i.e.,

$$(\mathbf{\Lambda} f, g) = (f, \mathbf{\Lambda}^* g) \quad \text{for } f,g \in \mathcal{D}(\mathbf{\Lambda}). \tag{3.2}$$

It is well known[7,25] that the function $H(x,k)$ [as well as $\tilde{H}(x,k)$] is a solution of the equation

$$\mathbf{\Lambda} H(x,k) = k^2 H(x,k), \quad \operatorname{Im} k \geqslant 0, \tag{3.3}$$

where $\tilde{H}(x,k)$ satisfies the boundary conditions (1.6). Similarly, the function $\Phi(x,k)$ solves the equation

$$\mathbf{\Lambda}^* \Phi'(x,k) = k^2 \Phi'(x,k), \tag{3.4}$$

with boundary conditions $\Phi(0,k) = \Phi'(0,k) = 0$, $\Phi''(0,k) = 2$.

These equations together with Theorem 1.1 show[1] that the expansions (1.7) are decompositions of unity for the operators $\mathbf{\Lambda}$ and $\mathbf{\Lambda}^*$, i.e.,

$$\mathbf{\Lambda} f(x) = -\int_0^\infty k^2 \tilde{H}(x,k)(f, \Phi'(k))\,dk \quad \text{for } f(x) \in \mathcal{D}(\mathbf{\Lambda}), \tag{3.5}$$

$$\mathbf{\Lambda}^* f(x) = -\int_0^\infty k^2 \Phi'(x,k)(f, \tilde{H}(k))\,dk \quad \text{for } f(x) \in \mathcal{D}(\mathbf{\Lambda}). \tag{3.6}$$

Let us now introduce the operators

$$\hat{\mathbf{\Lambda}}^* = \hat{\tilde{\mathbf{A}}}\mathbf{\Lambda}^*\hat{\tilde{\mathbf{B}}} \equiv \hat{\tilde{\mathbf{B}}}^{-1}\mathbf{\Lambda}^*\hat{\tilde{\mathbf{B}}}, \quad \hat{\mathbf{\Lambda}} = \hat{\mathbf{A}}\mathbf{\Lambda}\hat{\mathbf{B}} \equiv \hat{\mathbf{B}}^{-1}\mathbf{\Lambda}\hat{\mathbf{B}}, \tag{3.7}$$

acting in the space $\mathcal{N}_0^2(\mathcal{N}_\infty^2)$ according to

$$\hat{\mathbf{\Lambda}}^* \hat{f} = (\tilde{\mathbf{A}}\mathbf{\Lambda}^*\tilde{\mathbf{B}} f(x) + 2\alpha \tilde{\mathbf{A}}\mathbf{\Lambda}^* Y'(x), -(Y, \mathbf{\Lambda}^*\tilde{\mathbf{B}} f) - 2\alpha(Y, \mathbf{\Lambda}^* Y')), \tag{3.8}$$

$$\hat{\mathbf{\Lambda}} \hat{f} = (\mathbf{A}\mathbf{\Lambda}\mathbf{B} f(x) - \alpha \mathbf{A}\mathbf{\Lambda} Y(x), 2(Y', \mathbf{\Lambda}\mathbf{B} f) - 2\alpha(Y', \mathbf{\Lambda} Y)). \tag{3.9}$$

From (3.2) it follows that

$$(\hat{\mathbf{\Lambda}}\hat{f},\hat{g})_1=(\hat{f},\hat{\mathbf{\Lambda}}^*\hat{g})_1 \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}), \quad \hat{g}\in\mathcal{D}(\mathbf{\Lambda}^*),$$

where $\mathcal{D}(\hat{\mathbf{\Lambda}})=\hat{\mathbf{B}}\mathcal{D}(\mathbf{\Lambda})$ and $\mathcal{D}(\hat{\mathbf{\Lambda}}^*)=\hat{\hat{\mathbf{B}}}\mathcal{D}(\mathbf{\Lambda})$, i.e.,

$$\mathcal{D}(\hat{\mathbf{\Lambda}})=(\hat{f}\in\mathcal{N}_0^2 : f(0)=\alpha, f(x)\in C_0^2\cap L^1),$$

$$\mathcal{D}(\hat{\mathbf{\Lambda}}^*)=(\hat{f}\in\mathcal{N}_0^2 : f(0)=2(\gamma_1+\gamma_2)\alpha, f(x)\in C_0^2\cap L^1).$$

Now, having in mind Theorem 2.1, it is easy to obtain from Eqs. (3.3), (3.4) and decompositions (3.5), (3.6) the following theorem.

Theorem 3.1: *Let the operators* $\hat{\mathbf{\Lambda}}^*,\hat{\mathbf{\Lambda}}$ *be constructed as in (3.7). Then:* (i) *The function* $\hat{\hat{F}}(x,k)$ *defined by (1.9) is a solution of the equation*

$$\hat{\mathbf{\Lambda}}\hat{\hat{F}}(x,k)=k^2\hat{\hat{F}}(x,k)$$

and $\hat{\Psi}'(x,k)$ *defined by (1.10) is a solution of the equation*

$$\hat{\mathbf{\Lambda}}^*\hat{\Psi}'(x,k)=k^2\hat{\Psi}'(x,k)$$

with a boundary condition $\Psi'(0,k)=(\gamma_1+\gamma_2)\Psi(0,k)$, $(\Psi(0,k)=1)$.

(ii) *The expansion formulas (1.11) are decompositions of unity for the operators* $\hat{\mathbf{\Lambda}}^*$ *and* $\hat{\mathbf{\Lambda}}$, *i.e.,*

$$\hat{\mathbf{\Lambda}}^*\hat{f}=\int_0^\infty k^2\hat{\Psi}'(x,k)(\hat{f},\hat{\hat{F}}(k))_1 dk \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}^*), \tag{3.10}$$

$$\hat{\mathbf{\Lambda}}\hat{f}=\int_0^\infty k^2\hat{\hat{F}}(k,x)(\hat{f},\hat{\Psi}'(k))_1 dk \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}). \tag{3.11}$$

Next let us consider following Refs. 1 and 4 the operators

$$\hat{\mathbf{\Lambda}}_{\hat{v}}^*=\begin{pmatrix} \mathbf{\Lambda}_v^* & S^*(x) \\ -\frac{1}{4}\left.\frac{d}{dx}\right|_{x=0} & c^* \end{pmatrix}, \tag{3.12}$$

$$\hat{\mathbf{\Lambda}}_{\hat{v}}=\begin{pmatrix} \mathbf{\Lambda}_v & 0 \\ (\cdot,S^*)-\frac{1}{2}(\gamma_1+\gamma_2)\left.\frac{d}{dx}\right|_{x=0} & c^* \end{pmatrix}, \tag{3.13}$$

where $\mathbf{\Lambda}_v=\mathbf{\Lambda}_{x_0=\infty}$, $\mathbf{\Lambda}_v^*=(d/dx)\mathbf{\Lambda}_{x_0=0}\int_0^x$, $(r_n\to v_n)$ and $S^*(x)=\frac{1}{2}w(x)-\frac{1}{2}(\gamma_1-\gamma_2)\Delta(v;x)$, $c^*=\frac{1}{2}s(v;0)+\gamma_1\gamma_2$, $w(x)=s_x(v;x)-\Delta(v;x)\int_0^x\Delta(v;t)dt$. That is, for any function $\hat{f}\in\mathcal{N}_0^2(\mathcal{N}_\infty^2)$ we have

$$\hat{\mathbf{\Lambda}}_{\hat{v}}^*\hat{f}=(\mathbf{\Lambda}_v^*f(x)+\alpha S^*(x),\tfrac{1}{4}f'(0)+\alpha c^*)$$

and

$$\hat{\mathbf{\Lambda}}_{\hat{v}}\hat{f}=(\mathbf{\Lambda}_v f(x),(f,S^*)-\tfrac{1}{2}(\gamma_1+\gamma_2)f'(0)+\alpha c^*).$$

Then

$$\hat{\mathbf{\Lambda}}_{\hat{v}}^{*}\hat{f}=\int_0^\infty k^2\hat{\Psi}'(x,k)(\hat{f},\hat{\tilde{F}}(k))_1 dk \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}^*), \tag{3.14}$$

$$\hat{\mathbf{\Lambda}}_{\hat{v}}\hat{f}=\int_0^\infty k^2\hat{\tilde{F}}(k,x)(\hat{f},\hat{\Psi}'(k))_1 dk \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}). \tag{3.15}$$

Theorem 3.2: *Let the operators* $\hat{\mathbf{\Lambda}}^*,\hat{\mathbf{\Lambda}}$ *be constructed as in (3.7) and let the operators* $\hat{\mathbf{\Lambda}}_{\hat{v}}^*,\hat{\mathbf{\Lambda}}_{\hat{v}}$ *be defined as in (3.12), (3.13). Then:*

$$\hat{\mathbf{\Lambda}}^*\hat{f}=\hat{\mathbf{\Lambda}}_{\hat{v}}^*\hat{f} \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}^*), \quad \hat{\mathbf{\Lambda}}\hat{f}=\hat{\mathbf{\Lambda}}_{\hat{v}}\hat{f} \quad \text{for } \hat{f}\in\mathcal{D}(\hat{\mathbf{\Lambda}}), \tag{3.16}$$

where the explicit form of the operators $\hat{\mathbf{\Lambda}}$ *and* $\hat{\mathbf{\Lambda}}^*$ *in terms of* $v_n(x),\gamma_n$ *is given by the expressions*

$$\hat{\mathbf{\Lambda}}^*=\begin{pmatrix} \mathbf{\Lambda}_v^* & S^*(x) \\ -\frac{1}{4}\frac{d}{dx}\Big|_{x=0}+\frac{1}{4}(\gamma_1+\gamma_2)\Big|_{x=0} & c^*-\frac{1}{2}(\gamma_1+\gamma_2)^2 \end{pmatrix}, \tag{3.17}$$

$$\hat{\mathbf{\Lambda}}=\begin{pmatrix} \mathbf{\Lambda}_v & 0 \\ (\cdot,S^*)-\frac{1}{2}(\gamma_1+\gamma_2)\frac{d}{dx}\Big|_{x=0}+(c^*+\tau_0^2)|_{x=0} & -\tau_0^2 \end{pmatrix}. \tag{3.18}$$

Proof: By comparing (3.14), (3.15) with (3.10), (3.11) we obtain straightforwardly (3.16). In view of (2.5), Eq. (3.1) yields the equation

$$\hat{\mathbf{\Lambda}}Y(x)=-\tau_0^2 Y(x).$$

As a result, we find that

$$-\mathbf{A\Lambda}Y(x)=0, \quad -2(\mathbf{\Lambda}Y,Y')=-\tau_0^2, \quad -2(Y,\mathbf{\Lambda}^*Y')=\tfrac{1}{2}s(v;0)-\tfrac{1}{2}(\gamma_1^2+\gamma_2^2),$$

$$-(Y,\mathbf{\Lambda}^*\tilde{\mathbf{B}}g)=-\tfrac{1}{4}g'(0)+\tfrac{1}{4}(\gamma_1+\gamma_2)g(0),$$

and

$$2(Y',\mathbf{AB}f)=2(f,\tilde{\mathbf{A}}\mathbf{\Lambda}^*Y')-\tfrac{1}{2}(\gamma_1+\gamma_2)f'(0)+(\tau_0^2+\tfrac{1}{2}s(v;0)+\gamma_1\gamma_2)f(0).$$

By inserting these equalities in (3.8), (3.9) we obtain that if $g(0)=2(\gamma_1+\gamma_2)\beta$ then

$$-(Y,\mathbf{\Lambda}^*\tilde{\mathbf{B}}g)-2\beta(Y,\mathbf{\Lambda}^*Y'))=-\tfrac{1}{4}g'(0)+c^*\beta$$

and if $f(0)=\alpha$ then

$$2(Y',\mathbf{\Lambda B}f)-2\alpha(Y',\mathbf{\Lambda}Y))=(f,S^*)-\tfrac{1}{2}(\gamma_1+\gamma_2)f'(0)+c^*f(0).$$

Thus we obtain $S^*(x)=2\tilde{\mathbf{A}}\mathbf{\Lambda}^*Y'(x)$ since $f(x)$ is an arbitrary function in C_0^2. From here, in view of (3.16), we conclude due to the arbitrariness of $f(x)$ that $\Lambda_v^*=\tilde{\mathbf{A}}\mathbf{\Lambda}^*\tilde{\mathbf{B}}$, $\mathbf{\Lambda}_v=\mathbf{A\Lambda B}$. □

Remark 3.1: From the above Theorem one can see that the relations $\hat{\Lambda}\hat{f}=\hat{\Lambda}_{\hat{v}}\hat{f}$ and $\hat{\Lambda}^*\hat{f}=\hat{\Lambda}_{\hat{v}}^*\hat{f}$ do not hold in general (for an arbitrary function $\hat{f}$ in $\mathcal{N}_0^2$) since from (3.17), (3.18) it follows that the necessary and sufficient conditions for that are $-\tau_0^2=\frac{1}{2}s(v;0)+\gamma_1\gamma_2$, $\gamma_1+\gamma_2=0$.

IV. APPLICATIONS

In this section first we show that the operators generating the transforms in Sec. II are functional derivative of the operator (1.13),

$$\mathcal{F}(\hat{v};x) \overset{\text{def}}{=} v(x) - 2\frac{d^2}{dx^2}\ln z(x) = r(x), \tag{4.1}$$

where $z(x) = \psi(\hat{v};x,k_0) = \psi(x,k_0)$. The potential $\hat{v} = (v(x),\gamma)$, which determines the problem (1.1), (1.2) is considered as an element in the space $\mathcal{N}_1$, the potential $r(x)$ in (1.3) as an element in X_1 and $\mathcal{F}$ as an operator $\mathcal{F}:\mathcal{N}_1 \to X_1$. According to Lemma 2.2, the inverse to $\mathcal{F}(\hat{v};x)$ operator $\mathcal{G}(r;x):X_1 \to \mathcal{N}_1$, is given by the expression

$$\mathcal{G}(r;x) = \left(r(x) - 2\frac{d^2}{dx^2}\ln y(r;x), -\frac{d}{dx}\ln y(r;x)\bigg|_{x=0} \right), \tag{4.2}$$

where $y(r;x) = \psi^{-1}(\hat{v};x,k_0)$. The main result is the following.

Theorem 4.1: *At any point $\hat{v} \in \mathcal{N}_1$ there exists the derivative:*

$$\frac{d}{d\epsilon}\mathcal{F}(\hat{v}+\epsilon\hat{g};x)|_{\epsilon=0} = \frac{\partial \mathcal{F}}{\partial \hat{v}}\hat{g} = -\hat{\hat{\mathbf{B}}}\hat{g} \quad (\hat{g} = (g(x),\beta)), \tag{4.3}$$

where $\partial\mathcal{F}/\partial\hat{v} = (\partial\mathcal{F}/\partial v, \partial\mathcal{F}/\partial\gamma)$ and $\hat{\hat{\mathbf{B}}}$ is defined by (2.10) for $\hat{v}_1 = \hat{v}_2 = \hat{v}$. The operator $\mathcal{G}$ is differentiable at any point $r \in X_1$ and its derivative is

$$\frac{d}{d\epsilon}\mathcal{G}(r+\epsilon f;x)|_{\epsilon=0} = -\hat{\hat{\mathbf{A}}}f, \tag{4.4}$$

where $\hat{\hat{\mathbf{A}}}$ is defined by (2.8) with $r_1 = r_2 = r$.

Proof: Equation (4.1) yields

$$\frac{d}{d\epsilon}\mathcal{F}(v+\epsilon g,\gamma+\epsilon\beta;x)|_{\epsilon=0} = g(x) - 2\frac{d^2}{dx^2}\left(\psi^{-1}(\hat{v};x)\frac{\partial\psi(\hat{v};x)}{\partial v}g(x) \right) - \frac{d^2}{dx^2}\left(\psi^{-1}(\hat{v};x)\frac{\partial\psi(\hat{v};x)}{\partial\gamma}\beta \right). \tag{4.5}$$

In a standard way one obtains for any fixed k_0 and γ the following expression for the derivative:

$$\frac{\partial\psi(\hat{v};x,k_0)}{\partial v}g(x) = \psi(x,k_0)\int_0^x \psi^{-2}(t,k_0)\left(\int_0^t \psi^2(z,k_0)g(z)dz \right)dt.$$

Therefore,

$$-2\frac{d^2}{dx^2}\left(\psi^{-1}(x,k_0)\frac{\partial\psi(x,k_0)}{\partial v}g(x) \right) = -2Y'(x)\int_0^x Y^{-1}(t)g(t)dt - 2g(x). \tag{4.6}$$

In order to obtain

$$-2\frac{d^2}{dx^2}\left(\psi^{-1}(\hat{v};x,k_0)\frac{\partial\psi(\hat{v};x,k_0)}{\partial\gamma} \right) = -2Y'(x) \tag{4.7}$$

it remains to mention that $\partial\psi(\hat{v};x,k_0)/\partial\gamma=\psi(x,k_0)\int_0^x\psi^{-2}(t,k_0)dt$. Now we derive (4.3) by inserting (4.6) and (4.7) into the right-hand side of (4.5). The representation (4.4) is obtained in a similar manner. □

Let us denote by $\eta(\hat{v};k)$ the phase shift of the problem (1.1), (1.2) where $e(\hat{v};k)=|e(\hat{v};k)|\exp(i\eta(\hat{v};k))$ and by $\delta(r;k)$ the phase shift of the problem (1.3), (1.4) where $h(r;k)=|h(r;k)|\exp(i\delta(r;k))$. Then from (2.4) it follows that

$$\delta(\mathcal{F}(\hat{v});k)=\arctan\frac{k}{\tau_0}+\eta(\hat{v};k),\quad 0<k<\infty. \tag{4.8}$$

and

$$\rho(\mathcal{F}(\hat{v});k)=(k^2-k_0^2)\sigma(\hat{v};k), \tag{4.9}$$

where $\sigma(\hat{v};k)=(2/\pi)k^2|e(\hat{v};k)|^{-2}$ and $\rho(r;k)=(2/\pi)k^2|h(r;k)|^{-2}$ are the spectral density of the problems (1.1), (1.2) and (1.3), (1.4), respectively.

Now we recall (see, e.g., Ref. 24) that at any point $r\in X_1$ where $h(r;0)\neq 0$ there exists the derivative

$$\frac{\partial\delta(r;k)}{\partial r(x)}=\frac{k}{|H(r;k)|}\Phi(r;x,k). \tag{4.10}$$

Let us differentiate (4.8) with respect to $\hat{v}$. According to (4.3) we have

$$\left(\frac{\partial\delta(r;k)}{\partial r},\frac{\partial\mathcal{F}}{\partial\hat{v}}\hat{g}\right)=\left(\frac{\partial\eta(\hat{v};k)}{\partial\hat{v}},\hat{g}\right)_1, \tag{4.11}$$

where $\partial\eta(\hat{v};k)/\partial\hat{v}=(\partial\eta(\hat{v};k)/\partial v(x),\partial\eta(\hat{v};k)/\partial\gamma)$. By using the representations (2.12) and (4.9) we find that $\partial\eta(\hat{v};k)/\partial\hat{v}=k|E(\hat{v};k)|^{-1}(\Psi(\hat{v};x,k),1)$. Now let us replace $f(x)$ in the expansion (1.8) by $f(x)=\hat{\tilde{\mathbf{B}}}\hat{v}_t(x,t)$ where $\hat{v}(t)=(v(x,t),\gamma(t))$ is the family of differentiable in t potentials such that $\hat{v}_t=(v_t(x,t),\gamma_t(t))\in\mathcal{N}_1$. Having in mind (4.11) we obtain

$$\hat{\tilde{\mathbf{B}}}\hat{v}_t(x,t)=\int_0^\infty\chi'(x,k)\eta_t(\hat{v};k)dk, \tag{4.12}$$

where $\chi(x,k)=k^{-1}|H(k)|\tilde{H}(x,k)$, $\eta_t(\hat{v};k)=(\partial\eta(\hat{v};k)/\partial\hat{v},\hat{v}_t)_1$. The condition $r_t(x,t)=-\hat{\tilde{\mathbf{B}}}\hat{v}_t(x,t)\in L_1^0$ yields $I_{1,t}(\hat{v}(t))=0$, $I_1(\hat{v})=\gamma+\frac{1}{2}\int_0^\infty v(x)dx$. Note that I_1 determines[14] the asymptotics $\eta(\hat{v};k)=k^{-1}I_1(\hat{v})+o(k^{-1})$ as $k\to\infty$. Now we put $x=0$ in (4.12) and use (1.6) to obtain the trace formula

$$\frac{d}{dt}\{v(0,t)-2\gamma^2(t)\}=\frac{8}{\pi}\int_0^\infty k\eta_t(\hat{v};k)dk. \tag{4.13}$$

Note that (4.13) could be obtained directly from the well-known Faddeev–Newton[26,27] trace formula

$$r_t(0,t)=\frac{8}{\pi}\int_0^\infty k\delta_t(r;k)dk \tag{4.14}$$

by implementing (4.1). Let us here also make the remark that (4.14) follows from the expansion (1.8) with $f(x)=r_t(x,t)$, boundary conditions (1.6) and the expression (4.10) for $\partial\delta(r;k)/\partial r(x)$ in contrast to the formula (4.13) which is not a direct consequence of (1.12).

V. TRANSFORMS IN THE CASE OF A DISCRETE SPECTRUM

In this section is given a generalization of the scheme for deriving transforms proposed in Sec. II to the general case when we have a discrete spectrum. For the problem (1.3), (1.4) it is defined by the zeros of the characteristic function $h_n(k)$ at $\operatorname{Im} k>0$. We put

$$\sigma_n=\{k_{n,j}:h_n(k_{n,j})=0,k_{n,j}=i\tau_{n,j},\tau_{n,j}>0,\quad j=1,2,...,N_n\}$$

and $\sigma=\sigma_1\cup\sigma_2$, $\sigma''=\sigma_1\cap\sigma_2$, $\sigma'=\sigma\backslash\sigma''$. If $k_{n,j}\in\sigma'$ then we put

$$\tilde{H}_{n,j}(x)=-m_{n,j}H(x,k_{n,j}),\quad m_{n,j}=4k_{n,j}\dot{H}^{-1}(k_{n,j}),\quad (\dot{}=\partial/\partial k)$$

and with each $k_j\in\sigma''$ we associate a pair of functions

$$\tilde{H}_{j,1}(x)=-p_j(\dot{H}(x,k_j)+g_jH(x,k_j)),\tilde{H}_{j,2}(x)=-p_jH(x,k_j),$$

where $p_j=8k_j\ddot{H}^{-1}(k_j)$, $q_j=k_j^{-1}-\dddot{H}(k_j)(3\ddot{H}(k_j))^{-1}$. The analog of (1.7) here is the following expansion formula:[1]

$$f(x)=\int_0^\infty\tilde{H}(x,k)(f,\Phi'(k))dk+\Sigma_{k_{n,j}\in\sigma'}\tilde{H}_{n,j}(x)(f,\Phi'(k_{n,j}))$$
$$+\Sigma_{k_j\in\sigma''}\{\tilde{H}_{j,1}(x)(f,\Phi'(k_j))+\tilde{H}_{j,2}(x)(f,\dot{\Phi}'(k_j))\},\qquad(5.1)$$

where $f(x)$ is an absolutely continuous function in X_1.

In a similar way, for the problems (1.1), (1.2) we denote, as above; $\sigma_n=\{k_{n,j}:e_n(k_{n,j})=0,k_{n,j}=i\tau_{n,j},\tau_{n,j}>0,\quad j=1,2,...,N_n\}$ and $\sigma=\sigma_1\cup\sigma_2$, $\sigma''=\sigma_1\cap\sigma_2$, $\sigma'=\sigma\backslash\sigma''$. Note that under the condition (1.13) the spectrum σ_n of (1.1), (1.2) coincides with the spectrum σ_n of (1.3), (1.4) which can be seen from (2.4). Here we put

$$\hat{\tilde{F}}_{n,j}(x)=-a_{n,j}\hat{F}(x,k_{n,j}),\quad a_{n,j}=4k_{n,j}\dot{E}^{-1}(k_{n,j})\quad(k_{n,j}\in\sigma')$$

and

$$\hat{\tilde{F}}_{j,1}(x)=-b_j(\dot{\hat{F}}(x,k_j)+d_j\hat{F}(x,k_j)),\quad \hat{\tilde{F}}_{j,2}(x)=-b_j\hat{F}(x,k_j),$$

where $b_j=8k_j\ddot{E}^{-1}(k_j)$, $d_j=k_j^{-1}-\dddot{E}(k_j)(3\ddot{E}(k_j))^{-1}(k_j\in\sigma'')$.

The analog of (1.12) is the following expansion formula:[4]

$$\hat{f}=\int_0^\infty\hat{\tilde{F}}(x,k)(\hat{f},\hat{\Psi}'(k))_1dk+\Sigma_{k_{n,j}\in\sigma'}\hat{\tilde{F}}_{n,j}(x)(\hat{f},\hat{\Psi}'_{n,j})_1$$
$$+\Sigma_{k_j\in\sigma''}\{\hat{\tilde{F}}_{j,1}(x)(\hat{f},\hat{\Psi}'(k_j))_1+\hat{\tilde{F}}_{j,2}(x)(\hat{f},\dot{\hat{\Psi}}'(k_j))_1\},\qquad(5.2)$$

where $\hat{f}=(f(x),\alpha)\in\mathcal{N}_1$.

Here we sketch only the proof of the transition $(5.1)\rightarrow(5.2)$. Since the transform related to the continuous spectrum has already been obtained in Sec. II, here it is sufficient to consider only the transform of the expansion

$$f(x)=\tilde{H}_{j,1}(x)(f,\Phi'(k_j))+\tilde{H}_{j,2}(x)(f,\dot{\Phi}'(k_j))+\tilde{H}_{n,l}(x)(f,\Phi'(k_{n,l}))\qquad(5.3)$$

in order to derive (5.2) starting from (5.1). By using equality (2.4) where $\tau_0>\tau_{n,j}\tau_{n,j}\in\sigma$ we obtain that the coefficients $a_{n,j}=-(k_0+k_{n,j})^{-2}m_{n,j}$ $(k_{n,j}\in\sigma')$ and $b_j=-(k_0+k_j)^{-2}p_j$, $d_j=q_j-2(k_0+k_j)^{-1}(k_j\in\sigma'')$. Let us put in (5.3) $f=\hat{\mathbf{B}}\hat{g}$, $\hat{g}=(g(x),\beta)\in\mathcal{N}_1$. It follows from (2.13) that

$$(\hat{\mathbf{B}}\hat{g},\Phi'(k_{n,j}))=(k_0^2-k_{n,j}^2)^{-1}(\hat{g},\hat{\Psi}'(k_{n,j}))_1 \quad (k_{n,j}\in\sigma)$$

and

$$(\hat{\mathbf{B}}\hat{g},\dot{\Phi}'(k_j))=(k_0^2-k_j^2)^{-1}(\hat{g},\dot{\hat{\Psi}}'(k_j))_1+2k_j(k_0^2-k_j^2)^{-2}(\hat{g},\hat{\Psi}'(k_j))_1, \quad (k_j\in\sigma'').$$

Therefore, we obtain

$$\hat{\mathbf{B}}\hat{g}=\frac{k_0+k_j}{k_0-k_j}b_j\left(\dot{H}(x,k_j)+\left(d_j+\frac{2k_j}{k_0^2-k_j^2}\right)H(x,k_j)\right)(\hat{g},\hat{\Psi}'(k_j))_1$$
$$+\frac{k_0+k_j}{k_0-k_j}b_jH(x,k_j)(\hat{g},\dot{\hat{\Psi}}'(k_j))_1+\frac{k_0+k_{n,j}}{k_0-k_{n,l}}a_{n,l}H(x,k_{n,l})(\hat{g},\hat{\Psi}'(k_{n,l}))_1.$$

Finally, by applying the operator $\hat{\mathbf{A}}$, in view of (2.11) and (2.12) we come to

$$\hat{g}=\hat{\tilde{F}}_{j,1}(x)(\hat{g},\hat{\Psi}'(k_j))_1+\hat{\tilde{F}}_{j,2}(x)(\hat{g},\dot{\hat{\Psi}}'(k_j))_1+\hat{\tilde{F}}_{n,l}(x)(\hat{g},\hat{\Psi}'_{n,l})_1.$$

The case (5.2)→(5.1) can be treated just as above and so we omit the proof here.

(Received 8 June 1998; accepted for publication 4 November 1998)

The quantum supergroup $\mathrm{OSP}_q(1|2n)$ is studied systematically. A Haar functional is constructed, and an algebraic version of the Peter–Weyl theory is extended to this quantum supergroup. Quantum homogeneous superspaces and quantum homogeneous supervector bundles are defined following the strategy of Connes' theory. Parabolic induction is developed by employing the quantum homogeneous supervector bundles. Quantum Frobenius reciprocity and a generalized Borel–Weil theorem are established for the induced representations. © *1999 American Institute of Physics.* [S0022-2488(99)00205-4]

I. INTRODUCTION

Quantized universal enveloping algebras of Lie superalgebras were introduced in the late 1980s[1,2] to describe the type of supersymmetries exhibited by some two-dimensional statistical mechanics models.[3] Since then these quantum superalgebras have been intensively studied, leading to the development of an extensive theory on both the structure and representations. We mention in particular that the quasi-triangular Hopf superalgebraic structure of the quantum superalgebras was investigated in Ref. 4; the representation theory of the type I quantum superalgebras, the $\mathrm{gl}(m|n)$ super Yangians and the quantum affine superalgebras with symmetrizable Cartan matrices were developed in Ref. 5. The theory of quantum superalgebras had significant impact on a range of areas of physics and mathematics. Its applications to two-dimensional integrable models in statistical mechanics and quantum field theory were extensively explored in Refs. 1 and 6 and many other publications. The application to knot theory and three-manifolds[7,8] has yielded many new topological invariants, notably, the multi-parameter generalizations of Alexander–Conway polynomials.

The associated quantum supergroups are in contrast less studied in the literature. So far only the quantum supergroup $\mathrm{GL}_q(m|n)$ has been systematically investigated.[9] In Ref. 9, the structure and representation theories of $\mathrm{GL}_q(m|n)$ were developed. The irreducible covariant and contravariant tensorial representations were studied in detail within the framework of parabolic induction, resulting in a quantum Borel–Weil theorem for these representations. The aim of this paper is to treat the $\mathrm{osp}(1|2n)$ series of quantum supergroups at generic q.

The $\mathrm{osp}(1|2n)$ series of Lie superalgebras played an important role in the study of supersymmetry on de Sitter space.[10] These Lie superalgebras, especially $\mathrm{osp}(1|32)$, also featured prominently in recent developments of string theory. An Inonu–Wigner contraction of $\mathrm{osp}(1|32)$ yields the 11-dimensional Poincaré superalgebra with two and five form central charges, which is the underlying symmetry of M theory; the superalgebra $\mathrm{osp}(1|32)$ itself also plays an important role in the theory of supermembranes.[11] From a mathematical point of view, $\mathrm{osp}(1|2n)$ is also rather exceptional amongst all the finite-dimensional simple Lie superalgebras in that its Cartan matrix is symmetrizable, and the structure of its finite-dimensional representations is completely understood. In particular, it is known that all finite-dimensional representations are completely reducible.

Many properties of $\mathrm{osp}(1|2n)$ carry over to the quantum case when q is generic. It is particularly useful to recall that the Drinfeld version of $\mathrm{U}_q(\mathrm{osp}(1|2n))$ is, algebraically, a trivial deformation of $\mathrm{U}(\mathrm{osp}(1|2n))$ in the sense of Gerstenhaber. (This fact is known to experts, and may be easily inferred from results of Ref. 12.) Therefore, *finite-dimensional representations* of $\mathrm{U}_q(\mathrm{osp}(1|2n))$ *are also completely reducible*. This remains true for the Jimbo version of $\mathrm{U}_q(\mathrm{osp}(1|2n))$ at generic q. One way to see this is through the specialization of the indeterminate of the Drinfeld algebra to a generic complex parameter; the other is through the isomorphism between $\mathrm{U}_q(\mathrm{osp}(1|2n))$ and $U_{-q}(\mathrm{so}(2n+1))$ established by a kind of Bose–Fermi transmutation.[13] There is also an interesting connection between the representation theory of $\mathrm{U}_q(\mathrm{osp}(1|2n))$ and quantum para-statistics, details on which can be found in Ref. 14.

This paper will study structural and representation theoretical properties of the quantum supergroup $\mathrm{OSP}_q(1|2n)$, and also investigate its underlying geometries. This quantum supergroup will be defined by its superalgebra of functions, which is the $\mathbf{Z}_2$-graded Hopf algebra generated by the matrix elements of the vector representation of $\mathrm{U}_q(\mathrm{osp}(1|2n))$. Two major results in the structure theory are presented, namely, the existence of a left and right integral, which will be called a quantum Haar functional, and a quantum Peter–Weyl theorem.

Corresponding to each reductive subalgebra $\mathrm{U}_q(\mathbf{k})$ of $\mathrm{U}_q(\mathrm{osp}(1|2n))$, we introduce a quantum homogeneous superspace, which is defined by specifying its superalgebra of functions $\mathcal{A}_q^{\mathbf{k}}$. A quantum homogeneous supervector bundle over the quantum homogeneous superspace is induced from any given finite-dimensional $\mathrm{U}_q(\mathbf{k})$ module. We shall show that the space of sections $\Gamma_q^{\mathbf{k}}(V)$ of this bundle is projective and is of finite type both as a left and a right module over $\mathcal{A}_q^{\mathbf{k}}$. Therefore our definition of quantum homogeneous supervector bundles is consistent with the general definition of noncommutative vector bundles in Connes' theory.[15]

Quantum homogeneous supervector bundles will be applied to develop a theory of induced representations for $\mathrm{OSP}_q(1|2n)$. Amongst the results obtained are quantum versions of Frobenius reciprocity and the Borel–Weil theorem. The latter provides a concrete realization of finite-dimensional irreducible $\mathrm{OSP}_q(1|2n)$ representations in terms of quantum analogs of ''holomorphic'' sections of quantum homogeneous supervector bundles.

We wish to point out that in the context of Lie supergroups at the classical level, the mathematical theories of homogeneous superspaces and homogeneous supervector bundles were studied in Refs. 16 and 17. The development of a Bott–Borel–Weil theory was also initiated and extensively investigated by Penkov and co-workers.[17] However, complications arising from supermanifold geometry render these subjects very difficult to study. So far as we are aware, many aspects of the subjects remain to be fully developed. It seems that the Hopf algebraic approach developed here and in Ref. 9 is also worth exploring at the classical level, and is likely to provide a new method complementary to the geometric approach of Refs. 16 and 17.

The organization of the paper is as follows. In Sec. II we review some known facts about $\mathrm{U}_q(\mathrm{osp}(1|2n))$, which will be needed later. In Sec. III we study the quantum supergroup $\mathrm{OSP}_q(1|2n)$. In Sec. IV we investigate the quantum homogeneous superspaces and quantum homogeneous supervector bundles determined by this quantum supergroup, while the last section applies results of Sec. IV to study the representation theory of $\mathrm{OSP}_q(1|2n)$.

II. $\mathrm{U}_q(\mathrm{osp}(1|2n))$

This section reviews some known results on the quantized universal enveloping algebra $\mathrm{U}_q(\mathrm{osp}(1|2n))$. Let E be the n-dimensional Euclidean space spanned by the vectors ϵ_i, with the inner product (,) defined by $(\epsilon_i,\epsilon_j)=\delta_{ij}$. We can express the simple roots of the Lie superalgebra $\mathrm{osp}(1|2n)$ in terms of the ϵ's as

$$\alpha_i=\epsilon_i-\epsilon_{i+1},\quad i=1,2,\dots,n-1,\quad \alpha_n=\epsilon_n,$$

where α_n is the odd simple root. The Cartan matrix $A=(a_{ij})_{i,j=1}^n$ of $\mathrm{osp}(1|2n)$ is then given by $a_{ij}=2(\alpha_i,\alpha_j)/(\alpha_i,\alpha_i)$. An element $\mu\in E$ will be called integral if

$$l_i = \frac{2(\mu,\alpha_i)}{(\alpha_i,\alpha_i)} \in \mathbf{Z}, \quad \forall i<n, \quad l_n = \frac{(\mu,\alpha_n)}{(\alpha_n,\alpha_n)} \in \mathbf{Z},$$

and the set of all integral elements will be denoted by $\mathcal{P}$. (Note the unusual form of l_n.) Set $\mathcal{P}_+ = \{\mu \in \mathcal{P} | l_i, l_n \in \mathbf{Z}_+\}$. Elements of $\mathcal{P}_+$ will be called integral dominant.

The Jimbo version of the quantum superalgebra $\mathrm{U}_q(\mathrm{osp}(1|2n))$ is a $\mathbf{Z}_2$-graded complex associative algebra generated by $\{k_i^{\pm 1}, e_i, f_i, i \in \mathbf{N}_n\}$, $\mathbf{N}_n = \{1,2,...,n\}$, subject to the relations

$$\begin{gathered} k_i k_i^{-1} = 1, \quad k_i k_j = k_j k_i, \\ k_i e_j = q^{(\alpha_i,\alpha_j)} e_j k_i, \quad k_i f_j = q^{-(\alpha_i,\alpha_j)} f_j k_i, \\ [e_i, f_j\} = \delta_{ij} \frac{k_i - k_i}{q-q}, \quad \forall i,j \in I, \\ (\mathrm{Ad}\, e_i)^{1-a_{ij}}(e_j) = 0, \quad (\mathrm{Ad}\, f_i)^{1-a_{ij}}(f_j) = 0, \quad \forall i \neq j. \end{gathered} \tag{1}$$

All the generators are chosen to be homogeneous, with $k_i^{\pm 1}$, $\forall i$, and e_j, f_j, $j<n$, being even, and e_n, f_n being odd. For a homogeneous element x, we define $[x]=0$ if x is even, and $[x]=1$ when odd. The graded commutator $[.,.\}$ represents the usual commutator when any one of the two arguments is even, and the anticommutator when both arguments are odd. The adjoint operation Ad is defined by

$$\begin{gathered} \mathrm{Ad}\, e_i(x) = e_i x - (-1)^{[e_i][x]} k_i x k_i^{-1} e_i, \\ \mathrm{Ad}\, f_i(x) = f_i x - (-1)^{[f_i][x]} k_i x k_i^{-1} f_i. \end{gathered}$$

For x being a monomial in e_j's or f_j's it carries a definite weight $\omega(x) \in H^*$. Then $\mathrm{Ad}\, e_i(x) = e_i x - (-1)^{[e_i[x]} q^{(\alpha_i,\omega(x))} x e_i$, and similarly for $\mathrm{Ad}\, f_i(x)$. For convenience, we will use the notation $\mathbf{g}$ to denote $\mathrm{osp}(1|2n)$, and $\mathrm{U}_q(\mathbf{g})$ to denote $\mathrm{U}_q(\mathrm{osp}(1|2n))$. As is well known, this algebra has the structures of a $\mathbf{Z}_2$-graded Hopf algebra. We will denote the comultiplication by Δ, the counit by ϵ, and the antipode by S.

The representation theory of $\mathrm{U}_q(\mathbf{g})$ was developed in Ref. 13. For any finite-dimensional $\mathrm{U}_q(\mathbf{g})$ module, there exists a homogeneous basis relative to which the k_i are represented by diagonal matrices. Here we will only consider such finite-dimensional $\mathrm{U}_q(\mathbf{g})$ modules that the eigenvalues of the k_i tend to 1 as q approaches 1. We will denote the set of all such $\mathrm{U}_q(\mathbf{g})$ modules by $\mathbf{Mod}_q(\mathbf{g})$. Recall that all objects of $\mathbf{Mod}_q(\mathbf{g})$ are semi-simple.

If $W(\lambda)$ is a simple object of $\mathbf{Mod}_q(\mathbf{g})$, then there exists the unique (up to scalar multiples) highest weight vector v_+, such that

$$e_i v_+ = 0, \quad k_i v_+ = q^{(\lambda,\alpha_i)} v_+, \quad \lambda \in \mathcal{P}_+,$$

and the module $W(\lambda)$ is uniquely determined by the highest weight λ. We will denote the lowest weight of $W(\lambda)$ by $\overline{\lambda}$, and define $\lambda^\dagger = -\overline{\lambda}$. The dual module of $W(\lambda)$ has highest weight $\lambda^\dagger$.

The irreducible $\mathrm{U}_q(\mathbf{g})$ module with highest weight ϵ_1 plays a special role in the representation theory of $\mathrm{U}_q(\mathbf{g})$. We denote this module by $\mathbf{E}$, and refer to it as the vector module. Let us now examine this module in some detail. Denote by w_1 the highest weight vector of $\mathbf{E}$, which is assumed to be even. Define

$$\begin{gathered} w_i = f_{i-1} w_{i-1}, \quad 1 < i \leq n, \\ w_0 = f_n w_n, \quad w_{-n} = f_n w_n, \\ w_{-j} = f_j w_{-j-1}, \quad n > j \geq 1. \end{gathered}$$

Then $\{w_\mu|\mu=0,\pm1,\pm2,...,\pm n\}$ forms a weight basis of $\mathbf{E}$. We will denote by t the irreducible representation relative to this basis. The matrix elements of the e_i, f_i and k_i can be immediately written down. We have

$$t(e_i)_{\mu\nu}=\delta_{\mu i}\delta_{\nu,i+1}+\delta_{\mu,-i-1}\delta_{\nu,-i},$$

$$t(f_i)_{\mu\nu}=\delta_{\mu,i+1}\delta_{\nu i}+\delta_{\mu,-i}\delta_{\nu,-i-1},\quad i<n,$$

$$t(e_n)_{\mu\nu}=\delta_{\mu n}\delta_{\nu 0}-\delta_{\mu 0}\delta_{\nu,-n},$$

$$t(f_n)_{\mu\nu}=\delta_{\mu 0}\delta_{\nu n}+\delta_{\mu,-n}\delta_{\nu 0},$$

$$t(k_j)_{\mu\nu}=\delta_{\mu\nu}q^{(\alpha_j,\epsilon_\mu)},\quad 1\leqslant j\leqslant n,$$

where $\epsilon_0=0$, and $\epsilon_{-i}=-\epsilon_i$.

Let $\{w_\mu^*\}$ be the basis of $\mathbf{E}^*$ defined by $w_\mu^*(w_\nu)=\delta_{\mu\nu}$. Here $\mathbf{E}^*$ has a natural $\mathrm{U}_q(\mathbf{g})$-module structure with the $\mathrm{U}_q(\mathbf{g})$ action given by

$$xw_\mu^*=\sum_\nu (-1)^{[x]\delta_{\mu 0}}t(S(x))_{\mu\nu}w_\nu^*. \tag{2}$$

The lowest weight of $\mathbf{E}$ is $-\epsilon_1$. Thus the module $\mathbf{E}$ is self-dual. This implies that there exists a $\mathrm{U}_q(\mathbf{g})$-module isomorphism $M:\mathbf{E}\rightarrow\mathbf{E}^*$, which is unique up to scaler multiples. The w_{-1}^*, being the highest weight vector of $\mathbf{E}^*$, will be identified with w_1 so that this arbitrariness in M can be removed. Now let

$$w_\mu^*=\sum_\nu w_\nu M_{\nu\mu}.$$

Then

$$M_{\mu\nu}=m_\mu\delta_{\mu+\nu,0},\quad m_\mu=\begin{cases}(-q)^{\mu-1}, & \mu>0,\\ (-q)^n, & \mu=0,\\ (-q)^{2n+\mu}, & \mu<0.\end{cases} \tag{3}$$

It follows from earlier discussions that repeated tensor products of $\mathbf{E}$ are completely reducible. Furthermore, every finite-dimensional irreducible $\mathrm{U}_q(\mathbf{g})$ module is embedded in some $\mathbf{E}^{\otimes k}$ for at least one $k\geqslant 0$.

For later use, we consider two classes of $\mathbf{Z}_2$-graded Hopf subalgebras of $\mathrm{U}_q(\mathbf{g})$. Corresponding to any subset Θ of $\mathbf{N}_n$, we introduce

$$\mathcal{S}_k=\{k_i^{\pm1}, i\in\mathbf{N}_n;\quad e_j, f_j, j\in\boldsymbol{\Theta}\};$$

$$\mathcal{S}_p=\mathcal{S}_k\cup\{e_j, j\in\mathbf{N}_n\backslash\boldsymbol{\Theta}\}.$$

The elements of each set generate a $\mathbf{Z}_2$-graded Hopf subalgebra of $\mathrm{U}_q(\mathbf{g})$. The subalgebra generated by the elements of $\mathcal{S}_k$ will be denoted by $\mathrm{U}_q(\mathbf{k})$, and called a reductive subalgebra of $\mathrm{U}_q(\mathbf{g})$, while that generated by the elements of $\mathcal{S}_p$ will be denoted by $\mathrm{U}_q(\mathbf{p})$ and called a parabolic subalgebra. Note that $\mathrm{U}_q(\mathbf{k})$ is a $\mathbf{Z}_2$-graded Hopf subalgebra of $\mathrm{U}_q(\mathbf{p})$. If we replace e_i by f_i and vice versa in $\mathcal{S}_p$, we obtain another set, which will generate a $\mathbf{Z}_2$-graded Hopf subalgebra of $\mathrm{U}_q(\mathbf{g})$ having similar properties as $\mathrm{U}_q(\mathbf{p})$. Results presented in the remainder of the paper can also be formulated using such algebras.

Observe that there are two types of reductive subalgebras, depending on whether $\boldsymbol{\Theta}$ contains n. The first type arises when $n\notin\boldsymbol{\Theta}$, and in this case, $\mathrm{U}_q(\mathbf{k})$ is the direct product of quantized universal enveloping algebras associated with a series of ordinary (i.e., nongraded) Lie algebras of type A supplemented by the algebra generated by some $k_i^{\pm 1}$. The second type arises when $n \in \Theta$. This time, $\mathrm{U}_q(\mathbf{k})$ is the direct product of the first type with a $\mathrm{U}_q(\mathrm{osp}(1|2m))$ for some $m < n$. In both cases, the finite-dimensional representations of $\mathrm{U}_q(\mathbf{k})$ are completely reducible. This fact will be of great importance to the main subject of the paper.

Let V_μ be a finite-dimensional irreducible $\mathrm{U}_q(\mathbf{k})$ module. Then V_μ is of highest weight type. Let μ be the highest weight and $\tilde{\mu}$ the lowest weight of V_μ respectively. We can extend V_μ in a unique fashion to a $\mathrm{U}_q(\mathbf{p})$ module, which is still denoted by V_μ, such that the elements of $\mathcal{S}_p \backslash \mathcal{S}_k$ act by zero. It is not difficult to see that all finite dimensional irreducible $\mathrm{U}_q(\mathbf{p})$ modules are of this kind.

Consider a finite-dimensional irreducible $\mathrm{U}_q(\mathbf{g})$ module $W(\lambda)$, with highest weight λ and lowest weight $\bar{\lambda}$. $W(\lambda)$ can be restricted in a natural way to a $\mathrm{U}_q(\mathbf{p})$ module, which is always indecomposable, but not irreducible in general. It can be readily shown that

$$\dim_{\mathbf{C}} \mathrm{Hom}_{\mathrm{U}_q(\mathbf{p})}(W(\lambda), V_\mu) = \begin{cases} 1, & \bar{\lambda} = \tilde{\mu}, \\ 0, & \bar{\lambda} \neq \tilde{\mu}. \end{cases}$$

III. THE QUANTUM SUPERGROUP $\mathrm{OSP}_q(1|2n)$

There exist well-established methods for quantizing ordinary Lie groups in the nonsupersymmetric setting. (See Ref. 18 and references therein.) These methods can also be extended to construct $\mathrm{OSP}_q(1|2n)$, and this will be done here. However, we should point out that it is, in general, much more difficult to study quantum supergroups. See Ref. 9 for details on $\mathrm{GL}_q(m|n)$.

We will show that the quantum supergroup $\mathrm{OSP}_q(1|2n)$ admits a quantum Haar functional, and also a Peter–Weyl basis. This, however, is an exception rather than the rule. It is known that the finite-dimensional representations of all the quantum superalgebras but $\mathrm{U}_q(\mathrm{osp}(1|2n))$ are not completely reducible. This fact renders it impossible to construct Peter–Weyl bases for the corresponding quantum supergroups [which are yet to be defined except $\mathrm{GL}_q(m|n)$].

Let us recall some general results about $\mathbf{Z}_2$-graded Hopf algebras. Let A be a $\mathbf{Z}_2$-graded Hopf algebra with comultiplication Δ, counit ϵ, and antipode S. We define the finite dual A^0 of A to be a subspace of A^* such that for any $f \in A^0$, $\mathrm{Ker}\, f$ contains a two-sided ideal $\mathcal{I}$ of A which is of finite codimension, i.e., $\dim A/\mathcal{I} < \infty$. Of course in the most general situation, there is no guarantee that A^0 will not be zero. But when A^0 is nontrivial, then it is also a $\mathbf{Z}_2$-graded Hopf algebra with a structure dualizing that of A. More explicitly, the multiplication is defined, for f, $g \in A^0$, a, $b \in A$, by

$$\langle fg, a\rangle = \langle f \otimes g, \Delta(a)\rangle = \sum_{(a)} (-1)^{[g][a_{(1)}]} \langle f, a_{(1)}\rangle \langle g, a_{(2)}\rangle.$$

It is easy to see that the unit of A^0 is ϵ. Denote the comultiplication, the counit, and the antipode of A^0 respectively by Δ_0, ϵ^0 and S_0. Then

$$\langle \Delta_0(f), a \otimes b\rangle = \sum_{(f)} (-1)^{[f_{(1)}][f_{(2)}]} \langle f_{(1)}, a\rangle \langle f_{(2)}, b\rangle = \langle f, ab\rangle,$$

$$\langle S_0(f), a\rangle = \langle f, S(a)\rangle, \quad \epsilon^0(f) = \langle f, \mathbb{1}_A\rangle.$$

Now we come back to the quantum supergroup $\mathrm{OSP}_q(1|2n)$. As is well known, we cannot define the quantum supergroup directly. Instead, we need to find the algebra of functions on it. Introduce $t_{\mu\nu} \in (\mathrm{U}_q(\mathbf{g}))^*$, $\mu, \nu = 0, \pm 1, \pm 2, \ldots, \pm n$, defined by

$$t_{\mu\nu}(x) = t(x)_{\mu\nu}, \quad \forall x \in \mathrm{U}_q(\mathbf{q}),$$

where t is the vector representation of $\mathrm{U}_q(\mathbf{g})$. We call the $t_{\mu\nu}$ the matrix elements of t. Finite dimensionality of $\mathbf{E}$ implies that $t_{\mu\nu}\in(\mathrm{U}_q(\mathbf{g}))^0$, $\forall\mu,\ \nu$.

We define the superalgebra $\mathcal{T}_q(\mathbf{g})$ of functions on $\mathrm{OSP}_q(1|2n)$ to be the $\mathbf{Z}_2$-graded subalgebra of $(\mathrm{U}_q(\mathbf{g}))^0$ generated by the matrix elements of the vector representation of $\mathrm{U}_q(\mathbf{g})$, i.e., $t_{\mu\nu}$, $\mu,\nu=0,\pm 1,\pm 2,...,\pm n$. Then we have the following theorem.

Theorem 1: (1) *$\mathcal{T}_q(\mathbf{g})$ is a $\mathbf{Z}_2$-graded Hopf algebra.*

(2) *Let $t^{(\lambda)}$ be the irreducible representation of $\mathrm{U}_q(\mathbf{g})$ with highest weight $\lambda\in\mathcal{P}_+$, and let $t_{ij}^{(\lambda)}$, $i,j=1,2,...,d_\lambda$ $(d_\lambda=\dim t^{(\lambda)})$, be the matrix elements of $t^{(\lambda)}$. Then*

$$\mathcal{T}_q(\mathbf{g})=\bigoplus_{\lambda\in\mathcal{P}_+}\bigoplus_{i,j=1}^{d_\lambda}\mathbf{C}t_{ij}^{(\lambda)}. \tag{4}$$

Proof: The $\mathbf{Z}_2$-graded bialgebra structure of $\mathcal{T}_q(\mathbf{g})$ is obvious, and the existence of the antipode follows from the self-duality of the vector module $\mathbf{E}$ over $\mathrm{U}_q(\mathbf{g})$. Part (2) immediately follows from the complete reducibility of finite-dimensional representations of $\mathrm{U}_q(\mathbf{g})$. □

Let us now work out the explicit forms of the comultiplication and the antipode. The comultiplication is given by

$$\Delta_0(t_{\mu\nu})=\sum_\sigma\ (-1)^{(\delta_{\mu 0}+\delta_{\sigma 0})(\delta_{\nu 0}+\delta_{\sigma 0})}t_{\mu\sigma}\otimes t_{\sigma\nu}.$$

The antipode can be constructed from (2) by using the $\mathrm{U}_q(\mathbf{g})$-module isomorphism M. We have

$$\begin{aligned}S_0(t_{\mu\nu})&=(-1)^{(\delta_{\mu 0}+\delta_{\nu 0})\delta_{\mu 0}}(M^{-1}tM)_{\nu\mu}\\&=(-1)^{(\delta_{\mu 0}+\delta_{\nu 0})\delta_{\mu 0}}\frac{m_{-\mu}t_{-\nu,-\mu}}{m_{-\nu}},\end{aligned}$$

where m_μ is given by (3).

Here we introduce more notations for later use. Let $\{w_i^{(\lambda)}|i=1,2,...,d_\lambda\}$ be the homogeneous basis of $W(\lambda)$ with respect to which the representation $t^{(\lambda)}$ is defined. We denote by $\{\tilde{w}_i^{(\lambda)}|i=1,2,...,d_\lambda\}$ the basis of $W(\lambda)^*=W(\lambda^\dagger)$ such that $\tilde{w}_i^{(\lambda)}(w_j^{(\lambda)})=\delta_{ij}$. The $\mathrm{U}_q(\mathbf{g})$-module structure of $W(\lambda)^*$ enables us to define $\tilde{t}_{ij}^{(\lambda)}\in\mathcal{T}_q(\mathbf{g})$ by

$$x\tilde{w}_i^{(\lambda)}=\sum_j\ \tilde{t}_{ji}^{(\lambda)}(x)\tilde{w}_j^{(\lambda)},\quad \forall x\in\mathrm{U}_q(\mathbf{g}).$$

Then

$$\tilde{t}_{ji}^{(\lambda)}=(-1)^{[i]([i]+[j])}S_0(t_{ij}^{(\lambda)}),$$

where $[i]=0$ or 1 depending on whether w_i is even or odd. Clearly the $\tilde{t}_{ji}^{(\lambda)}$ are linear combinations of $t_{ij}^{(\lambda^\dagger)}$. Furthermore, the $\tilde{t}_{ji}^{(\lambda)}$, $\forall\lambda\in\mathcal{P}_+$, also form a basis of $\mathcal{T}_q(\mathbf{g})$.

From here on, we will omit the subscript 0 from Δ_0 and S_0.

Let us now turn to the discussion of a Haar functional on the quantum supergroup $\mathcal{T}_q(\mathbf{g})$. But before embarking on this task, we first consider the notion of an integral on an arbitrary $\mathbf{Z}_2$-graded Hopf algebra A. Let A^* be its dual, which has a natural $\mathbf{Z}_2$-graded algebraic structure induced by the co-algebraic structure of A. An even homogeneous element $\int^l\in A^*$ is called a left integral on A if

$$f\cdot\int^l=\langle f,\mathbb{1}_A\rangle\int^l,\quad \forall f\in A^*.$$

Similarly, an even homogeneous element $\int^r\in A^*$ is called a right integral on A if

$$\int^r \cdot f = \langle f, 1_A \rangle \int^r, \quad \forall f \in A^*.$$

A straightforward calculation shows that the defining properties of the integrals are equivalent to the following requirements

$$\left(\mathrm{id} \otimes \int^l\right) \Delta(x) = \int^l x, \quad \left(\int^r \otimes \mathrm{id}\right) \Delta(x) = \int^r x, \quad \forall x \in A. \tag{5}$$

where id is the identity map on A.

A Haar functional $\int \in A^*$ on A is an integral on A which is both left and right, and sends 1_A to 1, i.e.,

$$\begin{gathered} (i) \quad \left(\int \otimes \mathrm{id}\right) \Delta(x) = \left(\mathrm{id} \otimes \int\right) \Delta(x) = \int x, \quad \forall x \in A, \\ (ii) \quad \int 1_A = 1. \end{gathered} \tag{6}$$

In the case of $\mathcal{T}_q(\mathbf{g})$, it is an entirely straightforward matter to show the following.

Theorem 2: *The element* $\int \in (\mathcal{T}_q(\mathbf{g}))^*$ *defined by*

$$\int 1_{\mathcal{T}_q(\mathbf{g})} = 1; \quad \int t_{ij}^{(\lambda)} = 0, \quad 0 \neq \lambda \in \mathcal{P}_+,$$

gives rise to a Haar functional on $\mathcal{T}_q(\mathbf{g})$.

Denote by 2ρ the sum of the positive roots of $\mathbf{g}$. Let $K_{2\rho}$ be the product of powers of $k_i^{\pm 1}$'s such that

$$K_{2\rho} e_i K_{2\rho}^{-1} = q^{(2\rho, \alpha_i)} e_i, \quad \forall i.$$

Then it can be easily shown that

$$S^2(x) = K_{2\rho} x K_{2\rho}^{-1}, \quad \forall x \in \mathrm{U}_q(\mathbf{q}).$$

We define the quantum superdimension of the irreducible $\mathrm{U}_q(\mathbf{g})$ module $W(\lambda)$ by

$$\mathrm{SD}_q(\lambda) := \mathrm{Str}\{t^{(\lambda)}(K_{2\rho})\}.$$

For quantum superalgebras other than the $\mathrm{osp}(1|2n)$ series, there exists a class of finite-dimensional irreducible representations, the typicals, of which the super-dimensions vanish identically. Again, $\mathrm{U}_q(\mathrm{osp}(1|2n))$ is an exception, and we have the following important property: for any irreducible $\mathrm{U}_q(\mathrm{osp}(1|2n))$ module $W(\lambda)$ with highest weight $\lambda \in \mathcal{P}_+$,

$$\mathrm{SD}_q(\lambda) \neq 0.$$

Now the Haar functional $\int$ satisfies the following properties.

Lemma 1:

$$\begin{gathered} \int t_{ij}^{(\lambda)} \tilde{t}_{rs}^{(\mu)} (-1)^{[j][r]+[i]+[j]} = \delta_{ir} \delta_{\lambda\mu} \frac{t_{sj}^{(\lambda)}(K_{2\rho})}{SD_q(\lambda)}, \\ \int \tilde{t}_{ij}^{(\lambda)} t_{rs}^{(\mu)} (-1)^{[j][r]} = \delta_{js} \delta_{\lambda\mu} \frac{\tilde{t}_{ir}^{(\lambda)}(K_{2\rho})}{SD_q(\lambda)}. \end{gathered} \tag{7}$$

Proof: Consider the first equation. The $\lambda \neq \mu$ case is easy to prove: the integral vanishes because the tensor product $W(\lambda)\otimes W(\mu^{\dagger})$ does not contain the trivial $\mathrm{U}_q(\mathbf{g})$ module. When $\lambda = \mu$, we introduce the notations

$$\phi_{ir;sj}=\int t_{ij}^{(\lambda)}\tilde{t}_{rs}^{(\lambda)}(-1)^{[j][r]+[i]+[j]};\quad \Phi[s,j]=(\phi_{ir;sj})_{i,r=1}^{d_\lambda};\quad \Psi[i,r]=(\phi_{ir;sj})_{s,j=1}^{d_\lambda}.$$

It is clearly true that $\mathrm{Str}(\Psi[i,r])=\delta_{ir}$.

Note that corresponding to each $x\in \mathrm{U}_q(\mathbf{g})$, there exists an $\tilde{x}\in(\mathcal{T}_q(\mathbf{g}))^*$ defined by $\tilde{x}(a)=\langle a,x\rangle$, $\forall a\in\mathcal{T}_q(\mathbf{g})$. The left integral property of $\int$ leads to

$$\begin{aligned}\epsilon(x)\phi_{ir;sj}&=\left(\tilde{x}.\int\right)t_{ij}^{(\lambda)}\tilde{t}_{rs}^{(\lambda)}(-1)^{[j][r]+[i]+[j]}\\&=\sum_{(x)}\sum_{i',r'}t_{ii'}^{(\lambda)}(x_{(1)})t_{r'r}^{(\lambda)}(S(x_{(2)}))\phi_{i'r';sj}(-1)^{[x]([i]+[j])+[x_{(2)}]([j]+[s])},\end{aligned}$$

i.e.,

$$\epsilon(x)\Phi[s,j]=\sum_{(x)}t^{(\lambda)}(x_{(1)})\Phi[s,j]t^{(\lambda)}(S(x_{(2)}))(-1)^{[x_{(2)}]([j]+[s])},\quad \forall x\in \mathrm{U}_q(\mathbf{g}).$$

Schur's lemma forces $\Phi[s,j]$ to be proportional to the identity matrix, and we have

$$\Psi[i,r]=\delta_{ir}\psi,$$

for some $d_\lambda\times d_\lambda$ matrix ψ. The right integral property of $\int$ leads to

$$\epsilon(y)\psi=\sum_{(y)}t^{(\lambda)}(K_{2\rho})t^{(\lambda)}(y_{(1)})t^{(\lambda)}(K_{2\rho}^{-1})\psi t^{(\lambda)}(S(y_{(2)})).$$

Again by using Schur's lemma we conclude that ψ is proportional to $t^{(\lambda)}(K_{2\rho})$. Since its supertrace is 1, we have

$$\psi=\frac{t^{(\lambda)}(K_{2\rho})}{\mathrm{SD}_q(\lambda)}.$$

This completes the proof of the first equation of the lemma. The second equation can be shown in exactly the same way. □

It is worth observing that this Lemma and part (2) of Theorem 1 provide a quantum analog of the Peter–Weyl theorem for $\mathrm{OSP}_q(1|2n)$.

IV. QUANTUM HOMOGENEOUS SUPERVECTOR BUNDLES

In this section we will investigate the quantum homogeneous superspaces and quantum homogeneous supervector bundles arising from the quantum supergroup $\mathrm{OSP}_q(1|2n)$ by adapting the methods and techniques of Refs. 9 and 19 to the present context. Let us start by introducing two types of actions of $\mathrm{U}_q(\mathbf{g})$ on $\mathcal{T}_q(\mathbf{g})$. The first action will be denoted by $\circ$, which corresponds to the right translation in the classical theory of Lie groups. It is defined by

$$x\circ f=\sum_{(f)}(-1)^{[f_{(1)}][f_{(2)}]}f_{(1)}\langle f_{(2)},x\rangle,\quad x\in \mathrm{U}_q(\mathbf{g}),\quad f\in\mathcal{T}_q(\mathbf{g}).\tag{8}$$

Straightforward calculations show that

$$x\circ(y\circ f)=(xy)\circ f,\quad (x\circ f)(y)=f(yx),\quad (\mathrm{id}_{\mathcal{T}_q(\mathbf{g})}\otimes x\circ)\Delta(f)=\Delta(x\circ f).$$

The other action, which corresponds to the left translation in the classical Lie group theory, will be denoted by $\cdot$. It is defined by

$$x\cdot f=\sum_{(f)}\langle f_{(1)},S^{-1}(x)\rangle f_{(2)}.\tag{9}$$

It can be easily shown that

$$(x\cdot f)(y)=(-1)^{[x][y]}f(S^{-1}(x)y),$$

$$x\cdot(y\cdot f)=(xy)\cdot f,\quad x,y\in \mathrm{U}_q(\mathbf{g}),\quad f\in\mathcal{T}_q(\mathbf{g}).$$

Furthermore, the two actions graded commute in the following sense

$$x\circ(y\cdot f)=(-1)^{[x][y]}y\cdot(x\circ f),\quad x,y\in \mathrm{U}_q(\mathbf{g}),\quad f\in\mathcal{T}_q(\mathbf{g}).$$

Let V be a finite-dimensional module over $\mathrm{U}_q(\mathbf{k})$. We extend the actions $\circ$ and $\cdot$ trivially to $V\otimes\mathcal{T}_q(\mathbf{g})$: for any $\zeta=\Sigma v_i\otimes f_i\in V\otimes\mathcal{T}_q(\mathbf{g})$,

$$x\cdot\zeta=\sum(-1)^{[x][v_i]}v_i\otimes x\cdot f_i,$$

$$x\circ\zeta=\sum(-1)^{[x][v_i]}v_i\otimes x\circ f_i,\quad x\in \mathrm{U}_q(\mathbf{g}).$$

We now introduce two important definitions:

$$\mathcal{A}_q^{\mathbf{k}}:=\{f\in\mathcal{T}_q(\mathbf{g})|x\circ f=\epsilon(x)f,\quad \forall x\in \mathrm{U}_q(\mathbf{k})\};\tag{10}$$

$$\Gamma_q^{\mathbf{k}}(V):=\{\zeta\in V\otimes\mathcal{T}_q(\mathbf{g})|x\circ\zeta=(S(x)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\zeta,\quad\forall x\in \mathrm{U}_q(\mathbf{k})\}.\tag{11}$$

The remainder of this section is devoted to studying the properties of these objects. Let us first prove the following.

Proposition 1: (1) $A_q^{\mathbf{k}}$ *is an infinite-dimensional subalgebra of* $\mathcal{T}_q(\mathbf{g})$.

(2) $\Gamma_q^{\mathbf{k}}(V)$ *is an infinite-dimensional supervector space if the weight of any vector of V is* $\mathrm{U}_q(\mathbf{g})$ *integral, and is zero otherwise.*

Proof: We first show that $\mathcal{A}_q^{\mathbf{k}}$ is a subalgebra of $\mathcal{T}_q(\mathbf{g})$. Since $\mathrm{U}_q(\mathbf{k})$ is a Hopf subalgebra of $\mathrm{U}_q(\mathbf{g})$, for any $x\in \mathrm{U}_q(\mathbf{k})$, $\Delta(x)=\Sigma_{(x)}x_{(1)}\otimes x_{(2)}\in \mathrm{U}_q(\mathbf{k})\otimes \mathrm{U}_q(\mathbf{k})$. Hence

$$x\circ(ab)=\sum_{(x)}(-1)^{[x_{(2)}][a]}\{x_{(1)}\circ a\}\{x_{(2)}\circ b\}=\epsilon(x)ab,$$

that is, $ab\in\mathcal{A}_q^{\mathbf{k}}$.

Since the finite-dimensional representations of $\mathrm{U}_q(\mathbf{k})$ are completely reducible, the study of properties of $\Gamma_q^{\mathbf{k}}(V)$ reduces to the case when V is irreducible. Let V_μ be a finite-dimensional irreducible $\mathrm{U}_q(\mathbf{k})$ module with highest weight μ and lowest weight $\tilde{\mu}$. Any element $\zeta\in\Gamma_q^{\mathbf{k}}(V_\mu)$ can be expressed in the form

$$\zeta=\sum_{\lambda\in\mathcal{P}_+}\sum_{i,j}v_{ij}^{(\lambda)}\otimes\tilde{t}_{ij}^{(\lambda)},$$

for some $v_{ij}^{(\lambda)} \in V_\mu$. Fix an arbitrary $\lambda \in \mathcal{P}_+$. For any nonvanishing $w \in W(\lambda)$, the following linear map is clearly surjective:

$$\mathrm{Hom}_{\mathbf{C}}(W(\lambda), V_\mu) \otimes w \to V_\mu,$$

$$\phi \otimes w \mapsto \phi(w).$$

Thus there exist $\phi_i^{(\lambda)} \in \mathrm{Hom}_{\mathbf{C}}(W(\lambda), V_\mu)$ such that $v_{ij}^{(\lambda)} = \phi_i^{(\lambda)}(w_j^{(\lambda)})$, where $\{w_i^{(\lambda)}\}$ is the basis of $W(\lambda)$ discussed before. Therefore, we can rewrite ζ as

$$\zeta = \sum_{\lambda \in \mathcal{P}_+} \sum_{i,j} \phi_i^{(\lambda)}(w_j^{(\lambda)}) \otimes \tilde{t}_{ij}^{(\lambda)}.$$

The defining property of $\Gamma_q^{\mathbf{k}}(V_\mu)$ states that

$$\ell \circ \zeta = (\mathrm{id}_{\mathcal{T}_q(\mathbf{g})} \otimes S(\ell))\zeta, \quad \forall \ell \in \mathrm{U}_q(\mathbf{k}).$$

Thus we have

$$\sum_{\lambda \in \mathcal{P}_+} \sum_{i,j,k} t_{jk}^{(\lambda)}(S(\ell))\phi_i^{(\lambda)}(w_j^{(\lambda)}) \otimes (-1)^{[\ell][\phi_i^{(\lambda)}]}\tilde{t}_{ik}^{(\lambda)} = \sum_{\lambda \in \mathcal{P}_+} \sum_{i,j} S(\ell)\phi_i^{(\lambda)}(w_j^{(\lambda)}) \otimes \tilde{t}_{ij}^{(\lambda)}.$$

Recalling that the $\tilde{t}_{ki}^{(\lambda)}$ are linearly independent, the above is equivalent to

$$\ell \phi_i^{(\lambda)}(w_j^{\lambda}) = (-1)^{[\ell][\phi_i^{(\lambda)}]}\phi_i^{(\lambda)}(\ell w_j^{(\lambda)}), \quad \forall \ell \in \mathrm{U}_q(\mathbf{k}).$$

This equation is precisely the statement that the $\phi_i^{(\lambda)}$ be $\mathrm{U}_q(\mathbf{k})$-module homomorphisms of degrees $[\phi_i^{(\lambda)}]$,

$$\phi_i^{(\lambda)} \in \mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W(\lambda), V_\mu) \subset \mathrm{Hom}_{\mathbf{C}}(W(\lambda), V_\mu), \quad \forall i.$$

Thus finding sections in $\Gamma_q^{\mathbf{k}}(V_\mu)$ is equivalent to finding, for all $\lambda \in \mathcal{P}_+$, the homomorphisms $\phi^{(\lambda)} \in \mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W(\lambda), V_\mu)$. Note that each such homomorphism $\phi^{(\lambda)}$ determines d_λ linearly independent sections:

$$\zeta_i^{(\lambda)} = \sum_j \phi^{(\lambda)}(w_j^{(\lambda)}) \otimes \tilde{t}_{ij}^{(\lambda)}.$$

However, when μ is not integral with respect to $\mathrm{U}_q(\mathbf{g})$, $\mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W(\lambda), V_\mu) = 0$, and hence $\Gamma_q^{\mathbf{k}}(V_\mu)$ vanishes in this case.

Now consider the case with $\mu = 0$; we have $\Gamma_q^{\mathbf{k}}(V_{\mu=0}) = \mathcal{A}_q^{\mathbf{k}}$ as supervector spaces. There is a homomorphism from the trivial representation of $\mathrm{U}_q(\mathbf{g})$, $W(0) = \mathbf{C}$, onto $V_0 = \mathbf{C}$. This gives the constant sections of $\mathcal{A}_q^{\mathbf{k}}$. Let γ be the highest root of $\mathbf{g}$. Recall that in the classical situation, $\mathbf{k}$ is reductive with $N = r - |\Theta|$ independent central elements. This, transcribed to the quantum case, implies the existence of N linearly independent $\mathrm{U}_q(\mathbf{k})$ homomorphisms $W(\gamma) \to \mathbf{C}$. As mentioned above, each of these corresponds to $d = \dim(\mathbf{g})$ linearly independent sections. So the representation $W(\gamma)$ determines Nd linearly independent sections. Further linearly independent sections can be obtained using the following lemma.

Lemma 2: Suppose there are nontrivial $\mathrm{U}_q(\mathbf{k})$ *homomorphisms* $W(\lambda_1) \to V_{\mu_1}$ *and* $W(\lambda_2) \to V_{\mu_2}$. *Then there is an induced nontrivial* $\mathrm{U}_q(\mathbf{k})$ *homomorphism*

$$W(\lambda_1 + \lambda_2) \to V_{\mu_1 + \mu_2}.$$

For example, for any positive integer m, there exist $(m|N)$ (partition of m into $\leqslant N$ parts) linearly independent homomorphisms $W(m\gamma)\rightarrow\mathbf{C}$. Thus we have proved that the algebra $\mathcal{A}_q^{\mathbf{k}}$ is infinite dimensional.

Now let us consider the case with $0\neq\mu\in\mathcal{P}$. It is an elementary exercise to verify that V_μ is $\mathrm{U}_q(\mathbf{k})$-isomorphic to a $\mathrm{U}_q(\mathbf{k})$-irreducible part of $W(\lambda')$, where λ' is the dominant weight in the Weyl group orbit of μ. Thus there is a nontrivial $\mathrm{U}_q(\mathbf{k})$ homomorphism

$$W(\lambda')\rightarrow V_\mu,$$

and this determines at least $d_{\lambda'}$ linearly independent sections in $\Gamma_q^{\mathbf{k}}(V_\mu)$. Further linearly independent sections can be constructed explicitly using Lemma 2 which promises a family of homomorphisms

$$W(\lambda'+m\gamma)\rightarrow V_\mu, \quad m\in\mathbf{N}_+ .$$

This establishes that $\Gamma_q^{\mathbf{k}}(V_\mu)$ is infinite dimensional. □

$\mathcal{A}_q^{\mathbf{k}}$ may be regarded as the quantum analog of the algebra of functions over the superspace $\mathrm{OSP}(1|2n)/K$, where K is the subgroup of $\mathrm{OSP}(1|2n)$ with Lie superalgebra $\mathbf{k}$. Such homogeneous superspaces were studied in the work of Manin,[16] Penkov,[17] and others. Here we wish to make some investigations into their quantum analogs.

As is well known, one cannot define a noncommutative (in the $\mathbf{Z}_2$-graded sense) space directly in geometrical terms. Instead, such a space has to be defined by specifying its algebra of functions. We will take $\mathcal{A}_q^{\mathbf{k}}$ as the algebra of functions over the quantum homogeneous superspace which corresponds to $\mathrm{OSP}(1|2n)/K$ in the classical situation. Let us now study properties of $\Gamma_q^{\mathbf{k}}(V)$. First observe the following.

Theorem 3: *$\Gamma_q^{\mathbf{k}}(V)$ furnishes a two-sided $\mathcal{A}_q^{\mathbf{k}}$ module under the multiplication of $\mathcal{T}_q(\mathbf{g})$.*

Proof: The left and right actions of $\mathcal{A}_q^{\mathbf{k}}$ on $\Gamma_q^{\mathbf{k}}(V)$ are respectively defined by

$$a\zeta=\sum_r (-1)^{[a][v_i]}v_i\otimes af_i, \quad \zeta a=\sum_r v_i\otimes f_i a,$$

where $a\in\mathcal{A}_q^{\mathbf{k}}$ and $\zeta=\Sigma_i v_i\otimes f_i\in\Gamma_q^{\mathbf{k}}(V)$. Now for $p\in\mathrm{U}_q(\mathbf{k})$,

$$p\circ(a\zeta)=\sum_{(p)} (-1)^{[p_{(2)}][a]}\{p_{(1)}\circ a\}\{p_{(2)}\circ\zeta\}=(-1)^{[p][a]}a\{p\circ\zeta\}=(S(p)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})a\zeta;$$

$$p\circ(\zeta a)=\sum_{(p)} (-1)^{[p_{(2)}][\zeta]}\{p_{(1)}\circ\zeta\}\{p_{(2)}\circ a\}=\{p\circ\zeta\}a=(S(p)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\zeta a.$$

This completes the proof. □

When V is actually a $\mathrm{U}_q(\mathbf{g})$ module, the $\mathcal{A}_q^{\mathbf{k}}$ module $\Gamma_q^{\mathbf{k}}(V)$ has a particularly simple structure.

Proposition 2: Let W be a finite-dimensional left $\mathrm{U}_q(\mathbf{g})$ module, which we regard as a left $\mathrm{U}_q(\mathbf{k})$ module by restriction. Then $\Gamma_q^{\mathbf{k}}(W)$ is isomorphic to $W\otimes\mathcal{A}_q^{\mathbf{k}}$ either as a left or right $\mathcal{A}_q^{\mathbf{k}}$ module.

Proof: We first construct the right $\mathcal{A}_q^{\mathbf{k}}$ module isomorphism. Being a left $\mathrm{U}_q(\mathbf{g})$ module, W carries a natural right $\mathcal{T}_q(\mathbf{g})$ comodule structure with the comodule action $\delta: W\rightarrow W\otimes\mathcal{T}_q(\mathbf{g})$ defined by

$$\delta(w)(x)=xw, \quad x\in\mathrm{U}_q(\mathbf{g}), \quad w\in W. \tag{12}$$

[Here the notation requires some clarification. If we express $\delta(w)=\Sigma_{(w)}w_{(1)}\otimes w_{(2)}$, then $\delta(w)(x)=\Sigma_{(w)}(-1)^{[x][w_{(1)}]}w_{(1)}\langle w_{(2)},x\rangle$.] Define $\eta: W\otimes\mathcal{T}_q(\mathbf{g})\rightarrow W\otimes\mathcal{T}_q(\mathbf{g})$ by the composition of maps

$$W\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{\delta\otimes\mathrm{id}}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\to W\otimes\mathcal{T}_q(\mathbf{g}),$$

where the last map is the multiplication of $\mathcal{T}_q(\mathbf{g})$. Then η defines a right $\mathcal{A}_q^{\mathbf{k}}$ module isomorphism, with the inverse map given by the composition

$$W\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{\delta\otimes\mathrm{id}}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{(\mathrm{id}\otimes S\otimes\mathrm{id})}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\to W\otimes\mathcal{T}_q(\mathbf{g}),$$

where the last map is again the multiplication of $\mathcal{T}_q(\mathbf{g})$. It is not difficult to show that

$$x\circ\eta(\zeta)=\eta\left(\sum_{(x)}(x_{(1)}\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})x_{(2)}\circ\zeta\right),$$

$$x\circ\eta^{-1}(\zeta)=\eta^{-1}\left(\sum_{(x)}(S(x_{(1)})\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})x_{(2)}\circ\zeta\right),\quad\forall\zeta\in\mathcal{T}_q(\mathbf{g})\otimes W,\quad x\in\mathrm{U}_q(\mathbf{g}).$$

Consider $\zeta\in\Gamma_q^{\mathbf{k}}(W)$. We have

$$p\circ\eta(\zeta)=\eta\left(\sum_{(p)}(p_{(1)}\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})p_{(2)}\circ\zeta\right)=\eta\left(\sum_{(p)}(p_{(1)}S(p_{(2)})\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\zeta\right)$$
$$=\epsilon(p)\,\eta(\zeta),\quad\forall p\in\mathrm{U}_q(\mathbf{k}).$$

Hence $\eta(\Gamma_q^{\mathbf{k}}(W))\subset W\otimes\mathcal{A}_q^{\mathbf{k}}$. Conversely, given any $\xi\in W\otimes\mathcal{A}_q^{\mathbf{k}}$, we have

$$p\circ\eta^{-1}(\xi)=\eta^{-1}\left(\sum_{(p)}(S(p_{(1)})\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})p_{(2)}\circ\xi\right)$$
$$=\eta^{-1}\left(\sum_{(p)}(S(p_{(1)})\epsilon(p_{(2)})\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\xi\right)=(S(p)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\,\eta^{-1}(\xi),\quad\forall p\in\mathrm{U}_q(\mathbf{k}).$$

Thus $\eta^{-1}(W\otimes\mathcal{A}_q^{\mathbf{k}})\subset\Gamma_q^{\mathbf{k}}(W)$. Therefore the restriction of η to $\Gamma_q^{\mathbf{k}}(W)$ provides the desired right $\mathcal{A}_q^{\mathbf{k}}$ module isomorphism.

The left module isomorphism is given by the restriction to $\Gamma_q^{\mathbf{k}}(W)$ of the linear map $\kappa:W\otimes\mathcal{T}_q(\mathbf{g})\to W\otimes\mathcal{T}_q(\mathbf{g})$, which is defined by the following composition of maps

$$W\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{\delta\otimes\mathrm{id}}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{\mathrm{id}\otimes P(S^2\otimes\mathrm{id})}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\to W\otimes\mathcal{T}_q(\mathbf{g}),$$

where

$$P:\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\to\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g}),$$
$$a\otimes b\mapsto(-1)^{[a][b]}b\otimes a.\tag{13}$$

The inverse map κ^{-1} is given by

$$W\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{\delta\otimes\mathrm{id}}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\xrightarrow{\mathrm{id}\otimes P(S\otimes\mathrm{id})}W\otimes\mathcal{T}_q(\mathbf{g})\otimes\mathcal{T}_q(\mathbf{g})\to W\otimes\mathcal{T}_q(\mathbf{g}).$$

□

With the help of this Proposition, we can now prove the following important result.

Theorem 4: $\Gamma_q^{\mathbf{k}}(V)$ *is projective and of finite type both as a left and right module over the superalgebra* $\mathcal{A}_q^{\mathbf{k}}$ *of functions on the quantum homogeneous superspace.*

Proof: Since $\mathrm{U}_q(\mathbf{k})$ is a reductive subalgebra of $\mathrm{U}_q(\mathbf{g})$, all finite-dimensional representations of $\mathrm{U}_q(\mathbf{k})$ are completely reducible. Let V_s, $s=1,2,...,K<\infty$, be the irreducible direct summands of

V such that their weights are all integral with respect to $\mathrm{U}_q(\mathbf{g})$. Then $\Gamma_q^{\mathbf{k}}(V)=\oplus_s\Gamma_q^{\mathbf{k}}(V_s)$. Consider any V_s, and denote its highest weight by μ_s. There exists such a $\hat{\mu}_s$ in the Weyl group orbit of $\mathbf{g}$ that is integral dominant with respect to $\mathbf{g}$. Let $W(\hat{\mu}_s)$ be the irreducible $\mathrm{U}_q(\mathbf{g})$ module with highest weight $\hat{\mu}_s$, which can be regarded as a $\mathrm{U}_q(\mathbf{k})$ module in the natural way. There always exists a $\mathrm{U}_q(\mathbf{k})$ module $V_s^{\perp}$ such that $W(\hat{\mu}_s)=V_s\oplus V_s^{\perp}$. Write $V^{\perp}=\oplus_s V_s^{\perp}$, and $W=\oplus_s W(\hat{\mu}_s)$. We have

$$\Gamma_q^{\mathbf{k}}(V)\oplus\Gamma_q^{\mathbf{k}}(V^{\perp})=\Gamma_q^{\mathbf{k}}(W)\cong W\otimes\mathcal{A}_q^{\mathbf{k}},$$

where the last step follows from Proposition 2. □

Recall that in classical differential geometry, the space $\mathcal{H}$ of sections of a vector bundle over a compact manifold M furnishes a module over the algebra $\mathcal{A}(M)$ of functions on M. It then follows from Swan's theorem that this module must be projective and is of finite type. Conversely, any projective module of finite type over $\mathcal{A}(M)$ is isomorphic to the space of sections of some vector bundle over M. This result is taken as the starting point for studying vector bundles in noncommutative geometry: one defines a vector bundle over a noncommutative space in terms of the space of sections which is required to be a finite-type project module over the noncommutative algebra of functions on the virtual noncommutative space. Therefore, $\Gamma_q^{\mathbf{k}}(V)$ will be called the space of sections of a quantum supervector bundle over the quantum homogeneous superspace associated with $\mathcal{A}_q^{\mathbf{k}}$.

Homogeneous supervector bundles at the classical level were studied in Refs. 16 and 17. We will not enter the discussion of the subject, but merely mention that the subject proves to be extremely rich and many aspects of it remain to be developed.

Following the classical terminology, we will call a quantum supervector bundle trivial if the sections form a free module over the superalgebra of functions on the quantum superspace. The following proposition is an immediate consequence of Proposition 2.

Proposition 3: If the $\mathrm{U}_q(\mathbf{k})$ *module V is in fact a finite-dimensional left* $\mathrm{U}_q(\mathbf{g})$ *module, then the quantum homogeneous supervector bundle with the space of sections* $\Gamma_q^{\mathbf{k}}(V)$ *is trivial.*

V. INDUCED REPRESENTATIONS

In this section we will investigate induced representations of the quantum supergroup $\mathrm{OSP}_q(1|2n)$ by using results of the last section. The following proposition explains how quantum homogeneous supervector bundles enter representation theory.

Proposition 4: $\Gamma_q^{\mathbf{k}}(V)$ *furnishes a left* $\mathrm{U}_q(\mathbf{g})$ *module under the* $\cdot$ *action, and also a right* $\mathcal{T}_q(\mathbf{g})$ *comodule under the action* $\omega=\mathrm{id}_V\otimes(\mathrm{id}_{\mathcal{T}_q(\mathbf{g})}\otimes S^{-1})\Delta$.

Proof: For $p\in\mathrm{U}_q(\mathbf{k})$, $x\in\mathrm{U}_q(\mathbf{g})$, and $\zeta\in\Gamma_q^{\mathbf{k}}(V)$, we have

$$p\circ(x\cdot\zeta)=(-1)^{[p][x]}x\cdot(p\circ\zeta)=(S(p)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})(x\cdot\zeta).$$

Thus $\Gamma_q^{\mathbf{k}}(V)$ indeed furnishes a left $\mathrm{U}_q(\mathbf{g})$ module under the $\cdot$ action. The $\mathcal{T}_q(\mathbf{g})$ coaction ω is just the dual of this left $\mathrm{U}_q(\mathbf{g})$ action.

We call $\Gamma_q^{\mathbf{k}}(V)$ an induced $\mathrm{U}_q(\mathbf{g})$ module, and also an induced $\mathcal{T}_q(\mathbf{g})$ comodule. For such induced modules, we have the following quantum analog of Frobenius reciprocity.

Theorem 5: *Let W be a* $\mathrm{U}_q(\mathbf{g})$ *module, the restriction of which furnishes a* $\mathrm{U}_q(\mathbf{k})$ *module in a natural way. Then there exists a canonical isomorphism*

$$\mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V))\cong\mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W,V), \tag{14}$$

where $\mathrm{U}_q(\mathbf{g})$ *acts on the left module* $\Gamma_q^{\mathbf{k}}(V)$ *via the* $\cdot$ *action.*

Proof: We prove the proposition by explicitly constructing the isomorphism, which we claim to be the linear map

$$F:\mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V))\rightarrow \mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W,V), \quad \psi\mapsto\psi(1_{\mathrm{U}_q(\mathbf{g})}),$$

with the inverse map

$$\overline{F}:\mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W,V)\rightarrow \mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V)), \quad \phi\mapsto\overline{\phi}=(\phi\otimes S)\delta,$$

where $\delta: W\rightarrow W\otimes\mathcal{T}_q(\mathbf{g})$ is the right $\mathcal{T}_q(\mathbf{g})$ comodule action defined by (12).

To verify our claim, we first need to demonstrate that the image of F is contained in $\mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W,V)$. Consider $\psi\in\mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V))$. For any $p\in\mathrm{U}_q(\mathbf{k})$ and $w\in W$, we have

$$p(F\psi(w))=(S^{-1}(p)\circ\psi(w))(\mathbb{1}_{\mathrm{U}_q(\mathbf{g})}),$$

where we have used the defining property of $\Gamma_q^{\mathbf{k}}(V)$. Note that

$$(S^{-1}(p)\circ\psi(w))(\mathbb{1}_{\mathrm{U}_q(\mathbf{g})})=(p\cdot\psi(w))(\mathbb{1}_{\mathrm{U}_q(\mathbf{g})}).$$

The $\mathrm{U}_q(\mathbf{g})$-module structure of $\Gamma_q^{\mathbf{k}}(V)$ and the given condition that ψ is a $\mathrm{U}_q(\mathbf{g})$-module homomorphism immediately leads to

$$p(F\psi(w))=(-1)^{[\psi][p]}\psi(pw)(\mathbb{1}_{\mathrm{U}_q(\mathbf{g})})=(-1)^{[\psi][p]}F\psi(pw), \quad p\in\mathrm{U}_q(\mathbf{k}); \quad w\in W.$$

Now consider $\overline{F}$. We first show that the image $\mathrm{Im}(\overline{F})$ of $\overline{F}$ is contained in $\mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V))$. Note that $\mathrm{Im}(\overline{F})\subset\mathrm{Hom}_{\mathbf{C}}(W,V\otimes\mathcal{T}_q(\mathbf{g}))$. Some relatively simple manipulations lead to

$$(x\cdot\overline{\phi}(w))=\overline{\phi}(xw),$$

$$(p\circ\overline{\phi}(w))=(S(p)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\overline{\phi}(w), \quad x\in\mathrm{U}_q(\mathbf{g}), \quad p\in\mathrm{U}_q(\mathbf{k}), \quad w\in W.$$

Therefore, $\mathrm{Im}(\overline{F})\subset\mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V))$. Now we show that F and $\overline{F}$ are inverse to each other. For $\psi\in\mathrm{Hom}_{\mathrm{U}_q(\mathbf{g})}(W,\Gamma_q^{\mathbf{k}}(V))$, and $\phi\in\mathrm{Hom}_{\mathrm{U}_q(\mathbf{k})}(W,V)$, we have

$$(F\overline{F}\phi)(w)=(\overline{F}\phi)(w)(1_{\mathrm{U}_q(\mathbf{g})})=\phi(w),$$

$$\begin{aligned}(\overline{F}F\psi)(w)(x)&=(-1)^{[x]([w]+1)}(F\psi)(S(x)w)\\&=(-1)^{[x]([w]+1)}\psi(S(x)w)(1_{\mathrm{U}_q(\mathbf{g})})\\&=(-1)^{[x]([w]+[\psi]+1)}(S(x)\cdot\psi(w))(1_{\mathrm{U}_q(\mathbf{g})})=\psi(w)(x), \quad x\in\mathrm{U}_q(\mathbf{g}), \quad w\in W.\end{aligned}$$

This completes the proof of the Proposition. □

Let V_μ be a finite-dimensional irreducible $\mathrm{U}_q(\mathbf{p})$ module with highest weight μ and lowest weight $\tilde{\mu}$. Since V_μ is a $\mathrm{U}_q(\mathbf{p})$ module the following is a well-defined subspace of $\Gamma_q^{\mathbf{k}}(V_\mu)$,

$$\mathcal{O}_q(V_\mu):=\{\zeta\in\Gamma_q^{\mathbf{k}}(V_\mu)|p\circ\zeta=(S(p)\otimes\mathrm{id}_{\mathcal{T}_q(\mathbf{g})})\zeta, \quad \forall p\in\mathrm{U}_q(\mathbf{p})\}.$$

We may regard $\mathcal{O}_q(V_\mu)$ as the quantum analog of the space of ''holomorphic sections.'' Recall that the notation $W(\lambda)$ denotes the irreducible $\mathrm{U}_q(\mathbf{g})$ module with highest weight λ. We have the following result.

Theorem 6: *There exists the following* $\mathrm{U}_q(\mathbf{g})$ *module isomorphism*

$$\mathcal{O}_q(V_\mu)\cong\begin{cases}W((-\tilde{\mu})^\dagger), & -\tilde{\mu}\in\mathcal{P}_+,\\ 0, & \text{otherwise}.\end{cases} \tag{15}$$

Proof: Each $\zeta\in\mathcal{O}_q(V_\mu)$ can be expressed in the form

$$\zeta=\sum_{\lambda\in\mathcal{P}_+}\sum_{i,j} v_{ij}^{(\lambda)}\otimes\tilde{t}_{ij}^{(\lambda)},$$

for some $v_{ij}^{(\lambda)}\in V_\mu$ $(i,j=1,...,d_\lambda)$. Arguing as in the proof of Proposition 1 one concludes, for each $\lambda\in\mathcal{P}_+$, that there exist $\phi_i^{(\lambda)}\in\mathrm{Hom}_{\mathbf{C}}(W(\lambda),V_\mu)$ such that $v_{ij}^{(\lambda)}=\phi_i^{(\lambda)}(w_j^{(\lambda)})$, where $\{w_i^{(\lambda)}\}$ is the basis of $W(\lambda)$, relative to which the irreducible representation $t^{(\lambda)}$ of $\mathrm{U}_q(\mathbf{g})$ is defined. Thus we can rewrite ζ as

$$\zeta=\sum_{\lambda\in\mathcal{P}_+}\sum_{i,j} \phi_i^{(\lambda)}(w_j^{(\lambda)})\otimes\tilde{t}_{ij}^{(\lambda)}.$$

Similar reasoning as in the proof of Proposition 1 shows that the $\phi_i^{(\lambda)}$ must be $\mathrm{U}_q(\mathbf{p})$-module homomorphisms of degree $[\phi_i^{(\lambda)}]$. It immediately follows from (4) that

$$\phi_i^{(\lambda)}=c_i\phi^{(\lambda)},\quad c_i\in\mathbf{C},$$

and $\phi^{(\lambda)}$ may be nonzero only when

$$\overline{\lambda}=\tilde{\mu}.$$

Hence, if $-\tilde{\mu}\notin\mathcal{P}_+$, we have $\mathcal{O}_q(V_\mu)=0$. When $-\tilde{\mu}\in\mathcal{P}_+$, we set

$$\nu=(-\tilde{\mu})^{\dagger}.$$

Then, we may conclude that $\mathcal{O}_q(V_\mu)$ is spanned by

$$\zeta_i=\sum_j \phi^{(\nu)}(w_j^{(\nu)})\otimes\tilde{t}_{ij}^{(\lambda)},\tag{16}$$

which are obviously linearly independent. Furthermore,

$$x\cdot\zeta_i=(-1)^{[x][\phi^{(\nu)}]}\sum_j t_{ji}^{(\nu)}(x)\zeta_j,\quad x\in\mathrm{U}_q(\mathbf{g}).$$

Thus $\mathcal{O}_q(V_\mu)\cong W(\nu)$. More explicitly, the isomorphism is given by

$$W(\nu)\xrightarrow{(\mathrm{id}\otimes S)\delta}\mathcal{O}_q(W(\nu))\xrightarrow{\phi^{(\nu)}\otimes\mathrm{id}}\mathcal{O}_q(V_\mu).\tag{17}$$

This completes the proof of the theorem. □

This result provides an analog of the celebrated Borel–Weil theorem for the quantum supergroup $\mathrm{OSP}_q(1|2n)$. For the classical Lie supergroups, the program of developing a Bott–Borel–Weil theory was extensively investigated by Penkov and co-workers.[17] Also, a quantum Borel–Weil theorem for the covariant and contravariant tensor representations of quantum $\mathrm{GL}(m|n)$ was obtained in Ref. 9.

When $\mu=0$, the theorem implies that

$$\{f\in\mathcal{T}_q(\mathbf{g})|p\circ f=\epsilon(p)f,\quad\forall p\in\mathrm{U}_q(\mathbf{p})\}=\mathbf{C}\epsilon.$$

Combining this result with with Proposition 2, we obtain the following

Corollary: Let W be any finite-dimensional $\mathrm{U}_q(\mathbf{g})$ *module. Then, as* $\mathrm{U}_q(\mathbf{g})$*-modules,*

$$\mathcal{O}_q(W)\cong\epsilon\otimes W.$$

Toroidal and level 0 $U'_q(\widehat{sl_{n+1}})$ actions on $U_q(\widehat{gl_{n+1}})$ modules

Kei Miki
Department of Mathematics, Graduate School of Science, Osaka University, Toyonaka 560, Japan

(Received 14 August 1998; accepted for publication 17 March 1999)

(1) Utilizing a braid group action on a completion of $U_q(\widehat{sl_{n+1}})$, an algebra homomorphism from the toroidal algebra $U_q(sl_{n+1,\mathrm{tor}})$ $(n\geqslant 2)$ to a completion of $U_q(\widehat{gl_{n+1}})$ is obtained. (2) The toroidal actions by Saito induces a level 0 $U'_q(\widehat{sl_{n+1}})$ action on level 1 integrable highest weight modules of $U_q(\widehat{sl_{n+1}})$. Another level 0 $U'_q(\widehat{sl_{n+1}})$ action was defined by Jimbo *et al.*, in the case $n=1$. Using the fact that the intertwiners of $U_q(\widehat{sl_{n+1}})$ modules are intertwiners of toroidal modules for an appropriate comultiplication, the relation between these two level 0 $U'_q(\widehat{sl_{n+1}})$ actions is clarified.
[S0022-2488(99)04806-9]

I. INTRODUCTION

In Refs. 1 and 2, a quantum toroidal algebra $U_q(sl_{n+1,\mathrm{tor}})$ was introduced. Up to now several results have been obtained on this algebra. In Ref. 2 the connection between toroidal modules and an extension of the double affine Hecke algebra[3] was noticed and the Schur-type duality was obtained. The vertex representations were constructed on level 1 $U_q(\widehat{gl_{n+1}})$ modules by Saito.[4] In Ref. 5, toroidal actions were shown to be defined on any integrable highest weight module of $U_q(\widehat{gl_{n+1}})$, using the level—rank duality. Since the toroidal algebra has homomorphic images of $U_q(\widehat{sl_{n+1}})$ and $U'_q(\widehat{sl_{n+1}})$, $U_q(\widehat{sl_{n+1}})$ and $U'_q(\widehat{sl_{n+1}})$ actions are defined on toroidal modules. The known $U'_q(\widehat{sl_{n+1}})$ actions obtained in this way have level 0 (see Ref. 6). Therefore level 0 $U'_q(\widehat{sl_{n+1}})$ actions on $U_q(\widehat{sl_{n+1}})$ modules are closely related to toroidal modules. In Refs. 7 and 8, the level 1 $U_q(\widehat{sl_{n+1}})$ action on the fermionic Fock space[9] and the level 0 $U'_q(\widehat{sl_{n+1}})$ action via the affine Hecke algebra were shown to be combined into a toroidal action. In Ref. 10, motivated by Ref. 11, a level 0 $U'_q(\widehat{sl_2})$ action was defined on level 1 integrable $U_q(\widehat{sl_2})$ modules, utilizing the intertwiners and the representation of the affine Hecke algebra.

In this paper we obtain two results on these problems. In Sec. III, utilizing a braid group action on a completion of $U_q(\widehat{sl_{n+1}})$,[12] an algebra homomorphism from the toroidal algebra $U_q(sl_{n+1,\mathrm{tor}})$ $(n\geqslant 2)$ to a completion of $U_q(\widehat{gl_{n+1}})$ is constructed. This implies that any highest weight module of $U_q(\widehat{gl_{n+1}})$ is a toroidal module. This result corresponds to the fact that the algebra homomorphism from $U_q(\widehat{sl_{n+1}})$ to $U_q(gl_{n+1})$ by Jimbo[13] is neatly expressed in terms of the braid group action by Lusztig.[14] In Secs. IV and V, assuming a triangular decomposition of the toroidal algebra, we consider the level 1 toroidal modules by Saito. Utilizing the fact that the intertwiners of $U_q(\widehat{sl_{n+1}})$ modules are intertwiners of toroidal modules for an appropriate comultiplication, we clarify the relation between the level 0 $U'_q(\widehat{sl_{n+1}})$ action induced by the toroidal action and that in Ref. 10. Note that in Ref. 11, first, a Yangian action on level 1 integrable highest weight modules of $\widehat{sl}_2$ was constructed in terms of the currents and then the intertwining property of the vertex operators was used. Therefore our approach is closer to the original one. Clarifying the connection between our results and Refs. 5, 7, and 8 would be interesting.

II. DEFINITION OF ALGEBRAS

Let q be an indeterminate and set $F=\mathbf{Q}(q)$. Fix $n\geqslant 2$.

Let $(a_{ij})_{1\leqslant i,j\leqslant n}$ be the Cartan matrix of type A_n and set $\kappa_{ij}=1$. Let $\mathrm{U}_q(\widehat{sl_{n+1}})$ (Ref. 15) be the F algebra defined by generators $E_{i,m}$, $F_{i,m}$, $h_{i,r}$, $k_i^{\pm 1}$, $C^{\pm 1}$, $D^{\pm 1}$ $(1\leqslant i\leqslant n,\ m\in\mathbf{Z},\ r\in\mathbf{Z}\setminus\{0\})$ and relations,

$$C^{\pm 1}\text{central},\quad C^{\pm 1}C^{\mp 1}=D^{\pm 1}D^{\mp 1}=1,\quad DX_i(z)D^{-1}=X_i(z/q)\ \ (X=E,F), \tag{2.1}$$

$$k_i^{\pm 1}k_i^{\mp 1}=1,\quad D\phi_i^{\pm}(z)D^{-1}=\phi_i^{\pm}(z/q), \tag{2.2}$$

$$\phi_i^{\pm}(z)\phi_j^{\pm}(w)=\phi_j^{\pm}(w)\phi_i^{\pm}(z), \tag{2.3}$$

$$\frac{1-q^{-a_{ij}}C^{-1}\kappa_{ij}z/w}{1-q^{a_{ij}}C^{-1}\kappa_{ij}z/w}\,\phi_i^{+}(z)\phi_j^{-}(w)=\frac{1-q^{-a_{ij}}C\kappa_{ij}z/w}{1-q^{a_{ij}}C\kappa_{ij}z/w}\,\phi_j^{-}(w)\phi_i^{+}(z), \tag{2.4}$$

$$\phi_i^{\pm}(z)E_j(w)\phi_i^{\pm}(z)^{-1}=q^{\mp a_{ij}}\frac{1-q^{\pm a_{ij}}C^{-(1/2)\mp(1/2)}(\kappa_{ij}z/w)^{\pm 1}}{1-q^{\mp a_{ij}}C^{-(1/2)\mp(1/2)}(\kappa_{ij}z/w)^{\pm 1}}E_j(w), \tag{2.5}$$

$$\phi_i^{\pm}(z)F_j(w)\phi_i^{\pm}(z)^{-1}=q^{\pm a_{ij}}\frac{1-q^{\mp a_{ij}}C^{(1/2)\mp(1/2)}(\kappa_{ij}z/w)^{\pm 1}}{1-q^{\pm a_{ij}}C^{(1/2)\mp(1/2)}(\kappa_{ij}z/w)^{\pm 1}}F_j(w), \tag{2.6}$$

$$[E_i(z),F_j(w)]=\frac{\delta_{ij}}{q-q^{-1}}(\delta(Cw/z)\phi_i^{-}(z)-\delta(Cz/w)\phi_i^{+}(w)), \tag{2.7}$$

$$q^{a_{ij}}(1-q^{-a_{ij}}\kappa_{ij}z/w)E_i(z)E_j(w)=(1-q^{a_{ij}}\kappa_{ij}z/w)E_j(w)E_i(z), \tag{2.8}$$

$$q^{-a_{ij}}(1-q^{a_{ij}}\kappa_{ij}z/w)F_i(z)F_j(w)=(1-q^{-a_{ij}}\kappa_{ij}z/w)F_j(w)F_i(z); \tag{2.9}$$

for i,j such that $a_{ij}=-1$,

$$E_i(z_1)E_i(z_2)E_j(w)-(q+q^{-1})E_i(z_1)E_j(w)E_i(z_2)+E_j(w)E_i(z_1)E_i(z_2)+(z_1\leftrightarrow z_2)=0, \tag{2.10}$$

$$F_i(z_1)F_i(z_2)F_j(w)-(q+q^{-1})F_i(z_1)F_j(w)F_i(z_2)+F_j(w)F_i(z_1)F_i(z_2)+(z_1\leftrightarrow z_2)=0; \tag{2.11}$$

for i,j such that $a_{ij}=0$,

$$[E_i(z),E_j(w)]=0,\quad [F_i(z),F_j(w)]=0, \tag{2.12}$$

where

$$E_i(z)=\sum_{m\in\mathbf{Z}}E_{i,m}/z^m,\quad F_i(z)=\sum_{m\in\mathbf{Z}}F_{i,m}/z^m,$$

$$\phi_i^{\pm}(z)=k_i^{\mp 1}\exp\left(\mp(q-q^{-1})\sum_{r>0}h_{i,\mp r}z^{\pm r}\right). \tag{2.13}$$

As is well known, this algebra is also described by the Chevally generators e_i, f_i, $k_i^{\pm 1}(0\leqslant i\leqslant n)$, and $D^{\pm 1}$. Later we need its comultiplication Δ_0 determined by

$$\Delta_0(e_i)=e_i\otimes 1+k_i\otimes e_i,\quad \Delta_0(f_i)=f_i\otimes k_i^{-1}+1\otimes f_i,$$

$$\Delta_0(k_i)=k_i\otimes k_i,\quad \Delta_0(D)=D\otimes D. \tag{2.14}$$

$\mathrm{U}_q(\widehat{gl_{n+1}})$ (Ref. 16) is defined to be the F algebra generated by $E_{i,m}$, $F_{i,m}$, $a_{k,r}$, $t_k^{\pm 1}$, $C^{\pm 1}$, $D^{\pm 1}$ ($1 \leqslant i \leqslant n$, $1 \leqslant k \leqslant n+1$, $m \in \mathbf{Z}$, $r \in \mathbf{Z} \backslash \{0\}$) with defining relations (2.1), (2.7)–(2.12) and the following:

$$t_k^{\pm 1} t_k^{\mp 1} = 1, \quad D \psi_k^{\pm}(z) D^{-1} = \psi_k^{\pm}(z/q), \tag{2.15}$$

$$\psi_k^{\pm}(z) \psi_l^{\pm}(w) = \psi_l^{\pm}(w) \psi_k^{\pm}(z), \tag{2.16}$$

$$\begin{aligned} &\frac{1-q^{-2}C^{-1}z/w}{1-C^{-1}z/w} \frac{1-q^{2\theta(k>l)}C^{-1}z/w}{1-q^{-2\theta(k<l)}C^{-1}z/w} \psi_k^{+}(z) \psi_l^{-}(w) \\ &= \frac{1-Cz/w}{1-q^2 Cz/w} \frac{1-q^{2\theta(k>l)}Cz/w}{1-q^{-2\theta(k<l)}Cz/w} \psi_l^{-}(w) \psi_k^{+}(z), \end{aligned} \tag{2.17}$$

$$\psi_k^{\pm}(z) E_j(w) \psi_k^{\pm}(z)^{-1} = q^{\mp b_{kj}} \frac{1-q^{\pm(k-(1/2)+(1/2)b_{kj})} C^{-(1/2)\mp(1/2)} (z/w)^{\pm 1}}{1-q^{\pm(k-(1/2)-(3/2)b_{kj})} C^{-(1/2)\mp(1/2)} (z/w)^{\pm 1}} E_j(w), \tag{2.18}$$

$$\psi_k^{\pm}(z) F_j(w) \psi_k^{\pm}(z)^{-1} = q^{\pm b_{kj}} \frac{1-q^{\pm(k-(1/2)-(3/2)b_{kj})} C^{(1/2)\mp(1/2)} (z/w)^{\pm 1}}{1-q^{\pm(k-(1/2)+(1/2)b_{kj})} C^{(1/2)\mp(1/2)} (z/w)^{\pm 1}} F_j(w). \tag{2.19}$$

Here $b_{kj} = \delta_{kj} - \delta_{kj+1}$, $\theta(\cdot)$ is a step function, and

$$\psi_k^{\pm}(z) = t_k^{\mp 1} \exp\left(\mp (q-q^{-1}) \sum_{r>0} a_{k,\mp r} z^{\pm r} \right). \tag{2.20}$$

In Eq. (2.7), $\phi_i^{\pm}(z)$ should be understood as follows:

$$\phi_i^{\pm}(q^i z) = \psi_i^{\pm}(z) / \psi_{i+1}^{\pm}(z). \tag{2.21}$$

Let $(a_{ij})_{0 \leqslant i,j \leqslant n}$ be the Cartan matrix of type $A_n^{(1)}$ and set $\kappa_{ij} = 1$ $((i,j) \neq (n,0),(0,n))$, $\kappa_{n0} = \kappa_{0n}^{-1} = \kappa$. Let $\mathrm{U}_q(sl_{n+1,\mathrm{tor}})$ (Refs. 1 and 2) be the F algebra defined by generators $E_{i,m}$, $F_{i,m}$, $h_{i,r}$, $k_i^{\pm 1}$, $C^{\pm 1}$, $D^{\pm 1}$ ($0 \leqslant i \leqslant n$, $m \in \mathbf{Z}$, $r \in \mathbf{Z} \backslash \{0\}$), $\kappa^{\pm 1}$ and relations (2.1)–(2.12) and

$$\kappa^{\pm 1} \text{ central}, \quad \kappa^{\pm 1} \kappa^{\mp 1} = 1. \tag{2.22}$$

Note that we include only one scaling element D and its inverse among the generators.

Hereafter we shall write U for $\mathrm{U}_q(\widehat{sl_{n+1}})$ and let U^+, U^-, and U^0 denote the subalgebras of U generated by e_i ($0 \leqslant i \leqslant n$), f_i ($0 \leqslant i \leqslant n$), and $k_i^{\pm 1}$ ($0 \leqslant i \leqslant n$) and $D^{\pm 1}$, respectively.

At the end of the section, for completeness, we shall prove the following lemma, though it would be well known. The first claim enables us to identify U with the subalgebra of $\mathrm{U}_q(\widehat{gl_{n+1}})$ generated by $E_{i,m}$, $F_{i,m}$, $h_{i,r}$, $k_i^{\pm 1}$ ($1 \leqslant i \leqslant n$), $C^{\pm 1}$, and $D^{\pm 1}$.

Lemma 1: (1) The algebra homomorphism i: $U \to U_q(\widehat{gl_{n+1}})$ *such that*

$$\begin{aligned} &E_i(z) \mapsto E_i(z), \quad F_i(z) \mapsto F_i(z), \\ &\phi_i^{\pm}(q^i z) \mapsto \psi_i^{\pm}(z) \psi_{i+1}^{\pm}(z)^{-1}, \quad C \mapsto C, \quad D \mapsto D, \end{aligned} \tag{2.23}$$

is injective.

(2) Set $\beta_r = \sum_{k=1}^{n+1} q^{(2k-n-2)r} a_{k,r} / [(n+1)r]$ *where* $[m] = (q^m - q^{-m})/(q-q^{-1})$. *Let* $A^{\pm}$ *(resp.* A^0*) be the subalgebras of* $U_q(\widehat{gl_{n+1}})$ *generated by* $i(U^{\pm})$ *and* $\beta_{\pm r}$ $(r>0)$ *(resp.* $t_k^{\pm 1}$, $C^{\pm 1}$, *and* $D^{\pm 1}$*). Then the multiplication map* $A^- \otimes A^0 \otimes A^+ \to U_q(\widehat{gl_{n+1}})$ *is an isomorphism of vector spaces.*

Before proving the lemma, we shall introduce some notations, which we shall also need in Sec. IV A. Let $\mathcal{A}$ be the F algebra defined by generators $E_{i,m}$, $F_{i,m}$, $h_{i,r}$, $t_k^{\pm 1}$, $C^{\pm 1}$, $D^{\pm 1}$ ($1 \leqslant i \leqslant n$, $1 \leqslant k \leqslant n+1$, $m \in \mathbf{Z}$, $r \in \mathbf{Z} \backslash \{0\}$) and the relations

$$t_k^{\pm 1} t_k^{\mp 1} = 1, \quad t_k t_l = t_l t_k, \quad D t_k = t_k D, \quad t_k \phi_i^{\pm}(z) t_k^{-1} = \phi_i^{\pm}(z), \tag{2.24}$$

$$t_k E_j(z) t_k^{-1} = q^{b_{kj}} E_j(z), \quad t_k F_j(z) t_k^{-1} = q^{-b_{kj}} F_j(z), \tag{2.25}$$

and (2.1)–(2.12), where $(a_{ij})_{1 \leqslant i,j \leqslant n}$ is the Cartan matrix of type A_n, $\kappa_{ij}=1$ and $k_i = t_i t_{i+1}^{-1}$. Let further $\mathcal{B}$ be the F algebra generated by b_r ($r \in \mathbf{Z} \backslash \{0\}$), $C^{\pm 1}$, and $D^{\pm 1}$ with relations

$$C^{\pm 1} \text{ central}, \quad C^{\pm 1} C^{\mp 1} = D^{\pm 1} D^{\mp 1} = 1, \quad D b_r D^{-1} = q^r b_r,$$

$$[b_r, b_s] = \delta_{r+s,0} \frac{(q^{n+1}C)^r - (q^{n+1}C)^{-r}}{q - q^{-1}} \frac{[r]^2}{r[(n+1)r]}. \tag{2.26}$$

Finally let $j: \mathrm{U}_q(\widehat{gl_{n+1}}) \to \mathcal{A} \otimes \mathcal{B} / \langle C \otimes 1 - 1 \otimes C \rangle$ be the algebra homomorphism determined by

$$E_i(z) \mapsto E_i(z) \dot{\otimes} 1, \quad F_i(z) \mapsto F_i(z) \dot{\otimes} 1,$$

$$\psi_k^{\pm}(z) \mapsto (t_k^{\mp 1} \dot{\otimes} 1) \exp\left(\mp (q - q^{-1}) \sum_{r>0} \hat{a}_{k,\mp r} z^{\pm r} \right),$$

$$C \mapsto C \dot{\otimes} 1, \quad D \mapsto D \dot{\otimes} D, \tag{2.27}$$

where $x \dot{\otimes} y$ denotes the image of $x \otimes y$ under the quotient map $\mathcal{A} \otimes \mathcal{B} \to \mathcal{A} \otimes \mathcal{B} / \langle C \otimes 1 - 1 \otimes C \rangle$ and $\hat{a}_{k,r} = \overline{a}_{k,r} \dot{\otimes} 1 + 1 \dot{\otimes} b_r$ with

$$\overline{a}_{k,r} = \frac{1}{[(n+1)r]} \left(\sum_{i=k}^{n} [(n+1-i)r] h_{i,r} - q^{-(n+1)r} \sum_{i=1}^{k-1} [ir] h_{i,r} \right). \tag{2.28}$$

Proof of Lemma 1: Letting ζ be the algebra homomorphism from U to $\mathcal{A}$ such that

$$X_i(z) \mapsto X_i(z) \quad (X = E, F, \phi^{\pm}), \quad C \mapsto C, \quad D \mapsto D, \tag{2.29}$$

set $\mathcal{A}^{\pm} = \zeta(\mathrm{U}^{\pm})$. Let further $\mathcal{A}^0$ be the subalgebra of $\mathcal{A}$ generated by $t_k^{\pm 1}$, $C^{\pm 1}$, and $D^{\pm 1}$. Then Refs. 17 and 18 imply that $\mathcal{A}^- \otimes \mathcal{A}^0 \otimes \mathcal{A}^+ \simeq \mathcal{A}$, $\mathcal{A}^{\pm} \simeq \mathrm{U}^{\pm}$ and the vectors $\Pi_k t_k^{m_k} C^a D^b$ ($m_k, a, b \in \mathbf{Z}$) form a basis of $\mathcal{A}^0$. Note that this triangular decomposition of $\mathcal{A}$ proves the injectivity of ζ. Let $\mathcal{B}^{\pm}$ (resp. $\mathcal{B}^0$) be the subalgebras of $\mathcal{B}$ generated by $b_{\pm r}$ ($r>0$) (resp. $C^{\pm 1}$ and $D^{\pm 1}$). Then $\mathcal{B}^- \otimes \mathcal{B}^0 \otimes \mathcal{B}^+ \simeq \mathcal{B}$ and the vectors $\Pi_{r>0} b_{\pm r}^{m_r}$ ($m_r \in \mathbf{Z}_{\geqslant 0}$, $m_r = 0$ if $r \gg 0$) and $C^a D^b$ ($a, b \in \mathbf{Z}$) form bases of $\mathcal{B}^{\pm}$ and $\mathcal{B}^0$, respectively. Set $\mathcal{C}^0 = \mathcal{A}^0 \otimes \mathcal{B}^0 / \langle C \otimes 1 - 1 \otimes C \rangle$. Then from the above properties of $\mathcal{A}$ and $\mathcal{B}$ we find that $\mathcal{A} \otimes \mathcal{B} / \langle C \otimes 1 - 1 \otimes C \rangle$ has the triangular decomposition

$$(\mathcal{A}^- \otimes \mathcal{B}^-) \otimes \mathcal{C}^0 \otimes (\mathcal{A}^+ \otimes \mathcal{B}^+) \simeq \mathcal{A} \otimes \mathcal{B} / \langle C \otimes 1 - 1 \otimes C \rangle, \tag{2.30}$$

and a basis of $\mathcal{C}^0$ is given by the elements $\Pi_k t_k^{m_k} C^a D^b \otimes D^c$ ($m_k, a, b, c \in \mathbf{Z}$).

Let $\xi: \mathcal{A} \to \mathrm{U}_q(\widehat{gl_{n+1}})$ be the algebra homomorphism such that

$$X_i(z) \mapsto X_i(z) \quad (X = E, F), \quad \phi_i^{\pm}(q^i z) \mapsto \psi_i^{\pm}(z) \psi_{i+1}^{\pm}(z)^{-1},$$

$$t_k \to t_k, \quad C \mapsto C, \quad D \mapsto D. \tag{2.31}$$

From the above triangular decompositions of $\mathcal{A}$ and $\mathcal{A}\otimes\mathcal{B}/\langle C\otimes 1-1\otimes C\rangle$, we find that $j\circ\xi$ and, hence, $i=\xi\circ\zeta$ are injective. Since β_r's commute with $i(\mathrm{U}^{\pm})$, we have $A^{\pm}=\Sigma_{m_r}i(\mathrm{U}^{\pm})\Pi_{r>0}\beta_{\pm r}^{m_r}$. Noting this, $j(i(y))=\zeta(y)\dot{\otimes}1(y\in\mathrm{U}^{\pm})$ and $j(\beta_r)=1\dot{\otimes}b_r$, we find that the map j induces the isomorphisms $A^{\pm}\simeq\mathcal{A}^{\pm}\otimes\mathcal{B}^{\pm}$. This map j also induces the injective map $\mathcal{A}^0\rightarrow\mathcal{C}^0$. Therefore since $\mathrm{U}_q(\widehat{gl_{n+1}})=A^-A^0A^+$, we obtain (2). ∎

III. HOMOMORPHISM FROM $\mathrm{U}_q(sl_{n+1,\mathrm{tor}})$ TO A COMPLETION OF $\mathrm{U}_q(\widehat{gl_{n+1}})$

A. Braid group action on a completion of $\mathrm{U}_q(\widehat{sl_{n+1}})$

Setting

$$\mathrm{U}_r=\{y\in\mathrm{U}|DyD^{-1}=q^r y\},\quad (r\in\mathbf{Z}),\tag{3.1}$$

put

$$\mathrm{U}_{kl}=\sum_{\substack{r\geqslant k\\ s\geqslant l}}\mathrm{U}_{-r}\mathrm{U}\mathrm{U}_s,\quad (k,l\in\mathbf{Z}_{\geqslant 0}).\tag{3.2}$$

We introduce a linear topology on U by letting (U_{kl}) be a fundamental system of neighborhoods of the origin. Then U is a topological algebra. Define $\mathrm{U}_r^{\pm}$ similarly to U_r. Then the following holds:

$$\mathrm{U}_{kl}=\sum_{r\geqslant k}\mathrm{U}_{-r}^{-}\mathrm{U}^0\sum_{s\geqslant l}\mathrm{U}_s^{+}.\tag{3.3}$$

Therefore U is separated thanks to the triangular decomposition of U.[18] We shall denote the completion of U by $\hat{\mathrm{U}}$.

Let T_i $(1\leqslant i\leqslant n)$ (Ref. 12) be the continuous algebra automorphisms of $\hat{\mathrm{U}}$ determined by

$$E_i(z)\mapsto -F_i(z/Cq^2)\phi_i^-(z/q^2)^{-1},\quad F_i(z)\mapsto -\phi_i^+(z/q^2)^{-1}E_i(z/Cq^2),$$
$$\phi_i^{\pm}(z)\mapsto\phi_i^{\pm}(z/q^2)^{-1},\quad C^{\pm 1}\mapsto C^{\pm 1},\quad D^{\pm}\mapsto D^{\pm 1},\tag{3.4}$$

$$E_j(z)\mapsto\oint\frac{du}{u}\left(E_i(u)E_j(z)-q\frac{1-q^{-1}u/z}{1-qu/z}E_j(z)E_i(u)\right),$$

$$F_j(z)\mapsto\oint\frac{du}{u}\left(F_j(z)F_i(u)-q^{-1}\frac{1-qz/u}{1-q^{-1}z/u}F_i(u)F_j(z)\right),$$

$$\phi_j^{\pm}(z)\mapsto\phi_j^{\pm}(z)\phi_i^{\pm}(z/q),\ \text{when}\ |i-j|=1,\tag{3.5}$$

$$E_j(z)\mapsto E_j(z),\quad F_j(z)\mapsto F_j(z),\quad \phi_j^{\pm}(z)\mapsto\phi_j^{\pm}(z),\ \text{when}\ |i-j|>1.\tag{3.6}$$

Here $\oint(du/u)$ denotes the operation which picks out the coefficient of u^0. Then they satisfy the Coxeter relations,

$$T_iT_jT_i=T_jT_iT_j\ \text{when}\ |i-j|=1,$$
$$T_iT_j=T_jT_i\ \text{when}\ |i-j|>1,\tag{3.7}$$

and have the following property:

$$T_iT_{i\pm 1}X_i(z)=X_{i\pm 1}(z/q),\quad (X=E,F,\phi^{\pm}).\tag{3.8}$$

Note that the inverse T_i^{-1} is given by $\eta\circ T_i\circ\eta$ where η is the continuous algebra antiautomorphism of $\hat{\mathrm{U}}$ determined by

$$E_i(z)\mapsto E_i(z^{-1}),\quad F_i(z)\mapsto F_i(z^{-1}),\quad \phi_i^{\pm}(z)\mapsto\phi_i^{\mp}(Cz^{-1})\quad C^{\pm1}\mapsto C^{\pm1},\quad D^{\pm1}\mapsto D^{\pm1}. \tag{3.9}$$

B. Homomorphism from $\mathrm{U}_q(sl_{n+1,\mathrm{tor}})$ to a completion of $\mathrm{U}_q(\widehat{gl_{n+1}})$

As in the case U, we introduce a separated linear topology on $\mathrm{U}_q(\widehat{gl_{n+1}})$ and denote its completion by $\hat{\mathrm{U}}_q(\widehat{gl_{n+1}})$. Equation (3.3), the corresponding one for $\mathrm{U}_q(\widehat{gl_{n+1}})_{kl}$ and Lemma 1 give $\mathrm{U}_{kl}=\mathrm{U}\cap\mathrm{U}_q(\widehat{gl_{n+1}})_{kl}$. Therefore we can identify $\hat{\mathrm{U}}$ with the subalgebra of $\hat{\mathrm{U}}_q(\widehat{gl_{n+1}})$. Utilizing the above braid group action on $\hat{\mathrm{U}}$, we obtain the following theorem:

Theorem 1: *Set*

$$\tilde{E}_0^{(\epsilon)}(z)=-T_n^{\epsilon}\cdots T_1^{\epsilon}E_1(zq^{\epsilon}),\quad \tilde{F}_0^{(\epsilon)}(z)=-T_n^{\epsilon}\cdots T_1^{\epsilon}F_1(zq^{\epsilon}),$$

$$\tilde{\phi}_0^{\pm,(\epsilon)}(z)=T_n^{\epsilon}\cdots T_1^{\epsilon}\phi_1^{\pm}(zq^{\epsilon}),\quad (\epsilon=\pm1). \tag{3.10}$$

For $\epsilon=\pm1$, there exists an algebra homomorphism $f_\epsilon:U_q(sl_{n+1,tor})\to\hat{U}_q(\widehat{gl_{n+1}})$ determined by

$$E_i(z)\mapsto E_i(z),\quad F_i(z)\mapsto F_i(z),\quad \phi_i^{\pm}(z)\mapsto\phi_i^{\pm}(z),\quad (1\leqslant i\leqslant n),$$

$$C\mapsto C,\quad D\mapsto D,$$

$$E_0(z)\mapsto\psi_{n+1}^{+}(z/\mu_\epsilon)^{\epsilon}\tilde{E}_0^{(\epsilon)}(z)\psi_{n+1}^{-}(Cz/\mu_\epsilon)^{-\epsilon},$$

$$F_0(z)\mapsto\psi_{n+1}^{+}(Cz/\mu_\epsilon)^{-\epsilon}\tilde{F}_0^{(\epsilon)}(z)\psi_{n+1}^{-}(z/\mu_\epsilon)^{\epsilon},$$

$$\phi_0^{\pm}(z)\mapsto\tilde{\phi}_0^{\pm,(\epsilon)}(z)\psi_{n+1}^{\pm}(z/C\mu_\epsilon)^{\epsilon}\psi_{n+1}^{\pm}(Cz/\mu_\epsilon)^{-\epsilon},$$

$$\kappa\mapsto(\mu_0C^2)^{\epsilon}, \tag{3.11}$$

where $\mu_0=q^{n+1}$ and $\mu_\epsilon=\mu_0(\mu_0C)^{\epsilon}$.

Proof: As an example, we shall check the Serre relation (2.10) with $(i,j)=(0,n)$ for the case $\epsilon=1$. Set $T_w=T_n\cdots T_1$. Thanks to (3.8), we get

$$T_w^{-1}E_{n-1}(z/q)=E_n(z),\quad T_w^{-1}E_n(z/q)=-\tilde{\phi}_0^{+,(+)}(\kappa z/C)\tilde{E}_0^{(+)}(\kappa z)\tilde{\phi}_0^{-,(+)}(\kappa z)^{-1}, \tag{3.12}$$

where $\kappa=\mu_0C^2$. Therefore applying T_w^{-1} to the Serre relation (2.10) with $(i,j)=(n,n-1)$ of $\mathrm{U}_q(\widehat{gl_{n+1}})$ and using the relations among $\psi_k^{\pm}(z)$, $E_i(z)$, and $F_i(z)$, we obtain the desired relation. ■

Corollary 1: Let V be a $U_q(\widehat{gl_{n+1}})$ module such that

$$V=\oplus_{m\in\mathbf{Z}}V_m,\quad V_m=\{v\in V|Dv=q^m v\},\quad V_m=\{0\}\quad (m\gg0).$$

If C acts as $C_0\in F^{\times}$ on V, then V has two $U_q(sl_{n+1,tor})$ module structures where κ acts as $\mu_0C_0^2$ and $(\mu_0C_0^2)^{-1}$, *respectively.*

Corollary 2: The algebra homomorphism $g:U\to U_q(sl_{n+1,tor})$ such that

$$E_i(z)\mapsto E_i(z),\quad F_i(z)\mapsto F_i(z),\quad \phi_i^{\pm}(z)\mapsto\phi_i^{\pm}(z),\quad C\mapsto C,\quad D\mapsto D, \tag{3.13}$$

is injective.

Proof: The claim follows from the fact that the composite $f_\epsilon \circ g$ is the identity map from U to the subalgebra U of $\hat{\mathrm{U}}_q(\widehat{gl_{n+1}})$. ■

IV. INTERTWINERS OF TOROIDAL MODULES

A. Level 1 toroidal modules by Saito

For $\mu \in F^\times$, set $\mathcal{U}_\mu = \mathrm{U}_q(sl_{n+1,\mathrm{tor}})/\langle \kappa - \mu \rangle$. Hereafter we consider this algebra. We shall often use $p = \mu_0 \mu$ instead of μ.

Let Λ_i $(0 \leqslant i \leqslant n)$ be the fundamental weights of $\widehat{sl_{n+1}}$. Let further $V(\Lambda_i)$ be the irreducible highest weight module of U with highest weight Λ_i and v_{Λ_i} be its highest weight vector. Set $\mathcal{B}_1 = \mathcal{B}/I$, where I is the left ideal generated by b_r $(r>0)$, $C-q$ and $D-1$. For $m \in \mathbf{Z}$, set $W_m = V(\Lambda_j) \otimes \mathcal{B}_1$ where $j \equiv m \bmod n+1$. Let α_i's be the simple roots of $\widehat{sl_{n+1}}$ and $(\ |\ )$ be the standard symmetric bilinear form on the weight space of $\widehat{sl_{n+1}}$ normalized by $(\alpha_i | \alpha_i) = 2$. Set

$$\epsilon_k = \left(\sum_{i=k}^{n} (n+1-i)\alpha_i - \sum_{i=1}^{k-1} i\alpha_i \right)/(n+1), \quad (1 \leqslant k \leqslant n+1).$$

For $1 \leqslant k \leqslant n+1$, let ∂_{ϵ_k} be a linear operator on $V(\Lambda_j)$ such that $\partial_{\epsilon_k} v = (\epsilon_k | \nu) v$, where v is a weight vector with weight ν. Then W_m is a $\mathrm{U}_q(\widehat{gl_{n+1}})$ module via the map j if the U module $V(\Lambda_j)$ is extended to a $\mathcal{A}$ module by letting t_k acts as $q^{\partial_{\epsilon_k} + [m/(n+1)]}$.

The results by Saito[4] on level 1 toroidal modules can be stated as follows.

Proposition 1: Set $a = (-1)^{n-1} q^n$.

(1) For $\epsilon = \pm 1$, *the U module structure on* $V(\Lambda_j)$ $(0 \leqslant j \leqslant n)$ *is extended to a* $\mathcal{U}_{\mu_0^\epsilon}$ *module structure by*

$$E_0(z) = a \tilde{E}_0^{(\epsilon)}(z), \quad F_0(z) = a^{-1} \tilde{F}_0^{(\epsilon)}(z), \quad \phi_0^{\pm}(z) = \tilde{\phi}_0^{\pm,(\epsilon)}(z). \tag{4.1}$$

(2) Letting α_r $(r \in \mathbf{Z} \backslash \{0\})$ *be the elements of* $F^\times$ *such that*

$$\alpha_r \alpha_{-r} = \frac{\mu^r + \mu^{-r} - \mu_0^r - \mu_0^{-r}}{(q^r - q^{-r})(q^r \mu_0^r - q^{-r} \mu_0^{-r})}, \tag{4.2}$$

set

$$X^{\pm}(z) = \exp\left(\mp (q - q^{-1}) \sum_{r>0} x_{\mp r} z^{\pm r} \right),$$

$$x_r = (q\mu_0^2)^r \frac{(\mu/\mu_0)^r - 1}{q^{2r} - 1} \overline{a}_{n+1,r} \otimes 1 + \alpha_r 1 \otimes b_r . \tag{4.3}$$

Then the U module structure on W_m *is extended to a* $\mathcal{U}_\mu$ *module structure by*

$$E_0(z) = a X^+(z) (\tilde{E}_0^{(+)}(z) \otimes 1) X^{-1}(qz)^{-1} ((\mu_0/\mu)^{\partial_{\epsilon_{n+1}} + m/(n+1)} \otimes 1),$$

$$F_0(z) = a^{-1} (((\mu/\mu_0)^{\partial_{\epsilon_{n+1}} + m/(n+1)} \otimes 1) X^+(qz)^{-1} (\tilde{F}_0^{(+)}(z) \otimes 1) X^-(z),$$

$$\phi_0^{\pm}(z) = \frac{X^{\pm}(q^{-1}z)}{X^{\pm}(qz)} (\tilde{\phi}_0^{\pm,(+)}(z) \otimes 1). \tag{4.4}$$

We have chosen the above normalization of $E_0(z)$ and $F_0(z)$ for a later convenience. Note that in the case $\mu = \mu_0 q^2$ the above result coincides with Theorem 1.

B. Level 0 toroidal modules

Set $V=F^{n+1}$ and let $v_1,\ldots,v_{n+1}$ be its standard basis. $V[x,x^{-1}]$ is a U module by the following:

$$E_i(q^iz)=\delta(z/x)E_{ii+1},\quad F_i(q^iz)=\delta(z/x)E_{i+1i},$$

$$\phi_i^+(q^iz)=\sum_{k\neq i,i+1}E_{kk}+q^{-1}\frac{1-q^2z/x}{1-z/x}E_{ii}+q\frac{1-q^{-2}z/x}{1-z/x}E_{i+1i+1},$$

$$\phi_i^-(q^iz)=\sum_{k\neq i,i+1}E_{kk}+q\frac{1-q^{-2}x/z}{1-x/z}E_{ii}+q^{-1}\frac{1-q^2x/z}{1-x/z}E_{i+1i+1},\quad (1\leqslant i\leqslant n),$$

$$C^{\pm 1}=1,\quad D^{\pm 1}=q^{\pm\vartheta}. \tag{4.5}$$

Here E_{ij}'s are matrix units, $\delta(z)=\Sigma_{m\in\mathbf{Z}}z^m$, x acts by multiplication, and a^{ϑ} $(a\in F^{\times})$ is a linear operator on $V[x,x^{-1}]$ defined by $a^{\vartheta}v_{\epsilon}x^m=a^mv_{\epsilon}x^m$. We shall denote this representation by (π,V_x).

Set $p=\mu_0\mu$. The U module structure on V_x is extended to a $\mathcal{U}_{\mu}$ structure[2] by

$$E_0(z)=ap^{\vartheta}\delta(z/x)E_{n+11},\quad F_0(z)=a^{-1}\delta(z/x)E_{1n+1}p^{-\vartheta},$$

$$\phi_0^+(z)=\sum_{k\neq 1,n+1}E_{kk}+q^{-1}\frac{1-q^2z/px}{1-z/px}E_{n+1n+1}+q\frac{1-q^{-2}z/x}{1-z/x}E_{11},$$

$$\phi_0^-(z)=\sum_{k\neq 1,n+1}E_{kk}+q\frac{1-q^{-2}px/z}{1-px/z}E_{n+1n+1}+q^{-1}\frac{1-q^2x/z}{1-x/z}E_{11}, \tag{4.6}$$

where $a\in F^{\times}$. We shall denote this representation by (π_a,V_a).

C. Bialgebra structure of $\mathcal{U}_{\mu}$

In this subsection, fixing $\mu\in F^{\times}$, we omit the subscript μ of $\mathcal{U}_{\mu}$.

1. Completion $\mathcal{U}_{\mu}^{\hat{\otimes}N}$ and bialgebra structure of $\mathcal{U}_{\mu}$

Set $c_i=i(n+1-i)$ $(1\leqslant i\leqslant n)$ and put $K=D^{2(n+1)}\Pi_{1\leqslant i\leqslant n}k_i^{c_i}$. Note that $(\Sigma c_i\alpha_i|\alpha_j)=2$ for $1\leqslant j\leqslant n$. For $N\geqslant 1$ and $r\in\mathbf{Z}$, set

$$\mathcal{U}^{\otimes N}{}_r=\{y\in\mathcal{U}^{\otimes N}|K^{\otimes N}y(K^{\otimes N})^{-1}=q^ry\}. \tag{4.7}$$

We assume the following:

Assumption 1: (1) U is identified with the subalgebra of $\mathcal{U}$ generated by $E_{i,m}$, $F_{i,m}$, $h_{i,r}$, $k_1^{\pm 1}$ $(1\leqslant i\leqslant n)$, $C^{\pm 1}$ and $D^{\pm 1}$ *by the algebra homomorphism from U* to $\mathcal{U}$ *determined by*

$$E_i(z)\mapsto E_i(z),\quad F_i(z)\mapsto F_i(z),\quad \phi_i^{\pm}(z)\mapsto\phi_i^{\pm}(z)\quad C\mapsto C,\quad D\mapsto D. \tag{4.8}$$

(2) $\mathcal{U}$ has subalgebras $\mathcal{U}^-$, $\mathcal{U}^0$, and *$\mathcal{U}^+$ such that the multiplication map $\mathcal{U}^-\otimes\mathcal{U}^0\otimes\mathcal{U}^+\to\mathcal{U}$ is an isomorphism of vector spaces and*

$$U^{\pm}\subset\mathcal{U}^{\pm}=\oplus_{r\geqslant 0}\mathcal{U}^{\pm}\cap\mathcal{U}_{\pm r},\quad U^0\subset\mathcal{U}^0\subset\mathcal{U}_0. \tag{4.9}$$

Set

$$\mathcal{U}^{\otimes N}{}_{0l}=\sum_{s\geqslant l}\mathcal{U}^{\otimes N}\mathcal{U}^{\otimes N}{}_s,\quad (l\in\mathbf{Z}_{\geqslant 0}). \tag{4.10}$$

We introduce a linear topology on $\mathcal{U}^{\otimes N}$ by letting $(\mathcal{U}^{\otimes N}{}_{0l})_{l\geqslant 0}$ be a fundamental system of neighborhoods of the origin. [Hereafter we shall simply say ''introduce a linear topology by $(\mathcal{U}^{\otimes N}{}_{0l})$.''] The $\mathcal{U}^{\otimes N}$ is a separated topological algebra. We denote its completion by $\hat{\mathcal{U}}$ $(N=1)$ and $\mathcal{U}^{\hat{\otimes} N}$ $(N\geqslant 2)$. Note that for $N\geqslant 2$, the topology on $\mathcal{U}^{\otimes N}$ is equivalent to the tensor product topology.

Let $\overline{\Delta}_{\mathrm{I}}$ and $\overline{\Delta}_{\mathrm{II}}$ be the continuous algebra homomorphisms from $\hat{\mathcal{U}}$ to $\mathcal{U}\hat{\otimes}\mathcal{U}$ determined by

$$\overline{\Delta}_{\mathrm{I}}(C)=\overline{\Delta}_{\mathrm{II}}(C)=C\otimes C,\quad \overline{\Delta}_{\mathrm{I}}(D)=\overline{\Delta}_{\mathrm{II}}(D)=D\otimes D,$$

$$\overline{\Delta}_{\mathrm{I}}(\phi_i^+(z))=\phi_i^+(z/C_2)\otimes\phi_i^+(z),\quad \overline{\Delta}_{\mathrm{I}}(\phi_i^-(z))=\phi_i^-(z)\otimes\phi_i^-(z/C_1),$$

$$\overline{\Delta}_{\mathrm{I}}(E_i(z))=E_i(z)\otimes 1+\phi_i^-(z)\otimes E_i(z/C_1),\quad \overline{\Delta}_{\mathrm{I}}(F_i(z))=1\otimes F_i(z)+F_i(z/C_2)\otimes\phi_i^+(z),$$

$$\overline{\Delta}_{\mathrm{II}}(\phi_i^+(z))=\phi_i^+(z/C_2)\otimes\phi_i^+(z),\quad \overline{\Delta}_{\mathrm{II}}(\phi_i^-(z))=\phi_i^-(z)\otimes\phi_i^-(z/C_1),$$

$$\overline{\Delta}_{\mathrm{II}}(E_i(z))=E_i(z)\otimes 1+\phi_i^+(Cz)\otimes E_i(C_1z),\quad \overline{\Delta}_{\mathrm{II}}(F_i(z))=1\otimes F_i(z)+F_i(C_2z)\otimes\phi_i^-(Cz), \tag{4.11}$$

where $C_1=C\otimes 1$ and $C_2=1\otimes C$. Let further $\epsilon:\hat{\mathcal{U}}\to F$ denote the continuous algebra homomorphism determined by

$$\epsilon(E_i(z))=\epsilon(F_i(z))=0,\quad \epsilon(\phi_i^{\pm}(z))=\epsilon(C)=\epsilon(D)=1. \tag{4.12}$$

Here F is given a discrete topology. Then $(\hat{\mathcal{U}},\overline{\Delta}_i,\epsilon)$ $(i=\mathrm{I,II})$ are bialgebras. These are straightforward generalizations of the bialgebra structures found by Drinfeld for $\hat{U}$. Let $\mathcal{R}=\mathcal{R}^+\mathcal{R}^0\mathcal{R}^-$ be the Gauss decomposition of the universal R matrix of U with Δ_0 as a comultiplication.[19] Letting

$$\mathcal{F}_{\mathrm{I}}=\mathcal{R}^-,\quad \mathcal{F}_{\mathrm{II}}=\sigma(\mathcal{R}^+)^{-1},\quad (\sigma(a\otimes b)=b\otimes a), \tag{4.13}$$

set

$$\Delta_i(\cdot)=\mathcal{F}_i^{-1}\overline{\Delta}_i(\cdot)\mathcal{F}_i,\quad (i=\mathrm{I,II}). \tag{4.14}$$

It is known[19] that

$$(\epsilon\hat{\otimes}1)\mathcal{F}_i=(1\hat{\otimes}\epsilon)\mathcal{F}_i=1,\quad (\mathcal{F}_i)_{12}(\Delta_0\hat{\otimes}1)\mathcal{F}_i=(\mathcal{F}_i)_{23}(1\hat{\otimes}\Delta_0)\mathcal{F}_i, \tag{4.15}$$

$$\Delta_i(y)=\Delta_0(y),\quad (i=\mathrm{I,II},\ \ y\in U), \tag{4.16}$$

and that $(\hat{\mathcal{U}},\Delta_i,\epsilon)$ $(i=\mathrm{I,II})$ are bialgebras. Set $\Delta_{\mathrm{I}}^{\mathrm{op}}=\sigma\circ\Delta_{\mathrm{I}}$ and $\mathcal{F}_{\mathrm{I}}^{\mathrm{op}}=\sigma(\mathcal{F}_{\mathrm{I}})$. For $(\Delta,\mathcal{F})=(\Delta_{\mathrm{I}}^{\mathrm{op}},\mathcal{F}_{\mathrm{I}}^{\mathrm{op}})$, $(\Delta_{\mathrm{II}},\mathcal{F}_{\mathrm{II}})$, etc., we define $\Delta^{(N)}:\hat{\mathcal{U}}\to\mathcal{U}^{\hat{\otimes}N+1}$ $(N\geqslant 1)$ by

$$\Delta^{(1)}=\Delta,\quad \Delta^{(N)}=(\Delta\hat{\otimes}1^{\hat{\otimes}N-1})\circ\Delta^{(N-1)}\quad (N\geqslant 2) \tag{4.17}$$

and $\mathcal{F}^{(N)}\in\mathcal{U}^{\hat{\otimes}N}$ $(N\geqslant 2)$ by

$$\mathcal{F}^{(2)}=\mathcal{F},\quad \mathcal{F}^{(N)}=(\mathcal{F}^{(2)})_{12}(\Delta\hat{\otimes}1^{\hat{\otimes}N-2})\mathcal{F}^{(N-1)},\quad (N\geqslant 3). \tag{4.18}$$

Then the following holds:

$$\Delta^{(N-1)}(y)=\mathcal{F}^{(N)-1}\overline{\Delta}^{(N-1)}(y)\mathcal{F}^{(N)},\quad (y\in\mathcal{U}). \tag{4.19}$$

Later we need the following property of $\mathcal{F}_{\rm I}^{\rm op}$ and $\mathcal{F}_{\rm II}$.[19] Set $U^{\geqslant 0}=U^0U^+$ and $U^{\leqslant 0}=U^-U^0$. Set further $\overline{Q}=\oplus_{i=1}^n\mathbf{Z}\alpha_i$, $\overline{Q}_+=-\overline{Q}_-=\oplus_{i=1}^n\mathbf{Z}_{\geqslant 0}\alpha_i$, and $\delta=\Sigma_{i=0}^n\alpha_i$. For $a=\geqslant 0, \leqslant 0$, $m\in\mathbf{Z}$ and $\lambda\in\overline{Q}$, put

$$U^a_{m\delta+\lambda}=\{y\in U^a|DyD^{-1}=q^my,\quad k_iyk_i^{-1}=q^{(\alpha_i|\lambda)}y,\quad (1\leqslant i\leqslant n)\}.$$

Let $M_\pm$ be the closure of $\Sigma_{m\geqslant 0}\Sigma_{\lambda\in\overline{Q}_\pm\backslash\{0\}}U^{\leqslant 0}_{-(m\delta+\lambda)}\otimes U^{\geqslant 0}_{m\delta+\lambda}$. Then

$$\mathcal{F}_{\rm I}^{\rm op}-1\in M_-,\quad \mathcal{F}_{\rm II}-1\in M_+. \tag{4.20}$$

2. Completion $\widehat{\widetilde{\mathcal{U}_\mu^{\otimes N}}}$ and its representation $\hat{\mathcal{W}}$

For $N\geqslant 2$ and $m\in\mathbf{Z}$, set

$$\mathcal{U}^{\otimes N}(m)=\sum_{\Sigma_{i=2}^N(i-1)m_i\geqslant m}\mathcal{U}\otimes\mathcal{U}_{m_2}\otimes\cdots\otimes\mathcal{U}_{m_N}. \tag{4.21}$$

Let $\widetilde{\mathcal{U}^{\otimes N}}$ $(N\geqslant 2)$ be the F algebra $\mathcal{U}^{\otimes N}$ on which a linear topology is introduced by $(\mathcal{U}^{\otimes N}(m))$. Then $\widetilde{\mathcal{U}^{\otimes N}}$ is a separated topological algebra. We denote its completion by $\widehat{\widetilde{\mathcal{U}^{\otimes N}}}$.

Let $\mathcal{W}_i$ $(1\leqslant i\leqslant N)$ be $\mathcal{U}$ modules such that

$$\mathcal{W}_i=\oplus_{m\in\mathbf{Z}}\mathcal{W}_{i,m},\quad \mathcal{W}_{i,m}=\{w\in\mathcal{W}_i|Kw=q^mw\}, \tag{4.22}$$

and set $\mathcal{W}=\mathcal{W}_1\otimes\cdots\otimes\mathcal{W}_N$. For $m\in\mathbf{Z}$ setting

$$\mathcal{W}(m)=\sum_{\Sigma_{i=2}^N(i-1)m_i\geqslant m}\mathcal{W}_1\otimes\mathcal{W}_{2,m_2}\otimes\cdots\otimes\mathcal{W}_{N,m_N}, \tag{4.23}$$

introduce a separated linear topology on $\mathcal{W}$ by $(\mathcal{W}(m))$. Then $\hat{\mathcal{W}}$, the completion of $\mathcal{W}$, is a topological $\widehat{\widetilde{\mathcal{U}^{\otimes N}}}$ module.

Remark 1: $\hat{\mathcal{W}}=\mathcal{W}$ in the case $N=2$ and $\mathcal{W}_{N,m}=\{0\}$ $(m\geqslant 0)$.

3. U_μ module structure on $\hat{\mathcal{W}}$

Lemma 2: (1) Let τ be the identity map from $\widetilde{\mathcal{U}^{\otimes N}}$ to $\mathcal{U}^{\otimes N}$. Let further $\hat{\tau}:\widehat{\widetilde{\mathcal{U}^{\otimes N}}}\to\mathcal{U}^{\hat{\otimes}N}$ be the continuous extension of the continuous algebra homomorphism τ. Then $\hat{\tau}$ is injective.

(2) If we identify $\widehat{\widetilde{\mathcal{U}^{\otimes N}}}$ with a subalgebra of $\mathcal{U}^{\hat{\otimes}N}$ via the map $\hat{\tau}$, then the following holds:

$$\Delta_{\rm I}^{{\rm op}(N-1)}(\mathcal{U})\subset\widehat{\widetilde{\mathcal{U}^{\otimes N}}},\ \ \Delta_{\rm II}^{(N-1)}(\mathcal{U})\subset\widehat{\widetilde{\mathcal{U}^{\otimes N}}}. \tag{4.24}$$

Proof: (1) For $l\in\mathbf{Z}_{\geqslant 0}$, set

$$M_l=\sum_{\Sigma l_i=l}\mathcal{U}^{-\otimes N}\otimes\mathcal{U}^{0\otimes N}\otimes\mathcal{U}^+_{l_1}\otimes\cdots\otimes\mathcal{U}^+_{l_N}. \tag{4.25}$$

Let $m\geqslant 0$. Under the identification of $\mathcal{U}^{\otimes N}\simeq(\mathcal{U}^-\otimes\mathcal{U}^0\otimes\mathcal{U}^+)^{\otimes N}$ with $\mathcal{U}^{-\otimes N}\otimes\mathcal{U}^{0\otimes N}\otimes\mathcal{U}^{+\otimes N}$, the following holds:

$$\mathcal{U}^{\otimes N}(m)=\oplus_l(\mathcal{U}^{\otimes N}(m)\cap M_l),\quad \mathcal{U}^{\otimes N}_{0m}=\oplus_{l\geqslant m}M_l. \tag{4.26}$$

From this, we obtain

$$\cap_l(\mathcal{U}^{\otimes N}(m)+\mathcal{U}_{0l}^{\otimes N})=\mathcal{U}^{\otimes N}(m). \tag{4.27}$$

Utilizing the last equality, it is easy to show that any Cauchy sequence in $\widetilde{\mathcal{U}^{\otimes N}}$ whose image under τ converges to 0 in $\mathcal{U}^{\hat{\otimes} N}$ converges to 0 in $\widetilde{\widetilde{\mathcal{U}^{\otimes N}}}$.

(2) The claim can be easily shown for $\overline{\Delta}_{\rm I}^{\rm op}$ and $\overline{\Delta}_{\rm II}$ instead of $\Delta_{\rm I}^{\rm op}$ and $\Delta_{\rm II}$. Utilizing (4.18) and (4.20), we can check $\mathcal{F}_{\rm I}^{{\rm op}(N)}$, $\mathcal{F}_{\rm II}^{(N)}\in\widetilde{\widetilde{\mathcal{U}^{\otimes N}}}$. Therefore thanks to (4.19) we obtain the claim. ■

The above lemma and (4.16) give the following.

Proposition 2: The completion $\hat{\mathcal{W}}$ defined in Sec. IV C 2 is endowed with $\mathcal{U}$ module structures via the comultiplications $\Delta_1^{\rm op}$ and $\Delta_{\rm II}$. Their U module structures are the ones via the comultiplications $\Delta_0^{\rm op}$ and Δ_0, respectively.

Remark 2: For $(\Delta_{\rm I}^{\rm op},\mathcal{F}_{\rm I}^{\rm op})$, we can replace K by D in (4.7) and (4.22).

D. Intertwiners of toroidal modules

Let $\Phi^{(j)}$ and $\Psi^{(j)}$ $(0\leqslant j\leqslant n)$ denote the intertwiners of U modules determined by

$$\Phi^{(j)}:V(\Lambda_j)\otimes V_x\to V(\Lambda_{j+1}),\quad \Psi^{(j)}:V_x\otimes V(\Lambda_j)\to V(\Lambda_{j+1}),$$
$$\Phi^{(j)}(v_{\Lambda_j}\otimes v_{j+1})=v_{\Lambda_{j+1}},\quad \Psi^{(j)}(v_{j+1}\otimes v_{\Lambda_j})=v_{\Lambda_{j+1}}, \tag{4.28}$$

where $V(\Lambda_j)\otimes V_x$ and $V_x\otimes V(\Lambda_j)$ are U modules via the comultiplication Δ_0, and Λ_{n+1} should be understood as Λ_0. As usual we define their components by

$$\Phi_{k,m}^{(j)}u=\Phi^{(j)}(u\otimes v_kx^m),\quad \Psi_{k,m}^{(j)}u=\Psi^{(j)}(v_kx^m\otimes u), \tag{4.29}$$

and set

$$\Phi_k^{(j)}(z)=\sum_{m\in\mathbf{Z}}\Phi_{k,m}^{(j)}z^{-m},\quad \Psi_k^{(j)}(z)=\sum_{m\in\mathbf{Z}}\Psi_{k,m}^{(j)}z^{-m}. \tag{4.30}$$

Proposition 3: For $m\in\mathbf{Z}$, set $a_m=q^{2m}$. In the following, give $V(\Lambda_j)\otimes V_a$ and $W_m\otimes V_a$ (resp. $V_a\otimes V(\Lambda_j)$ and $V_a\otimes W_m$) toroidal module structures via the comultiplication $\Delta_{\rm I}$ (resp. $\Delta_{\rm II}$) (see Remark 1).

(1) For $0\leqslant j\leqslant n$, $\Phi^{(j)}:V(\Lambda_j)\otimes V_{a_j}\to V(\Lambda_{j+1})$ and $\Psi^{(j)}:V_{a_j}\otimes V(\Lambda_j)\to V(\Lambda_{j+1})$ are intertwiners of $\mathcal{U}_{\mu_0}$ modules.

(2) Let $p=\mu_0\mu\neq1$ and α_r's be the ones defined in Proposition 1. Setting

$$Y^{\pm}(z)=\exp\left(\mp(q-q^{-1})\sum_{r>0}\frac{p^{(r\pm r)/2}}{1-p^r}\alpha_{\mp r}b_{\mp r}z^{\pm r}\right), \tag{4.31}$$

put

$$\Xi(z)=Y^+(qz)Y^-(z),\quad \Sigma(z)=Y^+(z)Y^-(qz). \tag{4.32}$$

For $m=(n+1)s+j$ $(s\in\mathbf{Z},\ 0\leqslant j\leqslant n)$, define $\tilde{\Phi}^{(m)}:W_m\otimes V_{a_m/p^s}\to W_{m+1}$ and $\tilde{\Psi}^{(m)}:V_{a_m/p^s}\otimes W_m\to W_{m+1}$ by the generating series

$$\tilde{\Phi}_k^{(m)}(z)=\Phi_k^{(j)}(z)\otimes\Xi(z)\ \ and\ \ \tilde{\Psi}_k^{(m)}(z)=\Psi_k^{(j)}(z)\otimes\Sigma(z), \tag{4.33}$$

respectively. Here $\tilde{\Phi}_k^{(m)}(z)$ and $\tilde{\Psi}_k^{(m)}(z)$ are defined similarly to $\Phi_k^{(j)}(z)$ and $\Psi_k^{(j)}(z)$. Then $\tilde{\Phi}^{(m)}$ and $\tilde{\Psi}^{(m)}$ are intertwiners of $\mathcal{U}_\mu$ modules.

Proof: We consider the case $\tilde{\Phi}^{(m)}$. In this proof, we give $W_m\otimes V_a$ (resp. $V(\Lambda_j)\otimes V_x$) a $\mathcal{U}_\mu$ (resp. U) module structure via the comultiplication $\overline{\Delta}_{\rm I}$. Set $\check{\Phi}^{(m)}=\tilde{\Phi}^{(m)}\mathcal{F}_I^{-1}$ and $\overline{\Phi}^{(j)}=\Phi^{(j)}\mathcal{F}_I^{-1}$

so that $\check{\Phi}_k^{(m)}(z)=\overline{\Phi}_k^{(j)}(z)\otimes\Xi(z)$. Then $\overline{\Phi}^{(j)}:V(\Lambda_j)\otimes V_x\to V(\Lambda_{j+1})$ is an intertwiner of U modules and its explicit expression in terms of bosons is known.[20] Utilizing the expression, it is straightforward to show $\check{\Phi}^{(m)}:W_m\otimes V_{a_m/p^s}\to W_{m+1}$ is an intertwiner of $\mathcal{U}_\mu$ modules. The claim follows from this. ■

V. LEVEL 0 $U_q'(\widehat{sl_{n+1}})$ action on level 1 $U_q(\widehat{gl_{n+1}})$ and $U_q(\widehat{sl_{n+1}})$ modules

A. Completions of $V_x^{\otimes N}$

Following Ref. 10, we introduce two completions of $V_x^{\otimes N}$. For $m\in\mathbf{Z}$, set

$$\mathcal{V}_N[m]=\text{span}\left\{ v_{\epsilon_1}x^{m_1}\otimes\cdots\otimes v_{\epsilon_N}x^{m_N}\,\middle|\,\sum_{i=2}^{N}(i-1)m_i\geqslant m\right\}, \tag{5.1}$$

$$\mathcal{V}_N[[m]]=\text{span}\{v_{\epsilon_1}x^{m_1}\otimes\cdots\otimes v_{\epsilon_N}x^{m_N}|\max\{m_1,\ldots,m_N\}\geqslant m\}. \tag{5.2}$$

Introduce two linear topologies on the vector space $V_x^{\otimes N}$ by $(\mathcal{V}_N[m])$ and $(\mathcal{V}_N[[m]])$. We denote the thus obtained separated topological vector spaces by $\mathcal{V}_N'$ and $\mathcal{V}_N$, respectively, and let $\hat{\mathcal{V}}_N'$ and $\hat{\mathcal{V}}_N$ signify their completions. Let ι_N be the identity map from $\mathcal{V}_N'$ to $\mathcal{V}_N$. Let further $\hat{\iota}_N:\hat{\mathcal{V}}_N'\to\hat{\mathcal{V}}_N$ denote the continuous extension of the continuous linear map ι_N. (This map is shown to be injective as in Lemma 2.) Note that our completions are a little bit different from those in Ref. 10.

Lemma 3: The topology on $\mathcal{V}_N'$ is equivalent to the one by a family of subspaces $(\mathcal{V}_x^{\otimes N}(m))$ *defined in Sec. IV C 2.*

Proof: The claim is easily checked using the equality $Kv_\epsilon x^m=q^{2(n+1)m+n-2\epsilon+2}v_\epsilon x^m$. ■

Set

$$v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)=\sum_{m_i\in\mathbf{Z}}v_{\epsilon_1}x^{m_1}\otimes\cdots\otimes v_{\epsilon_N}x^{m_N}z_1^{-m_1}\cdots z_N^{-m_N}. \tag{5.3}$$

Let $\mathcal{N}_N'$ (resp. $\mathcal{N}_N$) be the closure in $\hat{\mathcal{V}}_N'$ (resp. $\hat{\mathcal{V}}_N$) of the span of the coefficients of the following generating series:

$$\begin{aligned}&v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_i,z_{i+1},\ldots)-(1-q^2)\frac{(z_i/z_{i+1})^{\theta(\epsilon_i<\epsilon_i+1)}}{1-q^2z_i/z_{i+1}}v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_{i+1},z_i,\ldots)\\&\quad+q\frac{1-z_i/z_{i+1}}{1-q^2z_i/z_{i+1}}v_{\ldots,\epsilon_{i+1},\epsilon_i,\ldots}(\ldots,z_{i+1},z_i,\ldots),\quad(\epsilon_i\neq\epsilon_{i+1}),\end{aligned}$$

$$v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_i,z_{i+1},\ldots)+q^2\frac{1-q^{-2}z_i/z_{i+1}}{1-q^2z_i/z_{i+1}}v_{\ldots,\epsilon_{i+1},\epsilon_i,\ldots}(\ldots,z_{i+1},z_i,\ldots),\quad(\epsilon_i=\epsilon_{i+1}), \tag{5.4}$$

where $1 \leqslant i \leqslant N-1$. Then $\mathcal{N}_N = \overline{\hat{\iota}_N(\mathcal{N}'_N)}$. Note that in terms of the R matrix $R(z) \in \mathrm{End}(V \otimes V) \times [[z]]$ defined by

$$R(z) v_{\epsilon_1} \otimes v_{\epsilon_2} = \sum_{\epsilon'_1, \epsilon'_2} R(z)^{\epsilon'_1, \epsilon'_2}_{\epsilon_1, \epsilon_2} v_{\epsilon'_1} \otimes v_{\epsilon'_2},$$

$$= (1-q^2) \frac{z^{\theta(\epsilon_1 < \epsilon_2)}}{1-q^2 z} v_{\epsilon_1} \otimes v_{\epsilon_2} - q \frac{1-z}{1-q^2 z} v_{\epsilon_2} \otimes v_{\epsilon_1}, \quad (\epsilon_1 \neq \epsilon_2),$$

$$= -q^2 \frac{1-q^{-2} z}{1-q^2 z} v_{\epsilon_1} \otimes v_{\epsilon_2}, \quad (\epsilon_1 = \epsilon_2), \tag{5.5}$$

the generating series (5.4) are written as follows:

$$v_{\ldots, \epsilon_i, \epsilon_{i+1}, \ldots}(\ldots, z_i, z_{i+1}, \ldots) - \sum_{\epsilon'_i, \epsilon'_{i+1}} R(z_i / z_{i+1})^{\epsilon'_{i+1}, \epsilon'_i}_{\epsilon_i, \epsilon_{i+1}} v_{\ldots, \epsilon'_{i+1}, \epsilon'_i, \ldots}(\ldots, z_{i+1}, z_i, \ldots). \tag{5.6}$$

B. Level 0 $U'_q(\widehat{sl_{n+1}})$ actions on $\hat{\mathcal{V}}'_{\mathcal{N}} / \mathcal{N}'_N$ and $\hat{\mathcal{V}}_N / \mathcal{N}_N$

Let $U'_q(\widehat{sl_{n+1}})$ be the subalgebra of $U_q(\widehat{sl_{n+1}})$ generated by e_i, f_i, and $k_i^{\pm 1}$ $(0 \leqslant i \leqslant n)$. Set $U'_{c=0} = U'_q(\widehat{sl_{n+1}}) / \langle k_0 \cdots k_n - 1 \rangle$ and give this algebra a discrete topology.

Proposition 4: Let $S_N : \hat{\mathcal{V}}'_N \to \hat{\mathcal{V}}'_N$ be the homeomorphic linear map defined by

$$v_{\epsilon_1, \ldots, \epsilon_N}(z_1, \ldots, z_N) \mapsto v_{\epsilon_1, \ldots, \epsilon_N}(z_1, \ldots, z_N) \Big/ \prod_{i<j} \eta(z_j / z_i), \tag{5.7}$$

where

$$\eta(z) = \frac{(q^2 p z; p)_\infty}{(p z; p)_\infty}, \quad (z;p)_\infty = \prod_{m=0}^{\infty} (1 - p^m z). \tag{5.8}$$

Let further $\sigma_N : \mathcal{U}_\mu \to \mathrm{End}\,(\hat{\mathcal{V}}'_N)$ be the map defined by

$$\sigma_N(y) = S_N^{-1} \circ (\pi_{a_{N-1}} \otimes \cdots \otimes \pi_{a_0}) \Delta_{\mathrm{I}}^{\mathrm{op}(N-1)}(y) \circ S_N, \quad y \in \mathcal{U}_\mu. \tag{5.9}$$

Then the following holds:

(1) $\hat{\mathcal{V}}'_N$ is a $\mathcal{U}_\mu$ module via the map σ_N.

(2) $\mathcal{N}'_N$ is $\mathcal{U}_\mu$ invariant and the $\mathcal{U}_\mu$ action on $\hat{\mathcal{V}}'_N$ induces a $\mathcal{U}_\mu$ action on $\hat{\mathcal{V}}'_N / \mathcal{N}'_N$.

(3) The $\mathcal{U}_\mu$ modules $\hat{\mathcal{V}}'_N$ and $\hat{\mathcal{V}}'_N / \mathcal{N}'_N$ are considered as $U'_{c=0}$ modules via the algebra homomorphism $\varphi : U'_q(\widehat{sl_{n+1}}) \to \mathcal{U}_\mu$ determined by $e_i \mapsto E_{i,0}$, $f_i \mapsto F_{i,0}$, $k_i \mapsto k_i$.

Proof: (1) Follows from Proposition 2 and Lemma 3. Thanks to Lemma A.3, (2) is proven if we show

$$S_N^{-1} \circ (\pi_{a_{N-1}} \otimes \cdots \otimes \pi_{a_0}) \overline{\Delta}_{\mathrm{I}}^{\mathrm{op}(N-1)}(y) \circ S_N(\mathcal{N}'^{\mathcal{F}}_N) \subset \mathcal{N}'^{\mathcal{F}}_N, \quad y \in \mathcal{U}_\mu. \tag{5.10}$$

(See Lemma A.3 for the definition of $\mathcal{N}'^{\mathcal{F}}_N$.) This is easily checked using (4.5), (4.6), and (4.11). (3) Follows simply from the fact that $k_0 \cdots k_n \in \mathcal{U}_\mu$ acts as 1 on $\hat{\mathcal{V}}'_N$. ■

Proposition 5 (Ref. 10): For $i \neq j$, letting K_{ij} be the operator which interchanges z_i and z_j, set $\xi_{ij} = q^{-1} + (q - q^{-1})[z_j / (z_i - z_j)](K_{ij} - 1) \in \mathrm{End}\, F[z_1^{\pm 1}, \ldots, z_N^{\pm 1}]$. Set further

$$Y_j = \xi_{j j+1} \cdots \xi_{jN} p^{\vartheta_j} \xi_{1j}^{-1} \cdots \xi_{j-1 j}^{-1}, \tag{5.11}$$

where $p=\mu_0\mu$ and p^{ϑ_j} signifies the scale operator p^{ϑ} acting on the variable z_j. Then

$$\sum_{m_i}(\hat{Y}_j v_{\epsilon_1}x^{m_1}\otimes\cdots\otimes v_{\epsilon_N}x^{m_N})z_1^{-m_1}\cdots z_N^{-m_N}=Y_j v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N), \tag{5.12}$$

define continuous linear operators $\hat{Y}_j$'s on $\hat{\mathcal{V}}_N$ and the following holds.

(1) $\hat{\mathcal{V}}_N$ is given a topological $U'_{c=0}$ module structure by the map

$$e_0\mapsto q^{N-1}\sum_{j=1}^{N}\hat{Y}_j^{-1}1^{\otimes j-1}\otimes E_{n+1,1}\otimes(q^{E_{n+1,n+1}-E_{1,1}})^{\otimes N-j},$$

$$f_0\mapsto q^{-(N-1)}\sum_{j=1}^{N}\hat{Y}_j(q^{E_{1,1}-E_{n+1,n+1}})^{\otimes j-1}\otimes E_{1,n+1}\otimes 1^{\otimes N-j},$$

$$k_0\mapsto(q^{E_{n+1,n+1}-E_{1,1}})^{\otimes N},$$

$$y\mapsto(\pi\otimes\cdots\otimes\pi)\Delta_0^{\mathrm{op}(N-1)}(y),\quad y=e_i,f_i,k_i,\quad(1\leqslant i\leqslant n). \tag{5.13}$$

(2) $\mathcal{N}_N$ is $U'_{c=0}$ invariant and the $U'_{c=0}$ action on $\hat{\mathcal{V}}_N$ induces a $U'_{c=0}$ action on $\hat{\mathcal{V}}_N/\mathcal{N}_N$.

For the two $U'_{c=0}$ modules $\hat{\mathcal{V}}'_N/\mathcal{N}'_N$ and $\hat{\mathcal{V}}_N/\mathcal{N}_N$, we can show the following:

Proposition 6: The map $\tilde{\iota}_N:\hat{\mathcal{V}}'_N/\mathcal{N}'_N\to\hat{\mathcal{V}}_N/\mathcal{N}_N$ induced by $\hat{\iota}_N$ is a homomorphism of $U'_{c=0}$ modules.

Proof: $\mathcal{V}'_N/\mathcal{N}'_N$ is a topological $U'_{c=0}$ module; $\tilde{\iota}_N$ is continuous; $\hat{\mathcal{V}}_N/\mathcal{N}_N$ is separated. Therefore the claim follows from the following two lemmas. ∎

Lemma 4: Let X_N denote the span of the vectors $v_{\epsilon_1}x^{m_1}\otimes\cdots\otimes v_{\epsilon_N}x^{m_N}$ ($\epsilon_1\leqslant\cdots\leqslant\epsilon_N$, $m_i\in\mathbf{Z}$). Then $(X_N+\mathcal{N}'_N)/\mathcal{N}'_N$ is dense in $\hat{\mathcal{V}}'_N/\mathcal{N}'_N$.

Proof: It is sufficient to show $\hat{\mathcal{V}}'_N=\overline{X_N+\mathcal{N}'_N}$. Therefore the claim follows if we show the following:

$$v_{\epsilon_1}x^{m_1}\otimes\cdots\otimes v_{\epsilon_N}x^{m_N}\in\overline{X_N+\mathcal{N}'_N}. \tag{5.14}$$

Let $\epsilon_i<\epsilon_{i+1}$ and Y_N be the the span of the coefficients of $v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_i,z_{i+1},\ldots)$. Equation (5.4) implies that the coefficients of

$$(1-(z_i/z_{i+1})^m)v_{\ldots,\epsilon_{i+1},\epsilon_i,\ldots}(\ldots,z_{i+1},z_i,\ldots)$$

belong to $Y_N+\mathcal{N}'_N$ for any integer m. Hence the coefficients of $v_{\ldots,\epsilon_{i+1},\epsilon_i\ldots}(\ldots,z_{i+1},z_i,\ldots)$ belong to $\overline{Y_N+\mathcal{N}'_N}$. Using the last argument repeatedly, we can show (5.14). ∎

Lemma 5: For $\epsilon_1\leqslant\cdots\leqslant\epsilon_N$ and $y=e_i$, f_i, $k_i^{\pm1}$ $(0\leqslant i\leqslant n)$, the following holds:

$$\tilde{\iota}_N(y\dot{v}_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N))=y\tilde{\iota}_N(\dot{v}_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)), \tag{5.15}$$

where $\dot{v}_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)$ signifies the image of $v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)$ under the quotient map $\hat{\mathcal{V}}'_N\to\hat{\mathcal{V}}'_N/\mathcal{N}'_N$.

Proof: The above equality clearly holds except for e_0 and f_0. The case e_0 is shown in the Appendix and the case f_0 is similarly proven. ∎

C. Level 0 $U'_q(\widehat{sl_{n+1}})$ actions on $\hat{\mathcal{V}}_N$ and W_N

Give W_N a discrete topology. Set $|0\rangle=v_{\Lambda_0}\otimes1\in W_0$. Let $\rho_N:\mathcal{V}_N\to W_N$ be the linear map defined by

$$v_{\epsilon_1,\dots,\epsilon_N}(z_1,\dots,z_N)\mapsto\tilde{\Phi}^{(N-1)}_{\epsilon_1}(z_1)\cdots\tilde{\Phi}^{(0)}_{\epsilon_N}(z_N)|0\rangle\prod_{0\le k\le N-1} z_{N-k}^{s_k}\Big/\prod_{i<j}\eta(z_j/z_i),\tag{5.16}$$

where s_k is the integer part of $k/(n+1)$. Then, as in Ref. 10, thanks to the commutation relations among the intertwiners $\tilde{\Phi}^{(m)}$,

$$\begin{aligned}&\tilde{\Phi}^{(m+1)}_{\epsilon_1}(z_1)\tilde{\Phi}^{(m)}_{\epsilon_2}(z_2)/\eta(z_2/z_1)\\&=\sum_{\epsilon_1',\epsilon_2'}(z_1/z_2)^{s_m-s_{m+1}}R(z_1/z_2)^{\epsilon_2',\epsilon_1'}_{\epsilon_1,\epsilon_2}\tilde{\Phi}^{(m+1)}_{\epsilon_2'}(z_2)\tilde{\Phi}^{(m)}_{\epsilon_1'}(z_1)/\eta(z_1/z_2),\end{aligned}\tag{5.17}$$

the map ρ_N is continuous and extends to a continuous linear map $\hat{\rho}_N:\hat{\mathcal{V}}_N\to W_N$. Moreover the latter map induces $\tilde{\rho}_N:\hat{\mathcal{V}}_N/\mathcal{N}_N\to W_N$.

Proposition 7: Let us regard the $\mathcal{U}_\mu$ module W_N as a $U'_{c=0}$ module via the map φ. Then $\tilde{\rho}'_N:=\tilde{\rho}_N\circ\tilde{\iota}_N:\hat{\mathcal{V}}'_N/\mathcal{N}'_N\to W_N$ is a homomorphism of $U'_{c=0}$ modules.

Proof: In this proof, we complete tensor products $V_{b_1}\otimes\cdots\otimes V_{b_k}$ and $V_{b_1}\otimes\cdots\otimes V_{b_k}\otimes W_m$ ($b_i\in F^\times$) as in Sec. IV C 2. We give the completions $\mathcal{U}_\mu$ module structures via the comultiplication $\Delta_1^{\rm op}$ as in Proposition 2 and consider them as $U'_{c=0}$ modules via the map φ. Note that we treat the completion $\hat{\mathcal{V}}'_N$ in the same way (not as in Proposition 4). To prove the proposition, it is sufficient to show that the continuous linear map $\hat{\rho}_N\circ\hat{\iota}_N\circ S_N^{-1}:\hat{\mathcal{V}}'_N\to W_N$ is $U'_{c=0}$ linear. Note that this map is determined by

$$v_{\epsilon_1,\dots,\epsilon_N}(z_1,\dots,z_N)\mapsto\tilde{\Phi}^{(N-1)}_{\epsilon_1}(z_1)\cdots\tilde{\Phi}^{(0)}_{\epsilon_N}(z_N)|0\rangle\prod_{0\le k\le N-1} z_{N-k}^{s_k}.\tag{5.18}$$

Let $\mathcal{F}$ and $\bar{\Delta}$ stand for $\mathcal{F}_1^{\rm op}$ and $\bar{\Delta}_1^{\rm op}$, respectively. From $(1^{\hat{\otimes}N}\hat{\otimes}\epsilon)\mathcal{F}^{(N+1)}=\mathcal{F}^{(N)}$ and (4.20), we get $\mathcal{F}^{(N+1)\pm1}(u\otimes|0\rangle)=(\mathcal{F}^{(N)\pm1}u)\otimes|0\rangle$ for $u\in\hat{\mathcal{V}}'_N$. Moreover we have $\bar{\Delta}^{(N)}(y)(u\otimes|0\rangle)=(\bar{\Delta}^{(N-1)}(y)u)\otimes|0\rangle$ for $y\in U'_{c=0}$ and $u\in\hat{\mathcal{V}}'_N$ since $E_{0,m}|0\rangle=F_{0,m}|0\rangle=0$ $(m\geqslant0)$ and $\phi_0^-(z)|0\rangle=|0\rangle$. Hence the continuous map from the completion of $V_{a_{N-1}}\otimes\cdots\otimes V_{a_0}$ to the completion of $V_{a_{N-1}}\otimes\cdots\otimes V_{a_0}\otimes W_0$ defined by $u\mapsto u\otimes|0\rangle$ is $U'_{c=0}$ linear. Set $\tilde{\Phi}^{{\rm op}(m)}=\tilde{\Phi}^{(m)}\circ(1\otimes x^{s_m})\circ\sigma$, $(\sigma(v\otimes w)=w\otimes v)$. The linear map $1^{\otimes N-m-1}\otimes\tilde{\Phi}^{{\rm op}(m)}:V_{a_{N-1}}\otimes\cdots\otimes V_{a_m}\otimes W_m\to V_{a_{N-1}}\otimes\cdots\otimes V_{a_{m+1}}\otimes W_{m+1}$ extends continuously to a map between the completions and the latter map is shown to be an intertwiner of $U'_{c=0}$ modules. From the above we can show the claim stated in the first part of the proof. ■

From Propositions 6 and 7, we can show the following:

Theorem 2: Regard $\hat{\mathcal{V}}_N$ and W_N as $U'_{c=0}$ modules as in Propositions 5 and 7. Then $\hat{\rho}_N:\hat{\mathcal{V}}_N\to W_N$ is a homomorphism of $U'_{c=0}$ modules.

Proof: Since $\tilde{\rho}_N\circ\tilde{\iota}_N=\tilde{\rho}'_N$ and the maps $\tilde{\iota}_N$ and $\tilde{\rho}'_N$ are $U'_{c=0}$ linear, we get $\tilde{\rho}_N(yw)=y\tilde{\rho}_N(w)$ for $y\in U'_{c=0}$ and $w\in{\rm Im}\,\tilde{\iota}_N$. ${\rm Im}\,\tilde{\iota}_N$ is dense in $\hat{\mathcal{V}}_N/\mathcal{N}_N$; $\hat{\mathcal{V}}_N/\mathcal{N}_N$ and W_N are separated topological $U'_{c=0}$ modules; $\tilde{\rho}_N$ is continuous. Therefore $\tilde{\rho}_N$ is a homomorphism of $U'_{c=0}$ modules. The claim follows from this. ■

Finally we consider the case $\mu=\mu_0$. Let $\hat{\gamma}_N:\hat{\mathcal{V}}_N\to V(\Lambda_j)$ $(j\equiv N\bmod n+1)$ denote the continuous linear map defined by (5.16) with $\tilde{\Phi}^{(m)}$ and $|0\rangle$ replaced by $\Phi^{(i)}(i\equiv m\bmod n+1)$ and v_{Λ_0}, respectively. Let further $\hat{\gamma}:\hat{\mathcal{V}}:=\oplus_{N\geqslant1}\hat{\mathcal{V}}_N\to\mathcal{H}:=\oplus_{j=0}^n V(\Lambda_j)$ signify the linear map obtained from $\hat{\gamma}_N$'s. We consider the $\mathcal{U}_{\mu_0}$ modules $\hat{\mathcal{V}}$ and $\mathcal{H}$ as $U'_{c=0}$ modules via the map φ.

Theorem 3: *Consider the case $\mu=\mu_0$ $(p=\mu_0^2)$ and let $\hat{\mathcal{V}}$, $\mathcal{H}$, and $\hat{\gamma}$ be as above. Then $\hat{\gamma}:\hat{\mathcal{V}}\to\mathcal{H}$ is a surjective homomorphism of $U'_{c=0}$ modules.*

Proof: The surjectivity is shown as in Ref. 10. Thanks to Proposition 3 (1), Proposition 7 holds also for the map $\hat{\mathcal{V}}'_N/\mathcal{N}'_N \to V(\Lambda_j)$ $(j \equiv N \bmod n+1)$ induced by $\hat{\gamma}_N \circ \hat{\iota}_N$. Therefore the remaining claim is proven as in Theorem 2. ■

Remark 3: In Ref. 10, in the case $n=1$, by showing that $Ker\ \hat{\gamma}$ is $U'_{c=0}$ invariant, a $U'_{c=0}$ action was defined on $\mathcal{H}$ so that $\hat{\gamma}$ is a homomorphism of $U'_{c=0}$ modules. Therefore Theorem 3 clarifies the relation between the $U'_{c=0}$ module structure on $\mathcal{H}$ induced by the toroidal action[4] and the one by the approach of Ref. 10.

APPENDIX: PROOF OF LEMMA 5

The following is immediate. See Ref. 10 for (1) and (4).

Lemma A.1: For $I \subset \{1,...,N\}$, let K_I be the set of generating series $w(z_1,\ldots,z_N) = \Sigma w_{m_1,\ldots,m_N} z_1^{-m_1} \cdots z_N^{-m_N}$ such that $w_{m_1,\ldots,m_N} \in \overline{\mathcal{V}_N[[M]]}$, where $M = \max\{m_i\}_{i\in I}$. For $I \subset \{1,...,N\}$ and $k \in \{1,...,N\}$, let $A_{I,k}$ denote the algebra of formal power series in the variables z_i/z_k $(i \in I \backslash \{k\})$.

(1) If f is a formal series of the form $f = \Sigma_{\Sigma m_i = m} f_{m_1,\ldots,m_r} z_{i_1}^{-m_1} \cdots z_{i_r}^{-m_r}$ $(1 \leqslant i_1 < \cdots < i_r \leqslant N$, $f_{m_1,\ldots,m_r} \in F$, $m \in \mathbf{Z})$ and $w \in K_{\{i_1,\ldots,i_r\}}$, then fw is a well defined formal series with $\hat{\mathcal{V}}_N$ as coefficients.

(2) $A_{I,k} K_I \subset K_{I\backslash\{k\}}$. Moreover $A_{I,k}$ acts on K_I when $k \notin I$.

(3) Let i, $j \in I$, $i \neq j$, k, $l \in \{1,...,N\} \backslash I$, $k \neq l$ and $w \in K_I$. Let further $f(z)$ and $g(z)$ be formal power series in z. Then for $(x,y) = (z_i/z_k, z_i/z_l)$ and $(z_i/z_j, z_j/z_k)$, the following holds:

$$f(x)(g(y)w) = g(y)(f(x)w) = (f(x)g(y))w.$$

(4) $\xi_{ij}^{\pm 1} K_I \subset K_I$ if $i,j \in I$.

(5) Let i, $j \in I$, $i \neq j$ and $k \in \{1,...,N\} \backslash I$. If $f \in A_{I,k}$ satisfies $f\xi_{ij} = \xi_{ij} f$ when acted on Laurent polynomials in z_l $(1 \leqslant l \leqslant N)$, then $f\xi_{ij}|_{K_I} = \xi_{ij} f|_{K_I}$.

Lemma A.2: Let L be the set of generating series $w(z_1,\ldots,z_N) = \Sigma w_{m_1,\ldots,m_N} z_1^{-m_N} \cdots z_N^{-m_N}$ such that $w_{m_1,\ldots,m_N} \in \overline{\mathcal{V}_N[M]}$, where $M = \Sigma_{i=2}^N (i-1) m_i$.

(1) Let B be the algebra of formal power series in the variables z_{i+1}/z_i $(1 \leqslant i < N)$. Then B acts on L.

(2) Set $u_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N) = \mathcal{F}_{\mathrm{I}}^{op(N)-1} v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)$. Then $u_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N) \in L$ for any ϵ_i, and $u_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N) = v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)$ when $\epsilon_1 \leqslant \cdots \leqslant \epsilon_N$.

Proof: (1) is immediate. (2) follows from (4.20). ■

Lemma A.3: Let $\mathcal{N}'^{\mathcal{F}}_N$ be the closure in $\hat{\mathcal{V}}'_N$ of the span of the coefficients of the following generating series:

$$v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_i,z_{i+1},\ldots) + q\,\frac{1 - z_i/z_{i+1}}{1 - q^2 z_i/z_{i+1}}\, v_{\ldots,\epsilon_{i+1},\epsilon_i,\ldots}(\ldots,z_{i+1},z_i,\ldots), \quad (\epsilon_i < \epsilon_{i+1}),$$

$$v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_i,z_{i+1},\ldots) + q^2\,\frac{1 - q^{-2} z_i/z_{i+1}}{1 - q^2 z_i/z_{i+1}}\, v_{\ldots,\epsilon_{i+1},\epsilon_i,\ldots}(\ldots,z_{i+1},z_i,\ldots), \quad (\epsilon_i = \epsilon_{i+1}), \tag{A1}$$

where $1 \leqslant i \leqslant N-1$. Then $\mathcal{F}_{\mathrm{I}}^{\mathrm{op}(N)} \mathcal{N}'_N = \mathcal{N}'^{\mathcal{F}}_N$.

Proof: Let $\mathcal{F}^{(N)}$ signify $\mathcal{F}_{\mathrm{I}}^{\mathrm{op}(N)}$. Firstly we consider the case $N=2$. Let $\epsilon_1 < \epsilon_2$. From the definition we get

$$v_{\epsilon_1,\epsilon_2}(z_1,z_2)+q\frac{1-z_2/z_1}{1-q^2z_2/z_1}v_{\epsilon_2,\epsilon_1}(z_1,z_2)+(z_1\leftrightarrow z_2)\in\mathcal{N}_2'^{\mathcal{F}}. \tag{A2}$$

This implies

$$\frac{z_2}{1-z_2/z_1}v_{\epsilon_1,\epsilon_2}(z_1,z_2)+\frac{qz_2}{1-q^2z_2/z_1}v_{\epsilon_2,\epsilon_1}(z_1,z_2)-(z_1\leftrightarrow z_2)\in\mathcal{N}_2'^{\mathcal{F}}. \tag{A3}$$

Let N_2' (resp. $N_2'^{\mathcal{F}}$) be the span of the coefficients of (5.4) (resp. (A1) and (A3)). From

$$\mathcal{F}^{(2)}v_{\epsilon_1,\epsilon_2}(z_1,z_2)=v_{\epsilon_1,\epsilon_2}(z_1,z_2),\quad(\epsilon_1\leqslant\epsilon_2),$$

$$=v_{\epsilon_1,\epsilon_2}(z_1,z_2)-(q-q^{-1})\frac{z_2/z_1}{1-z_2/z_1}v_{\epsilon_2,\epsilon_1}(z_1,z_2),\quad(\epsilon_1>\epsilon_2), \tag{A4}$$

we obtain $\mathcal{F}^{(2)}N_2'=N_2'^{\mathcal{F}}$ and, hence, the claim in the case $N=2$. Next we consider the case $N>2$. Equation (4.15) gives

$$\mathcal{F}^{(N)}=\mathcal{F}^{(2)}_{k,k+1}(1^{\hat{\otimes}k-1}\hat{\otimes}\Delta_{\mathrm{I}}^{\mathrm{op}}\hat{\otimes}1^{\hat{\otimes}N-k-1})\mathcal{F}^{(N-1)}\quad\text{for}\quad 1\leqslant k\leqslant N-1. \tag{A5}$$

It is easy to check that N_2' is U invariant. Hence we obtain

$$\mathcal{F}^{(N)}V_x^{\otimes k-1}\otimes N_2'\otimes V_x^{\otimes N-k-1}\subset\overline{V_x^{\otimes k-1}\otimes\mathcal{F}^{(2)}N_2'\otimes V_x^{\otimes N-k-1}}. \tag{A6}$$

From this, we get $\mathcal{F}^{(N)}\mathcal{N}_N'\subset\mathcal{N}_N'^{\mathcal{F}}$. The reverse inclusion is shown similarly. ∎

Hereafter we shall let $\equiv$ denote the equality in $\hat{\mathcal{V}}_N \bmod \mathcal{N}_N$.

Lemma A.4: The action of e_0 on the $U'_{c=0}$ module $\hat{\mathcal{V}}_N$ and that of $E_{0,0}$ on the $\mathcal{U}_\mu$ module $\hat{\mathcal{V}}'_N$ satisfy the following relations:

(1) $e_0v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N)$

$$\equiv(-q)^{N-1}\sum_{j=1}^{N}\delta_{\epsilon_j,1}(-1)^{j-1}q^{-\Sigma_{j<i\leqslant N}\delta_{\epsilon_i,1}}\xi_{j-1j}\cdots\xi_{1j}$$
$$\times v_{\epsilon_1,\ldots,\hat{\epsilon}_j,\ldots,\epsilon_N,n+1}(z_1,\ldots,\hat{z}_j,\ldots,z_N,z_j/p). \tag{A7}$$

(2) *For* $\epsilon_1\leqslant\cdots\leqslant\epsilon_N$,

$$\hat{\iota}_N(E_{0,0}v_{\epsilon_1,\ldots,\epsilon_N}(z_1,\ldots,z_N))$$
$$\equiv(-q)^{N-1}\sum_{j=1}^{N}\delta_{\epsilon_j,1}(-q)^{-(j-1)}q^{-\Sigma_{j<i\leqslant N}\delta_{\epsilon_i,1}}\prod_{i=1}^{j-1}\frac{1-q^2z_j/z_i}{1-z_j/z_i}\prod_{i=j+1}^{N}\left(\frac{1-q^2z_i/z_j}{1-z_i/z_j}\right)^{\delta_{\epsilon_i,1}}$$
$$\times v_{\epsilon_1,\ldots,\hat{\epsilon}_j,\ldots,\epsilon_N,n+1}(z_1,\ldots,\hat{z}_j,\ldots,z_N,z_j/p). \tag{A8}$$

Here $\hat{}$ denotes the deletion of variables.

Proof: (1) The definition of ξ_{ij} and (5.4) give

$$\xi_{ii+1}^{-1}v_{\ldots,\epsilon_i,\epsilon_{i+1},\ldots}(\ldots,z_i,z_{i+1},\ldots)\equiv-q^{-\delta_{\epsilon_i,\epsilon_{i+1}}}v_{\ldots,\epsilon_{i+1},\epsilon_i,\ldots}(\ldots,z_{i+1},z_i,\ldots),\quad(\epsilon_i\geqslant\epsilon_{i+1}). \tag{A9}$$

Using this equality, we get the claim.

(2) Set $f(z)=q^{-1}(1-q^2z)/(1-z)$. Set further $g_\epsilon(z)=q(1-z)/(1-q^2z)$ for $1\leqslant\epsilon\leqslant n$ and $=q^2(1-q^{-2}z)/(1-q^2z)$ for $\epsilon=n+1$. Then thanks to (4.19) we get

$$E_{0,0}u_{\epsilon_1,\dots\epsilon_N}(z_1,\dots,z_N)=q^{N-1}\sum_{j=1}^{N}\delta_{\epsilon_j,1}\prod_{i=1}^{j-1}f(z_j/z_i)\prod_{i=j+1}^{N}f(z_i/z_j)^{\delta_{\epsilon_i,1}}\times\prod_{i=j+1}^{N}g_{\epsilon_i}(pz_i/z_j)u_{\epsilon_1,\dots,\epsilon_{j-1},n+1,\epsilon_{j+1},\dots,\epsilon_N}(z_1,\dots,z_j/p,\dots,z_N), \tag{A10}$$

for any ϵ_i. Lemmas A.2 and A.3 imply

$$\hat{\iota}_N\left(\prod_{i=j+1}^{N}g_{\epsilon_i}(pz_i/z_j)u_{\epsilon_1,\dots,\epsilon_{j-1},n+1,\epsilon_{j+1},\dots,\epsilon_N}(z_1,\dots,z_j/p,\dots z_N)\right)\equiv(-1)^{N-j}\hat{\iota}_N(u_{\epsilon_1,\dots,\hat{\epsilon}_j,\dots,\epsilon_N,n+1}(z_1,\dots,\hat{z}_j,\dots,z_N,z_j/p)). \tag{A11}$$

In the case $\epsilon_1\leqslant\cdots\leqslant\epsilon_N$, thanks to Lemma A.1 (1) and Lemma A.2, multiplying the above equation by $\Pi_{i=1}^{j-1}f(z_j/z_i)\Pi_{i=j+1}^{N}f(z_i/z_j)^{\delta_{\epsilon_i,1}}$ is meaningful. Hence we obtain the claim. ■

Thanks to the above lemma, (5.15) with $y=e_0$ follows from the following lemma with $w(z_1,\dots,z_N)=v_{\underbrace{1,\dots,1}_{s-1},\epsilon_{s+1},\dots,\epsilon_N,n+1}(z_1,\dots,z_N)$ $(1<\epsilon_{s+1}\leqslant\cdots\leqslant\epsilon_N)$.

Lemma A.5: Let $1\leqslant t\leqslant s\leqslant N$ and $w(z_1,\dots,z_N)\in K_{\{t,\dots,N\}}$. If the coefficients of the generating series

$$w(z_1,\dots,z_i,z_{i+1},\dots,z_N)+q^2\frac{1-q^{-2}z_i/z_{i+1}}{1-q^2z_i/z_{i+1}}w(z_1,\dots,z_{i+1},z_i,\dots,z_N),\quad(t\leqslant i\leqslant s-2)$$

belong to $\mathcal{N}_N$, then the following equality holds in $\hat{\mathcal{V}}_N$:

$$\sum_{j=t}^{s}(-q)^{j-t}\xi_{j-1j}\cdots\xi_{tj}w(z_1,\dots,\hat{z}_j,\dots,z_N,z_j/p)\equiv\sum_{j=t}^{s}(-1)^{j-t}\prod_{i=t}^{j-1}\frac{1-q^2z_j/z_i}{1-z_j/z_i}\prod_{i=j+1}^{s}\frac{1-q^2z_i/z_j}{1-z_i/z_j}w(z_1,\dots,\hat{z}_j,\dots,z_N,z_j/p). \tag{A12}$$

Proof: This can be shown by induction on $s-t$. Thanks to Lemma A.1, the left hand side is rewritten as follows:

$$w(z_1,\dots,\hat{z}_t,\dots,z_N,z_t/p)+(1-q^2)\sum_{j=t+1}^{s}(-q)^{j-t-1}\xi_{j-1j}\cdots\xi_{t+1j}\times\frac{z_j/z_t}{1-z_j/z_t}w(z_1,\dots,z_{t-1},z_j,z_{t+1},\dots,\hat{z}_j,\dots,z_N,z_t/p)-\frac{1}{\Pi_{i>t}\eta(z_i/z_t)}\sum_{j=t+1}^{s}(-q)^{j-t-1}\xi_{j-1j}\cdots\xi_{t+1j}\overline{w}(z_1,\dots,\hat{z}_j,\dots,z_N,z_j/p), \tag{A13}$$

where

$$\overline{w}(z_1,\ldots,z_N)=\prod_{i>t}\eta(z_i/z_t)\times w(z_1,\ldots,z_N)\in K_{\{t+1,\ldots,N\}}. \tag{A14}$$

For $t+1\leqslant i<j\leqslant s$, thanks to Lemma A.1, we obtain,

$$\begin{aligned}&\xi_{ij}\frac{z_j/z_t}{1-z_j/z_t}w(z_1,\ldots,\hat{z}_t,\ldots,z_{i-1},z_j,z_i,\ldots,\hat{z}_j,\ldots,z_N,z_t/p)\\ &\quad\equiv -q^{-1}\frac{1-q^2z_i/z_t}{1-z_i/z_t}\,\frac{z_j/z_t}{1-z_j/z_t}w(z_1,\ldots,\hat{z}_t,\ldots,z_i,z_j,z_{i+1},\ldots,\hat{z}_j,\ldots,z_N,z_t/p).\end{aligned} \tag{A15}$$

Since the action of $\xi_{j-1j}\cdots\xi_{i+1j}$ on both sides of the above is well defined, we get the following equality:

$$\begin{aligned}&\xi_{j-1j}\cdots\xi_{ij}\frac{z_j/z_t}{1-z_j/z_t}w(z_1,\ldots,\hat{z}_t,\ldots,z_{i-1},z_j,z_i,\ldots,\hat{z}_j,\ldots,z_N,z_t/p)\\ &\quad\equiv -q^{-1}\frac{1-q^2z_i/z_t}{1-z_i/z_t}\,\xi_{j-1j}\cdots\xi_{i+1j}\frac{z_j/z_t}{1-z_j/z_t}w(z_1,\ldots,\hat{z}_t,\ldots,z_i,z_j,z_{i+1},\ldots,\hat{z}_j,\ldots,z_N,z_t/p).\end{aligned} \tag{A16}$$

Repeating this argument, the sum of the first two terms is found to be

$$\prod_{i=t+1}^{s}\frac{1-q^2z_i/z_t}{1-z_i/z_t}w(z_1,\ldots,\hat{z}_t,\ldots,z_N,z_t/p).$$

Applying the assumption of the induction to the last sum, we obtain the claim. ■

Picard–Fuchs ordinary differential systems in $N=2$ supersymmetric Yang–Mills theories

Yűji Ohta
Research Institute for Mathematical Sciences, Kyoto University, Sakyoku, Kyoto 606, Japan

(Received 21 December 1998; accepted for publication 26 January 1999)

In general, Picard–Fuchs systems in $N=2$ supersymmetric Yang–Mills theories are realized as a set of simultaneous partial differential equations. However, if the quantum chromodynamics (QCD) scale parameter is used as a unique independent variable instead of moduli, the resulting Picard–Fuchs systems are represented by a single ordinary differential equation (ODE) whose order coincides with the total number of independent periods. This paper discusses some properties of these Picard–Fuchs ODEs. In contrast with the usual Picard–Fuchs systems written in terms of moduli derivatives, there exists a Wronskian for this ordinary differential system and this Wronskian produces a new relation among periods, moduli, and QCD scale parameter, which in the case of SU(2) is reminiscent of the scaling relation of prepotential. On the other hand, in the case of the SU(3) theory, there are two kinds of ordinary differential equations, one of which is the equation directly constructed from periods and the other is derived from the SU(3) Picard–Fuchs equations in moduli derivatives identified with Appell's F_4 hypergeometric system, i.e., Burchnall's fifth-order ordinary differential equation published in 1942. It is shown that four of the five independent solutions to the latter equation actually correspond to the four periods in the SU(3) gauge theory and the closed form of the remaining one is established by the SU(3) Picard–Fuchs ODE. The formula for this fifth solution is a new one.

I. INTRODUCTION

It has been recognized that the low energy effective action of $N=2$ supersymmetric Yang–Mills theory for any Lie gauge group including at most two derivatives and four fermions is dominated by a holomorphic function called prepotential $\mathcal{F}$.[1] Perturbatively, this prepotential is a sum of the classical part and one-loop contribution, and further contributions from higher loop diagrams are excluded by the nonrenormalization theorem in $N=2$ theory. However, $\mathcal{F}$ was expected to be affected by instantons and hence its nonperturbative determination was a long-standing problem.

In the case of SU(2) gauge theory, without any quark hypermultiplet, Seiberg and Witten[2] showed that the vacuum configuration of the $N=2$ action was parametrized by the moduli $u=\langle \mathrm{tr}\,\phi^2\rangle$ (ϕ is a complex scalar field in the adjoint representation of the gauge group) and singularities on this parameter space (moduli space) could split into pieces by instanton effect. This instanton corrected moduli space is often called quantum moduli space and Seiberg and Witten[2,3] identified the quantum moduli space with the moduli space of a certain elliptic curve of genus one. According to their ansatz, since the vacuum expectation value $a=\langle\phi\rangle$ and its magnetic dual can also be regarded as periods of a meromorphic one-form on the elliptic Riemann surface, these periods can be calculated as a linear combination of solutions to Picard–Fuchs equations (for a historical review and introduction of the Picard–Fuchs equation in mathematics, see Gray[4]). Once the periods are calculated, it is immediate to obtain the prepotential because of rigid special geometry. In this way, Klemm *et al.*[5] determined the SU(2) prepotential.

Seiberg and Witten's approach to $N=2$ supersymmetric SU(2) Yang–Mills theory[2,3] was extended to other higher rank gauge group cases coupled with or without quark hypermultiplets,[5–16] and it was found that the quantum moduli spaces of those gauge theories could be identified with those of Riemann surfaces with certain genus. In these studies, general algorithms to get Picard–Fuchs equations were developed,[17–21] but these equations are in general realized as a set of simultaneous partial differential equations (PDEs) in terms of moduli derivatives. For this reason, it is not easy to solve Picard–Fuchs equations, especially, in higher rank gauge goup cases.

However, if the quantum chromodynamics (QCD) scale parameter instead of moduli is used as the unique independent variable, the resulting Picard–Fuchs systems will be represented by a single ordinary differential equation (ODE) whose order coincides with the total number of independent periods. Then the problem solving Picard–Fuchs equations can be encoded into the language of ODE and therefore the study of periods are simplified. As another feature of this formalism, we remark that in contrast with the usual Picard–Fuchs systems written in terms of moduli derivatives there exists a Wronskian for these ordinary differential systems and the Wronskian produces a new relation among periods, moduli, and QCD scale parameter. Especially, in the case of SU(2) it is quite reminiscent of the scaling relation of the prepotential.[22–24] This relation is highly nonlinear in the case of higher rank gauge group, but it reflects the structure of the Picard–Fuchs ODE. Section II discusses these Picard–Fuchs ordinary differential systems. This realization of Picard–Fuchs systems via ODE becomes interesting when we consider a relation to hypergeometric differential equations in multiple variables. For example, in the case of SU(3) gauge theory, we can find another ODE which gives equivalent periods. That is Burchnall's fifth-order equation directly constructed from Appell's F_4 hypergeometric differential equations.[25] In general, the dimension of the solution space of a single ODE constructed from simultaneous PDEs can exceed that of the original PDEs[25] (see also Srivastava and Karlsson[26] and references therein), and Burchnall's equation is the case. In addition, the extra solution which is not a solution to the original PDEs is known to have a very characteristic form. In the case of Burchnall's equation for the SU(3) gauge theory, since four of the five independent solutions are found to correspond to the four periods of the SU(3) gauge theory (this identification is explicitly checked at the semiclassical regime) and these four periods are also solutions to the SU(3) Picard–Fuchs ODE, it is possible to extract a differential equation only for the fifth solution (although the fifth solution is irrelevant to the underlying physics). The formula for this fifth solution obtained in this way is a new one and takes a very different form compared with other fifth-order ODEs constructed from a set of PDEs, e.g., a product of two Bessel functions or Whittaker functions (the ''fifth solution'' to these two cases are quite reminiscent of each other). In our derivation, it is crucial to notice that the fifth solution of the fifth-order ODE (that is, Burchnall's equation) associated with Appell's F_4 is constructed by ''subtracting'' the fourth-order equation satisfied only by periods of the SU(3) Seiberg–Witten curve which are part of the solutions to the fifth-order ODE. In Sec. III, we discuss these aspects of Burchnall's equation as an application of the SU(3) Picard–Fuchs ODE to a theory of hypergeometric equations. Section IV is a brief summary.

Remark: When we simply say ''Picard–Fuchs ODE,'' it always means a single ordinary differential equation in terms of QCD scale parameter derivatives.

II. PICARD–FUCHS ORDINARY DIFFERENTIAL SYSTEMS

A. The hyperelliptic curve

First, let us recall the exact solution to the $SU(n+1)(n\in\mathbf{N})$ gauge theory as an example. On the affine local coordinates $x,y\in\mathbf{C}$, the hyperelliptic curve and the Seiberg–Witten differential are given by[5–7,9,16]

$$y^2=\widetilde{W}^2_{SU(n+1)}-z,\quad \lambda_{SW}=\frac{x\,\partial_x\widetilde{W}_{SU(n+1)}}{y}\,dx, \tag{2.1}$$

where $z=\Lambda_{\mathrm{SU}(n+1)}^{2(n+1)}$ and

$$\widetilde{W}_{\mathrm{SU}(n+1)}=x^{n+1}-\sum_{i=2}^{n+1} s_i x^{n+1-i}. \tag{2.2}$$

Equation (2.2) shows the simple singularity with moduli s_i. This hyperelliptic curve can be compactified to a Riemann surface of genus n after addition of infinity, hence there must be noncontractible $2n$ cycles on this surface and these cycles can be chosen as the canonical bases, i.e., $\alpha_i \cap \alpha_j=\beta_i \cap \beta_j=0$, $\alpha_i \cap \beta_j=-\beta_j \cap \alpha_i=+\delta_{i,j}$. Then we introduce the period vector

$$\Pi=\begin{pmatrix} a_{D_i} \\ a_i \end{pmatrix}, \tag{2.3}$$

where

$$a_i=\oint_{\alpha_i}\lambda_{\mathrm{SW}}, \quad a_{D_i}=\oint_{\beta_i}\lambda_{\mathrm{SW}}. \tag{2.4}$$

Below, we often denote moduli as $u\equiv s_2$ and $v\equiv s_3$.

B. Derivation of Picard–Fuchs ODE

A physically interesting behavior of periods is in the weak coupling region. Of course, the study of periods can be proceeded by using Picard–Fuchs equations, and in general periods are represented by series in moduli. However, by some rearrangement they are found to have a striking feature in their form. Namely, they can be summarized as

$$\text{periods}=\text{classical part}+\text{quantum corrections}. \tag{2.5}$$

Equation (2.5) suggests that it is more convenient to construct periods as a series in QCD scale parameter Λ rather than moduli. In a sense, (2.5) might be implied by Ito and Sasakura[27] in their observation of a general form of (a certain type of) Picard–Fuchs operators, which is summarized schematically as

$$L=L_{\mathrm{cl}}+\Lambda L_{\Lambda}. \tag{2.6}$$

This equality means that the Picard–Fuchs operator L is a sum of the operator L_{cl} whose kernel is classical periods and some operator L_{Λ}. Once the classical periods are known, we can calculate instanton corrected periods, that is, the kernel of L, by assuming L_{Λ} as a perturbation term for small Λ (at semiclassical regime). However, since in the case of other gauge theories with higher rank gauge groups the Picard–Fuchs system is represented by a set of PDEs, such perturbative calculation involves technical problems, therefore another method to obtain instanton corrected periods should be developed. One of the candidates in view of the differential equation is to construct Picard–Fuchs equations by regarding Λ as a unique independent variable instead of moduli. Then the resulting Picard–Fuchs equations will be expressed by an ordinary differential equation. Since the QCD scale parameter always appears in any gauge theory with or without (massive) hypermultiplets, this formulation is convenient when we generalize the method to various gauge theories with any rank gauge group.

Now, let us consider the derivation of this ordinary differential equation. In general, k-times differentiation of λ_{SW} over z gives

$$\frac{d^k\lambda_{\mathrm{SW}}}{dz^k}=\frac{\text{polynomial in } x}{y^{2k+1}}dx, \tag{2.7}$$

but the right-hand side can be decomposed into a sum of Abelian differentials and a total derivative term, if the well-known reduction algorithm is used.[17–21] Accordingly, collecting (2.7) for various k can generate a differential equation. In addition, since all independent periods should be solutions to this equation, the order of the equation must coincide with the total number of them, and in fact it is determined as $2n$. This reduction method is easily confirmed, if the Seiberg–Witten curves are hyperelliptic type. In this way, we get the Picard–Fuchs ODE in the form

$$\left[\frac{d^{2n}}{dz^{2n}}+c_{2n-1}\frac{d^{2n-1}}{dz^{2n-1}}+\cdots+c_0\right]\Pi=0, \tag{2.8}$$

where c_i are functions in moduli.

Also when massive quarks are included, we can obtain a similar ordinary differential equation, but in this case a mass dependent polynomial appears in the denominator of the right-hand side of (2.7). Reduction of such massive differential was also recognized by Marshakov *et al.*[28] in their construction of massive WDVV equations.

C. Examples of Picard–Fuchs ODE

Let us see examples of Picard–Fuchs ODE. The first one is the SU(2) case and then the coefficients in (2.8) are given by

$$c_1=\frac{1}{z}, \quad c_0=\frac{1}{16z(u^2-z)}. \tag{2.9}$$

Next, let us consider the SU(3) case. In this case, the coefficients are

$$\begin{aligned}
c_0&=\frac{-45(3z-4u^3+27v^2)}{2z^2\tilde{\Delta}_{\mathrm{SU}(3)}},\\
c_1&=\frac{45(1053z^2-538zu^3+40u^6+3267zv^2-54u^3v^2-1458v^4)}{2z^2\tilde{\Delta}_{\mathrm{SU}(3)}},\\
c_2&=\frac{1}{4z^2\tilde{\Delta}_{\mathrm{SU}(3)}}[445\,905z^3-8(4u^3-27v^2)^3+z^2(-217\,368u^3+734\,589v^2)\\
&\quad+36z(676u^6-135u^3v^2-29\,889v^4)],\\
c_3&=\frac{1}{z\tilde{\Delta}_{\mathrm{SU}(3)}}[76\,545z^3-162z^2(244u^3-297v^2)-4(4u^3-27v^2)^3\\
&\quad+9z(656u^6-1080u^3v^2-22\,599v^4)],
\end{aligned} \tag{2.10}$$

where $\tilde{\Delta}_{\mathrm{SU}(3)}$ is the product

$$\tilde{\Delta}_{\mathrm{SU}(3)}=(15z-4u^3+27v^2)\Delta_{\mathrm{SU}(3)} \tag{2.11}$$

with the discriminant

$$\Delta_{\mathrm{SU}(3)}=[729z^2+(4u^3-27v^2)^2-54z(4u^3+27v^2)] \tag{2.12}$$

of the SU(3) hyperelliptic curve.

We can easily obtain Picard–Fuchs ODE for SO(5) or Sp(4) gauge group in a similar manner. Though the Sp(4) hyperelliptic curve may be seen to be different from that of the SO(5) theory, the isomorphism of Picard–Fuchs equations between these two theories could be observed by Ito and Sasakura.[27] Also in the case of Picard–Fuchs ODE, this isomorphism can be easily established by the same transformation.[27]

D. Wronskian

As is well known, the scaling relation of the SU(2) prepotential can be generated from Wronskian of the Picard–Fuchs equation, but this is valid only for this SU(2) theory because the Picard–Fuchs equations in other gauge theories consist of partial differential equations. In such theories, ''Wronskian'' does not generally exist. However, our Picard–Fuchs ODE (2.8) admits a Wronskian given by

$$W_{\mathrm{SU}(n+1)}=\begin{vmatrix} a_1 & \cdots & a_n & a_{D_1} & \cdots & a_{D_n} \\ a_1' & \cdots & a_n' & a_{D_1}' & \cdots & a_{D_n}' \\ \vdots & & \vdots & \vdots & & \vdots \\ a_1^{(2n-1)} & \cdots & a_n^{(2n-1)} & a_{D_1}^{(2n-1)} & \cdots & a_{D_n}^{(2n-1)} \end{vmatrix}, \tag{2.13}$$

where $'=d/dz$. Substituting (2.13) into (2.8) shows that $W_{\mathrm{SU}(n+1)}$ satisfies

$$W_{\mathrm{SU}(n+1)}'+c_{2n-1}W_{\mathrm{SU}(n+1)}=0, \tag{2.14}$$

which is integrated to give

$$W_{\mathrm{SU}(n+1)}=\text{const.}\exp\left(-\int c_{2n-1}dz\right), \tag{2.15}$$

where const. is the integration constant to be determined from the comparison of the left- and right-hand sides of (2.15) by asymptotic behavior of periods, but may depend on moduli because in our formulation moduli are regarded as constant.

Note that (2.15) produces a new nonlinear relation between periods and other parameters. For example, in the case of the SU(2) theory with the normalization used by Klemm *et al.*,[5] (2.15) gives

$$W_{\mathrm{SU}(2)}=-\frac{iu}{2\pi z}, \tag{2.16}$$

which is a quite reminiscent expression with the homogeneity relation of prepotential.[22–24] Similarly, for the SU(3) theory, we have

$$W_{\mathrm{SU}(3)}=\frac{15z-(4u^3-27v^2)}{z^4\Delta_{\mathrm{SU}(3)}^2}, \tag{2.17}$$

where the integration constant is normalized to 1 for convenience in Sec. III. Note that the regular singularities of (2.17) are the same as those of the SU(3) Picard–Fuchs ODE.

III. BURCHNALL'S EQUATION

A. Multiterm differential equation

Picard–Fuchs equations obtained in Sec. II can be shown to be classified in terms of a multiterm ordinary differential equation discussed by Burchnall in his study of the relationship among hypergeometric differential equations in multiple variables and certain types of ordinary differential equations.[25] Here, multiterm ordinary differential equation is defined by:

Definition: The k-term ordinary differential equation is the differential equation taking the form

$$\left[f(\theta_z)+\sum_{i=1}^{l} z^i g_i(\theta_z)\right]\Pi=0 \tag{3.1}$$

for some l, where f and g_i are polynomial differential operators in the Euler derivative $\theta_z = z d/dz$. k is the total number of f and nonzero g_i.

For example, in terms of the Euler derivative, our SU(3) Picard–Fuchs ODE can be rewritten as the four-term ODE with

$$\begin{aligned}
f&=2916(x-y)^3(-1+\theta_z)^2\theta_z{}^2,\\
g_1&=-81(x-y)\theta_z{}^2[43x-52y-60(x-y)\theta_z+4(23x+13y)\theta_z{}^2],\\
g_2&=9[(386x-251y)\theta_z{}^2+144(2x-7y)\theta_z{}^3+36(19x+y)\theta_z{}^4-(x-y)(10+13\theta_z)],\\
g_3&=-5(1+3\theta_z)(2+3\theta_z)(-1+6\theta_z)(1+6\theta_z),
\end{aligned} \tag{3.2}$$

where $x=4u^3/27$ and $y=v^2$.

According to Srivastava and Saran,[29] who extended the work of Burchnall to four-term ODE, our SU(3) Picard–Fuchs ODE seems to be representable by a hypergeometric function in the homogeneity form $F(pz,qz,rz)$, where p, q, and r are parameters. In this paper, we could not specify this function, but since the kernel of the SU(3) Picard–Fuchs ODE is essentially written by Appell's F_4 function, some property of F_4 may appear in our SU(3) Picard–Fuchs ODE as a four-term equation. Furthermore, more detailed study indicates that Picard–Fuchs ODE in any rank gauge group can be classified as a k-term equation, but k seems to correspond to $2\times$ (rank of the gauge group).

Finally, note that the Picard–Fuchs ODE in SU(3) gauge theory has a factor $(-1+\theta_z)^2\theta_z^2$ in f polynomial. Therefore, the indicial indices at semiclassical regime are degenerated to -1 and 0. This indicates that there are logarithmic solutions at this regime. Of course, similar observation also holds for SO(5) and Sp(4) Picard–Fuchs ODEs.

B. Appell's equations and Burchnall's equation

As is well known, a hypergeometric function admits a lot of transformations and reducibilities. For example, a Gaussian ${}_2F_1$ system has 24 solutions and Appell's F_1 has 60 solutions. However, these solutions can be more systematically constructed, if we consider an equivalent ODE. In fact, Srivastava and Saran succeeded in finding 120 solutions to the ODE for Lauricella's $F_D^{(3)}$ function.[29] Also in this sense, the study of ODE for a hypergeometric partial differential system is interesting. The method used in these studies followed Burchnall's work.[25] In this paper, we do not attempt to obtain all solutions to Burchnall's equation (see below) like Kummer's 24 solutions, but we can show that the five basic solutions to Burchnall's equation, especially, the extra solution which is not a solution to the F_4 system, can be derived by using SU(3) Picard–Fuchs ODE. Of course, it may also be interesting if this extra solution can be represented by Appell's F_4, but we do not know whether it is possible or not. Nevertheless, we can establish the fifth solution as a simple formula. The reader should notice that the method presented in this paper is to use a fourth-order ODE [SU(3) Picard–Fuchs ODE] satisfied by periods of Riemann surface in genus two [SU(3) Seiberg–Witten curve] and therefore our method is quite different from those mentioned above.

First, let us recall that the SU(3) Picard–Fuchs system[5]

$$\left[\theta_{\tilde{x}}\left(\theta_{\tilde{x}}-\frac{1}{3}\right)-\tilde{x}\left(\theta_{\tilde{x}}+\theta_{\tilde{y}}-\frac{1}{6}\right)\left(\theta_{\tilde{x}}+\theta_{\tilde{y}}-\frac{1}{6}\right)\right]\Pi=0,$$
$$\left[\theta_{\tilde{y}}\left(\theta_{\tilde{y}}-\frac{1}{2}\right)-\tilde{y}\left(\theta_{\tilde{x}}+\theta_{\tilde{y}}-\frac{1}{6}\right)\left(\theta_{\tilde{x}}+\theta_{\tilde{y}}-\frac{1}{6}\right)\right]\Pi=0, \tag{3.3}$$

where we have introduced $\tilde{x}=4u^3/(27\Lambda^6_{\mathrm{SU}(3)})$ and $\tilde{y}=v^2/\Lambda^6_{\mathrm{SU}(3)}$, and $\theta_x=x\partial/\partial x$ and $\theta_y=y\partial/\partial y$ are Euler partial derivatives. In the terminology of Sec. III A, (3.3) consists of two two-term equations and is nothing but the Appell's differential system for the type F_4 hypergeometric double series

$$F_4(\alpha,\beta;\gamma,\gamma';x,y)=\sum_{m,n=0}^{\infty}\frac{(\alpha)_{m+n}(\beta)_{m+n}}{(\gamma)_m(\gamma')_n}\frac{x^m}{m!}\frac{y^n}{n!}, \tag{3.4}$$

where $\alpha=\beta=-1/6$, $\gamma=2/3$, and $\gamma'=1/2$. However, by the scaling transformation

$$\tilde{x}=x\tilde{z},\quad \tilde{y}=y\tilde{z},\quad x=\frac{4u^3}{27},\quad y=v^2,\quad \tilde{z}=\frac{1}{\Lambda^6_{A_2}}, \tag{3.5}$$

we see that (3.3) turns to

$$[\theta_x(\theta_x+\gamma-1)-x\tilde{z}(\theta_x+\theta_y+\alpha)(\theta_x+\theta_y+\beta)]F=0,$$
$$[\theta_y(\theta_y+\gamma'-1)-y\tilde{z}(\theta_x+\theta_y+\alpha)(\theta_x+\theta_y+\beta)]F=0, \tag{3.6}$$

whose analytic solution near $(x,y)=(0,0)$ is given by

$$F(x\tilde{z},y\tilde{z})=\sum_{m,n=0}^{\infty}\frac{(\alpha)_{m+n}(\beta)_{m+n}}{(\gamma)_m(\gamma')_n}\frac{(x\tilde{z})^m}{m!}\frac{(y\tilde{z})^n}{n!}. \tag{3.7}$$

At first sight, since $F(x\tilde{z},y\tilde{z})$ reduces to F_4 for $\tilde{z}\to 1$, this scale transformation may be trivial, but (3.6) was used as a starting point in Burchnall's work on a set of partial differential equations.[25]

In fact, Burchnall noticed on the homogeneity relation of F

$$(\theta_x+\theta_y-\theta_{\tilde{z}})F=0, \tag{3.8}$$

where $\theta_{\tilde{z}}$ is the ordinary differential operator $\theta_{\tilde{z}}=\tilde{z}d/d\tilde{z}$, and finally arrived at the ordinary differential equation of fifth order (see also Appendix A)

$$\Big[f_0-2(x+y)\tilde{z}f_1(\theta_{\tilde{z}}+\alpha)(\theta_{\tilde{z}}+\beta)+\frac{1}{2}(x-y)\tilde{z}f_2(\theta_{\tilde{z}}+\alpha)(\theta_{\tilde{z}}+\beta)$$
$$+(x-y)^2\tilde{z}^2f_3(\theta_{\tilde{z}}+\alpha)(\theta_{\tilde{z}}+\alpha+1)(\theta_{\tilde{z}}+\beta)(\theta_{\tilde{z}}+\beta+1)\Big]F=0, \tag{3.9}$$

where

$$f_0=\theta_{\tilde{z}}(\theta_{\tilde{z}}+\gamma-1)(\theta_{\tilde{z}}+\gamma'-1)(\theta_{\tilde{z}}+\gamma+\gamma'-2)\left(\theta_{\tilde{z}}+\frac{\gamma}{2}+\frac{\gamma'}{2}-2\right),$$
$$f_1=\left(\theta_{\tilde{z}}+\frac{\gamma}{2}+\frac{\gamma'}{2}\right)\left(\theta_{\tilde{z}}+\frac{\gamma}{2}+\frac{\gamma'}{2}-\frac{1}{2}\right)\left(\theta_{\tilde{z}}+\frac{\gamma}{2}+\frac{\gamma'}{2}-1\right),$$
$$f_2=(\gamma-\gamma')(\gamma+\gamma'-2)\left(\theta_{\tilde{z}}+\frac{\gamma}{2}+\frac{\gamma'}{2}-\frac{1}{2}\right),$$
$$f_3=\left(\theta_{\tilde{z}}+\frac{\gamma}{2}+\frac{\gamma'}{2}+1\right). \tag{3.10}$$

In contrast with the SU(3) Picard–Fuchs ODE, since Burchnall's equation (3.9) is classified as a three-term ODE, it reflects a consequence of the nature of two variables hypergeometric function in the form $F(pz,qz)$, where p and q are parameters.[25]

As a direct calculation shows, (3.9) cannot be expressed in the form $[\theta_{\tilde{z}}+K(x,y,\tilde{z})]LF=0$, where $K(x,y,\tilde{z})$ is some function of x, y, and $\tilde{z}$, and L is some differential operator of fourth order. Accordingly, such L does not exist and therefore the relation between our SU(3) Picard–Fuchs ODE and Burchnall's equation is nontrivial. However, note that the coefficient of highest power in the Euler derivative corresponds to the discriminant of the SU(3) curve

$$\Delta\equiv[1-2(x+y)\tilde{z}+(x-y)^2\tilde{z}^2]=\frac{1}{729\Lambda_{\mathrm{SU}(3)}^{12}}[4u^3-27(v+\Lambda_{\mathrm{SU}(3)}^3)^2][4u^3-27(v-\Lambda_{A_2}^3)^2]. \tag{3.11}$$

Therefore, in a sense Burchnall's equation is reminiscent of the SU(3) Picard–Fuchs ODE, but these two are not completely equivalent. Clarifying the relation between these two equations is the subject of the rest of the paper.

C. Four solutions at semiclassical regime

It would be instructive to get solutions explicitly around $\Lambda_{\mathrm{SU}(3)}=0(\tilde{z}=\infty)$, which is a regular singular point of the equation. In the work of Burchnall, solutions of (3.9) were not calculated at any singularities, but since (3.9) is a linear ordinary differential equation, it is easy to solve it by traditional Frobenius's method under the assumption $F=\tilde{z}^{-\nu}\Sigma_{n=0}^{\infty}A_n\tilde{z}^{-n}$ for some ν and A_n. Then the indicial indices are determined as

$$\nu=\alpha,\beta,\alpha+1,\beta+1,(\gamma+\gamma'+2)/2 \tag{3.12}$$

or equivalently,

$$\nu_1=-1/6,\quad \nu_2=5/6,\quad \nu_3=19/12, \tag{3.13}$$

where ν_1 and ν_2 are actually double roots. The solution for ν_3 is the subject of Sec. III D.

Equation (3.9) produces the recursion relations

$$\begin{gathered}(x-y)^2\rho_1A_1-(\nu_i-\alpha)(\nu_i-\beta)\phi_1A_0=0,\\ (x-y)^2\rho_nA_n-(\nu_i+n-\alpha-1)(\nu_i+n-\beta-1)\sigma_nA_{n-1}+\chi_nA_{n-2}=0,\quad n>1,\end{gathered} \tag{3.14}$$

where

$$\begin{aligned}\rho_n&=(2\nu_i+2n-\gamma-\gamma'-2)(\nu_i+n-\alpha)(\nu_i+n-\beta)(\nu_i+n-\alpha-1)(\nu_i+n-\beta-1),\\ \sigma_n&=(\nu_i+n-\gamma-\gamma')(2\nu_i+2n-\gamma-\gamma')[x(\nu_i+n-\gamma'-1)+y(\nu_i+n-\gamma-1)]\\ &\quad+(\nu_i+n-1)(2\nu_i+2n-\gamma-\gamma'-2)[x(\nu_i+n-\gamma)+y(\nu_i+n-\gamma')],\\ \chi_n&=(\nu_i+n-2)(\nu_i+n-\gamma-1)(\nu_i+n-\gamma'-1)(\nu_i+n-\gamma-\gamma')(2\nu_i+2n-\gamma-\gamma')\end{aligned} \tag{3.15}$$

with $A_0=1$. Here, repeated indices are assumed *not* to be summed. If these recursion relations are used, the solutions corresponding to respective indicial indices will be obtained, but we must be careful, because there are indicial indices which differ by unit among them, i.e., α and $\alpha+1$, and β and $\beta+1$. For example, let $\nu=\alpha$. Then the recursion relations produce the nth coefficient as a linear combination of A_0 and A_1. Thus the solution is given by a linear combination of $\tilde{z}^{-\alpha}(A_0+\cdots)$ and $\tilde{z}^{-\alpha-1}(A_1+\cdots)$, but the ''indicial index'' of the last series can be seen as $\alpha+1$. Therefore, the last series can be also regarded as a solution corresponding to this index. In fact, it is easy to see that explicit construction of the solution supports this observation. Of course, in this case, since we would like to get a solution corresponding to the index α, A_1 can be set to zero without loss of generality. For this reason, A_1 is chosen as zero for the indices α and β, while that for $\alpha+1$, $\beta+1$, and $(\gamma+\gamma'-2)/2$ should be determined from the first equation in (3.14).

In this way, we get the regular series solutions ($i=1,2$)

$$\varphi_i=\tilde{z}^{-\nu_i}\sum_{n=1}^{\infty} A_{i,n}\tilde{z}^{-n}, \tag{3.16}$$

where the first few coefficients are given by

$$\begin{aligned} A_{i,0}&=1,\\ A_{1,1}&=0,\\ A_{1,2}&=\frac{5}{648(x-y)^2},\\ A_{1,3}&=\frac{35(41x+40y)}{209\,952(x-y)^4},\\ A_{2,1}&=\frac{5(5x+4y)}{48(x-y)^2},\\ A_{2,2}&=\frac{35(157x^2+460xy+112y^2)}{15\,552(x-y)^4},\\ A_{2,3}&=\frac{385(18\,671x^3+119\,352x^2y+105\,504xy^2+12\,352y^3)}{26\,873\,856(x-y)^6}. \end{aligned} \tag{3.17}$$

On the other hand, the degeneracy of ν_1 and ν_2 produce the logarithmic solutions ($j=1,2$)

$$\tilde{\varphi}_j=\varphi_j \ln\frac{1}{\tilde{z}}+\tilde{z}^{-\nu_j}\sum_{n=1}^{\infty} B_{j,n}\tilde{z}^{-n}, \tag{3.18}$$

where some of $B_{j,n}$ are

$$\begin{aligned} B_{1,1}&=0,\\ B_{1,2}&=-\frac{17}{1296(x-y)^2},\\ B_{1,3}&=-\frac{(11\,761x+11\,216y)}{1\,259\,712(x-y)^4},\\ B_{2,1}&=\frac{49x+104y}{144(x-y)^2},\\ B_{2,2}&=\frac{14\,273x^2+70\,940xy+28\,268y^2}{46\,656(x-y)^4},\\ B_{2,3}&=\frac{41\,936\,917x^3+383\,568\,144x^2y+472\,854\,144xy^2+79\,210\,112y^3}{161\,243\,136(x-y)^6}. \end{aligned} \tag{3.19}$$

It is interesting to notice that these series are composed by a series in powers of $1/(x-y)=27/(4u^3-27v^2)$ which detects the discriminant of the semiclassical SU(3) curve. This feature is useful when we consider the structure of the quantum moduli space of the SU(3) gauge theory.

For this purpose, let us recall the work of Klemm *et al.*[5] In the course of the analysis of the quantum moduli space of the SU(3) gauge theory, Klemm *et al.*[5] found that the quantum moduli space could be better understood as the complex projective space $\mathbf{CP}^2$ with singularities which correspond to the strong coupling regime. Then this space can be covered by the three local (inhomogeneous) coordinates

$$P_1:\left(\frac{4u^3}{27\Lambda^6}:\frac{v^2}{\Lambda^6}:1\right),\quad P_2:\left(\frac{4u^3}{27v^2}:1:\frac{\Lambda^6}{v^2}\right),\quad P_3:\left(1:\frac{27v^2}{4u^3}:\frac{27\Lambda^6}{4u^3}\right), \tag{3.20}$$

where $\Lambda\equiv\Lambda SU(3)$. For this reason, periods should be obtained at each coordinate patch, hence the periods derived in this way are locally valid. However, our solutions have a (slightly) nice property, because the basis of solution space are common both on P_2 and P_3. That is, to get periods on P_2, it is enough to further expand φ_i by v, while on P_3 by large u.

In fact, we can see that the four periods are expressed by linear combinations of (3.16) and (3.18). For example, to match periods on the patch P_3, let us define ω_i and Ω_j by linear combinations of φ_i

$$\tilde{\omega}_1=c_1\varphi_1+c_2\varphi_2,\quad \tilde{\omega}_2=c_3\varphi_1+c_4\varphi_2,$$

$$\tilde{\Omega}_1=\tilde{\omega}_1\ln\frac{27}{4u^3\tilde{z}}+\sum_{i=1}^{2}\sum_{n=1}^{\infty}c_iB_{i,n}\tilde{z}^{-\nu_i-n}+c_5\varphi_1+c_6\varphi_2, \tag{3.21}$$

$$\tilde{\Omega}_2=\tilde{\omega}_2\ln\frac{27}{4u^3\tilde{z}}+\sum_{i=1}^{2}\sum_{n=1}^{\infty}c_{i+2}B_{i,n}\tilde{z}^{-\nu_i-n}+c_7\varphi_1+c_8\varphi_2,$$

where

$$c_1={}_2F_1\left(-\frac{1}{6},\frac{1}{6};\frac{1}{2};\frac{27v^2}{4u^3}\right),\quad c_2=-\frac{3}{16u^3}\,{}_2F_1\left(\frac{5}{6},\frac{7}{6};\frac{1}{2};\frac{27v^2}{4u^3}\right),$$

$$c_3={}_2F_1\left(\frac{1}{3},\frac{2}{3};\frac{3}{2};\frac{27v^2}{4u^3}\right),\quad c_4=\frac{3}{2u^3}\,{}_2F_1\left(\frac{4}{3},\frac{5}{3};\frac{3}{2};\frac{27v^2}{4u^3}\right),$$

$$c_5=c_1+\sum_{n=1}^{\infty}\frac{(-1/6)_n(1/6)_n}{(1/2)_n n!}\left[\psi\left(n-\frac{1}{6}\right)-\psi\left(-\frac{1}{6}\right)+\psi\left(n+\frac{1}{6}\right)-\psi\left(\frac{1}{6}\right)\right]\left(\frac{27v^2}{4u^3}\right)^n, \tag{3.22}$$

$$c_6=c_2-\frac{3}{16u^3}\sum_{n=0}^{\infty}\frac{(5/6)_n(7/6)_n}{(1/2)_n n!}\left[2\psi(1)-2\psi(2)+\psi\left(n+\frac{5}{6}\right)-\psi\left(-\frac{1}{6}\right)+\psi\left(n+\frac{7}{6}\right)-\psi\left(\frac{1}{6}\right)\right]\times\left(\frac{27v^2}{4u^3}\right)^n,$$

$$c_7=c_3+\sum_{n=1}^{\infty}\frac{(1/3)_n(2/3)_n}{(3/2)_n n!}\left[\psi\left(n+\frac{1}{3}\right)-\psi\left(\frac{1}{3}\right)+\psi\left(n+\frac{2}{3}\right)-\psi\left(\frac{2}{3}\right)\right]\left(\frac{27v^2}{4u^3}\right)^n,$$

$$c_8 = c_4 + \frac{3}{2u^3}\sum_{n=0}^{\infty}\frac{(4/3)_n(5/3)_n}{(3/2)_n n!}\left[2\psi(1) - 2\psi(2) + \psi\left(n+\frac{4}{3}\right) - \psi\left(\frac{1}{3}\right) + \psi\left(n+\frac{5}{3}\right) - \psi\left(\frac{2}{3}\right)\right]$$
$$\times\left(\frac{27v^2}{4u^3}\right)^n.$$

Here, $\psi(x) = d\ln\Gamma(x)/dx$ is the digamma function and ${}_2F_1$ is the hypergeometric function whose series representation is given by

$$ {}_2F_1(a,b;c;x) = \sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(c)_n}\frac{x^n}{n!}, \tag{3.23}$$

where $(*)_n = \Gamma(*+n)/\Gamma(*)$ is the Pochhammer symbol. In order to make a contact with the normalization used by Klemm *et al.*,[5] we rescale as

$$\omega_1 = 2\sqrt{u}\Lambda\tilde{\omega}_1, \quad \omega_2 = \frac{v\Lambda}{u}\tilde{\omega}_2,$$
$$\Omega_1 = 2\sqrt{u}\Lambda\tilde{\Omega}_1, \quad \Omega_2 = \frac{v\Lambda}{u}\tilde{\Omega}_2. \tag{3.24}$$

Then the periods a_j and a_{D_j} can be given by

$$a_1 = \frac{1}{2}(\omega_1 + \omega_2), \quad a_2 = \frac{1}{2}(\omega_1 - \omega_2),$$
$$a_{D_1} = -\frac{i}{4}(\Omega_1 + 3\Omega_2) - \frac{i}{\pi}(\delta_1\omega_1 - \delta_2\omega_2), \tag{3.25}$$
$$a_{D_2} = -\frac{i}{4}(\Omega_1 - 3\Omega_2) - \frac{i}{\pi}(\delta_1\omega_1 + \delta_2\omega_2),$$

where $\delta_1 = i(5 - 3\ln 3 - 4\ln 2)/4$ and $\delta_2 = 3i(1 + 3\ln 3)/4$ are constants determined from asymptotic expansion of periods.[5] The identification of periods by our solutions can be easily established by expanding (3.25) at $u = \infty$. On the other hand, for large v, i.e., on the patch P_2, φ_i are expanded at $v = \infty$ and then consider similar linear combinations.

In this way, we can check that the series solutions for $v = v_1$ and v_2 comprise in fact the four periods.

D. The fifth solution

We have seen that the four solutions with indicial indices ν_1 and ν_2 of Burchnall's fifth-order equation in fact yield the four periods of the SU(3) gauge theory. However, there exists an extra solution in (3.9). Therefore, the appearance can be regarded as characteristic in the ordinary differential form of the partial differential system.

In this section, we show that it is possible to derive a fourth-order equation satisfied by this fifth solution with aid of the SU(3) Picard–Fuchs ODE and we derive the closed formula for this fifth solution as an application of the SU(3) Picard–Fuchs ODE.

First, let us rewrite (3.9) in the form

$$\left[\frac{d^5}{dz^5} + c_{B,4}\frac{d^4}{dz^4} + \cdots + c_{B,0}\right]F = 0, \tag{3.26}$$

where $z=1/\tilde{z}$ and $c_{B,i}$ are some functions in x, y, and z. As we have already seen in Sec. III C, since four of the five independent solutions to (3.9) are regarded as the four periods of the SU(3) gauge theory, we can write the Wronskian for (3.26) as

$$W_B=\begin{vmatrix} a_1 & a_2 & a_{D_1} & a_{D_2} & h \\ a_1' & a_2' & a_{D_1}' & a_{D_2}' & h' \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ a_1^{(4)} & a_2^{(4)} & a_{D_1}^{(4)} & a_{D_2}^{(4)} & h^{(4)} \end{vmatrix}, \tag{3.27}$$

where $'=d/dz$ and the fifth solution is denoted by h. Again from basic differential calculation, W_B is generated from $c_{B,4}$ and is found to be [cf. (2.15)]

$$W_B=\frac{1}{z^{85/12}[x^2+(y-z)^2-2x(y+z)]^3} \tag{3.28}$$

up to the normalization of integration constant, which is irrelevant to the following discussion.

Next, recall that the fourth-order derivatives of periods can be reduced to a linear combination of lower order derivatives by using the SU(3) Picard–Fuchs ODE. Therefore, from (3.27) with the SU(3) Picard–Fuchs ODE, we see that

$$W_B=W_{\mathrm{SU}(3)}(h^{(4)}+c_3h'''+c_2h''+c_1h'+c_0h), \tag{3.29}$$

where c_i are given by (2.10). From (3.28) and (2.17), it is immediate to obtain the differential equation for h,

$$h^{(4)}+c_3h'''+c_2h''+c_1h'+c_0h=R, \tag{3.30}$$

where

$$R=\frac{1}{z^{37/12}[5z-9(x-y)][x^2+(y-z)^2-2x(y+z)]}. \tag{3.31}$$

It is interesting to note that h satisfies the SU(3) Picard–Fuchs ODE with a source term. It is now easy to get a general solution to (3.30) (see also Appendix B)

$$h=\sum_{i=1}^{2}\rho_i a_i+\sum_{i=1}^{2}\epsilon_i a_{D_i}-a_1\int_0\frac{Rw_1}{W_{\mathrm{SU}(3)}}dx+a_2\int\frac{Rw_2}{W_{\mathrm{SU}(3)}}dx-a_{D_1}\int_0\frac{Rw_3}{W_{\mathrm{SU}(3)}}dx+a_{D_2}\int_0\frac{Rw_4}{W_{\mathrm{SU}(3)}}dx, \tag{3.32}$$

where ρ_i and ϵ_i are integration constants, the integration symbol is the integration constant free integral, and w_i are determinants defined by

$$w_1=\begin{vmatrix} a_2 & a_{D_1} & a_{D_2} \\ a_2' & a_{D_1}' & a_{D_2}' \\ a_2'' & a_{D_1}'' & a_{D_2}'' \end{vmatrix}, \quad w_2=\begin{vmatrix} a_1 & a_{D_1} & a_{D_2} \\ a_1' & a_{D_1}' & a_{D_2}' \\ a_1'' & a_{D_1}'' & a_{D_2}'' \end{vmatrix},$$

$$w_3=\begin{vmatrix} a_1 & a_2 & a_{D_2} \\ a_1' & a_2' & a_{D_2}' \\ a_1'' & a_2'' & a_{D_2}'' \end{vmatrix}, \quad w_4=\begin{vmatrix} a_1 & a_2 & a_{D_1} \\ a_1' & a_2' & a_{D_1}' \\ a_1'' & a_2'' & a_{D_1}'' \end{vmatrix}. \tag{3.33}$$

$W_{SU(3)}$ in (3.32) can be identified with (2.17).

To summarize, we have succeeded in finding a closed representation of the fifth solution by using the SU(3) Picard–Fuchs ODE. It is interesting to compare (3.32) with the fifth solution of other three-term differential equation discussed by Burchnall.[25] In the case of a product of two Bessel functions, for instance, the fifth solution is expressed by an integral of a product of two ''Wronskians'' each of which is written by two other independent solutions.[25] However, our fifth solution does not admit such factorization, so (3.32) seems to imply the fact that the Appell function F_4 with parameters $\alpha=\beta=-1/6$, $\gamma=2/3$, and $\gamma'=1/2$ [or equivalently, the SU(3) periods] cannot be factored into a product of two (nontrivial) functions.

Remark: In the semiclassical regime, series representation of this fifth solution corresponds to $\nu_3=19/12$ *in (3.13), and this can be also seen from the terms not including* ρ_i *and* ϵ_i *in (3.32).*

IV. SUMMARY

In this paper, we have discussed the Picard–Fuchs equations appearing in $N=2$ supersymmetric Yang–Mills theories in view of ordinary differential equation and realized Picard–Fuchs equations as a system of ODEs. This construction has given a new relation among periods, moduli, and QCD parameter by using the Wronskian and this is a systematic way to get such nonlinear relation among periods in higher rank gauge group cases.

In the case of SU(3), we have also found that Burchnall's ordinary differential equation for Appell's F_4 is a candidate of Picard–Fuchs ODE by identifying the SU(3) QCD mass scale parameter with the scaling variable used in Burchnall's observation and confirmed that four of the five solutions of Burchnall's equation in fact coincide with SU(3) periods. As for the fifth solution, it has been shown that it has a simple and closed form by using the SU(3) Picard–Fuchs ODE. Of course, even if we consider arbitrary Riemann surface of genus two and try to get a similar result for the fifth solution to Burchnall's equation, the derivation will be failed because we cannot always have an equation in fourth order like SU(3) Picard–Fuchs ODE. Note that the SU(3) Seiberg–Witten curve is a specific choice and the appearance of $\Lambda_{SU(3)}$ plays the central role in the discussion.

Generalization of Burchnall's construction of ordinary differential equation from a set of partial differential equations to Picard–Fuchs equations in other gauge theories is straightforward, but we do not know whether Burchnall type equations exist for Picard–Fuchs equations in those gauge theories. Studying these cases will open further aspects of Picard–Fuchs equations and hypergeometric nature of the equations constructed from the homogeneous hypergeometric equations in multiple variables.

Finally, as another direction, since our equation is ODE in contrast with the usual Picard–Fuchs systems, it may be possible to consider a relation to classical W-algebras in view of Picard–Fuchs ODE.[30]

ACKNOWLEDGMENT

I acknowledge Professor P. W. Karlsson, who kindly gave me a comment on my lengthy questions about Burchnall's work.

APPENDIX A: DERIVATION OF THE BURCHNALL'S EQUATION

In this appendix, we briefly review the derivation of Burchnall's equation. The reader is also recommended to refer to the original paper.[25]

First, notice that from (3.6) it is easy to obtain

$$(\theta_{\tilde{z}}+\gamma+\gamma'-2)\theta_x\theta_y F=(x\tilde{z}\theta_y+y\tilde{z}\theta_x)XF, \tag{A1}$$

where $X=(\theta_{\tilde{z}}+\alpha)(\theta_{\tilde{z}}+\beta)$. We can also obtain

$$UF \equiv [\theta_{\tilde z}(\theta_{\tilde z}+\gamma-1)-(x+y)\tilde zX]F=(2\theta_x+\gamma-\gamma')\theta_y F,$$
$$U'F \equiv [\theta_{\tilde z}(\theta_{\tilde z}+\gamma'-1)-(x+y)\tilde zX]F=(2\theta_y+\gamma'-\gamma)\theta_x F \tag{A2}$$

and

$$\theta_x(\theta_{\tilde z}+\gamma-1)(\theta_{\tilde z}+\gamma'-1)F=[(\theta_{\tilde z}+\gamma'-1)\theta_x\theta_y+x\tilde z(\theta_{\tilde z}+\gamma')X]F,$$
$$\theta_y(\theta_{\tilde z}+\gamma'-1)(\theta_{\tilde z}+\gamma-1)F=[(\theta_{\tilde z}+\gamma-1)\theta_x\theta_y+y\tilde z(\theta_{\tilde z}+\gamma)X]F. \tag{A3}$$

Addition of the two equations in (A3) provides

$$VF \equiv [\theta_{\tilde z}(\theta_{\tilde z}+\gamma-1)(\theta_{\tilde z}+\gamma'-1)-x\tilde z(\theta_{\tilde z}+\gamma')X-y\tilde z(\theta_{\tilde z}+\gamma)X]F=(2\theta_{\tilde z}+\gamma+\gamma'-2)\theta_x\theta_y F, \tag{A4}$$

thus

$$(\theta_{\tilde z}+\gamma+\gamma'-2)VF=[4xy\tilde z^2XX_{+1}+x\tilde zXU+y\tilde zXU'+2(\theta_{\tilde z}+\gamma+\gamma'-2)\theta_x\theta_y]F, \tag{A5}$$

where $X_{+1}=(\theta_{\tilde z}+\alpha+1)(\theta_{\tilde z}+\beta+1)$, and (A1) and (A2) have been used. Moreover, from (A5) we have

$$\begin{aligned} WF \equiv [&\theta_{\tilde z}(\theta_{\tilde z}+\gamma+\gamma'-2)(\theta_{\tilde z}+\gamma-1)(\theta_{\tilde z}+\gamma'-1)-x\tilde z[(\theta_{\tilde z}+\gamma+\gamma'-1)(\theta_{\tilde z}+\gamma') \\ &+\theta_{\tilde z}(\theta_{\tilde z}+\gamma-1)]X-y\tilde z[(\theta_{\tilde z}+\gamma+\gamma'-1)(\theta_{\tilde z}+\gamma)+\theta_{\tilde z}(\theta_{\tilde z}+\gamma'-1)]X \\ &+(x-y)^2\tilde z^2XX_{+1}]F=2(\theta_{\tilde z}+\gamma+\gamma'-2)\theta_x\theta_y F. \end{aligned} \tag{A6}$$

Therefore, the expected equation is given by rearrangement of

$$(2\theta_{\tilde z}+\gamma+\gamma'-2)WF=2(\theta_{\tilde z}+\gamma+\gamma'-2)VF, \tag{A7}$$

i.e.,

$$[Y_0-x\tilde zY_1X-y\tilde zY_2X+(x-y)^2\tilde z^2(2\theta_{\tilde z}+\gamma+\gamma'+2)XX_{+1}]F=0, \tag{A8}$$

where

$$\begin{aligned} Y_0&=\theta_{\tilde z}(\theta_{\tilde z}+\gamma-1)(\theta_{\tilde z}+\gamma'-1)(\theta_{\tilde z}+\gamma+\gamma'-2)(2\theta_{\tilde z}+\gamma+\gamma'-4), \\ Y_1&=(\theta_{\tilde z}+\gamma')(\theta_{\tilde z}+\gamma+\gamma'-1)(2\theta_{\tilde z}+\gamma+\gamma'-2)+\theta_{\tilde z}(\theta_{\tilde z}+\gamma-1)(2\theta_{\tilde z}+\gamma+\gamma'), \\ Y_2&=(\theta_{\tilde z}+\gamma)(\theta_{\tilde z}+\gamma+\gamma'-1)(2\theta_{\tilde z}+\gamma+\gamma'-2)+\theta_{\tilde z}(\theta_{\tilde z}+\gamma'-1)(2\theta_{\tilde z}+\gamma+\gamma'). \end{aligned} \tag{A9}$$

Of course (A8) is equivalent to (3.9).

APPENDIX B: GENERAL SOLUTION TO FOURTH-ORDER ODE

This Appendix reviews a construction of a general solution to the fourth-order linear ordinary differential equation

$$y^{(4)}+P(x)y'''+Q(x)y''+R(x)y'+S(x)y=T(x), \tag{B1}$$

where $'=d/dx$ and P, Q, R, S, and T are some functions in x.

First, let $T=0$ and let y_i $(i=1,...,4)$ be the fundamental solutions to

$$y^{(4)}+P(x)y'''+Q(x)y''+R(x)y'+S(x)y=0. \tag{B2}$$

Then we assume that the general solution to (B1) is represented in the form

$$y=\sum_{i=1}^{4} C_i(x)y_i \tag{B3}$$

by using unknown coefficients C_i. Differentiating (B3), we can obtain

$$y'=\sum_{i=1}^{4} C_i'y_i+\sum_{i=1}^{4} C_i y_i', \tag{B4}$$

but we further assume that the first term in the right-hand side vanishes. Namely, we have

$$\sum_{i=1}^{4} C_i'y_i=0 \tag{B5}$$

and

$$y'=\sum_{i=1}^{4} C_i y_i'. \tag{B6}$$

Repeating differentiation and imposing the vanishing of terms including C_i', we get

$$\sum_{i=1}^{4} C_i'y_i'=0, \quad \sum_{i=1}^{4} C_i'y_i''=0 \tag{B7}$$

and

$$y''=\sum_{i=1}^{4} C_i y_i'', \quad y'''=\sum_{i=1}^{4} C_i y_i'''. \tag{B8}$$

As for $y^{(4)}$, we assume

$$y^{(4)}=\sum_{i=1}^{4} C_i'y_i'''+\sum_{i=1}^{4} C_i y_i^{(4)}. \tag{B9}$$

Then from (B1), (B9), and (B8), we get

$$\sum_{i=1}^{4} C_i'y_i'''=T. \tag{B10}$$

In this way, we can arrive at the matrix equation determining all C_i

$$YC={}^{T}(0,0,0,T), \tag{B11}$$

where

$$Y=\begin{pmatrix} y_1 & \cdots & y_4 \\ y_1' & \cdots & y_4' \\ y_1'' & \cdots & y_4'' \\ y_1''' & \cdots & y_4''' \end{pmatrix}, \quad C=\begin{pmatrix} C_1' \\ \vdots \\ C_4' \end{pmatrix}. \tag{B12}$$

Consequently, C_i are given by

$$C_1=c_1-\int_0 \frac{Tw_1}{\det Y}dx, \quad C_2=c_2+\int_0 \frac{Tw_2}{\det Y}dx, \quad C_3=c_3-\int_0 \frac{Tw_3}{\det Y}dx, \quad C_4=c_4+\int_0 \frac{Tw_4}{\det Y}dx, \tag{B13}$$

where c_i are integration constants, the integration symbol is the integration constant free integral and

$$w_1=\begin{vmatrix} y_2 & y_3 & y_4 \\ y_2' & y_3' & y_4' \\ y_2'' & y_3'' & y_4'' \end{vmatrix}, \quad w_2=\begin{vmatrix} y_1 & y_3 & y_4 \\ y_1' & y_3' & y_4' \\ y_1'' & y_3'' & y_4'' \end{vmatrix}, \quad w_3=\begin{vmatrix} y_1 & y_2 & y_4 \\ y_1' & y_2' & y_4' \\ y_1'' & y_2'' & y_4'' \end{vmatrix}, \quad w_1=\begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}. \tag{B14}$$

We prove a conjecture of Zuber on the signature of intersection forms associated with affine algebras of type A, which is based on connections between $N=2$ integrable models in two dimensions and certain class of graphs. © *1999 American Institute of Physics.* [S0022-2488(99)03006-6]

I. INTRODUCTION

Let $N\geqslant 2$ be a positive integer and $\lambda'=(\lambda_1',\ldots,\lambda_{N-1}')$, $0<\lambda_i'<1$, $i=1,2,...,N-1$ with $\Sigma_{0<i<N}\lambda_i'<1$. Define

$$p_i(\lambda'):=\lambda_i'+\cdots+\lambda_{N-1}'-\frac{1}{N}\sum_{0<j<N} j\lambda_j', \quad i=1,2,...,N-1$$

and $p_N(\lambda'):=-(1/N)\Sigma_{0<j<N} j\lambda_j'$. Define

$$q_i(\lambda'):=-Np_i(\lambda')+\frac{N+1}{2}-i$$

and

$$g_i(\lambda'):=(-1)^i\prod_{r=1}^{N} 2\cos\left(\pi\left(p_r(\lambda')-\frac{i}{N}\right)\right), \quad i=1,2,...,N.$$

If S is a finite sequence of real numbers, we define $b_+(S)$ [respectively $b_-(S)$, $b_0(S)$] to be the number of positive (respectively, negative, zero) elements in S. Let $a(S):=b_+(S)-b_-(S)$ and denote by $Q_{\lambda'}$, $G_{\lambda'}$ the following two sets:

$$Q_{\lambda'}:=\{\cos(\pi q_1(\lambda')),\ldots,\cos(\pi q_N(\lambda'))\},$$

$$G_{\lambda'}:=\{g_1(\lambda'),\ldots,g_N(\lambda')\}.$$

Notice that since $\cos(\pi q_i(\lambda'))>0$ iff $q_i(\lambda')\in]2p-\frac{1}{2}, 2p+\frac{1}{2}[$for some integer p, $b_+(Q_{\lambda'})$ is much easier to calculate than $b_+(G_{\lambda'})$ and the same is true for b_-'s. The main theorem in this paper is the following:

Theorem 1: *Let $\lambda'=(\lambda_1',\ldots,\lambda_{N-1}')$ be as above. Then:*

$$b_+(Q_{\lambda'})=b_+(G_{\lambda'}),b_-(Q_{\lambda'})=b_-(G_{\lambda'}),b_0(Q_{\lambda'})=b_0(G_{\lambda'}).$$

This theorem implies Zuber's conjecture about the signature of intersection forms associated with affine algebras of type A (cf. Ref. 1) which is the motivation of this paper. Note that $b_0(Q_{\lambda'})=b_0(G_{\lambda'})$ is already noticed in a slightly different form in Ref. 1.

Zuber's conjecture appeared as Conjecture 2.5 of Ref. 1. It is based on the mysterious connections between integrable models with two supersymmetries $(N=2)$ in two dimensions (cf. Ref.

[a)]Electronic mail: xufeng@math.ou.edu

2) and the class of graphs constructed in Ref. 1 (see also Ref. 3). In the special case when the graphs are regular (cf. Sec. II C), the conjecture can be proved (cf. p. 14 of Ref. 4) by combining the results of Ref. 4 and Ref. 5. In fact, in Ref. 4, a connection between regular graphs and singularity theory is established, and combined with Ref. 5 which is based on mixed Hodge structures, gives a rather indirect proof of Zuber's conjecture in the special case when the graphs are regular. However, for other graphs in Ref. 1 (see also Ref. 6), the connection with singularity theory, if any, is not clear at all. We also failed to prove Zuber's conjecture by using the connection with Ref. 2 as mentioned in Ref. 1.

We came to the realization that a statement as in theorem 1 may be true by first observing lemma 1 (cf. Sec. II A) which was already noticed in a slightly different form in Ref. 1. We then checked that theorem 1 is true explicitly in the case when $N=3$, 4 and some other cases which motivated us to give a general proof.

The idea of the proof of theorem 1 is as follows. When λ' changes, $b_+(G_{\lambda'})$ [respectively, $b_-(G_{\lambda'})$] may change only if some of $g_i(\lambda')$'s become 0 or change its sign, i.e., $g_i(\lambda')$ intersect the hyperplanes on which $g_i(\lambda')=0$. By lemma 1 of Sec. II A, these hyperplanes are the same as the hyperplanes on which some $q_j(\lambda')$'s lie in $\mathbb{Z}+\frac{1}{2}$. Consider the domain $D:=\{\lambda'=(\lambda'_1,\ldots,\lambda'_{N-1})|0<\lambda'_i<1,\Sigma_{0<i<N}\lambda'_i<1\}$. D is separated by the above hyperplanes into disjoint open regions. In each open region, the set of numbers compared in theorem 1 should be completely determined. In Sec. II A we determine these numbers in a given open region and find that they miraculously satisfy theorem 1. In Sec. II B, we show that theorem 1 also holds for any $\lambda'\in D$ which is on the boundary of the open region: this follows from Sec. II A and lemma 1. In Sec. II C, after introducing Zuber's conjecture, we show how theorem 1 implies that the conjecture is true. In Sec. III, we present our conclusions and questions.

II. THE PROOF

A. The interior case

We shall use the notations of Sec. I. Recall

$$D=\left\{\lambda'=(\lambda'_1,\ldots,\lambda'_{N-1})|\lambda'_i>0,\quad \sum_{0<i<N}\lambda'_i<1\right\}.$$

For $\lambda'\in D$, recall

$$p_i(\lambda')=\lambda'_i+\cdots+\lambda'_{N-1}-\frac{1}{N}\sum_{0<j<N}j\lambda'_j$$

$$=\frac{1}{N}[(-\lambda'_1-2\lambda'_2-\cdots-(i-1)\lambda'_{i-1})+(N-i)\lambda'_i+\cdots+\lambda'_{N-1}]$$

for $i=1,2,\ldots,N-1$. We have:

$$p_i(\lambda')>\frac{1}{N}[(-\lambda'_1-2\lambda'_2-\cdots-(i-1)\lambda'_{i-1})]>-\frac{1}{N}(i-1)\sum_{0<j<N}\lambda'_j>-\frac{1}{N}(i-1)$$

and

$$p_i(\lambda')<\frac{1}{N}[(N-i)\lambda'_i+\cdots+\lambda'_{N-1}]<\frac{1}{N}(N-i)\sum_{0<j<N}\lambda'_j<\frac{1}{N}(N-i).$$

Similarly one can show $(1/N)(1-N)<p_N(\lambda')<0$. So we have:

$$\frac{1}{N}(1-i)<p_i(\lambda')<\frac{1}{N}(N-i),$$

$i=1,2,...,N$. If for some i, $q_i(\lambda')=-Np_i(\lambda')+\frac{1}{2}(N+1)-i=j+\frac{1}{2}$ with $j\in\mathbb{Z}$, then

$$i-\tfrac{1}{2}N<i+j<i+\tfrac{1}{2}N-1.$$

Define $0<r_{\lambda'}(i)<N+1$ to be the unique integer such that $(1/N)(r_{\lambda'}(i)+j+i)\in\mathbb{Z}$. In fact, if $j+i<0$, $r_{\lambda'}(i)=-(j+i)$, if $0\leqslant j+i<N$, $r_{\lambda'}(i)=N-(j+i)$, and if $N\leqslant(j+i)<\frac{3}{2}N$, $r_{\lambda'}(i)=2N-(j+i)$. It follows that

$$g_{r_{\lambda'}}(i)(\lambda')=0.$$

We have the following lemma which, in a slightly different form also appeared on p. 17 of Ref. 1.

Lemma 1: For any $\lambda'\in D$, *the map* $i\to r_{\lambda'}(i)$ *defined above from* $\{i|q_i(\lambda')\in\mathbb{Z}+\frac{1}{2}\}$ *to* $\{r|g_r(\lambda')=0\}$ *is a one to one and onto map. Moreover* $q_i(\lambda')\in\mathbb{Z}+\frac{1}{2}$ *iff* $g_{r_{\lambda'}}(i)(\lambda')=0$ *and* $r_{\lambda'}(i)$ *depends only on i and* $q_i(\lambda')$.

Proof: By using definitions we have

$$g_r(\lambda')=(-1)^r\prod_{i=1}^{N}2\sin\left(\frac{\pi}{N}\left(q_i(\lambda')+i+r-\frac{1}{2}\right)\right).$$

If $g_r(\lambda')=0$, then there exists $i:=i_{\lambda'}(r)$ such that

$$\frac{1}{N}\left(q_i(\lambda')+i+r-\frac{1}{2}\right)\in\mathbb{Z}.$$

Let $j\in\mathbb{Z}$ with $q_i(\lambda')+i+r-\frac{1}{2}=j+i+r$, then $q_i(\lambda')=-Np_i(\lambda')+\frac{1}{2}(N+1)-i\in\mathbb{Z}+\frac{1}{2}$. Using the fact that $0<|p_a-p_b|<1$ for any $1\leqslant a\neq b\leqslant N$, it is easy to see that such an $i:=i_{\lambda'}(r)$ is also unique. It is then easy to check that the map $i\to r_{\lambda'}(i)$ and $r\to i_{\lambda'}(r)$ are inverse to each other. The rest of the lemma follows from the definitions of $r_{\lambda'}(i)$.

Let $\beta_i:=\frac{1}{2}N-i+\gamma_i$ with $\gamma_i\in\mathbb{Z}$, $i=1,2,...,N$. Let $D_\gamma:=\{\lambda'\in D|\beta_i<Np_i(\lambda')<\beta_i+1, i=1,2,...,N\}$. D_γ will be called open regions. It is clear that if $\gamma\neq\gamma'$, then $D_\gamma\cap D_{\gamma'}=0$. Notice that $q_i(\lambda')\in\mathbb{Z}+\frac{1}{2}$ iff λ' lies on the boundary of some D_γ, and by lemma 1, $g_{r_{\lambda'}(i)}(\lambda')=0$ iff λ' lies on the boundary of some D_γ. Suppose $D_\gamma\neq\varnothing$ and $\lambda'\in D_\gamma$. Then we have:

(1) If $i<j$, then $\beta_i\geqslant\beta_j$ which follows from the fact that $i<j$, then $p_i(\lambda')>p_j(\lambda')$ and $\beta_i-\beta_j\in\mathbb{Z}$;

(2) $\beta_1-\beta_N\leqslant N$ which follows from $p_1(\lambda')-p_N(\lambda')<1$.

By (1) we can assume that

$$\beta_1=\cdots=\beta_{i_1}>\beta_{i_1+1}=\cdots=\beta_{i_2}>\cdots>\beta_{i_{t-1}+1}=\ldots=\beta_{i_t},$$

where $1\leqslant i_1<i_2<\cdots<i_t=N$. We determine the sign of $g_r(\lambda')$ for a fixed $1\leqslant r\leqslant N$. Since $0<p_1(\lambda')-p_N(\lambda')<1$, there is at most one $k+\frac{1}{2}$ with $k\in\mathbb{Z}$ such that

$$p_N(\lambda')-\frac{r}{N}<k+\frac{1}{2}<p_1(\lambda')-\frac{r}{N}.$$

Also notice that if

$$\frac{\beta_i-r}{N}<k+\frac{1}{2}<\frac{\beta_i-r+1}{N},$$

then we have

$$\gamma_i-i-Nk<r<\gamma_i-i-Nk+1,$$

which is impossible since r, γ_i are integers. So if there is a $k\in\mathbb{Z}$ such that

$$p_N(\lambda')-\frac{r}{N}<k+\frac{1}{2}<p_1(\lambda')-\frac{r}{N},$$

then there is a unique integer, denoted by $1\leqslant f(r)\leqslant t-1$, such that:

$$\frac{\beta_{i_{f(r)+1}}+1-r}{N}\leqslant k+\frac{1}{2}\leqslant\frac{\beta_{i_{f(r)}}-r}{N},$$

and the sign of $g_r(\lambda')$ is:

$$(-1)^r(-1)^{kk'}(-1)^{(k-1)(N-k')}=(-1)^{r+Nk-i_{f(r)}},$$

where $k':=\{\beta_j:\beta_j<\beta_{f(r)}\}^{\#}=N-i_{f(r)}$. If there is no $k_1\in\mathbb{Z}$ such that

$$p_N(\lambda')-\frac{r}{N}<k_1+\frac{1}{2}<p_1(\lambda')-\frac{r}{N},$$

then there is a $k\in\mathbb{Z}$ such that:

$$k-\frac{1}{2}\leqslant\frac{\beta_N-r}{N}<\frac{\beta_1+1-r}{N}\leqslant k+\frac{1}{2},$$

and the sign of $g_r(\lambda')$ is:

$$(-1)^{r+kN}.$$

We define $f(r)=t$ in this case. Let $s:=r+kN$, then the signs of the set $\{g_r(\lambda')\}$ with $1\leqslant f(r)\leqslant t-1$ are given by

$$(-1)^{s-i_{f(r)}}$$

with $\gamma_{i_{f(r)+1}}+1-i_{f(r)+1}\leqslant s\leqslant\gamma_{i_{f(r)}}-i_{f(r)}$, and the sign of the set $\{g_r(\lambda')\}$ with $f(r)=t$ is given by

$$(-1)^{s-i_t}$$

with $\gamma_{i_1}+1-i_1-N\leqslant s\leqslant\gamma_{i_t}-i_t$. Now we determine the sign of $\cos(\pi q_i(\lambda'))$. Recall $\beta_i=(N/2)-i+\gamma_i$, $q_i(\lambda')=-Np_i(\lambda')+(N+1)/2-i$, and $\beta_i<Np_i(\lambda')<\beta_i+1$, we have

$$-\gamma_i-\tfrac{1}{2}<q_i(\lambda')<-\gamma_i+\tfrac{1}{2}.$$

So $\cos(\pi q_i(\lambda'))>0$ [respectively, $\cos(\pi q_i(\lambda'))<0$] iff $\gamma_i\in 2\mathbb{Z}$ (respectively, $\gamma_i\in 2\mathbb{Z}+1$). Recall from the introduction we have that for a finite sequence S of real numbers $a(S)=b_+(S)-b_-(S)$. To save some writing for any integer x we define $\{x\}:=[1-(-1)^x]/2$. Then the a of the following sequence $\{\cos(\pi q_i(\lambda')),i_{u-1}+1\leqslant i\leqslant i_u\}$ is

$$(-1)^{\gamma_{i_u}}\{i_u-i_{u-1}\}$$

and the a of the following sequence $\{(-1)^{s-i_u},\gamma_{i_{u+1}}+1-i_{u+1}\leqslant s\leqslant\gamma_{i_u}-i_u\}$ is

$$(-1)^{\gamma_{i_u}}\{\gamma_{i_u}-\gamma_{i_{u+1}}+i_{u+1}-i_u\},$$

where we define $i_{u-1}=0$ if $u=1$, and $\gamma_{i_{u+1}}-i_{u+1}=\gamma_{i_1}-i_1-N$ if $u=t$. It follows that $a(G_{\lambda'})-a(Q_{\lambda'})$ is given by

$$\sum_{u=1}^{t}(-1)^{\gamma_{i_u}}(\{\gamma_{i_u}-\gamma_{i_{u+1}}+i_{u+1}-i_u\}-\{i_u-i_{u-1}\})$$
$$=(-1)^{\gamma_{i_1}}(\{\gamma_{i_1}-\gamma_{i_2}+i_2-i_1\}-\{i_1\})+(-1)^{\gamma_{i_2}}(\{\gamma_{i_2}-\gamma_{i_3}+i_3-i_2\}-\{i_2-i_1\})$$
$$+\ldots+(-1)^{\gamma_{i_{t-1}}}(\{\gamma_{i_{t-1}}-\gamma_{i_t}+i_t-i_{t-1}\}-\{i_{t-1}-i_{t-2}\})$$
$$+(-1)^{\gamma_{i_t}}(\{\gamma_{i_t}-\gamma_{i_t}+i_1\}-\{i_t-i_{t-1}\}).$$

By using

$$\{\gamma_{i_u}-\gamma_{i_{u+1}}+i_{u+1}-i_u\}=\{\gamma_{i_u}-\gamma_{i_{u+1}}\}+(-1)^{\gamma_{i_u}-\gamma_{i_{u+1}}}\{i_{u+1}-i_u\},$$

which follows easily from the definition of $\{.\}$, we see that $\pm\{i_{u+1}-i_u\}$ terms canceled each other in the above summation and the remaining terms are:

$$(-1)^{\gamma_{i_1}}\{\gamma_{i_1}-\gamma_{i_2}\}+(-1)^{\gamma_{i_2}}\{\gamma_{i_2}-\gamma_{i_3}\}+\cdots+(-1)^{\gamma_{i_t}}\{\gamma_{i_t}-\gamma_{i_1}\}$$

which is also 0 since $\{x\}=[1-(-1)^x]/2$. So we have shown that

$$a(G_{\lambda'})-a(Q_{\lambda'})=0,$$

i.e.,

$$b_+(G_{\lambda'})-b_-(G_{\lambda'})=b_+(Q_{\lambda'})-b_-(Q_{\lambda'}).$$

Since

$$b_+(G_{\lambda'})+b_-(G_{\lambda'})=N=b_+(Q_{\lambda'})+b_-(Q_{\lambda'}),$$

it follows that theorem 1 is true for $\lambda'\in D_\gamma$.

B. The boundary case

Assume $\lambda'\in D$ and λ' is on the boundary of some D_γ. Assume $\{q_i(\lambda')|q_i(\lambda')\in\mathbb{Z}+\frac{1}{2}\}=\{q_{k_1}(\lambda'),\ldots,q_{k_s}(\lambda'),s\geqslant 1\}$. Let $k_i\rightarrow r_{\lambda'}(k_i)$ be as in lemma 1. We can choose a small neighborhood W of λ' such that for any $\mu\in W$ and $l\neq k_i$, $i=1,\ldots,s$ [respectively, $m\neq r(k_i)$, $i=1,\ldots,s$], $\cos(\pi q_l(\mu))$ [respectively $g_m(\mu)$] has the same sign as $\cos(\pi q_l(\lambda'))$ [respectively $g_m(\lambda')$] since $\cos(\pi q_l(\lambda'))$ [respectively $g_m(\lambda')$] is not zero. Let $\mu_1\in D_\gamma\cap W$. We compare $b_+(G_{\lambda'})$ [respectively $b_+(Q_{\lambda'})$] with $b_+(G_{\mu_1})$ [respectively, $b_+(Q_{\mu_1})$]. Since $b_+(G_{\mu_1})=b_+(Q_{\mu_1})$ by Sec. II A, to prove $b_+(G_{\lambda'})=b_+(Q_{\lambda'})$ we just have to show that if $\cos(\pi q_{k_i}(\mu_1))>0$ for some k_i, $1\leqslant i\leqslant s$, then $g_{r_{\lambda'}(k_i)}(\mu_1)>0$ and vice versa. Let us consider a small line segment with end points μ_1, μ_2 which passes from D_γ to its neighbor $D_{\gamma'}$, intersects the hyperplane $q_{k_i}(\mu)=q_{k_i}(\lambda')$ at μ_0, and does not intersect any other hyperplanes. Then we have $\cos(\pi q_{k_i}(\mu_0))=0$, so by lemma 1, $g_{r_{\mu_0}(k_i)}(\mu_0)=0$. Again by lemma 1, $r_{\mu_0}(k_i)$ depends only on k_i and $q_{k_i}(\mu_0)=q_{k_i}(\lambda')$, so $r_{\mu_0}(k_i)=r_{\lambda'}(k_i)$. As μ goes from μ_1 to μ_2 on the above line segment, $\cos(\pi q_{k_i}(\mu))$, $g_{r_{\lambda'}(k_i)}(\mu)$ change their signs while the signs of all other $\cos(\pi q_i(\mu))$, $g_j(\mu)$'s do not change. By Sec. II A, $b_+(Q_{\mu_l})=b_+(Q_{\mu_l})$, $l=1, 2$, it follows that if $\cos(\pi q_{k_i}(\mu_1))>0$ for some k_i, $1\leqslant i\leqslant s$, then $g_{r_{\lambda'}(k_i)}(\mu_1)>0$ and vice versa. So we have proved that $b_+(G_{\lambda'})=b_+(Q_{\lambda'})$, and since $b_0(G_{\lambda'})=b_0(Q_{\lambda'})$ by lemma 1, and both $G_{\lambda'}$ and $Q_{\lambda'}$ have N elements, theorem 1 is proved for $\lambda'\in D$ which lies on the boundary of some D_γ. By Sec.II A and II B theorem 1 is proved.

C. Zuber's conjecture

To describe Zuber's conjecture, we have to introduce some notations from Ref. 1 to which the reader is referred for more details.

Let $\Lambda_1,\dots,\Lambda_{N-1}$ be the fundamental weights of $\mathrm{SL}(N)$. Let $k\in\mathbb{N}$. Recall that the set of integrable weights of the affine algebra $\mathrm{SL}(N)$ at level k is the following subset of the weight lattice of $\mathrm{SL}(N)$:

$$P_{++}^{(h)}=\{\lambda=\lambda_1\Lambda_1+\cdots+\lambda_{N-1}\Lambda_{N-1}|\lambda_i\in\mathbb{N},\lambda_1+\cdots+\lambda_{N-1}<h\},$$

where $h=k+N$. This set admits a $\mathbb{Z}_N$ automorphism generated by

$$\sigma:\lambda=(\lambda_1,\lambda_2,\dots,\lambda_{N-1})\rightarrow\sigma(\lambda)=\left(h-\sum_{j=1}^{N-1}\lambda_j,\lambda_1,\dots,\lambda_{N-2}\right).$$

We then introduce the weights e_i of the standard N-dimensional representation of $\mathrm{SL}(N)$

$$e_1=\Lambda_1,\quad e_i=\Lambda_i-\Lambda_{i-1},\quad i=2,\dots,N-1,\quad e_N=-\lambda_{N-1}$$

endowed with the scalar product $(e_i,e_j)=\delta_{ij}-1/N$. We shall be concerned with type II class of graphs introduced in Sec. 1 of Ref 1. These graphs generalize the classical *A, D, E* Dynkin diagrams which may be regarded as related to the SL(2) algebra. The axioms on these graphs are given in Sec. 1.2 of Ref. 1 as follows.

(1) A set ν of $|\nu|=n$ vertices is given. These vertices are denoted by Latin letters a, b,... . There exists an involution $a\rightarrow a$ and the set ν admits a $\mathbb{Z}_n$ grading denoted by $\tau(a)$ such that $\tau(\overline{a})=-\tau(a)\bmod N$.

(2) A set of $N-1$ commuting $n\times n$ matrices G_p, $p=1,2,\dots,N-1$ is given. Their matrix elements are assumed to be non-negative integers, so they may be regarded as adjacency matrices of $N-1$ graphs g_p. g_1 is also assumed to be connected.

(3) The edges of the graphs g_p are compatible with the grading τ in the sense that $(G_p)_{ab}=0$ if $\tau(b)\neq\tau(a)+p\bmod N$.

(4) The matrices are transposed of one another $G_p^t=G_{N-p}$ and $(G_p)_{ab}=(G_p)_{\overline{b}\overline{a}}$.

(5) As a consequence of axions (2) and (4), the matrices G_p are commuting normal matrices and may thus be simultaneously diagonalized in a common orthonormal basis. This basis, denoted by $\psi^{(\lambda,i)}$, is assumed to be labeled by the weights λ of $\mathrm{SL}(N)$, that are restricted to $P_{++}^{(h)}$, for some integer $h>N$, in a way that the eigenvalues $\gamma_p^{(\lambda)}$ have the form $\gamma_p^{(\lambda)}=\chi_p(M(\lambda))$, where χ_p is the ordinary character for the pth fundamental representation of the group $\mathrm{SU}(N)$, and $M(\lambda)$ denotes the diagonal matrix $M(\lambda)=\mathrm{diag}(\epsilon_j(\lambda))_{j=1,\dots,N}$. Here $\epsilon_j(\lambda):=\exp(-(2\pi i/h)(e_j,\lambda)$, and i in (λ,i) is an index integer, $1\leqslant i\leqslant m_\lambda$ with m_λ being the multiplicity of eigenvalue $\gamma_p^{(\lambda)}$. The set of (λ,i)'s will be denoted by Exp.

There exists a special class of solutions known for all N and $h>N$, namely the fusion graphs of the affine algebra $\mathrm{SL}(N)$ at level $k=h-N$. The vertices are the integrable weights described above, i.e., $\nu=P_{++}^{(h)}$. The matrices G_p are the Verlinde matrices, which describe the fusion by the pth fundamental representation. The fusion rules are given on p. 288 of Ref. 7. Their diagonalization is known, thanks to the Verlinde formula (cf. p. 288 of Ref. 7), and the eigenvalues are the $\gamma_p^{(\lambda)}$, where λ takes all the values in$=P_{++}^{(h)}$. We will call these graphs *regular graphs* in this paper. In the case of $N=2$, these regular graphs reduce to the A_{h-1} Dynkin diagrams.

More solutions are known (cf. Ref. 1). In Ref. 6 (in particular Theorem 3.10 and (5) of Theorem 3.8), infinite series of such graphs are constructed from the maximal conformal inclusions of the form $\mathrm{SU}(N)\subset G$ with G being a simple and simply connected compact Lie group.

Given graphs of the previous type, let V be a complex vector space with a basis α_a labeled by the vertices of the set ν. A bilinear form g is defined by:

$$g_{ab}=\langle\alpha_a,\alpha_b\rangle=2\delta_{ab}+G_{ab}$$

in terms of the matrix $G_{ab}=\Sigma_{p=1}^{N-1}(G_p)_{ab}$. g will be called the intersection form. This is the intersection form in the title of this paper.

The eigenvalue of the matrix (g_{ab}) with eigenvector $\psi_p^{(\lambda,i)}$ is (cf. (34) of Ref. 1):

$$g^{(\lambda)}=\prod_{i=1}^{N}\left(1+\exp\left(-\frac{2\pi i}{h}(e_i,\lambda)\right)\right).$$

For $(\lambda,i)\in\mathrm{Exp}$ define real numbers which depend only on λ (cf. (46) of Ref. 1) by:

$$q_\lambda^{(R)}:=\frac{1}{h}\sum_{j=1}^{N-1} j(\lambda_j-1)+\frac{(N-h)(N-1)}{2h}.$$

We can now state Zuber's conjecture on the signature of g (cf. Conjecture 2.5 of Ref. 1):

Zuber's Conjecture. The signature of the bilinear form g for class II graphs is $(x+,y-,z0)$ *where x is the number of* $q_\lambda^{(R)}$ *which fall in an interval* $]2p-\frac{1}{2},2p+\frac{1}{2}[$ *for some* $p\in\mathbb{Z}$ *(p may depend on* $q_\lambda^{(R)}$*,) y is the number of those in an interval* $]2p'+\frac{1}{2},2p'+\frac{3}{2}[$ *for some* $p'\in\mathbb{Z}$ *(p′* may depend on $q_\lambda^{(R)}$*, and* $t=n-r-s$ *is the number of those* $q_\lambda^{(R)}$ *which are half-integers.*

We now prove this conjecture.

Let us first notice a simple consequence of the axioms on the graphs. It follows from Proposition 1.2 of Ref. 1 that Exp is invariant under the action of σ. In fact, if $\Sigma_a\psi_a^{(\lambda,i)}a$ is an eigenvector of G_p with eigenvalue $\gamma_p^{(\lambda)}$, then Proposition 1.2 of Ref. 1 implies that $\Sigma_a\psi_a^{(\lambda,i)}\exp(2\pi i\tau(a)/N)a$ is an eigenvector of G_p with eigenvalue $\gamma_p^{(\sigma(\lambda))}$. Since $a\to\exp(2\pi i\tau(a)/N)a$ is an invertible map, it follows that the multiplicity of eigenvalue $\gamma_p^{(\sigma(\lambda))}$ is the same as that of eigenvalue $\gamma_p^{(\lambda)}$. We can therefore define $\sigma(\lambda,i)=(\sigma(\lambda),i)$. It follows that Exp can be written as a disjoint union of the orbits under the action of σ. To prove Zuber's conjecture, we just have to show it is true on each orbit.

Let $(\lambda,i)\in\mathrm{Exp}$ and let d be the smallest positive integer such that $\sigma^d(\lambda)=\lambda$. Then d/N and let $N=dd_1$. Let $G'_\lambda:=\{g^{(\sigma^i(\mu))},i=1,2,...,d\}$, $Q'_\lambda:=\{\cos(\pi q^{(R)}_{\sigma^i(\mu)}),i=1,2,...,d\}$, we need to show

$$b_+(G'_\lambda)=b_+(Q'_\lambda),b_0(G'_\lambda)=b_0(Q'_\lambda),b_-(G'_\lambda)=b_-(Q'_\lambda).$$

Note that $b_0(G'_\lambda)=b_0(Q'_\lambda)$ was already noticed on p. 17 of Ref. 1. Let $\lambda'=(\lambda_1/h,\ldots,\lambda_{N-1}/h)$, then $p_i(\lambda')=(e_i,\lambda)/h$, $i=1,2,...,N$. To use theorem 1, we make use of the following identities which follow from the definitions:

$$q^{(R)}_{\sigma^{-j}(\lambda)}=q_j(\lambda')$$

and

$$\begin{aligned}g^{(\sigma^j(\lambda))}&=\prod_{l=1}^{N}\left(1+\exp\left(+\frac{2\pi ij}{N}\epsilon_l(\lambda)\right)\right)\\&=\prod_{l=1}^{N}2\cos\left(\pi\left(p_l(\lambda')-\frac{j}{N}\right)\right)\times\exp\left(\pi ij-\sum_{l=1}^{N}\frac{1}{h}(\lambda,e_l)\right)\\&=(-1)^j\prod_{l=1}^{N}2\cos\left(\pi\left(p_l(\lambda')-\frac{j}{N}\right)\right)\\&=g_j(\lambda').\end{aligned}$$

Now it is clear that the size of $G_{\lambda'}$ (respectively, $Q_{\lambda'}$) is d_1 times the size of G'_λ (respectively, Q'_λ) and we have:

$$b_+(G_{\lambda'}) = d_1 b_+(G'_\lambda), \quad b_0(G_{\lambda'}) = d_1 b_0(G'_\lambda), \quad b_-(G_{\lambda'}) = d_1 b_-(G'_\lambda)$$

and

$$b_+(Q_{\lambda'}) = d_1 b_+(Q'_\lambda), \quad b_0(Q_{\lambda'}) = d_1 b_0(Q'_\lambda), \quad b_-(Q_{\lambda'}) = d_1 b_-(Q'_\lambda).$$

By theorem 1, we have proved:

$$b_+(G'_\lambda) = b_+(Q'_\lambda), \quad b_0(G'_\lambda) = b_0(Q'_\lambda), \quad b_-(G'_\lambda) = b_-(Q'_\lambda).$$

Let us summarize the result in the following:

Corollary 1: Zuber's Conjecture as stated above is true.

III. CONCLUSIONS AND QUESTIONS

In this paper we proved Zuber's conjecture on the signature of certain intersection forms by using theorem 1.

Our results imply that the infinite series of graphs which are constructed in Ref. 6 by using subfactors associated with conformal inclusions satisfy Zuber's conjecture. This lends further support to the idea that these graphs may be associated with the integrable models in Ref. 2 which is the basis of Zuber's conjecture. Such a relation is not very clear and should be very interesting.

Given a sequence of numbers $\{a_n\}$, it is always possible to find a set of Feynman rules that reproduce that sequence. For the special case of the partitions of the integers, the appropriate Feynman rules give rise to graphs that represent the partitions in a clear pictorial fashion. These Feynman rules can be used to generate the Bell numbers $B(n)$ and the Stirling numbers $S(n,k)$ that are associated with the partitions of the integers. © *1999 American Institute of Physics.*
[S0022-2488(99)03207-7]

I. INTRODUCTION

The *partition* of an integer n is the set of all distinct ways to represent n as a sum of positive integers smaller than or equal to n. The number of elements in the partition of n is designated $p(n)$. For example, since 5 can be represented as 1+1+1+1+1, 1+1+1+2, 1+1+3, 1+2+2, 1+4, 2+3, or simply 5, we have $p(5)=7$. Defining $p(0)=1$, we obtain a well-known formula for the generating function of the numbers $p(n)$.[1]

$$\sum_{n=0}^{\infty} p(n)x^n=\prod_{k=1}^{\infty} \frac{1}{1-x^k}. \tag{1}$$

There is a simple graphical way to represent the partitions because there is a one-to-one correspondence between the nth partition and the set of transitive nondirected n-vertex graphs. A graph is said to be *transitive* if for every path connecting two vertices there is an edge joining the two vertices. In Fig. 1 we display several transitive graphs and several nontransitive graphs.

In Fig. 2 we display the transitive graphs having from one through five vertices; note that the number of such n-vertex graphs equals the number of partitions $p(n)$: $p(1)=1$, $p(2)=2$, $p(3)=3$, $p(4)=5$, $p(5)=7$.

In the study of quantum field theory graphs are used to represent terms in a diagrammatic perturbation expansion. Here, one associates with each graph a numerical amplitude. This amplitude is the product of the symmetry number, the vertex numbers, and a Feynman integral for the graph.[2] In this paper we will work in zero-dimensional space only so that Feynman integrals become trivial and are merely the product of the line amplitudes.

To illustrate the procedure of assigning amplitudes to graphs, let us consider the graphs in Fig. 2. We associate symmetry numbers with each of the graphs shown in Fig. 2, take the vertex amplitudes and line amplitudes to be unity, and then sum over all graphs having n vertices. We obtain the result $B(n)/n!$, where $B(n)$ is the nth Bell number.[3] The *Bell numbers* $B(0)$, $B(1)$, $B(2)$, $B(3)$,... are a sequence of positive integers that begins 1, 1, 2, 5, 15, 52, 203, 877,... . The Bell number $B(n)$ is the number of *labeled* partitions of the positive integer n, which can be seen by labeling all the vertices in Fig. 2 and counting the number of transitive nondirected graphs. There is a simple generating function $G(x)$ for the Bell numbers:

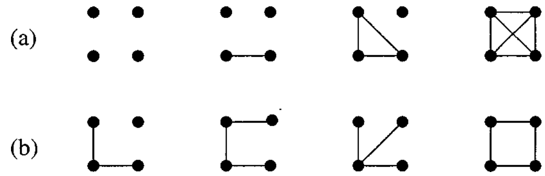

FIG. 1. Examples of (a) four transitive graphs and (b) four nontransitive graphs, each having four vertices.

$$G(x)=\exp(e^{x}-1)=\sum_{n=0}^{\infty}\frac{B(n)}{n!}x^{n}. \tag{2}$$

From this representation one can derive a representation for $B(n)$ in terms of a sum:

$$B(n)=\frac{1}{e}\sum_{k=0}^{\infty}\frac{k^{n}}{k!}. \tag{3}$$

In quantum field theory there is a simple and general formal construction for the set of all graphs in terms of the exponential of a derivative operator.[4] For example,

$$\exp\left(\frac{a}{2!}\frac{d^{2}}{dx^{2}}\right)\exp\left(\frac{g}{4!}x^{4}\right)\Bigg|_{x=0} \tag{4}$$

is the generating function for the set of all four-vertex vacuum diagrams, connected and disconnected, in which the line amplitude is a and the vertex amplitude is g. If we expand this expression as a series in powers of g, the coefficient of g^{n} is the sum over all four-vertex vacuum graphs containing n vertices with each graph weighted by its symmetry number.

We can generalize Eq. (4) to include n-point vertices and we can even extend these ideas to include generalized lines having m legs.[5] The formula

$$\exp\left(a\sum_{m=1}^{\infty}\frac{L_{m}}{m!}\frac{d^{m}}{dx^{m}}\right)\exp\left(g\sum_{n=1}^{\infty}\frac{V_{n}}{n!}x^{n}\right)\Bigg|_{x=0} \tag{5}$$

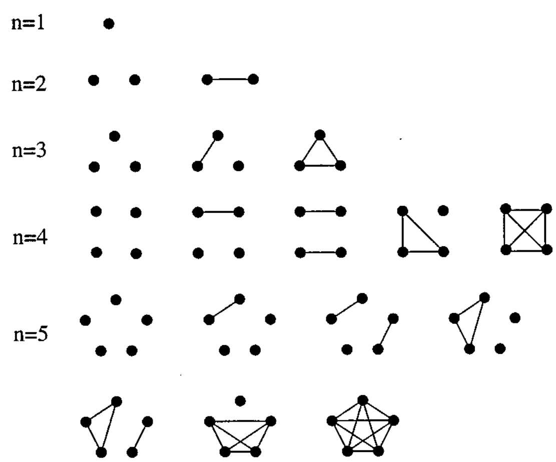

FIG. 2. Transitive nondirected graphs having from $n=1$ to $n=5$ vertices. Note that for each value of n, the number of such graphs is $p(n)$, the number of elements in the partition of the integer n.

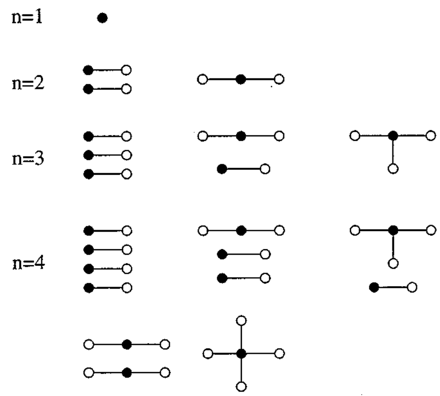

FIG. 3. The graphs in a field theory whose n-point vertex amplitudes are all unity and whose line amplitudes all vanish except for lines having just one end. If the amplitude of such lines is z, then the coefficient of z^n gives all n-line graphs contributing to the partition of the integer n. These graphs correspond exactly to the partition graphs shown in Fig. 2. This correspondence is seen by exchanging lines and vertices.

represents the set of all vacuum diagrams, connected and disconnected, constructed from n-point vertices whose amplitudes are V_n and generalized lines having m legs whose amplitudes are L_m. If we expand this expression as a formal power series in powers of a, then the coefficient of a^n is the sum of the symmetry numbers of all graphs having n lines, and if we expand this expression as a series in powers of g, then the coefficient of g^n is the sum of the symmetry numbers of all graphs having n vertices. If we first take the natural logarithm of the expression in (5) and then expand in formal power series in a or g, then the coefficients represent the sum of the symmetry numbers of just the *connected* graphs.[4] Note that, in general, these formal power series are divergent series because the number of graphs grows like a factorial.

II. PARTITIONS

Given the general graph construction procedure in Eq. (5) one may ask whether it is possible to find a quantum field theoretic set of Feynman rules for which the graphs in its perturbation expansion are the partition graphs in Fig. 2. Let us consider a field theory for which the n-vertex amplitudes and the coupling constant g are all unity. Note that this gives the potential

$$e^x - 1 = \sum_{n=1}^{\infty} \frac{V_n}{n!} x^n, \tag{6}$$

which implies that $V_n = 1$ for all n. Next, let us impose the requirement that there be only one kind of line, a line having just *one* end. We do so by taking $L_m = 0 (m > 1)$. Choosing $aL_1 = z$, we construct from Eq. (5) the n-line vacuum graphs in this theory; these graphs are shown, for the number of lines ranging from one through five, in Fig. 3. Observe that the graphs in Fig. 3 correspond, graph by graph, to the partition graphs in Fig. 2. From Eq. (5) we see that the generating function for these graphs is

$$G(z) = \exp\left(z \frac{d}{dx} \right) \exp(e^x - 1) \bigg|_{x=0}. \tag{7}$$

However, $\exp(zd/dx)$ is just the translation operator. Thus, (7) reduces immediately to

$$G(z) = \exp(e^z - 1). \tag{8}$$

This argument reproduces the generating function $G(x)$ in (2) for the Bell numbers $B(n)$.

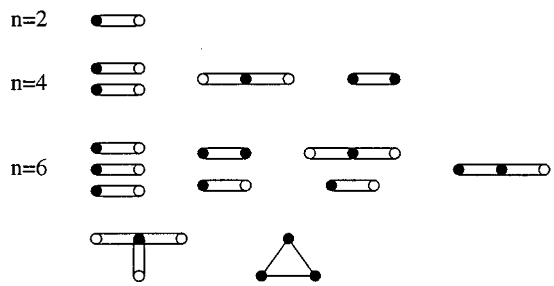

FIG. 4. The graphs in a theory whose Feynman rules allow for any number of even vertices but lines having only two ends. Summing the amplitudes of these graphs gives the generating function in (9).

An alternative way to derive Eq. (8) is to argue that in the field theory described by (7) there is only one connected graph having n lines. This graph consists of the n-point vertex to which n one-ended lines are attached. The symmetry number of this graph is just $1/n!$. Thus, the generating function $C(z)$ of the connected graphs is just $C(z)=\Sigma_{n=1}^{\infty}z^n/n!=e^z-1$. However, the generating function $G(z)$ for the set of all connected and disconnected graphs is just the exponential of the generating function $C(z)$ for the connected graphs. Thus, we have reproduced the result in (8).

Apparently, one can always translate the general problem of finding the nth term in a sequence of numbers to the problem of constructing a set of Feynman rules that produces this sequence. For example, let us ask whether there is a field theory (a set of Feynman rules) that reproduces directly the amplitudes in $C(z)$. This means that we want to find a quantum field theory whose graphs correspond to the connected graphs in Fig. 2. Let us return to Eq. (5) and consider a field theory whose lines have two ends ($L_m=0$ for $m\neq 2$) and which may have all even vertices but no odd vertices. Choosing $L_2=2$ and $g=1$ we find that the expansion of Eq. (5) as a series in powers of a has the form

$$1+aV_2+\tfrac{1}{2}a^2(V_4+3V_2^2)+\tfrac{1}{6}a^3(15V_2^2+15V_2V_4+V_6)$$
$$+\tfrac{1}{24}a^4(105V_2^4+210V_2^2V_4+35V_4^2+28V_2V_6+V_8)+\cdots. \tag{9}$$

The graphs that give rise to this sequence of coefficients are shown in Fig. 4.

If we demand that the coefficient of a^n agree with the coefficient of z^n in $C(z)$, then we obtain a sequence of algebraic equations for the vertex amplitudes V_2: $V_2=1$. $V_4+3V_2^2=1$, $15V_2^3+15V_2V_4+V_6=1$, and so on. The solution to this system of equations is $V_2=1$, $V_4=-2$, $V_6=16$, $V_8=-272$, and so on. These are the tangent numbers t_n:

$$\tanh x=\sum_{n=1}^{\infty}\frac{t_n}{(2n-1)!}x^{2n-1}. \tag{10}$$

To understand why the tangent numbers have appeared, note that upon integrating (10) with respect to x we get

$$\ln(\cosh x)=\sum_{n=1}^{\infty}\frac{t_n}{(2n)!}x^{2n}. \tag{11}$$

Thus, from Eq. (5) we have

$$\exp\left(a\frac{d^2}{dx^2}\right)\exp[\ln(\cosh x)]\bigg|_{x=0}=\sum_{n=0}^{\infty}\frac{a^n}{n!}\frac{d^{2n}}{dx^{2n}}\cosh x\bigg|_{x=0}=\sum_{n=0}^{\infty}\frac{a^n}{n!}=e^a, \tag{12}$$

which is precisely the generating function that we tried to reproduce.

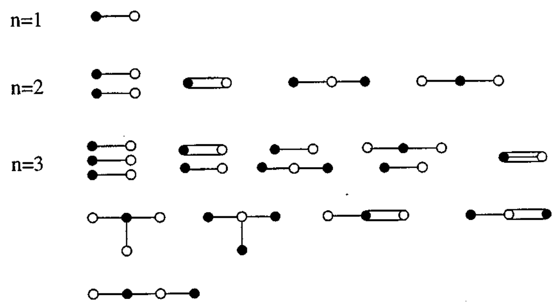

FIG. 5. The graphs in a theory whose Feynman rules allow for n-point vertices ($n=1,2,3,...$) and m-legged lines ($m=1,2,3,...$). If the vertex amplitudes are all unity and the m-legged line amplitude is z^m, then the generating function $G(z)$ for the graphs, as given in (17), has a Taylor expansion for which the coefficient of z^n is $[B(n)]^2/n!$. That is, the number of labeled graphs of order n is the square of the nth Bell number.

III. BELL NUMBERS

We can also examine alternative theories to the theory described in (7). Suppose, for example, we construct a field theory with the same vertices but with a two-ended line instead of a one-ended line,

$$G(z)=\exp\left(\frac{z}{2!}\frac{d^2}{dx^2}\right)\exp(e^x-1)\bigg|_{x=0}, \tag{13}$$

or even a generalized line having M ends,

$$G(z)=\exp\left(\frac{z}{M!}\frac{d^M}{dx^M}\right)\exp(e^x-1)\bigg|_{x=0}. \tag{14}$$

It is easy to show that the coefficient of z^n in the power series expansion of (14) is proportional to the nMth Bell number:

$$G(z)=\sum_{n=0}^{\infty}\frac{1}{n!}z^n(M!)^{-n}B(nM). \tag{15}$$

This line of thinking suggests that one can even construct a field theory whose lines have any number of ends:

$$G(z)=\exp(e^{zd/dx}-1)\exp(e^x-1)|_{x=0} \tag{16}$$

In this case we obtain the beautiful result that the coefficient of z^n is the *square* of the nth Bell number:

$$G(z)=\sum_{n=0}^{\infty}\frac{1}{n!}z^n[B(n)]^2. \tag{17}$$

The graphs contributing to the generating function in (17) are shown in Fig. 5. The numbers of these graphs are 1, 1, 4, 10, 33,..., which apparently is an unknown sequence. However, if we label the vertices for these graphs, then the number of corresponding graphs are given by the squares of the Bell numbers.

IV. STIRLING NUMBERS

The labeled partitions of the integers n can be grouped into classes described by the Stirling numbers $S(n,k)$.[6] Let the n be the number of objects and k be the number of groups. For example, consider the case $n=3$. Given three numbers, x, y, and z, we can group these objects *one* way as a sum of one group of three numbers $(x+y+z)$, *three* ways as a sum of two groups of numbers, $(x+y)+(z)$, $(x+z)+(y)$, and $(y+z)+(x)$, and *one* way as a sum of three numbers $(x)+(y)+(z)$. Thus, we say that $S(3,1)=1$, $S(3,2)=3$, and $S(3,3)=1$. The Stirling numbers are all integers: $S(1,1)=1$, $S(2,1)=S(2,2)=1$, $S(4,1)=1$, $S(4,2)=7$, $S(4,3)=6$, $S(4,4)=1$, $S(5,1)=1$, $S(5,2)=15$, $S(5,3)=25$, $S(5,4)=10$, $S(5,5)=1$, and so on. There is an elementary representation for $S(n,k)$ as a sum:

$$S(n,k) \equiv \sum_{j=1}^{k} \frac{(-1)^{k-j} j^n}{j!(k-j)!}. \tag{18}$$

Recall that the Bell number $B(n)$ represents the total number of labeled partitions of the positive integer n. Hence, summing with respect to k over the Stirling numbers $S(n,k)$ gives $B(n)$:

$$B(n) = \sum_{k=1}^{n} S(n,k). \tag{19}$$

The Stirling numbers emerge nicely in terms of Feynman rules. Let us generalize Eq. (7) slightly so that each vertex has amplitude v instead of 1:

$$G(z,v) = \exp\left(z \frac{d}{dx}\right) \exp[v(e^x - 1)]\bigg|_{x=0}. \tag{20}$$

If we now expand the generating $G(z,v)$ as a series in powers of z and v, then the coefficient of $z^n/n!$ and v^k is precisely the Stirling number $S(n,k)$:

$$G(z,v) = \sum_{n=0}^{\infty} \frac{z^n}{n!} \left(\sum_{k=1}^{n} S(n,k) v^k \right). \tag{21}$$

If we set $v=1$ in this equation and compare with Eq. (2), then we recover Eq. (19).

V. CONCLUSION

In this paper we have illustrated how one can impose purely combinatorial or topological constraints upon the dynamics of a quantum field theory. In particular, we have demonstrated examples of field theories that give rise to the various partitions of integers. If we introduce further structures in the underlying dynamics, such as Fermions (which give rise to directed graphs), then the method we have sketched here would shed insights to some very difficult problems in combinatorics, such as determining the number of partially ordered sets (posets). We hope to study these applications elsewhere.

(Received 5 January 1999; accepted for publication 5 April 1999)

Standard purification interlaces Hermitian and Riemannian metrics on the space of density operators with metrics and connections on the purifying Hilbert–Schmidt space. We discuss connections and metrics which are well adopted to purification, and present a selected set of relations between them. A connection, as well as a metric on state space, can be obtained from a metric on the purification space. We include a condition, with which this correspondence becomes one to one. Our methods are borrowed from elementary *-representation and fiber space theory. We lift, as an example, solutions of a von Neumann equation, write down holonomy invariants for cyclic ones, and ''add noise'' to a curve of pure states. © *1999 American Institute of Physics.* [S0022-2488(99)02107-6]

I. INTRODUCTION

In Ref. 1, see also Ref. 2, the monotone Hermitian and Riemannian metrics in the (finite dimensional) spaces of all density operators are classified. Based on the theory of operator means[3] they are indexed by a real function, f, operator monotone[4] on $(0,\infty)$. These metrics play an important role in domains like quantum information geometry, quantum versions of statistical estimation, and decision rules.[5–7]

D. Petz communicated his main results to us prior to publication, and about that time we started to ask for the effect of a purifying lift to these metrics. There are clear reasons for this. One of the present authors (A.U.) had defined 1986 in Ref. 8 an extension of the geometric phase,[9,10] see also Refs. 11 and 12, to curves of density operators by the help of a ''parallelity condition.'' The condition singles out, up to a global gauge (or a global partial isometry), a distinguished ''parallel lift'' within all purifying lifts of a curve of density operators. It turns out[13] that a connection form (a gauge potential), here called $\mathbf{a}^{\mathrm{geo}}$, is governing the transport of the purifying vectors, such that the parallelity condition results from the request for horizontality. In 1992 G. Rudolph and one of the authors (J.D.) considered a large class of gauge potentials, including $\mathbf{a}^{\mathrm{geo}}$, which rests on a purification scheme and which enables variants of the geometric phase along curves of density operators. It seems natural to ask for a link between these objects: (a) the connection forms just mentioned, (b) certain Hermitian (Riemannian) metrics on the purification space, and, if respecting the symmetry of the scheme, (c) metrics induced from (b) on the space of density operators.

Purification is essentially representation theory of observables and of the algebra in which they are contained. Principally one may use any unital *-representation of the ''algebra of observables'' over which the states can be defined. Its Hilbert representation space should only be large enough to allow for a representation of the states by vectors. If this condition is fulfilled, transport mechanism, its noncommutative phases, metrics, and other geometric objects can be constructed by relying on their form and appearance in the pure state case.

[a)]Electronic mail: dittmann@mathematik.uni-leipzig.de

In our paper we remain within an elementary setting: Our density operators live on a Hilbert space $\mathcal{H}$ of finite dimension n. In our convention, a density operator should not necessarily be normalized. We speak of ''density operators'' whether their trace is one or not. The algebra of observables is the algebra $\mathcal{B}(\mathcal{H})$ of all operators acting on $\mathcal{H}$. The representation or purification space, $\mathcal{W}$, is identified with the algebra of operators and equipped with the Hilbert–Schmidt scalar product. (In infinite dimensions $\mathcal{W}$ will be the space of Hilbert–Schmidt operators.) We try to emphasize the different meaning of operators by different notations: Operators acting on $\mathcal{H}$ are denoted by lower case letters, those acting on $\mathcal{W}$ often by capital letters. [Some authors call the operators of $\mathcal{B}(\mathcal{W})$ ''superoperators.''] Section II is devoted to explaining our notation in more details. In our paper purification takes place in the standard representation of $\mathcal{B}(\mathcal{H})$, i.e., in the GNS-representation based on the trace. For that reason we called it *standard purification*. In Sec. III the formalism is extended to velocity vectors, i.e., to tangents, at density operators and at their purifications. Purification defines vertical tangents in a canonical way. A tangent, orthogonal to the space of vertical tangents, is called horizontal, provided the tangent spaces carry a real Hilbert space structure, i.e., a Riemannian metric. Equivalently, within all purifying lifts of a given curve of density operators, those with the least length are horizontal.

Section IV exemplifies our task in defining horizontality by the real part of the Hilbert–Schmidt metric. As one knows, the Bures length of a curve of density operators and the Hilbert–Schmidt length of an horizontal lift are equal one to another. In deriving the parallelity condition we meet some peculiarities with tangents of purifying vectors if they belong to density operators with some vanishing eigenvalues. The reader will find a short account of the relation between the connection form $\mathbf{a}^{\text{geo}}$ (Ref. 13) governing the geometric phase, and the Riemannian Bures metric.

Indeed, we devote some time to asking, and giving an affirmative answer to the following question: Is the topological metric of Bures Riemannian?[14–16] Essential differential geometric properties are in Ref. 17, see also Ref. 18 for $\dim \mathcal{H}=3$. Relations to quantum information theory can be seen in Refs. 19 and 20. However, a parameterization in terms of the operators' matrix elements remains cumbersome, except for $\dim \mathcal{H}=2$.

Concerning $\mathbf{a}^{\text{geo}}$, which extends the geometric phase to (closed) curves of density operators, examples are shown in Sec. VIII. There is a further issue to be mentioned: The gauge potential for the two-dimensional density operators[21] living on a four-dimensional purification space, satisfies the Yang–Mills equations. With a certain cosmological constant, it even is a solution of the combined Yang–Mills–Einstein equations.[22] Meanwhile we know[23] $\mathbf{a}^{\text{geo}}$ satisfies the Yang–Mills equations for every finite dimension of the supporting Hilbert space $\mathcal{H}$. These findings may be seen as extensions to mixed states of numerous examples relating the original Berry phase to Dirac monopoles, and the Wilczek and Zee phase[24] to instantons.

Section VI is devoted to the class of connections introduced in Ref. 25, which are, so to say, ''relatives'' of $\mathbf{a}^{\text{geo}}$, compatible with the purification scheme. They are characterized by a function F, defined on $(0,\infty)$, and fulfilling $\overline{F}(1/t)=-F(t)$. Some equations become more appealing by using the function r, the arithmetic mean of $\overline{F}$ and 1. The connection forms $\mathbf{a}$ assign to every tangent x at the lift $w\in\mathcal{W}$ of $\varrho=ww^*$ a value in the Lie algebra of $U(n)$. The action of the gauge group induces the ''canonical'' connection $\mathbf{a}^{\text{can}}$. The canonical connection is gained with the choice $F=0$. The connection $\mathbf{a}^{\text{geo}}$ is constructed with $F(t)=(t-1)/(t+1)$. As we shall see, only connections with real F can be obtained from an appropriate Hermitian metric. We believe the complete class is a more natural object at the complexified tangents. They all decompose as $\theta-\theta^*$ with θ of type (1,0).

We specify the class of Hermitian metrics by another positive and real valued function, k, on the positive half-axis. The metrical form for the tangents at a purifying vector, w, will be given by the inverse of the (''super'')operator $k(\Delta_w)$, where Δ is the field of modular operators. There is an antilinear operator, a modification of Tomita–Takasaki's S_w operator, which admits just the horizontal tangents as fix points. The connection adjusted to the metric is characterized by various relations between the functions k, F, and r. Moreover, every one of the Hermitian metrics considered on the tangent space of $\mathcal{W}$ is a lift of exactly one Hermitian form on the space of density operators. The latter depends on a function f which is related to k. The Riemannian metric on the density operators is gained as the real part of the Hermitian one, and it corresponds to the harmonic mean of $f(t)$ and $tf(1/t)$. Further we discuss an additional condition, which enables us to assign a unique connection form to a given monotone Riemannian state space metric. These metrics are induced from the Hilbert–Schmidt metric by some constraints on the purifying vectors replacing the orthogonality condition of the Bures case.

The starting point has been a set of connections, compatible with the purification procedure, to define reasonable parallel transports along curves of density operators. We return to this issue in purifying horizontally solutions of von Neumann equations. Cyclic solutions give rise to some holonomy invariants. There are constraints on F for extending the parallelity conditions to the boundary, in particular to pure states. If they are fulfilled, the holonomy invariants reduce to the well-known geometric phase of Berry for pure states. At the end we ask what happened if ''noise'' is added to a closed path of pure states.

II. STANDARD PURIFICATION

We start by reviewing some basic ideas of the purification procedure. Let $\mathcal{H}$ be a complex Hilbert space of finite dimension n with scalar product $\langle .,. \rangle$ antilinear in its left argument. $\mathcal{B}(\mathcal{H})$ denotes the $*$-algebra of linear operators acting on $\mathcal{H}$. A *state* is a positive linear form over the algebra which takes the value 1 at the identity of $\mathcal{B}(\mathcal{H})$. Generally, a linear form l over our algebra is uniquely represented by

$$l(b) = \mathrm{Tr}\, b\omega, \quad \forall b \in \mathcal{B}(\mathcal{H}).$$

The linear form is positive if and only if ω is a positive element of $\mathcal{B}(\mathcal{H})$. We then call ω a *density operator* in accordance with its usage in physics. A density operator represents a state iff its trace is one.

A *purification* of a positive linear form over $\mathcal{B}(\mathcal{H})$ is a lift to a pure linear form of a larger algebra. A way to do so is as follows: With another auxiliary Hilbert space $\mathcal{H}^{\mathrm{aux}}$, with at least the same dimension, we consider

$$\mathcal{H} \otimes \mathcal{H}^{\mathrm{aux}}, \quad n = \dim \mathcal{H} \leqslant \mathcal{H}^{\mathrm{aux}}$$

and the inclusion (which, indeed, is a $*$-representation)

$$\mathcal{B}(\mathcal{H}) \hookrightarrow \mathcal{B}(\mathcal{H}) \otimes 1^{\mathrm{aux}} \subset \mathcal{B}(\mathcal{H} \otimes \mathcal{H}^{\mathrm{aux}}) \tag{1}$$

into the operator algebra of the extended Hilbert space. Let ϱ be the density operator of a positive linear form l over $\mathcal{B}(\mathcal{H})$. A vector ψ of $\mathcal{H} \otimes \mathcal{H}^{\mathrm{aux}}$ is said to *purify* l, and hence ϱ, iff

$$l(b) \equiv \mathrm{Tr}\, b\varrho = \langle \psi, b \otimes 1^{\mathrm{aux}} \psi \rangle \quad \forall b \in \mathcal{B}(\mathcal{H}). \tag{2}$$

A distinguished way to choose the auxiliary Hilbert space is to require

$$\mathcal{H}^{\mathrm{aux}} = \mathcal{H}^*, \quad \mathcal{W} := \mathcal{H} \otimes \mathcal{H}^*, \tag{3}$$

which results in the *standard purification,* based on the standard representation of $\mathcal{B}(\mathcal{H})$. In what follows this choice is assumed, and we have to fix some notations and conventions at the beginning.

Let $\phi \in \mathcal{H}$. The element $\phi^* \in \mathcal{H}^*$, is defined by $\phi^*(\phi') = \langle \phi, \phi' \rangle$. In Dirac's notation:

$$\phi \leftrightarrow |\phi\rangle, \quad \phi^* \leftrightarrow \langle \phi |.$$

Being in finite dimensions, every operator is Hilbert–Schmidt, and $\mathcal{W}$ is canonically isomorphic to $\mathcal{B}(\mathcal{H})$. This can be made explicit with two arbitrarily chosen orthonormal bases $\phi_1, \phi_2, \ldots$ and $\phi'_1, \phi'_2, \ldots$ of $\mathcal{H}$ in writing

$$w=\sum |\phi_j\rangle\langle\phi_j, w\phi_k'\rangle\langle\phi_k'|, \quad w\in\mathcal{W}. \tag{4}$$

The Hilbert–Schmidt scalar product on $\mathcal{W}$ is

$$(w_2, w_1) := \operatorname{Tr} w_2^* w_1 = \sum \langle w_2\phi_k', \phi_j\rangle\langle\phi_j, w_1\phi_k'\rangle. \tag{5}$$

The star operation in $\mathcal{B}(\mathcal{H})$ is equivalent with a conjugation in $\mathcal{W}$,

$$w \mapsto w^* \quad \text{or} \quad (\phi\otimes\tilde{\phi}^*)^* = \tilde{\phi}\otimes\phi^*.$$

We need some operators acting on $\mathcal{W}$. The standard representation of $\mathcal{B}(\mathcal{H})$ is the inclusion (1), specified by (3), and acting as follows:

$$b\mapsto L_b, \quad L_b w := bw, \quad b\in\mathcal{B}(\mathcal{H}).$$

We also need the right multiplication R_b, i.e., $R_b w = wb$. The right multiplication can be used to implement the standard representation of $\mathcal{B}(\mathcal{H}^*)$. Notice the different meaning of the *-operations on $\mathcal{W}=\mathcal{B}(\mathcal{H})$ and on $\mathcal{B}(\mathcal{W})$ seen in

$$(L_b)^* = L_{b^*}, \quad (L_b w)^* = (R_b)^* w^*$$

and in similar relations after exchanging L_b and R_b. Now, let $\hat{l}$ be a linear form on $\mathcal{B}(\mathcal{W})$ and l its *restriction* or reduction onto $\mathcal{B}(\mathcal{H})$. The relation

$$\hat{l}\mapsto l, \quad l(b) := \hat{l}(L_b), \quad b\in\mathcal{B}(\mathcal{H}) \tag{6}$$

encodes the partial trace over $\mathcal{H}^*$ on $\mathcal{W}$. Focusing our attention on the purification procedure, we shall apply this well-known mapping mainly to linear functionals of rank one. In that case the essence of the reduction mapping to the factors of $\mathcal{W}$ is contained in

$$(w_2, L_b R_c w_1) = \operatorname{Tr} w_2^* b w_1 c. \tag{7}$$

Its left-hand-side defines a linear form $B\mapsto(w_2, Bw_1)$ over $\mathcal{B}(\mathcal{W})$, and, varying w_1 and w_2 within $\mathcal{W}$, one can get every linear functional of rank one. Presently we need to consider (7) with $w_1 = w_2 = w$ and with either c or b the identity operator. Then, for $B\in\mathcal{B}(\mathcal{W})$ and $b,c\in\mathcal{B}(\mathcal{H})$, the left- and the right-hand sides of (7) may be rewritten

$$\hat{l}(B) = (w, Bw), \quad l(b) = \operatorname{Tr} ww^* b, \quad l'(c) = \operatorname{Tr} w^* w c.$$

$\varrho = \varrho_l := ww^*$ is called the *density* or the *density operator* of l, while w is said to *purify* l. In the same spirit, a positive linear functional $\hat{l}$ of rank one, which reduces to l, is a *purification* of l.

From now on, instead of switching forth and back between linear forms and their densities, we remain mainly with the latter. Accordingly we define the mappings

$$\Pi w = ww^*, \quad \Pi' w = w^* w.$$

The mapping Π (and similarly the mapping Π'), is slightly more subtle than the reduction mapping (6). Its domain of definition is $\mathcal{W}$. Thus Π is composed of a Hopf bifurcation from w to the rank one density operator $|w)(w|$, representing the linear form $B\to(w,Bw)$, followed by the reduction (6):

$$w\mapsto|w)(w|\mapsto ww^*.$$

Here we used Dirac's notation relative to the scalar product (5) in $\mathcal{W}$. Π is a bundle projection, where the bundle space is $\mathcal{W}$ and the base space is the cone of (not necessarily normalized) density operators (i.e., positive trace class operators). Being in finite dimension, the base space is the positive cone of $\mathcal{B}(\mathcal{H})$. The bundle fibers are manifolds. However, the dimension of the fibers vary with the rank n_w of $w \in \mathcal{W}$. Therefore certain discontinuities occur if the rank is changing.

All this can be seen by the ''diagonal'' form of (4), which is the Gram–Schmidt decomposition of w. Let $\lambda_1, \lambda_2, \ldots$ be the n_w nonzero eigenvalues of ww^* and $\phi_1, \phi_2, \ldots$ their orthonormal eigenvectors,

$$ww^* = \sum \lambda_j |\phi_j\rangle\langle\phi_j|, \quad \lambda_k > 0.$$

There exists exactly one other orthonormal basis of vectors, $\phi'_1, \phi'_2, \ldots$ of the same length n_w, fulfilling

$$w = \sum \sqrt{\lambda_k} |\phi_k\rangle\langle\phi'_k|, \quad w^* w = \sum \lambda_j |\phi'_j\rangle\langle\phi'_j| \tag{8}$$

and the positive numbers λ_j sum up to (w,w). From (8) one can read off the polar decompositions

$$w = \sqrt{ww^*}\, v = v \sqrt{w^* w}, \quad v = \sum |\phi_k\rangle\langle\phi'_k|. \tag{9}$$

The index k runs from 1 to n_w. One may call v the *phase of* w *relative to* $\varrho = ww^*$. The projection operators $v^* v$ and vv^*, attached to the partial isometry v, map $\mathcal{H}$ onto the support spaces of $w^* w$ and ww^*, respectively. Later on we need the operator $J = J_w$,

$$J_w x = v x^* v = \sum |\phi_j\rangle\langle\phi'_j, x^* \phi_k\rangle\langle\phi'_k|, \tag{10}$$

which, for completely entangled w, is the well-known *modular conjugation*. One easily establishes

$$(J_w)^2 x = (vv^*) x (v^* v), \quad (Jx, y) = (Jy, x). \tag{11}$$

If $\varrho \geqslant 0$ is a density operator, the set $\Pi^{-1}\varrho$ consists of all w satisfying $\varrho = ww^*$. Along this fiber the orthoframe $\phi'_1, \phi'_2 \ldots$ in (8) and (9) varies arbitrarily. Thus the fiber at ϱ is isomorphic, though not canonically, to a complex Stiefel manifold.[26] These isomorphisms are parametrized by the different possibilities to choose an orthoframe for the nonzero eigenvalues of ϱ. The *structure* or *gauge group* of $\Pi^{-1}\varrho$ consists of all unitary $u \in \mathcal{B}(\mathcal{H})$ acting by R_u.

Iff ϱ is already pure, $\varrho = |\phi\rangle\langle\phi|$, its purifications reads $w = |\phi\rangle\langle\phi'|$. That is, the purifying vectors are necessarily product vectors (''unentangled'' vectors).

In case the rank of ϱ is larger than one, w is called *entangled* in the domain of quantum information theory. Accordingly, *complete entanglement* of w is reached if the density operator ϱ is of maximal rank $n_w = \dim \mathcal{H}$. In this case, in traditional *-representation theory, ϱ is called *faithful* and w *separating*. $\varrho = ww^*$ is faithful iff w is invertible.

The set of all faithful ϱ is the base space of a principal fiber bundle with free action of the unitaries R_u. The fiber space consists of all invertible w, the projection is Π.

III. PURIFICATION AND TANGENTS

A smooth, oriented curve in $\mathcal{W}$, passing through w, defines at w a *tangent* or *velocity vector* x. Hence the tangent space, $\mathcal{T}_w$ at w, may be identified with $\mathcal{W}$ if considered as a real linear space.

Assume that w and the unitaries u depend smoothly on a parameter, and let us use a dot to show parameter differentiation. The gauge transformation $w \mapsto w' := wu$ induces the relation

$$x \mapsto x' = xu + w\dot{u}, \quad x = \dot{w}, \quad x' = \dot{w}'. \tag{12}$$

Let us now consider Π, and assume $\Pi w = \varrho$. Π induces a mapping Π_* from the tangent space of $\mathcal{W}$ into the density operator's tangents.

Being a first-order problem, it is sufficient for the following to assume a curve as simple as possible, say $w(\lambda) = w + \lambda x$. The curve is projected by Π to a curve of density operators $\varrho_\lambda = w(\lambda) w^*(\lambda)$ of $\mathcal{B}(\mathcal{H})$. Differentiating at $\lambda = 0$ results in a tangent $\Pi_* x = \xi$ at ϱ,

$$\xi = \dot{\varrho}, \quad \xi = (ww^*)^{\cdot} = xw^* + wx^*. \tag{13}$$

A tangent vector x at w is called *vertical* iff $\Pi_* x = 0$. The real vector space of the vertical tangents at w is denoted by $\mathcal{T}_w^{\mathrm{ver}}$. It is a straightforward and well-known exercise to show: The gauge transformation $x \mapsto x'$ of (12) maps vertical tangents at w to vertical tangents at w'.

We look at vertical tangents as labels for the physical phase. The phase of a single state or of its density operator is not an observable. Which purifying vector w we choose is physically irrelevant. What can be observed are relative phases, for example in interference experiments. The relative phases should depend on the way a density operator is changed to become another one. There should be a protocol according to which the tangents, and hence the phases, are transported along a curve within the space of density operators. This can be achieved by the help of a parallel transport.

The standard procedure is to split the tangent space at every w into a direct sum of the vertical and of an horizontal part. Respecting the complex linear structures, we restrict ourselves to decompositions defined by the real part of an Hermitian metric: We assume at every w a distinguished positive Hermitian sesquilinear form

$$w \mapsto (x_2, x_1)_w, \quad x_1, x_2 \in \mathcal{T}_w. \tag{14}$$

For completely entangled w it should be positive definite. Now $\mathrm{Re}\,(.,.)_w$, the real part of (14), converts the tangent space at w into a *real* Hilbert space. The *velocity* with which a curve goes through w is the square root of $(x,x)_w$ with x the tangent at that point. In this setting, parallel transport is asking for a minimal velocity lift of a given tangent at the base space. This, in turn, induces a metrical structure at the base space: One calls the *velocity of a base space tangent* the minimum of the velocities of all possible lifts.

Thus, the *horizontal part*, x^{hor}, of a tangent x at w is the unique element of the set $x + \mathcal{T}_w^{\mathrm{ver}}$ with the smallest velocity. This is in accordance with the definition of $\mathcal{T}_w^{\mathrm{hor}}$ as the orthogonal complement of $\mathcal{T}_w^{\mathrm{ver}}$ in the real Hilbert space $\mathcal{T}_w$, the latter equipped with the scalar product $\mathrm{Re}\,(.,.)_w$.

There is a distinguished real subspace, $\mathcal{T}_w^{\mathrm{Ver}} \subset \mathcal{T}_w^{\mathrm{ver}}$, containing all tangents

$$x = wa, \quad a = -a^* \in \mathcal{W},$$

which are obviously vertical. If w is invertible (completely entangled), every vertical tangent can be uniquely expressed in that way. But generally, $\mathcal{T}_w^{\mathrm{Ver}}$ is a proper subspace of $\mathcal{T}_w^{\mathrm{ver}}$. We call a vertical tangent *neutral* iff it is orthogonal to $\mathcal{T}_w^{\mathrm{Ver}}$ with respect to $\mathrm{Re}\,(.,.)_w$. Hence, every tangent x allows for an orthogonal decomposition

$$x = x^{\mathrm{hor}} + x^{\mathrm{ver}}, \quad x^{\mathrm{ver}} = x^{\mathrm{neutral}} + x^{\mathrm{Ver}}. \tag{15}$$

IV. PHASE TRANSPORT AND BURES METRIC

The most natural and simple choice for the Hermitian metric $(x_2, x_1)_w$ of (14) is certainly the Hilbert–Schmidt scalar product (5). This choice is particularly interesting for several reasons.

At first it gives a straightforward generalization of the geometric phase by the parallel transport evolving from this choice. Indeed, one obtains a natural extension of the Fock,[27], Berry,[9] Simon,[10] Wilczek and Zee[24] parallel transport to density operators.

Transport of state vectors along closed curves generates a holonomy problem. In the period between V. Fock and M. Berry this has become clear. B. Simons explained how to calculate the holonomy by the second Chern class of the Hilbert space if considered as a line bundle. There is an extensive literature on the transport of phases along curves and loops of pure states, see Ref. 28 for a selection of important results, applications, and references. Particular examples in using and calculating the geometric phase can already be found in papers of decades past.

Second, one gets a Riemannian metric[14] on the (not necessarily normalized) density operators of $\mathcal{B}(\mathcal{H})$. Its distance function is the distance introduced by Bures[29] in following a similar construction of Kakutani[30] in probability spaces. Being the infinitesimal version of *Bures' distance*, we call this Riemannian metric *Bures' metric*.

And, finally, already the choice

$$(x_2,x_1)_w=(x_2,x_1),\quad \forall w,$$

shows essential problems in deviating from a genuine fiber bundle.

We start by enumerating the tangents y orthogonal to $\mathcal{T}_w^{\mathrm{Ver}}$

$$(y,wa)+(wa,y)=0,\quad \forall a+a^*=0.$$

That condition straightforwardly comes down to

$$y^*w=w^*y \tag{16}$$

and y is orthogonal to all Ver-tangents iff w^*y is Hermitian. (16) is the *parallelity condition*,[8] which extends the transport condition for the geometric phase from pure to mixed states.

To decompose y in its neutral and horizontal part, we start by completing the two orthonormal systems of the Schmidt decomposition (8) arbitrarily and set $\lambda_j=0$ if $j>n_w$. By sandwiching (16) between the orthobase $\{\phi_i'\}$ we get

$$\sqrt{\lambda_k}\langle\phi_j',y^*\phi_k\rangle=\sqrt{\lambda_j}\langle\phi_j,y\phi_k'\rangle.$$

There evolve two conditions on the matrix elements:

$$j\leq n_w,\quad k>n_w\Rightarrow\langle\phi_j',y\phi_k\rangle=0.$$

$$k,j\leq n_w\Rightarrow\frac{\langle\phi_j',y^*\phi_k\rangle}{\sqrt{\lambda_j}}=\frac{\langle\phi_j,y\phi_k'\rangle}{\sqrt{\lambda_k}}.$$

No restriction occurs for $j>n_w$, $k\leq n_w$. There is an Hermitian g such that

$$\langle\phi_j,g\phi_k\rangle=\frac{\langle\phi_j,y\phi_k'\rangle}{\sqrt{\lambda_k}},\quad k\leq n_w.$$

One may choose the matrix elements of g with indices both larger than n_w arbitrarily but consistent with $g=g^*$.

The tangent $y_1=gw$ is horizontal[31,32] because it is orthogonal to all ver-tangents x. Indeed, $xw^*+wx^*=0$ implies $(gw,x)+(x,gw)=(g,xw^*+wx^*)=0$. What remains to check is the case of a tangent y_0, real orthogonal to all gw, $g=g^*$, and to all Ver-tangents. From the first condition it follows $wy_0^*+y_0w^*=0$, hence verticality, and from the second we obtain $w^*y_0=y_0^*w$. This is equivalent with

$$\langle\phi_j,y_0\phi_k'\rangle=0,\quad \forall j,k\leq n_w$$

or

$$y \quad \text{neutral} \quad \Leftrightarrow w^* y = y w^* = 0. \tag{17}$$

We conclude that every tangent x allows for a unique decomposition

$$x = gw + x_0 + wa \tag{18}$$

in a horizontal, a neutral, and a vertical part where g is Hermitian, a anti-Hermitian, and x_0 satisfies (17). With the extra conditions

$$\langle \phi_j , g\phi_k' \rangle = \langle \phi_j , a\phi_k' \rangle = 0, \quad k,j \geqslant n_w ,$$

both g and a are unique. The last conditions are equivalent to the choice of maximal null-spaces, i.e., *minimal supports* for g and a. They allow one to define g and a uniquely.

The transformation property (12) implies

$$w \mapsto w' = wu \Rightarrow a \mapsto a' = u^* a u + u^* \dot{u} , \tag{19}$$

so that $x \mapsto a$ is a connection form (gauge potential) **a** for the gauge group $u \mapsto R_u$. However, support properties may not change continuously. For parameter values at which the rank of w is changing, one has to understand g or a as equivalence class with respect to the kernel of $g \mapsto gw$ or $a \mapsto wa$, respectively. Then (19) remains meaningful even in those cases.

In our next step we look at g and a. g, which describes the horizontal part of a tangent vector x, can be expressed by $\xi := \Pi_* x$ and $\varrho := ww^* = \Pi w$. We need the pair x and $\tilde{\varrho} := w^* w$ to gain a. We get

$$\varrho g + g \varrho = \xi, \quad \tilde{\varrho} a + a \tilde{\varrho} = w^* x - x^* w. \tag{20}$$

The first equation[32,31] is obtained from (13). To see the second one,[13] insert (18) into its right-hand side.

Apart from an obvious restriction on ξ, (20) can be solved to get g or a, and several ways to do so are well known. A review is in Ref. 33. The restriction in question reads $\langle \phi, \xi \phi \rangle = 0$ whenever ϕ is in the null space of ϱ for the first equation, and $\langle \phi', \xi \phi' \rangle = 0$ whenever ϕ' is in the null space of $\tilde{\varrho}$. Below we assume they are satisfied.

With the solvability conditions in mind we rewrite (20) as equations between operators in $\mathcal{B}(\mathcal{W})$. In order not to overload notations we abbreviate

$$\mathrm{L} \equiv L_\varrho , \quad \mathrm{R} \equiv R_\varrho , \quad \tilde{\mathrm{L}} \equiv L_{\tilde{\varrho}} , \quad \tilde{\mathrm{R}} \equiv R_{\tilde{\varrho}} .$$

These are families of operators indexed by ϱ or $\tilde{\varrho}$.

Let us start now from (20). The equations can be solved by

$$g = (\mathrm{L} + \mathrm{R})^{-1} \xi, \quad a = (\tilde{\mathrm{L}} + \tilde{\mathrm{R}})^{-1} (w^* x - x^* w). \tag{21}$$

The operationally defined inverse exists by the solvability condition above. With two tangents ξ_j at ϱ and their horizontal lifts x_j^{hor} we get the Riemannian metric[16,14] belonging to the Bures distance

$$(\xi_2 , \xi_1)^{\mathrm{Bures}} := \mathrm{Re}\,(x_1^{\mathrm{hor}}, x_2^{\mathrm{hor}}) = \tfrac{1}{2} \mathrm{Tr}\, \varrho (g_1 g_2 + g_2 g_1) \tag{22a}$$

or, equivalently,

$$(\xi_2 , \xi_1)^{\mathrm{Bures}} = \tfrac{1}{2} \mathrm{Tr}\, \xi_2 g_1 = \tfrac{1}{2} \mathrm{Tr}\, \xi_2 (\mathrm{L} + \mathrm{R})^{-1} \xi_1 . \tag{22b}$$

There is a similar procedure with the second equation of (21) resulting in the connection $\mathbf{a}^{\text{geo}}$ with $\mathbf{a}^{\text{geo}}(x):=wa$. The superscript ''geo,'' if used, is a reminder for the physical important geometric phase. From (21) we get

$$\mathbf{a}^{\text{geo}}=\frac{\tilde{\mathrm{L}}}{\tilde{\mathrm{L}}+\tilde{\mathrm{R}}}(w^{-1}dw)-\frac{\tilde{\mathrm{R}}}{\tilde{\mathrm{L}}+\tilde{\mathrm{R}}}(w^{-1}dw)^{*}, \tag{23a}$$

where $w^{-1}\,dw$ is the left canonical 1-form with values in the Lie algebra of $\mathrm{GL}(\mathcal{H})$. $\mathbf{a}^{\text{geo}}$ takes values in the Lie algebra of the gauge group $U(\mathcal{H})$ acting from the right via $u\mapsto R_u$.

Formula (23a) represents $\mathbf{a}^{\text{geo}}$ as the difference of two Hermitian conjugated parts of type (1,0) and (0,1), respectively:

$$\mathbf{a}^{\text{geo}}=\mathbf{a}_{1,0}-\mathbf{a}_{0,1}, \quad \mathbf{a}_{0,1}=\mathbf{a}_{1,0}^{*}.$$

Another interesting equation expresses $\mathbf{a}^{\text{geo}}$ as sum of the canonical 1-form $\mathbf{a}^{\text{can}}$ of the bundle $\mathrm{GL}(\mathcal{H})/U(\mathcal{H})$ and a horizontal Ad-1-form[25]

$$\mathbf{a}^{\text{geo}}=\frac{w^{-1}\,dw-(w^{-1}\,dw)^{*}}{2}+\frac{\tilde{\mathrm{L}}-\tilde{\mathrm{R}}}{\tilde{\mathrm{L}}+\tilde{\mathrm{R}}}\,\frac{w^{-1}dw+(w^{-1}dw)^{*}}{2}. \tag{23b}$$

Since the second form is horizontal, it can be rewritten in terms of $d\varrho$ and we get

$$\mathbf{a}^{\text{geo}}=\mathbf{a}^{\text{can}}+w^{-1}\left(\frac{\mathrm{L}-\mathrm{R}}{2(\mathrm{L}+\mathrm{R})}\,d\varrho\right)(w^{-1})^{*} \tag{23b$'$}$$

$$=w^{-1}dw-w^{-1}\left(\frac{\mathrm{R}}{\mathrm{L}+\mathrm{R}}d\varrho\right)(w^{-1})^{*}. \tag{23c}$$

It becomes immediately clear that $\mathbf{a}^{\text{geo}}(x)=\mathbf{a}^{\text{can}}(x)$ iff $\mathrm{L}\xi=\mathrm{R}\xi$, where $\xi:=wx^{*}+xw^{*}$, i.e., iff ϱ commutes with $\dot{\varrho}$.

This observation motivates the decomposition

$$\mathcal{T}_{\varrho}=\mathcal{T}_{\varrho}^{\parallel}+\mathcal{T}_{\varrho}^{\perp} \tag{24}$$

of the tangent space $\mathcal{T}_{\varrho}$ into a direct sum, where $\xi\in\mathcal{T}_{\varrho}^{\parallel}$ iff ξ commutes with $\varrho=ww^{*}$ or, equivalently, iff $\langle\phi_j,\xi\phi_k\rangle=0$ for any two eigenvectors ϕ_j, ϕ_k, of ϱ with different eigenvalues. On the other hand, $\xi\in\mathcal{T}_{\varrho}^{\perp}$ iff it can be written as a commutator $i[b,\varrho]$ with a suitable Hermitian b. (24) is a well-known matrix decomposition: Assume ϱ represented as block diagonal matrix, every block belongs to just one eigenvalue. This induces a block representation of any matrix ξ. One gets $\xi^{\parallel}$ by setting zero every off-diagonal block of ξ. If the entries in the diagonal blocks are set to zero, one obtains $\xi^{\perp}$. In our present field of interest Hübner[18] obtained a decomposition (24) of the Bures Riemannian metric. For larger classes of metrics this has been done by Hasegawa and Petz (Refs. 34 and 35).

This brings us back to the metric (22). There is a solution g_1 commuting with ϱ iff ξ_1 does so: The support ϱ cannot be smaller than the support of ξ. Hence $2g_1=\varrho^{-1}\xi_1=\xi_1\varrho^{-1}$ is operational well defined. Inserting in (22b) results in

$$(\xi_2,\xi_1)^{\text{Bures}}=\tfrac{1}{4}\mathrm{Tr}\,\xi_2\xi_1\varrho^{-1}, \quad \xi_1\in\mathcal{T}_{\varrho}^{\parallel}. \tag{25}$$

Comparing this with the Riemannian metric

$$(\xi_2,\xi_1)^{\text{can}}:=\tfrac{1}{8}\mathrm{Tr}\,(\xi_2\xi_1+\xi_1\xi_2)\varrho^{-1}=\mathrm{Tr}\,\xi_2(\mathrm{L}^{-1}+\mathrm{R}^{-1})\xi_1,$$

the inequality $4/(\mathrm{L}+\mathrm{R})\leqslant(1/\mathrm{L})+(1/\mathrm{R})$ gives[36]

$$(\xi,\xi)^{\text{Bures}} \leqslant (\xi,\xi)^{\text{can}}$$

and equality holds if and only if $\xi \in \mathcal{T}_\varrho^\parallel$, or, what is the same, if ξ commutes with ϱ.

Let $\phi_1, \ldots$ be a complete orthonormal eigenvector basis of $\varrho = ww^*$ and ξ with eigenvalues λ_j and $\dot{\lambda}_j$, respectively. Then we get from (25) the following quadratic form:

$$\frac{1}{4}\sum d\lambda_j^2 \lambda_j^{-1} = \sum d\mu_j^2, \quad \mu_j := \sqrt{\lambda_j}.$$

This is an Euclidean metric. However, restricted to the state space, where $\lambda_1, \ldots$ becomes a probability vector, we get Fisher's metric (''Fisher–Rao metric'').[37]

If the Bures metric is restricted to a submanifold of mutual commuting states, the Fisher metric is obtained. Moreover, *on any submanifold of commuting density operators*, whether normalized or not, *the phase transport is holonomically trivial.*

Indeed, we can form the lift $\varrho \to w = \sqrt{\varrho}$. The assumed commutativity provides us with Hermitian and commutative w and $x = \dot{w}$, and with $\varrho = ww^* = w^*w = \tilde{\varrho}$. Hence (21) comes down to $\mathbf{a}(x) = 0$, and the lift is horizontal. There is no room for a nontrivial phase.

We see a nontrivial geometric phase is definitely an effect of noncommutativity. We need for them curves with mutually not commuting density operators.

V. AUXILIARY TOOLS

In order to extend our previous considerations to a larger class of connections[25] we need some auxiliary tools.

Looking at Eqs. (23) one can identify functions of L/R and $\tilde{\text{L}}/\tilde{\text{R}}$. These operators are relatives of $\text{L}/\tilde{\text{R}} = \Delta_w$, the Tomita–Takesaki modular operator of the representation $b \mapsto L_b$ with GNS-vector w. The operators are defined if w^{-1} exists, that is for completely entangled w. But, as (23) shows, certain functions of these operators can be defined for every w.

Let $t \mapsto f(t)$ be a function defined for $0 < t < \infty$. We assume the existence of

$$f(0) := \lim_{t\to 0} f(t), \quad f(\infty) := \lim_{t\to\infty} f(t). \tag{26}$$

The assumption is necessary if we like to extend the formalism to density operators which are not invertible. Without it, we have to restrict ourselves to completely entangled w, i.e., to faithful density operators.

To treat an example with the assumption (26), we define $f(\text{L}/\tilde{\text{R}}) =: f(\Delta)$. The positive operators L and $\tilde{\text{R}}$ commute. Let λ_j be the eigenvalue of ww^* and of w^*w with the eigenvectors ϕ_j and ϕ_j'. The eigenvectors, suitably chosen, collect in a complete orthonormal basis satisfying the Gram–Schmidt decomposition (8). λ_j is zero if $j > n_w$ and positive otherwise. Now

$$\text{L}v_{jk} = \lambda_j v_{jk}, \quad \tilde{\text{R}}v_{jk} = \lambda_k v_{jk}, \quad v_{jk} := |\phi_j\rangle\langle\phi_k'|.$$

The elements v_{jk} constitute a complete orthonormal basis of the Hilbert–Schmidt space $\mathcal{W}$. We like $f(\Delta)$ to be diagonalizable with eigenvectors v_{jk}. Remembering $\Delta = \text{L}/\tilde{\text{R}}$ we start with

$$f(\Delta)v_{jk} = f(\lambda_j/\lambda_k)v_{jk}, \quad \text{if } \lambda_k > 0.$$

The remaining possibility is done ''by hand'' in requiring

$$f(\Delta)v_{jk} = f(\infty)v_{jk}, \quad \text{if } \lambda_j > 0, \quad \lambda_k = 0,$$

$$f(\Delta)v_{jk} = f(1)v_{jk}, \quad \text{if } \lambda_j = \lambda_k = 0.$$

With this convention v_{jj} is an eigenvector of $f(\Delta)$ with eigenvalue $f(1)$ for all j.

The same game is to play with $f(\mathrm{L/R})$ and $f(\tilde{\mathrm{L}}/\tilde{\mathrm{R}})$. While the spectra of $f(\mathrm{L/R})$ and $f(\tilde{\mathrm{L}}/\tilde{\mathrm{R}})$ coincide with that of $f(\Delta)$, their eigenvectors are, respectively,

$$|\phi_j\rangle\langle\phi_k| = v_{ji} v_{ik}^*, \quad |\phi'_j\rangle\langle\phi'_k| = v_{ji}^* v_{ik}.$$

VI. A CLASS OF CONNECTIONS

Our aim is to describe a class of connections, essentially that of Dittmann and Rudolph[25]. These objects, as will be seen, are particularly well adapted to the purification of the $\mathcal{H}$-system by that of $\mathcal{W}=\mathcal{H}\otimes\mathcal{H}^*$. We assume w to be completely entangled, so that $\varrho=\Pi w$ is faithful (invertible). Whether it is possible to skip this assumption, either by calculating modulo neutral tangents or by continuity arguments, depends on the asymptotic behavior of certain functions to be introduced below.

Let $[0,\infty]\ni s\mapsto r(s)\in\mathbb{C}$ be a smooth function and $r(1)=1/2$. Then

$$(r(\tilde{\mathrm{L}}/\tilde{\mathrm{R}})y)^* = \overline{r}(\tilde{\mathrm{R}}/\tilde{\mathrm{L}})y^*.$$

Mimicking Eq. (23a) we define the form

$$\mathbf{a} := \overline{r}(\tilde{\mathrm{L}}/\tilde{\mathrm{R}})(w^{-1}\,dw) - r(\tilde{\mathrm{R}}/\tilde{\mathrm{L}})(w^{-1}\,dw)^*. \tag{27a}$$

It transforms like a connection and takes anti-Hermitian values. To be a connection it must take the correct values at vertical vectors, i.e., $\mathbf{a}(wa)=a$, for all anti-Hermitian a. Thus we need to have

$$\overline{r}(t)+r(1/t)=1, \quad F(t):=\overline{r}(t)-r(1/t)=-\overline{F}(1/t), \tag{28}$$

to get a genuine connection with respect to the gauge group $\mathrm{U}(\mathcal{H})$ acting by $u\mapsto R_u$. Furthermore, as a consequence of $r(1)=1/2$, one observes rescaling invariance of this connection form. Indeed, $\mathbf{a}$ is invariant under $w\mapsto\lambda(w)w$, where $\lambda:\mathcal{W}\to\mathbb{R}$:

$$\mathbf{a}_w(x) = \mathbf{a}_{\lambda w}(d\lambda(x)w+\lambda x),$$

so that there is no need to normalize w in calculating $\mathbf{a}$. The second equation in (28) introduces the function F used in Ref. 25 to label their gauge potentials, and we are allowed now to rewrite (27a) in a manner known already from (23):

$$\mathbf{a} = \mathbf{a}^{\mathrm{can}} + F(\tilde{\mathrm{L}}/\tilde{\mathrm{R}})\frac{(w^{-1}\,dw)+(w^{-1}\,dw)^*}{2} \tag{27b$'$}$$

$$= \mathbf{a}^{\mathrm{can}} + w^{-1}(F(\mathrm{L/R})\,d\varrho)(w^{-1})^* \tag{27b}$$

$$= w^{-1}\,dw - w^{-1}(r(\mathrm{R/L})\,d\varrho)(w^{-1})^*. \tag{27c}$$

One returns to the Bures case by

$$\mathbf{a}=\mathbf{a}^{\mathrm{geo}} \Leftrightarrow r(t)=\frac{t}{1+t} \Leftrightarrow F(t)=(t-1)/(t+1).$$

Before deriving expressions for the vertical and horizontal part of a given tangent x, we draw an important conclusion:

The value of a connection at the lift of a $\|$-tangent is independent of F, respectively, r. Indeed, $F(1)=0$ and $\mathrm{L}x=\mathrm{R}x$ for these tangents, and we get from (27b') immediately

$$\Pi_*(x) \in \mathcal{T}^{\|} \Rightarrow \mathbf{a}(x) = \mathbf{a}^{\text{can}}(x), \quad \forall F$$

allowing to extend a conclusion of Sec. IV:

On submanifolds with mutually commuting density operators the holonomy of every loop is trivial for the whole class of connections considered here.

Indeed, the lift $\varrho \to \sqrt{\varrho}$ is horizontal along every curve of commuting densities.

To obtain the vertical and horizontal part of a tangent x let us apply Eq. (27c) to x multiplied by w from the left. We assumed w to be separating so that there are no nonvanishing neutral tangents. Therefore

$$x^{\text{ver}} = x^{\text{Ver}} = w\mathbf{a}(x) = x - (r(\text{R}/\text{L})\xi)(w^*)^{-1} \tag{29a}$$

$$= x - r(\Delta^{-1})(x + wx^* w^{*-1}) \tag{29b}$$

$$= x - r(\Delta^{-1})[x + \Delta^{1/2}Jx], \tag{29c}$$

reminding $wx^*(w^*)^{-1} = \Delta^{1/2}Jx = J\Delta^{-1/2}x$. (29) reflects the decomposition of a general tangent into a vertical and a horizontal part, see (15). We conclude

$$x^{\text{hor}} = (r(\text{R}/\text{L})\xi)(w^*)^{-1} = r(\Delta^{-1})[x + \Delta^{1/2}Jx]. \tag{30}$$

A connection form $\mathbf{a}$ regulates the change of the phase v along a horizontal lift, $w_t = \sqrt{\varrho_t}v_t$, of a curve ϱ_t. We express $\mathbf{a}$ by

$$\begin{aligned}
\mathbf{a}(\dot{w}) = \mathbf{a}(\sqrt{\varrho}\dot{v} + (\sqrt{\varrho})^{\cdot} v) &= \mathbf{a}(\sqrt{\varrho} v v^* \dot{v} + (\sqrt{\varrho})^{\cdot} v) \\
&= v^*\dot{v} + v^*\mathbf{a}(\sqrt{\varrho}^{\cdot})v \\
&= v^*\dot{v} + v^*\mathbf{a}\left(\frac{1}{\sqrt{\text{L}} + \sqrt{\text{R}}}\dot{\varrho}\right)v \\
&= v^*\dot{v} + v^*\frac{1}{2}\frac{1}{\sqrt{\text{LR}}}\left(F(\text{L}/\text{R}) + \frac{\sqrt{\text{R}} - \sqrt{\text{L}}}{\sqrt{\text{R}} + \sqrt{\text{L}}}\right)(\dot{\varrho})v.
\end{aligned}$$

and see that the horizontality of w_t is equivalent with

$$0 = \dot{v}v^* + \frac{1}{2}\frac{1}{\sqrt{\text{LR}}}\left(F(\text{L}/\text{R}) + \frac{\sqrt{\text{R}} - \sqrt{\text{L}}}{\sqrt{\text{R}} + \sqrt{\text{L}}}\right)(\dot{\varrho}). \tag{31}$$

One observes, that there is one and only one connection in our setting with a global horizontal section, $\varrho \mapsto \sqrt{\varrho}$. That connection is given by

$$F(t) = -\frac{1 - \sqrt{t}}{1 + \sqrt{t}}, \quad r(t) = \frac{\sqrt{t}}{1 + \sqrt{t}}.$$

VII. CONNECTION AND METRIC

In this section we specify a class of Hermitian metrics (14) on $\mathcal{W}$, which respects the purification scheme. Our first task is to ask for Hermitian metrics on the complex manifold $\mathcal{W}$, the real part of which is compatible with a given connection form of Sec. VI. We demand: At every completely entangled $w \in \mathcal{W}$, the vertical tangents are real orthogonal to the horizontal ones. In the case where there exists a Hermitian metric doing this task, the functions F and r characterizing the connection have to be real. In the next step we describe the Hermitian and Riemannian metric one obtains by reduction from the purification space to that of (unnormalized) density operators.

Starting with a connection (27a), (28), there is some freedom in the choice of the Hermitian metric. It is an interesting question in its own right, whether, by a reasonable condition, the Hermitian metric becomes unique. We explain in the last part of this section how this can be done. If we start from a Riemannian metric on the density operators, the uniqueness problem is more involved. Nevertheless, our additional condition solves it also, at least for the monotone Riemannian metrics.

To start our little program we construct Hermitian metrics (14) by modifying the Hilbert Schmidt scalar product on $\mathcal{W}$ by a function $k(\Delta)$ of the modular operator. Like R and L the modular operator Δ depends on w. Our ansatz for the Hermitian product in $T_w\mathcal{W}$ reads

$$(x_2,x_1)_w := (x_2, k(\Delta_w)^{-1} x_1), \tag{32}$$

where k is a real positive smooth function defined either only on $0<t<\infty$ or on the closed interval $0\leqslant t\leqslant\infty$. We use the rules explained in Sec. V. There are two main merits with such a choice of the modified Hermitian metric: The symmetry group of the metric contains the unitary group $\mathrm{U}(\mathcal{H})\times\mathrm{U}(\mathcal{H}^*)$. The second is the rescaling invariance of Δ under $w\mapsto\lambda(w)w$, where $\lambda(w)$ denotes (a sufficiently smooth) real function on $\mathcal{W}$. Rescaling invariance is a further reason not to insist on normalized density operators.

In determining the connection form compatible with (32), we follow the recipe of Sec. III. We need the real-orthogonal complement of the vertical directions. They are to gain by the metrical independence of verticality. Namely, if a tangent x is real orthogonal to all vertical ones, $k(\Delta)^{-1}x$ is horizontal with respect to the Hilbert–Schmidt metric. Therefore, as shown in Sec. IV, we are allowed to write $x=gw$ with a Hermitian g. Conclusion:

A tangent x is horizontal with respect to (32), if it can be represented as

$$x = k(\Delta)(gw) = k(\mathrm{L}/\mathrm{R})(g)w, \quad g = g^*. \tag{33}$$

The real space of horizontal tangents is the fix point set of an antilinear operator, S_w^k, acting on $\mathcal{W}$. Our notation is borrowed from that of the Tomita–Takesaki operator $S_w = J\sqrt{\Delta}$, which will be returned if $k\equiv 1$. Our definition is

$$S_w^k := Jk(\Delta^{-1})k(\Delta)^{-1}\sqrt{\Delta} = k(\Delta)k(\Delta^{-1})^{-1}S_w. \tag{34a}$$

If this operator acts on $x=k(\Delta)(gw)$ the result is $k(\Delta)(g^*w)$. Comparison with (33) establishes: x is a fix point of S_w^k if and only if x is horizontal.

The square of the operator (34a) is J^2; compare (11). J^2 is the identity of $\mathcal{W}$ iff w is invertible. Further, the adjoint of S_w^k with respect to (32) is $\sqrt{\Delta}J$ and, as it should be, independent of k. (Tomita–Takesaki theory calls it "F_w.") Finally we polar decompose (34a) to get the appropriate modifications of the modular operator, $\Delta=\Delta_w$, and of the modular conjugation, $J=J_w$,

$$S_w^k = J_w^k |S_w^k|, \quad \Delta_w^k := |S_w^k|^2, \tag{34b}$$

$$\Delta_w^k = k(\Delta^{-1})k(\Delta)^{-1}\Delta, \quad J_w^k = J\sqrt{k(\Delta^{-1})k(\Delta)^{-1}}. \tag{34c}$$

We now ask for the connection coming with the metric. The connection form belonging to (32) annihilates all the horizontal vectors (33). This reasoning, applied to (27a) or (27b), determines the function r or F. The calculation shows, in accordance with (28),

$$r(t) = \frac{tk(1/t)}{k(t)+tk(1/t)}, \quad \text{respectively}, \quad F(t) = \frac{tk(1/t)-k(t)}{tk(1/t)+k(t)}. \tag{35}$$

Obviously, *the functions r and F are real valued* if the connection is gained from a Hermitian metric (32). A cross check of (35) is in setting $k \equiv 1$. We get $r(t) = t/(1+t)$ and $F(t) = (t-1)/(t+1)$ as it should be for the Bures case.

On the other hand, given r or F, there is some freedom for k since the induced connection depends on $k(t)/k(1/t)$ only.

$$\frac{k(t)}{k(1/t)} = 1 \Leftrightarrow r(t) = \frac{t}{1+t}, \quad F(t) = \frac{(t-1)}{(t+1)}, \quad \mathbf{a} = \mathbf{a}^{\text{geo}},$$

$$\frac{k(t)}{k(1/t)} = t \Leftrightarrow r(t) = \frac{1}{2}, \quad F(t) = 0, \quad \mathbf{a} = \mathbf{a}^{\text{can}}.$$

In particular, there is no modification of the Tomita–Takesaki operators by (34) if the connection is $\mathbf{a}^{\text{geo}}$. More generally, from (35) we get

$$\frac{k(t)}{k(1/t)} = t\frac{r(1/t)}{r(t)} = t\frac{1-F(t)}{1+F(t)} \tag{36}$$

and find, remarkably enough, the modified Tomita–Takesaki operators (34) depending on F only. Further, by (36), the positivity of k enforces the inequality

$$-1 < F(t) < 1 \tag{37}$$

for F to be obtained from a k. In order to invert (36), the inequality is also sufficient. According to (28) one needs only to check $F<1$ for real F. Then, given F, the general solution of the problem is

$$k(t) := \sqrt{t}(1-F(t))q(t),$$

q being an arbitrary positive function fulfilling $q(t) = q(1/t)$.

We started from a Hermitian metric on $\mathcal{W}$, derived conditions for horizontality, and determined the connection. Now we go back to $\mathcal{H}$ and to its density operators: We ask for the Hermitian and Riemannian metric induced on the space of density operators. That is, with two tangents ξ and η at $\Pi w = \varrho$, we are concerned with

$$(\eta,\xi)_\varrho := (y^{\text{hor}}, x^{\text{hor}})_w, \quad \text{Re}\,(\eta,\xi)_\varrho = \frac{(\eta,\xi)_\varrho + (\xi,\eta)_\varrho}{2}.$$

x^{hor} and y^{hor} are the horizontal lifts of ξ and η. In the present paper the $\mathbb{C}$-valued $\mathbb{R}$-linear form $\xi,\eta \mapsto (\eta,\xi)_\varrho$ is defined on the real tangents. Nevertheless, for obvious reasons, we call it ''Hermitian.'' Relying on (30) we conclude

$$(y^{\text{hor}}, x^{\text{hor}})_w = \text{Tr}\, r(\text{L/R})(\eta)\frac{r(\text{R/L})}{\text{R}k(\text{L/R})}(\xi) = \text{Tr}\,\eta\frac{r(\text{R/L})^2}{\text{R}k(\text{L/R})}\xi,$$

so that

$$(\eta,\xi)_\varrho = \text{Tr}\,\eta\frac{\text{R}k(\text{L/R})}{[\text{R}k(\text{L/R}) + \text{L}k(\text{R/L})]^2}\xi, \tag{38a}$$

where r has been substituted by k by the aid of (35). The real part is a Riemannian metric. By standard rules we get

$$\mathrm{Re}\,(\eta,\xi)_\varrho=\frac{1}{2}\mathrm{Tr}\,\eta\frac{1}{\mathrm{R}k(\mathrm{L}/\mathrm{R})+\mathrm{L}k(\mathrm{R}/\mathrm{L})}\xi. \tag{38b}$$

Petz[36,1,2] was able to classify all monotone Hermitian metrics on the state space, i.e., those for which $(\cdot,\cdot)_\varrho$ does not increase under the action of completely positive and unital mappings. At the heart of his result is the characterization of a monotone metric by an operator monotone function, *f*, defined on $0<t<\infty$, such that

$$(\eta,\xi)_\varrho=\frac{1}{4}\mathrm{Tr}\,\eta\frac{\mathrm{R}^{-1}}{f(\mathrm{L}/\mathrm{R})}\xi. \tag{39}$$

(The factor 1/4 is a normalization convention.) Note that this Hermitian metric becomes symmetric, and hence a Riemannian one, if and only if the function *f* satisfies $f(t)=tf(1/t)$. A function with this algebraic property we call self-transposed, following the terminology for operator means introduced in Ref. 3. Presently, however, the monotonicity of the metric (39) or of its real part is *not* assumed. We need a more general frame. Having this in mind, we compare (39) with (38a) and obtain

$$f(t)=\frac{(k(t)+tk(1/t))^2}{4k(t)}. \tag{40}$$

This equation has a unique solution for *k* depending on *f*, therefore, every Hermitian metric (39) can be reached by exactly one Hermitian metric (32) on the purification space. Indeed, the harmonic mean of $f(t)$ and its transpose, $tf(1/t)$, yields

$$\frac{1}{f(t)}+\frac{1}{tf(1/t)}=\frac{4}{k(t)+tk(1/t)}$$

so that one can insert this into the right-hand side of (40) to express *k* by *f*:

$$k(t)=f(t)\frac{4t^2f(1/t)^2}{[f(t)+tf(1/t)]^2}. \tag{41}$$

Moreover, using (35) we get

$$r(t)=\frac{f(t)}{f(t)+tf(1/t)},\quad F(t)=\frac{f(t)-t(1/t)}{f(t)+tf(1/t)}. \tag{42}$$

These equations describe the relation between the connection on $\mathcal{W}$ and the Hermitian metric living on the density operators. It is Riemannian iff *f* is self-transposed. (41) yields $f=k$ in this case, and (42) degenerates to $r\equiv 1/2$. Hence, *if the induced Hermitian form is Riemannian, the induced connection is necessarily the canonical one.* This way we do not get an interesting mapping from the class of Riemannian metrics to the class of connections. Especially, the function $f(t)=(1+t)/2$ belonging to the Bures metric cannot be gained from $\mathbf{a}^{\mathrm{geo}}$ as one might expect.

Moreover, if we like to gain the connection form $\mathbf{a}^{\mathrm{geo}}$, $r(t)=t/(t+1)$, belonging to the geometric phase, we need, according to (42), $t^2f(1/t)=f(t)$ or, equivalently, $k(t)=k(1/t)$. If *f* is operator monotone, so is $tf(1/t)$. Therefore, $t^2f(1/t)$ is convex (lemma 5.2 of Ref. 3). Thus, *f* is convex and, as an operator monotone function, concave. Being convex and concave, *f* has to be affine. An affine function on the positive real axis, fulfilling $t^2f(1/t)=f(t)$, is a multiple of *t*.

If $\mathbf{a}=\mathbf{a}^{\mathrm{geo}}$ *and f is operator monotone with* $f(1)=1$, *then* $f(t)=t$.

However, for $k(t)=1$ [respectively, $k(t)=2t/(t+1)$] we get $\mathbf{a}=\mathbf{a}^{\mathrm{geo}}$ (respectively, $\mathbf{a}=\mathbf{a}^{\mathrm{can}}$) and obtain from (38b) for the real part

$$\mathrm{Re}\,(\eta,\xi)_\varrho=\frac{1}{4}\mathrm{Tr}\,\eta\frac{R^{-1}}{f_s(L/R)}\xi \tag{43}$$

with $f_s(t)=(1+t)/2$ (respectively, $f_s(t)=2t/(t+1)$). These f_s are distinguished (self-transposed) operator monotone functions. Moreover, in these cases (38b) restricted to the horizontal vectors coincides with the real part of the Hilbert–Schmidt metric. This is the motivation to deal in the following with the real part of the Hermitian metric induced on the state space.

First of all, this Riemannian metric is of the form (43) with a certain self-transposed function f_s depending on k. From (38b) we get

$$f_s(t)=\frac{k(t)+tk(1/t)}{2}. \tag{44}$$

$f_s(t)$ is the harmonic mean of $f(t)$ and $tf(1/t)$, with f given by (40).

Clearly, in starting with a self-transposed f_s there is some arbitrariness in choosing k respecting (44). Moreover, given a self-transposed f_s, the only restriction for F is $-F(1/t)=F(t)<1$. Indeed, Eqs. (35) and (44) then have the unique solution

$$k(t)=f_s(t)(1-F(t)). \tag{45}$$

In order to remove the arbitrariness in going from f_s to F and vice versa or from f_s to k, we impose an additional requirement on the class (32) of Hermitian metrics $(x,y)_w$. The aim is to ensure that, given f_s, there is only one k and one F fulfilling (35) and (44). We shall prove that we meet our goal for operator monotone f_s by the following natural demand:

Condition HS: For x and y belonging to the horizontal spaces defined by the Hermitian metric (32), the real part, $\mathrm{Re}\,(x,y)_w$, *of* $(x,y)_w$ *coincides with the real part,* $\mathrm{Re}\,(x,y)$, *of the Hilbert–Schmidt product of x and y.*

At first, by the aid of (33), the condition HS becomes

$$\mathrm{Re}\,(k(\Delta)(gw),g'w)=\mathrm{Re}\,(k(\Delta)(gw),k(\Delta)(g'w))$$

with arbitrary Hermitian g and g'. It yields the constraint

$$k(t)+tk(1/t)=k(t)^2+tk(1/t)^2. \tag{46}$$

Next, we have the following crucial observation, which one verifies straightforwardly:

There is a one-to-one correspondence between positive functions k fulfilling the constraint (46) and functions F with $-F(1/t)=F(t)<1$. *The correspondence is given by (35) and*

$$k(t)=\frac{2t(1-F(t)}{(1+F(t))^2+t(1-F(t))^2}. \tag{47}$$

By (44) or, equally well, by (45) we get the relation between F and f_s,

$$f_s(t)=\frac{2t}{(1+F(t))^2+t(1-F(t))^2}. \tag{48}$$

Hence, under condition HS, a function f_s can be gained from a k iff f_s has a representation (48) with a suitable F, $F(t)<1$. To explain which functions f_s can be reached, we rewrite relation (48) into the equivalent form

$$\frac{1+t}{2}-f_s(t)=\frac{f_s(1/t)(1+t)^2}{4}\left(\frac{t-1}{t+1}-F(t)\right)^2.$$

Therefore, necessary conditions for f_s are $f_s(1)=1$, $f_s \leqslant (1+t)/2$ and, moreover, $t \mapsto (1+t)/2 - f_s(t)$ must be the square of a smooth function.

Now suppose we have such a pair f_s, F. We define an auxiliary smooth function

$$\delta(t) := \frac{\sqrt{f_s(1/t)}(1+t)}{2} \left(\frac{t-1}{t+1} - F(t) \right).$$

It fulfills

$$\delta(t)^2 = \frac{1+t}{2} - f_s(t), \quad \sqrt{t}\,\delta(1/t) + \delta(t) = 0. \tag{49}$$

The second equation is a consequence of $F(1/t) = -F(t)$ and $f_s(t) = t f_s(1/t)$. F can be expressed in terms of δ and f_s by

$$F(t) = \frac{t-1}{t+1} - \frac{2}{(1+t)\sqrt{f_s(1/t)}}\,\delta(t). \tag{50}$$

Conversely, for a given self-transposed f_s, $f_s(1)=1$, the possibilities in choosing δ with the properties (49) enumerate via (50) the solutions F of (48) and $-F(1/t) = F(t)$. But such an F may not fulfill $F(t) < 1$ if we did not choose appropriately the signs for δ in (49). The desired choice may be neither unique nor possible. But if so, the function k defined by

$$k(t) := \frac{2}{t+1} \left(f_s(t) + \sqrt{t f_s(t)}\,\delta(t) \right) \tag{51}$$

satisfies (44) and (35).

The question, which functions f_s, $f(1)=1$, bounded by $0 < f(t) \leqslant (1+t)/2$, can arise from F or, equivalently, from a Hermitian metric (32), depends also on regularity requirements on F and k. We do not discuss this in detail. Instead we have the following uniqueness result:

Lemma: For every self-transposed operator monotone function $f_s : (0,\infty) \to \mathbb{R}$ with $f(1)=1$ there exists exactly one positive real analytic function $k : (0,\infty) \to \mathbb{R}$ fulfilling (44) and (46). k and its corresponding function F are given by

$$k(t) = \frac{2 f_s(t)}{t+1} \left(1 + \frac{t-1}{|t-1|} \sqrt{t} \sqrt{\frac{1+t}{2 f_s(t)} - 1} \right), \tag{52}$$

$$F(t) = \frac{t-1}{t+1} \left(1 - \frac{2\sqrt{t}}{|t-1|} \sqrt{\frac{1+t}{2 f_s(t)} - 1} \right) \tag{53}$$

for $t \neq 1$ and $k(1)=1$, $F(1)=0$.

We prove this assertion in the Appendix. (It should be emphasized that k and F are real analytic although the last formulas involve $1/|t-1|$, see the Appendix.) From this lemma we get:

For every monotone Riemannian metric (43), $f_s(1)=1$, on the manifold of completely entangled states there exists exactly one Hermitian metric (32) satisfying the condition HS such that the real part of the induced Hermitian metric is just the given monotone metric. For a given f_s the Hermitian metric and the corresponding connection form are obtained from (52) and (53).

The obtained connection we call the connection associated to the monotone Riemannian metric. For the Bures metric we return to the Hilbert–Schmidt metric and the connection above called $\mathbf{a}^{\text{geo}}$.

Since we used only certain properties of operator monotone functions this assertion would be true for a larger class of metrics, but we will not deal with this problem.

Although the condition HS seems to be natural, perhaps a short comment would be worthwhile. The induced Riemannian metrics are obtained, essentially, by taking the real part of the Hermitian metric of horizontally lifted vectors. But, because of HS, this is the same as the real part of the Hilbert–Schmidt metric. Forgetting for a moment about the underlying Hermitian metric, which forced horizontality, we can take the following point of view: The monotone metrics are obtained from the originally given Hilbert–Schmidt metric similarly to the Bures metric (Sec. IV) whereas the deviation from the Bures metric is caused by some constraints on the purifying lifts.

VIII. EXAMPLES

At first we look at curves of density operators satisfying a von Neumann equation

$$i\dot{\varrho}=[h,\varrho],\quad h=h^*,\quad \dot{h}=0 \tag{54}$$

and their lifts. We may think of $h\in\mathcal{B}(\mathcal{H})$ as of a given Hamiltonian and of the curve parameter, t, as time. This interpretation is not obligatory: h may be the generator of any one-parameter group. (The parameter t should not be confused with the use of the same letter as a dummy variable in several functions like f, k, r, F.) To fix a solution of (54), we start at an initial time, $t_{\rm in}$, with an initial density operator $\varrho_{\rm in}$. The solution may be written

$$\varrho_t=u_t^*\varrho_{\rm in}u_t,\quad u_t:=\exp i(t-t_{\rm in})h. \tag{55}$$

Now a general lift w_t is polar decomposed, $w_t=\sqrt{\varrho_t}v_t$, according to (9).

Our aim is to prove the following: *Given a connection form and an initial* $\varrho_{\rm in}$ *at* $t_{\rm in}$ *there is a t-independent Hermitian* $\tilde{h}$ *such that*

$$u_tv_t=\exp i(t-t_{\rm in})\tilde{h} \tag{56}$$

implies horizontality of w_t. At first we see from (55) and (56) the validity of a Schrödinger equation in $\mathcal{W}$,

$$i\dot{w}=Hw,\quad Hw:=hw-w\tilde{h}. \tag{57}$$

By the help of our menagerie of equations it is not particularly difficult to prove the statement above and to obtain an expression for $\tilde{h}$. At first let us multiply (57) by w^* from the right. By (30) the condition for horizontality is in equating $i\dot{w}w^*$ with $r(R/L)i\dot{\varrho}$. Now (54) yields

$$r(\mathrm{R/L})(h\varrho-\varrho h)=h\varrho-w\tilde{h}w^*.$$

This equation is sufficient to guarantee horizontality. Now $w\tilde{h}w^*$ can be computed by (56) to $u_t^*\sqrt{\varrho_{\rm in}}\tilde{h}\sqrt{\varrho_{\rm in}}u_t$. Therefore, our horizontality condition is the Ad-transform with u_t^* of the equation

$$r(\mathrm{R_{in}/L_{in}})(h\varrho_{\rm in}-\varrho_{\rm in}h)=h\varrho_{\rm in}-\sqrt{\varrho_{\rm in}}\tilde{h}\sqrt{\varrho_{\rm in}},$$

where R and L at $t=t_{\rm in}$ is indexed by in. In other words, if we choose $\tilde{h}$ t-independent and v according to (56), we can satisfy the horizontality condition.

To get a unique $\tilde{h}$, we require the support of $\tilde{h}$ to be smaller than that of $\varrho_{\rm in}$. Finally, with the help of (28), we get the expression

$$\tilde{h}=(\sqrt{\mathrm{R/L}}\,r(\mathrm{L/R})+\sqrt{\mathrm{L/R}}\,r(\mathrm{R/L}))h,\quad t=t_{\rm in}. \tag{58}$$

Let us consider a solution (55) of (54) from $t_{\rm in}$ to $t_{\rm out}$. *Then* $w_{\rm out}w_{\rm in}^*$ *is a gauge invariant.* Its trace in $\mathcal{H}$,

$$(w_{\rm in},w_{\rm out})=(w_{\rm in},[\exp i(t_{\rm out}-t_{\rm in})H]w_{\rm in})=\operatorname{Tr}\sqrt{\varrho_{\rm in}}\sqrt{\varrho_{\rm out}}\exp(i(t_{\rm in}-t_{\rm out})h)\exp(i(t_{\rm out}-t_{\rm in})\tilde{h}), \tag{59}$$

may be called a *relative geometric phase*. For pure states that object has been introduced in Ref. 38. These authors called it the ''non-cyclic geometric phase.'' One may think of shortcutting the in- and the out-state to a closed curve by a Fubini Study geodesic arc. Whether one has a similar interpretation in our much more general case remains an open question.

For a cyclic solution of (54), i.e., $\varrho_{\rm in}=\varrho_{\rm out}$, $t_{\rm cycle}=t_{\rm out}-t_{\rm in}$, the expression $w_{\rm out}w_{\rm in}^*$ is a (pointed) holonomy invariant, i.e., it depends on the choice of $\varrho_{\rm in}$. To change the in-state of our cyclic curve one has to perform a u_t-transformation. Consequently, *all eigenvalues of* $w_{\rm out}w_{\rm in}^*$ *are (absolute) holonomy invariants*. of our cyclic curve. They are encoded in the traces

$$\operatorname{Tr}(w_{\rm out}w_{\rm in}^*)^m=\operatorname{Tr}[\varrho_{\rm in}\exp(-it_{\rm cycle}h)\exp(it_{\rm cycle}\tilde{h})]^m, \tag{60}$$

where $\exp(-it_{\rm cycle}h)$ commutes with $\varrho_{\rm in}$.

There are a few examples where one can become more explicit. One of them is in *adding noise to a curve of pure states* p_t. In this important example one can study the influence of ''noise'' on the geometric phase, and the behavior of gauge and holonomy invariants in coming from the interior to the extreme boundary of the cone of unnormalized density operators. For this purpose we fix two positive real numbers, α and β, and consider the curve of density operators ϱ,

$$\varrho=\alpha p+\beta\mathbf{1},\quad p=|\psi\rangle\langle\psi|,\quad \langle\psi,\psi\rangle=1. \tag{61}$$

$\alpha+\beta$ is a simple and β, if n denotes the dimension of $\mathcal{H}$, a $(n-1)$-fold eigenvalue of ϱ. ψ, p and ϱ depend on a parameter t, but we will not suppose a von Neumann equation.

Remark: The line element of this curve with respect to the metric induced from (32) is

$$ds^2=\frac{2\alpha(1-\tau)}{\tau k(1/\tau)+k(\tau)}ds^2_{\rm Bures},\quad \tau:=\frac{\beta}{\alpha+\beta},$$

where $ds^2_{\rm Bures}$ denotes the Bures line element of the curve of pure states p_t. □

All t-derivations will be indicated by a dot, in particular

$$\dot{\varrho}=\alpha\dot{p},\quad \dot{p}=\dot{p}p+p\dot{p},\quad p\dot{p}p=0.$$

$\dot{\varrho}$ belongs to $\mathcal{T}^\perp$. As an application one calculates

$$R_\varrho\dot{p}=\dot{p}(\alpha p+\beta\mathbf{1})=(\alpha+\beta)\dot{p}p+\beta p\dot{p}.$$

In this manner one gets

$$R_\varrho(p\dot{p})=\beta p\dot{p},\quad R_\varrho(\dot{p}p)=(\alpha+\beta)\dot{p}p,$$

$$L_\varrho(p\dot{p})=(\alpha+\beta)p\dot{p},\quad L_\varrho(\dot{p}p)=\beta\dot{p}p$$

and, finally, skipping the index of L_ϱ and R_ϱ,

$$({\rm L/R})(p\dot{p})=\left(\frac{\alpha+\beta}{\beta}\right)p\dot{p},\quad ({\rm L/R})(\dot{p}p)=\left(\frac{\beta}{\alpha+\beta}\right)\dot{p}p.$$

For instance, $\dot{p}p$ and $\dot{p}p$ are eigenvectors of LR with the eigenvalue $(\alpha+\beta)\beta$. At this stage we do not suppose a von Neumann equation (54) but rely on (31). From the last equation and $F(t)=-F(1/t)$, we get

$$F(\mathrm{L/R})\dot{p}=F\left(\frac{\beta}{\alpha+\beta}\right)(\dot{p}p-p\dot{p}).$$

Hence, in solving (31) with (61) we are faced with an equation

$$\dot{v}v^*=\frac{1}{2}\frac{\alpha}{\sqrt{(\alpha+\beta)\beta}}\left[F\left(\frac{\beta}{\alpha+\beta}\right)+\frac{\sqrt{\alpha+\beta}-\sqrt{\beta}}{\sqrt{\alpha+\beta}+\sqrt{\beta}}\right](p\dot{p}-\dot{p}p), \tag{62}$$

which may be rewritten as

$$\dot{v}^*=v^*(1-\mu)(p\dot{p}-\dot{p}p), \quad \mu=\frac{1}{2}\frac{\alpha}{\sqrt{(\alpha+\beta)\beta}}\left[F\left(\frac{\beta}{\alpha+\beta}\right)+\frac{\alpha+2\beta}{\alpha}\right]. \tag{63}$$

Can we go by $\beta\rightarrow 0$ to the pure states? A necessary condition is

$$F(0)=-1$$

or, equivalently, $r(0)=0$. To be sufficient we additionally need the existence of

$$\kappa:=\lim_{\beta\rightarrow 0}\mu=\lim_{\lambda\rightarrow 0}\frac{1+F(\lambda)}{2\sqrt{\lambda}}=\lim_{\lambda\rightarrow 0}\lambda^{-1/2}r(\lambda). \tag{64}$$

Then the limit $\beta\rightarrow 0$ can be performed in (62):

$$(v\dot{v}^*)^{\mathrm{pure}}=(1-\kappa)(p\dot{p}-\dot{p}p). \tag{65}$$

With $\mathbf{a}^{\mathrm{geo}}$, or, more generally, with $s>1/2$ in $r(\lambda)=\lambda^s/(1+\lambda^s)$, we get $\kappa=0$. *With* $\kappa=0$ *we obtain the Berry phase for pure states.*

Indeed, imposing $\langle\psi,\dot{\psi}\rangle=0$ a la Berry[9] and Fock[27], we find $\dot{v}^*\psi+v^*\dot{\psi}=0$ from (63). Hence, with $\kappa=0$, the vector $v^*\psi$ is t-independent. This yields $w=|\psi\rangle\langle\varphi|$, $\dot{\varphi}=0$. It then follows

$$\mathrm{Tr}\,(w_{\mathrm{out}}w_{\mathrm{in}}^*)^m=\langle\psi_{\mathrm{in}},\psi_{\mathrm{out}}\rangle^m.$$

This is the mth power of the Berry phase, because we had supposed the validity of Berry's transport condition. Remark that this goes not through if $\kappa\neq 0$ or if, as for $\mathbf{a}^{\mathrm{can}}$, (64) does not exist.

Something more can be said if (61) satisfies a von Neumann equation (54). Computing $\tilde{h}$ with this assumption by the help of (58) ends up with

$$\tilde{h}=h+\mu[(\mathbf{1}-p_{\mathrm{in}})hp_{\mathrm{in}}+p_{\mathrm{in}}h(\mathbf{1}-p_{\mathrm{in}})]. \tag{66}$$

Looking at $\tilde{h}$ as a block matrix with respect to p_{in} and $\mathbf{1}-p_{\mathrm{in}}$, the deviation from h is in multiplying the off-diagonal blocks by μ. If (64) exists and $\kappa=0$ then the off-diagonal blocks become zero at the pure state limit.

APPENDIX: PROOF OF THE LEMMA OF SECTION VII

Every self-transposed operator monotone function f_s with $f_s(1)=1$ has a unique integral representation

$$\begin{aligned} f_s(t) &= m(\{0\})\,\frac{1+t}{2} + \int_{(0,1]} \frac{1+x}{2}\left(\frac{t}{t+x}+\frac{t}{tx+1}\right) dm(x) \\ &= \frac{1+t}{2} + \int_{(0,1]} \left\{ -\frac{1+t}{2} + \frac{1+x}{2}\left(\frac{t}{t+x}+\frac{t}{tx+1}\right)\right\} dm(x) \\ &= \frac{1+t}{2} - (1-t)^2 \int_{(0,1]} \frac{x(t+1)}{2(t+x)(tx+1)}\, dm(x), \end{aligned} \tag{A1}$$

where m is a normalized positive Radon measure on $[0,1]$, see Ref. 3. If the measure is not concentrated at 0, the last integral is strictly positive for all $t\in\mathbb{R}_+$. Its positive root, for the time being denoted by τ, is a real analytic function. Hence, every such function f_s can be represented as

$$f_s(t) = \frac{1+t}{2} - (t-1)^2 \tau(t)^2 \tag{A2}$$

with a certain τ, positive or trivial. Therefore, $(1+t)/2 - f_s(t)$ has exactly two real analytic roots,

$$\delta_+(t) = (t-1)\,\tau(t), \quad \delta_-(t) = -(t-1)\,\tau(t),$$

or is vanishing. The self-transposeness of f_s implies $\tau(1/t)=\sqrt{t}\,\tau(t)$ and both roots fulfill the condition (49). As explained in Sec. VII, a solution for k of our problem corresponds to such a root δ, which leads via (50) to $F(t)<1$. We infer: If selecting the root δ_+, the condition $F(t)<1$, $t>0$, is equivalent to $f_s(t)>1/2$ for all $t>1$. Because f_s is monotone increasing and $f_s(1)=1$ the latter inequality is true. On the other hand, F cannot fulfill $F(t)<1$ for all $t>1$ if the root δ_- is chosen, except $\delta_-=0$. Otherwise we could conclude $f_s(t)>t/2$ for all $t>1$. But the self-transposeness effects $f_s'(1)=1/2$ and f_s must be concave. Therefore, $\delta := \delta_+$ is the only real analytic root leading to an appropriate F. Inserting

$$\delta(t) = (t-1)\,\tau(t) = \frac{t-1}{|t-1|}\sqrt{\frac{1+t}{2} - f_s(t)}, \quad \delta(1)=0, \tag{A3}$$

into formulas (50), (51) yields (53) and (52).

(Received 22 December 1998; accepted for publication 18 March 1999)

In this paper we point out a close connection between the Darboux transformation and the group of point transformations which preserve the form of the time-dependent Schrödinger equation (TDSE). In our main result, we prove that any pair of time-dependent real potentials related by a Darboux transformation for the TDSE may be transformed by a suitable point transformation into a pair of time-independent potentials related by a usual Darboux transformation for the stationary Schrödinger equation. Thus, any (real) potential solvable via a time-dependent Darboux transformation can alternatively be solved by applying an appropriate form-preserving point transformation of the TDSE to a time-independent potential. The pre-eminent role of the latter type of transformations in the solution of the TDSE is illustrated with a family of quasi-exactly solvable time-dependent anharmonic potentials. © *1999 American Institute of Physics.*

I. INTRODUCTION

A considerable amount of research has been devoted over the past few years to the exact solution of the time-dependent Schrödinger equation (TDSE) in $1+1$ dimensions. Several modifications of the celebrated Darboux transformation for the stationary Schrödinger equation,[1,2] have been proposed in this respect in the literature. Matveev and Salle showed that the usual Darboux transformation for the stationary Schrödinger equation could also be applied to the TDSE with a time-dependent potential.[3] An equivalent approach was followed by Bluman and Shtelen in Ref. 4, who considered a nonlocal transformation which is precisely the inverse map of the usual Darboux transformation. The Darboux transform of a time-dependent potential is in general a complex-valued function. (The explicit conditions for the resulting potential to be real-valued appear in a recent paper by Bagrov and Samsonov.[5]) For this reason, several generalizations of the Darboux transformation mapping real potentials to real potentials have been proposed in the literature. The best known of these generalizations is the binary Darboux transformation described in Ref. 3, which is in fact one of the main tools for finding exact solutions of integrable equations.

A seemingly unrelated method of constructing exact solutions of the TDSE which has proved remarkably successful is based on the use of point transformations which preserve the form of the TDSE. The idea goes back to the work of Leach on the time-dependent harmonic oscillator,[6] arising, e.g., in the study of the motion of charged particles in a Paul trap.[7] The method was subsequently extended by Bluman[8,9] and Ray[10] to obtain exact solutions of the TDSE for a quadratic potential with arbitrary time-dependent coefficients. The technique has also been applied to time-dependent harmonic oscillators with a repulsive barrier,[11] and to anisotropic time-dependent harmonic potentials in $2+1$ dimensions.[12]

The main purpose of this paper is to characterize the most general time-dependent real potential whose Darboux transform is real. A partial result along these lines for potentials rapidly decreasing at spatial infinity was mentioned in Ref. 13. As noted in this reference, the latter potentials are of limited interest regarded as solutions of the KP equation. However, potentials of this type (and, more generally, of the type considered in this paper) are interesting from the point of view of exactly solving the time-dependent Schrödinger equation, as underscored by the recent work of Bagrov and Samsonov.[5,14]

In this paper we show that the Darboux transformation for the TDSE is in fact closely related to the point transformation method. To this end, in Sec. II we briefly review the Darboux transformation and the point transformations preserving the form of the TDSE, applying the latter to construct a time-dependent anharmonic oscillator potential admitting a certain number of algebraically computable wave functions. In Sec. III we derive the main results of our paper, proving that any time-dependent real-valued potential for which the Darboux transformation yields a real potential may always be mapped to a time-independent potential by a form-preserving point transformation of the TDSE. Moreover, the Darboux transformation for any such potential is equivalent to a Darboux transformation for its associated time-independent potential, followed by the inverse of the corresponding point transformation. Finally, Sec. IV is devoted to our concluding remarks and related open questions.

II. GENERAL BACKGROUND

In this section we summarize the basics of the Darboux and the form-preserving point transformations for the TDSE. Following Bagrov and Samsonov,[5] we take as the starting point of the Darboux transformation for the TDSE the intertwining relation

$$L(i\partial_t - H_0) = (i\partial_t - H_1)L, \tag{1}$$

where

$$H_i = -\partial_x^2 + V_i(x,t), \quad i = 0,1, \tag{2}$$

and L is a first-order differential operator of the form

$$L = L_1(x,t)\partial_x + L_0(x,t).$$

It follows immediately from the intertwining relation (1) that if ψ_0 solves the TDSE with Hamiltonian H_0, then $\psi_1 = L\psi_0$ will solve the TDSE with Hamiltonian H_1. It is also easily verified that the intertwining relation (1) will be satisfied if and only if

$$L = L_1 \cdot (\partial_x + \chi_x), \quad V_1 = V_0 + 2\chi_{xx} + i(\log L_1)_t, \tag{3}$$

where $e^{-\chi}$ is a solution of the TDSE with the potential V_0, and $L_1 = L_1(t)$ is an arbitrary function. The transformed potential $V_1(x,t)$ is a real-valued function if and only if

$$\operatorname{Im} \chi_{xxx} = 0 \tag{4}$$

and

$$|L_1| = \exp\left[-2\int_{t_0}^{t} \operatorname{Im} \chi_{xx}(x,s)\,ds\right]. \tag{5}$$

Without loss of generality, we shall assume from now on that L_1 is real and positive, and is therefore given by the right-hand side of (5).

Just as in the time-independent case, the Darboux transformation for the TDSE can be inverted. Indeed, if ψ_1 is a solution of the TDSE with potential V_1 given by (3), the function

$$\psi_0(x,t)=\frac{e^{-\chi(x,t)}}{L_1(t)}\left[\int_{x_0}^{x}e^{\chi(y,t)}\psi_1(y,t)dy+c_0(t)\right] \tag{6}$$

with $c_0(t)$ given by

$$c_0(t)=iL_1(t)\int_{t_0}^{t}\frac{e^{\chi(x_0,s)}}{L_1(s)}(\psi_{1,x}(x_0,s)-\chi_x(x_0,s)\psi_1(x_0,s))ds$$

solves the TDSE with potential V_0. If the factor L_1 is taken as unity, the mapping $\psi_1\mapsto\psi_0$ given by (6) reduces to the nonlocal transformation considered by Bluman and Shtelen in Ref. 4.

The most general point transformation mapping the TDSE

$$(i\partial_t+\partial_x^2-V_0(x,t))\psi_0(x,t)=0 \tag{7}$$

for any given potential V_0 into another TDSE with potential $\overline{V}_0$ for the transformed wave function $\overline{\psi}_0$ is defined by

$$\overline{x}=\frac{x}{C(t)}+B(t),\quad \overline{t}=\int_{t_0}^{t}\frac{ds}{C^2(s)},$$

$$\psi_0(x,t)=|C|^{-1/2}\exp\left[\frac{i}{4}\left(\frac{\dot{C}}{C}x^2-2\dot{B}Cx+A(t)\right)\right]\overline{\psi}_0(\overline{x},\overline{t}), \tag{8}$$

$$V_0(x,t)=\frac{1}{C^2}\overline{V}_0(\overline{x},\overline{t})-\frac{\ddot{C}}{4C}x^2+\left(\frac{C\ddot{B}}{2}+\dot{B}\dot{C}\right)x-\frac{1}{4}(C^2\dot{B}^2+\dot{A}),$$

where *A*, *B*, and $C\neq0$ are real-valued functions of *t*. Note that square-integrability is preserved under the transformation (8). As remarked before, the point transformation (8) has been employed to construct exact solutions of the TDSE for quadratic potentials with time-dependent coefficients. The interest of the transformation (8) is not limited, however, to quadratic (or exactly solvable) time-dependent potentials, as evidenced by the following example:

Example: Consider the two-parameter family of anharmonic oscillator potentials given by[15–17]

$$\overline{V}(\overline{x})=\overline{x}^6+2\alpha\overline{x}^4+(\alpha^2-4n-3)\overline{x}^2, \tag{9}$$

where $\alpha\in\mathbb{R}$ and $n\in\mathbb{N}$. The sextic potential (9) is a well-known example of the class of *quasi-exactly solvable* potentials, for which a certain subset of the spectrum can be computed by purely algebraic means; see Ref. 18 for an extensive review of the field. The first $n+1$ even bound states of the potential (9) are of the form

$$\phi(\overline{x})=\exp\left[-\frac{1}{4}\overline{x}^4-\frac{\alpha}{2}\overline{x}^2\right]p(\overline{x}^2), \tag{10}$$

where $p(s)$ is a polynomial in s of degree less than or equal to n which can be computed algebraically. The point transformation (8) with $A=B=0$ and $C=\omega^{-1/2}$, $\omega=\omega(t)$ being a positive function, leads directly to the potential $V(x,t)$ given by

$$V(x,t)=\omega^4x^6+2\alpha\omega^3x^4+\left(\alpha^2-4n-3-\frac{3\dot{\omega}^2-2\omega\ddot{\omega}}{16\omega^4}\right)\omega^2x^2. \tag{11}$$

The TDSE with potential (11) possesses $n+1$ square-integrable solutions of the form

$$\psi(x,t)=\omega^{1/4}\exp\left[-i\left(\frac{\dot{\omega}}{8\omega}x^2+E\int_{t_0}^{t}\omega(s)ds\right)\right]\phi(\sqrt{\omega}x), \tag{12}$$

where $\phi(\overline{x})$ is an algebraic eigenfunction of the form (10) with eigenvalue E of the Hamiltonian

$$\overline{H}=-\partial_x^2+\overline{V}(\overline{x}).$$

The potential (11) thus provides a natural extension of the notion of quasi-exact solvability to the time-dependent case, in the sense that the associated TDSE admits a certain number of solutions which can be determined algebraically. In particular, note that if $\omega(t)$ is of the form

$$\omega_0(t)=\beta[\gamma+(\gamma^2-(\alpha^2-4n-3)\beta)^{1/2}\sin(4\sqrt{\beta}t+\delta)]^{-1},$$

with $\delta\in\mathbb{R}$, $\beta>0$ and $\gamma^2>(\alpha^2-4n-3)\beta>0$, the potential (11) reduces to a harmonic oscillator with a periodic-in-time anharmonic perturbation, namely,

$$V_0(x,t)=\omega_0^4(t)x^6+2\alpha\omega_0^3(t)x^4+\beta x^2.$$

III. THE REALITY CONDITION AND THE FORM-PRESERVING POINT TRANSFORMATIONS

In this section we prove the main results of our paper, starting with the following theorem:

Theorem: Let $e^{-\chi}$ be a solution of the TDSE with potential $V_0(x,t)$. If χ satisfies the reality condition (4), then $V_0(x,t)$ may be mapped to a time-independent potential $\overline{V_0}(\overline{x})$ by a point transformation (8).

Proof: Let $\chi_0=\mathrm{Re}\,\chi$, $\chi_1=\mathrm{Im}\,\chi$. The TDSE for $e^{-\chi}$ is then equivalent to the pair of real equations given by

$$\chi_{0,t}+\chi_{1,xx}-2\chi_{0,x}\chi_{1,x}=0, \tag{13}$$

$$V_0(x,t)=\chi_{1,t}-\chi_{0,xx}-\chi_{1,x}^2+\chi_{0,x}^2. \tag{14}$$

If the reality condition (4) holds, i.e., if χ_1 is of the form

$$\chi_1=a(t)x^2+b(t)x+c(t), \tag{15}$$

Eqs. (13) and (14) reduce to

$$\chi_{0,t}-2(2ax+b)\chi_{0,x}+2a=0, \tag{16}$$

$$V_0(x,t)=(\dot{a}-4a^2)x^2+(\dot{b}-4ab)x+\dot{c}-b^2+\chi_{0,x}^2-\chi_{0,xx}. \tag{17}$$

The general solution of Eq. (16) is of the form[19]

$$\chi_0=-2\int_{t_0}^{t}a(s)ds+F\left(e^{4\int_{t_0}^{t}a(s)ds}x+2\int_{t_0}^{t}b(s)e^{4\int_{t_0}^{s}a(r)dr}ds\right), \tag{18}$$

where F is an arbitrary real-valued function. Substituting this expression into (17), we immediately conclude that the transformation (8) determined by

$$C(t)=e^{-4\int_{t_0}^{t}a(s)ds},\quad B(t)=2\int_{t_0}^{t}\frac{b(s)}{C(s)}ds,\quad A(t)=-4c(t), \tag{19}$$

maps the potential $V_0(x,t)$ into the time-independent potential

$$\overline{V}_0(\overline{x}) = F'^2(\overline{x}) - F''(\overline{x}). \qquad \text{Q.E.D.}$$

Thus, any potential for which the Darboux transformation yields another real-valued potential may be mapped into a time-independent potential by a form-preserving point transformation. It is easy to check that the transform of $e^{-\chi}$ under the point transformation defined by (8), (15), (18), (19) is e^{-F}, which is therefore an eigenfunction of the time-independent potential $\overline{V}_0(\overline{x})$. The next Corollary shows that the usual Darboux transform of the associated time-independent potential generated by F is related to the Darboux transform of the original potential by the same point transformation.

Corollary: Let $e^{-\chi} = e^{-\chi_0 - i\chi_1}$ be a solution of the TDSE with potential $V_0(x,t)$, with χ satisfying the reality condition (4). Let $\mathcal{D}$ and $\mathcal{T}$ denote, respectively, the Darboux transformation (3) and the point transformation (8) defined by χ via Eqs. (15), (18), (19). Let $\overline{\mathcal{D}}$ denote the Darboux transformation generated by F. Then

$$\mathcal{T} \circ \mathcal{D} = \overline{\mathcal{D}} \circ \mathcal{T}. \tag{20}$$

Remark: This result may be easily visualized with the help of the following commutative diagram:

$$\begin{array}{ccc} V_0(x,t) & \xrightarrow{\mathcal{T}} & \overline{V}_0(\overline{x}) = F'^2 - F'' \\ \mathcal{D}\downarrow & & \downarrow\overline{\mathcal{D}} \\ V_1(x,t) & \xrightarrow{\mathcal{T}} & \overline{V}_1(\overline{x}) = F'^2 + F'' \end{array}.$$

Proof: The proof follows from a straightforward application of the appropriate formulas for the transformed potentials and wave functions. Q.E.D.

The above Corollary shows, in particular, that the potential $V_1(x,t)$ is the image under the inverse of the form-preserving point transformation $\mathcal{T}$ determined by (8), (15), (18), (19) of a time-independent potential $\overline{V}_1(\overline{x})$. Exact solutions of the TDSE with potential V_1 can therefore be obtained simply by applying the point transformation $\mathcal{T}^{-1}$ to solutions of the TDSE for the *time-independent* potential $\overline{V}_1$.

Another important consequence of the above Corollary is that, if the potential $\overline{V}_0$ satisfies (for instance) the condition

$$\int_{-\infty}^{\infty} |\overline{V}_0(\overline{x})|(1 + |\overline{x}|)\, d\overline{x} < \infty, \tag{21}$$

then the time-dependent Darboux transformation (3) preserves the square-integrability of eigenfunctions. Indeed, if $\overline{V}_0$ verifies (21) then the time-independent Darboux transformation $\overline{\mathcal{D}}$ determined by a nonvanishing eigenfunction of $\overline{V}_0$ preserves square integrability.[20,21] The result stated above then follows easily from (20), the invertibility of $\mathcal{T}$, and the fact that the form-preserving point transformation $\mathcal{T}$ always preserves square integrability.

Example: It is straightforward to verify that all the examples of time-dependent potentials appearing in Refs. 4, 5, 14 which are solvable by means of a Darboux transformation are indeed the images of certain exactly solvable time-independent potentials under suitable form-preserving point transformations.

For instance, the free-particle potential $V_0(x,t) = 0$ admits a one-parameter family of solutions

$$\psi_\lambda(x,t) = (1+t^2)^{-1/4} \exp\left[\frac{i}{4}\left(\frac{tx^2}{1+t^2} + 4\lambda \arctan t\right)\right] Q_\lambda(x/\sqrt{1+t^2})$$

satisfying the reality condition (4), where Q_λ is a (real-valued) solution of Weber's equation

$$Q''_\lambda(y)-\left(\frac{y^2}{4}+\lambda\right)Q_\lambda(y)=0 \tag{22}$$

(see Ref. 14, Eq. (18)). By the Theorem at the beginning of this section, it follows that V_0 is related to a certain time-independent potential $\overline{V}_0$ by a point transformation (8). Indeed, in this case we have

$$\chi_1=-\operatorname{Im}\log\psi_\lambda=-\frac{tx^2}{4(1+t^2)}-\lambda\arctan t,$$

so from (19) it follows that

$$C=\sqrt{1+t^2},\quad B=0,\quad A=4\lambda\arctan t. \tag{23}$$

Substituting these formulas into (8) we find that

$$\overline{x}=\frac{x}{\sqrt{1+t^2}} \tag{24}$$

and

$$\overline{V}_0(\overline{x})=\frac{\overline{x}^2}{4}+\lambda \tag{25}$$

is a harmonic oscillator potential.

For all $n\in\mathbb{N}$, let H_n denote the nth Hermite polynomial. The functions[22]

$$Q_{n+1/2}(y)=i^n e^{y^2/4}H_n(iy/\sqrt{2})$$

are real-valued solutions of Weber's equation (22) with $\lambda=n+\frac{1}{2}$ without zeros on the positive real semiaxis.[23] Hence, for all $n\in\mathbb{N}$ the Darboux transformation determined by the eigenfunction $\psi_{n+1/2}$ of V_0 is well-defined on the positive real semiaxis. From Eqs. (3), (5) and the definition of ψ_λ, it follows that the transformed potential V_1 is given by

$$V_1(x,t)=2\chi_{0,xx}=-2[\log Q_{n+1/2}(\overline{x})]_{xx}=\frac{2}{1+t^2}\left(\frac{Q'^2_{n+1/2}(\overline{x})}{Q^2_{n+1/2}(\overline{x})}-\frac{\overline{x}^2}{4}-n-\frac{1}{2}\right),$$

where $\overline{x}$ is given by (24). Using standard identities for the derivatives of the Hermite polynomials, the reader can easily verify that this formula for $V_1(x,t)$ agrees with the corresponding expression given in Ref. 14. As stated in the Corollary, the potential $V_1(x,t)$ is related by the point transformation (8) defined by (23) to a time-independent potential $\overline{V}_1(\overline{x})$ obtained from $\overline{V}_0(\overline{x})$ by applying a time-independent Darboux transformation $\overline{\mathcal{D}}$. From (18) and the definition of ψ_λ, it easily follows that the function $F(\overline{x})$ generating the Darboux transformation $\overline{\mathcal{D}}$ is given by

$$F(\overline{x})=-\log Q_{n+1/2}(\overline{x}),$$

and therefore

$$\overline{V}_1(\overline{x})=F'^2(\overline{x})+F''(\overline{x})=2\frac{Q'^2_{n+1/2}(\overline{x})}{Q^2_{n+1/2}(\overline{x})}-\frac{\overline{x}^2}{4}-n-\frac{1}{2}.$$

It is straightforward to check that the potentials $V_1(x,t)$ and $\overline{V}_1(\overline{x})$ are indeed related by the point transformation (8) determined by (23).

IV. CONCLUSIONS

In this paper, we have shown that the Darboux transformation for the time-dependent Schrödinger equation is essentially equivalent to the usual Darboux transformation for the stationary Schrödinger equation. Any (real) potential $V_1(x,t)$ solvable via a time-dependent Darboux transformation starting from a real potential $V_0(x,t)$ can alternatively be solved by applying a form-preserving point transformation to a time-independent potential $\overline{V_1}(\overline{x})$. As a matter of fact, although a large number of methods and papers have been devoted in recent times to the exact solution of the TDSE,[24] most of the associated time-dependent Hamiltonians either are not of the standard form (2), or are also obtainable from a time-independent Hamiltonian by a form-preserving point transformation.

The interest of the Darboux transformation for the TDSE as a useful method to obtain new (quasi-)exactly solvable time-dependent potentials is therefore very limited. It should be noted, however, that the Darboux transformation for the TDSE could still render helpful results if the starting potential is not a real-valued function but only the transformed potential is real.[25] As a final remark, we would like to stress that the Darboux transformation may still be useful to construct exact solutions to real-valued diffusion equations of the Fokker–Planck-type, for which no reality condition as Eq. (4) must be considered.

Lifetimes of impurity states in crossed magnetic and electric fields

Sébastien Gyger and Philippe A. Martin
Institut de Physique Théorique, Ecole Polytechnique Fédérale de Lausanne, CH-1015, Lausanne, Switzerland

(Received 12 January 1998; accepted for publication 9 February 1999)

We study the quantum dynamics of localized impurity states created by a point interaction for an electron moving in two dimensions under the influence of a perpendicular magnetic field and an in-plane weak electric field. All impurity states are unstable in presence of the electric field. Their lifetimes are computed and shown to grow in a Gaussian way as the electric field tends to zero. © *1999 American Institute of Physics.* [S0022-2488(99)01807-1]

I. INTRODUCTION

A detailed understanding of the dynamics of electrons in two dimensions (2D) in crossed magnetic and electric fields and in the presence of impurity scattering plays an important role in the context of the quantum Hall effect and transport theory.

We consider an electron of charge e and mass m confined to the two-dimensional plane (x,y) (without boundaries). A uniform magnetic field of magnitude B acts perpendicular to the plane and an electric field of magnitude E acts in the x direction. Moreover, an impurity located at the origin scatters the electron with a short-range potential $V(x,y)$. When $E=0$, the electron remains localized in the course of the time, both for the classical and the quantum dynamics. Classically, modeling for instance the interaction with the impurity by a hard disk of radius a, the electron accomplishes the usual circular cyclotronic motion outside of the disk or bounces around the surface of the disk by a succession of segments of cyclotronic motion. Quantum mechanically, the impurity potential, considered as a short-range perturbation of the pure magnetic problem (the Landau Hamiltonian), will preserve the essential spectrum (i.e., the infinitely degenerated Landau levels) and create at most point spectrum in-between these levels (and possibly below them if V is attractive).

When the electric field is applied, the situation changes. In the classical case, the center of the cyclotronic orbit acquires a constant drift of velocity E/B in the y direction: the trajectories around the disk get distorted by the acceleration imposed by the electric field and may eventually leave the disk. In the quantum case, the Hamiltonian of the homogeneous system with the crossed magnetic and electric fields has an absolutely continuous spectrum on $\mathbb{R}$ and this spectrum will remain present after the introduction of the short-range impurity potential, in view of general theorems on the stability of the absolutely continuous spectrum under such perturbations. An interesting result has recently been obtained for the classical dynamics: for nonzero but sufficiently small electric field, there exists a set of positive Lebesgue measure of trajectories that remain trapped near the disk.[1] The corresponding quantum mechanical question is whether point spectrum can survive the switching on of the electric field and remain embedded into the continuous spectrum, provided that this field is sufficiently weak. To our knowledge there is no definite answer to this question at the moment. The existence of an appreciable domain of the classical phase space supporting localized trajectories may be an argument in favor of a corresponding localized quantum state, but quantum interferences and tunneling phenomena may invalidate this anticipation.

In this article, we bring a partial contribution to this problem by considering a point impurity acting as a δ-potential. This model has been introduced by Prange[2] in relation with the quantum Hall effect (with the electron in a finite strip). Our contribution consists of a proof that all localized states created by the impurity are turned into resonances and of an exact determination of their lifetimes, shown to be of the order of $\exp((|B|/|e|\hbar)(\Delta/E)^2)$ as $E\to 0$ where Δ is the distance of the resonance energy to the closest Landau level (for a more precise formula, see Sec. IV). However, if one allows for an impurity interaction which is not of potential form (i.e., an integral kernel in configuration space), one can have a point spectrum embedded into the continuum. We give an example with a rank one perturbation (Sec. V). A closely related analysis by E. H. Hauge and J. M. J. van Leeuwen[3] will be discussed in our concluding remarks.

II. THE MODEL

We denote H^0 the 2D Hamiltonian of the electron in the crossed fields with potential vector $\mathbf{A}=(0,Bx)$ in the Landau gauge

$$H^0=\frac{1}{2}p_x^2+\frac{1}{2}(p_y-x)^2-\mu x,\quad p_x=-i\frac{\partial}{\partial x},\quad p_y=-i\frac{\partial}{\partial y}. \tag{1}$$

Here H^0 is written in dimensionless variables by choosing $\sqrt{\hbar/|eB|}$ as the unit of length and $\hbar|eB|/m$ as the unit of energy, with $\mu=E\sqrt{m^2/|eB^3|\hbar}$. Since p_y commutes with H^0, there is a direct integral decomposition of $H^0=\int^{\oplus}dk\,H_k^0$, with

$$H_k^0=-\frac{1}{2}\frac{d^2}{dx^2}+\frac{1}{2}(k-x)^2-\mu x,\quad k\in\mathbb{R}. \tag{2}$$

The spectral representation of H^0 is explicitly given in terms of the generalized eigenfunctions

$$(xy|nk\rangle=\frac{1}{\sqrt{2\pi}}e^{iky}u_n(x-k-\mu),\quad n=0,1,\ldots,\quad k\in\mathbb{R}, \tag{3}$$

and spectral branches

$$\epsilon_n(k)=\left(n+\frac{1}{2}\right)-\mu k-\frac{\mu^2}{2}. \tag{4}$$

In (3), u_n are the usual normalized eigenfunctions of a harmonic oscillator of frequency equal to one,

$$u_n(x)=\left(\frac{1}{\sqrt{\pi}2^n n!}\right)^{1/2}e^{-(1/2)x^2}H_n(x), \tag{5}$$

with H_n the nth Hermite polynomial. For $\mu\neq 0$, the branches $\epsilon_n(k)$ are linear functions of k, thus without points of constancy, implying that the spectrum of H^0 is absolutely continuous on $\mathbb{R}$.[4] If $\mu=0$, $\epsilon_n(k)=n+\frac{1}{2}$ are constant, the spectrum reduces to the infinitely degenerated Landau levels, and k labels the degeneracy in the corresponding subspaces.

The total Hamiltonian H is obtained by formally adding to H^0 the singular potential $V(x,y)=\lambda\delta(x,y)$, where $\delta(x,y)$ is the two-dimensional Dirac function. It is well known that this singularity is too strong in 2D and a renormalization of the coupling constant is needed.[5–7] Introducing the resolvents $R_z=(H-z)^{-1}$ and $R_z^0=(H^0-z)^{-1}$, $z\in C$, and solving the resolvent equation $R_z=R_z^0-R_z^0VR_z$ leads to

$$R_z=R_z^0-\frac{R_z^0|00)(00|R_z^0}{g(z)}, \tag{6}$$

$$g(z)=\lambda^{-1}+(00|R_z^0|00), \tag{7}$$

and from the spectral decomposition (3) of H^0

$$(00|R_z^0|00)=\sum_{n=0}^{\infty}\int dk\frac{|(00|nk)\rangle|^2}{\epsilon_n(k)-z}. \tag{8}$$

The n-summation in (8) diverges logarithmically since $\epsilon_n(k)\sim n,\ n\to\infty$. Following the same procedure as in Ref. 7, it can be made finite by substracting out the diverging part and combining it with the coupling constant [using also the normalization of the functions (3)]

$$g(z)=\lim_{N\to\infty}\left(\lambda^{-1}+\frac{1}{2\pi}\sum_{n=0}^{N}\frac{1}{n+\frac{1}{2}}\right)+\lim_{N\to\infty}\sum_{n=0}^{N}\int dk\,|(00|nk)|^2\left(\frac{1}{\epsilon_n(k)-z}-\frac{1}{n+\frac{1}{2}}\right). \tag{9}$$

In the first term of (9) one chooses $\lambda=\lambda_N<0$ be N-dependent and negative, and requires that $\lambda_N\to 0$ in such a way that $\lim_{N\to\infty}(\lambda_N^{-1}+(1/2\pi)\Sigma_{n=0}^{N}[1/(n+1/2)])=\lambda_r$, where λ_r is a finite renormalized coupling constant. The limit of the second term in (9) exists (see Appendix A) so that the model is defined by its resolvent (6) setting

$$g(z)=\lambda_r+\sum_{n=0}^{\infty}\int dk|(00|nk\rangle|^2\left(\frac{1}{\epsilon_n(k)-z}-\frac{1}{n+\frac{1}{2}}\right). \tag{10}$$

Its spectrum will be determined by the nature of the singularities of R_z as z approaches the real axis. When $\mu=0$, the model reduces to that studied in Ref. 7:

$$g(z)|_{\mu=0}=\lambda_r+\frac{1}{2\pi}\sum_{n=0}^{\infty}\left(\frac{1}{(n+\frac{1}{2})-z}-\frac{1}{n+\frac{1}{2}}\right) \tag{11}$$

has one zero ϵ_j in between each of the Landau levels, $j+1/2<\epsilon_j<j+3/2$, $j=0,1,\ldots$, and a zero $\epsilon_g<1/2$ lying below all Landau levels. These zeros give poles in $R_z|_{\mu=0}$ that correspond to nondegenerate eigenvalues ϵ_j of $H|_{\mu=0}$ with normalized eigenvectors ψ_j (impurity states). As $z\to\epsilon_j$, $g(z)|_{\mu=0}\sim a_j(z-\epsilon_j)$ and $(\epsilon_j-z)\langle\psi_j|R_z|_{\mu=0}|\psi_j\rangle\to 1$. From (6) this determines the coefficient a_j to be

$$a_j=|(00|R^0_{\epsilon_j}|_{\mu=0}|\psi_j\rangle|^2. \tag{12}$$

The poles coming from $R_z^0|_{\mu=0}$ correspond to the Landau levels that remain unaffected by the presence of the impurity (stability of the essential spectrum).

III. WEAK ELECTRIC FIELD ASYMPTOTICS

In presence of the electric field, the boundary values of $g(z)$ as $z=\zeta\pm i\eta$ approaches the real axis are obtained by an application of the Cauchy principal value formula (writing now explicitly the μ dependence in the arguments of the functions)

$$\lim_{\eta\to 0^+} g(\zeta\pm i\eta,\mu)=\alpha(\zeta,\mu)\pm i\beta(\zeta,\mu) \tag{13}$$

with

$$\alpha(\zeta,\mu)=\lambda_r+\sum_{n=0}^{\infty}\mathcal{P}\!\!\int dk|(00|nk\rangle|^2\left(\frac{1}{\epsilon_n(k)-\zeta}-\frac{1}{n+\frac{1}{2}}\right), \tag{14}$$

$$\beta(\zeta,\mu)=\frac{\pi}{\mu}\sum_{n=0}^{\infty}|(00|nk_n(\zeta,\mu)\rangle|^2, \tag{15}$$

where $k_n(\zeta,\mu)$ solves $\epsilon_n(k)=\zeta$, i.e.,

$$k_n(\zeta,\mu)=\frac{1}{\mu}\left(n+\frac{1}{2}-\zeta-\frac{\mu^2}{2}\right). \tag{16}$$

The functions $\alpha(\zeta,\mu)$ and $\beta(\zeta,\mu)$ will determine respectively the spectral shifts and the lifetimes of the impurity states as $\mu\to 0$. From now on we focus attention on the jth impurity state by studying these functions in a neighborhood of the unperturbed energy ϵ_j that does not contain the nearest Landau levels. At $\mu=0$, $\alpha(\zeta,0)$ reduces to the expression (11) and vanishes at ϵ_j with $\partial\alpha(\zeta,0)/\partial\zeta|_{\zeta=\epsilon_j}>0$: the implicit function theorem ensures then that for μ small, $\alpha(\zeta,\mu)$ has a nearby zero at $\zeta=\epsilon_j(\mu)$ and

$$\alpha(\zeta,\mu)=a_j(\mu)(\zeta-\epsilon_j(\mu))+O((\zeta-\epsilon_j(\mu))^2), \quad a_j(\mu)>0 \tag{17}$$

The spectral shift $\epsilon_j(\mu)-\epsilon_j=\epsilon_j^{(1)}\mu+O(\mu^2)$ can itself be expanded in μ and $a_j(\mu)=a_j+O(\mu)$ where a_j has the value (12).(One can verify that the linear correction $\epsilon_j^{(1)}\mu$ is also obtained by formally applying the regular perturbation theory to the eigenvalue ϵ_j when the electric field is switched on).

We study now asympotic behavior of $\beta(\zeta,\mu)$ as $\mu\to 0$ with ζ in a neighborhood of ϵ_j. We denote $\Delta_j=\min(\epsilon_j-(j+1/2),j+3/2-\epsilon_j)<1/2$ the gap between ϵ_j and the nearest Landau level: Δ_j can be equal to either quantity depending on the value of λ_r. For sake of definiteness assume in the sequel that $\Delta_j=\epsilon_j-(j+1/2)$.

Proposition: Set $\zeta-\mu^2/2=j+1/2+\delta$, $0<\delta<1/2$. Then

$$\beta(\zeta,\mu)=\frac{1}{2\sqrt{\pi}}\frac{2^j}{j!}\frac{1}{\mu}\left(\frac{\delta}{\mu}\right)^{2j}e^{-(\delta/\mu)^2}(1+O(\mu^2)). \tag{18}$$

Proof: From (3), (5), (15), and (16) $\beta(\zeta,\mu)$ reads

$$\beta(\zeta,\mu)=\frac{1}{2\sqrt{\pi}}\frac{1}{\mu}\sum_{n=0}^{\infty}\frac{1}{2^n n!}e^{-((n-j-\delta)/\mu)^2}H_n^2\left(\frac{n-j-\delta}{\mu}\right). \tag{19}$$

The control of these series necessitates an estimate of the Hermite polynomials when their argument is of the same magnitude as their order. This is provided by the next lemma (proof in Appendix B).

Lemma: Let x be any real number not equal to a positive integer. Then there exists $\mu_0>0$ such that

$$H_n\left(\frac{n-x}{\mu}\right)=2^n\left(\frac{n-x}{\mu}\right)^n(1-r_n(\mu)), \quad 0<\mu\leqslant\mu_0 \tag{20}$$

where $r_n(\mu)\geqslant 0$ and $r_n(\mu)=O(\mu^2)$ as $\mu\to 0$.

The lemma gives the upper bound

$$\beta(\zeta,\mu)\leqslant\sum_{n=0}^{\infty}b_n(\mu)=b_j(\mu)\left(1+\sum_{n\neq j}^{\infty}\frac{b_n(\mu)}{b_j(\mu)}\right) \tag{21}$$

with

$$b_n(\mu)=\frac{1}{2\sqrt{\pi}}\frac{2^n}{n!}\frac{1}{\mu}\left(\frac{n-j-\delta}{\mu}\right)^{2n}e^{-((n-j-\delta)/\mu)^2}. \tag{22}$$

For $n\neq j$, the largest Gaussian factor in the ratios $b_n(\mu)/b_j(\mu)$ occurs when $n=j+1$. Factorizing it out, we write these ratios in the form

$$\frac{b_n(\mu)}{b_j(\mu)}=\frac{1}{\mu^2}e^{-[(1-\delta)^2-\delta^2]/\mu^2}c_n(\mu). \tag{23}$$

One checks from (22) and the above definition that the $c_n(\mu)$ are bounded as $\mu\to 0$ and $c_n(\mu)\leqslant c_n(1)\sim n^n e^{-(n^2+O(n))}$ for n large. Hence the series $\Sigma_{n\neq j}^{\infty}c_n(\mu)$ converges and is uniformly bounded with respect to μ, implying with (21) and (23) that

$$\beta(\zeta,\mu)\leqslant b_j(\mu)(1+O(e^{-c/\mu^2})) \tag{24}$$

for some $C>0$. On the other hand, one concludes from (19) and the lemma that

$$\beta(\zeta,\mu)\geqslant b_j(\mu)(1-r_j(\mu))^2,\quad r_j(\mu)=O(\mu^2). \tag{25}$$

Combining (24) and (25) gives the result of the proposition.

IV. SHAPE OF RESONANCES AND LIFETIMES

The time-dependent decay amplitude $\langle\psi_j|\exp(-iHt)|\psi_j\rangle$ of the jth impurity state under a weak electric field is given by the Fourier transform of the density of states
